Before selecting certain maintenance tasks, the analyst needs to understand what the capabilities are, or are planned, for the system. In other words, what is or will be the available skill levels, what maintenance tools are available or are planned, and what are the diagnostics being designed into or for the system.

7-3.2.2 Sources of Data.

Table 7-3 lists some of the sources of data for the RCM analysis. The data elements from the FMEA that are applicable to RCM analysis are highlighted in paragraph 7-5.4.2. Note that when RCM is being applied to a product already in use, or when a maintenance program is updated during Life Exploration, historical maintenance and failure data will be inputs for the analysis. An effective Failure Reporting and Corrective Action System (FRACAS) is an invaluable source of data. FRACAS is a closed-loop system for collecting, analyzing, and documenting failures and recording any corrective action taken to eliminate or reduce the probability of future such failures. FRACAS is used when iterative tests or demonstrations are conducted on breadboard, or prototype products to identify mechanisms and trends for corrective action. FRACAS is used for existing systems to monitor performance.

Table 7-3 Data Sources for the RAM Analysis

Data Source	Comment
Lubrication requirements	Determined by designer. For off-the-shelf items being integrated into the product, lubrication requirements and instructions may be available.
Repair manuals	For off-the-shelf items being integrated into the product.
Engineering drawings	For new and off-the-shelf items being integrated into the product.
Repair parts list	
Quality deficiency reports	For off-the-shelf items being integrated into the product.
Other technical documentation	For new and off-the-shelf items being integrated into the product.
PREP Database	For new and off-the-shelf items being integrated into the product.
Recorded observations	From test of new items and field use of off-the-shelf items being integrated into the product.
Hardware block diagrams	For new and off-the-shelf items being integrated into the product.
Bill of Materials	For new and off-the-shelf items being integrated into the product.
Functional block diagrams	For new and off-the-shelf items being integrated into the product.
Existing maintenance plans	For off-the-shelf items being integrated into the product. Also, may be useful if the new product is a small evolutionary improvement of a previous product.
Maintenance technical orders/manuals	For off-the-shelf items being integrated into the product
Discussions with maintenance Personnel and field operators	For off-the-shelf items being integrated into the product. Also, may be useful if the new product is a small evolutionary improvement of a previous product.
Results of FMEA, FTA, and other reliability analyses	For new and off-the-shelf items being integrated into the product. Results may not be readily available for the latter.
Results of Maintenance task analysis	For new and off-the-shelf items being integrated into the product. Results may not be readily available for the latter.

7-3.3 Commitment to Life Cycle Support of the Program.

7-3.3.1 The Process Perspective.

As will be shown in this paragraph, RCM must be viewed as a continuing process, rather than an event that occurs once. Although a maintenance program based on RCM should be developed during design, it should be refined throughout the operational life of the system. In addition, RCM can be used to develop a maintenance program for an existing system for which the initial maintenance program was not based on RCM.

7-3.3.2 Learning from Experience.

Much of the information used to develop an RCM program, either during design for a new system or after fielding for an existing system will be based on estimates, may change over time, or be subject to some combination of these two factors. Consequently, it is essential to use experiential data to update the maintenance program.

7-3.3.3 Continuous PM Improvement.

RCM fundamentals established at design should be revisited on at least an annual interval. This process will maintain the efficiency intended for the facility at design. This takes into consideration changes in cost, Reliability degradation, changes in mission, changes in maintenance approach to name a few occurrences.

7-3.4 RCM as a Part of Design.

It is ideal to implement an RCM approach during the design and development of a new system to develop a maintenance program. The reasons will be briefly discussed here but will become clearer as the reader proceeds through the remaining paragraphs of this UFC.

7-3.4.1 Effective Use of Analyses.

During design and development, numerous analyses are performed. Many of these analyses directly support an RCM analysis. In turn, the results of going through the RCM process of developing a maintenance program can affect and contribute to these analyses. Obviously, implementing RCM during design and development makes very effective use of analyses that are usually performed.

7-3.4.2 Impact on Design.

As will be seen when the RCM logic diagrams are discussed, redesign is either mandatory or desirable in many cases. The cost and level of effort of design changes made during the design and development phase of a system are much less than if they were made after the system was fielded. Additionally, the effectiveness of design changes is higher when made during the design and development phase. Of course, RCM can and is used to develop maintenance programs for fielded systems, for which RCM was not applied during design and development. However, it is always best to implement RCM during design and development.

7-3.5 Focus on the Four Ws.

Discussion of the four Ws: what can fail, why does it fail, when will it fail, and what are the consequences of failures.

7-3.5.1 What can Fail?

In determining required maintenance, the first and most fundamental question that must be answered is what can fail. A variety of methods can be used to answer this question.

(1) Analytical methods. FMEA, FTA, and relayed analyses address, among other issues, what can fail that will prevent a system, subsystem, or component from performing its function(s).

(2) Test. Analytical methods are not infallible, and a particular failure may be overlooked or cannot be anticipated by analysis. Testing often reveals these failures. Testing can, of course, also be used to confirm or validate the results of analytical methods.

3) Field experience. Often, the same type of component, assembly, or even subsystem that is already used in one system may be used in a new system. If data is collected on field performance of these components, assemblies, and subsystems, it can be used to help answer the question, what can fail. Obviously, field experience is equally applicable to RCM when applied to an already fielded system.

7-3.5.2 Why Does an Item Fail?

To determine which, if any preventive maintenance tasks are appropriate, the reason for failure must be known. Insights into the modes and mechanisms of failure can be gained through analysis, test, and experience. Some of the analytical methods are the same as those used to determine What Can Fail. The methods include the FMEA and FTA. Others include root cause analysis, destructive physical analysis, and non-destructive inspection techniques. Table 7-4 lists some nondestructive inspection (NDI) techniques and Table 7-5 lists some of the modes and mechanisms of failure.

Table 7-4 Non-Destructive Inspection (NDI) Techniques, Briefly

Acoustic emission	Magnetic particle examination
Dye penetrant	Radiography
Eddy current	Spectrometric oil analysis
Emission spectroscopy	Stroboscopy
Ferrography	Thermography
Leak testing	Ultrasonics

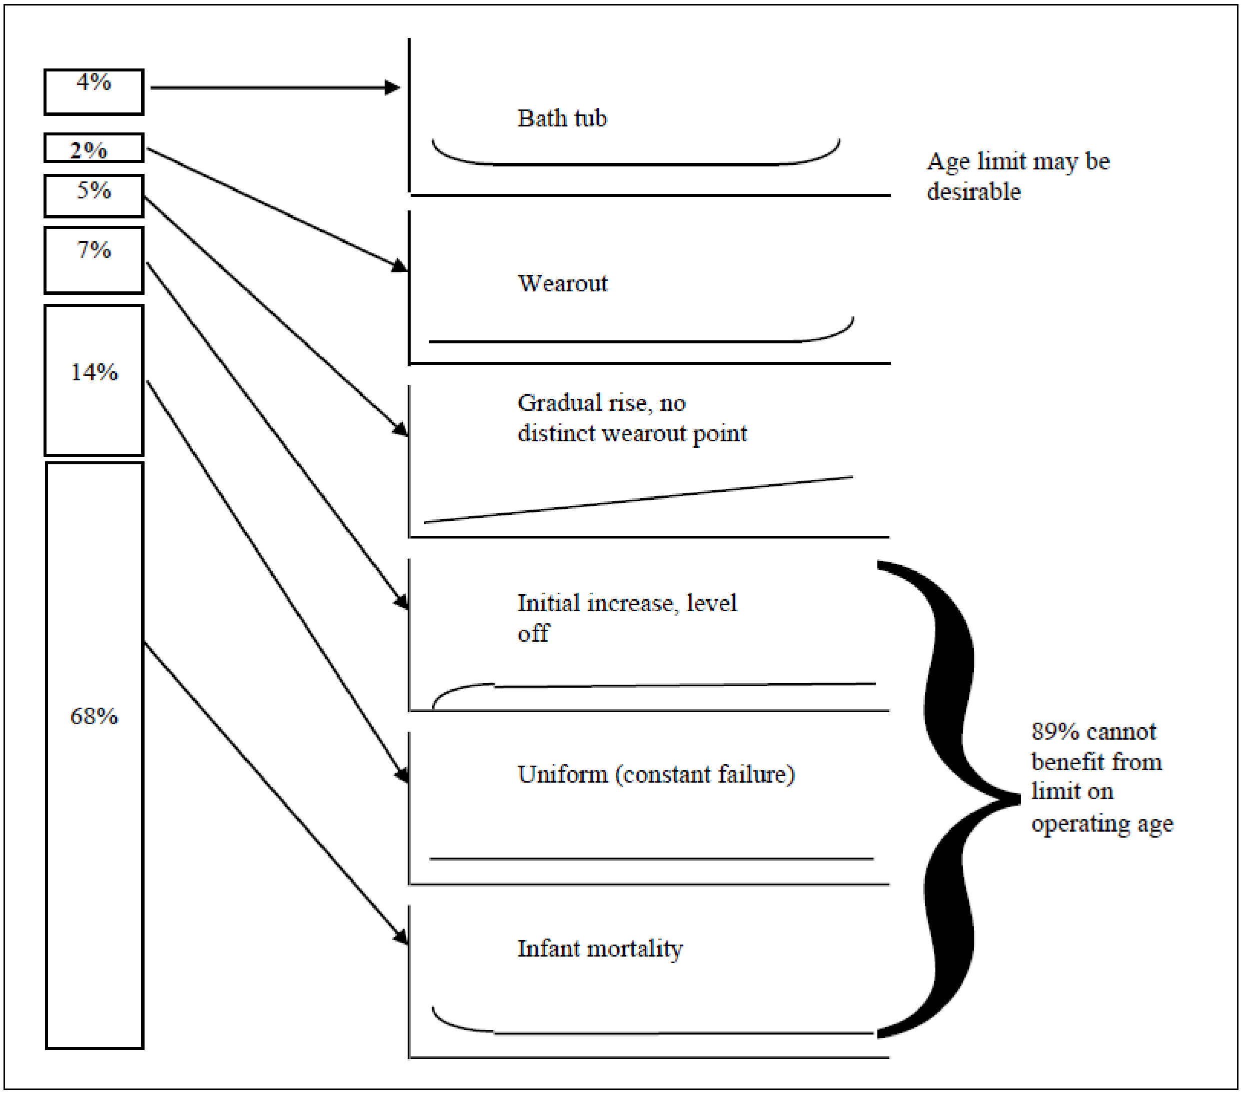
Table 7-5 Examples of Failure Mechanisms and Modes

Modes		
Stuck open (valve) Shorted (connector) Low torque (motor)	Fractured (shaft) Leakage (seal) Excessive friction (shaft journal)	Wear (bearing) Slippage (belt drive) Short (resistor)
Mechanisms		
Brinelling (bearing ring) Fretting (pump shaft) Ionization (microcircuit) Plastic deformation (springs)	Spalling (concrete) Condensation (circuit board) Glazing (clutch plate) Wear (clutch plate)	Elongation/yielding (structure) Freezing (battery) Fatigue (springs) Galvanic corrosion (structure)

7-3.5.3 When Will an Item Fail? (Occurrence).

If the underlying time to failure distribution is known for a part or assembly, then the probability of failure at any point in time can be predicted. For some items, the underlying distribution is exponential and the item exhibits a constant failure rate. In such cases, a new item used to replace an old item has the same probability of failing in the next instant of time as did the old item. Consequently, changing such an item at some prescribed interval has no effect on the probability of failure. It makes more sense to run the item to failure. If that is not possible, if safety is involved for example, then redesign is necessary. As shown in Figure 7-6, only a small percentage of items can benefit from PM. Knowing the underlying distribution of times to failure is essential in determining if PM is applicable.

Figure 7-6 Applicability of Age Limit Depending on Failure Pattern



7-3.5.4 What are the Consequences of the Item Failing? (Severity).

Not all failures are equal in their effect on the system. Obviously, any failures that can cause death or injury to system operators or maintainers, or others who may be served by the system (for example, airline passengers) or are nearby the most serious. Very close in seriousness are failures that can result in compromised mission requirements, pollution to the environment, or a violation of government statutes. At the bottom of the list are failures such as cosmetic damage and other problems that have no effect on system operation. Knowing the effect of a failure helps prioritize decisions. Serious failures usually demand some form of PM or redesign is necessary. Minor failures usually do not lead to redesign and PM is performed only if it is less expensive than running the item to failure. Table 7-6, on the following page, lists some examples of failure effect categorization used in FMEAs and in the RCM process. The way failure effects are categorized for C5ISR facilities should be based on the functions of the facility. Obviously, any failure that could kill or injure personnel or cause loss of the C5ISR mission would have to be categorized as the most serious. The criteria shown in Table 7-6, or some combination could be the basis for a C5ISR facility-specific categorization approach. Note that in using the RCM approach to developing a PM program, all failure must be put into one of three categories (Preventative Maintenance, Predictive Maintenance, Corrective Maintenance). These categories are used in the logic trees.

Table 7-6 Examples of Failure Effect Categorization

AIAG Standard (Automobile Industry Standard)		
Effect	**Severity of Effect**	**Ranking**
Hazardous without warning	Very high severity ranking when a potential failure mode affects safe system operation and/or involves noncompliance with federal safety regulation without warning	10
Hazardous with warning	Very high severity ranking when a potential failure mode affects safe system operation and/or involves noncompliance with federal safety regulation warning	9
Very High	System/item inoperable with loss of primary function	8
High	System/item operable, but at reduced performance level. User dissatisfied	7
Moderate	System/item operable, but comfort/convenience item inoperable	6
Low	System/item operable, but comfort/convenience item operate at reduced level	5
Very Low	Defect noticed by most customers	4
Minor	Defect noticed by average customers	3
Very Minor	Defect noticed by discriminating customers	2
None	No effect	1
Example of a Simplified Categorization		
Critical	Death, loss of system, violation of governmental statute	
High	Injury, loss of some system functions, very high economic loss	
Moderate	Damage to system requiring maintenance at first opportunity, economic loss	
Low	Minor damage to system, low economic loss	
Negligible	Cosmetic damage, no economic loss	
RCM Analysis		
Safety	Directly and adversely effects on operating safety	
Operational	Prevents the end system from completing a mission	
Economic	Does not adversely affect safety and does not adversely affect operations - the only effect is the cost to repair the failure	

7-4 FUNDAMENTALS OF RCM.

7-4.1 Objectives of RCM.

This chapter provides a discussion of the two primary objectives of RCM: Ensure safety through preventive maintenance actions, and, when safety is not a concern, preserve functionality in the most economical manner. For C5ISR facilities, mission should be considered at the same level as safety.

7-4.2 Applicability of Preventive Maintenance.

7-4.2.1 Effectiveness.

PM can be effective only when there is a quantitative indication of an impending functional failure or indication of a hidden failure. That is, if reduced resistance to failure can be detected (potential failure) and there is a consistent or predictable interval between potential failure and functional failure, then PM is applicable. Condition monitoring has long been used to monitor operating parameters that have been shown to be dependable predictors of an impending failure. Age limit information can also be utilized to determine effectiveness of preventative maintenance efforts (see Figure 7-6). Preventive maintenance (PM) is effective if a potential failure condition is definable or there is a quantitative indication of an impending failure. PM is generally effective only for items that wear out. It has no benefit for items that have a purely random pattern of failure (such as, failures are exponentially distributed, and the failure rate is constant – see Appendix B for a discussion of statistical distributions). Consequently, performing a PM action for electronics is rare, if ever, since electronics exhibit a random pattern of failures. Mechanical items, on the other hand, usually have a limited useful period of life and then begin to wear out.

7-4.2.2 Economic Viability.

The costs incurred with any PM being considered for an item must be less than for running the item to failure. The failure may have operational or non-operational consequences. The costs to be included in such a comparison for these two failure consequences are Operational and Nonoperational.

7-4.2.2.1 Operational.

The operational cost is defined as the indirect economic loss because of failure plus the direct cost of repair. An example of an operational cost is the revenue lost by an airline when a flight must be canceled and passengers booked another airline. For military organizations where profit is not an objective, an operational cost might be the cost of a second flight or mission. Sometimes, it may be difficult for a military organization to quantify an operational cost in terms of dollars and a subjective evaluation may be needed.

7-4.2.2.2 Non-Operational.

The non-operational cost is defined as the direct cost of repair. The direct cost of repair is the cost of labor, spare parts, and any other direct costs incurred because of repairing the failure (by removing and replacing the failed item or performing in-place repair of the item).

7-4.2.3 Preservation of Function.

The purpose of RCM is not to prevent failures but to preserve functions. Many maintenance people who are unfamiliar with RCM initially find this idea difficult to accept. For many years prior to and following World War II, the "modern" view within the maintenance community was that every effort should be made to prevent all failures. Preventing failure was the focus of every maintenance technician. But products became increasingly complex and maintenance costs increased both in absolute terms and as a percentage of a product's total life cycle costs. It was soon clear that preventing all failures was technically and economically impractical. Instead, attention was turned to preserving all the essential functions of a product. This shift from preventing failures to preserving function was fundamental to the development of the RCM approach to defining a maintenance program.

7-4.2.4 Opportunity Cost.

From time to time manufactures of equipment improve existing equipment maintenance capabilities by providing an improved part of a more effective maintenance process. Both can contribute to a cost-effective improvement of the overall RCM plan. Manufactures in general desire to improve their equipment and track performance and maintenance issues for continuous improvement and to keep ahead of competition.

7-4.3 Failure.

For RCM purposes, three types of failures are defined: functional, evident, and hidden.

7-4.3.1 Types of Failures.

7-4.3.1.1 Functional Failure.

A functional failure is one in which a function of the item is lost. A functional failure directly affects the mission of the system. To be able to determine that a functional failure has occurred, the required function(s) must be fully understood. As part of a FMEA, all functions have been defined. This definition can be very complex for products that have varying levels of performance (for example, full, degraded, and loss of function).

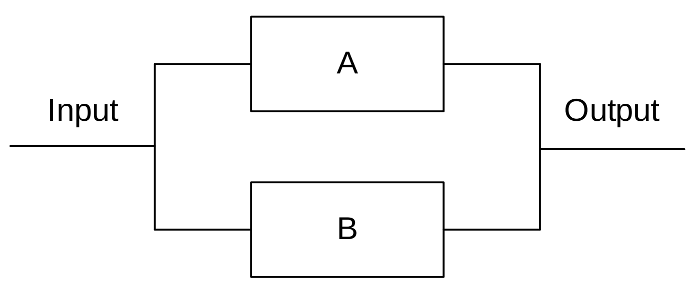
7-4.3.1.2 Evident Failures.

When the loss of a function can be observed or is made evident to the operator, the failure is said to be evident. In the latter case, dials or displays, audible or visual alarms, or other forms of instrumentation alert the operator to the failure.

7-4.3.1.3 Hidden Failures.

A hidden failure is a functional failure of an item that has occurred, has not affected performance of the end system, and is not evident to the operator, but will cause a functional failure of the end system if another item fails. In other words, because of redundancy or the nature of the item's function in the system, no single-point failure of the end system has occurred. If, on the other hand, multiple failures occur, then the system will fail to perform its function. A simple example is the system shown in Figure 7-7. Either of the two redundant items, A and B, can perform a critical function. Redundancy was used because the function is critical and a single point failure was unacceptable. If either item A or B can fail without the knowledge of the operator, it is considered a hidden failure. The system would now be subject to a single point failure (such as, the function can be lost by one more failure – the failure of the other redundant component). Hidden failures must be found by maintenance personnel.

Figure 7-7 Block Diagram of A simple Redundant System



7-4.3.2 Consequences of Failure.

A basic objective of the RCM analysis is to make decisions regarding the selection of a maintenance action for a specific functional failure of a specific item based on the consequence of the failure. Three categories of failure consequences are generally used. They are safety, operational (mission), and economic.

7-4.3.2.1 Safety.

If a functional failure directly has an adverse effect on operating safety, the failure effect is categorized as Safety. The functional failure must cause the effect by itself and not in combination with other failures. That is, the failure must be a single-point failure. (Note that a hidden failure for which no preventive maintenance is effective and which, in combination with another failure, would adversely affect safety must be treated as a safety-related failure. The methodology is designed to address this situation).

7-4.3.2.2 Operational.

When the failure does not adversely affect safety but prevents the end system from completing a mission, the failure is categorized as an Operational failure. For many end systems, operational failure results in loss of revenue. In other cases, a critical objective cannot be met. See Table 7-7 for examples.

(a) An adverse effect on safety means that the result of the failure is extremely serious or catastrophic. Results can include property damage, injury to operators or other personnel, death, or some combination of these.

(b) In some industries, this category is expanded to include failures that result in a federal statute being violated. An industry such as the petroleum or power industry often includes failures that would result in violations of the Environmental Protection Act. Other industries may include failures with other effects in this category.

Table 7-7 Examples of Effects of Operational Failures

End System	Effect of Operational Failure
Airliner	Airline must cancel flight and either send passengers to another airline or add a flight. In either case, revenue is adversely affected.
Manufacturing equipment	Production must be halted until repairs are made adversely affecting sales. Some orders may be canceled because delivery dates cannot be met (unless no other sources can provide the product to the customers – in that case, loss of customer confidence may result affecting future sales).
Military aircraft	Prolonged or lost conflict, inability to respond to a political crisis in a timely manner, or exposure to a period of vulnerability
Financial information system	Loss of revenue due to an inability to make investments, penalties due to late payments, etc.
C5ISR Facility	Facility cannot provide necessary electrical power to support an assigned mission.

7-4.3.2.3 Economic.

When a functional failure does not adversely affect safety and does not adversely affect operations, then the failure is said to have an Economic effect. The only penalty of such a failure is the cost to repair the failure.

7-5 RCM PROCESS.

7-5.1 C5ISR Candidates for RCM Analysis.

It is important to note from the onset that an RCM analysis is not beneficial for all products. The criteria listed in Table 7-8 will help the analyst determine if an RCM analysis is potentially of value. There are three major systems comprising C5ISR facilities that are candidates for RCM analysis, mechanical systems, electrical systems, and control systems. All three combine to support the facilities mission and provide the necessary environmental conditions to maintain operation of critical equipment and personnel. All the components shown in paragraph 7-5.1 are candidates for RCM optimization and require a maintenance program geared toward the mission requirement of the facility.

Table 7-8 Criteria for Applying RCM to Products

Criteria	Comment
Product has or is projected to have a large number of PM tasks.	Existing product already in service or new system for which the PM tasks were identified using an approach other than RCM.
Product maintenance costs are or are projected to be very high.	Existing product already in service. PM tasks identified using an approach other than RCM or RCM requires updating. New system for which maintenance tasks were identified using approach other than RCM
Product requires or is projected to require frequent corrective maintenance.	Existing product already in service. PM tasks either identified using an approach other than RCM or RCM requires updating. New System for which maintenance tasks were identified using an approach other than RCM.
Hazardous conditions could result from failure	New product, or existing product for which the PM tasks were identified using an approach other than RCM.

7-5.1.1 Mechanical Systems.

The types of mechanical systems typical for a C5ISR facility include those listed below.

- Chillers
- Boilers
- Cooling Towers
- HVAC distribution equipment including Fan Coil Units
- Valves
- Piping

7-5.1.1.2 Other Systems.

Mechanical systems also include generators, fuel oil delivery systems and storage and pumping components. These are critical to the mission of the facility but are frequently neglected.

7-5.1.1.3 Temperatures.

Mechanical systems not only maintain a comfortable environment for the occupants but are also designed to maintain optimal equipment operating temperatures.

7-5.1.2 Electrical Systems.

Electrical systems begin at the transformer feeding the building or the 13.8kV feeder and continue through the entire distribution system generally to the panels containing the 220 or 208/120-volt distribution. Some facility mission requirements require solutions all the way to the operating equipment at the wall outlet. Typical components comprising the electrical system include those listed below.

- Transformer, liquid filled and air cooled
- Connections
- Cables
- Switch Gear
- Circuit Breakers
- Motor Control Centers
- Motors
- Cable Connections
- UPS systems including Gel and Wet Cell Lead Acid Batteries

7-5.1.3 System Controls.

Control systems are the third major component making a C5ISR facility as reliable as possible. Control systems are the brains behind the operational characteristics during normal and abnormal conditions. Control systems are commonly identified as SCADA systems and are designed to monitor conditions and react in a manner to maintain a set point. Typical SCADA systems are comprised of a series of sensors sending signals to a central command center where the signals are interpreted. Signals are sent from the command center to actuators to throttle input conditions and provide the necessary environmental condition required for the mission operations. Typical components for a SCADA system are listed below.

- Computer access panel
- Digital drivers
- Power Supplies
- PLC
- Interface devices such as control panels or circuit breakers

7-5.2 RCM Data Sources.

Conducting an RCM analysis requires an extensive amount of information. Since much of this information is not available early in the design phase, RCM analysis for a new product cannot be completed until just prior to production. Table 7-9 lists some general sources of data for the RCM analysis. The data elements from the FMEA that are applicable to RCM analysis are highlighted in paragraph 7-5.4.2. Note that when RCM is being applied to a product already in use, or when a maintenance program is updated during Life Exploration, historical maintenance and failure data will be inputs for the analysis.

Table 7-9 General Data Sources for the RCM Analysis

Data Source	Comment
Lubrication requirements	Determined by designer. For off-the-shelf items being integrated into the product, lubrication requirements and instructions may be available.
Repair manuals	For off-the-shelf items being integrated into the product.
Engineering drawings	For new and off-the-shelf items being integrated into the product.
Repair parts list	
Quality deficiency reports	For off-the-shelf items being integrated into the product.
Other technical documentation	For new and off-the-shelf items being integrated into the product.
PREP Database	For new and off-the-shelf items being integrated into the product.
Recorded observations	From test of new items and field use of off-the-shelf items being integrated into the product.
Hardware block diagrams	For new and off-the-shelf items being integrated into the product.
Bill of Materials	For new and off-the-shelf items being integrated into the product.
Functional block diagrams	For new and off-the-shelf items being integrated into the product.
Existing maintenance plans	For off-the-shelf items being integrated into the product. Also, may be useful if the new product is a small evolutionary improvement of a previous product.
Maintenance technical orders/manuals	For off-the-shelf items being integrated into the product
Discussions with maintenance Personnel and field operators	For off-the-shelf items being integrated into the product. Also, may be useful if the new product is a small evolutionary improvement of a previous product.
Results of FMEA, FTA, and other reliability analyses	For new and off-the-shelf items being integrated into the product. Results may not be readily available for the latter.
Results of Maintenance task analysis	For new and off-the-shelf items being integrated into the product. Results may not be readily available for the latter.

7-5.2.1 C5ISR Data Sources.

RCM related data may be obtained from several different types of sources. Some potential sources of maintainability data include those listed below.

- Historical data from similar products used in similar conditions (PREP Database, IEEE Gold Book)
- Product design or manufacturing data
- Test data recoded during demonstration testing
- Field data

7-5.2.1.2 Expressing Data.

The data maybe expressed in a variety of terms. These include observed values or modified values (true, predicted, estimated, extrapolated, etc.) of the various maintainability measures. Some precautions are therefore necessary regarding the understanding and use of such data as listed below.

- Historical – Used primarily during the concept definition phase to generate specifications requirements. In later phases historical data may be compared with actual data obtained for the product. They can also serve as additional sources of information for maintainability verification.
- Product Design and Manufacturing – Data obtained using design analysis or prediction, or from data generated during the design phase or the manufacturing phase. Design data may be used as the basis for product qualification and acceptance, review and assessment of historical data relevancy and the validity of previous assessments. Before this type of data is used in an analysis the analyst must understand the data collection and analysis methodology, why the specific method was chosen, and any possible limitations.
- Product Demonstration and Field – These data are essential for sustaining engineering activities during the in-service phase of the system life cycle. They include maintainability related data obtained from formal or informal demonstration test on mock-ups, prototypes, or production equipment in either a true or simulated environment or data generated during actual item use.

7-5.2.1.3 Other Data Categories.

Other categories of data that would be beneficial to collect include information on the maintenance support conditions. Operational maintainability may not be determined solely by inherent maintainability, but by logistical factors. Therefore, information to be collected should include shortages in spares (due to inadequate initial provisioning, long pipeline times, etc.), test resources, and human resources. Such data are important to determine why a system's maintainability as measured in the field, may not be meeting the values expected based on the design data.

7-5.2.1.4 SCADA Systems.

SCADA systems are excellent data collection mechanisms, providing the system is initially designed to capture critical information. It can also be utilized to monitor trends of component operational conditions to provide information on proactive logistics supplies.

7-5.3 PM Tasks Under RCM.

7-5.3.1 Lubrication and Servicing Task.

Many mechanical items in which movement occurs require lubrication. Examples include internal combustion engines that require oil and periodic replacement of that oil (and associated filters). Lubrication and servicing tasks are sometimes overlooked due their relative simplicity and because they are "obvious." Prior to the latest version of the airline's RCM approach, lubrication and servicing tasks were often omitted from the decision logic tree, with the understanding that such tasks cannot be ignored. In the current MSG-3, these tasks are explicitly included in the decision logic, as they are in this document.

7-5.3.2 Inspection or Functional Check Task.

Inspections normally refer to examinations of items to ensure that no damage, failure, or other anomalies exist. Inspections can be made of an entire area (for example, the body or "under the hood"), a subsystem (for example, the engine, controls, or feed mechanism), and a specific item, installation, or assembly (for example, the battery, shaft, or flywheel).

7-5.3.2.1 Visual Inspections or Checks.

These are checks conducted to determine that an item is performing its intended function. The check may be performed by physically operating the item and observing parameters on displays or gauges, or by visually looking to see if the function is being performed properly. In neither case are quantitative tolerances required. A functional check consists of operating an item and comparing its operation with some pre-established standard. Functional checks often involve checking the output of an item (for example, pressure, torque, voltage, or power) and checking to determine if the output is acceptable (such as, within a pre-established range, greater than a pre-established minimum value, or less than a pre-established maximum value). These checks are conducted as failure finding tasks.

7-5.3.2.2 Use of NDI.

Inspections may consist of purely visual examinations or be made using special techniques or equipment. Many inspections require the special capability of non-destructive inspection (NDI) techniques. Table 7-10 lists some of the NDI methods available to maintenance personnel.

Table 7-10 NDI Techniques

Legend: C = Cracks; W = Wear; F = Fractures; CR = Corrosion; E = Erosion; L = Leaks; MA = Material Analysis; MC = Material Conditions; S = Stress; D = Deformation; MT = Material Thickness; DT = Deposit Thickness; PR = Physical Restrictions

NDE Method \ Main Application		C	W	F	CR	E	L	MA	MC	S	D	MT	DT	PR	OTHER	Remarks

7-5.3.3 Restoration Task.

Many items, primarily mechanical, wear out as they are used. At some point, it may be necessary, and possible, to restore the item to "like new" condition. Examples include internal combustion engines, electric motors, and pumps.

7-5.3.4 Discard Task.

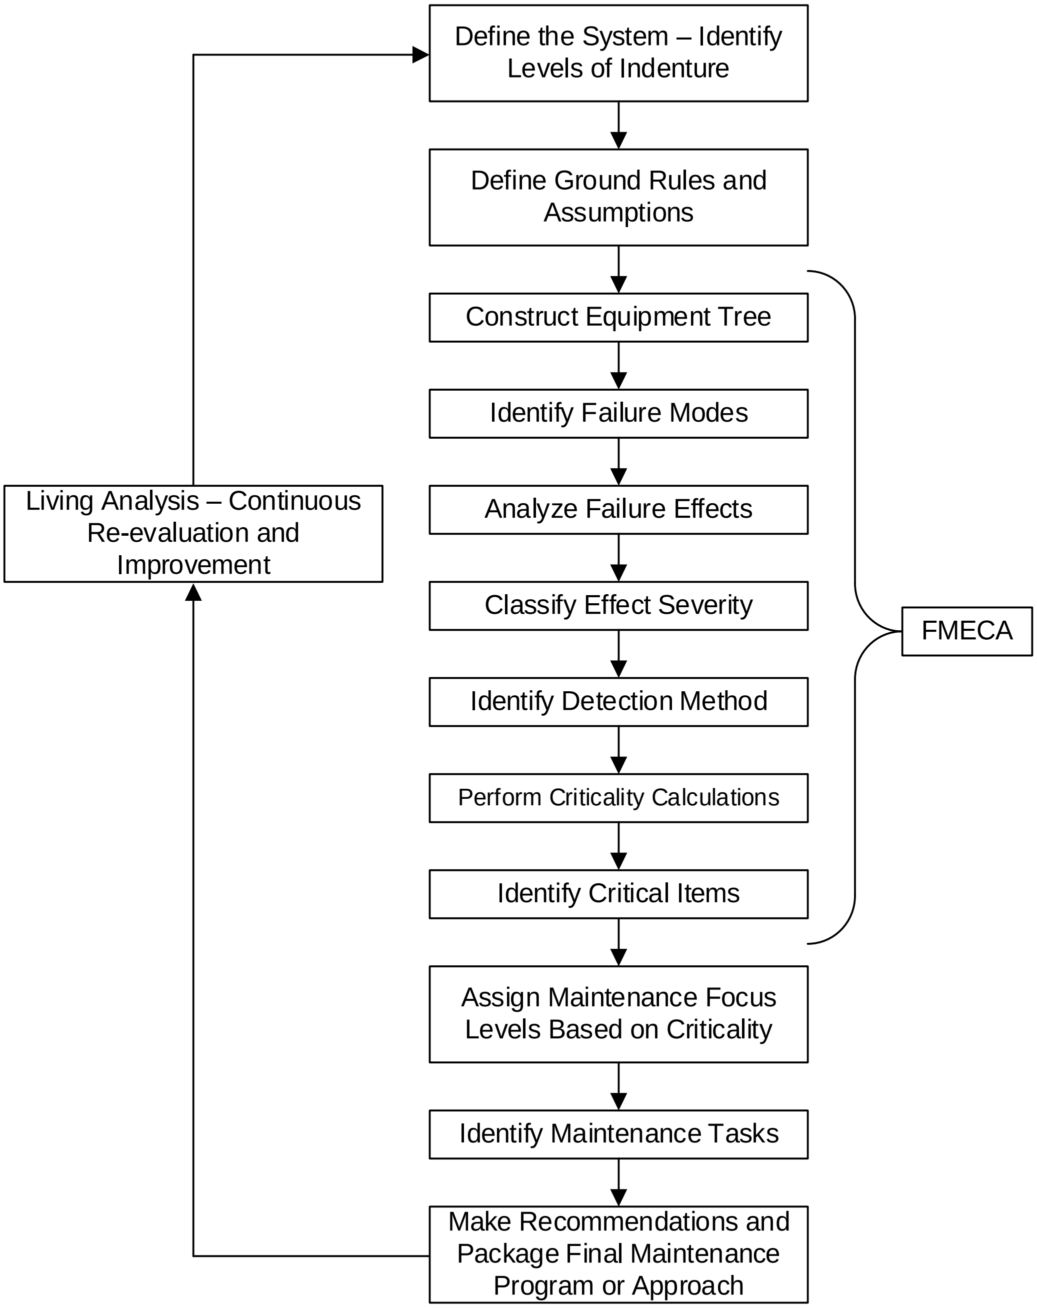
Some items upon failure or after their useful life has been reached (such as, they are worn out), cannot be repaired or restored. These items must be discarded and replaced with a new item identical in function. Examples include seals, fan belts, gaskets, screws (stripped threads), and oil filters.

7-5.4 The RCM Process.

The objective of conducting an RCM analysis is to rank all included equipment and systems by their relative importance, and risk, to the overall facility mission, and to prescribe PM tasks based on subsystem and system ranking. The RCM process is outlined below, by an expanded Figure 7-8, and following text.

- Define the System – Identify and document the boundaries of the analysis
    - Identify and document equipment included in the analysis
    - Identify and document the indenture level the analysis is intended to extend to
- Define Ground Rules and Assumptions – Identify and document ground rules and assumptions used to conduct the analysis
- Construct Equipment Tree – Construct equipment block diagrams to indicate equipment configuration, down to the lowest indenture level intended to be covered by the analysis
- Identify Failure Modes – Identify the potential failure modes for the analyzed equipment at the indenture levels covered by the analysis
- Analyze Failure Effects – Analyze the effects of the identified failure modes on the lowest levels of indenture and above
- Classify Effect Severity – Classify the effects of the identified failure modes on the lowest levels of indenture and above
- Identify Detection Method – Identify and classify the methods, in place, by which potential failures may be detected or avoided
- Perform Criticality Calculations – Perform Criticality Analysis

Figure 7-8 The RCM Process



- Identify Critical Items – Identify items within the analysis that ranked highly critical
- Assign Maintenance Focus Levels – Classify maintenance focus levels based on criticality rankings
- Apply RCM Decision Logic – Apply RCM logic trees for items, especially those identified as being critical

- Identify Maintenance Tasks – Identify maintenance tasks to be performed on the given item
- Package Maintenance Program – Develop a maintenance tasking schedule for the analyzed equipment

7-5.4.1 Identify the System Configuration.

Since the RCM analysis usually begins before the final design has been completed, the system configuration is changing. Even when the design is complete, model changes can be made. The configuration, of course, determines how functions are performed, the relationship of items within a product, and so forth. Consequently, it is important that the precise configuration of the product or system for which the RCM analysis is being conducted be documented as part of the analysis. It is also important that the analysis be updated to account for any changes in the configuration (some of which may be required as a direct result of the RCM analysis itself).

7-5.4.2 Perform a FMEA and Other Analyses.

To perform the RCM analysis, many pieces of information are needed. These include the information listed below.

- The types of failures that can occur in the product
- The failure characteristics of the items that make up the product being analyzed
- The nature of the failures (hidden, evident, safety, operational, ect.)
- The capabilities of the maintenance organization
- The maintenance concepts
- A thorough understanding of operation

Obviously, such information will probably not be known or be very shaky early in design. For that reason, the RCM analysis should not be started until sufficient and reasonably stable information is available. Of course, the objective is to develop and complete the initial maintenance program prior to the product being transferred to the customer.

RCM Analysis can be conducted using a traditional quantitative, qualitative, or flexible approach.

- Traditional quantitative approach can be used when there is sufficient failure rate data available to calculate criticality numbers. A quantitative approach is the preferred analysis method. However, to be effective, high levels of failure specific data must be available. When specific failure rates for specific failure modes and failure mechanisms are unavailable, analysis must be conducted qualitatively.

- Qualitative analysis must be used when specific part or item failure rates are not available. Therefore, failure mode ratio and failure mode probability are not used in this analysis. Instead, the equipment is ranked in terms of discrete occurrence levels. Under traditional qualitative analysis severity, occurrence, and detection method levels are determined subjectively and utilized to produce a component risk assessment.
- The flexible technique is born of traditional qualitative analysis. Under this approach, RPN calculations will be generated by the same formulas as given by traditional qualitative approach. However, the arguments of the component level RPN calculation (*O, S, D*) will be defined differently. See Equation 6-11.

7-5.4.2.2 Other Inputs.

When FTAs are needed to understand the effects of, for example, multiple failures, the information derived from these analyses can also be valuable inputs to the RCM analysis.

7-5.4.2.3 Other Information.

Other important sources of information for the RCM analysis include RBDs, Functional Block Diagrams, system requirements documents, descriptions of system applications, technical manuals/drawings/layouts, and indenture level identification system.

7-5.4.2.4 Sources.

To provide the needed information, various sources must be exploited. One of the most obvious sources is the body of analyses conducted as part of the design process. These include the Failure Mode and Effects Analysis (FMEA) or Failure Modes, Effects, and Criticality Analysis (FMECA), FTA, maintainability analysis, and so forth.

7-5.4.2.5 FMEA.

The FMEA can be a primary source of much of the information needed for the RCM analysis. Table 7-11 shows excerpts of the form prescribed in the Automotive Industry Group standard on FMEA/FMECA. Table 7-12 indicates the data in many of the columns can be directly used for the RCM analysis. The columns having data most applicable for the RCM analysis are shaded. In addition to those shown, columns can be added for functions, functional failure, compensating provisions, and three columns for failure effects: local effects, next higher level, and end effects. Other chart examples for recording FMECA data can be used as shown in Table 7-12. Further information is available in TM 5-698-4, Failure Modes, Effects and Criticality Analysis (FMECA) for C4ISR Facilities.

Table 7-11 Data Elements from FMEA that are Applicable to RCM Analysis

(Form from the Automotive Industry Group Standard on FMEA)

Item/ Function	Potential Failure Mode(s)	Potential Effect(s) of Failure	SEV	CLASS	Potential Cause(s)/ Mechanisms of Failure	OCC	Current Design Controls	DET	RPN	Recommended Action(s)	Responsibility & Target Completion Date	Action Results				
												Action Taken	New Sev	New Occ	New Det	New RPN

Legend: SEV – Severity of failure effect
OCC – Probability of occurrence
DET – Method of detection
RPN – Risk Priority Number

A completed chart may be similar to the following example:

Table 7-12 Example of Failure Modes and Effects Analysis Worksheet; DA Form 7610

ITEM NUMBER	ITEM/FUNC-TIONAL ID	POTENTIAL FAILURE MODES	FAILURE MECHANISM (CAUSE)	SEVERITY	FAILURE RATE λ_P (SOURCE)	DETECTION METHOD	CRITICALITY NUMBER (C_M)
130.2	Cooling Tower #1/ maintain a water temp of 75°F.	Fan failure	Motor winding open, Loss of power to motor	3	10.0518×10^{-6}	3	99.05×10^{-5}
310.1	Air Handler/ Provide 3200cfm of air to room, maintain room at 72°F,	Provide airflow at a rate less than 3200cfm	Reduced motor output –winding degradation, belt slippage- belt too loose, loose sheave, Dirty intake filter	3	1.7657×10^{-6}	2	1.06×10^{-5}
310.0	Air Handler/ Provide 3200cfm of air to room, maintain room at 72°F,	Maintain air at a temp higher than 72°F	Dirty coils	3	1.7657×10^{-6}	7	3.7×10^{-5}

DA FORM 7610 AUG 2006

Where:

- Failure modes are the generic way an item failed
- Failure mechanisms are the specific circumstances that allowed the given failure mode to occur
- Severity is the assessment of the consequence of a given failure
- Occurrence is the probability of the failure occurring (failure rate)

7-5.4.3 Applying RCM Decision Logic.

The overall decision logic for applying the RCM methodology is depicted in Figure 7-9. The decision logic represented in this figure is adapted from that used in the Reliability Analysis Center's Master Steering Group –3 (MSG-3). The most significant difference is in the portions of the tree labeled ②, ④, ⑦, and ⑧. MSG-1 through MSG-3 used the term "safety" for these portions of the tree.

7-5.4.3.1 Safety.

Safety is of paramount importance to the airline industry, as it is in other industries, such as the nuclear power industry.

7-5.4.3.2 Other Critical Considerations.

Many industries have concerns that are as important, or nearly so, as safety considerations. The petroleum and chemical industries, for example, are subject to severe economic and even criminal penalties under Federal statutes for events in which the environment is polluted. For other industries, failures that result in the violation of other Federal, state, or local statutes, or in other unacceptable consequences may be treated as seriously as safety-related failures are in the airline industry. For that reason, in the portions of the tree labeled ②, ④, ⑦, and ⑧, the term "hazardous effects" is used rather than "safety effects". (The circled numbers in this and following discussions refer to a corresponding numbered portion of the referenced figures.) When applying RCM decision logic, it is important to consider the criticality of the current item. Highly critical items have the direct potential to compromise mission goals, and risk should be heavily mitigated. It is important to recognize single point failures, as well as their functional contribution to critical and non-critical systems, and to prescribe maintenance approaches accordingly. Conversely, some items recognized as being very non-critical may be allowed to run to failure, especially non-critical items that are inherently very reliable. This viewpoint should also be incorporated into the use of RCM decision logic to build an intelligent, and cost effective, maintenance strategy.

7-5.4.4 Use of Logic Tree.

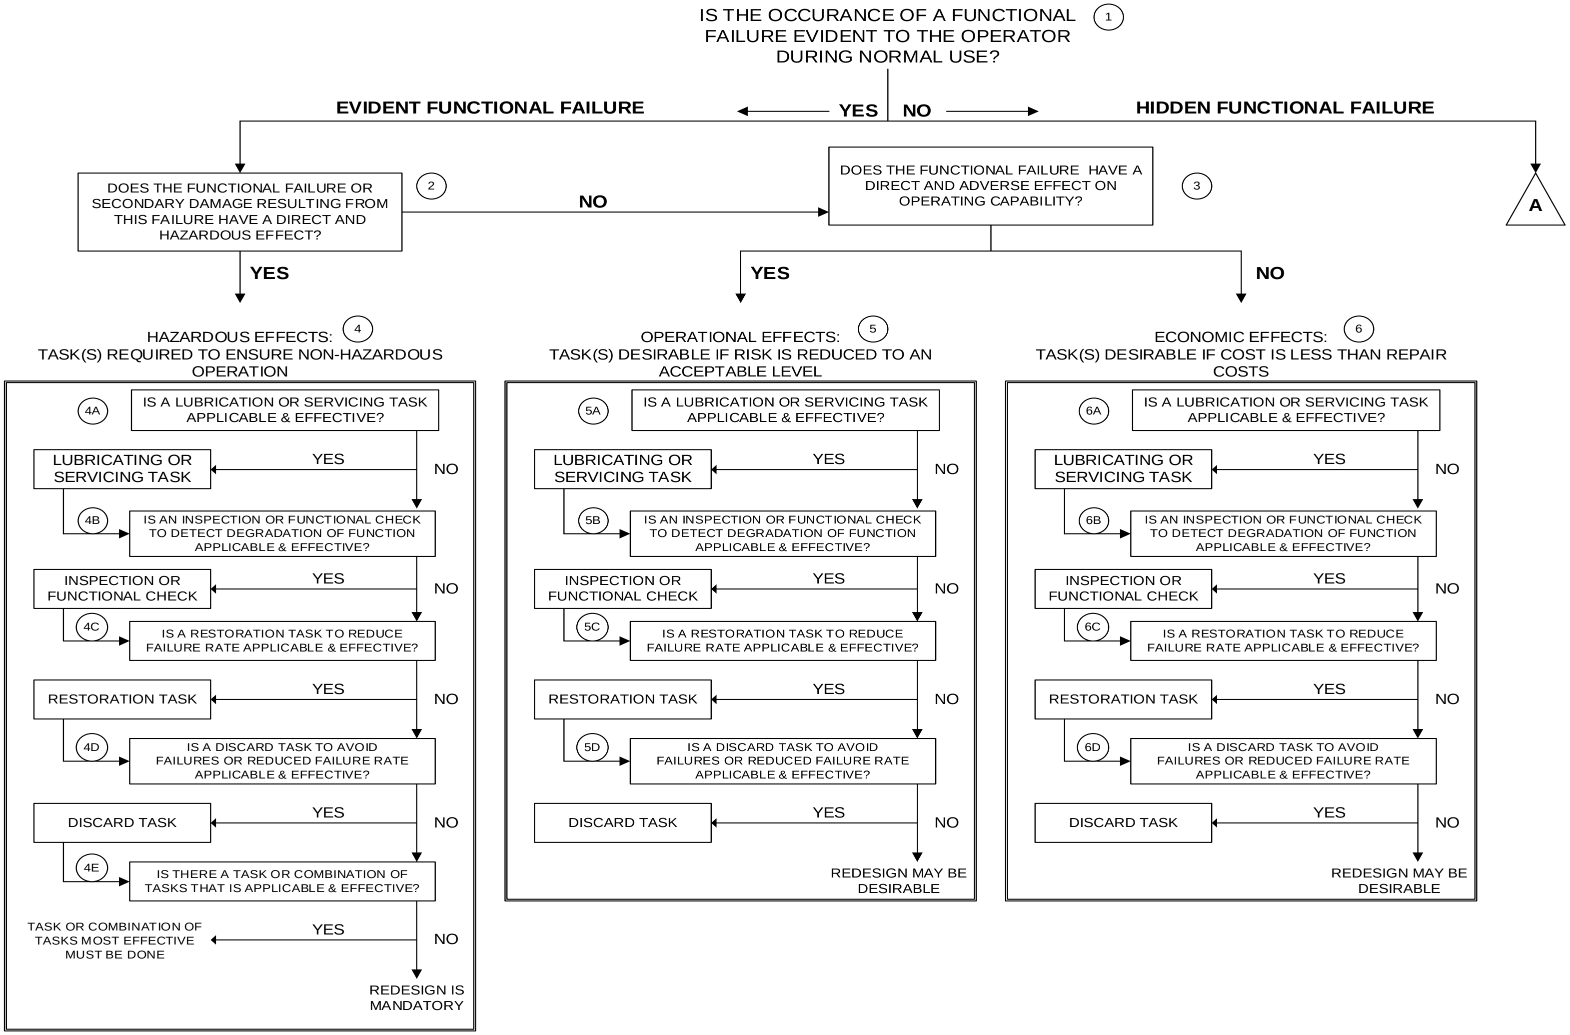
As can be seen from Figure 7-9, the decision logic tree consists of a series of Yes-No questions. The answers to these questions lead to a specific path through the tree. The questions are structured to meet the objectives of the RCM analysis: ensure the safe (non-hazardous) and economical operation and support of a product while maximizing the availability of that product. This objective is met by selecting preventive maintenance (PM) tasks when appropriate, redesign, some combination of PM and redesign, and by corrective maintenance (CM) when PM is either applicable or effective.

(1) The first question asked is "Is the occurrence of a functional failure evident to the operator or (or user) during normal use?" A "No" answer means that the failure is hidden, and the analyst is directed to ⑦ in the tree. The portion of the tree below ⑦ is discussed under paragraphs 7-5.4.8 and 7-5.4.9. A "Yes" answer means that the failure can be observed or is made known to the operator/user, in which case, the analyst is directed to ②.

(2) At ②, the question is "Does the (evident) functional failure or secondary damage resulting from the functional failure have a direct and hazardous effect?" A "Yes" answer directs the analyst to ④. The portion of the tree below ④ is discussed under paragraph

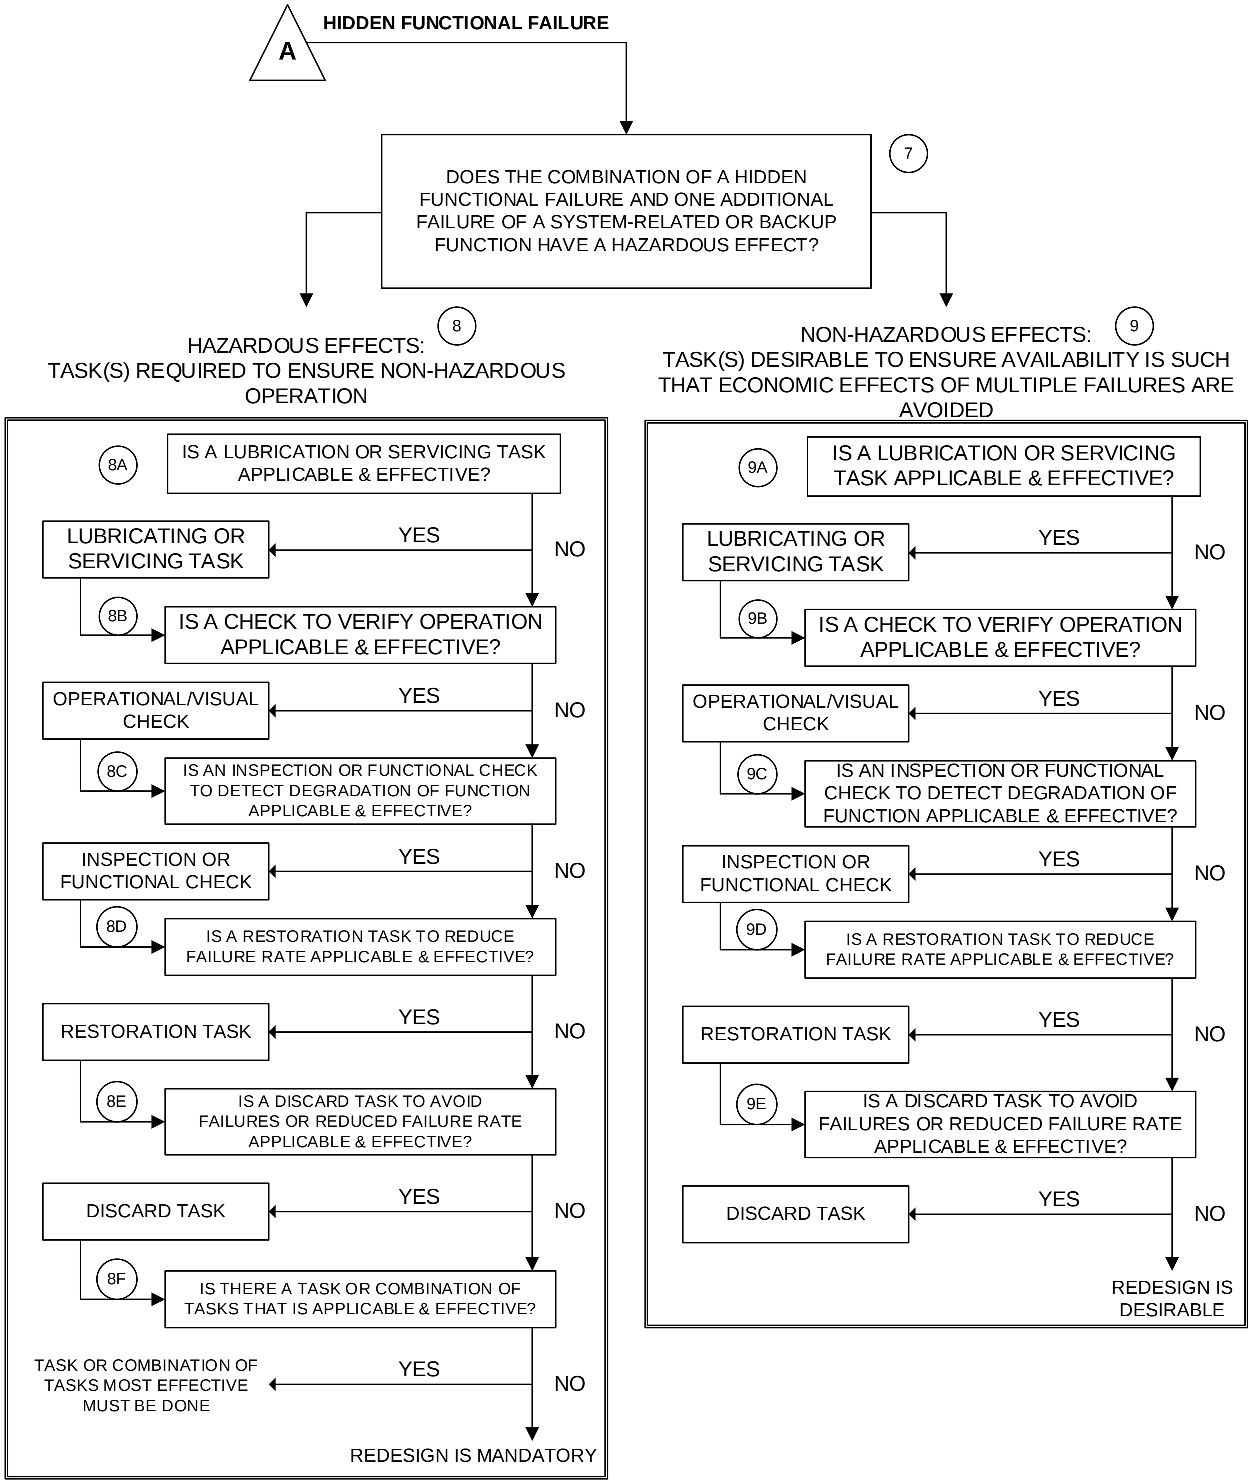
7-5.4.5. A "No" answer directs the analyst to ③. The portion of the tree below ③ is discussed under paragraphs 7-5.4.6 and 7-5.4.7.

Figure 7-9 RCM Decision Logic Tree (Adapted from MSG-3)



* Hazardous effects include property damage, injury or death to operators or other people, violation of Federal environmental or health statutes, and other effects determined by the company or industry to be serious or catastrophic.

Figure 7-9 RCM Decision Logic Tree (Adapted from MSG-3) (cont'd)



* Hazardous effects include property damage, injury or death to operators or other people, violation of Federal environmental or health statutes, and other effects determined by the company or industry to be serious or catastrophic.

7-5.4.5 Evident Failure – Hazardous Effects.

The portion of the decision logic tree that deals with situations where an evident functional failure has hazardous effects is shown in Figure 7-10.

(1) This portion of the tree steps the analyst through a series of questions intended to identify all PM tasks that will reduce to an acceptable level the probability of occurrence of the functional failure that results in the effects, reduce the effects to purely operational or economic effects, or result in a combination of these two improvements.

(2) If none of the PM tasks listed is either applicable or effective, then redesign is mandatory. The reason for making redesign mandatory is obvious. The effects categorized as "hazardous" are unacceptable. Consequently, when PM cannot fulfill any of the objectives listed, a redesign the product must be performed to eliminate the mode of failure that causes the hazardous effects, reduce to an acceptable level the probability of occurrence of the functional failure that results in the effects, or result in a combination
of these two improvements.

7-5.4.6 Evident Failure – Operational Effects.

The portion of the decision logic tree that deals with situations where an evident functional failure has a direct and adverse effect on operating capability is shown in Figure 7-11. This portion of the tree steps the analyst through a series of questions intended to identify all PM tasks that will reduce the risk of failure to an acceptable level. If none of the PM tasks listed is either applicable or effective, then redesign may be desirable. The cost of a functional failure that results in operational effects includes both the cost of the PM and the economic cost incurred because of the end system not completing a mission or being able to perform its function(s).

(1) If the costs exceed the cost to redesign the product, redesign is economically justified. The purpose of the redesign would be to eliminate the mode of failure that causes the operational effects, reduce to an acceptable level the probability of occurrence of the functional failure that results in the effects, or some combination of these.

(2) Even if redesign is economically justified, other considerations, such as schedule, may outweigh the advantages gained.

Figure 7-10 Evident Failure – Hazardous Effects

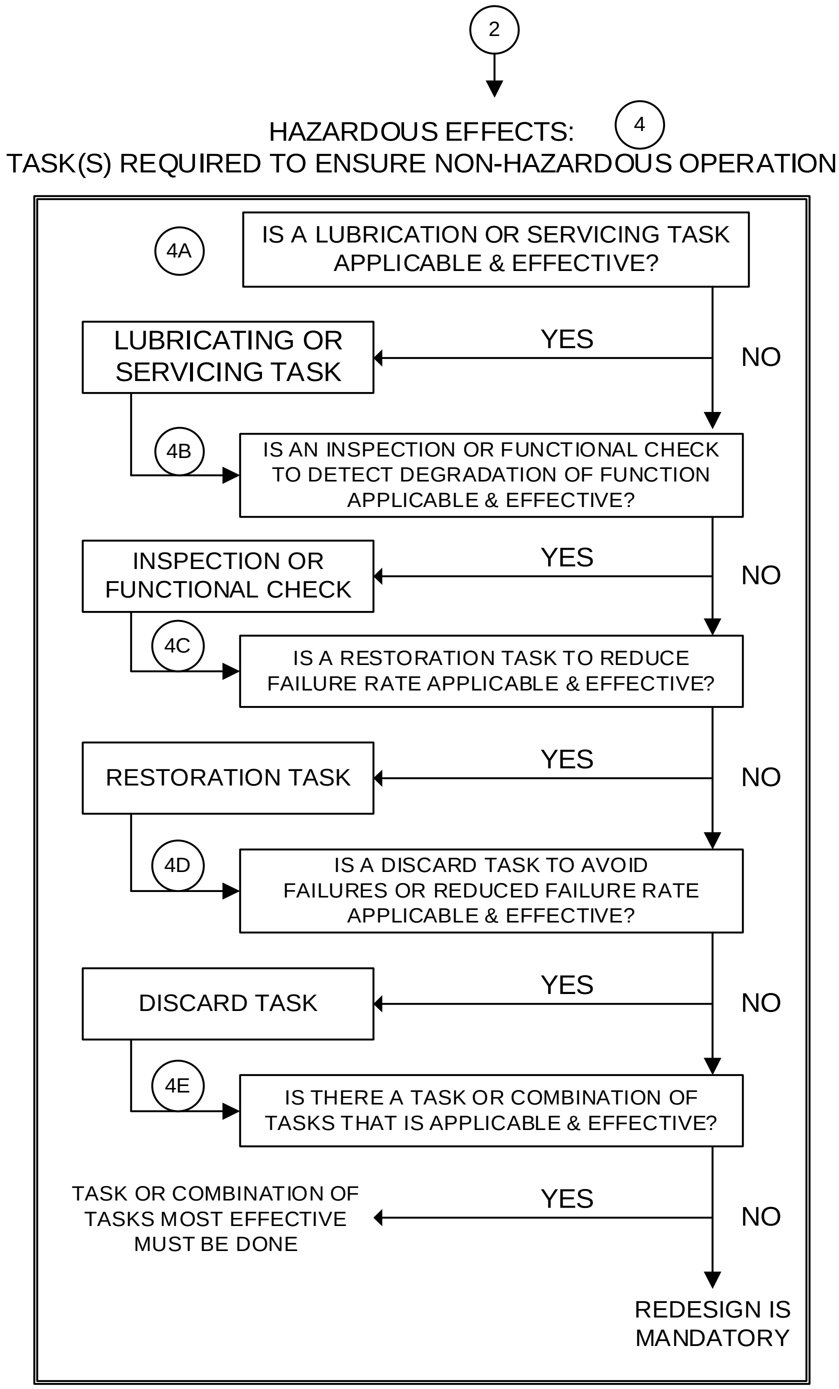


Figure 7-11 Evident Failure – Operational Effects

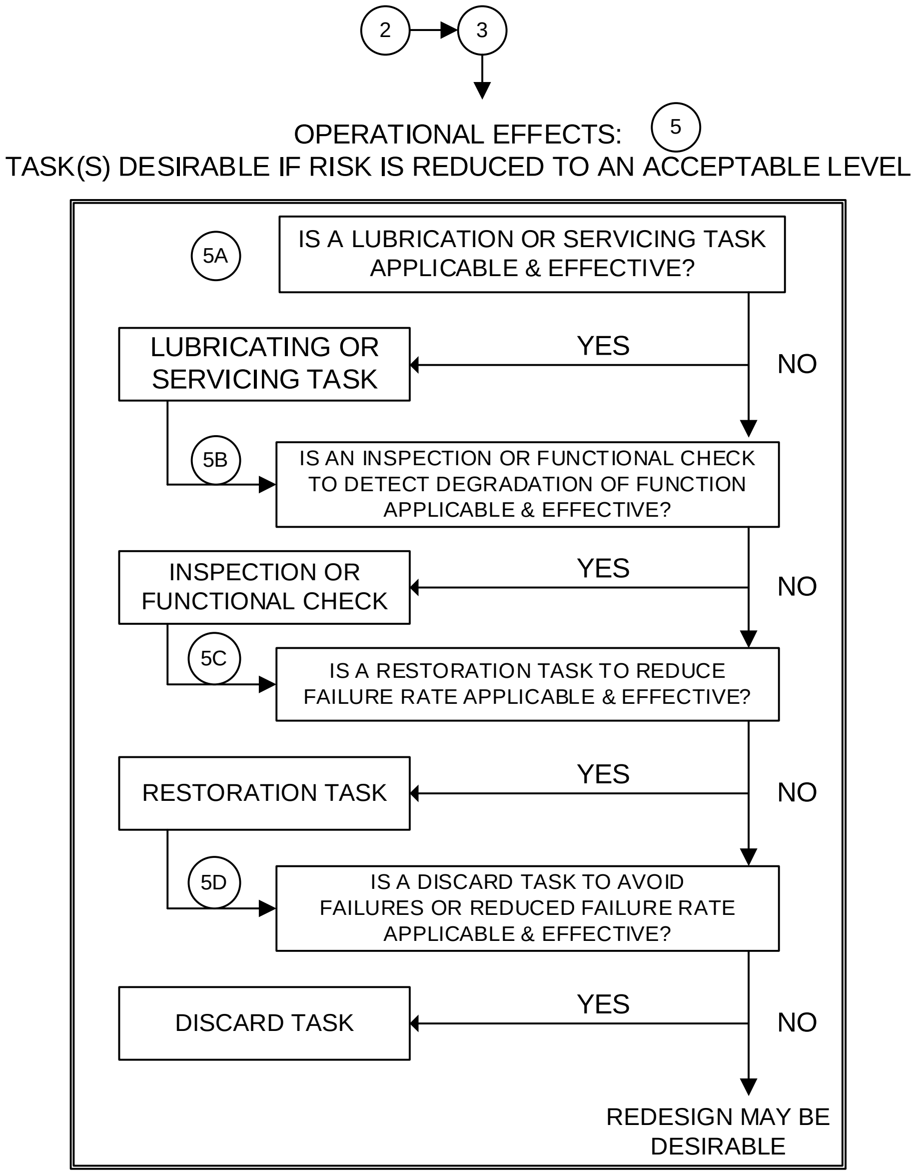
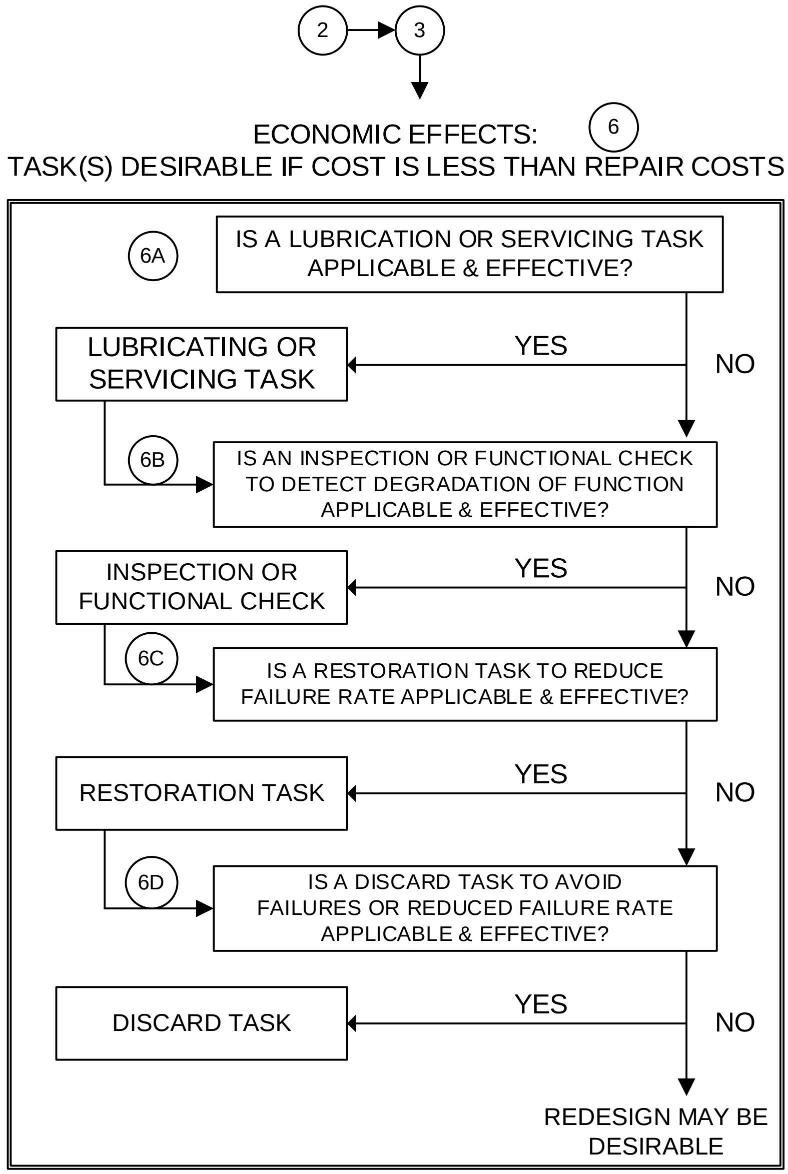


7-5.4.7 Evident Failure – Economic Effects.

The portion of the decision logic tree that deals with situations where an evident functional failure has only an economic effect is shown in Figure 7-12. This portion of the tree steps the analyst through a series of questions intended to identify all PM tasks that are desirable if their costs are less than the cost of repair. If none of the PM tasks listed is either applicable or effective, then redesign may be desirable. Again, the decision to redesign or not redesign is one of economics. If redesign is less than the economic effects of the failure, then it may be desirable. Otherwise, redesign is not justified.

Figure 7-12 Evident Failure – Economic Effects



7-5.4.8 Hidden Failure – Hazardous Effects.

The portion of the decision logic tree that deals with situations where a hidden functional failure has a hazardous effect in combination with another failure is shown in Figure 7-13. This portion of the tree steps the analyst through a series of questions intended to identify all PM tasks that are required to ensure non-hazardous operation. The tasks are effective if they reduce to an acceptable level the probability of occurrence of the functional failure that results in the effects, reduce the effects to purely operational or economic effects, or result in a combination of these.

(1) If none of the PM tasks listed is either applicable or effective, then redesign is mandatory. The reason for making redesign mandatory is obvious. The effects categorized as "hazardous" are unacceptable. Consequently, when PM cannot fulfill any of the objectives listed, a redesign must be performed the product to eliminate the mode of failure that causes the hazardous effects, reduce to an acceptable level the probability of occurrence of the functional failure that results in the effects, or result in a combination of these.

(2) Note that by redesigning to make the failure evident, the effects might be reduced to purely economic or operational.

7-5.4.9 Hidden Failure – Non-Hazardous Effects.

The portion of the decision logic tree that deals with situations where a hidden functional failure has a non-hazardous effect is shown in Figure 7-14. This portion of the tree steps the analyst through a series of questions intended to identify all PM tasks that are desirable to ensure availability is sufficiently high to avoid the economic effects of multiple failures. If none of the PM tasks listed is either applicable or effective, then redesign is desirable.

Figure 7-13 Hidden Failure – Hazardous Effects

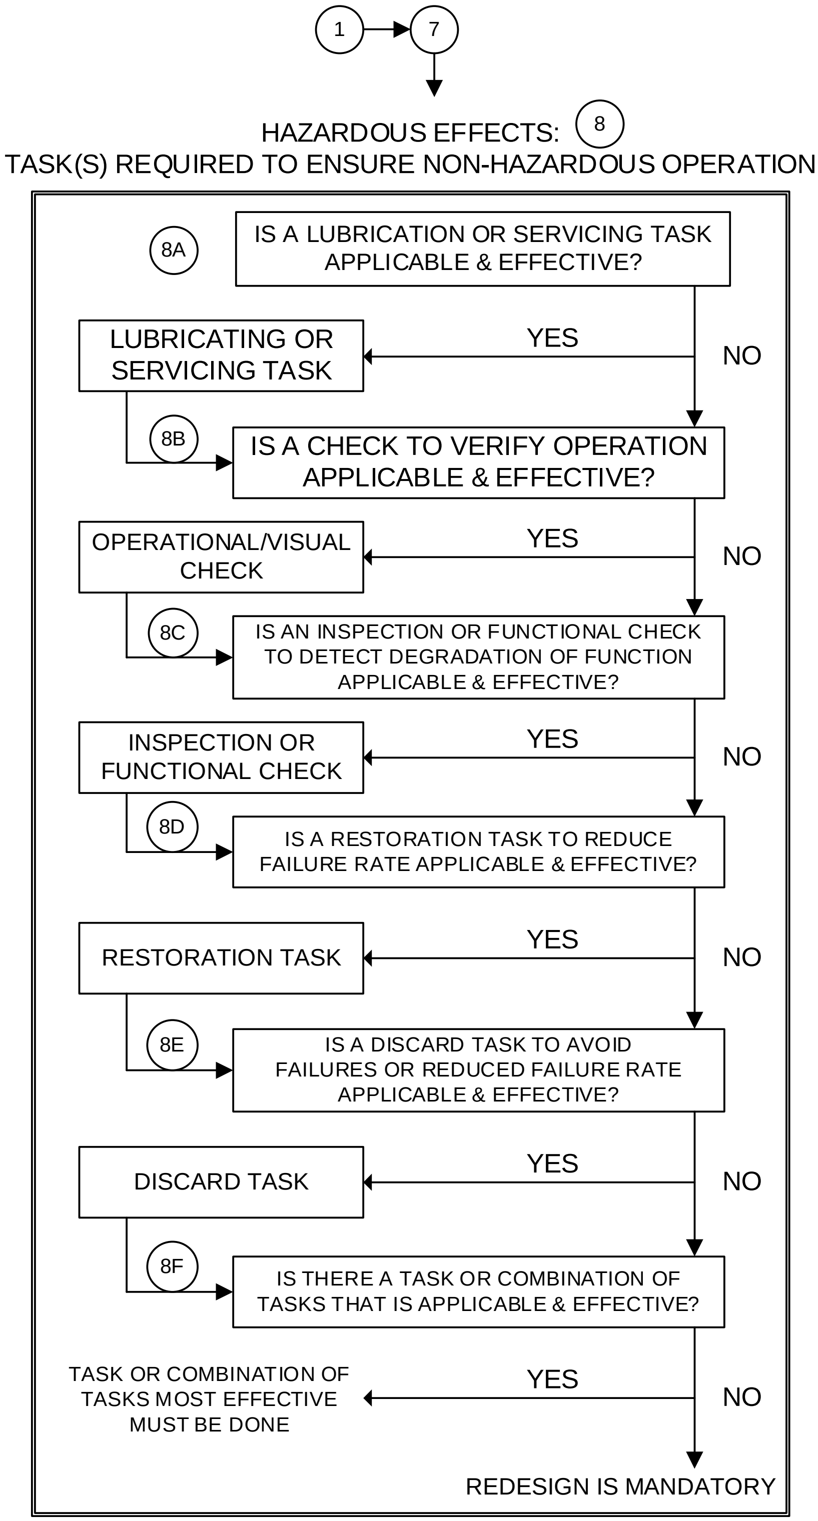


Figure 7-14 Hidden Failure – Non-Hazardous Effects

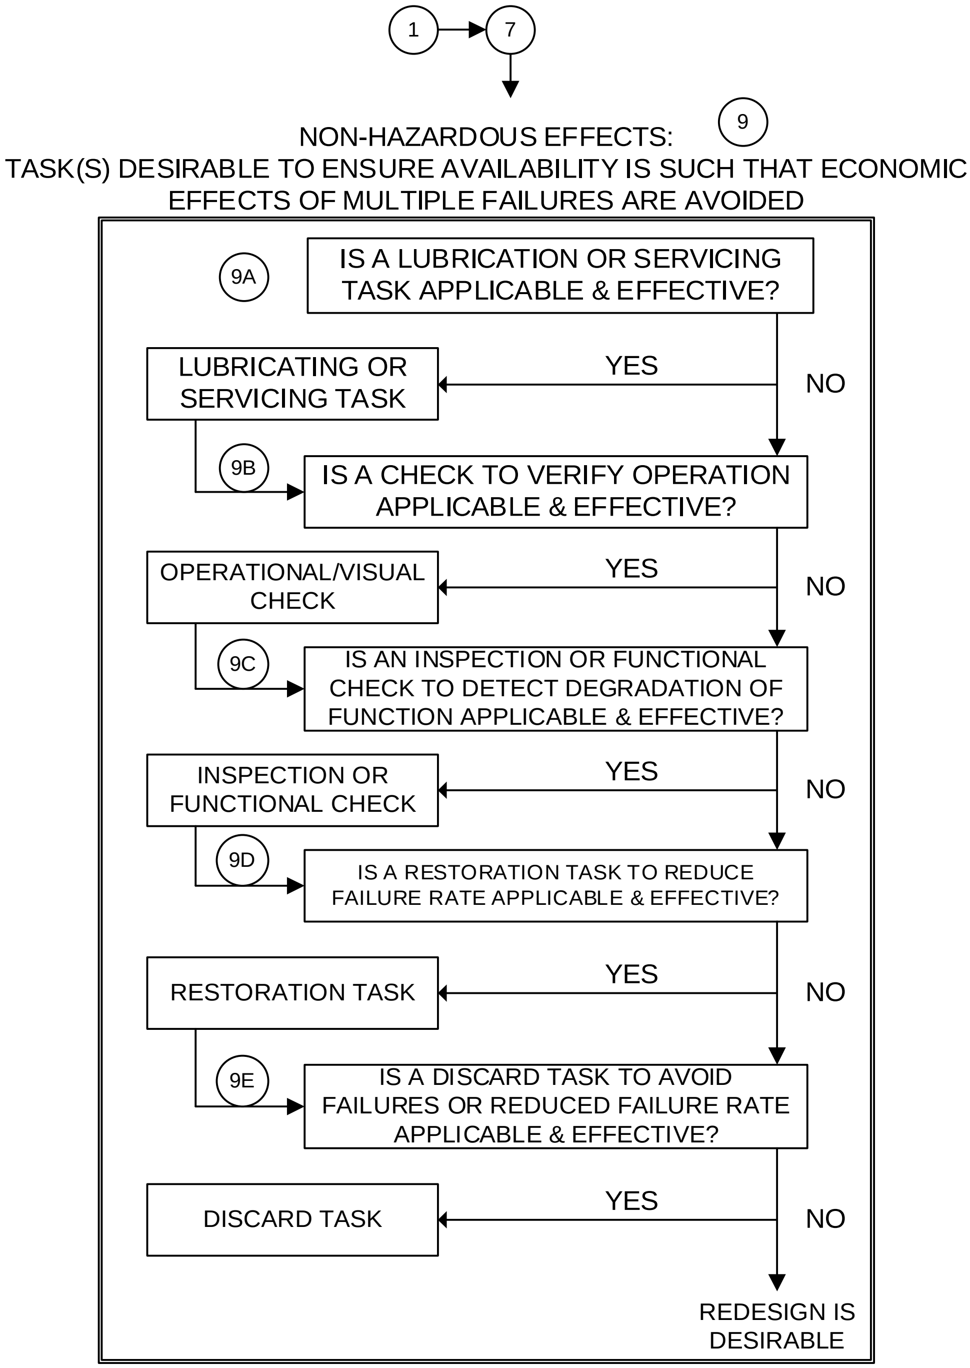

7-5.4.10 Package Final Maintenance Program.

The result of the RCM analysis will be a set of preventive maintenance (PM) tasks and, by default, a set of corrective maintenance (CM) tasks. PM will consist of on-condition and scheduled maintenance.

(1) Frequency of tasks. The frequency with which each of the scheduled PM tasks must be performed will no doubt vary from item to item. It is also probable that many of these tasks may be grouped and performed together at some calendar or operating time interval. The process of grouping the scheduled tasks into sets of tasks to be performed at some prescribed time is called "packaging" the maintenance program.

(2) Example of packaging. For example, it may be that for a given product that the scheduled tasks listed below were identified.

- Three visual inspections: A to be conducted every 45 hours of operation, B to be conducted every 52 hours of operation, and C to be conducted every 105 hours of operation.
- A lubrication performed every 55 hours of operation
- A non-destructive inspection every 100 hours of operation
- An overall task performed when a stated operating characteristic is out of limits
- A hard-time replacement task every 60 hours of operation

One way to package these tasks is listed below.

- Conduct the following PM every 50 operating hours (such as, at 50, 100, 150, 200, ect.)
    - Visual Inspections A and B
    - Lubrication
    - Hard-time replacement
- Conduct the following PM every 100 operating hours (such as, at 100, 200, 300, ect.)
    - Visual inspection C
- Perform overhaul task whenever the operating characteristic goes out of limits

Note that at the 100, 200, 300, etc. hour points, all the tasks except the overhaul task are performed. This example is purposely over-simplified, and many other factors may (and probably will) have to be considered when packaging the tasks. The point is that by packaging PM tasks, maintenance resources are used as effectively as possible and minimize the downtime of the product for PM.

7-5.4.11 Continuously Improve the Maintenance Program.

Given the possibility for errors in the initial maintenance program, it is prudent to implement the RCM process as an on-going effort, one requiring perpetual evaluation and adjustment, as depicted in Figure 7-8. The process for continuously improving the RCM-based maintenance program consists of Maintenance Audit, Trend Analysis, and Life Exploration. The purpose of this process is to continuously improve the initial maintenance program developed using the RCM concept.

7-5.4.11.1 The Initial Maintenance Program.

The maintenance program that is developed based on the RCM analysis done prior to the first product being delivered to the customer is the initial maintenance program. This initial program will have been based on the best information that was available at the time the analysis was performed. One of the critical pieces of information is the underlying failure distribution for each item. The information used in the initial RCM analysis was based on a mix of analysis and test results. When off-the-shelf items are used in the product, the information can include actual field experience. It must be recognized, however, that some of the information will not be 100% accurate.

7-5.4.11.2 Maintenance Audit.

Auditing the maintenance performed in actual service provides the data needed to refine and improve the maintenance program. In analyzing the data, the maintenance analysts and planners attempt to address the technical content of the program, intervals for performing tasks, packaging of tasks, training, the maintenance concept, and the support infrastructure.

(a) In addressing technical content, analysts and planners must determine if the current maintenance tasks cover all identified failure modes and result in the desired/required level of reliability. Failure modes may have been missed or the current maintenance tasks may not be effectively addressing identified failure modes. The latter may result from incorrectly identifying the underlying failure probability distribution function. Much of this information can be confirmed or updated through a reliability assessment. Listed below are the type of questions that can be answered by such an assessment.

- Were assessments of useful life too conservative?
- Have replacement intervals been made too short?
- Is wearout occurring later or earlier than anticipated?
- Have the operating conditions or concept changed?
- Has the reliability performance been as expected?
- Have any new failure modes been uncovered?

- Are failure modes identified in development occurring with the expected frequency and pattern (such as, underlying pdf of failures)?
- Have any modifications to the product been made or are any planned that would add or delete failure modes, change the effects of a given failure mode, or require additional or different PM tasks?
- Were the consequences of failures forecast during development adequately identified?

(b) In addressing performance interval, analysts and planners must determine if the intervals for PM tasks result in decreased resistance to failure. Most often, the objective is to extend the interval as much as possible, without compromising safety, when doing so will reduce costs. Initial intervals are frequently set at conservative levels.

(c) In addressing task packaging, analysts and planners must determine if like tasks with similar periodicity are or can be grouped together to minimize downtime and maximize effectiveness. Lessons learned during actual operation and maintenance may make it necessary to revise the initial packaging.

(d) The analysts and planners should evaluate if available personnel, as currently being trained and using available tools and data, are effectively performing the identified PM tasks. If not, changes to training, procedures, tools, and so forth should be considered.

(e) The analysts and planners should determine if the maintenance concept for the product is effective or should be revised.

(f) The analysts and planners should address the adequacy and responsiveness of the support infrastructure. If the performance of the infrastructure is not as anticipated, recommendations regarding policy, spares levels, and other factors should be considered.

7-5.4.11.3 Trend Analysis.

By collecting data on failures, time to failure, effectiveness of maintenance tasks, and costs of maintenance, trends can be identified. The objective of trend analysis is to anticipate problems and adjust the maintenance program to prevent their occurrence. For the RCM effort, two factors typically addressed by trend analysis are the rate of occurrence of failures and maintenance costs.

(a) For trending purposes, at least three data points are needed. The first two establish the trend (positive or negative) and the third serves as confirmation. In control charting used for quality control, a trend is said to exist when 7 consecutive points continue to rise or fall. However, when measurements are based upon sample surveys over time, data at different points in time may vary because the underlying phenomenon has changed (such as, a trend exists) or due to sampling error (such as, the underlying phenomenon has not changed at all). It is not an easy task to seek out the one from the other.

(b) Statistical methods can be used to determine if a trend exists. For example, if a system failure rate is changing (such as, it is not constant), the Laplace Statistic will show that a trend exists at a certain level of confidence. The Laplace transform is an integral transform perhaps second only to the Fourier transform in its utility in solving physical problems. The Laplace transform is particularly useful in solving linear ordinary differential equations such as those arising in the analysis of electronic circuits (Wolfram MathWorld).

(c) In addition to trend analysis, impending failures can be detected using pattern recognition, data comparison, tests against limits and ranges, correlation, and statistical process analysis.

7-5.4.11.4 Life Exploration.

The process of collecting and analyzing in-service or operational reliability data to update the maintenance program is called Life (or Age) Exploration. The data that should be collected during Life Exploration includes historical field service data. Historical field service data typically describes three kinds of maintenance activities: corrective maintenance actions, preventive maintenance action, and service maintenance action.

(a) Historical corrective maintenance data. Corrective maintenance actions occur in response to an operational failure of the system. Corrective maintenance actions are always unscheduled, unwanted, inconvenient, and random.

(b) Historical preventive maintenance data. Preventive maintenance actions occur in accordance with a schedule and are intended to minimize the need for corrective maintenance actions.

(c) Historical service maintenance data. Service maintenance actions are those tasks performed to replenish expended parts and supplies required to operate a system. Many assets require adjustment, replenishment of supplies, lubrication, and cleaning.

7-5.5 Specific Considerations for Implementing RCM for C5ISR Facilities.

7-5.5.1 Current Versus New Facilities.

Many C5ISR facilities were built, and the mechanical and electrical equipment developed and installed without an RCM analysis having been conducted. Implementing RCM for an existing C5ISR facility, when the current PM program was not based on RCM, is different from implementing it on a facility, new or old, for which the PM program was based on RCM.

7-5.5.1.1 Current PM Program in Place.

Of course, a program of preventive maintenance will already be in place for an existing facility. Without an RCM analysis, the PM program was probably based on past programs. Indications that the PM program is inefficient or ineffective are an excessive number of corrective maintenance actions (with an associated low facility availability), or an extremely large number of required PM actions that are imposing a very heavy economical penalty. Attempts to change the existing PM program may meet with some resistance (see paragraph 7-5.5.3.3).

7-5.5.1.2 Need for Supporting Analyses.

If an RCM analysis was not originally performed for the facility, its systems and equipment, much of the supporting analysis may also have been omitted. If such analyses, such as an FMEA, were not conducted, they must be conducted before an RCM-based PM program can be developed. For many of the installed systems and equipment, performing an FMEA or other analysis may be quite difficult because much of the data may not be available. Either the data was not acquired with the systems and equipment (such as, data rights were not procured), or the data is missing. In such cases, engineers will have to use engineering judgment and require more time to adequately analyze the systems and equipment.

7-5.5.1.3 Feasibility of Redesign.

If following the RCM logic, it is possible that the path may lead to a "Redesign is mandatory" or "redesign may be desirable" outcome. Redesign during initial development is a sometimes-difficult task. Once a system or piece of equipment is in operation, redesign is even more difficult. However, an advantage of a facility is that adding redundancy is less constrained, in terms of space and weight, than for other systems.

7-5.5.2 Training.

The RCM process is very disciplined and logical. It involves the integration of many different analytical tools, data, experience, and a decision logic tree. Without proper training, those assigned the responsibility of implementing RCM will find it difficult to succeed. Training in the RCM methodology and the related disciplines must be an essential element of an organization's plan for implementing RCM. For C5ISR facilities, especially when maintenance is outsourced, funding must be provided for training to ensure that an RCM analysis is properly performed. Of course, training to ensure maintenance is properly performed is also essential.

7-5.5.3 Pitfalls.

In implementing an RCM program in organizations where the concept is new, pitfalls can make implementation ineffective.

7-5.5.3.1 Run to Failure Shock.

For many maintenance managers and technicians, allowing an item to run to failure runs counter to conventional wisdom. It is important that they understand the concepts of reliability and turn their focus from preventing failures to preserving function.

7-5.5.3.2 Failure to Accept the "Preserve Function" Principle.

Most maintenance personnel traditionally have viewed their role as one of preventing failures. To effectively implement an RCM program, it is essential that maintenance personnel focus on preserving the function or functions of an item, not preventing failures.

7-5.5.3.3 Challenging the Past.

Tradition and conventional wisdom remain the principal guidance for many maintenance organizations. Challenging past practices almost always invokes strong resistance, especially if the new practices are not fully understood. Education is the best way to deal with cultural resistance.

7-5.5.3.4 Organization Structure.

The RCM process requires close coordination and cooperation among several groups of people, including but not limited to designers, maintainers, and logistic planners. Organizational structures can impede or even prevent the level of cooperation and coordination needed to make RCM a success. The concept of integrated process/product teams is one that facilitates and encourages cross-discipline cooperation.

7-5.5.3.5 Threat of Reduction in Staff.

When RCM was first implemented within the airline industry, drastic reductions in scheduled maintenance tasks were made possible. Consequently, the number labor hours and people required to, for example, conduct structural inspections of an aircraft were significantly reduced. When a segment of an organization perceives that a new policy or procedure will eliminate their jobs, the natural reaction is to fight against the new policy or procedure. However, with vision and planning, management can find ways to effectively use the resources freed up by implementing RCM and minimize the impact on jobs by using normal attrition, cross training, etc.

7-5.5.3.6 Inadequate Buy-in.

All too often, management implements a new policy or procedure without fully supporting that policy or procedure. If either resources or management interest is insufficient, the new policy or procedure will probably fall short of expectations. This is especially true for RCM, an approach that is often met with skepticism and resistance by the very same people who must help implement it.

7-5.5.3.7 Informal Procedures.

RCM is a very structured, disciplined method of developing a comprehensive and effective maintenance program. It cannot be effectively implemented on an informal or ad hoc basis. The procedures for implementing an RCM approach within an organization must be formal, documented, and managed.

7-5.5.3.8 Inadequate Data Collection.

If the underlying pattern of failures for a given item is unknown, one cannot objectively determine if PM should be considered. Without adequate information regarding the frequency of failure or the parameters of the failure PDF, one cannot objectively determine when a PM task should be performed. Data that is adequate in both quantity and type (for example, time to failure) is essential to the RCM process.

7-5.6 Evaluation of Alternatives.

As a result of performing an RCM analysis, alternatives will present themselves. These alternatives fall into two categories: Maintenance Tasks and Designs. Both categories are a natural result of the RCM analysis. Examining the logic trees in paragraph 7.5-4 indicates more than one type of maintenance task may be applicable and effective for a given failure. In some cases, for example where the effects of a failure are hazardous or a hidden failure can occur, redesign is mandatory or desirable. How is it determined which tasks to perform? How are the "best" design changes (for example, in the case of failures with hazardous effects) selected? How is it determined if a design change is cost-effective (for example, in the case of a hidden failure). These questions are addressed using Trade-off Studies, Operational Analysis, and Cost-Benefit Analysis.

7-5.6.1 Trade-off Studies.

Designing a new system or a change to an existing one, even a moderately complex one, requires a series of compromises. These compromises are inevitable, given the fact that requirements often conflict. Design decisions necessary to meet one requirement may result in another requirement not being met. For example, strength and fatigue life requirements drive the selection of materials and the size (bulk) of structures in one direction. The maximum weight requirement drives these same factors in the opposite direction. Systems engineering is the process of selecting design solutions that balance the requirements and provide an optimized system. Usually, this balance means that some requirements may not be fully met. The process of selecting one design solution over another is often referred to as design trade-offs. Trade-off studies consist of the steps listed below.

- Compare two or more design solutions
- Determine which provides the best results given cost and schedule constraints

- Determine if the system requirements can be met with the selected design solution
- If the system requirements cannot be met, determine the budget and schedule required to support a design solution that does allow the system requirements to be met, or re-evaluate the requirements

7-5.6.1.2 RCM and Desired Design Changes.

An RCM analysis may indicate that a change to the design is required or desirable. In such cases, trade-off studies will probably be needed to determine if a solution can be found that is effective (affordability is addressed in a cost-benefit analysis – see paragraph 7.5.6.2).

7-5.6.1.3 RCM and Mandatory Design Changes.

When the RCM analysis shows that two or more PM tasks are applicable, trade-off studies will be needed to determine which task(s) is (are) most effective. Of course, when a specific failure has hazardous effects, redesign is mandatory if no PM tasks are effective and applicable.

7-5.6.1.4 Operational Analysis.

To determine if a specific failure has operational effects (but no hazardous effects), an analysis of the operational concept is necessary. This analysis addresses the impact of a given failure on measures of operational performance. The measures are a function of the type of product and how that product is used. For the airline industry, for example, the cost of an operational failure includes lost revenue, potential penalties (in the form of compensation to passengers), loss of customer confidence and loyalty, and the cost of fixing the failure. For a military organization that operates aircraft, the costs might include a decrease in readiness, the inability to fulfill a mission, the cost of reassigning another aircraft to replace the original aircraft, and the cost to fix the failure. For a commercial company, the cost of an operational failure of a product could include the loss of customer confidence and loyalty, the cost of repair under warranty, and possible claims by the customer for lost revenue or other non-hazardous effects of the failure.

7-5.6.2 Cost-benefit Analysis.

Another type of analysis frequently used whenever one of two or more alternatives (design A vs. design B, task 1 vs. task 2, process I vs. process II, etc.) must be selected is a cost-benefit analysis (CBA).

7-5.6.2.1 Potential Benefits.

In a CBA, the potential life-cycle benefits of and life-cycle costs to implement a given alternative are compared with those of the other alternatives. One of the most difficult steps in a CBA is finding a common basis for comparison. That basis is almost always dollars, since the costs of implementing a choice can almost always be directly measured in terms of dollars. Some of the benefits of an alternative may be intangible. However, it may be possible to attach a dollar value to even these benefits. Benefits to which a dollar value cannot be assigned should be evaluated and assigned relative numeric values for comparison purposes. For example, a maximum benefit could be assigned a value of 5, an average benefit a value of 3, and a minimum benefit a value of 1. Evaluating and comparing benefits that have both dollar values and relative numeric values requires extra effort, but it allows all benefits to be considered in the analysis.

7-5.6.2.2 Costs.

In a simple CBA, the annual costs of implementing each alternative design change, for example, are estimated. For this purpose, the analyst would sum up the estimates of the costs listed below. The analyst would estimate the annual benefits of the first alternative and then repeat this process for each of the other alternative design.

- The cost of the labor hours needed to develop the design
- The cost of any additional testing required
- Any differences in material costs
- Changes in manufacturing costs
- Additional costs due to changes in schedule
- Other costs

7-5.6.2.3 Conversion.

The analyst must convert the annual estimates to a common unit of measurement to properly compare competing alternatives. This conversion is done by discounting future dollar values, which transforms future benefits and costs to their "present value." The present value (also referred to as the discounted value) of a future amount is calculated using Equation 7-1.

Equation 7-1. Present Value

$$PV = \frac{FV}{(1 + i)n}$$

Where:
PV = Present Value
FV = Future Value
i = Interest rate per period
n = Number of compounding periods

7-5.6.2.4 Comparison.

When the costs and benefits for each competing alternative have been discounted, the analyst compares and ranks the discounted net value (discounted benefit minus discounted cost) of the competing alternatives. In the ideal case one alternative will have the lowest discounted cost and provide the highest discounted benefits – it clearly would be the best alternative. More often, however, the choice is not so clear-cut, and other techniques must be used to determine which alternative is best.

7-5.6.2.5 Dollar Values.

Earlier, it was mentioned that some benefits may not be quantifiable in terms of dollars and may have relative numeric values assigned for comparison purposes. In those cases, these numeric values can be used as tie breakers if the cost figures do not show a clear winner among the competing alternatives, and if the non-quantifiable benefits are not key factors. If they are key factors, the quantified benefits can be converted to scaled numeric values consistent with the non-quantifiable benefits. The evaluation then consists of comparing the discounted costs and the relative values of the benefits for each alternative. When the alternative with the lowest discounted cost provides the highest relative benefits, it is clearly the best alternative (the same basic rule used when there are discounted benefits). If that is not the case, the evaluation is more complex.

7-5.6.2.6 Numerical Values.

Finally, if no benefits have dollar values, numerical values can be assigned (using some relative scale) to each benefit for each competing alternative. The evaluation and ranking are then completed in the manner described in the previous paragraph.

7-5.6.2.7 Sensitivity Analysis.

Sensitivity analysis can be used to test the sensitivity and reliability of the results obtained from a CBA. For more information on conducting a CBA and related analysis, see the references in TM 5-698-2 Appendix A.

APPENDIX A FACTORS INFLUENCING FIELD MEASURES OF RELIABILITY

A-1 INHERENT RELIABILITY VERSUS OPERATIONAL RELIABILITY.

The reliability achieved by diligent attention to failure modes and mechanisms during design and manufacture is defined as inherent reliability. The reliability observed during operation of the system in its intended environment is defined as operational reliability.

A-1.1 Inherent Reliability.

Inherent reliability is the level of reliability inherent in the system as designed and manufactured. All failures are due to inherent weaknesses in the design, flaws in the materials, or defects from the manufacturing processes. The level of inherent reliability achieved is determined through analysis and test. Although in applying analytical methods and in testing the system (the "actual" system or prototypes), the design and development team attempts to simulate the actual operating environment, it is difficult if not impossible to account for some aspects of operation.

A-1.2 Operational Reliability.

Operational reliability is the measure a customer or user of a system uses. Whenever a system fails to perform its function(s) or requires maintenance, the customer will count such events as failures, regardless of the cause. Inherent weaknesses in the design, flaws in the materials, and defects from the manufacturing processes will cause such failures, but so will maintenance errors, improper operation, and changes in operating concept. In addition, if the operating environment is substantively different from that defined during design, more failures or failure modes may occur than were addressed during design and manufacturing. Consequently, operational reliability can never be higher than inherent reliability and is usually lower.

A-2 ACCOUNTING FOR THE DIFFERENCES.

The differences between design and operational reliability can be accounted for. This can be done in two ways: the way procedures are designed and developed, and the way in which design requirements are developed.

A-2.1 Design of Procedure.

Recognizing that humans make mistakes, design techniques that minimize the chance of human error can be applied. For example, parts can be designed to mate in only one way, preventing maintenance personnel from making an incorrect connection. Displays can be designed so they are easy to read and use conventional symbols. Controls can be designed using standard orientation (for example, turn right to shut off a valve). In a similar manner, procedures can be written in a clear, concise, and logical manner. Such attention to the human element during design can minimize the opportunity for human error.

A-2.2 Design Requirements.

If the customer needs an operational reliability of 1000 hours Mean Time Between Failures (MTBF) for a system, 1000 hours cannot be used as the design requirement. If it was used and missed one failure mode due to the inexact understanding of the operating environment, the operational reliability requirement would not be met. The system must be designed to a higher level. An arbitrarily high inherent reliability requirement should not be set. To do so would drive up costs unnecessarily. A commonly used approach for setting the inherent reliability requirement is to use past experience. If experience with previous systems indicates that the operational reliability runs 10%-15% lower than what was measured during design and manufacture, then, as a rule of thumb, the inherent reliability requirement for new systems should be 12% higher than the operational reliability requirement. For example, if the inherent reliability for past systems was 1,000 hours MTBF and the observed operational reliability was only 850 hours (15% less), and the operational reliability requirement for a new system is 1,000 hours, the inherent reliability requirement must be about 11.8% higher or 1,180 hours. If this level of inherent reliability is achieved, then it is expected the operational reliability to be 1180 - (15% x 1180) = 1,003 hours.

APPENDIX B STATISTICAL DISTRIBUTION USED IN RELIABILITY AND MAINTAINABILITY

B-1 INTRODUCTION TO STATISTICAL DISTRIBUTION.

Many statistical distributions are used to model various reliability and maintainability parameters. The distribution used depends on the nature of the data being analyzed.

B-1.1 Exponential and Weibull.

These two distributions are commonly used for reliability modeling – the exponential is used because of its simplicity and because it has been shown in many cases to fit electronic equipment failure data, and the Weibull because it consists of a family of different distributions that can be used to fit a wide variety of data and it models wear out (such as, an increasing hazard function).

B-1.2 Normal and Lognormal.

Although also used to model reliability, the normal and lognormal distributions are more often used to model repair times. In this application, the normal is most applicable to simple maintenance tasks that consistently require a fixed amount of time to complete with little variation. The lognormal is applicable to maintenance tasks where the task time and frequency vary, which is often the case for complex systems and products.

B-2 THE EXPONENTIAL DISTRIBUTION.

The exponential distribution is widely used to model electronic reliability failures in the operating domain that tend to exhibit a constant failure rate. To fail exponentially means that the distribution of failure times fits the exponential distribution as shown in Table B-1. The characteristics of the exponential distribution are listed below.

- It has a single parameter, λ, which is the mean. For reliability applications, λ called the failure rate.
- λ, the failure rate, is a constant. If an item has survived for t hours, the chance of it failing during the next hour is the same as if it had just been placed into service.
- The mean-time-between-failure (MTBF) = $1/\lambda$.
- The mean of the distribution occurs at about the 63rd percentile. Thus, if an item with a 1000-hour MTBF had to operate continuously for 1000 hours, the probability of success (survival) would be only 37%.

Figure B-1 shows the exponential Probability Density Function for varying values of λ.

Table B-1 Summary of the Exponential Distribution

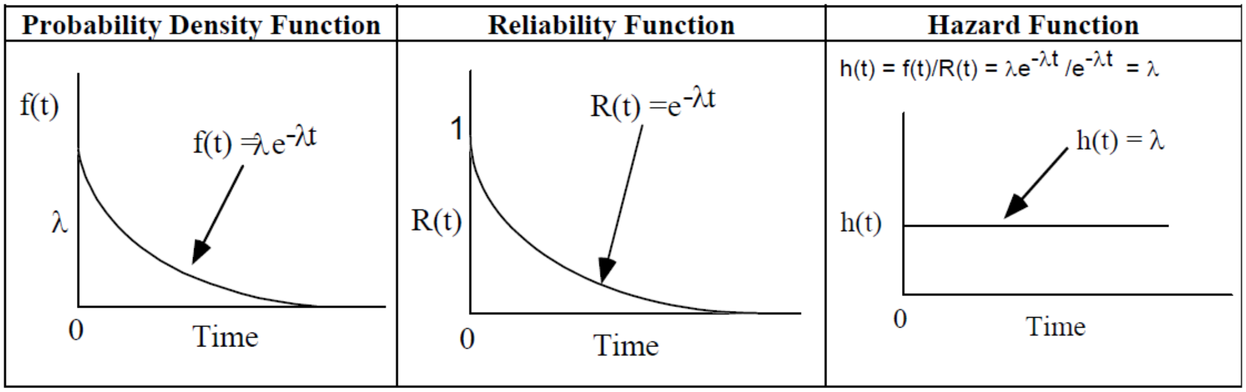

Figure B-1 The Exponential PDF for Varying Values of λ

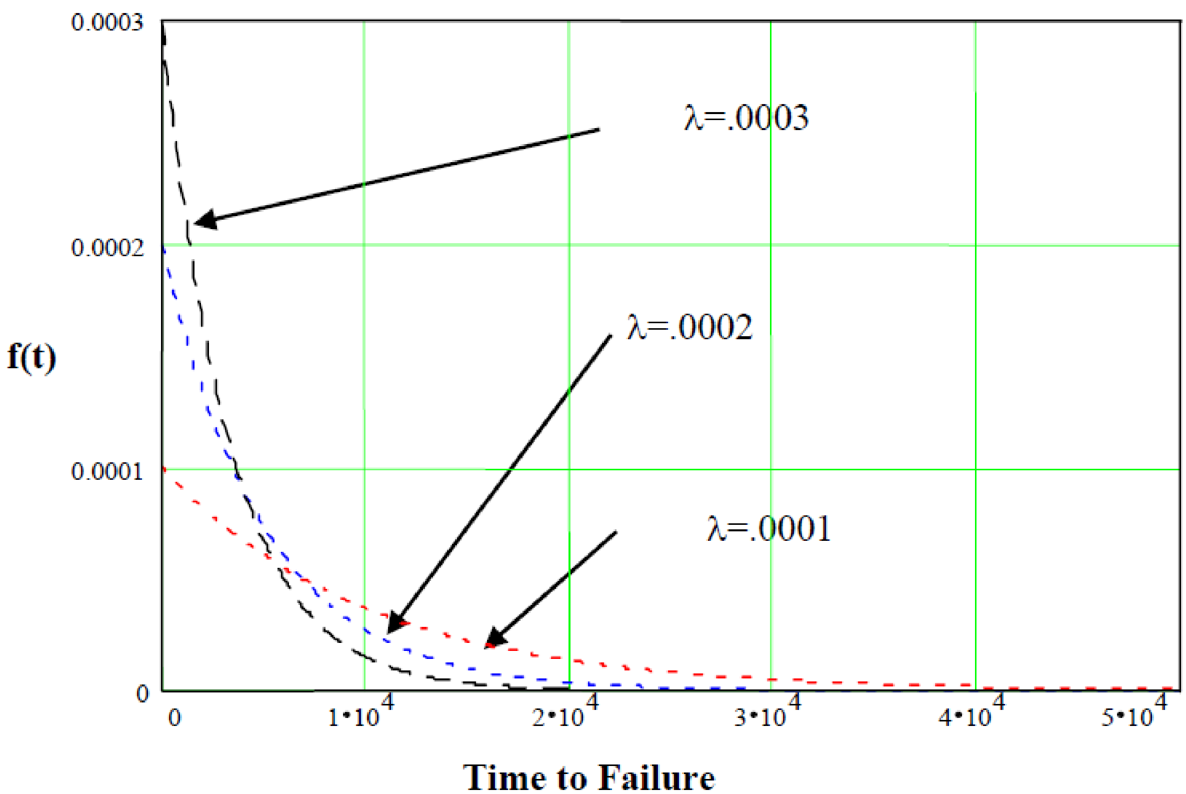


B-3 THE WEIBULL DISTRIBUTION.

The Weibull distribution is an important distribution because it can be used to represent many different pdfs; therefore, it has many applications. The characteristics of the Weibull are listed below.

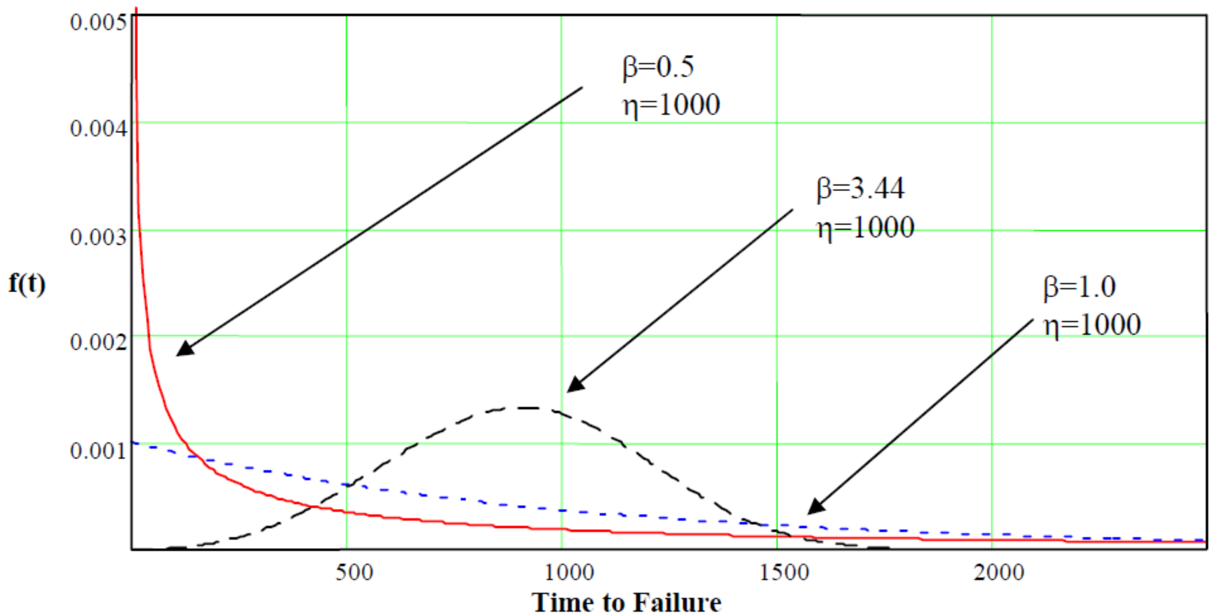
- It has 2 (β, η, and γ) parameters.
  - The shape parameter, β, describes the shape of the Probability Density Function.
  - The scale parameter, η, is the 63rd percentile value of the distribution and is called the characteristic life. In some texts, Θ, is used as the symbol for the characteristic life.
  - The location parameter, γ, is the value that represents a failure-free or prior use period for the item. If there is no prior use or period where the probability of failure is zero, then γ = 0 and the Weibull distribution becomes 2-parameter distribution.
- β, η, and γ can be estimated using Weibull probability paper or software programs.
- When β = 1 and γ = 0, the Weibull probability is exactly equivalent to the exponential distribution.
- When β, = 3.44, the Weibull closely approximates the normal distribution.

The distribution is described in Table B-2. Figure B-2 shows the 2-parameter Weibull pdf for different values of β, and a given value of η.

Table B-2 Summary of the Weibull Distribution

<table>
<tr><th>Probability Density Function</th><th>Reliability Function</th><th>Hazard Function</th></tr>
<tr>
<td>
$$f(t) = \frac{\beta}{\eta}\left(\frac{t-\gamma}{\eta}\right)^{\beta-1}\exp\left[-\frac{(t-\gamma)}{\eta}^{\beta}\right]$$</td>
<td>
$$R(t) = \exp\left[-\frac{(t-\gamma)^{\beta}}{\eta}\right]$$</td>
<td>
$$h(t) = \frac{\beta}{\eta}\left(\frac{t-\gamma}{\eta}\right)^{\beta-1}$$</td>
</tr>
</table>

Figure B-2 The Two-Parameter Weibull PDF for Different Values of *β* and a Given Value of *η*



B-4 THE NORMAL DISTRIBUTION.

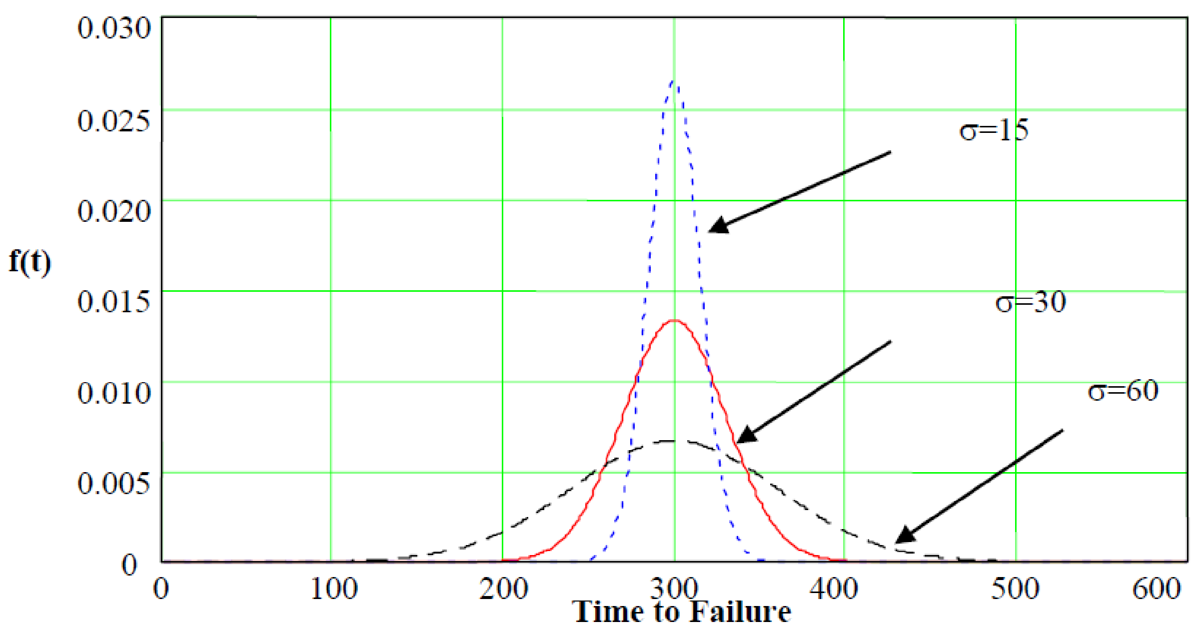
The pdf of the Normal distribution is often called the bell curve because of its distinctive shape. The Normal distribution is described in Table B-3. The characteristics of the Normal distribution are listed below.

- It has two parameters:
    - The mean, μ, is the 50th percentile of the distribution. The distribution is symmetrical around the mean.
    - The standard deviation, σ, is a measure of the amount of spread in the distribution.
- If *t* has the pdf defined in Figure B-3 and $\mu = 0$ and $\sigma = 1$, then t is said to have a standardized normal distribution.
- The integral of a distribution's pdf is its cumulative distribution function, used to derive the reliability function. The integral of the normal pdf cannot be evaluated using the Fundamental Theorem od Calculus because a function for which the derivative equals exp(-x/2) cannot be found. However, numerical integration methods have been used to evaluate the integral and tabulate values for the standard normal distribution.

Table B-3 Summary of the Normal Distribution

Probability Density Function	Reliability Function	Hazard Function
$f(t) = \frac{1}{\sigma\sqrt{2\pi}} e^{\frac{-(t-\mu)^2}{2\sigma^2}}$	$R(t) = \int_t^{\infty} f(t)dt$	$h(t) = \frac{f(t)}{R(t)}$

Figure B-3 The Normal PDF for Varying Values of *σ* and Fixed *μ*.



B-5 THE LOGNORMAL DISTRIBUTION.

The lognormal distribution is summarized in Table B-4. The characteristics of the lognormal distribution are listed below.

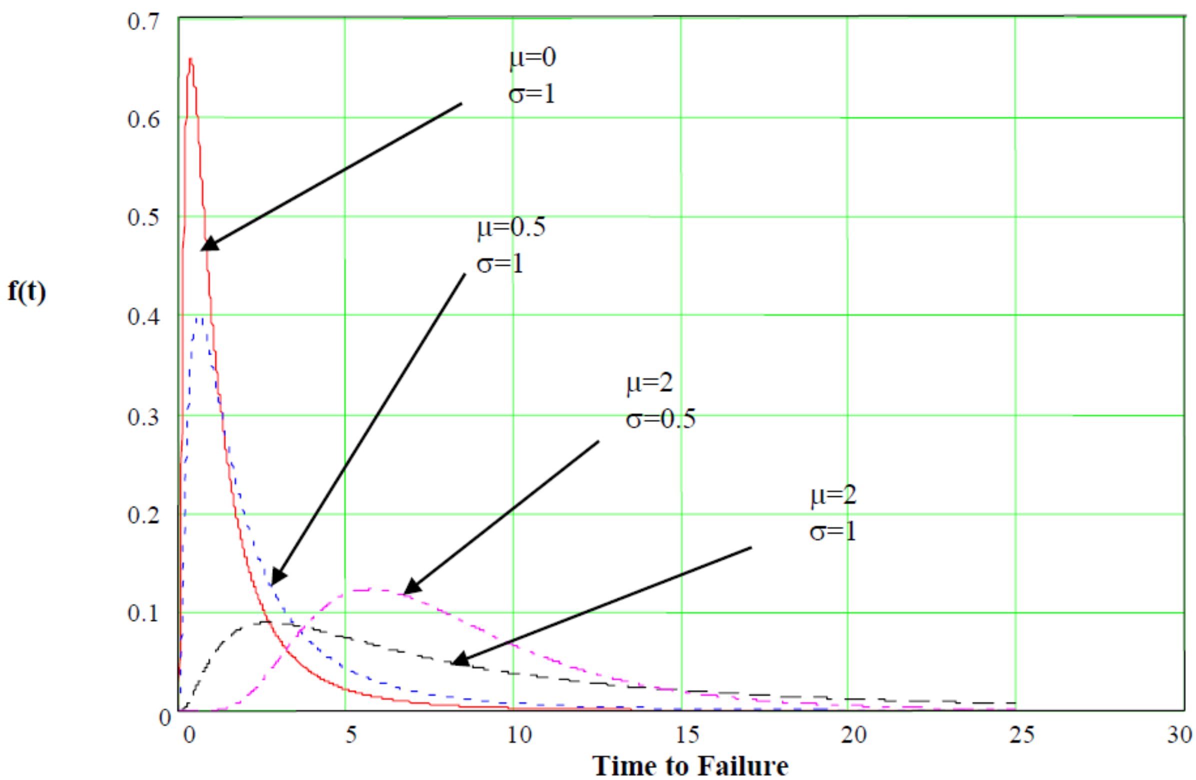
- It has two parameters:
  - The mean, μ. Unlike the mean of the Normal distribution, the mean of the lognormal is not the 50th percentile of the distribution and the distribution is not symmetrical around the mean.
  - The standard deviation, σ.
- The logarithms of the measurements of the parameter of interest (for example, time to failure, time to repair) are normally distributed.

Figure B-4 shows the distribution for different values of μ and σ.

Table B-4 Summary of the Lognormal Distribution

Probability Density Function	Reliability Function	Hazard Function
$f(t) = \frac{1}{\sigma t\sqrt{2\pi}} e^{\frac{-(\ln(t)-\mu)^2}{2\sigma^2}}$	$R(t) = \int_t^{\infty} f(t)dt$	$h(t) = \frac{f(t)}{R(t)}$

Figure B-4 The Lognormal PDF for Different Values of μ and a Fixed σ



APPENDIX C AVAILABILITY AND OPERATIONAL READINESS

C-1 AVAILABILITY.

In general, availability is the ability of a product or service to be ready for use when a customer wants to use it. That is, it is available if it is in the customer's possession and works when it's turned on or used. A product that's "in the shop" or is in the customer's possession but doesn't work is not available. Measures of availability are shown in Table C-1.

Table C-1 Quantitative Measures of Availability

Measure	Equation	Description
Inherent Availability: A_i	$\frac{MTBF}{MTBF + MTTR}$	• Where MTBF is the mean time between failure and MTTR is the mean time to repair • A probabilistic measure • Reflects the instantaneous probability that a component will be up. A_i considers only downtime for repair due to failures. No logistics delay time, preventative maintenance, etc. is included.
Operational Availability: A_O	$\frac{MTBM}{MTBM + MDT}$	• Where MTBM is the mean time between maintenance (preventative and corrective) and MDT is the mean downtime, which includes MTTR, and all other time involved with downtime such as logistic delays • A probabilistic measure • Similar to inherent availability but includes ALL downtime. Included is downtime for corrective maintenance and preventative maintenance, including any logistics delay time.

MTBF = Mean Time Between Failure MTBM = Mean Time Between Maintenance
MDT = Mean Downtime MTTR = Mean Time to Repair (corrective only)

C-1.1 Nature of the Equations.

Note that the equations are time independent and probabilistic in nature. The value of availability yielded by each equation is the same whether the period of performance being considered is 1 hour or a year.

C-1.2 Derivation of Steady State Equation for Availability.

The equations in Table C-1 are steady state equations. The equation for inherent availability (Equation C-1) is the steady state equation derived from Equation C-2, as time approaches infinity:

Equation C-1. Inherent Availability

$$A_i = \frac{MTBF}{MTBF + MTTR}$$

Equation C-2. Inherent Availability

$$A_i = \frac{MTBF}{MTBF + MTTR} + \frac{MTTR}{MTBF + MTTR} e^{-\left(\frac{1}{MTBF} + \frac{1}{MTTR}\right)t}$$

1. Equation C-1 represents a limit for inherent availability. It represents the long-term proportion of time that a system will be operational.

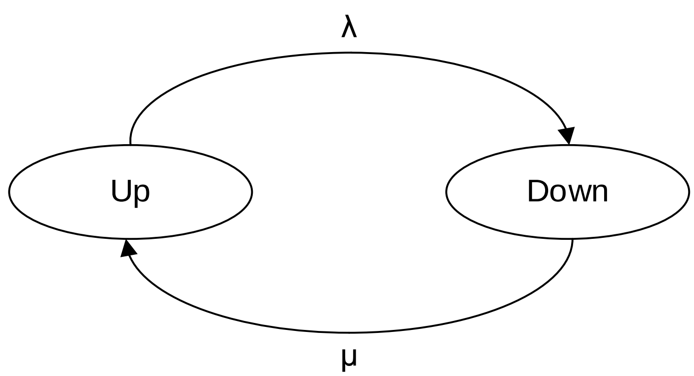
2. Assuming that the times to failure and time to repair are both exponentially distributed, with rates *λ* and *μ*, respectively, Equation C-1 can be expressed as:

Equation C-3. Inherent Availability

$$A_i = \frac{\frac{1}{\lambda}}{\frac{1}{\lambda} + \frac{1}{\mu}} = \frac{\mu}{\mu + \lambda}$$

3. The derivation of Equation C-1 now follows. A simple Markov model is used to evaluate availability. The probabilities of being in either the up state or the down state are determined using the Laplace transform. The model and equations are:

Figure C-1 Simple Markov Model



Equation C-4.

$$\frac{dP_{Up}(t)}{dt} = -\lambda \square_{Up}(t) + \mu P_{Down}(t)$$

Equation C-5.

$$sL_{Up}(s) - P_{Up}(0) = sL_{Up}(s) - 1 = -\lambda L_{Up}(s) + \mu L_{Down}(s)$$

Equation C-6.

$$1 - sL_{Up}(s) = sL_{Down}(s) = \lambda L_{Up}(s) - \mu L_{Down}(s)$$

Equation C-7.

From Equation C-4, $L_{Up}(s) = \frac{1+\mu L_{Down}(s)}{s+\lambda}$

Equation C-8.

From Equation C-5, $L_{Down}(s) = \frac{\lambda L_{Up}(s)}{s+\mu}$

4. Substituting the expression for $L_{Down}(s)$ into Equation C- 7,

Equation C-9.

$$L_{Up}(s) = \frac{1}{s+\mu+\lambda} + \frac{\mu}{s(s+\mu+\lambda)}$$

5. Then, availability equals the inverse of the Laplace transform for $L_{Up}(s)$. To obtain the inverse,

Equation C-10.

$$\frac{1}{s+\mu+\lambda} + \frac{\mu}{s(s+\mu+\lambda)} = \frac{1}{\lambda+\mu}\left(\frac{\mu(s+\mu+\lambda)+\lambda_s}{s(s+\mu+\lambda)}\right)$$

$$= \frac{1}{\lambda+\mu}\left(\frac{\mu}{s} + \frac{\lambda}{s+\mu+\lambda}\right)$$

$$= \frac{\mu}{\lambda+\mu} * \frac{1}{s} + \frac{\lambda}{\mu+\lambda} * \frac{1}{s+\mu+\lambda}$$

$$= \frac{1}{\lambda+\mu}\left(\frac{\mu}{s} + \frac{\lambda}{s+\mu+\lambda}\right)$$

$$= \frac{\mu}{\lambda+\mu} * \frac{1}{s} + \frac{\lambda}{\mu+\lambda} * \frac{1}{s+\mu+\lambda}$$

$$= \frac{\mu}{\lambda+\mu}\int_0^\infty e^{-st}dt + \frac{\lambda}{\lambda+\mu}\int_0^\infty e^{-(s+\mu+\lambda)t}dt$$

$$= \int_0^\infty \frac{\mu}{\lambda+\mu} e^{-st}dt + \frac{\lambda}{\lambda+\mu} e^{-(s+\mu+\lambda)t}dt$$

$$= \int_0^\infty \frac{\mu}{\lambda+\mu} e^{-st}dt + \frac{\lambda}{\lambda+\mu} e^{-(s+\mu+\lambda)t}dt$$

$$= L\left[\frac{\mu}{\lambda + \mu} + \frac{\lambda}{\lambda + \mu} e^{-(\mu+\lambda)t}\right]$$

$$A = \frac{\mu}{\lambda + \mu} + \frac{\lambda}{\lambda + \mu} e^{-(\mu+\lambda)t}$$

6. Taking the limit of Equation C-10 as t approaches infinity,

Equation C-11.

$$A_i = \frac{\mu}{\lambda + \mu} + \frac{\lambda}{\lambda + \mu} * 0 = \frac{\mu}{\lambda + \mu}$$

$$A_i = \frac{MTBF}{MTBF + MTTR}$$

Q.E.D

C-2 OPERATIONAL READINESS.

Closely related to the concept of operational availability but broader in scope is operational readiness. Operational readiness is defined as the ability of a military unit to respond to its operational plans upon receipt of an operations order. It is, therefore, a function not only of the product availability, but also of assigned numbers of operating and maintenance personnel, the supply, the adequacy of training, and so forth.

C-2.1 Readiness in the Commercial World.

Although operational readiness has traditionally been a military term, it is equally applicable in the commercial world. For example, a manufacturer may have designed and can make very reliable, maintainable products. What if he has a poor distribution and transportation system or does not provide the service or stock the parts needed by customers to effectively use the product? Then, the readiness of this manufacturer to go to market with the product is low.

C-2.2 Relationship of Availability and Operational Readiness.

The concepts of availability and operational readiness are obviously related. Important to note, however, is that while the inherent design characteristics of a product totally determine inherent availability, other factors influence operational availability and operational readiness. The reliability and maintainability engineers directly influence the design of the product. Together, they can affect other factors by providing logistics planners with the information needed to identify required personnel, spares, and other resources. This information includes the identification of maintenance tasks, repair procedures, and needed support equipment.

APPENDIX D PREP DATABASE IEEE DOT STANDARD 3006.8

The header below represents the header in the database. Each column heading is explained in the text boxes. The formulas, representing the column heading, are contained in the Table E-1 below.

Category	Class	Unit-Years	Failures	Failure Rate (Failures/Year)	MTBF	MTTR	MTTM	MDT
Name of the Category (Example: Boiler) of the item.	Name of the Class (Example: Boiler, Hot Water) of the item.	The number of calendar hours collected for each item divided by 8760.	The number of failures recorded for each item during the data collection.	Failure Rate based on a year.	Average time between failures in hours.	Mean time to replace or repair a failed component. Logistics delay time associated with the repair, such as parts acquisitions, crew mobilization, are not included	Average downtime for preventative maintenance. This includes any logistics delay time.	Average downtime caused by preventative and corrective maintenance, including any logistics delay time.

Table D-1 Reliability and Maintainability Calculations

Calculated Data	Formula for Calculation
A_i, Inherent Availability	A_i = MTBF/(MTBF+MTTR)
A_o, Operational Availability	A_o = MTBM/(MTBM+MDT)
λ, Failure Rate (failures/hour(h))	λ = Tf/Tp
λ_y, Failure Rate (failures/year(y))	λ_y = Tf/(Tp / 8760)
MDT, Mean Down Time (h)	MDT = (Rdt + Rlt + Mdt) / Tde
MTBF, Mean Time Between Failures (h)	MTBF = Tp / Tf
MTBM, Mean Time Between Maintenance (h)	MTBM = Tp / Tde
MTTM, Mean Time To Maintain (h)	MTTM = Mdt / Tma
MTTR, Mean Time To Repair (h)	MTTR = Rdt / Tf
R(t), Reliability (for time interval t)	$R(t) = e^{-\lambda t}$
Hrdt/Year, Hours Downtime per Year	Hrdt/Year = (1 - A_o) × 8760

E-2 DEFINITION OF TERMS.

Active Redundancy: Two or more components in a parallel combination where all are powered and active simultaneously. Not all components are required to function for the system (or next higher assembly) to function.

Active Time: That time during which an item is in an operational inventory.

Affordability: Affordability is a measure of how well customers can afford to purchase, operate, and maintain a product over its planned service life. Affordability is a function of product value and product costs. It is the result of a balanced design in which long-term support costs are considered equally with near-term development and manufacturing costs.

Alignment: Performing the adjustments that are necessary to return an item to specified operation.

Alpha (α): The probability, expressed as a decimal that a given part will fail in the identified mode. The sum of all alphas for a component will equal one (1).

Assessment: Current evaluation of a component's or system's reliability. A prediction.

Availability: The instantaneous probability that a component will be up.

Availability, Inherent (A_i): The instantaneous probability that a component will be up. Ai considers only downtime for repair due to failures. No logistics delay time, preventative maintenance, etc. is included.

Availability, Operational (A_o): A_o is the instantaneous probability that a component will be up but differs from inherent availability in that it includes ALL downtime. Included is downtime for both corrective maintenance and preventative maintenance, including any logistics delay time.

Beta (β): The conditional probability that the effect of a failure mode will occur, expressed as a decimal. If a failure is to occur, what is the probability that the outcome will occur.

Block Diagrams: Availability block diagrams and reliability block diagrams are visual representations of the interactions between contributors to reliability, availability, and maintainability. Each block tends to represent a physical component in the system and its associated reliability/availability.

Boolean Algebra: Boolean algebra is a method of calculating system availability based on logical interactions between components. AND and OR operators define mathematical operations.

Brownout: Occurs during a power failure when some power supply is retained, but the voltage level is below the minimum level specified for the system. A very dim household light is a symptom of a brownout.

Calibration: A comparison of a measuring device with a known standard and a subsequent adjustment to eliminate any differences. Not to be confused with alignment.

Cannot Duplicate (CND): A situation when a failure has been noted by the operator but cannot be duplicated by maintenance personnel attempting to correct the problem. Also see Retest OK.

Checkout: Tests or observations of an item to determine its condition or status.

Compensating Provision: Actions available or that can be taken to negate or reduce the effect of a failure on a system.

Component: A piece of electrical or mechanical equipment viewed as an entity for the purpose of reliability evaluation.

Condition-Based PM: Maintenance performed to assess an item's condition and performed as a result of that assessment. Some texts use terms such as predictive maintenance and on-condition. The definition of condition-based PM used herein includes these concepts. In summary, the objectives of condition-based PM are to first evaluate the condition of an item, then, based on the condition, either determine if a hidden failure has occurred or determine if a failure is imminent, and then take appropriate action. Maintenance that is required to correct a hidden failure is, of course, corrective maintenance.

Confidence Level/Interval: A statistical measure of the uncertainty associated with an estimate. For example, an estimate of MTBF is 103 hours. Using statistical techniques (such as the chi-square method) a 95% confidence interval of 100.1 to 105.9 is obtained. That is, 95% of the time, the actual MTBF will be between 100.1 and 105.9 hours. The confidence interval depends on sample size and variance.

Corrective Action: A documented design, process, procedure, or materials change implemented and validated to correct the cause of failure or design deficiency.

Corrective Maintenance (CM): All actions performed as a result of failure, to restore an item to a specified condition. Corrective maintenance can include any or all the following steps: Localization, Isolation, Disassembly, Interchange, Reassembly, Alignment and Checkout.

Cost: The expenditure of resources (usually expressed in monetary units) necessary to develop, acquire, or use a product over some defined period of time.

Critical Equipment/Systems: Critical equipment/systems include those items of equipment or systems that directly supply power to equipment and systems used to perform the primary mission(s) of the C5ISR site.

Criticality: A relative measure of the consequences of a failure mode and the frequency of its occurrence.

Criticality Analysis (CA): A procedure by which each potential failure mode is ranked according to the combined influence of severity and probability of occurrence.

Critical Load: That portion of the technical load used to successfully accomplish the site missions and having a requirement for 100 percent continuity in power service, such as from the Uninterruptible Power Supply (UPS) system. These loads also include any equipment which, upon loss of power, will create an unacceptable impact on the mission or mission equipment.

Dependability: A measure of the degree to which an item is operable and capable of performing its required function at any (random) time during a specified mission profile, given item availability at the start of the mission. (Item state during a mission includes the combined effects of the mission-related system R&M parameters but excludes non-mission time; see availability).

Design Agency: The agency responsible for the overall design of the facility.

Detection Method: The method by which a failure can be discovered by the system operator under normal system operation or by a maintenance crew carrying out a specific diagnostic action.

Diagnostics: The hardware, software, or other documented means used to determine that a malfunction has occurred and to isolate the cause of the malfunction. Also refers to "the action of detecting and isolating failures or faults."

Downtime: That element of time during which an item is in an operational inventory but is not in condition to perform its required function.

Effectiveness: The degree to which PM can provide a quantitative indication of an impending functional failure, reduce the frequency with which a functional failure occurs, or prevent a functional failure.

End Effect: The consequence a failure mode has upon the operation, function, or status at the highest indenture level.

Equipment: A general term designating an item or group of items capable of performing a complete function.

Failure (f): The termination of the ability of a component or system to perform a required function.

\1\ **Facility Energy:** The energy delivered to, generated by and/or consumed by an operational facility. /1/

Failure, Catastrophic: A failure that causes loss of the item, human life, or serious collateral damage to property.

Failure, Hidden: A failure that is not evident to the operator; that is, it is not a functional failure. A hidden failure may occur in two different ways. In the first, the item that has failed is one of two or more redundant items performing a given function. The loss of one or more of these items does not result in a loss of the function. The second way in which a hidden failure can occur is when the function performed by the item is normally inactive. Only when the function is eventually required will the failure become evident to the operator. Hidden failures must be detected by maintenance personnel.

Failure, Intermittent: Failure for a limited period of time, followed by the item's recovery of its ability to perform within specified limits without any remedial action.

Failure, Random: A failure, the occurrence of which cannot be predicted except in a probabilistic or statistical sense.

Failure Analysis: Subsequent to a failure, the logical systematic examination of an item, its construction, application, and documentation to identify the failure mode and determine the failure mechanism and its basic course.

Failure Cause: The physical or chemical processes, design defects, quality defects, part misapplication or other processes which are the basic reason for failure, or which can initiate the physical process by which deterioration proceeds to failure.

Failure Effect: The consequence(s) a failure mode has on the operation, function, or status of an item. Failure effects are typically classified as local, next higher level, and end.

Failure Mechanism: The physical, chemical, electrical, thermal, or other process which results in failure.

Failure Mode: The way in which a failure is observed, describes the way the failure occurs, such as, short, open, fracture and excessive wear.

Failure Mode and Effects Analysis (FMEA): A procedure by which each potential failure mode in a product (system) is analyzed to determine the results or effects thereof on the product and to classify each potential failure mode according to its severity or risk probability number.

Failure Modes, Effects, and Criticality Analysis (FMECA): The term is used to emphasize the classifying of failure modes as to their severity (criticality).

Failure Rate (λ): The mean (arithmetic average, also known as the forced outage rate) number of failures of a component and/or system per unit exposure time. The most common unit in reliability analyses is hours (h). However, some industries use failures per year (f/y) which is denoted by the symbol (λ_y).

Failure Reporting and Corrective Action System (FRACAS): A closed-loop system for collecting, analyzing, and documenting failures and recording any corrective action taken to eliminate or reduce the probability of future such failures.

False Alarm: A fault indicated by BIT or other monitoring circuitry where no fault can be found or confirmed.

Fault: Immediate cause of failure (for example, maladjustment, misalignment, defect, etc.).

Fault Detection (FD): A process that discovers the existence of faults.

Fault Isolation (FI): The process of determining the location of a fault to the indenture level necessary to affect repair.

Fault Tree Analysis: An analysis approach in which each potential system failure is traced back to all faults that could cause the failure. It is a top-down approach, whereas the FMEA is a bottom-up approach.

Hidden Failure: See Failure, Hidden.

Hours Downtime Per Year (Hrdt/Year): Average hours the item is expected to be not functional in a one-year period, caused by both preventative maintenance and failures. This includes any logistics delay time.

Indenture Levels: The levels which identify or describe the relative complexity of an assembly or function.

Isolation: Determining the location of a failure to the extent possible, using accessory equipment.

Item: Used interchangeably in this document with product or equipment. Usually refers to the individual article rather than the inclusive class or kind of product.

Item Criticality Number (C_r): A relative measure of consequence of an item failure and its frequency of occurrence. This factor is not applicable to a qualitative analysis.

Laplace Statistic: A statistic used to determine if a data set indicates a positive or negative trend, at a given level of confidence.

Levels of Maintenance: The division of maintenance, based on different and requisite technical skill, which jobs are allocated to organizations in accordance with the availability of personnel, tools, supplies, and the time within the organization. Typical maintenance levels are organizational, intermediate, and depot.

Life Cycle Cost (LCC): The sum of acquisition, logistics support, operating, and retirement and phase-out expenses.

Line Replaceable Unit (LRU): A unit designed to be removed upon failure from a larger entity (product or item) in the operational environment, normally at the organizational level.

Local Effect: The consequence a failure mode has on the operation, function or status of the specific item being analyzed.

Localization: Determining the location of a failure to the extent possible, without using accessory test equipment.

Logistic Delay Time: That element of downtime during which no maintenance is being accomplished on the item because of either supply or administrative delay.

Logistics Support: The materials and services required to enable the operating forces to operate, maintain, and repair the end item within the maintenance concept defined for that end item.

Maintainability: The relative ease and economy of time and resources with which an item can be retained in, or restored to, a specified condition when maintenance is performed by personnel having specified skill levels, using prescribed procedures and resources, at each prescribed level of maintenance and repair. Also, the probability that an item can be retained in, or restored to, a specified condition when maintenance is performed by personnel having specified skill levels, using prescribed procedures and resources, at each prescribed level of maintenance and repair.

Maintenance: All actions necessary for retaining an item in or restoring it to a specified condition.

Maintenance Action: An element of a maintenance event. One or more tasks (such as, fault localization, fault isolation, servicing, and inspection) necessary to retain an item's condition or restore it to a specified condition.

Maintenance Concept: A description of the planned general scheme for maintenance and support of an item in the operational environment. It provides a practical basis for design, layout, and packaging of the system and its test equipment. It establishes the scope of maintenance responsibility for each level of maintenance and the personnel resources required to maintain the system.

Maintenance Event: One or more maintenance actions required to effect corrective and preventive maintenance due to any type of failure or malfunction, false alarm, or scheduled maintenance plan.

Maintenance Task: The maintenance effort necessary for retaining an item in or changing/restoring it to a specified condition.

Maintenance Time: An element of downtime that excludes modification and delay time.

Mean: Also called the expected value of a random variable, the mean is defined as follows: Let X be a continuous random variable with a probability density function = *f*. The expected value of X is:

$$E(X) = \int_{x} x f(x) dx$$

The mean, or expected value, is analogous to the concept of center of mass in mechanics.

Mean Downtime (MDT): The average downtime caused by preventative and corrective maintenance, including any logistics delay time. This is synonymous with mean time to restore system (MTTRS) as found in some publications.

Mean Time Between Failures (MTBF): The mean exposure time between consecutive failures of a component. MTBF is a require measurement used for calculating inherent availability. It can be estimated by dividing the exposure time by the number of failures in that period.

Mean Time Between Maintenance (MTBM): The average time between all maintenance events that cause downtime, both preventative and corrective maintenance, and includes any associated logistics delay time.

Mean Time To Failure (MTTF): The mean exposure time between consecutive repairs (or installations) of a component and the next failure of that component. MTTF is commonly found for nonrepairable items such as fuses or bulbs, etc.

Mean Time To Maintain (MTTM): The average downtime for preventative maintenance. This includes any logistics delay time.

Mean Time To Repair (MTTR): The mean time to replace or repair a failed component. Logistics delay time associated with the repair, such as parts acquisitions, crew mobilization, are not included. It can be estimated by dividing the summation of repair times by the number of repairs and, therefore, is practically the average repair time. The most common unit in reliability analyses is hours (h/f).

Mission Phase Operational Mode: The statement of the mission phase and mode of operation of the system or equipment in which the failure occurs.

Mission Reliability: The probability that a system will complete its intended mission. Hardware failures that do not hinder the success of the mission (for example, due to redundancy) are not counted against mission reliability.

Next Higher Level Effect: The consequence a failure mode has on the operation, functions, or status of the items in the next higher indenture level above the specific item being analyzed.

Non-Destructive Inspection (NDI): Any method used for inspecting an item without physically, chemically, or otherwise destroying or changing the design characteristics of the item. However, it may be necessary to remove paint or other external coatings to use the NDI method. A wide range of technology and methods are usually described as nondestructive inspection, evaluation, or testing (collectively referred to as non-destructive evaluation or NDE). The core of NDE is commonly thought to contain ultrasonic, visual, radiographic, eddy current, liquid penetrant, and magnetic particle inspection methods. Other methodologies include acoustic emission, use of laser interference, microwaves, NMR and MRI, thermal imaging, and so forth.

On-Condition Maintenance: See Condition-based PM.

One-Line Diagram: A one-line diagram is a drawing of an electrical or mechanical system that shows how the parts interact. It shows paths of electrical flow, water flow, gas flow, etc. It will also list system component and component sizes.

Operating and Support (O&S) Costs: Those costs associated with operating and supporting (such as, using) a product after it is purchased or fielded.

Operational Readiness: The ability of a military unit to respond to its operation plan(s) upon receipt of an operations order. (A function of assigned strength, item availability, status, or supply, training, etc.).

Operational Reliability: The reliability of a system or equipment after it is put in operation.

Parallel Combination: The combining of two or more items in such a way that not all components are required for operation – thus, the parallel combination is characterized by alternate paths of operation.

Predicted: That which is expected at some future time, postulated on analysis of past experience and tests.

Predictive Maintenance: See Condition-based PM.

Preventative Maintenance (PM): All actions performed in an attempt to retain an item in a specified condition. These actions may or may not result in downtime for the component and may or may not be performed on a fixed interval.

Probability Distribution: A formula that describes the probabilities associated with the values of a discrete random variable.

Product: An equipment, item, or hardware contracted for by a customer. Usually used to describe the inclusive class or kind of item, equipment, etc., rather than each individual entity.

Qualitative Analysis: A means of conducting an analysis without data. Team member subjectively rank probabilities of occurrence, typically 1-10, in place of failure rates.

Quantitative Analysis: An analysis that is supported with data. Data is available for assigning failure rates and failure mode probabilities.

Reassembly: Assembling the items that were removed during disassembly and closing the reassembled items.

Redundancy: The existence of more than one means for accomplishing a given function. Each means of accomplishing the function need not necessarily be identical.

Reliability (R(t)): The probability that a component can perform its intended function for a specified time interval (t) under stated conditions. This calculation is based on the exponential distribution.

Reliability-Centered Maintenance (RCM): A disciplined logic or methodology used to identify preventive and corrective maintenance tasks to realize the inherent reliability of equipment at a minimum expenditure of resources, while ensuring safe operation and use.

Reliability Prediction: An estimate of reliability based on information that includes historical data, piece parts count, complexity, and piece part failure rates.

Retest Ok (RTOK): A situation where a failure was detected on the system, either through inspection or testing, but no fault can be found in the item that was eventually removed for repair at a field or depot location. Also see Cannot Duplicate.

Risk Priority Number (RPN): The Risk Priority Number (RPN) is the product of the Severity (1-10) and the Occurrence (1-10) ranking. The Risk Priority Number is used to rank and identify the concerns or risks associated with the operation due to the design. RPN = (S) x (O).

Severity: Considers the worst possible consequence of a failure classified by the degree of injury, property damage, system damage and mission loss that could occur.

Scheduled Maintenance: Periodic prescribed inspection and/or servicing of products or items accomplished on a calendar, mileage, or hours of operation basis. Included in Preventive Maintenance.

Servicing: The performance of any act needed to keep an item in operating condition, (such as lubricating, fueling, oiling, cleaning, etc.), but not including preventive maintenance of parts or corrective maintenance tasks.

Single-Point Failure: A failure of an item that causes the system to fail and for which no redundancy or alternative operational procedure exists.

Standby Redundancy: Two or more components in a parallel combination where not all components are required at any time. The other components are disconnected, and power is applied prior to or simultaneously with switching.

Subsystem: A combination of sets, groups, etc. that performs an operational function within a product (system) and is a major subdivision of the product. (Example: Data processing subsystem, guidance subsystem).

Success: Achievement of an objective or completion of a function or set of functions.

Switch: A device that selects one component in a parallel or redundant configuration as the functioning component. Used for standby redundancy. Incorporates such provisions as logic circuits and fault detection.

System: A group of components connected or associated in a fixed configuration to perform a specified function.

System Downtime: The time interval between the commencement of work on a system (product) malfunction and the time when the system has been repaired and/or checked by the maintenance person, and no further maintenance activity is executed.

Technical Load: That portion of the operational which consists of general lighting and heating, ventilating, and air conditioning (HVAC) systems necessary to maintain normal operations and loads directly associated with the C5ISR missions at the site.

Testability: A design characteristic that allows status (operable, inoperable, or degraded) of an item to be determined and the isolation of faults within the item to be performed in a timely manner.

Total Downtime Events (Tde): The total number of downtime events (including scheduled maintenance and failures) during the Tp.

Total Failures (Tf): The total number of failures during the Tp.

Total Maintenance Actions (Tma): The total number of preventative maintenance actions which take the component down during the Tp.

Total Period (Tp): The calendar time over which data for the item was collected.

Total System Downtime: The time interval between the reporting of a system (product) malfunction and the time when the system has been repaired and/or checked by the maintenance person, and no further maintenance activity is executed.

Unscheduled Maintenance: Corrective maintenance performed in response to a suspected failure.

Uptime: That element of ACTIVE TIME during which an item is in condition to perform its required functions. (Increases availability and dependability).

Useful Life: The number of life units from manufacture to when the item has an unrepairable failure or unacceptable failure rate. Also, the period of time before the failure rate increases due to wearout.

User: The using Government Agency.

Using Government Agency: The Government Agency that will be responsible for completing the site missions and will have operational authority for the facility.

Wearout: The process that results in an increase of the failure rate or probability of failure as the number of life units increases.

Year (y): The unit of time measurement approximately equal to 8765.81277 hours (h). Any rounding of this value will have adverse effects on analyses depending on the magnitude of that rounding. 8766 is used commonly as it is the result of rounding to 365.25×24 (which accounts for a leap year every 4th year). 8760, which is 365×24, is the most commonly used value in the power reliability field. By convention, 8760 will be used throughout this document.

This UFC supersedes UFC 3-520-05, dated 14 April 2008.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, \2*DOD Building Code*/2/, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
NEW DOCUMENT SUMMARY SHEET

Document: UFC 3-520-05, \2*Stationary and Mission Batteries/2/*

Superseding: This is a complete revision and reissuance of UFC 3-520-05, *Stationary Battery Areas*, dated April 14, 2008.

Description: This UFC 3-520-05 provides criteria for the design of stationary \2\and mission/2/ battery installations.

Reasons for Document:

- Provide technical requirements for enclosed battery areas.
- Address multi-discipline requirements for battery area layout and design. This document addresses architectural, electrical, mechanical, civil, fire protection, and plumbing requirements.
- Incorporate new and revised industry standards.

Impact: There are negligible cost impacts associated with this UFC. However, the following benefits should be realized:

- Standardized criteria have been prepared to assist engineers with the unique installation requirements for battery systems.
- Over design of battery areas should be avoided by ensuring that industry standard documents are preferentially applied.
- Safety requirements associated with batteries are addressed.

Unification Issues:

None.

TABLE OF CONTENTS

FIGURES

TABLES

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

Unified Facility Criteria (UFC) 3-520-05 provides design criteria for stationary secondary battery installations. These batteries are operated on a continuous float charge and may require ventilation to limit hydrogen gas concentrations. This UFC also addresses \2\mobile/2/ lithium-based batteries that are stored or charged inside facilities.

This UFC serves as a planning, engineering, and design reference for professional facility planners, designers, and constructors, including DoD personnel and Government contractors. Designers and planners will use this document for individual project planning, for preparing engineering documentation, and for preparing contract documents for construction and renovation projects.

1-1.1 UFC Hierarchy.

UFC 3-501-01 provides the governing criteria for electrical systems, explains the delineation between the different electrical-related UFCs, and refers to UFC 3-520-01 for interior electrical system requirements. This UFC cites and supplements existing Government and commercial standards and specifications governing the architectural, mechanical, plumbing, and electrical requirements for design of stationary secondary battery installations.

1-1.2 Upgrades and Modifications to Existing Systems.

Modernization of electrical systems within existing facilities solely for the purpose of meeting design criteria in this UFC is not required. Upgrades or modifications of existing facilities should consider the design criteria in this UFC, but it is not intended that an entire facility require modernization solely because of a minor modification to a part of the facility.

1-2 EXCLUSIONS.

Appendix B provides examples of battery installation types that are covered by this UFC.

1-2.1 Excluded Battery Applications.

Design of primary battery installations, mobile applications of secondary batteries, batteries used in consumer electronics, and battery maintenance facilities are not covered by this UFC.

1-2.2 Lithium Batteries.

Mobile applications of lithium batteries when the batteries are installed in the end-use application are not covered by this UFC.

Note: This UFC does provide guidance for lithium-based batteries when stored or charged inside a facility; refer to Chapter 3 for requirements. Refer to Appendix B for additional information regarding applicability of lithium-based batteries. Lithium-ion batteries are the most common technology used. In general, this UFC refers to batteries using lithium as "lithium batteries".

1-2.3 Electric Vehicle Charging.

Refer to NFPA 70 for charging requirements for electric vehicles.

1-3 APPLICATION.

1-3.1 Battery Types.

The following battery types are addressed:

- Vented (flooded) lead acid.
- Valve-regulated lead acid (VRLA).
- Vented (flooded) nickel cadmium.
- Lithium.

Note: NFPA 1 uses the term "flooded" to describe vented batteries with a free-flowing liquid electrolyte.

Note: The term "battery cabinet" refers to a cabinet or enclosure designed to contain one or more batteries or battery cells; this term is preferentially used to maintain consistency with industry codes and standards.

1-3.2 Facilities.

Criteria in this UFC apply to DoD-owned or -leased facilities located on or outside of DoD installations, whether acquired by appropriated or non-appropriated funds, or third-party financed and constructed. Facilities include all temporary or permanent structures independent of their size.

1-3.3 Conflicts.

If a conflict exists between this UFC and any other DoD document, referenced code, standard, or publication, this UFC takes precedence.

1-3.4 Compliance.

Comply with the design criteria of this UFC for new construction and major renovation projects. For Air Force projects, comply with the additional criteria of AFPAM 32-1186, *Valve-Regulated Lead Acid Batteries for Stationary Application*. Renovation of existing battery installations solely for the purpose of meeting the design criteria of this UFC is not required. Apply the criteria in this UFC for retrofits of existing installations.

1-4 SAFETY.

Comply with UFC 3-560-01, *Electrical Safety, O&M*, and NFPA 70E, *Standard for Electrical Safety in the Workplace*, Article 320, for battery-related electrical safety requirements. EM 385-1-1, *Safety and Health Requirements*, and OSHA 1926.441 also apply to this UFC.

1-5 REFERENCES.

Appendix A contains a complete list of references used in this manual. \1\ The publication date of the code or standard is not included in this document.

The design is intended to use the most current version of a publication, standard, or code in effect when the design contract is signed unless written direction is provided to the contrary. If dates are not indicated in the contract or in the absence or other direction, the issue/version of publication in effect at the time the design started is to be used. Designs that have been started and then delayed will need to evaluate which version is applicable, and may have to update to the newer version if considerable time has gone by. This may require some redesign. /1/

This Page Intentionally Left Blank

CHAPTER 2 STATIONARY BATTERY DESIGN CRITERIA

2-1 GENERAL.

2-1.1 Battery Types.

Chapter 2 provides requirements for the following battery types:

- Vented (flooded) lead acid.
- Valve-regulated lead acid (VRLA).
- Vented (flooded) nickel cadmium.

Note: UFC 3-520-01 prohibits lithium batteries for stationary applications in occupied facilities. Refer to Chapter 3 for requirements for lithium batteries used in military mission systems that are stored or charged inside facilities./2/

2-1.2 Required Criteria.

Comply with NFPA 70, *National Electrical Code* (NEC), and NFPA 1, *Fire Code*, for battery room design requirements. \1\ Apply the NFPA 1 criteria to all stationary batteries with a nominal voltage of 48 VDC or higher, regardless of the battery electrolyte capacity. /1/ Comply with UFC 3-520-01, *Interior Electrical Systems*, for battery selection, sizing, and application.

\1\ *Note: Refer to Appendix B-1 for examples of stationary batteries.* /1/

Regulatory requirements and restrictions vary depending upon location. Battery installations may require permits and environmental control and reporting due to their component heavy metals and acidic or basic electrolyte. Consult Title 29 Code of Federal Regulations (CFR) Parts 1910 and 1926 *Occupational Safety and Health Standards*, Title 40 Code of Federal Regulations *Protection of Environment*, and other applicable regulations for additional information.

2-2 ARCHITECTURAL REQUIREMENTS.

2-2.1 Location.

Where required by NFPA 1, install stationary batteries in a noncombustible, locked cabinet or other enclosure to prevent access by unauthorized personnel unless located in a separate equipment room accessible only to authorized personnel.

Locate the battery near the loads to be served while still satisfying the mechanical design criteria. UPS systems containing batteries can be located in the same room as the equipment they support.

2-2.2 Battery Rooms.

Provide the occupancy separation requirements specified in NFPA 1. When more than one battery chemistry is employed, locate each type of battery in a separate room with each room individually meeting the occupancy separation requirements and with no direct access between the rooms. Services not associated with the battery room must not pass through the room. Do not design the battery room to have access to other spaces. Do not use battery rooms for material storage, such as storage of office supplies, cleaning supplies, or spill control equipment; design a separate space for these materials.

2-2.3 Battery Cabinets.

Provide battery cabinets, including battery cabinets for UPS systems, that are a commercial manufactured product, designed and UL listed or third-party verified and tested for battery containment. Provide a minimum 200 mm (8 in.) working clearance around the batteries within the cabinet or provide drawout racks that allow for the specified working clearance. For outside installations prevent entry of contaminants, water, insects, and wildlife.

2-2.4 Spill Control.

Provide spill control for battery installations as required by NFPA 1. An electrolyte spill is defined as an unintended release of liquid electrolyte that exceeds 1.0 liters. Do not use battery cabinets without integral spill containment for vented lead acid or nickel cadmium batteries. Permanently installed physical containment structures must be capable of resisting continuous exposure to a 70 percent concentration of the electrolyte’s acid or alkaline chemical. Do not allow the containment area to encroach upon space designated for room egress.

Note: VRLA batteries do not require spill containment.

When floor drains are provided in the battery area, design them in accordance with UFC 3-420-01, *Plumbing Systems*.

2-2.5 Electrolyte Neutralization.

Provide for spilled electrolyte neutralization in accordance with NFPA 1. Provide neutralizing and absorbing materials local to, but outside of, the battery area to address local incidents.

Select a slip-resistant floor finish in all battery rooms. Select an acid or alkali resistant floor finish and battery cabinet finish as appropriate for the battery chemistry employed. Wall and ceiling finishes in vented (flooded) cell installations must be acid or alkali resistant.

2-2.6 Battery Racks.

Obtain the battery rack from the same manufacturer that supplies the battery. Racks and trays must resist corrosion from continuous exposure to a 70 percent concentration of the electrolyte's acid or base chemical. Provide insulated battery lifting devices and provide tools with insulated handles.

Select the battery rack to fit within the defined footprint while also satisfying the need for maintenance access. Figures 2-1 and 2-2 show acceptable battery rack configurations for vented cells.

Figure 2-1. Two-Step Battery Rack Configurations (End View)

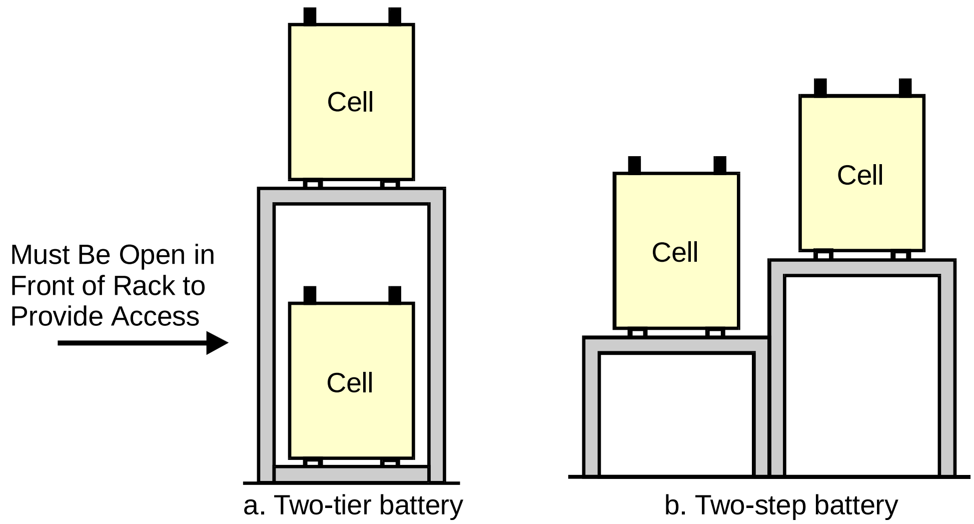

Figure 2-2. Larger Battery Rack Configurations (End View)

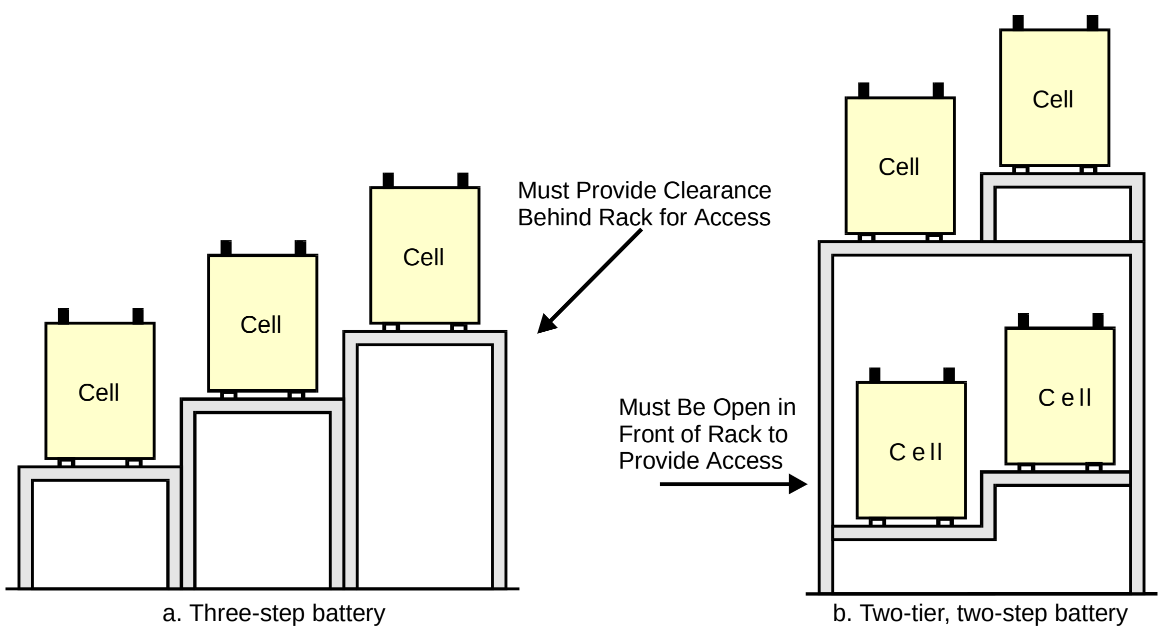

2-2.7 Seismic Design.

Provide restraints in all racks for vented cell installations to prevent the individual cells from overturning. In addition, comply with ASCE/SEI 7-10 for battery racks. Table 2-1 shows the rack requirements based on seismic design category.

Table 2-1. Battery Rack Requirements by Seismic Design Category

Seismic Design Category	Description
A—earthquakes are unlikely.	Racks do not require cell restraints.
B—distant earthquakes might cause minor motion.	Racks require side restraints.
C, D, E, F—local or nearby earthquake.	Racks require heavy-duty construction with side restraints and should have additional floor anchor points.

If the stationary battery supports a Mission-Critical Level 1 system as classified by UFC 3-310-04, *Seismic Design of Buildings*, seismically qualify the battery and battery rack in accordance with UFC 3-310-04 and IEEE 693, *IEEE Recommended Practice for Seismic Design of Substations*.

2-2.8 Additional Criteria.

Provide an overhead hoist or equivalent portable material handling equipment for the handling of batteries if the battery cells or modules each weigh over 50 lb (23 kg).

2-3 MECHANICAL REQUIREMENTS.

2-3.1 Installation.

Installation, operating, and maintenance requirements vary for each battery type. Comply with the following IEEE documents for installation criteria, as appropriate for the selected battery type:

IEEE Std 484, *IEEE Recommended Practice for Installation Design and Installation of Vented Lead acid Batteries for Stationary Applications*.

IEEE Std 1106, *IEEE Recommended Practice for Installation, Maintenance, Testing, and Replacement of Vented Nickel cadmium Batteries for Stationary Applications*.

IEEE Std 1187, *IEEE Recommended Practice for Installation Design and Installation of Valve-Regulated Lead acid Storage Batteries for Stationary Applications*.

IEEE 1635, *IEEE/ASHRAE Guide for the Ventilation and Thermal Management of Batteries for Stationary Applications*.

2-3.2 Ventilation and Hydrogen Control.

2-3.2.1 Hydrogen Generation.

Design ventilation systems to maintain concentrations of hydrogen gas in the battery room below 1 percent concentration.

Calculate the hydrogen generation rate based on the worst-case event of simultaneous boost (equalize) charging of all of the batteries in accordance with NFPA 1. \1\ Refer to IEEE 1635 for examples of fire code worst-case calculations. /1/ Obtain the hydrogen generation rate for the installed battery model and size from the battery manufacturer or apply IEEE 1635 if manufacturer data is not available. \1\ For VRLA stationary batteries, calculate the hydrogen generation rate based on a maximum hydrogen generation rate of 1.27×10^{-7} m^3/s (2.69×10^{-4} cfm) per charging ampere per cell at 25 °C and standard pressure. /1/

2-3.2.2 Ventilation System Design.

Provide ventilation and alarm in accordance with the *International Mechanical Code*, Section 502.4.

2-3.2.2.1 \2\Exhaust System./2/

\2\Provide an emergency exhaust system to contain and directly exhaust smoke and gases from storage and charging rooms. Ensure controls maintain exhaust fan operation under all conditions including ATFP, fire alarm, etc. unless exhaust fan operation would create an unsafe condition such as impeding egress./2/

2-3.2.2.2 \2\Battery Exhaust Duct Requirements./2/

\2\Battery room exhaust duct systems must extend directly to the exterior of the building and must follow the shortest route to the point of discharge. Do not install fire dampers in exhaust duct. Provide a continuous fire-rated duct wrap for the entire length of battery room exhaust duct.

Where battery room exhaust must pass through adjacent spaces, ensure the duct is maintained at a negative pressure. Provide exhaust duct with an upwardly directed discharge. Exhaust discharge opening must be at least 6 feet from exterior walls and roofs, 10 feet from operable openings into buildings, and 10 feet above grade. Exhaust fan must be ANSI/AMCA 99-16 type A with non-sparking wheel and motor location outside of the air stream./2/

2-3.2.2.3 System Design.

Design mechanical systems for continuous operation, free from excessive vibration. Provide green indicator light confirming fan operation located in battery area. Isolate mechanical equipment to eliminate structure-borne vibration that will have an adverse effect on battery usage and performance.

2-3.2.3 Ventilation for Batteries Inside Cabinets.

Provide ventilation for batteries inside cabinets, including UPS systems, in accordance with the *International Mechanical Code*, Section 502.5. The requirement to maintain concentrations of hydrogen gas below 1 percent concentration applies to the inside of the cabinet as well as the area in which the cabinet is installed.

2-3.3 Thermal Management.

The optimal operating temperature range for a lead acid or nickel cadmium battery is between 68° F (20° C) and 77° F (25° C). Operation in this range provides the best balance between capacity and service life. Maintaining the battery installation within the optimal temperature range reduces the possibility of thermal runaway in VRLA batteries.

Maintain the battery area temperature for lead acid batteries below 85° F (29° C) using transfer air when available.

2-4 ELECTRICAL REQUIREMENTS.

2-4.1 Electrical Equipment.

2-4.1.1 Overcurrent Protection and Isolation.

Provide overcurrent protection for each battery string. Provide separate overcurrent protection for each individual string in a paralleled battery string. If the DC conductors leave a separate battery room:

- Provide a disconnect device outside the room near the entrance, or
- Provide a shunt trip device near the entrance that opens a disconnect device inside the battery room.

2-4.1.2 Conductors and Terminations.

Do not use Type AC, NM, NMC, NMS, and UF cable in battery rooms. Do not use flexible metal conduit or flexible metallic tubing.

Install connections to battery terminal posts, including intercell connections, in a manner that minimizes strain on the battery posts.

2-4.1.3 Battery Charging.

Provide temperature compensated charging for VRLA batteries based on the battery temperature, not the ambient temperature.

Include temperature compensated charging for \1\ vented lead acid or nickel cadmium battery /1/ installations where the area is not environmentally controlled and large temperature variations can occur.

2-4.2 Bonding.

Bond conductive battery racks, cabinets, and cable racks to ground using #6 AWG minimum conductors.

2-4.3 Lighting.

Design illuminance levels in the battery room to comply with UFC 3-530-01 and IESNA Lighting Handbook Reference and Application recommendations with a minimum illumination level of 300 lux (30 fc). Consider the type of battery rack and the physical battery configuration to ensure that all points of connection, and maintenance and testing are adequately illuminated.

Install battery room lighting fixtures that are pendant or wall mounted, and do not provide a collection point for explosive gases. Provide fixtures that include lamp protection by shatterproof lenses or wire guards. Select fixtures in battery rooms for vented cells that are constructed to resist the corrosive effects of acid vapors. Luminaires and lamps must provide minimal heat output in general and provide minimal radiant heating of the batteries. Do not install lighting track in battery rooms. Fixture mounting must not interfere with operation of lifting devices used for battery maintenance. Receptacles and lighting switches should be located outside of the battery area.

2-4.4 Instrumentation and Control.

Provide instrumentation to measure battery voltage with high and low alarms, battery current, and ground detection for ungrounded systems. Provide the alarm system operation, level of reporting, and any additional instrumentation and alarm options appropriate for the specific conditions of each battery system.

2-5 EMERGENCY FACILITIES.

Provide portable or stationary water facilities for rinsing eyes and skin in case of electrolyte spillage. Locate within 20 feet of the battery. Design stationary facilities in accordance with UFC 3-420-01. Design portable facilities in accordance with ISEA Z358.1.

2-6 FIRE PROTECTION REQUIREMENTS.

Comply with UFC 3-600-01 and NFPA 1; however, smoke detection is not required.

2-6.1 Sprinkler System.

When the facility requires a wet-pipe automatic sprinkler system, provide an automatic sprinkler system in each battery room. Provide a supervised shut-off valve, check valve, flow switch, and test valve for the sprinkler line supplying a battery room. These items must be located outside of and adjacent to the associated battery room.

Actuation of the flow switch must remove power to the battery chargers that serve that battery room.

2-6.2 Portable Fire Extinguishers.

Portable fire extinguishers are not required to be installed.

This Page Intentionally Left Blank

CHAPTER 3 LITHIUM BATTERY DESIGN CRITERIA.

3-1 GENERAL.

\2\Chapter 3 provides requirements for military mission, lithium batteries that will be stored or charged inside facilities. For the Navy and Marine Corps, follow all requirements of NAVSEA S9310-AQ-SAF-010 *Technical Manual for Navy Lithium Battery Safety Program Responsibilities and Procedures*. Where conflicts exist, the most stringent requirement applies. Refer to Appendix B for a discussion of the typical military mission battery applications. Obtain the safety data package (SDP), preliminary hazards list (PHL), and preliminary hazards analysis (PHA) from the responsible program office./2/

\2\This chapter does not apply to portable, commercial-off-the-shelf (COTS) cells and batteries that are: UL listed, 18 volts or less, and less than 100 Watt-hours as defined in chapter 3 of NAVSEA S9310-AQ-SAF-010./2/

3-2 REQUIRED CRITERIA.

\2\Consider lithium batteries as hazardous. Comply with NFPA 70, *National Electrical Code* (NEC), NFPA 1, *Fire Code*, NFPA 704, *Standard System for the Identification of the Hazards of Materials for Emergency Response*, and NAVSEA S9310-AQ-SAF-010 for battery room design requirements. Comply with the additional requirements provided in the following sections and minimum safety requirements in Figure 3-1./2/

3-3 ARCHITECTURAL REQUIREMENTS.

3-3.1 Location.

\2\The preferred location for lithium battery storage is in an unoccupied, segregated shelter adjacent to the occupied building. If lithium batteries are located in an occupied building, locate the batteries in dedicated rooms, separated from other portions of the building by a fire barrier in accordance with NFPA 1. Isolate charging rooms from storage rooms and provide two means of egress with panic hardware.

Do not provide space for spent batteries. Spent batteries are batteries that are no longer serviceable. All spent batteries must be stored outdoors. Do not store or charge lithium batteries in the same room with either nickel cadmium or lead acid batteries.

NOTE: For unmanned underwater vehicles (UUV) batteries that are not removable for charging, the UUV hull acts as a pressure and fire barrier. In this case, separate storage and charging areas are not required. For UUV platforms with removable batteries, follow the requirements of this chapter./2/

3-3.2 \2\Storage Closets./2/

\2\Store military mission, lithium batteries in fire-rated closets of conventional construction designed specifically for the particular battery type. Provide a minimum of three (3) fire rated storage enclosures. Obtain concurrence from the supported command to determine the number of storage closets. The percentage of batteries that are subject to loss upon a catastrophic failure is determined by the number of closets. Coordinate with the supported command to determine the appropriate risk mitigation based on operational requirements and battery costs.

Closets must be provided with exhaust per paragraph 3-5.1. Provide sprinklers and makeup air for each battery storage closet. Provide each closet with grated storage shelving to allow airflow and sprinkler coverage./2/

3-3.3 \2\Charging Stations./2/

\2\Battery charging presents the greatest hazard for battery failure. Locate charging stations away from egress pathways and other battery room functions where personnel are likely to be.

Charge and discharge lithium batteries in designated stations designed specifically for the particular battery type. Size the charging station providing sufficient working clearance around the mission battery, FF&E battery charger, and FF&E charging table. Figure 3-1 indicates a typical dimension of 3 foot by 3 foot, but adjust this dimension to accommodate the mission battery and FF&E. Separate each station with a fire-rated, full-height wall. Ensure the open side of charging stations is not directed towards other charging cubbies or flammables. Provide each station with exhaust per Paragraph 3-5.1. Provide sprinklers directly overhead of charging stations./2/

3-3.4 Seismic Design.

Comply with Section 2-2.7.

3-3.5 \2\Signage./2/

\2\Provide signage for identification of hazardous material in battery rooms in accordance with UFC 3-600-01./2/

3-4 VENTILATION.

\2\Lithium batteries do not vent hydrogen under normal conditions, but will vent hazardous and explosive gases upon failure. Lithium batteries are designed to release overpressure due to thermal runaway through integral vent ports. Ventilate all spaces at a minimum of 6 air changes per hour (ACH) at all times.

Provide a combined emergency exhaust and ventilation system. Provide conditioned makeup air from adjacent spaces to ensure a negative pressure relationship between the battery rooms and adjacent spaces. Provide barometric dampers in transfer duct to create a negative pressure with respect to adjacent areas./2/

3-5 \2\BATTERY EXHAUST SYSTEM/2/

3-5.1 \2\Exhaust System./2/

\2\Provide an emergency exhaust system to contain and directly exhaust smoke and gases from storage and charging rooms. Provide a minimum emergency exhaust rate of 12 air changes per hour ACH. The design of the ventilation system is intended to limit the concentration of explosive gases to 25% of the lower explosive limit upon thermal runaway of a battery.

Provide a volatile organic compound (VOC) detector in the exhaust duct immediately before the exhaust fan inlet. Upon detection of VOCs, the exhaust fan shall increase speed to provide 12 ACH to all storage and charging areas. Provide a local control button and alarm in the battery charging room to energize emergency exhaust. Provide a local pilot light showing exhaust fan run status. Actuation of the emergency exhaust fan must remove power to the battery chargers. Ensure controls maintain exhaust fan operation under all conditions including ATFP, fire alarm, etc. unless exhaust fan operation would create an unsafe condition such as impeding egress./2/

3-5.2 \2\Battery Exhaust Duct Requirements./2/

\2\Extend battery room exhaust duct systems directly to the exterior of the building and follow the shortest route to the point of discharge. Do not install fire dampers in exhaust duct. Provide a continuous fire-rated duct wrap for the entire length of battery room exhaust duct.

Where battery room exhaust must pass through adjacent spaces, ensure the duct is maintained at a negative pressure. Provide exhaust duct with an upwardly directed discharge. Exhaust discharge opening must be at least 6 feet from exterior walls and roofs, 10 feet from operable openings into buildings, and 10 feet above grade. Exhaust fan must be ANSI/AMCA 99-16 type A with non-sparking wheel and motor location outside of the air stream. /2/

3-6 THERMAL MANAGEMENT.

\2\Provide a separate cooling system independent of the building HVAC system for each battery room designed to maintain an ambient temperature of 65 °F (18.3 °C)./2/

3-7 FIRE PROTECTION.

Comply with UFC 3-600-01 and NFPA 1; however, smoke detection is not required.

3-7.1 Sprinkler System.

Provide a wet-pipe automatic sprinkler system for each battery room. Provide a supervised shut-off valve, check valve, flow switch, and test valve for the sprinkler line supplying a battery room. These items must be located outside of and adjacent to the associated battery room. Actuation of the flow switch must remove power to the battery chargers. \2\Provide a fire alarm hand pull in the room./2/

Note: Sprinkler systems are not required for small remote facilities or mobile storage containers (Conex boxes) that have been designed specifically for storage and charging of lithium batteries, and are physically separated from other facilities by a minimum of 50 feet.

3-7.2 Fire Department.

Coordinate with and inform the base fire department of the type of operations performed at the facility and the maximum credible event mishap.

Note: The base Fire Map at the fire station(s) should include charging and storage areas for lithium batteries.

3-8 BATTERY CHARGING EQUIPMENT.

Install battery charging equipment designed for the specific lithium battery model. \2\Interlock battery charging circuits with emergency exhaust fan and sprinkler flow switch./2/

3-9 LIGHTING.

Design illuminance levels in the battery room to comply with UFC 3-530-01 and IESNA Lighting Handbook Reference and Application recommendations with a minimum illumination level of 300 lux (30 fc).

Install battery room lighting fixtures that are pendant or wall mounted. Provide fixtures that include lamp protection by shatterproof lenses or wire guards. Luminaires and lamps must provide minimal heat output in general and provide minimal radiant heating of the batteries. Do not install lighting track in battery rooms. Fixture mounting must not interfere with operation of lifting devices used for in the battery room. \2\Only dedicated receptacles for battery chargers may be located inside the battery rooms./2/

3-10 EMERGENCY FACILITIES.

Provide portable or stationary water facilities for rinsing eyes and skin in case of electrolyte spillage. Locate within 20 feet of the battery \2\enclosures./2/ Design stationary facilities in accordance with UFC 3-420-01. Design portable facilities in accordance with ANSI/ISEA Z358.1.

3-11 \2\ /2/

APPENDIX B STATIONARY BATTERY APPLICABILITY

Appendix B provides examples of the types of stationary batteries that are addressed by this UFC. Examples of batteries not addressed by this UFC are also provided. The examples are typically provided in terms of the end-use application.

B-1 APPLICABLE BATTERY TYPES/LOCATIONS.

- Power plant backup power applications.
- Substations and switching stations – switchgear power.
- UPS systems.
- Engine generator batteries, if installed inside enclosed areas.
- Centralized emergency lighting.
- Communication center batteries.
- Stationary batteries in storage on float charge.
- Stationary batteries maintained on float charge before shipboard installation.

B-2 EXCLUDED BATTERY TYPES/LOCATIONS.

- Small batteries used for portable equipment.
- Vehicle batteries.
- Batteries in storage and not on float charge.
- Small emergency lights with an internal battery.
- On board batteries, such as those on boats/amphibious craft or aircraft, are not addressed by this UFC except when those batteries are not installed in the craft but stored or maintained on float charge inside a facility prior to the intended use.
- Battery maintenance and repair facilities – these facilities typically handle large quantities of electrolyte, which leads to unique designs for ventilation control.

B-3 LITHIUM BATTERIES.

Lithium batteries are addressed by this UFC as follows:

- Lithium batteries for consumer electronics devices, such as cellular phones or notebook computers, are not addressed by this UFC.
- Lithium batteries for use in the traditional stationary applications listed above in Section B-1 are not addressed by this UFC and are not

authorized by UFC 3-520-01. Industry standards for the use of lithium batteries in stationary applications are still under development.

- Lithium batteries used in military mission systems are addressed by this UFC for their storage and charging inside a facility. These batteries are typically large format lithium-ion batteries and the end-use application is for shipboard, aircraft, and mobile applications.

Examples of military mission systems that use lithium-ion batteries include:

- Joint Strike Fighter aircraft – 28-volt and 270-volt systems.
- Ground Combat Vehicle program – rechargeable battery packs.
- Improved Target Acquisition System – rechargeable battery packs.
- Active Denial System – rechargeable battery packs.
- Global Hawk/Triton and similar unmanned aerial vehicle applications.
- \2\Knifefish Unmanned underwater Vehicle (UUV) – 30V rechargeable batteries./2/

APPENDIX C LITHIUM BATTERIES RISK ASSESSMENT

Appendix C provides an overview of lithium battery applications and failure modes.

C-1 DESCRIPTION.

Lithium batteries have been used in non-stationary applications for many years and lithium-ion batteries have become the dominant type of rechargeable battery for consumer electronics devices.

C-1.1 Design.

Lithium batteries use lithium metal or some other source of lithium ions in the negative electrode. During the battery discharge, the lithium ions travel to the positive electrode, which can be one of various materials, including a transition metal oxide, a transition metal phosphate, a sulfur compound, or even oxygen in the atmosphere or water. The electrolyte is typically a conductive salt in a solution, or a conductive polymer. Li-ion battery technology is most commonly used.

C-1.2 Packaging.

Lithium batteries are packaged as battery packs, which typically contain the individual cells, the battery management system (BMS), safety systems as necessary, thermal systems as necessary, and either a charger or the interface to an external charger. In order to ensure safety and performance, complete lithium-ion battery packs and systems should be provided as an integrated system and all manufacturer requirements must be followed.

C-2 FAILURE MODES.

Both energetic and non-energetic failures of lithium batteries can occur for a number of reasons including: poor cell design (electrochemical or mechanical), cell manufacturing flaws, external abuse of cells (thermal, mechanical, or electrical), poor battery pack design or manufacture, poor protection electronics design or manufacture, and poor charger or system design or manufacture. Reliability and safety is a function of the entire integrated system.

Refer to *Lithium-Ion Batteries Hazard and Use Assessment*, Fire Protection Research Foundation, for a detailed assessment of lithium battery failure modes and effects.

C-2.1 Non-Energetic Failures.

Lithium-ion batteries can fail in both non-energetic and energetic modes. Typical non-energetic failure modes (usually considered benign failures) include loss of capacity, internal impedance increase (loss of rate capability), activation of a permanent disabling mechanism, shutdown separator, fuse, or battery pack permanent disable, electrolyte leakage with subsequent cell dry-out, and cell swelling. The ideal lithium-ion battery failure mode is a slow capacity fade and internal impedance increase caused by normal aging of the cells within the battery. This is the most common failure mode.

C-2.2 Energetic Failures.

Energetic failures can cause overheating and fires. Energetic failures include thermal runaway, in which a cell rapidly releases its stored energy. These failures can initiate by thermal abuse, mechanical abuse, electrical abuse, poor design, or manufacturing. Although these types of failures are rare, the consequences of failure can be significant.

C-2.3 Charging.

Lithium batteries require that charging be matched to the battery for proper and safe operation. Proper matching of the battery and charger requires knowledge of the lithium cell chemistry, voltage, current requirements and all safety limitations. Improper matching can result in damage to the cells and possible cell failure.

C-3 STATIONARY APPLICATIONS.

Lithium batteries are still developing for stationary applications. They are considered suitable for various stationary battery applications with the proper design, and the proper safety and electronic control systems. Lithium batteries can be designed and optimized for high-power applications such as uninterruptible power supplies They can also be optimized for long-duration discharge applications such as telecommunications and renewable energy storage. Lithium batteries are smaller and lighter than most other battery alternatives, making them suitable as replacements and for applications that have limited space and increasing energy requirements. It is important to recognize that a lithium battery that is optimized for one stationary application may not be appropriate or safe to use in a different application.

Although lithium batteries have been used for several years in consumer electronics devices and are growing in their use for military mission applications, they are still not significantly used in traditional stationary applications. UFC 3-520-01 prohibits their use in stationary applications for the following reasons:

- The technology is new and is still developing for stationary applications.
- These batteries are still more expensive than equivalent lead acid or nickel cadmium batteries.
- \2\Deleted/2/
- The Tri-Service does not yet have criteria in place to assist with specifying this type of battery for stationary applications.

APPENDIX D GLOSSARY

ACRONYMS

A	Ampere
AC	Designation for NFPA 70 Armored Cable
Ah	Ampere-hour
AFPAM	Air Force Pamphlet
ANSI	American National Standards Institute
ASCE	American Society of Civil Engineers
AWG	American wire gauge
CFM	Cubic Feet per Minute
CFR	Code of Federal Regulations
DC	Direct Current
DoD	Department of Defense
Fc	Foot-candle
FRP	Fiberglass Reinforced Plastic
HR	Hydrogen Rate
IEEE	Institute of Electrical and Electronics Engineers
IESNA	Illuminating Engineering Society of North America
In	Inches
mm	Millimeters
NEC	National Electrical Code
NFPA	National Fire Protection Association
NM, NMC	Designations for NFPA 70 Nonmetallic Sheathed Cable
O&M	Operations & Maintenance
PVC	Polyvinyl Chloride

UF	Designation for NFPA 70 Underground Feeder and Branch-Circuit Cable
UFC	Unified Facility Criteria
VR	Ventilation Rate
VRLA	Valve-Regulated Lead acid

TERMS

Battery Cabinet: Refer to **Enclosure**.

Enclosure: A surrounding case or housing to protect the contained equipment against external conditions and to prevent personnel from accidentally contacting live parts. With respect to enclosures for stationary batteries, the enclosure might be a dedicated battery cabinet or it might contain additional equipment, such as an uninterruptible power supply.

Float Charge: The method of maintaining a battery in a charged condition by continuous, long-term charging at a level to balance self-discharge.

Full Float Operation: Operation of a dc system with the battery, battery charger, and load all connected in parallel, and with the battery charger supplying the normal dc load plus any self-discharge or charging current, or both, required by the battery. The battery will deliver current only when the load exceeds the charger output.

Primary Battery: A battery that produces electric current by electrochemical reactions without regard to the reversibility of those reactions. In the context of this UFC, a primary battery is not rechargeable, and is intended to be used once, then discarded.

Recombinant Cell: A battery cell characterized by the recombination of internally generated gases. For example, a VRLA cell is designed to recombine internally generated oxygen and suppression of hydrogen gas evolution to limit water consumption.

Room: A contained area within a facility, normally accessible through a door. With respect to stationary batteries, a room might be dedicated for the battery installation or it might contain additional equipment.

Secondary Battery: A battery that is capable of repeated use through chemical reactions that are reversible, i.e., the discharged energy can be restored by supplying electrical current to recharge the cell.

Stationary Battery: A storage battery designed for service in a permanent location.

Storage Battery: A battery consisting of one or more cells electrically connected for producing electric energy.

Valve-Regulated Lead acid (VRLA) Cell: A cell that is sealed with the exception of a valve that opens to the atmosphere when the internal gas pressure exceeds atmospheric pressure by a pre-selected amount. VRLA cells provide a means for recombination of internally generated oxygen and the suppression of hydrogen gas evolution to limit water consumption.

Vented Battery: A battery in which the products of electrolysis and evaporation are allowed to escape freely to the atmosphere. These batteries are commonly referred to as “flooded.”

This Page Intentionally Left Blank

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides requirements for the design of interior and exterior lighting systems and controls based on the Illuminating Engineering Society (IES) Lighting Library® and the Energy Policy Act of 2005. This UFC meets the current IES standard of practice and addresses general lighting requirements for DoD facilities.

1-2 REISSUES AND CANCELS.

This UFC reissues and cancels UFC 3-530-01, Design: Interior, Exterior Lighting and Controls, Change 4, 01 November 2019.

1-3 APPLICABILITY.

This document applies to the interior or exterior lighting systems for construction, repair, and maintenance projects. This UFC establishes the baseline requirement for:

- Energy efficiency
- Control strategy
- Lighting criteria
- Lighting best practices

For applications that are not listed in this UFC, refer to the IES Lighting Library for lighting criteria and lighting best practices.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-4.1 ASHRAE Compliance.

ASHRAE 90.1 applies to all projects except low-rise residential, which must comply with IECC. Refer to UFC 1-200-02 for applicable year of ASHRAE. **\1\ /1/** When UFC 1-200-02 adopts a newer publication year of ASHRAE 90.1, it will have precedence over these UFC requirements.

1-5 ENVIRONMENTAL SEVERITY AND HUMID LOCATIONS.

In corrosive and humid environments, provide design details and use materials, systems, components, and coatings that are durable and minimize the need for preventative and corrective maintenance over the expected service life of the component or system. UFC 1-200-01, section titled “Corrosion Prone Locations” identifies corrosive environments and humid locations requiring special attention. UFC 1-200-01, section titled “Requirements for Corrosion Prone Locations” provides examples of necessary actions. To determine Environmental Severity Classifications (ESC) for specific project locations, refer to UFC 1-200-01 Appendix titled “Environmental Severity Classifications (ESC) for DoD Locations”.

1-6 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-7 GLOSSARY.

APPENDIX F contains acronyms, abbreviations, and terms.

1-8 REFERENCES.

APPENDIX G contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 TECHNICAL REQUIREMENTS – INTERIOR LIGHTING

2-1 PRIORITIES FOR INTERIOR LIGHTING SYSTEMS.

Design interior lighting systems to reduce energy consumption, reduce maintenance costs, and improve lighting quality, at the lowest life cycle cost in DoD facilities.

2-1.1 Energy Reduction.

Provide Solid State Lighting/Light Emitting Diode (SSL/LED) systems for all interior lighting. SSL/LED systems are established technologies for interior lighting applications that have been proven to save energy over traditional light sources. There are few exceptions in specific medical applications where SSL systems are not allowed; refer to UFC 4-510-01 Design: Military Medical Facilities.

Reduce energy consumption by using energy efficient technologies, maintaining effective illuminance levels, and implementing control strategies. Maintain illumination level prescribed averages and uniformity ratios as closely as possible, in order to provide sufficient light levels without contributing to excessive energy usage.

2-1.2 Maintenance Reduction.

Reduce maintenance by technology selection, reducing equipment quantities, and implementing controls strategies. Select light sources, drivers, and controls that are rated and warranted for long useful lives to increase the amount of time between maintenance cycles. Minimize light source types on an individual project.

2-1.3 Luminaire Placement.

Locate luminaires in locations to ensure access for regular servicing such as driver replacement and cleaning.

Coordinate luminaire locations with ceiling obstructions, such as structure, HVAC, and fire suppression systems.

2-1.4 Lighting Quality.

Apply the following to ensure the priority of lighting quality is achieved.

2-1.4.1 Direct Glare.

In regularly occupied spaces, use luminaires with a luminance of less than 650 cd/ft^2 (7,000 cd/m^2) between 45 and 90 degrees from nadir. Exceptions include high and low bay luminaires in industrial applications, luminaires properly aimed at walls, and indirect luminaires that provide uplighting only, provided there is no view down into these uplights from a regularly occupied space above.

In non-regularly occupied spaces, shield light sources in luminaires with louvers, perforations, lenses, or other refracting technologies to avoid a direct view of the light sources and the resultant direct glare.

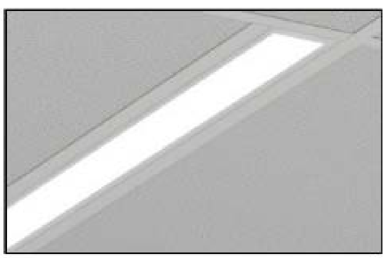
2-1.4.1.1 Luminance Comparison

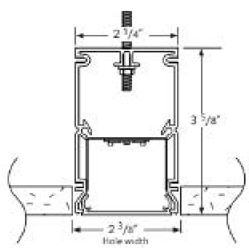
Figure 2-1 compares the luminance of two linear LED products. One has a nominal 2” (610 mm) wide lens and the other has a nominal 4” (1219 mm) wide lens. Both products have the same lumen output. The smaller lensed luminaire has values greater than 650 cd/ft^2 (7,000 cd/m^2) between 45 and 90 degrees from nadir. Therefore, this luminaire does not meet the luminance requirements and must be installed with a dimmer, see Alternate Path 1, because of its higher luminance values.

Figure 2-1 Luminance Comparison

CANDELA ARRAY

2 3/8" lens width, 500 lumens/foot output





LUMINANCE DATA (cd/sq.m)

Angle In Degrees	Average 0-Deg	Average 45-Deg	Average 90-Deg
45	11217	10095	9128
55	9632	8440	7438
65	7960	6924	6018
75	6129	5389	4649
85	4080	3765	3452

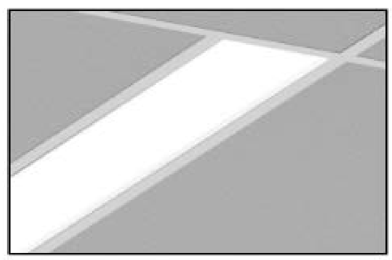
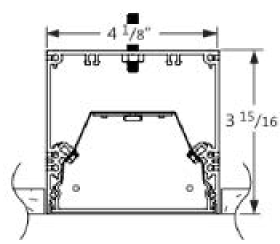
CANDELA ARRAY

4 1/8" lens width, 500 lumens/foot output





LUMINANCE DATA (cd/sq.m)

Angle In Degrees	Average 0-Deg	Average 45-Deg	Average 90-Deg
45	5663	5301	4953
55	5035	4638	4265
65	4380	4017	3698
75	3648	3414	3163
85	2721	2561	2455

*IES file used: Axis Lighting, Beam 4
BBRLED-500-80-35-FL-4
Source: https://www.axislighting.com/families/beam-4

- Alternate Path 1: Luminance values greater than 650 cd/ft^2 (7,000 cd/m^2) between 45 and 90 degrees from nadir are allowed when continuous dimming is provided and accessible to occupants.
- Alternate Path 2: Achieve a Unified Glare Rating (UGR) of <19 using software modelling calculations of the designed lighting calculated for the space.

2-1.4.2 Disability Glare.

Avoid disability glare caused by using bright luminaire components such as visible light sources or bright lenses that can reflect in the surface of tasks with glossy or specular finishes.

2-1.4.3 Luminance of Room Surfaces.

Illuminate surfaces to control the contrast between an occupant's task and the surrounding surface in the field of view. Avoid dark backgrounds when an occupant views a bright computer screen in the foreground. Control high luminance ratios for daylight fenestrations when direct sun is allowed to penetrate.

2-1.4.4 Uniformity.

Uniformly illuminate the task plane as well as room surfaces to avoid shadows or distracting patterns of light. Avoid large, backlighted translucent surfaces such as floors or walls that may be disorienting, especially for people with vision impairments.

2-1.4.5 Shadowing.

Minimize contrast with ambient and task lighting to fill in harsh shadows, especially for work surfaces where people are performing detail-oriented tasks. Shadows are beneficial when distinguishing between stair treads and risers.

2-1.4.6 Color Appearance.

Minimize contrast with ambient and task lighting to fill in harsh shadows, especially for work surfaces where people are performing detail-oriented tasks. Shadows are beneficial when distinguishing between stair treads and risers.

2-1.4.6.1 Color Temperature.

Provide light sources with a correlated color temperature (CCT) of no greater than 4100 K as stated on the manufacturer's luminaire information sheet for all interior spaces. Maintain one CCT in an area and maintain one CCT throughout the entire building where possible. The recommended CCT for most interior applications is 3500 K. For residential and hospitality applications, a CCT of 2700 K is recommended.

2-1.4.6.2 Tunable White Lighting.

Provide tunable white or dim-to-warm light sources in applications where the desired color temperature of light is variable. Residential, hospitality, and childcare applications are the most common recommended uses of adjustable color temperature. Use tunable white light if the quantity of light must remain constant. Use dim to warm light if warmer color temperatures are desirable only when there is also a reduction in light levels.

Tunable white lighting is not a substitute for spectral tuning and does not provide circadian rhythm-specific lighting conditions. For more information on circadian rhythm lighting, refer to APPENDIX D.

2-1.4.6.3 Color Rendering Index.

Use LED light sources with a color rendering index (CRI) of 80+ for all interior applications to accurately render the color of accent walls, architectural features, and artwork. In many high and low bay applications, a CRI of 70+ is acceptable unless a higher CRI is required for the task occurring in the space.

For applications where color identification is of high importance, such as copy/print rooms, command and control centers, kitchens, and areas with art installations, use light sources with a fidelity index greater than or equal to 80 ($R_f \geq 80$), and a gamut index between 97 and 110 ($97 \leq R_g \leq 110$), as defined in IES TM-30. If gamut and fidelity indices are not available, provide light sources with a CRI of 90+ with an R_9 value of at least 50 ($R_9 > 50$). Point(s) of Interest.

2-1.4.7 Modeling of Faces or Objects.

Include indirect lighting from multiple directions and angles for ambient lighting. Use multiple systems such as sconces, pendants, and wall washers to ensure the proper appearance of three-dimensional forms.

Focus visual attention and provide wayfinding with accent lighting. Create visual interest in special spaces as well as guidance through transitional areas with lighting highlights on wall displays and accenting signs.

2-1.4.8 Source/Task/Eye Geometry.

Locate luminaires in response to task areas to avoid shadows and direct and reflected glare.

2-1.4.9 Appearance of Space and Luminaires.

Use creative lighting design with aesthetic appearance of the space and of the luminaires for public building areas.

2-1.4.10 Surface Characteristics.

Review finish selection with Architect and Interior Designer. Coordinate selected surface characteristics with lighting calculations.

2-2 INTERIOR LIGHTING EQUIPMENT.

2-2.1 Light Source Technology.

Provide SSL/LED systems unless there is no equivalent SSL/LED product for the application. If another light source other than SSL/LED is specified, provide documentation regarding the selection of that light source in the project's Basis of Design. Refer to UFC 4-510-01 for specific medical applications that require alternatives to SSL/LED systems.

2-2.1.1 SSL/LED Drivers.

Provide lighting systems with accessible and replaceable drivers. Prioritize drivers that are integral to the luminaire. Use dimmable drivers compatible with standard dimming control circuit of 0-10V, DALI dimming, or DMX dimming. All dimming protocols must comply with cybersecurity requirements in paragraph 1-6.

2-2.1.2 Retrofit LED Lamps.

Provide linear LED lamps that are UL Type A. The datasheet must comply with ANSI C78.54. Use linear LED lamps with a beam angle of 270 degrees. When acceptable products with a 270-degree beam angle are not available, products with a beam angle of at least 180 degrees are allowable.

Retrofit LED light source replacements (screw base) are only permitted for the replacement of incandescent or compact fluorescent light sources. These must be NEMA SSL 7A[1] compliant and provided with a NEMA SSL 7A compliant dimmer to ensure that the electrical infrastructure is adequate to dim the lamps without flicker or dropouts in dimming range.

2-2.1.3 Incandescent and Tungsten-Halogen.

Do not use incandescent or tungsten halogen light sources, unless specifically required for medical applications where alternatives such as SSL/LED are unavailable.

2-2.2 Surge Protection Device.

Provide metal oxide varistor (MOV) surge protection devices at panel boards for all lighting panels or all circuits feeding interior lighting systems. For lighting circuits fed

[1] Department of Energy. *Dimming LEDs with Phase-Cut Dimmers: The Specifier's Process for Maximizing Success.* October 2013.

from load centers, surge protection devices are not required if surge protection is provided by the upstream panelboard.

2-3 LUMINAIRE BRACING AND SUPPORT.

Provide redundant supports to ensure that failure of a single supporting component does not result in luminaire falling. Mount overhead luminaires weighing more than 20 pounds (9 kilograms) with either rigid or flexible systems to reduce the likelihood that they will fall and injure building occupants or damage equipment. Ensure luminaires do not move horizontally in any direction more than 1 inch (25 mm) when subjected to force specified herein. Design equipment mountings to resist forces of 0.5 times the equipment weight in any horizontal direction and 1.5 times the equipment weight in the downward direction. This does not preclude the need to design equipment mountings for forces required by other criteria such as seismic design criteria of non-structural systems.

2-3.1 Luminaires Subject to Wind Loads.

In interior areas with a wind load, such as aircraft hangar bays or vehicle maintenance facilities with drive through maintenance bays, mount luminaires with stem hangers. If a single stem is used, provide a secondary means of support to ensure that failure of the stem does not result in luminaire falling.

2-4 INTERIOR LIGHTING CONTROLS.

Refer to CHAPTER 3 for control requirements specific to common applications and space types. Provide commissioning per ASHRAE 90.1 requirements, except for low-rise residential. Refer to ANSI/IES LP-6 for additional considerations for lighting control systems and ANSI/IES LP-8 for commission guidance for specific applications.

2-4.1 Control Strategies.

Provide a combination of control strategies per space as required in each Application page in CHAPTER 3. Indicate the control strategy for each space or subspace in the contract documents.

2-4.1.1 Manual Control.

Locate manual control devices at all room entries unless manual control devices are not required for the application. Locate manual control devices at the latch side of doors rather than the hinge side if space permits. Provide all required scenes at main entrances and exits, with secondary devices at secondary entrances and exits. Secondary devices are not required to provide full dimming and scene control, but they must provide at least one ON scene and one full OFF scene for the entire space. Provide additional manual control devices as required for specific applications as noted in CHAPTER 3.

Manual control devices consist of scene wallstations, wallbox switches, and wallbox dimmers. Provide clear labeling for scene wallstations, with buttons for each scene required for the application. If using wallbox dimmers instead of scene wallstations, provide wallbox dimmers for each luminaire type in the room, unless otherwise noted. Wallbox dimmers must allow for full range of dimming down to 10% minimum. Some applications, such as auditoriums and briefing rooms, may require dimming down to 1% or less.

2-4.1.2 Occupancy and Vacancy Sensing.

Provide occupancy and vacancy sensors to control lighting within a space or zone by detecting human activity. Occupancy mode is set for auto-on/auto-off, which is mostly utilized in large spaces, corridors, and spaces with no daylight. Vacancy mode is set for manual-on/auto-off, which is utilized in smaller spaces and spaces with daylight. This allows occupants to choose to turn lights on when entering the space, depending on surrounding light, daylighting, and individual activity.

Some applications allow for full or partial automatic on when occupancy is detected. This can be achieved either by turning all lights on to no more than 50% of full light output, or by turning on select luminaires, such as task-oriented luminaires, while leaving other luminaires off.

2-4.1.3 Ramped Dimming.

When automated dimming is required, program a gradual dimming rate so occupants of the space do not perceive a sudden change in light levels. This is especially important in maintenance spaces such as aircraft hangar bays and maintenance shops where personnel may be working in close proximity to energized equipment or running motors.

2-4.1.4 Time Schedules.

Time schedules built into centralized and distributed systems to allow for scheduled OFF and ON scenes, based on time of day. Provide time scheduled shutoffs for spaces that do not allow or require full OFF with vacancy sensors. In some networked lighting control systems, time schedules can be used to change response profiles for occupancy/vacancy controls. These profiles may include changes in time-delay, occupancy or vacancy mode, or associated control zones as defined in paragraph 2-3.3.6.

2-4.1.5 Daylighting Control.

Provide automatic control of the ambient electric lighting in response to daylight as defined in ASHRAE 90.1 for all spaces with access to daylight unless otherwise noted for the specific application. For spaces that receive daylight from windows, curtain walls, or any other sidelight area, the primary and secondary sidelighted areas must be controlled independently of each other. For spaces that receive daylight from skylights or roof monitors, the lighting control system must control the ambient electric lighting in response to daylight. For spaces that receive daylight from toplighting and sidelighting, the ambient lighting in overlapping zones must be controlled together. Consider daylighting modeling and analysis for determining daylighting control zones in complex spaces.

Provide automatic response to daylight with the following functionality:

- Ambient electric lighting with continuous dimming capable of dimming to 10% of full output or lower.
- Program a ramp dimming so occupants of the space do not perceive a sudden change in light levels.
- Photocontrol sensors. Layout, quantity, and programming of photocontrol sensors vary by manufacturer and strategy.
- Refer to APPENDIX B for additional daylighting control information.

2-4.1.5.1 Automated Shading.

When automated shading is provided to control glare and unwanted heat gain from daylighting, coordinate daylighting controls with automated shading controls. Refer to APPENDIX B Daylighting Controls Best Practices for additional information.

2-4.1.6 Zoning.

Areas of control are divided into separate zones for larger spaces, typically above 250 square feet (23 square meters). The specific zoning requirements will vary depending on the application. Provide separate, independent control for each zone. When required for the application, provide separate control for each luminaire type, within each area. Unless otherwise noted, follow control zone square footage requirements as outlined in ASHRAE 90.1.

Zoning may differ depending on control strategy, even within the same area. Establish occupancy and vacancy control zones based on tasks performed in each area. Establish daylighting control zones based on proximity and access to daylight, according to Daylighting Control Best Practices discussed in APPENDIX B.

2-4.1.6.1 Associated Control Zones.

In large spaces containing multiple zones, provide associated control zones where required for the application. Associated control zones connect adjacent zones that are visible and less than 600 square feet (56 square meter), such that activity in an occupied zone will trigger nearby unoccupied zones to provide a reduced level of light by turning on adjacent zones for comfort and security. Utilize associated control zones in regularly occupied spaces during hours of darkness to illuminate egress paths and adjacent unoccupied zones to a reduced level.

2-4.2 Controls for Means of Egress.

Comply with NFPA 101 for the lighting and controls in Means of Egress. Provide UL924 compliant lighting controls that interface with the fire alarm system where required by NFPA 101.

2-4.3 Controls for Electrical Workspaces.

Comply with NFPA 70 when controlling luminaires in working spaces around electrical equipment. Do not use occupancy sensors, vacancy sensors, or timers to control luminaires that provide illumination of the working space around electrical equipment such as service equipment, switchboards, switchgear, panelboards, or motor control centers. To reduce energy consumption, luminaires in the adjacent space that do not provide illumination of the working space may be dimmable a maximum of 50% of full light output and cannot be stepped dimmed. For this application, the luminaires may be controlled by an integrated or separate occupancy or vacancy sensor.

2-4.4 Wireless Networks.

The use of wireless networks must be pre-approved by the System Owner (SO) and the Authorizing Official (AO) as part of the Control System Impact Rating determination defined in UFC 4-010-06.

Coordinate wireless networks with base spectrum manager prior to specification in case of restrictions for wireless usage within the installation.

2-5 DAYLIGHTING.

Refer to UFC 1-200-02 and UFC 3-101-01 for Daylighting requirements. Coordinate architectural daylight design and lighting contribution into electrical lighting and controls design.

Refer to APPENDIX B for daylighting controls best practices.

2-6 ELECTRICAL ENERGY MONITORING.

For construction and renovation of buildings greater than 25,000 SF (2,322 m^2), terminate lighting branch circuits in dedicated lighting panelboards.

2-7 ELEVATORS.

Provide lighting in accordance with UFC 3-490-06.

2-8 ILLUMINATION FOR MEANS OF EGRESS.

Provide in accordance with NFPA 101.

2-8.1 Emergency Lighting.

Emergency lighting units must be LED. For renovation and retrofit projects, replacement of emergency lighting units with LED units is highly encourage but not required.

Install emergency lighting equipment in conspicuous and accessible locations to facilitate the periodic testing requirements.

2-8.2 Exit Signs.

Internally illuminated signs must be LED type and comply with UFC 3-600-01.

2-9 LIGHTING SYSTEM ALTERATIONS.

Alterations occur when luminaires are added, replaced, removed, when more than 10% have been relocated, or when ballasts or lamps are replaced with anything other than the original ballast or lamp. This does not include routine maintenance. Provide alterations to the lighting system to achieve the following benefits:

- Reduce energy through technology selection, providing appropriate illuminance levels and implementing control strategies. Energy savings in commercial applications of 47% on average is achieved by a combination of LED adoption and Networked Lighting Controls implementation.[2]

- Reduce maintenance through decreasing equipment quantities (luminaires), replacing obsolete light source technology with SSL/LED light sources, and implementing control strategies.

- Improve lighting quality through improved photometric distribution and glare reduction. Refer to IES LP-9 Upgrading Lighting Systems in Commercial and Institutional Spaces for additional information.

2-9.1 Lighting System Alteration Requirements.

Comply with the lighting power density (LPD) and control requirements of ASHRAE 90.1 as well as the control requirements in this UFC. Provide computer-generated photometric plans based on ANSI/IES LM-79 data for each space to verify proposed lighting alteration meets the required performance criteria using the applicable light loss factor (LLF). See 3-2 for more information on lighting calculations.

[2] DesignLights Consortium. *Energy Savings Potential of DLC Commercial Lighting and Networked Lighting Controls*. July 2018.

2-9.2 Types of Lighting System Alterations.

Lighting system alterations include redesign, luminaire replacement, luminaire conversion kits to light source retrofits. Redesign will maximize the long-term energy and sustainment savings while improving the lighting quality in existing spaces.

Only provide alternatives to redesign when a full redesign is either not necessary or not feasible.

2-9.2.1 Redesign.

Redesign includes new luminaires, luminaire layout, electrical circuits, and controls designed to meet current lighting criteria. Redesign lighting systems when the existing:

- Illuminance levels are not within 20% below or 50% above the illuminance levels listed in the specific application's performance requirements
- Lighting does not illuminate perimeter surfaces in regularly occupied spaces or shelving in warehouses and storage
- Lighting does not produce uniform illumination
- Luminaire spacing is too wide, or partition height obstructs light distribution
- Luminaires (or luminaire layout) are for when the tasks or physical layout of the space has changed or partition height obstructs light distribution
- Luminaires are in poor condition
- Lighting controls are inadequate

2-9.2.2 Luminaire Replacement.

Luminaire replacement is when existing luminaires are replaced with new luminaires. Luminaire replacement is acceptable when:

- Illuminance levels are within 20% below or 50% above the illuminance levels listed in the specific application's performance requirements
- Lighting produces excessive glare
- Lighting illuminates perimeter surfaces in regularly occupied spaces or shelving in warehouses and storage
- Lighting layout produces uniform illumination
- Luminaires (or luminaire layout) are appropriate for the tasks or physical layout of the space

2-9.2.3 Luminaire Conversion Kit.

Luminaire conversion kits replace reflectors, lampholders, ballast and light source within the housing of an existing luminaire. Conversion kits must meet UL 1598C and the resulting system must produce light levels and uniformity equivalent to the existing system or meet the lighting levels and uniformity required in the current criteria, whichever is lower. Luminaire conversion kits are only acceptable when:

- Illuminance levels are within 20% below or 50% above the illuminance levels listed in the specific application's performance requirements
- Lighting illuminates perimeter surfaces in regularly occupied spaces or shelving in warehouses and storage
- Lighting layout produces uniform illumination
- Luminaires (or layout) are appropriate for the tasks or physical layout of the space

Direct replacement of an incandescent, fluorescent, induction, or HID lamp to LED lamp, without any electrical or mechanical changes, is not considered a luminaire conversion. Linear LED lamp or tubular LED (TLED) are not allowed in luminaire conversion kits.

2-9.2.4 Lighting Source Retrofit.

Light source retrofit, sometimes referred to as a direct lamp replacement, is a system designed in the same form factor as the existing light source. An example is a linear LED lamp, or TLED, which is a direct replacement for a linear fluorescent lamp. Light source retrofit is only acceptable when no modifications to the existing luminaire are required (direct replacement) and when:

- Existing luminaires and lamp holders are in good condition
- Existing luminaires do not produce excessive glare
- Existing luminance levels are within 20% below or 50% above the illuminance levels listed in the specific application's performance requirements
- Existing lighting illuminates perimeter surfaces in regularly occupied spaces or shelving in warehouses and storage
- Existing lighting layout produces uniform illumination
- Existing luminaires (or layout) are appropriate for the tasks or physical layout of the space

- Existing lighting control systems function as intended without flicker and in full dimming range

2-9.2.5 Lighting Source Retrofit Requirements.

Do not use LED retrofit light sources or LED lighting modules that have been designed and constructed to be installed in existing HID or mercury vapor luminaire enclosures. LED retrofits are approved for replacement of CFL or incandescent sources (A-Type lamp replacements with Edison bases). Inserting a LED retrofit in an existing luminaire may void the luminaire’s warranty.

Linear LED lamp retrofits are allowed with the following criteria:

- UL 1993 Type A Certification.
- Type A is designed to operate with the existing fluorescent ballast and does not require mechanical or electrical changes to the luminaire. Dual Mode Lamps (UL Type A/Type B) designed to operate off the existing fluorescent ballast and line voltage are not acceptable.
- Compatible with existing ballast type. Do not bypass or remove the ballast of the existing luminaire. If the linear LED lamps are not compatible with the existing ballast, the existing ballast may be replaced with a compatible fluorescent lamp ballast suitable for ASHRAE 90.1 compliant lighting controls.
- Resulting glare from the luminaire is not increased
- Has been manufactured within one year of installation
- Dimmable without flicker fade outs
- Frosted or diffuse optic with a minimum beam angle of 270 degrees.
- Resulting system must produce light levels equivalent to the existing system or meet the lighting levels and uniformity required in the current criteria, whichever is lower.
- Inserting a linear LED lamp in an existing luminaire may void the luminaire’s warranty.

This Page Intentionally Left Blank

CHAPTER 3 INTERIOR LIGHTING APPLICATIONS

3-1 INTRODUCTION.

This chapter identifies typical interior facility applications. Each application details a conceptual lighting design example. The requirements for each application are for general ambient lighting. Coordinate accent and specialty lighting with architect and interior designer. Designs must meet the lighting performance and controls requirements defined in the application details, but layout, luminaire selection, and time schedules may vary.

Verify special lighting equipment requirements in hazardous (classified) locations.

3-2 LIGHTING CALCULATIONS.

Provide computer-generated photometric plans for each space to verify proposed lighting design meets the required performance criteria using the applicable light loss factor (LLF). Luminaire photometric files used in calculations must be derived from ANSI/IES LM-79 test results. Typical LLF is 0.81 for an office with luminaires that are L80 at 60,000 hours, and a 25-year life cycle. LLF varies based on environment, application, LED lumen depreciation, and building life cycle. It is understood that designers can use their discretion and experience to determine exactly where to draw calculation grids to provide informative calculations that meet the intent of the recommendations.

Target illumination levels are provided for each Interior Application. Depending on the application and the recommendations provided by the IES, values are given as one of the following:

- Minimum: No values anywhere on the calculation grid may be less than this value, within a 10% margin of error.

- Average: An average, taken over the entire general area for the application, may not be less than this value, within a 10% margin of error.

- Maximum: No values anywhere on the calculation grid may be greater than this value, within a 10% margin of error.

- Uniformity: Unless otherwise noted, uniformity is calculated as a ratio of the average calculated illuminance over the minimum calculated illuminance of the calculation grid.

3-2.1 Schematic Design and Concept Design.

For schematic and concept design phases prior to 60%, provide narrative indicating the following:

- Target average maintained illuminance level.

- Target lighting power density (watts per square foot or per square meter).

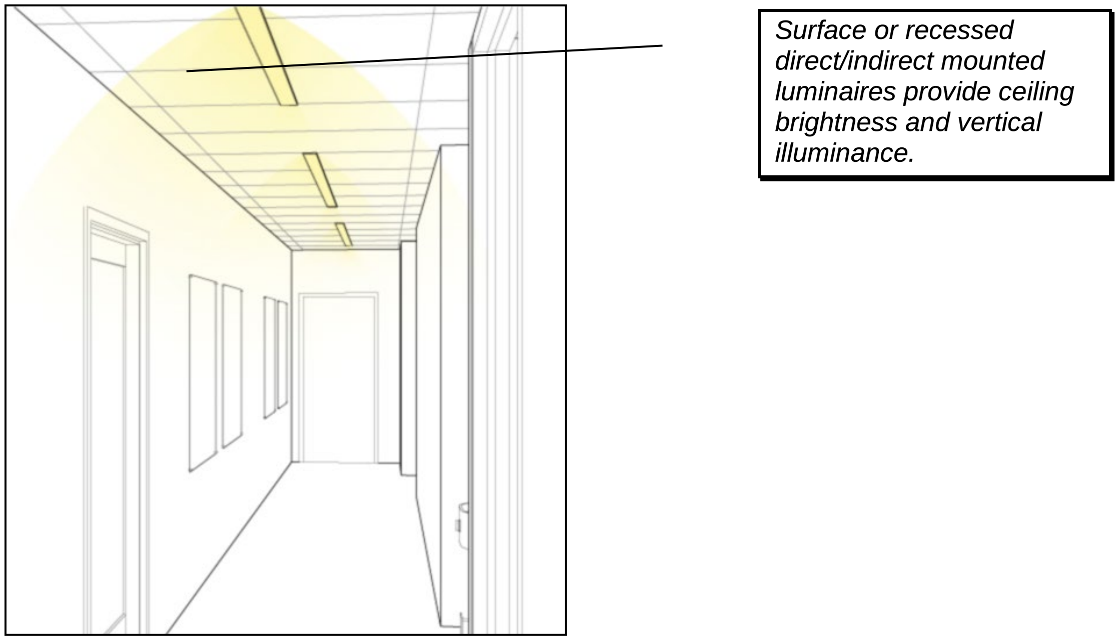
3-2.2 Designs at 60% or later.

For designs submitted at 60% or later, provide photometric plan calculations to include the following:

- The point by point spacing of the calculation grid of horizontal illuminance measurements at the workplane or other designated height above finished floor. The point spacing must be 1/3 of the luminaire mounting height, taken across the general area.
- Where applicable, vertical illuminance measurements at designated surface, taken at a maximum of every one foot (305 mm) across task area.
- Minimum and maximum maintained illuminance levels.
- Average maintained illuminance level.
- Average to minimum and maximum to minimum ratios for horizontal illuminance.
- Lighting power density (watts per square foot or per square meter).
- Where applicable, model the furniture, partitions in the lighting calculations with the proper reflectances, to accurately calculate the light levels of the space.
- Calculate the egress illuminance levels per NFPA 101 requirements.

3-3 GENERAL BUILDING SPACES.

3-3.1 Corridors.



3-3.1.1 Control Requirements.

Manual Control	None required if remote local control device is installed per ASHRAE 90.1
Occupancy/Vacancy	Automatic ON to 100% unless daylight is present Automatic full OFF after 20 minutes vacancy OR Automatic dimming to a maximum of 50% of full output after 20 minutes vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Per ASHRAE 90.1 requirements

3-3.1.2 Performance Requirements.

Target Criteria	Daytime/Nighttime
Average Horizontal Illuminance	5 fc (50 lux) at floor
Horizontal Illuminance Uniformity	3:1 average to minimum

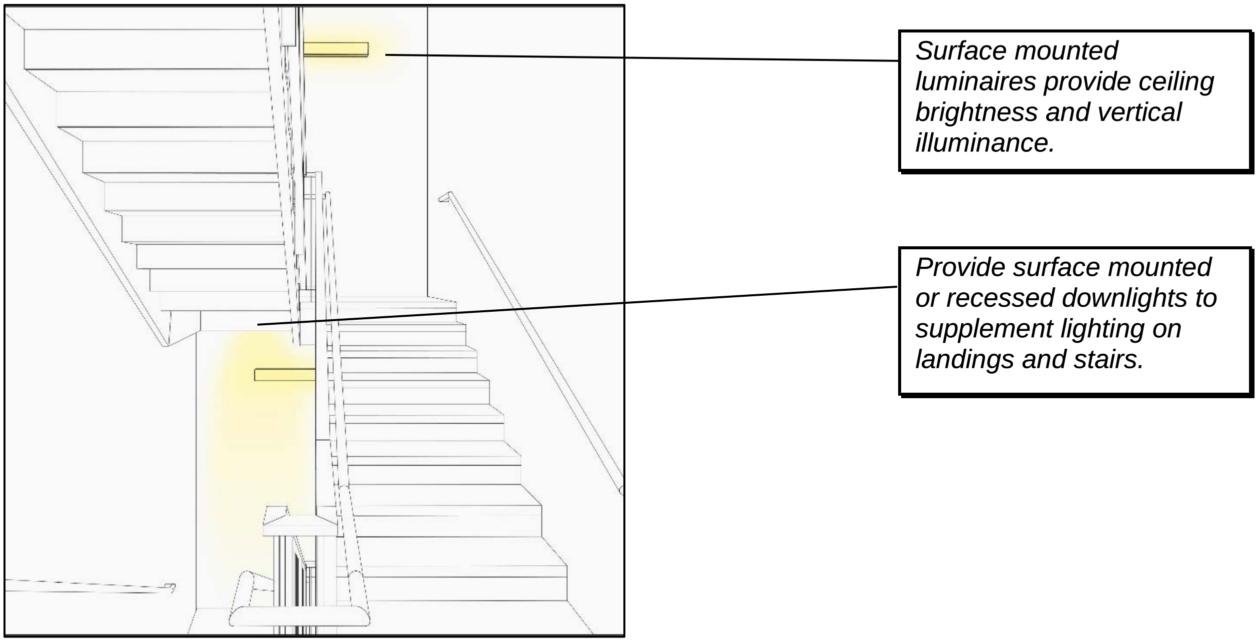
3-3.1.3 Critical Design Issues.

- Means of egress must comply with NFPA 101 control requirements and minimum light level requirements. When the corridor is means of egress, automatic off is allowable when control requirements are met. If area adjacent to corridor is lighted to illuminances greater than 50 fc, then immediate adjacent corridors may be lighted to a 1:10 ratio to minimize visual transition from brightly lighted area to darker corridor.

- When a corridor is adjacent to the open and visually accessible work or task areas, the illuminances of the passageway proper should be no less than 20% of the nearby task illuminances (ANSI/IES RP-1).

- Illuminate feature artwork and/or feature wall finishes.

3-3.2 Stairways.



3-3.2.1 Control Requirements.

Manual Control	None required if remote local control device is installed per ASHRAE 90.1
Occupancy/Vacancy	Automatic ON to 100% unless daylight is present Automatic dimming to a maximum of 50% after 20 minutes vacancy
Time Schedule	None required.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	None

3-3.2.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Minimum Illuminance	10 fc (100 lux) at walking surface (includes stair treads)
Horizontal Illuminance Uniformity	2:1 average to minimum

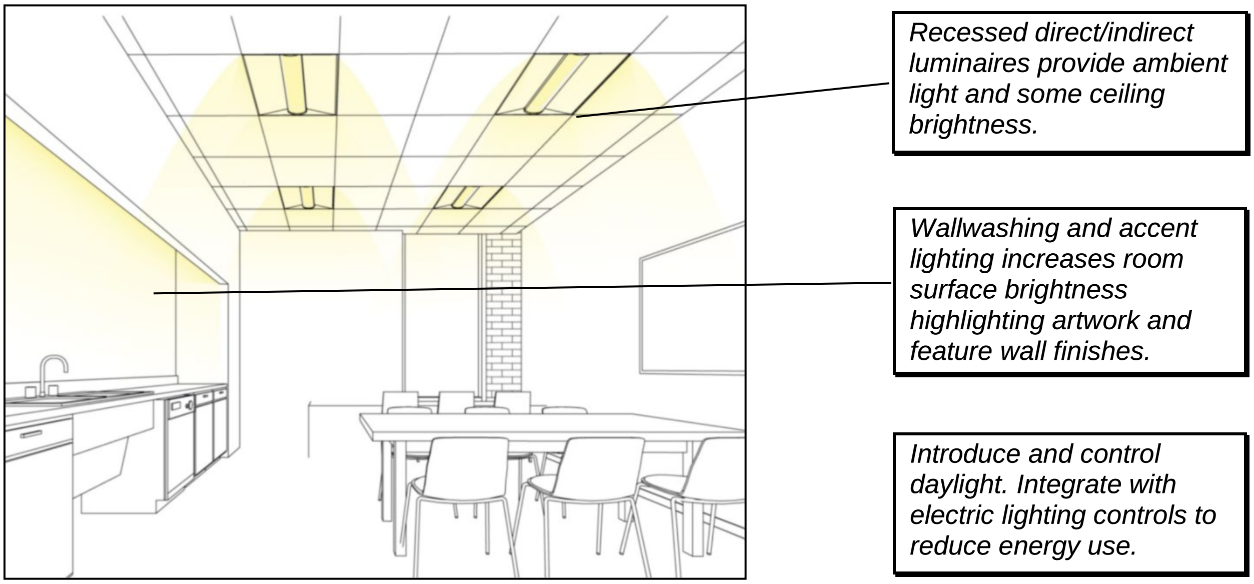
3-3.2.3 Critical Design Issues.

- Horizontal illuminance is calculated on stair treads and landings.

- Do not locate luminaires on the ceiling above the treads. Locate luminaires where they are easily accessible for maintenance.

- Means of egress must comply with NFPA 101 control requirements and minimum light level requirements. When the corridor is means of egress, automatic off is allowable when the NFPA 101 control requirements are met.

3-3.3 Lounge Areas/Breakroom.



3-3.3.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power OR One wallbox dimmer per luminaire control zone
Occupancy/Vacancy	Manual ON Automatic full OFF after 20 minutes of vacancy OR Automatic ON to a maximum of 50% of full lighting power Automatic full OFF after 20 minutes of vacancy
Time Schedule	None required
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for task lighting and ambient lighting

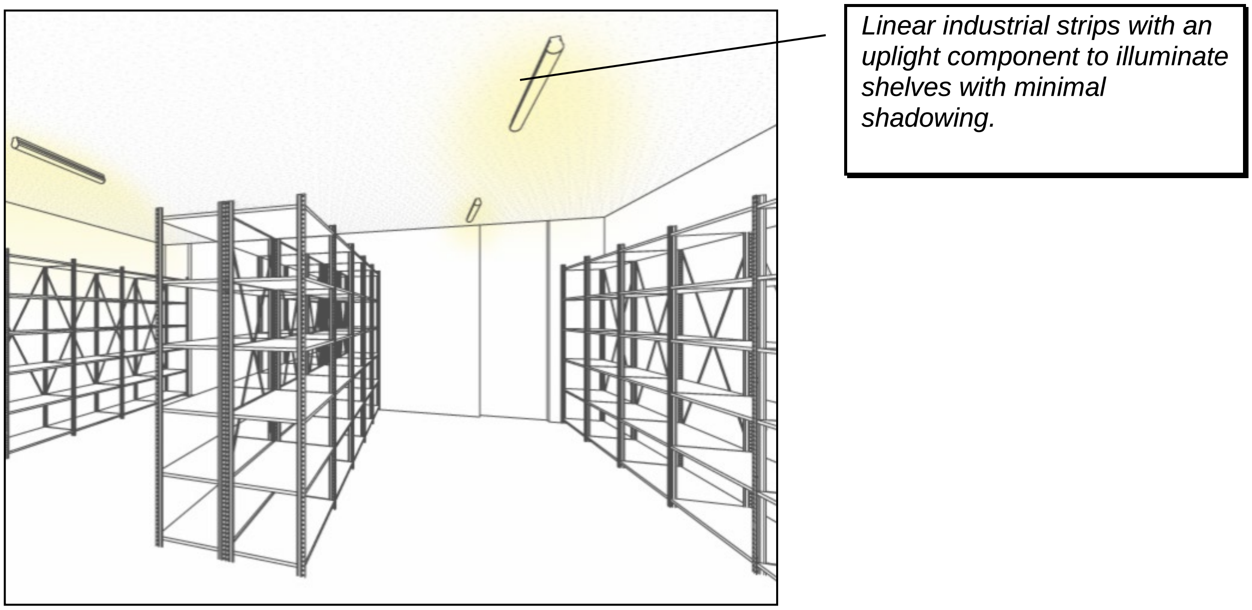
3-3.3.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance, Dining area, social	10 fc (100 lux) at 2’-6” (762 mm) AFF
Average Horizontal Illuminance, Leisure reading	20 fc (200 lux) at 2’-6” (762 mm) AFF
Average Horizontal Illuminance, Food prep, clean up, work areas	30 fc (300 lux) at 2’-6” (762 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-3.3.3 Critical Design Issues.

- Illuminate feature artwork and/or feature wall finishes.
- Illuminate sink areas and/or food prep areas.

3-3.4 Storage Rooms.



3-3.4.1 Control Requirements.

For storage rooms under 50 square feet:

Manual Control	A minimum of one wallbox switch
Occupancy/Vacancy	Automatic full ON Automatic full OFF after 20 minutes of vacancy
Time Schedule	None required
Daylight	No daylight sensing required
Zoning	None

For storage rooms greater than 50 square feet:

Manual Control	At least one wallbox switch or dimmer
Occupancy/Vacancy	Manual ON Automatic full OFF after 20 minutes of vacancy OR Automatic ON to 50% of general lighting power Automatic full OFF after 10 minutes of vacancy
Time Schedule	None required
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	None

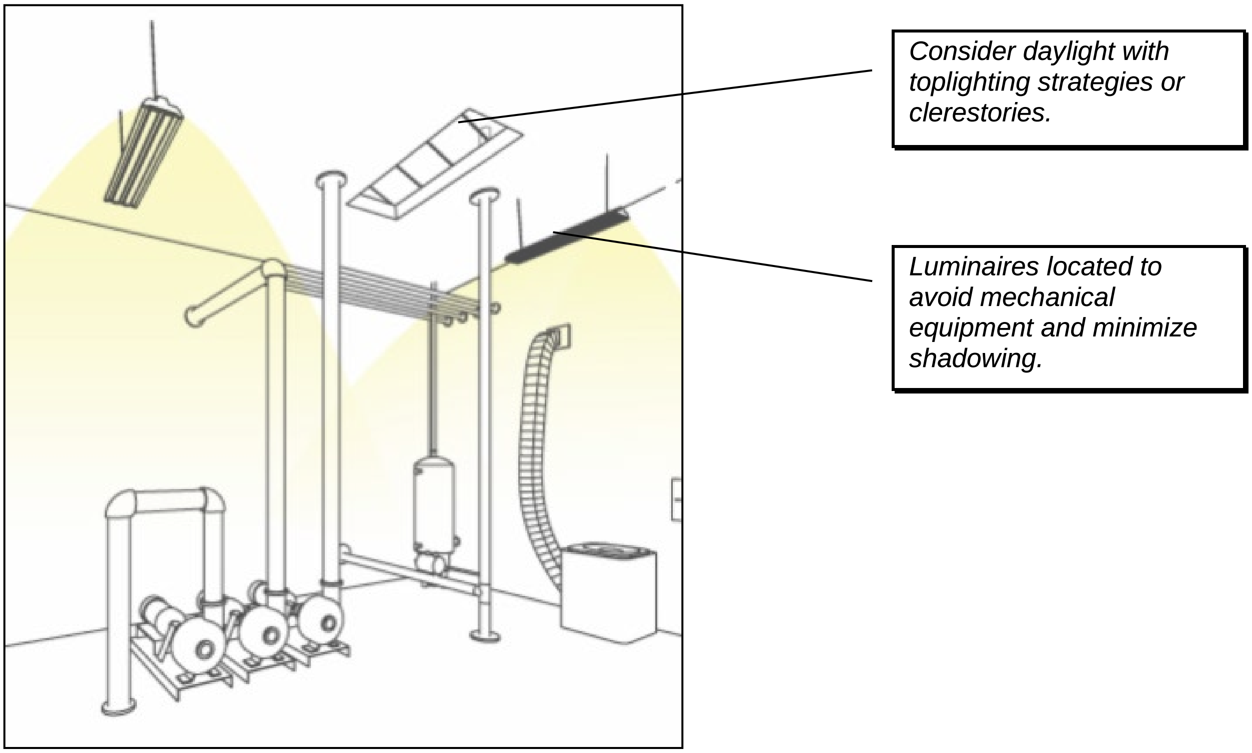
3-3.4.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	10 fc (100 lux) at floor
Average Vertical Illuminance	7.5 fc (75 lux) at 4’-0” (1219 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-3.4.3 Critical Design Issues.

- Lighting controls, including occupancy and vacancy sensors, should account for the shelving and layout of the room.

3-3.5 Mechanical Rooms.



3-3.5.1 Control Requirements.

Manual Control	A minimum of one wallbox switch at each room entrance
Occupancy/Vacancy	None required
Time Schedule	None required
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	None required

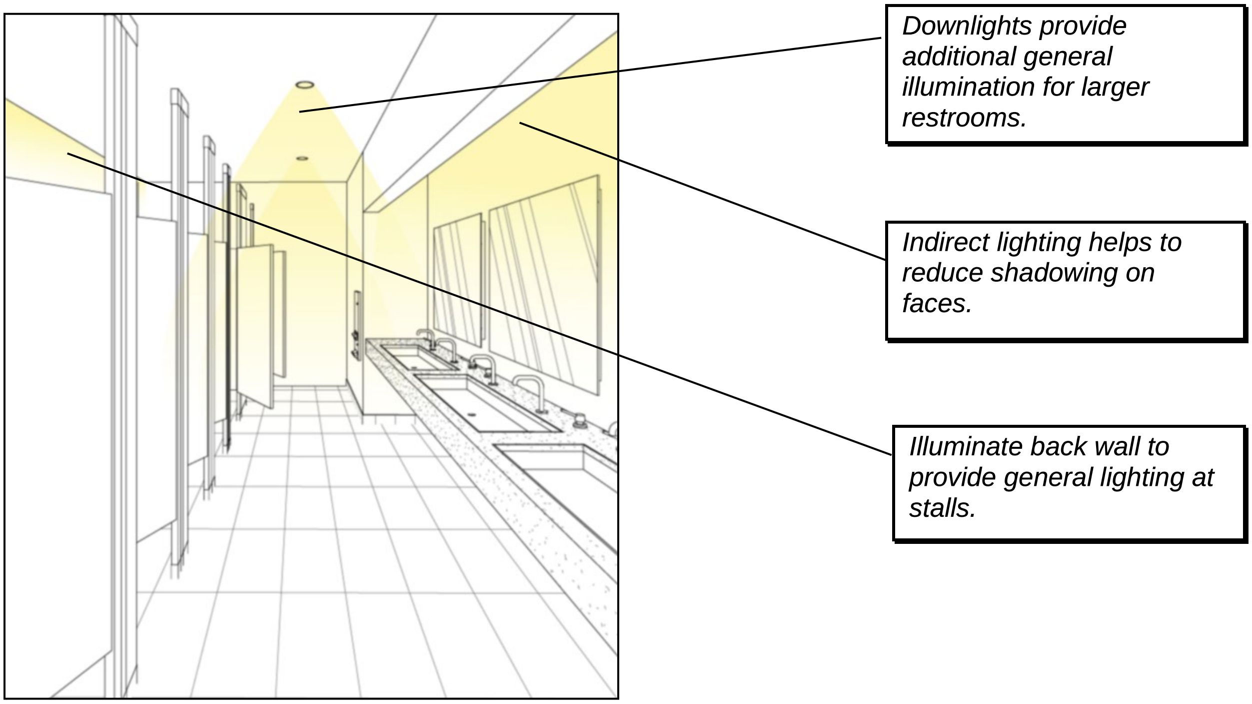
3-3.5.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	20 fc (200 lux) at 3’-6” (1067 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-3.5.3 Critical Design Issues.

- Coordinate luminaire locations with equipment.
- Calculation points within the equipment footprint may be removed.

3-3.6 Restrooms.



3-3.6.1 Control Requirements.

Manual Control	For single-occupancy restrooms only: one wallbox switch
Occupancy/Vacancy	Automatic ON with automatic full OFF after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	None required

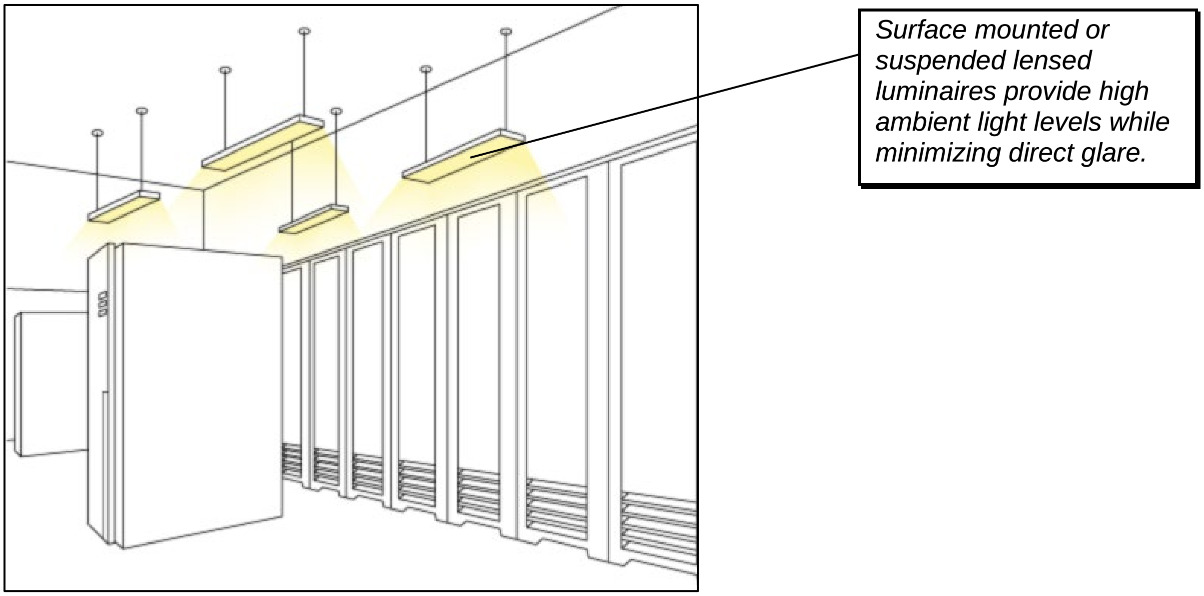
3-3.6.2 Performance Requirements.

Target Criteria	Daytime/Nighttime
Average Horizontal Illuminance, General	5 fc (50 lux) at floor
Average Horizontal Illuminance, Fixtures and vanities	15 fc (150 lux) at vanity surface
Average Horizontal Illuminance, Showers	10 fc (100 lux) at floor
Horizontal Illuminance Uniformity	3:1 average to minimum

3-3.6.3 Critical Design Issues.

- Utilize ultrasonic or dual-tech occupancy sensors.
- Locate occupancy sensors so that activity at restroom entrance and within stalls will trigger sensors.
- No local control required for multi-occupant restrooms.

3-3.7 Telecommunication/Equipment Rooms.



3-3.7.1 Control Requirements.

Manual Control	One wallbox switch
Occupancy/Vacancy	None
Time Schedule	None
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	None

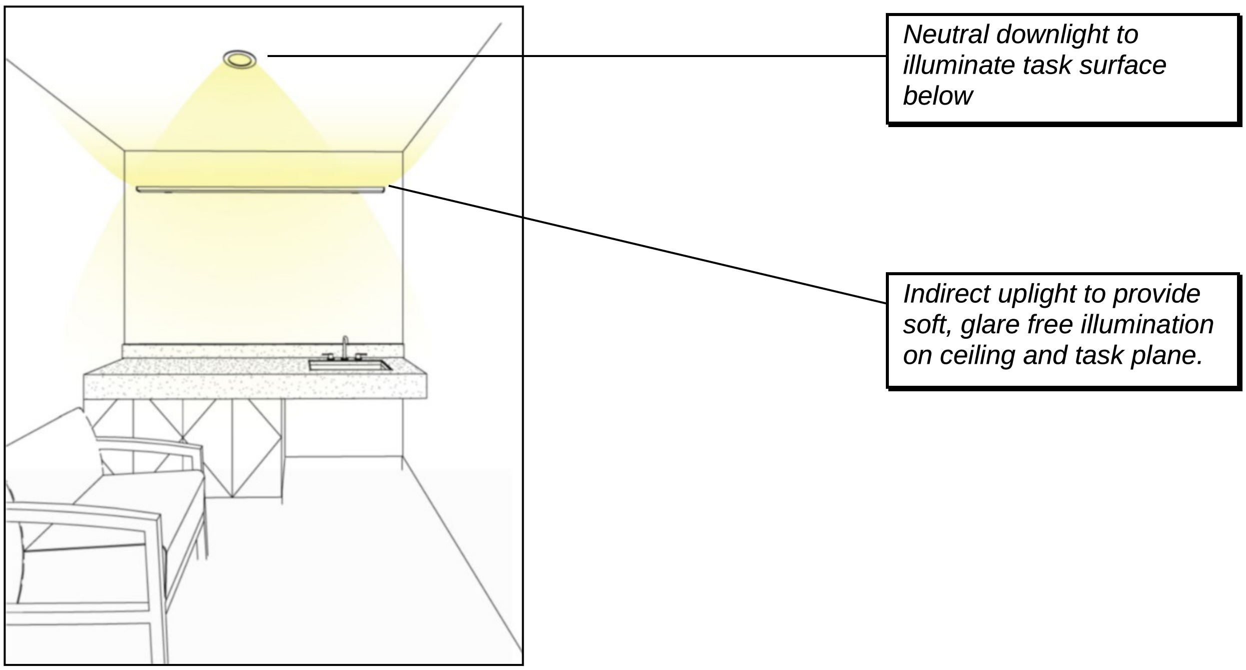
3-3.7.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Minimum Horizontal Illuminance	50 fc (500 lux) at 3’-0” (914 mm) AFF
Minimum Vertical Illuminance	30 fc (300 lux) at 3’-0” (914 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-3.7.3 Critical Design Issues.

- Coordinate luminaire locations with ceiling obstructions and cable trays. Do not mount luminaires directly above cable trays.

3-3.8 Nursing and Lactation Rooms.



3-3.8.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 50% of full lighting power OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON with automatic full OFF after 20 minutes of vacancy
Time Schedule	None
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for downlight and ambient uplight

3-3.8.2 Performance Requirements.

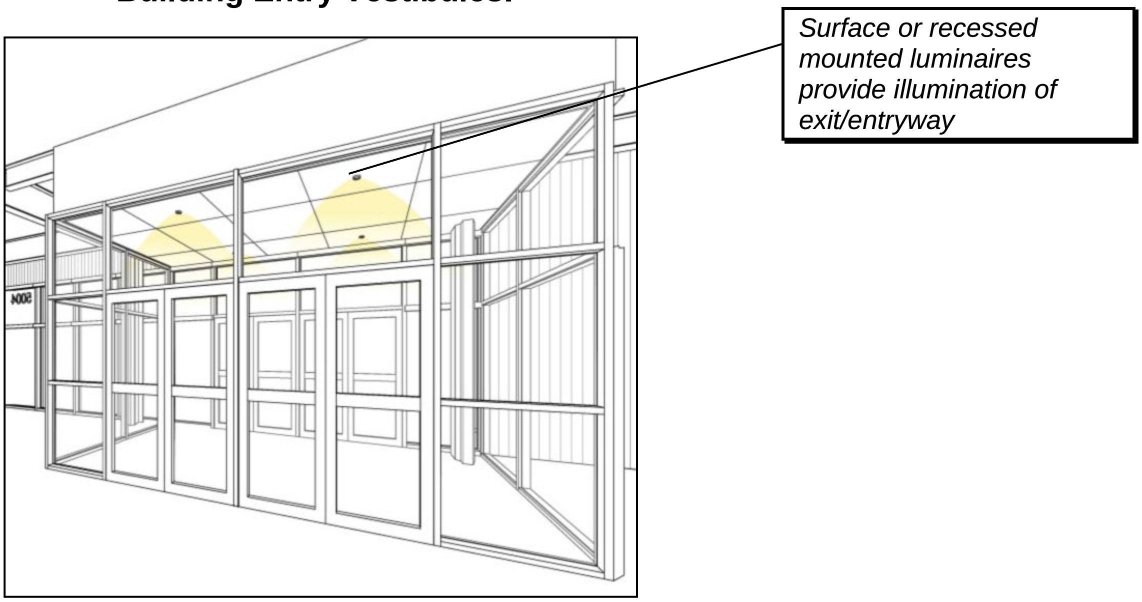
Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	20 fc (300 lux) at 2'-6" (762 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-3.8.3 Critical Design Issues.

- Minimize glare with solutions such as a diffuse lens, regressed lens, indirect optics, and/or shielded louvers.

- Light room surfaces to balance luminance ratios.

3-3.9 Building Entry Vestibules.



3-3.9.1 Control Requirements.

Manual Control	None required if remote local control device is installed per ASHRAE 90.1
Occupancy/Vacancy	Automatic ON to 100% unless daylight is present Automatic full OFF after 20 minutes vacancy OR Automatic lighting reduction by at least 50% after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when corridor is scheduled to be vacant, only if occupancy sensing does not utilize full OFF noted above
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Per ASHRAE 90.1 requirements

3-3.9.2 Performance Requirements.

Target Criteria	**Daytime**	**Nighttime**
Average Horizontal Illuminance, Main building entrance	15 fc (150 lux) at floor	4 fc (40 lux) at floor
Average Horizontal Illuminance, Secondary building entrance	10 fc (100 lux) at floor	5 fc (50 lux) at floor
Average Horizontal Illuminance, Interior vestibule	4 fc (40 lux) at floor	N/A
Horizontal Illuminance Uniformity	4:1 average to minimum	

3-3.9.3 Critical Design Issues.

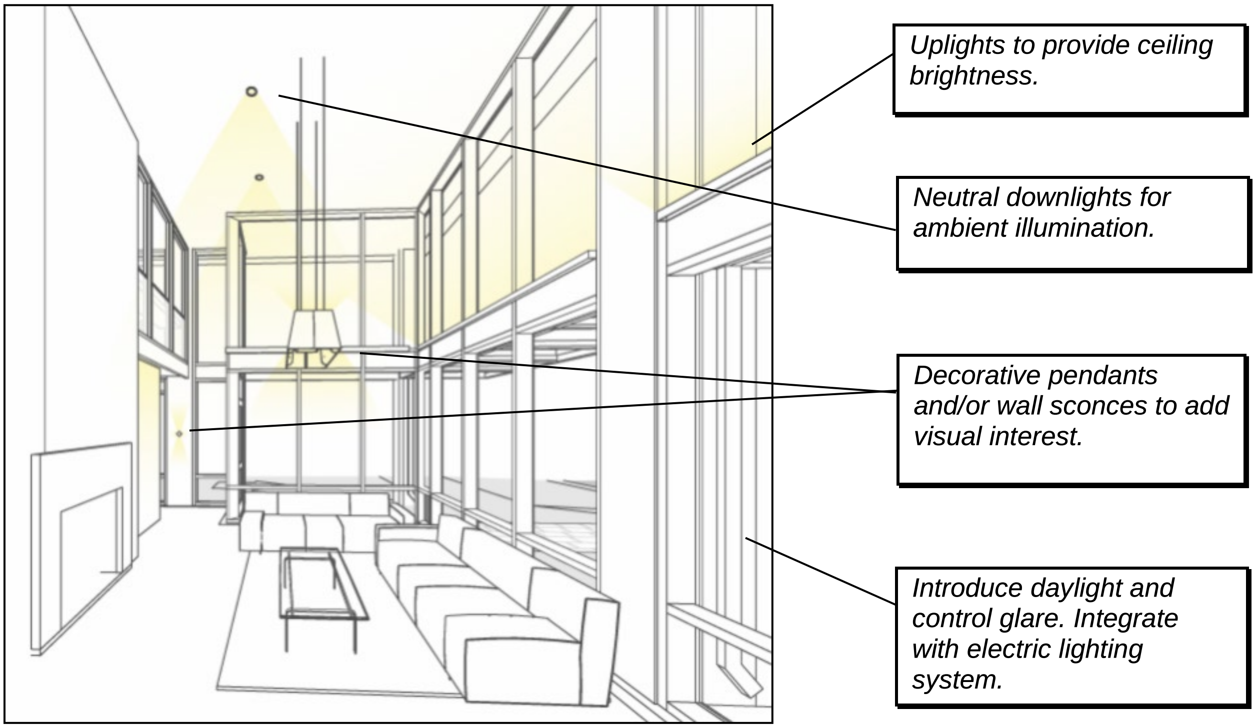
- Means of egress must comply with NFPA 101 control requirements and minimum light level requirements. When the vestibule is means of egress, automatic off is allowable when control requirements are met.

- Illuminate feature artwork and/or feature wall finishes.

- For buildings unoccupied at night, nighttime light level adjustments are not required.

3-4 ADMINISTRATIVE SPACES.

3-4.1 Large Lobbies.



3-4.1.1 Control Requirements.

Manual Control	Scene wallstation OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Automatic ON to 100% of daytime illuminance criteria unless daylight is present. During the night, automatic ON to 100% of nighttime illuminance criteria. Automatic dimming to a maximum of 50% after 20 minutes vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for each luminaire type

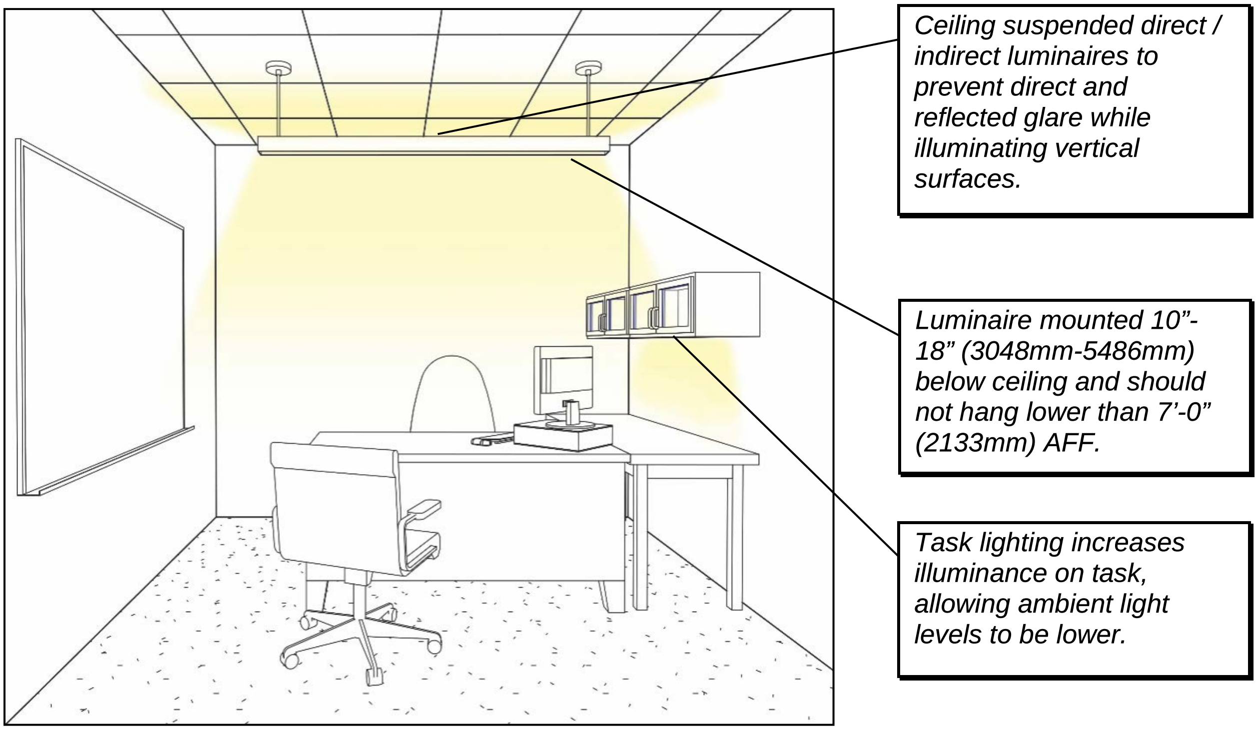
3-4.1.2 Performance Requirements.

Target Criteria	Daytime	Nighttime
Average Horizontal Illuminance, Social, waiting	10 fc (100 lux) at floor	5 fc (50 lux) at floor
Average Horizontal Illuminance, Reception desk	15 fc (150 lux) at 3'-6" (1067 mm) AFF	
Average Horizontal Illuminance, Security screening	20 fc (200 lux) at 3'-0" (910 mm) AFF	
Horizontal Illuminance Uniformity	3:1 average to minimum	

3-4.1.3 Critical Design Issues.

- Avoid visual clutter by selecting luminaires that are aesthetically pleasing.
- Eliminate harsh shadows by lighting surfaces within the space.
- Provide wayfinding guidance such as path to reception desk and elevators.
- Light room surfaces to balance luminance ratios.
- Illuminate feature walls.
- Means of egress must comply with NFPA 101 control requirements and minimum light level requirements. When the lobby is means of egress, automatic off is allowable when control requirements are met.
- Lighting controls must be within the lobby or easily accessible in order for building personnel to manually override controls.
- For elevator lobbies, the light levels should be approximately 1.5 times greater than the average horizontal illuminance of the adjacent corridor or equal to the average horizontal illuminance of the adjacent corridor with added vertical surface brightness (ANSI/IES RP-1).

3-4.2 Individual Offices.



3-4.2.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power OR One wallbox dimmer per luminaire type Task lighting may be toggle switch on luminaire
Occupancy/Vacancy	Manual ON with automatic full OFF after 20 minutes of vacancy Task lighting may be automatic ON
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for ambient lighting and task lighting

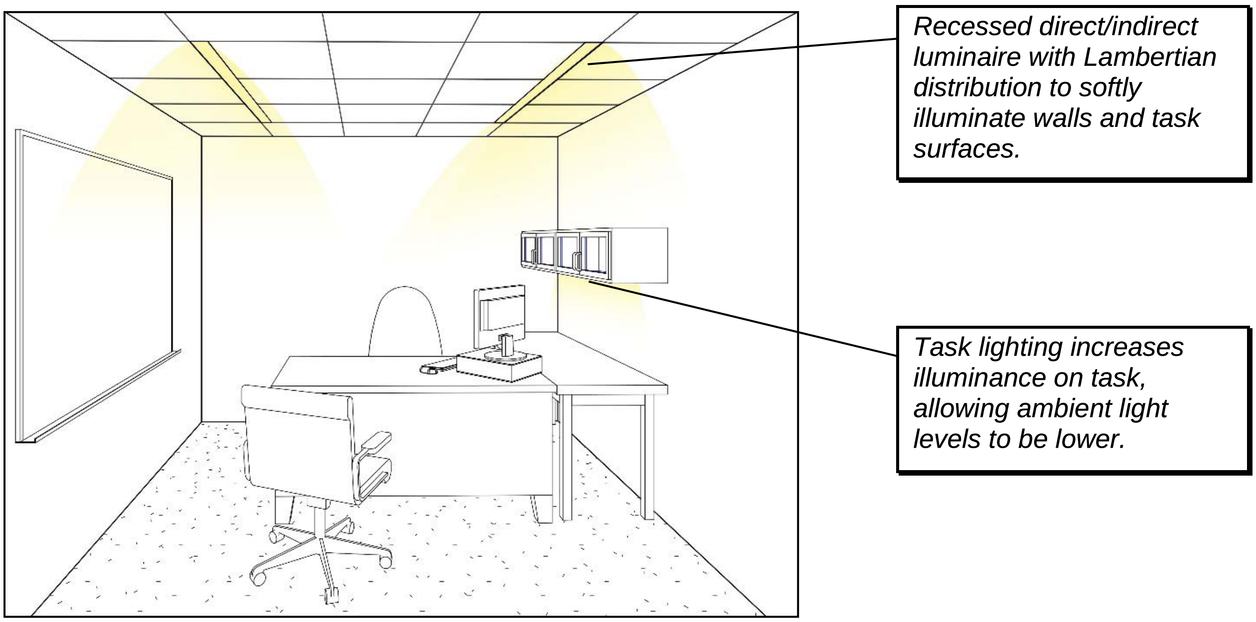
3-4.2.2 Performance Requirements.

Target Criteria	Daytime/Nighttime
Average Horizontal Illuminance	30 fc (300 lux) at 2’-6” (762 mm) AFF
Horizontal Illuminance Uniformity	2:1 average to minimum

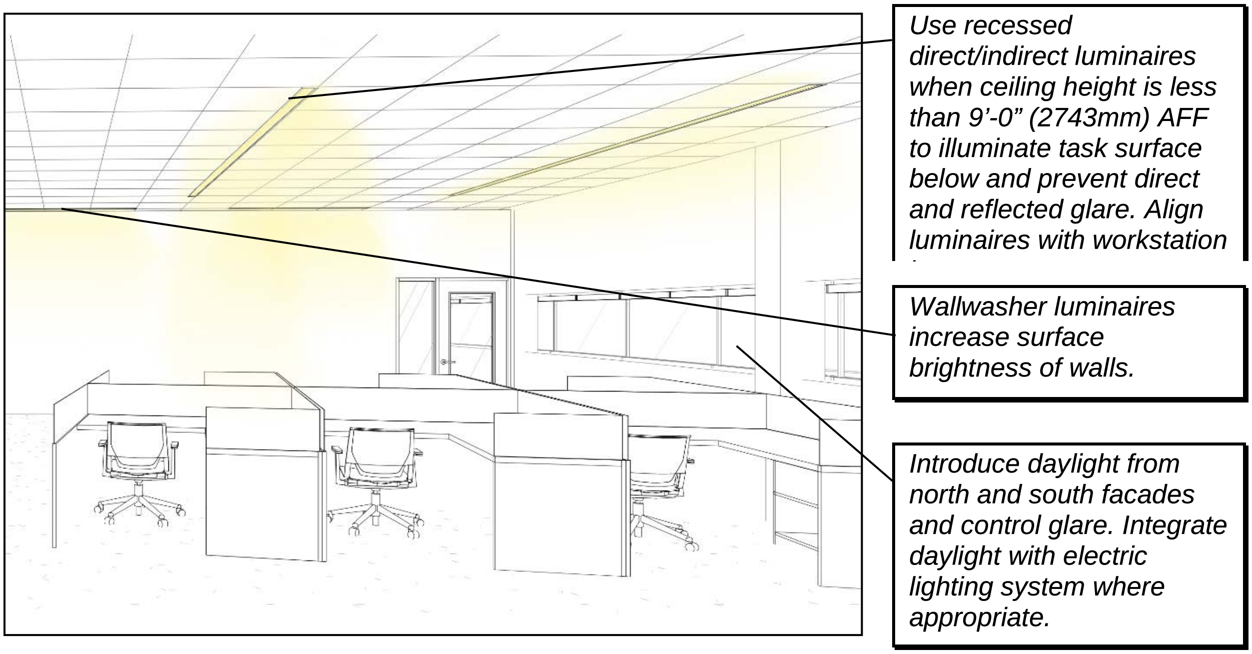
3-4.2.3 Critical Design Issues.

- Minimize glare with solutions such as a diffuse lens, regressed lens, indirect optics, and/or shielded louvers.
- Light room surfaces to balance luminance ratios.
- Coordinate luminaire mounting with ceiling obstructions.
- Provide illumination for vertical writing surfaces mounted on walls.
- Task lighting provided for each work area.

3-4.3 Individual Offices (Alternative Scheme).



3-4.4 Open Offices.



3-4.4.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power OR One wallbox dimmer per luminaire type Task lighting may be toggle switch on luminaire
Occupancy/Vacancy	Automatic ON to a maximum of 50% of full lighting power Automatic full OFF after 20 minutes of vacancy Task lighting may be automatic ON
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present. Activate associated control zones if applicable when daylight is not present.
Zoning	Zones must be a minimum of 600 square feet (56 square meters) and a maximum of 2,500 square feet (232 square meter) Provide associated control zones for zones under 250 square feet (23 square meter). Provide separate control for ambient lighting and task lighting

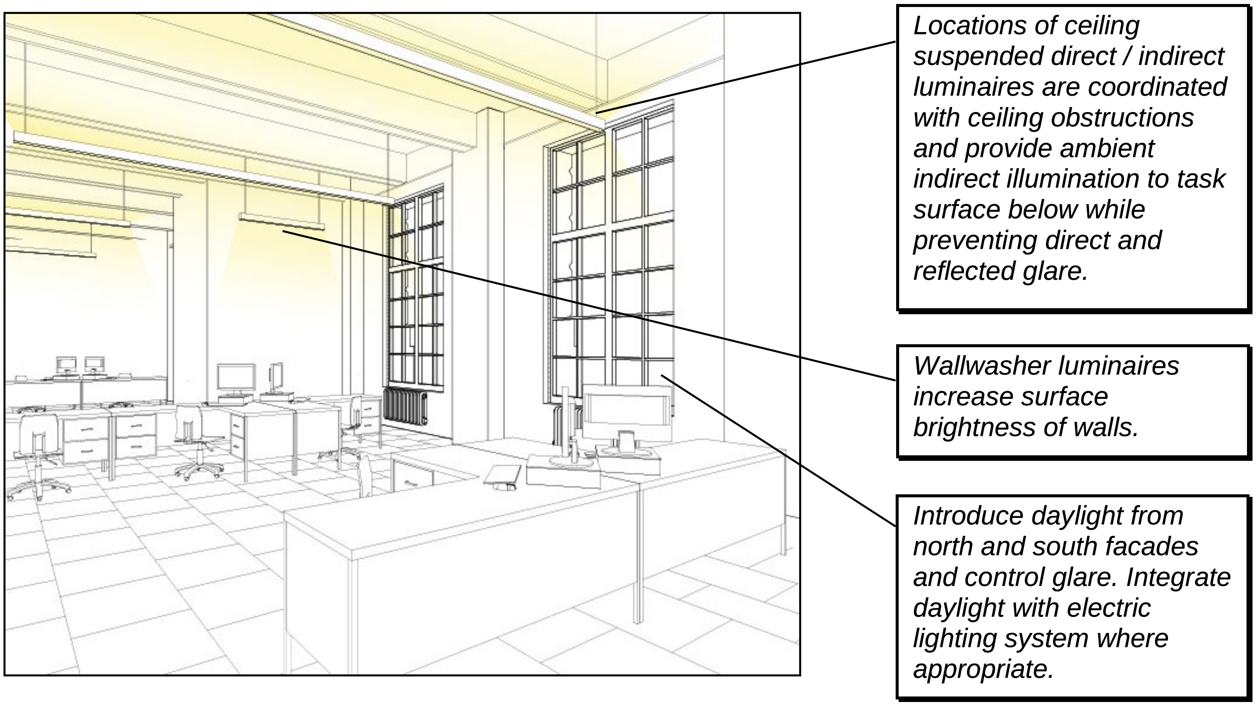
3-4.4.2 Performance Requirements.

Target Criteria	Daytime/Nighttime
Average Horizontal Illuminance	30 fc (300 lux) at 2’-6” (762 mm) AFF
Horizontal Illuminance Uniformity	2:1 average to minimum

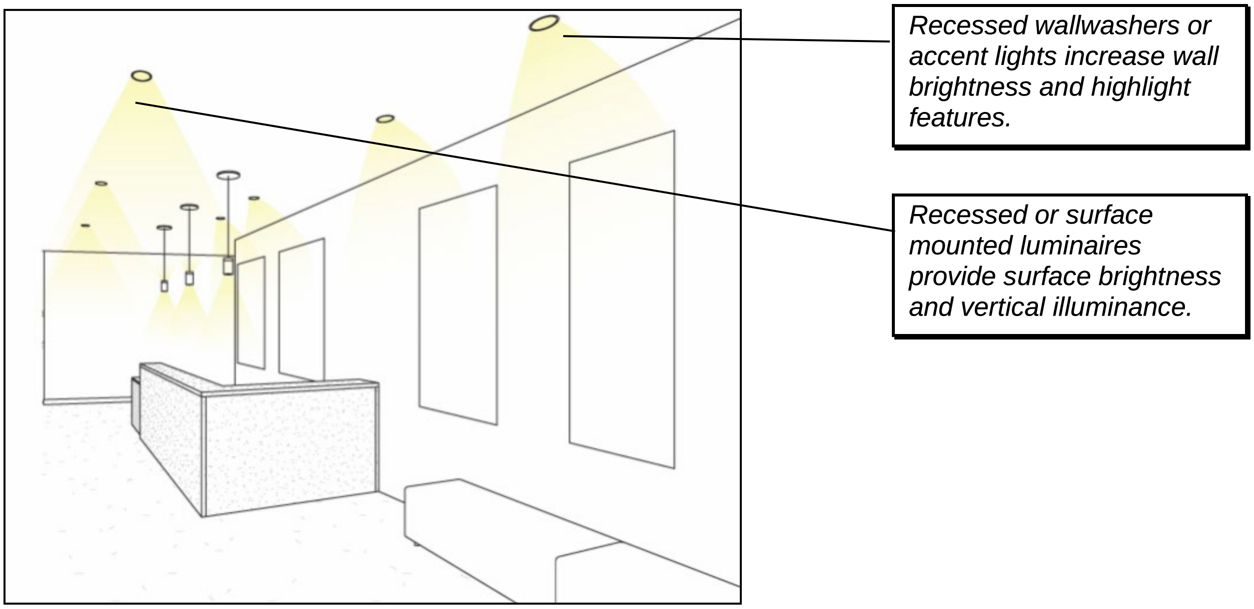
3-4.4.3 Critical Design Issues.

- Coordinate luminaire locations with ceiling obstructions such as structure, HVAC, and fire suppression systems.
- Minimize glare with solutions such as a diffuse lens, regressed lens, indirect optics, and/or shielded louvers.
- Light room surfaces to balance luminance ratios.
- Luminaire mounted 10”-18” (3048 mm - 5486 mm) below ceiling and should not hang lower than 7’-0” (2133 mm) AFF.
- In retrofit applications, ensure that heat management of luminaires is adequate and does not compromise rated life of luminaire.
- Provide undercabinet or desk mounted task lights to increase illuminance on task surface. Task lights must have occupancy sensor.
- Provide lighting control zones no larger than 2,500 square feet (232 square meter).
- Means of egress must comply with NFPA 101 for aisles and passageways leading to an exit.

3-4.5 Open Offices (Alternative Scheme).



3-4.6 Waiting Areas and Lobbies.



3-4.6.1 Control Requirements.

Manual Control	Scene wallstation OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON Automatic full OFF after 20 minutes of vacancy OR Automatic ON to a maximum of 70% of full lighting power Automatic full OFF after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for each luminaire type

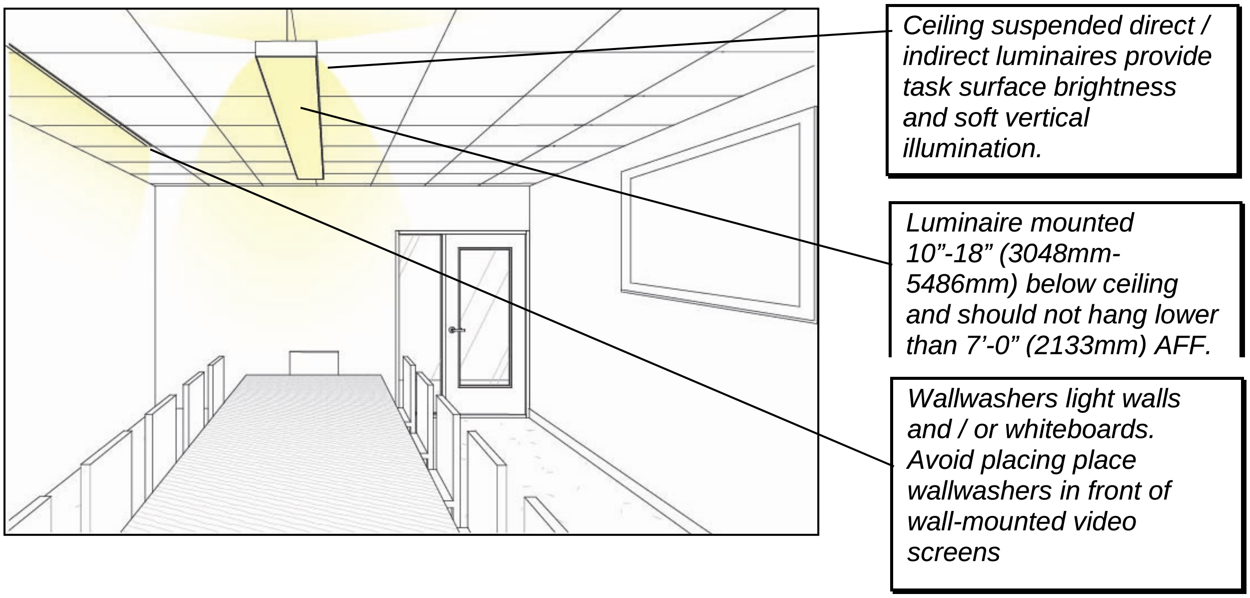
3-4.6.2 Performance Requirements.

Target Criteria	Daytime	Nighttime
Average Horizontal Illuminance, Social, waiting	10 fc (100 lux) at floor	5 fc (50 lux) at floor
Average Horizontal Illuminance, Reception desk	15 fc (150 lux) at 3’-6” (1067 mm) AFF	
Average Horizontal Illuminance, Security screening	20 fc (200 lux) at 3’-0” (910 mm) AFF	
Horizontal Illuminance Uniformity	3:1 average to minimum	

3-4.6.3 Critical Design Issues.

- Select aesthetically pleasing luminaires.
- Light room surfaces to balance luminance ratios.
- Provide task lighting for reception desk and security screening areas to meet performance requirements.
- Means of egress must comply with NFPA 101 control requirements and minimum light level requirements. When the waiting area and lobbies are means of egress, automatic off is allowable when control requirements are met.
- For circulation spaces, the light levels should be approximately 1.5 times greater than the average horizontal illuminance of the adjacent corridor or equal to the average horizontal illuminance of the adjacent corridor with added vertical surface brightness (ANSI/IES RP-1).

3-4.7 Small Meeting Rooms.



3-4.7.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power and continuous dimming capabilities OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON with automatic full OFF after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for ceiling luminaires and wallwash luminaires

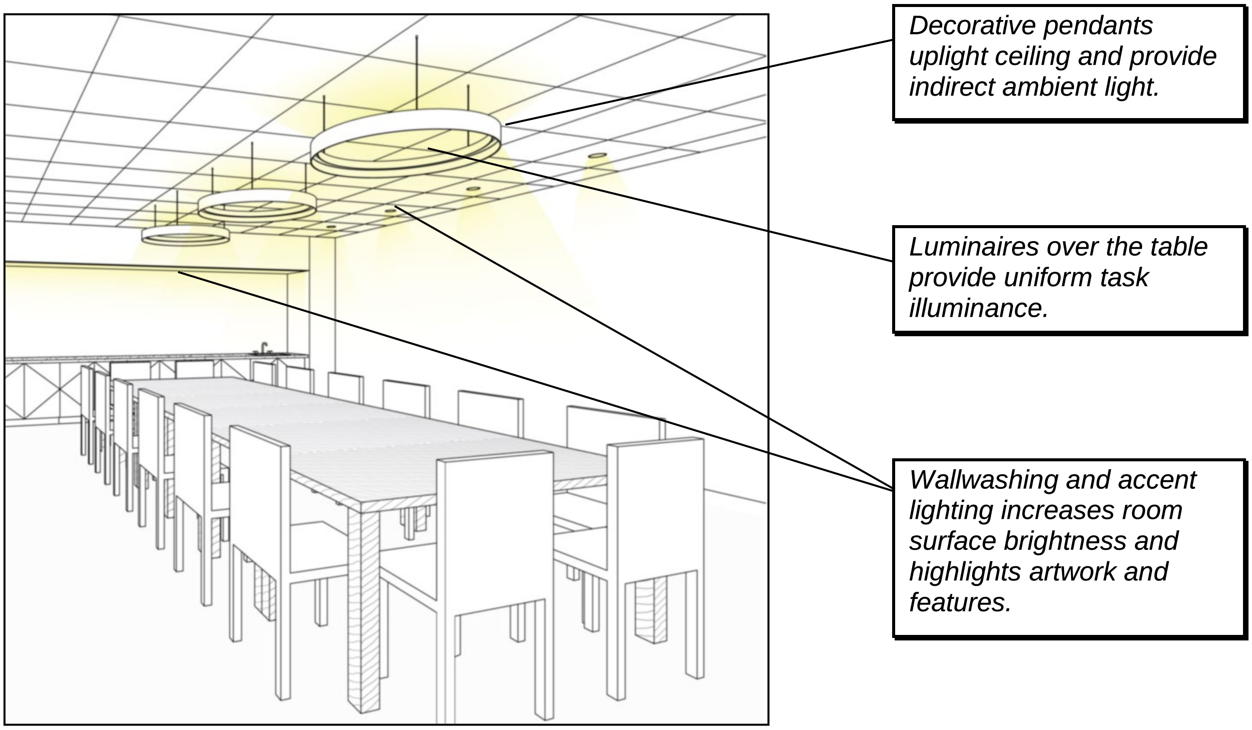
3-4.7.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	30 fc (300 lux) at 2'-6" (762 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-4.7.3 Critical Design Issues.

- Minimize glare with solutions such as a diffuse lens, regressed lens, indirect optics, and/or shielded louvers.
- Select aesthetically pleasing luminaires.
- Light room surfaces to balance luminance ratios.
- Coordinate luminaire locations with ceiling mounted AV equipment.
- Use recessed or surface mount direct/indirect luminaires if ceiling height is too low for suspended luminaires.
- Luminaires immediately adjacent to a display monitor should be on a separate control zone. This would allow those luminaires to be OFF while the display monitor is in use and allow the rest of the lighting in the room to be raised and lowered independently.
- In rooms used for video teleconferencing, use indirect lighting as much as possible to illuminate vertical surfaces such as faces to reduce shadowing and increase uniformity.

3-4.8 Multipurpose / Boardrooms / Large Conference Rooms.



3-4.8.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power and continuous dimming capabilities OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON with automatic full OFF after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for each luminaire type Provide an additional zone for luminaires that are illuminating a whiteboard, projection screen, or television

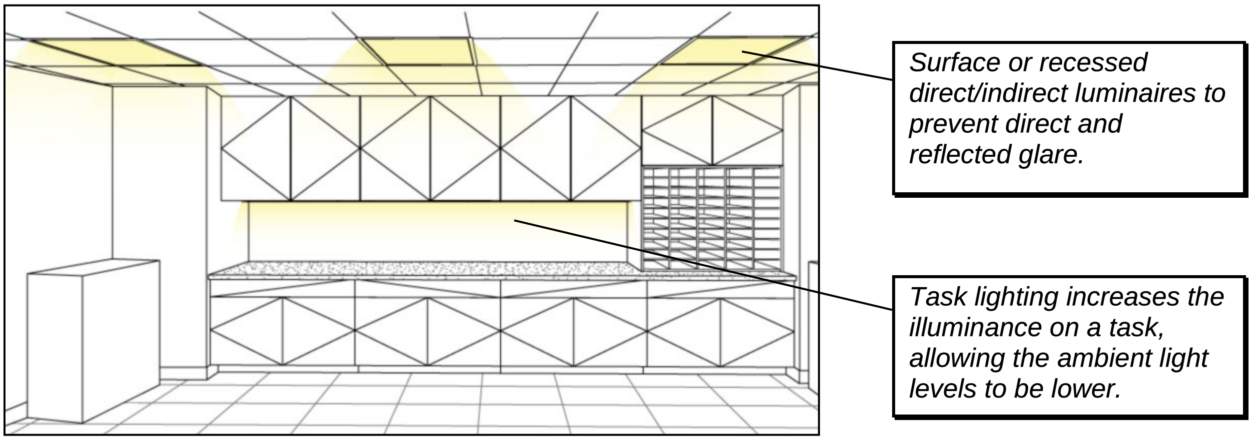
3-4.8.2 Performance Requirements.

Target Criteria	Daytime/Nighttime
Average Horizontal Illuminance	30 fc (300 lux) at 2'-6" (762 mm) AFF
Average Vertical Illuminance	15 fc (150 lux) at 4'-0" (1524 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-4.8.3 Critical Design Issues.

- Minimize glare with solutions such as a diffuse lens, regressed lens, indirect optics, and/or shielded louvers.
- Select aesthetically pleasing luminaires.
- Light room surfaces to balance luminance ratios.
- Coordinate luminaire locations with ceiling mounted AV equipment.
- Consider means of egress requirements if the conference room is over 300 sq ft and has multiple entrances.

3-4.9 Copy/Print and Office Support Areas.



3-4.9.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON Automatic full OFF after 20 minutes of vacancy for all lighting, including undercabinet. OR Automatic ON to a maximum of 50% of full lighting power Automatic full OFF after 20 minutes of vacancy for all lighting, including undercabinet.
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for task lighting and ambient lighting

3-4.9.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance, General (ambient)	10 fc (400 lux) at 0’-0” (0 mm) AFF
Average Horizontal Illuminance, Machines (task)	30 fc (300 lux) at task surface
Average Horizontal Illuminance, Printed material inspection (task)	50 fc (500 lux) at task surface
Horizontal Illuminance Uniformity	3:1 average to minimum

3-4.9.3 Critical Design Issues.

- Illuminate task surfaces with task lighting.
- Light room surfaces to balance luminance ratios.

3-4.10 Command and Control / Operation Centers.

Suspended indirect luminaires to prevent direct and reflected glare.

Task lighting increases the illuminance on a task, allowing the ambient light levels to be lower or remain off.

3-4.10.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power and continuous dimming to 1% OR One wallbox dimmer per luminaire type with dimming to 1% Task lighting may be toggle switch on luminaire
Occupancy/Vacancy	None
Time Schedule	None
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for ambient lighting and task lighting

3-4.10.2 Performance Requirements.

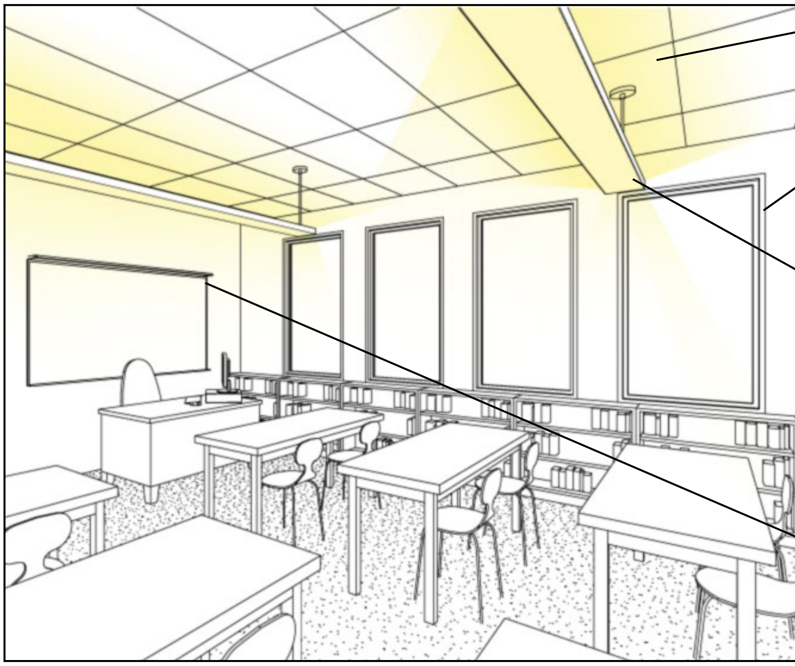
Target Criteria	Daytime/Nighttime
Average Horizontal Illuminance	30 fc (300 lux) at 2'-6" (762mm) AFF
Horizontal Illuminance Uniformity	2:1 average to minimum

3-4.10.3 Critical Design Issues.

- Eliminate direct and reflected glare.
- Luminaires may have to dim to lower than 1% due to special circumstances or tasks performed in the space.
- Task lighting should be shielded and directed so as not to disturb other occupants in the room.
- Only use recessed direct/indirect luminaires when ceilings are less than 9' or less.
- Ceiling reflectance can be no less than 80%.
- Means of egress must comply with NFPA 101 control requirements and minimum light level requirements. When the space is designated as a means of egress, automatic off is allowable when control requirements are met.
- Operation centers operate on 24-hour schedules, therefore no occupancy sensing needed.
- Consider spectral tuning luminaires when designing for spaces that routinely operate 24-hour schedules.

3-5 EDUCATIONAL SPACES.

3-5.1 Classroom / Training Rooms.



3-5.1.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power and continuous dimming capabilities OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON with automatic full OFF after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide a separate zone for luminaires that are illuminating a white board, projection screen, or television

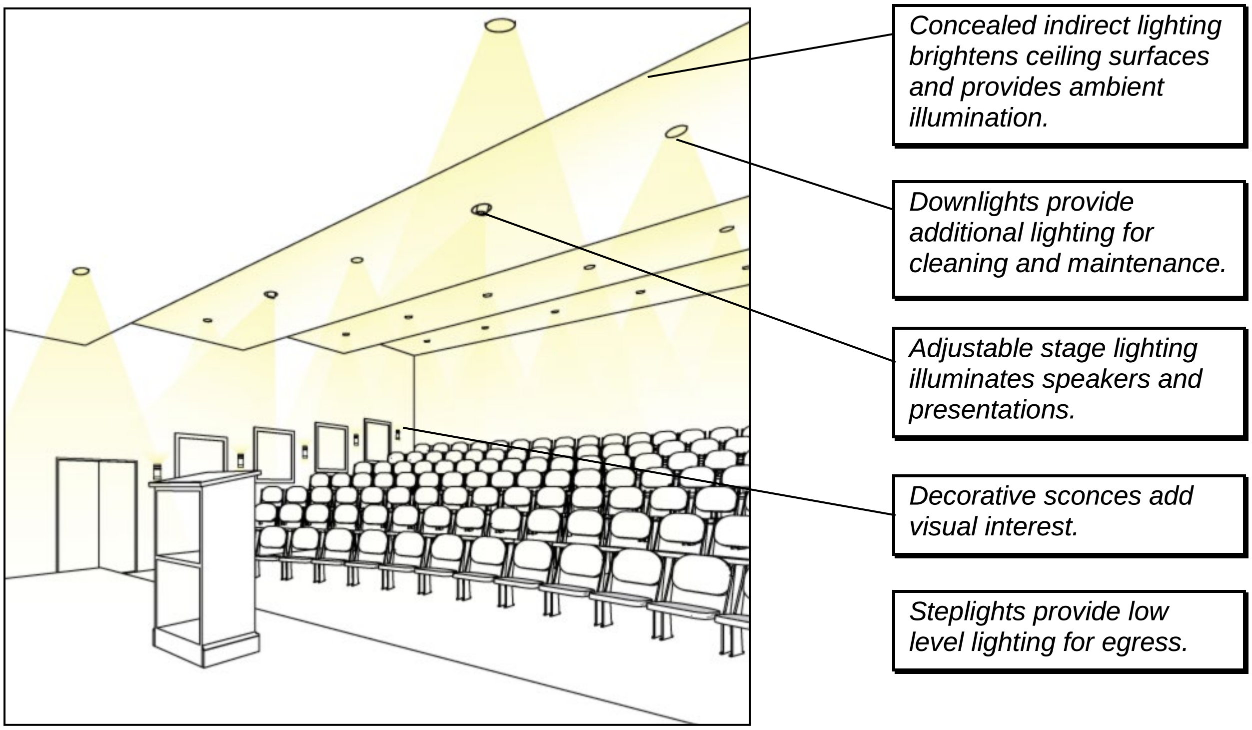
3-5.1.2 Performance Requirements.

Target Criteria	Daytime/Nighttime
Average Horizontal Illuminance	40 fc (400 lux) at 2’-6” (762 mm) AFF
Average Vertical Illuminance	15 fc (150 lux) at 4’ (1,219 mm) AFF on presentation wall
Horizontal Illuminance Uniformity	2:1 average to minimum

3-5.1.3 Critical Design Issues.

- Control glare from windows and clerestories.
- Provide even illumination (both electric and daylight) to the space.
- Minimize glare with solutions such as a diffuse lens, regressed lens, indirect optics, and/or shielded louvers.
- Light room surfaces to balance luminance ratios.
- Ceiling suspended direct/indirect luminaire mounted 10” - 18” (3048 mm - 5486 mm) below ceiling and should not hang lower than 7’-0” (2133 mm) AFF.
- Use recessed or surface mount direct/indirect luminaires if ceiling height is too low for suspended luminaires.
- Coordinate luminaire locations with ceiling mounted AV equipment.
- Additional guidance provided in ANSI/IES RP-3, Recommended Practice Lighting Educational Facilities.
- Luminaires may have to dim lower than 10% due to special circumstances.
- Provide scene wallstation near instructor’s desk at the front of the classroom.

3-5.2 Auditoriums.



3-5.2.1 Control Requirements.

Manual Control	At least one scene wallstation with: At least one preset “Presentation” scene At least one preset “All On” scene for cleaning Continuous dimming to 10% for all luminaires.
Occupancy/Vacancy	Manual ON with automatic full OFF after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for each luminaire type Provide an additional zone for luminaires that are illuminating a speaker podium or stage.

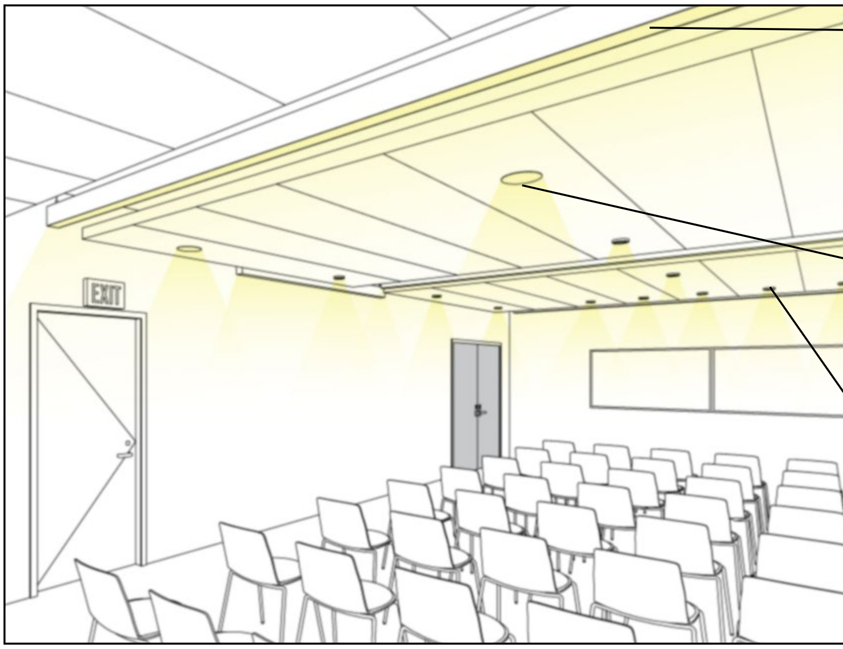
3-5.2.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance, Audience (ambient)	5 fc (50 lux) at 2'-0" (910 mm) AFF
Average Horizontal Illuminance, Panel Speaker (task)	30 fc (300 lux) at 2'-6" (762 mm) AFF
Average Horizontal Illuminance, Stage Demonstration (task)	50 fc (500 lux) at 3'-0" (1067 mm) AFF
Horizontal Illuminance Uniformity	2:1 average to minimum
Average Vertical Illuminance, Stage	20 fc (200 lux) at 5'-0" (1524 mm) AFF

3-5.2.3 Critical Design Issues.

- Minimize glare with solutions such as a diffuse lens, regressed lens, indirect optics, and/or shielded louvers.
- Use downlights with specular cones to minimize glare.
- Allow for low ambient lighting through zoning and dimmable controls.
- Provide accent lighting on speaker.
- Avoid harsh shadows by lighting the speaker from both sides.
- Provide egress lighting along the edge of the aisles per NFPA 101.
- Light room surfaces to balance luminance ratios.
- Coordinate luminaire locations with ceiling mounted AV equipment.
- Provide lighting for front of room vertical writing surfaces.
- Provide Scene Wallstation close to Podium and locate at Podium if possible. Provide additional scene control at all primary entrances.

3-5.3 Large Presentation and Briefing Areas.



Ambient illumination provides ceiling and vertical surface brightness.

Neutral downlights for additional layer of lighting control.

Adjustable accent lights highlight speaker or presentation.

3-5.3.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power and continuous dimming capabilities OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON with automatic full OFF after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for each luminaire type Provide an additional zone for luminaires that are illuminating a speaker podium, projection screen, or television

3-5.3.2 Performance Requirements.

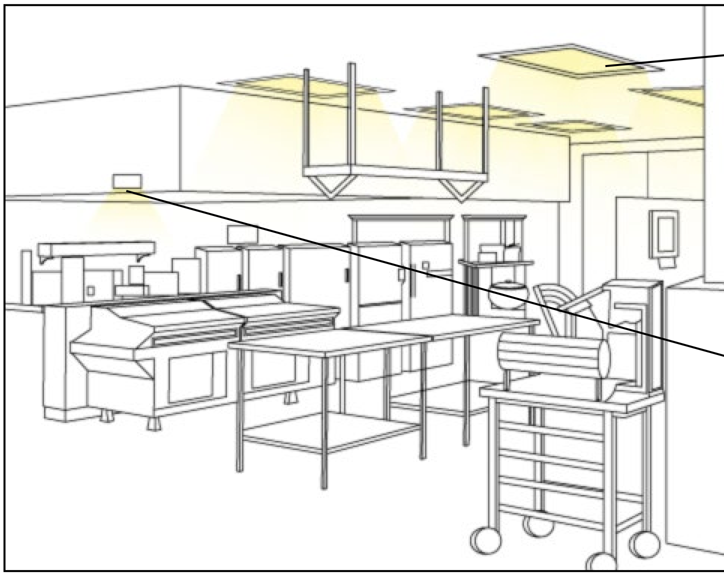
Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	10 fc (100 lux) at 2'-6" (762 mm) AFF
Average Horizontal Illuminance, Panel Speaker (task)	30 fc (300 lux) at 2'-6" (762 mm) AFF
Average Horizontal Illuminance, Stage Demonstration (task)	50 fc (500 lux) at 3'-0" (1067 mm) AFF
Horizontal Illuminance Uniformity	2:1 average to minimum
Average Vertical Illuminance, Stage	20 fc (200 lux) at 5'-0" (1524 mm) AFF

3-5.3.3 Critical Design Issues.

- Allow for low ambient lighting through zoning and dimmable controls.
- Provide dimming capabilities down to 10% for all lighting in the space.
- Provide accent lighting on speaker.
- Light room's surfaces to balance luminance ratios.
- Coordinate luminaire locations with ceiling mounted AV equipment.
- Means of egress must comply with NFPA 101 control requirements and minimum light level requirements. When the space is designated as a means of egress, automatic off is allowable when control requirements are met.

3-6 FOOD SERVICE SPACES.

3-6.1 Commercial Kitchens.



3-6.1.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON OR Automatic ON to a maximum of 50% of full lighting power
Time Schedule	None
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for task lighting and ambient lighting

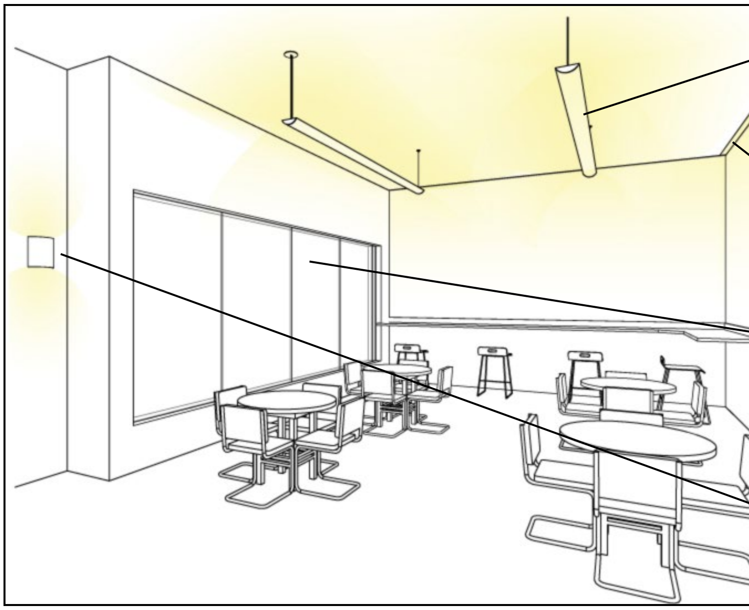
3-6.1.2 Performance Requirements.

Target Criteria	Daytime/Nighttime
Average Horizontal Illuminance, Food prep, handling, cleaning (task)	50 fc (500 lux) at food preparation surface
Average Vertical Illuminance, Food prep, handling, cleaning (task)	20 fc (200 lux) at food preparation surface
Horizontal Illuminance Uniformity	3:1 average to minimum at food preparation surface
Average Horizontal Illuminance, Dishwashing, pot washing (task)	20 fc (200 lux) at task surface
Average Vertical Illuminance, Dishwashing, pot washing (task)	10 fc (100 lux) at 4’-0” (1219 mm) AFF

3-6.1.3 Critical Design Issues.

- Locate luminaires to minimize shadows.
- Select luminaires designed for food processing facilities.
- Use high, 90+ CRI light sources in kitchen for proper rendering of food color.

3-6.2 Cafeterias.



3-6.2.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON Automatic full OFF after 20 minutes of vacancy OR Automatic ON to a maximum of 50% of full lighting power Automatic full OFF after 20 minutes of vacancy
Time Schedule	None
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for task lighting and ambient lighting

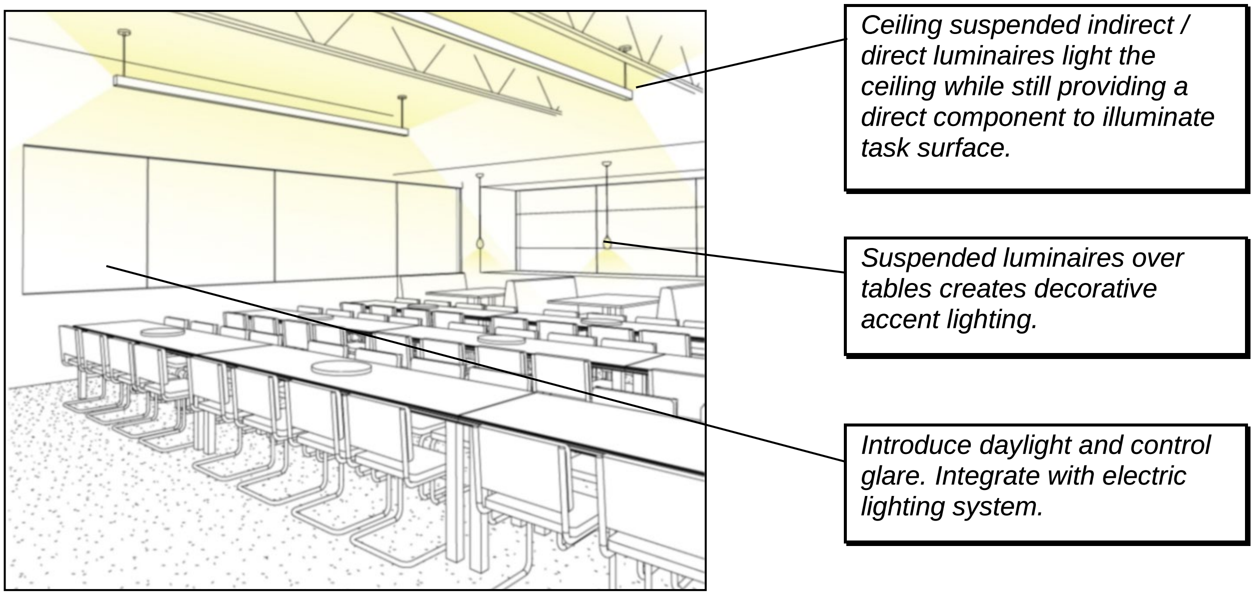
3-6.2.2 Performance Requirements.

Target Criteria	**Ambient**	**Food Display**	**Food Servery**
Average Horizontal Illuminance	15 fc (150 lux) at 2'-6" (762 mm) AFF	50 fc (500 lux) at food preparation surface	20 fc (200 lux) at task surface
Average Vertical Illuminance	NA	20 fc (200 lux) at food preparation surface	20 fc (200 lux) at task surface
Horizontal Illuminance Uniformity	3:1 average to minimum		

3-6.2.3 Critical Design Issues.

- Use accent lighting to provide wayfinding.
- Light room surfaces to balance luminance ratios.
- Means of egress must comply with NFPA 101 control requirements and minimum light level requirements. When the space is designated as a means of egress, automatic off is allowable when control requirements are met.
- Areas of food preparation do not have to have occupancy sensors.

3-6.3 Enlisted Dining Rooms.



3-6.3.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON Automatic full OFF after 20 minutes of vacancy OR Automatic ON to a maximum of 50% of full lighting power Automatic full OFF after 20 minutes of vacancy
Time Schedule	None
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control for task lighting and ambient lighting

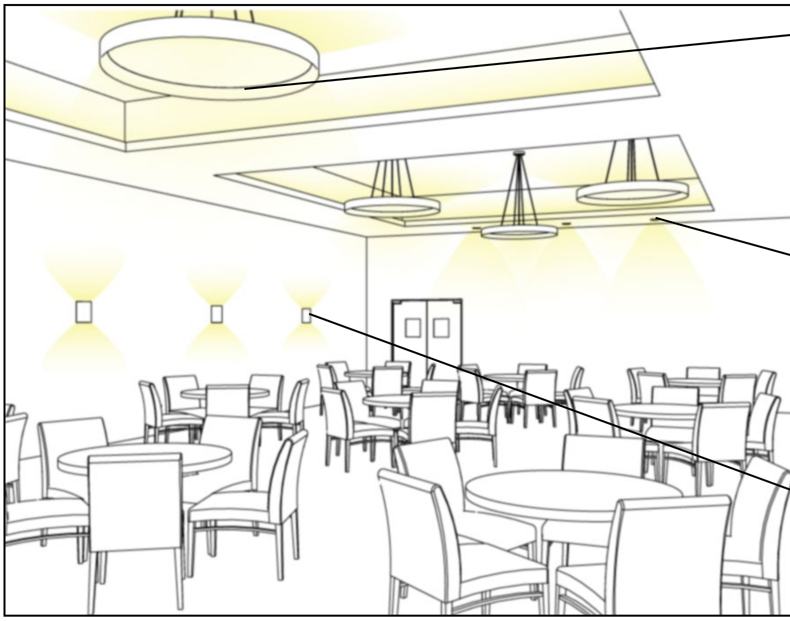
3-6.3.2 Performance Requirements.

Target Criteria	Ambient	Food Display
Average Horizontal Illuminance	15 fc (150 lux) at 2'-6" (762 mm) AFF	50 fc (500 lux) at food preparation surface
Average Vertical Illuminance	NA	20 fc (200 lux) at food preparation surface
Horizontal Illuminance Uniformity	3:1 average to minimum	

3-6.3.3 Critical Design Issues.

- Use accent lighting to provide wayfinding.
- Provide luminaires with low lumen output and dimming to avoid excessive brightness.
- Light room surfaces to balance luminance ratios.
- Means of egress must comply with NFPA 101 control requirements and minimum light level requirements. When the space is designated as a means of egress, automatic off is allowable when control requirements are met.

3-6.4 Officer Dining Rooms.



3-6.4.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power and continuous dimming capabilities OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON Automatic full OFF after 20 minutes of vacancy OR Automatic ON to a maximum of 50% of full lighting power Automatic full OFF after 20 minutes of vacancy
Time Schedule	None
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate control zone for each luminaire type.

3-6.4.2 Performance Requirements.

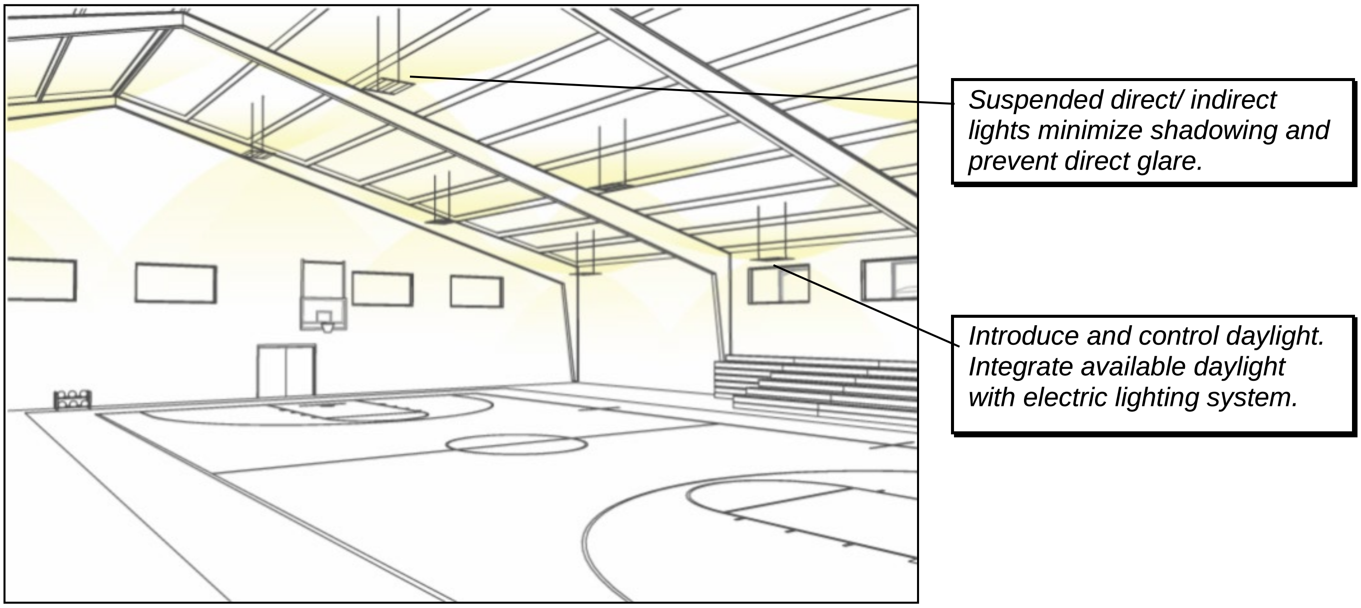
Target Criteria	**Ambient**	**Food Display**
Average Horizontal Illuminance	10 fc (100 lux) at table plane	50 fc (500 lux) at food preparation surface
Average Vertical Illuminance	NA	20 fc (200 lux) at food preparation surface
Horizontal Illuminance Uniformity	3:1 average to minimum	

3-6.4.3 Critical Design Issues.

- Select aesthetically pleasing luminaires.
- Provide luminaires with low lumen output and dimming to avoid excessive brightness.
- Light room surfaces to balance luminance ratios.
- Means of egress must comply with NFPA 101 control requirements and minimum light level requirements. When the space is designated as a means of egress, automatic off is allowable when control requirements are met.

3-7 RECREATIONAL SPACES.

3-7.1 Indoor Multi-use Gymnasiums.



3-7.1.1 Control Requirements.

Manual Control	Scene wallstation with preset scenes: - All lights on to 10% -40% (normal) - All lights on to 50% - 70% (recreation) - All lighting on to 80% - 100% (league play)
Occupancy/Vacancy	Automatic ON to a maximum of 50% of full lighting power with automatic full OFF after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide separate zones for each defined activity space, if more than one.

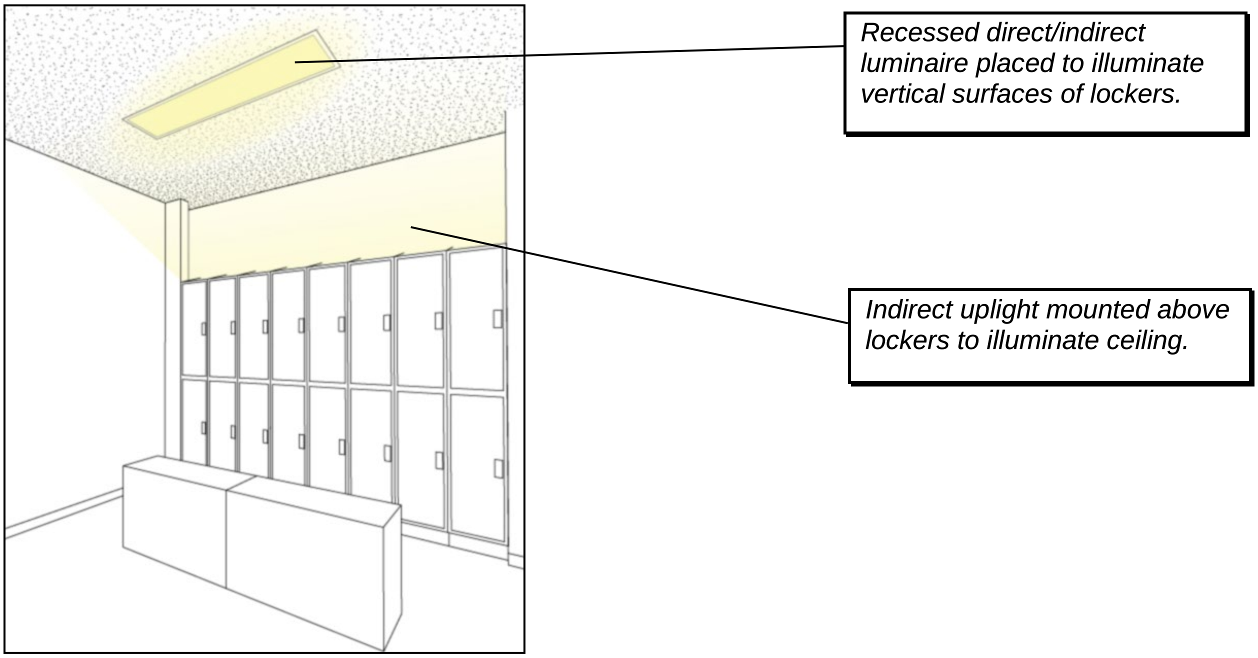
3-7.1.2 Performance Requirements.

Target Criteria	**Recreational**
Average Horizontal Illuminance	Refer to ANSI/IES RP-6 for specific indoor sport
Horizontal Illuminance Uniformity	Refer to ANSI/IES RP-6 for specific indoor sport

3-7.1.3 Critical Design Issues.

- Provide luminaires with lenses or louvers to minimize glare.
- Refer to ANSI/IES RP-6, *Recommended Practice: Lighting Sports and Recreational Areas* for specific criteria for different indoor sports. Use Class IV for all recreation lighting criteria. If more than one type of sport is intended to be played in the gymnasium, design the light levels for the sport requiring the most light.
- Refer to ANSI/IES RP-6, *Recommended Practice: Lighting Sports and Recreational Areas* for direction in luminaire placement to avoid glare.
- Provide uniform illuminance on the court.
- Minimize shadows to enhance view of objects and people.
- Light room surfaces to balance luminance ratios.
- Coordinate luminaire locations with ceiling equipment such as HVAC, and sports equipment.
- Use wire guards or polycarbonate lens where appropriate to protect luminaire.
- Refer to UFC 4-740-02 for additional requirements and considerations regarding recreational spaces in fitness centers.
- Provide keyed box for lighting controls near main entrance.

3-7.2 Locker Rooms.



3-7.2.1 Control Requirements.

Manual Control	At least one scene wallstation or wallbox dimmer
Occupancy/Vacancy	Manual ON Automatic full OFF after 20 minutes of vacancy OR Automatic ON to a maximum of 50% of full lighting power Automatic full OFF after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	None

3-7.2.2 Performance Requirements.

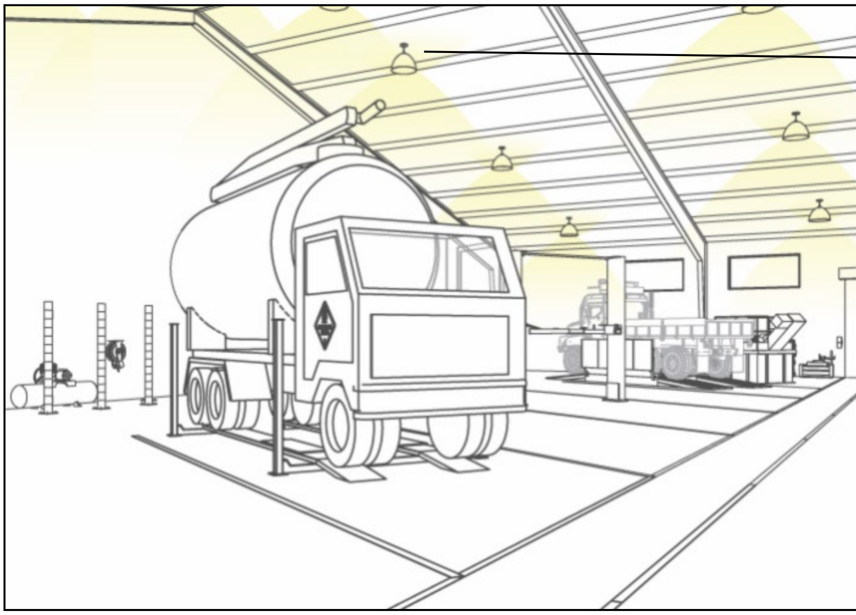
Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	5 fc (50 lux) at floor
Average Vertical Illuminance	10 fc (100 lux) at locker faces
Horizontal Illuminance Uniformity	3:1 average to minimum

3-7.2.3 Critical Design Issues.

- Provide luminaires with translucent, non-breakable, protective covers.
- Provide luminaires that are damp rated if they are located in close proximity to showers, pools, or other humid spaces.
- Light room surfaces to balance luminance ratios.
- Minimize shadows by providing diffuse lighting, especially at lockers and counters.
- Refer to UFC 4-740-02 for additional requirements and considerations regarding recreational spaces in fitness centers.
- For locker rooms greater than 300 square feet, means of egress must comply with NFPA 101 for passageways leading to an exit.

3-8 MAINTENANCE SPACES.

3-8.1 Vehicle Maintenance Areas.



Direct / indirect luminaires reduce direct glare.

Luminaire spacing provides uniform illuminance on task plane.

3-8.1.1 Control Requirements.

Manual Control	Manual OFF with scene wallstation with at least three preset scenes: full ON, lights dimmed between 30% and 70% of full lighting power, and OFF.
Occupancy/Vacancy	Manual ON Automatically dimmed by at least 50% after 20 minutes of vacancy
Time Schedule	Scheduled Full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Zone each service bay separately.

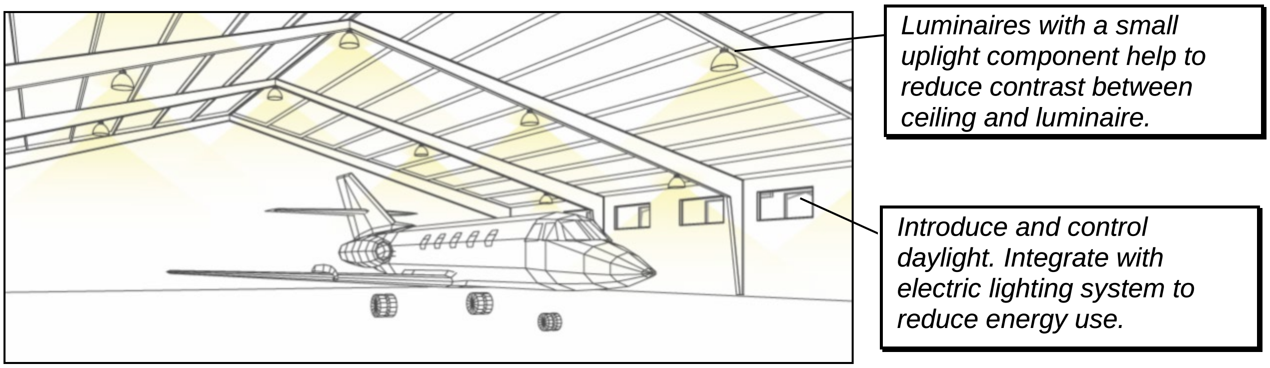
3-8.1.2 Performance Requirements.

Target Criteria	Daytime/Nighttime
Average Horizontal Illuminance	30 fc (300 lux) at floor
Average Vertical Illuminance	7.5 fc (75 lux) at 4’-0” (1219 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-8.1.3 Critical Design Issues.

- Use stem mounted luminaires in all drive through vehicle maintenance bays.
- Provide redundant supports to ensure that failure of a single supporting component does not result in luminaire falling.
- Locate lighting equipment to minimize shadows.
- Automated dimming must be ramped.
- Light room surfaces to balance luminance ratios.
- Uniformly light the work plane.
- Verify special lighting equipment requirements in hazardous (classified) locations.
- These service facilities employ ambient and task lighting systems. The two primary lighting strategies are:
- Wall-mounted luminaires to illuminate tasks (the bench and vehicle hood areas) or
- Strategically located luminaires at the ceiling at the tasks (hood areas).
- White ceilings and walls are necessary to maximize efficiency and diffusion.
- Target illuminance requirements are applicable when all luminaires are energized.
- Occupancy/Vacancy automatic OFF is not allowed.
- Manual control override of scheduled shutoff will not turn the lighting on for more than 2 hours during scheduled off periods.

3-8.2 Aircraft Hangar Bay.



3-8.2.1 Control Requirements.

Manual Control	Manual OFF with scene wallstation with at least three preset scenes: full ON, lights dimmed between 30% and 70% of full lighting power, and OFF.
Occupancy/Vacancy	Manual ON Automatically dimmed by at least 50% after 20 minutes of vacancy
Time Schedule	Scheduled dimmed to 20% or user defined level when hangar bay is scheduled to be vacant unless occupants enter the bay, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming per zone when daylight is present.
Zoning	Each aircraft maintenance area is a separate lighting control zone. ASHRAE 90.1 does not apply to aircraft maintenance areas.

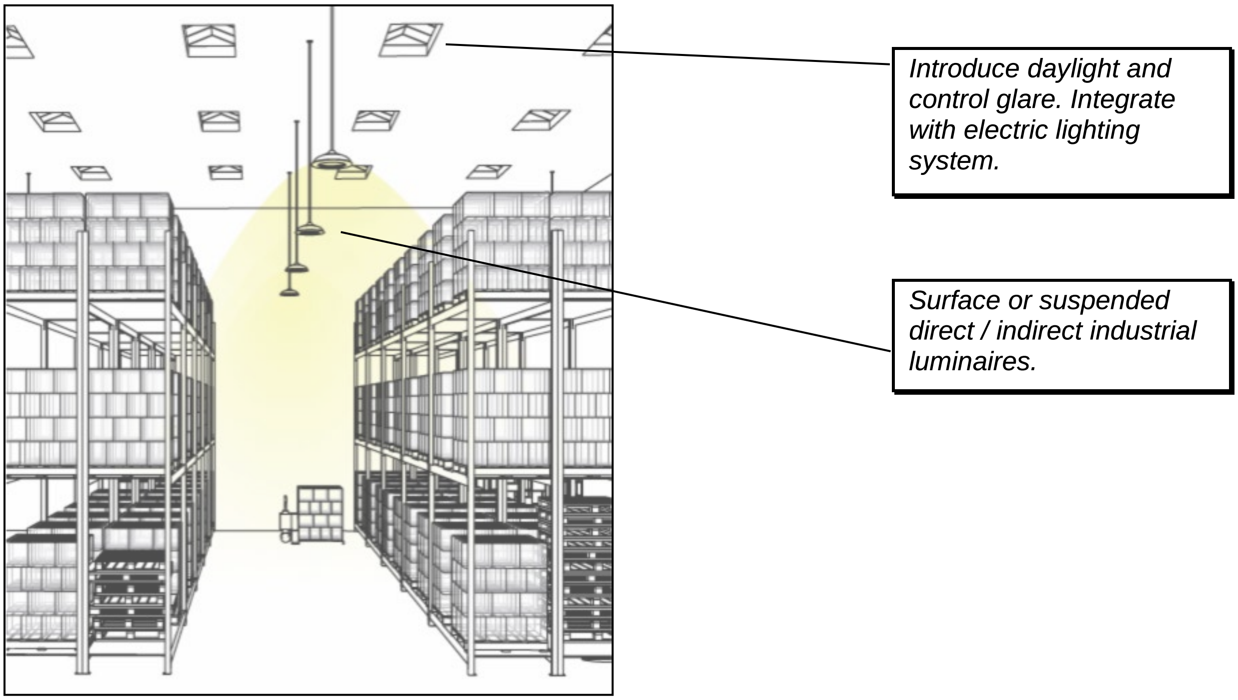
3-8.2.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	50 fc (500 lux) at 2'-6" (762 mm) AFF
Average Vertical Illuminance	50 fc (500 lux) at aircraft surface
Horizontal Illuminance Uniformity	3:1 average to minimum

3-8.2.3 Critical Design Issues.

- If there are no afterhours security requirements, the lights in the hangar bay may be shut off via Time Schedule. Coordinate security lighting requirements with security officer.
- Use stem mounted luminaires in aircraft hangar bays.
- Provide redundant supports to ensure that failure of a single supporting component does not result in luminaire falling.
- Locate lighting equipment to minimize shadows.
- Uniformly light the work plane.
- Automated dimming must be ramped.
- Occupancy/Vacancy automatic OFF is not allowed.
- Verify special lighting equipment requirements in hazardous (classified) locations.
- Refer to ANSI/IES RP-7 for additional considerations.
- Account for permanent illuminance-reduction installation features, such as instances where luminaires are installed above bird netting. 10% performance reduction is assumed in these situations. Ensure that luminaires be accessible for maintenance when bird netting is installed.
- UFC 4-211-02 requires 100 fc average for corrosion control hangar bays.
- Coordinate skylight and clerestory locations with aircraft control to ensure no visual light trespass conflicts with control tower night operations.

3-8.3 Warehouses.



3-8.3.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 70% of full lighting power OR One wallbox dimmer per zone
Occupancy/Vacancy	Manual ON Automatically dimmed by at least 50% after 20 minutes of vacancy OR Automatic ON to 50% of general lighting power Automatically dimmed by at least 50% after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	Provide zones that are no larger than 2,500 square feet, unless space is over 10,000 square feet, then larger zones can be used.

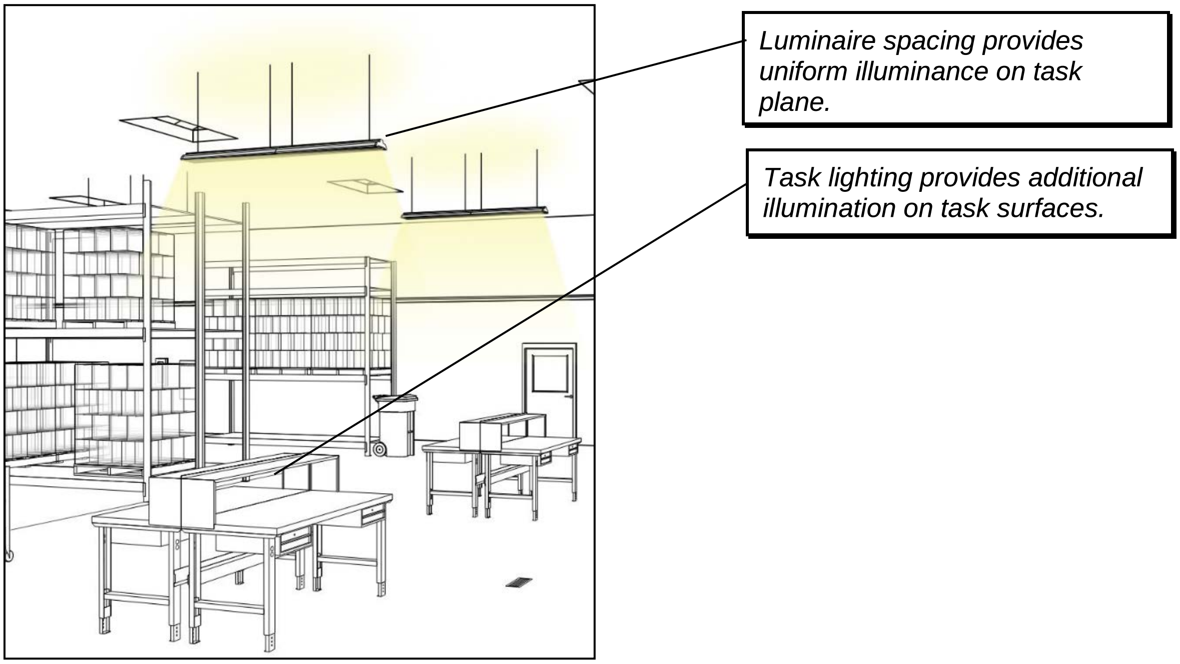
3-8.3.2 Performance Requirements.

Target Criteria	Small items	Medium items	Large items, infrequent use
Average Horizontal Illuminance	20 fc (300 lux) at floor	10 fc (100 lux) at floor	5 fc (50 lux) at floor
Average Vertical Illuminance	10 fc (100 lux) at 4'-0" (1220 mm) AFF	7.5 fc (75 lux) at 4'-0" (1220 mm) AFF	2 fc (20 lux) at 4'-0" (1220 mm) AFF
Horizontal and Vertical Illuminance Uniformity	3:1 average to minimum		

3-8.3.3 Critical Design Issues.

- Locate lighting equipment to minimize shadows.
- Coordinate lighting equipment locations with permanent shelving
- Light room surfaces to balance luminance ratios.
- Uniformly light the work plane.
- Distribution of luminaire to illuminate vertical surfaces of shelving.
- When spaces are larger than 10,000 square feet, zones can be larger in accordance with ASHRAE.
- Recommended occupancy zoning by aisle.
- Manual control override of scheduled shutoff will not turn the lighting on for more than 2 hours during scheduled off periods.

3-8.4 Maintenance Shops.



3-8.4.1 Control Requirements.

Manual Control	Manual OFF with scene wallstation with at least three preset scenes: full ON, lights dimmed between 30% and 70% of full lighting power, and OFF. Individual control for task lighting at work benches.
Occupancy/Vacancy	Manual ON Automatically dimmed by at least 50% after 20 minutes of vacancy
Time Schedule	Scheduled full OFF when building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	None

3-8.4.2 Performance Requirements.

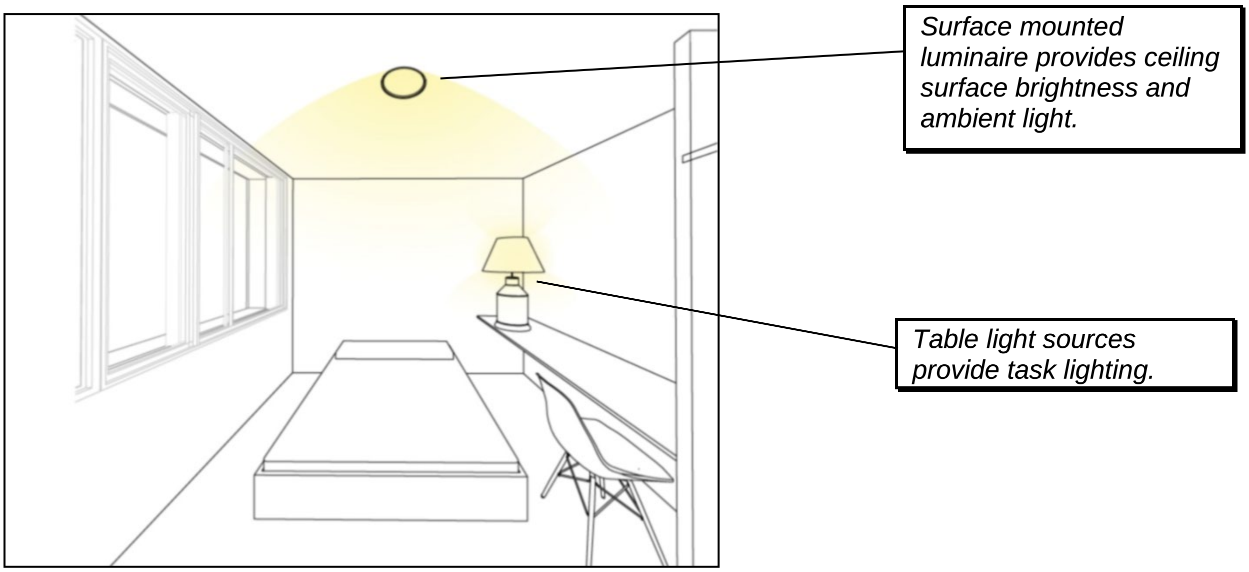
Target Criteria	**Ambient**	**Task**
Average Horizontal Illuminance	30 fc (300 lux)	50 fc (500 lux) at 3’-6” AFF
Horizontal Illuminance Uniformity	3:1 average to minimum	

3-8.4.3 Critical Design Issues.

- Maintenance shops are often located within other space types. Design lighting in the maintenance shop areas to be on own control zone and design to the light levels listed in the performance requirements.
- Locate lighting equipment to minimize shadows.
- Automated dimming must be ramped.
- Light room surfaces to balance luminance ratios.
- Uniformly light the work plane.
- Verify special lighting equipment requirements in hazardous (classified) locations.
- Manual control override of scheduled shutoff will not turn the lighting on for more than 2 hours during scheduled off periods.

3-9 HOUSING.

3-9.1 Bedrooms.



3-9.1.1 Control Requirements.

Manual Control	At least one wallbox dimmer with continuous dimming for ambient lighting.
Occupancy/Vacancy	None
Time Schedule	None
Daylight	None
Zoning	Provide separate switching for ambient lighting and task lighting.

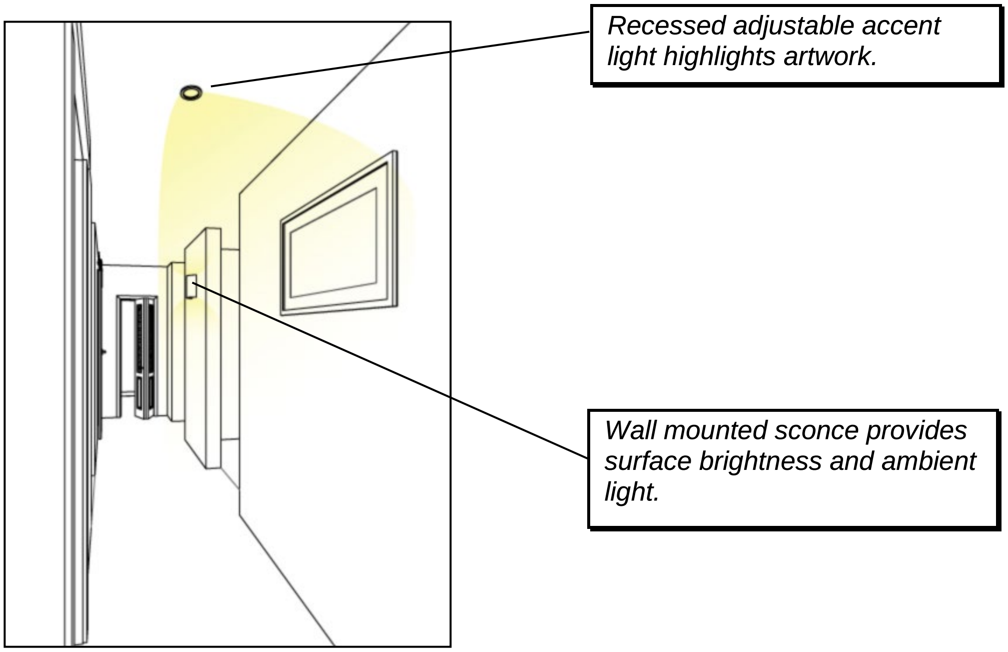
3-9.1.2 Performance Requirements.

Target Criteria	Daytime/Nighttime
Average Horizontal Illuminance	5 fc (50 lux) at 2'-0" (610 mm) AFF
Horizontal Illuminance Uniformity	5:1 average to minimum

3-9.1.3 Critical Design Issues.

- Light room surfaces to balance luminance ratios.
- Provide three-way switches at Unit/Room entrance and bedroom(s) doors.
- Provide overhead ambient lighting in bedrooms, separately switched and dimmed for each occupant side of the room.
- Per FC 4-721-10N Unaccompanied Housing, no “cloud type” light luminaires are allowed.
- Refer to FC 4-721-10N Unaccompanied Housing and UFC 3-353-1 for further guidance.

3-9.2 Hallways.



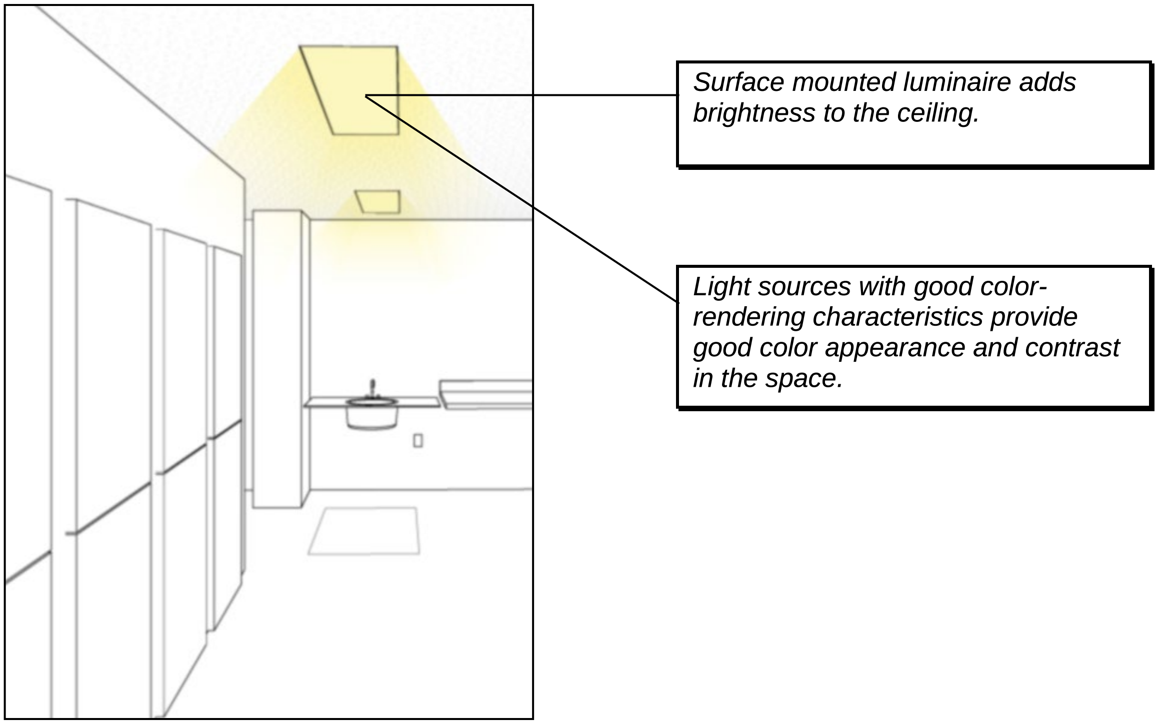
3-9.2.1 Control Requirements.

Manual Control	At least one wallbox dimmer or scene wallstation
Occupancy/Vacancy	Manual ON Automatically dimmed between 30% and 70% after 5 minutes of vacancy OR Manual ON Automatic OFF after 5 minutes of vacancy
Time Schedule	None
Daylight	None
Zoning	Provide separate switching for ambient lighting and accent lighting

3-9.2.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	3 fc (30 lux) at floor
Horizontal Illuminance Uniformity	5:1 average to minimum

3-9.3 Laundry Rooms.



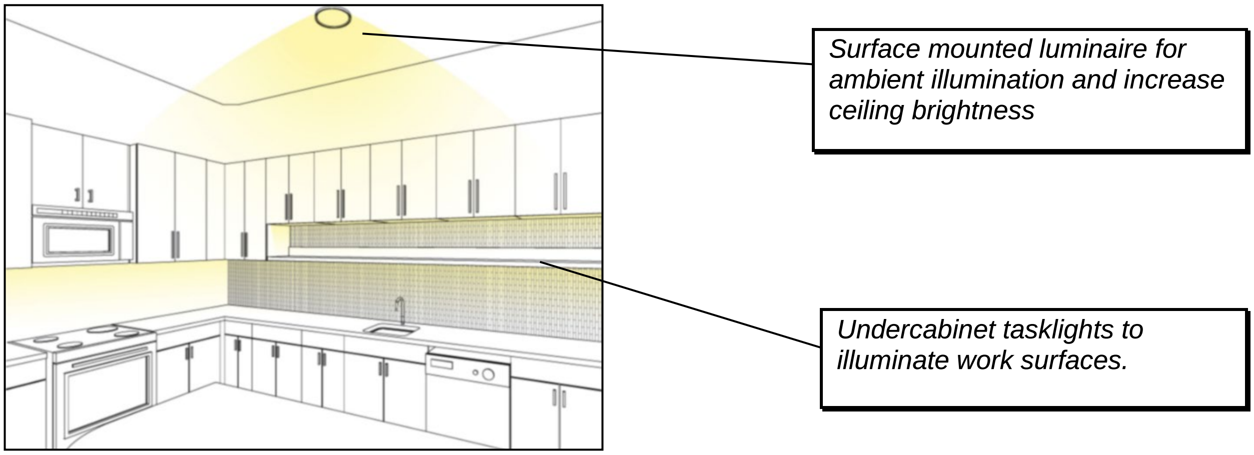
3-9.3.1 Control Requirements.

Manual Control	At least one wallbox dimmer or scene wallstation
Occupancy/Vacancy	Manual On Automatic full OFF after 5 minutes of vacancy
Time Schedule	None
Daylight	None
Zoning	None

3-9.3.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	20 fc (200 lux) at 3’-0” (914 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-9.4 Kitchens.



3-9.4.1 Control Requirements.

Manual Control	At least one wallbox dimmer or scene wallstation per luminaire type
Occupancy/Vacancy	None
Time Schedule	None
Daylight	None
Zoning	Provide separate switching or scene control for ambient lighting and task lighting. Provide separate switch for task lighting above sink and/or work surfaces.

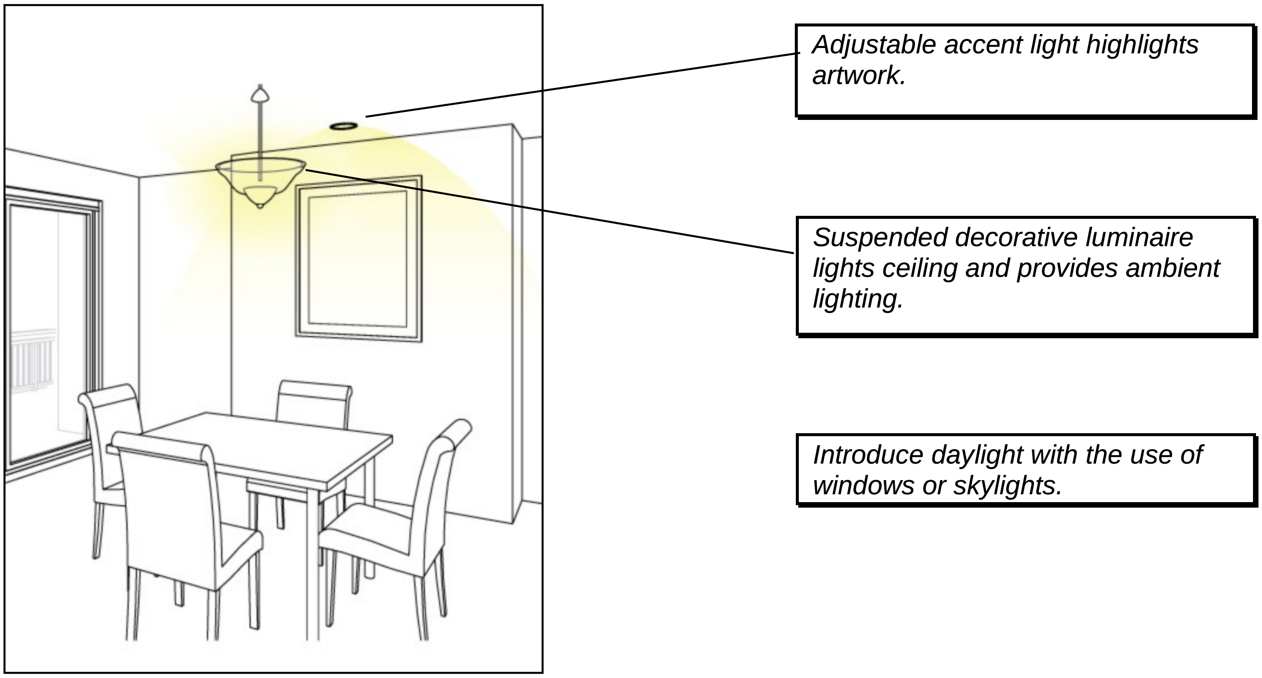
3-9.4.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance, General	5 fc (50 lux) at floor
Average Horizontal Illuminance, Task Surface	30 fc (300 lux) at cooking surface
Horizontal Illuminance Uniformity	3:1 average to minimum

3-9.4.3 Critical Design Issues.

- Locate lighting equipment to minimize shadows.
- Light room surfaces to balance luminance ratios.
- Illuminate work surfaces.

3-9.5 Dining Rooms.



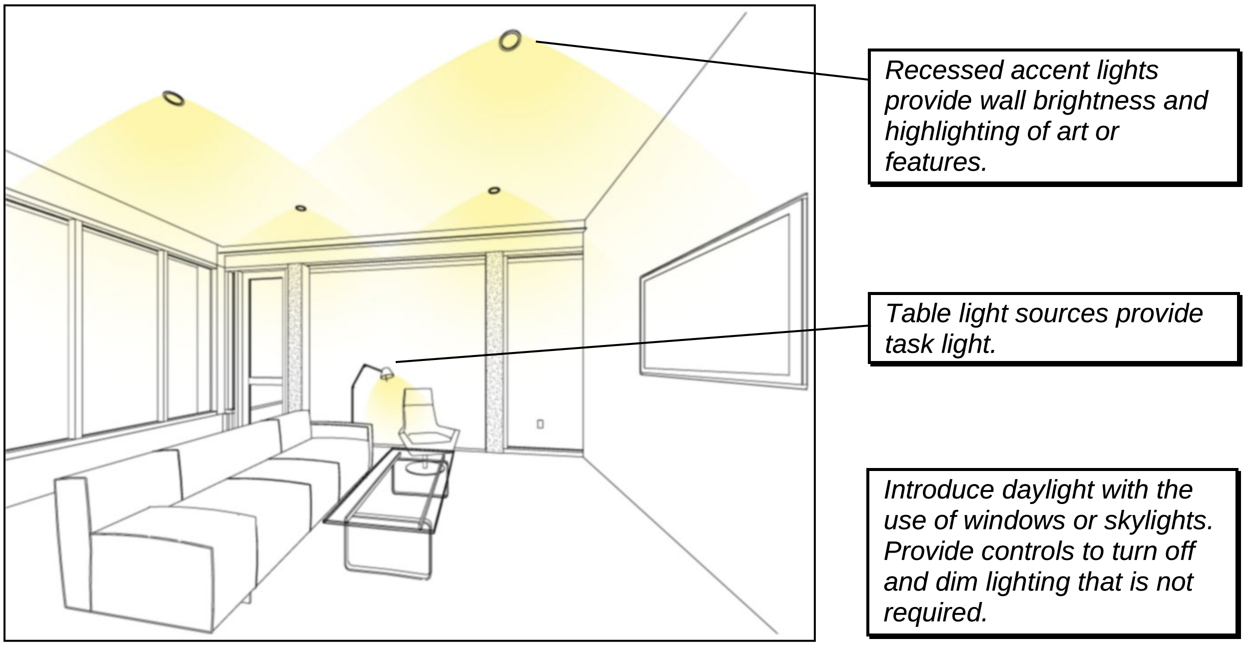
3-9.5.1 Control Requirements.

Manual Control	Local ON/OFF control device AND At least one scene wallstation or wallbox dimmer with continuous dimming
Occupancy/Vacancy	None
Time Schedule	None
Daylight	None
Zoning	Provide separate switching for ambient lighting and accent lighting. Each lighting type may dim as separate zone or part of scene controller

3-9.5.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	5 fc (50 lux) at table plane
Horizontal Illuminance Uniformity	4:1 average to minimum

3-9.6 Living Rooms.



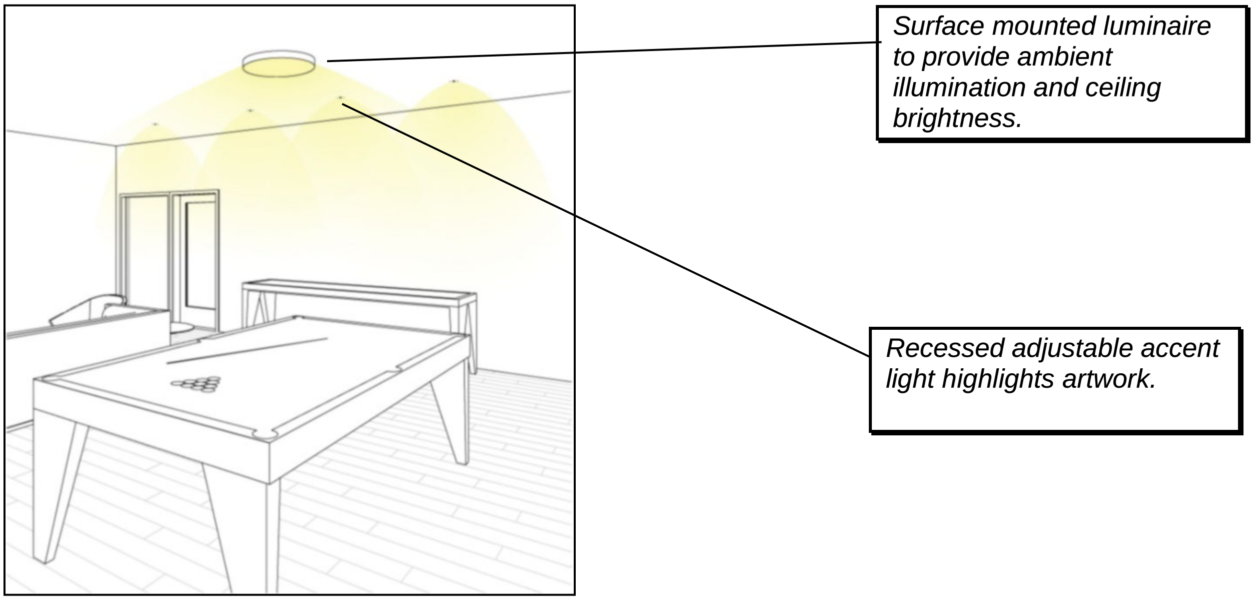
3-9.6.1 Control Requirements.

Manual Control	At least one wallbox dimmer or scene wallstation
Occupancy/Vacancy	None
Time Schedule	None
Daylight	None
Zoning	Provide separate switching or scene control for ambient lighting and task lighting

3-9.6.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	3 fc (30 lux) at floor
Horizontal Illuminance Uniformity	5:1 average to minimum

3-9.7 Rec Rooms.



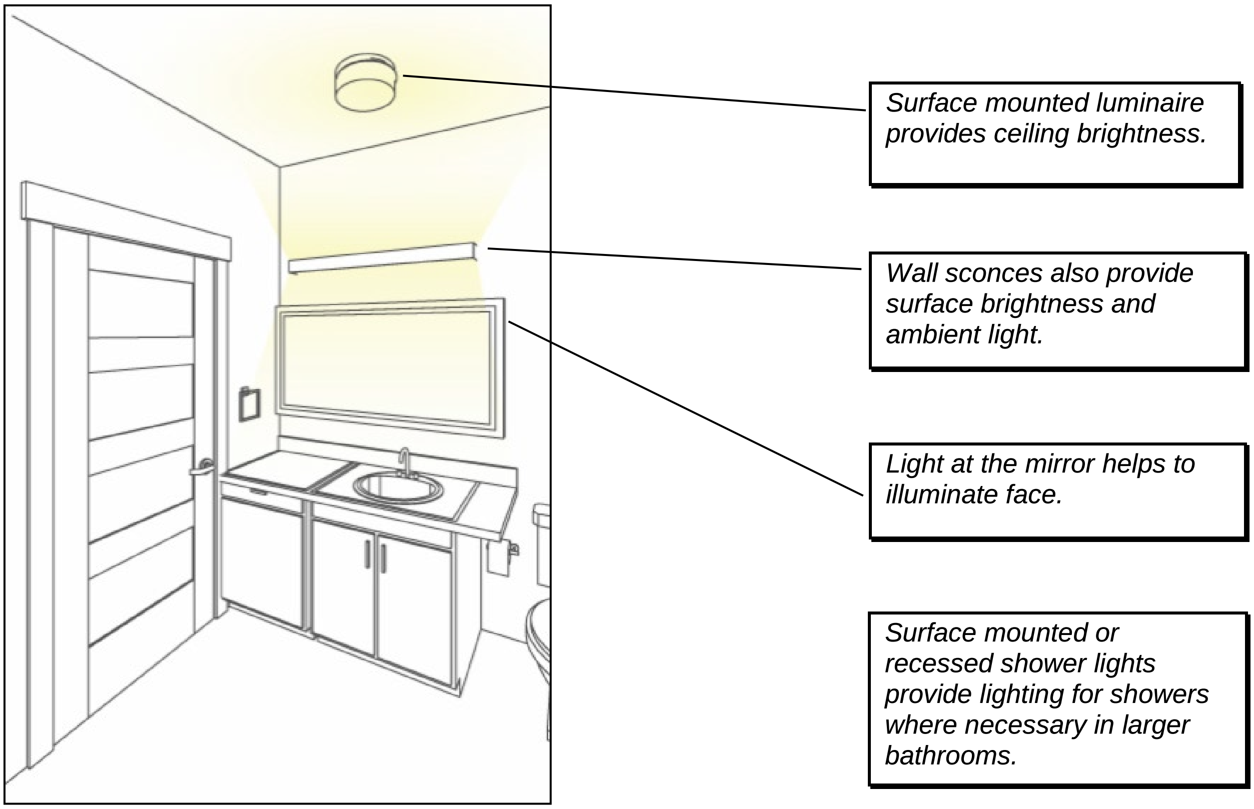
3-9.7.1 Control Requirements.

Manual Control	At least one wallbox dimmer or scene wallstation
Occupancy/Vacancy	Manual ON Automatic full OFF after 20 minutes of vacancy OR Automatic ON to a maximum of 50% of full lighting power Automatic full OFF after 20 minutes of vacancy
Time Schedule	None
Daylight	None
Zoning	Provide separate switching or scene control for ambient lighting and accent lighting

3-9.7.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	20 fc (200 lux) at 2’-6” (762 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-9.8 Bathrooms.



3-9.8.1 Control Requirements.

Manual Control	At least one wallbox dimmer or scene wallstation per luminaire type
Occupancy/Vacancy	Manual ON Automatic full OFF after 20 minutes of vacancy
Time Schedule	None
Daylight	None
Zoning	None

3-9.8.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	30 fc (300 lux) at 3'-0" (914 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-9.9 Garages.

3-9.9.1 Control Requirements.

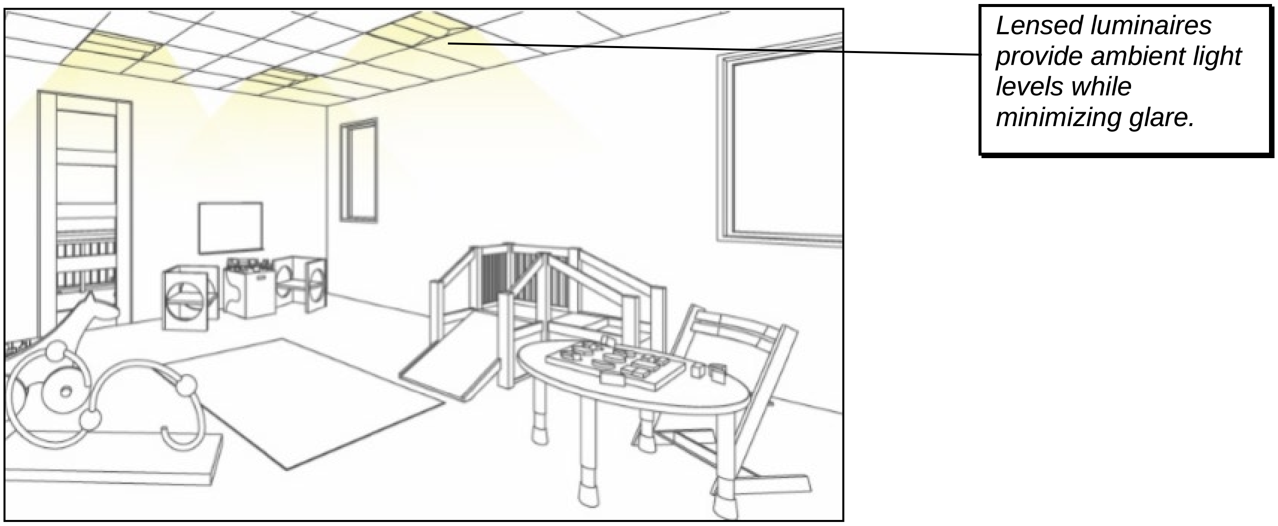
Manual Control	At least one wallbox switch or scene wallstation
Occupancy/Vacancy	Manual ON Automatic full OFF after 10 minutes of vacancy
Time Schedule	None
Daylight	None
Zoning	None

3-9.9.2 Performance Requirements.

Target Criteria	**Daytime/Nighttime**
Average Horizontal Illuminance	20 fc (200 lux) at 3’-0” (914 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-10 CHILDCARE SPACES.

3-10.1 Daycare Indoor Play Areas.



3-10.1.1 Control Requirements.

Manual Control	Scene wallstation with at least one preset scene with all lights dimmed between 30% and 50% of full lighting power OR One wallbox dimmer per luminaire type
Occupancy/Vacancy	Manual ON Automatically dimmed by at least 50% after 20 minutes of vacancy
Time Schedule	Scheduled shutoff for all lights in the space when the building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	None

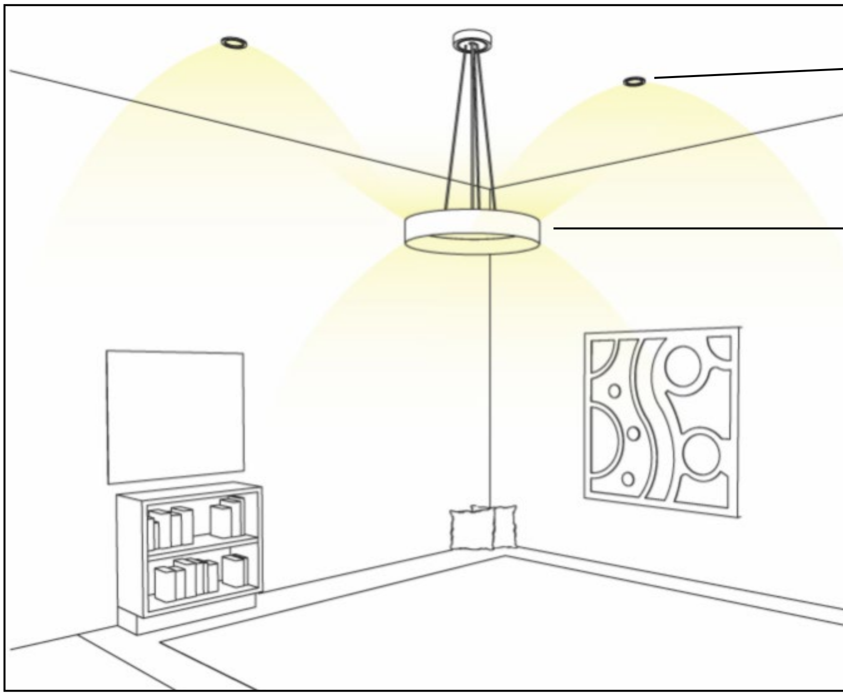
3-10.1.2 Performance Requirements.

Target Criteria	Daytime/Nighttime
Average Horizontal Illuminance	30 fc (300 lux) at 2'-0" (910 mm) AFF
Horizontal Illuminance Uniformity	3:1 average to minimum

3-10.1.3 Critical Design Issues.

- Light room surfaces to balance luminance ratios.
- Provide wall sconces to add decorative interest and illuminate wall surfaces.
- Refer to UFC 4-740-14 and FC 4-740-14N for additional requirements and considerations regarding child development centers.

3-10.2 Daycare Indoor Rest Areas.



Neutral surface mounted or recessed downlights for ambient illumination and cleaning.

Suspended luminaire lowers the "perceived ceiling" and helps to create a space within a larger space.

3-10.2.1 Control Requirements.

Manual Control	Scene wallstation with continuous dimming and preset scene for rest time
Occupancy/Vacancy	Manual ON Automatically dimmed by at least 50% after 20 minutes of vacancy
Time Schedule	Scheduled shutoff for all lights in the space when the building is scheduled to be vacant unless occupants enter the building, then use Manual Control and Occupancy/Vacancy sensor criteria.
Daylight	Automatic responsive daylight dimming when daylight is present
Zoning	None

3-10.2.2 Performance Requirements.

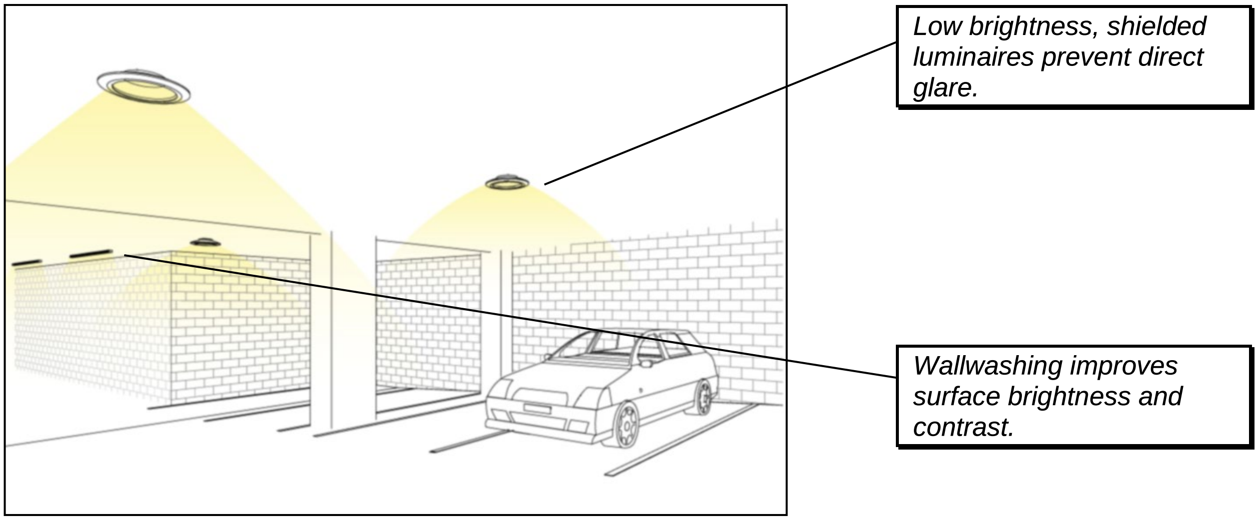
Target Criteria	**Daytime/Nighttime**
Minimum Horizontal Illuminance	1 fc (10 lux) at 2'-0" (910 mm) AFF (at all times)
Maximum Horizontal Illuminance	5 fc (50 lux) at 2'-0" (910 mm) AFF (during rest time)
Average Horizontal Illuminance	20 fc (200 lux) at 2'-0" (910 mm) AFF (outside of rest time)

3-10.2.3 Critical Design Issues.

- Provide dimmable lighting zones to reduce light levels during rest periods.
- Use dim-to-warm LED light sources to provide a warm CCT suitable for areas of rest.
- Provide layout of ambient lighting for cleaning.
- Refer to UFC 4-740-14 and FC 4-740-14N for additional requirements and considerations regarding child development centers.

3-11 PARKING.

3-11.1 Parking Structures.



3-11.1.1 Control Requirements.

Manual Control	None
Occupancy/Vacancy	Automatic ON with detected motion Automatically dimmed by at least 50% after 20 minutes of vacancy
Time Schedule	Scheduled shutoff for all lights in the space when the space is scheduled to be vacant
Daylight	Automatic reduction of daylight transition lighting to general light levels from Sunset to Sunrise Responsive continuous daylight dimming of luminaires within 20 feet of large perimeter wall openings
Zoning	Zones must be 3,600 square feet or less

3-11.1.2 Performance Requirements.

Target Criteria	Daytime	Nighttime
Minimum Horizontal Illuminance, General areas, active	1 fc (10 lux) at floor	1 fc (10 lux) at floor
Minimum Vertical Illuminance, General areas, active	0.5 fc (5 lux) at 5’-0” (1524mm) AFF	0.5 fc (5 lux) at 5’-0” (1524 mm) AFF
Minimum Horizontal Illuminance, General areas, inactive	0.2 fc (2 lux) at floor	0.2 fc (2 lux) at floor
Minimum Vertical Illuminance, General areas, inactive	0.1 fc (1 lux) at 5’-0” (1524 mm) AFF	0.1 fc (1 lux) at 5’-0” (1524 mm) AFF
Minimum Horizontal Illuminance, Vehicular entries and exit	50 fc (500 lux) at floor	1 fc (10 lux) at floor
Minimum Vertical Illuminance, Vehicular entries and exit	25 fc (250 lux) at 5’-0” (1524 mm) AFF	0.5 fc (5 lux) at 5’-0” (1524 mm) AFF
Minimum Horizontal Illuminance, Stairway	10 fc (100 lux) at walking surface	10 fc (100 lux) at walking surface
Minimum Vertical Illuminance, Stairway	25 fc (250 lux) at 5’-0” (1524 mm) AFF	1.2 fc (12.5 lux) at 5’-0” (1524 mm) AFF
Horizontal and Vertical Illuminance Uniformity	10:1 maximum to minimum	

3-11.1.3 Critical Design Issues.

- Provide daylight transition lighting at parking structure entrances.
- Stairs not on path of egress should use IES light levels in RP-8.

.

This Page Intentionally Left Blank

CHAPTER 4 EXTERIOR LIGHTING

4-1 PRIORITIES FOR EXTERIOR LIGHTING SYSTEMS.

Design exterior lighting systems to minimize energy consumption, reduce maintenance costs, improve lighting quality on DoD Installations, at the lowest life cycle cost.

4-1.1 Energy Reduction.

Provide SSL/LED systems for all exterior lighting. SSL/LED systems are established technologies for exterior lighting applications that have been proven to save energy over traditional light sources.

Minimize energy consumption by providing energy efficient technologies, maintaining effective luminance and illuminance levels, and implementing control strategies. Maintain illumination level prescribed averages as closely as possible, in order to provide sufficient light levels without contributing to excessive energy usage.

4-1.2 Maintenance Reduction.

Reduce maintenance by technology selection, reducing equipment quantities, and implementing controls strategies.

Select light sources, drivers, and controls that are rated and warranted for long useful lives to increase the amount of time between maintenance cycles. Match light sources in adjacent areas when appropriate.

4-1.3 Luminaire Placement.

Locate luminaires to reduce impact to adjacent properties. This is particularly important when lighting areas adjacent to residential neighborhoods and environmentally sensitive areas, including waterways.

4-1.4 Lighting Quality.

Apply the following to ensure the priority of lighting quality is achieved.

4-1.4.1 Direct Glare.

Avoid direct glare from luminaires and excessive contrast of surfaces. Use shielded light sources and as low a lumen output as possible. When using ANSI/IES TM-15 BUG ratings, a low ‘G’ rating would provide reduced glare.

4-1.4.2 Light Pollution / Trespass.

Use ANSI/IES TM-15 U0 luminaires to eliminate direct light above the horizontal plane. Refer to maximum allowable uplight (U) and backlight (B) ratings in specific lighting zones.

4-1.4.3 Modeling of Faces and Objects.

Provide light from multiple directions to accurately render objects and people.

4-1.4.4 Reflected Glare.

Select and locate luminaires to minimize wet surface reflected glare and polished surface reflection of a light source.

4-1.4.5 Shadows.

Locate poles such that the light from the luminaires minimizes shadows that could conceal potential hazards.

4-1.4.6 Vertical Illuminance.

Provide vertical illuminance on individuals' faces as well as potential hazards.

4-1.4.7 Appearance of Space and Luminaires.

Carefully select luminaires to match the aesthetic character of the building and contribute to a welcome designation to the building entry. Refer to the base-wide architectural plan to consolidate luminaire types.

4-1.4.8 Light Distribution on Surfaces.

Illuminate the walkway uniformly to avoid dark patches.

4-1.4.9 Point(s) of Interest.

Provide lighting for wayfinding and indicate points of interests, such as the building entry.

4-2 EXTERIOR LIGHTING EQUIPMENT.

4-2.1 Light Source Technology.

Provide SSL/LED systems unless there is no equivalent SSL/LED product for the application. If another light source other than SSL/LED is specified, provide documentation regarding the selection of that light source in the project's Basis of Design.

4-2.1.1 SSL/LED Light Sources.

Provide light sources with a CCT of no greater than 3000 K as stated on the manufacturer's specification information to reduce skyglow in exterior applications and minimize impact to human and animal circadian rhythms.[3 & 4] Use monochromatic amber LEDs in place of low pressure sodium (LPS) for sensitive environments such as wildlife habitat, wildlife nesting, or to meet dark sky requirements (observatories). Incorporate Fish and Wildlife, State, and local governing authority recommendations for lighting systems design and installation.

4-2.1.2 CCT and CRI.

Use a color rendering index (CRI) of no less than 70 for exterior applications. In some applications, where motorists' vision is of high importance, such as areas with high speeds and high vehicle conflicts, a CCT of 4000 K may be used.

4-2.1.3 SSL/LED Drivers.

Provide lighting systems with accessible and replaceable drivers. For current and future dimming requirements (smart grid, curfew, adaptive), use dimmable drivers compatible with standard dimming control circuit of 0-10V or DALI. Other dimming protocols must comply with cybersecurity requirements.

4-2.2 Surge Protection.

Provide MOV type surge protection devices at panelboards for all circuits feeding exterior lighting systems. LED luminaires require integral metal oxide varistors (MOV) type surge protection device with elevated 10-kVA surge protection.

4-2.3 Over Current Protection Device.

Provide in-line fuse in pole base or splice box for street and area lights.

4-2.4 Poles.

Do not use square poles. Provide compatible poles with all pole-mounted luminaires. Provide breakaway bases for poles adjacent to vehicle traffic in accordance with the American Association of State Highway and Transportation Officials (AASHTO) GL-6. Non-breakaway poles must be protected by a barrier or be barrier-mounted.

4-3 EXTERIOR LIGHTING CONTROLS.

Refer to CHAPTER 5 for control requirements specific to common applications. Refer to ANSI/IES LP-6 for additional considerations for lighting control systems, and ANSI/IES LP-8 for commission guidance for specific applications.

---

[3] IES TM-12-12, Lamp Spectral Effects at Mesopic Lighting Levels. The Illuminating Engineering Society. New York, NY.
[4] IES TM-18-18, Light and Human Health. The Illuminating Engineering Society, New York, NY.

4-3.1 Control Strategies.

Indicate in the contract documents the control strategy for each area type in accordance with required strategies in CHAPTER 5.

4-3.1.1 Manual Control.

The lights are manually turned on and manually turned off. This approach can only be used when other control strategies cannot be implemented due to operational requirements.

4-3.1.2 Motion Sensing.

Upon sensing vacancy, the lights dim to 30% of full light output. Do not provide motion sensing that fully turns off all lighting within a control zone.

4-3.1.3 Time Schedule.

Time scheduling controls the light based on a preset schedule. This is most beneficial when lights are controlled based on business hours. Time scheduling may be used in place of photosensing, for turning lights on when there is no longer sufficient daylight, and for turning lights off during hours of daylight. Use an astronomical timeclock when controlling exterior lighting using this method to ensure the schedule adjusts as sunrise and sunset shifts throughout the year.

When using time scheduled controls that are based on operating business hours, provide at least 15 minutes of luminaire operation before business open, when before dawn, and at least 15 minutes of luminaire operation after business close, when after dusk. Do not use time scheduled controls to completely turn off exterior lighting if occupants regularly occupy the building after officially scheduled hours.

4-3.1.4 Photosensing.

Photosensing measures the amount of daylight currently available and controls luminaires according to this. Typically, at sunset or shortly after, the lights automatically turn on. At sunrise or shortly before, the lights automatically turn off. Photocells may be located on each luminaire individually or located at the lighting control center. Photocells are typically used for exterior lighting systems that are not connected to a building lighting control system.

Provide photosensors with zero-cross technology to withstand severe in-rush current and extend relay life.

4-3.1.5 Zoning.

Provide separate control circuits for each luminaire application. For example, area lights may be on the same control circuit. However, area lights and step lights should not be on the same control circuit. Provide separate control zones for each use area.

4-3.2 Wireless Networks.

Coordinate wireless networks with base spectrum manager prior to specification in case of restrictions for wireless usage within the installation.

4-3.3 Control Equipment.

Provide lighting control equipment capable of meeting the strategies described in the contract documents. Control equipment must be designed to control the specific light sources and luminaires specified for each application. Provide photocells which meet elevated 10-kV/10-VA requirements per IEEE designed to operate exterior LED luminaires in order to eliminate inrush current system malfunction.

4-3.3.1 Multi-pin Receptacle.

Provide streetlights and parking lot lighting that are installed with an ANSI C136.41 seven-pin receptacle which accepts a standard three-pin photocell or shorting cap. This allows streetlights and parking lot lighting to be connected to a wireless control system in the future, since many wireless control system nodes are compatible with seven-pin receptacles.

4-4 EXTERIOR LIGHTING ZONES.

Lighting zones reflect the base (or ambient) light levels desired for an area. Adopt the lowest possible lighting zone. Lighting zones are best implemented as an overlay to the established zoning especially on installations where a variety of zone districts exist within a defined area or along an arterial street. Where zone districts are cohesive, it may be possible to assign lighting zones to established land use zoning. It is recommended that the lighting zone includes churches, schools, parks, and other uses embedded within residential communities or to any land assigned to a lower zone.

For DoD installations, it is important to consider all activities of an area's land use. Lighting zones must consider the surrounding areas as well. For example, adjacent lighting zones must not hinder nighttime operations. Additionally, outside the United States and its territories, it is important that the installation does not stand out as an exceptionally bright area compared to the adjacent development. Figure 4-1 and Table 4-1 show examples of how lighting zones from the IDA-IES *Model Lighting Ordinance* may be applied to DoD installations.

Figure 4-1 Example Lighting Zones on a Sample Installation

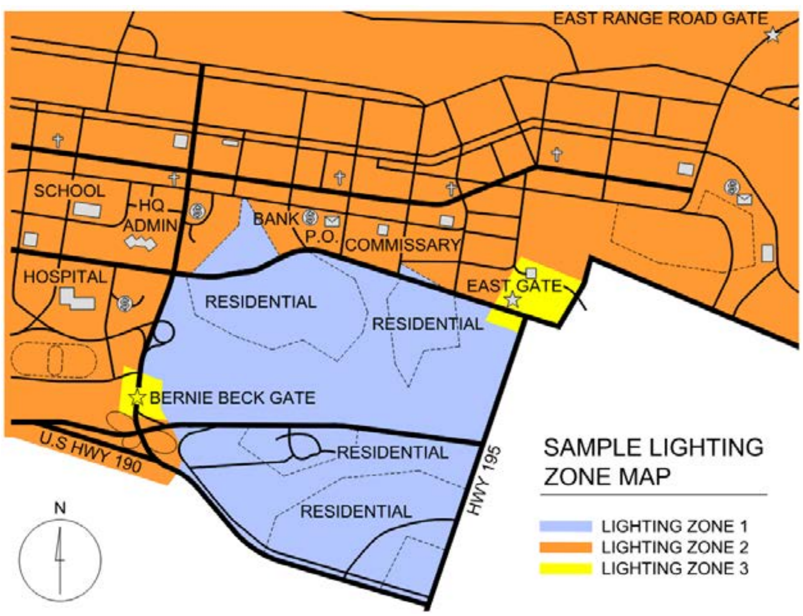


Table 4-1 Lighting Zones and DoD Applications.

MLO Lighting Zones	**Title**	**DoD Installation/Application**	
LZ0	No Ambient Lighting	**Training areas** Night vision training areas, endangered waterfront areas and other areas where there is expected no nighttime activity.	INCREASING NIGHTTIME ACTIVITY
LZ1	Low Ambient Lighting	**Personnel Support Districts** Unaccompanied quarters, single and multi-family residential, campgrounds, administration, and other non-nighttime use areas, golf course, exercise fields and paths **Airfield** (Nearby facilities may be higher zone)	
LZ2	Moderate Ambient Lighting	**Waterfront or Airfield Facilities** Administrative areas, common areas, service areas, parking. **Training Facilities** Academic instruction, educational services, applied instruction, reserve training, operational simulators **Administrative Facilities** Offices, conference centers, command centers, parking **Personnel Support Districts** Officer clubs, lodge, food service, fire and security, ITT, medical and dental clinics, family services, schools, childcare facilities, youth programs, religious facilities, banks, exchange, commissary, libraries, morale, welfare and recreation, hobby shops, theaters, gyms indoor sport facilities, outdoor pools, sports (tennis, basketball) courts, baseball and football fields **Industrial Facilities** Shipyards, ordinance handling/storage, manufacturing facilities, maintenance shops, depots	
LZ3	Moderately High Ambient Lighting	**Waterfront Facilities** Wharf and pier areas **Airfield Facilities** Aircraft hangars, air operations and headquarters, line shacks, terminal facilities, training areas, utility service areas **Entry Control Facilities** **Access Control Points**	
LZ4	High Ambient Lighting	No areas qualify for this lighting zone.	

4-5 ELECTRICAL ENERGY MONITORING.

For new construction buildings greater than 25,000 SF (2,322 m^2), terminate exterior lighting branch circuits in dedicated lighting panelboards. Provide metering requirements as required by UFC 1-200-02.

4-6 SOLAR LIGHTS.

Solar lights are permitted for use when:

- Electric utility services do not exist in the desired location of lighting.
- Centralized solar panels can be deployed to provide power to the lights.
- Sufficient battery capacity is provided to meet illumination requirements.
- Used with curfew controls to maximize battery life.

Solar lights are not permitted for use for security lighting or safety applications.

4-7 LIGHTING SYSTEM ALTERATIONS.

4-7.1 Types of Lighting System Alterations.

4-7.1.1 Redesign.

Redesign includes new luminaires, circuits, and controls designed to meet current lighting criteria. A new design must ensure reduced energy consumption, reduced maintenance, and lighting quality is improved at the lowest life cycle cost. Lighting redesign is required when a renovation involves changing lighting technologies such as fluorescent to LED and when renovation involves changing lighting with more efficient lighting within the same technology. Redesign lighting systems when existing:

- Illuminance levels are too low or too high
- Lighting produces glare
- Luminaire layout produces non-uniform illumination
- Luminaires are in poor condition
- Lighting control systems are inadequate
- Luminaires (or luminaire layout) is not appropriate because the physical layout of the area has changed

4-7.1.2 One-for-One Luminaire Replacement.

A luminaire replacement consists of the entire luminaire being replaced, including the housing. A luminaire replacement may be considered when the lighting design is sufficient, but more efficient luminaires are available. In instances where the existing luminaire is operating under dimming control, the lighting controls must be upgraded to be compatible with the operating characteristics of the replacement luminaire. Luminaire replacement is only acceptable when the resulting illuminance levels, glare, and distribution meet the current criteria.

4-7.1.2.1 Pole Modifications.

SSL/LED luminaire replacements have a different weight and Effective Projected Area than legacy luminaires, which impacts the structural performance of the pole. Most frequently, a reduction in weight at the top of the pole increases wind-induced vibration or pole galloping. Impact dampers reduce this phenomenon. Design and implementation of impact dampers must be coordinated with pole manufacturer or structural engineer.

4-7.1.2.2 Control Equipment Modifications.

Provide upgraded photocell replacements for all SSL/LED luminaire replacements that are controlled by photocell. Provide photocells which meet elevated 10 kV/10-VA requirements per IEEE designed to operate exterior LED luminaires in order to eliminate inrush current system malfunction.

4-7.1.3 Light Source Retrofit.

A light source retrofit is the replacement of the light source within the luminaire housing or the lighting module that has been designed to be installed in existing luminaire enclosures.

Do not use LED retrofit light sources or LED lighting modules that have been designed and constructed to be installed in existing HID, mercury vapor, or linear fluorescent luminaire enclosures. LED retrofits are only approved for replacement of CFL or incandescent sources (A-lamp replacements) with Edison bases.

4-8 SITE DESIGN COORDINATION.

Coordinate the design, luminaire selection, and placement with the location of trees, shrubs, and other site furnishing.

4-9 AIRFIELDS.

UFC 3-260-01 limits light emissions – either directly or indirectly (reflected) – that may interfere with pilot vision in runway clear zones. Exterior lighting must meet all FAA and airfield operational regulations. These regulations restrict the height, location, and technology of lighting located near airfields. Certain light sources may also interfere with night vision technologies. Obtain approval of lighting from installation's airfield safety office.

Use luminaires with a U0 rating to reduce glare and uplight which may affect airfield operations. If U0 rated luminaires are unable to satisfy lighting levels and performance criteria, utilize interior and external shielding to minimize glare and uplight. Do not exceed a glare rating of G2. Refer to UFC 3-535-01 for additional information.

CHAPTER 5 EXTERIOR LIGHTING APPLICATIONS

5-1 INTRODUCTION.

This chapter identifies typical exterior facility applications. Each application details a conceptual lighting design example. Designs must meet the lighting performance and controls requirements defined in the application details.

5-2 CALCULATIONS OF LIGHTING FOR EXTERIOR AREAS.

Computer-generated photometric plans for each area are required to verify proposed luminaires and locations meet the required performance criteria of the design using the applicable light loss factor (LLF).

Target illumination levels are provided for each Exterior Application. Depending on the application and the recommendations provided by the IES, values are given as one of the following:

- Minimum: No values anywhere on the calculation grid may be less than this value, within a 10% margin of error.
- Minimum Average: An average, taken over the entire task area for the application, may not be less than this value, within a 10% margin of error.
- Maximum: No values anywhere on the calculation grid may be greater than this value, within a 10% margin of error.
- Maximum Average: An average, taken over the entire task area for the application, may not be greater than this value, within a 10% margin of error.
- Uniformity: Unless otherwise noted, uniformity is calculated as a ratio of the average calculated illuminance over the minimum calculated illuminance of the calculation grid.

5-2.1 Schematic and Concept Design.

For Schematic and concept design phases prior to 60%, provide narrative indicating the following:

- When listing target criteria, include lighting zone in basis of design.
- Average maintained illuminance (or luminance for roadways) level.
- Lighting power density (watts per square foot or per square meter).

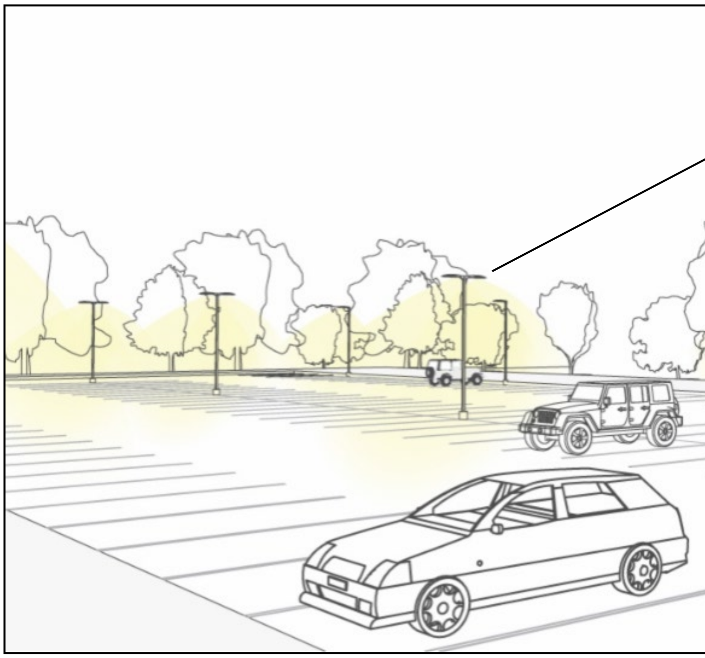
5-2.2 Designs submitted at 60% or later.

For designs submitted at 60% or later, provide photometric plan calculations to include the following:

- The point spacing of the calculation grid of horizontal illuminance (or luminance for roadways) measurements at finished grade, are to be 1/3 of the luminaire mounting height taken across the general area.
- Where applicable, vertical illuminance measurements at designated surface, taken at a maximum of every one foot (305 mm) across task area.
- Minimum and maximum illuminance (or luminance for roadways) levels.
- Average maintained illuminance (or luminance for roadways) level.
- Average to minimum and maximum to minimum ratios for horizontal illuminance (or luminance for roadways).
- Lighting power density (watts per square foot or per square meter).

5-3 PARKING FACILITIES.

5-3.1 Parking Lots.



Pole mounted luminaires with U0 rating control glare and reduce light pollution and trespass.

Spacing of luminaires provides uniform horizontal illuminance in parking areas.

5-3.1.1 Control Requirements.

Manual Control	None
Motion Sensing	None
Time Schedule	Automatic dimming to 30% within 15 minutes after business close and automatic full ON within 15 minutes before business open Astronomical timeclock ON at dusk and OFF at dawn, if not using photosensing
Photosensing	ON and OFF based on daylight availability, if not using astronomical timeclock
Zoning	None

5-3.1.2 Performance Requirements.

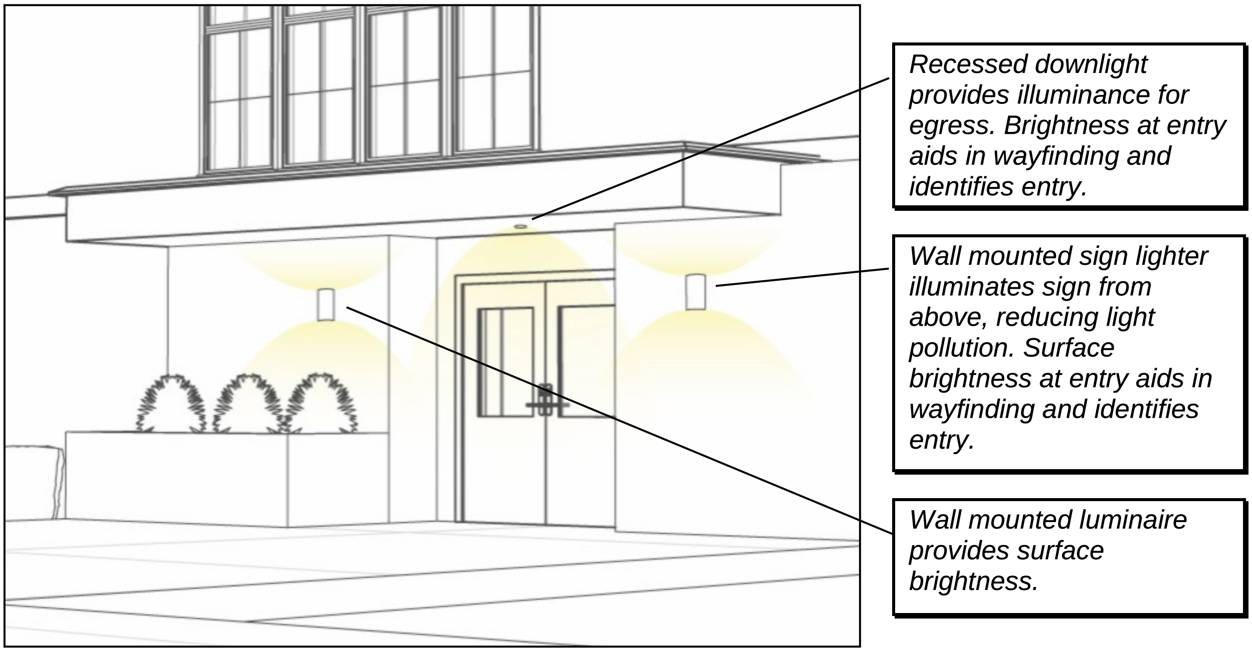
Target Criteria	All Lighting Zones
Minimum Horizontal Illuminance	0.2 (2 lux) at grade
Minimum Vertical Illuminance in center of drive lane, in direction of traffic flow	0.1 (1 lux) at 5’-0” (1524 mm) AFF
Horizontal Illuminance Uniformity	20:1 maximum to minimum

5-3.1.3 Critical Design Issues.

- Provide no greater than G2 and U0 rated luminaires with low lumen output to minimize glare and light pollution.
- Provide Type V distributions for luminaires within the center of parking areas. Use Type III and IV distributions along the perimeters to minimize light trespass on a neighboring property or building unless luminaires are intended to illuminate adjacent property or building.
- Use photocells specifically designed to operate SSL/LED lighting.
- Use an ANSI 7-pin photocell receptacle.

5-4 BUILDING LIGHTING.

5-4.1 Primary Entrances.



5-4.1.1 Control Requirements.

Manual Control	None
Motion Sensing	Automatically dim lights to 30% after 10 minutes of no detected motion
Time Schedule	Automatic dimming to 30% within 1 hour after business close and automatic full ON within 1 hour before business open Astronomical timeclock ON at dusk and OFF at dawn, if not using photosensing
Photosensing	ON and OFF based on daylight availability, if not using astronomical timeclock
Zoning	None

5-4.1.2 Performance Requirements.

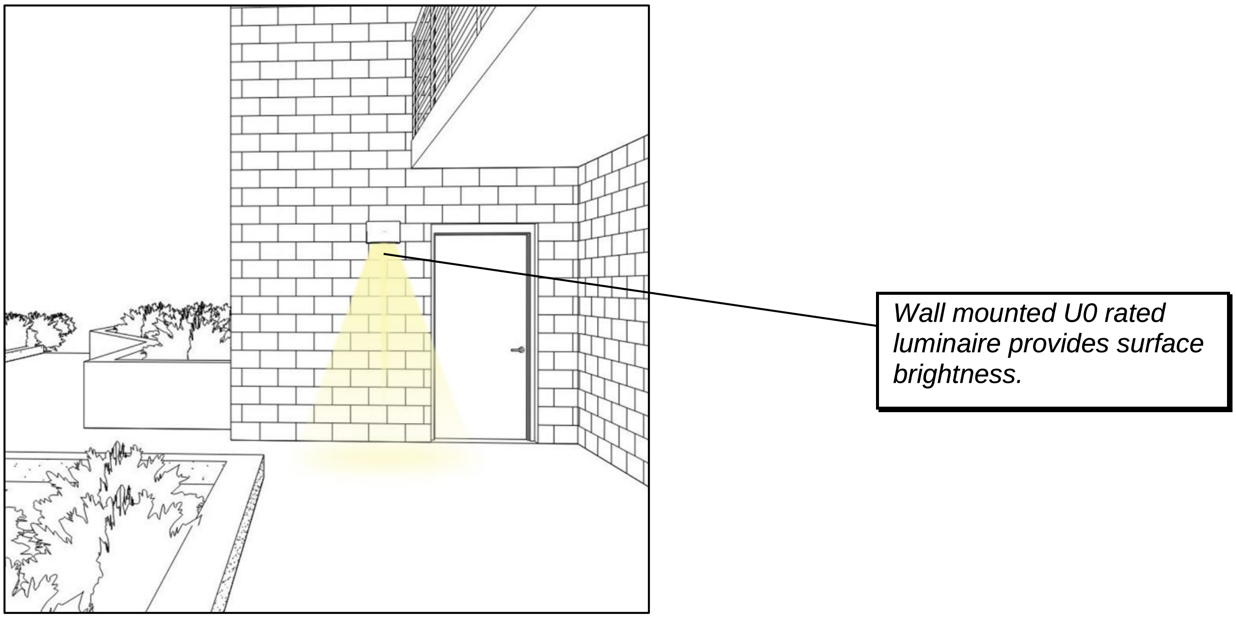
	LZ1 Low ambient	**LZ2 Moderate ambient**	**LZ3 Moderately high ambient**
Average Horizontal Illuminance	1 fc (10 lux) at grade*	Between 1 fc (10 lux) and 2 fc (20 lux) at grade	Between 2 fc (20 lux) and 4 fc (40 lux) at grade
Uniformity	5:1 average to minimum		

*If exit is in path of egress, meet LZ2 criteria.

5-4.1.3 Critical Design Issues.

- Select luminaires to match the aesthetic character of the building and contribute to a welcome designation to the building entry.
- Comply with NFPA 101 lighting requirements for each exit discharge.
- All luminaires must use shielded optics and/or low lumen light sources to minimize glare and light pollution.
- Select and locate lighting to eliminate shadows near entries and provide wayfinding.
- Exterior building mounted luminaires are to match the aesthetic design of the building.
- Luminaires may remain on to assist with building security and law enforcement.

5-4.2 Exits.



5-4.2.1 Control Requirements.

Manual Control	None
Motion Sensing	Automatically dim lights to 30% after 10 minutes of no detected motion
Time Schedule	Automatic full OFF within 1 hour after business close and automatic full ON within 1 hour before business open Astronomical timeclock ON at dusk and OFF at dawn, if not using photosensing
Photosensing	ON and OFF based on daylight availability, if not using astronomical timeclock
Zoning	None

5-4.2.2 Performance Requirements.

	LZ1 Low ambient	**LZ2 Moderate ambient**	**LZ3 Moderately high ambient**
Average Horizontal Illuminance	Between 0.5 fc (5 lux) and 2 fc (20 lux)* at grade	Between 1 fc (10 lux) and 3 fc (30 lux) at grade	Between 1 fc (10 lux) and 5 fc (50 lux) at grade
Uniformity	5:1 average to minimum		

*If exit is in path of egress, meet LZ2 criteria.

5-4.2.3 Critical Design Issues.

- Select luminaires to match the aesthetic character of the building.
- Comply with NFPA 101 lighting requirements for each exit discharge.
- All luminaires must use shielded optics and/or low lumen light sources to minimize glare and light pollution.
- Luminaires may remain on to assist with building security and law enforcement.

5-4.3 Housing Areas.

The use of U0 rated wall mounted luminaires, area lights, and downlighting on the façade (rather than uplighting) minimizes light pollution.

5-4.3.1 Control Requirements.

Manual Control	Wall-mounted LED luminaires at individual unit entries and patios are controlled by local control within the housing unit.
Motion Sensing	For lighting not at individual unit entries: Automatically dim lights to 30% after 15 minutes of no detected motion
Time Schedule	For lighting not at individual unit entries: Astronomical timeclock ON at dusk and OFF at dawn, if not using photosensing
Photosensing	For lighting not at individual unit entries: ON and OFF based on daylight availability, if not using astronomical timeclock
Zoning	Zone building-mounted lighting separately from site area lighting

5-4.3.2 Performance Requirements.

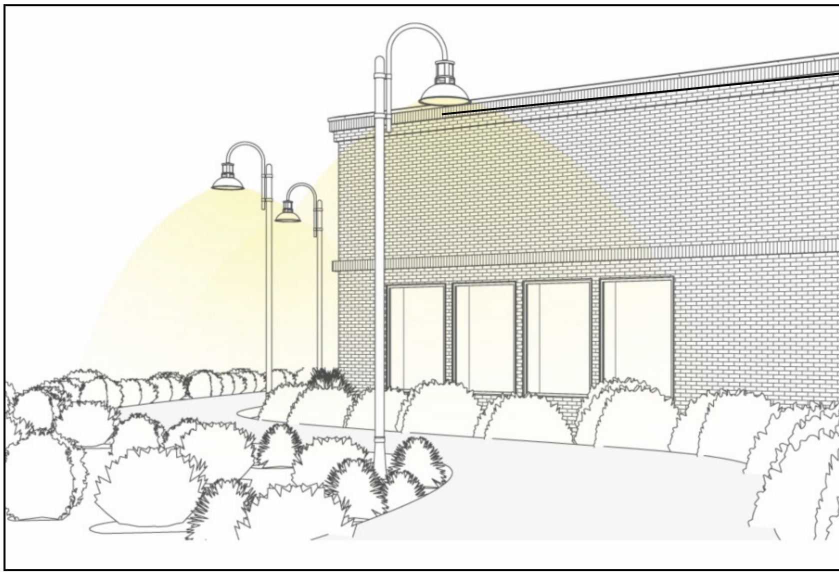
See requirements for Building Entries.

5-4.3.3 Critical Design Issues.

- Use U0 or U1 rated luminaires.
- Use G0 or G1 rated luminaires
- All luminaires must use shielded optics and/or low lumen light sources to minimize glare and light pollution.
- In locations underneath covered balcony or walkway, utilize indirect lighting solutions to provide vertical illumination of surfaces and occupants passing through the space.

5-5 PEDESTRIAN AREAS.

5-5.1 Walkways.



Luminaires with low lumen output reduce direct glare and provide adequate vertical illuminance while minimizing light pollution and trespass.

5-5.1.1 Control Requirements.

Manual Control	None
Motion Sensing	Automatically dim lights to 30% after 15 minutes of no detected motion
Time Schedule	Astronomical timeclock ON at dusk and OFF at dawn, if not using photosensing
Photosensing	ON and OFF based on daylight availability, if not using astronomical timeclock
Zoning	None

5-5.1.2 Performance Requirements.

	LZ1 Low ambient	**LZ2 Moderate ambient**	**LZ3 Moderately high ambient**
Average Horizontal Illuminance, adjacent to landscape	Between 0.2 fc (2 lux) and 0.4 fc (4 lux) at grade	Between 0.4 fc (4 lux) and 0.8 fc (8 lux) at grade	Between 0.5 fc (5 lux) and 1.5 fc (15 lux) at grade
Average Horizontal Illuminance, adjacent to architecture, exits, hardscapes, and waterfronts	Between 0.5 fc (5 lux) and 1.0 fc (10 lux) at grade	Between 1 fc (10 lux) and 2 fc (20 lux) at grade	Between 1 fc (10 lux) and 3 fc (30 lux) at grade
Uniformity	10:1 average to minimum		

5-5.1.3 Critical Design Issues.

- Match aesthetics of decorative poles to that of adjacent buildings.
- All luminaires must be U0 or U1 and must use shielded optics, such as a lens or louver.
- Use G0 or G1 low wattage light sources to minimize glare and light pollution.
- Place poles at potential conflict locations, such as intersections.

5-5.2 Plazas.

5-5.2.1 Control Requirements.

Manual Control	None
Motion Sensing	Automatically dim lights to 30% after 15 minutes of no detected motion
Time Schedule	Astronomical timeclock ON at dusk and OFF at dawn, if not using photosensing When associated with business, automatic full OFF within 1 hour after business close and automatic full ON within 1 hour before business open For landscape and façade lighting, automatically turn OFF the lighting at midnight or close of business (whichever is later)
Photosensing	ON and OFF based on daylight availability, if not using astronomical timeclock
Zoning	Provide separate control for each luminaire type

5-5.2.2 Performance Requirements.

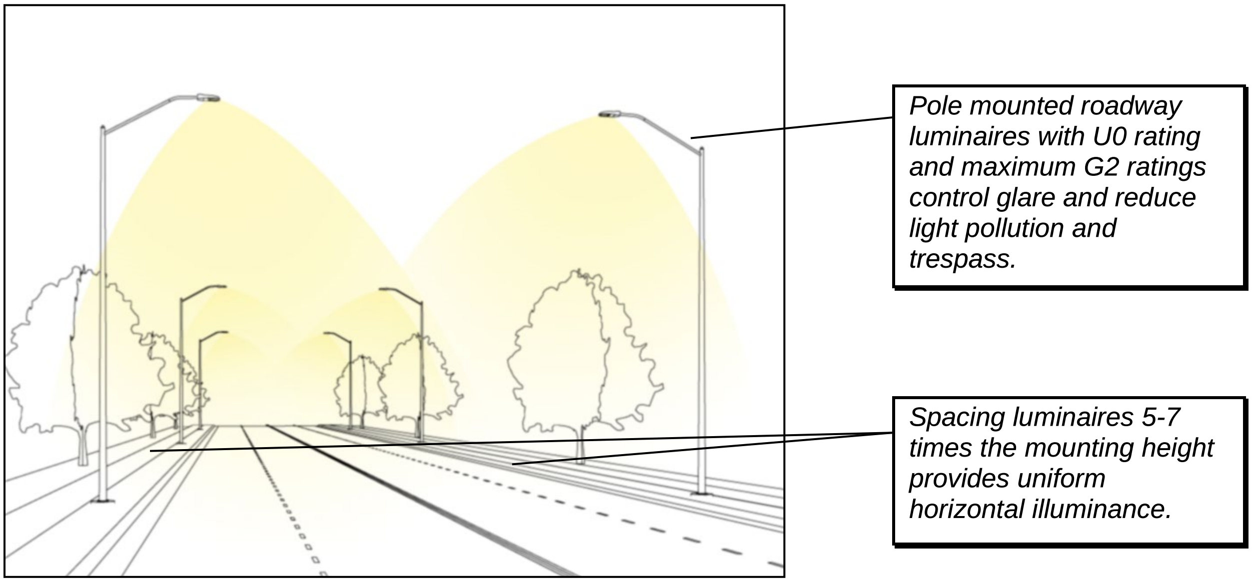
	LZ1 Low ambient	**LZ2 Moderate ambient**	**LZ3 Moderately high ambient**
Average Horizontal Illuminance	Between 0.5 fc (5 lux) and 1.0 fc (10 lux) at grade	Between 1 fc (10 lux) and 2 fc (20 lux) at grade	Between 1 fc (10 lux) and 3 fc (30 lux) at grade
Uniformity	10:1 average to minimum		

5-5.2.3 Critical Design Issues.

- Use U0 or U1 rated luminaires.
- Use G0 or G1 rated luminaires.

5-6 VEHICLE TRAFFIC AREAS.

5-6.1 Roadways and Streets.



5-6.1.1 Control Requirements.

Manual Control	None
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability
Zoning	None

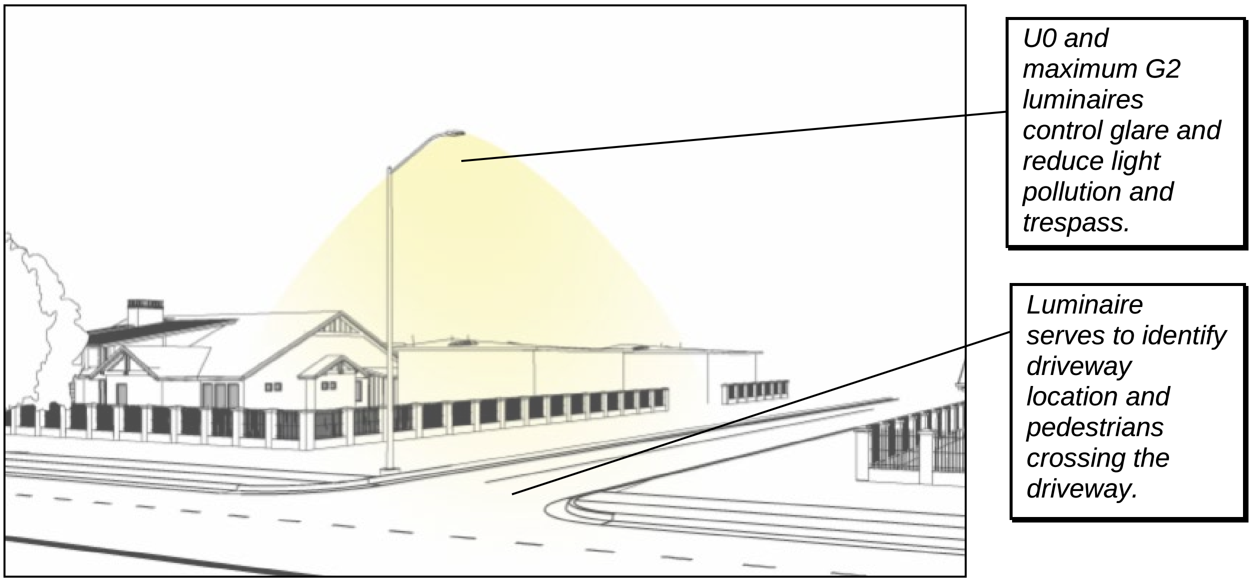
5-6.1.2 Performance Requirements.

Target Criteria	**All Lighting Zones**
Average Horizontal Luminance	ANSI/IES RP-8, *Recommended Practice: Lighting Roadway and Parking Facilities*
Uniformity (Average to Minimum)	

5-6.1.3 Critical Design Issues.

- Use U0 and maximum G2 luminaires to minimize glare and reduce light pollution.
- Locate poles in an opposite pattern versus a staggered pattern to increase visibility.
- Provide luminaires and poles to match installation standard.
- Use photocells specifically designed to operate SSL/LED lighting.
- Use an ANSI 7-pin photocell receptacle.
- Use breakaway bases in accordance with AASHTO GL-6 unless there are sidewalks adjacent to the street where pedestrians could be present.
- Follow ANSI/IES RP-8, Recommended Practice: Lighting Roadway and Parking Facilities for crosswalks located on roadways.

5-6.2 Driveways.



5-6.2.1 Control Requirements.

Manual Control	None
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability
Zoning	None

5-6.2.2 Performance Requirements.

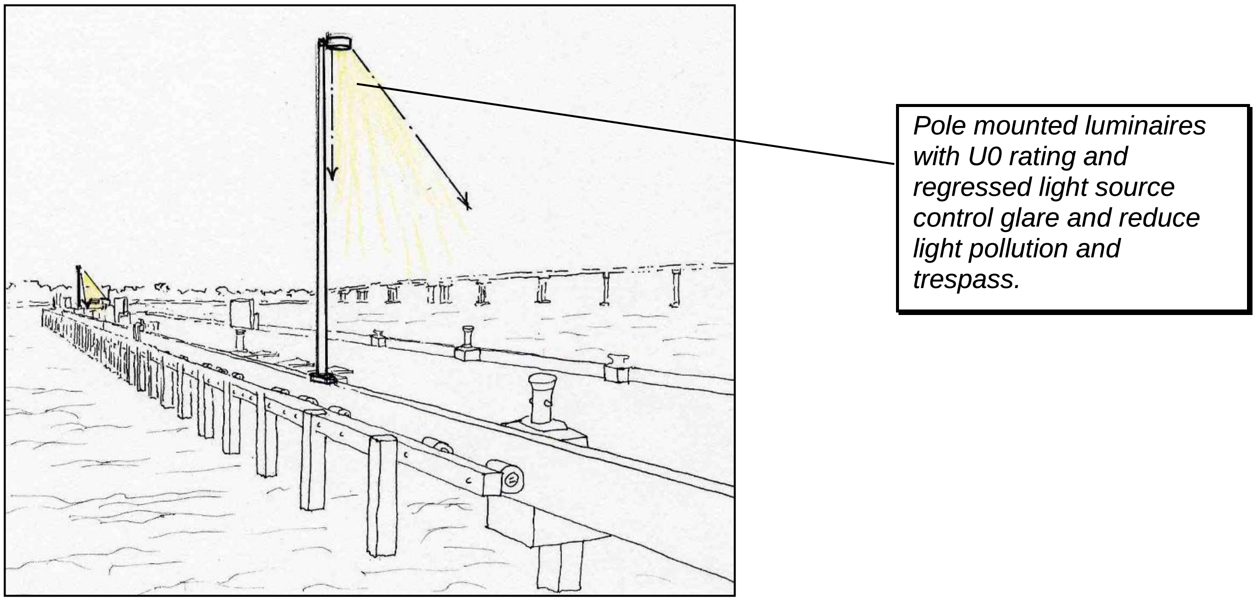
Install one pole mounted, U0 and maximum G2 rated roadway luminaire at the entrance to the driveway. Applies to all lighting zones.

5-6.2.3 Critical Design Issues.

- Use U0 and maximum G2 luminaires to minimize glare and reduce light pollution.
- Use photocells specifically designed to operate SSL/LED lighting.
- Use an ANSI 7-pin photocell receptacle.

5-7 OUTDOOR ACTIVIY AREAS.

5-7.1 Marinas.



5-7.1.1 Control Requirements.

Manual Control	None
Motion Sensing	Automatically dim lights to 30% after 10 minutes of no detected motion, if not dimming by Time Schedule
Time Schedule	Automatic dimming to 30% within 1 hour of business close and automatic full ON within 1 hour of business open, if not utilizing motion sensing Astronomical timeclock ON at dusk and OFF at dawn, if not using photosensing
Photosensing	ON and OFF based on daylight availability, if not using astronomical timeclock
Zoning	None

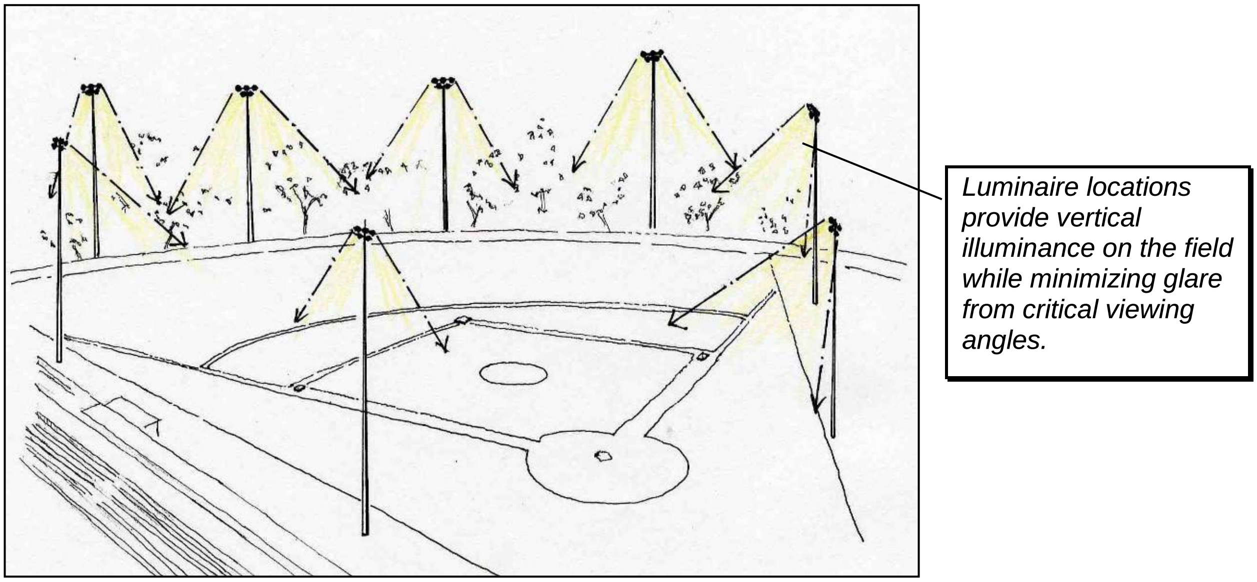
5-7.1.2 Performance Requirements.

Target Criteria	All Lighting Zones
Average Horizontal Illuminance	0.5 fc (5 lux) at grade

5-7.1.3 Critical Design Issues.

- Use U0 luminaires to minimize glare and to reduce light pollution. Use luminaires with regressed lenses to reduce glare, especially in environmentally sensitive areas.
- Use G0 or G1 rated luminaires
- Use luminaires with appropriate light distributions to eliminate light reflecting off of the water
- Use monochromatic LEDs for sensitive environments such as wildlife habitat, observatories, wildlife nesting, or to meet Dark Sky requirements.
- In instances where cranes are used, coordinate pole location and height with portal crane clearances.

5-7.2 Baseball and Softball Fields.



5-7.2.1 Control Requirements.

Manual Control	Manual on
Motion Sensing	None
Time Schedule	Automatic partial ON to 50% within 1 hour before field scheduled to be open Automatic full OFF within 1 hour after field scheduled to be closed. Astronomical timeclock ON at dusk and OFF at dawn, if not using photosensing
Photosensing	ON and OFF based on daylight availability
Zoning	Provide separate zones per field

5-7.2.2 Performance Requirements.

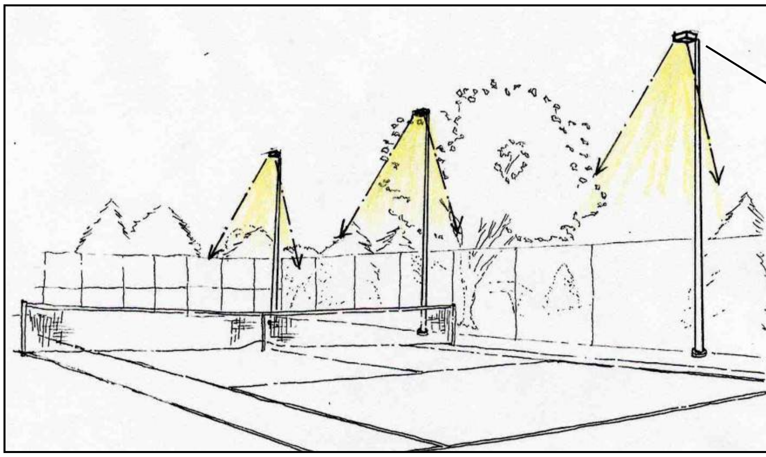
Target Criteria **(Class IV – Recreational*)**	**Infield**	**Outfield**
Average Horizontal Illuminance	30 fc (300 lux) at 3’-0” (910 mm) AFF	20 fc (200 lux) at 3’-0” (910 mm) AFF
Uniformity (Maximum to Minimum)	2.5:1	3:1

*For other classes of play, see ANSI/IES RP-6. Criteria apply to all lighting zones.

5-7.2.3 Critical Design Issues.

- Locate lighting poles outside of critical glare zones.
- Refer to ANSI/IES RP-6, Recommended Practice: Lighting Sports and Recreational Areas.
- Provide uniform illuminance on the field.
- Coordinate aiming of luminaires to minimize light trespass and glare.

5-8.1 Tennis Courts.



Pole mounted U0 area lights provide minimum glare and uniform illuminance on the court.

5-8.1.1 Control Requirements.

Manual Control	Manual On
Motion Sensing	None
Time Schedule	Automatic partial ON to 50% within 1 hour before courts scheduled to be open Automatic full OFF within 1 hour after courts scheduled to be closed. Astronomical timeclock ON at dusk and OFF at dawn, if not using photosensing
Photosensing	ON and OFF based on daylight availability
Zoning	Provide separate zones per court

5-8.1.2 Performance Requirements.

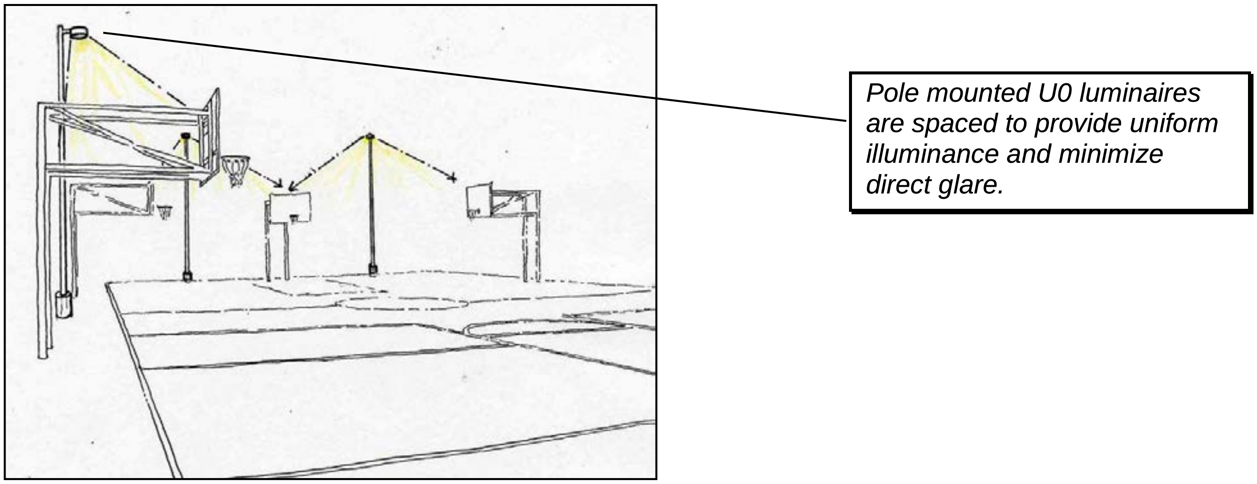
Target Criteria (Class IV – Recreational*)	**All Lighting Zones**
Average Horizontal Illuminance	30 fc (300 lux) at 3'-0" (910 mm) AFF
Uniformity (Maximum to Minimum)	2.5:1

*For other classes of play, see ANSI/IES RP-6. Criteria apply to all lighting zones.

5-8.1.3 Critical Design Issues.

- Use U0 luminaires to minimize glare and to reduce light pollution.
- Locate luminaires parallel to the direction of play.
- Locate lighting poles outside of critical glare zones.
- Refer to IES RP-6 for additional information on sports and recreational area lighting.
- Coordinate aiming of luminaires to minimize light trespass and glare.
- Provide uniform illuminance on the field.

5-8.2 Basketball Courts.



5-8.2.1 Control Requirements.

Manual Control	Manual On
Motion Sensing	None
Time Schedule	Automatic partial ON to 50% within 1 hour of courts scheduled to be open Automatic full OFF within 1 hour of courts scheduled to be closed. Astronomical timeclock ON at dusk and OFF at dawn, if not using photosensing
Photosensing	ON and OFF based on daylight availability
Zoning	Provide separate zones per court

5-8.2.2 Performance Requirements.

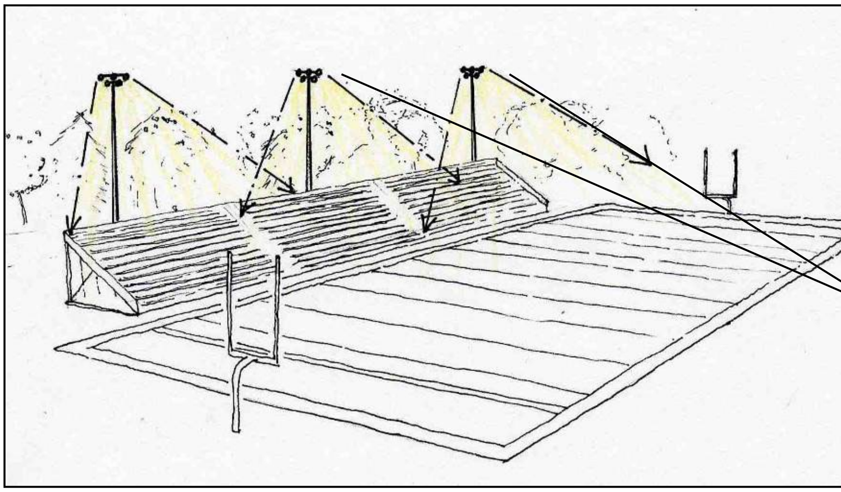
Target Criteria (Class IV – Recreational*)	**All Lighting Zones**
Average Horizontal Illuminance	20 fc (200 lux) at 3'-0" (910 mm) AFF
Uniformity (Maximum to Minimum)	4:1

*For other classes of play, see ANSI/IES RP-6. Criteria apply to all lighting zones.

5-8.2.3 Critical Design Issues.

- Use U0 luminaires to minimize light trespass and glare.
- Provide uniform illuminance on the court.
- Locate lighting poles outside of critical glare zones.
- Refer to ANSI/IES RP-6, for additional information on sports and recreational area lighting.
- Coordinate aiming of luminaires to minimize light trespass and glare.

5-8.3 Football Fields.



Pole mounted modular rack of adjustable sports lighting with internal and external shielding. Luminaire spacing provides uniform illuminance on the field.

5-8.3.1 Control Requirements.

Manual Control	Manual On
Motion Sensing	None
Time Schedule	Automatic partial ON to 50% within 1 hour before field scheduled to be open Automatic full OFF within 1 hour after field scheduled to be closed. Astronomical timeclock ON at dusk and OFF at dawn, if not using photosensing
Photosensing	ON and OFF based on daylight availability
Zoning	Provide separate zones per field

5-8.3.2 Performance Requirements.

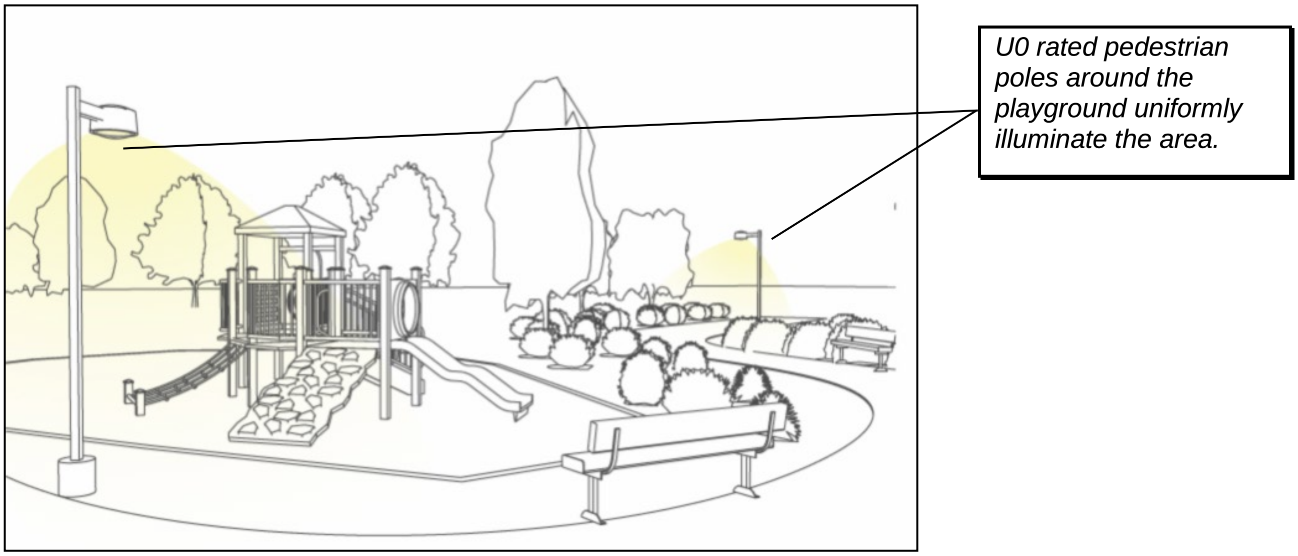
Target Criteria (Class IV – Recreational*)	**All Lighting Zones**
Average Horizontal Illuminance	20 fc (200 lux) at 3’-0” (910 mm) AFF
Uniformity (Maximum to Minimum)	4:1

*For other classes of play, see ANSI/IES RP-6. Criteria applies to all lighting zones.

5-8.3.3 Critical Design Issues.

- Locate lighting poles outside of critical glare zones.
- Refer to ANSI/IES RP-6 for additional information on sports and recreational area lighting.
- Provide uniform illuminance on the court.
- Coordinate aiming of luminaires to minimize light trespass and glare.

5-8.4 Playgrounds.



5-8.4.1 Control Requirements.

Manual Control	None
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability
Zoning	None

5-8.4.2 Performance Requirements.

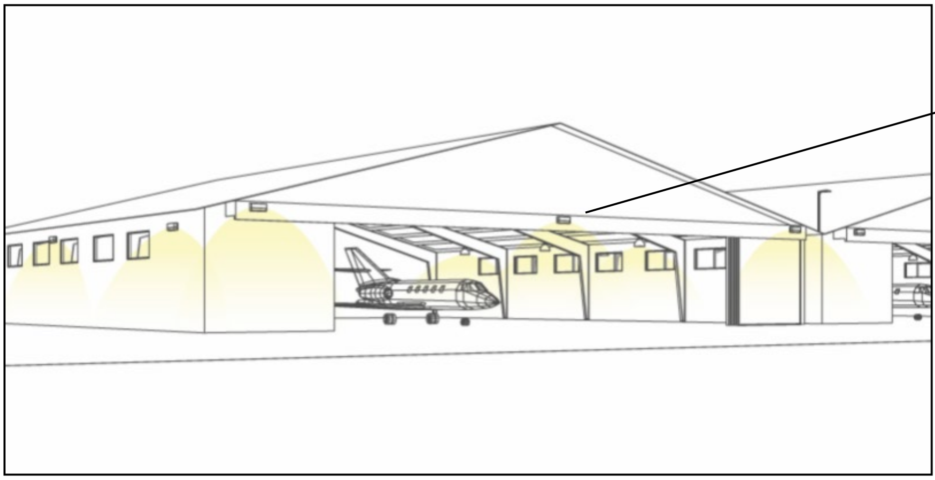
Target Criteria	All Lighting Zones
Average Horizontal Illuminance	1 fc (10 lux) at grade
Uniformity	5:1 average to minimum

5-8.4.3 Critical Design Issues.

- Provide uniform illuminance on the area surrounding the playground.
- Use U0 and maximum of G1 rated luminaires.
- All luminaires must use shielded optics and/or low lumen light sources to minimize glare and light pollution.

5-9 OTHER AREAS.

5-9.1 Airfields (Hangar Exterior).



Wall mounted U0 area luminaires illuminate both the hangar walls and the adjacent area. The U0 and G2 or less rating eliminates glare for approaching aircraft.

5-9.1.1 Control Requirements.

Manual Control	None
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability
Zoning	Control separately from other building mounting lighting systems

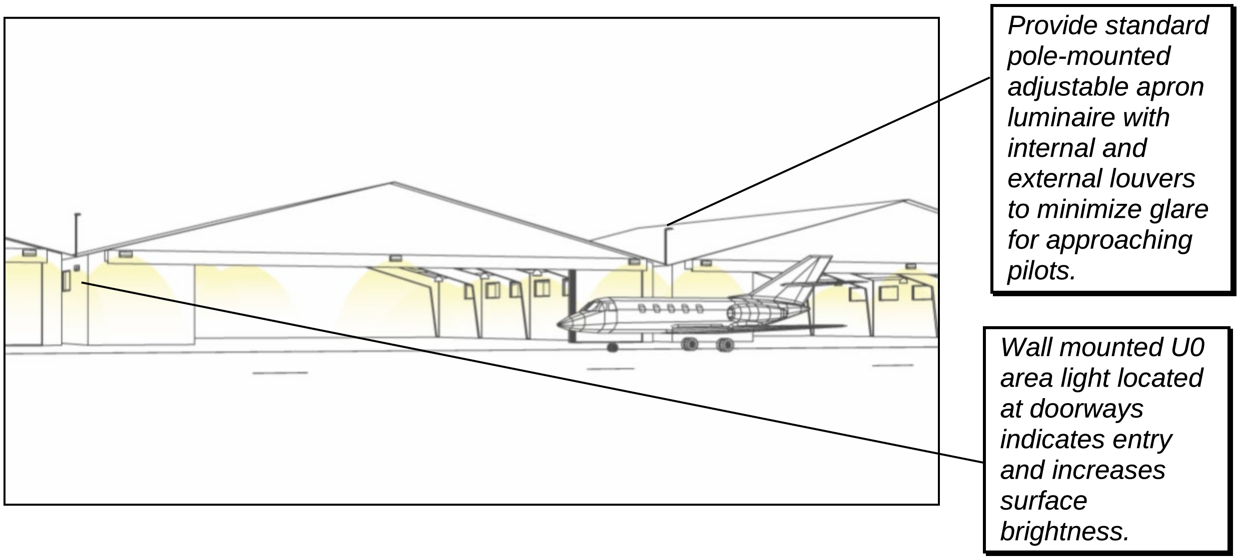
5-9.1.2 Performance Requirements.

Target Criteria	**All Lighting Zones**
Average Horizontal Illuminance	1 fc (10 lux) at grade
Uniformity	5:1 maximum to minimum

5-9.1.3 Critical Design Issues.

- Provide U0 and G2 rated luminaires with low lumen output to minimize glare and light pollution.
- Refer to section 4-9 for additional airfield lighting requirements.

5-9.2 Airfields (Apron).



5-9.2.1 Control Requirements.

Manual Control	None
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability
Zoning	Control separately from other building mounting lighting systems

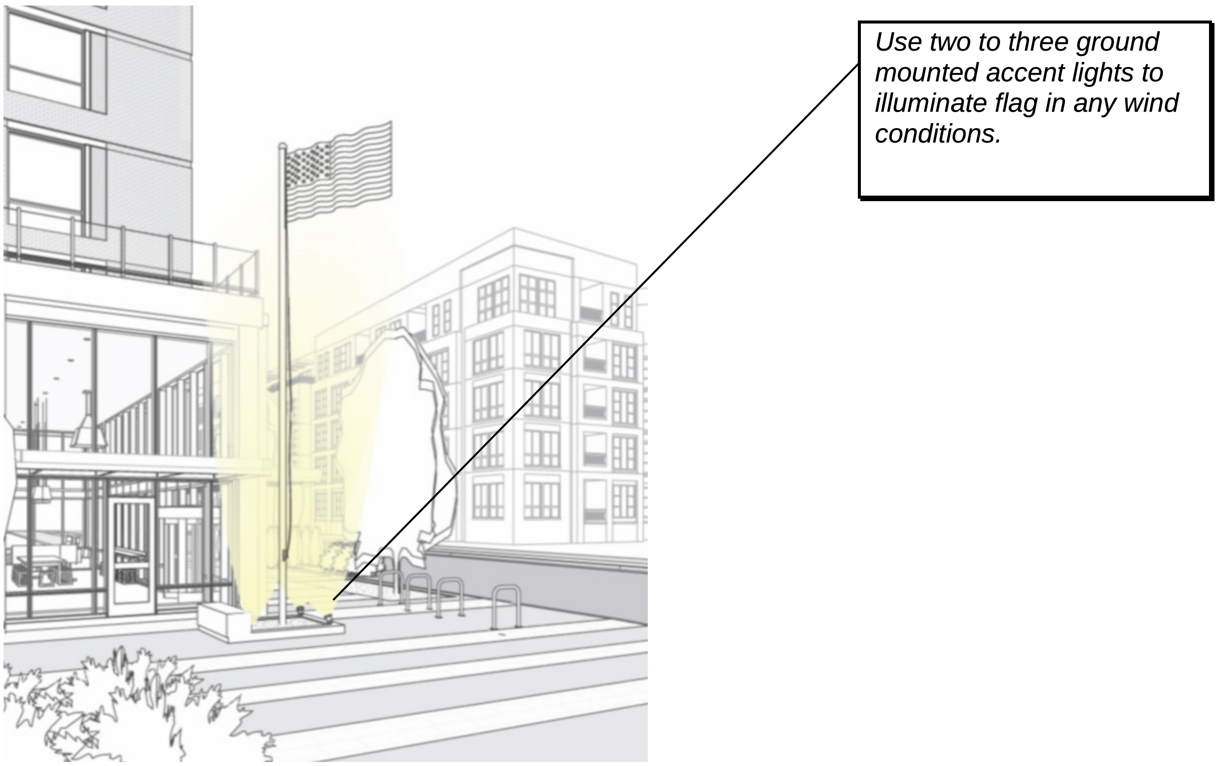
5-9.2.2 Performance Requirements.

Target Criteria	**Maintenance and service**
Average Horizontal Illuminance, Maintenance and service	2 fc (20 lux) at grade
Average Horizontal Illuminance, Aircraft parking	0.5 fc (5 lux) at grade
Average Horizontal Illuminance, Loading and unloading	2 fc (20 lux) at grade
Average Horizontal Illuminance, Other apron areas	1 fc (10 lux) at grade
Uniformity	4:1 average to minimum

5-9.2.3 Critical Design Issues.

- Coordinate with airfield manager for control methodologies.
- Provide U0 and maximum G2 rated luminaires with low lumen output to minimize glare and light pollution.
- Refer to section 4-9 for additional airfield lighting requirements.
- Reference UFC 3-535-01, Table 10-1, for uniformity criteria and apron area.

5-9.3 Flagpoles.



5-9.3.1 Control Requirements.

Manual Control	None
Motion Sensing	None
Time Schedule	Automatic full OFF within 1 hour after business close and automatic full ON within 1 hour before business open Astronomical timeclock ON at dusk and OFF at dawn
Photosensing	None
Zoning	None

5-9.3.2 Critical Design Issues.

- Ground mounted accent lights experience less water intrusion than in-grade uplights.
- In environmental sensitive areas and Lighting Zones 0 and 1, use integrated flagpole downlighting to eliminate uplight.
- If flags are removed at dusk, lighting is not required.

This Page Intentionally Left Blank

CHAPTER 6 TECHNICAL REQUIREMENTS – SECURITY LIGHTING

6-1 INTRODUCTION.

Exterior security lighting is an important issue for many facilities and not all of the specific criteria are addressed in this section. For lighting requirements, this UFC supersedes MIL-HDBK-1013/1A*, Design Guidelines for Physical Security of Facilities*. Security lighting provides illumination during periods of darkness or in areas of low visibility to aid in the detection, assessment, and interdiction of aggressors by security forces. Security lighting is sometimes referred to as protective lighting.

Refer to CHAPTER 2 and CHAPTER 4 for addition requirements for interior and exterior lighting and controls.

6-2 PHYSICAL SECURITY.

Physical security describes the part of security concerned with physical measures designed to safeguard personnel; to prevent or delay unauthorized access to equipment, installations, material, and documents; and to safeguard them against espionage, sabotage, damage, and theft.

6-2.1 Physical Security System.

A physical security system is comprised of people, equipment, and operational procedures that control access to critical facilities or assets. Security lighting is one of the elements that comprise the equipment component of a physical security system.

6-2.2 Security Lighting Objectives.

Security lighting is one component of a larger physical security system. While the level of protection may vary, the lighting must supplement and facilitate other measures taken to ensure the security of an asset. These other measures may take the form of security forces at an entry control point, sensitive inner areas, boundaries, or the use of video cameras. In all cases, the lighting enhances visibility for either an individual or device and facilitates their performance.

In the simplest form, security lighting provides a clear view of an area for security personnel while reducing concealment opportunities for aggressors. A physical security system must be able to detect a threat, assess the threat, and then neutralize the threat.

6-2.3 Deterrent Value.

Security lighting at a site may deter lesser threats and aggressors. While a security lighting system does not deter sophisticated criminals or terrorists, it may influence unsophisticated criminals or vandals. The mere presence of light increases the probability of detection or capture and may induce these types of aggressors to look for an easier target.

Similarly, the effective use of lighting can enhance the perception of security, which is important to the personnel who work within a secure area. This can be accomplished with glare reduction, lighted surfaces, proper uniformity, and adequate illuminance.

6-2.4 Defining Requirements.

Defining the requirements of a physical security system and its components involves an interdisciplinary planning team. The team considers all interests relating to a project to determine how security fits into the total project design.

Base the specific membership of the planning team on local considerations, but in general, the following functions are to be represented: facility user, antiterrorism officer, operations, security, logistics, engineering, life safety, and others as required. Use the process in UFC 4-020-01 to identify the design criteria, which includes the assets to be protected, the threats to those assets (the Design Basis Threat), and the levels of protection to be provided for the assets against the identified threats. In addition to those criteria elements, the team must also identify user constraints such as appearance, operational considerations, labor requirements or limitations, energy conservation and sustainment costs. Some areas such as water boundaries that cannot be patrolled do not require lighting.

6-2.5 Security Lighting Design.

The security lighting system must aid in the detection of aggressors and assist personnel in the assessment and response to potential threats. All security lighting designs must be coordinated with Security Forces. The type of site lighting system provided depends on the installation environment and intended use.

6-2.5.1 Continuous Lighting.

The most common security lighting system is a series of fixed lights arranged to illuminate a given area continuously.

6-2.5.2 Standby.

With this system, the luminaires are either automatically or manually turned on at times when suspicious activity is detected by security personnel or an intrusion detection system. A standby system creates the impression of activity and may offer a deterrent value while also achieving energy conservation. Use LED light source systems in lieu of light sources that require re-strike.

6-2.6 Controlled Lighting.

Controlled lighting is best used when it is necessary to limit the width of the lighted strip along the perimeter due to adjoining property. Minimize or eliminate silhouetting or illuminating security personnel on patrol. Illumination levels for controlled lighting must be adequate to detect a moving aggressor, either visually or by use of video cameras. Provide U0 rated luminaires mounted in the horizontal plane to minimize glare. Glare may hinder security personnel visibility and interfere with authorized activities or activities outside the installation. Figure 6-1 and Figure 6-2 show different configurations of controlled lighting.

Figure 6-1 Example of controlled lighting: single fence line

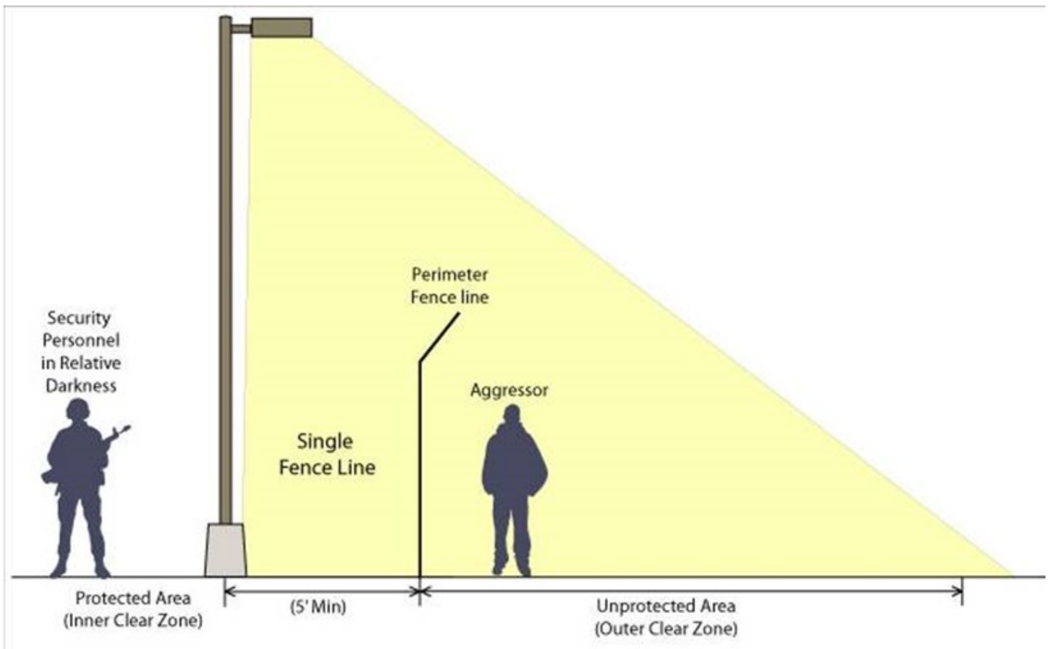


Figure 6-2 Example of controlled lighting: double fence line

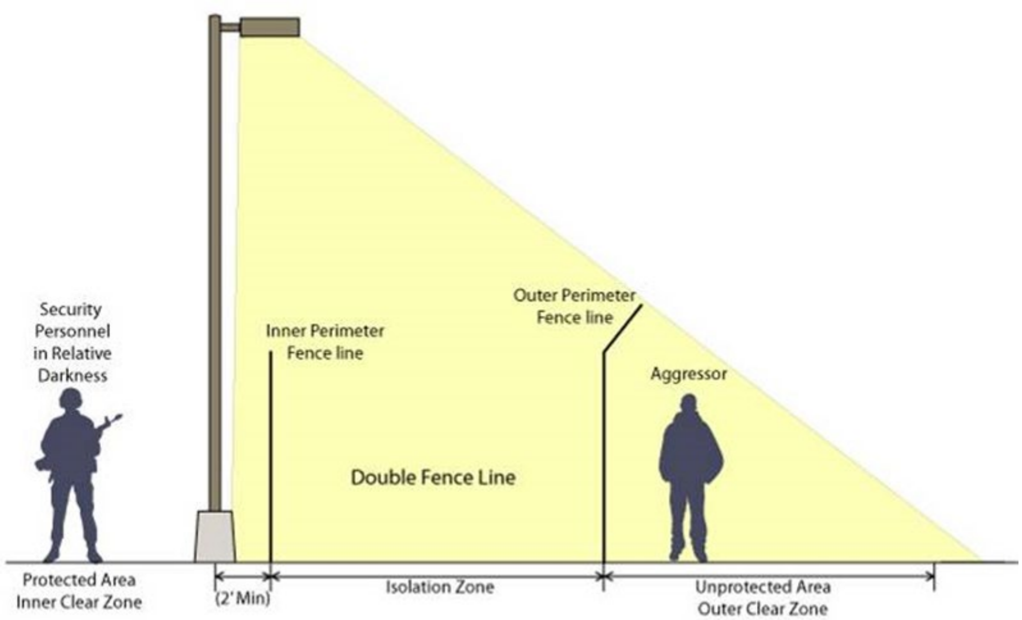

6-2.6.1 Glare Projection.

Glare projection is a lighting strategy used in isolated or expeditionary locations to increase the assessment zone by illuminating large flat areas outside the fence line. One technique for glare projection lighting is to place lights slightly inside a security perimeter and directed outward. Glare projection may be a deterrent to potential intruders because it makes it difficult to see inside the area being protected. It also protects security personnel by keeping them in comparative darkness and enabling them to observe intruders at a considerable distance beyond the perimeter. Figure 6-3 and Figure 6-4 show examples of glare projection

Figure 6-3 Example of glare projection: single fence line

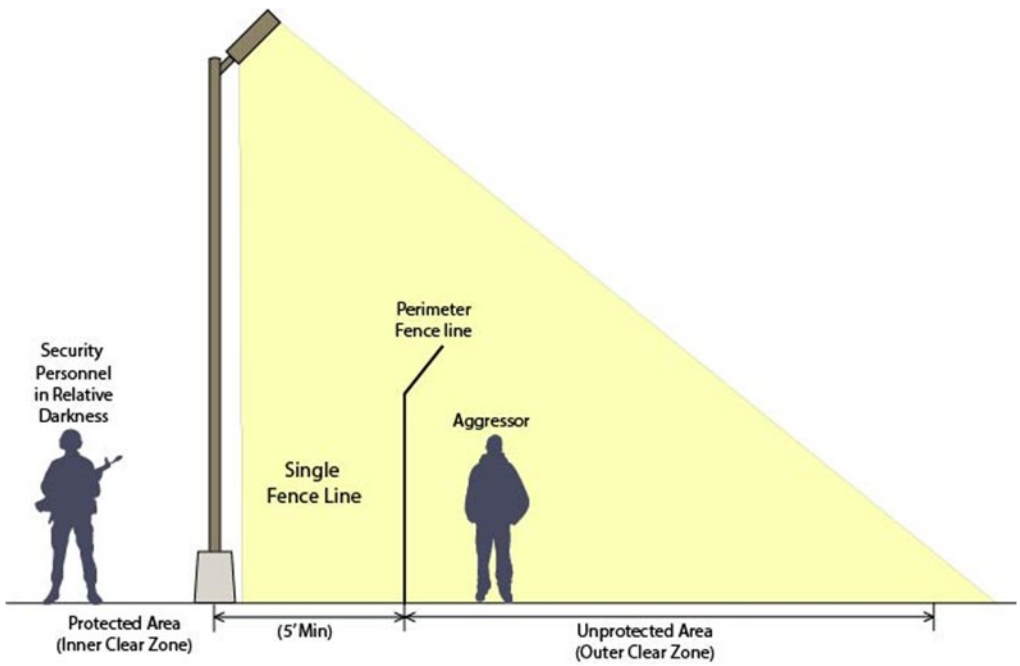

Figure 6-4 Example of glare projection: double fence line

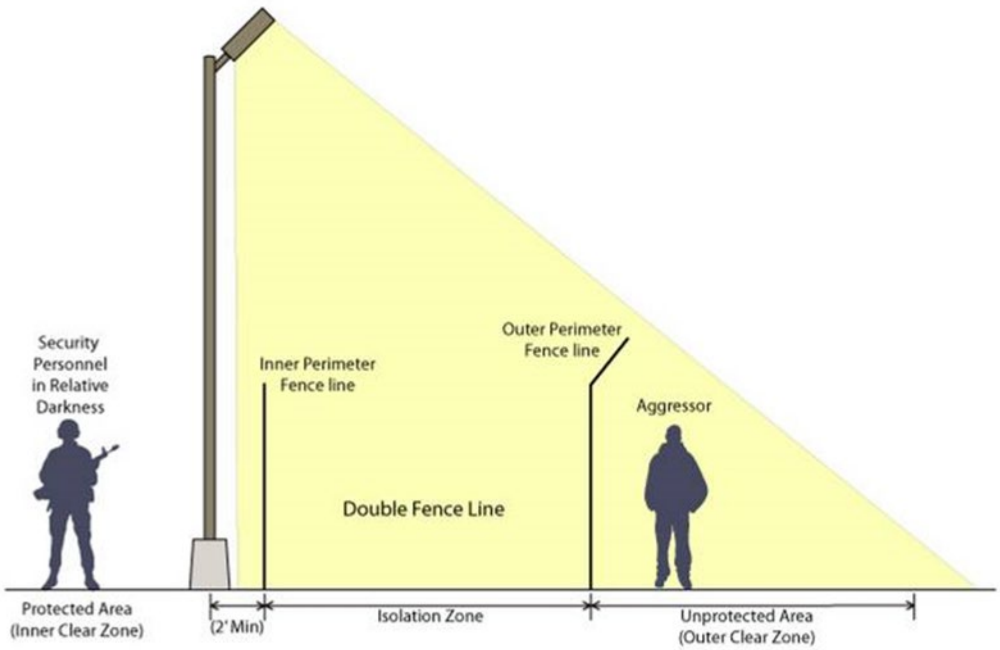


6-2.7 Security Lighting Criteria.

In all cases, mission safety or operational requirements govern over security lighting requirements. For example, if security lighting requires 0.2 fc (2 lux), and a lighting level of 5 fc (50 lux) is required to perform a task or operation, then 5 fc (50 lux) is the requirement. Illuminance values appropriate for security personnel may range from a minimum of 0.1 fc (1 lux) for large open areas to a minimum of 10 fc (100 lux) in area of ID checks for entry control points. If guards must perform any written task (such as inside a guardhouse), the illuminance on the task plane may reach an average 30 fc (300 lux). Illuminance values in excess of this may inhibit the individual's ability to adapt to lower lighted areas outside.

6-2.7.1 Low Level of Protection (LLOP).

Illumination is only required at building entries and exits. Use low brightness and well shielded luminaires so that it does not become a glare source in the much darker surroundings.

6-2.7.2 Medium Level of Protection (MLOP).

Requires LLOP criteria and illumination of the building exterior. U0 rated luminaires mounted on the building wall can illuminate the exterior of the building without adding light to the surrounding area or cause light trespass to neighboring properties.

6-2.7.3 High Level of Protection (HLOP).

Requires MLOP criteria and illumination of the area around the facility. This lighting may still be accomplished with wall mounted lighting on the building. By using a different luminaire distribution, light can be directed to the surrounding area rather than just at the building. For larger areas, poles may be necessary to light further from the building. With U0 rated luminaires, a perimeter width of 2-3 times the mounting height can be illuminated. When a perimeter fence is required for security, HLOP would dictate illumination of the perimeter fence including any required clear or isolation zones to aid in the detection, assessment, and interdiction of aggressors by security forces. Use controlled lighting, except when dictated by local threat environment.

6-3 SECURITY LIGHTING APPLICATIONS.

Refer to the CHAPTER 7 on Security Lighting Applications for additional information.

6-3.1 Building Entrances and Exits.

Increasing the lighting level at the building entrance guides visitors and other personnel to the appropriate building entry. It also serves as exit lighting to guide individuals out of a building for life safety in case of an emergency. The security lighting at these locations protects against forced entry and provide enough light for threat assessment. Building entrances and exits must be lighted for all levels of protection. Use concealed, U0 rated luminaires and/or low brightness sources to limit glare while still providing adequate illumination.

6-3.2 Building Exterior.

Lighting of the building frequently includes some area lighting as well. By using U0 rated, wall mounted luminaires; both the building and the adjacent area can be illuminated. Mounting luminaires at the top of the facade and aiming the light down increases the facade brightness and reduces light trespass and light pollution.

6-3.3 Perimeter Lighting.

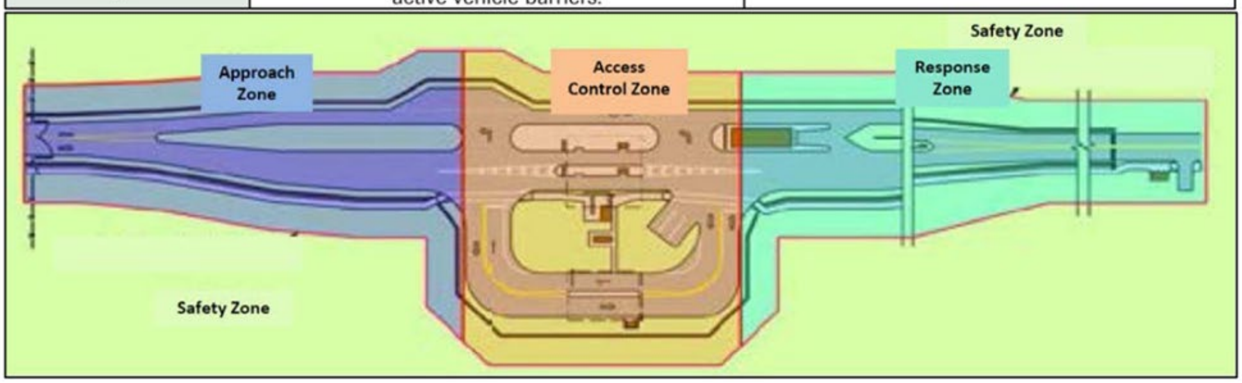
Illumination of a restricted area perimeter when required includes the exterior and interior clear zones adjacent to the fence or, in some applications, the area between a dual fence line (isolation zone). Provide poles, power circuits, and transformers within the protected area. Coordinate pole locations with the user to ensure that the applicable egress requirements and patrol routes of the clear zone are not violated. Provide poles that are not less than 5 feet (1.5 meters) from a single fence line, or less than 2 feet (0.6 meters) for a dual fence line. This 5-foot (1.5 meter) separation may not apply to a perimeter that is a solid wall. In the case of a solid wall, the designer needs to coordinate with the local security and service to determine the best approach. Provide perimeter lighting that is either continuous or standby, controlled or glare projection depending on the application and local threat environment. See Table 6-2 for additional criteria.

6-3.4 Entry Control Facilities, Access Control Points.

Refer to UFC 4-022-01 for Entry Control Facility/Access Control Points (ECF/ACP) Criteria and *Entry Control Facility/Access Control Point Lighting Analysis* for additional information. Entry Control Facilities/Access Control Points are separated into several zones, see Figure 6-5. These zones can be further subdivided into lighting zones, see Figure 6-6**.**. The lighting design for each zone is described in the following paragraphs.

Figure 6-5 ECF/ACP Zones*

Zone	Location	Goals
Safety	Extends in all directions beyond passive and active barriers.	Protect assets and personnel from explosions.
Approach	Installation boundary to a point just before the ID checkpoint.	Reduce speed, sort vehicles, provide stacking room, identify potential threats.
Access Control	A point just before and after the ID checkpoint.	Identify vehicles and personnel; provide surveillance, random inspection, visitor processing, and rejection capabilities.
Response	A point just after the ID checkpoint to the active vehicle barriers.	Provide measures to react to and resist a threat.



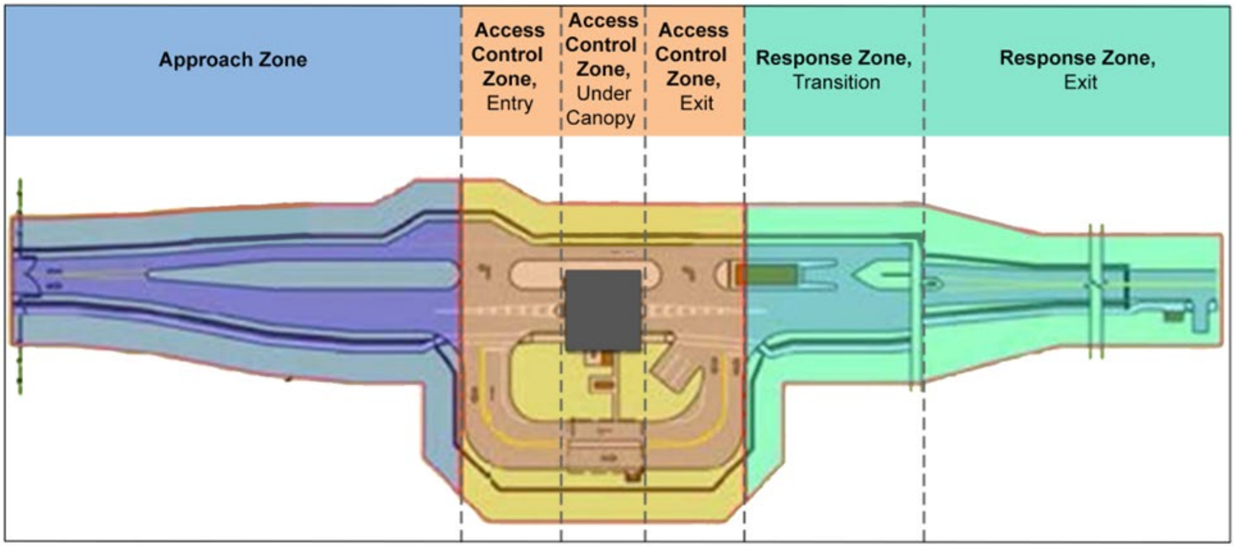
*Source: UFC 4-022-01.

6-3.4.2 Approach Zone.

Illuminate the Approach Zone to lead motorists safely to the Access Control Zone. Use U0 rated luminaires mounted in the horizontal plane to minimize glare. Glare rating not to exceed G2. To reduce glare for security personnel, provide signage to instruct motorists to turn off headlights as they approach the Access Control Zone.

To reduce adaptation issues for the motorist, gradually increase (transitional lighting) lighting levels as the motorist approaches the Access Control Zone, which has the highest light levels. Motorist’s eyes take time to adjust to sudden changes in light level, especially high to low. Extensive discussion of transitional lighting can be found in ANSI/IES RP-8. Typically, a minimum Approach Zone of 200 ft. (61 m) is adequate to achieve acceptable transitional lighting in the Approach Zone.

Figure 6-6 ECF/ACP Lighting Zones



6-3.4.3 Access Control Zone.

Lighting in the Access Control Zone/Access Control Points provides the highest light levels in the Entry Control Facility/Access Control Points. To provide the proper lighting adaptation levels for drivers and security personnel, the Access Control Zone is broken into three areas, see Figure 6-6. Increased light levels in the Access Control Zone, Entry allows the motorist to adapt to the brightness. Decreased light levels in the Access Control Zone, Exit, allows the motorist to adapt to lower light levels upon exit of the Access Control Zone.

The lighting system must provide for identification and inspection. For most of the Access Control Zone, U0 rated luminaires provide adequate lighting for most of these visual tasks. However, vertical illuminance on motorists' faces can be improved with the use of low brightness light sources (less than 3500-lumen light source output). Luminaires mounted to the side and behind security personnel improves identification tasks. Use a glare rating not to exceed G2.

6-3.4.4 Response Zone.

From the Access Control Zone, gradually return roadway lighting to lower light levels (transitional lighting) while still providing adequate uniformity; see Figure 6-6. Provide U0 rated luminaires mounted in the horizontal plane to minimize glare for motorists and security personnel in the Response Zone. Use a glare rating not to exceed G2. In addition, provide signage to instruct motorists to turn headlights back on after leaving the Access Control Zone.

6-3.4.5 Pedestrian Access.

Pedestrian zones must provide light for both pedestrians and security personnel. Pedestrians must have a clear view of gates and card access readers and security personnel must be able to see pedestrians approaching the ECF/ACP. Provide U0 rated luminaires mounted in the horizontal plane to minimize glare. Use a glare rating not to exceed G2.

6-3.4.6 Vehicle Inspection.

In areas where security personnel must identify visitors, check credentials, and read shipping manifests, provide lighting that does not interfere with the operations while vehicles approach, stop for inspection, and proceed. Having to continually adapt to different illuminance and brightness levels could lead to eyestrain and reduced performance by security personnel. Provide additional task lighting from behind the guard and light the person to identify or the vehicle to inspect.

6-3.4.7 Gatehouse/Guard Booth.

Inside the gatehouse, task lighting must be provided for reviewing identifications, paperwork, and possibly computer tasks. However, the interior light levels must be kept at a lower ambient light level than the exterior. Otherwise, the security personnel will have reduced visibility and those approaching the shack will have a clear view of the interior. While the ambient light level may be very low, task lighting at a desk or workstation can still be increased to a higher level. The location and shielding of interior lighting must minimize the chance of veiling reflections on the glass that may limit visibility to the outside. All luminaires must be dimmable to adjust inside lighting levels. Do not use colored light for task lighting when color is to be distinguished in the task.

6-3.4.8 Overwatch Position.

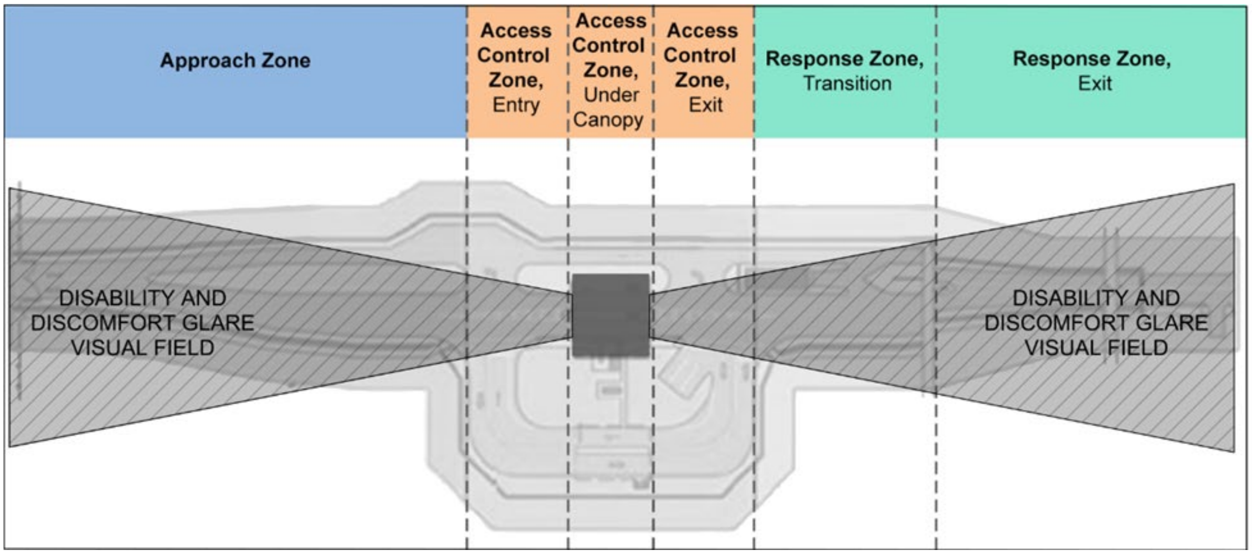
These locations must maintain an unobstructed view through the access and Response Zones. Additionally, inside the overwatch itself, lighting must be kept to extremely low levels or eliminated entirely to prevent the lighting of the security personnel. All luminaires must be dimmable to adjust lighting levels. While red colored light has been used in such applications to maintain the eye’s dark adaptation, do not use colored light for task lighting when color is to be distinguished within the Overwatch position.

6-3.4.9 Disability and Discomfort Glare Visual Field.

The Disability and Discomfort Glare Visual Field is the visual coverage of security personnel stationed at an ECF/ACP, located within the Access Control Zone. Luminaires within this field are most likely to cause disability and discomfort glare for Security Personnel.

Figure 6-7 overlays the Disability and Discomfort Glare Visual Field on the typical ECF/ACP layout. This figure is an example layout. ECF/ACP layout must consider the impact of the Disability and Discomfort Glare Visual Field on the lighting layout. See the *Entry Control Facility/Access Control Point Lighting Analysis* for more information.

Figure 6-7 ECF/ACP Disability and Discomfort Glare Visual Field



All luminaires placed within this visual field must take glare as a consideration in design:

- Minimize light source visibility from the security personnel position.
- The glare rating should be no greater than G1.
- Use Table 6-1 to establish maximum luminaire mounting heights per distance from security personnel position.

Table 6-1 Maximum Luminaire Mounting Height in the Disability and Discomfort Glare Visual Field

Distance from Security Personnel Position	At 20' (6 m)	At 30' (9 m)	Between 40' (12 m) and 60' (18 m)	Between 60' (18 m) and 80' (24 m)	Between 80' (24 m) and 100' (34 m)	>100' (34 m)
Maximum Luminaire Mounting Height*	14' (4 m)	18' (5 m)	Between 22' (7 m) and 32' (10 m)	Between 32' (10 m) and 40' (12 m)	Between 40' (12 m) and 50' (15 m)	>50' (15 m)

*Maximum luminaire mounting height is measured to the underside of luminaire.

6-3.5 Waterfront.

Refer to UFC 4-025-01 for Waterfront Security Criteria. Waterfront areas consist of a defined perimeter (landside and waterside), restricted area, Entry Control Facilities at the entrance into the waterfront area, access control points located at each pier, and pedestrian access control points along the perimeter. In waterfront areas, utilize high mast lighting to reduce the number of poles minimizing obstructions to waterfront operations and maintaining clear paths for equipment and vehicles. Provide U0 rated luminaires mounted in the horizontal plane to limit direct and reflected glare. Use a glare rating not to exceed G2. In some regions, white light sources may interfere with the marine environment. Coordinate marine issues with the local environmental authority.

Security lighting can visually interfere with lighting used as aids to navigation (ATON) by ships. Lighting ashore can camouflage, outshine, or otherwise conceal ATON. Ensure that lighting ashore and in the waterfront compound does not conflict with or otherwise conceal the ATON lights. Coordinate security lighting requirements with Port Operations.

6-3.5.1 Piers, Wharves and Shipyards.

Provide U0 rated luminaires to limit glare and uplight. Use a glare rating not to exceed G2. In general, high mast lighting provided for waterfront operations supply adequate illuminance for security requirements. Coordinate number, height, and location of poles and the associated concrete pedestals to minimize obstructions to pier, wharf and shipyard operations. Refer to UFC 4-152-01 for Pier and Wharf operational lighting requirements. Refer to for the minimum lighting intensity requirements for shipyards.

6-3.5.2 Pierhead and Wharf Guard Towers.

Lighting inside the guard towers must not degrade security personnel’s nighttime visibility. All luminaires must be dimmable and mounted at or near desk level. Switch task and general lighting separately. When colors are not used to distinguished tasks (colored lights or controls for alarm annunciations), consider red light sources for task lighting to reduce adaptation problems. Manually operated searchlights may be required to assist security personnel to locate and assess waterside threats within the restricted zone. Lighting controls must be under the direct control of security personnel. Coordinate lighting requirements with security personnel.

6-3.5.3 Water Surface.

High mast lighting on pier and wharves provides adequate illuminance for security requirements. Glare, poor distribution, and excessive light levels reduce security personnel’s ability to assess surface and subsurface threats.

6-3.5.4 Underwater Lighting.

Underwater lighting is not normally required for detection of subsurface threats and is discouraged due to limited benefit, high installation cost, and maintenance issues.

6-3.5.5 Underdeck Lighting.

Dedicated luminaires located beneath the pier are not normally required and are discouraged due to limited benefit, high installation cost, and maintenance issues.

6-3.5.6 Lower Deck Lighting.

On the lower deck of a double deck pier, provide utility and work areas with illuminance levels based on the tasks performed. Lower deck lighting in roadway and open areas must be multilevel and divided into sections to localize lighting control. Alternate control of luminaires between photocell and manual light switch or implement an intelligent control system. Provide an average of 0.5 fc (5 lx) with luminaires under photocell control. To reduce energy consumption, consider occupancy or vacancy sensors for control of lighting in enclosed spaces.

6-3.6 Video Cameras.

Cameras respond to a luminous environment differently than the human eye. The field of view of a camera refers to the extent of the scene that can be viewed at one time. Some devices may use motorized swivels to pan across a scene and increase the viewing area. Cameras adjust the view based on the brightest point in this field. If it must adjust for a hot spot, areas under low illuminance levels may not be visible at all. Uniform illuminance and U0 rated luminaires are vital to limit hot spots and improve video camera system performance. **Figure 6-8** illustrates how a large portion of the camera's view may be washed out if it must adjust to an excessively bright light source. Any luminaire that falls within the camera's field of view at any time must be shielded. If a light source can be seen directly by the camera, the glare and high contrast limit the visibility of the entire scene. Therefore, the source of illumination is best located above the level of the camera. Refer to UFC 4-021-02 *Electronic Security Systems* for additional information.

Figure 6-8 Video camera's view of scene with excessive glare

6-3.6.2 Color Rendering Index.

For color cameras, the color rendering index of the sources lighting the area must be above 80. Color rendering is less important for monochrome systems.

6-3.6.3 Uniform Vertical Illuminance.

Video cameras typically record objects and people in elevation. Therefore, the security lighting system must provide adequate and uniform vertical illuminance. As in many security lighting applications, the amount of vertical illuminance is far more important than horizontal. Vertical illuminance criteria average is 0.2 to 0.5 fc (2 to 5 lux) at 5 feet (1524 mm) above the ground. Uniformity criteria is 4:1 average to minimum. These criteria refer to vertical illuminance values measured in the same direction of the camera line of sight. Vertical illuminance does not need to be this high in all directions. Color cameras may require higher light levels than monochrome cameras. Review camera manufacturer recommendations and coordinate with the security system designer when designing the lighting system.

6-3.6.4 Infrared (IR) Cameras.

IR cameras utilize IR sources to illuminate the field of view. Light in the IR spectrum is not visible to the human eye. IR cameras then pick up the reflections of these wavelengths from objects in the area.

6-3.6.5 Thermal Imaging.

Devices using thermal technology do not require any light source to operate. They create images based on the heat differences between humans, vehicles, the ground, and foliage. Unlike other camera technologies, thermal imagery is not affected by glare from headlights or light sources. While this technology can indicate the presence of people and objects in complete darkness, they do not provide the detailed images obtainable from visible light or IR cameras.

6-3.6.6 Specific Lighting Criteria.

The specific lighting criteria and design issues may vary with application. Table 6-2 summarizes the minimum (not average) horizontal and vertical illuminance levels for typical facility applications. The inner clear zone noted in the table refers to the area along a perimeter fence line within the facility or installation. The isolation zone refers to the area between a double fence line. The outer clear zone describes the area along the perimeter fence on the outside of the protected area. Isolation and clear zones are typically 30 feet (9.1 meters) in width. It is important to note, however, that over-lighting and glare can cause just as many visibility problems as underlighting.

Table 6-2 Minimum Lighting Criteria for Unaided Guard Visual Assessment

Application				**Minimum or Average Illuminance (All Lighted Areas)**		**Maximum Uniformity**
Type	Lighting	Area	Width Feet (m)	Locations to Light	Footcandles (lux)[a]	(Avg:Min)
Perimeter	Controlled	Inner Clear Zone	20-30 (6.1-9.1)[c]	Outer edge fence	0 (0)[e] min	10:1
	Controlled	Outer Clear Zone	30 (9.1)[d]	Outer edge	0.2 (2) or 0.4 (4)[g] min	10:1
	Controlled	Isolation Zone[f]	30 (9.1)	Between fence lines	0.5 (5) or 1.0 (10)[b] min	6:1
Building Lighting	Controlled	LLOP	--	Building Entry and Exits	Refer to 5-4.1 and 5-4.2	20:1
	Controlled	MLOP	--	Same as LLOP and exterior walls.	0.2 to 0.5 (2 to 5) min	15:1
	Controlled	HLOP	30 (9.1)	Same as MLOP and area around facility.	0.5 to 1.0 (5 to 10) min	10:1

a. Horizontal plane at 3 feet (914 mm) above finished grade unless otherwise noted.
b. Vertical illuminance 6 inches (152 mm) above finished grade.
c. Width of inner clear zone is asset dependent. Refer to Service guidance for asset being protected.
d. Width of outer clear zone is asset dependent (typical clear zones is 30 feet (9144 mm). Refer to Service guidance for asset being protected. Glare projection may be required in areas with larger clear zones such as forward areas or high threat environments or when the assessment zone is extended beyond the clear zone.
e. Minimize illuminance in inner clear zone to prevent illuminating security personnel. Some applications may require illumination of inner clear zone (backlighting).
f. Only applies to dual fence line applications.
g. Vertical illuminance 3 feet (0.9 meters) above finished grade, at outer edge.

6-4 LIGHTING CONTROLS.

Refer to CHAPTER 7 for control requirements specific to common applications. Refer to CHAPTER 2 and CHAPTER 4 for information on lighting controls and control strategies.

6-5 ELECTRICAL REQUIREMENTS.

Backup power is not required for all security lighting systems. The results from assessment of risk and asset value determine this need. For critical security lighting systems, several different types of systems are available for providing backup power in the event of a power outage. All offer various advantages and disadvantages. They vary in amount of time that they can provide power, amount of downtime between a power outage and backup power, and cost. Refer to service specific guidance regarding facilities and equipment authorized backup power.

6-5.1 Generators.

Generators are commonly used to provide backup power but have some downtime between the outage and when the generator restores power. Minimum downtime can be as low as seconds. While this is one of the least expensive solutions, operations must be able to sustain the short period of darkness.

6-5.2 Uninterruptible Power Supply.

An uninterruptible power supply (UPS) is a battery source that provides instantaneous power in case of a power loss. UPS systems have a high initial cost and are expensive to maintain. Therefore, only provide a UPS for security lighting systems associated with the protection of critical assets or security operations when continuous, full brightness lighting is required.

6-5.3 Flywheels.

Flywheels provide instantaneous power in the case of power loss in the form of the kinetic energy in a constantly rotating wheel. This energy can be harnessed immediately in the event of a power outage and used to power critical lighting. These devices vary widely in price and capacity.

6-5.4 Battery Backup.

Individual battery packs are available for some luminaires. In the event of a power outage, these packs can power the lighting for times ranging from five minutes to two hours, depending on the battery capacity. For LED light sources, the battery powers the driver directly although the light source may not provide full light output.

6-5.5 Circuiting Techniques.

To minimize security degradation during faults, divide lighting system into two or more circuits. Circuiting luminaires onto separate circuits in the same space does not provide backup power but limits vulnerabilities during a fault or circuit failure. If the lighting system is divided onto two or more circuits, the loss of one does not affect the entire lighting system. Install multiple circuits, except where their use is clearly impractical. Locate the overcurrent devices, transformer, and wiring within the protected area. Locate circuits underground to minimize the possibility of sabotage or vandalism.

This Page Intentionally Left Blank

CHAPTER 7 SECURITY LIGHTING APPLICATIONS

7-1 INTRODUCTION.

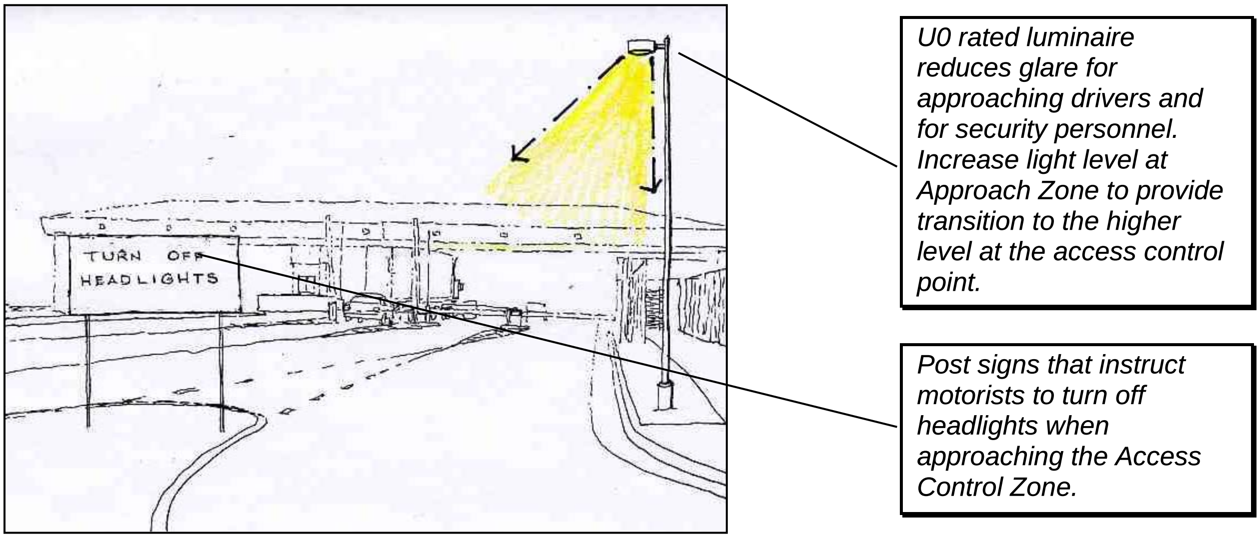
This section identifies typical security lighting applications. Each application details a conceptual lighting design example. Designers must meet the lighting performance and controls requirements.

7-2 CALCULATIONS FOR SECURITY LIGHTING.

Refer to CHAPTER 3 for lighting calculation requirements for interior lighting and CHAPTER 5 for calculations for exterior systems.

7-3 ENTRY CONTROL FACILITY/ ACCESS CONTROL POINTS.

7-3.1 Approach Zone.



7-3.1.1 Control Requirements.

Manual Control	None
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability
Zoning	None

7-3.1.2 Performance Requirements.

Target Criteria	**Minimum Distance**	**All Lighting Zones**
Average Horizontal Illuminance, Approach Zone	200' (61 m)	1.5 fc (15 lux) at grade
Uniformity	4:1 average to minimum	

7-3.1.3 Critical Design Issues.

- See Response Zone and UFC 4-022-01 for additional information on transition lighting.

- Refer to Figure 6-6 for diagram of ECF/ACP lighting zones.
- Provide transitional lighting between bright and dark regions for the Approach Zone of the gate to improve visual adaptation.
- Use luminaires with a G-Rating of G0 or G1, only use G2 for special conditions for roadway or area luminaires.
- For luminaires in the Discomfort and Disability Glare Visual Field, follow the design parameters outlined in section 6-3-4.1.

7-3.2 Access Control Zone Outside Canopy.

7-3.2.1 Control Requirements: Primary ECF/ACP.

Manual Control	Wallbox switch or scene wallstation in nearby accessible location with manual ON and manual OFF
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability with manual override
Zoning	None

7-3.2.2 Control Requirements: Secondary ECF/ACP.

Manual Control	Wallbox switch or scene wallstation in nearby accessible location with manual ON and manual OFF
Motion Sensing	None
Time Schedule	Automatic dimming to 50% 1 hour after ECF/ACP closing and automatic full ON 1 hour before opening
Photosensing	ON and OFF based on daylight availability with manual override
Zoning	None

7-3.2.3 Control Requirements: Limited Use ECF/ACP.

Manual Control	Wallbox switch or scene wallstation in nearby accessible location with manual ON and manual OFF
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability with manual override

Zoning	None

7-3.2.4 Performance Requirements.

Target Criteria	Minimum Distance	All Lighting Zones
Average Horizontal Illuminance, Access Control Zone, Entry	40’ (12 m)	3 fc (30 lux) at grade
Average Horizontal Illuminance, Access Control Zone, Exit	40’ (12 m)	3 fc (30 lux) at grade
Uniformity	4:1 average to minimum	

7-3.2.5 Critical Design Issues.

- Refer to UFC 4-022-01 for additional criteria on signage.
- Refer to Figure 6-6 for diagram of ECF lighting zones.
- Use luminaires with a G-Rating of G0, G1, or G2 for roadway or area luminaires.
- For luminaires in the Discomfort and Disability Glare Visual Field, follow the design parameters outlined in section 6-3-4.1.

7-3.3 Access Control Zone Underneath Canopy.

Locate low brightness luminaire behind and to side of inspection personnel to light the approaching vehicle and driver. This also eliminates glare for the guard.

7-3.3.1 Control Requirements: Primary ECF/ACP.

Manual Control	Wallbox switch or scene wallstation in nearby accessible location with manual ON and manual OFF
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability with manual override
Zoning	None

7-3.3.2 Control Requirements: Secondary ECF/ACP.

Manual Control	Wallbox switch or scene wallstation in nearby accessible location with manual ON and manual OFF
Motion Sensing	None
Time Schedule	Automatic dimming to 30% 1 hour after ECF/ACP closing and automatic full ON 1 hour before opening
Photosensing	ON and OFF based on daylight availability with manual override
Zoning	None

7-3.3.3 Control Requirements: Limited Use ECF/ACP.

Manual Control	Wallbox switch or scene wallstation in nearby accessible location with manual ON and manual OFF
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability with manual override
Zoning	None

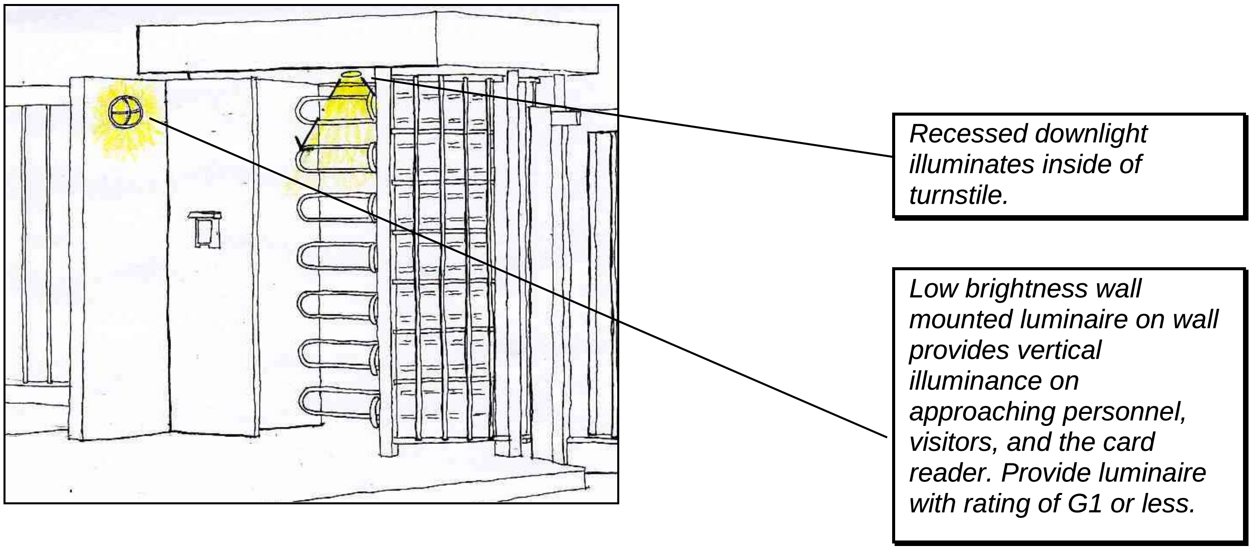
7-3.3.4 Performance Requirements.

Target Criteria	All Lighting Zones
Average Horizontal Illuminance under canopy at ID check	10 fc (100 lux) at grade
Uniformity under entire canopy	3:1 average to minimum

7-3.3.5 Critical Design Issues.

- Refer to Figure 6-6 for diagram of ECF/ACP lighting zones.
- Luminaires located on the wall must be less than 3500 initial light source lumens.
- Use luminaires with a G-Rating of G0 or G1 for canopy luminaires.
- Canopy luminaires should be semi-recessed or surface mounted with an uplight component. They will provide more illuminance onto the canopy ceiling surface, which improves uniformity and reduces contrast.
- Underneath the canopy, prioritize lighting at the ID check island, where ID Check is occurring.

7-3.4 Pedestrian Access.



7-3.4.1 Control Requirements.

Manual Control	None
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability
Zoning	None

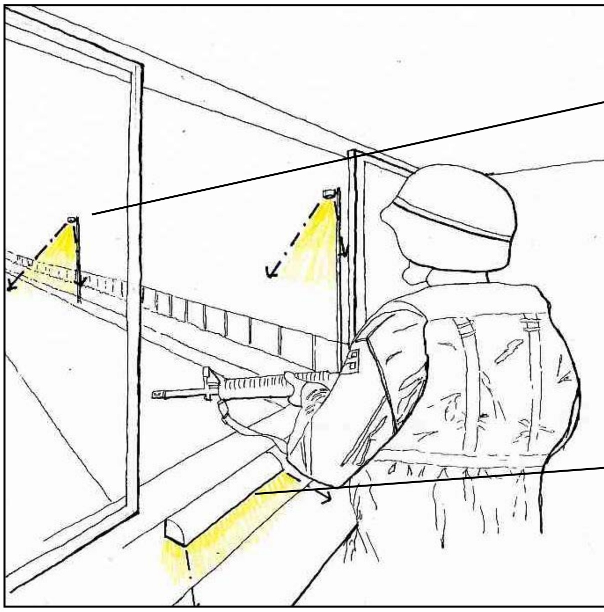
7-3.4.2 Performance Requirements.

Target Criteria	**All Lighting Zones**
Average Horizontal Illuminance	2 fc (20 lux)
Uniformity	3:1 average to minimum

7-3.4.3 Critical Design Issues.

- Luminaires located on the wall must be less than 3500 initial light source lumens.
- Locate luminaires to avoid harsh shadows.
- Refer to UFC 4-022-01 for additional criteria on signage.

7-3.5 Response Zone.



7-3.5.1 Control Requirements.

Manual Control	For interior task light, provide wallbox dimmer or scene wallstation with manual ON and manual OFF and manual dimming
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability
Zoning	None

7-3.5.2 Performance Requirements.

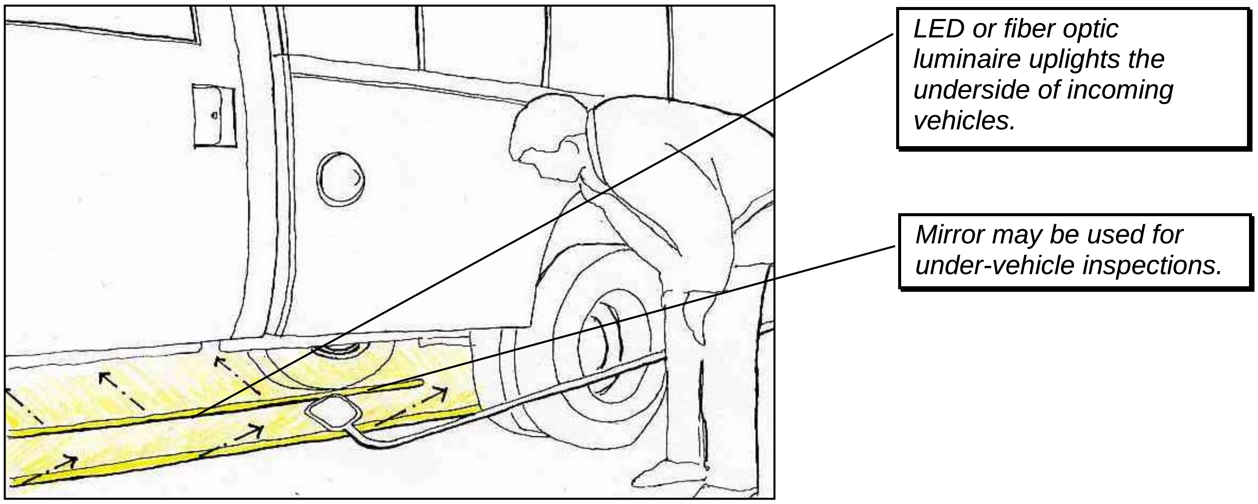
Target Criteria	Minimum Distance	All Lighting Zones
Average Horizontal Illuminance, Response Zone, Transition	60’ (18 m)	1.5 fc (15 lux) at grade
Average Horizontal Illuminance, Response Zone, Exit	80’ (24 m)	0.5 fc (5 lux) at grade
Uniformity	3:1 average to minimum	

7-3.5.3 Critical Design Issues.

- Refer to Figure 6-6 for diagram of ECF/ACP lighting zones.
- Use luminaires with a G-Rating of G0, G1, or G2 for roadway or area luminaires.
- Provide transitional lighting between bright and dark regions for the Response Zones of the gate to improve visual adaptation.
- For luminaires in the Discomfort and Disability Glare Visual Field, follow the design parameters outlined in section 6-3-4.1.

7-4 OTHER AREAS.

7-4.1 Under-Vehicle Inspection.



7-4.1.1 Control Requirements.

Manual Control	Wallbox switch or scene wallstation in nearby accessible location with manual ON and manual OFF
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability with manual override
Zoning	None

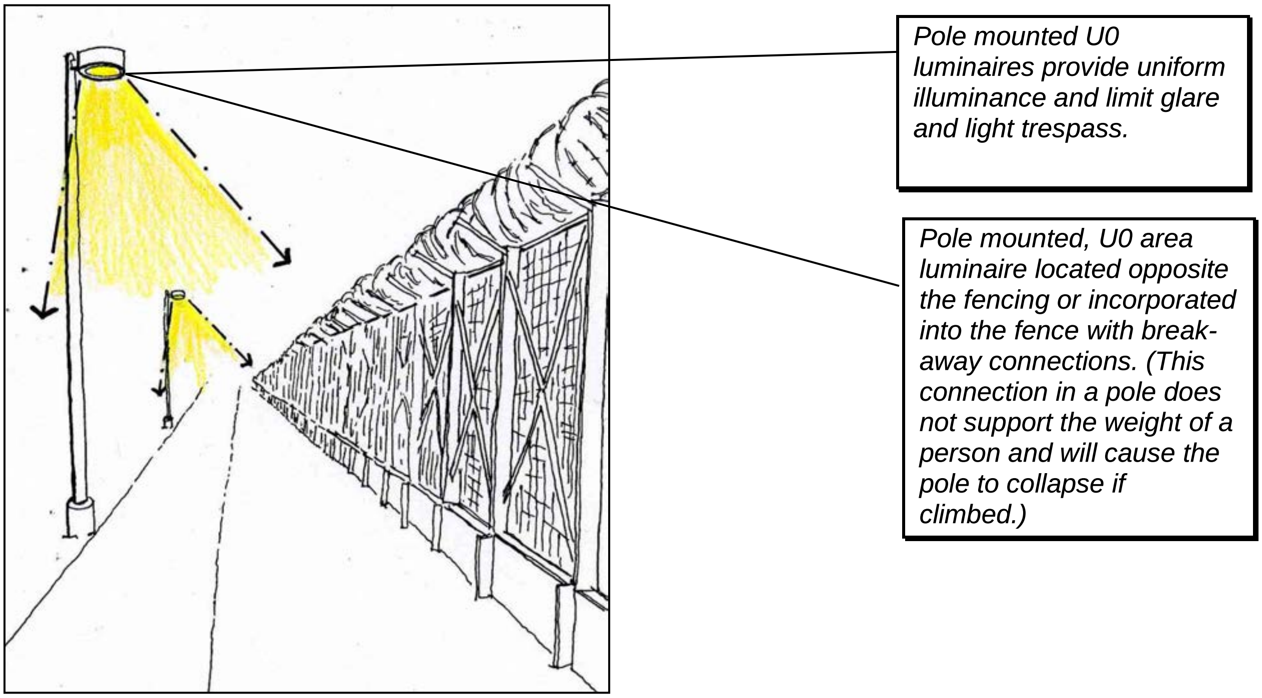
7-4.1.2 Performance Requirements.

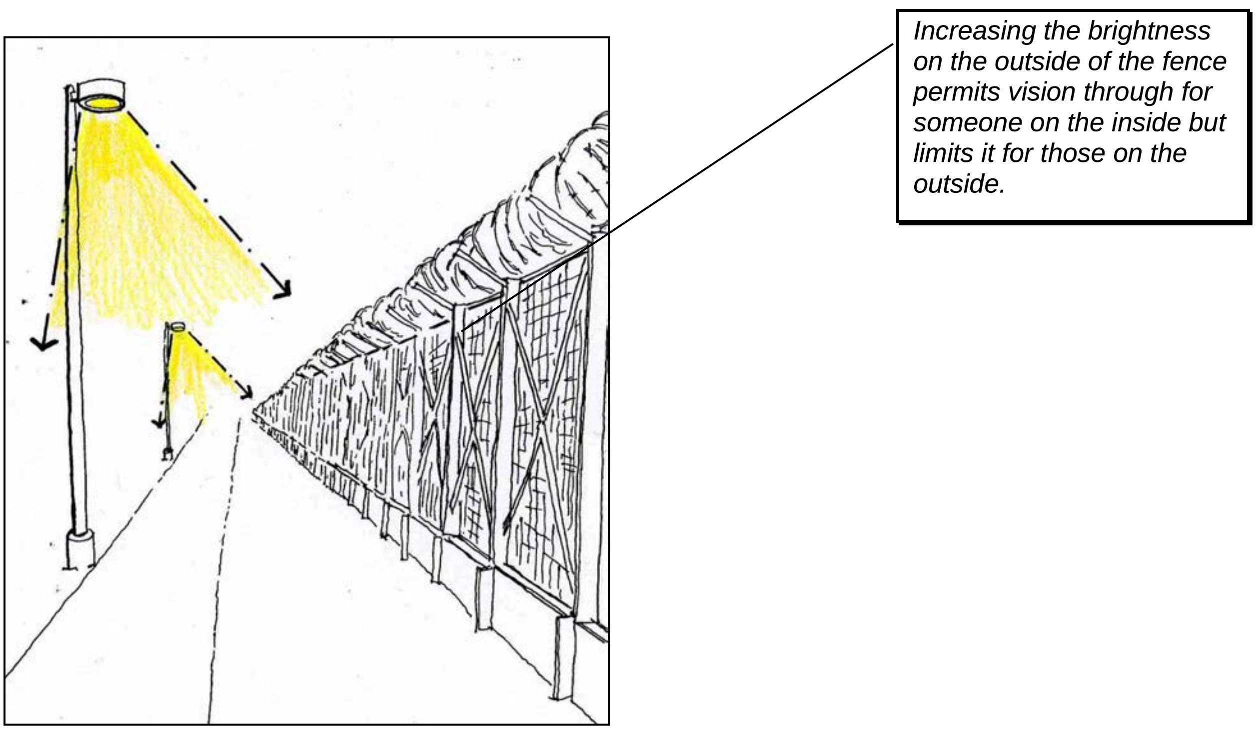
Target Criteria	**Daytime**	**Nighttime**
Minimum Horizontal Illuminance calculated from below	10 fc (100 lux) at 1’-0” (305 mm)	
Average Horizontal Illuminance at center of drive lane for surrounding parking and roadway	3 fc (30 lux)	
Uniformity	3:1 average to minimum	

7-4.1.3 Critical Design Issues.

- Luminaire brightness must be kept at a low level.
- Uniformly illuminate the underside of the vehicle.

7-4.2 Controlled Perimeters – Single Fence Line.





7-4.2.1 Control Requirements.

Manual Control	None
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on availability of daylight with manual override
Zoning	None

7-4.2.2 Performance Requirements.

Target Criteria	**All Lighting Zones**
Minimum Horizontal Illuminance	Between 0.2 and 4 fc (2 and 40 lux)
Uniformity	10:1 maximum to minimum

7-4.2.3 Critical Design Issues.

- Provide U0 rated and G2 or less luminaires with low lumen output to minimize glare and light pollution.
- Uniformly illuminate the area to minimize shadows along the perimeter.
- Coordinate lighting system with emergency backup power availability.

7-4.3 Restricted Area.

7-4.3.1 Control Requirements.

Manual Control	None
Motion Sensing	Automatically dim lights to 50% after 15 minutes of no detected motion
Time Schedule	None
Photosensing	ON and OFF based on daylight availability
Zoning	None

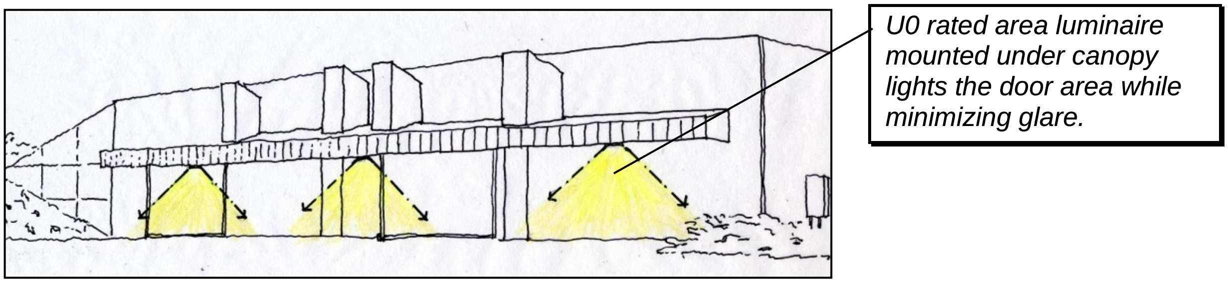
7-4.3.2 Performance Requirements.

Target Criteria	**All Lighting Zones**
Average Horizontal Illuminance	Between 2 and 5 fc (20 and 50 lux)

7-4.3.3 Critical Design Issues.

- Provide U0 rated and G2 or less luminaires with low lumen output to minimize glare and light pollution.

7-4.4 Magazines.



7-4.4.1 Control Requirements.

Manual Control	None
Motion Sensing	Automatically dim lights to 50% after 15 minutes of no detected motion
Time Schedule	None
Photosensing	ON and OFF based on daylight availability with manual override
Zoning	None

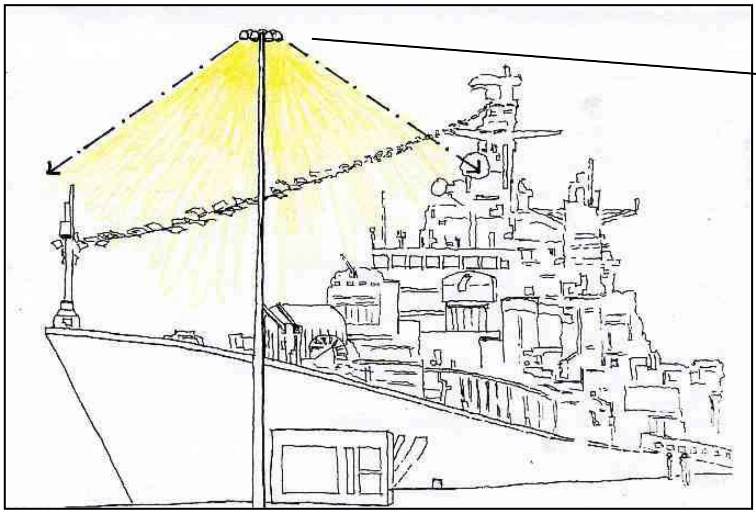
7-4.4.2 Performance Requirements.

Target Criteria	**All Lighting Zones**
Average Horizontal Illuminance	Between 0.2 and 5 fc (2 and 50 lux)

7-4.4.3 Critical Design Issues.

- Provide U0 and G2 or less luminaires with low lumen output to minimize glare and light pollution.
- Coordinate lighting system with emergency backup power availability.
- Reference UFC 4-420-01 for specific lighting requirements.

7-4.5 Piers and Wharves.



High mast luminaires provide uniform illuminance and minimize the number of poles necessary.

7-4.5.1 Control Requirements.

Manual Control	Optional: Two levels, operational and non-operational Switch location – guard position?
Motion Sensing	None
Time Schedule	None
Photosensing	ON and OFF based on daylight availability Turn lights to most recent manual setpoint
Zoning	None

7-4.5.2 Performance Requirements.

Target Criteria	**Active Work Areas**	**Other Areas**
Average Horizontal Illuminance	Between 3 and 5 fc (30-50 lux)	0.5 fc (5 lux)

7-4.5.3 Critical Design Issues.

- Provide U0 rated luminaires.
- Use the minimum number of high mast lighting poles and luminaires that provide uniformity.
- Refer to 29 CFR 1915.82 for the minimum lighting intensity requirements for shipyards.
- Refer to UFC 4-152-01 for Pier and Wharf operational lighting requirements.

APPENDIX A BEST PRACTICES: INTERIOR LIGHTING

A-1 MAINTENANCE.

Refer to ANSI/IES LP-9 Section 3.6 Service and Maintenance Issues, for maintenance best practices.

A-2 VISIBILITY.

Large tasks generally require less illuminance, brightness, and contrast to be performed. Small, detailed tasks may require task lighting to increase the light level significantly. Knowing a description of the task is essential to designing the lighting for that task. The luminance or brightness of a task increases the task visibility. Brighter tasks are easier to see, so long as it is not so much brighter than its surroundings that it becomes uncomfortable or a source of direct glare. As task contrast decreases, the light level required to see it increases. If the contrast is too low, it is difficult to distinguish various components of the task, reducing visibility.

A-2.1 Glare.

Direct glare can be minimized with careful equipment selection and placement. Indirect or reflected glare is caused by light reflecting off the task in such a manner that the contrast is “washed out.” Many work situations position the light directly in front of the task, producing reflected glare. See Figure A-1 for examples of direct glare.

Like direct glare, indirect glare can be minimized with the type and layout of lighting equipment. Locate direct light to the side or behind a critical task. Use semi-indirect light to bounce light off surfaces in order to provide uniform low glare light with less reflected disability glare. Direct luminaires that are immediately over an individual can cause glare even though the light source is not in the field of view. This type of glare can produce the same negative effects as direct or reflected glare including eye strain and headaches.

Figure A-1 Examples of Direct Glare

A-2.1.2 Considerations to Minimize Glare.

- Indirectly light the ceiling and walls for interior ambient lighting systems.
- Use direct light only in limited amounts for task and accent light.

A-2.2 Uniformity.

Lighting level or illuminance uniformity is important on work surfaces where sustained tasks are performed as well as on wall and ceiling surfaces that make up a significant portion of the field of view. See Figure A-2 and Figure A-3 for examples of uniformity. Poor uniformity can cause adaptation problems. It is very important to prevent “spotty” lighting especially in interior areas where people are working.

Figure A-2 Uniform ceiling brightness

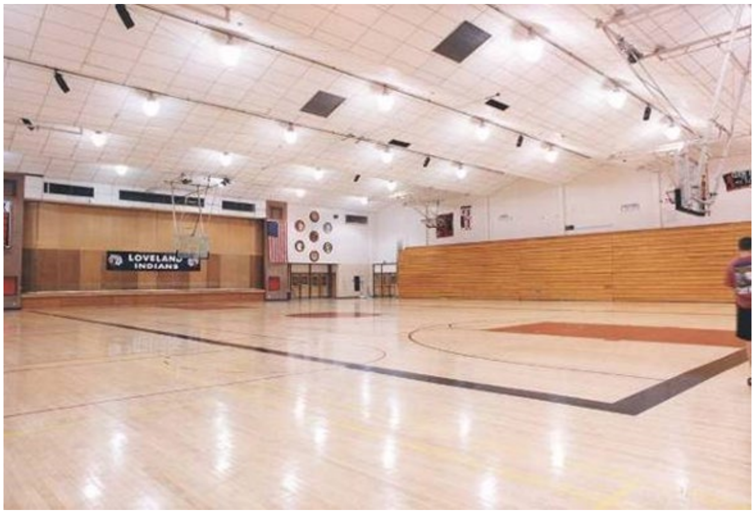


Figure A-3 Uniform illuminance

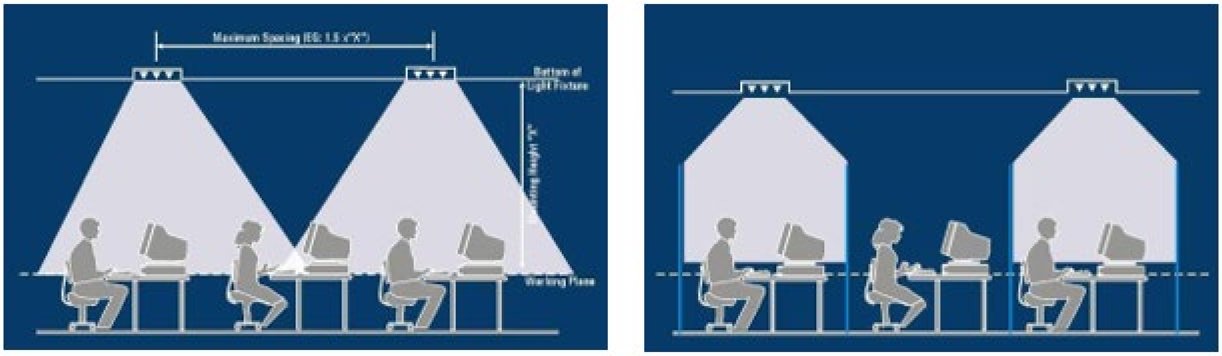
A-2.3 Maintaining Uniformity.

Carefully consider changes in lighting systems and furniture systems so that lighting uniformity is not compromised. As shown in Figure A-4, a lighting system that provides uniform illuminance on the work-plane in one furniture configuration may not provide the same uniformity in a different configuration.

In the case shown, an additional luminaire is required to adequately light the center workstation. This increases the amount of energy required to light the same area. In such a condition, the use of a semi-indirect, pendant system provides better uniformity and at the same time allow for flexibility in the workstation layout.

Figure A-4 Task plane illuminance uniformity[5]



A-2.3.2 Considerations for Uniformity.

- In office areas, uniformity should not exceed 5:1 average to minimum in immediate work surrounds, not including accent lighting.

A-2.4 Illuminance.

In many cases illuminance is no longer a top priority. Lighting wall and ceiling surfaces is usually more important than providing high levels of horizontal illuminance. In order to provide flexibility and interest in a space, light ceiling and wall surfaces with lower ambient lighting levels. Provide higher illuminance levels with individualized task lighting.

A-2.4.1 Considerations for Adequate Illuminance.

- Design ambient lighting levels to 1/3 to 1/2 task lighting levels. Add task lighting to increase light level at the task.
- Use white light for exterior lighting.

A-2.5 Surface Brightness.

Traditionally, illuminance has been the basis of lighting design; however, we see brightness. We do not see lighting levels. There are three different types of visual responses: Photopic or our day vision (5 cd/m² and higher), Scotopic or our night vision (0.001 cd/m² and below) and mesopic or a combination of night and day vision (0.001 cd/m² to 5 cd/m²). (ANSI/IES LS-1-21).

We “see” brightness (luminance); we don’t see lighting levels or (footcandles or lux). Our perception of spaces depends on how surfaces are lighted. The factors that lead to brightness as a response are object luminance, surround luminance, state of

[5] Used with permission. Hayden McKay Lighting Design.

adaptation, gradient, and spectral content.[6] It is important to light vertical surfaces such as walls and building facades as a first priority, then horizontal surfaces such as ceilings and canopies. The least effective surfaces to light are floors. Downlighting results in spaces feeling dark and "cave-like", see Figure A-5. Lighting surfaces improves the feel of the space, see Figure A-6.

Figure A-5 Downlighting only

Figure A-6 Improved surface brightness

A-2.6 Low Ceiling Applications.

In some applications, the ceiling height may be low and cannot be increased to accommodate pendant mounted lighting equipment. In these cases, the lighting design should still try to address the issue of surface brightness. One way to achieve surface brightness with low ceiling conditions is with recessed downlight/wallwash luminaires. The reflector on these luminaires looks similar to a standard downlight, but also uses a modification to light adjacent walls evenly. It is also designed to put light high on the wall next to the ceiling.

[6] ANSI/IES LS-8-20, Lighting Science: Vision – Perceptions and Performance. (New York: Illuminating Engineering Society; 2021.)

A-2.6.1 Indirect lighting.

Indirect lighting provides better visibility for offices and computer tasks than parabolic luminaires. Additionally, the installation cost of pendants can be lower than recessed direct/indirect troffer luminaires due to the reduced number of connection points. In low ceiling applications where a semi-indirect pendant system is not feasible, consider semi-indirect recessed for lighting the interior of the space. Downlight/wallwashers around the perimeter of the space increase the surface brightness of the walls. This strategy is a better choice to eliminate glare than the use of lensed troffers. However, avoid troffers designed to spread the light. These achieve wide distributions by lowering the light sources in the luminaire and thereby increasing the glare.

A-2.6.2 Semi-indirect pendant.

Semi-indirect pendant manufacturers offer short pendant luminaires for low ceiling applications. These luminaires use refined optics to spread light out and light the ceiling with a pendant length of under 12 in (0.3 m). These luminaires allow semi-indirect lighting systems in spaces with a ceiling height of 8 ft (2.4 m).

A-2.7 Considerations for Surface Brightness.

- Provide high surface reflectances for walls (60% minimum) and ceilings (85% minimum).
- Light ceilings with semi-direct wall or pendant mounted lighting.
- Light walls with wall washers.
- Direct daylight to ceilings and walls.
- For exterior applications, light vertical surfaces that are in pedestrians’ field of view.

A-3 LIGHT SOURCES.

A-3.1 Technical Considerations.

Refer to ANSI/IES LP-4-20, *Lighting Practice: Electric Light Sources – Properties, Selection, and Specification*.

A-3.2 Light Source Efficacy.

Refer to ANSI/IES LP-4-20, *Lighting Practice: Electric Light Sources – Properties, Selection, and Specification*.

A-3.3 Material Issues.

Fluorescent, metal halide, induction, and high-pressure sodium light sources contain liquid mercury to produce the mercury vapor necessary for operation. When light sources are broken or incinerated the mercury may be released into the soil or the atmosphere. Mercury has been linked to potential health risks. Some light source manufacturers offer product series that feature reduced mercury content.

A-3.4 Recycling.

Traditional light source types except incandescent sources contain some level of mercury. These light sources should be recycled to avoid release of any mercury into landfills. The cost of recycling light sources should be included in any life-cycle cost analysis.

A-4 EQUIPMENT PERFORMANCE.

A-4.1 Flicker.

Most light sources flicker but remain mostly imperceptible. SSL luminaires are particularly sensitive to noticeable flicker when dimmed, especially with incompatible dimming controls and inadequate electrical infrastructure. Utilizing 0-10V and DALI dimming protocols are recommended to reduce flicker across dimming ranges. For applications where these dimming protocols are not available, such as screw-base lamp replacements, provide dimmer compatible with SSL luminaires and ensure that electrical infrastructure is adequate to operate SSL luminaires.

A-4.2 Noise.

Provide LED drivers with a Class A noise rating.

A-4.3 Interference.

LED drivers have the potential to cause electromagnetic interference (EMI) and radio frequency interference (RFI) when operated near other high frequency electronic equipment. This can be a significant issue when installed near electronic medical equipment. LED drivers should be selected and rated for use near sensitive equipment, complying with FCC Title 47 Part 15.

A-4.4 Effects of Temperature.

Ambient air temperature affects the performance and output of fluorescent, SSL, and induction light sources. Low temperature has a positive effect on SSL sources, improving their life. For SSL luminaires, ANSI/IES LM-79 and ANSI/IES LM-80 testing reports show the lumen depreciation over time and temperature.

A-4.5 Life.

The operating temperature of drivers and power control units directly affects the life. The luminaire housing or enclosure should provide for adequate dissipation of heat. When drivers operate at excessive temperatures, the insulation degrades, resulting in a shortened driver life. High operating current in SSL luminaires can also shorten life. Review ANSI/IES LM-80, ANSI/IES LM-79, and ANSI/IES TM-21 data to determine actual life with designated operating current.

The life expectancy data given by LED light source manufacturers refers to the approximate operating time over which the LED light source will maintain 70% (L_{70}) of its initial light output.

A-5 CONTROL APPROACHES.

Lighting controls have the benefit of reducing energy use when lighting is not required. Lighting controls are required in meeting ASHRAE 90.1 energy codes. It is important to note that electric lighting controls should be incorporated with a daylight design to gain any energy savings from the daylight.

A-5.1 Occupancy Based Controls.

Occupancy sensors automatically turn the lights on when an occupant enters a space and automatically turn the lights off after a predetermined period in which no human activity is sensed. Vacancy sensors automatically turn the lights off after a predetermined period in which no human activity is sensed. The occupant manually turns on the lights when he or she enters the space. The operating technologies behind either an occupancy or vacancy sensor are passive infrared, ultrasonic, or dual technology.

Occupancy based controls may be ceiling mounted to cover large spaces or they may be integrated with wall switches for smaller spaces. Occupancy based controls are ideal for areas of convenience such as storage rooms where individuals often have their hands full when entering or leaving. For private offices without daylight, it may be ideal to have an auto-on occupancy sensor that turns the lights on to a preset light level, such as 50% with a manual 100%, and then automatically turns the lights off. Manual override may be necessary in spaces where the lights occasionally need to be turned off with occupants such as classrooms and conference rooms. It may also be useful to group luminaires and control with a single occupancy or vacancy sensor. Controls should have a time delay that can be adjusted up to 30 minutes. If the sensor fails, local override control should be available, or the system should revert to the ON position. Table B-1 summarizes strategies for selecting the appropriate occupancy-based control sensor.

A-5.2 Bilevel and Multi-level Switching.

Bilevel switching is less prevalent with SSL sources. It is most commonly seen today in direct/indirect luminaires with two circuits: one circuit controls the indirect, or uplight, component, and the other controls the direct, or downlight, component. It is also occasionally used to provide step dimming in areas, without requiring dimming controls. However, as SSL sources are less expensive to dim than their fluorescent predecessors, step dimming is seen less frequently. Bilevel switching should be used in stairwells and similar low occupancy spaces such as hallways to reduce energy consumption without the use of dimming controls. Controls should fail in the full-on position. Spaces should be equipped with bilevel luminaires controlled by an integrated or separate occupancy sensor. When the space is unoccupied; lighting should be reduced by a minimum percentage of 50% and maintain the minimum life safety code requirement for egress when the building is occupied. When utilizing bilevel switching in Means of Egress, the lighting and controls must comply with NFPA 101.

A-5.3 Daylight Dimming.

Daylight dimming is used to reduce the light output and energy usage of the electric lighting in spaces with daylight. This is achieved with the placement of photosensors to measure the amount of light on a task surface or the amount of available daylight outside. Electric light is either dimmed or shut off in response to the amount of light detected and the programming on the control system. Best practices of daylight dimming are discussed in detail in Appendix C.

A-5.4 Light Level Tuning.

Light level tuning is used to adjust the maximum light level to precisely set the lighting requirements based on the preference of the occupants in the space and the color of the carpets, office furniture, cubicles, and walls. Different spaces can have different maximum light levels and the ability to adjust the high-end output of the luminaire can offer typical lighting energy savings of 20% or more.

A-5.5 Scene Based Dimming.

One button touch allows multiple zones of light within a space to go to the appropriate light levels, known as a scene, for a specific task or use. Scene-based control should allow the integration of AV controls, shading, and lighting to work seamlessly with one button touch (lights dim, projection screen lowers, and shades go down).

A-5.6 Manual Switching.

Manual switching may be an ideal strategy where automatic control is not allowed, such as electrical rooms. The energy savings is diminished though, so a switch should be integrated with an occupancy-based sensor, where allowed.

A-5.7 Timeclocks.

Timeclocks control larger areas or groups of luminaires. They automatically adjust lighting levels based on the time of day or astronomical events such as sunrise and sunset. This type of control may be applicable in spaces where there is constant occupancy, limited daylight, and minimal activity in non-peak hours of the day.

A-5.8 Personal Control.

This provides an occupant with the ability to control and dim their own lighting even in an open office configuration. Personal controls may be accomplished with personal control over task lighting at a workstation.

A-5.9 Network Control Systems.

A network control system is required to integrate into a building automated, energy management system. Even in cases where integration with a building management system is not feasible, it may be appropriate to have a stand-alone network lighting control system. There are varying methods to create a network control system. A network-based system may provide the greatest flexibility and configuration options because zones can be created through software for spaces that may be reconfigured over time. A network control system with the capability of controlling each luminaire allows maximum flexibility for energy savings and reconfiguration of the spaces. When possible, a network control system will also allow use of control devices like occupancy sensors by other systems, such as controlled receptacle circuits.

A-6 CONTROL EQUIPMENT.

A-6.1 Sensors.

A-6.1.1 Occupancy Based Controls.

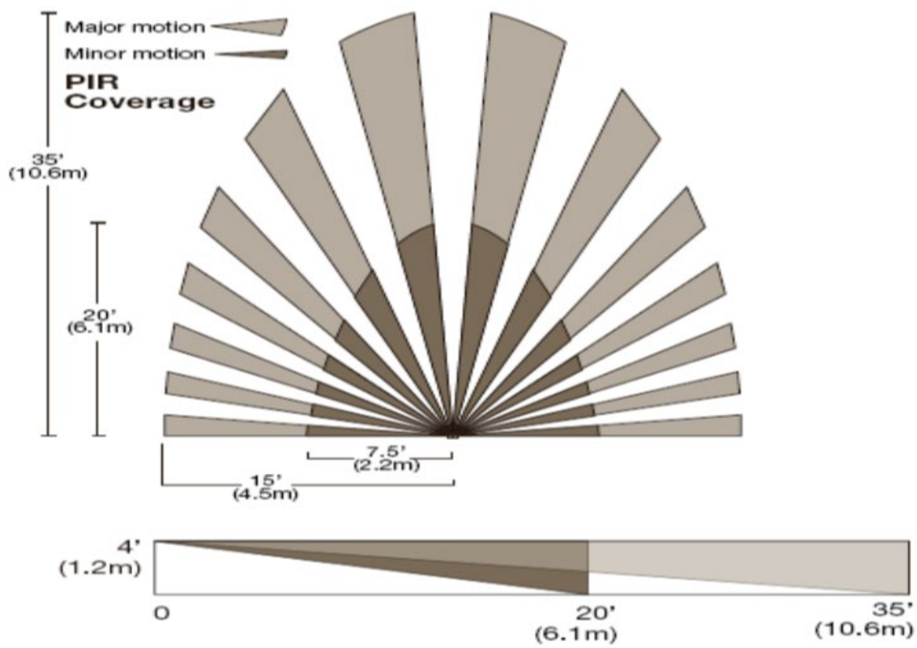
An occupancy sensor is used for interior applications to automatically turn the lights on when an occupant enters the space and automatically turn the lights off after a period of undetected occupancy.

A vacancy sensor requires the occupant to manually turn the lights on when they enter the space, and the sensor automatically turns the lights off after a period of undetected occupancy. More energy is saved when using vacancy sensors as occupants may not always require electric lighting when entering a space.

A-6.1.1.1 Passive Infrared.

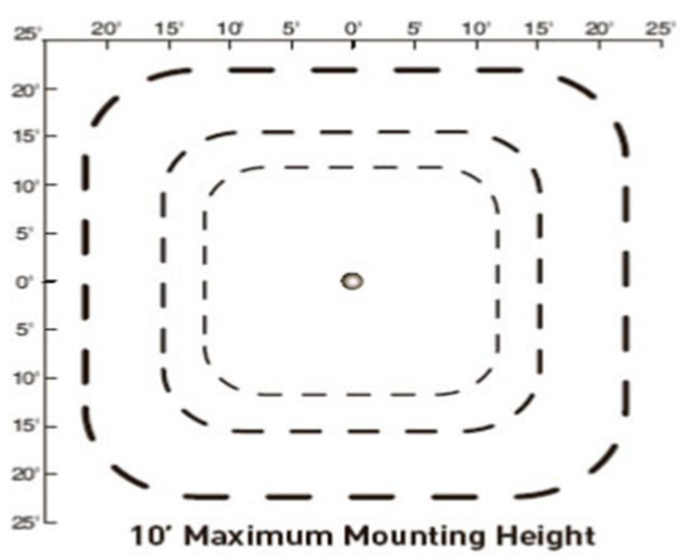
Passive infrared (PIR) sensors detect the difference in heat between a human and the surroundings. Because of this, the sensor has to be able to “see” the entire space and any obstruction such as partitions, shelves, or cabinets block detection. Changes in ambient temperature also reduce the effectiveness of the infrared sensors. The pattern of occupancy is dispersed in a fan shape where the distance between fan blades is small near the sensor but increases as the fan blades are directed away from the sensor, see Figure A-7.

Figure A-7 Coverage Pattern of PIR Sensor



Ultrasonic technology relies on high frequency sound waves to detect movement in the space, see Figure A-8 for typical coverage pattern. This movement could be a person moving, or air movement created by a person's activity. This type of sensor is therefore appropriate for spaces that have partitions such as restrooms or open office areas. Such sensors need to be located so that they do not sense the "false-occupancy" of an air vent or a passer-by in an adjacent space. Room finishes such as carpeting may absorb the ultrasonic waves and reduce effectiveness.

Figure A-8 Coverage Pattern of Ultrasonic Sensor

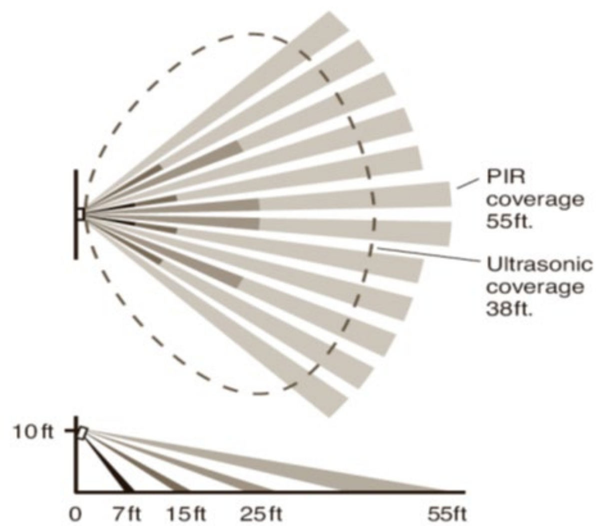


A-6.1.1.2 Dual Technology.

Dual technology sensors combine both the capabilities of PIR and ultrasonic to detect occupancy. See Figure A-9 for coverage pattern. Both an ultrasonic and PIR detection of occupancy is required for the lights to turn on but only one sensor technology is required for the lights to remain on. This type of sensor is best used in large spaces with low occupant activity levels.

Figure A-9 Coverage Pattern of Dual Technology Sensor

(Courtesy of Wattstopper/Legrand)



A-6.1.1.3 Microphonic.

Microphonic passive occupancy sensors are available with dual sensors. These sensors use PIR technology to first detect motion in the space and then use a microphone to monitor sounds to indicate continued occupancy.

Micophonic sensor technology is not recommended for most spaces since noise from HVAC, refrigerators, traffic, radios, telephones, and other systems may cause false occupancies detection.

A-6.1.1.4 Sensor Considerations.

See Table A-1 for guidance on where to use sensor types. Each type of occupancy or vacancy sensor should be equipped with a time delay. This time delay leaves the lights on for a predetermined amount of time after the last occupant has been detected. The purpose of the time delay is to ensure that occupants are not left without lighting and to reduce the number of on/off cycles. Since occupancy patterns vary with time of day as well as day of the week, and are not easily scheduled, it is best to select a time delay that works for both periods of increased and decreased occupant activity.

Manufacturers typically have preset time delays at 5, 10, 15, 20, or 30 minutes. It is recommended that a time delay setting of 20 minutes be used for most spaces. Should another time delay setting be selected, consideration should be given to the increased energy consumption, driver type, and increased life of the light source due to the reduced number of on/off cycles.

In addition to the time delay, there should also be a setting for the sensitivity. The sensitivity needs to be calibrated appropriately according to the activity in the space. For example, if there is limited movement in the space, the sensitivity should be calibrated to detect very slight movement.

Table A-1 Guide for Using Sensors

DO	**DON'T**
Use ultrasonic sensors in large open areas with partitions or furniture	Use ultrasonic sensors where there is high air flow.
Place sensors in proximity to where the main activity in the space will occur.	Install an in-wall sensor where it is blocked by furniture or behind the door.
Use PIR in enclosed spaces.	Use ultrasonic sensors in small, enclosed spaces where they may react to activity outside the space.
For large areas, create zones of light to manage light.	Install ultrasonic or dual tech sensors higher than 12 feet.
Overlap sensor coverage patterns by at least 20% to ensure adequate coverage.	Install sensors within 6 feet of an HVAC vent.
Ensure PIR line of sight does not extend out doorways. This can be achieved by either sensor placement or lens masking.	Use PIR sensors when there are multiple obstructions (furniture, partitions) which prevent line of sight of the sensor.

A-6.1.1.5 Self-Adapting.

Self-adapting technologies “learn” how the space is used by occupants and adjusts the lights as necessary. The technology responds in real-time and automatically adjusts both the sensitivity of the sensor and the delay time. Self-adapting sensors are best used in spaces where neither the occupants nor the activities vary from day to day. Self-adapting technology is not recommended for classrooms and conference rooms but may be ideal for private offices.

A-6.2 Manual Controls.

Considerable energy savings can be achieved by allowing occupants to control (on/off) or vary the light levels.

Energy savings from dimming lights is nearly linear. Furthermore, users seldom require maximum light levels and studies show that allowing users to adjust illuminance for different tasks saves 35% - 42% lighting energy.

A-6.2.1 Switches.

Manual controls for occupants can be a good way to increase worker autonomy and give occupants greater control ability, although the energy savings is not as great as automatic controls and is not allowed by the energy code in most regularly occupied spaces.

A-6.2.2 Dimmers.

Manual dimming occurs with a control action initiated by the occupant. This type of dimming may be useful in spaces where several different activities can take place. A conference room is an example where the lights may need to be dimmed for an A/V presentation, but also may need to be full output for meetings. Manual dimming also results in high satisfaction rating for occupants and should be encouraged for regularly occupied areas.

A-6.3 Time Controls.

A-6.3.1 Time Switch.

Automatic switching takes place in conjunction with occupancy controls when the space becomes unoccupied. The lights turn off after a designated period of inactivity.

A-6.3.2 Timeclock.

A timeclock is a device that automatically adjusts the lights at a specific time or based on astronomical events such as sunrise or sunset. Manufacturers typically allow the preset time to vary between 5 minutes and 12 hours. This type of control may be applicable in spaces where there is constant occupancy, limited daylight, and minimal activity in non-peak hours of the day.

A-6.3.3 Schedule.

A preset schedule can be programmed to automatically turn the lights on or off based upon trends in occupancy. Different schedules are created for weekdays, weekends, evenings, and holidays.

A-7 NETWORK CONTROL SYSTEM.

A network control system can be connected in a number of different ways. Implementing addressable drivers provides digital addresses for all drivers and connects them as a system through network cabling. The digital addresses allow control over each driver individually and allow for flexibility of the system as the needs of the space evolve over time. A wireless system communicates with all devices (sensors, dimming drivers, and area controllers) over radio frequency. The zoning of such a system is configured through software and provides flexibility as the needs of the space evolve over time.

ANSI/IES LP-6 provides technical information regarding the varying architectures, topologies, and protocols that are currently available for lighting controls. The document may be useful especially when integrating one protocol with another or integrating a lighting control system with a building automation system. Typical uses are outlined along with limits/extents, interoperation with other protocols, and designer responsibilities specification recommendations.

A-8 EMERGENCY AND EXIT LIGHTING.

Mark and illuminate means of egress in accordance with NFPA 101. The purpose of emergency lighting is to ensure the continuation of illuminance along the means of egress from a building and provide adequate light for the orderly cessation of activities in the building. The purpose of exit lights is to identify the means of egress. Both types of lighting are powered from both a normal power source and an emergency source, with automatic switching from one to the other.

In some specific situations, emergency lighting might be required for specific spaces or work areas that are not on the means of egress. There are often areas where work of a critical nature has to continue regardless of loss of normal power, such as a computer server room. In health care facilities, including hospitals, skilled nursing homes, and residential custodial care facilities, lighting for the means of egress (including exit signs) and elevator cabs is considered “life safety” lighting and connected to the life safety branch of the facility’s emergency power system. Task illumination at anesthetizing locations, patient care areas, laboratories, intensive care units, recovery rooms, and other locations as required by NFPA 70, Article 517 are considered “critical” lighting and powered from the critical power branch of the facility’s emergency power system. In applications where the loss of light, even momentary, would endanger personnel or risk other loss or damage, provide lighting systems to maintain constant illumination through the use of an uninterruptible power supply of sufficient capacity to permit an orderly cessation of activity.

A-8.1 Testing of Emergency Lighting Equipment.

Because of the periodic testing requirements, accessibility of equipment is an important design consideration. Consider self-testing or self-diagnostic emergency lighting equipment.

A-9 REPLACEMENT OF LUMINAIRES.

A-9.1 Fluorescent Industrial Luminaires, Wraparound, Strip Lights, and Recessed Direct/Indirect Troffers.

Convert T-12 and T-8 lighting systems to dedicated LED luminaire. Properly dispose of fluorescent lamps that contain mercury.

A-9.2 Incandescent Downlights.

Where possible, replace incandescent downlights with dedicated LED luminaire replacements. If a full replacement is not possible, retrofit LED lamps are available for direct one-to-one replacement for most incandescent lamps. Confirm appropriate CCT selection, lumen output, and dimming capabilities. Many retrofit LED lamps are not rated for enclosed luminaires. Check lamp specifications prior to installation.

A-9.3 HID, Floodlights, Downlights and Other Luminaires.

Replace existing luminaires with LED systems. This replacement is especially appropriate for applications where switching or dimming could be encouraged to save energy in addition to improving visibility. LED retrofit kits are not a one-for-one replacement of HID luminaires but rather an alternate lighting system.

A-9.4 Exit Signs.

Retrofit incandescent exit signs with LED type.

A-9.5 Lighting Control System.

Consider lighting controls for a lighting replacement project to improve the energy efficiency of the space. Use the installed cost of the system when analyzing the life-cycle cost for a lighting replacement with controls. Integrate the lighting control system directly into the HVAC system to provide reduced HVAC load requirements and improve the buildings energy efficiency.

APPENDIX B BEST PRACTICES: DAYLIGHTING CONTROLS

B-1 INTRODUCTION.

Refer to ANSI/IES LP-3-20, *Lighting Practice: Designing and Specifying Daylighting for Buildings* for additional information.

B-2 SYSTEM INTEGRATION.

If the majority of areas are daylighted, then the electric lighting becomes supplemental during daytime periods. Since our appetite for light is less in the evening and nighttime hours, daylighting does not need to be duplicated with electric lighting. Design electric lighting to supplement the daylighting. For example, when daylight is plentiful, the electric lighting dims near the daylight source. In other areas where the daylight penetration is not as great, the electric lighting can be increased. Electric lighting controls (daylight, occupancy, and vacancy sensors) can typically save up to 50% of the lighting energy in existing buildings and up to 35% in new buildings.[7]

B-3 CONTROLS.

B-3.1 Daylight Sensor Technologies.

Open loop photosensors determine the light level by measuring the outside light availability. Based upon the light level measured, a signal is sent to the electric lighting to either increase or decrease the light level depending on the exterior daylight availability.

Closed loop photosensors determine the light level in a space by measuring the inside light availability. Based upon the light level measured, a signal is sent to the electric lighting to either increase or decrease the light level depending on the interior daylight availability. Table B-1 provides a summary of daylight sensor technologies.

B-3.1.1 Larger Areas.

In larger areas with one daylight zone adjacent to the same window wall and no corner windows, open loop sensor works well. In other spaces, with multiple zones, closed loop works well with one sensor per zone. Networked lighting control systems typically deploy closed loop sensors.

[7] New Buildings Institute, Inc. “Lighting Controls”, *Advanced Lighting Guidelines,* Chapter 8. 2001 Edition, p. 8-1

Table B-1 Summary of Daylight Sensors

Use This Equipment	In This Type of Space	And Be Aware for These Issues
Open loop	Spaces where the outside daylight availability gives an accurate representation of the daylight into the space.	- Sensor should be placed outside or inside pointed towards the daylight opening - Use multiple sensors for spaces with more than one daylight opening - Outside conditions are accounted for, but not space conditions (geometry and reflectance)
Closed loop	Spaces where a constant level of illumination is desired.	- Room surfaces (reflectances) and physical obstacles may affect the light level readings - More reliable and effective at measuring light levels than open loop photosensors

A hybrid adaptation of open loop and closed loop sensors is available. Open loop systems only measure changes in daylight, and not changes in electric lighting. This reduces the likelihood of system imbalance, but by locating these sensors outside of the space does not provide the most accurate daylight dimming but can cause some system imbalance. A hybrid system is located in the space for accurate daylight dimming, but by subtracting the electric lighting contribution to the sensor, system imbalance is not a problem.

B-3.2 Automatic Lighting Controls.

Continuous dimming provides a seamless transition of light level to occupants. The light level is adjusted over a period of typically several seconds does not distract occupants which is ideal for daylight availability dimming. Step dimming creates more abrupt changes in light level. The range of dimming is limited to a few preset light levels and does not allow for transitions and may be noticeable, even distracting, to occupants.

B-3.3 Task Dominant Areas.

Task dominant area examples include offices, conference rooms, classrooms, maintenance areas, and other regularly occupied areas. Daylight dimming provides the highest level of satisfaction since the lighting smoothly responds to daylight availability versus an abrupt on/off. Ideally, manual dimming with an upper daylight limit provides the greatest flexibility and highest acceptance since people have control over their areas. In addition, occupancy and vacancy sensors turn off the lighting if no one is in the area.

B-3.4 Non-task Dominant Areas.

Non-task dominant area examples include transition areas such as corridors, lobbies, atriums, or support areas such as cafeterias, restrooms, and storage areas. Exterior lighting is typically a non-task dominated area. Automatic daylight on/off or bilevel switching is acceptable in these areas, yet dimming is still preferred. Occupancy sensors in these public areas save the most energy, though lights can be turned off with an energy management system. If occupancy devices allow adequate time, especially in transition areas, then the lighting is not disrupted during normal hours of operation.

B-3.5 Control Strategies.

Luminaires in primary and secondary zones switch or dim in response to daylight. See Figure B-1 for layout of primary and secondary zones. Locate sensors according to manufacturer's recommendations. Integrate electric lighting with daylight controls. The electric lighting should begin to dim when the daylight contribution exceeds the target illuminance level on the task plane. Continuous dimming is recommended instead of step dimming to minimize visual disruption to occupants. Harvesting daylight is best suited in spaces that are frequently occupied and a significant amount of daylight enters the space.

When selecting daylight zones, consider the exterior environment in addition to the proximity to glazing. As Figure B-1 and Figure B-2 indicate, if exterior buildings or foliage are blocking some of the daylight contribution into the building, treat those zones as secondary, see Figure B-3. Note that the zoning changes depending on the floor level. Locate the electric lighting parallel to the daylight zones for dimming control.

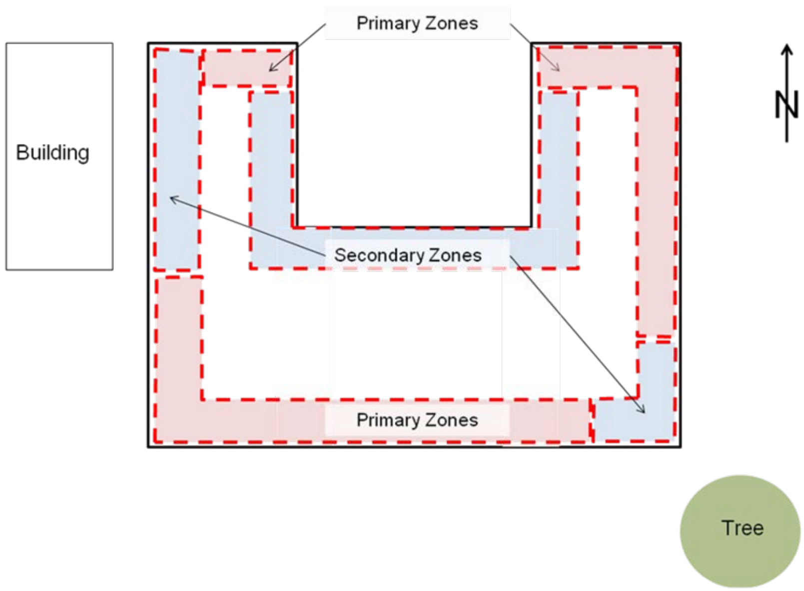
Figure B-3 Daylight Control Zones with Obstructions (Lower Floors)



B-4 AUTOMATED SHADING.

When utilizing automated shading, coordinate daylighting controls with automated shading controls.

APPENDIX C BEST PRACTICES: EXTERIOR LIGHTING

C-1 LIGHTING QUALITY.

C-1.1 Luminance.

There are three different types of visual responses: Photopic or our day vision (5 cd/m² and higher), Scotopic or our night vision (0.001 cd/m² and below) and mesopic or a combination of night and day vision (0.001 cd/m² to 5 cd/m²). Reference ANSI/IES LS-7-20, *Lighting Science: Vision – Eye and Brain*, Sections 5 through 5.4, for more on the ranges for photopic and scotopic vision. The majority of exterior lighting is designed in the mesopic range.

C-1.1.1 Mesopic.

Since light source lumen ratings are all based on photopic sensitivity, they need to be adjusted for nighttime applications. Photopic and mesopic lumens are determined from the spectral power distribution of the light source. In addition, photopic luminous efficiency function applies to visual fields 2 degrees or smaller. This means that only tasks that are on-axis or one that is focusing straight ahead apply to the photopic light source lumen ratings. Any task that is in our peripheral vision does not. Peripheral vision shifts to shorter wavelength sensitivity.

Mesopic multipliers may be used to account for the improved visibility provided by white light. The process for calculating mesopic multipliers can be performed with luminance values or with illuminance values that are converted to luminance values as a function of the background reflectance. Point-by-point mesopic multipliers, as outlined in CIE 191:*2010 Recommended System for Mesopic Photometry Based on Visual Performance* adjust not only the average luminance, but also the uniformity.

C-1.2 Light Pollution.

Light pollution or sky glow is caused by light aimed up into the sky and by light reflected off the ground or objects, see Figure C-1. Sky glow prevents the public and astronomers from seeing the night sky.

Floodlights, wall packs, and other un-shielded luminaires; see Figure C-2, are the major contributors to sky glow. Over-lighting, even with shielded luminaires, reflects unnecessary light back into the atmosphere and adds to the sky glow. This often occurs at outdoor areas such as motor pools and sports fields.

Figure C-1 Los Angeles, 1908 (left), Los Angeles, 2002 (right) [8]

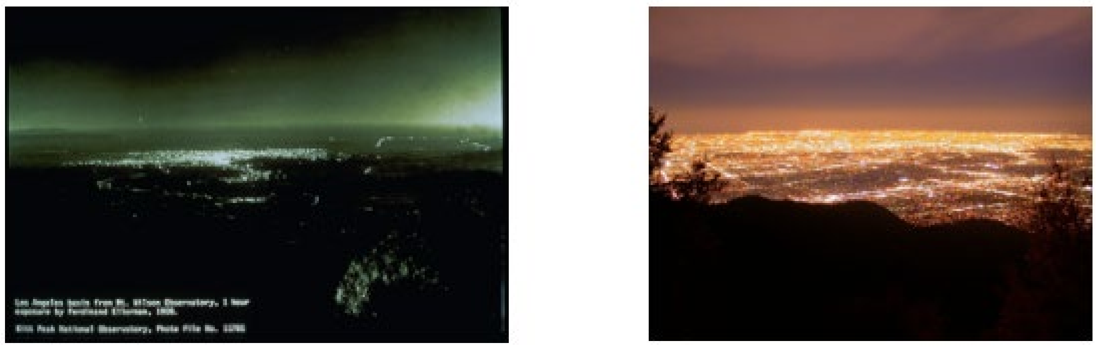


Figure C-2 Unshielded and Non-Cutoff Luminaires

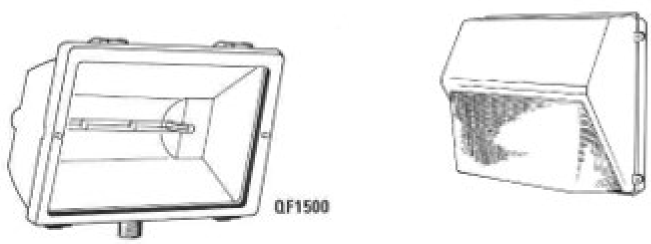
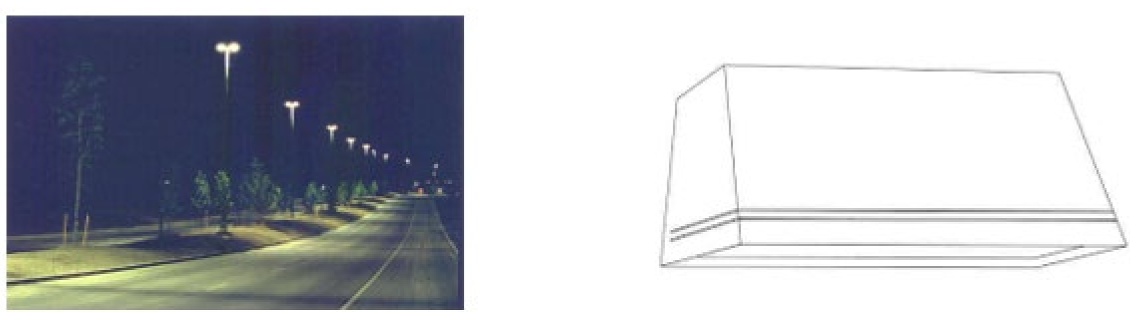


To minimize light pollution, use U0 rated luminaires for area and roadway lighting as illustrated in Figure C-3. Provide uniform low glare lighting and do not over-light exterior areas. Also, control lighting with time clocks, photocells, and motion sensors such that lighting is only energized when needed.

Figure C-3 Examples of IES TM-15 U0 rated luminaires



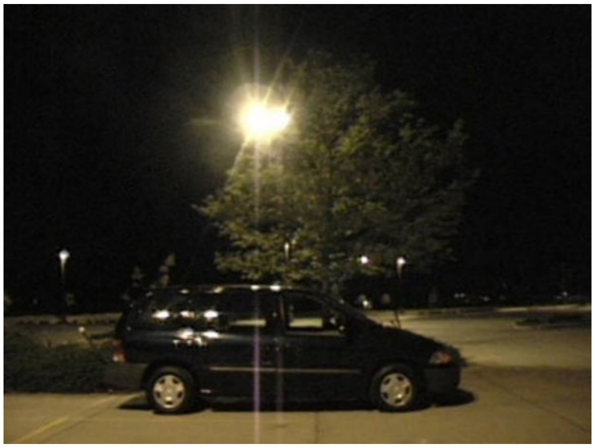
C-1.3 Light Trespass.

Light trespass is referred to as nuisance glare or the “light shining in my window” effect. It is usually caused by a glare source that is bright compared to the darker night surround, see Figure C-4. Since glare inhibits our ability to “see” tasks and decreases contrast, minimize glare. Uncontrolled light sources (floodlights) are usually the cause of

[8] © 2003 by Prof. Dr. Gerhard Eisenbeis University of Mainz/Germany

light trespass. Not only does light trespass cause neighbor annoyance, but it also increases light pollution.

Figure C-4 Uncontrolled Light Source



To minimize light trespass, use only U0 and a maximum of G1 rated luminaires for area lighting, see Figure C-5. When unshielded luminaires such as wall packs and decorative luminaires are used at low mounting heights, reduce the light source brightness to that of a 4,200-lumen light source or less. Do not over-light areas because reflected light can also result in complaints and poor visibility by increasing visual adaptation. Also, consider dimming or turning lighting off when not needed and activate with motion sensors or timers when activity occurs.

Figure C-5 IES TM-15 U0 Rated Luminaires

C-2 CLASSIFICATION SYSTEMS FOR OUTDOOR LUMINAIRES.

There are three systems in use today for categorizing outdoor light fixtures, two defined by the Illuminating Engineering Society (IES) and one by the National Electrical Manufacturers Association (NEMA). In two of the systems, the luminaires are categorized according to the distribution of light emitted from the luminaire, and in the third by the pattern of light produced on the ground.

C-2.1 The IES Categories.

The IES categorizes outdoor area and roadway luminaires (non-floodlights) according to the pattern of illumination they produce on the ground, from Type I, which doesn't project very far forward to backward but tends to be very wide from side to side, to Type V and Type VS, which have symmetric round and square-shaped distributions, respectively. Table C-3 shows these classifications and the general shape of each distribution's pattern of illumination.

Table C-1 Exterior Luminaire Distribution Classification.

Type	Description	Plan View
Type I	Narrow, symmetric illuminance pattern.	Type II	Slightly wider illuminance pattern than Type I.	Type III	Wide illuminance pattern.	Type IV	Widest illuminance pattern.	Type V	Symmetrical circular illuminance pattern.	Type VS	Symmetrical, nearly square illuminance pattern.	
C-2.2 NEMA Classifications.

NEMA classifies floodlights, including those used for sports applications, according to the intensity distribution of the light within the beam, considering the "horizontal" and "vertical" parts of the beam separately. The categories range from 1 to 7, with the smaller numbers indicating tighter beams and thus a longer useful projection distance or "throw". Table C-2 shows the NEMA beam type categories. The broader the beam, the more difficult it is to control the light distribution and prevent stray light, including glare and unwanted uplight.

Table C-2 NEMA Beam Angle Classifications.

Beam Type	Beam Spread Degree Range	Projection Distance
1	10 to 18	240 ft and greater
2	18 to 29	200 to 240 ft
3	29 to 46	175 to 200 ft
4	46 to 70	145 to 175 ft
5	70 to 100	105 to 145 ft
6	100 to 130	80 to 105 ft
7	130 and up	under 80 ft

C-2.3 BUG Ratings.

The classification of exterior luminaires changed in a significant way in 2011. The former “cutoff” classification system was abandoned and was replaced by a new system, defined and explained in ANSI/TM-15, first published in 2007. In 2011, the Backlight-Uplight-Glare (BUG) rating system was added.

BUG ratings for luminaires are useful in evaluating optical performance in exterior environments. BUG ratings are based on zonal lumen output. It is difficult to compare the BUG ratings to the previously used cutoff classifications, as the cutoff classifications were determined from the luminaire’s luminous intensity values (measured in candelas) above 80 degrees, rather than luminaire lumens. Table C-3 illustrates the lack of correlation between the previous classification system and the current BUG ratings. The three components of BUG ratings are illustrated in Figure C-6 and Table C-4 and are explained further in the subsections that follow.

Table C-3 Correlation between BUG Ratings and Cutoff Classifications

BUG Rating	Full Cutoff	Cutoff	Semi-Cutoff	Non-Cutoff
B	B0-B5	B0-B5	B0-B5	B0-B5
U	U0	U1-U5	U1-U5	U1-U5
G	G0-G5	G0-G5	G0-G5	G0-G5

Figure C-6 Exterior Luminaire BUG Classification

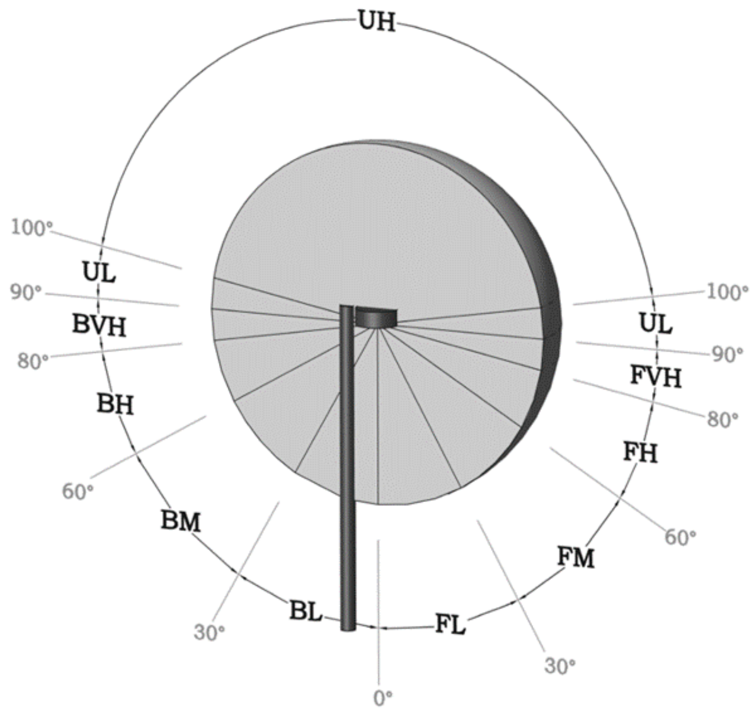

Table C-4 Exterior Luminaire BUG Classification Key

UH	Uplight High
UL	Uplight Low
BVH	Backlight Very High
BH	Backlight High
BM	Backlight Medium
BL	Backlight Low
FVH	Forward Light Very High
FH	Forward Light High
FM	Forward Light Medium
FL	Forward Light Low

C-2.3.2 Backlight (B) Rating.

Backlight from a luminaire can create light trespass if the luminaire is located near the edge of a property. The “B” rating takes into account the amount of backlight in the low (BL), medium (BM), high (BH), and very high (BVH) zones, which are generally to the “rear” of the luminaire. The closer to a property line a luminaire is located, the stricter, or lower, the “B” rating should be. If the luminaire is located more than two mounting heights from the property line, then a higher B rating may be appropriate.

C-2.3.3 Uplight (U) Rating.

Uplight is a significant source of sky glow. Uplight emitted at angles near horizontal (UL) cause the most sky glow and negatively affects professional and academic astronomy. Higher-angle uplight (UH) not reflected off a surface is mostly energy waste. The “U” rating defines the amount of light emitted into the upper hemisphere, with greater concern for the light at or near the horizontal (UL).

C-2.3.4 Glare (G) Rating.

Glare can be annoying or visually disabling. The “G” rating takes in to account the amount of forward-emitted light in the high (FH) and very high (FVH) zones and the amount of backward-emitted light in the high (BH) and very high (BVH) zones.

C-2.3.5 Considerations.

In general, a higher BUG rating means that more light is emitted in the relevant solid angles, and the allowable rating increases with higher-numbered lighting zones (see Section C-4). However, a higher “B” (backlight) rating simply indicates that the luminaire directs a significant portion of light behind the pole, so allowed “B” ratings are based on the location of the luminaire with respect to the property boundary. A high “B” rating maximizes the luminaire’s spread of light and is effective and efficient when used far from the property boundary. When luminaires are located near the property boundary, a lower “B” rating prevents unwanted light from interfering with neighboring properties.

C-3 LIGHTING ZONES.

C-3.1 LZ0: No Ambient Lighting.

LZ0 areas are those where the natural environment will be seriously and adversely affected by lighting. Impacts include disturbing the biological cycles of flora and fauna and/or detracting from human enjoyment and appreciation of the natural environment. In these areas, human activity is subordinate in importance to nature. The vision of human residents and users is adapted to the total darkness, and they expect to see little or no lighting. When not needed, lighting should be extinguished.

C-3.2 LZ1: Low Ambient Lighting.

LZ1 areas are those where lighting might adversely affect flora and fauna or disturb the character of the area. The vision of human residents and users is adapted to low light levels. Lighting may be used for safety, security, and/or convenience, but it is not necessarily uniform or continuous. After curfew, most lighting should be extinguished or reduced as activity levels decline.

C-3.3 LZ2: Moderate Ambient Lighting.

LZ2 areas are areas of human activity where the vision of human residents and users is adapted to moderate light levels. Lighting may typically be used for safety, security, and/or convenience but it is not necessarily uniform or continuous. After curfew, lighting may be extinguished or reduced as activity levels decline.

C-3.4 LZ3: Moderately High Ambient Lighting.

LZ3 areas are areas of human activity where the vision of human residents and users is adapted to moderately high light levels. Lighting may typically be used for safety, security and/or convenience and is often uniform and/or continuous. After curfew, lighting may be extinguished or reduced as activity levels decline.

C-3.5 LZ4: High Ambient Lighting.

LZ4 areas are areas of human activity where the vision of human residents and users is adapted to high light levels. Lighting is generally considered necessary for safety, security and/or convenience and it is mostly uniform and/or continuous. After curfew, lighting may be extinguished or reduced in some areas as activity levels decline.

C-3.6 Potential Reasons for Classifying an Area at a Lower Lighting Zone.

- Very low or no activity at night
- Adjacent lighting zone, either DoD or Civilian, is lower and has a low level of activity

C-3.7 Potential Reasons for Classifying an Area at a Higher Lighting Zone.

- Sensitive areas requiring a high level of security
- High level of activity at night as well as high number of users

C-4 CONTROL APPROACHES.

C-4.1 Manual Switching.

Manual switching is not ideal for controlling exterior lighting.

C-4.2 Photocontrol.

A photocell is a device that measures the illuminance level and is set to turn on or off the luminaire at a preset illuminance level. The light levels are set to ideally have the luminaires turn on before sunset and extinguish after sunrise.

C-4.3 Occupancy Based Controls.

The use of motion sensors in exterior applications is widely accepted in residential applications. In commercial or industrial applications, occupancy sensors can be implemented in some applications. It is important to ensure that the occupancy sensor being used does not leave any ‘dead’ zones where occupancy cannot be detected for safety concerns.

C-4.4 Adaptive Lighting.

Adaptive lighting is concept of adjusting the light levels to suit the activity level. This is accomplished with bilevel switching and motion sensors or preset continuous dimming. When no occupancy is detected in a zone, or late at night when traffic and pedestrian volumes are known to be minimal, lighting levels are reduced to a minimum of 30% full light output. Adaptive lighting is ideally suited for wall-mounted, roadway, area, pathway, parking lot, or pedestrian luminaires.

All street lighting luminaires are required to have a multipin receptacle that is capable of accepting a dimming control node. With a similar form factor to that of a standard photocell, a dimming control node is installed on top of the luminaire. The control node communicates through a networked control system to allow for two-way communication. See Section A-5.9 Network Control Systems for additional information.

C-5 CONTROL EQUIPMENT.

C-5.1 Sensors.

C-5.1.1 Photosensors.

Photosensors can be used as an exterior lighting control strategy. A single photosensor can be installed on each luminaire or on a lighting control center linking a group of luminaires together. Diligently maintain the photosensor.

C-5.1.2 Motion Sensors.

Motion sensors used for exterior luminaires are the same as for interior luminaires. As such, the coverage patterns can be too small and result in coverage gaps when used to control exterior luminaires.

C-5.2 Timeclocks.

Timeclocks or time switches are used to automatically turn the lights on or off on a daily basis. Typically, time clocks are programmed to turn on and off based on astronomical events such as sunset and sunrise or when activity has ceased. The astronomic time clock automatically keeps track of what day it is and geographic location of the luminaires. As the exact time of sunset and sunrise fluctuates throughout the year, the time clock adjusts accordingly.

C-5.3 Network Control Systems.

Exterior control systems are beginning to follow the same path as interior addressable systems. By communicating with the driver or power control unit of each roadway or area luminaire, a centralized control system can monitor a wide range of characteristics including energy consumption and outages. Additionally, this control strategy accommodates the concept of adaptive lighting standards. This concept recognizes that lighting criteria provides for the worst-case scenario – conditions that may only exist for a fraction of the night or year. With more advanced control systems and dimmable sources, exterior lighting can provide the appropriate amount of light for the time of day, time of year, and weather conditions, while significantly reducing energy use.

C-5.3.1 Power Line Frequency.

A power line carrier network system uses the physical electrical wiring to communicate between devices. Each luminaire has its own device and therefore its own unique address. The devices can then all be linked together to form a network that is adjustable through a software program. From the software, zoning can be established as well as scheduling. Additionally, maintenance issues can be identified. In order to dim, a separate dimming driver may be required.

C-5.3.2 Radio Frequency.

A radio frequency (RF) lighting control system uses embedded RF transmitters and receivers to connect devices (sensors, user controls, power equipment) to one another. These systems can be stand alone or part of a networked lighting control solution. Care should be taken to evaluate the RF lighting control solution on the frequency range it operates in (is it densely or sparsely populated?), how the system propagates and ensures proper RF communication between devices, RF device installation and cost, and whether the type of space being controlled supports the use of RF devices. A mockup of the RF lighting control system is a recommended best practice to ensure that the system will perform as expected in the application/operating environment.

APPENDIX D BEST PRACTICES: LIGHTING FOR CIRCADIAN RHYTHMS

D-1 INTRODUCTION

The human body operates on an approximately 24-hour sleep-wake cycle that regulates our natural biological processes. These variations are known as the human circadian rhythms (animals and plants have them also), and the primary driver of this cycle is light.[9] This process is called entrainment and involves the synchronization of different rhythmic cycles that interact with each other. Nearly every cell in the human body has a circadian clock. Correct entrainment has been shown to lower risk of cancer, neurodegenerative diseases, substance addiction, and obesity.[10]

Humans have evolved under the sun during the day and in darkness at night. For millennia, the presence of absence of daylight has informed our bodies of each day's start and end. In the modern world, people are no longer continuously exposed to daylight during daytime hours, but instead are often exposed to much lower light levels in our homes and workplaces. Regulating our circadian rhythms is more difficult with less sunlight exposure and with electric lighting operating during periods of what would normally be natural darkness.[11] [12] [13]

D-2 RECOMMENDATIONS.

The lighting recommendations in this appendix are based on the current known research of circadian lighting design. While human well-being is important, it is nearly impossible to predict the outcomes and changes due to a circadian lighting design, both positive and negative.

D-3 OVERVIEW.

Electric lighting systems that are designed to impact the human circadian rhythm are referred to as circadian lighting systems. The concept behind these systems is that electric light could be used to support human health and typically revolves around the potential for melatonin suppression using light. Circadian lighting systems and luminaires are designed by modulating the quantity and spectral distribution of the light source.

D-3.1 Light and the Human Circadian System.

Human circadian rhythms are mediated by the suprachiasmatic nuclei (SCN), which is the part of the brain that controls the internal daily clock.[14] Within the human eye, there are three known groups of photoreceptors. Two of these groups, the rods and cones, are image-forming photoreceptors while the third group, the intrinsically photoreceptive retinal ganglion cells (ipRGCs), are non-image-forming. ipRGCs are essential in converting neural signals from the retina to the SCN.

The ipRGCs contain a photopigment called melanopsin, also known as the "darkness hormone," which is a photopigment that is especially sensitive to blue wavelengths.[15] [16] Melatonin production begins at the retina and travels to the SCN which signals the pineal gland to release the hormone in nighttime conditions.[6] This photopigment is believed to be the main aspect of the non-image-forming system.[17] The research on these cells and how they operate is ongoing, but researchers have concluded that the ipRGCs respond best to blue light, and that the ipRGCs are not limited to circadian entrainment alone.[18]

D-3.2 Circadian Lighting Metrics

Current metrics have been developed, researched, and vetted to try and measure what spectrum, timing, duration, quantity, and distribution of light will elicit a circadian response. Current ways to measure circadian lighting include but are not limited to:

- Equivalent Melanopic Lux (EML, used by the WELL Building Standard)
- Melanopic Irradiance (CIE)
- Melanopic Equivalent Daylight Illuminance (mEDI, by CIE)
- Melanopic Daylight Efficacy Ratio (mDER, by CIE)
- Circadian Stimulus (CS, by LHRC)
- Circadian Bio-Active Blue (CIRCADIAN Light)

D-4 INFLUENCING FACTORS FOR CIRCADIAN LIGHTING SYSTEMS.

Spectrum, timing, duration, quantity, and distribution at the retina are all critical components in creating a circadian lighting response.[19] A circadian lighting system must consider all of these components in the design.

D-4.1 Spectrum.

The relative light output from a luminaire across the visual spectrum is referred to as its spectral power distribution (SPD). The goal in circadian design is to link the SPD of a luminaire to the effectiveness of stimulating ipRGCs. The peak sensitivity of the ipRGCs is generally accepted to be 480 nm, with multiple studies suggesting different peak sensitivities between 477 nm and 480 nm.[20] These wavelengths are found in the blue region of the spectrum. Research to determine the peak spectral sensitivity of the ipRGCs remains inconclusive, since they are positioned in such a way that they receive input from the rods and cones as well.[21]

D-4.2 Timing.

Time of day is a contributing factor in determining the impacts that spectrum and quantity of light have on human well-being. Sunlight in the morning is the best solution for entraining and establishing a healthy circadian rhythm.[22,23] Sunlight not only contains the necessary wavelengths, but is also sufficiently bright to stimulate the ipRGCs.

Reducing the amount of light in the evenings is equally important. Depending on when someone is exposed to light, a delay or advancement in their biological clock may occur, which is known as phase shifting. Studies show that blue light can entrain or disrupt the circadian rhythm, depending on the time of day someone was exposed to it.[24]

D-4.3 Duration.

The phase-shifting effects of light is dependent on duration and pattern of light. Phase-shifts vary exponentially dependent upon duration.[25] Phase-shifting has a different response when the light exposure is continuous versus intermittent. Current research reveals that intermittent light at the eye induces a greater phase shift than predicted by a simple linear response to optical radiation duration.[17,26,27]

D-4.4 Quantity.

The quantity of light Illuminance) received at the eye influences the effect that the light will have on the human circadian rhythms. Studies have shown that luminaires with higher correlated color temperatures (CCT), such as 6500 K, can have little to no impact on melatonin suppression if they are under a certain threshold. For one specific study, the threshold was found to be 30 lux.[28] It has also been found that using the "nightshift" mode on self-luminous displays has little to no impact on melatonin suppression if the brightness is still high.[29]

D-4.5 Distribution.

Distribution of light at the retina also plays an important role. Most standards and guidelines for lighting are developed for lighting a horizontal plane, such as working surfaces and roadways, but vertical illuminance is important for circadian lighting. Light exposure on the lower retina (thus, coming from above) has been found to suppress melatonin at a higher rate than light hitting the upper or central retina (thus, coming from below or straight ahead).[18] From a design standpoint, this could mean that circadian disruption could be reduced if there were less light at night falling on the lower half of the retina. Research continues to uncover more information about how the different aspects of light can have an impact on human well-being.

D-5 CIRCADIAN LIGHTING LUMINAIRES.

Commercially available circadian lighting luminaires are marketed by lighting manufacturers as tools to be used to improve the well-being and productivity of workers in typical indoor environments. These luminaires differ from systems that are often referred to as "white-tuning" luminaires, which allow the user to change how the light

appears by modulating the correlated color temperature. Circadian lighting luminaires also change the appearance of the light, but as a result of modulating the spectrum of the light. The timing, duration, quantity, and distribution of the light from these luminaires is entirely dependent on the quantity and mounting locations of the luminaires, as well as the programming of the lighting control system.

D-5.1 Spectral Power Distribution.

The specific group of wavelengths that are emitted from a luminaire across the visible spectrum is referred to as its spectral power distribution (SPD). When the SPDs of red, green, and blue light are combined, white light is produced. Additionally, different CCTs of white light can be combined to allow for more variety of spectra. Within a luminaire, the higher number of different LEDs, the more options that are available for creating different spectra. Figure D-1 shows the normalized SPD of sunlight compared to a typical 3500-K LED luminaire.

D-5.1.1 White Tuning.

For example, a typical white-tuning LED luminaire that can fluctuate between 2700 K and 6500 K is a combination of two different LED diodes, 2700 K and 6500 K. The only spectra that can be produced by this luminaire is a combination of the SPDs of each of these diodes. Figure D-2 has the following diodes: 2700 K and 6500 K. This is considered a two-channel luminaire.

D-5.1.2 Multichannel.

To produce a wider variety of spectra, a multi-channel luminaire is used. Not only does this provide more options for different color temperatures, but it also allows designers to target specific wavelengths without drastically changing the color of the produced light. The luminaire in graph in Figure D-3 has the following diodes: red, green, blue, 2700 K, two 3500 K, and 6500 K.

D-5.1.3 Circadian.

Circadian lighting design attempts to recreate daylight, which changes in SPD throughout the day, by mixing the light from several different LED diodes within the luminaire. However, these luminaires are not able to perfectly replicate daylight.

Figure D-1 SPD of Sunlight and 3500-K LED Luminaire

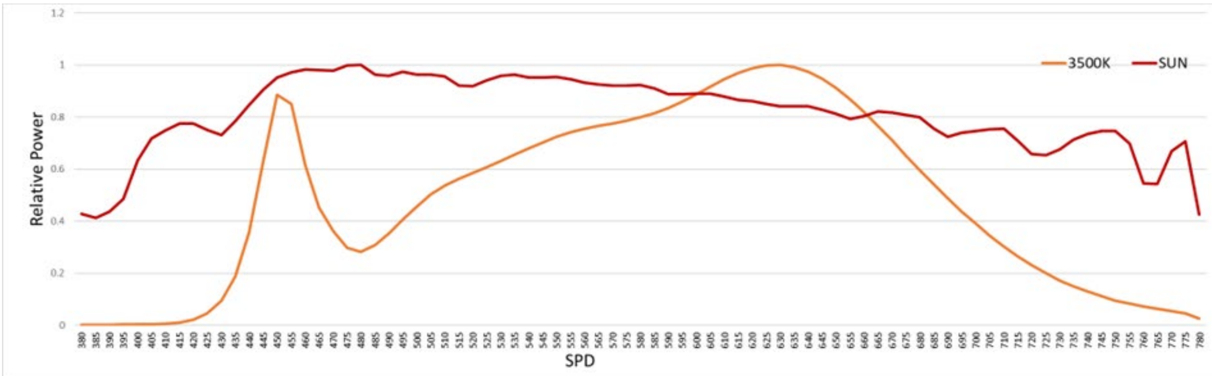

Figure D-2 SPD of a Two Channel Luminaire

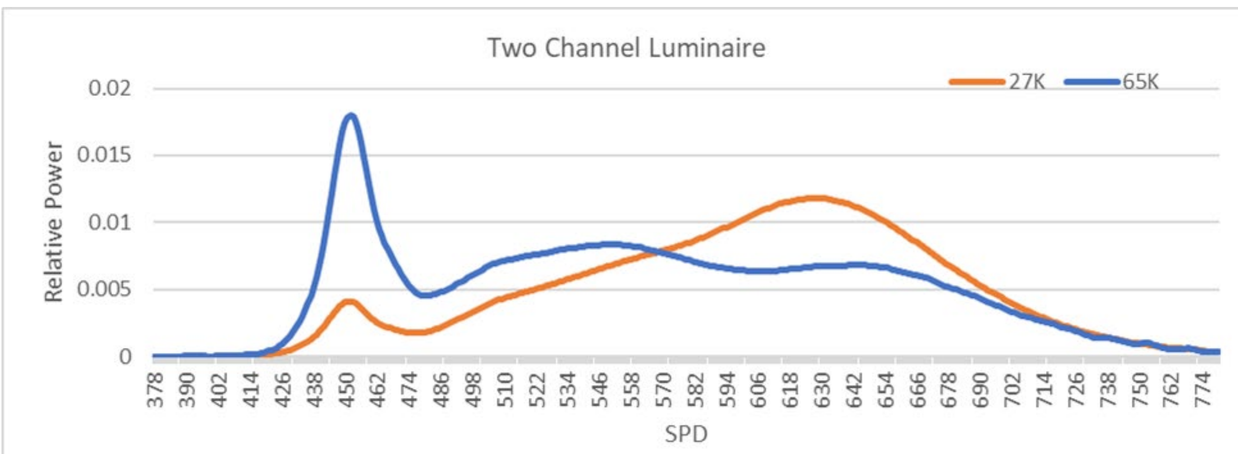

Figure D-3 SPD of a Six Channel Luminaire

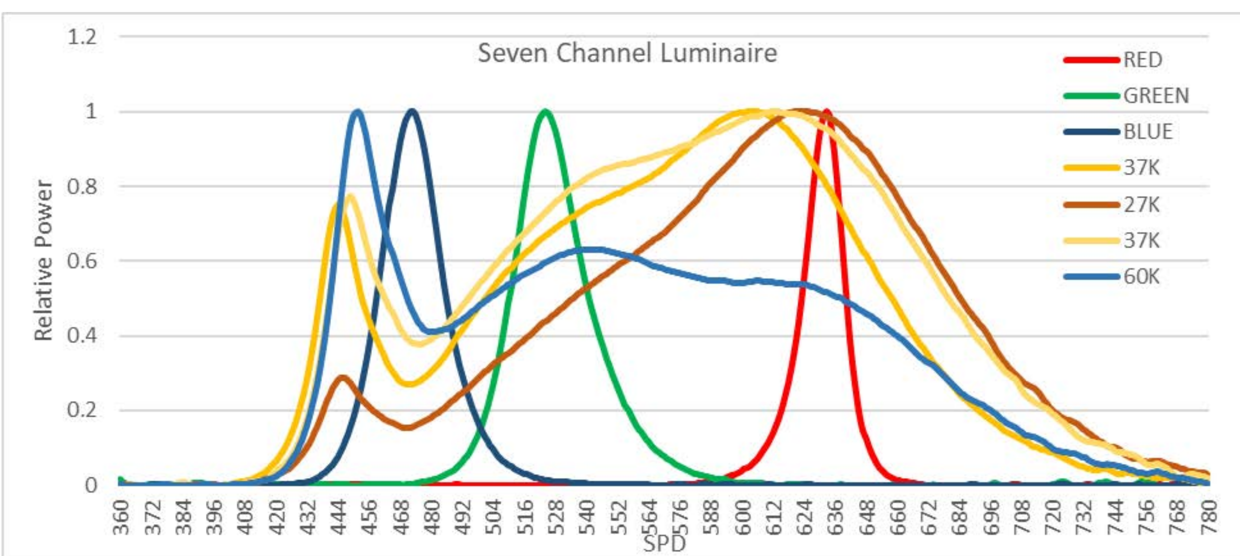

D-6 DAYLIGHT AND VIEWS.

The daylighting and views in typical office spaces, where occupants work eight-hour shifts during daylight hours, will help workers maintain healthy circadian rhythms that are in synch with their home/work schedule. Harnessing the power of daylight reduces energy usage, provides daylight, and promotes a healthier condition for human well-being in an office environment.

Daylight and views in office spaces have been linked to improved sleep quality and mood among office workers.[30] Several elements influence how a worker can have better circadian entrainment, including location of workspace, the view of the outside, and window treatments.[31]

D-6.1 Harvesting the Benefits of Daylight.

To maximize the benefits of circadian lighting, workstations should be within 20 feet of a window. If the workstation is over 20 feet from a window, the view of the worker should be facing towards the nearest window. If there are any windows in the office space, blinds should be opened to let natural light into the space and allow workers to look outside. To maximize the circadian potential of daylight, high quality daylight and views should be present in the workspace. This requires coordinating with the architect and other members of the daylighting design team to optimize window placement, maximize views internal and external shade controls, while minimizing glare.

D-7 IMPLEMENTING CIRCADIAN LIGHTING SYSTEMS.

Circadian lighting metrics are all based on the assumption that it takes a certain combination of spectrum, timing, duration, quantity, and distribution of light to produce melatonin suppression, which will result in phase shifting. However, current research reveals that implementing a circadian lighting design in indoor environments can cause circadian disruption for some individuals more than others.[32] The other assumption is that melatonin suppression will cause a parallel phase shift in the circadian clock, but there is evidence of divergent phase shifting and melatonin response in humans.

The evidence is inconclusive that a certain dosage of light will create a phase shift and melatonin suppression in the indoor lighting environment. Most notably, it cannot be stated with assurance that all people will react in the same way to indoor lighting environments. Research has shown a wide range of results regarding the implementation of circadian lighting, both having positive and negative effects on human well-being. These inconsistencies cannot predict how human well-being will be

impacted on a large-scale by circadian lighting design. It is not recommended that universal approaches be applied at this time, since shifts to occupants' circadian cycles cannot be done with enough certainty and consistency.

D-7.1 Typical Work Environments.

Without more research, it is not recommended to install a lighting system specifically engineered to shift occupants' circadian cycles in typical workspaces, where occupants work the majority of their shift during the day. However, daylight and views may be used; this resource provides many benefits to indoor work environments, including natural impacts to circadian cycles.

D-7.2 Secure Environments.

Some work environments are unable to provide regular, continuous access to daylight due to the type of work or security of the facility. When possible, provide breakrooms with windows with clear views to exterior.

D-7.3 24-Hour Facilities.

In 24-hour facilities, occupants are not typically working a normal daytime shift, and therefore their circadian rhythms may not be in tune with a normal day. The goal of the lighting in these environments is to stimulate occupants during their shift to keep them alert without disrupting melatonin. Circadian disruption has been associated with increased risk for metabolic syndrome, diabetes, cardiovascular disease, and cancer.[33] However, there are inconsistencies and contradictions in different studies linking light at night to certain disease risks.[34] Therefore, broadly implementing circadian lighting systems is not recommended even in 24-hour facilities.

Electric lighting can provide both a positive and negative effect on human well-being, depending on how it is designed.[35] [36] [37] For a lighting system to be successful in a circadian lighting application, it must be able to adapt to the changing and evolving research on the spectral sensitivity of the ipRGCs and the recommendations made by experts in the field.

D-7.4 Circadian Lighting Luminaire Selection.

[37] Zielinska-Dabkowska KM. Make lighting healthier. Nature. 2018;553(7688):274–6.

If there is a desire to explore circadian lighting implementation in a specific room or area, select equipment that allows for flexibility and modifications as research evolves. Luminaires must have at least four channels: red, green, blue, and 3500 K. However, it is recommended that each luminaire should have at least six channels: red, green, blue, 2700 K, 3500 K, and 6500 K. Regardless of the number of channels, the control system must be adaptable to different light outputs and must be able to adjust the spectral power distribution throughout the day. By implementing a luminaire with more channels, more spectral power distributions are possible. The six-channel luminaire will be able to adapt to future recommendations more effectively.

Current findings do not recommend blue light at night because the risk it causes of disrupting the daily circadian rhythms. Research is being conducted to analyze the effectiveness in stimulating alertness by using red light, which does not cause circadian disruption.[38]

APPENDIX E BEST PRACTICES: GERMICIDAL ULTRA-VIOLET LIGHTING

E-1 INTRODUCTION.

Germicidal ultraviolet (GUV) systems emit ultraviolet radiation (UVR) that inhibits microbial reproduction. They are used to sterilize surfaces, liquids, and air. GUV systems have generated significant interest due to their ability to kill antibiotic-resistant microbes. While GUV systems may be a step towards better disinfection when in conjunction with other Centers for Disease Control and Prevention (CDC) protocols, it is important to note the safety concerns and limitations of this equipment. There is limited industry consensus on the best and most appropriate way to use these systems, which is especially important to keep in mind as some lighting manufacturers are ready to produce and sell GUV products during the heightened concern for sanitizing spaces due to the Covid-19 pandemic. Without this consensus, widely implementing these strategies in DoD facilities is not currently recommended, but there are some limited applications and approaches that may be appropriate should decision-makers determine that GUV systems are to be deployed despite the risks. This appendix will explain GUV systems, review current known limitations and cautions, and discuss potential design applications.

In addition, refer to ANSI/IES RP-44-21 for specific guidance on the use of these kinds of systems.

E-2 OVERVIEW.

E-2.1 Ultraviolet (UV) Interactions with Microbes.

There are three primary types of UVR, including ultraviolet A (UV-A), ultraviolet B (UV-B), and ultraviolet C (UV-C). UV-A radiation has the longest wavelengths of UVR, ranging from 315 nm to 400 nm, UV-B radiation falls in the middle, with wavelengths ranging from 280 nm to 315 nm, and UV-C radiation has the shortest wavelengths, ranging from 200 nm to 280 nm. UVR interacts with microorganisms through two primary mechanisms. UV-A excites photoreactive molecules, creating active species that damage DNA and other biological components.[39] UV-B and UV-C directly damage DNA, thus hindering reproduction.[40]

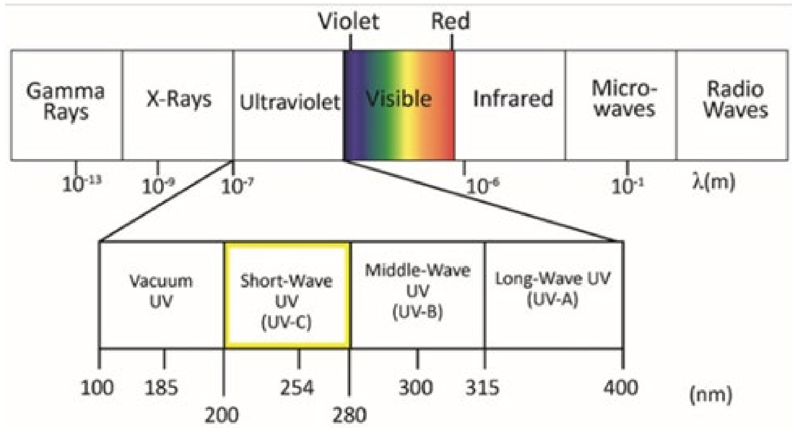
Figure E-1 Spectrum of UV Light (www.ies.org)



UVR exposure is measured as “dosage” which is the product of the irradiance and the duration of exposure. Irradiance is a function of the source strength moderated by the distance from the target to the emitter and any attenuation that may occur along the way. The target’s material properties may also affect dosage, influencing how much energy is absorbed, reflected, or transmitted. While small amounts of UVR are reflected off of surfaces, for UVR to be an effective sterilizer direct exposure is required.

E-2.1.2 GUV Effectiveness.

Viruses and bacteria can only be inactivated by direct GUV, so the effectiveness varies based on which surfaces are exposed to GUV and whether water, air droplets, or humidity is present. Generally, shorter wavelengths are more effective than longer wavelengths, with a peak efficacy around 260 nm.[41,42] Far UV-C (< 222 nm) is nearly as effective as 254-nm UV-C. Some bacteria have the ability to repair themselves using the energy provided by UV-A and visible light, so short, intense exposures may be more effective than long, low-intensity applications.[43,44,45,46]

E-2.1.3 UVR Dosage.

Currently, there are no specific industry standards or operation protocols defining the frequency and duration of UVR exposure with regard to its effectiveness. It is difficult to define standardized dose-response curves for different microbes in different mediums, but most of the literature suggest that relatively small dosages of UV-C radiation can eliminate microbial communities on surfaces and in the air.

This increased susceptibility to high dosages may explain why pulsed UV exposure appears to be more effective at neutralizing bacteria than continuous exposures of the same total dosage. Pathogens that are incapable of self-repair do not display this behavior.[47] Other studies, with different methodologies, have found no significant difference in the efficacy of pulsed vs. continuous exposure.[48] However, they do state that pulsed dosages can often be delivered in much shorter time frames, facilitating clinical applications and potentially limiting reactivation. In most cases, however, sterilization is a function of total dosage and is not impacted by dose rate.

E-2.1.4 Normal Solar Exposure.

Average annual UV dose from solar exposure ranges from 1,000 - 3,000 mJ/cm^2 in Europe and the U.S.[49] The spectral composition of this irradiance is heavily weighted toward UV-A, with a small UV-B component. UV-C radiation is completely filtered out in the upper atmosphere. In healthy adults, most UVR is filtered by the lens and the cornea, with very little reaching the retina. Children and adults who have undergone cataract surgery are at risk of increased exposure. UV-B radiation that does reach the retina can cause DNA damage and oxidative stress.[50] The current recommended daily maximum exposure is 32 mJ/cm^2 in an 8-hour period.[51] The effects of overexposure tend to be minor and short-lived.[52] However, repeated or long-term exposure can cause premature aging and increases the risk of cancer.[53] There is some evidence that

intermittent exposure patterns are correlated with an increased risk of skin cancer compared to more regular exposure patterns.[54]

E-3 LIMITATIONS OF GUV.

Even though GUV, and especially UV-C, technology is known to inactivate viruses and bacteria, it has not been widely implemented. Because of this, there are significant gaps in data and long-term research. True sterilization is difficult and may create undesired side effects, which are important to consider. GUV radiation affects microbial interactions, building occupants, and building materials, in addition to increasing energy usage. All of these concerns must be addressed when considering a GUV design.

E-3.1 Secondary Microbial Interactions.

While GUV systems show significant potential, there are a number of moderating factors to consider. 100% sterilization is difficult, and surviving microbes will adapt; both bacteria and viruses have been shown to develop UV resistance with repeated exposure. Recent research advocates for an approach in which the interior microbiome is considered as a living system that can be beneficially managed rather than something to be exterminated.[55,56]

GUV radiation kills or inactivates all microbes, good and bad, within its path, which could potentially harm our environment. The rise of antibiotic-resistant bacteria due to the overuse of antibiotics is rapidly becoming a global health crisis. GUV systems can be a useful tool in the fight against antibiotic-resistant bacteria, but care should be taken to avoid similar mistakes.[57,58] Many studies have shown that repeated exposure to UV

radiation leads to the proliferation of bacteria and viruses that are more resistant to UV irradiation.[59,60,61]

E-3.2 Interactions with Building Occupants.

Exposure to UVR can have detrimental impacts on building occupants and, while these negative effects tend to heal quickly, there is a risk that repeated exposure could increase the risk of developing certain skin cancers. Far UV-C (<222 nm), which is nearly as effective as 254-nm UV-C, is of particular interest because it does not penetrate human skin or eye tissue.

E-3.2.1 Far UV-C Radiation.

Mice models and human clinical trials show that 222-nm far UV-C radiation, even in extreme doses, does not cause skin damage or irritation but does reduce bacterial counts on skin.[62,63] This suggests that it may be deployed in occupied spaces without causing direct harm to humans.[64,65] However, as far UV-C radiation is not naturally encountered within our atmosphere, there are potentially significant unknown consequences that could arise if it were widely deployed. The use of far UV-C radiation lessens the likelihood of direct harm to humans when compared to longer wavelengths of UVR, but the long-term effects are still unknown.

E-3.3 Interactions with Building Materials.

UVR impacts interior materials, causing visual degradation and structural damage that can reduce the lifespan of these materials and, if significant surface wear occurs, pathogens can potentially be harbored in the resultant pits or cracks. Surface properties also impact the efficacy of GUV systems. Rough surfaces can limit uniform exposure,

while high-reflectance surfaces tend to scatter more visible light, potentially increasing bacterial photorepair.[66] Relative humidity has also been shown to moderate the impacts of UVR on certain bacteria and viruses in addition to influencing their transmission and survival characteristics.

- Polymers, plastics, and rubbers tend to chalk, crack, and lose strength.67,68
- Varnishes and coatings blister and crater.69
- Artificial flooring material treated with UV-resistant coatings displayed an increased formaldehyde release rate when exposed to UVR.70
- Wood becomes discolored even after brief UV exposure.71,72 Surface treatments can mitigate these effects, which are dependent on the surface grain patterns, with exposed end-grains being more susceptible to damage.73

E-3.3.1 Repeated Exposure.

Repeated exposure to UVR could cause surface damage to many common interior materials, potentially creating structures that may harbor pathogens and inhibit future disinfection efforts. Interestingly, both increased surface roughness and reflectivity have been shown to decrease sterilization efficiency.[74,75] The former is likely due to non-uniform 'clumps' of pathogens collecting in surface topological features, thereby

increasing the chance that some survive. The latter effect may be due to increased photoreactivation caused by reflected visible light.

E-3.4 Effectiveness.

As most materials reflect UVR less effectively than visible light, direct exposure is necessary to ensure effective sterilization.[76] Similarly, dirt or grime has the potential to shield pathogens from UVR, so sterilization efforts with UVR should be preceded by some form of surface cleaning. Increased relative humidity (RH) has been shown to increase the resistance of aerosolized bacteria to 254-nm UVR. As RH does not impact overall UV irradiance, this effect must be a result of interactions at the particle level. Certain bacteria may increase in size or water content as RH rises, potentially shielding their DNA from UVR.[77,78] The effect seems to be most pronounced as RH rises above 50%.[79]

E-3.5 Sustainability Concerns.

To reduce the increased energy and material usage, do not install a GUV system in every space, and do not schedule such systems to run continuously. If implemented, a GUV system must only be installed in spaces that have a high risk of disease transmission and must only operate periodically.

E-3.5.1 Energy Use.

The energy usage and cost of a building with installed GUV systems will be higher than the current baseline. As stated previously, it is not recommended that a GUV system be used in place of traditional sanitation practices. Therefore, there would be no direct cost savings by implementing this system. However, during periods of increased risk of infection from pathogens, buildings may integrate more features at the expense of increased energy usage, including improved HVAC systems with better filtration and increased airflow; utilizing pathogen detection tools in the building; and implementing a GUV system in certain areas.

Currently, North American energy codes do not provide guidance for GUV systems. This results in ambiguity for how GUV systems will impact energy code compliance at this time. GUV lamps are exempt from California’s Title 20 efficacy standards.

E-3.5.2 Lamp Replacement and Waste.

[76] Chinnis, D., Karlicek, R., Pfund, D. (2020, August 30). IALD Webinar: Lighting Design and GUV Technology [video file]. Retrieved from https://www.youtube.com/watch?v=prEFfrtQGjQ

GUV systems will also require continuous maintenance, including lamp, ballast, or driver replacement. Many GUV systems utilize mercury vapor lamps, which require proper disposal to limit mercury contamination.

E-4 TYPES OF GUV LAMPS.

There are currently three primary types of GUV lamps: mercury vapor, light-emitting diodes (LED), and excimer lamps. Each lamp type has special considerations. It is important to note that all GUV lamps have relatively low lifetime hours, as listed below, compared to standard lamps and need to be replaced more often. While lamps used for general illumination are evaluated in terms of lumens per watt, GUV lamps cannot be defined with the same metric because they do not produce light in the visual spectrum (i.e., lumens) unless specifically engineered to do so as a safeguard. As such, efficiency for GUV lamps is defined as the percentage of the lamp's total input power that produces UVR.

- Low-pressure mercury vapor (LPM) lamps are the most efficient and most widely used GUV source currently available. These lamps emit monochromatically at a peak of 254 nm and are approximately 30% efficient, which is the highest among the three types. Their lifetime hours are approximately 10,000 hours, and they are the lowest cost GUV lamp.

- LEDs are the least efficient of this group, with efficiency around 3% to 7%. These lamps emit wavelengths that typically range from 265 nm to 280 nm, with an L_{70} of 5,000 to 10,000 hours. LED sources have been manufactured to produce far UV-C wavelengths. However, production of these shorter wavelengths is even less efficient than for longer wavelengths.

- Excimer lamps are slightly less efficient than LPM lamps, with a similar lifetime. Excimer lamps emit at a lower wavelength of 222 nm (far UV-C).

Conventional GUV systems use low-pressure lamps that emit monochromatically at a peak of 254 nm. Medium-pressure lamps that emit a broad range of UV light from 200 nm to 600 nm are also available and, more recently, UV LEDs and plasma-excimer lamps have been developed with emission peaks as low as 210 nm.[80]

E-5 TYPES OF GUV LIGHTING SYSTEMS.

GUV radiation has been proven effective for disinfection in multiple kinds of applications, including water treatment, hospitals, and HVAC integration. During the Covid-19 pandemic, many lighting manufacturers began creating and advertising new GUV systems. Some of these systems have been around for many years, with the intent of disinfecting environments such as surgical suites that require complete sterilization. There are also newer systems that have not been widely implemented.

[80] Taniyasu, Y., Kasu, M., & Makimoto, T. (2006). An aluminium nitride light-emitting diode with a wavelength of 210 nanometres. Nature, 441(7091), 325-328.

GUV systems are typically deployed in four different configurations: direct fixtures, indirect upper-room fixtures, moveable units, and lamps integral to HVAC equipment.

E-5.1 Building-Integrated GUV Fixtures.

Building-integrated systems use direct GUV luminaires for surface disinfection. These are permanent installations in the building. GUV radiation can be integrated into luminaires used for lighting the space or installed as independent luminaires for the sole purpose of GUV disinfection. This style, especially with UV-A and UV-B lamps, has been utilized for several years in select hospital spaces where sterilization is a priority. Direct, building-integrated UV-C luminaires have not been widely implemented and are a recent development. As such, there are no industry standards or specific recommendations that manufacturers must adhere to when designing and implementing these systems.

E-5.1.1 Uses.

Direct GUV fixtures can be effective against surface contamination, but the presence of shadows reduces the effectiveness of the installation. Direct GUV luminaires continue to be an effective option for healthcare settings when used selectively. They may also be an effective solution during times of increased risk of disease in office spaces with high-touch spaces like conference rooms and gathering spaces when used while the spaces are not occupied.

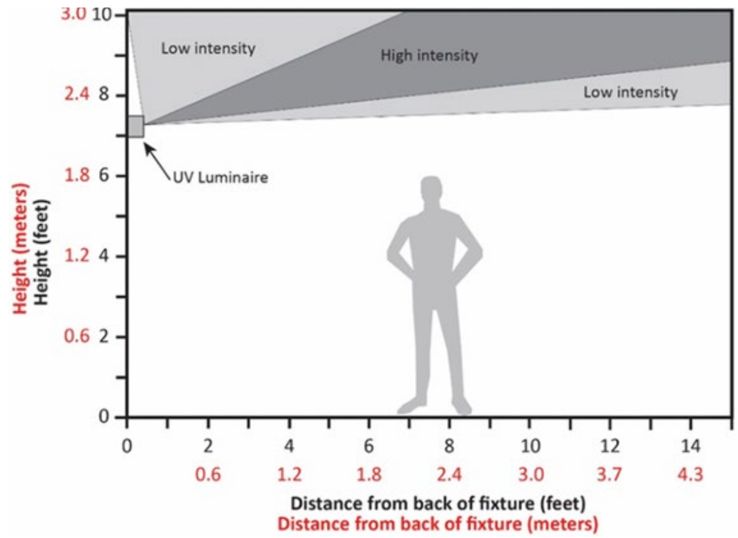
E-5.1.2 Additional Considerations.

Due to safety considerations, advanced controls must be implemented to guarantee that GUV luminaires are energized only when occupants are not present, especially with longer wavelength UV-A, UV-B, and some UV-C lamps. These systems pose a safety risk, which needs to be mitigated appropriately with adequate fail-safe measures. While far UV-C radiation does not currently show any risk to occupants, there are still too many unknowns to recommend continuous use while occupants are present. Further research is recommended, in addition to the development of industry standards.

E-5.2 Indirect Upper-Room GUV Systems.

Indirect upper-room systems are designed with GUV luminaires aimed toward the upper portion of the room, with no direct exposure in the occupied volume, see 0. This type of system can deactivate viral particles in the air, reducing the risk of airborne spread in occupied areas. Indirect upper-room GUV systems are functionally part of the HVAC system, and implementation should be coordinated with the mechanical engineer. A lighting engineer will likely not be involved with this system beyond controls integration.

Figure E-2 Upper-Air GUV Installation (www.ies.org)



E-5.2.2 Uses.

This design should be used in a room with high ceilings. There should be enough space such that a significant amount of air can pass over the system, while leaving the bottom of the system at 7 feet AFF, minimum. This design works best when the air is constantly moving via fans and the HVAC system. Extensive coordination with mechanical engineers is necessary. This system may operate in areas that are occupied, since it is indirect and above head height, but continuous operation is not recommended.

E-5.2.3 Additional Considerations.

This design heavily relies on the airflow within a room. To reduce odor and CO_2 in a room, a relatively low air change per hour (ACH) rate of 1-2 ACH needs to occur. When using an indirect upper-room GUV system, the ACH rate needs to be significantly higher, at 6-12 ACH.[81] The additional energy consumption and HVAC equipment needs to be noted.

The effectiveness of this type of system is highly dependent on the number of air changes per hour. The exact number depends on the desired level of risk mitigation. There are many variables that are specific to each space and HVAC configuration that impact pathogen distribution. In general, a higher ACH rate is generally better from a ventilation perspective.

E-5.2.4 Other Upper-Room Fixture Styles.

Similar to indirect upper-room systems, there are also luminaires with integrated fans and indirect GUV lamps. These are intended to operate similarly to indirect upper-room

[81] Illuminated Engineering Society. IES CR-2-20-V1, *Committee Report: Germicidal Ultraviolet – Frequently Asked Questions*. New York: IES; 2020.

GUV systems but are self-contained fixtures. Typically, these luminaires contain a UV emitter that is internal to the body of the fixture. These could be used to eliminate viral particles in the air and could be used to mitigate risk during occupied hours. However, these also require extensive coordination with mechanical engineers. Without industry standard protocols, designers must understand standard best practice based on current research and commonly used protocols. It is not recommended that designers rely on the manufacturer's claims regarding the system's effectiveness and deployment strategies. Therefore, these systems must be considered with caution but may be considered if upper-room GUV disinfection is desired but not implementable due to ceiling height.

E-5.3 Moveable GUV Units.

Moveable GUV systems are mounted in carts or handheld emitters and are temporarily transported into spaces to be used to sterilize surfaces as part of a cleaning regime. This system is best for disinfecting surfaces in areas that would not normally have permanent GUV installations, such as temporary medical shelters, emergency response areas, operating rooms, and other areas needing disinfection.

Movable GUV systems can be used to disinfect air or surfaces in rooms that do not have permanent systems. While this is an option, there still must be significant airflow within the room, just as in a permanent installation, and the room needs to be unoccupied during GUV operation to limit direct UVR exposure. If the UV emitter is internal to an enclosure or angled upward out of direct view, it could be used to eliminate viral particles in the air and could be used to mitigate risk during occupied hours.

E-5.3.1 Portable handheld devices.

Portable handheld devices may be used to disinfect surfaces in areas that do not have permanent direct GUV systems. The GUV emitted from the device needs to be applied to a surface area for several seconds to disinfect properly. If not applied long enough, the result may be only partially sanitized surfaces, which then contribute to a false sense of security, and this method must then be implemented in addition to traditional cleaning practices. Additionally, these systems rely on an operator to safely direct the UV source away from any humans.

E-5.3.2 Additional Considerations.

Moveable GUV systems that purify the air within a room require a high ACH rate, so their implementation must be coordinated with mechanical engineers. They are best suited for use in small rooms in order to be efficient. Since these are moveable devices, the user needs to make sure the proper controls are in place to protect the safety of the occupants and user. Movable units, especially handheld devices and self-contained home-use sterilization boxes, are not certified by UL.

E-5.4 Integral to HVAC System.

GUV systems that are integral to HVAC systems are installed within HVAC ductwork and kill or inactivate pathogens in the passing airstream. A lighting engineer would not be involved in selecting or implementing this kind of system, since this is the responsibility of the mechanical engineers. This use of GUV radiation has been around for many years as part of HVAC systems.

These systems have little effect on person-to-person pathogen transmission in a room and are no more effective than a simple HEPA air filter. Properly filtering air via the HVAC system is highly recommended, whether using physical or GUV filters, and will reduce airborne viral concentrations without interrupting occupancy. It is important to note that too much airflow will reduce the efficacy of these systems.

E-6 IMPLEMENTING GUV SYSTEMS.

The lack of standards for GUV systems makes it difficult to determine the best products to select and the most efficient use of them. Without standards, designers and engineers are given few resources with which to evaluate products that manufacturers market with few restrictions. With any new technology, claims around UV-C radiation should be considered with skepticism until industry standards have been developed, peer reviewed, and widely accepted by experts. The architectural engineering community has not reached consensus on the best type of GUV system, nor how widely it should be implemented.

E-6.1 Determining if a GUV System is appropriate.

Determining if any GUV system is right for a given space or building will not be determined solely by the lighting designer or electrical engineer. Selecting the correct disease mitigation strategy will require input from the building owner, project manager, public health officials, infectious disease experts, mechanical engineers, and lighting engineers. There are many recommended strategies that building designers can implement to reduce the potential spread of pathogens within the building. Many of these are modifications to the HVAC system design, including increased fresh air, filtration, and air flow. These modifications do not have any known complications, nor will they fully sterilize the environment which increases the risk of viral and bacterial mutations.

If improving the HVAC system is not feasible or is determined to be an insufficient measure on its own, then a GUV system may be considered if implemented correctly. The most effective GUV system is still unknown and varies widely by area type or building.

E-6.2 Selecting a GUV System.

Research indicates that far UV-C radiation is the preferred choice because it is at least as effective as UV-A or UV-B radiation, and it is safer for occupants. This will reduce the risk of exposure and complications if controls do fail. Even though it is not currently recommended to use a direct far UV-C system when occupants are present, further research may indicate that the unintended consequences are minimal, and deployment of the system could be modified to increase usage during times of occupation. UV-A, UV-B, and UV-C systems should never be used in this application.

E-6.2.1 Evaluating GUV Systems.

Many manufacturers are promoting UV-C technology as safe and effective solutions, but these systems are not without complications. Yet currently, there are no standards for GUV-system selection criteria and operation. As noted previously, continuous operation of far UV-C should not be implemented without extreme caution, since this range of wavelengths is not naturally present in our atmosphere and there remain many unknowns regarding long-term effects on humans and the environment. Designers must use caution when selecting a GUV system and must remain vigilant to manufacturers' assertions regarding their products, including but not limited to:

- Unrealistic claims about how frequently the system should be operated
- Disregarding unintended consequences and unknown long-term effects
- No mention of controls
- Stating that it is a catch-all disinfectant that can replace regular cleaning practices

Manufacturers that understand the limitations of GUV systems are likely to suggest a system that is a realistic strategy.

E-6.2.2 System Selection.

GUV systems are an integrated solution that needs input from specialists in HVAC, risk management specialists, and public health officials. Lighting manufacturers are promoting GUV technology since these systems have many shared properties with light. However, lighting designers and electrical engineers do not typically have the expertise to make decisions about the sanitation of facilities. Other disciplines must be involved, especially in the decision-making process. Heavy coordination is required with mechanical engineers to evaluate whether appropriate airflow can be achieved to effectively deploy indirect GUV systems.

Select far UV-C systems for the most flexibility in use: If control safeguards fail during operation, there will be no direct or immediate harm to any humans present in the space. Additionally, if far UV-C radiation is determined to be completely safe, even regarding long-term effects, then the system may potentially be used when the space is occupied in the future.

E-6.3 Deployment.

GUV radiation can be a useful addition to infection control options but should be deployed as part of a multi-pronged response to specific conditions and criteria. Ubiquitous, continuous deployment is not recommended, to minimize the risk of unknown potential side effects.

- Use surface-cleaning systems in addition to traditional sanitation procedures to increase their effectiveness.
- Use air-cleaning systems to mitigate spread, even in occupied spaces, during high-risk events.
- Coordinate with HVAC for potential GUV deployment in air handling units and/or fan coil units

As with any system, there are trade-offs that should be considered, weighing the needs of the moment against future hazards. If deployed carefully, GUV systems can significantly reduce the risk of disease transmission within buildings and help combat the spread of antibiotic-resistant bacteria. The use of a GUV system should not be continuous, and such a system should be used along with regular cleaning protocols, not instead of these protocols. These GUV systems may also be installed in the air handling units and/or fan coil units. The most successful and safe deployment will be heavily reliant on reliable controls, which will require that the GUV system communicates with both the building automation system (BAS) and the lighting control system. Refer to ANSI/IES RP-44-21, *Recommended Practice: Ultraviolet Germicidal Irradiation (UVGI)*, Section 9.0 Systems: Comparison, for details on how to select and compare systems based on application type. Also refer to Section 9.5 Summary Tables for comparisons of systems, including various systems' advantages and disadvantages.

E-6.3.1 GUV System Controls.

GUV systems must be controlled completely independently from the lighting systems within any given space. However, the GUV system controls must also communicate with the BAS and lighting control system to receive occupancy status, building occupancy schedules, and ACH data. For each space, control of GUV systems needs special consideration regarding the use of the space and the type of system installed in order to protect public safety and health. These control systems must be implemented in order to protect maintenance personnel from direct exposure during maintenance operations.

- The GUV system must be controlled independent of the lighting system.
- Each room or area that contains a GUV system must be controlled independently of any other room or area.

- Direct GUV systems must not operate when occupancy sensors detect that the room is occupied. This information can be obtained through the lighting control system. This is especially important for direct UV-A, UV-B, and UV-C systems, where exposure can be immediately harmful to humans.

- All GUV systems must have local, manual shut-off. Refer to ANSI/IES RP-44-21, *Recommended Practice: Ultraviolet Germicidal Irradiation (UVGI)*, Section 9.0 Systems: Comparison, for details on how to select and compare systems based on application type. Also refer to Section 9.5 Summary Tables for comparisons of systems including various systems' advantages and disadvantages.

- Moveable GUV units, which cannot be connected to the lighting control system, should be operated via a remote control.

- It is recommended that the GUV system be only turned on in association with a higher risk event, which should also coincide with increased fresh air and airflow.

E-6.3.2 System Maintenance.

Do not implement a GUV system without considering system commissioning and on-going maintenance. Without industry guidelines for deploying and maintaining these systems, specifiers must evaluate manufacturer's recommendations, if any, regarding the long-term use of these products. Do not consider manufacturers that do not address the longevity or maintenance of their systems.

Typically, Operations and Maintenance staff will not have the expertise or tools available to monitor, control, and update a GUV system. When specifying a GUV system, establish protocol for on-going maintenance, including continuous support from outside specialists. Specialists must:

- Verify that the system is functioning as intended with calibrated meters

- Utilize personal protective equipment (PPE) when working under energized UVR fixtures

- Maintain lamp replacement schedule to ensure proper function

E-6.3.2.1 Lamp Replacement.

GUV systems must provide a notification system indicating that the GUV lamp life has deteriorated and must be replaced. There are currently no standards for notification systems. Unless regular UV measurements are taken in-field, this notification system will be based on estimated lamp life by the lamp manufacturer.

W watt

F-2 DEFINITIONS OF TERMS.

The definitions of lighting terms are from ANSI/IES LS-1-21, *Lighting Science: Nomenclature and Definitions for Illuminating Engineering*.

Adaptation: The process by which the retina becomes accustomed to more or less light than it was exposed to during an immediately preceding period. It results in a change in the sensitivity to light.

Aircraft Maintenance Area: The full area designated for aircraft parking and maintenance area. Typically includes the depth from the hangar bay door to the back wall and width from the centerline boundary of the neighboring aircraft maintenance zones or to the side wall.

Altitude: The angular distance of a heavenly body measured on the great circle that passes perpendicular to the plane of the horizon, through the body and through the zenith. It is measure positively from the horizon to the zenith, from 0 degrees to 90 degrees.

Ambient Lighting: Lighting throughout an area that produces general illumination

Area Lighting Luminaire: A complete lighting device consisting of a light source and driver, where appropriate, together with its direct appurtenances such as globe, reflector, refractor, housing, and such support as is integral with the housing. The pole, post, or bracket is not considered part of the luminaire.

Luminance: Luminance is a property of a geometric ray. Luminance as measured by conventional meters is averaged with respect to two independent variables, area and solid angle; both must be defined for a complete description of a luminance measurement.

Azimuth: The angular distance between the vertical plane containing a given line or celestial body and the plane of the meridian.

Baffle: A single opaque or translucent element to shield a source from direct view at certain angles, to absorb or block unwanted light, or to reflect and redirect light.

Ballast: A device used with an electric-discharge light source to obtain the necessary circuit conditions (voltage, current, and waveform) for starting and operating.

Bollard: A type of luminaire having the appearance of a short, thick post, used for walkway and grounds lighting. The optical components are usually top-mounted.

Bowl: An open-top diffusing glass or plastic enclosure used to shield a light source from direct view and to redirect or scatter the light.

Bracket (mast arm): An attachment to a light source post or pole from which a luminaire is suspended.

BUG (Backlight, Uplight, Glare): Backlight – the amount of percent lamp lumens or the luminaire zonal lumens distributed behind a luminaire between zero degrees vertical (nadir) and 90 degrees vertical. Uplight – the percent lamp lumens or the amount of luminaire zonal lumens distributed above a luminaire between 90 and 180 degrees vertical. Glare – the amount of percent lamp lumens or the luminaire zonal lumens distributed 60 and 90 degrees vertical.

Candela, cd: The SI unit of luminous intensity, equal to one lumen per steradian (lm/sr).

Candlepower (cp): Another term for luminous intensity," expressed in candelas.

Clerestory: That part of a building that rises clear of the roofs or other parts and whose walls contain windows for lighting the interior.

Coefficient of Utilization (CU): The ratio of luminous flux (lumens) calculated as received on the work plane to the total luminous flux (lumens) emitted by the light sources alone. It is equal to the product of room utilization factor and luminaire efficiency.

Color Matching: The action of making a color appear the same as a given color.

Color Rendering: Effect of an illuminant on the color appearance of objects by conscious or subconscious comparison with their color appearance under a reference illuminant.

Color Rendering Index (of a light source) (CRI): A measure of the degree of color shift objects undergo when illuminated by the light source as compared with those same objects when illuminated by a reference source of comparable color temperature.

Color Temperature (of a light source): See Correlated Color Temperature.

Contrast: *See Luminance Contrast.*

Correlated Color Temperature (of a light source) (CCT): The absolute temperature of a blackbody whose chromaticity most nearly resembles that of the light source.

Daylight Availability: The luminous flux from the sun plus sky at a specific location, time, date, and sky condition.

Diffused Lighting: Lighting provided on the work plane or on an object that is not incident predominantly from any particular direction.

Dimmer: A device used to control the intensity of light emitted by a luminaire or light source by controlling the voltage or current available to it.

Direct Component: That portion of the light from a luminaire that arrives at the work plane without being reflected by room surfaces.

Direct Glare: Glare resulting from high luminances or insufficiently shielded light sources in the field of view. It is usually associated with bright areas, such as luminaires, ceilings, and windows that are outside the visual task or region being viewed. A direct glare source can also affect performance by distracting attention.

Direct-Indirect Lighting: A variant of general diffuse lighting in which the luminaires emit little or no light at angles near the horizontal.

Direct Lighting: Lighting involves luminaires that distribute 90 to 100% of the emitted light in the general direction of the surface to be illuminated. The term usually refers to light emitted in a downward direction.

Directional Lighting: Lighting provided on the workplane or on an object, predominantly from a preferred direction.

Disability Glare: The effect of stray light in the eye whereby the contrast of the retinal image is reduced and, consequently, whereby visibility and visual performance are reduced. A direct glare source that produces discomfort can also produce disability glare by introducing a measurable amount of stray light in the eye.

Discomfort Glare: Glare that produces discomfort. It does not necessarily interfere with visual performance or visibility.

Downlight: A small direct lighting unit that directs the light downward and can be recessed, surface-mounted, or suspended.

Efficacy: See *Luminous Efficacy of a Source of Light.*

Efficiency: See *Luminaire Efficiency*.

Electroluminescence: The emission of light from a phosphor excited by an electromagnetic field.

Emergency Exit: A way out of the premises that is intended to be used only during an emergency.

Emergency Lighting: Lighting designed to supply illumination essential to the safety of life and property in the event of a failure of the normal supply. The system must be capable of providing minimum required illuminance specified in NFPA 101.

Exit Sign: A graphic device including words or symbols that indicates or identifies an escape route or the location of, or direct to, an exit or emergency exit.

Floodlight: A projector designed for lighting a scene or object to a luminance considerably greater than its surroundings.

Fluorescent Light Source: A low pressure mercury electric-discharge light source in which a fluorescing coating (phosphor) transforms some of the UV energy generated by the discharge into light.

Flush-mounted or Recessed Direct/Indirect Luminaire: A luminaire that is mounted above the ceiling (or behind a wall or other surface) with the opening of the luminaire level with the surface.

Footcandle, fc: A unit of illuminance equal to 1 lm/ft^2.

Glare: The sensation produced by luminances within the visual field that are sufficiently greater than the luminance to which the eyes are adapted, which causes annoyance, discomfort, or loss in visual performance, and visibility. Direct glare is caused by excessive light entering the eye from a bright light source. The potential for direct glare exists anytime one has a direct view of a light source. With direct glare, the eye has a harder time seeing contrast and details. A system designed solely on lighting levels, tends to aim more light directly towards a task, thus producing more potential for glare. Direct glare can be minimized with careful equipment selection and placement.

Globe: A transparent or diffusing enclosure intended to protect a light source, to diffuse and redirect its light, or to change the color of the light.

High Ambient Temperatures: Above 50 degrees Celsius.

High-Intensity Discharge (HID) Light Source: An electric-discharge light source in which the light-producing arc is stabilized by bulb wall temperature, and the arc tube has a bulb wall loading in excess of 3 W/cm^2. HID light sources include groups of light sources known as mercury, metal halide, and high-pressure sodium.

High-Mast Lighting: Illumination of a large area by means of a group of luminaires that are designed to be mounted in a fixed orientation at the top of a high mast, generally 20 m (65 ft.) or higher.

High-Pressure Sodium (HPS) Light Source: A high intensity discharge (HID) light source in which light is produced by radiation from sodium vapor.

Illuminance: The areal density of the luminous flux incident at a point on a surface. Units: lux or footcandles.

Illuminance (footcandle or lux) Meter: An instrument for measuring illuminance on a plane. The instrument comprises some form of photodetector with or without a filter driving a digital or analog readout through appropriate circuitry.

Illumination: An alternative but deprecated term for illuminance. In this document, it is used in its more general sense of simply “lighting.”

Incandescent Filament Light Source: A light source in which light is produced by a filament heated to incandescence by an electric current.

Indirect Component: The portion of the luminous flux from a luminaire that arrives at the workplane after being reflected by room surfaces.

Indirect Lighting: Lighting involving luminaires that distribute 90 to 100% of the emitted light upward.

Induction Lighting: Lighting technology that uses electric current to induce an electromagnetic field within the phosphor coated light source. No filaments are used. Its advantages include instant on/off operation, white light with good color rendering characteristics, and a long light source life of 100,000 hours.

Intensity (candlepower) Distribution Curve: A curve, often polar, that represents the variation of luminous intensity of a light source or luminaire in the plane through the light center.

Isolux (Isofootcandle) Line: A line plotted on any appropriate set of coordinates to show all the points on a surface where the illuminance is the same.

Kelvin: The unit of absolute temperature used to designate the color temperature or correlated color temperature of a light source. Symbol: K.

Light Source: A generic term for a source created to produce optical radiation.

Light Source Lumen Depreciation (LLD) Factor: The fractional loss of light source lumens at rated operating conditions that progressively occurs during light source operation.

Lens: A glass or plastic element used in luminaires to change the direction and control the distribution of light rays.

Light: Radiant energy that is capable of exciting the retina and producing a visual sensation.

Light-Emitting Diode (LED): A p-n junction solid state diode whose radiated output is a function of its physical construction, material used, and exciting current.

Light Loss Factor (LLF): Formerly called maintenance factor. The ratio of illuminance (or exitance or luminance) for a given area to the value that would occur if light sources operated at their (initial) rated lumens and if no system variation or depreciation had occurred.

Light Meter: A common name for an illuminance meter.

Light Source Color: The color of the light emitted by a source.

Louver: An optical-control element, usually used in multiples, to shield a source from view at certain angles, to absorb or block unwanted light, or to reflect or redirect light.

Low-Bay Lighting: Interior lighting where the roof trusses or ceiling height is approximately 6.1 m (20 ft.) or less above the floor.

Low-Pressure Mercury Vapor (LPM) Light Source: A discharge light source (with or without a phosphor coating) in which the partial pressure of mercury vapor does not exceed 100 Pa during operation.

Low-Pressure Sodium (LPS) Light Source: A discharge light source in which light is produced by radiation from sodium vapor.

Lumen, lm: SI unit of luminous flux. Radiometrically, it is determined from the radiant power (see luminous flux). Photometrically, it is the luminous flux emitted within a unit solid angle (one steradian) by a point source having a uniform luminous intensity of one candela.

Lumen Depreciation: The decrease in lumen output that occurs as a lamp is operated, until failure.

Lumen Method: A procedure used to determine the relationship between the number and types of lamps, light sources and luminaires, the room characteristics, and the average level of illuminance on the work plane. It takes into account both direct and reflected flux.

Luminaire (light fixture): A complete lighting unit consisting of a light source or light sources and driver(s) (when applicable) together with the parts designed to distribute the light, to position and protect the light sources, and to connect the light sources to the power supply.

Luminaire Dirt Depreciation (LDD): The ratio of lumens emitted from a luminaire with dirt accumulated to the lumens emitted from the same luminaire when clean.

Luminaire Efficiency: The luminous flux emitted by a luminaire, divided by the luminous flux emitted by the source(s). Sometimes called light output ratio (LOR).

Luminance: The apparent brightness of a surface, measured in candelas per foot (cd/ft^2) or square meter (cd/m^2), sometimes called nits.

Luminance Contrast: The relationship between the luminances of an object and its immediate background.

Luminance Ratio: The ratio between the luminances any two areas in the visual field.

Luminous Efficacy of a Source of Light: The quotient of the total luminous flux emitted to the total light source power input. It is expressed in lumens per watt.

Luminous Flux: The time rate of flow of radiant energy, evaluated in terms of a standardized visual response. Units: lumens.

Matte Surface: A surface from which the reflection is predominantly diffuse, with or without a negligible specular component.

Means of Egress: An unobstructed and continuous way of exit from any point in a building or structure to a public way. It consists of three distinct parts: the exit access, the exit, and the exit discharge. A means of egress consists of the vertical and horizontal travel ways, including intervening room spaces, doorways, hallways, corridors, passageways, ramps, stairs, lobbies, horizontal exits, escalators, enclosures, courts, balconies, and yards.

Mercury Light Source: A high-intensity discharge (HID) light source in which the major portion of the light is produced by radiation from mercury operating at a partial pressure in excess of 10s Pa.

Mesopic Vision: Vision with fully adapted eyes at luminance conditions between those of photopic and scotopic vision.

Multi-level Switching: Multi-level switching allows multiple light sources within a luminaire to be switched independently. For example, a three light source luminaire would offer four light output settings: 100%, 66%, 33%, and OFF.

Orientation: The position of a building with respect to compass directions.

Overhang: In roadway lighting: the distance between a vertical line passing through a specified point (often the photometric center) of a luminaire and the curb or edge of a roadway.

Pendant Luminaire: *See Suspended* luminaire.

Peripheral Vision: The seeing of objects displaced from the primary line of sight and outside the central visual field.

Photometry: The measurement of quantities associated with light.

Photopic Vision: Vision mediated essentially or exclusively by the cones. It is generally associated with adaptation to a luminance of at least 5 cd/m^2.

Point-by-Point Method: A method of lighting calculation, now called the point method.

Point Method: A procedure for predetermining the illuminance at various locations in lighting installations by use of luminaire photometric data. The direct component of illuminance due to the luminaires and the interreflected component of illuminance due to the room surfaces are calculated separately. The sum is the total illuminance at a point.

Point Source: A source of radiation, whose dimensions are sufficiently small, compared with the distance between the source and the irradiated surface, that these dimensions can be neglected in calculations and measurements.

Pole (roadway lighting): A standard support generally used where luminaires are located.

Quality of Lighting: Pertains to the distribution of luminance in a visual environment. The term is used in a positive sense and implies that all luminances contribute favorably to visual performance, visual comfort, ease of seeing, safety, and aesthetics for the specific visual tasks involved.

Ramped Dimming: A gradual dimming rate that ensures occupants in the space will not perceive a sudden change in light levels.

Rated Light Source Life: The life value assigned to a particular type of light source. This is commonly a statistically determined estimate of average or of median operational life.

Reflected Glare: Glare resulting from reflections of high luminances in polished or glossy surfaces in the field of view.

Reflection: A general term for the process by which the incident flux leaves a (stationary) surface or medium from the incident side without change in frequency.

Reflector: A device used to redirect the flux from a light source by the process of reflection.

Scotopic Vision: Vision mediated essentially or exclusively by the rods. It is generally associated with adaptation to a luminance below about 0.001 cd/m^2.

Self-Ballasted Light Sources: Any arc discharge light source of which the current limiting devices is an integral part.

Solid State Lighting: Light sources that generate light through electroluminescence rather than filaments or gas discharge. SSL sources include light emitting diodes (LEDs), organic light emitting diodes (OLEDs), and polymer light emitting diodes (PLED).

Spacing: For roadway lighting, the distance between successive lighting units, measured along the centerline of the street.

Spacing-to-Mounting-Height Ratio: The ratio of the actual distance between luminaire centers to the mounting height above the horizontal ground or work plane.

Suspended (pendant) Luminaire: A luminaire that is hung from a ceiling by supports.

Table Lamp: A portable luminaire with a short stand, suitable for mounting on furniture.

Translucent: Transmitting light diffusely or imperfectly.

Transmission: A general term for the process by which incident flux leaves a surface or medium on a side other than the incident side, without change in frequency.

Transmittance: The ratio of the transmitted flux to the incident flux.

Transmittance, Visible (T_{vis}): The percentage of the visible spectrum transmitted.

Transparent: Having the property of transmitting rays of light through its substance so that bodies situated beyond or behind can be distinctly seen.

Troffer: A long recessed direct/indirect lighting unit usually installed with the opening flush with the ceiling.

Tungsten-Halogen Light Source: A gas-filled tungsten filament incandescent light source containing a certain proportion of halogens in an inert gas whose pressure exceeds 3 atm.

Uniformity: Lighting level or illuminance uniformity is important to work surfaces where sustained tasks are performed as well as on wall and ceiling surfaces that make up a significant portion of the field of view. Poor uniformity can cause adaptation problems. Flicker or strobing of luminaires can cause annoyances as well as headaches and fatigue.

Valance: A longitudinal shielding member mounted across the top of a window or along a wall (and is usually parallel to the wall) to conceal light sources, giving both upward and downward distributions.

Valance Lighting: Lighting comprising light sources shielded by a panel parallel to the wall at the top of a window.

Veiling Reflection: Regular (specular) reflection, superimposed on diffuse reflection from an object, that partially or totally obscures the details to be seen by reducing the contrast. This sometimes is called reflected glare. Another kind of veiling reflection occurs when one looks through a pane of glass. A reflected image of a bright element or surface may be seen superimposed on what is viewed through the glass pane.

Visibility: The quality or state of being perceivable by the eye. In many outdoor applications, visibility is defined in terms of the distance at which an object can be just perceived by the eye. In indoor applications, it usually is defined in terms of the contrast or size of a standard test object when observed under standardized viewing conditions and having the same threshold as the given object.

Volt: The difference in electrical potential between two points in a circuit.

Watt: The unit of power (rate of doing work). In electrical calculation, one watt is the power produced by a current of one ampere across a potential difference of one volt.

Workplane: The plane on which a visual task is usually done, and on which the illuminance is specified and measured. Unless otherwise indicated, this is assumed to be a horizontal plane 0.76 meters (30 inches) above the floor.

AIR FORCE CIVIL ENGINEER SUPPORT AGENCY (Preparing Activity)

Record of Changes (changes are indicated by **\4** ... /**4**/)

Change No.	Date	Location
1	7 March 2018	Paragraphs 1-6.4, 1-6.7, 12-1.4.17, and 12-1.8.3 modified; Chapters 13 and 14 deleted.
2	6 April 2021	Paragraphs 1-6.7, 1-11.1.1, 2-5.1.1, 2-5.1.2, 2-5.2, Figure 3-2, Appendix C, AFIC references throughout
3	21 May 2021	Paragraphs 1-7, 1-8.1.2, 1-8.2.2, Table 2-1A
4	25 April 2023	Chapter 14 inserted to relocate Landing Zone configuration from UFC 3-260-0 to UFC 3-535-01, for the purpose of having all lighting configurations in one UFC. Update for allowance of LEDs is included.

This UFC supersedes UFC 3-535-01, dated 11 April 2017, including Change 3.

This UFC will be formatted IAW the UFC Template upon next full revision.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
CHANGE SUMMARY SHEET

Subject: UFC 3-535-01, *Visual Air Navigation Systems*

Supersedes: UFC 3-535-01, 11 April 2017, including Change 3.

Description of Changes: This change brings requirements for new airfields into compliance with new FAA criteria for AC 150-5345-53 for LED criteria, adds a reference to AC 90-106, *Enhanced Flight Vision System Operations* , updates taxiway lighting to include allowance of LED type fixtures with various emitters or filters (Engineering Brief 67D), adds a chapter on Expeditionary Airfield Lighting (EALS), changed paragraph 1-17 title to Supplemental Criteria with added content provides guidance for navigational aids with integral LED obstruction lights at elevations under 35 feet in height, and provides guidance on replacement of approach light systems with LEDs, coordinated with AFFSA. Sign temperature requirements have been included IAW AC150-5345-44.

Reasons for Changes:

- Incorporate new FAA guidance and changes
- **\4** Incorporate changes in technology based on availability of parts from industry.
- Clarify Army- and Air Force-only requirements that Introduce Landing Zone light configuration.
- Introduce compensation configuration to be used for Aircraft with Head Up Displays, which do not detect LED lights.
- Introduce guidance on solar components of ALS. **/4/**
- Provide information on testing and inspection of systems prior to service and information on the characteristics of an airfield lighting system
- **\1** Chapters 13 and 14 were removed and converted to TSEWG TP-20, *Air Visual Air Navigation Facilities: Qualifying Equipment,"* and TSEWG TP-21, *Visual Air Navigation Facilities: Air Facility Equipment Inspection and Testing,* respectively (see Appendix A, "References"). **/1/**
- **\2** Update prohibited and allowed placements of LED fixtures based on industry progress. Clarify relationships between Air Force MAJCOMs and AFIMSC Detachments relative to Air Force waiver requests. Add guidance for solar powered airfield lighting fixtures. Revise terms to meet changes in FAA terminology. Update power requirements to modern technology requirements.

Revise Table 3-6, Visual Threshold Crossing Height Groups, to include C-130, C-17, and C-5. Update reference documents to account for renaming, rescissions, merges and cancellations. Add appendix of technological considerations and applications for design. **/2/**

- **\3** Clarify guidance regarding fixture outage thresholds. **/3/**

Impact: Cost impact is negligible. However, the following benefit should be realized:

- Designers may have a better understanding of the design requirements.

Unification Issues

- Paragraph 1-2 states the document scope and indicates that "Navy requirements are currently contained in Naval Air Systems Command (NAVAIR) 51-50AAA-2. When using the NAVAIR document, be certain that the complementary markings are installed and that no conflict occurs with the placement of light fixtures. The Navy should clarify what "…no conflict occurs" means, as it is unclear whether it references joint bases or only naval facilities.

- Paragraphs 1-5 and 1-6: This UFC applies to the Army and Air Force. Navy uses Naval Air Systems Command (NAVAIR) 51-50AAA-2, except for excerpts contained within this document which apply specifically to Navy and are not covered in NAVAIR 51-50AAA-2.

- Paragraph 1-7: The Army and the Air Force generally follow FAA standards that are primarily published as ACs, Engineering Briefs, handbooks, and specifications. However, when FAA documents are in conflict with the Air Force or Army requirements contained herein, this UFC takes precedence. When FAA documents are in conflict with Navy guidance included in this UFC or in NAVAIR 51-50AAA-2, UFC or NAVAIR 51-50AAA02 guidance takes precedence.

- Paragraph 1-8.2.1: NATO STANAGs apply at Army and Air Force facilities in NATO theater countries except the United States and Canada, or wherever NATO funding is provided for the work, regardless of location. Navy application of NATO Standardization Agreements is guided by NAVAIR 51-50AAA-2.

- Paragraph 1-10: The Army and Air Force have established tables within this document, which provide visual air navigation aids appropriate for operational requirements and associated electronic aids. See Table 2-1A for Air Force Airfield Visual Facilities Requirements. Note 18 was added to advise that outage thresholds for each system are established by FAA and must be followed for revised airfield operations during system outages; See Table 2-1B, for US Army Airfield Visual Facilities Requirements; or Table 2-3, Theater of Operations (TO) Airfield Heliport/Helipad Visual Requirements. For the Navy, NAVAIR 51-50AAA-2 identifies visual air navigation aids appropriate for operational requirements.

- Waivers: Paragraph 1-11 provides the Air Force process for obtaining waivers to requirements of visual air navigation aids. Paragraph 1-12 provides the Army process for obtaining waivers to requirements of visual air navigation aids. Navy waiver process is covered in NAVAIR 51-50AAA-2. These waiver processes are geared to the individual missions of these three services.

- Table 2-1A provides visual facilities requirements for Air Force airfields. Table 2-1B provides visual facilities requirements for Army airfields. Navy visual facilities requirements are provided in NAVAIR 51-50AAA-2. These visual facilities requirements are geared to the individual missions of these three services with the exception that Joint bases may have additional requirements. This issue has been resolved by Army-Air Force coordination on Table 2-1A. Navy-Air Force coordination has not been made on Table 2-1A.

- Table 3-6, Visual Threshold Crossing Height Groups, is modified and contains Army and Air Force coordinated information. Navy aircraft are not included.

- Figure 4-4A and Figure 4-4B provide threshold light configurations for Air Force and Army, respectively. They differ, based on mission.

- Figures 4-5A through Figure 4-5D provide threshold light circuiting for Air Force and Army, respectively. Interleaving is not recommended for Air Force airfields. (Twice the conductor lengths are necessary with one regulator for each circuit and specific outage thresholds for each system are established by FAA and must be followed for revised airfield operations during system outages. Interleaving may conflict with FAA revised airfield operations.)

- Para 12-3, “Siting PAPI”: For aircraft in height group 4 (Table 3-6) for Army airfields only, the PAPI is sited at the RPI plus an additional 300 feet (90 meters), +50 feet –0 feet (+15 meters –0 meters), from threshold.

- Para 12-3.1.2.2, Threshold Crossing Height (TCH): See Table 3-6. For the Air Force, the TCH is based on the most predominant aircraft using the runway (the MAJCOM will make this determination). For the Army, the TCH is based on the most demanding aircraft height group expected to use the runway (the aviation community will coordinate with US Army Aeronautical Service Agency (USAASA) for this determination).

CONTENTS

FIGURES

TABLES

CHAPTER 1 INTRODUCTION TO STANDARDS AND CRITERIA

1-1 PURPOSE.

This document provides guidance and detailed information on standard configurations and equipment for airfield lighting. Use this document when designing, planning, constructing, and installing new systems, for repairing and testing existing systems, and for introducing new aircraft technologies such as Head Up Display system lighting requirements.

1-2 SCOPE.

This document applies to Army and Air National Guard and to Army and Air Force Reserve bases with responsibility for maintaining their airfield facilities. Joint use with Civil Airport Authorities may require coordination. Existing systems and components are not required to be upgraded to these standards unless as part of a major rehabilitation. It is also important to note that the absence of a formerly FAA-approved NAVAID or piece of equipment from the current AC 150/5345-53, Appendix 3 Addendum is not an indication that this equipment is no longer approved for use. It means that particular NAVAID or piece of equipment is no longer manufactured. Much of this equipment is still supported for repairs by a sub-party of the former manufacturer and this NAVAID/piece of equipment may be more reliable and powerful than the one currently listed in the AC. Contact AFCEC/COSM if told that a NAVAID or piece of equipment is no longer approved for use. Beacons are one example of this situation.

This document contains the configuration standards, application and installation criteria, and a listing of applicable specifications for all visual air navigation facilities, except marking, at Air Force and US Army facilities.

Navy requirements are currently contained in Naval Air Systems Command (NAVAIR) 51-50AAA-2. When using the NAVAIR document, be certain that the complementary markings are installed and that no conflict occurs with the placement of light fixtures.

1-3 SUMMARY OF CHANGES.

This document aligns Air Force/Army airfield lighting requirements to be as close as possible to those of the FAA, with the exception of requirements that are unique to Air Force/Army facilities. FAA Advisory Circulars (AC) that are equivalent to Air Force/Army requirements are referenced. Specific requirements for the Air Force/Army are stated with appropriate data and figures provided.

a. Requirements for lightning protection (installation of a counterpoise) and equipment safety grounding systems are modified.

b. Figures and details are added to further clarify requirements.

c. In-paragraph FAA references are provided when context of a specific change is important.

d. References to other documents and guidance are updated due to cancellations or revisions.

e. The "Special Air Force Requirements" of Chapter 12 are now required for all installations.

f. Constant current regulators (CCR) are required to be ferro-resonant type. Silicon controlled rectifier (SCR) types are no longer approved for designs of new vault and lighting system installations. In-kind replacements of SCRs for existing systems and circuits may be approved under some circumstances (consult AHJ or designated individual of Service). ***/2/***

g. 50 kW and 70 kW constant current regulators (CCR) and 2400 VAC input regulators are no longer approved for new installations (A/C150-5345-10 details the requirements for constant current regulators (CCRs) and a monitor system for use with airport series lighting circuits.). The FAA objective is to transition to a 480 volt airfield lighting system for constant current systems. 30 kW is the maximum FAA-allowed CCR output. FOR AIR FORCE, 50kw and 70kW CCRs and the 2400 VAC system may remain in service with use of 2400V:480V transformers used to serve the vault additions/expansions, until funds are available for replacement of the existing service, generator and regulators.

h. Mixing of incandescent and light-emitting diode (LED) lighting technologies on a single taxiway is not permitted due to varying characteristics which affect light color, etc. In addition, mixing of fixtures by LED manufacturers on a single taxiway is not permitted for the same reason. If two taxiways are on a single circuit, fixtures for each taxiway must be uniform by type and manufacturer, not on the entire circuit, provided constant current regulator is not overloaded.

i. The FAA has changed specifications for light emitting diode (LED)-based red obstruction lights to make them visible to pilots using certain night vision goggle systems. Effective with the implementation of this change in FAA AC 150/5345-43, Specification for Obstruction Lighting Equipment, manufacturers will be required to meet the new specification for certified red LED-based obstruction lights.

1-4 BACKGROUND.

The term "visual air navigation facilities" refers to all lights (excluding ballpark-type lights for aprons and ramps which are covered in UFC 3-530-01), signs, symbols, and other visual aid devices located on and in the vicinity of an airfield. These facilities provide a visual reference and guidance to pilots when operating aircraft on the ground and in the air, and supplement the guidance provided by electronic aids such as Tactical Air Navigation (TACAN), Precision Approach Radar (PAR), and Instrument Landing System

(ILS), for operating aircraft. Criteria for Air Force airfield markings are contained in UFC 3-260-04, *Airfield And Heliport Marking.*

1-4.1 Visual air navigation facilities and systems must be standardized for operational safety. Standardization means that the configuration and color of the lights at each airfield is identical and has the same meaning. Standardization enables pilots to readily interpret the guidance information.

1-4.2 Per Public Law 85-726, the FAA regulates and promotes civil aviation to foster its development and to provide for the safe and efficient use of the airspace by both civil and military aircraft. The FAA develops, modifies, tests, and evaluates systems, procedures, facilities, and devices. It also defines the performance characteristics needed for safe and efficient navigation and traffic control of all civil and military aviation.

1-5 APPLICATION.

Use this document for all major rehabilitation (i.e., when over half of the lighting system requires replacement), or for the establishment of new visual air navigation facilities at Air Force and US Army installations.

Do not install visual air navigation facilities or equipment other than those covered in this publication except when an appropriate waiver has been obtained (refer to paragraph 1-11 for Air Force waivers, or paragraph 1-12 for US Army waivers). Exceptions are when international military standards apply, when Standards of Forces Agreements apply and *where existing facilities configured to prior standards and criteria continues to give satisfactory service*.

1-6 NAVY REQUIREMENTS.

Department of the Navy (Navy) requirements are contained in NAVAIR 51-50AAA-2. Use NAVAIR 51-50AAA-2 on all Navy airfield construction projects. NAVAIR 51-50AAA-2 takes precedence over this UFC and over FAA and International Civil Aviation Organization (ICAO) documents. This paragraph takes precedence over information presented elsewhere in this UFC regarding Navy requirements.

1-6.1 Navy airfield requirements are listed in in Table 1, “Approach Visual Aids Requirements,” in NAVAIR 51-50AAA-2.

1-6.2 LED-lighted obstruction lights are not permitted on Navy projects due to the use of Night Vision Goggles (NVG) by rotary wing aircraft operations. FAA Safety Alert for Operators (SAFO) 09007 contains additional information.

1-6.3 LED-lighted airfield lighting fixtures are permitted on Navy projects with the acknowledgement from the CO or Airfield Manager that LEDs may not be compatible with Enhanced Flight Vision System (EFVS) technology. EFVS is not known to be used on current Navy aircraft.

1-6.4 Additional Navy requirements that differ from Tri-service guidance include:

a. Install counterpoise systems using the equipotential method: above airfield lighting circuits and connected to all airfield lighting equipment, including light bases, guidance signs, and other metallic structures. Reference National Fire Protection Association (NFPA) 780, Chapter 11, "Protection for Airfield Lighting Circuits." **\1** The required use of the equipotential method of counterpoise takes precedence over NAVAIR 51-50AAA-2 counterpoise requirements.**/1/**

b. Install counterpoise ground rods at a 2,000 foot maximum spacing and at all changes in direction, terminations, crossings, and connection to existing counterpoise.

c. Ground rods are not required in cans or on cans with counterpoise systems.

d. Do not use counterpoise wire in conduit with circuit conductors.

e. An equipment ground is not required in constant current circuit conduits.

f. Encase constant current circuit ducts in concrete only when installing under new roadways.

g. For airfield constant current and low-voltage circuits, use aircraft-rated hand holes. Manholes are required for medium-voltage power systems, per UFC 3-550-01.

h. Use 2-inch (53 mm) PVC duct for airfield constant current circuits, with a maximum of two airfield cables and two constant current circuits per duct, and a maximum of two constant current circuits. This permits the interleaving of two circuits within one conduit. **/2/**

i. A drain system in light bases using a duct system or hand holes is not required.

j. Insert PVC conduit through grommets 1 inch (25 mm) (minimum) to 1.5 inches (38 mm) (maximum) into the light base.

k. Only in-pavement fixtures use L-868 cans; elevated lights and signs use L-867 cans.

l. Except for runway in-pavement lights, use anti-seize compound on all threaded connections made on-site to cans, light supports, and sign legs. For runway in-pavement lights use ceramic fluoropolymer coated steel bolts without anti-seize.

m. Photometric testing of newly installed airfield light fixtures, as specified in Unified Facilities Guide Specification (UFGS) 26 56 20 is not required.

n. Consider at taxiway or runway intersections or crossings, provide two spare 2-inch (53 mm) PVC duct bank crossings with hand holes for future use and maintenance use.

1-6.5 Airfield Lighting Control Systems (AFLCS) for Navy projects are normally provided using project funding by **\4** Naval Information Warfare Systems Command (NAVVWARSYSCOM). Coordinate with NAVWARSYSCOM during the 1391 development and during the at early stages of the project design.**/4/**

1-6.6 **\1** Precision approach path indicators (PAPI) systems for Navy projects normally require coordination with the **\4** NAVWARSYSCOM **/4/**. Coordinate with NAVWARSYSCOM during the early stages of the project design.**/1//4/**

1-6.7 **\2** NAVAIR 51-50AAA-2 can be found on the Whole Building Design Guide site at https://www.wbdg.org/ffc/dod/supplemental-technical-documents/tsewg-navair-51-50AAA-2 **/2/**

1-7 FAA STANDARDS.

\3 The Army and Air Force generally follow FAA standards that are primarily published as Advisory Circulars, Engineering Briefs, handbooks, and specifications. However, when FAA documents are in conflict with the Air Force or Army requirements, this UFC takes precedence. Outage thresholds for individual NAVAID systems are identified by FAA. **/3/** **\4** (This means, when there is an outage on the airfield at any time, FAA guidance dictates the steps to take, in priority order, to avoid an airfield shutdown. This guidance is available in the Control Tower.) When FAA documents are in conflict with Navy guidance included in this UFC or in NAVAIR 51-50AAA-2, UFC or NAVAIR 51-50AAA-2 guidance takes precedence. **/4/**

1-8 INTERNATIONAL MILITARY STANDARDS.

1-8.1 This UFC satisfies the requirements of international military standards to the greatest extent possible.

1-8.1.1 NATO Standardization Agreements (STANAGs) are promulgated by the NATO Standardization Office (NSO).
\3
1-8.1.2 AFIC Air Standards (AIR STD) are promulgated by representatives of the military air forces of Australia, Canada, New Zealand, United Kingdom, and the United States. AIR STDs governing airfield lighting and marking, obstructions, helipads, and heliports have been cancelled. **/3/**

1-8.2 Applicable international military standards take precedence over standards in this UFC as follows:

1-8.2.1 NATO.

NATO STANAGs apply at Army and Air Force facilities in NATO theater countries except the United States and Canada, or wherever NATO funding is provided for the work, regardless of location.

\3

1-8.2.2 AFIC.

At Army and Air Force facilities in New Zealand and Australia, contact:

FVEY Air Force Interoperability Council – Management Committee

1-9 CONSTRUCTION AGREEMENTS WITH OTHER NATIONS.

All construction outside of the United States is governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

\4 SOFA replaced or supplements Base Rights Agreements. Information is at https://2009-2017.state.gov/documents/organization/236456.pdf, but it is unclear whether this has been updated ***/4/***.

1-10 VISUAL AND ELECTRONIC AIDS.

Provide visual air navigation aids appropriate for operational requirements and associated electronic aids. See Table 2-1A, “Air Force Airfield Visual Facilities Requirements,” Table 2-1B, “US Army Airfield Visual Facilities Requirements” or Table 2-3 “Theater of Operations (TO) Airfield Heliport/Helipad Visual Requirements.” Except for Visual Flight Rules (VFR) operation, electronic aids are needed to provide initial positioning and direction information to approaching aircraft. Visual landing aids ensure a timely and safe transition from the instrument phase to the visual phase of an approach. Failure to provide the necessary visual aids on an instrument runway will degrade the utility of the electronic systems. Furthermore, enhancing a runway with unnecessary visual aids wastes resources, may cause confusion, and offers minimal operational advantages. Do not upgrade visual aids for a higher level of operations unless the runway, taxiway, or helipad is approved for that level, and appropriate electronic aids are programmed for installation. Waivers are required for all deviations. Also reference paragraphs 1-11, 1-12, and 2-3.

1-10.1 Electrical support equipment, including the emergency power system, for visual and air navigational aids are not airfield obstructions. If a visual or air navigation aid is classified/categorized a "permissible deviation," then the power equipment supporting that visual or air navigation aid is also classified a "permissible deviation," provided:

- The support equipment is installed behind the equipment it supports, from the perspective of a landing aircraft; and
- The horizontal footprint of the equipment, from the perspective of a landing aircraft, is minimized.

1-11 AIR FORCE WAIVERS OF REQUIREMENTS.

The major command Vice Commander may waive requirements of this UFC if compliance is not practical or feasible. In exercising this waiver authority, the Commander or Vice Commander must not adversely impact the effectiveness or safety of operations for any aircraft which may use the airfield. Under normal circumstances, funding or budgetary constraints are not adequate justification for granting a waiver.

1-11.1 Approval Authority.

Authority to approve waivers resides with the major command Commander or Vice Commander and may be delegated to the Director of Operations (DO), depending upon the waiver content, but may not be re-delegated by DO.

1-11.1.1 Installation Representative.

The installation's representative will:

a. Coordinate all waiver requests with the operations/airfield management and wing safety offices through the base level operations and safety divisions. In accordance with AFMAN 13-204V2 and Air Force Policy Directive (AFPD) 13-2, the operations/airfield management offices must coordinate as necessary with local wings and air traffic control agencies (e.g., FAA) providing terminal instrument procedures (TERPS) services for the affected locations.

b. Submit installation commander-approved waiver requests to AFIMSC/IZB for technical review; AFCEC Operations Directorate (AFCEC/CO) will provide subject matter expert (SME) support to AFIMSC.

c. Notify the FAA of waiver requests involving facilities at joint-use airfields subject to provisions of Title 14 Code of Federal Regulations (CFR) Part 77. Contact the regional FAA Airports Division having jurisdiction over the airfield for the requirements and coordination process. For contact information, consult http://www.faa.gov/about/office_org/headquarters_offices/arc/ro_center/ for National

Engagement and Regional Administration and http://www.faa.gov/airports/news_information/contact_info/regional/ (for Contact Information for FAA Regional Airports Offices (current as of October 2021). Also consult local U.S. Government telephone listings for contact numbers.

d. Maintain a complete record of all waivers requested and the disposition of each (approved or disapproved). Document all approved waivers and make these waiver packages a part of the permanent facility records, available for examination during inspections. Include a list of required waivers and those approved for a specific project in the project design analysis of future projects. **\4** Include active airfield waivers in the package of documents to be resigned by a new Commander, if applicable. ***/4/***

\2

e. Refer to paragraph 1-7. Waiver processes for fixture replacements are outlined by FAA. ***/2/***

f. Forward copies of the completed documentation for each approved waiver with detailed justification to: SMEs:

1-11.1.2 AFIMSC.

AFIMSC will:

a. Ensure that all required coordination has been accomplished.

b. Ensure that the type of waiver requested is clearly identified as either "Temporary" or "Permanent." Permanent waivers are required when no further mitigating actions are intended, necessary, or available. Temporary waivers are issued for a specified period during which additional actions to mitigate the situation must be initiated to fully comply with criteria or to allow the acquisition of a permanent waiver. Follow-up inspections will be necessary to ensure that mitigating actions proposed for each temporary waiver are on schedule or progressing. Re-accomplish temporary waivers at the end of the initial period or annually, whichever is earlier.

1-11.2 Existing Air Force Facilities (Grandfather Clause).

A waiver to requirements within this UFC is not required where existing facilities meet prior standards and continue to give satisfactory service.

1-12 US ARMY WAIVERS OF REQUIREMENT.

1-12.1 Waiver Procedures.

1-12.1.1 The installation's design agent, aviation representative (safety officer, operations officer, and/or Air Traffic and Airspace (AT&A) officer) and installation master planner will:

a. Jointly prepare/initiate waiver requests.

b. Submit requests through the installation to the major command (ACOM).

c. Maintain a complete record of all waivers requested and the disposition of each waiver (approved or disapproved). Include a list of required waivers and waivers approved for a specific project in the project design analysis prepared by the design agent aviation representative or installation master planner.

1-12.1.2 The ACOM will:

a. Ensure that all required coordination has been accomplished.

b. Ensure that the type of waiver requested is clearly identified as either "Temporary" or "Permanent." Permanent waivers are required when no further mitigating actions are intended or necessary. Temporary waivers are issued for a specified period during which additional actions to mitigate the situation must be initiated to fully comply with criteria or to obtain a permanent waiver. Follow-up inspections will be necessary to ensure that mitigating actions proposed for each temporary waiver granted have been accomplished.

c. Review waiver requests and forward to US Army Aeronautical Service Agency (USAASA) for action. To expedite the waiver process, ACOMs are urged to simultaneously forward copies of requests to:

Director, US Army Aeronautical Services Agency (USAASA)	ATTN: MOAS-AI 9325 Gunston Road, Suite N319 Fort Belvoir VA 22060-5582
Commander, US Army Safety Center (USASC)	ATTN: CSSC-SPC Bldg. 4905, 5th Ave. Fort Rucker AL 36362-5363
Director, US Army Aviation Center (USAAVNC)	ATTN: ATZQ-ATC-AT Fort Rucker AL 36362-5265
Director, USACE Transportation Systems Center (TSMCX)	ATTN: CENWO-ED-TX 1616 Capitol Ave. Omaha NE 68102-2403

1-12.1.3 USAASA is responsible for coordinating the following reviews for each waiver request:

- Air traffic control and safety and risk assessments by USASC.
- Technical engineering review by TSMCX.

Based upon these reviews, USAASA makes a final determination. USAASA is responsible for all waiver actions related to Army operational airfield/airspace criteria.

1-12.2 Contents of Waiver Requests.

Reference the standard/criterion to be waived, citing paragraph and page numbers.

1-12.2.1 Justification for Waivers.

Demonstrate that safety and cost factors have been considered in justification for noncompliance, and that they adequately support the Army's mission. Reference special studies which support the decision. Adequate justification for waivers of a requirement are when:

- Specific site conditions (physical and functional constraints) make compliance with existing criteria impractical and/or unsafe:
  - Recurring adverse weather conditions require hangar space to be provided for all aircraft.
  - Lack of land/space makes it necessary to expand hangar space closer to and within the runway clearances.

- Maintaining fixed-wing Class A clearance when support of Class B fixed-wing aircraft operations exceeds 10 percent of airfield operations.

- Deviation(s) from criteria fall within a reasonable margin of safety and do not impair construction of a facility long-range; for example, installing security fencing around and within established clearance areas.

- Construction that does not conform to criteria is the only alternative to meet mission requirements. Evidence of analysis and efforts taken to adhere to criteria and standards must be documented and referenced.

1-12.2.2 Operational Factors.

Include information on the following existing and/or proposed operational factors used in the assessment:

- Mission urgency.
- All aircraft by type and operational characteristics.
- Density of aircraft operations at each air operational facility.
- Facility capability Visual Flight Rules (VFR) or Instrument Flight Rules (IFR)).
- Use of self-powered parking versus manual parking.
- Safety of operations (risk management).
- Existing navigational aids (NAVAID).

1-12.2.3 Alternatives Considered.

Record all alternatives considered, their consequences, required mitigation, and evidence of coordination.

1-12.3 Existing US Army Facilities. (Grandfather Clause)

A waiver to requirements within this UFC is not required where existing facilities meet prior standards and continue to give satisfactory service.

1-13 METRICATION OF DIMENSIONS.

Use ICAO standard English or metric equivalents rounded off (e.g., 30 meters equals 100 feet), although they do not represent exact conversions. No change in standard dimensions, tolerances, or performance specifications is needed if they are applied consistently.

Note: Executive Order 12770, signed by President George H. W. Bush on July 25, 1991, citing the Metric Conversion Act of 1975 (Public Law 94-168 (15 U.S.C. 205a et seq), directs departments and agencies within the executive branch of the United States Government to "take all appropriate measures within their authority" to use metric units in federal programs - Federal Register page and date: 56 FR 35801; July 29, 1991

1-14 PHOTOMETRIC REQUIREMENTS.

Photometric requirements in this UFC are based on standards established by the ICAO and FAA**.** They have been modified as necessary to accommodate Air Force requirements.

1-15 EXISTING FACILITIES.

Do not use this document as the sole basis for advancing standards for existing facilities and equipment, except where necessary for a minimum acceptable level of safety, quality, and performance. If there is a change in mission that results in a reclassification of the facility, an upgrade to current standards is required. When existing facilities are modified, construction must conform to the criteria in this UFC unless waived per paragraphs 1-11 and 1-12. If new generation equipment must be integrated with older equipment, make certain any differences in individual performance do not degrade performance of the overall system.

1-16 DOCUMENT ORGANIZATION.

Chapters 1 through 11 provide siting criteria for the design of specific installations. They also provide application criteria to ensure that planned installations are appropriate for their intended purpose.

Chapters 12 and 13 contain information concerning design, installation and performance characteristics for each system, including an explanation of the purpose, configuration, construction, photometrics, and related equipment guidelines approved for US Army and Air Force use.

1-17 \4\ SUPPLEMENTAL CRITERIA 21 May 2018

The following documents supplement this UFC. The technical papers provide additional information for airfield lighting and NAVAIDS equipment that is suitable for use on military airfields, inspection requirements on an ongoing basis for airfield visual aid systems, and the Army's portable lighting requirements for theater of operations airfields. Air Force Expeditionary Airfield Lighting Systems guidance for contingency and expeditionary operations and temporary FOBs are provided at https://www.wbdg.org/ffc/dod/supplemental-technical-documents.

- UFC 3-535-02, *Design Drawings for visual Air Navigation Facilities*, supplements this UFC and provides drawing details for design and construction of individual components of visual navigation facilities. Note that some details apply only to a specific Service. Ensure that the appropriate Service detail is used for the specific project under design.

- TSEWG TP-20, *Air Visual Air Navigation Facilities: Qualifying Equipment*

- TSEWG TP-21, *Visual Air Navigation Facilities: Air Facility Equipment Inspection And Testing*

- Army Only: TSEWG TP-22, *Airfield/Heliport/Helipad Portable Lighting Requirements in a Theater of Operations (TO).* ***/4/***

This Page Intentionally Left Blank

CHAPTER 2 APPLICATION CRITERIA

2-1 PURPOSE OF CHAPTER.

This chapter provides application criteria to ensure that the installation of visual air navigation facilities is appropriate for the purposes intended and that they are adequate to support desired levels of operation.

2-2 RELATION TO ELECTRONIC FACILITIES.

Except for Visual Flight Rules (VFR) operations, electronic facilities are required to provide initial positioning and direction information to an approaching aircraft. Visual air navigation aids are necessary to ensure a timely and safe transition from the instrument phase of an approach to its visual phase. The planned operational level for an instrument runway can be achieved only through a combination of appropriate electronic and visual guidance systems. Failure to include the required visual aids in the planning of an instrument runway will degrade the utility of the electronic systems. Conversely, enhancing a runway with inappropriate visual aids will waste resources while providing little operational advantage.

2-3 APPLICATION OF REQUIREMENTS.

Use the criteria in this chapter for planning, budgeting, and installing visual air navigation facilities. Do not upgrade or increase visual aids to a support a higher operational requirement unless the runway, taxiway, or helipad has been officially approved for the new level of operation and all appropriate electronic aids have been installed or are programmed for installation. Waivers are required for all deviations in accordance with paragraph 1-11 (Air Force) or 1-12 (US Army), as applicable.

2-4 REQUIREMENTS.

Table 2-1A contains requirements for Air Force airfields; requirements for US Army airfields are contained in Table 2-1B. Helipad/heliport requirements are listed in Table 2-2. Theater of Operations (TO) Airport Heliport/Helipad Visual Requirements are listed in Table 2-3. Each table contains application criteria for operational categories and the related visual aid requirements. A table of criteria for Navy airfields/heliports is contained in NAVAIR 51-50AAA-2.

2-4.1 Not Required (NR) designates a visual aid which is not required for a particular operation and is therefore not specifically provided to support that operation.

2-4.2 Not Applicable (NA) designates a visual aid whose operational performance is not necessary to support a particular operation or where a particular operation that could be supported is not required.

2-4.3 Optional (OPT) designates a visual aid which is not required under normal conditions, but may be installed to support or enhance operations. It may also apply to a visual aid which is required only under certain conditions, meteorological or otherwise. Design of any installed visual aid must comply with provisions of this UFC or the FAA Advisory Circular referenced, in that priority order.

2-5 LIGHT EMITTING DIODE (LED) LIGHT FIXTURES.

Increased use of airport LED light fixtures on the air operations area (AOA) has created problems when these fixtures are interspersed with their incandescent counterparts. LED light fixtures are essentially monochromatic (aviation white excepted); as such, their perceived color and/or brightness differs from equivalent incandescent fixtures. These differences may distort the visual presentation to a pilot. Therefore, LED light fixtures must not be interspersed with incandescent lights of the same type.

Example: An airport adds an extension to a runway. On the existing runway, the runway centerline light fixtures are incandescent. The airport decides to install LED runway centerline fixtures on the new section of runway and retains the incandescent fixtures on the existing section. This interspersion of dissimilar technology is not approved for installation.

In addition, defective incandescent fixtures must not be replaced with their LED counterparts. When replacing a defective light fixture, make certain that the replacement uses the same light source technology to maintain a uniform appearance.

\4

2-5.1 LED Placements.

2-5.1.1 Permitted Placements.

LED fixtures are permitted for the following locations:

- Runway guard lights (RGL).
- Stop bars.
- Taxiway edge lights.
- Wind cones - available only with integral LED L-810s with IR component.
- Obstruction Lights (exceptions): weather equipment and navaids under 35 feet with integral LED w/IR may be used, with the agreement of airfield management.
- Lead-on and lead-off lights.
- Airfield signage.

- PAPI installations in current projects, but PAPIs may not be upgraded to LEDs for the sole purpose of removing incandescent PAPIs.

For each of these approved systems, each circuit and paired signs/fixtures (e.g., fixtures operating as a system and located on each side of a taxiway or a runway entrance/exit) must be either LED or incandescent technology.

For Air Force: Surge protection is required. The interface circuitry (if any) and solid state devices must be designed to withstand and/or include separate surge protective devices which have been tested against defined waveforms detailed in Table 4*,* "Location Category C2" of ANSI/IEEE C62.41-1991*, Recommended Practice on Surge Voltages in Low Voltage AC Power Circuits*, *Standard 1.2/50 microsecond (µS) — 8/20 µS combination wave*. Peak voltage is 10 kilovolts; peak current is 5 kiloamps with a nominal ratio of peak open circuit voltage to peak short circuit current of 2 ohms.

When LED fixtures are installed on an airfield, FAA AC 150/5340-30J, Section 1.4 applies.

2-5.1.2 Air Force Placement Restrictions and Prohibitions.

- Runway edge lights: Lamp availability may become an issue. LEDs are prohibited as long as incandescent lamps are available. New projects may be coordinated with MAJCOM/A3 relative to LED option.

- Touchdown zone lights: MR16 quartz lamps are still readily available. When edge lights are replaced with LEDs, TDZ lights may also be replaced with LEDs in the same project.

- Approach lights and systems: PAR56 (300-500 watt) lamps and PAR38 (150 watt) lamps for elevated approach lights are becoming scarce. As long as lamps are available, continue to use existing systems. Exception (coordinated with MAJCOM/A3): replacement of the elevated approach light fixtures on bases without routine covert operations may be by LED when other lamps become unavailable, with written coordination between CE and base Operations. Notify base Operations to publish use of LEDs for the approach systems in the Flight Information Publication (FLIP). For bases with routine covert operations, these systems may be supplemented with a 4- or 6-fixture landing zone system, to identify beginning and end of runway usable area during covert operations.

- Runway centerline lights: MR16 quartz lamps are still readily available. For Air Force Category II and III airfields, runway centerline lights may be replaced with LEDs in the project that replaces edge lights and TDZ lights with LEDs.

- Obstruction lights: FAA certified LED L-810 fixtures are available with an IR component. There is currently no availability with a heat signature.

When the inventory of lamps can no longer be replenished by the manufacturer, a project to install LED edge lights with an IR emitter component may be programmed, with coordination with airfield management.

If any exception is exercised, ensure airfield management publishes a warning on the use of LEDs in the Flight Information Plan (FLIP). Rationale: Any critical piece of the lighting system attached to the runway environment needs to be published so transitory aircrew will understand their limitations on using that field for NVG operations.

Bases which are home to aircraft with head up displays in the cockpits should incorporate a modified LZ layout of five incandescent fixtures at the threshold and approach. These fixtures should be a separate circuit not tied to a circuit consisting of LED fixtures. Photometric requirements apply.

2-5.1.3 Army Placement Restrictions and Prohibitions.

Use of LED fixtures is optional for all airfield lighting systems on Army airfields.

For each of these systems, each circuit, system, or paired signs/fixtures (e.g., fixtures operating as a system and located on each side of a taxiway or a runway entrance/exit) must be either LED or incandescent technology. Intermixing of lighting technology is not allowed.

Runway edge, threshold, and end lights must all be the same lighting technology. Steady burn approach lights may be a different lighting technology from the approach lighting sequenced flashers and runway edge, threshold, and end lights.

Airfields must:

- Consider the availability of replacement lamps and fixtures.
- Determine if LED fixtures will have any potential impact on the DoD mission (USTRANSCOM, Air Mobility Command) and equipment (night vision imaging systems).
- Ensure that LEDs on Army airfields are certified as meeting FAA specifications or Host Nation agreements.
- Conduct a hazard analysis of impact to local operations and ensure risk is accepted at the appropriate level.
- Publish use of LED fixtures in the approach lighting system or runway perimeter lighting in the Flight Information Publication (FLIP). ***/4/***

2-5.2 Signage.

2-5.2.1 Sign Temperature Requirements.

Signs must withstand the following operating temperature ranges

Class 1 signs: -4 to -131 degrees F (-20 to +55 degrees C)

Class 2 signs: -40 to 131 degrees F (-40 to +55 degrees C)

Shipping and storage temperatures for Class I and 2 signs range from -67 degrees F (-55 degrees C) to 131 degrees F (55 degrees C). Sign temperature requirements are modified to accommodate LEDs. Reference AC 150-5345-44.

2-5.2.2 Sign Definitions.

See AC 150-5345-44, paragraph 1.2.6.

2-5.2.3

- Mandatory and informational signs.
- Distance remaining signs.
- Runway holding position signs.
- Separate signs in a sign array.

\2 Each signage system/array/paired array must be all LED or all incandescent technology. ***/2/***

2-5.3 LED Performance Requirements.

FAA Engineering Brief (EB) 67 provided detailed information in 2012 relative to LED concerns, but updates through Airport Improvement Program guidance indicate that, for normal operations, LEDs may be used for HIRL. At the same time, considerations for Enhanced Visual Systems must be addressed on an airfield use basis – for military, this translates to airfield mission.). AIP Program Guidance Letter 19-02 for HIRL airfields sums it up by the statement of vigilance, “EFVS users with IR-based sensors are reminded to review Safety Alert for Operator (SAFO) 09007.”

https://www.faa.gov/airports/aip/guidance_letters/media/aip-pgl-19-02-LED-HIRL.pdf

Legend:

Note: Backup power must be provided for visual landing aids listed as "R" (required).

R Required.
OPT Optional, as recommended by the wing commander and approved by the MAJCOM.
NR Not required.
NA Not applicable. Not appropriate for this application.
(1) MAJCOM approval is required to substitute MALSR for an ALSF-1 to avoid installation errors.
(2) Required only on primary runways.

(3) All new taxiway location and direction signs, RDRs, and mandatory signs are required to be internally lighted. See paragraph 9-1.4.
(4) Wind direction indicators are required to meet ICAO Annex 14 (paragraph 5.1, "Indicators and Signaling Devices"). Lighted cone is required. Integral LED obstruction light is allowed.
(5) Emergency power required for all equipment designated "R."
(6) Apron edge lighting is not required if apron flood lighting is provided. Base Ops may approve reflective markers.
(7) Apron edge lighting is required for safety concerns, even if apron flood lighting is provided. Base Ops may approve reflective markers. See UFC 3-530-01 for Apron Floodlighting.
(8) For surface movement and guidance of CAT III systems, refer to FAA AC 120-57.
(9) Runway guard lights require monitoring IAW FAA AC 150/5345-46, paragraph 3.7.3.4.
(10) Use of retroreflective markers is allowed where additional marking is required, but are not a substitute for apron edge lights.
(11) FAA requires guidance signs for the purpose of clear guidance and direction and presents signage for average airfield configuration, but simple airfields (single runway and few entering taxiways) or airfields which utilize a "follow me" vehicle, may not require complicated signage. Required with the use of REILS.
(12) Optional with the use of REILS.
(13) Required for medium intensity.
(14) Required for RVR <600 only.
(15) For RVR ≥ 2400 only.
(16) Waiver is required.
(17) Waiver is not required when used as a subsystem of ALSF-1.
\3\ (18) Outage thresholds (relating to number of missing fixtures, both total and consecutive, that invoke various stages of airfield shutdown) are identified by FAA. **/3/**
\4(19) Visual Approach Slope Indicators may be used in visual approach conditions if Airfield Operations requires.
(20) For bases home to aircraft with Head Up Displays, use a modified LZ incandescent configuration if threshold lights are LED.**/4/**

2-6 REFERENCE DOCUMENTS.

Use the most current revision or publication date for documents referenced in this UFC.

This UFC is supplemented by technical papers for various topics supporting the selection, testing and maintenance of airfield navigation aids. See Appendix A for references citations.

R Required

OPT Optional - highly recommended when situation and operational environment permits.

(1) The lighting system must be connected to an emergency power source such as a diesel-generator or independent utility. For US Army-only aviation operations the emergency power source need only be readily available for connection.

(2) Runway distance remaining signs are not required to be lighted, but must conform to UFC 3-535-01 RDR lighted standards. Runway distance remaining signs are optional for rotary-wing aircraft-only operations.

(3) FAA Type L-853 Retro-reflective Markers may be used when power is not available.

NOTES:

1. A TO in Joint Publication 3-0, Joint Operations, is defined as an operational area defined by the geographic combatant commander for the conduct or support of specific military operations.
2. Technical Paper 22 (TSEWG TP22) provides criteria and other essential information for this lighting.

This Page Intentionally Left Blan

CHAPTER 3 STANDARDS FOR LIGHTED APPROACH AIDS

3-1 APPROACH LIGHT SYSTEM WITH SEQUENCED FLASHING LIGHTS (ALSF-1).

Approach lighting systems provide the basic means to transition from instrument flight to visual flight for landing. Descriptions of ALS types follow.

3-1.1 Purpose.

The ALSF-1 is a high intensity approach lighting system with sequenced flashing lights required for operations under Category I conditions. This system provides visual guidance to pilots aligning approaching aircraft with the runway and attempting final corrections before landing at night or during low visibility.

3-1.2 Associated Systems.

In addition to electronic aids such as an Instrument Landing System (ILS), Radar Approach Control (RAPCON)-(includes a Primary Surveillance Radar (PSR) subsystem and a Secondary Surveillance Radar (SSR), a Precision Approach Radar (PAR) Subsystem, and an Operations Subsystem), or microwave landing system (MLS), the ALSF-1 should include features described in paragraphs 3-1.2.1 through 3-1.2.3:

Note: NATO interoperability requires that we use RAPCON until at least 2040 because there is not a better system for military use.

3-1.2.1 A paved runway at least 150 feet (50 meters) wide and 6,000 feet (2,000 meters) long. Shorter runways may be approved for special operating conditions. The runway must be equipped with:

- Precision approach markings.
- High-intensity edge lights.
- High-intensity threshold lights.
- End lights.
- Runway distance remaining signs (RDR). Runway distance remaining signs are used to provide distance remaining information to pilots during takeoff and landing operations. The signs are located along the side(s) of the runway, and the inscription is a white numeral on a black background, as shown in Figure 15 to indicate the runway distance remaining in increments of 1,000 feet.

- Runway visual range (RVR) system.

3-1.2.2 An approach having a paved or stabilized end zone area extending 1,000 feet (300 meters) into the approach area and wider than the runway. The first 300 feet (100 meters) of paved or stabilized area requires the same slope as the first 1,000 feet (300 meters) of the runway. Slope of the remainder of paved or stabilized area may not exceed ±1.5 percent. These criteria and further details are provided in UFC 3-260-01.

3-1.2.3 Air traffic control support during normal operating hours.

3-1.3 Configuration.

The ALSF-1 consists of a pre-threshold light bar, a terminating bar, a 1,000 foot (300 meter) cross bar, centerline lights (barrettes), sequenced flashing lights, and threshold lights. Figure 3-1 shows a typical layout. The system centerline coincides with the extended runway centerline. The overall system length is 3,000 feet (900 meters), extending from the runway threshold into the approach zone. The generally accepted convention for locating lights along the longitudinal axis of approach light systems for the standard is that the longitudinal axis is divided in 100-foot (30 meters) stations with station 0+00 located at the threshold and higher station numbers located farther into the approach. Thus, a light a station 1+10 would be located 110 feet (33 meters) into the approach, measured from the threshold. Subsequent stations would be at 2+10, 3+10, etc. If a site condition requires a wider separation, the separation may be divided between barrettes. For example, a deviation resulting in a 34-foot increase in separation may result in 1+10, 2+20, 3+34, 4+34, etc. with a maximum deviation of 50 feet (15.2 meters) for the entire 3,000 foot approach.

Configurations of individual system elements are illustrated in Figure 3-1.

\4 For the Air Force: If terrain or other local conditions prevent a full-length installation, the system may be shortened to not less than 2,400 feet (720 meters). **/4/**

3-1.3.1 Pre-threshold Bar.

The pre-threshold bar consists of two barrettes in aviation red lights placed symmetrically about the system centerline at station 1+00. Each barrette consists of five lights on 3.5-foot (1-meter) centers, with the innermost light centers located not less than 75 feet (22.5 meters) nor more than 80 feet (24 meters) from the system centerline.

3-1.3.2 Terminating Bar.

The terminating bar consists of two barrettes in aviation red lights located symmetrically about and perpendicular to the system centerline at station 2+00. Each barrette consists of three lights on 5 foot (1.5 meter) centers, with the outermost light centers located 25 feet (7.5 meters) from the system centerline.

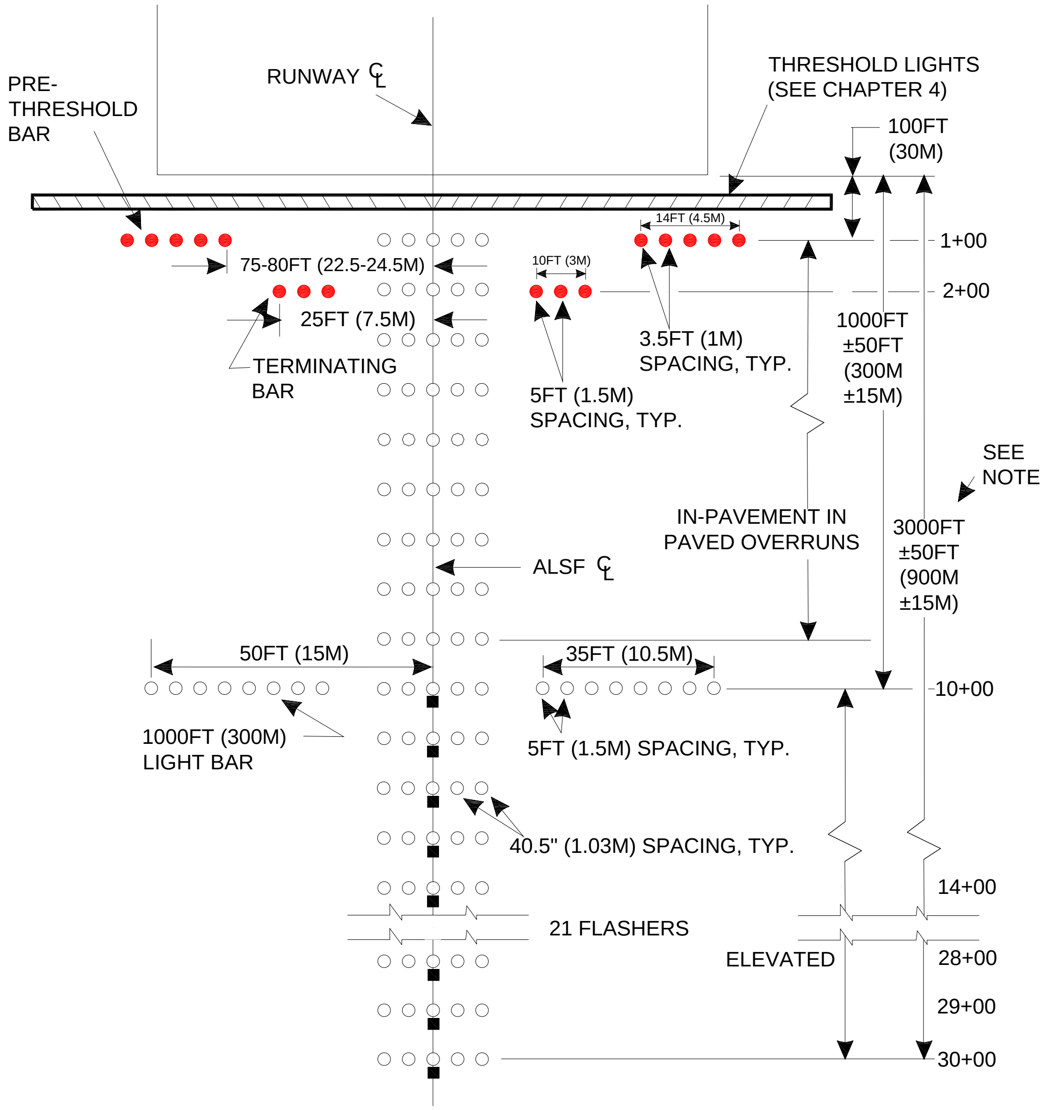
3-1.3.3 1,000-Foot (300-meter) Light Bar.

This light bar consists of two barrettes in aviation white lights located symmetrically about and perpendicular to the system centerline at station 10+00 and in line with the centerline barrette at that station. Each barrette consists of 8 lights on 5-foot (1.5-meter) centers with the outermost light center located 50 feet (15 meters) from the system centerline.

3-1.3.4 Centerline Lights.

The centerline lights consist of a series of barrettes with aviation white lights located at 100-foot (30-meter) intervals along the system centerline, from station 1+00 to station 30+00. Each barrette consists of five lights spaced at 40.5 inches (1.03 meters) on centers, centered on and perpendicular to the system centerline. Centerline lights on elevated supports may be spaced at 40.5 inches (1.03 meters) to fit standard FAA support hardware.

Figure 3-1 ALSF-1 Configuration



LEGEND:
- ○ WHITE LIGHTS
- ● RED LIGHTS
- ■ SFL (WHITE)

NOTE:
SEE TEXT FOR ADJUSTMENTS AND TOLERANCES.

NOT TO SCALE

3-1.3.5 Sequenced Flashing Lights (SFL).

The sequenced flashing lights are a series of twenty-one (21) flashing lights located on the system centerline, beginning at station 10+00, 1,000 feet (300 meters) from the threshold and ending at station 30+00. The light flashes at a rate of twice per second, in sequence from the outermost light station toward the threshold, appearing as a ball of white light traveling toward the runway. Sequenced flashing lights may be uniformly mounted a maximum of 4 feet (1.2 meters) below the steady burning lights, or when in-pavement lights are used, they may be displaced a maximum of 5 feet (1.5 meters) into the approach along the system centerline to avoid visual or physical interference between light units. (Note: SFLs are sometimes referred to in the field as “rabbits.”)

3-1.3.6 Threshold Lights.

While threshold lights are not actually a section of the approach light system, they must be present and installed according to paragraph 4-4.

3-1.4 Photometrics.

Optimum aiming of lights depends on the design and light output of the fixtures used in the system. Light fixtures may be designed to support several applications and may have fixed patterns and aiming angles which differ from the standard. Light aiming and patterns other than those prescribed in this UFC may be used, provided the resultant light pattern produces equivalent light intensities in the areas required by this UFC.

3-1.4.1 Intensity.

Luminous characteristics for the lights used in the ALSF-1 system are described below. The beam widths are measured symmetrically about the mechanical axis of the light unit, unless otherwise noted. Elevated and in-pavement SFLs must provide light intensities as specified in Tables 3-1 and 3-2. Steady burning lights used in the system must meet the intensity requirements presented in Figure 3-2.

Table 3-1 Required Intensities for Elevated SFLs

Intensity Setting	Maximum Effective Intensity (Candelas)	Minimum Effective Intensity (Candelas)
High	20,000	8,000
Medium	2,000	800
Low	450	150

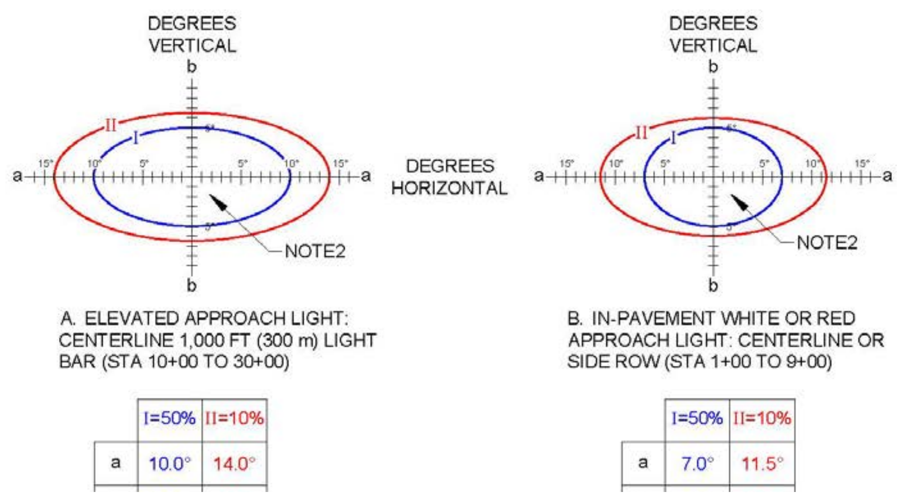
Measure effective intensity over a rectangular pattern not less than 10 degrees by 30 degrees. Corners may be rounded on a 5 degree radius to determine compliance.

Table 3-2 Required Intensities for In-Pavement SFLs

Intensity Setting	Maximum Effective Intensity (Candelas)	Minimum Effective Intensity (Candelas)
High	20,000	5,000
Medium	2,000	500
Low	600	150

Measure effective intensity over a rectangular pattern not less than 10 degrees by 30 degrees. The geometric center of this 10 degree by 30 degree pattern must be 7 degrees ± 1/3 degree above horizontal. Corners may be rounded on a 5 degree radius to determine compliance.

Figure 3-2 Approach Lighting Photometrics



NOTES:
1. ALL CONTOURS ARE ELLIPSES CALCULATED BY EQUATION: $(X/a)^2 = (Y/b)^2 = 1$.
2. THE MINIMUM AVERAGE INTENSITY OF THE MAIN BEAM (INSIDE CONTOUR i) IS 20,000 CD WHITE OR 5,000 CD RED.
3: **\2** ACTUAL AVERAGE INTENSITY MAY CHANGE OVER TIME. ***/2/***
4. CONTOURS I AND II INDICATE THE MINIMUM PERCENT VALUES OF THE MAIN BEAM INTENSITY.
5. FOR IN-PAVEMENT FIXTURES, THE PORTION OF LIGHT CUT OFF BY THE MOUNTING SURFACE MAY BE DISREGARDED.

3-1.4.2 Intensity Control.

Provide brightness control with five intensity steps for steady burning lights and three intensity steps for flashing lights. Match the intensity of the sequenced flashing lights to the intensity of the steady burning lights in accordance with Table 3-3.

Table 3-3 Steady and Flashing Light (SFL) Intensity Percentages

Intensity Step	Steady Light Intensity Percentage	Flashing Light Intensity Percentage	Intensity Step
1	0.16	2.00	1
2	0.8	2.00	1
3	4.00	10.00	2
4	20.00	100.00	3
5	100.00	100.00	3

3-1.4.3 Aiming.

Aim the beams of all approach lights into the approach zone and away from the threshold, with the beam axis parallel to the extended runway centerline. Vertically aim elevated, unidirectional, steady burning lights in accordance with Table 3-4. Aiming angles are based on a three-degree glide slope. If other glide slope angles are used, adjust the vertical aiming for the same degree of difference. Some existing SFLs may have fixed angles for the beam. Refer to paragraph 4-4.8 when threshold lights are used as part of an approach system.

Table 3-4 Elevation Setting Angles for ALSF-1

STEADY-BURNING TYPE FAA-E-982 LIGHTS					
Station	Setting Angle Above Horizontal* (Degrees)		Station	Setting Angle Above Horizontal* (Degrees)	
	Preferred	Permitted		Preferred	Permitted
30+00	8.0	8.0	14+00	7.0	7.0
29+00	7.9	8.0	13+00	6.9	7.0
28+00	7.9	8.0	12+00	6.9	7.0
27+00	7.8	8.0	11+00	6.8	7.0
26+00	7.7	7.5	10+00	6.7	6.5
25+00	7.7	7.5	9+00	6.7	6.5
24+00	7.6	7.5	8+00	6.6	6.5
23+00	7.6	7.5	7+00	6.5	6.5
22+00	7.5	7.5	6+00	6.5	6.5
21+00	7.4	7.5	5+00	6.4	6.5
20+00	7.4	7.5	4+00	6.3	6.5
19+00	7.3	7.5	3+00	6.3	6.5
18+00	7.2	7.0	2+00	6.2	6.0
17+00	7.2	7.0	1+00	6.2	6.0
16+00	7.1	7.0	0+00	6.1	6.0
15+00	7.0	7.0			

*See airfield commander for glide slope. For glide slopes other than 3 degrees, increase or decrease the setting angle by the amount of approach slope variance. For example, given a 2½ degree glide slope, the setting angle would be decreased by ½ degree.
Tolerances are ± 0.2 degrees.
Elevated SFLs are all aimed 6 degrees above horizontal.

3-1.4.4 Obstruction Clearances.

3-1.4.4.1 A light plane (or planes) in which the lights of the system are located is used for determining obstruction clearances of the approach lights.

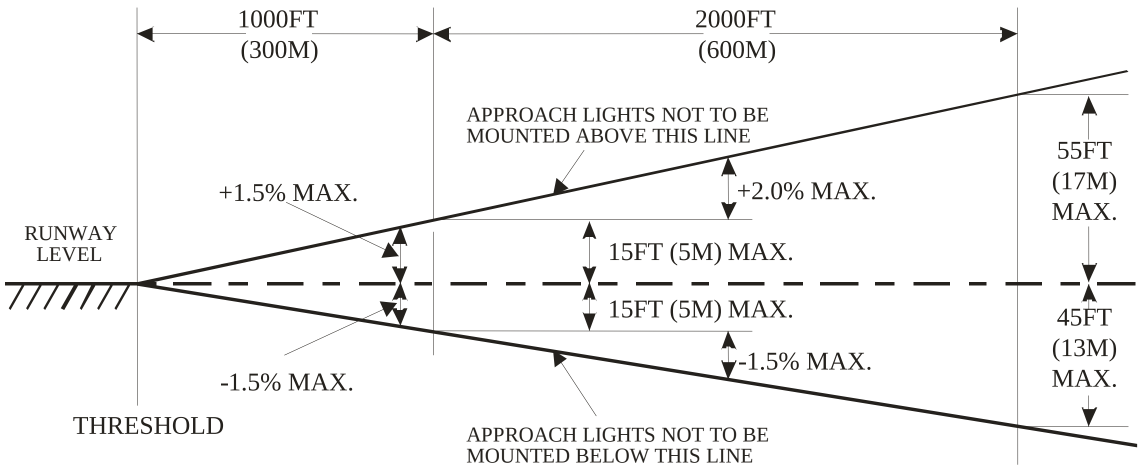
3-1.4.4.2 Side boundaries of the light plane are 200 feet (60 meters) on each side of the extended runway centerline (except SFL).

3-1.4.4.3 End boundaries are at the runway threshold and at 200 feet (60 meters) before the start of the approach light system.

3-1.4.4.4 All lines in the plane perpendicular to the centerline are level.

3-1.4.4.5 The ideal light plane (Figure 3-3) is a single horizontal plane through the runway threshold. If the 1,000 feet (300 meters) of the runway at the threshold end is sloped, the first 300 feet (100 meters) of the paved or stabilized area of the approach zone and the light plane for this area must continue with the same slope.

Figure 3-3 Ideal Light Plane Elevation Limits



NOTE: THE BOUNDARIES OF THE LIGHT PLANES ARE THE RUNWAY THRESHOLD, 200FT (60M) AHEAD OF THE END LIGHT STATION, AND 200FT (60M) EACH SIDE OF CENTERLINE.

3-1.4.4.6 The final 700 feet (210 meters) of the paved or stabilized area may have a slope of not more than 1.5 percent up or down. From the 1,000-foot (300-meter) light bar to the beginning of the approach light system, the preferred light plane is horizontal and includes the 1,000-foot (300-meter) light bar lights.

3-1.4.4.7 If the clearance of obstructions or terrain prohibits using a horizontal light plane, this plane may be sloped. The slope of this plane must not exceed 2 percent up or 1.5 percent down. The preferred light plane in the area beyond the 1,000-foot (300-meter) light bar is a single plane, but changes in the slope of the plane are permitted. All light planes start and end at a light station and contain not less than three light stations.

3-1.4.5 Light Plane Obstructions.

3-1.4.5.1 No objects may penetrate the light plane except for ILS components and components of airfield lighting systems that are fixed by function. These components must not interfere with the pilot's view of the approach lights when on a normal approach and must be obstruction lighted. For clearance purposes, all roads, vehicle parking areas, and railroads are considered vertical solid objects.

3-1.4.5.2 To avoid roads, buildings, railroads, or other obstacles, it may be necessary to move a light station away from its nominal location. Where this is so, see paragraph 3-1.3.

3-1.4.5.3 Obtaining needed clearance above a road is preferred over controlling traffic. Obstructions beyond the approach light system must comply with UFC 3-260-01.

3-1.4.6 Configuration Adjustments.

Siting considerations may require adjustment of the approach light system configuration. Adjustments described in paragraphs 3-1.4.6.1 and 3-1.4.6.2 are permitted without a waiver.

3-1.4.6.1 System Centerline.

The system centerline may be offset laterally not more than 2 feet (0.6 meters) to maintain alignment with runway centerline lights or to avoid installation problems.

3-1.4.6.2 Light Station Adjustments.

To avoid roads, buildings, railroads, or other obstacles, it may be necessary to move a light station longitudinally away from its nominal location. In such instances, change the light bar spacing to distribute the difference uniformly so the spacing between adjacent light stations is kept at 100 feet ± 10 feet (30 meters ± 3 meters) and the system length is maintained.

3-1.4.7 Construction Tolerances.

Tolerances for positioning ALSF-1 and ALSF-2 lights are as follows:

- Light stations must be installed longitudinally within ± 6 inches (150 millimeters) of the designated location.
- The lateral tolerance for installation of a light bar is ± 3 inches (± 75 millimeters).
- The tolerance for distance between individual lights is ± 1 inch (± 25 millimeters).
- Mounting height tolerances are:

Support Height	Mounting Tolerance
0-6 ft (0-1.8 m)	1 in. (25 mm)
6–40 ft (1.8-12 m)	2 in. (50 mm)
40+ ft (12+ m)	3 in. (75 mm)

- Deviation from a line perpendicular to the ALS centerline is ± 1 inch (± 25 millimeters) maximum.
- Vertical angular alignment of a light must be within 1 degree.
- Horizontal angular alignment of a light must be within 5 degrees.

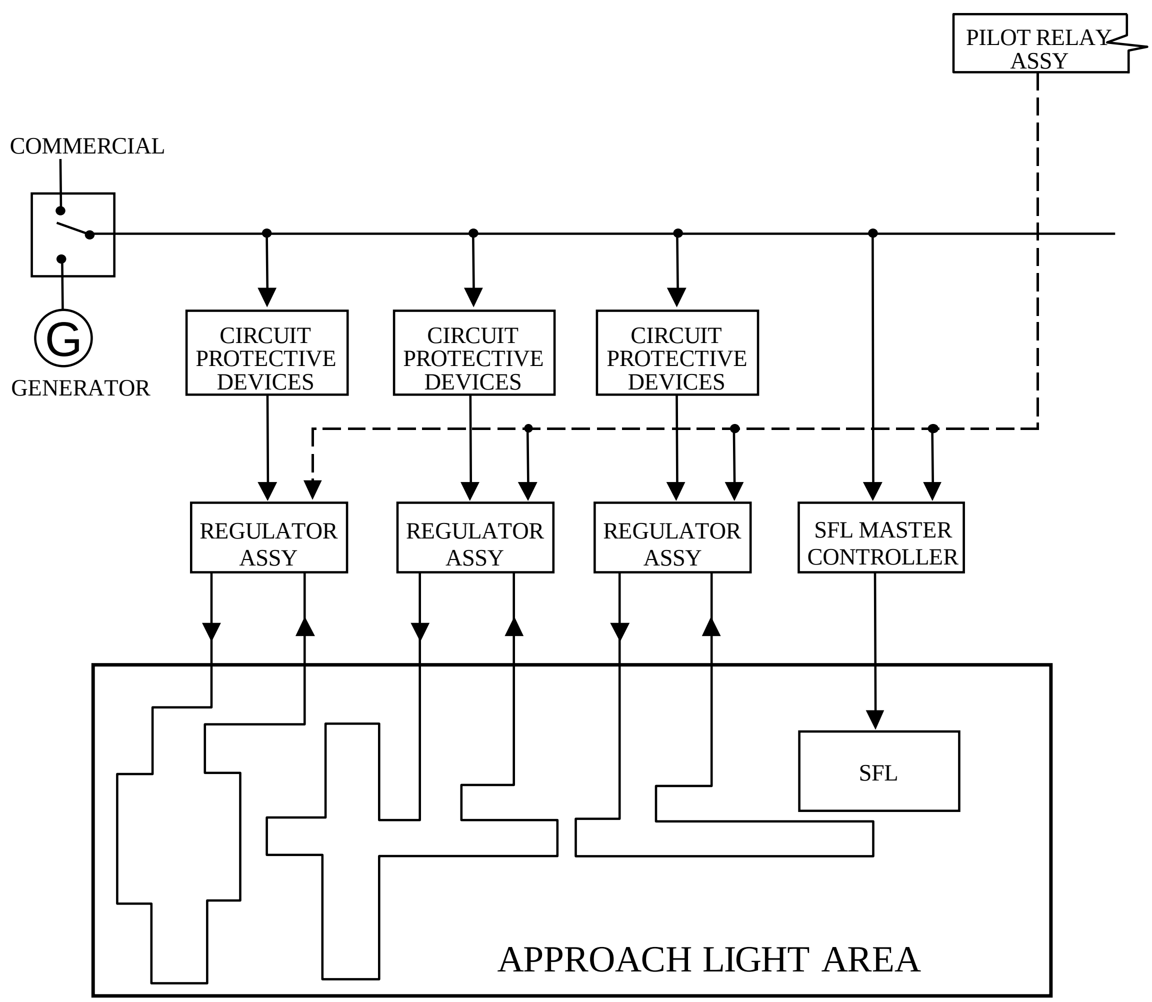
3-1.5 Power Requirements.

Provide a standby power system with automatic transfer in accordance with UFC 3-540-01, *Engine-Driven Generator Systems for Backup Power Applications*. Do not locate the power and control substation or the standby power equipment within the approach light area, shown in Figure 3-4. For Air Force, voltage driven navaids may be supported by larger conductors and other design elements such as step up/down transformers, to assist with voltage drop. Any transformers located near the navaid served must be either installed outside the mandatory zone of frangibility or low profile or both.

Figure 3-4 Block Diagram-Approach Lighting, ALSF-1

FAA L-854 Radio Controller

Assembly (Pilot Controlled Lights)



3-1.6 Control Requirements.

Provide remote on-and-off and five-step intensity control for the steady burning lights. Provide remote on-and-off for SFL with automatic three-step intensity matched with steady burning lights (reference paragraph 3-1.4.2). Provide new systems or systems receiving major upgrades with the capability of being electrically switched from the ALSF-1 configuration to the simplified short approach lighting system with runway alignment indicator lights (SSALR) configuration described in paragraph 3-4. No waiver is required for this configuration capability. Provide a selector switch in the control tower to switch from ALSF-1 to SSALR. SFLs must not be operated without steady burning lights.

3-1.7 Monitoring Requirements.

Monitoring is required if the runway will be used when the RVR is below 2,400 feet (720 meters). Provide monitoring when required, which, at a minimum, gives a positive indication at the control facility that power is provided to the system. Refer to FAA AC 150/5345-10 for additional information about monitoring and AC 150/5345-56, *Specification for L-890 Airport Lighting Control and Monitoring System (ALCMS).*

3-1.8 Equipment.

3-1.8.1 Fixtures.

Use in-pavement fixtures in paved overruns and in displaced thresholds and other locations where fixtures are subject to damage by jet blast. They must be mounted on corrosion-resistant anodized aluminum light bases set in a concrete foundation. No part of the unit must extend more than 1 inch (25 millimeters) above surrounding pavement. All other fixtures must be elevated and capable of being aimed as required by this UFC.

3-1.8.2 Fixture Support.

Support elevated fixtures on frangible, low-impact resistant, or semi-frangible supports depending on the required mounting height:

Mounting Height	Support Type
0-6 ft (0-1.8 meters)	Frangible
6-40 ft (1.8-12 meters)	Low impact resistant
40+ ft (12+ meters)	Semi-frangible

See FAA AC 150/5345-45 for more information about the available classifications (types and styles) of support structures. See also FAA AC 150/5220-23 for additional information about the selection and installation of frangible fittings.

3-1.9 Compliance with International Military Standards.

3-1.9.1 AFIC.

AFIC AIR STD 90/27 has been cancelled.

3-1.9.2 NATO.

This standard meets requirements for a Type II approach lighting system as described in NATO STANAG 3316 (Edition 11). except for the vertical aiming of the lights.

3-2 ALSF-2.

3-2.1 Purpose.

The ALSF-2 is a high intensity approach light system for operations under Category II or Category III conditions.

3-2.2 Configuration.

The ALSF-2 (reference Figure 3-5) is configured as an ALSF-1 system modified as described in paragraphs 3-2.2.1 through 3-2.2.4.

3-2.2.1 Pre-threshold Bar.

The red lights at the pre-threshold bar are removed.

3-2.2.2 Terminating Bar.

The red lights are re-designated to nine stations of side row lights.

3-2.2.3 500 Foot (150 Meter) Light Bar.

A 500 foot (150 meter) light bar is added. It consists of two barrettes of aviation white lights, located symmetrically about and perpendicular to the runway centerline, in line with the centerline barrette at that station. Each barrette consists of four aviation white lights on 5 foot (1.5 meter) centers, centered in the space between the centerline lights and the side row lights.

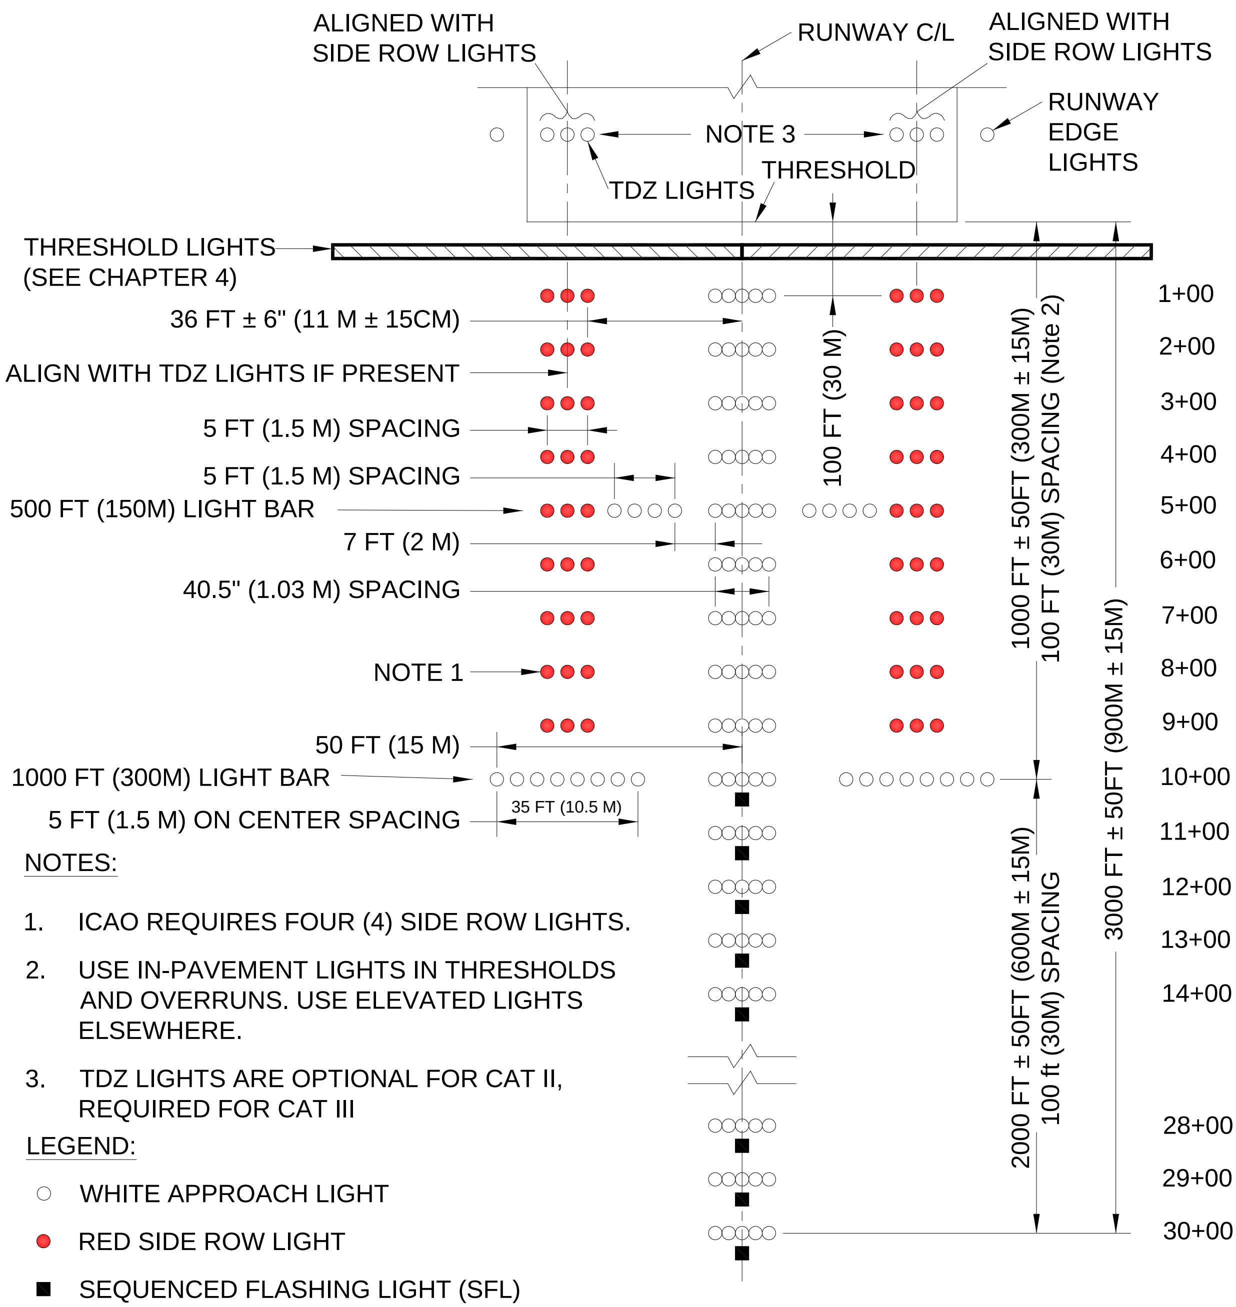
3-2.2.4 Side Row Lights.

Side row lights are added to the inner nine lights' stations at stations 1+00 through 9+00. They consist of barrettes containing three aviation red lights, located symmetrically about and perpendicular to the extended runway centerline at each of the light stations 1+00 through 9+00. The lights in each barrette are on 5 foot (1.5 meter) centers, with the innermost light spaced 36 feet (11 meters) from the extended runway centerline.

3-2.3 Photometrics.

The requirements in paragraphs 3-1.4 and 3-1.4.1 for ALSF-1 apply.

Figure 3-5 ALSF-2 Configuration



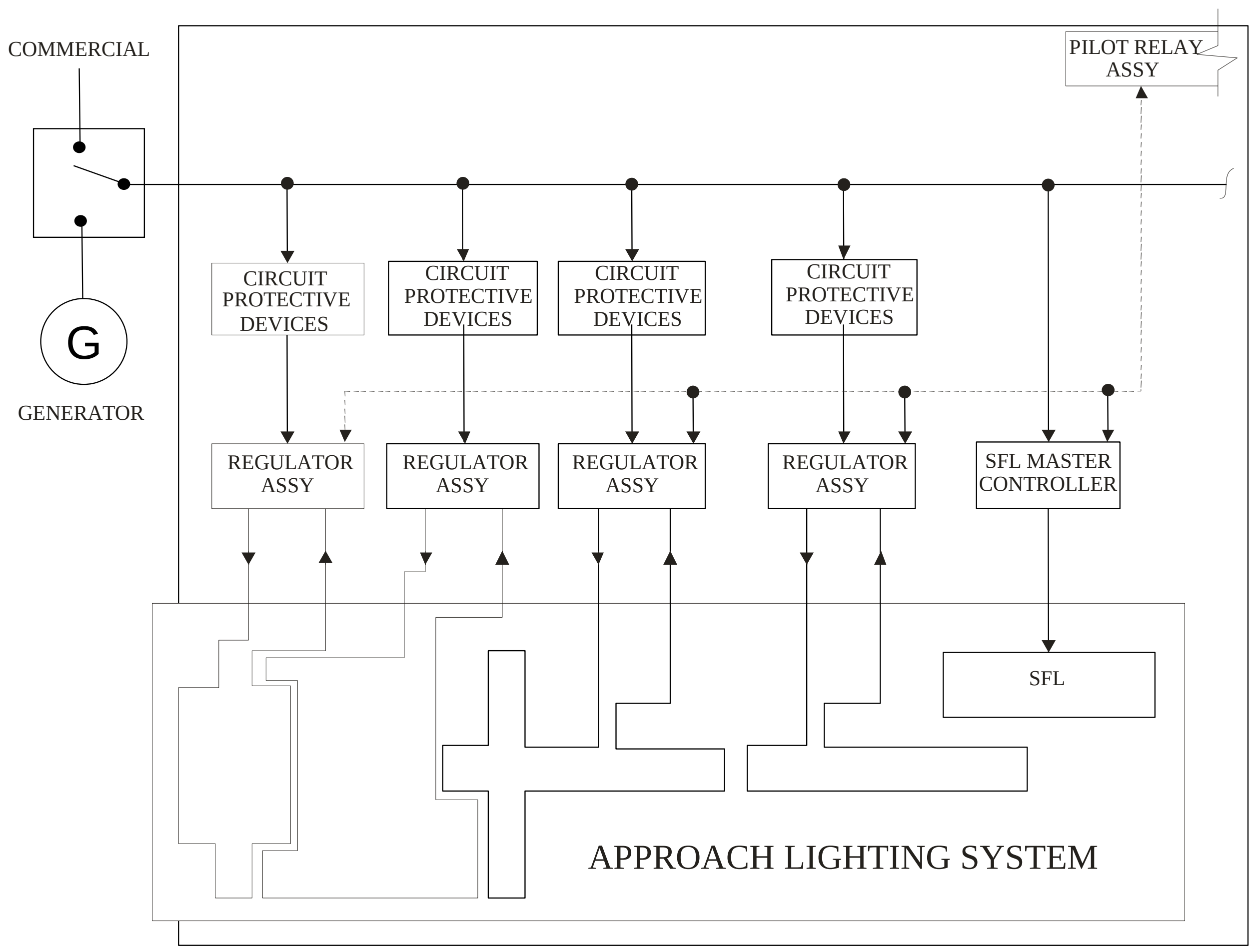
3-2.4 Aiming Criteria.

The aiming criteria as specified in paragraphs 3-1.4.2 through 3-1.4.5 for ALSF-1 apply, except that the red side row lights must be aligned with any existing touchdown zone lights.

3-2.5 Power Requirements.

Provide a standby power system with an automatic transfer switch. Switch should be complete with 30 seconds of power loss. Consider manual transfer, prior to a predicted severe thunderstorm, for a CAT II or CAT III operational runway. Allow the generator to run prior to the storm and until 30 minutes past the end of the storm. Operating parameters should be recorded prior to switching back to commercial power. This operation may be used as the generator test for the month. ***/2/***

Figure 3-6 Block Diagram-Approach Lighting, ALSF-2



3-2.6 Control Requirements.

The control requirements in paragraph 3-1.6 for ALSF-1 systems apply. Provide a selector switch in the control tower to switch from ALSF-2 to SSALR.

3-2.7 Monitoring Requirements.

Provide monitoring that, at a minimum, gives a positive indication at a control facility that power is being provided to the system. Refer to FAA AC 150/5345-10 for additional information about monitoring.

3-2.8 Equipment.

See paragraph 13-9.1; fixtures and supports for ALSF-1 apply.

3-2.9 Compliance with International Military Standards.

3-2.9.1 AFIC.

AFIC AIR STD 90/27 has been cancelled.

3-2.9.2 NATO.

This standard meets the requirements for a Type II system as described in NATO STANAG 3316 (Edition 11). except for the vertical aiming of the lights.

3-3 SHORT APPROACH LIGHTING SYSTEM (SALS).

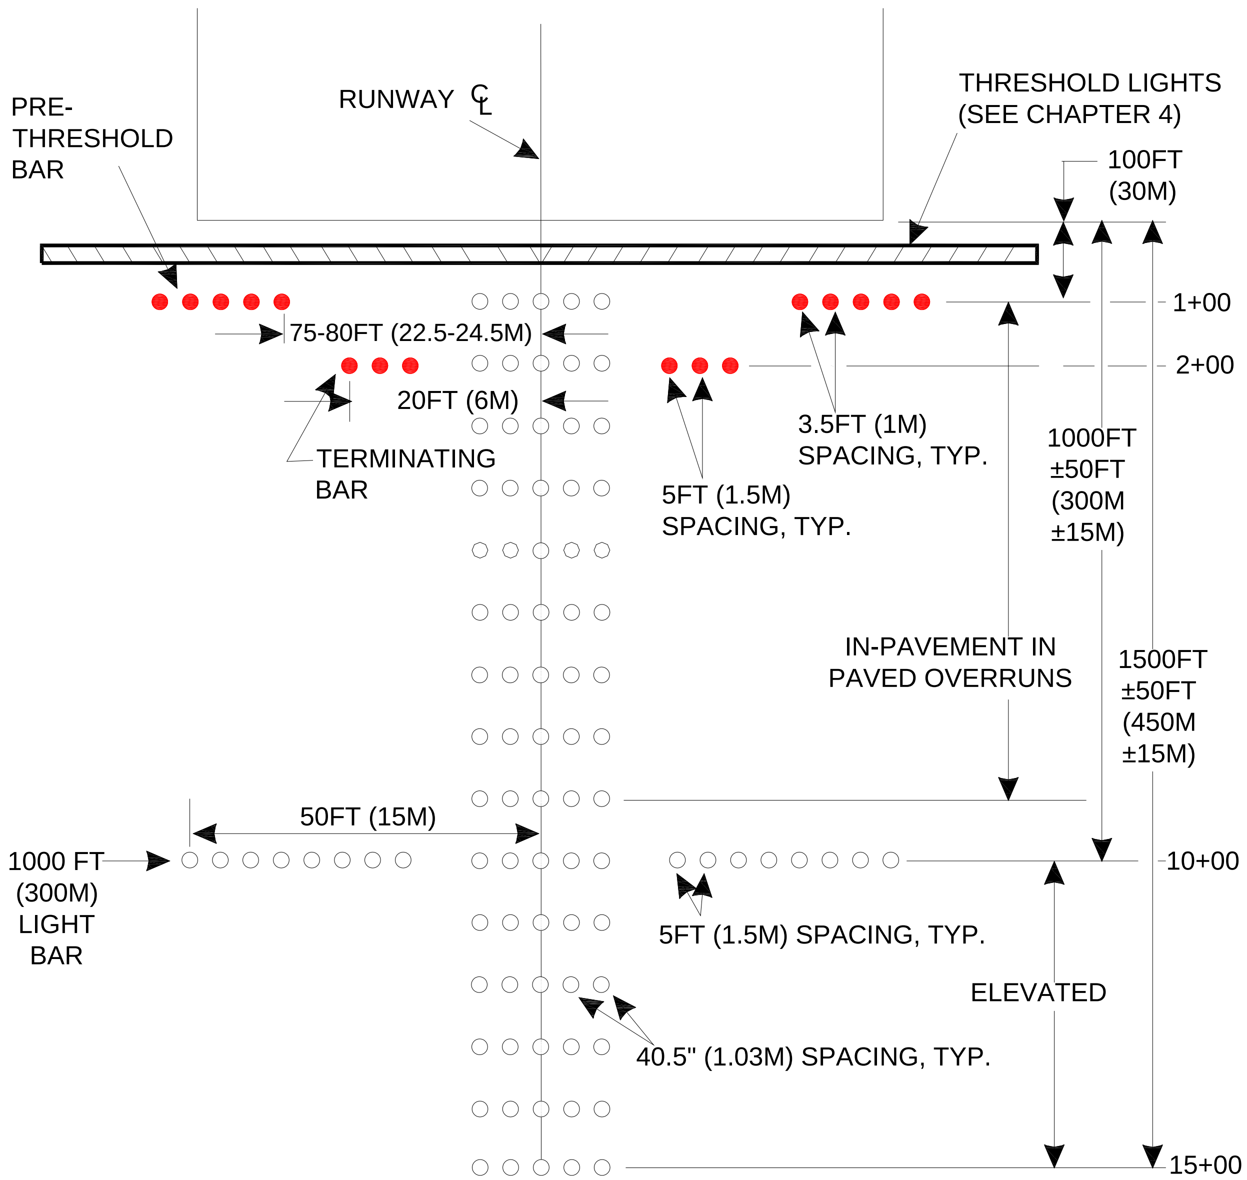
3-3.1 Purpose.

The SALS is a high intensity approach lighting system used at locations where installation space is limited and non-precision approaches are conducted. This configuration requires a waiver. See paragraphs 1-11 or 1-12 for Air Force and Army waiver processes, respectively.

3-3.2 Configuration.

The SALS, as shown in Figure 3-7, is configured as an ALSF-1, except the system is 1,500 feet (450 meters) long and does not have sequenced flashing lights.

Figure 3-7 SALS Configuration



LEGEND:

○ WHITE LIGHTS

● RED LIGHTS

NOTE: Requires a waiver for Air Force use.

3-3.3 Photometrics.

The requirements in paragraph 3-1.4 for ALSF-1 apply.

3-3.4 Power, Control and Monitoring.

The requirements in paragraphs 3-1.5, 3-1.6 and 3-1.7 for the ALSF-1 system apply. See Figure 3-4 for the system block diagram.

3-3.5 Equipment Used.

See paragraph 13-9.1 for applicable components.

3-3.6 Compliance with International Standards.

There are no equivalent systems in the previous AFIC AIR STDs or current NATO STANAGs.

3-4 SIMPLIFIED SHORT APPROACH LIGHTING SYSTEM WITH RUNWAY ALIGNMENT INDICATOR LIGHTS (SSALR).

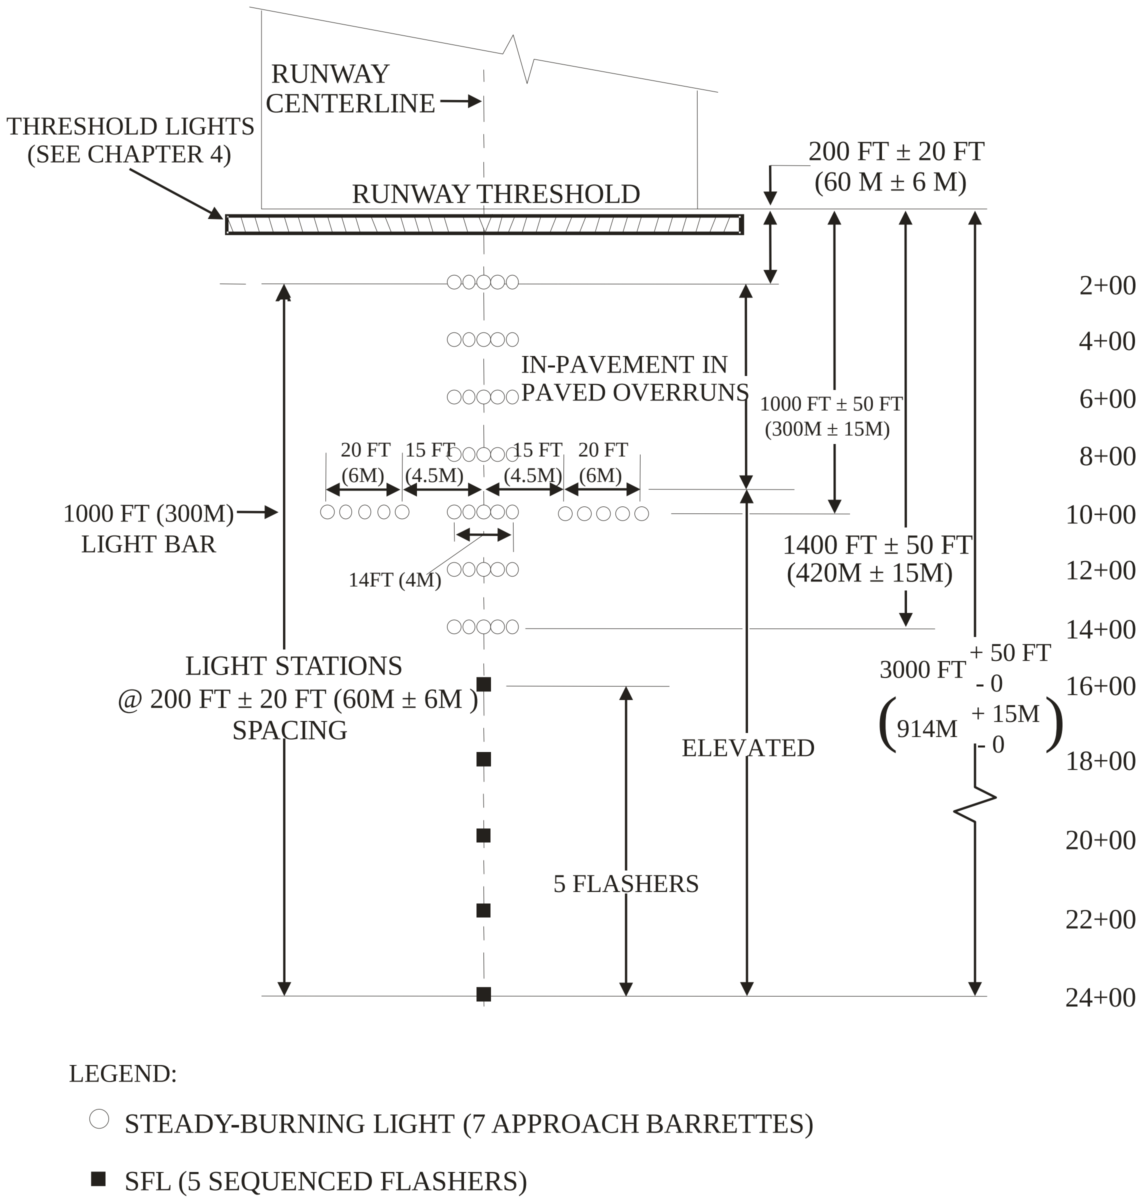
3-4.1 Purpose.

The SSALR is a simplified version of the ALSF-1 or ALSF-2. This system configuration is achieved by electrically switching off elements of an ALSF-1 or ALSF-2 for energy conservation purposes, when weather conditions permit.

3-4.2 Configuration.

The SSALR, shown in Figure 3-8, is configured as an ALSF-1, except that the outer 16 light stations of the steady burning lights are inoperative, as are the odd numbered light stations on the inner 1,400 feet (420 meters), the outer three lights at each end of the 1,000-foot (300 meter) light bar, and the red lights in the terminating and pre-threshold bars. Also, the sequenced flashing lights are inoperative at stations 10+00 through 15+00 and at the odd numbered stations thereafter.

Figure 3-8 SSALR Configuration



3-4.3 Other Requirements.

All other requirements in paragraph 3-1 for ALSF-1 apply.

3-4.4 Compliance with International Standards.

There are no equivalent systems in the previous AFIC AIR STDs or NATO STANAGs.

3-5 MEDIUM INTENSITY APPROACH LIGHT SYSTEM WITH RUNWAY ALIGNMENT INDICATOR LIGHTS (MALSR).

3-5.1 Purpose.

The MALSR is an economy medium intensity approach light system (MALS) with SFLs used as the FAA standard system for Category I runways. This system provides visual approach area identification, centerline alignment, and roll reference for aircraft making approaches for landings during day or night operations. Although the MALSR system is FAA-approved for Category I approaches, a waiver is required for the system to be installed at an Air Force base. See paragraph 1-11.

3-5.2 Associated Systems.

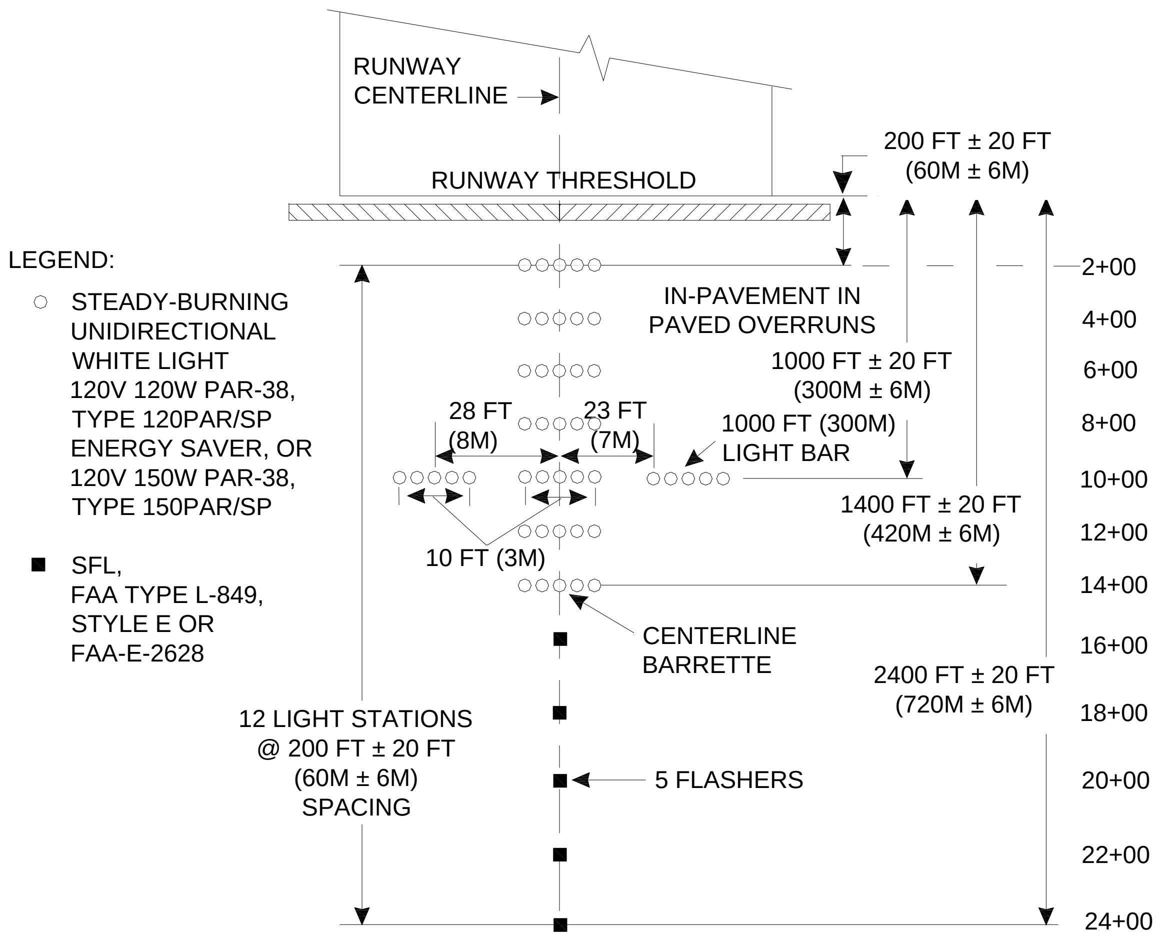
In addition to electronic aids such as ILS, which provide electronic guidance down to a minimum of not less than 200 feet (60 meters) minimum decision height Category I condition, the MALSR includes the following:

- Non-precision or precision approach instrument runway markings.
- Runway threshold lights or displaced threshold lights.
- PAPI.

3-5.3 Configuration.

The MALSR is a system of light bars, barrettes, and SFLs in the approach zone immediately ahead of the runway threshold. The MALSR is configured the same as a SSALR, except the SSALR is a subsystem of an ALSF-1, while the MALSR is a complete system. The MALSR consists of 12 light stations made up of seven approach barrettes and five SFLs located at even numbered-stations. The 1,000-foot (300-meter) bar consists of five lights either side of the approach barrette.

Figure 3-9 MALSR Configuration



3-5.4 Photometrics.

See FAA-E-2980 for information about MALSR photometric requirements. The color of the steady-burning lights must be aviation white for the centerline and 1,000 foot (300 meter) light bar lights. The color of the SFL may be aviation white or bluish-white (xenon flash tube). The intensity steps based on rated intensity must be 100 percent for high setting, 20 percent for medium setting, and 4 percent for low setting for the steady burning centerline and 100 foot (30 meter) light bar lights; and 100 percent for high setting, 10 percent for medium setting, and 2 percent for low setting for the SFL. The SFL must flash in sequence from the outer end toward the runway threshold at a steady rate between 60 and 120 times per minute. The interval between flashes of adjacent lights must nominally be 1/30 seconds.

3-5.5 Aiming Criteria.

See FAA-E-2980 for information about MALSR light aiming settings. Aim the beams of all approach lights into the approach zone and away from the threshold with the axis of the beams parallel in azimuth to the extended runway centerline. Aim the elevated lights vertically in accordance with Table 3-5. The in-pavement lights have fixed elevation angles for the beams, and only require that the light base flange be level.

Table 3-5 Elevation Setting Angles for MALSR

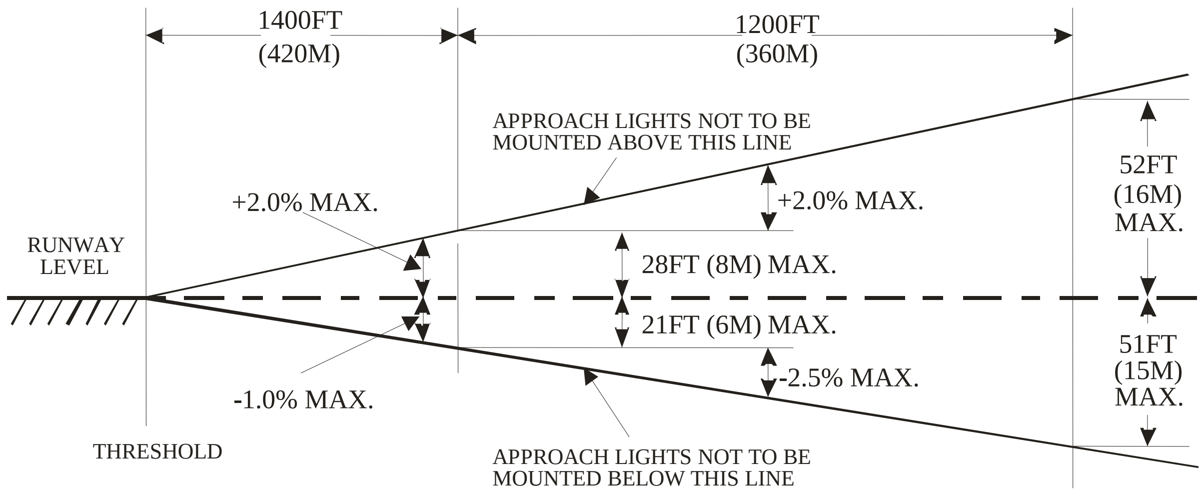
ELEVATED UNIDIRECTIONAL LIGHTS Steady-Burning Lights					
Station	Setting Angle above Horizontal (Degrees)		Station	Setting Angle above Horizontal (Degrees)	
	Preferred	Permitted		Preferred	Permitted
14+00	3.7	3.5	6+00	3.4	3.5
12+00	3.6	3.5	4+00	3.3	3.5
10+00	3.5	3.5	2+00	3.2	3.0
8+00	3.4	3.5			
All elevated SFL are aimed 6 degrees above horizontal.					

3-5.6 Approach Light Planes.

See FAA-E-2980 and FAA JO 6850.2B for information about MALSR approach light planes. Restrictions described in paragraphs 3-5.6.1 and 3-5.6.2 apply for a MALSR installation.

3-5.6.1 The approach light plane (Figure 3-10) is an area 400 feet (120 meters) wide centered on the extended runway centerline which begins at the runway threshold and extends 200 feet (60 meters) beyond the outermost light in which the approach light centers are located. All lines in the planes perpendicular to the runway centerline are horizontal. Ideally, all the lights will be installed in a single horizontal plane at the same elevation as the runway threshold without any penetrations by fixed solid objects. Where deviations are necessary for terrain or objects which cannot be removed, the sections starting from the first approach light station from the threshold must have a slope not exceeding +2.0 percent upward or -1.0 percent downward for the steady-burning barrette lights. For the SFL section, the slope of the light planes must not exceed +2.0 percent or -2.5 percent. Any sloping or horizontal plane must contain not less than three light stations.

Figure 3-10 Light Plane Elevation Limits



NOTE: THE BOUNDARIES OF THE LIGHT PLANES ARE THE RUNWAY THRESHOLD, 200FT (60M) AHEAD OF THE END LIGHT STATION, AND 200FT (60M) EACH SIDE OF CENTERLINE.

3-5.6.2 No object may penetrate the light plane except for ILS components and components of airfield lighting systems which are fixed by their function. These components must not interfere with the pilot’s view of the approach lights when on a normal approach and must be obstruction lighted. For clearance purposes, all roads, vehicle parking areas and railroads are considered as vertical solid objects. The required clearance above railroads is 23 feet (6.9 meters) and above interstate highways is17 feet (5.1 meters). The clearance required above other public roads and parking lots is 15 feet (4.5 meters). The clearance above private and military roads is 10 feet (3 meters). Airfield service roads, where traffic is controlled, are not considered as obstructions. Control of the service road traffic must be accomplished by appropriate signs or directly by the control tower; parking or stopping is prohibited between the signs. The airfield commander must approve the means of control and the wording of signs. It is preferred to get the needed clearance above a road, rather than controlling the traffic so the clearance is not necessary. Obstructions beyond the approach light system must be in accordance with UFC 3-260-01/TM 5-803-7.

3-5.6.2.1 Every effort must be made to remove or relocate objects which penetrate the light plane. For objects which cannot be moved, the height must be the minimum possible and located as far from the runway threshold as possible.

3-5.6.2.2 The major command has waiver authority to adjust the slope of the light plane beyond the allowances in this UFC to avoid interference from obstacles that cannot be removed or lowered.

3-5.7 Tolerance.

The tolerances for positioning steady burning MALSR lights are as follows:

- Lateral tolerance of a light bar is 6 inches (150 mm).
- Distance between individual light centers in a barrette is 2 inches (50 mm).
- Height for light centers up to 6 feet (1.8 meters) is 2 inches (50 mm).
- Height for light centers over 40 feet (12 meters) is 6 inches (150 mm).
- Tolerance for vertical aiming of light units is 1.0 degree.
- Tolerance for horizontal aiming of light unit is 5 degrees.

Longitudinal deviation for light bars or single SFL from a designated station is 20 feet (6 meters), except light stations may be displaced 100 feet (30 meters) to avoid omitting a light station where obstructions cannot be removed or cleared by acceptable clearance planes. Where a light station must be located more than 20 feet (6 meters) from the usual station, position the nearby light stations to provide more uniform spacing between lights.

3-5.8 Power Requirements.

Electrical power for the MALSR approach lights must be supplied as described in paragraphs 3-5.8.1 and 3-5.8.2.

3-5.8.1 For the centerline and 1,000 foot (300 meter) light bar steady-burning lights, a special power unit must furnish power to these lights from a multiple circuit rated at 120 volts or 120/240 volts 3-wire. This power unit must energize the lights at any of the three intensity settings selected.

3-5.8.2 For the SFL, the power to operate these lights is furnished by the master control unit at 120 volts. These lights have individual power supply units which may be combined with or separated from the flasher head. Allow an additional 5 KVA of transformer capacity for the SFL.

Note: Emergency power is not essential for the MALSR system, but if emergency power is available, it requires automatic emergency power transfer – an automatic transfer switch with isolation bypass.

3-5.9 Control Requirements.

The MALSR must be remotely controlled from the airfield lighting control panel in the control tower. Alternate control from the airfield lighting vault is desirable. A separate control must provide for switching ON and OFF and for selecting the intensity setting of the centerline lights, the 1,000 foot (300 meter) light bar lights, and the SFL.

3-5.10 Monitoring Requirements.

Automatic monitoring is not required, but must be operational if installed.

3-5.11 Equipment.

See paragraphs 13-9.5 through 13-9.5.3 for typical MALSR components.

3-5.11.1 Light Supports.

The type of supports used for MALSR lights depends on the height the light or barrette is above the surface, as described in paragraphs 3-5.11.2.1 through 3-5.11.2.3.

3-5.11.1.1 Mount light supports on corrosion resistant aluminum light bases, set in a concrete foundation. In-pavement lights may not project more than 0.75 inch (19 millimeters) above the paved surface.

Use frangible supports for elevated lights 6 feet (1.8 meters) or less.. The support consists of a frangible coupling and sections of 2-inch -(53-millimeter-) diameter conduit elbows set in concrete foundation.

3-5.11.1.2 Use low-impact-resistant supports (LIR) for lights greater than 6 feet (1.8 meters) and 40 feet (12 meters)or less. The individual SFL or five-light barrettes must be installed on low-impact-resistant supports of the correct height. These supports may be non-metallic or of the triangular antenna type; see FAA AC 150/5345-45 or FAA-E-2702.

3-5.11.1.3 For lights more than 40 feet (12 meters) in height, use semi-frangible supports; see descriptions in FAA AC 150/5345-45. The top 20 feet (6 meters) of supports for individual SFL or five-light barrettes must be low-impact resistant and installed on a rigid support of the correct height.

3-5.12 Compliance with International Standards.

There are no equivalents for the MALSR systems in previous AFIC AIR STDs or current NATO STANAGs; however, MALSR systems satisfy requirements for a Category I approach approved by the FAA.

3-6 RUNWAY END IDENTIFIER LIGHTS (REIL).

3-6.1 Purpose.

The REIL system is used to identify the threshold (approach end) of a visual or instrument non-precision runway and provides guidance to pilots during approach for landing. They are effective for identification of a runway surrounded by a preponderance of other lighting, identification of a runway which lacks contrast with surrounding terrain, and identification of a runway during reduced visibility.

The REIL consists of two uni-directional or omni-directional simultaneous discharge-type flashing lights. A light is located at each side of the runway threshold.

The Omni-Directional Approach Light System (ODALS) system uses seven omni-directional discharge-type flashing lights, five of which are installed on an extended runway centerline. The lights flash in sequence and appear as a ball of light traveling toward the runway threshold. This aids the pilot in determining which runway is in use. In addition to the five centerline lights, two lights are installed in a REIL configuration. The two REIL system lights flash simultaneously after the last flash of the centerline lights.

3-6.2 Associated Systems.

Several visual aids must be used when REILs are installed: high intensity runway edge lights, runway threshold lights or displaced threshold lights, and runway markings. The PAPI system may also be an associated visual aid.

3-6.3 Description.

A REIL system consists of two synchronized flashing lights placed symmetrically about the runway centerline in the vicinity of the runway threshold, and are only allowed for use with a PAPI system.

3-6.4 Configuration/Location/Aiming.

See FAA AC 150/5340-30 for REIL installation details.

3-6.5 Photometric Requirements.

3-6.5.1 Unidirectional Fixtures.

See FAA AC 150/5345-51 for equipment-specific details and photometric data.

3-6.5.2 Omnidirectional Fixtures.

Omnidirectional fixtures must flash once per second, producing a white light through 360 degrees horizontally and vertically from +2 degrees to +10 degrees above the horizontal. Light units must be capable of being shielded when required by local conditions. Mount all REIL fixtures on frangible supports. See FAA AC 150/5345-51 for equipment-specific details and photometric data.

3-6.6 Power Requirements.

The system may be powered separately or by use of a power adapter unit connected to the runway light circuit. There is no requirement for standby power.

3-6.7 Control Requirements.

REIL systems may be controlled separately or matched to the associated runway edge light circuit through current sensing relays or other devices. When coupled to the runway edge lights, joint operation with edge lights is as follows:

Edge Light Intensity	REIL Intensity
Off	Off
Step 1 or 2	Low
Step 3	Medium
Step 4 or 5	High

3-6.8 Monitoring Requirements.

There are no monitoring requirements for the REIL system.

3-6.9 Compliance with International Standards.

3-6.9.1 NATO.

The unidirectional flashing lights meet the requirements of NATO STANAG 3316 (Edition 11). except for the displacement distance from the runway edge and the aiming angle.

3-6.9.2 AFIC.

AFIC AIR STD 90/27 has been cancelled.

3-7 PRECISION APPROACH PATH INDICATOR (PAPI) SYSTEM.

3-7.1 Purpose.

The PAPI is an unattended system that provides visual glide path guidance for landing an aircraft. See paragraph 12-3 for PAPI siting.

3-7.1.1 Justification.

For the US Army, a PAPI will be provided where one or more of the following conditions exists:

- The runway is used by turbojet or other aircraft with similar approach guidance requirements.

- The pilot of any type of aircraft may have difficulty judging the approach due to inadequate visual guidance that may be experienced during an approach over water or featureless terrain by day, or in the absence of sufficient extraneous lights in the approach area by night.

- If judging the approach is difficult due to misleading information, such as produced by deceptive surrounding terrain or runway slopes. Objects in the approach area may present a serious hazard if an aircraft descends below the normal approach path, especially if there are no navigation aids to give warning of these objects.

- Physical conditions at either end of the runway present a serious hazard in the event of an aircraft undershooting or overrunning the runway.

- Terrain or prevalent meteorological conditions are such that the aircraft may be subjected to unusual turbulence during approach.

3-7.2 Configuration.

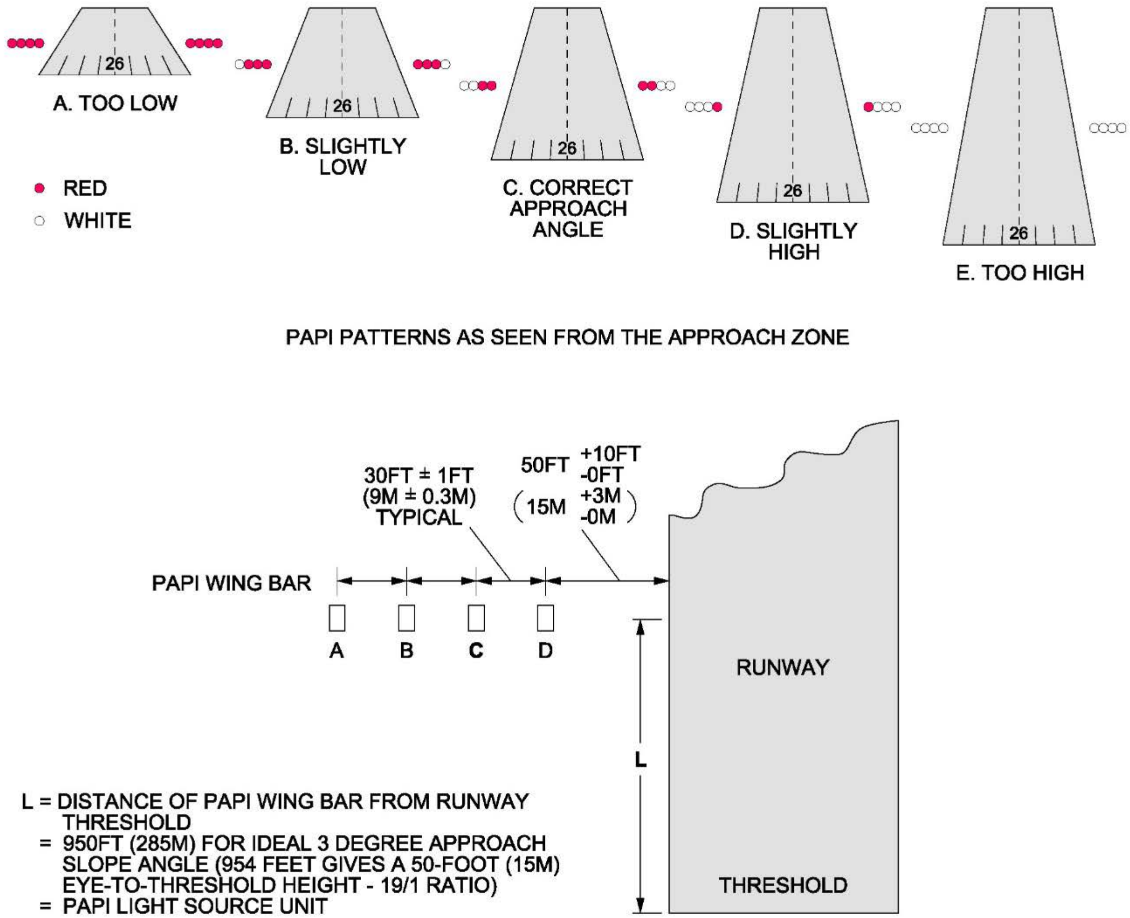
For airfields serving fixed wing aircraft, the PAPI system consists of a light bar with four light units (FAA L-880, per FAA AC 150/5345-28) placed on the left side of the runway in the vicinity of the touchdown point. (See Figure 3-11.)

3-7.2.1 Each light unit must be mounted on frangible fittings. Each unit must contain a minimum of two lamps (three lamps are preferred) and an optical system that produces a horizontally split, two-color (white over red) light beam.

3-7.2.2 Beginning at the out-board-most units, each unit in a light bar is aimed into the approach at a successively higher angle above the horizontal. When on a proper approach path, the pilot sees the two inboard lights in both light bars as red and the two outboard lights as white. As the approaching aircraft settles below the proper path, the pilot sees an increasing number of red lights in each light bar. As the aircraft rises above the path, the pilot sees an increasing number of white lights. (See Figure 3-11.)

3-7.2.3 See FAA AC 150/5340-30 for PAPI installation requirements.

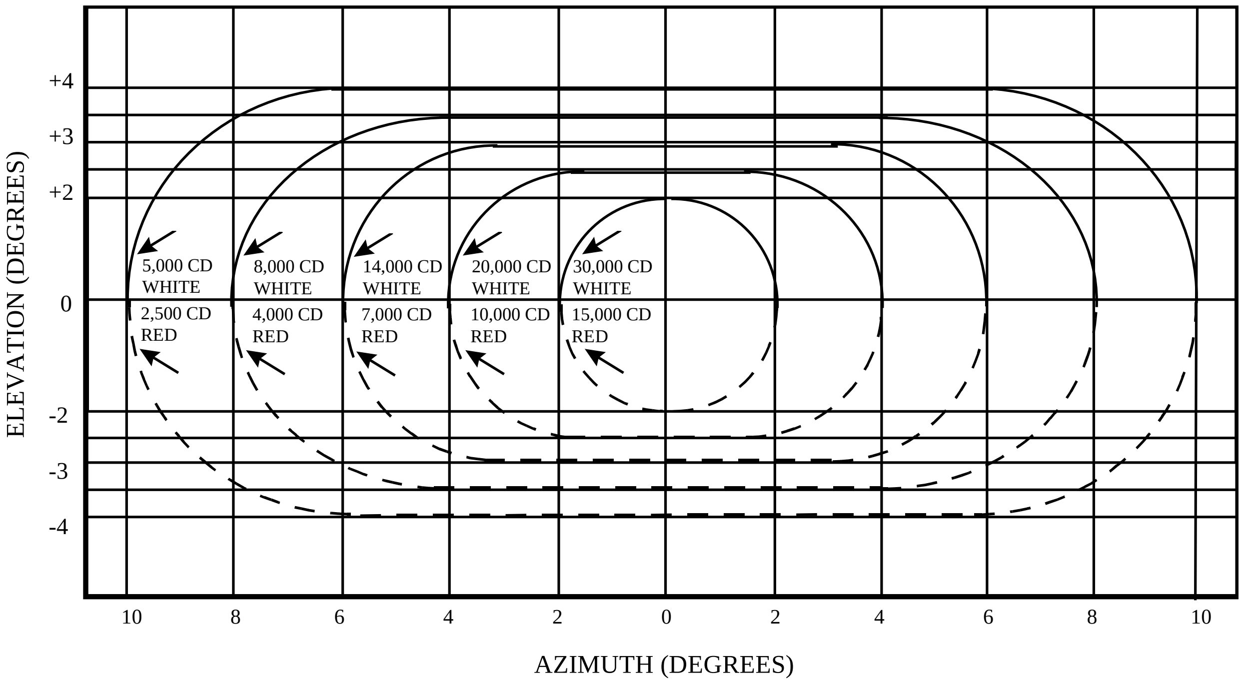
Figure 3-11 PAPI Configuration



3-7.3 Photometric Requirements.

See Figure 3-12 and FAA AC 150/5345-28 for detailed PAPI photometric requirements.

Figure 3-12 PAPI Photometric Requirements



3-7.3.1 Aim PAPI units in accordance with FAA AC 150/5340-30, parallel with the approach within 0.5 degrees. Aim successive light units in a light bar vertically, beginning with the out-board-most unit, and incrementally at increasingly higher angles. The glide path angle is the mean of the highest and lowest angle setting. (See Figure 3-13.) Set the angular difference between successive light units as follows:

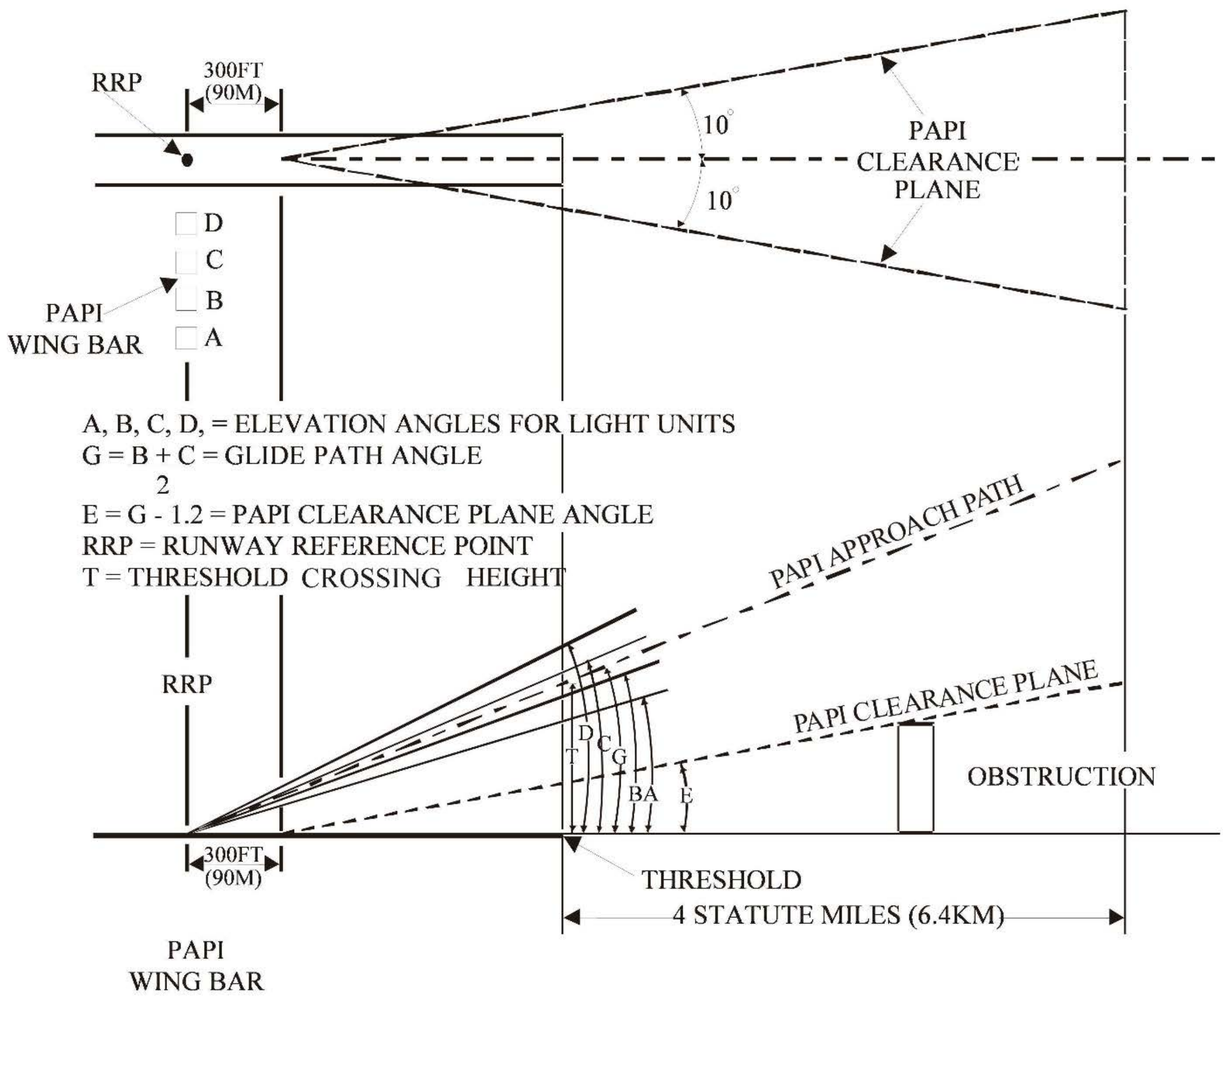
Approach Angle	Angular Difference
2 to 4 degrees	20 minutes
over 4 to 7 degrees	30 minutes
over 7 degrees	1 degree

3-7.3.2 The location and alignment of the PAPI may be varied to meet local conditions if the effective glide path is not less than 2.5 degrees or more than 4.0 degrees above the horizontal. Unless otherwise directed or where conditions dictate otherwise, use 3.0 degrees for the design glide path angle. For design purposes, the visual glide path begins at the PAPI runway reference point (RRP), which is a point on the runway centerline at the PAPI light bar (through lens center of light units) coinciding with the elevation of the lens center of the light units, and which projects into the approach at the glide path angle. (See Figure 3-13.) On a precision instrument runway, aim the PAPI at the same angle as the electronic glide path.

a. For the Army only, this procedure must be modified for runways that serve aircraft in height group 4 (Table 3-6); for these runways, the distance of the PAPI from the threshold must equal the distance to the electronic glide slope source plus an additional 300 feet (90 meters).

b. For the Air Force only, PAPI locating procedures will ensure a minimum safe wheel height above the threshold for all height groups using the runway.

Figure 3-13 PAPI Aiming Criteria



3-7.4 Considerations.

At a minimum, the following factors must be considered when siting a PAPI: existing or planned ILS glide slope; the established glide path (aiming angle, typically 3 degrees);

the threshold crossing height (TCH) for the selected aircraft height group; and the runway gradient (longitudinal slope) from the threshold to the PAPI location.

3-7.4.1 When used on a runway with ILS, the PAPI must be located the same distance from the runway threshold as the virtual source of the ILS glide slope, in accordance with FAA AC 150/5340-30. For Army airfield only, this is modified for aircraft in the height group #4 (Table 3-6), in which case the PAPI is sited at the runway point of intercept (RPI), plus an additional 300 feet (90 meters), +50 feet, -0 feet (+15 meters – 0 meters) from threshold. (See paragraph 12-3 to site PAPI.)

Table 3-6 Visual Threshold Crossing Height Groups

Height Group	Approximate Cockpit-to-Wheel Height	Visual Threshold Crossing Height
#1. General Aviation, Small Commuters, Corporate Turbojets, T-37, T-38, C-21, T-1, C-12, C-20 Fighter Jets	10 ft (3 m) or less	40 ft (+5, -20) (12 m (+1.5, -6))
#2. F-28, CV-340/440/580, B-737, DC-9, DC-8,	15 ft (4.5 m)	45 ft (+5, -20) (13.5 m (+1.5, -6))
#3. B-727/707/720/757, C-130, C-17	20 ft (6 m)	50 ft (+5,-15) (15 m (+1.5, -4.5))
#4. B747/767, L-1011, DC-10, A300, KC-46, C-5	over 25 ft (7.6 m)	75 ft (+5, -15) (22.5 m (+1.5, -4.5))
Refer to FAA AC 150/5340-30 for Group 4, ILS Glide Slope-PAPI coordination and other additional information.		

3-7.4.2 Without an ILS, determine the position and aiming for the PAPI that will yield the required TCH and clearance over obstacles in the approach area, per procedures in FAA AC 150/5340-30.

3-7.4.3 No light unit can be closer than 50 feet (15 meters) to any other runway, taxiway, or apron. Avoid locations where the system could be obscured by other installations. Do not place other lights so close to the PAPI as to cause pilot confusion. Where these conditions cannot readily be satisfied with the system located on the left side of the runway, the system, with waiver approval (paragraph 1-11 or paragraph 1-12), may be sited on the right side of the runway.

3-7.4.4 Establish a PAPI obstruction clearance plane per procedures in FAA AC-150/5340-30.

3-7.4.5 Per Air Force Flight Standards Agency: Any PAPI calibrated to a height group other than #3 will be annotated in the appropriate aircrew flight publications." Rationale: This sets a standard an give clarity to aircrews on what TCH the PAPIs are set to and if it different those aircrew can then adjust their landing profile to touch down at the appropriate point vs touching down too long or too short.

3-7.5 Power Requirements.

Provide the electrical power for the PAPI system from a separate 120/240 volt circuit or a 6.6A series circuit. The 120/240 volt circuit is for parallel operation with control by photocell and selector switch at the unit. Energize the 6.6A series circuit by a constant-current regulator. A 4 kW constant current regulator, five intensity steps, is used to energize the PAPI on a series circuit. When the PAPI is required to be on a series circuit, the lights must be connected to the series circuit by series isolation transformers of suitable capacity for each lamp housing assembly. For emergency power requirements, see Chapter 2. Monitoring of the PAPI is not required, except for daily visual checks of operations and periodic checks for proper aiming. See FAA AC 150/5340-30 for additional information about PAPI power requirements.

3-7.6 Control Requirements.

Control the PAPI on/off manually from the air traffic control tower and from the airfield lighting vault. Brightness control will be manual; however, the PAPI may also be controlled by photocell or pilot radio control at airfields without air traffic controllers, or where the air traffic control tower is not manned full time. At these locations, provide an electrical interlock between the PAPI and the runway edge lights. This interlock may be an electrical contractor or radio interface unit to ensure that, during the hours of darkness the PAPI is on only when the runway edge lights are on. During daylight hours, the PAPI will be capable of operating independently of the runway edge lights. PAPI on/off and intensity controls must be included on the airfield lighting control panel.

3-7.6.1 Provide radio control when required by using an FAA L-854 radio controller (see FAA AC 150/5345-49), which allows the PAPI to be turned on by a pilot on approach or by a ground control station. Note: For radio controller, the low end of environmental temperature range is changed to -40 degrees F (-40 degrees C) for better parts availability (per 150/5245-49D).

3-7.6.2 The photocell must operate per requirements in FAA AC 150/5345-28. The photoelectric control requires a time delay of at least 30 seconds to prevent false switching caused by stray light or temporary shadows. Install the photocell at an unobstructed location and aim it towards the northern horizon.

3-7.7 Foundations.

Foundations for mounting light boxes and a power control unit (PCU) will be made of concrete and designed for the region, to prevent frost heave or other displacement. Extend the foundation at least 12 inches (300 millimeters) below the frost line. To minimize damage from mowers, extend the foundation at least 12 inches (300 millimeters) beyond the light boxes and do not install the foundation more than 1 inch (25 millimeters) above grade. All light boxes will be frangible-mounted to the foundation.

3-7.8 Equipment.

See FAA AC 150/5345-28 for additional information.

3-7.9 Flight Inspections.

Refer to AFJMAN 11-225(I) for flight inspection requirements (commissioning flight) prior to use.

3-7.10 PAPI Siting.

Refer to paragraph 12-3.

3-7.11 Compliance with International Standards.

3-7.11.1 NATO.

These PAPI criteria satisfy requirements of NATO STANAG 3316 (Edition 11) with the exception that the Air Force system is located on only one runway side.

3-7.11.2 AFIC.

AFIC AIR STD 90/27 has been cancelled.

CHAPTER 4 STANDARDS FOR RUNWAY LIGHTING SYSTEMS

4-1 MIXING OF LIGHT SOURCE TECHNOLOGIES.

LED light fixtures must not be interspersed with incandescent light fixtures of the same type.

> *Example:* An airport adds an extension to a runway. On the existing runway, the runway centerline light fixtures are incandescent. The airport decides to install LED runway centerline fixtures on the new section of runway and retains the incandescent fixtures on the existing section. This interspersion of dissimilar technology is not approved for installation. See FAA Engineering Brief 67D for mixed light source uses.

When replacing a defective light fixture, ensure the replacement is of the same light source technology, to maintain a uniform appearance. For Air Force and Army airfields, Paragraph 2-5 lists LED light fixtures that are prohibited and allowed.

4-1.1 Runway Perimeter Lighting.

Runway edge lights, threshold lights, and runway end lights are used to outline the lateral and longitudinal limits of the usable surface of the runway. They are required for VFR night operation and for all categories of instrument operations.

For new construction, medium intensity is standard for Army airfields; high intensity is standard for Air Force airfields.

4-1.2 Runway Surface Lighting.

When Category III instrument operations are necessary, the runway perimeter lighting is augmented with touchdown zone and centerline lighting in-pavement light fixtures. For Category II instrument operations, touchdown zone and centerline lighting are optional.

4-1.3 Runway Visual Aid Requirements.

Table 2-1A and Table 2-1B show the visual landing aids required under various conditions.

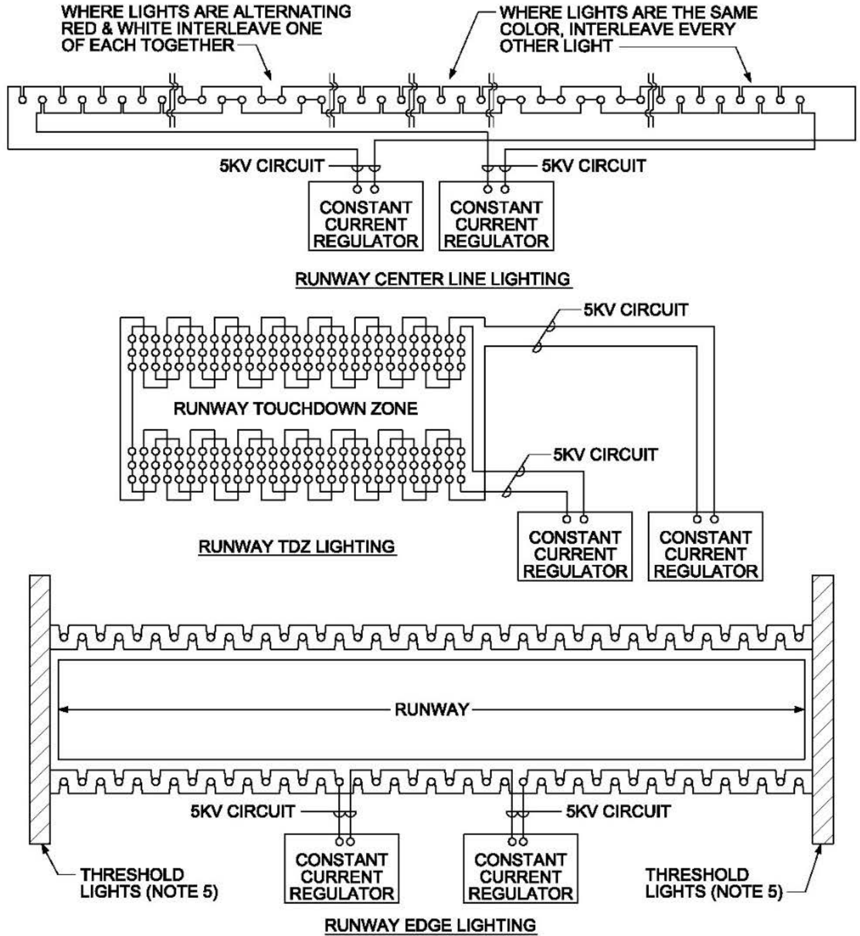
4-1.4 Runway Circuiting Requirements.

Each runway lighting system (edge, center line and touchdown zone) must be served with two separate regulators. Light fixtures may be connected in an interleaved manner as shown in Figure 4-1, but interleaving is not recommended for Air Force.

4-1.5 Photometric Testing.

Photometric testing is recommended to be performed on all newly installed runway edge, centerline, touchdown cone, threshold and end lights on site. The purpose of these tests is to verify the installed fixtures meet or exceed the minimum photometric requirements.

Figure 4-1 Optional Interleaved Runway Lighting Circuits (not recommended for Air Force airfields)



NOTES:

1. EXAMPLES ABOVE ARE ILLUSTRATIONS OF INTERLEAVED RUNWAY LIGHTING CIRCUITS.
2. INBOARD IN-PAVEMENT THRESHOLD LIGHTS SHOULD ALTERNATE BETWEEN APPROACH LIGHT CIRCUIT AND RUNWAY EDGE LIGHT CIRCUIT(S).
3. THE ONLY TYPE OF GUIDANCE SIGNS THAT SHOULD BE CONNECTED TO THE RUNWAY EDGE LIGHT CIRCUIT ARE MANDATORY HOLD SIGNS AND ARRESTING GEAR MARKERS. RUNWAY EXIT SIGNS SHOULD BE CONNECTED TO RESPECTIVE TAXIWAY EDGE LIGHT CIRCUITS. IF RUNWAY DISTANCE REMAINING SIGNS ARE CONNECTED TO RUNWAY EDGE LIGHTS THEY SHOULD ALL BE ON ONE OF THE INTERLEAVED CIRCUITS. IT IS PREFERRED THAT RUNWAY DISTANCE REMAINING SIGNS ARE ON A SEPARATE CIRCUIT.
4. EACH RUNWAY EDGE, TDZ AND CENTER LINE CIRCUIT SHOULD BE INSTALLED IN A DEDICATED 2" (53MM) CONDUIT.
5. FOR INTERLEAVING OF THRESHOLD LIGHTS REFER TO FIGURE 4-5A AND 4-5B (AIR FORCE) OR FIGURES 4-5C AND 4-5D (ARMY).

4-2 HIGH INTENSITY RUNWAY LIGHTS (HIRL) – RUNWAY EDGE LIGHTS.

4-2.1 Purpose.

A runway edge lighting system is a configuration of lights that defines the lateral and longitudinal limits of the usable landing area of the runway. Two straight lines of lights installed parallel to and at equal distances from the runway centerline define the lateral limits. Longitudinal limits of the usable landing area are defined at each end of the area by straight lines of lights called threshold/runway end lights, which are installed perpendicular to the lines of runway edge lights. HIRLs provide visual guidance during takeoff and landing operations at night and under low visibility conditions. High intensity runway edge lights are required for Air Force Night VMC, Non-Precision, and Category I, II, and III instrument operations. High intensity runway edge lights are required for Army for Category I operations.

4-2.2 Configuration.

See FAA AC 150/5340-30 for additional runway edge light configuration and installation information. Locate runway edge lights along the full length of the runway in two parallel rows equidistant from the centerline. Place along the edge of the area declared for use as the runway or outside the edge of the area not more than 10 feet (3 meters). (See Figure 4-2.) It is recommended that lights be placed at a distance of 7 to 8 feet (2.1 to 2.4 meters) unless otherwise justified.

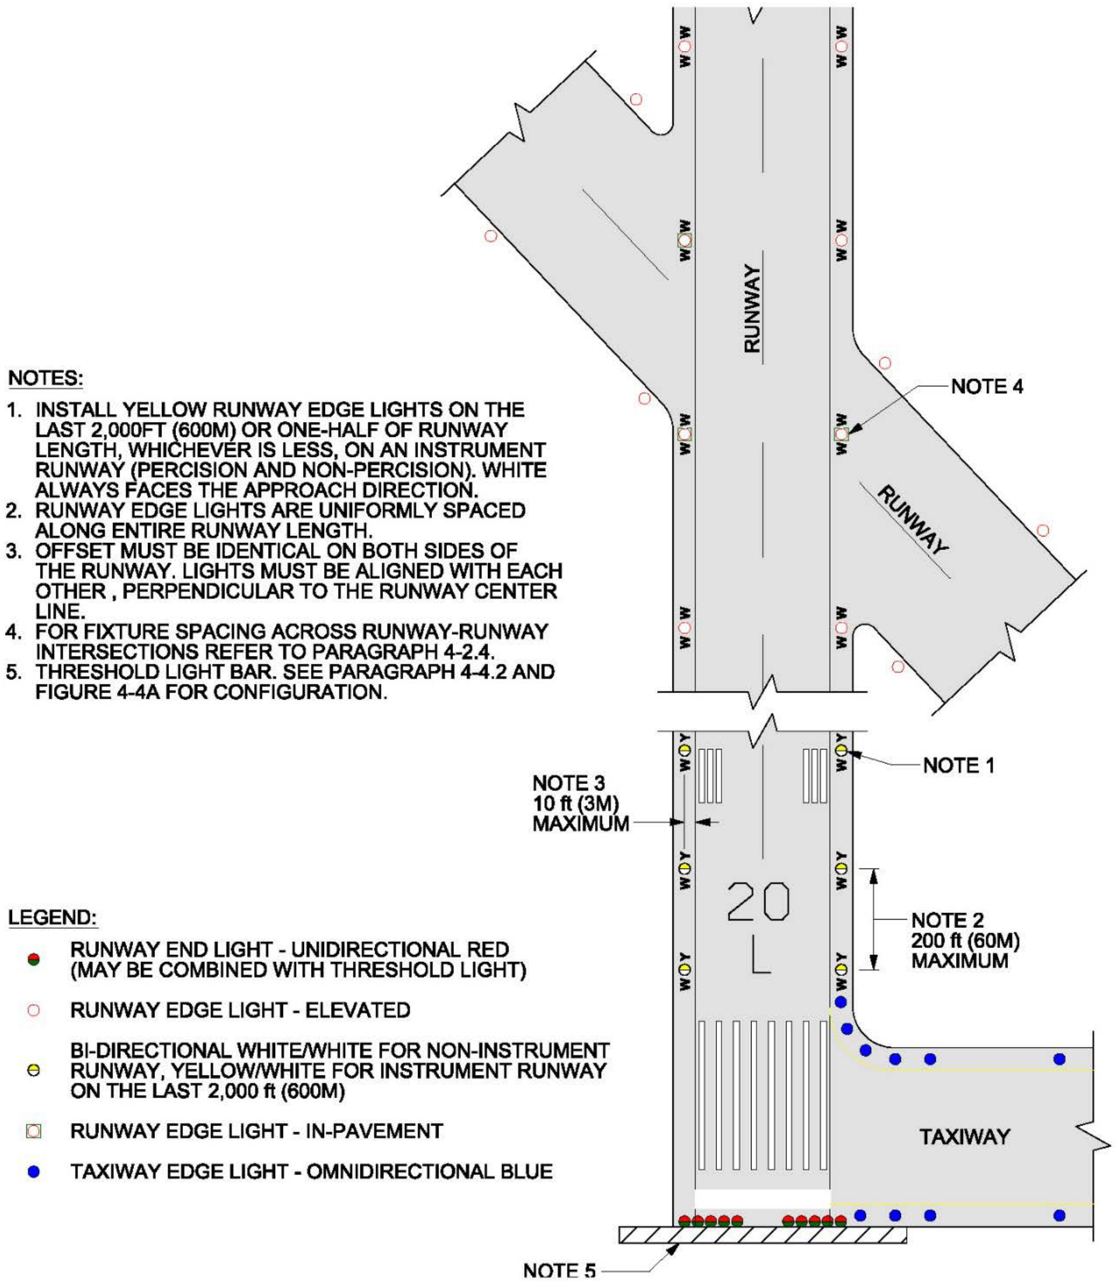
4-2.2.1 Light Spacing (HIRL).

Longitudinally, space the lights along the runway light lines at equal distances not exceeding 200 feet (60 meters). Determine the distance between lights by dividing the length of the runway light line between the threshold light lines into equal spaces approaching but not exceeding 200 feet (60 meters).

4-2.2.2 Elevated Lights.

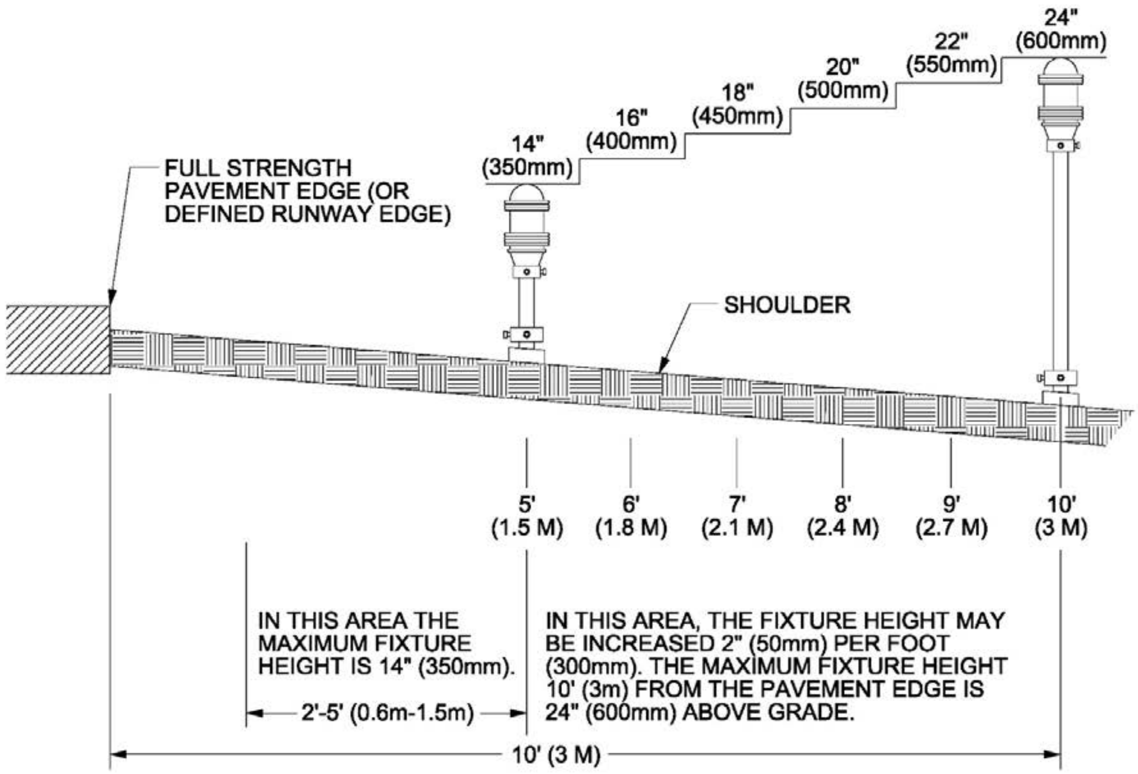
Use elevated lights in all instances except as noted in paragraph 4-2.2.3. If it is known that some fixtures will be changed to in-pavement fixtures in the near future, size the fixtures, light bases, and transformer housings to accept in-pavement fixtures.

Figure 4-2 Runway Edge Light Configuration



Note: This configuration for runway aligned taxiways will not be approved for new construction.

Figure 4-3 Elevated Fixture Height



NOTES:

1. WHEN LIGHTS ARE ELEVATED ABOVE 14" (350mm) (STANDARD), A MINIMUM CLEARANCE OF 6" (150MM) MUST BE MAINTAINED BETWEEN THE FIXTURE AND ANY OVERHANGING PART OF AN AIRCRAFT.
2. FOR OTHER HEIGHT VARIANCES, SEE FAA AC150-5340-30.

3\4

4-2.2.3 In-Pavement Fixtures.

Use in-pavement units in areas where elevated lights are subject to damage from jet blast, operation of an arresting system, or interference with aircraft operation. See paragraph 3-1. All bolts, studs, nuts, lock washers, and other similar fasteners used for the light fixture assemblies must be fabricated from 316L (equivalent to EN 1.4404), 18-8, 410, or 416 stainless steel. If 18-8, 410, or 416 stainless steel is utilized it shall be passivated and be free from any discoloration. All screw threads must be Class 2 or Class 3 per ANSI B1.1. This paragraph does not apply to current carrying components. Note: Paragraph 3.10.1.1 does not apply to fasteners that are used to attach the light fixture to the light base; see AC 150/5345-42, Specification for Airport Light Bases, Transformer Housings, Junction Boxes, and Accessories, for additional information. In addition, refer to the light fixture manufacturer's installation instructions about recommended bolt torque, locking washers, and the use of anti-seize and thread-locking compounds. **/4/**

4-2.3 Photometric Requirements.

See FAA AC 150/5345-46 for detailed photometric requirements of runway edge light fixtures. See FAA AC 150/5340-26 for additional information about the toe-in of runway edge light fixtures. Follow the manufacturer's instructions for proper fixture toe-in alignment. Use bidirectional high intensity runway edge lights. The lights must be white, except that the last 2,000 feet (600 meters) on an instrument runway must be yellow (caution zone indication to the pilot). The runway edge lights may be capable of providing small amounts of omnidirectional light to provide circling guidance to the runway. Ensure the omnidirectional component is capable of being shielded during times of emergency. The main beams must be toed-in 3.5 degrees and elevated 4 degrees above the horizontal. Edge lights are operated at five intensity steps:

Intensity Step	Minimum Light Intensity Percentage
1 (2.8 A)	0.15 %
2 (3.4 A)	1.0 %
3 (4.1 A)	3.9 %
4 (5.2 A)	16.9 %
5 (6.6 A)	100.00 %

4-2.4 Runway/Runway Intersections.

For runways that are approved for CAT III operations, maintain uniform spacing across intersections by installing in-pavement edge lights on the intersecting runway.

For other operations on runways with HIRL, the installation of an in-pavement edge light is based on the following:

- The availability of other visual cues at the intersection, such as guidance signs or runway centerline lighting.
- The geometric complexity of the intersection, such as crossing runways. When the gap exceeds 400 feet (120 meters install an in-pavement light fixture to maintain uniform spacing.
- Whether the addition or not the addition of an in-pavement edge light could cause confusion with ground operations.

4-2.4.1 In-Pavement Fixtures in Sweep Area of Arresting Gear Marker Tape

The runway edge lights in the immediate area of the arresting gear markers are vulnerable to being swept by the tape when an aircraft engages the arresting gear. The lights in the sweep area must be in-pavement fixtures. The length of the sweep area (B) along the row of edge lights on each side of the runway is calculated by: $B = A \times C / ((R / 2) + A – D)$, where:

A = the displacement of the arresting gear sheave from the runway edge.

C = the cable runout, normally 1,333 feet (400 meters).

R = the runway width.

D = the distance from the runway centerline to the point of engagement on the pendant wire. The maximum expected distance is 40 feet (12 meters).

The sweep area is in the direction of engagement of the arresting gear and can be in either runway direction, if the arresting gear can be engaged in either direction.

4-2.5 Equipment.

Elevated fixtures must be mounted on a frangible fitting at a maximum height of 14 inches (350 millimeters) at 2 to 5 feet (0.6 to 1.5 meters) from the defined pavement edge. At locations with frequent snow accumulations of 12 inches (300 millimeters) or more, the mounting height may be increased to not more than 24 inches (600 millimeters) in height at 10 feet (3 meters) from the defined pavement edge. No part of in-pavement fixtures must extend more than 1 inch (25 millimeters) above the surrounding surface. See Figure 4-3 for heights.

4-2.6 Power Requirements.

Provide a main and a standby power system with automatic transfer. Where used in support of Category II or III instrument operations, the transfer must occur within 1 second of a failure of the system. For other operations, transfer must occur within 15 seconds of the power failure.

4-2.7 Control Requirements.

When used in support of instrument operations below 2,400 feet (720 meters) RVR, provide system monitoring which, at a minimum, gives positive indication at the control facility that power is being delivered to the system. For interleaved edge lights, do not place adjacent edge lights on the same side of the runway on the same circuit. Lights on direct opposite sides of the runway must be on the same circuit.

4-2.8 Compliance with International Military Standards.

4-2.8.1 NATO.

These standards meet NATO STANAG 3316 (Edition 11) – Airfield Lighting.

4-2.8.2 AFIC.

AFIC AIR STD 90/27 is cancelled.

4-3 MEDIUM INTENSITY RUNWAY LIGHTS (MIRL).

4-3.1 Purpose.

MIRL edge lights are used on VFR runways, or on non-precision Instrument Flight Rule runways, for either circling or straight-in approaches. MIRL edge lights are not installed on runways intended for precision approaches.

4-3.2 Configuration.

The configuration must be per paragraph 4-2.2 for high intensity runway edge lighting.

4-3.3 Photometric Requirements.

See FAA AC 150/5345-46 for detailed photometric requirements of runway edge light fixtures. See FAA AC 150/5340-26 for additional information about the toe-in of runway edge light fixtures. Follow the manufacturer's instructions for proper fixture toe-in alignment.

Optimum aiming of lights depends on the design and output of the fixtures used in the system. Light fixtures may be designed to cover several applications and may have fixed patterns and aiming angles that differ from this document. Light aiming and patterns other than those given in this document may be used if the resultant light pattern produces equivalent light intensities in the required areas. Medium intensity runway edge lights must be omnidirectional and white. Where in-pavement lights are required, they may be bidirectional. The edge lights must be operated at three intensities as follows:

Intensity Step	Percent of Full Intensity
1	10%
2	30%
3	100%

4-3.4 Runway/Runway Intersections

For runways using MIRL, where the configuration across the intersection does not allow the matching of edge lights on the opposite side of the runway to be maintained, the distance must not exceed 400 feet (120 meters). If the distance between the runway edge lights is greater than 400 feet (120 meters), install an FAA Type L-852D taxiway centerline light fixture. Modify the light fixture to produce white light (remove the filters) and maintain the designed spacing.

4-3.5 Equipment.

Elevated fixtures must be mounted on a frangible fitting at a maximum height of 14 inches (350 millimeters) at 2 to 5 feet (0.6 to 1.5 meters) from the defined pavement edge. At locations with frequent snow accumulations of 12 inches (300 millimeters) or more, the mounting height may be increased to not more than 24 inches (600 millimeters) in height at 10 feet (3 meters) from the defined pavement edge. See FAA AC 150/5340-30 and Figure 4-3 for additional information about light fixture height versus distance from the defined pavement edge.

4-3.6 Power Requirements.

Standby power is not required for medium intensity runway lights, except where they are installed on the primary runway. When installed on the primary runway, provide a main and a standby power system with automatic transfer within 15 seconds of failure of the system in use.

4-3.7 Control Requirements.

Provide remote on, off, and brightness control.

4-3.8 Compliance with International Military Standards.

4-3.8.1 AFIC.

Previous AFIC AIR STD 90/27 cancelled.

4-3.8.2 NATO.

This system does not meet NATO STANAG 3316 (Edition 11) – Airfield Lighting for lighting of subsidiary runways.

4-4 THRESHOLD LIGHTS.

4-4.1 Purpose.

Threshold lights provide positive identification of the beginning of the operational runway surface for approaching aircraft at night or under instrument weather conditions.

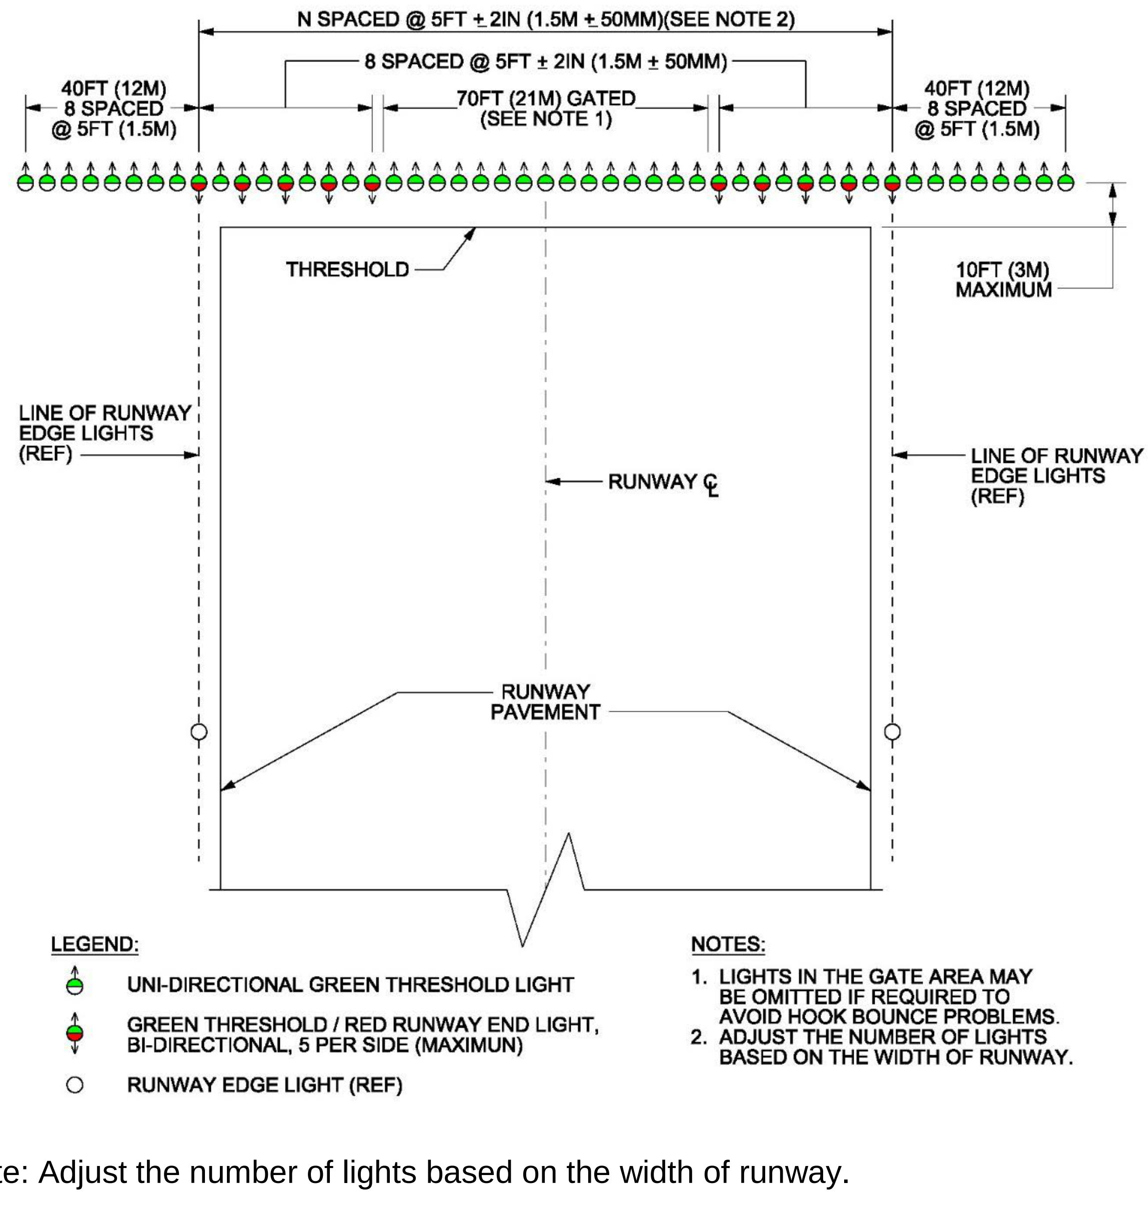
4-4.2 High Intensity Threshold Light Configuration.

Install threshold lights in a line perpendicular to the extended runway centerline outside the usable landing area a distance of not more than 10 feet (3 meters). The line of lights is symmetrical about the runway centerline and extends 40 feet (12 meters) outboard of the lines of runway edge lights. (See Figure 4-4A for the Air Force configuration, and Figure 4-4B for the Army configuration). Determine the position of the lights as follows:

4-4.2.1 Place a light where the line of threshold lights intersects the line of runway edge lights. Then place lights at 5 feet (1.5 meters) for a distance of 40 feet (12 meters) outboard of the runway edge light lines.

4-4.2.2 Place lights at uniform intervals between the lines of runway edge lights and along the line of the threshold lights. Space as near to 5 feet (1.5 meters) as possible and do not exceed 5 feet 2 inches (1.55 meters). The line of threshold lights may be gated to lessen the problem of tail hook bounce by eliminating those lights in the center 70-foot (21-meter) portion of the threshold. For new installations, it is recommended that where fixtures are not installed, bases be installed with blank covers that are flush with the runway surface and are suitable for future in-pavement fixtures. This is intended to accommodate future mission requirements where tail hook equipped aircraft are no longer using the runway.

Figure 4-4A1 Threshold Light Configuration for Air Force



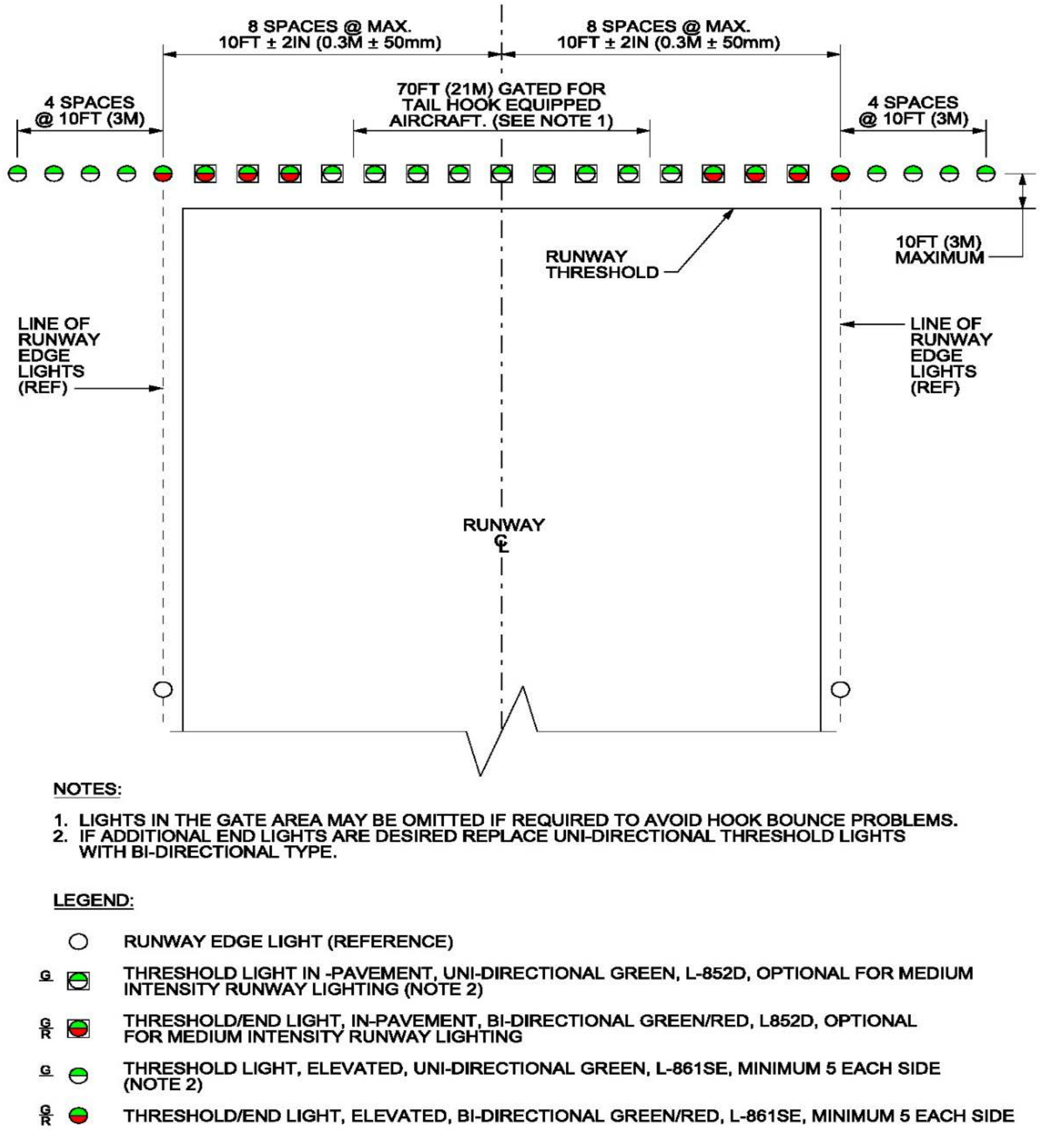
Note: Adjust the number of lights based on the width of runway.

Figure 4-4A2 Modified Threshold Light Configuration for Introduction of FLIR Component Used by Aircraft with Head Up Displays

\4 TBD – Next Full Revision ***/4/***

Note: Aircraft with Head Up Display systems require a wavelength consistent with Forward Looking InfraRed systems which are based on a Heat Signature. When the Threshold consists of LED fixtures, a modified LZ configuration of five fixtures (four threshold and one approach) should be used so that the runway end is clearly indicated on the HOD of the aircraft. These five incandescent fixtures should not be on the same circuit as the LEDs, but should be controlled from the same regulator so that light output is consistent between the two circuits.

Figure 4-4B Threshold Light Configuration for Army



4-4.3 Medium Intensity Threshold Lights.

Install threshold lights in a line perpendicular to the extended runway centerline outside the usable landing area a distance of not more than 10 feet (3 meters). The line of lights is symmetrical about the runway centerline and extends 40 feet (12 meters) outboard of the lines of runway edge lights. (See Figure 4-5C and Figure 4-5D.) Determine the position of the lights as follows:

- Place a light where the line of threshold lights intersects the line of runway edge lights. Next, place lights at 10 feet (3 meters) for a distance of 40 feet (12 meters) outboard of the runway edge light lines.

- If inboard lights are used, place lights at uniform intervals between the lines of runway edge lights and along the line of the threshold lights. The interval must be a maximum of 10 feet (3 meters).

4-4.4 Photometric Requirements.

See Figure 4-6 for detailed photometric information for high intensity runway threshold lights. See FAA AC 150/5345-46 for detailed photometric information for medium intensity runway threshold lights.

4-4.4.1 High Intensity Threshold Lights.

The runway threshold lights must be unidirectional green aimed into the runway approach with intensities per Figure 4-6 when used with high intensity runway edge lights or approach lights. The light beams are aimed parallel with the runway centerline and angled upward at an angle of 4.5 degrees. High intensity threshold lights must operate at five intensity levels, together with the associated runway edge lights. High intensity runway edge lights will be used with high intensity threshold lights.

4-4.4.2 Medium Intensity Threshold Lights.

The lights must be bidirectional red/green, with green aimed towards the approach. Outboard threshold elevated lights must be FAA L-861SE, and inboard threshold in-pavement lights must be FAA L-852D. See FAA AC 150/5345-46 for additional requirements.

Figure 4-5A Threshold Light Circuiting for Air Force (Interleaved)

Note: Interleaving is allowed, but not recommended.

Figure 4-5B Air Force (Non-interleaved)

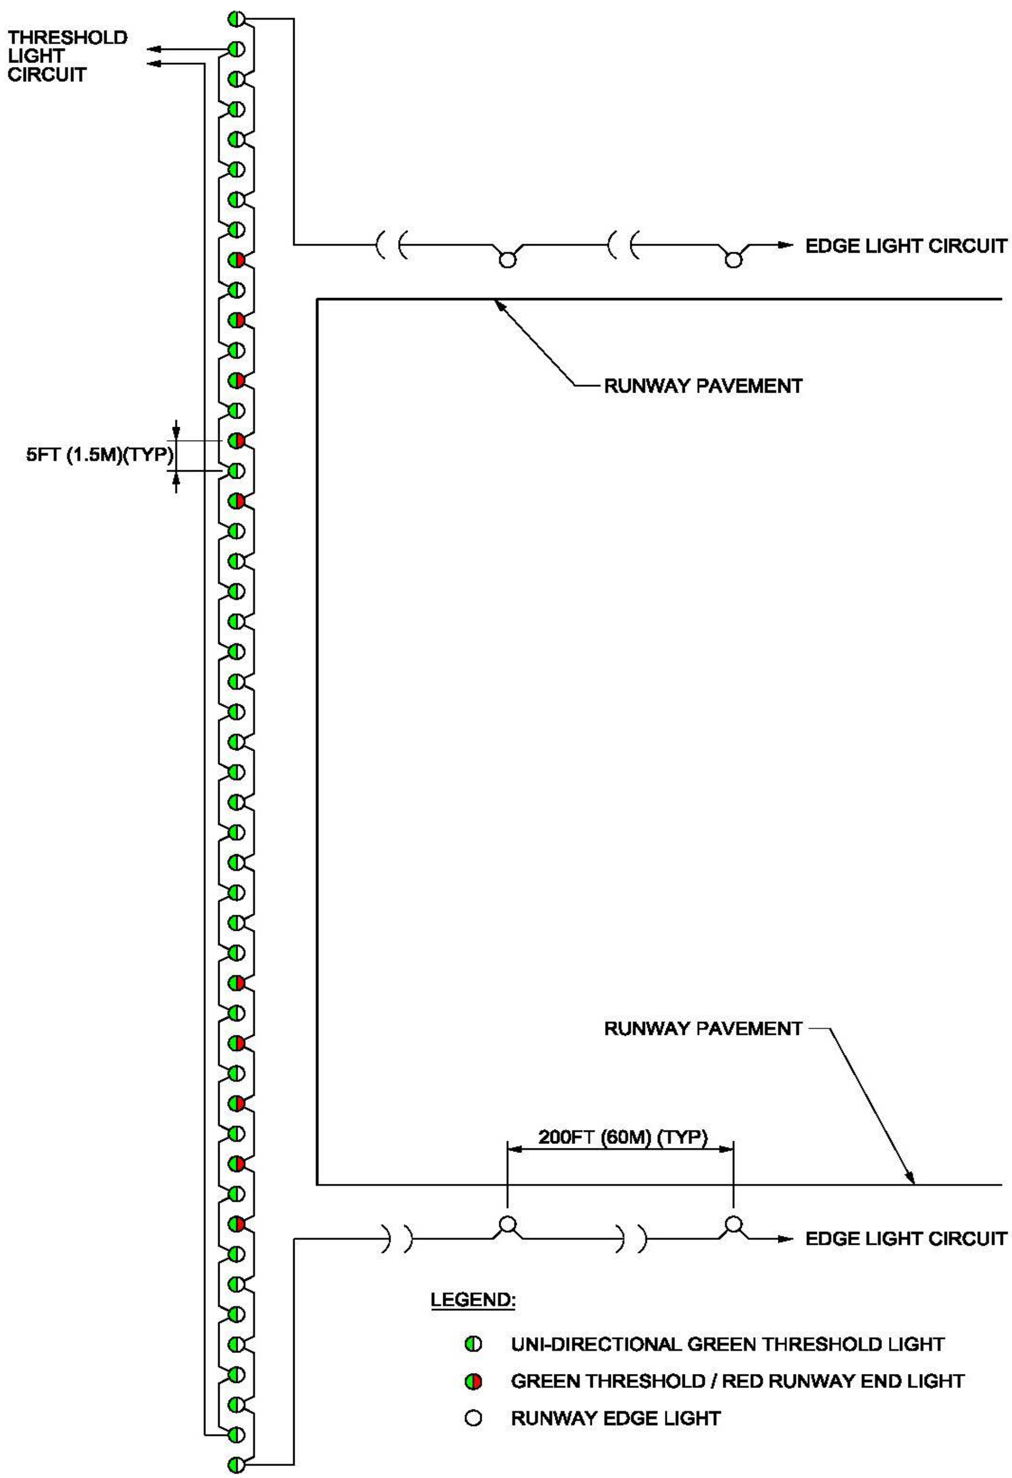


Figure 4-5C Threshold Light Circuiting for Army (Interleaved)

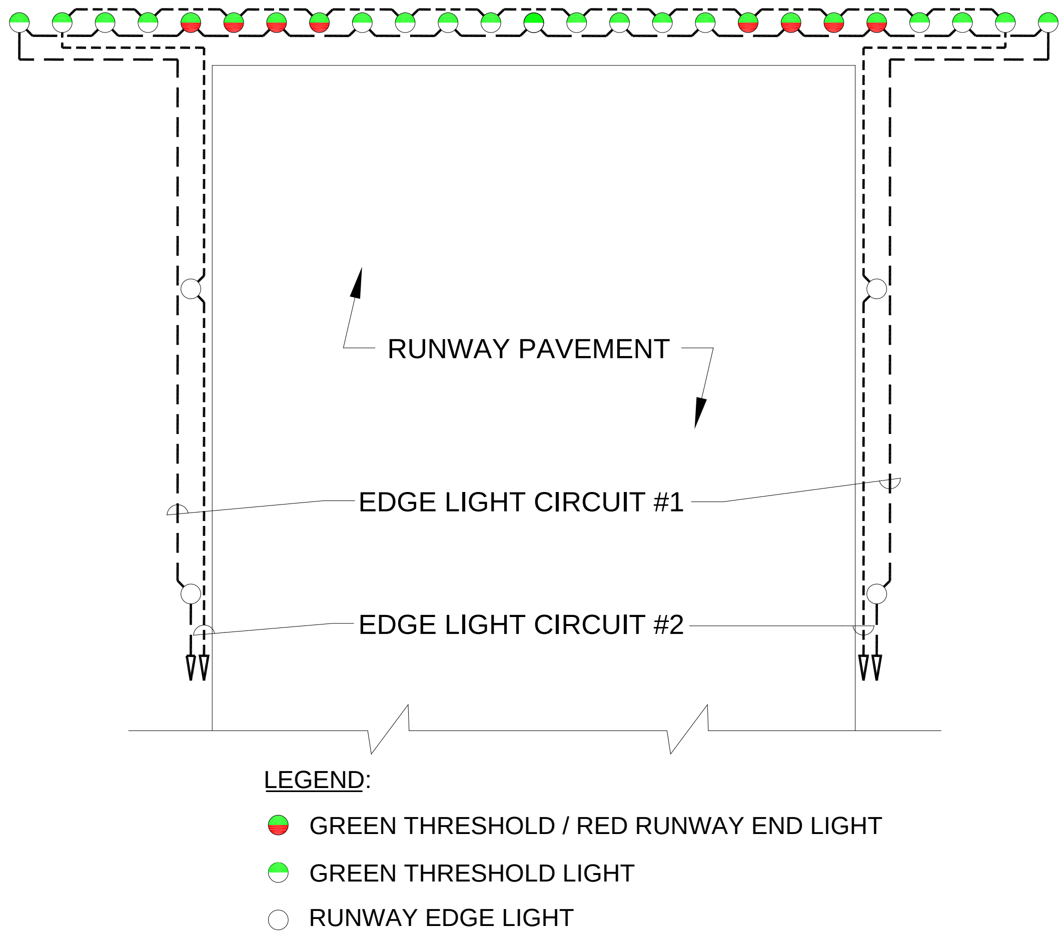

Figure 4-5D Army (Non-interleaved)

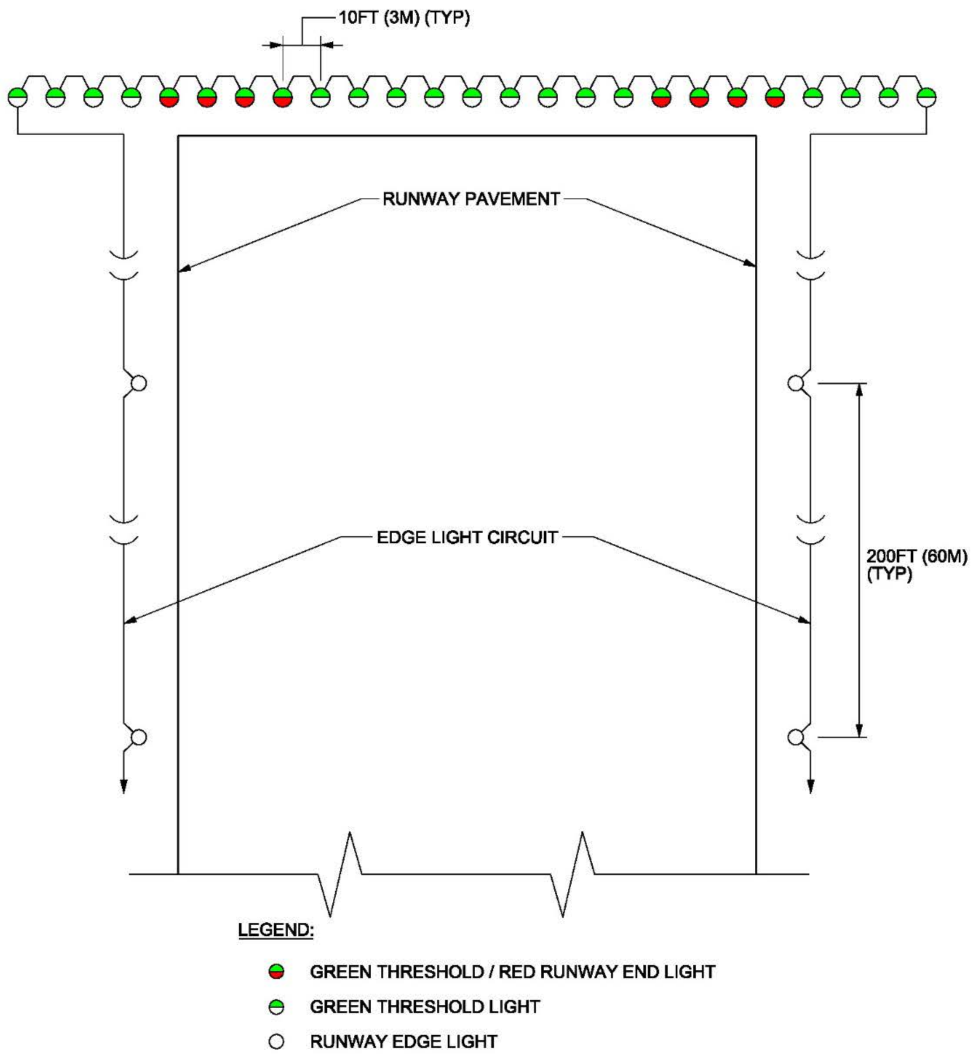

Figure 4-6 Threshold Light Photometric Requirements

	I=50%	II=10%
a	5.5°	7.5°
b	4.5°	6.0°

NOTES:
1. ALL CONTOURS ARE ELLIPSES CALCULATED BY EQUATION: $(X/a)^2 + (Y/b)^2 = 1$
2. THE MINIMUM AVERAGE CANDELA IN GREEN LIGHT OF THE MAIN BEAM (INSIDE CONTOUR I) IS 10,000 CD FOR HIGH INTENSITY SYSTEMS AND 100 CD FOR MEDIUM INTENSITY SYSTEMS.
3. MAXIMUM INTENSITY MUST NOT EXCEED 3 TIMES AVERAGE CANDELA SPECIFIED AND THE AVERAGE INTENSITY MUST NOT EXCEED 1.5 TIMES MINIMUM AVERAGE INTENSITY SPECIFIED.
4. PORTIONS OF THE LIGHT BEAM CUT OFF BY THE MOUNTING SURFACE MAY BE DISREGARDED.
5. CONTOURS I AND II INDICATE THE MINIMUM PERCENT VALUES OF THE MAIN BEAM INTENSITY.

4-4.5 Equipment.

Inboard threshold lights use in-pavement fixtures with no part of the fixture protruding more than 1 inch (25 millimeters) above the surrounding surface. Outboard threshold lights use elevated fixtures, frangible mounted. Where the opposite direction runway end is collocated with the threshold, runway end lights may be incorporated into threshold light fixtures. The number of bidirectional fixtures must be the minimum required to satisfy the requirement for end light fixtures. Where traffic patterns or arresting gear equipment interfere with the use of elevated fixtures, in-pavement fixtures must be used. (See paragraphs 13-12.3. and 13-12.3.1)

4-4.6 Power Requirements.

4-4.6.1 For Air Force airfields, connect the threshold lights with the interleaved runway edge light circuits as in Figure 4-5A. If the runway edge lights are not interleaved, connect the threshold lights as in Figure 4-5B.

4-4.6.2 For Army airfields, connect the threshold lights with the interleaved runway edge light circuits as in Figure 4-5C. If the runway edge lights are not interleaved, connect the threshold lights as in Figure 4-5D.

4-4.7 Control Requirements.

4-4.7.1 Where there is no approach light system, provide remote on and off and intensity levels to correspond to the runway edge light controls. The intensity levels must be the same as the runway edge lights.

4-4.7.2 When installing approach lights, the threshold lights may be circuited so approximately half of them are controlled by the approach light system. Interleave the threshold lights selected for operation with the approach lights, with the threshold lights to be operated with the runway lights so they present a uniform pattern symmetrical about the runway centerline when operated without runway lights. This may require that the two innermost lights be operated off the same circuit. Bidirectional fixtures are not allowed for operation with approach lights when runway end lights are installed. Interleaving of runway edge lights are allowed, but are not encouraged. When runway edge lights are interleaved with two circuits, connect the runway threshold lights so that a uniform symmetrical pattern will remain if either of the runway edge light circuits fails.

4-4.8 Aiming Threshold/Approach.

When used as part of an approach light system, bidirectional threshold lights, both in-pavement and elevated, have fixed aiming angles (with 3.5 to 4.0 degree toe-in on the red side only) for the beams and cannot be adjusted.

4-4.9 Monitoring Requirements.

Threshold lights have the same monitoring requirements as the edge lights.

4-4.10 Compliance with International Military Standards.

4-4.10.1 NATO.

The standard meets NATO STANAG 3316 (Edition 11) – Airfield Lighting,, for high intensity threshold lights.

4-4.10.2 AFIC.

Previous AFIC AIR STD 90/27 cancelled.

4-5 LIGHTING WITH DISPLACED THRESHOLDS.

4-5.1 General.

The runway threshold is the beginning of the landing area, and may not be located at the physical beginning or end of the full strength runway. It may be used for takeoff, but not for landing. After landing at the other end, the landing aircraft may use the displaced portion of the runway for roll out. Displacements may be permanent or temporary. Reasons for permanent displacement may be to give arriving aircraft clearance over an obstruction while still allowing departing aircraft the maximum amount of runway available, because of operational problems, or as noise mitigation measures. Reasons for temporary displacement may be for ongoing construction, for repairs after accidents or to displace landing position to a stronger part of full strength pavement if the keel is unreliable. Displaced runways require waivers. The area of full strength pavement in front of the threshold may be required for takeoff or for rollout on landings from the opposite direction. Where this occurs, changes to the standards for runway lighting are required.

4-5.2 Configuration for Permanent Displacement.

See Figure 4-7 and Figure 4-8 for typical layouts of permanent displaced thresholds.

4-5.2.1 Install threshold lights, as specified in paragraph 4-4, with dimensions referenced to the theoretical beginning of the usable landing area.

4-5.2.2 Install runway end lights, as specified in paragraph 4-6 with measurements referenced from the end of the usable takeoff and rollout area.

4-5.2.3 When the displaced runway area is used for specific operations (takeoff, rollout, taxiing) appropriate edge lights for the function are installed to delineate the outline.

4-5.2.4 The runway centerline lights facing the approach direction in the displaced area must be blanked out if the length of the displacement is less than 700 feet (210 meters). If the displacement is 700 feet (210 meters) or greater, circuit the centerline lights in the area separately. Provide the capability to turn runway centerline lights off during landing operations. If a high intensity approach light system is installed, this switching capability is not required.

4-5.2.5 Install approach lights and visual approach slope indicators, such as PAPI, as specified in this standard using the theoretical beginning of the usable landing area (threshold) as the reference. Ensure coordination has been performed for relocation of any instrument approach aids.

4-5.2.6 Where the abandoned runway surface is not used for aircraft movement, the threshold lighting is relocated to the new threshold location. Lights in or along the abandoned surface are not required.

4-5.3 Configuration for Temporary Displacement.

See Figure 4-9 for a typical layout of temporary displaced threshold with construction or obstructions on the approach end. See Figure 4-10 for layout when threshold/end of runway lights are co-located.

Where the threshold is temporarily displaced and the duration of the displacement is insufficient to warrant the relocation of all facilities (normally 6 months or less), the following applies:

Figure 4-7 Displaced Threshold Light Configuration (Permanent) Where Runway Surface is Used as a Taxiway with Taxiway End Lights

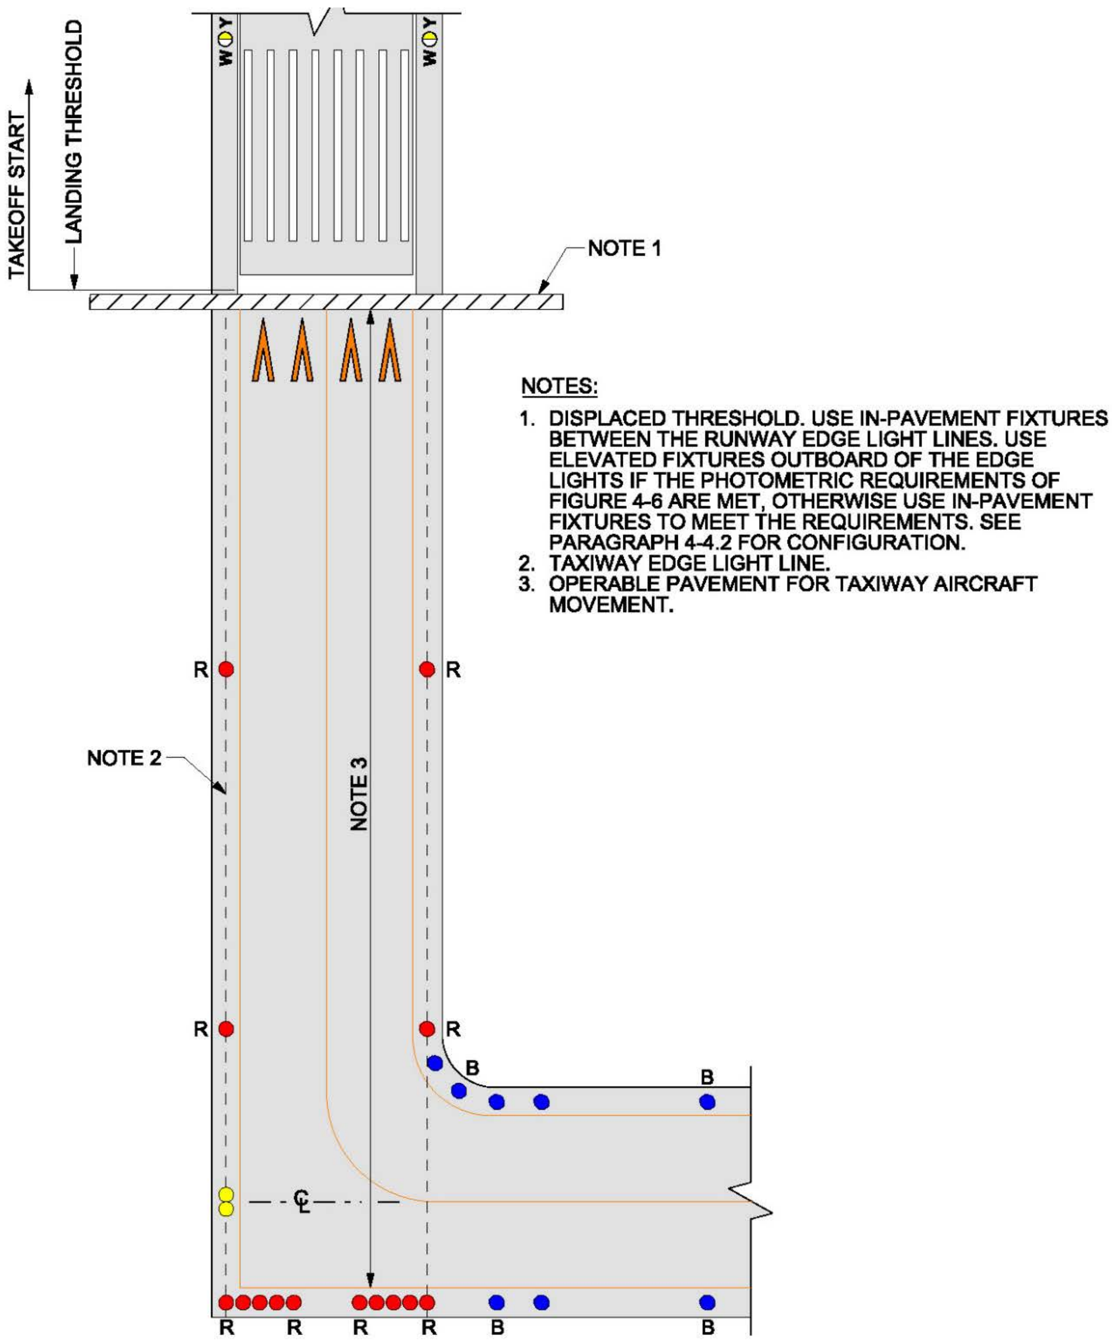

Figure 4-8 Displaced Threshold Light Configuration (Permanent) Where Runway Surface is Used for Takeoff and Landing Rollout

Note: Not supported for new construction.

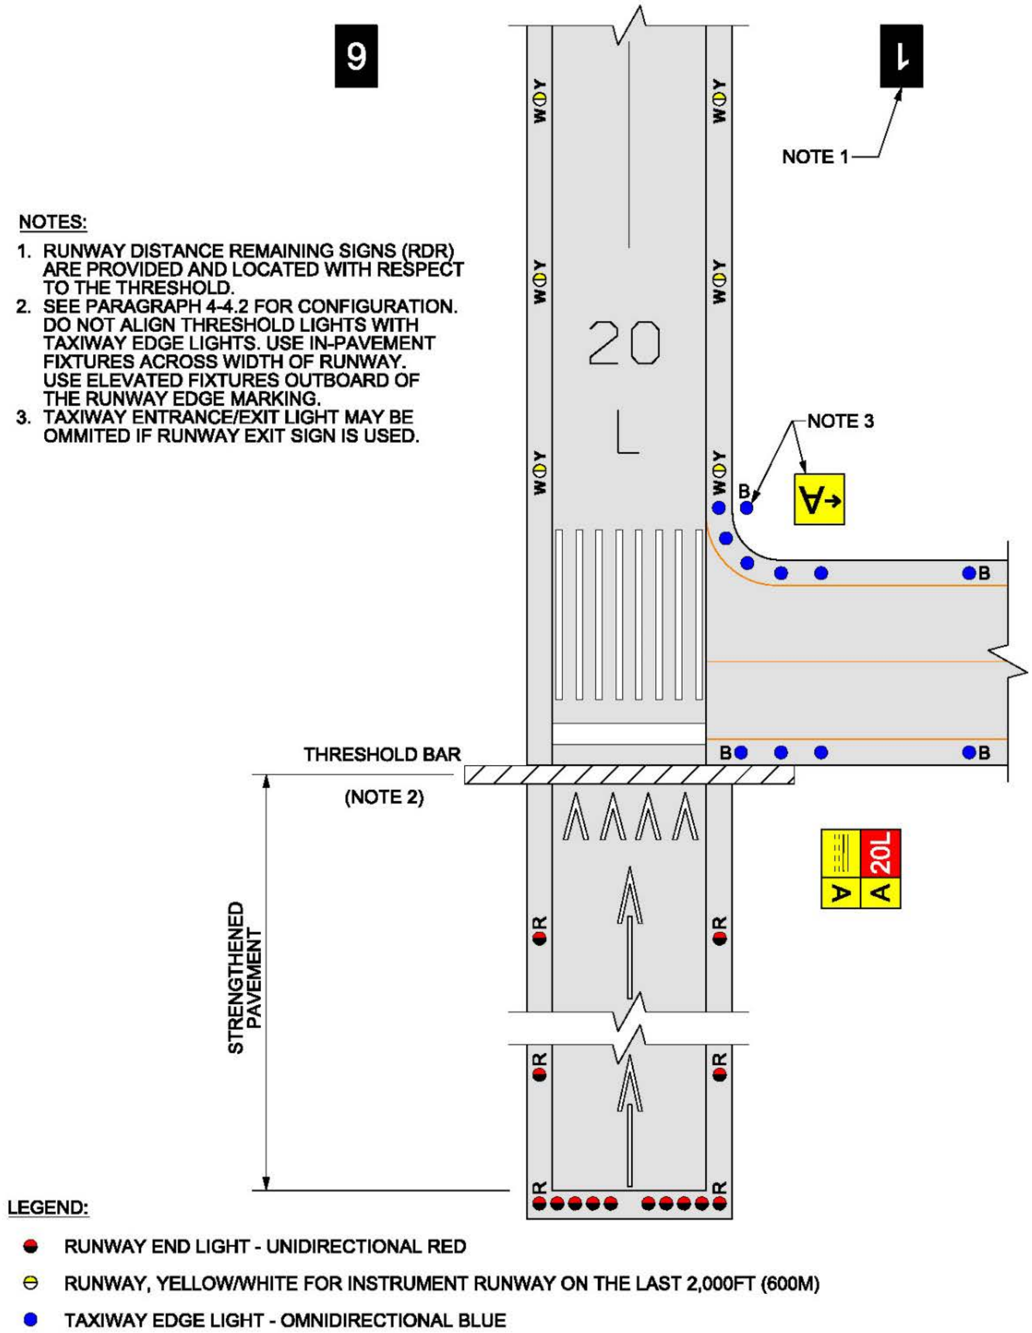

Figure 4-9 Displaced Threshold Lighting Configuration (Temporary)

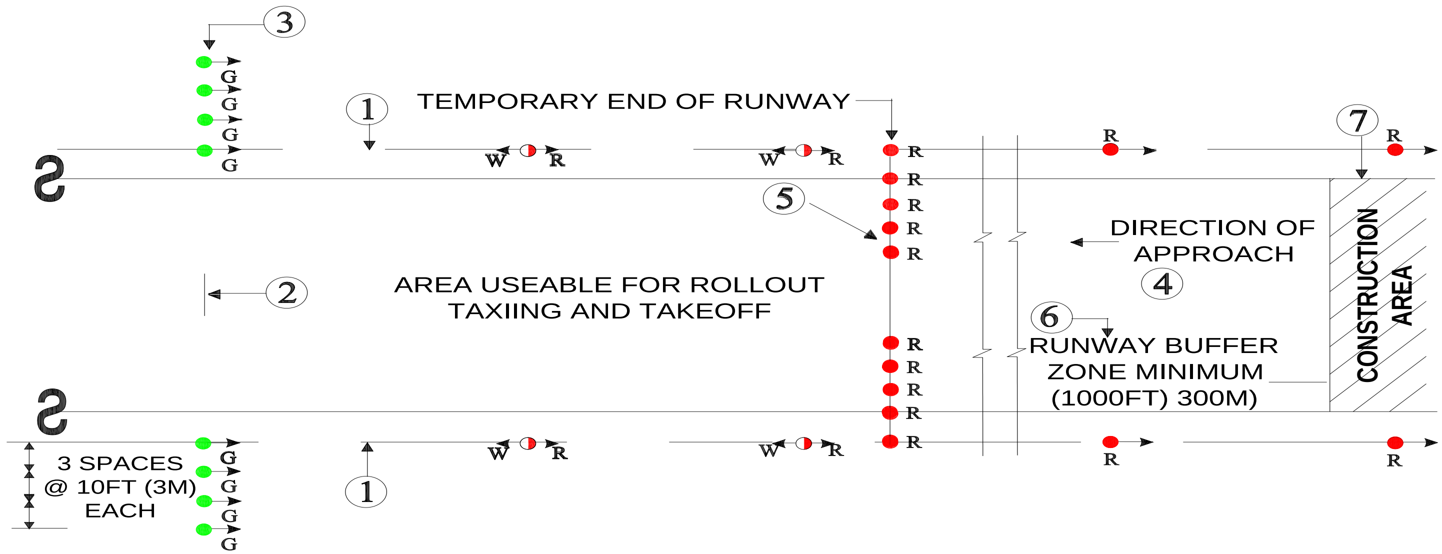
Precautionary Note: Means must be provided to secure the plank and fixtures to prevent any movement arising from jet blast. Where spikes (asphalt) or concrete anchors (PCC) are used to secure the plank to the pavement, the holes left in the pavement after removal must be repaired.



LEGEND:

- G — GREEN THRESHOLD LIGHT, PLANK MOUNTED

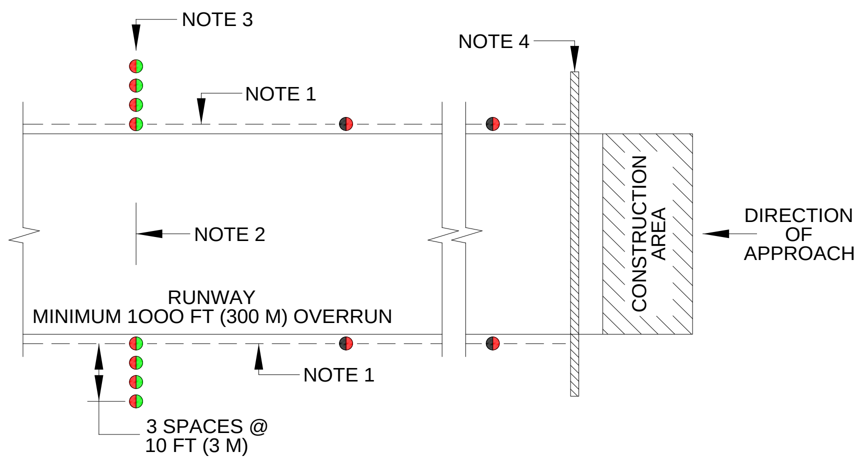
LEGEND:

THRESHOLD/RUNWAY END LIGHT - BI-DIRECTIONAL RED/GREEN

EXISTING RUNWAY EDGE LIGHTS. CHANGE TO RED TOWARD APPROACH AND BLANK TOWARD TEMPORARY THRESHOLD (MAY BE WHITE TOWARD TEMPORARY THRESHOLD IF USED FOR ROLL-OUT).



NOTES:

1. RUNWAY EDGE LIGHT LINE.
2. LOCATION OF THRESHOLD OF USEABLE LANDING AREA.
3. LINE OF THRESHOLD LIGHTS MARKING LOCATION OF THRESHOLD OF USEABLE LANDING AREA. (L-862 FOR HIRL, L-861 FOR MIRL) LIGHTS MAY BE STAKE OR PLANK MOUNTED.
4. EXISTING APPROACH THRESHOLD LIGHTS DISCONNECTED. RUNWAY END LIGHTS (UNI-DIRECTIONAL RED TOWARD RUNWAY) SHALL REMAIN ACTIVE IF AREA BEWTEEN TEMPORARY AND EXISTING THRESHOLDS IS USED ROLL-OUT.

4-5.3.1 Coordinate with TERPS specialist or FAA equivalent, airfield manager, CE Community planner, safety, and standardization and evaluation office to determine placement of the threshold.

Include temporary displaced threshold layout and configuration, along with temporary PAPIs as required, in the construction phasing plan and submit temporary displaced threshold requirement/configuration as a part of the temporary waiver request to the installation commander for a construction project within the airfield environment.

4-5.3.2 Disable the permanent runway threshold lights, runway end lights, approach lighting system, visual glide slope indicating systems such as PAPI or VASI, and any touchdown zone lights serving that end of the runway and runway edge lights along the section of runway not used for aircraft traffic.

4-5.3.3. Install temporary runway threshold lights, per Figure 4-9 or Figure 4-10, with dimensions referenced to the theoretical beginning of the usable landing area. Additional lights maybe added for a 300 foot (90 meter) wide runway. Reference UFC 3-260-01, Table 3-2, Runways.

4-5.3.4 Install temporary runway end lights, as specified in paragraph 4-6, with dimensions referenced from the end of the usable takeoff and rollout area.

Note: When temporary displacement is due to construction work, place the runway end lights to allow an additional 1,000 feet (300 meters) for emergency roll-out or to protect the Approach-Departure Clearance Surface from the tallest equipment that will be erected in the approach-departure zone. See UFC 3-260-01 for geometric requirements of the Approach-Departure Clearance Surface.

4-5.3.5 All fixtures are elevated and may be stake mounted or mounted on planks fastened to the runway surface.

4-5.3.6 Cables and transformers may be laid on the surface but must be protected from damage.

4-5.3.7 Modify runway edge lights in the temporary displaced area to show red light toward the approach direction (see Figure 4-9 and Figure 4-10). (When the displaced area is intended to be used for rollout or taxiing operations, the color of the edge lights must be modified with red toward approach and white toward the runway.) See paragraph 4-2.3 for photometric requirements on instrument runways.

4-5.3.8 Runway centerline lights in the displaced area will be blanked toward the approach direction and red toward the runway opposite the approach.

4-5.3.9 Runway Distance Remaining Signs (RDR) number panels facing toward the opposite end approach must be blanked or temporarily replaced with the new number panels reflecting the shorter distance to go. Renumbering is done so that at least 1,000 feet (300 meters) remain between the last number (#1) and the displaced runway end.

4-5.4 Equipment.

See paragraphs 13-12.3. and 13-12.3.1

4-5.5 Power, Control and Monitoring.

See paragraphs 4-4.6 and 4-4.7.

4-5.6 Compliance with International Standards.

4-5.6.1 NATO.

Same as paragraph 4-4.10.

4-5.6.2 AFIC.

Same as paragraph 4-4.10.

4-5.7 Additional Information.

See FAA AC 150/5345-46 for more information.

4-6 RUNWAY END LIGHTS.

4-6.1 Purpose.

Runway end lights define the end of the operational runway surface for aircraft for landing, rollout or takeoff. They are required on all lighted operational runways.

4-6.2 Configuration.

Runway end lights consist of 10 red lights in two groups of 5 lights for Air Force and 8 red lights in two groups of 4 lights for Army. Place the groups symmetrically and on a line perpendicular to, the runway centerline within 10 feet (3 meters) of the end of the usable runway surface. The lights in each group must have a uniform spacing of 5 feet ± 2 inch (1.5 meters ±50 mm) for Air Force and 10 feet ±2 inch (3 meters ±50 mm) for Army. The outboard-most light in each group must be in line with the line of the runway edge lights on that side of the runway. Runway end lights are usually co-located with the opposite end threshold lights. Where they are co-located, runway end lights may be incorporated into the opposite end threshold fixtures provided the photometric requirements are met. (See Figure 4-4A for the Air Force configuration, and Figure 4-4B for the Army configuration). When runway width exceeds 150 feet (45 meters) additional runway end lights may be added.

4-6.3 Photometric Requirements.

Optimum aiming of lights depends on the design and output of the fixtures used in the system. Light fixtures may be designed to cover several applications and may have fixed patterns and aiming angles that differ from this document. Light aiming and patterns other than those in the standard may be used if the resultant light pattern produces equivalent light intensities in the areas required by this standard. Use unidirectional red runway end lights facing toward the runway. Aim the lights parallel with the runway centerline and upward at 3 degrees above the horizontal. They must operate at five intensities as specified in paragraph 4-2.3 for HIRL.
Note: This configuration for runway aligned taxiways will not be approved for new construction.

Runway end lights used with MIRL must have reduced intensities compatible with the edge lights and operate at three intensity steps. (See Figure 4-11.)

For detailed photometric requirements for runway end lights, see FAA AC 150/5345-46.

Figure 4-11 Runway End Light Photometrics

	I=50%	II=10%
a	6.0°	7.5°
b	2.25°	5.0°

RUNWAY END LIGHT, RED

NOTES:

1. ALL CONTOURS ARE ELLIPSES CALCULATED BY EQUATION: $(X/a)^2 + (Y/b)^2 = 1$.
2. THE MINIMUM AVERAGE INTENSITY OF THE MAIN BEAM (INSIDE CONTOUR I) IS 2,500 CD AVIATION RED, MAXIMUM INTENSITY SHOULD NOT EXCEED 1.5 TIMES ACTUAL AVERAGE INTENSITY.
3. CONTOURS I AND II INDICATE THE MINIMUM PERCENT VALUES OF THE MAIN BEAM INTENSITY.

4-6.4 Equipment.

Unless the lights are to be located in an area not paved, use in-pavement fixtures with no part protruding more than 0.75 inch (19 millimeters) above the surrounding surface. Where the runway end is co-located with the opposite direction threshold, the threshold and runway end lights may not be incorporated into the same fixture unless the photometrics meet the requirements for both the red and green colors. For Army only, fixtures meeting FAA AC 150/5345-46 Type L-862 may be used. (See paragraph 13-12.4.)

4-6.5 Compliance with International Military Standards.

4-6.5.1 NATO.

These standards meet NATO STANAG 3316 (Edition 11) – Airfield Lighting.

4-6.5.2 AFIC.

Previous AFIC AIR STD 90/27 cancelled.

4-6.6 Additional Information.

See FAA AC 150/5345-46 for more information.

4-7 RUNWAY CENTERLINE LIGHTS (RCL).

4-7.1 Purpose.

The runway centerline lights provide lateral guidance during landing, rollout and takeoff roll under low visibility conditions. They are optional for Category II and are required for Category III instrument operations.

4-7.2 Configuration.

The runway centerline lighting system is a straight line of lights which runs parallel with and within 2 feet (0.6 meters) of the runway centerline. Configure the system as shown in Figure 4-12. The lighting system extends from 75 feet (22.5 meters) of the upwind end of the runway. It is desirable to offset centerline light fixtures on runways equipped with aircraft arresting systems to avoid hook-skip problems and damage to the centerline light fixtures. Up to five fixtures may be omitted in the vicinity of the arresting gear pendant cables to avoid hook bounce and minimize light damage. Remove existing centerline light fixtures within this area and replace with blank cover plates.

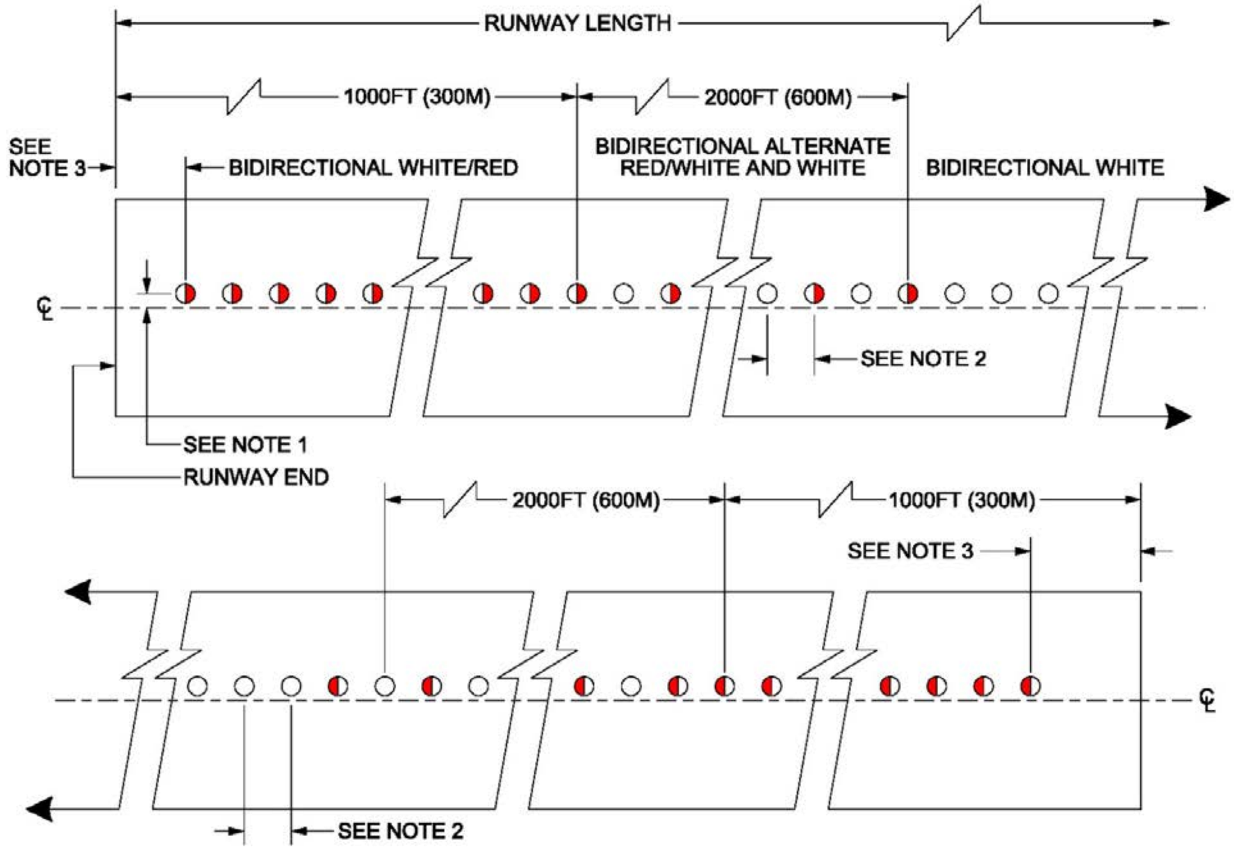
4-7.3 Photometric Requirements.

See FAA AC 150/5345-46 for photometric requirements for runway centerline light fixtures. The lights must meet the intensity requirements shown in Figure 4-13. They must be aimed parallel with the runway centerline ±1/2 degree and upward at 4.5 degrees. They must operate at 5 intensity steps as specified in paragraph 4-2.3 for runway edge lights.

4-7.3.1 Color Coding.

The last 3,000-foot (900 meters) portion of the runway centerline lighting system is color coded to warn pilots of the impending runway end. Alternating red and white lights are installed, starting with red, as seen from 3,000 feet (900 meters) to 1,000 feet (300 meters) from the runway end, and red lights are installed in the last 1,000 foot (300 meters) portion.

Figure 4-12 Runway Centerline Light Configuration



NOTES:

1. THE RCL LINE MAY BE OFFSET NOT MORE THAN 2FT (0.6M) RIGHT OR LEFT OF THE RUNWAY CENTERLINE. THE LATERAL TOLERANCE FROM THE LINE OF LIGHTS ± 1IN (25MM).
2. THE RCL MUST BE EQUALLY SPACED AT 50FT (15M) FOR FAA TYPE L-850A LIGHTS. THE LONGITUDINAL TOLERANCES IS ± 2FT (0.6M).
3. THE FIRST LIGHT FROM EITHER END OF THE RUNWAY MUST BE FOR FAA TYPE L-850A LIGHTS NOT LESS THAN 50FT (15M) AND NOT MORE THAN 87.5FT (26.25M).

LEGEND:

○ BIDIRECTIONAL RCL - WHITE BOTH DIRECTIONS

◐ BIDIRECTIONAL RCL - RED IN DIRECTION OF SHADED SIDE, WHITE IN DIRECTION OF WHITE SIDE.

Figure 4-13 Runway Centerline Light Photometric Configuration

a	5.0°	7.0°
b	4.5°	8.5°

B.

	I=50%	II=10%
a	5.0°	7.0°
b	3.5°	6.0°

NOTES:

1. ALL CONTOURS ARE ELLIPSES CALCULATED BY EQUATION: $(X/a)^2 + (Y/b)^2 = 1$.
2. THE MINIMUM AVERAGE INTENSITY OF THE MAIN BEAM (INSIDE CONTOUR I) IS 250 CD WHITE OR 150CD RED FOR 25 FT (7.5M) SPACING; 5,000 CD WHITE AND 750 CD RED FOR 50 FT (15M) SPACING. MAXIMUM INTENSITY SHOULD NOT EXCEED 1.5 TIMES ACTUAL AVERAGE INTENSITY.
3. CONTOURS I AND II INDICATE THE MINIMUM PERCENT VALUES OF THE MAIN BEAM INTENSITY.

4-7.4 Adjustment and Tolerances.

The line of runway centerline lights may be uniformly offset laterally to the same side of the physical runway centerline a maximum of 2.5 feet (0.75 meters) (tolerance ±1 inch (25millimeters) measured from the physical runway centerline to the fixture centerline. For any new runway, the light base installation must be no closer than 2 feet (0.6 meters) (measured to the edge of the fixture base) to any pavement joints. The mounting surface of the fixture must be level within 1 degree in any direction and the horizontal must be within 1 degree of that specified.

4-7.5 Equipment.

Use in-pavement fixtures with no part protruding more than 0.5 inch (13 mm) above the surrounding surface.

4-7.6 Power Requirements.

For Categories II and III operations, provide a main and standby power system with automatic transfer within one second of a failure of the system. For Category I operation, a 15 second transfer is adequate.

4-7.7 Control Requirements.

Provide remote on-off and intensity control.

4-7.8 Monitoring Requirements.

When supporting of operations below 2,400 feet (720 meters) RVR, provide system monitoring which, at a minimum, gives positive indication at the control facility that power is being delivered to the lights.

4-7.9 Compliance with International Military Standards.

4-7.9.1 AFIC.

Previous AFIC AIR STD 90/27 cancelled.

4-7.9.2 NATO.

These standards meet the NATO STANAG 3316 (Edition 11) – Airfield Lighting.

4-7.9.3 Additional Information.

See FAA AC 150/5340-30 for more information.

4-8 TOUCHDOWN ZONE LIGHTS (TDZL).

4-8.1 Purpose.

Touchdown zone lights provide continuity when crossing the threshold into the touchdown area and provide visual cues during the flare out and touchdown phases of the landing. They are required for Category II or III operations. The Touchdown zone (sometimes called the Landing Zone) is the portion of a runway, beyond the threshold, intended as the first point of contact between landing aircraft and the runway. For rotary-wing and vectored-thrust aircraft, it is the portion of the helipad or runway used for landing.

4-8.2 Configuration.

Touchdown zone lights consist of 2 rows of transverse light bars located symmetrically about the runway centerline per FAA AC 150/5340-30J, **\4** Figure A-35 **/4/**. Each light bar consists of 3 unidirectional lights facing the landing threshold. The rows of light bars extend to 3,000 feet (900 meters), or one-half the runway length for runways less than 6,000 feet (1,800 meters), from the threshold with the first light bars located 100 feet (30 meters) from the threshold. See FAA AC 150/5340-30J for additional information about TDZ lights and installation adjustments (light optical assembly toe-in). (See Figure 4-14.)

4-8.3 Photometric Requirements.

Optimum aiming of the lights depends on the design and layout of the fixtures used in the system. The light fixtures may be designed to cover several applications and may have fixed patterns and aiming angles which differ from this document. The light aiming and patterns other than those cited in this standard may be used if the resultant light pattern produces equivalent light intensities in the areas regulated by the standard. TDZ lights must emit unidirectional aviation white light as shown FAA AC 150/5340-30. They must be toed in 4 degrees toward the centerline and aimed upward 5.5 degrees. This is achieved by either installing light fixtures that have had their optical assembly toed 4 degrees, in accordance with FAA AC 150/5340-30, or by angling the light base 4 degrees and installing the light fixture. The lights must operate at five intensity steps per paragraph 4-2.3 for HIRL.

Figure 4-14 Touchdown Zone Light Photometric Requirements

	I=50%	II=10%
a	5.0°	7.0°
b	3.5°	6.0°

TOUCHDOWN ZONE LIGHT, WHITE

NOTES:

1. ALL CONTOURS ARE ELLIPSES CALCULATED BY EQUATION: $(X/a)^2 + (Y/b)^2 = 1$.
2. THE MINIMUM AVERAGE INTENSITY OF THE MAIN BEAM (INSIDE CONTOUR I) IS 5,000 CD WHITE, MAXIMUM INTENSITY SHOULD NOT EXCEED 1.5 TIMES ACTUAL AVERAGE INTENSITY.
3. CONTOURS I AND II INDICATE THE MINIMUM PERCENT VALUES OF THE MAIN BEAM INTENSITY.
4. THE INTENSITY REQUIREMENTS FOR ANGLES BELOW THE SURFACE OF THE PAVEMENT MAY BE DISREGARDED.

4-8.4 Adjustment and Tolerances.

Refer to notes in Figure 4-15 for installation tolerances. All light bars must be located at the same distance from the runway centerline. The mounting surface of the fixture must be level within 1 degree in any direction and the horizontal aiming must be within 1 degree.

4-8.5 Equipment.

Use in-pavement fixtures with no part protruding more than 0.5 inches (13 mm) above the surrounding surface.

4-8.6 Power, Control and Monitoring.

The requirements in paragraphs 4-7.6 through 4-7.8 for runway centerline lights apply.

4-8.7 Compliance with International Standards.

4-8.7.1 AFIC.

Previous AFIC AIR STD 90/27 cancelled.

4-8.7.2 NATO.

These standards meet the requirement of STANAG 3316 (Edition 11) – Airfield Lighting.

4-8.8 Additional Information.

See FAA AC 150/5340-30 for more information.

CHAPTER 5 STANDARDS FOR TAXIWAY LIGHTING

5-1 TAXIWAY EDGE LIGHTING.

5-1.1 Purpose.

Taxiway edge lights define the lateral limits and direction of a taxiing route. Taxiway edge lighting must be installed for night VMC operations and for day and night instrument operations.

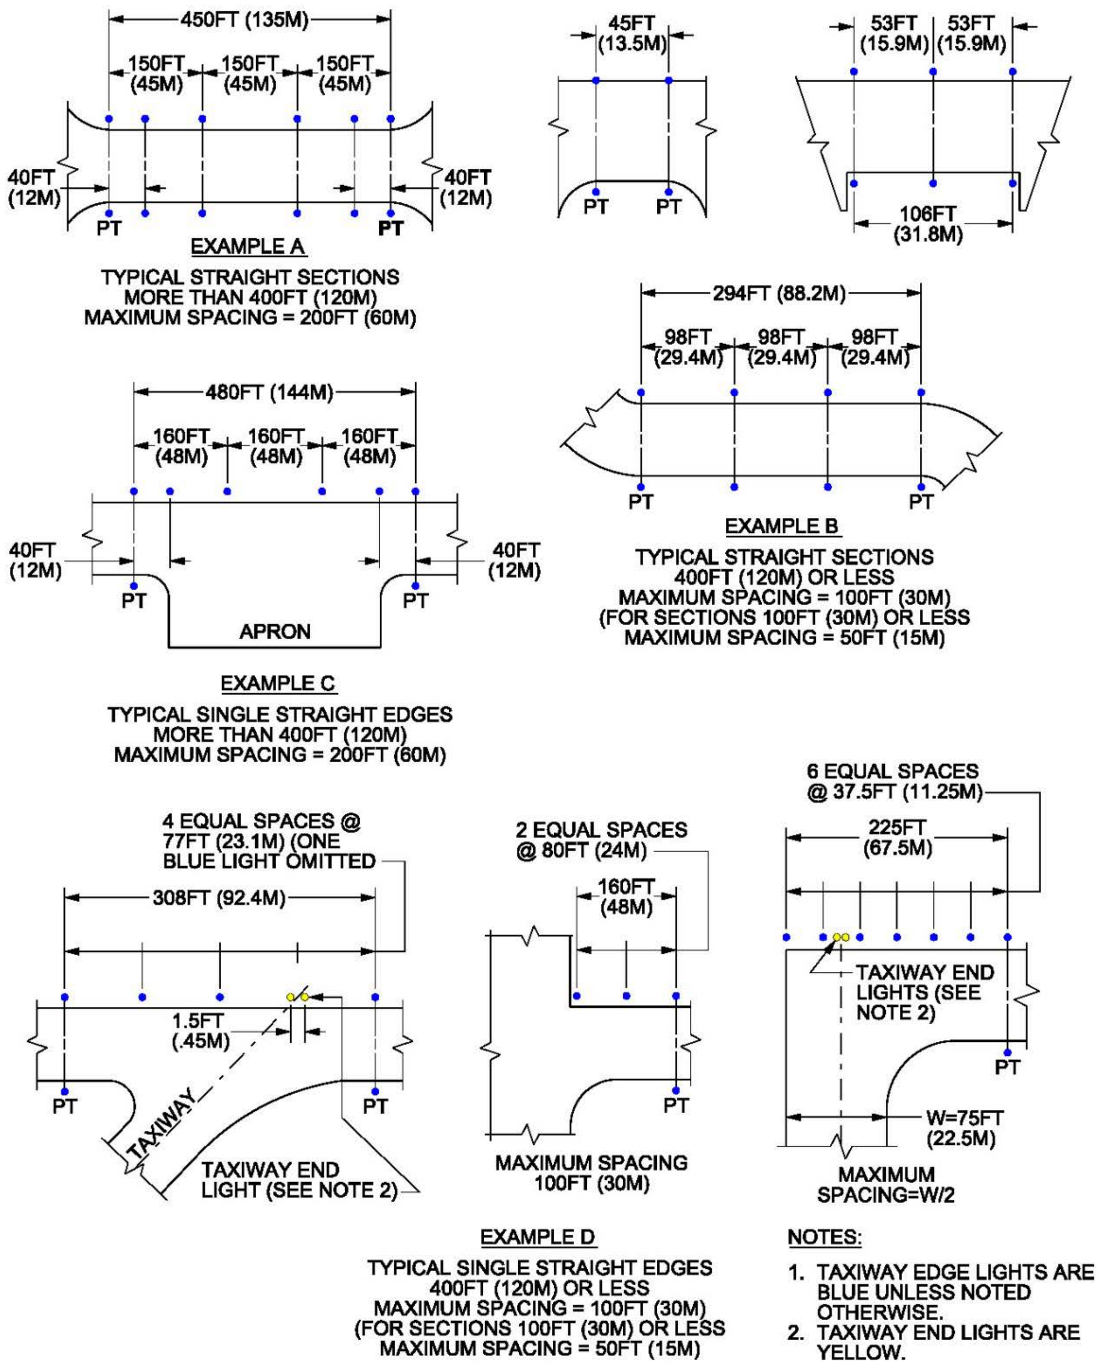
5-1.2 Configuration.

Locate the center line of taxiway edge lights on each side of the taxiway no more than 10 feet (3 meters) from the edge of the full-strength paving, and no closer than the edge of the full-strength paving. The line of lights on both sides of a taxiway must be the same distance from their respective taxiway sides. Runway aligned taxiways are not approved for new construction. For existing installations, it is strongly recommended that runway aligned lights ahead of the runway threshold be changed to red. To determine the spacing of lights along the taxiway length, such as intersections with runways and other taxiways or changes in alignment or width, a discontinuity on one side of a taxiway applies to the other side as well; Figure 5-1 illustrates most situations. Place an edge light at each discontinuity. For intersecting pavements, place them at the point of tangency (PT) of each fillet. Place a companion light on the side opposite the discontinuity as well.

5-1.2.1 Straight Sections.

Place edge lights along all straight taxiway edges at uniform intervals between the lights, as in paragraph 5-1.2. Where the length of the section is greater than 400 feet (120 meters), the spacing must not exceed 200 feet (60 meters) (see Figure 5-1, examples A and C). Where the light spacing exceeds 100 feet (30 meters), place one additional light 40 feet (12 meters) from each end of the section (See Figure 5-1, examples A and C). If the section under consideration is opposite an intersecting taxiway, the uniform spacing must not exceed 1/2 the width of the intersecting taxiway. Where the length of the section is equal to or less than 400 feet (120 meters) the spacing must not exceed 100 feet (30 meters) (see Figure 5-1, examples B and D). Where the section is opposite an ending taxiway, the uniform spacing must not exceed 1/2 the width of the ending taxiway (see Figure 5-1, example D). Place companion lights along the opposite edge where there is no intersecting pavement. Place all companion lights on lines perpendicular to the taxiway centerline (see Figure 5-1, examples A and B).

Figure 5-1 Taxiway Edge Lighting Configuration (Straight)



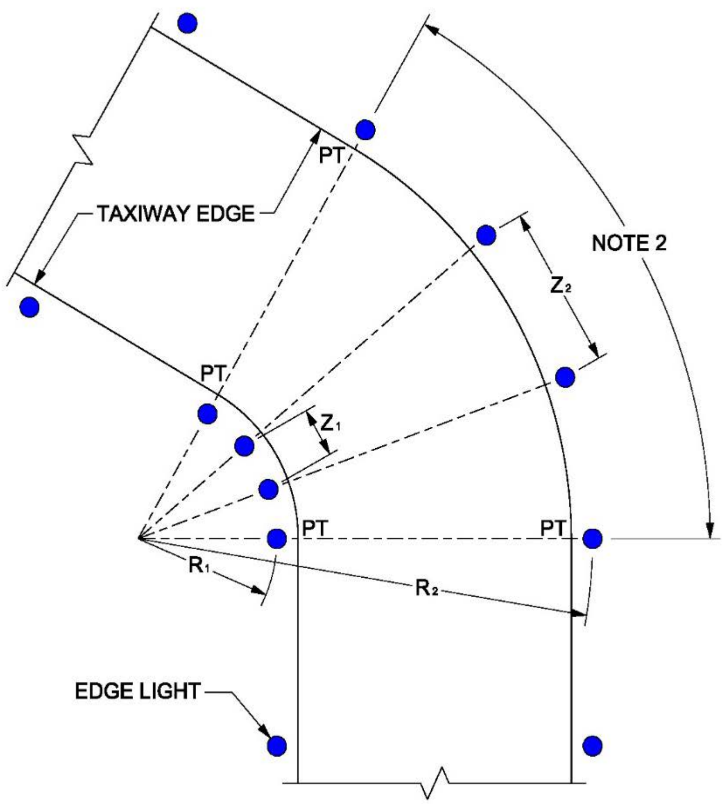
Note: See paragraph 5-1.2.3 for taxiway end lights.

\4\
5-1.2.2 Curved Sections.

Place edge lights along all curved taxiway sections. Uniformly space the lights on the outer line at a distance, not to exceed the value obtained from the formula given in Figure 5-2. Place the lights on the inner line on radials from the outer line of lights, except where the resultant spacing would be less than 20 feet (6 meters). In this case, select spacing not less than 20 feet (6 meters) for the inner line of lights and place the outer line of lights on radials from the inner line.

Place uniformly spaced edge lights at all fillets as shown in Figure 5-3. The spacing must not exceed one half the width of the straight taxiway section.

Figure 5-2 Taxiway Edge Lighting Configuration (Curves)



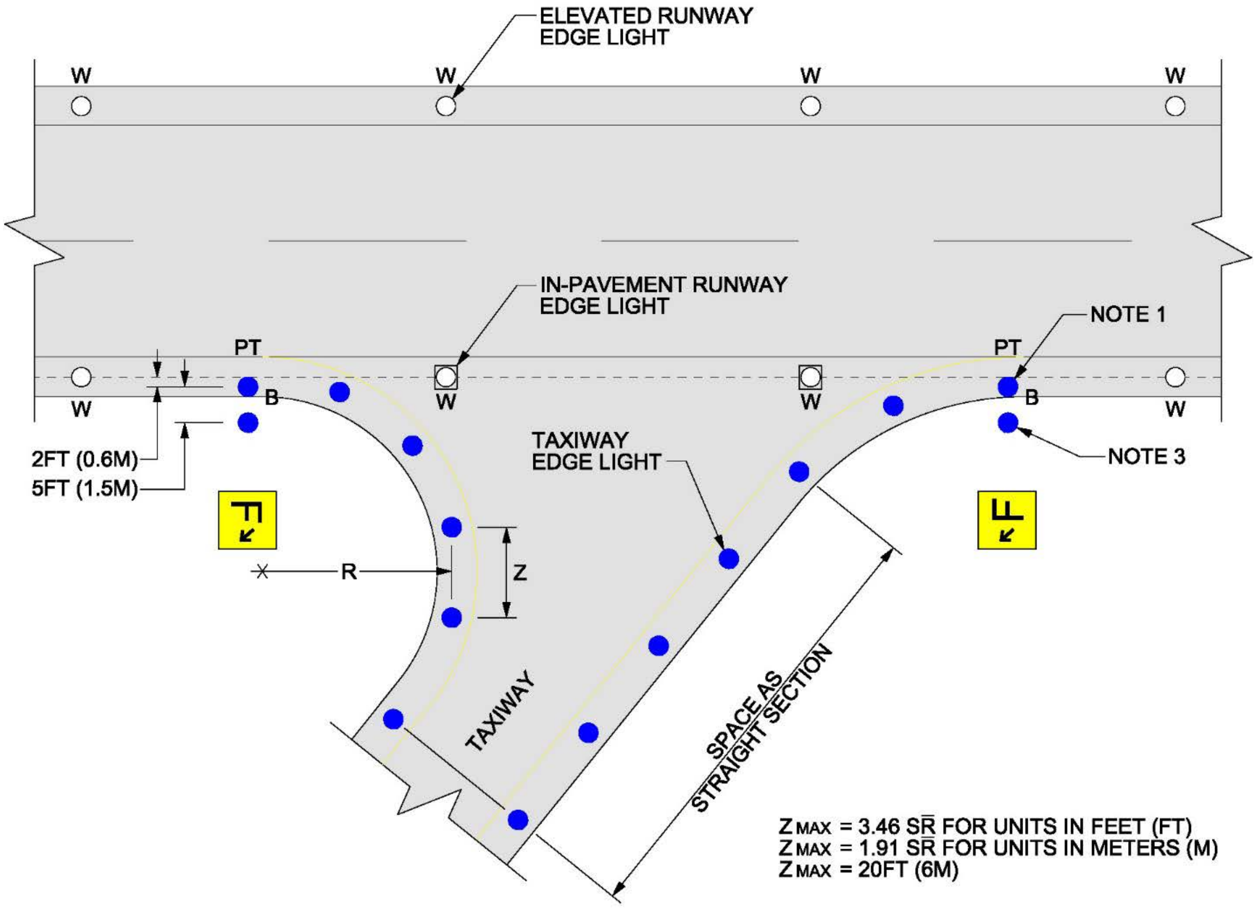
Z_{MAX} = 3.46 x R FOR UNITS IN FEET (FT)
Z_{MAX} = 1.91 x R FOR UNITS IN METERS (M)

NOTES:

1. SPACE LIGHTS UNIFORMILY ON BOTH SIDES OF THE TAXIWAY BETWEEN POINTS OF TANGENCY (PT). DETERMINE SPACING BY DIVIDING TOTAL ARC INTO INCREMENTS (Z).
2. ON ALL CURVES IN EXCESS OF 30° OF ARC, USE A MINIMUM OF THREE EDGE LIGHTS, INCLUDING THOSE AT THE PTs FOR A CURVE OF 30° OR LESS PROVIDE LIGHTS ONLY AT THE PTs.
3. ALIGN LIGHTS ON THE INSIDE RADIUS (R_1) WITH THOSE ON THE OUTSIDE RADIUS (R_2). IF $Z_1 < 20$FT (6M) DECREASE THE NUMBER OF LIGHTS ON R_1 UNTIL $Z_1 \geq 20$FT (6M) AND SPACE EVENLY ALONG RADIUS R_1.

/4/

Figure 5-3 Taxiway Edge Lighting Configuration Entrance/Exit



NOTES:
1. TAXIWAY LIGHTS MUST NOT BE IN LINE WITH RUNWAY LIGHTS.
2. PT = POINT OF TANGENCY.
3. TAXIWAY ENTRANCE/EXIT LIGHT MAY BE OMITTED IF RUNWAY EXIT SIGN IS USED.

5-1.2.3 Taxiway End Lights.

Where a taxiway ends at a crossing taxiway, place two yellow lights spaced 1.5 feet (0.45 meters) apart and in the line of the edge lights of the crossing taxiway. Center them on the point where the extended centerline of the ending taxiway intersects. If a yellow light falls within 5 feet (1.5 meters) of a blue edge light, the blue light may be eliminated (see Figure 5-1, examples C and D). Not supported for new construction.

5-1.2.4 Entrance/Exit Lights.

On intersections of taxiways with runways or aprons, place entrance/exit lights at the point of tangency of the taxiway fillet with the runway or apron. Do not place them at an intersection of taxiways. An entrance/exit light consists of 2 taxiway edge lights spaced 5 feet (1.5 meters) apart. One is located 5 feet (1.5 meters) out, on a line extending through the first light and perpendicular to the side of the runway or apron. The entrance/exit light may be omitted if a taxiway exit direction sign is used on the runway. See Figure 5-3.

FAA taxiway fillet geometry changed in 2018, AC 150/5354-30J, Design and Installation Details for Airport visual Aids, but application of this geometry does not apply to Army and Air Force airfields. Current fillet geometry is acceptable.

5-1.2.5 Apron Taxiways.

For a taxiway that is adjacent to, or on the edge of, an apron, the taxiway edge lights are usually placed only on the side of the taxiway farthest from the apron. (“Taxiing” routes through an apron will not have these lights.)

5-1.2.6 Apron Perimeter Lights Without a Taxiway

Aircraft parking aprons are arranged in many ways, with perimeters defined by open spaces or hangars or other facilities. Generally, the edge lighting of the perimeter defined by an open space can have taxiway edge lights that are placed according to the spacing examples for straight and curved taxiway edge lighting.

5-1.3 Tolerances.

Adjust the longitudinal location of any light a maximum of 5 feet (1.5 meters) to avoid installation problems. Move the companion light the same amount, if practical, to maintain the relationship between the two lights. Install taxiway edge lights within 6 inches (150 mm) laterally or longitudinally of the design location.

5-1.4 Photometric Requirements.

Optimum aiming of lights depends on the design and output of the fixtures used in the system. See FAA AC 150/5345-46 for additional detailed photometric information about taxiway edge lights.

5-1.5 Equipment.

Use frangible mounted elevated fixtures in all areas, including Category II and Category III operations, as described. Mount elevated fixtures a maximum of 14 inches (350 millimeters) above grade. Where there are frequent snow accumulations of 12 inches (300 millimeters) or more, the mounting height may be increased as shown in Figure 4-3.

5-1.5.1 Provide a fixture base that houses the isolation transformer; fixture base and can should be a standard size that will fit both elevated and in-pavement fixture types. This facilitates future runway and taxiway configuration changes or modifications should an elevated fixture no longer be suitable. The light base and can installation must be no closer than 2 ft (0.6 m) (measured to the edge of the fixture base) from any pavement joint.

5-1.5.2 To reduce the "sea of blue lights" effect at an airfield with many taxi routes, hoods may be used on elevated fixtures. Do not use hoods on taxiway entrance/exit light fixtures.

5-1.5.3 Where elevated lights may be damaged by jet blast or operation of an arresting gear, or where they interfere with aircraft operation such as B-52 outrigger gears, use in-pavement fixtures.

5-1.6 Power Requirements.

Provide a main power system and circuits which permit independent control of the taxiways. Provide standby power only for those taxiways supporting precision instrument approaches. Transfer time from the failed power system must not exceed 15 seconds.

5-1.7 Control Requirements.

Taxiway lighting circuits must be segmented and controlled to provide the degree of flexibility required for airfield operations. (See Figure 5-4.) Provide remote on/off control for all taxiway segments, and provide a three step intensity control.

5-1.8 Monitoring Requirements.

There is no requirement for monitoring taxiway circuits.

5-1.9 Compliance with International Standards.

5-1.9.1 AFIC.

Previous AFIC AIR STD 90/27 cancelled.

5-1.9.2 NATO.

These standards meet the requirements of STANAG 3316 (Edition 11) – Airfield Lighting, except for the light spacing on curves.

5-2 TAXIWAY CENTERLINE LIGHTS.

5-2.1 Purpose.

Taxiway centerline lights are a system of aviation green in-pavement lights installed along the taxiway centerlines to provide alignment and course guidance information in specific instances of visibility, established by FAA AC 120-57A, *Surface Movement Guidance and Control System.* They may be installed where it is impractical to install taxiway edge lights. On taxiways which support Category II and Category III operations, the particular use of taxiway centerline lights depends upon the runway visual range (RVR) and allowable landing conditions.

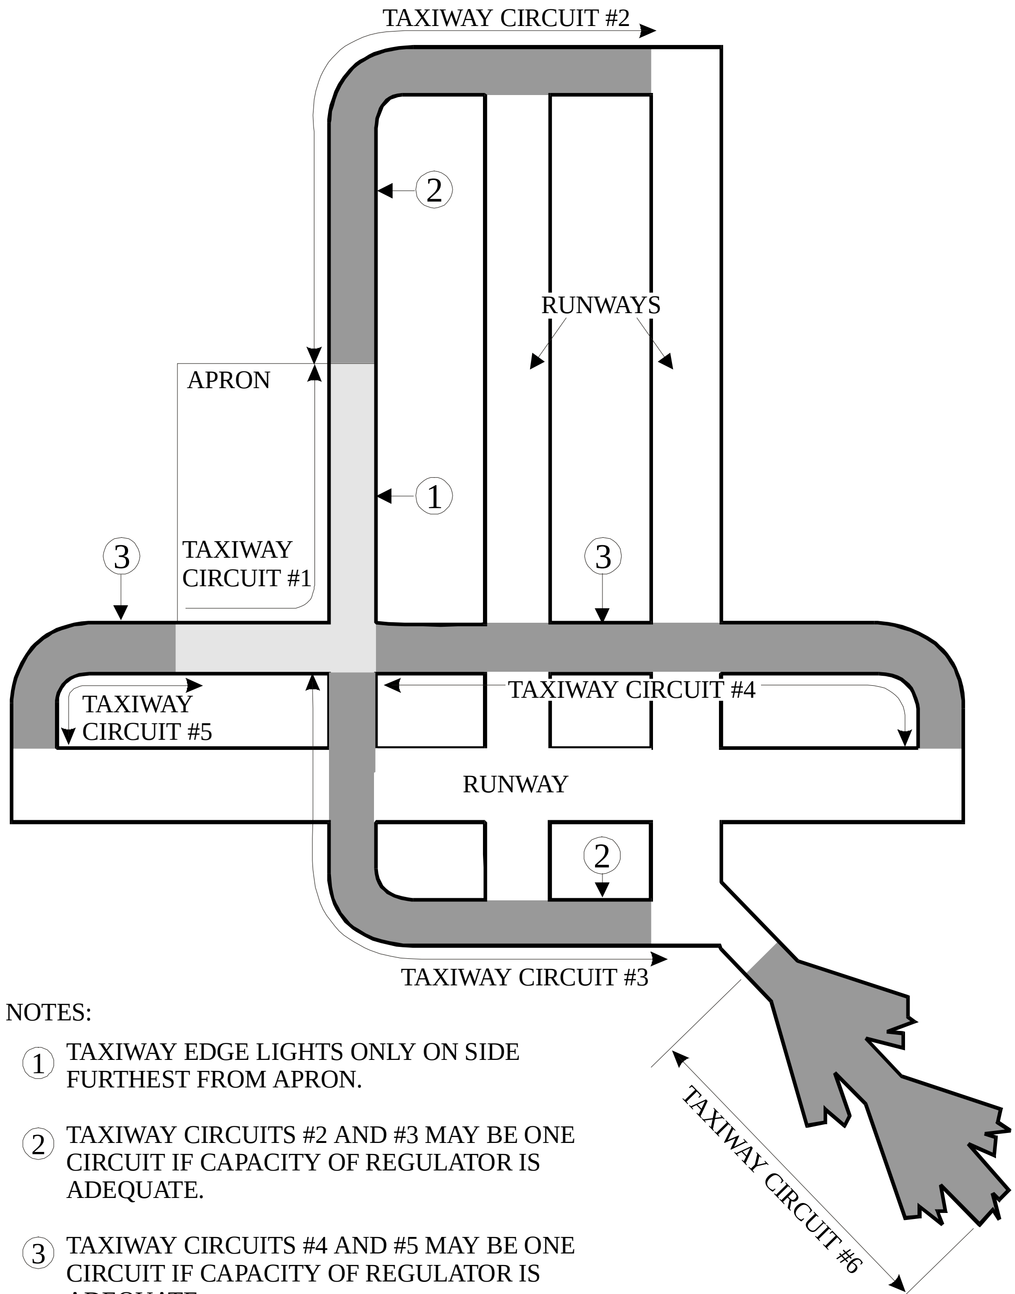
Taxiway centerline light requirements are determined within FAA AC 120-57A, paragraph 8, "Visual Aid Requirements." When required, they are installed in accordance with FAA AC 150-5340-30, *Design and Installation Details for Airport Visual Aids*, Chapter 4, "Taxiway Lighting Systems."

5-2.2 Configuration.

Install taxiway centerline lights in smooth lines along the taxiway centerline. To avoid construction joints or markings, the line of lights may be offset uniformly a maximum of 2 feet (0.6 meters) from the centerline. Actual configuration and spacing must conform with FAA AC 150-5340-30.

5-2.2.1 Place a light at each holding position, at each PT of a curved section, at each taxiway end, at each intersection with a runway edge or apron, and at the PTs of all fillets. Where taxiways cross, place a light at the intersection of the centerlines.

Figure 5-4 Taxiway Circuit Layout



NOTES:

1. TAXIWAY EDGE LIGHTS ONLY ON SIDE FURTHEST FROM APRON.
2. TAXIWAY CIRCUITS #2 AND #3 MAY BE ONE CIRCUIT IF CAPACITY OF REGULATOR IS ADEQUATE.
3. TAXIWAY CIRCUITS #4 AND #5 MAY BE ONE CIRCUIT IF CAPACITY OF REGULATOR IS ADEQUATE.

LEGEND:

LIGHTED TAXIING ROUTE

LIGHTED TAXIING ROUTE ALONG EDGE OF APRON

5-2.2.2 Place uniformly spaced lights between the points defined above, along all straight and curved sections of the taxiway. The uniform spacing will approach, but not exceed, the criteria given in Figure 5-5. The location of individual lights may be adjusted along the line of lights a maximum of 2 feet (0.6 meters) to avoid construction problems. Note: See AC 120-57A, Chapter 8, for taxiway lighting requirements in the movement area.

5-2.2.3 At taxiway intersections, place lights along an arc drawn tangent to the centerlines of the taxiways (or lines of lights) in the direction of all aircraft turns. To reduce confusion where aircraft turns are not anticipated, the arc of lights may be omitted. The minimum clearance to the inner edge of either taxiway must be equal to one half the width of the narrower taxiway. Select the largest radius that will provide the clearance for the arc of lights. Do not install taxiway centerline lights on runway surfaces, except as specified for runway exit lights.

5-2.3 Tolerances.

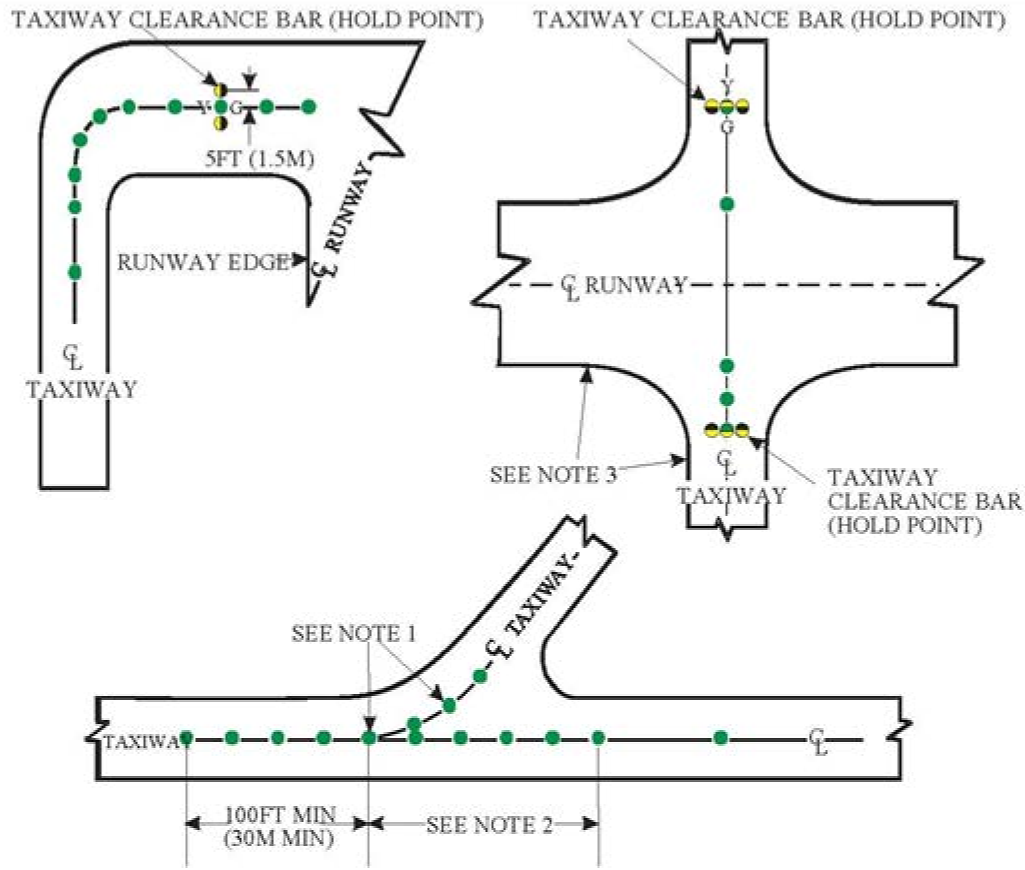
Taxiway centerline lights must not be more than 3 inches (75 millimeters) off of the designated line of lights and not more than 6 inches (150 millimeters) from the designated locations along the line of lights.

5-2.4 Equipment.

Use in-pavement fixtures which do not protrude more than 0.50 inch (13 millimeters) above the pavement. They must be bidirectional aviation green except as follows:

- At crossing taxiways, the light at the intersection must be omnidirectional aviation yellow.
- On taxiways where the aircraft movement is in one direction only, the lights may be unidirectional and facing the oncoming aircraft.
- Where hold lights are installed, the centerline light must be aviation yellow facing the holding aircraft.

Figure 5-5 Taxiway Centerline Lighting Configuration (See FAA AC 120-57A)



LONGITUDINAL SPACING CRITERIA

		CAT II/III IFR	ALL OTHER
NOMINAL		50FT (15M)	100FT (30M)
AT INTERSECTIONS (SEE NOTE 2)		50FT (15M)	50FT (15M)
CURVES	RADIUS LESS THAN 400FT (120M)	12.5FT (3.75M)	25FT (7.5M)
(SEE	RADIUS 400FT (122M) TO 1200FT (360M)	25FT (7.5M)	50FT (15M)
NOTE 1)	RADIUS GREATER THAN 1200FT (360M)	50FT (15M)	100FT (30M)

NOTES:

1. LOCATE LIGHTS AT PT1 AND PT2, AND SPACE INTERMEDIATE LIGHTS EQUALLY ALONG SELECTED CURVE IN COMPLIANCE WITH SPACING CRITERIA.
2. SPACE LIGHTS EQUALLY BETWEEN PT1 AND CLEARANCE BAR (HOLD POINT) LIGHTS.
3. RUNWAY AND TAXIWAY EDGE LIGHTS NOT SHOWN.

LEGEND:

Y/G ● BIDIRECTIONAL, GREEN AND YELLOW

● BIDIRECTIONAL, GREEN

● UNIDIRECTIONAL, YELLOW

5-2.5 Photometric Requirements.

See FAA AC 150/5345-46 for taxiway centerline light fixture photometric requirements. Taxiway centerline lights must be bidirectional and emit aviation green light at three intensity steps: 100 percent, 30 percent, or 10 percent of full brightness. The minimum intensities and beam widths are shown in Table 5-1.

Table 5-1 Taxiway Centerline Light Intensity and Beam Widths

Application	Average Intensity of Main Beam	---------------- BEAM WIDTH ----------------			
		50% Of Main Beam Average		10% Of Main Beam Average	
		Hor.	Vert.	Hor.	Vert.
Category II					
Straight (L-852A)	20 cd	±10	1 to 4	±16	0.5 to 10
Curved (L-852B)	20 cd	±30	1 to 4	±30	0.5 to 10
Category III					
Straight (L-852C)	200 cd	±3.5	1 t 8	±4.5	0 to 13
Curved (L-852D)	100 cd	±30	1 to 10	±30	0 to 15

5-2.5.1 Horizontal Aiming.

Aim lights on straight sections parallel with the taxiway centerline. Aim lights on curved sections along the tangent at the light location. See FAA AC 150/5340-30 for additional detailed information about light fixture aiming.

5-2.6 Power Requirements.

Provide a main power system and circuits which permit independent control of the taxiways. Provide standby power only for those taxiways essential for precision instrument approaches. Transfer time from the failed system to standby system must not exceed 15 seconds for CAT I runways and 1 second for CAT II and CAT III runways.

5-2.7 Control Requirements.

For new installations, provide remote ON, OFF and stepped intensity control. Provide 3 step intensity control for taxiway edge lights. Provide 5 step (preferred) or 3 step intensity control for taxiway centerline lights. The system may be segmented to provide flexibility in choosing taxiway routing.

5-2.8 Monitoring Requirements.

There is no monitoring requirement for taxiways.

5-2.9 Compliance with International Standards.

5-2.9.1 AFIC.

Previous AFIC AIR STD 90/27 cancelled.

5-2.9.2 NATO.

These standards meet the requirements of STANAG 3316 (Edition 11) – Airfield Lighting, except for the light spacing on curves.

5-3 RUNWAY LEAD-OFF LIGHTS.

5-3.1 Purpose.

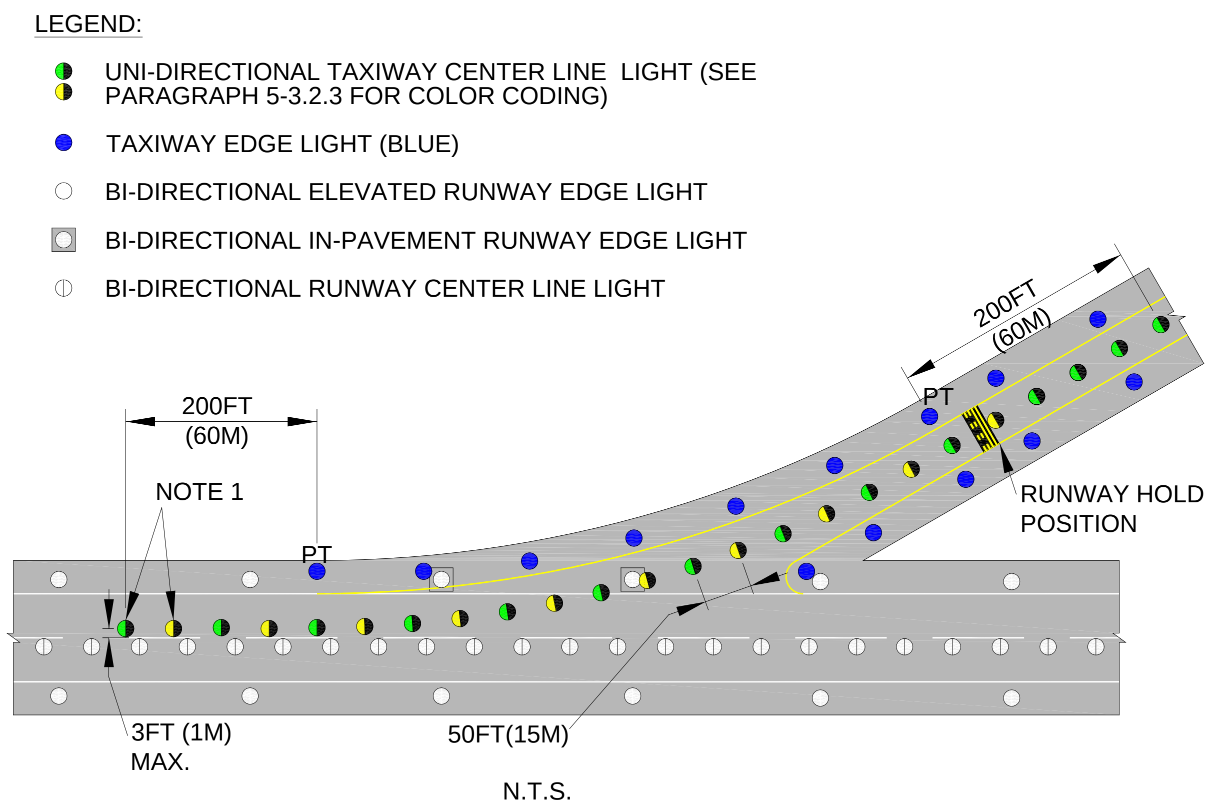
Runway lead-off lights are taxiway centerline lights that provide visual guidance to aircraft exiting the runway. They are color-coded green/yellow to warn pilots and vehicle drivers that they are within the runway environment or instrument landing system/microwave landing system (ILS/MLS) critical area. See FAA AC 150/5340-30 for detailed information about lead-off light installation.

5-3.2 Configuration.

5-3.2.1 Long Radius Exits.

Long radius exit lights are installed on exits with radii exceeding 1,200 feet (360 meters). They consist of a line of unidirectional taxiway centerline lights. The line begins at a point which is a maximum of 3 feet (1 meter) off the runway centerline and 200 feet (60 meters) before the beginning of the taxiway centerline curve. The line of lights runs parallel to the runway to the beginning of the taxiway centerline curve. It then follows the taxiway centerline curve to a point which is a minimum of 200 feet (60 meters) beyond the beginning of the straight portion of the taxiway. The lights are uniformly spaced at a distance of not more than 50 feet (15 meters). (See Figure 5-6.)

Figure 5-6 Taxiway Long Radius High Speed Exit Lights, Radius > 1,200 FT (360 M) (See FAA AC 120-57A)



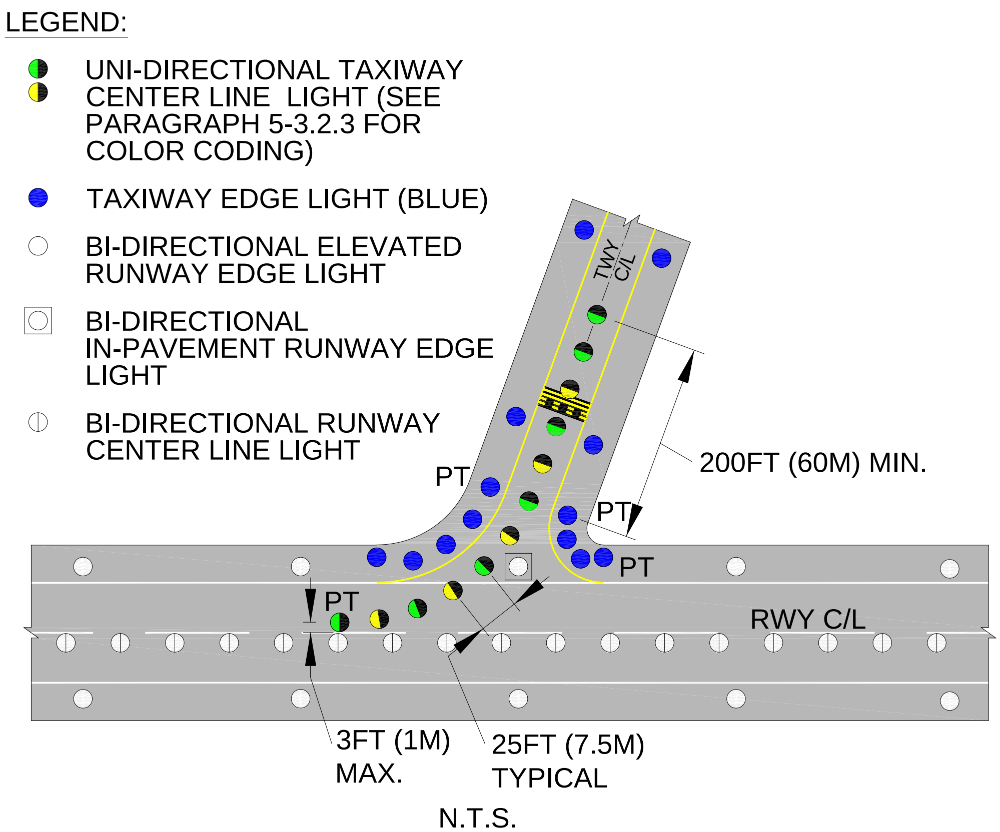
NOTES:

1. THE FIRST LIGHT ON THE RUNWAY IS GREEN. IF THERE IS AN ODD NUMBER OF COLOR-CODED LIGHTS, THE FIRST TWO LIGHTS SHOULD BE GREEN.
2. IF THERE IS AN ILS/MLS CRITICAL AREA PRESENT BEYOND THE RUNWAY HOLDING POSITION, THE COLOR-CODED LIGHTS CONTINUE TO THE ILS/MLS CRITICAL AREA HOLDING POSITION WITH THE LAST YELLOW LIGHT SIMILARLY LOCATED BEYOND THE CRITICAL AREA HOLDING POSITION.

5.3.2.2 Short Radius Exits.

Short radius exit lights consist of a line of taxiway centerline lights. The line of lights begins at a point that is not more than 3 feet (0.9 meter) off the runway centerline on the near side and is the PT of the exit curve. Ensure the radius of the curve is the largest that will provide a minimum clearance to the pavement edge equal to one half the width of the taxiway. The line of lights runs along the arc to the PT with the taxiway centerline. It then follows the taxiway centerline for a minimum of 200 feet (60 meters). The spacing between the lights is not greater than 25 feet (7.5 meters). (See Figure 5-7.)

Figure 5-7 Taxiway Short Radius High Speed Exit Lights Radius ≤ 1,200 FT (360 M) (See FAA AC 120-57A)



NOTES:

1. THE FIRST LIGHT ON THE RUNWAY IS GREEN. IF THERE IS AN ODD NUMBER OF COLOR-CODED LIGHTS, THE FIRST TWO LIGHTS SHOULD BE GREEN.
2. IF THERE IS AN ILS/MLS CRITICAL AREA PRESENT BEYOND THE RUNWAY HOLDING POSITION, THE COLOR-CODED LIGHTS CONTINUE TO THE ILS/MLS CRITICAL AREA HOLDING POSITION WITH THE LAST YELLOW LIGHT SIMILARLY LOCATED BEYOND THE CRITICAL AREA HOLDING POSITION.
3. TAXIWAY CENTERLINE LIGHTS MAY BE BI-DIRECTIONAL (GREEN-GREEN OR YELLOW-YELLOW) IF USED FOR BI-DIRECTIONAL TRAFFIC.

5-3.2.3 Color Coding.

Color-code taxiway exit lights within the runway safety area FAA aviation green or yellow. The first light on the runway must be green. Fixtures between the runway centerline and the runway hold position must alternate green and yellow. The first fixture past the runway hold position must be yellow. If there are an odd number of color-coded lights, the first two lights must be green. Taxiway centerline lights beyond the first fixture past the runway hold position on the runway must be green. Where fixtures are used for bidirectional traffic, fixtures must be color coded in both directions.

5-3.3 Adjustments and Tolerances.

The requirements in paragraph 5-2.3 for taxiway centerline lights apply.

5-3.4 Photometric Requirements and Horizontal Aiming.

The requirements in paragraph 5-2.5 for taxiway centerline lights apply.

5-3.5 Equipment.

Use unidirectional, in-pavement fixtures with no part extending more than 0.5 inch (13 mm) above the surrounding pavement. (See paragraph 13-13.2.)

5-3.6 Power Requirements.

Provide a main power supply and circuits that permit independent control except on a taxiway with centerline lighting. In this case, they may be connected to and controlled with the taxiway centerline lights.

5-3.7 Control Requirements.

Provide remote on/off and intensity control. Runway exit lights shall be controlled with associated taxiway centerline lights.

5-3.8 Monitoring Requirements.

There are no monitoring requirements.

5-3.9 Compliance with International Military Standards.

5-3.9.1 AFIC.

Previous AFIC AIR STD 90/27 cancelled.

5-3.9.2 NATO.

These standards meet NATO STANAG 3316 (Edition 11) – Airfield Lighting.

5-4 TAXIWAY CLEARANCE BARS.

5-4.1 Purpose.

For Category III airfield operation (below 600 RVR), clearance bars serve two purposes:

5-4.1.1 In low visibility, clearance bars warn pilots and vehicle drivers that they are approaching a hold point (other than a runway holding position). They are installed at designated hold points on the taxiway for operations below 600 feet (180 meters) RVR.

5-4.1.2 At night and in inclement weather, clearance bars warn pilots and vehicle drivers that they are approaching an intersecting taxiway. They are generally installed at taxiway intersections where the taxiway centerline lights do not follow the taxiway curve and taxiway edge lights are not installed.

5-4.2 Configuration.

See FAA AC 150/5340-30 for information about taxiway clearance bar configuration.

A clearance bar consists of a row of three in-pavement yellow lights to indicate a low visibility hold point (see Figure 5-5). The fixtures are normally unidirectional but may be bidirectional depending upon whether the hold point is intended to be used in one or two directions. In addition, with the below exceptions, clearance bars are installed (without regard to visibility) at a taxiway intersection with non-standard fillets or where the taxiway centerline lights do not follow curves at intersections. Clearance bars installed for this purpose consist of unidirectional fixtures.

5-4.2.1 Clearance bars may be omitted if taxiway edge lights are installed at the intersection.

5-4.2.2 If the angle between the centerlines of any two adjacent segments of the pavement is 90 degrees ±10 degrees, clearance bars at a “T” or “+” shaped taxiway/taxiway intersection may be substituted by or supplemented with an omnidirectional yellow taxiway intersection light (L-852E or F, as appropriate) installed near the intersection of the centerline markings.

5-4.2.3 The clearance bar located on an exit taxiway may be omitted if it would be located before, or within 200 feet (60 meters) beyond, a runway holding position (as viewed while exiting the runway).

5-4.3 Location of a Clearance Bar Installed at a Low Visibility Hold Point.

A low visibility hold point consists of a taxiway/taxiway holding position marking, a geographic position marking, and a clearance bar. However, hold points are not necessarily located at taxiway/taxiway intersections. In-pavement clearance bar lights are centered on an imaginary line that is parallel to, and 2 feet (600 millimeters) from, the holding side of the taxiway/taxiway holding position marking. The lights may vary from this imaginary line up to ±2 inches (±50 millimeters) (perpendicular to the holding position marking). If a conflict occurs with rigid pavement joints or other undesirable spots, the taxiway/taxiway holding position marking, geographic position marking, and the clearance bar may all be moved longitudinally any amount necessary to resolve the conflict. However, if the hold point is located at a taxiway/taxiway intersection, move the aforementioned items away from the intersecting taxiway by the minimum necessary to resolve the conflict. If a conflict occurs between the center fixture in the clearance bar and a centerline light, the center fixture may take the place of an existing centerline light.

5-4.4 Location of a Clearance Bar Installed at a Taxiway Intersection.

A clearance bar installed at a taxiway intersection is located in accordance with the criteria of paragraph 5-4.3 if that location is established as a hold point and taxiway/taxiway holding position markings are present. Otherwise, locate the clearance bar in the same manner as if the holding position marking were present. This allows room for the possible future installation of the marking.

5-4.4.1 Lateral Spacing.

The center light of the clearance bar is installed in line with existing or planned taxiway centerline lights. The two remaining lights are installed outboard of the center fixture on 5 foot (1.5 meter) intervals, center-to-center. The outboard fixtures may be moved laterally a maximum of ±1 foot (±300 millimeters) to avoid an undesirable spot (e.g., conduit).

5-4.5 Light Beam Orientation for Clearance Bars.

The axis of the light beam for each fixture is parallel to the centerline of the designated taxiway path with a tolerance of ±1 degree.

5-4.6 Equipment.

Use in-pavement fixtures with no part extending more than 0.50 inches (13 millimeters) above the surrounding pavement. Hold lights must emit unidirectional aviation yellow light toward the holding aircraft. When installed with taxiway centerline lights, the center light must be bidirectional aviation yellow/green with the yellow light toward the holding aircraft.

5-4.7 Photometric Requirements.

See FAA AC 150/5345-46 for taxiway clearance bar light fixture photometric requirements. All other photometric requirements in paragraph 5-2.5 for straight section taxiway centerline lights apply.

5-4.8 Fixtures.

Power and Control Requirements. The requirements for taxiway centerline lights apply. Power and control the fixtures with the associated taxiway lighting system.

5-4.9 Monitoring.

There is no requirement for monitoring.

5-4.10 Compliance with International Military Standards.

Previous AFIC AIR STDs and current NATO STANAGs contain no comparable systems.

5-5 RUNWAY GUARD LIGHTS (RGL).

5-5.1 Purpose.

RGLs provide a distinctive warning to anyone approaching the runway holding position that they are about to enter an active runway.

5-5.2 Configuration.

See FAA AC 50/5340-30 for detailed information about both elevated and in-pavement runway guard light installation and configuration.

Elevated and in-pavement RGLs serve the same purpose and are not generally both installed at the same runway holding position. However, if snow could obscure in-pavement RGLs or there is an acute angle between the holding position and the direction of approach to the holding position, it may be advantageous to supplement in-pavement RGLs with elevated RGLs. Each elevated RGL fixture consists of two alternately illuminated unidirectional yellow lights. In-pavement RGLs consist of a row or alternately illuminated unidirectional yellow lights.

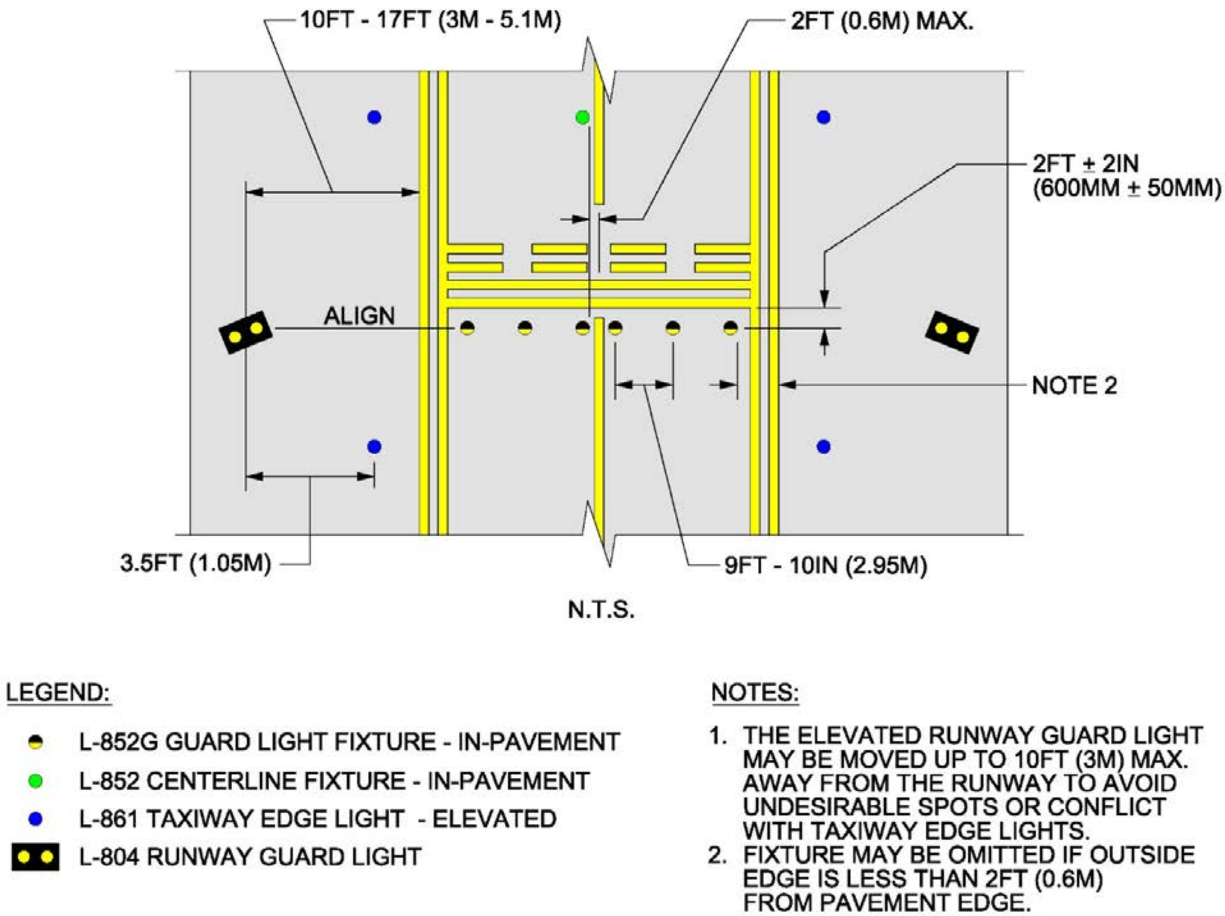
5-5.3 Location of In-pavement Runway Guard Lights.

In-pavement RGLs are centered on an imaginary line that is parallel to, and 2 feet (600 millimeters) from, the holding side of the runway holding position marking (see Figure 5-8). The lights may vary from this imaginary line up to ±2 inches (±50 millimeters) in a direction perpendicular to the holding position marking. If a conflict with rigid pavement joints occurs, the RGLs may be moved away from the runway the minimum distance required to resolve the conflict.

5-5.3.1 Lateral Spacing – Preferred Method.

The lights are spaced across the entire taxiway, including fillets and holding bays, at intervals of 9 feet 10 inches (3 meters), ±2 inches (±50 millimeters), on-center. The lights are spaced in relation to a reference fixture that is installed in-line (longitudinally) with existing or planned taxiway centerline lights. However, it is not intended that the reference fixture replace a taxiway centerline light. If a conflict between the reference fixture and a centerline light occurs, the reference fixture may take the place of an existing centerline light and a new centerline light should be installed in accordance with the criteria in FAA AC 150/5340-30, paragraph 4.3c. If the holding position marking is intersected by multiple taxiway centerline markings, set the reference fixture at the centerline. A fixture whose outboard edge falls at a point less than 2 feet (0.6 meters) from the defined edge of the taxiway (outboard edge of the taxiway marking) may be omitted. Individual fixtures may be moved laterally maximum of ±1 foot (±0.3meters) to avoid undesirable spots (e.g., conduit). Note: Generally, undesirable spots must be avoided by a total of 2 feet (0.6 meters). If this cannot be met by applying the aforementioned ±1 foot (±0.3meters) tolerance, then use the following alternate method.

Figure 5-8 Runway Guard Light Configuration



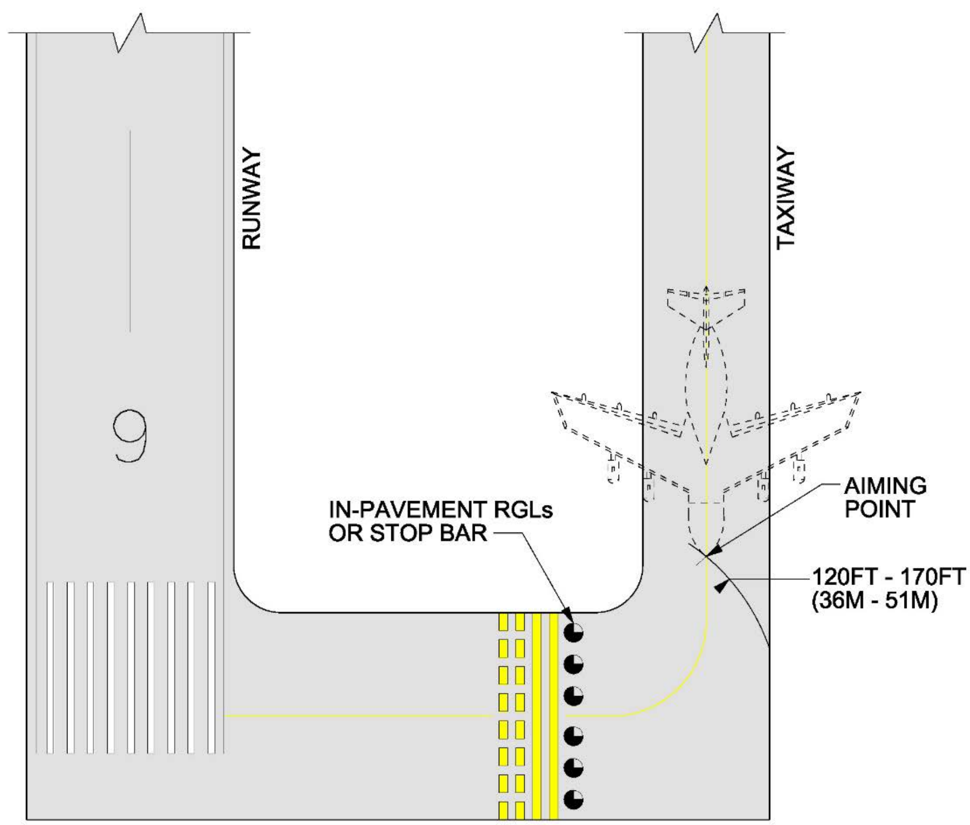
5-5.3.2 Lateral Spacing – Alternate Method.

Use the following alternate method of spacing the lights if it is not possible to meet the preferred method specified in paragraph 4.4b(1), Lateral Spacing – Preferred Method, of FAA AC 150/5340-30. The lights are spaced across the entire taxiway, including fillets and holding bays. If allowing the reference fixture to be moved any amount laterally makes it possible to meet paragraph 4.4b(1) requirements, then use that method. Otherwise, space the lights as uniformly as possible with a minimum spacing of 8 feet (2.4 meters) and a maximum of 13 feet (3.9 meters).

5-5.3.3 Light Beam Orientation for In-pavement RGLs.

Install L-868 bases for in-pavement RGLs such that a line through one pair of bolt holes on opposite sides of the base is parallel to the runway holding position marking. Each fixture is installed so that the light beam faces away from the runway and is perpendicular to the runway holding position marking within a tolerance of ±1 degree. For some pavement configurations, it may be necessary to orient the lights at some angle to the marking. To accomplish this, install a 12 bolt-hole base using the above procedure. This allows the light fixtures to be adjusted 30 degrees left or right, as required. See Figure 5-9 for typical examples.

Figure 5-9 Light Beam Aiming Point for In-Pavement RGLs and Stop Bars



5-5.4 Location of Elevated RGLs.

Elevated RGLs are collocated with the runway holding position marking and are normally installed on each side of the taxiway (see Figure 5-8). Generally, elevated RGLs should be located as close as practical to the taxiway edge to maximize their conspicuity. The distance from the defined taxiway edge to the near side of an installed light fixture should be 10 to 17 feet (3 to 5.1 meters). To avoid undesirable spots, the RGL may be moved up to 10 feet (3 meters) farther from the runway, but may not be moved toward the runway. If a stop bar is installed at the runway holding position, the elevated RGL should be located at least 3 feet, 6 inches (1.05 meter) outboard of the elevated stop bar light. The RGL should not be located where it will interfere with the readability of the runway holding position sign.

5-5.4.1 Light Beam Orientation for Elevated RGLs.

RGLs should be oriented to maximize the visibility of the light by pilots of aircraft approaching the runway holding position. In general, the orientation should be specified by the design engineer to aim the center of the light beam toward the aircraft cockpit, when the aircraft is between 150 feet (45 meters) and 200 feet (60 meters) from the holding position, along the predominant taxi path to the holding position. The vertical aiming angle should be set between 5 degrees and 10 degrees above the horizontal. The designer should specify aiming of the lights such that the steady burning intensity at all viewing positions between 150 feet (45 meters) and 200 feet (60 meters) from the holding position is at least 300 cd when operated at the highest intensity step. (Refer to FAA AC 150/5345-46 for specifications for the light intensity and beam spread of the L-804 RGL fixture.) If these criteria cannot be met for all taxi paths to the holding position, consider the following: use of multiple fixtures aimed to adequately cover the different taxi paths, use of in-pavement fixtures to increase the viewing coverage, or aiming the single fixtures on each side of the holding position to optimize the illumination of the predominant taxi path.

5-5.5 Equipment.

Install the elevated RGLs on light bases, or on conduit set in concrete foundations, using frangible supports. The transformers, or power supply unit may be placed in the same light fixture base. The light emitted must be aviation yellow, and alternately flash 50 to 60 times per minute. The illumination period of each flash must not be less than 1/2 or more than 2/3 of the total cycle.

5-5.6 Power, Control and Monitoring.

Provide the electrical power for the guard lights with a dedicated 3-step regulator for each runway where they are installed. The regulator must be configured to operate only at steps two and three. There is no monitoring requirement.

5-5.7 Compliance with International Standards.

Previous AFIC AIR STDs and current NATO STANAGs contain no comparable systems.

5-6 RUNWAY STOP BAR.

5-6.1 Purpose.

Stop bars provide a distinctive "stop" signal to anyone approaching a runway.

5-6.1.1 Low Visibility.

In low visibility conditions, controlled stop bars are used to permit access to the active runway. Uncontrolled stop bars protect the active runway at taxiway/runway intersections that are not part of the low visibility taxi route. Stop bars are required for operations below 600 feet (180 meters) RVR on illuminated taxiways that provide access to the active runway.

5-6.1.2 Runway Incursion.

Stop bars may also be used as a means of preventing runway incursions regardless of visibility conditions. For example, stop bars could be illuminated in certain airfield configurations that would prevent aircraft access from particular taxiways to active, as well as closed runways.

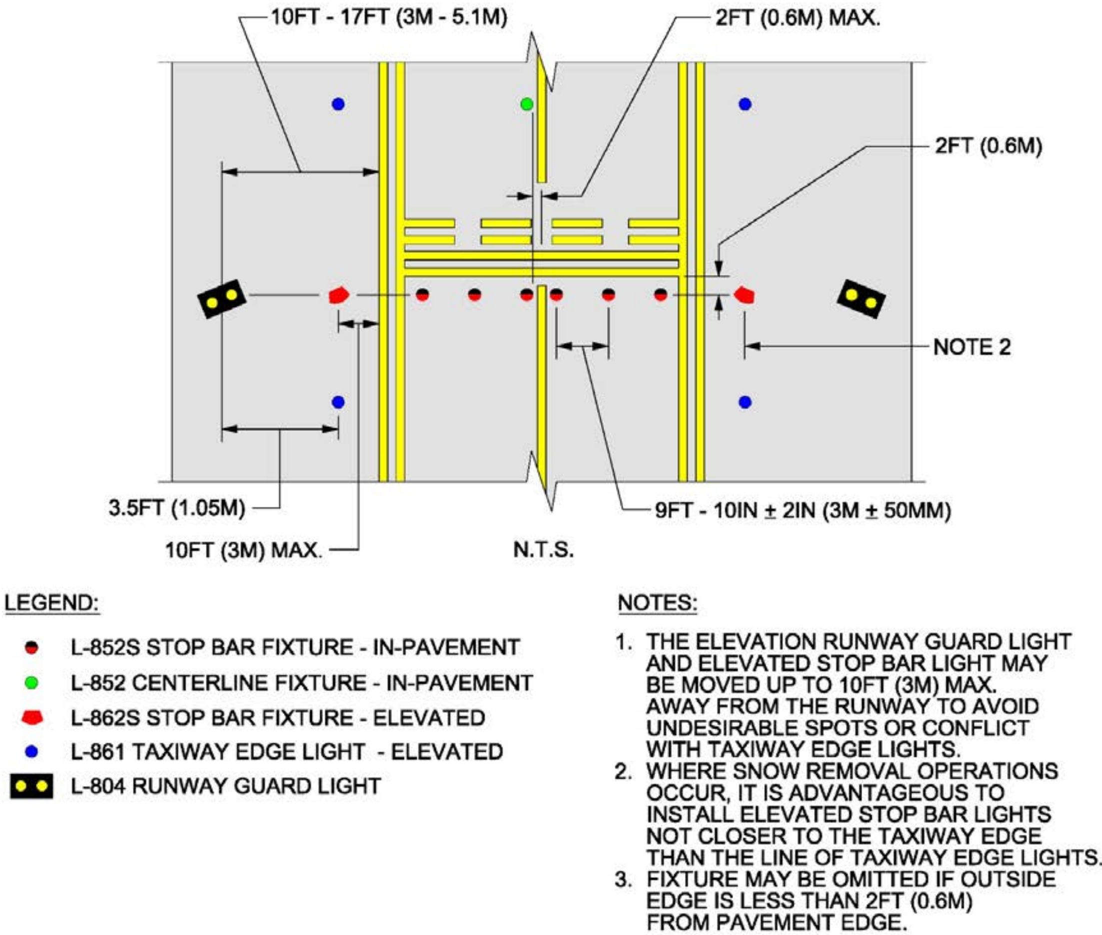
5-6.2 Configuration.

A stop bar consists of a row of unidirectional in-pavement red lights and an elevated red light on each side of the taxiway.

5-6.3 Location of In-Pavement Stop Bar Lights.

In-pavement stop bar lights are centered on an imaginary line which is parallel to, and 2 feet (0.6 meters) from, the center of the fixture and the holding side of the runway holding position marking, as shown in Figure 5-10. The lights may vary from this imaginary line up to ±2 in (±50 mm) in a direction perpendicular to the holding position marking. Holding position marking locations are described in FAA AC 150/5340-1. If a conflict with rigid pavement joints occurs, move both the runway holding position marking and the stop bar lights away from the runway the minimum distance required to resolve the conflict.

Figure 5-10 Runway Stop Bar Configuration



5-6.3.1 Lateral Spacing – Preferred Method.

The lights are spaced across the entire taxiway, including fillets, holding bays, etc., at intervals of 9 feet 10 inches ±2 inches (3 meters ±50 millimeters), center-to-center, as shown in Figure 5-10. The lights are spaced in relation to a reference fixture which is installed inline (longitudinally) with existing or planned taxiway centerline lights. However, it is not intended that the reference fixture replace a taxiway centerline light. If a conflict between the reference fixture and a centerline light occurs, the reference fixture takes the place of an existing centerline light and a new centerline light must be installed per the criteria in paragraph 5-2.2. If the holding position marking is intersected by multiple taxiway centerline markings, the reference fixture must be set at the centerline that is used most. If a fixture's outboard edge falls at a point less than 2 feet (0.6 meters) from the defined edge of the taxiway marking, the outboard edge of the taxiway marking may be omitted. Individual fixtures may be moved laterally ± a maximum of 1 foot (0.3 meters) to avoid undesirable spots (e.g., conduit). If undesirable spots cannot be avoided in this way, fixtures may be moved no more than 2 feet (0.6 meters) using the following alternate method.

5-6.3.2 Lateral Spacing – Alternate Method.

This alternate method of spacing the lights should be followed if it is not possible to meet the preferred method per paragraph 5-6.3.1. The lights are spaced across the entire taxiway, including fillets, holding bays, etc. If it is possible to meet paragraph 5-6.3.1 by allowing the reference fixture to be moved any amount laterally, then that method should be used. Otherwise, the lights should be spaced as uniformly as possible with a minimum spacing of 8 feet (2.4 meters) and a maximum spacing of 13 feet (4 meters).

5-6.3.3 Light Beam Orientation for Elevated Stop Bar Lights.

Elevated stop bar lights should be oriented to enhance conspicuity of the light by pilots of aircraft approaching the runway holding position. In general, the orientation must be specified by the design engineer to aim the axis of the light beam toward the aircraft cockpit when the aircraft is between 120 feet (36 meters) and 170 feet (51 meters) from the holding position, along the predominant taxi path to the holding position. The vertical aiming angle must be set between 5 degrees and 10 degrees above the horizontal. The designer must specify aiming of the lights such that the axis of the light beams intersects the primary taxiway centerline between 120 feet (36 meters) and 170 feet (51 meters) from the holding position (see Figure 5-9).

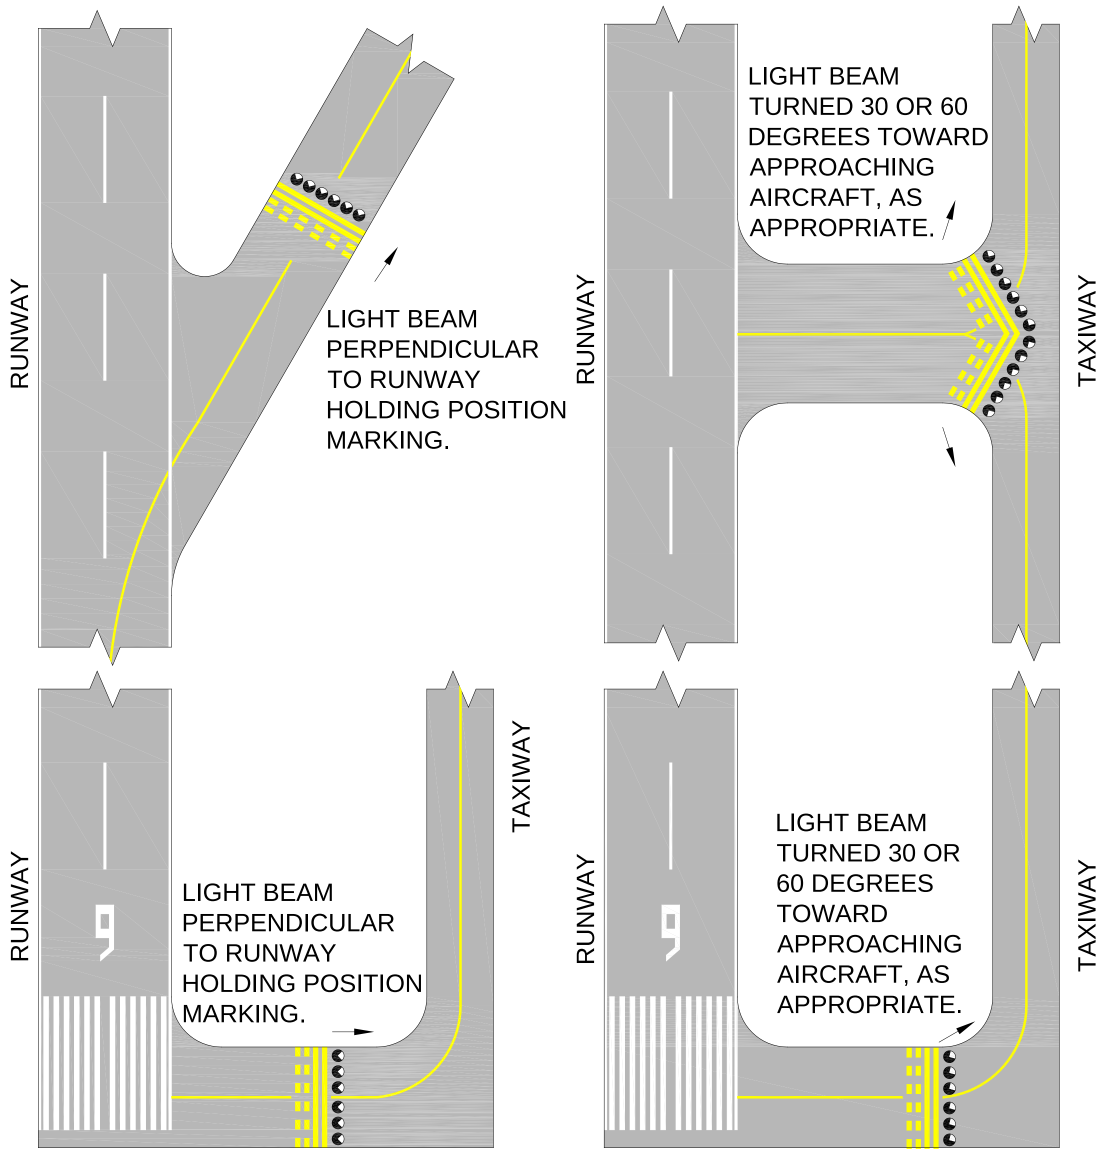
5-6.4 Location of Elevated Stop Bar Lights.

Elevated stop bar lights are installed in line with the in-pavement stop bar lights on each side of the taxiway. They are located not more than 10 feet (3 meters) from the defined edge of the taxiway. For airports that perform any snow removal operations, if taxiway edge lights are present, the elevated stop bar light should not be installed closer to the taxiway edge than the line of taxiway edge lights. This is to help prevent the elevated stop bar light from being struck by snow removal equipment. To avoid conflicts with taxiway edge lights or undesirable spots, the elevated stop bar lights may be moved up to 10 feet (3 meters) farther from the runway, but may not be moved toward the runway. See Figure 5-10.

5-6.4.1 Light Beam Orientation for In-Pavement Stop Bar Lights.

L-868 bases for in-pavement stop bar lights must be installed such that a line through one pair of bolt holes on opposite sides of the base is parallel to the runway holding position marking. Each fixture is installed so that the axis of the light beam faces away from the runway and is perpendicular to the marking with a tolerance of ±1 degree. In some instances, it may be necessary to aim the lights at some angle to the marking. To accomplish this, install a 12 bolt-hole base using the above procedure. This allows the light fixtures to be adjusted 30 degrees left or right, as required. See Figure 5-11 for typical examples.

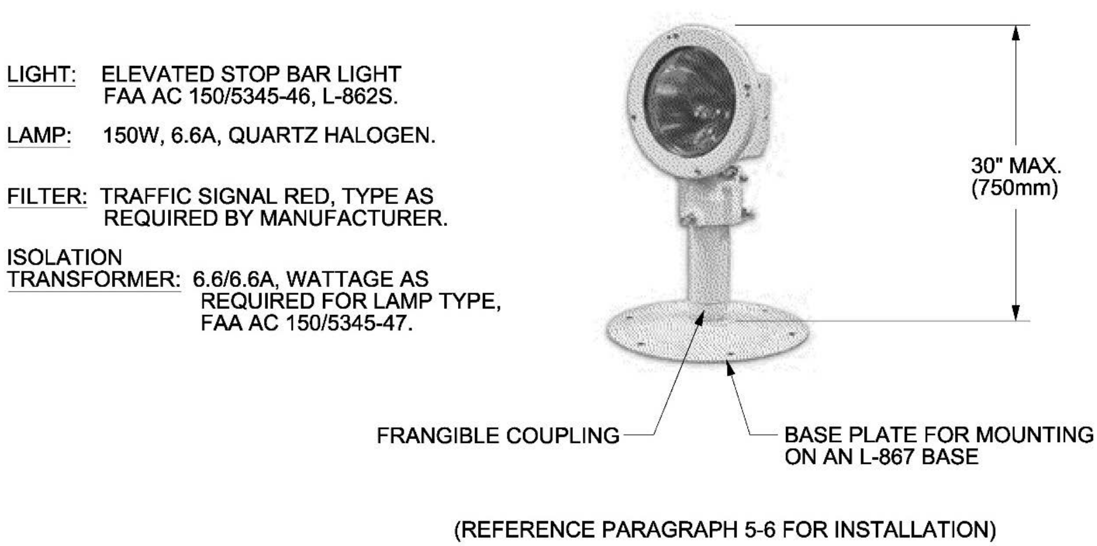
Figure 5-11 Typical Light Beam Orientation for In-Pavement RGLs and Stop Bars



5-6.5 Equipment.

Install the elevated stop bar fixture on an FAA L-867 light base, using frangible supports. Install the in-pavement stop bar fixture on and FAA L-868 base. The current transformer may be placed in the same light fixture base. The light emitted must be traffic signal red. See Figure 5-12 for a typical elevated fixture.

Figure 5-12 FAA L-862S, Elevated Stop Bar Light



5.6.6 Power and Control.

You must power elevated and in-pavement stop bar light circuits from an appropriately sized L-828, Class 1, Style 1 (3-step) CCR. Brightness control is achieved by varying the output current of the CCR. You must install elevated stop bar fixtures on the same circuit as the associated in-pavement stop bar fixtures. There are two types of stop bars: controlled and uncontrolled. Controlled stop bars are controlled individually via FAA L-821 stop bar control panel(s) or via buttons on a touch screen display panel in the Air Traffic Control Tower (ATCT). Uncontrolled stop bars are generally "on" for the duration of operations below 1,200 feet (360 meters) RVR. If the need arises for an uncontrolled stop bar to be turned off, all stop bars for a given low visibility runway may be temporarily turned off via a master stop bar button for each low visibility runway.

5-6.6 Monitoring Requirements for Controlled Stop Bars.

Controlled stop bars and associated lead-on lights must be electronically monitored. Within 5 seconds of pressing the stop bar button, the actual status of the lights must be displayed on the stop bar control panel in the ATCT. This response time reflects the state-of-the-art for local control devices. Ideally, the lights would be switched and their status returned to the ATCT within 2 seconds of pressing the stop bar button. A standard L-827 monitor or L-829 CCR with integral monitor may be used if it is accurately calibrated to indicate a fault indication with approximately 2 stop bar or lead-on lights not functioning. In locations where the circuit resistance to ground varies widely from day to day, it may not be possible to use the L-827 monitor for this level of precision. Because this monitoring system is not capable of determining adjacency, a visual inspection would have to be made to determine whether or not the failed lights are adjacent. There is individual lamp monitoring technology currently available; the system manufacturer must be consulted for the application of this technology.

5-6.7 Compliance with International Standards.

Previous AFIC AIR STDs and current NATO STANAGs contain no comparable systems.

CHAPTER 6 STANDARDS FOR OBSTRUCTION LIGHTING

6-1 PURPOSE.

Obstruction lighting defines the vertical and horizontal limits of natural or manmade objects which are considered a hazard to air navigation. Typical examples of various obstruction lighting arrangements are shown in Figure 6-1, Figure 6-2, Figure 6-3 and Figure 6-4.

6-2 OBJECTS TO BE LIGHTED.

6.2.1 Permanent Structures.

Objects that penetrate the planes and surfaces defined in UFC 3-260-01 are hazards to air navigation and must have obstruction lights installed. Other objects, which are hazards due to their nature or location even though they do not penetrate the planes and surfaces, as defined above, must also be lighted. This includes obstructions that affect TERPS criteria. Construction or objects which may impact navigable airspace under the provisions of FAR Part 77 are also subject to the administrative procedures in FAA AC 70/7460-1 for determining obstruction marking and lighting requirements. Also, obstruction lighting is required on the facilities and other obstructions along the periphery of the Building Restriction Line defined in UFC 3-260-01.

6.2.2 Temporary Structures.

For marking and lighting of *temporary structures*, See AC 70/7460-1, added Chapter 14, *Marking and Lighting Temporary Structures*, and associated figures in the FAA Appendix, Figures A-31 through A-33.

6-3 LIGHTING CONFIGURATION.

The number and arrangement of obstruction lights must ensure unobstructed visibility of one or more lights from an aircraft at any normal angle of approach. Arrange obstruction lights per FAA AC 70/7460-1.

Figure 6-1 Obstruction Light Configuration, Height up to 350 Feet (105 Meters)

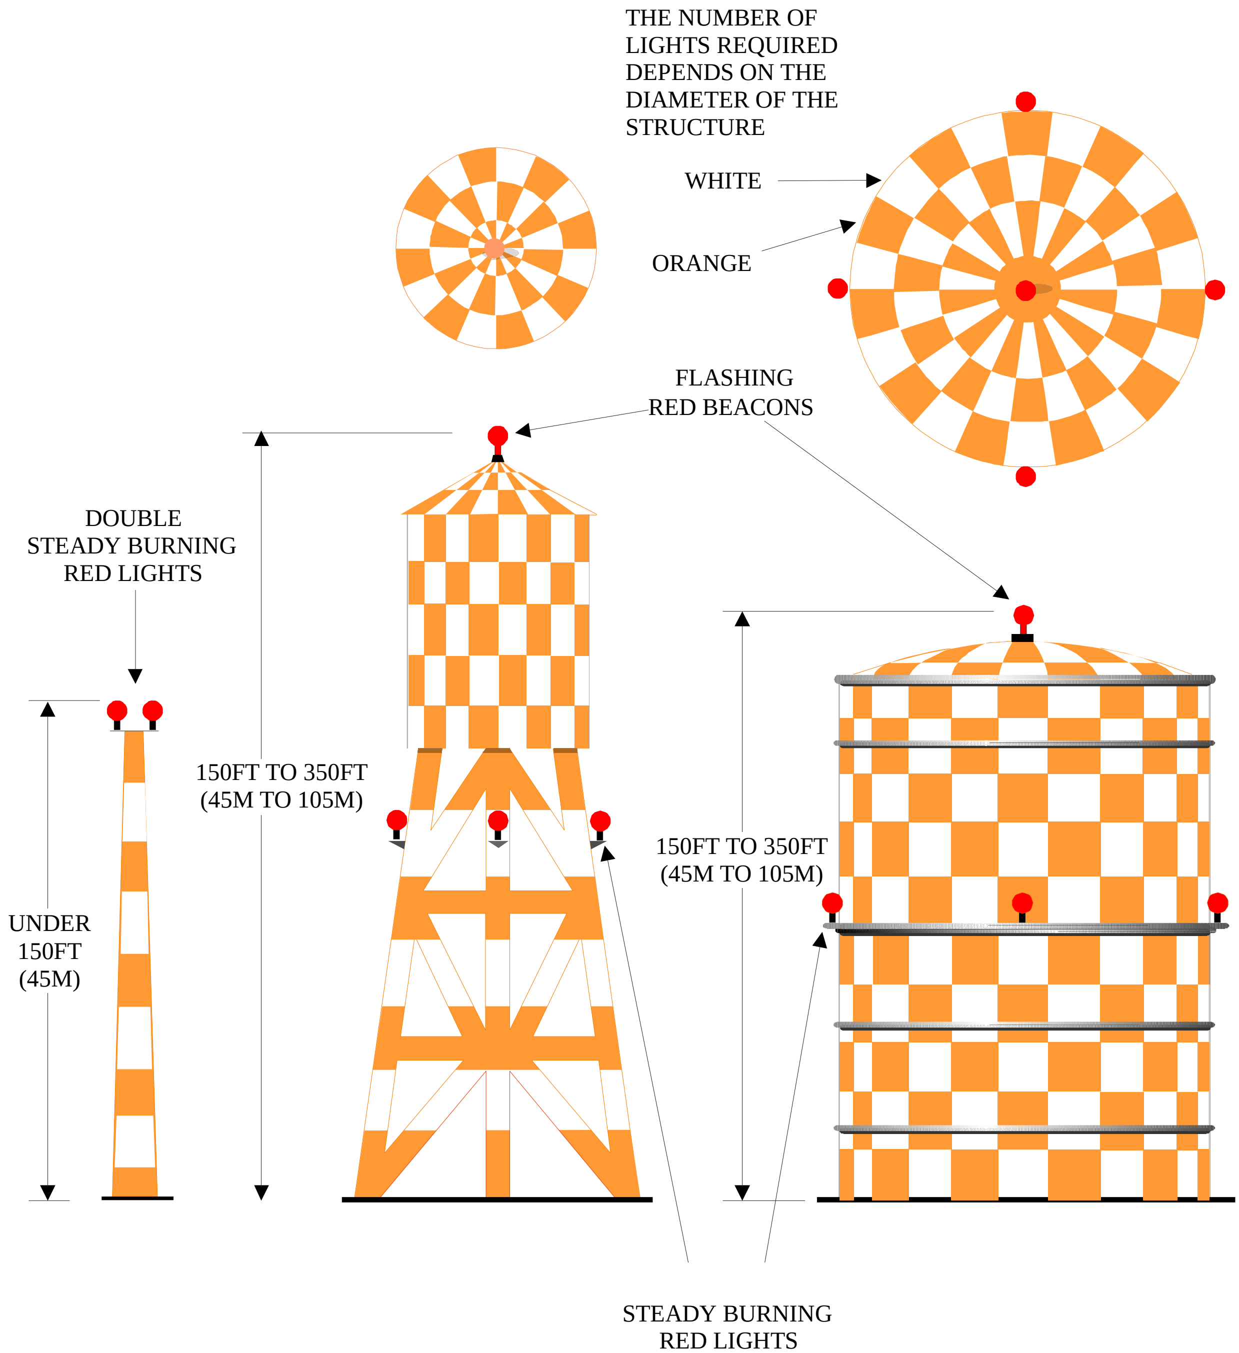


Figure 6-2 Obstruction Light Configuration Height 150 to 350 Feet (45 to 105 Meters)

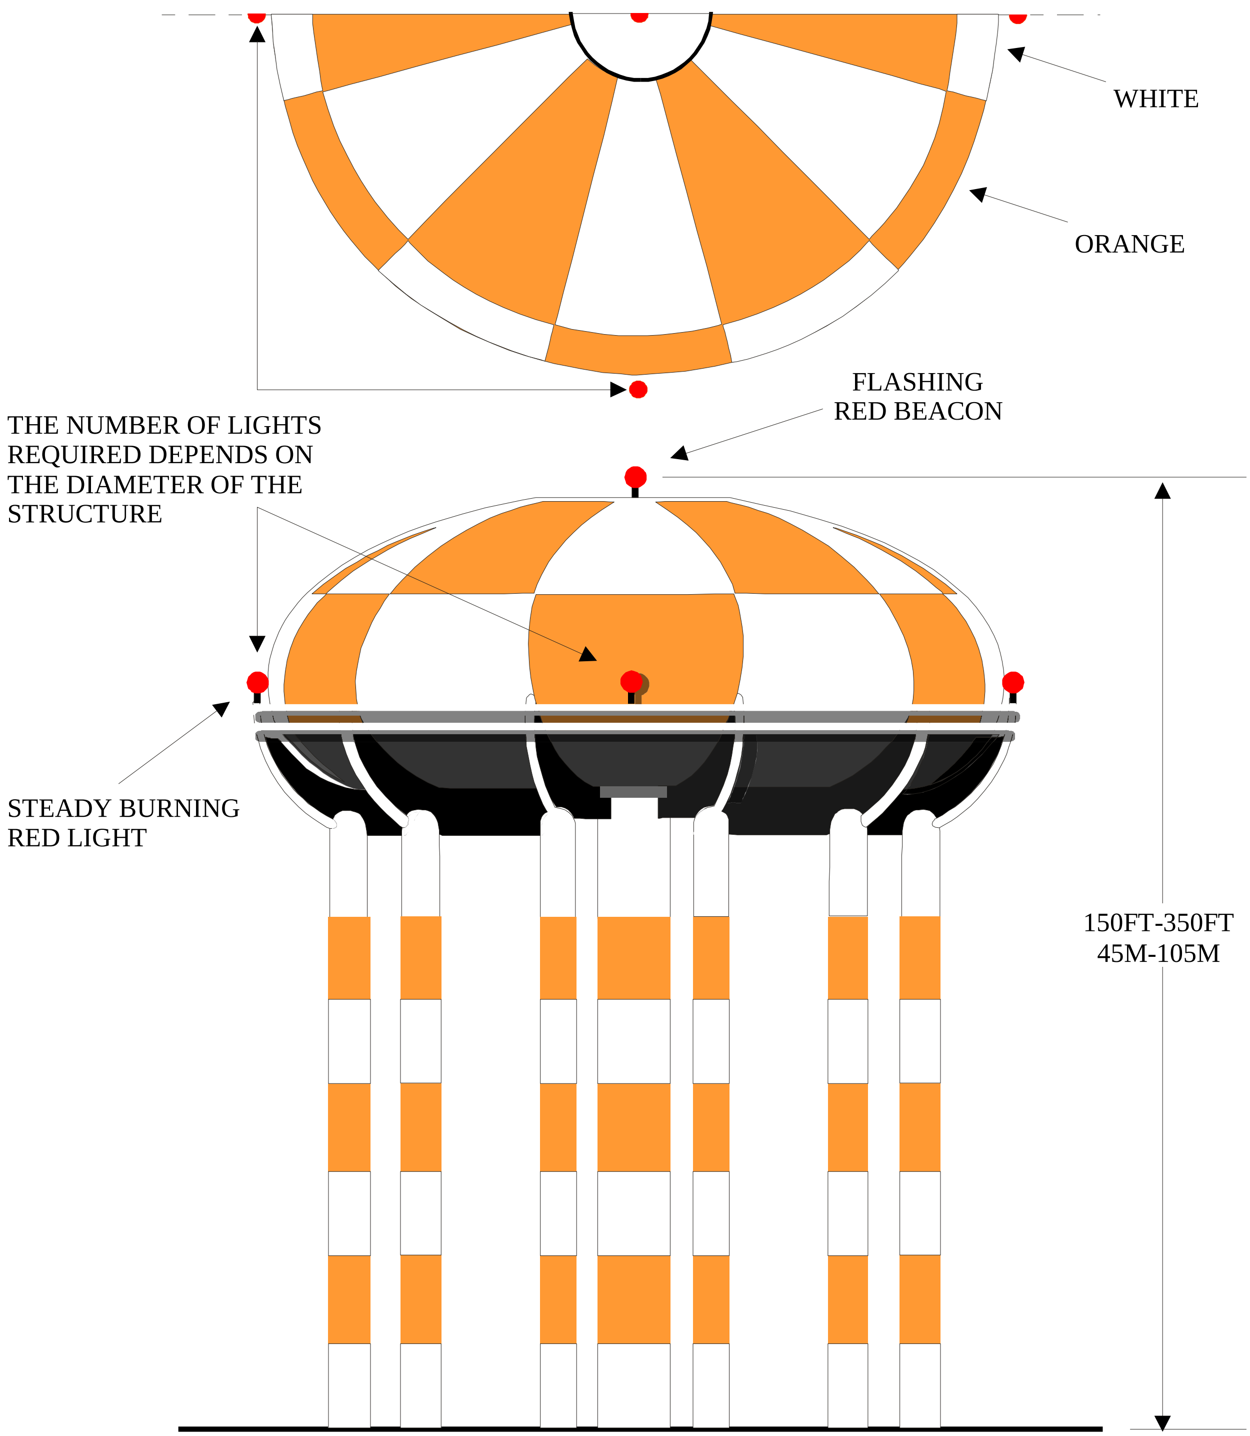

Figure 6-3 Obstruction Light Configuration Height 350 to 700 Feet (105 to 210 Meters)

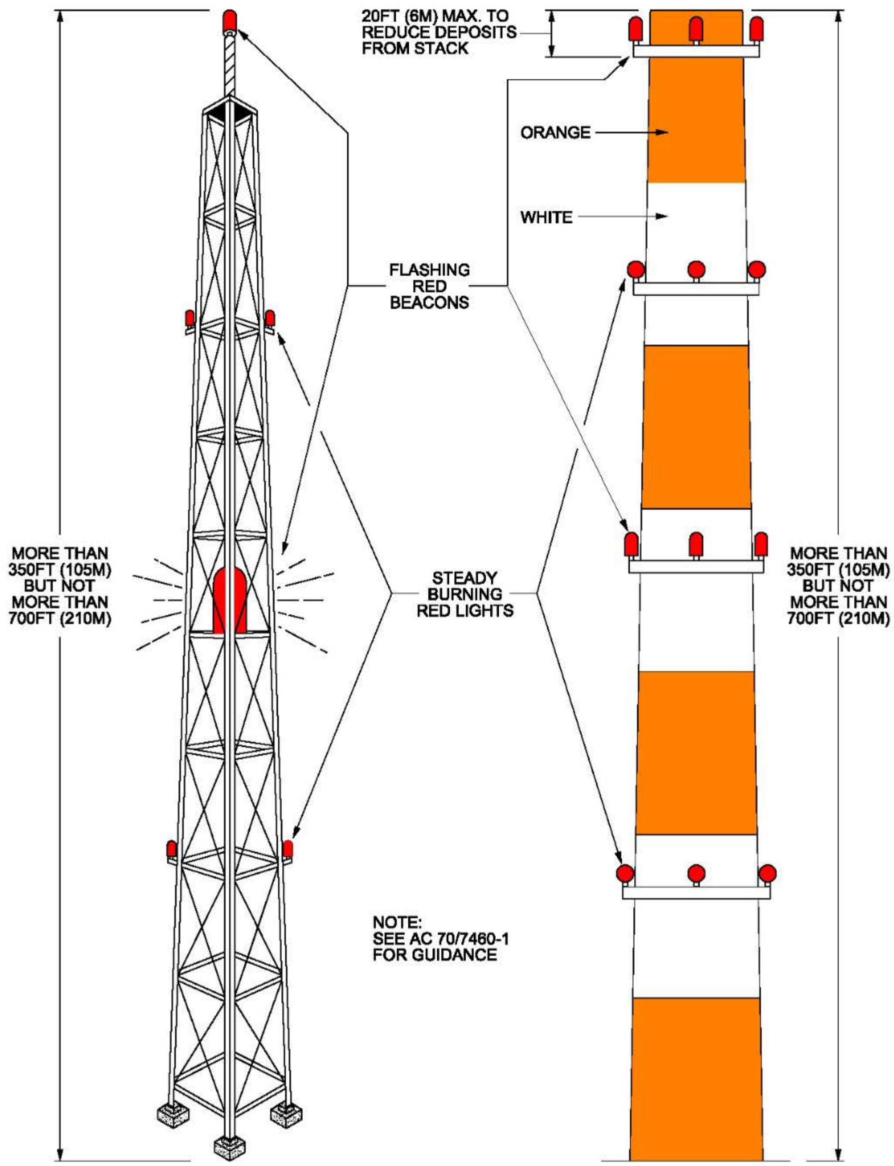

Figure 6-4 Obstruction Lights on Buildings

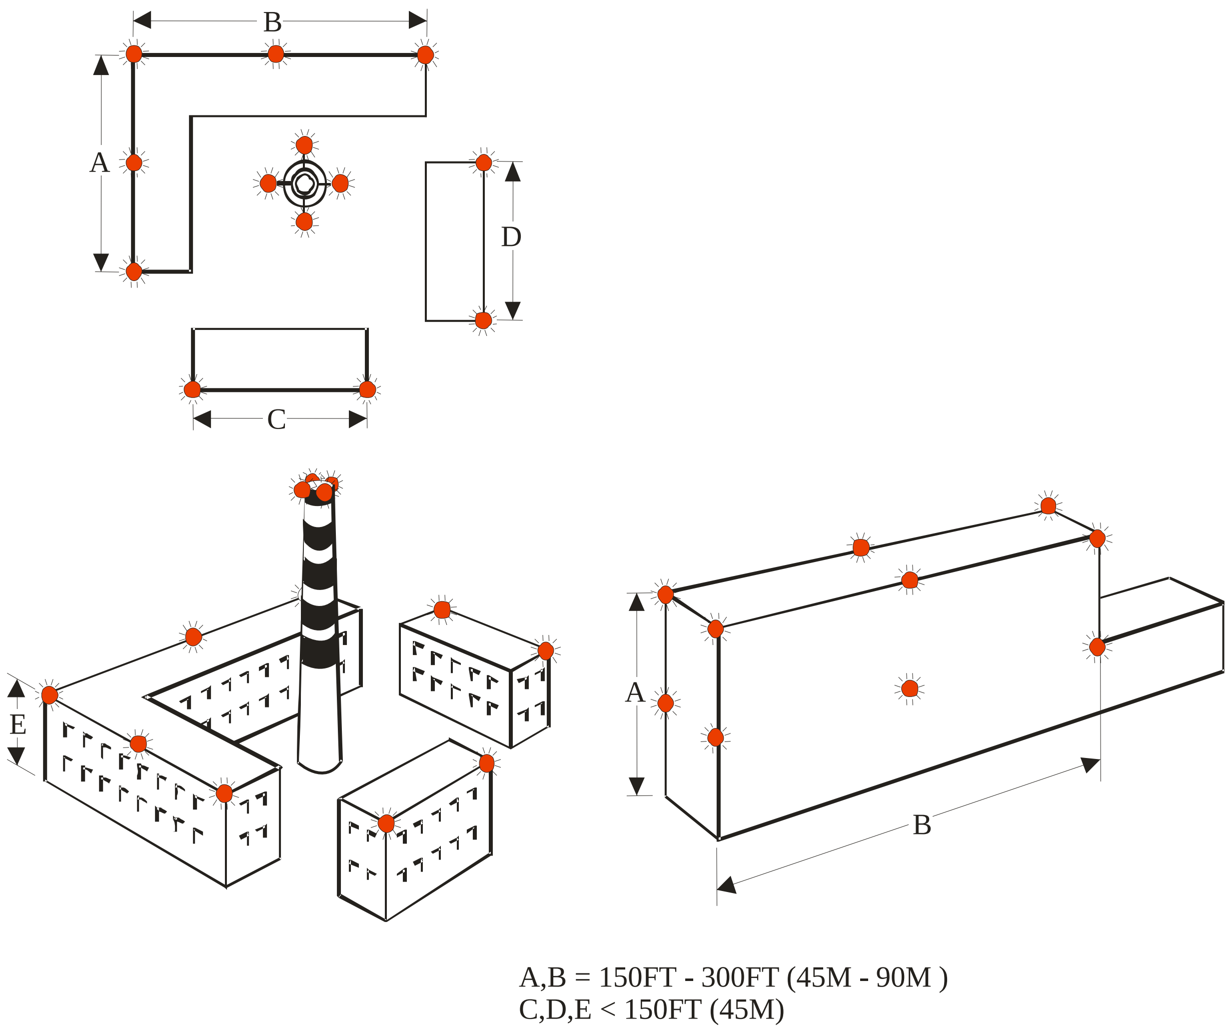

6-4 LIGHTING VERSUS DAY MARKING.

Flashing white obstruction lighting may be used instead of obstruction marking on structures less than 200 feet (60 meters) tall with major command approval. Do not install these lights in clear zones or on objects in the immediate vicinity of runways where approaching pilots may mistake them for other flashing white lights.

6-5 WAIVERS.

The military component decision to waive obstruction lighting requirements must be coordinated with appropriate civil aviation authorities to ensure there is no negative impact to civil aviation. (See paragraph 1-11 for Air Force waivers and paragraph 1-12 for US Army waivers.)

6-6 EQUIPMENT.

The equipment shown meets the requirements of the FAA.

6-6.1 LED-Based Obstruction Lights.

\4 On Air Force bases, LED-based obstruction lights with integral IR emitters are allowed on weather equipment and NAVAIDs under 35 feet with agreement from Airfield Management.

On Army airfields and posts, obstruction lights may be incandescent or LED. If LED obstruction lights are used, they must have an integral IR emitter. **/4/**

6-7 POWER REQUIREMENTS.

Depending on the equipment installed, the power is usually 120/240 volts AC. Emergency power is not a requirement but is desirable if readily available.

6-7.1 Intensity Requirements.

See FAA AC 150/5345-43 for required obstruction light photometric characteristics.

6-8 CONTROL REQUIREMENTS.

6-8.1 Obstruction Lights

Obstruction lights intended for day marking must remain on at all times and have automatically selected reduced intensity levels for night operations. Other obstruction lights must be on when the northern sky illumination falls on a vertical surface to a level of not less than 35 footcandles (350 lux), or during daytime, when visibility is restricted. The lights may be turned off when the northern sky illuminance rises to a level of 58 footcandles (580 lux) or more. If practicable, obstruction lights should be controlled from the airfield lighting control panel. Otherwise use automatic controls and provide an auxiliary manual control (that can be locked) at ground level on the exterior of the object to be lighted.

For Flashing White Obstruction Lighting Systems, comply with paragraph 3.3.5 of AC 150/5345-43.

Equipment with solid state devices must be designed to withstand and/or include separate surge protective devices that are tested against defined waveforms per IEEE C62.41-1991, Table 4, Location Category C1 for single phase modes (line to ground, line to neutral, line, and neutral to ground). Note: Does not apply to DC powered systems.

6-8.2 Dual Lighting.

See FAA AC 70/7460-1 for information and requirements about dual lighting systems that use red lights for night operation and white medium or high intensity lights for day operation.

6-9 MONITORING REQUIREMENTS.

Obstruction lights should be visually observed for proper operation at least once each 24 hours. If the lighting cannot be readily observed, provide a remote monitoring system to indicate the malfunction of all the top lights and any flashing or rotating beacons regardless of their position.

6-10 COMPLIANCE WITH INTERNATIONAL STANDARDS.

6-10.1 NATO.

These standards meet the requirements of STANAG 3346 (Edition 7) – Marking and Lighting of Airfield Obstructions, 26 November 2012, except for the use of high intensity white lights.

6-10.2 AFIC.

AFIC AIR STD 90/19 is cancelled.

This Page Intentionally Left Blank

CHAPTER 7 STANDARDS FOR LIGHTING HELIPADS

7-1 GENERAL DESCRIPTION.

Helipad lighting defines the helicopter landing pad during operations at night and during periods of poor visibility. It is used for single helicopter landing pads. For heliport and helicopter landing lanes lighting system criteria, refer to Chapter 8.

7-2 HELIPAD PERIMETER LIGHTS.

7-2.1 Purpose.

Perimeter lights provide visual cues to pilots for identifying the safe operational limits of the helipad during takeoff, landing or hover operations.

7-2.2 Standard Perimeter Light Configuration.

Place aviation yellow, omnidirectional lights at each corner of the helipad, with three more lights spaced equally along each side between the corner lights. Lights on opposite sides of the helipad must be opposite each other. They must be equidistant and parallel to the extended centerlines of the helipad. They are usually located on the perimeter of the helipad, but may be placed not more than 7.5 feet (2.25 meters) away from the edge of the pad. In-pavement (FAA L-852E) fixtures must be used where taxiing of wheeled helicopters, skid mounted helicopters or other vehicular traffic is required. Elevated light fixtures (FAA L-861) should preferably be 14 inches (350 millimeters) maximum. Elevated light fixtures may be used where only approach and departure procedures are conducted. (See Figure 7-1.)

7-2.3 Hospital Pad Perimeter Light Configuration.

The lighting of a hospital helipad is the same as the standard helipad perimeter lights in paragraph 7-2.2, except there are additional wing lights located on the geometric centerlines of the helipad at a distance of 25 feet (7.5 meters), as shown in Figure 7-2, outboard of the existing perimeter light fittings.

7-3 HELIPAD VFR LANDING DIRECTION AND APPROACH LIGHTS.

These lights are installed to indicate a specific landing direction, in the procedure for touchdown or hover at the helipad.

Figure 7-1 Helipad Perimeter Lights, Standard Configuration

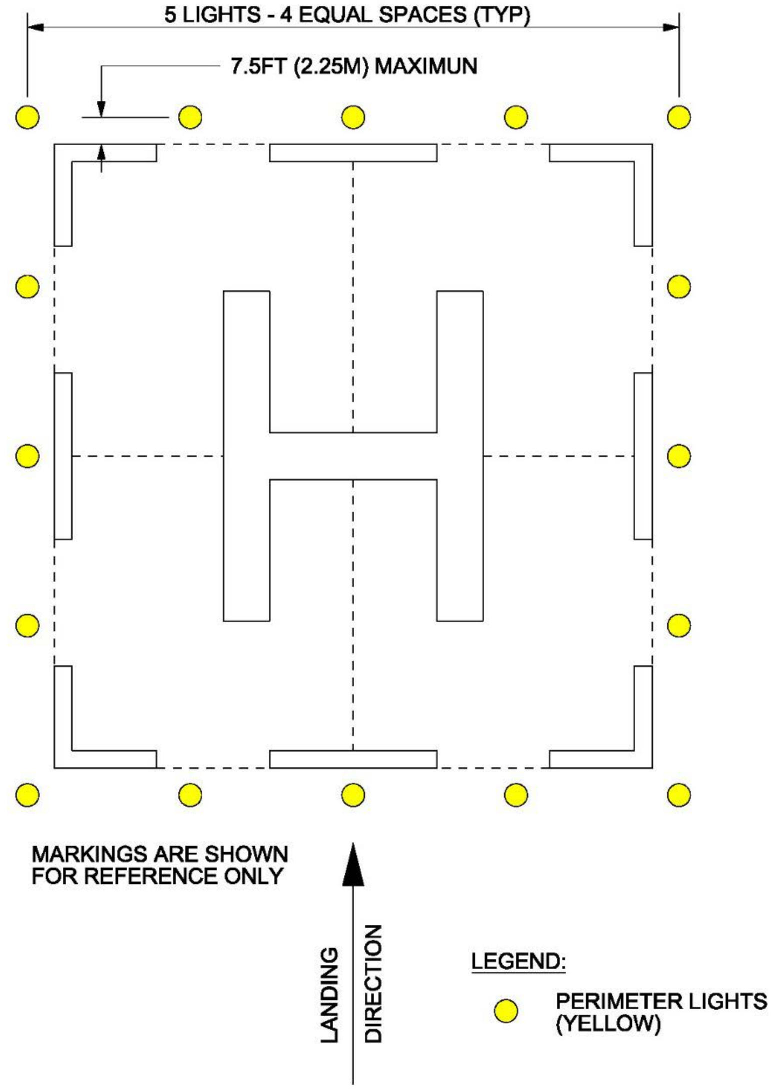

Figure 7-2 Helipad Perimeter Lights, Hospital Configuration

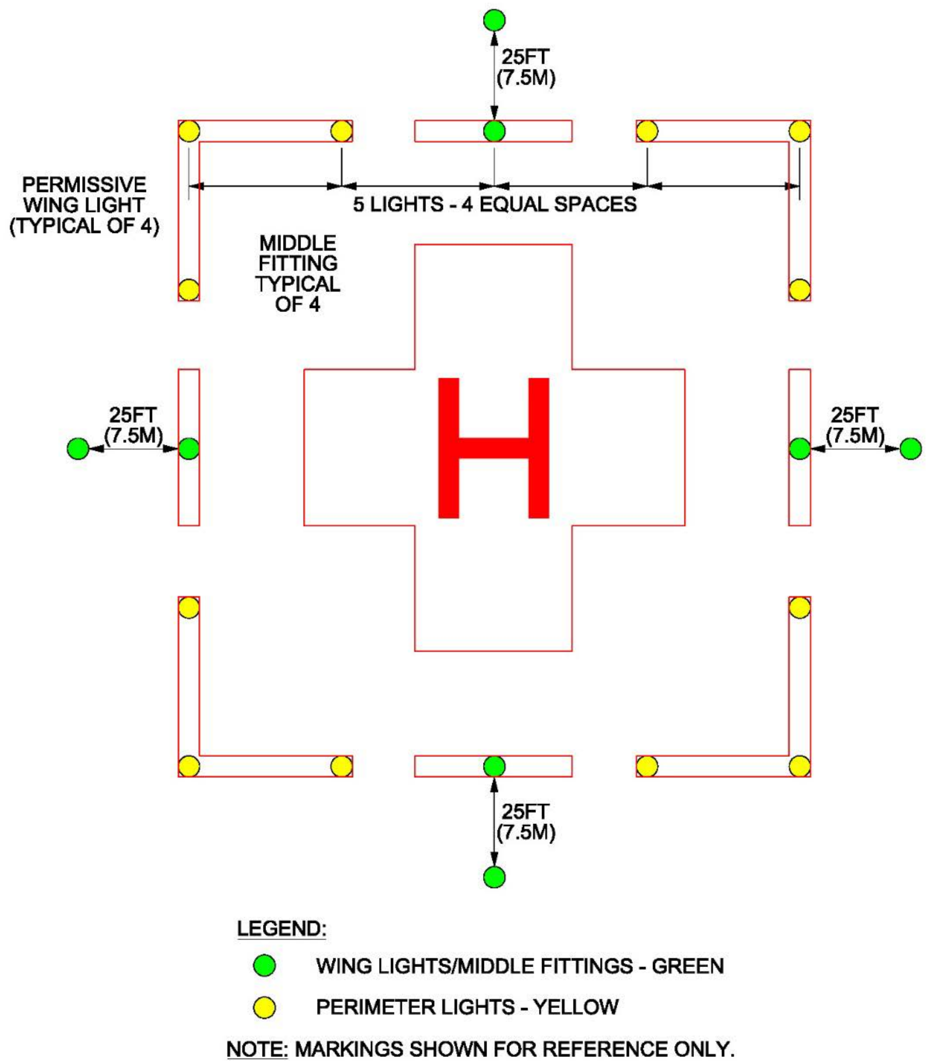
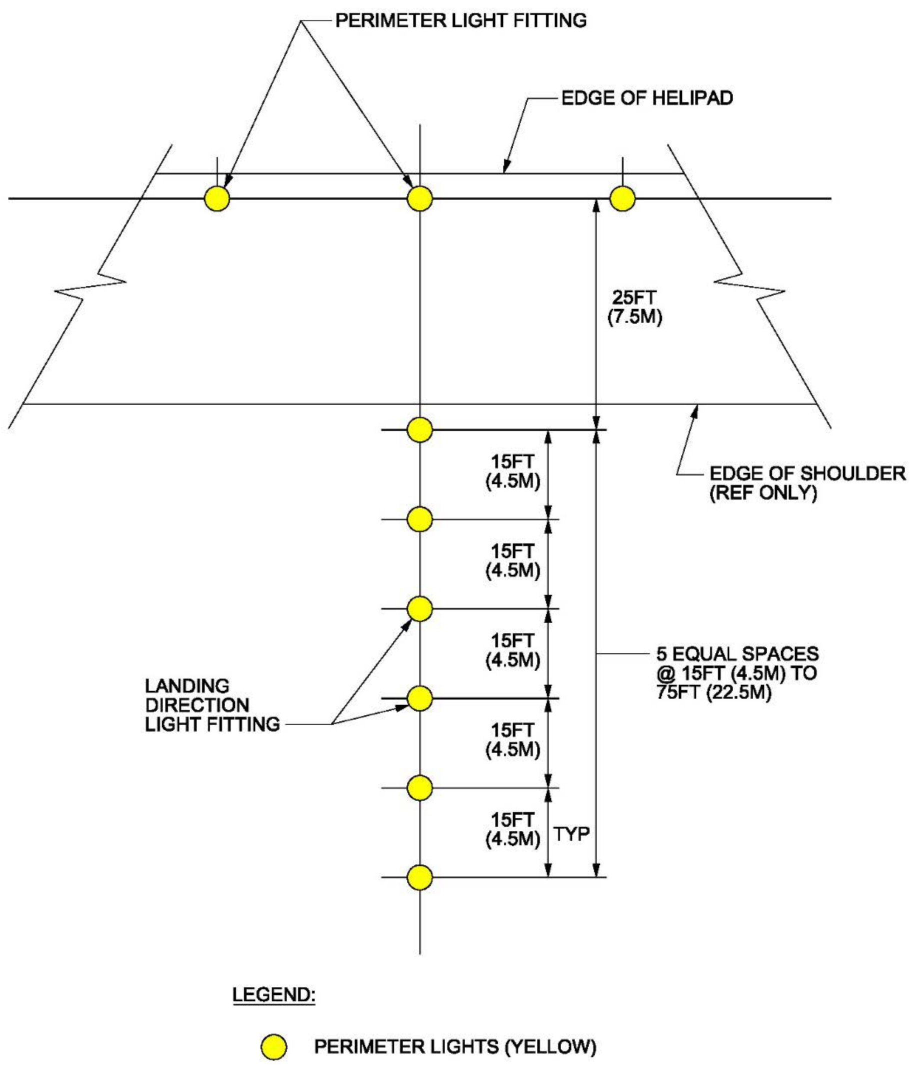


7-3.1 Configuration of Landing Direction Lights.

Provide aviation yellow omnidirectional lights (FAA L-861) in a straight line along one or more of the centerlines of the helipad, extended, and perpendicular to the perimeter lights. They must consist of six lights spaced 15 feet (4.5 meters) apart and starting 25 feet (7.5 meters) from the middle perimeter light. Locate the lights in a horizontal plane. (If a deviation is necessary, a tolerance of plus 2 percent or minus 1 percent in the longitudinal slope is permitted.) Use elevated fixtures on frangible supports, except use in-pavement fixtures when taxiing is a requirement. (See Figure 7-3.)

Figure 7-3 VFR Helipad Landing Direction Lights



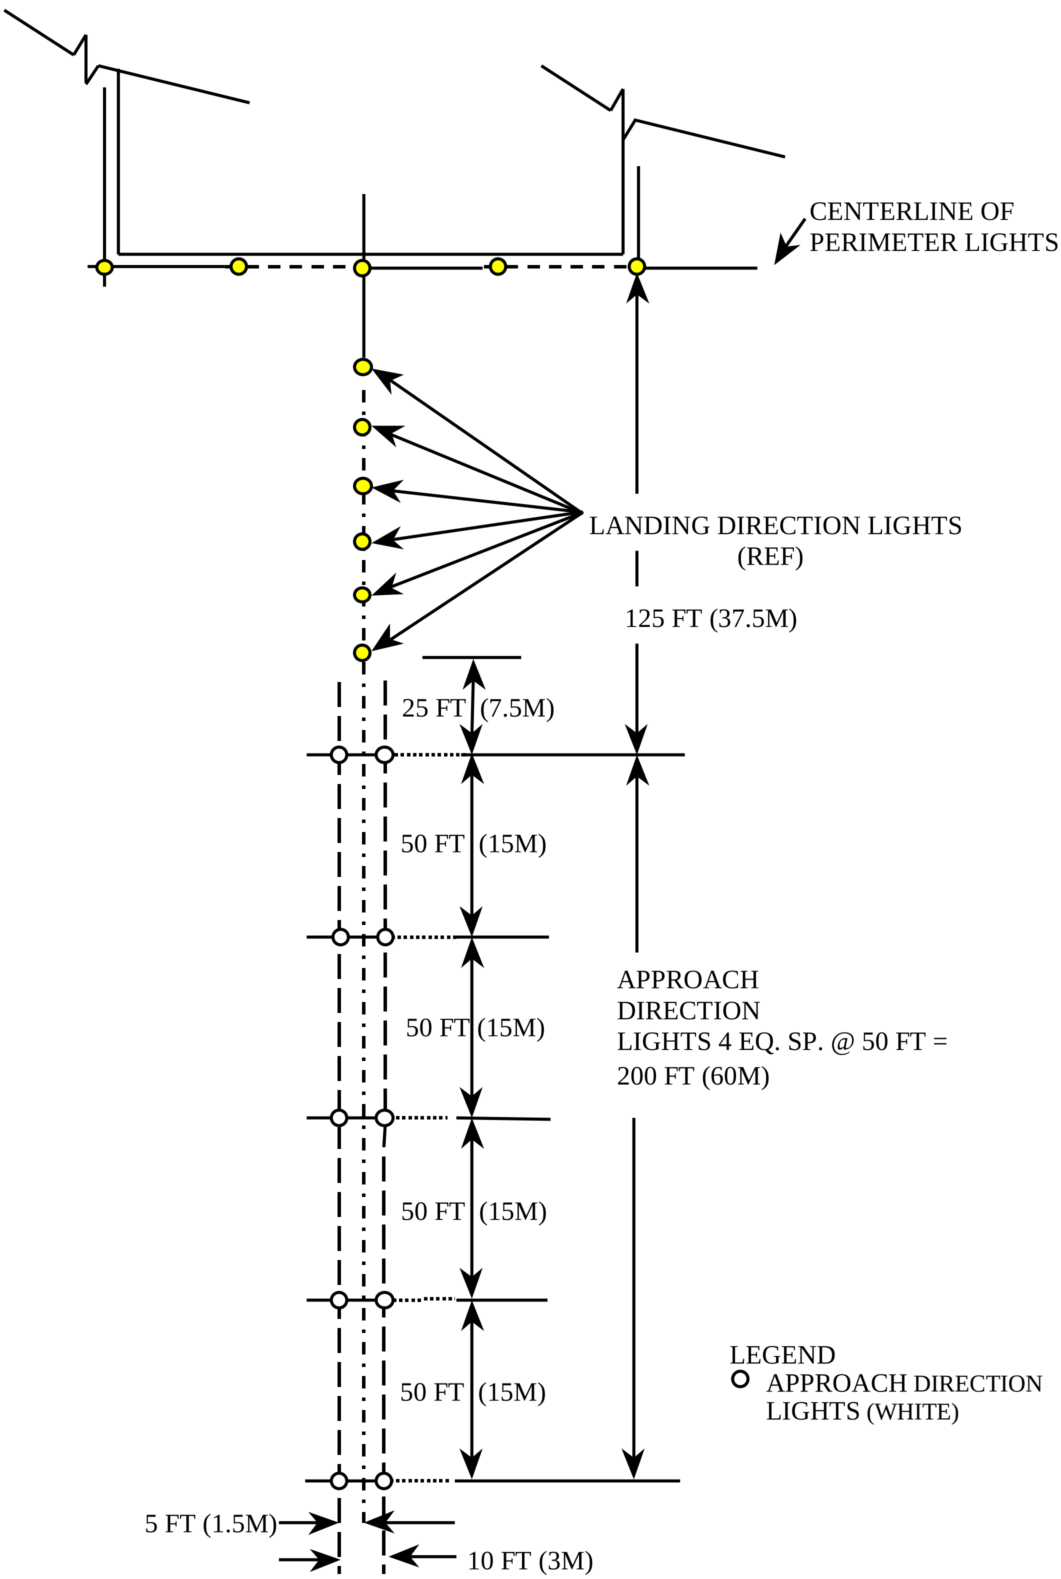
7-3.2 Purpose of Approach Direction Lights.

These lights are installed to provide approach guidance in order to restrict the path of approach to the helipad or when additional guidance is needed by the pilots.

7-3.2.1 Configuration of Approach Direction Lights.

Provide aviation white, unidirectional lights in two parallel rows extending out from the landing direction lights. Each row must consist of five lights spaced 50 feet (15 meters) apart, starting 125 feet (37.5 meters) from the perimeter lights and offset 5 feet (1.5 meters) either side of the extended centerline of the landing direction lights. The slope of the approach direction lights must be the same as that used for the landing direction lights. (See Figure 7-4.)

Figure 7-4 Helipad VFR Approach Direction Lights



7-3.3 Helipad IMC Approach Lights Category I.

7-3.3.1 Purpose.

These lights provide additional approach guidance for instrument meteorological conditions, with a decision height of 200 feet (60 meters) and an RVR of 2,400 feet (720 meters).

7-3.3.2 Configuration of IMC Approach Lights.

The approach lighting system will be symmetrical about, and extend for the entire length of, the centerline of the helipad direction lights. This additional light system starts at the position of the approach direction lights, shown in Figure 7-3, at 125 feet (37.5 meters) from the helipad and extending out to 1,025 feet (307.5 meters), shown in Figure 7-5.

7-4 REFUELING AREA LIGHTS.

Refueling areas are class 1, division 1, group D hazardous locations as defined in NFPA 70 National Electrical Code. See paragraphs 8-4 and 8-6.5 for more information.

7-5 HELIPAD FLOODLIGHTS.

7-5.1 Purpose.

Helipad floodlights illuminate the helipad surface at night to provide visual cues to the pilot for determining his height above the surface during the touchdown phase of his approach. To prevent interference with or damage to an aircraft, the helipad floodlights must be as close to grade as practical and have frangible couplings. The floodlights must provide a uniform illumination of the helipad surface. When installed, the fixtures must not permit any direct light to be visible above the horizontal. The fixtures emit a narrow fan-shaped illuminating beam for which the axis of the beam must be adjustable in elevation between 1 degree up and 5 degrees from horizontal. Another purpose is for ground operations on a helipad where access to a lighted apron is not available for loading or unloading of equipment or personnel. A typical application would be a helipad located near a hospital or headquarters building.

7-5.2 Configuration.

Locate these lights a minimum of 16 feet (4.8 meters) beyond the edges of the helipad on two opposite sides, parallel to the normal approach to the helipad. Mount the floodlights not over 16 inches (400 millimeters) above the grade of the helipad with a small obstruction light at each floodlight visible from any direction. The number of floodlights installed depends on the size of the helipad and the light output of the fixtures used. (See Figure 7-6.)

Figure 7-5 Approach Lights Category I

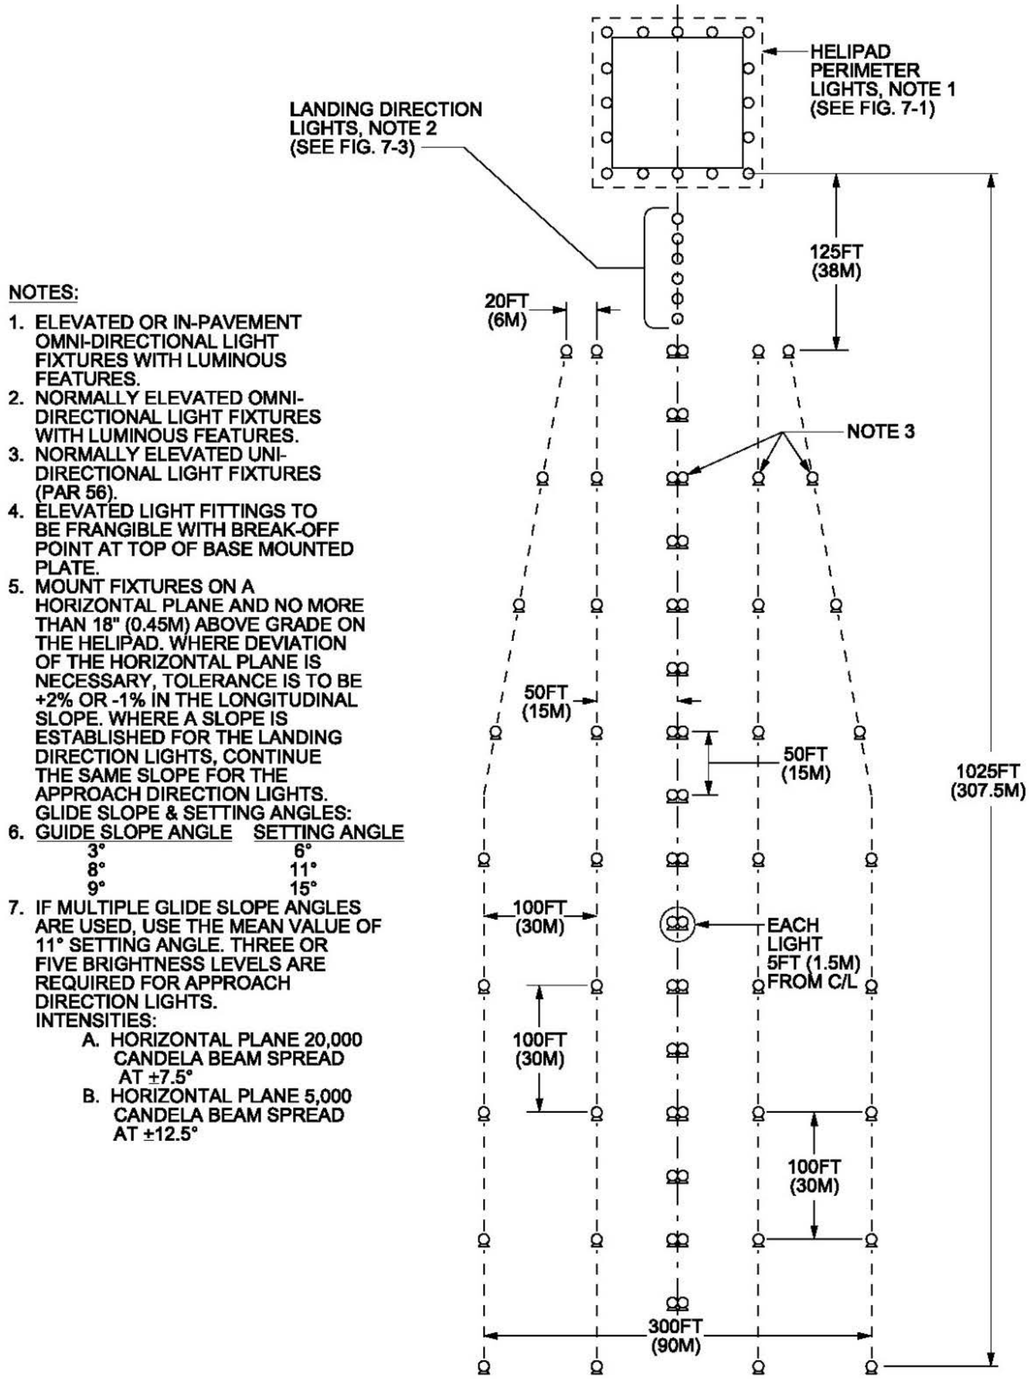


Figure 7-6 Helipad Floodlight Typical Configuration

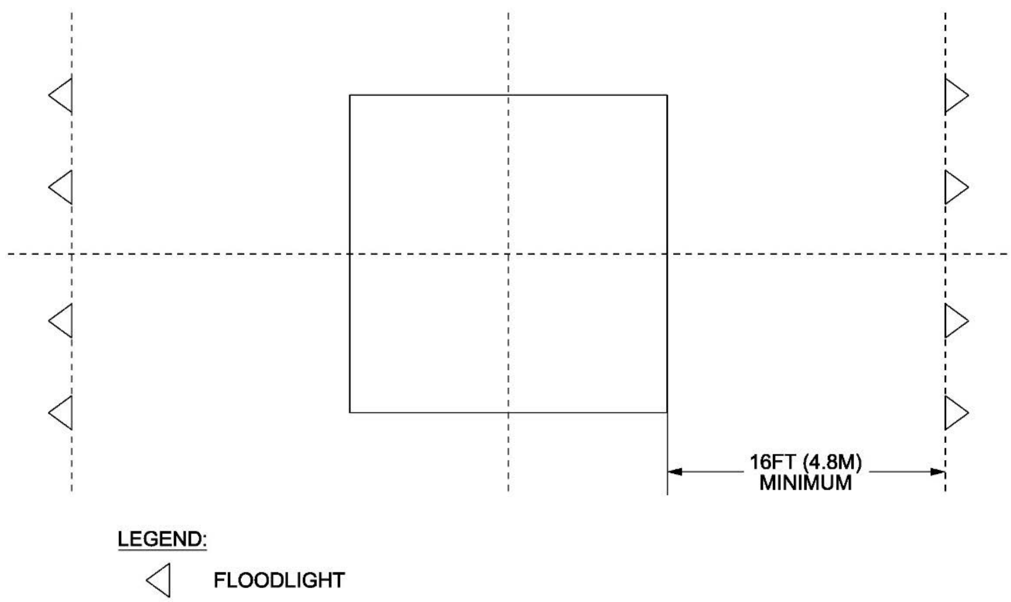


7-5.3 Helipad Refueling Floodlights.

Helipad refueling floodlights are class 1, division 1, group D hazardous locations, as defined in NFPA 70 National Electrical Code. See paragraphs 8-4 and 8-6.5 for more information.

7-6 HELIPAD APPROACH SLOPE INDICATOR.

7-6.1 Purpose.

A visual glide slope indicator should be provided for a helipad when obstacle clearance, noise abatement or traffic control procedures require a particular approach slope angle be flown, when the environment of a helipad provides few visual cues, or when the characteristics of a particular helicopter requires a stabilized approach path. The preferred system is CHAPI. An FAA L-881 2-light housing assembly PAPI system is optional.

\4

7-6.2 Justification.

A Visual Glide Slope Indicator System shall be provided to serve the approach whether or not there are other visual approach aids or by non-visual aids where one or more of the following conditions exist, especially at night:

7-6.2.1 Obstacle clearance, noise abatement or traffic control procedures require a particular slope to be flown.

7-6.2.2 The characteristics of the helicopter required a stabilized approach.

7-6.2.3 The pilot of any type of aircraft may have difficulty judging the approach due to inadequate visual guidance that may be experienced during an approach over water or featureless terrain by day, or in the absence of sufficient extraneous lights in the approach area by night.

7-6.2.5 If judging the approach is difficult due to misleading information produced by deceptive surrounding terrain or runway slopes. The presence of objects in the approach area may present a serious hazard if an aircraft descends below the normal approach path, especially if there are no navigation aids to give warning of these objects.

7-6.2.6 Physical conditions at either end of the runway present a serious hazard in the event of an aircraft undershooting or overrunning the runway.

7-6.2.7 Terrain or prevalent meteorological conditions are such that the aircraft may be subjected to unusual turbulence during approach.

7-6.2.8 If a stabilized approach is required due to the possible medical condition of patients that will be transported to a hospital.

7-6.3 Configuration.

The CHAPI system consists of two transition light units projecting red/green/white lights. They are located forward of the helipad on the extended centerline at a distance determined in order to project an on glide path angle (usually 6 degrees) at the helipad hover point prior to touchdown. The glide slope must be determined based on the site conditions. The glide slope angle must provide a minimum of 1 degree above obstructions from the lowest on-course visual signal. For precision approaches, the glide slope of the CHAPI must be must be consistent with the approach lighting system, instrument landing system (ILS), or other electronic NAVAID. The units are positioned at approximately 20 feet (6 meters) apart lateral (horizontal). The CHAPI system must be constructed and mounted as low as possible and be sufficiently lightweight and frangible so as not to constitute a hazard to helicopter operations. **/4/**

7-7 HELIPAD BEACON.

7-7.1 Purpose.

A helipad beacon provides long-range guidance and helipad identification.

7-7.2 Configuration.

The beacon must contain a sequence of three lights. For Army or Air Force medical facilities – double-peaked white, a single green, and a single red. For all other facilities – double-peaked white, a single green, and a single yellow. For Navy medical facilities – double-peaked white, green, yellow as per NAVAIR 51-50AAA-2. The flash must be 10 to 15 sequences of flashes per minute. The time between each color should be one-third of the total sequence time. The beacon should not be installed within 1 mile (1.6 km) of any existing airport beacon or other helipad area.

7-7.3 Construction.

The beacon should be visible for a distance of 1 mile (1.6 kilometers) in 1 mile (1.6 kilometer) VMC visibility daylight, and 3 miles (4.8 kilometers) in 3 mile (4.8 kilometer) VMC at night, both from an altitude of 3,000 feet (900 meters) above ground level. The beacon should be mounted a minimum of 50 feet (15 meters) above the helipad surface. Where a control tower or control area is utilized the beacon should be no closer than 400 feet (120 meters), nor further than 3,500 feet (1,050 meters), from that area, and not located between the control tower and the helipad. The beacon will be installed so that the base is not less than 15 feet (5 meters) above the floor of the control tower or operations room.

7-7.4 Luminous Features.

The main beam of the light should be aimed a minimum of 5 degrees above the horizontal and should not produce light below the horizontal in excess of 1,000 candelas. Light shields may be used to reduce the intensity below the horizontal.

7-8 HELIPAD WIND DIRECTION INDICATORS.

7-8.1 Purpose.

Helipad wind direction indicators enhance operational capabilities, increase safety and reduce pilot workload during approach, hover and takeoff operations.

7-8.2 Configuration.

A helipad should be equipped with at least one wind direction indicator located in a position to indicate the wind conditions over the final approach and take-off area. The wind indicator must be free from the effects of air flow disturbances caused by nearby objects or rotor wash. It must be visible from a helicopter in flight, in a hover, or on the movement area. Where a helipad may be subject to a disturbed air flow, additional indicators located close to the area should be provided to indicate surface winds.

7-8.3 Construction.

A wind direction indicator must be constructed to give a clear indication of the wind direction and a general indication of the wind speed. An indicator should be a truncated cone made of light weight fabric. The approximate minimum dimensions are 8 feet (2.4 meters) long, 18 inches (450 millimeters) diameter (large end), and 12 inches (300 millimeters) diameter (small end). The color selected must make it clearly visible and understandable from a height of at least 650 feet (195 meters) above the helipad. When practical the preferred colors should be white or orange. Where it is necessary to provide adequate conspicuity against varied backgrounds, combined colors are permitted such as orange and white, red and white, or black and white.

7-8.4 Illumination.

A wind direction indicator intended for use at night must be illuminated, and have a red obstruction light mounted on the mast.

7-9 PHOTOMETRIC REQUIREMENTS.

7-9.1 Perimeter and Landing Direction Lights.

These lights must emit omnidirectional aviation yellow light with intensities as follows:

2 to 10 degrees vertical	37 cd min.	67 cd average
10 to 15 degrees vertical	20 cd min.	

7-9.1.1 A 25 percent reduction in light output is permitted at structural ribs on in-pavement lights.

7-9.2 Approach Direction Lights.

These lights must emit directional aviation white light with intensities as follows:

2 to 10 degrees vertical	5 cd min.	125 cd average
10 to 15 degrees vertical	40 cd min.	

7-9.2.1 A 25 percent reduction in light output is permitted at structural ribs of in-pavement lights.

7-9.3 Helipad Floodlights.

These fixtures must direct the entire output of the fixture below the horizontal. The minimum average luminance in the horizontal helipad surface must be 2 footcandles (20 lux) with a uniformity ratio (average to minimum) that should be not more than 4 to 1.

7-9.4 Helipad Beacons.

These lights are rotating or flashing lights. They must appear to an observer at any azimuth as a series of flashing lights coded white-green-yellow or white-green-red as applicable. The flash duration must be 75 to 300 milliseconds. The effective intensities of white light for vertical angles above the horizontal must be:

1 to 2 degrees	12,500 cd
2 to 8 degrees	25,000 cd
8 to 10 degrees	12,500 cd

The minimum intensities of the green must be 15 percent of those given for the white light, and the minimum effective intensities of the yellow flashes must be 40 percent of that given for the white light.

\4
7-9.5 CHAPI Systems.

The CHAPI light units are similar to a PAPI system (see paragraph 3-7.1), with the addition of a 2.0 degree wide green sector command path. The vertical color sectors for the CHAPI system are:

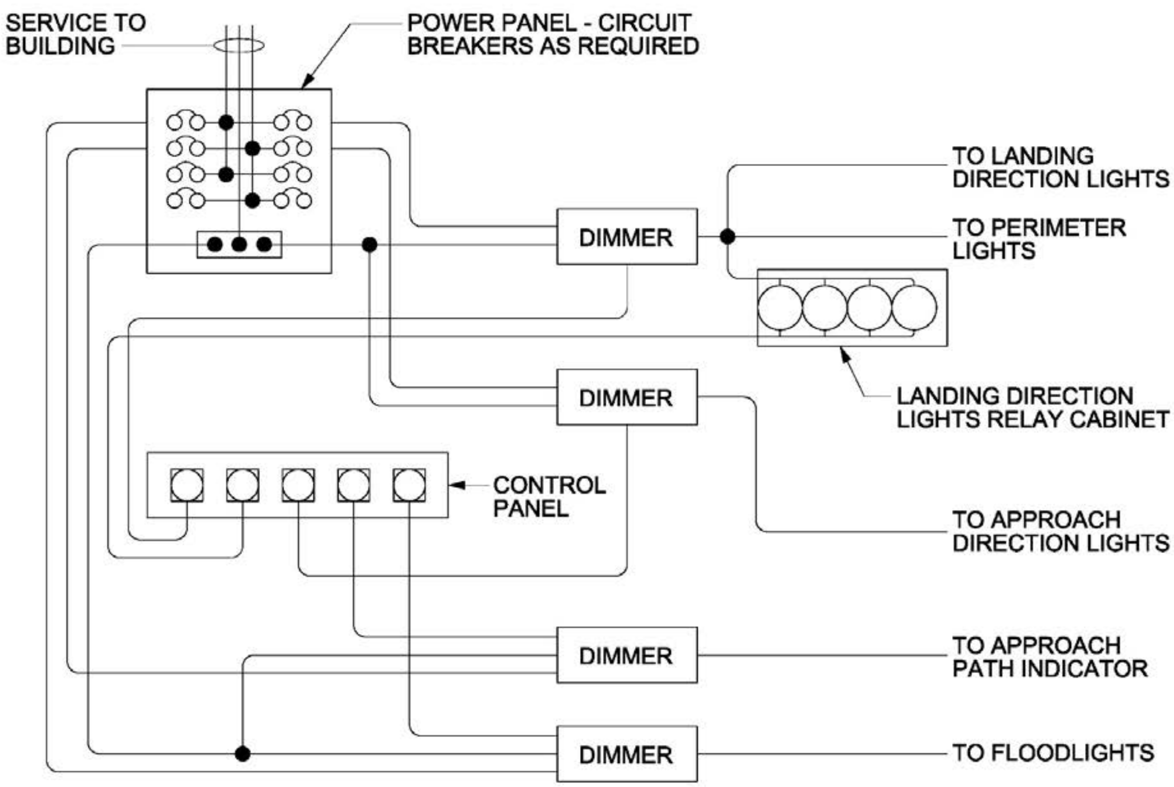
above course	7.5 degrees or more	W	W
slightly high	6.5 to 7.5 degrees	W	G
on course	6.0 degrees	G	G
slightly low	4.5 to 5.5 degrees	G	R
below course	4.5 degrees or less	R	R

Adjust the CHAPI to accommodate the required glide slope angle to provide 1.0 degrees between the approach departure clearance surface and the ‘below course’ signal. ***/4/***

7-10 POWER REQUIREMENTS.

Provide a main and an alternate power system with the capability to automatically transfer within 15 seconds from the system in use if a system fails. Typical lighting control diagrams for helipad lighting systems are shown in Figure 7-7 for systems without a control tower, and in Figure 7-8 with systems with a control tower.

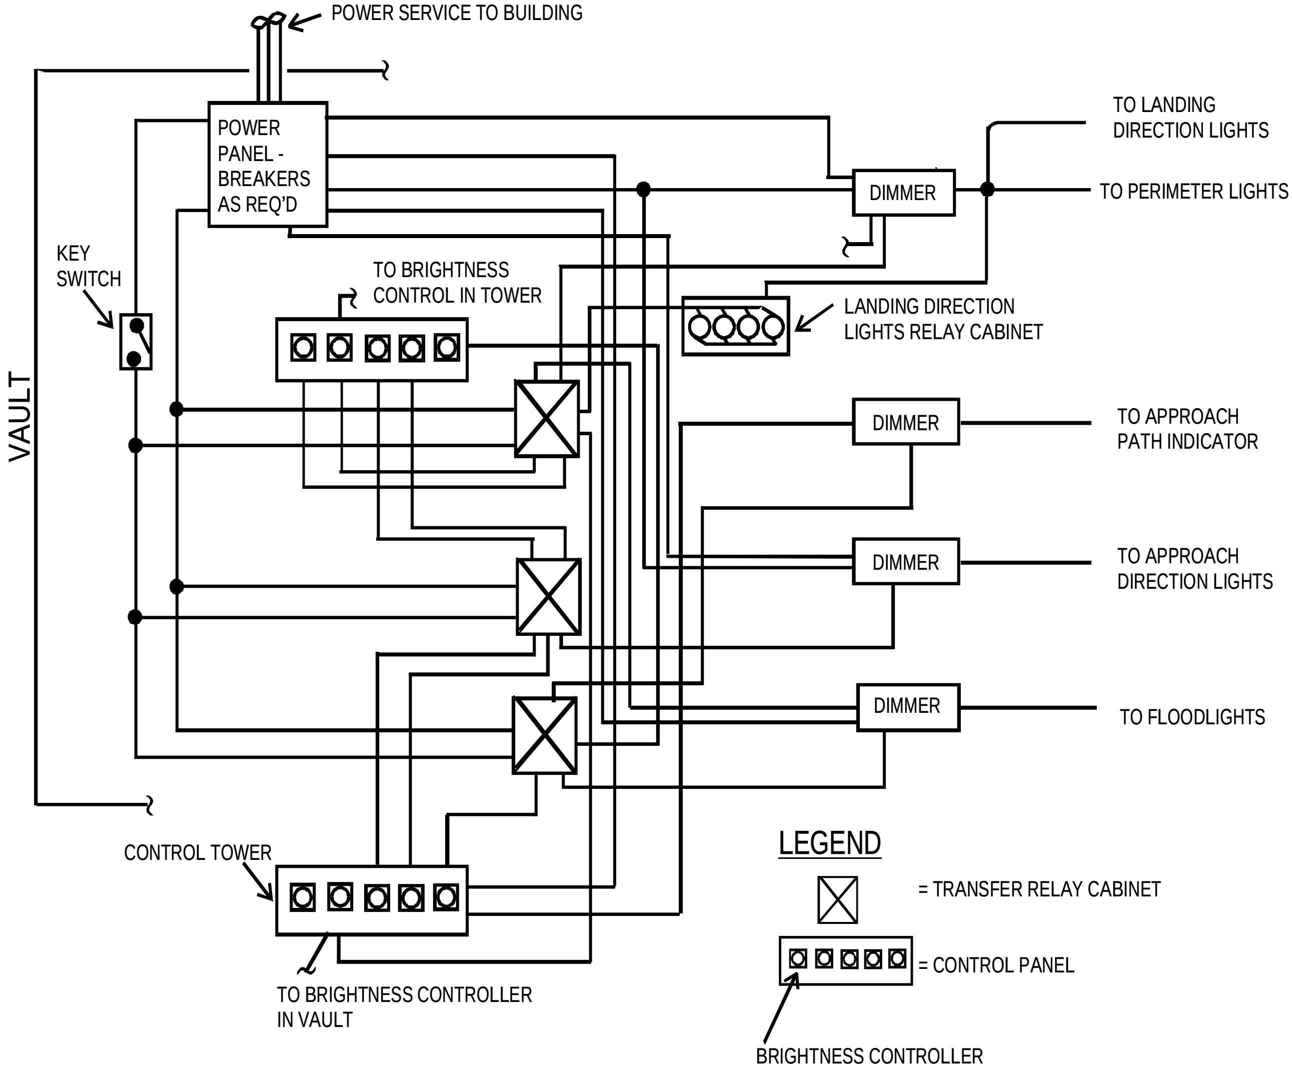
Figure 7-7 Block Diagram Without Tower



NOTE:

DELETE UNNEEDED COMPONENTS WHEN NOT USED IN THE HELIPAD LIGHTING SYSTEM.

Figure 7-8 Block Diagram with Tower



7-11 CONTROL REQUIREMENTS.

7-11.1 Perimeter Lights.

Provide on and off control and a three-step intensity control.

7-11.2 Landing Direction Lights.

Provide on and off control and a three-step intensity control. Interconnect the controls with the perimeter light controls to prevent operation without the perimeter lights being activated; however, they must have the capability of being independently turned off.

7-11.3 Approach Direction Lights.

Provide on and off control and a three-step intensity control. Interconnect the controls to the landing direction light circuit in order to prevent their operation unless the landing direction lights are activated; however, they must also be capable of being turned off independently. The intensity controls may be connected to the same regulator as the landing direction lights.

7-11.4 Helipad Floodlights.

\4 Helipad floodlights require on and off control. ***/4/***

7-11.5 Helipad Beacons.

Provide on and off control only.

7-11.6 CHAPI.

Provide on and off control and a minimum of three-step intensity control, similar to the PAPI system.

7-12 MONITORING REQUIREMENTS.

There are no requirements for monitoring helipad lighting systems.

7-13 COMPLIANCE WITH INTERNATIONAL STANDARDS.

7-13.1 AFIC.

Previous AFIC AIR STD 90/34 cancelled.

7-13.2 NATO.

These standards meet the requirements of STANAG 3619 (Edition 5) – Helipad Marking and Lighting, 6 June 2013.

7-14 EQUIPMENT.

See paragraph 13-14 for appropriate Helipad lighting equipment.

This Page Intentionally Left Blank

CHAPTER 8 STANDARDS FOR LIGHTING HELIPORTS

8-1 GENERAL DESCRIPTION.

8-1.1 Helicopter Runway

A helicopter runway is a prepared surface used for the approach and departure of rotary wing aircraft. It is not intended for use of fixed wing aircraft.

8-1.2 Design Criteria.

The design criteria set forth herein are intended to guide in designing and installing a permanent heliport lighting system utilizing elevated and in-pavement lights. Figure 8-1 illustrates a typical heliport having two 75 foot (22.5 meter) wide by 1,600 foot (480 meter) long intersecting runways with 40 foot (12 meter) wide connecting taxiways and 25 foot (7.5 meter) wide adjacent surface treated shoulders. Changes in the layout or design may be necessary to fit the requirements of a particular heliport runway installation, including a basic one runway configuration.

Figure 8-1 Layout Heliport Lighting

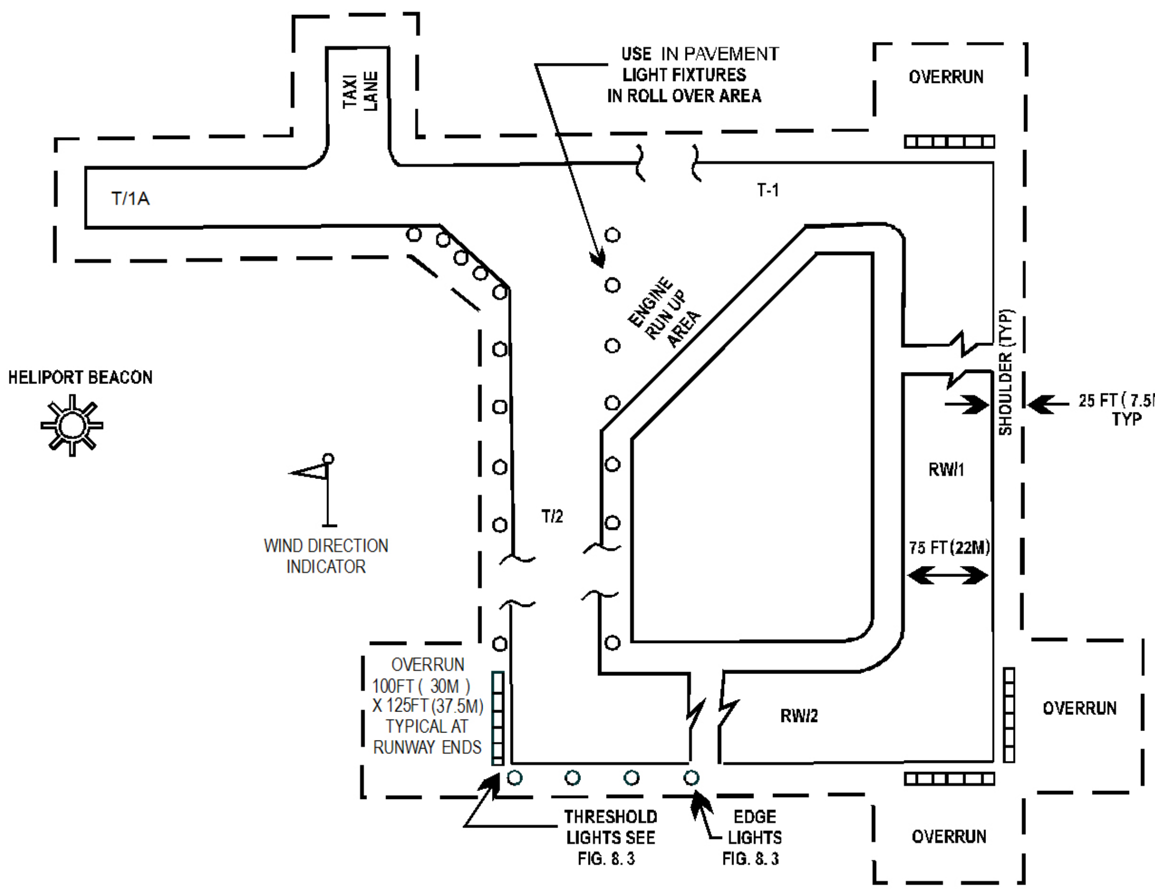


Figure 8-2 Rotary Wing Landing Lane

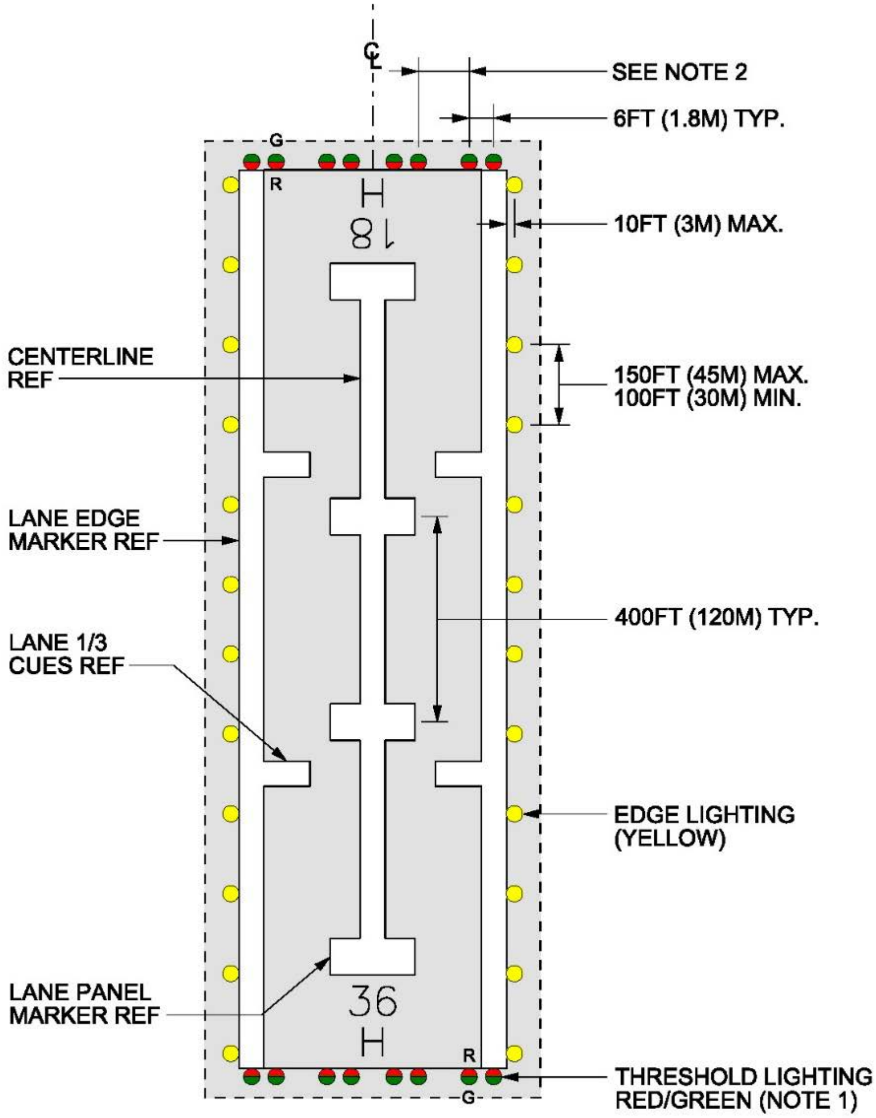

NOTES:

1. THRESHOLD LIGHTING MAY BE PLACED ON OR OFF THE PAVEMENT.
2. THE DISTANCE BETWEEN THE LIGHT GROUPS WILL VARY DEPENDING ON LANDING WIDTH. FOR EXAMPLE, 75FT (22.5M) = 17FT (5.1M) SPACING.

8-2 HELIPORT LIGHTS.

8-2.1 Runway Edge Lights (White).

The line of edge lights, aviation white, must be located on each side of a heliport runway, and not less than 5 feet (1.5 meters), nor more than 10 feet (3 meters) from the paved edge of the runway. The lights will be of the elevated type and will be uniformly spaced at 100 feet (30 meters).

8-2.2 Taxiway Edge Lights (Blue).

When a runway is also used as a taxiway, such as two runways at 90 degree intersections, where one of the runways leads to a taxiway opposite of the approach end, aviation blue taxiway lights will be installed in addition to the white lights. The line of blue lights will be spaced at 100 feet (30 meter) maximum intervals, between the white lights (Figure 8-3). Connect these blue lights to the appropriate intersecting taxiway circuit. The blue edge lights must not be ON when the white edge lights are ON (runway is active). Where only one runway is constructed, blue lights will not be installed. All lights, both white and blue, located in runway or taxiway intersections where subjected to rollover traffic will be the in-pavement type.

Figure 8-3 Heliport Threshold and Edge Light Details

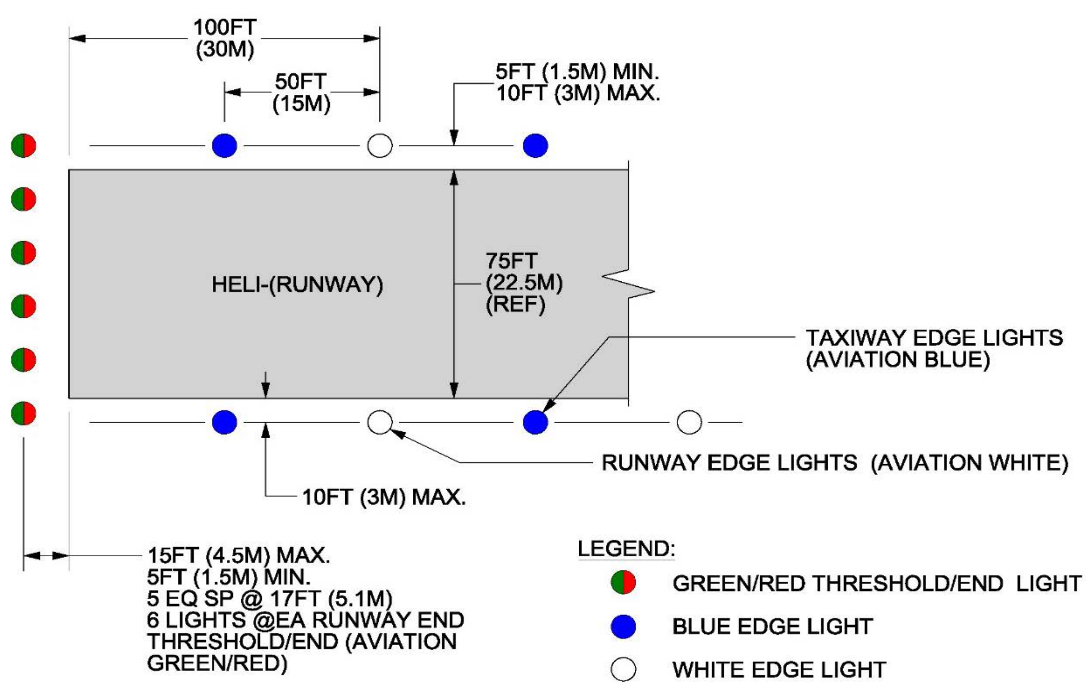

Figure 8-4 Runway/Runway L Intersection

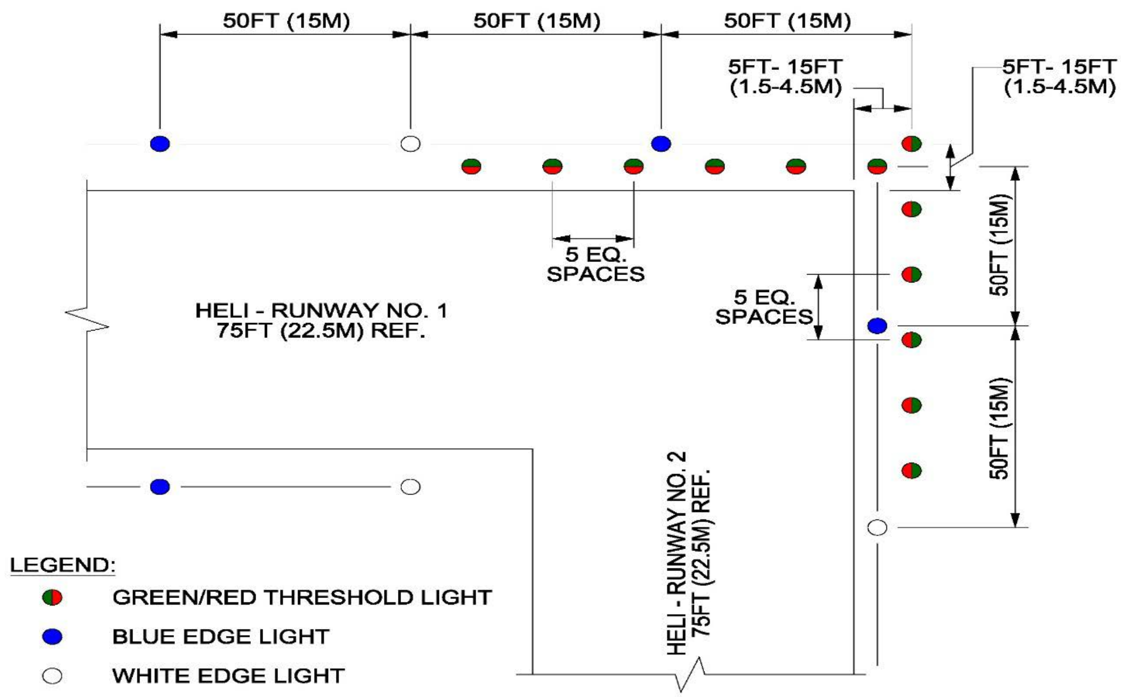

Figure 8-5 Runway/Runway T Intersection

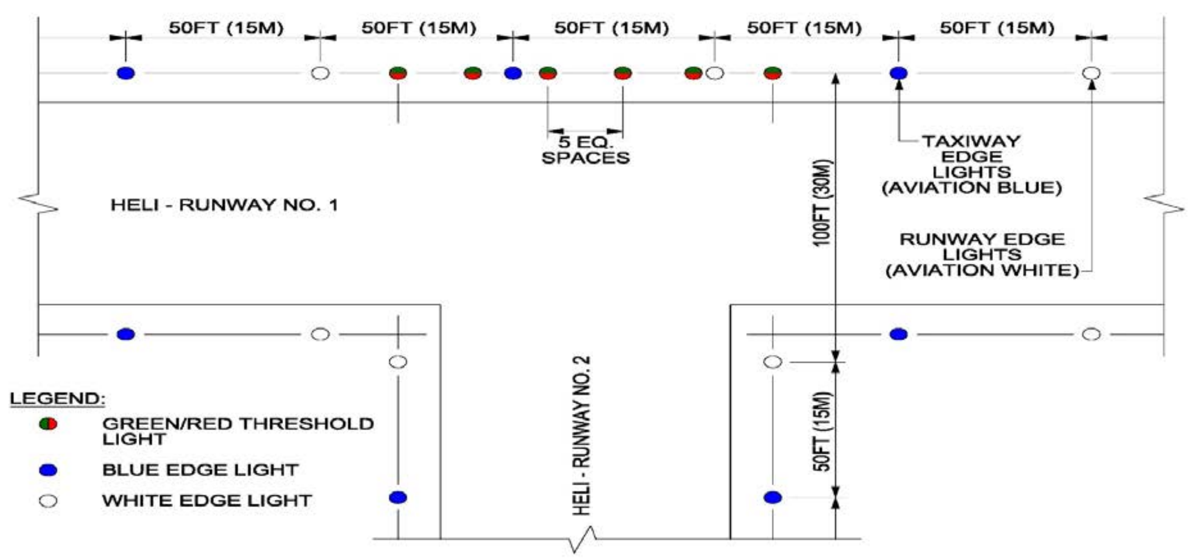


8-2.3 Runway Threshold Lights.

The line of in-pavement threshold lights must be bidirectional, 180 degrees aviation green and 180 degrees aviation red, located not less than 5 feet (1.5 meters) or more than 15 feet (4.5 meters) from the runway ends, with the lights spaced approximately 17 feet (5.1 meters) on centers. The outermost light of each group will be located in line with the corresponding row of runway edge lights. Each group of threshold lights will contain a minimum of six lights. When the line of runway edge lights are located at the maximum distance of 10 feet (3 meters) from the pavement edge of the runway, an additional in-pavement light will be installed in each group for a total of seven lights in each group. The threshold lights should be controlled with the runway edge light circuit.

8-2.4 Taxiway Lights and Signs.

Taxiway lighting (per Chapter 5) and associated taxiway guidance signs will be in accordance with the criteria stated in Chapter 9.

8-2.5 Approach Lights.

Approach light systems, when considered necessary, should be installed in accordance with the criteria cited in Chapter 7 for VFR or IFR conditions as appropriate.

8-2.6 Heliport/Helipad Identification Beacon.

8-2.6.1 Purpose.

A heliport beacon provides long-range guidance and helipad identification.

8-2.6.2 Configuration.

The beacon must contain a colored sequence of lights, double peak white flash, and a single peak green and yellow. The flash must be 10 to 15 sequences of flashes per minute. The time between each color should be one-third of the total sequence time. The beacon should not be installed within 1 mile (1.6 kilometers) of any existing airport beacon or other helipad area.

8-2.6.3 Construction.

The beacon should be visible for a distance of 1 mile (1.6 kilometers) in 1 mile (1.6 kilometer) VMC visibility daylight, and 3 miles (4.8 kilometers) in 3 miles (4.8 kilometer) VMC at night, both from an altitude of 3,000 feet (900 meters) above ground level. The beacon should be mounted a minimum of 50 feet (15 meters) above the helipad surface. Where a control tower or control area is utilized the beacon should be no closer than 400 feet (120 meters) nor further than 3,500 feet (1,050 meters) from that area, and not located between the control tower and the helipad. The beacon will be installed so that the base is not less than 15 feet (4.5 meters) above the floor of the control tower or operations room.

8-2.6.4 Luminous Features.

The main beam of the light should be aimed a minimum of 5 degrees above the horizontal and should not produce light below the horizontal in excess of 1,000 candelas. Light shields may be used to reduce the intensity below the horizontal.

8-3 ROTARY WING LANDING LANES.

8-3.1 Rotary Wing Landing Lanes (formerly Stagefields).

Figure 8-2 and the associated design criteria contained herein are intended to guide in designing and installing a permanent Army rotary wing landing lane, which is normally 1,600 feet (480 meters) long and 75 feet (22.5 meters) wide, utilizing elevated or in-pavement light fixtures.

8-3.2 Rotary wing landing lanes permit efficient simultaneous operations by a number of helicopters (in most cases, up to four at one time) while additional helicopters are in a designated traffic pattern.

8-3.3 Edge Lights.

The edge lights on landing lanes must be aviation white in color, located on a line 3 feet (0.9 meter) maximum from the edge of the full strength pavement that is designated for lane use, as illustrated in Figure 8-2.

8-3.4 Other Requirements.

The longitudinal spacing must be uniform and not greater than 150 feet (45 meters) and not less than 100 feet (30 meters) on each side of the landing lane. The height of the light fixture will not exceed 14 inches (350 millimeters) above grade except, when snow accumulations of 12 inches (300 millimeters) will be frequent, the edge light height may be increased to 24 inches (600 millimeters) above grade. The light fixtures will be mounted on frangible posts of not more than 2 inches (50 millimeters) in diameter. Each landing lane edge light system will be equipped with a 5-step constant current regulator which permits control from blackout to full intensity. For additional information see Chapter 13, or refer to FAA AC 150/5340-30.

8-3.5 Threshold/End Lights.

Combination threshold and lane end light fixtures must be located on a line perpendicular to the extended centerline of the landing lanes. The line of lights must not be less than 2 feet (0.6 meters) nor more than 10 feet (3 meters) outboard from the designated threshold of the landing lane. The lights must consist of four groups of two lights, symmetrically located perpendicular to the extended centerline of the landing lanes (see Figure 8-2).

8-4 REFUELING AREA LIGHTS.

A hazardous location exists within 50 feet (15 meters) of an aircraft fuel inlet or fuel system vent and within 63 feet (18.9 meters) of an aircraft direct fuel outlet/fuel-dispensing nozzle. Refueling areas are Class 1, Division 1, Group D hazardous locations as defined in National Fire Protection Association NFPA 70 National Electrical Code. The light fixture assemblies and associated wiring must be suitable for installation in the hazardous location. Refer to FAA AC 150/5345-39 for the use of retro-reflective markers.

8-5 HOVERLANE LIGHTING SYSTEMS.

8-5.1 A hoverlane is a designated aerial traffic lane (air taxi) for the directed movement of helicopters between a helipad or hover point and the servicing and parking area of a heliport or airfield.

8-5.2 Hoverlane lighting systems will consist of a single row of alternating aviation green and yellow taxiway light fixtures located along the centerline of the hoverlane (see Figure 8-4). Elevated fixtures (FAA L-861T light fixture modified with lens color as indicated) will be installed and will be spaced nominally 50 feet (15 meters) on center for long straight sections, and mounted on metal light base fittings. For curves, fixtures will be spaced nominally 25 feet (7.5 meters) on centers.

8-5.2.1 When hoverlanes terminate adjacent to hanger access aprons or boundaries of other areas not intended for own-power operation, the desirable limit of helicopter travel along hoverlanes toward such areas will be indicated by three lighting fixtures emitting aviation red light. Two red hoverlane limit lights will each be installed on opposite sides of, and approximately 15 feet (4.5 meters) from, the hoverlane centerline. The third light, forming a line of three such lights perpendicular to the alternating aviation green and yellow hoverlane lights, will be located in line with the alternating aviation green and yellow hoverlane lights.

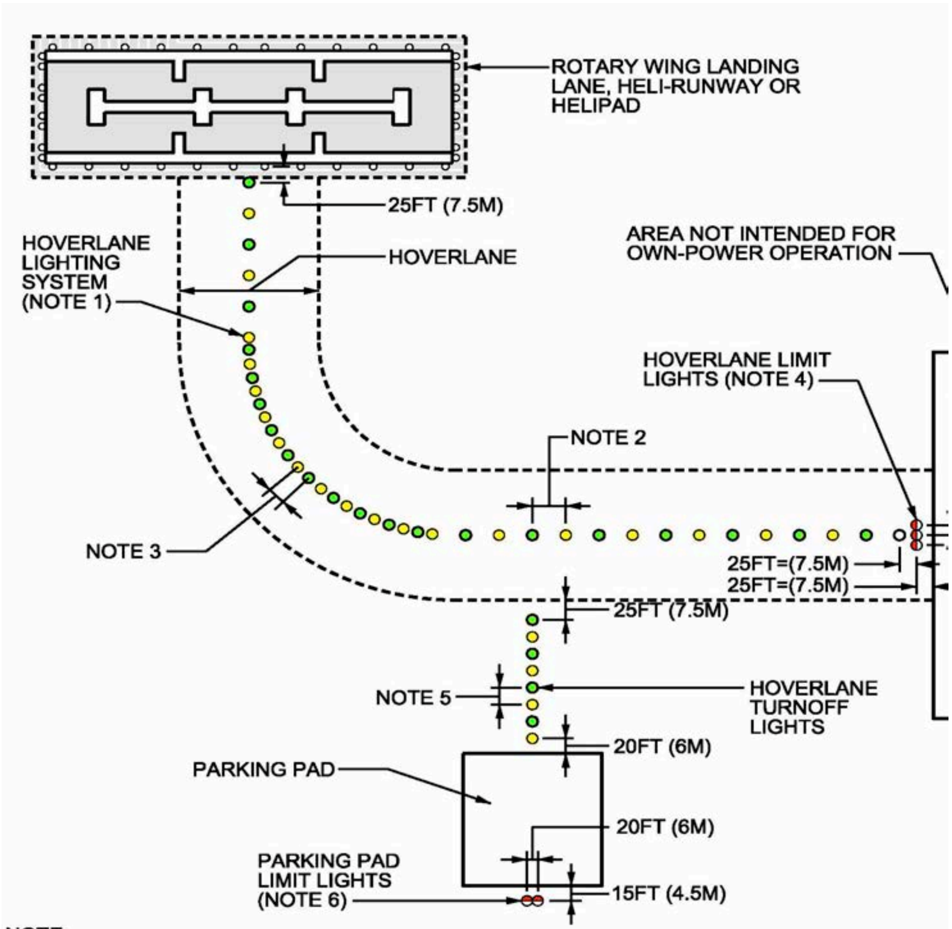
8-5.2.2 Red hoverlane limit lights will provide unidirectional guidance by use of a combat-type hood attached to a taxiway light fitting. The row of alternating aviation green and yellow hoverlane lights described above will terminate approximately 25 feet (7.5 meters) from the red limit lights, outward from the apron or boundary.

8-5.2.3 Hoverlane limit light mountings and types will be as for the alternating aviation green and yellow hoverlane lights described above. Hoverlane turnoffs to individual parking pads will be indicated by aviation green and yellow hoverlane lights beginning approximately 25 feet (7.5 meters) from and perpendicular to the hoverlane, installed on nominal 25 foot (7.5 meter) centers. The line of hoverlane turnoff lights will terminate approximately 25 feet (7.5 meters) from the edge of the parking pad nearest the hoverlane.

8-5.2.4 The limit of helicopter travel from the hoverlane toward the pad, along the turnoff, will be indicated by two parking pad limit lights, which will be located approximately 20 feet (6 meters) beyond the pad, 15 feet (4.5 meters) apart, and perpendicular to the turnoff light line.

8-5.2.5 Parking pad limit lights will emit aviation red light, and will provide unidirectional guidance with a combat-type hood, attached to a taxiway light fitting with red lens. All hoverlane limit and parking pad limit lights will be provided with brightness control and circuited separately, as a group, from other lights. Hoverlane lighting will not be installed in the rigid pavement area of mass parking aprons.

Figure 8-6 Hoverlane Lighting System



NOTE:

1. HOVERLANE LIGHTING SYSTEMS CONSIST OF ELEVATED ALTERNATING AVIATION GREEN YELLOW TAXIWAY LIGHT FIXTURES LOCATED ALONG THE CENTERLINE OF THE HOVERLA (REFERENCE PARAGRAPH 8-5.2.)
2. FIXTURES SPACED NOMINALLY 50FT (15M) ON CENTER FOR LONG STRAIGHT SECTIONS.
3. FOR CURVES, FIXTURES ARE SPACED NOMINALLY 25FT (7.5M) ON CENTERS.
4. UNI-DIRECTIONAL RED LIMIT LIGHTS INDICATE HOVERLANE TERMINATION ADJACENT TO HANGER ACCESS APRONS OR BOUNDARIES OF OTHER AREAS NOT INTENDED FOR OWN-POWER OPERATION.
5. HOVERLANE TURNOFF LIGHTS ARE ALTERNATING AVIATION GREEN AND YELLOW FIXTUR SPACED NOMINALLY 25FT (7.5M) ON CENTER.
6. UNI-DIRECTIONAL RED LIMIT LIGHTS INDICATE THE END OF TRAVEL FROM HOVERLANE T PARKING PAD.

8-6 LIGHTING EQUIPMENT.

8-6.1 Elevated Runway and Landing Lane Edge Lights.

Elevated runway edge lights will be omnidirectional, medium intensity, FAA type L-861. The lamp for this light will be approximately 30 watts, 6.6 amperes, as recommended by the manufacturer (Figure 13-11).

8-6.2 In-pavement Runway Lights.

In-pavement runway lights will be medium intensity, FAA type L-852 E (FAA Type L-852D with colored lenses removed). Where rollover is anticipated on a runway or taxiway, use in-pavement light fixtures of the appropriate color.

8-6.3 Threshold Lights.

8-6.3.1 **\4** In-pavement threshold lights will be FAA type L-852D with red and green light filters. No toe-in is required for this fixture. **/4/**

8-6.3.2 Elevated threshold lights must be FAA Type L-861SE. A 180 degree aviation red filter will be supplied with the light fixture.

8-6.4 Runway Blue Lights.

Elevated and in-pavement lights will be aviation blue, FAA type L-861T or L-852T.

8-6.5 Refueling Area Lights.

Fixture assembly must meet the requirements Underwriters Laboratories (UL) test and approval requirements as stated in UL 844 for class 1, division 1, group D hazardous locations as defined in NFPA 70. The fixture assembly will include a light fixture, frangible coupling, power disconnect switch that will kill power if the frangible mount is broken, and a junction box. As an alternative, use the light fixture assemblies and associated wiring that are intrinsically safe and meet Underwriters Laboratories (UL) test and approval requirements as stated in UL 913 for class 1, division 1, group D hazardous locations as defined in NFPA 70.

8-6.6 Runway and Taxiway Signs.

When operational requirements consider it necessary to install informational mandatory guidance signs, see Chapter 5 for guidance. Runway and taxiway signs are designated in two groups: mandatory signs are white letters on a red background, and information signs are black letters on a yellow background.

8-6.7 Auxiliary Lighting.

For auxiliary lighting such as floodlights, protective lighting and intensities, see paragraph 10-4.

8-7 POWER REQUIREMENTS.

Runway lighting systems will be supplied through interleaved or non-interleaved series circuits served by constant current regulators. The regulators are available in various load capacities and output current values, and have brightness controls so that the light output can be adjusted to suit the visibility conditions.

8-7.1 Circuit Criteria.

The number and type of regulators required will be determined by the circuit length. Address power losses from cable lengths to and from the lighting vault to the lights and the isolation transformer loss when designing the lighting system.

8-7.2 Cable Connectors, Plugs and Receptacles.

See Chapter 13.

8-7.3 Cables.

Cables used for series circuit. Will be No.8 or No. 6 1/C stranded copper, 5,000 volt, cross-linked polyethylene (XLP). See paragraph 13-8.7 and FAA AC 150/5345-7. Use No. 6 cable on all 20 ampere circuits.

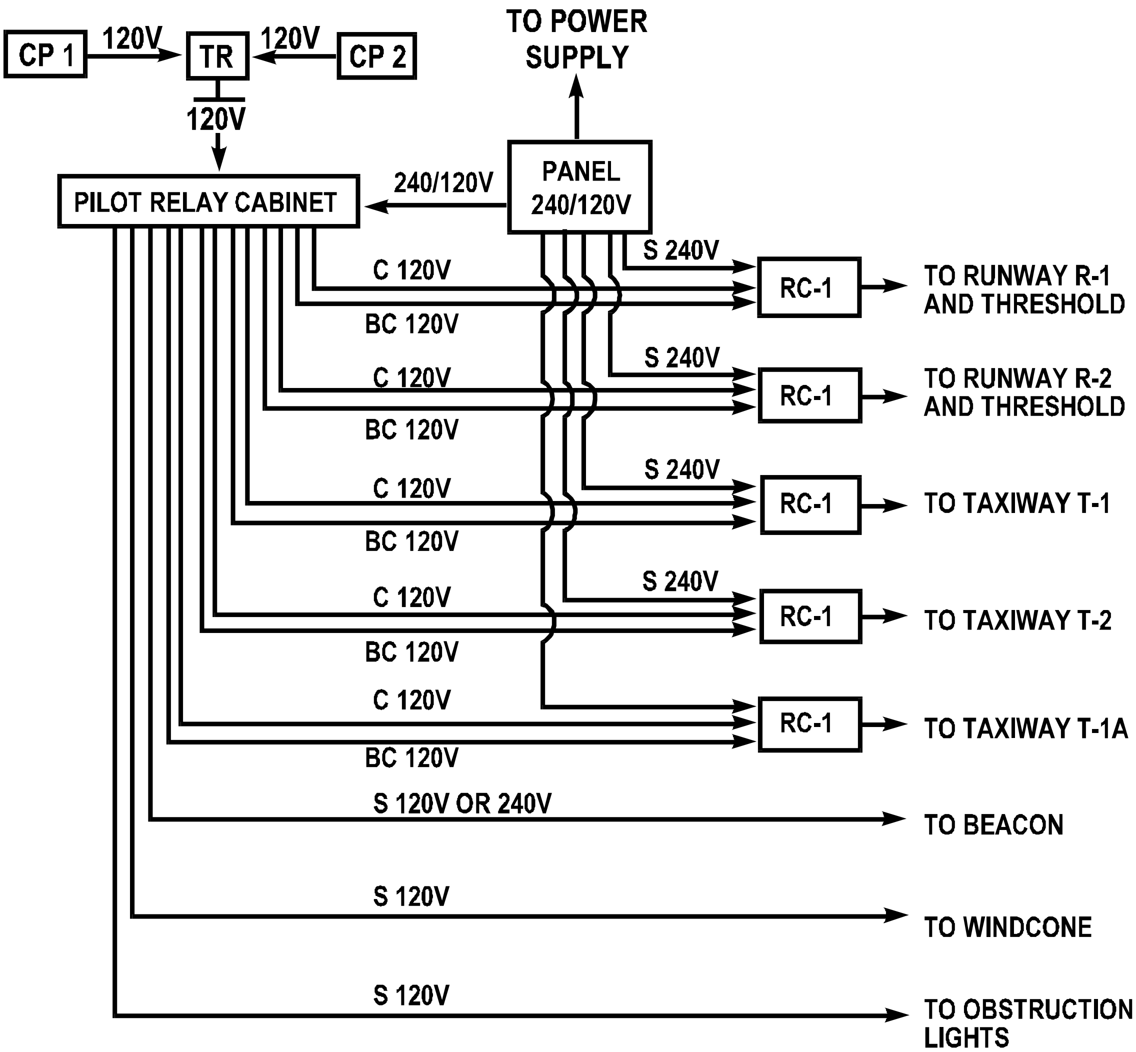
8-7.4 Isolation Transformers.

See paragraph 13-8.9.

8-8 CONTROL REQUIREMENTS.

The heliport lighting control system is an integral part of the control system for all heliport lighting facilities. The function of this portion of the control system is to energize and de-energize the selected runway lighting systems, and to control the brightness of the lights. All lights will be controlled from the control tower and from the lighting equipment vault. The circuits will be provided and connected as indicated in Figure 8-5, with the runway/taxiway combination control panels and associated equipment connected to permit separate control of each heliport lighting system, independent of each other, and permit simultaneous control of the taxiway circuits in combination. Coordinate the need to interlock the lighting on intersecting runways so that both runway lighting systems cannot be energized simultaneously. Taxiway circuit T-1A will be connected with separate individual control to permit flexibility in the operation of the runway and taxiway lights either singly, in combination, or simultaneously, as required for the heliport operations by the control tower operator. The layout will also allow for future changes, and expansion in the methods of operation with a minimum of expense and interruption of service.

Figure 8-7 Block Diagram Typical System



LEGEND

- CP-1 - Control Point Primary (Control Tower)
- CP-2 - Control Point Alternate (Vault)
- RC-1 - Regulator
- TR - Transfer Relay
- BC - Brightness Control
- C - Control
- S - Supply

NOTE: Electric power source, main service switch, emergency generator and transfer switch and main distribution panel not shown. Installation of theses items will be designed to meet local conditions.

8-8.1 Provide edge lights and threshold lights with 3 intensities as follows:

Intensity Step	Percent of Full Intensity
1	10%
2	20%
3	100%

If required by the operations community, for compatibility with night vision goggles, the edge lights and threshold lights may be provided with 5 intensities as follows:

Intensity Step	Percent of Full Intensity
1	0.16%
2	0.8%
3	4.0%
4	20%
5	100%

8-8.2 The initial sequence of operations of the heliport lighting circuits anticipated is such that when helicopters are utilizing the night landing facilities of the heliport: the blue taxiway lights (circuits T-1 and T-2) will be turned on, but only the white edge lights and green/red threshold lights (circuits R-1 or R-2) of the runway in use will be turned on. Use Figure 8-1 as a reference.

Example: White edge lights, R-1, ON
Threshold lights, R-1, ON
Blue edge lights, R-2, ON
Blue edge lights, T-2, ON
Blue edge lights, T-1A, ON
All other taxiway/runway lights, OFF

The above example will allow a helicopter to land on R-1, taxi on R-2, taxi on T-2, and proceed to a designated area via T-1A.

8-9 MONITORING REQUIREMENTS.

There are no requirements for monitoring the lighting systems on heliports or rotary landing lanes.

8-10 COMPLIANCE WITH INTERNATIONAL STANDARDS.

8-10.1 AFIC.

There are no AIR STDs for heliports or landing lanes.

8-10.2 NATO.

There are no standards for heliports or landing lanes; however, STANAG 3619 (Edition 5) – Helipad Marking and Lighting, 6 June 2013, makes reference to the US Army criteria for IFR approach lighting.

8-11 EQUIPMENT.

See Chapter 13 for lighting equipment.

This Page Intentionally Left Blank

CHAPTER 9 STANDARDS FOR AIRFIELD SIGNS AND MARKERS

9-1 GENERAL.

9-1.1 Purpose.

Signs and markers provide important guidance and control for the safe and efficient surface movement of aircraft on an airfield. Proper signing provides information on location, direction, destination, mandatory holding positions, important boundaries, and other information. Additionally, runway distance remaining markers provide to the pilot the remaining distance on a runway for landing and take-off operations. See AC 150/5340-18, paragraph 1.13

\4 This UFC provides signing standards consistent with current FAA and ICAO requirements and standards, including: FAA AC 150/5340-18, FAA AC 150/5345-44 and ICAO Annex 14, Chapter 5, Visual Aids for Navigation. The signing criteria in this chapter and in the references above should be applied at all airfields to the extent that they do not conflict with any special local requirements. All signs must be internally lighted and meet the luminance values indicated.

9-1.2 General Signing Conventions.

9-1.2.1 If signs are installed on both sides of the taxiway at the same location, the sign faces are identical, except for holding position signs, where the taxiway location signs are located outboard of the runway holding position sign. There is also an exception for runway exits, where an RSA/OFZ boundary sign is installed on the right side of the exit taxiway and if a taxiway direction sign is needed, then a taxiway direction sign maybe installed on the left side. Signs are not installed between the taxiway location/runway holding position sign and the runway.

9-1.2.2 Signs may be located on the right side of the taxiway when necessary to meet clearance requirements or where it is impractical to install them on the left side because of terrain or conflicts with other objects.

9-1.2.3 Signs that may be installed in this manner include: RSA/OFZ boundary signs which may be installed on the back of taxiway/runway intersection holding position sign. ILS critical area boundary signs, which may be installed on the back of ILS critical area holding position signs. Taxiway location signs, which may be installed on the back of direction signs when they are installed on the far side of an intersection. Note: Location signs installed in this manner do not negate the need for location signs installed on the left of the runway holding position sign prior to the intersection. Taxiway location signs, which may be installed on the back of holding position signs. Destination signs, which may be installed on the back of direction signs on the far side of intersections when the destination referred to is straight ahead.

9-1.2.4 Taxiway location signs installed in conjunction with holding position signs for taxiway/runway intersections are installed outboard of the holding position sign.

9-1.2.5 Location signs are normally included as part of a direction sign array, which is located prior to the taxiway intersection. Except for intersections of only two taxiways (see 5/10/2019 AC 150/5340-18G 1-16 paragraph 1.13.8), the location sign is placed in the array so the designations for all turns to the left are located to the left of the location sign; the designations for all turns to the right or straight ahead, when required, are located to the right of the location sign.

9-1.2.6 When more than one taxiway direction sign is installed at the same location, the designations of the intersecting taxiways and their respective arrows are arranged left to right in a clockwise manner, starting from the taxiway or runway on which the aircraft is located.

9-1.2.7 All direction signs have arrows. Arrows on signs are oriented to the approximate direction of the turn. Each designation appearing in an array of direction signs is accompanied by only one arrow. A direction sign with an arrow indicating that a taxiway continues straight ahead (25 degrees or less change in alignment at the intersection) is not normally needed. Where the intersection alignment changes more than 25 degrees, a sign with an arrow approximating the direction of the taxiway is used. If the taxiway continues straight ahead (25 degrees or less change in alignment) and the designation of the taxiway changes at the intersection, then a direction sign with an arrow is used.

9-1.2.8 When a taxiway intersection comprises only two crossing taxiways, it is permissible to use a double arrow direction sign in place of separate direction sign panels. In this case, the location sign panel is on the left side of the sign array. For this type of installation, the taxiway that the pilot is on may not change designation or alignment (more than 25 degrees) on the other side of the intersection.

9-1.2.9 In some cases, location signs may not be needed in conjunction with direction signs. Consider all information concerning the intersection when analyzing the need for a location sign. This would include but is not limited to: • Complexity of the intersection layout. • Distance from the last location sign. • Complexity of prior intersections. Traffic flow patterns through the intersection. • Visibility conditions under which the intersection is used.

9-1.2.10 Destination signs are usually installed in advance of intersections prior to turns. However, they may also be installed on the far side of an intersection when the taxiway route continues ahead and the destination sign is installed on the back of another sign. Destination signs usually are not collocated with other signs because it could result in abnormally long signs.

9-1.2.11 Information signs are not collocated with mandatory instruction, location, direction, or destination signs.

9-1.2.12 Each designation and its associated arrow included in an array of direction signs or destination signs are delineated from the other designations in the array by a black vertical border. When it is appropriate, a location sign may be used to provide this delineation.

9-1.2.13 On a sign face, a dot means “and.” It is used on signs where one arrow is common to two designations. For example, if the routes to two different runway ends involve the same taxiways, the runway numbers appearing on an outbound destination sign would be separated by a dot; the directional arrow on the sign face would be applicable to both runway ends.

9-1.2.14 A dash is used only with mandatory instruction signs. On these signs, a dash is used to separate the designations for opposite ends of the same runway (for example: 18-36) or to separate the runway designation from the abbreviation "APCH" or "DEP" on holding position signs for runway approach/departure areas.

9-1.2.15 When replacing sign panels due to damage or changing message elements, the entire message element should be replaced. This will avoid panel-to-panel color changes that may be distracting to pilots. See AC 150/5345-44 for additional information about replacement sign panels.

9-1.2.16 A sign may be "canted" or angled towards the pilot's line of vision when necessary to improve its visibility. This situation is illustrated where a pilot would have difficulty seeing the sign on the left due to its proximity to the edge of the parallel taxiway. The back of a canted sign is not available for use because it may not be visible to pilots.

9-1.2.17 When using two separate signs in an array, do not separate message elements between the two signs. For example, do not locate the arrow for a sign panel on a separate sign in the array. Extension of an existing sign (i.e., physically increase its length by adding modules to it) requires all of the following criteria be met: The existing sign meets the applicable standards in AC 150/5345-44. The length of the sign (existing plus extension) cannot exceed the maximum overall length limitations per AC 150/5345-44. Unless the extension involves the addition of only a location sign, the sign face (existing plus extension) meets the standards for legend, borders, arrows, spacing, and color per AC 150/5345-44. • The extension meets the electrical and frangibility standards of AC 150/5345-44. 12/23/2020 AC 150/5340-18G Change 1 1-18 The separation between individual sign housings meets the requirements in AC 150/5345-44. **/4/**

9-1.3 Components of a Sign System.

The following types and styles of signs, discussed more below, are basic components of a sign system for an airfield:

9-1.3.1 Mandatory Instruction Signs.

Type L-858R, white legend on a red background (see FAA AC 150/4345-44, Appendix C, Figure 12, for examples of typical lighted signs). Note: the black outline is considered as background and does not add to the spacing to the next character or border (FAA AC 150/4345-44, Appendix I, Figure 18. Current requirement for new signage contains a 0.75 inch black outline around all characters.

9-1.3.2 Direction, Destination, and Boundary signs.

Use Type L-858Y, black legend on a yellow background (see FAA AC 150/4345-44, Appendix C, Figures 11 and 12, for examples of typical signs).

9-1.3.3 Taxiway Location Signs.

Use Type L-858L, yellow legend and border on a black background indicating the surface on which the aircraft is operating. The yellow border is inset from the inner edge of the sign to provide a continuous black margin (see FAA AC 150/4345-44, Appendix C, Figures 11 and 12, for an example of a typical sign). While primarily indicating taxiway location, these also may be used to indicate runway location at potentially confusing areas.

9-1.3.3 Sign Arrays.

Signs are often established as a sign array with several messages. For example, a location sign may be grouped with a mandatory holding position sign or with one or several direction sign messages as a sign array. However, not all types of signs may be grouped together; for example, guidance and information signs may not be co-located with mandatory signs.

9-1.3.4 Runway Distance Remaining Signs.

Use Type L-858B, white legend on a black background, with a single number indicating in multiples of 1,000 feet (300 meters) the remaining runway distance for pilots during takeoff and landing operations. Metric measure is not used for this sign. (See FAA AC 150/4345-44, Appendix F, Figure 14.)

9-1.3.5 Arresting Gear Markers.

Use a yellow circle on black background, identifying the location of arresting system cables on the runway (similar to FAA Type L-858B).

9-1.3.6 Other Signs.

Other signs serving special situations may be used, provided they do not conflict with the sign standards, or have the potential for confusing ground traffic with respect to standard signing. Vehicle control signs conforming to the Manual of Uniform Traffic Control Devices (MUTCD) (Air Force use UFC 3-120-01), such as the standard octagonal stop sign, may be used at locations that would apply only to vehicles.

9-1.4 Sign Styles.

Lighted signs can be powered from a 3-step 6.6 ampere series circuit (FAA Style 2), a 5-step 6.6 or 20 ampere series circuit (FAA Style 3) or a dedicated 5.5 ampere series circuit (FAA Style 5). Unlighted signs are FAA Style 4.

For new installations, mandatory signs, runway exit signs, RDR and AGM must be FAA Style 5 and connected to a dedicated 5.5 ampere, 1-step regulator. The intent is to have a more reliable sign system for these signs by eliminating the electronics required to maintain uniform brightness over the range of a 3 or 5 step regulator. Taxiway guidance and information signs and location signs may be either FAA Style 2 or FAA Style 3 depending on the series circuit intensity steps the signs are connected to. See FAA AC 150/5345-44 for more information about sign power and electrical requirements.

9-1.5 Failure of Lighted Signs.

The failure of any light source within a sign must not result in a potential miscommunication of the intended message to a pilot. If the failure of an internal lamp(s) in a sign causes a panel or any section of a panel to be dark, or have an average luminance less than the minimum required in FAA A/C 150-5345-44, paragraph 3.2.5.6, sign operation must be automatically discontinued.

9-2 MANDATORY SIGNS.

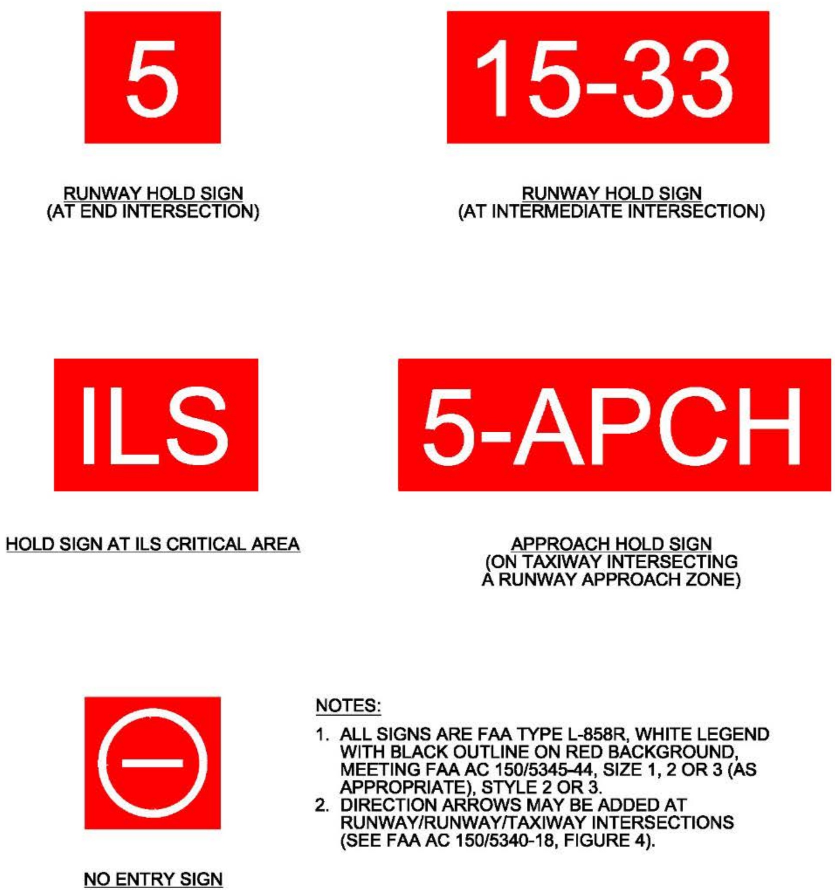
9-2.1 Purpose.

Mandatory signs provide an instruction that must be followed. They denote an entrance to a runway or critical area, or other situation such as a no-entry location. At controlled airfields (with active tower), aircraft and vehicles are required to hold at the holding position unless cleared by air traffic control. At uncontrolled airfields, the intent is that traffic may only proceed beyond the sign after appropriate precautions are taken by the pilot. Examples of mandatory sign messages are in FAA AC 150/5340-18 and 150/5345-44.

Note: All mandatory instruction sign white legends are now outlined in black (see Figure 9-1). See FAA AC 150/5345-44 for additional information about the black outline. Signs with white legends may be used until stock is exhausted.

Figure 9-1 Typical Mandatory Signs

Note**:** These signs represent the bulk of existing signs and comply with previous edition of FAA AC 150/5345-44. These signs do not require replacement until the end of their economic lives or with a major renovation to the airfield. See current edition of FAA AC for new sign message elements. Current edition of AC 150/5345-44



9-2.2 Installation.

Mandatory signs are installed on the left-hand side at taxiway/runway intersections, runway/runway intersections, ILS critical areas, runway approach zones, no entry areas.

9-2.2.1 At some locations, signs should be installed on both sides of runways and taxiways. This includes: runways more than 150 feet (45 meters) in width; runways of any width which are used for “land and hold short” operations; or taxiways that are 150 feet (45 meters) or greater in width.

9-2.2.2 Holding position signs should be collocated with holding position markings and located at a distance from the intersecting runway to meet the clearance requirements of the intersecting runway or ILS critical area. Coordinate this distance with Airfield Management and Flight Safety Offices. On taxiways in approach areas, the sign is installed where an aircraft would cross the runway safety area or penetrate the required airspace for approaches and departures.

9-2.2.3 Mandatory signs may be FAA Size 1, 2 or 3. Size 3 signs are recommended for Category I facilities and higher. From the defined edge of runway or taxiway, locate a Size 3 sign 35-60 feet (10.5-18 meters), a Size 2 sign 20-35 feet (6-10.5 meters), and a Size 1 sign 10-20 feet (3-6 meters). The distance indicated is the perpendicular distance from defined pavement edge to near side of sign. Signs are oriented perpendicular to the runway or taxiway centerline, but may be canted up to 15 degrees to increase visibility if the sign is not a double-face sign. At locations where large wingspan aircraft operations are common, place signs far enough from taxiway edges to allow required wingtip clearance. Signs must provide 12 inches (300 millimeters) of clearance between the top of any sign in an array and any part of the most critical aircraft using, or expected to use, the airfield when the aircraft's wheels are at the defined pavement edge.

9-2.2.4 Mandatory signs may be grouped in an array with a location sign, or may have a location sign or a Safety Area/Obstacle Free Zone (OFZ) or ILS Critical Area boundary sign on the back face. Direction or destination signs may not be grouped with a mandatory sign. In an array, the location sign is always positioned outboard of the mandatory sign. See FAA AC 150/5340-18 for further guidance on grouping several sign messages in an array. The Air Force will use “INST” instead of “ILS” for the instrument holding position/critical area boundary when more than just the ILS is available, such as PAR, MLS, or GPS.

9-2.3 Characteristics.

See Chapter 13 and FAA AC 150/5345-44 for additional sign characteristics information.

9-2.3.1 Message.

See FAA AC 150/5345-44 for technical information concerning sign legend sizes, fonts, spacing, border requirements, power requirements, sign sizes, and mounting methods.

9-2.3.2 Dimensions.

See FAA AC 150/5345-44 Tables 1 and 2 for sign and legend height dimensions. As an example, an FAA Size 3 sign has a legend height of 18 inches (457 millimeters), legend panel height of 30 inches (762 millimeters), overall sign mounting height of 3 to 3.5 feet (0.9-1.05 meters), maximum overall sign length of 170 inches (4.318 meters), and minimum sign length of 42 inches (1.07 meters).

9-2.3.3 Electrical.

For new installations, it is preferred that mandatory signs be FAA Style 5 and connected to the 5.5 amp, 1-step RDR circuit. The intent is to have a more reliable sign system by eliminating the electronics required to maintain uniform brightness over the range or a 3 or 5-step regulator. The mandatory sign 5.5 amp circuit can also be used for RDR signs and AGM signs.

9-2.3.4 Photometrics.

See FAA AC 150/5345-44 for detailed information about sign luminance and methods of measurement. It is recommended that photometric testing be performed on all newly installed mandatory signs on site. The purpose of these tests is to verify the installed fixtures meet or exceed the minimum photometric requirements.

9-2.4 Power and Control.

For new installations, mandatory signs will be powered from a dedicated 1-step (5.5 ampere) circuit. Control of the circuit will be interlocked with the corresponding runway edge lighting circuit so as to turn on and off with its runway edge lighting.

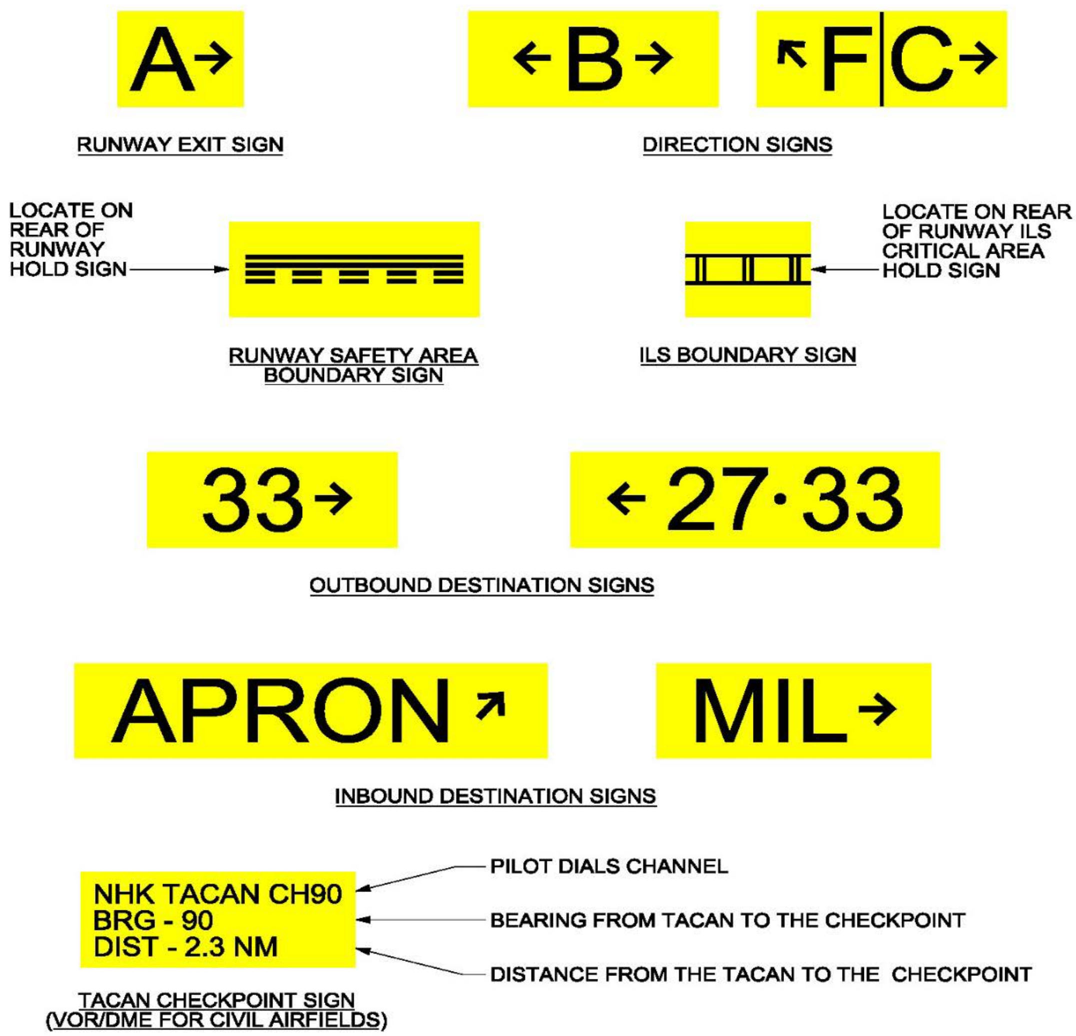
9-3 TAXIWAY GUIDANCE AND INFORMATION SIGNS.

9-3.1 Purpose.

See FAA AC 150/5340-18 for detailed information about taxiway guidance and information sign function, location, and rules for location. Taxiway guidance signs include direction signs, destination signs, other informational signs, and boundary signs. Direction signs indicate the direction of taxiways leading out of an intersection, and are installed at runway exits, taxiway intersections, and other locations. Destination signs indicate the general direction to a remote location. For example, outbound destination signs are used to identify the direction to takeoff runways, while inbound destination signs are used to indicate direction to major areas such as aprons, fueling points, and other locations. Both direction and destination sign messages include an arrow. Boundary signs indicate important boundaries such as ILS critical areas and runway approach areas. Other signs are used to provide specific information such as noise abatement procedures, check points, and others. Examples of guidance sign messages are shown in Figure 9-2.

Figure 9-2 Typical Taxiway Guidance and Information Signs

Note: These signs represent the bulk of existing signs and comply with previous edition of FAA AC 150/5345-44. These signs do not require replacement until the end of their economic lives or with a major renovation to the airfield. See current edition of FAA AC for new sign message elements.



NOTE:

1. ALL SIGNS, EXCEPT TACAN CHECKPOINT SIGNS, ARE FAA TYPE L-858Y, WITH BLACK LEGEND ON YELLOW BACKGROUND, MEETING FAA AC 150/5345, SIZE 3, STYLE 2 OR 3.

9-3.2 Installation.

Signs are installed on the left side of the taxiway unless aircraft operations require otherwise.

9-3.2.1 Runway exits signs are located prior to the runway/taxiway intersection on the side and in the direction from which the aircraft is expected to exit. If a taxiway crosses a runway and an aircraft can be expected to exit on either side, then exit signs are located on both sides of the runway. For taxiways that are intended only to be used as exits from the runway in one direction, such as taxiways located near the end of the runway or intersecting the runway at an acute angle, the signs should be installed only for the runway direction in which they are intended to be used. When two acute-angle taxiways (e.g., high speed exits) are intended to be used in opposite directions and intersect the runway at a common point, the exit signs are located prior to the common point intersection rather than in the area between the two exits (see FAA AC 150/5340-18, Figure 18). “Bracketing” a runway exit sign (where a sign is placed before and after the exit) is not permitted. A runway exit sign should never have more than one arrow for each taxiway designation shown on the sign.

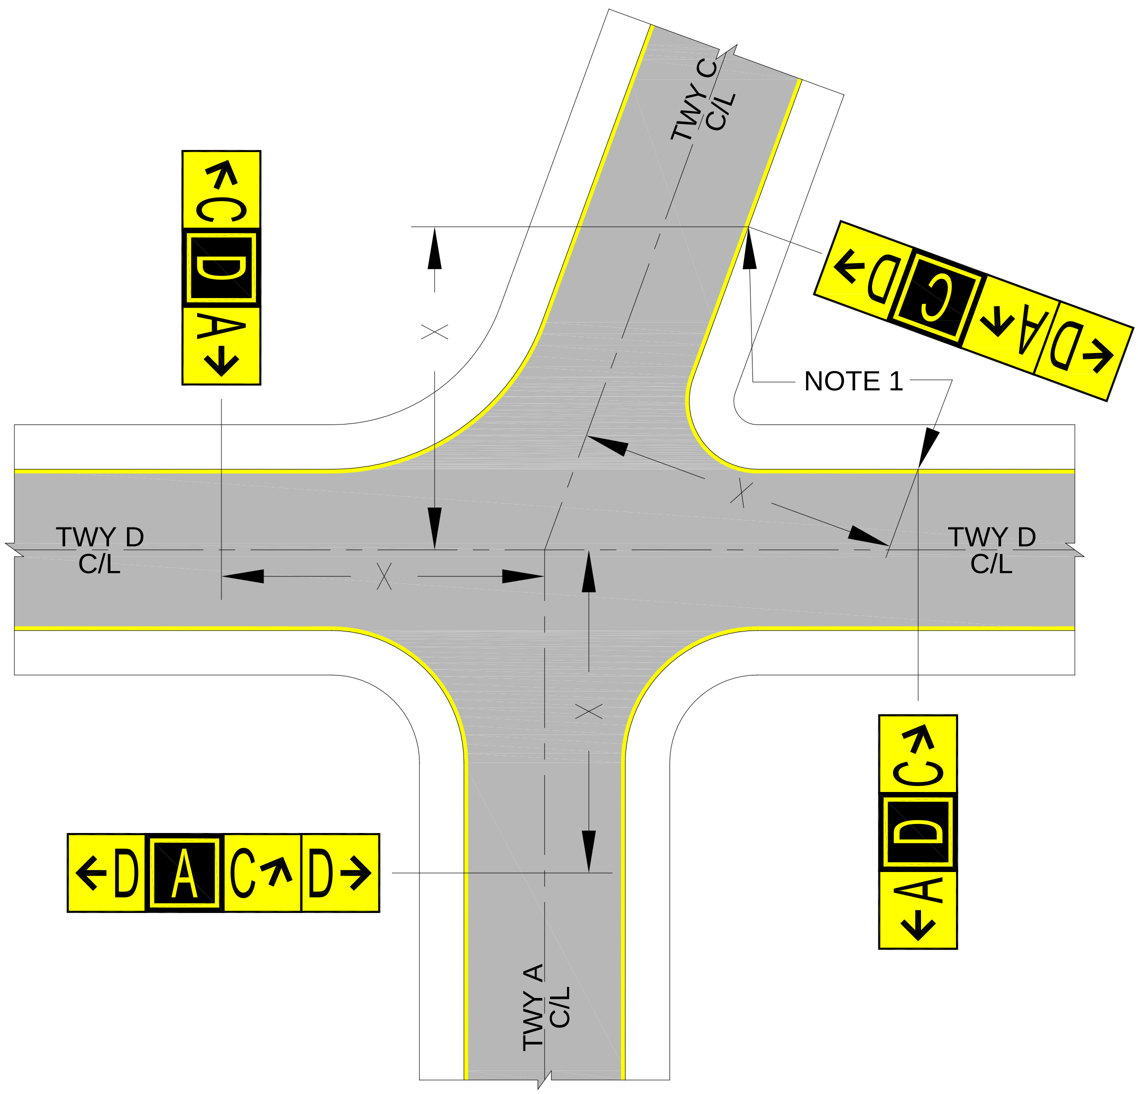
9-3.2.2 A direction sign is installed prior to an intersection. If there is no surface painted hold position marking at a taxiway intersection then the location of the direction sign can be used by the control tower to direct an aircraft to hold for crossing traffic. Typically they are installed at the point of tangency of the taxiway intersection, but not closer than the minimum distance from the intersecting taxiway centerline indicated in Table 9-1 (see Figure 9-3). The distance used for a given airfield should be applied uniformly and should be based on the predominant operating aircraft.

Table 9-1 Perpendicular Distances for Taxiway Signage from Centerline of Crossing Taxiway

AIRCRAFT DESIGN GROUP (ADG) (FAA AC 150/5300-13)	I	II	III	IV	V	VI
WING SPAN	<49ft (<15m)	49ft- <79ft (15m- <24m)	79ft- <118ft (24m- <36m)	118ft- <171ft (36m- <52m)	171ft- <214ft (52m- <65m)	214ft- <262ft (65m- <85m)
AIRCRAFT TYPE	T-1, T-37, T-38, C-21	C-12, C-20, F28 (1000/2000)	T-43, C-9, F28 (3000/4000) CV-340/440/580, B-727, B-737, DC-9	C-17, C-130, C-141, B-1B, KC-10, KC-135 B-707/720, B-757/767, L-1011, A-300, DC-8, DC-10	B-2, B-52, B-747, VC-25	C-5
PERPENDICULAR DISTANCE FROM CENTERLINE OF CROSSING TAXIWAY (1)	44.5ft (13.5m)	65.5ft (20m)	93ft (28.5m)	129.5ft (39m)	160ft (48.5m)	193ft (59m)

(1) DISTANCE IS DERIVED USING THE FORMULA: 0.7 X MAX. WINGSPAN IN ADG + 10ft (3m). REFERENCE FAA AC 150/5300-13.

Figure 9-3 Example of Taxiway-Taxiway Intersection Sign Location



X = THE PERPENDICULAR DISTANCE FROM CENTERLINE OF THE CROSSING TAXIWAY (SEE TABLE 9-1).

NOTES:

1. SIGNS SHOULD BE LOCATED PERPENDICULAR TO THE POINT AT WHICH THE DISTANCE "X" INTERSECTS THE EDGE OF PAVEMENT THAT IS FARTHEST FROM THE INTERSECTION OF THE TAXIWAY CENTERLINES. THIS ASSURES THAT THE ENTIRETY OF AN AIRCRAFT AT THAT LOCATION IS BEHIND THE CLEAR DISTANCE "X".

9-3.2.3 Destination signs are not always needed where direction signs are used, but are helpful where direction signs alone do not adequately guide a pilot to the desired destination. They may be particularly helpful at uncontrolled airfields. Destination signs should be located where they will not cause confusion with direction signs, and are subject to the same minimum distances from intersecting taxiways. See FAA AC 150/5340-18 for additional guidance.

9-3.2.4 An ILS Critical Area boundary sign is installed at the boundary limit to indicate where it is clear of the ILS Critical Area.

9-3.2.5 TACAN checkpoint signs are provided when an airfield has a TACAN system and provides information for the pilot who verifies the operation of the navigational aid in the aircraft before takeoff. The sign includes information on the type of navigational aid, identification code, radio channel, magnetic bearing, and the distance in nautical miles to the transmitting antenna from the checkpoint marking. The sign is positioned so it will be visible to the pilot of the aircraft properly positioned on the checkpoint marking. See Figure 9-7.

9-3.2.6 When runway end elevations differ by 25 feet (7.5 meters) from the published field elevations, an “Altimeter Check Point Sign” is required. Coordinate with TERPS to verify runway and field elevations. This sign should be combined and/or collocated with the TACAN checkpoint sign when available, as the same height and lettering requirements apply. Lettering may be abbreviated as follows: “ALT CHK PT - ELEV: XXXX,” where “XXXX” is the elevation in feet above mean sea level.

9-3.2.7 Other informational signs have messages and are located as determined by operations.

9-3.2.8 Guidance and information signs may be FAA Size 1, 2 or 3. Size 3 signs are recommended for Category I facilities and higher. Locate a Size 3 sign 35-60 feet (10.5-18 meters), a Size 2 sign 20-35 feet (6-10.5 meters), and a Size 1 sign 10-20 feet (3-6 meters) from the defined edge of runway or taxiway. The distance indicated is to the perpendicular distance from defined pavement edge to near side of the sign. Signs are oriented perpendicular to the runway or taxiway centerline, but may be canted up to 15 degrees to increase visibility if the sign is not a double-face sign.

9-3.2.9 Direction signs other than runway exit signs may be grouped in an array with a location sign. Destination signs may not be grouped with other signs, but may be on the back of another sign in which case it would be on the right-hand side for traffic. See guidance in paragraph 9-5 for conventions on sign arrays. See FAA AC 150/5340-18 for further guidance on grouping several sign messages in an array.

9-3.3 Characteristics.

See Chapter 13 and FAA AC 150/5345-44 for additional sign characteristic information.

9-3.3.1 Dimensions.

See paragraph 9-2.3.2. For TACAN checkpoint signs, the character height must not be less than 6 inches (152 millimeters) or more than 9 inches (229 millimeters), and the stroke width not less than 1 inch (25 millimeters). The height of a TACAN checkpoint sign must not be more than 32 inches (0.8 meters) with the maximum sign elevation above the taxiway edge not more than 40 inches (1 meter). The TACAN checkpoint sign should not be located less than 50 feet (15 meters) from the taxiway edge.

9-3.3.2 Electrical.

See paragraph 9-1.4.

9-3.3.3 Photometrics.

See FAA AC 150/5345-44 for detailed information about sign luminance and measurement methods.

9-3.3.3.1 Photometric Testing.

Photometric testing must be performed on all newly installed runway exit signs on site. The purpose of these tests is to verify the installed fixtures meet or exceed the minimum photometric requirements.

9-3.4 Power and Control.

For new installations, runway exit signs will be powered from a dedicated 1-step (5.5 ampere) circuit. Control of the circuit will be interlocked with the corresponding runway edge lighting circuit so as to turn on and off with its runway edge lighting. Other lighted guidance signs as well as information signs are typically connected to taxiway edge lighting circuits. This configuration permits the signs to be turned on and off with the respective runway or taxiway lighting.

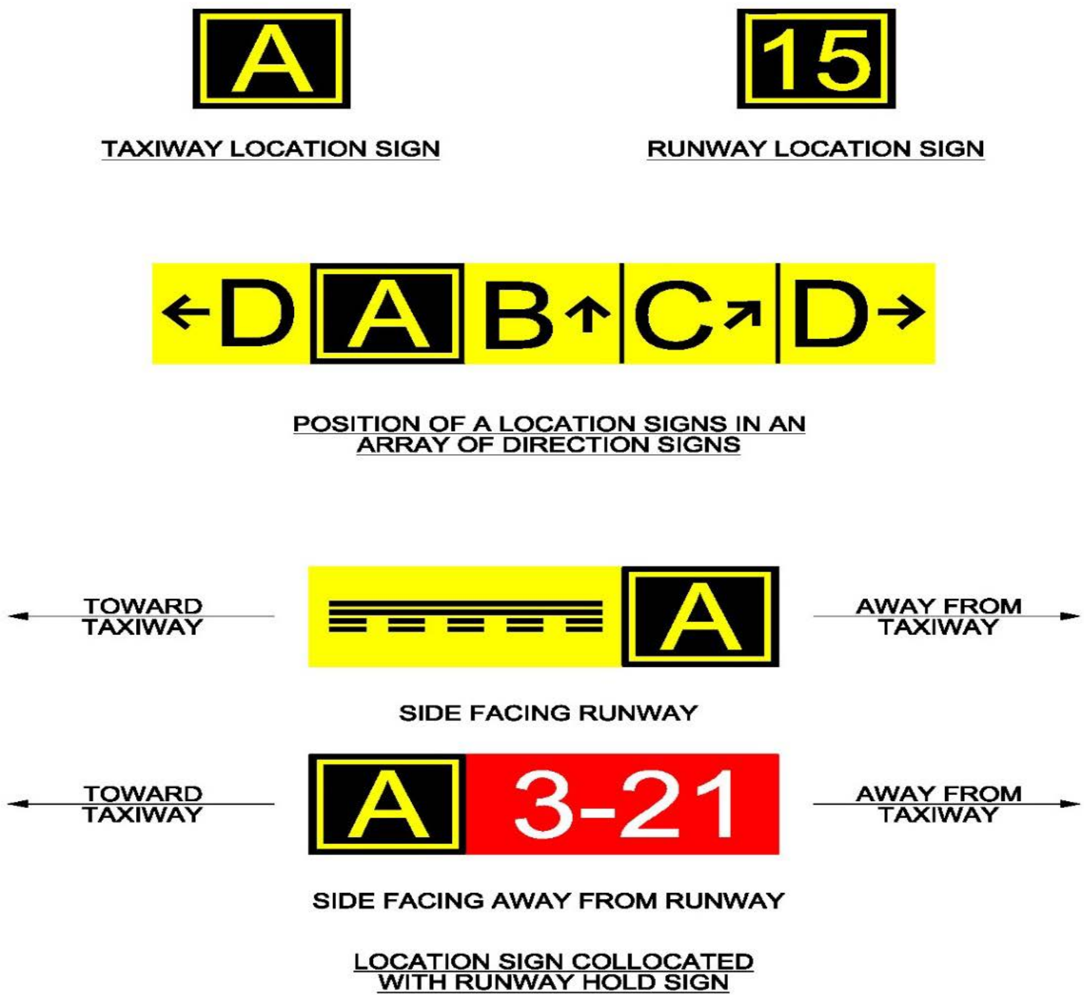
9-4 LOCATION SIGNS.

9-4.1 Purpose.

Location signs identify the taxiway or runway on which the aircraft is located. Examples of location sign messages are shown in Figure 9-4.

Figure 9-4 Typical Location Signs

Note: These signs represent the bulk of existing signs and comply with previous edition of FAA AC 150/5345-44. These signs do not require replacement until the end of their economic lives or with a major renovation to the airfield. See current edition of FAA AC for new sign message elements.



NOTE:

1. LOCATION SIGNS ARE FAA TYPE L-858L, WITH YELLOW LEGEND AND BORDER ON BLACK BACKGROUND, MEETING FFA AC 150/5340-44, SIZE 3, STYLE 2 OR 3.

9-4.2 Installation.

Location signs are typically installed on the left side of a taxiway, but also may be on the right side if this helps visibility. Often taxiway location signs are part of a sign array, hence may be together with a mandatory hold sign or a guidance direction sign (although not with a runway exit sign). Runway location signs may be installed on runways where two runways are in proximity, which could create confusion, and are located to clearly indicate the runways for pilots. Runway location signs are not part of a sign array, and contain the runway designation only for the one runway end.

9-4.2.1 Location signs are subject to the same siting criteria as the direction and information signs in paragraph 9-3. Taxiway location signs may be part of a direction sign array, or may be stand-alone between taxiways where it would be helpful to reinforce pilot information as to location.

9-4.2.2 Location signs may be FAA Size 1, 2 or 3. Size 3 signs are recommended for Category I facilities and higher. Locate signs as indicated in paragraph 9-3.2.8.

9-4.2.3 A location sign may be grouped in a sign array. With mandatory signs, the location sign should always be positioned outboard. With a direction sign array, the location sign is placed so that all turns to the left would be located to the left of the location sign, and all turns to the right or straight ahead would be located to the right of the location sign. An exception is when only two taxiways intersect and the direction sign indicates the crossing taxiway with arrows both ways, in which case the location sign is positioned to the left.

9-4.2.4 Location signs are not always needed in conjunction with a direction sign. The need is determined from evaluating the complexity of the intersection layout, distance from the last location sign, complexity of prior intersections, traffic flow, and typical conditions under which the intersection is used. Do not include a location sign as an array with a destination sign or other information sign. See guidance in paragraph 9-5 for conventions on sign arrays. See FAA AC 150/5340-18 for further guidance on grouping several sign messages in an array.

9-4.3 Characteristics.

See Chapter 13 and FAA AC 150/5345-44 for additional characteristic information.

9-4.3.1 Message.

See paragraph 9-2.3.1.

9-4.3.2 Dimensions.

See paragraph 9-2.3.2.

9-4.3.3 Electrical.

See paragraph 9-1.4.

9-4.3.4 Photometrics.

See paragraph 9-3.3.3.

9-4.4 Power and Control.

Runway location signs are connected to the runway edge lighting series circuit. Taxiway location sign are typically connected to taxiway edge lighting circuits similar to taxiway guidance and information signs in paragraph 9-3.

9-5 SIGNING CONVENTIONS FOR AIRFIELD SIGNS.

9-5.1 There is no standard configuration for signing that applies to all airfields. In laying out signing for an airfield, first conduct a thorough study of the runway and taxiway layout drawings with local traffic controllers and the operational group using the airfield. Signs are not necessarily needed at all potential locations on an airfield, and judgment must be made based on standards, other guidance, and operational need to provide clear, non-conflicting direction to pilots. It is recommended that the appropriate local engineering function maintain and update a master sign plan for the entire airfield.

9-5.2 The following are general signing conventions to be followed for all airfields:

a. Signs should always be placed on the left side of a taxiway as seen by the pilot of approaching aircraft. Exceptions are:

b. Where signs are placed on both sides of a surface (for example, at wide throat entrances to intersections).

c. Where a sign may be placed on the back of a left-handed sign for traffic in the other direction (such as a location or boundary sign on the back of a mandatory hold sign).

d. Where a destination sign might be placed at the top of a “T” at a “T” intersection.

e. Where necessary for clearance requirements.

f. Where it is impractical to install on the left because of terrain or conflicts with other objects.

9-5.2.1 If signs are installed on both sides of a taxiway at the same location, the sign faces should be identical. An exception is for holding position signs, where a location sign in the array should always be outboard of the mandatory sign.

9-5.2.2 All direction signs have arrows. Arrows on signs should be oriented to approximate the direction of the turn. Each designation on an array of direction signs should be accompanied only by one arrow. An exception is when an intersection has only two taxiways where it is permissible to have the designation of the cross taxiway with arrows both ways.

9-5.2.3 Location signs are typically included as part of a direction sign array. The location sign is placed so that the designations for all turns to the left are on the left of the location sign, and all turns to the right or straight ahead (if used) are on the right of the location sign. A location sign installed together with a mandatory sign is always located outboard of the mandatory sign.

9-5.2.4 A direction sign with an arrow indicating a taxiway continues straight ahead (25 degrees or less change in alignment) is usually not needed, unless the designation of the taxiway changes at the intersection.

9-5.2.5 Information signs should not be collocated with mandatory, location, direction, or destination signs.

9-5.2.6 Each designation and its associated arrow in a direction sign array should be delineated from the other designations in the array by a black vertical border. Where appropriate, a location sign may provide this delineation.

9-5.2.7 Destination signs are never grouped with other signs in a sign array. Destination signs may be installed on the back side of a direction sign on the far side of an intersection when the destination referred to is straight ahead. At intersections or junctions of runways, taxiways, or runways and taxiways, where there are alternate routes to a particular destination from a given direction of travel, indicate only one route on the destination sign.

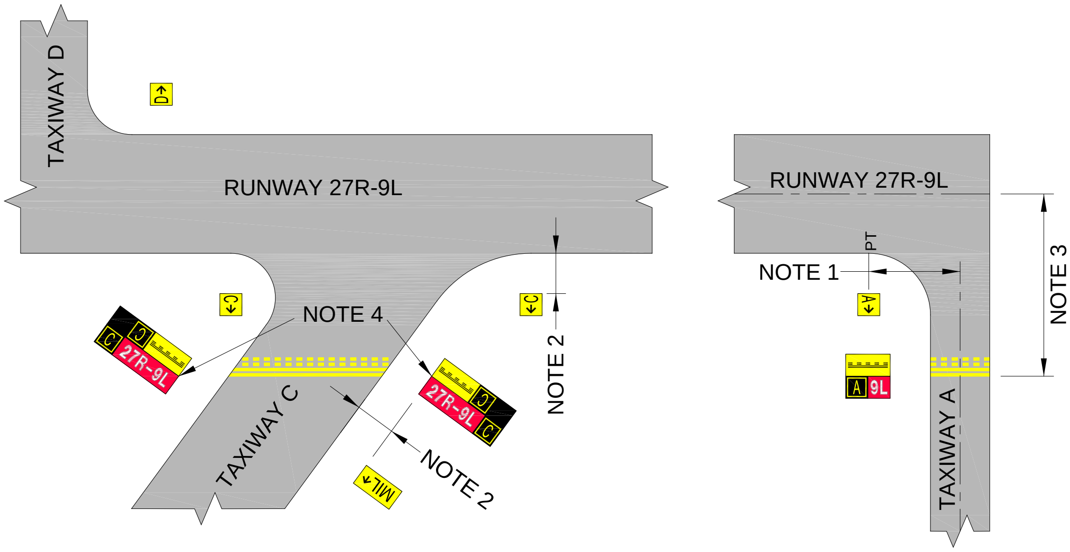
9-5.2.8 Mark outbound routes from their beginning to their termination point with destination signs showing the appropriate runway(s) designation. Outbound routes usually begin at the entrance of a taxiway from an apron area; its termination point is the takeoff end of the appropriate runway. Outbound destination signs may show more than one runway destination number if the direction of travel on a taxiing route is the same to all the runway destinations shown on the sign. In such cases, separate any pair of runway designation numbers by a circular dot.

9-5.2.9 Mark inbound routes from their beginning with destination signs showing the appropriate symbols. Inbound routes usually begin at the entrance to a taxiway from a runway. Mark inbound traffic routes at the beginning with appropriate destination areas on the airfield as required. Typical examples are “APRON,” “FUEL,” “MIL,” and “CARGO” with an arrow indicating the route. This is a general guide and may be varied to meet local conditions, ground traffic, and variations in airport layout.

9-5.3 It is recommended that all mandatory taxiway guidance and information signs, and location signs be of the same size for a runway and associated taxiway complex. FAA Size 3 signs are recommended for facilities that have Category I operational capability, and for other higher volume airfields. An exception can be made at a particular location where a sign must be positioned closer to a runway or taxiway allowed for a Size 3 sign. In this case a smaller sign may be installed within its allowable distance from the surface.

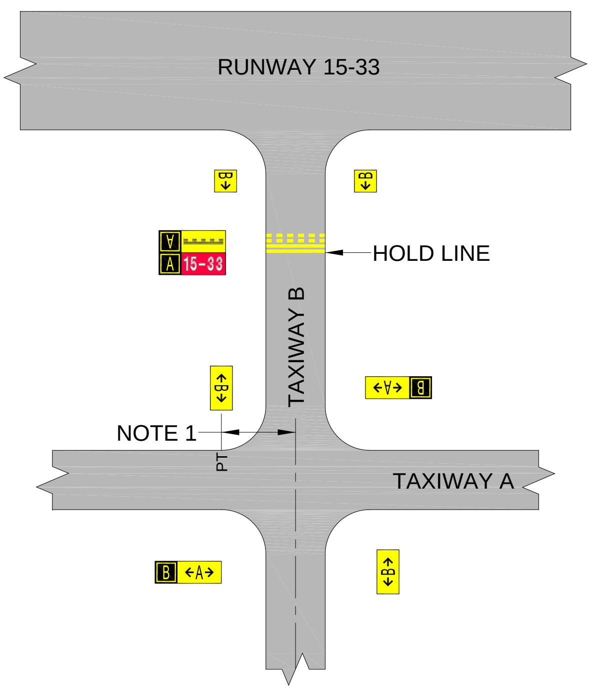
9-5.4 Examples of sign layouts are shown in Figure 9-5 and Figure 9-6. An example for positioning a TACAN checkpoint sign is shown in Figure 9-7.

Figure 9-5 Examples of Signing Conventions



SIGNAGE AT WIDE INTERSECTIONS WITH RUNWAY

TYPICAL SIGNAGE AT END OF RUNWAY



TYPICAL SIGNAGE LAYOUT

NOTES:

1. LOCATE SIGN AT THE RUNWAY/ TAXIWAY PT OR THE DISTANCE FROM TAXIWAY CENTERLINE INDICATED IN TABLE 9-1, WHICHEVER IS GREATER.
2. DISTANCE FROM EDGE OF DEFINED RUNWAY OR TAXIWAY IS 35-60 FT (10.5 - 18 M) FOR FAA SIZE 3 SIGNS.
3. HOLD SIGNS COLLOCATED WITH HOLD MARKING. DISTANCE FROM RUNWAY CENTERLINE IS BASED ON APPROACH CATEGORY AND AIRCRAFT, AND WILL BE DEFINED BY MIL FOR EACH SITE.
4. INSTALL SIGNS ON BOTH SIDES OF DEFINED TAXIWAY WHEN THE WIDTH IS 150 FT (45 M) OR GREATER. SIGN LEGEND ON BOTH SIDES SHALL BE IDENTICAL. THE LOCATION SIGN MUST ALWAYS BE OUTBOARD OF THE MANDATORY SIGN.
5. SEE FAA AC 150/5340-18 FOR MORE INFORMATION ON SIGNAGE CONVENTIONS.

Figure 9-6 Signing Examples

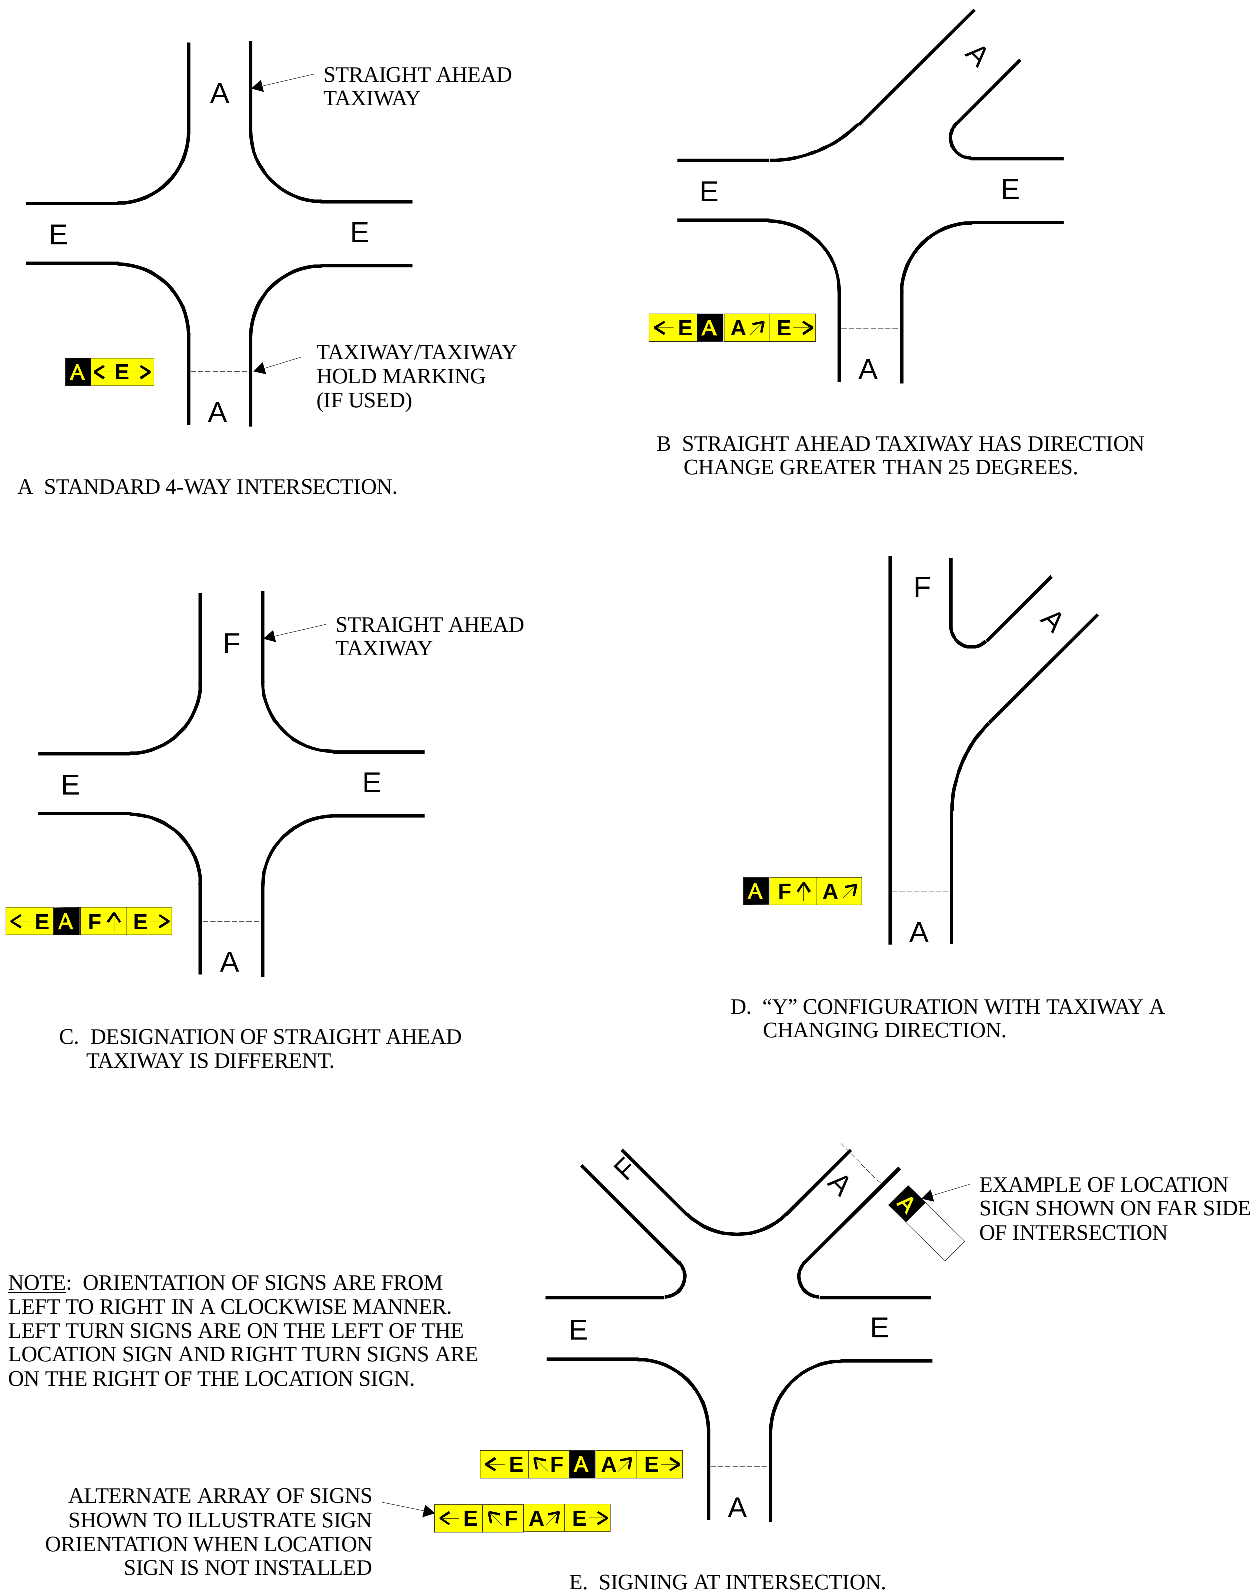


Figure 9-7 TACAN Sign Location

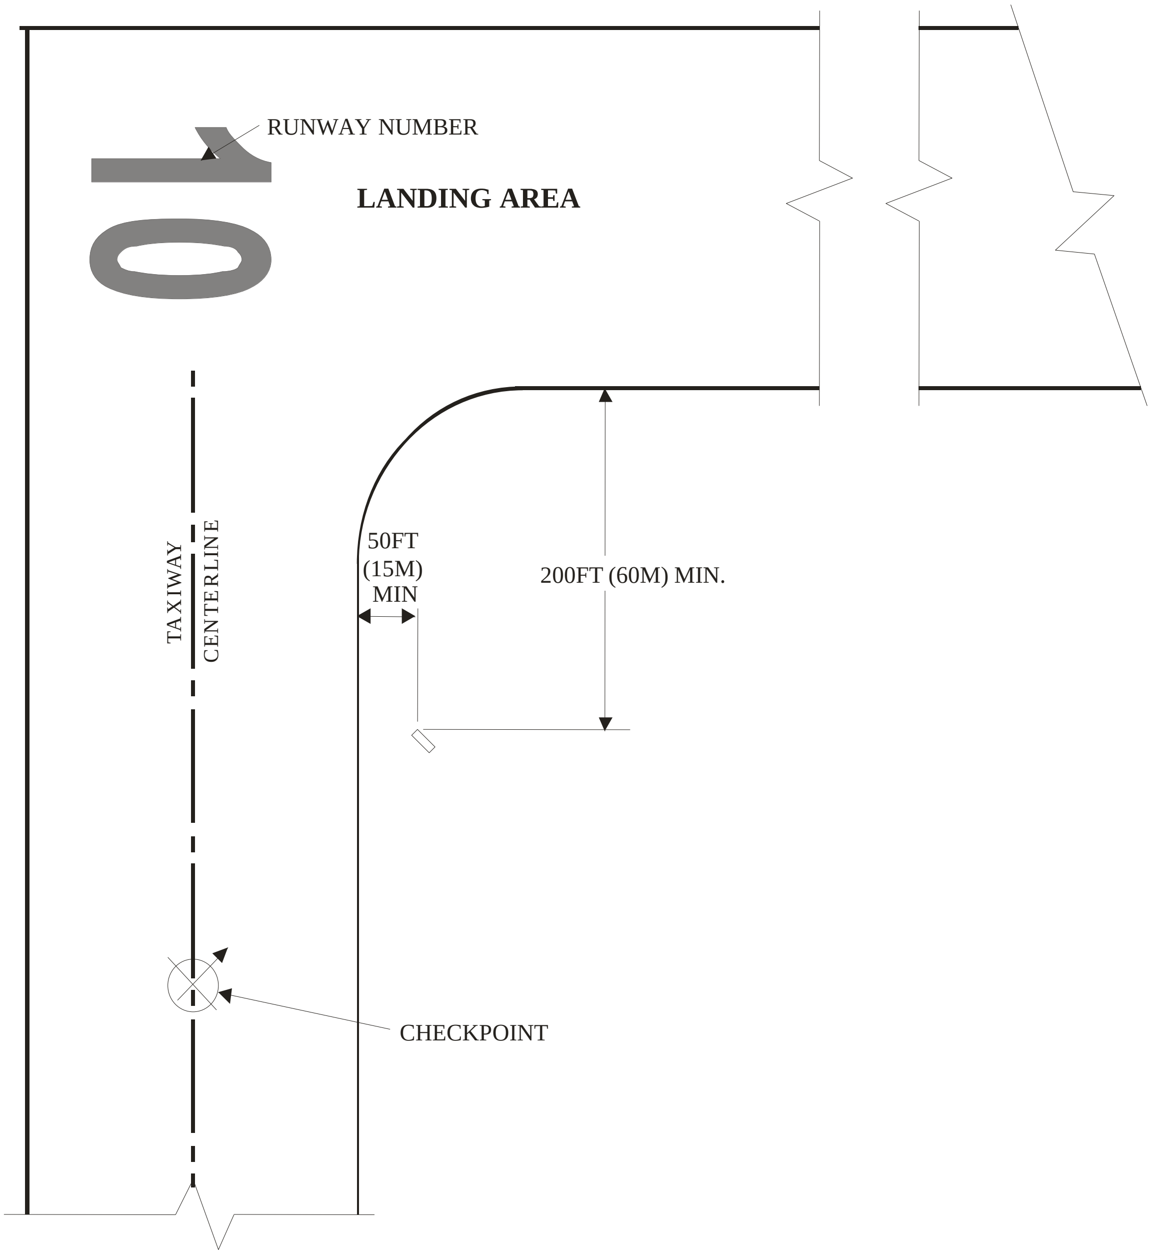


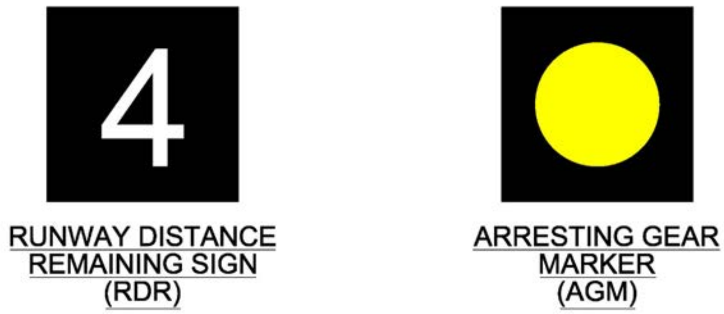
9-6 RUNWAY DISTANCE REMAINING (RDR) SIGNS.

9-6.1 Purpose.

Runway Distance Remaining (RDR) Signs are used to provide distance remaining information to pilots during takeoff and landing operations. The RDR are located along both sides of the runway, and the white numeral on the black background indicates the runway distance remaining in increments of 1,000 feet (metric units are not used). A typical runway distance remaining sign is shown in Figure 9-8.

Figure 9-8 Typical RDR Signs and AGM

Note: These signs represent the bulk of existing signs and comply with previous edition of FAA AC 150/5345-44. These signs do not require replacement until the end of their economic lives or with a major renovation to the airfield. See current edition of FAA AC for new sign message elements.



NOTES:

1. RDM ARE FAA TYPE L-858B, WITH WHITE LEGEND ON BLACK BACKGROUND, MEETING FAA AC 150/5345-44, SIZE 4.
2. AGM HAVE CHARACTERISTICS OF RDM BUT WITH A YELLOW CIRCLE 39" (1M) IN DIA. ON BLACK BACKGROUND, MEETING FAA AC 150/5345-44, SIZE 4.

9-6.2 Installation.

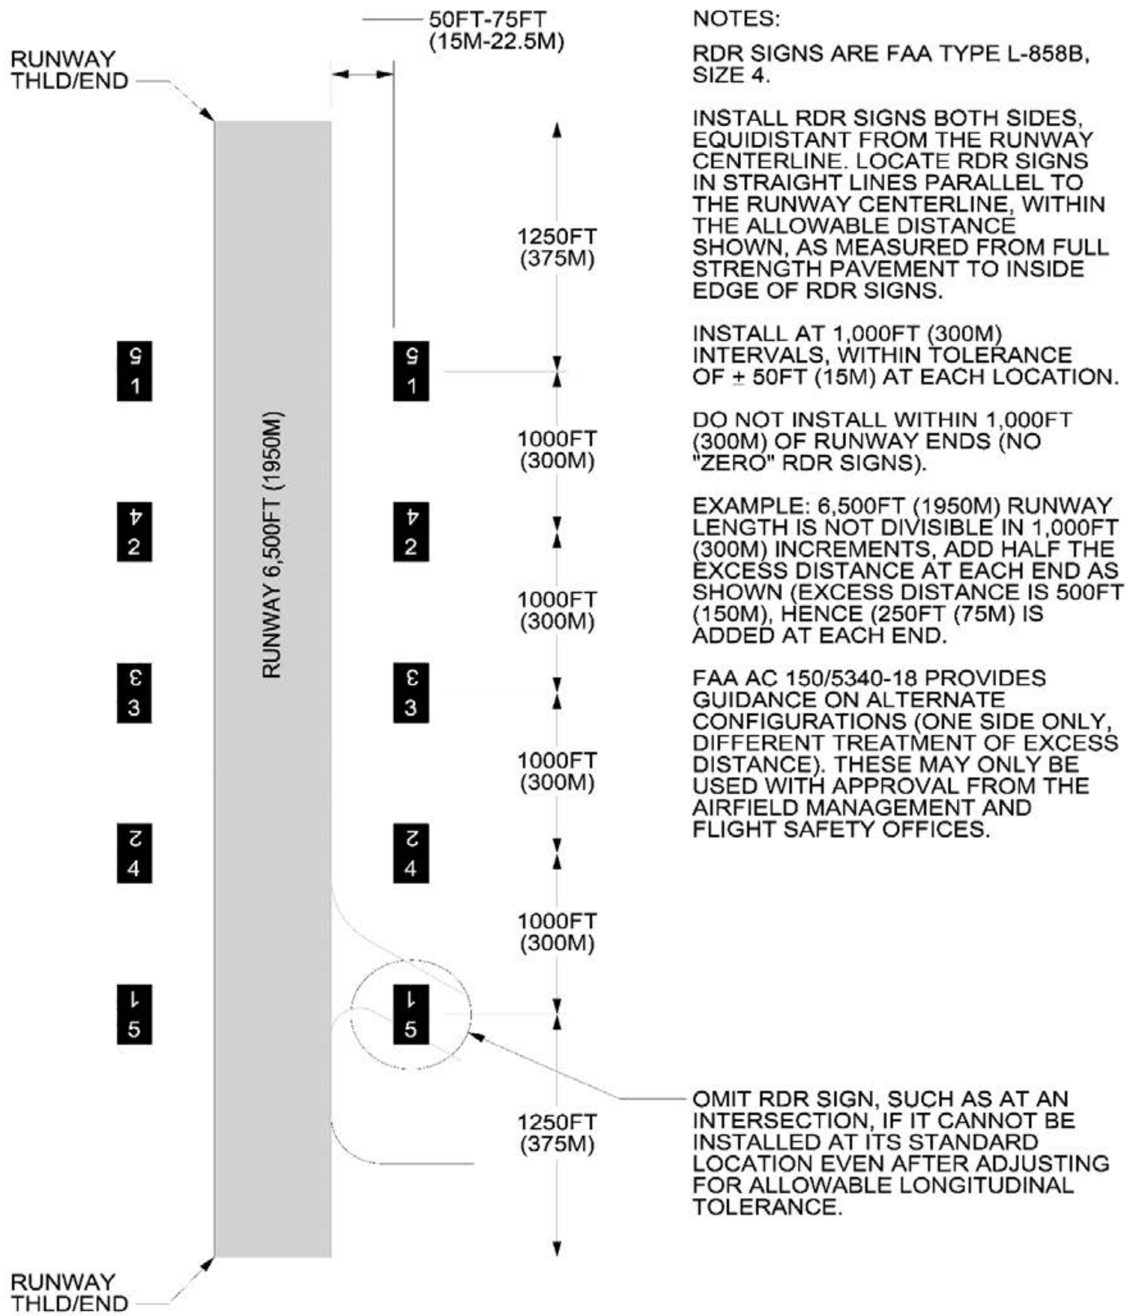
An RDR sign system (previously referred to as a Runway Distance Marker [RDM]) is required for all runways per Table 2-1A and Table 2-1B.

9-6.2.1 The row of markers along each side of the runway is parallel to the runway centerline, and equal distance from the runway edge. FAA Size 4 RDR signs are positioned 50-75 feet (15-22.5 meters) from the runway edge. Use only FAA Size 4 RDRs.

9-6.2.2 RDR signs are spaced at 1,000 foot (300 meter) intervals along the runway, excluding the threshold and runway end. Displaced threshold areas that are used for takeoffs and/or rollout are treated as part of the runway for purposes of locating the markers. Numerals are shown on both faces of the markers so the distance remaining can be seen in either direction of operations.

9-6.2.3 For runway lengths that are not an exact multiple of 1,000 feet (300 meters), one-half the excess distance is added to the distance of each marker for each runway end. For example, for a runway length of 6,500 feet (1,950 meters), the excess distance is 500 feet (150 meters) and the location of the last marker on each runway end is 1,000 feet (300 meters) plus one-half of 500 feet (150 meters), or 1,250 feet (375 meters). A longitudinal tolerance of ±50 feet (±15 meters) is allowed if a marker cannot be installed at its standard location. A marker should be omitted if it cannot be installed within this tolerance. This standard procedure for siting RDR signs is illustrated by Figure 9-9. Alternative methods can be found in FAA AC 150/5340-18, as allowed by the appropriate command.

Figure 9-9 RDR Sign Layout Configuration



9-6.2.4 Runway Distance Remaining (RDR) Signs for military airfields are FAA Size 4, and are located 50-75 feet (15-22.5 meters) from runway edge. The distance indicated is to the inside edge of the sign. Signs are oriented perpendicular to and located equidistant from the runway centerline.

9-6.3 Characteristics.

See Chapter 13, FAA AC 150/5340-18, Chapter 2, and FAA AC 150/5345-44, Appendix 1, for additional characteristic information.

9-6.3.1 Message.

Signs are double face, internally lighted, with retro-reflective message faces that meet the color and reflectivity requirements of ASTM D 4956, Type I Sheeting. The spacing, stroke, and shape of legend characters, numerals, and symbols must be in accordance with FAA AC 150/5345-44, Appendices A-I.

9-6.3.2 Dimensions.

See FAA AC 150/5340-18 for marker and legend height dimensions. The marker should provide at least 12 inches (300 millimeters) clearance between the top of the sign and any part of the most critical aircraft expected to use the runway when the aircraft wheels are at the pavement edge.

9-6.3.3 Electrical.

For new installations, it is required that RDR signs be FAA Style 5 and connected to the 5.5 amp, 1-step RDR circuit. The intent is to have a more reliable sign system by eliminating the electronics required to maintain uniform brightness over the range or a 3 or 5-step regulator.

9-6.3.4 Photometrics.

The average minimum sign luminance for all intensity steps must be white legend, 300 CD/M^2 (88 foot-lamberts). It is recommended that photometric testing be performed on all newly installed RDR signs on site. The purpose of these tests is to verify the installed fixtures meet or exceed the minimum photometric requirements.

9-6.4 Power and Control.

For new installations, RDR signs will be powered from a dedicated 1-step (5.5 ampere) circuit. Control of the circuit will be interlocked with the corresponding runway edge lighting circuit so as to turn on and off with its runway edge lighting.

9-7 ARRESTING GEAR MARKERS.

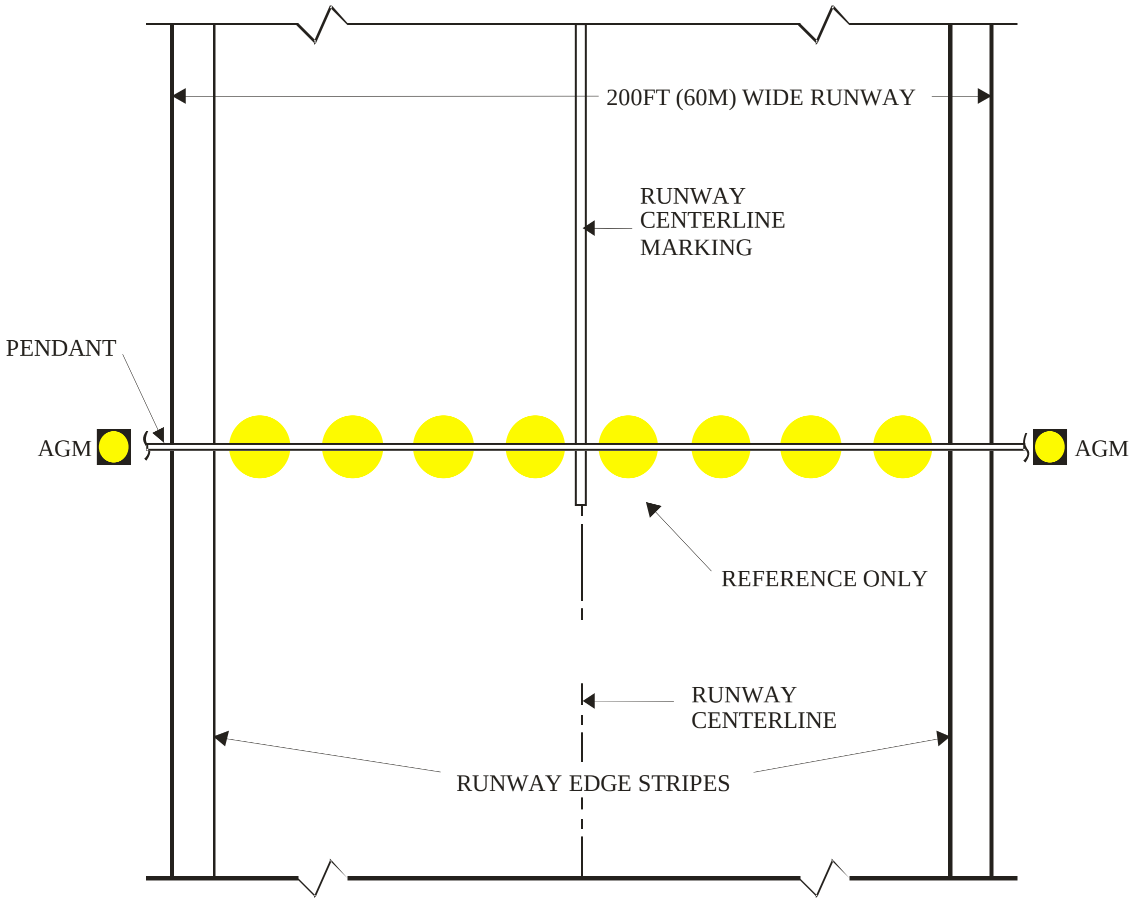
9-7.1 Purpose.

Arresting Gear Markers (AGM) identify arresting gear pendant cables or barriers on the operational runway surface. The AGMs are located adjacent to the location of arresting system cables on the runway. An AGM is shown in Figure 9-8.

9-7.2 Installation.

Arresting pendant cables must be identified by AGM on both sides of the runway. The AGM are located in line with the cable ± 10 feet (3 meters) and equidistant from the runway edge. AGM are similar to Size 4 RDR signs, and are positioned 50-75 feet (15-22.5 meters) from the runway edge. Where RDR signs are installed, locate the AGMs in line with the RDR signs, except where the AGM is within 20 feet (6 meters) of an RDR sign. In this case relocate the RDR sign to be in line with the AGM and 5 feet (1.5 meters) outboard of the AGM. The distance indicated is to the inside edge of the marker. If the arresting gear is in the overrun, signs are not allowed but obstruction lights are required on the structures housing the operating system. See Chapter 6. This is a common requirement for the BAK-15. Markers are oriented perpendicular to the runway centerline. Typical installation of AGM is shown in Figure 9-10.

Figure 9-10 Arresting Gear Marker (AGM) Configuration



NOTES:

1. Install AGM in line with RDR Signs.
2. If an RDR sign is within 20ft (6m) of an AGM, then move the RDR sign even with the AGM and install it 5ft (1.5m) outboard of the AGM.

9-7.3 Characteristics.

See Chapter 13 for additional characteristic information.

9-7.3.1 Message.

Messaging is similar to RDR sign (paragraph 9-6.3.1) except that the white numeral of the RDR sign is replaced with a yellow translucent circle approximately 39 inches (1 meter) in diameter facing both runway directions.

9-7.3.2 Dimensions.

See paragraph 9-6.3.1 for legend dimensions. FAA Size 4 sign has a marker panel height of 48 inches (1,219 millimeters) and overall mounting height of 54-60 inches (1,350–1,500 millimeters). As with RDR, the marker provides at least 12 inches (300 millimeter) clearance between the top of the sign and any part of the most critical aircraft expected to use the runway when the aircraft wheels are at the pavement edge.

9-7.3.3 Electrical.

For new installations, it is required that AGMs be FAA Style 5 and connected to the 5.5 amp, 1-step RDR circuit. The intent is to have a more reliable sign system by eliminating the electronics required to maintain uniform brightness over the range or a 3 or 5-step regulator.

9-7.3.4 Photometrics.

The average minimum sign luminance for all intensity steps must be yellow legend, 44 foot-lamberts (150 CD/M$^{2)}$).

9-7.3.4.1 Photometric Testing.

It is recommended that photometric testing be performed on all newly installed AGMs on site. The purpose of these tests is to verify the installed fixtures meet or exceed the minimum photometric requirements.

9-7.4 Power and Control.

See paragraph 9-6.4. Power the AGM to operate in unison with the runway edge lights. If the runway is used by Remotely Piloted Aircraft (RPA) or Unmanned Aerial Vehicles (UAVs), the Wing Commander may take written responsibility for powering them separately, for the safety of the RPAs or UAVs or a permanent waiver may be processed.

9-8 OTHER SIGNS.

9-8.1 Purpose.

Other signs not listed above may be installed on the airfield to serve special needs. This may include signs that apply only to vehicle traffic and special purpose signs that are not included in current standards but that may meet specific needs.

9-8.2 Installation.

Signs other than those listed in previous paragraphs must not conflict with current sign standards, and must not present confusing situations for ground traffic with respect to the sign's function and the standard signing on the airfield.

9-8.2.1 Signs intended for vehicles only, such as on vehicle service roads or lanes, typically follow the MUTCD. For example, standard highway stop signs may be installed on vehicle roadways at the intersection of each roadway with a runway or taxiway. A yield sign may be used in place of a stop sign at intersections with taxiways. See FAA AC 150/5340-18 for additional information and requirements for vehicle roadway signs. Such signs should not be placed closer than a runway holding position for the same runway. Appropriate safe offset distances from Table 9-1 must also be used where roadways cross taxiways.

9-8.2.2 Special purpose signs other than those listed above should be approved by the appropriate military authority based on a specific need at an airfield. Also, special circumstances may dictate that a standard sign is unsuitable for a particular location sign. Placement of non-standard signs should be as needed, but should not violate the requirements for standard signing listed above in terms of proximity to runways and taxiways. To the extent allowable and as appropriate for the application, non-standard signs should follow the guidelines contained in FAA AC 150/5340-18 and FAA AC 150/5345-44.

9-8.2.3 In some cases standard signs may be painted on a pavement surface to enhance messaging. Painted signs on pavements should conform to UFC 3-260-04.

9-8.3 Characteristics.

Vehicle signs should follow the requirements of the MUTCD. These are normally unlit signs, although in some cases external lighting may be useful. Other special purpose signs will be as required by the need, but must not conflict with or cause confusion with standard airfield signing.

9-9 COMPLIANCE WITH INTERNATIONAL STANDARDS.

9-9.1 AFIC.

Previous AFIC AIR STD 90/27 cancelled.

9-9.2 NATO.

This standard meets the requirements of **\4** AATMP-07 Edition A, ***/4/*** *Airfield Lighting*, for taxiway signs, except for minimum size of signs and the location of some signs at intersections.

9-9.3 Additional Information.

See FAA AC 150/5340-18, FAA AC 150/5345-44, and ICAO Annex 14 for more information.

This Page Intentionally Left Blank

CHAPTER 10 STANDARDS FOR MISCELLANEOUS VISUAL AIDS

10-1 AIRPORT BEACONS.

10-1.1 Purpose.

Airport beacons are high-intensity flashing lights which provide a visual signal to pilots to assist in locating and identifying the airfield or a hazardous obstruction at night, or in restricted visibility conditions. These beacons may be rotating or fixed, but must provide the signal through 360 degrees of azimuth. These requirements are to be used for new installations of airport beacons. Existing installations may continue to be used and maintained until the first airfield lighting upgrade project. The absence of a formerly FAA-approved or Mil-Spec NAVAID, or other piece of equipment from the current AC 150/5345-53, Appendix 3 Addendum is not an indication that this equipment is no longer approved for use. Absence from the AC means that particular NAVAID or piece of equipment is no longer manufactured. Beacons fitting this situation, such as the Model DCB-224M military beacon, is still supported for repairs by a sub-party of the former manufacturer and is typically more reliable and powerful than currently marketed beacons. Contact AFCEC/COSM for support information, if repairs to older beacons are required.

10-1.2 Beacon Types.

10-1.2.1 Airfield Rotating Beacon.

Each lighted airfield, except where one rotating beacon serves more than one airfield in close proximity, must use a high-intensity military type beacon (FAA Type L-802M). This beacon must have a double-peaked white beam to denote a military airfield and a single-peaked green beam to indicate that the airfield has lighted facilities for operations at night or in restricted visibility. The two beams must be directed 180 degrees apart. The signal from the beacon must be visible through 360 degrees of azimuth by rotating at six revolutions per minute (RPM). The airfield rotating beacon must be operated during twilight and night hours and during daytime when Instrument Flight Rules (IFR) are in effect. Alternating white and green flashes identify a lighted civil airport, and white flashes identify an unlighted civil airport.

10-1.2.2 Identification or Code Beacon.

For Air Force only, the identification beacon is used only at airfields where the airfield rotating beacon is located more than 6,000 feet (1,800 meters) from the nearest runway or where the airfield rotating beacon serves more than one airfield. The identification beacon is a non-rotating flashing omnidirectional light visible through 360 degrees. This beacon flashes a green coded signal at approximately 40 flashes per minute. The signal is an assigned code of characters to identify the particular airfield. The identification beacon must be operated whenever the associated airfield rotating beacon is operated.

10-1.3 Location Requirements.

See FAA AC 150/5340-30 for information about the location of beacon towers that are less than 200 feet (60 meters) above ground level (AGL). See the same AC for information about the construction of tubular or structural steel towers. For tower construction specific information see FAA AC 150/5370-10, Item L103, Airport Beacon Towers.

10-1.3.1 Visible through 360 degrees of azimuth if possible.

10-1.3.2 Not less than 1,000 feet (300 meters) from the centerline or centerline extended of the nearest runway.

10-1.3.3 Not in the line of sight from the control tower to the approach zone of any runway or to within 75 feet (22.5 meters) vertically over any runway.

10-1.3.4 Located 750 feet (225 meters) or more from the control tower. This is intended to prevent light reflection during foggy conditions which reduce visibility and interfere with light gun signals from the control tower cab.

10-1.3.5 Not more than 6,000 feet (1,800 meters) from the nearest point of usable landing area, except if surrounding terrain will restrict visibility of the beacon through an appreciable angle in some directions or the beacon will serve more than one airfield. If terrain restricts viewing the beacon or the beacon will serve more than one airfield, the distance of the beacon from the nearest runway may be increased to not more than two miles.

10-1.3.6 The base of the beacon must be not less than 20 feet (6 meters) higher than the elevation of the floor of the control tower cab. If the airfield rotating beacon is located more than 6,000 feet (1,800 meters) from the nearest point of usable landing area, an identification beacon must be installed and not more than 6,000 feet (1,800 meters) from the nearest point of usable landing area.

10-1.4 Photometric Requirements.

See FAA AC 150/5345-12 for detailed photometric beacon requirements.

10-1.4.1 Colors.

The color of the emitted light must be standard aviation colors per FAA AC 150/5345-12.

10-1.4.2 Airfield Rotating Beacon.

See FAA AC 150/5345-12 for airfield rotating beacon intensity values and methods of measurement.

10-1.4.3 Identification Beacon.

With the beacon operating steadily (not flashing) at rated voltage, the intensity of the green light must be not less than 1,500 candelas for a distribution through 360 degrees horizontally and 2 degrees vertically. The areas of the beam where the support rods are located may be less than these required intensities.

10-1.5 Aiming.

The vertical aiming of the beacons should be properly focused and aimed when manufactured, and leveling should be all that is required for aiming during installation. The axes of the beams vertically should be approximately five degrees above the horizontal for the rotating beacon. For the identification beacon, the center of the beam must be approximately 3 degrees above horizontal.

10-1.6 Equipment.

The airfield rotating beacon and the identification beacon equipment must be as shown in paragraph 13-12. The identification beacon must be provided with a keyer to flash the assigned identification code. The identification beacon is for Air Force only.

10-1.7 Power Requirements.

See FAA AC 150/5340-30 for additional information about the airport beacon power requirements. See also FAA AC 150/5370-10, Item L-103, Airport Beacon Towers, for construction, wiring, and contract requirements. The electrical power requirement for the beacons is 120 volts. The source of power may be from the airfield lighting vault or from a local source that is continuously available. If the distance from the power source is long and the line voltage drop is large, transmission of power at a higher voltage and step-down to 120 volts at the site may be desirable. Base the KVA rating of the step-up and step-down transformers on the total KVA load of the equipment. Emergency power is not required for the airport beacons, but should be used if it is available.

10-1.8 Control Requirements.

See FAA AC 150/5345-12 for airport/airbase beacon control requirements and description. The controls for the airport beacons are only those required to energize and switch off the beacon and its drive motor or keyer. Preferably, these beacons should be controlled remotely from the lighting control panel in the control tower or the airfield lighting vault. Control may be furnished by an automatic photoelectric switch or a clock-driven timer.

10-1.9 Monitoring Requirements.

There is no requirement for monitoring.

10-1.10 Compliance with International Military Standards.

There are no International Military Standards for airport beacons.

10-2 WIND DIRECTION INDICATORS (CONES).

10-2.1 Purpose.

Wind cones are installed near landing surfaces to provide a clear indication of the direction of the surface wind and a general indication of wind speed. Wind cones are lighted for night operation.

\4

10-2.2 Siting Requirements.

10-2.2.1 Fixed Wing. Locate wind cones not less than 400 feet (120 meters) from the runway centerline and in a location free from the effects of air disturbances caused by nearby objects. If a wind cone is more than 27 feet (8.1 meters) above ground elevation a waiver to UFC 3-260-01 is required.

10-2.2.2 Rotary Wing. See B13-2.19.1 Wind cone mountings are of two types. Type L-806 is mounted on a low-mass supporting structure (frangible); Type L-807 is mounted on a rigid supporting structure (non-frangible). Either type must be located not less than 91.4 meters/300 feet (Class A/Rotary-Wing Runways/Helipads) or 121.9 meters/400 feet (Class B) from the centerline of the runway to the centerline of the wind cone and in a location free from the effects of air disturbances caused by nearby objects. If a waiver is approved to be sited within 300 feet (Class A/Rotary-Wing Runway/Helipads) or 400 ft (Class B) of a runway centerline, only the L-806 (frangible) wing cone will be used. A height of more than 8.23 meters (27 feet) above ground elevation (not including the obstruction light) requires a waiver. **/4/**

10-2.3 Wind Cone Configuration.

10-2.3.1 The wind cones must be in the form of a truncated cone made of fabric. They must have a length of not less than 8 feet (2.4 meters) and a diameter at the larger end of not less than 18 inches (450 millimeters). They must be constructed so it gives a clear indication of the direction of the surface wind and a general indication of the wind speed. Wind cones must extend fully in a fifteen knot wind.

10-2.3.2 The color(s) must be selected with consideration given to the background and to make the indicator clearly visible and understandable from a height of at least 1,000 feet (300 meters). Where practicable, use a single color, preferably white or orange. When a combination of two colors is required to provide conspicuity, the preferred colors are orange and white, red and white, or black and white. The colors must be arranged in 5 alternate bands, the first and last band being the darker.

10-2.3.3 There are two types of wind cone mounting structures: FAA Type L-806 (frangible) and FAA Type L-807 (rigid). Type L-806 is used for supplemental wind cones located near the ends of runways. Type L-807 is used for the primary wind cone. Refer to FAA AC 150/5340-30, for additional information about wind cone installation.

10-2.4 Lighting Requirements.

Illuminate the wind cone with floodlights which are arranged to provide a minimum illumination level of 2 footcandles (20 lux) at any point on the horizontal plane described by a complete rotation of the upper surface of a fully extended cone. The lights must be shielded to prevent light emission above the horizontal. Equip the wind cone support with an obstruction light.

10-2.5 Power Requirements.

Provide a main power source only. If powered from the associated runway edge lights, they will have the provision so the cone floodlight brightness does not vary more than 20 percent with the available light, meeting the requirements of paragraph 10-2.4, at the lowest setting of the runway edge lights. Refer to paragraph 13-6.2 for additional information about runway edge light circuit power.

10-2.6 Control Requirements.

On and off control is the only requirement and may be accomplished via the runway edge light circuit if used.

10-2.7 Monitoring Requirements.

There are no requirements for monitoring wind cones.

10-2.8 Equipment.

The wind indicators must be as shown in paragraph 13-12.3 **\4** (reference UFC 3-535-01, 11 April 2017) **/4/**.

10-2.9 Compliance with International Standards.

There are no AFIC AIR STDs or NATO STANAGs for wind indicators.

10-2.10 Additional Information.

See FAA AC 150/5345-27 and FAA AC 150/5340-30 for additional information.

10-3 RUNWAY AND TAXIWAY RETRO-REFLECTIVE MARKERS.

10-3.1 Purpose.

Reflectors and retro-reflective markers may be used to supplement existing runway and taxiway lighting, or for temporary installations. However, a waiver must be granted by the major command for their use.

10-3.2 Characteristics.

The retro-reflective materials used are designed to reflect light approaching at an oblique angle, back toward the light source.

10-3.3 Equipment.

For additional guidance on the types and styles of the markers refer to FAA AC 150/5345-39 and FAA AC 150/5340-30.

10-4 FLOOD, SECURITY, OR AUXILIARY LIGHTING.

10-4.1 Special Lighting Arrangements.

Special arrangements of lights, such as apron or parking are floodlights and protective and security lighting, may be required at an installation. These lights will not be connected to the airfield lighting circuits. Hangar access aprons (hangar entrances) may be lighted by floodlights installed around the apron or mounted on the hangar. Floodlights provided for these areas are considered as part of the hangar construction.

10-4.2 Floodlights.

10-4.2.1 Purpose.

Hangar areas are typically lighted to 1 foot candle. The functions of the apron floodlights are:

- Assist the pilot in taxiing the aircraft into and out of the final parking position.
- Provide lighting suitable for passengers to embark and debark; for personnel to load and unload cargo and refuel; and to perform other apron service functions.
- Maintain airfield security.
- See UFC 3-530-01 for apron flood lighting requirements.

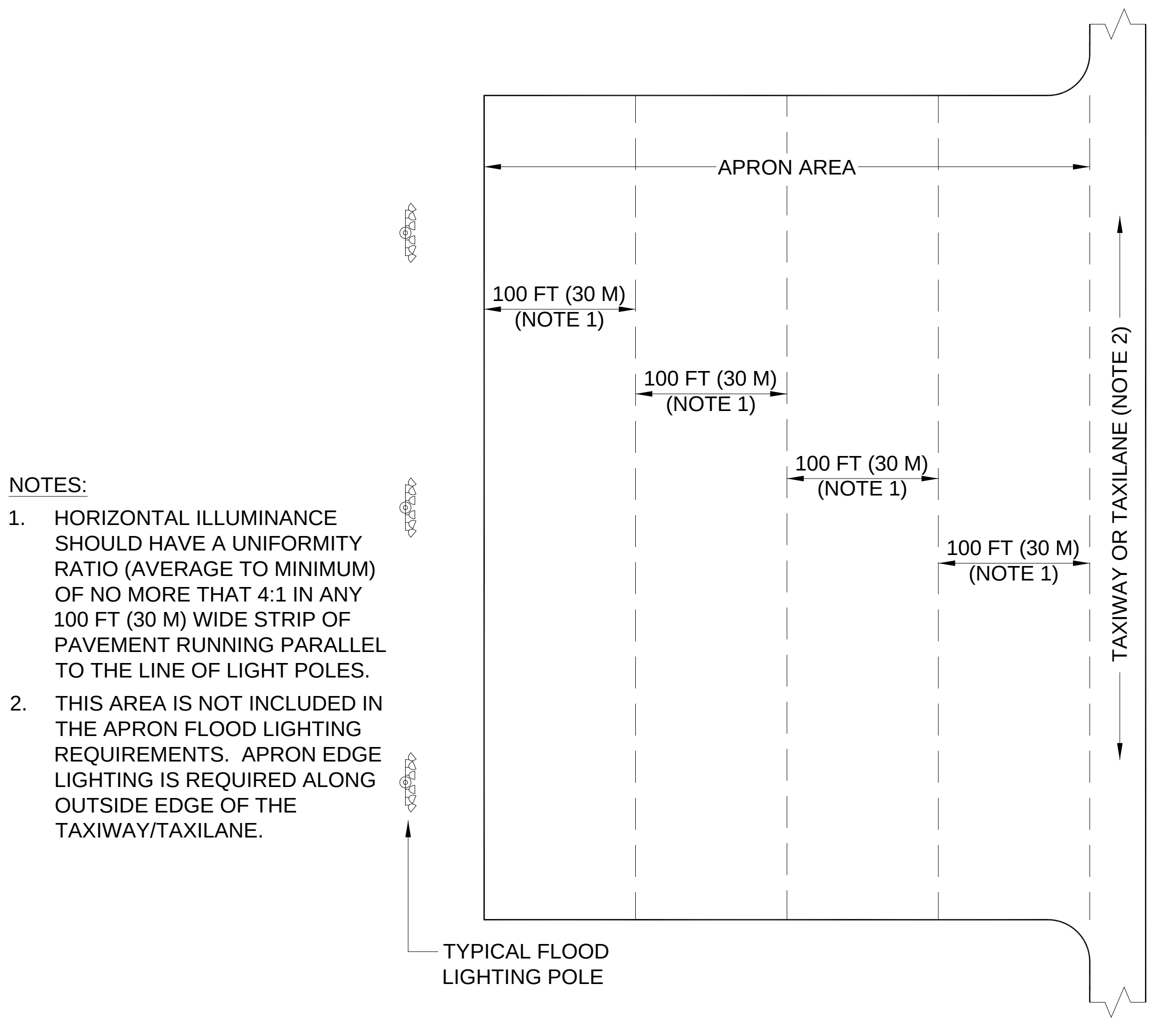
10-4.2.2 Fixed Floodlights Glare Control.

Direct lamp light from the floodlights will be avoided in the direction of a control tower cab and landing and departing aircraft. Aiming of the floodlights should be, as far as practicable, in the directions away from a control tower cab and landing and departing aircraft. Direct light above the horizontal plane through a floodlight must be avoided. To minimize direct and indirect glare, the mounting height of the floodlights should be at least two times the maximum aircraft eye height of pilots of aircraft regularly using the airfield. Also, the location and height of the masts should be such that inconvenience to ground personnel due to glare is kept to a minimum. To meet these requirements, the floodlight light distribution may have to be restricted by use of glare shields. The maximum obtrusive light from all flood lights for the apron project must be no more than 1 lux (0.093 fc). If control tower personnel experience objectionable glare after flood lights are installed, re-aim lights until glare is eliminated.

10-4.2.3 Fixed Floodlights Design Considerations.

Floodlight masts must meet relevant obstacle clearance requirements. Locate and aim the floodlights to minimize shadows. Horizontal illuminance should have a uniformity ratio (average to minimum) of no more that 4:1 in any 100-foot (30 meter)- wide strip of pavement running parallel to the line of light poles. See Figure 10-1. See UFC 3-530-01 for specific illumination values, fixtures specifications, lamp specifications, description of a typical flood lighting pole/mast, and other design requirements other than obstacle clearance.

Figure 10-1 Apron Area Flood Lighting Uniformity Criteria



10-4.3 Lighting Intensities.

The various areas of the airfield, heliport, or helipad requiring normal and/or protective floodlighting will be lighted to meet the following minimum intensities in horizontal footcandles, in the horizontal plane at the pavement surface.

10-4.3.1 Apron Area Floodlighting.

Security Area (1)	0.50
Parking Area	0.50
Loading Area (including hydrant fuel area)	2.00
Other Apron Areas	1.00
Maintenance	2.00

Notes:

(1) Flood lighting for Army Security is required by AFR 190-51 if the installations security authority determines that the apron area is a risk level 3 asset.

(2) Taxiways and taxi lanes on or through aprons do not require flood lighting where apron edge lights are provided.

(3) It is assumed that supplemental lighting for maintenance is provided by portable light plant(s).

10-4.3.2 Protective and Security Lighting.

Boundary	0.20
Entrances	
Active, pedestrian and/or conveyance	5.00
Inactive, normally locked, infrequently used	1.00
Building surroundings	1.00

10-4.4 Additional Guidance.

Additional information on auxiliary lighting can be found in joint services technical manuals:

- Army/Navy/Air Force TM 5-684/NAVFAC MO 200/AFJMAN 32-1082
- UFC 3-260-01 and **\4** UFC 3-550-01 ***/4/***

CHAPTER 11A PORTABLE EMERGENCY LIGHTING

11A-1 GENERAL REQUIREMENTS.

In times of emergency, when standard airfield lighting is not available and aircraft operations must be performed at night, it may be necessary to use portable lighting devices to support operations. The lighting design standards in this section may be suitable for use in VFR night operations but do not qualify the airfield for instrument operations of any kind, except in the case of this UFC's Table 2-3 and Electrical Technical Paper (TP) 22. The standards in this section do not apply to requirements for portable lighting in a Theater of Operations (TO), forward tactical airfields or landing zones; see Table 2-3, Electrical TP 22, and AFI 13-217 for guidance. (Note: Landing zones are addressed in ETL 09-6; access is restricted: "For Official Use Only.") Care should be taken when installing portable lights to ensure that they are secured in a manner that will prevent movement as a result of jet blast or other forces. When application of the criteria in this section would result in a light location in an active paved area, the light must be omitted or relocated. Information on the Army's Airfield Lighting System (ALS), a TO portable ALS, is available from the Army's materiel developer, Program Manager – Air Traffic Control (PM-ATC), at Redstone Arsenal, AL: Tel (256) 955-9008 or (256) 842-4954.

11A-2 RUNWAY LIGHTING.

11A-2.1 Runway Edge Lighting.

Portable edge light configurations generally follow the standard configuration except that the spacing may be a maximum of 300 feet (90 meters) and the offset may be a maximum of 10 feet (3 meters) from the runway edge. The runway edge lights must be white.

11A-2.2 Runway End and Threshold Lighting.

The number of lights required for runway end and threshold lights is reduced to 10. At each end of the runway they must be placed in two groups of 5 with the outermost lights in each group in line with the line of the runway lights spaced at 10 feet (3 meters) intervals toward the center. The line of threshold and runway end lights may be offset no more than 5 feet (1.5 meters) from the end of the runway. The lights must be red toward the runway and green toward the approach.

11A-3 TAXIWAY EDGE LIGHTING.

The techniques for designing an emergency taxiway edge lighting system are generally the same as for a standard system except that the spacing is increased as follows:

11A-3.1 Straight Sections.

The spacing must not exceed 220 feet (66 meters).

11A-3.2 Curved Sections.

The spacing must not exceed 100 feet (30 meters).

11A-4 HELIPAD LIGHTING.

Emergency helipad lighting must follow the standard configurations for perimeter, landing direction, and approach direction lighting except the adherence to light plane criteria is not required.

11A-5 FIXTURES.

Fixtures may be omnidirectional, bidirectional or unidirectional. Where unidirectional fixtures are employed, they must be aimed in the direction of the planned operation. If the operational direction changes they must be installed for the new direction. Unidirectional fixtures generally have better light output for the energy being consumed than the other types. Omnidirectional fixtures meeting MIL-L-19661 Type I may be used with filters as appropriate for the application. Unidirectional and bidirectional fixtures meeting FAA AC 150/5345-50 may also be used. Other portable fixtures that are suitable for outdoor use, meet the duty cycle requirements and meet or exceed the light output of the specified fixtures may be considered.

11A-6 CONTROLS.

The specified lights have individual on/off controls and are not capable of control from a central point. They may have been provided with a flashing mode which must not be used during periods when aircraft operations are being conducted.

11A-7 COMPLIANCE WITH INTERNATIONAL MILITARY STANDARDS.

11A-7.1 AFIC.

Previous AFIC AIR STD 90/20 cancelled.

11A-7.2 NATO.

These standards comply with NATO STANAG 3534 (Edition 7) – Airfield Lighting, Marking and Tone Down Systems for Non-Permanent / Deployed Operations, 6 June 2013.

CHAPTER 11B INTERIM EXPEDITIONARY AIRFIELD LIGHTING SYSTEM (EALS-C – AIR FORCE ONLY)

11B-1 GENERAL REQUIREMENTS.

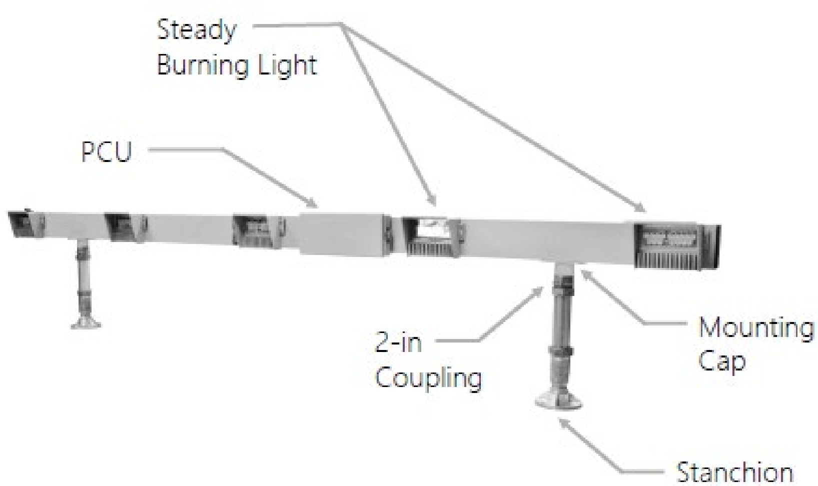
The new EALS (Expeditionary Airfield Lighting System) is the Air Force's the first-ever deployable LED-lighting system that provides significant lighting improvements over the older, legacy EALS. Additionally, the light fixtures contain solar panels and internal batteries that permit operation with or without external power or generators. This not only saves fuel, but also reduces EALS installation times, an important task Civil Engineers are responsible for during airfield damage repair and recovery after attacks. Any references to NGEALS and EALS-B in past guidance are irrelevant. The official name is EALS-C.

11B-1.1 Stand-alone Steady Burning Light.

- Self-contained solar stand alone
- VIS/IR
- 30 per system (15 per MALSR, 7 per SSEALS)
- 5 intensity levels
- 10,000 Cd

11B-1.2 Folding Steady Burning Light.

- Foldable 1- ft. Aluminum
- 5 Steady Burning Lights
- 5 Barrettes per MALSR
- Produces 10,000 Cd
- 5 intensity levels
- PCU side mounted



11B-1.3 Sequenced Flashing Lights.

- Flash in a strobing pattern called “running rabbit”
- Comprised of three subsystems
    - Chassis contains batteries, charging, and PLC

  - o Light head
  - o External solar panel
- Labeled 1 through 5 (with label1 flashing first)5 Steady Burning Lights
- SFL #1 positioned farthest from the runway

Figure 11B-1 Sequenced Flashing Light Fixture

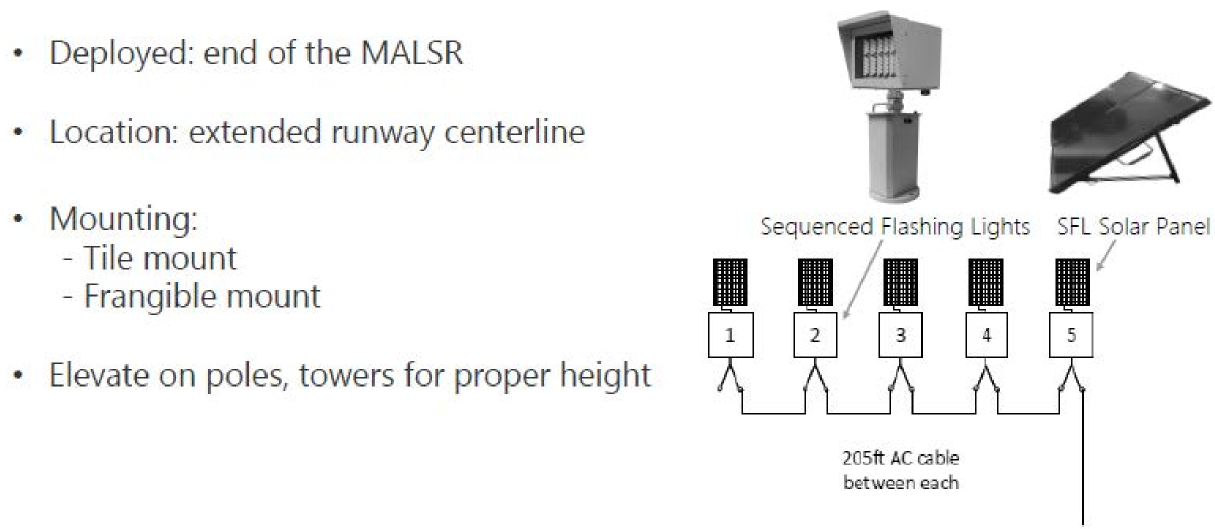

Figure 11B-5a Approach 2: Installation: SSEALS

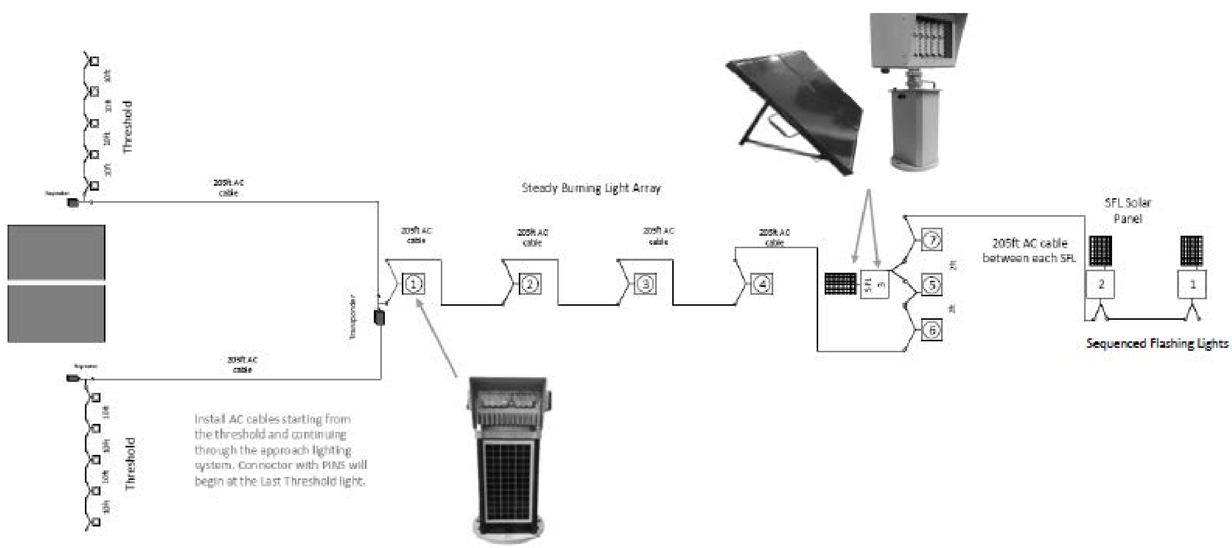

Figure 11B-5b Approach 2: Sequenced Flashing Light (SSEALS)

- Deployed at the end of the Stand-alone Steady-burning Light
- Location: Extended runway centerline
- Mounting:
  - Tile mount
  - Frangible mount
- Elevate on poles/towers for proper height

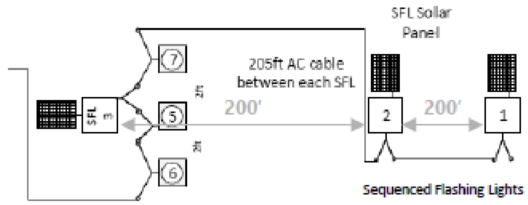

Figure 11B-5c Approach 2: Steady Burning Light (SSEALS)

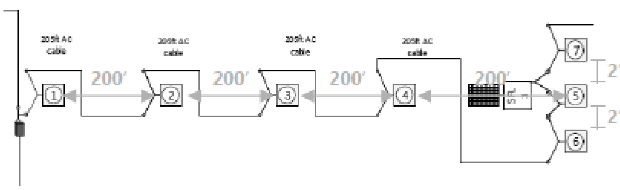
- Deployed at the end of runway
- Location: extended runway centerline
- Mounting:
  - Tile
  - Frangible
- Elevate on poles/towers for proper height



CHAPTER 11C SOLAR LIGHTING FOR NAVIGATIONAL AIDS (AIR FORCE ONLY)

11C-1 Solar-powered fixtures are approved for use in expeditionary locations, ranges, and areas used only for training for the following applications.

11C-2 Runway/taxiway fixtures shall conform to the minimum intensity requirements in FAA AC 150/5345-50, *Specification for Portable Runway and Taxiway Lights*, Table 1, "Photometric Requirements." Solar-powered runway RDR shall meet the minimum luminance requirement of 10 to 30 foot Lamberts (fL).

11C-3 Solar-powered, steady-burning, non-LED (light-emitting diode), red obstruction lights shall conform to the photometric requirements for L-810 light units in FAA AC 150/5345-43, *Specification for Obstruction Lighting Equipment*.

11C-4 Additionally, solar fixtures are approved for continental United States (CONUS) installations for non-LED obstruction lights where 120-volt power is inaccessible or cost prohibitive; and for temporary uses to facilitate repair of sub-systems, when required by UFC 3-535-01 to be operational, with a waiver.

11C-5 Fixtures shall have an integrated solar panel, with the exception of the obstruction light. Fixtures with integral batteries (inaccessible batteries that necessitate replacing the entire fixture rather than only the batteries) are not approved for use even if they are FAA-approved. Fixtures utilizing lead acid batteries are not approved for use due to lower comparable life with other battery types.

11C-6 Fixtures shall be stored in accordance with manufacturer's instructions and shall not be stored in a location or manner where prolonged self-discharge will render the battery unserviceable (in most cases they cannot be stored in darkness).

CHAPTER 12 DESIGN AND INSTALLATION

12-1 REQUIREMENTS.

When design options exist and operational requirements do not allow a clear choice between them, base the decision on the results of a life cycle cost analysis rather than the lowest first cost. All interior and exterior elements of the airfield lighting systems must meet the requirements of this document. Refer to UFC 3-535-02 for detailed installation information.

\4

12-1.1 Light Fixture Mounting.

12-1.1.1 Wherever practical, mount the light fixtures on bases installed in a concrete envelope. The mounting bases support the light fixture and normally house the isolation transformer. For temporary construction the light fixtures may be stake mounted, and the transformers may be surface mounted. Beyond the shoulders, the top surface of foundations, covers, and frames must not exceed 2 inches (50 millimeters).

12-1.1.2 Frangible couplings and points for new elevated fixtures, signs or NAVAIDS shall meet the design and testing criteria given in ICAO Document 9157, Aerodrome Design Manual, Part 6, “Frangibility”, and UFC 3-260-01. **/4/**

12-1.2 Concrete Foundations.

All foundations for lights, signs, towers, and other equipment must be flush with the grade and the surrounding area stabilized and compacted to prevent erosion and excessive rutting in the event an aircraft strays from the pavement.

12-1.3 Cable and Duct Installation.

12-1.3.1 Wherever practical, install cables in approved underground duct. Cable must be suitable for underground installation, and installed in direct buried duct. (Consider direct burial for locations with a high water table.) For multiple duct installation, spacers are required to maintain proper duct separation. Use concrete encased duct under paved areas. Maintain relative positions of multiple ducts from manhole/hand hole to manhole/hand hole.

12-1.3.2 The ducts under paved areas must have a minimum of 3 inches (75 millimeters) concrete encasement all around. For directional boring, maintain the relative positions of multiple conduit from manhole to manhole (ducts should not cross each other).

When installation under existing pavement is required, the designer must select the best conduit for the application considering strength and corrosion resistance. For temporary construction, the cables may be direct-buried. Make connections between the lighting cable, isolation transformers, and light fixtures with FAA L-823 connectors. Recommendations for the designer to consider regarding cable and duct installation are contained in Table 12-1.

Table 12-1 Considerations for Cable and Duct Installation

14. Install cables in the same location and running in the same general direction in the same trench or duct bank. Whenever possible, route cables in straight duct segments between manholes and hand holes, or between light bases.

When practical, route cables and duct rectilinear (parallel and at right angle) to runways, taxiways, and other surfaces.

2. Separate low voltage (≤ 600V) from higher voltage cables (> 600V – 5,000V). Separate all power cables from control, telephone, and coaxial type cables.
   - place 600V and 5,000V power cables in separate duct, or separate a minimum 4" (100mm) if direct buried in trench.
   - Power cables of more than 5,000V must be separated from all other cables by minimum 12" (300mm).
   - place all power cables in a separate duct bank from all control, telephone, coaxial type cables, or separate a minimum 6" (150mm) if either is direct buried.
3. If cables are placed at more than one level, install so that the minimum vertical separation is the same as the minimum horizontal separation. Do not directly overlap cables, so damage may be avoided during the compaction process.
4. Do not direct-bury cables under paved areas, roadways, railroad tracks or ditches. In these locations, install cable in concrete encased duct schedule 80 PVC, or PVC-coated rigid galvanized steel where encasement is impractical. FOR AIR FORCE, the cable shall be installed in concrete encased duct schedule 40 PVC.
5. Where rock is encountered during excavation, install cable in duct. Remove rock to depth of at least 3" (8 cm) below required depth of duct, and use adequate bedding material to provide uniform support along entire length. Bedrock requires other action. Refer this to the designer.
6. Construct trenches for single-duct lines that are not encased with concrete so that they are not less than 6" (150mm) or more than 12" (300mm) wide. Construct the trench for 2 or more ducts proportionately wider.
7. For duct banks, use interlocking duct spacers at not more than 5' (1.5m) to ensure uniform spacing between ducts and to hold duct in place when concrete encasing. Stagger joints in adjacent duct at least 2' (0.6m).
8. Provide burial below frost line to prevent damage from frost heave if local experience has indicated problems.
9. Concrete encased duct may be used, as appropriate, for areas inhabited by digging rodents or animals to provide additional physical protection.
10. Slope duct lines where practical for drainage towards manholes/hand holes, or duct ends.
11. Provide grounding bushings where rigid conduits enter or leave a manhole.
12. Provide, whenever possible, a spare duct in each duct bank.
13. Where conduit is bound in pavement or other structural feature, provide conduit expansion joints when crossing pavement expansion joints. Consider conduit expansion joints also where local experience has indicated expansion problems.
14. When crossing pavements, large bodies of water and other environmentally sensitive locations, follow guidelines for trenchless directional boring contained in UFC 3-550-01.

[See also typical installation details, UFC 3-535-02**. \4** Ensure changes from 3/4 inch 10 foot (19 mm 3 m) is coordinated with UFC 3-535-02. **/4/**

12-1.4 Manhole/Handhole Design.

12-1.4.1 Each manhole/hand hole must have its own design detail to show orientation (with north arrow). This detail must include the access lid location. It is preferred that manholes/hand holes be cast with only one joint at the top.

12-1.4.2 The assembled manholes/hand holes including their access lids must meet wheel load ratings according to UFC 3-260-01. In areas not addressed by UFC 3-260-01, design manholes and hand holes to take HL-93 wheel loading per AASHTO LRFD Bridge Design Specifications, Section 3, “Loads and Load Factors.” When calculating load ratings for manholes/hand holes, consider heavy tractors and fire trucks that will pass over them.

A project design analysis or basis of design must indicate the manufacture’s information showing that the manhole/hand hole covers and frames will support the design loads. Structural calculations showing that the complete structure can support the required aircraft loading where located in the runway, taxiway, or shoulder areas described in UFC 3-260-01 must also be included.

12-1.4.3 The single wheel load rating for the manhole/hand hole and access lid assembly must be cast in the concrete top of each manhole/hand hole. The year of installation must be cast as “Installed Year - xxxx” in the each concrete top or the metal hatch. The words “Airfield Lighting” must be cast in the top of the each manhole/hand hole metal hatch used for airfield lighting circuits.

12-1.4.4 Design and orient manhole access lids so as to not interfere with cable runs through the manhole.

12-1.4.5 Design and orient manhole access lids and ladder rungs so as to not interfere with sump holes.

12-1.4.6 Manhole/hand hole access lids must be spring-assisted in opening when the access lid weighs over 30 pounds. Minimum opening must be 24" (0.6 meters) to allow portable ladder use. Safety arms used in keeping the lids locked open must not fall down into the hand hole/manhole. Safety arm(s) must not make contact with the cable(s) in the hand hole/manhole. Frames for access lids must have a ground lug attached on the inside of the manhole/hand hole. Access lids must be easily closed and have a minimum of two bolts to keep the lid closed.

12-1.4.7 Tie manhole tops to the side walls with rebar cast into the concrete tops and side walls. Install rebar so that it is not exposed.

12-1.4.8 Coat manholes/hand hole exteriors with a water sealant on the bottom and all sides. Sealant must not be placed on the manhole/hand hole tops, but can be on the sides of the top.

12-1.4.9 Show manhole/hand hole conduit penetration details on the construction contract documents. Female conduit connections cast into the manhole/hand hole are required. Show the outside seal and the inside seal at the concrete/conduit interface in conduit detail(s). The outside seal should not allow water to pass between the outside surface of the conduit and the manhole/hand hole wall. Provide unused conduits with plugs that are removable from within the manhole/hand hole. Seal conduits filled with cable(s) around the cable with duct seal, unless directed otherwise by the base electrical engineer. Cast rebar in place in the manhole/hand hole wall and stubbed out so that it can be used to attach the manhole/hand hole to the concrete-encased conduit system/duct bank it is mating to. Stubbed-out rebar lengths and diameters must be shown in design details.

12-1.4.10 Provide for future duct bank entrances to manhole with cast-in-place removeable window for installing duct bank.

12-1.4.11 Show a fold-down diagram on the construction contract documents for each new manhole. Fold-down diagrams must show conduits on each face, size, and material of conduit, circuits (cables) included in each conduit calling out the name of the circuit, and cable type/size. Use tables together with the fold-down diagrams to help convey the information.

12-1.4.12 It is preferred that cables take the shortest route through the manhole/hand hole. Do not loop cable inside the manhole/hand hole unless specifically directed by the base electrical engineer. If directed to loop the cables in hand holes/manholes, designate such on the construction contract documents.

12-1.4.13 Place non-metallic cable racks on all manhole walls whether currently used or not. Cable racks must be able to support 300 pounds (136 kilograms) without breaking.

12-1.4.14 Tie cables to racks using cable ties.

12-1.4.15 Identify cables with a tag using cable ties.

12-1.4.16 Cable ties and tags must be made of heavy-duty, corrosion resistant material or as directed by the base electrical engineer.

12-1.4.17 **\1**Each manhole/hand hole must have either a low point (sloped floor) or a sump hole. A sump hole will require a drain lid over the sump hole. Place the sump hole or low spot for easy access in lowering a portable sump pump into the manhole/hand hole from outside the manhole/hand hole. Do not allow sump holes to penetrate the floor unless each one is tied to a drain line. Tie drain lines to the base storm drainage system, and drain to daylight, or drain to an approved French drain. Build into the manhole rungs for access to the manhole. When attaching rungs to the manhole wall, use fasteners that will hold at least 300 pounds.**/1/**

12-1.4.18 Each manhole/hand hole must have a **\4** 5/8-inch by 8-foot (16-millimeter by 2.44-meter) **/4/** copper clad ground rod driven through a precast hole in the floor after the manhole/hand hole has been placed into its final position. Seat the precast manhole/hand hole water-tight with a non-corrosive sealant after installation of the ground rod. The ground rod must “stub up” a minimum 6 inches (150 millimeters) above the manhole/hand hole floor, with a ground lug attached for ground connections. Ground connections must be provided to all metal equipment in the manhole/hand hole using a AWG #4 (25 square mm) bare stranded copper cable. This includes the metal frame for the manhole/hand hole lid, cable racks, and system ground wires that feed through the conduits. **\4** The bonding conductor shall be connected to each metallic item within the manhole/handhole in such a manner that the disconnection of any one item will not result in the disconnection of any other grounded item. **/4/** The counterpoise must not be tied to this ground.

12-1.4.19 The soil grade around the manholes/hand holes must start one half inch below the top of the manhole/hand hole and slope one quarter inch per foot away from the manhole/hand hole for 15 feet (4.5 meters).

12-1.4.20 Place manholes/hand holes on undisturbed soil.

12-1.5 Safety (Equipment) Grounding System.

12-1.5.1 The safety ground is a separate system and must never be confused with the counterpoise. A safety ground must be installed at each light fixture. In-pavement (L-868) fixture bases, where the counterpoise is connected to the base can, are exempt. The purpose of the safety ground is to protect personnel from possible contact with an energized light base or mounting stake that may result from a shorted power cable or isolation transformer.

12-1.5.2 The safety ground must be a AWG #6 (16 square mm) solid bare copper conductor with one hole lug bolted to the exterior ground lug at the fixture base. The other end is connected to a **\4** 5/8-inch by 8-foot (16-millimeter by 2.44-meter) **/4/** ground rod installed beside the fixture. Ensure resistance-to-ground of the rod is 25 ohms or less in accordance with manufacturer's requirements.

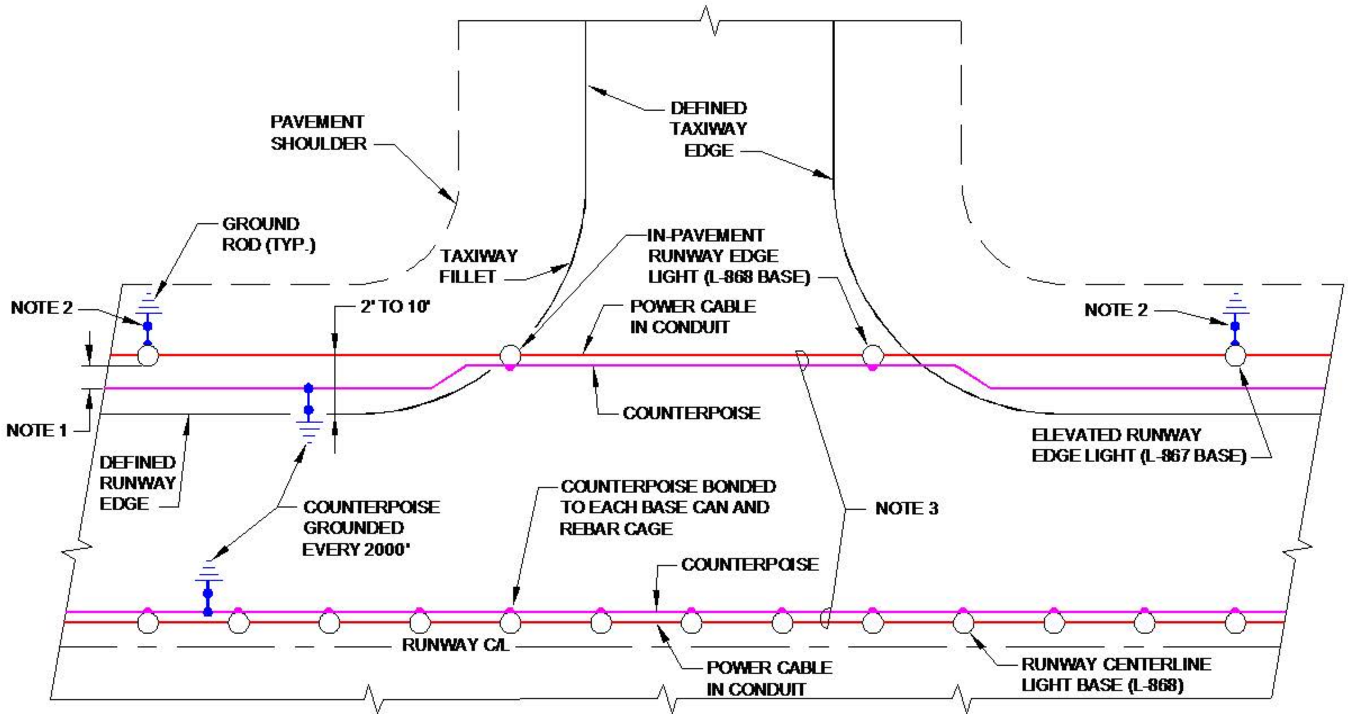
12-1.5.3 Do not exothermically weld connections to a galvanized light base. See FAA AC 150/5340-30, Chapter 12, for additional detailed ground connection information.

12-1.5.4 See the NEC Handbook for additional information about grounding electrode installation and testing. Additionally, in-pavement fixtures and base plates for elevated fixtures must be fitted with a braided ground strap connected to the interior ground lug of the base can. All exterior grounding connections must be bolted exothermic-weld-type. Ground connections interior to the can must be bolted-type connections.

12-1.6 Counterpoise Lightning Protection System.

The purpose of the counterpoise or lightning protection system is to provide low resistance preferred paths for the energy of lightning discharges to safely dissipate without causing damage to equipment or damage which could later cause injury to personnel. The counterpoise is a separate system and must not be confused with equipment safety grounds that provide personnel protection from electrical shock hazards. Provide a continuous counterpoise of minimum AWG #6 (16 square mm) bare, stranded copper wire to protect the entire length of all primary circuits supplying airfield lighting, with a minimum 10 feet (3.0 meter) ground rod installed at least every 2,000 feet (600 meters). Do not connect counterpoise system to the light bases except at in-pavement fixtures. **\4** Reference NFPA 780, Figure 11.4.2.6.2 for pertinent information. **/4/**

Figure 12-1 Counterpoise and Ground Rod Installation



Notes:

1. Install the counterpoise along the pavement shoulder in a separate trench half-way between the line of edge lights and the defined runway edge. Route the counterpoise around the can a minimum of 12 in (0.3 m) toward the runway pavement. Typically, any lighting strike will hit the crown of the pavement first and migrate across the pavement toward the counterpoise.
2. Equipment ground per paragraph 12-1.5.
3. Power cable and counterpoise located in the same trench (counterpoise on top) under pavement subject to routine aircraft traffic.
4. Ground bonds must be exothermic weld type unless and ground lug is provided.
5. Installation of counterpoise for taxiway edge lighting in paved or unpaved shoulders is the same as for elevated runway edge lights.

12-1.6.1 Counterpoise Criteria.

Along runway/taxiway or apron shoulders, install the counterpoise halfway between the pavement and at approximately half the depth of the duct (or cable, if direct buried) if at all possible. If this is not practical, install counterpoise 4-6 inches (100-150 millimeters) above the duct or direct-buried cable. Route the counterpoise around each light base or unit, at a distance of no less than 12 inches (300 millimeters) from the unit; do not connect to the unit. For duct not along a shoulder or for duct bank, lay the counterpoise 4-6 inches (100-150 millimeters) above the uppermost layer of direct buried ducts, or on the top of the concrete envelope of an encased duct bank. Provide only the quantity of counterpoise wires for cables for the same duct bank based on the width and depth of the duct bank as shown in NFPA 780. Connect all counterpoise wires leading to a duct bank to the single counterpoise wire for the duct bank. Lay the counterpoise at least 12 inches (300 millimeters) away from manholes or hand holes. Do not connect the counterpoise to the lighting vault power grounding system. Use exothermic-type weld for all connections. The counterpoise resistance to ground must not exceed 25 ohms at any point using the drop of potential method.

12-1.7 Frangibility and Accident-Avoidance Construction.

In the areas around the runway, including the approach zone, all above-grade structures must be lightweight and of a frangible or low impact resistant construction using breakaway sections to minimize hazards to aircraft. Concrete foundation or mounting slabs must not extend above the finished grade of the surrounding surface.

12-1.7.1 ALSF Frangibility.

A slight trade-off in frangibility can result in significant savings in energy. Older ALSF systems use 300 watt lamps in the outer 2,000 feet (600 meters) to satisfy the photometric requirements, which can actually be met with newer 200 watt lamps. However, the 200-watt lamps are rated at 6.6 amps rather than 20 amps and their use would require a change in isolation transformers. This would not be difficult in major renovations or new installations except that eight additional wires must be installed in low impact resistant and semi-frangible light supports. The major command may accept the slight loss of frangibility to achieve the energy savings.

12-1.8 Airfield Lighting Vault.

Vaults house the regulator and control equipment, emergency generator and power transfer switch, and other electrical equipment needed for operation of the airfield lighting system. The vault may be a separate building or structure, or an enclosure within a larger structure, as appropriate. Vaults must be of concrete or masonry construction meeting all building codes for the type of structure. Vaults constructed in the past generally had a primary service of 4.16/2.4 kV, 3 phase, 60 hertz power. All existing vaults not meeting the above described criteria may be used, provided the existing structure is otherwise adequate to serve the overall purpose or can be modified economically to provide the desired facility. For new construction or major modernization, the following is recommended:

12-1.8.1 Vault Voltage.

Use 480 volts as a primary voltage within the vault for new installations.

12-1.8.2 Vault Location.

Locate vaults a minimum horizontal distance of 350 feet (105 meters) from the control tower to prevent radio interference with control equipment. The maximum horizontal distance between an airfield lighting vault and the control tower where nominal 120 volt control system is used (with L-841 relay panel and multi-conductor control cable) is 7,350 feet (1.4 miles)(2,205 meters). As an alternative, 48 volts dc can be used for long distance control. An existing vault not meeting required locations may be used, provided the existing structure is otherwise adequate to serve the overall purpose or can be modified economically to provide the desired facility.

12-1.8.3 Main Lighting Vault.

\1Design the main airfield lighting vault to contain power distribution and control equipment for runway and taxiway lighting circuits and any other lighting circuits that can be fed from the lighting vault. Provide adequate space for the maintenance of the systems interior to the lighting vault. Auxiliary vaults may be required for other airfield systems depending on the airfield configuration and layout. Locate the vaults above grade in locations that are the most suitable as supply points. For Army airfields, size the vault for the required equipment and work space and space allowances indicated in UFC 3-260-01. Provide a two-hour fire rated wall to isolate the engine generator room from the regulator room.**/1/**

12-1.8.4 Circuit Selector Switches.

For new construction, circuit selector switches are not allowed for Army facilities. For new construction, circuit selector switches are not recommended for Air Force Facilities.

12-1.8.5 Floor Mounted Equipment.

Securely bolt all floor-mounted equipment to the floor to prevent movement during seismic disturbances.

12-1.8.6 Constant Current Regulators.

Constant current regulators require adequate work space for maintenance access and high voltage safety. The following minimum spacing is recommended: 3 feet (0.9 meter) from back wall to regulator and between regulators; 4 feet (1.2 meters) in front of regulator for access.

Cabinet enclosure must meet National Electrical Manufacturers Association (NEMA 1) requirements.

12-1.8.6.1 Environmental requirements.

The equipment must be designed for continuous operation under the following conditions: a. Temperature range is from -40° to 131° Fahrenheit (F) (-40° to 55° Celsius (C)). b. For monitoring circuitry, the temperature range is from 32° to 131°F (0° to 55°C). c. Relative humidity range is from 10 to 95 percent. d. Altitude range is from zero to 6,600 feet above sea level (2,000 meters).

Table 12-2 Constant Current Output

Class	Style	Step	Nominal output amperes (A) root mean square (RMS)	Allowable range (A RMS)
1	1	3	6.6	6.50 – 6.70
		2	5.5	5.40 – 5.60
		1	4.8	4.70 – 4.90
1	2	5	6.6	6.50 – 6.70
		4	5.2	5.10 – 5.30
		3	4.1	4.00 – 4.20
		2	3.4	3.30 – 3.50
		1	2.8	2.70 – 2.90
2	2	5	20.0	19.70 – 20.30
		4	15.8	15.50 – 16.10
		3	12.4	12.10 – 12.70
		2	10.3	10.00 – 10.60
		1	8.5	8.20 – 8.80

12-1.8.6.2 Efficiency.

The efficiency of a CCR operated at its maximum intensity setting, rated input voltage, with 100 percent load at unity power factor (PF) must not be less than the values shown in Table 12-2.

Table 12-3 Constant Current Efficiency

CCR size kilowatts (kW)	Minimum overall Efficiency (percent)
Less than 30	90
30	92
50	93
70	94

12-1.8.6.3 Power Factor (PF).

The PF for CCRs 10 kW or less must not be less than 0.90 (90 percent). and PF for larger than 10 kW the PF must be not less than 0.95 (95 percent).

12-1.8.6.4 Protection for Devices and for Safety.

Open-circuit protection and over-current protection must be provided. The CCR must use a primary switching device that interrupts the input power prior to the current regulating/transformer circuits. The CCR must provide, located for ready access on the CCR, without opening doors or removing covers, a means for the operator to select the remote/local modes and the desired current step.

12-1.8.6.5 Assembly Size.

The overall size of a complete CCR assembly must allow it to pass through an opening 39.0 inches (1.0 meter (m)) wide by 78.0 inches (2.0 m) high.

\4
12-1.8.6.6 Input Power Loss.

If there is a short duration loss of CCR AC input power of up to 500 milliseconds, the CCR must resume operation (CCR is “ON” at the same current step and producing current) within one second after the power interruption (ac input power is restored after 500 milliseconds). ***/4/***

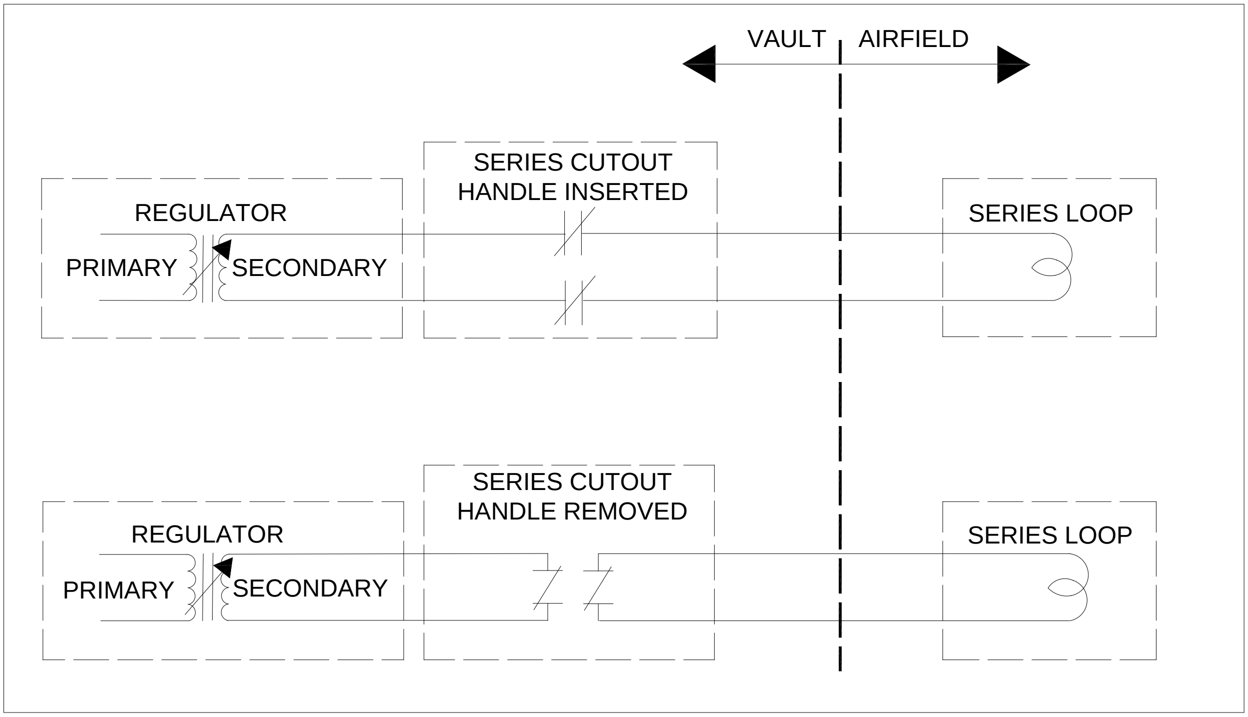
12-1.8.6.7 CCR Monitor.

The monitor must detect the status of the CCR and the series lighting circuit. Type L-829 CCRs must use integral monitoring. A CCR without monitoring is designated Type L-828. A monitor may be offered as a separate module designated Type L-827. If monitoring is added to a Type L-828 regulator, it becomes a Type L-829.

12-1.8.7 Vault Wiring Safety.

Series cutouts provide safety by preventing inadvertent live wires during maintenance on field circuits. These are recommended at the output to field circuits for constant current regulators. Install series cutouts in NEMA 1 enclosures. A circuit diagram for a series cutout is shown in Figure 12-2.

Figure 12-2 Series Cutout Circuit Diagram



12-1.8.8 New Installations.

\4 L-824 conductors are not rated for installation in cable tray, however, the NEC allows this installation when only qualified persons can access, install, or service the cable. For military installations, L-824 conductors will only be installed in cable tray as part of a switchgear regulator assembly. Run L-824 cables outside of switchgear regulator assemblies in rigid galvanized steel (RGS) conduit, intermediate metallic conduit, wireways or other wiring methods allowed by the National Electrical Code (NEC). **/4/** Run low voltage feeders and control wires in rigid galvanized steel (RGS) conduit or intermediate metal conduit when run under the floor slab; in rigid galvanized steel (RGS) conduit, intermediate metallic (IMC) conduit, or electrical metallic tubing (EMT) when run on the walls or ceiling; and in cable trays supported from the ceiling or walls, IAW the NEC, when routing multiple cables or when a future expansion is a possibility within five years. Do not install conduit in concrete slabs on grade. Bring primary series cable from regulators and various other feeders out of the vault in PVC coated rigid steel galvanized conduit minimum 2 feet (0.6 meters) below grade.

12-1.8.8.1 To facilitate installation or replacement of constant current regulators and other heavy equipment, allow at least 8 feet (2.4 meters) of space between rows of equipment to allow access for lifting equipment or a truck to on-load or off-load/offload regulators. Provide a garage door to allow the truck or lifting equipment access to the building and consider installing a ceiling hoist system to install or remove regulators.

12-1.8.8.2 Provide an HVAC system with filtered outside air intake to maintain proper temperatures and humidity within the vault and to minimize dust levels. Insulate the vault envelope to reduce HVAC system run time and to minimize life cycle cost.

12-1.8.9 Installation Compliance.

Comply with the requirements of the NEC (NFPA 70) for the installation of power distribution equipment and control equipment in lighting vaults. See manufactuer's requirements for lightning and surge protection design. It is recommended to review the checklist for vault contained in Chapter 14.

12-1.8.10 Short Circuit Analysis.

Provide a short circuit analysis that complies with NEC Section 110-9, Section 110-10 and Section 110-12; and FAA Order 6950.27, as part of the design (to enhance reliability and safety). Include in the analysis critical points such as:

- Service entrance.
- Switchboards and panelboards.
- Transformer's primary and secondary.
- Transfer switches.
- Load centers.
- Fusible disconnects.

12-1.8.11 Surge Protective Device (SPD)/Lightning Protection.

To protect airfield lighting vault equipment from the effects of transient voltage surges, the main switchboard and panelboards serving regulators and field lighting control equipment must be provided with SPD equipment. Units must be either integral or external to the equipment being protected. Additionally, constant current regulators must have lightning arrestor protection.

12-1.8.11.1 SPD devices must be listed and labeled as defined in NFPA 70, Article 100, by an independent certified testing agency and marked for intended use. Design the SPD protection system for the airfield vault equipment in accordance with IEEE C62.41.1 and IEEE C62.41.2.

12-1.8.11.2 Surge protective device technology must be metal oxide varistor (MOV); silicone avalanche diode technology is not acceptable.

12-1.8.11.3 The short circuit current rating of a protection device must match or exceed that specified for the panel from which the surge protection device is fed.

12-1.8.11.4 For constant current regulators, arrestors of the proper rating to protect the CCR from lightning-induced voltage and current surges must be installed at both the input and output terminals of the CCR. The CCR input lightning arresters must be rated for pulses per IEEE C62.41-1991, paragraph 4.2.17b, Table 6, Category B2, Medium. The CCR output lightning arrestors must be rated for Location Category C3 in IEEE 62.41-1991, Table 4 (A 1.2/50 microsecond (µs) 8/20 µs combination wave at 20 kilovolts and 10 kiloamperes **\4** RMS **/4/** - the nominal ratio of RMS open circuit voltage to RMS short circuit current is 2 ohms). The ground side of the arresters must be connected to the cabinet grounding lug or other electrically equivalent ground location. If a bonding jumper wire is used, it must not be smaller than 6.

12-1.9 Emergency Power.

Provide an emergency generator or other independent power source at each vault which services systems requiring standby power for continuous operation if the principal power source fails. See FAA AC 150/5340-30 for additional design information and requirements for emergency power systems.

12-1.9.1 Engine Generator (E/G).

Where engine generators are installed, provide a separate room or shelter with independent ventilation. Make provision for engine exhaust to the exterior of the shelter. Mufflers may be installed inside or outside the building. If installed inside, they must be insulated. Engine cooling may be provided by externally-mounted radiators or by use of a radiator duct to an external exhaust louver. Make provisions for mounting and cooling resistive load banks for diesel engine testing if the station load is inadequate or cannot be made available for engine testing. Provide fuel storage capacity for 72 hours of uninterrupted operation of the standby power system. Also provide automatic starting and switching capable of supplying the rated load within 15 seconds of a power failure except where Category II instrument operations are conducted. During Category II and III instrument operations, a one-second power transfer is required. This is normally done by providing a remote start capability which permits operation of the lighting systems on the engine generator during Category II or III weather conditions. Standby power availability is then subject only to switching time. The actual procedure used must be locally coordinated. See FAA AC 150/5340-30, Chapter 9, for additional information. Provide an automatic battery charger for the starting batteries. Isolate the E/G foundation slab to reduce vibration and noise transmission to other parts of the vault. Comply with the requirements of the NEC, OSHA and local jurisdictions for emergency power.

12-1.10 Independent Power Sources.

An alternate independent power source qualifies as emergency standby power only if it is generated by a separate generating station and routed over separate power lines. In most cases in the past, careful investigation revealed that seemingly independent sources were so interconnected that failure of one could result in failure of the other. Exercise extreme care when determining the qualifications of alternate power sources before opting against an engine/generator for standby power.

12-1.11 Airfield Lighting Control.

The control system for airfield lighting consists of control panels, relaying equipment, accessories, and circuits which energize, de-energize, select lamp brightness, and otherwise control various airfield lighting circuits based on operational requirements. Control of any one airfield lighting system is normally provided at two points only: the air traffic control tower, and the lighting equipment vault. See Figure 12-3 for a typical lighting vault block diagram. A transfer relay assembly is provided at the vault to transfer control from the remote location to the vault when necessary:

12-1.11.1 Control Voltages.

Standard practice is to provide a 120 VAC control system using low burden pilot relays (pilot relay assemblies) to activate the power switches, contacts, and relays controlling the regulators and transformers supplying power to the airfield lighting circuits. The maximum horizontal distance from the control tower to the lighting vault is limited, for proper function of the pilot relay assemblies, to 7,350 feet (2,240 meters) when using 120 VAC control systems. There may be capacitance issues in long 120-volt ac control circuits. Where the distance between the tower and the vault exceeds the maximum, consider using a 48 VDC control system as described in FAA AC 150/5340-30, Figures 29, 30, and 70. Where both types of control system are installed, ensure the control power systems are isolated. See Figure 12-4 for a high level example of airfield lighting control.

12-1.11.2 Control Circuitry.

Design the control system to ensure the following:

- Lighting on intersecting runways cannot be energized simultaneously.
- All circuits supplying the lights for any one lighting system (for example, runway edge lighting) are energized simultaneously and operated at the same brightness step.
- Runway centerline lights cannot be energized unless the runway edge lights are energized.
- Touchdown zone lighting (TDZL) cannot be energized unless the runway centerline lights are energized.
- Certain systems associated with low-visibility operations (such as runway guard lights, hold-position lights, lead-in lights, land-and-hold-short lights), if installed, may also require linkage of control to runway lights. Recommend following guidance in applicable FAA documents, such as FAA AC 120-57 and FAA AC 150/5340-30.

Figure 12-3 Installation Plan, Power Equipment

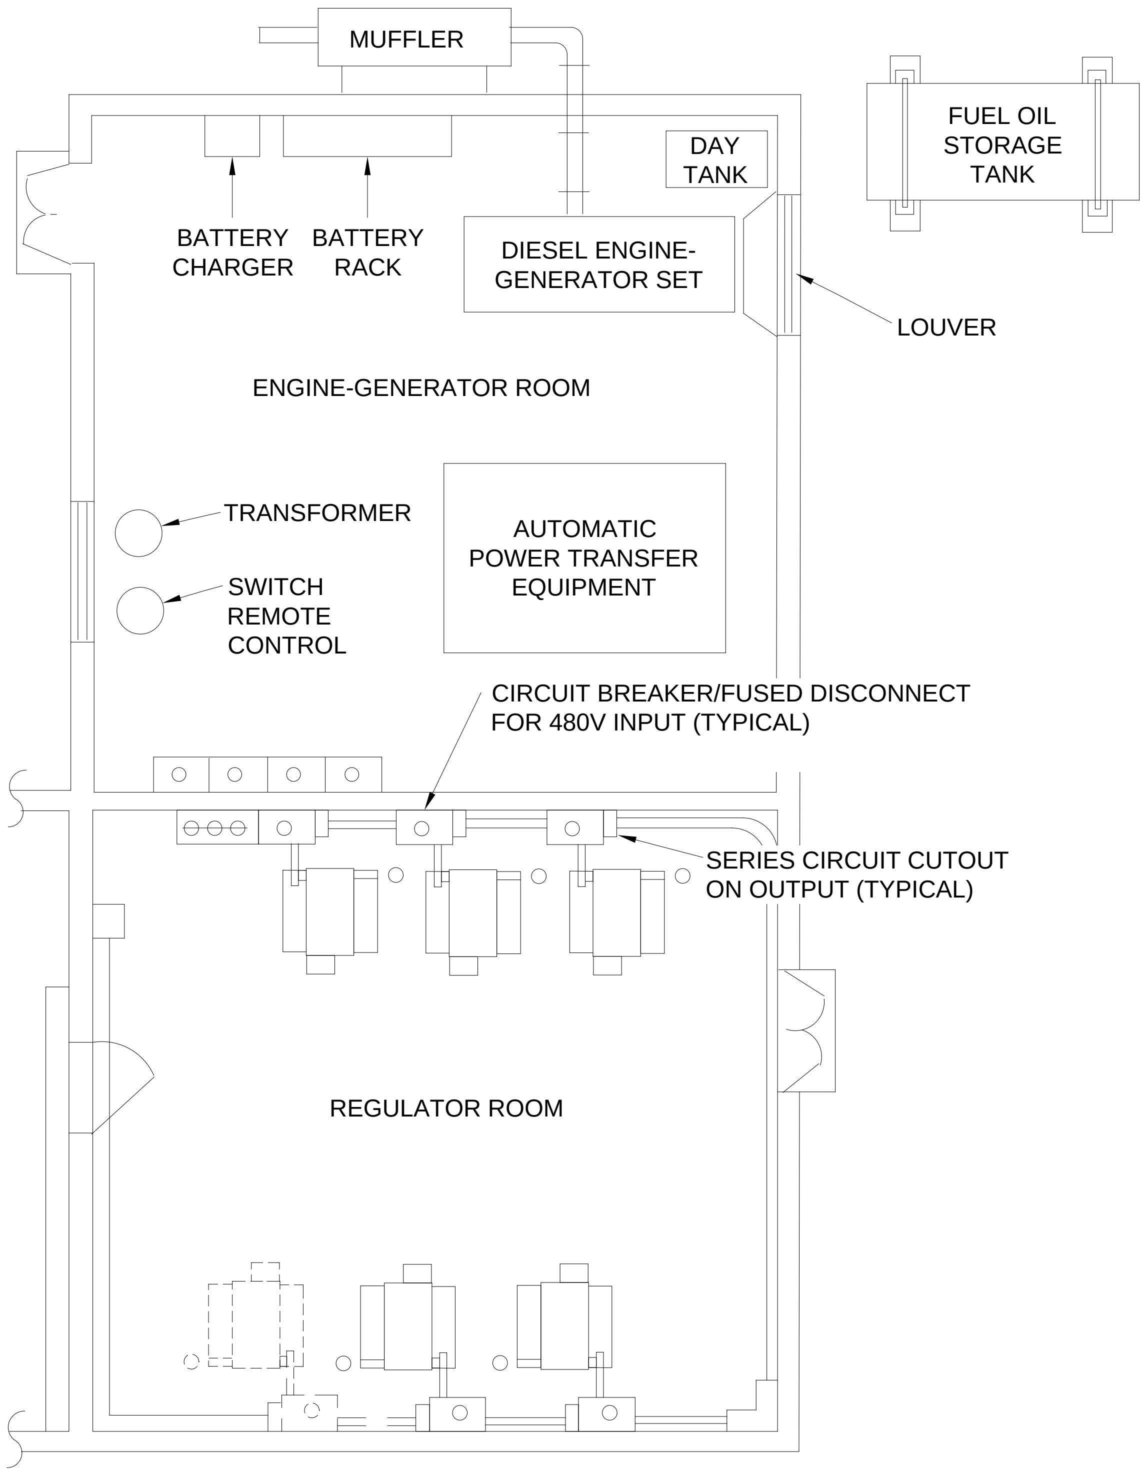


Figure 12-4 Power and Control System Block Diagram

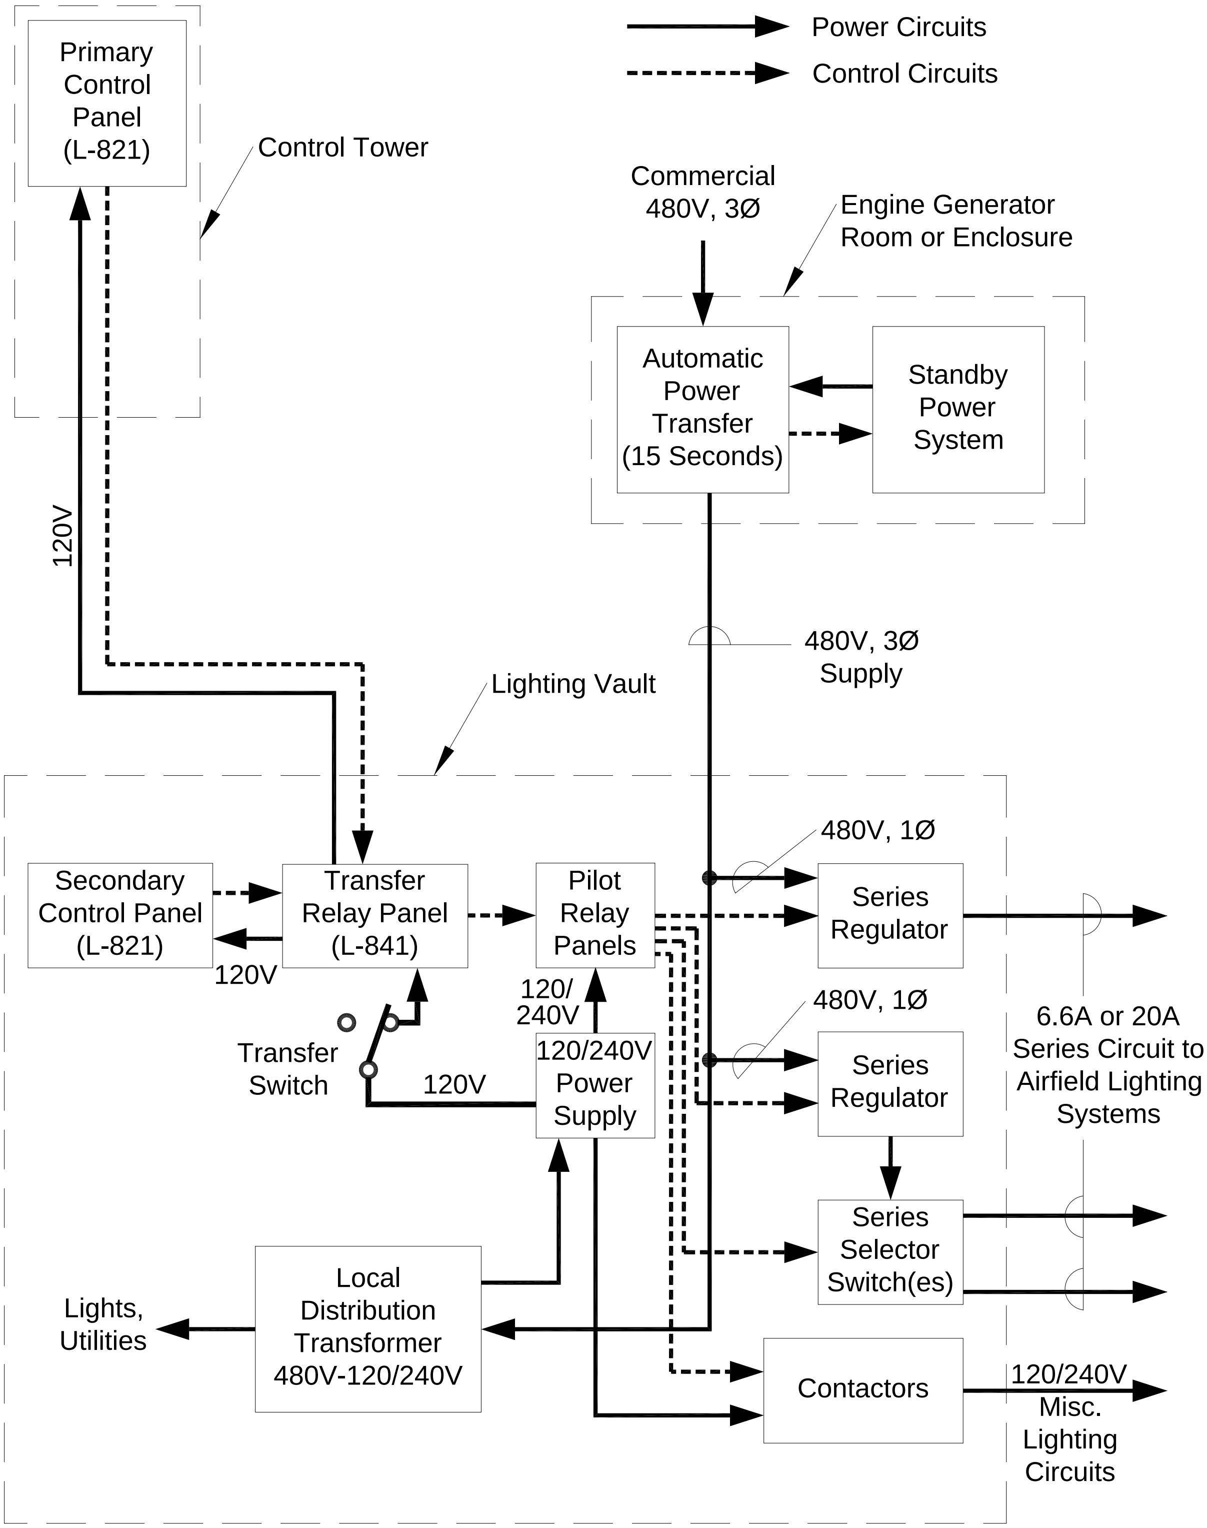

12-1.11.3 Control System Modernization.

Major commands are encouraged to consider the use of control systems, where significant economies or operational improvements can be achieved. If an approved specification is not available, the use of such systems is subject to the requirements of paragraphs 1-11 or 1-12 of this document. Control systems using electromagnetic emissions also require the express approval of AFCEC/COSM. As examples, Figure 12-5 shows a block diagram for a control system using programmable logic controllers (PLC), and Figure 12-6 shows a block diagram for a PC-based control system. Further discussion of computerized control systems is also provided in Chapter 13.

Figure 12-5 Computerized Control System using PLC Block Diagram

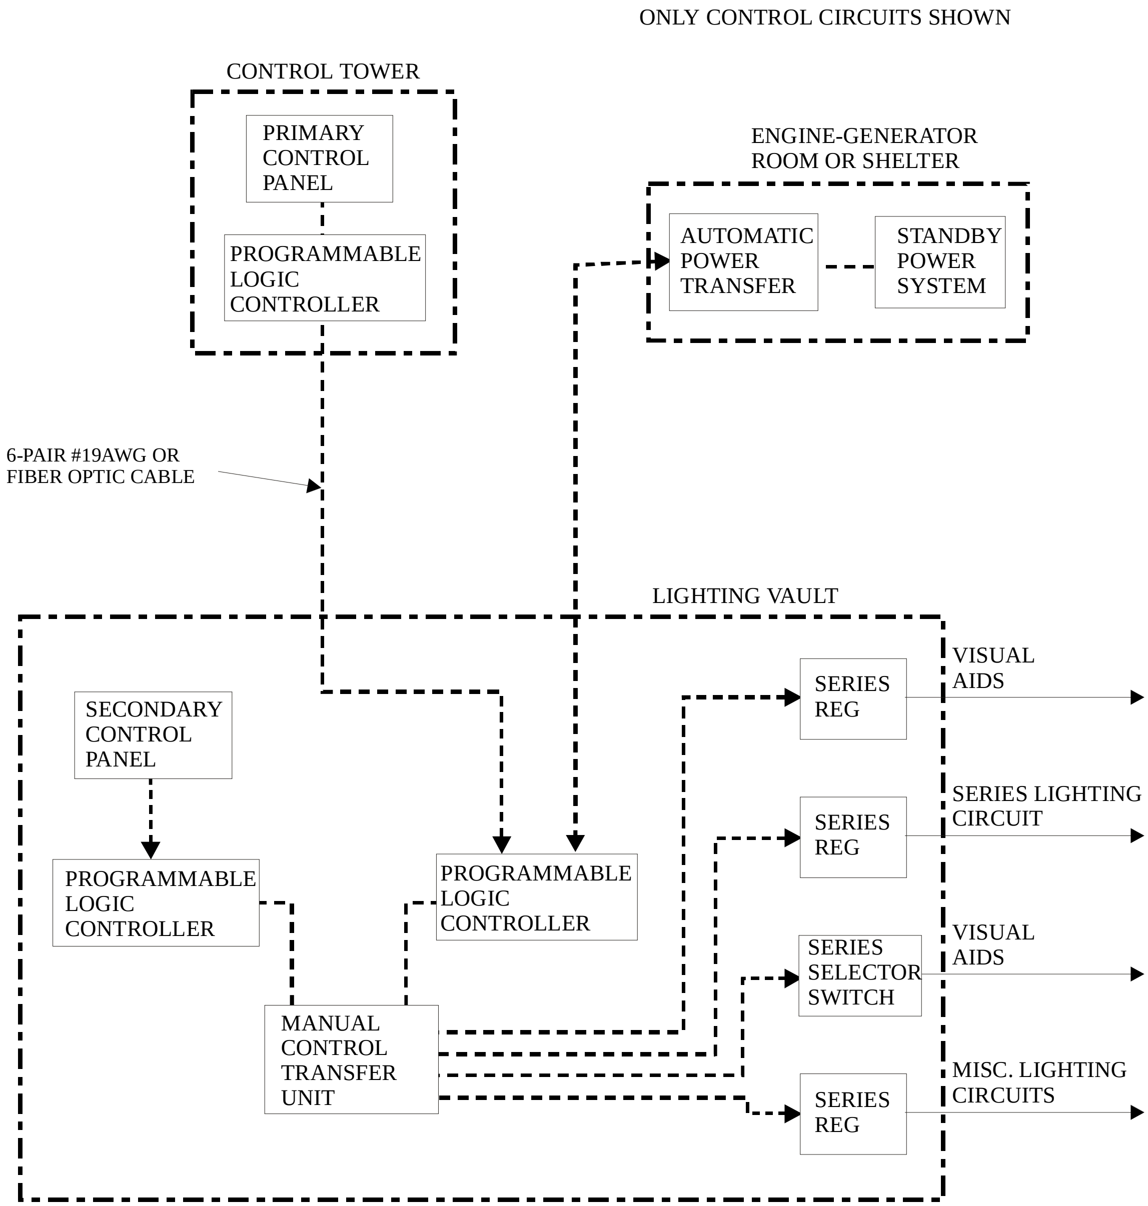

Figure 12-6 Computerized Control System using PC Block Diagram

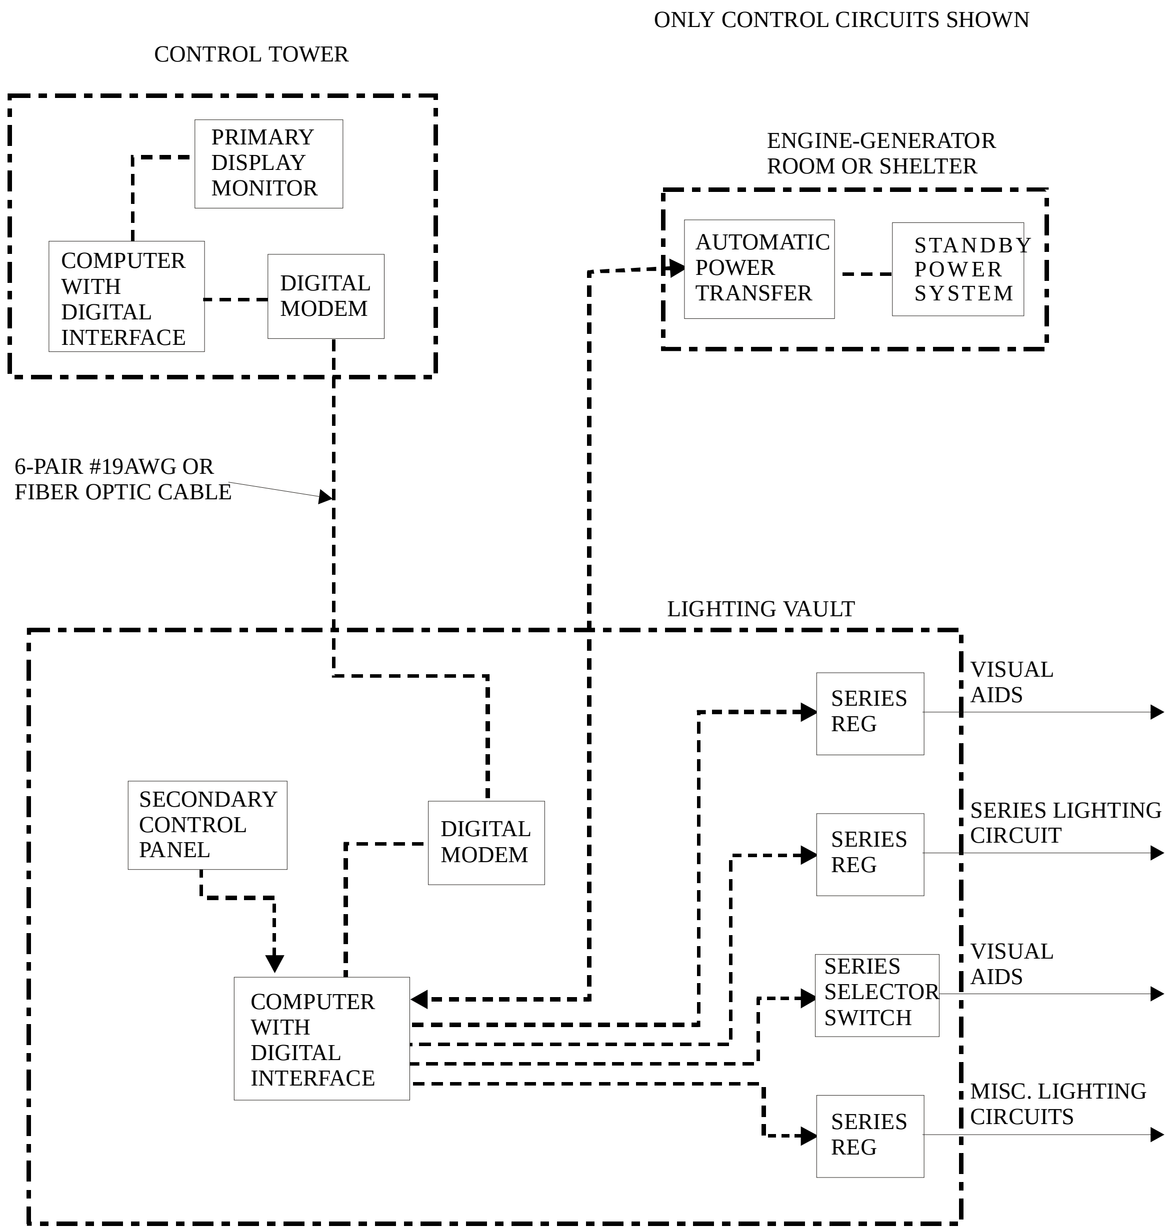


See FAA AC 150/5345-56 for detailed ALCMS equipment requirements. See also FAA AC 150/5345-30, for ALCMS installation and operational requirements.

12-1.12 Light Colors.

For a complete description of incandescent aviation light colors, see SAE AS25050, the applicable FAA Advisory Circular, and a Chromaticity (CIE) color coordinate diagram.

For light emitting diode color requirements, see FAA Engineering Brief 67.

12-1.13 Light Intensity.

12-1.13.1 The brightness steps for the levels of incandescent lamp intensity are shown in Table 12-2.

Table 12-4 Intensity Requirement Levels for Incandescent Light Circuits

Brightness Step	Amperage Reading 20-Ampere Circuit	Amperage Reading 6.6-Ampere Circuit	Approximate Percent Rated Intensity
1	8.5	2.8	0.16
2	10.3	3.4	0.80
3	12.4	4.1	4.00
4	15.8	5.2	20.00
5	20.0	6.6	100.00

12-1.13.2 The brightness steps for three levels of incandescent lamp intensity are achieved by varying the current in the lighting circuit as follows:

Brightness Level	Service Systems Lamp Current (amps)	Percent Brightness
High	6.6	100
Medium	5.5	30
Low	4.8	10

For light emitting diode intensities, see FAA Engineering Brief 67.

12-1.14 Special Considerations for Series Circuits.

12-1.14.1 Selection of 6.6- or 20-Ampere Circuit.

12-1.14.1.1 See FAA AC 150/5340-30 for detailed information about airport series lighting system design. The FAA no longer allows 50 and 70 kW constant current regulators for new designs; these regulators can be used for replacements only. The FAA also suspended the use of 2400 V AC input regulators for all new designs; these regulators may only be used for replacements.

12-1.14.1.2 The determination of whether to use a 6.6 amperes or 20 amperes series circuit must be based on several factors relating to the characteristics of the circuit and the anticipated conditions under which the circuit will be operated. In general, if a circuit is not expected to operate at highest intensity more than 5 percent of the time, and if design calculations show that the voltage will not exceed 2.4 kV when operated at the midlevel (step 2 for 3-step circuits, step 3 for 5-step circuits), then a 6.6 ampere circuit is recommended. If a circuit is expected to operate at highest intensity more than 5 percent of the time, and if design calculations show that the line voltage will be more than 2.4 kV at the mid-level, then consideration should be given to using a 20 amperes circuit, or alternatively using more than one 6.6 amperes circuit.

12-1.14.1.3 The primary circuit cables are insulated for 5,000 volts. If the load is over 33 kW and operated at 6.6 A, the required voltage would exceed 5,000 volts. Therefore, the circuit should be operated at 20 A to reduce the voltage below the insulation rating of the series lighting circuit high voltage cable.

12-1.14.1.4 Analysis should consider the economics over the expected life of the system, typically 20 years. A more detailed discussion of this can be found in Chapter 13. Recommend designing for multiple 6.6 ampere circuits instead of 20 ampere circuits.

12-1.14.2 REIL on Series Circuits.

REIL (runway end identifier lights) are typically connected to the runway edge lighting series circuit via a power adapter, or to a separate power source of 120/240 volts. If connected to a series circuit, it is necessary to consider the sizing of the regulator carefully to allow for the pulsing type of load. The impact on the constant current regulator may be up to 10 times the power requirement indicated by the manufacturer. More information on this can be found in Chapter 13.

12-2 ADDITIONAL GUIDANCE.

The FAA has published guide specifications for installation of airfield lighting systems. FAA guide specifications come in two forms: advisory circulars in the 5340 series, and FAA-E specifications. A listing of applicable publications is provided below. Where those guides are in conflict with the Air Force requirements listed above, the Air Force requirements take precedence. The FAA has an Advisory Check List AC 00-X.X that provides a list of documents, and how to order them. Contact the FAA at 1-800-FAA-SURE, (fax: 301-386-5394).

12-2.1 FAA Advisory Circulars (ACs).

FAA Advisory Circulars and Engineering Briefs may be downloaded free of charge from the FAA website: http://www.faa.gov/airports/engineering/.

12-2.1.1 FAA AC 150/5340-30 covers runway/taxiway lighting, visual aids (PAPI, REIL, Airport Beacons, Wind Cones, MALSF).

12-2.1.2 FAA AC 150/5340-18 describes the recommended standards for design and installation of a taxiway guidance sign system.

12-3 SITING PAPI.

12-3.1 Considerations.

Siting a PAPI requires consideration of the following: if there is or will be an ILS glide slope, the established glide path (aiming angle, typically 3 degrees), the threshold crossing height (TCH) for the selected aircraft height group, the runway gradient (longitudinal slope) from the threshold to the PAPI location, and other factors.

12-3.1.1 With an ILS glide slope, the PAPI is located the same distance from the runway threshold so that the elevation of the lens center of the light units intercepts the runway at the same location as the virtual source of the ILS glide slope, within a tolerance of ±30 feet (±9 meters), and is aimed at the same angle as the ILS glide slope. The virtual source is the Runway Point of Intercept (RPI), where the glide path intercepts the ground elevation along the runway centerline. PAPI location considers the light beam, where the elevation of the lens center of the PAPI light units should intercept the ground elevation along the runway centerline (within tolerance). For aircraft in height group 4 (Table 3-6) for Army airfields only, the PAPI is sited at the RPI plus an additional 300 feet (90 meters), +50 feet –0 feet (+15 meters –0 meters), from threshold.

12-3.1.2 If there is no ILS or Precision Approach RADAR (PAR) glide slope, the PAPI is sited as shown in Figure 12-7. First determine the following:

12-3.1.2.1 Glide Path.

Typically this is 3 degrees, but it may vary at some locations.

12-3.1.2.2 Threshold Crossing Height (TCH).

See Table 3-6. For the Air Force, the TCH is based on the most predominant aircraft using the runway (the major command will make this determination). For the Army, the TCH is based on the most demanding aircraft height group expected to use the runway (the aviation community will coordinate with USAASA for this determination).

12-3.1.2.3 Runway Gradient.

This may be available from record drawings, or determined by field survey. Usually the grade is given as a percent representing the vertical elevation difference over a longitudinal distance (threshold through approximate PAPI location). For example, a 1 percent grade represents a 12 inch (300 millimeters) height difference over a 100 feet (30 meter) length. This is converted to an angle in degrees, α, using the relationship: $\tan \alpha$ = percent grade (expressed as decimal). With this relationship, a grade of 1 percent represents a runway slope of 0.573 degrees (from the horizontal).

12-3.1.3 Determine the Runway Reference Point (RRP) based on runway gradient, as shown in Figure 12-7, establishing the RRP where the elevation of the lens center of the light units coincides with the elevation of the runway centerline. The method provides a direct solution, based on two equations and two unknowns, when the grade of the runway is relatively uniform. The RRP is based on the PAPI light beam, where the elevation of the lens center of the PAPI light units intercept the ground elevation along the runway centerline (within tolerance). Case 4 in Figure 12-7 provides an iteration method for locating the RRP when the runway grade varies significantly through the first approximately 1,500 feet (450 meters).

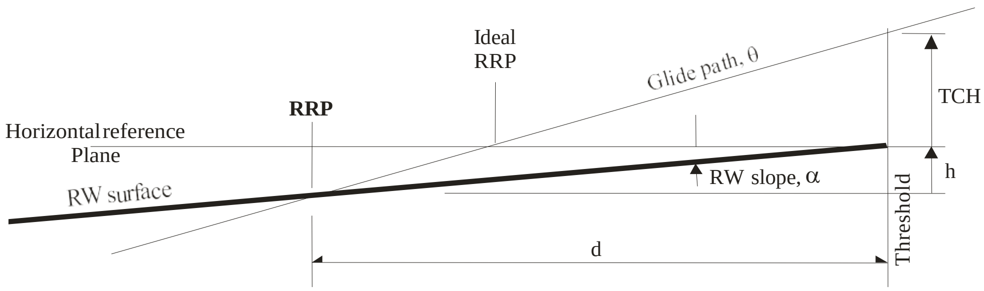
12-3.1.4 Adjust the location of the PAPI for cross slope or other factors, as required. Several examples of how the location of the RRP or location of the PAPI might be adjusted are presented below. Stay within allowable tolerances and other dimensional requirements of paragraph 12-3.2. See Figure 12-8 for guidance on tolerances and adjustments if PAPI cannot be located at the RRP.

12-3.1.4.1 Where the terrain drops off rapidly near the approach threshold and severe turbulence is typically experienced, it would be beneficial to locate the RRP and PAPI farther from the threshold if sufficient runway length is available. In this case consider using the maximum TCH allowed by tolerance in determining the RRP.

12-3.1.4.2 On shorter runways, the RRP and PAPI may be located nearer the threshold to provide the maximum amount of runway for braking after landing. In this case consider using a lower TCH as allowed by tolerance in determining the RRP.

Figure 12-7 Siting PAPI without an ILS Glide Slope (1 of 2)

a. Case 1 - Runway with downward grade.

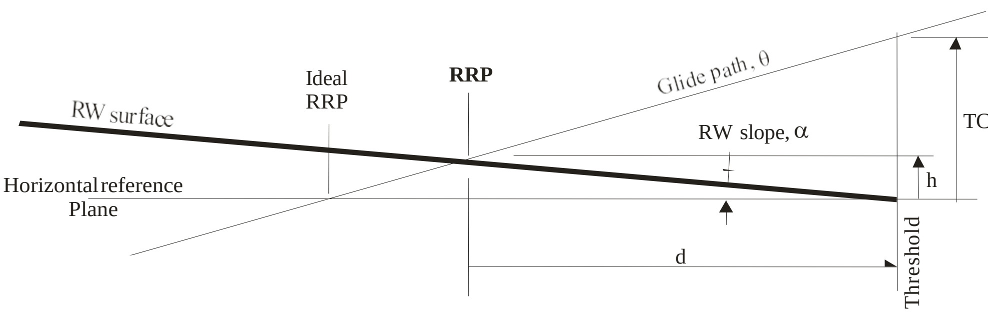


Two relationships can be defined which have two unknowns (d, h):

$\tan\theta = \frac{TCH+h}{d}$, and $\tan\alpha = \frac{h}{d}$

Substituting and solving the above, d is determined directly by: $\mathbf{d} = \frac{\mathbf{TCH}}{(\tan\theta - \tan\alpha)}$

b. Case 2 - Runway with upward grade.



From the relationships, d is determined directly by: $\mathbf{d} = \frac{\mathbf{TCH}}{(\tan\theta + \tan\alpha)}$

EXAMPLES (Assume the following: TCH = 50 feet (15 meters), θ = 3 degrees)

Case 1 (RW with 1% downward grade, α = 0.573 degrees) => d = 50/[tan 3 degrees - tan 0.573 degrees] = 1,179 feet (360 meters)

Case 2 (RW with 1% upward grade, α = 0.573 degrees) => d = 50/[tan 3 degrees + tan 0.573 degrees] = 801 feet (244 meters)

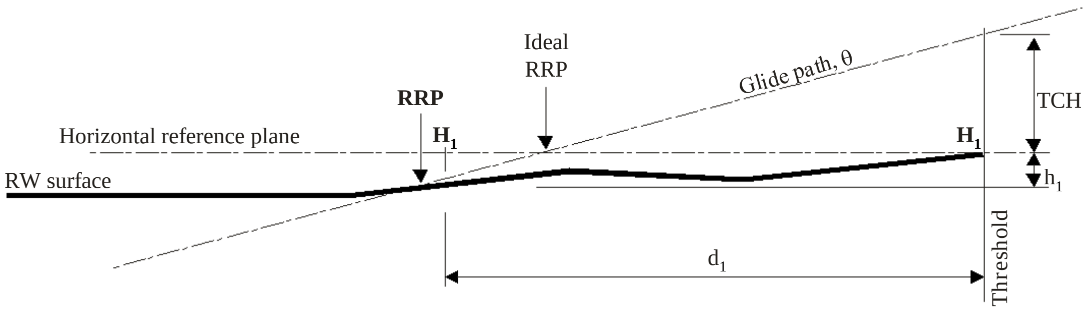
Case 3 (RW is level - 0% grade, α and tan α are both 0) => d = 50/[tan 3 degrees] = 954 feet (290 meters) [*not illustrated*]

While the slope should be constant through the first part of a runway, if the existing slope varies too much to directly apply Case 1, 2 or 3, then a trial method illustrated by Case 4 can be used. In all cases, the location of the glide path intercept with the actual runway surface (RRP) must be determined.

Case 4 - Runway grade varies too much to apply above methods => [*See sheet 2 of 2*]

Figure 12-7 Siting PAPI without an ILS Glide Slope (2 of 2)

c. Case 4 - Runway with varying grade.



Use this method if longitudinal runway grade changes within 2200 feet (671 meters) from the runway threshold.

Consider that a 0.1% change in runway grade at about 500' (150M) from threshold translates to a 6" (15cm) change in elevation at 300M (1,000'), and about a 10' (3M) error in calculating the RRP, using the runway grade beginning at the threshold. The trial method requires elevation data along the runway centerline in proximity of the PAPI site.

(1) Select a trial value for d_1 (“d”). [*Case 1 or Case 2 can be used to select initial trial value*].

(2)At distance d_1, determine elevation difference from threshold ($\mathbf{H_0 - H_1 = h_1}$)

(3) Test d_1 and h_1 in following equation: $\mathbf{\frac{TCH + h_1}{d_1} =? \tan\theta}$

[*NOTE: tan θ = 0.0524 for glide path angle of 3* .]

(4)If value in (3) is larger than tan θ, then increase d, determine new h, and test equation in (3). If value is smaller than tan θ, then decrease d, determine new h, and test equation in (3). Continue until within about ±0.0001 of tan θ [*this yields a value for “d” within about ±2' of where RRP should be located* .

Example data from field survey				
Point	Station	D	H	h
Thld, 0	0+00	0	110.4'	-
1	9+50	950'	114.6'	4.2'
2	10+00	1,000'	115.0'	4.6'
3	10+50	1,050'	115.4'	5.0'

EXAMPLE Case 4 (Assume the following: TCH = 50', θ = 3°).

At d_1 = 950', h_1 = 4.2', and (TCH+h)/d = 0.0571 (too large)

At d_2 = 1,000', h_2 = 4.6', and (TCH+h)/d = 0.0546 (closer)

At d_3 = 1,050', h_3 = 5.0', and (TCH+h)/d = 0.0524 (matches tan θ - OK)

[*NOTE: Suggested longitudinal tolerance for locating PAPI is + or - 10'*.]

DEFINITIONS:

RRP = RW reference point, where PAPI is located based on adjustment for runway grade.

Ideal RRP = RW reference point if runway has 0% grade (no slope).

RW = Runway

TCH = Threshold crossing height

d = Distance PAPI is located from runway threshold, based on adjustment for runway grade.

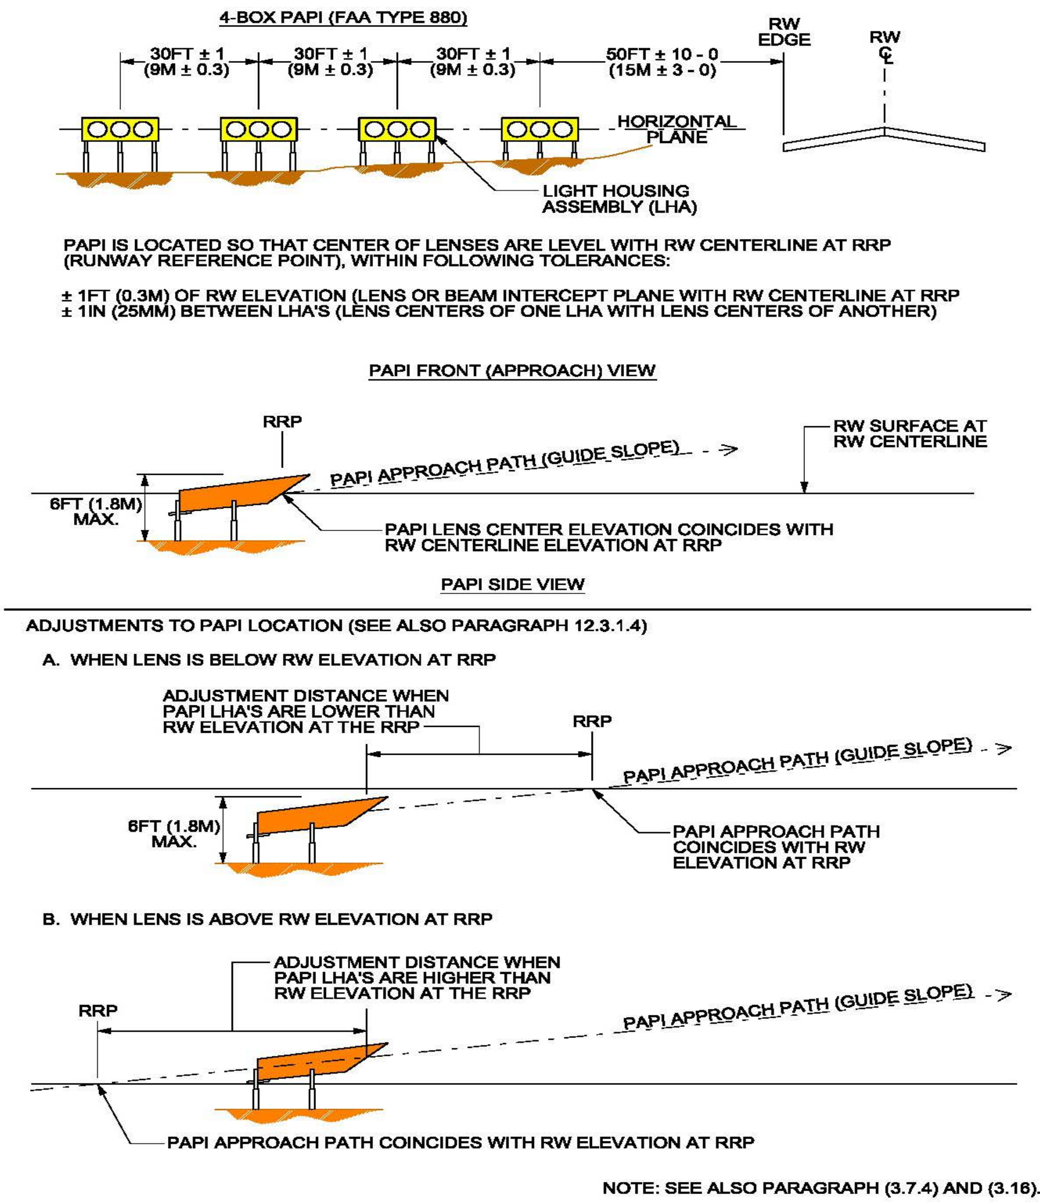
θ = Glide path angle, degrees (from horizontal).

α = Runway slope, degrees (use positive value in above equations).

h = Elevation (height) difference between RW threshold and RRP, measured on RW centerline surface.

H = Elevation at a point along runway centerline.

Figure 12-8 PAPI Positioning Guidance



12-3.1.4.3 At locations where snow is likely to obscure the light beams, the light units may be installed so the top of the unit is a maximum 6 feet (1.8 meters) above ground level. This may require locating the light units farther from the runway edge to ensure adequate clearance for the most critical aircraft. If the light beams are higher than the allowable tolerance, with respect to the elevation of the runway centerline (raising the TCH for the visual glide path), the PAPI may be relocated closer to the threshold to maintain the RRP and TCH.

12-3.1.4.4 The cross slope at the preliminary RRP location may result in the light units sitting too high or too low with respect to the runway centerline elevation. In such cases, the PAPI may be relocated closer to or farther from the threshold to maintain the RRP and TCH and remain within tolerance.

12-3.2 Other Dimensions and Tolerances for PAPI.

12-3.2.1 Distance from Runway Edge.

Install the inboard PAPI light unit no closer than 50 feet, +10 feet –0 feet (15 meters, +3 meters –0 meters) from the runway edge, or from the edge of other runways or taxiways.

12-3.2.2 Separation Between Light Units.

Provide lateral separation of 30 feet (9 meters) between light units. This may be reduced to no less than 20 feet (6 meters) if warranted by conditions. The distance between light units must be equal and not vary by more than 1 foot (0.3 meters).

12-3.2.3 Azimuthal Aiming.

Aim each light unit towards the approach zone on a line parallel to the runway centerline, within a tolerance of ± 0.5 degree.

12-3.2.4 Mounting Height Tolerance.

The beam centers of the four light units must be within ±1 inch (±25 millimeters) of a horizontal plane. This plane must be within ±1 foot (±0.3 meters) of the elevation of the runway centerline at the intercept point of the visual glide path with the runway (RRP), except for adjustments under conditions in paragraph 12-3.1.4.

12-3.2.5 Tolerance Along Line Perpendicular to Runway.

The front face of each light unit in a light bar must be located on a line perpendicular to the runway centerline within a tolerance of ±6 inches (±150 millimeters).

12-3.2.6 Vertical Aiming of Light Beams.

For 4-box L-880 PAPI, the units are aimed as shown in Table 12-4.

Table 12-5 Aiming of FAA Type L-880 PAPI Relative to Glide Path

Light Unit	Aiming Angle (in minutes of arc)	
	Standard installation	Height Group 4 Aircraft on Runway with ILS
Unit nearest runway (#1)	30' above glide path	35' above glide path
Next adjacent unit (#2)	10' above glide path	15' above glide path
Next adjacent unit (#3)	10' below glide path	15' below glide path
Next adjacent (outside) unit (#4)	30' below glide path	35' below glide path

12-4 PULLING CABLE INTO DUCT.

12-4.1 Pull cable into ducts carefully to prevent harmful stretching of the conductor, injury to the insulation, or damage to the outer protective covering. Duct should be verified as open, continuous, and free of debris prior to installing cable. The following summarizes guidance for pulling cable from FAA Specification FAA C-1391. This document may be referenced for additional information.

12-4.2 Seal all cable ends with moisture-sealing tape before pulling, and maintain seals until connections are made. All cables to be installed in one duct should be pulled at the same time. Splices should not be pulled into a duct.

12-4.3 Apparatus for pulling cable at entrances to structures may include a pulling tube or framework and two sheaves. The diameter of the sheaves should be at least 10 times the diameter of the largest cable to be pulled. Cable may be pulled by power winch or by hand. Adequate cable pulling compound should be used of an approved type (do not use petroleum grease).

12-4.4 Structures such as manholes, hand holes, junction boxes, and light bases are typically spaced so as to avoid excessively long cable pulls. The spacing should not exceed 600 feet (180 meters), and spacing not more than 400 – 500 feet (120 – 150 meters) is preferred.

12-4.5 If possible, the maximum allowable cable length to be pulled should be obtained from the cable manufacturer. An estimate of the absolute maximum length of pull based on new, level, straight plastic duct and the use of adequate pulling compound is as follows:

$$L = T/CW$$

Where:
L = Length of cable pulled (in feet)
T = Total tension (in pounds)
C = Coefficient of friction (0.3 for single cables, 0.4 for multiple cables)
W = Weight of all cables being pulled (in pounds/foot)

12-4.6 A dynamometer should be used to monitor the cable tension during pulling. Alternatively, a contractor may adapt a rope harness properly sized to limit pull tension. Types and sizes for ropes used in this manner may be found in FAA C-1391 Table 1. Maximum pulling tension should be no greater than manufacturer's data on allowable cable pulling tension. Any combination of a group of cables to be pulled into a duct must not exceed the sum of individual allowable tension of each cable plus 15 percent. Typical examples of the allowable maximum tension for various types of cable are shown in Table 12-5.

Table 12-6 Maximum Allowable Non-Armored Cable Pulling Tension, Using Dynamometer

Cable	Tension Lb (Kg)
2 – 1/C AWG #8 solid (10 square mm)	275 (125)
3 – 1/C AWG #8 solid (10 square mm)	367 (167)
4 – 1/C AWG #8 solid (10 square mm)	550 (250)
2 – 1/C AWG #6 stranded (16 square mm)	420 (191)
3 – 1/C AWG #6 stranded (16 square mm)	630 (286)
4 – 1/C AWG #6 stranded (16 square mm)	840 (382)
1 – 2/C AWG #8 stranded (10 square mm)	305 (139)
1 – 3/C AWG #8 stranded (10 square mm)	395 (180)
1 – 4/C AWG #8 stranded (10 square mm)	585 (266)
1 – 2/C AWG #6 stranded (16 square mm)	455 (207)
1 – 3/C AWG #6 stranded (16 square mm)	685 (311)
1 – 4/C AWG #6 stranded (16 square mm)	880 (400)
1 – 6/C AWG #12 stranded (4 square mm)	315 (143)
1 – 12/C AWG #12 stranded (4 square mm)	630 (286)
1 – 12 pair AWG #19 solid (0.75 square mm)	230 (105)
1 – 25 pair AWG #19 solid (0.75 square mm)	541 (246)
1 – 50 pair AWG #19 solid (0.75 square mm)	1,061 (482)
1 – 100 pair AWG #19 solid (0.75 square mm)	2,000 (909)

12-4.7 The pressure on a cable or cables being pulled is affected by a radius or bend in a duct. For non-straight segments of duct the following, based on manufacturer information, is recommended as a guide in limiting the tension with duct radius (T is the maximum allowable pulling tension, and R is the radius of the duct):

$$T(lbs) / R(ft) \leq 300 \text{ (English Units) or } T(kg) / R(m) \leq 456 \text{ (Metric Units)}$$

12-5 ICE DAMAGE PREVENTION.

Water in light bases is very common. In cold regions placing several 2 by 8 inch (50 millimeter by 200 millimeter) closed cell foam disks in the light base will help prevent ice damage to the base, light fixture and isolation transformer.

CHAPTER 13 \1\ CHARACTERISTICS OF AIRFIELD GROUND LIGHTING

13-1 GENERAL.

Airfield ground lighting (AGL) typically includes separate series-circuited lighting systems that provide visual guidance to the pilot for aircraft operations. The systems usually have brightness control for adapting to various visibility conditions. The types of lighting systems installed for a particular runway are an important part in determining the conditions under which aircraft operations are allowed (e.g., Visual Flight Rules (VFR), Category I, Category II, or Category III). The various lighting systems that may be installed for a runway are shown in Figure 13-1. Not included in this figure are the several approach lighting systems (ALS) which may also be installed. Details for lighted approach aids, runway lighting systems, and taxiway lighting are provided in Chapter 3, Chapter 4 and Chapter 5, respectively.

13-1.1 Airfield ground lighting is characterized by constant current series electrical circuits, which provide constant current for intensity control of lighting components. This system allows for selectively changing the brightness of the lighting components by increasing or decreasing the level of the constant current in the series loop. While some older systems use constant voltage for shorter length series circuits, most systems today are constant current type. The series circuit provides energy at constant current to each device (such as a light or sign) on the circuit, supplied from a CCR.

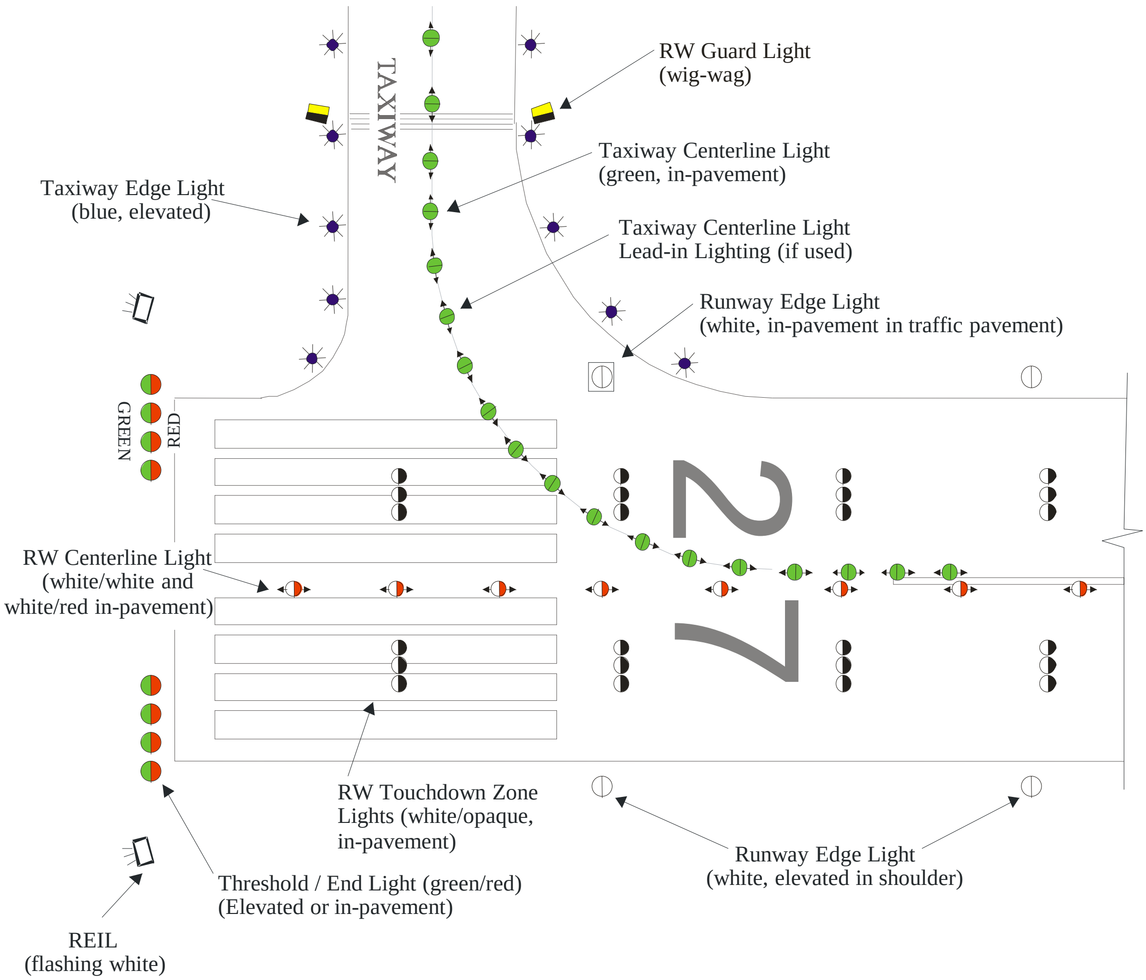
13-1.2 The major parts of a series circuit are: the CCR (power source), the primary circuit cable, isolation transformers, and lighting components (such as lights and signs). The isolation transformers are connected in series on the primary side, with connected loads on the secondary side of each isolation transformer (Figure 13-2). The system is characterized as follows:

- A constant current is delivered along the entire loop on the primary side of the isolation transformers, independent of the number of lighting loads. Power is provided by the CCR.
- The magnitude of the voltage along the series circuit primary depends on the number and size of connected lighting loads. The voltage along the primary cable will measure different at each point. (Calculating voltages for the constant current series circuit is illustrated later in this chapter.)
- The circuit is considered high voltage on the primary side, which typically may be several thousand volts (5kV cable is used), and low voltage on the secondary side or load side of the isolating transformers, which typically is less than 30V.

- The isolation transformer provides an effective short for the primary circuit in the event of a lamp filament failure, which opens the secondary circuit. This prevents failure of a connected light from causing an open condition on the series primary circuit.

- A constant current series circuit can also be used to power equipment with specific voltage requirements. In this case a power adapter is used. The power adapter also serves to isolate the device from the primary side similar to an isolation transformer. Examples of equipment which may be connected to series lighting circuits include: wind cones, PAPI, REIL, and others which typically may require 120/240V power. NOTE: The lighting circuit must be ON for the equipment to receive power with this type of arrangement.

Figure 13-1 Typical AGL Layout



NOTES:

1. RW EDGE LIGHTING: For high intensity system (HIRL) bidirectional, white/white, with yellow on rollout for last 2,000' (610M) (L-862 elevated, with L-850C for in-pavement). Runway edge lights are spaced about 200' (61M) apart.

2. THRESHOLD/END (T/E) LIGHTS: Group of 4 or 5, spaced 10' (3M) apart symmetrical about centerline. Outer light in each group lines up with RW edge lights. Groups may be wing-out bars, where inner light in each group lines up with RW edge lights.

   T/E lights show green to aircraft approaching for landing, and red to landing aircraft coming to end of the RW.

3. RW CENTERLINE LIGHTS: Bi-directional white/white, with alternating red/white and white/white from 3,000' to 2,000' (915M to 610M) from end of RW, and red/white for last 2,000' (610M) of RW.

4. RW TOUCHDOWN ZONE LIGHTS: Uni-directional, with white towards approaching aircraft.

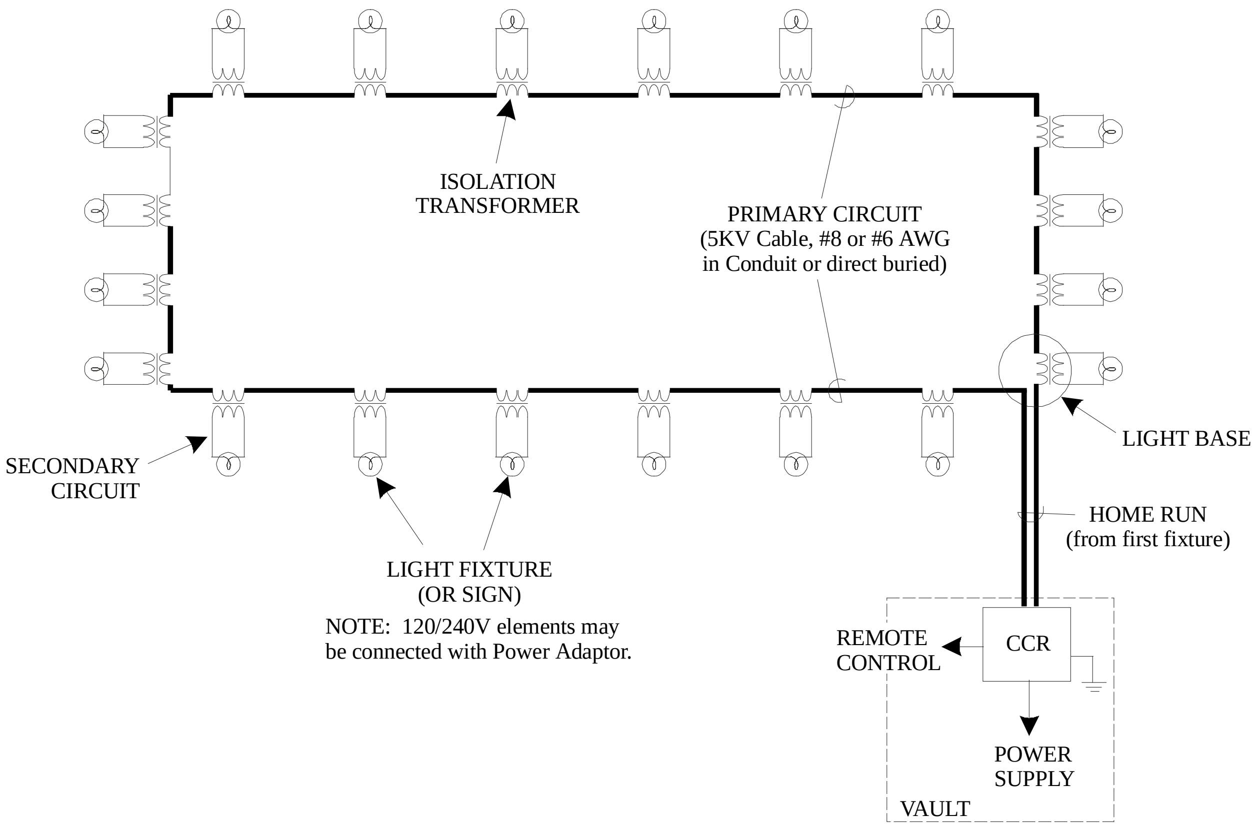
5. TW EDGE LIGHTS: Omni-directional blue (L-861T).

6. TW CENTERLINE LIGHTING: Bi-directional green/green, but may be green/yellow or yellow/yellow for some conditions.

7. REIL: Runway End Identifier Lights, discharge type flashing white lights (about 90 times/min.), Aimed 15 deg outward and 10 deg above horizontal.

8. RW GUARD LIGHT: Uni-directional, flashing yellow. Elevated outside TW, or may be bar of in-pavement across pavement (L-804).

Figure 13-2 Typical AGL Series Lighting Circuit



13-1.3 Parallel circuits are briefly discussed as these may be used to serve facilities such as wind cones, PAPI, REIL, and others. This may be directly from a power source, or via power adapter from a series lighting circuit.

13-2 POWER.

Upstream power for the CCR feeding the AGL may be from a variety of sources. Equipment vaults for AGL may be fed from a variety of sources, and in many cases have emergency standby generator power with automatic transfer in case of outages. Older systems typically feed the CCR at 2400V, while newer installations feed vault CCRs at 480V; 2400V input CCR equipment is for replacement only. The upstream power distribution feeding the CCR is not covered in this section.

13-3 CONTROL AND MONITORING SYSTEMS.

Traditional control/monitoring systems, both military and commercial, are relay systems. L-821 relay panels are very reliable and are suitable for nearly all military airfields. Typically, cables required for these types of systems are multi-pair (50 or more pairs) cables to connect the airfield lighting vault on the airfield with the air traffic control tower. On many air bases, the distance between the two facilities is great, resulting in a costly cable installation with the cable vulnerable to possible damage or failure of one or more pairs in the cable. In addition, these communications cables require separate duct systems to eliminate interference from the power cables. The traditional relay panel and multi-conductor control cable can also be simplified by using a multiplexer, which requires only one pair cable to communicate between the vault and tower (or other station). A multiplexer can also be built into a PLC system.

13-3.1 Some airfield control/monitoring systems have been installed using Programmable Logic Controllers (PLCs). The PLC industrial systems use high I/O modules that reduce the need for multi-pair cable installation. Cables with 2 to 6 pairs are typically needed, although fiber optic cable can also be used.

13-3.2 PC-based systems are currently being used, with computers (Windows 7 operating system is approved by AF Chief Information Officer) located in the tower, the vault, and/or other work stations. These systems have the capability of displaying the necessary information on a monitor. This is the most flexible system in use today, with off-the-shelf units readily available. Typically, standard operating software is used, and off-the-shelf graphics software is tailored for a specific site. The communications cable requirements are 2 to 6 pairs of cable or fiber optics. Fiber optic cable eliminates the need for separate ducts since there will be no interference between power cable and fiber optic cable. The control panel typically is a touch-screen type. At the time of this writing the essential system PCs are recommended to have the following characteristics: 19" (480 millimeter) rack mount form factor, fully enclosed metal housing, redundant hot-swappable solid state software and data storage devices, redundant hot-swappable cooling system, redundant hot-swappable power supplies. The systems incorporate uninterruptible power supplies (UPS) for primary power to all system components required for normal operation for a duration of fifteen minutes.

13-3.3 Compared to the traditional FAA Type L-821 control/monitoring systems, the PLC or PC-based systems are easily expanded and provide data for the air traffic controller and maintenance personnel. Refer to FAA AC 150/5345-56. Some industrial standards the PLCs meet are NEMA ICS1, NEMA ICS2, NEMA ICS 3, UL 508, ANSI/IEEE C 37.90.1-1989, CAN/CSA C22.2 No. 142, MIL-STD-461B, MIL-STD-810 and ISO 9000.

13-3.4 Often, the computerized system is based on one specific manufacturer's equipment. This limits the facility to one manufacturer for both service and parts. A good system design will avoid this by establishing competitive parameters in the procurement document.

13-3.5 Considerations for the design of a computerized control/monitoring system are in paragraph 13-18.6.

13-3.6 Factors for consideration when selecting a control system:

- Monitoring AGL equipment: the PLC based system must be customized for each type of CCR.

- For PC based systems, software has been developed and tested, and is easily configured to monitor AGL equipment. Software developed for PC systems is specific for the task and works with all types of CCRs and other related AGL equipment.
- With PLC systems there are established industrial standards and criteria for mean-time-between-failure (MTBF).

13-4 CONSTANT CURRENT SERIES CIRCUITS.

A constant current series circuit is an ungrounded system, where circuit elements are connected in a string with the same current flowing to each element. The circuit is one continuous loop starting and ending at the power source (the constant current regulator for the AGL circuit). The CCR maintains a constant current independent of the load on the circuit.

13-4.1 Circuit Failure.

With constant current, a short-circuit across the output of the CCR is a no-load condition, and an open-circuit is an overload. In a simple series circuit, a lamp failure would cause an open-circuit. For this reason a bypass device such as an isolating transformer is installed between the primary side and secondary side as part of each light fixture connection, or for connecting other loads such as guidance signs. In certain cases, such as for approach lights where 5 steady-burning lights are on a single secondary circuit isolated from the primary series circuit by one or more isolation transformers, a film disc cutout may be used. Film disc cutouts operate in such a way that when a lamp burns out, the film-disc cutout shorts the failed lamp, thereby allowing current to flow to the remaining connected fixtures.

13-4.2 Advantages of Series Lighting Circuits.

- All lamps operate at the same current, hence same intensity.
- Single-conductor cable of one size and insulation voltage rating can be used throughout the circuit.
- Intensity control of lights can be obtained over a wide range.
- A single ground fault along the circuit will not affect light operation.
- Ground faults are easily located.

13-4.3 Major Disadvantages of Series Lighting Circuits.

- Installation costs are high when considering the CCR and isolating transformers.
- Poor efficiency in use of electrical power.
- All components on the primary side must be insulated for full voltage.

- An open-circuit anywhere on the primary side makes the entire circuit inoperative and could damage cable insulation or the CCR.
- Locating faults such as open-circuit conditions can be time-consuming and may be difficult.

13-4.4 Typical Usage.

Series circuits are usually used for runway and taxiway lighting systems and most steady-burning lights of approach lighting systems because they provide more uniform intensity and better intensity control of the lights.

13-5 CONSTANT CURRENT REGULATORS.

The power input to the AGL circuits is controlled by the CCR to which the circuit is connected. While the CCR produces constant current to the circuits depending on the brightness step setting, the voltage input to the circuit varies with the actual load.

13-5.1 Basically, there are three types of constant current regulators used at airports:

- Resonant network circuit (ferro-resonant type using a resonant network control system to produce output current).
- Saturable reactor (ferro-resonant type, where the amount of reactor saturation via closed control loop determines output current).
- Silicon controlled rectifier (SCR) (uses SCR type thyristors to convert constant voltage source to constant current output, with solid state control circuiting). These are not ferro-resonant and are not approved for new installations.

13-5.2 The first two types have been reliable over the years, but fluctuations in input voltage will cause corresponding changes in the output current. Most CCRs now manufactured are SCR type.

13-5.3 Tests have shown that, as circuit load increases toward the rated capacity of a CCR, harmonic distortion is reduced and the wave form approaches a sine wave. This suggests that loading closer to rated capacity results in better circuit performance. However, lamp failures and other factors may increase the output voltage, and this needs to be considered when matching circuit load to CCR size.

13-5.4 CCRs have "taps" for adjustment to accommodate loads. Some manufacturers have introduced taps which automatically adjust to the circuit load, while others use manual taps which are typically set when the CCR is installed, but can be changed later to accommodate changes in the load.

13-5.5 The allowable tolerances in CCR output current are shown in FAA AC 150/5345-10. The allowable tolerances are small, because small changes result in large changes in light output. For a 6.6 amp circuit, reducing the current by 3 percent (to 6.4 amps) will reduce the light output over 15 percent, and reducing the current by 6 percent (to 6.2 amps) will reduce the light output by over 30 percent. The impact is the opposite on lamp life, where a current lower than maximum will significantly increase lamp life, and a higher current will reduce lamp life. The percent of full brightness obtained at each of the nominal current levels for 3 and 5 step systems can be found in paragraph 12-1.11.

13-5.6 15KW through 30KW CCRs may be selected for either 20 or 6.6 amperes output current. Intensity steps are either 5-step or 3-step for all CCRs.

13-5.7 50 kW and 70 kW regulators operating with 20A output current are not approved for new installations and are allowed for replacement only. Regulators with 2400V input are not approved for new installations.

13-6 REGULATOR SIZING.

13-6.1 For steady burning loads such as edge, centerline and touchdown zone lights sizing the regulator is fairly straight forward. Steady burning lights and circuit conductors are resistive loads and therefore will vary as the current varies. Current transformers are impedance loads and have the same electrical characteristics as resistive loads. See Figure 13-3A for calculating the load as the current varies; i.e., at the lowest brightness step. Using Ohms Law (P=IE), the maximum load at the lowest brightness level for a five-step regulator is determined by the ratio of the currents; i.e., (2.8/6.6) or (8.5/20) or 42.4% of the regulator rating. For a three-step regulator it is 4.8/6.6, or 72.7% of the regulator rating. It can be seen that these load percentages are greater than the ones calculated in Figure 13-3A. Therefore, a regulator fully loaded only with lights (and associated transformers) will not overload at the lowest current level.

Figure 13-3A Calculation of Steady Burning Load at the Lowest Brightness Level

DATA:

P = Steady Burning Light Load

I = Regulator Current

R = Steady Burning Light Load Resistance

Subscript $_H$ is the value at the Highest Brightness Step

Subscript $_L$ is the value at the Lowest Brightness Step

Ohms Law: $P = I^2 \times R$

CALCULATIONS:

$P_H = (I_H)^2 \times R \rightarrow R = P_H / I_H)^2$

$P_L = (I_L)^2 \times R \rightarrow R = P_L / (I_L)^2$

The resistance of the lamp filaments remains constant, therefore

$P_L / (I_L)^2 = P_H / I_H)^2 \rightarrow P_L = P_H \times (I_L)^2 / I_H)^2 \rightarrow P_L = P_H \times (I_L / I_H)^2$

The effective load of the steady burning fixtures at the lowest brightness step (P_L) is the load at the highest brightness step (P_H) times the squared ratio of the low (I_L) and high (I_H) currents.

For a 6.6A five step regulator the current ratio squared is $(2.8/6.6)^2$ or 0.18 or 18%.

For a 20A five step regulator the current ratio squared is $(8.5/20)^2$ or 0.18 or 18%.

For a three step regulator the current ratio squared is $(4.8/6.6)^2$ or 0.53 or 53%.

SUMMARY:

For five step regulators the load of steady burning lights at the lowest brightness step is 18% of the load at the highest brightness step.

For three step regulators the load of steady burning lights at the lowest brightness step is 53% of the load at the highest brightness step.

13-6.2 When loads such as REILs, PAPIs, windsocks and airfield signage are connected to a series circuit, consideration must be given to accommodate the effect of these loads on the regulator. Loads such as these have unique power requirements. PAPIs, signs and windsocks must maintain a constant level of light output and require a constant input voltage. When they are connected to a series circuit that has varying current levels the power from the current regulator must be converted to a constant voltage source within the equipment. Airfield signs are required to maintain a constant level of illuminance on the sign face and electronics are needed to operate them from a varying current source. The commonality with all these loads is that they present a constant load to the regulator regardless of current level on the circuit. When the circuit is a combination of steady burning lights and signs or other constant loads, the engineer must insure that the calculated load at the lowest brightness level does not exceed the percentage of the regulator rating as indicated above. Figure 13-3B shows an example where the regulator is over loaded at the lowest brightness step. Although most regulators will continue to operate when over loaded there are risks associated with that. Depending on the degree of overloading, negative effects may include the regulator's inability to stay within the FAA current tolerances. The result would be improper brightness levels. Operating an overloaded regulator can also lead to the premature failure of critical components because the regulator will raise the output voltage to maintain the required current level.

13-6.3 In its Advisory Circulars, the FAA does not address the load imposed on the CCRs by the constant current to constant voltage adapters necessary for REIL operation, or the REIL that are connected into series circuits. With the constant flashing of the lights and the resulting discharging of the capacitor, the REIL place a very short, but heavy, pulsing load on the regulator. Occasionally, this type of pulsing load results in pulsation of the illumination of the steady burning lights on the circuit. This "reflective" pulsation depends on the characteristics of the regulator powering the circuit and on the characteristics of the REIL connected into the circuit. The design engineer needs to ascertain from the regulator manufacturer which type of CCR will handle the overall series circuit load with the addition of the REIL pulse-type load without adverse effect. It has been shown that the problem will be minimized if the REIL are connected into series circuits that have primarily incandescent loads and the circuit load approaches the capacity of the regulator.

13-6.3.1 The actual regulator capacity needed to operate the REIL properly is much greater than the rated load indicated in the typical product literature. Usually the average power requirement is provided; however, the regulator has to accommodate the instantaneous, or pulsing, load to provide the flashing characteristics of the REIL. That REIL may be rated to require only 400 watts to operate, but may actually require up to 4 kilowatts of regulator capacity to meet the pulsing load requirements when also including the impact of the series circuit adapters between the series circuit and the REIL. The series circuit adapters convert 6.6 amps to 120 volts for REIL operation, and often have low efficiency that imposes higher than expected loads on the regulator. The proper sizing of the regulator requires careful consideration of the types of loads on the circuit and the true impact of those loads on the regulator.

Figure 13-3B Sample Calculation of CCR with High Signage Load

DATA:

CCR: 30KW, 480V input, 5-step (2.8A – 6.6A)

Cable: AWG #6, 5kV, L-824 Type C, 20,000 feet primary circuit

Circuit Loads:	Steady Burn Lights	13,000 W
	Transformer Losses (26% of Light Load)	3,380VA
	Signage	13,000 VA
	Cable losses (19 VA / 1,000’)	383 VA

Circuit power factor is assumed to be 0.85.

CALCULATIONS:

1. Total connected load, VA = 13,000 + 3,380 + 13,000 + 383 = 29,763 VA
2. CCR Rated Load @ Lowest Brightness Step: (Reference paragraph 15-6.1)

   30KW x (2.8/6.6) = 12.72 KW or 14.97 KVA

3. Calculated Load @ Lowest Brightness Step: Reference Figure 3-13A(Reference Figure 15-3A)

   (Lights + Losses) x $(2.8/6.6)^2$ + Signage =
   ((13,000 + 3,380 + 383) x 0.18) + 13,000 = 16,017 VA

Because the signage load does not change for the various brightness steps the resulting demand on the regulator at the low step (16.02 KVA) is higher than the rated load for the regulator at the low step (14.97 KVA). While the load at the highest step (29.76 KVA) is less than the rating of the regulator, it will be overloaded at the lowest step; therefore, do not operate in this load configuration.

Loads such as signs, REILs, PAPIs and windsocks are constant regardless of the brightness level and must be carefully considered in circuit design and regulator sizing.

Where:

E = volts (V)	W = Wattage of light fixtures
I = Current, in amperes (A)	VA = Volt-Amps
P = Power Load	kW = kilowatts
	kVA = kilovolt-amps
	P.F. = Power Factor

Ohms Law: P = IE, E=IR, $P=I^2R$

13-6.3.2 As described in paragraph 13-6.1, the REIL can impose significant loads on the CCR powering the circuits to which they may be connected. It is preferable, if the budget permits, to have separate circuits with 240/120 volt service to power the REILs, thereby eliminating any adverse impacts on series lighting circuits.

13-6.3.3 Sample calculations and comparison with test data, as well as guidance for setting taps, are shown in Figure 13-4. A table format for calculating airfield lighting series circuit loads is shown in Table 13-1. Carefully consider the notes in Table 13-1 when determining load values.

13-6.3.4 Normally the airfield signage load on a circuit is less than the steady burning light load. When the sign load is significant on a circuit, care must be taken to prevent overloading the regulator at the lowest brightness step. Figure 13-3B shows an example calculation where the sign load is high enough to present a problem.

13-7 CABLE.

The primary series circuit utilizes FAA L-824 Type B or C cable. L-823 connectors are used for connections. For 6.6 ampere primary series AGL circuits, an AWG #8 conductor is normally used. An AWG #6 conductor is used with 20 ampere circuits. For the secondary side lighting loads, a two-conductor AWG #10, 600V insulation is normally used.

13-7.1 The cable is installed in conduit, although it may be direct buried (L-824 cable is rated for direct burial). It is important that insulation is intact and that proper connections are made. Deteriorated or damaged cable can result in current leakage and may present a high voltage hazard to maintenance personnel. While installation in conduit may cost more, this method usually provides longer circuit life, and makes troubleshooting and replacement of cable segments easier. Where cable is installed in the regulator vault it must be in conduit, wireway or conduit or wireway in a floor trench with a solid top. L-824 cable is not rated for installation in cable tray.

13-7.2 The types of faults associated with series circuit cable are open circuit conditions and shorts-to-ground. An open circuit condition will turn off all the lights. A single short-to-ground will not impact the lighting, but multiple shorts-to-ground can cause dimming of lights or outages for portions of the circuit or for the entire circuit.

Figure 13-4 Sample Calculation of CCR Test Data

(1 of 2)

SAMPLE CALCULATIONS, CCR TESTING

DATA: CCR: 30KW, 480V input, 5-step (2.8A - 6.6A), with Power Factor of 0.43

Cable: AWG #8, 5kV, L-824 Type C, 20,000 feet primary circuit

Circuit Load: 70 Edge lights @ 120W (100W transformer)
16 Threshold/end lights @ 200W (200W transformer)

10 signs @ 100VA (at step 5)
5 signs @ 200VA (at step 5) } *(at the input to the isolation transformer*)
3 signs @ 300VA (at step 5)

1 REIL system (2 units) @ 400W, connected by power adapter. [Note that in this example the REIL is only adjusted for PF. Some REIL may require further adjustment, based on manufacturer's information.]

Cable losses (resistance) @25°C: 0.68Ω/1,000'
Fixture losses (obtain from Mfg - This example assumes 18 percent for 120W, and 11 percent for 200W lights)

CALCULATIONS:

1. CCR rated output voltage, V_{RMS} = 30KW/6.6A = 4,545V

2. Total connected load, KVA = $\frac{[W_{lamps} + W_{REIL} + VA_{signs}]/PF + Fixture\ Loss + Cable\ loss}{1,000}$

Fixture losses = (70 x 120 x 0.18) + (16 x 200 x 0.11) = 1,864W

Cable losses = $I^2R = [6.6]^2 \times (0.68 \times 20)$ = 592W

TOTAL KVA = $\frac{[(70x120) + (16x200) + (400) + (10x100 + 5x200 + 3x300)]/0.43 + 1,864 + 592}{1,000}$

= 17.57 KVA

where:

KVA = kilovolt-amperes
V = volts
A = amperes
KW = kilowatts
CCR = Constant Current Regulator
R = Resistance in Ohms, Ω
V_{RMS} = Rated output voltage of CCR
W_{lamps} = Wattage of light fixtures
W_{REIL} = Wattage of REIL
PF = Power Factor
I = Current, in amperes

Figure 13-4 Sample Calculation of CCR Test Data (Cont.)

(2 of 2)

SAMPLE CALCULATIONS, CCR TESTING (Cont.)

NOTE: Traditional method for determining the load KW assumes that the CCR powers a unity power factor lamp circuit. With REILs, new type signs, and runway guard lights (wig-wags), a unity power factor is not representative, and power factor must be considered.

MEASURED RESULTS (Case 1):

- Output current at Step 5 = 6.52A
- Output voltage at Step 5 = 2,880V

Total KVA Load based on measurements = 6.52A x 2.88kV = 18.8KVA

CONCLUSIONS: The output current is within FAA tolerance. The total KVA measured is slightly higher than the calculated load. This may be due to slightly higher actual fixture losses than assumed values. Overall, the CCR is operating satisfactorily.

MEASURED RESULTS (Case 2):

- Output current at Step 5 = 6.52A
- Output voltage at Step 5 = 1,880V

Total KVA Load based on measurements = 6.52A x 1.88kV = 12.3KVA

CONCLUSIONS: The output current is within FAA tolerance. The total KVA measured is significantly less than the calculated load. The results suggest a partial shorting of the load.

MEASURED RESULTS (Case 3):

- Output current at Step 5 = 6.30A
- Output voltage at Step 5 = 2,550V

From test results, Total KVA Load = 6.30A x 2.55kV = 16.1KVA

CONCLUSIONS: The output current is below that allowed by FAA tolerance. The total KVA measured is below the normal value (2,880V) as found in first test. Results indicate faulty CCR. Perform a short circuit test on the CCR before it is used.

NOTE: Analysis compares KVA with KW. This is because the rated output of the CCR is specified in KW in compliance with FAA AC 150/5345-10. However, load measurements result in KVA. The requirement for total load in KVA to be below the CCR output in KW under operational conditions ensures that the CCR is not overloaded.

Table 13-1 AGL Series Circuit Load Calculation Data Sheet

CKT No.	Regulator (CCR) (Runway or Taxiway, Etc.)	CKT Type (Amps)	Cable Size (AWG)	CCR Rating (KVA) (1)	CCR Input (V)	Steady Burning Light Load (KVA) (2)	Sign Load (KVA) (3)	Other Loads (KVA) (4)	Total Connected Load (KVA)	Transformer Losses (KVA) (5)	Cable Length FT or M)	Cable Losses (KVA) (6)	Calculated CCR Load (KVA)

NOTES:
(1) CCR rating may be in KW. To determine KVA, divide KW by power factor (PF) and CFR efficiency (EF) based on full load. Obtain PF and EF from manufacturer.
(2) To determine KVA for steady burning lights by summing "[no. of fixtures] x [lamp wattage] / 1000" for all lights on circuit. Steady burning lights can be runway edge lights, threshold/end lights, centerline lights, touchdown zone lights, taxiway edge and centerline lights, and approach lights.
(3) Determine KVA for signs based on manufacturer rating or specified limit VA for each size and length (modules or width) of sign on circuit.
(4) Other loads may be pulsing lights such as REIL. Determine KVA based on manufacturer data for each type.
(5) Isolation transformer losses may be estimated at 26% of connected load.
(6) Determine cable losses based on cable length and manufacturer cable data on conductor resistance. Loss per unit length is typically based on the relationship I^2R = W and assumed PF of unity for the cable.
Typical values for cable losses are: 34VA / 1,000ft (34VA / 300M) for 6.6A circuits with uncoated stranded #8 AWG conductor, and 196VA / 1,000ft (196VA / 300M) for 20A circuits with uncoated stranded #6 AWG conductor.

Refer to Paragraph 5-3.2.3, Color Coding.

13-8 TRANSFORMERS.

The isolation transformer provides: electrical isolation between the high voltage series circuit and the low voltage secondary feeding the lighting load (such as a fixture or sign), constant current output for a constant current input at the correct ratio, and an effective short circuit in the event of an open condition in the light fixture, for example with lamp filament failure.

13-8.1 Isolation Transformers.

With the isolation transformer, only low voltage is brought to the light fixture (via the secondary circuit), and failure of the light does not cause an open condition on the primary circuit that would result in other lights and other connected loads to be shut off.

Isolation transformers for AGL are covered by FAA Specification L-830 (for 60 Hz) and FAA Specification L-831 (for 50 Hz), and are typically 6.6 amperes on the secondary side, with either 6.6 amperes or 20 amperes on the primary side for series lighting circuits at the highest intensity step. The wattage of the isolation transformer is approximately matched to the connected load on the secondary side.

13-8.2 Transformer Load.

Ensure the load powered by the transformer is within ±10 percent of the transformer wattage rating to maintain isolation transformer efficiency. Light fixture manufacturers have their fixtures certified using a specified wattage for the isolation transformers. Use the light fixture manufacturer’s recommended size for isolation transformers.

\4\ 13-8.3 Series Circuit Selector Switches.

Use switches in accordance with FAA AC 150/5345-5, Type L-847. Series circuit selector switches can be high-maintenance equipment and should be avoided whenever possible.

13-8.4 Control Cables.

Control cables for 120 VAC control systems must be multi-conductor, 600 volts, 12 AWG copper, rated for direct earth burial. Cables for 48 VDC control circuits must be multi-conductor, stranded 19 AWG copper, with 300 volt polyvinyl insulation suitable for installation in wet locations and meeting REA Bulletin 345-14 or 345-67. Color-code all conductors.

13-8.5 Constant Current Regulators (CCR).

Use CCRs per FAA AC 150/5345-10 of a suitable type and style. The size selected should normally provide for approximately 20 percent expansion of the load.

13-8.6 Engine/Generators.

Use engine/generators meeting Specification FAA-E-2204 with Type I automatic power transfer. Also see AFMAN 32-1062 and UFC 3-540-01.

13-8.7 Series Cable Selection.

Cables must be unshielded, 5000 volt FAA AC 150/5345-7 (Latest Issue) L-824 cable.

13-8.8 Connectors.

Use connectors meeting FAA AC 150/5345-26 for L-823 plug and receptacle cable connectors to interconnect fixtures, isolation transformers, and distribution cables.

13-8.9 Isolation Transformers.

Use isolation transformers meeting FAA AC 150/5345-47. When specifying, ensure the input/output currents are compatible with the regulator and current rating of the lamp.

13-8.10 Mounting Bases and Transformer Housings.

Use bases meeting FAA AC 150/5345-42. When specifying FAA type bases, use Type L-867 for non-traffic areas (such as elevated light systems located on the edges of runways and taxiways) and Type L-868 for load bearing applications (subject to loading by aircraft, including overruns) containing lights that are in-pavement. Non-metallic bases (FAA Class II) must not be used.

13-8.11 Frangible Supports.

If frangible mounting is required and the device is not provided with an integral fracture mechanism, mount the device on electric metallic tubing (EMT) or intermediate metallic conduit attached to the mounting base by a frangible coupling meeting FAA Drawing C-6046. For additional detailed information about and requirements for frangible supports, see FAA AC 150/5220-23.

13-8.12 Fixtures, Filters, and Lamps.

Use fixtures and lamps as specified for each system. If more than one fixture is connected to an isolation transformer, the fixture must have a shorting device or bypass relay to avoid multiple light outage if a lamp fails. Filter colors must meet the latest FAA Advisory Circular criteria, also refer to the CIE color coordinate diagram. (See Figure 13-1.)***/4/***

13-9 LAMPS.

The connected load typically includes light fixtures, lighted guidance signs, and in some cases other lighted visual aids such as REIL, PAPI, or lighted wind cones.

(a) Runway and taxiway lights may have newer quartz-type lamps or incandescent-type lamps. Quartz-type lamps provide improved photometrics at lower wattage for higher intensity systems, hence lower energy consumption. Quartz lamp life can be significantly reduced if the lamp is installed with bare hands. Fingerprint (oil) deposit on the quartz lamp will cause premature failure.

(b) Light fixtures basically provide a resistive type load on a series circuit. Some items, such as flashing REIL, or signs using electronics to provide light output within a certain range at all circuit intensity steps, introduce other reactive type loads into a circuit, which may distort the waveform and have an adverse effect on performance and control. Incandescent lamps have an initial cost lower than quartz lamps.

(c) Current levels have been established such that, for 5-step system, the light output (brightness) is 100 percent, 20 percent, 4 percent, 0.8 percent, and 0.16 percent. A system with 3-step control provides light output at 100 percent, 30 percent and 10 percent at the respective brightness steps.

(d) FAA-specified types of connected loads that may be used for AGL systems are:

<u>Elevated Light Fixtures</u>

L-860	RW edge, low intensity
L-860E	RW threshold/end, low intensity
L-861	RW edge, medium intensity
L-861SE	RW threshold/end, medium intensity.
L-861E	RW threshold/end, medium intensity (may be used instead of SE for RWs with either REIL, PAPI or medium approach lighting (MALS).
L-862	RW edge, high intensity
L-862E	RW threshold/end, high intensity
L-861T	TW edge
L-804	Runway guard light.
L-862S	Runway stop bar light

<u>In-pavement Light Fixtures</u>

L-850A	RW centerline, high intensity
L-850B	RW touchdown zone, high intensity
L-850C	RW edge, high intensity
L-850D	RW threshold/end, high intensity
L-852A	TW centerline, for straight portion (narrow beam) (non-Category III). Also used for caution bar.
L-852B	TW centerline, for curved portion (wide beam) (non-Category III).
L-852C	TW centerline, for straight sections (narrow beam) (Category III)

L-852D	TW centerline, for curved portion (narrow beam) (Category III)
L-852E	TW intersection (non-Category III)
L-852F	TW intersection (Category III)
L-852G	Runway guard light
L-852S	Runway stop bar light
L-852T	Taxiway/Apron edge

<u>Light Bases for Lights or as Junction Boxes.</u>

L-867	Non-load bearing (used in shoulder areas or other non-traffic areas).	
L-868	Load bearing (used in RW and TW pavements and other aircraft load areas).	
Sizes	A - 10" (25 cm) dia. (L-868 only)	C - 15" (38 cm) dia. (L-868 only)
	B - 12" (30 cm) dia. (L-867 & L-868)	D - 16" (40 cm) dia. (L-867 only)
L-869	In-pavement junction box (used with cables in saw kerfs, 6" (15 cm) dia.)	

<u>Airfield Signs</u>

L-858Y	Direction, Destination and Boundary. Black legend on yellow background.
L-858R	Mandatory Instruction. White legend on red background.
L-858L	TW and RW Location. Yellow legend and border on black background.
L-858B	Runway Distance Remaining. White legend on black background.

<u>Other Examples</u>

L-849	REIL
L-880	PAPI system with 4 light units
L-881	PAPI system with 2 light units

Some of the above have variations specific for certain military applications.

13-9.1 Medium Intensity Approach Light System with Runway Alignment Indicator Lights (MALSR).

See paragraph 3-5.10

13-9.1.1 Centerline Light Barrettes.

Use fixtures meeting FAA-E-2325, PAR-38 lamp holders. (See Figure 13-4.)

TYPE 150PAR/SP.

POWER UNIT: (NOT SHOWN) DISTRIBUTION VOLTAGE TO 120V RATED, 3-INTENSITY SETTINGS AS REQUIRED BY MANUFACTURER (ONE UNIT FOR SYSTEM)

LAMPHOLDER

13-9.1.2 General Lamp Guidelines.

Use lamps recommended by the manufacturer to meet the requirement. Different manufacturers may meet the requirement using different lamps. In the interest of energy conservation, the lower wattage lamps are preferred. When using lamps rated at 6.6 amps, they must be connected to individual 6.6/20A isolation transformers. When using lamps rated at 20A, they must be connected to individual 20A/20A isolation transformers. Use 200W isolation transformers, or as otherwise recommended by the lamp manufacturer. If the overall mounting height is greater than 6 feet (2 meters), the lights in a light bar must be connected in series to the transformer specified in paragraph 13-9.5.1. Fixtures connected in series to a single isolating transformer must have bypass relays to bypass failed lamps.

13-9.1.3 1,000-foot Light Bar.

See paragraph 13-9.5.1.

13-10 PARALLEL CIRCUITS.

Parallel (or multiple) circuits have circuit elements connected across the conductors to which input voltage is applied. In theory, the same voltage is applied to each light, although voltage drop occurs along the conductor, which can be significant for longer circuits. The reduced voltage can reduce the intensity of lights at the far end of a circuit. If intensity control is required for this type lighting circuit, tapped transformers of inductive-voltage regulators are used, which increases the cost and reduces efficiency of the circuit.

13-10.1 Advantages of Parallel Lighting Circuits.

- Lower cost installation, particularly if voltage regulation and intensity control are not required.
- More efficient utilization of electrical power.
- Easy to add to or reduce an existing circuit.
- Circuits are more familiar to most people.
- Cable faults such as open-circuits are easier to locate.
- An open-circuit may not disable entire circuit.

13-10.2 Disadvantages of Parallel Lighting Circuits.

- Intensity of lights decreases with line voltage drop along the circuit. This could be misinterpreted if noticeable in a pattern of many lights.
- Two conductors are required along the complete circuit, and larger conductors may be needed to reduce voltage drop.
- Lamp filaments are usually longer which may require larger optics and larger light fixtures.
- Intensity control, particularly at the lower intensity, is more difficult to achieve without added equipment cost.
- A single ground fault on the high voltage feeder will disable the circuits.
- Ground faults are difficult to locate.

13-10.3 Common Uses.

Parallel circuits are used for most area illumination, individual or small numbers of visual aids, and power distribution. AGL systems typically using parallel circuits are apron floodlighting, other apron lights, sequence-flashing lights, special purpose visual aids such as beacons and wind direction indicators, some obstacle lights, and electrical distribution circuits.

13-11 CURRENT AND VOLTAGE ON SERIES CIRCUITS.

The output current for AGL constant current series circuits have become standardized at either 6.6 amperes or 20 amperes (at highest intensity). The loaded output voltage from the CCR is limited to 5,000 volts because the cable used for the primary lighting circuit is rated for 5kV.

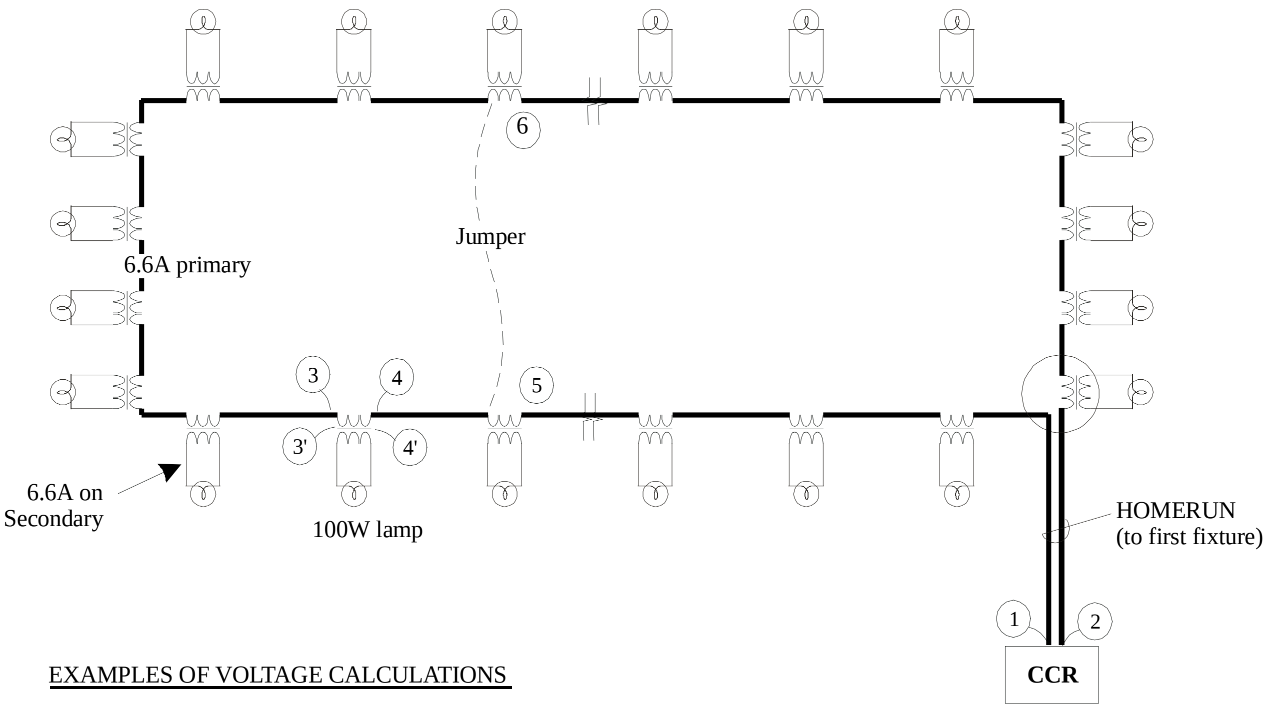
13-11.1 The voltage will vary depending on the load. Figure 13-4 illustrates the constant current and varying voltage through several examples. As seen from Figure 13-4, the voltage measured across the outputs of the CCR (at highest intensity step) is simply the total watts divided by 6.6 A (assuming power factor of 1.0), or 3,030V for 200 each 100W lamps (such as light fixtures or signs). With 200W lamps, the voltage is calculated at 6,060V, which exceeds the 5kV cable rating of the primary circuit. However, if a 20A circuit is used, the voltage calculates to be only 2,000V at the CCR. Similarly, if 45W lamps are used in the above example, the voltage across the CCR output terminals is calculated at 1,364V.

13-11.2 The examples above show that the voltage on the primary circuit is additive and will vary with the load, but the current will remain the same. The secondary circuit is always 6.6A (highest intensity step), with a 6.6A/6.6A isolation transformer used with 6.6A primary circuits, and 20A/20A or 20A/6.6A isolation transformers used with 20A primary circuits.

13-11.3 Figure 13-5 shows that measuring the voltage across the secondary circuit for a 100W light fixture will yield 15.15V. Similarly, the voltage will be 30.3V with a 200W light, and only 6.8V with a 45W light. This illustrates the much lower voltage that is present on the secondary side of a lighting circuit. From the examples it can be seen that:

- The current is constant regardless of load (within limits), while the voltage is will vary with load.
- The low voltage on the secondary side is isolated from the high voltage primary side by the isolation transformer.

Figure 13-7 Current and Voltage Illustration



EXAMPLES OF VOLTAGE CALCULATIONS

ASSUMPTIONS 200 lights on 6.6A primary series circuit
Each light 100W (fixture or sign, etc)
Power factor of 1.0 for all components.

1. Measured across homeruns at CCR, (1) & (2) voltage = $\frac{200\text{ea} \times 100\text{W}}{6.6\text{A}}$ = 3,030V

   If only 100 lights, then voltage is 1,515V

2. Measured across isolation transformer primary (3) & (4) or secondary (3') & (4')

   Voltage = $\frac{100\text{W}}{6.6\text{A}}$ = 15.15V

   With 200W light, voltage on secondary = $\frac{200\text{W}}{6.6\text{A}}$ = 30.3V

   With 200W lamps, voltage at CCR = $\frac{200\text{ea} \times 200\text{W}}{6.6\text{A}}$ = 6,060V

3. With 200W lamps and a 20A primary, voltage at CCR = $\frac{200\text{ea} \times 200\text{W}}{20\text{A}}$ = 2,000V

4. If jumper across at light fixtures (5) & (6), the voltage at CCR is based on load remaining on circuit.

5. If 85 each 200W lights remain on 6.6A circuit: Voltage = $\frac{85\text{ea} \times 200\text{W}}{6.6\text{A}}$ = 2,576V

Note that: (1) Current is constant regardless of load, while voltage varies and is additive, depending on load.

(2) The low voltage secondary side is isolated from the high voltage primary side by the isolation transformer.

13-11.4 When more than one light is connected to a secondary circuit, they are connected in series. An isolation transformer is designed to provide a proper variable operating voltage on its secondary. This forces a constant load current to flow so that each light in the secondary will receive the same current regardless of the wattage of the lamp or the quantity of lamps (within the design limits of the transformer). This approach may be seen on light bars for approach lighting systems, on runway centerline lights configured as smaller segments with several lights on a single transformer, and other applications.

13-11.5 It is important to recognize that the isolation transformer, which is similar to a current transformer, operates differently than the standard voltage transformer. The current will remain constant even when the secondary side is shorted. The output terminals of the CCR are not grounded, hence the airfield lighting series circuit is an ungrounded system. The result is that one short-to-ground in the primary circuit will not shut down the system. When the secondary side is open (for example a burned out lamp), the instantaneous voltage present at the lamp socket can be very high, presenting a potential hazard for maintenance personnel. This can be the condition when changing lamps and a short occurs between the socket terminals and the body of the light fixture. Maintenance personnel are prohibited from working on energized circuits.

13-12 CONSIDERATIONS FOR CIRCUIT DESIGN.

Two major considerations in designing an airfield lighting series circuit are: maximum allowable voltage on the primary series cable (discussed in paragraph 15-12 in the selection of 6.6A or 20A circuit); and the insulation resistance of the entire primary circuit.

(a) FAA has established a minimum insulation resistance of 50 megohms for new installations. Experience from many projects has shown that this value is achievable in most installation configurations. However, insulation resistance depends on the length of the primary series cable, the number of splices on the circuit, soil conditions, and primarily the number of isolation transformers of the circuit. Consider all these factors in configuring a lighting circuit.

(b) From the standpoint of economy, life expectancy and reliability, it may be practical to use 50 megohms as the minimum insulation resistance. The selected value depends on the specific configuration of the particular system being designed. It is recommended the following criteria be applied in optimizing design of new airfield lighting circuits:

- Limit the voltage to 2.4 kV, at least for 90 percent of the operational time (assume this to be step 2 for 3-step CCR, step 3 for 5-step CCR).
- Limit the number of isolation transformers on any one primary circuit to not more than 130.

- Limit the number of splices on any one primary circuit (not including those connecting isolation transformers) to not more than 8.

\4\ 13-12.1 Runway Threshold Lighting.

See paragraph 4-4.

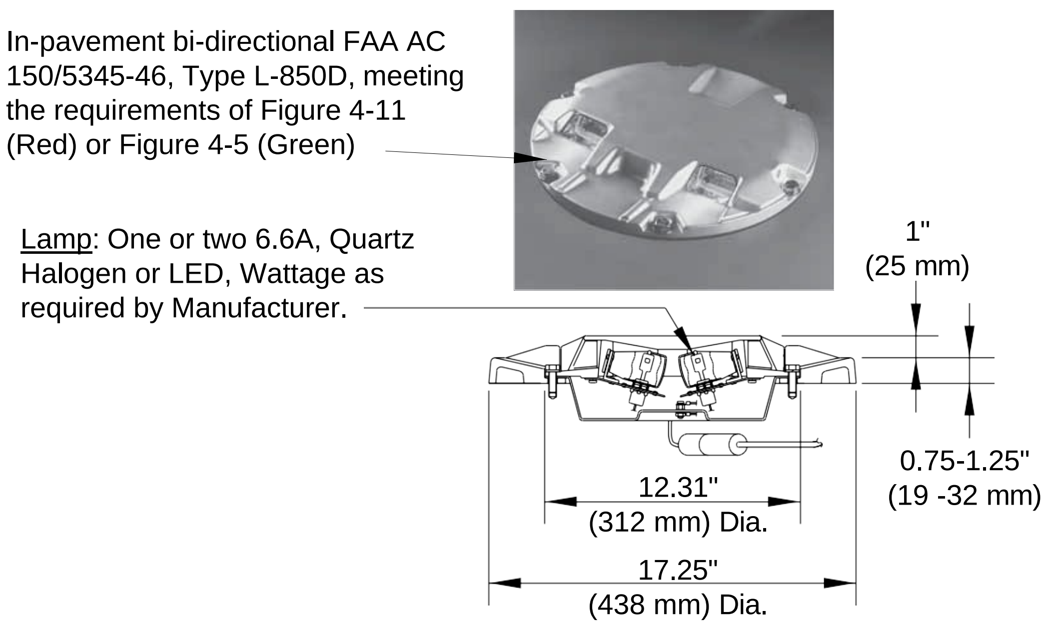
13-12.1.1 In-pavement Fixtures, Unidirectional, Green or Red.

Use light fixtures meeting FAA AC 150/5345-46, Type L-850E and photometric requirements in Figure 4-6 (for green light) or Figure 4-11 (for red light). (See Figure 13-13.) FAA Type L-850D (Figure 13-13) does not meet the threshold light photometric requirements so are not acceptable. For displaced thresholds and thresholds adjacent to strengthened pavements, in-pavement fixtures must be used for in-board threshold lights.**/4/**

13-12.2 High Intensity Elevated Light Fixtures.

Use Par 56 fixtures meeting FAA –E-982. For Army installations only, fixtures meeting FAA AC 150/5345-46 Type L-862E may be used.

Figure 13-8 FAA-L-850D, In-pavement, Bi-directional



(Dimensions are for reference only)

13-13 CIRCUIT CONFIGURATION.

There are three circuit configurations that are normally used to power runway and taxiway systems:

13-13.1 Single Circuit per Lighting System.

This is the standard FAA configuration, with a single circuit for each of the different lighting systems (for example, one circuit for the runway edge lights, one for the touchdown zone lights, or one for the runway centerline lights). It is the most economical configuration. In some cases, however, this approach may create very high voltages on the primary series circuit, which can reduce the life and reliability of the system and increase the potential hazards for maintenance personnel. In addition, in the event of a fault in the circuit, the entire circuit is out of service. Also, the trouble-shooting of line faults can be a lengthy, time consuming process because of the length of the circuit.

13-13.2 Multiple Circuits per Lighting System - Split Circuits.

Advantages include easier troubleshooting and reduction in circuit voltages. A disadvantage with this configuration is the higher cost compared with a single circuit, particularly if the available space in the vault or the duct system is limited. Consider the possible consequences of a partial system failure. For example, where two circuits power a runway edge lighting system, the failure of one circuit leaves the other circuit to light only half the runway, indicating a much shorter available runway to the pilot. It may be necessary to install an interlock between the regulators so that both circuits will shut down if either circuit fails.

13-13.3 Multiple Circuits per Lighting System - Interleaved Circuits.

This is the type of circuit configuration specified by ICAO. Although this is the most expensive configuration, requiring more cable, it has the advantage of preserving the full pattern of the airfield lighting system for the pilots in the event of one circuit failure, hence provides a measure of additional operational safety. Further, it has the advantages noted for the split circuit configuration. Because of operational disadvantages, this is not recommended for Air Force airfields.

13-14 PARALLEL CIRCUITS.

Parallel (or multiple) circuits have circuit elements connected across the conductors to which input voltage is applied. In theory, the same voltage is applied to each light, although voltage drop occurs along the conductor, which can be significant for longer circuits. The reduced voltage can reduce the intensity of lights at the far end of a circuit. If intensity control is required for this type lighting circuit, tapped transformers of inductive-voltage regulators are used, which increases the cost and reduces efficiency of the circuit.

13-15 PHOTOMETRIC CHARACTERISTICS OF LIGHT FIXTURES.

13-15.1 Airfield Lighting.

Airfield lighting provides visible light to pilots for guidance during landing and taxiing operations. The guidance provided is a function of configuration of the lights, light color, and strength and "shape" of the light output (photometric performance). The strength is the brightness or intensity of the light output, measured in candelas. The required shape of the light "beam" from a light fixture is typically represented by an ellipse (an "isocandela curve" of same values), although for some fixtures the requirements may be rectangular or simply numerical. Examples are shown in Figure 13-6 (high intensity white or "clear" runway edge light) and Figure 4-6 (high intensity green threshold light), which illustrate the photometric requirements at highest intensity step for the type of light.

Figure 13-9 Runway Edge Light Photometric Requirements

	I=50%	II=10%
a	5.5°	7.5°
b	3.5°	6.0°

	I=50%	II=10%
a	6.5°	8.5°
b	3.5°	6.0°

NOTES:

1. ALL CONTOURS ARE ELLIPSES CALCULATED BY EQUATION: $(X/a)^2 + (Y/b)^2 = 1$
2. THE MINIMUM AVERAGE INTENSITY OF THE MAIN BEAM (INSIDE CONTOUR I) IS 10,000 CD WHITE OR 5,000 CD YELLOW. MAXIMUM INTENSITY SHOULD NOT EXCEED 1.5 TIMES ACTUAL AVERAGE INTENSITY.
3. CONTOURS I AND II INDICATE THE MINIMUM PERCENT VALUES OF THE MAIN BEAM INTENSITY.

13-15.2 Wattage.

The wattage of lamp(s) and other light fixture characteristics are determined by each manufacturer to meet the photometric requirements for a particular type of light, which are tested and certified for compliance with the requirements. A light fixture design is based on achieving the required photometric output at full rated lamp wattages, in fixtures connected on a 6.6 amperes series lighting circuit. The lower current steps of series lighting circuits are based on achieving lower levels of light output.

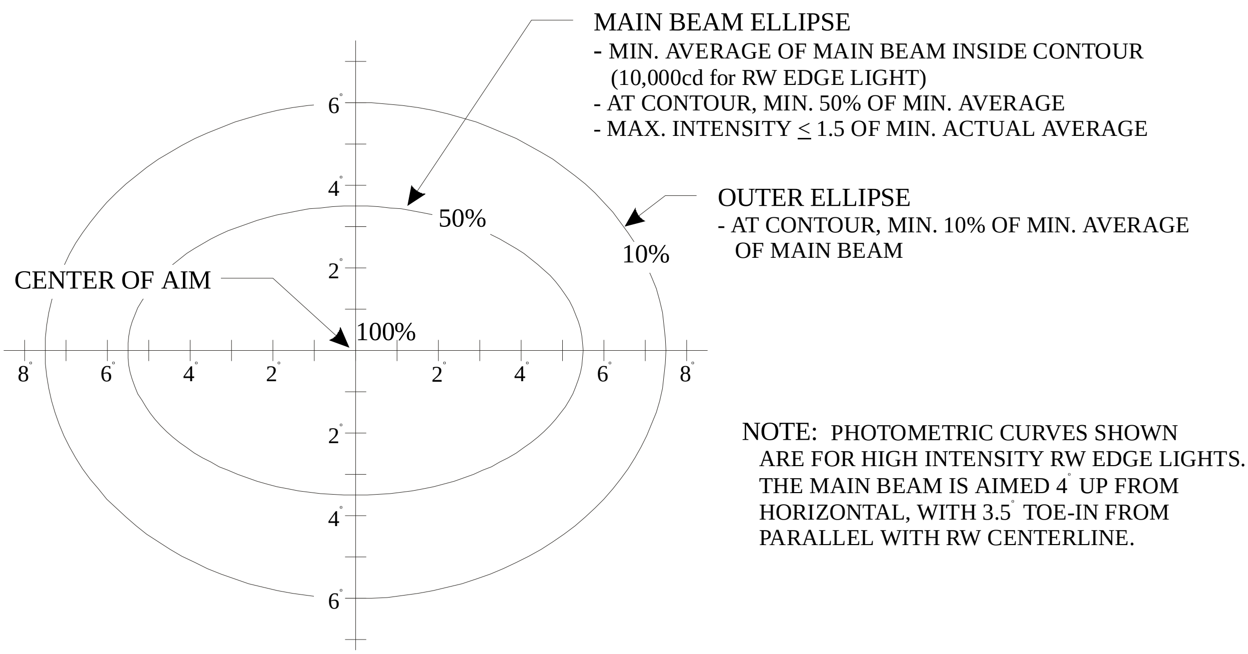
13-15.3 Isocandela Curves

Figure 15-7 shows a typical photometric requirements or “isocandela curves” for a runway edge light. The ellipses are defined by degree of angle from the center along vertical and horizontal axes. The requirements for the inner ellipse, or “main beam,” are:

- Minimum average intensity (10,000 cd, aviation white in the example).
- Minimum intensity no less than 50 percent of the minimum average intensity (5,000 cd in this case).
- Maximum intensity should not exceed 1.5 times the actual average intensity.

For the outer ellipse, the minimum intensity should not be less than 10 percent of the minimum average intensity (1,000 cd in the example).

Figure 13-10 Photometric Isocandela Curves



13-15.4 Main Beam Ellipse.

For the example shown by Figure 13-7 (high intensity runway edge light for runways less than 200 feet (60 meters) wide), the inner or main beam ellipse is defined by ±5.5 degrees on the horizontal axis and ±3.5 degrees and –3.5 degrees on the vertical axis, while the outer ellipse is defined by ±7.5degrees on the horizontal axis and ±6degrees on the vertical axis. Note that in Figure 13-6, the runway edge lights have a wider beam ellipse for runways 200 feet (60 meters) or more wide, providing broader light coverage. The runway edge lights are "toed-in" 3.5 degrees and aimed up 4 degrees above the horizontal. Threshold lights are parallel with the runway centerline and aimed up 4.5 degrees. Other lights may also have a toe-in or aimed vertically upward; however, this is identified separately and not indicated on the photometric curves.

13-15.5 Photometric Testing of New Airfield Lighting Systems.

Photometric testing:

New airfields or construction: Photometric testing can now be as simple as having a company, with proper photometric equipment mounted on a vehicle, drive the airfield with lights energized, for the purpose of presenting a data driven report of recorded photometrics. This should be part the acceptance testing for new projects and may include the evaluation of a variety of factors in the lighting system being tested, depending upon the equipment used.

For existing airfields: Photometric testing may be a routine test at intervals determined by the Airfield Manager. As airport runway access time is limited, photometric measurement runs need to be completed as quickly as possible and can be conducted at speeds up to 60 km/hr without affecting accuracy. The test report generated provides the candela value of each light and identifies any defect requiring action to be taken.

While field testing the photometrics of installed lights has not been practical in the past, the same technology described above enables the testing of an existing system. in a relatively short period of time.. In addition to verifying the photometric performance of installed light fixtures, testing can also help identify the following:

- Possible leakage on the secondary side of the isolation transformer.
- Improper alignment of fixtures.
- Loose sockets and brackets.
- If improper lamps have been installed.
- Possible damage to lenses from sandblasting or other source of abrasion.
- Improper current output from the constant current regulator.

- These types of deficiencies may cause significant reductions in the photometric output of a fixture, as well as the quality of the overall system performance. The cost of photometric testing is relatively inexpensive compared with the cost of a new airfield lighting system, while providing assurances for operational safety. The testing can usually be performed with minimal disruption to airfield operations, and is typically performed at night during periods of low or no aircraft traffic.

- **\4** Fixtures that may have become unlevel due to elevation/drainage changes. Lack of aiming can appear as inadequate photometrics. **/4/**

13-15.6 Photometric Testing of Existing Lighting Systems.

Photometric testing can provide benefits similar to acceptance testing of new lighting systems. Typically, photometric performance deteriorates over time, and periodic testing will provide an up-to-date evaluation of performance. When photometric output is validated at between 50 percent and 70 percent of the minimum specified output, document and investigate for the possible cause and for possible corrective action. Two options are replacement of small sections or repair-by-replacement of the system(s) in question. Test results enable the airfield to repair/replace fixtures on a “need” basis rather than scheduled basis, with possible cost savings plus the assurance that the lighting system is providing the proper light output.**/1/**

\4 If deteriorated cable insulation is suspected, megger the cable to verify. Cable insulation should be 1 M-ohm if new. If system is below 100 k-ohms, locate the failing section. Note that a single 200-foot section of runway cable may not always correct the issue, but may move the issue down the circuit (direction away from the vault). A new piece of cable with proper resistance can cause the next section of cable to fail – evidenced by smoke coming out of the ground. If below 100 k-ohms, replaclement cable should be planned and budgeted for. **/4/**

This Page Intentionally Left Blank

\4\ CHAPTER 14 LANDING ZONE REQUIREMENTS

14.1 LANDING ZONE LIGHTING.

Airfield lighting systems are used during nighttime operations to provide visual cues to pilots about the location and dimensions of the LZ runway. The type of lighting system installed may vary between the minimum requirements for temporary applications and the long-term-use system. Equipment selection will depend on the available equipment and mission requirements. Lights are not required if night operations are not anticipated. Lighting that is planned to be permanent should be compatible with NVD.

14.1.1 Minimum Lighting Requirements for Temporary Applications.

14.1.1.1 Lights.

If available, lights should be omni-directional, steady-burn or flashing, with a minimum output rating of 15 candela for night operations. In accordance with AFI 13-217, virtually any type of overt lighting system is acceptable if all participating units are briefed and concur with its use. Contingency lighting kits **(**Expeditionary Airfield Lighting System (EALS-C)**)** or other materials may be used, as available and determined to be suitable by the STT.

14.1.1.2 Location.

There are three types of airfield lighting patterns for LZs, designated AMP-1, AMP-2, and AMP-3, as defined in AFI 13-217. AMP-4 is lights-out, no markings, and used only for appropriate special operations. The STT will decide which arrangement of lights will be installed. The AMP-1, AMP-2, and AMP-3 layouts are illustrated in Figures 14-1, 14-2, and 14-3. Although AMP-2 is also defined in AFI 13-217, the AMP-2 configuration will not be used for newly constructed, temporary or permanent LZs by AMC. When constructing new LZs, even if the immediate operational need is for AMP-3, consideration should still be given to installing the light bases and conduits to support the AMP-1 configuration.

14-1.2 Lighting Requirements for Permanent Applications.

When intended for long term use, use permanently installed lights of the type and in the locations described below.

14.1.2.1 Light Fixtures.

All light fixtures must be certified and listed in FAA AC 150/5345-53, Airport Lighting Equipment Certification Program, and FAA AC 150/5345-46, *Specification for Runway and Taxiway Light Fixtures***.** Per paragraph 11.7, listed fixtures must be used with infrared (IR) filters as covert fixtures.

14.1.2.1.1 Runway high-intensity edge light fixtures should be used for permanent LZ lighting installations. Runway edge lights should be elevated FAA Type L-862. Use the L-850C when an insert light is required in place of the L-862. If all edge lights are in-pavement edge lights, use the FAA Type L-850A, Style 3 (Runway, Uni-directional) towards the approach. (Where circling guidance is needed, bi-directional light fixtures may be used.). LZ light lens colors shall be as indicated in Figures 14-1, 14-2, and 14-3. Five-step regulators should be installed. (Steps 1 through 3 are compatible with NVG operations using a five-step regulator.)

14.1.2.1.2 Taxiway medium-intensity edge light fixtures should be used for permanent lighting installations. Taxiway edge lights should be elevated FAA Type L-861T. If needed, in-pavement edge lights should be FAA Type L-852T, Style 3 (Taxiway, Omni-directional). Taxiway and turnaround edge light lenses shall be blue. Three-step regulators should be installed for intensity control.

14.1.2.1.3 Flashing Strobe Lights (FSL) (Sequenced Flashers - SFL) are located at the end of the LZ in the AMP-3 and AMP-2 configurations and at each side of the approach threshold in the AMP-1 configuration. These lights are unidirectional and must flash at a rate of 28 to 34 flashes per minute, producing a white light. In-pavement fixtures (FAA-E-2952, Style A, white) should be installed with the edge of the fixture extending no more than 1.5 millimeters (0.0625 inch) below and 0.0 millimeter (0.0 inch) above the pavement top. Aim the fixture(s) down the runway parallel to the centerline for AMP-2 and AMP-3 and towards the approach for AMP-1.

14.2 LIGHT BASES.

Light fixtures must be attached to full-depth light bases (L-868, Class IB). Light bases must be offset so the fixture center is a minimum of 0.6 meter (2 feet) from any pavement joint. Light bases shall be installed in accordance with UFC 3-535-02, Figures 11A, 11B, 12, 13, and 14. For elevated light fixtures, provide steel adaptor rings (see Jaquith Industries part numbers AF5402 and AR5421; Olson Industries part numbers 128TS and 128S; or equivalent).

Light construction tolerances are:

- Longitudinal ± 13 millimeters (0.5 inch) from stationing
- Transverse ± 13 millimeters (0.5 inch) transverse from centerline
- Base orientation Parallel to T/W centerline ± 0.5 degree
- Elevation +0 to -1.5 millimeters (+0 to –0.0625 inch) from finished pavement surface, flush with the surrounding grade or pavement.

14.3 LIGHT LOCATIONS.

14.3.1 LZ Lights.

If the LZ is built on an existing runway or taxiway where normal flight operations are conducted, then use in-pavement light fixtures.

14.3.1.1 AMP-1.

Place lights at each threshold and at 152 meters (500 feet) from each threshold. Intermediate lights shall be 152 meters minimum/305 meters maximum (500 feet minimum/1000 feet maximum) spacing throughout the length of the runway, as illustrated in Figures 14-1 and 14-4. Spacing should be consistent through the intermediate lights. If a conflict with the lights exists on one or both sides of the LZ (e.g., at locations where a taxiway connects to the LZ), that light should be an in-pavement light. Install synchronized FSLs at the threshold as illustrated in Figures 14-1 and 14-4. Install steady-burning light fixtures at 1.6 meters (5 feet) plus 0.6 meter (2 feet) to minus 0.0 meter (0.0 foot) from the edge of the LZ surface (i.e., within the shoulder pavement). Position light pairs perpendicular and equidistant from the runway centerline to be symmetrical about the runway or LZ centerline.

14.3.1.2 AMP-2.

Place lights at each threshold and at 152 meters (500 feet) from each threshold. Intermediate lights shall be 152 meters minimum/305 meters maximum (500 feet minimum/1000 feet maximum) spacing throughout the length of the runway, as illustrated in Figure 14-2. Spacing should be consistent through the intermediate lights. If a conflict with the lights exists on one or both sides of the LZ (e.g., at locations where a taxiway connects to the LZ), that light should be an in-pavement light. An FSL is also installed on the centerline of the departure end threshold not more than 1.6 meters (5 feet) from the threshold or overrun end. Locate the FSL as close to the runway centerline as possible. Install steady-burning light fixtures 1.6 meters (5 feet) plus 0.6 meter (2 feet) to minus 0.0 meter (0.0 foot) from the edge of the LZ surface (i.e., within the shoulder pavement). For covert applications see paragraph 14.7.

14.3.1.3 AMP-3.

Light locations and colors are derived from the AMP-3 configuration in AFI 13-217, Figure 3.6. Place steady-burning lights at the threshold and at 152 meters (500 feet) from the approach end threshold, forming a box, as shown in Figures 14-1, 14-5, and 14-6. An FSL is also installed on the centerline of the departure end threshold not more than 1.6 meters (5 feet) from the threshold or overrun end. Locate the FSL as close to the runway centerline as possible. Install steady-burning light fixtures at 1.6 meters (5 feet) plus 0.6 meter (2 feet) to minus 0.0 meter (0.0 foot) from the edge of the LZ surface (i.e., within the shoulder pavement). For covert applications see paragraph 11.7.

14.3.2 Turnaround, Taxiway, and Apron Edge Lights.

Install all lights at 1.6 meters (5 feet) plus 0.6 meter (2 feet) or minus 0.0 meter (0.0 foot) from the edge of the load-bearing surface. On straight sections of taxiway or turnaround, space lights evenly with a maximum of 152 meters (500 feet) between lights. See Figures 14-7 and 14-8, for typical turnaround and taxiway edge light locations. Reduce light spacing to between 3 meters and 10.6 meters (10 feet and 35 feet) on curves and at corners or intersections. On curved sections, space lights evenly from point of tangency (PT) to PT, with the maximum spacing between lights equal to half the taxiway width. For all corners and all curves exceeding 30 degrees of arc, there must be a minimum of three lights. See Chapter 5 for additional edge light location details.

14.3.3 Overrun Edge Lights.

Overruns do not normally require edge lights; however, for overruns used as taxiways or turnarounds, edge lights may be installed using the location criteria stated in paragraph 11.3.2. In addition, the first pair of edge lights installed on overruns should not be more than 30.5 meters (100 feet) from the runway threshold.

14.4 LIGHT CIRCUITS AND CONTROLS.

Designers should investigate all required configurations of lighting (AMP-1, AMP-3, Infrared AMP-3, etc.) and develop a circuit and control system that can achieve all the required configurations and operations.

14.4.1 Ferro-Resonant Regulators.

All new regulators used for LZ lighting systems shall be ferro-resonant type (See FAA AC 150/5345-10, Specification for Constant Current Regulators and Regulator Monitors**).**

14.4.2 Multi-Regulator Systems.

In this configuration, separate regulators will be needed to control lights for AMP-1, AMP-3 Overt, AMP-3 Covert, and taxiway circuits.

14.4.3 Single-Regulator Systems with Addressable Lights.

Systems are now available to have “assignable control” of individual lights via a carrier signal. For this type of configuration, all LZ runway lights could be powered by one regulator, with each configuration assigned to a different control setup.

14.5 LIGHT REFLECTOR PANELS (OPTIONAL).

Light reflectors may be installed at the midpoint between LZ runway edge lights or taxiway edge lights. Contact the STT for information on obtaining light reflector panels.

14.6 OVERT AMP-3 LZ LIGHTS SUPERIMPOSED ON STANDARD OPERATIONAL RUNWAYS.

In some cases, it may be desirable to use a standard full-length runway for LZ training operations. Only the AMP-3 configuration should be installed in this situation. For this purpose, the LZ lighting scheme illustrated in Figures 14-5 and 14-6, shall be applied, subject to the following conditions. MAJCOM approval is required before installation of AMP-2 configuration.

14.6.1 LZ Light Fixtures.

High-intensity light fixtures must be installed flush with the pavement surface to allow traffic to pass over them. In-pavement lights shall be FAA Type L-850A, Style 3, uni-directional, or an International Civil Aviation Organization (ICAO) equivalent. LZ light lens colors shall be white. Five-step regulators should be installed on the LZ circuit(s) for light intensity control compatible with NVG operations (steps 1 through 3 are compatible with NVG operations).

14.6.2 LZ Location on the Runway.

When possible, the LZ threshold should be sited between 91 meters (300 feet) and 152 meters (500 feet) from the runway threshold. This will ensure aircraft loads are concentrated in the portion of the runway designed for heavier loads and avoid conflicts with runway pavement markings.

14.6.3 LZ Lighting Conflicts with Standard Runway Markings.

The LZ should be sited so the LZ light fixtures do not conflict with threshold markings, runway designation markings, touchdown zone markings, or fixed distance markings. An ideal location for the LZ threshold is 91 meters (300 feet) from the runway threshold. This will position the LZ light fixtures in the gaps between the standard runway markings. If LZ lights fall within a standard marking, the light fixture should be masked whenever repainting occurs and removed when repainting is accomplished.

14.6.4 LZ Lighting Conflicts with Approach Lights and Touchdown Zone (TDZ) Lights.

Runway approach lights and TDZ lights are spaced every 30 meters (100 feet) throughout the overrun and for the first 914 meters (3000 feet) of the runway. TDZ lights are installed in groups of three, starting 11 meters (36 feet) each side of the runway centerline and spaced over a 3-meter (10-foot) light bar. LZ lights for C-17s will not conflict with TDZ lights because LZ lights are 15 meters (50 feet) each side of the centerline. C-130 LZ lights are installed 10.5 meters (35 feet) each side of the centerline, so conflicts should not occur. If TDZ lights are installed on the runway, move the LZ lights closer to the LZ edge to position them inside the TDZ lights.

14.7 AMP-3 COVERT INFRARED (IR) LIGHTS.

14.7.1 Installation.

At some locations, IR lights may be needed in addition to standard visual spectrum lights. IR lights can be installed in accordance with Figures 14-4, 14-5, 14-6 and 14-8.

14.7.2 IR Light Fixtures.

These fixtures should be FAA L-850A Style 3 fixtures, with a special IR filter installed on the lens. Infrared transmitting filters must meet the specifications in Table 14-1 and be certified to comply with the specifications in this paragraph by an FAA-approved laboratory (currently Intertek Test Lab). Before installation on-site, the manufacturer must supply an FAA-approved lab (currently Intertek Test Lab) report certifying compliance.

Figure 14-1 AMP-1 Lighting Plan

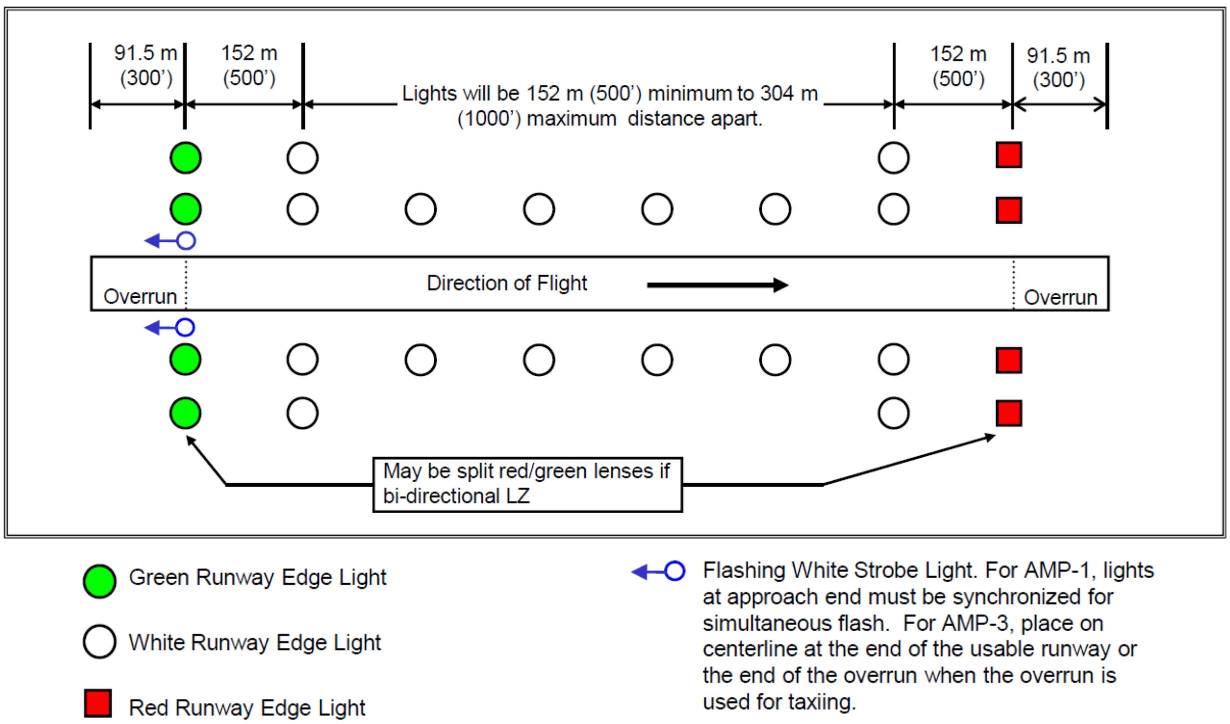


Figure 14-2 AMP-2 Lighting Plan

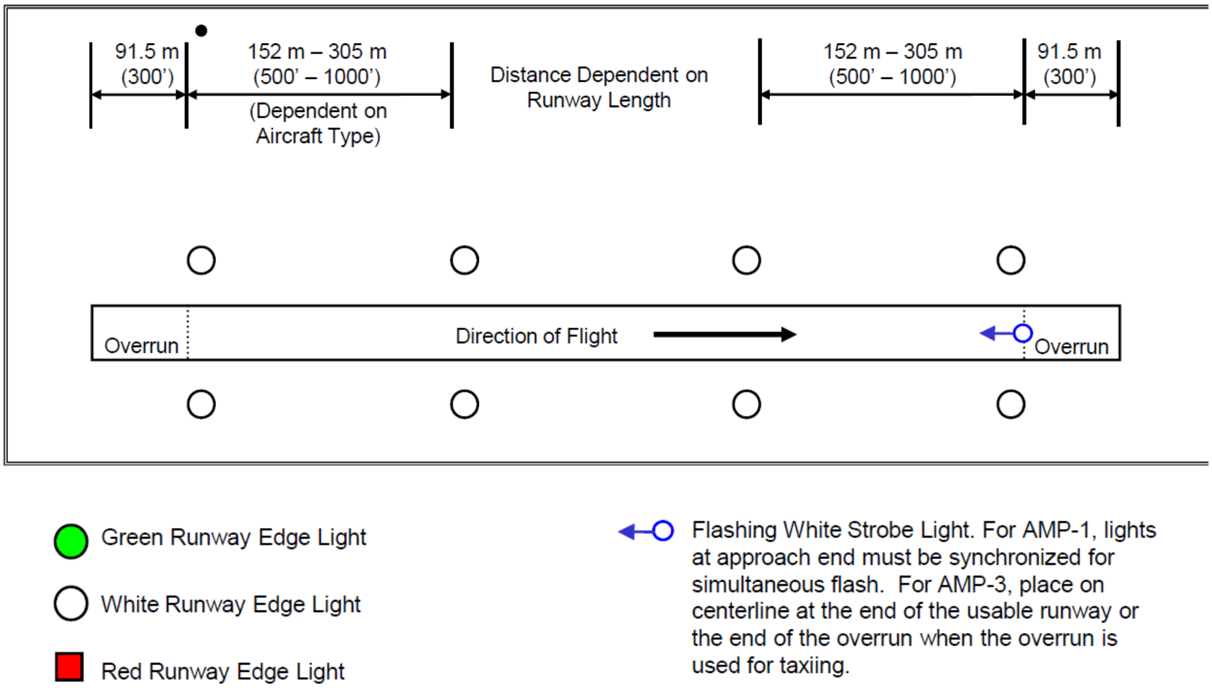

Figure 14-3 AMP-3 Lighting Plan

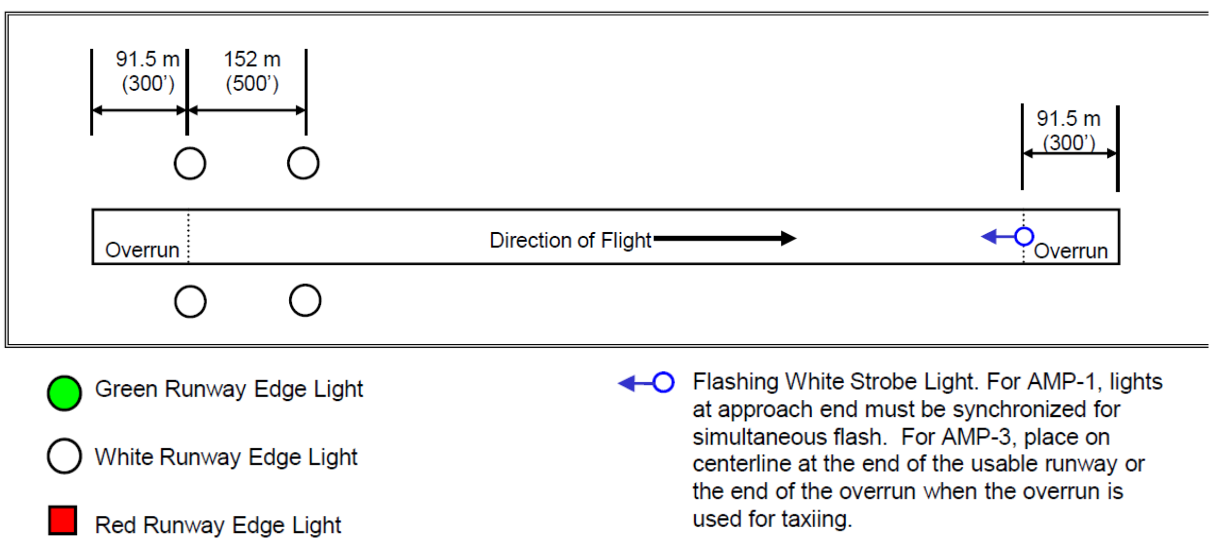

Figure 14-4 Light and Marker PANEL Layout Detail on a Landing Zone with Combination AMP-1, AMP-3 Overt, and AMP-3 Covert

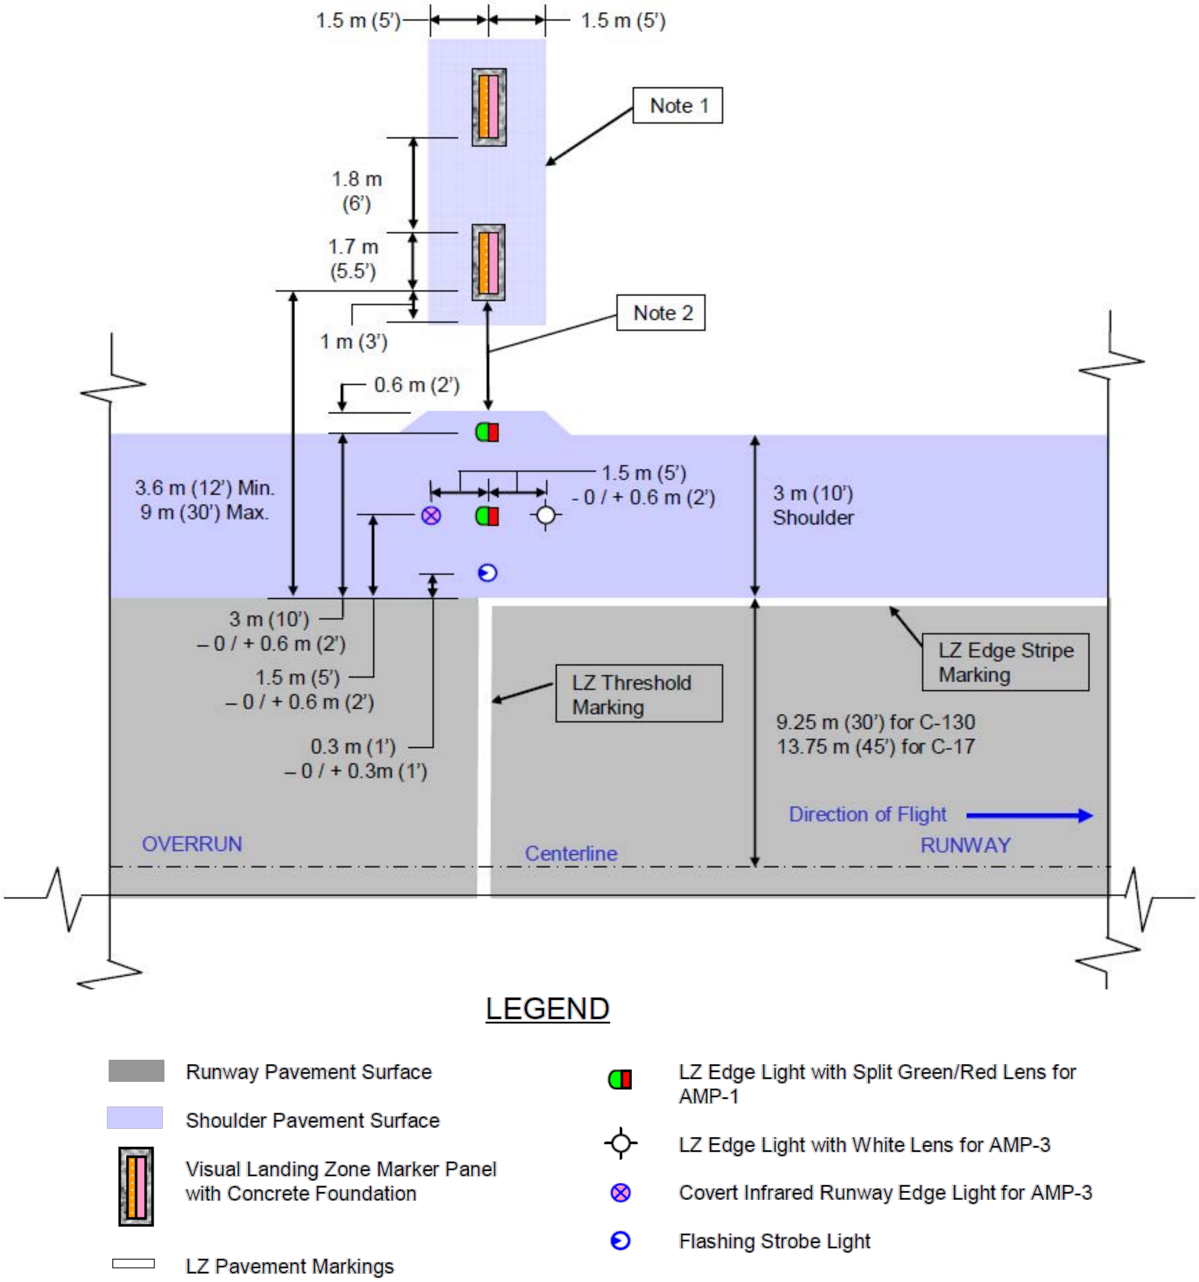
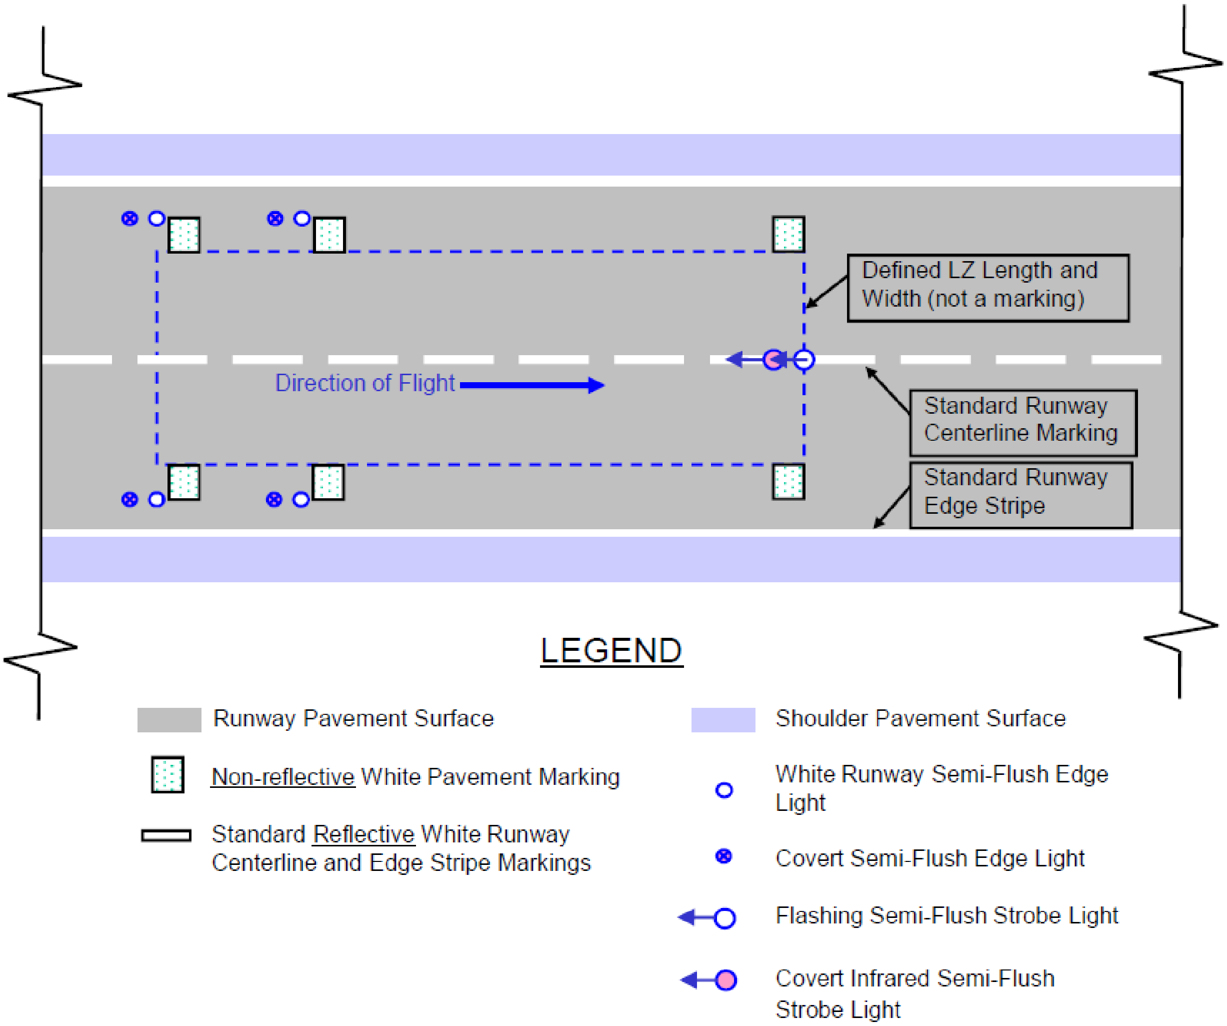


Notes:

1. Paved pad surrounding sign bases is recommended to eliminate need for mowing close to and between signs.
2. If gap between paved shoulder and sign foundation is less than 2.4 m (8'), pave entire gap.
3. LZ edge lights must be on the same longitudinal alignment throughout the length of the LZ. Pairs of lights should be perpendicular and equidistant from the centerline.
4. All LZ lights should be located at least 0.6 m (2') from PCC pavement joints.
5. Minimum 1.2 m (4') spacing between flashing strobe and inboard edge light. Minimum 1.5 m (5') spacing between edge light pairs.

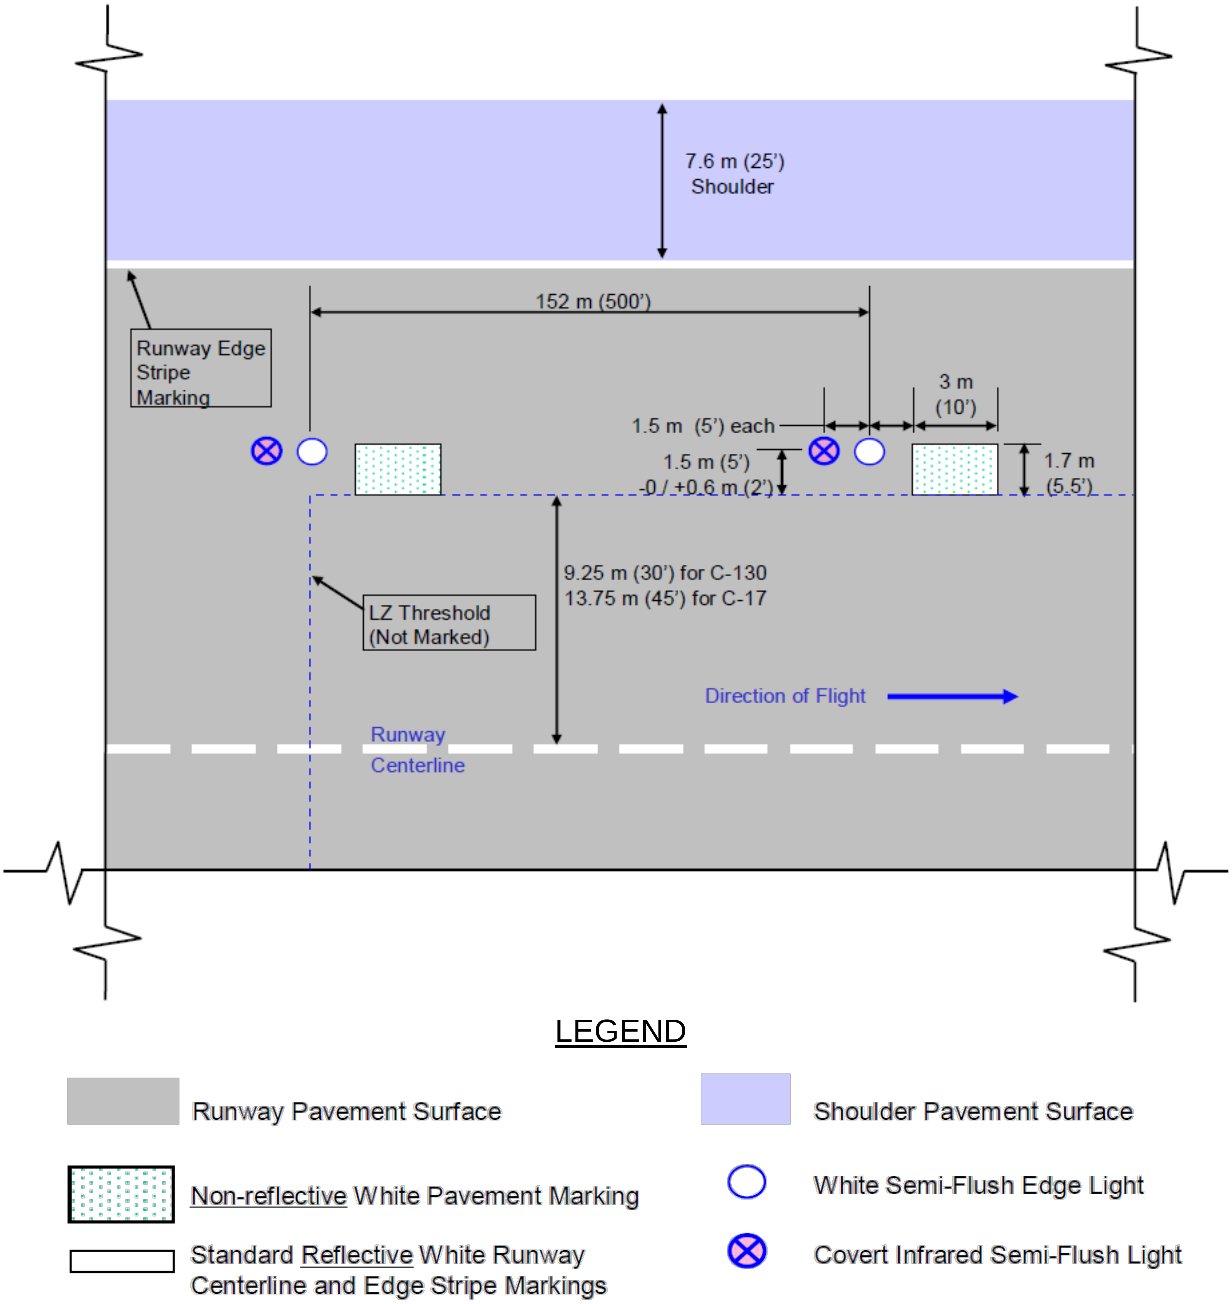
Figure 14-5 AMP-3 Lighting and Marking Scheme for LZ Superimposed on Standard Class B Runway



Notes:

1. LZ pavement markings should be installed with the inside edge aligned with the edge of the LZ. The back edge should be aligned with the measurement from the threshold. Markings should be 3.0 m (10') long (parallel to runway centerline) and 1.7 m (5.5') wide.
2. If the flashing strobe light is not semi-flush, install at the end of the usable runway.

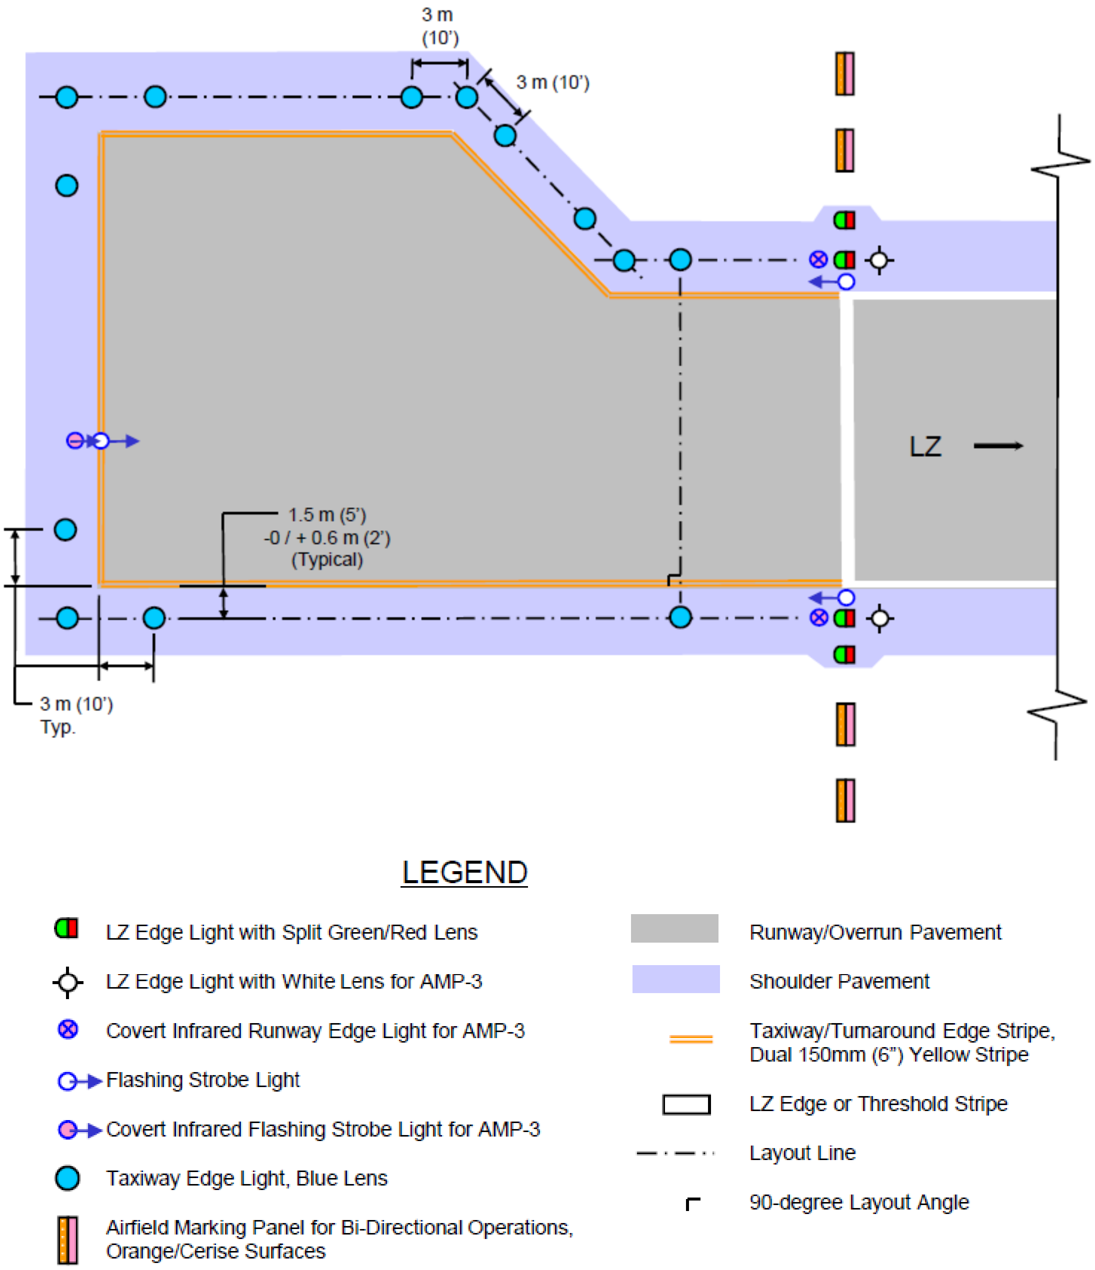
Figure 14-6 AMP-3 Overt and Covert Lighting and Marking Layout Detail for LZ Superimposed on Standard Class B Runway



Notes:

1. LZ threshold should be sited so that conflicts with standard lights and markings are avoided.
2. All LZ lights should be located at least 0.6 m (2') from PCC pavement joints.

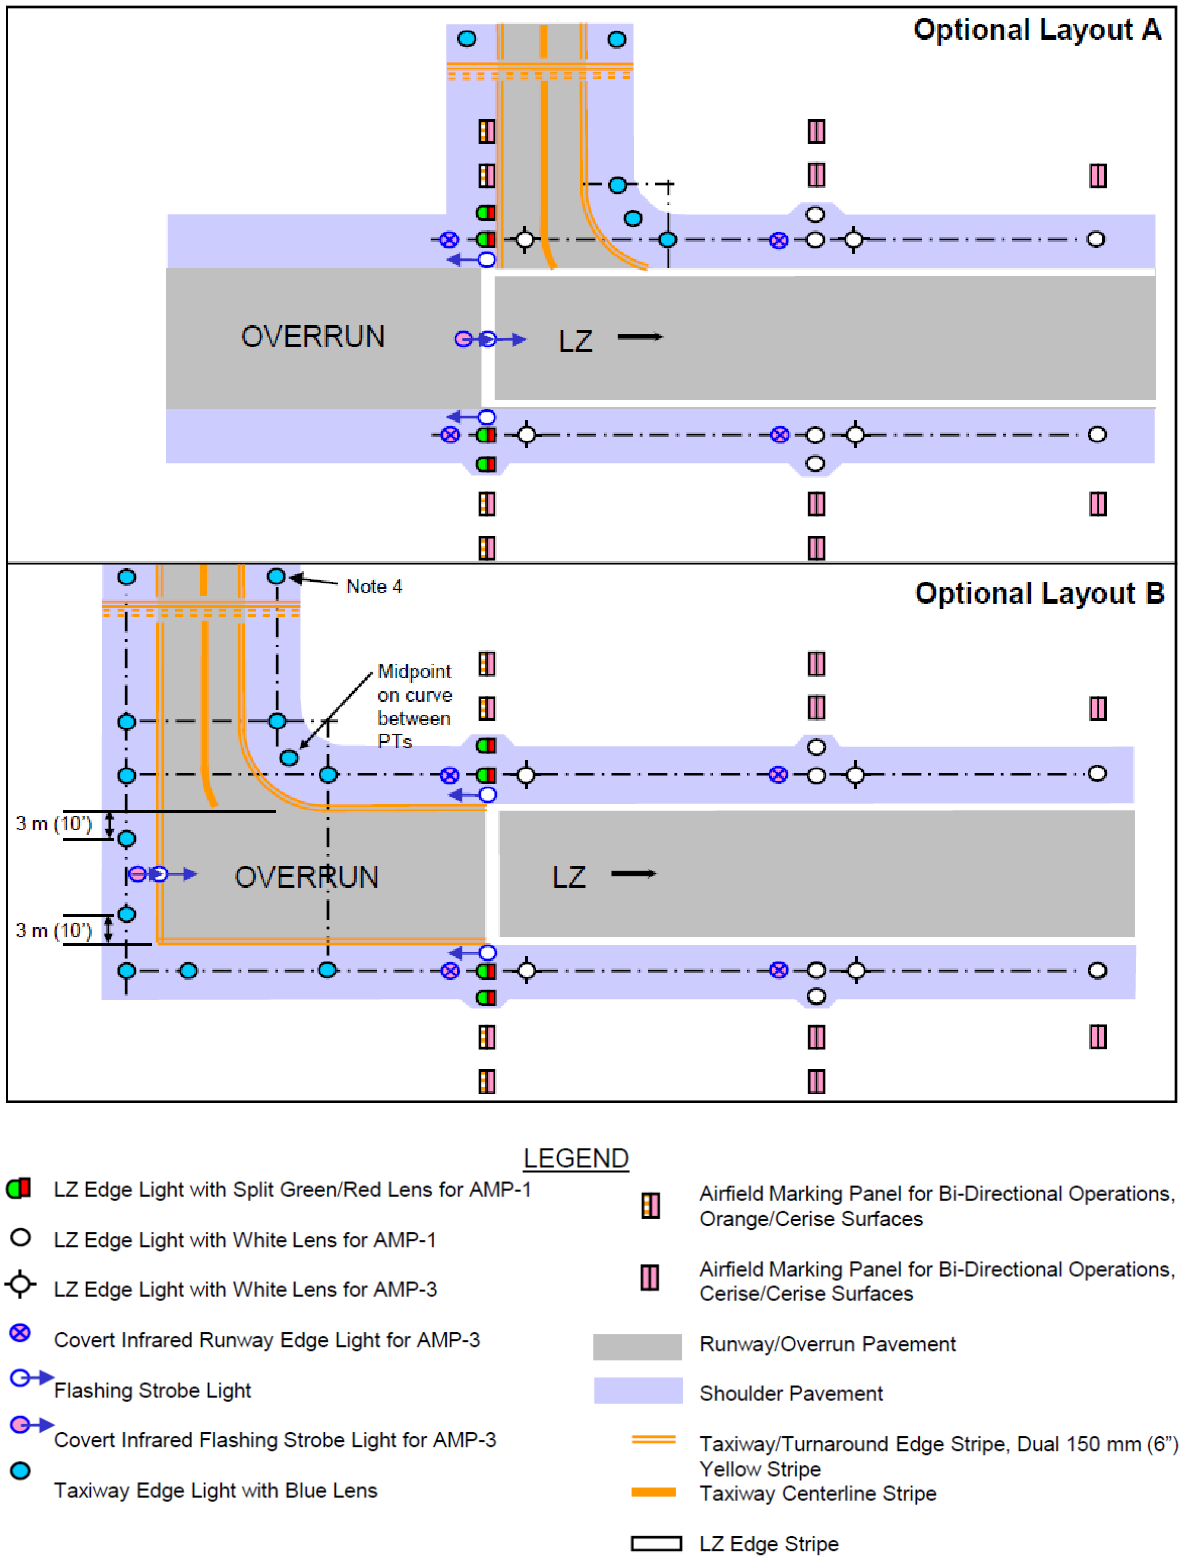
Figure 14-7 Typical Turnaround Marking and Lighting Layout



Notes:

1. LZ is configured for bi-directional operations.
2. All taxiway lights must be equidistant from taxiway/turnaround edge. Design tolerance is 1.5m (5') – 0/+ 0.6m (2').

Figure 14-8 Typical Bi-Directional Runway/Taxiway Marking and Lighting Layout



Notes:
1. LZ is marked and lighted for bi-directional operations.

2. Taxiway lights must be equidistant from taxiway/turnaround edge. Design tolerance is 1.5m (5′) – 0.6m (2′).

3. Locate taxiway lights behind the hold line according to this UFC, but no more than 60m (200′) from the point of tangency.

B-2 DEFINITION OF TERMS

Approach Light Plane: An imaginary plane that passes through the beam centers of the lights in the system. The plane is rectangular, centered on the ALS centerline, starting at the landing threshold and extending 200 feet (60 meters) beyond the last light at the approach end of system. The plane may have irregularities. The width varies according to the lighting system.

Decision Height: The height above the highest elevation in the touchdown zone, specified for a glide slope approach at which a missed approach procedure must be initiated if the required reference has not been established.

Displaced Threshold Area: An area of full strength pavement on the approach slope of the threshold intended for use during takeoff or during rollout after landing from the opposite direction.

Footcandle: One lumen per square foot (10.8 lux).

Frangible Support: A support for elevated fixtures or other devices composed of a supporting element with a fracture mechanism at its base. It is designed to present a minimum of mass and to break at the base when impacted.

Helipad: A prepared area designated and used for takeoff and landing of helicopters (includes touchdown and hoverpoint). May be located at facilities with fixed and rotary wing aircraft.

Heliport: A facility designed for the exclusive operating, basing, servicing and maintaining of rotary-wing aircraft (helicopters). The facility may contain a rotary-wing runway and/or helipads.

In-pavement Fixtures: Fixtures whose surface are within 0.5 inches above the runway surface. Note that terminology has changed from "Semi-flush", but some references remain titled with the term "Semi-Flush." These terms should be interchangeable.

Instrument Runway: A runway served by non-visual aids giving directional guidance adequate for a straight in approach. It may be further classified as:

Non-Precision Approach Runway: A runway with two-dimensional operations conducted under IFR using lateral guidance but not vertical guidance.

Precision Approach Runway, Category I: A runway served by an instrument landing system (ILS), microwave landing system (MLS), or precision approach radar (PAR) and visual aids intended for operations down to 200 feet (60 meters) decision height, and down to a runway visual range (RVR) on the order of 2,400 feet (720 meters). These criteria also apply to visual lighting aids supporting Air Force precision approach radar approaches down to a decision height of 100 feet (30 meters) and an RVR on the order of 1,200 feet (360 meters).

Precision Approach Runway, Category II: A runway served by ILS or MLS and visual aids intended for operations down to 100 feet (30 meters) decision height and down to an RVR on the order of 1,200 feet (360 meters).

Precision Approach Runway, Category III: A runway served by ILS or MLS (no decision height being applicable) and:

Category IIIa: By visual aids intended for operations down to an RVR on the order of 700 feet (210 meters).

Category IIIb: By visual aids intended for operations down to an RVR on the order of 150 feet (45 meters).

Category IIIc: Intended for operations without reliance on external visual reference. (The RVR is 0).

Light Bar: A set of lights arranged in a row perpendicular to the light system centerline, also known as a barrette.

Lux: One lumen per square meter (1/10 (0.0929)) footcandle).

Message Element: the use of characters, symbols, or a combination of characters and symbols in its simplest form used to communicate a location, direction, or action where aircraft operate. (See paragraph 9-1.)

Overrun: An area on the approach side of the runway threshold which is stabilized or paved but is not intended for normal operational use. It serves as a safety area for aircraft which overrun the end of the runway or touch down short of the threshold.

Positive Slope: A slope of the approach light plane upward and outward from the landing threshold.

Rigid Support: A support for elevated lights or other devices which has been designed to support the lights under all foreseeable weather conditions without regard for impact resistance. Do not use these supports in new construction for systems in safety clearance zones or where there is present danger of impact by aircraft.

Runway Centerline: A line halfway between the edges of the surface designated for normal aircraft landing and takeoff operations.

Runway Edge: The sides of a runway designated as full strength and capable of supporting aircraft wheel loads; any area beyond that point is a non-operational area.

Runway End: The longitudinal limit of usable runway opposite the runway threshold. It often, but not always, coincides with the threshold of the opposite direction runway surface.

Runway Visual Range (RVR): The maximum distance in the direction of take-off or landing from which the runway (or the specified lights or markers delineating it) can be seen from a position above a specified point on the runway centerline and at a height corresponding to the average eye level of pilots at touchdown.

Semi-Flush fixtures: Fixtures whose surface is within 0.5 inches above the runway surface. Note that terminology has changed to In-pavement fixtures, but some references remain titled with the term “Semi-Flush.”

Semi-frangible Support: A two element support for light fixtures or other devices designed for use in applications where the mounting is over 40 feet (12 meters) above the ground and exceeds the design limits for low impact resistant supports mounted on a rigid support and a means to lower the lights for servicing.

Sign array: message elements that may be within multiple individual housings (see paragraph 9-1.)

Special Tactics Team: Special Tactics Teams (STTs) are elite USAF special operations units who operate on the ground, often alongside other Special Operations Forces (SOF) such as Rangers, Special Forces and Navy SEALs.

Theater of Operations: (TO) An operational area defined by the geographic combatant commander for the conduct or support of specific military operations. (Joint Publication 3-0)

\2\ APPENDIX C LIGHT EMITTING DIODES AND NIGHT VISION DEVICES

DoD personnel responsible for the content of UFCs are constantly monitoring changes made to FAA documents and are working closely with industry on military needs as these fixtures evolve to be safe for all aviation contexts. This appendix clarifies the operational characteristics of NVDs and their interaction with LEDs to assist users of FAA, ICAO, and DOE standards and regulations.

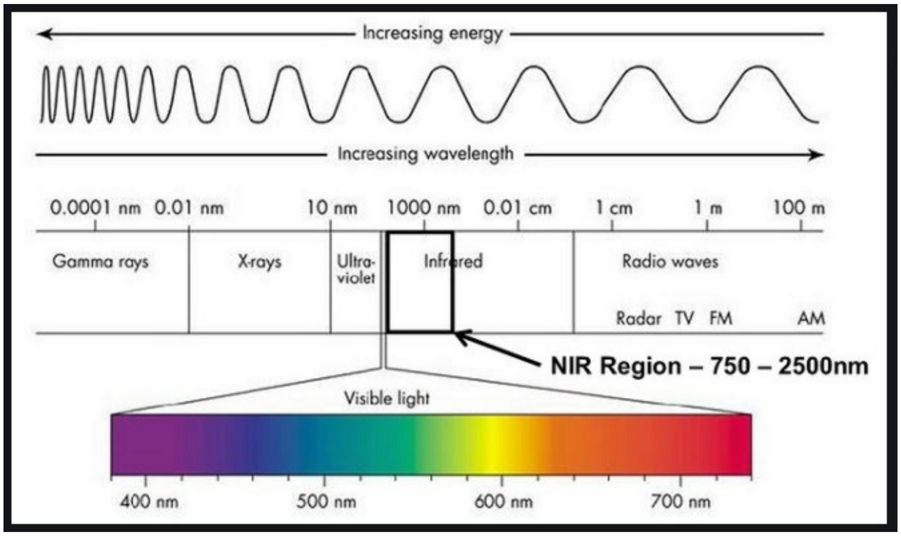
When one reads documents created by FAA, ICAO, DoD, DoE, etc., one must be familiar with the definitions and parameters of specific terms found within those documents. Because assumptions may be inherently associated with the use of a term, it is important to know if the term is specific; i.e., including assumptions, or is generic. The topic of this appendix is interaction between night vision devices (NVDs) and light emitting diodes (LEDs).

C-1 NVDs, NVGs, AND EVDS DEFINED.

Night vision devices include night vision goggles (NVGs) and enhanced vision devices (EVDs). While all NVGs are NVDs, all NVDs are not NVGs. Night vision goggles (NVGs) operate on the principle of multiplying whatever light is present. NVGs require at least some amount of ambient light or there is nothing to multiply. Common NVGs require about 0.3 foot-candles of ambient light or the device detects no light and provides no output. NVDs operate on the principle of a measure of heat energy, which cannot be seen with the naked eye.

All NVDs operate in the spectrum area just above the visible light spectrum. The Infrared region lies between the visible and microwave portions of the electromagnetic spectrum. Infrared rays are invisible to the human eye but they can be focused, reflected and polarized, just like visible light. This region is divided into three parts: Near-Infrared, Mid-Infrared and Far-Infrared.

Figure C-1 Electromagnetic Spectrum with Near IR Region Designated



The infrared portion of the electromagnetic spectrum ranges from 750 nm to 2500 nm, and is broken up into three parts, near IR (NIR), medium IR (MIR), and far IR (FIR). NVGs operate between visible light (just after the red) and almost 900 nm.

C-2 IR EMITTERS FOR AIRFIELD LIGHTING.

Typical IR emitters added to LED airfield lighting fixtures for visibility with NVGs operate optimally between 830 and 870 nm. Other NVDs, such as forward-looking infrared (FLIR), operate in the near-to-medium IR region of 2500 nm to 4000 nm. Therefore, IR emitters for NVG don't support FLIR.

The lower wavelengths for each show that emitters for NVGs do not work for FLIRs and other NVDs such as EVDs:

830 nm = 0.000000830 meters or 830 billionths of a meter (for NVGs)

2500 nm = 0.000002500 meters or 2.5 millionths of a meter (for FLIR devices)

Equation C-1 Relationship of Energy to Wavelength Where h and c Are Constants (Reference Figure A-1)

$$E = \frac{hc}{\lambda}$$

Where:
E = energy
H = Planck's constant
C = speed of light
Λ = wavelength

C-3 FAA GUIDANCE.

FAA Airport Engineering Brief 98, *Infrared Specifications for Aviation Obstruction Light Compatibility with Night Vision Goggles (NVGs),* paragraph 7-7.5, states, "Provide LED obstruction lights where the users and airfield manager can verify that night vision goggles (NVG) or vision enhancement systems are not used…" The same clarifications regarding compatibility with NVGs are addressed in FAA Advisory Circular (AC) 150/5345-43, *Specifications for Obstruction Lighting*.

Note that unlike civilian airfield managers, military airfield managers must be delegated this decision-making authority by the appropriate installation or wing commander.

Also note that, in AC 150/5345-53D, *Airport Lighting Equipment Certification Program, November 2020 Addendum*, the following statement is at the bottom of every page listing certified equipment: [1]

> *"Any runway fixture listed above that uses a LED lighting source may not be compatible with Enhanced Flight Vision Systems that use IR energy emissions for imaging. 3 (L) Indicates LED fixture IR element present is not tested nor certified under this program as to compatibility with any night vision equipment."* ***/2/***

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source: Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Subject: UFC 3-535-02, *Design Drawings for Visual Air Navigation Facilities*

Supersedes: UFC 3-535-02 (Draft), 30 JUNE 2014

Description of Changes: This revision updates the graphics details that have been in a draft document into the form of a UFC document required by UFC 3-100-01. Each graphic detail has been updated to be consistent with UFC 3-535-01 and NAVAIR 51-50 AAA-2. The details have been provided with updated designer notes and notes to be used with the drawings. AutoCAD cells of these graphics details and drawing notes will be located on a public web site for use by designers of airfield lighting projects. The details will be readily accessible and easily modified for each project. Where the technical content varies according to the needs of the military services (Air Force, Army, Navy) service-specific technical content has been provided in the details.

Reasons for Changes:

- The changes were made to bring the draft details up to the current state of military airfield lighting practice. The previous details were not consistent in graphic style, and did not meet current military graphics standards. They were not suitable for use on new projects without re-drawing each detail for each project.

Impact: Cost impact is negligible. However, the following benefit should be realized:

- Designers will have a better understanding of the design requirements.

Unification Issues

- Chapter 9 Wave-off & Wheels-up Lighting Systems and Chapter 10 Simulated Carrier Deck Systems are Navy only requirements from NAVAIR 51-50AAA-2 General Requirements for Shorebased Airfield Marking and Lighting.
- Lighting base can details may indicate a drain, this drain can be used on Army/Air Force projects, but is not used on Navy projects. This service difference will be indicated throughout this UFC wherever there is a light base can.
- Lighting base can details have service differences for the counterpoise lightning protection system. The Navy has differences in connecting the counterpoise wire to all metal objects on the airfield. Army/Air Force requirements are

selective on where the counterpoise is connected. This service difference will be indicated throughout this UFC wherever there is a light base can.

- Figures 50A, 50B, 50C, 51, 56 and 57 are service specific due to the runway threshold lighting configurations being different between the services. For the Navy this requirement is from NAVAIR 51-50AAA-2.

Table of Contents

This page intentionally left blank.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE.

This document provides drawing details for design and construction of individual components of visual navigation facilities. Use this document when designing, planning, constructing, and installing new systems.

1-2 SCOPE.

This document applies to United States Air Force, Army, Navy, Air National Guard, Army National Guard, Air Reserve, Army Reserve and Naval Reserve bases with responsibility for maintaining their airfield facilities. Existing systems and components are not required to be upgraded to these drawing details unless as part of a major rehabilitation.

This document contains the drawing details for design and construction for visual air navigation facilities, except marking, at Air Force, Navy, and US Army facilities.

Additional Navy requirements are currently contained in Naval Air Systems Command (NAVAIR) 51-50AAA-2. When using the NAVAIR document, be certain that the complementary markings are installed and that no conflict occurs with the placement of light fixtures.

1-3 SUMMARY OF CHANGES.

This edition of UFC 3-535-02, *Design Drawings for Visual Air Navigation Facilities*, supersedes the draft version dated 30 June 2014. Drawings are representative and not to scale. The English units govern.

1-4 APPLICATION.

This volume is not intended as a design specification or an instruction manual for untrained persons. A trained person is one who has the skills and knowledge related to the design, construction and operation of the airfield lighting systems and has received technical and safety training to design, construct and operate airfield lighting systems while recognizing and avoiding the hazards.

When using this manual, be certain that the complementary markings are installed and that no conflict occurs with the placement of light fixtures.

Specifically, this document contains figures that reference individual AutoCAD files containing the drawings, individual files containing the notes to designer for each diagram (text also provided within this document), and figure numbers for cross-referencing the drawings with this document.

1-5 FAA STANDARDS.

The Army and Air Force generally follow FAA standards that are primarily published as Advisory Circulars (ACs), handbooks, and specifications. However, when FAA documents are in conflict with the Air Force or Army requirements, this UFC takes precedence.

1-6 INTERNATIONAL MILITARY STANDARDS.

1-6.1 This UFC satisfies the requirements of international military standards to the greatest extent possible.

1-6.1.1 NATO STANAGs are promulgated by the NATO Standardization Office (NSO).

1-6.1.2 ASIC Air Standards (AIR STD) are promulgated by representatives of the military air forces of Australia, Canada, New Zealand, United Kingdom, and the United States. AIR STDs governing airfield lighting and marking, obstructions, helipads, and heliports have been cancelled.

1-6.2 Applicable international military standards take precedence over standards in this UFC as follows:

1-6.2.1 NATO.

NATO STANAGs apply at Army and Air Force facilities in NATO theater countries except the United States and Canada, or wherever NATO funding is provided for the work, regardless of location.

1-6.2.2 ASIC.

At Army and Air Force facilities in New Zealand and Australia, contact:
AF/A8XX - USAF International Standardization Office
ASIC (Air & Space Interoperability Council)
Andrews AFB MD
+1.240.612.4237 DSN 312.612.4237

1-7 BASE RIGHTS AGREEMENTS.

When the Army or Air Force builds an airfield in a foreign country, the United States obtains a Base Rights Agreement. Provisions of the Base Rights Agreement must be observed and may require that construction complies with standards of the host nation. Under such an agreement, and whether or not international standards conform with standards of the host nation, the host nation must approve all plans. It may also be desirable to use equipment produced in the host nation.

1-8 METRICATION OF DIMENSIONS.

Generally, all dimensions are provided in English units with metric units following in parentheses. It is expected that designers who use these details will be using the English dimensions for stateside construction projects, and the metric dimensions for international projects. The alternate dimensions will be deleted from the graphic details for each project.

English and metric units for manufactured products are described to the precision of the manufacturer's published dimensions.

English conduit sizes are standard trade sizes listed in the National Electrical Code (NEC). Metric conduit sizes are the metric designation for the same conduits listed in the NEC. They are not the same as the metric sizes for conduits provided on the international market.

English wire sizes are standard trade sizes listed in the NEC. Metric wire sizes are metric wire sizes that are available on the international market.

English and metric units for field construction dimensions are nominal dimensions that allow for the normal variance in field construction. The round-off from English to metric units follows the convention used in ICAO standards, as follows: 1 inch = 25 mm, 12 inches = 300 mm, 5 feet = 1.5 meters, 10 feet = 3 meters, 100 feet = 30 meters, 1000 feet = 300 meters, etc.

Note that Executive Order 12770 requires use of metric units in procurement of supplies and services.

1-9 PHOTOMETRIC REQUIREMENTS.

Photometric requirements in this UFC are based on standards established by the ICAO and FAA. They have been modified as necessary to accommodate Air Force requirements.

1-10 STRUCTURAL DESIGN.

Details that indicate the construction of steel-reinforced concrete structures, pads and foundations must be designed by a licensed or registered structural engineer. Concrete used in underground structures, such as manholes, handholes and foundations must be designed with minimum 28-day structural strength of 4000 psi, except structures in areas where freeze AutoCAD files for the details in this UFC can be downloaded from the following site:
http://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-535-02

and thaw conditions are common. They must be designed with concrete with minimum 28-day structural strength of 4500 psi. Concrete used for non-structural equipment pads, mowing buffers and similar items must be designed with minimum 28-day structural strength of 2000 psi.

1-11 SUPPLEMENTAL INFORMATION.

This volume supplements UFC 3-535-01, *Design Standards for Visual Air Navigation Facilities* (Army and Air Force only). Technical Manual NAVAIR 51-50AAA-2, *General Requirements for Shorebased Airfield Marking and Lighting* (Navy only), provides the guidance and detailed information on standard configurations and equipment, and is generally in compliance with the FAA criteria. Use these manuals when designing, planning, constructing, and installing new systems. AutoCAD files for the details in this UFC can be downloaded from the following site:

http://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-3-535-02

CHAPTER 2 UNDERGROUND CABLE, CONDUIT AND DUCTS

2-1 DIRECT BURIED DUCT/CONDUIT DETAILS.

2-1.1 Figures 1A, 1B.

2-1.1.1 Notes to Designer.

1. Where duct / conduit is installed under pavement, specify the type of pavement to be installed on top of the trench. Where trench is cut through existing pavement, specify that the pavement on top of trench match existing material and strength.

2. Location of Counterpoise:

   a. For Air Force / Army projects, the counterpoise is located half way between the full-strength runway or taxiway pavement and the row of edge light fixtures. The counterpoise is not connected to the light base cans for elevated light fixtures. The counterpoise is connected to the light base cans for in-pavement light fixtures.

   b. For Navy projects, the counterpoise is located above the conduits between the light base cans. The counterpoise is connected to each light base can.

3. All counterpoise must be solid bare copper wire (conductor) #6 (16 square mm) minimum for Air Force/Army and stranded bare copper wire (conductor) #4 (25 square mm) minimum for Navy, and will be bonded to ground rods using exothermic welds.

4. All ground rods must be ¾" (20mm) diameter minimum and 10' (3m) long.

5. Refer to UFC 3-535-01, Chapter 1 for more information. Refer to Figures 6A, 6B and 6C for more requirements.

6. Where soil is highly corrosive, refer to NFPA 780, Chapter 11 for more information.

2-1.1.2 Drawing Notes for Figure 1A (Air Force / Army).

1. Ducts under full strength pavement must be concrete encased with a minimum of 3" (75mm) concrete encasement on top, bottom, and sides. Ducts under turf or paved shoulders must be installed in a bed of sand backfill.

2. Locate counterpoise half way between full-strength runway or taxiway pavement and center line of light base cans. Install counterpoise 8" (200mm) minimum below finished grade.

3. Provide minimum conduit slope of 0.5 percent, where possible.

4. Where duct or conduit is below a paved shoulder, the patch material must match the existing pavement.

2-1.1.3 **Drawing Notes for Figure 1B (Navy).**

1. Ducts under full-strength pavement, turf or paved shoulders must be installed in a bed of sand backfill.

2. Locate counterpoise above the conduits between the light base cans. Install counterpoise 8" (200mm) to 12" (300mm) above top duct / conduit.

3. Provide minimum duct / conduit slope of 0.5 percent where possible.

4. Where duct or conduit is below a paved shoulder, the patch material must match the existing pavement.

2-1.2 **Figures 2A, 2B.**

2-1.2.1 **Drawing Notes for Figure 2A (Air Force / Army).**

1. Locate counterpoise half way between full strength runway or taxiway pavement and center line of light base cans. Install counterpoise 8" (200mm) minimum below finished grade.

2. See Figure 3A for grounding connection to external lug on light base can.

3. If light base cans are spaced more than 5' (1.5m), the cans are isolated and must each have a ground rod.

4. Install counterpoise ground rods every 2000' (600M) maximum on straight runs of ducts/conduits.

2-1.2.2 **Drawing Notes for Figure 2B (Navy).**

1. Locate counterpoise above the conduits between the center line of light base cans. Install counterpoise 8" (200mm) to 12" (300mm) above top duct / conduit.

2. See Figure 3B for connection to external lug on light base can.

3. Install ground rods every 2000' (600m) maximum on straight runs of ducts / conduits.

2-1.3 **Figures 3A, 3B.**

2-1.3.1 **Notes to Designer.**

1. These details show the grounding connections to light base cans.

2. Location of Counterpoise:

    a. For Air Force / Army projects, the counterpoise is located half way between the full-strength runway or taxiway pavement and the row of edge light fixtures. The counterpoise is not connected to the light base cans.

    b. For Navy projects, the counterpoise is located above the conduits between the light base cans. The counterpoise is connected to each light base can.

3. Install the ground rod on the side of the trench that is closest to the pavement.

4. All counterpoise and grounding conductors must be #6 (16 square mm) solid bare copper minimum bonded to ground rods using exothermic welds for Air Force/Army projects. Use #4 (25 square mm) for Navy projects.

5. All ground rods must be 3/4" x 10' (20mm x 3m).

6. Where soil is highly corrosive, refer to NFPA 780, Chapter 11, for additional information.

2-1.3.2 **Drawing Notes for Figure 3A (Air Force / Army).**

1. Each light base can must have an external one-hole ground lug. Connect an exothermic one-hole lug to grounding cable. Connect cable lug to base can lug with bronze or stainless steel bolted hardware.

2. Connect grounding cable to reinforcement cage, if one is provided. Use exothermic weld.

3. Connect ground rods to counterpoise at 2000' (600m) maximum spacing for straight runs, using exothermic welds. Do not break counterpoise.

4. Locate counterpoise half way between full-strength runway or taxiway pavement and center line of light base cans.

5. Install the ground rod on the side of the trench that is closest to the runway or taxiway pavement. Ground rod must be separated from counterpoise by minimum 12" (300mm).

2-1.3.3 **Drawing Notes for Figure 3B (Navy).**

1. Each light base can must have an external one-hole ground lug. Connect an exothermic one-hole lug to grounding cable connected to counterpoise. Connect cable lug to base can lug with bronze or stainless steel bolted hardware.

2. Connect ground rods to counterpoise at 2000' (600m) maximum spacing for straight runs, using exothermic welds. Do not break counterpoise.

3. Locate counterpoise above the conduits between the light base cans.

4. Install the ground rod on the side of the trench that is closest to the runway or taxiway pavement.

2-2 Marker Installation at Pavement Edge.

2-2.1 Figure 4.

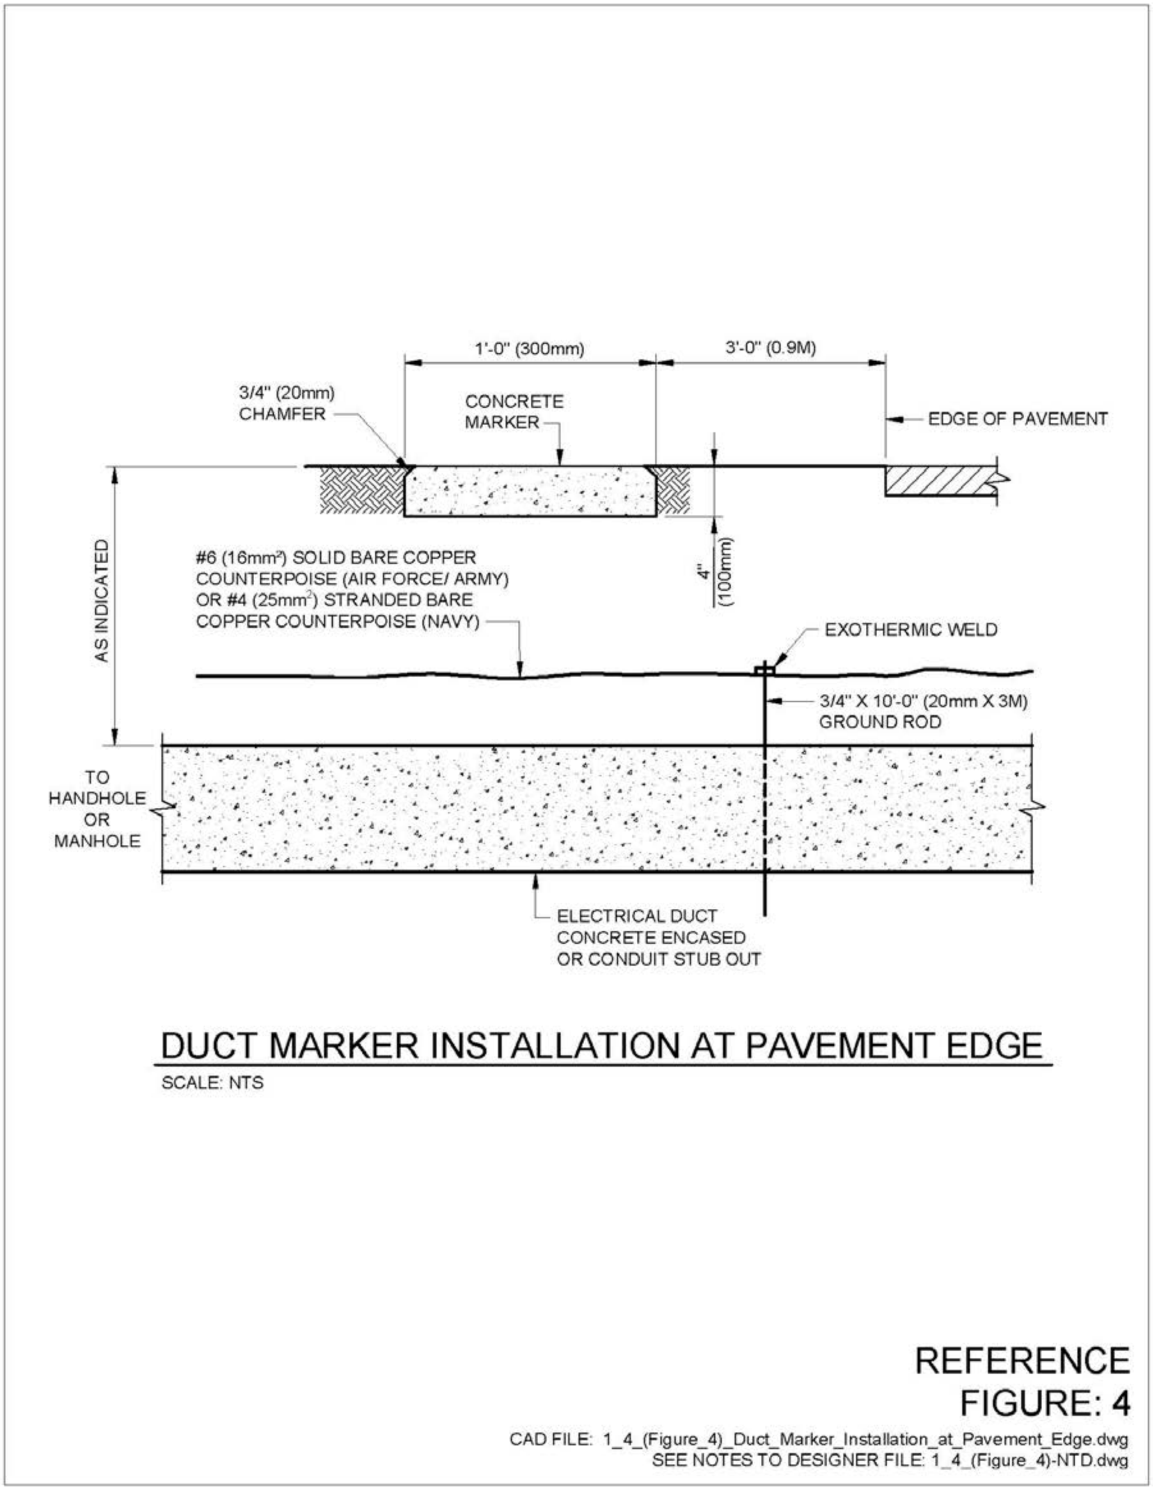
2-2.1.1 Notes to Designer.

1. An option for installing the counterpoise would be to ground the counterpoise to a ground rod 3' (0.9m) before the runway or taxiway pavement and not install counterpoise over duct bank where duct run is beneath pavement.

2. The depth of the duct bank below pavement should be indicated in the duct bank details.

3. All counterpoise must be solid bare copper wire (conductor) #6 (16 square mm) minimum (Air Force/Army) and stranded bare copper wire (conductor) #4 (25 square mm) minimum (Navy), and must be bonded to ground rods using exothermic welds.

Figure 4. Duct Marker Installation at Pavement Edge



2-3 Duct Markers.

2-3.1 Figure 5.

2-3.1.1 Notes to Designer.

1. Duct markers are placed directly over the cable trench with the arrows indicating direction of duct run. Maximum spacing of markers should not exceed 200' (60m) and place the duct run changes direction. No markers are required where the duct runs in a straight line from light base to light base.

2. Duct markers are typically used at the edges of pavement to locate duct crossings beneath pavement. Where the entire lighting system is in ducts or conduit, locate the duct markers the same as cable markers.

2-3.1.2 Drawings Notes for Figure 5, Typical Duct Marker Layout.

1. Install duct markers at each change of direction.

2. Install duct marker every 200' (60m) along straight runs with no access structure.

3. On straight runs less than 200' (60m) install duct marker at midpoint.

4. Install duct marker at ends of ducts that are not terminated at manholes.

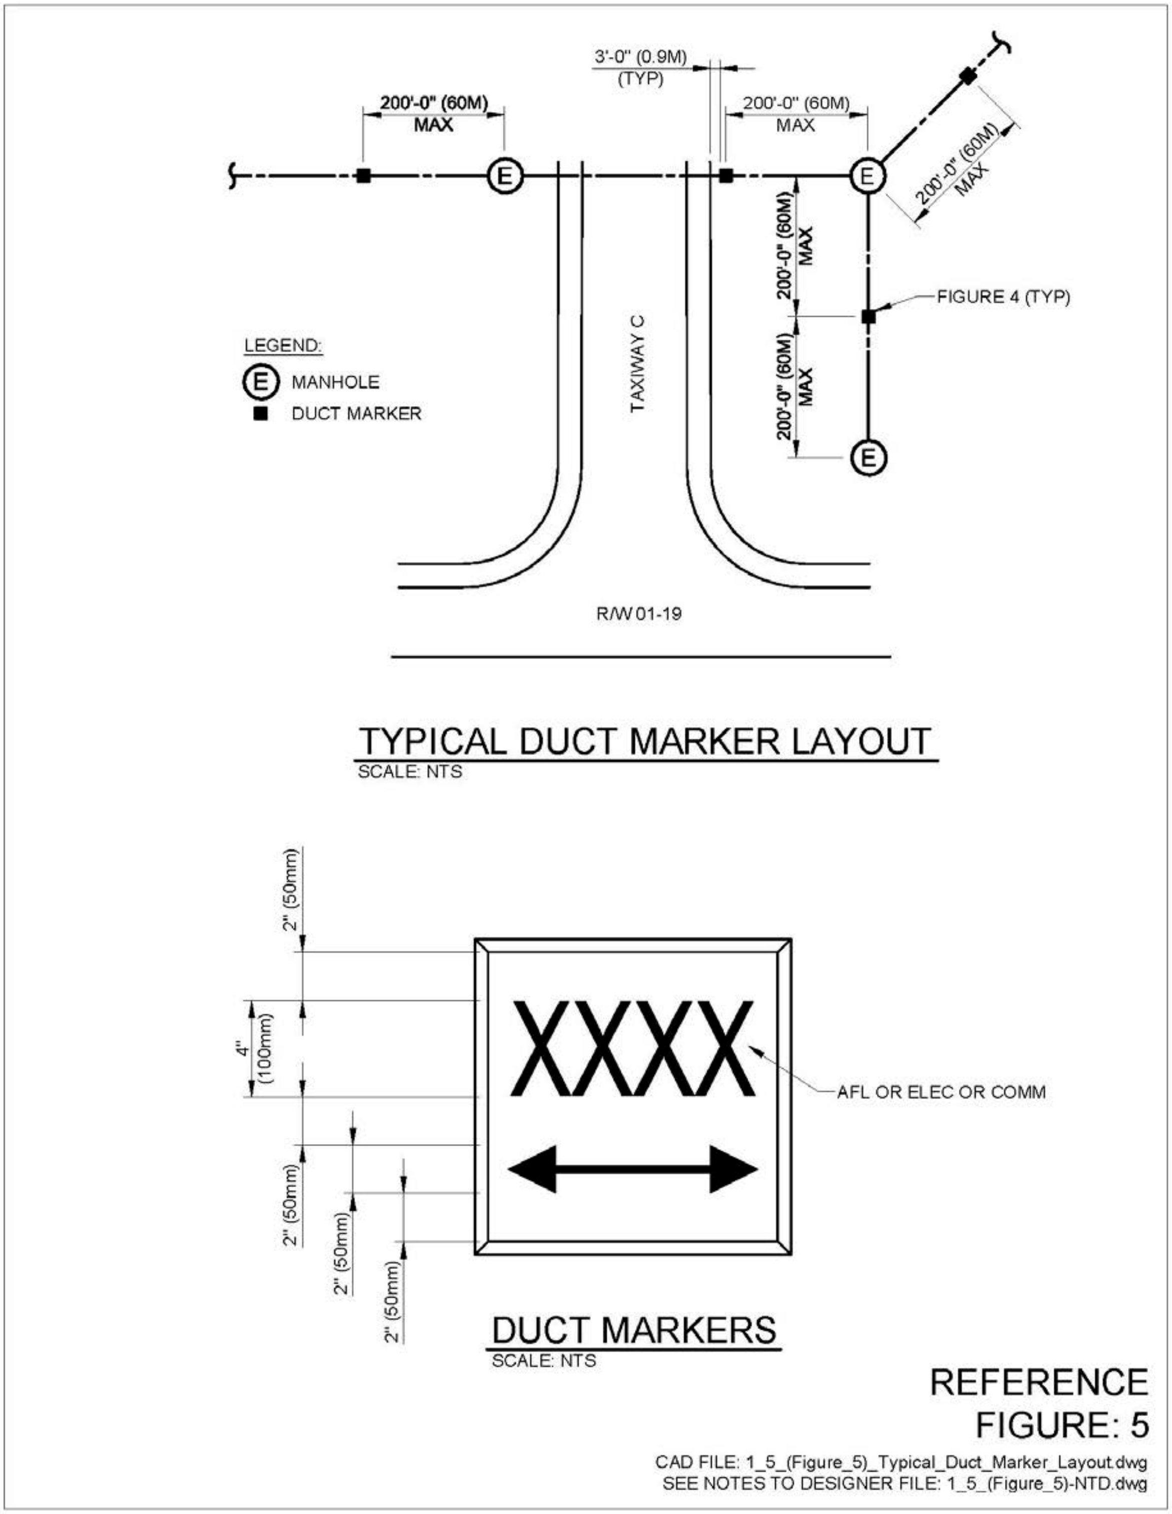
2-3.1.3 Drawings Notes for Figure 5, Duct Markers.

1. Hand lettering not allowed on markers. Lettering is to be boldly impressed. Line width must be 1/2" (13mm) minimum. Depth of impression must be 1/4" (6mm) minimum.

2. Arrow on marker to indicate direction of ducts (where applicable).

3. All markers are concrete with a minimum of 4" (100mm) in thickness.

Figure 5. Duct Markers



2-4 Concrete Encased Duct Bank Details – Typical Arrangements.

2-4.1 Figures 6A, 6B, 6C.

2-4.1.1 Notes to Designer.

1. Indicated to minimize weak points in the duct bank.

2. Several types of duct spacers will accomplish the required duct spacing. Some spacers allow for installation of several tiers on a single duct spacer thereby requiring less labor for installation.

3. It is recommended the minimum depth of the duct bank be at least 12" (300mm) below frost line.

4. If there are no communication ducts intended, they may be deleted from the details.

5. Ducts should terminate in handholes, junction plazas, or manholes wherever possible. The handholes or manholes should be located outside of the runway or taxiway safety areas, if feasible.

6. Slope duct lines (minimum 0.5% slope) where practical for drainage towards manholes/handholes, or duct ends. Where handholes or manholes do not exist at the ends of duct banks for drainage, consider the use of available natural features that are environmentally-approved or environmentally-friendly. Drainage should be designed to limit possible wildlife entrance.

7. Spacing of ducts indicated is minimum in power group for series circuits. Refer to Article 310 in the National Electrical Code, NFPA-70, when ducts are carrying parallel (constant voltage) AC circuits.

8. Number and size of ducts will vary depending on project. Adjust duct number, arrangement and layout accordingly.

9. Red concrete is recommended for Air Force and Army projects. Red concrete is not required for Navy projects.

10. Use UG plates for Navy projects.

11. All counterpoise will be solid bare copper wire (conductor) #6 (16 square mm) minimum (Air Force/Army) and stranded bare copper wire (conductor) #4 (25 square mm) minimum (Navy), and will be bonded to ground rods using exothermic welds.

12. See Paragraph 2.1, UFC 3-535-02, UFC 3-585-01 and NFPA 780, Chapter 11 for location of counterpoise(s) above duct banks.

2-4.1.2 **Drawings Notes for Figures 6A and 6B, Duct Banks.**

1. For size and number of conduits as well as duct bank formation, see plans.

2. Separate the communications conduit group from the power group on either left or right side as indicated on plans.

3. Concrete cover on top; bottom and sides must be 3" (75mm) minimum.

4. Duct banks may be bored under existing pavement. No open cutting of the pavement may occur without base approval. All installation techniques, methods, materials, etc., must be submitted to contracting officer for review prior to starting work. Refer to UFC 3-550-01, and NAVAIR 51-500 AAA-2 for guidance.

5. Conduit and duct bank runs must be straight (±4" (100mm) of centerline between manholes, handholes, and base cans) except where designated differently on design drawings.

6. Conduit temperature must be at burial temperature for 24 hours before covering or making manhole/handhole connections.

2-4.1.3 **Drawings Notes for Hold Down Bar, Figure 6C.**

1. The hold down bar is used to prevent duct flotation during the concrete pour.

2. Drive rebar into the ground at an angle of approximately 15 to 25 degrees off perpendicular. Drive rebar until hold down bar is slightly deformed. Use additional rebars according to number of ducts used.

3. Install retaining ring above hold down bar. Place rebar cover above retaining ring.

4. Place hold down bars up to 5' (1.5m) apart unless conduit is stacked more than one duct high. It may be necessary to place hold down bars closer together if it is not possible to get a good anchor in the ground with the rebar.

5. Contractor must watch concrete pour to ensure that concrete does not hit one end on the hold down bar and cause bar to rotate and release ducts.

Figure 6A. Concrete Encased Duct Bank Details – Typical Arrangements

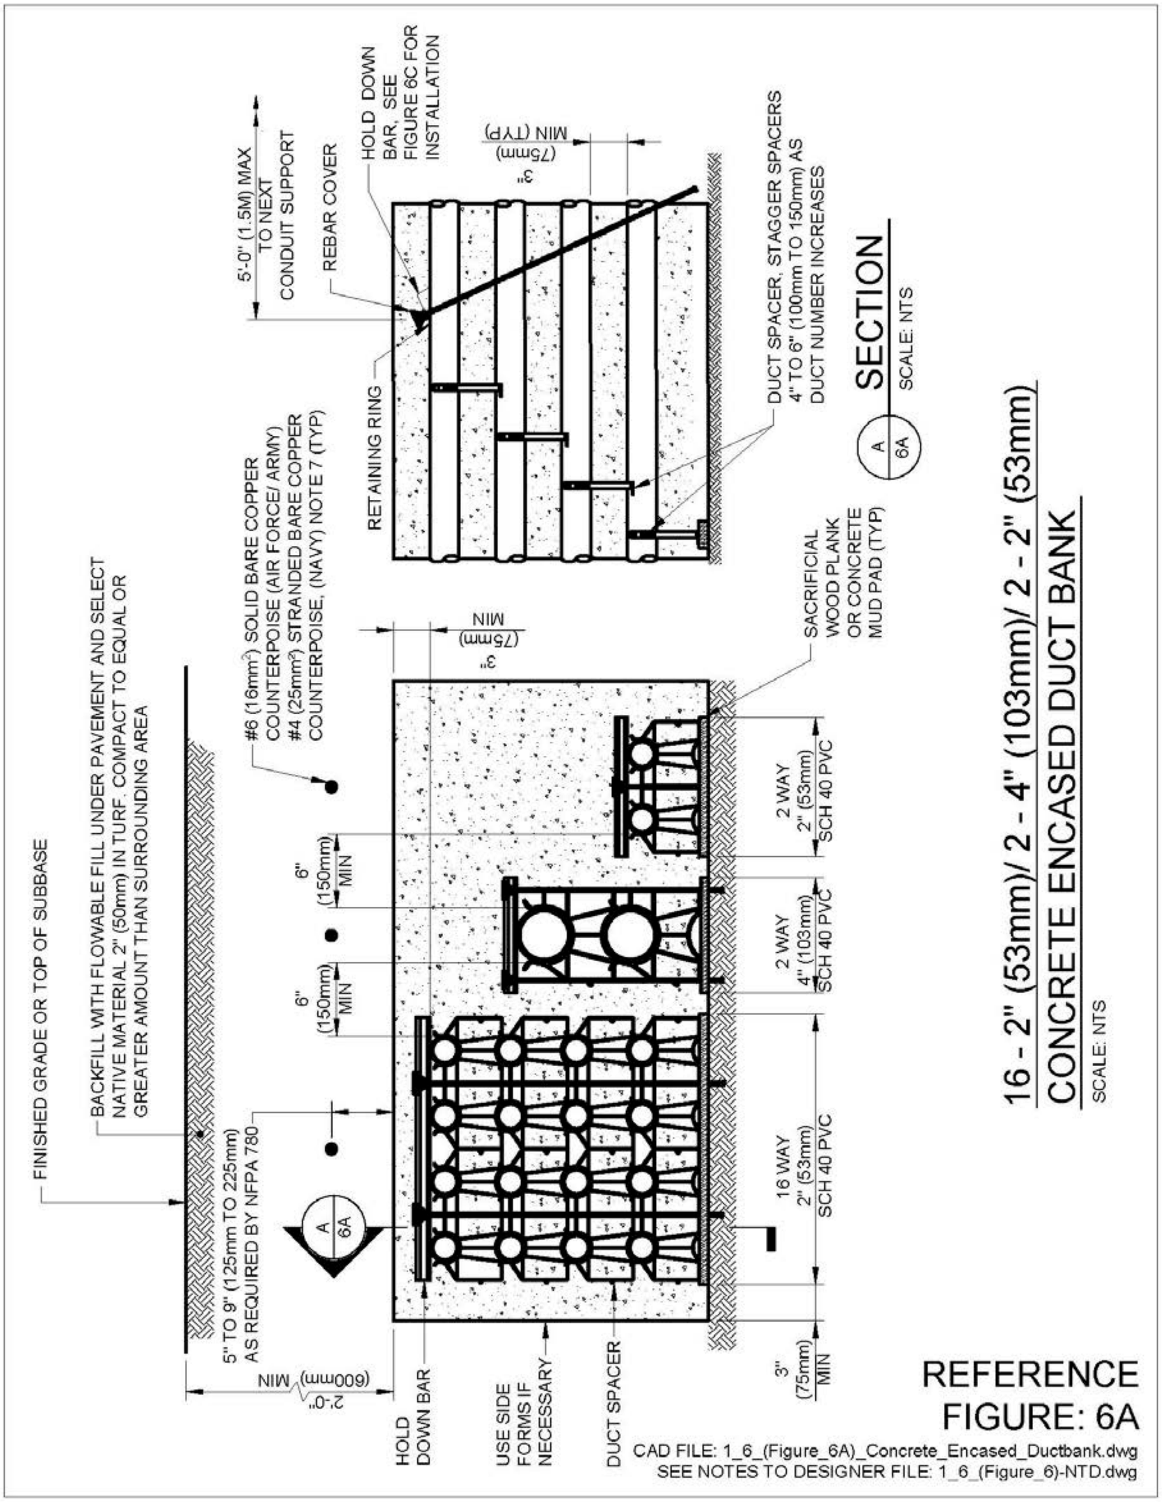


Figure 6B. Concrete Encased Duct Bank Details – Typical Arrangements (continued)

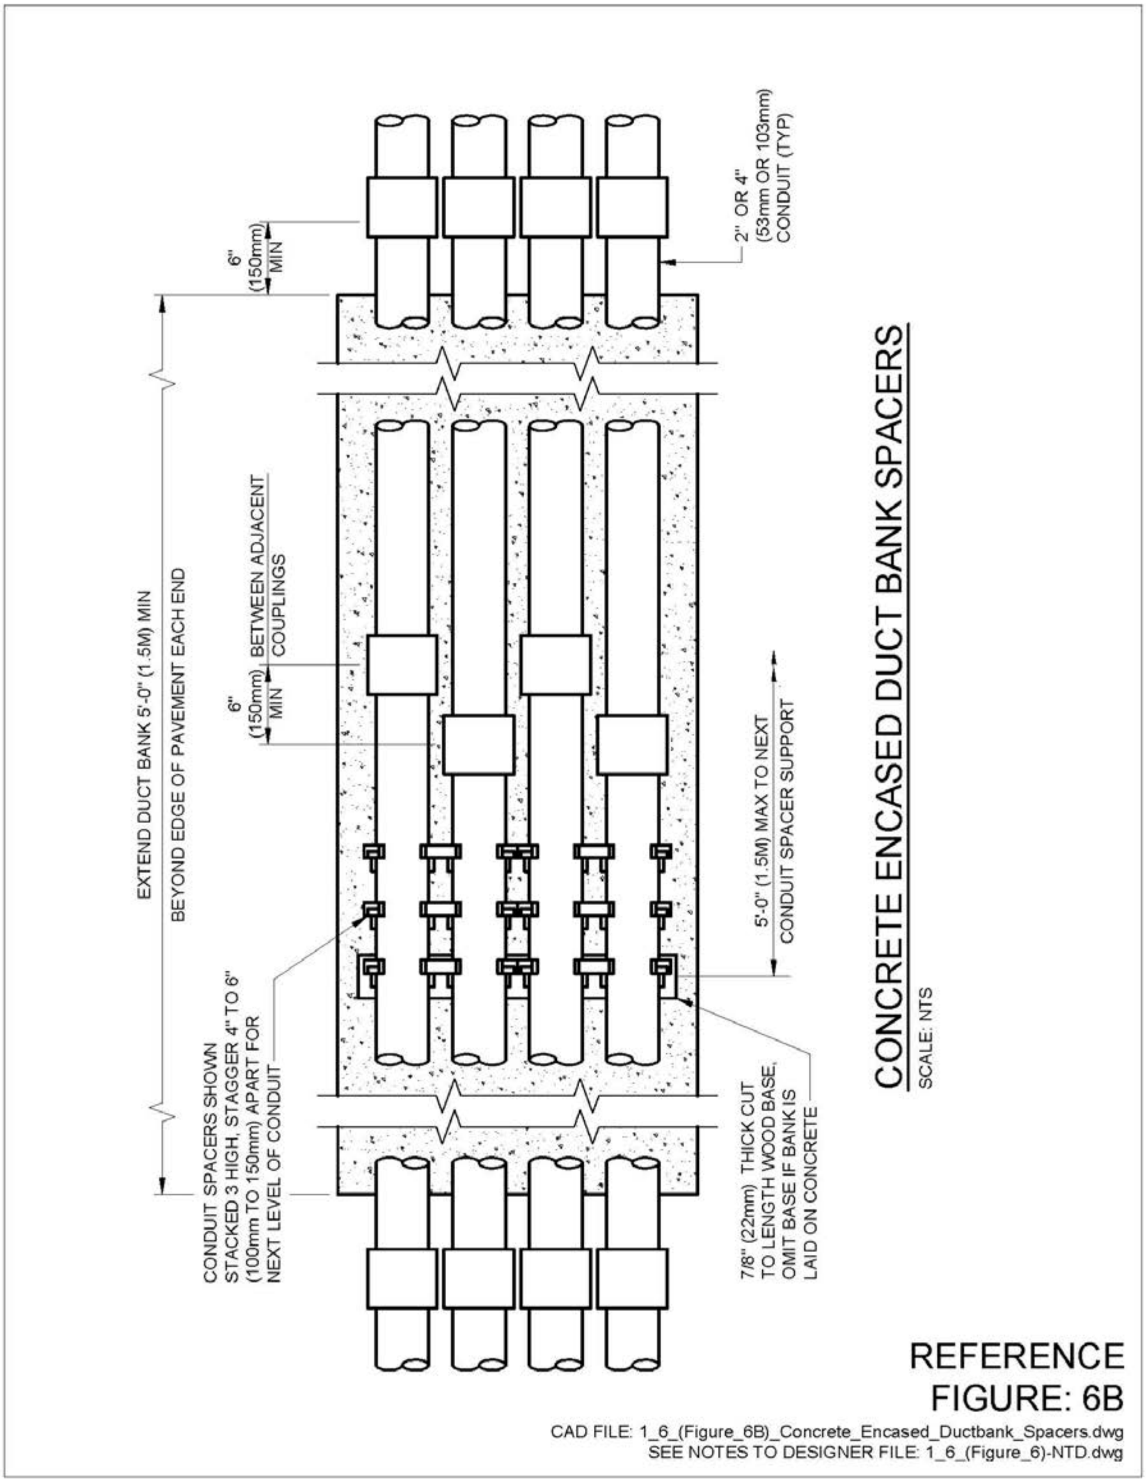

Figure 6C. Hold Down Bar Installation Detail

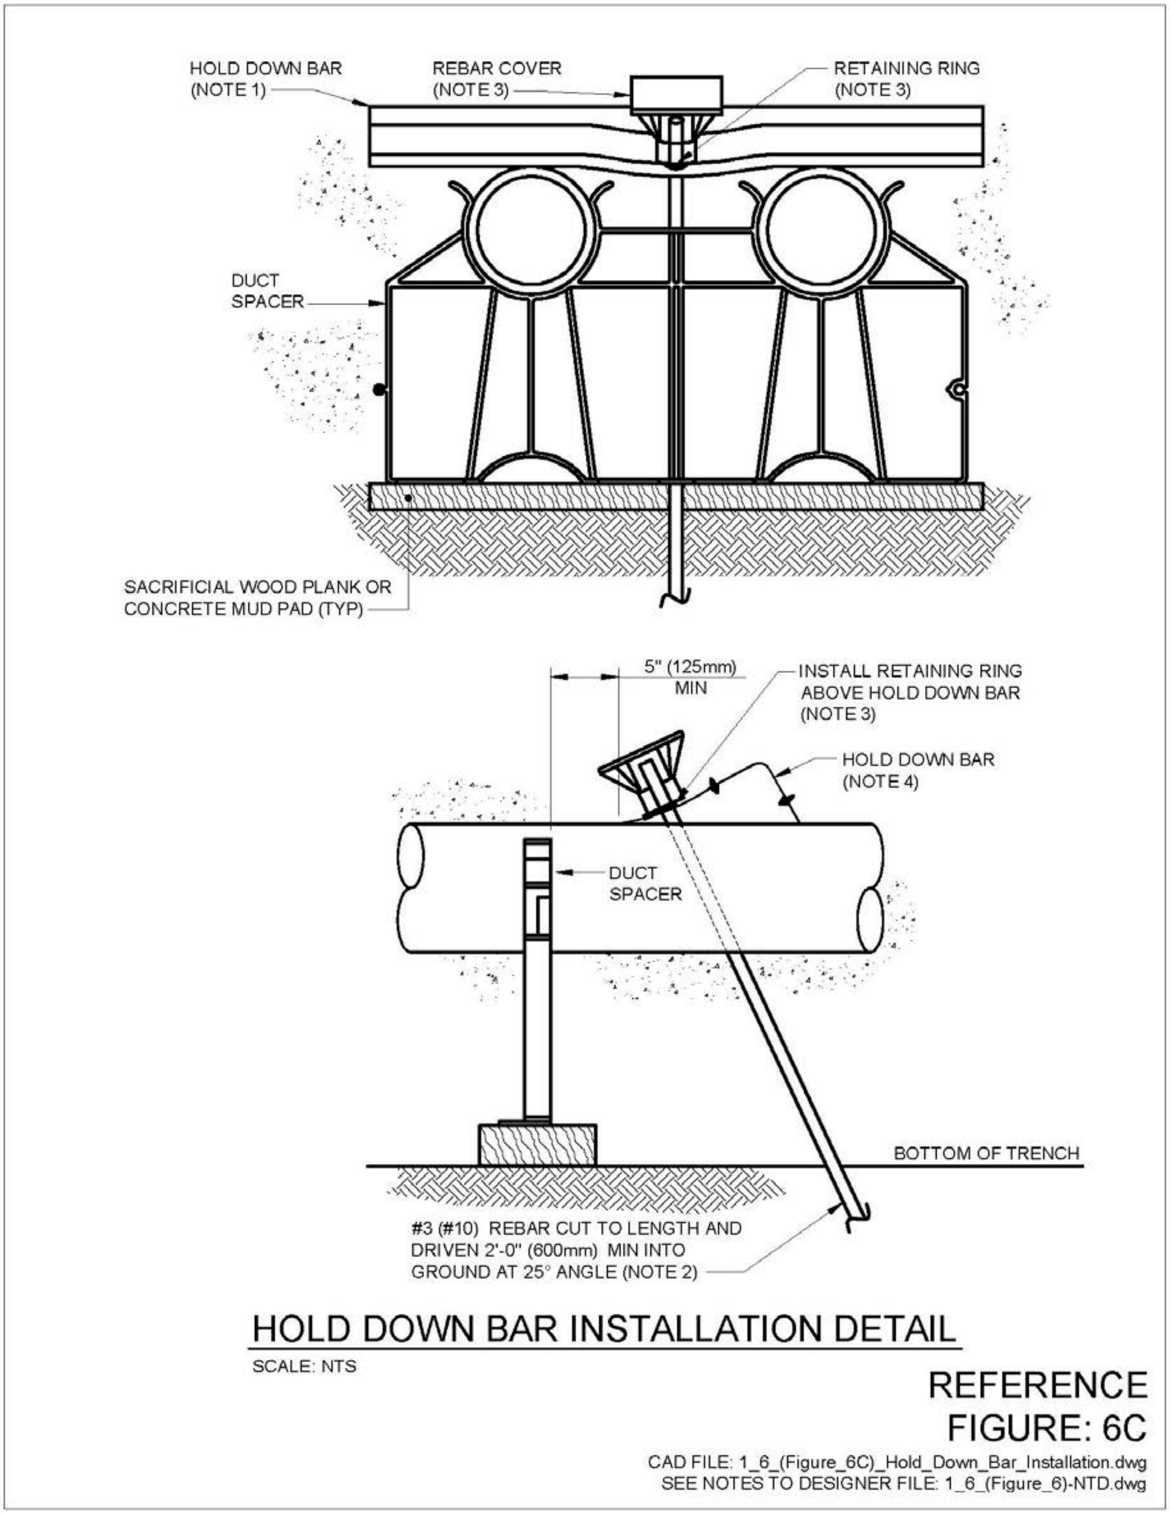

2-5 Field Attached Plug-in Splice FAA Type L-823.

2-5.1 Figures 7A, 7B.

2-5.1.1 Notes to Designer.

1. If heat-shrink tubing is used, it is recommended that single piece heat-shrink tubing and sealant be applied only at each end of the splice. Tubing with sealant coated on the entire interior will actually adhere to the L-823 connector thereby requiring a new connector be installed every time the splice is entered.

2. The cable ties act as an indicator to maintenance personnel for the location of the mating faces on the connector. When maintenance personnel need to enter the splice, the tubing is cut between the two ridges formed by the cable ties. Each piece of the tubing may now be rolled back to expose the connector. To re-seal the splice, the old tubing is removed and a new piece of heat-shrink with sealant at ends is installed.

3. The designer should contact several manufacturers of L-823 splice connectors and become familiar with their recommended installation requirements. See Figure 7B.

4. Make cable conductor connections using a crimping tool designed to make a complete crimp before the tool can be removed.

2-5.1.2 Drawings Notes for Figure 7A.

1. Interior pin and sockets are not indicated for clarity.

2. Attach each cable tie 1/8" (3mm) from the mating face of the connector housing. Tighten cable tie enough to hold in place without compressing housing. Trim off excess cable tie.

3. Installation of L-823 and heat shrink tubing must be in strict conformance with manufacturer’s requirements.

2-5.1.3 Drawings Notes for Figure 7B.

1. Contractor must provide cable circuit identification markers attached to both sides of each cable connection.

2. Attach cable identification markers with corrosion resistant material.
3. Thoroughly clean the cable prior to the installation of the L-823 connector kit.

4. Complete installation of the pin/receptacle with “crimping” tool supplied or recommended by the manufacturer and designed for this specific purpose. Two crimping tools must be turned over to the government upon completion of the project.

5. Attach each cable tie enough to hold in place without compressing housing. Trim off excess cable tie.

6. Installation of complete kit connector must be in strict conformance with manufacturer’s requirements.

CHAPTER 3 Runway and Taxiway Lighting

3-1 Fixture Installation Tolerances.

Figure 8. Reserved.

3-1.1 Notes to Designer.

Tolerances below must be indicated in the airfield lighting system specifications.

Light Fixture Installation Tolerances

	IN-PAVEMENT	ELEVATED
ELEVATION (relative to finished pavement surface for in-pavement; relative to finished grade at fixture for elevated)	+0", -1/16" (1.6mm) (fixture edge on low side in snow areas or on high side in non-snow areas) +1/4" (6mm), -0"	
AZIMUTH (*) (w/respect to line parallel to RW/TW centerline)	±1/2 degree	±1/2 degree
LEVEL	±1/2 degree	±1/2 degree
STATIONING (in line parallel to RW/TW centerline)	±2" (50mm)	±2" (50mm)
OFFSET (perpendicular to RW/TW centerline)	±1/4" (6mm)	±1/4" (6mm)

3-2 Base Mounted Elevated Fixture Installation.

3-2.1 Figure 9.

3-2.1.1 Notes to Designer.

1. Flexible conduit, if required, allows for minor adjustments in alignment during installation and also allows flexibility of the conduit runs during freeze/thaw cycles in cold climates. Conduit must meet the requirements of NEMA TC12 and should be at least 12" (300mm) long.

2. Many contractors will purchase L-867 bases and send them to pre-cast shops for the concrete encasement. Conduit stubs are slid through the grommets prior to casting. A minimum of 6" (150mm) should be protruding from the encasement to allow installation of the conduit couplings.

3. Some installations have underdrains around the runway or taxiway. The designer should review the profile of the lighting system together with the profile of the pavement. For Air Force and Army airfields, bases at the low point should be ordered with an additional hub and a 2" (53mm) conduit should be connected between the underdrain and the light base. Where there is no underdrain exists, the conduit may run to the closest storm water catch basin. For Navy airfields, the bottom drain is not used. Maintain slope so that water drains out of light base toward underdrain or catch basin.

4. All counterpoise will be solid bare copper wire (conductor) #6 (16 square mm) minimum (Air Force/Army) and stranded bare copper wire (conductor) #4 (25 square mm) minimum (Navy), and will be bonded to ground rods using exothermic welds.

5. For installations in existing pavement that do not require new conduit, and where no counterpoise is available, add an external ground rod outside of light base, and connect it to the base can with #6 (16 square mm) solid bare copper wire (Air Force/Army) or #4 (25 square mm) stranded bare copper wire (Navy). Use exothermic welds to connect the ground wire to the ground rod. Exothermically weld a one-hole ground lug to the wire, and bolt the lugs together.

3-2.1.2 Drawings Notes for Figure 9.

1. Standard height is 14" (350mm). Height may be adjusted in areas subject to snow conditions.

2. Air Force / Army Airfields: Ground rod location is outside the base can on the side adjacent to the counterpoise and connected to the external ground lug and reinforcement cage. Provide 12" (300mm) separation from counterpoise. Navy Airfields: Connect the counterpoise to the external ground lug and reinforcement cage.

3. Air Force / Army Airfields: Bottom drain is optional. Navy Airfields: Bottom drain not required.

4. Provide 48" (1200mm) braided copper grounding strap equivalent to #6 (16 square mm) wire.

Figure 9. Base Mounted Elevated Fixture Installation

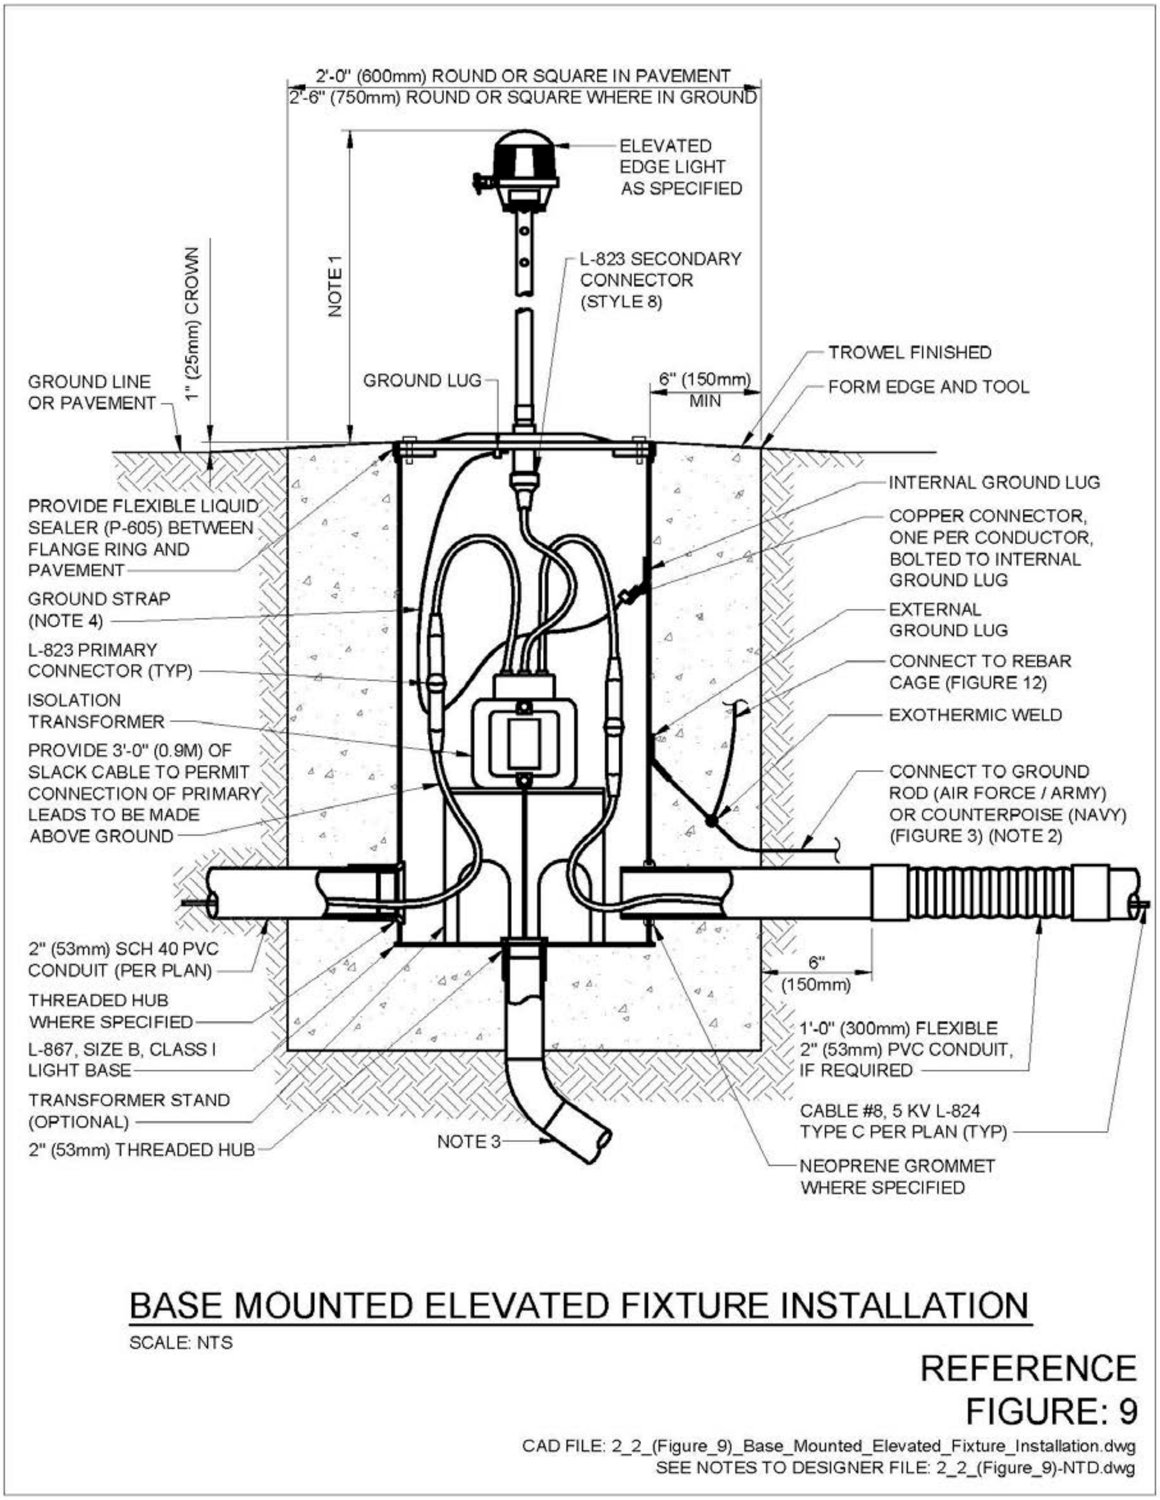

Figure 10. Reserved.

3-3 In-Pavement Runway Light (Deep Base).

3-3.1 Figures 11A, 11B.

3-3.1.1 Notes to Designer.

1. All in-pavement lights should be installed on a load-bearing base FAA type L-868. The diameter of the base will depend on the fixture manufacturer and type of fixture being installed.

2. It is recommended that the fixture be set inside a flange ring that has an integral pavement ring. Spacer rings (or shims) should be set on top of the base and the flange ring will mount on top of the spacer rings. This allows lowering of the fixture in flexible pavements if the pavement is slumping. No more than 2 spacer rings should be used.

3. The sealing compound must be compatible with the adjacent pavement material and the contractor must follow the manufacturer's preparation instructions.

4. It is recommended that the designer should review the profile of the in-pavement lighting system and provide drainage at the low points.

5. Installation methods for in-pavement fixtures are also contained in advisory circular (AC) 150/5340-30, Design and Installation Details for Airport Visual Aids.

6. For installations in existing pavement that do not require new conduit, no counterpoise is required.

7. This detail covers runway and taxiway airfield lighting fixtures installed in a deep base.

3-3.1.2 Drawings Notes for Figure 11A.

1. Refer to Figure 12 for base installation details.

2. Air Force / Army Airfields: Ground rod location is outside the base can on the side opposite the counterpoise and connected to the external ground lug. Navy Airfields: Connect counterpoise to external grounded lug and reinforcement cage.

3. Air Force / Army Airfields: Bottom drain is optional. Navy Airfields: Bottom drain not required.

4. Provide 48" (1200mm) braided copper ground strap between light base can and light fixture. Strap must be equivalent to No. 6 (16 square mm) cable.

3-3.1.3 **Drawings Notes for Figure 11B.**

1. Refer to Figure 12 for base installation details.

2. Two-piece stainless steel locking washer. Do not use split-ring type.

3. Spacer rings may be required for proper alignment of the light fixture.

4. Do not use anti-seize compound on ceramic-metallic fluoropolymer coated bolt.

Figure 11A. In-Pavement Fixture Installation (Deep Base)

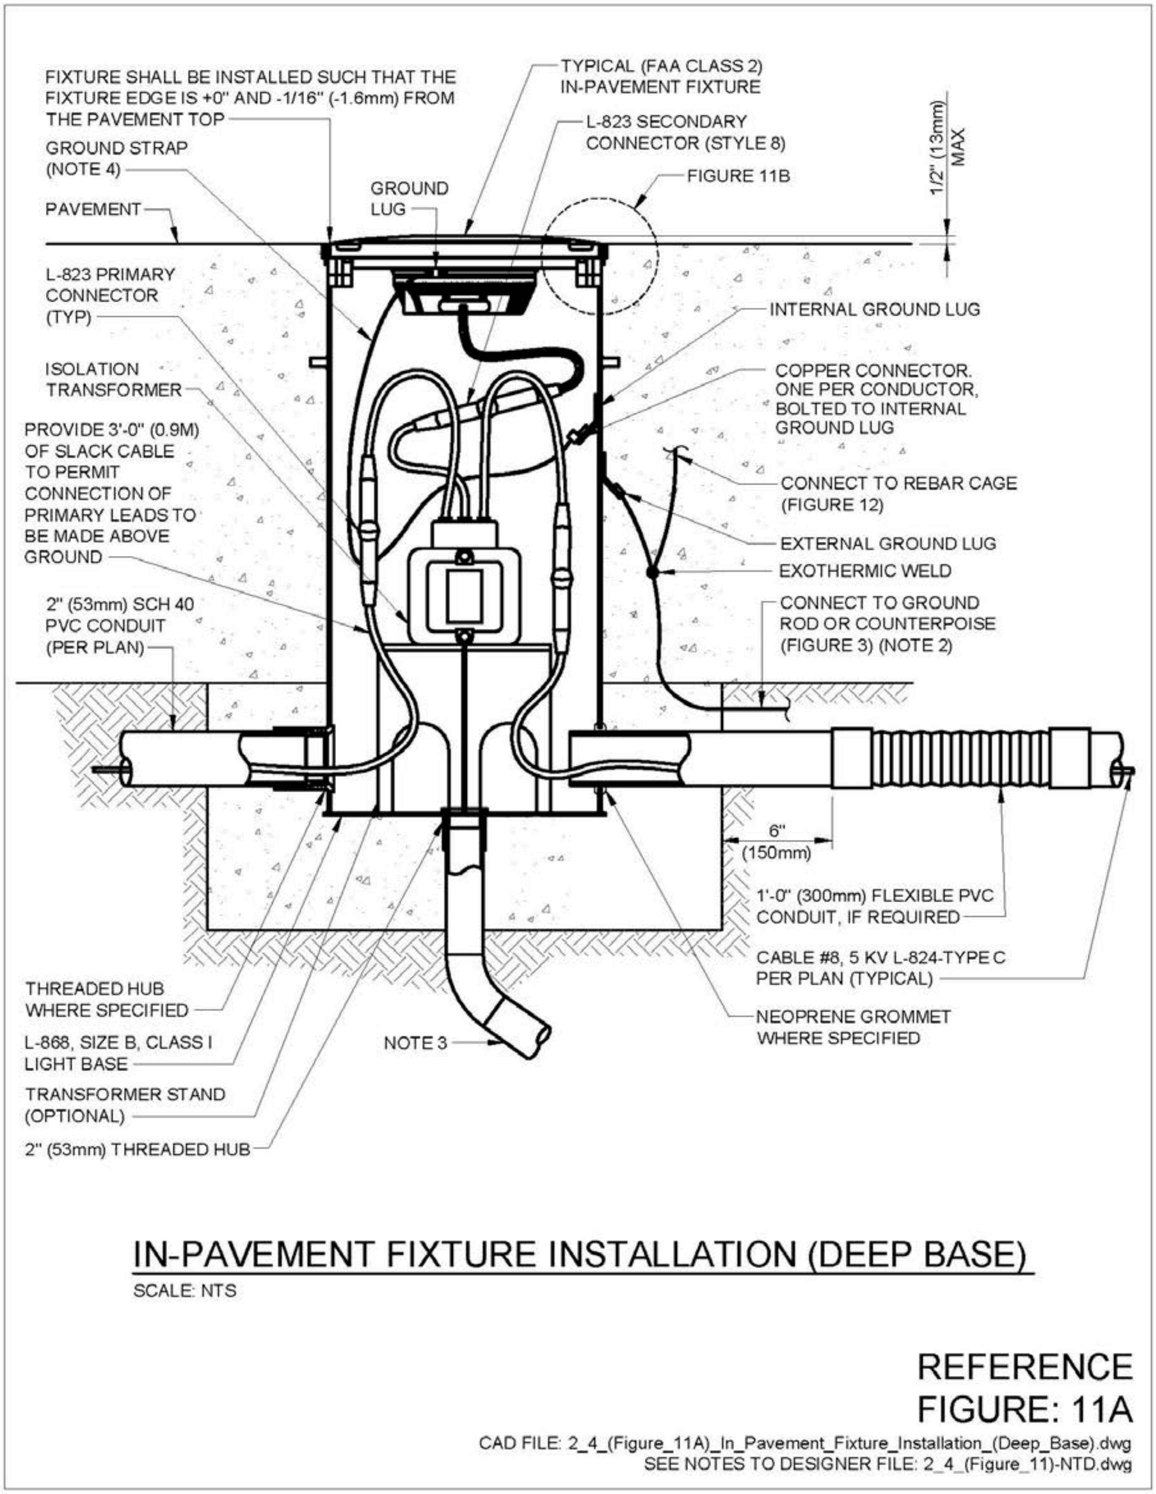

Figure 11B. In-Pavement Light Detail (Deep Base)

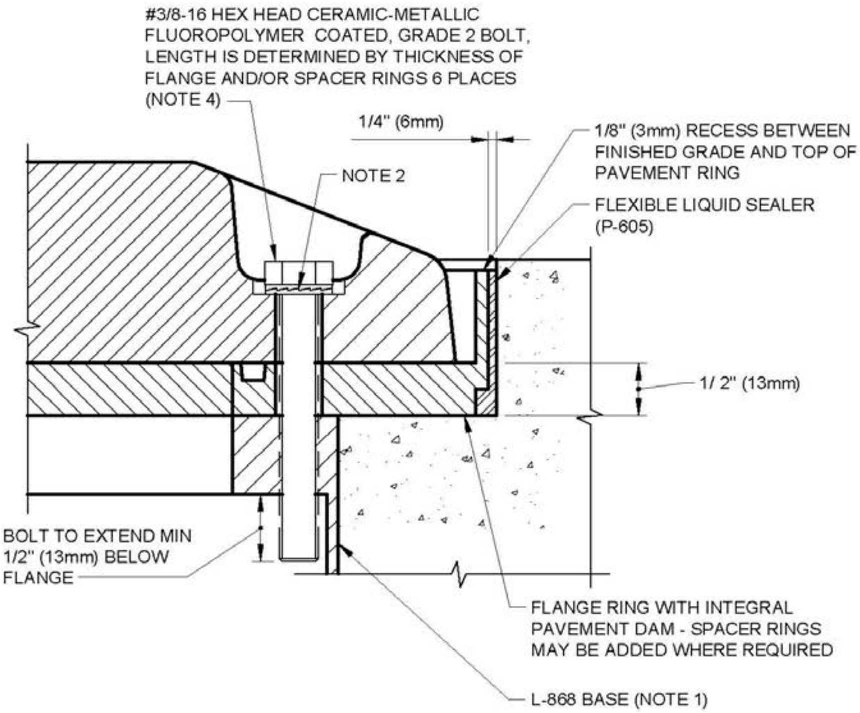

IN-PAVEMENT LIGHT DETAIL (DEEP BASE)

SCALE: NTS

REFERENCE

SEE NOTES TO DESIGNER FILE: 2_4_(Figure_11)-NTD.dwg

3-4 Base and Anchor Details (New Construction).

3-4.1 Figure 12.

3-4.1.1 Notes to Designer.

1. Construction methods will be specified in the project specifications for the type of pavement. Details should be indicated on the drawings in enough detail to complement the specifications.

2. Preparation for the base and anchor in either rigid or flexible pavement is the same. At each light location a hole is excavated in the sub base which will be minimum 12" (300mm) wider than the light base and 6" (150mm) below the bottom of the light base. A trench is excavated between the light base locations for the conduit. Depth of the trench must provide a minimum 2" (50mm) cover over and 3" (75mm) below the conduit and also allow the conduit to enter the base at the proper elevation.

3. A single section light base is used in rigid pavements and a two or three section light base (depending on pavement depth and lifts) must be used in flexible pavements.

4. The flexible conduit allows for minor base adjustments before the concrete anchor hardens.

5. A reinforcement cage is installed around the light base in rigid pavement.

6. For flexible pavement, a 2-piece light base may be used as an alternative to a 1-piece base.

7. See The Design, Installation, & Maintenance of In-Pavement Airport Lighting (Reference book by Arthur S. Schai). Available from FAA website:

http://www.faa.gov/airports/engineering/airport_lighting/media/schai_airport_lighting.pdf

3-4.1.2 **Drawings Notes for Figure 12.**

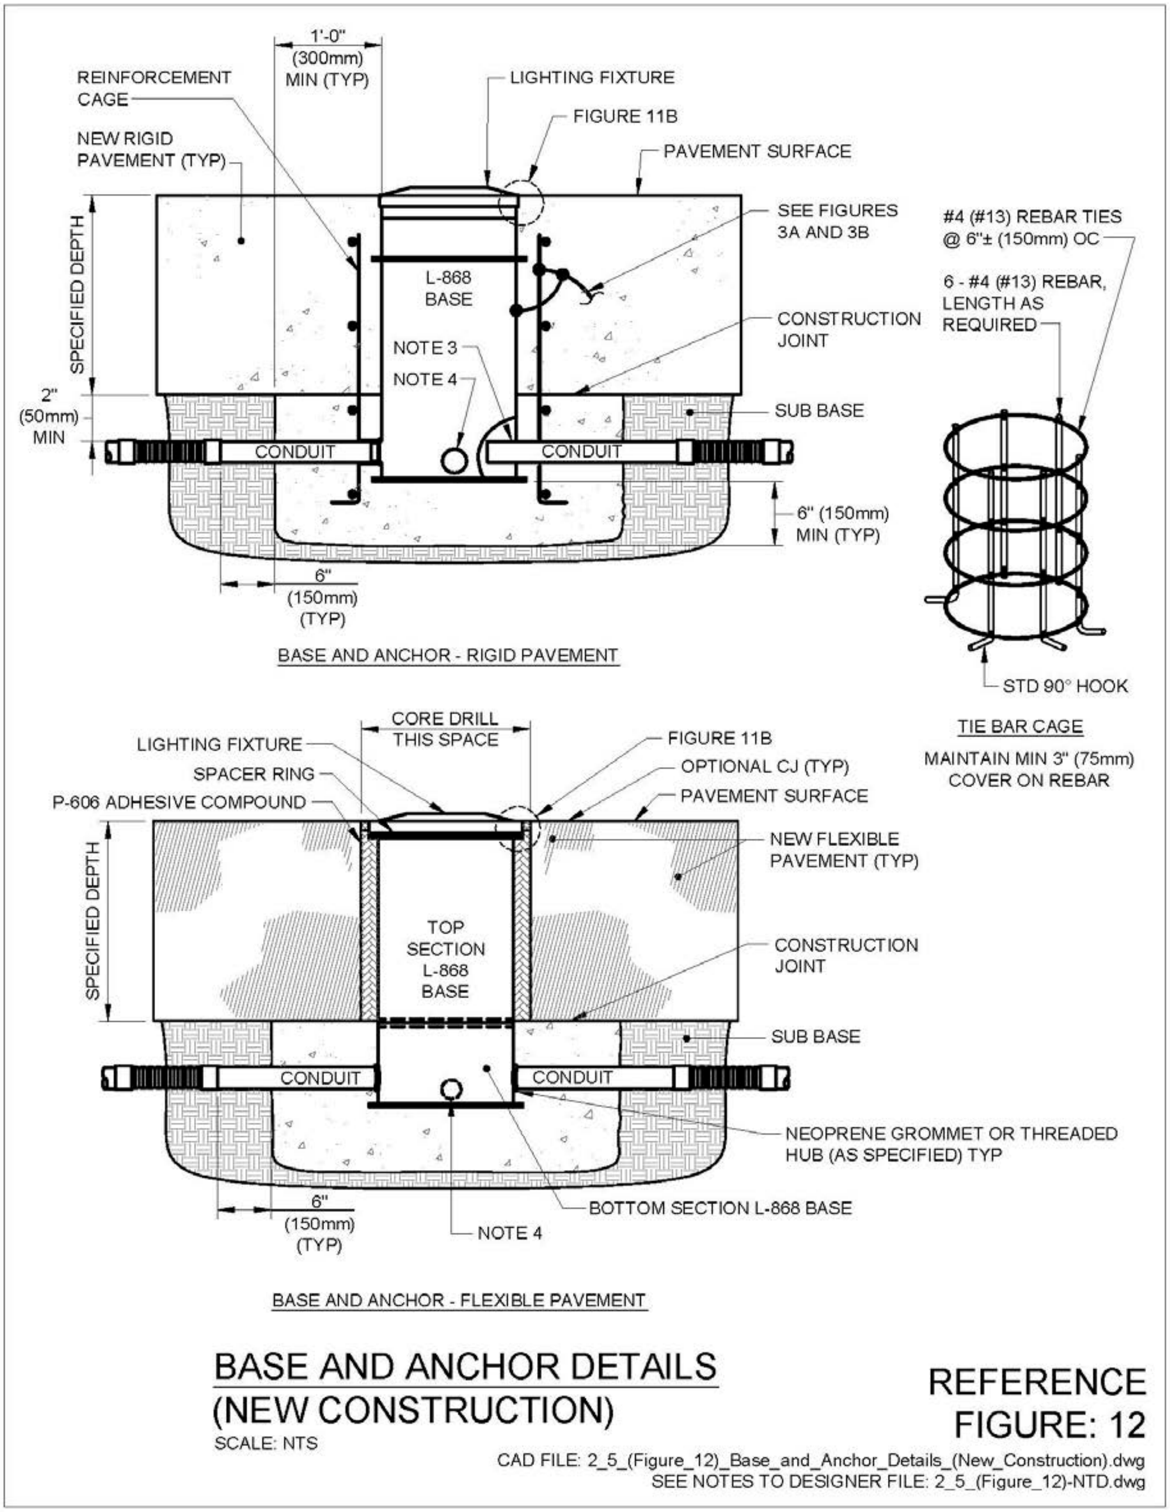
1. The use of mud plates, spacer rings, extensions, etc., is dependent on paving techniques.

2. Orientation tolerance for the base is ±1/2 degree from the centerline indicated on the plans.

3. Conduit entrance can be made with either a hub or grommet. If grommet is used, conduits must protrude into light base not more than 3/4" (19mm) for steel and 1" (25mm) to 1-1/2" (38mm) for PVC.

4. Air Force / Army Airfields: 2" (53mm) PVC conduit to nearest catch basin or French drain is optional, typically at each low point of lighting system. Navy Airfields: Side drain not required.

Figure 12. Base and Anchor Details (New Construction)



3-5 Deep Base Installation in Rigid Pavement (New Construction).

3-5.1 Figure 13.

3-5.1.1 Notes to Designer.

1. Light location, elevation, azimuth (direction of the light beam measured in a horizontal plane) is extremely critical. It is recommended that contract documents require all points for setting the lights be accomplished by survey and a mandatory construction meeting be included with representatives from the Architect-Engineer (A/E) team, contractor, government and field personnel. The purpose of this meeting will be to review the proposed construction techniques.

2. For flexible pavement, a two-piece light base may be used as an alternative to a one-piece light base.

3. See The Design, Installation, & Maintenance of In-Pavement Airport Lighting (Reference book by Arthur S. Schai). Available at the FAA website:

http://www.faa.gov/airports/engineering/airport_lighting/media/schai_airport_lighting.pdf

3-5.1.2 Drawings Notes for Figure 13.

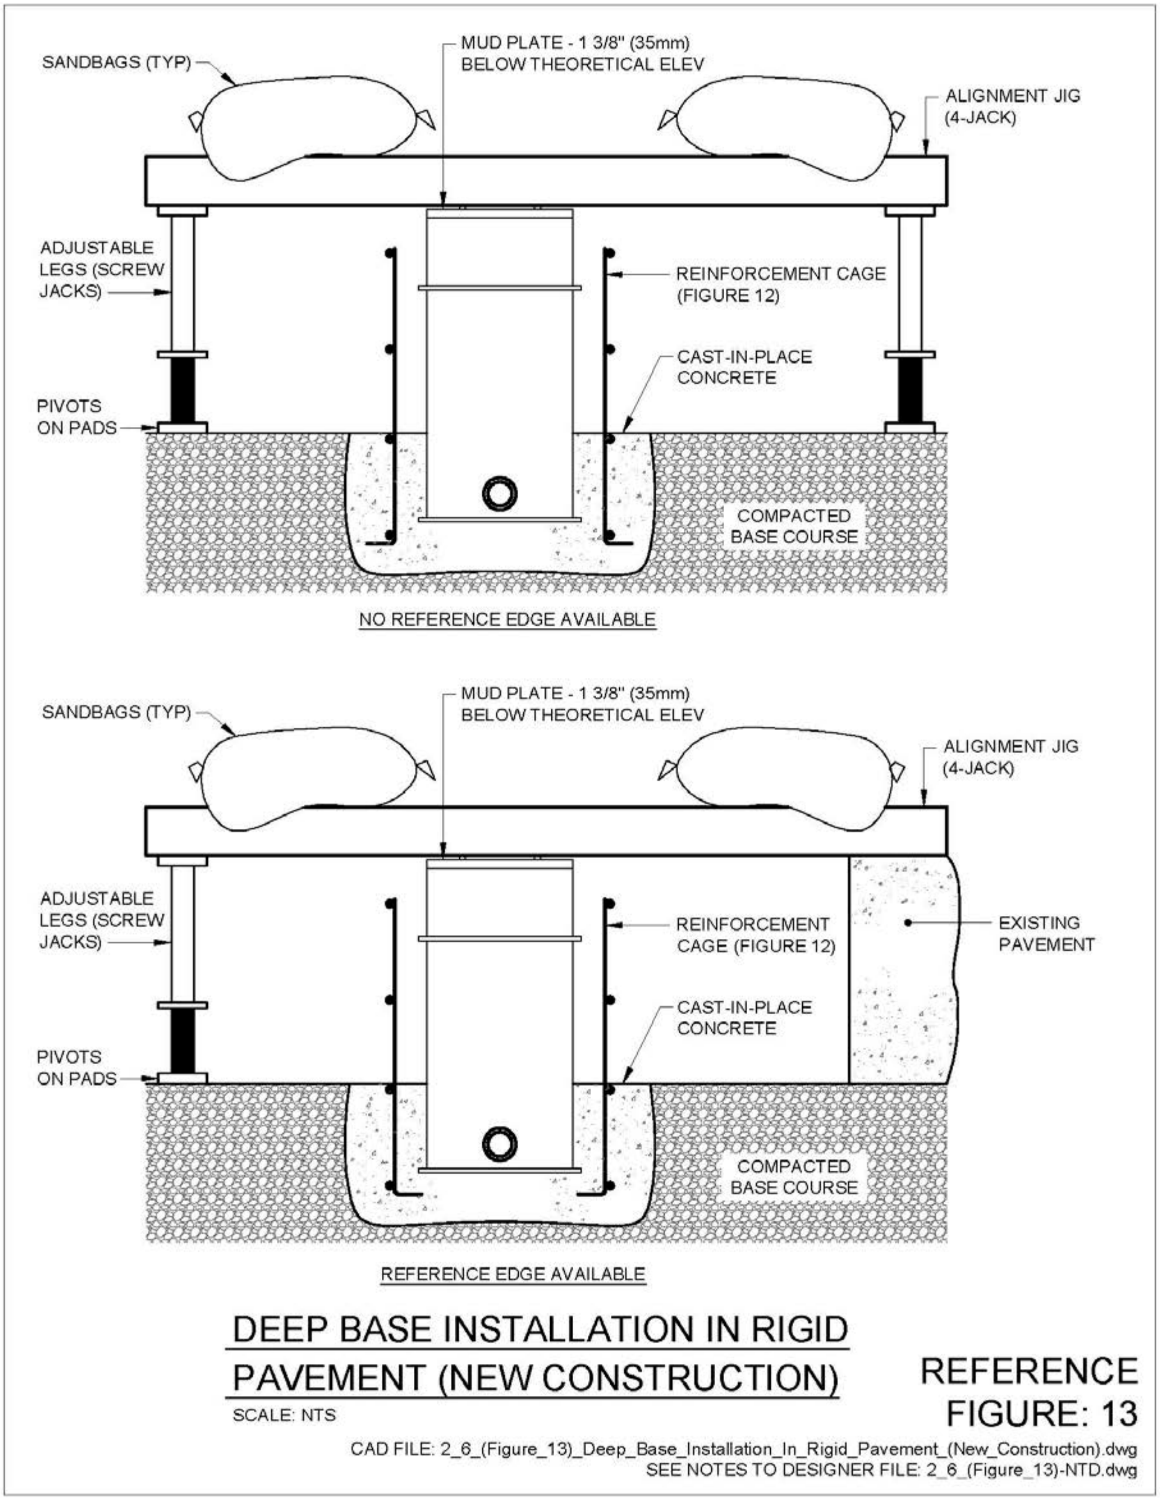
1. Install the alignment jig per the base manufacturer's requirements. The jig should be provided with adjustable legs for setting elevation and alignment pins for setting azimuth.

2. Once light bases are set at correct elevation, conduit is installed between the bases and reinforcement cages are formed around the base. Sufficient weight, such as sand bags, should be placed on top of the jig to prevent the light base from floating during concrete installation. The concrete anchor is poured around the base and along the conduit trench. Instruct the contractor to ensure that all voids or loose material beneath the conduit have been eliminated prior to encasing in concrete. Concrete should be flush with sub base and not protrude above sub base.

3. Once the concrete has cured a minimum of 24 hours, the jig may be removed.

4. Paving cannot commence until light base concrete anchor has cured for 3 days or reached a strength of 3000 psi.

Figure 13. Deep Base Installation in Rigid Pavement (New Construction)



3-6 Flexible Pavement or Overlay (Flexible, Rigid) Installation.

3-6.1 Figure 14.

3-6.1.1 Notes to Designer.

1. Installation in flexible pavement is similar to rigid except a sectional base is used and there is no reinforcement cage.

3-6.1.2 Drawings Notes for Figure 14.

1. Typical installation in new flexible pavement or overlay of flexible or rigid (PCC) pavement.

2. Two-piece stainless steel locking washer. Do not use split-ring type.

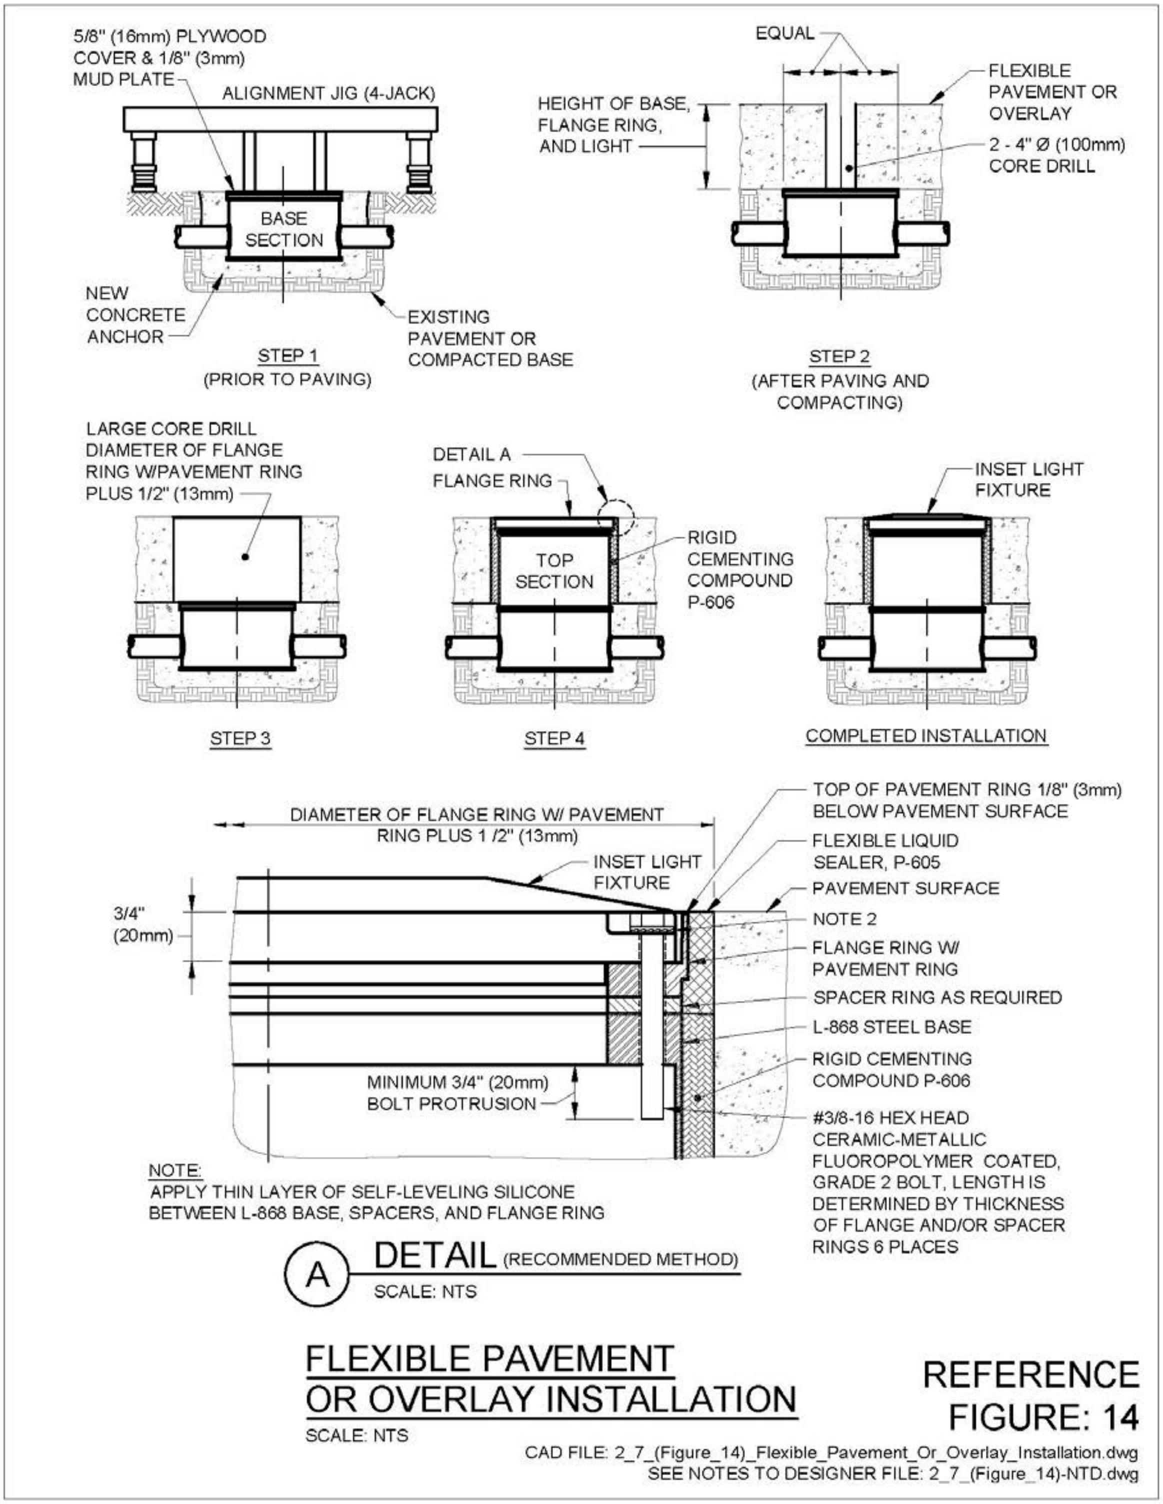
3. The bottom section of the light base is set at an elevation such that the top of the plywood cover and mud plate is flush with the surrounding base course. The concrete anchor is poured and allowed to cure for 24 hours.

4. The jig may then be removed and paving operations may be accomplished.

5. Ensure core drilling for the light bases is accomplished after compaction has been completed and the pavement has been accepted by the government.

6. Rigid Cementing Compound P-606 is used to firmly set the top section or base extension in place and bond to pavement. The flexible P-605 is installed from the top of the top section or base extension to the top of the finished pavement surface. This allows future adjustment of the fixture by removing or adding spacer rings without disruption of the base. Both P-606 and P-605 must be specified as being compatible with type of pavement being installed.

Figure 14. Flexible Pavement or Overlay Installation



3-7 In-Pavement Light Fixture on Full Base and Snow Plow Ring in Rigid (PCC) Pavement.

Figure 15. Reserved.

Figure 16. Reserved.

3-7.1 Figures 17A, 17B, 17C, 18A, 18B, 19A, 19B.

3-7.1.1 Notes to Designer.

1. Figures 18A, 18B, 19A and 19B show the installation of an in-pavement light fixture in PCC pavement. The fixture is mounted in a snow plow ring in lieu of the standard flange ring with pavement dam. The purpose of the snow plow ring is to minimize the potential for damage to the fixture by snow plow blades (snow plow blades must be rubber or some other flexible material) during snow removal operations. Special attention should be paid to the thickness and diameter of the ring and the installation elevation.

2. Where the pavement may be higher at one side of the base than the other, the use of beveled spacer rings may be required. This allows an adjustment of the ring to compensate for the slope of pavement at the outside edge of the ring.

3-7.1.2 Drawing Notes for In-Pavement Fixtures, Figures 18A and 18B.

1. Install corner edge of snow plow ring flush with pavement surface with a tolerance of +0", -1/16" (1.6mm).

2. Submit all base can installation techniques, methods, materials, etc., to the government for review and approval prior to the start of work.

3. Before paving may proceed, the contractor must demonstrate to the government that the base cans are at the correct location, elevation, azimuth and rotation and that the proper clearance exists between the base can and the paver.

4. The spacer ring is designed as a nominal 3/4" (19mm) thickness. The spacer ring may be required to be thinner or thicker depending on base can installation and paving techniques / tolerances. This contractor must measure and determine the required thickness of each individual spacer ring required to put the airfield lighting fixture at the correct elevation, azimuth and rotation. The contractor may use multiple spacer rings of varying heights. No more than 3 spacer rings may be used on any one light installation. The maximum height displacement for one or more spacer rings will be 2" (50mm) or less.

5. The finished pavement surface must be protected from foreign substances which could cause staining, i.e. concrete, oil, etc. The contractor must immediately clean all spills and correct/clean any stained surfaces at the contractor's expense.

6. The base can cover mounting bolts must extend thru the base can mounting flange into the base can a minimum of ½" (13mm). The bolts must be threaded the full length of the bolt.

7. For blank base cans, delete light fixture and install ¾" (19mm) steel blank cover.

8. Connect to ground rod (Air Force/Army) or counterpoise (Navy) to base cans.

9. Install top of edge of snow plow ring flush with pavement surface with a tolerance of +0", -1/16" (1.6mm).

10. If the distance between the edge of the snow ring and concrete is 1/8" (3mm) or less, seal top of opening with P-605 silicone sealant and delete the P-606 compound.

11. The top of fixture must not exceed the top of the snow plow ring (+0", -1/8" (3mm)).

12. The contractor must pre-assemble in-pavement light fixture with snow plow rings to assure each individual unit assembly is within tolerance. Use a straight edge to verify the fixture is level (to 1/8" (3mm)). Any units not within this tolerance will be rejected. Assure snow plow rings are configured with correct number and width of openings.

    The contractor must install a 25" (635mm) deep base can where the PCC pavement thickness is 15" (375mm) and must install a 30" (750mm) deep base can where the pavement thickness is 20" (500mm).

13. Contractor must ensure sealant installation is in accordance with elevation tolerances of light fixture installation.

14. Contractor must ensure snow plow rings are compatible and appropriate for use with base cans and fixtures.

15. Use drainage layer and concrete for Air Force/Army installations.

16. Use the following installation tolerances for Figure 18B:

Installation Tolerance

Item	**Tolerance**
Light beam orientation	±1/2" (13mm)
Lateral spacing	±1/4" (6mm)
Fixture level	±1/2 degree in X and Y direction
Fixture elevation (low side of pavement)	+0 - 1/16" (1.6mm)
Longitudinal spacing	±1/4 degree

3-7.1.3 **Drawing Notes for Straightedge Check, Figure 19B.**

1. Straightedge should be 10' (3m) long. Notch approximately 1" (25mm) high, and about 1"-2" (25mm-50mm) longer than fixture diameter.

2. A 1/16" (1.6mm) Allen wrench is a good tool to use to determine height tolerance of fixture (or snow plow ring) relative to low side of pavement. Slide straightedge on to fixture or snow plow ring edge to measure. If straightedge rides up on the edge, fixture is too high. If edge is more than 1/16" (1.6mm) below straightedge, the fixture is too low.

3. Check straightedge in both directions to verify there is no unusual pavement build-up in the proximity of the light that might block part of the light beam.

4. A level on top of the straightedge can verify compliance with level tolerance.

3-8 Elevated Runway Guard Light/Holding Position Edge Light Detail.

3-8.1 Figures 20A, 20B.

3-8.1.1 Notes to Designer.

1. Holding position edge lights (HPL) are similar fixtures for Navy facilities. Designer must refer to NAVAIR 51-50AAA-2 for Navy requirements.

2. Elevated runway guard lights are optional at Army facilities and optional at Air Force facilities for Category I precision approach runways down to a runway visual range (RVR) of 2400' (720m). They are required at Air Force facilities that conduct operations at Category II (down to an RVR of 1200' (360m).

3. Installation of the base can and top section is similar to the installation of an elevated fixture in shoulder pavement. See Figure 9.

3-8.1.2 Drawing Notes for Runway Guard Lights, Figures 20A and 20B.

1. Power the elevated runway guard lights (RGL/HPL) from the circuit indicated.

2. Before coring in pavement may proceed, the contractor must demonstrate to the contracting officer that the base cans are at the correct location. Before casting concrete around base can, the contractor must demonstrate to the contracting officer that the base cans are at the correct elevation, azimuth and rotation.

3. Air Force/Army Airfields: Bottom drain is optional. Navy Airfields: Bottom drain not required.

4. The inside edge of the RGL housing must be 10' (3m) to 17' (5.1m) from the edge of full strength pavement. The inside edge of the HPL must be not less than 3' (0.9m) beyond the outside edge of the holding position sign for Navy airfields.

5. The finished pavement surface must be protected from foreign substances which could cause staining, i.e. concrete, oil, etc. The contractor must immediately clean all spills and correct/clean any stained surfaces at the contractor’s expense.

6. The contractor must use a heavy duty base plate for installation of the L-804 RGL/HLP. Provide stainless steel tether for RGL/HLP.

7. Installation of the base can is similar to the installation of an elevated fixture in shoulder pavement. See Figures 20A and 20B.

8. Provide braided cooper ground strap between light base can and light fixture. Strap must be equivalent to No. 6 (16 square mm) cable.

Figure 28. Reserved.

CHAPTER 4 Airfield Guidance Signs

4-1 Airfield Guidance Sign Detail.

4-1.1 Figures 29A, 29B.

4-1.1.1 Notes to Designer.

1. The L-867 base houses the sign's isolation transformer. It is typically mounted separately from the sign but within 3' (900mm) from the sign's adjacent edge. This is done to allow access to the transformer without removing the sign. The following points should be noted about the installation of the power wiring to the sign:

    a. A secondary jumper cable must be provided to connect the transformer's output cable to the sign's input cable. Though the output cable on an isolation transformer is 48" (1.2m) ± in length, do not connect this to the sign's input cable since it would defeat the purpose of mounting the isolation transformer separately.

    b. The type of retaining clips (or cable clamps) will depend on the type of mounting used for the sign's power leg (i.e. L-867 base or 2" (53mm) conduit and floor flange) and the style of L-823 connector on the secondary jumper cable. The retaining clips hold the secondary jumper cable in place below the frangible coupling.

2. Recommend the project contract documents contain specifications for the maximum VA load allowed for each size of sign. VA load should include the losses in the sign's isolation transformer.

3. The guidance sign foundation should be designed by a licensed structural engineer. The foundation will vary in thickness and reinforcing depending on the number of sign modules, sign size, and wind loading (jet blast) either 200 mph or 300 mph. Some of the factors that must be taken into account for the foundation design are:

    a. Are the signs located in an area where there is a potential for high soil saturation?

    b. Breaking point of the frangible couplings (wind speed of 200 mph or 300 mph).

c. Soil bearing capacity.

d. Concrete weight.

e. Sign weight including one, two, three or four modules.

f. Minimum 1.2 factor of safety against overturning.

g. Minimum 1.2 factor of safety against sliding.

h. Soil conditions regarding passive pressure consideration for the transformer base can below the footing.

i. There should be no tolerance for sign foundation movement.

j. Considerations for freeze/thaw conditions in areas prone to frost.

4-1.1.2 **Drawing Notes for Figure 29A.**

1. Air Force / Army: Do not connect counterpoise to the transformer base. Connect transformer base and counterpoise to separate ground rods.

2. Sign pad must have a 1/2" (13mm) chamfer on all exposed horizontal edges. Extend pad 36" (900mm) clear on all sides of sign. Slope the top surface to drain away from sign, approximately 1% (1/8"/ft) (3mm/300mm). The top of the pad must be approximately 1" (25mm) above the surrounding grade.

3. Maximum overall sign length: size 3 - 14'-2"(4290mm).

4. One tether at each end of the sign if separate sign modules are connected together within a continuous frame.

5. The frangibility point must be no greater than 3" (75mm) above the grade adjacent to the pad.

6. Surrounding grade must slope 1/4" (6mm) per foot away from the pad for 15' (4.5m). Sod or seed as required.

7. Pad thickness and reinforcing will vary depending on the length and number of sign modules installed as well as the wind loading (jet blast) expected.

4-1.1.3 **Drawing Notes for Figure 29B.**

1. Navy: Delete grounds rods. Connect counterpoise to base can.

2. Sign pad must have a 1/2" (13mm) chamfer on all exposed horizontal edges. Extend pad 36" (900mm) clear on all sides of sign. Slope the top surface to drain away from sign, approximately 1% (1/8"/ft) (3mm/300mm). The top of the pad must be approximately 1" (25mm) above the surrounding grade.

3. Maximum overall sign length: size 3 - 14'-2"(4290mm).

4. One tether at each end of the sign if separate sign modules are connected together within a continuous frame.

5. The frangibility point must be no greater than 3" (76mm) above the grade adjacent to the pad.

6. Surrounding grade must slope 1/4" (6mm) per foot away from the pad for 15' (4.5m). Sod or seed as required.

7. Pad thickness and reinforcing will vary depending on the length and number of sign modules installed as well as the wind loading (jet blast) expected.

8. For Navy Size 2 signs, distance from RW or TW can be 25' to 35' (7.5m to 10.5m) if sign height is not more than 2'-0" (0.6m) above RW or TW edge of full-strength pavement.

Figure 29A. Airfield Guidance Sign Detail (Air Force / Army)

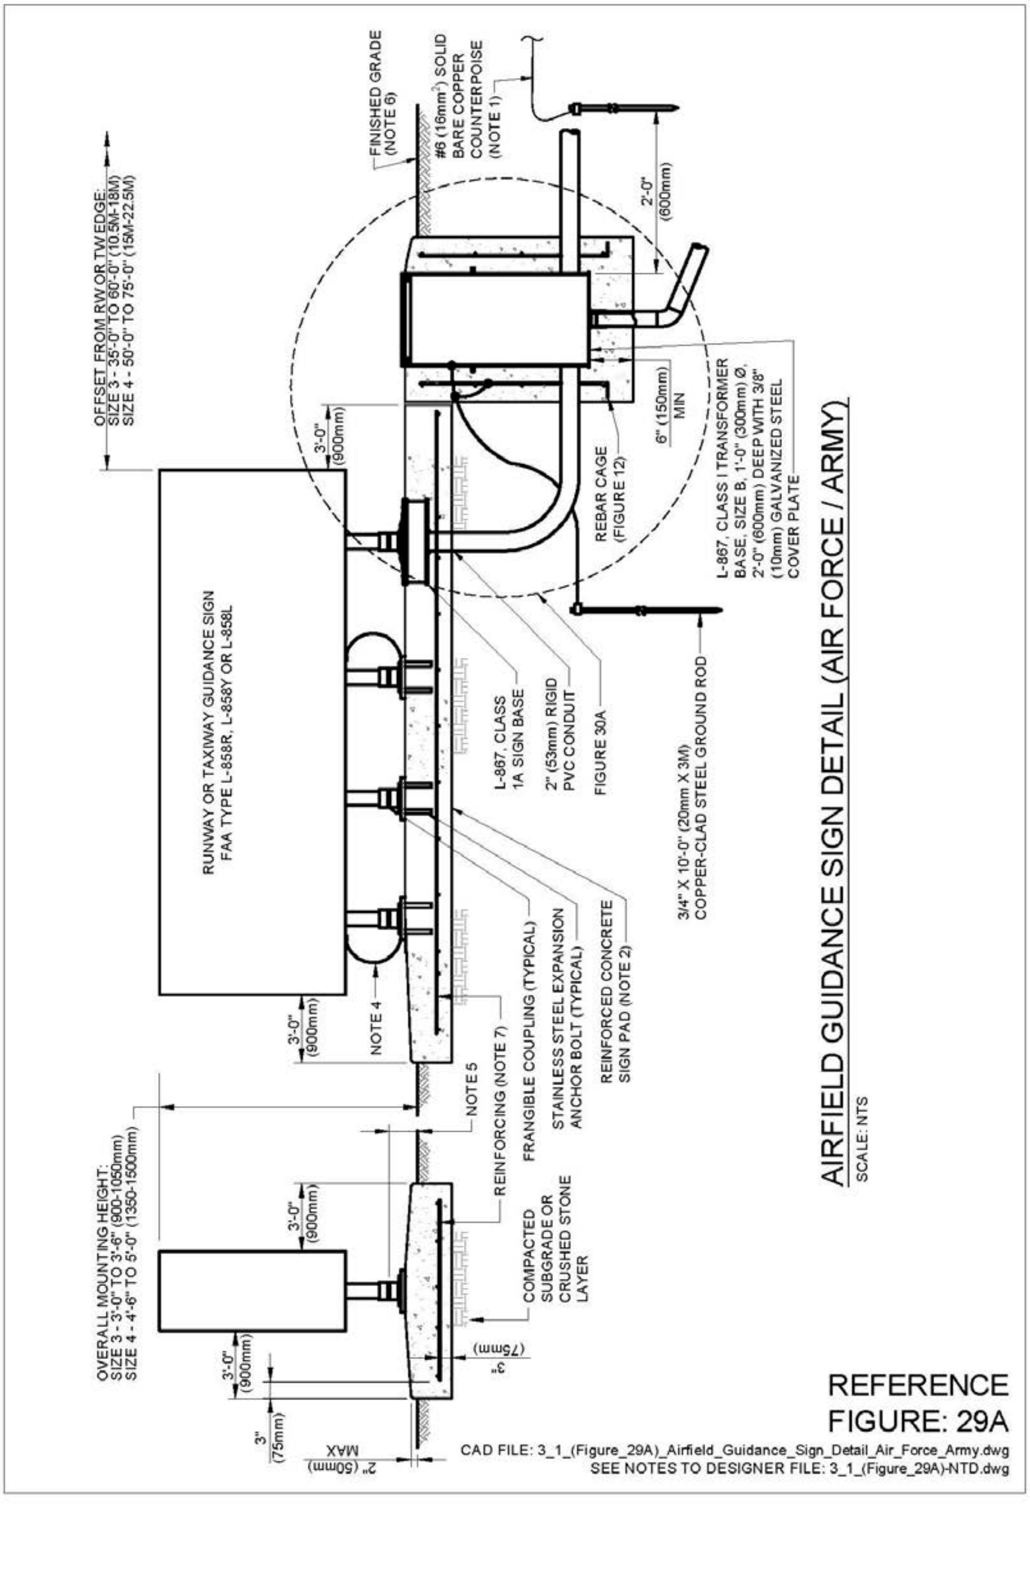

Figure 29B. Airfield Guidance Sign Detail (Navy)

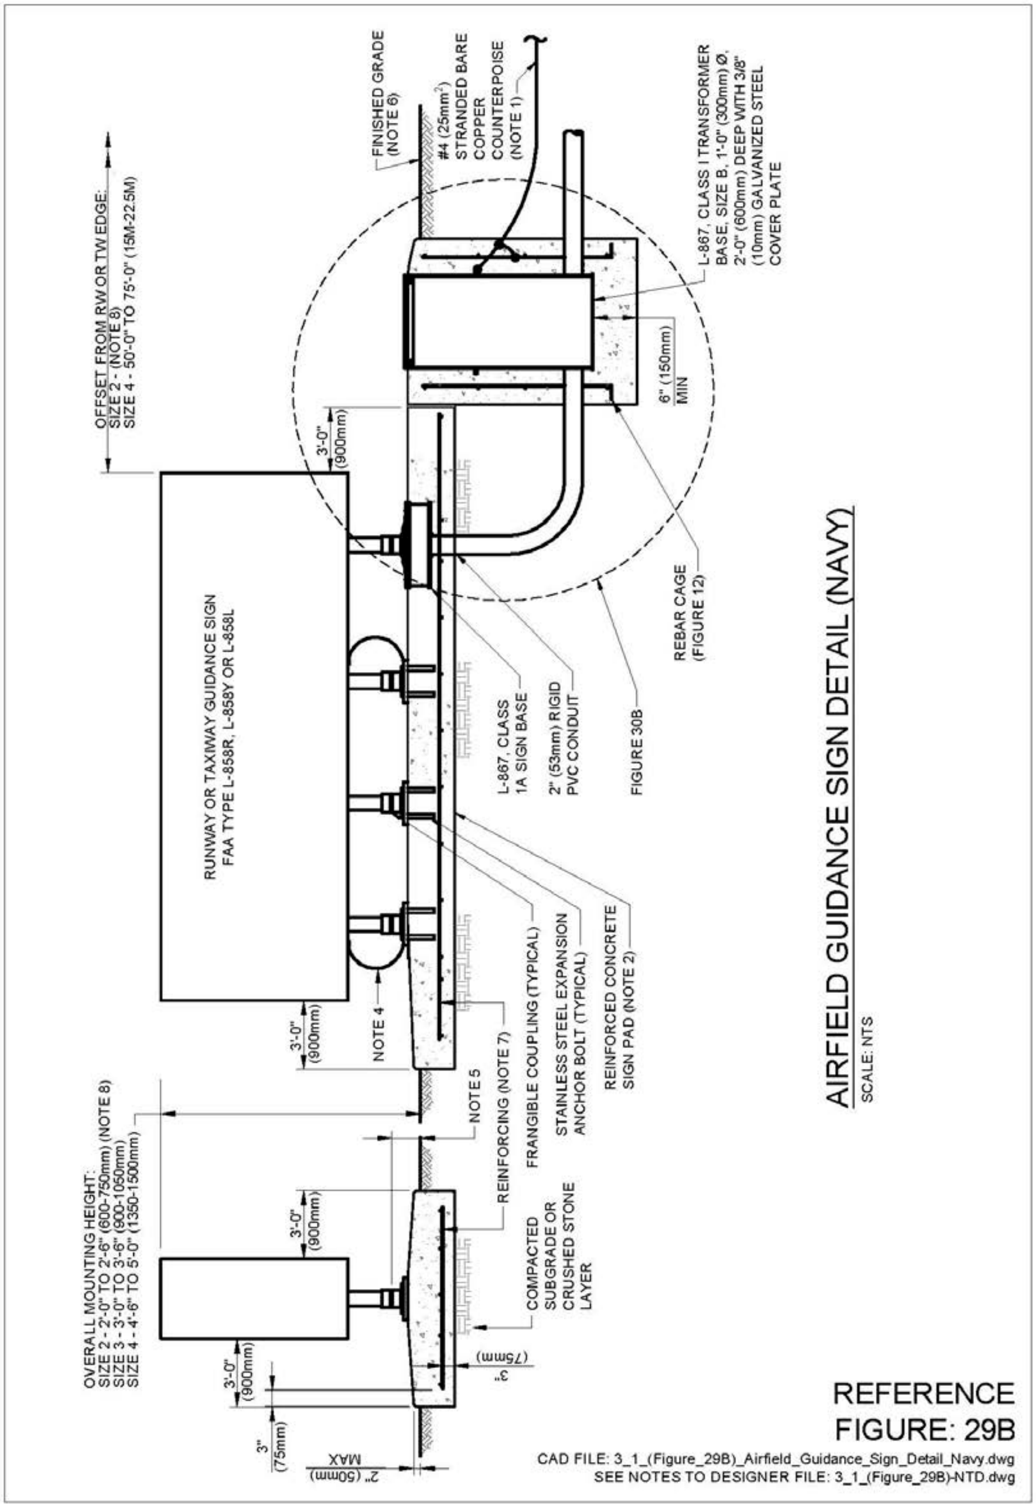

4-2 Sign Base Power Leg Mounting Detail.

4-2.1 Figures 30A, 30B.

4-2.1.1 Notes to Designer.

1. The mounting for the power leg of the sign will usually be determined by the sign designer and manufacturer options. The following details show several approved options. Details indicated on contract documents should state that installation must be in accordance with the sign manufacturer's requirements.

4-2.1.2 Drawing Notes for Figures 30A and 30B.

1. See specifications for additional grounding requirements inside the sign.

2. Grounding conductors must be THWN-2 or XHHW-2.

3. Gravel sump below fixture base is not required where drain line is run to pavement under-drain system. The preferred method for draining the base can is to route the drain line to pavement under drain system or closest catch basin. If a gravel sump (French drain) is installed, caution should be taken to prevent the undermining of the sign foundation.

Figure 30A. Sign Base Power Leg Mounting Detail (Air Force / Army)

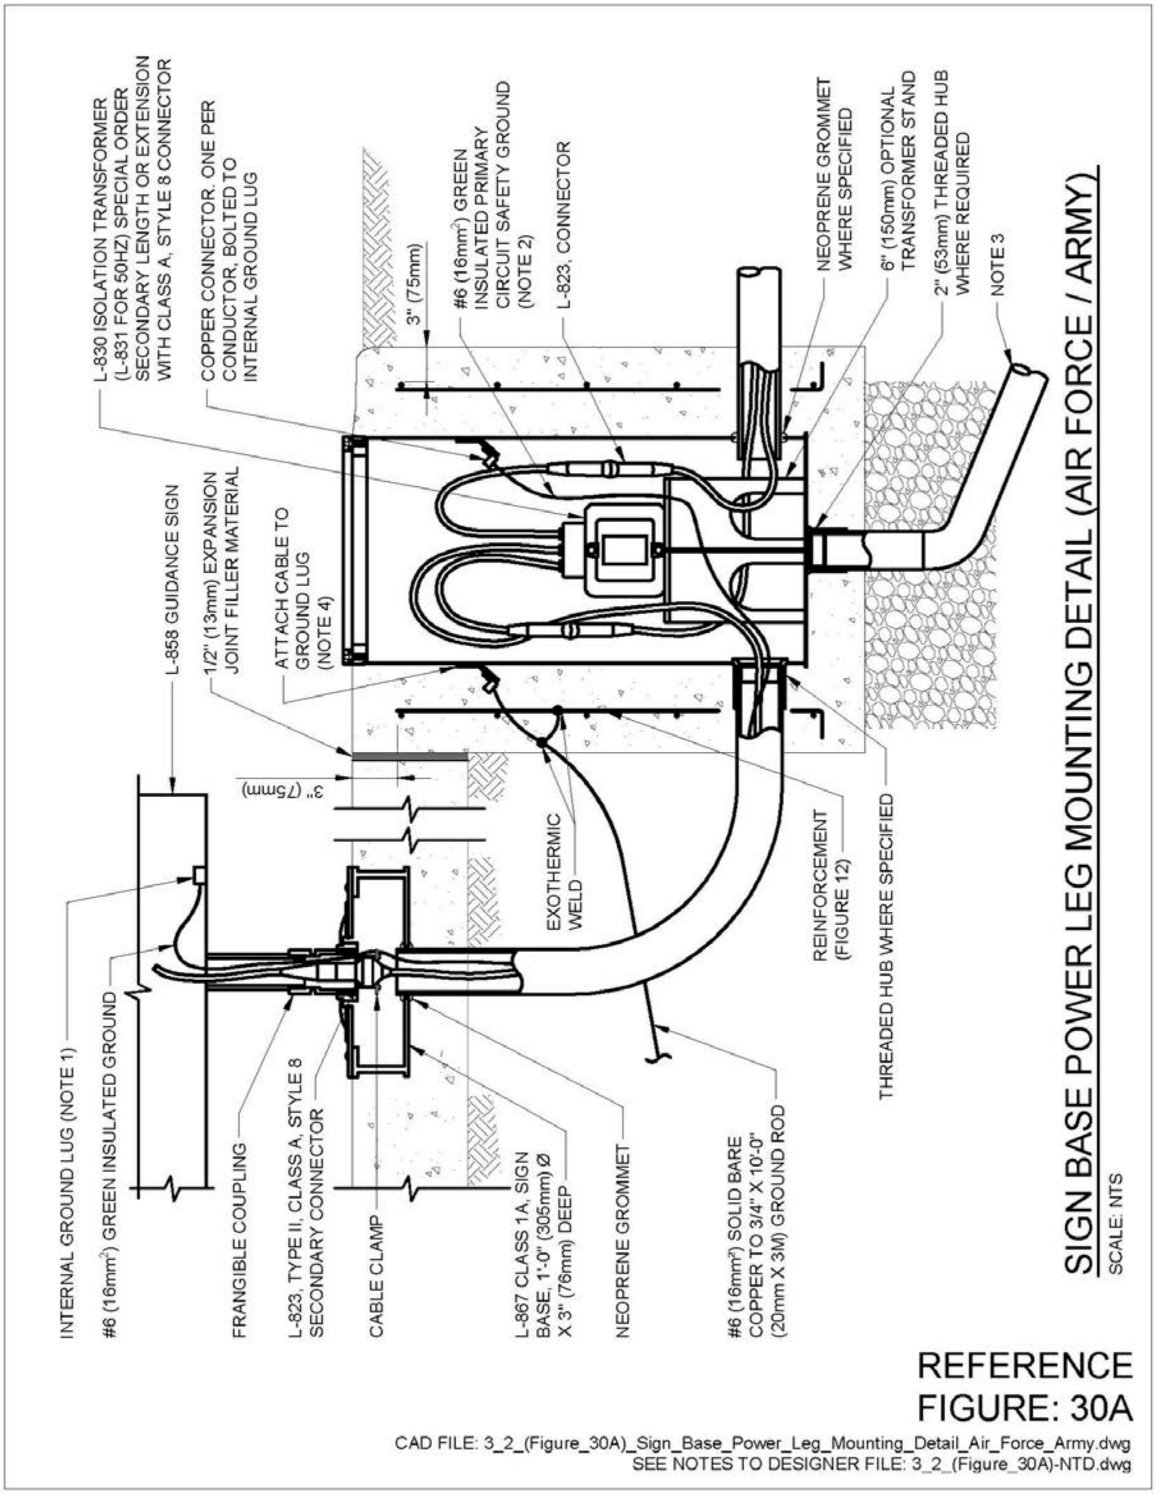

Figure 30B. Sign Base Power Leg Mounting Detail (Navy)

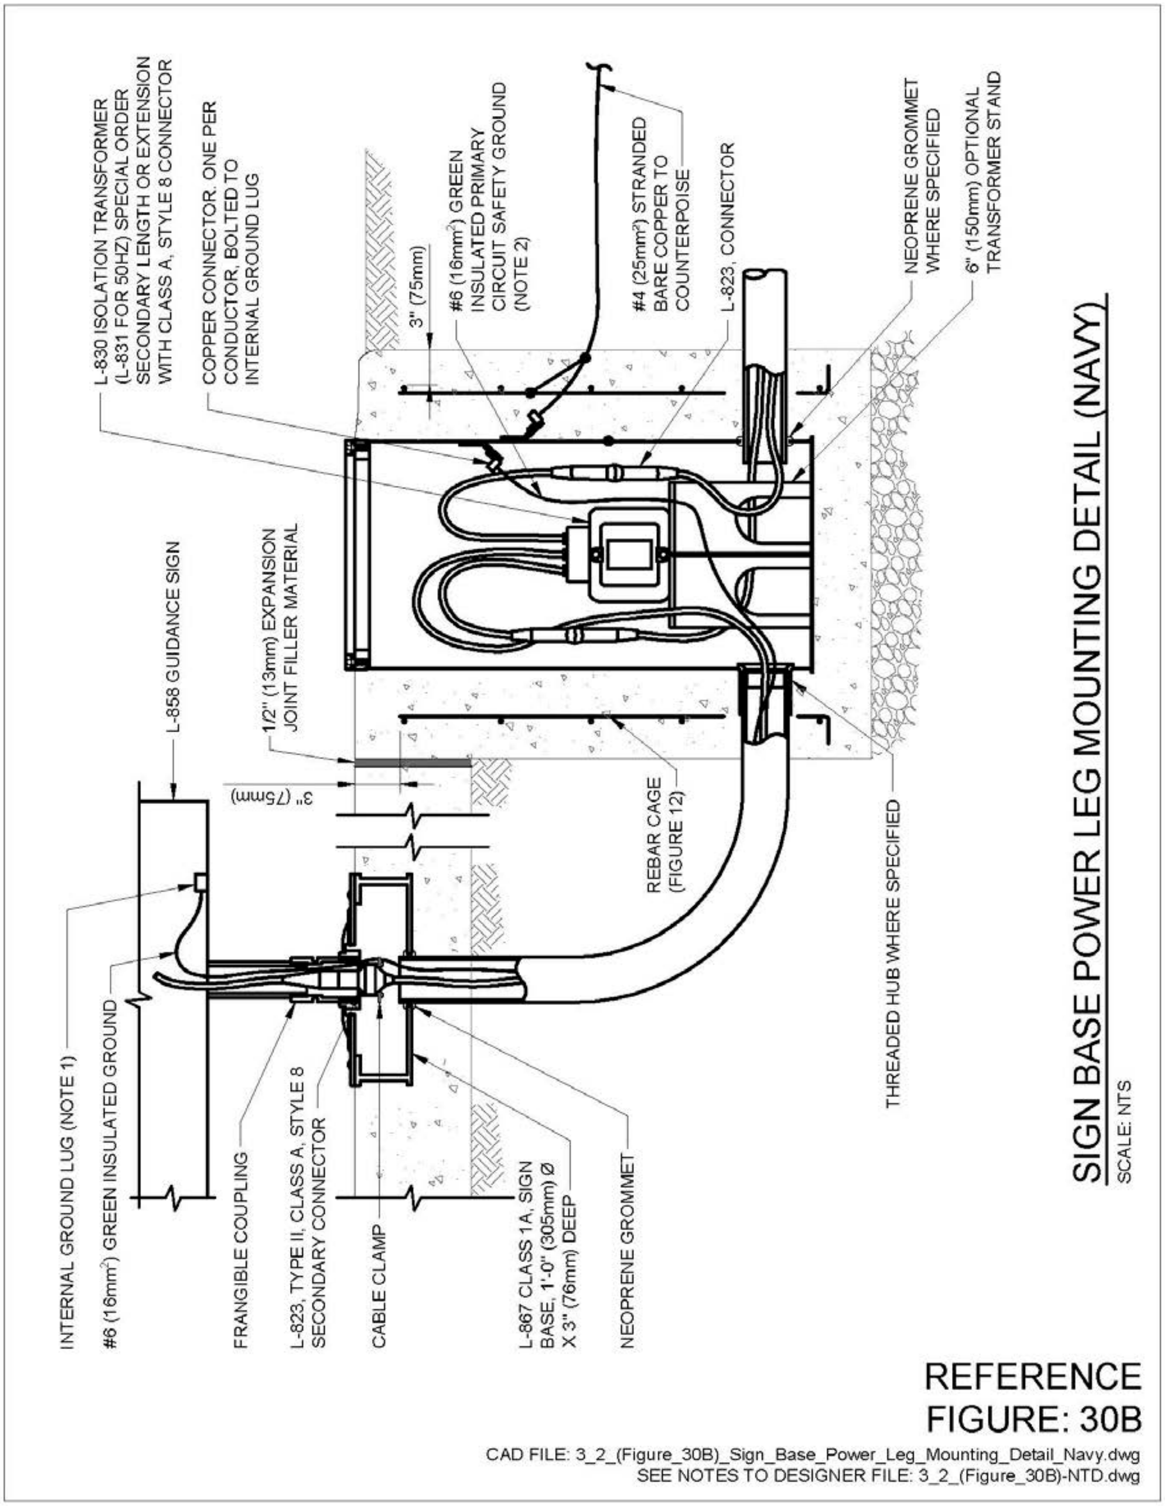


CHAPTER 5 Approach Lighting Systems

5-1 L-867 Size D Handhole.

5-1.1 Figure 31.

5-1.1.1 Notes to Designer.

1. A handhole is required at each sequenced flasher station and tower-mounted approach light station to house isolation transformers. Handholes must contain any hardware which may aid with cable pulling.

2. The flexible conduit allows for movement during freeze/thaw cycles in cold climates thereby reducing the possibility of shearing the conduits.

3. The 2" (53mm) conduit between handholes is a minimum. The actual dimension depends on the number of cables being routed. Ensure contract documents specify hub size.

5-1.1.2 Drawing Notes for Figure 31.

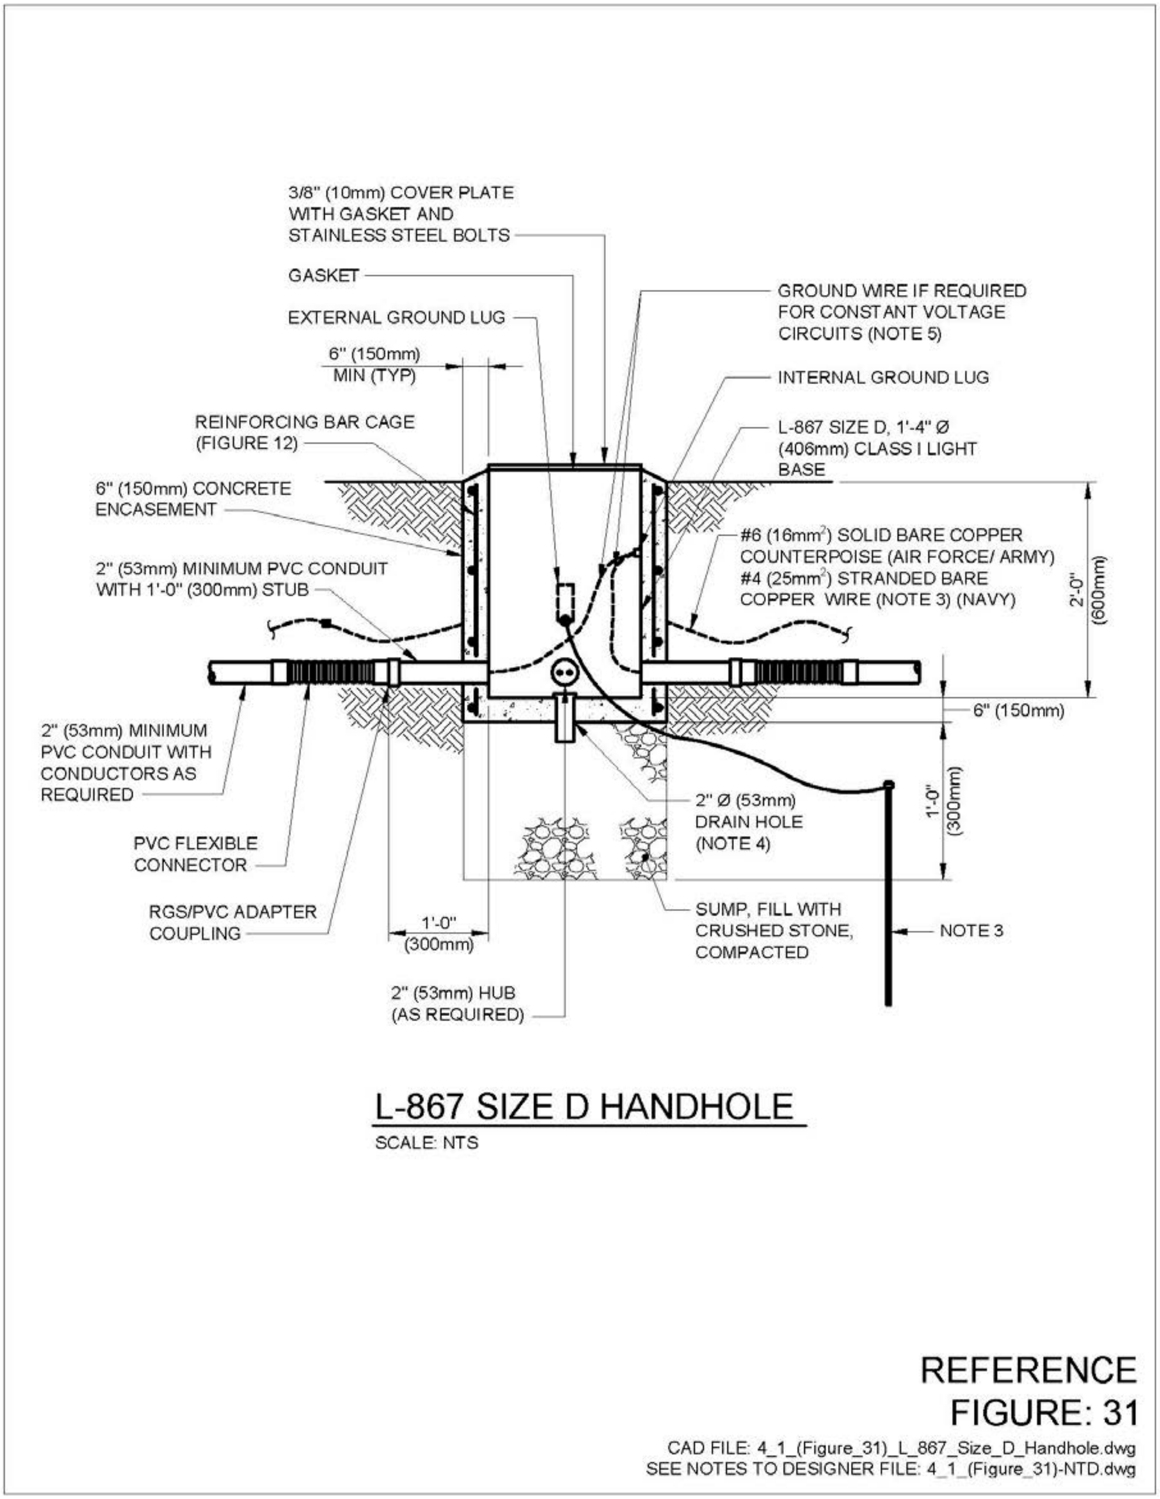
1. If constant voltage circuits are routed through the handholes the minimum #6 (16 square mm) equipment ground must be routed with the system conductors in the conduit and connected to the ground lug in each light base. It must also be bonded to the electrical ground at the system's substation (vault) power supply ground bus. Provide green insulated THWN-2 or XHHW-2 ground wire sized per NEC for constant voltage circuits.

2. The flexible connector must be PVC.

3. For Air Force / Army Airfields, connect ground rod to handhole external ground lug with #6 (16 square mm) solid bare copper and let counterpoise pass the handhole without connection. For Navy airfields, connect #4 (25 square mm) stranded bare copper counterpoise to external ground lug. Do not provide ground rod at handhole.

4. For Air Force / Army Airfields, bottom drain is optional. For Navy airfields, bottom drain is not required.

Figure 31. L-867 Size D Handhole



5-2 Voltage Driven Sequenced Flasher Power Supply and Junction Box Mounting Detail

5-2.1 Figure 32.

5-2.1.1 Notes to Designer.

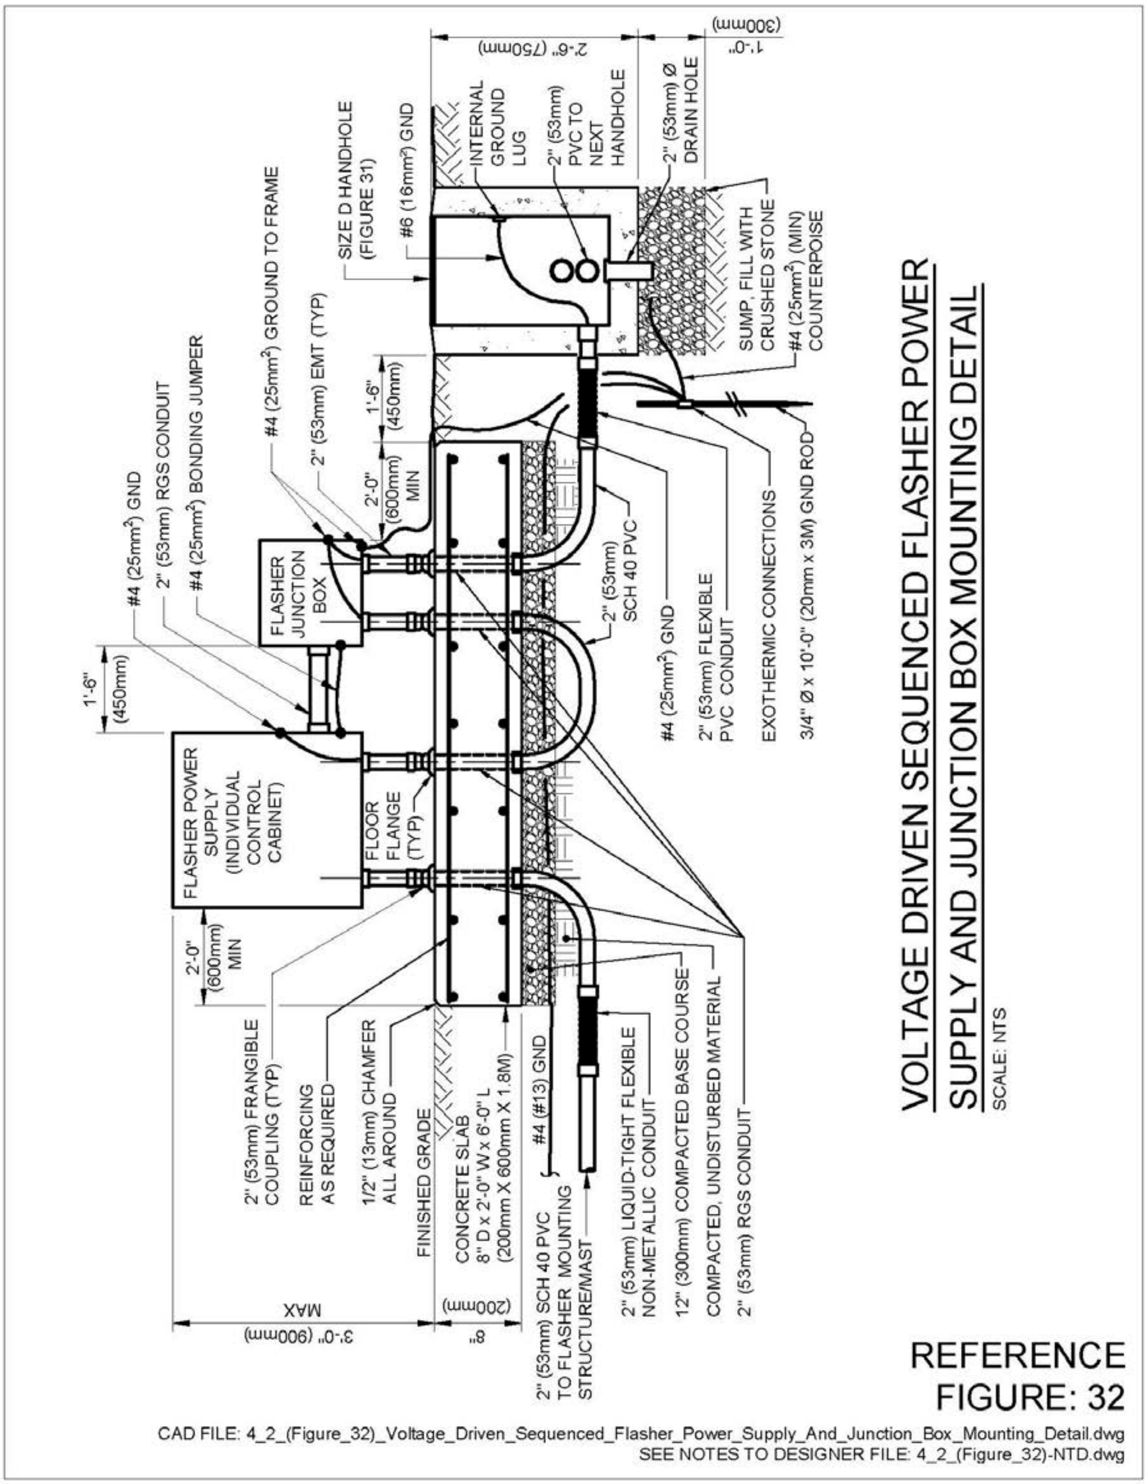
1. Each sequenced flasher requires its own power supply (individual control cabinet) and junction box. These are normally mounted as close to the flash head as possible. The standard manufacturer furnished cable between the flash head and the power supply is 60' (18m) maximum. The interconnecting wiring between the flasher junction box and the power supply is furnished by the contractor. If the flasher is mounted on a structure that is above 40' (12m), then the power supply is mounted up on the maintenance platform and the junction box is mounted at the base of the tower.

2. The flexible conduit allows for shifting due to freeze/thaw cycles in cold climates or to align conduits. If freeze/thaw cycles are not a problem, then the use of the flexible conduit is optional.

3. Recommend becoming familiar installation requirements from several different manufacturers.

4. The connection between the junction box and power supply is indicated below grade by a 2" (53mm) conduit. Some manufacturers connect the two directly with a short section of 2" (53mm) conduit.

Figure 32. Voltage Driven Sequenced Flasher Power Supply and Junction Box



Mounting Detail

5-3 Typical MG-20 L.I.R. Structure 6'-1" (1854mm) to 21'-1" (6.43m).

5-3.1 Figure 33.

5-3.1.1 Notes to Designer.

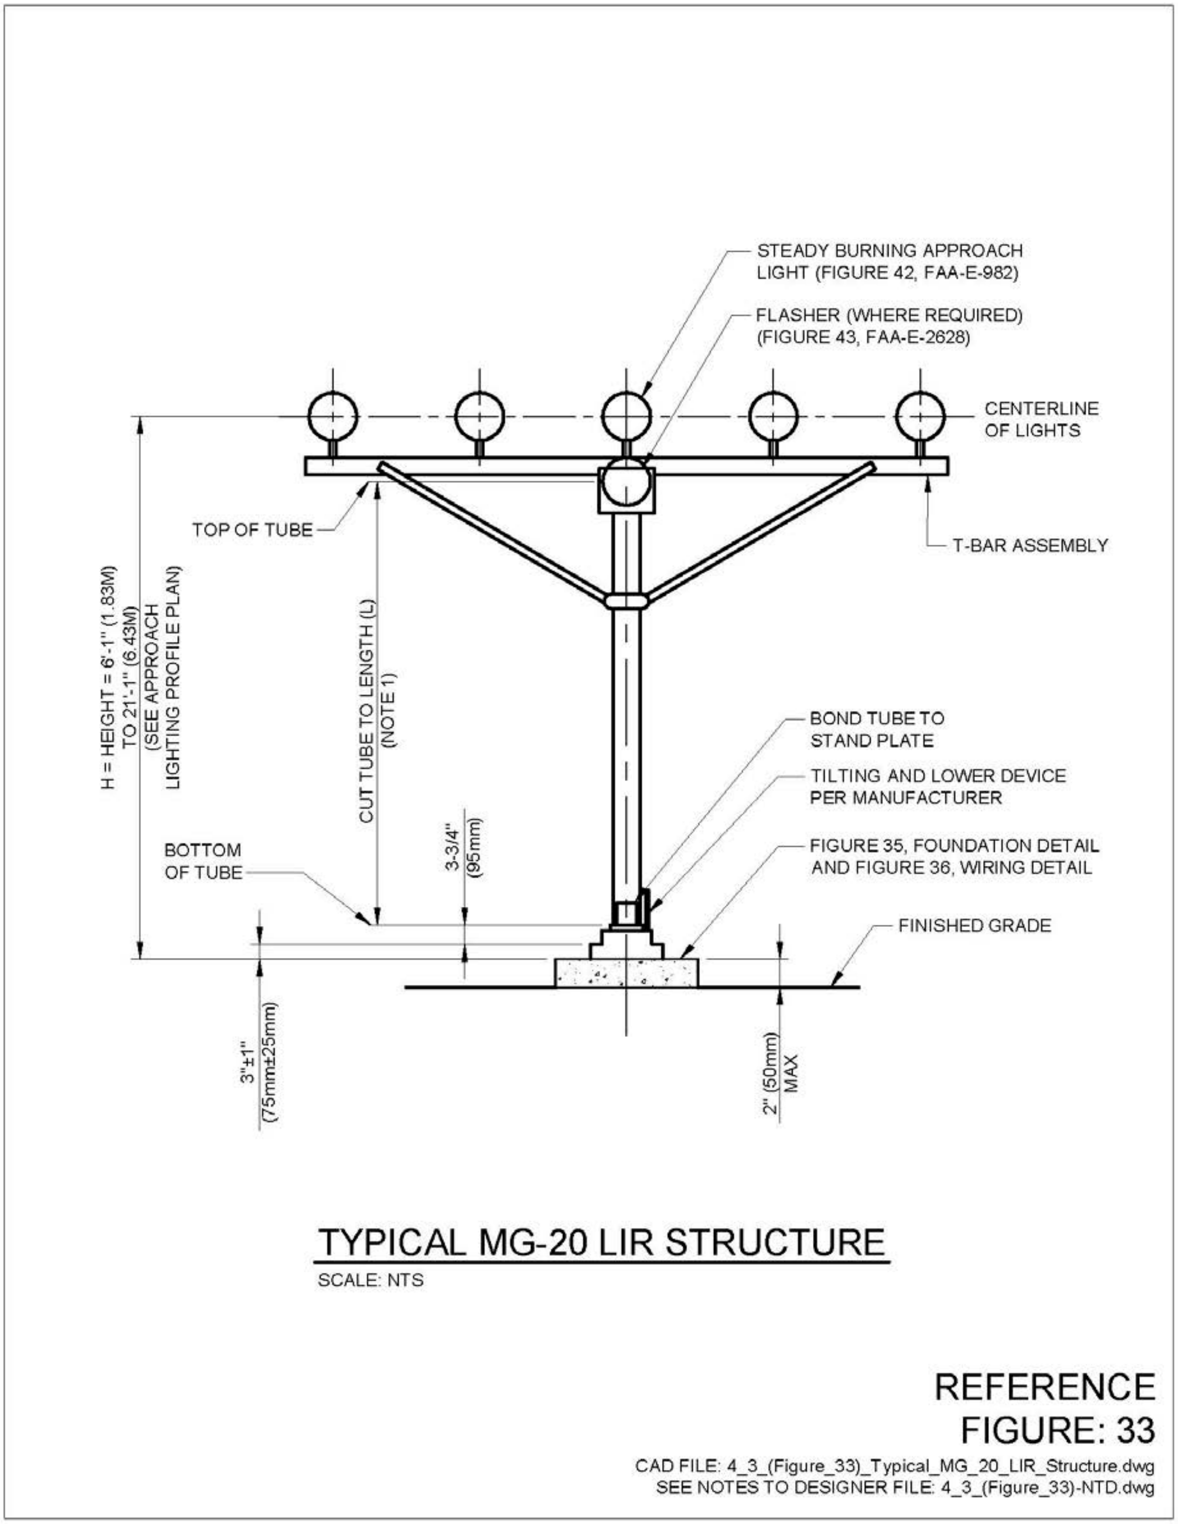
1. The contract documents should include an approach lighting profile plan that will state by station # the height above grade.

2. Refer to Chapter 3 in UFC 3-535-01 (Air Force/Army) or NAVAIR 51-50AAA-2 (Navy) for the spacing and number of the lights on the T-bar assembly. Specify the appropriate spacing (for the system being installed) in this detail and modify the detail to show the appropriate number of lights.

5-3.1.2 Drawing Notes for Figure 33.

1. Determine exact length of tube in accordance with manufacturer’s instructions.

Figure 33. Typical MG-20 L.I.R. Structure 6'-1" (1854mm) to 21'-1" (6.43m)



5-4 **Foundation for L.I.R. Structure MG-20 Plan View**

5-4.1 **Figure 34.**

5-4.1.1 **Notes to Designer.**

1. The female couplings are for mounting the 2" (53mm) frangible couplings and condulets for wiring to the tower. Two are required (one on each side) if both a sequenced flasher and steady burn lights are co-located on a tower.

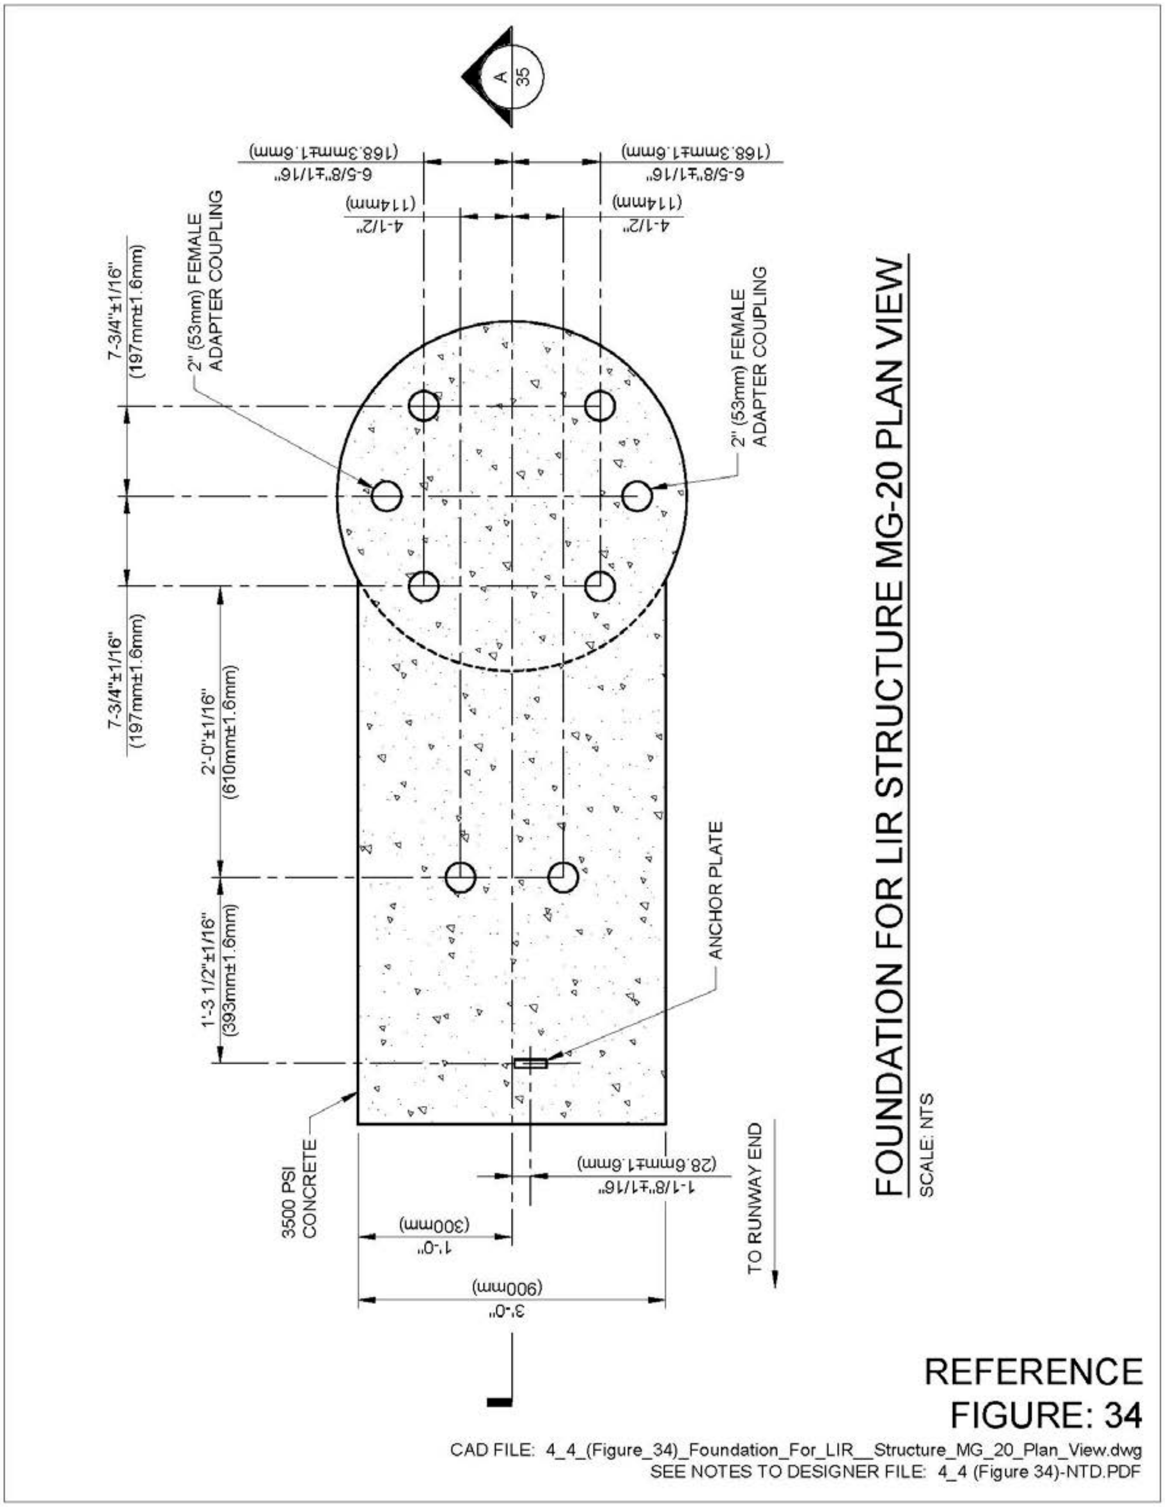
2. Foundation indicated is as recommended by tower manufacturer. However, rectangular foundations have been used in some installations. Consult with tower manufacturer for different options based on soil conditions, bearing capacity, etc.

5-4.1.2 **Drawing Notes for Figure 34.**

1. Refer to Figure 35, Section A.

2. Actual dimensions may vary. Coordinate with manufacturer prior to construction and construct per manufacturer's requirements.

Figure 34. Foundation for L.I.R. Structure MG-20 Plan View



5-5 Foundation for L.I.R. Structure MG-20 Sections A and B.

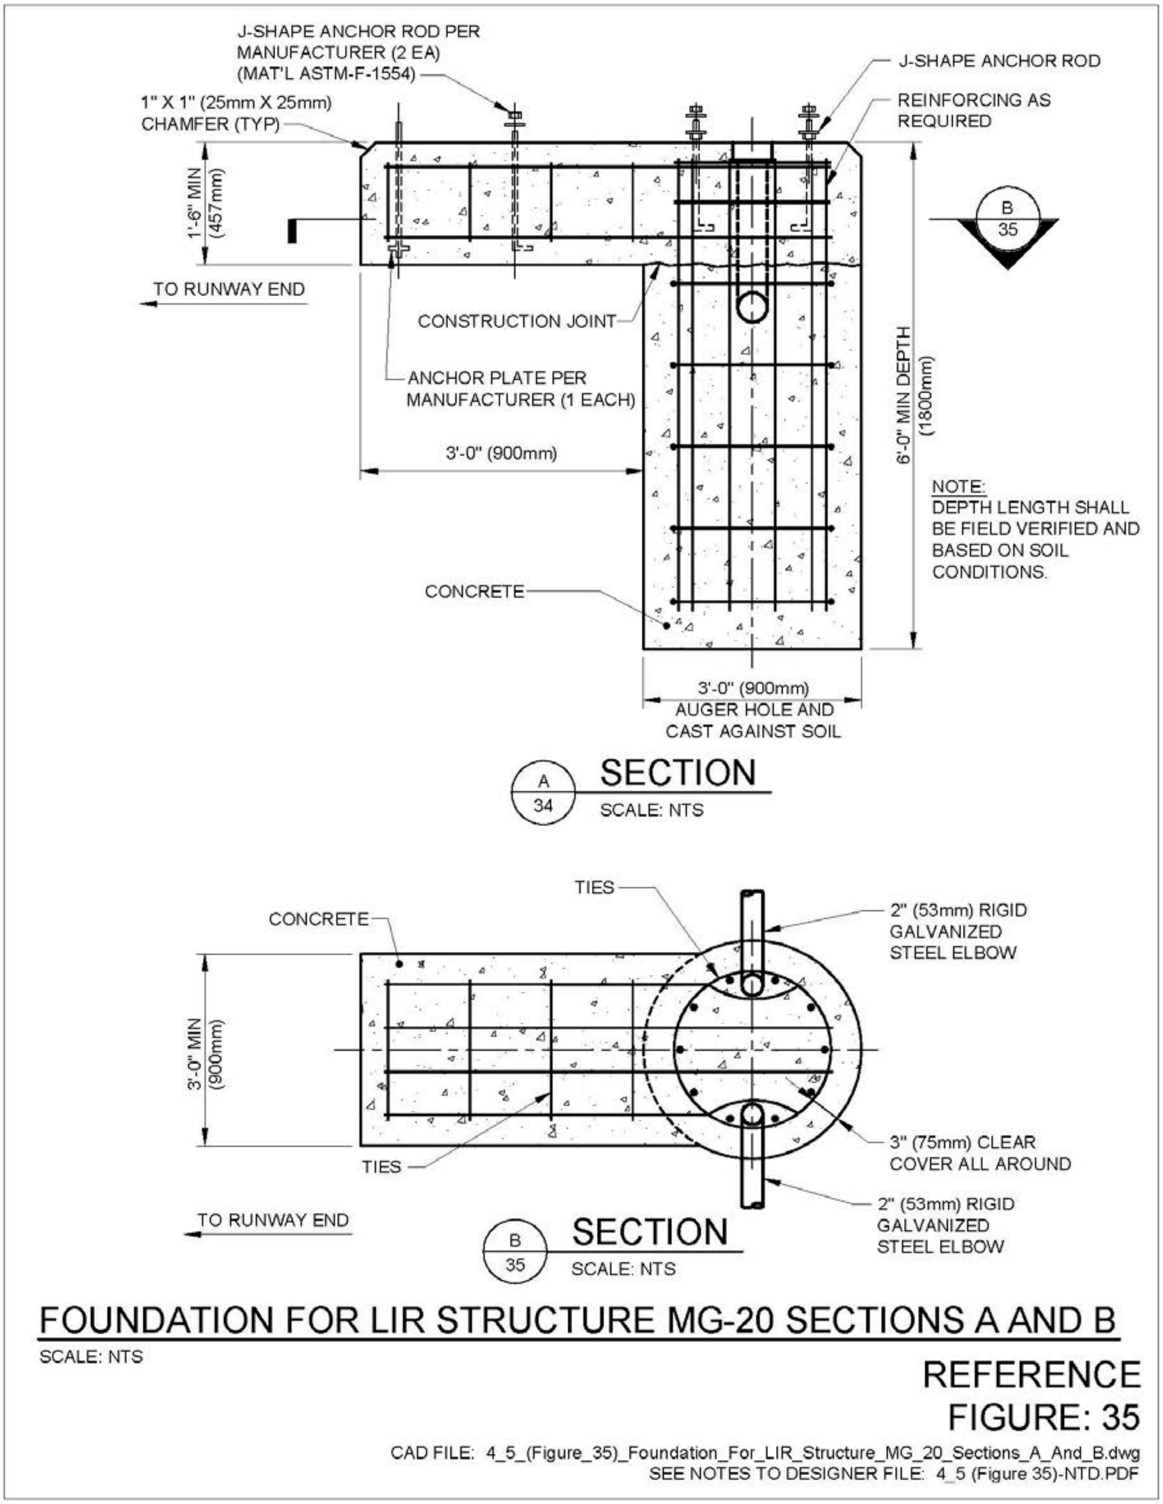
5-5.1 Figure 35.

5-5.1.1 Notes to Designer.

1. The foundation indicated is a suggested foundation from one tower manufacturer. The diameter was increased to allow the installation of the conduits in the foundation and still allow clearance for the tilt base on the tower.

2. Prior to designing the foundation for the tower, borings should be taken in the field for soil analysis. Many factors will affect the type and size of foundation to be installed (i.e. type of soil, existence of rock or ledge, soil bearing capacity, frost depth, etc.). The designer should base the foundation design on these factors and consult with the tower manufacturer regarding EPA (Effective Projected Area) for wind loading. The wind loading must include the proposed fixtures and hardware to be installed on the tower.

Figure 35. Foundation for L.I.R. Structure MG-20 Sections A and B



5-6 **Typical MG-20 L.I.R. Structure Tower Wiring Detail.**

5-6.1 **Figure 36.**

5-6.1.1 **Notes to Designer.**

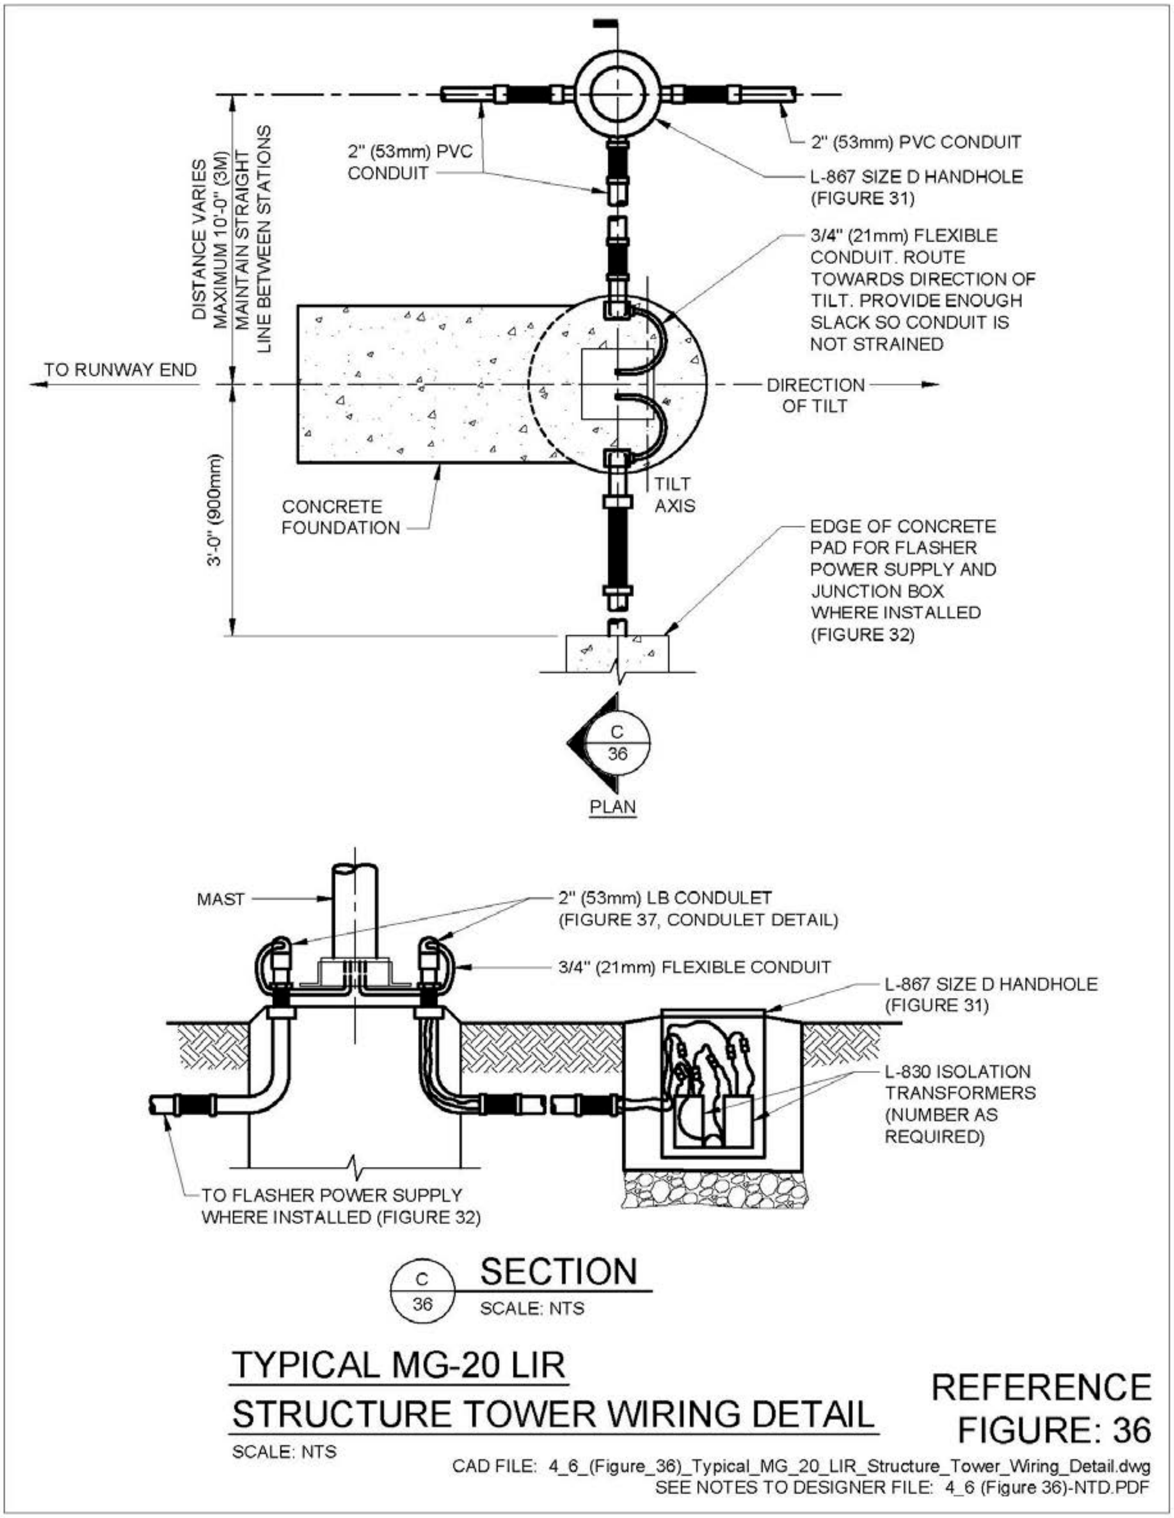
1. Location of the handhole with respect to the tower foundation will depend on system layout. Recommend keeping same distance from each tower foundation throughout system thereby allowing a straight run between handholes.

2. The tower tilts away from the end of runway and towards the approach. Routing the conduit towards the direction of the tilt and maintaining slack will prevent putting strain on the conduit while the tower is raised and lowered.

3. The number of isolation transformers will depend on the wattage and number of lamps to be installed. If more than one lamp is installed per isolation transformer, then the steady burn approach light must be specified with a lamp shorting device so the other lamps will remain on if one lamp burns out.

4. Number of conductors will vary depending on number of isolation transformers used, requirements of sequenced flashers, etc. Verify requirements with system wiring diagrams and provide (furnish and install) necessary conductors.

Figure 36. Typical MG-20 L.I.R. Structure Tower Wiring Detail



5-7 2" (53mm) LB Conduit Detail.

5-7.1 Figure 37.

5-7.1.1 Notes to Designer:

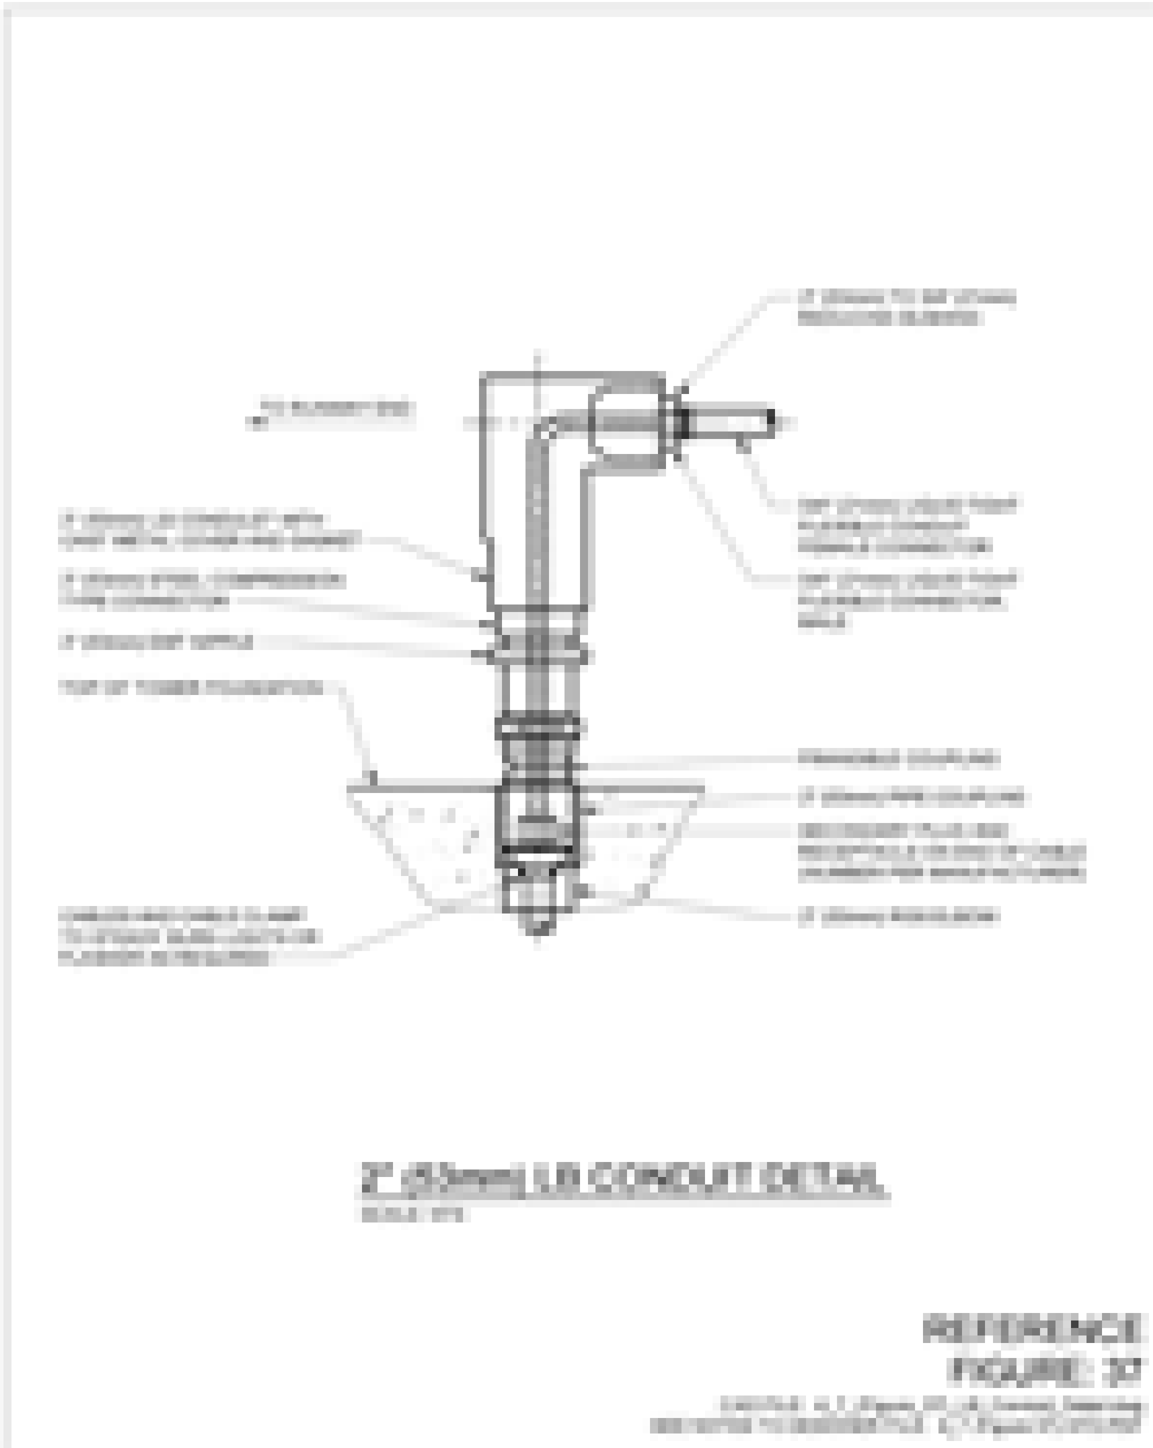
1. Figure is self-explanatory.

5-7.1.2 Drawing Notes for Figure 37.

1. Provide number of cables as required. Refer to system wiring diagrams.

2. Face conduit away from runway end and toward approach.

Figure 37. 2" (53mm) LB Conduit Detail



5-8 Typical MG-30 L.I.R. Structure 21'-2" (6.45m) to 30'-0" (9.14m).

5-8.1 Figure 38.

5-8.1.1 Notes to Designer.

1. The contract documents should include an approach lighting profile plan that will state by station # the height above grade.

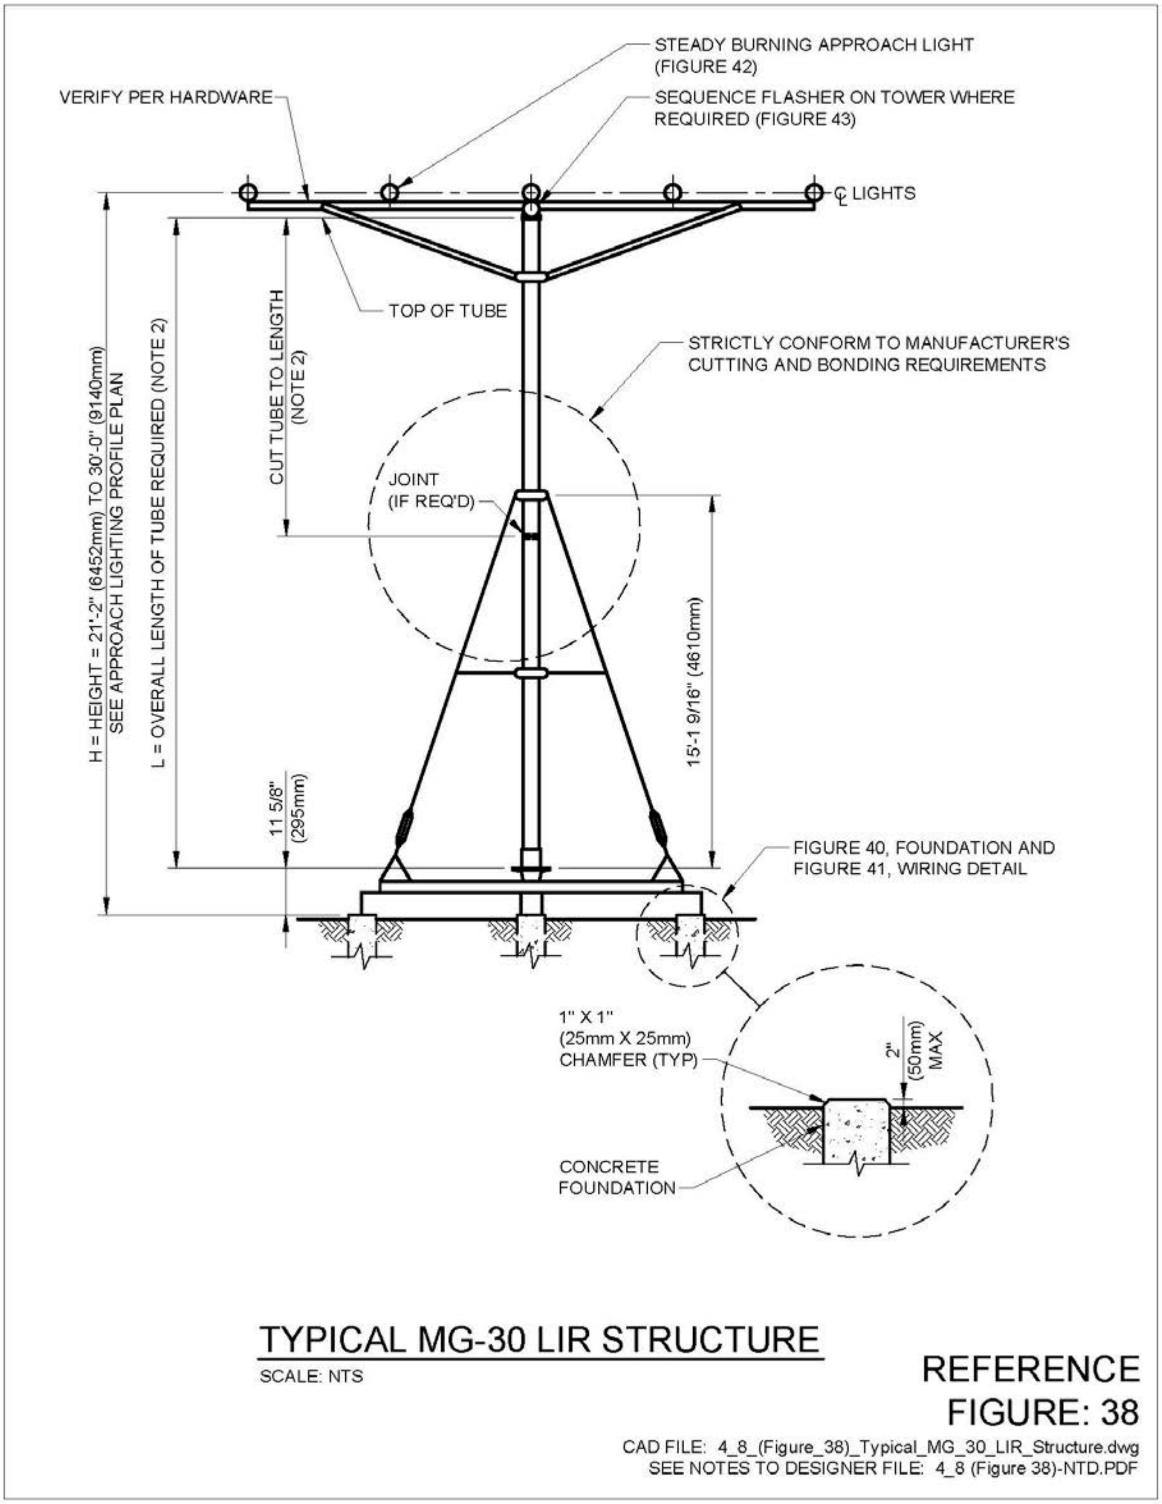
2. Refer to Chapter 3 in UFC 3-535-01 for spacing and number of lights on the T-bar assembly. Specify the appropriate spacing (for the system being installed) in this detail and modify the detail to show the appropriate number of lights.

5-8.1.2 Drawing Notes for Figure 38.

1. Foundations, connections, stabilizers, tilt devices, and associated components must be per manufacturer’s written specifications.

2. Determine length of tube per manufacturer’s requirements.

Figure 38. Typical MG-30 L.I.R. Structure 21'-2" (6.45m) to 30'-0" (9.14m)



5-9 Typical MG-40 L.I.R. Structure 30'-0" (9.14m) to 40'-0" (12.19m).

5-9.1 Figure 39.

5-9.1.1 Notes to Designer.

1. The contract documents should include an approach lighting profile plan that will state by station # the height above grade.

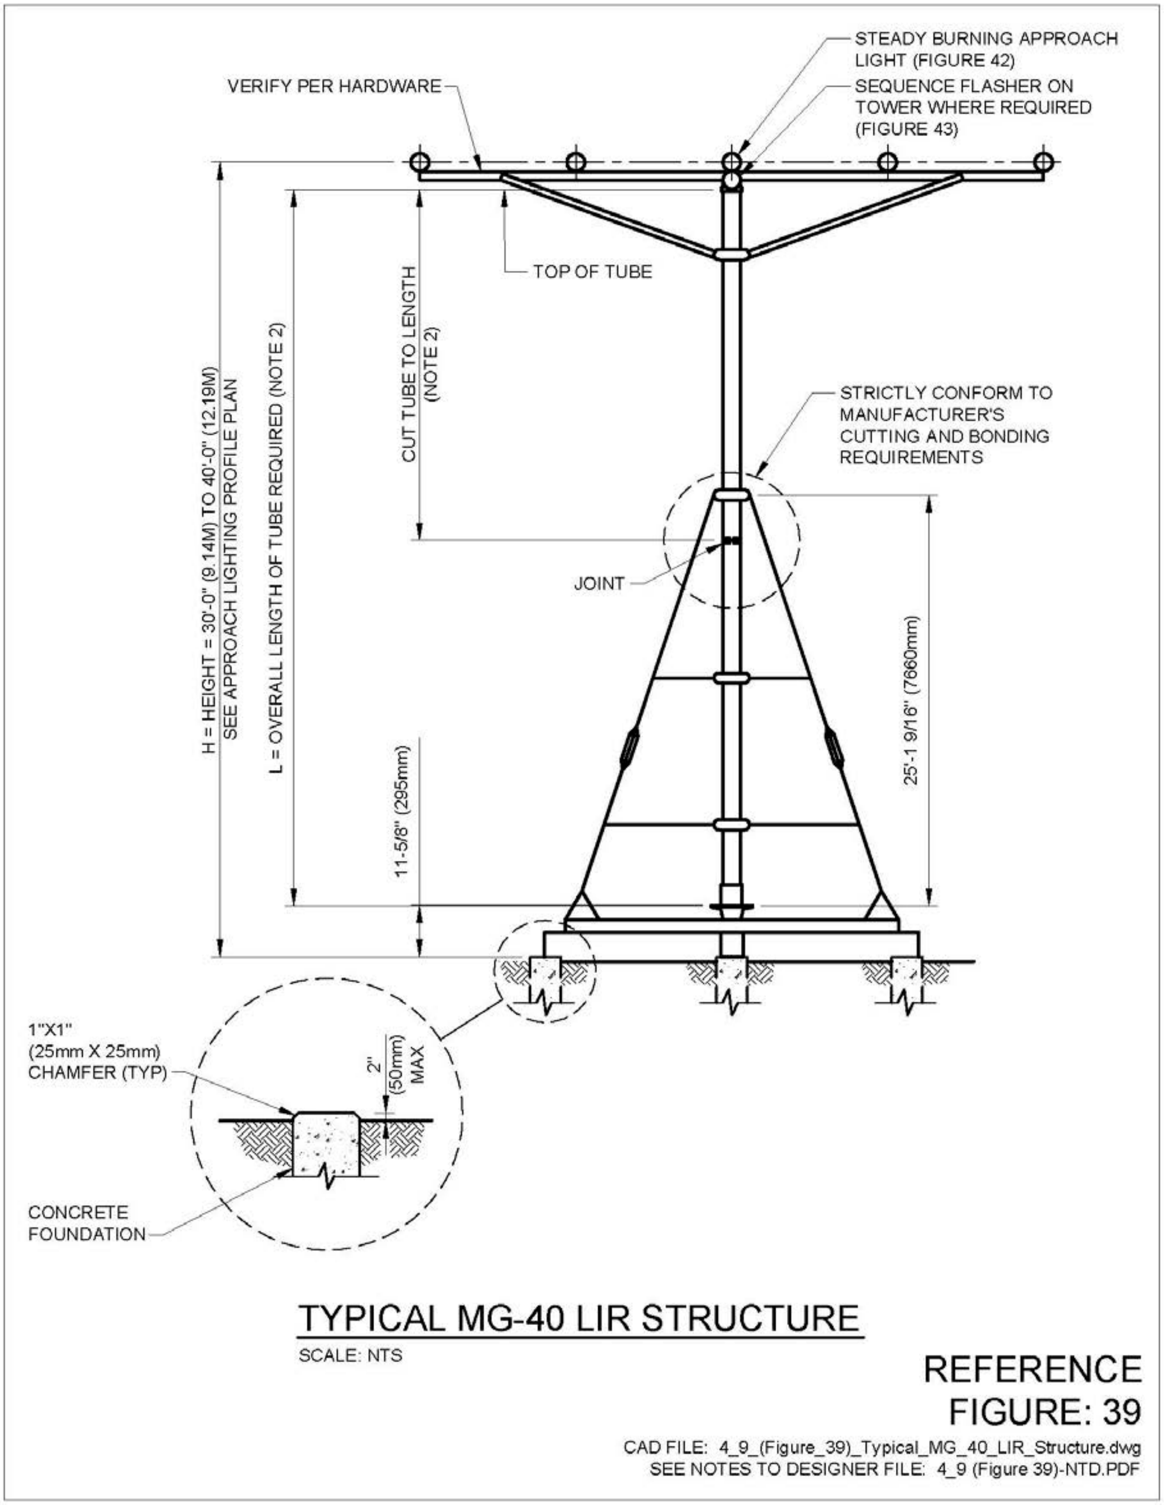
2. Refer to Chapter 3 in UFC 3-535-01 for spacing and number of lights on the T-bar assembly. Specify the appropriate spacing (for the system being installed) in this detail and modify the detail to show the appropriate number of lights.

5-9.1.2 Drawing Notes for Figure 39.

1. Foundations, connections, stabilizers, tilt devices, and associated components must be per manufacturer's written specifications.

2. Determine length of tube per manufacturer's requirements.

Figure 39. Typical MG-40 L.I.R. Structure 30'-0" (9.14m) to 40'-0" (12.19m)



5-10 Foundation for MG-30/40 L.I.R. Structures.

5-10.1 Figure 40.

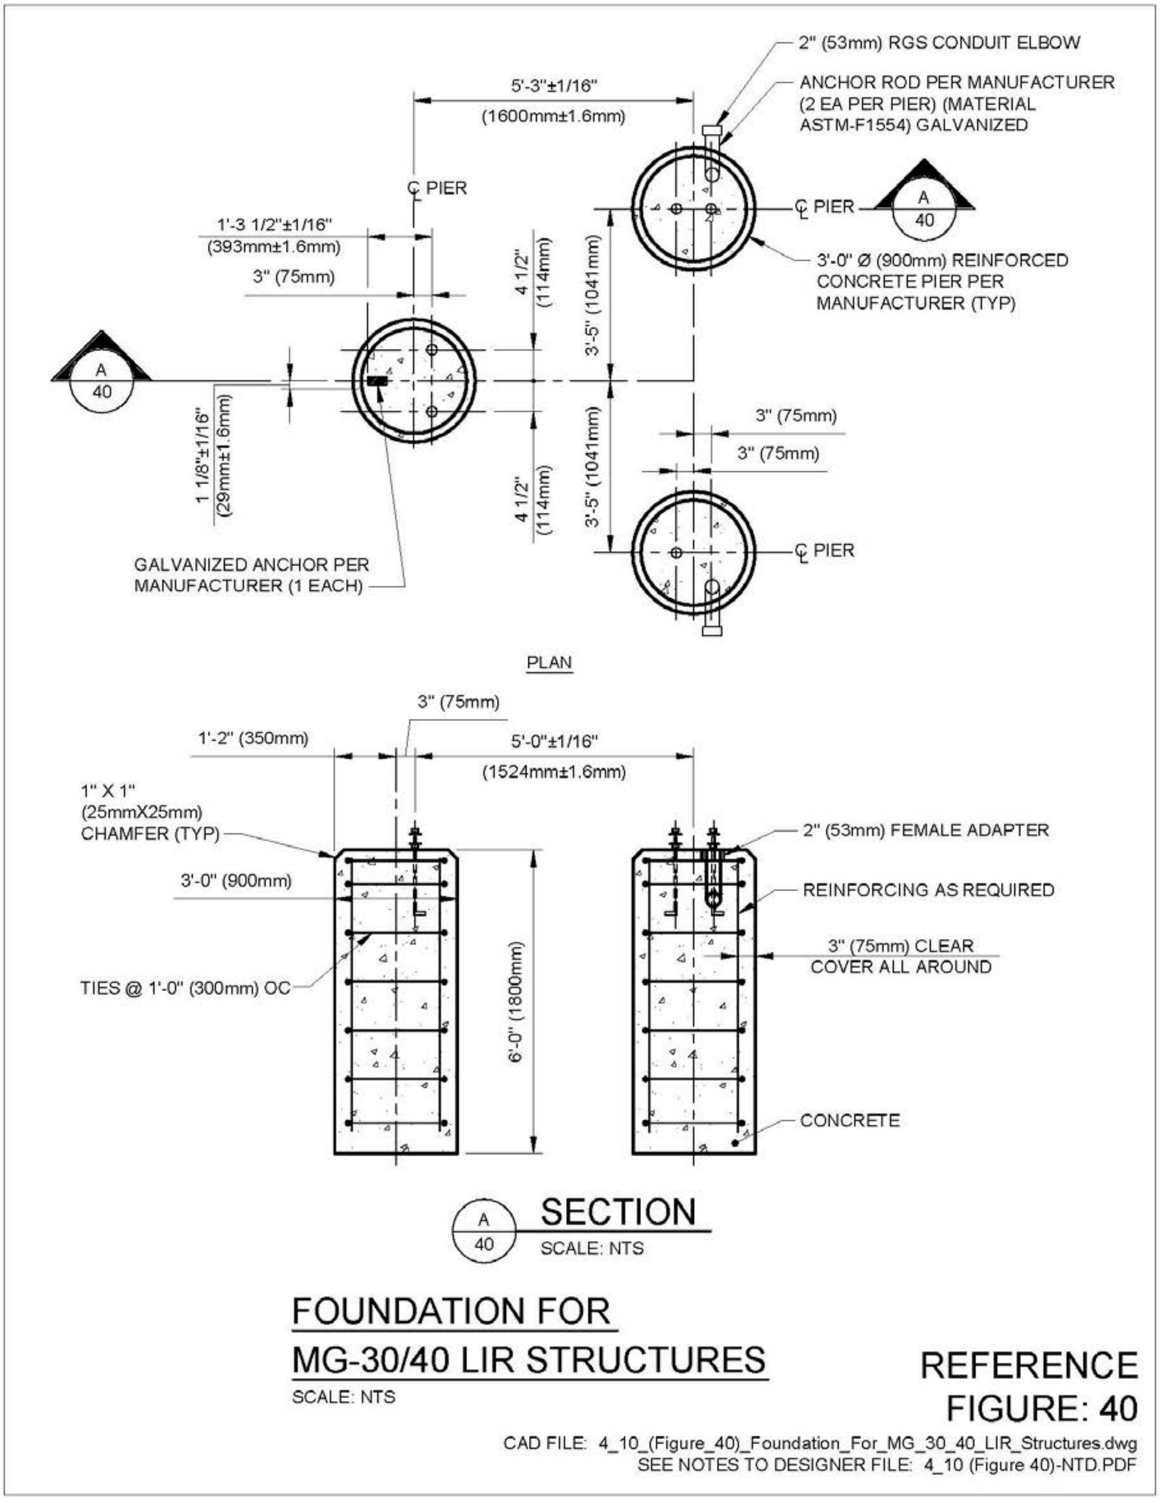
5-10.1.1 Notes to Designer.

1. The foundation indicated is a suggested foundation from one tower manufacturer. The diameter was increased to allow the installation of the conduits in the foundation and still allow clearance for the tilt base on the tower.

2. Prior to designing the foundation for the tower, borings should be taken in the field for soil analysis. Many factors will affect the type and size of foundation to be installed (i.e. type of soil, existence of rock or ledge, soil bearing capacity, frost depth, etc.). The designer should base the foundation design on these factors and consult with the tower manufacturer regarding EPA (Effective Projected Area) for wind loading. The wind loading must include the proposed fixtures and hardware to be installed on the tower.

3. Reinforce per the manufacturer’s written requirements.

Figure 40. Foundation for MG-30/40 L.I.R. Structures



5-11 Typical MG-30/40 L.I.R. Structure Tower Wiring Detail.

5-11.1 Figure 41.

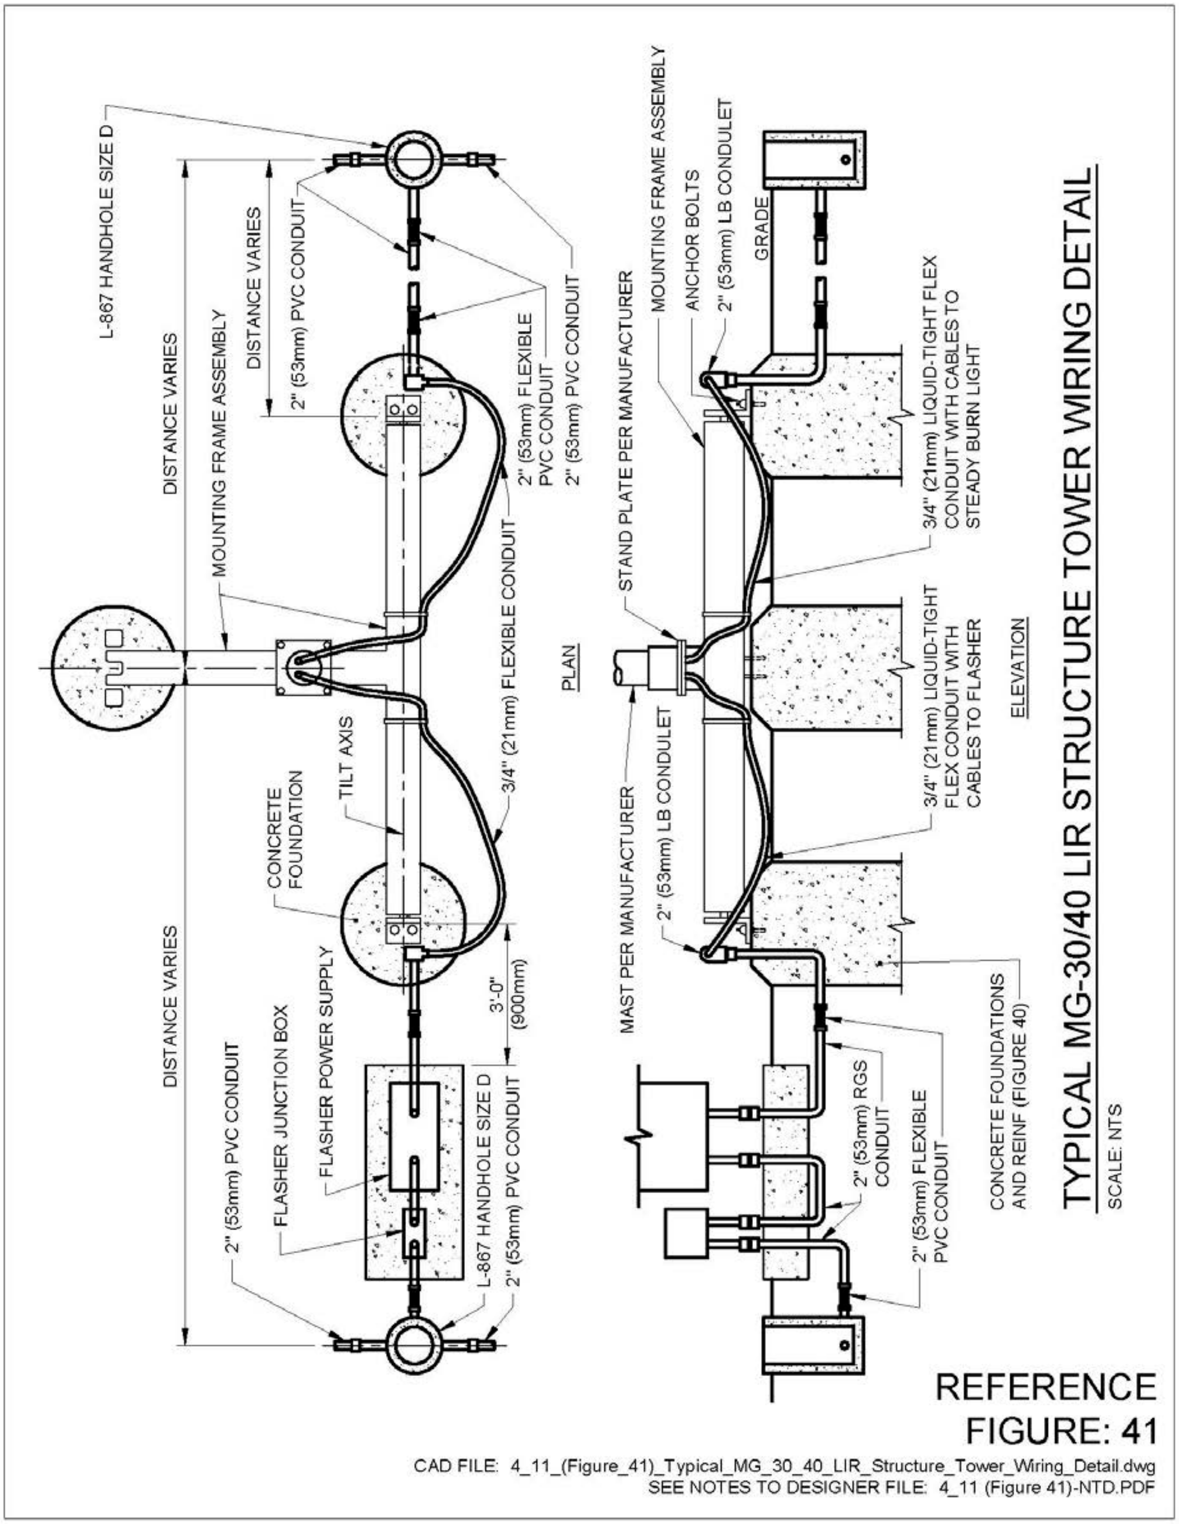
5-11.1.1 Notes to Designer.

1. Location of the handhole with respect to the tower foundation will depend on system layout. Recommend keeping same distance from each tower foundation throughout system thereby allowing a straight run between handholes.

2. The tower tilts away from the end of runway and towards the approach. Routing the conduit towards the direction of the tilt and maintaining slack will prevent putting strain on the conduit while the tower is raised and lowered.

3. The number of isolation transformers will depend on the wattage and number of lamps to be installed. If more than one lamp is installed per isolation transformer, then the steady burn approach light must be specified with a lamp shorting device so the other lamps will remain on if one lamp burns out.

Figure 41. Typical MG-30/40 L.I.R. Structure Tower Wiring Detail



5-12 Tower Mounted Steady Burning Approach Light Detail.

5-12.1 Figure 42.

5-12.1.1 Notes to Designer.

1. The FAA does not require a grounding terminal in the lamp holder. However, more recent installations have installed an equipment ground to the lamp holder. The ground conductor is routed with the circuit conductors and is bonded to the steel base plate and mounting assembly. This in turn is bonded to a ground.

5-12.1.2 Drawing Notes for Figure 42.

1. Measure distance between center of light and top of tube using actual equipment installed.

2. Attach #12 (4 square mm) ground to fixture housing by installing a #8 screw through hole provided in bottom of housing. Sand away paint and anodizing around hole on inside of housing to bare metal. Push screw up through hole and install star washer over screw on interior of housing. Crimp an insulated ring terminal on the end of the ground wire and install on screw. Place lock washer and nut on screw and tighten. Verify with manufacturer length and size of screw, star washer, lock washer, and nut to be utilized to maintain clearance from terminal block assembly.

5-13 Tower Mounted SFL and Approach Light Detail.

5-13.1 Figure 43.

5-13.1.1 Notes to Designer.

1. The flasher equipment ground conductor may be bonded to the ground conductor for the steady burn lights inside the tube cap assembly.

2. The number of conductors to the flasher must be verified. Typically, 2 #12 (4 square mm) and 3 #16 (1.5 square mm), 3kV, are used and are provided by the manufacturer. Ensure size of flexible conduit is adequate for these cables.

5-13.1.2 Drawing Notes for Figure 43.

1. Flasher junction box/bracket and bracket clamp furnished as an assembly. Install on mast per manufacturer’s requirements.

2. Install ground lug on one of the 2 aluminum angles inside the junction box and route a #12 (4 square mm) THWN-2 from flasher and fiberglass mast to lug. Terminate ground wire on lug.

5-14 **MALSR and SSALR Approach Light System Configuration.**

5-14.1 **Figure 44A, 44B.**

5-14.1.1 **Notes to Designer.**

1. Recommend including the system layout as part of the contract documents.

2. The SSALR configuration may be achieved with a dual mode ALSF/SSALR system and is used when Category I weather conditions exist thereby allowing an energy savings without having to use the full ALSF-2 system.

Figure 44A. MALSR Approach Light System Configuration

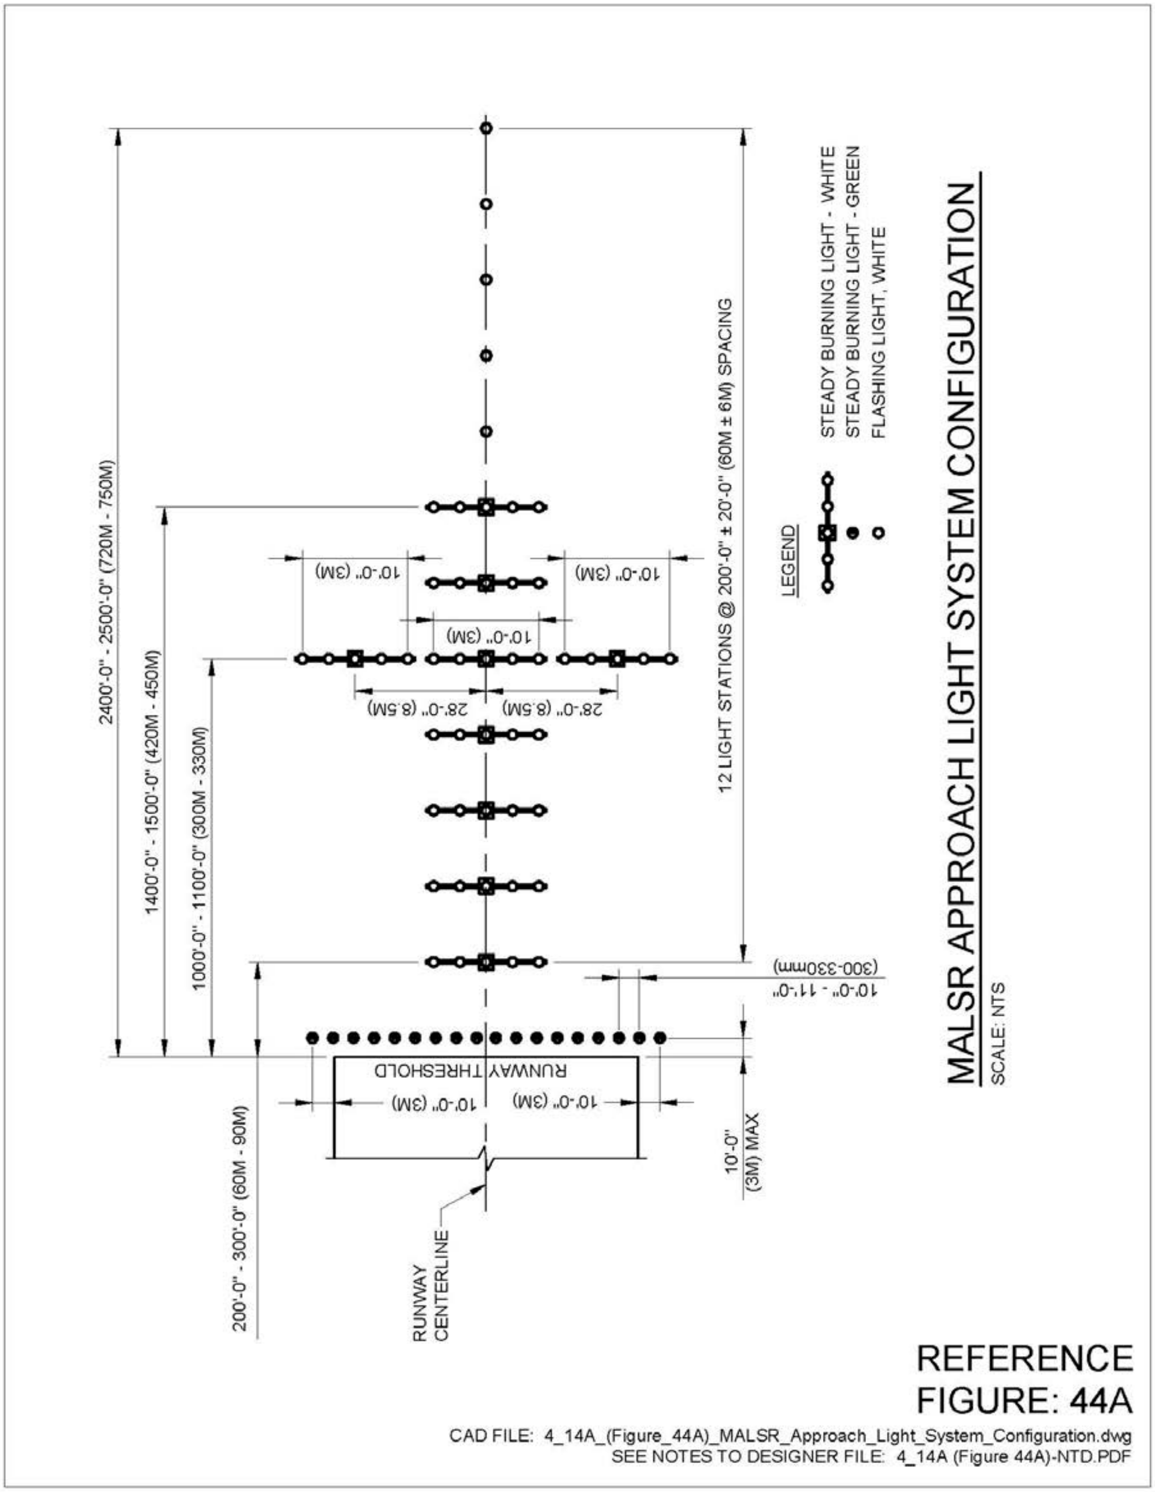

Figure 44B. SSALR Approach Light System Configuration

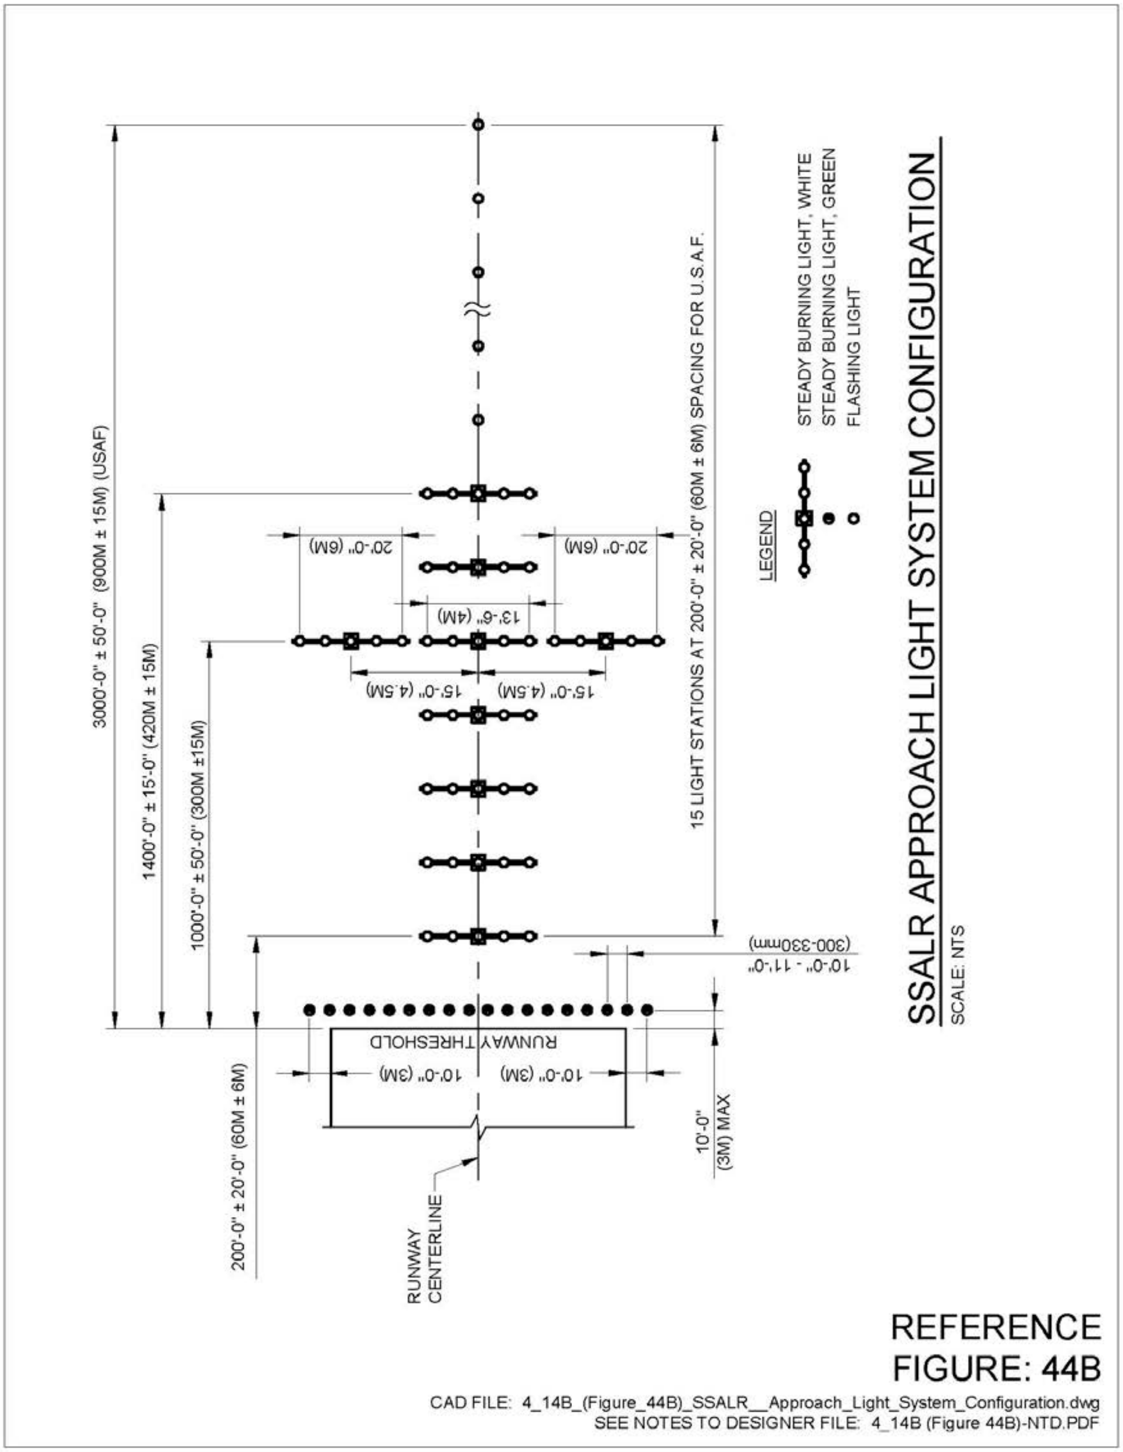


5-15 emote Flasher Installation 6' 0" (1800mm) Maximum.

5-15.1 Figure 45.

5-15.1.1 Notes to Designer.

1. This detail shows a remote flasher installation. The high voltage cable is normally supplied with the flasher and about 50' (15m) in length. Locate the flasher power supply within this distance.

2. Where the flasher is co-located with an approach light bar; the flasher may be mounted a maximum 5' (1.5m) in front of light bar and a maximum of 4' (1.2m) below the centerline of the approach light plane. When the flashers are mounted below the centerline, they must be uniformly mounted throughout the system.

5-15.1.2 Drawing Notes for Figure 45.

1. Maximum mounting height of configuration indicated is 5'-11" (1.775m) for mounting installation of more than 6'-0" (1800mm) see tower installation details.

2. Terminate all conduits with a standard grounding bushing.

3. Connection must be clean and dry with a light coating of silicone grease only.

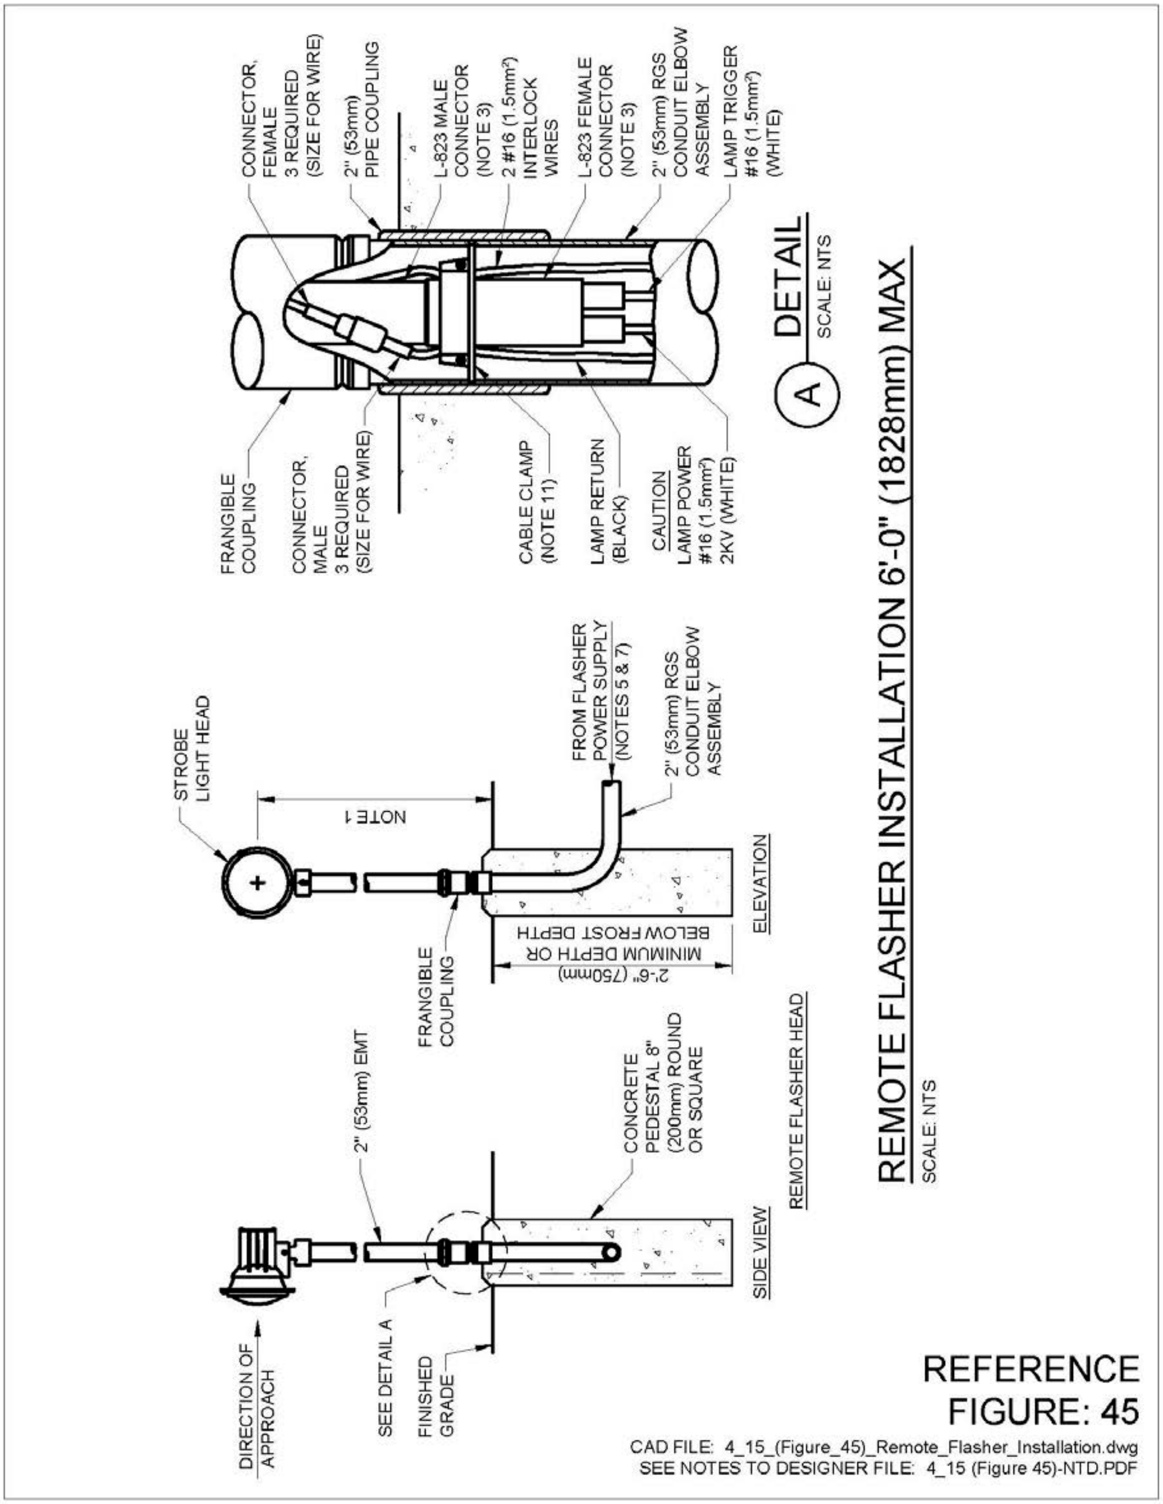
4. Continuity of power cables must be maintained between flasher stations. Where splices are required, they must be epoxy resin type with plastic shell. Equip conductors with mechanical wire clamps.

5. Ground clearance of electrical boxes must be determined in field, and must be 8" (200mm) minimum.

6. Flasher power supply/junction box unit must be located 35' (10.5m) from extended centerline of runway.

7. Insert lamp return wire into cable clamp prior to final assembly/tightening.

Figure 45. Remote Flasher Installation 6' 0" (1828mm) Maximum



5-16 Typical High Intensity Approach Light Bar.

5-16.1 Figures 46A, 46B, 46C, 46D, 46E, 46F, 46G.

5-16.1.1 Notes to Designer.

1. Figures 46A, 46B, 46C, 46D, 46E and 46F show the installation of an approach light bar in a concrete monolith. The pavement is excavated at the location where the bar will be installed. Depth and width of the excavation must be enough to allow setting the base cans, installing reinforcement and backfill with concrete.

2. Figures 46E and 46F show setting the base cans with the support brace spanning the excavated area. Sandbags are used on top of the bracing to prevent the base from floating during concrete installation.

3. The thickness of the snow plow ring is crucial in setting the base at the correct height. The plywood cover must match the diameter and thickness of the snowplow ring so that when removed the ring will fit properly and the outside edge of the ring is flush with the existing top of pavement.

5-16.1.2 Drawing Notes for Figure 46D.

1. Set the light base that mimic exact diameter and thickness of snow ring. Completely wrap plywood cover in roofing paper. See Figures 46E and 46F.

2. Light bases must meet or exceed to AC 150/5345-42, Specification for Airport Light Bases and Transformer Housing, Type L-868.

3. The contractor must provide 3/8" (10mm) -16 × 1-1/4" (30mm) long stainless steel bolts and stainless steel split lock-washers for bolting snow plow ring to L-868 base can.

4. Fill space with sealing compound P-606 for concrete or flexible pavement. Provide certification that sealer is compatible with pavement type.

5. Seal unused hole in light bases with pipe plugs.

5-16.1.3 Drawing Notes for Figures 46E, 46F and 46G.

1. Details for high intensity approach in-pavement light fixture/base can only. Installation methodology indicated for contractor information only. The methodology indicated on this sheet is general in nature. Final installation methodology must be determined by the contractor.

2. See civil plans for typical pavement section.

Figure 46A. In-Pavement High Intensity Approach Light Bar – Section View Materials

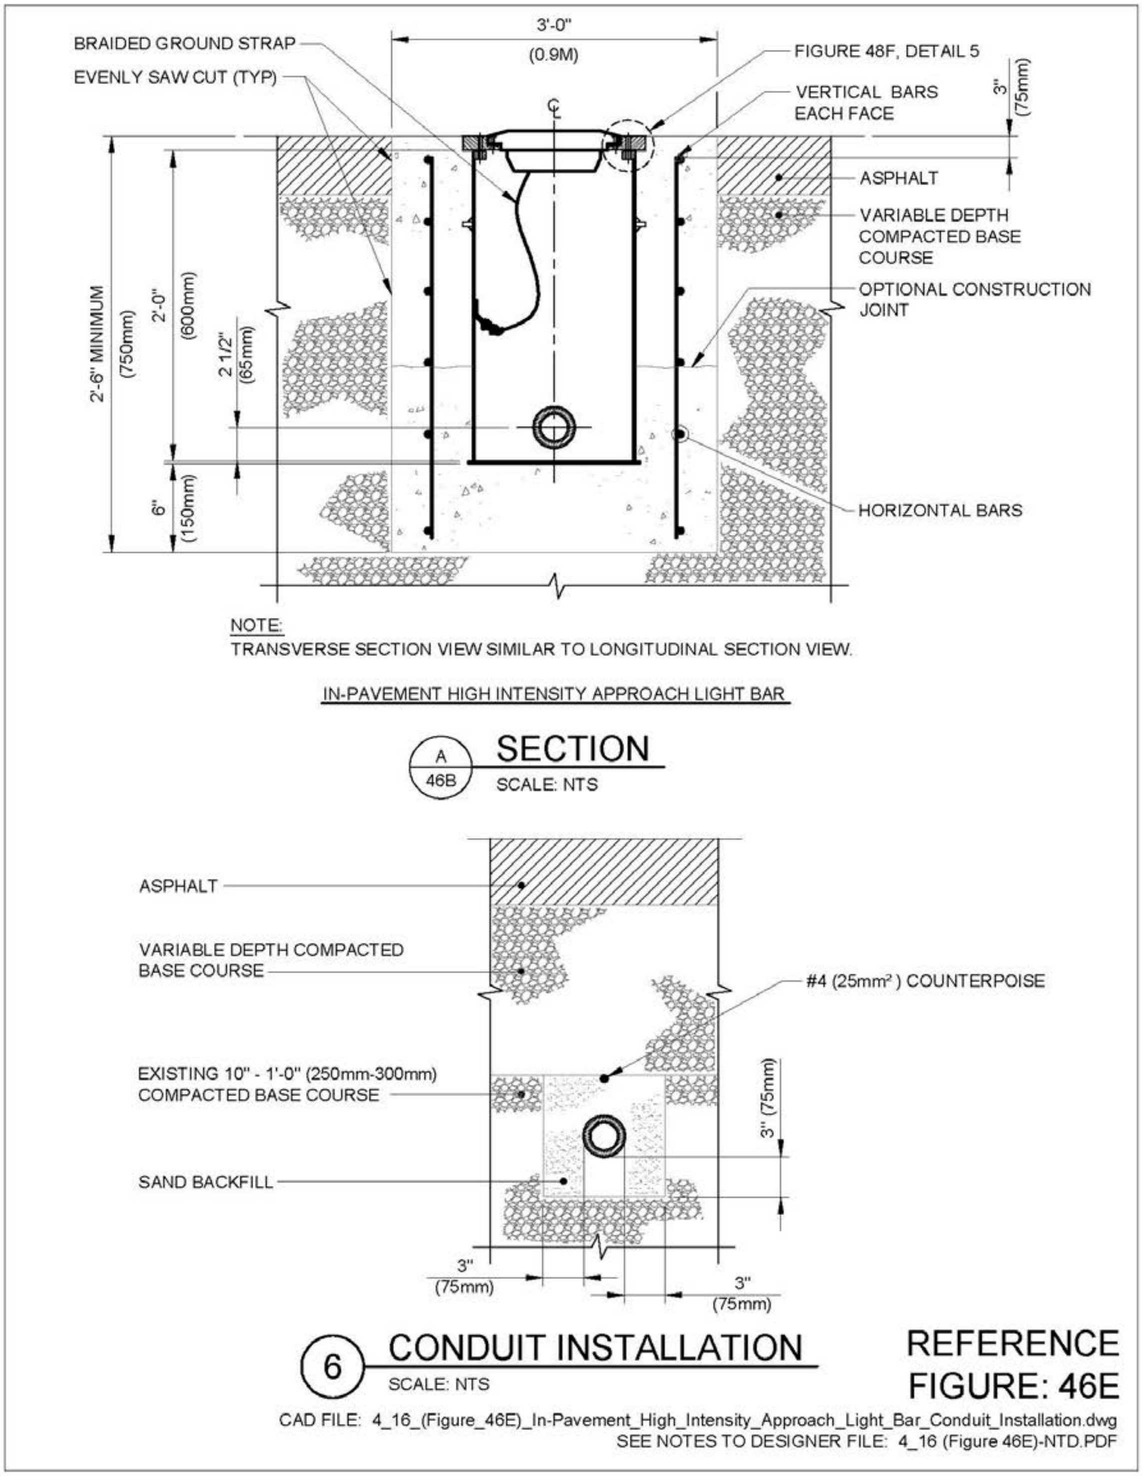

Figure 46F. Existing Trenching, Sawcut Asphalt and Trench, Set L-868 Base Can and Framework

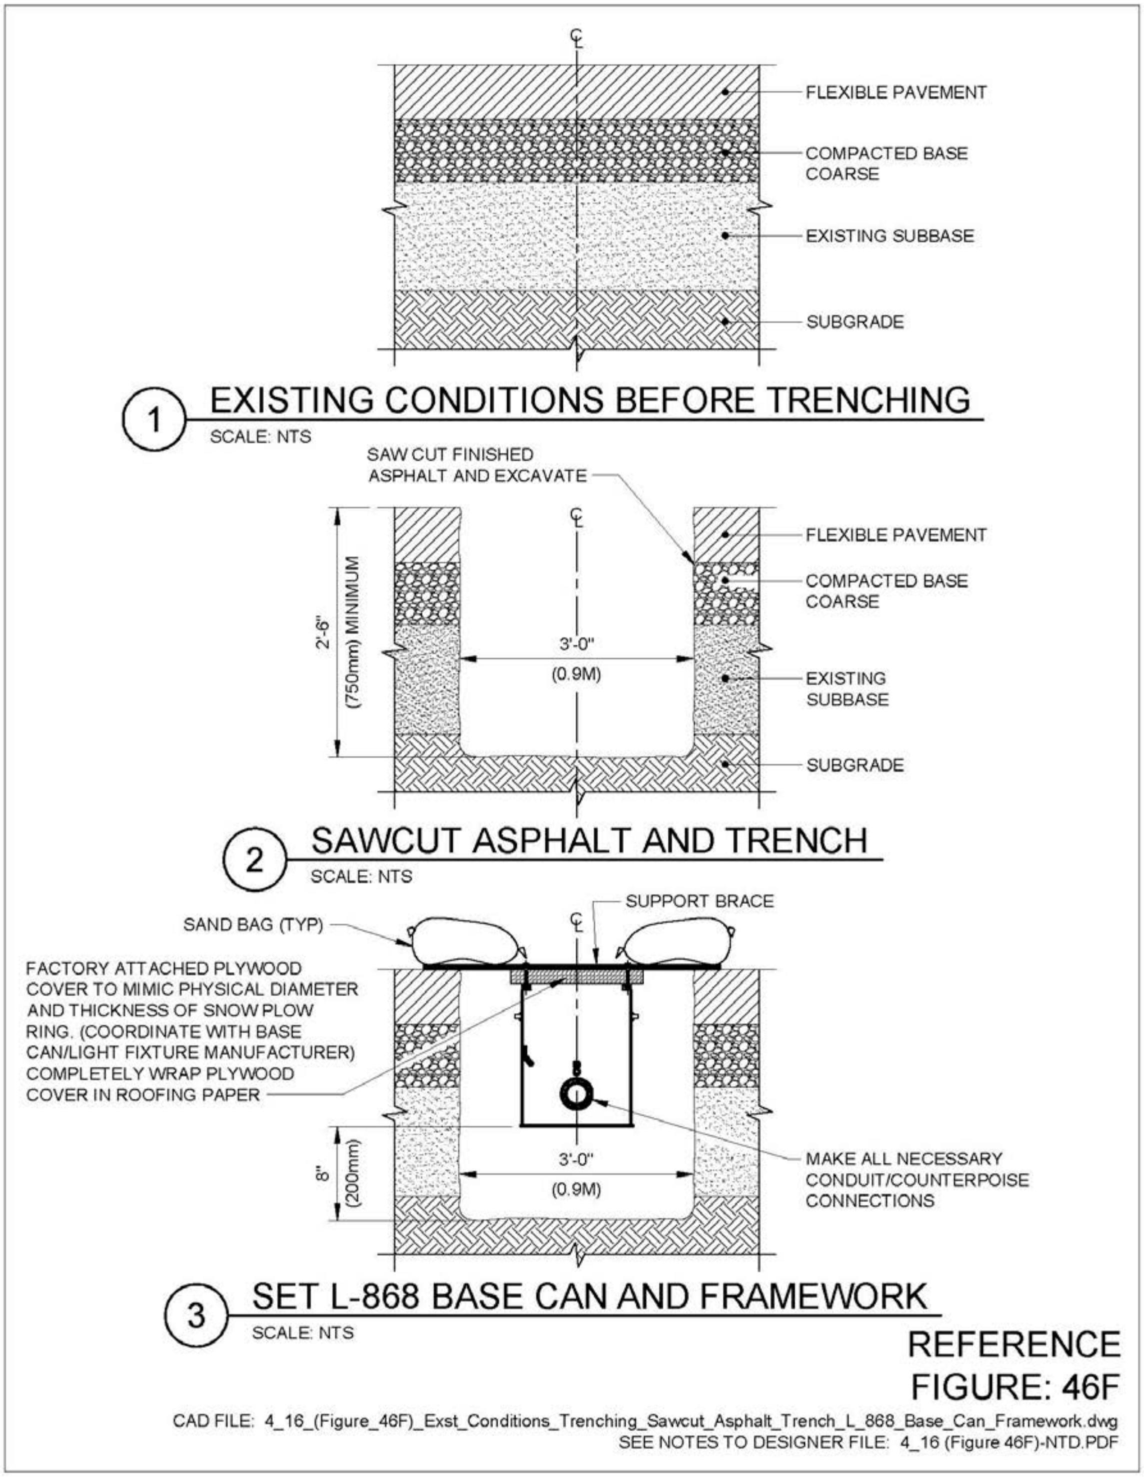

Figure 46G. Place Concrete, Remove Brace/Plywood Cover, Base Can in Place

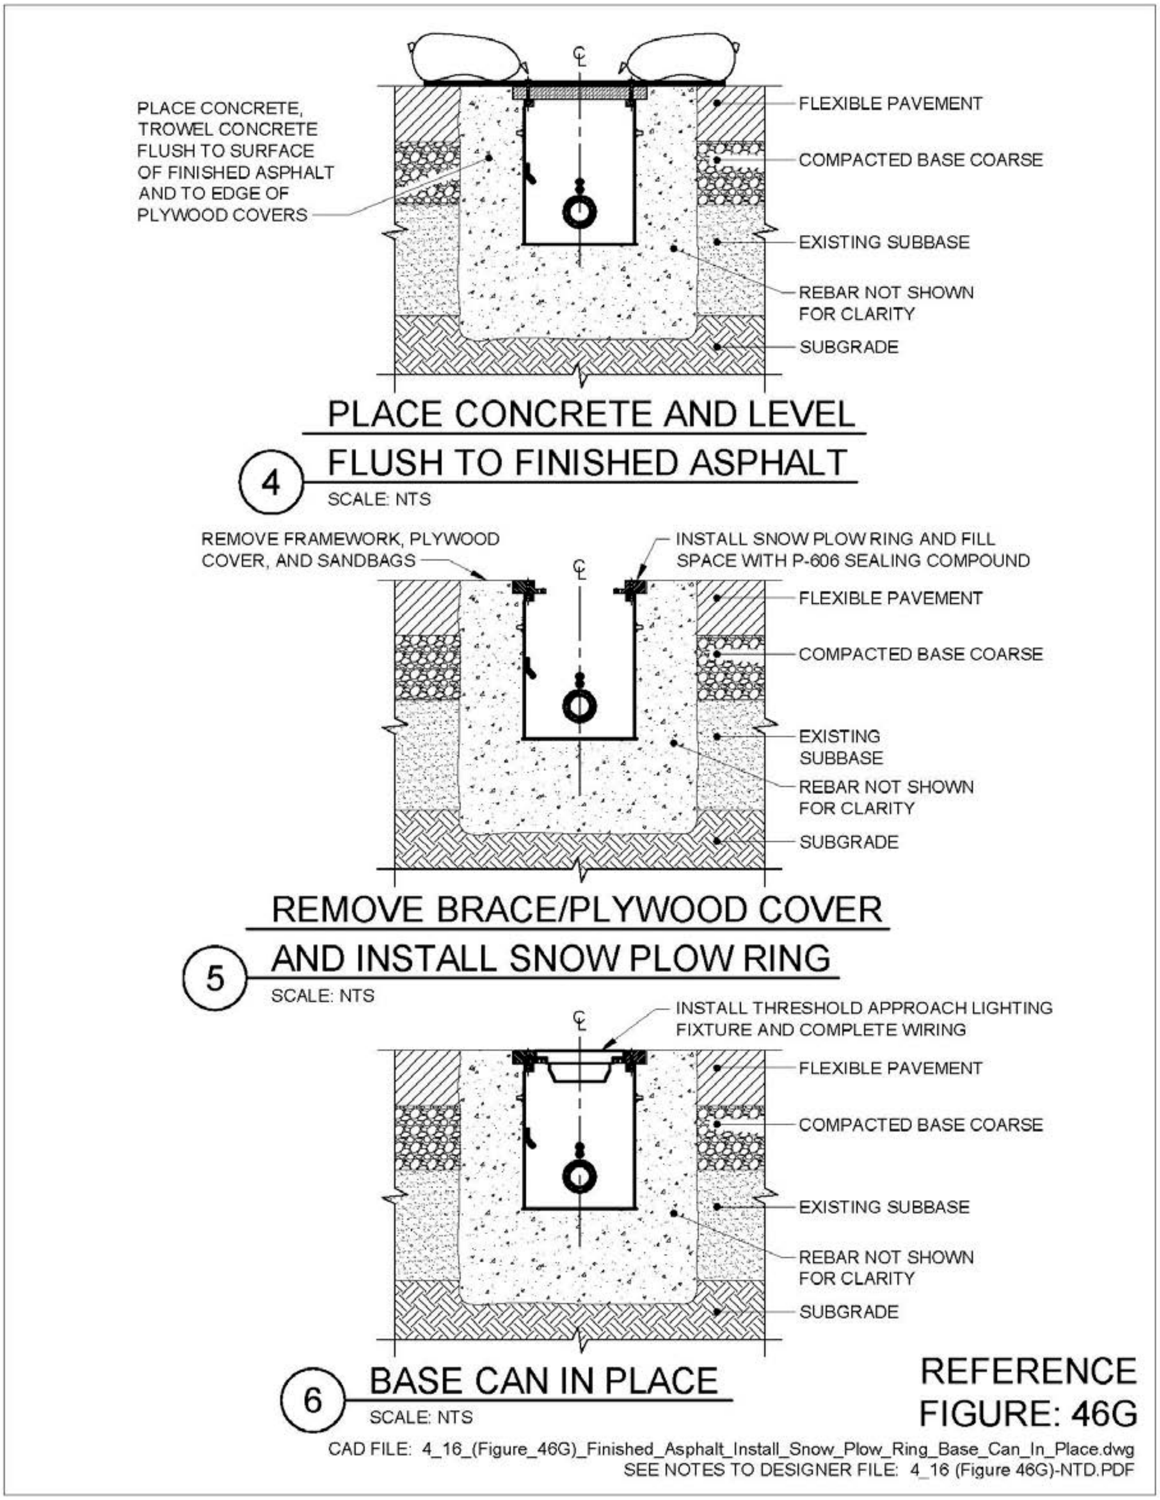


5-17 Typical Elevated High Intensity Approach Light Bar 0' to 6'0" (0mm to 1800mm) Maximum.

5-17.1 Figure 47.

5-17.1.1 Notes to Designer.

1. This detail shows the elevated approach light bar. Spacing between the lights will depend on which system is installed.

2. The contract documents should contain an overall layout plan showing the spacing of the lights. Refer to UFC 3-535-01 for the spacing requirements for each system.

3. The flexible conduit allows for shifting due to freeze/thaw cycles in cold climates. If freeze/thaw cycles are not a problem, then the use of the flexible conduit is optional.

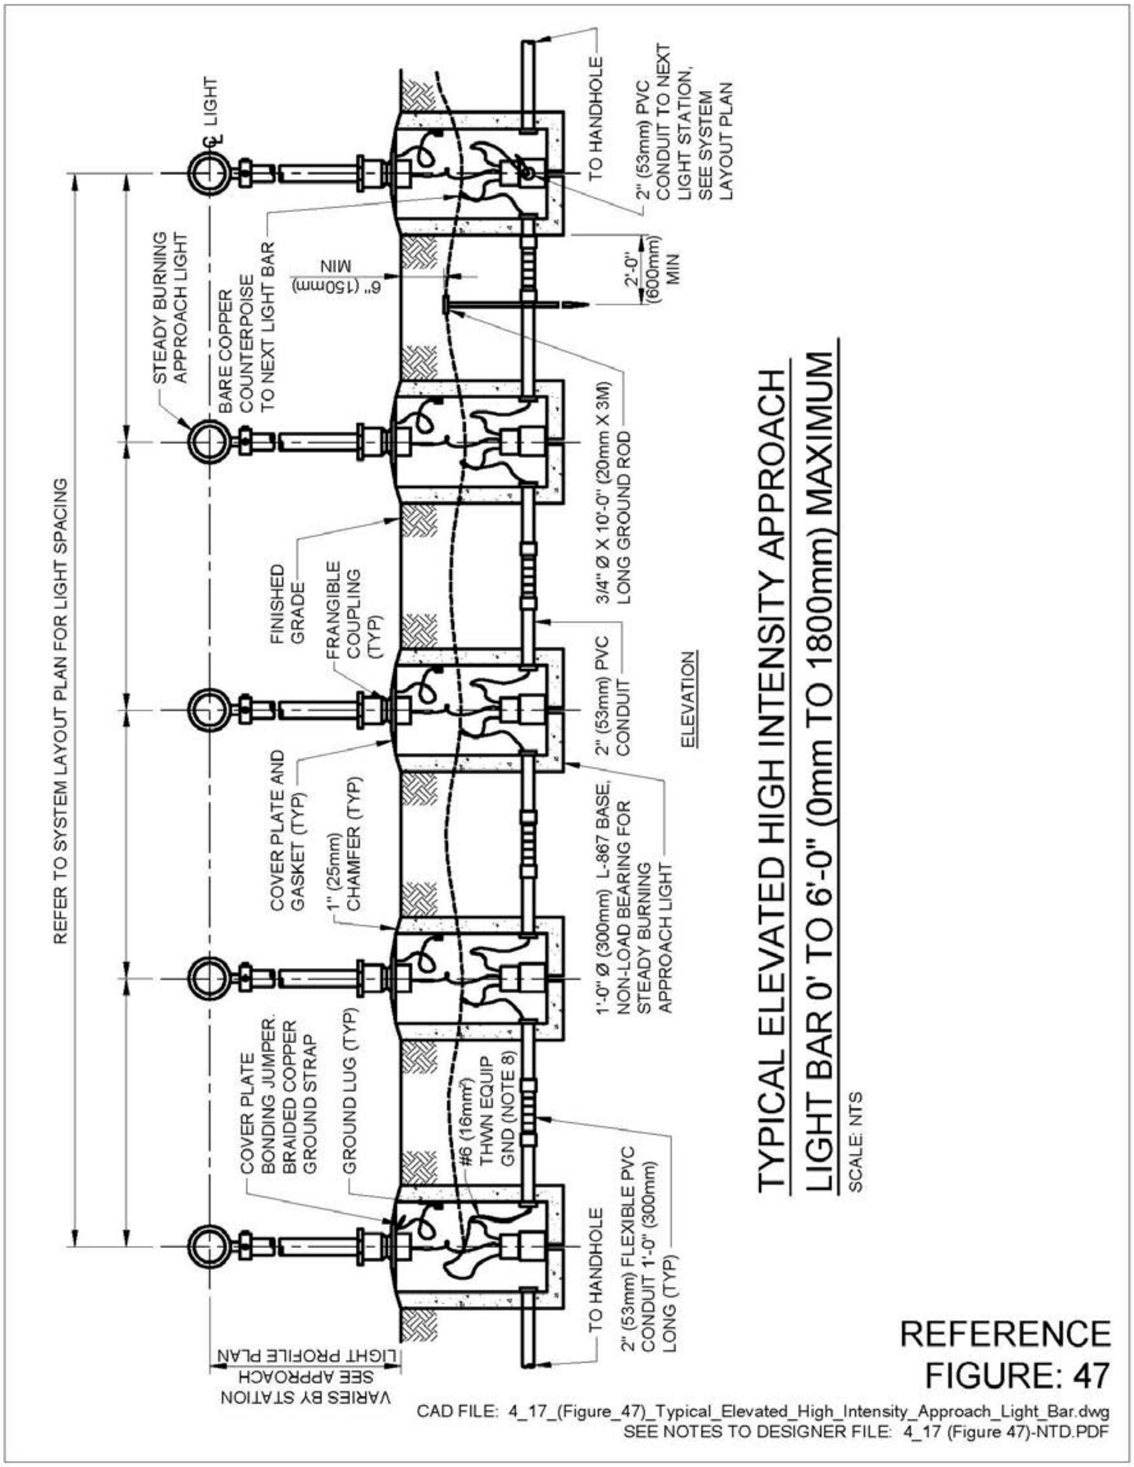
4. In some instances, the light bar may be installed in a reinforced concrete foundation similar to an in-pavement light bar as indicated in Figures 46A, 46B, 46C, 46D, 46E and 46F. The installation of the foundation would be the same except the light fixtures would be elevated. Typically, L-867 (non-loadbearing) base cans are used when the lights are located in turf areas. However, some commands require L-868 (load-bearing) base cans. Attention should be paid to the difference in the bolt circles for the two cans and providing the correct cover plate for the can being installed. L-867 cans utilize a 10 ½" (265mm) B.C. and L-868 utilize an 11 ¼" (285mm) B.C. Also, in some instances, a 15" (380mm) diameter can is required rather than 12" (305mm) diameter. The designer should consult with the Major Command for which the project is being designed for their requirements.

5-17.1.2 Drawing Notes for Figure 47.

1. Place all elevated light fixtures on 12" (305mm)∅ L-867, non-load bearing bases.

2. Maximum mounting height of configuration indicated is 6'-0" (1800mm). For mounting installation of more than 6'-0" (1800mm), see tower installation details.

Figure 47. Typical Elevated High Intensity Approach Light Bar 0' to 6'0" (0mm to 1800mm) Maximum



5-18 Typical In-Pavement High Intensity Threshold Light Foundation with Interleaved Edge Light Circuits.

5-18.1 Figures 48A, 48B, 48C, 48D, 48E.

5-18.1.1 Notes to Designer.

1. These figures show a typical foundation for a threshold light bar with interleaved edge light circuits.

2. No more than five lights should be in a bar before an expansion joint is installed.

3. Ensure photometric requirements are specified. Threshold lights must meet 10,000 CD min. average in green for a high intensity system.

4. The use of high-density polyethylene (HDPE) conduit allows the flexibility required of routing the conduit around cans. Two edge light and one threshold circuit feed the lights in the threshold bar. Refer to Figure 56 for high intensity threshold bar wiring diagram.

5-18.1.2 Drawing Notes for Figures 48A and 48B.

1. Not all fixtures in threshold bar are indicated for clarity. Threshold bar continues across runway and is symmetrical about runway centerline.

2. Interweave conduits as indicated.

3. Refer to Figure 56 for typical wiring diagram.

5-18.1.3 Drawing Notes for Flush Fixtures, Figure 48E.

1. Install corner edge of snow plow ring flush with pavement surface with a tolerance of +0", -1/16" (1.6mm). Check tolerance with straight edge. See Figure 19B.

2. Submit all base can installation techniques, methods, materials, etc., to the government for review and approval prior to the start of work.

3. Before backfilling around the base cans, the contractor must demonstrate to the government that the base cans are at the correct location, elevation, azimuth, and rotation.

4. Protect the finished pavement surface from foreign substances which could cause staining, i.e., concrete, oil, etc. The contractor must immediately clean all spills and correct/clean any stained surfaces at no additional cost to the government.

5. The base can cover mounting bolts must extend thru the base can mounting flange into the base can a minimum of 0.5" (13mm). The bolts must be threaded the full length of the bolt.

6. Concrete around base cans and duct/conduit must be completely consolidated by mechanical means and free of any voids.

7. For blank base cans, delete light fixture and install 3/4" (19mm) steel blank cover.

8. Air Force / Army Airfields: Connect local ground rod to base cans. Route counterpoise around base cans. Navy Airfields: Connect counterpoise to base cans.

9. Install top of edge of snow plow ring flush with pavement surface with a tolerance of +0", -1/16" (1.6mm).

10. If the distance between the edge of the snow ring and concrete is 1/8" (3mm) or less, seal top of opening with P-605 sealant and delete the P-606 compound.

11. The top of fixture must not exceed the top of the snow plow ring (+0, -1/8" (3mm)).

12. Install finished surface of concrete beam flush with adjacent pavement (+0, -1/16" (1.6mm))

5-19 **Typical Elevated High Intensity Approach/ Threshold Light 6'0" (1800mm) Maximum.**

5-19.1 **Figure 49.**

5-19.1.1 **Notes to Designer.**

1. The color filter used is dictated by the system.

2. Ensure proper lamp wattage is utilized to meet the photometric requirements specified in UFC 3-535-01. Recommend specifying photometric requirements in the contract documents.

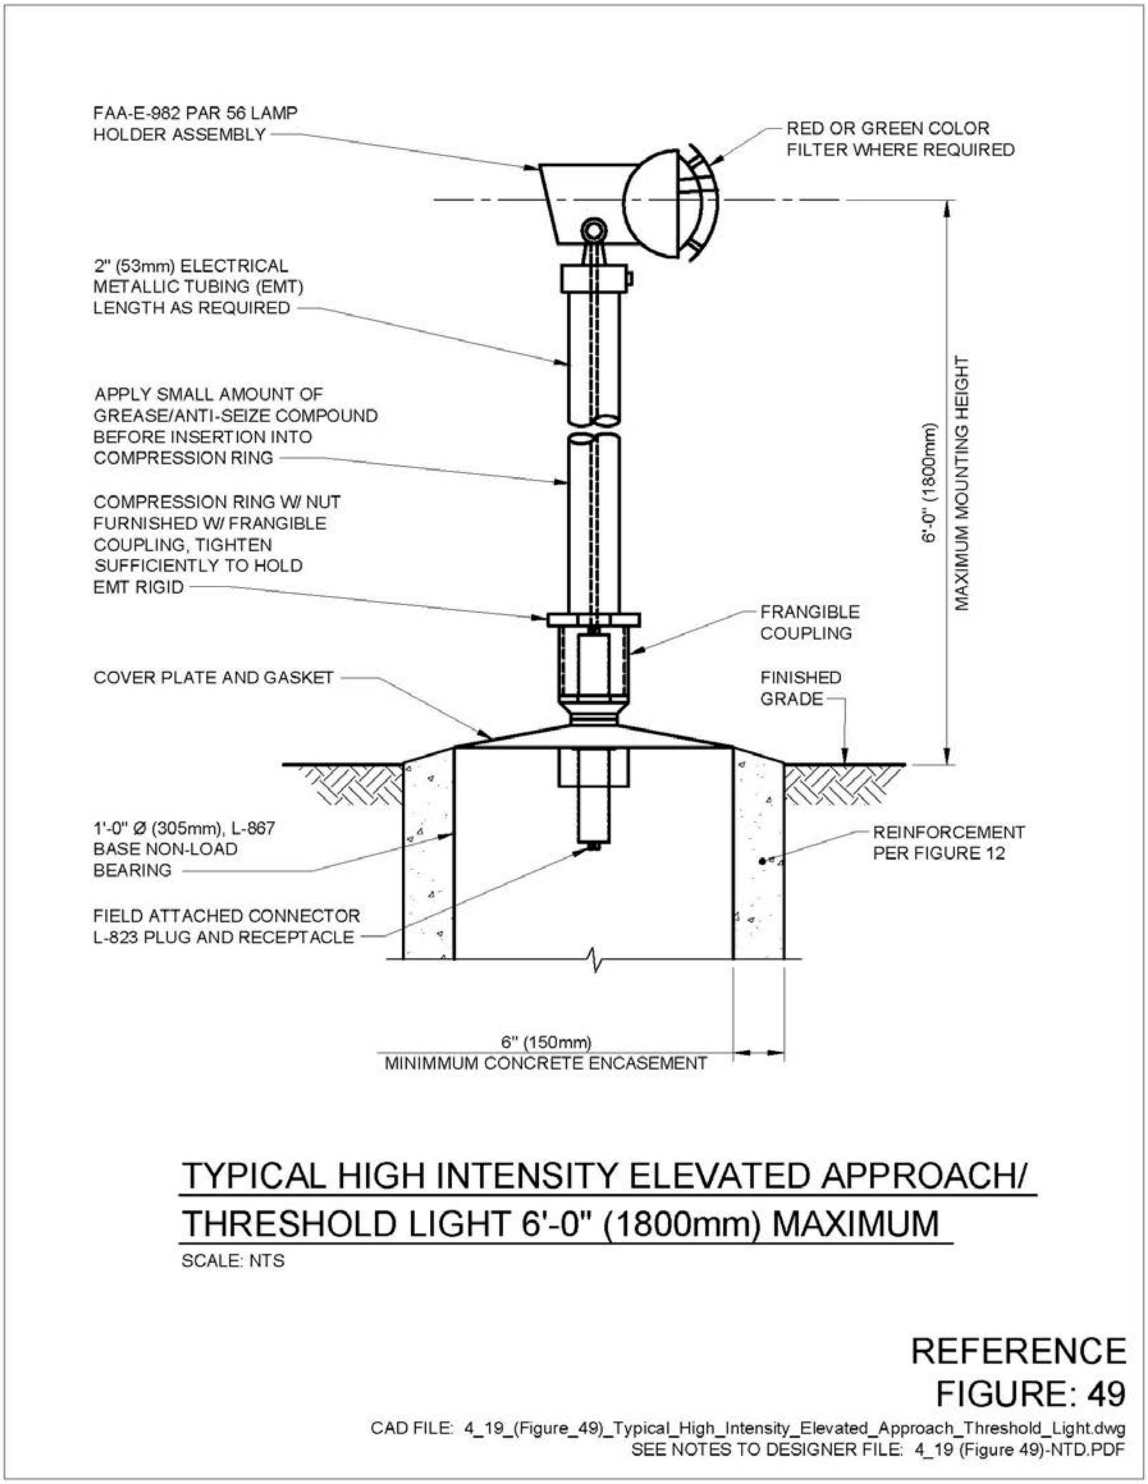
5-19.1.2 **Drawing Notes for Figure 49.**

1. Green color filter for threshold bar.

2. Red color filter for side row barrettes (ALSF-2); pre-threshold and terminating bars (ALSF-1, SALS).

3. No color filter for centerline bars; 500' (150m) bar (ALSF-2); 1000' (300m) bar (ALSF-1, ALSF-2, SALS, SSALR).

Figure 49. Typical High Intensity Elevated Approach/Threshold Light 6'0"



(1800mm) Maximum

5-20 **ALSF-1 Approach Light System Configuration.**

5-20.1 **Figures 50A, 50B, 50C.**

5-20.1.1 **Notes to Designer.**

1. Recommend including the system layout as part of the contract documents.

5-20.1.2 **Drawing Notes for Figures 50A, 50B, 50C.**

1. The threshold and the approach light system up to and including station 9+00 are in-pavement in paved overruns, and elevated in non-paved overruns.

2. For reference only, runway end lights consist of 10 red lights arranged in two groups of 5 lights. The lights in each group must have a uniform spacing of 10' (3m). The outboard most light in each group must be in line with the line of the runway edge lights on that side of the runway. The groups must be located symmetrically about, and on a line perpendicular to, the runway centerline within 10' (3m) of the end of the usable runway surface. Where they are collocated, runway end lights may be incorporated into the opposite end threshold fixtures.

3. The threshold bar may be “gated” to alleviate the problem of tail hook bounce. The threshold gate is accomplished by eliminating those lights in the center 70' (21m) portion centered about the runway centerline.

5-22 MALSR Wiring Diagram.

5-22.1 Figure 52.

5-22.1.1 Notes to Designer.

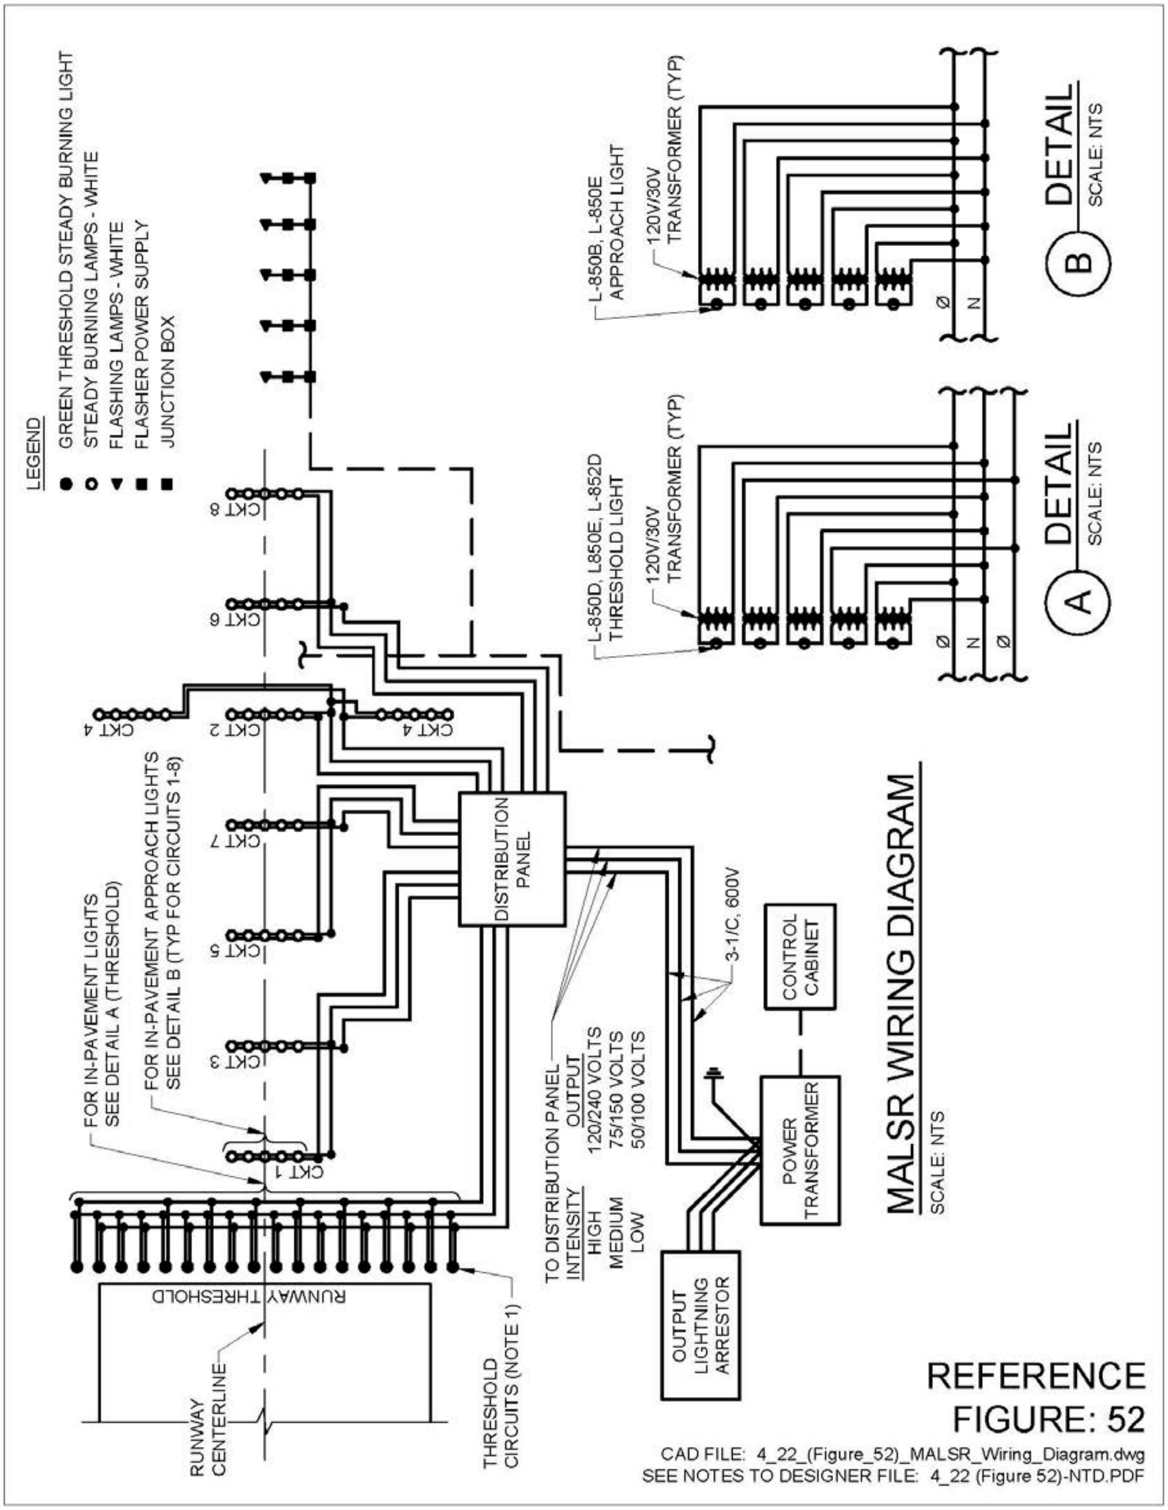
1. The MALSR system is a constant voltage (parallel) system. When designing system close attention must be given to voltage drop.

2. The MALSR system utilizes the same type of LIR structures as the high intensity ALSF systems. The light spacing on the T-bar assembly is different, however, and the lamp holder is for a PAR 38 in lieu of a PAR 56 as used on a high intensity system.

5-22.1.2 Drawing Notes for Figure 52.

1. Threshold lights are wired alternately between phases and are fed by a 2-pole breaker.

Figure 52. MALSR Wiring Diagram



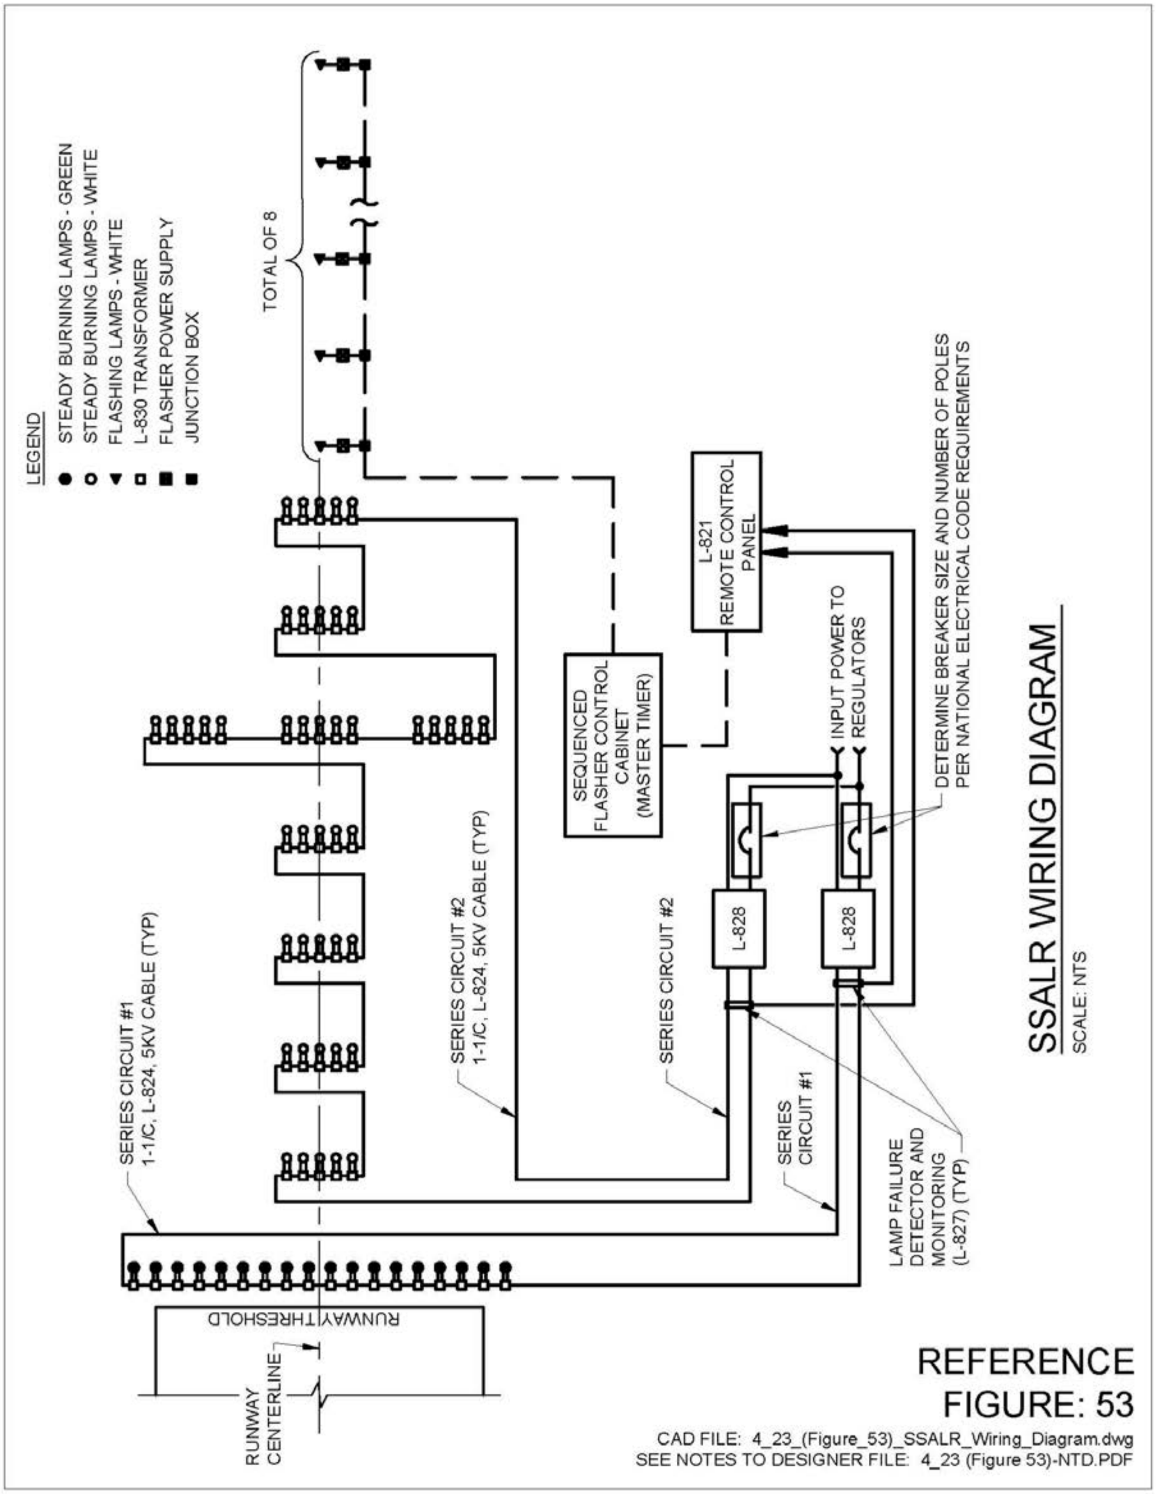
5-23 SSALR Wiring Diagram.

5-23.1 Figure 53.

5-23.1.1 Notes to Designer.

1. Typically high intensity approach light systems are 20 amp circuits. The size of the regulators depends on the fixtures to be used. On major upgrades or new installations recommend researching the use of most recent 200 watt 6.6 amp lamp that meets the photometric requirements for the steady burn lamp. An energy savings and smaller regulator size may result. Refer to UFC 3-535-01 for more information.

Figure 53. SSALR Wiring Diagram



5-24 L.I.R. Structure MS-20.

5-24.1 Figure 54.

5-24.1.1 Notes to Designer.

1. The MS-20 structure includes the crossbar and lowering device. The manufacturer provides standard details for mounting the MS-20 structure onto the tower platform. These details should be given to the proposed tower manufacturer.

2. Conduit and wiring details for the structure should be included in the contract documents. Conduit size and number of conductors will depend on the number and types of lights installed. Approved manufacturers of approach light systems should be consulted.

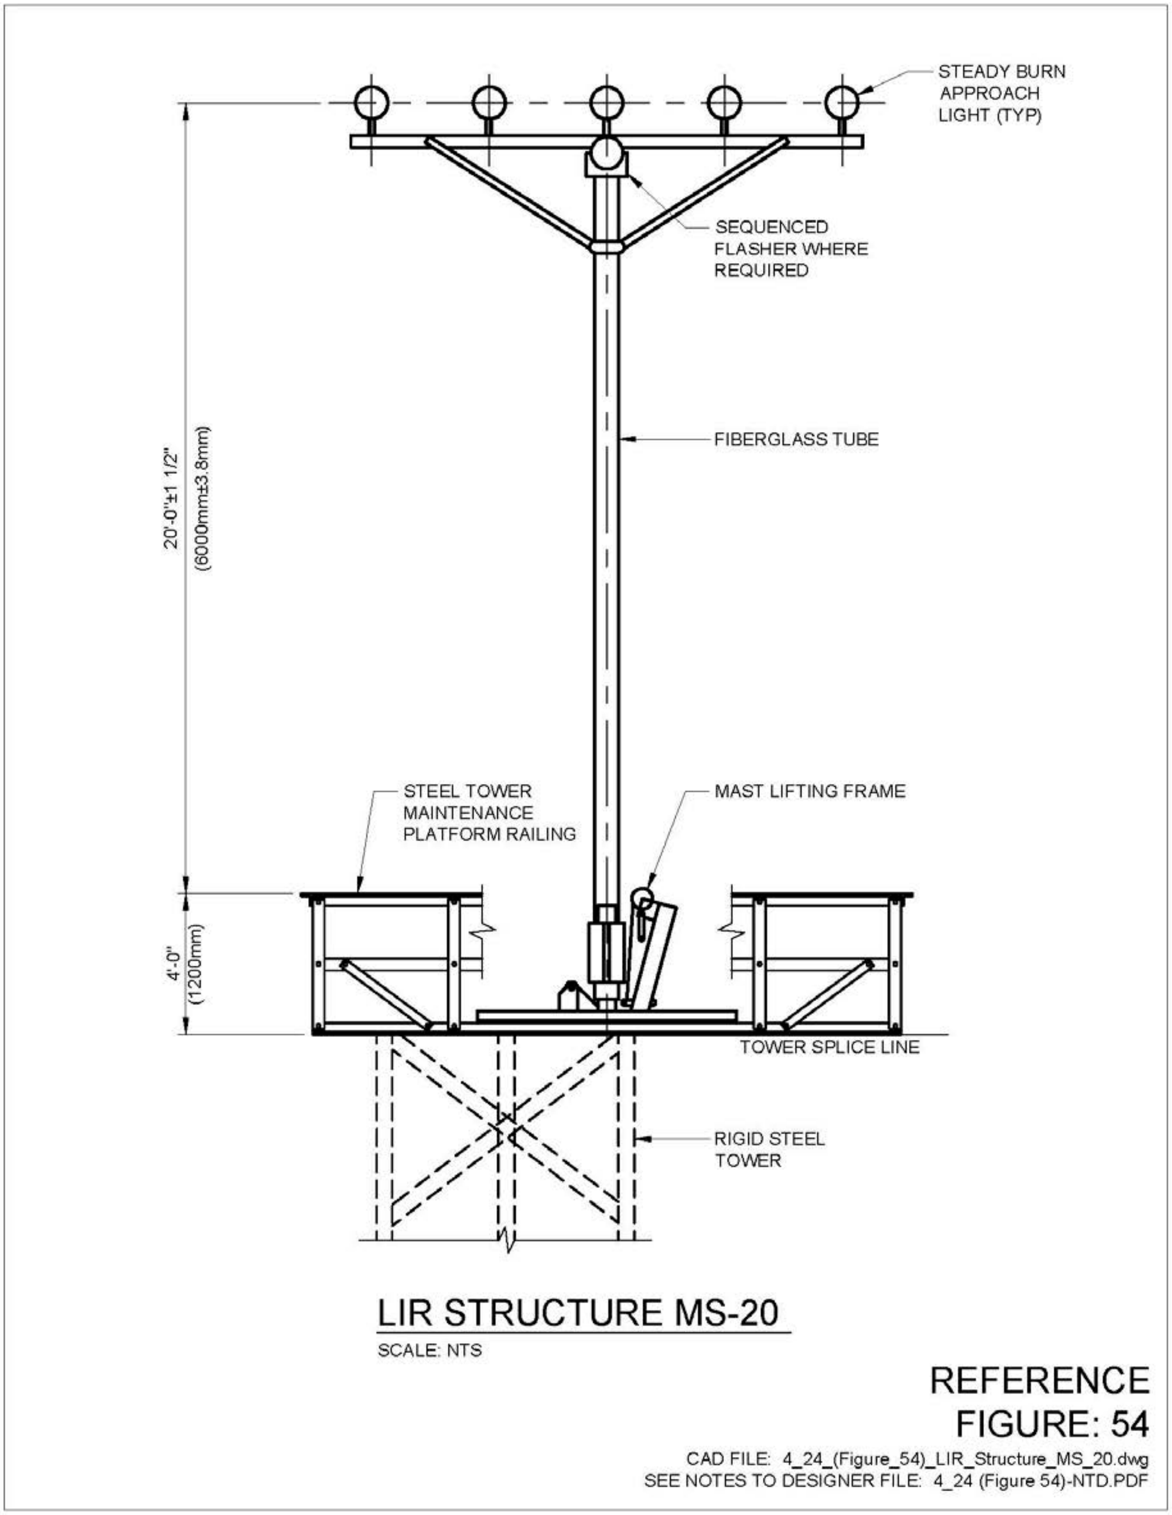
3. If a sequenced flasher is to be installed, the flasher power supply should be installed on the maintenance platform and the flasher junction box should be installed at grade. However, if installation is in a flood plain or wet area both flasher power supply and junction box should be installed on the maintenance platform. Cables may then be routed underground or aerially.

5-24.1.2 Drawing Notes for Figure 54.

1. Install mast lifting frame, fiberglass tube, and lights per manufacturer’s requirements.

2. Install maintenance platform on steel tower per manufacturer’s requirements.

Figure 54. L.I.R. Structure MS-20



5-25 **Approach Light Structure 40' to 128' (12m to 38.4m).**

5-25.1 **Figure 55.**

5-25.1.1 **Notes to Designer.**

1. The top 20' (6m) of the structure is the low impact resistant portion of the overall structure. The height of the required rigid steel tower is determined by subtracting 20' (6m) for the L.I.R. structure and 4'-0" (1.2m) for the maintenance platform and railing from the overall height as indicated in the approach light system profile plan.

2. Prior to designing the foundation for the tower, borings should be taken in the field for soil analysis. Many factors will affect the type and size of foundation to be installed (i.e. type of soil, existence of rock or ledge, soil bearing capacity, frost depth, etc.). The designer should base the foundation design on these factors and consult with the tower manufacturer regarding EPA (Effective Projected Area) for wind loading. The wind loading must include the proposed fixtures and hardware to be installed on the tower.

5-25.1.2 **Drawing Notes for Figure 55.**

1. Design tower for appropriate loads based on ANSI/TIA-222, or on stricter local codes if required at site.

2. Base foundation design on local terrain and subsurface conditions, and tower loads.

3. Provide ladder for climbing entire height of rigid tower, with safety climbing device, meeting ANSI/TIA-222.

4. Provide suitable locking device for nuts on all tower and anchor bolts.

5. Tower manufacturer should provide detail fabrication drawings based on furnished height and load requirements.

6. Provide grounding for the steel tower and platform per ANSI/TIA-222.

5-26 **High Intensity Threshold Bar Wiring Diagram (Air Force).**

5-26.1 **Figure 56.**

5-26.1.1 **Notes to Designer.**

1. Figure is self-explanatory.

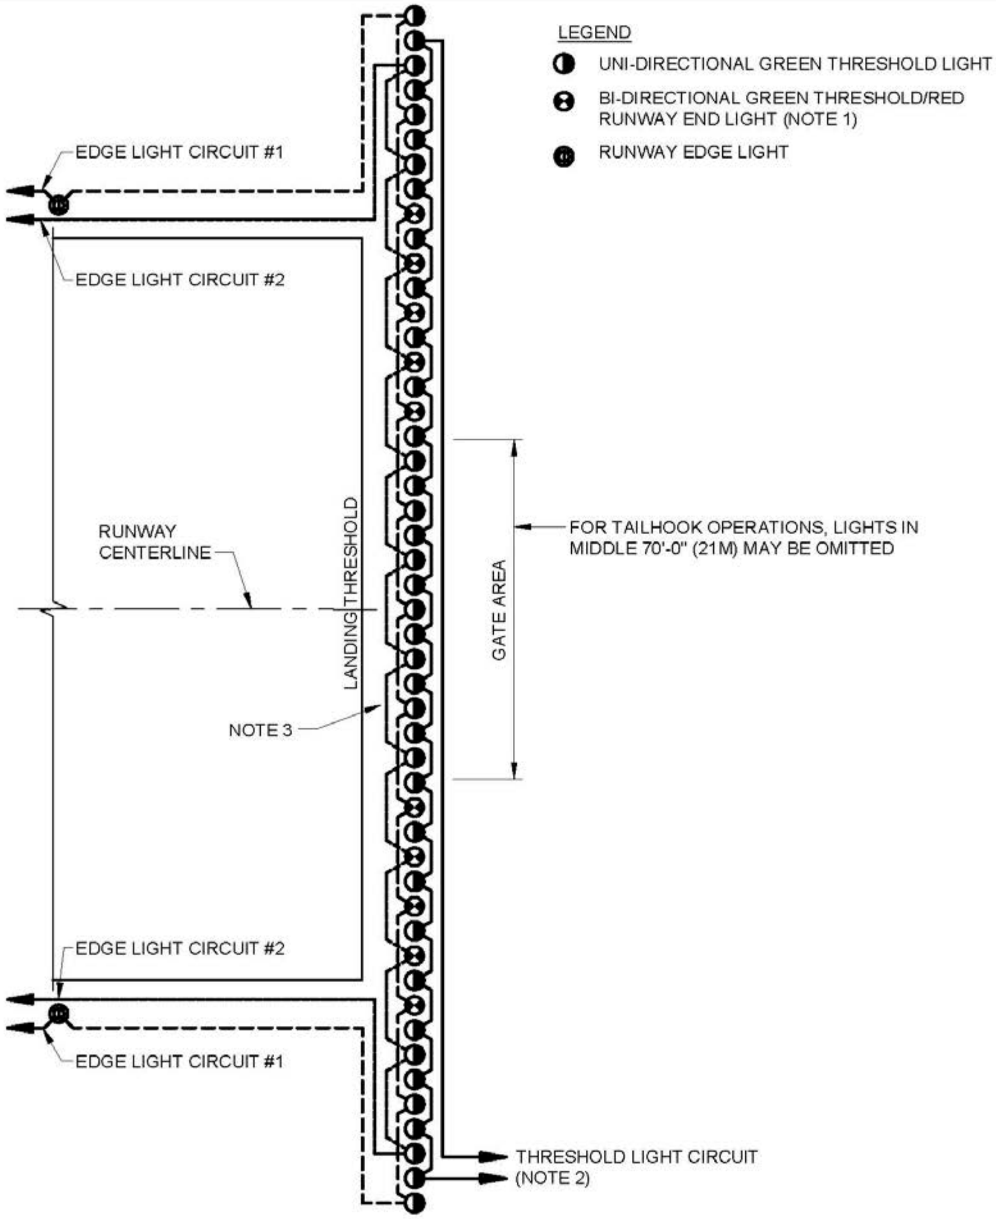
5-26.1.2 **Drawing Notes for Figure 56.**

1. The bi-directional runway end/threshold light may be installed as separate uni-directional fixtures. The bi-directional fixture must meet the photometrics for threshold and end lights as indicated in UFC 3-535-01.

2. Control circuits for threshold regulator must be wired in parallel with edge lighting control circuits. For runway edge light regulator(s) such that threshold lights are energized and at same intensity as runway edge lights.

3. Where there are an even number of threshold bar lights, the two adjacent lights about the runway centerline must be connected to the same circuit to provide a symmetrical lighting pattern on each side of the runway centerline.

Figure 56. High Intensity Threshold Bar Interleaved Wiring Diagram (Air Force)



HIGH INTENSITY THRESHOLD BAR INTERLEAVED WIRING DIAGRAM (AIR FORCE)

SCALE: NTS

REFERENCE FIGURE: 56

5-27 **Threshold Bar Wiring Diagram (Army).**

5-27.1 **Figure 57.**

5-27.1.1 **Notes to Designer.**

Figure is self-explanatory.

5-27.1.2 **Drawing Note for Figure 57.**

Where there are an even number of threshold bar lights, the two adjacent lights about the runway centerline must be connected to the same circuit to provide a symmetrical lighting pattern on each side of the runway centerline.

Figure 57. Threshold Bar Wiring Diagram (Army)

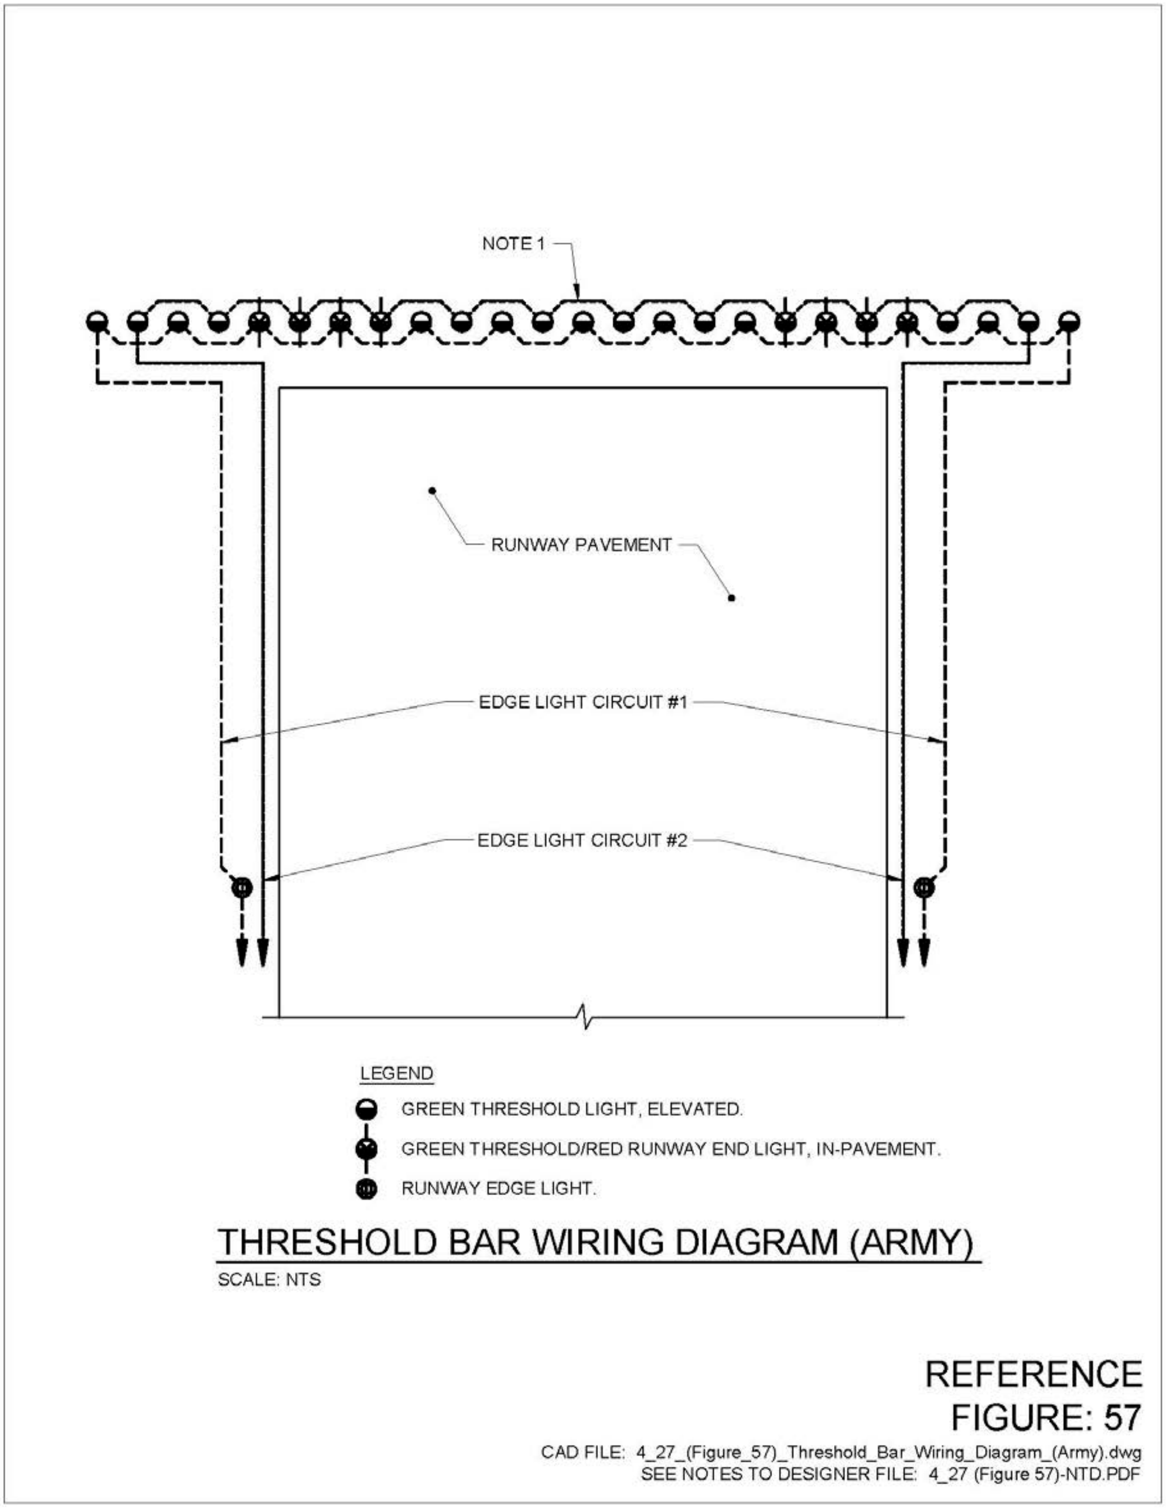

Figure 58. Reserved.

5-28 High Intensity ALSF-1/SSALR Wiring Diagram.

5-28.1 Figure 59.

5-28.1.1 Notes to Designer.

1. When designing the approach light system, several factors must be taken into account:

    a. Each regulator should be equal in kw capacity,

    b. No two adjacent light bars should be on the same circuit.

    c. Circuiting should be symmetrical about the runway centerline.

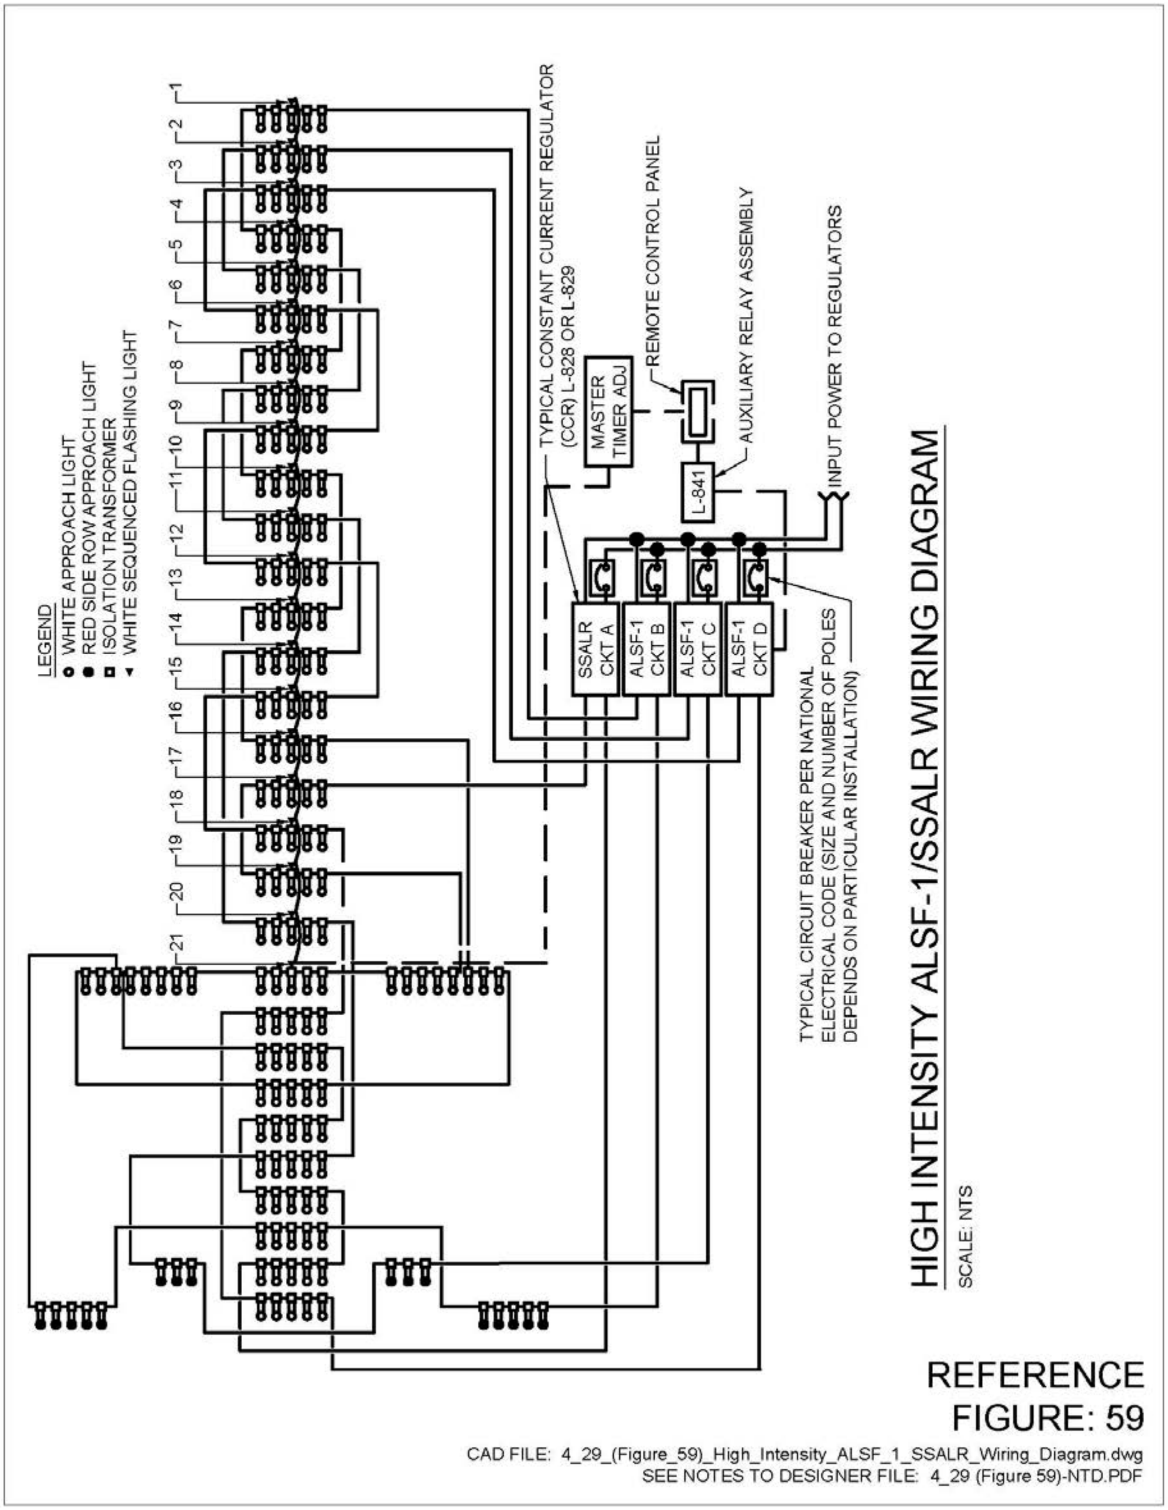
2. Some locations may use a single 1500 watt isolation transformer to feed five 300 watt tower mounted lights.

3. The present trend is to limit the regulator size to 30kw, 20 amp. This is being done to lower the available voltage throughout the system for safety reasons. Also, the trend may be to utilize 6.6 amps rather than 20 amps and newly developed light sources.

4. 50kw and 70kw regulators and 2400V input are not approved by FAA for new installations, only for replacement of existing units.

5. In SSALR mode, only flashers #1, 3, 5, 7, 9, 11, 13 and 15 operate. All 21 flashers operate in full ALSF mode.

Figure 59. High Intensity ALSF-1/SSALR Wiring Diagram



5-29 High Intensity ALSF-2/SSALR Wiring Diagram.

5-29.1 Figure 60A.

5-29.1.1 Notes to Designer.

1. When designing the approach light system, several factors must be taken into account:

    a. Each regulator should be equal in kw capacity,

    b. No two adjacent light bars should be on the same circuit, and

    c. Circuiting should be symmetrical about the runway centerline.

2. Some locations may use a single 1500 watt isolation transformer to feed (5) 300 watt tower mounted lights.

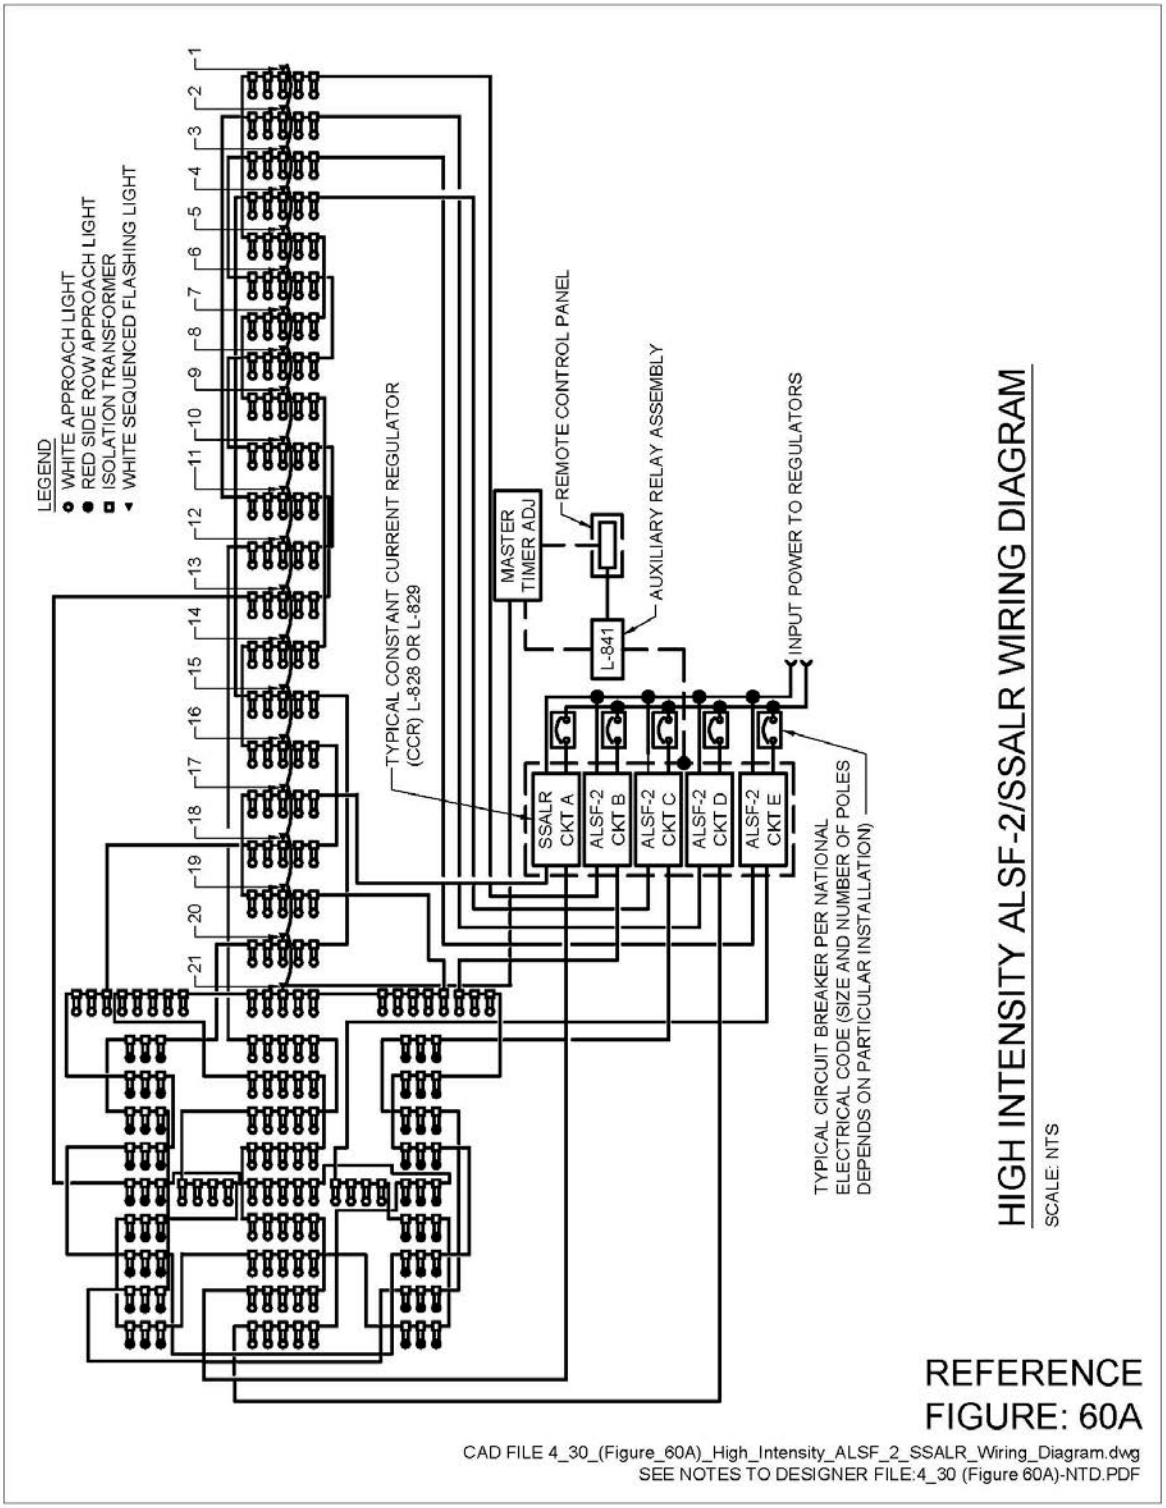
3. The present trend is to limit the regulator size to 30kw, 20 amp. This is being done to lower the available voltage throughout the system for safety reasons. Also, the trend may be to utilize 6.6 amps rather than 20 amps and newly developed light sources.

4. This wiring diagram depicts the latest circuiting from the FAA utilizing (5) 30kw regulators in lieu of (3) 50kw regulators used in older systems.

5. 50 kw and 70 kw regulators and 2400V input is not approved by FAA for new installations, only for replacement of existing units.

6. In SSALR mode, only flashers #1, 3, 5, 7, 9, 11, 13 and 15 operate. All 21 flashers operate in full ALSF mode.

Figure 60A. High Intensity ALSF-2/SSALR Wiring Diagram



5-30 ALSF-2/SSALR Wiring Diagram Modification.

5-30.1 Figures 60A, 60B, 60C.

5-30.1.1 Notes to Designer.

1. Figure 60A depicts a wiring diagram for an ALSF-2/SSALR system using more efficient lamps. Older FAA systems utilized 300-watt lamps for elevated lights and 500-watt lamps for in-pavement lights.

2. The isolation transformer must be sized by the fixture manufacturer and the photometric requirements of the fixture must conform to UFC 3-535-01.

3. This wiring diagram depicts four circuit loops for the ALSF-2/SSALR system and one circuit loop for the threshold.

4. Similarly, an ALSF-1/SSALR system could be reduced to three circuit loops for the system and one circuit loop for the threshold

5. The contract documents for the installation of an approach light system should include a plan and profile of the complete system showing stationing and light plane slopes.

Figure 60B. ALSF-2/SSALR Wiring Diagram Modification – Sheet 1

CHAPTER 6 PAPI and REIL Systems

6-1 FAA L-880 Style A (Constant Voltage) PCU Mounting Details.

6-1.1 Figure 61.

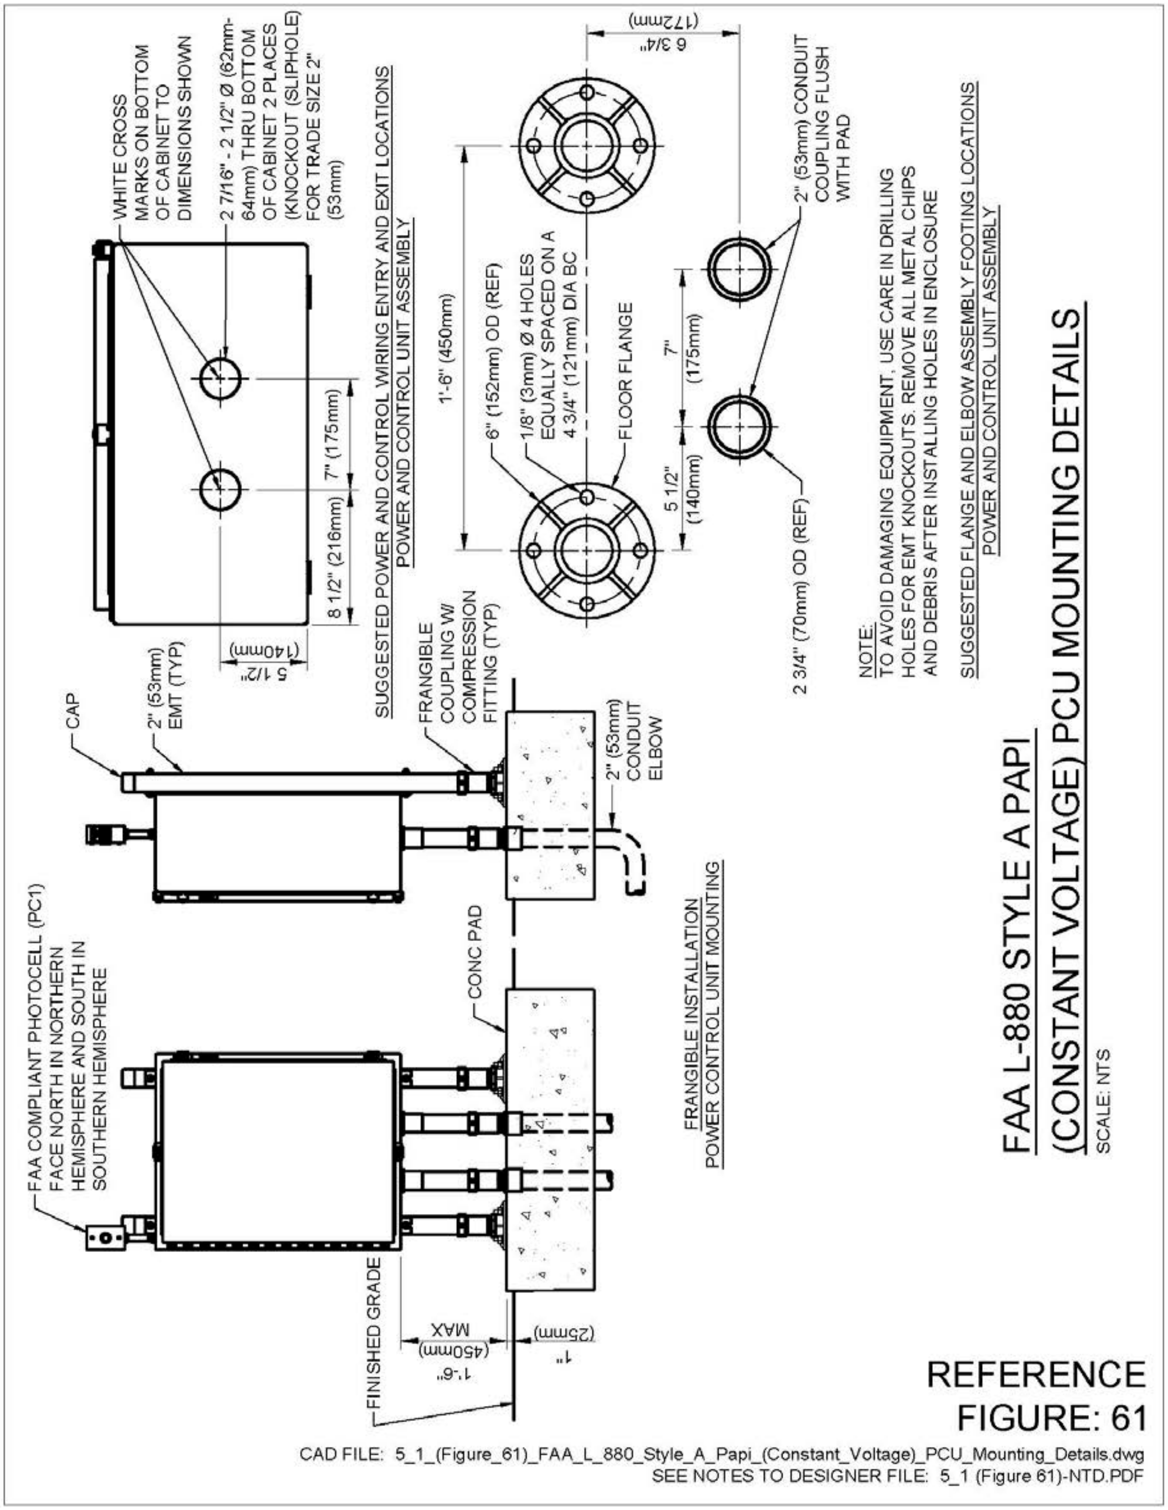
6-1.1.1 Notes to Designer.

1. Verify with manufacturer mounting dimensions and hardware.
2. Pad size indicated is minimum for this particular unit. Pad must be designed by a Registered Structural Engineer.

6-1.1.2 Drawing Notes for Figure 61.

1. Verify dimensions with equipment manufacturer.
2. Concrete pad must be minimum 30" × 18" × 12" (750mm × 450mm × 300mm).
3. Mounting hardware must be stainless steel sized per manufacturer’s requirements.
4. Installation must be per manufacturer’s requirements.

Figure 61. FAA L-880 Style A (Constant Voltage) PCU Mounting Details



6-2 **FAA L-880 Style A (Constant Voltage) System Wiring Diagram.**

6-2.1 **Figures 62A, 62B.**

6-2.1.1 **Notes to Designer.**

1. The L-880 Style A uses a constant voltage to power the system. Intensity control is accomplished automatically by an integral photocell. The system is at maximum brightness during the daytime and lower brightness ≈ 20% during hours of darkness.

2. A constant voltage source must be available within the vicinity of the system. Design must take into account voltage drop back to the supply.

3. The three-lamp version is preferred. However, newer units utilizing two lamps that meet the photometric requirements have been developed.

4. Consult with manufacturer for power requirements.

Figure 62A. FAA L-880 Style A (Constant Voltage) System Wiring Diagram

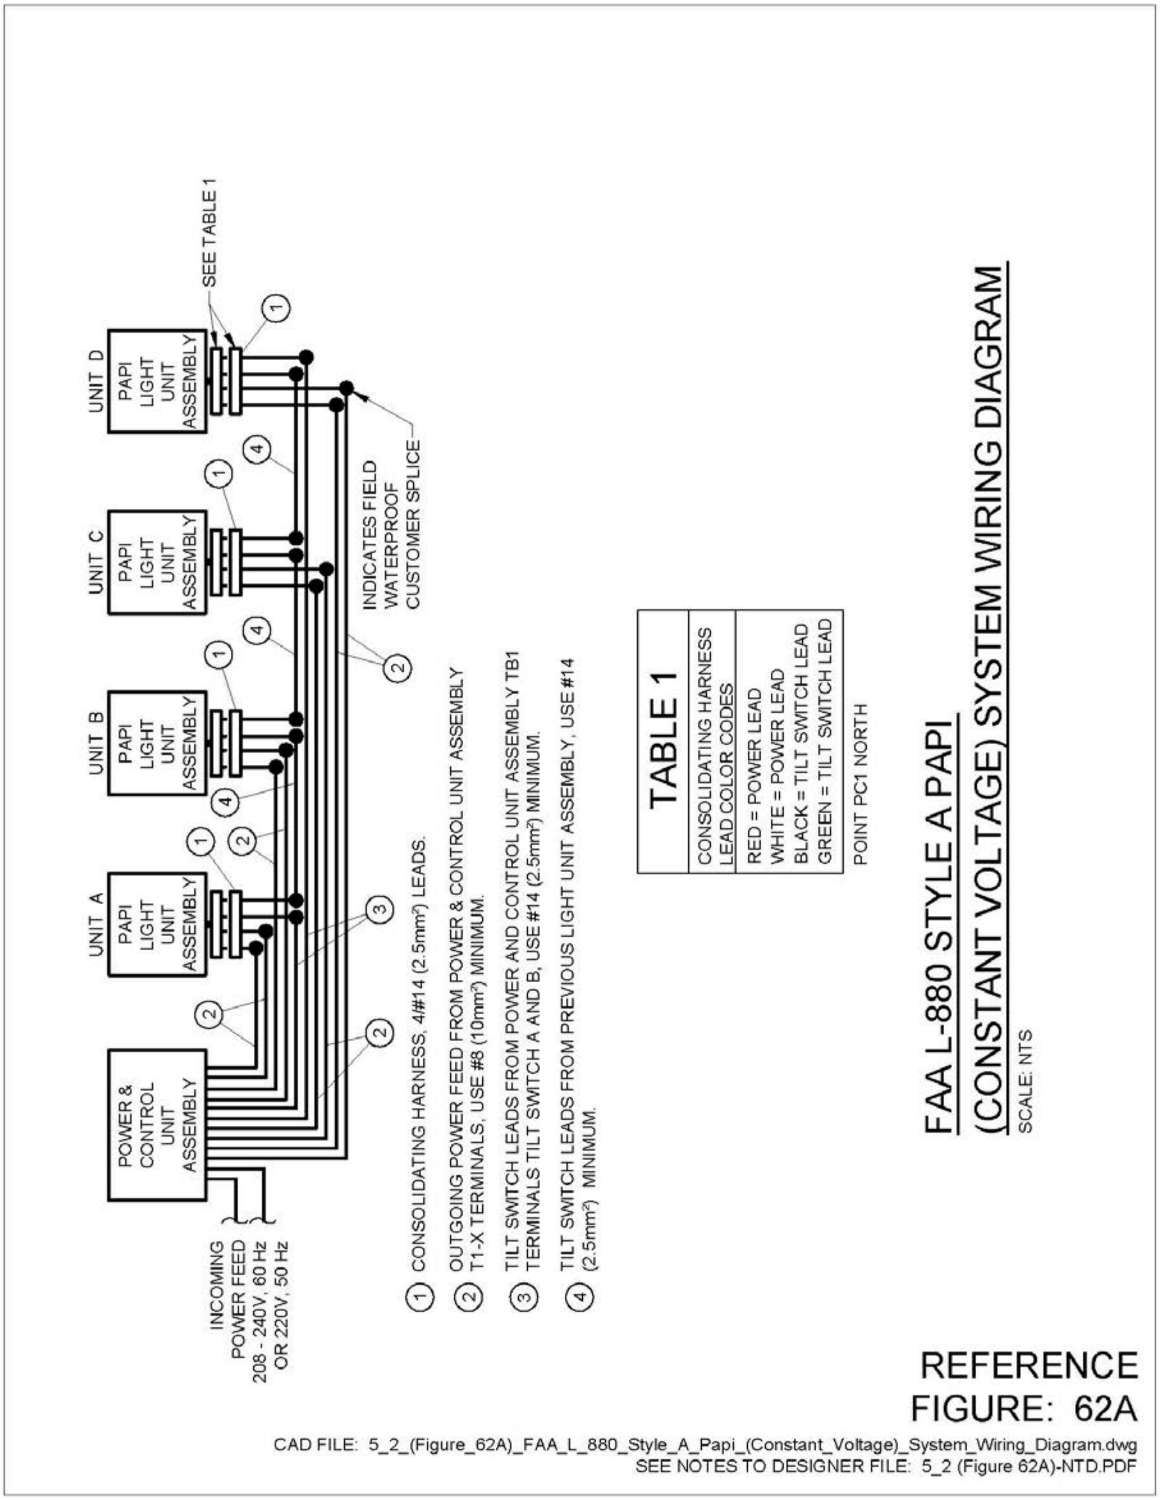


Figure 62B. Power Control Unit 3 Lamp, 4 Projector

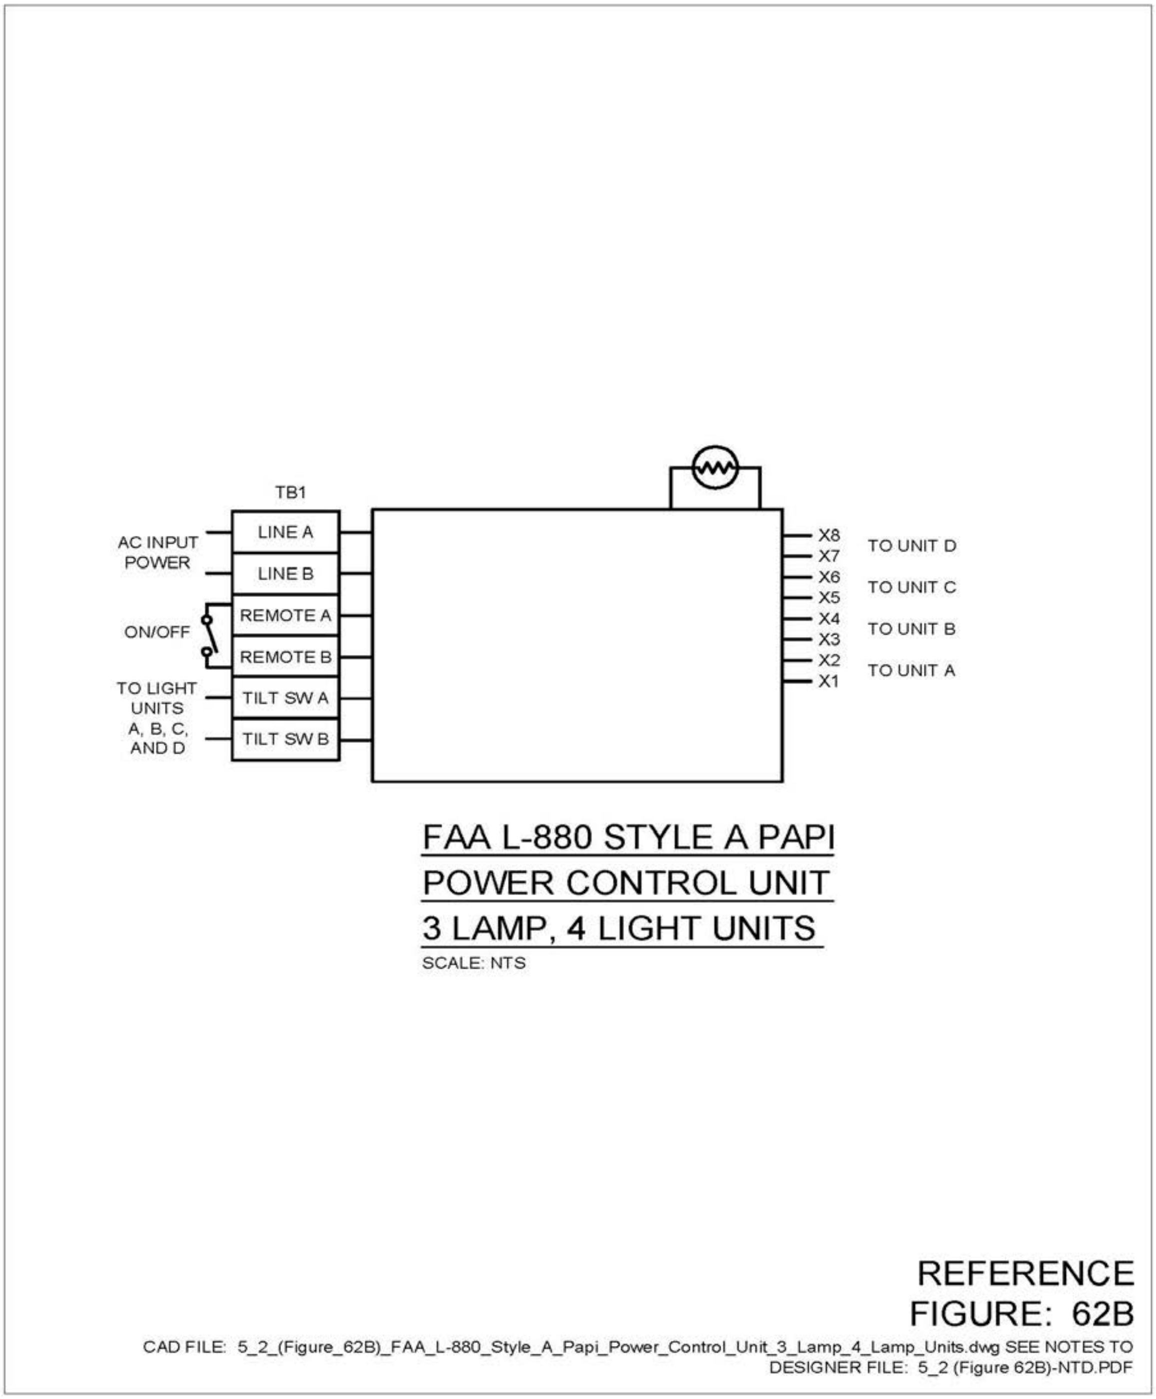
FAA L-880 Style B (Constant Current) System Wiring Diagram.



6-2.2 **Figure 63.**

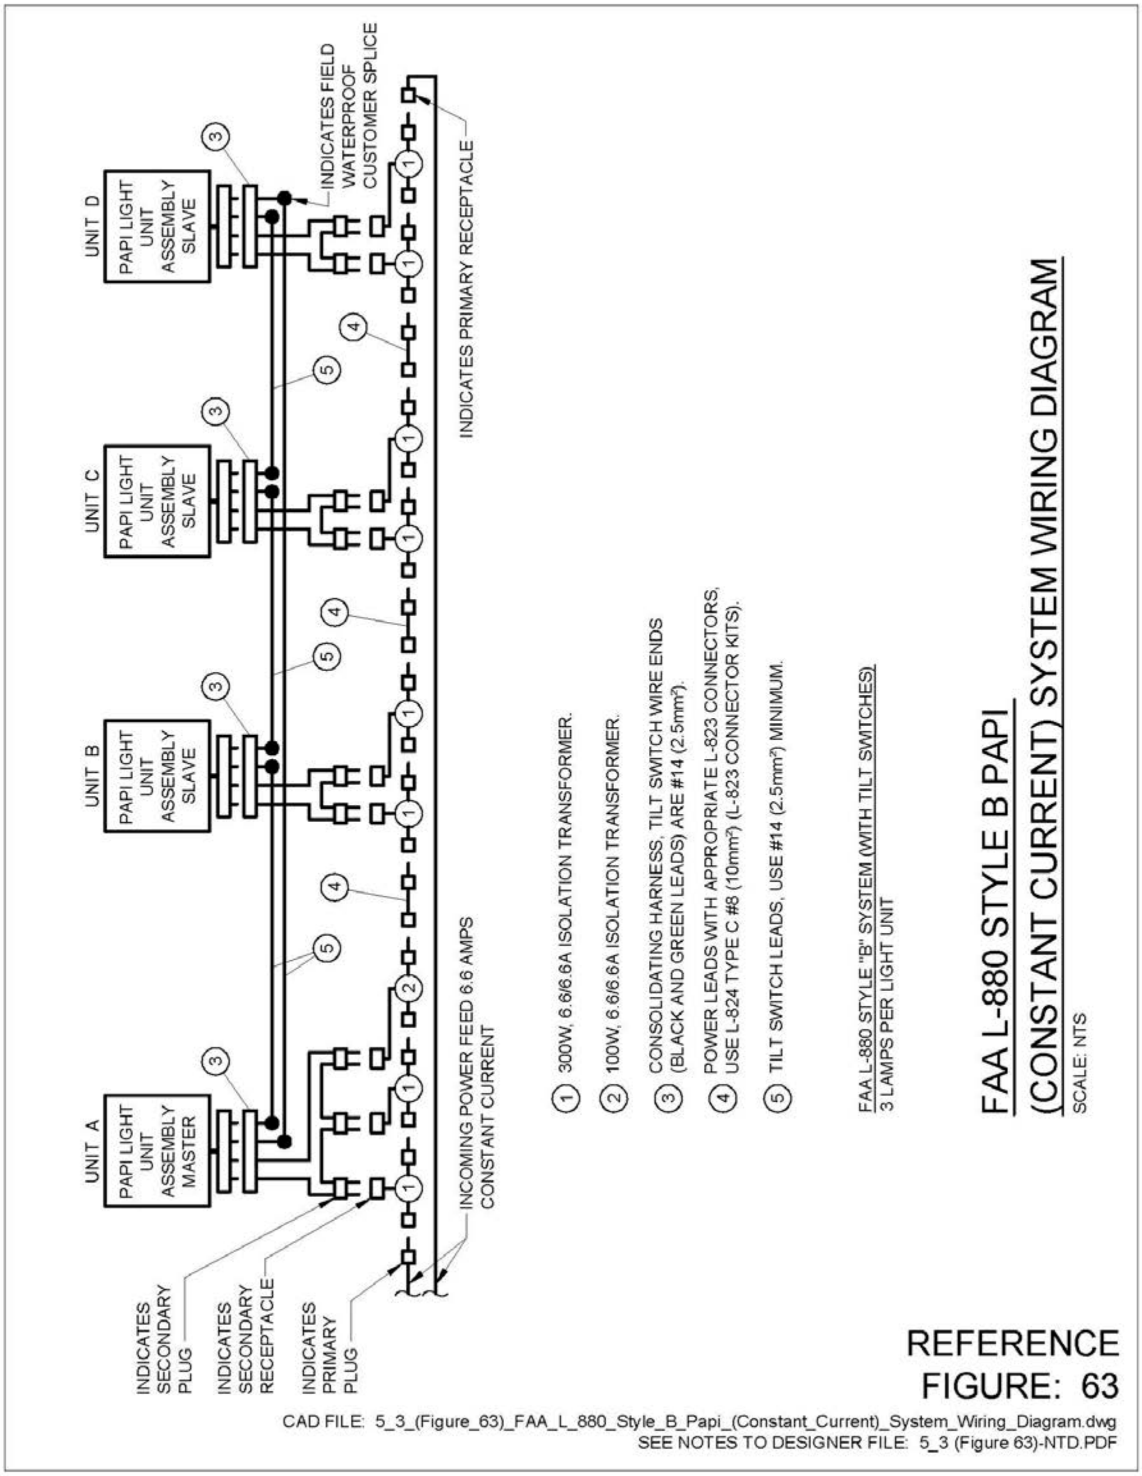
6-2.2.1 **Notes to Designer.**

1. The L-880 Style B uses a constant current source to power the system. This is typically done using a 4kw constant current regulator with 5 brightness steps. Intensity is selected manually at the control panel in the tower or vault at airfields that have 24-hour tower control. A different control scheme is used at part time or unmanned tower airfields.

2. The three-lamp version is preferred. However, newer units utilizing two lamps that meet the photometric requirements have been developed.

3. Consult with manufacturer for power requirements.

Figure 63. FAA L-880 Style B (Constant Current) System Wiring Diagram



6-3 FAA L-880 Style B (Constant Current) PAPI Power and Control Schematic Diagram.

6-3.1 Figure 64.

6-3.1.1 Notes to Designer.

1. This detail shows a typical schematic diagram of a Style B system. The actual control diagram used will depend on site specific requirements.

2. Newer installations may use computer control systems with touch-screen monitors for the control panels.

3. Although this diagram is provided for a constant current powered PAPI system served by 5-step constant current regulator, it can be used for any 5-step regulator powered system with control panels in two locations.

Figure 64. FAA L-880 Style B (Constant Current) PAPI Power and Control Schematic Diagram

SEE NOTES TO DESIGNER FILE: 5_4 (Figure 64)-NTD.PDF

6-4 PAPI Light Housing Unit (LHU) Installation Detail.

6-4.1 Figures 65A, 65B.

6-4.1.1 Notes to Designer.

1. The contract documents should show location of PAPI units and aiming angles. Refer to UFC 3-535-01 for siting requirements.

2. Verify with manufacturer pad dimensions and number of openings in cover of L-867 can.

3. The detail shows a 4" (100mm) thick concrete mow pad around the housing unit. The mow pad acts as a weed barrier 10' (3m) in front of the unit and 5' (1.5m) behind the unit. Some installations continue the weed barrier between the units. Recommend the weed barrier is extended at least 5' (1.5m) on each side of concrete foundation for the light housing unit.

4. Concrete foundation must be designed by a Registered Structural Engineer.

6-4.1.2 Drawing Notes for Figures 65A and 65B.

1. Each light unit must be aimed outward into the approach zone on a line parallel to the runway centerline within ±1/2 degree.

2. The beam centers of all light units must be within ±1" (25mm) of horizontal plane.

3. The front face of each light unit in a bar must be located on a line perpendicular to the runway centerline within a tolerance of ±1" (25mm).

4. Dimensions are approximate and must be coordinated with PAPI manufacturer.

5. Aiming angle and location of units must be indicated on contract documents.

Figure 65A. PAPI Light Housing Unit (LHU) Installation Detail

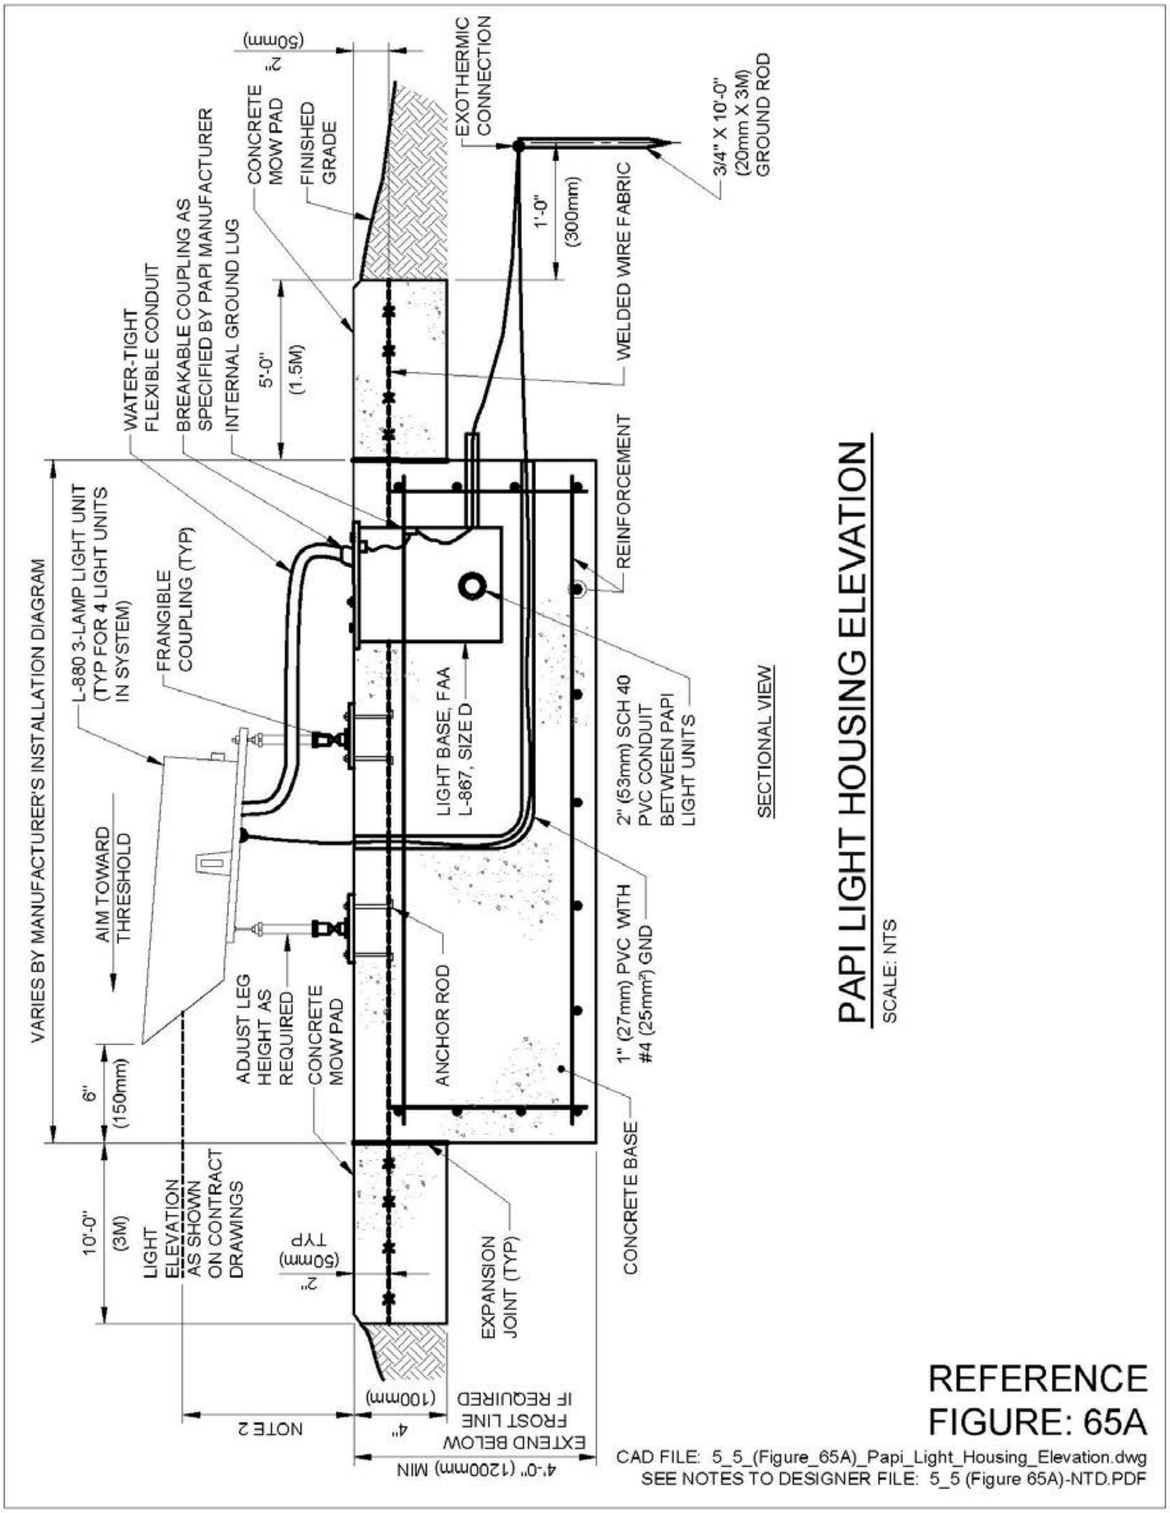

Figure 65B. PAPI Light Housing Unit (LHU) Installation Detail (continued)

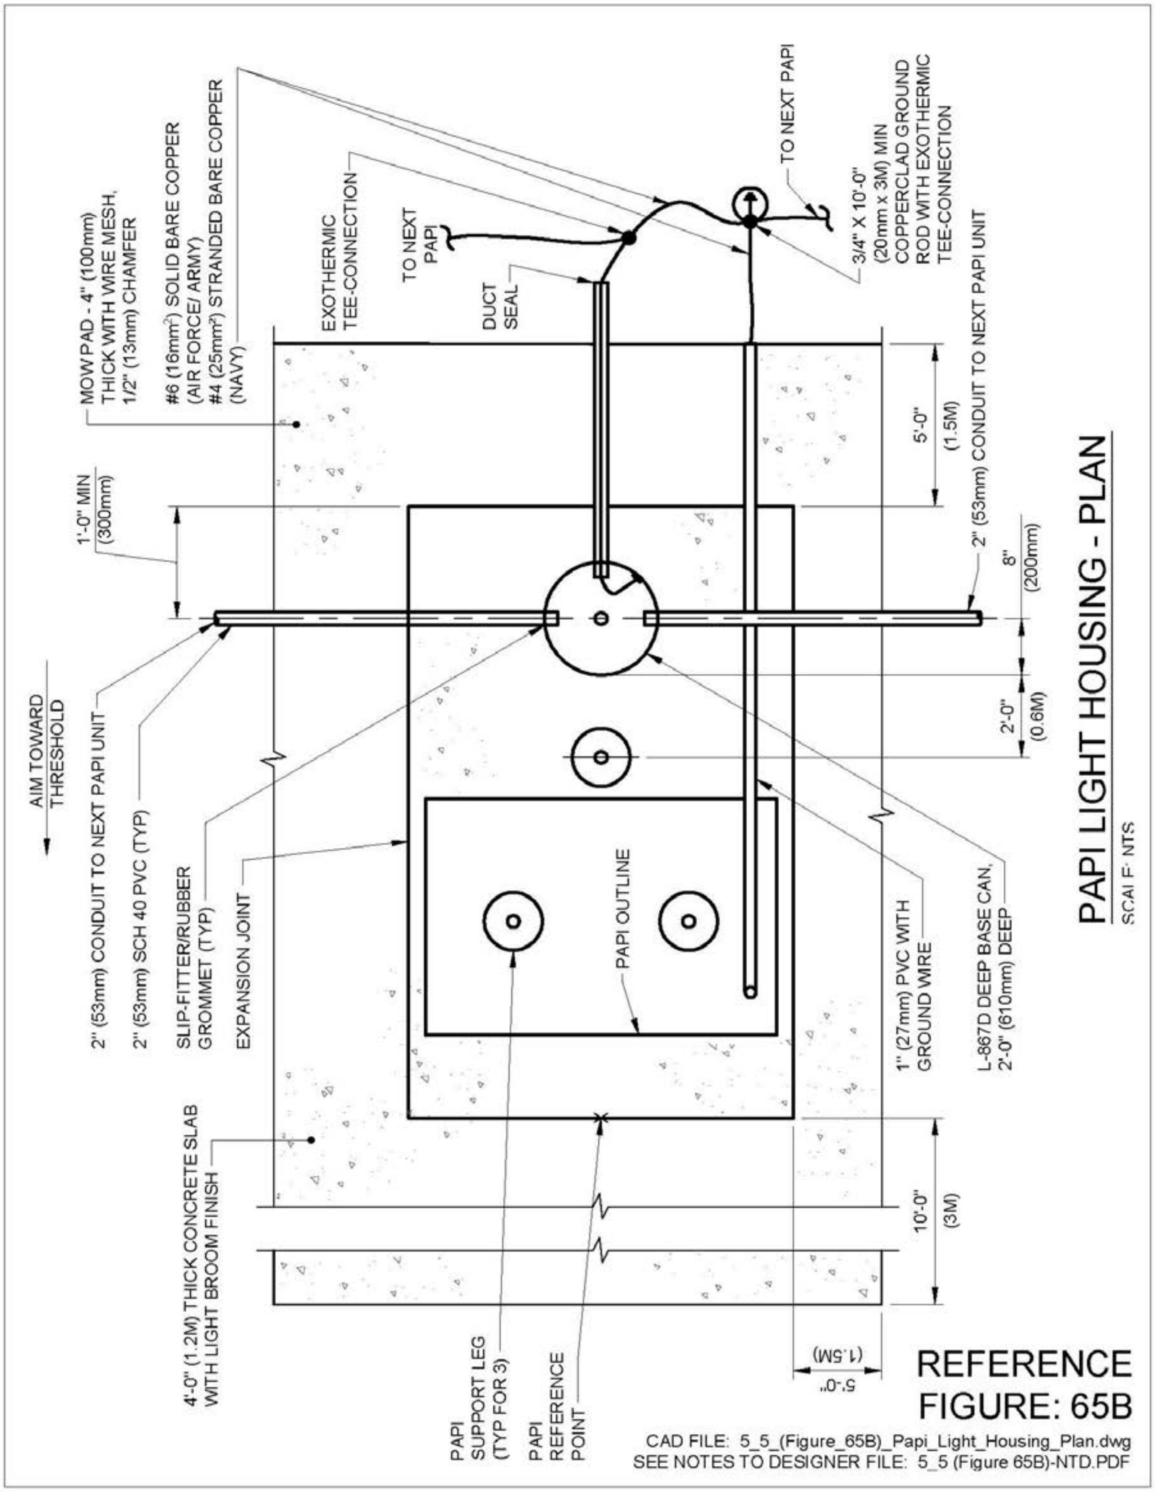


6-5 PAPI Sighting Calculations and Obstacle Clearance Surfaces.

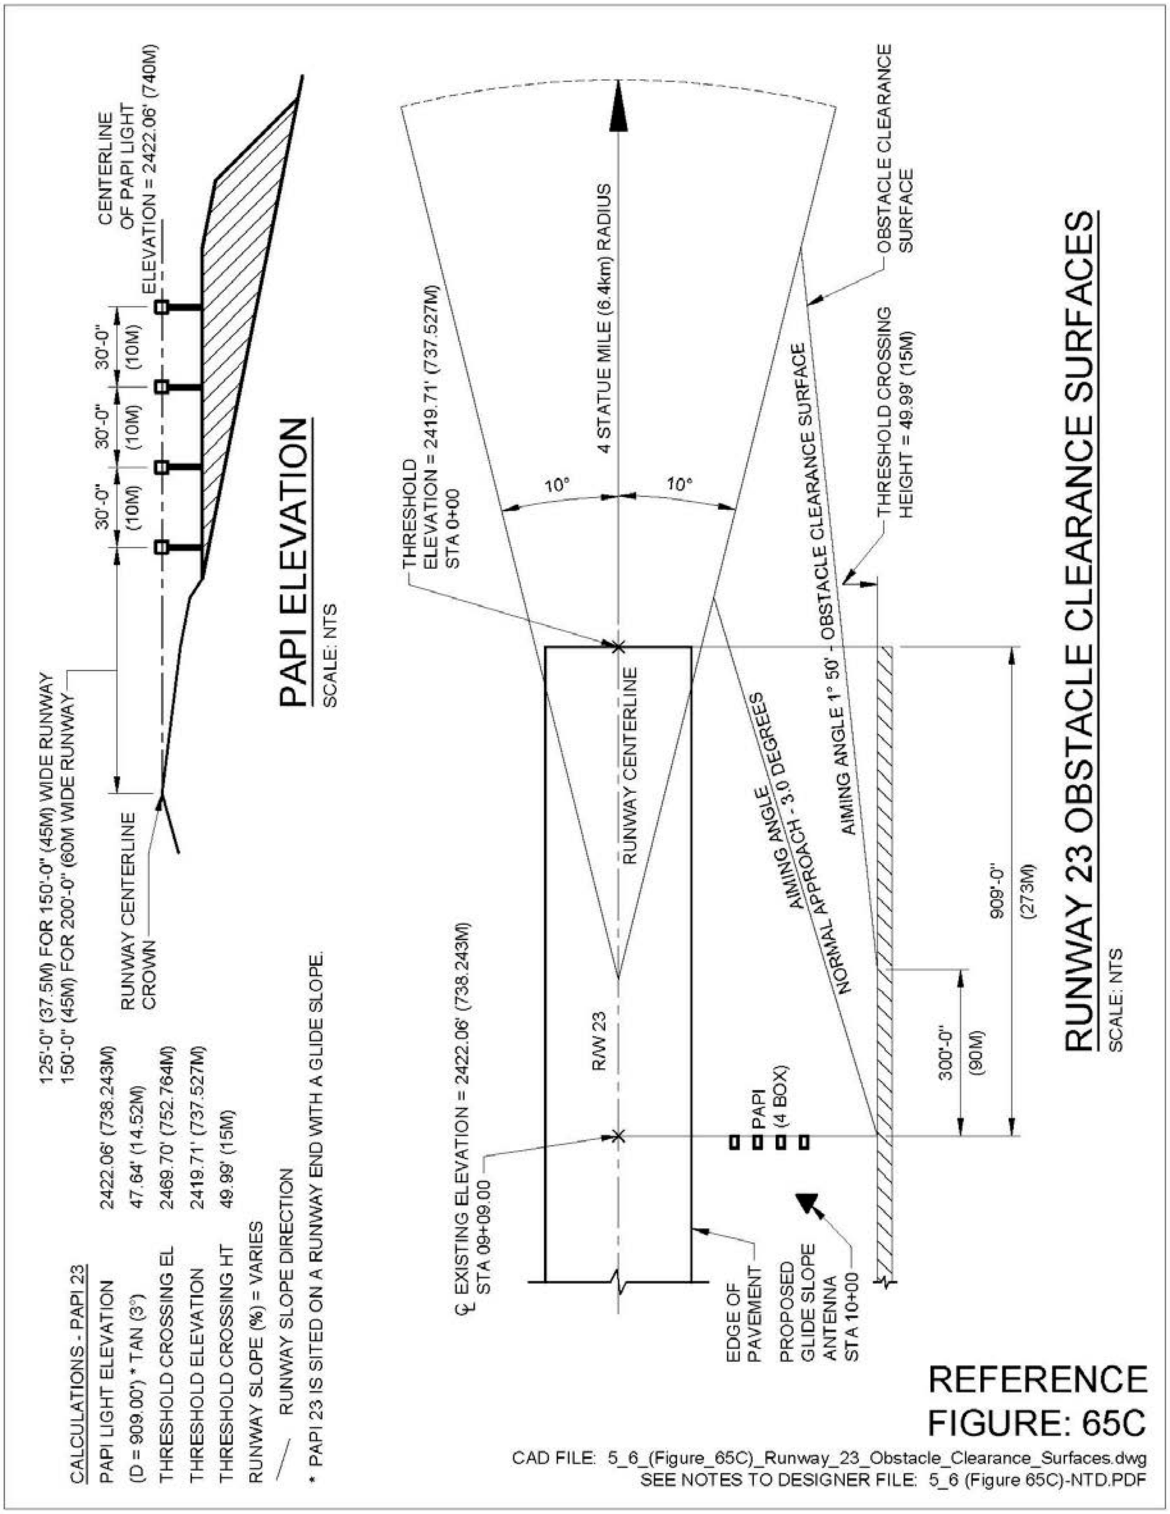
6-5.1 Figure 65C.

6-5.1.1 Notes to Designer.

1. Figure 65C shows examples of PAPI siting calculations (in accordance with UFC 3-535-01) and obstacle clearance surfaces. This information should be included on the contract documents for the project.

2. TCH is based on aiming angle (3 degrees), the same as the glideslope angle.

Figure 65C. Obstacle Clearance Surfaces



6-6 L-880 Signal Presentation and Installation Tolerances.

6-6.1 Figure 65D.

6-6.1.1 Notes to Designer.

1. Figure 65D shows the light signal presentation of a 4-box PAPI (L-880) installation as seen from an approaching aircraft. Also indicated are the installation tolerances and aiming angles of the light units. This information should be included on the contract documents for the project.

6-6.1.2 Drawing Notes for Figure 65D.

1. Aiming Parameter table:

Aiming of PAPI relative to pre-selected glide path

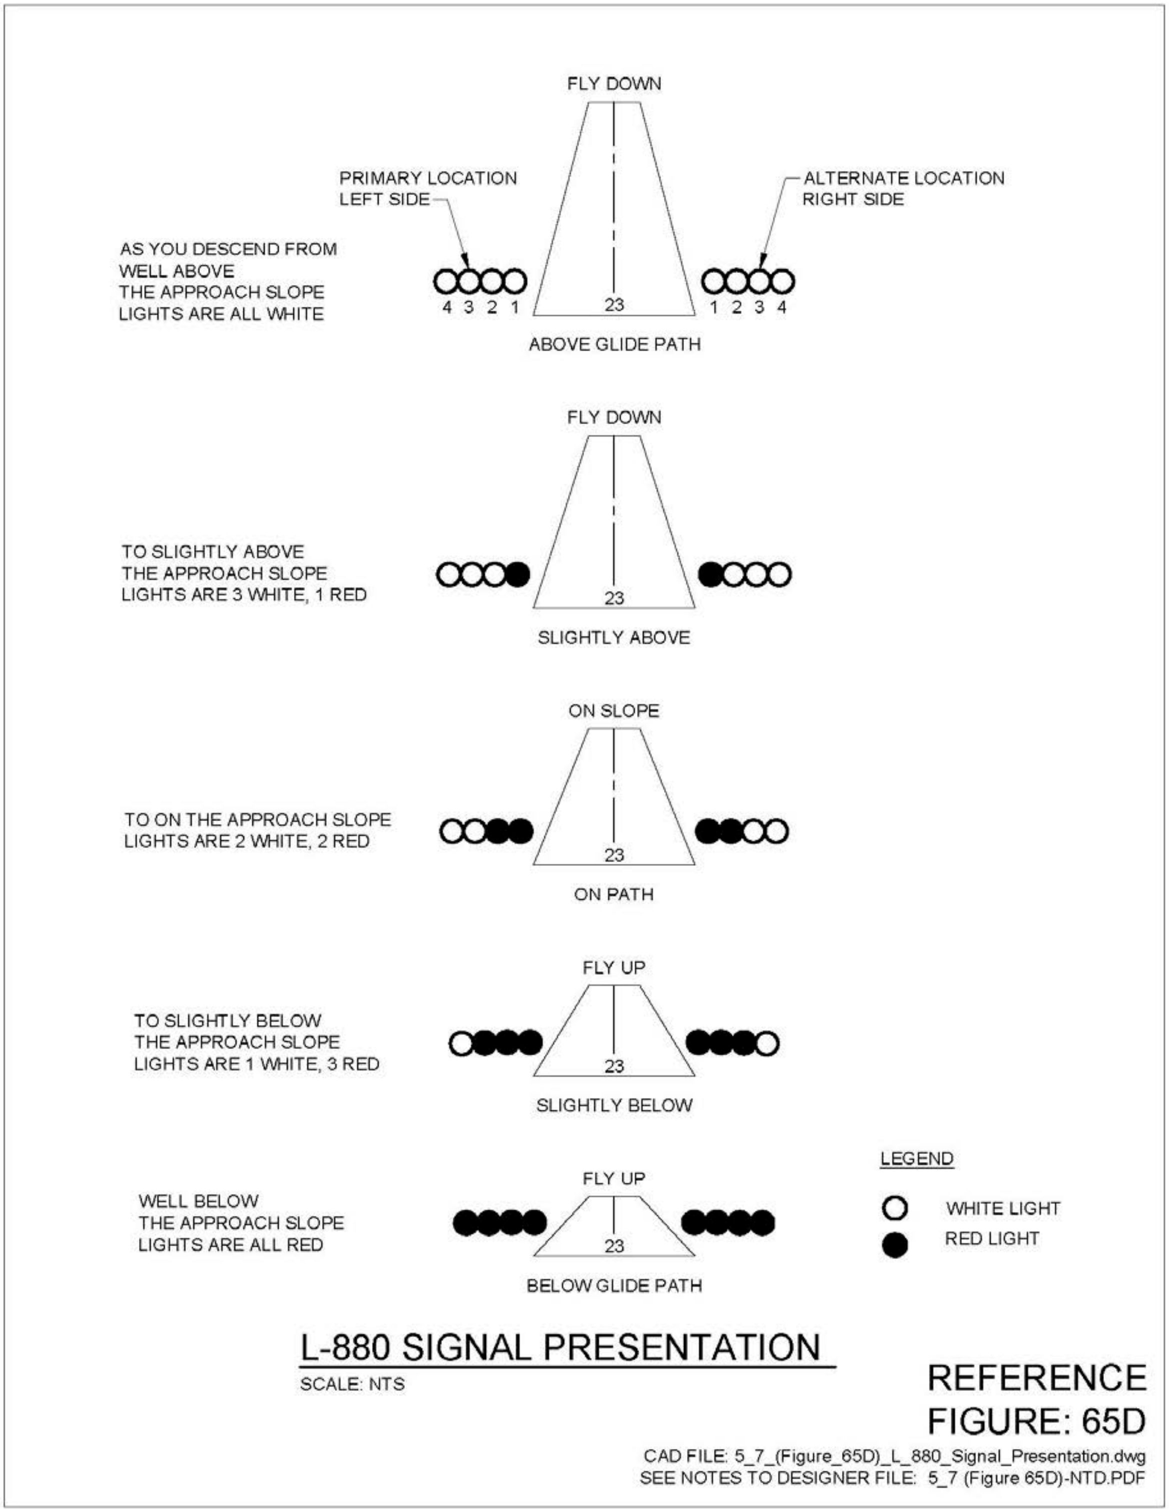
Light unit	Aiming angle (in minutes of arc)
Unit nearest runway	30' (minutes) above glide path
Next adjacent unit	10' (minutes) above glide path
Next adjacent unit	10' (minutes) below glide path
Next adjacent unit	30' (minutes) below glide path

2. Installation Tolerance table:

Installation Tolerance

Item	Tolerance
Azimuthal aiming	±1/2 degrees
Mounting height tolerance (from horizontal planes)	±1" (25mm)
Tolerance along line perpendicular to runway	±1" (25mm)
Horizontal plane through beam center to elevation of runway centerline at intercept point	±12" (305mm)

Figure 65D. L-880 Signal Presentation



6-7 REIL Systems Schematic Wiring Diagrams.

6-7.1 Figure 66.

6-7.1.1 Notes to Designer.

1. The most common system presently in use is depicted in Detail 1. This system uses a separate 120/240 volt source for the incoming power. When designing this system ensure the separate power source is available near the master unit.

2. Detail 2 uses a power adapter that is installed in series with the series runway lighting circuit. The power adapter converts the constant current from the lighting circuit to a 120/240 volt output. This output is used as the 120/240 volt source to power the system.

3. Some special precautions should be taken when designing this type of system:

    a. Power adapters often have varied performance. Variations in brightness levels selected, load, and regulators will produce variations in voltage output.

    b. System may add up to an additional 4kw to runway lighting system.

    c. System may not work well with certain types of regulators.

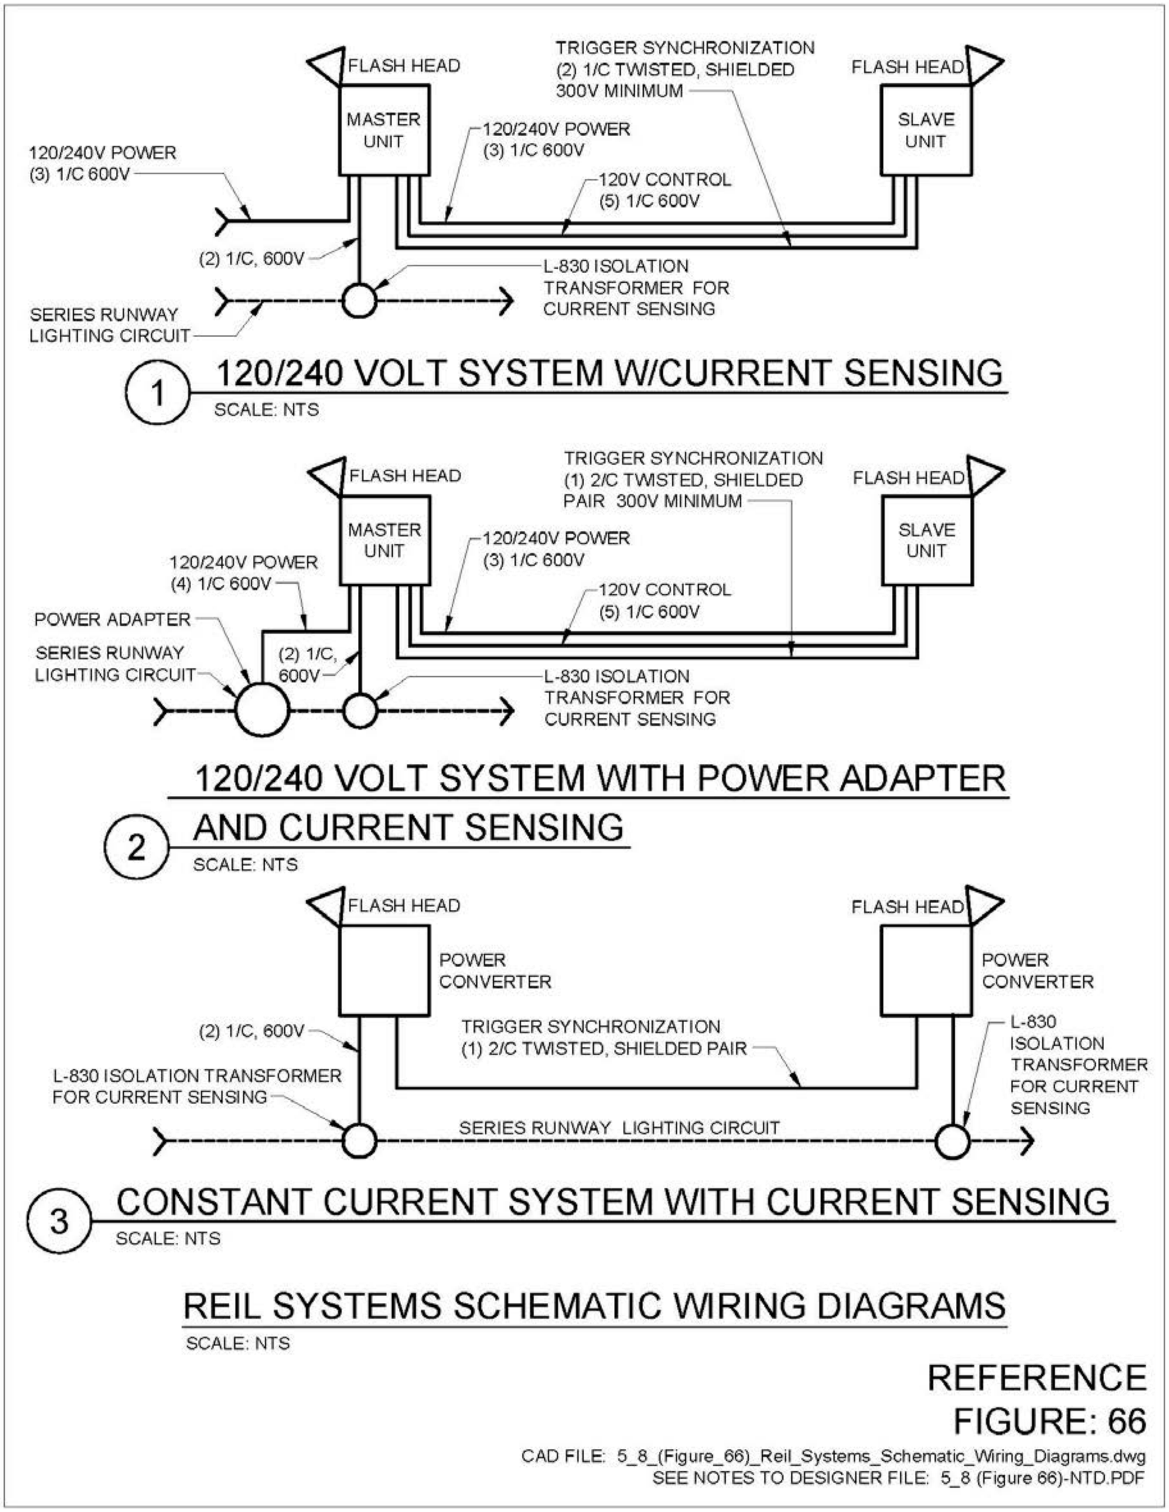
4. Recommend coordinating with manufacturer prior to designing this type of system.

5. The system in Detail 3 uses the constant current as the power feed to each unit via an L-830 isolation transformer. The flash heads are synchronized via the twisted pair between the two units. Load on the runway lighting circuit is about 150 watts per flash head or 300 watts for the system.

6. The contract documents should only show the schematic wiring diagram of the actual system to be utilized. Designer should delete the other diagrams.

7. Size and number of conductors must be verified with manufacturer.

Figure 66. REIL Systems Schematic Wiring Diagrams



6-8 Master and Slave REIL Unit Installation.

6-8.1 Figure 67.

6-8.1.1 Notes to Designer.

1. This detail shows a typical 120/240 volt system installation. All manufacturers are similar but arrangements of conduit entrances and support legs may be different. Recommend verifying requirements with several different manufacturers.

2. Foundations will vary with manufacturer.

3. Ensure contract documents show location of REILs and power source. Locations will be as specified in UFC 3-535-01.

6-8.1.2 Drawing Notes for Figure 67.

1. Dimensions and layout vary with manufacturer. Install per manufacturer's requirements.

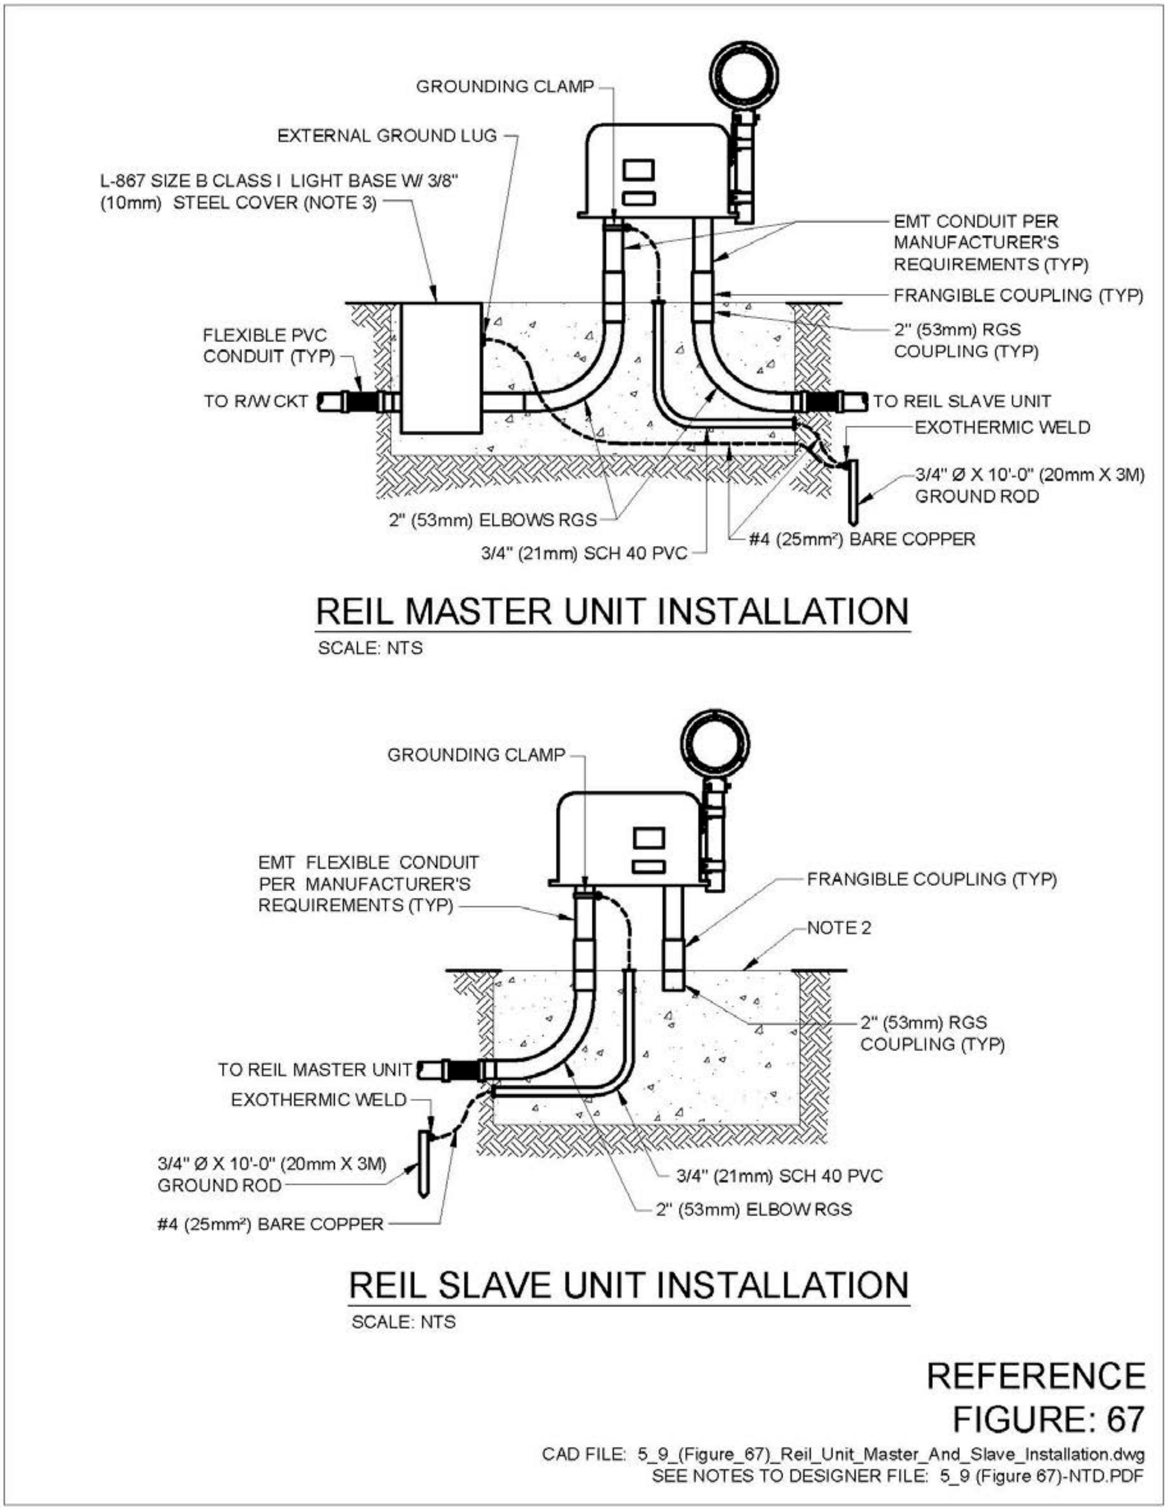
2. Dimension of concrete foundation varies with equipment supplied. Depth must be 36" (900mm) or 6" (150mm) below frost line whichever is greater.

3. L-867 base for mounting L-830 isolation transformer may be part of foundation or mounted separately.

4. Wire per manufacturer's requirements.

5. Incoming power wiring and conduit not indicated for clarity. Power wiring may enter L-867 light base in a separate conduit from the series circuit lighting cables.

Figure 67. Master and Slave REIL Unit Installation



CHAPTER 7 Miscellaneous (Rotating Beacons, Wind Cones, Can Plazas, Manholes, and High Mast Lighting)

7-1 51' (15.5m) Pre-Fabricated Beacon Tower.

7-1.1 Figure 68.

7-1.1.1 Notes to Designer.

1. This diagram shows a typical self-supporting 51' (15.5m) tower. Actual height of tower will depend on site conditions. Refer to UFC 3-535-01 for additional information.

2. Tower is designed by manufacturer. Recommend furnishing manufacturer with following data based on actual site:

   a. Weight and Effective Projected Area (EPA) of proposed beacon

   b. Beacon mounting footprint

   c. Overall height of tower

   d. Soil bearing capacity and analysis based on borings taken at site.

7-1.1.2 Drawing Notes for Figure 68.

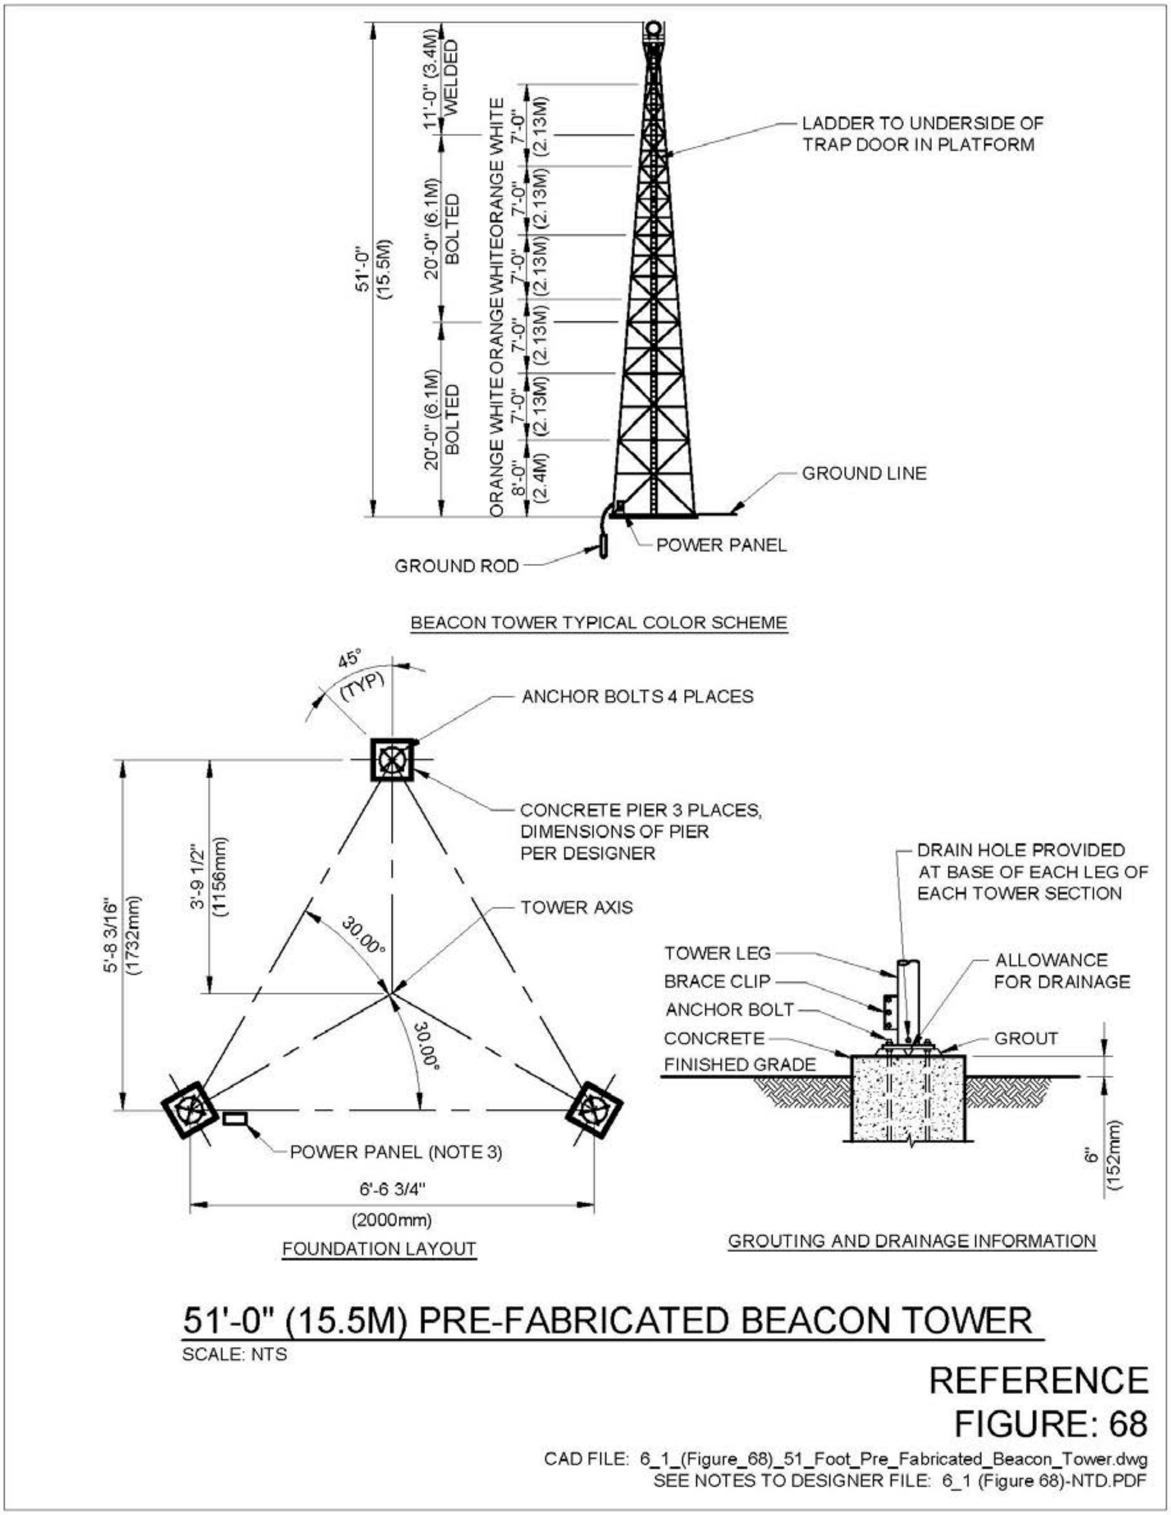
1. Ladder must be furnished with OSHA approved safety climbing tower.

2. Size of piers per Registered Structural Engineer.

3. Install power panel with top at 5'-0" (1.5m) above finished grade.

4. Provide circuits to top of tower for beacon, motor, heater, and obstruction light. Provide disconnect switch for each circuit at top of tower.

Figure 68. 51' (15.5m) Pre-Fabricated Beacon Tower



7-2 Beacon Dimensions and Wiring Diagram.

7-2.1 Figure 69.

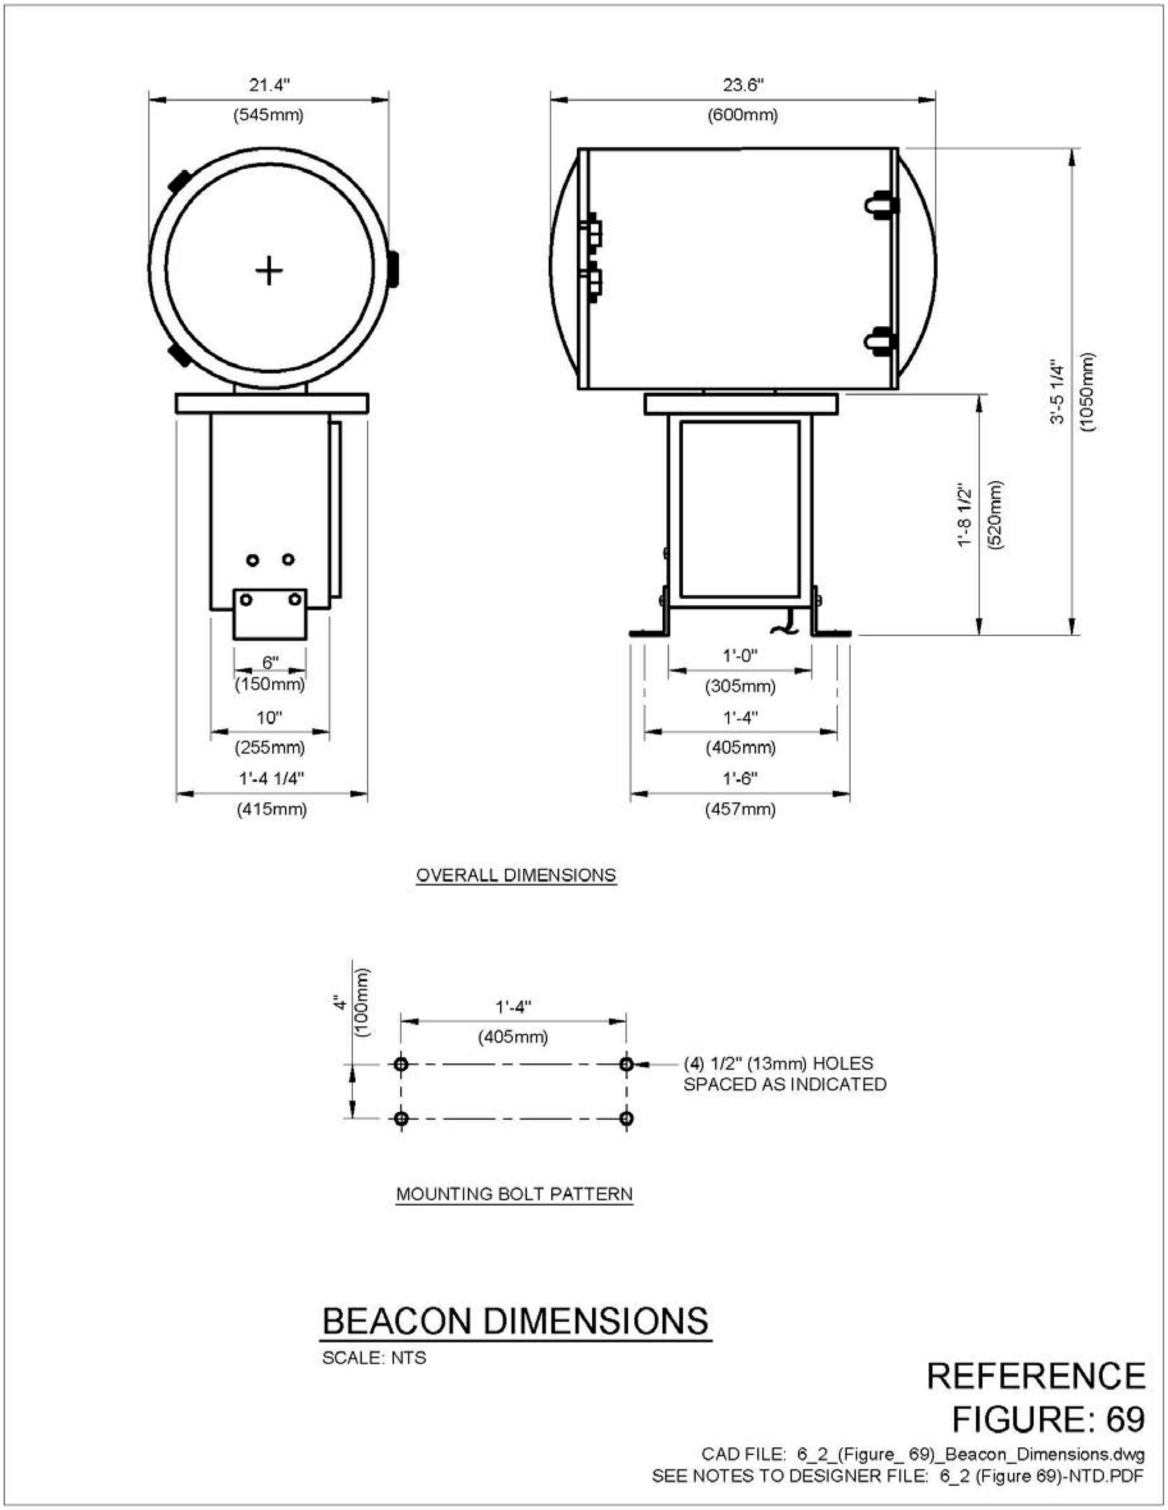
7-2.1.1 Notes to Designer.

1. The dimensions may vary between manufacturers.

2. Control of the beacon is typically automatic by a photocell or timeclock. Means should be provided in the control tower for overriding the photocell or timeclock. The beacon could be located up to 5000' (1500m) from the nearest runway and power wiring will come from the closest source. The control feed from the tower override could be by radio link, telephone switching relay, etc. Recommend during design that control route and available power be verified.

3. Verify dimensions and wiring with manufacturer.

Figure 69. Beacon Dimensions



7-3 Beacon Tower Platform Details.

7-3.1 Figure 70.

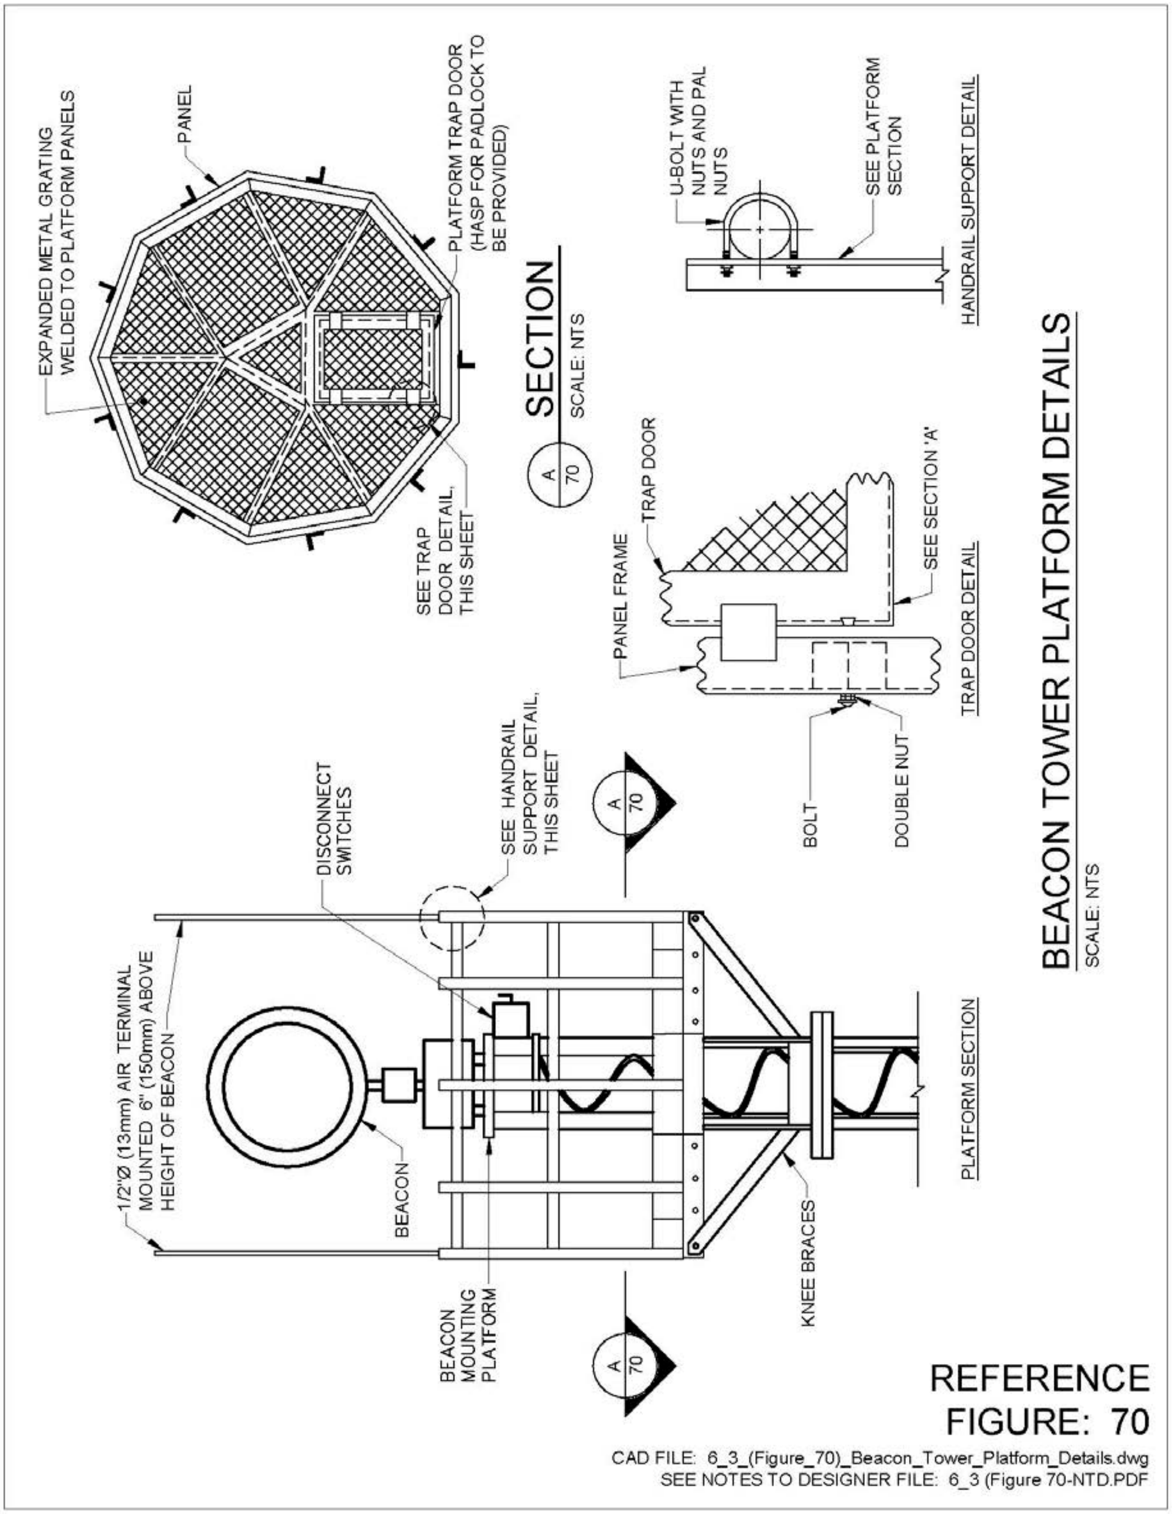
7-3.1.1 Notes to Designer.

1. Figure is self-explanatory.

7-3.1.2 Drawing Notes for all Tower Components, Figure 70.

1. All tower components must be hot dipped galvanized after fabrication.
2. Install per manufacturer’s requirements.
3. Locate disconnect switches on walkway handrail or center structure.

Figure 70. Beacon Tower Platform Details



7-4 Tower Safety Climbing Device.

7-4.1 Figure 71.

7-4.1.1 Notes to Designer.

1. Figure is self-explanatory.

7-4.1.2 Drawing Notes for Figure 71.

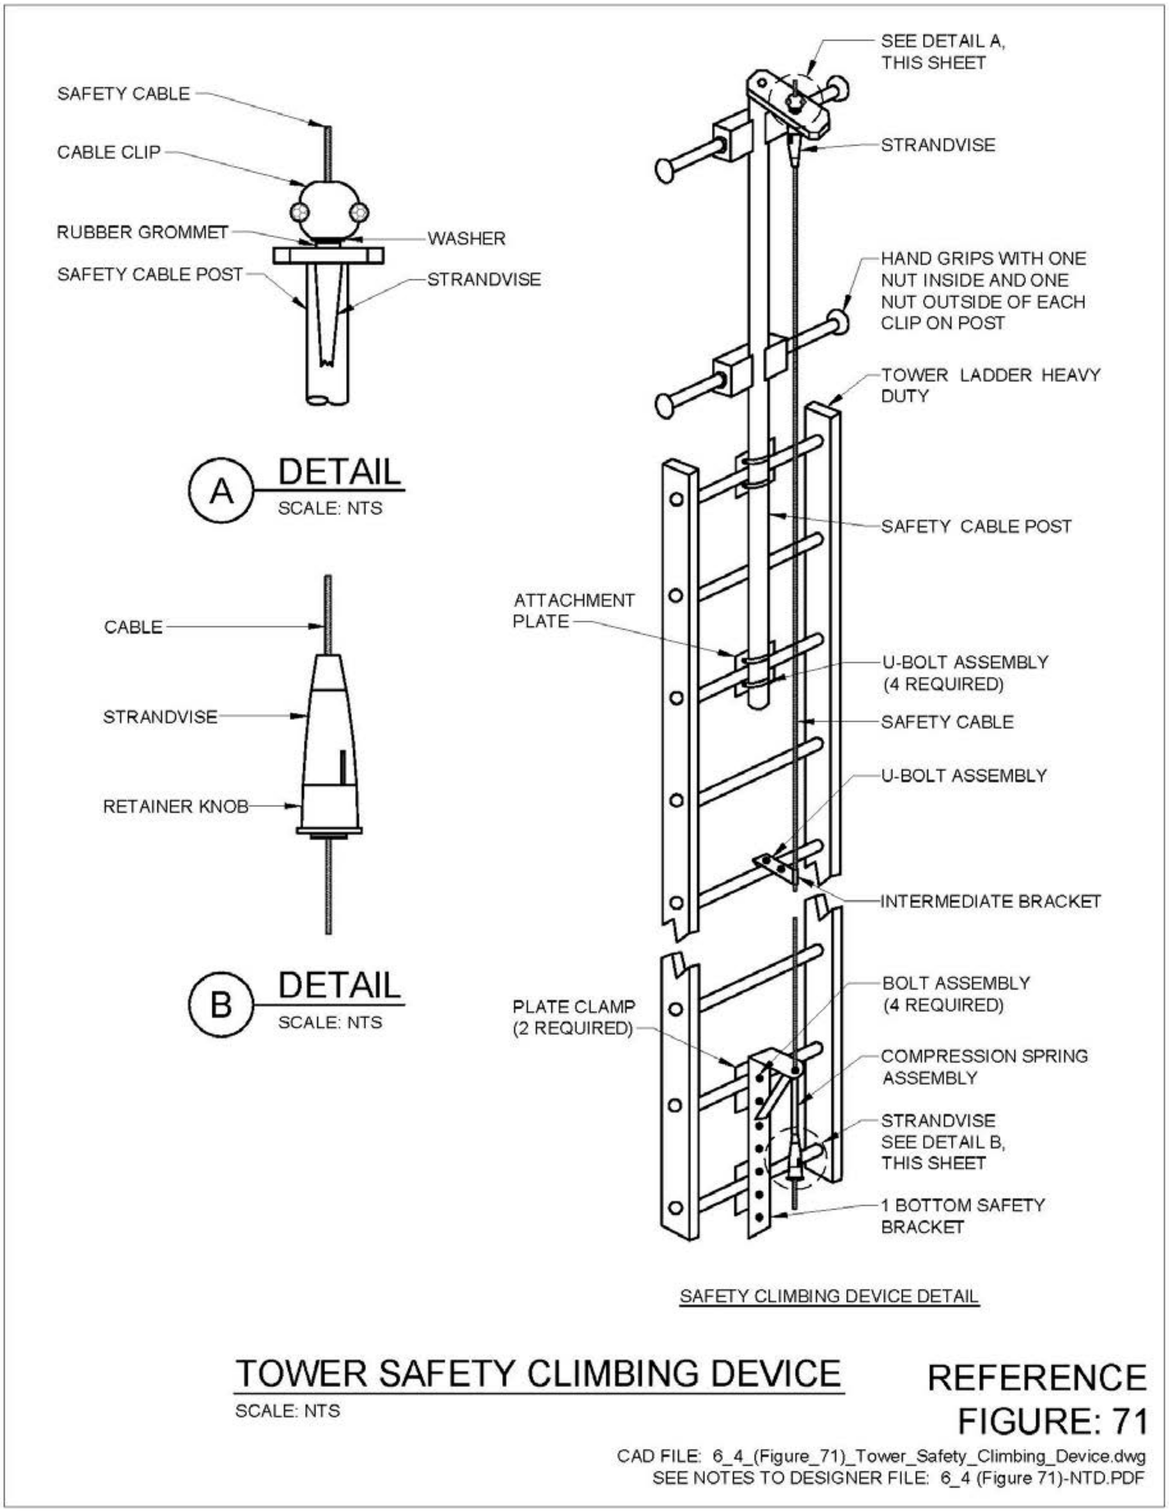
1. Installation per manufacturer’s requirements.

2. Contractor must provide two full body harnesses equipped with d-rings at front, back and both sides. Harness must be fully compatible for use with safety climbing device.

3. Contractor must provide two 6' (1829mm) shock absorbing lanyards, nylon/dacron construction.

4. Climbing device must meet latest OSHA and ANSI standards.

Figure 71. Tower Safety Climbing Device



7-5 **L-806 Windcone Assembly (Frangible).**

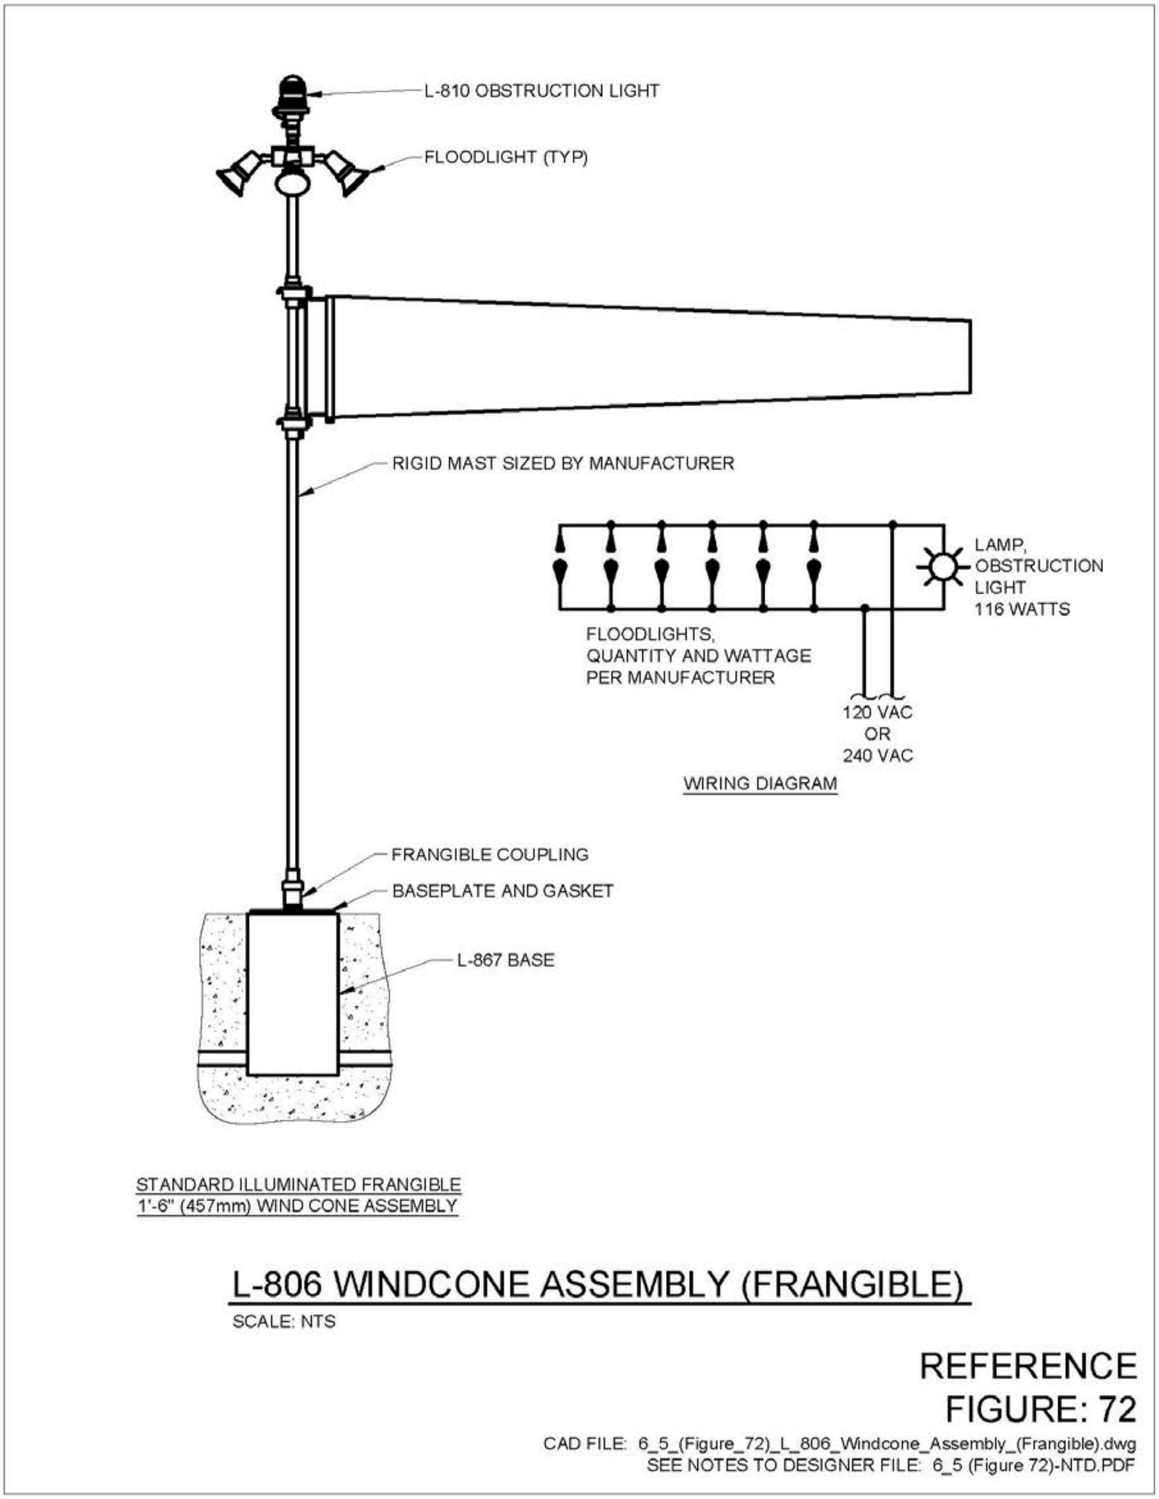
7-5.1 **Figure 72.**

7-5.1.1 **Notes to Designer.**

1. Typically, windcones are powered from a 120 or 240 volt ac source. Voltage drop must be analyzed. Depending on the length of run, a boosting transformer may have to be added.

2. The windcone should be powered and controlled from a separate circuit independent of runway edge lights.

Figure 72. L-806 Windcone Assembly (Frangible)



7-6 L-807 Windcone Assembly (Rigid Installation).

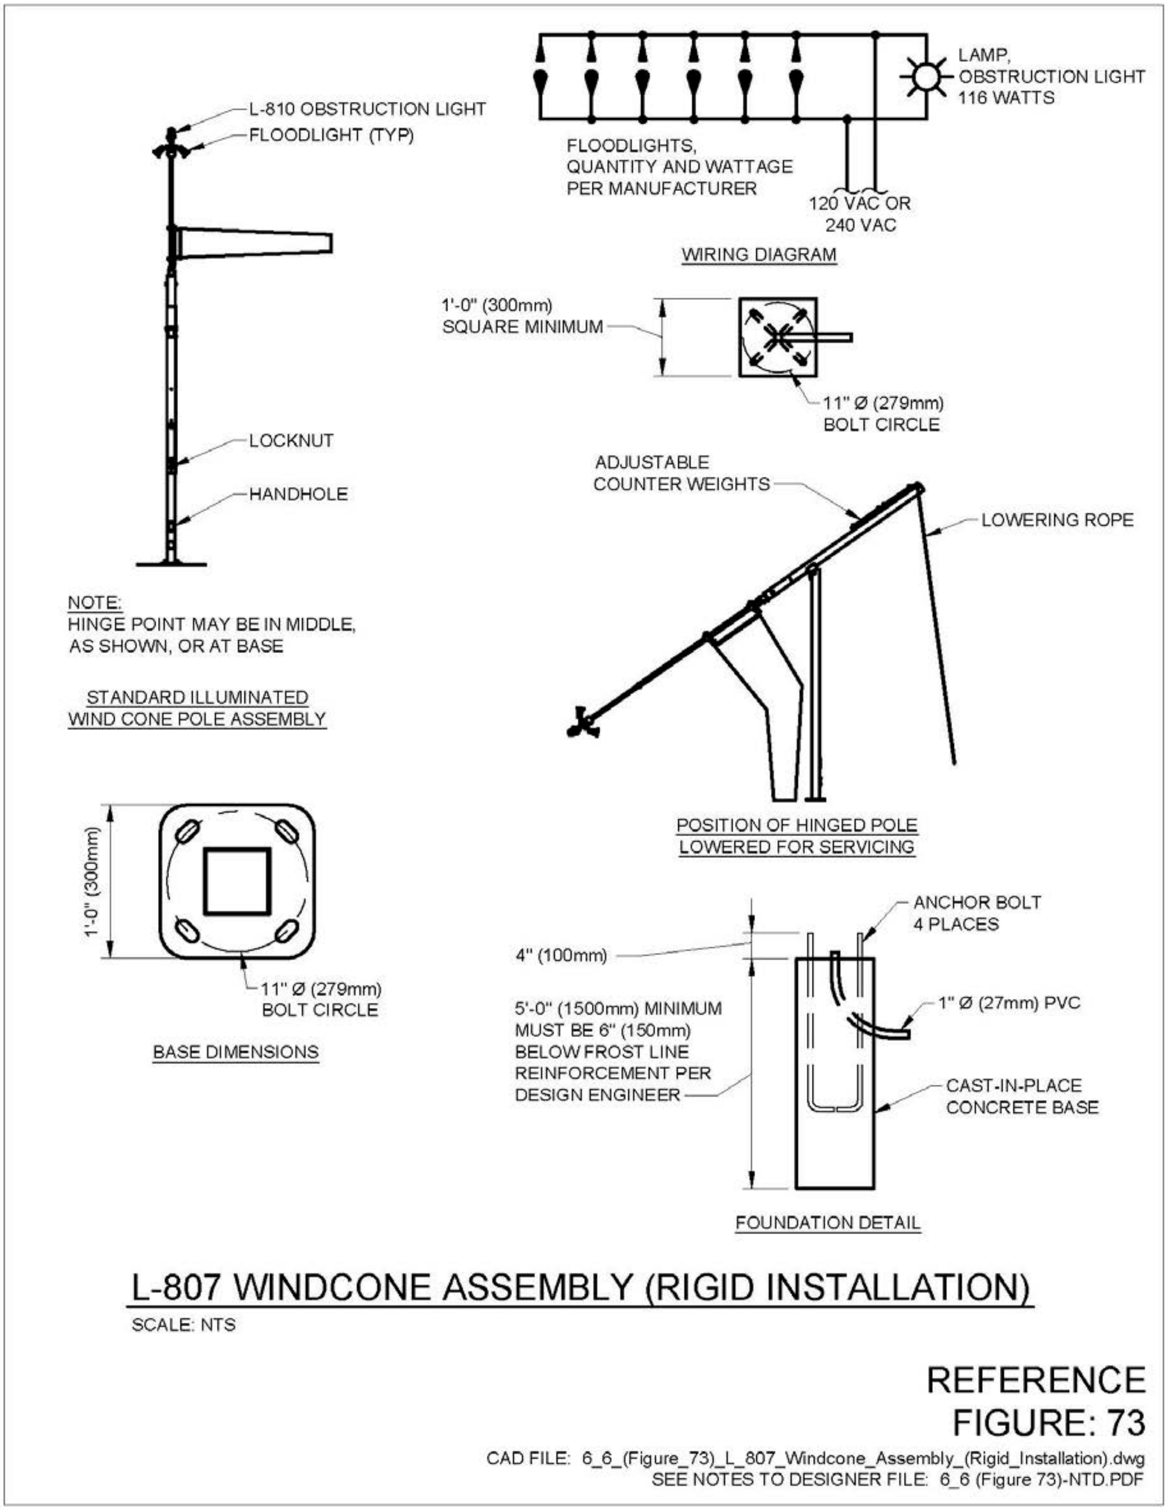
7-6.1 Figure 73.

7-6.1.1 Notes to Designer.

1. Typically, windcones are powered from a 120 or 240 volt source. Voltage drop must be analyzed. Depending on the length of run, a boosting transformer may have to be added.

2. The windcone should be powered and controlled from a separate circuit independent of runway edge lights.

Figure 73. L-807 Windcone Assembly (Rigid Installation)



7-7 Junction Can Plaza, Type A.

7-7.1 Figure 74.

7-7.1.1 Notes to Designer.

1. The purpose of individual base cans is to segregate the field circuits into separate conduit runs and provide access to each circuit. The advantages are:
    a. A fault in one circuit will not affect the others.
    b. Maintenance personnel do not have to be confined space trained (presently required by OSHA to enter manholes).
    c. Access time is considerably less than manholes.

2. Circuit and junction can plaza IDs should be indicated on the layout plans. The designer should coordinate with maintenance and operations personnel during the design review process to ensure each circuit and junction can is identified correctly for the specific installation.

7-7.1.2 Drawing Notes for Figure 74.

1. Number of junction cans and conduit configurations vary. See layout plan sheets for orientation.

2. Conduits which are not used in the project must be capped 12" (300mm) outside of plaza concrete.

3. Orient plaza as indicated on layout plan sheets.

4. Contractor must provide a 2" (50mm) diameter domed bronze marker at each junction can as indicated. Marker must be stamped with circuit identification as indicated on layout plan sheets.

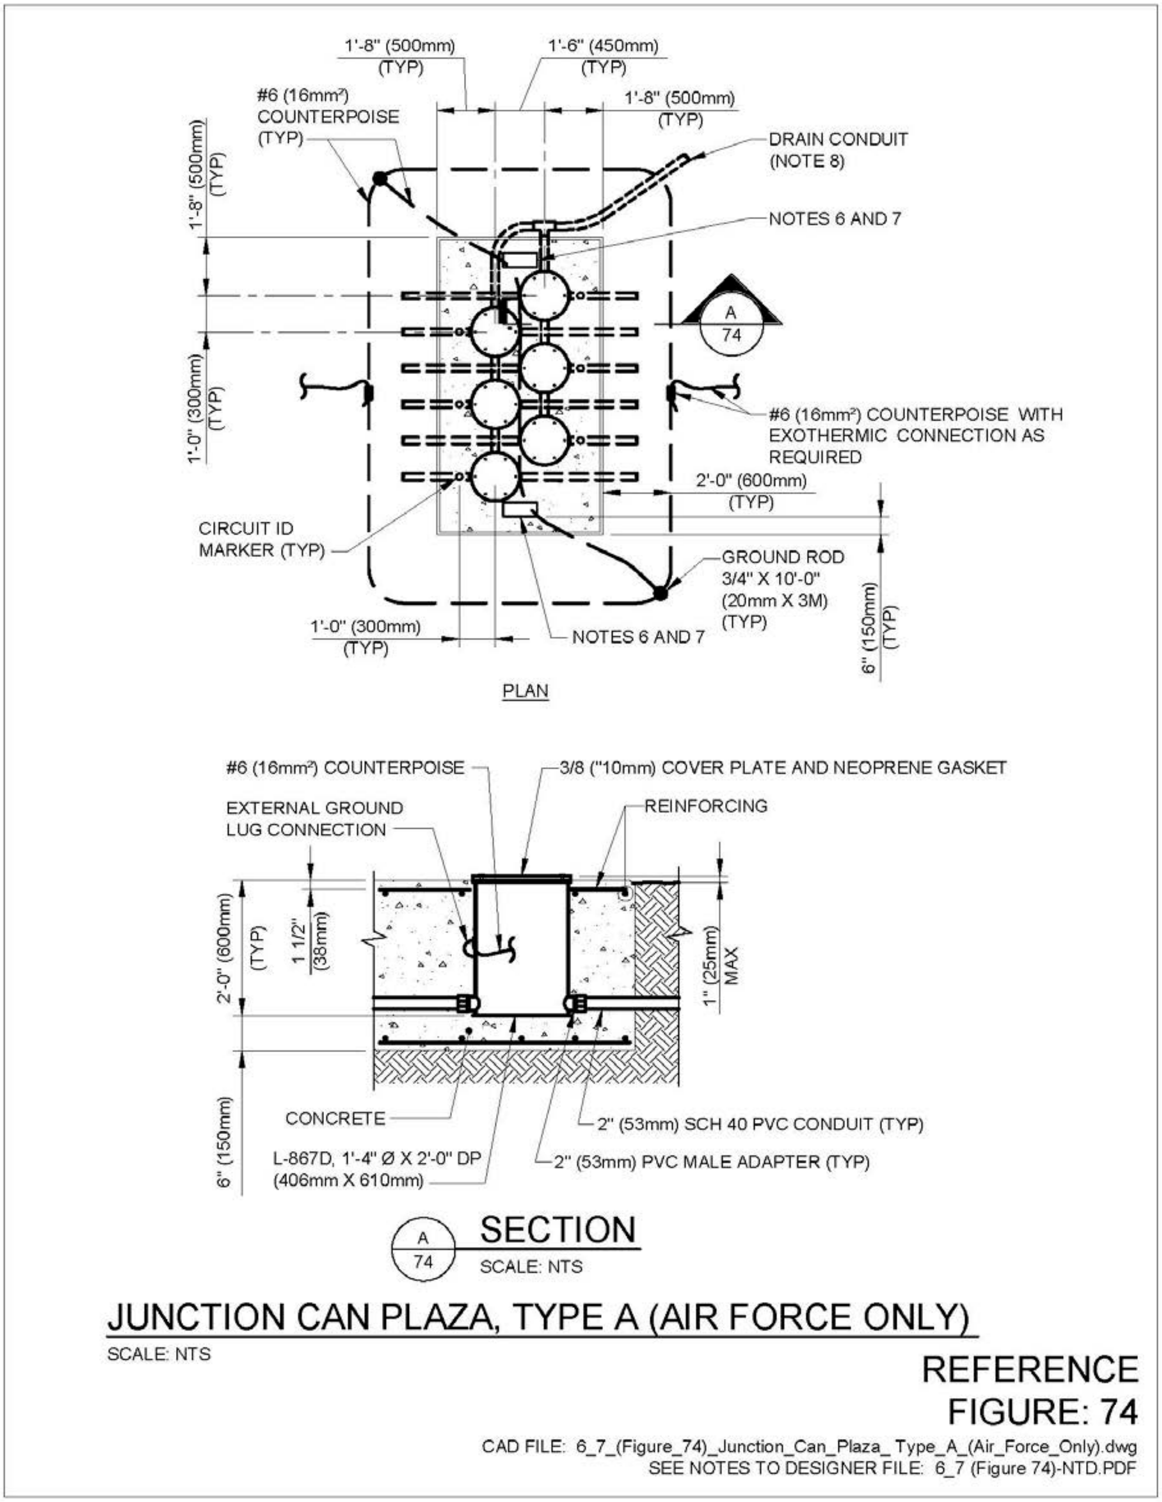
5. Install ground rods and ground loop at all junction can plazas as indicated. Two ground rods per plaza located at opposite corners must be provided. Counterpoise must be located nominally 12" (300mm) below existing grade.

6. Contractor must label 2 ends of each junction can plaza (JCP) by impressing the JCP identification number into the concrete foundation during placement. Letters and numbers must be 4" (100mm) in height, proportional in width, and have a stroke width of 1/2" (13mm) and 1/4" (6mm) depth.

7. See layout plan sheets for JCP identification numbers.

8. Drain conduits must be provided where indicated on the lighting and signage layout sheets. See Figure 76 for connection to junction cans.

Figure 74. Junction Can Plaza, Type A



7-8 **Junction Can Plaza, Type B.**

7-8.1 **Figure 75.**

7-8.1.1 **Notes to Designer.**

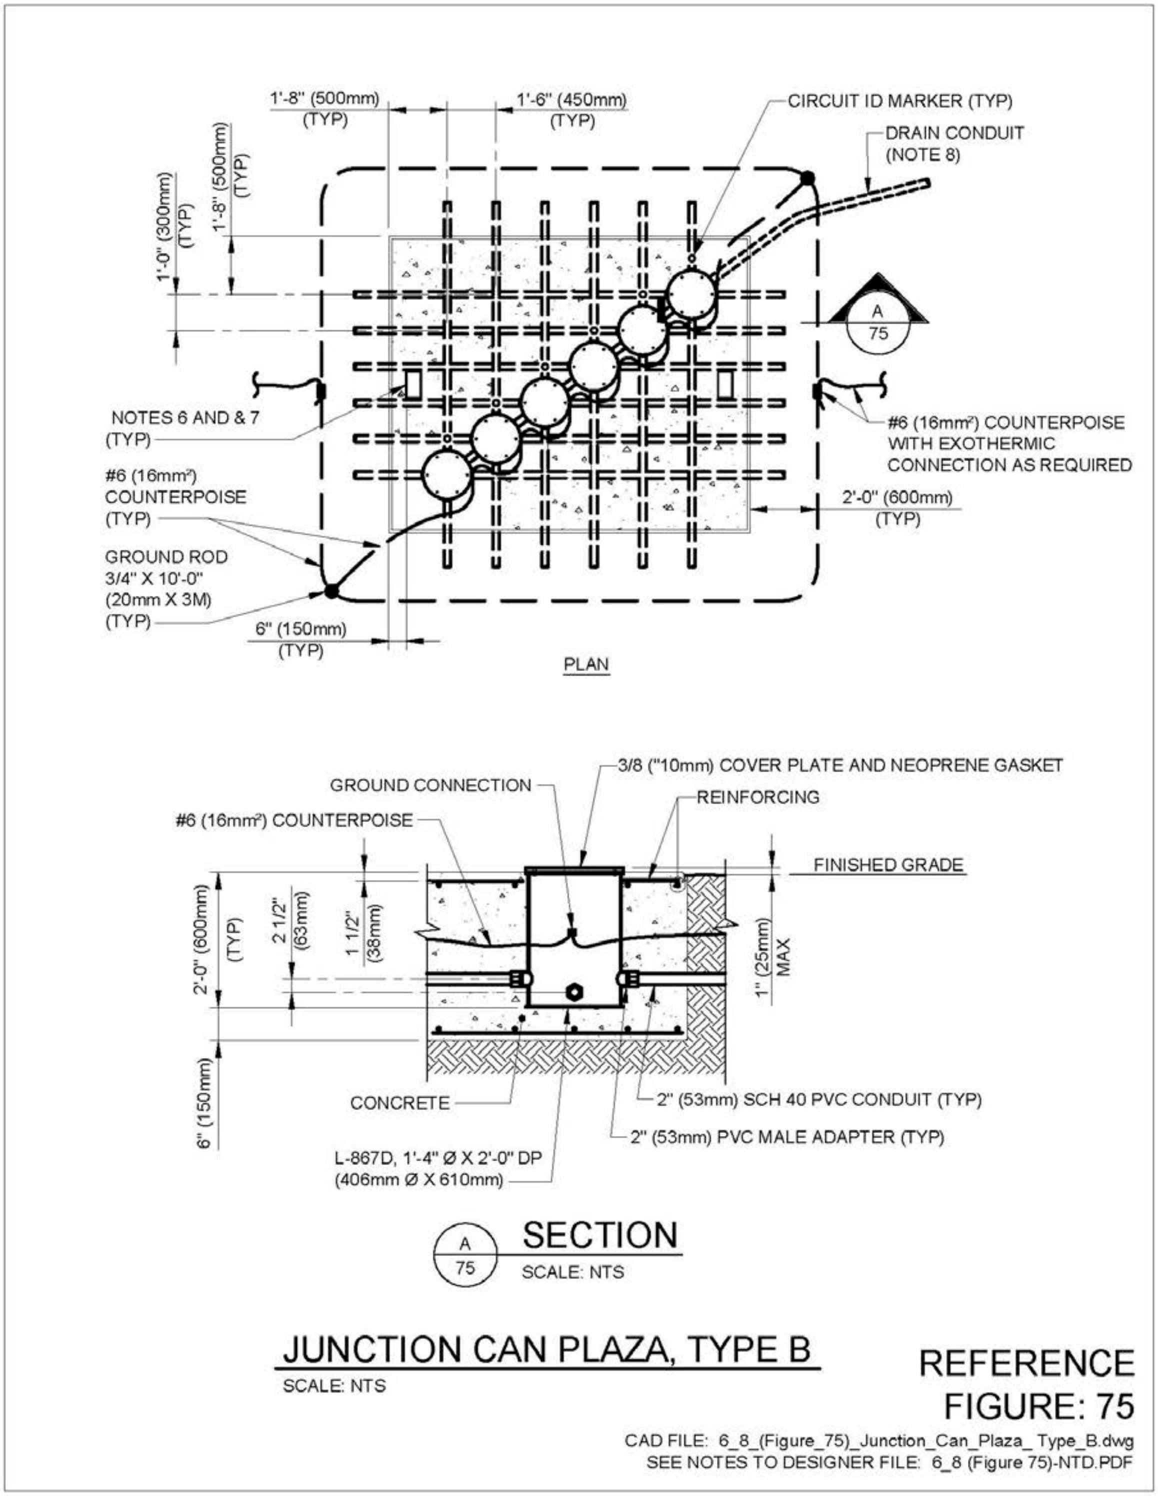
1. The purpose of the base cans is to segregate the field circuits into separate conduit runs and provide access to each circuit. The advantages are:
   a. A fault in one circuit will not affect the others.
   b. Maintenance personnel do not have to be confined space trained (presently required by OSHA to enter manholes).
   c. Access time is considerably less than for manholes.
2. Circuit and junction can plaza IDs should be indicated on the layout plans. The designer should coordinate with maintenance and operations personnel during the design review process to ensure each circuit and junction can is identified correctly for the specific installation.

7-8.1.2 **Drawing Notes for Figure 75.**

1. Number of junction cans and conduit configurations vary. See layout plan sheets for orientation.
2. Conduits which are not used in the project must be capped 12" (300mm) outside of plaza concrete.
3. Orient plaza as indicated on layout plan sheets.
4. Contractor must provide a 2" (50mm) diameter domed bronze marker at each junction can as indicated. Marker must be stamped with circuit identification as indicated on layout plan sheets.
5. Install ground rods and ground loop at all junction can plazas as indicated. Two ground rods per plaza located at opposite corners must be provided. Counterpoise must be located nominally 12" (300mm) below existing grade.
6. Contractor must label 2 ends of each junction can plaza (JCP) by impressing the JCP identification number into the concrete foundation during placement. Letters and numbers must be 4" (100mm) in height, proportional in width, and have a stroke width of 1/2" (13mm) and 1/4" (6mm) depth.
7. See layout plan sheets for JCP identification numbers.

8. Provide drain conduits where indicated on the lighting and signage layout sheets. See Figure 76 for connection to junction cans.

Figure 75. Junction Can Plaza, Type B



7-9 Drain for Junction Cans (Air Force Only).

7-9.1 Figure 76.

7-9.1.1 Notes to Designer.

1. The junction can plaza is for Air Force installations only.

2. The purpose is to segregate the field circuits into separate conduit runs and provide access to each circuit. The advantages are:

   a. A fault in one circuit will not affect the others.

   b. Maintenance personnel do not have to be confined space trained (presently required by OSHA to enter manholes).

   c. Access time is considerably less than manholes.

7-9.1.2 Drawing Notes for Figure 76.

1. See layout plan sheets for location of drain conduits.

2. Slope drain conduits 1/8" per foot (3mm per 300mm) minimum toward drainage structures.

3. Penetrate inlet/manhole with drain conduit above storm sewer pipes where possible while maintaining slope requirement.

4. Seal entry around drain conduit at the inlet/manhole with compatible non-shrink grout.

7-10 Manhole Grounding, Optional Cable Rack and Marker Details.

Figure 77. Reserved

Figure 78. Reserved

7-10.1 Figure 80A.

7-10.1.1 Notes to Designer.

1. Manhole grounding must be installed in all manholes and handholes. Typically, the metal frame of the access cover is grounded by a #4 (25 square mm) solid bare copper conductor connected to a ground lug on the frame and the ground rod. If the cover is removable grounding is also required, utilize flexible cable such as welding cable and connect to the frame and cover. The length of flexible cable should be long enough to allow removal of the cover away from the frame to allow access into the manhole.

2. The length of the cable rack arm is indicated at 14" (355 mm). There are smaller arms available as well as “U” shaped saddle rack that meet the minimum 300 lb loading. In 3' (0.9m) × 3' (0.9m) handholes, the 14" (355mm) arm may hinder access. Recommend using an 8" (200mm) arm or saddle rack.

3. The brass survey marker is used to identify the handhole or manhole for circuit routing and duct bank layouts as well as maintenance schedules. The actual identification number to be used should be coordinated with the facility maintenance personnel.

7-10.1.2 Drawing Notes for Figure 80A.

1. All conduits that contain copper cables for constant voltage circuits must be equipped with a minimum #6 (16 square mm), TW green ground wire. All conduits that are empty must not contain a ground wire.

2. Ground all metallic parts of the manhole with a #4 (25 square mm) bare stranded ground wire.

3. The contractor must install a 200 lb polypropylene pull rope/string in each duct and conduit installed and plug or cap the duct. The rope must be securely attached to the pull iron in each manhole, or a stake where the duct terminates underground.

4. All manholes must be installed as indicated on the plans. Coordinate final location with grading and drainage plans. When extending existing duct to new manhole, put manhole in line with existing duct when possible. Manholes must not be installed in ditches, drainage swales or where water will pond on top of the manhole.

5. All PVC conduit and fittings must be Schedule 40 and must be U.L. listed.

6. PVC plugs must be installed in each empty sleeve and duct.

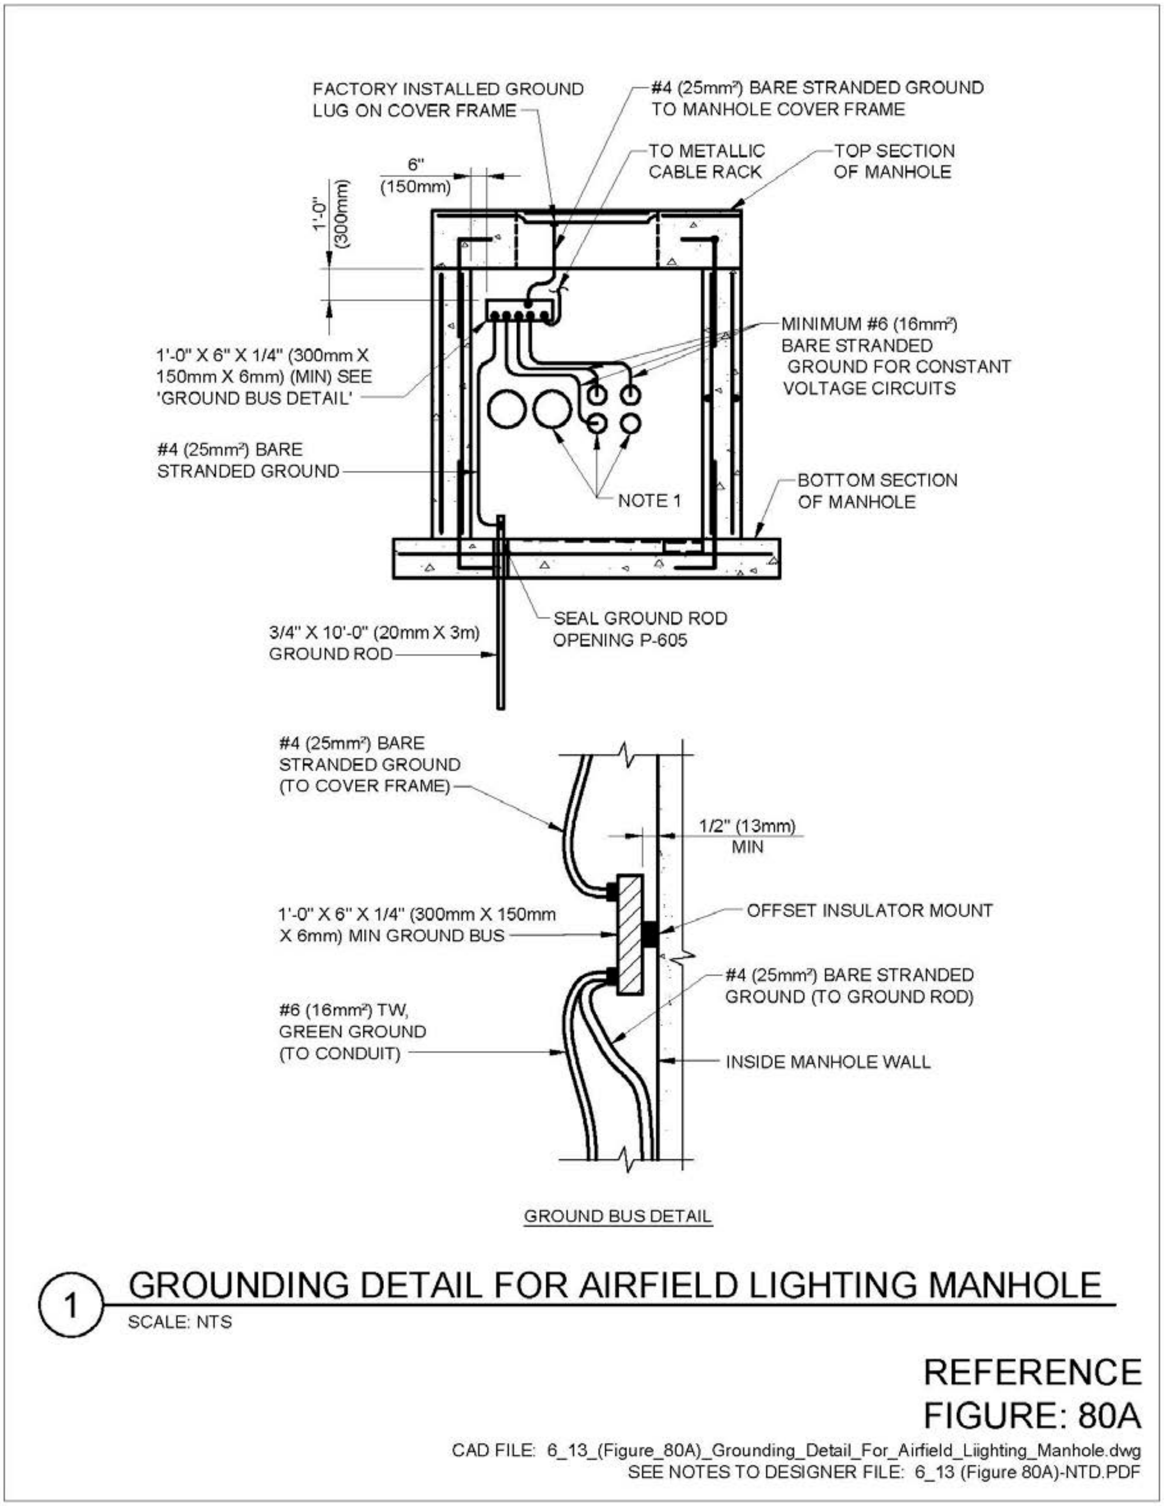
7. Provide pulling irons on all walls opposite conduit entry points.

8. All wall reinforcement (loop and vertical) affected by ductwork must be relocated on either side of the duct and detailed in the submittal.

9. The contractor must submit shop drawings showing all reinforcing steel and other construction details (ship-lap joint, etc.) prior to fabrication.

10. Each duct crossing under pavement must be located and dimensioned on the record drawings, accurate to 0.5' (150mm). The entrance and exit from under the pavement must be marked with an embedded id marker and stamped with the duct bank number.

igure 80A. Grounding Detail for Airfield Lighting Manhole



7-10.2 **Figure 80B.**

7-10.2.1 **Drawing Notes for Figure 80B.**

1. The cable racking system must be rated for 300 lbs. Cable racks must be placed on all manhole walls whether currently used or not. Cables must be tied to racks using cable ties.

2. Ground all metallic parts of the manhole with a #4 bare stranded ground wire.

Figure 80B. Cable Rack Option Detail

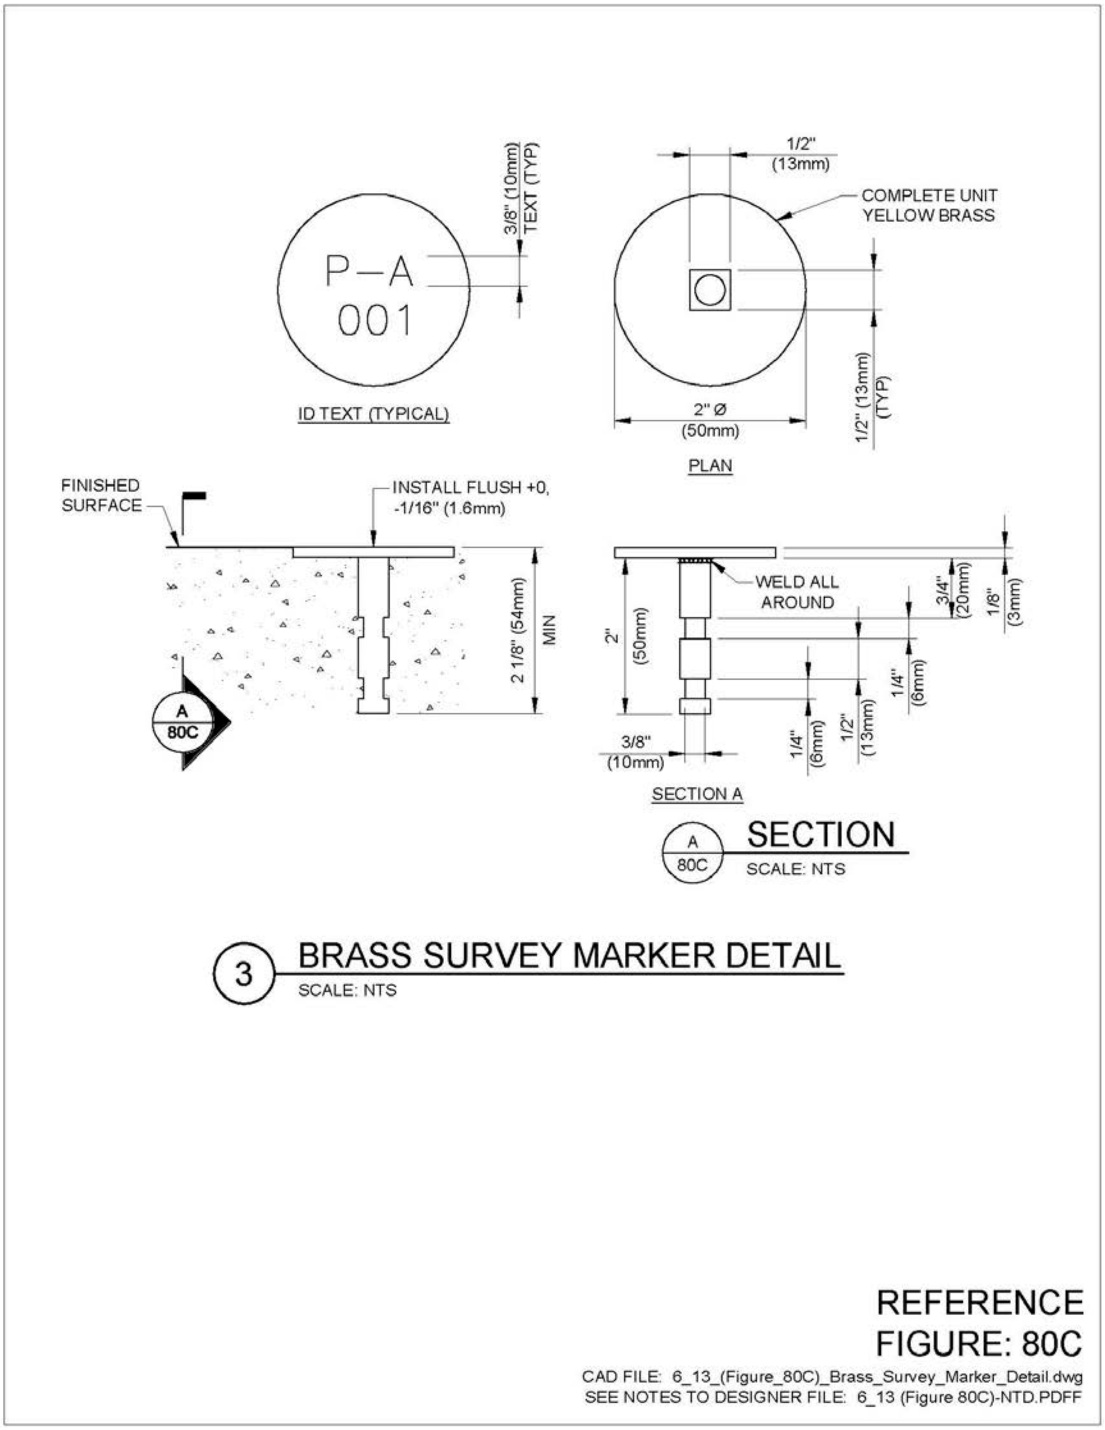
SEE NOTES TO DESIGNER FILE: 6_13 (Figure 80B)-NTD.PDFF

7-10.3 **Figure 80C.**

7-10.3.1 **Drawing Notes for Figure 80C.**

1. Provide a brass survey marker with ID text stamped into it for each airfield lighting manhole.

Figure 80C. Brass Survey Marker Detail



Manhole Foldout Diagrams and Circuit Schedule.

7-10.4 **Figures 80D, 80E.**

7-10.4.1 **Notes to Designer.**

1. The Manhole Foldout Diagram indicates the number and size of duct/conduit entering each wall of a manhole or handhole. For each wall, identify the duct/conduit and the circuits contained within the duct/conduit.

2. A foldout diagram should be provided for each manhole or handhole that a circuit(s) enters from the source, through the duct bank system and to the last manhole or handhole for that circuit.

3. The circuit schedule tabulates the manholes and ducts/conduits within the manholes a specific enters. The manholes are listed in succession and are coordinated with the manhole foldout diagrams.

Example Circuit Schedule Table:

7-11 **Traffic Signs and Signals Installation.**

7-11.1 **Figures 84A, 84B, 84C, 84D.**

7-11.1.1 **Notes to Designer.**

1. Figures 84A, 84B, 84C and 84D show the installation of traffic signs and signals installed on a roadway that crosses the approach end of a runway. The purpose is to provide visual warning to vehicle traffic that they are near low flying aircraft.

2. Control of the flashing signals is initiated by air traffic control by transmission over a fiber optic cable to the master controller. Ground-to-ground radio transmission might also be used.

3. Figure 84A shows a plan view of master and slave flashers and sign locations. Figures 84B, 84C, and 84D show details of the roadway sign and signal assembly.

7-11.1.2 **Drawing Notes for Figure 84C.**

1. Install signal controller with 8-position M49 cabinet.

2. Integrate signal controller and cabinet into proposed fiber optic system with single mode data transceiver and interconnect center compatible with other fiber optic equipment provided.

3. Signal rests in “dark” mode. Air traffic control will activate signal. Upon activation, display a flashing yellow signal indication, for 5.0 seconds, followed by a 5.0 second solid yellow change interval. Follow change interval with two alternating red signals (i.e. wig-wag). Air traffic control will terminate flashing red. Upon termination of red signal will revert to “dark” mode.

CHAPTER 8 Helicopter Pad Systems

8-1 Helipad Perimeter Lighting.

8-1.1 Figure 85.

8-1.1.1 Notes to Designer.

1. The standard elevated fixture is an FAA type L-861 base mounted with 45 watt lamp. The maximum height is 14" (350mm) above grade except in areas where snow accumulations of 12" (300mm) or more are frequent, the mounting height may be increased to 24" (600mm) above grade.

2. In areas that are paved and used by wheeled helicopters or vehicles, in-pavement fixtures are used and are FAA type L-852E base mounted fixtures.

3. The perimeter lights are normally powered from a constant current regulator with a minimum of 3 brightness steps. However, some installations may utilize constant voltage circuits (120/240V) such as helipads on rooftops and/or hospitals.

4. The series circuit cable is FAA type L-824C #8 5 kV for 6.6 amp circuits.

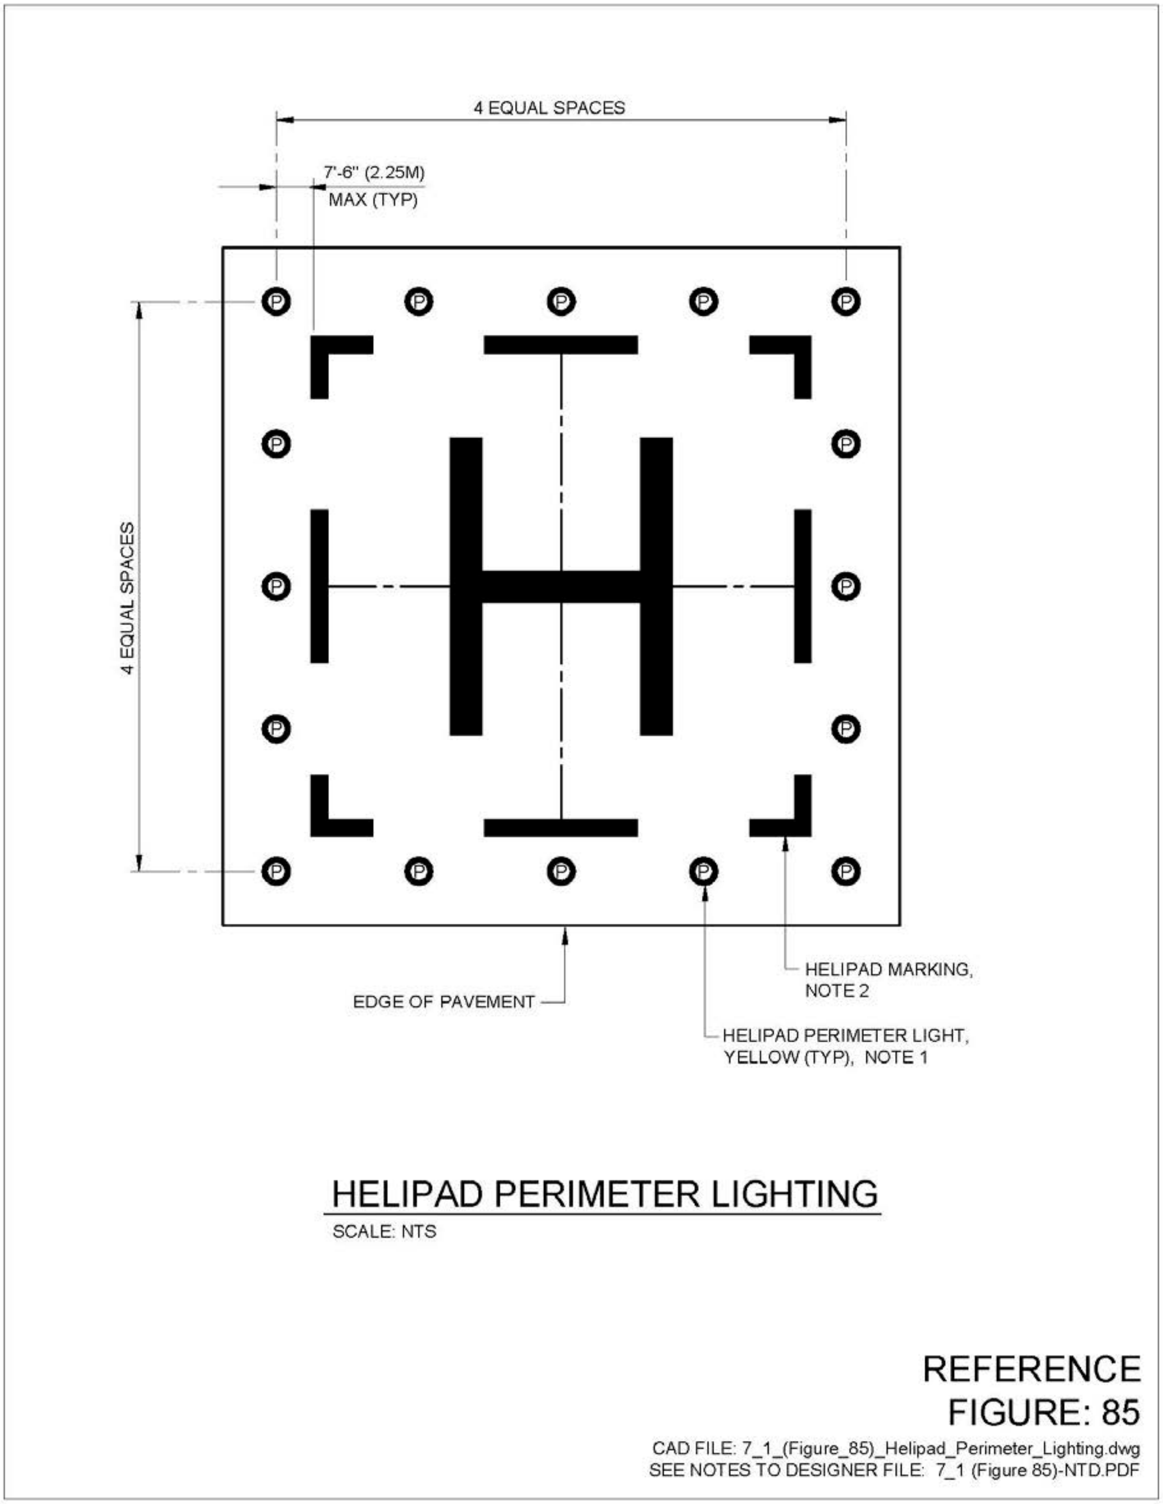
5. See ETL 04-2 for Air Force / Army marking standards and NAVAIR 51-50AAA-2 for Navy marking standards.

8-1.1.2 Drawing Notes for Figure 85.

1. Elevated lights must be base mounted FAA type L-861. In-pavement lights must be base mounted FAA type L-852E.

2. Markings based on 100' (30m) x 100' (30m) helipad. For other pads, markings will appear different.

Figure 85. Helipad Perimeter Lighting



8-2 Hospital Helipad Perimeter Lighting.

8-2.1 Figure 86.

8-2.1.1 Notes to Designer.

1. The hospital helipad perimeter light configuration is similar to the standard helipad light configuration except 4 additional lights are added. These lights are located 25' (7.5m) from the middle light on each side of the helipad. These lights and the corresponding middle lights are green. The remaining perimeter lights are yellow.

2. The color of lights for the hospital helipad should be coordinated with the user prior to design.

3. In areas where vehicle traffic will be crossing or accessing the helipad use in-pavement fixtures.

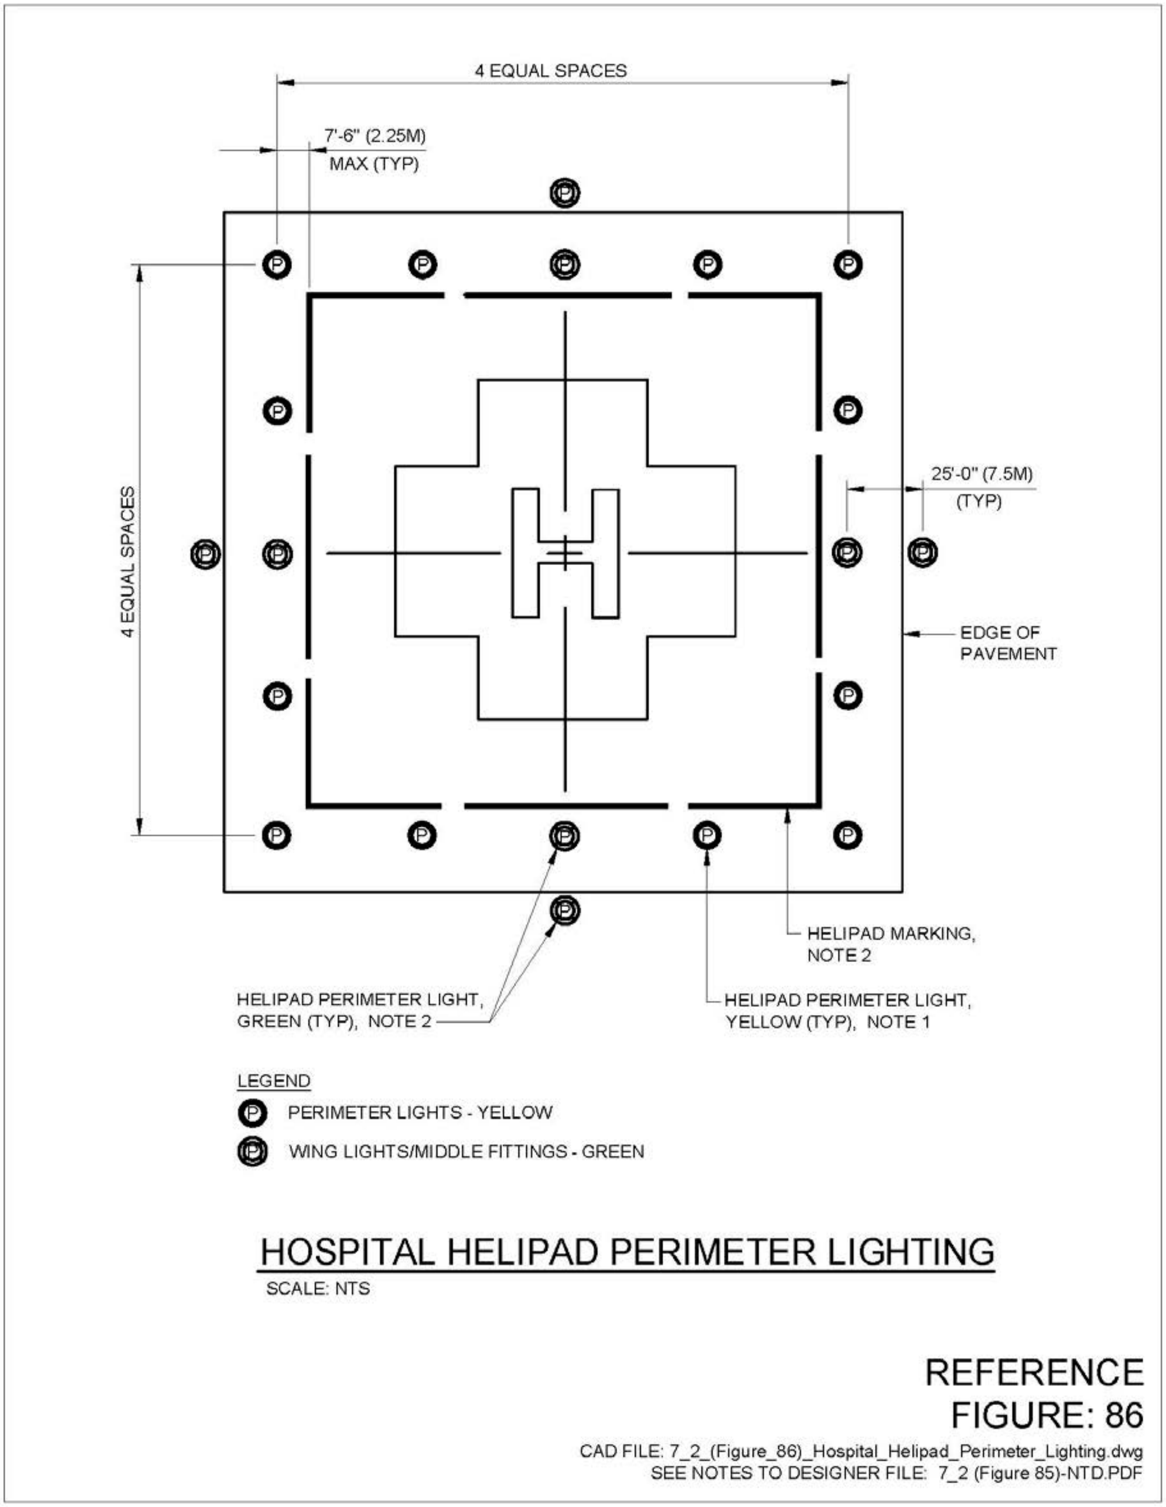
4. See ETL 04-2 for Air Force / Army marking standards and NAVAIR 51-50AAA-2 for Navy marking standards.

8-2.1.2 Drawing Notes for Figure 86.

1. Elevated lights must be base mounted FAA type L-861. In-pavement lights must be base mounted FAA TYPE L-852E.

2. Markings based on 100’ (30 m) x 100’ (30 m) helipad. For other pads, markings will appear different.

Figure 86. Hospital Helipad Perimeter Lighting



8-3 Helipad Landing Direction Lights.

8-3.1 Figure 87.

8-3.1.1 Notes to Designer.

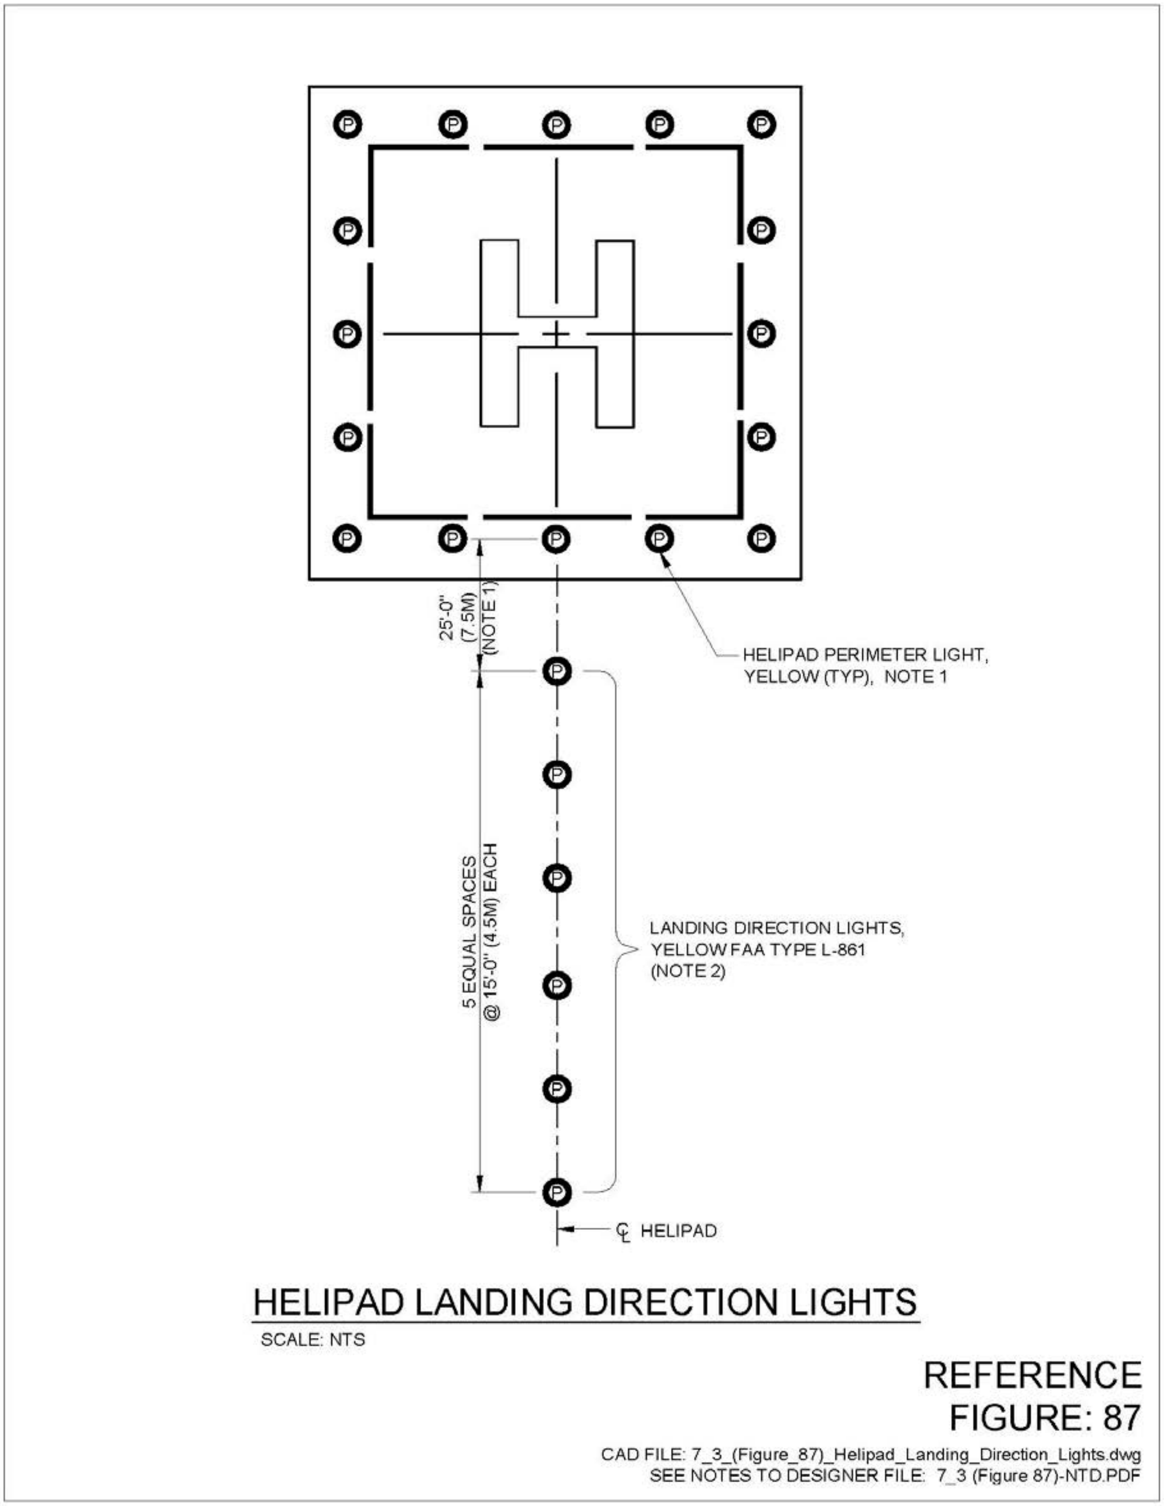
1. The landing direction lights may be powered from the regulator feeding the perimeter lights. The circuit may be separated by using an FAA type L-847 circuit selector switch, thereby allowing the direction lights to be switched off independently. The landing lights may not be switched on unless the perimeter lights are on.

8-3.1.2 Drawing Notes for Figure 87.

1. Landing direction light configuration for hospital helipad must start 25' (7.5m) from the outer perimeter light.

2. In-pavement fixtures must be used in areas of vehicle traffic and must be FAA type L-852E.

Figure 87. Helipad Landing Direction Lights



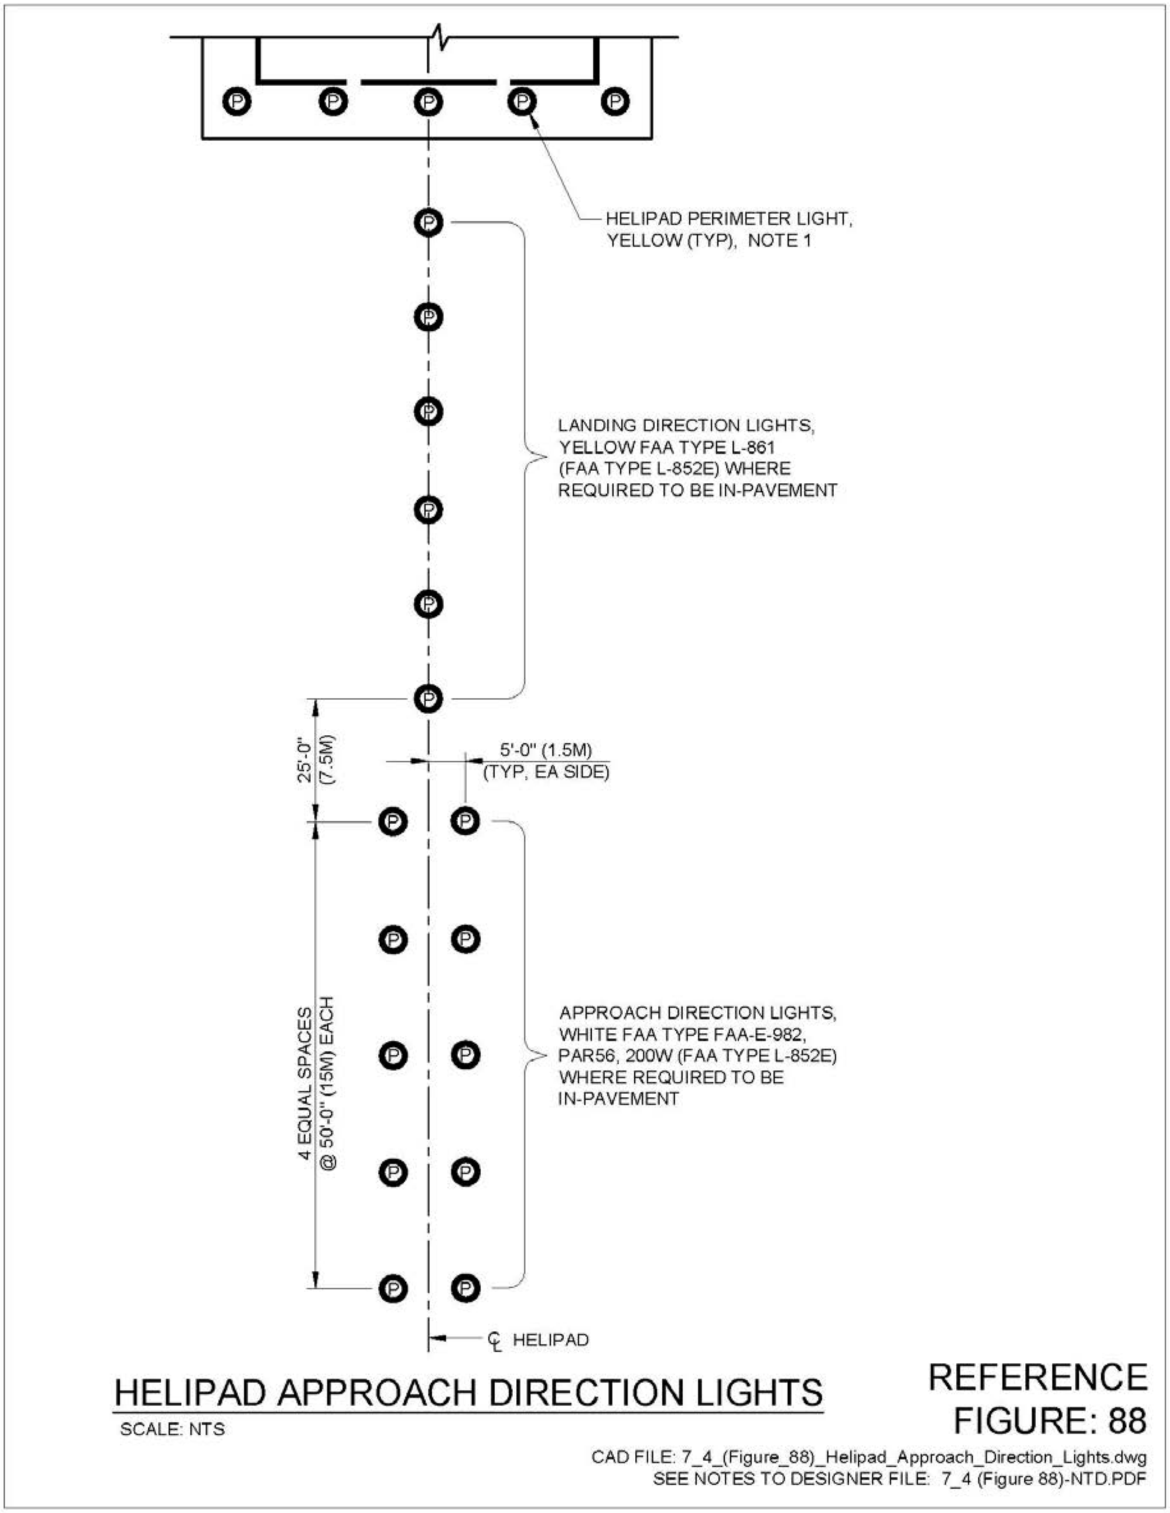
8-4 **Helipad Approach Direction Lights.**

8-4.1 **Figure 88.**

8-4.1.1 **Notes to Designer.**

1. The approach direction lights may be powered from the regulator feeding the perimeter and landing direction lights. The circuits may be separated by using an FAA type L-847 circuit selector switch, thereby allowing the approach direction lights to be switched off independently. The approach direction lights may not be switched on unless the perimeter and landing direction lights are on.

Figure 88. Helipad Approach Direction Lights



8-5 Helipad Lighting Wiring and Control Diagram.

8-5.1 Figure 89.

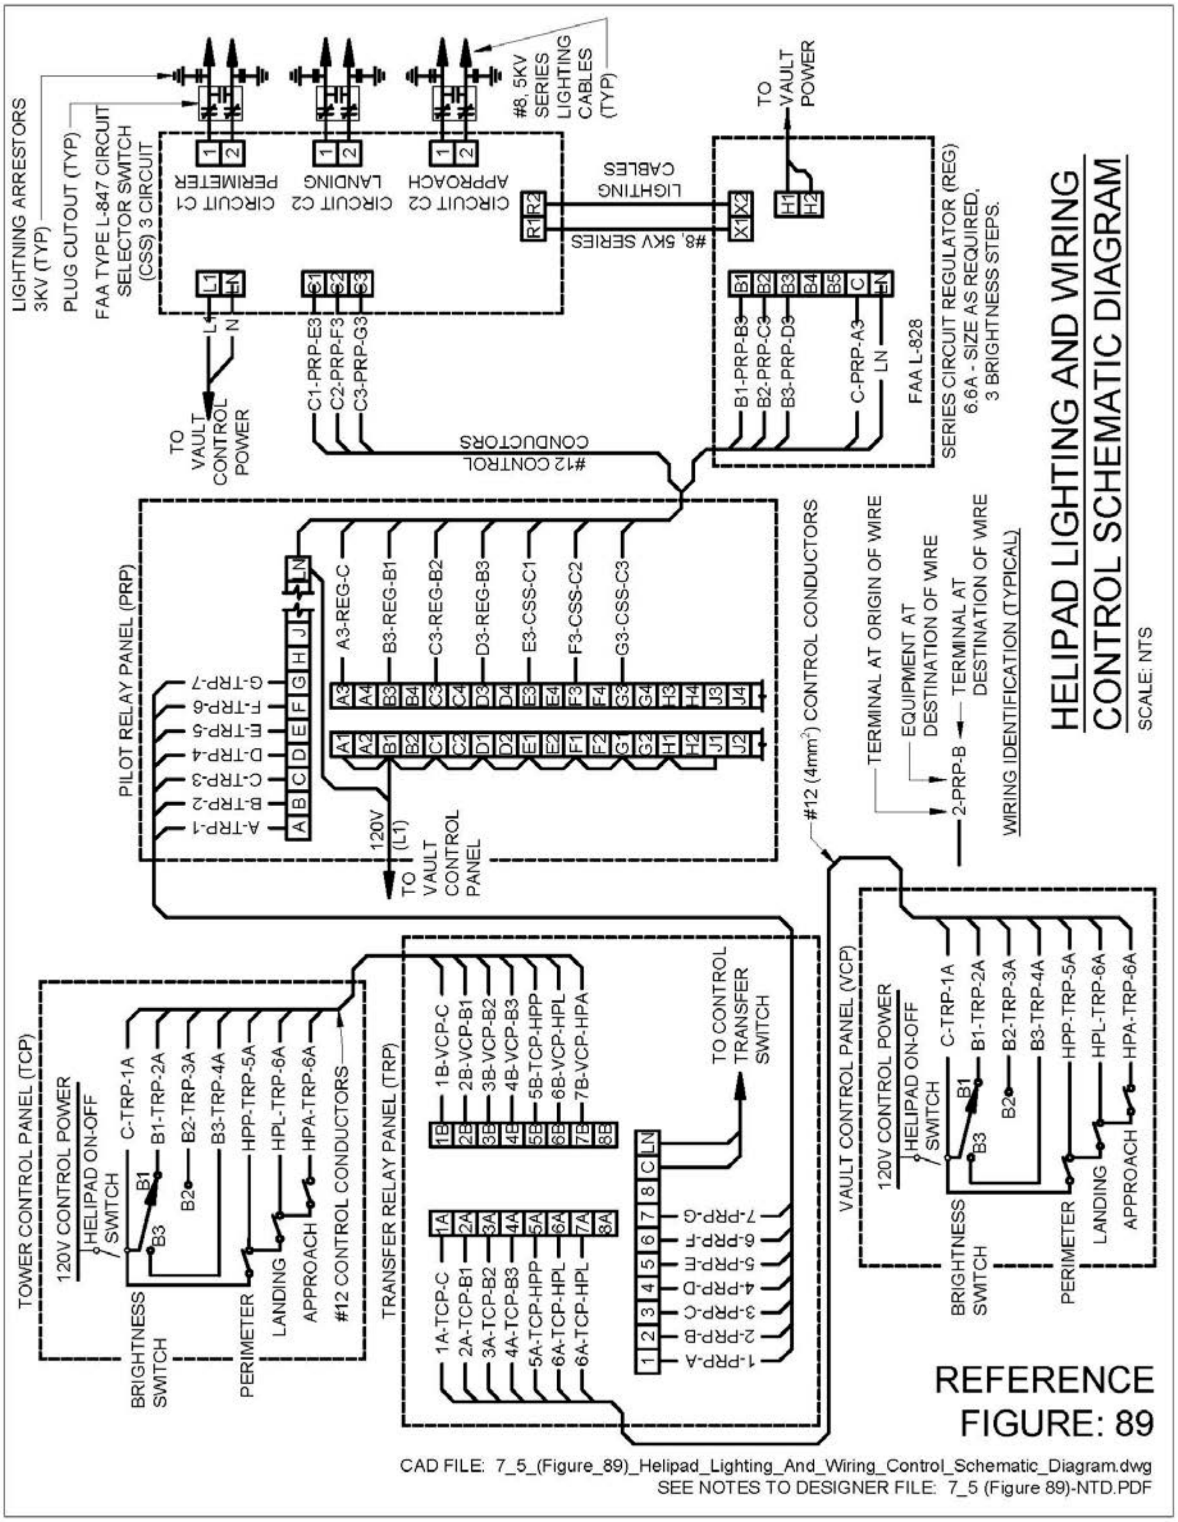
8-5.1.1 Notes to Designer.

1. Figure 89 shows a typical control diagram at a facility with an airfield lighting vault and control tower. A single constant current regulator with 3 brightness steps is used to power the system.

2. The helipad lights are separated into 3 circuits: C1 – perimeter, C2 – landing direction, and C3 – approach direction. Each circuit is operated by a SPST toggle switch that energizes the corresponding loop relay in the L-847 circuit selector switch. The 3 switches are connected such that the landing direction lights cannot be on unless the perimeter lights are on and the approach direction lights cannot be on unless the landing direction lights are on.

3. In some installations 120/240V is used to power the circuits in lieu of constant current regulators. In these cases separate branch circuits are used together with lighting contactors and interlock switches.

Figure 89. Helipad Lighting Wiring and Control Schematic Diagram



CHAPTER 9 Naval Facilities Specific Wave-Off & Wheels-Up Lighting Systems

9-1 Location Plans: Wave-Off & Wheels-Up Lighting Systems.

9-1.1 Figure 90.

Notes to Designer.

9-1.1.1 Wave-off Lighting System.

1. Description. The runway wave-off light system consists of sets of simultaneously flashing red lights installed adjacent to the runway which are aimed toward the threshold. They are intended to inform the pilot that an emergency wave-off or missed approach procedure is necessary. The runway wave-off must be activated from either the control tower, airfield lighting vault, or the wheels-watch station.

2. Power Requirements. Power for the wave-off power converter unit (PCU) must be from a 480 volt source. A single 10 kVA minimum 2400/480V pad mount (weatherproof) transformer may supply the power for the wave-off lights via the PCU.

3. Control Requirements. The wave-off lights must be controlled manually using momentary-contact type switches. The switches must be located only at the control tower, airfield lighting vault, and the wheels-watch station.

4. Control relay must be general purpose, hermetically sealed, 4pdt, 3 amp contacts with 120vac, 60hz coil.

5. Time delay relay must have 10 amp, 120vac contacts with 120vac 60hz coil relay must have one normally-open instantaneous contacts and one normally-closed time delay opening contact adjustable from 5 to 60 second delay on energizing but initially set for 15 seconds delay.

6. Contactor must have two normally-open 30 amp, 480vac contacts with 120vac, 60hz coil.

7. Wave-off pushbuttons must be normally-open momentary contacts. Locate pushbuttons within control tower as directed by the air traffic control officer.

8. If possible use spare conductors in the control tower that runs between the airfield lighting vault and the control panel within the control tower.

9. If available use spare pilot and transfer relays within the airfield lighting vault.

10. Provide 2 - 2" (53mm) conduits (1 - spare) between power converter units (PCU). Also provide 2 - 2" (53mm) conduits (1 - spare) between PCU and threshold.

11. Provide 1 - 2" (53mm) conduit between PCUs and optical assembly units.

9-1.1.2 **Wheels-up Lighting System.**

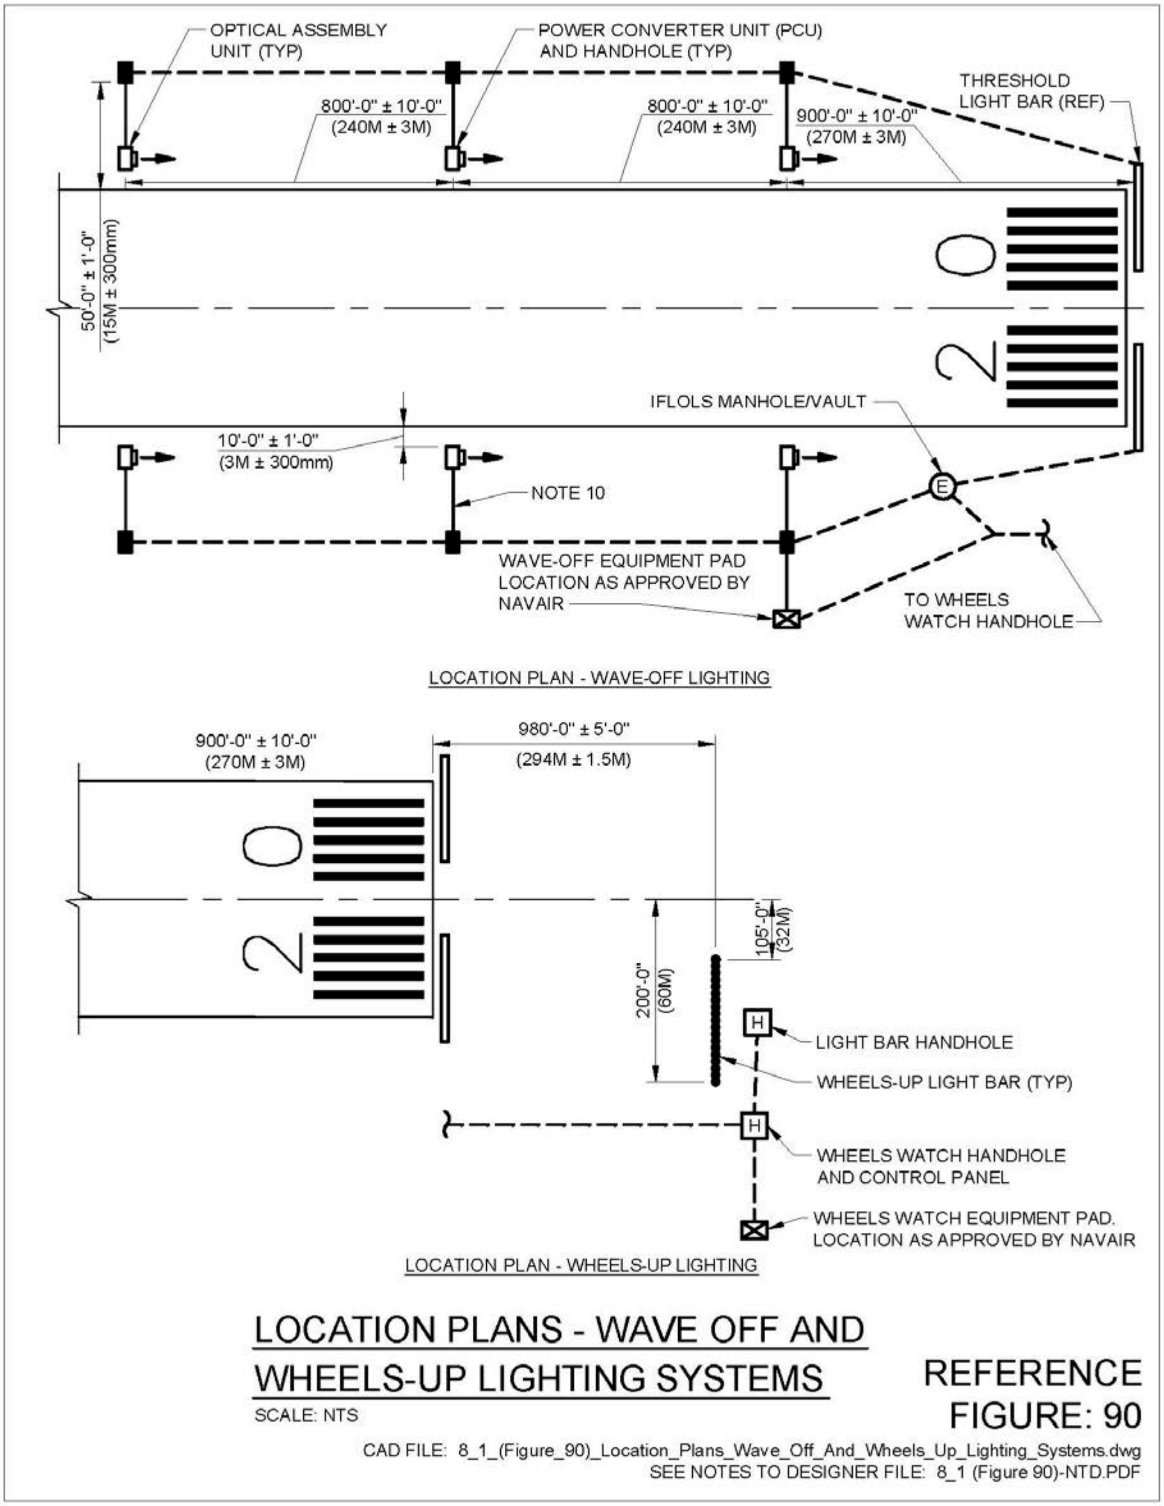
1. Description. Wheels-up lights are a bar of white lights installed under the approach which are aimed upward and toward the threshold. They are intended to illuminate the underside of landing aircraft to permit observers to determine that the landing gear is fully lowered. The system also includes a portable government furnished wheels-watch shelter which protects the observer from the weather and a wheels-watch control panel.

2. Power Requirements. Wheels-up lights are connected to 120 Vac multiple circuits requiring somewhat in excess of 10kW. A 15 kVA pad mount transformer (weatherproof) is recommended.

3. Control Requirements. Wheels-up lights require on/off control and continuous intensity control from 10 to 100 percent of intensity at the rated voltage. This control is required only at the wheels-watch control panel.

4. The wheels-watch control panel also contains a switch which is activated by the observer that energizes the wave-off lighting system.

Figure 90. Location Plans – Wave-Off & Wheels-Up Lighting Systems



9-2 Equipment Pad and Duct Details.

9-2.1 Figure 91.

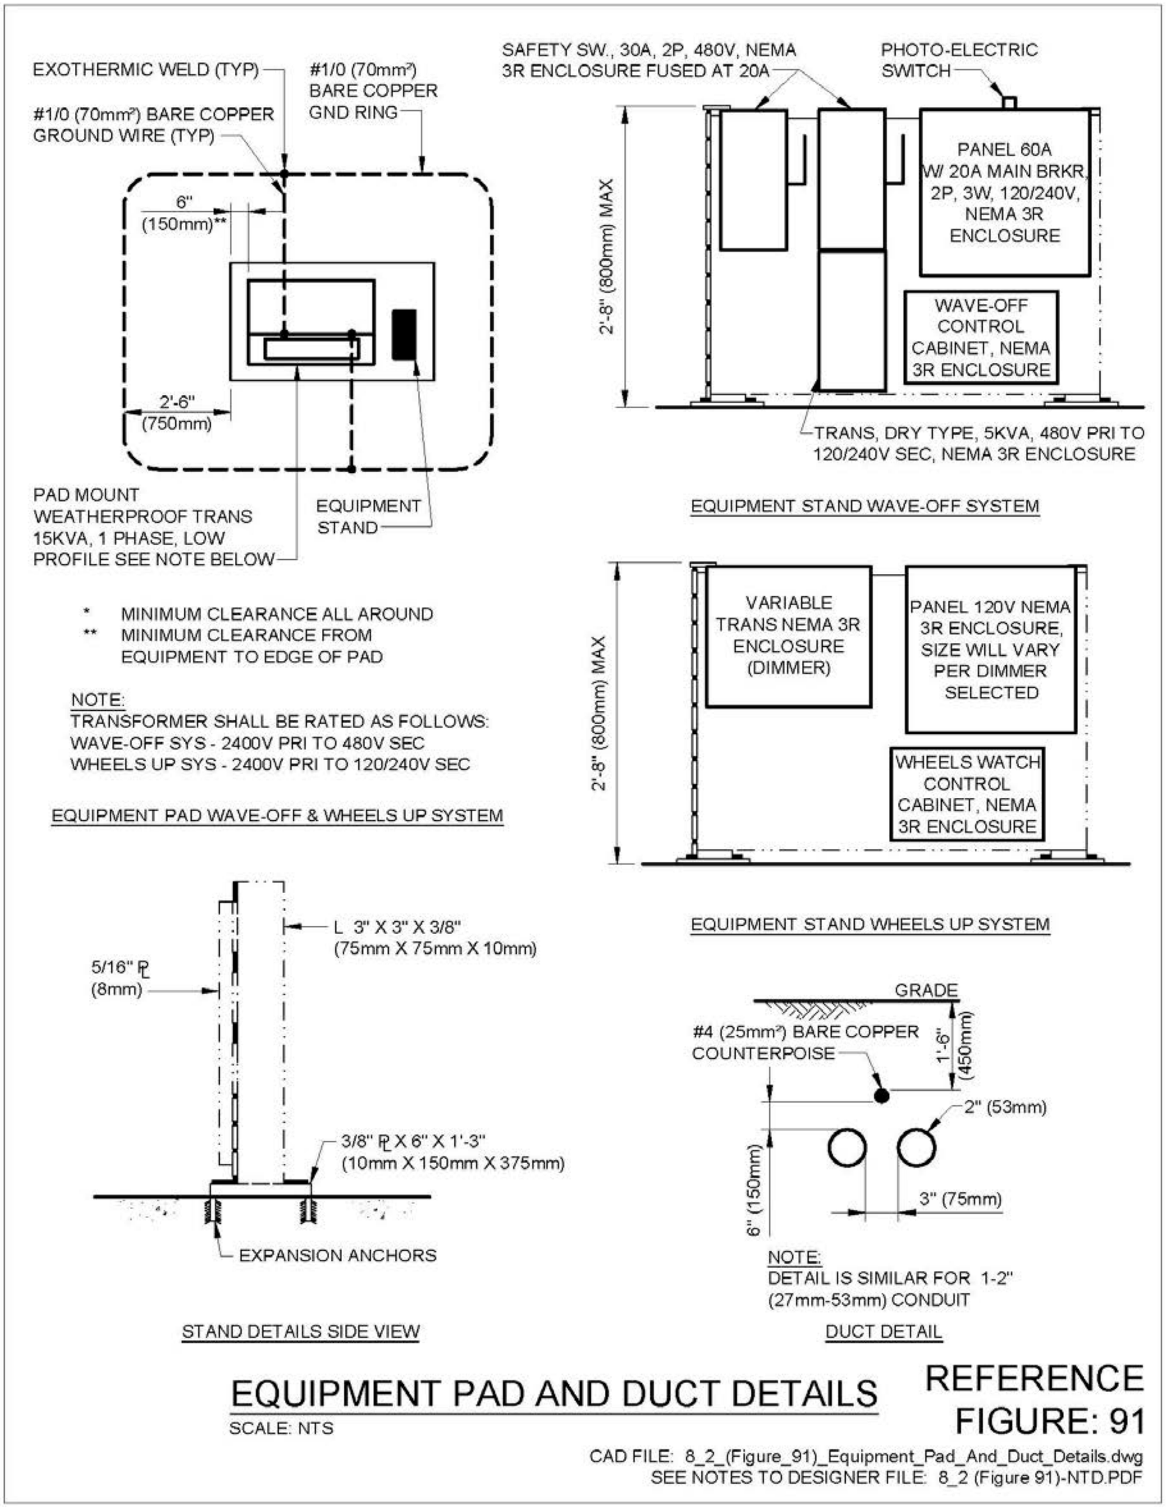
9-2.1.1 Notes to Designer.

1. The equipment stands for the wave-off and wheels-up lighting systems are freestanding and a maximum of 32" (800mm) above grade.

2. The equipment is rated NEMA 3R (weatherproof). In some areas where corrosion may be a problem (i.e. salt, sand, etc.); the use of NEMA 4X rated equipment may be justified.

3. The equipment pads should be located as close as possible to the lighting system (first power converter unit (PCU) of wave-off system and wheels-watch control panel) to limit the voltage drop to the system components. However, NAVFAC ENGCOM should be consulted before placement within the runway safety area or object free zone.

Figure 91. Equipment Pad and Duct Details



9-3 Wave-Off System Wiring Details.

9-3.1 Figure 92.

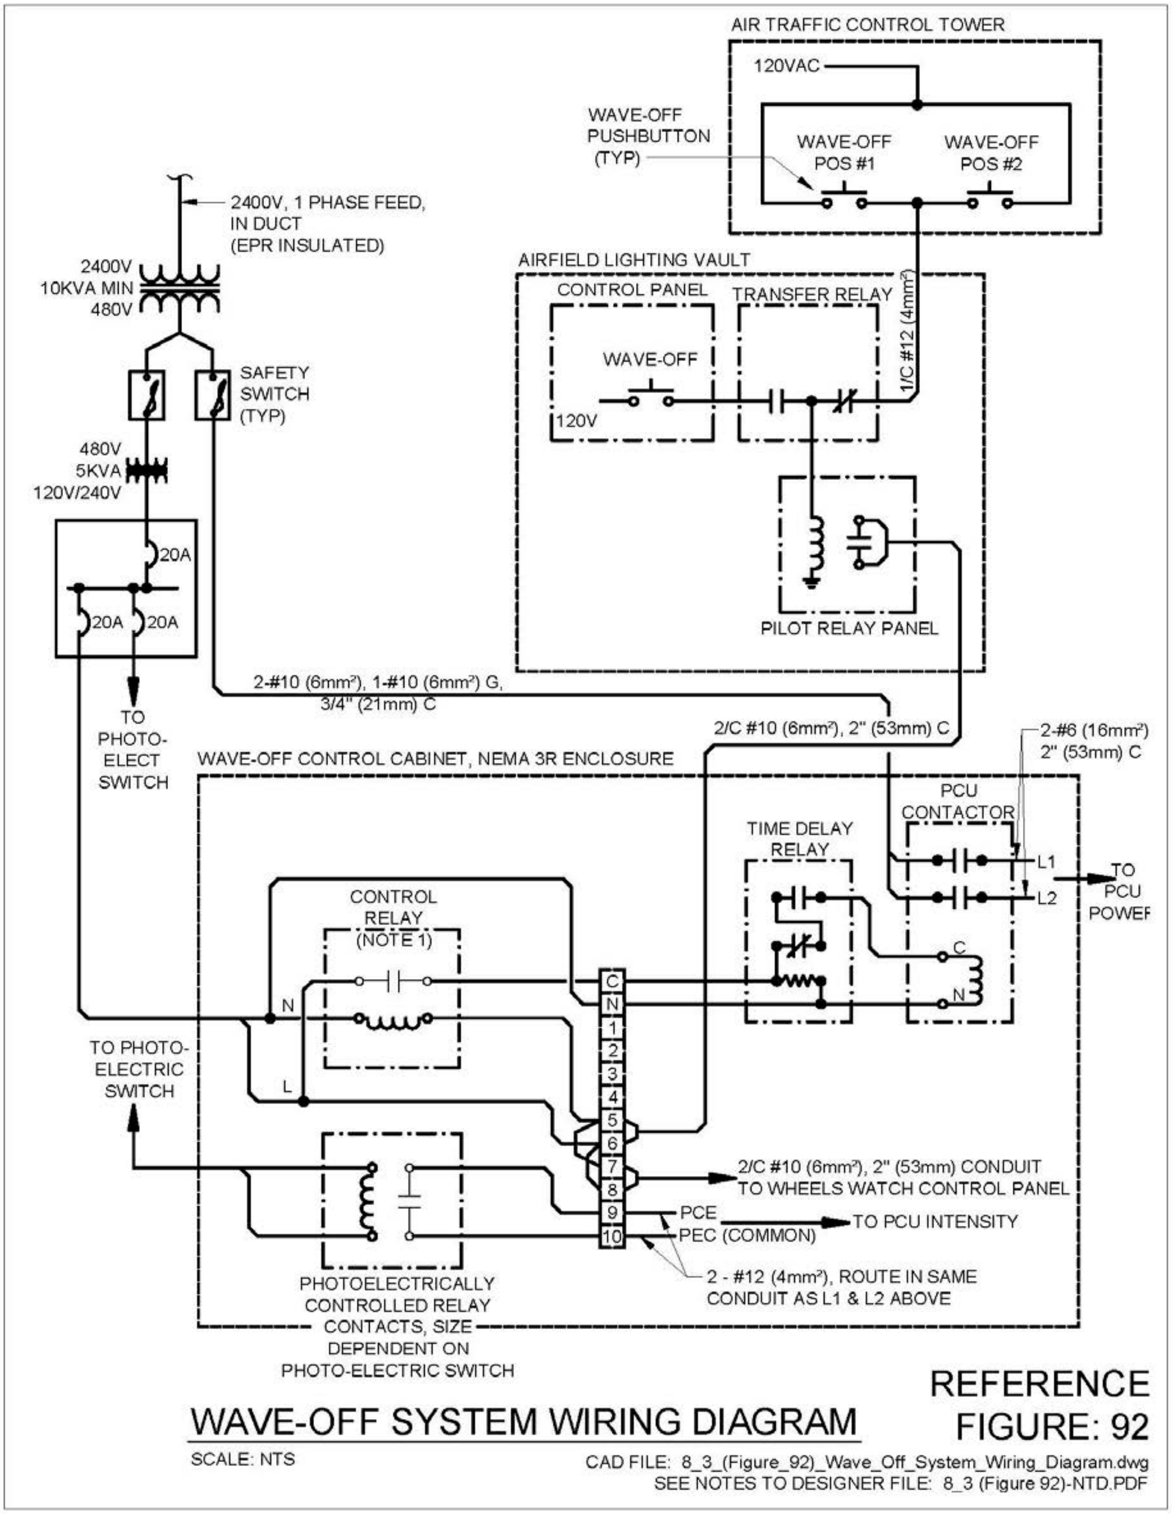
9-3.1.1 Notes to Designer.

1. The wave-off system may be activated by the air traffic controller in the control tower or by personnel in the airfield lighting vault via the transfer relay.

2. The system may also be activated by the observer at the wheels watch control panel.

3. The photoelectric switch controls the intensity of the wave-off system. The system operates at maximum intensity during daytime hours and reduced intensity during hours of darkness.

Figure 92. Wave-Off System Wiring Details



9-4 Flashhead and PCU Wiring Diagram.

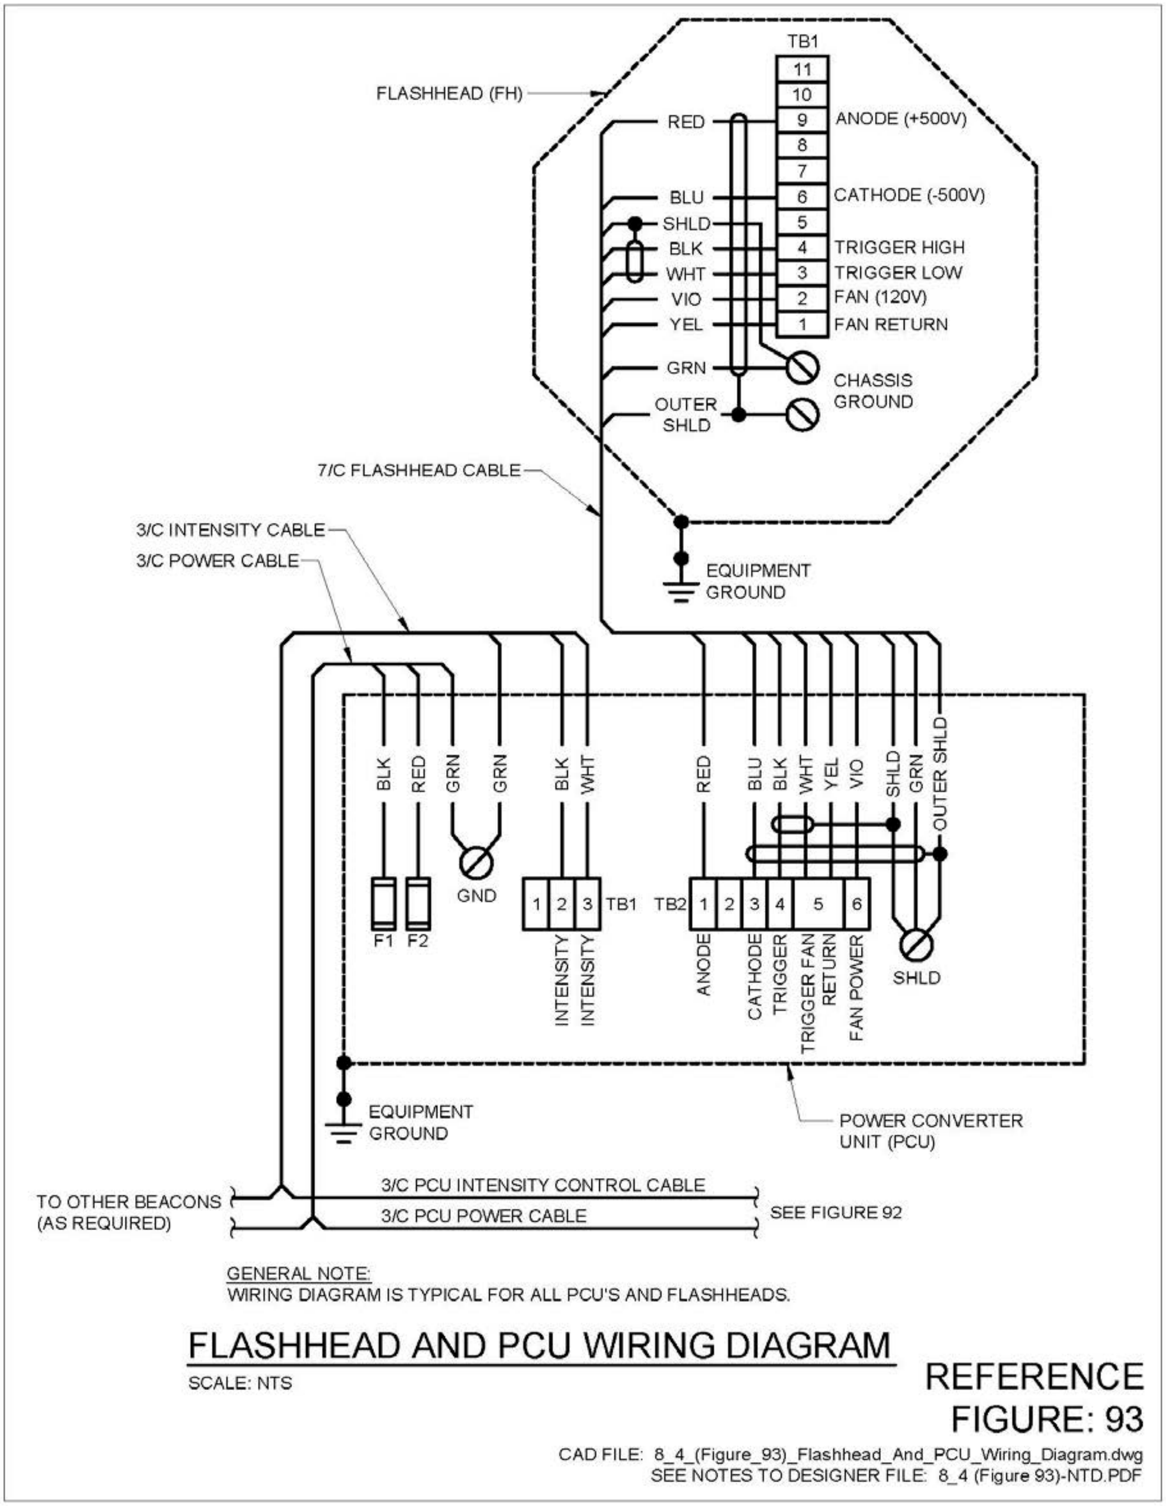
9-4.1 Figure 93.

9-4.1.1 Notes to Designer.

1. 480 Volts, single phase power is delivered to each power converter unit (PCU) from the PCU contactor located in the wave-off control cabinet.

2. Intensity control to each PCU is routed in the same conduit as the power conductors and originates at the photo-electrically controlled relay in the wave-off control cabinet.

Figure 93. Flashhead and PCU Wiring Diagram



9-5 **Wave-Off Fixture Mounting.**

9-5.1 **Figure 94.**

9-5.1.1 **Notes to Designer.**

1. The optical assembly (flash head) is mounted on an FAA type L-867 concrete encased light base.

2. The flexible non-metallic conduit allows movement in the 2" (53mm) conduit due to freeze-thaw cycles in frost susceptible areas.

9-5.1.2 **Drawing Notes for Figure 94.**

1. Reinforcing cage indicated on Figure 12.

9-6 **Wave-Off Fixture Aiming.**

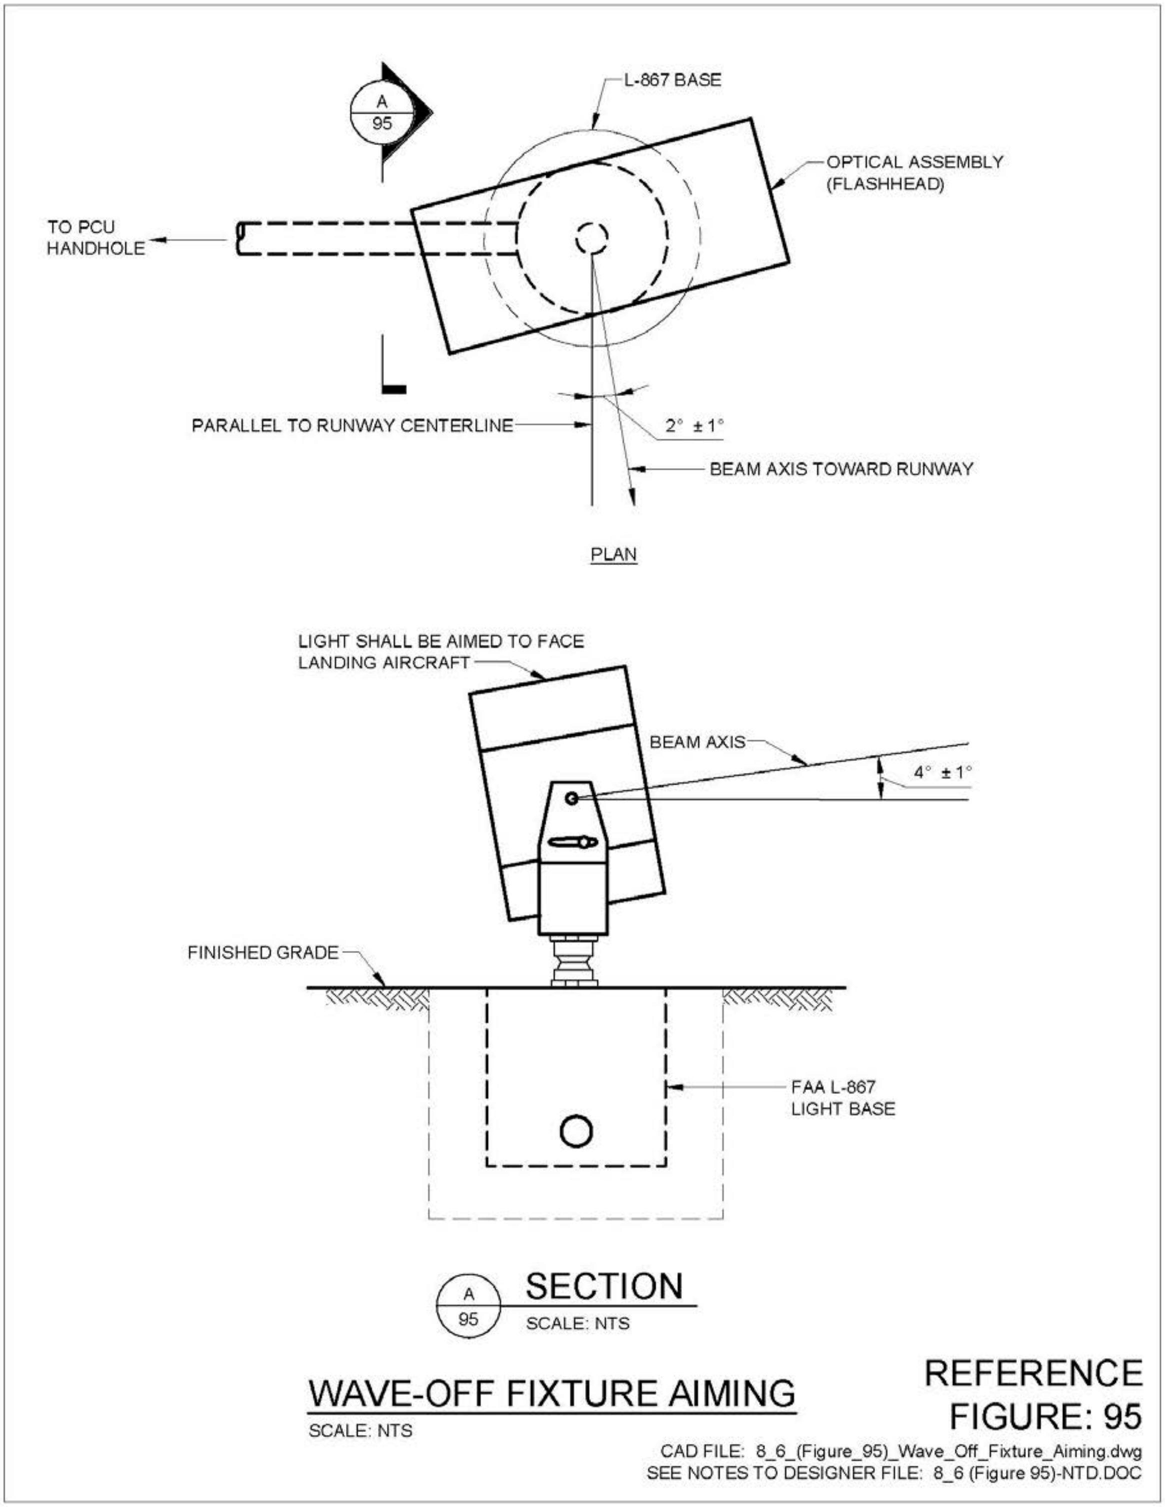
9-6.1 **Figure 95.**

9-6.1.1 **Notes to Designer.**

1. The wave-off fixture is aimed towards the landing aircraft as indicated.

2. Construction document should include the aiming requirements.

Figure 95. Wave-Off Fixture Aiming



9-7 Power Converter Unit.

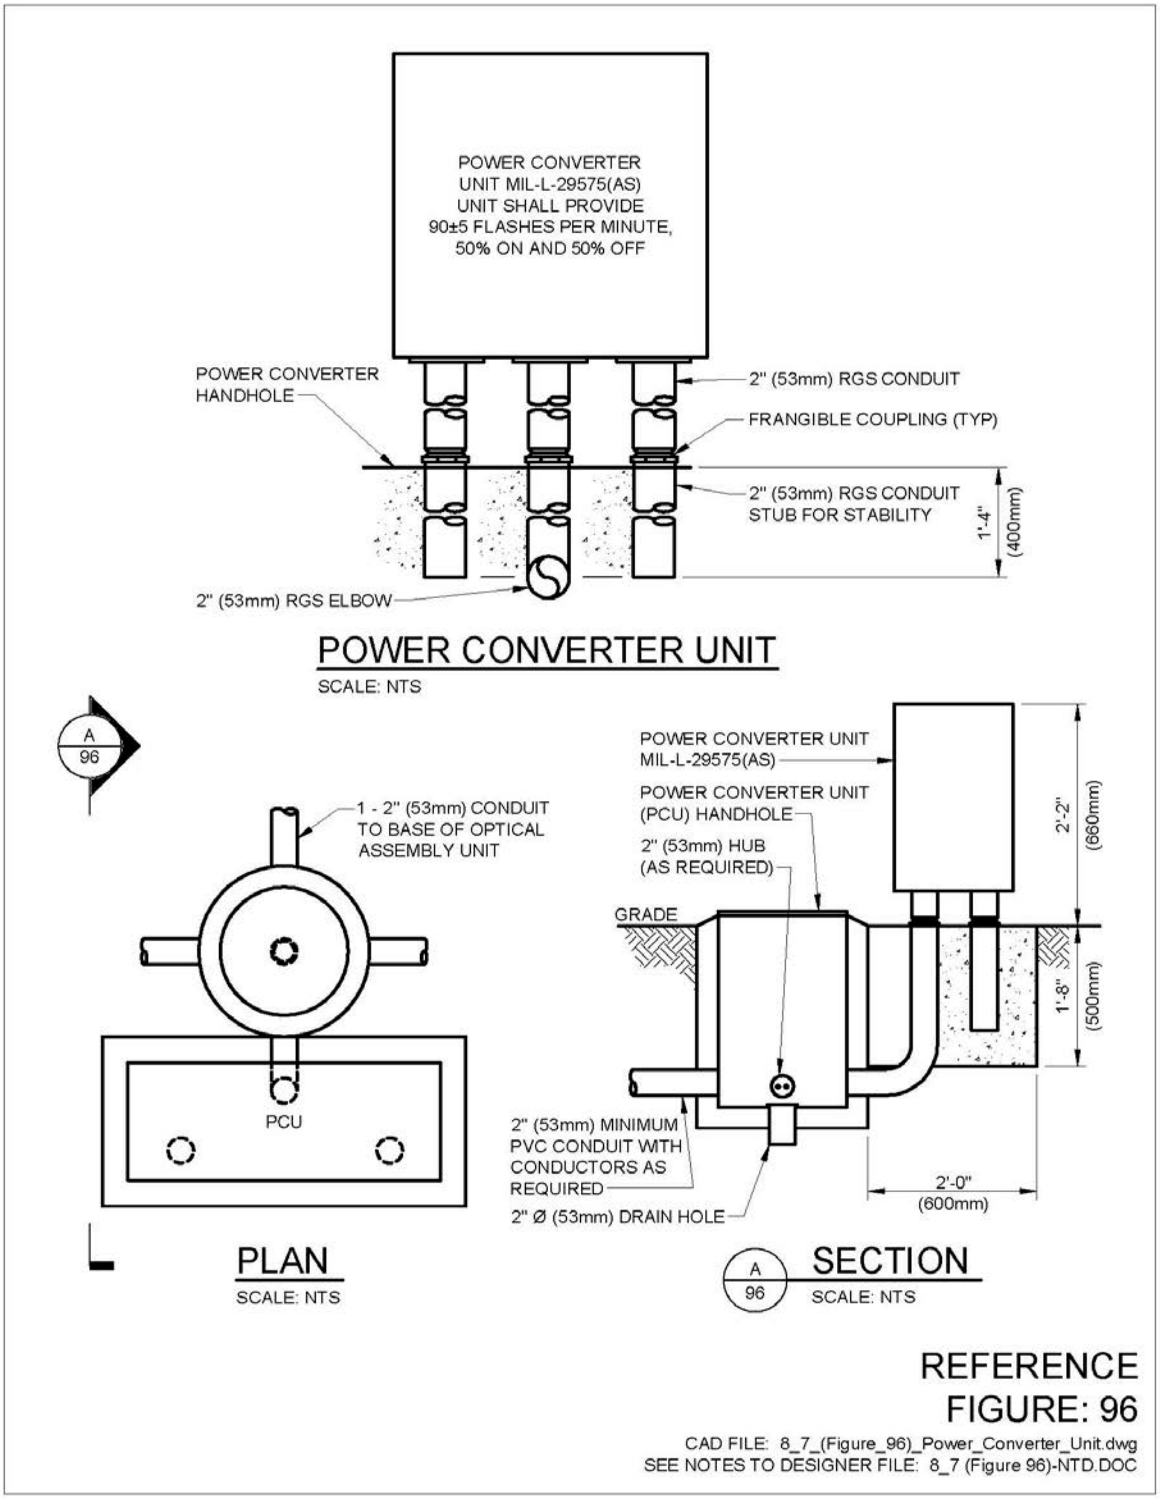
9-7.1 Figure 96.

9-7.1.1 Notes to Designer.

1. Use an FAA type L-867 Size D (16" ∅) light base concrete encased. Conduit openings are 2" thread hubs and must be specified ((2) 2" (53mm) one above the other at 0 degrees and 180 degrees, (1) 2" (53mm) at 90 degrees and 270 degrees).

2. Install 6" (150mm) long flexible non-metallic conduit (not indicated) on each conduit after leaving handhole.

Figure 96. Power Converter Unit



9-8 Wheels-Up Lighting System Layout.

Figure 97. Reserved

Figure 98. Reserved.

9-8.1 Figure 99.

9-8.1.1 Notes to Designer.

1. The wheels-up lights are located and aimed as indicated.

2. Coordinate with NAVAIR on location of the equipment pad. Design for a maximum voltage drop of ±4% total from the equipment pad to the farthest fixture in the system. #6 (16 square mm) must be the minimum wire size.

9-8.1.2 Drawing Notes for Figure 99.

1. Wheels up light bar must be located on same side of runway as the control tower.

2. Relocation or re-aiming of light bar requires approval of NAVFACENGCOM.

3. Provide L-867D handhole per Figure 31.

4. Conductor size between light bar handhole and wheels up equipment pad must be determined once location of equipment pad is approved by NAVAIR. The total voltage drop for the wheels-up lighting circuit must be maintained to ±4% or less.

5. Conductor size between light bar handhole and wheels-up lights must be 2 #6 (16 square mm), 1 #6 (16 square mm) ground in 2" (53mm) conduit.

6. The three (3) inner most lights are aimed toward the runway at an angle of 25 degrees.

9-9 **Wheels-Up Lighting Wiring Diagram.**

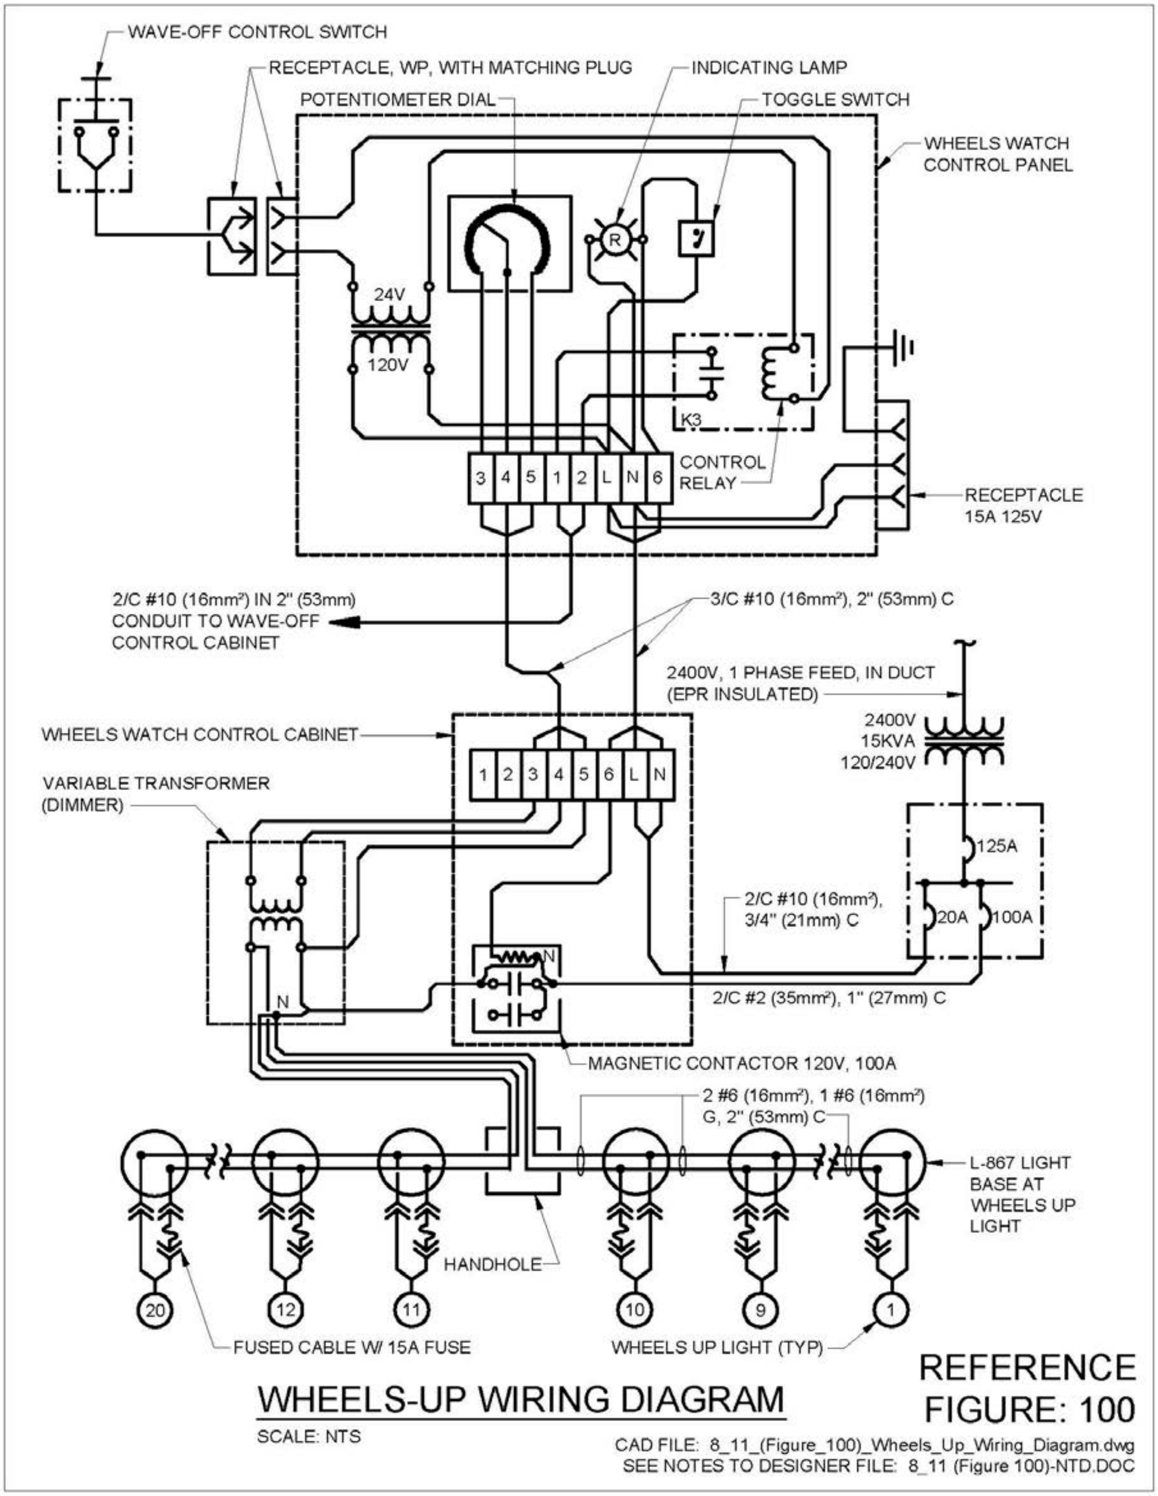
9-9.1 **Figure 100.**

9-9.1.1 **Notes to Designer.**

1. The observer varies the intensity of the lights by the potentiometer located in the control panel.

2. Activation of the wave-off system is accomplished by the wave-off control connected to the control panel by a flexible cord.

Figure 100. Wheels-Up Wiring Diagram



9-10 Wheels-Up Light Fixture.

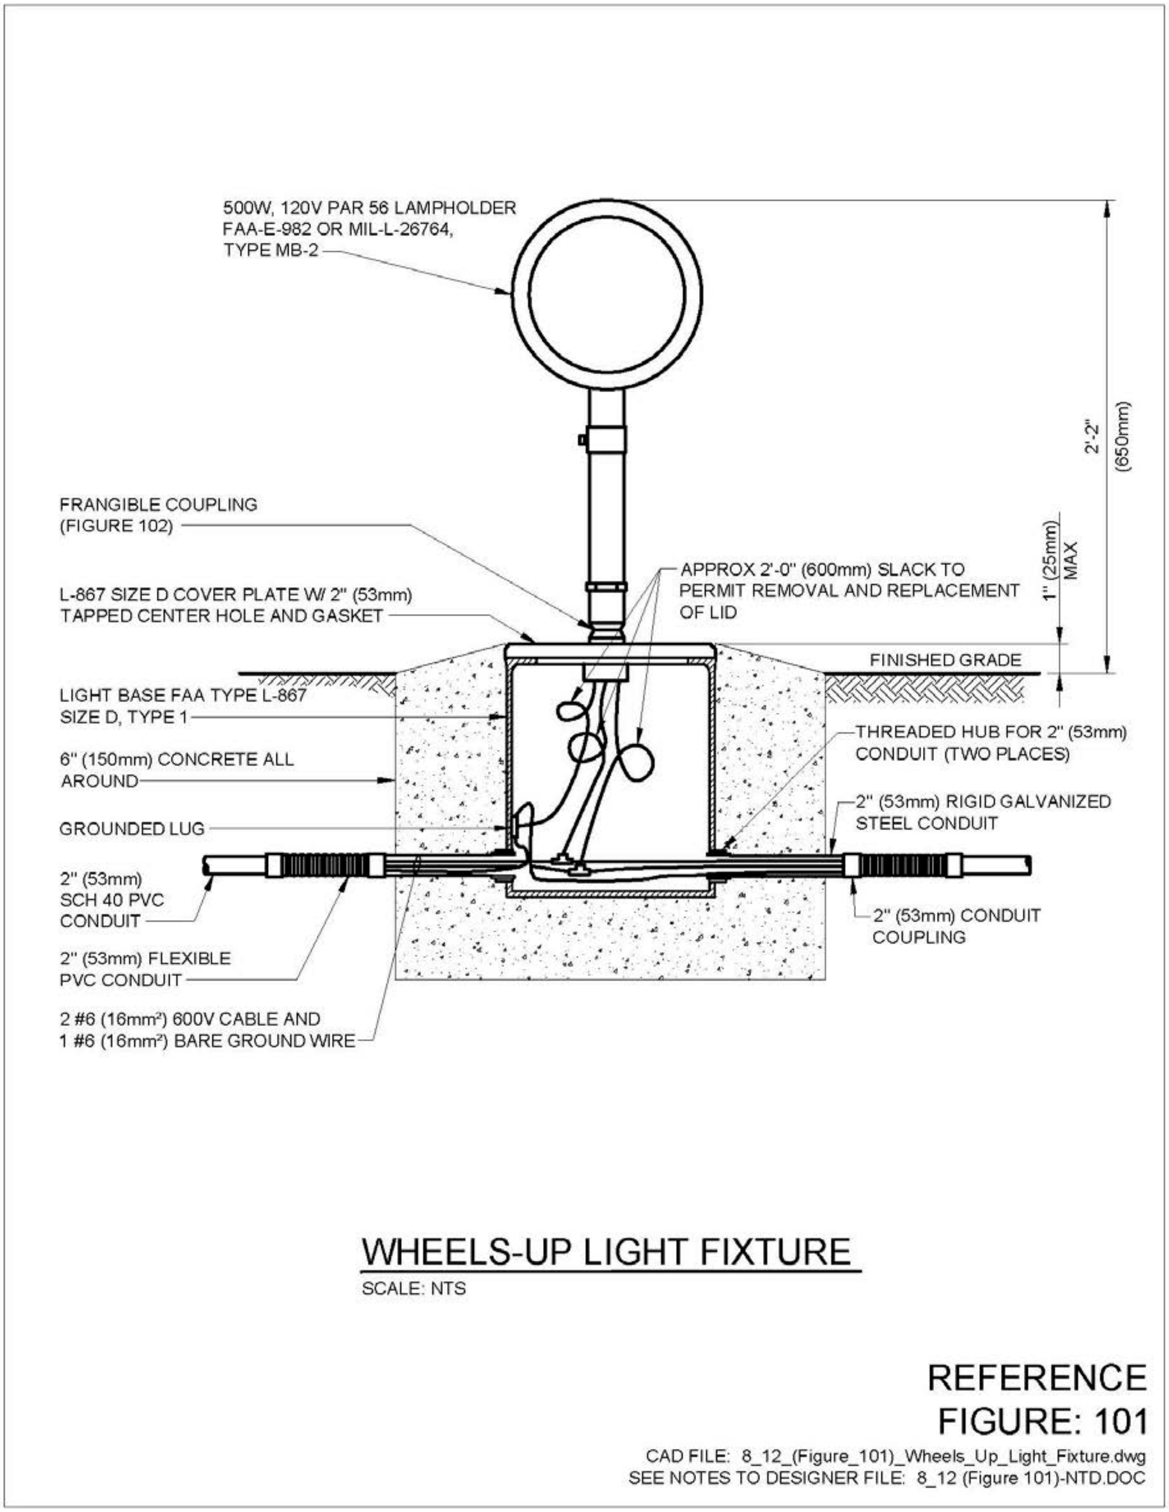
9-10.1 Figure 101.

9-10.1.1 Notes to Designer.

1. The wheels-up lighting system is a constant voltage system. The lamp shorting device which is part of an FAA-E-982 fixture is not used.

2. The flexible non-metallic conduit allows play in the conduit due to freeze-thaw cycles in areas susceptible to frost penetration or alignment with conduits.

Figure 101. Wheels-Up Light Fixture



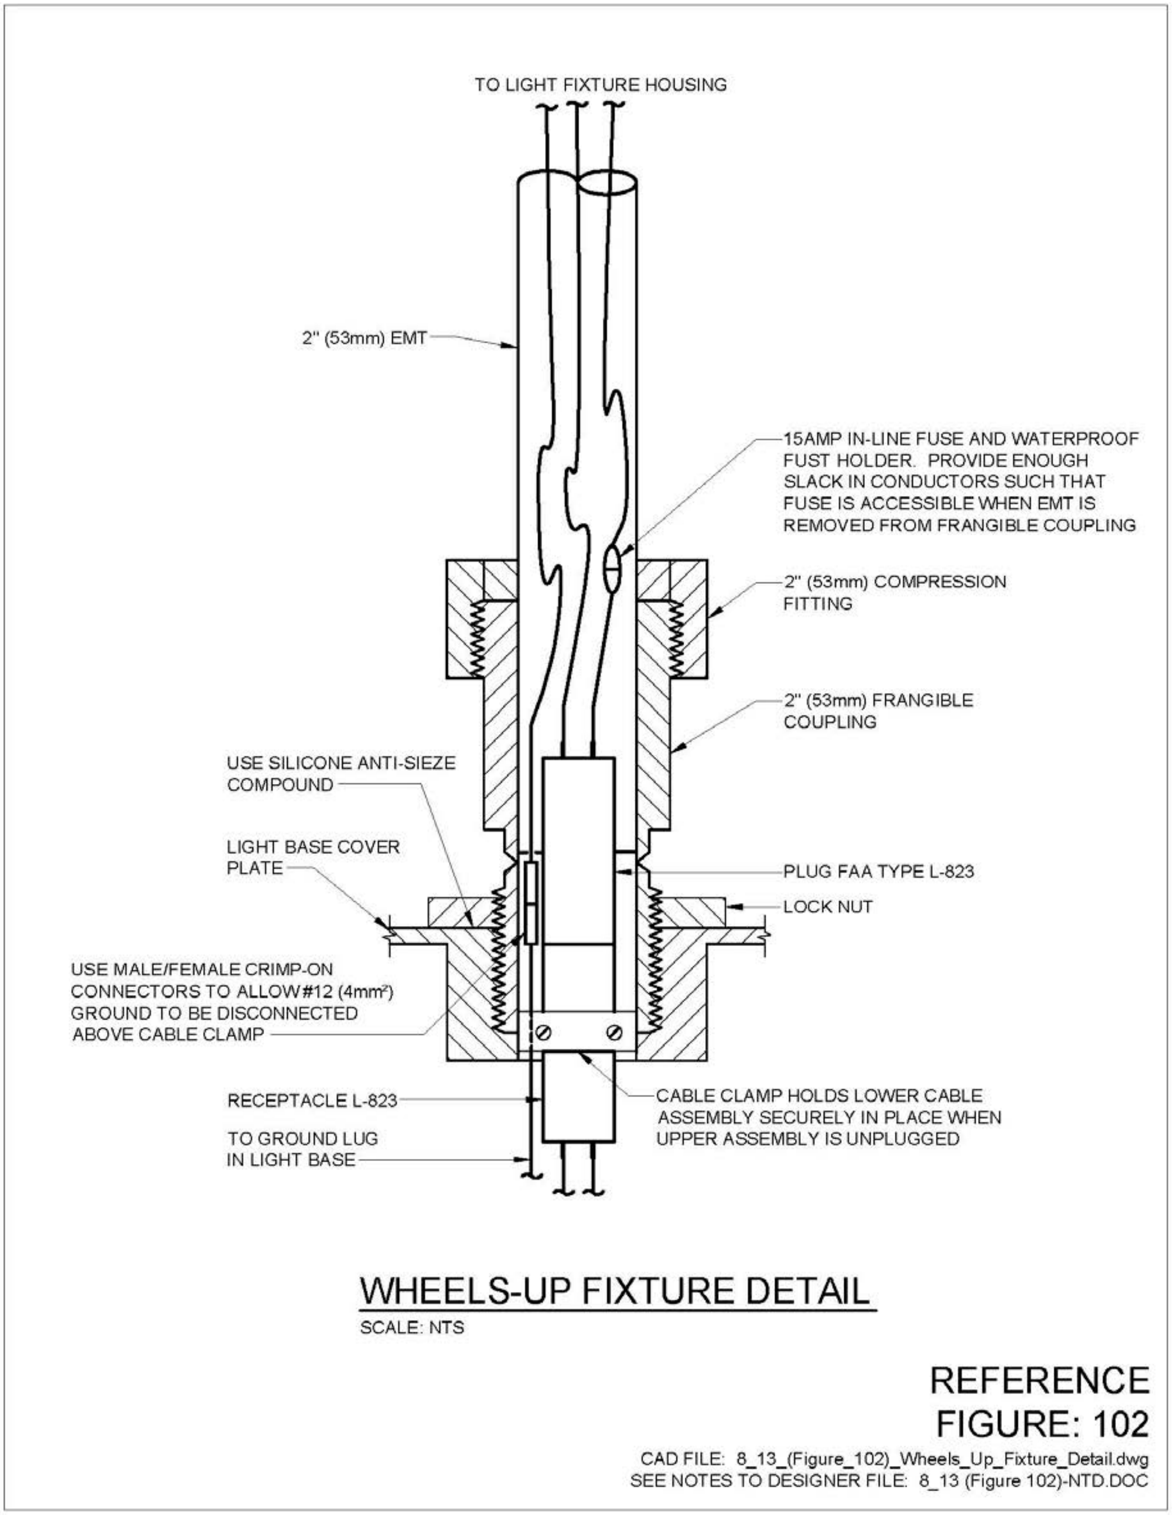
9-11 **Wheels-Up Light Fixture.**

9-11.1 **Figure 102.**

9-11.1.1 **Note to Designer.**

1. The in-line fuse sets inside the EMT conduit. Enough slack should be provided such that the fuse is accessible when the EMT is removed from the frangible coupling.

Figure 102. Wheels-Up Light Fixture



9-12 **Wheels-Watch Control Panel.**

9-12.1 **Figures 103A, 103B.**

9-12.1.1 **Note to Designer.**

1. Use an FAA type L-867 Size D (16" ∅) concrete encase light base with 2" (53mm) threaded hubs for conduit located at 0 degrees, 90 degrees, and 180 degrees.

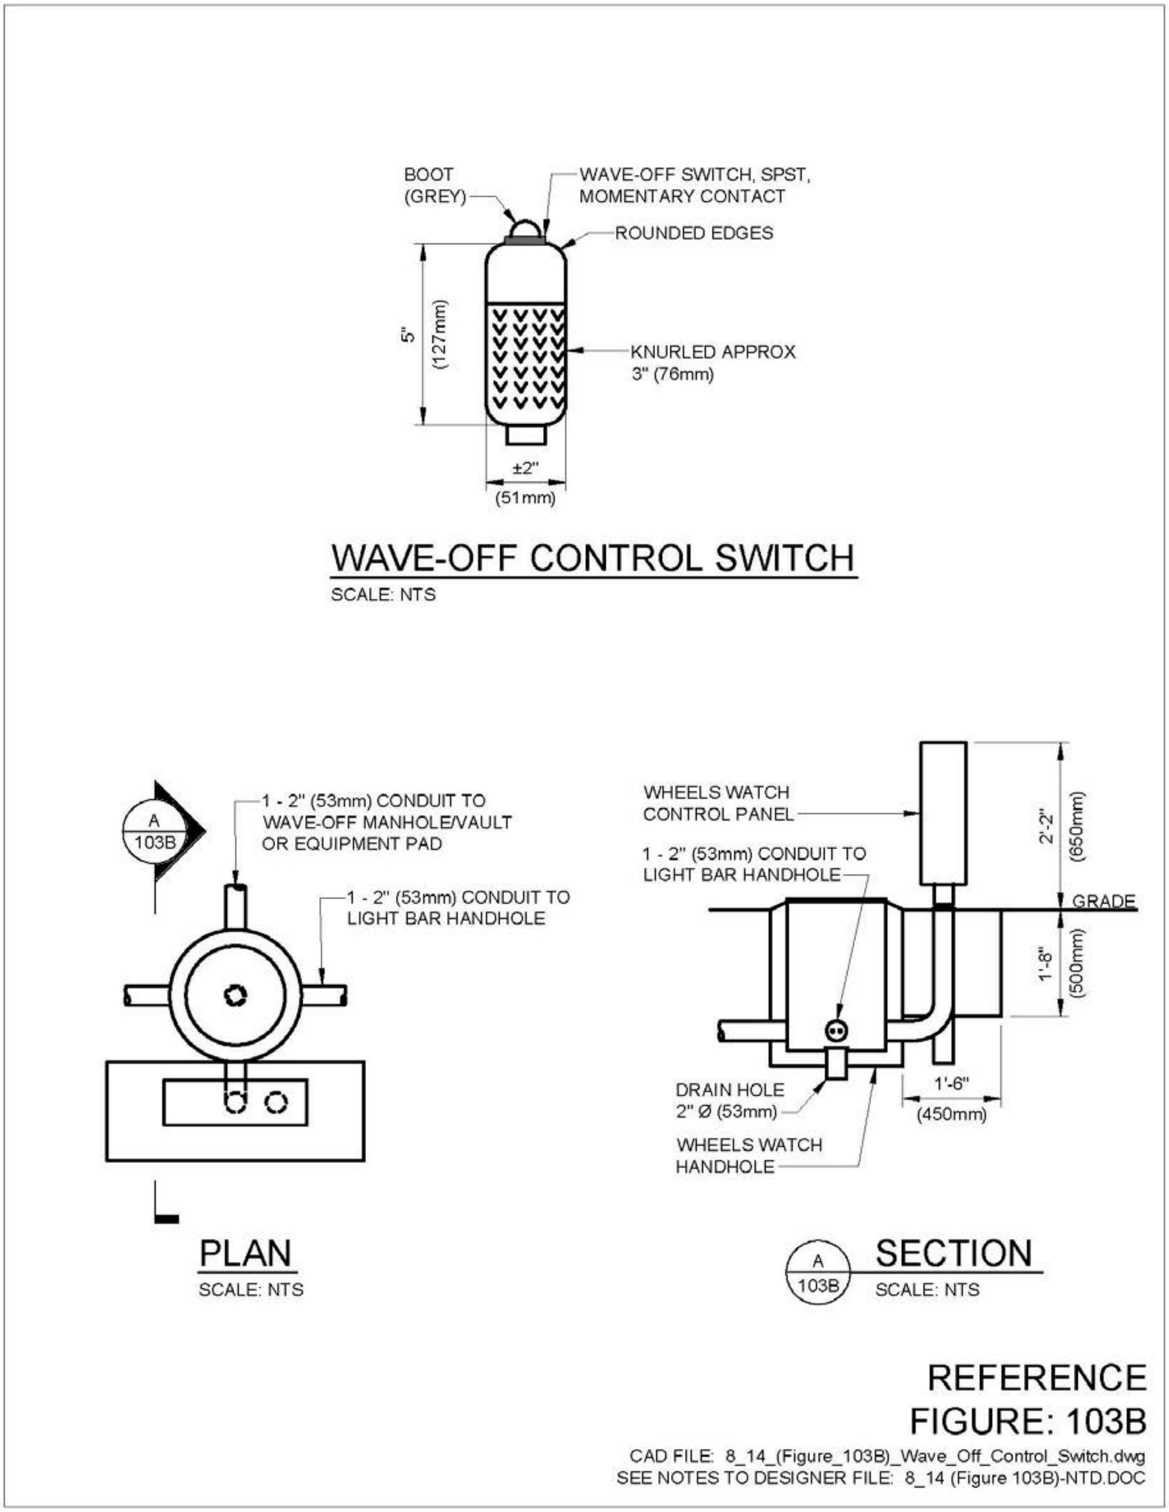
Figure 103B. Wave-Off Control SW



CHAPTER 10 Naval Facilities Specific Simulated Carrier Deck Systems

10-1 Simulated Carrier Deck Lighting System Layout Plan & Wiring Diagram.

10-1.1 Figures 104A, 104B, 104C.

10-1.1.1 Notes to Designer.

1. The simulated carrier deck lighting system is installed on a runway along with the associated carrier deck markings to provide a training and practice environment for carrier deck approaches and landings. The system is controlled by a landing signals officer (LSO) via a portable control panel and control switch. The panel and switch are connected to a submersible terminal box located in the LSO handhole.

2. Siting of simulated carrier deck lighting system must be in accordance with NAVAIR 51-50AAA-2.

3. Designer must lay out simulated carrier deck saw kerfs for minimal crossing of centerline lighting system saw kerfs.

4. All wiring installed in saw kerfs must be single conductor #10 (6 square mm), 600V, type THWN-2.

5. For new runway construction, the entire width of the deck lighting system must be Portland Cement Concrete (PCC). Airfield lighting designer must coordinate installation of FAA L-868 light bases and 2" (53mm) conduit with isolation transformers in each light base.

6. Where simulated carrier deck lighting systems are to be installed in existing runways having a flexible pavement surface, guidance must be received from COMNAVFACENGCOM.

7. Inset light fixtures must be a 45 watt, 6.6 amp, in-pavement, unidirectional inset light per FAA L-852N, type V or VI. Base mounted type must be either type VII or VIII. Fixture must have extra strength stainless steel housing and thickened, hardened top optical casting. Lamps must be provided with a shorting disc to allow operation of other lamps upon single lamp burnout.

8. Distance from runway to handhole varies up to 10 ft (3m) maximum. Designer will minimize offset distance to satisfy field conditions.

9. Marking of runway pavement for simulated carrier deck system must comply with NAVAIR 51-50AAA-2.

10. Lights are aimed parallel with the centerline and toward the runway threshold.

11. Outermost lights on ramp athwartship, and forward athwartship lights must be in line with the carrier deck edge lights; all lights are on 5’ (1.5m) spacing.

12. There are 17 centerline lights, 34 edge lights, 12 ramp athwartship lights, and 12 forward athwartship lights.

Figure 104A. Simulated Carrier Deck Lighting System – Layout Plan

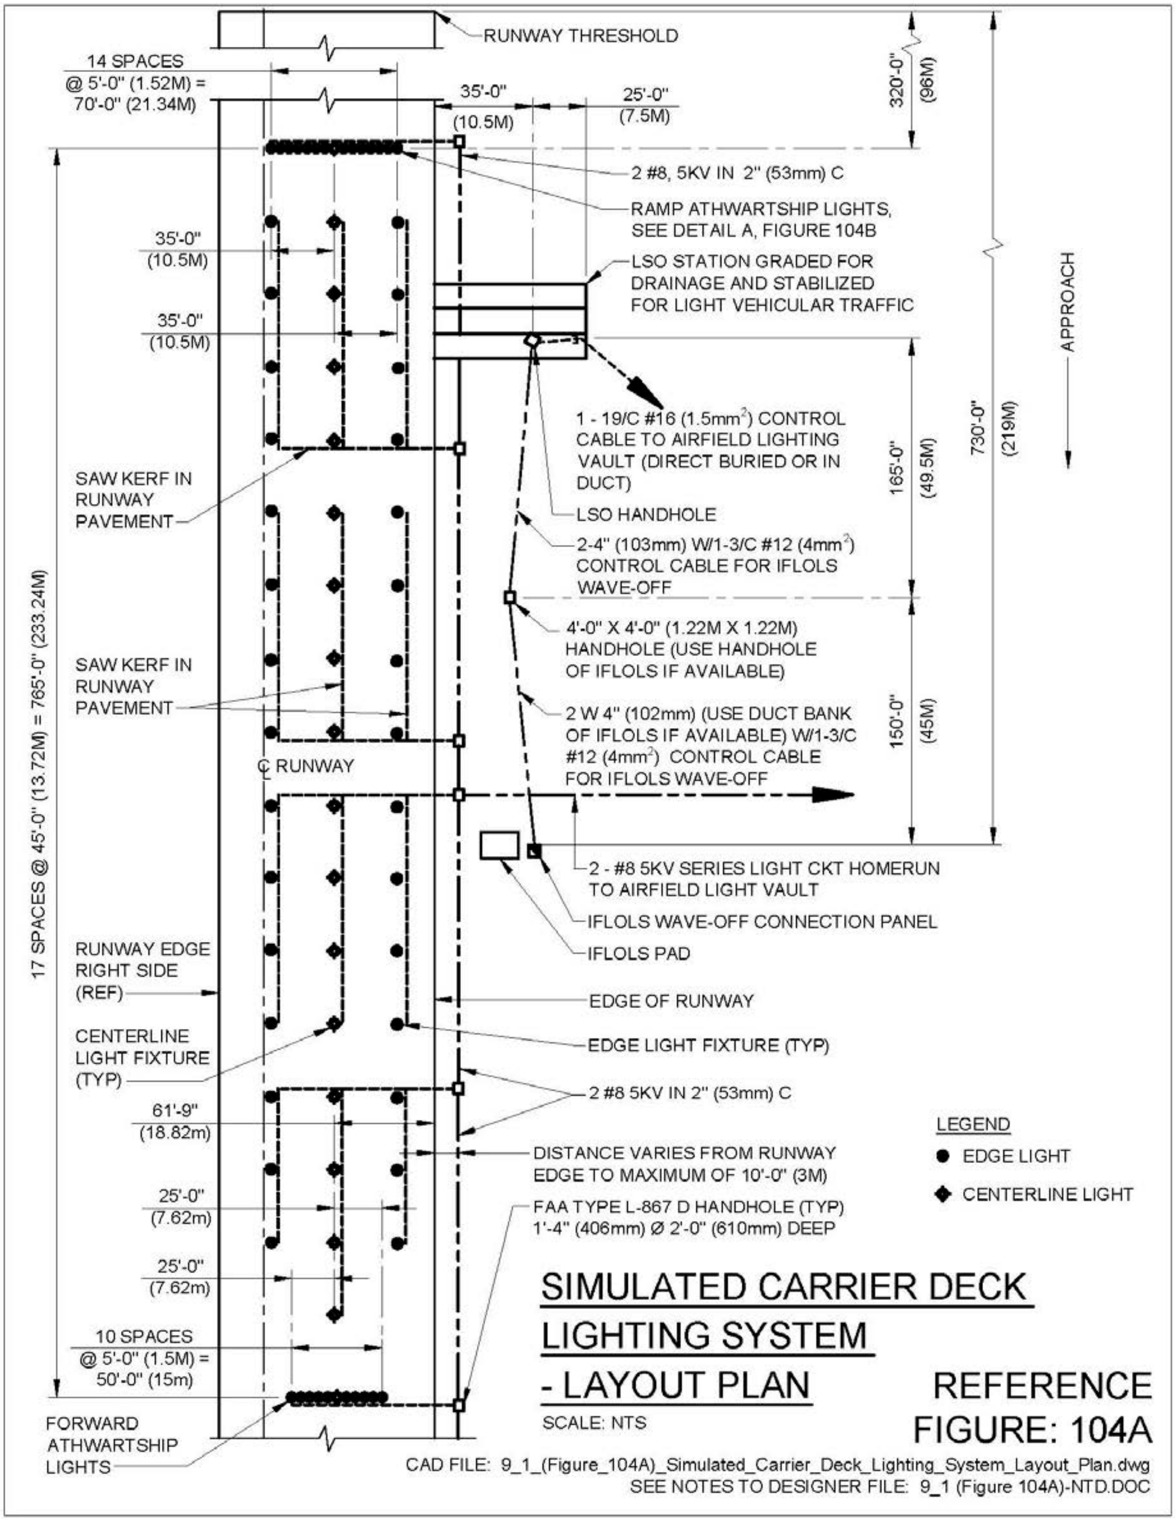


Figure 104B. Simulated Carrier Deck Lighting System – Detail

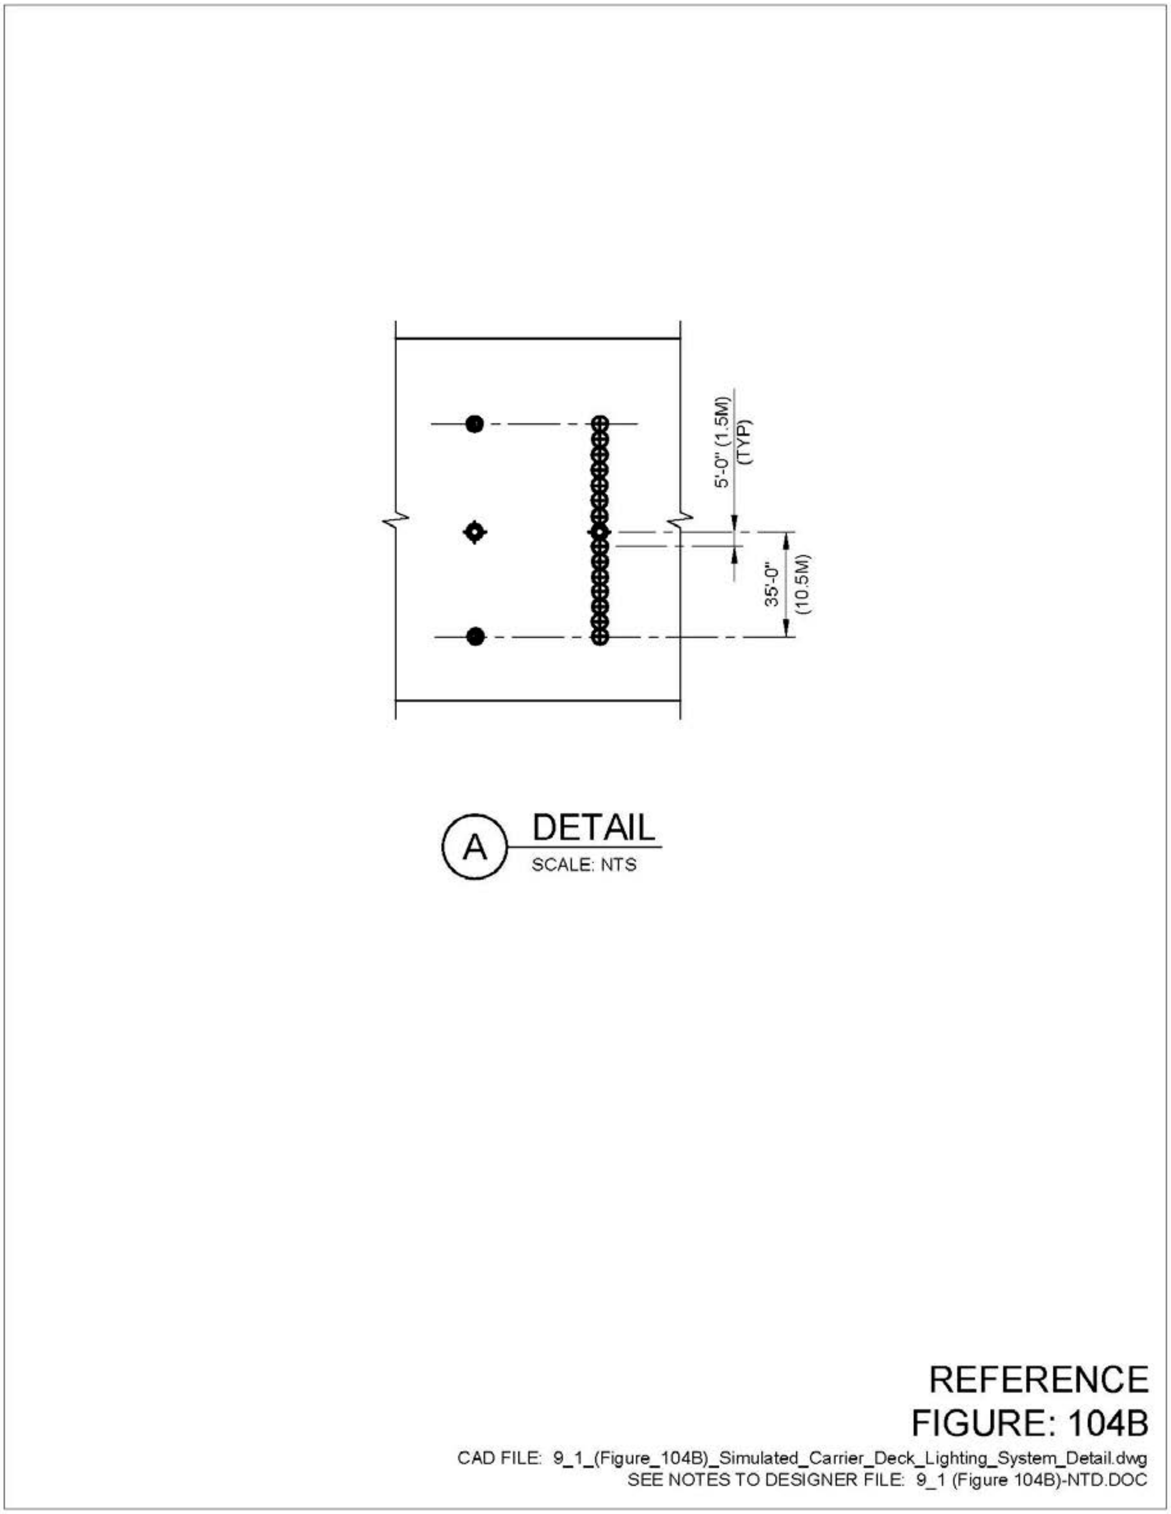

Figure 104C. Simulated Carrier Deck Lighting System – Wiring Diagram

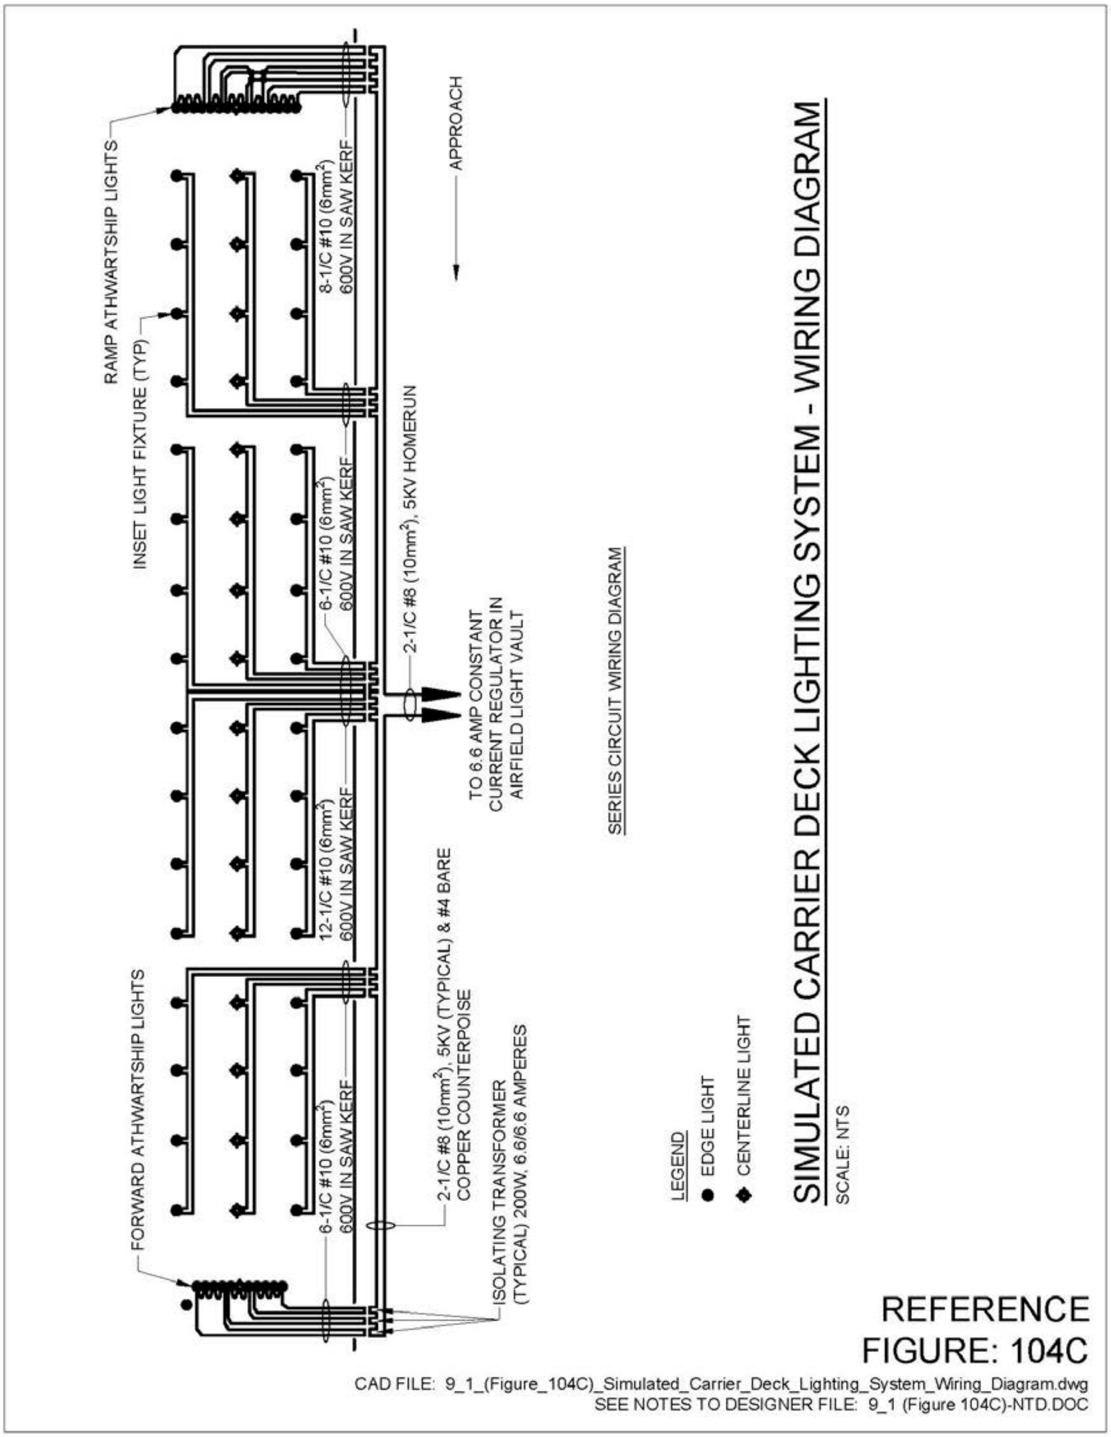


10-2 **LSO Handhole Details.**

10-2.1 **Figure 105.**

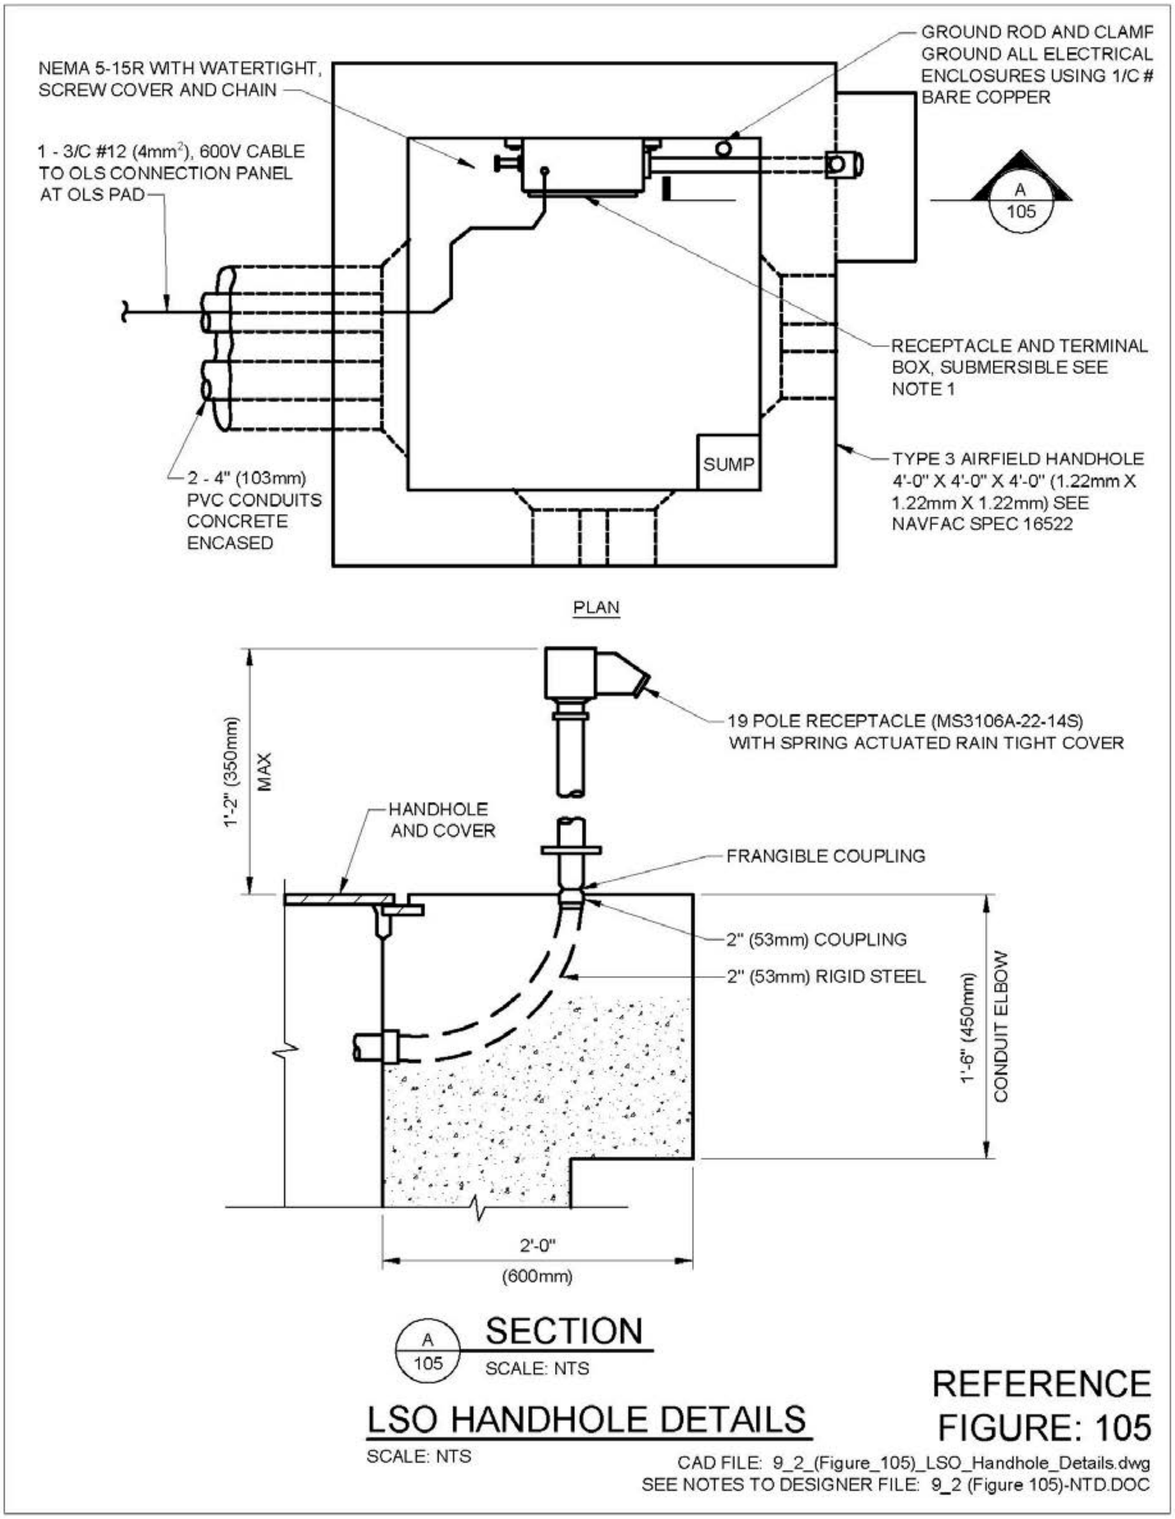
10-2.2 Notes to Designer.

1. The LSO handhole has an above-grade terminal box and receptacle. This serves as a junction point for connecting the multiconductor cables from the L.S.O. control panel, portable OLS (optical landing system), and the airfield lighting vault.

2. The handhole is located 115' (34.5m) upwind from the ramp athwartship lights and 62' (18.6m) outboard of the simulated carrier deck edge lights. A 44' (13.2m) wide area extending outboard 60' (18m) from the runway edge must be provided. This area must be graded for drainage and stabilized for light vehicular traffic.

3. Receptacle and terminal box must be rated NEMA 4 and must have threaded hubs.

Figure 105. LSO Handhole Details



10-3 Handhole and Transformer Housing.

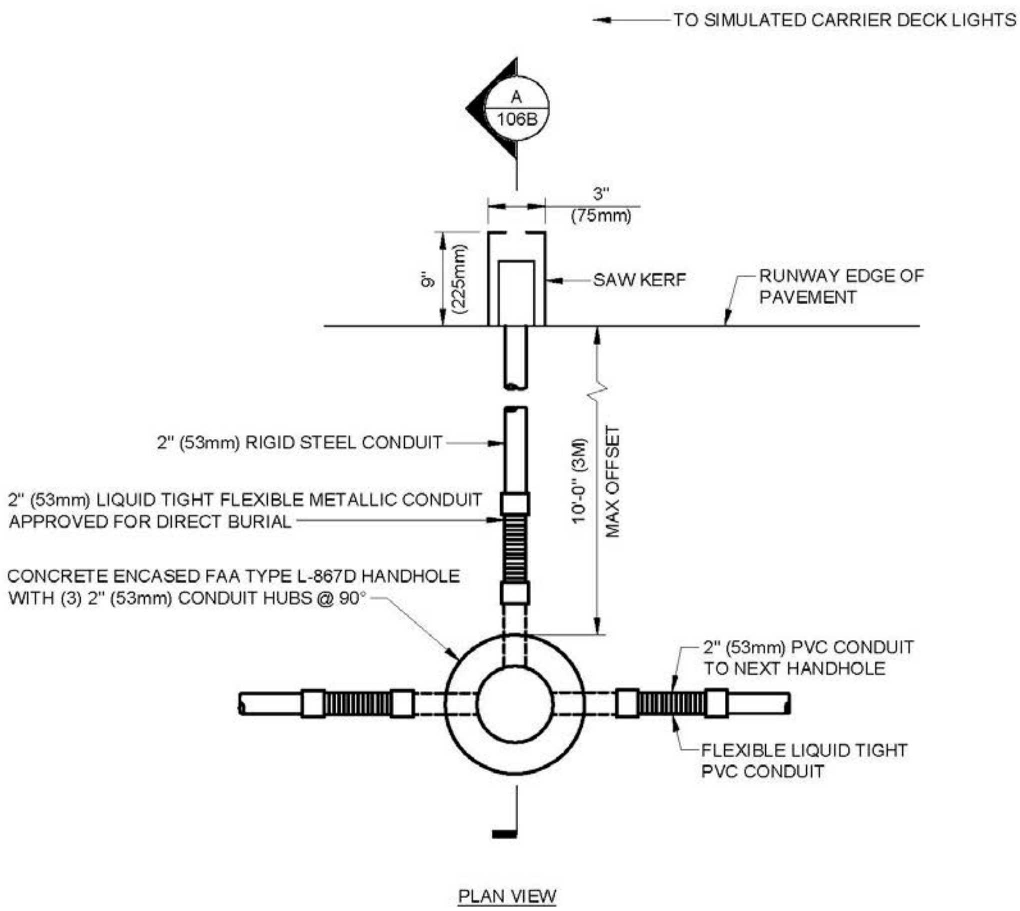
10-3.1 Figures 106A, 106B.

10-3.1.1 Notes to Designer.

1. The flexible conduit allows for flexibility of the conduit runs during freeze/thaw cycles in cold climates and should be at least 12" (300mm) long.

2. The handhole should be specified with both an internal and external ground lug. The entire handhole is then bonded to a ground rod by a #6 (16 square mm) bare copper pigtail.

Figure 106A. Handhole and Transformer Housing



HANDHOLE AND TRANSFORMER HOUSING

10-4 Simulated Carrier Deck Lighting Control Wiring Diagram.

10-4.1 Figure 107A, 107B.

10-4.1.1 Notes to Designer.

1. The control wiring diagram indicated is for two carrier deck lighting systems at opposite ends of the runway. Where a single system is installed and/or a 5 step regulator is used, modify the wiring diagram as required to show the type system installed.

2. When the carrier deck system is using an optical landing system (OLS), the runway wave-off system must not be used.

3. Contact NAVAIR NAWC for Lighting Control.

Figure 107A. Simulated Carrier Deck Lighting – Control Wiring Diagram – Sheet 1

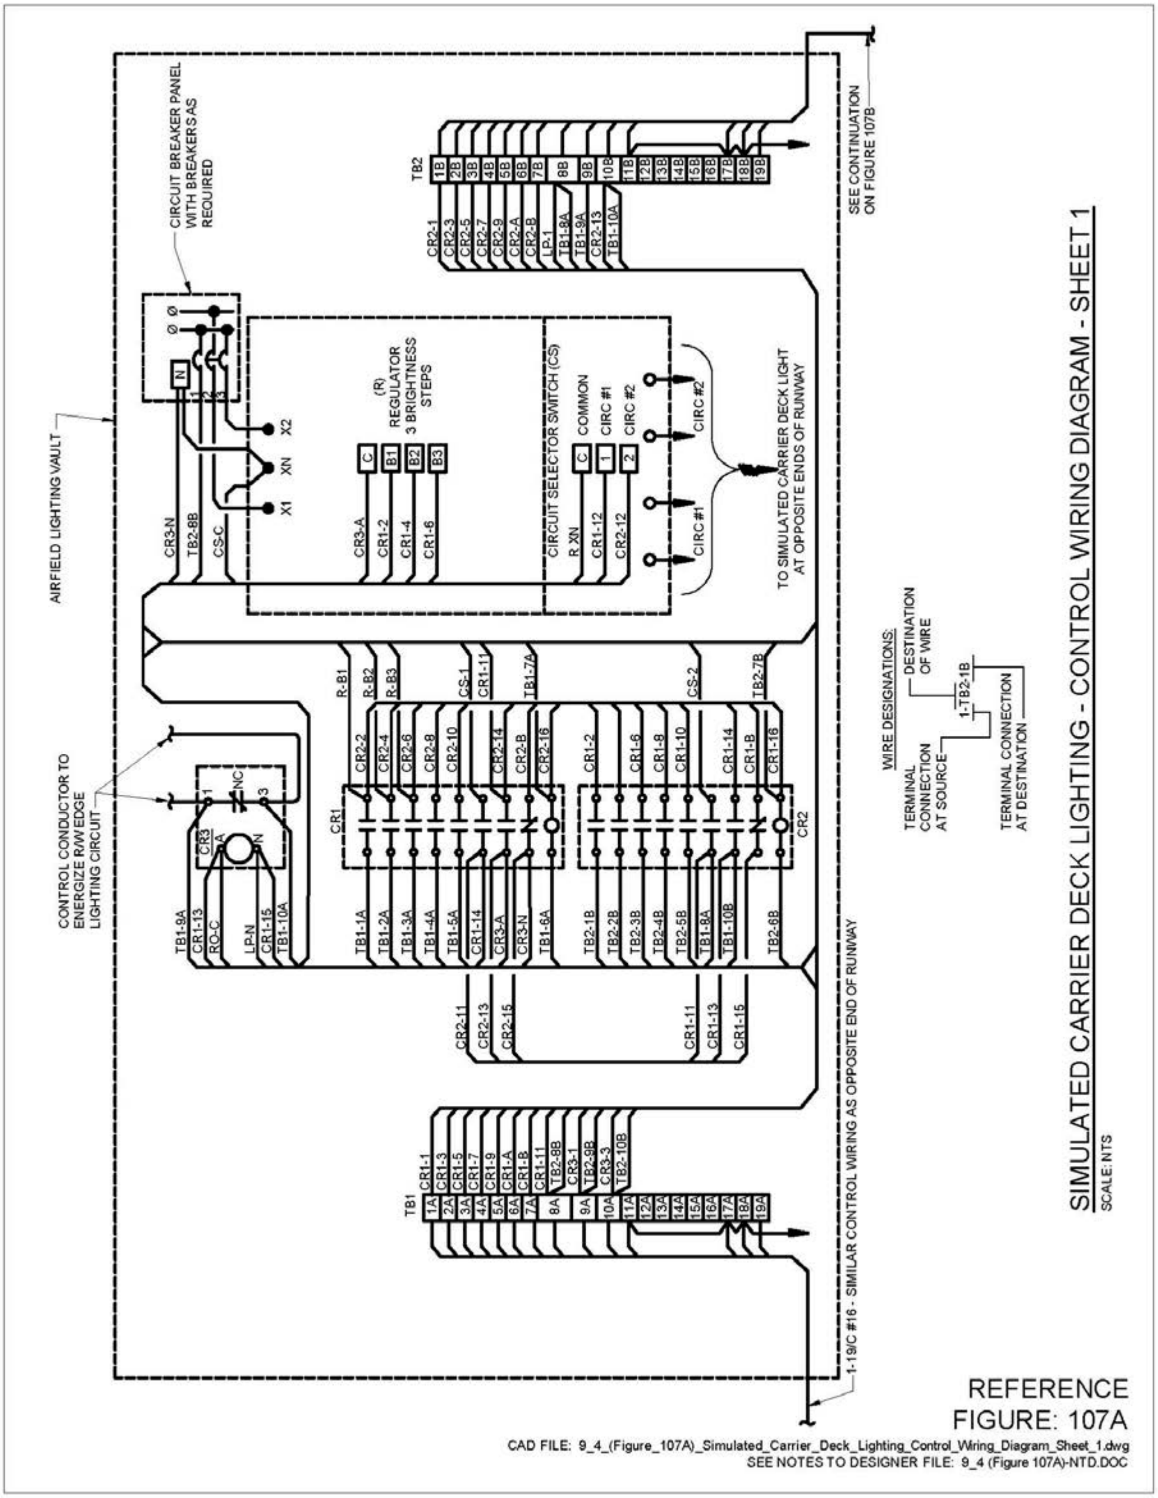

Figure 107B. Simulated Carrier Deck Lighting – Control Wiring Diagram – Sheet 2

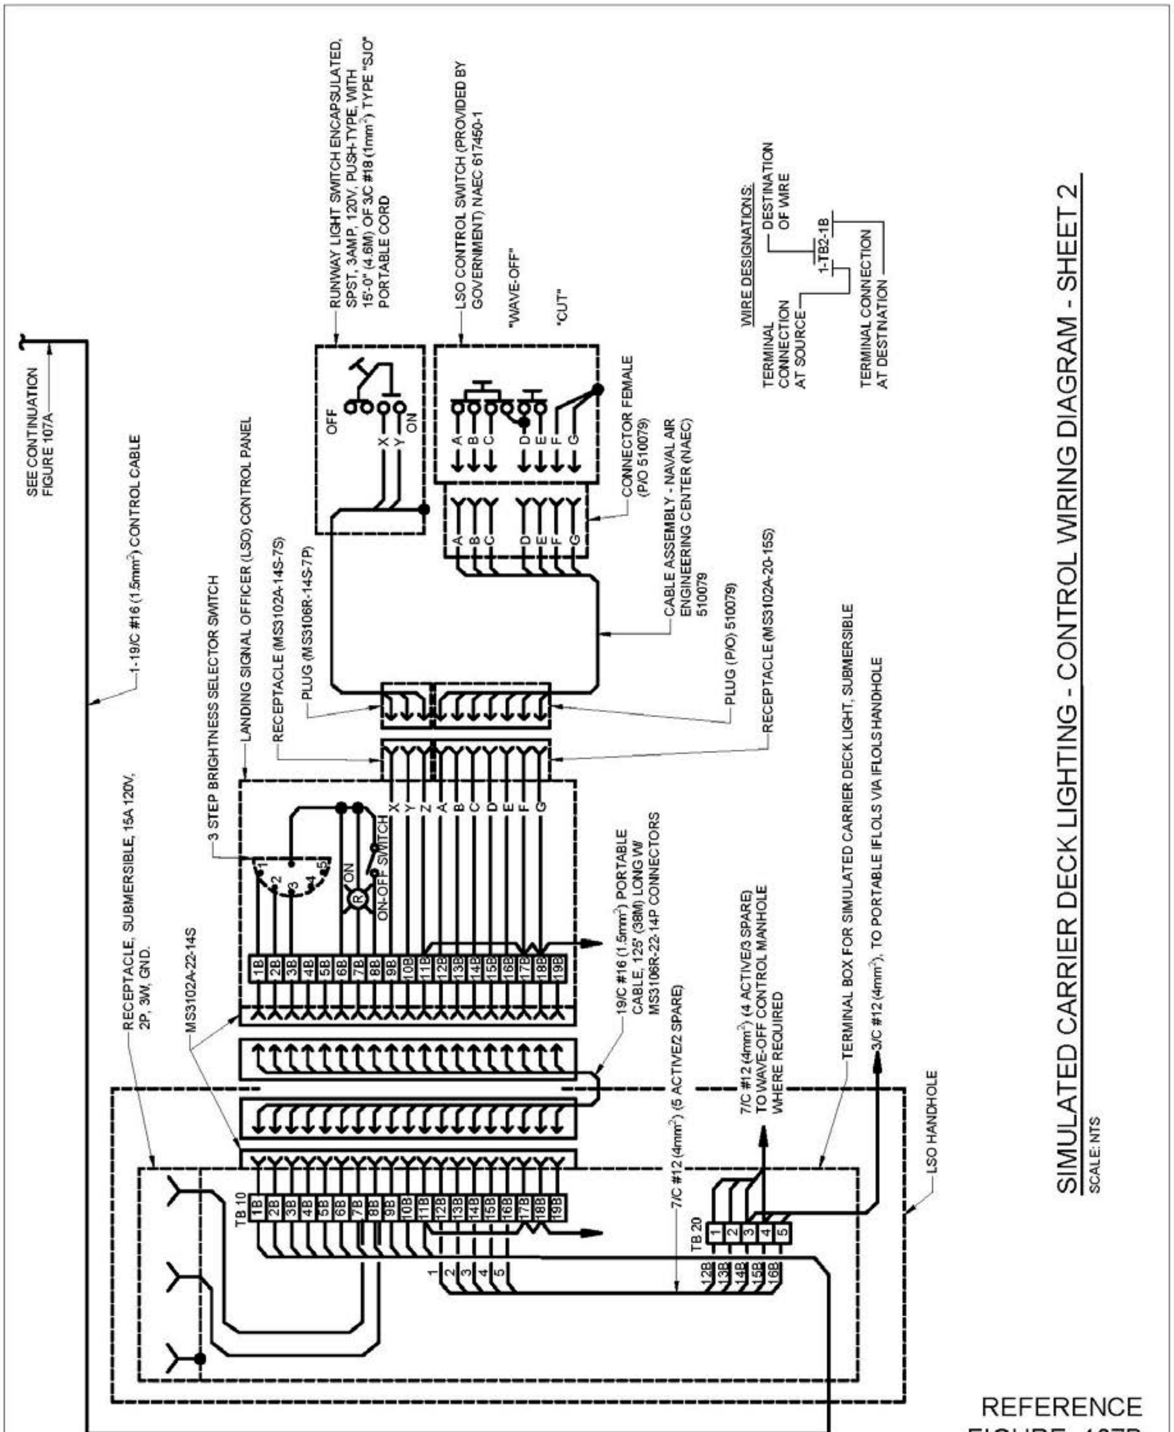

REFERENCE
FIGURE: 107B

CAD FILE: 9_4_(Figure_107B)_Simulated_Carrier_Deck_Lighting_Control_Wiring_Diagram_Sheet_2.dwg

10-5 **LSO Control Panel and Portable Control Switch.**

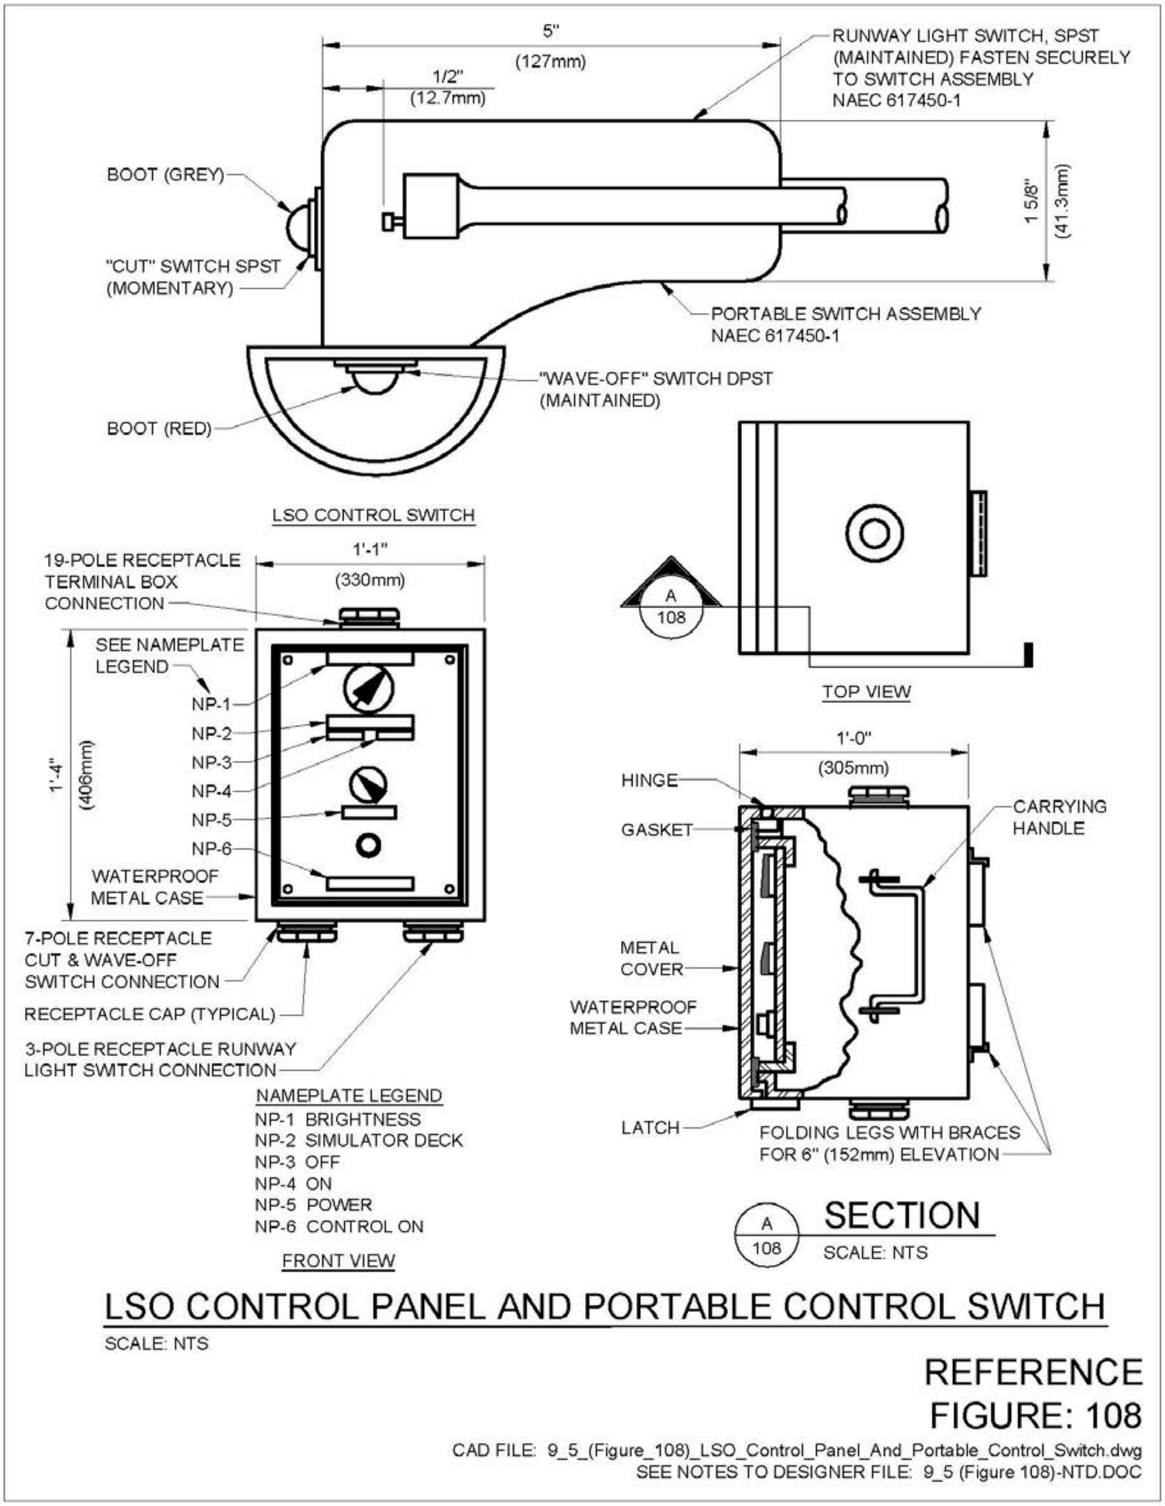
10-5.1 **Figure 108.**

10-5.1.1 **Notes to Designer.**

1. The control panel connects to the adjacent terminal box above the LSO handhole by a 19/c cable which mates with the above grade receptacle above the handhole.

2. Cabinet, cover and panel of landing signal officer control panel must be of 1/8" (3mm) aluminum alloy 5052-H32. Cover must be hinged and have two or more protective closing latches. Entire assembly must be NEMA 4, watertight and dust tight.

Figure 108. LSO Control Panel and Portable Control Switch



10-6 Simulated Carrier Deck Light Fixture – Shallow Base and Saw Kerf Installation.

10-6.1 Figure 109.

10-6.1.1 Notes to Designer.

1. The shallow base installation is used when a system is being installed on an existing runway. The #10 (6 square mm) branch circuit conductors and #6 ground are connected inside the base and run to a handhole at the edge of the pavement where the isolation transformers are housed.

2. The base has anti-rotational and anti-lift fins on the bottom. The base is held in place with rigid FAA type P-606 sealant that is installed flush with the top of the base. The sealant must be compatible with the pavement.

3. A spacer ring and flange ring with pavement ring is then installed on the base. The void between the rings and edge of pavement is then filled with a self-leveling silicone sealer which allows removal of fixture and rings. The sealer is flexible and compatible with both concrete and asphalt pavements.

4. The purpose of the spacer ring is to allow the fixture to be lowered in case of pavement slumping around the fixture. Different thickness rings are available in 1/16" (1.6mm) increments up to 2" (51mm).

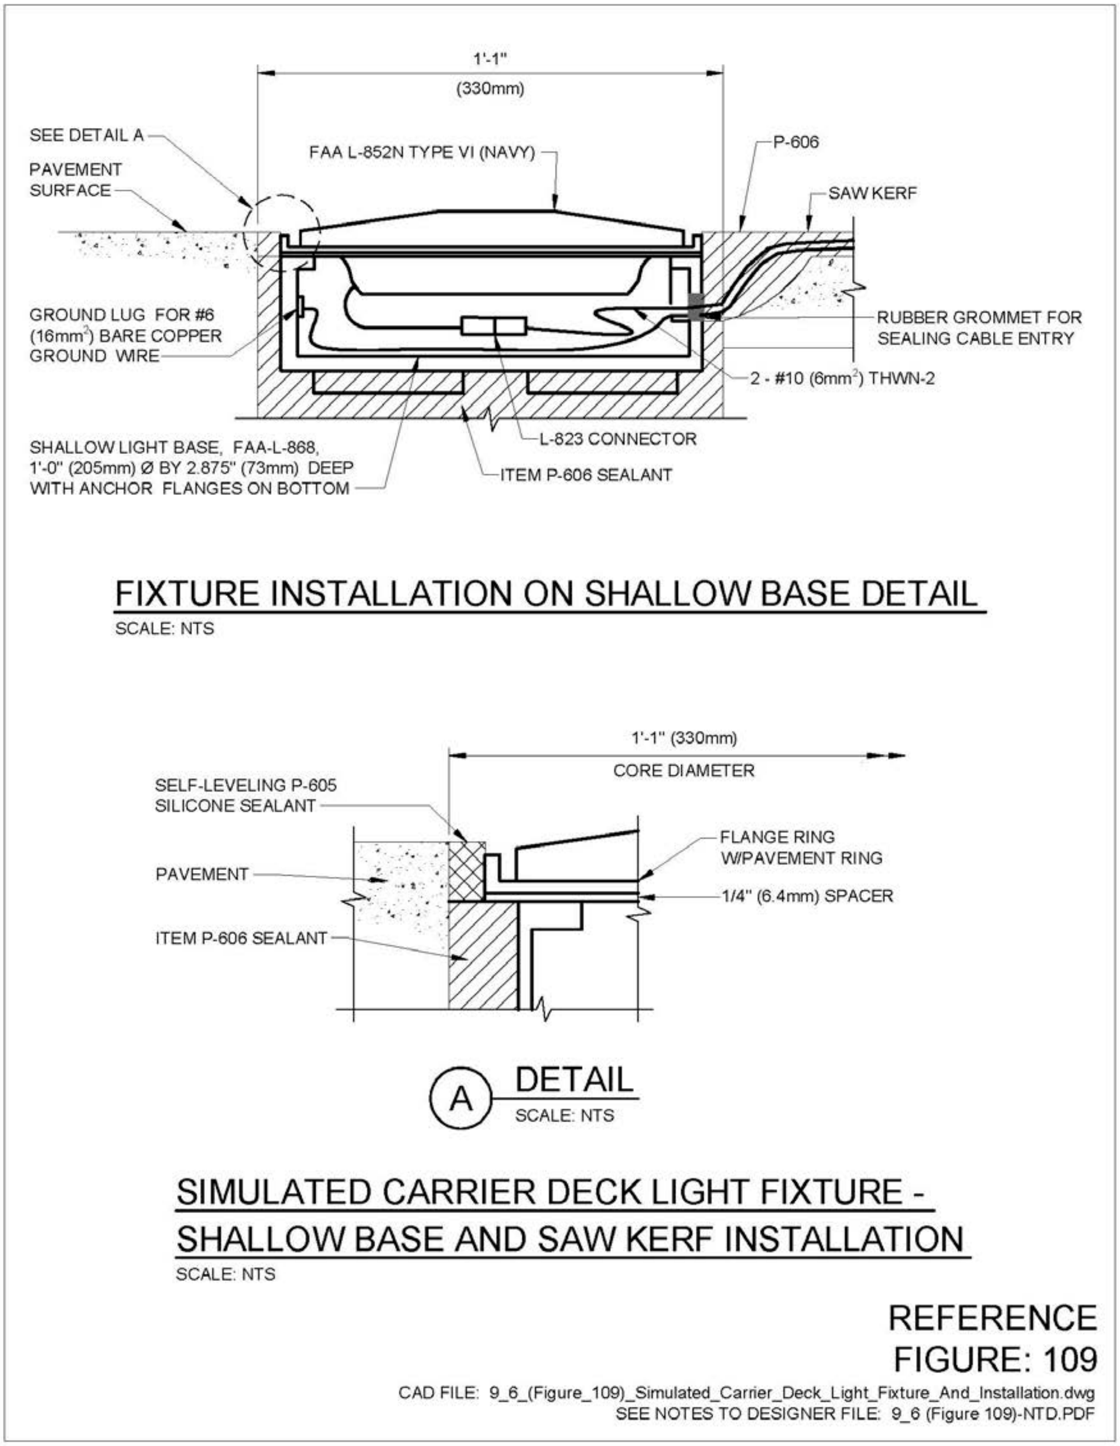
10-6.1.2 Drawing Notes for Figure 109.

1. Contractor must use a setting jig to hold the base at the proper elevation and azimuth while the P-606 is hardening.

2. Use sealants and embedding compounds that are chemically compatible with the pavement material. It is extremely important to carefully research past use history of the sealant to be specified.

3. Core dimensions must be verified with fixture manufacturer prior to core drilling.

Figure 109. Simulated Carrier Deck Light Fixture – Shallow Base and Saw Kerf Installation



10-7 Simulated Carrier Deck Light Core Details.

10-7.1 Figure 110.

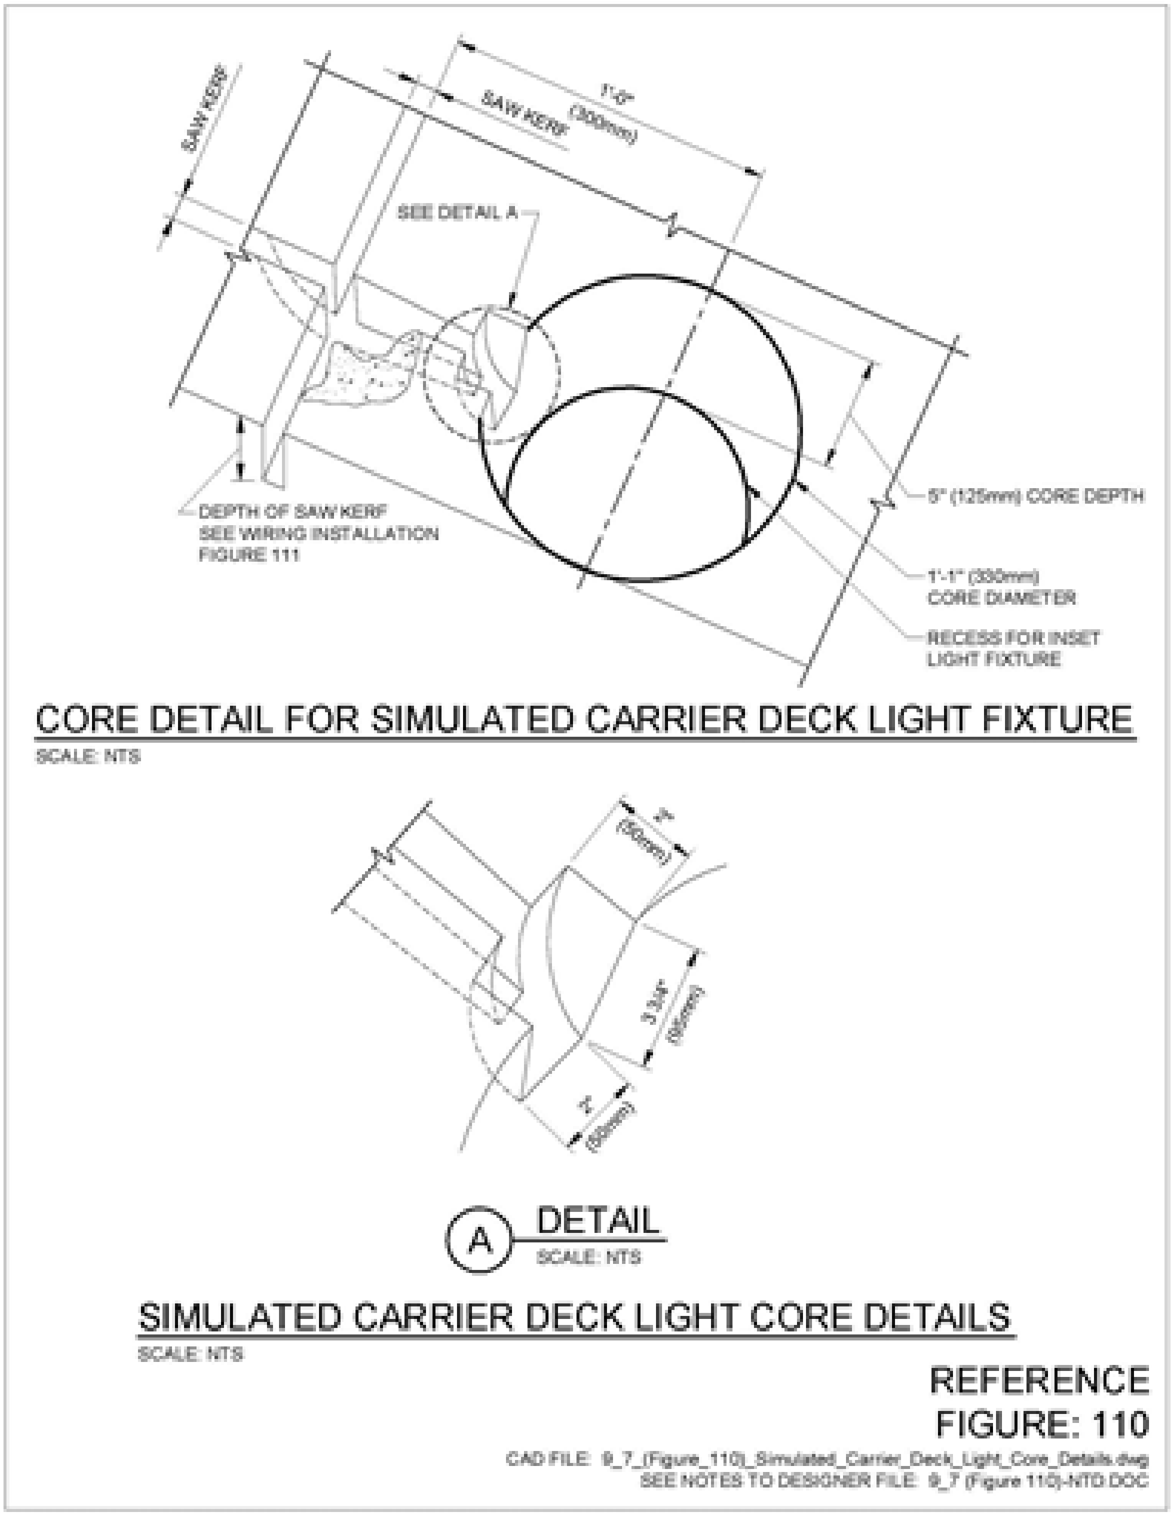
10-7.1.1 Notes to Designer.

1. Actual core depth and diameter should be verified with fixture supplier.
2. Ensure saw kerfs, walls and bottom of core are clean of any loose material or debris prior to fixture and wiring installation.
3. Detail A shows a channel for installing the wiring into the fixture.

10-7.1.2 Drawing Notes for Figure 110.

1. Edges of saw kerfs and fixture corings must be kept a minimum of 12" (300mm) from existing pavement joints. Where a conflict occurs, relocate fixtures longitudinally to avoid joints.
2. Where a new saw kerf crosses an existing saw kerf or pavement joint, new wiring must be installed as indicated in Figure 111.

Figure 110. Simulated Carrier Deck Light Core Details



10-8 Saw Kerf Wireway Details – Simulated Carrier Deck Lights.

10-8.1 Figure 111.

10-8.1.1 Notes to Designer.

1. The preferred method for installation of simulated carrier deck lights in new construction is to utilize a deep base at each light housing the individual isolation transformer. Each base is connected by a conduit system. Installation of lights in existing pavement utilizes shallow bases for the lights. The secondary wiring from the lights are run in a saw kerf to the side of the runway and into an L-867 base which houses the isolation transformer(s) for the lights.

2. More recent installations have been utilizing conduit for the secondary wiring in lieu of installing the wires directly in the saw kerf. If conduit is used, a water tight seal where the conduit enters the base must be specified.

3. The backer rod in the saw kerf serves three purposes. It acts as a shock absorber, it keeps the wiring in the saw kerf, and it acts as a sealant dam so if the wiring has to be changed they aren't encased in the sealant. The backer rod should be specified to have a diameter that is 25% maximum larger than the width of the saw kerf.

4. The sealant is a self-leveling cold applied silicone sealant that is compatible with both asphalt and concrete pavements.

10-8.1.2 Drawing Notes for Figure 111.

1. Diameter of backer rod must be 25% maximum larger than width of saw kerf.

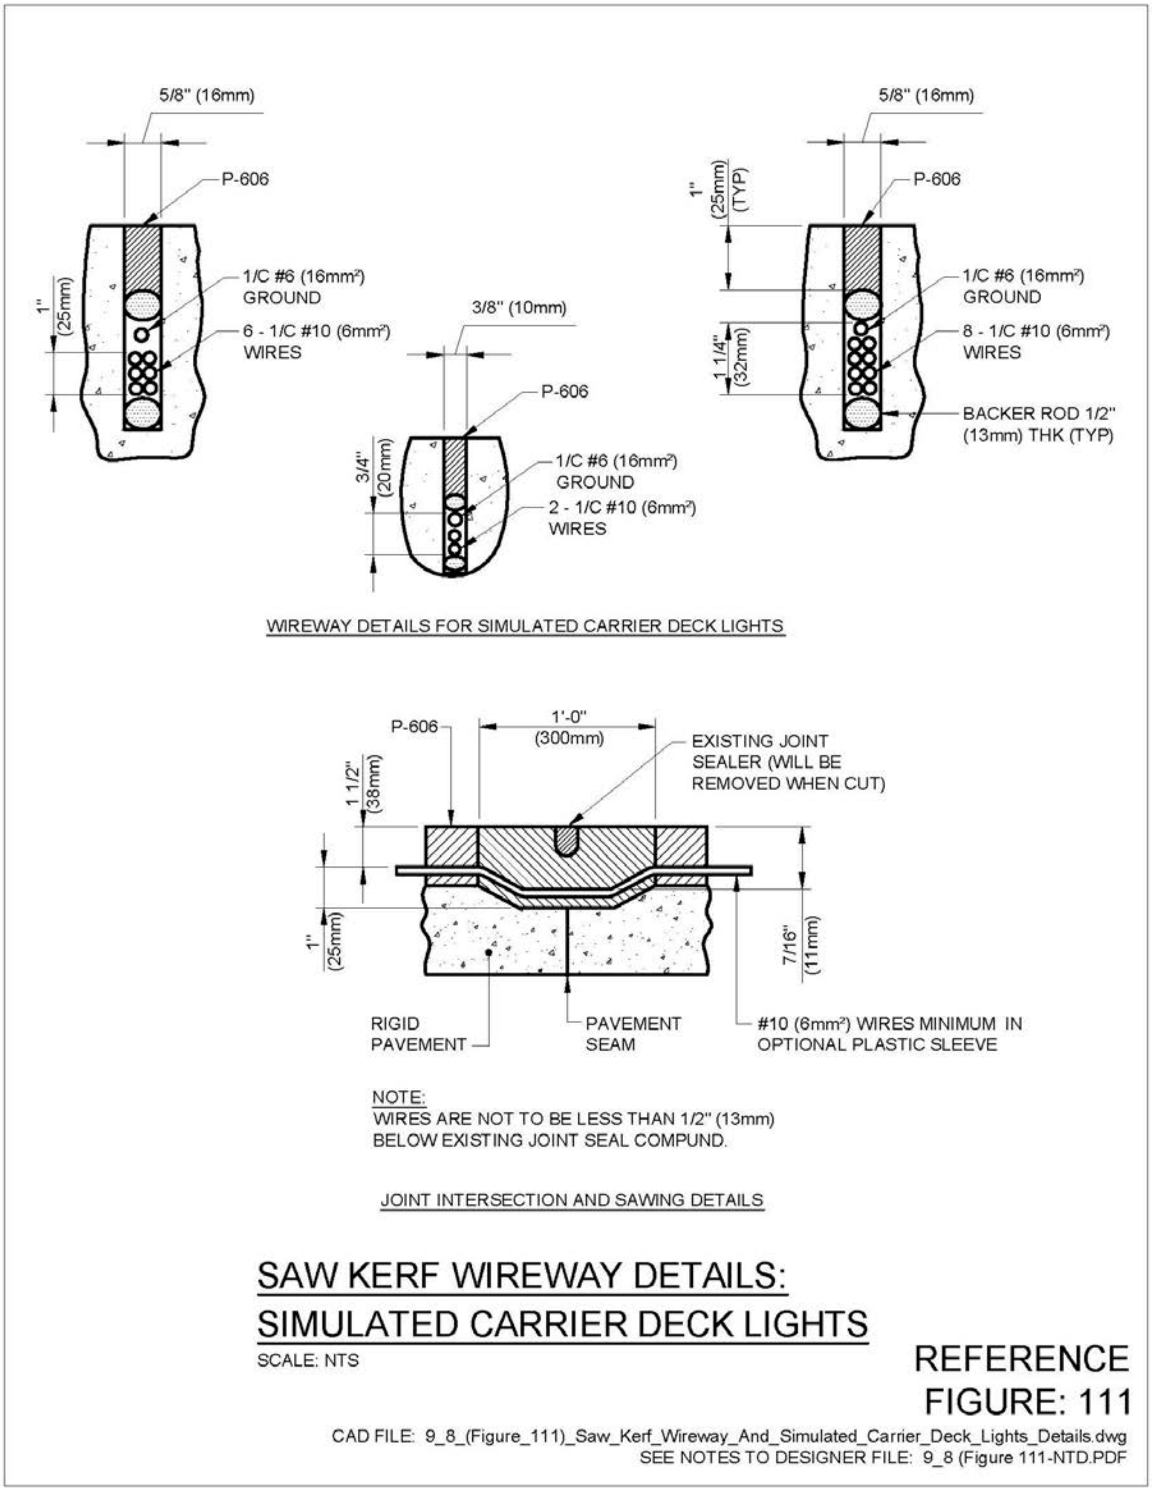
2. In existing pavement, the easiest method of installing in-pavement lighting is to core a hole for the fixture and make a saw kerf for the wireways. Primary cables and transformers in this case are located at the edge of the runway.

3. To assure a successful installation, care must be taken to see that all surfaces are sand blasted and dried before the sealer is applied.

4. Use sealants that are chemically compatible with the pavement material. It is extremely important to carefully research past use history of the sealant to be specified.

5. Bond #6 (16 square mm) ground wire from each fixture to a single #6 (16 square mm) ground wire and install with circuit conductors back to handhole.

Figure 111. Saw Kerf Wireway Details: Simulated Carrier Deck Lights



10-9 IFLOLS Pad Location.

10-9.1 Figure 112.

10-9.1.1 Notes to Designer.

1. The IFLOLS/MOVLAS (Improved Fresnel Lens Optical Landing System/Manually Operated Visual Landing Aid System) are optical landing aids which provide pilots with a visual signal to assist in intercepting and maintaining the correct approach glide slope.

2. Optical Landing Aids (OLA) is a required visual aid for landings on aircraft carriers, but on shore based airfields the OLA is primarily an aid for training or practice. The IFLOLS is a fixed signal system which automatically indicates to the pilot his position in relationship to the established glide path. Power Requirements for the IFLOLS is 10kVA, 120VAC, 60Hz three phase, 5 wire or 10kVA, 120VAC, 60Hz single phase, 5 wire. The wave-off lights in the IFLOLS are controlled by the LSO when FCLPs are being conducted. The MOVLAS is a temporary replacement system for which the LSO (Landing Signal Officer) controls the position of the source (meatball) light. Power requirements for the MOVLAS is 4.6kVA, 120V, single phase, 3 wire.

3. Both systems are mobile and normally government furnished. The equipment pad is at the simulated carrier deck centerline elevation. A permanent survey marker should be installed on the pad giving correct location and alignment of the IFLOLS centerline cells or MOLS mirror. A survey monument for the siting mirror is located 150' (45m) toward the runway threshold from the position for the face of the cells and parallel to the runway centerline. This monument or pad must have a permanent survey marker for correct location on the siting mirror and must be at the same elevation as the OLA equipment mounting pad.

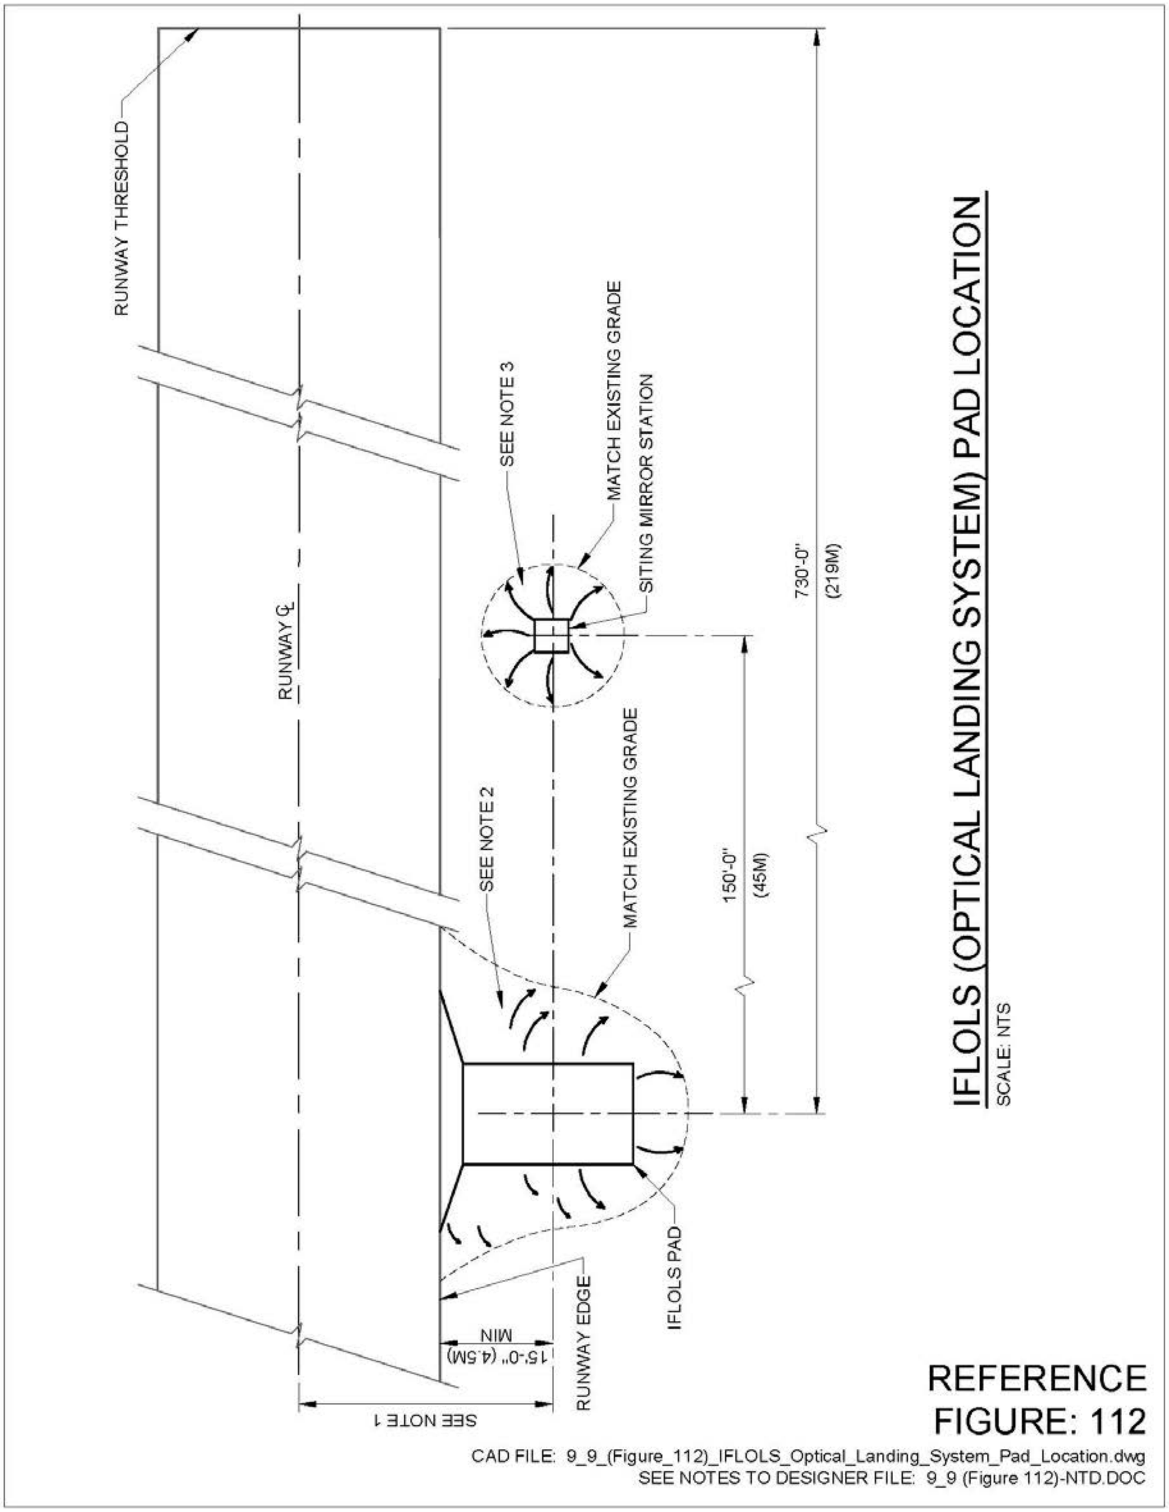
10-9.1.2 Drawing Notes for Figure 112.

1. Distance from R/W CL for runways 200' (60m) or less:
   a. 115' (34.5m) minimum
   b. 119' +1' / -0m (35.7m +0.3m / -0m) maximum
   c. For runways used by C-5A or B-747 or equivalent aircraft:
   d. 153' +1' / 0'
   e. (45.9m +0.3m / -0m)

2. Area to be filled, graded, and stabilized to allow vehicle access to pad. Maximum slope of graded fill material from top of pad elevation out to existing grade must be 2%.

3. Area to be filled, and graded from top of mirror station elevation out to existing grade with a maximum slope of 2%.

Figure 112. IFLOLS (Optical Landing System) Pad Location



10-10 **IFLOLS and Siting Mirror Pad Details.**

10-10.1 **Figure 113.**

10-10.1.1 **Notes to Designer.**

1. Top of pad elevations are required to be at the same elevation as the simulated carrier deck centerline. The requirement could put the top of the pads more than 3" (75mm) above existing grade and possible damage to aircraft could result if accidentally struck. Suggest sloping up to top of pad with graded material at a maximum slope of 2%. This would minimize damage to aircraft and allow for drainage. The material used around the IFLOLS pad should be stabilized enough to allow vehicle access while installing and removing a FLOLS or MOVLAS.

2. Each pad must have a permanent non-corrosive plaque (brass) set flush with top of pad. The plaque must be either engraved or brazed lettering identifying location alignment of the equipment. It should also state runway centerline elevation.

This UFC supersedes UFC 3-540-04N, *Design: Diesel Electric Generating Plants.*

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

(Installations and Environment)

UNIFIED FACILITIES CRITERIA (UFC)
CHANGE SUMMARY SHEET

Document: 3-540-01, *Engine-Driven Generator Systems for Prime and Standby Power Applications*

Superseding:

- UFC 3-540-04N, *Design: Diesel Electric Generating Plants*

Description: This UFC provides criteria for the design and installation of engine generator systems for use as standby and prime power systems.

Reasons for Document:

- Provide technical requirements for design.
- Consolidate design criteria currently located in multiple documents.
- Update the existing material to reflect new and revised industry standards.

Impact: There are minor cost impacts associated with this UFC. However, the following benefits should be realized:

- Standardized criteria has been prepared to assist engineers in the development of the plans, specifications, calculations, and Design / Build Request for Proposals (RFPs).
- Overlap of material with other UFCs has also been eliminated with the issue of this UFC.
- Adopting NFPA 110 as a basis for engine generator design results in additional requirements; however, these requirements are intended to improve the reliability of emergency generator installations.

Unification Issues

None.

CHAPTER 1 INTRODUCTION

1-1 REISSUES AND CANCELS.

This UFC supersedes UFC 3-540-04N, dated 16 Jan 2004.

1-2 PURPOSE AND SCOPE.

This UFC provides criteria for the design of engine-driven generator systems for standby and prime power applications. Information provided here must be used by engineers in the development of the plans, specifications, calculations, and Design/Build Request for Proposals (RFP) and serves as the minimum design requirements. Project conditions may dictate the need for a design that exceeds these minimum requirements.

1-3 APPLICABILITY.

Compliance with this UFC is mandatory for the design and installation of engine-driven (fossil fueled) generator systems for standby and prime power applications at all DoD installations. Connection of generator systems to a facility is covered by this UFC. It applies to the traditional services customary for Design-Bid-Build construction contracts and for Design-Build construction contracts. Refer to Appendix H regarding generator connection design criteria. This UFC does not apply to tactical engine generators.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and referenced government criteria. Also, review siting for possible damage from flooding, wind/wind-blown debris, and seismic events.

Modernization of existing systems for the sole purpose of meeting design criteria of this UFC is not required. Upgrades or modifications of existing facilities should consider the design criteria in this UFC, but an entire facility may not require modernization solely because of a minor modification to a part of the facility.

1-5 EMI/EMP PROTECTION SYSTEMS.

Prime power generators and switchgear that serve mission critical, mission essential and Command, Control, Communications, Computers, Intelligence, Surveillance, and Reconnaissance (C4ISR) facilities must be evaluated for protection from electromagnetic interference (EMI) and electromagnetic pulse (EMP) in accordance with TM 5-690, QSTAG 244, Edition 4, MIL-STD-461G and MIL-STD-2169. Operation and maintenance of generator facilities must not introduce unacceptable levels of degradation into EMI/EMP survivability of a system scored to the above criteria. To ensure continued EMI/EMP survivability, a Life Cycle Nuclear Survivability program must be established in accordance with AR 70-75, DoDD 5000.1, and DoDI 3150.09.

1-6 PROJECT REQUIREMENTS.

Provide analyses that document the multi-discipline requirements and impacts of the following:

- Facility features and siting for passive survivability
- System sizing and rating
- System configuration
- System operation and control
- Physical and cybersecurity
- Emissions and permitting
- Noise mitigation
- Seismic classification
- Fuel
- Utility requirements for paralleling

Appendix C provides a checklist of items to consider as part of system planning and design.

1-7 MISSION FACILITY SUPPORT REQUIREMENTS.

Generator design must be based upon the mission's requirements for transient and steady state loads, startup, and charging of uninterruptable power supply (UPS). **3**\ For the Air Force, sizing the generator for UPS load will be based on maintaining a minimum float charge rather than a deep discharge or the full capacity. **/3/**

1-8 \3\ CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy. /**3**/

1-9 GLOSSARY.

3\ Appendix I contains acronyms, abbreviations, and terms. /**3**/

1-10 \3\ REFERENCES.

Appendix A contains a list of references used in this UFC. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies. References applicable to a specific topic are also listed and described in the appropriate sections of this UFC. /**3**/

This Page Intentionally Left Blank

CHAPTER 2 STANDBY POWER GENERATORS DESIGN CRITERIA

2-1 APPLICATIONS.

Refer to Appendix F for a list of facility types and typical applications within DoD. For the Army and Navy, the major command or program element determines if a generator system for standby power is required and its classification.

2-1.1 Design Guidance.

Provide designs for non-medical backup power applications in accordance with IEEE Std 446. Refer to UFC 4-510-01 for generator system requirements associated with Medical Military Facilities.

2-1.2 NFPA 110 Compliance.

For permanently installed generator systems, comply with the NFPA 110 requirements for emergency power supply systems (EPSS) with the following clarifications.

2-1.2.1 Classification.

Designate the EPSS as Class X, where “X” is the required operating time in hours.

Designate the EPSS as Type 10 for medical systems covered by UFC 4-510-01 and Type 60 for all other applications.

2-1.2.2 Remote Manual Stop.

Provide a remote manual stop station for the EPSS in one of the following locations:

- In a separate room of the same building that houses the generator system.
- In a building separate from the building served by the generator system.
- On the outside of the building that houses the generator system.
- On the outside of an enclosure that contains the generator system.

The requirement for a remote manual stop station may be deleted, such as when it has been determined that a location that restricts access to unqualified operators is not available. The designer of record must receive documentation from the activity that the fire chief or designated equivalent concurs with this determination.

2-1.2.3 Remote Control and Alarm.

Provide a remote control and alarm panel for the EPSS in a separate room of the same building that houses the generator system or in a building separate from the one that the generator system is serving. The requirement for a remote control and alarm panel may be deleted when it has been determined that a location is not available that restricts access to unqualified operators or if not desired by the activity. The designer of record must receive documentation from the activity for this determination.

Provide a remote common audible alarm to a 24-hour staffed location when the EPSS location is not staffed 24 hours per day. The requirement for a remote common audible alarm may be deleted when it has been determined that a suitable location is not available or if not desired by the activity. The designer of record must receive documentation from the activity for this determination.

2-1.3 NFPA 70 and NFPA 110 Compliance.

Comply with NFPA 70 and NFPA 110 as follows.

- Generator systems required to comply with NFPA 70 Article 700 must also comply with NFPA 110 Level 1 criteria.
- Generator systems required to comply with NFPA 70 Article 708 must also comply with NFPA 110 Level 2 criteria.
- Systems using permanently installed generators not designated as emergency systems or critical operations power system (COPS) must comply with NFPA 70 Article 701 **3**\ **(**systems required by law) and NFPA 110 Level 2 (used when failure is less critical to human life and safety) /**3**/ criteria.
- Systems using portable generators must comply with NFPA 70 Article 702 (optional standby systems).

2-2 AUTHORIZED FUEL TYPES.

Select fuel oil (diesel or jet fuel) as the primary fuel source for applications where onsite storage is required. Natural gas may be used as the primary fuel source only for applications where onsite storage of fuel is not required.

- Diesel/natural gas dual fuel units are allowed.
- **For the Air Force:** Natural gas systems are not allowed.
- Bio-diesel and liquefied petroleum gas (LPG) fuel types are not allowed.

2-3 ONSITE FUEL STORAGE CAPACITY.

Provide a minimum of seven days of fuel storage either in a dedicated on-site main fuel tank or from a confirmed delivery source. If the fuel storage is from a confirmed delivery source, ensure the delivery source can provide reliable deliveries during long-duration power outages. Base this storage capacity on the fuel consumption required to support the mission load. When the seven-day requirement is accomplished by a delivery source, provide each generator set with a minimum local 24-hour capacity tank based on the full-load fuel consumption rate of the engine.

\3 Fuel stored on site for 24-hour or longer capacity for diesel generators/engines should not be bio-diesel because a 1-hour run time for a test never uses all the fuel in the storage tank**.** /**3**/ The above requirements may be modified when it is validated (documented in writing and dated) that mission operations require a different operational duration (longer or shorter). For Army secure critical missions, the Army will reduce the risk by being capable of providing necessary energy and water for fourteen days. See Army Directive 2020-03.

2-4 ANALYSIS REQUIREMENTS.

2-4.1 Design Analysis.

Provide a design analysis which covers the general facility design requirements in accordance with UFC 1-200-01 and its referenced documents. Document in the design analysis how compliance with NFPA 37, NFPA 70, and NFPA 110 is achieved. In addition to the UFC 3-501-01 requirements for preliminary basis of design and follow-on submittals (short circuit analysis, protective device time-current coordination study, arc flash analysis, voltage drop analysis, motor starting/flicker analysis), provide the following general system-specific analysis information.

2-4.1.1 Facility – Features and Siting.

- Facility design features for maintenance, including lay-down space for major overhauls and access for repair by replacement, without removal of major components or building system equipment/features.
- Geographic and operating environment, including coastal locations/corrosive conditions, humidity, altitude, seismic zones, and ambient temperature extremes.
- Exhaust system design, including stack height, sampling port orientation, and location.
- Vibration (transmitted to structures).
- Ventilation.

2-4.1.2 Engine Generator Sizing.

- Generator sizing calculations. The Designer of Record must use commercially available generator sizing software provided by a generator manufacturer to determine the required rating. **\3\ deleted /3/** Refer to Appendix D for additional information regarding generator sizing. Verify the commercially available sizing software addresses the generator sizing topics listed in Appendix D.
- Accommodate the effects or rating adjustments for nonlinear loads, transformer in-rush, motor starting, and UPS systems.

2-4.1.3 System Configuration.

- Classification of loads.
- Redundancy (reliability, availability, maintainability factors).
- Maintenance and testing.

2-4.1.4 System Operation and Control.

- Load shed plan.
- Communications plan.
- Electrical protection scheme.
- Modes of operation delineation and impacts analysis.
- Refueling capability to support generator operation during extended power outages at mission essential/critical facilities.

2-4.1.5 Focused Electrical System Analysis.

Perform harmonic analysis where switching power supplies contribute 25 percent or greater to the system loads, and/or electromagnetic filters are installed to mitigate the effects of high-energy EMP.

2-4.2 Environmental.

Evaluate environmental requirements (e.g., noise, air pollution, wildlife, storm water) developed during the initial project planning stages.

- Verify site is suitable for construction (e.g., are wetlands present, is the ground contaminated) without major environmental impacts.
- Field verify, through environmental and biological surveys, that impacts will be minimal and can be mitigated.
- All design and construction will provide electrical systems which must comply with Federal, state, and local environmental regulations. For overseas locations, follow the guidance specified in Host Nation-specific Final Governing Standards, or if none exist, the current DoD Overseas Environmental Baseline Guidance Document (OEBGD) and applicable Host Nation laws.
- **3**\ **For Air Force:** Consult AFI 32-7001 and AFI 32-7091 for additional guidance. /**3**/

2-4.2.1 Environmental Studies and Permitting.

Plan for a permitting process that may take years, with duration depending upon the selected system and the locality (country, State, county and municipality) that is jurisdictionally responsible. Federal, state, and local requirements will vary with the local ambient air quality, size of the project and potential emissions. All new or modified stationary power generators (both engine- and turbine-based) are required to comply with applicable Environmental Protection Agency (EPA) New Source Performance Standards (NSPS). The specific characteristics of an emissions source determine the applicability of a particular NSPS. See 40 CFR Part 60 Subpart KKKK or 40 CFR Part 60 Subpart JJJJ. Studies and permitting requirements exist at all levels (Federal, state, and local) and may include:

- 316(a) – thermal discharge
- 316(b) – cooling water intake
- air permitting
- aquatic ecology
- avian and bat studies / protection
- cultural resources
- dredge and fill
- endangered species
- encroachment
- erosion and sediment control
- floodplain management
- lake management
- land and right-of-way grants
- Native American consultation
- natural resources
- National Environmental Policy Act
  - Environmental Assessments (EAs)
  - Environmental Impact Studies (EISs)
- noise/odor
- river crossing permits
- transmission line routing
- stormwater/water quality
- wetlands permitting, mitigation and design

2-4.2.2 Noise Mitigation.

Comply with Federal, state, and local codes, and for overseas locations, Host nation laws, for maximum noise levels permitted at property line or Table 2.1, whichever is less. Use A-weighting filter criteria (dBA) as adopted by the Occupational Safety and Health Administration (OSHA) as the official regulated sound level unit.

Table 2-1 Generator Noise Level Regulation

Noise Zone	Peak Daytime dBA	Peak Nighttime dBA	Continuous Daytime dBA	Continuous Nighttime dBA
Residential	62	52	57	47
Light Industrial	67	57	62	52
Heavy Industrial	72	62	67	57
Hospital	45	40	35	30

2-4.3 Seismic Classification.

Comply with UFC 1-200-01, including all referenced criteria and standards.

2-4.4 Fuel Storage Design and Capacity.

Apply UFC 3-460-01 to petroleum fuel facilities designs.

2-4.5 Utility Requirements for Paralleling.

Where the generation equipment is connected to the utility's system bus and is required to operate in parallel with the utility's electric system, comply with specific utility provider guidelines on parallel generation connection accommodations.

3\ **For the Air Force:** Equipment Authorization Inventory Data (EAID) or Real Property Installed Equipment (RPIE) generators, or any generator owned by another agency, will not operate in parallel with any utility provider unless authorized by AFCEC/CO in accordance with AFMAN 32-1062. /**3**/

2-4.6 Power Rating Category.

Determine the required power-rating category in accordance with Electrical Generating Systems Association (EGSA) 101P for DoD facilities and International Standards Organization (ISO 8528-1) for Host Nation facilities, as appropriate.

Each manufacturer has developed its own unique rating definitions that may or may not comply with these standards.

2-4.6.1 Continuous Power.

Continuous power is the maximum power, which the generating set is capable of delivering continuously and safely, while supplying a constant electrical load when operated for an unlimited number of hours per year under the agreed operating conditions with the maintenance intervals and procedures being carried out as prescribed by the manufacturer.

Note: The continuous power category is unlikely to be required for the standby power applications associated with this UFC.

2-4.6.2 Prime Power.

Prime power is the maximum power a generating set is capable of delivering continuously while supplying a variable electrical load when operated for an unlimited number of hours per year under the agreed operating conditions and crucially with maintenance intervals being carried out as per the manufacturers guidelines. Typically an overload of 10% is allowed for 1 hour in 12. Prime power is also defined by IEEE 446 as “The source of supply of electrical energy that is normally available and used continuously day and night, usually supplied by an electric utility company, but sometimes supplied by base-loaded user-owned generators.” EGSA Standard 101P defines a prime power generator as “a utility-type power plant that will deliver continuous power under normal varying load factors.” Wind turbines or solar generation cannot, by definition, be prime power.

Note: The prime power rating category is required for generator systems designated as COPS in accordance with NFPA 70 Article 708.

2-4.6.3 Limited Time Running Power.

Limited time running power is the maximum power available, under the agreed operating conditions, for which the generating set is capable of delivering for up to 500 hours of operation per year with the maintenance intervals and procedures being carried out as prescribed by the manufacturer.

2-4.6.4 Emergency Standby Power.

Emergency standby power is the maximum power available during a variable electrical power sequence, under the stated operating conditions, which a generating set is capable of delivering in the event of a utility power outage or under test conditions for up to 200 hours of operation per year with the maintenance intervals and procedures being carried out as prescribed by the manufacturer.

2-4.7 Performance Class Transient Limits.

Determine the required electrical performance class in accordance with ISO 8528-1, **3**\ Part 1 and as described in paragraphs 2-4.7.1 through 2-4.7.4. /**3**/ Transient response limits are provided in Table 2-2 in accordance with ISO 8528-5:2013, Part 5.

2-4.7.1 Class G1.

Connected loads require only basic parameters of voltage such as general purpose lighting and other simple electrical loads.

2-4.7.2 Class G2.

In Class G2 applications, required voltage characteristics are very similar to those for the commercial public utility electrical power system with which it operates. When load changes occur, there may be temporary but acceptable deviations of voltage and frequency. Examples of this category include lighting systems, pumps, fans, and hoists.

2-4.7.3 Class G3.

In Class G3 applications, connected equipment makes severe demands on the stability and level of the frequency, voltage, and waveform characteristics of the electrical power supplied by the generating set. Examples of this category include telecommunications and thyristor-controlled loads. Note that both rectifier and thyristor-controlled loads may need special consideration with respect to their effect on generator-voltage waveform. Class G3 loads require an evaluation by the designer of record to document the system voltage and frequency limitations, including transient response.

2-4.7.4 Class G4.

In Class G4 applications, demands made on the stability and level of the frequency, voltage and waveform characteristics of the electrical power supplied by the generating set are exceptionally severe. Examples include data-processing equipment or computer systems. Class G4 loads require an evaluation by the designer of record to document the system voltage and frequency limitations, including transient response.

Table 2-2 Performance Class Transient Limits

Parameter	Performance Class			
	G1	G2	G3	*G4
Frequency Deviation (%) for 100 % Load Increase	<-15	<-10	<-7	TBD
Frequency Deviation (%) for 100 % Load Decrease	<+18	<+12	<+10	TBD
Frequency Recovery Time (sec) for 100 % Load Change	<10	<5	<3	TBD
Voltage Deviation (%) for 100 % Load Increase	<-25	<-20	<-15	TBD
Voltage Deviation (%) for 100 % Load Decrease	<+35	<+25	<+20	TBD
Voltage Recovery Time (sec) for 100 % Load Change	<10	<6	<4	TBD
Frequency Droop (%)	<-8	<-5	<-3	TBD
Steady-State Frequency Band (%)	<2.5	<1.5	<0.5	TBD
Steady-State Voltage Regulation (%)	<5	<2.5	<1	TBD

\3\ ***A site-specific analysis is required to determine voltage and frequency limits. See manufacturer's recommendations. **/3/

2-5 DESIGN CRITERIA.

Appendix B provides examples of various configurations.

2-5.1 Circuit Wiring for Legally Required and Optional Standby Systems.

For Legally Required (NFPA 70, Article 701) or Optional Standby Systems (NFPA 70, Article 702), keep the circuit wiring from the generator to the loads served entirely independent of all other wiring unless otherwise permitted in NFPA 70, Article 700.

2-5.2 Automatic Operation.

Use fixed (permanently installed) generators with automatic startup for facilities designated as emergency and COPS systems. Generators associated with facilities designated as standby systems may be either fixed or portable with automatic or manual operation. Equip generators configured for automatic operation with intelligent electronic controls to protect the generator sets and manage startup, operation, and shutdown.

2-5.3 Single Operation Generator Sets.

2-5.3.1 Configuration.

Configure single operation generator sets as separately derived systems.

Provide four-pole devices for a three-phase system to switch the supply to essential loads and to switch between multiple single operation generator sets.

2\ **For Air Force:** Submit a design approval request to AFCEC/COSM at the 65 percent design milestone. Generators must be sized to achieve greater than 50 percent rated load using only facility loads. Whole building generators are approved only when the mission-essential load is greater than 70 percent of the total facility load. /**2**/

2-5.3.2 Automatic Transfer Switches.

Use automatic transfer switches (ATS) listed in accordance with UL 1008. Provide automatic transfer switches with integral maintenance bypass isolation for systems designated as emergency, COPS, or where validated (documented in writing and dated) by the user as being required.

2-5.3.2.1 Double-Throw Safety Switches.

A design using double-throw safety switches to accomplish maintenance bypass is not allowed under any circumstances.

2\ **For Air Force:** Use of a double-throw design within line of site from the ATS to facilitate ATS replacement without mission impact is acceptable. /**2**/

2-5.3.2.2 Transition Transfer.

Provide an open transition transfer scheme unless facility operating procedures require paralleling with the utility. Closed transition transfer is rarely required for standby power applications. Closed transition will require coordination with the local utility and will require designing for the higher available short circuit current of the combined parallel power sources.

2-5.3.3 Metal Clad/Metal Enclosed Switchgear.

Provide free-standing metal clad or metal enclosed switchgear as required for generator voltage rating, load capacity, fault capacity (withstand/interrupting ratings), paralleling requirements, and operating scenarios.

CAUTION
To protect personnel, non-enclosed ATS must be contained in a dedicated isolated compartment when installed in switchgear or switchboards.

2-5.3.4 Automatic Transfer Switch Maintenance Access.

Provide switchboard or switchgear construction with draw out power or insulated case circuit breakers for the main power distribution equipment. Provide working clearance around each circuit breaker when in its withdrawn position in accordance with NFPA 70, Table 110.26 (A)(1).

2-5.3.5 Utility Service.

To allow for maintenance without incurring power outages when redundant utility services are provided, provide draw out circuit breakers to disconnect the utility service.

2-5.4 Requirements for Paralleling.

2-5.4.1 Parallel Operation with Public Utility.

Where the generation equipment is connected to the utility's system bus and is required to operate in parallel with the utility's electric system, comply with IEEE 1547 – Series, and specific utility provider guidelines on parallel generation connection agreements.

For the Air Force: EAID or RPIE generators or any generator owned by another agency will not operate in parallel with any utility provider unless authorized by AFCEC/CO in accordance with AFMAN 32-1062.

2-5.4.2 Parallel Operation with Other Distributed Energy Resources.

Where the generation equipment is connected to a local electrical distribution system bus and is required to operate in parallel with the other distributed energy generation resources (DERs) in islanded mode, comply with IEEE 1547–4.

For the Air Force: EAID or RPIE generators or any generator owned by another agency will not operate in parallel.

2-5.4.3 Main Power Distribution Equipment.

Provide switchboard or switchgear construction with draw out power or insulated case circuit breakers for the main power distribution equipment. Provide a minimum of 30 inches' working clearance around each circuit breaker when in its withdrawn position.

2-5.4.4 Control Power.

Provide redundant AC control power for systems designated as emergency, COPS, or where validated by the user as being required. Provide a redundant AC control power system that is selectable via an ATS.

Provide redundant DC control power for systems designated as emergency, COPS, or where validated by the user as being required. Provide a redundant DC control power system through a best battery selector.

2-5.4.5 Control System.

2-5.4.5.1 Provide generator and electrical system protection in accordance with IEEE Std 446 and IEEE Std 242.

2-5.4.5.2 Provide redundant IEDs to run the logic for all programmed and operator-initiated automatic system sequences. Redundant master programmable logic controllers (PLCs) must control and monitor the main breakers, the tiebreakers, the feeder breakers (if load shedding is required), and the common system auxiliaries via paralleled input/output points.

2-5.4.5.3 Provide separate, dedicated generator controllers to run the logic for operation of each generator set. Automatic startup of the generator sets must be achieved via commands from the master controllers. Design the system so that manual startup of the generator sets is achieved via operator initiated commands independent of the master controllers. Generator controllers must control and monitor the generator breakers and associated generator set auxiliaries.

2-5.4.5.4 Provide close control commands for synchronizing that are direct outputs from separate controllers for each respective utility source and generator circuit breaker.

2-5.4.5.5 Provide system operator interface via minimum 15-inch thin film transfer (TFT) color touch panels. Provide a touch panel for each generator set, plus one additional local panel and an optional remote panel. Each display controller must provide real-time graphical control and monitoring for the system and all generators.

2-5.4.5.6 Communication should be via Ethernet and support IEC 61850 communications functions and protocols for supervisory control and data acquisition (SCADA) and relay devices.

2-5.4.5.7 Provide a breaker control switch for each main breaker, tie breaker, feeder breaker (if control is required for load shedding), and generator breaker to enable automatic control when the switch is in the “normal after close” position and disable automatic control when the switch is in the “normal after trip” position.

2-5.4.6 Generator Electrical Protection.

Install current transformers (CT) on the neutral side of the generator windings. Use these CTs as an input to a generator protective relay for overcurrent protection. For medium voltage delta generators, provide zigzag grounding transformers with a grounding resistor connected to the generator bus via a circuit breaker. Provide differential protection for the zigzag transformer. Do not provide ground fault protection; the purpose of the zigzag transformer is to enable a reduced ground fault current.

Wye-wound generators require only a resistor or reactor from the wye point of the generator to ground. Install a CT in this circuit for ground fault protection.

\1\ CHAPTER 3 PRIME POWER GENERATORS /1/

\1\ 3-1 PRIME POWER GENERATORS.

3-1.1 Purpose.

This chapter defines requirements for fossil fuel (reciprocating, gas/steam turbine) generators used for prime power applications.

3-1.2 Definitions.

Prime power generators are classified by manufacturing standards and operational requirements. For manufacturing standards and equipment specifications, EGSA 101P is used by manufacturers to classify their equipment. For operational requirements, ISO 8528, NFPA 70, and NFPA 110 are used to classify generators.

3-1.2.1 EGSA Classification.

EGSA 101P classifies generators by generator set rating, application class, criteria of use, and classification of operation. Prime power is a generator set rating defined by EGSA 101P as a generator set rating to include power that the generator set will deliver when used as a utility-type power plant under normal varying load factors to run continuously with a minimum momentary overload capability of 10 percent.

3-1.2.2 ISO 8528 Classification.

ISO 8528 classifies reciprocating generators by application criteria and performance class. There are four different application criteria modes for reciprocating engine generators including continuous and prime. The ISO 8528 application criteria mode for prime power is for variable loads with unlimited running hours where a generator set is used to supply power 24 hours a day, 365 days a year where there is no supply network or electrical service available or the service is down.

3-1.2.3 NFPA Classifications.

NFPA 70 Articles 701, 702, or 708 are used to determine the application classification of the load as being legally required or emergency, optional standby, or COPS. The Air Force defines optional standby as Other Permanently Installed and also has separate classifications for POL/Fuels and Portable.

NFPA 110 classifies generators by Class, Type, and Level. The Class is the minimum time hours for which the generator is designed to operate at its rated load without being refueled. The Type is the maximum time, in seconds, permitted for the generator to start and the load to transfer. The Level establishes whether loss of human life or serious injury will result if the generator fails to perform.

3-1.3 Renewable Power.

Due to intermittent generation, solar and wind systems are not considered prime power. Geothermal and hydroelectric systems may be considered prime power, based upon their design. Similar generation and control systems exist for these systems; however, this UFC applies only to fuel-based prime power plants.

3-2 PRIME POWER GENERATOR CLASSIFICATION.

3-2.1 Rating Classification.

Determine generator rating classification as prime power per EGSA 101P for DoD facilities and ISO 8528 for host nation facilities, as appropriate. For combined heat and power plants, evaluate if generator is a continuous power classification with constant load and unlimited running hours. Unlike continuous generators that are designed for limited load fluctuations, prime generators can accommodate varying loads on an unlimited basis throughout the year. However, the average load factor cannot exceed 70 percent of the prime rating. Therefore, the primary calculations are to determine the load, the stability, and the amount of fluctuation.

3-2.2 Application Classes.

Determine generator application class per EGSA 101P for DoD facilities and ISO 8528 for host nation facilities as appropriate. ISO requirements are adopted by Europe and several other nations, and therefore are relevant only to those host nations which have adopted this standard.

3-2.3 Fuels Classification.

POL/fuels classification applies to Fuels Information Service Centers (Fuels Operation) and Type III, IV, and V hydrant fueling systems designed in accordance with Department of Defense Standard Designs AW 078-24-28 and AW 078-24-29 with a manual interlocked transfer switch. Size generators supporting hydrant fueling systems to 50 percent of pumping capacity for locations within the continental United States (CONUS) and 100 percent of pumping capacity for locations outside of the continental United States.

3-3 GENERATOR TYPE.

Generators must meet the requirements of ANSI C50.10, IEEE C50.13, and ANSI C50.14. **2**\ For CONUS locations, /**2**/ use reciprocating engine generators for prime power generators of 100 kW to 3 MW capacity and gas turbine generators for capacities of 1 to 20 MW. Use life cycle cost analysis and mission factors to decide between gas turbine and reciprocating engines in the 1 to 3 MW size. For combined heat and power plants, steam turbines may be used where there is waste heat recovery using heat recovery steam generators between 1 to 20 MW. For generators over 20 MW capacity, obtain user agency approval.

3-4 PRIME POWER GENERATOR DESIGN.

3-4.1 Reliability, Availability and Maintainability (RAM).

3-4.1.1 Goals.

RAM goals will be provided by the user and must be propagated throughout the generation system and supporting subsystems (electrical, fuel, cooling). The designer will determine the system configuration necessary to meet the RAM requirements, and accomplish the design. Support design selections with RAM analyses and calculations. IEEE 3006 series standards for reliability must be followed for Power Systems RAM analyses.

3-4.1.2 Resilience.

Depending upon mission requirements, a given level of high resilience will be required. Ensure generator sets can adapt to changing conditions and withstand, respond to, and recover from, disruptions.

The largest disruption known is cascading generator failure based upon loading too close to online generator capacity. When there are large amounts of critical loads that cannot be adapted to hierarchical elimination by frequency load shedding, spinning reserve must be employed. This will require multiple generators running at a maximum of 50% loading, so that if one generator fails, the entire load may be picked up by the other generator without shutting down the entire power source. This is different from reliability, as the focus is the capability to recover quickly from problems.

3-4.2 Capacity Factors.

Capacity considerations are found in Appendix D.

3-4.3 General Requirements.

Locate equipment for accessibility, and for ease of operation, maintenance and repair. Provide sufficient room between equipment items to facilitate ladders, working platforms, lifts and other equipment required for component removal and replacement.

3-4.4 Generator Sets.

Provide an alternator with a voltage capable of matching the distribution system on the facility. The alternator must have a base level with the prime engine.

Provide appropriate air circulation for generator set cooling.

3-4.4.1 Internal Combustion Engine.

Internal combustion reciprocating prime movers for prime power must use fuel oil (diesel, JP-5 or JP-8). Generators are revolving field, salient pole, air-cooled, open-type, and direct-connected, with amortisseur windings to dampen pulsating engine torque. The required number of poles is six or more to match low speeds typical of large fuel oil engines.

Prime mover for prime power can be diesel or spark-ignited natural gas engines. Cooling must be coolant based with an air exchanger. Engine speed should be determined by factors such as load profile, emissions limits, maintenance intervals.

3-4.4.2 Gas Turbine.

Prime mover for prime power gas turbine service must use natural gas, landfill gas, or fuel oil (diesel, JP-5 or JP-8) with alternators that are revolving field, non-salient or salient pole, self-ventilated, open drip-proof type. If outdoors, alternators must be Totally Enclosed Fan Cooled (TEFC).

3-4.4.3 Steam Turbine.

Use triple pressure, single, or multiple casing, condensing type steam turbines with a heat recovery steam generator. Design for a 30-year life cycle. Steam turbine-driven generators must be service rated for 5-20 MVA, revolving field, non-salient, two-pole, totally enclosed, air-cooled with water cooling for air coolers, direct connected, and 3,600 rpm for 60 Hz frequency (sometimes connected through a gear reducer up to 10 MVA or more). Self-ventilation is provided for generators larger than 5 MVA by some manufacturers, but this is not recommended for steam power plant service.

Steam turbine driven generators rated 5 MVA and below are revolving field, non-salient or salient pole, self-ventilated, open drip-proof type. Base the generator turbine, gear, and generator configuration on economic evaluation. Configuration analysis is typically done by the manufacturer. Steam turbines are not used for standby generation.

3-4.5 Liquid Fuel Systems.

For self-contained prime power generators, provide with under-belly tank or bulk storage fuel system. For bulk storage fuel system, provide a separate day tank for each generator. Calculate fuel storage on the mission run time, volume required for delays in delivery of replacement fuel and excessive fuel consumption. For bulk storage systems, provide fuel management, fuel maintenance and leak detection systems. Fuel system must meet the requirements of UFC 3-460-01. Provide duplex filters system to allow continuous operations during filter change out.

3-4.6 Air Intake System.

Locate air filters and silencers where readily accessible for maintenance. Silencers must be capable of reducing the noise level of the intake so the sound air pressure conforms to Table 2-1 and Occupational Safety and Health Act (OSHA) requirements. Perform analysis and document in accordance with UFC 3-450-01. The filtration system must protect the safety of life and prevent harmful foreign material, including water, from entering the system. Configure filtration system to the operational environment providing anti-icing and water separators as appropriate.

3-4.7 Lubrication System.

Provide either wet sump or dry sump lubricating systems. Provide lubrication system, filtration, and cooler per manufacturer recommendations.

3-4.8 Cooling System.

For packaged or modular (example, packaged in ISO containers or weather resistant containers) reciprocating engine prime power systems (example, packaged in ISO containers or weather resistant containers), use self-contained, liquid to air cooled heat exchanger system or air-cooled system.

For all other systems, use closed-cycle wet cooling system.

3-4.9 Exhaust/Air Emissions Control System.

Exhaust/air emissions from prime power generators must comply with federal, state, local and host nation air quality rules and regulations. Comply with approved operating permits. Adding a selective catalytic reduction (SCR) or other EPA-mandated emission control devices to a prime power generator may adversely affect its operation. Prior to adding SCR or other EPA-mandated emission control devices to a primer power generator, a thorough design review should be conducted and approved by the engine manufacturer prior to installation.

3-4.10 Starting System.

Mission requirements dictate reliability for starting systems. Select the starting system based upon mission requirements and life cycle cost analysis. Electric starters may be used for units up through 3 MW, if start times are met. Pneumatic starting may be used for units where a pneumatic system exists or the life cycle costs justify its use. For legally required or emergency stand-by generators, use electric starting systems.

3-4.11 Control System.

Provide generator and electrical system protection in accordance with IEEE Std 446 and IEEE Std 242.

3-4.11.1 Industrial Control Systems (ICS).

Provide an ICS for electrical power generation control and protection, either analog, programmable logic controllers, microprocessor, or distributed control system (DCS) as required by the sophistication required for operation of the generating units and associated systems.

3-4.11.2 SCADA.

Provide a SCADA system as required for operation of the generating units and associated subsystems and the needs for operator monitoring and control. Government will have a licensed copy of the required software and the right to operate changes in the controller's settings.

Power plant control systems are operational technology that must be standalone and meet the requirements of DoDI 8500.01 and NIST 800-82. NIST Special Publication 800-37 must be used during development of control system designs. Analog systems may be provided only as a part of an existing analog system. No new or grass root systems with analog controls are to be provided for new generators. Controls and redundancy including a supporting network must be based upon need (criticality and RAM factors). Open communication protocols (Modbus) must be deployed to allow future interface and connection to other manufacturers.

3-4.11.3 Subsystems.

Provide management control stations at strategic points in the plan for maintenance and redundant control requirements. Provide automated subsystems for the following:

- each engine-generator
- fuel system
- air pollution control equipment
- electrical substation
- emergency shutdown
- balance of plant controls

3-4.11.4 Analog.

Analog control is to be considered only when matching to an existing system.

3-4.11.5 Microprocessor-Based Control Stations.

Use programmable logic controllers (PLC) when fast response times are required, such as near real-time actions such as a safety shutdown or firing control. Provide a separate controller for safety systems. A PLC can handle only a few thousand input/output (I/O) points and is not easily scalable.

If redundancy is required, evaluate use of PLCs versus using a DCS.

3-4.11.6 Attributes.

The control system must include the following information and abilities:

- generator status information (for each generating unit)

- running/not running
- lubricating oil pressure
- engine temperature
- starting system status (battery/pneumatic receiver status)
- cooling system temperature
- starting aid status (jacket water/oil sump heater condition/temperature)
- fuel system status information
- switchgear breaker control switches available to the operator
- pressure and temperature indications of the engine and exhaust
- vibration notification
- generator loading, voltage, frequency and current
- cooling water temperature
- automatic synchronization
- startup, shutdown and emergency shutdown capability
- non-resettable run time hours
- exhaust pressure and/or temperature indicators to track/monitor operation of air emissions controls systems for environmental compliance with site permit

Note: Vibration monitoring is warranted on only limited applications and larger generator sizes.

3-4.11.7 Control Room.

The control room should be located in or close to the turbine/engine area to allow quick operational access. Provide a completely enclosed control room with sound attenuation. Mount instruments on a panel within the control room. Provide a heating/cooling system with high efficiency filtration to maintain positive pressure within the control room and to keep dust and other dirt particles from entering.

The control room must have:

- clean, dry atmosphere
- relatively constant temperature and humidity
- no vibration
- adequate light
- reliable electric power, free of surges in voltage and frequency

- air conditioning (a necessity for electronic distributive control systems and computers)
- direct visual (windows) or video surveillance of generators

3-4.12 Direct Current (DC) Power System.

Prime generator sets under 2500 kVA may not need a 125 VDC battery system, as other reliable power may be available. Those units that are stand-alone or requiring a black-start must have a 125 or 250 VDC dual power system comprised of two battery banks, one being the redundant set, two battery chargers and inverters, racks, and circuit breaker distribution for powering switchgear protection and metering. In addition, provide a dual 24 VDC power system with a UPS for generator controls, safety and emergency systems. Configure the DC power systems in crosstie configurations and provide battery disconnection means for safe battery maintenance. Stationary battery areas must comply with UFC 3-520-05.

3-4.13 Paralleling Switchgear.

Connect two or more generators and synchronize with respect to frequency, voltage, and phase angle using paralleling switchgear. This arrangement is suitable for paralleling switchgear operating at a voltage of 4.16 kV and up to approximately 10 MVA. For paralleling switchgear operating at 13.8 kV, this arrangement is the best for stations up to about 25 or 32 MVA.

For larger stations, the fault duty on the common bus reaches a level that requires more expensive feeder breakers, and the bus should be split. The bus and switchgear must be in the form of a factory fabricated metal clad switchgear. For plants with multiple generators and outgoing circuits, the bus must be split for reliability using a bus tie breaker to permit separation of approximately one-half of the generators and lines on each side of the split.

3-4.13.1 Integrated Paralleling Switchgear.

For permanent packaged or modular prime power plant configurations, pre-engineered integrated parallel switchgear may be used. Switchgear must provide automatic matching of on-line generators to loads. Provide with a dedicated controller and industrial graphical color HMI and include emergency stop buttons for each generator.

3-4.14 Distribution Switchgear.

If the plant is 20 MVA or larger, and the area covered by the distribution system requires distribution feeders in excess of two miles, it is cost advantageous to connect the generators to a higher voltage bus and feed several distribution substations from that bus with step-down substation transformers at each distribution substation. Distribution switchgear must conform to UFC 3-520-01 and UFC 3-550-01.

Select the high voltage bus configuration for reliability and economy. Alternative bus arrangements include main and transfer bus, ring bus, and breaker-and-a-half schemes. The main and transfer arrangement is the lowest cost alternative but is subject to loss of all circuits due to a bus fault. The ring bus arrangement costs only slightly more than the main and transfer bus arrangement and eliminates the possibility of losing all circuits from a bus fault, since each bus section is included in the protected area of its circuit. Normally, it will not be used with more than eight bus sections because of the possibility of simultaneous outages resulting in the bus being split into two parts. The breaker-and-a-half arrangement is the highest cost alternative and provides the highest reliability without limitation on the number of circuits.

Distribution selection is based upon criticality and reliability. Normal configuration for prime power generators is a two-bus (an A and B bus) system.

3-4.15 Split Bus.

A split bus panelboard has two separate portions of bus, one on top and the other on the bottom. The bottom bus may be sub-fed, or may be completely separate. The primary reason for this separation is to identify those items that must be fed by a generator, allowing the others to be switched off during a utility outage. This configuration is not recommended due to the possibility of someone assuming that the entire panel is off when in actuality it is not.

However, in controlled circumstances, where the labelling is done correctly, and the identification is correct, this methodology can be used to handle identification of loads requiring standby. This would occur in locations such as dining facilities (DFAC), where refrigerators and freezers require generator power, while room receptacles and auxiliary lighting do not require standby power. The preferred method is using separate panelboards for critical and non-critical loads. Refer to UFC 3-540-07 for additional guidance.

3-4.16 Black Start Generator.

For power plants with generators that cannot start without utility power, provide a self-contained engine generator that allows the power plant to recover from a total or partial shutdown and allows the individual generators to start from a completely dead or inactive state. Size the battery system to have reserve power that support a minimum of three firing attempts.

3-4.17 Communications and Alarms.

Communications systems must conform to UFC 3-580-01. Communication must allow operators to monitor generator loading and provide an alarm when the generator is near overload or in overload condition.

Alarms must encompass oil levels, fuel levels and flow, vibration, generator temperature, emissions, electrical system monitoring, relay systems and first out and subsequent trip list. Incorporate applicable NFPA 110 alarms.

3-5 ENVIRONMENTAL.

Comply with paragraph 2-4.2.

3-6 COMMISSIONING.

The purpose of commissioning is to make sure all parts of the generation system perform as designed and function properly according to the manufacturer's recommendations. Commissioning must be performed with a disruption of incoming power upstream of the incoming service. At the end of design, if a generator is de-rated for any reason, it must be documented in the O&M manuals and labelled appropriately.

Systems to be commissioned are:

- generator
- prime mover
- controls
- battery system
- switches
- fuel system
- load system transfer (ATS or switchgear)
- grounding

3-7 GENERATOR PLANT SECURITY.

Provide plants and facilities with security and protection against possible harmful events. Refer to UFC 4-010-01 for security requirements in buildings and facilities. /**1**/

APPENDIX B EXAMPLES OF SYSTEM CONFIGURATIONS

B-1 INTRODUCTION.

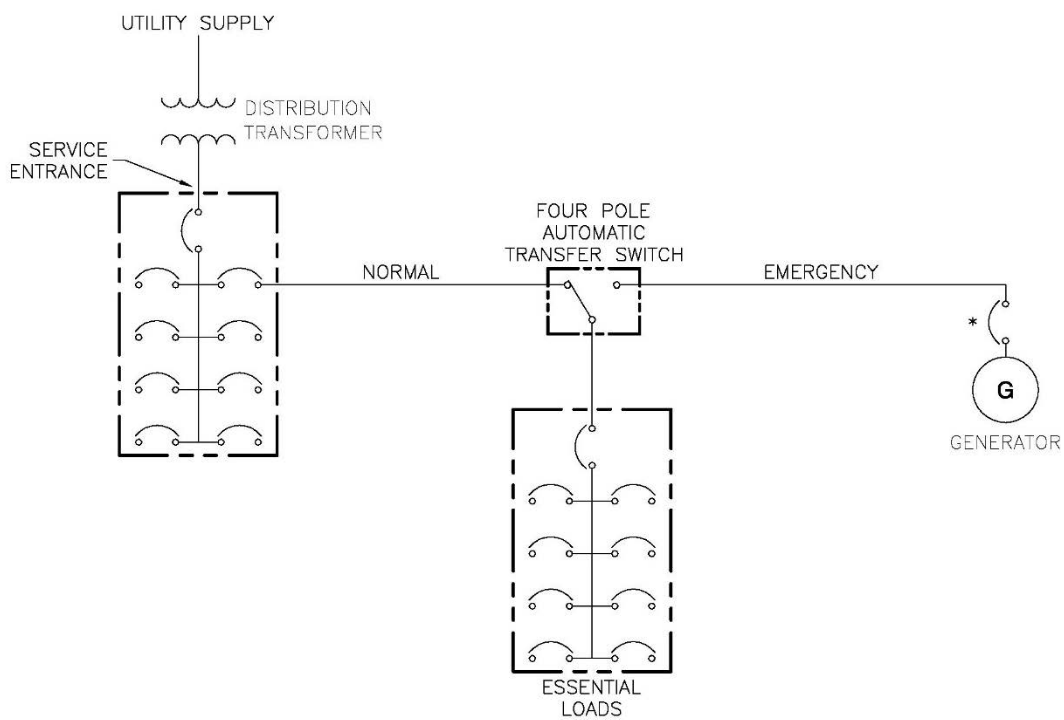
Appendix B provides examples and simple depictions of different configurations.

B-2 SINGLE GENERATOR SYSTEM CONFIGURATIONS.

B-2.1 Single Engine Generator Supply to Essential Loads.

If the facility has a permanently installed emergency power source, provide a separate panel to supply only the loads requiring emergency power. This panel will normally be supplied by the upstream main distribution panel. Figure B-1 provides an example of this configuration.

Figure B-1 Typical Single Engine Generator Configuration

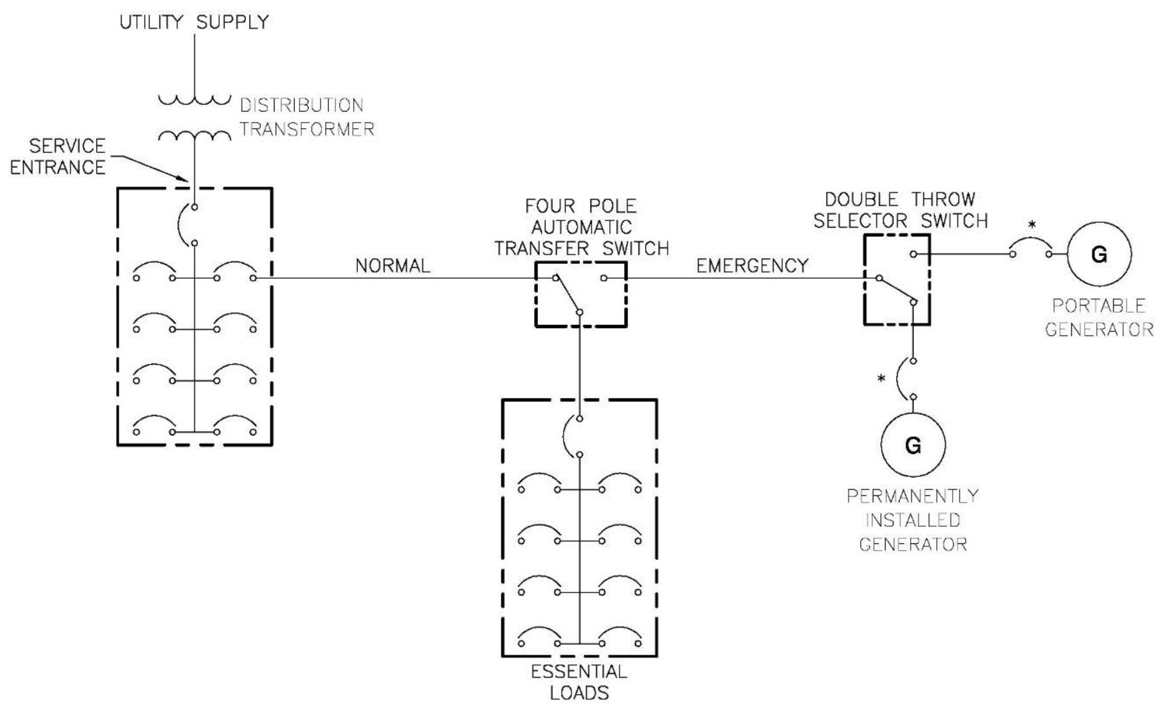


Note: The circuit breaker shown on the generator can be located on the generator skid, in a separate enclosure mounted adjacent to the ATS, or integral with the ATS.

B-2.2 Permanently Installed Engine Generator with Portable Connection.

If the facility is designed with a permanently installed generator and a connection for a portable generator, do not connect the conductors for both generators directly onto the emergency side of the associated ATS. Install a double-throw switch upstream of the ATS; connect the permanently installed generator and the portable generator connection to this double-throw switch, with the output of the switch connected to the ATS. Figure B-2 provides an example.

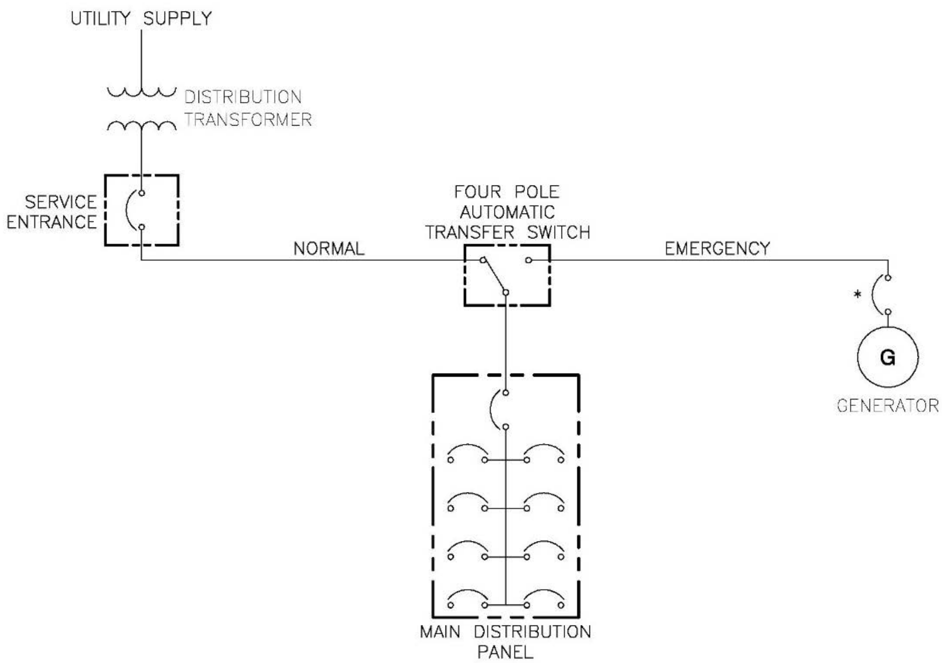
Figure B-2 Configuration for Permanently Installed and Portable Generators



B-2.3 Single Engine Generator Configuration for Whole Building Supply.

If the engine generator is designed to supply the entire facility, provide circuit breakers on each supply to the ATS as shown in Figure B-3.

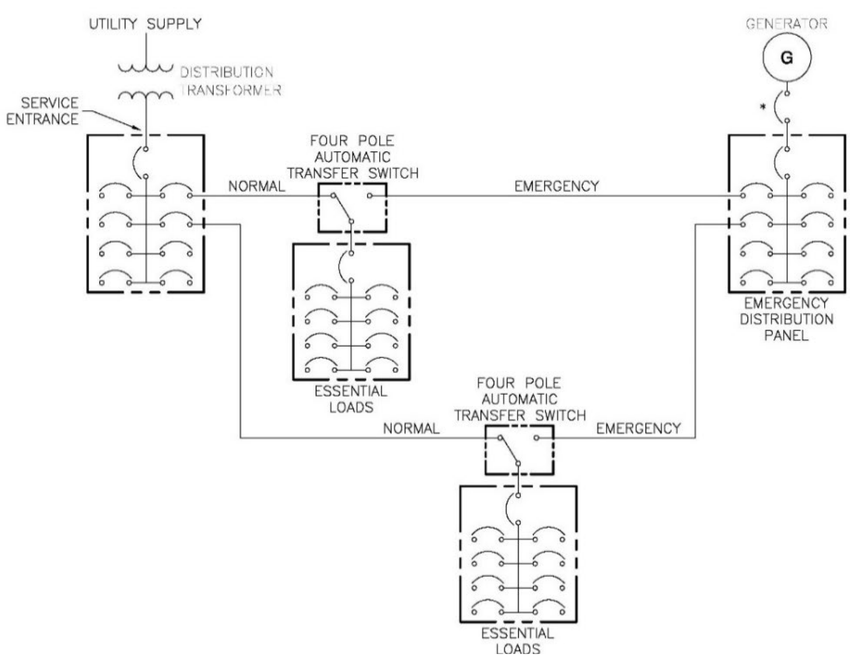
Figure B-3 Whole Building Generator Supply Configuration



B-2.4 Single Engine Generator Configuration with Multiple ATS.

If the engine generator supplies more than one ATS, install an emergency distribution panelboard or switchboard as shown in Figure B-4.

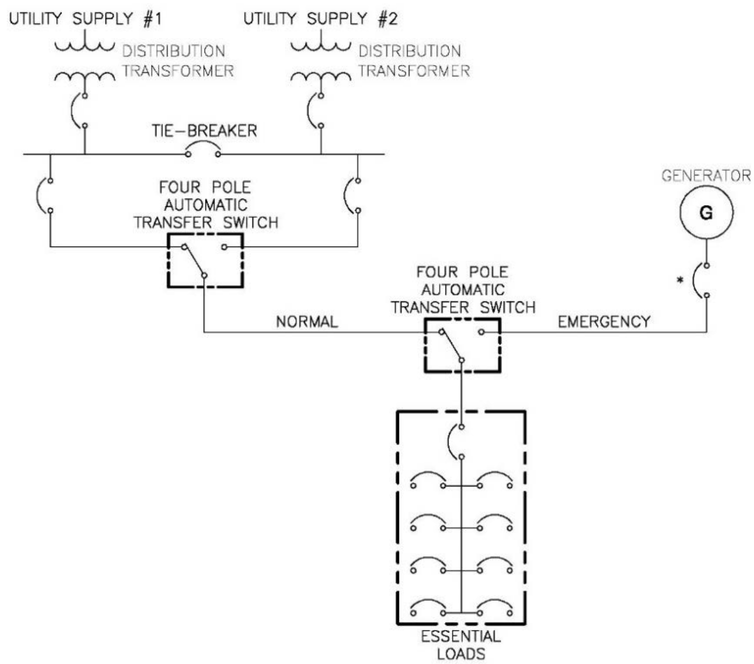
Figure B-4 Configuration to Supply Multiple ATS



B-2.5 Single Engine Generator with Redundant Utility Supply.

If redundant utility sources are available, design the system to select either normal utility source with the generator as a standby if both utility sources fail. See Figure B-5.

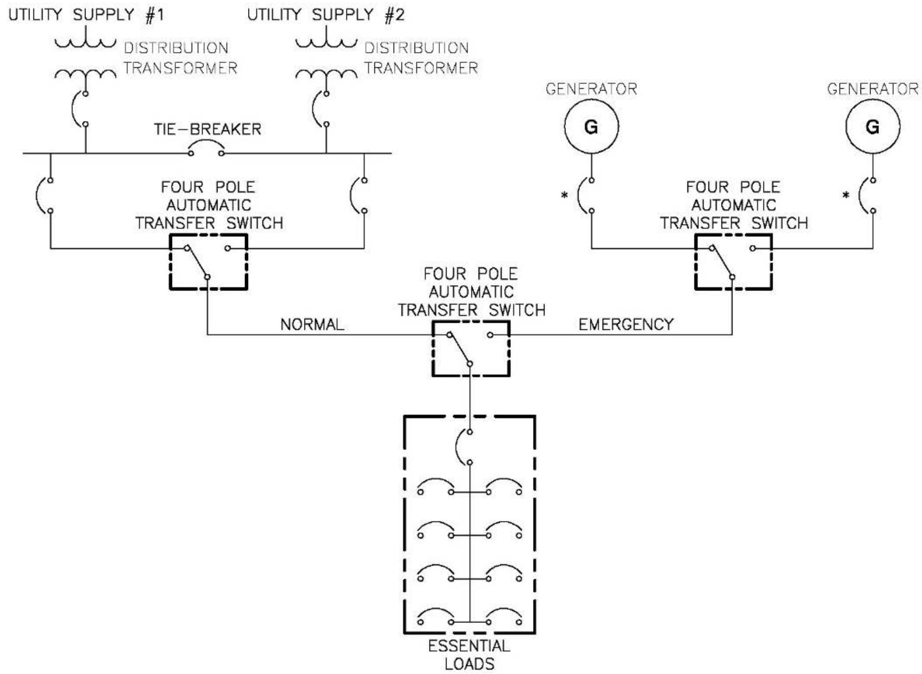
Figure B-5 Selection Between Redundant Utility Supply and Generator



B-2.6 Dual Engine Generator with Redundant Utility Supply.

If redundant utility sources are available, design the system to select either normal utility source with the generator as a standby if both utility sources fail. If dual rather than parallel generators are provided, use an ATS to select between the generator supplies. Figure B-6 provides an example.

Figure B-6 Selection Between Redundant Utility Supply and Dual Generators



B-3 PARALLEL GENERATOR SYSTEM CONFIGURATIONS.

B-3.1 Utility Supply.

Parallel generators require use of paralleling switchgear that results in a more complex operating system. Determine if a single utility supply (Figure B-7) satisfies reliability requirements. If additional system reliability is required, install an alternate commercial power supply as shown in Figure B-8. If feasible for the commercial power distribution system design, provide an alternate commercial power supply from a different source than the normal supply. Figure B-9 shows the preferred configuration if UPS systems are also supplied by alternate commercial and emergency power.

Figure B-7 Parallel Generators with Single Utility Supply

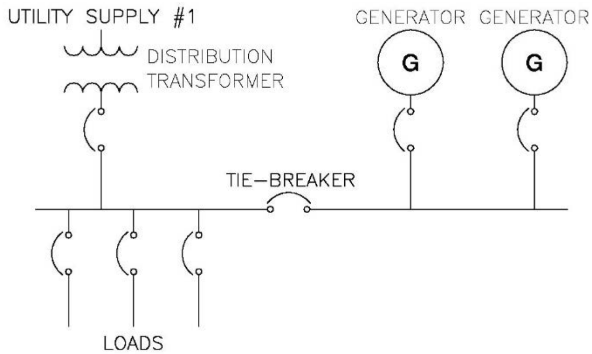


Figure B-8 Parallel Generators with Alternate Utility Supply

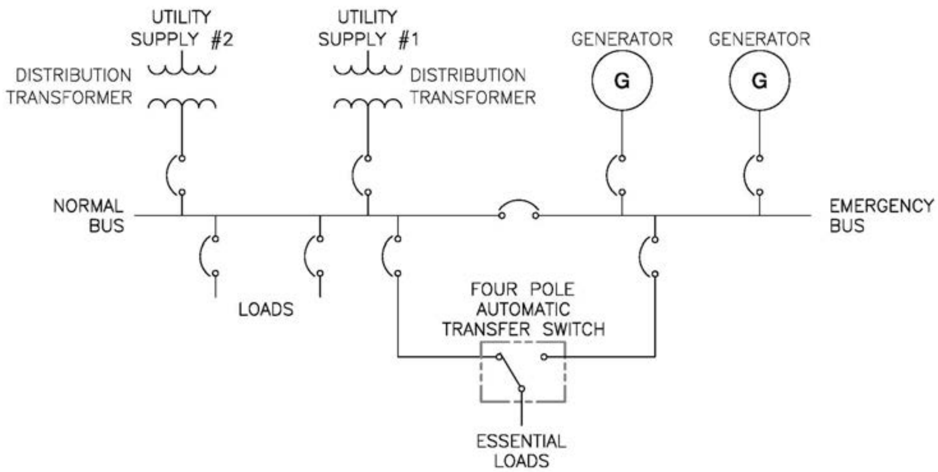

Figure B-9 Parallel Generators with Alternate Utility Supply for UPS Systems

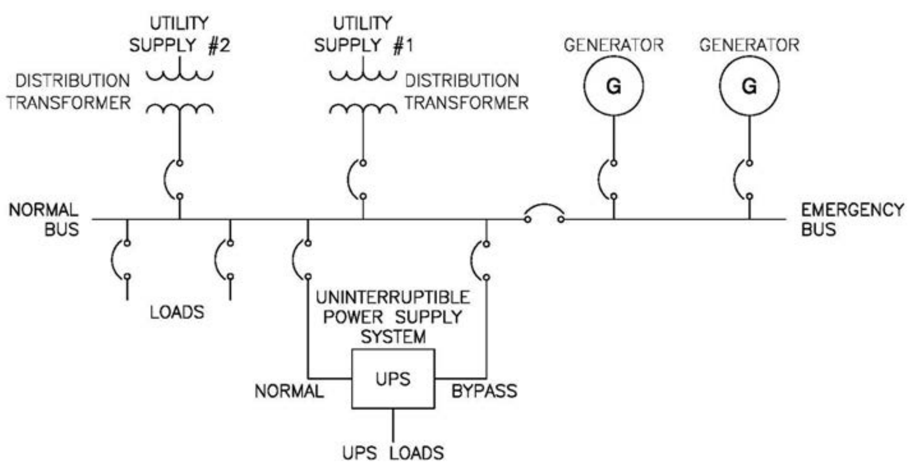
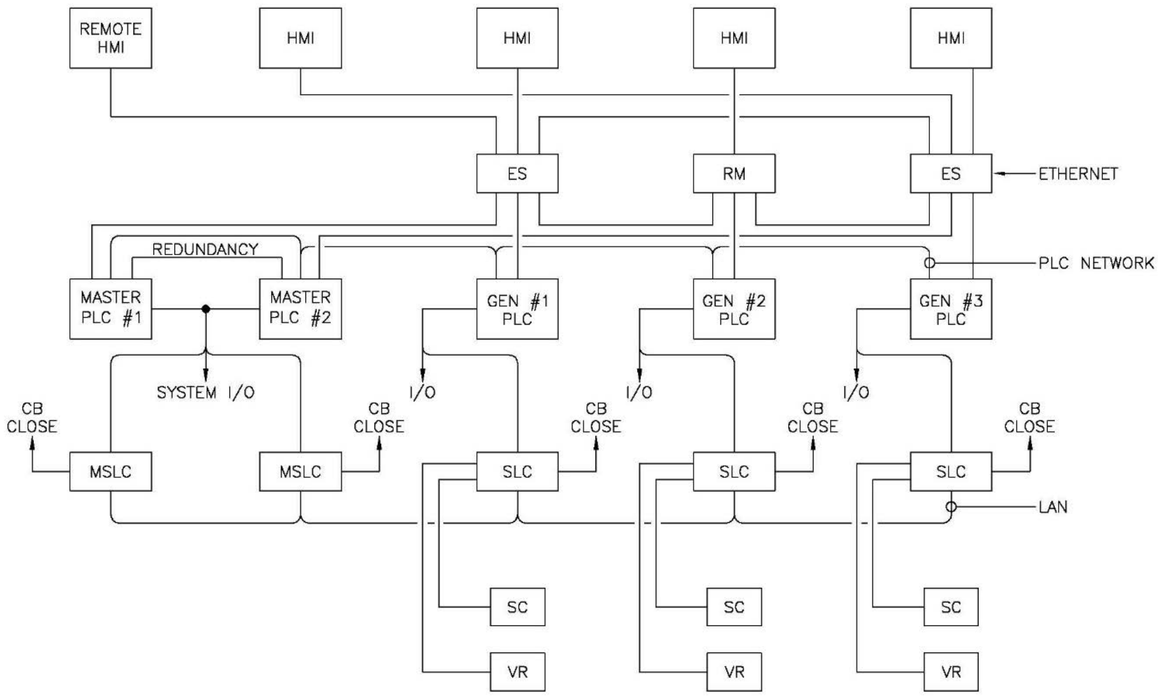


B-3.2 Parallel Generator Control Systems.

Provide a redundant system in which any control system display can operate the control system. Design redundant PLCs for system control. A properly designed system can withstand a single failure and still operate. Figure B-10 shows an example of the control system architecture.

Figure B-10 Parallel Generator Control System Architecture



B-4 AUTOMATIC TRANSFER SWITCH CONFIGURATIONS.

Figure B-11 shows a simplified configuration with a four-pole ATS. For purposes of comparison, Figure B-12 shows a simplified configuration with a three-pole ATS.

Figure B-11 Figure

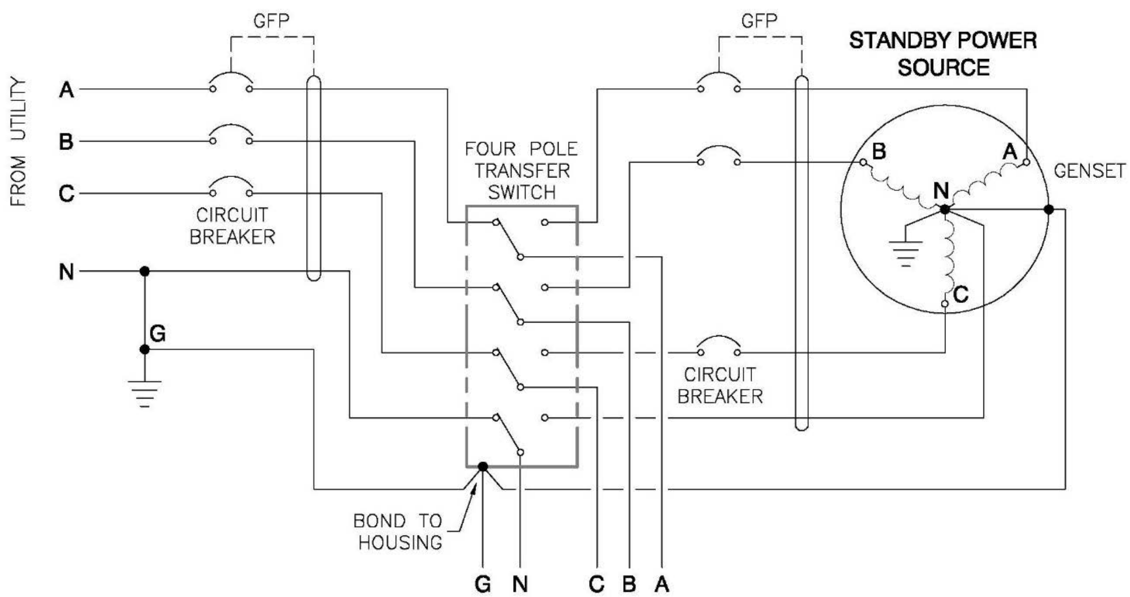


Figure B-12 Typical Three-Pole ATS Arrangement

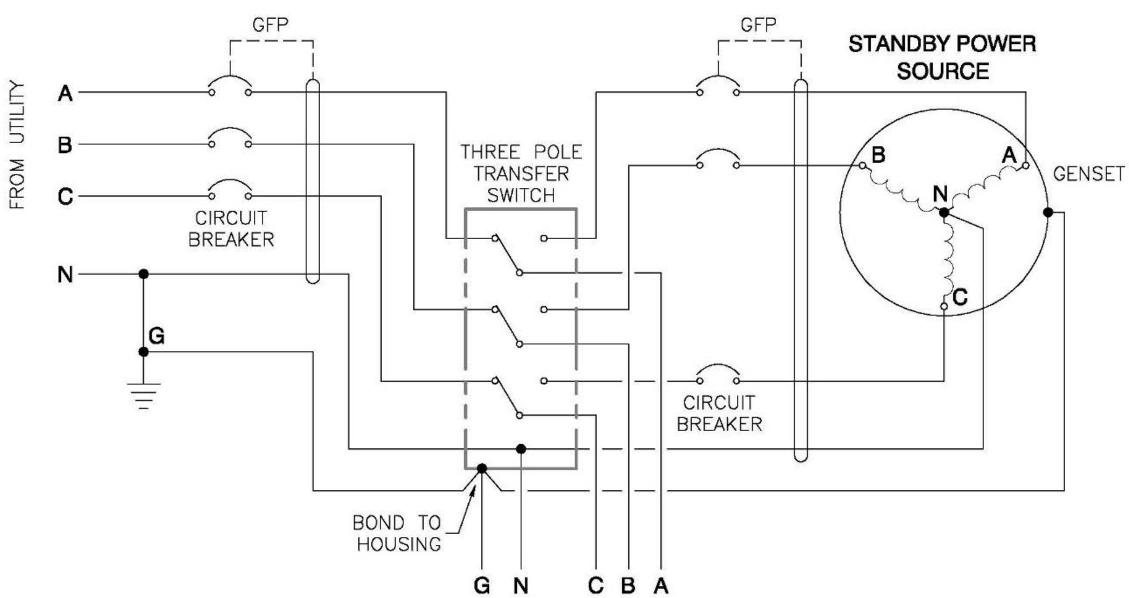

APPENDIX C DESIGN CHECKLIST

C-1 INTRODUCTION.

This Appendix provides a design checklist of items to consider or address as part of the system design.

C-2 GENERAL.

A. <u>Physical Space Requirements</u>

Engine-generator dimensions
Operation and maintenance space
Cooling system space
Fuel system space
Ventilation (cooling air intake and exhaust)
Electrical panels, transfer switches, control panel spaces
Exhaust system space and silencer location
Starting system (electrical / air start)
Draw-out equipment requirements

B. <u>Power Rating</u> – Continuous, prime, limited time running power, or emergency standby power.

C. <u>Maximum time to start and be ready to assume load</u>

(Emergency application consequences)

D. <u>Emissions</u>

1. Exhaust gas composition and particulate limits

Noise limits
Thermal emissions (air/water)
Fuel system constraints

E. <u>Generator Paralleling</u>

1. Define sources.

Define configuration. Provide single-line diagram with the 35% design submittal.

C-3 ELECTRICAL.

A. <u>Generator Sizing</u>

1. Electrical load (kVA) – facility loads plus loads for fans, fuel pumps, lighting, battery charging

Motor starting kVA
Nonlinear loads and effect on generator rating

Power factor
Engine-generator application – single set / parallel
Frequency bandwidth (steady state)
Frequency regulation maximum – no load to full load
Voltage regulation – no load to full load
Voltage bandwidth – steady state
Frequency – 50/60 Hz
Voltage – output volts
Phases – 3 phase, wye / delta, single phase
Max step load increase – kVA
Transient recovery time – seconds (voltage and frequency)
Maximum voltage deviation (transient)
Maximum frequency deviation – Hz
Convenience duplex receptacles in generator room (for tools, testing, house-keeping)

B. Generator Protection

1. Subtransient reactance – percent (minimum)
Switchgear/breaker size, location, characteristics, enclosure
Parallel generators – current transformers installed on neutral side of generator windings

C. Automatic Transfer Switch

1. Sizing, controls, transfer options
Coordination of ground fault protection (four-pole/three pole)
In-phase protection for large motors downstream of transfer switch
Define sequence of operation "Upon loss of normal power" Define load shedding, motor starting sequence, if required, multiple generator operation, method of return to normal power (time delays).

D. Starting System (Electric-Start)

1. Battery location – on skid
Battery charger location
Circuit size and routing
Ventilation for battery charging
Battery temperature limitations

E. Starting System Controls

F. Generator Controls

G. Additional Circuits – coolant pumps, fuel transfer pumps, engine heaters, fuel heaters, piping heat-trace, cathodic protection

H. Grounding

1. Generator grounding - ungrounded, solidly-grounded, impedance-grounded

Equipment grounding
Building grounding and connections
Surge arrester grounding

I. Lighting

1. Equipment room normal lighting

Equipment room alternate-source lighting
Equipment room emergency lighting
Outdoor enclosure lighting (access for controls)

J. Electrical Connections

1. Connections with strain relief on power and communication connections to generator circuit breakers

K. Load Bank Requirements for Future Testing

L. Safety

1. Arc flash analysis and warning labels

Posting of applicable safety signage based on expected hazards (e.g., Personal Protective Equipment signage, high voltage)
Automatic External Defibrillators (AEDs) may be warranted if medical assistance is unable to respond within 4 minutes
Enclosure of electrical hazards
Posting of applicable safety signage based on expected hazards (e.g., Noise Hazard)

C-4 MECHANICAL.

Evaluate system for compliance with NFPA 30, 37, and 110.

A. Engine

1. Installation elevation above sea level (derating)

Maximum speed (900/1200/1800 rpm)
Fuel consumption
Starting system (air-start)
Ambient temperature extremes (HVAC, and/or derating)
Vibration limitations
Ancillary equipment

B. Fuel System

1. Main fuel tank (location, fill point, environmental requirements, cathodic protection) – UFC 3-460-01

Day tank (space, location, shape, venting, NFPA 30 – capacity constraints, elevation relative to fuel injectors)
Fuel level controls
Fuel transfer pump
Supply line/return line routing
Fuel coolers
Fuel heaters

C. Lube-Oil System

1. Integral to engine

External to engine
Space and provision for changing the oil

D. Governor

1. Type: droop or isochronous.

Frequency bandwidth (steady state).
Frequency regulation maximum – no load to full load.

E. Engine Cooling

1. Heat exchanger location (local / remote)

Cooling system design:

a. Local – Usually unit mounted radiator ducted through wall
b. Remote heat exchanger – Usually requires expansion tank, pumps, piping, local heat exchanger, remote heat exchanger (radiator, cooling tower)

Maximum summer outdoor temperature (ambient)
Minimum winter outdoor temperature (ambient)
Cooling medium (glycol/water, raw water)

F. Engine Room Ventilation

1. Cooling - Maximum allowable heat transferred to engine generator space at rated output capacity

Maximum summer indoor temperature (prior to generator operation)
Minimum winter indoor temperature (prior to generator operation)
Combustion air source (separate from cooling system)

G. Engine Controls (NFPA 37)

H. Exhaust System

1. Insulated/non-insulated)
Silencer (muffler location – inside/outside)
Penetration (roof/wall, location, thimble detail)
Multiple generating units - common exhaust considerations
Exhaust considerations: flappers, gooseneck, bird-screen, rain shields

I. Sound Limitations (OSHA, State, City Ordinances, Post Base Regulations)

1. Mechanical noise mitigation (interior/exterior)
Combustion-air intake noise mitigation (interior/exterior)
Exhaust noise mitigation (exterior)
Posting of signage - Hearing Protection Required

J. Safety

1. Guarding of mechanical hazards
Insulation of hot equipment
Enclosure of electrical hazards
Posting of signage for equipment which may auto-start
Posting of applicable safety signage based on expected hazards (e.g., Noise Hazard)

C-5 CIVIL/STRUCTURAL.

A. Seismic zone design

B. Vibration isolation

C. Foundation, house-keeping pads

D. Grading, fuel tank installation

C-6 ARCHITECTURAL.

A. Building design, louvers, doors

B. Bird screens for penetrations

C. Enclosure type – corrosion and high humidity location, desert environment

This Page Intentionally Left Blank.

APPENDIX D GENERATOR SIZING

D-1 INTRODUCTION.

Appendix D discusses the input data required as part of a generator sizing calculation.

D-2 LOAD EVALUATION.

When specifying engine-generator sets, the designer will analyze the load characteristics and profiles of the load to be served to determine the peak demand, maximum step load increase and decrease, motor starting requirements (represented as starting kVA), continuous and non-continuous loads (cyclical/periodic), and the non-linear loads to be placed on the engine generator set. This information represents the essential elements that determine generator capacity and controls requirements. Engine generator set configuration is determined to some degree by characterization of the loads to be served and the interaction of that load with the engine generator set. Size, speed, allowable alternator temperature rise, and generator controls are all greatly affected by the character of the load to be served, and any of the above factors may determine generator sizing.

D-2.1 Uninterruptible, Essential, and Nonessential Loads.

As part of the standby power load analysis, classify each load as to the type of power that it should have. Determine which loads within the facility need to continue to function following a loss of normal power. Evaluate which loads must be uninterruptible, those to which power must be restored to perform an essential function (essential), or are not required for the facility/mission to function if the normal power source is interrupted (non-essential).

- Uninterruptible – Loads in this category require continuous power and cannot experience even momentary power disruptions. Loads in this category usually involve life safety or include hazardous or industrial process equipment, or command, control, computer, data center, and communications systems. These loads will usually require use of battery standby or an uninterruptible power system (UPS) to power them until supplied with power from an engine generator system.
- Essential –Loads in this category require standby power, but can be de-energized until they can be supplied from an engine generator system. Loads in this category usually include HVAC loads to vital facilities or other load types that can be de-energized for short periods without severe consequence.
- Nonessential – Loads in this category can be de-energized for extended periods without severe consequence. Although these loads might be classified as nonessential, they might still be capable of being energized from engine generators, depending on the facility design. For most systems, nonessential loads do not require generator standby.

D-2.2 Conditions of Loading.

Peak demand calculation provides one factor that determines the alternator size. Peak demand is the sum of continuous loads and non-continuous loads that are likely to be coincident.

- Continuous loads are energized for periods greater than 3 hours, such as lighting, UPS systems, and some HVAC equipment.
- Non-continuous loads do not meet the definition of continuous and the proportion of on-to-off time varies with each load.
- Coincident loads are those that are not prevented by character or controls from being energized at the same time.
- Non-coincident loads are dissimilar loads, fed from a common source that are prevented by character or controls from being energized at the same time. An example of a non-coincident load might be all compressors on an air conditioning chiller that are sequenced by a control system such that they do not operate simultaneously.

D-2.3 Nonlinear Loads.

Identify loads that are nonlinear. Non-linear loads are loads that draw a non-sinusoidal current waveform when supplied by a sinusoidal voltage source. Typical non-linear loads include solid state switching power supplies, computer power supplies (including those found in desktop PCs, UPSs, variable frequency drives, radar power supplies, and solid state ballasts in fluorescent light fixtures. These loads cause distortion of the source voltage and current waveforms that can have harmful effects on many types of electrical equipment and electronics, including generators. A low generator sub-transient reactance minimizes the voltage waveform distortion in the presence of such loads. For this reason, when the non-linear loads comprise 25 percent or more of the loads served, the generator sub-transient reactance should be limited to no more than 0.12.

Provide the assessment of the proportion of linear versus nonlinear loads to the generator supplier. Depending on the proportion of nonlinear loads, the generator supplier might recommend oversizing the generator, might modify the generator control system, or provide a generator with a lower sub-transient reactance.

D-2.4 Step Loading.

Step load increase/decrease is used to account for the addition or loss of significant blocks of load. The significance of this is that the generator must be sized and controlled to maintain voltage and frequency within specific limits after sudden acquisition/loss of load (described as transient response). Establish the step loads that will be applied to or removed from the generator after startup. Some systems might apply all loads in a single step and other systems might establish multiple steps to limit the voltage and frequency transient during generator loading/unloading.

If the calculated generator size is based on transient response capability (control of voltage or frequency excursion from rated value) rather than peak load, consider load steps to reduce the amount of loads acquired at any single instant. Consider the following as part of the load analysis:

- Smaller generator systems will usually have a ATS and all required loads will be energized at the same time.
- Larger generator systems might have multiple ATS, which can allow staggering of the load with discrete load steps.
- Some connected loads can have restart time delays independent of any ATS time delay.
- Parallel generator systems will usually have multiple ATS or distribution circuit breakers in the paralleling switchgear to establish step loading time delays.

D-2.5 Motor Starting Requirements.

Motor starting requirements are important to properly size engine generator sets because the starting current (inrush) for motors can be as much as six times the running current, and can cause generator output voltage and frequency to drop, even though the generator system has been sized to carry the running load. The designer must analyze the motor loads to determine if the starting characteristics of a motor or a group of motors to be started simultaneously will result in inadequate system performance.

Provide a motor starting kVA value for the largest motor or combination of motors to be started simultaneously. An increase in the size rating of the engine generator may be necessary to compensate for the inrush current. This information assists the engine generator supplier in properly sizing the engine generator set.

D-3 GENERATOR RATING.

The generator rating depends on the load analysis results, the projected annual and continuous run-time, and the overall system design and configuration.

D-3.1 Industry Ratings.

The generators addressed by this UFC will normally be rated based on their limited time running power classification (EGSA 101P, ISO 8528-1), which engine generator manufacturers often refer to as the standby rating.

Apply the generator prime power rating for the installation if any of the following conditions apply:

- The expected annual operating time is longer than stated above, which might occur if the system will be used for utility peak shaving.

- The generator will be operating at near 100 percent of rating and the load is nonvarying. **Note:** Historical experience indicates that most diesel generators will rarely be loaded near 100 percent and less than 50 percent loading is common.
- The system is designated as a COPS in accordance with NFPA 70 Article 708.

D-3.2 Generator Capacity Rating.

The required generator capacity depends on:

- Load analysis results (refer to paragraph D-2). Size the generator based on expected power demand rather than connected load.
- Magnitude of load steps that will be applied to the generator, together with the desired transient response characteristics.
- Allowable voltage and frequency variation, including initial loading effect.
- Oversizing to mitigate the effects of nonlinear loads*.* **Note:** For combinations of linear and non-linear loads where the percentage of non-linear loads is small relative to the capacity rating of the generator (25% or less), standard generator configurations are normally acceptable.

Small generators with a relatively simple load analysis can be sized by hand calculations. Larger generator systems with a large proportion of nonlinear loads or multiple load steps will require software specifically designed for generator sizing. Generator suppliers can provide this software or will perform the calculations.

D-3.3 UPS Systems.

UPS systems can have a detrimental effect on generator control systems and need to be considered in the generator performance requirements and generator commissioning. Ensure the following are addressed in the design:

- Generator and UPS communication so that the UPS recognizes when it is operating on a generator.
- Allowed battery charging current while the UPS operates on a generator source. UPS battery charging is not considered a critical/mission-essential load during generator operation and should be reduced to the minimum allowed by the UPS design, if it is an available UPS design feature.
- Power walk-in – Limit the rate at which the UPS transfers from its internal battery to the generator, if available in the UPS design.
- UPS input filter energized only after adequate load is established. Generator sets inherently have difficulty controlling voltage with leading power factors, which can cause an increasing voltage as the voltage

regulator attempts to control voltage. This condition can be exacerbated during UPS startup by the power walk-in feature. Typically, a UPS has some means of gradually applying load to the source over a 3 to 60 second period. An unloaded input filter may cause a leading capacitive power factor load beyond the generator's voltage control ability. Other loads connected to the generator will counter this effect. Disconnecting the filter at lower UPS loads will minimize this effect. This is an essential design requirement.

- Rotary UPS on DC bus – Limit the rotary recharge rate when the UPS is operating on generator.
- If the system has step loading capability, energize nonlinear loads such as a UPS after other mechanical-type loads have been energized.

Ensure the engine generator commissioning process confirms acceptable operation of the fully connected system with the UPS systems in service.

D-3.4 Power Quality.

The load analysis described in paragraph D-2 requires an assessment of the proportion of linear versus nonlinear loads. Nonlinear loads can adversely affect the generator control system. Provide this information to the generator supplier for evaluation.

Ensure the engine generator commissioning process confirms acceptable operation of the fully connected system with the nonlinear loads in service. If power factor correction capacitors are installed, ensure they are energized during the commissioning process if they are to remain in service.

This Page Intentionally Left Blank

APPENDIX E CONNECTION METHODS FOR PORTABLE GENERATORS

E-1 INTRODUCTION.

This (Cannon plug) or NFPA 70, UL-listed, CSA-certified, double-locking, single pole connectors (Cam-Lok style) as quick connection/disconnection devices for portable generator connections of 600 volts or less for facilities. This is the typical Air Force connection method for portable generators. Special use applications such as providing shore power for backup power to a nuclear reactor per UFC 4-150-02 is not covered in this UFC.

For Air Force: Portable generators are referred to as standby generators and are classified as EAID generators.

E-2 CONNECTION METHODS.

Generator facility connections must either be hardwired or employ connection methods as noted below.

E-2.1 MIL-DTL-22992F, Class L, QWLD-Rated Connectors.

Heavy-duty cylindrical, MIL-DTL-22992F, Class L, QWLD-rated connectors (Cannon plug) with appropriately rated disconnect switches selected in accordance with NFPA 70 are permitted as follows:

- Up to three (3) connections per generator are permitted. The maximum single connector rating must be 200 amperes. Mobile electric power (MEP) 6/806 units are permitted to use a single 200A Cannon plug connection.
- Combined loads from multiple connections must not exceed the rated capacity of the standby generator.
- The single conductor size used in any connector must not exceed #4/0 American Wire Gauge (AWG).
- Unused connector receptacles must be capped with manufacturer-recommended covers to prevent exposure to live electrical contacts. Plastic dust caps are not acceptable.
- A data plate style placard must be permanently attached, using sheet metal screws or rivets, adjacent to the connection(s), which reads:

DANGER

**UNUSED CONNECTOR RECEPTACLES ARE ENERGIZED
DURING GENERATOR OPERATION
EXERCISE EXTREME CAUTION
PROPER PPE REQUIRED WHEN MAKING CONNECTIONS**

- Cable assemblies connected in parallel must comply with all of the following:
  - Be the same length.
  - Have the same conductor material.
  - Be the same size in circular mil area.
  - Have the same insulation type, including cable assembly sheathing.
  - Be terminated in the same manner and be of the same rating. For example, a 200-ampere connection cannot be paralleled with a 60-ampere connection, even though the cable assemblies are rated for 200 amperes.
- All operators must be trained on the danger associated with multiple connections on the generator bulkhead. Supervisors must document this training.

E-2.2 Single-Pole (Cam-Lok style) Connectors.

Single-pole (cam-lok style) connectors and receptacles that are double-locking in accordance with the National Electrical Code (NEC) and NEMA 3R-rated are permitted with limitations. For standby generators, paralleled connections are prohibited. A single connector per phase must be used for each load and meet the following requirements (**Note:** MEP 6/806 units are permitted to use a single 200-ampere cam-lok style connector/plug connection per phase).

- Connectors and receptacles must be rated 200 amperes or less, UL listed and Canadian Standards Association (CSA) certified.
- Connector and receptacle contacts must be made of high-conductivity copper base alloy.
- Connector and receptacle must provide a double-locking means to ensure a minimum 600 lb/in^2 pressure on contact.
- Connector contacts must be recessed. A thermoplastic rubber or neoprene-insulated jacket must extend past the ends of both the male and female contacts and meet the strain relief requirements listed below.
- Receptacles must be provided with NEMA 3R color-coded (for phase and ground identification) snap-back covers (150 amperes and less) or protective caps.
- Cable plugs must be provided with color-coded (for phase and ground identification) protective caps with lanyards.
- Tapping tees are not permitted.
- Connectors and cable plugs must be fully rated for intended use.

- Cable-to-plug connections must be crimped. Set-screw connections are not allowed because of their tendency to loosen due to heating/cooling, high load, and vibration.
- The only approved cable strain relief is vulcanized style terminations.

Up to three (3) cam-lok style connectors (maximum twelve [12] single-phase connectors) per generator are permitted to allow connection to three separate loads. The maximum single connector rating must be less than 200 amperes.

This Page Intentionally Left Blank

APPENDIX F FACILITY DESIGN TYPES

Appendix F discusses different facility design types that might be authorized to have a standby power system.

For Army: Each major command/program defines its standby and emergency power requirements based on mission requirements, location/environmental parameters, and the NFPA criteria (life-safety). Typical applications that require standby or emergency power include: Command, Control, Communications, Computers (data centers), health care, industrial process facilities, RDT&E facilities, laboratories, and Installation Critical Support Services (including Force Protection, Readiness, Community Support).

For Navy: Table F-1 provides a list of the types of facilities that are typically authorized to have emergency generators. This information was obtained from UFC 2-000-05N and is not considered a complete list; it only contains the occurrences in UFC 2-000-05N where generators are mentioned.

For Tri-Service: Table F-2 provides a summary of facilities that are authorized to have emergency power. This information was obtained from UFCs.

Table F-1 Naval Facilities Authorized for Standby Power

Category Code	Facility Type	Comments
12330	Vehicle and Equipment Ready Fuel Storage	Authorized for buildings and utilities that may be needed in a hurricane or other base emergency.
13120	Communications Relay Facility	Contains rack mounted communications receiving, amplification, and transmitting equipment, along with a UPS and an emergency generator.
13122	VHF/UHF Communications Facility	Contains a small UPS and an emergency generator.
13135	Receiver Building	Contains a UPS and an emergency generator.
13140	Telephone Exchange Building	Can contain the telephone switch, main distribution frame, intermediate distribution frame, staff support spaces, operators work positions, maintenance and storage spaces, and is supported by UPS and emergency generators.
13150	Transmitter Building	Contains a UPS and an emergency generator.
13372	Military Terminal Radar Approach Control Facility	Space is provided in the mechanical room for an emergency generator and UPS system.
13373	Fleet Area Control Surveillance Facility	The mechanical space should include sufficient room for as emergency generator and a UPS system.
13374	Joint Control Facility	The mechanical spaces should include sufficient space for an emergency generator and UPS system.
13375	Air Surveillance Radar (ASR) Facility	The building and its associated antenna tower are located in a remote area of the airfield and an access road and emergency generator are required.
14365	Operations Control Center	UPS and emergency generators are required for continuous operation during natural disasters and increased security postures.

Category Code	Facility Type	Comments
14380	Command, Control, Communications, Computers, and Intelligence Facility (C4I)	The technical and operational mission of a C4I will require that it contain, Secure Compartmented Information Facility (SCIF) areas, a UPS, emergency generators, and in selected cases, radio frequency interference (RFI) shielding, electromagnetic interference (EMI) shielding, and Telecommunications Electronics Material Protected from Emanating Spurious Transmissions (TEMPEST) protection.
14385	Joint Reserve Intelligence Center (JRIC)	The technical and operational mission of a JRIC will require that it contain, SCIF areas, a UPS, emergency generator(s), and in selected cases, RFI shielding, EMI shielding, and TEMPEST protection.
51010	Hospital	Standby/emergency electrical generation, operational fuel storage of the generators or building heat systems and electrical transformers in direct support of the medical facilities should have the BUMED activity as the User and Maintenance UIC. The BUMED facility is not a complete and useable facility without the inclusion of these directly supporting utility systems.
81159	Standby Generator Building	Standby generators are used to provide electrical power when the normal source of power is not available. This category includes all necessary equipment for the production of the commodity, including tanks, pumps, electrical equipment, and all other equipment for electrical generation.
81160	Standby Generator Plant	Standby generators are used to provide electrical power when the normal source of power is not available. This category includes all necessary equipment for the production of the commodity, including tanks, pumps, electrical equipment, and all other equipment for electrical generation.

Table F-2 UFCs Addressing Standby Power Requirements

UFC	Title	Requirement Summary
4-133-01	Navy Air Traffic Control Facilities	Requires emergency generators for various facility types, including radar air traffic control facilities (RATCF), fleet area control and surveillance facility (FACSFAC), joint control facility (JCF), and air traffic control tower (ATCT).
4-141-04	Emergency Operations Center Planning and Design	When required, only essential systems should be placed on the emergency system with a generator being the primary emergency power source. The type, size and number of generators is based on the operational requirements of the EOC.
4-141-10N	Design: Aviation Operation and Support Facilities	UFC 4-141-10N re-issues MIL-HDBK-1024/1 for use for Navy applications. Requires emergency generators for a variety of aviation operation and support facilities.
4-150-02	Dockside Utilities for Ship Service	Requires standby power for nuclear submarines.
4-211-01	Aircraft Maintenance Hangars: Type I, Type II, and Type III	Coordinate and provide emergency power as dictated by the mission. At a minimum, hangar doors must be operable in the event of utility power failure by means of a generator.
4-213-10	Graving Drydocks	Install a back-up emergency diesel generator near each pumphouse to run at least the drainage pumps and alarms in the event all electrical power is lost.
4-510-01	Design: Medical Military Facilities	Requires emergency generators for hospitals.
4-722-01F	Air Force Dining Facilities	AFMAN 32-1062 authorizes an emergency generator for one feeding facility per installation, with MAJCOM having authority to approve additional eating facilities.

UFC	Title	Requirement Summary
4-722-01N	Navy and Marine Corps Dining Facilities	Provide facility service entrance with the capability to temporarily connect a portable generator via an external connection point. Systems utilizing portable generators must comply with NFPA 70 Article 702. If the facility has been designated as a Mass Care feeding facility, provide a permanent, external self-contained emergency generator that must power the entire facility load. Provide 72 hours of fuel storage.
4-730-04AN (INACTIVE)	Military Police Facilities	Auxiliary support power backup power may be provided as auxiliary support by individual battery units, a central battery system or by an engine-generator set. Determination of the type of auxiliary support provided will be based upon economics alone. Special requirements exist for an automatic emergency source or power for critical communications and surveillance security systems using monitoring devices (CCTV I D alarms) linked to the MP desk and for other special equipment or functional areas where power outage would jeopardize mission-effectiveness.

UFC	Title	Requirement Summary
4-730-10	Fire Stations	Provide 100% emergency generator back-up power for HQ/main and large HQ stations. For satellite stations, provide emergency back-up power, at a minimum, for the following spaces/systems: • Apparatus bay lighting and doors. • Watch Desk/Dispatch and all associated equipment. • IT room systems related to the Dispatch and communication functions. • Lighting. If required by Installation mission requirements, consider providing emergency power for additional spaces, such as the Day Room, or providing 100% emergency back-up power for the entire satellite station.
4-470-02	Fitness Centers	Provide facility service entrance with the capability to temporarily connect a portable generator, via an external connection point. Systems using portable generators must comply with NFPA 70 Article 702. Coordinate with activity representatives to develop a written, manual load-shedding procedure for the facility. Document size of generator required to support design conditions.

APPENDIX G AIR FORCE GENERATOR AUTHORIZATIONS

Reference AFMAN 32-1062.

This Page Intentionally Left Blank

APPENDIX H POWER PLANT CONSIDERATIONS

H-1 PLANT LOCATION FACTORS.

Power plant location should be determined after evaluating the factors listed in Table H-1. Design power plant and its systems to operate appropriately in the selected location's environmental conditions.

Table H-1 Power Plant Location Factors

Factor	Impact
Climate	Will determine type of architecture of building, wall and roof U factors, heating, and ventilating
Maximum and minimum dry bulb	Affects export heating, maximum wet bulb temperature load heating, and cooling degree days
Maximum and minimum wind	Affects heating load and velocities structural loading
Topography grades	Affects architecture and floor levels, fuel handling, fuel storage, and drainage.
Soil	Bearing value and water tables determine structural foundations, drainage, and underground pipe distribution.
Maximum high water	Affects floor levels, level pumps, suction lifts, and foundations
Frost line	Determines depth of water and sewer lines
Cathodic analysis	Determines cathodic protection requirements to reduce systems corrosion
Seismic zone	Determines structural reinforcement requirements
Future expansion	Affects allocation of space in plant for expansion
Altitude height above sea level	Affects air density and stack height
Orientation near air field	Determines maximum stack heights and hazards near docks, railroads, and affects transportation, roads of fuel and materials
Water supply	Determines condenser cooling, jacket cooling, makeup water, and domestic water. This affects plant location, water treatment and filtering requirements
Local rules and regulations	May determine materials of material construction, air pollution permit requirements, water, sewers, landfill and fuel storage

H-2 ACOUSTICAL CONSIDERATIONS.

Consider acoustical noise in selection of generator location using Table 2-1.

An economic study must show that modifications and additions to an existing plant, to serve additional loads, is the most economical approach compared to other options such as additional production using third-party-funded construction and operation.

H-3 PRIME POWER PLANTS.

Prime power plants must have adequate capacity to meet all peacetime requirements. Types of plants for installations not requiring export steam or heat:

- Purchased electric power.
- Reciprocating engine-generator or gas turbine-generator rated for prime or continuous duty.
- Steam boilers with turbine generators of matched capacity. Turbines can be straight condensing or combination condensing and back pressure as required to suit plant steam usage.

Types of plants for installations requiring export steam:

- Purchased electric power and steam plus steam heating boiler.
- High pressure steam boilers with backpressure steam turbines of matched capacity. Steam heating boilers can be used to supplement the requirements of the export steam load.
- High pressure steam boilers with automatic extraction condensing turbines. Steam heating boilers can be used to supplement the requirements of the export steam load.

H-3.1 Boiler Requirements.

Certify boiler operations in accordance with UFC 3-430-07. Obtain boiler operating permit from state and local authorities as appropriate and if required.

H-3.2 Load Requirements.

H-3.2.1 Electrical.

Determine loads in kW. Determine winter and summer, types of electric loads separately.

Table H-2 Electrical Load Types

Load Type	Notes
Export	See UFC-3-501-01
Plant	See UFC-3-501-01
Switchgear	See UFC-3-501-01
Line losses	12% of subtotal (unless more accurate data is available.
Total present load	Total of above
Total ultimate load	See UFC-3-501-01 (may be estimated by extending current load trend)
Minimum continuous	See UFC-3-501-01 (as for a summer night)
Emergency load	See UFC-3-501-01 (demand of services that cannot tolerate a 4-hour interruption)

H-3.2.2 Steam.

If steam is considered a requirement, then the following needs to be calculated as well. (Determine loads in kBtu/hr.) Determine winter and summer, types of steam load and winter loads separately.

Table H-3 Steam Load Types

Load Type	Notes
Condensing turbine	Rated kW × heat rate
Auto-extraction turbine	Rated kW × heat rate
Plant auxiliaries	Steam jet air ejector
Condensing turbine	Rated kW × heat rate
Fuel oil heating	
Export Space heating (radiation)	Use diversity factor of 1.0
Export space heating (ventilation)	Use diversity factor of 0.8
Export utilities (hot water and laundry)	Use diversity factor of 0.65 For kitchen use diversity factor of 1.0
Refrigeration (turbine drive)	

Load Type	Notes
Refrigeration (absorption type)	
Process use	
Distribution losses	
Total present load	Total of above steam loads.
Total ultimate load	Maximum expected steam load for electrical power generation plant steam requirements and export steam loads (including projected present and additional future load)
Minimum continuous	Same as distribution loss
Emergency load	Demand of services that cannot tolerate a 4-hour interruption
Typical load curves	For an example of a typical load curve, see Figure G-1.

H-3.2.3 Growth Curves.

In (a) of Figure H-1, note the normal trend growth of total steam and electric demands and the additional loads when new buildings or processes are added.

This curve is useful in timing power plant additions of equipment.

H-3.2.3.1 Load Curves.

The average of daily steam and electric demands, (b) of Figure H-1, for the season or year under consideration for each hour of a 24 hour day is also important. Such curves are useful in determining load factors and duration of certain demands, and in dividing the total load among the plant units.

Fire pump loading must be considered for any installation with an electric fire pump. This loading is covered under NEC 695-7. This means that the generator must be oversized to have a voltage dip no more than 15% during normal starting of the fire pump motor. Ensure minimum generator loading is at least 35% of the rated kW, without the fire pump load, to avoid wet stacking and soot buildup.

H-3.2.3.2 Load Duration Curves.

Plot the number of hours of duration of each load during a year for present and future load conditions of steam and electricity usage for the activity. See (c) of Figure H-1. This type of curve is useful in determining load factors and in sizing units of power plant equipment.

Load duration curves for various conditions are shown on Figures H-2, H-3 and H-4.

Figure H-1 Typical Steam and Electric Load Curves

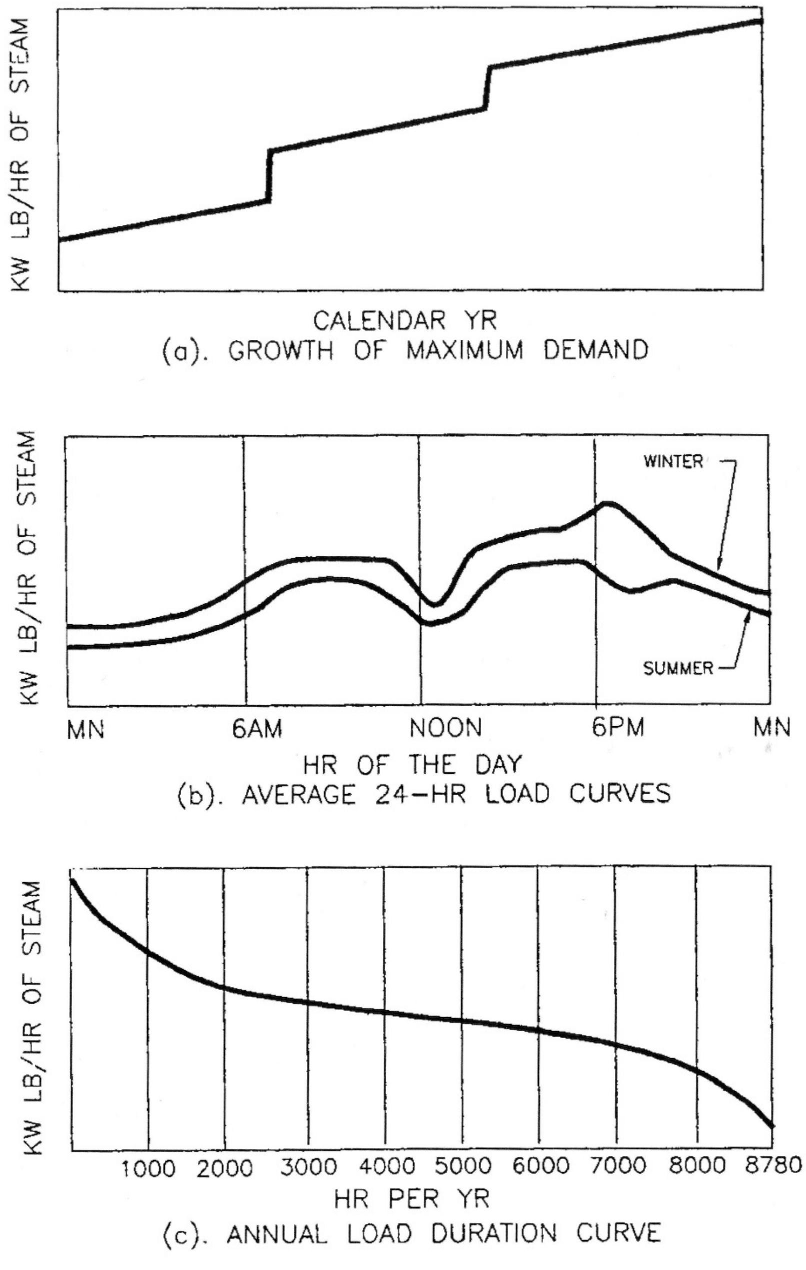

Figure H-2 Typical Load Duration Curves

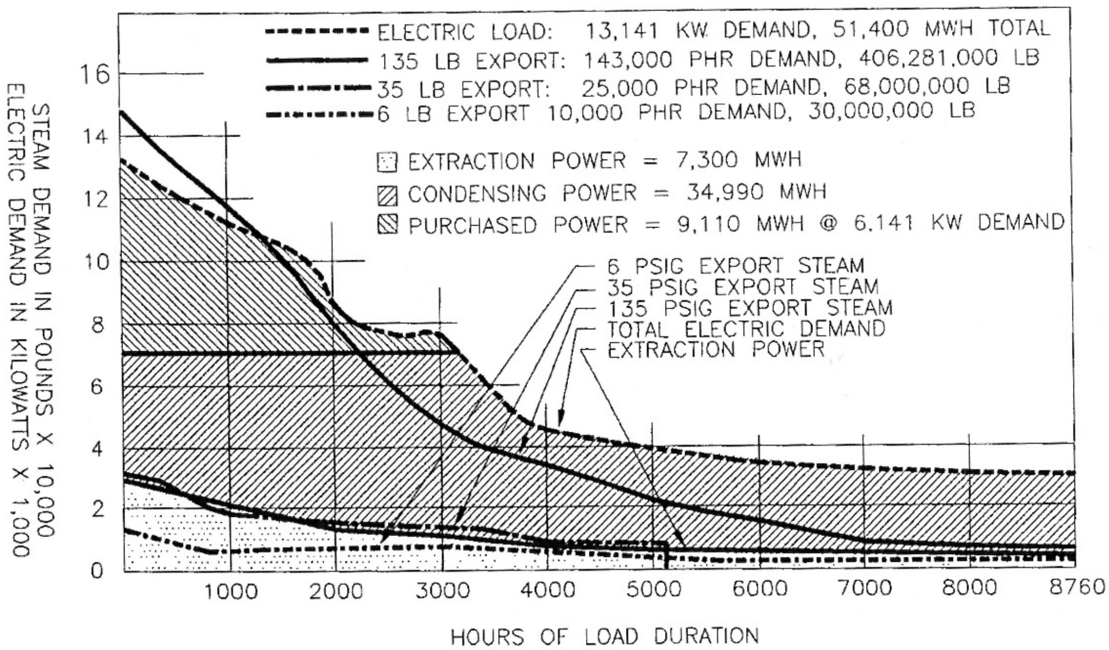

Figure H-2: Typical load duration curve - base load on power plant, load swings on purchased power, all export steam from power plant.

Figure H-3 Typical Load Duration Curves

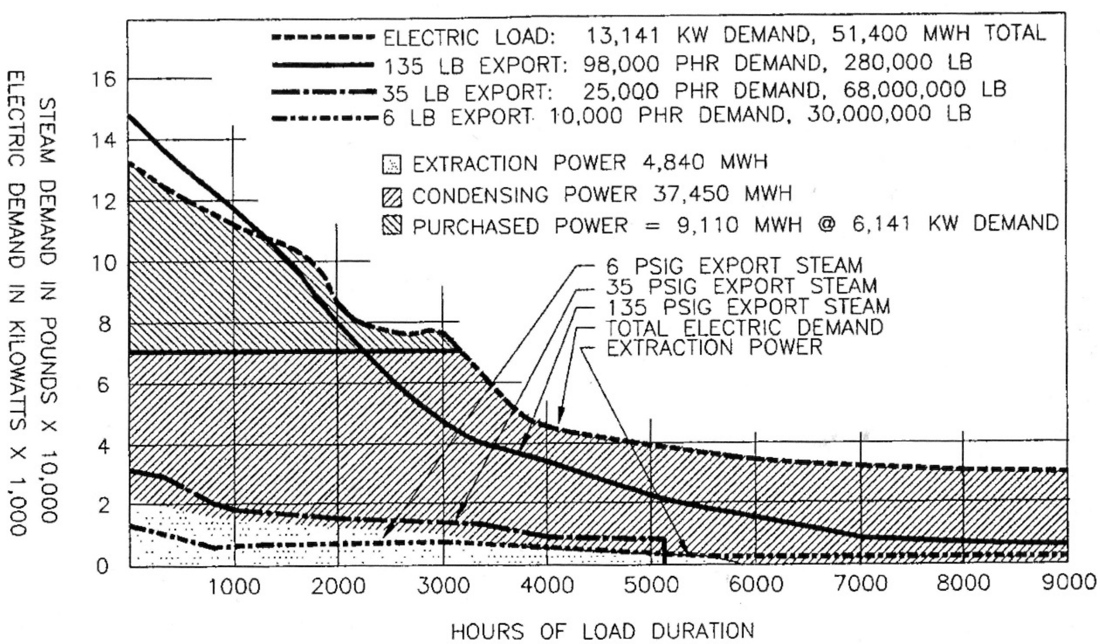

Figure H-3: Typical load duration curve - base load on power plant, load swings on purchased power, portion of export steam on central heating plant.

Figure H-4 Typical Load Duration Curves

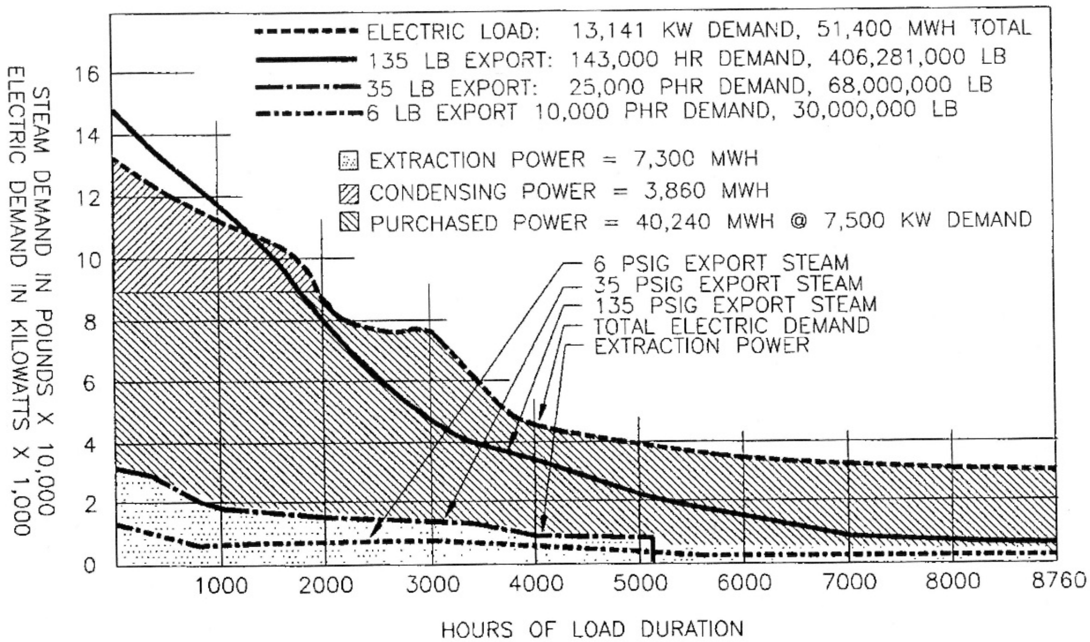

Figure H-4: Typical load duration curve – load priority as follows: (a) extraction generations; (b) purchased power; (c) condensing generation.

H-3.2.4 Utility Interconnect.

Under parallel operation, the generation plant is electrically interconnected and synchronized with an electric utility distribution or transmission system, with both the generator and electric utility generating electricity simultaneously. Under parallel operation, some electricity will be flowing either to or from the generation system. With few exceptions, the DoD does not own and operate a prime power plant in parallel with an independently owned upstream utility grid. This may be a consideration only in a national emergency, or if the plant is third-party owned and operated as part of an enhanced use lease agreement. In such situations, comply with utility provider requirements and IEEE 1547.

Integrated paralleling considerations must be taken into account prior to initial design. Paralleling generators offers expandability, flexibility, higher ease of maintenance, and higher cost effectiveness. However, to accomplish this, the controls between generators must be able to communicate. It is preferable that the generator controllers be identical, the voltages must be identical, and the generator pitch must be identical. Without these criteria, the generators will not work well together.

H-3.2.4.1 Utility Agreements.

The generators must first comply with Public Utility Regulatory Policies Act (PURPA) and all state and Federal regulatory requirements. The utility must approve any interconnection details prior to attachment to the utility system. Requirements vary depending upon:

- whether the transition transfer is open or closed
- system voltage
- interconnection power flow (one-way or two-way)
- size of the proposed generator

The utility will use their completed application and one-line diagram to determine if a preliminary interconnection study is needed. With the preliminary interconnection study, the utility will make a cost estimate and schedule to accommodate the proposed generation. Additional details will be requested as necessary. Since the study outcome may affect the equipment purchase, it is strongly recommended that no final purchase agreements are completed concerning the interconnection generator or switchgear until this study has been completed. Additional diagrams will be required, including site plans, relaying diagrams, metering diagrams, and telemetry, equipment specifications and details of generators, transformers, circuit breakers, protective relays, current transformers, voltage transformers, and isolation disconnects.

H-3.2.4.2 Metering.

Meters must be provided on fuel lines, electrical and water services to the buildings, and to the major equipment and boilers in the building. Advanced metering infrastructure (AMI) systems must be provided on these required locations. These requirements are promulgated by the Electric Power Research Institute (EPRI) and the United States Department of Energy (DOE).

Steam output metering of the header and at each steam generator must be provided for periodic reports and testing. Meters will be electronic in nature and capable of being polled remotely with single mode fiber-optic means.

APPENDIX I GLOSSARY

I-1 ACRONYMS.

A	amperes
AC	alternating current
AED	automatic external defibrillator
AFI	Air Force Instruction
AHJ	authority having jurisdiction
AFMAN	Air Force Manual
AMI	advanced metering infrastructure
ASR	air surveillance radar
ATS	automatic transfer switch
AWG	American Wire Gauge
BUMED	Navy Bureau of Medicine and Surgery
C4ISR	Command, Control, Communications, Computers, Intelligence, Surveillance, and Reconnaissance
CCTV	closed circuit television
CONUS	continental United States
COPS	Critical Operations Power Systems
CSA	Canadian Standards Association
CT	current transformer
dBA	decibels, A-weighted
DC	direct current
DCS	distributed control system
DDC	direct digital control
DER	distributed energy (generation) resources
DOE	Department of Energy

EA	environmental assessment
EAID	Equipment Authorization Inventory Data
EGSA	Electrical Generating Systems Association
EIS	environmental impact study
EMF	electromagnetic field
EMI	electromagnetic interference
EMP	electromagnetic pulse
EOC	Emergency Operations Center
EPA	Environmental Protection Agency
EPRI	Electric Power Research Institute
EPSS	emergency power supply system
FACSFAC	Fleet Area Control and Surveillance Facility
HMI	human-machine interface
hr	hour
HVAC	heating, ventilating, and air conditioning
Hz	hertz
I/O	input/output
ICS	industrial control systems
IED	intelligent electronic devices
ISO	International Standards Organization
JCF	joint control facility
JRIC	Joint Reserve Intelligence Center
kBtu/hr	thousand British thermal units per hour
kV	kilovolt
kVA	kilo-volt-amperes

kW	kilowatt
kWlb/hr	kilowatt-pounds per hour
lb/in^2	pounds per square inch
LPG	liquefied petroleum gas
MP	Military Police
MEP	mobile electric power
MVA	million-volt-amperes
MWh	megawatt hour
NAVFAC	Naval Facilities Command
NEC	National Electrical Code
NEMA	National Electrical Manufacturers Association
NSPS	New Source Performance Standards
OEBGD	(DoD) Overseas Environmental Baseline Guidance Document
OSHA	Occupational Safety and Health Act
PLC	programmable logic controller
POL	petroleum, oil, and lubricants
psig	pounds per square inch gauge
PURPA	Public Utility Regulatory Policies Act
QSTAG	*Quadripartite Standardization Agreement*
QWLD	quick (connect), waterproof, type l disconnect
RAM	reliability, availability, and maintainability
RATCF	radar air traffic control facilities
RDT&E	research, development, test and evaluation
RFI	radio frequency interference
RFP	request for proposal

RPIE	real property installed equipment
rpm	revolutions per minute
SCADA	Supervisory Control and Data Acquisition
SCIF	Secure Compartmented Information Facility
SCR	selective catalytic reduction
sec	second
TEFC	totally enclosed fan cooled
TEMPEST	Telecommunications Electronics Material Protected from Emanating Spurious Transmissions
TFT	thin film transfer
UFC	Unified Facilities Criteria
UIC	Unit Identification Code
UL	Underwriters Laboratories
UPS	uninterruptible power supply
VDC	volts, direct current

I-2 DEFINITION OF TERMS.

Automatic Transfer Switch (ATS): A switch designed to sense the loss of one power source and automatically transfer the load to another source of power.

Availability: The long-term probability of success with repair and scheduled maintenance of electrical power plants, generators, and power systems. Calculate availability as the ratio in percentage of total period minus repair downtime minus maintenance downtime to total period. The calculation assumes power generated meets quality standards.

Critical Operations Power Systems: Systems that are installed in vital infrastructure facilities that, if destroyed or incapacitated, would disrupt national security, the economy, public health or safety; and where enhanced electrical infrastructure for continuity of operation has been deemed necessary by governmental authority. COPS design criteria are specified by NFPA 70 Article 708.

Emergency Systems: As specified by NFPA 70, emergency systems are those systems legally required and classed as emergency by municipal, state, Federal, or other codes, or by any governmental agency having jurisdiction. These systems are intended to automatically supply illumination, power, or both, to designated areas and equipment in the event of failure of the normal supply or in the event of accident to elements of a system intended to supply, distribute, and control power and illumination essential for safety to human life.

Harmonic: A sinusoidal component of a periodic wave or quantity having a frequency that is an integral multiple of the fundamental frequency.

Legally Required Standby Systems: Those systems required and so classed as legally required standby by municipal, state, Federal, or other codes or by any governmental agency having jurisdiction. These systems are intended to automatically supply power to selected loads (other than those classed as emergency systems) in the event of failure of the normal source.

Linear Load: An electrical load device that presents an essentially constant load impedance to the power source throughout the cycle of applied voltage in steady-state operation.

Listed: Applies to equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction. The organization periodically inspects production and certifies that the items meet appropriate standards or tests as suitable for a specific use.

Nonlinear Load: A steady state electrical load that draws current discontinuously or has the impedance vary throughout the input AC voltage waveform cycle. Alternatively, a load that draws a nonsinusoidal current when supplied by a sinusoidal voltage source.

Optional Standby Systems: Those systems intended to supply power to public or private facilities or property where life safety does not depend on the performance of the system. Optional standby systems are intended to supply on-site generated power to selected loads either automatically or manually.

Power Quality: The concept of powering and grounding sensitive equipment in a manner that is suitable to the operation of that equipment.

Transfer Switch: A device for transferring one or more load conductor connections from one power source to another.

Uninterruptible Power Supply System: A system that converts unregulated input power to voltage- and frequency-controlled filtered AC power that continues without interruption even with the deterioration of the input AC power.

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	5 Nov 2019	Updated the Summary Sheet, Chapters 1, 2, 3, 5, and 8 (Chap. 8 formerly App. C) and App. A (formerly App. D); renumbered former Appendices A and B as Appendices B and C. Numerous non-substantive corrections throughout for format, grammar, missing/outdated references, and paragraph numbering; these changes are not marked.

This UFC supersedes Engineering Technical Letter (ETL) 13-4, *Standby Generator Design, Maintenance, and Testing Criteria.*

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and, in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing Service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective Service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet site below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure they are current.

UNIFIED FACILITIES CRITERIA (UFC)
SUMMARY SHEET

Document: UFC 3-540-07, *Operation and Maintenance (O&M): Generators*

Superseding: Air Force ETL 13-4, *Standby Generator Design, Maintenance, and Testing Criteria*

Description: UFC 3-540-07 provides guidance for O&M of standby, emergency, and prime power generators.

Reasons for Document: Provide guidance for O&M of generators.

Impact: There are no impacts on design and initial cost, energy savings, or life cycle costs.

\1\ Unification Issues: Air Force-only requirements are in Chapter 8. **/1/**

TABLE OF CONTENTS

FIGURES

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Proper O&M of generators is essential to ensuring continuous electrical system operation and reliability. A comprehensive O&M program with proven practices and well-performed maintenance prevents downtime and mission loss or delay.

1-2 PURPOSE AND SCOPE.

This UFC provides the minimum guidance and standards for O&M of standby, emergency, and prime power generators and is intended to be used by operations and maintenance personnel. It includes safety requirements, standard operating instructions, maintenance instructions, and test procedures. This UFC is intended to be used with the generator manufacturer's recommended operational procedures and maintenance manuals.

1-3 APPLICABILITY.

The guidance and standards contained within are the minimum requirements acceptable for military installations for efficiency, economy, durability, maintainability, and reliability of generator systems. The provided guidance does not automatically supersede equipment manufacturers' instructions and requirements. When conflicts exist, follow the most rigorous requirement. The guidance and standards herein are not intended to be retroactively mandatory. Provide, as a minimum, the level of maintenance required to meet critical mission reliability goals.

- Comply with the requirements of 29 CFR 1910, *Occupational Safety and Health Standards.*
- Comply with the requirements of Title 40 CFR 1 to 1100, *Environmental Protection Agency*.
- Comply with UFC 3-550-01, *Exterior Electrical Power Distribution*, for minimum system and component design standards.
- Comply with UFC 3-520-01, *Interior Electrical Systems*.
- Comply with UFC 3-560-01, *O&M: Electrical Safety*, for electrical safety requirements applicable to the installation and operation of electrical systems.
- Comply with UFC 3-540-01, *Engine-Driven Generator Systems for Backup Power Applications*, for backup power applications.

\1\ Note: The Air Force will follow operations, maintenance, and testing requirements outlined in Chapter 8. **/1/**

1-4 SAFETY.

1-4.1 Minimizing Hazards.

Before starting maintenance, be aware that a generator can start without warning and cause serious injury or death. Use lockout/tagout (LOTO) procedures and wear appropriate personal protective equipment (PPE). Comply with UFC 3-560-01 for electrical safety requirements.

Apply standard operating procedures (SOP), where available, for reducing/minimizing/eliminating potential hazards with PPE, proper training, and rescue procedures and equipment.

1-4.2 Qualifications of Generator and Electrical Workers.

1-4.2.1 Training.

Generator and electrical workers must be qualified through training and demonstrated skills and knowledge in specific hazards associated with their potential exposure in accordance with OSHA requirements and safety-related practices contained in NFPA 70E, *Standard for Electrical Safety in the Workplace*, and IEEE C2, *National Electrical Safety Code (NESC)*. Trained and qualified generator and electrical workers must be familiar with the following:

- The skills and techniques necessary to distinguish exposed live parts from other parts of electric equipment.
- The skills and techniques necessary to determine the nominal voltage of exposed live parts.
- The clearances specified in NFPA 70E and IEEE C2.
- Operating (starting, running, shutdown procedures) and maintaining generators, generator synchronizers, generator control system, fuel system, cooling system, exhaust system, and switchgear.

1-4.2.2 Generator Workers and Operators.

Maintain a list of qualified generator operators. The generator operator and worker must have the knowledge to monitor indicating devices that reflect system operation and manipulate controls necessary to properly start, operate, and shut down generator equipment. Ensure the facility manager or others (operators) at the facility are trained to operate and check generator status. It is the responsibility of the facility or mission owner to request annual training from the base civil engineer (BCE)/Public Works as required.

1-5 CYBERSECURITY.

Operate and maintain all generator-related control systems to maintain compliance with the network system authorization as required by DoDI 8500.01, *Cybersecurity*, and

DoDI 8510.01, *Risk Management Framework (RMF) for DoD Information Technology (IT)*. See UFC 4-010-06, *Cybersecurity of Facility-Related Control Systems*, for additional information.

\1 [Deleted note.] **/1/**

1-6 PERSONNEL SAFETY.

Generator and electrical workers must wear proper safety clothing in the work area per OSHA 1910.132. Workers must be trained and certified in use and care of PPE, insulating protective equipment (IPE), and LOTO controls. Personnel must follow safety procedures, conduct hazard analyses, and attend job safety briefings in accordance with OSHA and UFC 3-560-01 safety requirements. Proper tools must also be used in accordance with 29 CFR 1926. Electrical gloves must be tested according to ASTM F496, *Standard Specification for In-Service Care of Insulating Gloves and Sleeves*. NAVFAC must also follow local specific regulations.

1-7 REFERENCES.

Appendix B contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance or edition of the reference is used.

1-8 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

This Page Intentionally Left Blank

CHAPTER 2 GENERATOR CONFIGURATION

2-1 GENERAL REQUIREMENTS.

Maintenance of the generator consists of all systems associated with the generator, including cables, prime movers, and ancillary equipment.

Note: There are differences between the EPA and NFPA definitions for an emergency generator and generator operators must ensure they are using the correct reference within each context to avoid misunderstandings.

2-2 RECIPROCATING ENGINE PRIME MOVER.

There are two primary types of reciprocating engines: compression ignition and spark ignition. Compression ignition includes diesel fuel engines. Spark ignition includes gasoline, natural gas, and liquid petroleum gas (LPG) engines.

The major components of reciprocating engine requiring maintenance include:

- Engine block assembly (block, crankshaft, pistons and rings, camshaft, lifters, connecting rods, intake and exhaust valves, and cylinder heads)
- Fuel system
- Cooling system
- Exhaust system
- Lubrication system
- Starting system
- Battery and charging system
- Automatic transfer switch (ATS)
- **\1** Manual transfer switch (MTS) **/1/**
- Ignition system
- Air intake system
- Control system
- Exercise

2-3 GENERATOR.

2-3.1 AC Generator.

AC generators used are synchronous except for wind turbines.

2-3.2 Mechanical.

The mechanical portion of a generator system consists of the fuel system, starting system (either pneumatic or electric), lubrication system, cooling system, and intake/exhaust system.

2-4 FUEL SYSTEM.

A common reason for generators not starting is a clogged fuel filter due to old or contaminated fuel; therefore, the fuel filters and fuel must be checked as part of routine maintenance.

2-5 LUBRICATING SYSTEMS – RECIPROCATING ENGINES.

Reciprocating engine lubrication system components requiring maintenance typically include:

- Sump/oil tank
- Lubrication filter
- Lubrication cooler
- Oil pump
- Tubing, hoses, and fittings

On larger size engines, the clean oil tank, waste oil tank, and pre-lubrication pumps are separate and require maintenance.

2-6 ENGINE COOLING SYSTEMS.

Engine water cooling system components typically requiring maintenance include water pumps, radiator, thermostat, cooling fan, hoses, thermostats, and instrumentation.

2-7 INTAKE AIR AND EXHAUST SYSTEMS.

2-7.1 Intake Air.

The intake air system cleans the air entering the generator engine or turbine. Air filtration systems for reciprocating engines typically use weather protection and final filters.

Intake air system components typically requiring maintenance include filters, filter housings and air intake horns, dampers, damper actuators, inertial separators, moisture coalescers, anti-icing systems, and instrumentation.

2-7.2 Exhaust System.

The exhaust system removes the combustion gases from the engine. Exhaust system components that typically require maintenance include draining the condensate and examining the manifold for leaks and holes.

2-8 DC POWER AND CHARGING SYSTEM.

Two types of batteries are vented cell batteries and sealed cell batteries. The vented, or open, batteries require periodic liquid levels observation and refilling, as necessary. Lead calcium flooded batteries have typical lifetimes of 20 years. **\1** Sealed cell, valve regulated lead acid (VRLA) batteries generally recommended are versions of sealed wet cell or absorbent glass mat (AGM). **/1/** Pure lead versions of these batteries have lifetimes over four years. A lifetime cost analysis must be done to choose what type batteries are required for the application. Maintenance must be included in these calculations. Load test all batteries according to IEEE 450, *Recommended Practice for Maintenance, Testing, and replacement of Vented Lead-Acid Batteries for Stationary Applications*. According to manufacturers, the top two reasons standby generators fail to automatically start or run are that the generator START switch is in the OFF position instead of AUTO or the starting batteries are dead or insufficiently charged.

2-9 AC POWER DISTRIBUTION SYSTEM.

Refer to UFC 3-550-01 for exterior electrical power distribution.

2-10 AUTOMATIC TRANSFER SWITCHES (ATS).

Most standby and emergency generators will have an associated ATS that requires maintenance. Those systems that do not have an ATS will have switchgear that accomplishes the same result or synchronizes with the utility. The ATS is an integral part of a generator system and must be tested to ensure proper operation. Refer to UFC 3-540-01 for design requirements.

2-11 MANUAL TRANSFER SWITCHES (MTS).

MTSs must be maintained by visually inspecting for rust and corrosion and ensuring moving components are greased with electrically conductive grease. They must also be exercised during generator system testing.

2-12 GROUNDING SYSTEMS.

Grounding systems should be visually inspected during generator inspections and testing for physical continuity for separately derived systems is required every two years (specifically at expeditionary sites).

This Page Intentionally Left Blank

CHAPTER 3 DEVELOPING AN O&M PROGRAM

3-1 O&M MANAGEMENT.

3-1.1 Administration and Structure.

The O&M administration structure must include the elements of operations, maintenance, engineering support, training, and administration. Operations is responsible for management and control of operation activities, equipment control and status, and operator knowledge and performance to support safe and reliable operations. Maintenance is responsible for effective management and control of maintenance activities, efficient performance of the work control system, safe conduct of maintenance activities, and maintenance procedures and documentation. Engineering support ensures effective implementation and control of technical support, equipment modifications, equipment performance monitoring, and engineer support of procedures and documentation. The Commanding officer, in conjunction with the generator subject matter expert (SME), must implement and control training activities, general training, maintenance training, operations training, training facilities, and equipment. Administration plans and implements policies, develops management objectives to improve performance, monitors activities, oversees industrial safety, and ensures personnel are appropriately trained.

Operational testing/operation must be done per the manufacturer’s recommendations. NFPA 110, *Standard for Emergency and Standby Power Systems*, also specifies emergency generator testing requirements. This includes full-load generator testing and exercise of circuit breakers and switches.

Note: The Air Force will follow the test requirements in Chapter 8.

3-1.2 Quality Assurance Program.

The O&M quality assurance program must measure the quality or effectiveness of the quality assurance program. Each plant is recommended to have a quality assurance plan to ensure the maintenance program is effective; however, it is not a minimum requirement.

3-1.2.1 Quality Assurance Metrics.

Use the following metrics to measure the quality or effectiveness of the quality assurance program:

- Plant reliability
- Work orders generated and closed out
- Corrective maintenance backlog
- Safety record
- Environmental record

- Energy use
- Inventory control
- Overtime worked
- Absentee rate
- Staff turnover

3-1.2.2 Base Period.

Track performance metrics on a periodic basis but not less than monthly.

3-1.3 Contracted Maintenance.

During the warranty period, the manufacturer must be contacted for resolution. Technicians will have documented training/experience on maintaining assigned generators. The contracted maintenance must include a submittal of a preventive maintenance schedule that meets or exceeds the generator manufacturer's recommended requirements.

3-2 TRAINING.

Fully train all personnel to perform O&M on specific installed generators. At a minimum, train personnel on the following:

- O&M of the equipment
- Proper use of tools, protective equipment, and precautionary techniques
- Electrical hazards associated with electrical equipment
- Techniques and skills to practice O&M activities on electrical equipment
- Job planning
- Maintaining a safe work environment
- Familiarization of the one-line electrical connection diagram/control diagrams for specific generator facility connection and layout

3-2.1 Qualifications of Generator Workers.

Personnel must be fully qualified/trained to perform O&M on generators and must follow/obey safety procedures in their work area.

3-2.1.1 Electricians.

Electrical workers must be trained and qualified to operate and maintain the electrical switchgear, including relays and circuit breakers, switchgear control system, transformers, DC power system, and other electrical ancillary equipment.

3-2.2 Safety.

Safety considerations must be taken into account to maintain the generators in accordance with UFC 3-560-01 and, for the Air Force, AFI 32-1064, *Electrical Safe Practices*. This involves access to generators, location of generators, tool locations, grouping of equipment, spacing requirements dictated by manufacturer's instructions, and NEC Article 110.

3-3 TOOLS AND EQUIPMENT.

3-3.1 Electrical Tools and Equipment Standards.

Industry standards describe the requirements for electrical protective equipment and tools. **\1** These standards were developed so tools, equipment, materials, and test methods used by electrical workers will provide protection from electrical hazards. Tool and equipment terminology and in-service maintenance and electrical testing are included in IEEE 935, *IEEE Guide on Terminology for Tools and Equipment to Be Used in Live Line Working*, and IEEE 516, *IEEE Guide for Maintenance Methods on Energized Power Lines*, respectively. **/1/** UFC 3-560-01 also contains tool and equipment requirements. In case of conflict, always use the most stringent safety requirement.

3-3.2 Standard Tools and Equipment.

For simplicity and convenience, the tools and equipment required for electrical inspection and maintenance are classified as follows:

3-3.2.1 Tools.

Tools include hand tools, digging tools, hot line tools, miscellaneous and special tools, and tackle.

3-3.2.2 Protective Equipment.

Protective equipment includes required PPE, such as eye and hearing protection, helmets, gloves, footwear, and arc flash clothing, and non-PPE items such as LOTO locks, barricades, and warning devices. Follow PPE requirements in UFC 3-560-01 and, for the Air Force, AFI 32-1062, *Electrical Systems, Power Plants and Generators*.

3-3.2.3 Large Portable and Mobile Equipment.

Large portable and mobile equipment includes relatively large and easily transportable equipment for use in maintenance work, such as line trucks, aerial lift trucks, motor-generator sets, posthole diggers, load banks, and similar apparatus.

3-3.3 Care and Storage of Tools and Equipment.

Tools and equipment will be kept in proper operating condition and used only for the purpose for which they were designed. If proper and safe tools are unavailable, report tool needs to a supervisor.

Inspect all tools at regular intervals and any tool that develops defects when in use will be taken from service, tagged, and not used again until restored to proper working condition.

3-3.4 Electrical Inspecting and Testing Equipment.

The number and types of testing/inspection devices needed depends on local needs. When available, follow the manufacturer’s instructions for the care and maintenance of test equipment. Schedules for calibrating and testing instruments and meters are dependent upon the particular installation. When precision is not essential, the period between tests is not critical and may be assigned as convenient. For units provided with built-in diagnostic capabilities, check diagnostics when their associated power apparatus is checked.

3-3.4.1 Maintenance of Instruments, Meters, and Test Equipment.

Only personnel trained and qualified to maintain instruments, meters, and test equipment, or personnel under the immediate supervision of such qualified personnel, are allowed to perform accuracy tests, repairs, calibrations, and adjustments of instruments and meters. When selecting meters, match meter accuracy to the requirements of which the reading and records are being used. Procuring equipment with higher accuracy than requirements dictate must be economically justified.

3-3.4.2 Frequency of Inspections.

If calibration standards and equipment are not available, instruments and meters of nearly the same rating can be checked against each other. When wide discrepancies are noted or the instrument or meter is obviously incorrect, recalibrate and make any needed repairs.

3-3.4.3 Test Instrument Calibrations.

Calibrate instruments according to manufacturer's recommendations and agency requirements.

- Air Force: Perform calibration in accordance with AFI 21-113, *Air Force Metrology and Calibration (AFMETCAL) Management*, and T.O. 00-20-14, *Air Force Metrology and Calibration Program*.
- Army: Perform calibration in accordance with U.S. Army Test, Measurement, and Diagnostic Equipment Activity (USATA) requirements, AR 750-43, *Army Test, Measurement, and Diagnostic Equipment*, and TB

43-180, *Calibration and Repair Requirements for the Maintenance of Army Materiel*.

- Navy and Marine Corps: Perform calibration in accordance with the NSWC Corona Measurement Science and Technology Laboratory Measurement and Calibration (METCAL) program.

3-3.5 Required Electrical Safety Program.

Implement and document an overall electrical safety program that directs activity appropriate for the electrical hazards, voltage, energy level, and circuit conditions. Refer to NFPA 70E and UFC 3-560-01.

Note: For the Air Force, see AFMAN 91-203, *Air Force Occupational Safety, Fire, and Health Standards*, and AFI 32-1064.

3-4 HAZARDOUS MATERIAL PROCEDURES.

Implement a hazard communication program in accordance with 29 CFR 1910.1200 or 29 CFR 1926.59 and DoDI 6050.05, *DoD Hazard Communication (HAZCOM) Program*, as amended by agency guidance. The major hazardous items to which electrical workers may be exposed are asbestos, polychlorinated biphenyls (PCBs), sulfur hexafluoride (SF6), and some of the chemicals used to control undesirable brush or pests or to preserve wood. For PCBs, comply with 40 CFR 761 and DoD 4715.05-G, *Overseas Environmental Baseline Guidance Document* (OEBGD).

Note: For the Air Force, see AFMAN 91-203.

3-5 SYSTEM DATA, EQUIPMENT DATA, AND DOCUMENTATION.

3-5.1 Operating Procedures.

Operating procedures must be documented and readily available. Mandatory testing, validation, approval, and review requirements must be kept in a permanent or appropriate record for the various types of generator configurations.

3-5.2 Manufacturer O&M Manuals.

Ensure manufacturer O&M manuals, parts manuals, and technical manuals/orders (if applicable) are always available and in a convenient location for access. Manufacturer manuals provide essential guidance on recommended frequency for inspections and maintenance for generators. Ensure at least one set of O&M manuals are supplied by the generator manufacturer at the time of acquisition.

3-5.3 Derating.

If something has changed on the generator, such as moving it from one location to another, and therefore the altitude, secondary fuel, or environmental conditions change, the generator must be de-rated **\1** by the authority having jurisdiction (AHJ) for each

Service. This de-rating must be documented in the O&M manuals and properly labeled. **/1/**

3-5.4 Installation Drawings.

Ensure at least two sets of installation drawings are provided by the installation contractor and maintained by the shop to give guidance to the operator and maintainer on equipment installation and other related activities. Circuit drawings must be updated with any modifications by the responsible party as required by NFPA 70E and 29 CFR 1910.

3-5.5 Control Diagrams.

Control diagrams are functional representations of the interconnection of the electrical equipment and contain one-lines, schematics, and wiring diagrams. They include the required content, format, and verification process for control diagrams for the operator and maintainer.

3-5.6 Maintenance Forms and Records.

Record maintenance information and test data for generators on Service-approved forms and checklists. Forms serve as an equipment inspection guide or checklist in order to maintain the generators in optimum working condition. Retain records for the Service-defined period of time and make available to the AHJ, as requested. Figures 3-1, 3-2, and 3-3 are typical maintenance forms to use for generator inspection activities.

1. ☐ Change oil and lube oil filters.
2. ☐ Remove unused oil from premises.
3. ☐ Change fuel oil elements.
4. ☐ Service crankcase breather.
5. ☐ Inspect air cleaner element, clean if required. If replacement is required, element(s) will be billed separately. Price of element(s) not included in contract price.
6. ☐ Check coolant level and maintain safe degree of protection. Engine mounted radiators only. (Remote radiators, cooling towers & heat exchangers serviced at user's request on a time and material basis.)
7. ☐ Check manifolds, brackets, mountings and flex connections.
8. ☐ Inspect fan belts, adjust if required.
9. ☐ Check pulley hub, bearings, lubricate if required.
10. ☐ Check operation of auxiliary water pump or fan motor.
11. ☐ Check operation of automatic louvers.
12. ☐ Repair minor fuel, coolant and lube oil leaks.
13. ☐ Check operation of jacket water heater(s).
14. ☐ Inspect generator, perform any routine maintenance as required.
    ☐ Megger
15. ☐ Inspect governor/actuator linkage.
16. ☐ Check battery electrolyte level and maintain to include:
    ☐ Temperature ☐ Specific Gravity ☐ Voltage
17. ☐ Check operation of charger and/or alternator.
18. ☐ Inspect fuel supply system for leaks or low level, inform owner of any discrepancies.
19. ☐ Drain condensation from day tank and check for any contamination. ONLY if day tank is equipped with a drain valve.
20. ☐ Check operation of transfer pump.
21. ☐ Check for correct generator output voltage & frequency, adjust if required.
22. ☐ Simulate & check operation of each safety shutdown and alarm device, relay type control panels only.
23. ☐ Check operation of generator control instrumentation; volts, amps, etc.
24. ☐ Test fault lamps & replace bulbs as required, panels with lamp test only.
25. ☐ Tank crankcase oil sample, owner to be notified of any discrepancies.
26. ☐ Submit report to owner
27. ☐ Auto start test.

Generator Operation:

- Can these generators run in parallel with the utility power sources? ❑ Yes ❑ No
- The generators are being used as: ❑ Backup source ❑ Peak shaving ❑ Prime source
- Are the generators properly protected against overload? ❑ Yes ❑ No abnormal conditions? ❑ Yes ❑ No or reverse power flow (if generators can run in parallel with utility source)? ❑ Yes ❑ No
- Can the generators automatically start? ❑ Yes ❑ No and automatically shut off? ❑ Yes ❑ No
- How many times did generator fail to start or break down (with unknown reason) during the last few years?_____

Maintenance:

- Does the generator operation log book exist and is it up to date? ❑ Yes ❑ No
- How often does the generator run for maintenance? _____times per week/month, ❑ with loads or ❑ without loads.
- How long did the generator run during each maintenance period? _____ minutes
- How often is the generator fuel system checked? _____times per week/month

Generator Grounding System:

- ❑ Solidly grounded ❑ High resistance ❑ Low resistance ❑ Reactance
- Measured ground impedance in ohms:_____
- Is the generator's neutral bus connected to ground? ❑ Yes ❑ No
- Is the generator frame connected to ground? ❑ Yes ❑ No

3-5.7 Spare Parts Lists.

Identify high-rate-of-mortality parts by historical experience. Ensure spare parts for each system of the generator is available for use when there is a need for replacement. Refer to the spare parts lists provided by the equipment manufacturer.

3-5.8 Service Contract Documents.

Describe typical service contract types and contract documents necessary to manage the service contract program if a service contract is utilized.

CHAPTER 4 OPERATIONS

4-1 OPERATING PROCEDURES.

4-1.1 Responsibilities.

There are levels of approval required for **any** changes to occur to generators. Know the changes, who/what it impacts, and obtain appropriate approvals before executing.

Know and ask advice from the appropriate SME.

\1\ Note: The Air Force will follow operations, maintenance, and testing requirements in Chapter 8. **/1/**

4-1.2 Fire Emergency.

Train operators on fire safety procedures. In fire emergencies, call the fire department and identify the specific fire emergency area.

4-2 AIR QUALITY PERMITTING.

Comply with UFC 1-200-01, *DoD Building Code (General Building Requirements)*, and agency-specific environmental regulations, restrictions, and specific applicable environmental guidance. In addition to the listed permitting activities herein, contact state and local environmental and development offices to verify additional permitting requirements. Maintainer/operator must coordinate with the local environmental office to ensure continued compliance with operating permits, especially when changes occur.

Obtain and maintain all required air permitting in accordance with the rules of the Clean Air Act (CAA) regulatory agency (federal or state/local/tribal) with delegated authority over the location of subject operations.

\1 [Note deleted] **/1/**

4-2.1 New Permits and Modifications to Existing Permits.

Initial permitting activities are accomplished during the design phase and prior to equipment installation. When changes are made to a unit (e.g., modified, remanufactured, relocated, and/or how it is used/operated), operators will immediately notify the appropriate environmental management office(s) that hold existing permit(s) of these changes and provide them with the necessary system information required to update those permits. This is necessary to ensure continued compliance with applicable federal, state, and local laws.

4-2.2 Changes.

Operational permitting is done during design and installation. Existing standby generators require additional permitting when operating hours exceed the permit. However, when changes are made to the unit or how it is used, the operators will immediately notify their office(s) that holds the existing operating permit(s) of these changes and provide them with the necessary system information required to update the operating permits. This will ensure continued compliance with applicable federal, state, and local laws.

4-3 COMPLIANCE MONITORING AND INSPECTIONS.

4-3.1 OSHA Compliance and Monitoring.

The generator must comply with the requirements and regulations of OSHA for personnel safety, including safe work practices.

4-3.2 Air Quality Compliance.

Generator engines must meet and maintain compliance with the requirements of federal, state, and local regulations and facility-specific permits. Air quality regulations/permits may specify monitoring, recordkeeping, and reporting requirements, as well as O&M frequencies/practices.

\1\ Note: The Air Force will follow operations, maintenance, and testing requirements in Chapter 8. **/1/**

4-3.3 Clean Water Act (CWA) Compliance and Monitoring.

Generators must comply with CWA regulations to prevent the spill of oil, petroleum, or other contaminants to the water.

4-3.4 Resource Conservation and Recovery Act (RCRA) Compliance Monitoring.

Generators are required by RCRA to properly control and manage hazardous waste.

CHAPTER 5 RELIABILITY MAINTENANCE-CENTERED PRACTICES

5-1 PURPOSE AND SCOPE.

This chapter provides guidance on typical preventive maintenance practices to keep generators in good performance.

5-2 PREVENTIVE MAINTENANCE ELEMENTS (TIME-BASED).

5-2.1 General.

Refer to manufacturers' manuals for maintenance and repair requirements, frequencies, and consumables specifications. On standby generators in locations without SCADA or communications links, the self-test alarm is not monitored. For these applications, or applications where there are no self-diagnostics on the relays, the relays should be tested every one to six years. The timespan is based upon the relay installation, atmosphere, debris, temperature, and humidity.

5-2.2 Load Bank Optimization.

Load banks are used for load optimization, allowing the generator to run at a higher load than needed for facility power to prevent engine damage to certain types of prime movers. Use load banks to augment facility load to optimize generator performance when the prime mover is operating at less than the manufacturer's minimum rated load for continuous operation.

5-2.3 Prime Mover (Engines).

Prime mover preventive maintenance activities are mandatory. These activities are required to ensure the prime mover reaches their expected life expectancy as they are an expensive and essential part of the generator set. Maintenance activities include the following:

5-2.3.1 Structures and Enclosures.

Check structures and enclosures for corrosion. For corroded areas, clean, prepare and apply corrosion-control treatment on affected surfaces to avoid further deterioration.

5-2.3.2 Power Takeoff Assemblies and Couplings.

Check for coupling alignment in accordance with manufacturer's maintenance schedule.

5-2.3.3 Bearing Lubrication.

Inspect and ensure the proper amount of grease on bearings and replace as required by the maintenance schedule.

5-2.3.4 Belt-Driven Equipment Checks.

Check misalignments on belt-driven equipment. Replace belts if damaged, as required.

5-2.4 Cooling System.

Dust can foul cooling passages, increase operating temperature, and negatively affect the generator's/engine's performance. Clean radiators of dust and debris. Use soft brush or cloth. Avoid damaging the fins. Use low-pressure air or water in the reverse direction from normal flow to clean the radiator.

5-2.4.1 Coolant Levels.

- Check the coolant levels during shutdown periods. Premix the coolant in a clean tank when replacing the coolant to an engine.
- Never add antifreeze directly into the engine cooling system.
- Avoid adding coolant to an overheated engine.
- Avoid adding coolant at a rate of more than 10 gallons per minute when filling and emptying the engine cooling system.
- Check heat exchangers. Poor coolant maintenance can result in heat exchanger damage.

5-2.4.2 Coolant.

Engines with wet liners are subject to liner pitting and pumps/seals are subject to failure if the cooling system is not properly maintained**.** Use the coolant recommended by the engine manufacturer.

The following are unacceptable coolant maintenance practices:

- Use of non-treated (distilled or de-ionized) water.
- Use of water alone as coolant.
- High or low concentrations of supplemental coolant additive (SCA).
- Use of anti-freeze or SCA that are high in silicates or do not meet original equipment manufacturer (OEM) specifications.
- Topping off coolant system without proper SCA.

5-2.4.3 Coolant Maintenance.

Perform the following coolant maintenance:

- Test the coolant a minimum of twice a year for freeze protection, coolant/water percentages, nitrite or SCA level, pH, visual color and appearance, and reserve alkalinity. Use a spectro-chemical test with results reported in parts per million (ppm) and SCA.
- Drain and replace coolant at intervals in accordance with the engine and/or coolant manufacturer's recommendation or when coolant analysis dictates replacement.

- When topping off, add coolant until the level is at the radiator cap's lower sealing surface.
- Store coolants out of direct sunlight and replace when shelf life has expired.

5-2.4.4 Air Intake/Ventilation Systems.

- Check for obstructions to cooling air lines or paths.
- Check for deterioration of cooling air ducts. This deterioration can lead to leakage of airflow, reducing its capacity.
- Check for dust and dirt of cooling air ducts.
- Check for loose or misaligned airline connections.

5-2.4.5 Coolant Pumps.

Inspect and maintain coolant pumps in accordance with maintenance schedule.

5-2.4.6 Engine Water Jacket Heaters.

Inspect engine water jacket heaters while in operation and observe for leaks at hoses, adapters, cylinder heads, pump seals, and block seals. Check for engine water jacket heater damage or deterioration. Inspect and maintain jacket water heaters in accordance with manufacturer's recommendations.

5-2.4.7 Valve Exercising.

- Verify correct position/alignment on valves.
- Check for leaking seals.
- Verify correct operation of valves.

5-2.4.8 Safety Relief Valve Tests.

- Check for leaks on safety relief valves and replace if leaks continue.
- Check that the safety relief discharge piping is working properly.
- Check that the safety relief valve opens at the acceptable pressure value.
- If the safety relief valve opens at a pressure below the acceptable range, it may indicate that the relief valve is in a deteriorated condition and requires replacement.
- If the safety relief remains closed, do not operate the system until the safety relief valve is completely replaced.

5-2.5 Lubrication System.

Maintain lubrication systems to comply with applicable standards and specifications.

5-2.5.1 Oil Level.

Ensure generator oil levels comply with the indications presented on the manufacturer's instruction manuals to keep the generator in good performance. Test the oil quality to determine oil level, conditioning, or replacement. For accurate readings on the dipstick, wait at least 10 minutes after shutting off the engine to allow the oil to drain to the bottom.

5-2.5.2 Oil Change.

- Replace oil according to the recommendations given by the manufacturer.
- Drain oil while warm.
- Test a sample of the drained oil to examine for fuel dilution, acidity, and the presence of solids and contaminants.
- Ensure oil change frequency is in accordance with manufacturer and environmental air quality regulatory requirements.

5-2.5.3 Oil Filter Change.

\1 Inspect oil filters periodically and replace when an accumulation of sludge or other contaminants is present. **/1/** The frequency is shown in Table 6.1.

5-2.5.4 Crankcase Breather.

Check crankcase breather each time the generator is taken down for maintenance to make sure it is not clogged and unusable.

5-2.5.5 Oil Leaks.

Check for oil leaks and follow the instructions of the manufacturer if oil leaks are found.

5-2.5.6 Gauges and Safety Mechanisms.

During maintenance, observe gauges and safety mechanisms and check fuel and temperature gauges to ensure proper operation.

5-2.6 Fuel System (Including Long-Term Fuel Storage).

Inspect and clean fuel systems. Remove contaminants such as dirt and sediments from tanks storing fuel to ensure proper engine operation. Test and analyze a sample of fuel taken from the storage tank to check for the presence of contaminants. One of these samples must include one sample taken from the inside bottom of the tank.

Note: For the Air Force, fuel testing should be coordinated with the Logistics Readiness Squadron (LRS) POL Fuels Lab.

5-2.6.1 Fuel Additives.

Check the proper levels of fuel additives in the system.

5-2.6.2 Fuel Filters.

Inspect and clean fuel filters as recommended by the manufacturer for identifying contaminants, sediments, or microorganisms.

5-2.6.3 Water/Condensate Removal.

Sample fuel from the fuel tank to detect the presence of water. Fuel and water tend to separate and water will sink to the bottom of the container. Remove water accumulation from storage fuel tanks with the provision and use of drain valves.

5-2.6.4 Fuel System Components.

Check fuel oil components such as fuel hoses, fuel pipes, fuel filters, injector pumps, etc. If damage to these components is encountered, replace following the instructions provided by the manufacturer. Make sure the lines are not rubbing against anything that could cause an eventual failure. Immediately repair any leaks or alter line routing to eliminate wear.

5-2.6.5 Gauges and Safety Mechanisms.

Check for accuracy on fuel level gauges and repair gauges as required.

5-2.6.6 Fuel Pumps.

Fuel pumps must be maintained to deliver sufficient fuel and sustain a satisfactory combustion to operate the generator. Fuel pumps must be cleaned by removing contaminants such as dirt, sand, and water.

5-2.6.7 Fuel Storage Tank Maintenance.

Clean and inspect fuel storage tanks every 10 years in accordance with API Standard 2015, *Requirements for Safe Entry and Cleaning of Petroleum Tanks*.

Drain tanks of water monthly to minimize corrosion of the inner tank surface. Bacterial growth in diesel fuel will be a problem in warm areas. **\1** Test fuel for contamination and polish as required if fuel is not used within three months. **/1/**

\1 [Note deleted.] **/1/**

5-2.7 Air Intake Systems.

5-2.7.1 Air Filters.

Prior to removing the intake air filters, remove accumulations of dirt from the air filter housing. Remove air filters and wipe to remove excess dust and dirt. Replace intake air filters per recommendations of the manufacturer.

5-2.7.2 Unlined Expansion Joints.

Inspect unlined expansion joint belts for cuts, worn sections, and cracks. Replace belts that are excessively worn and have cracks. Repair or replace belts with cuts per manufacturer's instructions. Inspect backing bars, mating flanges and hardware for corrosion. Refer to manufacturer's instructions for corrosion repair. Check fastener torque and re-torque to manufacturer's recommendations, as appropriate.

5-2.7.3 Unlined Duct.

Clean duct and check for corrosion and signs of water and air leakage. For paint, corrosion repair, and gasket replacement, refer to manufacturer's instructions.

5-2.7.4 Silencer Duct.

Clean duct and check for corrosion and signs of water and air leakage. For paint, corrosion repair, and gasket replacement, refer to manufacturer instructions.

Check acoustic insulation lining for water damage, corrosion, and cracking. For repair, refer to manufacturer's instructions.

5-2.7.5 Acoustically Lined Duct.

Clean duct and check for corrosion and signs of water and air leakage. For paint, corrosion repair, and gasket replacement, refer to manufacturer's instructions. Check acoustic insulation lining for water damage, corrosion, and cracking. Check access hatches and maintenance ports for air-tight seals. For repair, refer to manufacturer's instructions.

5-2.7.6 Trash Screens.

Inspect screen and framework for damage, including broken wires and missing screens. Replace damaged screens and tighten loose wires. Check screen frame and screen holder for corrosion. For repair, refer to manufacturer's instructions.

Check screen for deflection using hand pressure. If deflection is greater than 4 inches (100 mm), replace screen.

5-2.7.7 Expansion Joints.

Inspect expansion joint belts for cuts, worn sections, and cracks. Replace belts that are excessively worn and have cracks. Check manufacturer’s repair instructions for cracked belts as this typically indicates a system malfunction or alignment problem. Repair or replace belts with cuts per manufacturer’s instructions.

Inspect backing bars, mating flanges, and hardware for corrosion. Refer to manufacturer’s instructions for corrosion repair. Check fastener torque and re-torque to manufacturer’s recommendations, as appropriate.

5-2.7.8 Inlet Plenum and Cone.

Inspect and repair inlet plenum per manufacturer’s instructions.

5-2.8 Exhaust System.

Exhaust systems need to be maintained to keep the generator in good performance. Check for leaks at all connections, welds, gaskets, and joints. Make sure the exhaust systems are not heating the surrounding areas more than normal. Check for excessive smoke upon starting; this indicates air quality problems.

5-2.8.1 Air Induction Piping.

Exhaust system piping of generators must have suitable devices to prevent the entry of water from rain.

5-2.8.2 Turbochargers and Blowers.

Clean and maintain turbochargers in accordance with manufacturer’s recommendations.

5-2.8.3 Exhaust Manifolds.

Check exhaust manifolds for rust and corrosion.

5-2.8.4 Emissions System and Controls.

Maintain emissions system controls (e.g., catalytic oxidizers, exhaust particulate filters) and monitoring devices (e.g., continuous emissions monitoring systems) in accordance with manufacturer’s and environmental regulations/requirements. Manufacturer's instructions should be consulted for procedures specific to each model. Contact the environmental compliance office when problems are identified.

5-2.9 Generator Components.

Accomplish generator inspection, maintenance, and service in accordance with manufacturer’s requirements, environmental regulations/requirements, and/or recommendations or applicable technical orders. Listen and look for changes in performance or sound. Misfires and changes in oil consumption indicate service will be required.

There may be regulatory maintenance and maintenance recordkeeping requirements that vary greatly from engine to engine, according to whether the engine is:

- New or existing
- Located at an area source or major source of hazardous air pollutant (HAP) emissions
- A compression ignition or a spark ignition engine; include requirements associated with 40 CFR Part 63 Subpart ZZZZ, 40 CFR Part 60 Subpart JJJJ, and 40 CFR Part 60 Subpart IIII

5-2.9.1 Stator and Rotor Windings.

Clean stator and inspect the following items:

- Check coil ends for distortion or movement.
- Check damaged, missing, or broken wedges. Wedges that have lifted in the dovetail or have been burned must be replaced.
- **\1** Open, check, and clean cooling passages. **/1/**
- Check security of lashing and spacers.
- Check tightness of coil supports.
- Check partial discharge activity and other damages to coil insulation, including end windings and in the slot.
- Check connections between coils.
- Measure insulation resistance between winding and ground at the machine terminals.

Clean rotor and inspect the following items:

- Check clearance between blower and coils.
- Check damper winding for loose bars.
- Check proper connection between each bar and its ring segment.
- Check connections between field coils and collector rings.
- Check field coils for separation or movement.
- Clean oil and dirt from air passages and winding.
- Measure resistance between field coils.
- Check damaged bearings and journals.
- Check for insulation damages.

- Measure vibration limits at starting.

Refer to manufacturer's manuals for instructions on stator and rotor maintenance and repairs, and frequencies. Note that the intent is to follow manufacturer's instructions. Small units call for a much less stringent set of inspections.

5-2.9.2 Brushes.

Typical preventive maintenance practices on brushes are the following:

- Check brush faces for heat cracks and replace if damaged.
- Check for loose brush studs.
- Check brush shunts to ensure they are properly secured to the brushes and holders.
- Check that the brushes are resting at the correct angle and in the neutral plane.
- Ensure brushes are properly spaced on the commutator and brush holders are properly spaced from the commutator.

Refer to manufacturer's manuals for instructions on brush maintenance and repairs, and frequencies. Note that the intent is to follow manufacturer's instructions. Small units call for a much less stringent set of inspections.

5-2.9.3 Collector Rings.

Typical preventive maintenance practices on collector rings are the following:

- Clean collector rings using a solvent cleaner and a stiff brush.
- Check insulation resistance between ring and shaft for defective bushings and collars.
- Check brush holder endplay to prevent grooving of collector rings.

Refer to manufacturer's manuals for instructions on collector rings maintenance and repairs, and frequencies. Note that the intent is to follow manufacturer's instructions. Small units call for a much less stringent set of inspections.

5-2.9.4 Commutators.

Typical preventive maintenance practices on commutators are the following:

- Check commutator surface for grooving, scratches, or roughness.
- Check commutator concentricity with a dial gauge.
- Remove every trace of carbon, copper, or dust when the commutators are being cleaned.

Refer to manufacturer's manuals for instructions on commutators maintenance and repairs, and frequencies. Note that the intent is to follow manufacturer's instructions. Small units call for a much less stringent set of inspections.

5-2.9.5 Sleeve Bearings.

Typical preventive maintenance practices on sleeve bearings are the following:

- For old sleeve bearing types, the oil needs to be replaced at least every year.
- Check the oil level for new sleeve bearing types.
- Check that bearing insulation is not short-circuited by bearing temperature detectors or by lubricating oil piping. Bearing insulation is important to eliminate bearing circulating currents, preventing pitting of the shaft and bearing.

Refer to manufacturer's manuals for instructions on commutators maintenance and repairs and frequencies. Note that the intent is to follow manufacturer's instructions. Small units call for a much less stringent set of inspections.

5-2.9.6 Ball and Roller Bearings.

Typical preventive maintenance practices on ball and roller bearings are the following:

- The bearing housing and bearing itself should be greased. Check the condition of the bearings and grease. Clean and add grease as needed.
- Follow manufacturer's manuals for recommendations regarding the type and quantity of lubricant/grease to be applied. Note that the intent is to follow manufacturer's instructions. Small units call for a much less stringent set of inspections.

5-2.9.7 Insulation Structures.

Typical preventive maintenance practices on insulation structures are the following:

- All insulation structures clogged with mud from weather events must be washed with pressure water not exceeding 25 psi (172.4 kPa), unless otherwise noted on the manufacturer's instruction manual.
- Dry all electrical insulations at 185 °F (85 °C) for four hours, followed by 225 °F (105 °C) to 248 °F (120 °C) for another four hours, unless otherwise noted on the manufacturer's instruction manual.
- After drying, measure winding insulation resistance with an insulation test instrument. The measurements must be in accordance with the insulation levels presented in IEEE 43, *IEEE Recommended Practice for Testing Insulation Resistance of Electric Machinery*.

5-2.10 DC Electrical System.

Check circuit breakers and exercise breakers. Check wiring for loose connections and perform an insulation test of all wiring.

5-2.10.1 Battery Electrolyte Level/Specific Gravity.

Typical preventive maintenance practices on insulation structures are the following:

- Inspect storage batteries, including electrolyte levels, every week and maintain by following the manufacturer's instructions.
- Check electrolyte levels before water is added by following the manufacturer's recommendations. Excessive water consumption can be an indication of overcharging, cell damage, or aging.
- Test and record monthly the lead-acid battery electrolyte specific gravity.
- Perform battery discharge tests a maximum of twice a year. This is also called load testing or capacity testing in some locations.

5-2.10.2 Battery Compartment.

- Inspect battery compartment damage as a result of vibration.
- If vibration is observed, isolate the batteries from vibration by following the manufacturer's prescribed procedures.

5-2.10.3 Battery Connections.

- Check battery interconnections for tight connections and corrosion.
- Clean and torque battery terminal connections.

5-2.10.4 Battery Charging System.

- Verify battery chargers' output voltage minimum of once per month.
- Check battery charger cable interconnections and cell connectors.
- Check for dirt, wear, and corrosion.
- Maintain battery chargers following the manufacturer's recommendations.

5-2.11 AC Electrical System.

Check relays and cable as scheduled and perform cable testing on medium-voltage cables every three years.

5-2.11.1 Voltage Regulator.

Follow manufacturer's instructions for maintenance of voltage regulators.

5-2.11.2 Control Panel.

Open up the control panels, look for corrosion, and dust, and perform an infrared (IR) scan of the inner equipment. Clean where necessary. Ensure the control system is logging data (where required).

5-2.11.3 Switchgear.

- Check for switchgear conditions causing carbon tracks.
- Check for damaged barriers and shutters.
- Perform insulation resistance tests (phase-phase [p-p] and phase-ground [p-grnd]) with the use of a megohmmeter.
- Check for discoloration of circuit breaker conductors, indicating overheating.
- Test circuit breaker contacts for opening and closing sequences.
- Test for alarm condition activation of switchgear alarms (if equipped).
- Consult manufacturer’s recommendations.

5-2.11.4 Automatic Transfer Switches (ATS).

Perform the following monthly, according to NFPA 110:

- Inspect, operate and lubricate mechanical linkages.
- Verify mechanical interlocks operation.
- Test switch performance and operation by manually initiating transfers in both directions.
- Verify correct indication light operation.

Consult manufacturer’s recommendations.

5-3 PREDICTIVE MAINTENANCE ELEMENTS (CONDITION-BASED).

5-3.1 General.

Refer to manufacturers’ manuals for maintenance and repair requirements, frequencies, and consumables specifications.

Note: The Air Force will follow requirements in Chapter 8.

5-3.1.1 Visual Inspections.

Perform visual inspections for every generator system as indicated in Figures 3-1 and 3-2.

5-3.1.2 Application and Scanning.

- Electrical and mechanical systems
- Electrical components
- Corrosion damage

5-3.2 Electrical and Mechanical Systems.

5-3.2.1 Electrical Components.

All switchgear, transformer connections, switchgear connections and panelboards should be IR scanned on a programmed basis based on available resources.

5-3.2.2 Corrosion Damage.

Remove any corrosion damage to base metal. Prime and paint with the same paint originally recommended by the manufacturer.

5-4 GENERATOR LOAD TESTING.

When load testing, use facility loads first and load banks as secondary loads only. Load banks should only be used when facility loads are insufficient to bring the generator to the required level of load/temperature.

This Page Intentionally Left Blank

CHAPTER 6 TYPICAL INSPECTION AND MAINTENANCE SCHEDULES

6-1 PURPOSE AND SCOPE.

Follow manufacturer's maintenance schedules, as modified by generator loading.

6-2 PREVENTIVE MAINTENANCE (PM) SCHEDULES.

See Table A-1 for sample PM schedule.

6-3 PREDICTIVE MAINTENANCE SCHEDULES.

Provide typical predictive inspection and maintenance schedules and guidance—broken down by hourly, daily, weekly, monthly, and annually—for generator systems and components in table format (refer to Table 6.1 as an example). Review EPA regulations to ensure EPA-required O&M frequencies/practices for key systems have been incorporated into inspection and maintenance. Ensure requirements in 40 CFR Part 63 Subpart ZZZZ, 40 CFR Part 60 Subpart JJJJ, 40 CFR Part 60 Subpart IIII, and 40 CFR Part 89 are not violated (when applicable, based on generator age and location).

Emergency power supply systems (EPSS) should follow the maintenance schedule described in Annex A of NFPA 110 and Figure A.8.3.1(a) of that Annex.

Table 6-1 Typical Generator Maintenance Schedule

	Service Time		
Maintenance Items	**Monthly**	**6 Months**	**Yearly**
Visual inspection	X		
Check coolant heater	X		
Check coolant level	X		
Check oil level	X		
Check fuel level	X		
Check charge-air piping	X		
Check/clean air cleaner	X		
Check battery charger	X		
Drain fuel filter	X		
Drain water from fuel tank	X		
Check coolant concentration	X		
Check drive belt tension	X		
Drain exhaust condensate	X		
Check starting batteries	X		
Change oil and filter		X	
Change coolant filter		X	
Clean crankcase breather		X	
Check radiator hoses		X	
Change fuel filters		X	
Clean cooling systems			X

CHAPTER 7 PRIME POWER

7-1 GENERAL REQUIREMENTS.

The maintenance of the generator includes all associated generator systems, including cables, prime movers, and ancillary equipment. This chapter covers additional prime power considerations in addition to the requirements of the previous chapters.

7-2 CERTIFICATION OF GENERATOR WORKERS.

Turbine generator and power plant operators must have a valid power engineer's license or DoD plant operator license issued by the National Institute for the Uniform Licensing of Power Engineers, Inc. (NIULPE) (http://www.niulpe.org/certification.shtml) or an approved internationally recognized third-party certification agency. This licensing is only required for a power plant connected to the grid and **not** standby generators.

7-3 COMBUSTION TURBINE ENGINE.

Combustion turbine engines use a jet engine to burn fuel with the exhaust gases rotating a turbine generator. The major components of combustion turbine engine requiring maintenance typically include:

- Air intakes
- Compressors
- Combustors
- Turbines
- Afterburners
- Nozzles
- Cooling system
- Fuel system
- Starting system
- Ignition system
- Lubrication system
- Control system

7-4 GASEOUS FUELS.

Gaseous fuel systems components requiring maintenance include:

- Storage system (if not direct utility provided)
- Regulating stations and relief devices
- Automatic shutoff devices

- Coalescing filters
- Gas fuel heating system
- Gas fuel scrubber
- Corrosion control system

7-5 FUEL OIL.

Fuel oil system components that typically require maintenance include:

- A fuel receiving station(s) from either a truck, train, ship, or pipeline, or combination thereof
- Bulk storage system (above ground and below ground)
- Day tanks
- Transfer pumps
- Fuel maintenance (filtration) system
- Fuel coolers
- Supply and return piping system
- Corrosion control system
- Leak detection systems
- Control system

7-6 LUBRICATING SYSTEMS – GAS TURBINE ENGINES.

The typical components for a gas turbine engine requiring maintenance include:

- Tanks
- Pressure pumps
- Scavenger pumps
- Filters
- Oil coolers
- Relief valves
- Breathers and pressurizing components
- Pressure gauges and instrumentation
- Temperature regulating valves
- Oil-jet nozzles
- Magnetic chip detectors
- Tubing, hose, and fittings

7-6.1 Oil Analysis.

Test generator oil on a recurring maintenance schedule. General and physical tests are suggested twice a year.

7-6.1.1 Oil Sampling Technique.

Oil sampling in generator engines should be taken at the following sampling points and sealed:

- Through dipstick holder
- Sample valve on crankcase sump wall
- Return line before filter

7-6.1.2 Chemical and Physical Testing.

Perform chemical and physical testing for every generator system as specified in Figure 3-1.

7-6.2 Ultrasonic Scanning.

Check if weld leaks are detected in the lines or corrosive liquids are carried through the lines. Perform this validation at least once every five years.

Scanning welds requires a high level of operator training. It is recommended a third party be contracted to perform these inspections if in-house expertise is not available.

7-6.3 Weld Inspection.

Physically inspect welds to verify no cracks or corrosion are occurring on the welds for piping not ultrasonically tested. These should be examined every five years.

7-6.3.1 Instrumentation, Transducers, and Transformers.

Ensure calibration cycles are:

- As recommended by the manufacturer of the instrument;
- One year for electrical, electronic and mechanical test equipment or three years for mechanical test equipment made of solid materials not subject to deterioration.

Calibration intervals may be extended based on the following conditions and the reasons must be documented:

- Passive electrical test equipment, such as current shunts, current transformers, and potential transformers, may be extended to three years with good results for the initial calibration period and if not subject to severe-use conditions.

- Where there is sufficient calibration data to statistically establish a trend of the test equipment to assure good measurement results for a longer period.

7-6.3.2 Scanning Analysis.

After the test data is gathered, this data should be compared to earlier testing data to determine any changes. Data showing corrosion or high resistances must be addressed.

7-6.3.3 Application and Technique.

Items to look for when analyzing data include:

7-6.3.3.1 Applications.

- Surface breaking cracks
- Metal thinning
- Tube inspection
- Conductivity
- Thickness

7-6.3.3.2 Scanning.

- Multi-frequency
- Swept frequency
- Pulsed
- Remote field
- Impedance matching

7-6.3.4 Equipment and Probes.

The equipment for scanning is called a multi-frequency probe. It is hand-held, with ultrasonic scanner diagnostics. Other probes, such as pulsed and impedance matching, remote field, etc., can be found from the same manufacturers that produce other ultra-frequency scanners.

7-6.3.5 Inspection Analysis.

Inspection analysis can usually be gathered directly from the scanner or it can be available through a software application with input from the scanner.

7-6.4 Steam Turbine System.

There are two main types of steam turbines: superheated steam and saturated steam. In a saturated steam turbine, the increased moisture in the steam path accelerates blade erosion, diminishes efficiency, and requires a water removal system in the saturated steam inlet lines. The more complex saturated steam systems have increased maintenance requirements.

7-7 PRIME COOLING SYSTEMS.

7-7.1 Stator Cooling Systems.

On very large units (over 40 MW), there may be a stator cooling system. The stator cooling system maintains the stator bars and screen plates within operating temperature range using demineralized cooling water. Ensure the system operates at a pressure lower than the hydrogen seal pressure, filters particulates that can plug or damage the stator tubes, and the demineralized make-up water system provides required make-up water due to loss or leaks. Also, ensure the leak detection system is operating within the manufacturer's operating parameters and venting to atmosphere is provided for over-pressure of hydrogen gas.

Ensure the generator hydrogen seal oil system operates under all conditions and maintains the seal oil at correct operating temperatures and differential pressure.

7-7.1.1 Stator Water Cooling System.

Stator water cooling system components typically requiring maintenance include:

- Demineralized water system
- Pumps
- Emergency pump
- Water cooler
- De-oxygenating unit
- Strainer
- Resistance columns
- Gas detraining chamber

7-7.1.2 Stator Hydrogen Cooling System.

Hydrogen cooling system components typically requiring maintenance include:

- Gas supplies
- Hydrogen dryer
- Hydrogen gas analyzer

- Centrifugal fans
- Hydrogen coolers
- Seal oil pumps (AC and DC)
- Seal oil pump pressure control valve
- Seal oil loop seal
- Seal oil cooler
- Filters
- Detraining chamber
- Gas trap
- Bearing seals
- Hydrogen dryer
- Air scavenging
- Purity monitor
- Stator coolant system (strainers, demineralization plant, flow measurement instrumentation, gas alarm and automatic release chamber, and gas detraining chamber)

7-8 INTAKE AIR MAINTENANCE.

7-8.1 Gas Turbine Intake Air.

For gas turbine engines, the consequences of poor inlet filtration are more significant with foreign object damage, erosion, fouling, particle fusion, or corrosion of the compressor fans. As such, gas turbine air filtration systems typically use multiple stages of weather protection, inertial separators, pre-filters, coalescers, and final filters.

7-9 SPECIALTY TOOLS AND EQUIPMENT.

Consider acquiring and using the following specialty tools and equipment:

- Lube oil flush system
- Coolant flush system
- Valve and bearing inspection tools
- Exhaust analyzer
- Remote racking mechanisms for switchgear circuit breakers (Several manufacturers provide remote racking mechanisms that allow the electrical worker to stay well outside the arc flash boundary during circuit breaker racking operation.)

- Remote switching actuators for circuit breakers (Enables remote circuit breaker operation [open or close].)
- Thermal imaging cameras
- Power quality data loggers (For evaluating normal system parameters, such as voltage, current, power factor and harmonic distortion, as well as evaluating abnormal events, such as voltage swells, sags, or outages.)
- Wet/dry hot stick tester
- Fault locating equipment

7-10 TOOL SAFETY

7-10.1 Energized Lines.

The methods used when working on energized lines, such as gloving, use of hot line tools, and provision of electrically insulated buckets, will be in accordance with the applicable services' safety manuals. Safety rules governing the use of such tools and equipment are given in these manuals and in applicable OSHA regulations, 29 CFR 1910 and 29 CFR 1926.

7-10.1.1 Climbing Equipment.

When generators/equipment are over 6 feet (1.8 meters) in height, climbing equipment must be used if there are no permanent ladders and walkways. Climbing equipment includes body belts, safety and climber straps, climbers, and ladders. Refer to 29 CFR 1926.501 for OSHA details. Use personal fall arrest systems in accordance with 29 CFR 1910.269(g)(2)(iv)(B) and 1926.502(d).

7-10.2 Insulating Hydraulic Fluid.

An insulating-type hydraulic fluid is required in all hydraulic hand tools used on or near energized lines and in insulated sections of aerial lift trucks. Hazardous material procedures must be followed when dealing with such substances.

7-11 POWR PLANT OPERATIONS.

7-11.1 Load Shedding.

Load shedding should be the deliberate and selective dropping of electrical load in accordance with a preplanned program specific to a base. There must be a plan to load-shed circuits that minimizes impact to critical loads.

7-11.2 Methods of Load Shedding.

To have proper load shedding, a prioritized load-shedding program must be established and implemented. This scenario arises most often when loads are added after the initial installation. The criteria for load shedding are primarily frequency based, and must occur when the frequency drops below 56.6 Hz for diesel reciprocating units and 58 Hz for turbines.

7-11.3 Requirements for Load Reduction.

A scenario could involve an isolated plant (not interconnected with a utility), with several generating units loaded at or near their combined capability. Should one unit trip, the remaining units would experience a sudden load increase, possibly leading to loss of the plant.

7-11.4 Total Load Reduction.

The load-shedding plan must accomplish a total load reduction sufficient to relieve the plant overload and provide a slight underload so the plant will have reserve capacity to reaccelerate to the normal operating frequency. One must also consider the loss of capacity that results from under-frequency operation.

7-11.5 Methods of Load Shedding.

There are many methods of load shedding, both automatic and manual. The automatic methods include under-frequency relaying and various transfer-trip arrangements. All of these methods have relative advantages and disadvantages and the choice of the most advantageous method should be based on the specific conditions that prevail. However, load shedding by under-frequency relaying is the most common and generally the preferred method.

7-11.6 Electrical Usage and Criticality.

In general, the least-critical loads should be tripped first and the load-shedding should proceed in stages, with progressively more critical loads being shed at each stage. The following provides guidelines for the determination of the relative criticality of loads.

7-11.6.1 Critical Loads.

To develop a load-shedding plan, identify the critical loads first along with an estimate of the magnitude of each. Design the load-shedding plan so the critical loads are shed last. In some cases, it may be necessary to divide the critical loads into two or more categories and assign relative priorities to each category.

7-11.6.2 Mission-Critical Loads.

Mission-critical loads are loads essential for the operation of the facility and broader agency mission support. If these loads are shed, they would adversely affect the facility mission, national security, critical communications, the warfighting mission, or base security.

7-11.6.3 Life Support Loads.

Life support loads include hospitals and similar high-occupancy facilities where loss of power may endanger life.

7-11.6.4 Time-Critical Loads.

In many cases, load criticality will vary with time. Take time variations into account when designing the load-shedding plan.

7-11.6.5 Seasonal Variations.

In a severely cold climate, a load related to providing heat could be considered critical during the winter and noncritical during the summer. Under the same conditions, the power supply to a frozen food storage facility could be considered critical during the summer and non-critical during the winter.

7-11.6.6 Diurnal Variations.

The criticality of some loads may vary from day to night or from weekday to weekend because of changing usage. Examples may include auditoriums, theaters, and offices.

7-11.6.7 Interruptible Loads.

Some loads can withstand short interruptions but not lengthy interruptions. Examples may include community facilities with emergency (battery-powered) lighting. These loads can be classified non-critical for load shedding but could also be given a high priority for load restoration.

7-11.7 Stable Operation and Overload Capability.

Generating plants are highly sensitive to frequency drop. There are two major problem areas: motor speed and turbine blade fatigue.

7-11.7.1 Operating to Avoid Turbine Blade Fatigue.

The last rows of long, low-pressure blades in steam turbines are tuned to operate free of resonance in a narrow band of frequencies around 60 Hz. When running under heavy load at about 58.5 Hz or below, the steam excitation frequency approaches blade resonance. Under this condition, the blades may vibrate severely, producing fatigue stress. On average, blades should not be subjected to more than ten minutes of severe vibration total over their lifespan, as fatigue is cumulative. Operation below about 58.0 to 58.5 Hz should be avoided; the generator protective devices may trip the unit in this speed range, regardless of load. This is not applicable to emergency generators.

7-11.7.2 Motor Speed.

Motor-driven auxiliaries will slow down, reducing generator output. Safety margins in generator-cooling and bearing lubricating systems will be reduced. The lowest safe plant operating speed will depend on the safety margins included in the plant design. However, operation below the 56.6 to 57.5 Hz range is generally not advisable.

7-11.7.3 Other Implications.

In some cases, the selection of critical loads must be made on a purely subjective basis, considering the effect on the community of providing power or of not providing power to a specific load during a widespread power failure.

7-12 OPERATIONAL CONSIDERATIONS.

7-12.1 Isolated Operation.

Under isolated operation, the generator operates independently of the electric utility and provides all electricity and steam needed and used by the facilities that it serves.

7-12.2 Base Loads.

Under base load electric operation, the cogeneration equipment is sized and installed to generate electricity at a constant (base) load equal to the minimum annual (or some other period) electrical demand.

7-12.3 Alternate Energy Sources.

Variable renewable energy sources do not operate in parallel with mission-critical generation.

7-13 POWER PLANT OPERATIONS.

7-13.1 Power Plant Supervisors.

Power plant supervisor's and operator's responsibilities are set by each Service.

7-13.2 Work Schedule

Work in three shifts, 24 hours per day, all year. Schedule maintenance shifts, one shift or two, based upon size of the facility and have an on-call program to call maintenance personnel in case of an emergency.

7-13.3 Dead Plant Start-Up.

To start up power plants that are in the dead state, the operator must:

1) Ensure all loads to external switchgear are disconnected.
2) Ensure there is air for starting air-operated generators or battery power for generator starting.
3) If air or battery power is not available, start the black start generator manually if it has not started automatically. Energize lighting, fuel pumps, lube oil, and controls from the black start bus.

4) If there is no black start generator, use utility power to provide power to the plant controls, fuel pumps, lube oil, and lighting.

5) Once the black start bus has been energized, and all controls are activated, the prime power generator may be started. Start by making sure the fuel pumps, lube oil, and controls are operational. When this generator is started and running, energize the main bus and then synchronize to either the utility or another generator.

6) After one or more generators have been energized, pick up loads one-by-one and add onto the generator.

7) When all loads have been picked up and the power plant is operating in normal mode, shut down the black start generator and prepare it for the next occurrence.

7-13.4 Power Outage.

Ensure scheduled outages are communicated to all affected parties. Communicate unscheduled outage information to all applicable parties as soon as possible. Include the reason for the outage and, if the plant has not been re-started, an estimated plant restart time.

7-13.5 Emergency Plant Shutdown.

Emergency plant shutdown procedures are required for potential abnormal operating conditions, fire, or other natural event that may occur and damage or disrupt facility power generation. Ensure approved emergency plant shutdown procedures are readily available in the main plant control room and the procedures have clear roles and responsibilities for plant personnel duties. The procedures must ensure the following:

- Plant shutdown without injury to personnel, damage to equipment, and damage to the environment
- Minimum environmental emissions
- Protect equipment from over-pressure or over-temperature damage

7-13.6 Micro-Grid Operation.

The Department of Energy defines a micro-grid as, “A group of interconnected loads and distributed energy resources (DER) with clearly defined electrical boundaries that act as a single controllable entity with respect to the grid [and can] connect and disconnect from the grid to enable it to operate in both grid connected or island mode.” Only use micro-grid operations when feasible and when they do not interfere with mission-critical standby/emergency generators according to Service guidance and policy.

7-13.6.1 Island Mode.

There are three events to cause a transition to island mode:

- Emergency situation when a utility outage occurs and sufficient generation is available
- Black start when an outage occurs and sufficient generation is **not** online
- Planned island mode required due to combat situations, forecasts in unfavorable weather, and economic situations

7-13.6.2 Typical Island Mode Operational Sequence.

The typical operator actions for the island mode operations sequence include:

1) Operator finds out about an emergency.
2) The plant is islanded from the utility using breaker controls.
3) Additional generators are started to have rolling reserve capacity.
4) Enable load restoration of shed loads if any have been shed when emergency disconnect occurred.
5) If the emergency has passed, make sure that frequency and voltage in island operations are within tolerance ranges.
6) Re-synchronize, when possible.

7-14 OPERATIONAL PERMITTING.

See NERC Standard PRC-005-2, *Protection System Maintenance Program*, as appropriate for large systems over 75 MVA in total or 20 MVA individually.

7-14.1 Wastewater Discharge Permit.

As appropriate, obtain a National Pollutant Discharge Elimination System (NPDES) permit in accordance with the Clean Water Act (CWA). Renew the permit every five years or per the requirements of the issuing authority.

7-14.2 FAA Permit.

For prime power facilities located in the flight path of airports and heliports, obtain FAA permitting for exterior maintenance activities that exceed the height of existing facilities, could affect flight operations, or the stack height changes. Consult the FAA Obstruction Evaluation/Airport Airspace Analysis (OE/AAA) (https://oeaaa.faa.gov/oeaaa/external/portal.jsp). This process should start with the nearest FAA Airports Regional Office. This is covered under 14 CFR 77, *Safe, Efficient Use, and Preservation of the Navigable Airspace*.

7-14.3 Incidental Take.

Obtain permits and retain compliance records required under the Endangered Species Act of 1973 for activities that may "take" (kill) native threatened or endangered species. Contact the nearest U.S. Fish and Wildlife Service (USFWS) Ecological Services Office to determine if the proposed facility is likely to result in a take, whether a permit is required, or if other options require consideration. Obtain an Incidental Take Permit in accordance with 50 CFR Part 13 and 50 CFR Part 17.

7-15 PREVENTIVE MAINTENANCE.

Table 7-1 provides a typical prime generator maintenance schedule. Review EPA regulations to ensure EPA-required O&M frequencies/practices for key systems have been incorporated into inspection and maintenance. Ensure requirements in 40 CFR Part 63 Subpart ZZZZ, 40 CFR Part 60 Subpart JJJJ, 40 CFR Part 60 Subpart IIII, and 40 CFR Part 89 are not violated (when applicable, based on generator age and location).

7-15.1 Corrosion Control.

Prime power plants have elements that can fail due to corrosion and cause equipment failure or create a life safety risk. Preventive maintenance must include corrosion control for the following elements: boilers, steam drums, feed water heaters, super heater, turbine, pipes, cooling tower, and structural supports.

Table 7-1 Typical Prime Generator Maintenance Schedule

Item/Component	Action					Frequency					
	Visual Inspection	Check	Change / Replace	Clean	Test	Daily	Weekly	Monthly	Quarterly	6 Months	Yearly
Prime Mover											
General Inspection	X						X

Power factor					X						X

7-16 BAGHOUSE LEAK DETECTION AND PERFORMANCE MEASUREMENTS.

7-16.1 Inspection.

Each sensor should be inspected at regular intervals to remove any buildup of material that may collect on the probe or insulator. A buildup of material on the probe may dampen or decrease the signal strength and material on the insulator can form a conductive electrical bridge across the insulator, increasing the signal strength and resulting in a high alarm.

7-16.2 Trial Period.

An initial 30-day trial period is recommended to verify the setup of the instrument is appropriate in order to prevent frequent false alarms and ensure the instrument has sufficient detection capability. Another reason such a trial period is recommended is to verify the system selected will perform reliably in the application and the environment to which it is exposed. Some monitors may have higher sensitivity upon initial installation but over a period of several days will stabilize and remain repeatable. The monitor lacks the ability to compensate for a buildup of particulate on the probe, so conditioning the system to the process environment is critical to reliable and repeatable operation.

After the sensitivity, response time, alarm levels, and alarm delay (if applicable) have been set and undergone the 30-day trial period, they should not be readjusted unless normal process conditions change in a manner that affects the characteristics of the particles or exhaust gas stream, such as:

- Change out of filter bags, repair of leaks, or other process improvement that would reduce particulate emissions.
- Slow drift of signal due to environmental factors such as humidity. If the sensitivity drifts more than -50 to 100 percent from the initial setup, the monitoring system and control device should be inspected and any necessary repairs performed.
- Equipment is taken out of service for repair, replacement, or upgrading.

7-17 SPECIALIZED INSPECTIONS (GAS TURBINE ONLY).

7-17.1 Borescope Inspection.

Conduct a borescope inspection of all compressor stages, buckets, and nozzles annually for natural gas and distillate fuels or semi-annually for heavy fuel oils. Inspect for signs of excessive gas path fouling, symptoms of surface degradation (such as erosion, corrosion, or spalling), displaced components, deformation or object damage, material loss, nicks, dents, cracking, indications of contact or rubbing, or other anomalous conditions.

7-17.2 Hot Gas Path Inspection.

Conduct an inspection of the turbine hot gas path at intervals recommended by the manufacturer (typically 24,000 hours) in accordance with the manufacturer’s O&M manual requirements.

- Inspect condition of nozzles, nozzle seals and hook fits, diaphragms, and diaphragm packings.
- Inspect bucket seals and cutter teeth on tip shroud buckets.
- Inspect turbine rotor and compressor.
- Inspect turbine shell.

7-17.3 Major Inspection.

Conduct a major inspection of the gas turbine at intervals recommended by the manufacturer (typically 48,000 hours) in accordance with the manufacturer’s O&M manual requirements. Inspection includes hot gas path inspection items and the following:

- Inspect casings, frames, and diffusers.
- Inspect compressor inlet and compressor flow paths.
- Inspect rotor and stator compressor blades and check tip clearance.

- Conduct a non-destructive inspection (NDI) of turbine buckets and wheel dovetails.
- Inspect bearings, liners, and seals.
- Inspect compressor and compressor discharge case and inner barrel.
- Check gas turbine to generator alignment.

7-17.3.1 Step-Up Transformers Associated with Power Plant.

- Check transformers for electrical insulation discoloration.
- Perform dielectric strength tests to insulating oil for liquid-filled transformers in accordance with ASTM D877, *Standard Test Method for Dielectric Breakdown Voltage of Insulating Liquids Using Disk Electrodes*.
- Perform acidity tests to insulating oil for liquid-filled transformers in accordance with ASTM D1534, *Standard Test Method for Approximate Acidity in Electrical Insulating Liquids by Color-Indicator Titration*.
- Perform color test to insulating oil for liquid-filled transformers in accordance with ASTM D1524, *Standard Test Method for Visual Examination of Used Electrical Insulating Liquids in the Field*.
- Check damage on cooling system equipment for transformers equipped with forced-cooling systems.
- Test for transformer alarm condition activation (temperature, level, pressure), if equipped.
- Check that cooling passages for transformers are not being fouled by dust.
- Remove and test transformer oil to record its temperature and observe if it is in optimum working condition.
- Perform the following tests:
    - Power factor/dissipation factor test
    - Dissolved gas/chromatograph test
    - Karl Fischer moisture test
    - Furanic compound test
    - Total dissolved combustible gases ppm
    - Dissolved metals test
    - Appearance
    - Dielectric breakdown test
    - Test on transformer oil every three years

7-17.3.2 Cable Testing of Medium Voltage Cables.

Periodic maintenance tests are needed during the life of the cable to determine whether or not there has been significant insulation deterioration due to operational or environmental conditions. The maintenance schedule for power cables only pertains to cables associated with critical equipment. High potential tests (hipot) effectively reduce in service failures from faults of the cable or its accessories. When done properly, maintenance tests can detect problems in cables that are approaching failure without accelerating the deterioration process. Except for infrared scanning, de-energize the cable circuit before maintenance. An insulation test using a DC ramp test is recommended at a five-year interval.

This Page Intentionally Left Blank

CHAPTER 8 AIR FORCE REQUIREMENTS

8-1 SUMMARY OF REQUIREMENTS.

This chapter supplements AFI 32-1062 and applies to Air Force real property installed equipment (RPIE) and equipment authorized inventory data (EAID) electrical generator systems, inspection, maintenance, testing, and refueling criteria. The BCE or equivalent will operate, and maintain all RPIE electrical generator systems and equipment, including EAID electrical generators and equipment assigned to the BCE. Electrical generator systems not assigned to the BCE should have a signed memorandum of agreement (MOA) on file. Perform preventive maintenance in accordance with approved Air Force preventive maintenance procedures prescribed by AFI 32-1001, *Operations Management*, and testing requirement frequency outlined in this chapter. Documentation of preventive maintenance actions, electrical generator system testing (e.g., test records, run-times, electrical testing parameters), oil analysis results, and system repairs must be documented by the BCE. The Air Force Air Program Information Management System (APIMS), in accordance with recordkeeping requirements of AFI 32-7040, *Air Quality Compliance and Resource Management*, is recognized as an official record. The BCE is encouraged to use APIMS as their official record; however, if a shop uses APIMS as the official shop record then the shop must upload and manage the information in APIMS.

8-2 DEFINITIONS.

8-2.1 Standby power is an alternate power source that is available through either automatic or manual operation. Standby power may be RPIE or EAID based on AFCEC/COSM authorization.

8-2.2 Prime power is standby power capable of operating continuously. The generator may be considered prime when the utility source is not available or unreliable. Generators designed to operate in parallel with the utility are also considered to be prime power.

8-2.3 Backup generators may be RPIE or EAID portable units. RPIE generators support mission-critical functions where delayed power restoration is unacceptable. RPIE generators may be approved for missions that require immediate power restoration, uninterrupted power, or support to **\1** standby **/1/** systems defined in NFPA 70, *National Electrical Code* (NEC), Article 700. EAID generators support mission-critical or infrastructure-critical functions where delayed power restoration is acceptable. During a commercial power outage, a lack of infrastructure-critical function could result in an environmental or other non-mission-related condition.

8-2.4 Classifications of generator authorizations: RPIE – Emergency **\1** (same facility life-safety systems, i.e., not mission systems), **/1/** RPIE – COPS, RPIE – POLS/Fuels, RPIE – Other Permanently Installed; EAID – Portable, and EAID – POLS/Fuels. Refer to AFI 32-1062 for definitions or classifications and approval process.

8-2.5 Deployable generators are defined as those assigned to a Civil Engineering (CE) Squadron unit type code (UTC).

8-3 GENERATOR PREVENTIVE MAINTENANCE FREQUENCIES, MAINTENANCE REQUIREMENTS, AND TESTING.

- The minimum inspection and testing frequencies required for RPIE and EAID generator systems are prescribed in Table 8-1.
- Use the approved Air Force Preventive Maintenance Task List (AF-PMTL) for the required maintenance procedures per AFI 32-1001 on RPIE and EAID generator systems.
- AF-PMTLs are built to address reoccurring Air Force preventive maintenance requirements, common manufacturer's preventive maintenance requirements, and preventive maintenance requirements outlined in NEC Articles 700, 701, 702, 705, and 708, and in NFPA 110 (Level 1 and 2).
- AF-PMTLs do not address unique local laws, regulations, and uncommon manufacturer's unique reoccurring preventive maintenance. Coordinate local supplements to AF-PMTLs through the AFCEC/COO Preventive Maintenance Program Manager.

8-3.1 Requirements for Select Mission-Essential Facilities Compliance with Published Guidance.

- Exercise other **\1** standby **/1/** systems supporting navigational aids for air traffic control facilities according to AFI 13-204V3, *Airfield Operations Procedures and Programs,* in addition to requirements in this chapter.
- **\1** Exercise other standby systems supporting Defense Communications Systems (DCS) or related communications activities according to Defense Information Systems Agency Circular (DISAC) 350-195-2*, *Tests and Evaluations - Electric Power Systems for Department of Defense Information Network (DODIN) Facilities.* **/1/**
- Exercise emergency power systems that support medical facilities according to NFPA 99, *Health Care Facilities Code*, in addition to requirements in this chapter.
- Generator systems required to comply with NEC Article 708 must also comply with NFPA 110 Level 2 criteria. **\1** Application of NEC Article 708 is more costly than the other generator requirements of the NEC. **/1/**

Table 8-1 Generator System Inspection and Testing Frequency Requirements

Classification (ref: AFI 32-1062)	Preventive Maintenance / Inspection Frequency				
	Semi-Monthly[3](J)	Monthly (M)	Quarterly (Q)	Semi-Annual (SA)	Annual (A)
RPIE - Emergency	X	X		X	
RPIE - COPS	X	X		X	
RPIE - POL/FUELS		X	X		X
RPIE - Other Permanently Installed	X	X		X	
EAID - Portable		X	X		X
EAID - POL/Fuels		X	X		X
Supporting Equipment					
Transfer switch (ATS / MTS / paralleling switchgear)[1]	X	X	X	X	X
Fuel system[2]	X	X	X	X	X

Terms:

Semi-monthly: Twice a month; activities are generally separated by enough time so the occurrences are equally distributed across the month

Monthly: Once a month

Quarterly: Once every three months

Semi-Annual: Once six months

Annual: Once a year

Notes:

1: Inspect ATS / MTS / paralleling switchgear during each required PM frequency for the generator it is supporting.

2: Inspect fuel system during each required PM frequency for the generator it is supporting.

3: Geographically separated equipment located more than 20 miles (32 km) from the servicing installation may be inspected monthly if the batteries and generator operation are monitored by a remote monitoring system complying with UFC 4-010-06.

8-3.2 RPIE Generator and Transfer Switch Inspections and Operational Testing Requirements.

This section addresses generator system operational testing requirements for RPIE generator systems classified by AFCEC/COSM as RPIE - Emergency, RPIE – COPS, and RPIE - Other Permanently Installed.

Document all inspection actions on AF Form 487, *Generator Operating Log (Inspection Checklist)*, and file the form with the generator record.

8-3.2.1 Semi-monthly RPIE Generator and Transfer Switch Inspections.

Conduct and document visual inspection of the generator, ATS/MTS/switchgear, and system batteries. Engine start is optional.

8-3.2.2 Monthly RPIE Generator and Transfer Switch Testing.

Test the RPIE generator system monthly by exercising the generator for a minimum of one hour using either Exercising Method 1 or 2. Load generator with facility load first, annotate load on AF Form 487 and, if facility load is not adequate to meet minimum operating conditions for the selected Exercising Method, use a load bank in combination with facility load to increase the total load on the generator to meet the Exercising Method. Test generator systems monthly under facility load with the electrical service entrance to the transfer switch/switchgear switched off.

8-3.2.2.1 Monthly Generator Exercising Method 1.

Conduct this test under loading that maintains the minimum exhaust gas temperature (EGT) recommended by the manufacturer. The one-hour generator exercise time for Method 1 operational inspections includes warmup, load test, and cool-down.

8-3.2.2.2 Monthly Generator Exercising Method 2.

Conduct this test under operating temperature conditions and at no less than 50 percent of the generator nameplate kW rating. The one-hour generator exercise time for Method 2 operational inspections includes warmup, load test, and cool down.

Note: RPIE generators rated 25 kW and lower are not required to meet monthly generator Exercising Method 1 or 2 and shall be tested with actual facility loads for a minimum of one hour.

Note: Additional semiannual testing is required if a monthly test accomplished between semiannual tests does not meet the requirements of either monthly generator Exercising Method 1 or 2.

8-3.2.2.3 Monthly Exercising of \1\ MTS/Switchgear. /1/

Test the **\1** MTS/switchgear **/1/** monthly by exercising the operation of the switch with facility loads. The monthly test of the switch must consist of operating the switch from its primary position to the electrical generator power source position and then return to the primary position upon completion of the generator test.

The criteria set forth in NFPA 110 Section 4.3 and Table 4.1(b) is not required during the monthly testing of the EPSS.

8-3.2.2.4 Monthly Exercising of Paralleling Switchgear.

Test the paralleling switchgear monthly by exercising the operation of the paralleling switchgear with facility loads. The monthly test of the paralleling switchgear must consist of operating the paralleling switchgear, paralleling of the connected generators, and operating the switchgear from its primary position to the electrical generator power source position and then return to the primary position upon completion of the generator test.

8-3.2.3 Semiannual RPIE Generator Full-System Testing.

Test the full generator system semiannually with the facility electrical service entrance power switched off upstream of the facility for a minimum of one hour. **\1** A longer generator test of greater than one hour is strongly encouraged on an annual basis to verify the proper configuration and operation of all downstream loads. **/1/** Testing conducted with only the power source disconnected to the transfer switch/switchgear will only test the generator system and does not assure that mission equipment and facility support equipment are connected to the correct electrical distribution panels. Testing the generator system with the facility electrical service entrance power switched off upstream of the facility verifies which mission equipment and facility support equipment is sustained by the generator system and which portions of the facility are not sustained by the generator system. **\1** Where multiple generators provide standby power to the same facility, a custom test plan must be developed to verify proper configuration and operation. **/1/**

Note: Additional semiannual testing is required if a monthly test accomplished between semiannual tests does not meet the requirements of either monthly generator Exercising Method 1 or 2. For generator systems not meeting the monthly testing methods, load the generator system with available facility load (augmented with load banks, as necessary) to achieve not less than 50 percent of the generator nameplate kW rating for one continuous hour and then not less than 75 percent of the generator nameplate kW rating for one additional continuous hour, for a total test duration of not less than two continuous hours.

8-3.2.3.1 Exemptions to Semiannual Inspection and Testing.

Generators supporting an actual power outage during a six-month period do not require an additional semiannual full-system test, provided the following conditions are met:

- The outage duration was at least one hour. Separate outages cannot be added together to meet this requirement.
- The transfer switch operated properly during the outage.
- All items were checked/annotated on AF Form 487, including the facility representative section.
- A post-operational inspection was accomplished.
- **\1** Generator load was greater than 50 percent. **/1/**

8-3.2.3.2 Denial Authority for Semiannual Testing.

Refer to AFI 32-1062 regarding denial of semiannual RPIE generator full-system testing.

8-3.3 RPIE POL/Fuels Generator and Transfer Switch Testing.

This section addresses generator system operational testing requirements for RPIE generator systems classified by AFCEC/COSM as RPIE POL/Fuels.

Document all inspection actions on AF Form 487, Generator Operating Log (Inspection Check List) and file the form with the generator record.

8-3.3.1 Monthly RPIE POL/Fuels Inspections and Testing.

Conduct and document visual inspection of the generator, ATS/MTS/switchgear, and system batteries. Engine start is required.

8-3.3.2 Quarterly RPIE POL/Fuels Testing.

Test the RPIE POL/Fuels generator system quarterly by exercising the generator system for a minimum of one hour using the designed pumping capability. Verify operation of transfer switch or interlocked switching devices.

8-3.3.3 Annual RPIE POL/Fuel Testing.

Test the RPIE POL/Fuels generator system annually by exercising the generator with a load bank, as necessary to achieve not less than 50 percent of the generator nameplate kW rating for one continuous hour and not less than 75 percent of the generator nameplate kW rating for one continuous hour, for a total test duration of not less than two continuous hours. Facility load is not required during annual test.

8-3.4 EAID Generator and Transfer Switch Inspections and Operational Testing Requirements.

This section addresses generator system operational testing requirements for EAID generator systems classified by AFCEC/COSM as EAID Portable and EAID POL/Fuels.

Document all inspection actions on AF Form 487 and file the form with the generator record.

8-3.4.1 Monthly EAID Inspections and Testing.

Conduct and document visual inspection of the generator, ATS / MTS / Switchgear, and system batteries. Engine start is required.

8-3.4.2 Quarterly EAID Testing.

Test the EAID generator system quarterly by exercising the generator system with a load bank to achieve not less than 50 percent of the generator nameplate kW rating for 30 continuous minutes and not less than 75 percent of the generator nameplate kW rating for one continuous hour, for a total test duration of not less than 90 continuous minutes.

8-3.4.3 Annual EAID Testing.

Test the EAID generator system annually by exercising the EAID generator system connected to the facility or system they primarily support, transfer facility, or system electrical load to the EAID generator. Exercise the generator for one continuous hour.

Test the ATS/MTS/switchgear connected to the EAID generator by exercising the operation of the switch with facility loads. The test of the switch must consist of operating the switch from its primary position to the electrical generator power source position and then return to the primary position upon completion of the generator test.

The criteria set forth in NFPA 110 Section 4.3 and Table 4.1(b) is not required during EAID generator system testing.

8-3.4.4 Portable Generator Facility Connections.

Portable generator facility connections must comply with UFC 3-540-01. Generator connections described in UFC 3-540-01 cannot also be used as an emergency means of isolation required by the NEC.

Inspect portable generator electrical connection plugs and receptacles for corrosion before each use. Repair as necessary and coat contacts with proper electrical connection corrosion-preventive compound.

8-3.5 Deployable Generator Inspections and Testing.

This section addresses generator system inspection and testing for generators defined as deployable generators.

Deployable generators are defined as those assigned to a CE Squadron UTC.

Document all inspection actions on AF Form 487 and AF Form 719, *Historical Record – Diesel-Electric Generator and System*, and file the forms with the deployable generator record.

8-3.5.1 Deployable Generators Testing Upon Receipt.

Power production personnel must test CE deployable generators upon initial receipt. After testing and documenting operating parameters, purge, shelve, and prepare the generators for immediate deployment.

8-3.5.2 Annual Inspection and Operational Testing.

Inspect and operationally test CE deployable generators annually for a minimum of one continuous hour while loaded to at least 75 percent of rated capacity.

8-3.5.3 CE Deployable Generator Maintenance.

Maintain CE deployable generators in accordance with T.O. data or manufacturer’s manuals.

8-3.5.4 Non-CE Deployable Generators.

Maintenance, testing, and operation of non-CE deployable generators (e.g., Combat Communication, Air Control Squadron, and Maintenance Squadron) are governed by their own T.O.s or the manufacturer's guidance instead of this chapter.

8-4 MISSION UNINTERRUPTIBLE POWER SUPPLIES (UPS).

\1 [Deleted paragraph] **/1/**

Mission operators, e.g. UPS owner, should not plan for UPS support longer than 15 minutes. If generators do not operate correctly during commercial power outages, mission operators should take immediate actions following their established mission shut-down and transfer processes to avoid mission disruption and equipment damage. During generator inspection and testing events, the mission operator should monitor their UPS status to ensure they do not falsely conclude the mission load was carried by the generator.

\1\ Note: Power condition and continuation interfacing equipment (PCCIE), which typically includes UPSs, is classified as equipment and must be owned by the mission and not the BCE. For guidance on acquisition and maintenance of UPS equipment, contact the PCCIE Product Group Manager, 500 CBSS/GBLD, Building 1207-N, 6029 Wardleigh Road, Hill AFB, UT 84056-5838. **/1/**

8-5 LUBRICATING OILS.

Follow the engine manufacturer's recommendations for the type and grade of oil as closely as possible. Lubricating oils satisfying minimum requirements of military specifications MIL-PRF-2104, *Lubricating Oil, Internal Combustion Engine, Combat/Tactical Service*, and MIL-PRF-46167, *Lubricating Oil, Internal Combustion Engine, Arctic*, are acceptable for many diesel engines but may not be adequate for some high-speed engines.

Confirm the suitability of military specification lubricating oils with the engine manufacturer before use.

This section addresses deviations from manufacturer's service intervals for RPIE and EAID generator engine lubrication systems.

8-5.1 Deviation from Manufacturer's Service Intervals.

Refer to AFI 32-1062 regarding deviation authority from manufacturer's service intervals.

8-5.1.1 RPIE Oil Change Interval Deviations.

RPIE generator engine oil change intervals may be extended from the manufacturer's specified service interval to 24 months or 1,000 engine hours between engine oil and oil filter change if all of the following apply:

- Ensure requirements in 40 CFR Part 63 Subpart ZZZZ (all stationary prime power generators), 40 CFR Part 60 Subpart JJJJ (all stationary spark ignition [SI] generators), 40 CFR Part 60 Subpart IIII (all stationary compression ignition [CI] generators), and 40 CFR Part 89 (portable diesel generators), are not violated (when applicable, based on generator age and location).
- Verify the RPIE generator is not under warranty and is at least three years old.
- Ensure oil change interval never exceeds 24 months or 1,000 engine hours of operation.
- Verify oil analysis results conducted at the same frequency specified for changing the oil are within the required limits specified by the manufacturer and 40 CFR Part 60 Subpart IIII and 40 CFR Part 63 Subpart ZZZZ paragraph 63.6625(i). The analysis must include viscosity, acid content, particulates, water, or other contaminants, and recommended actions after results are provided. Total engine hours and time since last oil change must be printed on the oil analysis results.
- **\1** [Deleted text] **/1/**
- Ensure the servicing environmental office is engaged to determine if deviation affects permitting requirements.
- Maintain a copy of the approved deviation memo with the RPIE generator maintenance record.

8-5.1.2 EAID Oil Change Interval Deviations.

EAID generator engine oil change intervals may be deferred up to 12 months from the manufacturer’s specified service interval if all of the following apply:

- Verify the EAID generator is not under warranty.
- Ensure oil change interval never exceeds 24 months or 1,000 engine hours of operation.
- Total operating hours are less than 150 within the last 12 months.
- Verify oil analysis results conducted at the same frequency specified for changing the oil are within the required limits specified by the manufacturer and 40 CFR Part 60 Subpart IIII and 40 CFR Part 63 Subpart ZZZZ paragraph 63.6625(i). The analysis must include viscosity, acid content, particulates, water, or other contaminants, and recommended actions after results are provided. Total engine hours and time since last oil change must be printed on the oil analysis results.
- **\1** [Deleted text] **/1/**

- Ensure the servicing environmental office is engaged to determine if deviation affects permitting requirements.
- Maintain a copy of the approved deviation memo with the RPIE generator maintenance record.

8-5.1.3 Oil Analysis.

Oil analysis requirements (40 CFR 63.6625 condemning factors: total base number is less than 30 percent of the total base number of the oil when new; viscosity of the oil has changed by more than 20 percent from the viscosity of the oil when new; or percent water content [by volume] is greater than 0.5) are in 40 CFR Part 63 Subpart ZZZZ. The oil analysis must be part of an oil analysis program and included in the engine's maintenance plan. If any of the condemning limits are exceeded, the oil must be changed within two business days of receiving the results.

Sample in accordance with manufacturer's recommendations and field test using oil analysis kit NSN 6630-01-096-4792, *Test Kit, Oil Condition*, or an independent oil analysis company test kit (e.g., Cummins Filtration #CC2543, Caterpillar S•O•SSM, Wix filters; verify the kit meets EPA requirements). Record results on AF Form 487 and AF Form 719. If an approved field test kit is not available or the above tests are not performed, the oil must be changed.

8-6 FUELS.

This section addresses fuel types approved for use with RPIE and EAID generator systems, fuel-related training, fuel tanks, and fuel supply.

8-6.1 Fuel Oils.

\1 Fuel oils used for RPIE and EAID generators must meet ASTM D975, *Standard Specification for Diesel Fuel Oils*, or European Committee for Standardization EN 590, *Automotive Fuels - Diesel - Requirements and Test Methods*, or host nation equivalent. Consult T.O. 42B-1-1, *Quality Control of Fuels*, for additional information. Follow the specific temperature and applicable service conditions and ensure sulfur content does not exceed environmental restrictions or original equipment manufacturer's fuel requirements. Do not mix different grades of fuel. Consult T.O. 42B-1-1 and MIL-STD-3004-1, *Quality Assurance for Bulk Fuels, Lubricants and Related Products*, for additional information. Comply with 40 CFR 60.4207 (stationary CI internal combustion engines) and 60.4216 (engines located in Alaska). ***/1/***

8-6.2 Jet Fuels.

\1 Jet fuel potentially may be used with required additives when diesel is not available. Consult AFCEC/CO or the installation environmental office and the EPA for emission restrictions. Deviation from requirements to use diesel fuel in 40 CFR 60.4207 can be authorized through the provisions of 40 CFR 60.4216, 60.4217, or 40 CFR 1068.225 (National Security Exemption) where applicable. Use of non-standard fuels in diesel equipment may incur significant costs for testing and permitting efforts. Consult T.O.

42B-1-1 for more information. Consult the manufacturer for kW de-rating when using JP-8, JP-5, TS-1, F-24 (Jet A with additives), Jet A-1, or Jet A. **/1/**

8-6.3 Natural Gas, Liquid Petroleum Gas, and Bio-Diesel.

\1 Use of natural gas (NG), liquid petroleum gas (LPG), or bio-diesel/bio-diesel blend fuels is not permitted for RPIE or EAID generator authorizations. NG, LPG, or alternative fuels (renewable diesel fuel blend where the alternative fuel is produced using a hydro-treating process) may be authorized for prime power generation or co-generation. BCEs must either program existing generators that use NG, LPG, or bio-diesel/bio-diesel blend for replacement within five years or request a waiver from AFCEC/CO for continued operation. Consult T.O. 42B-1-1. BCEs will ensure refueling plans address backup fuel support for existing generators using NG or LPG in the event of fuel supply disruption.

Rewrite paragraph A-7.1 of this UFC to read: "Diesel fuel should comply with ASTM D975, EN 590, or host nation equivalent. These specifications include winter (No. 1) and summer (No. 2) grades available as both low sulfur and ultra-low sulfur. All are suitable for use under applicable temperature and service conditions. Alternately, MIL-DTL 83133 (JP-8), MIL-DTL-5624 (JP-5), or MIL-DTL-16884 (F-76) can be used as a diesel fuel substitute, noting that all have a high sulfur content and are not suitable for equipment requiring low sulfur or ultra-low sulfur diesel fuels. Different grades of fuel should not be mixed. It should be noted that all diesel specifications allow for a limited content of bio-diesel. Consult T.O. 42B-1-1 for additional information." **/1/**

8-6.4 Fuel Storage Tank Training.

Personnel must be trained to manage fuel storage tanks in accordance with AFI 23-204, *Organizational Fuel Tanks*.

8-6.5 Fuel Tanks of Emergency Generators.

Emergency generator fuel tanks must comply with requirements of NFPA 30, *Flammable and Combustible Liquids Code*, NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*, NFPA 54, *National Fuel Gas Code*, NFPA 58, *Liquefied Petroleum Gas Code*, NFPA 110, and applicable state regulations.

8-6.5.1 Fuel Tanks for New Systems.

For new systems, coordinate with BCE's Installation Management Flight to ensure the emergency generator fuel tank is included on the installation Spill Prevention Control and Countermeasures (SPCC) plan per 40 CFR 112 and included in the installation fuel tank inventory per AFI 32-7044, *Storage Tank Environmental Compliance*.

8-6.5.2 Containment.

Provide secondary containment as required by 40 CFR 112 or equivalent where required and at overseas locations.

8-6.5.3 Signage.

Install hazard identification signs as specified in NFPA 704, *Standard System for the Identification of the Hazards of Materials for Emergency Response*, on stationary aboveground tanks or per Final Governing Standards for overseas locations. Ensure storage tanks are marked according to fuel type and warning signs are appropriately located. If an external fuel tank is installed, post a one-line diagram of the fuel system indicating tank size and valve locations.

8-6.5.4 Inspection.

Emergency generator fuel tanks will be inspected monthly and annually as required by AFI 32-7044 with results of inspections posted in the Storage Tank Accounting and Reporting (STAR) system.

8-6.5.5 Fuel Supply.

Plan for and provide a minimum seven-day fuel supply (based on actual generator load), either in a dedicated on-site storage tank or from a confirmed delivery source when a delivery source is used to meet the seven-day requirement. The refueling schedule must take into account the assigned EAID generator tank capacity. RPIE generators will have a minimum 24-hour local capacity based on the actual generator load fuel consumption rate of the engine.

8-7 COOLANT.

The coolant used in diesel engines usually consists of a mixture of ethylene glycol antifreeze, corrosion inhibitor, and fresh water. When the engine is used in an extremely cold area, such as Arctic regions, a special antifreeze mixture is used. Specifications related to the mixtures are as follows:

- **\1** Antifreeze, Ethylene glycol MIL-A-46153
- Specification for cooling system conditioner and inhibitor is MIL-C-10597
- Antifreeze, Ethylene glycol A-A-52624
- Antifreeze, Arctic-type A-A-52624
- 5 Inhibitor, Corrosion MIL-A-53009 or MIL-A-46153 **/1/**

8-7.1 Engine Water Treatment.

8-7.1.1 Acceptable Conditions.

In most modern diesel engines, the following cooling water conditions are acceptable:

- pH 8.5 to 10
- Chloride and sulfate 100 ppm

- Total dissolved solids 500 ppm
- Total hardness 200 ppm

8-7.1.2 Softened Water.

If possible, softened water should be used to reduce the total hardness level of the engine cooling loop. The use of softened water will increase engine performance by reducing the precipitation of calcium and magnesium at elevated temperature conditions, ensuring higher heat transfer rates.

8-7.1.3 Antifreeze.

Typical engine cooling systems incorporate antifreeze solutions that inhibit scale and protect the cooling system when temperatures are encountered below freezing. Ethylene glycol mixed with a corrosion inhibitor such as triazoles form an inhibiting film on metal surfaces that acts as a barrier to the corrosion process. Table A-18 concentrations should be utilized when adding glycol solutions to the engine cooling system.

8-7.1.3.1 Concentration.

The ethylene glycol concentration should exceed 30 percent. If more than 60 percent of solution is added, two effects will be realized: 1) a decrease in heat transfer rates, 2) a lowering of the system freeze protection.

8-7.2 Cooling System Maintenance.

Maintenance consists of periodically testing the antifreeze, inspecting the coolant for cleanliness, and flushing or cleaning the system with compound when necessary.

8-7.2.1 Testing Antifreeze.

Perform tests to verify freeze protection and reserve alkalinity:

- Test for freeze protection using the combination antifreeze and battery tester (stock number 6630-00-105-1418). Instructions for using the tester are included with it.
- Test for reserve alkalinity (corrosion protection) using the reserve alkalinity test kit (stock number 6630-00-169-1506).
- Cooling systems with freeze protection below -7 °F (-22 °C) that fail the reserve alkalinity test may be replenished with corrosion inhibitor (stock number 6850-00-753-4967). Replenishment is a one-time service. If the reserve alkalinity test is failed again, replace the coolant. If the system passes the test, record the date.

8-7.2.2 Inspecting Coolant.

Inspect the coolant visually for cleanliness. Obtain a coolant sample and place it in a clean glass container. After allowing about five minutes for settling, examine the sample for contamination (rust, foreign particles, and/or sediment). The sample may have some color (same color as original antifreeze) and should be clear.

Examine the sample to determine the type and quantity of contamination. Rust, a chemical combination of iron, water, and air, is frequently found. The presence of rubber particles usually indicates deterioration of hoses. Replacement hoses may be indicated. Sediment may be caused by impurities in the water used in the coolant. Contaminants in the coolant can clog a radiator or heat exchanger and cause engine and generating system breakdown.

8-7.2.3 Cleaning the System.

Clean the cooling system whenever the coolant is drained. Usually the system requires nothing more than a thorough flushing with fresh water. Refer to the engine manufacturer's literature for instructions. If any part of the system is rusted or partially clogged, it is necessary to use cooling system cleaning compound and conditioner, stock number 6850-00-598-7328. Do not use the compound as a routine maintenance procedure. Instructions for using the compound are included with it.

8-7.2.4 Filling the System.

Refer to the engine manufacturer's literature for instructions on filling the cooling system. This is applicable to either new systems or those just cleaned and serviced.

8-7.2.4.1 Ethylene Glycol Antifreeze.

Cooling system protection is required for all liquid cooled diesel engines. In areas where temperatures no lower than -55 °F (-48 °C) are expected, prepare a solution according to the information presented in Table A-18. When temperatures below freezing are not expected, use a weak solution such as 1 pint of ethylene glycol antifreeze for each gallon of solution for general protection against rust buildup and scale formation within the engine.

8-7.2.4.2 Arctic-Type Antifreeze.

Use arctic-type antifreeze in areas where temperatures below -55 °F (-48 °C) are expected. Do not dilute arctic-type antifreeze with water or inhibitor; it is ready for use as issued.

\1\

8-8 ACCOUNTING FOR GENERATORS.

8-8.1 RPIE Generators.

Notify the real property office if these generators are temporarily or permanently relocated from one facility to another. Document and account for all RPIE generators awaiting installation in the appropriate work order documents. For excess generators and associated equipment (i.e., ATS), request MAJCOM review and disposition instructions before removing the generator and associated equipment from a RPIE facility. After removing a generator, account for it on DD Form 1149, *Requisition and Invoice/Shipping Document*, if the generator is shipped to another base or to CEMIRT. If the generator is turned in to the Defense Reutilization and Marketing Office, account for it on DD Form 1348-1A, *Issue Release/Receipt Document*.

8-8.2 EAID Generators.

EAID generators are listed in the Allowance Standard (AS), requisitioned from Warner Robins Air Force Life Cycle Management Center (AFLCMC/WNZEC), 235 Byron Street (Building 300-West Wing, Bay D), Robins AFB, GA 31098-1647, DSN 472-1640, commercial (478) 222-1640, and accounted for by Base Supply and AFLCMC/WNZEC. EAID units must be reclassified as RPIE and coordinated with the Item Manager, AFLCMC/WNZEC, when they no longer meet the definition for an EAID or turned in to Base Supply.

8-8.3 AFLCMC/WNZEC.

Report excess EAID generators to AFLCMC/WNZEC. Any RPIE or commercial EAID generators that are no longer required or are inoperable must be identified to the MAJCOM for review and disposition coordination. Disposal of mobile electric power (MEP) EAID generators must first be coordinated with the EAID Item Manager at AFLCMC/WNZEC. If generators are not required or needed by AFLCMC/WNZEC, they must be disposed of in the same manner as RPIE and commercial EAID generators.

8-8.4 Reporting RPIE Generators.

If functional load testing indicates the generator is loaded less than 30 percent of rated capacity over a 12-month period, BCEs will take actions described in paragraphs 8-8.4.1 through 8-8.4.1.2.

8-8.4.1 Compile a list of generators that do not meet the required 30 percent loading for facility loads over a 12-month period. Categorize and certify the generators as “Replacement Eligible,” “Replace by Attrition,” or “Replacement Not Feasible” and document the category in a memo and file it with the generator records.

8-8.4.1.1 RPIE generators used to support large in-rush currents may be sized for starting current. These generators may be excluded from paragraph 8-8.4.1.

8-8.4.1.2 RPIE generators for fire pumps and RPIE generators rated 25 kW and lower are not required to comply with paragraph 8-8.4.1.

8-8.4.2 Any generator installation (new or replacement) and generator removal or relocation requires AFCEC/CZ coordination to ensure EPA clean air compliance regulations are met.

8-8.4.3 Consult with AFCEC/CZ when an EPA-permitted generator is removed from the base; that generator must be removed from the Clean Air Act Title V air permit. Additionally, because the permit requires an accurate list of active permitted generators on base, the BCE must check with AFCEC/CZ to determine if the generator size is small enough to be excluded from the permit.

8-8.4.4 By 1 October each year, MAJCOM senior engineers will review base generator inventory reports and provide AFCEC/COM CEMIRT a list of “Replacement Eligible” generators that cannot be redistributed within their command.

8-8.4.5 By 1 August, BCEs must revalidate the generator authorization memorandum for changes to mission or modifications to the authorized RPIE electrical system and provide a list of “Replacement Eligible” generators to AFCEC/COM.

8-8.4.5.1 AFCEC/COSM must be notified by the BCE when a generator authorization is no longer required.

8-8.4.5.2 The BCE will prepare a plan for all generators that do not have an AFCEC authorization and are available for relocation or disposition. The plan is included as a part of the annual revalidation process. **/1/**

APPENDIX A SAMPLE O&M PROCEDURES AND FREQUENCY

A-1 STRUCTURE AND ENCLOSURES.

Perform structure and enclosure preventive maintenance per Table A-1.

Table A-1 Structure and Enclosures PM Schedule

Item No.	Maintenance Item	Service Time							
		Daily	Weekly	Bi-Weekly	Monthly	3 Months	6 Months	Yearly	Other
1.0	Structure and Enclosures								
1.1	Exercise damper actuators	X							
1.2	Lubricate door hinges						X		
1.3	Lubricate door locks						X		
1.4	Fastener checks				X				
1.5	Corrosion control checks						X		
1.6	Rodent control checks		X						
2.0	PTO Assemblies/Couplings								
2.1	PTO access door / cover		X						
2.2	Noise checks	X							
2.3	Coupling alignment check							X	
3.0	Bearing Lubrication

4.0	Belt-Driven Equipment								
4.1	Check Belts for Wear		X						
4.2	Replace drive belts							X	
4.3	Check pulleys/idler wheels			X					

A-1.1 Service Practices.

A-1.1.1 Maintenance Program.

Service practices for diesel engines consist of a complete maintenance program built around records and observations. The maintenance program includes appropriate analysis of these records. DD Form 2744, *Emergency/Auxiliary Generator Operation Log*, should be used to record inspection testing of emergency/auxiliary generators.

A-1.1.1.1 Recordkeeping.

Engine log sheets are an important part of recordkeeping. The sheets must be developed to suit individual applications (i.e., auxiliary use) and related instrumentation. Personnel must use Service-approved forms, such as AFTO Form 781A, *Maintenance Discrepancy and Work Document*, and, for the Air Force, AF Form 487. Accurate records are essential to good operations. Notes should be made of all events that are or appear to be outside of normal range. Detailed reports should be logged. Worn or failed parts should be tagged and protectively stored for possible future reference and failure analysis. This is especially important when specific failures become repetitive over a period of time, which may be years.

A-1.1.1.2 Log Sheet Data.

Log sheets should include engine starts and stops, fuel and lubrication oil consumption, and a cumulative record of the following:

- Hours since last oil change
- Hours since last overhaul
- Total hours on engine
- Selected temperatures and pressures

A-1.1.2 Troubleshooting.

Perform troubleshooting procedures when abnormal operation of the equipment is observed. Maintenance personnel should then refer to log sheets for interpretation and comparison of performance data. Comparisons of operation should be made under similar conditions of load and ambient temperature. The general scheme for troubleshooting is outlined in the following paragraphs.

A-1.1.2.1 Industrial Practices.

Use recognized industrial practices as the general guide for engine servicing. Service information is provided in the manufacturer’s literature and appendixes.

A-1.1.2.2 Reference Literature.

The engine user must refer to manufacturer’s literature for specific information on individual units. For example, refer to Table A-2 for troubleshooting an engine that has developed a problem.

Table A-2 Diesel Engines Troubleshooting

Cause	Remedy
HARD STARTING OR FAILS TO START	
Air intake restricted	Check intake and correct as required.
Fuel shut-off closed	Make sure shut-off is open and supply is at proper level and not low.
Poor-quality fuel	Replenish fuel supply with fresh, proper-quality fuel.
Clogged injector	Clean all injectors.
Injector inlet or drain	Check all connections and correct as required.
Engine due for overhaul	Schedule the overhaul and correct as required.
Incorrect timing	Perform timing procedure.
ENGINE MISSES DURING OPERATION	
Air leaks in fuel suction lines	Check fuel suction lines and correct as required.
Restricted fuel lines	Check fuel lines and correct as required.
Leakage at engine	Refer to manufacturer's instructions and correct valves as required.
Incorrect timing	Perform timing procedure.
EXCESSIVE SMOKING AT IDLE	
Restricted fuel lines	Check fuel lines and correct as required.
Clogged injector	Clean all injectors. Refer leaking head gasket to manufacturer's instructions and correct as or blow by.
Engine due for overhaul	Schedule the overhaul and correct.
Incorrect timing	Perform timing procedures.

Cause	Remedy
EXCESSIVE SMOKING UNDER LOAD	
The same causes for “idle” apply	The same remedies for “idle” apply.
Air intake restricted	Check air intake and correct as required.
High exhaust backpressure	Check exhaust system and turbocharger; correct as required.
Poor-quality fuel	Replenish fuel supply with fresh, proper-quality fuel.
Engine overloaded	Reduce load to proper level.
LOW POWER OR LOSS OF POWER	
Air intake restricted	Check air intake and correct as required.
Poor quality fuel	Replenish fuel supply with fresh, proper-quality fuel.
Clogged injector	Clean all injectors.
Faulty throttle linkage or governor setting too low	Check linkage and governor; refer to manufacturer’s instructions and correct as required.
Clogged filters and screens	Clean filters and screens.
Engine overloaded	Reduce load to proper level.
Engine due for overhaul	Schedule the overhaul and correct as required.
Incorrect timing	Perform timing procedure.
Engine requires tune-up	Perform tune-up procedure.
DOES NOT REACH GOVERNED SPEED	
The same causes for “low power” apply.	The same remedies for “low power” apply.
EXCESSIVE FUEL CONSUMPTION	
Air intake restricted	Check air intake and correct as required.
High exhaust back-pressure	Check exhaust system and turbocharger; correct as required.

Cause	Remedy
Poor-quality fuel	Replenish fuel supply with fresh, proper-quality fuel.
Faulty injector	Clean all injectors.
Engine overloaded	Reduce load to proper level.
Engine due for overhaul	Schedule the overhaul and correct as required.
Incorrect timing	Perform timing procedure.
ENGINE QUITS	
High exhaust backpressure turbocharger	Check exhaust system and correct as required.
Air intake restricted	Check air intake and correct as required.
Fuel shut-off closed; low supply of fuel	Make sure shut-off is open and supply is at proper level.
Poor-quality fuel	Replenish fuel supply with fresh, proper-quality fuel.
Faulty injector	Clean all injectors.
ENGINE SURGES AT GOVERNED SPEED	
Air leaks in fuel suction lines	Check fuel suction lines and correct as required.
Faulty injector	Clean all injectors.
Leaks in oil system	Check for oil leaks, check oil lines, check crankcase drain plug and gasket; correct as required. Piston rings or cylinder liners may be worn.
Engine due for overhaul	Schedule the overhaul and correct as required.
SLUDGE IN CRANKCASE	
Fouled lubricating oil strainer or filter	Check strainers and filters, remove and service as required, reinstall on engine with new gaskets.

Cause	Remedy
Faulty thermostat	Check coolant thermostats; engine may be too cool.
Dirty lubricating oil	Drain old oil, service strainers and filters, refill with fresh oil.
LUBRICATING OIL DILUTED	
Fuel in lubricating oil	Check for loose injector inlet or drain connection; correct as required. Drain old oil, service strainers and filters, refill with fresh oil.
Coolant in lubricating oil	Check for internal coolant leaks. Correct as required. Drain old oil, service strainers and filters, refill with fresh oil.
LOW LUBRICATING OIL PRESSURE	
Faulty oil line, suction level	**\1** Check oil lines for good condition; fill oil to proper oil level. **/1/** Piston rings, crankshaft bearings, or cylinder liners may be worn.
Engine due for overhaul	Schedule overhaul and correct as required.
ENGINE RUNNING TOO HOT	
High exhaust backpressure	Check exhaust system and turbocharger; correct as required.
Faulty thermostat	Check coolant thermostats; correct as required.
Low lubricating oil level	Fill to proper level with fresh oil.
Engine overload	Reduce load to proper level.
Faulty cooling system component (pump, hose, radiator fan belt)	Check components; correct as required. Fill cooling system to proper level with coolant.
Low coolant level	Air in system. Refer to **\1** TM 5-685, Appendix D. **/1/**

Cause	Remedy
ENGINE KNOCKS	
Poor-quality fuel	Replenish fuel supply with fresh, proper-quality fuel.
Air leaks in fuel suction lines	Check fuel suction lines and correct as required.
Engine overloaded	Reduce load to proper level.
Engine running too hot	Repeat the procedures for “too hot” above.
Faulty vibration damper or flywheel	Correct as required; refer to manufacturer’s instructions.
Engine due for overhaul	Schedule the overhaul and correct as required.

A-1.1.3 Overhaul Procedure.

Engine overhaul requires disassembly of the engine. Verify that all engine parts comply with the manufacturer’s specifications and tolerances.

A-1.1.4 Inspection of Structural Parts.

Inspect structural parts as follows:

- Foundations for deformation and cracks.
- Bedplate for cracks and distortion; bearing supports for good condition.
- Foundation bolts for tightness and general good condition, including straightness.
- Frames for cracks, distortion, and general good condition.
- Cylinders and cylinder blocks for cracks; water jacket areas for corrosion, scale, and rust; machined surfaces for smoothness.
- Cylinder heads for cracks; water jacket areas for corrosion, scale, and rust; valve seats for cracks; machined surfaces for smoothness.
- Covers and gaskets for distortion and cracks; use compliant gaskets only after annealing; use new seals and gaskets other than copper.

A-1.1.5 Moving Parts.

Inspect moving parts as follows:

- Crankshaft for out-of-alignment condition; journal surfaces for highly polished condition and absence of scratches, nicks, etc.; and counterweights, gears, and flywheels for proper condition. Verify that crankshaft complies with manufacturer's requirements. An engine crankshaft is a costly and vulnerable component. Special care in handling is required. Accurate alignment is essential to good engine operation. Removal or installation may require hoisting. Refer to the manufacturer's instructions for details and proper procedures.
- Main bearings for highly polished condition, cracks, deformation and absence of scratches, nicks, etc.
- Thrust bearings for cracks and deformation; surfaces for smoothness and absence of scratches and nicks.
- Camshaft cams and cam faces for worn or deformed condition; journal surfaces and bearings for highly polished condition and absence of scratches, nicks, etc.; cam contours and cam followers for good condition.
- Connecting rods for cracks or other flaws by magnaflux or dye penetrant method and for bending and parallelism; bearings for highly polished condition and absence of scratches, nicks, cracks, and deformation.
- Pistons for cracks and warped condition; verify pistons, rings, and pins comply with manufacturer's requirements; rings and pins for general good condition.
- Timing gear mechanisms for good condition; backlash for manufacturer's tolerance requirements; gear teeth for general good condition.
- Auxiliary or accessory drives for good operating condition. Consult the specific manufacturer's literature for instructions.

A-1.1.6 Repair Parts and Supplies.

Certain repair parts and supplies must be available for immediate use. Refer to specific manufacturer's literature for recommendations. The following information is a general guide:

- The following parts should be renewed at each component change: gaskets, rubber sleeves, and seals. Adequate quantities should be maintained.
- The following parts have a reasonably predictable service life and require replacement at predictable periods: fuel injectors, pumps, governors, and valves. A one-year supply should be maintained.
- The following parts have a normally long life and, if failure occurs, could disable the engine for a long period of time: cylinder head, cylinder liner, piston and connecting rod, gear and chain drive parts, and oil pressure pump. One item of each part for an engine should be available.

A-1.1.7 Parts Salvage.

Certain parts may be replaced prior to their failure due to a preventive maintenance program. It may be possible to restore these parts to specified tolerances. Refer to specific manufacturer's literature for recommendations and instructions. The following information is a general guide:

- Worn pump shafts and cylinder liners may be built up and machined to specified dimensions.
- Grooves in pistons may be machined and install oversize rings specified for use.
- Press-fitted bushings and bearings may loosen. The related body part may be machined to a new dimension and oversize bushings and bearings fitted.
- Worn journals on crankshafts and camshafts may be built up and machined to specified dimensions.

A-2 GENERATOR MAINTENANCE.

A-2.1 Service and Troubleshooting.

Service consists of performing basic and preventive maintenance checks that are outlined in Table A-3. If troubles develop or if these actions do not correct a problem, refer to Table A-4. Maintenance personnel must remember that the manufacturer's literature supersedes the information provided herein.

A-2.2 Operational Check.

Check the equipment during operation and observe the following indications:

- Unusual noises or noisy operation may indicate excessive bearing wear or faulty bearing alignment. Shut down and investigate.
- Equipment overheats or smokes. Shut down and investigate.
- Equipment brushes spark frequently. Occasional sparking is normal but frequent sparking indicates dirty commutator and/or brush or brush spring defects. Shut down and investigate.

A-2.3 Preventive Maintenance.

Inspect the equipment as described once a month. Maintenance personnel should make a checklist suited to their particular needs. The actions listed in Table A-3 are provided as a guide and may be modified. Refer to manufacturer's instructions.

A-2.4 Troubleshooting.

Perform general troubleshooting of the equipment as outlined in Table A-4 if a problem develops. Table A-6 provides guidance on interpreting insulation test results and Table A-7 provides low voltage circuit breaker troubleshooting checks. Refer to the manufacturer's literature for repair information after diagnosis.

Table A-3 Generator Inspection Checklist

Inspect	Check For
Brushes	Amount of wear, improper wear, spring tension
Commutator	Dirt, amount of wear, loose leads, loose bars
Collector rings	Grooves or wear, dirt, carbon and/or copper accumulation, greenish coating (verdigris)
Insulation	Damaged insulation; measure and record insulation resistance
Windings	Dust and dirt, connections, loose windings or connections
Bearings	Loose shaft or excessive endplay, vibration (defective bearing)
Bearing housing	Lubricant leakage; dirt or sludge in oil (sleeve bearings)
Ventilation and cooling	Obstruction of air ducts or screens; loose or bent fan blades

Table A-4 Generator Troubleshooting

Cause	Remedy
NOISY OPERATION	
Unbalanced load or coupling	Balance load and check alignment misalignment
Air gap not uniform	Center rotor by replacing or shimming bearings
Coupling loose	Tighten coupling
OVERHEATING	
Electrical load unbalanced	Balance load
Open line fuse	Replace line fuse
Restricted ventilation	Clean; remove obstructions
Rotor winding shorted, opened, or grounded	Repair or replace defective coil

Cause	Remedy
Stator winding shorted, opened, or grounded	Repair or replace defective coil
Dry bearings	Lubricate
Insufficient heat transfer of cooler	Verify design flow rate: repair or replace unit
NO OUTPUT VOLTAGE	
Stator coil open or shorted	Repair or replace coil
Rotor coils open or shorted	Repair or replace coils
Restricted ventilation	Clean; remove obstructions
Shorted slip rings	Repair as directed by manufacturer
Internal moisture	Dry winding (indicated by low-resistance reading on megger)
Voltmeter defective	Replace
Ammeter shunt open	Replace ammeter and shunt
OUTPUT VOLTAGE UNSTEADY	
Poor commutation	Clean slip rings and reseat brushes
Loose terminal	Clean and tighten all contact connections
Fluctuating load	Adjust voltage regulator and governor speed
OUTPUT VOLTAGE TOO HIGH	
Over-excited	Adjust voltage regulator
One leg of delta-connected stator open	Replace or repair defective coils
FREQUENCY INCORRECT OR FLUCTUATING	
Speed incorrect or fluctuating	Adjust speed-governing device
VOLTAGE HUNTING	
External field resistance in out position	Adjust resistance
Voltage regulator contacts dirty	Clean and reseat contacts
STATOR OVERHEATS IN SPOTS	
Open phase winding	Cut open coil out of circuit and replace at first opportunity; cut and replace the same coil from other phases
Rotor not centered	Realign and replace bearings, if necessary

Cause	Remedy
Unbalanced circuits	Balance circuits
Loose connections or wrong connections	Tighten connections or correct wrong polarity coil connections
Shorted coil	Cut coil out of circuit and replace at first opportunity
FIELD OVERHEATING	
Shorted field coil	Replace or repair
Improper ventilation	Remove ducts obstruction, clean air filter
ALTERNATOR PRODUCES SHOCK WHEN TOUCHED	
Reversed field coil.	Check polarity. Change coil leads.
Static charge.	High-speed charge belts build up a static. Connect alternator ground strip frame to a ground strip.

Table A-5 Interpreting Insulation Resistance Test Results

Test Results Condition	What to Do
Fair to high values and well-maintained	No cause for concern
Fair to high values but showing a constant tendency towards lower values	Locate and remedy the cause then check the downward trend
Low but well-maintained	Condition is probably all right, but cause of low values should be checked
So low as to be unsafe	Clean, dry out, or otherwise raise the values before placing equipment in service (test wet equipment while drying out)
Fair or high values, previously well-maintained but showing sudden lowering	Make tests at frequent intervals until the cause of low values is located and remedied; or until the values have become steady at a lower level but safe for operation; or until values become so low that it is unsafe to keep the equipment in operation

Table A-6 Condition of Insulation Indicated Absorption Ratios by Dielectric Insulation

Insulation	60/30-Second Ratio	10/1 - Minute Polarization Ratio Index
Dangerous	--	Less than 1
Questionable	1.0 to 1.25	1.0 to 2
Good	1.4 to 1.6	2 to 4
Excellent	Above 1.6	Above 4

Table A-7 Low Voltage Circuit Breaker Troubleshooting

Issue	
Cause	**Remedy**
Note: Refer to manufacturer's literature for specific information on circuit breakers.	
OVERHEATING	
Contacts not aligned	Adjust contacts
Contacts dirty, greasy, or coated with dark film	Clean contacts
Contacts badly burned or pitted	Replace contacts
Current-carrying surfaces dirty	Clean surfaces of current-carrying parts
Corrosive atmosphere	Relocate or provide adequate enclosure
Insufficient bus or cable capacity	Increase capacity of bus or cable
Bolts and nuts at terminal connections not tight	Tighten but do not exceed elastic limit of bolts or fittings
Current in excess of breaker rating	Check breaker applications or modify circuit by decreasing load
Inductive heating	Correct bus or cable arrangement
FAILURE TO TRIP	
Travel of tripping device does not provide positive release of tripping latch.	Adjust or replace tripping device.
Worn or damaged trip unit	Replace trip unit
Mechanical binding in overcurrent trip device	Correct binding condition or replace overcurrent trip device

Issue	
Cause	**Remedy**
Electrical connectors for power sensor loose	Tighten, connect, or replace electrical connectors
Loose or broken power sensor connections	Tighten or re-connect tap coil tap connections
FALSE TRIPPING	
Overcurrent pick-up too low	Check application of overcurrent trip device
Overcurrent time setting too short	Check application of overcurrent trip device
Mechanical binding in over condition current trip device	Correct binding or replace overcurrent trip device
Captive thumbscrew on power sensor loose. Fail safe circuitry reverts characteristics to minimum setting and maximum time delay.	Adjust power sensor. Tighten thumbscrew on desired setting.
Ground sensor coil improperly connected	Check polarity of connections to coil. Check continuity of shield and conductors connecting the external ground sensor coil.
FAILURE TO CLOSE AND LATCH	
Binding in attachments preventing resetting of latch	Realign and adjust attachments
Latch out of adjustment	Adjust latch
Latch return spring too weak or broken	Replace spring
Hardened or gummy lubricant	Clean bearing and latch surfaces
Safety pin left in push rod	Remove safety pin
Motor burned out	Replace motor
Faulty control circuit component	Replace or adjust faulty device
BURNED MAIN CONTACTS	
Improper contact sequence (main not sufficiently parted when arcing contacts part)	Increase arcing contact wipe. Adjust contacts contact opening sequence. Refer to manufacturer’s literature for contact maintenance and adjustment information.
Short-circuit current level above interrupting rating of breaker	Requires system study and possible replacement with breaker having adequate interrupting capacity.

A-3 MEDIUM-VOLTAGE ELEMENTS.

A-3.1 Troubleshooting.

Use recognized industrial practices as the general guide for servicing. Refer to manufacturer's literature for specific information on individual voltage regulators. Troubleshooting procedures include the following: (a) check voltage for compliance with manufacturer's specifications, and (b) check for loose or insecure electrical connections.

A-3.2 Switchgear Equipment Troubleshooting.

Use recognized industrial practices as the general guide for servicing. Refer to manufacturer's literature for specific information on individual voltage regulators.

Troubleshooting procedures include the following:

- Check voltage for compliance with manufacturer's specifications.
- Check for loose or insecure electrical connections.
- Check for correct setting; refer to manufacturer's literature.
- Check for unregulated voltage; refer to manufacturer's literature.
- Check the enclosure; should be weather-tight.
- Check motor for proper operation and loose connections. Clean and lubricate as required. Refer to manufacturer's literature for details.
- Voltage regulators and associated equipment are normally mounted within switchgear equipment and are interconnected with different components. The proper operation and troubleshooting of voltage regulator equipment can depend on these different components. Perform the procedures in Table A-8.

Table A-8 Switchgear Equipment Troubleshooting

Issue	
Cause	**Remedy**
Note: Refer to manufacturer's literature for specific information on individual equipment.	
WATTHOUR METER INACCURATE	
Meter may be dirty or damaged	Install new meter, return faulty meter to repair depot for repair and calibration.
Faulty wiring or connections	Inspect and repair as necessary.
WATTHOUR METER FAILS TO REGISTER	
Blown potential transformer fuse, wiring broken wires, or other fault in connections	Renew blown fuses. Check and repair as required.
Wedge or block accidently left at time of test or inspection	Remove wedge or block. Verify that meter is in good operating condition.
DAMAGED CONTROL, INSTRUMENT TRANSFER SWITCH, OR TEST BLOCKS	
Burned or pitted contacts	Dress or clean burned contacts or replace with new contacts if necessary.
RELAYS FAILING TO TRIP BREAKERS	
Improper setting	Adjust setting to correspond with circuit conditions. Refer to manufacturer's instructions.
Dirty, corroded, or tarnished contacts	Clean contact with knife or tile. Do not use emery cloth or sandpaper.
RELAYS FAILING TO TRIP BREAKERS	
Contacts improperly adjusted	Adjust contacts. Verify proper wipe action.
Open or short circuit connections	Check to verify that voltage is applied and current is passing through relay in question.
Improper application of target	Verify proper tripping action of target and holding coil.
Faulty or improperly adjusted timing devices	If timing device is of bellows or oil-film type, clean and adjust. If an induction-disk type, check for mechanical interference. Refer to manufacturer's literature.
NOISES DUE TO VIBRATING PARTS	
Loose bolts or nuts permitting excessive vibration	Tighten to proper torque value.

Issue	
Cause	**Remedy**
Loose laminations in cores of transformers, reactors, etc.	Tighten loose nuts or core clamps to proper torque value.
CONNECTIONS OVERHEATING	
Increase of current due to overload conditions	Increase the carrying capacity (increase the number or size of conductors). Remove excess current.
Connecting bolts and nuts not tight	Tighten ail bolts and nuts to proper torque value.
FAILURE IN FUNCTION OF ALL INSTRUMENTS AND DEVICES HAVING POTENTIAL WINDINGS	
Loose nuts, binding screws, or broken wire at terminals	Tighten all loose connections to proper torque value or repair broken wire circuits.
Blown fuse in potential transformer circuit	Renew blown fuses.
Open circuit in potential transformer primary or secondary circuits	Repair open circuit and check entire circuit for continuity and good condition.
BREAKER FAILS TO TRIP	
Mechanism binding or sticking	**\1** Lubricate breaker mechanism; refer to manufacturer's instructions. **/1/**
Mechanism out of adjustment	Adjust all mechanical devices (toggles, stops, buffers, opening springs, etc.) according to manufacturer's instructions.
Failure of latching device	Examine surface of latch; replace latch if worn or corroded. Check latch wipe; adjust according to manufacturer's instructions.
Damaged trip coil	Replace damaged coil.
Blown fuse in control circuit (where trip coils are potential type)	Replace blown fuse.
Faulty connections (loose or broken wire) in trip circuit	Repair faulty wiring; tighten all binding screws to proper torque value.
OIL CONTAMINATED	
Carbonization from too many operations	Drain oil and filter; clean or replace. Add fresh oil. Clean inside of tank and all internal parts of breaker; refer to manufacturer's instructions.
Condensation due to atmospheric conditions	Same procedure as above.
Overheating	Eliminate cause of overheating.

Issue	
Cause	**Remedy**
RELAY TROUBLESHOOTING	
Note: Refer to manufacturer’s literature for specific information on individual equipment.	
MAGNET-OPERATED INSTANTANEOUS TYPE	
High Trip Action	
Faulty coil	Install coil with correct rating.
Low Trip Action	
Shorted turns on high trip	Test coil and replace with new coil if found defective.
Mechanical binding; dirt, corrosion	Clean parts.
Assembled incorrectly	See manufacturer’s instructions.
MAGNET-OPERATED INVERSE-TIME TYPE	
Slow Action Trip	
Fluid too heavy, vent too small, or temperature too low	Change fluid and open vent slightly; regulate temperature.
Worn parts	Replace and adjust.
Fast Trip Action	
Worn, broken parts	Replace and adjust.
Fluid too light, vent too large, or temperature too high	Change fluid to proper grade. Close vent slightly or regulate temperature. Clean dashpots and refill with fresh fluid or proper grade.
THERMAL TYPE	
Fails to Trip, Causing Motor Burnout	
Wrong size heater	Check rating with recommendations on instruction sheet.
Mechanical binding; dirt, corrosion	Clean and adjust.
Relay damaged by short circuit	Replace relay.
Motor and relay in different ambient temperature	Install motor and control near each other or make temperature uniform for both.

A-3.3 Routine Maintenance.

Routine maintenance instructions for prime movers consist of short- and long-term checklists for diesel and gas turbine engines.

A-3.3.1 Diesel Engines Short-term Checklist.

Before performing any tasks required by Table A-9, review the station log sheets, related records, and manufacturer's recommendations.

Table A-9 Diesel Engines Short-Term Checklist

Item	Action
Valves	Check valve operation.
Fuel injection nozzles	Check fuel-injection nozzles for secure mounting and connections each time the engine is shut down. Torque down the nozzle according to the manufacturer's instructions.
Starting system	Check the general condition of the air compressor, air lines, and valves, when applicable. Briefly open the system's safety valve weekly. Check for proper operation. Refer to manufacturer's instructions for details.
Governor alarms and instruments	Check operation of governor alarms and instruments. Refer to manufacturer's instructions.
Pressure gauges	Check pressure gauges and clean exposed indicating elements. Refer to manufacturer's instructions.
Intake and exhaust systems	Check air filters and engine exhaust. A smoking exhaust indicates incorrect adjustments. Clean air filters as necessary.
Exhaust lines	Clean and inspect exhaust lines. On two-cycle engines, remove carbon from exhaust ports and clean thermocouples. Refer to manufacturer's instructions for frequency of checks.

Item	Action
Evaporative cooling	Refer to manufacturer's instructions for cooling tower maintenance. Inspect and oil fan shaft bearings, oil damper bearings, and linkage. Inspect spray nozzles; clean as necessary. Clean pump suction screen. Clean sump pan. Inspect cooling coil. If scale has formed, circulate cleaning solution. Do not operate fan while cleaning coil. Check belts for condition and proper tension. Refer to manufacturer's instructions.
Fuel oil system	Clean fuel oil strainers as required by operating conditions. Check the system components for clean condition. Refer to manufacturer's recommendations.
Fuel filters and centrifuges	Check fuel oil filters and centrifuges. Check fuel oil system for leaks and correct as required. Refer to manufacturer's instructions.
Lubricating systems	Check mechanical lubrication hourly during operation. Oil all hand lubrication points, following manufacturer's instructions. Correct leaks.
Sight-feed lubricators	Clean sight-feed lubricating oil strainers as necessary. Check for adequate lubricant supply.
Lubricating oil filters	Check lubricating oil filters. Clean and replace filter elements as necessary.
Piston assembly and connecting rods	On two-cycle engines, remove upper handhole inspection cover from side of engine immediately after the engine is shut down and inspect the piston for proper lubrication.
Cylinders and cylinder heads	Use compressed air to blow out indicator connections. Clean indicators and install. Refer to manufacturer's instructions.
Crankshaft, crankpin and main bearings	Remove crankcase covers immediately after engine is shut down. Check main and crankpin bearings for proper lubrication. Check bearing temperatures for excessive heat by hand-touch. Refer to manufacturer's instructions for frequency of checks.

Item	Action
Gauges and instruments	Verify that gauges and instruments have up-to-date calibration certifications. Read and record all indications of gauges, thermometers, and other instruments at regular intervals as required by the operating log.
Turbocharger	Observe every four hours during operation. Check for general condition and signs of vibration. Evaluate vibration if present.
Turbocharger impeller	Check turbocharger impeller for accumulated dirt and axial endplay. Dirt may indicate faulty filtering equipment. Clean and service according to manufacturer’s instructions.

A-3.4 Diesel Engines Long-Term Checklist.

Performance of checklist tasks is related to frequency and extent of use of the auxiliary power plant. Table A-10 tasks should be performed annually unless otherwise noted, following performance of short-term checks.

Table A-10 Long-Term Checklist for Diesel Engines

Item	Action
Valve inspection	Inspect exhaust valves; clean and remove carbon on two-cycle engines and valves as necessary. Refer to manufacturer’s instructions.
Inlet valves	Inspect and regrind inlet and exhaust valves and valve seats as necessary. Refer to manufacturer’s instructions.
Valve springs and guides	Check valve spring length and tension and inspect valve stems, bushings, and guides annually or after 2,000 hours of use, whichever comes first. Replace parts as necessary. Refer to manufacturer’s instructions.
Camshaft and drive	Check and adjust gears and/or timing chain. Refer to manufacturer’s instructions.
Camshaft bearings	Inspect and adjust camshaft bearing clearances. Refer to manufacturer’s instructions.

Item	Action
Fuel injection nozzle inspection	After 2,000 hours of use, remove and check nozzles in the test stand. Service and adjust nozzles following manufacturer's instructions.
Fuel injection pumps	Inspect fuel injection pumps for secure mounting, cleanliness, and proper operation.
Fuel injection pump inspection	Disassemble and recondition all injection pump nozzles after 2,000 hours of use. Repair or replace worn or damaged parts. Reassemble and adjust, following the manufacturer's instructions.
Air lines	Drain water from air lines and tank monthly or as necessary. Drain valves are usually located at the lowest point(s) in the air feed system.
Air valves	Clean air valves and reseat if necessary. Refer to manufacturer's instructions.
Air compressor	Disassemble and overhaul air compressor and starting equipment every five years based on frequency of use of the auxiliary power plant.
Pressure gauge inspection	Check the date of calibration. Verify that gauges have valid calibration certification. Calibrate per manufacturer's instructions as required.
Governor overhaul	Overhaul the governor after 2,000 hours of use or when needed, as indicated. Repair or replace worn or damaged parts. Reassemble and adjust, following the manufacturer's instructions.
Muffler (silencer)	Keep the muffler and waste heat equipment, boiler, or heat exchange clean. Accumulations of unburned lubricating oil and soot or carbon are potential fire hazards. Make sure fuel combustion is as efficient as possible. Refer to manufacturer's instructions.
Cooling systems	Inspect piping and valves for leaks and clean the heat exchanger. Perform cooling system maintenance; refer to manufacturer's instructions.
Cooling tower	Drain and clean cooling tower; clean and inspect piping, circulating pumps, and equipment.

Item	Action
Cooling system service	Clean and inspect entire cooling system yearly. Overhaul pumps and recondition valves and other equipment as necessary. Refer to manufacturer's instructions.
Fuel oil tanks and lines	Drain service tanks and lines. Remove water and sediment. Check heating coil for proper operation.
Lubricating oil cooler	Clean and inspect lubricating oil cooler for leaks and good condition. Clean outer surfaces more often under dusty operating conditions for more efficient cooling. Refer to manufacturer's instructions.
Crankcase	Drain crankcase semiannually or more frequently based on number of hours run per manufacturer's recommendations or acceptable industrial engine maintenance procedures. Inspect lubricating oil pumps; flush crankcase and refill. **\1** Refer to manufacturer's instructions and, for Army, PAM 750-8, *The Army Maintenance Management System (TAMMS) User's Manual*. **/1/**
Lubricating oil pump	Inspect the pump after 2,000 hours of use for proper operation. Refer to manufacturer's specifications for the pump.
Cylinder heads	Remove cylinder heads according to manufacturer's instructions after 2,000 hours of use. Inspect cylinder liners. Clean and inspect water jackets. Remove scale and corrosion as necessary. Inspect and measure diameter of cylinder liners. Check gaskets for annealing, brittleness, or cracks. Install new gaskets if necessary.
Piston assembly inspection	On four-cycle engines, pull one piston after 2,000 hours of use and inspect for proper cooling, lubrication, and carbon deposits. Inspect piston rings and wrist pin and the cylinder liner for compliance with engine manufacturer's specifications.
Pistons inspection	Pull pistons after 4,000 hours of engine use. Clean and inspect all parts for wear, proper lubrication, and cooling. Verify that rings and ring clearances comply with engine manufacturer's specifications.

Item	Action
Cylinder inspection	Use the barring device (jacking bar) to turn each piston to top dead center during inspection. Inspect each cylinder liner for scoring. Refer to manufacturer's instructions.
Anchor bolts	Check anchor bolts for proper torque value.
Flywheel bolts	Check flywheel bolts for proper torque value. Refer to manufacturer's instructions. Verify alignment and coupling to generator; comply with specifications.
Main and crankpin bearings	Remove bearing caps; check journals and bearings for proper lubrication, wear, or scoring. Check main bearings for proper alignment. Refer to manufacturer's instructions.
Crankshaft	Verify compliance with engine manufacturer's specifications. Examine crankshaft for cracks. Measure distance between crank webs for crankshaft deflection. Check journal level and clean oil passages. Replace bearings as necessary and adjust running clearance, following the manufacturer's instructions.
Turbocharger inspection	Disassemble, clean, and inspect entire turbocharger following manufacturer's instructions and specifications.
General overhaul	Overhaul diesel engines and driven equipment every ten years or about 16,000 hours of auxiliary use. Follow the manufacturer's recommendations and instructions. Comply with the manufacturer's specifications.

A-3.5 Short-Term Checklist for Gas Turbines.

Checks are limited to inspection and cleaning tasks that can be performed on the exterior of an engine.

A-3.5.1 General.

Before performing any tasks required by the following checklist, review the station log sheets, related records, and the manufacturer's recommendations. The following precautions must be met.

- Shut the engine down.
- Apply "Do not operate" tags to the operating controls.

- Open the engine automatic start circuit.
- Deactivate the fire extinguishing system.
- Keep all engine enclosure doors open while working on the engine.
- Allow engine to cool down before working on it.

A-3.5.2 Short-Term Checklist.

Table A-11 provides a short-term checklist for gas turbines.

Table A-11 Gas Turbine Short-Term Checklist

Item	Action
Inlet inspection	Verify the inlet drain at lower part of duct is open and free of any obstruction so moisture (rain or condensation) can run off. Check inlet temperature sensor for signs of damage. Clean sensor and surrounding area with approved solvent to remove dirt and contaminants. Refer to manufacturer’s instructions. Make sure sensor is securely attached to engine.
Exhaust Inspection	Visually inspect engine exhaust casing, struts, and center body for cracks, nicks, and other signs of damage. Refer to manufacturer’s instructions. Inspect exhaust stack for freedom from obstructions and general good condition
Chip Detectors	Engines usually have plugs with magnetic chip detectors at lubrication sumps. During normal operation, some fuzz-like particles will be found on the detectors. Also, other materials (non-metallic sludge and/or flakes, bronze powder, aluminum chips, etc.) may accumulate on the plugs. Refer to manufacturer’s literature for specific information. Check chip detectors for electrical continuity while installed. Continuity is an indication of contamination. Remove chip detectors if contaminated. Discard packing and clean chip detector. Check chip detector for good thread and proper magnetism. Place new packings on chip detectors and install on engine. Tighten to proper torque.

Item	Action
External Inspection	Inspect engine tubes, hoses, tube/hose fittings, electrical assemblies and connectors for security, and overheating and damage due to leakage. Perform inlet and exhaust inspection as previously described. Check standoffs, brackets, and struts for looseness, cracks, and damage. Check ignition exciter, igniter plugs and leads for damage, overheating, and security. Check mechanical control for signs of excessive wear, damage, and security. Check fuel manifold for leaks, signs of damage, and security. Check for rust and/or corrosion.

A-3.6 Long-Term Checklist for Gas Turbines.

Long-term checks usually affect interior areas of the engine and are seldom performed in the field. Repairs, if necessary, may involve changes in component balance relationships and should be performed at the designated overhaul location. Refer to the manufacturer’s literature for information.

A-4 GENERATORS AND EXCITERS.

Routine maintenance instructions for generators and exciters consist of short- and long-term checklists for rotating and static type equipment.

A-4.1 Short-term Checklist.

Before performing any Table A-12 tasks, review the station log sheets, related records, and the manufacturer's recommendations.

Table A-12 Generators and Exciters Short-Term Checklist

Item	Action
Air screens or filters	Air screens or filters should be changed when the air flow is restricted enough to increase generator operating temperature. Refer to manufacturer's literature.
Exciter coupling (if applicable)	When generator unit is shut down prior to operation, wipe off excess lubrication from the coupling to prevent spatter.
Coupling leaks and alignment	When generator has been shut down, check for lubrication leaks and tightness of coupling. Note any evidence of improper alignment and correct if necessary.
Axial position	Check axial position of the prime mover, generator, and exciter shafts for correct alignment and angularity.
Bearings	Lubrication of generator and exciter bearings is required. Refer to manufacturer's literature for instructions for pressure and non-pressure lubricated bearings.
Rotary exciters, brushes, and brush rigging	Remove carbon dust from collector ring and commutator with vacuum and dry with compressed air at about 25 psi (172 kPa) monthly. Check brushes for wear and indications of arcing and chattering monthly. Check condition of slip rings. Refer to manufacturer's instructions.
Static exciters	Verify the equipment is clean and free from dirt and moisture. Verify all connections are tight. Check connections for corrosion and clean as required.

A-4.2 Long-term Checklist.

Table A-13 tasks should be performed annually unless otherwise noted in manufacturer's instructions, and following execution of short-term checks.

Table A-13 Generators and Exciters Long-Term Checklist

Item	Action
Coupling lubrication	Drain lubricant, disassemble, and clean coupling annually or whenever necessary. Reassemble, using new gaskets and fresh lubricant. Refer to manufacturer's instructions for flexible coupling.
Brush replacement	When brushes have worn to half their original length, replace, seat properly, and adjust brush rigging tension from 2.5 to 3.6 psi (17.2 to 24.8 kPa) on brush riding surface. Repair and replace damaged or worn brush rigging parts. Refer to manufacturer's instructions.
Brush electrolysis	Electrolytic action can occur at collector ring surfaces. This action forms a greenish coating (verdigris) on brass, bronze, or copper. Effects of this action can be reduced or eliminated by reversing the polarity annually or as required. Refer to manufacturer's instructions.
Commutator and collector rings	Clean commutator and collector rings with vacuum. Clean oil film and dirt with approved solvent. Dry with compressed air at about 25 psi (172 kPa). Check for roughness, hard spots, and out-of-round condition. Service commutator and collector rings as necessary, following manufacturer's instructions.
Rotor winding	Rotor maintenance begins with measuring and recording the insulation resistance before the unit is placed in service. Refer to manufacturer's literature for instructions. The rotor should be thoroughly cleaned annually and inspected as follows: • Check the damper winding for loose bars and the connection of each bar to its ring segment. • Check the joints in the ring segments between poles. Refer to manufacturer's instructions. • Check clearance per manufacturer's specifications between blower and coils.

Item	Action
	• Check the field coils for movement and separation. • Clean dirt and oil from winding and air passages. • Check condition of turn-to-turn insulation on strap field coils. • Verify condition of ground insulation on pole pieces. • Check all connections between field coils and lead-out connections to collector rings. • Measure and record insulation resistance between field coils and ground, including the collector rings. Refer to manufacturer's instructions. • Check bearings and journals for damage or excessive wear. • Compare micrometer readings with the manufacturer's table of wear limits. • Repair or replace mechanical parts to meet these specifications. • Dry out according to manufacturer's instructions. • Repair insulation damage and coat with approved insulating varnish.
Rotor balancing	Measure and record vibration limits of repaired unit when it is started. Refer to manufacturer's specifications for vibration limits for the specific unit. Perform static or dynamic balancing of the unit, according to instructions, if necessary.
Stator winding	Measure and record insulation resistance between stator winding and ground at the machine terminals annually.
Stator service	Open up the stator annually. Clean thoroughly and inspect for the following: broken, damaged, loose, or missing wedges; movement or distortion of coil ends; security of all lashing and spacers; tightness of coil supports; cooling passages are open and clean; looseness of coils in slots; cracks or other damage to coil insulation; and connections between coils and around the frame. Measure and record insulation resistance between winding and ground at the machine terminals. Compare the values with those recorded when the machine was first put in service.

A-4.3 Checklist and Schedule for Solid-state Exciters.

Solid-state equipment does not require long-term checks. If the equipment does not function properly, refer to the manufacturer's literature for information. Repair or replace as required.

A-5 SWITCHGEAR MAINTENANCE.

Routine maintenance instructions for switchgear consist of short- and long-term checklists. De-energize switchgear before performing maintenance. Disconnect primary and secondary sources of power.

A-5.1 Short-Term Checklist.

Before performing any tasks in Table A-14, review the station log sheets, related records, manufacturer's recommendations, and NFPA 70E.

Table A-14 Switchgear Maintenance Short-Term Checklist

Item	Action
Panels and other exterior surfaces	Panels and exterior surfaces must be kept scrupulously clean at all times.
Relays and actuating mechanisms	Clean and inspect relays and actuating mechanisms monthly. Many types of relays are used. Identify the relays such as thermal, current overload, over speed, liquid level, lubricating oil pressure and/or flow, frequency change, etc. Refer to manufacturer's literature for inspection procedures. Verify all connections are tight and free of corrosion.
Conductors and coils	Clean and inspect conductors and coils monthly. Verify coating of insulating varnish is in good condition (clean, smooth, and polished) and there are no indications of overheating or corona arcing.
Switches	Inspect switches for proper alignment, firm contacts, and smooth operation monthly. Burned or pitted copper contact surfaces may be dressed with 2/O sandpaper. Do not dress silver contacts.
Circuit breakers	Trip and close circuit breakers; check for proper operation quarterly. Check time delay and freedom of movement. Refer to manufacturer's instructions.
Coils and heaters	Check coils and heaters quarterly for secure mounting and circuit continuity. Check controls and thermostats for proper operation; refer to manufacturer's instructions.
Contactors	Check magnet surfaces of contactors quarterly for cleanliness. Remove gum, rust, or corrosion. Adjust for even contact pressure according to manufacturer's instructions.
Voltage regulators	Check voltage regulators for proper operation and adjustments quarterly. Various makes and types are used. Refer to manufacturer's literature for instructions.

A-5.2 Long-term Checklist.

Performance of tasks is related to frequency and extent of use of the auxiliary power plant. Table A-15 tasks should be performed annually unless otherwise noted in manufacturer's guidance and following the execution of short-term checks. The procedures are general but apply primarily to draw-out equipment.

Before performing any tasks required by the following checklist, review the station log sheets, related records, manufacturer's recommendations, and NFPA 70E.

Table A-15 Switchgear Maintenance Long-Term Checklist

Item	Action
Panels and other exterior surfaces	Panels and exterior surfaces must be kept clean at all times.
Meters and instruments	Check meters and instruments against a verified standard. Return defective or inaccurate meters and instruments to the manufacturer or designated repair location for service and calibration.
Buses	Inspect buses and connections for signs of overheating or weakening of insulating supports. Overheating is indicated by discoloration of the bus bar. Inspect insulators for cracks and/or arc tracks. Replace defective insulators. Tighten bus bar and terminal connections to the proper torque value.
Indicating devices and interlocks	Check indicating devices and interlocks for proper operation. Refer to manufacturer's instructions.
Disconnecting devices	Check primary disconnecting device contacts for signs of overheating or abnormal wear. Clean contacts with silver polish. Clean disconnecting device contacts and apply light coating of approved lubricant.
Enclosure	Verify that interior anchor bolts and structural bolts are tight. Inspect cable connections for signs of overheating. Tighten loose connections as required.
Circuit breakers	Manually operate each breaker while in test position; verify proper operation. Refer to manufacturer's instructions.

Item	Action
Environmental conditions	More frequent inspections of the switchgear must be made when unusual service conditions exist, such as contaminating fumes, excessive moisture, or extreme heat or cold. Additional protection may be required if adverse conditions are present.
Ground resistance	Measure and record ground resistance values using a ground resistance test set. Compare these values with those recorded during previous tests. The tests indicate grounding system effectiveness and possible deterioration since the last tests.

A-6 OIL MAINTENANCE PROCEDURES.

Table A-16 provides a general guide for maintenance of lubricating oil. Table A-17 provides normal and maximum oil quality standards.

Table A-16 Oil Maintenance

Item	Action
Water and sediment	Clean by centrifuging.
Viscosity	Treat with oil reclaimer to drive off dilution. Centrifuge (hot) to remove heavy sludge. If necessary, add straight run mineral oil of lower viscosity.
Corrosion	Treat with activated-type reclaimer. If an additive oil is in use, the presence of corrosive qualities indicates the additive is exhausted. New oil must be used if the benefit of additives is required. Used oil may be reclaimed and used for other services not requiring the additive.
Particles	Passage of particles larger than the filter’s specifications are a definite sign of channeling or structural damage to filter elements. Replace filter cartridges.

Table A-17 Oil Quality Standards

Item	Normal	Maximum
Water and sediment	1.0%	5.0%
Water	0.5%	3.0%
Sediment	0.5%	2.0%
Viscosity	±5%	±10%
Corrosion (copper strip)	None	Dull
pH	7% or higher	6.8%
Filtered particles (% of total residue)		
Larger than oil filter	None	2%
Metallic under 1 micron	Few	1%
Over 5 microns	None	1%

A-7 FUEL AND FUEL STORAGE.

A-7.1 Diesel Fuel.

Diesel fuel should comply with Federal Specifications W-F-800 MIL-F-16884, or specifications for JP-8. These specifications include grades DF-A, DF-1, DF-2, or types I and II. All are suitable for use under applicable temperature and service conditions. Different grades of fuel should not be mixed.

\1\ Note: For Air Force, see paragraph 8-6.3. **/1/**

A-7.1.1 Cleanliness.

Fuel must be clean. All dirt, dust, water, sediment, and other contaminants must be kept out of the fuel to prevent damage to engine fuel injection equipment. The specified grade of clean fuel must be used to ensure long, economical engine operation. Handling of fuel must be reduced to a minimum to avoid entry of contaminants. Delivery of fuel to storage tanks and then pumping it directly to the day tank through filters is a recommended procedure. Filters must be installed in all engine fuel lines and must be cleaned as recommended by the engine manufacturer.

A-7.1.2 Contamination.

Stored fuel and fuel storage systems must be inspected at regular intervals at a minimum of every 90 days. **\1** Consult T.O. 42B-1-1 for additional information on fuel contamination, testing, and quality surveillance. **/1/** Samples for detecting fuel contaminations are as follows:

1) Inspect fuel filters for indication of microorganism growth, rust, scale, or sediment. In a glass jar, collect a sample of diesel fuel from the bottom of the tank. Solid contaminants will settle and collect at the bottom of the jar. Clean the filters as directed by manufacturer's instructions.

2) Detect water in diesel fuel by collecting in a glass jar a sample of fuel from the bottom of the tank. Fuel and water will separate when the sample is allowed to settle, water will sink to the bottom of the jar. Fuel with water in it may appear white and cloudy when agitated.

3) Detect gasoline or kerosene in diesel fuel by collecting a sample (see above). Fuel and contaminants will separate when the sample is allowed to settle; the gasoline or kerosene will float on the fuel.

4) Detect oil-soluble soaps in diesel fuel by having an appropriate laboratory test performed. Avoid this kind of contamination; do not use galvanized storage tanks or piping.

5) Prevent condensation within storage tanks by keeping the tanks full. Tanks must be kept full during cold weather.

A-7.1.3 Storage.

Fuel tanks used for storage must have drain valves for removal of bottom water (to be done once every six months). Deterioration of stored fuel is caused by three factors: oxidation, microorganism contamination, and corrosion.

1) Oxidation occurs directly or through catalytic action. Oxygen from the air or fuel combines with fuel hydrocarbons, causing oxidation. Resultant oxidation continues as long as oxygen is present. Metals suspended in the fuel act as catalysts. Metals can enter the fuel during refining, distribution, or storage. The engine fuel system can thereby be damaged.

2) Microorganism contamination is caused by bacteria and fungus that exist in the bottom water. Waste by-products of the microorganisms form a self-sustaining corrosive environment. The byproducts can form a gelatinous mass that plugs fuel lines and filters and forms a fuel sludge, thereby reducing engine efficiency and possibly damaging the engine.

3) Corrosion of the storage tank does not directly deteriorate the fuel. Corrosion can destroy a metal storage tank, usually at the bottom. Metals that enter the fuel act chemically to speed up oxidation. The combination of microorganism growth and water causes oxidation.

A-7.2 Gas Turbine Fuel.

\1 Fuel for gas turbines consists of natural gas or light distillate oil such as kerosene, military jet engine fuel (JP-8, JP-5, TS-1, F-24), or commercial jet engine fuel (Jet A, Jet A-1). All are suitable for use under applicable temperature and service conditions. Most gas turbines can burn fuels used by diesel engines. Gas and oil fuels should not be mixed. Consult T.O. 42B-1-1 for additional information. **/1/**

A-7.2.1 Cleanliness.

Fuel must be clean. All dirt, dust, water, sediment, and other contaminants must be kept out of fuel to prevent damage to engine components. Only the specified grade of clean fuel should be used to ensure reliable engine operation. Handling of fuel must be reduced to a minimum to avoid entry of contaminants. Natural gas should be passed through several fine screen filters to remove solid particles and water vapor before it is fed to the gas turbine engine.

A-7.2.2 Contamination.

Stored fuel and fuel storage systems must be inspected at regular intervals at a minimum of every 90 days. Perform the following checks when cleaning filters for a natural gas system.

- Inspect the solid particles removed by fine screen filters. Determine if the particles are dust or dirt, or the type of metal if metallic.
- Inspect water accumulation for acid or alkaline content.

A-7.3 Storage.

Information relating to storing natural gas fuel follows:

- Natural gas can be stored in low-pressure surface containers or high-pressure sub-surface containers and metal bottles.
- Liquefied natural gas can be stored in insulated metal tanks installed as sub-surface units.
- The type of storage employed for natural gas depends on plant requirements and fuel availability.

A-7.4 Fuel Storage Maintenance Procedures.

Provide the base engineer’s office with the reports and results of inspections performed. The base engineer will review this data and take appropriate corrective action, which may include any or all of the following:

- Add an antioxidant to prevent oxidation or “aging” of a fuel.
- Add a fungicide or biocide to destroy organisms present in the water beneath stored fuel.
- Add a metal deactivator because metals in fuel catalyze or speed up oxidation. Inhibitors that place an amine film on metal surfaces are available. Amines are organic compounds that neutralize an electrical charge in metals.

Note that any chemical or additive that is added to stored fuel must be approved by the EPA. Also, the base engineer's office should monitor the removal of bottom water from storage tanks.

A-8 LUBRICATING OIL.

A-8.1 Diesel Engine Oil.

\1 Lubricating oil for diesel engines should comply with specifications MIL-PRF-2104 and MIL-PRF-9000. Oil that complies with the specifications produces acceptable amounts of carbon residue during engine use and has acceptable pour, flash, and fire points. Straight mineral oil is the basic ingredient. Inhibitors or chemicals are added to the oil by the oil refiner to ensure compatibility with a range of engines operating under varying conditions. The user must observe recommendations by the engine manufacturer for specific types and grades of oil for optimum engine performance. **/1/**

A-8.1.1 Characteristics.

Engine lubrication requires selection of the proper oil. Refer to the engine manufacturer's instructions. Examples of required oil characteristics are as follows:

- Oil should have sufficient viscosity to prevent metal-to-metal contact. Oils with lower SAE numbers are lighter and flow more readily than oils with higher numbers. Heavier oils, those with higher SAE numbers, may cause sluggish operation and power loss.
- Oil should remain stable during use under changing temperatures and conditions for satisfactory service.
- Check the engine periodically, such as every six months, for accumulation of sludge in the engine filters and strainers and around valve springs. Refer to the engine manufacturer's literature for specific information.
- Oil must be free of water and sediment. Collect a sample of oil in a glass jar. Allow the sample to settle. Water and solid contaminants settle to the bottom of the jar.

A-8.1.2 Additives.

Straight mineral oil does not have detergent qualities; therefore, various compounds are added to the oil. These additives keep the engine clean by controlling varnish formation or resisting chemical changes to reduce oxidation. Other additives form a protective film against corrosive acids.

A-8.1.3 Mixing Oils.

Different refineries may use different types of additives or certain characteristics of the mineral oil may vary. Mixing types of oil may change the necessary detergent actions. To obtain maximum benefit from additive type oils, do not mix them with straight mineral oil. Concentrations of the additives are reduced when detergent oils and straight oils are mixed.

A-8.1.4 Changing Oil.

Lubricating oil must be changed periodically. Refer to recommendations by the engine manufacturer to specific conditions, time intervals, and instructions. General oil change procedures are as follows:

- Operate the engine before draining old oil. Oil should be drained while warm and immediately after engine shutdown because contaminants are in suspension and will readily drain.
- Obtain a sample of the drained oil and deliver it to the base engineer for testing. Drained oil should be examined for fuel dilution, acidity, and presence of solids and other contaminants. Testing helps establish the overall condition of the engine and approximate frequency of need for oil changes.
- Observe the viscosity of drained oil. In diesel engines, oil viscosity increases during service due to the gradual oxidation of the oil. Viscosity decreases if fuel gets into the oil by passing the piston rings or through leaks.

A-8.1.5 Oil Analysis Program.

Personnel in the engineer’s office and other cognizant personnel should refer to PAM 750-8, *The Army Maintenance Management System (TAMMS) User’s Manual*, for sampling and analysis information. The analysis of periodic samples of the lubricating oil should report the character and amount of contaminants, wear-metals, and additives in the oil. However, some amounts of wear metals and contaminants will have been collected by the chip collectors, strainers, filters, separators of the system, and also as sludge. To secure the total picture it is necessary to analyze all such collected material to determine the total rate of increase/decrease of each. This will indicate what has occurred during the period between samples.

Log and use all such data to track trends that give warning of conditions that may result, if uncorrected, in major problems.

A-8.2 GAS TURBINE OIL.

\1 Lubricating oil for gas turbines should comply with specifications MIL-PRF-23699 or MIL-PRF-7808. Oil that complies with the specification can withstand the high temperatures encountered during engine operation. **/1/**

A-8.2.1 Additives.

Various compounds are added to mineral oil to provide the special characteristics required for use in gas turbines. The user must observe lubricating oil recommendations by the engine manufacturer for optimum engine performance.

A-8.2.2 Changing Oil.

Refer to the engine manufacturer's literature for recommendations related to specific conditions, time intervals, and instructions for changing the lubricating oil. An oil analysis program is usually recommended, including a spectrometric analysis of the metal particles. It is necessary to collect and evaluate data for type and quantity of engine wear-metals. Study of this data shows trends of engine wear and expected future reliability.

- Collect a sample of old oil when oil is drained from the engine storage tank. Examine the drain plug or valve, filter, and chip detector (if used) for metal particles. Save the particles for analysis.
- Deliver the drain oil sample and particles to the base engineer for tests and analysis. The presence of some particles in the drain oil is usually considered normal by the engine manufacturer.

A-8.3 Coolant.

\1 The coolant used in diesel engines typically consists of a mixture of ethylene glycol antifreeze, corrosion inhibitor, and fresh water. When the engine is used in an extremely cold area, such as Arctic regions, a special antifreeze mixture is used. Specifications related to the mixtures are as follows:

- Antifreeze, Ethylene glycol MIL-A-46153
- Specification for cooling system conditioner and inhibitor is MIL-C-10597
- Antifreeze, Ethylene glycol A-A-52624
- Antifreeze, Arctic-type A-A-52624
- 5 Inhibitor, Corrosion MIL-A-53009 or MIL-A-46153 **/1/**

A-8.3.1 Engine Water Treatment.

A-8.3.1.1 Acceptable Conditions.

In most modern diesel engines, the following cooling water conditions are acceptable:

- pH 8.5 to 10
- Chloride and sulfate 100 ppm
- Total dissolved solids 500 ppm
- Total hardness 200 ppm

A-8.3.1.2 Softened Water.

If possible, softened water should be used to reduce the total hardness level of the engine cooling loop. The use of softened water will increase engine performance by reducing the precipitation of calcium and magnesium at elevated temperature conditions, ensuring higher heat transfer rates.

A-8.3.1.3 Antifreeze.

Typical engine cooling systems incorporate antifreeze solutions that inhibit scale and protect the cooling system when temperatures are encountered below freezing. Ethylene glycol mixed with a corrosion inhibitor such as triazoles form an inhibiting film on metal surfaces that acts as a barrier to the corrosion process. Table A-18 concentrations should be utilized when adding glycol solutions to the engine cooling system.

A-8.3.1.4 Concentration.

The ethylene glycol concentration should exceed 30 percent. If more than 60 percent of solution is added, two effects will be realized: 1) a decrease in heat transfer rates, 2) a lowering of the system freeze protection.

A-8.3.2 Cooling System Maintenance.

Maintenance consists of periodically testing the antifreeze, inspecting the coolant for cleanliness, and flushing or cleaning the system with compound when necessary.

A-8.3.2.1 Testing Antifreeze.

Perform tests to verify freeze protection and reserve alkalinity:

- Test for freeze protection using the combination antifreeze and battery tester (stock number 6630-00-105-1418). Instructions for using the tester are included with it.
- Test for reserve alkalinity (corrosion protection) using the reserve alkalinity test kit (stock number 6630-00-169-1506).
- Cooling systems with freeze protection below -7 °F (-22 °C) that fail the reserve alkalinity test may be replenished with corrosion inhibitor (stock number 6850-00-753-4967). Replenishment is a one-time service. If the reserve alkalinity test is failed again, replace the coolant. If the system passes the test, record the date.

A-8.3.2.2 Inspecting Coolant.

Inspect the coolant visually for cleanliness. Obtain a coolant sample and place it in a clean glass container. After allowing about five minutes for settling, examine the sample for contamination (rust, foreign particles, and/or sediment). The sample may have some color (same color as original antifreeze) and should be clear.

Examine the sample to determine the type and quantity of contamination. Rust, a chemical combination of iron, water, and air, is frequently found. The presence of rubber particles usually indicates deterioration of hoses. Replacement hoses may be indicated. Sediment may be caused by impurities in the water used in the coolant. Contaminants in the coolant can clog a radiator or heat exchanger and cause engine and generator system breakdown.

A-8.3.2.3 Cleaning the System.

Clean the cooling system whenever the coolant is drained. Usually the system requires nothing more than a thorough flushing with fresh water. Refer to the engine manufacturer's literature for instructions. If any part of the system is rusted or partially clogged, it is necessary to use cooling system cleaning compound and conditioner, stock number 6850-00-598-7328. Do not use the compound as a routine maintenance procedure. Instructions for using the compound are included with it.

A-8.3.2.4 Filling the System.

Refer to the engine manufacturer's literature for instructions on filling the cooling system. This is applicable to either new systems or those just cleaned and serviced.

A-8.3.2.4.1 Ethylene Glycol Antifreeze.

Cooling system protection is required for all liquid cooled diesel engines. In areas where temperatures no lower than -55 °F (-48 °C) are expected, prepare a solution according to the information presented in Table A-18. When temperatures below freezing are not expected, use a weak solution such as 1 pint of ethylene glycol antifreeze for each gallon of solution for general protection against rust buildup and scale formation within the engine.

A-8.3.2.4.2 Arctic-Type Antifreeze.

Use arctic-type antifreeze in areas where temperatures below -55 °F (-48 °C) are expected. Do not dilute arctic-type antifreeze with water or inhibitor; it is ready for use as issued.

Table A-18 Antifreeze Solutions

Guide for Preparing Ethylene Glycol Antifreeze Solutions	
Lowest Estimated Temperature in Area	**Pints of Antifreeze Needed to Prepare 1 Gallon of Solution**
+20 °F (-7 °C)	1.50
+10 °F (-12 °C)	2.00
0 °F (-18 °C)	2.75
-10 °F (-23 °C)	3.25
-20 °F (-29 °C)	3.50
-30 °F (-34 °C)	4.00
-40 °F (-40 °C)	4.25
-50 °F (-46 °C)	4.50
-55 °F (-48 °C)	4.75

A-9 ATS MAINTENANCE.

The following ATS maintenance actions are recommended:

- Follow NFPA 110 for visual inspection and cleaning, specifically Annex A.
- De-energize the switchgear and the ATS.
- Bypass isolation ATS may remain energized only to rack out the automatic switch.
- Remove the arc chutes and pole covers. Consult the manufacturer's information for proper procedure. This step will allow visual inspection of the main and arcing contacts.
- Test and recalibrate all trip-sensing and time-delay functions in the switchgear. Depending on the manufacturer, the steps required will vary. The focus should be to verify and record what current settings are and ensure the current adjustments meet the customer's needs and expectations. If adjustments are necessary, the means to make and verify those adjustments need to be examined. For example, a voltage pick-up or dropout adjustment may require the use of a variable source, such as a variable ac transformer. The standby engine can be a source of variable frequency, etc. Refer to manufacturer’s recommendation.
- Vacuum the accumulated dust from the switchgear and accessory panels. Do not use air to blow out dirt.

- Inspect for moisture or signs of previous wetness or dripping.
- Clean grime with an approved solvent. Consult the manufacturer's recommendations.
- Inspect all insulating parts for cracks or discoloration due to excessive heat. Use infrared scan if available.
- Inspect all main arcing contacts for excessive erosion. Replace contacts if damaged.
- Inspect all main current-carrying contacts for pitting and discoloration due to excessive heat.
- Inspect all control relay contacts for excessive erosion and discoloration due to excessive heat. If damaged, replace.
- Manually operate the main transfer movement to check proper contact alignment, deflection, gap, and wiping action.
- Check all cable and control wire connections to the transfer switch control and sensing panel and other system components and tighten if necessary.
- Re-energize the switchgear and conduct a test by simulating a normal source failure.
- ATS must be operated monthly.
- Circuit breakers should be tested under simulated overload conditions every two years.
- Simulate a power outage without turning off the normal power.

C-2 DEFINITIONS OF TERMS.

Generator Assembly: Assembly of prime mover, electrical machinery, and all ancillary equipment. In this UFC context, it is shortened to “generator.”

Power Plant: A building or group of buildings necessary for the generation of power, including generators.

Prime Mover: Combustion engine that provides the mechanical energy in alternating electrical power. Synchronous AC machines are alternators. DC machines are generators, but not covered by the scope of this UFC.

Take: Includes to pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest, or disturb wildlife. This is based upon 16 USC 1531, 16 USC 668, and 50 CFR 223.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
NEW SUMMARY SHEET

Document: UFC 3-540-08, Utility-Scale Renewable Energy Systems

Superseding: None

Description: This UFC provides requirements for the planning, design, construction, and operations and maintenance of solar photovoltaic, horizontal axis wind turbine, waste to energy, landfill gas, and geothermal renewable energy power generation systems.

Reasons for Document:

- To provide unified Department of Defense renewable energy power generation criteria and create more consistency in DoD designs.

Impact:

This uniform effort will result in the more effective use of DoD funds in the following ways:

- Standardized guidance of utility-scaled renewable energy power production planning, design, construction, and operations and maintenance among the Services.
- Consolidation of utility-scaled renewable energy power technologies and summary requirements in UFC 3-540-08 allows Services to evaluate technologies and infrastructure needs to economically use available site specific resources.

Unification Issues:

- None

TABLE OF CONTENTS

FIGURES

TABLES

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC) provides guidance for designing and installing renewable power generation (RPG) systems that interface with an installation's power grid. The criteria contained herein are intended to ensure durable, efficient, and reliable systems and installations. Whenever unique conditions and problems are not specifically covered by this UFC, use the applicable referenced industry standards and other documents for design guidance.

1-2 ORGANIZATION.

Chapter 2, *Planning and Development*, provides preliminary planning considerations for technologies applicable to installation location. Site attributes, including available space, topography, accessibility, location, and ecology, impact the technology selection. Chapters 3-7 provide additional details on each renewable power generation technology and Chapter 8 provides interconnection guidance.

1-3 APPLICABILITY.

This UFC applies to the planning, design, and construction, of utility scaled renewable energy facilities and installations, regardless of funding source. Per DoD Instruction 4270.5, the design criteria of this UFC do not apply to privatized housing or to projects acquired through a real property exchange agreement. This UFC also applies to overseas facilities, considering mission objectives and Host Nation standards, to the greatest extent practical.

Compliance with this UFC is mandatory for the design of renewable power generation systems that interface with an installation's power grid at all facilities and bases. This UFC applies to the creation of utility scaled power generation systems for installation power needs, and not for individual facility systems. For facility-level renewable energy systems, refer to UFC 3-440-01.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines, building systems, accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to the UFCs and government criteria referenced therein.

1-5 ENERGY RESILIENCE.

All energy systems must be planned, designed, acquired, executed, and maintained in accordance with DoD Instruction 4170.11, Installation Energy Management, and as required by individual Service and Defense Agency policies on energy resilience.

1-6 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06 and as required by individual Service Implementation Policy.

1-7 COPYRIGHT RELEASES.

National Renewable Energy Laboratory (NREL) developed maps and charts are not to be used to imply an endorsement by the NREL, the Alliance for Sustainable Energy, LLC, the operator of NREL, or the U.S. Department of Energy.

Use of energy associations' and organizations' data and references does not imply any DoD endorsement. Use of associations' and organizations' data is subject to individual terms of use.

1-8 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-9 GLOSSARY.

Appendix G contains acronyms, abbreviations, and terms.

CHAPTER 2 PLANNING AND DEVELOPMENT

2-1 INTRODUCTION.

This chapter provides preliminary planning considerations for renewable power generation technologies applicable to the installation location. Site specific attributes, including resource quality, space availability, topography, site location and accessibility, and ecology, impact the technology selection.

2-2 TECHNOLOGY SELECTION.

Installation location is a significant factor that governs which renewable energy sources are available for economic power generation development.

NREL provides dynamic resource maps, graphic information system data, and analysis tools for preliminary evaluations. The National Resources Conservation Service (NRCS) provides annual precipitation in the lower 48 states. Higher annual precipitation indicates increased biomass potential. National Oceanographic and Atmospheric Administration (NOAA) provides current and historical severe weather data for planning and design considerations. Review current resource maps and data for preliminary site analysis and planning only. Additional selection considerations are provided in individual RPG technologies chapters.

- NREL: http://www.nrel.gov/gis/re_potential.html
- NRCS: http://www.wcc.nrcs.usda.gov/climate/prism.html
- NOAA: https://www.ncdc.noaa.gov/data-access/severe-weather

2-3 CAPACITY FACTORS.

Capacity factor is a representation, in percent, of a generator's actual energy production divided by the generator's maximum power that it is rated to produce at continuous full power operation during the same period. For illustration, a one (1) megawatt (MW) generator at a 50% capacity factor produces 4,380 MW hour (MWh) of power annually (1MW x 50% capacity x 8,760 hours/year).

Waste to Energy (WTE), Landfill Gas (LFG), and geothermal plants are more stable power producers than solar or wind, whose generation capacity can vary significantly during any given hour due to clouds, gusts, and other environmental effects. Table 2-1 provides a summary of historical generation capacity factors, based upon Jan 2013-Feb 2015 data available from U.S. Energy Information Administration. Understand and account for the limiting factors and availability associated with each technology when determining an installation's overall energy supply portfolio.

Table 2-1 Generation Systems Capacity Factors

Technology	Capacity Factor Range		
	Low	Median	High
Solar Photovoltaic (PV)	15.6%	27.8%	32.0%
Wind	28.0%	33.1%	43.1%
Geothermal	67.3%	71.2%	76.8%
Solid Waste and LFG	61.4%	68.9%	72.4%

2-4 PLANT LOCATION FACTORS.

2-4.1 Siting Considerations.

Use the joint Natural Resources Defense Council / DoD primer, *Working with the Department of Defense: Siting Renewable Energy Development*, to screen renewable energy development, generation, or transmission sites.

2-4.2 Transmission Infrastructure.

The North America transmission system is monitored and controlled by the *Independent Systems Operators/Regional Transmission Operators* (ISO/RTO) (http://www.isorto.org). Bulk system reliability is under the *North American Electric Reliability Corporation* (NERC) (www.nerc.com) jurisdiction. Compliance with applicable NERC and ISO/RTO standards and requirements is mandatory. Coordinate with the applicable ISO/RTO for RPG system for transmission grid information, connection requirements, and future grid expansion.

Evaluate and address any gap(s) between the transmission infrastructure at/near the RPG site(s) and the required infrastructure/right of ways necessary to connect to installation's grid. Coordinate with the local ISO/RTO or the ISO/RTO Council, for smart grid connection requirements and ISO/RTO areas of responsibilities. Comply with Chapter 8 "UTILITY INTERCONNECTION" requirements.

2-4.3 Site Acreage Requirements.

Renewable energy power generation requires an extensive footprint. Actual site requirements are a function of location, system configuration, resource quality, and system efficiency as shown by the standard deviation column in Table 2-2. For initial planning purposes, use NREL average values as presented in Table 2-2 for initial RPG acreage planning factors, unless more actuate local data is available. For photovoltaic (PV) systems, the minimum footprint requirement can be calculated with the following formula:

$$A(\varphi) = 0.00205 \cdot \varphi^2 + 0.0493 \cdot \varphi + 2.21$$

Where: *A* is area in acres and φ is latitude in degrees North.

Table 2-2 Renewable Power Systems Footprints

Technology Type	Size (acres / MW) (tons / MW for LFG)	Size Std. Dev.(acres / MW)
Photovoltaic 1 – 10 MW	6.1	1.7
Wind 1 – 10 MW	44.7	25.0
Biomass Combustion Combined Heat and Power	3.5	1.9
Geothermal	1.6	-
Landfill Gas (LFG)	7900 tons/MW[1] (7200 metric ton/MW)	

[1] For planning purposes, use tonnage or gate-yard receipts, if available. Six gate-yards is approximately one ton of MW. If receipts not available, compacted landfill density ranges from 750-1,250 pounds per CY.

2-5 LOAD REQUIREMENTS.

2-5.1 Electrical Load Considerations.

Determine desired peak and annual power generation requirements. Address 24-hour and annual load considerations, and capacity factors associated with the evaluated RPG system. Account for RPG plant operational loads that reduce power transmitted to the grid.

2-5.2 Cogeneration Considerations.

Consider installation needs for secondary use of waste heat generated.

2-5.3 Energy Storage Considerations.

Consider thermal storage for off-generation use of thermal energy. Consider energy storage systems for power management of solar and wind systems. Energy storage is classified by its energy form: mechanical, chemical, electrochemical, thermal, magnetic, or electric field. Commercial utility scaled energy storage technologies in use include pumped hydroelectric (significant majority of U.S. capacity), compressed air, and conventional battery. Other technologies in use, and in development, include capacitors, flywheels, high temperature and flow batteries, superconducting, thermal storage, hydrogen, and potential energy systems.

2-5.4 Capacity Factors.

Account for capacity factors in project planning, and installation microgrid and islanding strategies. Use solar or wind power generation as a complementary power source, not as the sole primary power replacement option, unless a suitable storage technology is being utilized to provide power when solar and wind are not available.

2-6 UTILITY INTERCONNECT.

Individual states may have power connection limits. The Database of State Incentives for Renewables & Efficiencies (DSIRE) website, www.dsireusa.org, provides a summary of State interconnection policies and applicable State contact information. Coordinate with applicable State offices, local power company, and the ISO/RTO for limits and interconnection requirements. Comply with Chapter 8 titled "UTILITY INTERCONNECTION" requirements and IEEE 1547.

2-7 METERING.

Comply with the local utility company's metering requirements as well as the OUSD (AT&L) *Utilities Metering Policy* as detailed in the following website: (http://www.acq.osd.mil/eie/IE/FEP_Policy_Program_Guidance.html) and DoDI 4170-11 Installation Energy Management.

2-8 SITE SPECIFIC DESIGN PLANNING.

2-8.1 Seismic.

Comply with UFC 1-200-01, including all referenced criteria and standards.

2-8.2 Topography.

Evaluate topography for system interferences and optimization, flood plains, and accessibility during planning, construction, and operation.

2-8.3 Site Access.

Evaluate transportation routes to site for accessibility for oversized loads and weights. Evaluate routes for impact and costs from construction traffic and loading. Ensure adequate laydown area is available during construction period and service roads to sites and supporting structures are provided.

2-8.4 Safety.

Comply with UFC 1-200-01 and UFC 3-600-01 for fire and life safety compliance.

2-8.5 Environmental.

Evaluate environmental requirements (e.g. noise, air pollution, wildlife, storm water) developed during the initial project planning stages in accordance with the National Environmental Policy Act NEPA.

2-8.5.1 Site Suitability

Confirm site is suitable for construction without major environmental impacts (e.g. are wetlands present?, is the ground contaminated?, endangered species?, etc.). If environmental concerns are present, survey and evaluate if they can be economically mitigated to meet applicable regulatory requirements.

2-8.5.2 Surveys

Field verify, through environmental, ecological, and biological surveys, that project's environmental impact will be minimal and can economically mitigated, if present.

2-8.5.3 Permitting

Once all environmental impacts have been assessed, then the actual permitting can begin. Permitting that is required by local and federal law has to address the renewable energy project construction and operational phases.

2-8.5.4 Compliance

All design and construction will provide electrical systems which must comply with Federal, State, and local environmental regulations. For overseas locations, follow the guidance specified in Host Nation-specific Final Governing Standards, or if none exists, the current DoD Overseas Environmental Baseline Guidance Document (OEBGD) and applicable Host Nation laws. For Air Force, consult AFI 32-7006 for additional guidance.

2-8.6 Environmental Studies and Permitting.

Plan for a permitting process that may take years, with duration depending upon the selected system and the locality (country, State, county and municipality) that is jurisdictionally responsible. Studies and permitting requirements exist at all levels (Federal, State, and local) and may include:

- 316(a) – Thermal discharge;
- 316(b) – Cooling water intake;
- Air permitting;
- Aquatic ecology;
- Avian and bat studies/protection;
- Cultural resources;
- Disposal (ash, slag);
- Dredge and fill;
- Encroachment;
- Erosion and sediment control;
- Floodplain management;
- Lake management;

- Land and right-of-way grants;
- Native American consultation;
- Natural resources;
- National Environmental Policy Act (Environmental Assessments (EAs), Environmental Impact Studies (EISs))
- Noise/Odor;
- River crossing permits;
- Threatened and Endangered species;
- Transmission line routing;
- Stormwater / Water quality; and
- Wetlands permitting, mitigation and design

2-8.6.1 Typical Permitting Process.

The next phase of a typical permitting process, after identifying all required permits, consists of the following six stages.

2-8.6.1.1 Stage 1 Pre-application.

Pre-application may take a few days to a year prior to filing a permit application. During this phase, developer and permitting agencies should meet to help ensure that both understand the project concept, permitting process, and possible issues. Make sure no gaps exist to minimize project schedule delays.

2-8.6.1.2 Stage 2 Permit Development and Submittal.

Complete all permit applications thoroughly, honestly, and timely. Use professional environmental consultants or attorneys if complexity of project warrants.

2-8.6.1.3 Stage 3 Application Review.

Activities vary, depending upon the agency reviewing the applications. Expect requirements for public sessions, meetings, and site visits to allow for discovery and alternative/modifications.

2-8.6.1.4 Stage 4 Decision Making.

Reviewing agencies will provide a decision with compliance requirements. This phase likely requires public hearings.

2-8.6.1.5 Stage 5 Administrative and Judicial Review.

If the decision is contested, the first avenue of appeal is administrative and it is directly to the decision maker. If the administrative appeal is not granted, the second stage is judicial review to assess if decision was fairly executed within accepted legal procedures.

2-8.6.1.6 Stage 6 Permit Compliance.

This phase is the final stage and extends throughout the project's lifetime including construction inspection and monitoring; operation; and decommissioning, to ensure project complies with all the terms and conditions of its permit and applicable laws.

2-8.6.2 Federal and State Policies and Incentives.

The DSIRE website provides a convenient source for Federal and State renewable energy policies and incentives. Review and address policies applicable to the site, and incorporate available incentives into economic analysis.

2-8.7 Industrial Control Systems and Network Risk Management.

Information systems connected to, or software loaded onto DoD information grids, must receive an interim or full authorization to operate/test prior to connection to the DoD information grid in accordance with UFC 4-010-06 and as required by individual Service Implementation Policy.

2-9 COST FACTORS.

Provide project life cycle cost analysis. NREL provides summary costs charts for RPG at http://www.nrel.gov/analysis/tech_cost_dg.html. Chart data is from U.S. Department of Energy (DoE) Federal Energy Management Program (FEMP).

Note: The cost factors referenced in the NREL site are representative of an average commercial acquisition, and may not reflect the cost factors associated with Federal government acquisition methodologies.

2-9.1 System Useful Life.

Use Table 2-3 for initial planning factors and life cycle cost analysis.

Table 2-3 Renewable Power System Useful Life

Renewable Power System	Useful Life
Photovoltaic Cells	25 to 40 yrs.
Inverters	10 yrs.
Wind	20 yrs.
Biomass Combined Heat and Power	20 to 30 yrs.
Biomass Heat	20 to 30 yrs.

2-9.2 Historical Capital and Operations and Maintenance (O&M) Costs.

RPG capital, operation, and maintenance costs are highly dependent upon location and plant size. Use The NREL average Table 2-4 costs for solar, wind, and biomass combustion systems for initial cost planning purposes.

Table 2-4 NREL Distributed Generation Renewable Energy Installed Costs

	Generator Type / Size System		
	PV 1–10 MW	**Wind 1–10 MW**	**Biomass Combined Heat & Power***
Mean installed cost $/kW	$2,667	$2,644	$6,067
Installed cost Std. Dev +/- $/kW.	$763	$900	$4,000
Fixed O&M $/kW-yr.	$20	$36	$91
Fixed O&M Std. Dev. +/- $/kW-yr.	$10	$16	$33
Variable O&M $/kWh	n/a	n/a	$0.06
Variable O&M +/- $/kWh	n/a	n/a	$0.02
Lifetime yr.	33	20	28
Lifetime Std. Dev. yr.	9	7	8
Fuel or water cost $/kWh	n/a	n/a	$0.04
Fuel or water Std. Dev. $/kWh	n/a	n/a	$0.02

*Unit cost is per kilowatt of the electrical generator, not the boiler heat capacity.
Geothermal cost breakdown not available. See Appendix F for planning factors and cost models.
Costs are NREL update of August 2013.

2-9.3 Levelized Cost of Energy.

Table 2-5 illustrates projected ranges of cost to produce a MWh of energy, by generation technology/energy source, before incentives are included. Both renewable and non-renewable systems are provided as a reference. As renewable energy technologies improve, their levelized cost of energy may become very competitive with or exceed most traditional energy sources.

Evaluate and make preliminary RPG system selections based upon current energy costs, quantifiable and non-quantifiable benefits to mission, and system life cycle cost. More cost effective renewable systems may not be suitable for specific installation or mission requirements. NREL website, http://www.nrel.gov/analysis/tech_lcoe.html, provides a planning calculator for levelized cost of energy.

Table 2-5 Levelized Cost of Energy

Regional Variation in Levelized Cost of Electricity (LCOE) for New Generation Resources, On Line Starting 2020 Range for Total System LCOE (2013 $/MWh) w/o subsidies			
Plant type	**Minimum**	**Average**	**Maximum**
Renewable			
Geothermal	$ 43.80	$ 47.80	$ 52.10
Biomass	$ 90.00	$ 100.50	$ 117.40
Wind	$ 65.60	$ 73.60	$ 81.60
Solar PV	$ 97.80	$ 125.30	$ 193.30
Conventional			
Conventional Coal	$ 87.10	$ 95.10	$ 119.00
Advanced Coal	$ 106.10	$ 115.70	$ 136.10
Advanced Coal with CCS*	$ 132.90	$ 144.40	$ 160.40
Natural Gas-fired			
Conventional Combined Cycle	$ 70.40	$ 75.20	$ 85.50
Advanced Combined Cycle	$ 68.60	$ 72.60	$ 81.70
Advanced CC with CCS*	$ 93.30	$ 100.20	$ 110.80
Conventional Combustion Turbine	$ 107.30	$ 141.50	$ 156.40
Advanced Combustion Turbine	$ 94.60	$ 113.50	$ 126.80
*CCS Carbon Control and Sequestration			

2-10 FUNDING SOURCES AND ECONOMIC ANALYSIS.

DoD funding is very limited for large scale RPG. One funding program is the Energy Conservation Investment Program (ECIP). Execution is through the standard construction contract mechanisms.

Third party funding options include Power Purchase Agreements (PPA) and Enhanced Used Lease (EUL)/out grant/leases. Energy Savings Performance Contracts (ESPCs) and Utility Energy Service Contracts (UESCs) are financed contracting options which do not require DoD funding upfront. Additionally, ESPCs provide risk mitigation through performance guarantees and contracted O&M and repair and replacement services (beyond just warranty period services) for the financed contract term up to 25 years. Energy savings in UESCs are stipulated by the Utility as well as the Government. O&M, repair, and replacement services can be included; however, the contract term is most often shorter.

2-10.1 Power Purchase Agreement (PPA).

Under a PPA, a developer typically installs a renewable energy system on agency property under an agreement that the agency will purchase the power generated by the system. However, in some cases the renewable energy system can be installed on property owned by the developer and the energy production can be delivered either behind the meter through the base distribution system or ahead of the meter through the commercial grid into the base distribution system. After installation, the developer owns, operates, and maintains the system for contract life.

2-10.2 EUL/Out Grant/Leases.

Title 10 USC § 2667, gives DoD the authority to enter into long-term and short-term leases for non-excess DoD controlled land or facilities.

Evaluate In-Kind Consideration and the Deposit and Use of Proceeds from EUL/out grant/leases in accordance with 10 USC § 2667, Office of the Under Secretary of Defense Financing of Renewable Energy Projects Policy, and other associated directives.

2-10.2.1 Energy EUL/Out Grant/Leased Facility.

An energy EUL/out grant/leased facility may be designed and operated completely independent from an installation's power grid, that is, generated energy is transmitted to the commercial grid. In this configuration, the facility is typically designed and operated in accordance with commercial specifications, agreements, and contracts between the utility and the private sector developer. The facility is not designed for Government use or occupation, so UFC compliance is limited to interoperability, safety, and security requirements.

Consideration from energy EUL/out grant/leases may include capabilities that enable installation energy security or fund specific energy initiatives. In this configuration, the facility is generally designed and operated in accordance with commercial specifications, but also includes certain interfaces with an installation's power grid. Ensure these interfaces are compatible with the paragraph titled "GENERAL COMPLIANCE REQUIREMENTS" in Chapter 1.

2-10.2.2 EUL/Out Grant/Lease Objective.

EUL/out grant/lease program's primary objective is to optimize the value of non-excess properties in accordance with Executive Order 13327, which promotes the efficient and economical use of America's real property assets. Demonstrating and documenting that a proposed out grant/lease is technically and economically viable and compliant with applicable statutory authorities is the responsibility of each Service. Economic and technical analysis, mission compatibility and other out grant/lease project specific due diligence is conducted in accordance with Service specific out grant/lease Playbooks, Instructions and Directives.

Contact Service leads for additional EUL/out grant/leased information and requirements:

- Army: http://www.nab.usace.army.mil/Businesswithus/realestate/EUL.aspx
- Air Force: http://www.afcec.af.mil/EUL/

2-10.3 Additional Cost Considerations.

Include operations and maintenance, decommissioning, and site restoration costs in economic analysis.

2-10.4 Economic Analysis.

Use UFC 3-730-01, UFC 3-740-05, applicable design agency guidance, and installation policies and procedures.

2-11 COORDINATION.

2-11.1 Office of the Secretary of Defense (OSD) Coordination.

32 CFR Part 211 requires OSD to conduct mission compatibility evaluation of proposed projects. Request a preliminary determination from the OSD Clearing House (website: http://www.acq.osd.mil/dodsc/) at osd.dod-siting-clearinghouse@mail.mil once preliminary details are available.

A formal review is mandatory for projects filed with the 49 USC Section 44718, as well as other projects proposed for construction within military training routes or special use airspace, whether on private, State, or Federal property, such as Bureau of Land Management lands. See http://www.acq.osd.mil/dodsc/ for specific data and reporting requirements.

2-11.1.1 Airspace Coordination.

Comply with UFC 3-260-01 when evaluating renewable power generation systems and equipment siting near an airfield or related facilities and equipment used to sustain flight operations. Provide applicable data items required for the OSD coordination. Submit plans to site renewable power generation systems and equipment near an airfield to the Airfield Manager and Safety Officer for approval.

2-11.1.2 Military Training Route and DoD Siting Clearinghouse.

The Military Training Route (MTR) program is a joint venture by the Federal Aviation Administration (FAA) and the DoD to develop routes for the purpose of conducting low-altitude, high-speed testing, and training activities. Improper site planning can negatively affect the MTR program. Contact the DoD Siting Clearinghouse (http://www.acq.osd.mil/dodsc/) during initial planning, and prior to applying for permits on any Federal or non-Federal lands, for project site vetting. Provide applicable data items required for the DoD Siting coordination.

2-11.1.3 FAA Requirements.

FAA requires early planning coordination for structures and assessment of glare from solar panels. For structure assessment, complete FAA Form 7460-1. Glare assessments are covered under FAA interim policy, FAA Review of Solar Energy System Projects on Federally Obligated Airports. This interim policy requires use of the

Solar Glare Hazard Analysis Tool (SGHAT). Provide both FAA Form 7460-1 and SGHAT report to the DoD Siting Clearinghouse. SGHAT registration located at: www.sandia.gov/glare. Coordinate international sites through the DoD Siting Clearinghouse to ensure International Civil Aviation Organization (ICAO) requirements are addressed.

2-12 PROGRAMMING.

Use Table 2-6 to determine primary Category Codes for RPG projects. No geothermal Category Code currently exists.

Table 2-6 Category Codes

	PV	Wind	WTE	LFG
Air Force	811145	811146	811145	811145
Army	81122	81146	81113	81117
Navy	81150	81146	81125	81145

CHAPTER 3 DESIGN CRITERIA - PHOTOVOLTIAC (PV) SYSTEMS

3-1 INTRODUCTION.

This chapter identifies typical applications and defines the data that must be developed to establish engineering design bases, to evaluate between various solar PV designs, and ownership alternatives for utility scaled PV systems (system output greater than 1 MW).

3-1.1 Technology.

Solar PV technology generates direct current (DC) electrical power from semiconductors when they are excited by the sun. DC power is converted into alternating current (AC) through inverters and voltage stepped up for transmission.

3-2 PLANNING.

If not previously established, create an energy capacity plan covering the installation's planning vision, goals, and objectives to identify the system power and operational requirements. Coordinate plan with the system owner and utility provider to allow a comprehensive economic and site selection evaluation. Ensure economic analysis includes currently available local, state, and Federal incentives. Complete an environmental impact study to ensure project site is viable.

3-2.1 DoD Siting Clearinghouse.

Perform proposed and final siting coordination with OSD. 32 CFR Part 211 requires DoD to conduct mission compatibility evaluation of proposed site and project. Early project awareness and coordination with OSD is mandatory. Request a preliminary siting determination from the OSD Clearing House at osd.dod-siting-clearinghouse@mail.mil to avoid invalid site selections.

3-2.2 Climatic Zones.

Basic engineering practices governing design and construction of electrical power systems in arctic and subarctic zones will comply with agency criteria and UFC 1-200-01. Refer to UFC 3-440-05N (for Navy). For other Agencies, use UFC 3-440-05N as a reference and comply with Agency specific guidance for design and construction of electrical power systems in temperate areas.

3-2.3 Permitting.

Comply with paragraph titled "DESIGN APPROVALS AND PERMITS" in UFC 3-201-01 for permitting requirements.

3-2.4 Interconnection Analysis and Coordination.

Contact the local utility provider for utility-specific interconnection equipment and ownership requirements in the design concept stage due to utility-specific requirements. Refer to Chapter 8 titled “UTILITY INTERCONNECTION” for guidance.

3-3 DESIGN CRITERIA.

Address mounting systems, solar PV modules, raceways and DC cabling, system grounding, lightning protection system, surge protection, raceway and AC cabling, metering, system criteria and selection, interconnections, warranty requirements, and site maintenance considerations in the design.

3-3.1 Structural Components.

Comply with UFC 1-200-01, including all referenced criteria and standards for all structures and structural elements, including PV array structures.

3-3.1.1 Mounting Systems.

Mounting systems are either active or fixed tracking. Select mounting system appropriate for site conditions and project requirements. Evaluate the cost verses power generation benefit of using an active tracking system over a fixed tracking system. Include initial and operation and maintenance costs in the cost analysis.

3-3.1.2 Ground Mounting.

Comply with UFC 3-301-01 for requirements related to the foundation, soil stability, and seismic analysis. Use ground mounting systems of the same manufacturer for the entire project array. The system must withstand the expected wind loads for the location. Complete an environmental impact assessment for the site. Foundation must be either concrete, concrete pad ballast, driven pile, or helical pile.

3-3.1.3 Tracking Array System.

Design for solar PV tracking system in accordance with IEC 62727.

3-3.1.4 Array Tilt Angle.

Tilt the array to the latitude plus or minus 10 degrees. It should be noted that as the tilt angle increases, the minimum spacing between rows must be increased due to shading. Do not allow inter-row shading between 9 a.m. and 3 p.m., when the bulk of the energy collection occurs.

3-3.1.5 Array Azimuth Angle.

For optimum performance, orient the module true south in the northern hemisphere and true north in the southern hemisphere; however, slightly west of south or north (azimuth angle of true south or north plus 10 degrees) may be preferable in some locations if an early morning haze or fog is a regular occurrence. Design the array's azimuth angle off of due south or north as coordinated with the Basis of Design.

3-3.1.6 Site.

Account for shading, grounds maintenance requirements, and winter snow levels when determining mounting heights, spacing, and ground cover. Closed landfill sites require non-penetrating foundations to avoid breaching cap.

3-3.2 Direct Current (DC) System Components.

3-3.2.1 Solar PV Module.

Conform to UL 1703 and IEC 61215 for crystalline types, or IEC 61646 for thin film types. Require submission of manufacturer's guarantee on backsheet and encapsulant construction. Select one commercially-available PV module type based on life cycle cost analysis, required energy production, site location environmental conditions, space available, and maintainability.

3-3.2.2 Solar PV Array.

Comply with National Fire Protection Act (NFPA) 1 for array arrangement requirements.

3-3.2.3 Raceway and DC Cabling.

Provide UL 4703 listed PV wiring. Comply with UFC 3-501-01 for requirements related to raceway and DC cabling sizing.

3-3.2.4 Combiner Box.

Provide UL 1741 listed combiner box.

3-3.2.5 DC Switching.

If stand-alone unit, DC disconnect switches must conform to UL 98 or UL 98B. Rate switch for maximum system voltage and maximum system continuous and short circuit currents. If combined with inverter, refer to paragraph entitled "Inverter" for guidance.

3-3.2.6 Inverter.

Conform to UL 1741, comply with IEEE 1547 and NFPA 70, and be identified for use in solar PV power systems for allowance of monitoring. The selection of inverter type, i.e. central, micro-inverter, or string inverter, will depend on the system size, budget, and site-specific parameters. Consider use of inverters with integral medium voltage transformers. Place inverters in location to allow for adequate air circulation. Where possible, employ maintainable design practices when selecting number of inverters for project to prevent the failure of one inverter from affecting the entire system. Limit inverter sizes to 750 kW maximum, with a minimum 95% efficiency.

3-3.3 Alternating Current (AC) System Components.

3-3.3.1 Transformer.

Provide transformers in accordance with IEEE Std 1547 and NFPA 70. Provide primary and secondary over-current protection in accordance with NFPA 70. Refer to UFC 3-520-01 and 3-550-01 for additional requirements. Use USACE ETL 1110-3-412 (Army only) as a reference for the selection and application of transformers and dielectrics. Ensure transformer and separately derived systems installation strictly comply with NFPA 70, Article 250.

3-3.3.2 Raceway and AC Cabling.

Provide UL 4703 listed PV wiring. Raceway and AC cabling sizing must conform to UFC 3-520-01 and NFPA 70. Install all cabling in raceways unless specifically indicated otherwise.

3-3.3.3 AC Switching.

Rate switch for maximum system voltage and maximum system continuous and short circuit currents. If stand-alone unit, AC disconnect switches must conform to UL 98 or UL 98B. If combined with inverter, refer to paragraph entitled “Inverter” for guidance.

3-3.3.4 Metering.

Coordinate revenue metering requirements with the utility provider and DoD installation regarding interconnection-specific data and guidelines. Coordinate with Activity and utility provider for requirements and plan of action to manage excess energy, including the utilization of net metering.

3-3.3.5 System Monitoring.

Provide system monitoring in accordance with IEC 61724. Provide features to transmit real time system and status data to an energy information system (via network system assets or cellular technology).

3-3.4 Grounding and Lightning Protection.

3-3.4.1 System Grounding.

Grounding is a common system failure point. Strictly comply with UFC 3-550-01, NFPA 70, and IEEE C2 for requirements related to general system grounding.

3-3.4.2 Lightning Protection System.

Provide surge protection in accordance with NFPA 780. Comply with UFC 3-520-01 for requirements related to providing a lightning protection system. Provide side flash calculations as required by NFPA 780.

3-3.4.3 Surge Protection.

Provide surge protection devices for all systems identified in NFPA 780 and UFC 3-575-01. Show location of all surge protective devices on drawings.

3-3.5 Climatic Considerations.

Design system to operate under the location's maximum and minimum documented temperatures during summer and winter. Account for snow depths and known snowdrift patterns when determining locations and mounting heights in Snowbelt locations.

3-3.6 Project Planning Considerations.

Appendix D provides listing of factors to consider during the design. Tailor as appropriate for project scope.

3-4 OPERATION AND MAINTENANCE.

Maintenance considerations consists of two categories: scheduled/preventive maintenance and unscheduled maintenance/troubleshooting. Treat solar PV equipment with the same caution and care as regular electrical power service equipment. Comply with the requirements of UFC 3-560-01 and manufacturers' documentation, as required. Refer to Appendix E for additional O&M guidance.

3-4.1 Preventive Maintenance.

Preventive maintenance scheduling and frequency is dictated by a number of factors including, but not limited to, technology selected, site environmental conditions, warranty terms, and seasonal variances. Conduct scheduled maintenance at intervals in accordance with the manufacturers' recommendations, as required by equipment warranties, and at times to reduce production impacts.

3-4.2 Unscheduled Maintenance.

Unscheduled maintenance, or troubleshooting, is carried out in response to equipment failures. Refer to manufacturer's system documentation for troubleshooting steps for the failed components.

It is important to maintain an adequate supply of spare components in stock to facilitate rapid response times. The number of required spares depends on the system size, site-specific parameters, parts availability, budget, and desired system availability (reliability).

3-4.3 Safety.

Comply to applicable provisions in 29 CFR 1910, 29 CFR 1925, and 29 CFR 1926, and local/agency codes and requirements.

3-4.4 Warranty.

Specific system components warranties vary by manufacturer. PV module warranty typically ranges from 5-10 years with top brand providing 20 to 25 year warranty. Performance warranty is based upon minimum continuous power output of 80 percent at typically 20 years. Inverter warranties average from 5-10 years, dependent upon manufacturer and technology. PV mounting system warranty typically varies between 5-10 years.

Require a minimum of a five (5) year Contractor parts and labor warranty for component failure due to workmanship, defective components or assemblies on the entire solar PV system, regardless if the component manufacturers are still in business or not. Include warranty costs in the economic analysis.

3-4.5 Security.

Comply with UFC 4-010-01 and UFC 4-020-01 for security concerns, theft and vandalism protection, and unauthorized area entry.

CHAPTER 4 DESIGN CRITERIA – WIND SYSTEMS

4-1 INTRODUCTION.

This chapter presents the planning, design, and O&M requirements for renewable energy produced by a wind driven utility scaled (greater than 1 MW total output) horizontal axis wind turbines (HAWT).

4-1.1 Technology.

Two primary wind turbine configurations exist: HAWT and vertical axis wind turbine (VAWT).

4-1.1.1 HAWT.

HAWT configuration has the rotor blades' plane perpendicular to the wind direction and with the axis of main rotor shaft rotation lying in the horizontal plane. HAWTs are the most widely used turbine technology utilized in the world.

HAWT systems with a minimum of three (3) years of proven commercial power generation are generally approved for use in the DoD for utility-scaled power generation.

4-1.1.2 VAWT.

VAWT configuration has the main rotor shaft axis of rotation lying in the vertical plane. VAWTs have minimal utility-scale power generation history.

VAWTs are not approved for use in the DoD for utility-scaled renewable power generation.

4-1.2 Application.

Large commercial and utility-scale wind turbines (0.5 - 7.5 MW) are generally grouped in wind 'farms' for producing power plant scale energy for sale. The increased efficiency and high availability rates for these systems allow for cost-competitive electricity generation. Due to the height, size, and land requirements for utility-scale wind power generation, projects require extensive environmental, utility, and public coordination, detailed site resource assessments, legal and financial due diligence, utility integration, and financial analysis planning before project execution.

4-2 PLANNING.

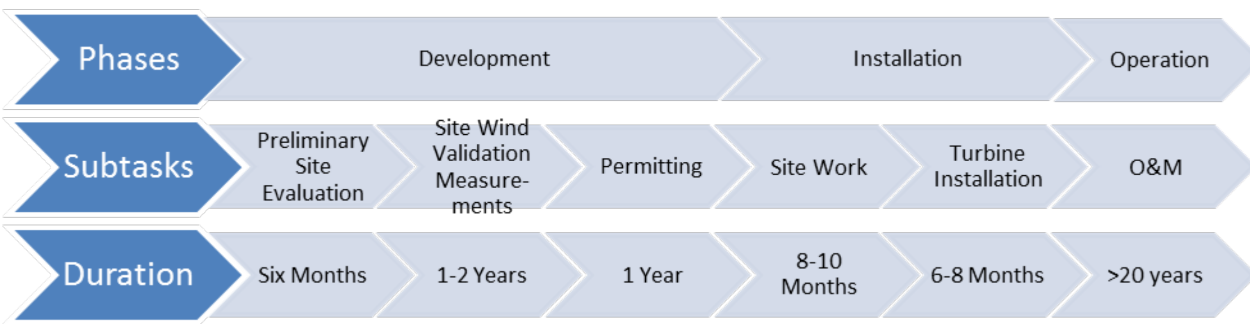
4-2.1 DoD Siting Clearinghouse.

Perform proposed and final siting coordination with OSD. 32 CFR Part 211 requires DoD to conduct mission compatibility evaluation of proposed site and project. Early project awareness and coordination with OSD is mandatory. Request a preliminary siting determination from the OSD Clearing House at osd.dod-siting-clearinghouse@mail.mil to avoid invalid site selections.

4-2.2 Wind Farm Project Development.

ASCE/AWEA RP2011 provides a planning flow chart for a typical commercial wind farm project, from initial site evaluation through operation that will aid wind farm planners. A wind farm project may take up to four years from concept to full production. Figure 4-1 provides typical project timeline.

Figure 4-1 Wind Turbine Typical Project Timeline



4-2.3 Site Selection.

4-2.3.1 Adequate Wind Resources.

DoE Energy Efficiency & Renewable Energy (EERE) web site provides utility scale wind resource maps. Use the 260 ft. (80 m) wind resource map for initial planning considerations for commercial power generation. Localized site data is also available from commercial sources. Once initial planning indicates viable wind resources are available, a site-specific wind study is required to categorize wind energy characteristics for feasibility analysis.

4-2.3.2 Transmission Lines.

Perform transmission study to evaluate, as a minimum, line proximity, available line capacity, reliability, and connection costs. Refer to Chapter 8 titled “UTILITY INTERCONNECTION” for guidance.

4-2.3.3 Site Footprint.

Use Table 2-2 for initial site size planning factors. Turbine(s) layout depends upon site’s topography, site boundaries, exclusion zones, and setback/buffer zones. Layouts are typically either linear (single or multiple strings, or parallel) or clustered. Wind turbines are typically not sited within five (5) rotor diameters of each other. Require computational optimization of turbine layout, as a little as 1% improvement in efficiency provides a significant long-term energy production benefit.

Account for acreage required for short-term (construction) and long-term (operations). Identify and address staging and lay down areas and impacts during planning. Estimate short-term site impact as twice the acreage as the final operation area boundaries. Identify final site layout to include operational areas, exclusion zones, safety zones, and buffers.

4-2.3.4 Site Access.

Account for the construction access for heavy and long/oversized loads. Perform delivery route analysis for roads, bridges, underpasses, inclines/declines, and overhead utilities.

4-2.4 Wind Assessment.

Perform a two-phase site wind assessment: 1) preliminary evaluation using historical data and 2) site specific analysis using meteorological towers to collect wind direction, speeds, and frequencies. If commercial financing is being sought for the project, an investment grade wind resource study is required to establish the quality, reliability, and value of the wind resource. Wind resource assessment guidance including a Wind Resource Assessment Handbook is available at the following National Renewable Energy Laboratory (NREL) website:
http://www.nrel.gov/wind/resource_assessment.html

4-2.4.1 Historical Data.

Historical wind data is available from NREL and commercial sources. Use historical data to perform preliminary site assessment. Sites with greater than 6 meters per second (m/s) average wind speed are considered viable.

4-2.4.2 Site Assessment.

Once site passes preliminary assessment using historical data, perform site specific wind analysis using meteorological towers. Quality of wind depends upon turbine location with respect to plains, buttes, ridges, facilities, and general topography roughness on the turbine’s windward site. If site topography varies significantly, more than one meteorological tower may be required to adequately characterize site’s wind potential. Perform site assessment for at least one year to account for seasonal changes.

Collect wind speed and direction using anemometers and wind vanes. Place sensors two or three heights (two anemometers and one vane per height) on the tower. Place top sensors as close to projected turbine hub height as possible to ensure more accurate power estimates. Use booms for sensors to reduce tower wake effects on wind data. Collect average wind speed and direction at 10-minute intervals.

4-2.4.3 Site Energy Projections.

Site wind speeds, frequencies, directions, and durations are utilized to generate power projections. Use collected wind data to generate site power production projections using specific wind turbines' power curves.

4-2.5 Community Concerns.

Early community involvement is critical for project success. Typical community concerns include generated sound, visual impacts to include blade flicker (shadows), and increased traffic during construction. Initiate a community outreach program early in the planning stage to ensure community concerns and requirements are known and mitigated early in the program development.

4-2.5.1 Sound.

The dominant noise-generating component of large-scale wind turbines is aerodynamic. Conduct baseline and predictive noise studies to generate maps of isophones to determine potential mitigation areas and for community discussions. Follow IEC 61400-11.

4-2.5.2 Visual.

Installation of 260 ft. (80 m), or higher, wind towers will change the site and surrounding areas visual aspect. Conduct a Zone of Visual Influence Study to calculate where the wind farm will be visual and to what extent. Conduct Worst-Case Scenario Study for shadow fluttering on surrounding occupied structures and active roadways. Mitigate negative findings by adjusting turbine siting, diameter, or height. Use studies to articulate impact with community and to analyze mitigation actions.

4-2.5.3 Traffic.

Construction and materials movement will affect local communities. Coordinate with local communities on routes, impacts, and timing.

4-2.6 Environmental.

4-2.6.1 Endangered Species.

Evaluate site for seasonal and year-round endangered species. Address and implement mitigation actions. Obtain permits and authorizations required under the Endangered Species Act of 1973 for activities that may take native threatened or endangered species. Contact nearest U.S. National Fish and Wildlife Service (USFWS) Ecological Services Office and determine if the proposed project is likely to result in "take," whether a permit is required, and if other options are required to be considered.

4-2.6.2 Avian and Bat Studies.

Conduct avian and bat study for projected impacts. Address recommendations and implement mitigation actions.

4-2.6.3 Historical, Cultural and Archeological Studies.

Evaluate site for historical, cultural, and archeological aspects. Address findings and implement mitigation actions.

4-2.6.4 Wetlands Reviews.

Conduct wetland reviews. Address findings and implement mitigation actions.

4-2.7 Federal Aviation Administration Coordination.

4-2.7.1 Flight Path Concerns.

The FAA has legal jurisdiction over structures 200 ft. (61 m) tall and above. Additionally, structures less than 200 ft. (61 m), but within 20,000 ft. (6 km) of a runway, may still penetrate navigable airspace. FAA evaluation starts with submitting FAA Form 7460-1. The FAA will issue either a Determination of No Hazard, or a Determination of Presumed Hazard, which may initiate a process of negotiation and appeal.

4-2.7.2 Radar Concerns.

Static electricity generated by the blades moving through the air may create radar 'blind spots.' The OSD and U.S. Air Force coordination with the FAA will analyze the site for conflicts and mitigation requirements, if required.

4-2.8 Interconnect Studies.

Designer must perform interconnect studies. Refer to Chapter 8 titled "UTILITY INTERCONNECTION" for guidance.

4-2.9 Permitting.

4-2.9.1 Land Use Permits.

Coordinate with OSD Clearinghouse and Bureau of Land Management for public lands, and State environmental and energy planning offices for land use permits.

4-2.9.2 Building Permits.

Comply with applicable city/State / Federal for building permits requirements.

4-2.9.3 Incidental Take Permit.

Obtain Incidental Take Permit in accordance with 50 CFR Part 13 and 50 CFR Part 17.

4-2.10 Economics.

4-2.10.1 Power Projections.

Require developer to provide life cycle power projections based upon site specific resource conditions, and turbine manufacturer and model.

4-2.10.2 Rate Structures and Terms.

Coordinate with local power company and ISO/RTO for installation site rate structures. Engage the following offices for utility term negotiations:

- U.S. Air Force: U.S. Air Force Civil Engineer Center, Energy Directorate (AFCEC/CN).
- U.S. Army: U.S. Army Engineering and Support Center, Huntsville, Energy Division, Commercial Utilities Program.
- U.S. Navy: Naval Facilities Engineering Command Headquarters, Public Works Business Line, Utilities and Energy Management, Washington Navy Yard, Washington, D.C. (NAVFAC HQ PW UEM).

4-2.10.3 Project Costs.

Installed costs fall under three categories, turbine cost, soft costs, and balance of station costs. For preliminary project estimation, use values in Table 2-4 and use the percentages in Figure 4-2 to estimate sub-factor capital costs.

4-2.10.4 Operations and Maintenance Contracts.

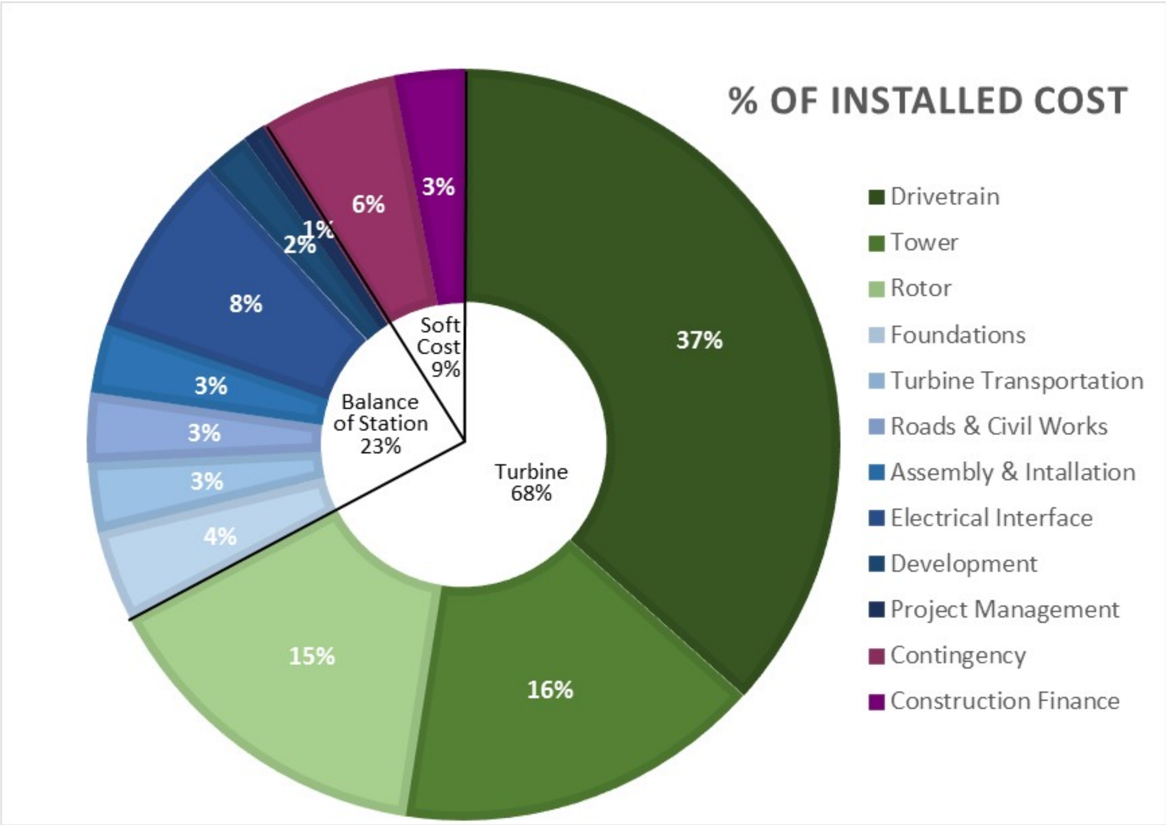
Use American Wind Energy Association's *Operations and Maintenance Recommended Practices* for O&M requirements in contract statement of works and basis for cost estimation.

4-2.10.5 Extended Warranties.

Estimated economical life of wind turbines is 20 years. Perform cost/benefit analysis to obtain extended equipment warranties versus cost of O&M contracts for the period between the standard warranty and the extended warranty.

Note: At end-of-life, wind turbines may be decommissioned and site restored; components refurbished; and/or replaced with new turbine systems, depending up economics and available technology. As a minimum, use similar end-of-life scenarios to determine economic differences between the selected options in the economic analysis.

Figure 4-2 Land Based Wind Turbine Systems Installed Capital Costs (AWEA)



4-3 DESIGN CRITERIA.

Primary wind industry design standards are codified under the International Electrotechnical Commission (IEC) IEC 61400 series. A lead wind association assisting in codifying U.S. standards is the American Wind Energy Association. Review both resources for current design requirements.

4-3.1 Wind Turbine System.

4-3.1.1 Classes.

Comply with IEC 61400-1. Table 4-1 represents IEC 61400-1 wind turbine classifications data. A class IIB wind turbine, for example, is designed for average wind conditions, at hub height, for 95 mph (42.5 m/s) with medium turbulence characteristics. Designer of Record to select the wind turbine class based upon site conditions.

Table 4-1 Wind Turbine Classes

Wind Turbine Class	I	II	III	S
Average wind speed over 10 minutes at hub height.	50 m/s (112 mph)	42.5 m/s (95 mph)	37.5 m/s (84 mph)	Values specified by designer
	Expected turbulence intensity at 15 m/s (33 mph)			
A – high turbulence characteristics	0.16			
B – med turbulence characteristics	0.14			
C – low turbulence characteristics	0.12			

4-3.1.2 Design Life.

Require wind turbine design lifetime for a minimum of 20 years.

4-3.1.3 Components.

Evaluate during site planning phase the individual wind turbine component shipping, site access, and lay down area requirements. Common blade lengths range from 100 – 165 ft. (30 – 50 m) long. Towers range from 195 – 260 ft. (60 – 80 m) high, but are typically shipped in three sections. Component lengths will eliminate certain road access routes. Heavy components, such as hubs which weight from 7 – 20 tons (6,350 – 18,147 kg), may eliminate bridge or road routes due to weight limits.

4-3.1.4 Structural Design.

Structural design, including foundations, to comply with ASCE/AWEA PR2011, as updated.

4-3.2 Electrical.

Figure 4-3 diagramically presents a wind farm electrical system and connection to transmission grid. Comply with current editions of UFC 3-501-01 and UFC 3-550-01. Comply with Chapter 8 titled “UTILITY INTERCONNECTION” and coordinate electrical system with host utility provider.

4-3.2.1 Grounding.

Comply with NFPA 70.

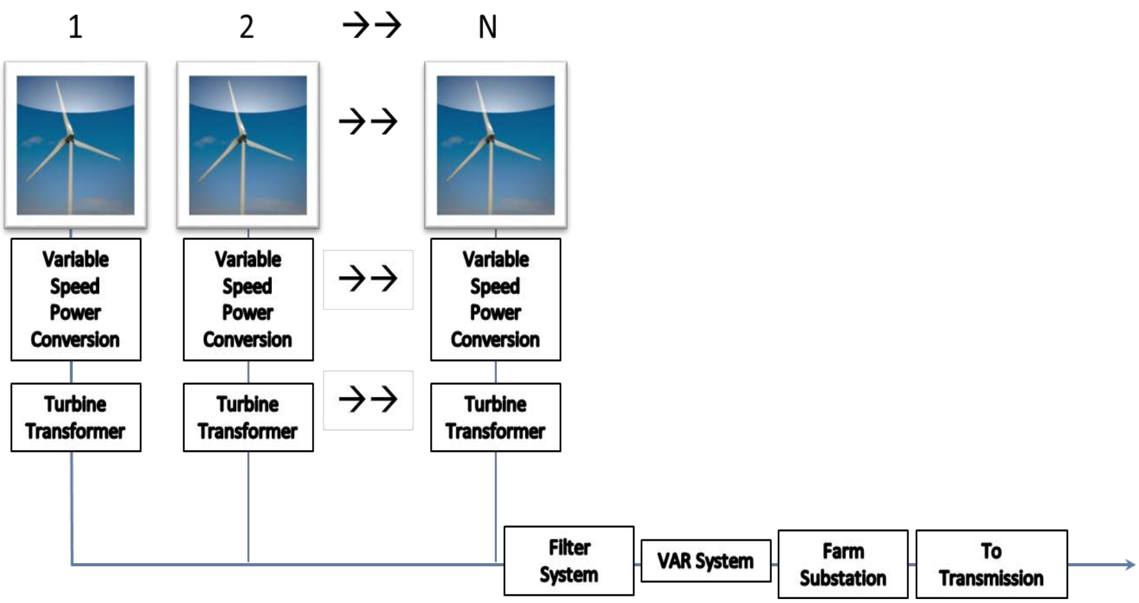
4-3.2.2 Lightning Protection.

Comply with IEC 61400-24 and NFPA 780.

4-3.2.3 Interconnection.

Comply with Chapter 8, titled “UTILITY INTERCONNECTION,” IEEE 1547, and IEEE 519.

Figure 4-3 Illustrative Wind Farm Components



4-4 OPERATIONS AND MAINTENANCE.

4-4.1 Contract Based Operations and Maintenance.

O&M service contracts starts after the warranty period expires and are typically based upon a system operating life of 20 years. Contracts are based on either time (e.g. years) or amount energy produced. Address site and equipment O&M requirements and ensure O&M is available at turbine startup, either by warranty contract or by service contract. Appendix E provides additional O&M guidance.

Comply with specific turbine manufacturer’s recommendations. Use predictive maintenance on high value components, such as yaw and pitch systems, gearbox, and generators. Perform annual infrared study on mechanical and electrical components. Use preventive maintenance on remaining components, such as structures and supporting infrastructure.

4-4.1.1 Turnover Inspections.

Perform a turnover inspection a minimum of three (3) months prior to warranty ending to identify and resolve warranty-based issues. Minimum inspection requirements include:

- Visual structural and component inspection;

- Qualitative checks on items such as bolting torque settings, component oil leaks, pitch linkage wear, cable routing, electrical terminations and installed safety equipment;
- Gearbox vibration monitoring;
- Oil sampling and analysis;
- Site-wide infrared analysis;
- Review of all service reports and parts usage during the warranty period; and
- Perform condition baseline inspection at start of O&M contract.

4-4.1.2 Monitoring.

Require 24-hour remote monitoring of wind turbine systems to include predictive maintenance sensors for key attributes, e.g. rpm, wind speeds, blade positions, vibration, temperature, fluid levels, power output.

4-4.2 Safety.

Establish safety and response plans for the following items:

4-4.2.1 Solid and Hazardous Wastes.

Address the transportation, handling, storage, and disposal of hazardous materials to and from site.

4-4.2.2 Ice Shedding.

Provide ice detection and shutdown response to reduce ice projection and blade imbalance. Conduct ice throw risk assessment to identify potential risks. Provide warning signs in impact zones to alert operational personnel of potential of falling ice.

4-4.2.3 Blade Failure.

Provide warning signs for potential blade impact zones, in case of a catastrophic blade failure.

4-4.2.4 Fire.

Create fire response plans and provide close coordination with and training for local firefighters. Train all on-site personnel on fire and emergency response plans. Adhere to regular and appropriate maintenance schedules.

4-4.2.5 Lightning Strikes.

Adhere to safety protocols including stopping work when thunderstorm warnings or watches are issues. Require annual training on awareness and evacuation procedures.

Identify site designated shelter and provide lightening prediction and warning system, with communications, to maintenance team.

4-4.2.6 Worker Fall Protection.

Compliance with work fall protection standards is critically important due to wind turbine heights and operating environment. Comply with applicable 29 CFR 1910 and 29 CFR 1926 standards. Primary fall standards include 29 CFR 1910 Subpart D; 29 CFR 1910 Subpart I; 29 CFR 1910.269(g), 29 CFR 1926 Subpart E, 29 CFR 1926 Subpart M, and ANSI Z359.

4-4.3 Non-Performance.

Ensure non-performance and remedy clauses are in maintenance contract to address non-conformance. Ensure liquidated damages address power generation revenue loss and mission impacts.

4-4.4 Warranties.

Typical wind turbine installation warranties are for two to five (2-5) years, followed by a service contract modeled on an operating life of 20 years.

Specific component warranties will vary with manufacturer. Warranties are typically limited to repair or replace, at manufacturers' discretion, the defective components, or assemblies. Warranty limits may include causes for materials, supplies, and equipment not manufactured or supplied by the manufacturer, unauthorized repairs or modifications, Acts of God, and incidental or consequential damages. If warranty does not include O&M requirements, ensure O&M contract is in place once turbine is operational.

4-4.5 Project Planning Considerations.

Appendix D provides listing of factors to consider during the design. Tailor as appropriate for project scope.

This Page Intentionally Left Blank

CHAPTER 5 DESIGN CRITERIA – BIOMASS SOLID WASTE TO ENERGY SYSTEMS

5-1 INTRODUCTION.

Solid Waste to Energy conversion is a biomass process that converts solid waste into various forms of fuel that can be used to produce thermal and electrical energy.

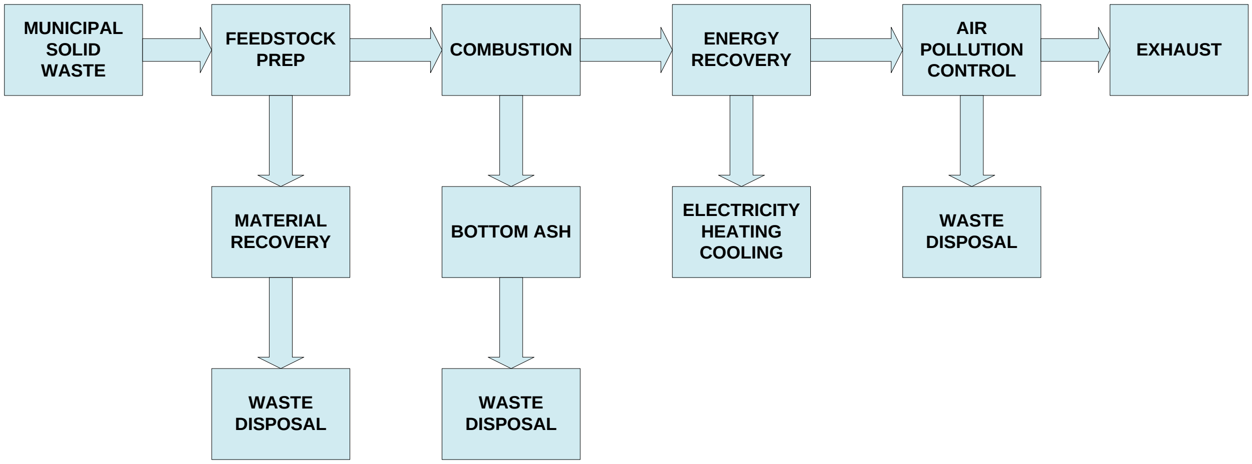
This chapter establishes the requirements for thermal conversion of solid waste to generate steam and produce electricity using combustion of municipal solid wastes in what is described as a mass burn, water wall plant.

5-1.1 Technology.

The predominant large solid waste combustors technology is the Mass Burn / Water Wall type combustor. In this type system, minimum or non-processed waste is delivered by overhead crane into the furnace through a feed hopper that uses hydraulic rams and reciprocating or roller grates.

The mass burn thermal conversion process is depicted in Figure 5-1. The mass burn plant is a direct combustion process for producing heat, electrical power, combined heat and power, or combined heat, power and cooling. The solid waste is delivered to the plant where it is prepped for feedstock by removing recyclable and hazardous materials. The feedstock is then burned with the ash being sent to waste disposal and the heat being recovered for generation of electricity, steam or high temperature hot water, and in some plants, chilled water using adsorption chiller units. The flue emissions are processed through air pollution control (APC) equipment with removal of toxic gases, acids, and particulate matter then exhausted from the plant.

Figure 5-1 Mass Burn Process of Solid Waste to Energy



5-1.2 Application.

Mass burn solid waste to energy plants require a large and continuous source of municipal waste, a large land area with access to water, sewer and natural gas, and proximity to utility transmission lines. Locate plant near large town or city industrial areas. Extensive environmental studies and permitting are required as well as extensive utility and public coordination. These plants are best suited for a municipal and utility partnering agreement using a design-build-operate contractor approach.

5-2 PLANNING.

The planning section identifies biomass technology unique planning requirements including determining the energy recovery potential, complying with environmental regulations and restrictions, and permitting.

Perform proposed and final siting coordination with OSD. 32 CFR Part 211 requires DoD to conduct mission compatibility evaluation of proposed site and project. Early project awareness and coordination with OSD is mandatory. Request a preliminary siting determination from the OSD Clearing House at osd.dod-siting-clearinghouse@mail.mil to avoid invalid site selections.

5-2.1 General Requirements.

Design and operate facility to cost effectively maximize power generation and district heating (if available) capacity. The fuel supply is from municipal solid waste delivered by solid waste haulers and self-haulers. 10 USC 2692 restricts the types, storage, and use of non-DoD materials, and may affect projected fuel supply. Design facility for 24 hour/365 day operation at maximum continuous rating and at maximum continuous turndown for extended time without supplemental natural gas fuel firing. Design facility life for thirty (30) years.

Provide appropriate redundancy in the chute to stack, furnace/boilers, turbine-generators, steam distribution, electrical switchgear and transformation, pollution control, and other equipment, to minimize unscheduled outages. Provide normal and emergency power systems, with the facility being self-powered during operations except in emergencies and start up conditions. Provide natural gas supplementation for boiler system start up and maintenance heating.

5-2.1.1 General Development Plan.

Prepare a general development plan for the project life cycle. Include the following phases as a minimum: feasibility, design, construction, operation, and decommissioning.

5-2.1.2 Site Planning and Development.

Use UFC 3-240-05A, Chapter 2 (for Army), and UFC 3-430-02FA, Chapter 2 (for Army/Air Force), for general site planning and development. *Note: Navy to use UFC 3-*

240-05A and UFC 3-430-02FA as reference only. Follow local shore installations planning guidance. Consider Table 5-1 during site planning evaluation:

Table 5-1 Plant Site Planning Considerations

Area	Consideration
Zoning	• Use local land use planning and zoning regulations in siting plant. • Plant should be located in a heavy industrial area, preferably close to existing power plants. • Locate plants in open areas where flue emissions are not trapped by terrain or wind patterns and the emissions are not prone to create smog. • Locate plant away from airfields and flight paths to accommodate the flue stack(s).
Economics	• Plant should be within economic range for transfer or waste truck delivery. • A properly designed and operated landfill for disposal of ash and waste residue must be within plant economic range. • Plant should be located in proximity to the waste generation area. • If supplying district heating or cooling, locate plant in economic proximity to existing district heating/cooling supply and return mains.
Infrastructure	• An adequate source of water must be available for plant operations. • Natural gas must be available for furnace starting and boiler operation in the event of a solid waste fuel interruption. • Municipal sanitary sewer should be nearby to receive the wastewater discharge polluted by waste storage liquids, slag cooling, and flue gas cleaning system. • Electrical power transmission lines and available right of ways should be nearby to connect the plant to the electrical network without high construction costs.

5-2.2 Critical Criteria.

The following criteria are critical to the municipal solid waste to energy plant planning:

5-2.2.1 Energy Recovery Potential Assessment.

Use the NREL Renewable Energy Optimization (REO) tool to model the energy generation and costs in the project defined location. Use the U.S. EPA – Research Triangle Institute (RTI) International Municipal Solid Waste Decision Support Tool (MSW-DST) (https://mswdst.rti.org/) to conduct a comprehensive energy, environmental impact, and cost model for the determining the preliminary energy recovery potential and life cycle cost analysis. Develop model based upon waste generation from residences, multi-family residences, and commercial entities.

5-2.2.2 Local Conditions / Existing Waste Management Practices.

Conduct a waste survey and forecast to establish the expected amount and composition of waste generated during the facility lifetime using the RTI MSW-DST. Assume a 30 year life cycle period.

5-2.2.3 Waste Physical and Chemical Characteristics.

Solid waste used for fuel includes Municipal Solid Waste (MSW) per 40 CFR Part 60.51b. The average lower calorific value of waste must not be less than 3,000 Btu/lb (7 MJ/kg). If actual MSW caloric value not known, use an aggregate heating value of 5,000 Btu/lb (11.6 MJ/kg) for fuel energy calculations. MSW with higher caloric values reduces the volume necessary for same unit of energy produced. Evaluate other non-MSW combustible solid waste streams as a fuel source, as permitted. Consider the following solid waste streams in planning and characterization:

- Wood pallets, clean wood, and land clearing debris;
- Packaging materials;
- Clothing materials; and
- Rugs, carpets, and floor coverings except asbestos materials.

Some solid waste, other than MSW, may be allowed in a limited segregated burn scenario, if authorized by State and Federal permits. Consider the following solid waste streams in planning and characterization:

- Waste tires;
- Construction debris;
- Waste oil and waste oil products; and
- Human and animal processed product waste (e.g. foodstuff, personal care products, pharmaceuticals, cosmetics, cleaners, detergents, waxes, etc.).

5-2.2.4 Prohibited Materials.

10 USC 2692 restricts types and use of non-DoD materials. Design and operate plant to prevent combustion of:

- Materials prohibited by State and Federal laws;
- Hazardous waste;
- Nuclear and radioactive waste;
- Explosives;
- Sewage sludge;
- Biomedical and biological waste;
- Waste containing beryllium (40 CFR Part 61, Subpart C);
- Waste containing mercury;
- Lead acid batteries;
- NiCad batteries; and
- Pressure treated wood.

5-2.2.5 Seasonal Fluctuations in Waste Quantity and Quality.

Design plant systems to account for seasonal fluctuations in waste quantities and quality.

5-2.2.6 Treatment of Rejects / Effluents.

Provide for treatment/re-use of liquid rejects / effluents from APC process wastewater, other process wastewater (boiler feed, blowdown, and bottom ash system), sanitary sewer, storm wastewater, and cooling towers. Evaluate and implement as appropriate the following best available technologies: on-site physical/chemical treatment; re-circulation of wet scrubber effluent; effluent flow buffering and storage; scrubber dioxin and furan breakthrough control; and ammonia stripping.

5-2.3 Environmental Regulation and Restrictions.

5-2.3.1 General.

Comply with UFC 1-200-01 and agency specific environmental regulations, restrictions, and specific applicable environmental guidance. In addition to Federal regulations, State and local municipality regulations may require permits, licenses, and approvals for construction and operation. Identify and compile these regulatory items and documentation requirements during the mass burn plant design, construction, and operation.

5-2.3.2 Air Quality Regulations.

A mass burn plant is subject to multiple provisions of the Clean Air Act of 1990. Comply with the two main provisions applicable to mass burn plants including Section 129 Solid Waste Combustion and Section 165 Pre-Construction Requirements. The mass burn plant will be designed to satisfy all emission requirements of 40 CFR Part 257 and 40 CFR Part 60.

5-2.3.3 Water Quality Regulations.

Design and operate the plant to ensure surface water is not polluted in accordance with the Water Pollution Act of 1956 or the Clean Water Act of 1990. Design and operate the plant to ensure ground water is not polluted in accordance with the Clean Water Act of 1972 and 40 CFR Part 257.

5-2.3.4 Solid Waste Disposal Regulations.

Limit ash emissions to not to exceed 5%, as determined by EPA Reference Method 22 per 40 CFR Part 60.

5-2.4 Interconnect Studies.

Perform interconnect studies. Refer to Chapter 8 titled "UTILITY INTERCONNECTION" for guidance.

5-2.5 Permits.

Obtain pre-construction and operating permits required to ensure facilities comply with applicable Federal, State, and local laws to ensure the facilities operators and public health and safety protection, to prevent and reduce polluting the environment, and to protect endangered species. In addition to the listed permitting activities herein, contact the state and local environmental and development offices to verify additional permitting requirements.

5-2.5.1 Environmental Impact Statement.

Perform a project Environmental Impact Statement / Environmental Assessment.

5-2.5.2 Air Permits.

Obtain State and local permitting as required under 40 CFR Part 70. For states that have not been granted full approval authority under 40 CFR Part 70, Indian country, outer continental shelf areas, and other areas/authorities not covered by 40 CFR Part 70, permitting is required under 40 CFR Part 71.

5-2.5.3 Wastewater Discharge Permits.

Waste Water or Stormwater Permit. Obtain a National Pollutant Discharge Elimination System (NPDES) permit in accordance with the Clean Water Act.

Solid Waste Disposal Permit. Regularly sample and test the mass burn solid waste ash and other residues in accordance with permit requirements to determine if ash is hazardous waste. Hazardous material and hazardous waste ash must be disposed of as hazardous waste in accordance with the Resource Conservation and Recovery Act (RCRA) and 40 CFR Parts 266-273.

5-2.5.4 Dredge and Fill Permit.

Structures or work affecting the course, condition, location, or capacity of navigable waterways or wetlands requires a Department of the Army Permit from the United States Army Corps of Engineers (USACE).

5-2.5.5 Haze and Visibility / Prevention of Significant Deterioration (PSD).

Consultation and agreement with U.S. Department of Interior - National Park Service and USFWS, and U.S. Department of Agriculture - National Forest Service Federal Land Manager(s) is required if plant is located within 185 mi (300 km) of a Class I area in accordance with 40 CFR Part 81.

5-2.5.6 Incidental Take Statement / Permits.

Obtain permits and authorizations required under the Endangered Species Act of 1973 for activities that may “take” (kill) native threatened or endangered species. Contact the nearest USFWS Ecological Services Office and determine if the proposed project is likely to result in a take, whether a permit is required or if other options require consideration. Obtain an Incidental Take Permit in accordance with 50 CFR Part 13 and 50 CFR Part 17.

5-2.5.7 FAA Permit.

Comply with 14 CFR Part 77 and file a Notice of Proposed Construction or Alteration with FAA.

5-2.5.8 Other State and Local Permits.

Contact State and local environmental, development, and transportation offices for construction and operating permits for the following:

- Boiler / pressure vessel;
- Elevator and kindred equipment;
- Oversize/overweight vehicles;
- Highway construction;
- Land use; and
- Historic sites review.

5-2.5.9 Permits.

Coordinate and obtain utility permits for water, sanitary sewer, fuel gas, and electric utilities.

5-2.6 Cost Estimation / Analysis.

Use the MSW-DST to provide a screening level cost and a report of environment aspects for the proposed waste to energy plant.

5-2.6.1 Capital Costs.

Use capital cost data from the U.S. Energy Information Administration for initial capital cost estimates. Capital costs to include the total investment costs for equipment, construction, and engineering, for the plant, electrical grid connection, roads, utilities, and new infrastructure to support the plant.

5-2.6.2 Operation and Maintenance Costs.

For initial planning, calculate fixed O&M and variable O&M costs using O&M cost data from the U.S. Energy Information Administration.

5-2.6.3 Sale of Energy.

Include the sale of energy from the plant in the economic analysis. The income includes the sale of electricity and, where district heating is available, can include the sale of steam or high temperature hot water.

5-2.6.4 Sale of Materials Recovery.

Include in the economic analysis the potential value of selling recovered materials. As a minimum, include ferrous and alumina recovery.

5-2.7 Coordination.

Establish an institutional framework consisting of the four major project stakeholders of government authorities, waste sector companies, community groups, and energy sector companies. Review with the stakeholders the financial, environmental, and waste flow issues. Perform a comprehensive stakeholder analysis for both the existing waste disposal and future waste to energy plant. Establish agreements that resolve issues before the plans are made to build the plant.

5-3 DESIGN CRITERIA.

5-3.1 General Buildings.

Administrative, maintenance, operations, security, and other similar facilities of the plant must comply with UFC 1-200-01. Refer to UFC 3-240-05A (for Army) for additional facility requirements. For other Agencies, use UFC 3-240-05A as a reference and comply with Agency specific guidance.

5-3.2 Mass Burn Plant.

5-3.2.1 Functional Design of Plant.

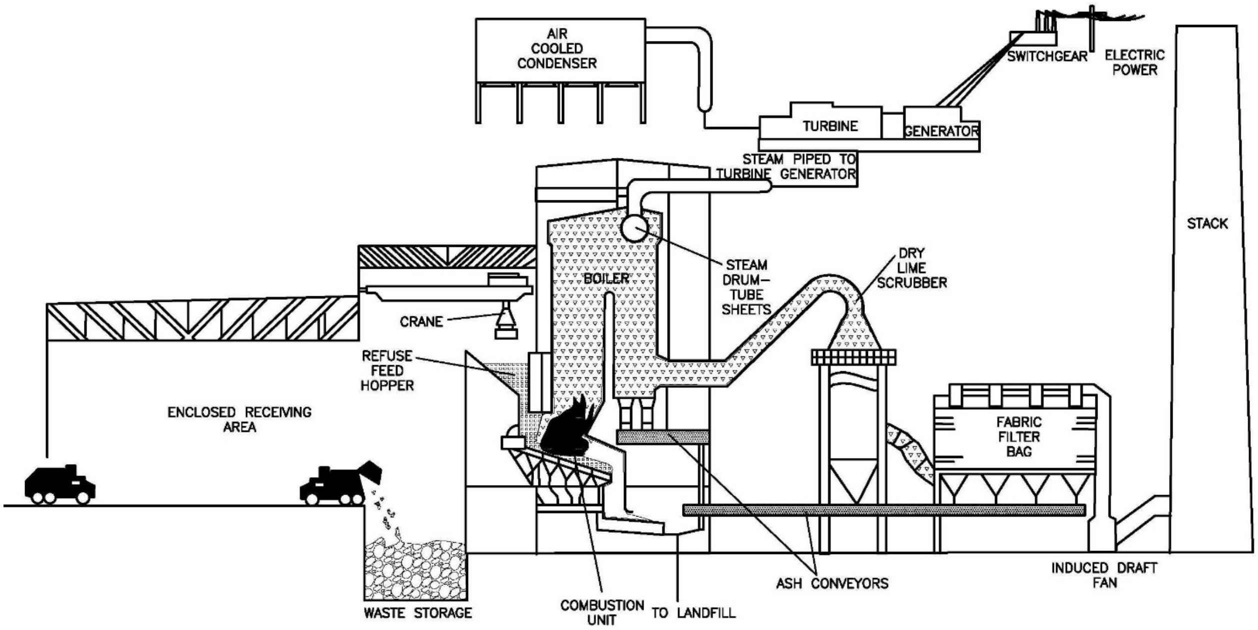
The Mass Burn Plant primary functions are to include: 1) receive the solid waste; 2) process and store the waste; 3) convert the solid waste to energy; 4) distribute the energy from the solid waste conversion; and 5) energy conversion process waste by-products disposal. To accomplish this, provide the following main systems: refuse receiving, handling and storage system; combustion and steam generation system; flue gas system (APC equipment); power generation system; steam condenser and make up water systems; residual waste disposal system; and supporting systems.

5-3.2.2 Process Flow and Layout.

Use the Figure 5-1 process flow as a guide to developing the plant layout. Figure 5-2 presents a typical plant layout. The waste to energy plant receives MSW on the tipping floor where it is prepped for feedstock. Large, bulky, and hazardous items are removed from the waste. In some operations, metals are removed and waste reduced to an optimum burning size. MSW moves from the storage pit to the boiler feed hopper for combustion. The feed hopper places MSW onto a grate using control gates and hydraulic rams to push the waste on to a grate in the furnace where it is dried out and combusted on the grate. Ash is discharged through the grate bottom into a water filled quench pit, and then transferred by a conveyor to an ash load out area for disposal in a landfill.

Energy recovery from the combustion process is transferred by water from the boiler walls and from the flue gas off the boiler. The heat absorbed creates steam that is used to operate a steam turbine. The steam from the turbine is condensed through a cooling tower and re-cycled through the boiler. The turbine is connected to a synchronous generator that rotates and produces electricity. In many applications, the heat is also transferred to district heating through steam or high temperature hot water systems. In some applications, the heat is converted to chilled water using absorption chiller units. The flue emissions are processed through APC equipment including spray dryers for acid gas, activated carbon injection for mercury control, ammonia for NOx control, and a baghouse for fly ash. The flue gas is then released through the plant flue stack.

Figure 5-2 Solid Waste to Energy Mass Burn Plant



5-3.2.3 Specific Building Requirements.

Provide the following solid waste to energy plant facilities:

- Gatehouse / scales;
- Tipping floor / waste sorting;
- Waste storage pit;
- Boiler building;
- Spray dryer;
- Baghouse;
- Waste material storage facility;
- Turbine-generator building;
- Cooling towers;
- Switchgear facility;
- Utility substation;
- Black start generator plant;
- Continuous Emission Monitoring System (CEMS) facility;
- Fire pump house;
- Administration;

- Maintenance; and
- Security guardhouse.

5-3.2.4 Layout.

Design facility with the concept of providing efficient operations and maintenance activities throughout the facility life. The design process must include a general configuration of all proposed buildings and structures, roads, parking and paved areas, as well as drainage features and any associated retention basins.

Design the facility roadway system to provide a traffic pattern allowing simultaneous traffic to both enter and exit the facility, and allow unencumbered travel of vehicles in both directions throughout the facility.

5-3.2.5 Materials.

Select all materials used for durability and longevity.

- Facility structure: concrete or steel construction.
- Exterior wall surfaces: steel with factory finished coating system or architectural masonry.
- Roofing: metal, sloped for drainage.
- Exterior personnel doors: painted galvanized insulated core steel with window lights where appropriate.
- Overhead doors: painted galvanized steel.
- Windows: insulated double pane glass with insulated aluminum jambs.
- Floors: select finishes based upon safety and use.
- Open grate working platforms, open grate stairs, ladders, ladder cages, and handrails: use steel with galvanized coated after fabrication. Where exposed to corrosive materials, coat steel with a suitable coating system resistant to the specific corrosive materials.

5-3.3 Refuse Receiving, Handling and Storage System.

The refuse receiving, handling and storage system includes the refuse receiving area, tipping floor, waste storage, and overhead grappling cranes.

5-3.3.1 Refuse Receiving Area.

The refuse receiving area accommodates the business operation for logging, weighing and receiving waste from commercial waste haulers and self-haulers (residential customers). Design the receiving area for:

- Weighing all vehicles entering and leaving;

- Eliminating waste transfer trailers and trucks backing up needs, except at the tipping floor;
- Allowing only commercial waste haulers to enter the tipping floor;
- Providing separate area for residential customers to unload into a container area with the containers shuttled to the tipping floor by the plant personnel;
- Locating site refuse receiving area facilities to eliminate or minimize: intersections; backing up; sharp turns or U-turns; and
- Adequate off-street queuing during peak operating times.

Design on-site traffic control in accordance with the Federal Highway Administration Manual of Uniform Traffic Control Devices requirements. Provide a truck helper shelter before the scales so that only the truck driver is permitted to enter the tipping floor to maximize safety by minimizing the number of personnel in the facility. Provide heating and cooling of truck helper shelter and include single toilet room with lavatory and water closet. Provide area lighting in accordance with UFC 3-530-01. Provide area lighting for all process equipment that may require maintenance after dark. Numerous states have siting and design requirements for waste transfer operations. Consult these requirements for the state where the plant is being located.

5-3.3.2 Scale House.

The scale house is located after the entry gate and usually set back sufficiently from the gate to ensure off-road queuing. Provide:

- A scale house building with number of scales sized for the daily and hourly arrival patterns of waste delivery;
- Capability for adding additional future scale(s) for growth;
- Inbound and outbound truck scales with unattended self-service terminal and remote weight display (aboveground pit-less, full truck, concrete deck type with weighbridge supported by the load cells);
- Truck scales (in the United States and North America) compliant with United States National Institute of Standards and Technology (NIST) Handbook 44 requirements and carry the National Type Evaluation Program (NTEP) Certification issued by the National Conference on Weights and Measures;
- Truck scales (in other areas) that meet the local government or the International Organization of Legal Metrology requirements, as appropriate;
- Walk up deck adjacent to aboveground scales, receiving windows and doors on inbound and outbound sides, trucker lobby with customer window, business area, employee toilet room, employee break area,

storage area, IT and scale equipment closet, and separate truck helper shelter;

- Inbound and outbound automated gates; and
- Telecommunications equipment.

Provide two radiation detectors at the scale house to monitor for radioactive materials. Detectors are to alarm at the scale house, security guardhouse, administration building, and central control room. Provide a paved area, at safe distance from occupied structures, to allow vehicles with detected radioactive material to park until State authorities are notified and can verify concentration levels.

5-3.3.3 Tipping Floor.

Use the following requirements in the tipping floor design:

- Provide metal building with partial reinforced concrete walls;
- Reinforce concrete tipping floor walls to a minimum height of 5 ft. (1.5 m);
- Construct walls and floors subject to damage through repeated impacts with 6000 psi (41 MPa) reinforced concrete;
- Provide truck receiving area to accommodate multiple waste trucks without stacking;
- Provide truck doors with minimum opening of 20 ft. wide by 20 ft. high (6 m x 6 m);
- Provide protective bollards inside and outside truck doors;
- Totally enclose the tipping floor and sized for a minimum of 130 sq. ft. (12 sq. m) for each ton-per-day incinerator capacity per UFC 3-240-05A (for Army). For other Agencies, use UFC 3-240-05A as a reference and comply with Agency specific guidance;
- Size tipping floor area for peak container unloading and for tractor trailer size load of solid waste delivery;
- Size tipping floor for tractor trailer turn radius with minimum width of 150 ft. (46 m);
- Provide tipping floors to accommodate vehicles with maximum of 75 ft. (23 m) length and maximum legal weight limit of 80,000 lbs. (36,000 kg) gross, single axle of 20,000 lbs. (9,100 kg), tandem axle of 34,000 lbs. (15,400 kg), triple axel of 42,000 lbs. (19,000 kg), and quad axle of 50,000 lbs. (22,700 kg);
- Provide tipping floor with an additional 3 in (7.6 cm) concrete wear layer;
- Provide embedded galvanized steel protection on outside corners and edges subject to damage from trucks and grappling cranes; and

- Provide vehicle stops in front of each pit with spacing for drainage and broom cleaning of tipping floor into pit.

5-3.3.4 Sorting and Contaminant Removal.

Hand picking, hazardous material removal, and size reduction are required processes to render the waste easier to handle and make particles the size required by the furnace. Provide hand picking area with tables, hoppers and sorting belts, at tipping floor to remove large items (i.e. appliances, refrigerators, and equipment), batteries, and other specified hazardous materials. Size reduction can be single or multi-stage depending upon the furnace size and combustion requirements. Evaluate guillotine hydraulic shears and shredders for reducing oversized material for combustion based upon oversized material volume, explosion risk, and economic analysis. Provide size reduction equipment based upon the analysis. Provide guillotine-type hydraulic shears for reducing oversized items. Provide adequate access, lighting, overhead hoists, and welding equipment receptacles for equipment maintenance.

Evaluate throughput, availability, and redundancy for the material recovery and contaminant removal system. Include environmental control equipment for dust collection, noise suppression, odor control, explosion control, and HVAC. Refer to UFC 3-240-05A (for Army) for waste processing and bypass requirements. For other Agencies, use UFC 3-240-05A as a reference and comply with Agency specific guidance.

5-3.3.5 Ferrous Recovery.

For ferrous metals, use multi-stage magnetic separators to achieve a minimum recovery yield of 85% consisting of magnetic belts, mixed waste conveyor, ferrous waste conveyors, and non-ferrous collection conveyor. Provide conveyor to transfer to ferrous bulk storage.

5-3.3.6 Aluminum Recovery.

Use eddy current separators to eject aluminum material from the moving waste stream. Provide a can flattener for ejected waste. Provide a conveyor to transfer to aluminum bulk storage.

5-3.3.7 Waste Storage.

Provide a waste storage building sized for a minimum five (5) day capacity at facility's maximum continuous rating to facilitate major equipment repairs. Site the waste storage building adjacent to the boiler building.

5-3.3.8 Pit Storage.

Design the waste storage pit for a minimum five (5) day capacity based upon a bulk density of 500 lb/yd^3 (300 kg/m^3). The pit storage volume will be based upon the pit volume up to the tipping floor and the volume above the tipping floor assuming the waste above the tipping floor is stacked at a 45 degree angle from the charging floor wall to the tippling floor. The pit storage capacity will include 2/3 below the tipping floor and 1/3 above the tipping floor as geotechnical conditions allow. The pit depth should be 30 to 45 ft. (9-14 m) below grade, if possible, as groundwater conditions allow. The number and arrangement of bays for refuse truck unloading will be based on the peak container flow.

Include the following storage pit components/requirements:

- Construct using 6000 psi (41 MPa) reinforced concrete, minimum;
- Slope storage pit floor to perimeter sump;
- Totally enclose storage pit under negative pressure using the boiler combustion air system;
- Provide dust control spray system;
- Provide rodent and bird controls; and
- Include fire canons controlled from the pit operator control station and standpipe systems at tipping floor and charging floor.

5-3.3.9 Refuse Handling Crane.

Provide a minimum of two (2) refuse handling cranes. Select cranes rated for MH CMAA 70 Class F (continuous severe service) in accordance with UFC 3-240-05A (for Army). For other Agencies, use UFC 3-240-05A as a reference and comply with Agency specific guidance. Cranes are to be overhead bridge, non-riding, type meeting the requirements of ASME B30.2. Specify cranes for continuous operation configured to manage refuse in the receiving and storage facility as well as to feed refuse to the charge hoppers to the boilers and capable of operating with a full load at minimum speeds. Cranes must be capable of weighing each bucket or grab load prior to discharge into feed chute. Provide separate motors for the hoist bridge, trolley drive, and grapple. Use interchangeable orange peel type grapples. Size the grapple based upon duty cycle quantity analysis of material being moved from the pit to the furnaces, the distance to move the material, crane speeds, and time required for mixing and stacking material in the pit.

Design the crane operator control station (or pulpit) to accommodate a minimum of two operators and control consoles, and allow operation of both cranes simultaneously. Design the control station to provide full view of the storage pit and charging hoppers. Provide control station with independent heating, ventilation and air conditioning system at positive air pressure relative to the pit and tipping floor. Provide control station with CCTV to monitor charging hopper level and incoming waste delivery at the tipping floor. The cranes will be equipped with semi-automatic operation features to minimize operator stress.

5-3.4 Combustion and Steam Generation System (Boiler).

5-3.4.1 Feed System.

The charging hopper discharges the solid waste into the delivery chute. Provide a top loading charging hopper for each combustion train. Design charging hoppers to be large enough to prevent spillage on the charging floor and with slopes steep enough to prevent solid waste bridging. Provide hydraulically actuated gate between the charging hopper and upper chute. Gate to automatically close in the event of a power failure.

Design the waste chute feeding the refuse stokers for sufficient height to provide an air seal to the furnace stokers. Design chutes with dimensions and contour for self-relieving to avoid bridging, but not less than 4 ft. (120 cm) wide and the furnace width. Provide means of access to reposition or remove particles in the chute and to assist in firefighting. Provide charging throat with water cooling and refractory lining. Include chute refuse level sensor to alarm crane operator and control room, and include hydraulic shutoff grate to prevent back burn during shutdown.

5-3.4.2 Refuse Stokers and Grates.

Design stokers and grates for burning solid waste, to avoid excessive refuse turning, and to even incoming waste distribution. Use a minimum of three grate sections, including drying grate, burning grate, and finishing grate. Bottom ash is discharged from the finishing grate into a water quench pit, and from there, it is transported by conveyor to the ash storage facility. Locate grates mechanisms outside the furnace. The grates are typically air cooled independent of primary air. If high calorific waste is used, water cool the grates. Feed waste refuse onto the grate with a charging ram. Charging rams will be hydraulic type with at least one hydraulic cylinder for each longitudinal grate section.

Provide a complete hydraulic system for each boiler system for operation of grates, charging rams, feed chute, and ash recovery. Include a fully automatic, forced, central lubrication system for lubricating the stoker with pumps and alarm system.

5-3.4.3 Auxiliary Fuel Burners.

Provide auxiliary fuel burners for use during start-up and shut down with total capacity of not less than 40% of the boiler's maximum continuous rating. Burners are water cooled, natural gas type with low NOx emission. Design burner in accordance with NFPA codes.

5-3.4.4 Ash Quench Pit.

Ash quench pits are water filled troughs with submerged chain driven mechanical conveyors powered by hydraulic motors. Provide double chamber troughs formed from a single piece of steel. Provide with abrasion resistant side wear liners and plate separators. Provide dewatering ramp and chute for disposal of ash into concrete bunker. Extend boiler seal plates directly into the water in the upper trough or provide transition hopper. Seal plate pinch point minimum clearance is 4 ft. (120 cm). Include roll out wheels to allow the entire system to move on rails to the side to allow boiler shutdown maintenance.

5-3.4.5 Combustion Air.

Use 100% excess air to burn municipal solid waste. Pull all combustion air from the refuse storage and reception building to minimize dust and odor. Provide primary combustion air beneath the grate with adjustable zoning. Inject secondary combustion air at high velocity above the grate through ports spaced equally around the grate's perimeter. Regulate primary and secondary combustion air flow against feed rate, type of waste temperature, and oxygen levels using computer controls.

Provide a minimum of one underfire fan with pre-heat, one overfire fan, one induced draft fan, and one secondary air fan for each boiler with air ducts. Provide 20% to 40% of total air as overfire air and 60% to 80% as under fire air to allow a total maximum air flow of 120%. Size fans for combustion air requirements and ambient conditions. Locate induced draft fan after APC equipment. Pre-heat under-fire air with steam heating coil located between the underfire fan and air plenums. Size coils for worst-case ambient conditions and provide freeze protection. Fit air duct systems with non-plugging type flow measuring device with a transmitter for remote read out and use in combustion rate control systems. Provide ducts with straight sections or flow straighteners upstream and downstream of the flow measuring device to assure the measuring device's accuracy.

5-3.4.6 Ash Load Out.

Discharge moist ash from ash quench pits by conveyor system and transport to the storage area using an ash conveying system. Design the complete ash conveying system to consist of both a primary and secondary conveyor to transport furnace bottom ash, grate siftings, fly ash and APC fly ash to a centralized location. Provide two (2) 100% capacity ash conveyors to remove bottom ash from the boilers and convey the bottom ash and fly ash to the ash load out area, for maximum combustion units' availability. Provide two (2) 100% capacity conveyors to transfer APC fly ash from the APC fly ash collection equipment to the storage area. Include provisions for combining the APC fly ash with bypassed bottom ash in the event that the metals recovery system is not operational. Design the ash conveying system for a minimum of 100 lb/ft^3 (1602 kg/m^3).

5-3.4.7 Interior Equipment.

Place interior equipment (the grizzly scalper, ferrous and non-ferrous metal separating equipment, and fly ash conditioning equipment) and support steel at grade elevation on six (6) in (15 cm) minimum concrete housekeeping pads. Design the structural steel above the ferrous recovery system for hoisting equipment as required for optimizing system performance and maintenance. Protect all exterior walls that come in contact with ash laden water, such as the area around the inclined ash conveyor entrance and walls adjacent to the ferrous recovery equipment, with fiberglass panels or other corrosion resistant materials. Provide translucent panels for lighting during daylight hours to minimize energy use.

5-3.4.8 Waste Material Storage.

Design the waste material storage building for processing and storing ash load out, ferrous and non-ferrous metals, and oversized materials. Include a grizzly scalper and the inclined conveyor in the footprint of this structure. Provide wheel wash system for ash and metal handling trucks prior to exiting the structure. Accommodate a minimum of five (5) days storage for processing, separating, and storage of non-ferrous and ferrous metals in the ash load out area. Protect all interior panels, purlins, grits, steel structures, and equipment against high pH ashes, high humidity, and a hot atmosphere. Apply a protective coating to structural components and non-metallic building siding. Enclose the area within a concrete structure with cladding to ensure dust suppression. Design the ash concrete bunker as a water retaining structure, with draining slopes at the bottom of the trench to a sump.

Route wastewater from the waste material storage building drains to a settling basin located immediately outside of the building. Include removable covers to prevent rainwater from entering the settling basin system. Position the sump such that water may drain from the ash bunkers into the sump by means of sleeves located at the building wall base. Gravity drain collected sump wastewater through a minimum of 24 in (61 cm) wide floor trenches fitted with removable diamond plating and route wastewater to the settling basin.

5-3.4.9 Material Recovery.

Design the ferrous recovery, associated conveying and storage area to achieve a throughput rate of 150% of projected recovery tonnage per day. Provide a ferrous recovery system with a minimum collection rate of 80% of magnetic ferrous materials within the ash waste over one (1) in (2.5 cm) in diameter including ferrous metal removed by the grizzly scalper. The ferrous metals recovery system is located at the discharge end of the quenched bottom ash conveyors in the Ash Load Out building. Provide a separate storage area for ferrous materials inside the Ash Load Out building. Provide roll-off containers or other suitable vehicle for transport for recovered ferrous material loaded the storage areas. Design the separation and recovery system with at least one magnet, one vibratory feeder screen, and necessary chute work and product distribution conveyors. Provide transfer conveyors as required to transport ferrous metals and remaining ash residue to separate storage bunkers or containers. Include ample space and access for maintenance of all system components. Design the system to minimize residual ash being carried with the recovered metal.

Design the non-ferrous recovery, associated conveying and storage area to achieve a throughput rate of 150% of projected recovery tonnage per day. Provide a non-ferrous recovery system with a minimum collection rate of 60% of non-ferrous materials greater than 5/8 in (1.6 cm). Recovery to occur upon completion of recovery of ferrous materials from the ash. Use eddy-current separators in order to minimize possible damage from errant ferrous material. Provide a separate storage areas for non-ferrous metal inside the Ash Load Out building. Recovered non-ferrous material is then loaded from its storage bunker into roll-off containers or other suitable vehicle for transport. Provide transfer conveyors as required to transport non-ferrous metals and remaining ash residue to separate storage bunkers or containers. Include ample space and access for maintenance of all system components.

5-3.4.10 Waste Heat Recovery / Steam Generation System.

Provide single drum, multiple pass water tube type with integral welded membrane waterwall cooled furnace, superheater and economizer steam generating equipment. Directly couple each boiler to its respective refuse combustion stoker.

Design each combustion train to be automatically controlled when in operation and control of each combustion train is independent of the others. Provide manual controls to select desired steam flow. Ensure control system maintains all process conditions within safe limits and that emissions, including NOx, $S0_2$, HCl, dioxin and furnace concentrations, are within specified limits of the environmental permits.

5-3.4.11 Heat Transfer Cleaning System.

Determine cleaning frequency by the fouling problem severity. Perform trade off analysis of cleaning process while the plant remains in operation (on-line cleaning) and for when plant is shut down the (off-line cleaning). Implement the best approach comparing operational, technical, and cost factors.

Steam soot blowers, mechanical rappers, or combination of methods may be utilized in conjunction with on-line water washing, if needed, to meet on-line operating requirements and downtime limitations as well as environmental guarantees. Space and arrange tubes to minimize erosion, slagging, and fouling and to promote effective cleaning of tube surfaces with soot blowers or a rapper system.

5-3.5 Flue Gas System.

5-3.5.1 Air Pollution and Control Equipment.

Use UFC 3-430-03 for identification of air pollution emission rates and selection of control equipment required to meet, local, State and Federal compliance levels.

5-3.5.2 Air Quality Control Requirements.

Ensure APC equipment has capability to meet U.S. EPA and State requirements for control of NOx, dioxin, mercury, acid gas, and particulate removal. Provide separate APC systems for each combustion train in the plan. Dump stacks that release any untreated flue gases are not allowed.

Select air pollution and control equipment by using EPA Best Available Control Technology (BACT) Analysis. BACT air pollution emissions are limited based upon the maximum degree of reduction for each type of regulated pollutant achievable through processes and systems available. BACT is determined by State permitting agencies on a case-by-case basis considering energy, environmental, economic, and other costs in its determination. BACT cannot be less stringent than the Federal New Source Performance Standards (NSPS), but it can be more. BACT requires that emissions of any pollutant not exceed the standards under 40 CFR Part 60 and 40 CFR Part 61.

5-3.5.3 NOx Control.

Use one of two the different methods for control of NOx used in North America: Selective Catalytic Reduction (SCR) or Selective Non-catalyst Reduction (SNCR). Perform operational trade off and life cycle cost analysis and determine the best approach to meet NOx control objectives.

5-3.5.4 Activated Carbon Injection (ACI) System – Mercury/ Volatile Organics Control.

ACI is currently designated as the BACT by the EPA to control the release of trace organics including dioxins, furans, and mercury into the atmosphere by adsorbing these chemicals onto its surface. Use powered activated carbon (PAC) injection. One ACI system will be provided for each boiler/furnace system. Include redundancy of spare blowers and feeders to assure reliable operation. Injection will be between the spray dryer and the baghouse.

For the ACI System, include the following:

- Storage silo for minimum seven (7) day storage;
- Feed hopper;
- Truck unloading station;
- Blowers to provide motive air for transporting PAC to the injection points;
- Feeder;
- Controls to include truck unloading control, radar level sensing, and bin vent filter pressure differential; and
- Personnel safety equipment.

5-3.5.5 Acid Gas Scrubber.

Provide acid gas scrubbers to control acid gas emissions of HCl, SO_2, and HF. There are numerous technologies for acid gas removal including wet scrubbing, semi-wet scrubbing, and dry scrubbing. Provide dedicated acid gas spray drying scrubber for each combustion train using spray drying method. Design the scrubber so that the flue gas exiting the spray dry scrubber is kept above the acid dew point temperature.

For the Acid Gas Scrubber system, include the following:

- Spray drying scrubber (also known as spray dryer adsorber) of lime slurry reagent to meet Subpart E. b. emission standards for SO_2 and HCl and the BACT Emission limit for sulfuric acid mist and fluorides;
- Truck unloading station;
- A minimum of two lime/hydrated lime storage silos;
- Two lime slurry preparation systems;
- Spray dryer absorber vessel, atomizers, product removal system, and support equipment;
- Instrumentation and controls; and
- Personnel safety equipment.

5-3.5.6 Fabric Filter System (Baghouse).

Provide fabric filter system. Use reverse air or pulse jet type cleaning baghouse with multi-compartments to facilitate cleaning and maintenance. Provide a filter bag leak detection system that is capable of continuously monitoring relative particulate emissions (dust) loadings in the baghouse exhaust in order to detect bag leaks and other upset conditions. Include hoppers to store collected ash discharged from the baghouse filters during the cleaning process. Provide instrumentation and controls for the baghouse to include air pressure monitoring, cleaning cycle control, hopper level alarms, hopper heater control, differential pressure measurement, fan motor current, and inlet gas temperature measurement.

Provide inspection access at the following points:

- Stack exit;
- Filter clean side;
- Bags, cages and bag attachments;
- Cleaning mechanisms and equipment;
- Stack pressure gauges;
- Solid discharge valves; and
- Hoppers.

5-3.5.7 Flue Stack.

Design and construct flue stack in accordance with ASCE/SEI 7 and NFPA 211. Base flue stack height upon pollutant dispersion analysis and FAA requirements. Design stack for all environmental and seismic conditions which it may be subjected.

Construct flues of steel with circular cross section. Provide an insulated, self-ventilating flue liner to limit heat loss of flue gas to not more than ten (10) ^{o}F (-12 ^{o}C) after exiting the NOx reduction system. Include access platforms, safety railings and ladders will be provided to access inspection, test and cleanout ports, obstruction lighting, and lightning protection system in accordance with Occupational Safety and Health Acto (OSHA) requirements. Provide obstruction marking and lighting for aviation safety in accordance with FAA AC 70/7460-1K.

5-3.6 Power Generation System.

Use condensing turbine-generators in a packaged configuration, complete with condenser, sized for steam. Rate boilers at the maximum combustion rate (MCR).

5-3.6.1 System Design.

Ensure the power generation system design includes the turbine, generator, oil system, hydraulic system, backup power, and operating controls.

5-3.6.2 Operating Conditions.

Ensure the turbine – generator operates over the broad range of combined heating plant system utility load and temperature requirements, if used.

5-3.6.3 Turbine.

Provide steam turbines that conform with ISO 14661 *g*eneral requirements. Where using cogeneration system that simultaneously supplies power, and heating or cooling, conform to ISO 26382:2010*.* Select the best steam turbine classification based upon economic analysis in accordance with DoD Instruction 7041.3. Use present value analysis and include the following cost elements:

- Capital costs; and
- Operating and maintenance costs (include equipment operating efficiencies).

Design turbine(s) as a complete package system mounted on bases for quick installation and alignment verification with steam extraction points at different pressures corresponding to different system temperatures based upon economic analysis. Design turbine to operate at a constant speed. Combine high pressure and intermediate pressure sections into a single casing to provide a compact system minimizing plant floor space. Low pressure section(s) are typically housed in a separate casing if not a single stage turbine. Provide DC backup power for critical lubrication systems.

5-3.6.4 Generator.

Provide a totally enclosed, air or hydrogen cooled, synchronous generator sized for continuous operation and directly connected to steam turbine. Use air cooling for generators up to 60 MW in capacity. Use hydrogen cooling for generators for over 60 MW in capacity. Provide on-site hydrogen generation system for hydrogen cooled generators.

Provide turning gear to thermally stabilize generators for a period of 24 hours or until the generator is cooled below 212 ^{o}F (100 ^{o}C), whichever is greater. The turning gear will start when the turbine speed drops to 100 rpm, then engage and rotate the turbine at a speed of 30 rpm to ensure an oil film is maintained in the journal bearings and to create turbulence in the cylinder to cool the cylinder and shaft uniformly.

5-3.7 Steam Condenser System.

5-3.7.1 Steam Dump.

Provide a steam dump capable of handling the following events: 1) turbine over-current protection device trip; 2) turbine failure; 3) continued furnace solid waste process at MCR regardless of turbine outage; or 4) other system failure. The steam dump will release steam until the plant can achieve an orderly shutdown or turbine operation can be restored.

5-3.7.2 Cooling Tower.

Design the condenser cooling tower in accordance with the weather data requirements of UFC 3-400-02 and NFPA 214. Size cooling towers to meet the turbine condenser(s) and other plant cooling loads requirements. Account for prevailing winds, proximity to existing or proposed transmission lines and facilities, and the boiler stack when siting cooling towers.

Provide cooling towers with fiberglass or concrete frame and film filled as appropriate for maximum wind conditions. Partition tower cells such that each cell can be operated independently of remaining cells. Conduct an on-site thermal performance test in accordance with the CTI ATC-105 standards to ensure installed tower(s) meet thermal performance requirements. Use high efficiency fill and drift eliminators. Size cooling towers to have a minimum 10 ^{o}F design approach between the cooling water outlet and the ambient wet bulb temperature at the design wet bulb temperature.

5-3.7.3 Circulating Pumps.

Provide separate primary and alternate circulating pumps for the turbine condenser(s) and separate primary and alternate water pumps for the other plant cooling loads.

5-3.7.4 Chemical Feed System.

Provide complete chemical feed system for cooling system circulating water to protect against corrosion and bio-growth.

5-3.7.5 Air Removal Equipment.

Provide air removal equipment for each condenser.

5-3.7.6 Surface Condenser.

Design condenser in accordance with Heat Exchange Institute (HEI) allowable stresses for tubes per ASME, and bypass headers in accordance with EPRI standards and codes. Provide a surface condenser with shell and tube exchanger. Equip the condenser with a minimum of two tube passes and divided water box. Provide an ejector assembly, atmospheric relief valve, and limit the inlet velocity to header to 200 to 300 feet per second (fps) (60 – 90 m/s). Extend the bypass headers are to extend along the entire tubes length and equip with the smallest diameter orifice. Provide impingement protection for tubes to also include dummy tubes.

5-3.7.7 Dump or Bypass Condenser.

Provide a dump or bypass condenser and use in conjunction with the surface condenser during periods of startup, shutdown, and turbine generator unavailability.

5-3.7.8 Condenser Hotwells.

Size the hotwell to contain all condensate produced in the condenser in a period of one minute under conditions of design load in accordance with HEI Standards for Steam Surface Condensers. Employ hotwell level controls with three level transmitters to maintain a normal level in the condenser hotwell. Controls will be dual redundant.

5-3.7.9 Blowdown Control and Treatment.

Provide automatic modulating blowdown control to maintain dissolved solids in accordance with recommended practices of ASME Consensus on Operating Practices for the Control of Feedwater and Boiler Water Quality in Modern Industrial Boilers. If economically justified, employ a boiler blowdown heat recovery system using a flash tank and heat exchanger.

5-3.7.10 Boiler Feed Pumps.

Provide one boiler feed pump per boiler. Size the pump for 125% of boiler steam capacity.

5-3.7.11 Feedwater Control System.

Provide a minimum of two (2) high pressure boiler feedwater pumps providing 200% of total design. Design the feedwater system to achieve the maximum flexibility for operations ranging from 33% MCR to peak facility operation. Utilize a boiler feed pump system driven by an electric motor, steam turbine drive, or combination of the two with an option for variable speed drive for the electric motor. The feedwater pump arrangement must be capable of providing the feedwater flow required for full capacity plant operation as well as providing partial flow to individual boilers if one or more boilers are shut down. The design must assure adequate NPSH is available to the boiler feed pumps during transient load conditions, including turbine trip at full load.

Rate pumps capacities to meet ASME code when pressure relief valves are open on high drum pressure.

Provide a three-element feedwater control system to include at a minimum: drum level transmitter, steam flow transmitter, feedwater flow transmitter, drum level controller, manual/automatic control station, feedwater control valve, steam flow element and feedwater flow element.

5-3.7.12 Condensate Pumps and Circulating Pumps.

Provide two motor driven, variable speed condensate pumps per boiler. Size each pump for 125% of boiler steam capacity. Provide bypass orifice at each pump.

Provide a minimum of two (2) circulating water pumps for condensing heat exchanger arrangement, each with a capacity equal to either unit MCR or facility MCR, as appropriate.

5-3.7.13 Miscellaneous Pumps.

Provide miscellaneous pumps and accessories as required by the final facility design. Provide 100% redundancy for all pumps. Include motors, couplings, coupling guards and baseplates for all pumps as applicable. Provide all special tools required for maintenance and installation of applicable pumps. Pump capacities to include a minimum of 10% margin, and a 20% margin for head, for all pumps, based on the final piping arrangement. Design pumps, as a minimum, in accordance with the manufacturer's standard for the service intended.

Perform a failure mode and effects analysis for the various pump categories as required. Additionally, provide a hierarchy according to which pump functions are grouped based on critical safety needs. Provide this during the design review. The results of this analysis shall indicate which functions require redundant pumps, priority circuitry, and back-up power supplies.

5-3.8 Water Supply, Makeup and Treatment.

5-3.8.1 Design.

Design domestic water supply, and makeup and treatment systems in accordance with UFC 3-401-01 and UFC 3-420-01*.*

5-3.8.2 Domestic Water Supply.

Obtain all facility domestic water (potable water) by connecting to the local utility supplier or through an on-site water well that is permitted, designed, and installed in accordance with local, State and Federal requirements. Provide all piping, valves, chambers, meters, and services to connect to the designated water supply source at the interface point. Treat water in accordance with UFC 3-230-02.

5-3.8.3 Water Treatment Equipment.

Provide a permanent water treatment system designed for continuous use. Design the water treatment system for automatic operation with minimal operator intervention. Include the option of providing a Reverse Osmosis (RO) unit, chemical-based treatment system, or combination of the two. The chemical-based treatment system is to include a dual-train demineralizer of the anion-cation type complete with regeneration equipment, piping, valves, and controls for treatment of public supply potable water, and industrial supply well water. Provide water treatment equipment to fulfill the following functions: boiler makeup water treatment; chemical feed systems; sampling systems; and, treated water storage.

Provide potable water for sanitary uses as required by applicable laws. Supply water for other facility needs from the following sources in the priority listed below:

- Blowdown from cooling towers (use for quench water for the bottom ash and dilution water for the scrubbers at a minimum);
- Harvested stormwater (as available);
- Industrial supply water (as available);
- De-chlorinated potable water; and
- Potable water (for selected process uses). Minimize to the greatest extent possible the need for potable water for non-sanitary usage.

5-3.8.4 Storage.

Store all harvested stormwater, industrial supply water, de-chlorinated potable water, and potable water in the facility recycle and reuse tank. Store cooling tower blowdown water in the facility’s wastewater tank prior to use at the facility.

5-3.8.5 Water Meters.

Install water meters to track water consumption (instantaneous and total) from all sources. Use electronic meters and track using the plant distributed control system. Comply with the local utility company’s metering requirements as well as the OUSD (AT&L) Utilities Metering Policy as detailed in the following website: (http://www.acq.osd.mil/eie/IE/FEP_Policy_Program_Guidance.html) and DoDI 4170-11 Installation Energy Management.

5-3.8.6 Treatment.

Provide water treatment for boiler make-up water, cooling tower make-up water, and auxiliary cooling water. Treat water to equipment system manufacturer's requirements.

5-3.8.7 Water Storage Tanks.

At a minimum, provide a condensate storage tank, demineralized water storage tank, auxiliary cooling water head tank (if applicable), flue gas condensate tank (if applicable), raw water storage tank (if applicable), firefighting water storage tank, wastewater storage tank, and any other miscellaneous tanks necessary to the design must be provided.

5-3.8.8 Centralized Chemical Sampling System.

Provide a centralized chemical sampling station in order to provide information on chemical conditions in the feed, condensate, steam, and cooling tower systems. Continuously draw samples from defined points and analyze automatically.

Design so that each analyzers is capable of an indication at the local sample panel and in the control room. An indication of chemical conditions that are out of the acceptable range must be communicated via an annunciator in the control room. Design the local sample panel to accommodate the taking of grab samples.

5-3.8.9 De-mineralized Water System.

Provide two (2) full capacity skid-mounted operational demineralizers. Each demineralization must be capable of producing the required quantity and quality of make-up water for the facility feedwater-condensate water system.

Design the demineralizer system for push-button automatic operation. The demineralized water is to conform to the boiler and turbine manufacturer's requirements. In addition to boiler makeup, this system is required to provide makeup as necessary to other plant systems. Utilization of a RO system followed by electro deionization to provide boiler make-up water is acceptable.

5-3.8.10 Water Storage Tank (Fire).

Design and install the fire water storage tank and site main systems. Size the fire pump, water supply, and fire water storage tank systems to supply the minimum fire flow required by code.

5-3.8.11 Auxiliary Cooling Water System.

Design an auxiliary cooling tower capable of operation at full capacity with one closed cooling water pump to dissipate heat. Include sufficient cooling capacity to accommodate loads identified in the final design. Provide a chemical feed system.

5-3.9 Residue Hauling and Storage System.

Provide a complete furnished and installed residue conveying system for each boiler/furnace/steam generating unit. Provide a common conveyor system, consisting of primary and secondary conveyors, to transport residue from each unit to the ash management building. Provide an adequate means of redundancy that would prevent the shutdown of more than one boiler/furnace/steam generating unit if a system component must be taken out of service. The system proposed must be amenable to separate collection of APC residue (fly ash and spent salts of reaction) and bottom ash without requiring building modification.

5-3.9.1 Design Criteria.

Design the ash system for the quantity resulting from waste processing at the Contractor-specified ash density but no less than 100 lb/ft^3 (1602 kg/m^3) density with suitable margin for upset and peak conditions. Use a reasonable ash design density for volumetric sizing and conveyor and structural sizing. Design the system to start under fully loaded conditions assuming a two-hour interruption in the ash handling system.

Provide the quantity and compositions of residue ash expected to be produced at the facility from the furnace/boiler and APC systems and ensure that this residue ash is not considered hazardous based on applicable laws.

5-3.9.2 Bottom Ash Conveyors.

Provide two 100% capacity ash conveyors to remove the bottom ash from the boilers and convey the bottom ash and fly ash to the ash management building. Provide a grizzly scalper on each bottom ash conveyor as well as any other redundancy measures deemed necessary to keep the boilers in operation if an ash system component is taken out of service.

5-3.9.3 Fly Ash Conveyors.

Under normal operating conditions, the APC fly ash is combined with the bottom ash in the ash management building following the metals recovery system. Provide two 100% capacity conveyors to transfer the APC fly ash from the APC fly ash collection equipment to the ash management building. Include provisions for combining the APC fly ash with bypassed bottom ash if the metals recovery system is not operational.

5-3.9.4 Metal Recovery Conveyors and Storage.

Design ferrous and non-ferrous recovery and associated conveying and storage facilities to accommodate the waste throughput design rate.

5-3.9.5 Wet Residue Removal System.

Discharge residue from the grates, boiler and economizer hoppers, and siftings from under the grates for each unit into a pusher type residue discharger. Design equipment to be capable of using wastewater from the other facility operations. Provide the pusher type residue dischargers with a quench tank equipped with a hydraulically operated residue pusher. Discharge residue from the residue pushers directly into the residue pit or onto a series of conveyors and convey the residue to a residue building. Design all system components with housekeeping and safety in mind.

5-3.9.6 Residue Storage.

Include concrete, drainable pits in residue storage facility for placing residue containers or trucks during loading operations. Residue containers must be enclosed, watertight and dust-proof so as not to present a hazard to either plant personnel or the general public while residue is being loaded and transported to the landfill. Fully enclose the loading station. In general, design all residue loading and unloading systems to be dust free and designed to meet the general requirements for residue loadout established by U.S. EPA. In particular, no visible emissions of dust from any doorway, window, vent, louver, or other opening is allowed.

5-3.9.7 Residue Pit.

Design the residue pit for a minimum of five days' usable storage of residue for a 1,500 tons (1400 metric tons) per day (tpd) facility. Completely enclosed residue pit and all conveyors external to buildings with a filtered ventilation system. Do not connect the residue pit to any other structures in such a fashion as to enable dust to infiltrate to other plant parts.

5-3.9.8 Truck Loading Station.

Design the truck loading station with a 1.0% slope from the truck loading zone to the ash storage bunkers. Install four (4) ft. (122 cm) wide by four (4) in (10 cm) high speed bumps at the entrance and exit ramps. Supply the entrance and exit ramps bases with a trench drain, draining back to the building sumps, to capture any potential ash or water spillage. Place bollards on both the inside and outside of all truck door openings. Provide a reinforced push wall surrounding the bunker areas and extending to the truck entrance and exit doors with a minimum height of 14 ft. (4.2 m). Line the inside building perimeter, excluding the bunker areas, with a reinforced concrete wall at a minimum of two (2) ft. (61 cm) high by one (1) ft. (30.5 cm) thick.

5-3.9.9 Fly Ash Collection System.

Design the APC fly ash collection system to collect APC fly ash from the scrubber and baghouse, which may include spent lime reagent, carbon reagent, and collected salts. Provide two, 100% capacity, conveyors to transfer the APC fly ash from the APC fly ash collection equipment to the ash management building. Combine APC fly ash with bottom ash only after the bottom ash has passed through the metals recovery system. The fly ash handling system is not limited to screw conveyors, but must be a commercially proven design.

Collect APC fly ash from each APC system hopper with drag or screw conveyors. Convey fly ash to the residue pit, conveyor, or residue building after the point of ferrous metal recovery from bottom ash and then to a residue conditioner for disposal. Semi-dry reactors may incorporate air slides for conveying APC fly ash from the baghouse to the scrubber for fly ash reuse purposes. Utilize screw conveyors or drag conveyors for conveying APC fly ash to the APC fly ash conditioning system. Provide a completely dust-tight APC fly ash drag or screw conveyor area to prevent leakage of APC fly ash.

5-3.9.10 Ventilation System.

Include exhaust hoods at transfer points connecting to a central dust control system for all ash handling equipment within the ash management building. Connect this central dust control system to a wet scrubber or baghouse. Design the ash management building with a separate ventilation system designed to permit a minimum of two air changes per hour. Comply with current ASHRAE HVAC Applications Handbook ventilations standards.

5-3.9.11 Instruments and Controls.

Design the residue handling systems to be fully automatic between the furnace and the residue storage pit or residue building. Provide sensors with alarms for readout and recorded on the Distributed Control System (DCS) in the central control room for any system failure.

5-3.10 Control and Instrumentation.

5-3.10.1 Central Plant Controls.

Provide a central plant DCS with redundant processors and local area network with automatic switchover to enhance reliability of the control system. Plant controls are to be operated from the central plant control room, and include boiler, turbine, feedwater and condensate system, condensing system and water treatment system controls. Provide management control stations at strategic points in the plan for maintenance and redundant control requirements. Provide automated subsystems for the following:

- Each boiler train for steam production and air pollution control;
- Turbine and thermal cycle;
- Electrical substation;
- Emergency shut down; and
- Balance of plant controls.

Integrate asset management and maintenance activities into the central plant control. Asset management functions are to interoperate with the control system to plan maintenance operations. Use information from the plant instrumentation to perform statistic predictive maintenance. The following systems are to be handled locally or are automated systems.

5-3.10.1.1 Waste Handling Crane.

Crane control is maintained at a stationary operating station also called the crane pulpit. Provide voice communication between the control room and the crane pulpit. Provide video feeds covering the waste storage pit to the control room.

5-3.10.1.2 Residue Handling System.

Design the residue handling system between the furnace and the residue storage pit to be automatic. Design other residue handling systems for locally manual control. Operating status of all conveyors must be indicated in the control room. Install video feeds of all conveyor paths to the control room.

5-3.10.1.3 Waste water discharge

Design for local control.

5-3.10.1.4 Chemical addition systems

Design for automatic and locally controlled.

5-3.10.2 Control Room.

Provide a central plant control room and include DCS operator stations, DCS engineering station, and asset management station. Provide inter-facility start-up from the control room, with select systems started locally as detailed in previous sections. Ensure operators are able to supersede the automatic controls and operate the facility manually from the control room. Back up normal plant control systems and procedures by separate interlocks or safety systems designed to effect action in cases of emergency.

5-3.10.3 Control Pneumatics.

Provide separate controls for plant air and instrumentation air. Design air compressor system to provide plant air and instrument air for the facility. Equip plant air piping system with automated shutoff valves to non-essential headers in the event of a loss of primary compressed air. Install air dryers with the capability of being bypassed for maintenance without shutting down both compressors and associated accessories.

Provide redundant full capacity air compressors with aftercoolers. Provide separate stand-by redundant compressors sized for critical equipment operation. Compressors and compressor motors must be provided with manufacturer's standard offering control system which must load and unload the compressors during operation. Compressor operation must alternate between the two (2) compressors during normal operation. If one air compressor trips, the control system will automatically place the stand-by compressor in operation without low air pressure trip. Cover all couplings and drives with metal guards.

5-3.11 Fire Protection.

Design and construct the fire protection systems in accordance with UFC 3-600-01, and NFPA 101 and 850 as modified by UFC 3-600-01. Design and construct systems to prevent and control explosions in accordance with NFPA 69 at the tipping floor, waste storage pit, and material storage silos created by flammable concentrations of gases, vapors or dusts created by waste processes or hazardous waste not removed during the waste processing.

5-3.11.1 Fire Fighting Control Room.

Provide a self-contained firefighting control room adjacent to the plant control room. Locate the master fire alarm control panel, parallel displays of the plant closed circuit television (CCTV) system, and fire fighter telephone master console system, elevator status panels, and fan override controls in the control room.

5-3.11.2 Fire Fighter Telephone System.

Provide a fire fighter telephone system in the plant where fire fighter radios will not operate to enable two-way communications and in key areas as directed by the local fire authority having jurisdiction (AHJ). Use a common communication talk line system.

5-3.11.3 Interior Sprinkler System.

Provide all interior areas with sprinkler systems.

5-3.11.4 Exterior Sprinkler System.

Provide dry sprinkler system at all exterior areas with process equipment. Provide fire sprinkler system at cooling towers unless cooling towers are non-combustible.

5-3.11.5 Monitor Nozzles.

In addition to a dry pipe sprinkler system located over the pit and charging hopper parapet, provide local and remote operation of high capacity monitor nozzles. Locate monitor nozzles to facilitate ease of access by, and provide safe distance, for firefighting personnel. Space monitor nozzles to provide 100% coverage of the tipping and pit floors, and arrange to avoid inadvertent impact by the crane grapple. Protect monitor nozzle piping systems exposed to freezing temperatures from freezing.

5-3.11.6 Fire Fighting Water Storage.

Design the fire pump system to pressurize the fire water site main and take suction from the fire water storage tank. Size the fire pump, water supply, and fire water storage tank systems to provide fire water protection requirements for a 3-hour duration, or more. Arrange for the installation of at least two (2) fire water pumps unless a risk analysis eliminates the need for redundancy. Consider pump failure modes, electrical system failure modes, fire and explosion spread potential, life safety risk to fire fighters and plant personnel, environmental impact, pump maintenance requirements and local fire authority having jurisdiction requirements in the analysis. Where redundant pumps are used, one of the pumps must be isolated in a fireproof enclosure. Wire the redundant pump for a priority power from an emergency diesel generator or drive pump with a diesel engine.

5-3.11.7 Fire Alarm and Signaling Systems.

Provide fire alarm and Mass Notification Systems (MNS). Fire alarm systems must conform to NFPA 72 and UFC 3-600-01. MNS are to comply with UFC 4-021-01.

5-3.11.8 Smoke Relief Hatches.

Large emergency smoke relief hatches (solenoid release operated) are to be provided in the roof above the parapet-pit area.

5-3.11.9 Deflagration Venting.

Conduct a hazard analysis and provide deflagration venting systems in accordance with NFPA 68.

5-3.12 Water Pollution and Control Equipment.

5-3.12.1 Water Pollution Control Requirements.

Stormwater drainage and collection for all site areas to comply with all State requirements including all appropriate notifications and filings. Collect stormwater inside the site area discharged to a predetermined location. Utilize gasketed stormwater piping in areas subject to plant operations contamination and route to the facility wastewater treatment plant.

5-3.12.2 Process Waste Water Pollution Control Requirements.

Provide an onsite wastewater collection and treatment system to meet the wastewater discharge quality limit for the facility, including treatment of all process wastes, spent chemicals, backwash and rinse waters. Design facility wastewater system to maximize water reuse and reduce discharges to a minimum.

5-3.13 Heating Ventilation and Air Conditioning (HVAC) Systems.

Provide heating, ventilation, and air conditioning to remove dust, remove radiated process heat, control odor, minimize condensation, and provide a safe and comfortable working environment. Keep normally occupied areas such as the offices, control room, and crane operator control room at positive air pressure in relation to plant machinery and solid waste operation areas. Design and construct facility HVAC systems in accordance with UFC 3-401-01, UFC 3-410-01, UFC 3-410-04N (for Navy), and ACGIH Industrial Ventilation: A Manual of Recommended Practice, as appropriate for the facility area classifications.

Provide HVAC systems as indicated in the following sections. Where air conditioning is not provided, calculate ventilation rates for heat removal in summer conditions not to exceed 104 ^{o}F (40 ^{o}C) where practical. When 104 ^{o}F (40 ^{o}C) is exceeded, ensure all equipment upper operating temperatures are considered in the design. Limit forced air ventilation to not to exceed 60 air changes per hour. Preheat outside ventilation air to prevent freezing of piping and plant equipment as appropriate.

5-3.13.1 Refuse Receiving and Storage Building.

Design the refuse receiving and storage building ventilation to provide a minimum of 12 air changes per hour. Provide filters and scrubbers on exhaust air.

5-3.13.2 Boiler Building.

Design the boiler building for operating temperature between 45-55 ^{o}F (7-13 ^{o}C) heating only and ventilation of a minimum of 30 air changes per hour below the burners and 15 air changes per hour above the burners. Provide multiple units. Source air through the refuse pit. Provide filters and scrubbers on exhaust air.

5-3.13.3 Control Room.

Design the control room for operating temperature between 72-76 ^{o}F (22-24 ^{o}C) cooling and 68-72 ^{o}F (20-22 ^{o}C) heating with relative humidity between 30 to 50%. Ventilation is to be per ASHRAE 62.1. Noise Criteria (NC) not to exceed 40. Provide two independent units for 100% redundancy. Control room air pressure to be positive to remainder of facility with filtration efficiency of 90% and ultraviolent (UV) sterilized.

5-3.13.4 Server Room.

Design the server room for operating temperature between 68-72 ^{o}F (20-22 ^{o}C) and relative humidity between 30 to 50%.

5-3.13.5 Crane Operator Control Room.

Design the crane operator control room for operating temperature between 72-78 ^{o}F (22-25 ^{o}C) cooling and 68-72 ^{o}F (20-22 ^{o}C) heating with relative humidity between 30 to 50%. Ventilation to be per ASHRAE 62.1. NC not to exceed 40. Provide two independent units for 100% redundancy. Control room air pressure to be positive to remainder of facility with filtration efficiency of 90% and UV sterilized. Provide a system with energy recovery units on exhaust air.

5-3.13.6 Steam Turbine Area.

Design the turbine area for operating temperature between 45-55 ^{o}F (7-13 ^{o}C) heating only and ventilation of a minimum of 10 air changes per hour.

5-3.13.7 Administrative Offices.

Design the administrative offices for operating temperature between 74-78 ^{o}F (23-25 ^{o}C) cooling and 68-72 ^{o}F (20-22 ^{o}C) heating with relative humidity between 30 to 50%. Where administrative offices are included in the main plant facility, the air pressure is to be positive to remainder of facility with filtration efficiency of 90% and UV sterilized. Provide energy recovery units on exhaust air.

5-3.13.8 Air Pollution Control Building.

Design the area for operating temperature between 45-55 ^{o}F (7-13 ^{o}C) heating only and ventilation of a minimum of 5 air changes per hour. Provide filters and scrubbers on exhaust air.

5-3.13.9 Ash Conveying Areas.

Design building for operating temperature between 45-55 ^{o}F (7-13 ^{o}C) heating only and ventilation of a minimum of five (5) air changes per hour but not less than that required to prevent explosive dust accumulation. Provide filters and scrubbers on exhaust air.

5-3.13.10 Residue Management Building.

Design the building for processing and storing ash, ferrous and non-ferrous metals, and oversized materials. Size the Residue Management Building for five days storage for processing, separating, and storage of non-ferrous and ferrous metals; and four days storage of ash. Determine the Residue Management Building dimensions based on operating and space requirements.

5-3.14 Plumbing Systems.

Design plumbing systems in accordance with UFC 3-420-01.

5-3.15 Electrical Systems.

Design plant electrical system as a unit type system with the utility transformers connected solidly to the generator bus and switched with the generator. Design electrical systems in accordance with UFC 3-501-01.

5-3.15.1 Utility Interconnect.

Refer to Chapter 8 titled “UTILITY INTERCONNECTION” for guidance.

5-3.15.2 Synchronizing Switchgear.

Provide a substation on the facility site of a modern, fenced, low-profile design, complete with bus duct connection between generator switchgear and facility step-up transformer. Protect all the electrical equipment from electrical fault damage by protective relays. Design substation to operate over the range from import of full station auxiliary power requirement to export of full net plant real and reactive power capability to the transmission system while maintaining standard operating voltage limits on the facility buses.

5-3.15.3 Electrical Power Distribution System.

Provide a complete electrical system of medium-voltage, low-voltage, and DC power to all loads in the power plant under all service conditions including start-up, operation, failures, and shutdown. Plant medium and low voltage distribution system are to be grounded wye. Provide parallel medium voltage to low voltage unit substations for redundancy. Plant critical loads include the following:

- Fire pumps;
- Fire jockey pumps;
- Uninterruptable Power Supply(ies) (UPS);
- DC power system and battery chargers;
- Cooling water pumps;
- Hydraulic pumps;
- Critical lubrication systems;
- Elevators;
- Security systems;
- Distributed control system;
- Control and server room HVAC systems;
- Motor control center and switchgear HVAC systems;
- Critical instrumentation;
- Telecommunication systems;
- Aviation obstruction lighting;
- Perimeter security lighting; and
- Emergency and exit lighting.

Design the system with the following criteria:

5-3.15.3.1 DC System.

Provide a DC system, with UPS, for the plant DCS to provide for an orderly facility shutdown in the event of a loss of normal power. The DC power is to conform to the requirements of UFC 3-520-05.

5-3.15.3.2 Emergency Power System.

Provide an emergency power system for operating the plant critical loads in the event of a loss of normal power.

5-3.15.3.2.1 Uninterrupted Power System

Provide a UPS for the following critical loads: fire alarm system and MNS; telecommunications system; security systems; plant DCS; and critical instrumentation.

5-3.15.3.2.2 Generator

Provide natural or diesel gas generator(s) if natural gas is not available, sized to handle the plant critical loads and an N+1 redundancy. If using diesel gas generator(s), provide a minimum fuel storage for operating at full emergency power for five (5) days.

5-3.15.4 Lighting.

Conform to UFC 3-530-01 and National Electrical Contractors Association (NECA)/IESNA 502-2006.

5-3.15.5 Grounding/Lightning Protection System.

Conform to the following: IEEE C2, IEEE 142, NFPA 70, NFPA 780, and UFC 3-575-01.

5-3.15.6 Communications and Signal Systems.

Conform to UFC 3-580-01.

5-3.16 Project Planning Considerations.

Appendix D provides listing of factors to consider during the design. Tailor as appropriate for project scope.

5-4 OPERATION AND MAINTENANCE.

5-4.1 Non-Performance.

Ensure non-performance and remedy clauses are included in the maintenance contract to address contractor non-conformance. Ensure liquidated damages address loss of power generation revenue and mission impacts.

5-4.2 Warranties.

Specific component warranties will vary with manufacturer. Arrange for a five (5) year extended warranty period after date of project acceptance for the following major equipment and sub-systems: scales, cranes, steam generating systems, APC systems, DCS system, CEM systems, turbine-generators, condensers, cooling towers, and feedwater-cooling tower pumps. Warranties are typically limited to repair or replace, at manufacturers' discretion, the defective components, or assemblies. Warranty limits may include causes for materials, supplies, and equipment not manufactured or supplied by the manufacturer, unauthorized repairs or modifications, Acts of God, and incidental or consequential damages.

5-4.3 Power Plant Operation.

Design plant so that each boiler/generator unit may be operated independently, and a single failure of mechanical equipment common to all boiler / generator units will not trip any operating boiler/generator unit.

The plant and each boiler/generator unit is to be fully dispatchable with automatic generation control (AGC) and capable of being dispatched from minimum to full load. The facility and each Unit will also be capable of cycling operation. The balance-of-plant design will not limit operation over the full range of site ambient conditions.

5-4.4 Maintenance Requirements.

Provide for and equip maintenance facilities with required tools and repair plant equipment. Organize the maintenance facility that is organized into defined work spaces. Provide hoists/monorails as required for the shop. Size maintenance area doors to accommodate expected maintained equipment sizes. Work spaces to include, at a minimum, a machine shop, hot work area, vehicle maintenance and storage garage, and painting work area with ventilation. Maintain critical spares as necessary to meet mission reliability/availability requirements.

5-4.5 Safety.

Comply to applicable provisions in 29 CFR 1910 and 29 CFR 1925, American Conference of Governmental Industrial Hygienists Threshold Limit Values and Biological Exposure Indices, and local/agency codes and requirements.

CHAPTER 6 DESIGN CRITERIA – LANDFILL GAS RECOVERY POWER PLANT

6-1 INTRODUCTION.

This chapter presents the planning, design, O&M requirements, and equipment calibration for renewable energy produced by landfill gas collection and processing systems.

6-1.1 Technology.

Use technology that utilizes waste gas (from landfills) to energy technology of low-grade, medium-grade, and high-grade landfill gas. Use resources and references specifically for a medium-grade landfill gas system.

6-1.2 Landfill Gas (LFG) To Energy.

Refer to USEPA for various applications for LFG to energy (http://www.epa.gov/lmop). USACE EM 200-1-22, as amended by Agency guidance, provides information on systems design to monitor, collect, transport, and treat LFG from landfills.

6-1.2.1 Land Fill Gas Overview.

Employ systems and technologies associated with analyzing, extraction, collection, processing, and treatment of LFG, produced by decomposing organic waste, and then converted into a useable energy source. Provide the aforementioned systems to have the capability to simultaneously lower the quantity of greenhouse gas emissions released into the atmosphere and nuisance odors.

6-1.2.2 Landfill Gas Systems Types.

Passive Collection Systems: Utilize passive collection systems for control of migrating gases through the use of vertical and horizontal wells, liners, vents with all applicable appurtenances.

Active Collection Systems: Utilize active collection systems for the collection of LFG by mechanical means to create a vacuum to influence the gases to a desired location through the use of blowers or vacuums, vertical and horizontal wells, vents, valve systems, controls and analyzers, and with all applicable appurtenances.

6-1.2.3 Landfill Gas Grades.

Determine landfill gas quality grade to produce based upon end use specifications.

6-1.2.3.1 Low-Grade.

Low-grade LFG requires only minimal processing to remove moisture and particulates and produces a low-grade fuel that may be adequate for the facility operational requirements.

6-1.2.3.2 Medium-Grade.

Providing medium-grade LFG requires increased level of processing to remove moisture, volatile organic compounds (VOC), siloxanes, and sulphur compounds. Medium-grade LFG is used for most heating applications and electricity generation.

6-1.2.3.3 High-Grade.

Processing LFG to a high-grade quality requires removing moisture, particulates, VOCs, sulphur compounds, siloxanes, halogenated compounds, carbon dioxide, nitrogen, and oxygen. Process LFG to high-grade when pipeline quality is desired.

6-2 PLANNING.

Perform proposed and final siting coordination with OSD. 32 CFR Part 211 requires DoD to conduct mission compatibility evaluation of proposed site and project. Early project awareness and coordination with OSD is mandatory. Request a preliminary siting determination from the OSD Clearing House at osd.dod-siting-clearinghouse@mail.mil to avoid invalid site selections.

6-2.1 Waste Type and Quality Site Assessment.

Overestimating available LFG resources is a common project pitfall. Perform site due diligence and conservatively estimate recoverable methane quantities and quality by using up to date computer simulation software.

6-2.1.1 Composition.

Confirm that landfill composition has sufficient organic material, such as yard waste, food waste and sewage waste, suitable for bacterial growth, and avoid hazardous wastes.

6-2.1.2 Moisture Content.

Evaluate the landfill moisture content because the moisture content is a major factor of methane generation. Provide important data such as weather conditions, initial waste moisture, liner design, leachate collection systems, and cover types. The optimum moisture content should be in the 50% to 60% range.

6-2.1.3 Temperature.

Analyze landfill temperature. Evaluate the landfill depth to predict temperature fluctuations in the landfill since deep landfills provide more stable temperatures whereas shallow landfills are affected by surface weather conditions causing greater fluctuations in temperature. Optimum temperature for aerobic decomposition is 130 ^{o}F to 160 ^{o}F (54-71 ^{o}C) and for anaerobic decomposition are 85 ^{o}F to 105 ^{o}F (29-40 ^{o}C).

6-2.1.4 pH.

Analyze the landfill pH as methane generation is maximized when the landfill pH is neutral. The pH is generally in the range of 6.5 to 8.0 during methane generation. Leachate pH range is expected between 5.0 and 9.0.

6-2.1.5 Waste Density and Particle Size.

Confirm the waste density, which is a factor of waste size and compaction techniques.

6-2.1.6 Waste Age.

Confirm the landfill age, since landfill gas generation is typically significant for 10-20 years. Landfills with an age greater than 20 years are less likely to produce large quantities of landfill gas.

6-2.1.7 Moisture Access.

Evaluate means of access for water entry into the landfill in order to calculate and predict moisture levels within the waste.

6-2.2 Landfill Gas Generation Modeling.

Scholl Canyon and EPA-600/R-05/047 LandGEM models are the preferred models for use by the U.S. EPA and USACE respectively. Use the Scholl Canyon Model (First Order Decay) to determine the amount of methane produced by calculating the amount of waste disposed each year and the amount time after the landfill is closed, which are the primary variables required. Use the LandGEM Model which modifies the Scholl Canyon Model by dividing the waste by a factor of 10.

Perform a pump test for landfill sites with a large potential of LFG quantities and recovery. The tests should consist of installing extraction wells, blowers, and monitoring probes to collect and analyze the gas composition. The test results must include LFG flow measurements, landfill pressures, and the final calculated LFG production rate.

6-2.3 Landfill Gas Quality.

The preferred LFG composition consists of 40-60% methane (CH_4) and the remainder mostly comprised of carbon dioxide (CO_2). Evaluate and design system based upon LFG quality and quantity. Adhere to the following quality criteria in the analysis:

6-2.3.1 Saturation Water (Water Vapor).

The preferred quantity of saturation water vapor within the LFG is 4-7% by LFG volume created.

6-2.3.2 Sulfur Compounds.

Process and filter LFG to keep sulfur compounds within acceptable limits set forth by the monitoring equipment's manufacturer's recommendations.

6-2.3.3 Siloxanes.

Process and filter LFG to keep siloxanes within acceptable limits set forth by the equipment manufacturer's recommendations.

6-2.3.4 Halogenated Compounds.

Process and filter LFG to keep halogenated compounds within acceptable limits set forth by the equipment manufacturer's recommendations.

6-2.3.5 Volatile Organic Compounds (VOCs).

Process and filter LFG to keep VOCs within acceptable limits set forth by the equipment manufacturer's recommendations.

6-2.4 Environmental Regulations and Restrictions.

6-2.4.1 Resource Conservation and Recovery Act (RCRA) Requirements.

Comply with RCRA requirements if LFG is emitted or if condensate is treated and disposed. Comply with:

- 40 CFR Part 258;
- 40 CFR Part 260;
- 40 CFR Part 261;
- 40 CFR Part 262; and
- 40 CFR Part 268.

6-2.4.2 Air Quality Regulations.

Comply with local Air Quality Board requirements.

6-2.4.3 National Ambient Air Quality Standards (NAAQS).

Comply with NAAQS standards.

6-2.4.4 Clean Air Act (CAA).

Comply with CAA, including:

- 40 CFR Part 60;
- 40 CFR Part 63;

- New Source Review (NSR) permitting;
- 40 CFR Part 70, Title V permitting; and
- Information collection authority used to implement greenhouse gas reporting program.

6-2.4.5 Water Quality Regulations.

Comply with Clean Water Act (CWA) regulations.

6-2.4.6 Solid Waste Disposal Regulations.

Comply with landfills RCRA requirements.

6-2.4.7 Other Restrictions and Requirements.

Consult with states and local authorities that may have adopted rules concerning LFG emissions and condensate disposal to ensure compliance with all applicable regulations. Monitor emissions and comply with personnel exposure threshold limits.

Comply with industry standards and equipment manufacturer specifications where codes do not govern specific equipment or system features.

6-2.4.8 Nuisance Odor.

Provide a design to efficiently collect LFG, without overpull, to minimize the gas release to the atmosphere causing nuisance odors. Hydrogen Sulphide is a trace compound found in LFG within a typical range of 100 parts per million (ppm).

6-2.4.9 Vegetation Stress.

Monitor signs of vegetation stress due to high levels of oxygen or other gases which indicate an imbalance in the system or possible loss of control components.

6-2.4.10 Potential Explosive Gas.

Use infrared LFG analyzers to monitor methane levels at the landfill perimeters and other structures on or adjacent to the landfill and to initiate alarms and safe shutdown procedures before the lower explosive limit (LEL) of methane in air (5%) is reached.

6-2.4.11 Greenhouse Gas Release.

The design must incorporate redundant equipment, redundant extraction methods and LFG destruction schemes, and control systems to prevent greenhouse gas release to the atmosphere.

6-2.5 Interconnect Studies.

Perform interconnect studies. Refer to Chapter 8 titled "UTILITY INTERCONNECTION" for guidance.

6-2.6 Permits.

Confirm all Federal, State, and local permitting requirements prior to the design and construction of a landfill gas to energy project.

6-2.6.1 Environmental Impact Statement.

Provide an Environmental Impact Statement (EIS) which is a required document describing how the human environmental quality is affected both positively and negatively. This document must discuss how the environment is affected and the environmental consequences associated with the project. Provide a list of required alternatives that are to be included in the document. Include the following in the EIS:

- All required air permits;
- Any required construction permits are required for new LFG projects under the NSR;
- All documentation regarding the Prevention of Significant Deterioration (PSD);
- Title V operating permit;
- A National Pollutant Discharge Elimination System (NPDES) permit which regulates point sources that discharge pollutants into United States waters and include separate permitting for storm water run-off associated with the landfill;
- Solid waste disposal permits as required for the project and as required by the local authorities; and
- Dredge and Fill permits as required to meet the CWA Section 404 which regulates the discharge of dredged or fill materials into the United States waters.

6-2.7 Cost Estimation / Analysis.

Cost analyses for landfill gas entail unique cost estimation requirements and parameters including waste tonnage estimation, landfill gas collection efficiency, greenhouse gas (GHG) emission reductions, annual fixed and variable O&M costs, and calculation of capital costs.

6-2.7.1 Waste Tonnage Estimation Methodology.

Use waste tonnage estimation methodology to predict the total quantity of LFG output for a landfill over a set period based on the amount of LFG produced each year versus the amount of waste added each year. The estimation must show the increasing and decreasing quantities of LFG produced over the landfill life in relation to the increasing and decreasing quantities of waste added each year.

6-2.7.2 LFG Collection Efficiency Estimation Methodology.

Use the LFG collection efficiency estimation methodology to determine the average amount of LFG collected in a year divided by the LFG generation that was modeled for that same year. The LFG flow composition is assumed will be 50% methane. The LFG collection and management systems efficiency is expected to be a minimum of 75%.

6-2.7.3 Greenhouse Gas Emission Reductions.

Comply with the CAA emission regulations and implement the greenhouse gas reporting program.

6-2.7.4 Capital Costs.

The capital cost associated with constructing an LFG to energy project are typically $1,000 per kilowatt of electricity produced.

6-2.8 Coordination.

Establish an institutional framework consisting of the major project stakeholders including government authorities, the landfill owner / operator, community groups, and energy sector companies. Review with the stakeholders the financial, environmental and energy plant operational issues. Perform a comprehensive stakeholder analysis to identify potential issues involving energy plant construction and operation. Establish agreements that resolve issues before the plans are made to build the plant.

6-3 DESIGN CRITERIA.

6-3.1 General Design Requirements.

Design landfill gas recovery systems to extract the landfill gas through a gas collection system of piping and wells. Design the condensate in the landfill piping to be collected and treated through a condensate collection and treatment system. Design a primarily active type system were gas in the collection piping is pulled by vacuum blower(s) to an extraction plant where the gas receives further treatment to remove contaminants and improve the gas quality and while the condensate entrained in the gas is separated and filtered out. Include gas conditioning and filtering prior to being, burned in a flare, burned in a boiler to produce heating, or burned in a generator that powers an alternator to produce electric energy. Consider site climate to determine if equipment should be enclosed in a structure.

6-3.1.1 Site Considerations.

Investigate the site to determine the landfill elevation at which the landfill collects waste, in relation to the surrounding grade. Consider the elevation at which the landfill collects waste, in relation to the surrounding grade, which can affect the quantity of LFG collected, gas released to the atmosphere, and migration of gases to surrounding areas. Design slopes around collected waste to be more gradual and less acute and not to exceed 25% (4 horizontal to 1 vertical unit) to provide increased collection, efficiency, decrease potential for oxygen overpull, and increase simplicity for cover construction and maintenance.

Provide service roads. Design the site to provide proper vehicle access for by service personnel and emergency vehicles. Use a perimeter fence with lockable and accessible gates, at a minimum, to secure facilities and remote pieces of equipment. Ensure access is available to fire hydrants or other fire protection features. Provide all necessary utilities, such as sanitary sewer, water, electricity, and telecommunications, required for plant operations. Refer to UFC 3-600-01 for additional guidance.

6-3.1.2 Hydro-geological Condition.

Investigate site hydro-geological conditions to assess off-site LFG migration to determine high and low permeability materials, depth of ground water, moisture content, and other geologic conditions. See Table 6-1 below for suggested parameters and test methods. USACE references are mandatory for U.S. Army. For other Agencies, comply with agency specific requirements.

Table 6-1 Parameters and Test Methods for Landfill Gas Migration

Parameters and Test Methods for Landfill Gas Off-Site Migration (Adapted from USACE EM 200-1-22 table 2-1)		
Parameter Tested:	**Collection Method:**	**Reference:**
Atterberg Limits	Soil Borings	ASTM D4318
Depth to Groundwater	Monitoring Wells	ASTM D4750
Grain Size and Porosity	Soil Borings	ASTM D422
Heterogeneity / Utility Trenches	Geophysical Investigations	USACE EM 1110-1-1804
Moisture Content	Soil Borings	ASTM D2216
Stratigraphy	Soil Borings	ASTM D2487 ASTM D2488 USACE EM 1110-1-1804
Vapor Phase Concentrations	LFG Monitoring Probes	EPA TO 14a

6-3.1.3 Landfill Cover Design.

Design cover to prevent intrusion of air into the waste. Design must consider the effects of changing barometric pressures. Design the cover to prevent air intrusion into the waste to prevent oxygen overpull. Refer to UFC 3-240-10A (for Army) for final cover design. For other Agencies, use UFC 3-240-05A as a reference and comply with Agency specific guidance.

6-3.1.4 Landfill Liner Design.

Refer to UFC 3-240-10A (for Army), for landfill liners design. For other Agencies, use UFC 3-240-05A as a reference and comply with Agency specific guidance.

6-3.1.5 Moisture Addition and Leachate Recirculation.

Introduce moisture to landfill or recirculate leachate as required to optimize LFG production by accelerating decomposition and to remove water soluble contaminants in the waste. Contaminants in the landfill can be removed by moisture percolating through the waste.

6-3.1.6 Oxygen Overpull.

Use monitoring equipment in the extraction well to assess the oxygen content in the LFG. The monitoring equipment must be capable of measuring the oxygen content to help determine oxygen overpull, locate possible leaks in the processing equipment, balance the wells to achieve the LFG quality desired, and to improve the extraction process efficiency. Oxygen levels should be less than 2.5% by volume.

6-3.1.7 Drilling Rig Access.

Provide adequate access, service roads, and space for the mobilization of drilling equipment and for drilling equipment usage when drilling LFG extraction wells.

6-3.2 Collection System Design.

Refer to USACE EM 1110-1-4016, or Agency specific guidance, for landfill gas collection system design.

6-3.2.1 Active Systems.

Design an active LFG collection system to consist of a blower system, extraction wells, a piping system with valves, flares, and electronic controls and meters. Use blowers to draw the LFG from the extraction wells through the piping system and delivered to the extraction plant where the gas is processed and combusted. Use an active system to capture and collect LFG.

6-3.2.2 Passive Systems.

Design a passive LFG collection system to consist of horizontal trenches filled with a coarse granular fill. Use passive systems only to supplement an active system and be used to prevent LFG from migrating out of the landfill to the surrounding soils or out to the atmosphere. Design passive systems to be located at the perimeter around the landfill and at shallow areas of the landfill.

6-3.2.3 Collection System.

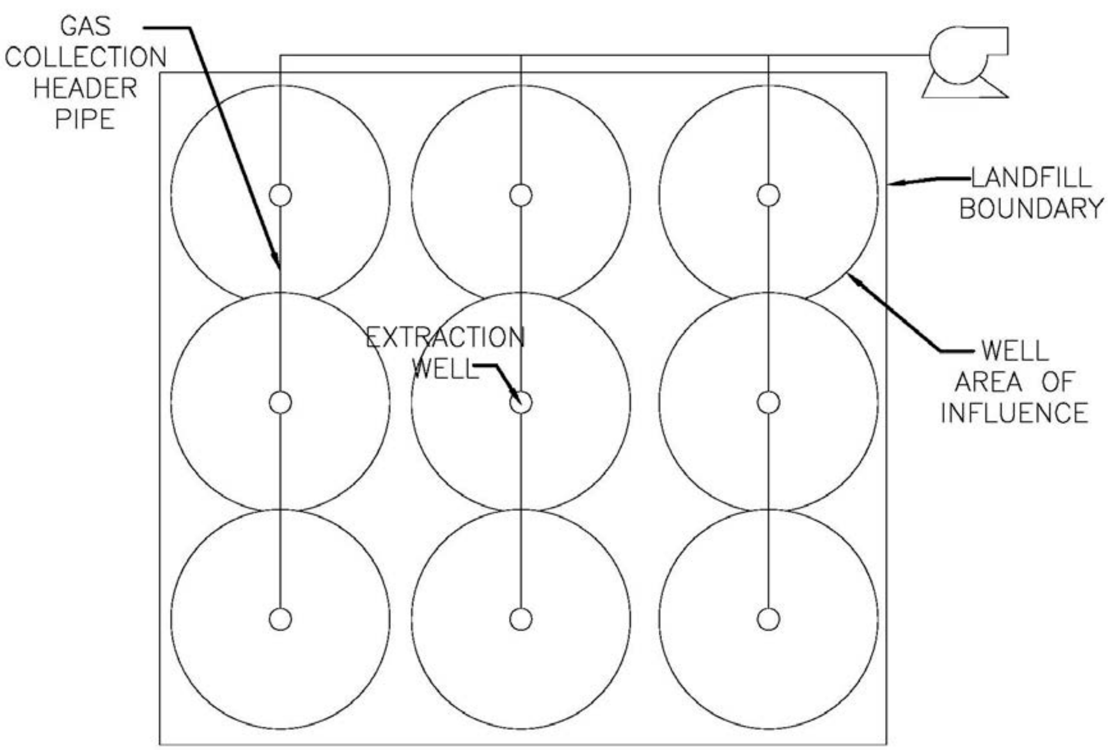
Collect landfill gas using a blanket collection system consisting of vertical extraction wells, and possibly with a combination of horizontal collection trenches. A blanket collection system consists of collecting LFG through a permeable layer of sand or gravel that is covered by an impermeable layer, a drainage layer, and a soil cover layer. A preferred permeable layer thickness is 1.0 ft. (30 cm) thick. Install a perforated pipe in the permeable layer connecting to a vent pipe. Space vent pipes 200 ft. (61 m) apart.

6-3.2.4 Vertical Extraction Wells.

Use vertical extraction wells primarily to extract LFG after landfill filling operations have been completed. Design vertical extraction wells to consist of perforated or slotted pipe that penetrate near the refuse bottom or near the saturated waste depth. The typical minimum depth of a landfill using vertical extraction wells is 40 ft. (12 m). Investigate the specific site confirm landfill depths and ensure a proper design.

Use the design procedures in USACE EM 200-1-22, or Agency specific guidance, and State regulatory requirements when determining the well spacing. Design vertical collection wells for 50 to 200 ft. (15-61m) spacing (Figure 6-1).

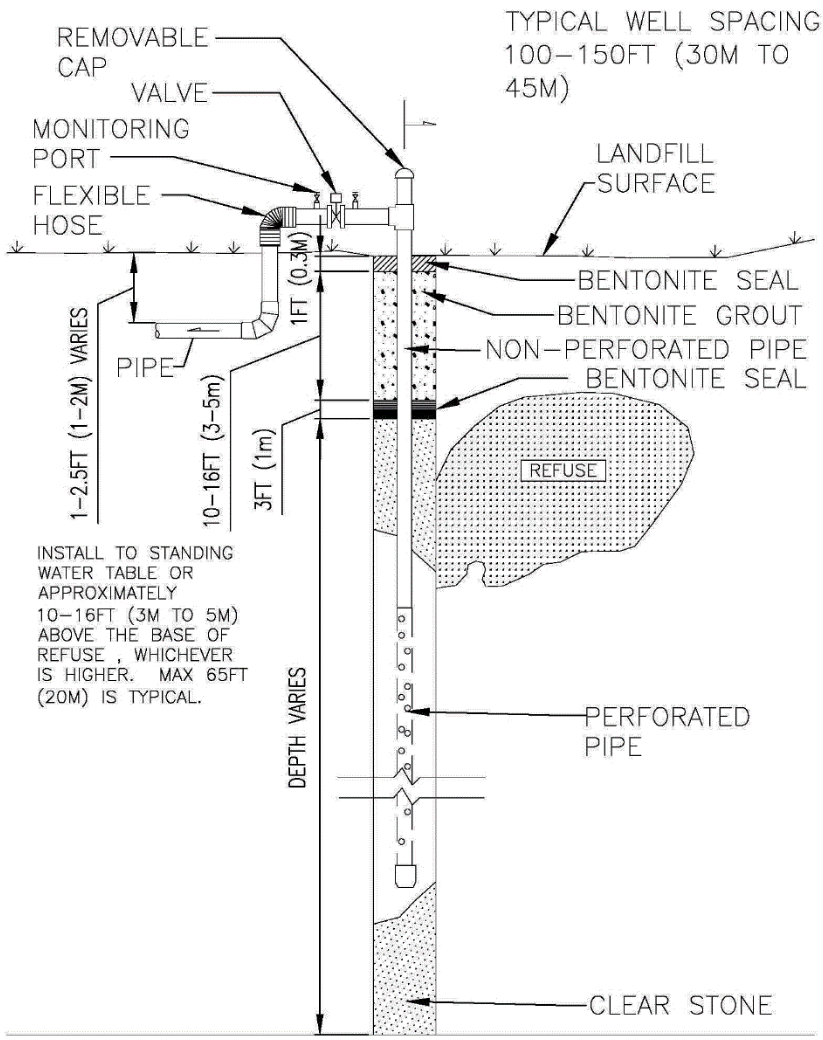
Figure 6-1 Well Spacing



6-3.2.5 Vertical Extraction Well Design.

Design a well to have a perforated pipe installed in the borehole center and then backfilled with an approved aggregate with a bentonite seal used to prevent air infiltration. Backfill the remaining borehole with soil. Analyze the LFG production rate and the radius of influence around a well to properly design the well system. The LFG recovery rate from a single well is expected to range from 10 – 50 cubic ft. per minute (cfm) (4.7- 23.6 l/s). The recommended design vacuum pressure for each extraction well is 10 – 25 in (25.4-63.5 cm) of water column (wc) to achieve higher LFG collection efficiency and to prevent a landfill fire or explosion. Where possible, design for higher efficiency operations to maximize the radius of influence while minimizing air (oxygen) intrusion into the landfill (Figure 6-2).

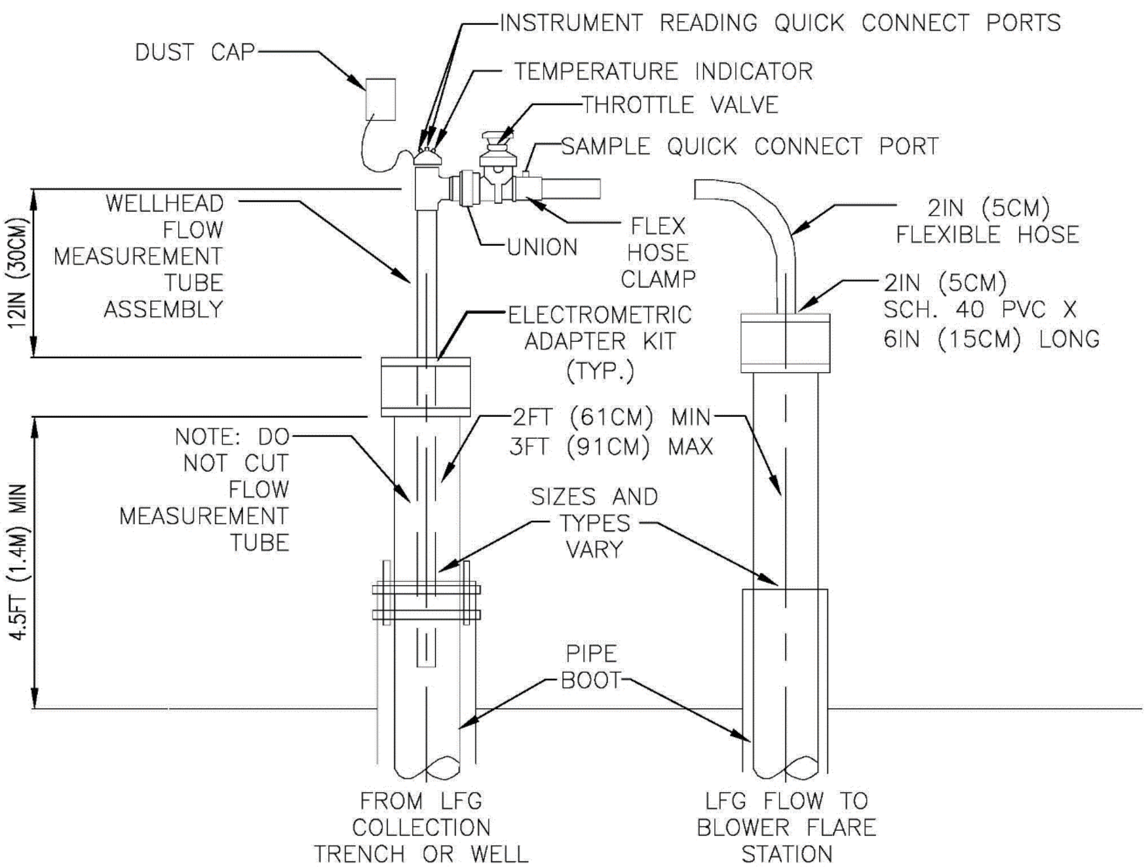
Figure 6-2 Typical Vertical Extraction Well



6-3.2.6 Vertical Extraction Well Heads.

Locate the well head assembly (Figure 6-3) above the landfill surface to allow for LFG sampling, measurement, adjustment, and inspection. Construct the well head assembly to incorporate a flow measurement tube, instrument connections, a sampling port, a control valve, a flexible hose, and a removable access at the perforated pipe top for inspection, maintenance, and leachate removal. Design pipe sleeves and boots for piping penetrating into extraction well. Size the control valve, or well head valve, to provide a high degree of control precision without over sizing valves. Preferred control valve types are butterfly and globe valves. Only use gate valves for isolation or on/off operation.

Figure 6-3 Well Head Assembly



6-3.2.7 Horizontal Collection Trenches.

Horizontal Collection Trenches. Use horizontal collection trench systems (Figure 6-4) for active landfills currently receiving waste or in shallow areas of the landfill. Use the horizontal trenches as part of the active type system. Limit passive type horizontal trenches to landfill perimeters only. Install the collection trenches in layers as the refuse is added (Figure 6-5).

Figure 6-4 Horizontal Collection Trench

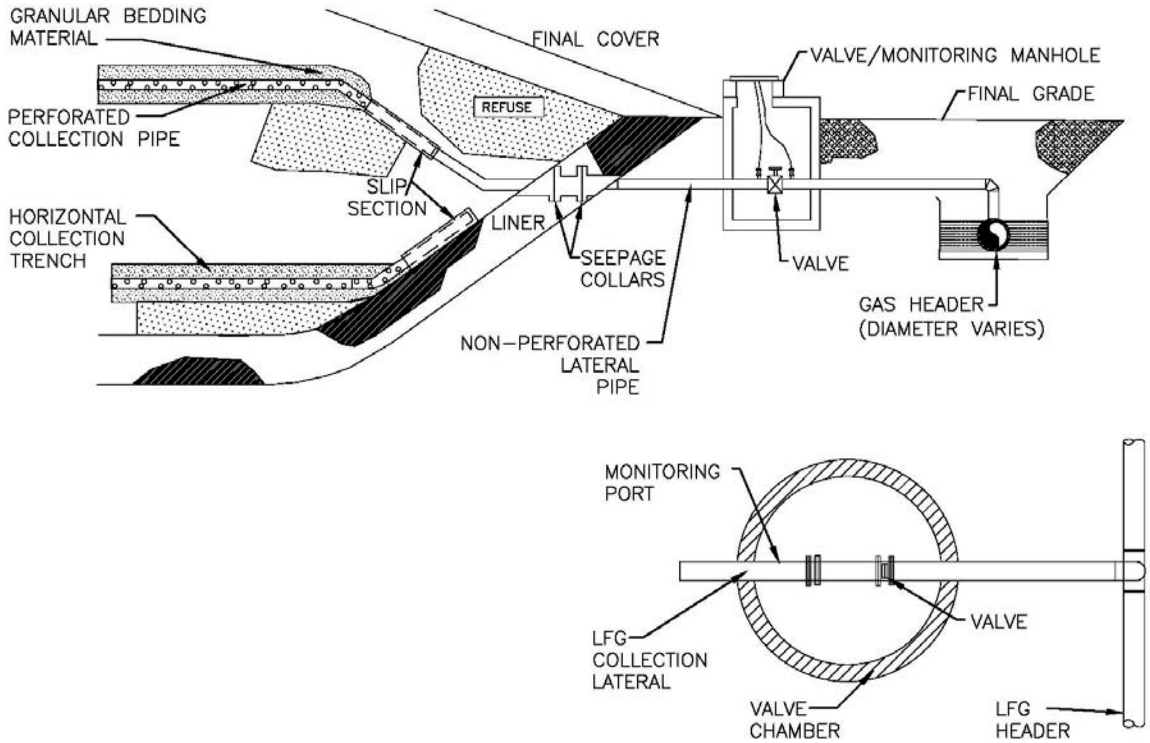


Figure 6-5 Horizontal Trench Layering

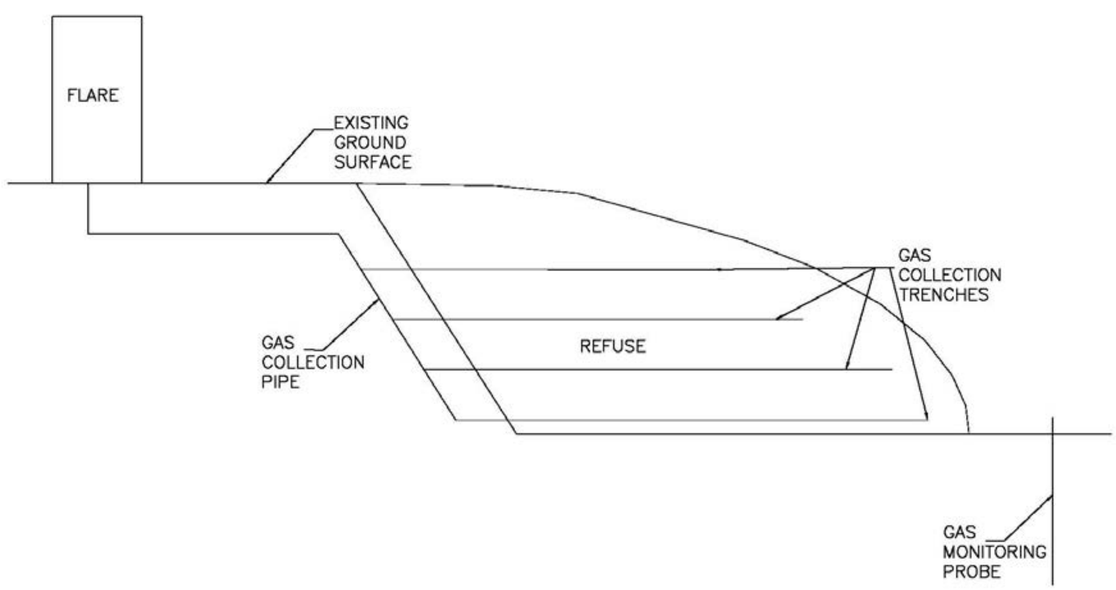


6-3.2.8 Horizontal Collection Trench Design and Construction

Refer to the design procedures in USACE EM 200-1-22 and State regulatory requirements when determining the well spacing. Space wells 200 ft. (61 m) apart.

Trench horizontal wells into the landfill using an approved aggregate bedding with a perforated pipe in the center of the trench. Backfill the trench with an approved aggregate. Apply a geotextile fabric on the trench top to prevent clogging. Use a bentonite seal to prevent air infiltration and back fill the trench with soil or waste. Construct the well head assembly similar to the configuration described for the vertical extraction well head.

6-3.2.9 LFG Collection Piping.

Design collection piping to transport LFG from the extraction wells, using blowers, to a burner or to a gas processing system prior to the end use equipment. Use a pipe header system to connect multiple extraction wells together. Design the LFG collection piping for below grade, wherever possible, to minimize condensate freezing and pipe clogging.

6-3.2.10 Header Configurations.

Take into account in the header configuration design, system components, landfill size and depth, types of waste, radius of influence, system friction losses in equipment and the subsurface components, and the extraction rate of LFG. Use one or more of the following three preferred methods for header configurations: (Figure 6-6).

6-3.2.10.1 Branch (Radial).

Design the branch header configuration to consist of a series of subheaders (branches) that connect to one main collection header. Use isolation valves to isolate individual branches for maintenance and service without shutting down large portions of the collection system.

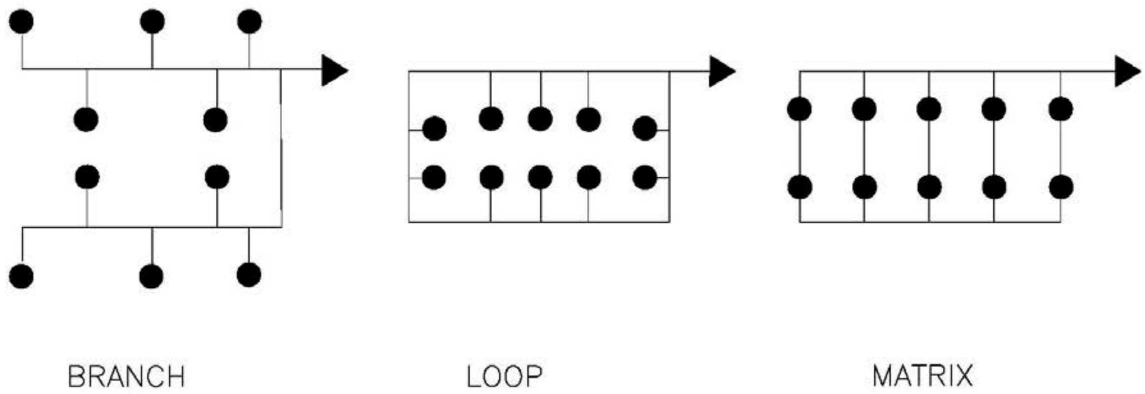
6-3.2.10.2 Loop.

Design the loop header configuration to consist of a main header that loops around the landfill with each well inside the loop connecting to the main header. Use isolation valves to shut down individual wells without shutting down major portions of the collection system. Ensure the design has adequate capacity to allow the LFG to flow in more than one direction.

6-3.2.10.3 Matrix (Herringbone).

Design the matrix header configuration to consist of a main header that loops around the landfill with the subheaders connected to the main header at both ends of the subheader. Connect the wells to the subheader that connect to the header. Use isolation valves to isolate individual subheaders for maintenance and service without shutting down large portions of the collection system. Ensure the design allows the LFG to have the capability to flow in more than one direction.

Figure 6-6 Typical Header Layouts



6-3.2.11 LFG Piping.

6-3.2.11.1 Sizing.

Size the piping system to have a frictional pressure drop, in the pipe, less than 10 in (25.4 cm) of water column with respect to the varying flow rates of LFG.

6-3.2.11.2 Header.

Slope the LFG header and subheader piping allow the condensate to adequately drain to a collection point and to prevent condensate collecting in pipes and potentially clogging the pipe. Provide 3- 5% slope in header and subheader piping. Design system to accommodate waste and soils settlement and account for settlement when determining pipe slopes.

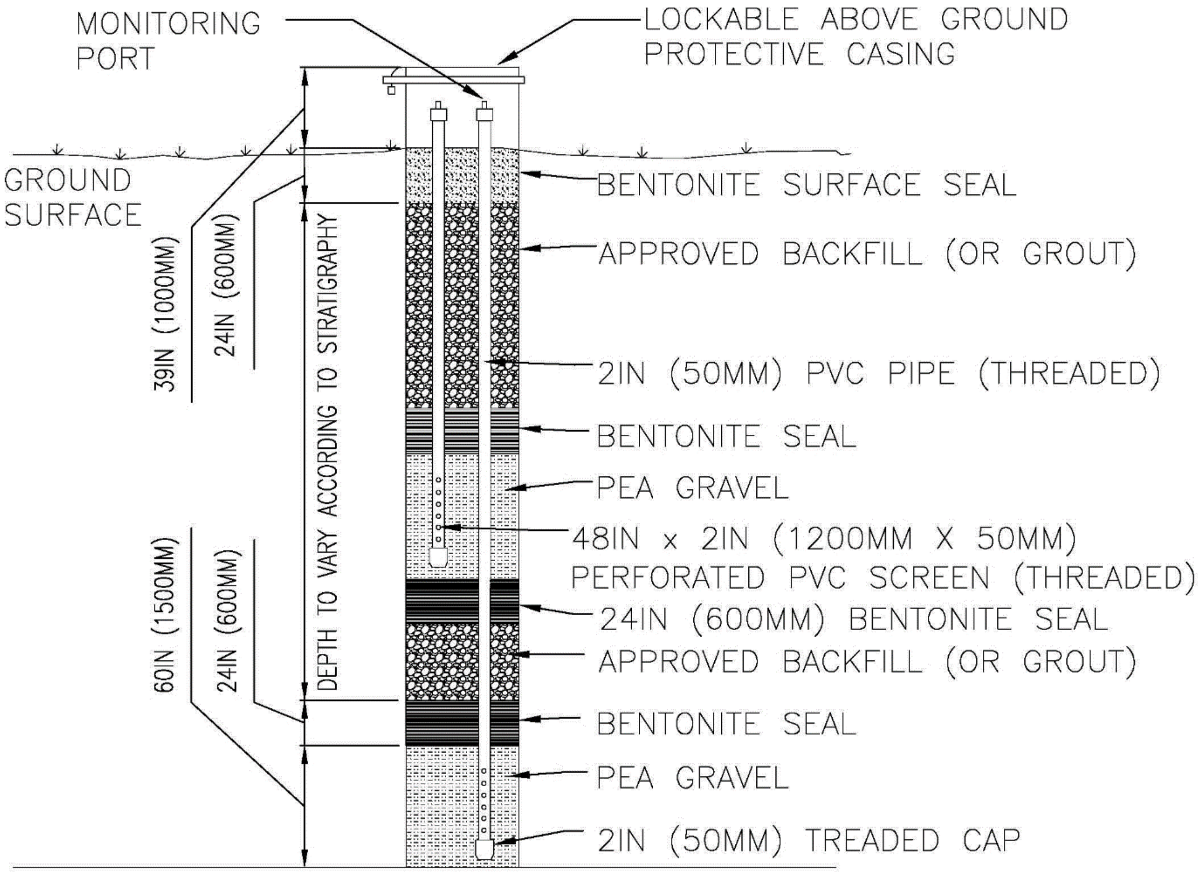
6-3.2.11.3 Materials.

Use polyvinyl chloride (PVC) or high density polyethylene (HDPE) pipe. HDPE is the preferred pipe type due its ability to withstand settlement damage and is less susceptible to damage from ultraviolet radiation than PVC.

6-3.2.11.4 Monitoring Probes.

Provide gas monitoring probes along the landfill perimeter to monitor LFG migration outside of the landfill and possible migration into adjacent structures. The preferred gas monitoring probe is a multilevel / multiple probe type to more accurately assess the migrating gases by defining the gas vertical profiles. Figure 6-7 illustrates a typical design of a multilevel / multiple gas probe.

Figure 6-7 Typical Gas Monitoring Probe Installation



6-3.3 Condensate Collection and Treatment System in LFG Collection Systems.

LFG condensate forms in the piping headers and subheaders. Design system to flow freely without blocking the pipe. Size the collection piping to allow for LFG and condensate to flow within the same pipe, and at times where the flow of LFG and the flow of condensate are in opposing directions. Provide for condensate collection low points. Provide air traps to avoid air intrusion into the waste. Use sump pumps to pump the condensate to a designated storage tank or treatment system for proper disposal or redistribution back into the landfill.

Provide for treatment and moisture / particulate filtering upstream of the blower to prevent damage to equipment and to ensure effective combustion at the flare. A condensate knockout system is the preferred type, to lower the velocity of LFG to allow an opportunity for the condensate to separate from the gas.

6-3.4 Extraction Plant.

Design an extraction plant consisting of equipment necessary to collect the LFG and primarily treat the LFG prior to being combusted for electricity generation or transmission.

6-3.4.1 Facility.

Design facility to effectively extract LFG from the landfill, remove condensate and particulates, combust the gas or divert the gas for electricity generation, and allow for adequate access and space for maintenance. Use blowers to create a negative pressure to extract LFG from the landfill and provide positive pressure to transport LFG to the flare where the gas is combusted, or for further treatment and use for electricity generation. Use flares to combust LFG for effective gas control and prevent LFG release to the atmosphere. Provide all controls, instrumentation, and monitoring equipment necessary for effective collection and processing of LFG.

6-3.4.2 Components.

6-3.4.2.1 Condensate Knockout and Particulate Removal.

Use a simple drum type condensate knockout system where low pressure centrifugal blowers are used for LFG extraction. Provide filters to remove particulates out of the LFG. Stainless steel or plastic mesh screen filters are preferred for particulate removal and added moisture removal.

6-3.4.2.2 Blowers.

Use centrifugal or positive displacement rotary lobe blowers recommended by USACE EM 200-1-22 or Agency guidance. Provide explosion proof blowers suitable for NFPA 70, Class I, Division I, Group D. Provide anti-corrosion protective coating for blower components in contact with landfill gas. Provide a full redundant unit for equipment maintenance and downtime as needed to avoid any potential health hazards. Design the blower system to take into account the LFG piping arrangement, sizes, flow rates of LFG, the pressure losses in the system piping and wells, the pressure losses in the system components, and all other system effects.

6-3.4.2.3 Gas Condenser (Refrigerated Dryer).

Use a gas condenser to further process the landfill gas by removing water vapor and organic impurities and to improve the combustion efficiency. Condensers utilizing a refrigerated system to cool the LFG to its dew point temperature to condense the water vapor out of the LFG stream are preferred. Use a refrigerated system that will bring the dew point for LFG down to 36 ^{o}– 38 ^{o}F. Use a gas condenser system that will remove impurities that are water soluble, such as halogens and H_2S, when water is condensed from the cooled LFG. Do not use systems containing chlorofluorocarbons refrigerants. Coordinate condenser LFG output quality and flow with any other LFG treatment technologies requirements that may be incorporated in the design, such as activated media. Provide a condensate drain and piping, as required by the equipment manufacturer, for condensate disposal.

6-3.4.3 Flare and Propane Feed.

Use a high temperature flare to combust the LFG when the processing plant is down or when a surplus of LFG is collected. Provide an oxygen content alarm to maintain safe flare operation and prevent oxygen intrusion into landfill and potential combustion. Select enclosed or candlestick flare based upon the approval authority requirements and project economics. Use flares that are self-supporting and designed for the wind and seismic conditions specific to the area where they will be installed. Comply with EPA Non-Methane Organic Compound Emission Guidelines.

6-3.4.4 Enclosed Flare.

The enclosed flare is preferred for methane and trace compounds combustion as these flares are considered more efficient at reduction of greenhouse gas emissions and typically provide more sensing and control options. The enclosed flare is also considered more visually pleasing as LFG combustion is not as noticeable as is with a candlestick flare.

6-3.4.5 Candlestick (Open) Flare.

Candlestick flares combust the waste gas at the flare top. Construct the flare of steel with a windbreaker and include a control outlet, flame arrestor, and propane ignition system. Use a flare with a shell comprised of steel and a refractory insulating material. Provide with flame arrestor, control valve, air damper and temperature and flame sensors, and controls. Consider using a purge blower to purge traces of LFG from the flare prior to ignition. Include a propane or natural gas pilot system. Design flare for a minimum retention time and temperature to allow for an effective and complete LFG combustion.

6-3.4.6 LFG Primary Treatment Plant.

Design the primary treatment plant to further process the LFG after the extraction plant and before use in electricity or heat generation. The treatment plant consists of equipment, aligned in series, for removing condensate, particulates, hydrogen sulfide, siloxanes, and halogenated compounds from LFG. Use economics evaluation and the desired fuel grade required for the end use to determine gas treatment requirements.

6-3.4.7 Facility.

Design the facility to ensure safe operation, a secure premises, proper maintenance space, and adequate separation of spaces to meet hazardous area classifications. Design the facility to have provisions for future expansion and installation of more equipment if expansion potential exists. Provide all buildings with gas monitoring probes to detect gas collecting around and underneath the building foundation.

At a minimum, construct a steel framed building with a roof and a concrete foundation. Design enclosed buildings, consisting of a roof, walls, and concrete foundation, as necessary to house the equipment type being utilized and support maintenance requirements. Separate electrical panels and equipment in enclosed buildings from any gas piping or other gas processing and conveying equipment. Provide a security fence surrounding the premises. Equip all enclosed buildings with an indoor air quality (IAQ) detection system with sensors, alarms, and interlocks to other safety devices and equipment such as mechanical ventilation and exhaust systems.

6-3.4.8 Components.

6-3.4.8.1 Blowers.

Add blowers, downstream from the extraction blowers, to increase the LFG pressure to overcome pressure losses in the treatment components.

6-3.4.8.2 After Cooler.

Use after coolers, following a blower, to lower the gas temperature as required by equipment downstream of the blower. Select after coolers to include a heat exchanger. Select an air cooled or refrigerant cooled machine based upon required equipment performance.

6-3.4.8.3 Pretreatment.

Pretreat or precondition the gas, prior to its end use, to prevent equipment inefficiencies, equipment damage, and frequent maintenance service.

6-3.4.8.4 Treatment Requirements.

Determine the expected final LFG fuel grade prior to selecting treatment equipment and technologies.

6-3.4.8.5 Treatment Technology.

Use treatment technologies that provide the proper conditioning and filtering required while requiring minimal maintenance and waste. Equipment utilizing a combination of technologies to remove multiple contaminants may be used.

6-3.4.8.6 Water Removal.

Use either refrigeration type technologies which employ heat exchangers, utilizing refrigerant or chilled water, or use a desiccant type system, which may use a silica type gel. A combination of systems may be employed to dry the air. Use a combination of condensate knockout tanks throughout the treatment system to further reduce the gas moisture content. Provide a condensate drain, as required by the equipment manufacturer, for condensate disposal.

6-3.4.8.7 Particulate Removal.

Use stainless steel mesh screens after the condensate knockout located in the LFG piping, and before the blower inlet. Use mesh screens to filter particles as small as 1.0 micron. Verify screens use are required prior to other treatment technologies and equipment, and select recommend micron size.

6-3.4.8.8 Foam Removal.

Use coalescing stainless steel mesh screens after the condensate knockout located in the LFG piping upstream of the blower. Provide a condensate drain, as required, for condensate disposal.

6-3.4.8.9 Siloxane Removal.

Use activated alumina, activated carbons, refrigeration type systems or a combination of these systems may be used to remove siloxane. The concentration range of siloxane after removal should be less than 100 parts per billion (ppb). Provide a condensate drain as required for condensate disposal.

6-3.4.8.10 Hydrogen Sulfide Removal.

Use an iron sponge to further reduce hydrogen sulfide. Provide a regeneration system as required by the equipment manufacturer. Provide a condensate drain, as required, for condensate disposal.

6-3.5 Condensate Collection and Treatment System in LFG Treatment Systems.

Treat collected condensate to local standards before final discharge.

6-3.5.1 Design Considerations.

Landfill gas typically contains water vapor. When the LFG is cooled, the water vapor in the gas stream will form droplets and the droplets combine to form condensate. The condensate quality from LFG depends on a number of factors from where the condensate originated. Condensate typically contains a number of volatile organic compounds (VOCs). The factors affecting the condensate quality are listed below:

- Waste type and nature;
- Age of waste;
- Climatic conditions;
- Moisture content within the landfill;
- Ambient temperatures and temperatures within the landfill;
- Landfill site configuration;
- Landfill overall size;
- Landfill covers and liners and their effectiveness; and
- Condensate production rate.

Estimate the condensate production rate by assuming the LFG is fully saturated and assuming that all the condensate will condense out of the LFG while it is cooled in the component cooling the gas. Size condensate piping for estimated condensate flow.

6-3.5.2 Condensate Piping.

The preferred condensate piping is HDPE type.

6-3.5.3 Condensate Pumps.

Use compressed air or electrical condensate pumps sized to accommodate the modeled condensate production rate.

6-3.5.4 Condensate Treatment System.

If allowed by local, State and Federal regulatory agency guidelines, drain generated condensate back into the landfill for processing. If the amount and / or characteristics of the condensate do not allow draining back into the landfill, determine and implement appropriate pretreatment measures before discharging into a local wastewater treatment system.

6-3.6 Power Generation Plant.

Internal combustion engines and gas turbines are the most common technologies for LFG energy generation. These technologies can be used individually or together maximizing the best and most efficient use of projected gas flow from the landfill over time.

6-3.6.1 Energy Conversion Technology.

Select the energy conversion technology based upon the developed electrical energy output as follows:

- 800 kilowatts (kW) to 3 megawatts (MW) – use internal combustion engines with multiple engines for 1 MW to 3 MW range unless gas turbines are determined to be the most effective / cost efficient;
- 5 MW or More – use gas turbine engines;
- Less than 250 kW – use microturbines.

6-3.7 Process Controls and Alarms.

Refer to EM 200-1-22 for landfill off-gas collection and treatment design requirements. Automated process controls are the preferred type. Provisions for the control points, at the minimum, must include:

- Flare and blower interlocks;
- Flare temperature;
- Pilot ignition status with blower operation sequence;
- Emergency fail-safe operation to isolate piping during power loss or outage;

- Pressure and flow measurements for each well;
- Pressure measurements for blower inlet and outlet;
- Thermal overload protection for blower motors;
- Vacuum relief valves or switches / blower shutdown;
- Facility IAQ monitoring/alarm (minimum of methane and hydrogen sulfide);
- Near surface emissions monitoring/alarm;
- Methane LEL monitoring and emergency shutdown;
- Condensate collection monitoring/alarm; and
- Power plant generation technology and switchgear status.

6-3.8 Project Planning Considerations.

Appendix D provides listing of factors to consider during the design. Tailor as appropriate for project scope.

6-4 OPERATION AND MAINTENANCE.

6-4.1 Contract Based Operations and Maintenance.

Minimum plant O&M requirements for plant equipment and material are those necessary to meet warranty, compliance, and expected life expectancy requirements. Ensure that:

- All equipment O&M and warranty materials are collected and consolidated into a comprehensive O&M guide for review before plant operations start;
- O&M service contracts are in place to start after the warranty period and are based upon an operating life of 20 years;
- Contractor provides all plant operation and maintenance necessary for contract and environmental compliance; and
- Contractor compliance requirements include collecting and providing all recurring data collection and report generation necessary for permit(s) compliance.

See Appendix E for addition O&M guidance.

6-4.2 Safety.

Comply to applicable provisions in 29 CFR 1910 and 29 CFR 1925, American Conference of Governmental Industrial Hygienists Threshold Limit Values and Biological Exposure Indices, 40 CFR Part 60, Appendix A, and 40 CFR Part 63, Appendix A. and local/agency codes and requirements. Provide air monitoring for indoor air quality and outdoor ambient conditions. Provide near surface methane monitor to ensure proper plant extraction operations and take corrective actions if methane readings are more than 500 ppm above background.

6-4.2.1 Non-Performance.

Ensure non-performance and remedy clauses are in maintenance contract to address non-conformance. Ensure liquidated damages address loss of power generation revenue and mission impacts.

6-4.2.2 Warranties.

Specific component warranties will vary with manufacturer. Warranties are typically limited to repair or replace, at manufacturers' discretion, the defective components, or assemblies. Warranty limits may include causes for materials, supplies, and equipment not manufactured or supplied by the manufacturer, unauthorized repairs or modifications, Acts of God, and incidental or consequential damages.

This Page Intentionally Left Blank

CHAPTER 7 DESIGN CRITERIA - GEOTHERMAL SYSTEMS

7-1 INTRODUCTION.

This chapter identifies typical applications and defines the data development requirements to establish design criteria for a geothermal power generation plant. Ground source heat pump technology is not consider utility level power generation technology and is not discussed in this UFC. Viable geothermal power production requires a geothermal resource with three attributes:

- Fluid – Water naturally existing in the geothermal reservoir is used to extract heat in quantities necessary to meet power production requirements;
- Heat – Earth's natural temperature which increases with depth. High grade resources vary based upon geographic locations. Geothermal power plants are 8-15% energy efficient, dictating using only higher quality geothermal resources; and
- Permeability – The working fluid's (water) ability to adequately move through the geothermal resource between the production and injection wells via natural or induced fractures.

7-1.1 Technology.

Select technology based on the available geothermal resource temperature and type – dry steam, wet steam, temperature, and technologies. Table 7-1 provides technology considerations for available geothermal resource. Geothermal plant economics is greatly affected by resource characteristics such as temperature, flow rate, and depth, drill rig availability, and plant cost.

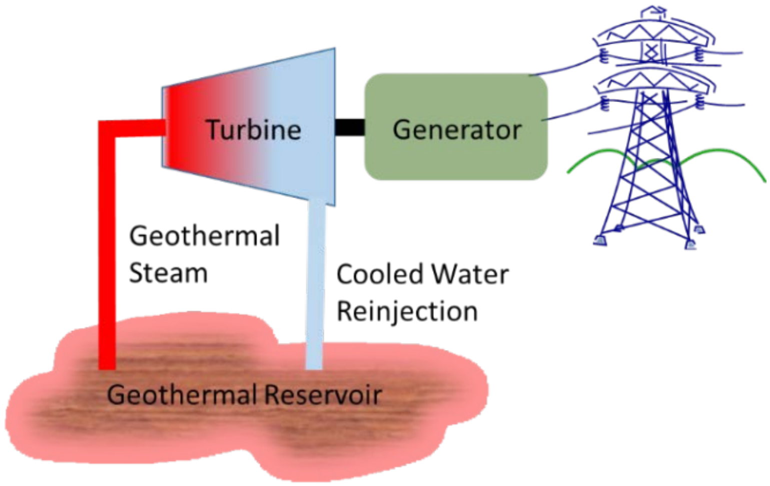
Table 7-1 Geothermal Resource Technologies

Resource Temperatures	Considerations for Use/Technologies
>400 °F (200°C) - High	Power generation – dry, flash, double flash, combination
300-400 °F (150-200°C) - Medium	Power generation – binary
<300°F (<150°C) - Low	Power generation – binary Direct use – processes, space heating, agriculture and aquaculture

7-1.1.1 Dry Steam Power Plants.

Use a dry steam power plant for a geothermal source producing high temperature steam, which does not contain water, to power the steam turbines. Inject spent geothermal fluid or low pressure steam back into the subsurface reservoir to continue the thermal cycle, as illustrated in Figure 7-1.

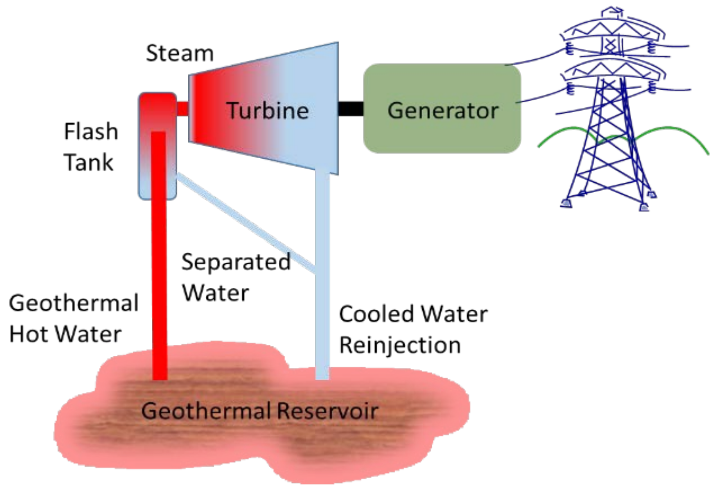
Figure 7-1 Dry Steam Power Plant



7-1.1.2 Flash Steam Power Plants.

Use a flash steam power plant when the geothermal source is high pressure hot water at the subsurface level. Design the system to flash high pressure / high temperature water into steam to power the turbines. Inject spent geothermal fluid or low pressure steam back into the subsurface reservoir to continue the thermal cycle, as illustrated in Figure 7-2. Evaluate binary generation economics using residual condensate.

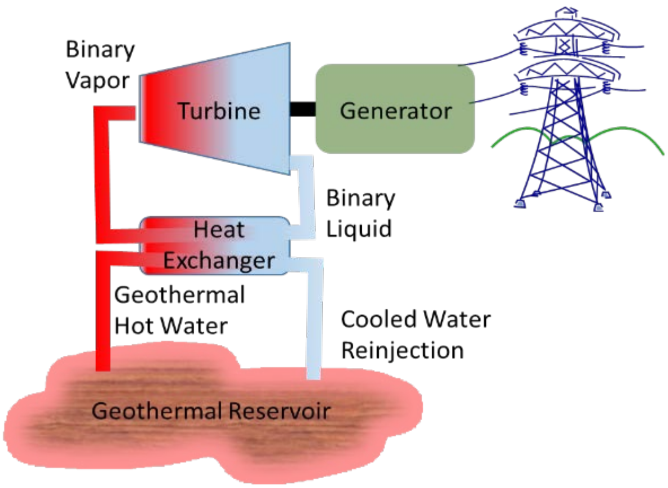
Figure 7-2 Flash Steam Power Plant



7-1.1.3 Binary Power Plants.

Use a binary power plant when the geothermal source has lower temperatures and in areas with sensitive environments. Design the binary power plant to have two separately piped, closed loop systems with pumps to move a working fluid and the geothermal fluid through a heat exchanger that will prevent the two fluids from coming into contact with one another. Select a working fluid that has a lower boiling point than water to allow it to vaporize into steam at lower temperatures. Inject spent geothermal fluid or low pressure steam back into the subsurface reservoir to continue the thermal cycle. Figure 7-3 illustrates Binary Power Plant.

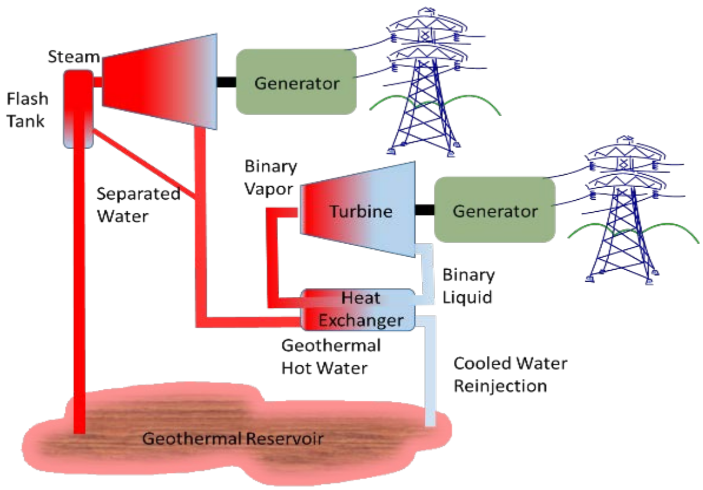
Figure 7-3 Binary Power Plant



7-1.1.4 Combination Flash and Binary Power Plants.

Use a combination flash and binary power plant when more than one geothermal source type is available at the location and sufficient residual thermal energy is available from the primary power cycle to economically use in a binary power plant. Figure 7-4 illustrates the application of a Combined Flash and Binary Power Plant.

Figure 7-4 Combination Flash and Binary Power Plants



7-1.1.5 Backpressure Plants.

Backpressure plants are not authorized. Back pressure plants discharge directly into the atmosphere and are less efficient than other plant types. Not re-injecting fluids limits the geothermal resource life and released fluids may have a chemical composition hazardous to the environment.

7-1.2 Geothermal Resource Types.

7-1.2.1 Conventional Hydrothermal.

Conventional hydrothermal resources are defined by level of development, and include:

- Conventional hydrothermal unproduced resource is a geothermal resource that has not been previously used;
- Conventional hydrothermal produced resource is a geothermal resource that has been previously used to support geothermal power plant(s); and
- Conventional hydrothermal expansion resource is an existing power plant and associated drilled areas.

7-1.2.2 Enhanced Geothermal.

Enhanced geothermal is a geothermal resource in sufficient temperature, but lacks water or permeability for sufficient geothermal fluid production for power production. Hydro-fracturing is used to create new and increase existing fractures to increase permeability in the geothermal reservoir. Surface or subsurface water is pumped through the more permeable geothermal reservoir to produce the necessary working fluid flow for power production in the power plants previously described for enhanced resource temperatures and pressures.

7-1.2.3 Other Geothermal Resources.

Other resource types include 1) geopressured system – high pressure water/gas reservoir which contain a gas (typically methane) and water/brine mix; and, 2) co-production – geothermal and hydrocarbon resource that uses high temperature fluids resulting from oil/gas field development.

7-1.2.4 Geopressured Systems.

Geopressured pilot plants utilizing the produced natural gas and the water’s thermal energy have been proven viable. Plant technologies included natural gas fired engines and binary geothermal plants. Spent geopressured fluids may be re-injected or processed for potable water and brines.

7-1.2.5 Co-production.

Water by-product is typically re-injected into the production strata. Before re-injection, the water volume and temperature may be sufficient for used in a closed loop binary plant.

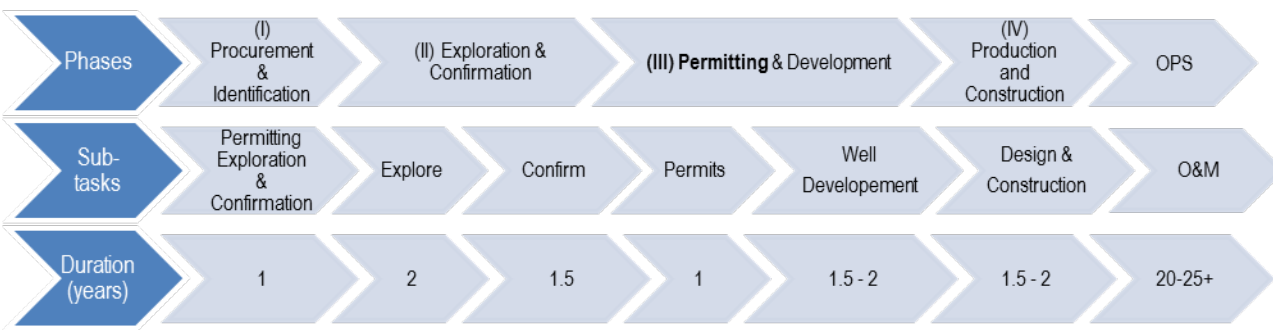
7-2 PLANNING.

32 CFR Part 211 requires DoD to conduct mission compatibility evaluation of proposed site and project. Early project awareness and coordination is mandatory. Request a preliminary siting determination from the OSD Clearing House at osd.dod-siting-clearinghouse@mail.mil. Refer to paragraph entitled "COORDINATIONS" in Chapter 2 for required submission information.

7-2.1 Project Development Phases.

Consider using the Geothermal Energy Association four phase geothermal power project development timeline, listed below, for project development. These phases are described further in paragraphs 7-2.3 through 7-2.6. Figure 7-5 provides estimated planning timelines, by phase. Actual timelines are location and capacity specific. Some tasks may occur concurrently. Total project development timeline is typically 4-7 years.

Figure 7-5 Geothermal Project Planning Timeline



7-2.2 Geothermal Terms and Definitions.

The Geothermal Energy Association provides terms and definitions, by phase, at http://geo-energy.org/pdf/NewGeothermalTermsandDefinitions_January2011.pdf.

7-2.3 Phase I Resource Procurement and Identification.

This phase results in a Possible Resource Estimate and Possible Installed Capacity Estimate for the geothermal resource and the power plant. Review available data to determine evidence of geothermal potential in the desired area and what issues may arise in a procuring a geothermal plant. Refer to paragraph titled "COORDINATIONS" in Chapter 2.

7-2.3.1 Geothermal Assessment.

The highest risk for geothermal power production is finding a viable geothermal reservoir. Due diligence during Phase I is critical to reducing risk. Review information and literature pertaining to geological, hydrological, hot spring, thermal data, drilling data, active remote sensing (LIDAR, radar), passive remote sensing (multispectral, thermal, hyperspectral alteration mineralogy), and anecdotal information from local personnel. The U.S. Geological Survey contains maps, geochemical analyses, and geothermal activity information that are valuable resources. New evaluation techniques are being developed to find and assess ‘blind’, i.e. no surface indications, geothermal resources.

Once the site is defined, and before drilling initial test holes, perform geoscientific surveys / studies such as geochemical, geological, magnetotellurics, and geophysical tests, to minimize exploratory drilling costs.

7-2.3.2 Location Restrictions.

Preform initial power transmission analysis (availability, access, and capacity) to determine viable avenues to transmit power to the electrical grid. Perform initial infrastructure capabilities and restrictions, e.g. roads, water, power, bridges, communications. Use UFC 3-201-01 to evaluate existing site conditions and site development requirements.

7-2.3.3 Environmental Concerns.

Evaluate water, site, and air permitting requirements applicable to geothermal plant type. Begin initial discussions with local and State environmental organizations and local water/aquifer districts. Geothermal power generation plants do no burn fuel; however, they can emit trace amounts of nitrogen oxides, almost no sulfur dioxide or particulate matter, small amounts of carbon dioxide, and sometimes hydrogen sulfide, which is naturally present in many geothermal reservoirs. Other pollutants, such as mercury, may be present in trace amounts. Geothermal waters can be dangerous to humans and surrounding ecosystems as they contain varying concentrations of potentially toxic minerals and elements, and are extremely hot. However, geothermal waters are typically re-injected into the geothermal reservoir and do not contact surface ecosystems or drinking/irrigation aquifers.

7-2.3.4 Scaling and Corrosion.

Mineral scaling on or corrosion of equipment and piping are major operational concerns. Boiling point scaling may consist of calcium carbonate and metal sulfides; and, calcium carbonate and amorphous silica in surface equipment and re-injection wells scaling. Corrosion may include sulfide stress cracking in well piping; sulfuric acid corrosion at wellheads; hydrochloric and carbonic acids corrosion in surface and condensate pipeline; and, stress corrosion cracking in exchangers.

As hydrogen sulfide (H_2S) corrodes copper into Cu_2S, ensure surface electrical wiring and electronics are protected against a H_2S atmosphere, if present. Control humidity using sealed containers, coatings, sealants on wires, electronics, and control equipment, and clean air ventilation to reduce H_2S induced copper corrosion.

7-2.3.5 Scale and Corrosion Testing Requirements.

Perform water testing and hydrogeochemical model to determine expected corrosion or scaling mineral composition, and implement applicable countering means and methods. Perform mineral composition analysis on any accumulated scale before system cleaning and disposal operations. Perform the following water sample measurements as a minimum: pH, SiO_2, Na, K, Ca, Mg, Cl, SO_4, HCO_3/CO_3, and key trace elements Li, Rb, Cs, B, F, Al and Fe.

If site has environmental concerns, include As and Hg measurements. Test for the following gas sample measurements as a minimum: CO2, H_2S, NH_3, N_2, CH_4, H_2, Ar and O_2.

7-2.3.6 Recharge and Cooling Water.

Evaluate plant cooling water requirements, available source(s) (fresh, geothermal, effluent), and for adequate cooling water during planning phase. Table 7-2 provides median water use. Consider secondary use of rejected heat, such as space heating and agriculture. Consider sewage effluent as a geothermal reservoir recharge option. High temperature (400 ^{0}F / 200 ^{0}C) environments sterilize any residual organic material and this alternate disposal method eliminates waterway discharges.

Table 7-2 Median Water Use

Cooling Type	Technology	Median gal/MWh (l/MWh)
Tower	Dry Steam	1,796 (6799)
	Flash (freshwater)	10 (38)
	Flash (geothermal fluid)	2,583 (9778)
	Binary	3,600 (13627)
	EGS	4,784 (18109)
Dry	Flash	0 (0)
	Binary	135 (511)
	EGS	850 (3218)
Hybrid	Binary	221 (836)
	EGS	1,406 (5322)

7-2.3.7 Visual and Sound.

Geothermal power plants have minimal visual and noise impact once construction is complete. Cooling tower steam plumes are the most likely visual item noted. A plant's mechanical equipment may produce undesirable noise levels unless sound attenuation is specified. Specify overall plant maximum sound pressure (ex. 85 decibels at 1 m from enclosure) based upon local codes. Do not specify individual equipment sound pressures as reverberations and reflections compound individual sound pressures and may exceed specified decibel limit. Comply with UFC 3-450-01.

7-2.3.8 Subsidence.

Geothermal condensate re-injection minimizes subsidence caused by power generation. Tectonically active areas have naturally occurring subsidence. Document these natural movements in the planning and permitting documentation and measure local subsidence a minimum of every five years.

7-2.3.9 Induced Seismic Activity.

Geothermal reservoirs are typically located in areas of natural tectonic activity. The process of enhancing geothermal resources and reinjection may induce or increase frequency of micro-tremors. These micro-tremors are rarely the magnitude for humans to feel and are not in any general sense problematic for life or property surrounding the plant. Public awareness and mitigation planning is required to ensure community concerns are fully addressed early in the project timeline.

Perform initial screening, community outreach, baseline criteria and seismic monitoring, event hazard analysis, risk decision analysis for plant design, and risk-based mitigation plan for operations. Refer to paragraph entitled “GEOTHERMAL POWER GENERATION” in Appendix B for additional details on the recommended seven step protocol. Install a micro-earthquake monitoring system before production drilling to establish a seismic baseline and to monitor earthquake activity during operations.

7-2.3.10 Resource Evaluation.

Determine geothermal resource legal ownership as resource likely extends outside of installation boundaries. Establish legal rights to the geothermal resource before developing.

7-2.3.11 Power Agreements.

Coordinate with the local utility(ies) and transmission services provider(s), as well as the agency / installation involved on viability of obtaining power purchase agreements (PPA) and interconnection agreements for the proposed plant.

7-2.3.12 Planning Capital Expenditure.

For initial planning purposes, use the average plant capital expenditures for plants completed from 2011 to 2013 – $2.65 million/MW for flash plants, and $5.18 million/MW for binary plants – and escalate to mid-point of expected construction. Update costs at each phase as project requirements are further refined.

7-2.3.13 Phase I Findings.

Use Phase I findings to create an outstanding issues cost / risk / benefit matrix to support a project go / no-go decision before proceeding to Phase II.

7-2.4 Phase II Resource Exploration and Confirmation.

This phase results in a refined Possible Resource Estimate and refined Possible Installed Capacity Estimate for the geothermal resource and the power plant. Once site is validated under Phase I assessment, determine if site resources meet power generation requirements, transmission capabilities, and site development criteria.

7-2.4.1 Permit Applications.

Generate and submit appropriate permits for approval to drill resource development wells described under resource development. Coordinate with State and local environmental offices and water resource organizations.

7-2.4.2 Resource Capacity Analysis.

At the potential sites developed under Phase I, drill wells to gather site specific thermal data to refine resource location and to develop the Phase II geothermal *Possible Resource Capacity*. Drilling may be accomplished in a multi-step process to reduce costs: 1) drilling of shallow holes across suspect area to determine viable thermal gradients; if viable area found, then, 2) drilling of a ‘slim hole’ to validate thermal gradient; if a viable gradient is found, 3) extending the slim hole to penetrate the reservoir; and if a viable reservoir is found, 4) re-drilling the slim hole to full diameter production well or drilling new production sized well.

7-2.4.3 Transmission Development.

Initiate detailed utility transmission and interconnect requirements analysis and feasibility studies with grid owners. Refer to Chapter 8 titled “UTILITY INTERCONNECTION” for guidance.

7-2.4.4 Phase II Findings.

Generate a *Possible Resource* capacity estimate and a *Possible Installed Capacity Estimate* specifically used for the financial evaluation for plant’s geothermal power production. Identify any initial potential project issues associated with local communities, transmission, sites, environmental, and any other applicable issue area.

Use Phase II findings create an outstanding issues cost/risk/benefit matrix to support a project go/no-go decision before proceeding to Phase III.

7-2.5 Phase III Permitting and Initial Development.

This phase results in a Delineated Resource Estimate and Delineated Installed Capacity Estimate for the geothermal resource and the power plant.

7-2.5.1 Permit Applications and Contracts.

Obtain applicable drill permit(s) for one full size production well. Start initial plant permit applications and Power Purchase Agreements (PPA). Developer to determine financing avenues to meet PPA requirements.

7-2.5.2 Resource Development.

The size and cost of a steam gathering system is affected by site topography, slope stability, steam field size and spread, and resource temperature and pressure. Locate production and injection well(s) to optimize reservoir recharge capacity. Injecting spent (cooled) geothermal liquid too close to a production well may locally cool the reservoir and subsequent production. Injecting spent geothermal liquid too far from the project well(s) may not sufficiently replenish the reservoir and steam pressure may decline.

Drill one full size production well with sufficient bottom hole temperature and flow rates for a commercial size geothermal well (3-5 MW gross equivalence). Drill one full size injection well capable of recharging the geothermal resource. Size production and injection well to allow the equivalent of at least 20% of proposed plant capacity. Use the production and injection well flow and thermal data to characterize the overall geothermal resource fluid flow and sustainable capacity.

7-2.5.3 Transmission Development.

Complete an interconnection feasibility Study and System Impact Study (SIS) to determine connection requirements. Request the utility to start the interconnection facility study to address the steps, equipment, and facilities required to connect to the grid. The developer shall submit the transmission service request to permit power transmission.

7-2.5.4 Phase III Findings.

Generate a *Delineated Resource Estimate* and a *Delineated Installed Capacity Estimate* specifically used to revise the Phase II financial evaluation for plant's geothermal power production. Identify any additional potential project issues associated with local communities, transmission, sites, environmental, and possible resolutions.

Use Phase III findings create an outstanding issues cost / risk / benefit matrix to support a project go / no-go decision to proceed with project approval, contactor selection and award, and before proceeding to Phase IV activities.

7-2.6 Phase IV Resource Production and Power Plant Construction.

This phase results in a *Confirmed Resource Estimate* and *Confirmed Installed Capacity Estimate* for the geothermal resource and the power plant. At Phase IV, activities shift primarily to selected contactor activities.

7-2.6.1 Resource Development.

The selected contractor finalizes plant design; begins production well(s) development; and plant construction starts.

7-2.6.2 Transmission Development.

Complete interconnect requirements analysis and feasibility studies. Obtain signed interconnection agreement with utility.

7-2.6.3 Permitting and Contracts.

Finalize PPA terms and conditions; plant construction permits approvals, and contract to design-build power plant, remaining production wells, steam gathering system, transmission lines, and remaining infrastructure to initial final design and construction.

7-2.6.4 Phase IV Findings.

Generate a *Confirmed Resource Estimate* and a *Confirmed Installed Capacity Estimate* specifically used for the financial evaluation for plant's geothermal power production. Identify any additional potential project issues associated with local communities, transmission, sites, environmental, and possible resolutions.

7-3 DESIGN CRITERIA.

7-3.1 General Design Requirements.

Comply with UFC 1-200-01. Geothermal power plant designs typically include:

- Site civil engineering;
- Well development;
- Steam enhancement and cleaning;
- Turbines;
- Condensing, gas ejection and cooling systems;
- Distributed control systems (DCS);
- Piping, valves and power island blowout preventer (BOP);
- Electric power generation and plant support systems;
- Electrical cabling, substation, and high voltage power interconnection; and
- Supporting structures consisting of turbine/generation building, black start generation, emission monitoring, gatehouse and security spaces, administrative and maintenance spaces, and fire pump house.

7-3.1.1 Layout.

The facility is to be designed with the concept of providing efficient operations and maintenance activities throughout the facility life. The design process must include a general configuration of all proposed buildings and structures, piping runs, wellheads, roads, parking and paved areas, as well as drainage features and any associated retention basins during site development / construction, and long term operation stages. Layout site to minimize footprint while protecting equipment and electrical systems from steam vetting to reduce equipment corrosion. If cost effective, consider redundant systems to allow O&M actions while maintaining operations.

The facility roadway system design must provide a traffic pattern allowing simultaneous traffic to both enter and exit the facility, and allow unencumbered travel of vehicles in both directions throughout the facility.

7-3.1.2 Materials.

Geothermal fluids are corrosive. All materials used will be selected for durability and longevity for their respective environments and in compliance with local architectural standards. As a minimum, the facility structure will be of concrete or steel construction with factory finished coating system steel exterior wall surfaces or architectural masonry. Use metal roofing, sloped for drainage. Exterior personnel doors will be galvanized insulated core steel with window lights and security systems, where appropriate. Overhead doors will be galvanized steel. Windows will be insulated double pane glass with insulated aluminum jambs. Floor finishes will be selected based upon safety and use.

All open grate working platforms, open grate stairs, ladders, ladder cages, and handrails at the exterior are to be galvanized steel coated after fabrication. Where steel components are exposed to corrosive materials, use coating systems that are specifically resistant to the corrosive materials.

7-3.2 Well Development.

Geothermal well development is very similar to oil / gas well development. Use drillers licensed for the location and have experience with large diameter geothermal wells. Size well casings for function (conductor, surface, intermediate, production), flow, and working pressure. Use static seals with no external energizing. Ensure the design accommodates casing expansion without restricting flow. The design shall allow installation before the casing cementing process to allow for alignment and casing reciprocation during cementing. Provide blowout prevention and other safety equipment as required for hazard classification. See “GEOTHERMAL POWER GENERATION” in Appendix B for drilling and materials best practices.

Specify pipe according to well conditions, fluid chemistry, and depth. Wells will have multiple casing materials; for example, two separate, 3 mi (5 km) deep, enhanced geothermal EGS wells have the following material characteristics, as shown in Table 73.

Table 7-3 Example EGS Well Material Design

Well Depth (km/mi)	Casing Schedule	Material	Depth (m/ft.)	Casing Length (m/ft.)	Hole Diameter (cm/in)	Casing Diameter (cm/in)
EGS#1 5 / 3.1	Conductor Pipe	Welded wall	24 / 79	24 / 79	91.4 / 36	76.2 / 30
	Surface Casing	Welded wall	381 / 955	381 / 955	71.1 / 28	55.8 / 22
	Intermediate Liner	K-55 Premium	1524 / 5000	1204 / 3950	50.8 / 20	40.6 / 16
	Production Casing	T-95 Premium	3999 / 13120	3999 / 13120	37.4 / 15	29.8 / 12
	Production Slotted Liner	K-55 Buttress	4999 / 16400	1061 / 3480	26.3 / 10-1/2	21.9 / 8-5/8
EGS#2 5 / 3.1	Conductor Pipe	Welded wall	30 / 98	30 / 98	106.6 / 42	91.4 / 36
	Surface Casing	Welded wall	381 / 1250	381 / 1250	81.2 / 32	71.1 / 28
	Intermediate Liner #1	K-55 Premium	1524 / 5000	1204 / 3950	66.0 / 26	55.8 / 22
	Intermediate Liner #2	K-55 Premium	3048 / 10000	1280 / 4200	50.8 / 20	40.6 / 16
	Production Casing	T-95 Premium	3999 / 13120	3999 / 13120	36.2 / 14-1/4	29.8 / 12
	Production Slotted Liner	K-55 Buttress	4999 / 16400	1061 / 3480	23.0 / 9	21.9 / 8-5/8

7-3.3 Steam Enhancement and Cleaning.

Evaluate geothermal fluid chemical characteristics and select equipment materials tailored to reduce corrosion characteristics. Evaluate and account for non-condensable gases (NCG) removal, such as hydrogen sulfide (H_2S) and carbon dioxide (CO_2). NCG reduces plant efficiencies due to equipment parasitic loads and NCG accumulation in the condenser leads to a higher turbine outlet pressure and a lower power output per unit of steam.

Use centrifugal or cyclone type steam separator designed for site specific geothermal fluids. Evaluate separator location to optimize plant performance and life cycle costs. Locations include adjacent to wells to reduce two phase liquid piping losses between the well and turbine, or near the turbines to reduce piping losses and allowing more brine to flash to steam.

7-3.4 Turbines.

Select turbines with materials specifically designed for site specific geothermal fluid, and to minimize and protect against dissolved gases, impurities, and water droplets corrosive effects.

7-3.4.1 Materials.

Require corrosion resistance treatment, such as Stellite alloy and induction treatment, to increase blade and turbine life.

7-3.4.2 Condensate Removal.

Require turbines have excessive condensate removal systems to reduce water droplet erosion.

7-3.4.3 Valves.

Require fast closing inlet valves for system emergency shutdown. Require low fouling or scaling valves to reduce potential closure failures.

7-3.4.4 Seals.

Evaluate and select shaft seals designed for simplicity, long life, and maintainability.

7-3.5 Condensing, Gas Ejection and Cooling Systems.

Use vacuum pump systems to extract NCG from the condenser to maintain condenser efficiency. Design H_2S systems to comply with location specific environmental, health and safety requirements and laws. Ensure sufficient contingency capacity is included in NCG systems. The amount and type of H_2S abatement required varies considerably and is dependent upon the reservoir characteristics. NCG concentration and the corresponding H_2S concentration may vary dramatically from reservoir to reservoir and from well to well within the same reservoir. H_2S removal systems include exhausting, thermal oxidation to covert to sulfur dioxide (SO_2), and solid (example iron) and liquid scavengers. Evaluate and select environmentally viable removal systems, including consumables and disposal costs, for best life cycle cost.

Evaluate air or water cooling / condensing system based upon environmental considerations, resource availability, and life cycle costs. Water-based cooling systems have higher heat transfer rates than dry air. Water based systems include direct contact condensers where both the cooling water and steam are combined and sprayed in the condenser; once through condensers using surface water source; and wet cooling towers. Dry type cooling towers have significantly less thermal rejection efficiency and water based systems. Use of dry type cooling towers will increase project costs by 10-20%, but may be only solution for sites with inadequate water supplies, strict water use regulations, or extremely low ambient conditions which causes water tower drift to freeze on surrounding surfaces and plants. Ensure the safety control and valve system prevents condenser backflow into the turbine.

7-3.5.1 Piping, Valves and Blowout Preventer.

Piping system designs must be robust to handle brine, two-phase liquids, steam, and entranced debris. Accommodate thermal expansion, condensate collection and disposal, slug flow, erosion from and elimination of entrained debris, and elevation induced pressure issues. Evaluate life cycle cost between use of corrosion resistant materials (stainless/alloys) or corrosion resistive coatings on lower cost carbon steel.

7-3.5.1.1 Two-Phase Fluids.

Minimize two-phase piping lengths to reduce pressure losses. Upslope two-phase piping design is not allowed as it encourages slugging. Evaluate brine line saturation pressure to ensure the brine will not flash into steam and create two-phase conditions.

7-3.5.1.2 Insulation.

Insulate piping to reduce thermal gradient and energy loss between the piped geothermal fluids and the ambient air.

7-3.5.1.3 Pipe Loading.

Evaluate gravity loads for piping on long slopes. Analysis of areas near support anchors is especially important to ensure pipe design strength is sufficient to resist buckling.

7-3.5.1.4 Valves.

Select valve for specific service (e.g. steam, brine, water). Valve designed to minimize seal and operations issues from deposits. Provide seats with upstream and downstream metal-to-metal seals. Provide adjustable packing glands. Provide an overpressure rupture disk, or similar, for over pressurization protection. Free passage design for minimum pressure drop and turbulence. Select body material and overlays, such as Stellite alloy, for corrosion protection.

7-3.5.1.5 Blowout Preventer.

Provide either an annular or a ram type blowout preventer, with accumulator operating system, selected for pipe size and pressure rating in accordance with State and Federal regulations.

7-3.5.1.6 Standards.

Comply with ASME B31.1, ASME B31.3, API Spec 6A and ANSI B16.34.

7-3.6 Pumps.

Select pumps for specific service: e.g. steam, brine, temperature, flow, and pressure.

7-3.7 Heat Exchangers.

Evaluate preheater and vaporizer heat exchanger layout for increased efficiency on binary plants. Select material for specific service conditions and working fluids.

7-3.8 Working Fluids (Organic Motive Fluids).

For binary plants, select organic motive fluid formulations to cost effectively maximize the plant power output for site specific thermodynamic characteristics.

7-3.9 Distributed Control System (DCS).

Install a Distributed Control System consisting of an open standards software with programmable logic controllers for expandability, self-diagnostics, and backup modules. Include data points monitoring flows, pressures and temperature changes, vibration, fluid levels, control valves status, and equipment status. Minimum human interface requirements include plant systems diagrams, trend graphs, control loop diagrams, alarm events with time stamping for fault analysis, and logic monitoring. H_2S corrodes copper; ensure mounted control component are sealed (NEMA 4X). Ensure sensors contacting geothermal fluid are stainless steel rated for the fluid's chemistry.

No direct communications with any DoD installation network is allowed unless system is certified through the DoD Information Assurance Certification and Accreditation Process and receive an Approval to Operate certificate. All Internet Connection Sharing (ICS) networks must be certified and have approval to operate regardless if they are connected the DoD NIPR network or not.

7-3.10 Electrical Systems.

7-3.10.1 General.

The electrical system for the plant will be a unit type system with the utility transformers connected solidly to the generator bus and switched with the generator.

7-3.10.2 Utility Interconnect.

Comply with the requirements of Chapter 8 of this UFC.

7-3.10.3 Generator.

Provide totally enclosed, synchronous generator sized for continuous operation directly connected to steam turbine. Generators up to 60 MW are to be air cooled. Coordinate output characteristics with ITO/RTO and local utility. Comply with UFC 3-540-01.

7-3.10.4 Synchronizing Switchgear.

Provide a substation on the facility site of a modern, fenced, low-profile design, and complete with bus duct connection between generator switchgear and facility step-up transformer. All the electrical equipment is to be protected from electrical fault damage by protective relays. The substation is to operate over the range from import of full station auxiliary power requirement to export of full net plant real and reactive power capability to the transmission system while maintaining standard operating voltage limits on the facility buses.

7-3.10.5 Plant Electrical System.

Provide a complete electrical system of medium-voltage, low-voltage, and DC power to all loads in the power plant under all service conditions including start-up, operation, failures, and shutdown. Provide unit substations with parallel step down transformers between the medium voltage and low voltage systems.

7-3.10.6 Plant Critical Loads.

Plant critical loads to operate off the low system include:

- Fire Pumps;
- Fire Jockey Pumps;
- Uninterruptable Power Supply(ies);
- DC Power System and Battery Chargers;
- Cooling Water Pumps;
- Hydraulic Pumps;
- Critical Lubrication Systems;
- Elevators; and
- Emergency Lighting.

7-3.10.7 DC System.

Provide a DC power system, with UPS, to provide for an orderly facility shutdown in the event of a loss of normal power. The DC power is to conform to the requirements of UFC 3-520-05.

7-3.10.8 Emergency Power System.

Provide an emergency power system for operating the plant critical loads in the event of a loss of normal power.

7-3.10.8.1 Uninterruptable Power Supply (UPS).

Provide a UPS system for the following critical loads:

- Fire alarm system;
- Mass notification system;
- Telecommunications system;
- Security systems;
- Plant distributed control system; and
- Critical instrumentation.

7-3.10.8.2 Generator.

Provide natural or diesel gas generator(s) if natural gas is not available, sized to handle the plant critical loads and an N+1 redundancy.

7-3.10.8.3 Transfer Switches.

Use automatic, bypass/isolation, overlapping neutral type transfer switches.

7-3.10.8.4 Fuel Storage.

If using diesel gas generator(s), provide a minimum fuel storage for operating at full emergency power for 5 days.

7-3.10.9 Lighting.

Lighting is to conform to UFC 3-530-01 and NECA/IESNA 502-2006.

7-3.10.10 Grounding/Lightning Protection System.

Grounding and lightning protection systems are to conform the following: IEEE C2, IEEE 142, NFPA 70, NFPA 780, and UFC 3-575-01.

7-3.10.11 Communications and Signal Systems.

Comply with UFC 3-580-01.

7-3.11 Project Planning Considerations.

Appendix D provides listing of factors to consider during the design. Tailor as appropriate for project scope.

7-4 COMMISSIONING.

7-4.1 Commissioning.

Create and execute a commissioning plan for geothermal and supporting systems in accordance with manufacturer's recommendations. Demonstrate all routine and emergency operations, and start-up and recovery actions. Include the following systems/sub-components in the commissioning plan, as a minimum:

- Supply/Return: blowout preventer, pumps, valves, meters and controls, and emergency shutdown;
- Plant: heat exchanger, turbine, generator, condenser, NCG scrubber, cooling tower, water storage, water treatment, pumps, valves, meters and controls, and emergency shutdown; and
- Transmission: transformer, switches, meters, and controls.

7-4.2 Measurement and Verification (M&V).

Develop and execute a M&V plan to evaluate plant performance throughout the life of the plant. Include the following systems/sub-components in the M&V plan, as a minimum, to verify plant and subsystems are operating within design parameters:

- Supply and injection;
- Plant heat exchanger, turbine, generator, cooling tower, condenser; and
- Electrical transmission.

Ensure M&V report provides summary analysis showing design flows, operating parameters, energy production verses design model (guaranteed production); actions taken to correct findings, and future improvement recommendations.

7-4.2.1 First Year.

Complete a full M&V during plant startup and at the end of the first full year after the plant reaches full operational capability, but no later than the end of the warranty period to identify and document production / warranty issues. Review results verses stated objectives and take appropriate actions to resolve unsatisfactory conditions. Perform system components baseline measurements and verify against plant design and component operating parameters. Perform mass and energy analysis to verify modeled performance verses actual flows and energy production.

Ensure the M&V report provides summary analysis showing design flows, operating parameters, energy production verses design model (guaranteed production), actions taken to correct findings, and future improvement recommendations.

7-4.2.2 Annual Measurement and Verification.

Review previous M&V reports and perform an annual M&V to evaluate plant performance and trends verses model and contract requirements. Identify trends and areas of concern, generate corrective actions, and create / update future improvement plant recommendations.

7-5 OPERATIONS AND MAINTENANCE.

7-5.1 Operations and Maintenance.

Minimum plant O&M requirements for plant equipment and material are those necessary to meet warranty and life expectancy requirements. Ensure all equipment O&M and warranty materials are collected and consolidated into a comprehensive O&M guide for review before plant operations start. Ensure plant operations procedures include compliance requirements for data collection and report generation, e.g. injection reports, production reports, blowout preventer inspections, annual water resource management plan updates, and monitoring and preventive actions to address corrosion and scaling concerns.

7-5.2 Contract Based Operations and Maintenance.

In contractor owned / operated enterprises, payments are based upon power delivered ($/megawatt-hour). Plant operations to meet all applicable local, State, and Federal operating permits. Ensure the Contractor provides all plant operation and maintenance necessary for contract compliance; and the Contract requirements include collecting recurring data and report generation necessary for permit(s) compliance, e.g. injection reports, production reports, blowout preventer inspections, annual water resource management plan updates, and monitoring and preventive actions to address corrosion and scaling concerns.

7-5.3 Safety.

Comply to applicable provisions in 29 CFR 1910, 29 CFR 1925, and 29 CFR 1926, and local/agency codes and requirements.

7-5.3.1 Non-Performance.

Ensure non-performance and remedy clauses are in maintenance contract to address non-conformance. Ensure liquidated damages address loss of power generation revenue and mission impacts.

7-5.3.2 Warranties.

Specific component warranties will vary with manufacturer. Warranties are typically limited to repair or replace, at manufacturers’ discretion, the defective components, or assemblies. Warranty limits may include causes for materials, supplies, and equipment not manufactured or supplied by the manufacturer, unauthorized repairs or modifications, Acts of God, and incidental or consequential damages.

CHAPTER 8 UTILITY INTERCONNECTION

8-1 INTRODUCTION.

This chapter provides the requirements and general procedures for utility interconnection as well as describes processes for plant performance.

8-1.1 Federal Energy Regulatory Commission (FERC) Rules.

Comply with the applicable FERC rule / standard when connecting a generator to a transmission system. Coordinate with local transmission and interconnection services provider for specific procedures in accordance with the provider's pro forma Open Access Transmission Tariff.

8-1.1.1 Standardization of Generator Interconnection Agreements and Procedures.

This encompasses interconnections greater than 20 MW. For additional information, the latest issue of Order No. 2003 can be referenced herein: http://www.ferc.gov/industries/electric/indus-act/gi/stnd-gen.asp

8-1.1.2 Standardization of Small Generation Interconnection Agreements and Procedures.

This encompasses interconnections of 20 MW or less. For additional information, the latest issue of Order No. 2006 can be referenced herein: http://www.ferc.gov/industries/electric/indus-act/gi/small-gen.asp

8-1.2 Non-FERC Standards.

Refer to the Interstate Renewable Energy Council's (IREC) interconnection standard for specific Level 4 procedures not subject to FERC. Comply with utility company current standards.

Comply with all the requirements of IEEE Std 1547. This standard addresses the interconnection technical and testing requirements necessary for electrical systems to operate under normal conditions without degradation. Prior to interconnection, provide proper documentation and certifications detailing all generation equipment, installation, operation, and maintenance compliance with IEEE Std 1547.

8-2 INTERCONNECTION REQUEST.

Contact the local transmission and interconnection services provider for the specific process to request interconnecting with the utility. The form requests information, such as project size, proposed point of interconnection, technical data and evidence of site control. A monetary deposit is usually associated with application request.

8-3 SYSTEM STUDY REQUIREMENTS.

After the initial interconnection request is submitted, it is appropriate for the transmission provider to perform a series of studies to ensure electrical power system safety and reliability by performing a feasibility study, system impact study, and facility study. Refer to IEEE Std 1547 for guidance on studies required based upon distributed generation and utility grid feeder characteristics.

8-3.1 Feasibility Study.

The feasibility study and scope will be based upon information set forth in interconnection request to transmission provider. The purpose of this study is to identify potential undesirable system impacts resulting from interconnection before additional studies are performed.

8-3.2 System Impact Study.

If any impact is identified from the feasibility study, a system impact study is then performed. The purpose of this study is to assess the impact of interconnection on the electrical system reliability, without any modifications.

8-3.2.1 Existing Infrastructure.

Maximize the use of existing infrastructure where appropriate in order to help minimize environmental and cultural impacts.

8-3.2.2 Planned System Modifications.

Consult the utility provider for any associated fees or additional studies required for planned system modifications needed for interconnection.

8-3.2.3 Load Flow Analysis.

Determine if the existing transmission facility is adequate to carry the additional generation reliably.

8-3.2.4 System Protection.

Refer to utility provider for specific requirements on types and models of equipment to ensure the proper operation, equipment compatibility, and stability of system.

8-3.2.5 Communications.

Consult with the utility provider for requirements of voice and data communications required for monitoring, recording, and transferring essential data.

8-3.2.6 Metering.

Refer to utility provider for functional specifications and design for the metering equipment. Comply with the local utility company's metering requirements as well as the OUSD (AT&L) Utilities Metering Policy as detailed in the following website http://www.acq.osd.mil/eie/IE/FEP_Policy_Program_Guidance.html and DoDI 4170-11 Installation Energy Management.

8-3.2.7 Other Considerations.

In addition to utility provider specific considerations, consider system upgrade costs, system security, contingency, and generation type.

8-3.3 Facility Study.

The facility study is performed to determine specific equipment and necessary modifications required to complete the interconnection. Also, associated costs and schedule for installation or upgrades are developed.

8-4 CONNECTION OPTIONS.

The generation facility's physical connection to the utility provider's transmission system can be accomplished by one of two types: station type or line type connection. The particular connection type will be determined by installation's location within the transmission system. Select the connection type using life cycle cost analysis and discussions with utility provider. Once the connection typed is determined, the generation facility can constructed to operate in parallel with the utility provider or as a detached system.

8-4.1 Station Type Connection.

In a station type connection, the generation facility is connected to an existing substation with direct lines and circuit breakers. Proper design and coordination is necessary in determining amount of lines and corresponding circuit breakers. Comply with specific utility provider guidelines for connection design.

8-4.2 Line Type Connection.

In a line type connection, the generation facility is connected to an existing transmission line with new transmission lines and a new switching station. Comply with specific utility provider guidelines on switching station configuration and design.

8-4.3 Parallel / Non-Parallel Connection.

In parallel connection, the generation equipment is connected to the utility's system bus and is operating in parallel with the utility's electric system. Comply with specific utility provider guidelines on parallel generation connection accommodations.

In non-parallel connection, there is no simultaneous connection between the generation equipment and the utility's electric system. Use a transfer switching arrangement to allow load shifting between the two systems in an open, or non-parallel, mode.

8-5 DESIGN REQUIREMENTS AND CONSIDERATIONS.

The following requirements and considerations apply to parallel operation and synchronization to the transmission system.

8-5.1 Voltage Requirements.

Design generation equipment to operate within the utility provider's established threshold.

8-5.2 Power Factor Requirements.

Coordinate with the utility provider on specific lagging/leading power factor ranges required at the interconnection point. If required by utility provider, consideration of supplying reactive power must be taken when in parallel connection to maintain desired power factor range.

8-5.3 Power Quality Requirements.

Comply with the following power quality requirements.

8-5.3.1 Voltage Flicker.

Generation equipment is not to cause voltage flicker exceeding the term limits specified in IEEE Std 1453.

8-5.3.2 Harmonic Distortion.

Comply with harmonic limits specified in the most recent revision of IEEE Std 519.

8-5.3.3 Communication Interference.

The total communication interference not to exceed the levels specified in IEEE Std 519.

8-5.4 Frequency Requirements.

When connecting to the utility, frequency deviations may be expected and can effect an entire interconnection. The system operating frequency to operate at the utility provider system nominal frequency range.

8-5.5 Abnormal Frequency Operation.

Provide frequency sensing equipment required to protect all generation equipment and facility during abnormal frequency operation.

8-5.6 Generator Step Up (GSU) Transformer Configuration.

Comply with the utility provider's specific protection, metering and operating requirements for parallel generation.

8-5.7 Induction Generator Unique Requirements.

Installing capacitors for reactive power supply at or near an induction generator can significantly increase self-excitation. During planning and design, verify the need by a system analysis. Refer to TSWEG TP-2 for additional information if power factor correction is considered.

8-5.7.1 Low Voltage Ride Through (LVRT) and Low Frequency Ride Through (LFRT).

Comply with IEEE Standard 1547. Voltage and frequency stability analysis studies system oscillations and is required when adding distributed generation into a system. Stable voltage and frequencies are primary concerns for transmission systems; therefore, this study must be performed prior to design completion because modifications of the proposed system may be required. The drop in voltage caused by reactive power deficiencies in the system are a severe concern. Generator rotor angle instability is also a cause of voltage instability. The most extreme instability is complete voltage collapse. Sudden changes in generation or load may result in system frequencies deviating from their normal ranges.

LVRT and LFRT Analysis involve the study of a distributed generation system's ability to continue after faults or disturbances in the system require wind turbines, PV systems, or small generators to drop off the system. Some generators use electricity to generate a magnetic field in order to function. If the voltage drops, these generators will drop off line. Synchronous machines will slip their frequency if the stator voltage drops significantly. If additional generation or load trips due to voltage or frequency disturbance, it has a potential to amplify the disturbance when more and more units rapidly fall off the line. This analysis determines which units will drop off, and if they will remain off or automatically restart. If the analyses show an issue, an engineered solution has to be designed to dampen or modulate voltage / frequency disturbances. Design renewable generation plants with LVRT and LFRT capability and adhere to applicable ISO / RTO standards or criteria. Coordinate with the utility provider in determining required clearing times.

8-5.8 System Grounding.

Comply with the requirements of IEEE Std 142.

8-5.9 Transient Stability.

Coordinate with the utility provider for specific criteria related to generator transient stability performance.

8-5.10 Excitation Control.

The excitation control system response ratio to conform to the latest edition requirements of ANSI Standard C50.13. Conform to applicable utility provider requirements.

8-5.11 Speed Governing.

Comply with the requirements of UFC 3-540-01 for generator speed governing systems.

8-5.12 Automatic Generation Control.

Coordinate with the utility provider for specific guidance and provisions.

8-5.13 Black Start Capability.

Depending upon the geographic location and other considerations, the utility provider may request generator black start capability in the event of a blackout. Coordinate with the utility provider for black start requirements.

8-5.14 Sub-Synchronous Torsional Interactions or Resonance.

Conform to the utility provider guidance and appropriate controls to eliminate damaging torsional oscillations resulting from voltage variations.

8-5.15 Metering.

All utility metering equipment shall conform to IEEE Std 1547. Refer to utility provider for specific metering, SCADA and communications requirements. Coordinate with the Base Operating Support (BOS) group for specific activity requirements or preferences and obtain approval from the AHJ for communication systems that enable remote access.

8-5.16 Transmission Line Design.

Transmission line design shall conform to the requirements in UFC 3-550-01. Determine the interconnection point and construct new transmission lines in accordance with utility provider criteria.

8-5.17 Protective Devices and Coordination.

All utility grade protective devices to conform to ANSI/IEEE Std C37.90. Prior to implementation, obtain utility provider approval for the selective coordination of overcurrent protective devices. Refer to IEEE Std 242 for guidance concerning coordinated power system protection.

8-5.17.1 Special Considerations.

Discuss with and determine the utility provider's specific protective devices specifications and installation requirements. Ensure protective relays are able to sense ground faults and automatic reclosing protection conforms to IEEE Std C37.60. Coordinate specific transformer zero sequence impedance requirements and generator under-frequency protection with NERC mandated automatic load shedding protection settings.

8-6 SUBSTATION EQUIPMENT.

Refer to IEEE Std 1613 for specific regulations governing the installation of substation equipment. If substation is utility-owned, obtain pertinent design information of utility-owned equipment to facilitate requirements for downstream equipment.

8-7 SCADA REQUIREMENTS.

8-7.1 General Requirements.

Refer to 18 CFR Part 35 and utility provider for general SCADA requirements and procedures. In addition, refer to applicable DoD directives concerning information assurance requirements for intelligence community (IC) systems. SCADA is to be equipped to monitor and report the location of a fault in any panel in a solar PV system.

8-7.1.1 Hardware.

Refer to utility provider guidance on approved interface equipment, communication, and hardware requirements for remote terminal unit (RTU) installations.

8-7.1.2 Revenue Metering Data.

Coordinate revenue metering requirements with the utility provider regarding interconnection-specific data.

8-7.2 Data Requirements.

Coordinate with the utility provider on determination of data and control points assignment / list and requirements. The RTU contains input/output functions to handle analog and digital data.

8-7.3 Supervisory Control Requirements.

Coordinate with the utility provider on requirements regarding supervisory control capability and responsibility.

8-8 TRANSMISSION OPERATIONAL REQUIREMENTS.

Coordinate the transmission operational requirements with utility provider based upon NERC and applicable RTO / ISO reliability standards. These requirements will be factors for interconnection including, but not limited to, in-service coordination, NERC registration, normal operating voltage schedule, and planned outage schedule.

APPENDIX B BEST PRACTICES AND REFERENCE INFORMATION

B-1 BEST INDUSTRY PRACTICES.

B-1.1 Solar Power Generation.

Solar Energy Industry Association website, http://seia.org provides information on best practices.

B-1.2 Wind Power Generation.

American Wind Energy Association website, http://www.awea.org provides information on best practices.

Additional best practices:

B-1.2.1 Site selection:

- Average wind speeds above 6 m/s (13.5 mph)
- Coordination with utility company for capacity, connections, and connection costs
- Site access constraints
- Investment (funding) approach

B-1.2.2 Environmental:

- Visual aspect and impact on important public viewpoints.
- Proximity to dwellings due to noise, shadow flicker, visual domination and reflected light.
- Ecology to include protected species found in the area either seasonally or year round. May require an Environmental Management Plan during construction and operation.
- Presence of archaeological and historical heritage artifacts may affect acceptability of a site.
- Impact on close recreational areas should be considered.
- Baseline hydrological assessment, where considered appropriate.
- Use a three step approach, 1) preliminary site assessment; 2) detail assessment requirements from local planning authority; 3) detailed assessment execution.
- Site selection discussion and rationale:
- Visual and landscape assessment. Create “zone of visual influence.” Consider sun motion and reflections.

- Noise assessment. Characterize current background noise level and provide sound level predictions.

B-1.2.3 Dialogue.

- Initial discussion and coordination with local planning authorities to identify and address potential issues to address.
- Communications plan for local planning authority and community awareness, and feedback.
- Create economic impact details, short (construction) and long (maintenance) impacts, and renewable energy impact.

B-1.2.4 Technical.

- Telecommunications. Existing systems may be affected. Coordinate with owners.
- Air Traffic. Local air traffic authorities must be consulted.
- Secured Areas: Proximities to restricted security areas should be evaluated.
- Testing. Local planning authority permission for and use of anemometers for detailed wind measurements at favorable sites. Duration of not less than 6 months and in some cases more than 1 year.
- Existing Land Uses. Discussions with landowner for best integration between land use and wind farm to include locations and access roads.
- Ground Conditions. Examine if construction areas and access is feasible. Investigate previous land uses and infrastructure for incompatibility.
- Site Access. Consult local authorities on impact of large and heavy goods movement over public and private roads and what improvements are required. Sharp turns and steep gradients may limit materials access.
- Electrical Connection. Connection to the grid can vary significantly by site. The local utility company can give information about likely connection points and connection costs.
- Draft Project Design. Create draft design showing potential number and size of turbines for use during initial project consultations.
- Safety. Assessment on tower integrity verses intended site; layout to avoid shadow flicker on roadways.

- Electrical Connections. Addressing land use and environmental impact of new transmission lines should run parallel with the wind farm development.

B-1.2.5 Operations.

- Complaint System. Owner has formal system for recording and addressing concerns.
- Accessibility: Owner/owner representative is accessible to the public for issues and status updates.

B-1.2.6 Decommissioning.

- Decommissioning. Initial site planning assessment to address decommissioning and site restoration.

B-1.3 Waste to Energy Power Plant.

The Energy Recovery Council website, www.wte.org, provides information on benefits of waste to energy plants.

B-1.4 Landfill Gas Power Generation.

The Environmental Protection Agency Landfill Methane Outreach Program, (http://www.epa.gov/lmop/index.html), provides best practices presentations and LFG project development guidance.

B-1.5 Geothermal Power Generation.

The Geothermal Energy Association website, http://geo-energy.org, provides information on best practices: http://geo-energy.org/reports/Geothermal%20Best%20Practices%20Publication%20Final%20CL188154847.pdf

B-1.6 Utility Interconnections.

Contact ISO/RTO Council members (http://www.isorto.org/pages/home) for North American Independent System Operators/Regional Transmission Organization requirements and best practices.

B-1.7 Policies and Incentives.

The Database of State Incentives for Renewables & Efficiency (DSIRE®) website (http://www.dsireusa.org/) provides a convenient summary of renewable energy policies and incentives.

General Federal and State “regulatory roadmap” flow charts are available for reference only at OpenEI (http://en.openei.org/wiki/Main_Page). Use of reference materials does not relieve designer from compliance with current laws and policies.

APPENDIX C PROJECT PLANNING CHECKLISTS

C-1 INTRODUCTION.

Use/adapt the example project questionnaire from the U.S. Department of Energy FEMP Guidance Developing *Renewable Energy Projects Larger than 10 MWs at Federal Facilities* to assist project planning.

- http://www1.eere.energy.gov/femp/pdfs/large-scalereguide.pdf

For geothermal projects, adapt the *Geothermal Regulator Roadmap* to create project development checklist or use commercial the following project development checklist, based upon project phase.

- http://en.openei.org/wiki/RAPID/Roadmap/Geo

C-2 GEOTHERMAL POWER DEVELOPMENT CHECKLIST.

Summarized from www.geo-energy.org terms and definitions.

Phase I – Resource Procurement and Identification	
Resource Development - meet at least two of the following criteria; and	
Y/N	Literature Survey Complete
Y/N	Geologic Mapping Completed, Geophysical and Geochemical Sample Sites Identified
Y/N	Geochemical and geophysical surveys in progress
Transmission Development - complete the following criteria; and	
Y/N	Internal transmission analysis complete
External Development - complete all of the following criteria to be considered Phase I.	
Y/N	Land or lease acquired
Y/N	Permitting process for exploration drilling (TGH, slim holes) underway

A completed Phase I level project will have two capacity estimates: a Possible Resource Estimate (estimated total subsurface geothermal resource energy value) and a, Possible Install Capacity Estimate (estimated installed capacity, in MW).

Phase II – Resource Exploration and Confirmation	
Resource Development - meet at least one of the following criteria; and	
Y/N	Temperature Gradient Holes (TGH) Drilled
Y/N	Slim Hole Drilled
Y/N	One Full Size Discovery Well Drilled
Transmission Development - meet at least one of the following criteria; and	
Y/N	Interconnection application submitted and queue position established
Y/N	Transmission feasibility studies underway
External Development - complete at least one of the following criteria to be considered Phase II.	
Y/N	Permit for Slim Hole Drilling Applied for or Approved
Y/N	Permit for Production Well Drilling Applied for or Approved

A completed Phase II level project will have two refined capacity estimates: a Possible Resource Estimate; and a, Possible Install Capacity Estimate.

Phase III – Permitting and Initial Development	
Resource Development - meet at least two of the following criteria; and	
Y/N	At least one full size production well drilled and operational
Y/N	At least one full size injection well drilled and operational
Y/N	Reservoir characterization completed and sustainable reservoir capacity determined
Transmission Development - meet at least two of the following criteria; and	
Y/N	Interconnection feasibility study complete
Y/N	System impact study (SIS) underway or complete
Y/N	Interconnection facility study underway
Y/N	Transmission Service Request Submitted (if appropriate)
External Development - complete at least two of the following criteria to be considered Phase III.	
Y/N	Plant permit application complete or in process
Y/N	Power purchase agreement secured or in negotiation
Y/N	Financing secured, or being secured, for portion of project construction

A completed Phase III level project has two refined capacity estimates: a Delineated Resource Estimate and a Delineated Install Capacity Estimate.

Phase IV – Resource Production and Power Plant Construction	
Resource Development - meet at least two of the following criteria; and	
Y/N	Majority of plant equipment on order
Y/N	Plant construction underway
Y/N	Production and injection drilling underway. 50% of geothermal resource confirmed.
Transmission Development - meet at least two of the following criteria; and	
Y/N	Interconnection Agreement Signed
Y/N	Transmission System Service Request studies completed
External Development - complete all of the following criteria to be considered Phase IV.	
Y/N	Plant permit(s) approved
Y/N	EPC contract signed
Y/N	PPA secured

A completed Phase IV level project have two refined capacity estimates: a Confirmed Resource Estimate and a Confirmed Install Capacity Estimate.

APPENDIX D PROJECT DESIGN PLANNING

D-1 INTRODUCTION.

Address areas and tailor as applicable for energy source.

D-1.1 Physical Space Requirements.

- Operation and maintenance space.
- Cooling system space.
- Fuel storage space.
- Ventilation (cooling air intake and exhaust).
- Electrical panels, transfer switches, control panel spaces.
- Exhaust system space and silencer location.
- Starting system (electrical/air start).
- Collection piping and infrastructure.
- Transmission infrastructure.
- Site access.

D-1.2 Power Rating.

- Design to power requirement.

D-1.3 Start Times.

- Maximum time to start and be ready to assume load, including black start and emergency application, and procedures.

D-1.4 Emissions.

- Exhaust gas composition and particulate limits.
- Condensates and ash.
- Noise. Equipment and total plant.
- Thermal (air/water).
- Odors.
- Visual vapors (steam, water).

D-2 ELECTRICAL.

D-2.1 Generator and Inverter.

- Electrical load (kVA) – facility loads plus loads e.g. fans, fuel pumps, lighting, and battery charging.
- Motor starting kVA.
- Nonlinear loads and effect on generator rating.
- Power factor.
- Turbine/engine-generator application – single set / parallel.
- Frequency bandwidth (steady state).
- Frequency regulation maximum – no load to full load.
- Voltage regulation – no load to full load.
- Voltage bandwidth – steady state.
- Frequency – 50/60 Hz.
- Voltage – output volts.
- Phases – 3 phase, wye / delta, single phase.
- Max step load increase – kVA.
- Transient recovery time – seconds (voltage and frequency).
- Maximum voltage deviation (transient).
- Maximum frequency deviation – Hz.

D-2.2 Protection.

- Subtransient reactance – percent (minimum).
- Switchgear/breaker size, location, characteristics, enclosure.

D-2.3 Automatic Transfer Switch.

- Sizing, controls, transfer options.
- Coordination of ground fault protection (four-pole/three pole).
- In-phase protection for large motors downstream of transfer switch.
- Define sequence of operation "Upon loss of normal power…" Define load shedding, motor starting sequence, if required, multiple generator operation, method of return to normal power (time delays).

D-2.4 Starting System and Operation Controls.

- Black start requirements.
- System operational controls and emergency shutdown.

D-2.5 Additional Circuits

- Pumps, pumps, heaters, piping heat-trace, cooling towers, cranes, conveyors, cathodic protection.

D-2.6 Grounding.

- System Grounding.
  - Grounding Electrode System.
  - Bonding.
  - Ground Fault Protection.
  - Transient Voltage Surge Suppression.
- Equipment Grounding.
  - Component Grounding.
  - Electronic Equipment Grounding.
- Generator grounding - ungrounded, solidly-grounded, impedance-grounded.
- Substation Grounding
  - Safety Criteria and Exposure Mechanisms.
  - Soil Parameters.
  - Surfacing.
  - System Parameters.
  - Ground Grid Design.
  - Fence Grounding.
- Static and Lightning Protection Grounding.
- Testing Criteria and Methodology.

D-2.7 Lighting.

- Normal lighting.
- Emergency lighting.
- Outdoor enclosure lighting (access for controls).

D-2.8 Communications.

- Equipment authority to operate certificates.

D-3 MECHANICAL.

D-3.1 Engine.

- Installation elevation above sea level (derating).
- Maximum speed (rpm).
- Fuel consumption/flow.
- Starting system.
- Ambient temperature extremes (HVAC, derating).
- Vibration limitations.
- Ancillary equipment.

D-3.2 Fuel System.

- Fuel level controls.
- Fuel transfer pump.
- Supply line/return line routing.
- Pressure.
- Flow (CFM, tons/hour, GPM).

D-3.3 Lube-Oil System.

- Integral to equipment.
- External to equipment.
- Space and provision for changing the oil.

D-3.4 Governor.

- Type.
- Frequency bandwidth (steady state).
- Frequency regulation maximum – No load to full load.

D-3.5 Cooling.

- Heat exchanger location (local/remote).
- Cooling system design (local/remote heat exchanger)

- Maximum summer outdoor temperature (ambient).
- Minimum winter outdoor temperature (ambient).
- Cooling medium (e.g., glycol/water, raw water).

D-3.6 Plant Climate Control.

- Cooling capacity.
- Maximum summer indoor temperature.
- Minimum winter indoor temperature.
- Heating capacity.

D-3.7 Generator Controls.

D-3.8 Exhaust System.

- Insulated / non-insulated.
- Silencer.
- Scrubbers.
- Penetration.
- Exhaust considerations: flappers, gooseneck, bird-screen, rain shields.

D-3.9 Sound Limitations

- OSHA, State, City Ordinances, Post/Base regulations.
- Mechanical noise mitigation (interior/exterior). Baseline monitoring.
- Combustion-air intake noise mitigation (interior/exterior).
- Exhaust noise mitigation (exterior).
- Posting of signage - Hearing Protection Required.

D-3.10 Safety.

- Guarding of mechanical hazards.
- Posting of signage for equipment which may auto-start.
- Insulation of hot equipment.
- Enclosure of electrical hazards.
- Fall protection.

D-4 CIVIL/STRUCTURAL.

- Seismic zone design compliance. Baseline monitoring.
- Vibration isolation.
- Foundation, house-keeping pads.
- Wind turbine site and structure, ASCE/AWEA RP2011, Chapter 9.

D-5 ARCHITECTURAL.

- Code and compatibility compliance.
- Bird nesting prevention.
- Climate specific corrosion resistance materials.

APPENDIX E O&M CRITERIA AND TIMING

E-1 MAINTENANCE CATEGORIES.

Maintenance falls under two categories, preventive maintenance, and predictive maintenance.

E-1.1 Preventive Maintenance.

Preventive, or time-based, maintenance is based upon equipment manufacturer's recommendations; supplemented by local knowledge.

E-1.2 Predictive Maintenance.

Predictive, or condition-based, maintenance activities are based upon feedback analysis from sensors placed on or in the equipment. The goal of predictive maintenance is to allow for advanced parts ordering, scheduling work, and planning for the repair-refurbish activities. An effective predictive maintenance program will minimize unplanned outages and maximize equipment power generation. A predictive maintenance program for critical components will dramatically reduce the threat of sudden and unexpected failures in these components, and the overall system.

E-2 O&M CRITERIA

Base O&M upon specific site requirements, available resources, and installed equipment. Obtain equipment specific training and certifications, such as those provided by manufactures or a nationally accredited program, for personnel maintaining systems. Use equipment manufacturer's recommended O&M guidelines and the following information to assist in developing O&M practices for applicable energy systems. Table E-1 provides a sample checklist.

E-2.1 Solar PV.

Use *Solar Access to Public Capital (SAPC) Working Group Best Practices in PV System Operations and Maintenance* Version 1.0, March 2015, as a reference for the O&M program (http://www.nrel.gov/docs/fy15osti/63235.pdf).

Table E-1 Sample Solar PV O&M Procedures

MAINTENANCE PROCEDURES	General Inspection	
Required Maintenance Actions	**Frequency**	**Crew Size**
Perform regular system monitoring, review system reports, respond to system alarms, and re **Travis McLeod, P.E.** Vice President port system failures based on severity level.	Daily	1
Check for insect and rodent infestation.	Monthly	1
Clean all equipment items from dust buildup.	Monthly	1
Clean all debris.	Quarterly	1
Ensure roof penetrations are watertight.	Semi-annual	2
Check for new vegetation growth or other shade items.	Semi-annual	1
Check for ground erosion near footings.	Semi-annual	1
Confirm proper signage is in place.	Semi-annual	1
Confirm electrical enclosures are secured and accessible to authorized personnel only.	Semi-annual	1
Check for corrosion on enclosures and mounting system.	Semi-annual	1
Check for low hanging wiring.	Semi-annual	1
Check for animal infestation.	Semi-annual	1
Perform site visits.	Semi-annual	2
Check all the system conduits, junction boxes, and connections for damage.	Semi-annual	2

MAINTENANCE PROCEDURES	PV Modules	
Required Maintenance Actions	**Frequency**	**Crew Size**
Inspect for defects such as delamination, broken glass, burn marks, cracking, and discoloration.	Semi-annual	2
Clean PV modules using demineralized water.	Semi-annual	2
Check for loose or exposed wiring.	Semi-annual	2
Test voltage / current through wires and PV modules.	Semi-annual	2
Check for shading by trees, objects, facilities around modules.	Semi-annual	1
Inspect components for moisture.	Annual	2

MAINTENANCE PROCEDURES	Mounting System/Support Structure	
Required Maintenance Actions	**Frequency**	**Crew Size**
Check array structure mechanical security.	Quarterly	2
Inspect for defects such as corrosion, missing or broken clips/bolts, rust, and corrosion.	Semi-annual	2
Check integrity of all penetrations.	Semi-annual	2
Grease actuator gears and filling hydraulic fluid on track components, if applicable.	Semi-annual	2
Make seasonal tilt adjustments, if applicable.	Semi-annual	2
Check proper alignment on tracking components, if applicable.	Semi-annual	2

MAINTENANCE PROCEDURES	Combiner Box	
Required Maintenance Actions	**Frequency**	**Crew Size**
Re-torque all connections. Repair or replace the cabling, if applicable.	Semi-annual	1
Check for debris and water intrusion inside of enclosure.	Annual	1
Check status of breakers/fuses.	Annual	1
Check for switch blockage or obstruction. Clean switch contacts.	Annual	1

MAINTENANCE PROCEDURES	Disconnect Switch	
Required Maintenance Actions	**Frequency**	**Crew Size**
Perform visual inspection.	Bi-annual	1
Inspect, operate, adjust, and lubricate mechanical linkages. Replace components as required.	Annual	2
Verify operation of mechanical interlocks.	Annual	2
Inspect and dress current carrying contacts in accordance with manufacturer's recommendations.	Annual	2
Perform insulation resistance test using a megohmeter of each critical load switch.	Annual	2
Perform contact resistance test on each critical load switch.	Annual	2
Perform thermal imaging of modules, inverters, and combiner boxes while under resistive load.	Annual	1
Repair enclosure rust spots and paint if needed.	3 years	1
Inspect the base and mounting for loose bolts and insecure or inadequate support and tighten.	3 years	1
Clean and inspect ventilators, replace as needed.	3 years	1
Check bolts on the buses and splices for manufacturer's recommended torque.	3 years	2
Inspect insulators for chipped or broken porcelain, excessive dirt film, and tracking; clean as necessary; replace broken insulators; tighten base and cap bolts.	3 years	2
Verify space heater operation or operate continuously to overcome thermostat malfunction.	3 years	2
Ensure the main switch blades are proper seated in the contacts; operate the switch several times and see that blades are properly aligned to engage contacts; clean contact surfaces if corroded; lubricate; tighten bolts and screws.	3 years	2
Check pressure springs in contact and hinge and replace, if not adequate; replace flexible shunts, if frayed.	3 years	2
Confirm that blade latches, where provided, are engaged; check latches for proper engaging and holding blade against opening force. See that stops are in place and tight.	3 years	2
Check for condition, alignment, and proper operation of arc chutes and interrupter device.	3 years	2
Adjust mechanism and linkage for adequate contact	3 years	2

closure and over travel; lubricate.		
Check and tighten bolts, screws, and locknuts; see that rods, levers, and cranks are in serviceable condition and repair as necessary; lubricate pivot points and bearings.	3 years	2
Check gears and bearings; flush out oil or grease and re-lubricate.	3 years	2
Check motor operation and Megger®; check adjustment of brake.	3 years	2
Check condition of contacts and refinish with fine file if burned or corroded; check contact springs, operating rods, and levers; check closing and opening positions with respect to main switch contacts, travel, or motor mechanism.	3 years	2
Check functional test of door and interlocks for proper sequence.	3 years	2
Lubricate switch disconnect studs and finger clusters (if drawout type) unless manufacturer's instruction says otherwise.	3 years	2
Clean and inspect cable terminations and connections for surface tracking; check connections for correct tightness.	3 years	2
Check calibration of meters (if applicable).	3 years	2
Check fuse clips for adequate spring pressure and proper fuse rating.	3 years	2
Check base and operating handle ground connections; see that ground cable is not broken.	3 years	2
Evaluate and make necessary repairs on potential, current, and control transformers.	3 years	2
Confirm that switch operating hot sticks are in good condition and are kept in a dry place; inspect hot sticks for damage and deterioration; discard suspect switch operating hot sticks; test hot sticks per requirements under FIST Volume 4-1B, section 25.	3 years	2
Review equipment ratings.	5 years	1

MAINTENANCE PROCEDURES	Inverter	
Required Maintenance Actions	**Frequency**	**Crew Size**
Verify proper operation of cooling fan. Remove debris from fan and filter.	Monthly	1
Conduct visual inspection (interior and exterior)	Quarterly	1
Inspect heat sink for debris. Check for debris and water intrusion inside enclosure.	Semi-annual	1
Re-torque all connections. Inspect all connections and replace damaged wiring.	Semi-annual	1
Inspect enclosure door seal and replace, if damaged.	Semi-annual	1
Verify installed software is current.	Annual	1

E-2.2 Wind Power Generation.

Use AWEA *Operations and Maintenance Recommended Practices*.[1] This manual presents recommendations for gearboxes, generators, rotors/blades, towers, data collection and reporting, balance of plant, warranty, and condition monitoring. Use ASCE/AWEA RP2011, Chapter 10, for structure inspection criteria.

E-2.3 Waste to Energy Power Plant.

Require builder to provide equipment manufacturers' recommended operation and maintenance practices for installed equipment. Use recommended operation and maintenance practices to generate O&M checklist and frequency. See Chapter 6 for typical waste to energy power plant equipment.

E-2.4 Landfill Gas Power Generation.

Require builder to provide equipment manufacturers' recommended operation and maintenance practices for installed equipment. Use equipment manufacturers' recommended practices to generate O&M procedures and frequency checklist for installed equipment.

Recommended documentation may include:

[1] http://www.awea.org/oandm

- Daily reading and log sheets;
- Individual extraction well logs
  - Individual monitoring probe logs
  - Regulatory monitoring data logs
  - Generator operation parameters
- Records of gas or electricity sold;
- Maintenance schedules per manufacturer's recommendation and frequency;
- Record of maintenance performed and parts used;
- Consumables, lubricant and chemicals used; and
- Equipment calibration records.

E-2.5 Geothermal Power Generation.

Require builder to provide equipment manufacturers' recommended operation and maintenance practices for installed equipment. Use equipment manufacturers' recommended practices to generate O&M procedures and frequency checklist for installed equipment. Installed equipment may include:

- Blowout preventer(s);
- Separator(s);
- Valves;
- Pipe lines; steam/brine supply and re-injection system;
- Heat exchanger including pre-heater, vaporizer and recuperator exchanger;
- Turbine and accessories;
- Generator and accessories;
- Condenser;
- Auxiliary systems (e.g. compressors, pumps, HVAC, fire, cooling systems, drainage systems, detecting systems);
- Control system(s);
- Electrical components (e.g. switch gears, bus bars, transmission lines); and
- Emergency stand by diesel generator.

Table E-2 provides a sample inspection checklist:

Table E-2 Sample Geothermal O&M Checklist

Daily
• Check for system warnings, correct and clear as necessary.
• Check generator, turbines, gearbox, pipes, feed pump and oil pumps for vibrations, noise or oil leaks, repaired as necessary
• Check/record power output and compare against design/historical for trend
• Adjust the settings to operate within set parameters
Weekly
• Record flows and power output, and compare against design point values. Adjust/bleed condenser air to operate within set parameters.
• Check oil levels; fill as necessary. Replace oil as manufacturer's recommended frequency.
• Verify proper operation of control valves.
• Inspect for vibrations of turbine, generator gearbox and feed pump.
• Check valve shafts and feed pump mechanical seal for leaks.
Monthly
• Check valve shafts and pump seals for leaks.
• Check the oil ring in the bearing housings visually.
• Check battery(s)
• Check for hot spots in the power and control cabinets
• Clean strainers
• Replace filter elements
• Grease all motors and couplings according to manufacturer's instructions.
Semi-Annual
• Perform monthly inspection actions.
• Tighten all construction bolts.
• Check for leaks (use a leak detector).
• Verify tightness of all power terminals and cables.
• Grease all electrical motors and couplings.
• Change gearbox oil check oil, perform oil analysis.
Annual
• Perform 6-month inspection actions.
• Check feed pumps shut-off pressure.
• Perform equipment maintenance as required by manufacturer.
• Check turbine/gearbox alignments, correct if required.
• Replace oil in lubrication system(s).
• Check for leaks.
• Calibrate gages and transducers.

• Check/repair contractors.
• Replace filters in the hydraulic block.
• Check/adjust lubrication systems.

Two Years
• Perform annual inspection.
• Perform internal turbine inspection
• Test pump performance; check and repair feed pumps mechanical seals.
• Perform manufacturer’s generator and gearbox preventive maintenance.
• Visual inspect supply and re-injection pipe, exchangers, for scaling/pitting; repair as necessary.

This Page Intentionally Left Blank

APPENDIX F COST PLANNING

F-1 CREST

NREL website provides the comprehensive renewable energy 'Cost of Renewable Energy Spreadsheet Tool' (CREST) for solar, wind, and geothermal renewable energy systems. Models are located at https://financere.nrel.gov/finance/content/crest-cost-energy-models. Use these models for preliminary project evaluations.

F-1.1 Landfill Gas

For landfill gas projects, perform simple payback analysis.

F-1.2 Geothermal

For geothermal projects, use Table F-1 planning factors, or more current, if available, in project payback analysis.

Table F-1 Example 50 MW Geothermal Power Plant Planning Factors

Phase	Subfactors	Installed Cost*
Field Work and Power Plant Planning Factor		$3-5,000+ / kW
Example 50MW Plant	Resource Identification	<1% of total cost, ~ $14/kW
	Resource Evaluation	8% of total cost, ~ $300/kW
	Test Well	5% of total cost, ~ $169/kW
	Production Wells	38% of total cost, ~ $1,376/kW
	Plant Construction	49% of total cost, ~ $1,800/kW
Operations and Maintenance Planning Factor		$0.01-0.03 / kWh

*Installed costs is highly dependent upon drilling costs, which, in turn, is affected by drilling activity supporting oil and gas exploration, especially shale fracking, as it uses the same type drilling equipment.

wc	water column
WTE	waste to energy
yd^3	cubic yard

G-2 DEFINITIONS OF TERMS

3D Seismic Tomography: Uses seismic waves produced by explosives or vibrators to produce a 3D image. Common in oil and gas industries.

Aeromagnetics: Detects subsurface magnetic fields from aerial flights. Detects demagnetization from low temperature geothermal alteration. Much of US already surveyed.

Controlled Source Audio-Frequency Magnetotellurics (CSAMT): Similar to MT, but uses a man-made signal source. CSAMT has significantly less depth range than MT, at less than two miles (1.6 km).

DC Resistivity, Electrical Resistivity, Schlumberger, Vertical Sounding (VES): Uses electrical currents to measure resistivity/conductivity. Effective depth is proportional to distance between electrodes.

Energy Resilience: The ability to prepare for and recover from energy disruptions that impact mission assurance on military installations.

E-Scan: Proprietary DC method.

Gravity: Measures gravitational field to determine subsurface rock density.

Induced Polarization (IP): Uses direct current residual conductivity measurements. May be difficult to interpret.

Magnetotellurics (MT): Measures subsurface electricity created by naturally occurring magnetic fields. Indirectly detects temperature and permeability patterns. Can measure several miles deep and can be used to develop 3D images.

Paleomagnetics: Laboratory based measurement of magnetic field variations (rotation) in rock samples to determine crust dilations use to predict possible geothermal.

Time Domain Electromagnetics (TDEM or TEM): Uses manmade magnetic field to determine subsurface conductivity. TDEM has less distortion than other electrode based techniques.

Self-Potential (SP): Uses electrodes to measure natural subsurface electrical potentials. Useful when shallow groundwater flow is of interest

Synthetic Aperture Radar (InSAR): Uses changes in data from two separate flights, on two different dates, to detect subsidence or inflation between flight dates. Changes may indicate volume changes caused by reservoir pumping, or cooling of rock.

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	23 Mar 2017	Removed reference to IEEE C57.12.22 and updated reference to IEEE C57.12.34 in section 3-5.1 and Appendix A references.
2	13 Mar 2019	Section 1-3 and Appendix A revised for cybersecurity requirements. Section 1-4 Cybersecurity added. Added the clarification Notes to section 2-2, 3-4, 3-5.1, 3-6.1, and Appendix A. Section 3-5 Pad-mounted transformer revised Section 3-10.9 Sectionalizer added. Section 3-10.10. Ground Connections revised. Section 3.11.6 Locating Underground Structures revised. Revised section 3-14.2.1. Appendix A added references to IEEE Guides mitigating bird and wildlife-related power interruptions.
3	01 Nov 2019	Added Environmental Severity Classification and humidity design requirements and updated corrosion prevention requirements in 1-3.1, Appendix A and Appendix D.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: 3-550-01, *Exterior Electrical Power Distribution*

Superseding: UFC 3-550-01, *Exterior Electrical Power Distribution*, dated Feb 3, 2010, including Change 1, dated Jul 1, 2012.

Description: This UFC 3-550-01 provides design guidance for the design of exterior distribution systems.

Reasons for Document:

- Provide technical requirements.
- Incorporate new and revised industry standards.

Impact: There are negligible cost impacts associated with this UFC. However, the following benefits should be realized.

- Standardized guidance has been prepared to assist engineers with unique installation requirements.
- Exterior electrical equipment design criteria are specified to ensure that a reliable installation is realized.

Unification Issues:

The Air Force has the following noted exceptions:

- Paragraph 3-11.5.1 Permits use of pad-mounted sectionalizing cabinets instead of manholes.
- Paragraph 3-11.5.2 Prohibits T splices and Y splices on any MV system.
- Paragraph 3-11.5.5 Does not permit manholes in aircraft aprons.

The Navy has the following noted exceptions:

- Paragraph 3-2.3 Requires 600V insulated neutral conductor in pole riser and ductbanks.
- Paragraph 3-7 Requires switchgear to be SF-6 gas or high fire point liquid insulated.
- Paragraph 3-11.8 Does not permit concentric neutral conductors in ductbanks.
- Paragraph 3-11.8 Requires EPR insulation for MV cables.

TABLE OF CONTENTS

FIGURES

CHAPTER 1 GENERAL

1-1 PURPOSE.

This UFC provides policy and guidance for design criteria and standards for electrical power and distribution systems. The information provided here must be utilized by electrical engineers in the development of the plans, specifications, calculations, and Design/Build Request for Proposals (RFP) and must serve as the minimum electrical design requirements. It is applicable to the traditional electrical services customary for Design-Bid-Build construction contracts and for Design-Build construction contracts. Project conditions may dictate the need for a design that exceeds these minimum requirements.

UFC 3-501-01 provides the governing criteria for electrical systems, explains the delineation between the different electrical-related UFCs, and refers to UFC 3-550-01 for exterior electrical system requirements. Refer to UFC 3-501-01 for design analysis, calculation, and drawing requirements.

1-2 APPLICABILITY.

The design criteria and standards contained within are the minimum requirements acceptable for military installations for efficiency, economy, durability, maintainability, and reliability of electrical power supply and distribution systems. The criteria and standards herein are not intended to be retroactively mandatory.

1-2.1 NFPA 70 and IEEE C2.

Comply with the requirements of NFPA 70 and IEEE C2. Generally, IEEE C2 is the basis for UFC 3-550-01 and NFPA 70 is the basis for UFC 3-520-01. However, there are exceptions to which standard applies to each UFC, including:

- Systems covered by other UFCs, such as airfield lighting and shore power systems.
- Exterior circuits such as lighting and service entrance (overhead and underground), which are covered by NFPA 70.

For medium voltage applications, feeder conductor sizing is permitted to be determined by qualified persons under engineering supervision as defined by NFPA 70 Article 215.2 (B) (3), *Supervised Installations*.

1-2.2 Additional References.

Comply with UFC 3-560-01 for electrical safety requirements applicable to the installation and operation of electrical systems.

Comply with UFC 4-010-01 and UFC 4-020-01 for security requirements related to exterior electrical distribution systems.

1-2.3 Exclusions.

Onsite generation is not addressed by this UFC.

1-3 GENERAL BUILDING REQUIREMENTS.

2\ Comply with UFC 1-200-01, *DoD Building Code (General Building Requirements)*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, physical security, cybersecurity, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFC and government criteria referenced therein.

1-3.1 \3\ Environmental Severity and Humid Locations.

In corrosive and humid environments, provide design detailing, and use materials, systems, components, and coatings that are durable and minimize the need for preventative and corrective maintenance over the expected service life of the component or system. UFC 1-200-01, section titled "Corrosion Prone Locations" identifies corrosive environments and humid locations requiring special attention. UFC 1-200-01, section titled "Requirements for Corrosion Prone Locations" provides examples of necessary actions. To determine Environmental Severity Classifications (ESC) for specific project locations refer to UFC 1-200-01 Appendix titled "Environmental Severity Classifications (ESC) for DoD Locations". /3/

1-4 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06 and as required by individual Service Implementation Policy.

Cybersecurity is implemented to mitigate vulnerabilities to all DoD real property facility-related control systems to a level that is acceptable to the System Owner and Authorizing Official. UFC 4-010-06 provides requirements for integrating cybersecurity into the design and construction of control systems. /**2**/

1-5 CRITERIA WAIVER PROCESS.

The criteria waiver process is provided in MIL-STD 3007.

1-6 REFERENCES.

Codes and standards are referenced throughout this UFC. The publication date of the code or standard is not routinely included with the document identification throughout the text of the document. In general, the latest issuance of a code or standard has been assumed for use. Refer to Appendix A to determine the publication date of the codes and standards referenced in this UFC.

1-7 UTILITY-OWNED AND OPERATED DISTRIBUTION SYSTEMS ON FEDERAL PROPERTY.

This UFC does not apply to:

- Utility-owned and operated distribution systems with right-of-way or easements on Federal property.
- Military installations that have privatized their electrical distribution system.

CHAPTER 2 ELECTRICAL POWER REQUIREMENTS

2-1 ELECTRICAL POWER REQUIREMENTS: GENERAL.

Virtually all military bases have an existing overhead and underground distribution system that has been in service for many years. As part of any new design project, review the existing design with base personnel to determine which existing features should not be duplicated in future designs. Address design preferences with responsible engineering and operations personnel as part of the system design analysis.

2-2 SELECTION OF PRIMARY VOLTAGE.

NEMA C84.1 establishes typical voltages and voltage ranges for 60 Hz systems.

Facilities located outside of the United States must also comply with the applicable host nation standards; refer to UFC 1-202-01 and UFC 3-510-01 Foreign Voltage and Frequencies Guide (inactive), for additional information.

2-3 DESIGN FOR MAINTENANCE.

Design primary distribution system equipment installations with future periodic maintenance as a principal consideration. Equipment must be capable of removal from service while minimizing the outage time of affected facilities and missions. Looped and alternate feed designs are essential to allow periodic maintenance.

Provide maintenance criteria with the design analysis as part of the basis for the design as specified in UFC 3-501-01.

This Page Intentionally Left Blank

CHAPTER 3 DESIGN CRITERIA

3-1 MAIN AND UTILIZATION ELECTRIC SUPPLY STATIONS.

For all main and electric supply stations/substations, comply with the requirements of IEEE C2 Part 1, *Rules for the Installation and Maintenance of Electric Supply Stations and Equipment*, as follows:

- Electric Supply Stations are defined as stations that transform the energy level (voltage) for further bulk distribution at medium voltage levels.
- Comply with the requirements of NFPA 70 for the low voltage equipment in a main or electric supply station (equipment that is being served from a Utilization Electric Supply Station).

3-1.1 Main Electric Supply Stations.

The main electric supply station is the installation/utility interface point where further transmission, distribution and utilization of electrical power, the monitoring and control of such power or equipment and the protection of electrical equipment or systems usually becomes the sole responsibility of the Government or their contracted representatives. Coordinate the design of new stations, or modifications to existing stations with the supplying utility and with any other suppliers or users of power supplied through the station.

3-1.2 Utilization Electric Supply Stations.

Utilization Electric Supply Stations are defined as equipment such as pole or pad-mounted transformers, secondary unit substations, or primary unit substations that transforms the energy level (voltage) to a utilization voltage for consumer use. Some examples of Utilization Electric Supply Stations are station service transformers (serving low voltage equipment in a Main Electric Supply Station), a lighting transformer (serving equipment for a roadway lighting system), a pole or pad-mounted transformer (serving a building), or a secondary unit substation (serving piers and wharfs electrical systems)

3-2 GENERAL ELECTRICAL REQUIREMENTS.

Refer to Appendix C for Best Practices-General Electrical Power Requirements.

3-2.1 Industry Standards.

Overhead systems – comply with the requirements of IEEE C2 Part 2, *Safety Rules for the Installation and Maintenance of Overhead Electric Supply and Communication Lines*.

Underground systems – comply with the requirements of IEEE C2 Part 3*, Safety Rules for the Installation and Maintenance of Underground Electric Supply and Communication Lines*.

3-2.2 Arc Flash Analysis Criteria.

Refer to UFC 3-560-01 Section 1-4.1.1 for arc-flash criteria and the delineation points between IEEE C2 and NFPA 70E conformance requirements.

3-2.3 System Design.

Design new primary distribution systems as four wire, multi-grounded systems that are wye connected at the source transformer. Provide a system grounded neutral conductor throughout the system. Provide a bare conductor for the neutral on overhead systems.

Note: For the Navy, provide a neutral that is a 600 volt insulated conductor for pole riser and underground systems.

When a project is limited to connecting to an existing three wire system and the primary electrical characteristics are established and defined, continuation of the existing system is permitted with the following requirements:

- For extensions from underground structures, provide a four wire extension. Bond the grounded neutral conductor at each end of the extension to the applicable grounding electrode systems.
- For extensions from overhead pole lines, provide a four wire extension. Bond the grounded neutral conductor at each end of the extension to the applicable grounding electrode systems.

Note: Design of the extensions as four wire systems does not change any circuit classifications. It provides an extended grounding electrode system to facilitate any future circuit conversions to four wire systems.

3-2.4 Pad-Mounted Equipment.

Provide pad-mounted equipment foundation pads and ensure a minimum of 10 ft (3 m) clear workspace in front of pad-mounted equipment for hot stick work. Orient equipment so that adjacent equipment will not interfere with the clear workspace. Provide bollards in areas where equipment is subject to vehicular damage.

3-3 PRIMARY UNIT SUBSTATIONS.

Provide primary unit substations to distribute underground medium voltage circuits. Comply with the following industry standards as applicable for the specified configuration:

- IEEE C37.06, *AC High-Voltage Circuit Breakers Rated on a Symmetrical Basis – Preferred Ratings and Related Required Capabilities*.
- IEEE C37.46, *High Voltage Expulsion and Current-Limiting Type Power Class Fuses and Fuse Disconnection Switches*.

- IEEE C37.121, *Switchgear – Unit Substations Requirements*.
- IEEE C57.12.28, *Pad-Mounted Equipment – Enclosure Integrity*.
- IEEE C57.12.00, *General Requirements for Liquid-Immersed Distribution, Power, and Regulating Transformers*.
- IEEE C57.12.80, *Terminology for Power and Distribution Transformers*.
- IEEE C57.12.90, *Test Code for Liquid-Immersed Distribution, Power, and Regulating Transformers*.
- IEEE C57.96, *Loading Dry-Type Distribution and Power Transformers*.
- IEEE C57.98, *Guide for Transformer Impulse Tests*.
- IEEE C37.74, *IEEE Standard Requirements for Subsurface, Vault, and Padmounted Load- Interrupter Switchgear and Fused Load-Interrupter Switchgear for Alternating Current Systems up to 38 kV*.

3-4 SECONDARY UNIT SUBSTATIONS.

Provide secondary unit substations when secondary currents exceed 3,000 amperes at 1,000 volts and below. Comply with the following industry standards as applicable for the specified configuration:

- IEEE C57.12.28, *Pad-Mounted Equipment – Enclosure Integrity*.
- IEEE 57.12.50, *Ventilated Dry-Type Distribution Transformers, 1 to 500 kVA, Single-Phase, and 15 to 500 kVA Three-Phase, with High-Voltage 601 to 34,500 Volts, Low-Voltage 120-600 Volts*.
- IEEE 57.12.51, *Ventilated Dry-Type Power Transformers, 501 kVA and larger, Three-Phase, with High-Voltage 601 to 34,500 Volts, Low-Voltage 208Y/120 to 4160 Volts*.
- IEEE C57.12.00, *General Requirements for Liquid-Immersed Distribution, Power, and Regulating Transformers*.
- IEEE C57.12.01, *General Requirements for Dry-Type Distribution and Power Transformers Including Those with Solid-Cast and/or Resin-Encapsulated Windings*.
- IEEE C57.12.80, *Terminology for Power and Distribution Transformers*.
- IEEE C57.12.90, *Test Code for Liquid-Immersed Distribution, Power, and Regulating Transformers*.
- IEEE C57.12.91, *Test Code for Dry-Type Distribution and Power Transformers*.
- IEEE C57.96, *Loading Dry-Type Distribution and Power Transformers*.
- IEEE C57.98, *Guide for Transformer Impulse Tests*.

- IEEE C57.124, *Detection of Partial Discharge and the Measurement of Apparent Charge in Dry-Type Transformers*.

3-5 PAD-MOUNTED DISTRIBUTION TRANSFORMERS.

3-5.1 Reference Criteria.

Comply with the following industry standards:

- IEEE C57.12.28, *Pad-Mounted Equipment – Enclosure Integrity*.
- IEEE C57.12.00, *General Requirements for Liquid-Immersed Distribution, Power, and Regulating Transformers*.
- **1**\\IEEE C57.12.34, *Pad-Mounted, Compartmental-Type, Self-Cooled, Three-Phase Distribution Transformers, 10 MVA and Smaller High-Voltage, 34.5 kV Nominal System Voltage and Below; Low-Voltage, 15 kV Nominal System Voltage and Below*. /**1**/
- IEEE C57.12.80, *Terminology for Power and Distribution Transformers*.
- IEEE C57.12.90, *Test Code for Liquid-Immersed Distribution, Power, and Regulating Transformers*.
- IEEE C57.98, *Guide for Transformer Impulse Tests*.

3-5.2 Configuration.

Use dead-front construction for pad-mounted transformers unless not available within system parameters.

Three-phase pad-mounted transformers must be loop-feed capable with 6 bushings. Provide two-position, oil-immersed, load break switches that are appropriate for the application. If the transformer might be used as part of a loop-feed design, provide three switches to permit closed transition loop feed and sectionalizing. If the transformer will be installed at the end of a radial supply with no intention of future loop feed capability, provide a single on-off switch. Provide a spare conduit in the high voltage section extending 5 ft (1.5 m) out from the transformer pad.

3-5.3 Size and Secondary Voltage.

Do not use pad-mounted transformers with secondary currents exceeding 3,000 amperes because of the size and quantity of secondary conductors. Transformers rated above 1,000 kVA serving 208Y/120 volt loads and above 2,500 kVA serving 480Y/277 volt loads must be in a secondary unit substation configuration.

Minimize double transformations to reduce energy consumption and to minimize items of equipment. Provide two \2\liquid/2/-filled pad-mounted transformers in lieu of one 480Y/277 volt service if the required 208Y/120 volt load using dry-type transformers exceeds 40 percent of the 480 volt service transformer capability. Connect equipment at the highest available voltage to minimize the capital cost and energy losses of transformation equipment.

3-5.4 Winding Configuration.

Provide \2\step-down/2/ delta-wye \2\grounded connections and step-up grounded wye-wye/2/ connections for three phase systems.

3-5.5 Surge Protection.

Provide bushing-mounted elbow type arresters at the ends of all radials and in normally open locations in loops. Provide arresters for all voltage levels above 5 kV.

3-5.6 Drawing Details.

When using a pad-mounted transformer, select the applicable pad-mounted transformer detail in AutoCAD or PDF format from: http://www.wbdg.org/ccb/NAVGRAPH/graphtoc.pdf , supply the missing data, and incorporate that detail onto the contract drawings. Pad-mounted transformer details are contained in the UFGS 26 27 14.00 20 Electricity Metering file. These drawing details represent typical situations but may not meet all requirements. Modify transformer details as required to indicate the actual requirements for each particular installation.

In rare cases when “live front construction” is required due to equipment ratings (available system fault current values), obtain approval from the Authority Having Jurisdiction (AHJ), as defined in UFC 1-200-01. Do not use the pad-mounted transformer details to show secondary unit substations.

3-6 MEDIUM VOLTAGE SWITCHGEAR.

3-6.1 Metal-Clad Switchgear.

Metal-clad switchgear can include either SF6 or vacuum style breakers and must consist of a single section or multiple section line-up of NEMA 1 or NEMA 3R enclosures. Either walk-in or non-walk-in construction can be provided. Medium voltage metal-clad switchgear can be provided as unit substation construction or as stand-alone switchgear. The sections must contain the breakers and the necessary accessory components. The equipment must be factory-assembled (except for necessary shipping splits) and be operationally checked before shipment. As an electrical safety consideration, provide a remote racking mechanism to rack breakers in and out. As an electrical safety consideration, provide ground ball studs on the load side of each circuit breaker to allow for connection of temporary grounding sets.

Comply with the following industry standards:

- IEEE C37.06, *AC High-Voltage Circuit Breakers Rated on a Symmetrical Current Basis – Preferred Ratings and Related Required Capabilities*.
- IEEE C37.121, *Switchgear – Unit Substations Requirements*.

- IEEE C37.04, *Rating Structure for AC High-Voltage Circuit Breakers Rated on a Symmetrical Current Basis*.
- IEEE C37.20.2, *Metal-Clad Switchgear*.
- IEEE C37.90, *Relays and Relay Systems Associated with Electric Power Apparatus*.

3-6.2 Metal-Enclosed Switchgear.

Do not use metal-enclosed switchgear. Instead, use either a vacuum fault interrupter (VFI) in a unit substation configuration or pad-mounted switchgear.

3-6.3 Circuit Breaker Operation Design.

Provide batteries with battery charger for dc opening and closing of circuit breakers. Do not use ac or capacitor control methods.

3-7 PAD-MOUNTED SWITCHGEAR (SWITCHES).

For the Navy, utilize multi-way pad-mounted switchgear when switching, isolation, or electrical protection is required. Specify SF6 gas or high fire point liquid (non-temperature dependent) insulation technology and vacuum bottle interruption technology. Specify dead front construction with stainless steel tanks and operator full size viewing windows for each switching way. Specify three position (On/Off/Ground) switch ways for all new construction. For switch replacements when existing switching arrangement is On/Off/Tie, a similar arrangement without ground position is permissible. Specify switch design which incorporates operating handles on the opposite side of the tank from the cable entrance bushings, terminations and cables. Specify 600 ampere dead break connectors with 200 ampere interface bushings for each switch way. Coordinate with the Activity and include ground fault circuit indicators in accordance with the base design standard. Air-insulated (fused or non-fused) technology is not permitted. Comply with the following industry standards:

- IEEE C57.12.28, *Pad-Mounted Equipment – Enclosure Integrity*.
- IEEE C37.60, *Requirements for Overhead, Pad-Mounted, Dry Vault, and Submersible Automatic Circuit Reclosers and Fault Interrupters for Alternating Current Systems Up to 38 kV*.
- IEEE C37.74, *IEEE Standard Requirements for Subsurface, Vault, and Padmounted Load- Interrupter Switchgear and Fused Load-Interrupter Switchgear for Alternating Current Systems up to 38 kV*.

For the Army and Air Force, air-insulated and fused switches can be used in either a live-front or dead-front configuration. Do not use air-insulated switches in corrosive and high humidity areas as defined in UFC 3-501-01 unless the installation experience for the installed location confirms that switch corrosion and tracking is not a problem.

3-8 PAD-MOUNTED SECTIONALIZING TERMINATION CABINETS.

Apply pad-mounted sectionalizing termination cabinets only when switching, isolation, or electrical protection for the downstream circuit is not required or anticipated. Sectionalizing termination cabinets can be used instead of in-line splices in manholes or for minor loads that do not warrant the expense of pad-mounted switchgear. Sectionalizing cabinets are available up to 35 kV. Provide low profile sectionalizing termination cabinets when the conductor size is 4/0 AWG or smaller. Coordinate with the Activity and include ground fault circuit indicators in accordance with the base design standard.

3-9 CAPACITORS.

3-9.1 Application.

Do not use capacitors unless they are needed for power factor correction or to minimize line losses. Verify the need by a system analysis; the analysis must consider the potential adverse effects of transients caused by capacitor switching. Refer to TSEWG TP-2: *Capacitors for Power Factor Correction*, at http://www.wbdg.org/ccb/browse_cat.php?o=29&c=248 for additional information if power factor correction is considered.

Underground distribution has more capacitance than equivalent overhead distribution. When converting from overhead distribution to underground distribution, provide pad-mounted capacitors on a distribution system only if supported by the design analysis. Do not automatically replace existing pole-mounted capacitors with equivalent pad-mounted capacitors.

3-9.2 Disconnect Design.

For safety purposes, include an oil switch disconnect with pole-mounted capacitors.

3-10 OVERHEAD POWER DISTRIBUTION.

Design overhead lines to IEEE C2 Grade B construction complying with the following:

a. Limit the initial loaded conductor tension to a maximum of 50% of the conductor rated breaking strength. Lesser tensions are usually applicable and generally more preferred. Utility distribution line design is generally in the range of 25% to 35% of the rated breaking strength.

b. Provide clearance requirements using final sag values in conformance with IEEE C2 Part 2.

c. Limit the maximum design tensions for any conductors to 4,750 pounds (2,154 kg). Base all clearance values on the following maximum conductor temperatures.

- Copper phase conductors – 167 degrees F (75 degrees C).

- Aluminum/aluminum alloy phase conductors – 194 degrees F (90 degrees C).
- Neutral conductors for multi-phase circuits – 120 degrees F (49 degrees C).
- The maximum conductor temperature for single-phase neutral conductors is identical to the phase conductors.

Match the existing base construction methods. Match those construction methods used by the local utility when directed. Where new overhead distribution is required, route the overhead distribution along roadways and other major topographical features; the poles must be accessible for future maintenance or work. Coordinate pole locations with land-use planning to ensure that new poles do not interfere with future facility plans.

3-10.1 Drawing Details.

Use NAVFAC pole details OH-1.1 through OH-41. NAVFAC pole details are available in Adobe PDF format and in AutoCAD format http://www.wbdg.org/ccb/NAVGRAPH/graphtoc.pdf. In situations where an applicable pole detail has not been developed, provide new detail drawings as required. For designer developed details, provide a level of detail equivalent to NAVFAC pole details and include material requirements. Refer to UFC 3-501-01 for additional pole detail requirements.

3-10.2 Pole Types.

Use solid wood poles for electric distribution lines. Concrete or steel poles may be justified for medium-voltage distribution circuits where wood poles do not provide adequate strength, or where climatic conditions cause wood poles to deteriorate rapidly. Do not use laminated wood poles for electric distribution lines.

3-10.3 Conductors.

Due to the increasing technology improvements with aluminum conductors and connectors, and the economic disadvantage of providing copper conductors, provide aluminum conductor steel reinforced (ACSR) or aluminum alloys for new overhead lines and extensions of existing lines. Do not use ACSR conductors in corrosive and high humidity areas. For corrosive and high humidity areas, provide Type ACSS conductors.

Except for grounding systems, the use of copper conductors is prohibited without specific approval and documentation by the applicable local engineering authority. The local engineering authority is defined by the following:

- For the Navy, the Facilities Engineering Command (FEC) organization's chief engineer has the authority to use copper product for their applicable jurisdiction.

- For the Army, the Installation Department of Public Works Chief Engineer has the authority to use copper product for their applicable jurisdiction if documented in the planning process and the design analysis.

- For the Air Force, the Base Civil Engineer has the authority to exercise the criteria option of copper product for their applicable jurisdiction if documented in the planning process and the design analysis.

3-10.4 Pole-Mounted Transformers.

3-10.4.1 Maximum kVA Rating.

Provide pad-mounted transformers rather than pole-mounted transformers for new three-phase installations larger than 75 kVA.

Limit pole-mounted transformer sizes (except for projects involving system conversions to a different operating voltage) as follows:

- Three-phase installations – limited to three 25 kVA transformers or smaller.
- Single-phase installations – limited to one 75 kVA transformer or smaller.

3-10.4.2 Configuration.

Use only single phase transformers for pole-mounted installations. For single phase installations and when banking single phase transformers for three phase applications, apply phase-to-neutral primary connections unless installed on three wire distribution systems.

Do not use self-protected transformers. Self-protected transformers have internal primary fuses that must be replaced by experienced personnel.

3-10.4.3 Mounting and Location.

Do not use pole-platform mounting (two-pole structure or H-frame).

Aerially mounted installations might supply several buildings. When that is the case, install the transformers at the pole location closest to the building with the greatest load. Secondary wiring should drop directly to the buildings served, if the span does not exceed 125 feet; otherwise, intermediate poles are required.

3-10.5 Pole-Top Switches.

Pole top switches are installed at important system locations to allow either isolation of the downstream circuit or cross-connection to a different circuit. Where ground operated, gang type, three phase, air break switches are used with non-insulated operator handles, provide a metal plate or grate at ground level for the operator to stand on when operating the switch. Connect the metal plate or grate to the pole ground conductor as well as through a braided conductor connection to the switch handle mechanism. Include a provision for locking ground accessible switch handles in the open and closed position.

Single-pole knife blade switches and copper barrels inside distribution cutouts are only acceptable for use in locations where frequent switching is not expected.

3-10.6 Surge Arresters.

Provide surge arresters on the line side of:

- Pole mounted transformers.
- Overhead to underground terminal poles.
- All “normally open” switch ways of pad-mounted sectionalizing switches connected to and served from overhead lines.
- Underground primary metering installations connected to and served from overhead lines.

Provide surge arresters on the line and load sides of:

- Gang operated airbreak switches on overhead lines.
- Primary metering applications on overhead lines.
- Recloser/sectionalizer applications on overhead lines.

3-10.7 Fuse Protection.

Provide IEEE C37.41 rated backup current limiting fuses in series with Type K expulsion fuses on systems that are:

- Greater than 15 kV.
- 15 kV and lower that have available fault currents equal to or greater than 7,000 asymmetrical amperes.

Note: Existing systems should continue to use the expulsion fuse link type that represents the standard for that system.

3-10.8 Automatic Circuit Reclosing.

Do not provide automatic circuit reclosing on underground distribution circuits. \2\

3-10.9 Sectionalizer.

Comply with IEEE C37.63. Use sectionalizer as a not load break switch in conjunction with an upstream recloser or circuit breaker. It counts the interruptions created by a recloser during a fault sequence. On a preset count, the sectionalizer trips during the dead time of the upstream recloser and isolates the faulty network section.

Note: Sectionalizer with a separate Controller requires an auxiliary power source. Sectionalizer with an integral electronic control incorporates electronic logic and trip circuits which are controlled and powered by current transformers. /2/

3-10.10 Ground Connections.

\2\ All pole mounted equipment and metallic frames must have two connections to the multi-grounded system neutral conductor. /2/ Keep ground wires straight and short. Minimize bends in all ground connections.

3-11 UNDERGROUND ELECTRICAL SYSTEMS.

3-11.1 Underground Distribution General Criteria.

3-11.1.1 Locations.

Provide underground distribution as follows:

- In areas where the primary distribution is already underground.
- In locations where overhead distribution is operationally hazardous, such as within airfield clearance zones.
- As required to supply pad-mounted equipment and transformers.
- Near electronics or munitions facilities that have clearance requirements for overhead power lines.
- Near piers and loading areas where overhead cranes operate.
- In congested industrial areas.
- In areas where storm and hurricanes or typhoons can damage overhead distribution.

3-11.1.2 Conductor Type.

Due to the increasing technology improvements with aluminum conductors and connectors and the economic disadvantage of providing copper conductors, provide aluminum conductors for new underground lines and extensions of existing circuits. This includes all new medium voltage system designs that do not require interface (splicing copper to aluminum in underground structures) with existing copper infrastructure. Provide only copper grounding electrode systems. The use of copper conductors is authorized for extensions of existing systems in which the use of aluminum results in technical limitations, such as:

- Maintaining required circuit ampacity, including derating associated with number of circuits in a common ductbank or burial depth.

- Maintaining base infrastructure capacity, including feeder cross-tie capability.
- Conduit size. All phases are required to be installed in the same conduit.
- Undersized or congested structures necessitating tape splices of aluminum cable to existing copper cable. *Note: If adequate space exists for the use of improved technology "heat shrink or cold shrink" splices, or if proper aluminum to copper compression connectors designed for the natural offset of size difference between the conductor materials is available as a standard manufactured product, provide the copper to aluminum cable extension*.

Approval of copper conductors is authorized as follows:

- For the Navy, the Facilities Engineering Command (FEC) organization's chief engineer has the authority to use copper product for applications within their applicable jurisdiction, in addition to the above authorized use for extensions.
- For the Army, the Installation Department of Public Works Chief Engineer has the authority to use copper product, in addition to the above authorized use for extensions, within their applicable jurisdiction if documented in the planning process and the design analysis.
- For the Air Force, the Base Civil Engineer has the authority to exercise the criteria option of copper product, in addition to the above authorized use for extensions, within their applicable jurisdiction if documented in the planning process and the design analysis.

3-11.1.3 Routing.

Do not route primary underground utilities under buildings. Do not route systems greater than 600 volts under buildings except as a direct service entrance to a single interior transformer.

3-11.1.4 Marking and Labeling.

Tag all underground cables in all accessible locations such as in manholes, transformers, switches and switchgear. Install a detectable locator tape above all buried underground circuits. Marking must meet the base utility standards.

3-11.2 Ductbanks.

The definition of the terms ductbank, conduit, and duct are often confused. Within this UFC, a ductbank consists of two or more conduits (or ducts) routed together in a common excavation with or without concrete encasement.

3-11.2.1 Conduit Size.

Minimum conduit sizes must be as follows:

- Provide concrete encasement for primary distribution conduits between underground structures, and between underground structures and associated equipment, except in locations where soil conditions prohibit a stable environment. With approval of the Activity, utilize directional boring where conditions are not conducive to concrete-encased ductbanks.

  Primary Distribution Conduits (along main run and on laterals between underground structures and associated equipment) – size as needed to satisfy conduit fill and jam ratio criteria for the selected conductor size and voltage class, with 5 in (127 mm) minimum. For primary distribution conduits serving Navy dockside utilities, provide 6 in (155 mm) minimum.

  Secondary Distribution Conduits (Low Voltage) – size as needed to satisfy conduit fill and jam ratio criteria for the selected conductor size, with 4 in (103 mm) minimum for conductor sizes 500 kcmil and larger. In this case, secondary distribution conduits refer to the low voltage conduit routing from the distribution transformer to the service entrance equipment. This requirement does not apply to street lighting circuits, secondary supplies to housing, or secondary circuits originating from an interior panel.

- Telecommunication Conduits – 4 in (103 mm) for main telecommunications circuits.

  Specialty telecommunications circuits, such as cable television or alarm circuits, can select conduit sizes as needed for the application.

  Example: a cable television circuit might only require a 2 in (52 mm) conduit stubbed out to a fiberglass composite handhole.

3-11.2.2 Installation.

- Use Type EB Schedule 20 PVC conduits (minimum thickness) for conduits installed in concrete encasement. Provide at least 3 in (75 mm) of concrete encasement.
- Use Schedule 40 PVC conduit (minimum thickness) for conduits that are not installed in concrete encasement.
- Install all phase conductors and neutral conductor, if applicable, in the same conduit for three-phase circuits and delta-connected single-phase circuits. *Note: some utilities install each phase conductor in a separate conduit. This practice is not authorized*.
- Bury conduit at a minimum depth of 18 in (450 mm) below grade. Conduits must be 24 in (600 mm) minimum depth under roads and

pavement, and for voltages between 22 kV and 40 kV. Apply conductor ampacity derating when exceeding the NFPA 70 maximum burial depths.

- Provide 3 in (75 mm) clearance between conduits utilizing interlocking plastic spacers.
- For primary distribution circuits, provide spare conduits such that at least 1/3 of the ductbank contains empty conduits with a minimum of at least one spare conduit.
- For secondary distribution circuits on the secondary side of distribution transformers, provide one spare conduit.
- Include pull wires (pull string or pull rope) in all spare ducts.
- Provide a transition from Type EB conduit to Schedule 40 PVC conduit before emerging from underground.
- Use directional boring or jack-and-bore techniques for routing conduit(s) under existing pavement for roadways, aircraft aprons, runways and taxiways. Directional boring can be used for other locations where excavation can adversely affect daily operations.

  Note: Comply with Appendix B for the use of directional boring for conduit installations.
- For permafrost locations, use ductbank installation methods that are the standard for the base, post, or local utility.

3-11.3 Direct Buried Wiring Methods.

The term direct buried wiring refers to the direct burial of conductors without any conduit or concrete encasement. Comply with IEEE C2 for all direct burial systems.

3-11.3.1 Authorized Locations.

With approval of the Activity, direct buried wiring methods for low or medium voltage systems may be allowed for specific applications such as:

- Special applications in remote or extremely controlled areas. Examples of such applications could be ranges or range facilities, renewable energy projects such as wind farms or bulk photovoltaic (PV) facilities provided for the purpose of supplementing system demand loading.
- Housing projects utilizing residential type distribution principles of single-phase, pad-mounted transformer designs and single-phase distribution principles for balanced three phase system loading.
- Bulk power transfer (feeder) from point to point crossing remote or controlled real estate which will revert to public utility ownership and maintenance upon completion.

Direct buried wiring methods are not authorized for any application which constitutes a part of the base utility core distribution infrastructure.

3-11.3.2 Conductor Type.

All approved direct burial medium voltage systems can utilize concentric neutral underground distribution cable design instead of the typical Type MV tape-shielded conductor design utilizing a separate 600 volt insulated neutral conductor.

3-11.3.3 Crossing of Paved Areas.

Provide a spare conduit system with associated enclosures for direct buried systems under all streets, roads, and parking areas to provide for future maintenance capability without having to disrupt pavements. Provide minimum Schedule 40 PVC extending 5 feet on each side and capped for future use.

For crossing existing paved areas, the directional boring technology referenced in the paragraph titled Directional Boring, also applies for installation of the direct buried system.

3-11.4 Directional Boring.

Directional boring (DB) is a trenchless technology method to install high density polyethylene electrical (HDPE) conduit used for underground electrical distribution systems.

3-11.4.1 Authorized Locations.

Do not select DB methods as an installation means in lieu of concrete encasement or other approved jack-and-sleeve techniques, based solely on cost. Concrete encasement and jack-and-sleeve techniques always provide the best means to protect conduit and conductors; therefore, DB is authorized only for crossing under the following:

- Roads.
- Parking lots.
- Airfield aprons, taxiways, or runways (not airfield lighting circuits due to counterpoise requirements).
- Bodies of water.
- Environmentally sensitive areas with appropriate federal, state, and local government approval.
- Historical preservation areas with appropriate federal, state, and local government approval.

DB is also authorized for locations where earth setting has caused shearing of conduits. Document this basis for selection of DB as part of the design analysis.

3-11.4.2 Limitations.

DB is applicable to medium-voltage (MV) underground distribution systems between 1000 volts (V) and 34.5 kilovolts (kV) (nominal) and all low-voltage distribution systems (less than 1000 V). It is not applicable to airfield lighting circuits. Use of DB techniques to install electrical conduit distribution for voltages greater than 34.5 kV (nominal) is prohibited.

Refer to Appendix B regarding depth of DB. The depth can be less if a detailed survey is performed and documented before starting boring.

3-11.5 Underground Structures (Manholes and Handholes).

3-11.5.1 General Requirements.

Provide separate power and communication manholes. When power and communication duct lines follow the same route, use a common trench and locate power and communication manholes in close proximity to one another and staggered. Use manholes for main duct runs and wherever shielded medium voltage cable is installed. For the Air Force, pad-mounted sectionalizing termination cabinets can be used instead of manholes for locations that do not have multiple feeders.

Handholes can only be used for airfield lighting circuits, for other non-shielded medium voltage circuits, and for low-voltage and communication lines.

3-11.5.2 Equipment Prohibited Inside Manholes.

The following equipment is prohibited inside underground structures:

- Load junctions.
- Separable splices (bolt-T connections).
- T-splices and Y-splices on systems rated for greater than 15 kV.
- For the Air Force, T-splices and Y-splices on all medium voltage systems.
- Power distribution equipment, including transformers and switches.

3-11.5.3 Splice Locations.

All in-line splices must be in underground structures. Do not use handholes for splicing shielded power cables.

3-11.5.4 Fireproofing.

Individually fireproof medium voltage cables in all underground structures.

3-11.5.5 Design Loading.

Specify H20 highway loading for most locations. Structures subject to aircraft loading must be indicated to the Contractor. Design decks and covers subject to aircraft loadings per FAA AC-150/5320-6 except as follows:

- Design covers for 100,000 lb (45,000 kg) wheel loads with 250 psi (1.72 MPa) tire pressure.
- For spans of less than 2 ft (0.6 m) in the least direction, use a uniform live load of 325 psi (2.24 MPa).
- For spans of 2 ft (0.6 m) or greater in the least direction, the design must be based on the number of wheels which will fit the span. Use wheel loads of 75,000 lb (34,000 kg) each.

Note: For the Air Force, do not install electrical manholes in aprons. Maintain a distance of 50 ft (15 m) from the edge of paving, 50 ft (15 m) from any hydrant lateral control pit, and 200 ft (60 m) from a fueling point for all manholes.

3-11.5.6 Manhole Size.

Determine the size of power manholes by the number of circuits, voltage ratings and splicing requirements of the cables within. Provide manholes that are a minimum 6.5 ft (2 m) deep. For circuits rated above 15 kV, provide manholes that are a minimum of 9 ft by 12 ft (2.8 m by 3.7 m) in interior size. Provide cable racks in all new manholes. When reworking cables in existing manholes, provide racks for new cables. Route cable installations inside manholes along those walls providing the longest route and the maximum spare cable lengths.

Size communications manholes for equipment and splices contained, including future projections. Manholes must accommodate racking of splice closure of largest multi-pair cable while keeping cable bending radii greater than 10 times cable diameter.

3-11.5.7 Manhole Drawing Details.

Provide manhole foldout details or exploded views for all multiple-circuit primary systems and all primary systems requiring splices. Indicate the entrance of all conduits and the routing of all conductors in the manholes. Manhole details are available in AutoCAD or Adobe PDF format at http://www.wbdg.org/ccb/NAVGRAPH/graphtoc.pdf .

3-11.6 Locating Underground Structures.

Provide where \2\any of three the following conditions exists:

- Where/2/ splices are required,
- \2\Where/2/ duct lines change direction \2\unless the field manufactured longsweep bends having a minimum radius of 25 feet (7.6 m) can be used for a change of direction of more than 5 degrees, either horizontally or vertically, using

a combination of curved and straight sections with the maximum manufactured curved sections of no more than 30 degrees,

- Within/2/ 100 ft (30 m) of every riser pole, pad mounted transformer, or unit substation unless a calculation is provided to justify a greater distance. The distance must not exceed 200 ft (60 m).

Separation on straight runs must not exceed 400 ft (120 m). In situations where greater separation is desired and this greater separation is not prohibited by either excessive pulling tension or site requirements, separation of up to 600 ft (180 m) is permitted.

3-11.7 Pull Boxes.

Pull boxes are used for electric circuits supplying low-voltage electric loads which require conductors no larger than 1/0 AWG and no more than one 2-inch (52 mm) conduit entrance at each side. Wherever larger conduits are installed, use handholes or manholes. Do not use pull boxes in areas subject to vehicular traffic.

3-11.8 Medium Voltage Cable.

Comply with NEMA WC 74 and select type MV (105°C) aluminum or copper based on the specific applications as defined in Para. 3-11.1. Provide a 600 volt insulated neutral when required. For the Army and Air Force, concentric neutral conductors are also authorized.

Comply with the following:

- Cable Jacket – PVC or polyethylene jacket suitable for wet conditions.
- Insulation Type – Provide ethylene propylene rubber (EPR). For the Army and Air Force, cross-linked polyethylene is also authorized. Do not use paper insulated lead covered (PILC) for new installations.
- Insulation Level – Provide a 100% minimum insulation level for all circuits classified as multi-grounded (4 wire systems throughout the entire circuit). Provide a 133% insulation level for all other classification of circuits.
- Cable Shields – Use copper-tape shielded cables and ensure minimum bending radii of 12 times the overall cable diameter. Use copper-wire shielded cables only where existing manholes are utilized and the minimum cable bending radii of tape shielded cables cannot be realized. Refer to NEMA WC 74 for cable bending radii.
- Number of Conductors – Use single conductor cable as a general rule. Three conductor cable may be used only when splicing to existing three conductor cable.

3-12 CONCRETE FOR UNDERGROUND ELECTRICAL SYSTEMS.

Concrete for encasement of underground ducts must be 3000 psi (20 MPa), minimum 28-day compressive strength. Concrete associated with electrical work for other than encasement of underground ducts must be 4000 psi (30 MPa), minimum 28-day compressive strength unless specified otherwise.

3-13 HOUSING DISTRIBUTION.

Comply with the following requirements for electrical distribution to housing units:

- Serve single dwelling units, duplexes and quadraplexes in housing areas by single-phase, 240/120V transformers.
- Serve no more than 6 dwelling units; 4 duplexes; or 2 quadraplexes per transformer.
- Minimum conductor size from the transformer to the service entrance equipment should be 3/0 copper in underground conduit.
- Provide a maximum length of 220 ft (67 m) for the service lateral conductors from the distribution transformer to the service entrance device (or meter base).
- Design the distribution system such that the available fault current at the service equipment is less than 10,000 amperes.

Where an underground 3-phase circuit is used to feed single-phase transformers, provide a separate 3-phase pad-mounted switch or sectionalizing cabinet with a radial supply to the single-phase transformers.

3-14 DISTRIBUTION SYSTEM GROUNDING.

Comply with the requirements of IEEE C2 Section 9, *Grounding Methods for Electric Supply and Communication Facilities*, for distribution system grounding (medium voltage systems classified as multi-grounded, single point grounded at source transformer either solidly or with grounding resistors, and ungrounded).

Design in accordance with IEEE Std 80 main electric supply stations and all supply stations consisting of equipment for the purpose of transforming the voltage level for further bulk distribution. Complete measurements of the station grounding system prior to inter-connection with other systems and prior to station energization to assure the limits of step and touch potentials as required by IEEE Std 80 have been attained.

3-14.1 Separation of Grounding Conductors.

Comply with the requirement for separation of grounding conductors between classes of equipment operating in excess of 750 volts and below 750 volts for the design of all facilities. The exception for connecting the different classes of equipment "to a sufficiently heavy ground bus or system ground cable that is well connected to ground at more than one place" is the Government's engineering basis for interconnecting the different classes of equipment connected to existing systems.

Note: The predominant classification of existing Government medium voltage systems is a classification of something other than multi-grounded. For designs on new systems or existing systems classified as multi-grounded, the standard grounding detail of a 4/0 ground ring and interconnecting ground rods on utilization electric supply stations may be omitted and replaced with a simpler system complying with the requirements of IEEE C2 Section 9.

3-14.2 Materials and Special Requirements.

3-14.2.1 Ground Rods.

Comply with IEEE C2 Section 9 for ground rod composition, minimum spacing requirements and connections except provide ground rods with minimum dimensions of 10 ft (3.0 m) in length and ¾ inch (17 mm) in diameter. Provide copper-clad steel, solid copper, or stainless steel ground rods. Sectional ground rods are permitted. All connections to ground rods below ground level must be by exothermic weld connection or with a high compression connection using a hydraulic or electric compression tool to provide the correct circumferential pressure. Accessible connections above ground level and in test wells can be accomplished by clamping. Pole–butt plates and wire wraps recognized by IEEE C2 Section 9 are not authorized as grounding electrodes.

Spacing for driving additional grounds must be a minimum of \2\6 ft (1.8 m)/2/. Bond these driven electrodes together with a minimum of 4 AWG soft drawn bare copper wire buried to a depth of at least 12 in (300 mm).

3-14.2.2 Ground Rings.

Comply with the requirements of NFPA 70 Section 250 for ground rings. If the system is not classified as multi-grounded, utilization electric supply stations, switchgear, and sectionalizing cabinets require a 4/0 bare copper ground ring with a minimum of four ground rods for three phase service. Single phase service installations can be modified to minimum 1/0 copper and two ground rods for the ground ring. Test wells are permitted on specific applications as required.

If metal bollards are installed and are within 8 feet of the pad-mounted equipment, bond each bollard to the ground ring.

3-14.3 Low Voltage Grounding Interface With Utilization Electric Supply Stations.

For design purposes, the secondary terminals of the utilization electric supply station are the demarcation point between IEEE C2 and NFPA 70. The transition between the grounded neutral conductor (functioning as a neutral and a grounding conductor per IEEE C2) and the grounded conductor (functioning as a neutral conductor only per NFPA 70) must be at the "service point" as defined by UFC 3-501-01 Chapter 2.

- The service point for low-voltage conductors from utilization electric supply stations containing no secondary overcurrent protection device is defined as the line side terminals for the facility service equipment.
- The service point for utilization electric supply stations containing an overcurrent protection device is at the main breaker on the secondary side of the utilization electric supply station. This is the transition point from IEEE C2 to NFPA 70 grounding where the service main bonding jumper is located.

3-14.4 Grounding Requirements – Fences.

Ground metal fences for electrical equipment in accordance with IEEE C2 Section 9.

Other metal fences that are electrically continuous with metal posts extending at least 24 inches (610 mm) into the ground require no additional grounding unless specifically required by other criteria.

3-14.4.1 Ordnance Facilities.

Ordnance facilities or locations where ordnance and explosives are handled and stored require special protective measures. Refer to the following service-specific criteria for grounding of metal fences near these facilities:

- NAVSEA OP-5, *Volume 1, Ammunition and Explosives Ashore*.
- AFMAN 91-201, *Explosive Safety Standards*.
- AFMAN 91-118, *Safety Design and Evaluation Criteria for Nuclear Weapon Systems*.
- Department of the Army Pamphlet 385-64, *Ammunition and Explosives Safety Standards*.

3-14.4.2 Plastic Coated Fencing.

Plastic coated fencing is prohibited for fences that require grounding.

3-15 METERING.

Provide metering in accordance with UFC 3-520-01.

3-16 EXTERIOR SITE LIGHTING.

Provide exterior lighting in accordance with UFC 3-530-01.

3-17 CATHODIC PROTECTION SYSTEMS.

Provide cathodic protection in accordance with UFC 3-570-01.

3-18 ENVIRONMENTAL CONSIDERATIONS.

Consider oil spill containment for substation transformers. Containment is not authorized for pad-mounted oil-filled distribution transformers and switches.

Do not use askarel-insulated and nonflammable, fluid-insulated transformers because of environmental concerns as to their insulation liquid.

3-19 FIRE PROTECTION CONSIDERATIONS.

Provide fire protection and specify installation location for oil-filled equipment in accordance with UFC 3-600-01.

Oil-filled transformers using mineral oil can only be used outdoors. Less-flammable liquid (fire point of not less than 300 degrees C (575 degrees F)) transformers may be used either outdoors or indoors.

APPENDIX B DIRECTIONAL BORING

B-1 CONDUIT TYPE.

Provide smoothwall HDPE conduit, approved/listed for directional boring, approved/listed for electrical system installations, and minimum Schedule 80 meeting ASTM D2447/F2160/NEMA TC-7 (latest editions).

Note: Install HDPE conduit below freeze lines and in no case can the conduit be installed less than the minimum depths noted below.

B-1.1 Conduit Design – 1,000 Volts to 34,500 Volts.

Provide a minimum size HDPE conduit of 5 inches (130 mm) for distribution voltages greater than 1,000 V and less than 34.5 kV (nominal). Do not exceed 30 percent conduit fill.

Install HDPE conduit with a minimum ground cover of:

- 120 inches (3 m) in non-pavement-covered areas.
- 48 inches (1.2 m) in pavement-covered areas.

B-1.2 Conduit Design – Less Than 1,000 Volts.

Provide a minimum size HDPE conduit of 4 inches (100 mm) for distribution voltages less than 1,000 V. Do not exceed 35 percent conduit fill.

Install HDPE conduit with a minimum ground cover of 48 inches (1.2 m) in pavement- or non-pavement-covered areas.

B-1.3 Conduit Design – Branch Circuit Wiring Less Than 600 Volts.

Provide a minimum size HDPE conduit for branch circuit wiring less than 600 V that is determined by calculation, addressing, as a minimum, branch circuit conductor size, maximum allowable pulling tension, and maximum 5 percent voltage drop. Do not exceed 40 percent conduit fill.

Install HDPE conduit with a minimum ground cover of 24 inches (610 mm) min pavement- or non-pavement-covered areas.

B-2 INSTALLATION METHODS.

The use of specific conductor or insulation types for either high- or low-voltage installations is not mandated here. However, the combination of a chosen conductor and insulation type may not meet the requirements for the installation methods required in the following paragraphs where length, depth, and routing of the directional bore conduit may require an alternative conductor material and/or insulation type (i.e., maximum pulling tensions are different for aluminum and copper conductors).

B-2.1 Ampacity.

If the directional bored portion of the cable run is more than 25 percent of the total run length, evaluate and document the conductor derated ampacity in accordance with NFPA 70 Article 310.60 (C) (2).

B-2.2 Installation.

Water-jetting is not permitted. Use drilling fluids for DB methods that are approved by federal, state, and local codes and authorized for use by the BCE.

Pre-installed cable-in-conduit is not permitted. Install the conduit(s) immediately after the conduit hole is completed.

B-2.3 Allowable Pulling Tension.

B-2.3.1 Distance.

There is no restriction on DB distances provided the allowable pulling tension of the conduit and installed conductors are not exceeded, conductor splices are not within the conduit, and maximum ampacity of conductors due to depth derating is not exceeded.

B-2.3.2 Calculation Requirements.

A registered Professional Engineer (PE) must calculate pulling tension requirements for each directional bore, taking into consideration the HDPE conduit(s) size and type, bend radius, elevation changes, vertical and horizontal path deviations, installed electrical conductor size and type, and any conductor ampacity derating due to depth of HDPE conduit. The electrical contractor must provide certification of compliance with the PE's design requirements.

The professional engineering design process must include consideration of tensile forces and bend radii created during the installation so that allowable limits are not exceeded. Allowable tensile forces must be determined by a PE, including accounting for the conduit's allowable bend radius to prevent ovalization and kinking from installation. Do not exceed 5 percent ovalization of the conduit.

B-2.4 Termination into Equipment Pads.

Terminate HDPE conduits into concrete-pad-mounted electrical equipment from either a pavement or non-pavement transitional area as indicated in Figures B-1 through B-5. Route and terminate HDPE or rigid conduit within the concrete pad such that no conductor exiting the conduit is bent past the vertical plane formed with the equipment pad when routed to conductor terminations and with approved insulated bushings (Figure B-1).

Figure B-1 HDPE or Rigid Conduit Electrical Equipment Transition

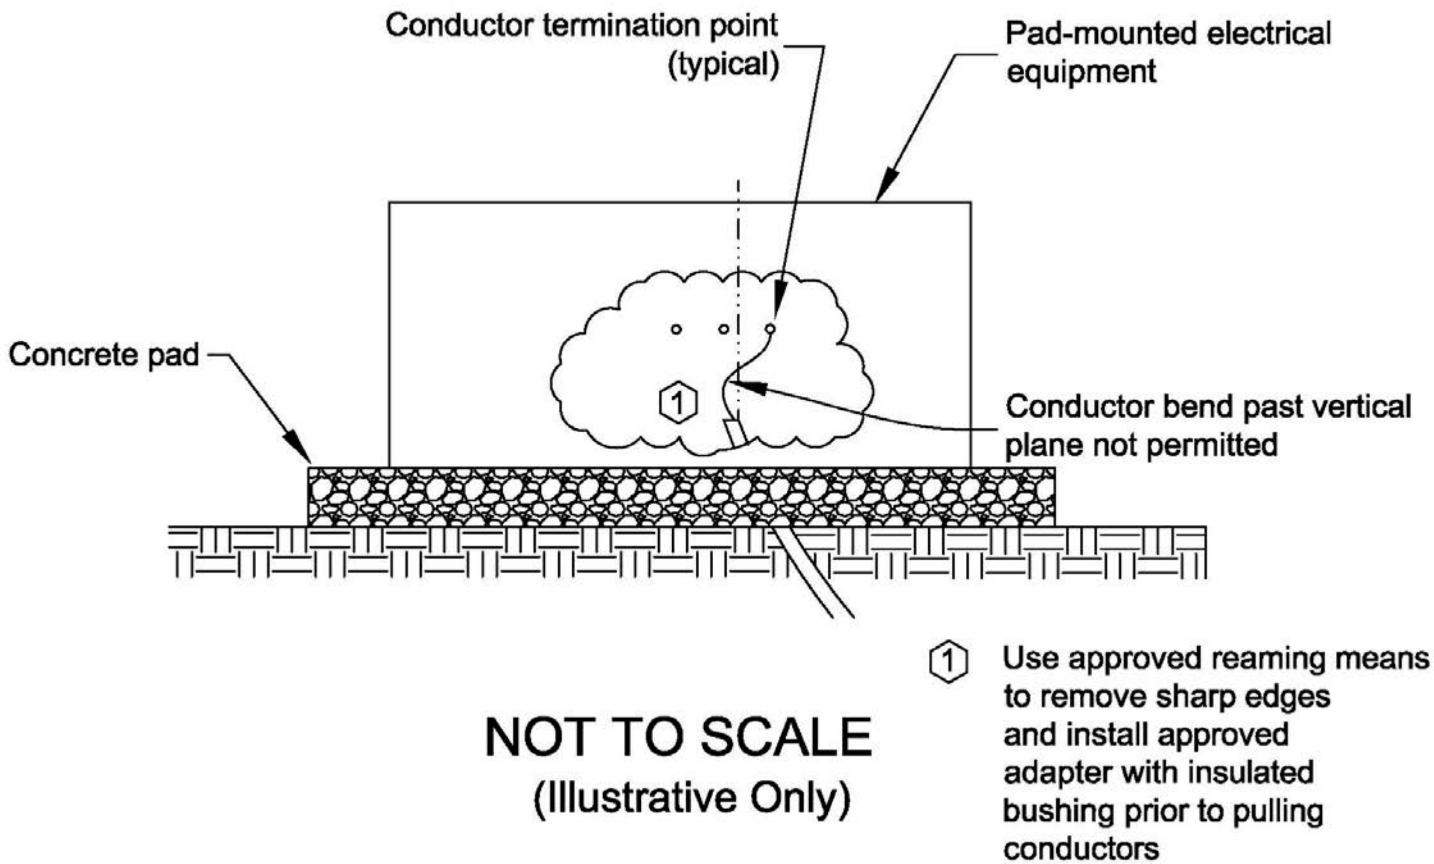

Figure B-2 Pavement Covered Area to Electrical Equipment Transition – Rigid Conduit (45˚–90˚)

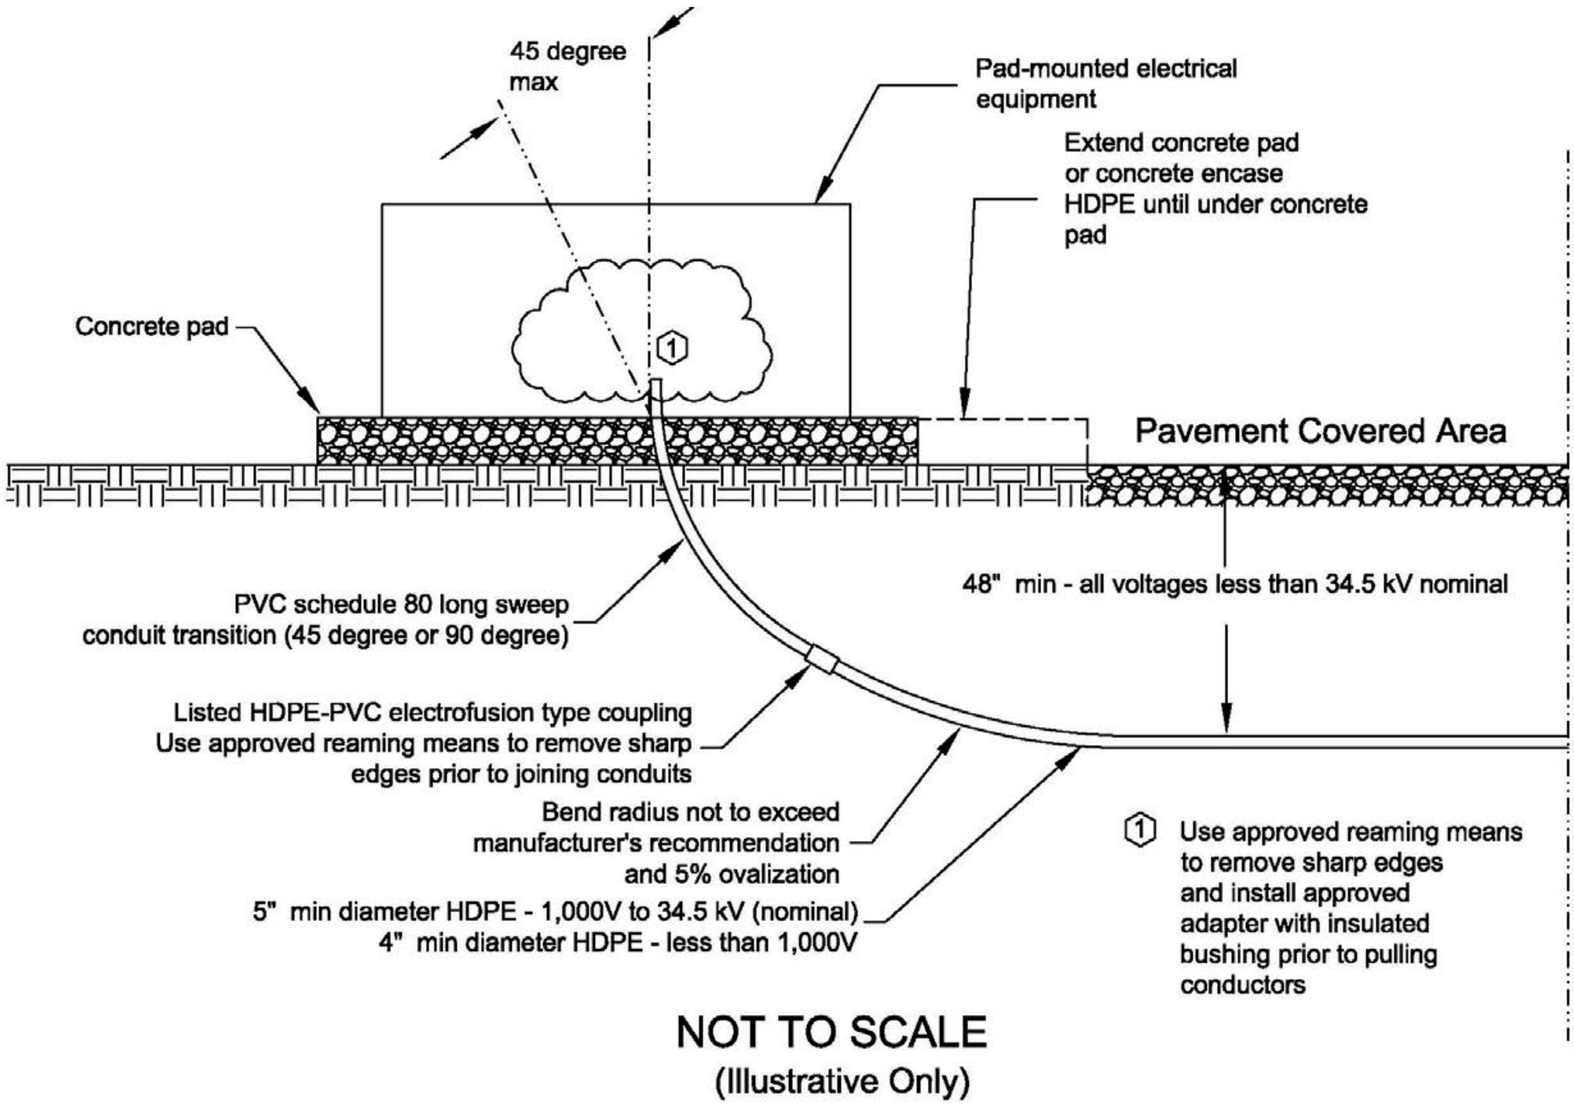

Figure B-3 Pavement Covered Area to Electrical Equipment Transition – HDPE Conduit (20˚–45˚)

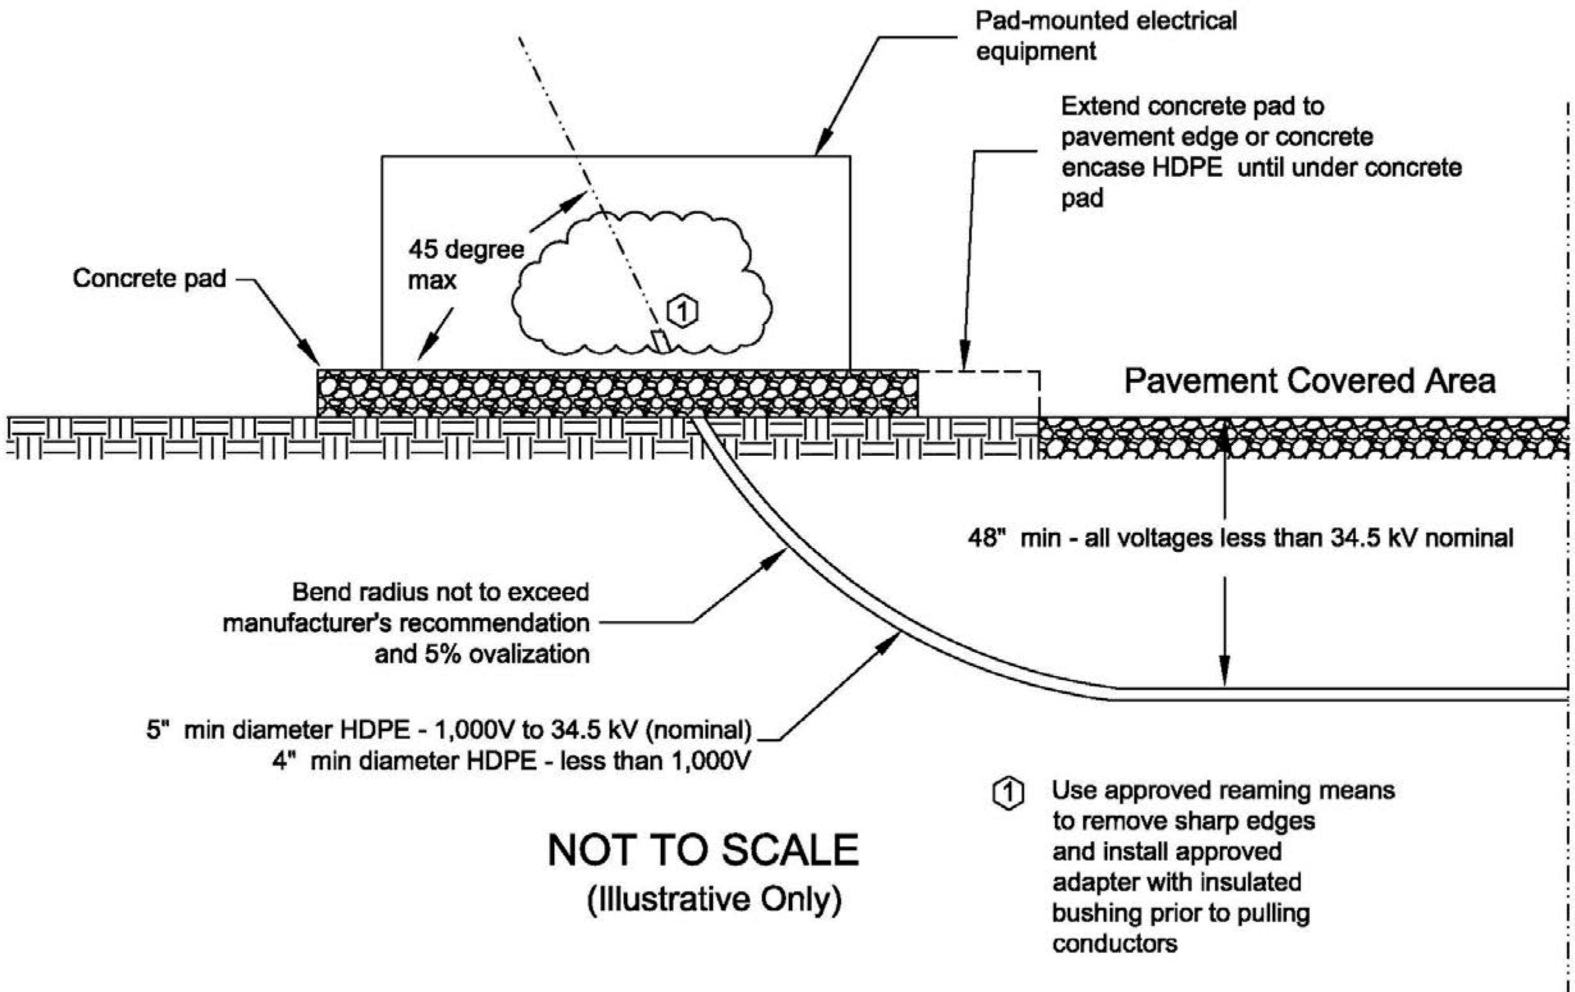

Figure B-4 Non-Pavement Covered Area to Electrical Equipment Transition – Rigid Conduit (45˚–90˚)

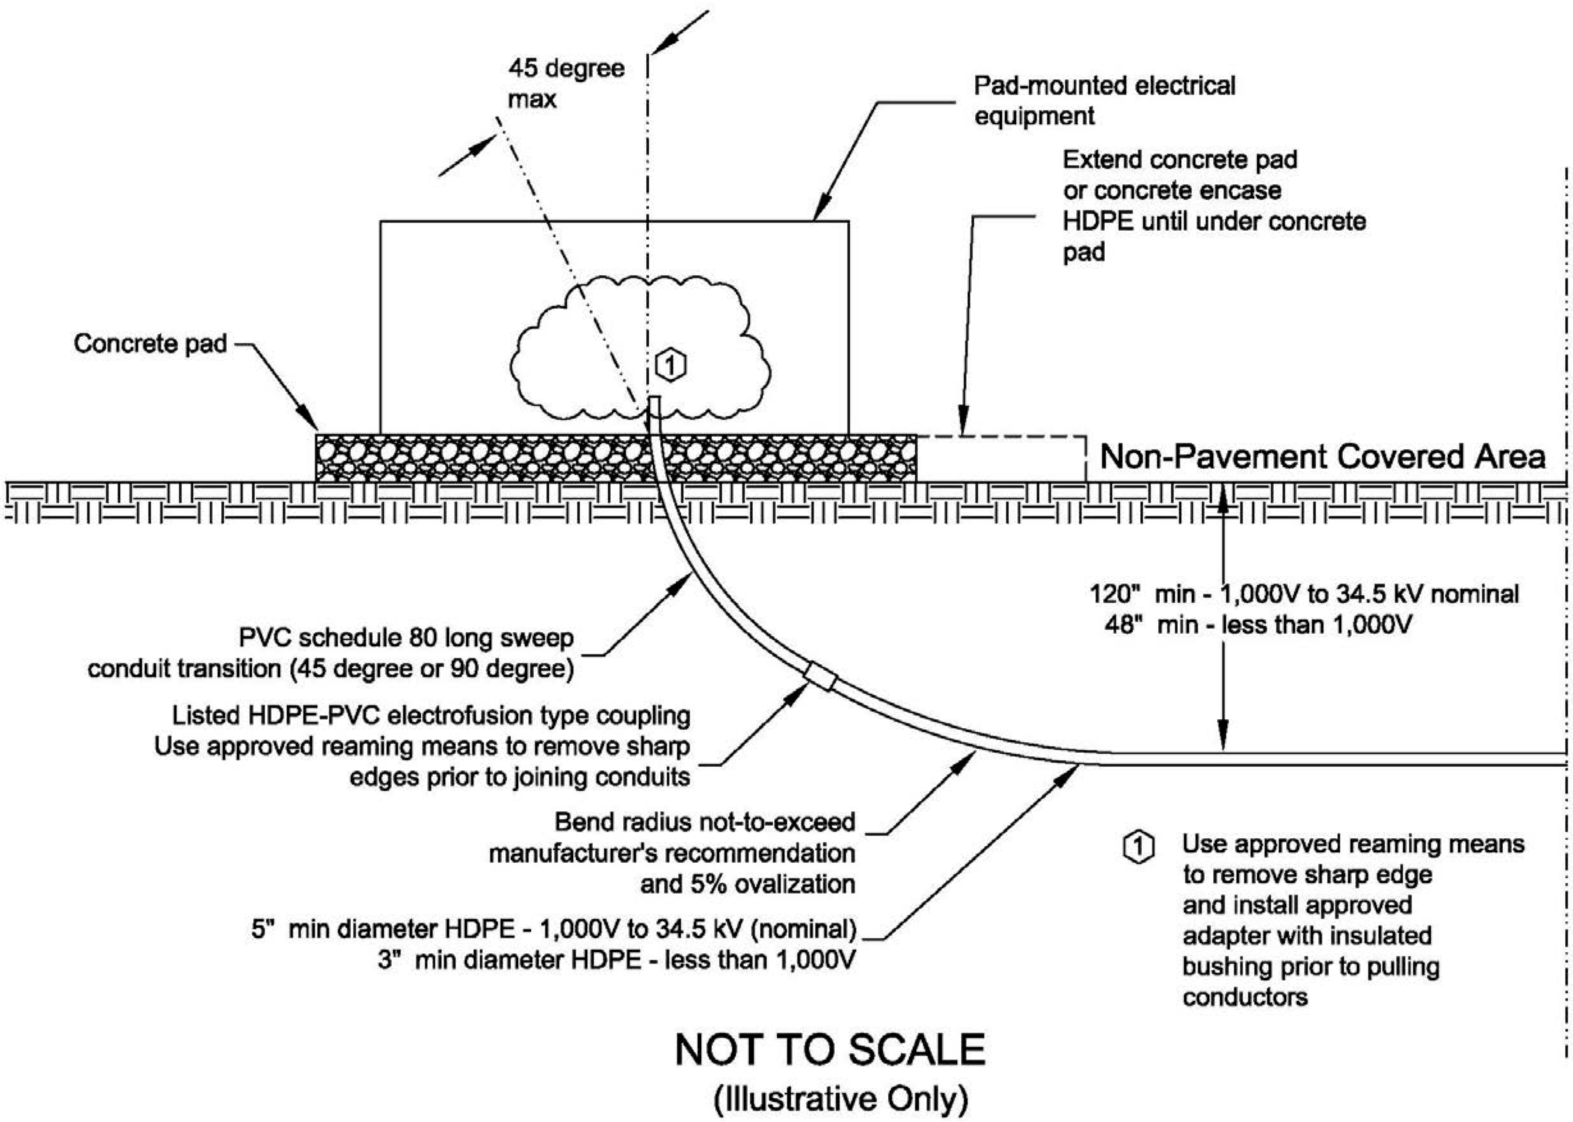

Figure B-5 Non-Pavement Covered Area to Electrical Equipment Transition – HDPE Conduit (20˚–45˚)

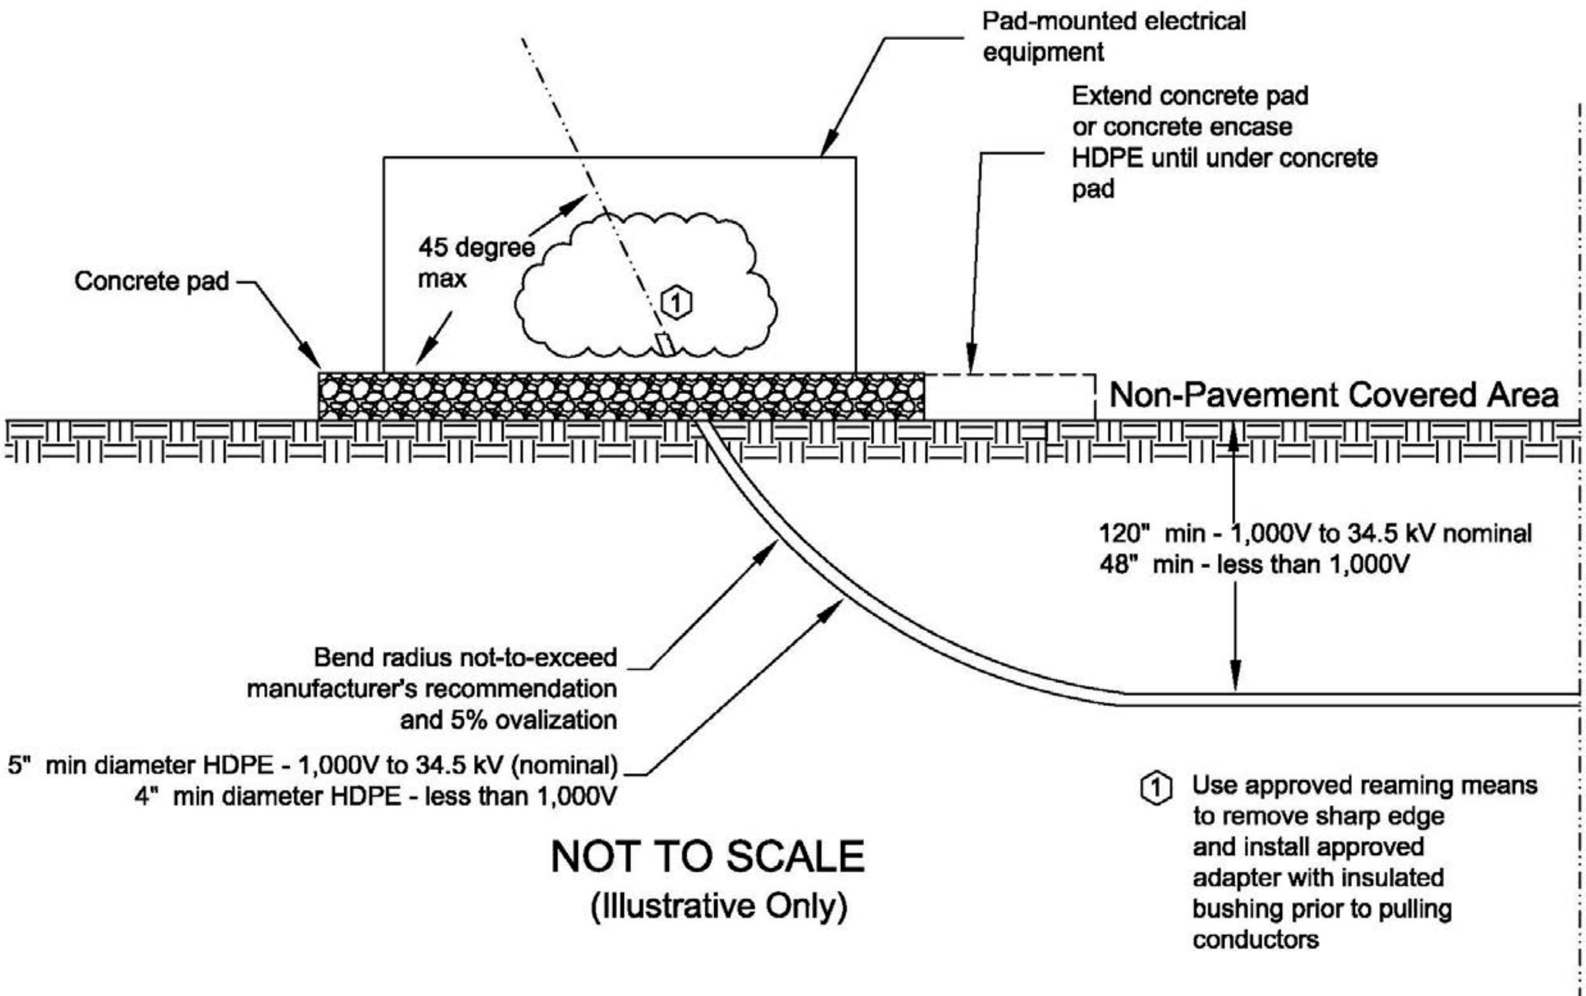

B-2.5 Multiple Conduits and Wiring Methods.

B-2.5.1 Installation.

Multiple HDPE conduits are permitted to be pulled through each bore. Designs requiring multiple conduits to accommodate parallel conductor installations must comply with NFPA 70 grounding and wiring methods requirements. As an example, one set of paralleled conductor requirements is illustrated in the following excerpt from NFPA 70, Article \2\310.10.(H)(2)/2/, which states:

> *"The paralleled conductors in each phase, polarity, neutral, \2\grounded circuit conductor, equipment grounding conductor, or equipment bonding jumper/2/ shall comply with all of the following:*
> *(1) Be the same length*
> *(2)\2\ Consist of/2/ the same conductor material*
> *(3) Be the same size in circular mil area*
> *(4) Have the same insulation type*
> *(5) Be terminated in the same manner*"

Thus, using DB methods to comply with (1) from the NFPA 70 excerpt, as well as other requirements, may not be possible, especially for long boring distances. NFPA 70 has other requirements for paralleled conductor installations that must also be considered when designing for these types of installations.

Note: Any deviations from NFPA 70 requirements must be approved by the AHJ.

B-2.5.2 Ampacity.

If the directional bored portion of the cable run is more than 25 percent of the total run length, evaluate and document the conductor derated ampacity in accordance with NFPA 70 Article 310.60 (C) (2).

B-2.6 Joining Methods.

Butt and electrofusion joining means are the only joining methods approved for HDPE conduit installations. Complete installations by persons certified in the process and in accordance with the manufacturer's procedures.

B-2.7 Transition from HDPE to PVC.

Make the transition from HDPE to PVC using only electrofusion coupling means with approved and listed materials. Perform coupling installation by persons certified on the equipment and process.

Complete coupling between HDPE and concrete-encased duct banks from pavement or non-pavement transitional areas as indicated in Figures B-6 and B-7. Perform the transition from HDPE to concrete manholes from pavement or non-pavement transitional areas as indicated in Figures B-8 and B-9.

Figure B-6 HDPE-to-PVC Pavement Covered Area Concrete Ductbank Transition

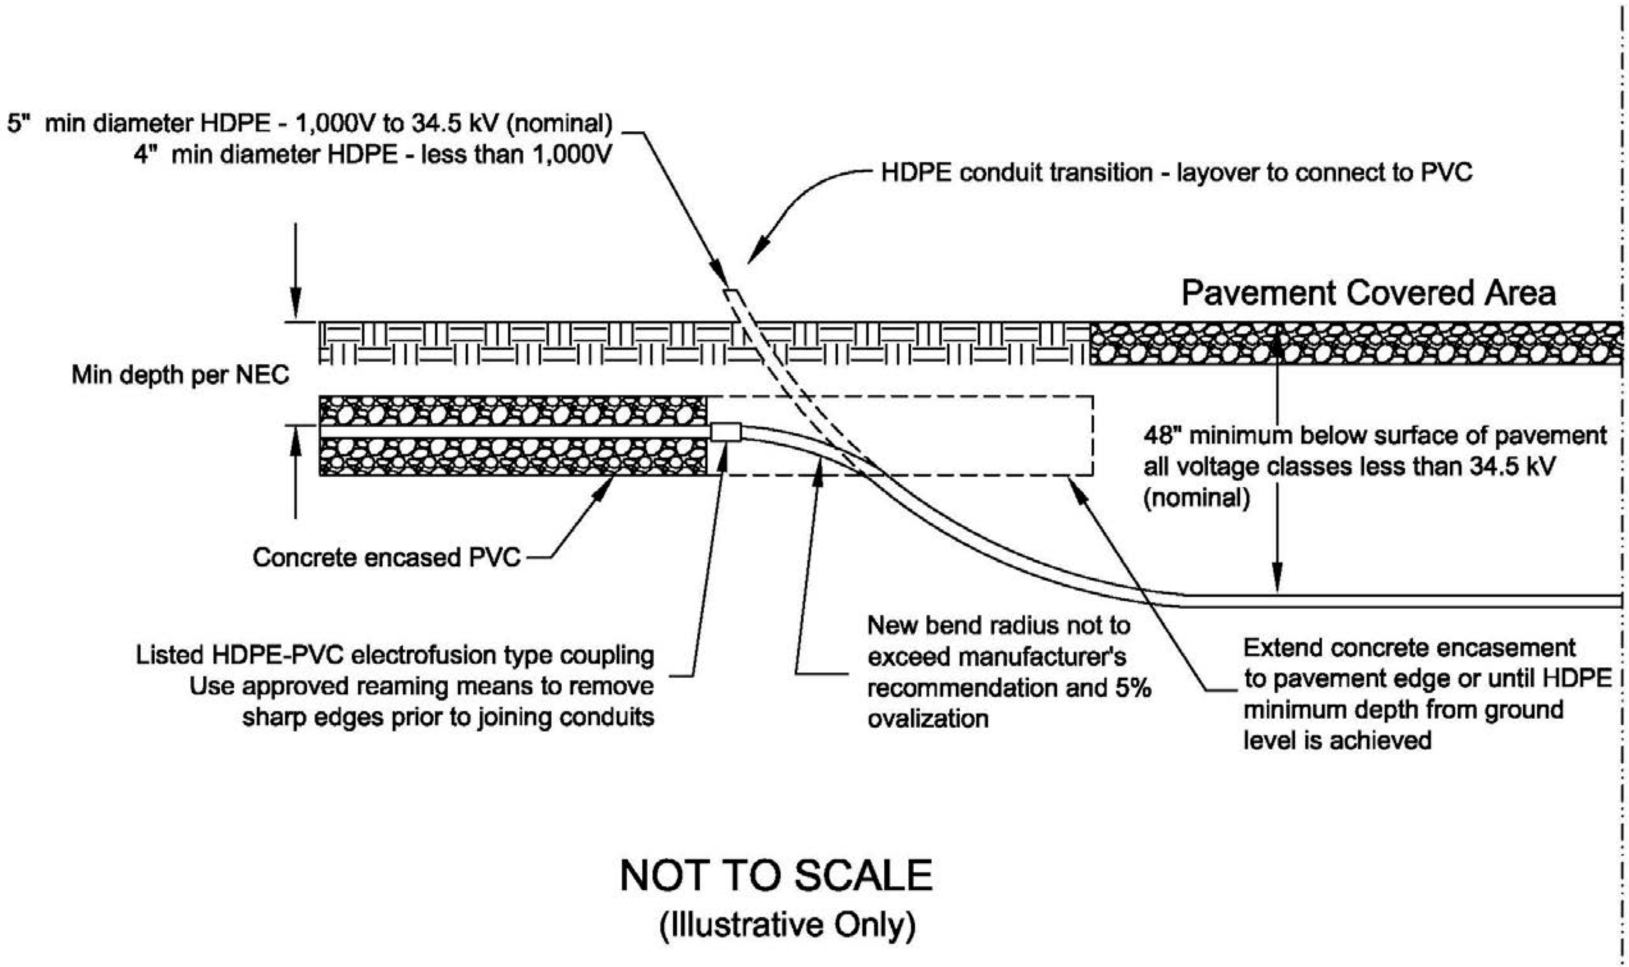

Figure B-7 HDPE-to-PVC Non-Pavement Covered Area Concrete Ductbank Transition

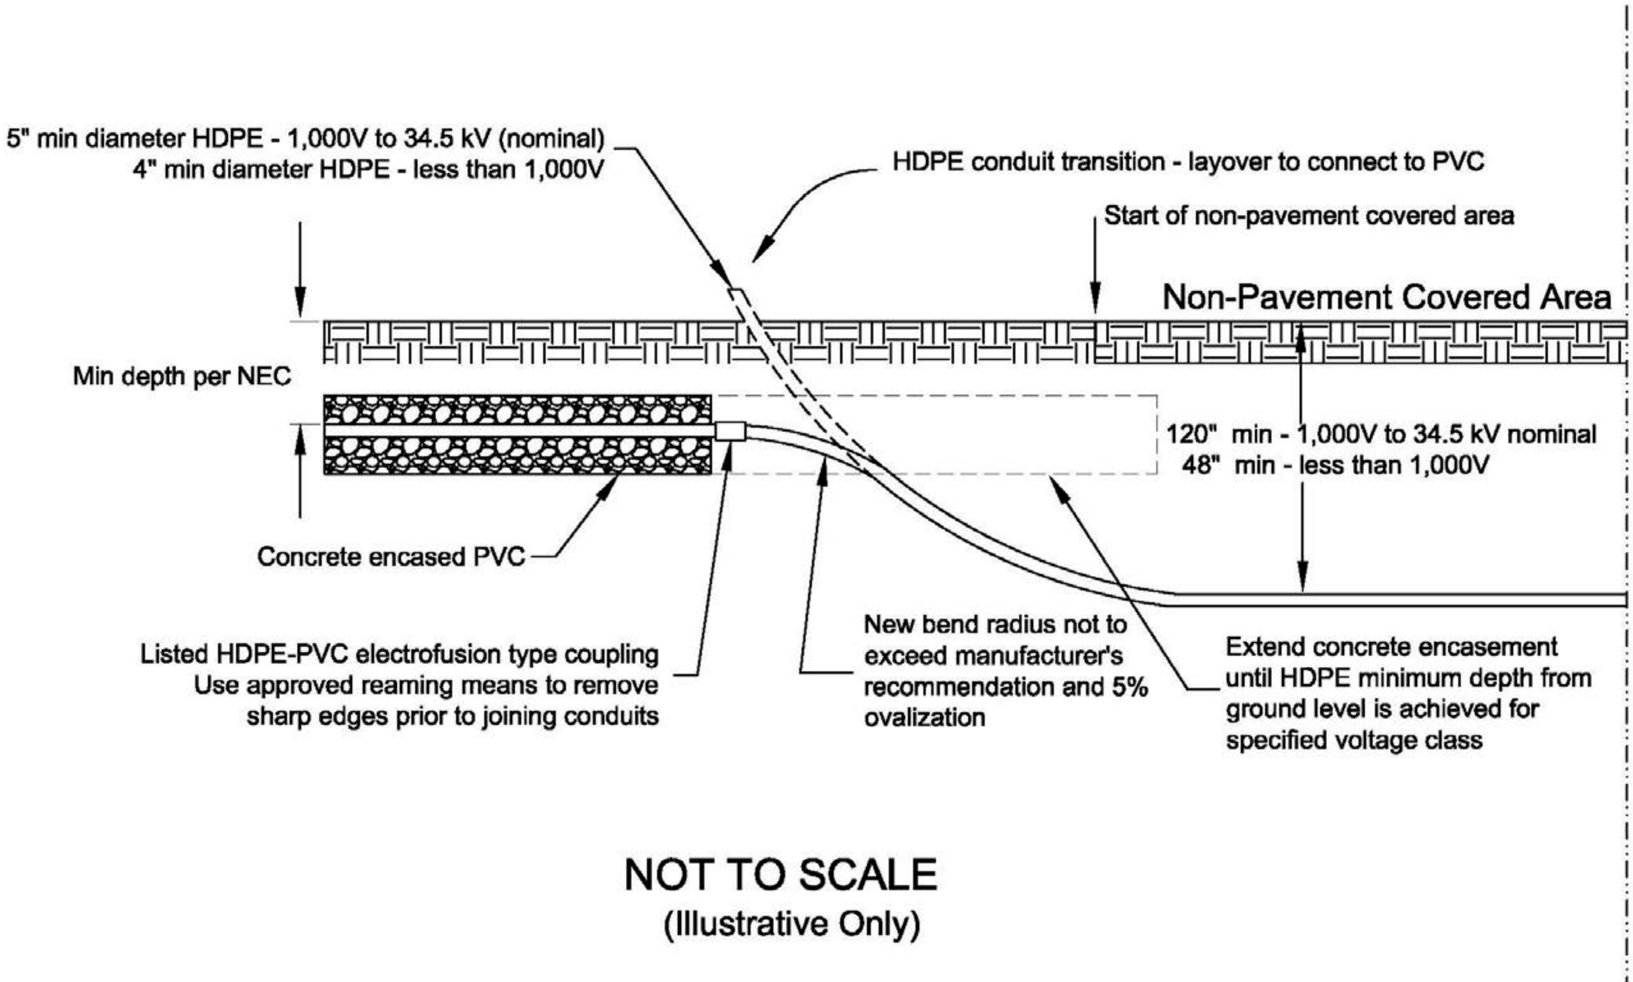

Figure B-8 HDPE-to-Manhole Pavement Covered Area Transition

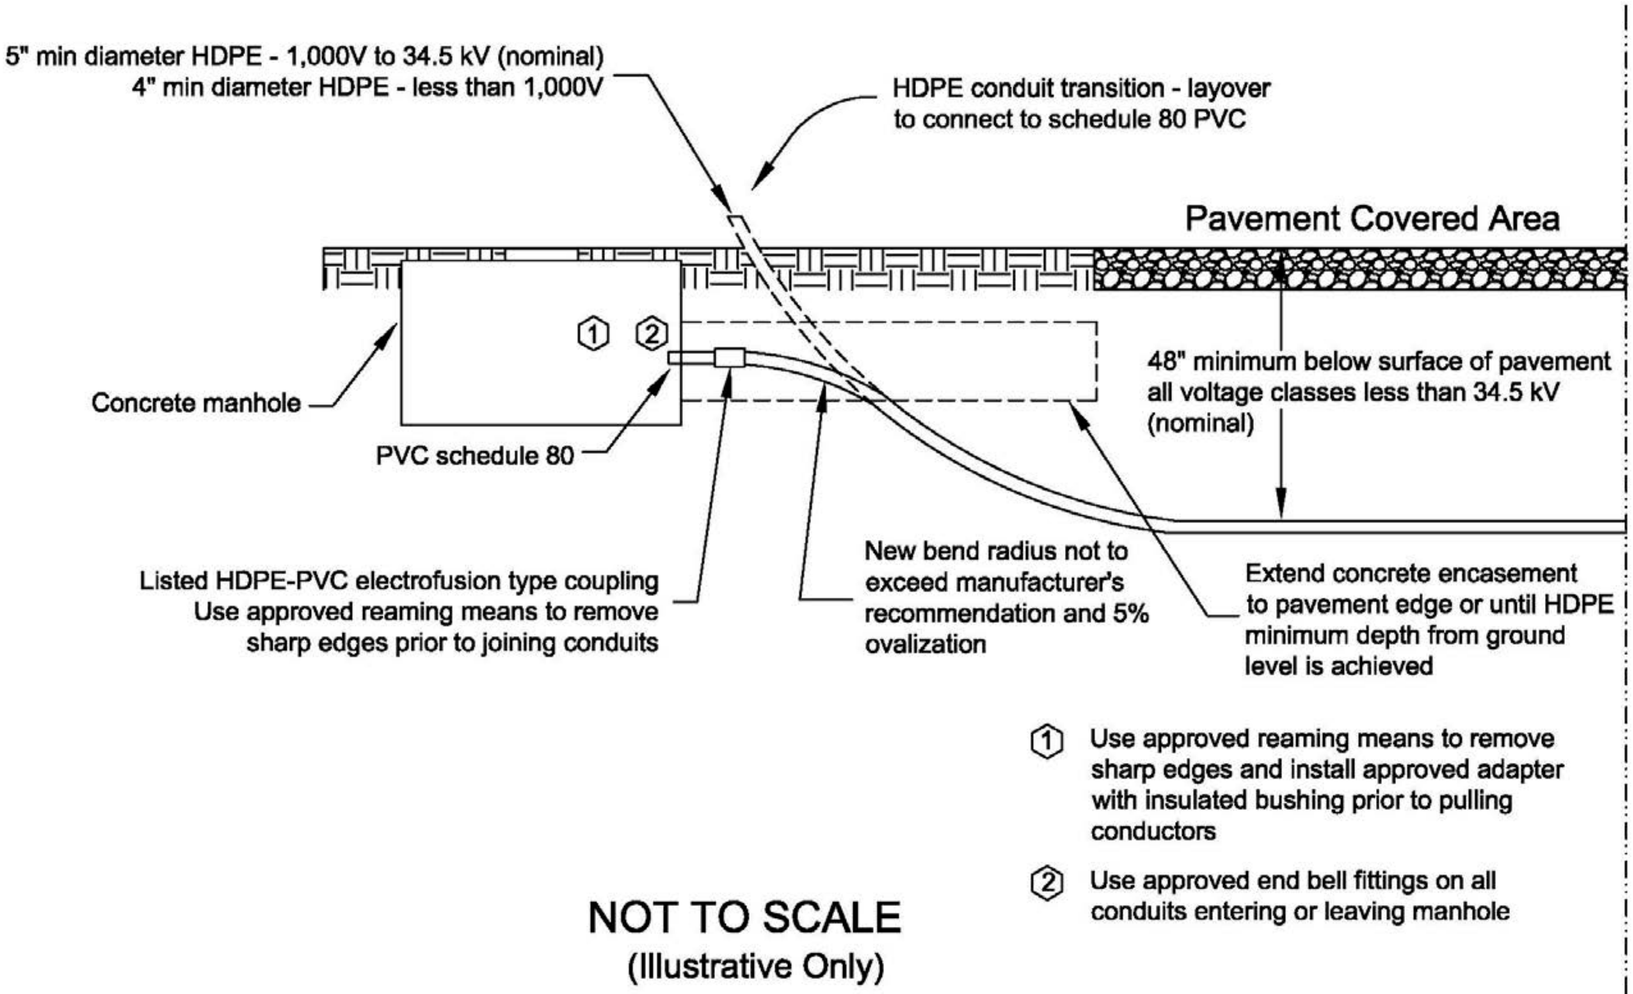

Figure B-9 HDPE-to-Manhole Pavement Covered Area Transition

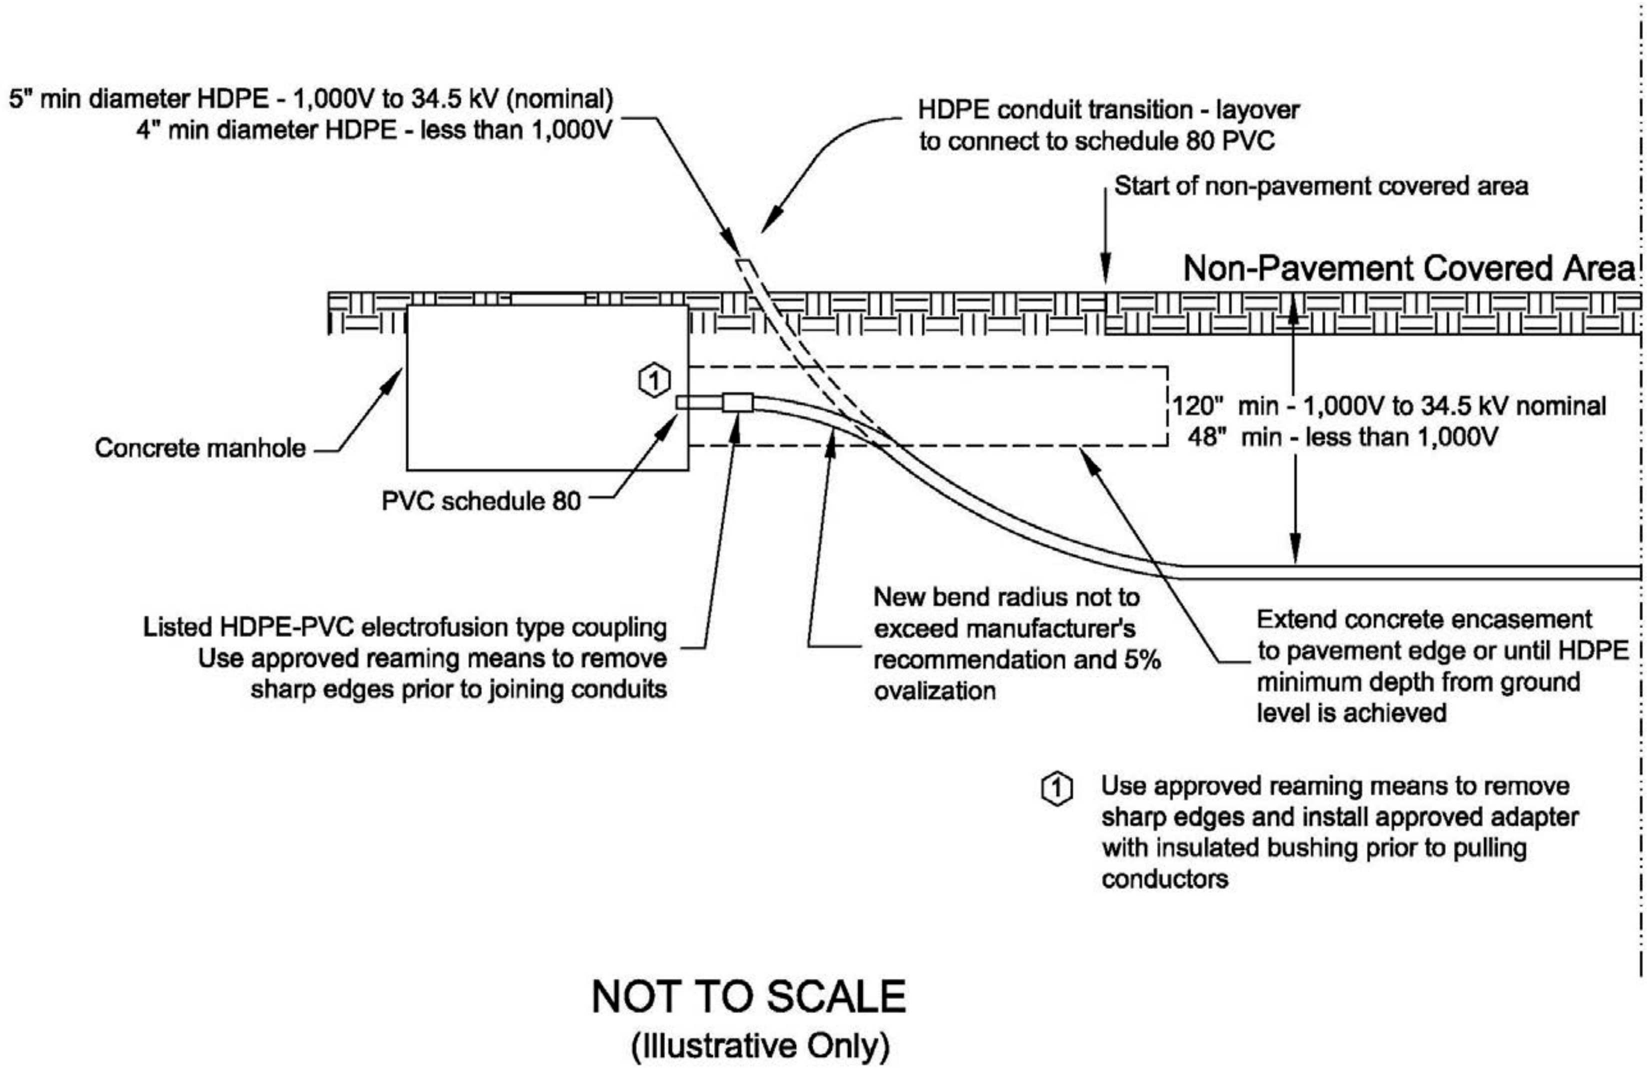

B-3 DOCUMENTATION.

Record the location and depth of DB-installed HDPE electrical conduit on applicable as-built drawings. Use Global Positioning System (GPS) recording means with “resource grade” accuracy to record HDPE conduit bore path. Record GPS coordinates at intervals not to exceed 50 feet (15 m) along the bore path. Provide this information, along with the size of conduit, number of conductors, conductor size, and insulation type, to the appropriate base civil engineering office for incorporation into the GeoBase database.

This Page Intentionally Left Blank

APPENDIX C BEST PRACTICES – GENERAL ELECTRICAL POWER REQUIREMENTS

C-1 EXTERIOR SYSTEM DESIGN.

Consider the following general criteria as part of any exterior electrical system design:

- Looped versus radial primary distribution. The alternate supply capability of a looped system for primary distribution system feeders can enable the system to continue operation even with a failed conductor. Evaluate design changes to the existing system to ensure that the potential impact of conductor failure is minimized.
- Cross-tie (alternate supply) capability. The ability to remove a feeder supply from service while ensuring continuity of power is essential for a reliable and maintainable design. Feeder cross-tie capability should be provided near the beginning of the feeder (to reduce voltage drop) and at key points downstream (to provide alternate supply capability for a portion of the feeder). Address cross-tie capability and how it is improved in the design analysis.
- Mission essential facilities. These facilities require additional consideration for the exterior electrical system design. Even if the facility is equipped with standby generation, minimize single points of failure in the exterior electrical system design. Provide redundant power supplies to the facility fed from different feeders, if multiple feeders are available.
- Communication. Determine communication requirements for the system, including SCADA, security, access, metering, and breaker control. Include security requirements as an input to the electrical system design criteria.
- Safety. Include electrical safety as a design consideration. Equipment selection, redundancy, installation approach, and how the equipment can be removed from service can all affect equipment and personnel safety.
- Reliability and maintenance. NFPA 70B, NETA MTS, and the manufacturers' documents provide periodic maintenance criteria applicable to exterior electrical equipment. Consider maintenance requirements in the specification of equipment and in the installation design of the equipment. As an example, a single manhole located near a substation should not contain the cables for all base feeders; in this example, the design should install multiple manholes with fewer distribution feeders located inside each manhole.

C-2 METERING.

Coordinate metering, system design, protection, electrical coordination, load requirements, and short circuit limitations with the local utility. If the supply station/substation is owned by the utility, obtain sufficient design information for the utility-owned equipment to help establish design requirements for downstream equipment.

Coordinate revenue metering requirements with the local utility. Provide a government-owned revenue meter for the supply station/substation even when the local utility meters the incoming supply.

C-3 DEMARCATION.

Clearly define the point of demarcation between the utility-owned system and the government owned equipment. Define ownership for the incoming utility supply lines if there are any shared equipment, such as overhead distribution with utility and government-owned lines sharing the same power poles.

C-4 SUBSTATIONS AND SWITCHING STATIONS.

Use or modify existing substations unless a new substation is required for capacity or unique requirements. Aging substations will often require complete replacement.

Design a main electric supply station/substation for reliability of service and maintenance. Address the following in the design analysis for the supply station/substation:

- Formal design. Substations require a formal design. Address the structure and foundation design, lightning protection, manholes and vaults, grounding, lighting, protective relaying, and the other electrical items listed below.
- Dual substation transformers. Coordinate with the utility to provide separate utility feeders, if available. The transformers should be sized so that either transformer and incoming supply line can carry the entire substation peak demand, including load increase projections for the next 10 years.
- Voltage regulation. Either transformer load-tap changing (LTC) transformers or separate voltage regulators are acceptable. Separate voltage regulators, wherever installed, must be provided with bypass and disconnect switches.
- Circuit breaker or circuit switcher on each substation transformer primary side for local isolation of the incoming supply. For substations with overhead bus structure, include a load-break or non-load break switch as an additional isolation device.
- Circuit breaker on each substation transformer secondary side. This is typically the main breaker to the substation switchgear. For substations with overhead bus structure, include a load-break or non-load break switch as an additional isolation device.

- Separate switchgear for each transformer with cross-tie capability between switchgear. Provide spare breakers and evaluate the need for additional distribution system feeders.
- Electronic protective relays to allow circuit protection, monitoring, and event recording.
- Station class surge arresters.
- SCADA controls. If remote SCADA control is included, provide dedicated fiber-optic lines between the facility and the desired control location. Obtain approval from the AHJ for communication systems that enable remote access.
- Connections between the transformer secondary and the main circuit breaker. Preferred connection methods include cables in conduit or cable trays. Busway transitions are discouraged, but if they are used, it must be labeled for the application by Underwriter’s Laboratories, or equivalent; designed for outdoor service, including a stainless steel housing and hardware for corrosion control; rated and braced for the maximum expected continuous current and short circuit current; designed to control condensation and its effects; and designed to allow access for periodic inspection following the NETA MTS guidance.

D-2 DEFINITION OF TERMS

Activity: With respect to this UFC, approval is provided by the following:

- For the Air Force, this is the Base Civil Engineer.
- For the Navy, this is the Public Works Officer.
- For the Army, this is the Installation Director of Public Works.

Contractor: Person(s) doing actual construction portion of a project.

Corrosive Area: An area identified by the Technical Reviewing Authority as requiring special equipment corrosion mitigation methods. **3**\ Corrosive areas include locations with an Environmental Severity Classification (ESC) of C3, C4, and C5. See UFC 1-200-01 for determination of ESC for project locations. /**3**/

Designer of Record: The engineer responsible for the actual preparation of the construction documents.

Main Electric Supply Station: A main electric supply station is also referred to as a “switching station” and does not have power transformers to transform from the utility transmission voltage to a lower distribution voltage. The main electric supply station is the installation/utility interface point where further transmission, distribution and utilization of electrical power, the monitoring and control of such power or equipment and the protection of electrical equipment or systems usually becomes the sole responsibility of the Government or their contracted representatives.

Main Electric Supply Substation: A main electric supply station that also transforms the energy level (voltage) for further bulk distribution at medium voltage levels. A main electric supply substation includes power (substation) transformers.

Facility Core Distribution Infrastructure: System components that constitute a part of the base infrastructure system that are required to provide electrical service to multiple users.

Low Voltage System: An electrical system having a maximum root-mean-square (rms) voltage of less than 1,000 volts.

Medium Voltage System: An electrical system having a maximum RMS ac voltage of 1,000 volts to 34.5 kV. Some documents such as NEMA C84.1 define the medium voltage upper limit as 100 kV, but this definition is inappropriate for facility applications.

Primary Distribution: A system of alternating-current distribution for supplying the primary of distribution transformers from the generating station or substation distribution buses. Primary distribution can be supplied either overhead or underground and includes all associated equipment.

Project Manager: Engineer charged with the administration of the project.

Secondary Distribution: An alternating-current system that connects the secondaries of distribution transformers to the consumers' services. A secondary distribution is typically operating at low voltage, but could be operating at medium voltage.

Service: The conductors and equipment for delivering electrical energy from the serving utility or Government-owned system to the wiring system of the premises served.

Site Electrical Utilities: Site Electrical Utilities are the primary electric power distribution to the facilities and other electrical loads, all exterior lighting not attached to the building; and all telecommunication services (fiber optic, copper cable, CATV, etc.) required by the Facilities.

Switching Station: refer to Main Electric Supply Station.

Utilization Electric Supply Station: Equipment such as pole or pad-mounted transformers or secondary unit substations that transforms the energy level (voltage) to a utilization voltage for consumer use.

UNIFIED FACILITIES CRITERIA (UFC)

RESILIENT INSTALLATION MICROGRID DESIGN

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

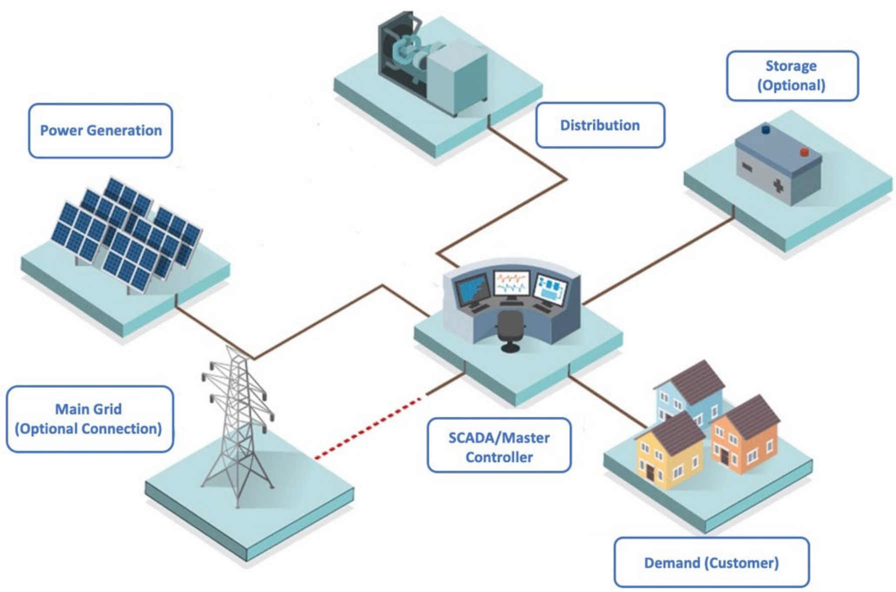
CHAPTER 1 INTRODUCTION

1-1 GENERAL.

The primary objective of networked standby power systems (e.g., microgrids) is to deliver resilient, ride-through power to installation operations during extended contingencies resulting from commercial service failure, natural disaster, or cyber-attack. Microgrid systems deliver contingency power to loads inside a facility, a facility cluster, several facilities on a feeder(s), across a substation(s), or an entire installation campus. Islanded operation is a fundamental characteristic of all microgrid designs governed by this document. A microgrid's primary benefit is its ability, as a bounded system, to disconnect from the commercial grid during an emergency and deliver resilient, ride-through power with optimized off-grid endurance. Figure 1-1 shows components of a microgrid.

Figure 1-1 Components of a Microgrid

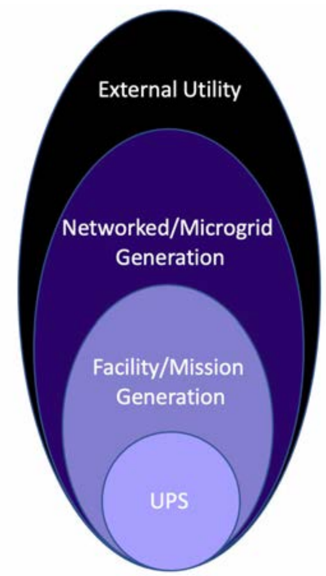


1-2 BACKGROUND.

Facility-dedicated backup power architectures represent DoD's de-facto approach to backing up mission loads during commercial power outages, in accordance with UFC 3-540-01. This approach has several noteworthy advantages: relative simplicity of operation (mission-dedicated generation supports specific mission loads), clear demarcation of real property ownership, and limited ambiguity of sustainment cost share (a tenant or mission owner generally maintains that facility's backup generator). However, such load-dedicated standby power solutions can be ill-suited to carry critical operations over extended periods of time (each load is completely dependent on its mated facility generator, and increasing redundancy at each load requires additional infrastructure at each load). Further, such solutions offer limited ability to interconnect and leverage large renewable energy systems (or exploit their sustainability and economic benefit), as modestly sized facility generators may be subject to extremely high ramp rates, load-following conditions, and power quality variability when networked with large renewable systems. Finally, cyber-securing each of the IP-addressable assets and controllers in a facility dedicated standby environment is generally costlier and laborious than securing a single, large, centralized utility monitoring and control system.

Microgrids and networked standby power systems deliver a complementary solution supporting a layered framework for contingency power (see Figure 1-2). Using this approach, each layer of contingency power relieves the power system in the layer below. Accordingly, when the microgrid is active, mission-dedicated assets are relieved by the network, allowing the installation to maintain a more unified and resilient standby power posture.

Figure 1-2 Layered Approach to Contingency Power



Multi-Layered Approach to Contingency Power

1-3 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC) provides criteria on installation microgrid design requirements, performance metrics to inform design, sequence of operations, commissioning and validation, and sustainment. Design tenets and criteria contained herein are intended to ensure resilient, robust, and standardized solutions based on performance-based criteria and best design practices.

1-4 APPLICABILITY.

This UFC is applicable to all networked “islandable” standby power systems (systems capable of isolating and operating independently from the external grid). Compliance with this UFC is mandatory for the planning, design, construction, and commissioning of networked standby power systems, including microgrids for facilities and installations, regardless of funding source. This UFC also applies to overseas facilities, considering mission objectives and Host Nation standards, to the greatest extent practicable. This criteria addresses both prime and continuous power application under islanded and grid-connected conditions of operation. This guidance does not forego adherence to prevailing guidance for stationery engine-drive power systems as stated in UFC 3-540-01. Whenever unique conditions and problems are not specifically addressed by this UFC, use the applicable referenced industry standards and other documents for design guidance.

Per DoD Instruction 4270.5, the design criteria of this UFC does not apply to privatized housing or to projects acquired through a real property exchange agreement. This guidance is not applicable or intended to address mobility power system or mobile generation solutions. This UFC is not applicable to individual facility or load-dedicated standby power systems.

1-5 MICROGRID POINTS OF CONTACT BY SERVICE.

For any DoD project involving networked standby power or microgrid design, the relevant agency for each service must be contacted as soon as possible. Information, design support, system modeling, and other assistance is available from the following organizations:

- **Army**: US Army Corps of Engineers (USACE)
- **Navy and Marine Corps**: Naval Facilities Engineering Systems Command (NAVFAC), HQ NAVFAC Utilities, Washington Navy Yard
- **Air Force and Space Force**: Air Force Civil Engineer Center (AFCEC), Operations Director, Tyndall AFB

1-6 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-7 ENERGY RESILIENCE.

All energy systems must be planned, designed, acquired, constructed, and maintained in accordance with Title 10, U.S.C., Section 2911(a), DoD Instruction 4170.11, and as required by individual Service and Defense Agency policies on energy resilience.

Resilience is the ability to anticipate, prepare for, and adapt to changing conditions and withstand, respond and recover rapidly from high-impact, low-probability disruptions (including events resulting from climate change) impacting mission readiness per DoDD 4715.21. It is determined by the ability of a system to anticipate, resist, absorb, respond, adapt, and recover from disturbances such as natural disasters, terrorism, cyber-attack, or other significant and adverse impacts.

1-8 OWNERSHIP AND SUSTAINMENT.

To determine if a microgrid is a viable and sustainable solution, mission and public works personnel should review the installation master plan, energy plan, existing resilience posture, and commercial utility historical service performance including System Average Interruption Duration Index (SAIDI) and System Average Interruption Frequency Index (SAIFI) metrics per IEEE 1366 (an example of these metrics is given in Table D-1). Microgrids should be evaluated against alternative resilience enhancement solutions that reduce reliance on external commercial systems, improve resilience score, operational based readiness, and minimize lifecycle sustainment cost. When evaluating resilience enhancement options, refer to official policy and guidance provided by the appropriate military service.

Since microgrids primarily address resilience and mission assurance metrics, mission and public works personnel need to be consulted to determine 1) if a microgrid is an appropriate approach to advance these metrics, 2) ownership of the microgrid, 3) and capacity to operate and sustain a dedicated microgrid system. Real property and cybersecurity ownership, appropriate accreditation authority, and cyber-sustainment strategy must be identified.

1-9 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy. All information systems connected to, or with software loaded onto, DoD information grids must receive an interim or full authorization to operate/test prior to connection in accordance with UFC 4-010-06 and as required by individual Service Implementation Policy.

1-10 TOPOLOGY.

Microgrids are generally classified with respect to their sources and architecture. All installation microgrids are composed of energy sources, loads, one or more points of common coupling (PCCs), electrical distribution, switchgear, and secure controls (Figure 1-1). Specific microgrid topology is based on a distributed or central-plant architecture. Distributed microgrid architectures are composed of geographically disparate distributed energy resources (DERs) networked across the distribution system using secure controls and communications. Alternatively, central plant-based microgrids include co-located, generally large DER (for example, reciprocating internal combustion engines) to deliver power to the load, but generally with greater reliance on the distribution system. Regardless of architecture, type of DER, or configuration, all interconnected DER assets are subject to anti-islanding, mandatory minimum voltage ride-through, and under/over-voltage trip time safety requirements per IEEE 1547.8 when the microgrid is connected to the external grid. Inverter-based DER may only interconnect to the islanded microgrid once the inverter has detected that the distribution has been energized by dispatchable (firm) DER (as listed under the Predictable Electrical Output column in Table 1-1).

1-10.1 Distributed Systems.

Distributed systems network discrete sources located throughout the microgrid boundary. Sources can be a combination of existing sources such as facility-level DERs or new microgrid-dedicated DERs. Distributed control points, switchgear, fiber network infrastructure, and the human machine interface (HMI) are the backbone of a distributed control system. While more communications intensive, distributed generation solutions offer the advantage of leveraging existing capital asset investments at many installations. See service-specific informing references in APPENDIX I.

The building block of a distributed energy microgrid's functionality is the facility generator's switchgear, which is generally sited near facilities with emergency generators (Figure 1-3). The microgrid architecture incorporates dedicated paralleling switchgear, breaker protection, and updated device protection settings to allow facility-level DERs to parallel and energize an islanded distribution feeder.

Figure 1-3 Distributed Generation Architecture

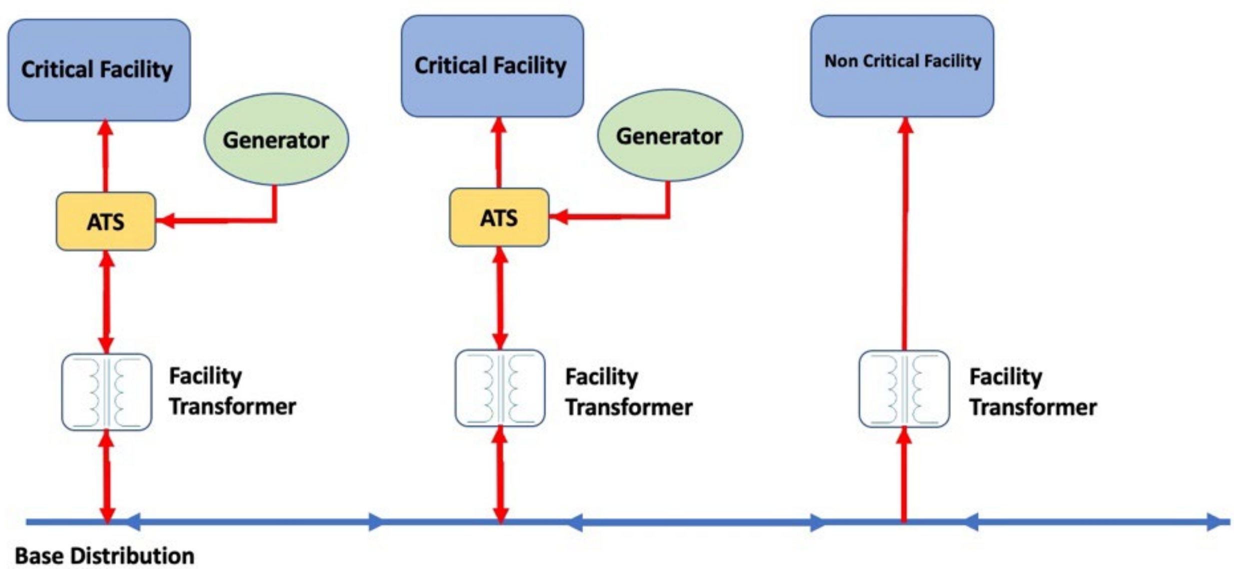


Figure 1-4 shows normal and emergency switchgear configurations across the ATS allowing increased functionality, beyond simply isolating a given facility and its generator from the distribution system. The emergency configuration is used to network each standby generator inside the microgrid boundary to a common bus using existing galvanic isolating devices. The bus is energized by the distributed generator fleet (much like discrete power plants supporting a utility's commercial transmission system, albeit at smaller scale).

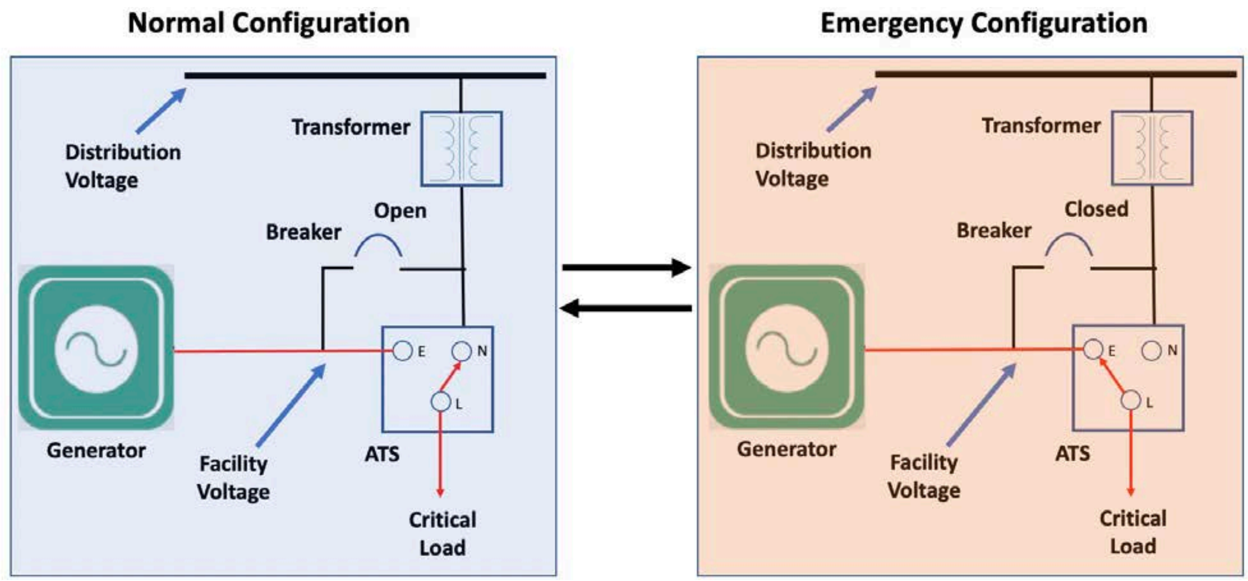
Figure 1-4 Normal and Emergency Switchgear Configuration Across ATS



As soon as external grid power is lost, facility-level DERs come online. Many of these facility-level DERs are standard emergency generators associated with specific loads.

The DERs operate autonomously per UFC 3-501-01 (Electrical Engineering) and UFC 3-550-01 (Exterior Electrical Power Distribution), and tend to be out of phase with each other. When the interconnection point is opened and the installation is disconnected from the external grid, the DERs must first synchronize before forming a microgrid. DERs must operate "in phase" as they are connected (this is also true of the renewable resources that are subsequently networked to the microgrid). A reference frequency is selected from the DERs and the remaining DERs synchronize to this reference. The synchronization process repeats when the external grid is restored and the microgrid prepares to reconnect at the PCC. In this case, however, the microgrid DERs (in unison) use the external grid frequency as the reference when synchronizing to the utility.

An important benefit to this approach is that it leverages DoD's existing fleet of fuel-based generation. Infrastructure already specified in current design guidance can be applied to support a distributed microgrid, with paralleling switchgear and modification in engine governor controls. Since many facility-level DERs require dedicated paralleling gear and updated protection settings, it is advisable and prudent to network larger DERs with significant remaining service life and appropriate generator and emissions certification (for example, larger than 250kW, prime/continuous rated Tier 4).

1-10.2 Central Plant Systems.

Central-plant based systems employ a central generating plant, often including RICE units, combined heat and power, co-generation, or other configurations, with co-located DER (e.g., turbines, reciprocating engine, gas-fired, fuel-fired, or fuel oil-fired generators). While generally more dependent on distribution system, these solutions are typically more efficient when backing up large base loads. Additionally, central plant systems can typically tolerate greater contributions and variability of renewable energy generation without energy storage.

1-10.3 Fuel-Based, Dispatchable (Firm) Generation.

These are assets that deliver “firm” dispatchable power and include turbines, diesel, propane, or natural gas generators. Fuel and gas-based generation (including facility-dedicated standby systems) are dispatchable. These systems are typically capable of black start, grid-forming operation, and load following.

These systems are frequently sited on DoD installations with automatic transfer or automatic distribution switches (to support dedicated standby operation following loss of service) and are capable of operation without an energized distribution system or microgrid signal. These assets are generally capable of black start operation (when the distribution bus is not energized) and can be networked within an islanded distribution grid (sometimes requiring engine governor modification). These DERs can be permitted for standby, prime, or continuous application (emergency operation, unlimited hours at variable load, or unlimited hours at a constant load, respectively).

1-10.4 Inverter-Based Generation.

Contributions from inverter-based and renewable DERs may defer fuel resources and extend off-grid operational endurance in an extended emergency. The electrical output of these DERs is delivered in direct current (DC), requiring one or more inverters to interface with installation distribution. Because these systems rely on differing inverters at their output, their degree of visibility, controllability, and flexibility to support the microgrid design intent can vary significantly. Inverter based generation is subject to UL 1741 per UFC 3-540-08. Additional tolerance (capacity) factors should be included when generation is intermittent or non-dispatchable.

Higher interconnection of inverter-based assets on small microgrids can often necessitate increased firm, dispatchable generation with reserve capacity to manage source intermittency, islanded load variability, non-linear loads, inductive and motor start loads, and other high-VAR load requirements.

1-11 ENERGY RESOURCE CLASSIFICATION GUIDE.

Table 1-1 provides DER attributes and common applications to inform design. For clarity, the table column categories are explained below:

- Primary power: the primary energy resource, used to reliably meet largest portion of load – can be replaced with utility
- Base load power: the ability to provide base load power is highly variable, depending on the size of loads served
- Load following: the DER follows the load and can adjust power output to amount of power needed
- Power quality correcting: also referred to as improve power quality
- Inverter based system: systems may include inverters that convert power from DC to AC
- Predictable electrical output: may also be referred to as firm or availability of power when needed
- Grid forming DER now includes all DERs listed under Predictable Electrical Output column of Table 1-1

1-12 PROGRAMMING.

Primary Category Codes for microgrid resilience and backup power projects include 81109, 81110, 81160, etc. Revisions to this UFC will include additional category codes for networked standby power projects.

1-13 GLOSSARY.

APPENDIX G contains acronyms, abbreviations, and terms.

1-14 REFERENCES.

APPENDIX H contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 TECHNICAL REQUIREMENTS

2-1 MINIMUM DESIGN REQUIREMENTS.

To be in compliance with the criteria prescribed herein, the design must:

a. Be capable of islanding with ability to network (or parallel) more than one disparate source of generation per UFC 3-540-01

b. Be a Bounded System with autonomous generation, distribution, controls, and Human-Machine Interface (HMI)

c. Include Black Start[1] Capability: Be capable of grid-independent black start with a minimum of one grid-forming DER[2]

d. Contain sufficient generating sources, stored form of energy, and reserve capacity[3] to meet the peak critical load within the system boundary with off-grid endurance not less than the duration of time required by mission and service policy (independent of renewable energy sources)

e. Include System Balancing: Contain Grid-Independent ability to energize critical loads and optimize load factor

f. Include fail-safe ability that resorts to load-dedicated (or pre-microgrid) operation following electrical system, communication, or other network disruption

g. Have risk management framework process initiated. This may include a Cybersecurity Authorization to Operate (ATO) by a DoD Approving Official (AO)

h. Use technology that is commercial, warrantied, and supports permanent infrastructure improvement. This UFC does is not intended to govern research, development, demonstration, emerging practice, or developmental technology.

The following considerations represent recommended best practice and should be included as scope and funding of a project allows:

- Redundant networked sources of generation
- Energy storage
- Bi-directional soft, “blinkless” transition

[1] Black start is starting a microgrid system after unplanned grid failure with no energized generation resources.
[2] Energy Resilience Readiness Exercise (ERRE) tests the operational capabilities of microgrids to support mission operations in the absence of normal utility power.
[3] Reserve capacity is the uncommitted, immediately-available generation capacity on the network, accounting for islanded load variability, non-linear loads, motor start, and other high-VAR, inductive, and nonlinear load requirements.

- Grid connected support, with capability for demand response, and ancillary services such as frequency support, voltage management, and black start
- Redundant (min 2) grid forming assets
- Redundant (min 2) HMI Visualization HMI Front-Ends
- Redundant (min 2) Independent Black Start Sources
- Load Shedding Capability
- Be capable of re-synchronization and soft (seamless) transition back to the external grid

2-2 PERFORMANCE REQUIREMENTS.

Agency policy, mission needs, and installation requirements should inform the performance requirement, which then informs the basis of design and, subsequently, the acquisition. All installation microgrids must include the following elements: energy sources, loads, one or more PCCs, electrical distribution and switchgear, and secure controls. The following requirements listed in paragraphs 2-2.1 to 2-2.4 are also mandatory.

2-2.1 Autonomous Operation.

A microgrid must be capable of providing power independently of all external power and communication networks. In this respect, microgrids are autonomous. However, the degree to which a microgrid is configured to automatically enter into its active states of operation following an outage must be carefully considered based on mission Continuity of Operations (CONOPS) and personnel requirements. Degree of automation can vary from having a required "human in the loop" input command between each system configuration and operational state, to fully automated systems that are "Always Sensing" systems with no required user intervention between each system state.

2-2.2 Safety and Grounding.

Because the systems often integrate generation on the load side of facility transformers and operate independently from the external grid, designs may require dedicated or modified grounding during certain conditions of operation. Special design consideration must be given to islanded operational states requiring dedicated grounding and protection configurations per AFMAN 32-1065. Prior to integrating microgrids into existing installation systems, evaluate if:

- existing installation distribution equipment and switchgear are integrated;
- dedicated or modified grounding during certain conditions of operation are required;
- any islanded operational states require dedicated grounding or updated protections at any location.

2-2.2.1 Safety and Arc Flash.

Designs often include system simulation or modeling to update arc flash and safety protections and identify issues with equipment duty ratings that require upgrading or replacing existing equipment, or increases in arc flash that require mitigation and protective device coordination. Any analysis developed or updated must be performed in the prevailing modeling environment used by public works and the local utility. The model must be updated per NFPA 70E by a qualified engineer. All updated model files should remain the property of the government.

2-2.2.2 System Grounding.

Grounding needs specific attention when the microgrid is designed. Grounding configuration must be assessed during all conditions of the microgrid, including all operational modes and all temporary modes that may conceivably exist during microgrid formation and disconnect. Grounding systems are required although equipment may be disconnected from the main power but remain live at different points. Careful analysis, including modeling, is required for both the grid connected and islanded modes (and all configurations between) to protect equipment and personnel during fault conditions.

2-2.2.3 Fault Protection.

Specific attention must be given to islanded fault protection. When connected to the utility grid, the distribution system is capable of delivering the necessary short circuit system performance based on protective relay settings at substations. When the distribution is energized in islanded mode, system inrush current may cause deviation in islanded voltage and frequency triggering generator under speed protection or other DER protections. Short-circuit characteristics of the networked sources may not consistently produce sufficient current to be detected using existing protection settings; allowing faults to be undetected and potentially cause system damage. Consequently, the grid-connected protection configuration (before a microgrid is implemented) may not offer adequate fault protection. The design must include updated protection settings at system and device level to isolate or clear faults to prevent damage to equipment and loads. Analysis of the system protection architecture includes system simulation or modeling prior to final design approval. In some cases, protective device coordination studies are performed as part of design and updated during construction. Refer to APPENDIX E for additional performance metric and safety information.

2-2.3 Cybersecurity and Risk Management Framework.

Designers must refer to UFC 4-010-06 for all microgrid designs as the primary resource for planning cybersecurity protocols in advance of acquisition. Within DoD, each agency has an AO who determines the “Authority To Operate (ATO)” based on risk, and approves the final implementation (representing minimized, well-managed risk). Based on the organizational mission and details of the control system, the System Owner and AO determine impact levels (LOW, MODERATE, or HIGH) for the control system. The Designer of Record must coordinate with the relevant service-specific authorities and ensure that the DoD approved evaluation processes and risk management framework for cyber security concerns are addressed.

When Applying Risk Management Framework to Microgrid Controls Systems, the network boundary should include all control points and IP-addressable assets constructed as part of, or controlled by, the microgrid system. Facility control systems are not information technology (IT) systems; they should not use standard IT system approaches and not be connected to public systems, especially internet systems, and not have remote access. (no access outside of defined and approved system architecture network boundary).

2-2.4 Utility Management Control System (UMCS) Integration.

System design must demonstrate minimum interoperability with existing (or planned) UMCS, specifically any data required from UMCS as part of microgrid operation or information from microgrid system to UMCS for display or other purposes. Interoperability may support aspects of microgrid design including communication with, or control of, primary assets of the Utility Control Systems (UCS) as described in UFC 3-470-01.

CHAPTER 3 PERFORMANCE METRICS

Consistent with OSD Metrics and Standards for Energy Resilience at Military Installations (2021), the microgrid performance-based design process must identify performance metrics and goals to inform the basis of design. This includes the following metrics described in this chapter.

3-1 OFF-GRID SYSTEM ENDURANCE.

Off-grid endurance is a primary performance metric that must be used to inform system design and must be identified in the basis of design. This refers to the total duration the microgrid can carry the peak critical load without the return of commercial power or refueling service (i.e. islanding duration). Regardless of what level of off-grid endurance is targeted, the final design must provide a total amount of onsite stored form of energy (fuel, gas, compressed gas, electrical energy, etc.) that meets the target.

This target metric must be informed by prevailing DoD service policy and mission assurance requirements. Traditional standby generation design practices have targeted 72 hours of system endurance for all critical loads served by the network. UFC 3-540-01 includes a requirement of 7 days of onsite fuel storage capacity, with a provision for confirmed delivery of sources. OSD Metrics and Standards for Energy Resilience at Military Installations promotes a 14 day target for mission loads. DoDD 3020.26 includes language to ensure performance of Mission Essential Functions during any emergency for a period of up to 30 days or "until normal operation can be resumed”.

3-2 PEAK CRITICAL LOAD SERVED.

The design must have the capacity to support the peak load demand of critical systems when they are engaged in normal and peak mission activity (along with any non-critical loads that are incidental or non-segregable). Analysis of mission load profile during times of normal and peak mission activity must be conducted to verify adequate generation as well as load following capacity is available.

The load analysis must give specific consideration to step loads, highly nonlinear loads, motor and high-VAR inductive loads, as well as projected and actual or tested requirements in island mode. Load analysis must be conducted for both grid-connected and island modes.

3-3 LOAD SHEDDING.

Load shedding is the capacity of the design to shed load to maximize endurance of higher priority mission operations. The engineering analysis must include options for active load management and load shedding maximize off-grid endurance of mission loads. The load shedding plan must consider mission dependency criteria and installation load restoration plan to support the level of energy resilience required for the microgrid’s essential facilities (see Table 4-2). Load shedding can be implemented by sequential restoration at substation breakers or via under frequency load shedding. For cases with nominal non-critical loads (or that are not easily segregable), designers must assess the tradeoff between incorporating additional load-shedding switchgear against the marginal cost of additional generation and system capacity required to support those loads.

3-4 RESTORATION TIME AND SOFT TRANSITION.

The microgrid system is responsible for transitioning to islanded power following a commercial power outage, as well as transition back to external power following commercial system restoration. Restoration time to supply power to all critical loads in the network is an important performance factor. This includes the time required for the system to island at all points of interconnection, parallel and synchronize generation, and deliver power to the designated critical load(s) in accordance with mission and installation circuit priority. This can range from soft transitions with instant “blinkless” power to the critical loads, to seconds or minutes (see Figure 4-3).

While not an explicit criteria requirement, designers must consider any specific operational needs or loads that may require soft transition both to and from islanded operation.

3-5 OPTIMIZED DER LOAD FACTOR.

Optimize DER load factor to the extent to which the design minimizes low load factor operation of individual DER assets including operation of assets in a reserve capacity. This includes minimized operation of fuel-based generation operating at low load factor, load banks, and other operational inefficiencies. Optimizing target DER load factor improves off-grid endurance and economizes system operation by preferring lowest-cost form of generation, renewable generation assets, and energy storage. Designers must assess the tradeoff between larger DERs (associated with more attractive capital and operational cost per unit output) against smaller DERs (as a network, can support system requirement at higher load factor).

3-6 ENERGY SURETY AND REDUNDANCY.

Redundancy is the allowance for failure or loss of at least one significant generation network DER and still serve the peak critical load requirement.[1] The aggregate generation capacity of the network must meet or exceed the maximum peak critical load based on the load analysis. The degree of required redundancy in the network must correspond with the resilience requirement of the load. See load designations in Figure 4-3.

3-7 DEGREE OF RENEWABLE ENERGY CONTRIBUTION.

Designs with greater contributions of power produced by climate-friendly technologies offer more sustainable operation and advance DoD climate impact goals. Though not firm or dispatchable forms of generation, renewable DER sources reduce or defer fuel

[1] This degree of redundancy may not be viable for large-scale projects, peaking plants, or designs primarily targeting grid support (often comprising very large DER systems).

use or energy storage discharge to deliver greater off-grid endurance. Systems exclusively using renewable generation sources must verify sufficient available storage and black start performance to manage islanded resilience requirements as well as climate goals.

3-8 OPERATIONAL VISIBILITY AND GRAPHICAL INTERFACE.

Designers must include the graphical human-machine interface (HMI) that conspicuously illustrates system state, operational parameters and condition of major components, available reserve fuel and other forms of stored energy, position of major switchgear components, and flow of power within the system boundary. The HMI should be intuitive and interactive for system operators. Interface elements shall conform to accepted power system industry standards per IEEE 1826. The HMI must include dedicated uninterruptible power supply (UPS) of no less than 2 hours to accommodate operation during changes in operational state.

3-9 EXPANDABILITY AND RECONFIGURABILITY.

System design needs to accommodate load growth or mission expansion with minimal design reconfiguration, reprogramming, and recurring engineering costs. Scalable designs can accommodate mission growth by expanding the number of network sources, the size and location of the addressable load, and reconfigure/reprioritize load without significant re-design, retrofit or replacement of capital assets (distribution switchgear, motor controllers, substation equipment, etc.). All design modification and expansion must accommodate and adhere to installation configuration management protocols. Designs with looped distribution, multi-terminal switches, and bypass of DERs and switchgear (to minimize impact of equipment maintenance and testing) should also be considered. A MILCON is valid for five years; expansion after that five-year period requires a new MILCON. Should a new project require modification or expansion of the microgrid, then that activity must fund all required upgrade to the system, including any additional generation, to maintain operational functionality. Perform studies to determine if a microgrid is appropriate. For bases with existing microgrids, study to determine if new construction requires a new microgrid or if it can be integrated to an existing microgrid as an expansion.

3-10 GRID-CONNECTED AND ECONOMIC APPLICATIONS.

The degree to which the design allows for grid-connected operation or applications supporting economic incentives including demand response, load curtailment, grid-support services, or other ancillary arrangements that improve lifecycle payback. The lifecycle value of these design attributes is a function of site location, degree to which the region is energy constrained, nature of existing power purchase agreements, and commercial utility needs.

3-11 POWER QUALITY.

Power quality is a significant consideration for islanded microgrids. Because microgrids energize smaller systems than commercial grids (and generally operate with less reserve generation capacity), loads can be impacted by ramping effects from large renewable systems, power system transients, and other power quality events. Transients resulting from normal operations such as switching, renewable energy variability, and transformer inrush currents must be managed to avoid equipment damage. The design must accommodate large motor starting and other nonlinear and reactive power events during islanded operation. Grid modeling and short-circuit analysis is generally required at sites with: low short-circuit ratio, substantial dynamic power system considerations, other power quality challenges, or where required by the commercial utility operator. Microgrid systems are now capable of following the load and provide power to the systems needed.

CHAPTER 4 PLANNING, DESIGN AND ACQUISITION

4-1 MICROGRID PERFORMANCE-BASED PLANNING AND DESIGN.

Planning and design must be informed by performance criteria. Performance-based acquisition uses performance criteria, rather than prescriptive criteria, to inform planning, design, and acquisition (for example, total amount and duration of load to be supported rather than prescribing the number and size of DERs, switches.) Such a performance-informed approach allows the DoD to assure salient service policy and installation requirements are fully reflected in the project from inception, without being unnecessarily prescriptive as to the type or form of generation solutions, size, or controls in advance of acquisition.

For USAF projects, AFMAN 32-1062 specifies USAF approval process of generators for prime power, cogeneration, or microgrid applications. Air Force Civil Engineer Center/Operating Directorate (AFCEC/CO) must coordinate on all government funded microgrids, and AFCEC Energy Directorate (AFCEC/CN) must coordinate on all third party funded microgrids. Commissioning should include all items needed on hand for O&M/Repair such as spares/repair parts/supplies/special tools/special test equipment. Develop a configuration management plan and implementation of procedures for controlling changes to the design baseline over time.

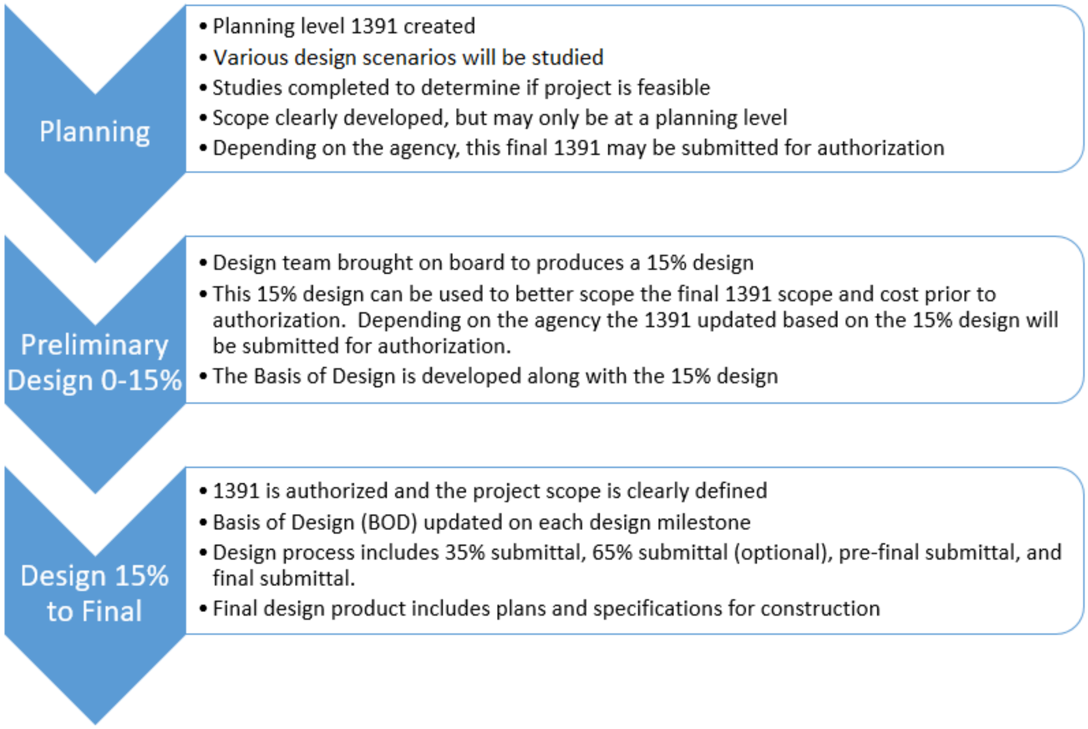
4-1.1 Performance-Based Planning and Design Process.

The planning and design process includes identifying and applying salient organizational policies, including application of DoD energy resilience policy and directives (e.g., DoDI 4170.11) as defined by 10 USC 2911, climate goals, and UFGS/UFC criteria early in the concept development. Refer to Figure 4-1 for the microgrid design progression. Planning includes:

- Defining objectives
- Defining scope
- Assessment of options
- Condition assessment
- Other operational requirements

All design activities must consult the Public Works/Public Works Officer (PW/PWO) office and utility operations to ensure all equipment selection, specification, documentation requirements, HMIs, software configuration, sequence of operations, operational visibility, and other elements aligns with mission and installation operation and protocol.

Figure 4-1 The Microgrid Design Progression



4-1.2 Checklist for Compiling a Planning DD1391.

DoD uses DD Form 1391 to support funding requests for military construction projects to Congress. The form is used to record the installation's program in relation to personnel strengths, real property improvements, mission and functions. A sample DD1391 is provided in paragraph D-2.1. Reference annual planning guidance for the Energy Resilience and Conservation Investment Program (ERCIP) issued by Office of the Secretary of Defense (OSD) for the latest DD-1391 format and required information with respect to ERCIP submissions. ERCIP submissions from all components are evaluated annually for funding and need to contain required information in prescribed format.

4-1.3 Methods of Procurement.

Microgrid systems can be acquired either directly through installation resilience resources such as DoD MILCON, ERCIP, and Intergovernmental Service Agreement (IGSA), or under alternative third-party financed arrangements such options include Energy Savings Performance Contracts (ESPC), Power Purchase Agreements (PPAs), Utility Energy Service Contract (UESC), Utility Privatization (UP), or as part of in-kind consideration with a public utility or independent power provider for leased military sites. Resources required to support system O&M and testing throughout the system lifecycle should be identified and microgrid performance should be recorded as required by each Service.

4-1.4 Construction Sequencing.

The designer must include sequence of construction. Schedule coordination with ongoing operations is critical, particularly for cut-in/tie-in work and equipment upgrade and swap out. Construction activities can be coordinated with normal maintenance shutdowns and affected component Commands for acceptable outage times.

Additionally, the sequence of construction needs to be considered. For example, if a high-penetration level of PV renewable energy is to be installed with a battery energy storage system (BESS), it is best to install the BESS first, to manage power stability prior to installing of the PV system.

4-2 PLANNING AND MODELING (0-10%).

Planning and modeling determines feasibility and viability of a networked standby power solution. Mission needs and lifecycle costs (capital and operational) are considered. Options for a combination of energy sources, to include renewable energy and energy storage options must be investigated at the start of any microgrid project (often referred to as techno-economic analysis). Mission requirement, service policy, and prevailing DoD guidance must inform the early design.

The planning phase must also identify existing power system models (for example, Easypower, ETAP, SKM, and PSCAD) and include scope to reflect all changes and impacts from the microgrid project.

The conceptual design should include the following elements. Refer to Sections 4-2.1.1-4-2.1.11 for further details on each element.

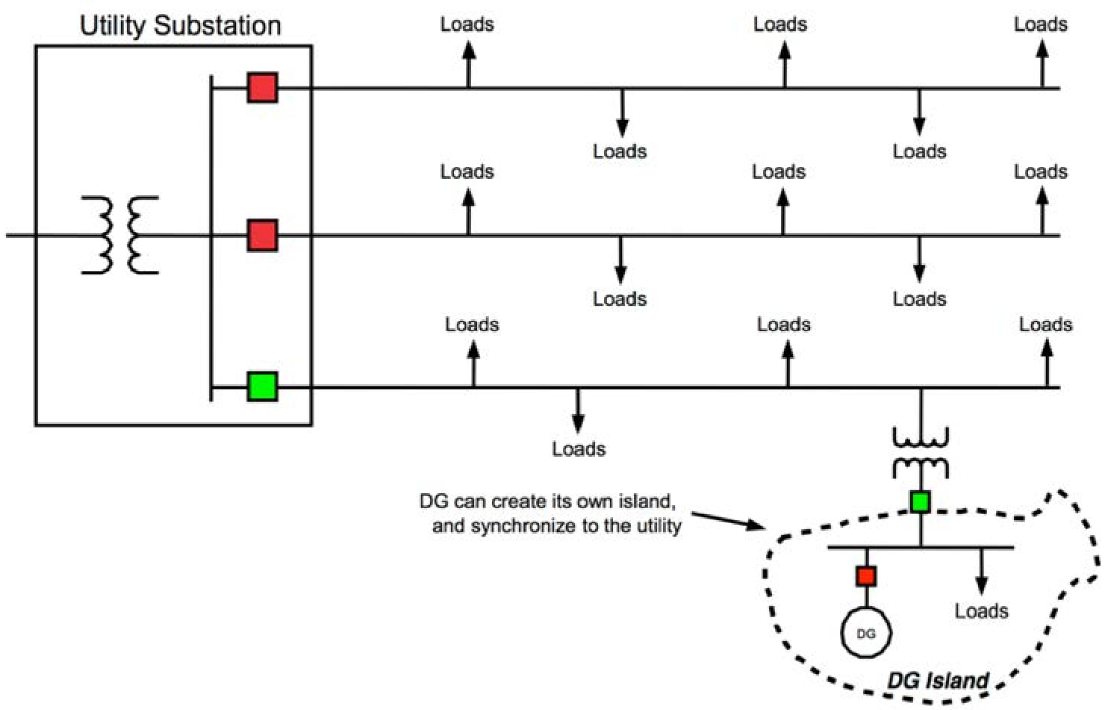
- Defining system boundary (based on stakeholders and mission commands with elevated security requirements)
- Identification of critical loads to support with microgrid
- Identification of mission owners, system owner, and cybersecurity accreditation authority (UFC 4-010-06 is the primary resource for planning cybersecurity)
- Identification of areas requiring electrical system modeling or updating
- Feasibility and constructability of alternatives
- Utility interconnection application and studies
- Compiling draft layout and list of systems components
- Complete cost estimation and cost-benefit analysis

4-2.1 Conceptual Design Elements.

4-2.1.1 Defining System Boundary.

The system boundary must be defined based on mission need, infrastructure configuration, and operational requirement (see Figure 4-2). A system boundary is determined based on mission requirements, existing power generation and distribution infrastructure, ease of electrical isolation (based on the one-line diagram), deficiencies in resilience related to the electrical supply to loads, and optimization of new and existing and DER sources, power distribution, and supporting fuel supply.

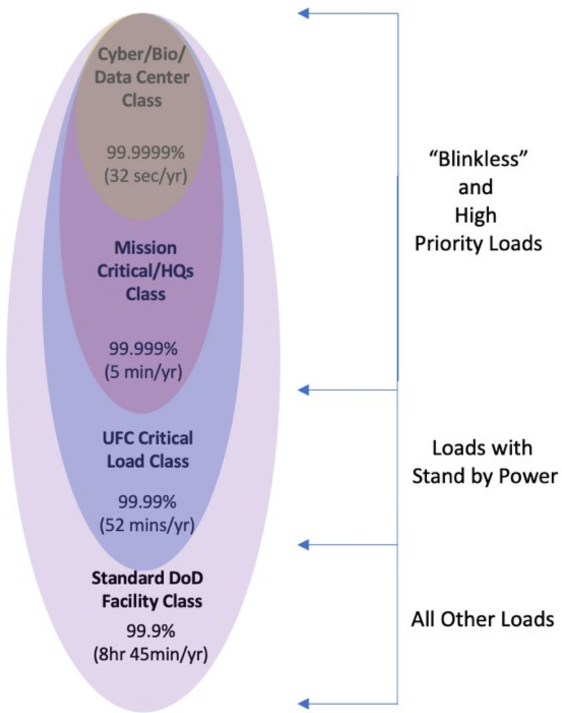
Figure 4-2 Microgrid Boundary



4-2.1.2 Identifying Critical Loads.

During the conceptual design phase, critical loads need to be identified. Designers must consult with the affected mission owners to define requirements, associated dependencies, and critical loads that, if lost, will ultimately lead to a failure of an identified mission-critical system. A notional example of load designations based on allowable annual outage duration is shown in Figure 4-3.

Figure 4-3 Load Class Designations and Annual Down Time



Identification and prioritizing of critical loads is informed by the mission. Buildings, systems, and other critical elements required to support the mission elements must be identified. The following are characteristics of microgrid critical assets and systems:

- Time Basis: Loads should be identified as to how long after power outage they are needed (uninterruptible, seconds, minutes, hours, days, and weeks). Also, how long must load be supplied each day?
- Load Requirements: Full load, peak load, average load, or minimum load need to be subdivided into critical and non-critical loads. Can control systems be used to drop non-critical loads?

During the iterative stakeholder process, the designers must tailor microgrid performance to meet mission requirements according to each of the performance metrics in CHAPTER 3.

Certain critical loads may already have load-specific generation that cannot be interconnected to the microgrid for technical or mission reasons. Under these conditions, designers can proceed with a system designed to relieve mission-dedicated generation without controlling or interconnecting load-dedicated generator(s). Under this scenario, the local facility's Automatic Transfer Switch (ATS) system identifies energized distribution (due to normal grid or microgrid operation) and refrains from switching to emergency position. In this way, the local facility generator serves as an additional level of redundancy for that facility above and beyond what is delivered by the microgrid (see Figure 1-2).

4-2.1.3 Power System Modeling and Microgrid Design Modeling.

DoD is required to use analytical tools when evaluating energy resilience measures, such as microgrids, that are accurate and effective in projecting the costs and performance of such measures (10 U.S.C. 2911). Two types of models are used to inform microgrid planning: Microgrid Design Modeling and Power System Modeling. Refer to Table 4-1. APPENDIX B provides an assessment of available microgrid design tools relative to these requirements to aid designers in picking the best tool for the installation. As microgrid design tools continue to evolve, APPENDIX B will be updated.

Microgrid design modeling is instrumental to inform planning. This modeling employs microgrid design tools (see Table 4-1) to produce a techno-economic analysis of optimal DER type and size based on energy resource costs, impacts of interdependent design decisions, attractive economic or lifecycle solutions, and other performance factors necessary to interpret the design space and evaluate the tradeoff of alternatives. Microgrid design tools account for mission requirements and distributed energy resources' performance to facilitate defining conceptual designs. It allows installations to understand the design space and evaluate the cost and performance of alternatives.

Power system modeling determines grid maximum short circuit available and performance of the power system by calculating short-circuit analysis. Small, isolated grids with higher penetration of power-electronic-based DER typically operate at lower short-circuit ratio (SCR) performance. A grid's SCR performance is bounded by the theoretical conditions of 1) an infinitely stiff bus behaving as an ideal voltage source with zero impedance, such that any attempt to change the voltage produces an infinite supply of current, maintaining a constant voltage, or 2) a weak bus where it is easy to change the voltage by sourcing small amounts of current.

Table 4-1 Microgrid Modeling Tools Vs Power System Analysis Tools

	Microgrid Modeling Tools	Power System Analysis Tools
Focus Area	Technology Tradeoff and Economic Analysis of DER	Power System Stability and Operation Performance
Components Sized or Designed	Turbine-Drive DER, Engine or Gas-Driven DER, Renewable DER, Storage-Based DER, etc.	Protective Device Selection, Time-current curves, Relays, and ArcFlash Reduction Maintenance Settings, etc.
Output	Techno-economic Alternatives of Microgrid Concepts and Lifecycle Costs	Short Circuit, Arc-Flash, load-flow, or Grid stability analysis
Supports	Planning (0-10%)	Modeling and Detailed Design (10-100%)
Notable Examples	Listed in APPENDIX B	SKM, Easy Power, ETAP and PSCAD.

4-2.1.4 Constructability, Feasibility, and Site Constraints.

Microgrid implementation will consist of installing controls, adding switches, realigning supported loads to high priority feeders, and changing operational procedures. Planned modifications and infrastructure improvements to the distribution system must be integrated and leveraged during conceptual design. Designers must specify candidate load centers and design options, and provide alternative options (for example, centralized or distributed generation solutions) to support maximum critical load given current operational conditions, practices, and CONOPS.

The following site constraints or restrictions raise unique issues for microgrid design projects and careful consideration must be taken:

- Footprint and environmental permitting issues associated with one or more microgrid DERS and energy-storage locations. Often it is attractive to centralize any new generating capacity near substations and to use larger generators because cost per unit capacity is lower.
- Site space, permit, and climate factors associated with renewable energy: this includes site operational issues, such as mission conflicts with wind turbine operation. Planners must reference the prevailing design guidance for facility-scale renewable assets (UFC 3-440-01) and utility-scale renewable assets (UFC 3-540-08).
- Building code issues
- Restrictions on commercial power procurement agreement with local electric utility and options available to modify the service contract: includes options available to cost share (capital cost or maintenance cost)

- Other challenges aligning infrastructure with microgrid operation
- Fire protection offsets, especially for further addition of battery storage (UFC 3-600-01)

4-2.1.5 Facility Classification.

Prioritization of facility loads must be informed by their mission profile, installation's emergency response plan, installation energy and water plan, and established/identified deficiencies (interrelationships and dependencies of those loads must be confirmed). See Table 4-2. Additional documents to be reviewed include the Critical Infrastructure Program, Mission Assurance Program, and Mission Dependency Index.

Table 4-2 Facility Designation in Microgrid System

Facility Designation	Microgrid Supported Conditions	Examples
Microgrid Essential Facilities	Supported under all modes of operation	Facilities meeting criteria of UFC 3-540-01, or with other significant mission-dependence
Microgrid Supported Facilities	Served by microgrid under most conditions, can be shed during extended grid events	Facilities meeting criteria of UFC 3-540-01, or with other significant mission-dependence (HQ, command and control, data or communication centers)
Microgrid Discretionary Facilities	Can be served by microgrid, located within system boundary	Discretionary facilities not consistently requiring secure power for the entirety of an outage event
Non-Microgrid Facilities	Are not located within system boundary	Facilities that do not have an elevated stand-by power requirement

4-2.1.6 Load Analysis & AMI Data.

The microgrid must support the peak-load demand of mission critical systems. A load analysis is necessary to size system components and develop an informed load shedding capability schedule. Essential loads to be served by the microgrid and optional loads, as defined by facility categories in Table 4-2, must be identified during the engineering analysis.

The highest resolution energy consumption data must be used and must include load variation due to season, mission operational tempo, and other major impacts to load profile. For many sites, high-fidelity load data is stored in digital relay devices, or is reported via Smartgrid or UMCS enterprise systems. At other locations, AMI meter data is most accessible. Realistic estimates of real world data, with reasoning provided will inform the design and critical engineering decisions. If AMI data is available, the difference between total base load and AMI metered load can be used to estimate and create a load curve for the remaining loads. Additional techniques that may be used to determine this include the following:

- Refine estimates by studying the available load curves based on season, time of day, day of the week, holiday, workload, outside temperature, and operating information and discuss the requirements with building and system owners (AMI, with gaps estimated.)
- For certain building types, such as office buildings, typical load information for the building design and use may be available.
- For some large, non-critical loads, it may be possible to make a rough estimate by dropping the load and seeing how much the closest upstream meter moves.
- For critical loads with existing emergency generators, the generator output during past utility outages is a good indicator of load that must be supported by the new microgrid.

4-2.1.6.1 Peak Loads.

The microgrid must support the peak-load demand of critical systems when they are engaged in normal mission activity. The engineering analysis must include options for managing loads, including loads in critical buildings that are not mission critical. Simpler design and operations can often be realized by backing up an entire load center should a facility or load center contain non-segregable critical and non-critical loads.

4-2.1.6.2 Thermal and Non-Electrical Loads.

During analysis, the designers must give special consideration to thermal and other non-electrical requirements, including heating, cooling, industrial loads, mechanical loads, pollution-abatement systems, or other specialty functions. Startup requirements of these loads, associated in-rush or motor start needs, and other non-linear load requirements must be specifically addressed if such systems are to be supported by the microgrid during islanded operation.

Other areas to consider for thermal and non-electrical load analysis include:

- Magnitude of real (Watts) and reactive (Vars) power for each phase and total
- Apparent power in VAs for each phase and total
- Power factor for each phase and average
- Averages of energy in kWh and reactive
- Rated capacities of infrastructure
- Seasonal effects of temperature and usage
- Derating factors for equipment

- Theoretical additional load information

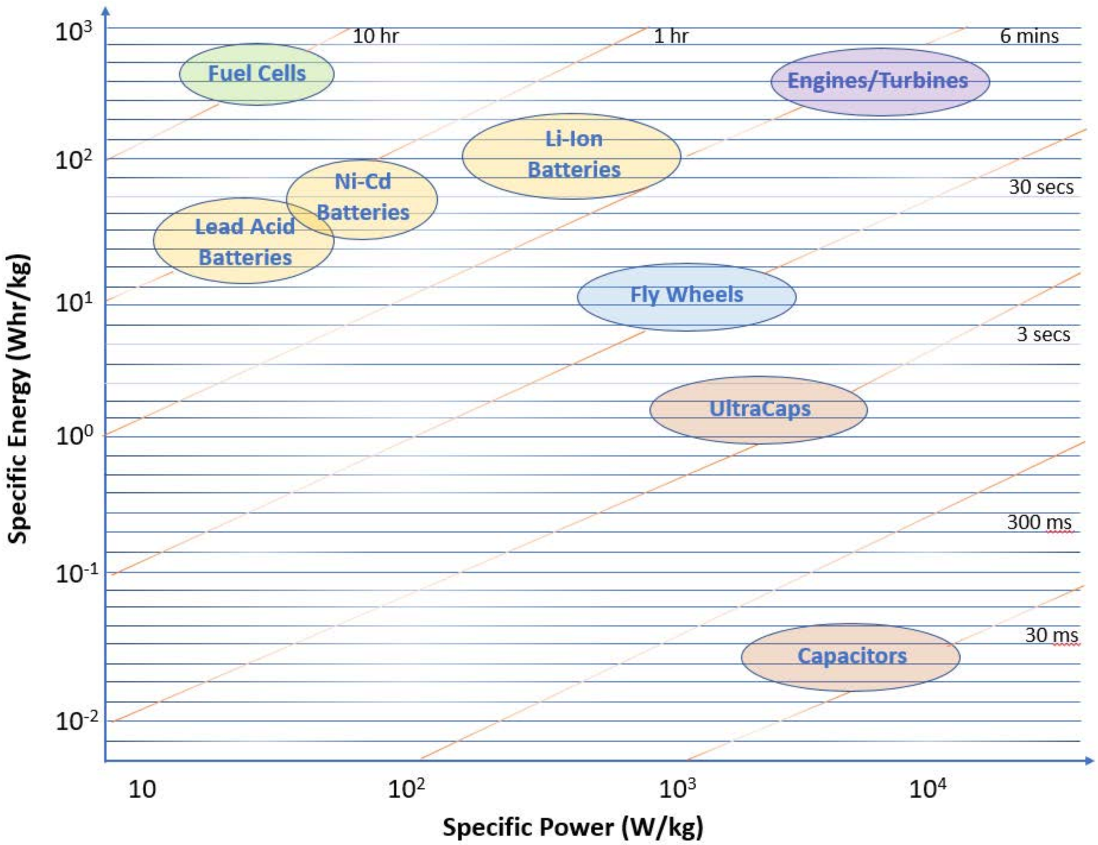
4-2.1.7 Integrating Storage-Based DER.

Integrating energy storage technology can enable many additional use cases for microgrids. Figure 4-4 provides performance attributes of different energy storage technologies. Electrical energy storage can be considered if the design must support any of the following performance requirements:

- Blinkless transition to or from external grid power
- Rapid load restoration, UPS-grade support
- Rapid load-following
- Facilitate very high percentages of renewable utilization
- Firming Renewable DER Output (for example, solar "smoothing")
- Minimizing unnecessary spinning reserve and fuel-based generation
- Active power quality support
- Supporting demand response, peak-shaving or other grid services

Should energy storage be deemed prudent, designers must define the applications, operational states, and scenarios the storage will support. This allows both appropriate type of storage (Figure 4-4), sizing of the storage system (and inverter), how the system should manage State of Charge (SOC), and rate of charge/discharge (greater discharge “C-rates” generally result in less cycle efficiency for electrochemical-based storage systems).

Figure 4-4 Specific Energy vs. Specific Power for Storage DER Assets



4-2.1.8 Candidate Evaluation Study.

The following considerations must be taken into account:

- Installation master plan and development plan with projected load growth
- Mission impact, allowable downtime, and required restoration time: facility or load ratings on the site depending on criticality
- Sample critical facilities list
- Available reports, energy audits, and studies
- Available historical data and studies regarding outages and potential natural disasters
- Documentation of frequency, duration, and magnitude of outages at target locations, existing CONOPS during outages, and operational capability gaps to improve or automate the CONOPS
- Existing electrical site loads and load profile

- Utility maps, one-line drawings, substation configuration, other electrical infrastructure information
- Generator lists
- Communications diagrams, network diagrams, and fiber diagrams
- Site drawings with significant buildings and features identified
- Site electrical load information (by buildings and equipment)
- Smart meter or AMI data, if available
- Load shedding, facility, and installation/utility restoration plans

4-2.1.9 Ability to Support Critical Facility Loads.

Microgrid candidate designs must be evaluated based on their ability to maximize the amount of critical load served. Design options serving greater amounts of critical load within project cost are considered more favorably. Facilities are characterized based on their level of service during microgrid operation. For each facility supported by the microgrid, NFPA 110 describes a Standard Classification of Emergency Power for Emergency and Standby Power Systems including:

- Installation, maintenance, operation, and testing requirements as they pertain to the performance of the emergency power supply system (EPSS).
- Class - minimum time, in hours, for which the EPSS is designed to operate at its rated load without being refueled or recharged.
- Type - maximum time that the EPSS will permit the load terminals of the transfer switch to be without acceptable electrical power.
- Level - two levels of equipment installation, performance, and maintenance.

4-2.1.10 Availability of Existing Infrastructure.

Candidate microgrid designs that leverage more existing capital assets are considered more favorably than candidate solutions that require significant replacement or upgrade and additional capital investment. The design must ensure existing infrastructure is adequate to support all operational conditions required by the microgrid.

4-2.1.11 Cost Estimate.

At the conceptual design phase, a cost estimate may be completed with a mix of vendor information and standard cost-estimating data. For specific high-cost elements (such as generators, energy storage systems, transformers, and renewable energy systems), designers must request preliminary vendor budget pricing information on the specific high-cost equipment being planned. The vendor is typically supplied with system performance specifications (as opposed to a detailed design specification), and will typically provide the cost of a component(s) with allowance for installation, specification descriptions, and estimated delivery schedule. The budget information is non-binding and the budget must include an allowance for potential changes or unknowns. DD1391 has percentages assigned for these unknowns. Designers will also be responsible for identifying items such as management overhead, permits, and contingency. For cost estimating, refer to DoD Area Cost Factors by region.

Designers must update cost estimates throughout the design process. The cost estimate from the 10-15% design is more relevant to the authorization for funding than the initial planning estimate. Service-specific preferences and "buy American" clauses are key components of estimates. Refer to UFC 3-740-05 Section 8-2.2 and the Federal Acquisition Regulation (FAR) for further information on the "buy American" clause.

Local personnel or the relevant DoD agency can provide assistance with adjustment factors. See UFC 3-701-01 and UFC 3-730-01.

4-3 PRELIMINARY DESIGN (10-15%)

The preliminary design advances the conceptual design by considering feasibility of integrating existing infrastructure, equipment and control system requirements governed by installation standardization efforts, "constructability" of proposed infrastructure, developing modes of operation and performance metrics, and location/available footprint needs of new assets. The purpose of the preliminary design is for the government to produce a performance-driven scope of work and inform performance-based acquisition to produce a detailed design.

4-3.1 Preliminary Design Elements.

4-3.1.1 Detailed Load Analysis.

This includes higher fidelity load estimating, and power system analysis per UFC 3-501 and incorporates the following:

- AMI system, 15-minute metered data, feeder loading data, or some form of continuous output (if available)[1].
- Loads for non-metered facilities and equipment: the difference between total base load and AMI metered load can be used to estimate loads.
- Available load curves based on season, time of day, day of the week, holiday, workload, outside temperature, and operating information.
- Load specific information from facility engineers, onsite personnel, or system owners.
- Facility-dedicated generator loading data (this data may not represent normal facility loading if generator testing typically occurs during non-

[1] Existing generation should be taken into account when analyzing load data to ensure that the gross load is determined and not net load.

business or non-mission hours; therefore, it is important to run these generators under full emergency operations load simulating a grid outage when retrieving loading data).

4-3.1.2 Defining Storage Assets.

The below table (Table 4-3) is intended to aid planners and designers in reviewing the realities of energy storage options, prior to acquisition. Some options included for context are emerging or nascent technologies that are not currently available as commercial-off-the-shelf (COTS), or are infrequently used. Values assigned in the columns are estimated for the benefit of planners. All listed technologies are subject to individual considerations, for example, the lithium ion battery requires reliable air conditioning, due to the fire threat at high temperatures.

Table 4-3 Energy Storage-based DER (as of January 2023)

DER Type	Availability (COTS)	Hazardous Material Waste (EOL)	Energy Density	DoD History as Permanent Infrastructure	Lifecycle (Years)	Greenhouse Gas Emissions	Energy Time Provided Prior to Recharging
Fossil Fuel	Yes	State-Dependent	High	Yes	N/A	Yes	N/A
Iron Flow (BESS)	No	No	Low	No	25	No	Up to 12 Hours
Lead Acid	Yes	Yes	High	Yes	3-12	No	2 Hours
Lithium Ion	Yes	Yes	High	No	10	No	Up to 4 Hours
Compressed Air	No	No	Low	No	30	No	TBD
Fly Wheel (FESS)	Yes	No	Low	Yes	20	No	30 Minutes
Pumped Hydro	Yes	No	Low	Yes	>40	No	Up to 12 Hours
Super Capacitor	No	TBD	High	No	10-20	No	TBD
Hydrogen	No	No	TBD	No	N/A	No	N/A

4-3.1.3 Identifying Infrastructure Gaps and Deficiencies.

Infrastructure deficiencies and gaps must be identified prior to implementation of the networked system. This may include:

- Addressing areas in need of infrastructure improvement including additional generation, distribution capacity, or fiber communication capacity.
- Identifying mechanically inoperative breakers and switchgear that is not normally engaged.

- Recapitalization or other integration of legacy infrastructure to meet performance standards.

4-3.1.4 Continuity of Operation (CONOPS).

The basis of design must be informed by mission CONOPS requirements. This includes microgrid (or microgrid operator's) islanding, restoration sequence, and load shedding decisions. These design requirements must be reflected in the operating procedures and are the basis for programming the control system. During design development, designers must specify operating procedures and the exact behavior of individual equipment and control elements.

4-4 DETAILED (ENGINEERING) DESIGN.

The detailed design is the final design product of the performance-based acquisition. It specifies every aspect of construction, device type and interconnection, programming, cabling, wiring, and fiber. This is the engineering level specification that would be furnished to a bid-build contractor. The detailed design must include the following:

- Description of how all generation sources are integrated and configured into the network to best deliver firm, reliable power to the critical loads per UFC 3-410-02 and UFC 3-470-01.
- Devices: List of devices, device IDs, device attributes including type, model, location, dimension, rating, interconnection type and attribute (e.g., black start, grid-forming, droop-controlled, grid-following), software/firmware version, and communication protocols.
- Pathways and Conduits: List of utility conduits, fiber pathways, cable type/length, capacities, etc.
- Schematics and Diagrams: Device schematics, network diagrams, wiring diagrams, flow diagram, trenching plans, site designations, equipment specification, cut sheets, etc.
- States of Operation: A complete listing of each state of operation, order of events under each state. For each state of operation, the exact commands and actions taken by each asset/device/component and the expected result of all other devices in the system. This must include load restoration and load shedding sequences.
- Device Isolation: Description of generation bypass and other device isolation, loaded testing, step loading with planning for oversizing generation or ensuring loads can be added, removed, or segregated in manageable increments.
- Configuration management plan and implemental of procedures for controlling changes to the design baseline over time.
- Nonstandard hardware components needed on hand for O&M/Repair including spares, repair parts and supplies, tools, test equipment, etc.

- Equipment/System Documentation: In-depth operational training material for addressing step-by-step microgrid operation for each system condition and state of operation, common troubleshooting and maintenance procedures. This must include material to identify anomalous operation, and troubleshooting, vendor contact, and warranty information.

4-4.1 Aligning Microgrid Operation with Existing Infrastructure.

Microgrids leverage existing capital infrastructure with new power system assets and controls. Consequently, many design solutions may involve nontrivial levels of effort to validate proper operation of existing electrical systems, require specialized reprogramming of existing systems to support microgrid functionality intent, or involve other hardware or software costs. For new facilities to be “microgrid-ready”, construction must include paralleling switchgear at the point of electrical service as well as the following attributes for inverters.

- Programmable output capable of accepting an external control signal from the master controller (in some cases, inverter oversizing might be prudent to support both reactive power and planned real power needs)
- Adjustable inverter trip levels and clearing times
- Ability to network control signals from Microgrid master controller
- Logical output curtailment from Microgrid master controller
- Extended voltage and frequency operating ranges
- 4-quadrant operation and control (for new construction with battery-based storage)

4-4.2 Aligning Generation Sources for Islanded Operation.

Islanded operation requires black start generation to energize the islanded distribution, along with sufficient additional generation capacity to support full critical load.

4-4.3 Aligning Renewable Systems for Islanded Operation.

When interconnecting renewable sources of power to the installation power system, the inverter-based device must adhere to IEEE1547 Clause 8, including Anti-islanding and Ride-through requirements. During islanded operation, both grid-following and grid-forming sources can support islanded operation provided at least one black start, grid-forming asset is available in the islanded system. Systems solely containing renewable sources and energy storage must maintain sufficient state of charge (SOC) operating margins to ensure mission assurance posture should commercial power be lost when renewable power is unavailable.

4-4.4 Aligning Controls and Switchgear for Islanded Operation.

All control systems and switchgear whose operation is required during black start operation must be fitted with a UPS (this is particularly applicable to switchgear that is not typically operated from a dead bus condition).

4-4.5 Aligning Switches and Transformers.

Devices that are normally configured for the flow of power in one direction must be certified by the manufacturer for bi-directional operation without negative impact to the life expectancy or warranty of the equipment.

This Page Intentionally Left Blank

CHAPTER 5 COMMISIONING AND PERFORMANCE VALIDATION

The microgrid commissioning (or recommissioning) and testing planning must be received and approved by the government and independently supervised, verified, and certified by the government as fully functional. Microgrid commissioning ensures that:

- Each subsystem operates as designed
- The interconnected system operates in every state of operation as designed
- Design supports contingency of operations and installation emergency response plan
- The system meets each of the performance metrics used to inform design

The commissioning phase not only validates system operation using target performance metrics, but also identifies troubleshooting procedures that must inform training plan documents that facilitate efficient sustainment and operation. The commissioning phase is generally the most effective time to diagnose areas of improper operation of legacy capital assets, devices, and alignment of existing infrastructure components. Equally important, sequential operation of device assets and system-level commissioning allows designers to further optimize controls, device and relay settings, and device logic to achieve or exceed the respective performance targets. An independent, third-party validator is advisable during system commissioning. The validator must approve the system commissioning plan and validate fielded operational performance in accordance with each of the stated operational states, performance objectives, and metrics.

The commissioning phase includes the following steps:

- Commissioning plan
- Device/component level commissioning
- System-level commissioning

5-1 COMMISSIONING PLAN.

During system design, a detailed commissioning plan must be developed in parallel based on each operational state the system is designed to support (with a detailed sequence of operations for each scenario). The sequence of operations must state device configuration and expected result for each step of the test and record configuration of switchgear, device load factor, and indication of unexpected or anomalous operation. Load banks or energy storage devices can be integrated into the testing process to avoid unnecessary impact to active facilities that do not need to be disrupted for the early part of the testing procedure. An energy storage system may be used as a load rather than a load bank. Final system testing must demonstrate the system's ability to support actual targeted mission loads.

The commissioning plan must clearly identify performance metrics (see CHAPTER 3) and thresholds to be achieved for every operational state under test. Measurement and verification of all performance objectives must be explicitly stated in the commissioning plan. Commissioning must include all items needed on hand for O&M/Repair such as spares/repair parts/supplies/special tools/special test equipment. Develop a configuration management plan and implementation of procedures for controlling changes to the design baseline over time.

5-2 DEVICE/COMPONENT LEVEL COMMISSIONING.

Each device and subsystem component must be independently tested prior to system commissioning. The project construction plan generally includes equipment and software acceptance testing for each subsystem commissioning. Site staff must receive training before these stages and be involved in these processes as part of their training.

This includes start-up of each device using standard vendor (local) control to verify proper operation prior to interconnection with network (remote) control assets or other network equipment. Subsequent phases of device level commissioning must address remote operation of devices, verification that remote device operation is reflected and controlled at the master control location, as well as validation of device settings, timing, controls, paralleling, and protections. In some cases, testing of two or more microgrid elements prior to interconnection with the whole microgrid/grid is prudent (e.g., protection devices and islanded DERs). Each component of the commissioning must be designed to best simulate real world operations, under fully loaded conditions. This is especially critical during system-level commissioning.

5-3 SYSTEM-LEVEL COMMISSIONING.

Upon completion of component testing, system-level commissioning verifies the full system's capacity to react to an unplanned outage. This includes:

- Synchronize all of the local sources of power,
- Reenergizing critical loads in the appropriate sequence of restoration,
- Optimized load factor and operational endurance,
- Transition back to commercial power.

Close coordination with the commercial utility is encouraged to facilitate disconnection/reconnection to the external power system, as well as validate that the system meets all the technical requirements of the interconnection agreement. Commissioning must include all items needed on hand for O&M/Repair such as spares/repair parts/supplies/special tools/special test equipment.

5-3.1 Identify Software/Hardware Configuration Changes

System-level commissioning may identify software or hardware configurations needing further attention including switching operations, device timing, communications or fiber functionality, inter-device coordination and protection settings, or devices requiring independent power to and other. During commissioning, breakers, switches, or other substation or facility equipment may require dedicated UPS, modification in set point, timing, or other re-programming to facilitate off-grid operation.

5-3.2 Validate Operational State

Each operational state of the system must be independently validated during commissioning including black start, microgrid formation, generator paralleling and islanded inverter-based device interconnection, supporting variable load states, ability to support load after during loss of generation or communications, fail safe operation, and safe reconnection back to commercial power. To the extent possible, metrics and targets must be assigned to each phase of the commissioning to quantify operational improvement resulting from microgrid operation, as well as to validate performance goals associated with the ERCIP Program and other DoD Installation Energy Resilience Policy.

A critical aspect of system commissioning is to operate in conditions as faithfully as normal installation conditions as possible. While device and initial system commissioning can take place during off-peak times (to minimize impact to business operations), microgrid performance cannot be fully validated until the system is exercised in a manner faithfully reproducing an unplanned utility outage under full load (with no ancillary connections or external sources of power). Utility system managers and facility engineers must work with tenants and mission stakeholders to facilitate such a “real world” microgrid system commissioning. This may include testing under normal loading, during normal business hours, etc. In some cases, mobile or other alternative contingency generation can be temporarily sited should testing and commissioning render existing stand by power systems inoperable.

5-3.3 Periodic Reverification Testing

There must be periodic reverification testing at intervals prescribed by the Operations and Maintenance Test plan, typically three to five years. System performance reverification and testing is performed by a qualified testing organization such as an AFCEC/COM (CEMIRT) type organization or by an approved commissioning contractor.

CHAPTER 6 SEQUENCE OF OPERATIONS

6-1 STATES OF OPERATION.

Islanding and reconnection to the commercial utility must be performed safely and seamlessly to the priority loads. The microgrid controller must support the elements of power system interoperability per IEEE 2030 and is responsible for each state transition, each associated sequence of operation, and visualization of the distribution system and generation asset output under all conditions. The following items are typical microgrid states of operation (some alternatives are possible for systems with adjustable droop-type controls, closed-loop fast-feedback controls, PMUs or other devices):

- Normal operation (grid-connected, standby)
- Isolation from external utility (islanding)
- Microgrid formation (soft transition or black start)
- Islanded operation (optimized operation for resilience and endurance)
- Re-synchronization back to external utility (soft transition only)
- Testing and diagnostic mode (supports regularly scheduled loaded testing, device testing, and troubleshooting)

There are two primary scenarios for totally disconnecting from the grid: emergency disconnect (unplanned disconnect as the result of grid failure) and planned disconnect. This is done in anticipation of an impending failure or for business reasons, such as operation as part of a Voluntary Protection Program (VPP) in support of the local utility.

An example of how the system can manage these operations is provided in UFC 3-540-08, Chapter 8. This reference covers information related to utility relations and financial incentives.

6-1.1 Normal Operation (Grid-Connected, Standby).

This is the normal state of operation. The system remains in standby and awaits a grid event to notify a human operator or take autonomous action.

6-1.2 Isolation from External Utility.

Upon unscheduled loss of utility power, all facility loads are lost[1], renewable generation systems disconnect, and the system controller begins a timer (based on a programmable time delay parameter). Should stable utility power resume within this period, no action is taken. If the utility power is not restored within the programmed time, the operator or system commits to entering islanded operation and issues a command

[1] Blinkless designs running parallel with the external grid may not lose power during islanding (paragraph 3-4).

to open the interconnecting breaker(s) or recloser(s) at the point(s) of common coupling (PCCs), and system boundaries are established (IEEE 1547 Clause 8).

6-1.3 Microgrid Formation.

All microgrid systems must be capable of black start (reenergizing the microgrid island after unplanned grid failure with no energized generation resources). Because there is no utility reference, the resources must be able to define their own reference frequency and synchronize all resources uniformly to the reference. A start-up command is sent to black-start generators under microgrid control that are not dedicated to facilities (regardless of magnitude of connected load prior to the outage). The first networked generator to reach the rated voltage and frequency connects (provides power) to the distribution bus, and operates under synchronous control mode (subsequent generators and inverter-based systems joining the network operate in droop control mode). For microgrid designs with fully distributed, agent-based control, this generator (and its local controller) can be designated as the master controller by the rest of the controllers (this avoids having a predetermined master control point which could be a single point of failure should its generator or communications be lost during start up). Under this logic, each of the subsequent generators' voltage, frequency and phase are matched to the master/bus voltage, frequency, and phase before their respective paralleling breakers close to the bus. As previously mentioned, controls and switchgear whose operation is required for black start should be fitted with UPS (this is particularly applicable to switchgear that is not typically operated from a dead bus condition).

If the system is responsible for supporting facilities with dedicated backup generators, the automatic transfer switch (ATS) at each facility generator detects loss of power on its normal side and transfers to emergency (generator) position and each facility generator starts (see Figure 1-4). Once all facility generators have restored their respective loads, the microgrid closes its breaker between the emergency side of the ATS and the secondary side the facility transformer to allow the facility generator to feed the transformer and outside distribution system. Once the ATS determines its normal side is energized with stable voltage, it switches back to its normal position to allow the facility generators to energize the distribution system, depending on the relevant topology. Once all generators are online, paralleled, and the master controller is defined, breakers at the facility loads are closed to the bus in a predefined sequence corresponding to the installation's facility load restoration plan. The system monitors system load as these breakers are closed and issues a stop command once it determines that the load has reached a level corresponding to the N+1 generator redundancy target (i.e. should any generator fail to maintain load or be e-stopped, the system still maintains the energized network at that load level). The system never commits the generator network to a higher load than this, unless specifically commanded by a human user.

6-1.3.1 High-Speed and Low-Speed Controls and Operation.

Microgrids manage every aspect of the power system including islanding, paralleling, interconnection, system protection, load following, and renewable energy management.

Microgrid control takes place at two levels: high-speed controls and low-speed controls. The two levels of microgrid control are comparable to an individual controlling a modern automobile (the driver sends comparatively slow commands to the vehicle, while the vehicle control system responds accordingly by issuing commands to internal vehicle systems at much faster response times).

6-1.3.1.1 High-Speed Control Functions.

First, the phase and frequency is set by a master source controller, and is followed by the other generators to synchronize systems using high-speed, sub-cycle generator controllers. These device-level, high-speed controllers and governors manage voltage and frequency output and other high-speed parameters relating to electrical power stability. These are used to synchronize and measure electrical magnitude and phase angle of electricity as well as to synchronize time and coordinate the distributed power sources prior to merging.

6-1.3.1.2 Low-Speed Control Functions.

While the high-speed system is programmed to verify that all the prime movers on the system are synchronized, it may not monitor operational set points, load factors and power output. These attributes are optimized by a low-speed control supervisory controller, which manages distributed control points over slower communications. Given a specific operational scenario, the system issues commands to generator controllers and energy storage for each asset to compensate for renewable energy output fluctuation, load variation, demand response programs, etc. A microgrid system’s low speed control is also responsible for:

- Management of renewable energy system output
- Management of energy storage
- Optimization of fossil fuel based generation load factors
- Dynamic load following
- Optimization of network efficiency and endurance

6-1.4 Islanded Operation for Resilience and Endurance.

Once the full load is served, the microgrid can optimize operation by 1) Managing load factor of paralleled generation 2) Paralleling inverter-based generation devices, and 3) Shedding discretionary loads to increase system endurance.

The system begins to optimize load factor at each generator unit and shuts off units if the load can be supported with fewer units running (at higher load factors). Should each of the running units be operating below a threshold load factor (for example, 50 percent), one generator is commanded to shut down to increase load factor of the remaining units. Conversely, should each of the running units be operating over a threshold load factor (for example, 80 percent), an additional DER or energy storage service is engaged in reserve to rapidly ramp up in case a load spike occurs during this time.

By this time, inverter based (renewable) assets have sensed the energized system and begin to provide renewable power (for example, PV) or stored energy (for example, 4-quadrant energy storage devices) to the network, thereby deferring the amount of power the generator fleet must deliver.

The microgrid master controller continuously iterates the full network optimization based on the changes in load, renewable energy availability, state of charge of storage devices, and status of generator/fuel availability. Finally, the system may open breakers to discretionary loads to meet system endurance targets during extended utility outages. Load shedding actions may be triggered based on pre-determined thresholds including remaining fuel levels, devices state(s) of charge, or projected remaining overall system endurance.

6-1.5 Re-Synchronization Back to External Utility (Soft Transition Only).

Once the system detects utility power has returned on the primary side of the PCC, it waits a predefined period of time to determine if the utility is stable and begins the process to soft transition back to commercial power. Because the microgrid's signal will likely be out of phase with the utility, the system phase locks the utility's phase with the microgrid by waiting for the microgrid signal's phase to align with the incoming utility signal's phase, synchronizes the systems and closes the substation breaker.

Loads not supported by the microgrid are slowly added, sequentially; the objective is to maintain a steady escalation of power and avoid a disturbance that trips the breakers. Once all loads are online, the microgrid issues shut down commands to its networked generator fleet.

6-1.6 Testing and Diagnostic Mode.

The microgrid system must be tested periodically verify proper operational capability. Testing must be monthly or quarterly (as often as the mission allows) to verify working order of the equipment and system. Testing can incorporate emergency generator testing and can allow sources to be tested under load while mitigating unnecessary facility outages associated with moving to and from generator power. Refer to paragraph 7-2 for further information on testing.

6-2 UTILITY CONSIDERATIONS.

See UFC 3-540-08, Chapter 8 for information related to utility relations and financial incentives. An example of such utility incentives can be found at California Public Utilities Commission Rule 21.

6-2.1 Utility Interconnection and Secure Islanding.

A properly designed microgrid can become a resource during normal operations to self-manage power consumption and cost, independent of the commercial utility provider. Installation personnel can also use the microgrid to negotiate alternative rate structures with the utility in exchange for cooperation in managing the grid loads. Some commercial utilities have significant limitations with respect to interconnection agreements, including limitations on: power export, operating in parallel with the external grid, device isolation/lock out requirements, etc. Early discussion with the commercial power provider must be part of the preliminary background data gathering. Bases are encouraged to use any available Utility Company Fast Track / Pre-Application processes, whenever possible.

Designers must coordinate with the local commercial power utility to identify microgrid performance and interconnection requirements relating to islanding, protection, and paralleling (if permitted by the grid operator). Depending on the nature of the site and prevailing utility contractual arrangements, technical discussions may be necessary to address system operation when grid-connected. Discussions must include options for regularly scheduled demand reduction, power export, and paralleling with the utility if possible. When this is not possible, “hard transitions” to islanded operation could be necessary, and even then, utility operators may allow “soft transitions” to utility power by having the site remain on microgrid power following phase-lock resynchronization to the grid. This approach allows load to be gradually shifted back to the commercial power system, once it is restored and stable.

When developing the microgrid project, it is prudent to perform energy audits of the loads within the microgrid boundary in order to identify opportunities to reduce load, thereby reducing microgrid size and cost. Communication with the local electric utility should include the process for adding future electrical load within the microgrid boundary as operations move from current fossil-fueled operations to carbon-free energy supply. As noted above, it is critical to involve utility representatives early in the design process to discuss tariff interactions, policy guardrails, and the interconnection process, which can be lengthy given the potential size and complexity of these projects. For example, Southern California Edison (SCE) Account Managers in SCE’s Business Customer Division helps manage interconnection process and provides information related to available incentive programs.

6-2.2 Commercial Utility Relations.

Establishing a microgrid can significantly change the business relationship between the military installation and commercial utility. If the installation uses a standard large service rate-structure contract, the microgrid can be used to manage energy and reduce the installation’s cost under its existing agreement. Additionally, the opportunity exists to coordinate the microgrid with commercial utility’s operation; in such cases, the commercial utility may offer a modified rate schedule in exchange for a benefit. The commercial utility may be able to invest in the project capital or operating cost budget.

The Federal Energy Regulatory Commission establishes reserve requirements for utilities. Many utilities will offer alternative rate structures with incentives to customers if the customers can help reduce the need for utility investment in reserve resources (which are expensive and produce little or no revenue).

Curtailable Service: In exchange for rate benefits, the customer agrees to reduce power usage according to a mutually agreed upon schedule. Distributed System Generation (DSG): In exchange for benefits, the customer agrees to bring generators online at the request of the utility. There are limits on the amount of power that must be provided by the customer and the customer has the right to refuse under certain circumstances.

All networked devices and systems must be in compliance with IEEE 1547 Chapter 8 requirements. Inverter based devices must comply with UL 1741.

Special design attention must be given to cases requiring accommodation of the following:

- Paralleling with the commercial utility grid (if permitted by the grid operator)
- Interconnection of “blinkless” devices intended to continually parallel with the utility in order to provide soft transition in and out of islanded operation
- Special operational needs and requirements of grid operators of smaller utility systems that may allow wider grid operating ranges involving customized calibration and field validation of controls, protection, and isolation.

CHAPTER 7 OPERATIONS AND SUSTAINMENT CONSIDERATIONS

Long-term, user-friendly, and sustainable operation is the primary consideration of all aspects of design, commissioning, training, and transitioning of the microgrid system. While automation and device-integrated controls represent valuable opportunities to improve mission resilience and system efficiency, such capabilities must be integrated into the system transparently, intuitively, and easily managed by installation public works personnel. Systems must have the capacity to operate safely, securely, and logically with maximized operational visibility over the lifecycle. For Army, Navy and Air Force, microgrids that support mission critical facilities must support a mission of 14 days (or more days during unscheduled electric power outages). Note that Air Force microgrids require a 7-day fuel plan but that is not intended to state that USAF policy is to island for 7 days. A 7-day fuel plan is designed so that all USAF generators have a plan to operate beyond their local storage requirement. Other areas of consideration may include the following:

- Automated operation and restoration sequences consistent with installation and mission CONOPS
- Provisions for testing including testing under load (as well as use of load banks)
- Testing controls
- Startup and RE integration sequence
- Integration with existing or planned supervisory control and data system/ industrial control system (SCADA/ICS) based grid operation
- Real time user visibility to operational metrics
- HMI based user accessibility
- Standardized ICS configuration management for streamlined operation
- Cyber sustainment and re-configurability

7-1 SYSTEM TRAINING.

To successfully transition a complex microgrid system from design to operation, personnel training is critical. Implement training using information acquired during the detailed engineering design phase.

The training material and strategy must be customized to the specific installation and complexity of the microgrid system. Additional roles and responsibilities may be added including: CIO and cybersecurity hygiene, ICS maintenance, operation of HMI, and SCADA familiarity, etc. Separate training regiments must be considered and developed for each role/responsibility (public works officers, CIO, operators, maintenance personnel).

Specific personnel needs must be determined based on lessons learned during commissioning, as well as interviews with key personnel to account for current operations, focus areas, and roles. Training material and strategy must be updated appropriately to reflect system improvements and modifications.

7-2 PERIODIC OPERATIONAL TESTING.

Periodic testing of the microgrid system provides higher confidence in generator readiness and familiarity by operators during times of need. Testing can be monthly or quarterly to verify working order of the equipment and system. At a minimum, the system must be tested for black start annually (this can be coordinated with DoD's Energy Resilience Readiness Exercises). If facility-level DERs are part of the microgrid, testing must be coordinated with facility generator testing per UFC 3-540-01. Generator assets must be tested in accordance with maintenance intervals and procedures as prescribed by the manufacturers. Load banks must only be used where no alternative exists to test the system under load without unacceptable mission disruption.

Testing must include operating generation under variable load factors and with reduced mission disruption or hard transition to end users (moving to and from generator power). This can be facilitated by operating the system in parallel with the external grid or redirecting power via looped distribution systems. This will also test the microgrid's ability to island and black start all supported mission loads without external grid support (per DoD Framework for Planning and Executing Black Start Exercises). Testing under real world mission and load conditions is strongly recommended.

Microgrid performance results (as required by each service) must be kept on file with annual reporting of the overall system status to the office of responsibility for system certification.

APPENDIX A MICROGRID BACKGROUND INFORMATION

A-1 MICROGRIDS AND DOD INSTALLATION ENERGY POLICY.

Microgrids and Networked standby solutions advance 3 broad areas of DoD installation policy; 1) Mission Resilience and Off-Grid Endurance, 2) Increased Utilization of Renewable Energy Systems, and 3) Consolidated Cybersecurity within Defined Network Boundaries with Defense in Depth.

A-1.1 Executive Orders
