Provide heating and cooling appropriate for personnel, the electronic and electrical systems or fixtures, and the security support equipment. The HVAC requirements must be based on existing service design guidance and installation requirements. Consider protection from chemical or biological agents used during an attack based on the anticipated threats. However, due to the small size of the facility, comprehensive protection is often not feasible. To limit airborne contamination and maximize the time for security personnel to shelter in place to initiate a response, utilize protective gear, and respond to an attack. When required, design of the HVAC system to include the minimum measures outlined in UFC 4-010-01. For guard booths and overwatch positions, provide adequate storage for all CBRN personnel protective equipment.

5-7.5.4 **Interior Lighting.**

Interior lighting must comply with UFC 3-530-01 “Design: Interior and Exterior Lighting and Controls “and with the sustainability requirements. The interior lighting must be diffused lighting and must be provided with dimmer controls to aid with night vision and reduce the ability of those outside the guard facility to see inside. The interior lighting must be connected to the backup power source. As discussed in the IESNA Handbook-10, the illuminance inside the guard facility must be limited to the minimum required for comfortable completion of the expected tasks and functions. As indicated in Figure 29-17 of the IESNA Handbook-10, the recommended average illuminance for the gatehouse is 30 foot-candles (323 lux) on the work plane in the gatehouse. Additional recommendations from the Hanbook-10, include providing well-shielded task luminaires to avoid reflections on monitors and windows. Consider providing magenta filters for interior lighting to lessen the impact of interior lighting on the night vision of security personnel.

5-7.6 **Visitor Control Center.**

Most installations require one visitor control center (VCC). The visitor occupancy number is calculated by dividing the peak hourly visitor demand by the number of processors, then divided by the number of visitors processed per hour. Then add the number of security processing personnel within the building to obtain the number of personnel routinely occupying the VCC. Example: Peak hourly visitor demand of 120 visitors, divided by 2 processors then divided by 12 to represent a 5 min processing time per visitor. This equals 5 visitors. Add the 2 security personnel processing the passes plus 1 security supervisor and the routine occupancy of the visitors center is 8. This calculation is used to determine in the VCC is required to comply with UFC 4-010-01. Where appropriate, future demands and accommodations for installations with special periodic demands will be considered and evaluated based on traffic engineering study. Figures 5-8 and 5-9 shows example plans for a visitor control center. Table 5-3 provides information on the areas/elements that are typical for a visitor center. Consult with the installation/service for specific requirements.

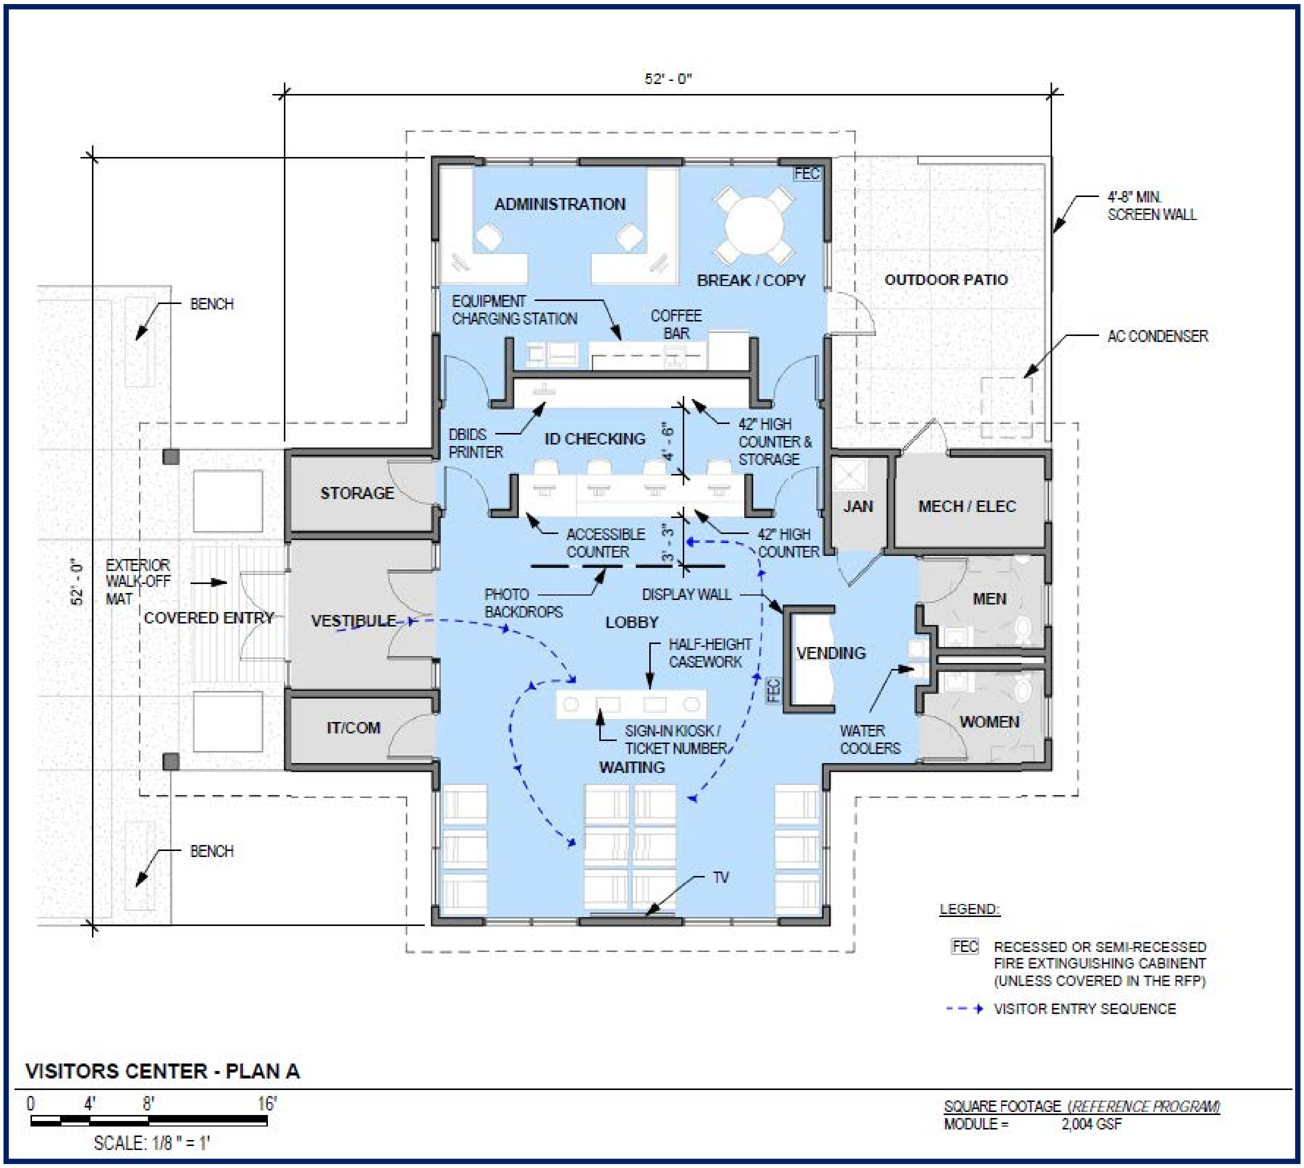
5-7.6.1 **VCC Parking.**

Adequate parking must be provided for all visitors and employees. Parking must be designed in accordance with SDDCTEA Pamphlet 55-15 and must include adequate parking based on typical peak volume. Provide employee parking based on normal operating conditions. . Refer to SDDCTEA Pamphlet 55-15 for additional guidance, updates, and example layouts.

5-7.6.2 **VCC Design and Location Considerations.**

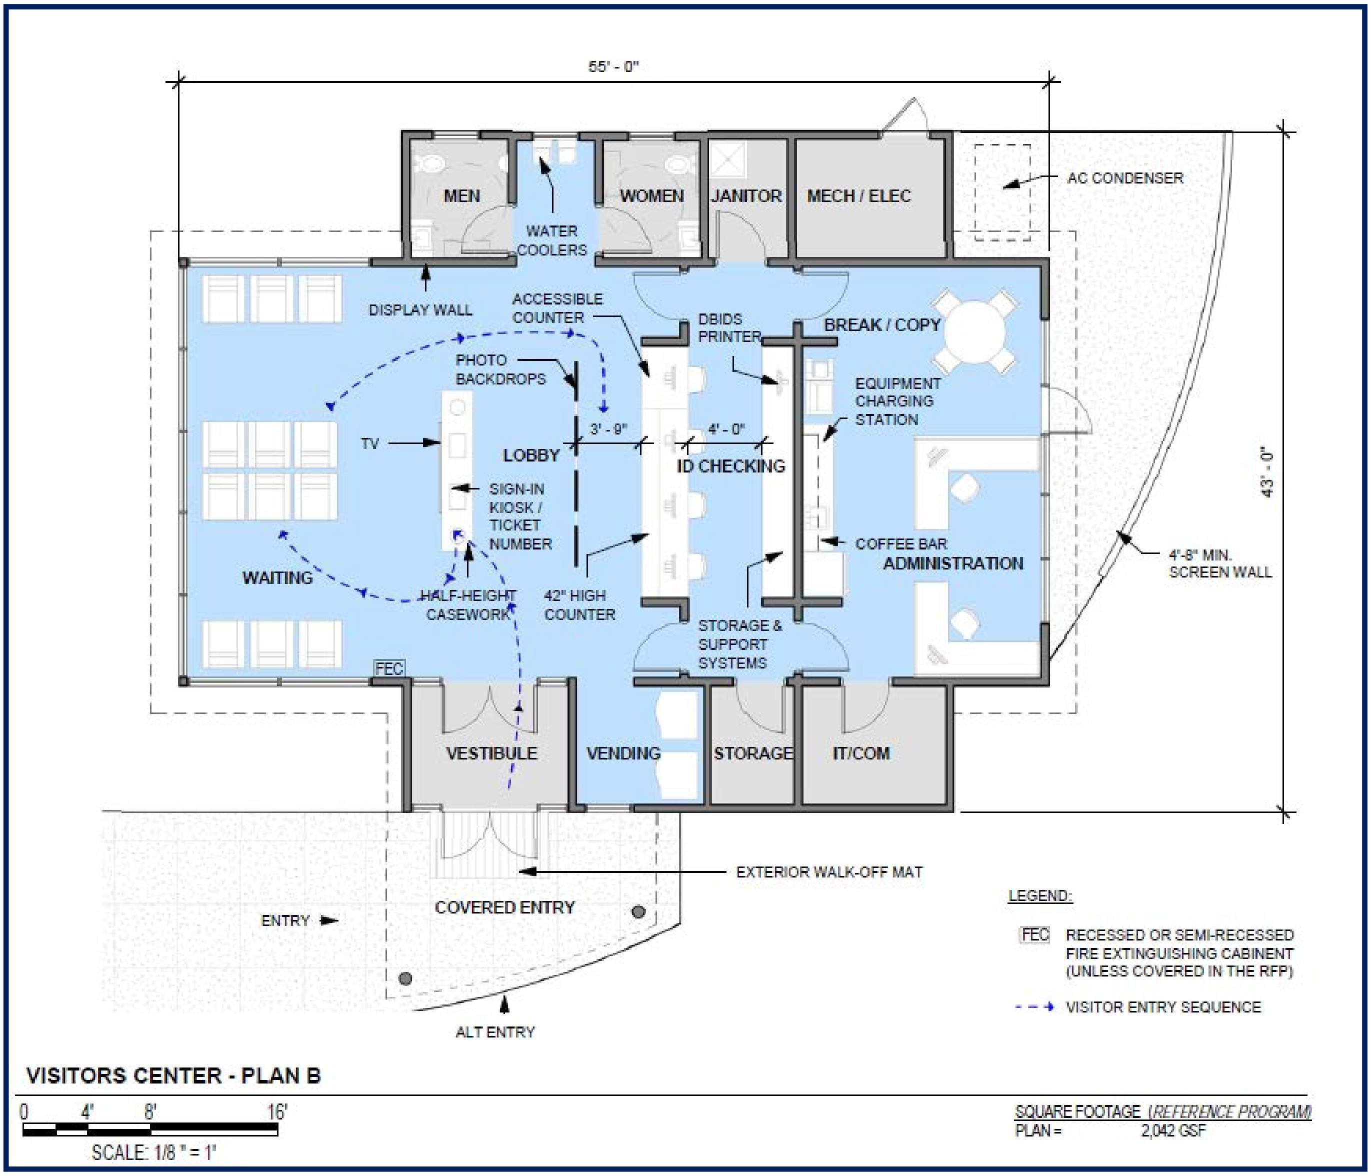
The Visitor Control Center (VCC), if present, must be placed such that the processing of visitors is done prior to entry into the installation. This means that the visitor vetting is conducted prior to inbound traffic (vehicular and pedestrian) reaching the ID check and search area. The building and surrounding site must be highly visible and must be understandable to visitors as a public facility. The building and site must be designed and constructed in accordance with the Architectural Barriers Act including required reserved accessible parking, curb ramps, and sidewalks. The visitor's center may need to meet the required stand-off distance if it is considered an "inhabited" facility (see UFC 4-010-01). If an "inhabited" Visitor's Center cannot meet the required distances, it may need to be hardened per UFC 4-010-01.

Figure 5-8 Model Visitors Center



Source: Air Force Civil Engineer Center

Figure 5-9 Model Visitors Center



Source: Air Force Civil Engineer Center

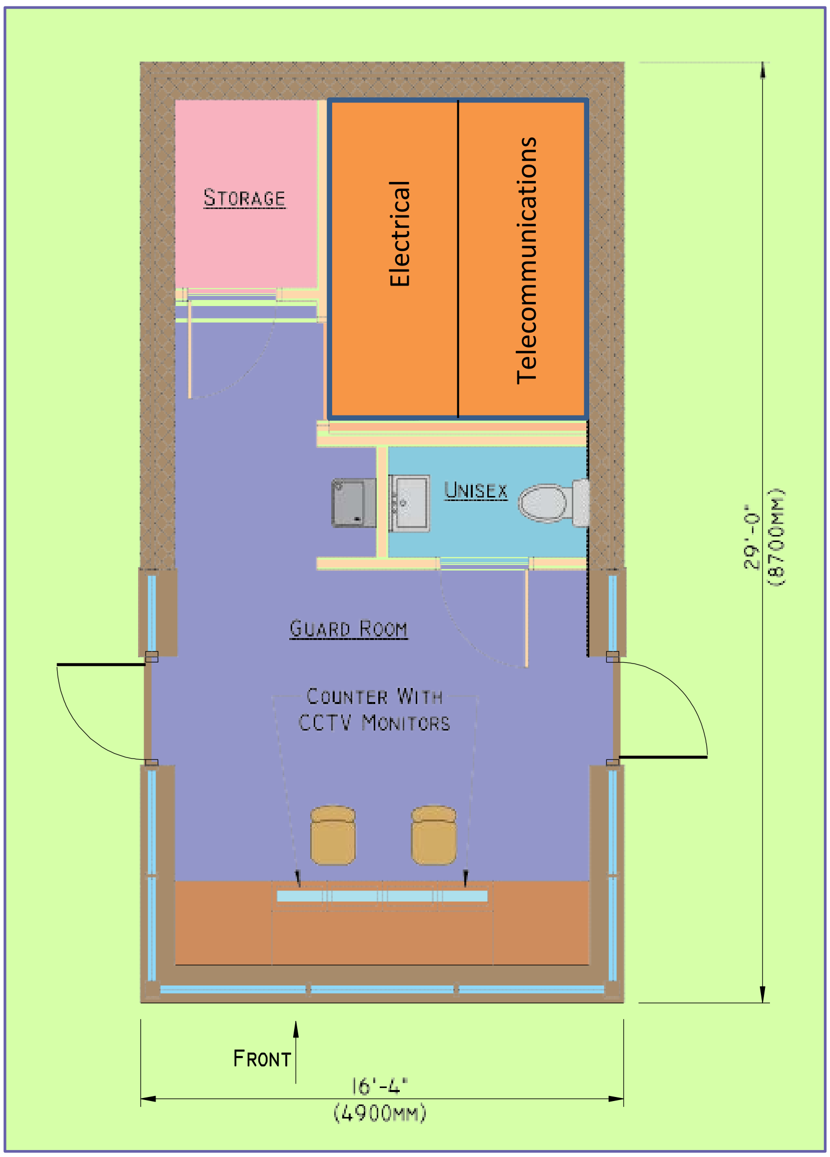
Table 5-3 Visitors Center Elements

Area	Element
Waiting Area	• Provide a comfortable environment with adequate seating for visitors. • Provide a water fountain. • Provide a vestibule with walk-off mat • Provide a designated area for a computer station to be used by visitors to enter registration information. This computer station must network from each processing station to the office area so that registration information can be accessed.
Service Counter	• Include sufficient desktop work surfaces and countertop space for required processing station based on anticipated usage. • Allow three to five minutes per person for processing. • Assume that approximately 12-20 people can be processed each hour on average per processing station. • Include a computer station with networking and Internet access for each processing station. • Provide photo ID capability at each processing station. Install a photo backdrop. • Provide wiring at each processing station for a duress alarm.
Administration Area	• Provide an enclosed office for two workstations and a filing cabinet. • Provide video surveillance equipment for the interior and exterior areas of the Visitors Center. • Provide Internet connectivity, telecommunications, a closed-circuit television system, and a radio battery recharging area.
Break Room	• Locate the break room so that it is out of the direct line of sight of the waiting/seating area. • Provide a refrigerator, microwave, and sink. • Provide seating for four staff.
Rest Rooms	• Provide men’s and women’s restrooms for public and security personnel use per ABA requirements. • Consider accommodations for baby-changing stations in each restroom if appropriate.
Environmental Controls	• Provide heating and cooling appropriate for personnel, the electronic and electrical systems or fixtures, and the security support equipment. The HVAC requirements must be based on existing service design guidance and installation requirements.

5-7.7 Gatehouse.

The gatehouse serves as the control center for the ECF/ACP and provides shelter for security personnel. Every Primary and Secondary ECF/ACP must have a gatehouse designed to support the desired number of security personnel. As the control center, the gatehouse controls the AVB and other ECF/ACP security systems. Do not locate controls for other aspects of an installation security system in the gatehouse or at other facilities associated with an ECF/ACP. Locate the installation security center or emergency control center within the controlled perimeter of the installation. The gatehouse must serve only as the control center for equipment associated with the ECF/ACP only.

Figure 5-10 Model Gatehouse Floor Plan



5-7.7.1 **Design Considerations.**

Base the design of the gatehouse (See Figure 5-10) on the following equipment and functions:

- Communications equipment
- Electronic control panels for all current or anticipated future equipment for automated entry
- Monitor stations for closed circuit television or computer monitors associated with automation controls
- An electrical room for the main electric panel boards
- Storage for traffic control devices, weapons, and personnel equipment including vehicle inspection kits and the storage of personal protective equipment for Chemical, Biological, and Radiological (CBR) exposure
- Computer servers for future AIE systems
- Counter or work space
- A unisex restroom

5-7.7.2 **Location Considerations.**

Typically, a gatehouse is centered in the ECF/ACP between the inbound and outbound lanes and adjacent to the ID check area (see Figures 5-11 and 5-12), or alternatively the gatehouse may be located to the side of the roadway. The gatehouse may also be located after the last turn around/denial/exit point to give security personnel in the gatehouse an overall view of the access control zone operations and vehicles directed to the turn around/denial/exit point or vehicle inspection area. If the gatehouse is located to the side of the roadway or after the last turn around/denial/exit point, consider providing a guard booth in the central island of the access control zone or in between entry lanes to provide easily accessible shelter and protection for the guards operating the ECF/ACP. See Figure 5-1 for additional gatehouse location options.

5-7.7.3 **Parking Considerations.**

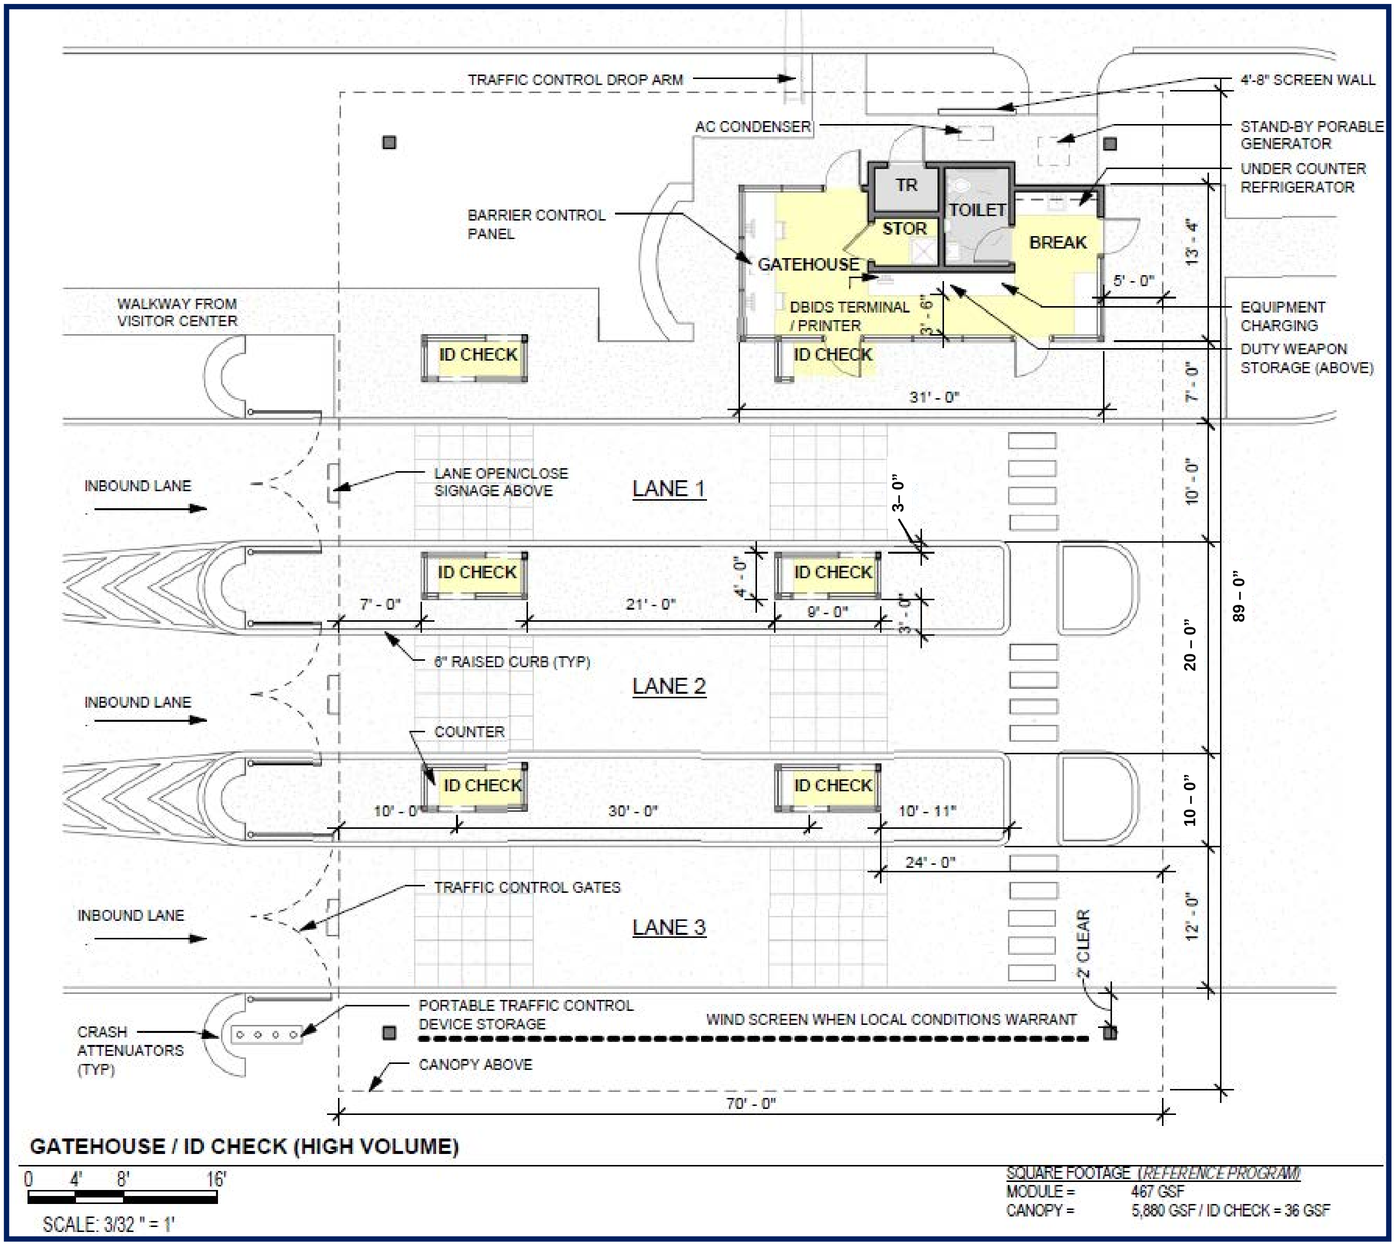
It is beneficial to provide parking for security forces staff in close proximity to the gatehouse. At a minimum, provide one space for a chase vehicle sited as close to the gatehouse as practical. The chase vehicle parking will be located for quick response and will be sized for the planned response vehicle.

5-7.8 ID Check Island and Guard Booth.

The ID check is located in a median island or channelization island between traffic lanes. The area must provide minimum of one guard with protection against the weather and potential threats. The island must have appropriate pavement markings identified in SDDCTEA Pamphlet 55-15. The guard booth must have space allotted for electronic control panels for ECF/ ACP automation equipment, EFO, duress alarm, intercom, workspace incorporating space for computer monitors, and an electrical panel board. There may be up to two guard booths per lane; however, at installations where the second processing area is not readily utilized, it may be more appropriate to not construct a second guard booth but to reserve an area for processing.

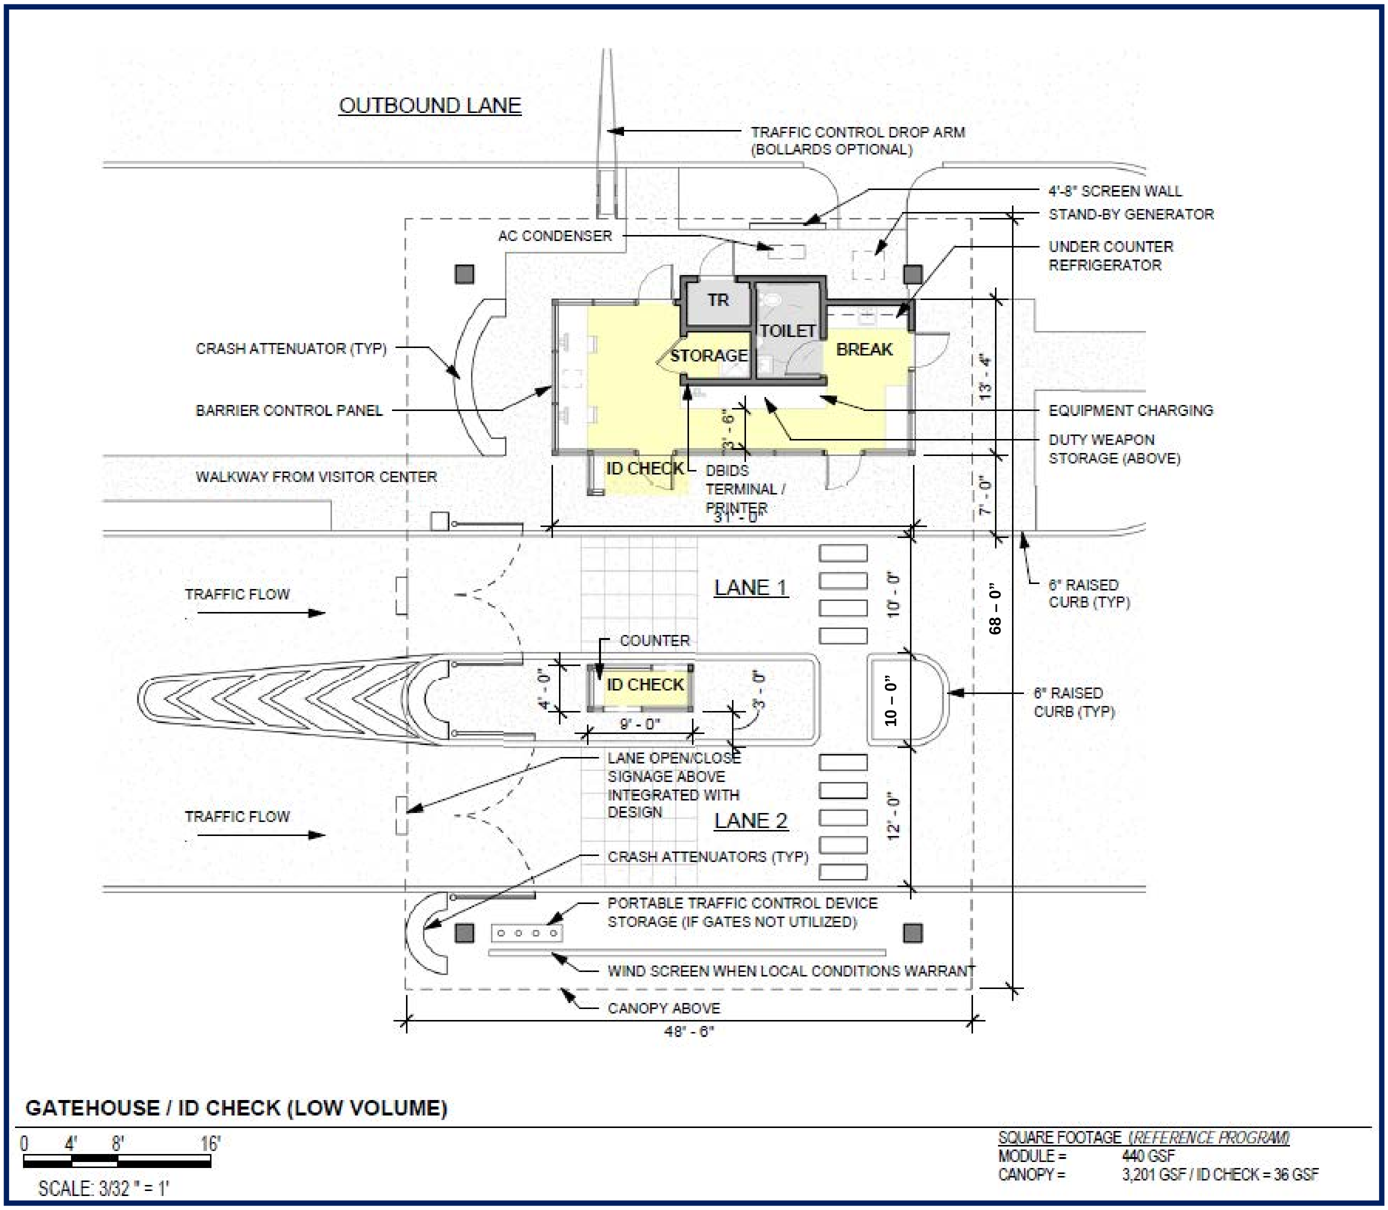
When guards need to stand between lanes of traffic, raised islands provide a measure of safety and separation. Consider designing the ID check area with a depressed step down area so that guards can process motorists at eye-level without having to bend over or step into traffic. The depressed area or sloped area must be designed to promote proper drainage so that it does not become an impediment to vehicular traffic. For all designs, items like guard safety, ponding water and automated equipment installation need to be reviewed in detail and impacts (both pro and con) identified and evaluated. Typically, ID check areas should be 50 (15.25 m) to 75 feet (23 m) long. Providing 75 feet (23 m) of length will allow tandem checking of vehicles, if required. Maintain a minimum 3 foot (0.9 m) setback from the face of curb to the guard facilities on the island. Must also include, as a minimum, a 1 foot (0.3 m) horizontal clearance between face of traffic island curb and guard facility roof, gutters or any other objects protruding from the guard facility. Maintain a minimum lateral clearance of 2 ft (610 mm) in the access control zone to allow security personnel to pass between fixed objects and obstructions and the roadway. See Figures 5-11 and 5-12 for additional details.

Figure 5-11 Model ID Check Island Details – High Volume



Source: Air Force Civil Engineer Center

Figure 5-12 Model ID Check Island Details – Low Volume



Source: Air Force Civil Engineer Center.

5-7.9 **Overwatch Position.**

Installations must consider additional position(s) for security personnel to facilitate a response to a threat. These positions known as overwatch are normally placed in the response zone to facilitate surveillance and armed response. This position may be fixed or temporary/portable. Manning of the overwatch position must be in accordance with the installation physical security plans. If an overwatch position is not being considered in the initial design, the site plan must provide a location and utility stub out or a future permanent/temporary one.

The overwatch (Figure 5-13) must be provided with an intercom, EFO controls to activate the AVBs and an enunciator to alert security personnel of the duress alarm being triggered at the other guard facilities. The overwatch must maximize visibility with 360-degree visibility. The overwatch position must have a direct line of sight to the access control zone of the ECF/ACP including identification and inspection areas.

5-7.9.1 **Permanent Facility.**

In most cases, the overwatch position will be located at or near the end of the response zone to provide sufficient distance for this response. In all designs, coordinate the location with security personnel to ensure proper line of fire and safety considerations. If required, elevate the facility to aid the observation of incoming traffic and reduce incidental/collateral damage by creating a plunging fire scenario.

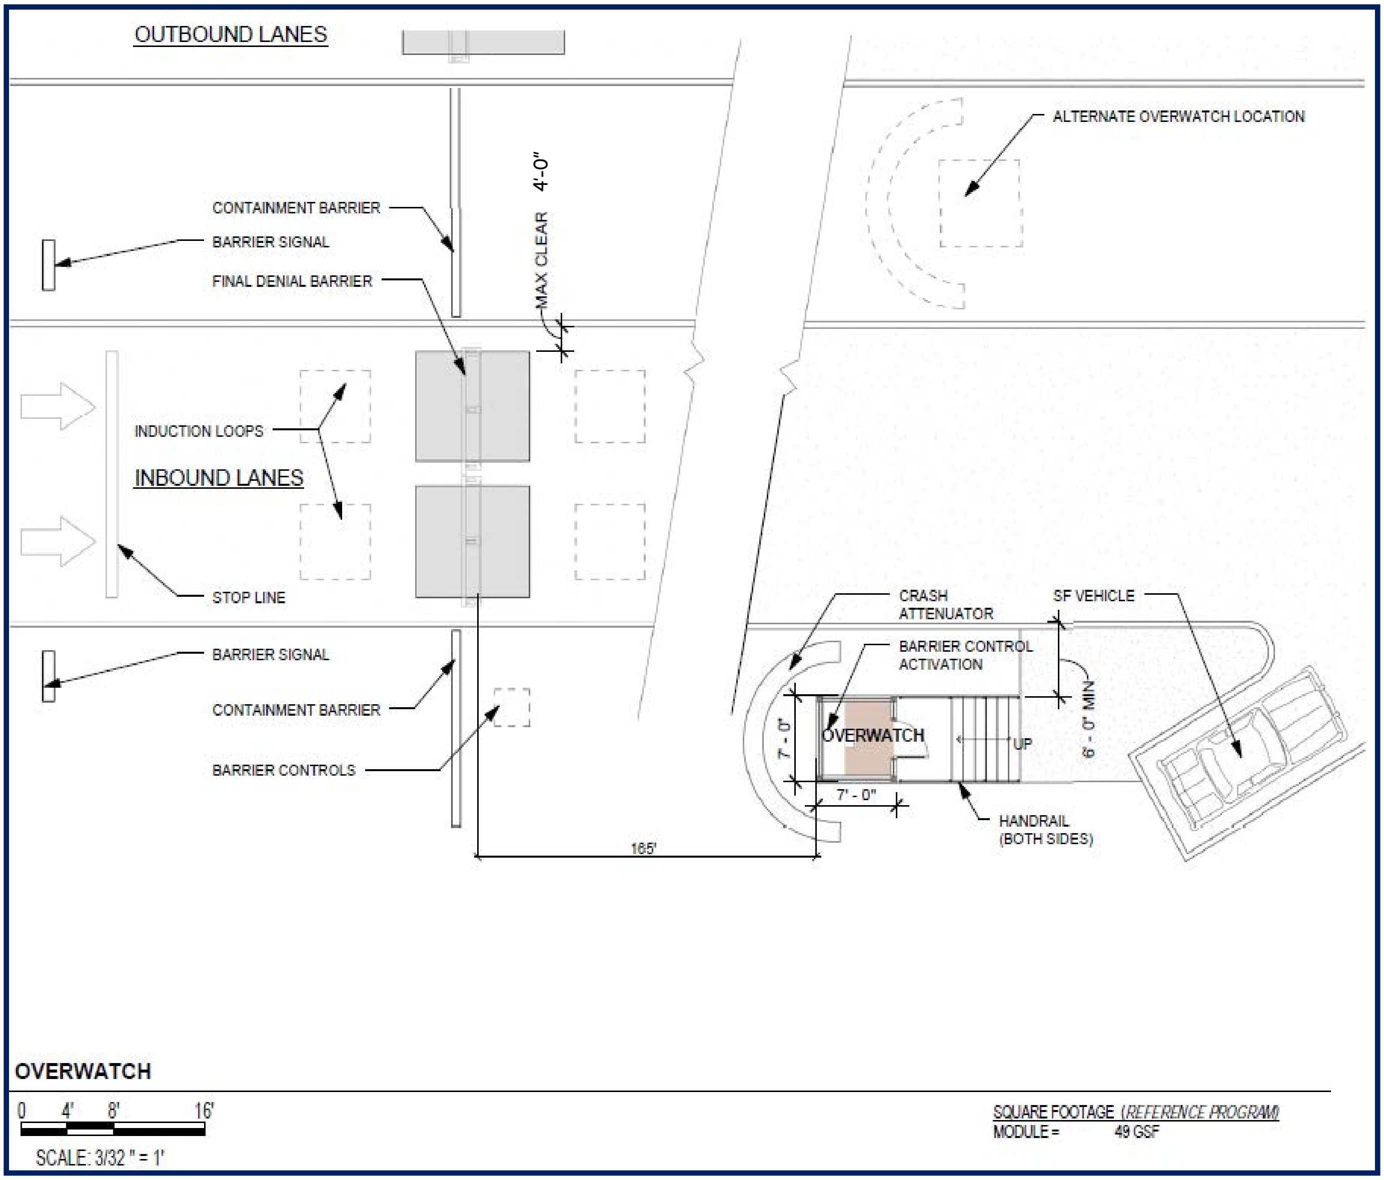
5-7.9.1.1 **Dimensions.**

Dimensions must be sufficient for movement of guard personnel within the structure. Design must provide adequate space for movement of a guard and use of both handgun and shoulder fired weapon with gunports. Gunports must be provided on each face of the overwatch. All gunports must be usable for both handgun and shoulder fired weapons. Gunport design must not require weapons to be oriented in an unusual way (e.g. gunport being placed immediately above counter and counter interfering with vertical orientation of pistol magazine).

5-7.9.2 **Temporary Facility.**

If the overwatch position is established as a temporary facility, an asphalt or otherwise paved pad must be provided at the overwatch location to accommodate a security forces vehicle or temporary facility during increased FPCONs. A communications stub must be provided for this facility as well as ruggedized and lockable EFO AVB controls.

Figure 5-13 Model Overwatch



Source: Air Force Civil Engineer Center

5-7.10 **Overhead Canopy.**

Provide canopies in the following areas:

- ID check area/access control zone (inbound lanes)

Provide an open/close visual indicator on canopy(s) over each lane that is controlled in accordance with the MUTCD/ DoD Supplement to the MUTCD. The preferred style of indicator is the red “X” and green “Arrow”, but the two head traffic signal (red/green) is allowed. If there is only one search lane, then it is up to the installation to determine if a visual indicator is desired.

5-7.10.1 **Benefits.**

Canopies provide the following benefits:

- Protection from weather (sun, rain, and snow) for ID check and inspection areas.
- Improved lighting since lighting can be installed under the canopy.
- Improved security since CCTV can be installed under the canopy.
- Improved security by allowing for more thorough processing during inclement weather.
- Support for automation systems.
- A structure to mount lane use signals and signs.
- A “gateway” for motorists which encourages lower speeds.

5-7.10.2 **Vertical Clearance Requirements.**

The minimum desirable clear height must be 17.5 feet (5.3 m) where commercial traffic at the ECF/ACP is allowed and facilitate use of the overhead canopy for signage, lighting or security equipment. Where the ECF/ACP use is limited to POVs the clear height must be 15 feet. This clear height is measured from the pavement to the lowest point on the overhead canopy, including light fixtures and other equipment.

5-7.10.3 **Design Considerations.**

The architectural appearance of the canopy should match surrounding features and meet the requirements of the installation exterior architectural plan. Avoid the use of structural elements that could obstruct visibility where individual canopy columns must limit field of view from ID check guard booth by no more than 11 degrees. Structural elements should be strategically located where possible behind attenuators or barrier walls and must be placed at least 3 feet (0.9 m) behind the face of curb.

5-8 ELECTRICAL AND COMMUNICATIONS REQUIREMENTS.

Electrical design must consider current power demands as well as the communication and power requirements for future traffic control devices, identification equipment, and other devices associated with potential automation of the ECF/ACP. Coordinate power requirements for security systems with the manufacturer. Some systems may require three-power configuration.

5-8.1 **General Guidance.**

Space must be reserved in the gatehouse for the controls and electric panel boards associated with the future control systems.

5-8.2 **Alternate Electrical Power Source.**

In the event of a loss of the primary electrical source, a reliable alternate power source is necessary to ensure continuous operation of the ECF/ACP. Follow service guidance for approval of backup power authorization and design.

The alternate power source status must be monitored at Command and Control (Gatehouse) to include alarms for loss of normal power, malfunction, and low fuel. It is recommended that generator be installed so that it is at least 30 feet from the service entrance transformer to allow for ease of maintenance. Ensure the alternate power source location allows access for maintenance of the unit as well as adding fuel.

5-8.2.1 **Standby Generator.**

Use a standby generator or other equivalent means as the alternate electrical power source. Provide an automatic means of starting the generator and load transfer depending on the permissible duration of the electrical power outage per UFC 3-550-01, UFC 3-520-01, and UFC 3-501-01. Recommend the generator be installed so that it is at least 30 feet (9 m) from the service entrance transformer to allow for ease of maintenance and adding fuel.

5-8.2.2 **System Considerations.**

Equipment on back-up power must include:

- Command and Control / Gatehouse interior and exterior lighting
- Canopy lighting
- Exterior lighting in the access control zone
- Roadway lighting within 100 ft (30.3m) of both sides of the access control zone
- ID check area and inspection area traffic arms
- Roadway lighting within 150 feet (47.5m) at the final denial vehicle barrier location(s)
- Exterior lighting in the inspection area(s) including 100 feet (30.3m) on both sides of the canopy
- Traffic control systems
- Automated systems
- Uninterruptible power supply (UPS).

Generator systems must include Command and Control / Gatehouse notification of the following

- Loss of primary power
- Standby generator malfunction
- Low fuel.

5-8.2.3 **Back-up Power and Auto-start Requirements.**

The generator must be provided with sufficient fuel to provide back-up power for a period of at least 12 hours or as required to support the installation's plan for refueling operations. For a fixed generator provide auto-start capability within 10 seconds of primary source failure. When natural gas generators are allowed they are not required to have a 12 hour tank.

5-8.2.4 **Portable Generators.**

In some cases, installations may specify the use of portable generators in addition to stationary auxiliary electrical power sources. Where portable units are utilized, provide a suitable location, power connection point, and access for trailer mounted portable generator.

5-8.3 **Uninterruptible Power Supply.**

To maintain security and barrier safety functions, provide a UPS for use during generator starting and load transfer. The UPS system supports computerized equipment to avoid power disruption. At a minimum, provide UPS for the following:

- Primary communications system
- Duress alarm system
- Computers
- CCTV systems
- Intrusion Detection Systems (IDS)
- Enunciator
- Access Control Equipment including AVB systems, traffic control devices and automated systems.
- AVB Systems include:
  - Active vehicle barrier controls.
  - Active barrier activation system for one complete operation cycle (opens to close and close to open). Hydraulic systems do not need to have the pump motor on UPS, if the system can maintain enough pressure for one complete cycle. The hydraulic pump motor then only needs to be on generator back-up power.
  - Traffic arms located at the active vehicle barriers.
  - Traffic sensors (wrong way, over speed, and presence detectors).
  - Traffic signals and warning lights.

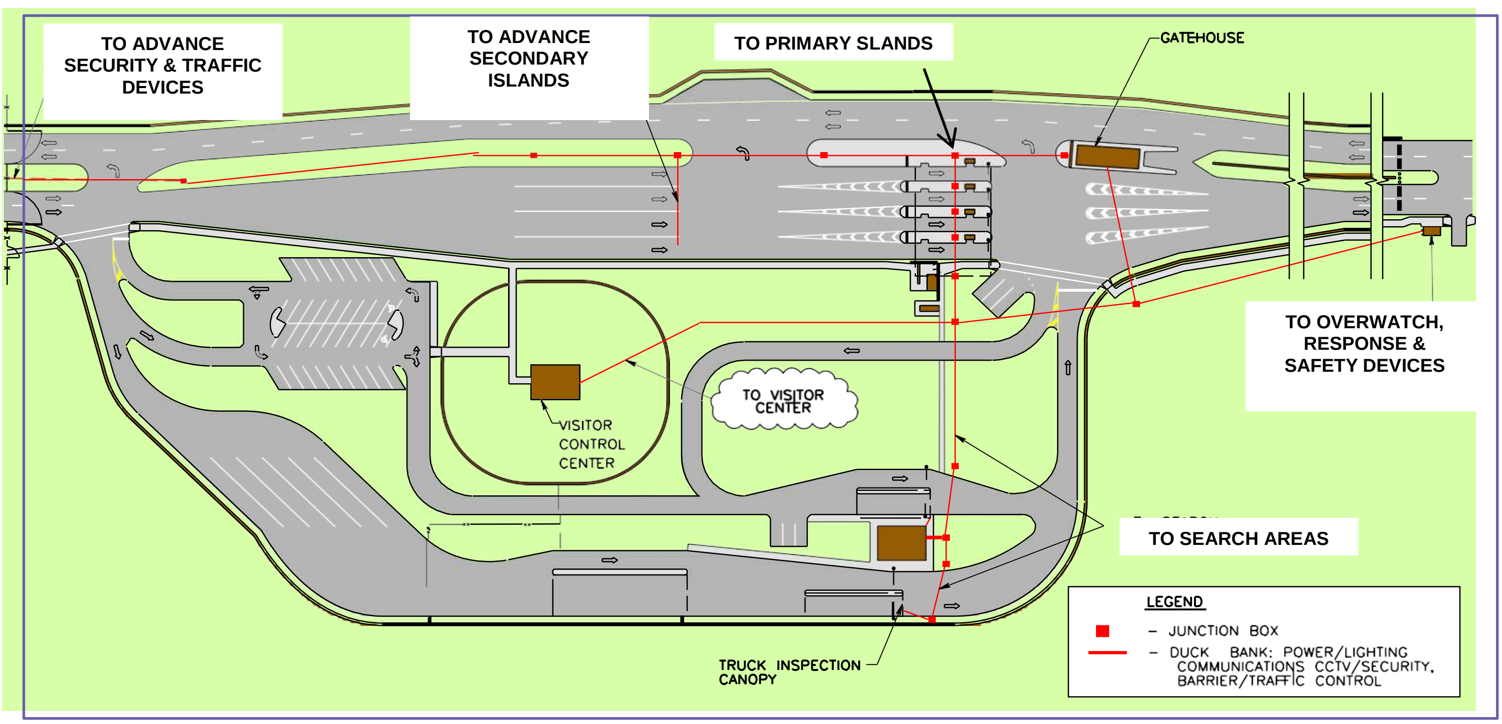
An UPS is not normally used for security lighting per UFC 3-530-01 due to the nonlinear nature of most luminaires. Provide limited lighting at the control consoles in the gatehouse (command and control) and inspection (search) office. Provide some luminaires at the ID check area (one per lane near the guard position) and at the active vehicle barrier location when required by other criteria or by the installation. The design should clearly identify the nonlinear nature and switching patterns of the load to be served by the UPS. It may be desirable to place limited lighting on the UPS to avoid restrike concerns.

5-8.4 Infrastructure.

In areas close to the gatehouse, physical interconnection is more feasible. In those cases, conduits and duct banks must be part of the overall design. Communication conduits are to be separated from power conduits and from signal/security system conduits. Provide spare conduits in all exterior pathways so that future devices can be added to the ECF/ACP. Conduits must connect all key features to the gatehouse including guard booths, inspection areas, AVBs, overwatch positions, and the visitor's center.

At a minimum, provide a system of underground duct banks and hand-holes for distribution of power, control, and communications/data wiring from the ECF/ACP gatehouse to each area as illustrated in Figure 5-14 Model Duct Bank Plan.

Figure 5-14 Model Duct Bank Plan



Source: SDDCTEA Pamphlet 55-15

5-8.5 **Information Technology.**

Each ECF/ACP must have at least two means of communication from the ECF/ACP to a central monitoring point. The type of communication is dependent on the devices being utilized and site conditions. CCTV systems require higher bandwidth. Coordinate the requirements for radio-based communication with the installation. Some installations may require an emergency ring down telephone, which provides a direct, hard-wired duress alarm to the installation emergency dispatch or control center.

Provide a central duress alarm, which signals the installation emergency control center, dispatch center, or similar designated location in each gatehouse, guard booth, inspection area, and overwatch position. The duress alarm must be silent in the ECF/ACP to avoid alerting aggressors of its activation.

5-8.5.1 **Installation-Wide Networks.**

The ECF/ACP must be capable of connecting to installation-wide, information technology systems. As services continue to enhance security at ECFs/ACPs, the need for reliable, high-speed data connectivity at installation perimeters becomes increasingly important. While many installations have been proactive in extending their fiber optic backbone to the perimeter, many ECF/ACP security upgrade projects continue to be hampered by the inability to transmit data from ECFs/ACPs back to security monitoring and administration facilities. Although a dedicated copper phone circuit is generally sufficient for transmitting basic ECF alarm messages (guard duress, door forced, enclosure tamper, etc.), ECF/ACP video and access control data demand a much faster connection that is best provided by fiber optic cable. To ensure adequate connectivity for an ECF/ACP security upgrade, the project team must first confirm the availability of fiber at each ECF/ACP and then design and build a network capable of transmitting all required data.

5-8.5.2 **Stand-Alone Networks.**

A stand-alone ECF/ACP network, physically separated from the information management network, is preferred due to the criticality and sensitivity of the data being transferred. This network must provide multiple connections at each ECF/ACP and at security administration, monitoring and dispatch facilities. For example, the network switch at a single ECF/ACP could require local ports/connections for a digital video recorder (DVR), video workstation computer, automated system servers and workstation computers. The port configuration of the ECF/ACP switch should include a fiber optic uplink to the backbone switch and enough local spares to accommodate new equipment in the future. The network must support Ethernet and Transmission Control Protocol/Internet Protocol (TCP/IP) protocols, and the data rate must be no less than 100 Mbps. A properly designed ECF/ACP network will support “plug-and-play” connectivity for a wide range of security equipment and ultimately enhance the force protection posture at the installation perimeter.

5-8.6 Closed Circuit Television (CCTV).

ECFs/ACPs must be equipped with a CCTV system. The system must be equipped with DVR capability for 24 hours and 7 days a week operation. Camera(s) must provide a perspective of ECF/ACP operations to include the following:

- ID check area
- Inspection areas
- Visitor’s center
- The approach zone
- Response zone to monitor traffic approaching from both directions unless not required by the individual service.
- Neighboring intersections and roadways that may be impacted by ECF/ACP operations.

Each inbound lane of traffic must be equipped with cameras capable of reading license plates and viewing drivers in the identification check areas and inspection areas.

The CCTV system must be monitored in the gatehouse, inspection office, and the Installation’s Central Security Monitoring Station (Military Police (MP) Desk, 911 Desk, Installation Emergency Operations Center (EOC), etc.).

5-8.7 Intrusion Detection System (IDS).

Coordinate with the installation and the service for these requirements. Provide balanced magnetic switches (BMS) on the exterior doors to the Command and Control/Gatehouse, Guard Booths, Overwatch, Search Office, and Visitors Control Center. Provide BMS on interior doors that go to rooms that contain communication, CCTV, or security equipment. Storage rooms that do not contain any security, CCTV or Communication equipment are not required to have BMS. See UFC 4-021-02, Electronic Security Systems (ESS) for additional information and guidance.

5-8.7.1 Tamper Switches.

Coordinate with the installation and the service for these requirements. The tamper switch can be part of the equipment itself and monitored by its system e.g. the active vehicle barrier control system can monitor the tampers on its system including the manholes/handholes. When the IDS panel is not monitoring the tamper switches, then the IDS panel must receive a general alarm from the other system when a tamper switch is activated.

Provide tamper switches on the following:

- Electronic control cabinets for Communications, AIE, CCTV, and security controls.

- Active vehicle barrier cabinets that contain controllers and power units. Operating control panels associated with the AVB controls (master, guard booth, local, etc.) are required to be equipped with tamper switches.
- The junction box at the Overwatch Position pad (if provided).
- Manholes and handholes that contain duress alarm, AIE, CCTV, intrusion detection or AVB control wiring and have splices present.
- Uninterruptible power supply (UPS) cabinets must be equipped with tamper switches.

5-8.8 **General Power Requirements.**

- Ensure power panel board are not be installed below a counter which includes pre-fabricated structures such as the guard booths, pedestrian check area booth and overwatch.
- Direct buried wiring is not allowed unless specifically requested by the installation or service in writing. Provide all 600V or less wiring in conduit. If the conduit is within eight (8) ft of a roadway, then concrete encased the conduit or use rigid steel conduit.
- Provide power receptacles per NFPA 70. The following are in addition to the general requirements.
    - Search Function/Bus Shelter is to have at least one duplex receptacle.
    - ID Check Guard Booth, Pedestrian ID Check, Overwatch Building. Provide one duplex receptacle at the counter that is either on a UPS circuit or provide a standalone UPS.
    - ID Check Guard Booth. Provide an exterior receptacle on each of the narrow ends. Provide at least one receptacle below the eave along each of the long sides.
    - Overwatch Pad. Provide a duplex receptacle at the pad.
    - ID Check Canopy. Provide at least one duplex receptacle per island.
    - Truck Search Area Canopy, Passenger Vehicle Search Area Canopy. Provide at least one duplex receptacle on a column on each side of the inspection space. Provide a dedicated circuit for each side of the inspection space receptacles.
    - ID Check Canopy, Truck Search Area Canopy, Passenger Vehicle Search Area Canopy. Provide one 20 amp circuit at either 208VAC, 240VAC, 277VAC or similar voltage depending on the country that can be used by heaters or other equipment. Provide an appropriate receptacle for the amperage and voltage configuration and have an adjacent disconnecting means.

5-9 **EXTERIOR LIGHTING.**

Lighting is required for guards to perform their security functions. ECF/ACP lighting is important so that motorists and guards can see each other. ECFs/ACPs must be designed with lighting features that support the operational requirements during dawn, dusk, or nighttime periods. Even if the ECF/ACP is intended to be used only during daytime hours, lighting must be considered in the event there is a change in usage.

Lighting must be complete and continuous. Specific areas of the ECF/ACP require their own lighting requirements. These requirements are governed by UFC 3-530-01 and criteria established by the individual services. The lighting plan for the ECF/ACP must transition from the existing roadway lighting so that it does not blind the driver or backlight signs. Proper design of the lighting system will increase safety and efficiency, aid security forces, enhance appearance, and reduce light pollution.

5-9.1 **General Requirements.**

Provide the ECF/ACP with multiple, redundant luminaries to ensure the loss of a single luminaire does not seriously degrade the total lighting available for security personnel. Transitional lighting is necessary on approaches (approach zone) and departures (response zone) to the ECF/ACP to minimize blinding effects as drivers travel into and out of a brightly illuminated access control zone of the ECF/ACP. Within the ECF/ACP, the lighting requirements vary depending on the zone of the ECF/ACP as noted UFC 3-530-01 Table 6-1, Minimum Lighting for Unaided Guard Visual Assessment.

The lighting at the ECF/ACP must be designed as controlled lighting, to reduce light pollution and increase traffic safety. Glare projection or glare lighting must be avoided where a safety hazard would be created. Use luminaires that are classified as cutoff or semi-cutoff.

5-9.1.1 **Placement of Luminaires.**

Light poles can be placed along the roadway or in the median. In some cases, light poles in the median may reduce the number of poles needed. However, at wider ECFs/ACPs with numerous lanes, the needed illumination may not be achievable with light poles only in the median. Therefore, light poles must be placed on both sides of the road. Provide exterior lighting poles and the electrical connections that are frangible when required by MUTCD/ DoD Supplement to the MUTCD. Poles can be no shorter than 15 feet.

When light poles are in uncurbed areas, the pole must be located outside of the roadway clear zone. In curbed areas, light poles must be located at least 2 feet (0.6 m) behind the face of the curb.

5-9.1.2 **Color Rendition Index.**

The ability to identify colors accurately and confidently is determined by the light source spectral power distribution and the illuminance level. This capability is commonly referred to as color rendition and is measured by the color rendition index (CRI). To ensure appropriate color rendition, use a light source with CRI greater than or equal to 65-in the ID check area, access control zone, and search areas, and use any nominally white light source (CRI greater than or equal to 50) at the illuminances typically encountered in the remaining areas of an ECF/ACP.

When CCTV is used as part of the security operations, it is important to coordinate the design of lighting and CCTV systems such that enough illumination and CRI is provided per CCTV equipment specifications.

5-9.1.3 **Restrike or Restart Capability.**

Another important consideration in the design of the site lighting, is the restart or restrike time for the selected lamps. Restart occurs when a lamp experiences a loss of power and there is a time delay before backup power restores power to the lamp and the subsequent restrike or restart of the lamp. Coordinate the restart capability with the user. As an example, high intensity discharge (HID) lamps are more energy conserving than incandescent lamps, however, they require several minutes to warm up and restart after power is interrupted. This period of time, which could be 15 to 20 minutes, is unsatisfactory for security operations. The installation should designate the maximum acceptable period for which loss of illumination can be tolerated, however, without specific data two minutes is considered the maximum outage period acceptable. The selection of light sources, especially in the Access Control Zone, must include an evaluation of restart or restrike time. It will be necessary to provide lamps and auxiliary equipment for rapid startup and restrike to provide minimal adequate lighting in the event of a power interruption.

5-9.2 **Approach and Response Zone Lighting.**

The approach and response zones require roadway lighting. The roadway lighting must provide enough intensity so that pedestrians, security personnel, islands, signage, and other hazards are visible. The lighting must not be directed in the driver's eyes and it must not backlight important signage. See UFC 3-530-01 and criteria established by the individual services.

Transitional lighting is necessary on approaches to the ECF/ACP so that drivers are not blinded during arrival and departure. See UFC 3-530-01, SDDCTEA Pamphlet 55-15, and criteria established by the individual services for transitional lighting guidance. Transition lighting goes from the lower light levels prior to the Approach Zone up to the required light level for the Approach Zone and then again up to the required level for the Access Control Zone. Then the lighting will transition from the Access Control Zone to the lower level for the Response Zone. After the active vehicle barriers the light level needs to transition down to the lower light level for the street. Roadway geometry may impact the ability to do the transition lighting per the criteria. Actual lighting locations must be determined on a case-by-case basis and depend on the height, light source, and lens distribution.

5-9.3 **Access Control Zone Lighting.**

In the Access Control Zone, area lighting is provided in the vicinity of the facilities. The lighting needs to illuminate the exterior and interior of a vehicle to facilitate identification of the occupants and the vehicle contents. Good vertical illuminance facilitates the identification and inspection procedures per UFC 3-530-01. Lighting levels above those indicated in UFC 3-530-01 Table 6-1 or those established by the individual services may be appropriate where practical and desired. However, careful consideration of the potential adaptation problems and the design of the lighting of surrounding areas are required for the safety of traffic and security personnel.

It may also be necessary to provide additional task lighting in the ID and inspection areas to support adequate identification of vehicle occupants and contents. Such lighting must be directed transverse to the roadway; it will then illuminate the roadway in front of the gatehouse, the driver, and the guard.

5-9.3.1 **Under-Vehicle Inspection Lighting.**

Per UFC 3-530-01, lighting may also be mounted at or below pavement level to facilitate under vehicle inspection. The system must eliminate shadows and create contrast.

5-10 **CONSTRUCTION PHASING.**

If the project involves the modification of an existing ECF/ACP, pay considerable attention to the phasing of construction. In most cases, it is desirable to minimize the interruption of the ECF/ACP operations especially during periods of peak demand.

This Page Intentionally Left Blank

CHAPTER 6 LARGE COMMERCIAL VEHICLE AND TRUCK INSPECTION FACILITIES

6-1 INTRODUCTION.

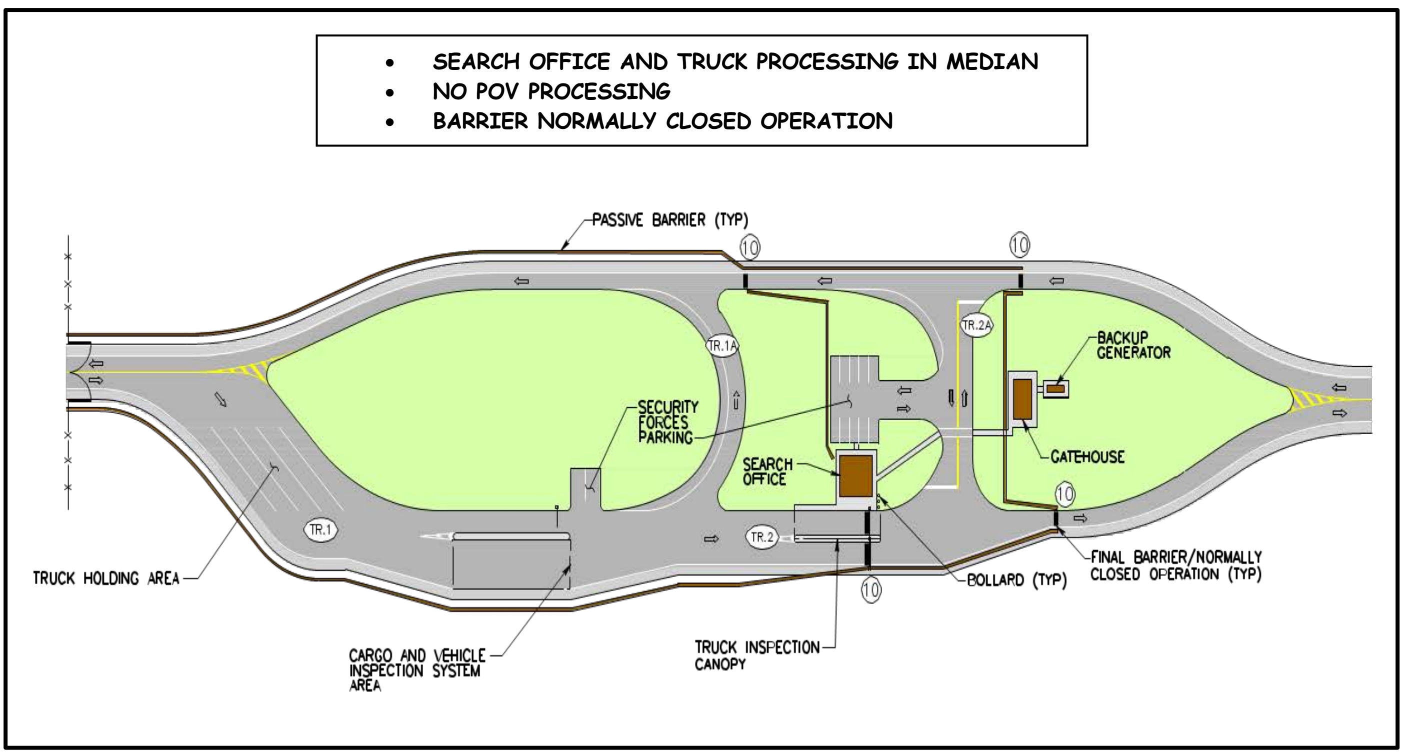
A large vehicle inspection facility may be a separate centralized facility or combined into the functions of a primary ECF/ACP as indicated in the function diagram in Figure 2-4. See Figure 5-7 for example layout of Commercial Vehicle Shelter and Inspection Office.

Key considerations in determining the need for segregated facilities include:

- Mission
- Location
- Population
- Truck traffic volume
- Security procedures
- Availability of land

The following criteria are intended to provide minimum requirements and general considerations in the design of such an inspection facility. The same ECF/ACP design features (i.e. IDS, duress system, and lighting) employed for POV only facilities are required for commercial vehicle/truck ECF/ACPs. See Chapter 5 Design Guidelines for design criteria/guidance on those features.

Figure 6-1 Example of Commercial Vehicle Only ECF/ACP



6-2 MISSION AND OPERATION.

An installation large vehicle inspection facility is intended to be the single point of inspection for all large commercial and truck traffic intending to enter the installation. It is envisioned that once a vehicle is inspected and authorized to access an installation, that the vehicle may be tracked and monitored until it enters the installation.

6-3 SIZING OF LARGE VEHICLE INSPECTION FACILITIES.

The capacity and truck holding requirements of a large vehicle inspection facility must be determined by a traffic engineering study as per SDDCTEA Pamphlet 55-15. The calculations must consider the longer processing times of trucks and the larger vehicle size. In some cases, where there is significant truck volume over several hours, the cumulative demands must be considered. All hours of the day when trucks are being accepted must be reviewed to determine the actual design truck demand.

Processing times vary based on security procedures, but often range from three to five minutes per vehicle, which equates to 12 to 20 trucks per hour processed. Where two inspection lanes are present, these rates are doubled. Once the number of vehicles not processed is known, that number represents the size of holding area needed.

6-4 INSPECTION EQUIPMENT.

Base the design of the large vehicle inspection station on the use of large vehicle inspection equipment. Some examples of these technologies are x-ray, ion mobility spectrometry, gamma ray imaging, and neutron analysis. An ever-increasing number of these devices are being installed. The design must include space for vehicle inspection equipment and utility conduits. The inspection equipment may be a mobile or fixed installation. It must be noted that some detection equipment is built-in to a large, drive-through structure. If this type of equipment is anticipated, then this must be coordinated and incorporated into the inspection office, drive through structure or overhead canopy facilities.

In addition, many installations desire CCTV inspection of the top and underside of vehicles. Mount these cameras on the overhead canopy and in the pavement below the vehicle. As a minimum, the inspection facility must possess the infrastructure to support the installation of CCTV inspection equipment, including adequate lighting to illuminate the underside of the vehicles during inspection. Some installations may also consider the use of vehicle inspection pits, although this type of facility is not recommended due to commonly encountered soil conditions and anticipated operational safety issues. The following sections contain information on various inspection-related devices to facilitate the layout of the truck inspection facility and the determination of the required infrastructure to support inspection equipment.

Follow service guidance for approval of inspection equipment authorization and design.

6-4.1 Under Vehicle Search Systems (UVSS).

If a CCTV UVSS is utilized, evaluate the following considerations and guidelines.

- Consider maintenance requirements.
- If installed below grade, the enclosure must be waterproof.
- Install the system within the ECF/ACP footprint so that the largest vehicle can pass over the equipment without entering the installation.
- Drainage must be established such that water drains away from the equipment.
- When providing drains from the equipment enclosure, provide backflow prevention valves to prevent water from entering the vault. Ensure any water that may be captured in the vault will not drain through control conduit to the control center.
- The electrical circuit serving the equipment must be a ground fault interrupt (GFI) circuit.
- Monitoring area must be free of glare.
- Vehicle speed must be kept below 15 mph (24.1 km/h) to ensure adequate performance.
- Where exposed to freezing temperatures, the equipment installation must include heaters.

6-4.2 Cargo and Vehicle Inspection Systems.

There are many types of automated inspection equipment for large vehicle or cargo inspection. Some of the types available, which provide an image of the contents of a vehicle or container, include X-ray and Gamma Ray inspection systems. There are other systems available, such as neutron or vapor/particle analysis, which aim to detect the common chemical elements associated with explosives or other contraband. Many installations are considering procuring mobile systems that afford the possibility of varying the location of the equipment amongst various ECFs/ACPs. Consider a fixed installation for Installations that plan centralized truck inspection facilities, which potentially have an increased throughput and a reduced space requirement. Due to the wide-ranging requirements for the different manufactured systems, it is not possible to provide detailed guidance that will support all types of this equipment. Consult with manufacturers of these systems during the design of an ECF/ACP to ensure data concerning operational considerations is both current and the best available, and to assure that the area where the system will be used is properly sized.

6-4.2.1 Safety and Regulatory Considerations.

Due to the use of gamma or x-ray radiation, there are safety and regulatory considerations in the use of these systems. The requirements vary depending on the system. Normally an exclusion zone, an area where personnel are not permitted during operation of the equipment, is established within and around the inspection equipment.

The region outside of the exclusion zone is considered safe for personnel during scanning operations. The size of the exclusion zone varies greatly depending on the type of equipment.

Nuclear Regulatory Commission regulations state that radiation dose limits in Public-Uncontrolled areas are 2 milli-Roentgens (mR) in any hour or 100 mR in any year. Therefore, depending on the characteristics of the source, the frequency of scans, and the expected occupancies, the exclusion zone can vary. Additionally, a shielding wall can be constructed to reduce the dose substantially. Some x-ray systems have qualified as a “cabinet x-ray system” in accordance with Food and Drug Administration (FDA) regulations or similar standards, meaning minimal shielding is required and the exclusion zone does not extend outside of the footprint of the inspection area. To qualify for this designation, FDA regulations require an emission limit of 0.5 mR per hour at 2 inches (5 cm) from the surface of the cabinet. Other regulatory considerations are that systems utilizing radioactive sources may require operation under a radiation materials license held and administered by the owner of the equipment (the installation) and a permit for operation may be required**.**

6-5 LAYOUT OF COMMERCIAL VEHICLE INPECTION FACILITY.

The layout of the large vehicle inspection facility is extremely important to ensure the facility will function properly. The civil design must consider the turning radius and other operating characteristics of the expected vehicle types. In addition, the facility should consider having multiple lanes of inspection to support different vehicle types, or varying inspection levels. The design must have adequate stacking distances for the anticipated queue and parking for vehicles to be inspected and security vehicles. Size parking areas for the range of expected vehicles and consider the anticipated volume of vehicles to be inspected.

6-5.1 Security Considerations.

Consider providing a “sally port” in the inspection area. A “sally port” configuration is created through the use of vehicle barricades or traffic gates. These barriers are intended to confine the vehicle during inspection until it is determined that the vehicle is authorized to proceed or if the vehicle is denied admission to the installation. The barriers can also be used to aid in positioning the vehicle relative to inspection equipment.

Some installations may require screening of the inspection operations from the remaining portions of the ECF/ACP. Screening may increase safety and shields the inspection procedures from public view to prevent visual surveillance from unauthorized personnel.

6-5.2 Inspection Equipment Considerations.

The inspection equipment can have a significant impact on the layout of a truck inspection facility. It is difficult to develop a layout that can support all potential types of automated inspection equipment. If the installation specifies the anticipated inspection systems, then the layout can be customized. If the specific system is not identified, but the use of imaging or related inspection equipment is anticipated, the layout must facilitate the future incorporation of this equipment.

APPENDIX B NAVY GATE AUTOMATION

B-1 GATE AUTOMATION.

Entry control facilities ensure the proper level of access control to all DoD personnel, visitors, and commercial traffic entering an installation. Currently, security personnel visually inspect the vehicle and driver credentials as they enter DoD Installations. The DoD is moving to automate the vehicle and driver validation process to reduce manpower and improve access control for DoD Installations. An Installation's perimeter access control is the first line of defense in the concept of defense-in-depth. Access control measures such as guards, gates, passive vehicle barriers, and active barriers must perform as an integrated system to protect DoD installations from the terrorist threat.

The primary objectives of the Navy's Automated Vehicle Gate – Low Volume program are as follows:

- Protect personnel and operationally critical assets onboard Navy Installations.
- Standardize and integrate identification, authorization, authentication, credentialing, and access into an enterprise-wide system onboard Installations per Homeland Security Presidential Directive (HSPD-12) through the use of Navy Access Control Management System (NACMS) enabled Physical Access Control Systems (PACS).
- Limit access to Installations based on a Navy Physical Access Control System (NPACS) authorization and authentication process.
- Increase manpower efficiencies.

B-1.1 Major Equipment (Per Lane):

- Access Pedestal – Contains card reader, intercom, and driver's image capture.
- Vehicle Presence Sensor -Used to monitor vehicle transition through the ECF.
- Barrier Signal – Physically located on the drop arm, containment gate and final denial barrier. Red and flashing yellow lights.
- Drop Arm – Used to control vehicle movement at the access pedestal.
- Vehicle Trap – Used to control vehicle movement through the ECF during unmanned operations. Prevents tailgating and pass back of user credentials.
- Vehicle Trap Gate – Used to maintain a secure perimeter and forms the initial portion of the vehicle trap.
- Vehicle Trap Barrier – Not to be confused with AVBs. Used to form the final portion of the vehicle trap.

- Situational Awareness (SA) Closed circuit television (CCTV) cameras – Used to provide SA of the ECF as well as rear mounted vehicle license plate and vehicle operator.
- Dynamic Message Sign – used to notify vehicle operators of current gate status (Open / Closed).
- Fixed signage to indicate and direct traffic flow. Approach zone signage will become critical for traffic throughput. Provide signage to lane use and direct traffic into the appropriate lanes.
- Guard Interface Panel – NPACS enabled panel used by the Contact Guard to configure ECF automation.
- Wrong-way detection sensors (outbound lanes)
- Excessive speed detection sensors (inbound lanes)
- Gate automation hardware - Includes NEMA-4X rated enclosure, chassis/power supply, digital input modules and digital output modules used to control gate automation. The gate automation I/O modules interface the various input and output devices to include the following equipment:
    - Traffic Gate Arm
    - Vehicle Presence Sensors
    - Dynamic Message Sign
    - Guard Interface

B-1.2 Major Equipment (ABA Compliant Pedestrian Turnstiles).

- Access Pedestal – Contains card reader, intercom, and pedestrian image capture.
- Situational Awareness (SA) Closed circuit television (CCTV) cameras – Used to provide SA of the ECF as well as the card holder.

B-1.3 Major Equipment (Guard House):

- Storage for handheld credential scanners (2/inbound lane plus spares).
- Guard Interface– NPACS enabled panel used by the Contact Guard to configure ECF automation.

B-1.4 Major Equipment (Visitor’s Center):

- Card holder ID management system with enrollment workstations.

B-1.5 Major Equipment (Primary and Secondary Monitoring locations):

- Main Distribution Frame – Houses servers, LAN gear, UPS, and other required equipment.

- Physical Security Information Management (PSIM) client - Used to monitor system status, alarms, communications, SA, and perform system administration.

B-1.6 Connectivity (Guard House):

- In addition to standard Installation voice and data connectivity, a minimum of one 12 strand single mode optical fiber cable is required for gate automation systems. Coordinate point of service with installation. Typically, point of connection/service will be the Installation's dispatch Center.

B-1.7 Connectivity (Visitor's Center):

- Connectivity will be supported by the Navy's PSNet network.

Figure B-1 Example of Lane Layout for Gage Automation

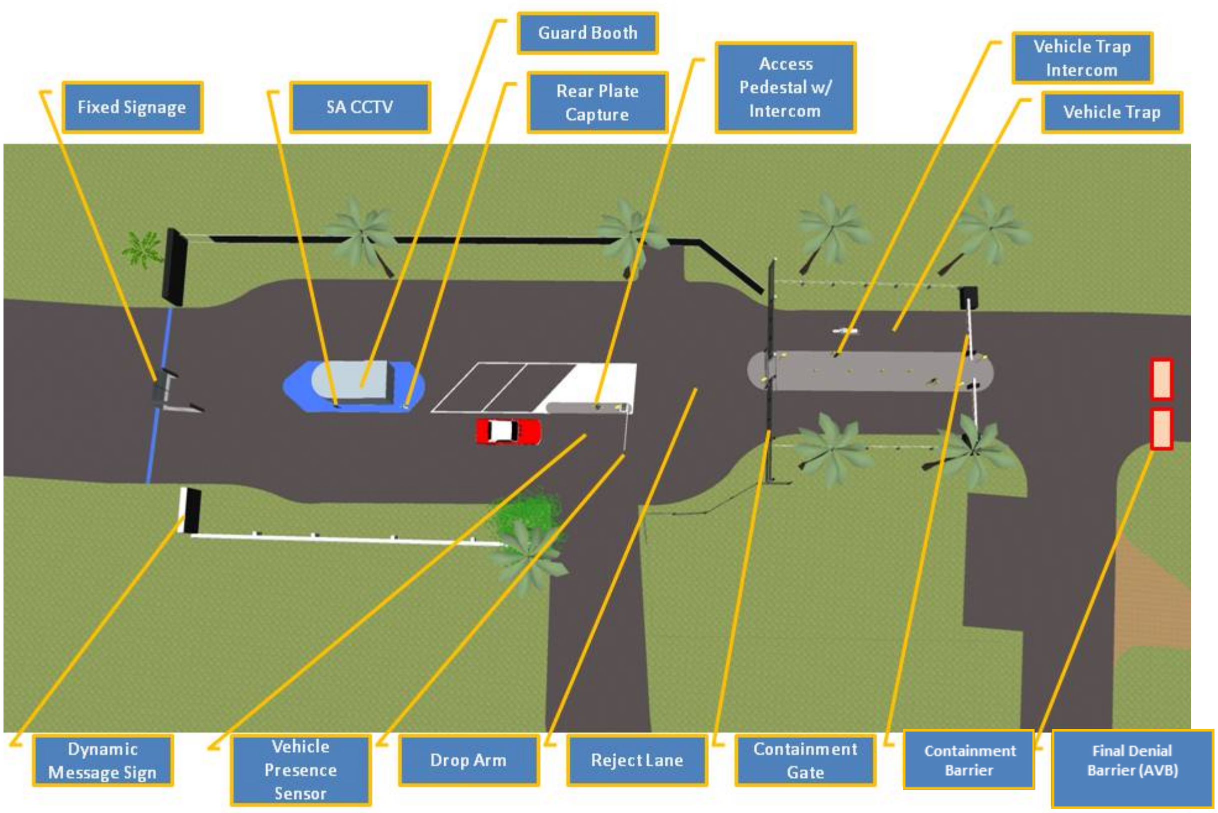

Figure B-2 Gate Automation System Schematic
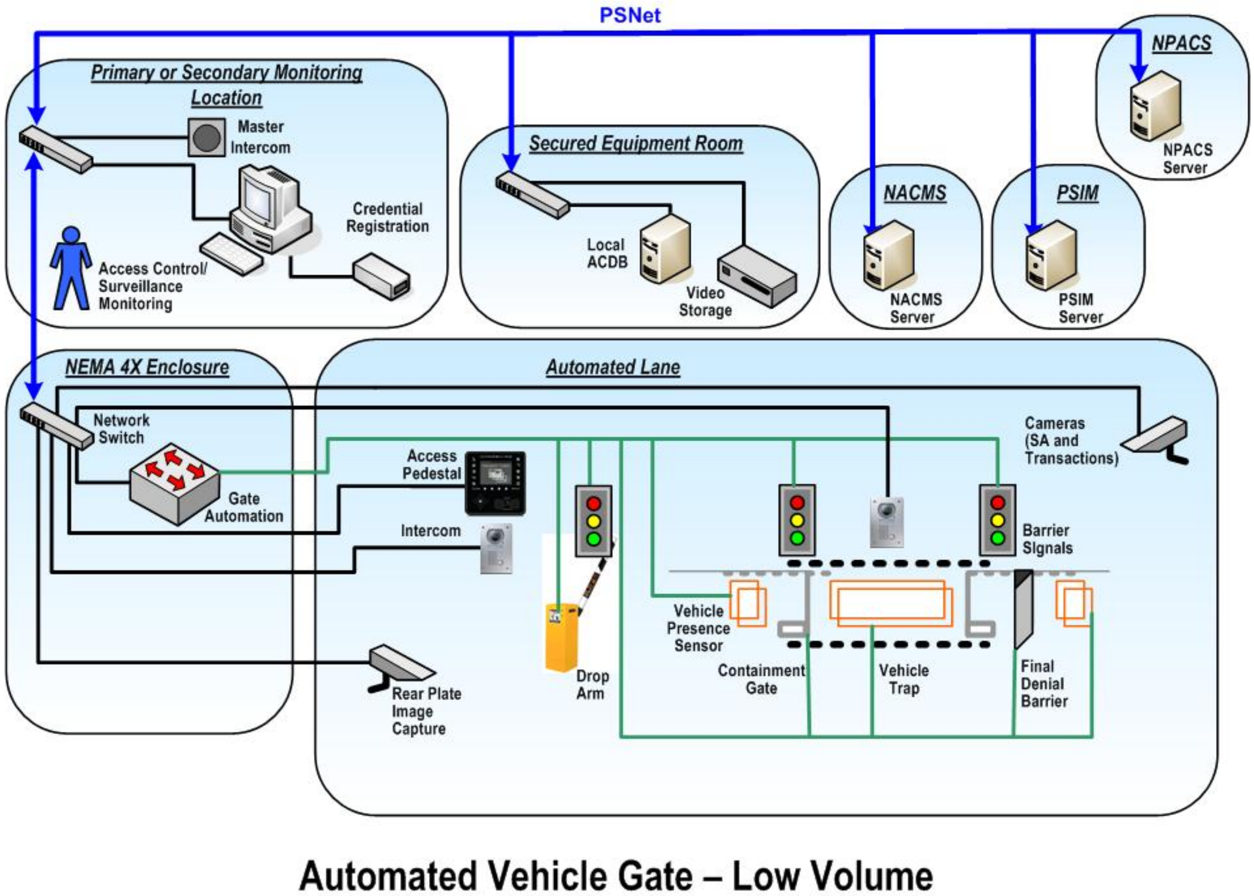
(Does not include wrong way and speed detection)



APPENDIX C ARMY GATE AUTOMATION

C-1 GATE AUTOMATION.

The Automated Installation Entry (AIE) System provides a cost effective system that enhances security of Army Installation Access Control Points (ACPs), automates identity authentication and verification of authorized registered personnel entering the Installation, maintains or increases pedestrian and vehicle throughput with enhanced security, and allows for adaptation of increased authentication requirements at high threat levels.

The AIE System provides automated access control for vehicular traffic and pedestrians that have been enrolled in the system and are authorized access In Accordance With (IAW) the Department of Defense (DOD), Army and Installation Commander's policies. The System is modular and scalable to allow future extensions to other security, access control and force protection systems. The System is flexible and can support future upgrades and technical advancements. AIE consists of Fixed-Full and wireless Handheld configurations. The Handheld configuration provides AIE capabilities to Installations that do not require the full System.

C-1.1 Major Equipment (Per Lane).

Table C-1 Major Equipment Per Lane

Video Cameras	Cameras to capture font of vehicle, rear of vehicle (for vehicle lane), and person's face (vehicle and pedestrian gates).
Lane Control Workstation	Touch-enhanced workstation for use by Guard to monitor and control devices at the lane or multiple lanes.
ACP Monitoring Workstation	Touch-enhanced workstation for use by Guard to monitor and control devices at one or more lanes.
Remote Monitoring Workstation	Touch-enhanced workstation for use by Guard to monitor and control devices at one or more lanes.
Guard Booth Intercom Station	Intercom station that allows Guard to answer and initiate calls from/to the vehicle and pedestrian lanes.
ACP Intercom Station	Intercom station that allows Guard to answer and initiate calls from/to the vehicle and pedestrian lanes.
Remote Monitoring Intercom Station	Intercom station that allows Guard to answer and initiate calls from/to the vehicle and pedestrian lanes.
Rhino Reader Pedestal	Multi-credential reader with display, biometric verification, and PIN pad.
Handheld Device	Retrieves all data in real time from the ACP server and presents it to the operator for situational awareness
Traffic Light	The Traffic Light interface is the Human-Machine Interface (HMI) that informs the vehicle driver to proceed (green light) or not proceed (red light).

Drop Arm	Used to control vehicle movement at the access pedestal

C-1.1.1 Lane Controls.

Lane Controls is the physical interface between an access control card reader and the Physical Access Control System (PACS) that controls the gate arm and coordinates other activities such as situational awareness, common operating picture, and services management. The PACS responds with two signal lines generally intended to light a red (access denied) or green (access granted) indicator that are presented to the user (driver or pedestrian).

C-1.2 Major Equipment (Per ACP).

Table C-2 Major Equipment Per ACP

ACP Monitoring Workstation	Touch-enhanced workstation for use by Guard to monitor and control devices at one or more lanes.
ACP Intercom Station	Intercom station that allows Guard to answer and initiate calls from/to the vehicle and pedestrian lanes.

C-1.3 Registration Operations.

Registration Stations interface displays registration information for the registrar as it is collected. The registrar interacts with the Entry Point registration workstation through the touchscreen monitor or with keyboard and mouse to assist the registrant in presenting appropriate information in expected order. Registration of personnel can also be conducted at the vehicle lane using the pedestal scanner or handheld device.

C-1.4 Registration Equipment.

Registration Data Collection interface allows the registrant to provide the data needed to vet the individual for potential registration in the AIE System. The data collection includes driver’s license and passport scanner, fingerprint scanner, signature capture, and PIN entry pad.

C-1.5 Registration Data Package.

The Registration Data Package interface utilizes the IP network to send the collected and packaged PIR data from the Entry Point Client to the Entry Point Server.

C-1.6 Database Overview.

The AIE System makes use of several databases that are described below in Figures C-1 and C-2. The databases are all managed by Microsoft (MS) SQL Server, Enterprise Edition. The choice of Microsoft SQL Server was made by the manufacturers of the COTS software – this is the only database management system (DBMS) that is supported by all software component manufacturers.

Figure C-1 AIE Operational View

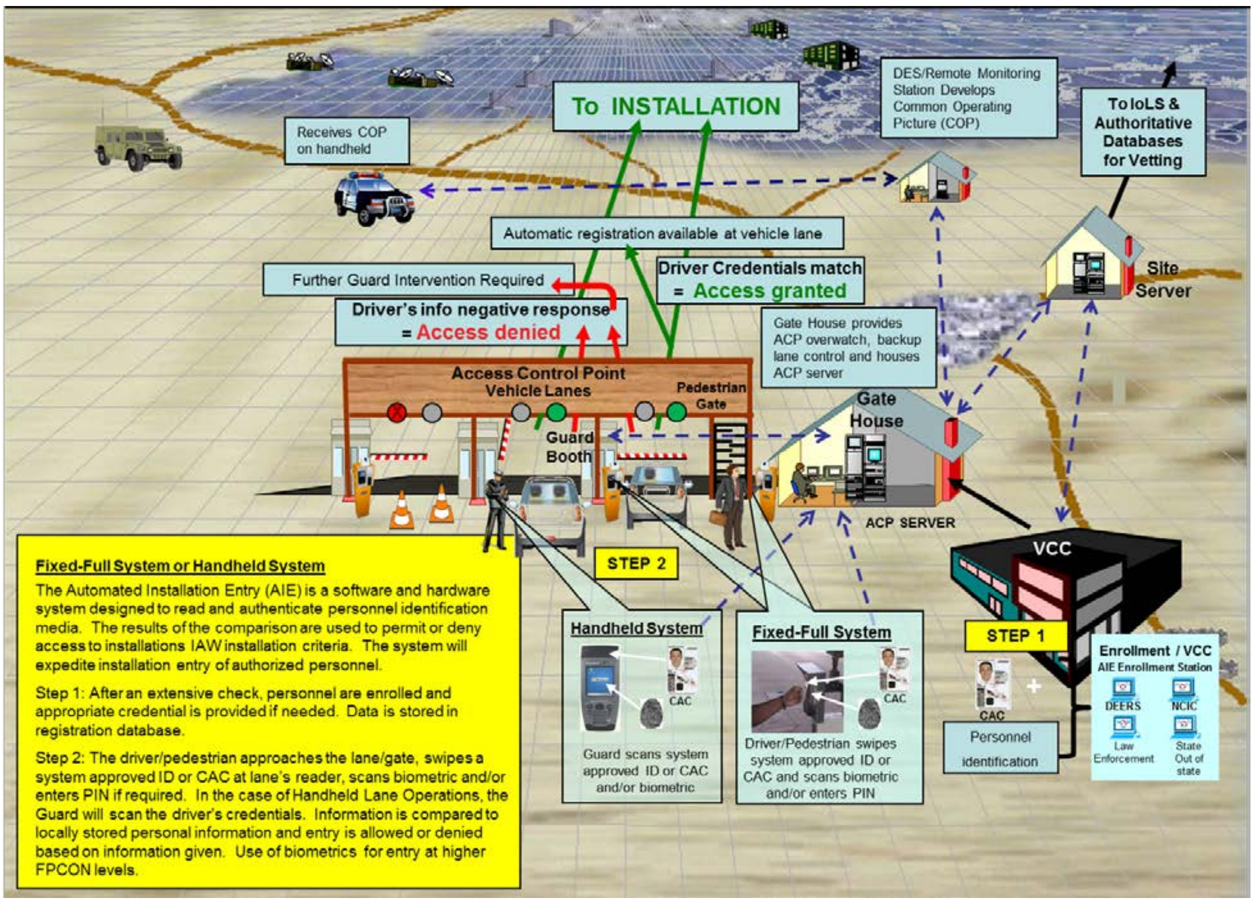


Figure C-2 System Connectivity and Interface Description

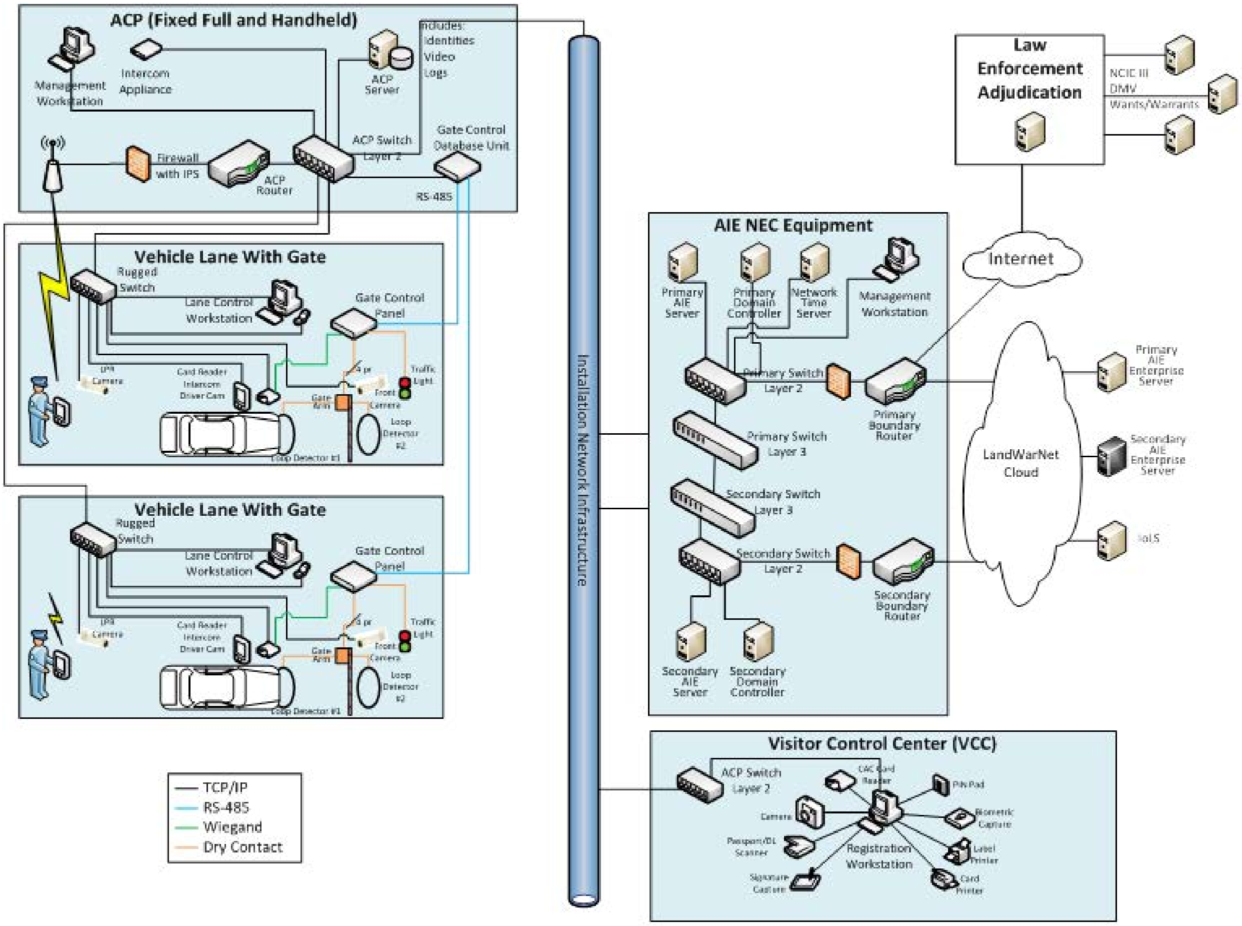

APPENDIX D ECF/ACP DEVELOPMENT CHECKLIST

This checklist is provided to assist the planning and design/RFP teams to determine the requirements and major features for an ECF/ACP project. This checklist should be utilized by the planning team, and validated by the RFP/Design team.

Arrange a stakeholder coordination meeting. If possible, include the following Base personnel and public representatives

Stakeholder	Representative Name	Organization	Title
Base Security			
Base Operations/Facilities			
Base Public Works/Utilties			
Base Enviromental			
Base Planning			
Base Antiterrorism Officer (ATO)			
Base Traffic Engineer			
Base Safety			
ECF EIC/Project Manager			
Local Municipality			
State/Local DOT			

Existing ECF/ACP:

1) What type of ECF/ACP? Primary / Secondary / Limited Use

2) What are the ECF/ACP hours of operation? ____________________

3) What are peak times and staffing levels at those times? ____________________

4) What are the staffing levels at off peak times? ____________________

5) How many inbound lanes? ____________________

6) How many outbound Lanes? ____________________

7) How are POVs processed? Single / Tandem

8) Are there traffic queuing issues? Yes / No

9) Does the ECF/ACP traffic affect the local community? Yes / No

10) Are current processing times unacceptable? Yes / No

11) Is the ECF/ACP a high crash area? Yes / No

Planning:

1) Was a traffic study done? *(if Yes, go to #6)* Yes / No

2) Will a traffic study be required to update/estimate traffic volumes necessary to validate scope and budget? Yes / No

3) Who will coordinate traffic study and when will it be performed?

__________________________/_______________

4) What are the queuing requirements? POV ________ Truck ________

5) How many vehicles/hour must the ECF/ACP process? __________________

6) Will future demand fluctuate due to mission changes, joint basing, or base closure? Yes / No

7) Will the ECF/ACP need to be designed for future demand? Yes / No

If Yes, please explain future demands:

____
____
____
____

8) Has a Conceptual Design Workshop been completed? Yes / No

If No, convene conceptual Design Workshop if necessary to establish conceptual design. Workshop may be necessary to confirm budget and scope of project.

9) Are there any site-specific challenges unique to the project such as Historical significance or Installation Appearance Plan (IAP), or current site/area availabilities that may affect budget or design? Yes / No

If Yes, explain site specific challenges:

____
____
____
____

10) Are there any environmental considerations such as wetlands, protected habitats, or cultural resources? Yes / No

If Yes, explain considerations:

____
____
____
____

11) May the current ECF/ACP be closed for the duration of construction? Yes / No

12) Will a secondary gate be opened? Yes / No

If Yes, which gate? ___________________________

13) Will a temporary ECF/ACP have to be constructed? Yes / No

14) During ECF construction, will traffic be rerouted? Yes / No

15) What are the contractor's responsibilities in regards to gate closure and traffic rerouting?

____
____

16) Will this ECF/ACP process Commercial/Large Vehicles? Yes / No

If NO, go to #22

17) Will Commercial/Large Vehicle Inspections be conducted at the ECF/ACP or at a remote site? Yes / No

18) What is the queuing requirement for the Commercial/Large Vehicle Inspection facilities?

19) Will Large Commercial Vehicle/Truck Inspection Facilities require a canopy?

Yes / No

20) Will Large Commercial Vehicle/Truck Inspection facilities require an inspection office?

Yes / No

21) How will Commercial/Large Vehicles be processed?

22) What commercial vehicle inspection equipment will be incorporated and are the specifications available?

23) Will this ECF/ACP process Buses/other Public Transportation vehicles? Yes / No

If Yes, how will uses be processed?

24) Are bus shelters required for this ECF/ACP? Yes / No

If Yes, list requirements for shelter:

____

____

25) Will the ECF/ACP process pedestrians? Yes / No

If Yes, how will pedestrians processed?

____

____

____

____

26) Will the ECF/ACP process bicycles? Yes / No

If Yes, how will bicycles processed?

____

____

____

____

27) Will the ECF/ACP process visitors? Yes / No

If Yes, will a visitor's center be required? Yes / No

28) Will the ECF/ACP process any unique vehicles? Yes / No
(Construction/Weight Handling/Wide Load Vehicles)

____

____

____

29) What is the design threat vehicle? _____ lb. / kg

30) Will a new Gatehouse be required for the ECF/ACP? Yes / No

31) Will new Guard Booths be required for the ECF? Yes / No

If Yes, how many Guard Booths are required? ________

32) Are prefabricated guard booths/houses acceptable? Yes / No

33) Will an Overwatch Position be required for the ECF/ACP? Yes / No

If Yes, will it be permanent structure or concrete pad? Structure / Pad

34) Will an Overhead Canopy be required for the ECF/ACP? Yes / No

35) Will signal light timing have to be coordinated with off installation systems?

Yes / No

36) Will public roadways or signal lights have to be modified to implement new ECF/ACP? Yes / No

If Yes, describe modifications.

____

____

____

____

37) Will active and passive vehicle barriers be required? Yes / No

If Yes, what type of active barrier does the base have or desire?

Net / Wedge / Bollards

38) What type of fencing will be required to match existing appearance?

Chain-Link / Ornamental / ____________

39) Locate utility connection points:

Change No.	**Date**	**Location**
1	August 9, 2010	Revisions throughout Document: Deleted Appendix B – List of Manufacturers; revised document text and appendices accordingly.

This UFC supersedes MIL-HDBK-1013/14, dated 1 February 1999.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD(AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Center for Engineering and the Environment (AFCEE) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

(Installations and Environment)

UNIFIED FACILITIES CRITERIA (UFC)
NEW DOCUMENT SUMMARY SHEET

Document: UFC 4-022-02, Selection and Application of Vehicle Barriers
Superseding: Military Handbook 1013/14, Selection and Application of Vehicle Barriers

Description: Provides a unified approach for the design, selection, and installation of active and passive vehicle barriers associated with Department of Defense (DoD) facilities. The examples provided in this UFC are for illustration only and shall be modified and adapted to satisfy installation specific constraints. This UFC is not intended to address procedural issues such as threat levels or to provide specific design criteria such as impact forces.

This UFC was developed by consolidating and refining criteria from USACE Protective Design Center, Security Engineering Working Group (SEWG); Naval Facilities Engineering Command (NAVFACENGCOM), Engineering Criteria Office, Engineering Service Center and available military, government, and commercial sources\1\ /1/.

Commanders, security and antiterrorism personnel, planners, designers, architects, and engineers should use this UFC when evaluating existing and providing new vehicle barriers. Technical information considered generally known to professional designers, architects, engineers, or readily available in technical references (UFC, Military Handbooks, Technical Manuals, etc.) has not been included.

Reasons for Document: Vehicle barriers are primarily used as one of many elements that define perimeters that require a final denial barrier to be provided for certain restricted areas. This UFC focuses of the design, selection, and application of active and passive vehicle barriers.

Impact: The following direct benefits will result:

- A standardized approach for identifying and justifying security and antiterrorism design criteria for DoD facilities;
- A standardized nomenclature and criteria for asset, threat, and level of protection definition;
- A standardized procedure for identifying costs for DoD facilities with security and antiterrorism requirements to a planning level of detail;
- A standardized process for evaluating design criteria and protection options based on cost and risk management;
- Guidance for incorporating security and antiterrorism principles into installation master planning; and
- There are no adverse impacts on environmental, sustainability, or constructability policies or practices.

CHAPTER 1 - INTRODUCTION

1-1 PURPOSE.

This UFC provides the design requirements necessary to plan, design, construct, and maintain vehicle counter-mobility barriers used within Entry Control Facilities (ECF) or as perimeter protection. This UFC is to be used during the design of Department of Defense (DoD) facilities to ensure an optimal vehicle barrier system is selected by engineers and security personnel for a specific operation within an installation. Barrier performance, maintenance, and cost should all be optimized. It is intended to establish consistent requirements, standards, and design basis for barrier planning, design, construction, and maintenance for all military departments. This UFC identifies design features necessary to ensure that infrastructure constructed today will have the flexibility to support future technologies, a changing threat environment, and changes in operations.

1-2 INTRODUCTION.

A vehicle barrier selection and placement process is presented herein, along with criteria for the design, selection, installation, operation, and maintenance of security barrier systems. The selected barrier system must effectively stop and/or disable vehicles that pose a threat, including explosive laden vehicles, of breaching the perimeter of a protected area. Both passive (static or non-movable) perimeter barriers and active (operational for access control) barriers at facility entrances are included. The examples presented in this UFC are for illustration purposes only and should be modified and adapted to satisfy installation specific constraints. This UFC is not intended to address procedural issues such as tactics and techniques; however, an appropriately designed vehicle barrier system used within an ECF/ACP or along an installation perimeter can enhance and improve operations.

1-3 BACKGROUND.

Guidance and documentation regarding issues of vehicle barriers and vehicle counter-mobility design are provided within the joint military services. Each document presents useful information to engineers, planners, architects, and security personnel responsible for Entry Control Facilities (ECFs) and Access Control Points (ACPs), both existing and new facility construction involving vehicle barriers and counter-mobility techniques.

Until now, there has been no single DoD document that provides all the information required for vehicle barrier design. This UFC, in conjunction with UFC 4-022-01 for Entry Control Facilities/Access Control Points, establishes consistent standards and requirements for each military service branch. The UFC supplements and is referenced by the Security Engineering Facility Planning Manual (UFC 4-020-01) and the Security Engineering Facility Design Manual (UFC 4-020-02). The design of a vehicle barrier system should begin with planning as directed in UFC 4-020-01, then graduate to design guidance provided in UFC 4-020-02, then culminate with selection and installation of a barrier system using this UFC.

1-4 SCOPE AND USE OF GUIDANCE.

Commanders, security personnel, planners, designers, and engineers should use this UFC when designing vehicle barrier systems for ECFs or other perimeter locations. Technical information considered generally known to professional designers or engineers or readily available in existing technical references (Unified Facility Criteria, Military Handbooks, Technical Manuals, etc.) has not been included.

1-5 SECURITY ENGINEERING UFC SERIES.

This UFC is one of a series of security engineering Unified Facilities Criteria documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include the following:

a. DoD Minimum Antiterrorism Standards for Buildings. UFC 4-010-01 DoD Minimum Antiterrorism Standards for Buildings and UFC 4-010-02 DoD Minimum Antiterrorism Standoff Distances for Buildings establish standards that provide minimum levels of protection against terrorist attacks for the occupants of all DoD inhabited buildings. Those UFC are intended to be used by security and antiterrorism personnel and design teams to identify the minimum requirements that must be incorporated into the design of all new constructions and major renovations of inhabited DoD buildings. They also include recommendations that should be, but are not required to be, incorporated into all such buildings.

b. Security Engineering Facilities Planning Manual. UFC 4-020-01 *Security Engineering Facilities Planning Manual* presents processes for developing the design criteria necessary to incorporate security and antiterrorism into DoD facilities and for identifying the cost implications of applying those design criteria. Those design criteria may be limited to the requirements of the minimum standards, or they may include protection of assets other than those addressed in the minimum standards (people), aggressor tactics that are not addressed in the minimum standards or levels of protection beyond those required by the minimum standards. The cost implications for security and antiterrorism are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they represent only representative construction that will meet the requirements of the design criteria. The manual also includes a means to assess the tradeoffs between cost and risk. The Security Engineering Planning Manual is intended to be used by planners as well as security and antiterrorism personnel with support from planning team members.

c. Security Engineering Facilities Design Manual. UFC 4-020-02 *Security Engineering Facilities Design Manual* provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established using UFC 4-020-01. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them all work as a system. The information in UFC 4-020-02 is in sufficient detail to support concept level project development, and as such can provide a good basis for a more detailed design. The manual also provides a process for assessing the impact of protective measures on risk. The primary audience for the Security Engineering Facility Design Manual is the design team, but it can also be used by security and antiterrorism personnel.

d. Security Engineering Support Manuals. In addition to the standards, planning, and design UFC mentioned above, there is a series of additional UFC that provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02. These support manuals provide specialized, discipline specific design guidance. Some address specific tactics such as direct fire weapons, forced entry, or airborne contamination. Others address limited aspects of design such as resistance to progressive collapse or design of portions of buildings such as mailrooms. Still others address details of designs for specific protective measures such as vehicle barriers or fences. The Security Engineering Support Manuals are intended to be used by the design team during the development of final design packages.

CHAPTER 2 - EXISTING REQUIREMENTS AND TECHNICAL GUIDANCE

2-1 GENERAL.

This UFC should be used in conjunction and coordination with UFC 4-020-01 Security Engineering Facilities Planning Manual, UFC 4-020-02 Security Engineering Facilities Design Manual, UFC 4-022-01 Security Engineering: Entry Control Facilities/Access Control Points, and UFC 4-022-03 Security Engineering: Fences, Gates and Guard Facilities to guide the user through a selection process to establish a protective barrier system around a DoD installation and designated restricted areas within the installation (enclave areas). A systematic approach is used. The main issues to be considered during the selection and design of a vehicle barrier include:

a. *Threat Analysis* – to quantify the potential threat. For threat analysis, refer to UFC 4-020-01 Security Engineering Facilities Planning Manual and UFC 4-020-02 Security Engineering Facilities Design Manual. The procedures in these manuals will quantify and qualify all potential threats, including the "moving" vehicle bomb threat necessary for the determination of the appropriate vehicle barrier for a given location.

b. *Performance* – to determine the appropriate levels of protection (both to personnel and property). An acceptable level of protection must be defined by the installation commander.

c. *Access Control Measures* – physical controls, operating procedures, hardware and software features used in various combinations to allow, detect, or prevent access.

d. *Requirements* – appropriate standoff distance to maintain a level of protection compatible with operational needs; passive or active barrier systems to stop the threat vehicle; barrier reliability and maintainability, safety, sabotage and malfunction protection, and cost effectiveness.

e. *Response* – potential structural damage to the vehicle barrier from blast loads produced during an explosion.

f. *Liabilities* – potential liability effects on the decision to protect assets against the effects of a terrorist act.

g. *Cost* – security expenditures based on the value of the asset to be protected and the importance of the asset to national security and readiness. For protection against vehicle bombs, the potential loss of human life generally drives the cost of security, overriding the value of the property to be protected. The decision to use vehicle barriers and provide protection against terrorist vehicle bombs is primarily motivated by protection of personnel.

2-2 **DOD REQUIREMENTS**. There are several instructions and publications within the Department of Defense that establish access control, physical security, and antiterrorism requirements for the Department of Defense installations and restricted areas.

2-2.1 **DOD 5200.8-R Physical Security Program**.

This regulation requires DOD Components to determine the necessary access control based on the requirements of a developed physical security program. Emergency planning is specified to include establishment of a system for positive identification of personnel and equipment authorized to enter and exit the installation and maintenance of adequate physical barriers that will be deployed to control access to the installation. Planning will also include increasing vigilance and access restrictions during higher force protection conditions

2-2.2 **DOD 2000.12 DOD Antiterrorism (AT) Program**.

This directive provides DOD policies for ATFP and assigns responsibilities for implementing the procedures for the DOD ATFP Program. It authorized the publication of DOD O-2000.16 as the DOD standards for ATFP and DOD O-2000.12-H DOD Antiterrorism Handbook as guidance for the DOD standards. DOD O-2000.12H defines the DOD Force Protection Condition (FPCON) System, which describes the potential threat levels and the applicable FPCON measures to be enacted for each level. It also requires Commanders to develop and implement Random Antiterrorism Measures (RAM) as an integral part of their AT Program.

2-2.3 **DOD 2000.16 DOD Antiterrorism Standards**.

This instruction and service directives require the installation or activity Commanding Officer to define the access control measures at installations. Additionally DOD 2000.16 requires Commanders at all levels to develop and implement a comprehensive Antiterrorism (AT) Program, which should define the necessary action sets, including identification and inspection procedures, at each of the potential Force Protection Condition (FPCON) levels.

2-3 **COMBATANT COMMANDER REQUIREMENTS**

Combatant Commanders issue requirements for Antiterrorism and physical security for installations within their area of responsibility. Ensure any such requirements are incorporated in addition to the requirements found in this UFC

2-4 **ADDITIONAL REFERENCES**.

Other documents, drawings, and publications that could contribute to the guidance provided in this UFC are listed below.

2-5 **REFERENCE WEBSITES**.

Copies of many of the documents referenced in this chapter can be obtained from the following websites.

a. Whole Building Design Guide web site http://www.wbdg.org/references/pa_dod.php (See Service Specific information on the right hand side of the website.)

b. United States Army Corps of Engineers (USACE), Protective Design Center, Omaha District https:/pdc.usace.army.mil/library/drawings/acp

CHAPTER 3 - DEFINITIONS

3-1 **ACRONYMS**.

The acronyms used in this UFC are defined below.

a) BDAM - Blast Damage Assessment Model

b) CCTV - Closed-Circuit Television

b) DOD - Department of Defense

c) DODISS - DOD Index of Specifications and Standards

d) DOS - Department of State

e) ERASDAC - Explosive Risk and Structural Damage Assessment Code

f) FACEDAP - Facility and Component Explosive Damage Assessment Program

g) FRF - Fragment-Retention Film

h) MIL-HDBK - Military Handbook

i) NAVFAC - Naval Facilities Engineering Command

j) NFESC - Naval Facilities Engineering Service Center

k) PDC - Protective Design Center

CHAPTER 4 - VEHICLE BARRIER DESIGN PARAMETERS

4-1 GENERAL.

Vehicles loaded with explosives can detonate as a large bomb, inflicting severe damage on critical military facilities and potentially injuring DoD personnel. Such vehicle bombs are effective terrorist tools because they facilitate the transport of large quantities of explosives to any desired location. When planning and selecting vehicle barriers to be used for facility perimeter protection, the first step is to determine the Design Basis Threat (DBT) for any given location in the facility. Table B-1 provides active vehicle barrier kinetic energy rating and vehicle penetration based on the SD-STD-02.1 Revision A test standard. The DBT may vary within and around the installation. It can be affected by guidance instructions specific to the area and service specific guidance. UFC 4-010-01 *DoD Minimum Antiterrorism Standards for Buildings*, as well as local and service specific guidance documents, should be consulted in defining Design Basis Threats at each location where barriers are required.

Several factors should be considered when setting up defense against the DBT: (1) the occupied structures in a particular area; (2) the barrier penetration capabilities of the DBT vehicle (based on the maximum vehicle velocity to the barrier location, the angle of impact, and the area around the barrier location); and (3) the structural response of and potential debris throw from the barrier, if the vehicle bomb detonates.

Both stationary and moving vehicle bombs need to be considered. To effectively prevent a moving vehicle from getting close to the intended target, the perimeter barrier must absorb the kinetic energy produced by the total weight of the vehicle bomb (vehicle weight plus the weight of explosives and any other cargo in the vehicle) and the vehicle's maximum attainable speed at the point of impact. Thus, kinetic energy is a primary factor used to establish performance requirements for moving vehicle barriers.

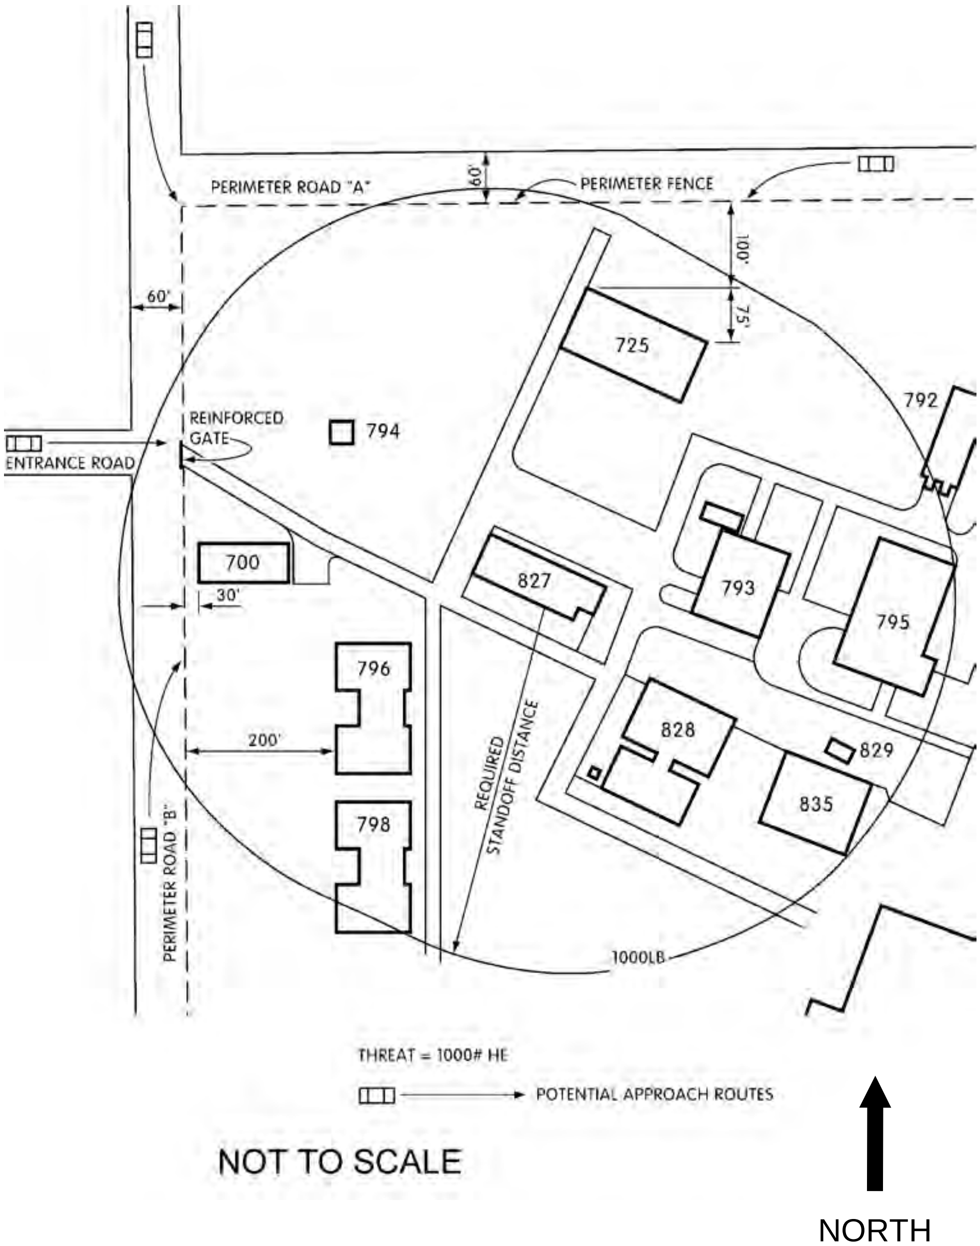
Another primary consideration for either stationary or moving vehicle bombs should be the barrier's response to the load produced by detonation of the explosives in the vehicle. The amount of debris produced and subsequent debris throw distance should also factor into the selection of appropriate barriers.

4-2 SITE SURVEY.

The process of selecting and designing a barrier system begins with determination of the Design Basis Threat (DBT) and required levels of protection. Reference UFC 4-020-01, *Security Engineering Facilities Planning Manual* and UFC 4-020-02, *Security Engineering Facilities Design Manual* for methods to determine the DBT and levels of protection. Next, preparations are made for a site survey. First, a scaled map of the protected area must be prepared from detailed plans of the facility that must include at least one block beyond the perimeter. This map should include the relative locations, major dimensions and descriptions of structures, roads, terrain and landscaping, existing security features, and property perimeter. Any features outside the perimeter (within one block or so) that could possibly be used to reduce vehicle speed, prevent access to the perimeter barrier, shield structures from damage in the event of an explosion, or affect an aggressor's progress in any other way should be shown on the site map as well. This map will permit careful analysis of distances and topographical features between the perimeter and the facility. The map identifies potential vulnerabilities. Due to the information included on any such site map, it may need to be a classified document. Figure 4-1 shows an example site map for a facility.

As shown in Figure 4-1, the individual segments of the perimeter can be attacked from a variety of paths. For example, for Building 827 with a controlled area on two sides of the perimeter, the two remaining sides (Perimeter Roads "A" and "B") are vulnerable to a vehicle attack. The Entrance Road and the extension of Perimeter Road "B" are perpendicular and lead directly to the compound boundary. Each of these roads is a potential attack path. Certain segments of the perimeter can be attacked from more than one street. In addition, for Perimeter Roads "A" and "B", running parallel to the perimeter, there are an infinite number of impact points and angles depending upon vehicle location and speed. As a result, a large number of potential impact conditions (the combination of vehicle speed and impact angle) can occur at any point along the perimeter boundary.

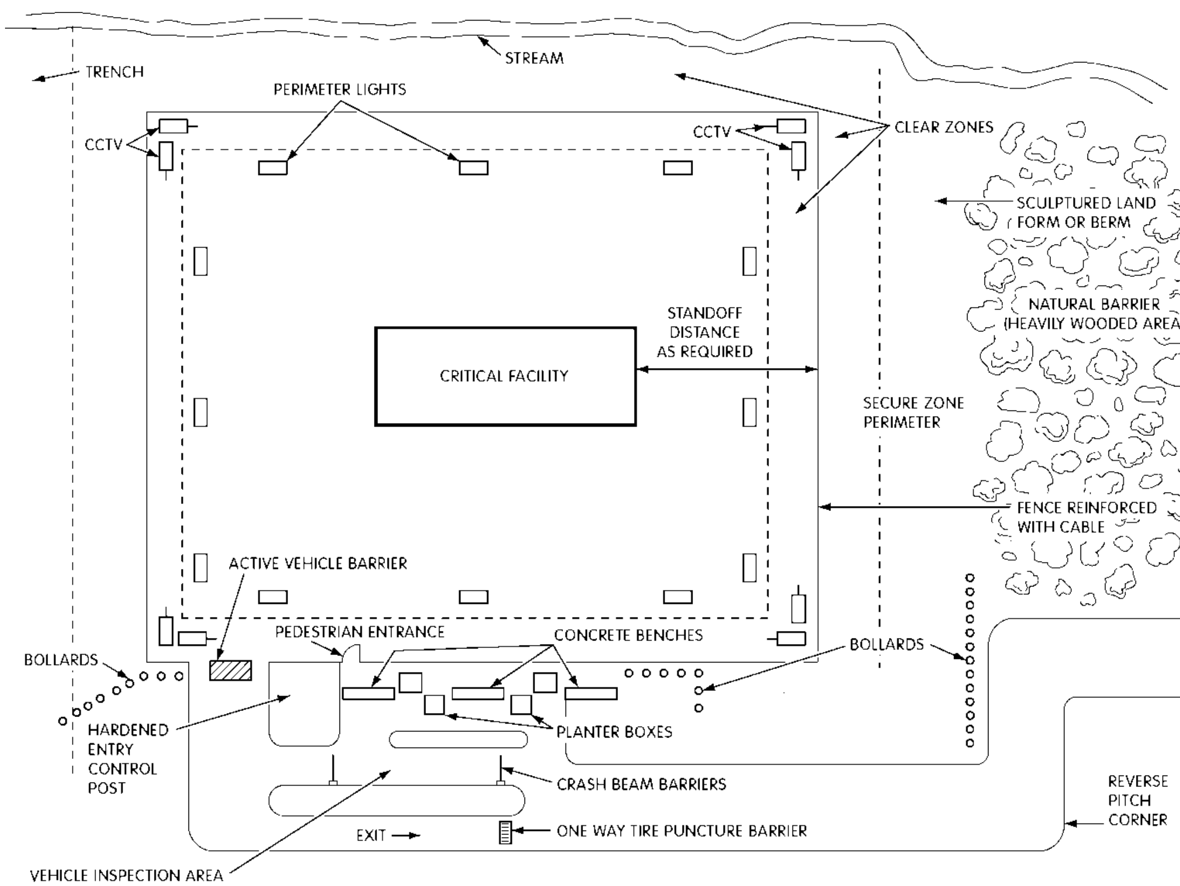
Figure 4-1 Example Site Layout



4-3 INTEGRATED PHYSICAL SECURITY SYSTEM.

Any vulnerabilities identified in the site survey should be addressed by developing an integrated physical security protection system. Design Basis Threats identified for the specific facility and current security requirements need to be considered. These threats are determined by assessment of site-specific threats or are specified by an installation. Comprehensive protection can be provided by coordinating physical barriers (such as fences, active barriers, and passive barriers) with other security components and options. For example, perimeter sensors, lights, and closed circuit television can be used to detect vehicles attempting to covertly penetrate the perimeter. Sallyports can be used to detect bombs hidden in vehicles entering a facility. Performance of the perimeter barrier can be enhanced with strategic placement of bollards, ditches, and planters. A wide range of potential threats can be detected early using clear zones as well. All barrier requirements should be coordinated with the ECF design guidance given in UFC 4-022-01 *Security Engineering: Entry Control Facilities/Access Control Points.* Figure 4-2 illustrates some examples of integrated physical security measures.

Figure 4-2 Integrated Physical Security System



4-4 ATTAINABLE VEHICLE SPEED.

The speed of a vehicle at the point of impact on a vehicle barrier is a major parameter in determining the required performance of the barrier. The impact is calculated from the initial speed, "**v**", the acceleration rate, "**a**", and the distance, "**s**", available for acceleration between the starting point and the point of impact. Additional factors that must be considered are the general terrain, the surface condition of the path, whether or not the path is straight, curved, or banked. Information presented in Figure 4-1 through Figure 4-7 allows calculation of maximum attainable vehicle speed, or suggests strategies for modifying possible attack paths to control vehicle speed.

The impact speed along the perimeter should be calculated for all possible driving paths identified on the site survey map. The strategy for barrier system design, selection, and installation can then be developed using this data.

The methods presented in this section for determining attainable vehicle speeds assume flat roadway surfaces. Most roadways are not flat, either due to super-elevation or to typical roadway crowning and constructed transverse slopes. If a driver can use a non-flat roadway surface to his advantage in attaining a higher speed, this needs to be taken into consideration. The use of any geometrics in the selection of barriers and design of an ECF should only be provided under the guidance of an engineer experienced in roadway/transportation engineering. Otherwise, some of the assumptions for the methods in this section may be highly conservative and may lead to designs that are treacherous for vehicles traveling at normal/design speeds, for vehicles traveling during wet conditions, or for large commercial and emergency vehicles.

Consult with the AASHTO Roadside Design Guide and AASHTO Geometric Design of Highways and Streets for roadway design and road geometry/geometric requirements.

4-4.1 Attainable Vehicle Speed on a Straight Path.

The highest attainable vehicle speed results from a long, straight path between the starting point and a vehicle barrier.

a) On a Horizontal Surface. On a horizontal, straight path, the speed attainable by an accelerating vehicle depends primarily on its initial speed, "$\mathbf{v_0}$", the acceleration, "**a**", and the distance, "**s**", traveled during acceleration. The relationship among these parameters is given in Equation (1).

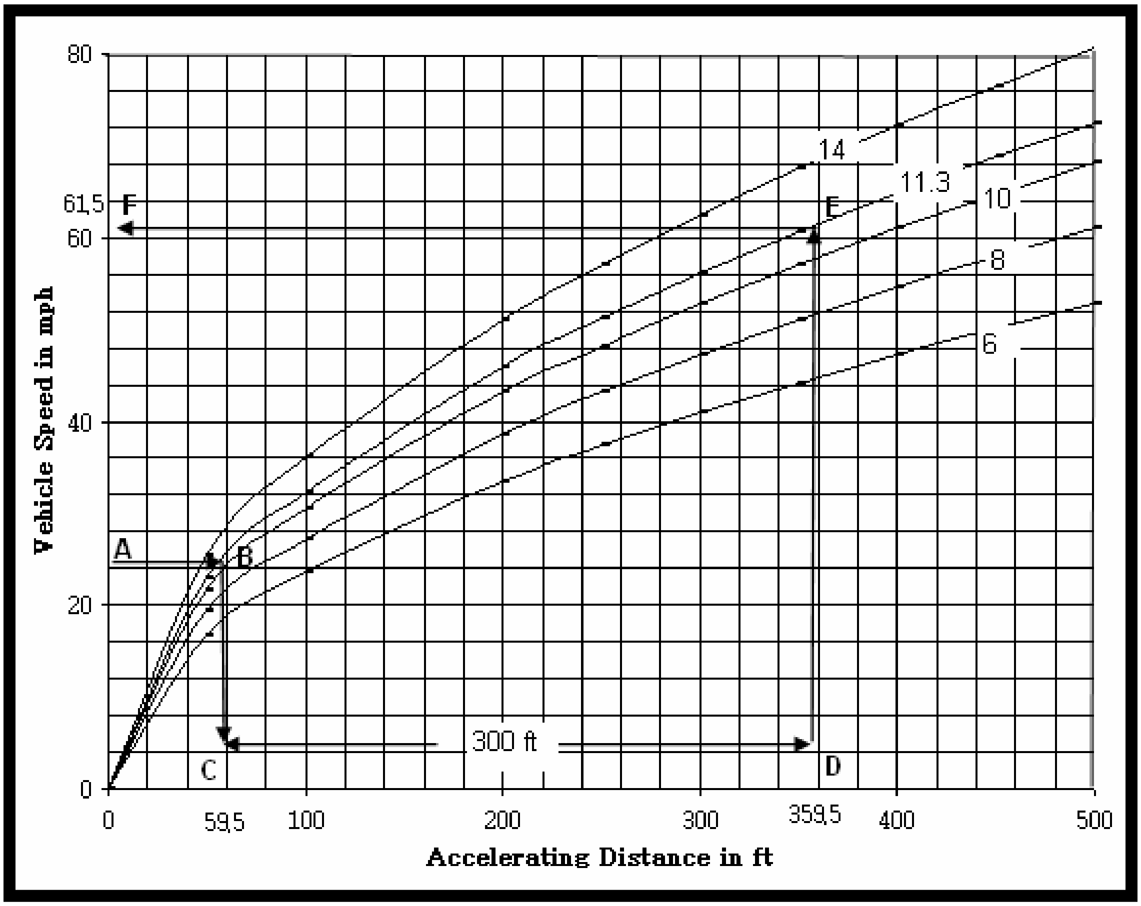
$$\mathbf{v = (v_0^2 + 2as)^{1/2}} \quad (1)$$

where:

- $\mathbf{v}$ = final vehicle speed (mph or kph)
- $\mathbf{v_0}$ = initial vehicle speed (mph or kph)
- $\mathbf{a}$ = acceleration (ft/sec^2 or m/sec^2)
- $\mathbf{s}$ = distance traveled (feet or meters)

For convenience, Equation (1) is plotted as Figure 4-3, using a conversion factor for values in ft/sec^2 and mph.

Figure 4-3 Vehicle Speed vs. Acceleration Distance



To illustrate its use, consider the case of a high performance car accelerating on a 300-ft (91.5 m), straight, horizontal path with initial speed, $\mathbf{v_0}$ = 25 mph (15.53 kph), and acceleration, **a** = 11.3 ft/sec^2 (3.4 m/sec^2). The speed at the end of the path will be determined as follows:

Locate $\mathbf{v_0}$ = 25 mph (15.53 kph) on the vertical axis (point A).

Draw a horizontal line from point A until it intersects the curve (at point B) for **a** = 11.3 feet per second^2 (3.4 m/sec^2).

Draw a vertical line down from point B until it intersects the horizontal axis (point C). This is the point from which velocity will be calculated.

Locate point D on the horizontal axis so that the distance between points C and D is the accelerating distance [300 feet (91.5 m) in this example].

Draw a vertical line up from point D until it intersects the curve (at point E) for **a** = 11.3 ft/sec^2 (3.4 m/sec^2).

Draw a horizontal line from point E until it intersects the vertical axis (point F).

The value of the speed, "**v**", at point F, 61.5 mph (98.97 kph), is the answer.

Note: If "$\mathbf{v_0}$" = 0, the graph can be used to determine velocity from a dead start.

b) On a Slope. Due to gravitational effect, to achieve the same final speed as that on a horizontal path, the required distance for acceleration on a slope will be shorter (longer) if the vehicle is traveling downhill (uphill). Let, "**s**", be the acceleration distance needed to also attain final speed, "**v**", on a horizontal path, and let, "**s'**", be the acceleration distance needed to attain, "**v**", on a sloped path. The following relationship shown in Equation (2) applies:

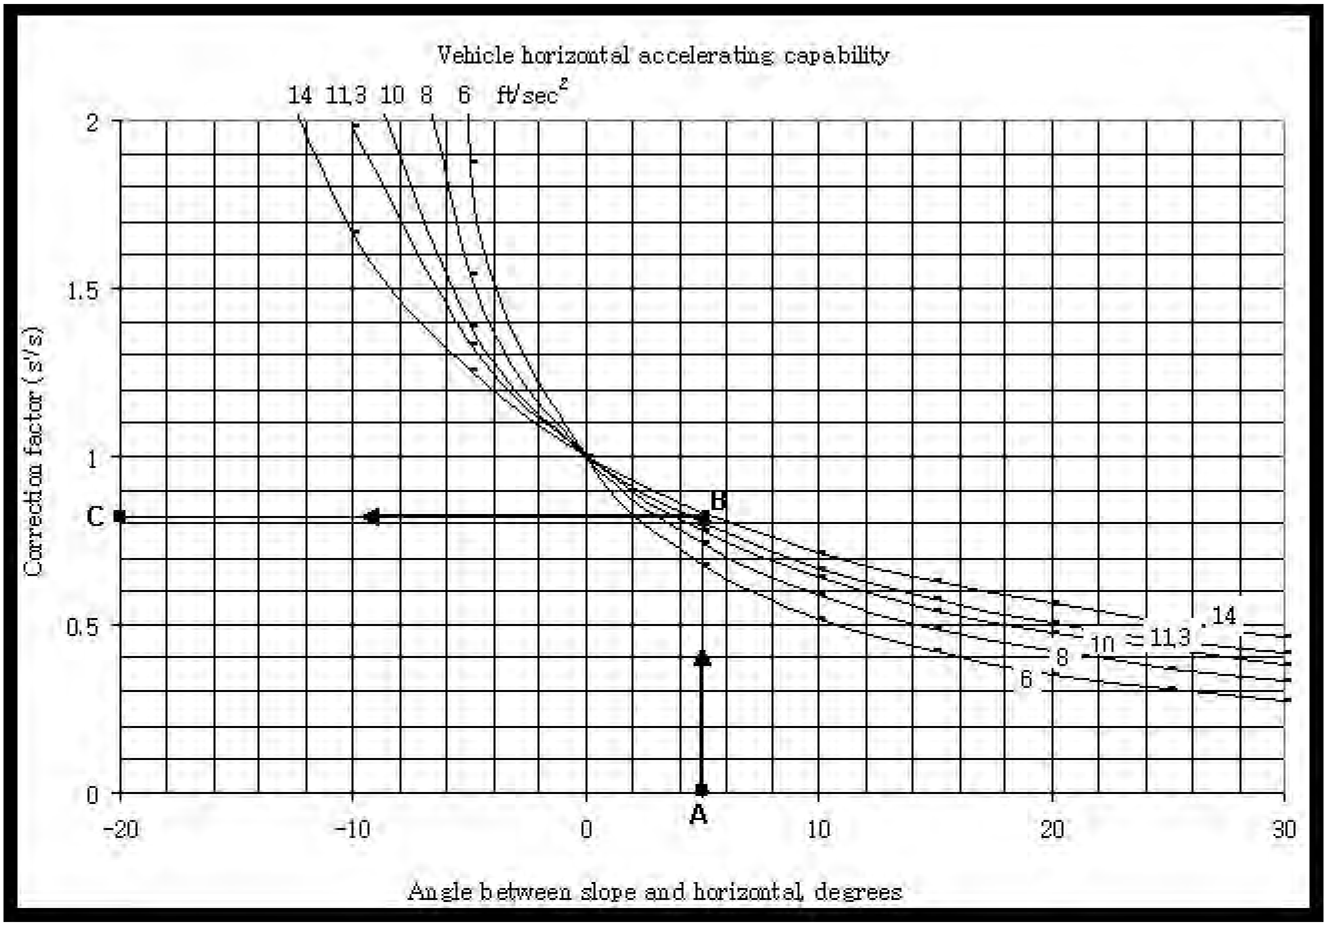
$$\mathbf{s'/s = 1/[1 + (g/a)\sin\theta]} \quad (2)$$

where:

- **s'** = acceleration distance needed to attain final speed on a sloped path
- **s** = acceleration distance needed to attain final speed on a horizontal path
- **g** = gravitational constant = 32.2 ft/sec2 (9.82 m/sec2)
- **a** = acceleration of the vehicle, ft/sec2
- θ = angle between the slope and the horizontal in degrees

This correction factor relationship is plotted as Figure 4-4.

Figure 4-4 Speed Correction Factor for Vehicles Driving on a Sloped Path



To illustrate the use of this figure, consider the example used in 4-4.1a, except the vehicle is traveling downhill on a 5-degree slope. The steps are:

Locate 5 degrees on the horizontal axis (point A).

Draw a vertical line up from point A until it intersects the curve (at point B) for **a** = 11.3 ft/sec^2 (3.4 m/sec^2).

Draw a horizontal line from point B toward the vertical axis and read off the "**s'/s**" value at the intersecting point C.

The value of **s'/s** is 0.8. Because **s' = s x (s'/s)** and **s** = 300 feet (91.5 m), therefore **s'** = 300 feet (91.5 m) x 0.8 = 240 feet (73.2 m).

This example shows that to accelerate the vehicle to the same 61.5 mph speed (98.97 kph), a 5-degree slope will help shorten the accelerating distance from 300 feet (91.5 m) to 240 feet (73.2 m). It clearly demonstrates the increased vulnerability caused by local terrain sloping down toward a protected area. Modifying the local terrain is an effective way to minimize vulnerability.

4-4.2 **Attainable Vehicle Speed on a Curved Path**.

Centrifugal force makes it difficult to drive fast on a curve unless the road surface is properly banked. The centrifugal force, "**CF**", of a vehicle moving on a curved path depends on its weight, "**w**", the radius of the curvature, "**r**", and the speed, "**v**", and **g** = gravitational constant = 32.2 ft/sec^2 (9.82 m/sec^2), as shown in Equation (3).

$$\mathbf{CF = wv^2 /(gr)} \qquad (3)$$

where:

CF = centrifugal force (lbs/kgs)
W = vehicle weight (lbs/kgs)
r = radius of curvature (feet/meters)
v = vehicle speed (mph/kph)
g = gravitational constant = 32.2 ft/sec2 (9.82 m/sec2)

When the "**CF**" is large enough, it will overcome the road friction and a vehicle will skid. The vehicle could also topple if its center of gravity is too high. Because skidding usually occurs first, only this condition will be considered here. Road friction force, "**FF**," equals the product of the vehicle weight, "**w**," and the friction coefficient, "**f**," between the tires and the road surface, as shown in Equation (4).

$$\mathbf{FF = fw} \qquad (4)$$

where:

FF = road friction force
f = friction coefficient
w = vehicle weight

NOTE: The value of friction coefficient, "f", is between 0 and 1 and is highly variable. It depends on the tire and its condition, the material and condition of the drive path, any oil or water on the drive surface, etc. On a roadway, under normal conditions, f = 0.6 is usually used. If unable to determine, use f = 1, which will provide a more conservative value.

a) On a Horizontal Surface. The skidding speed (the speed at which skidding occurs), "$\mathbf{v_S}$", is obtained by equating the centrifugal force and the road friction force, as shown in Equations (5) and (6).

$$\mathbf{fw = w\, v_S^2 /(gr)} \qquad (5)$$

where:

f = friction coefficient
w = vehicle weight
$\mathbf{v_S}$ = skidding speed
g = gravitational constant
r = radius of curvature

From which,

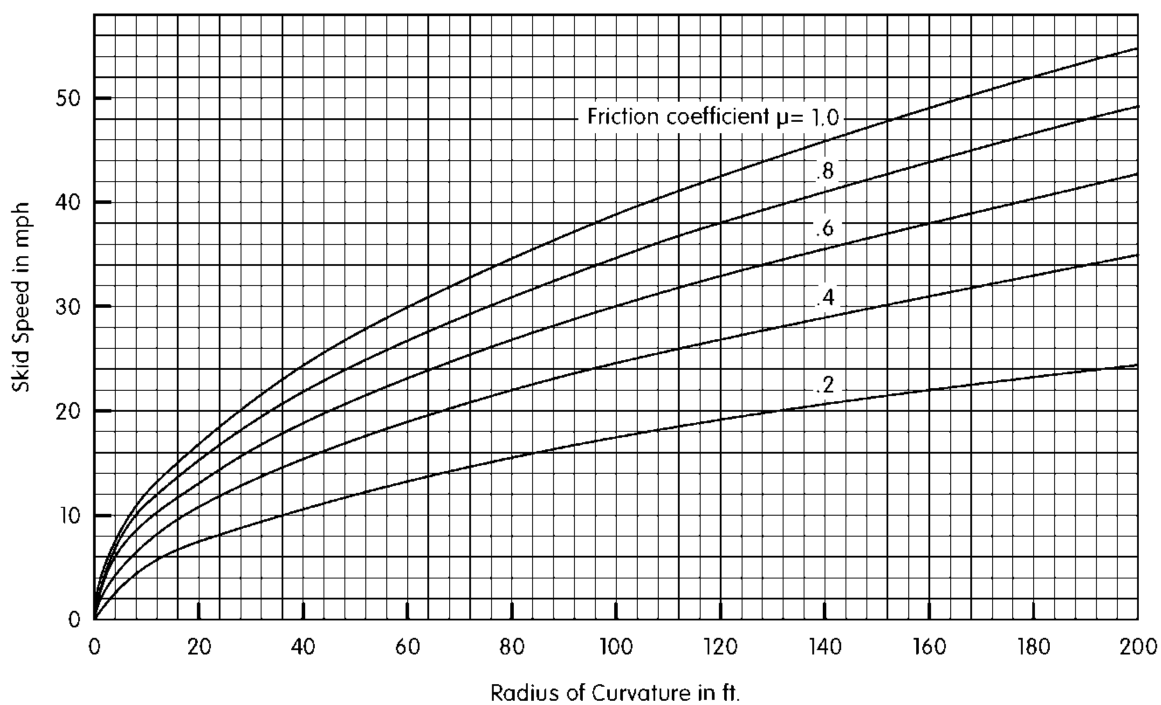
$$\mathbf{v_S} = \sqrt{fgr} \qquad (6)$$

where:

- $\mathbf{v_S}$ = skidding speed
- **f** = friction coefficient
- **g** = gravitational constant = 32.2 ft/sec^2 (9.82 m/sec^2)
- **r** = radius of curvature

Because "**v**" must be made as small as possible for the most cost-effective protection, this relationship suggests that options for the physical security planner include making the drive path slippery, with a small radius of curvature, or both. The above relationship is plotted as Figure 4-5, using "**f**" as a parameter using a conversion factor for values in ft and mph.

Figure 4-5 Skid Speed vs. Radius of Curvature



Using this figure, with a chosen value of "**f**" (see previous Note) and the tolerable vehicle impact speed of the selected barrier, a curved path can be designed to cause any vehicle driving above that velocity to skid.

b) On a Slope. Unlike a straight downhill path (see Paragraph 4-4.1), a curved downhill path is actually effective in deterring vehicle attacks. This is because the extra velocity gained from traveling downhill can easily cause the vehicle to skid or topple. Therefore, if a protected area has downhill approach paths, the local terrain can be modified so that a straight driving path is impossible. Caution should be exercised when designing roads to decrease velocity. Posting speed restrictions along the path is strongly recommended to reduce the possibility of accidental skidding.

To determine the final velocity at the end of a curved path, use the length of the curved path as the acceleration distance in Figure 4-3 and as the acceleration distance needed to attain final speed on a horizontal path (s) in Figure 4-3. Figure 4-4 can then be used to determine the velocity at which the vehicle will skid.

4-4.3 **Attack Routes Parallel to the Barrier**.

A reduction in energy transferred to a barrier can be accomplished by forcing a vehicle to make an abrupt (short radius) turn before impacting the barrier. Short radius turns effectively reduce vehicle speed by forcing the vehicle to slow down to avoid skidding, reducing the load transfer if the impact angle is less than 90 degrees to the barrier. Thus, the amount of energy that must be absorbed by a perimeter barrier depends on the impact angle, see Figure 4-1, perimeter roads A and B for a graphical representation of this angle of impact) and the final speed of the vehicle at impact. The load transferred to the barrier is determined by the perpendicular component of the velocity. By using Figure 4-6 and Figure 4-7, the impact angle directed toward the barrier, based on the offset distance (distance between restricting barriers, i.e., the distance between curbs or barriers that will limit the available turning radius), can be determined. These figures are based on the formulas provided in Paragraphs 4-4.2 and 4-4.3. Figure 4-6 and Figure 4-7 show the impact angle versus speed for a given offset distance for friction factors **f** = 0.5 and **f** = 0.9. The curves can be used to determine the angle of impact, "θ", knowing the values of the friction coefficient, "**f**", speed at the start of the turn, "**v**", and the offset distance available.

Once the angle of impact is determined from Figure 4-6 and Figure 4-7, the speed component perpendicular to the barrier, "**Vp**", can be calculated using Equation (7), where "**sinθ**" is the correction factor.

$$\mathbf{Vp = v \sin\theta} \qquad (7)$$

where:

Vp = speed component perpendicular to barrier
V = speed at start of turn
θ = angle of impact

Figure 4-6 Correction Factor for Vehicle Traveling Parallel to Barrier (Based on Coefficient of Friction, f = 0.5)

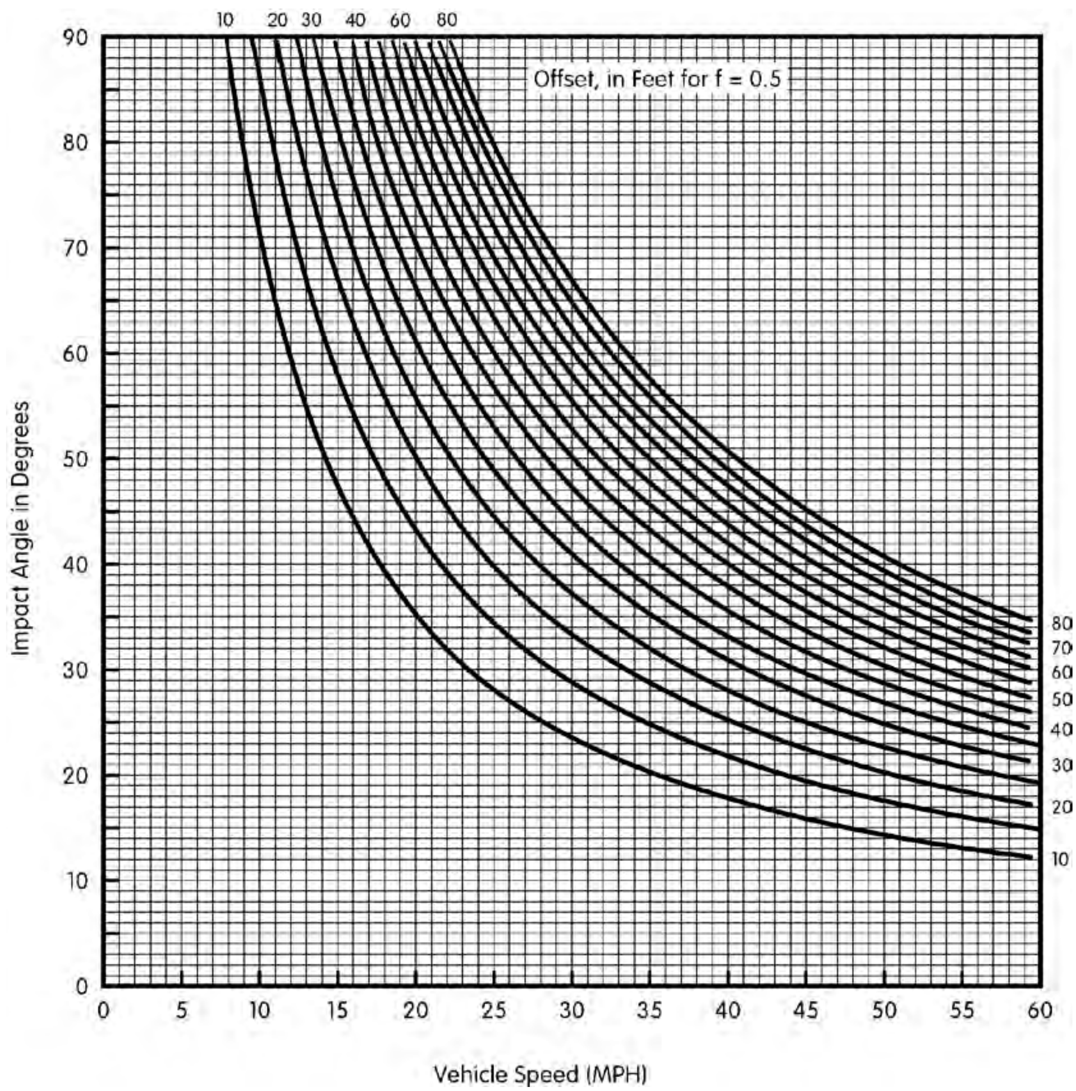


Figure 4-7 Correction Factor for Vehicle Traveling Parallel to Barrier (Based on Coefficient of Friction, f = 0.9)

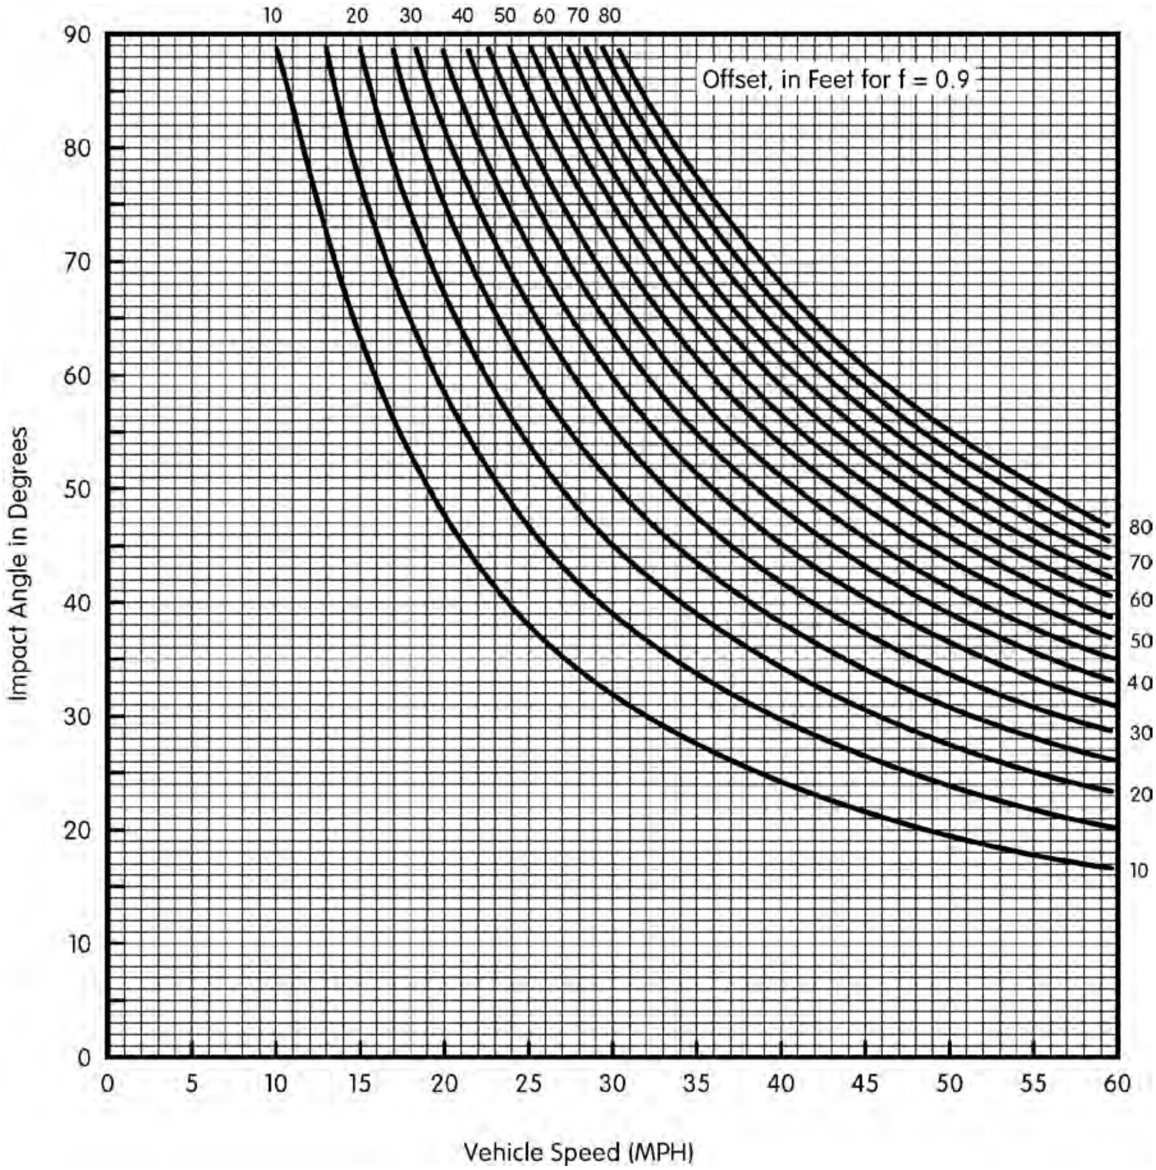

For convenience, Table 4-1 provides a correction factor for "**Vp**" based on the speed of the vehicle at the beginning of the turn, the offset distance available for negotiating the turn, and a friction coefficient **f** = 1.0 (the most conservative value). Thus, "**Vp**" is calculated by multiplying the initial speed of the vehicle by the correction factor from Table 4-1.

Table 4-1 Speed Correction Factor for a Vehicle Traveling Parallel to Barrier (Based on Friction Coefficient = 1.0)

Speed of Vehicle in mph (kph)→	20 (32)	30 (48)	40 (64)	50 (80)	60 (97)	70 (113)	80 (129)
Max. Radius of Curve @ f=1.0 ft (m)→	27 (8)	60 (18)	107 (33)	167 (51)	240 (73)	327 (100)	427 (56)

4-5 **VEHICLE KINETIC ENERGY**.

The kinetic energy of a moving vehicle is measured by its weight and speed, calculated as shown in Equation (8).

$$KE\ (ft\text{-}lbf) = 0.0334\ wv^2 \qquad (8)$$
$$KE\ (kgf\text{-}m) = 0.0039\ wv^2$$

where:

KE = kinetic energy in ft-lbs force (kgf-m)
W = vehicle total weight in lbs (kg)
V = vehicle speed in mph (kph)

A vehicle must have a certain amount of kinetic energy to penetrate perimeter security barriers. The vehicle must penetrate these barriers to inflict damage on a protected facility. Since kinetic energy is a function of vehicle weight and speed, a heavy vehicle moving slowly and a lighter vehicle moving fast could have the same kinetic energy.

Kinetic energy for 4,000-lb and 15,000-lb vehicles, traveling at various speeds, is shown in Table 4-2. Once the kinetic energy of the vehicle has been determined, active and passive barriers that are capable of stopping the vehicle can be selected from the information contained in Chapters 5 and 6.

In some cases (with dead men, bollards, cabled concrete tee walls or chained vehicles etc.) some of these being unique expeditionary uses based on available material there may be a requirement for the design of system of barriers other than those listed herein. Those cases may require the computation of an impact force to design that system. An impact force is a high force or shock applied over a short time period. Since force is the product of mass times acceleration for a mass *m* accelerating at an *acceleration*, then assuming an ideal system, we can set the impact force as, mass times the difference in velocity for a time interval *dt*. (F= mXdv/dt)

For example, a car that weighs 1 kg moving at 500 m/s and that hits a 'perfect' steel barrier where it uniformly decelerates from 500 m/s to 0 m/s in .02 seconds, has an approximate impact force of 25000 N. Thus, a body, which decelerates more quickly, has a greater effective impact force than one that decelerates more slowly.

Table 4-2 Kinetic Energy Developed by Vehicle, ft-lbf (kgf-m) x 1,000

	Speed of Vehicle in mph (kph)

CHAPTER 5 - VEHICLE BARRIER SELECTION, DESIGN, AND INSTALLATION

5-1 **VEHICLE BARRIER TYPES**.

Vehicle barriers are categorized as either active or passive. Active and passive barriers can be fixed or movable, depending on how they are made, operated, or used. Some commercial barriers are dual-classified, when they meet the requirements for both categories (e.g., fixed-active, portable-passive, etc.) There is no industry-wide standard terminology for vehicle barriers. For this UFC, the following definitions will be used.

5-1.1 **Active Barrier Systems**.

An active barrier requires some action, either by personnel, equipment, or both, to permit or deny entry of a vehicle. The system has some form of moving parts. Active barrier systems include barricades, bollards, beams, gates, and active tire shredders.

5-1.2 **Passive Barrier Systems**.

A passive barrier has no moving parts. Passive barrier effectiveness relies on its ability to absorb energy and transmit the energy to its foundation. Highway medians (Jersey), bollards or posts, tires, guardrails, ditches, and reinforced fences are examples of passive barriers.

5-1.3 **Fixed Barrier Systems**.

A fixed barrier is permanently installed or requires heavy equipment to move or dismantle. Examples include hydraulically-operated rotation or retracting systems, pits, and concrete or steel barriers. Fixed barrier systems can be either active or passive.

5-1.4 **Portable/Movable Barrier Systems**.

A portable/movable barrier system can be relocated from place to place. It may require heavy equipment to assist in the transfer. Hydraulically operated, sled-type, barricade systems, highway medians, or filled 55-gallon drums that are not set in foundations are typical examples. Portable/movable barrier systems can be either active or passive.

5-2 **DESIGN CONSIDERATIONS**.

In addition to the calculation of the kinetic energy of a threat vehicle described in Chapter 4 many factors must be considered before selecting an appropriate barrier system. The Security Engineering: Entry Control Facilities/Access Control Points UFC 4-022-01 is a required document for planning vehicle barrier design and installation. An outline is presented below to serve as a checklist of key information that is important to the facility planner, security professional, designer, user, and maintainer in the design of barrier systems. Some of these issues are discussed in more detail following the outline.

- Design Basis Threat (s)
    - The Attack Vehicle(s)
        - Type
        - Weight
        - Maximum Velocity
        - Contents
        - Calculated Kinetic Energy
    - Points of Attack
    - Path of Attack(s)
    - Direction of Attack(s)
    - Type of Attack
        - Single
        - Multiple Vehicles
    - Country in Which Installation Resides

- Allowable Penetration Beyond the line of Barrier(s)

- Sufficient Standoff Distance Between Planned Barrier and Protected Structure

- Existing or Desired Traffic Patterns
    - Levels of Authorized Traffic
        - Peak Levels
        - Average Levels per Day
    - Types of Traffic
        - Staff
        - Freight
        - Visitors
    - Number of Available Traffic Lanes
        - One-Way Only
        - Reversible
        - Width and Separation
    - Minimization of Access Points

- Vehicle Barrier Operating Protocol(s).
    - Deploy and Inspect
        - Maximum Throughput Rate
            - Per Day
            - Per Hour (peak)
    - Threat Dependent, Local / Remote Option
    - Sally Port Interlock with other Visual Barriers

Automatic (Emergency Deployment)
    Deployment Signal Source
        Manual
        Velocity Sensors
        Direction Sensors
        Other
    Minimum Speed of Deployment
Automatic (Normal Authorized Traffic) Vehicle Identification Means
Parade
Lock down
Free Flow

- Site (Civil Engineering)
  - Roadway Layout
    - Number of Lanes
    - Width
    - Flat / Sloping/ Crowned
    - Islands, etc.
    - Lane Separator(s)
    - Boundary / Passive Barriers
  - Approaching or Crossroad Locations
  - Sub Surface Conditions
  - Berms
  - Landscaping
  - Buried Utilities
  - Drainage
  - Frost Line
  - Water Table Height

- Site (Facility Engineering)
  - Power Distribution Points
  - Communication Lines

    - Local
    - Existing Network Type
    - Required Network Type (Bus, Ring, Multiple Rings, Mesh, or Combination)
  - Drainage
  - Utility Cabinets/ Equipment Lockers
  - Lighting
  - Traffic Signals/ Controls
  - Buried Vehicle Sensors

- Site (General)
  - Environmental

        High/ Low Temperatures
        Rain Fall
        Snow
        Frost Line
        Other
    Power Sources
        Location
        Type
            Local
            Post-Emergency Backup
        Voltage/ Phase/ Frequency

- Barrier Selection
    DOS / DoD Crash Rating

    Note:

    Both the U. S. Department of State and the U. S. Department of Defense rate barriers based on full scale crash tests conducted by independent test laboratories or government-approved facilities. See United States Army Corps of Engineers (USACE) Protective Design Center website for latest DoS and DoD certified barriers: https://pdc.usace.army.mil/library/BarrierCertification/

    The 'K' in a rating refers to the Kinetic Energy (K.E.) of the test vehicle at the moment of impact.

    A rating of K12, for example, indicates K.E. of approximately 1,200,000 ft-lb (165,960 kg-m) of energy (15,000 lb @ 50 mph [6,818 kg @ 80 kph]). A rating of K8, 800,000 ft-lb (110,640 kg-m) of energy (15,000 lb @ 40 mph [6,818 kg @ 64 kph]) and K4, 400,000 ft-lb (55,320 kg-m) of energy, (15,000 lb @ 30 mph [6,818 kg @ 48 kph]).

    The 'L' rating refers to the penetration of the vehicle beyond the front line of the barrier. A rating of 'L3' indicates the truck penetrated less than 3.0 feet (0.9 m). A rating of 'L2' means penetration of less than 20.0 feet (6 m). And 'L1' means the penetration was less than 50.0 feet (15 m).

    Active or Passive
    Temporary or Permanent
    Style of Barrier(s)
        Wedge, Plate type (Phalanx) (In ground / surface / shallow mount)
        Bollard
        Rolling Gate

        - Drop Arm
        - Transportable
    - Required Aesthetics, if any
    - Flush Mount Barriers to Road Surface
    - Width of Lane(s) to be Protected
    - Number of Lanes
    - Barriers to be Operated
        - Independently
        - Sets
        - Sally Port(s)
    - Speed of Operation
        - Normal
        - Emergency
    - Number of Operating Cycles per Barrier
        - Per Day
        - Per Hour (peak)

        - Automatic Sensors
        - Master(s) / Slave Panels(s)
        - Deploy Barriers/Speed
    - Lock Out
        - Slave Panels
        - Sub Masters
        - Automatic Entrance Controls
    - Deactivate (EFO)
        - Signal Source
            - Local Panel Authority
                - Local Guard
                - Supervisor
                    - Key Switch
                    - PIN
            - Master Panel Authority / Level

Some of these design and operating considerations, as well as other key issues, are discussed in more detail in the following sections.

5-2.1 **Fencing**.

Fences should not be considered as protection against a moving vehicle attack. Most fences can be easily penetrated by a moving vehicle and will resist impact only if reinforcement is added. Fences are primarily used to:

a. Provide a legal boundary by defining the outermost limit of a facility

b. Assist in controlling and screening authorized vehicle entries into a secured area by deterring overt entry elsewhere along the boundary

c. Support detection, assessment, and other security functions by providing a "clear zone" for installing lighting, intrusion detection equipment and CCTV

d. Deter "casual" intruders from penetrating into a secured area by presenting a barrier that requires an overt action to penetrate

e. Cause an intruder to make an overt action that will demonstrate intent

f. Briefly delay penetration into a secured area or facility, thereby increasing the possibility of detection

In the field of security, perimeter barriers provide the first line of defense for a facility. The true value of a perimeter security fence comes in its association with other components of a security system. When perimeter security is required, the security fence forms the basic building block for the rest of the system. UFC 4-022-03, *Security Engineering: Fences, Gates and Guard Facilities* should be consulted for details on the use of fencing in barrier systems.

5-2.2 **Location**.

Active vehicle barriers can be located at facility entrances, enclave entry points (gates), or selected interior locations (e.g., entrances to restricted areas). Exact locations may vary among installations; however, in each case, the barrier should be located as far from the critical structure as practical to minimize damage due to possible explosion. Also, locate support equipment (e.g., hydraulic power, generator, batteries, etc.) on the secure side and away from guard posts to lower the threat of sabotage and injury to security personnel. Passive barriers can be used at entry points, if traffic flow is restricted or sporadic (i.e., gates that are rarely used). Passive barriers are normally used for perimeter protection. For more information regarding the location of vehicle barriers, consult UFC 4-022-01, *Security Engineering: Entry Control Facilities/Access Control Points.*

5-2.3 **Aesthetics**.

The overall appearance of a vehicle barrier plays an important role in its selection and acceptance. Many barriers are now made to blend in with the environment and be aesthetically pleasing, minimizing a “fortress look”.

5-2.4 **Safety**.

An active vehicle barrier system is capable of inflicting serious injury. Even when used for its intended purpose, it can kill or seriously injure individuals when activated inadvertently, either by operator error or equipment malfunction. Warning signs, lights, bells, and bright colors should be used to mark the presence of a barrier and make it visible to oncoming traffic. These safety features must always be provided to ensure personnel safety. The following issues should be addressed to manufacturers and users to identify potential safety issues affecting the selection of an active barrier system:

a. Backup power;

b. Emergency cutoff switch;

c. Adequate lighting;

d. Installation of safety options, such as alarms, strobes (or rotating beacons), and safety interlock detectors to prevent the barrier from being accidentally raised in front of or under an authorized vehicle;

e. Army exception – Installation of Traffic Safety Schemes; i.e., Vehicle Presence Detection, Vehicle Platooning, etc., as outlined in the "Standard Definitive Designs; Access Control Points for U.S. Army Installations".

Once installed, vehicle barriers should be well marked and pedestrian traffic channeled away from the barrier system. For high-flow conditions, vehicle barriers are normally open (allowing vehicles to pass) and used only when a threat has been detected. In this case, the barrier must be located far enough from the guard post to allow time to activate and close the barrier before the threat vehicle can reach it. For low-flow conditions, or where threat conditions are high, barriers are normally closed (stopping vehicle flow) and lowered only after authorization has been approved.

5-2.5 **Security**.

Vehicle barriers must be ready to function when needed. A potential for sabotage exists when barriers are left unattended or are located in remote or unsecured areas. For these installation conditions, tamper switches should be installed on all vehicle barrier access doors to controllers, emergency operation controls and hydraulic systems. Tamper switches should be connected directly to a central alarm station so that security of the barrier system can be monitored on a continuous basis. Provide tamper resistant screws at all controls and junction boxes.

5-2.6 **Reliability**.

Many barrier systems have been in production long enough to develop an operations history under a variety of installation conditions. Reliability data from manufacturers show less than a three-percent failure rate when these barriers are properly maintained. Some systems have been placed in environments not known to the manufacturer, while others have developed problems not anticipated by either the manufacturer or user. Most manufacturers will help resolve problems that arise in their systems. Backup generators or manual override provisions are needed to ensure continued operation of active vehicle barriers during power failure or equipment malfunction. Spare parts and supplies should also be on hand to ensure that barriers are quickly returned to full operation. If a high cycle rate is anticipated, or the environmental impact from hydraulic fluid contamination is a concern, the selection of a pneumatic operating system is recommended. Operate barrier system at least once every 24 hours to assure performance for security operations. Perform this operation at low traffic period or before opening to traffic. Maintain log of this operation.

5-2.7 **Maintainability**.

Many manufacturers provide wiring and hydraulic diagrams, maintenance schedules, and maintenance procedures for their systems. They should also have spare parts available to keep barriers in continuous operation. The manufacturer should provide barrier maintenance support in the form of training, operation manuals, and maintenance manuals. Maintenance contracts are available from most manufacturers and are recommended to ensure proper maintenance of the barrier and assurance that the barrier will function as intended. Reliability and maintainability data are available from most manufacturers. Yearly maintenance contracts are usually available from the manufacturer and should be included in the planning process and budgeted. Maintenance contracts should include inspection, adjustment, cleaning, pressure checks on hydraulic systems, and replacement of worn parts.

5-2.8 **Cost**.

Traffic in restricted or sensitive areas should be minimized and the number of access control points limited. Reducing traffic flow and the number of control points will increase security and lower the overall cost of the system. Installation and operational costs are a significant part of the overall cost of a barrier system and must be addressed during the barrier selection process. Complexity and lack of standardized components can result in high costs for maintenance and create long, costly downtime periods. Reliability, availability, and maintainability requirements on the system also affect costs. Annual maintenance needs to be included in the cost of the system.

5-2.9 **Barrier Operations**.

A barrier must be capable of operating continuously and with minimal maintenance and downtime to properly satisfy security requirements. System failure modes must be evaluated to ensure that the barrier will fail in a predetermined position (open or closed) based on security and operational considerations. Selecting a normally open (allowing access) or closed (preventing access) option should be evaluated based on traffic flow conditions at the site (either existing or expected) and the overall site security plan. Emergency operation systems (backup generators or manual override systems) should be in place to operate the barrier in case of breakdowns or power failure. Security personnel should be involved in the decision to deploy and use a vehicle barrier system. If a normally open (allows traffic through) operation is selected, there must be sufficient distance between the guard and the vehicle barrier to allow for guard reaction time to activate the barrier, barrier deployment time, and time required for selected safety regimes. Certain barriers use locking pins (most notably crash beam type barriers) to lock down barrier. There have been incidents when controls were activated to raise arm with locking pins inserted causing damage to beam portion of barrier. Determine if pin is required for full performance of barrier and inquire of manufacturer if a sensor system is available that detects presence of pin. Ensure training of personnel to verify pin status prior to operation of crash beam barriers.

5-2.10 **Unobstructed Space**.

Barriers installed in inner and outer security unobstructed space must be designed so they will not provide a protective shield or hiding place. Tall, continuous barriers, such as planters, Jersey Barriers, guardrails, and other similar passive vehicle barriers can be a violation of mandated requirements, if installed in a designated unobstructed space. Placement of any barriers near or within this unobstructed space must be coordinated with the activity security officer.

5-2.11 **Environment**.

The environment must be considered during the selection process. Hinges, hydraulics, or surfaces with critical tolerances may require heaters to resist freezing temperatures and ice buildup. They may also require protection from excessive heat, dirt, humidity, salt water, sand, high water table, and debris. If options for protection against environmental conditions are not available, the system may be unsuitable for a specific location. Maintenance should be increased and/or compensating options (i.e., sump pumps, heaters, hydraulic fluid coolers, etc.) selected for vehicle barriers subject to severe environmental conditions to ensure acceptable operation. In cold regions and during winter months, it is recommended to increase operation of the barrier system to cycle hydraulic fluids through lines. See Reliability paragraph above.

5-2.12 **Installation Requirements**.

The vehicle barrier selected must be compatible with the available power source and with other security equipment installed at the selected site, such as perimeter intrusion detection and CCTVs designed to detect and assess covert penetration of the perimeter. Power requirements can vary depending upon the manufacturer and location of the installation.

5-2.13 **Facility Compatibility**.

The chosen barrier system must be compatible with other security components in place at a site. For example, an active barrier system should not be installed adjacent to an unhardened, chain-link fence because the fence then becomes the weakest path. The cost and value of the active barrier as a preventive measure is then lost. Any decisions on facility compatibility should be coordinated with UFC 4-022-01, *Security Engineering: Entry Control Facilities/Access Control Points.*

5-2.14 **Operator Training**.

Most manufacturers recommend operator training for active barrier systems. Operator training prevents serious injury and legal liability, as well as equipment damage caused by improper operations. If a manufacturer does not provide a thorough program for operator training, the user should develop a checklist for normal and emergency operating procedures.

5-2.15 **Options**.

Manufacturers offer a number of optional features that can be added to the baseline systems. Some options enhance system performance, while others improve maintainability or safety. Options increase system cost and may also increase maintenance requirements. Selection of options depends on operational, safety, security, site, and environmental conditions. The manufacturers of certified DoS anti-ram vehicle barriers listed in can be contacted to determine available options for specific vehicle barrier systems. These manufacturers can provide guidance on available options and will make recommendations that will enhance barrier operations.

5-2.16 **Operational Cycle**.

The frequency of operation must be considered in the selection process. Where traffic flow is light, a manually operated or removable passive system may work well at considerable savings. However, for high-traffic conditions (especially during peak hours), an automatically controlled system designed for repeated and fast open and close operation (pneumatic or hydraulic) would be more desirable. The use of one or more barriers at an entry point can also improve throughput.

5-2.17 **Methods of Access Control**.

When selecting an active barrier, consider how vehicles will be allowed access. If a vehicle must be searched for explosives, a sally port design should be used, which will trap the vehicle between two active barriers while it is being searched.

This will prevent the vehicle from proceeding into the secured area before it has been searched and prevent escape (see Figure 4-2).

Access control can be accomplished with a staffed guard station or, remotely, using card or biometric access control devices that automatically activate the barrier (subject to random searches). The barrier can also be operated from a protected location other than the entry control point, using CCTV and remote controls. Access control systems are available as options from vehicle barrier manufacturers (see \1\manufacturer specific website for additional information/1/). Vehicle-sensing loops on the secure side of the vehicle barrier should always be included to prevent activation of the barrier until the vehicle has completely cleared the system. If card access control systems are used, procedures must be included to prevent tailgating (authorized vehicle must wait until the barrier has closed completely before proceeding).

5-2.18 **Cost Effectiveness**.

Tradeoffs on protective measures may include:

a. Locating the vehicle barrier to provide optimum separation distance

b. Slowing down vehicles approaching the barrier, using obstructions or redesign of the access route

c. Barrier open to permit access vs. closed to prevent access

d. Active vs. passive barriers

e. System-activating options: manual vs. automatic, local vs. remote, electrical vs. hydraulic

f. Safety, reliability, availability, and maintainability characteristics

5-2.19 **Liabilities**.

Possible legal issues resulting from accidents (i.e., deaths, injuries) and legal jurisdiction (i.e., state, local, foreign country) must be deliberated with the installation legal representatives when deciding to install an active vehicle barrier system.

5-3 **ADDITIONAL DESIGN CONSIDERATIONS**.

The following actions are also to be considered when selecting and installing barrier systems.

a. If the location of a vehicle barrier is in an area of high water table, consider using a surface mounted or shallow profile barrier system.

Below ground barriers can be installed if the required installation depth is above the water table. If the excavation cannot be drained, water collection could cause corrosion, and freezing weather may incapacitate the system.

b. When barriers are installed at entrance and exit gates, also consider installing passive barrier systems along the remaining accessible perimeter of the protected area.

c. Protection of individual buildings or zones within the perimeter is generally more cost-effective than extensive protection of a large facility perimeter. For example, passive barriers installed in areas where vehicles cannot reach, just to complete a perimeter barrier system, are not effective use of security funding

d. Since most types of active barriers can be easily sabotaged, consider installing active barriers only in areas where they can be under continuous observation.

e. Barriers should be used to divert traffic or prevent entry or exit. Installation of barriers immediately adjacent to guard posts is not desirable because the possibility of injury should be minimized. Consider keeping vehicle barriers as far from guard posts as possible.

f. Barriers should be installed on the exit side of an access control point, as well as the entrance.

g. Long, straight paths to a crash-resistant barrier can result in increased vehicle speed and greater kinetic energy upon possible impact. Where this cannot be avoided, installation of a passive-type barrier maze should be considered to slow the vehicle.

h. Design passive barrier systems to comply the requirements of the DEPSECDEF Memorandum, "Access for People with Disabilities" dated 31 October 2008. The memorandum updates the DoD standards for making facilities accessible to people with disabilities. The US Access Board issued an update of the accessibility guidelines which the DEPSECDEF Memorandum implements with military unique requirements specified in the memorandum attachment. The new DoD, "ABA (Architectural Barriers Act) Accessibility Standard" and the DEPSECDEF Memorandum are located at http://www.access-board.gov/ada%2daba/aba-standards-dod.cfm .

5-4 **BARRIER CAPABILITY**.

In general, vehicle-crash-resistant barriers should be considered at vehicle access points to sensitive areas and enclaves. Active and passive barriers should be tested against specific threats (vehicle weight and speed). Passive barrier only designs can be analyzed using finite element analysis or computer programs specifically developed to analyze performance of vehicle barriers. It is recommended that passive barriers be physically tested before being utilized. All active barriers concepts are required to be physically tested in accordance with DoS/ASTM standards prior to deployment. Supplemental gate and fencing reinforcements may also be needed to provide the same level of protection.

The acceptable penetration distance will vary among installations, depending upon the locations of the barriers relative to the assets to be protected. The appropriate penetration distance for a given facility should be determined by the threat and risk assessments and physical security survey results as indicated by the process outlined in UFC 4-020-01, *Security Engineering Facilities Planning Manual* and UFC 4-020-02, *Security Engineering Facilities Design Manual*. For an illustration, refer to Example 1 in Appendix \1\D/1/ of this document.

In the example, the barrier system selected as a candidate barrier must be capable of stopping the vehicle and allowing little or no penetration. Sufficient standoff distance is not available to protect Building 827 from the expected explosive-loading conditions. Possible options would include moving the barriers further away from the target, closing the perimeter roads to traffic, hardening building 827 against increased blast-loading conditions or accepting additional risk to the structure.

For static perimeter barriers, it is important to note that weight alone will not prevent penetration. As described in paragraph 6-2.2, concrete barriers used to protect against vehicle impact should be anchored to a concrete foundation, if the impact angle is expected to exceed 30 degrees.

5-5 **VEHICLE BARRIER CERTIFICATION**.

When the Department of State (DoS) published the standard SD-STD-02.01, Revision A, March 2003 “Test Method for Vehicle Crash Testing of Perimeter Barriers and Gates”, the penetration distance of a vehicle into a barrier was limited to 1 m. The DoS list of certified barriers was developed under ‘Revision A’ and all barriers allowing penetration in excess of 1 m were removed from the list. Most DoD components have sufficient standoff and can utilize barriers which allow penetration distances in excess of 1m. Due to this and other needs the requirement for a national standard for crash testing of perimeter was established.

ASTM F 2656-07 Standard Test Method for Vehicle Crash Testing of Perimeter Barriers has been published and is being adopted by both DoD and DoS for certification/approval of vehicle barriers. This standard includes more vehicle types and differing penetration depths. The ASTM test vehicles, overall test protocol, instrumentation, measurements, and report requirements are standardized to provide consistent procedures and requirements for barrier manufacturers and accredited testing facilities.

Under ASTM F 2656-07 barrier manufacturers are required to utilize an accredited independent testing laboratory. Laboratory accreditation must be done in accordance with ISO/IEC 17025. Laboratories that are not ISO/IEC 1705 accredited but whose testing protocols are accepted by a federal agency may also conduct tests for a period of one year after performing the first test using ASTM F 2656-07. However, it is unlikely that this acceptance will be extended beyond those facilities which have previously been given permission to conduct tests in accordance with the current DoS anti-ram vehicle barrier testing criteria. Without the federal agency acceptance, the testing facilities will be required to complete accreditation prior to crash testing of vehicle barriers under this ASTM.

The PDC will continue to maintain a list of approved anti-ram vehicle barriers for DoD. Currently DoS is maintaining their list as well. Barriers on either the DoS list or DoD list are approved for use on DoD projects. If a time comes when the DoS list is no longer kept the PDC will take the information from the DoS list and incorporate it into the DoD list to make it a comprehensive list of barriers for DoD application. Note that not all DoD sites have standoff suitable for barriers which allow more than 1m of penetration. The list of DoD approved anti-ram vehicle barriers and the DoS list of certified anti-ram vehicle barriers are available on the PDC web site: https://pdc.usace.army.mil/library/BarrierCertification

Any barrier that is on the current DoS-certified anti-ram vehicle barrier list may be used by DoD, as well as any barriers listed on the current DoD approved anti-ram vehicle barrier list. The DoD list includes information on permissible barrier widths as well as information on penetration of the vehicle during the impact test. Barrier systems must be installed in the ‘as certified’ condition. Only those widths contained in the DoS and DoD approved anti-ram barrier lists are considered acceptable for DoD use.

CHAPTER 6 - ACTIVE AND PASSIVE BARRIERS

6-1 ACTIVE BARRIER SYSTEMS.

Commercially available active vehicle barrier systems are presented in this section as generic representations. Inclusion of any equipment in this section does not constitute an endorsement, nor is this a complete listing of vehicle barriers that are commercially available. The equipment shown here is for illustration purposes only. Selection of a specific barrier should be based on site conditions and results of the design, selection, and installation checklist provided in Chapter 5. Results of this checklist can be used to establish cost, operational, performance, and environmental requirements. The checklist results can also be used to select the optimum active and passive barriers from those presented in this section. Users are advised to consult with manufacturers on current and more detailed information regarding products and options available. \1\ /1/ See United States Army Corps of Engineers (USACE), Protective Design Center, Omaha District (https://pdc.usace.army.mil/library/BarrierCertification for latest versions of DoS and DoD certified anti-ram vehicle barriers. Currently barriers are being tested to be in conformance with ASTM F 2656-07. DoS and DoD are beginning to accept vehicle barriers systems tested in conformance with ASTM F 2656-07.

Barrier systems used must be listed in either the Department of State (DoS) certified or Department of Defense (DoD) approved anti-ram vehicle barrier lists. Barrier widths shall be 'as certified/approved' on these lists. Alternatively, if a barrier system's width is between the widths of two listed barrier systems that are identical except for their widths, then that barrier system is also acceptable. Exceptions and acceptable widths will only be taken from the DoD anti-ram vehicle barrier list. The design and structural materials of the vehicle barrier furnished shall be the same as those used in the crash tested barrier. Crash test must have be performed and data compiled by an approved independent testing agency in accordance with either ASTM F 2656 or SD-STD-02.01. Barriers tested and certified on the previous Department of State standard, SD-STD-02.01, April 1985, and listed on the DoD approved anti-ram vehicle barrier list are also acceptable.

6-1.1 Portable Vehicle Barriers.

6-1.1.1 Description.

The portable vehicle barrier shown in Figure 6-1 is a movable, self-contained, portable roadway barrier, referred to as the vehicle surface barrier system (Example 1). It can be controlled as a manned checkpoint. Example standard equipment for this sample portable vehicle barrier is a 50-ft (15.2-m) cord attached to a control box. For unmanned control, options include either an electric card reader or keypad. The self-contained hydraulic system is located in the curb panels and sealed to prevent fluid leaks. The unit can be placed on any roadway or other flat surface (with passive barriers installed to prevent bypass). Once the electricity is connected, the system is operational. This barrier is best used for temporary installations, where high water table is a concern, or where portability is a requirement. Contact the manufacturer for current cost information. Example performance data are shown in Table 6-1 as Example 1.

A second example of a portable barrier system is depicted in Figure 6-2. This portable high security anti-terrorist vehicle crash barrier can be towed into position by a medium-sized truck. The barrier can be deployed in 15 minutes and can be operated either locally or remotely. The wheels are stored on the side, and the vehicle ramps are folded out upon deployment. Its deployment, retrieval, and operation are all hydraulic and push-button controlled. The system can be equipped with a battery-operated power unit or a hydraulic power unit operated on a locally-supplied power or full manual system, or combination. Example performance data are provided in Table 6-1 as Example 2.

Another portable barrier system (Example 3) is shown in Figure 6-3. This barrier is designed to be rapidly deployed in an emergency situation and fully operational in 15 minutes. It can be towed to a site by a truck then lowered into position using built-in jacks. The barrier can be an instant road block and can be installed in areas where foundation work cannot be safely or quickly poured. Stabilizers on the back side of the unit serve as additional reinforcement. The electro-hydraulic version of this barrier uses standard relay logic to allow control of the barrier with the supplied push-button control station. Example performance data are provided in Table 6-1 as Example 3.

A fourth example of a portable barrier system is illustrated in Figure 6-4. This maximum security vehicle arrest barrier can be relocated and deployed in less than 20 minutes upon arriving at its intended setup destination. The barrier does not require excavation and will not mark or damage the road surface. Although it is normally operated manually, it can be supplied with a hydraulic operating system. Example performance data are provided in Table 6-1 as Example 4.

6-1.1.2 **Testing**.

The vehicle surface barrier (Example 1) was tested by the Naval Facilities Engineering Command (NAVFAC), Naval Facilities Engineering Service Center (NFESC) at a vehicle barrier test bed in China Lake, California. Upon impact, the cab of a 15,200-lb (6,909-kg) truck, moving at 50.5 mph (81 kph), was crushed. The portable vehicle barrier, with the truck on top, slid 9.2 ft (2.8 m).

Both the Example 2 and Example 3 portable barrier systems have been certified by DoS as Level K4/L1 barriers. They will stop and disable a 15,000-lb (6,818-kg) truck, moving at 30 mph (48 kph). The manufacturers can provide crash test data.

The Example 4 portable barrier system has several versions. The version depicted in Figure 6-4 has been crash-certified by DoS as K12/L2. It will stop a 15,000-lb (6,818-kg) truck, traveling at 50 mph (80 kph). Specific crash test data can be obtained from the manufacturer.

Figure 6-1 Vehicle Surface Barrier (Example 1)

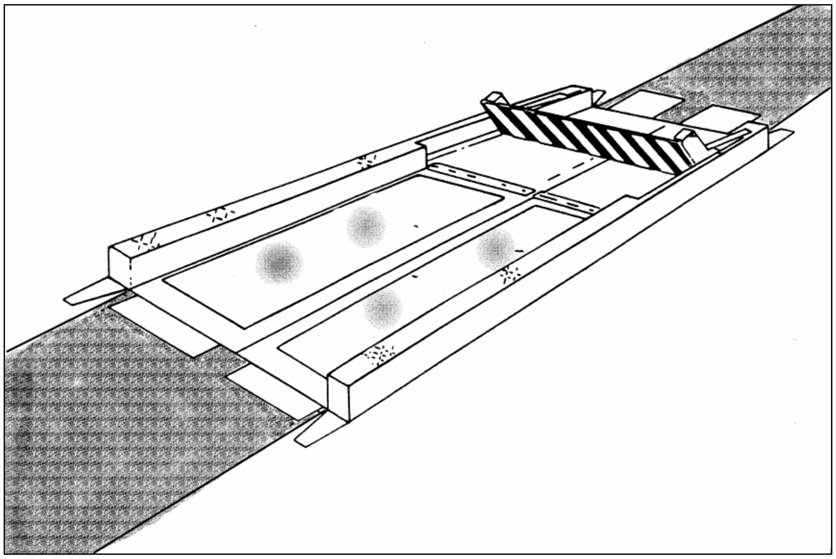

Table 6-1 Performance Data for Portable Vehicle Barriers

	Example 1*	Example 2*	Example 3*	Example 4*
Height, in. (cm)	30 (76)			31 (78.7)
Width, in. (cm)	96 (244)		144 (366)	144 (366)
Normal operating cycle (seconds)	3	10 - 15	15	3 - 5
Emergency operating cycle (seconds)	1			
Kinetic energy absorbed in impact testing, ft-lbf (kgf-m) x one million	1.2 (0.16)			1.2 (0.16)

*DoS certified

Figure 6-2 Portable High Security Anti-Terrorist Vehicle Crash Barrier (Example 2)

Figure 6-3 Portable Barrier (Example 3)

Figure 6-4 Maximum Security Vehicle Arrest Barrier (Example 4)

6-1.2 **High-Security Barricade System**.

6-1.2.1 **Description**.

The high-security barricade systems, shown in Figure 6-5 and Figure 6-6, are self-contained, hydraulically or pneumatically-operated units that, depending on the model, rise to various heights. These barriers are intended for high-speed impact conditions. Models are available for site conditions where shallow foundations are required. Performance data for an example system are shown in Table 6-2.

6-1.2.2 **Testing**.

Numerous manufacturers now produce DoS-certified high-security barriers which have been formally crash-tested\1\ /1/ The manufacturers should provide crash data for DoS-certified models. An example model was tested by Sandia National Laboratories with a 6,000-lb (2,727-kg) vehicle, traveling at 50 mph (80 kph), that penetrated the barrier 27 ft (8.2 m) and an 18,000-lb (8,182-kg) vehicle, traveling at 30 mph (48 kph), that penetrated 29 ft (8.8 m). Another model was tested by Southwest Research Institute for DoS using a 15,000-lb (6,818-kg) vehicle, traveling at 50 mph (80 kph), that penetrated less than 3 ft (0.9 m). A manufacturer tested a third model, using a 15,000-lb (6,818-kg) vehicle, traveling at 50 mph (80 kph), that penetrated less than 3 ft (0.9 m).

Figure 6-5 Example High-Security Barricade System (Wedge Type)

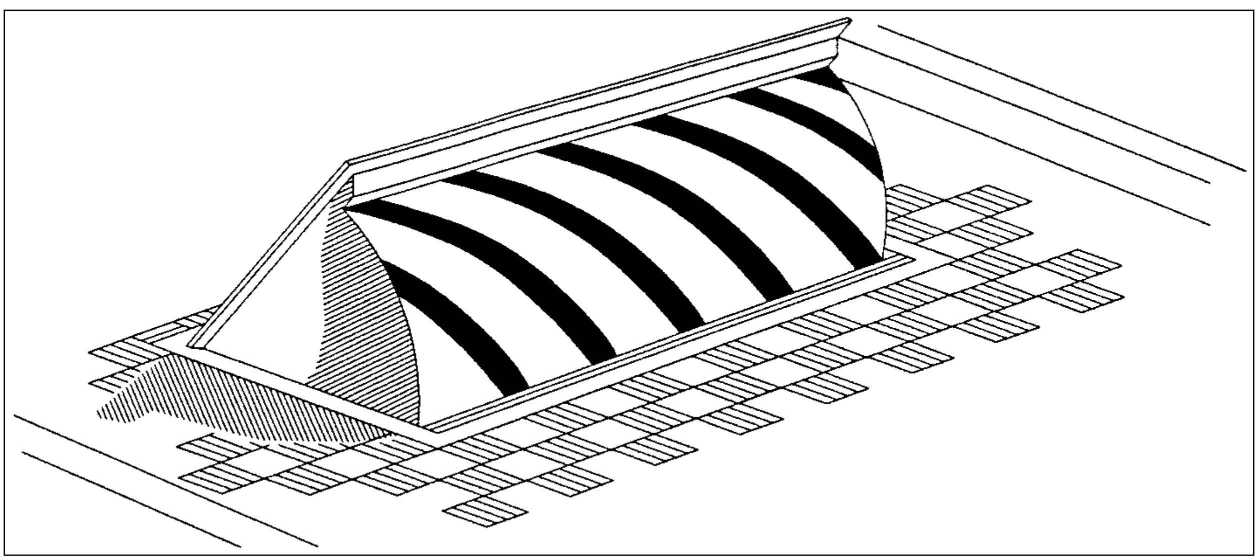

Figure 6-6 Example High-Security Barricade System (Flush-Mounted)

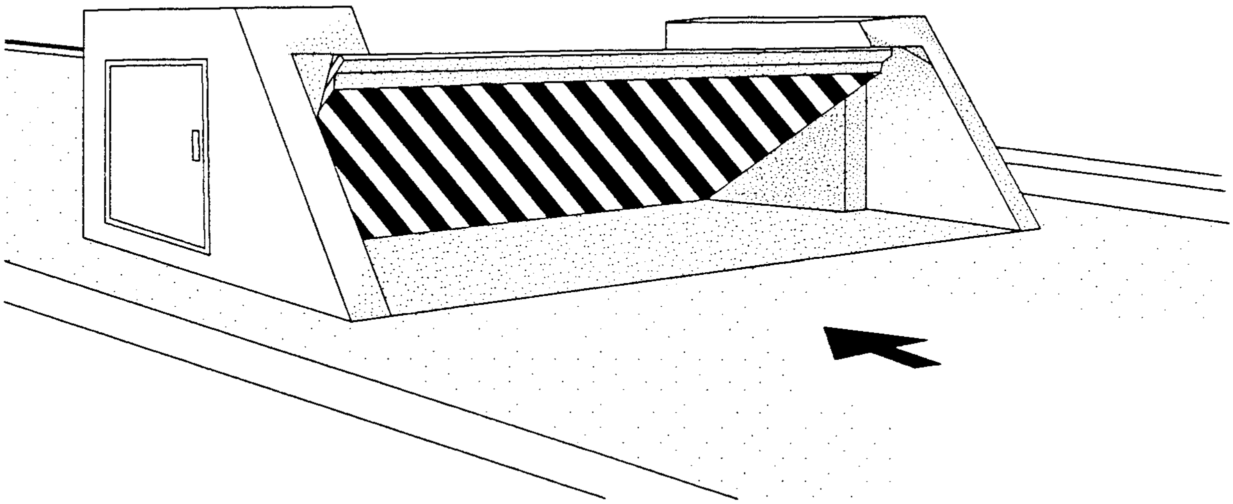

Table 6-2 Performance Data for Example High-Security Barricade System

	Example System*	Example Flush-Mounted System*
Height, in. (cm)	38 (96)	36 (91)
Width, in. (cm)	84 to 144 (213 to 366)	144 (366)
Normal operating cycle (seconds)	3 to 15	3 to 15
Emergency operating cycle (seconds)	<1.5	<1.5
Kinetic energy absorbed in impact testing, ft-lbf (kgf-m) x one million	.12 (0.16)	.12 (0.16)
Kinetic energy rating by engineering analysis, ft-lbf (kgf-m) x one million (destruction of vehicle with some damage to barrier)	.40 (0.55)	.32 (0.44)

*DoS certified

6-1.3 **Bollard System**.

6-1.3.1 **Description**.

Numerous manufacturers now produce DoS-certified bollard systems which have been formally crash-tested. \1\ /1/ The manufacturers should provide crash data for DoS-certified models. The example bollards shown in Figure 6-7 are 10-in (25.4-cm) diameter steel bollards that are 30 in. (0.76 m) high. They can be lifted into position either manually (60-lb (27-kg) pull) or hydraulically. The compact size and ease of operation make this system particularly well-suited as either a stand-alone or a backup to existing pedestrian gates in the single post configuration. They can also be used to secure wide entrances when the cost for installing larger systems becomes prohibitive. Flush mount top of bollard system to surrounding pavement is required.

Hydraulically-operated bollards can be operated individually or in sets, with up to 24 bollards controlled from a single hydraulic power unit. Typical performance data are shown in Table 6-3.

See paragraph 5.3 h Additional Design Considerations, for handicap accessibility requirements.

6-1.3.2 **Testing**.

Sandia National Laboratories tested an example model with a 15,180-lb (6,900-kg) vehicle at 32 mph (51 kph), penetrating the barrier 12.2 ft (3.7 m). An example model was tested by the NFESC and DoS with a 10,000-lb (4,545-kg) vehicle at 40 mph (64 kph) that failed to penetrate the barrier.

Figure 6-7 Example Bollard System

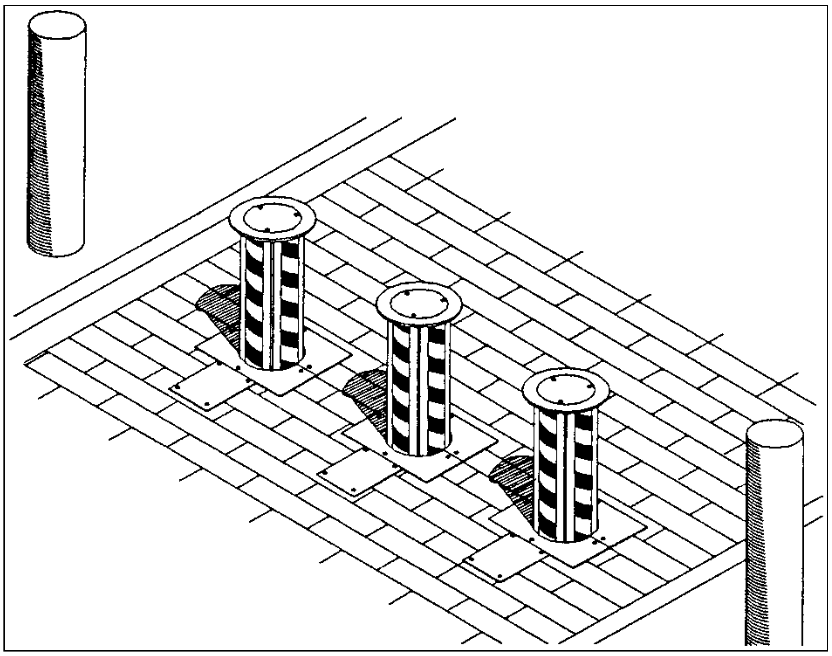

Table 6-3 Performance Data for Example Bollard System

	Example *
Height, in. (cm)	30 (76)
Width, in. (cm)	10 (25) @ 2 ft (0.6 m) on center
Normal operating cycle (seconds)	3 to 15
Emergency operating cycle (seconds)	<1.5
Kinetic energy absorbed in impact testing, ft-lbf (kgf-m) x one million	0.445 (0.06)
Kinetic energy rating by engineering analysis, ft-lbf (kgf-m) x one million (destruction of vehicle with some damage to barrier)	1.9 (0.26)

*DoS certified

6-1.4 **Crash Beam Barrier System**.

6-1.4.1 **Description**.

Numerous manufacturers now produce DoS-certified crash beam barrier systems which have been formally crash-tested\1\ /1/ The manufacturers should provide crash data for DoS-certified models. Crash beam barrier systems, such as the one shown in Figure 6-8, are cable-reinforced, manually or hydraulically-operated, bollard-mounted barriers. The beam is counterbalanced and lifts at one end to allow vehicle access. This system is frequently used for low impact conditions (when vehicle speed can be limited) and as the interior barrier (after a primary high impact barrier) for vehicle inspection areas or sally ports. Typical performance data for an example barrier are shown in Table 6-4. See “Barrier Operations” paragraph, 5.2.9, for specific operation requirements for crash beam systems.

Figure 6-8 Cable-Reinforced Crash Beams

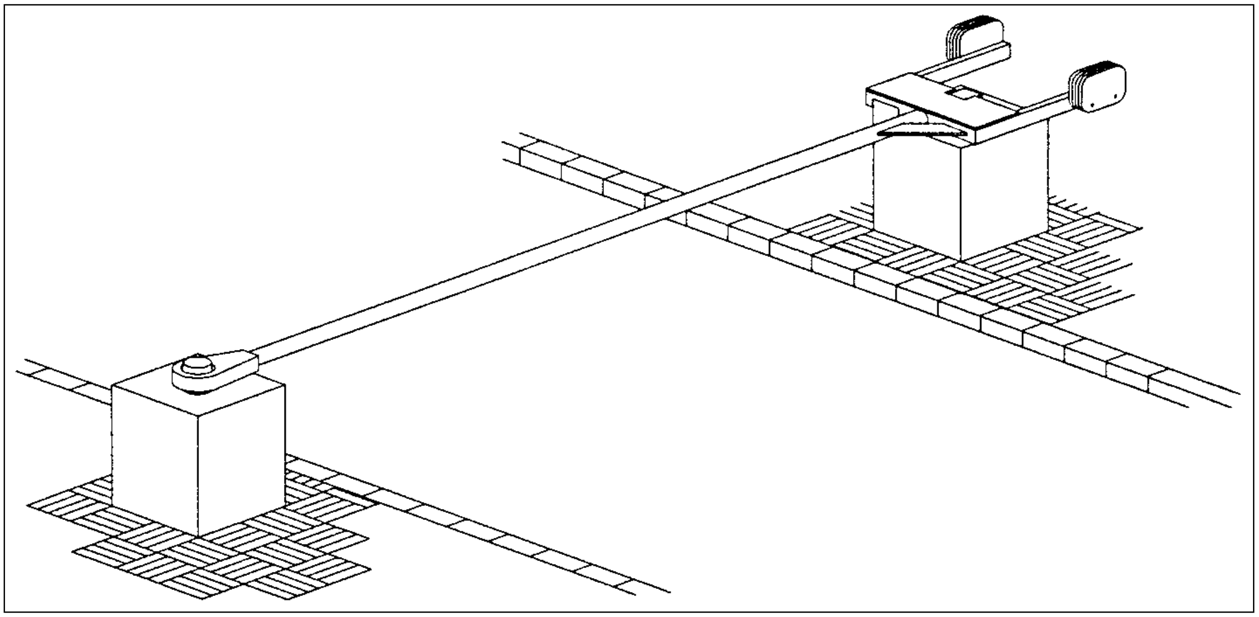

Table 6-4 Performance Data for Cable-Reinforced Crash Beams

	Example Model
Height, in. (cm)	30 (76) to 36 (91)
Length, in. (cm)	120 (305) to 240 (610) Note 1
Normal operating cycle (seconds)	8 to 15
Emergency operating cycle (seconds)	Not available
Kinetic energy absorbed in impact testing, ft-lbf (kgf-m) x one million	0.0965 (0.013)
1. Contact vendor to verify length and performance of barrier tested	

6-1.4.2 **Testing**.

The example crash beam barrier has been tested by the NFESC at the China Lake test facility. A 10,000-lb (4,545-kg) vehicle at 17 mph (27 kph) impacted the sample barrier and rebounded. There is now a K12 certified crash beam barrier system available as well.

6-1.5 **Crash Gate System**.

6-1.5.1 **Description**.

A crash gate system, such as the example system illustrated in Figure 6-9, is a sliding gate that offers pedestrian access and resistance to heavy vehicle impact. The example system is electromechanically operated with a 30 to 100 ft/min (9 to 30 m/min) sliding speed (instantly reversible). Safety infrared sensors and front edge obstacle sensors are standard features. A tested manual version of a crash gate is also available. Gate systems are normally used where aesthetics is an issue or where wide opening is required [up to 25-ft (7.6 m) clear opening]. Most systems can be used for both portable and permanent construction. Typical performance data are shown in Table 6-5.

Figure 6-9 Example Linear Crash Gate

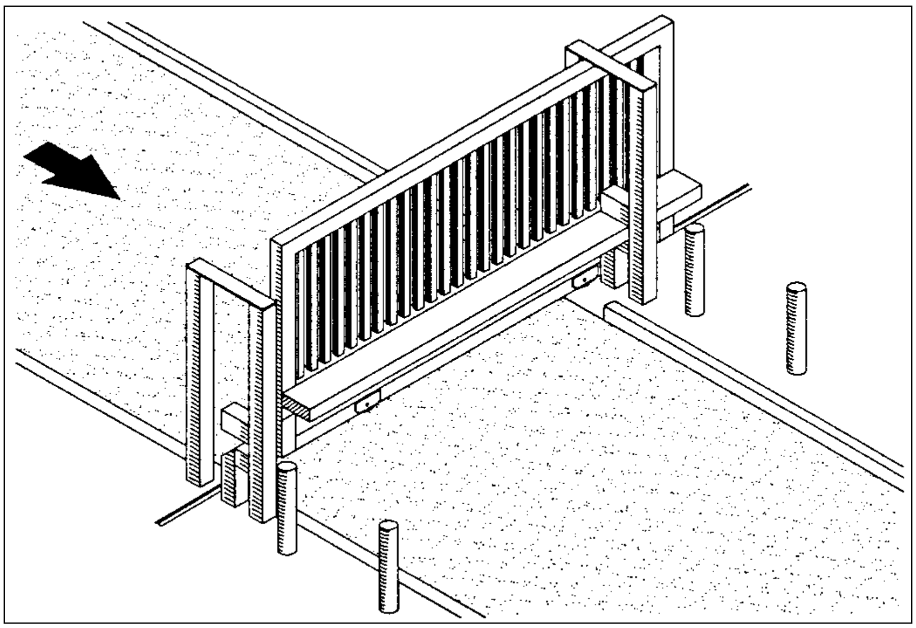

Table 6-5 Performance Data for Example Linear Crash Gate

	Example System*
Height, in. (cm)	108 (274)
Length, in. (cm)	144 (365) to 300 (762)
Normal operating cycle (Ft (m) per minute)	30 (9) to 100 (30)
Emergency operating cycle (seconds)	Not applicable
Kinetic energy absorbed in impact testing, ft-lbf (kgf-m) x one million	1.2 (0.16)

*DoS certified

6-1.5.2 **Testing**.

Three tests have been conducted on the example crash gate system by the NFESC, in conjunction with DoS, using vehicles weighing approximately 15,000 lbs (6,818 kg). At speeds of 34 and 40 mph (55 and 65 kph), the vehicle did not penetrate the sliding gate. At 55 mph (89 kph), the vehicle penetrated the sliding gate 5.5 ft (1.7 m).

6-1.6 **Ground Retractable Automobile Barrier (GRAB)**.

6-1.6.1 **Description**.

A ground retractable barrier is an attenuating device designed to span a roadway or traffic lane to bring an encroaching vehicle to a controlled stop and prevent its passage. An example system consists of a steel anchor post at each end, four hydraulic energy absorbers, and a cable/net assembly. The anchor posts are made from two sections of A36 steel pipe – a fixed 25-mm thick inner pipe with a 305-mm outer diameter and a 19-mm thick, 381-mm outer diameter outer pipe, free to rotate around the anchor post. Reusable hydraulic cylinders are set between the anchor posts and the net (two at each end). The net consists of upper and lower 19-mm diameter Extra High Strength (EHS) wire strands, with a 16-mm diameter wire rope in the center and 16-mm diameter wire rope woven up and down along the width of the net and attached to the top, middle, and bottom cables with clamps.

6-1.6.2 **Testing**.

The example GRAB was tested to the National Highway Research Program (NCHRP) Report 350 test level 2, with both the 1,800-lb (820-kg) car and the 4,400-lb (2000-kg) truck impacting at the third point of the net at a nominal speed of 45-mph (70 km/h). Both vehicles were stopped smoothly with no significant roll, pitch, or yaw. The maximum dynamic deflection of the example GRAB was 20.7 ft (6.3 m) with the car and 21.7 ft (6.6 m) with the truck.

6-1.7 **Maximum Security Barrier (MSB)**.

6-1.7.1 **Description**.

The MSB vehicle barrier (see example in Figure 6-10) is a hydraulically-operated barrier, 31 in. (79 cm) high by 14 ft (4.3 m) wide. It has a fully electronic, programmable controller that provides a range of functions. Multiple barriers can be controlled from a single hydraulic power system. Typical models can be moved without roadway rebuilding. Installation can be completed in 24 hours by bolting the barriers to the roadway. Some specific models are certified by DoS.

This type of barrier can also be an underground, flush-mounted barrier, as shown in Figure 6-11. Most MSB models are similar in construction and operation, varying only in the height of the barrier and surface foundation pad construction. Typical performance data are shown in Table 6-6.

The MSB also is available as a surface-mounted barrier with a gate arm. It has been crash-tested by the manufacturer, however they are not DoS certified. This system is frequently used for low impact conditions (when vehicle speed can be limited) and as the inside barrier (after a primary high impact barrier) for vehicle inspection areas or sally ports. Typical performance data are shown in Table 6-6.

Figure 6-10 Example MSB Vehicle Barrier (Lift Plate Barricade System)

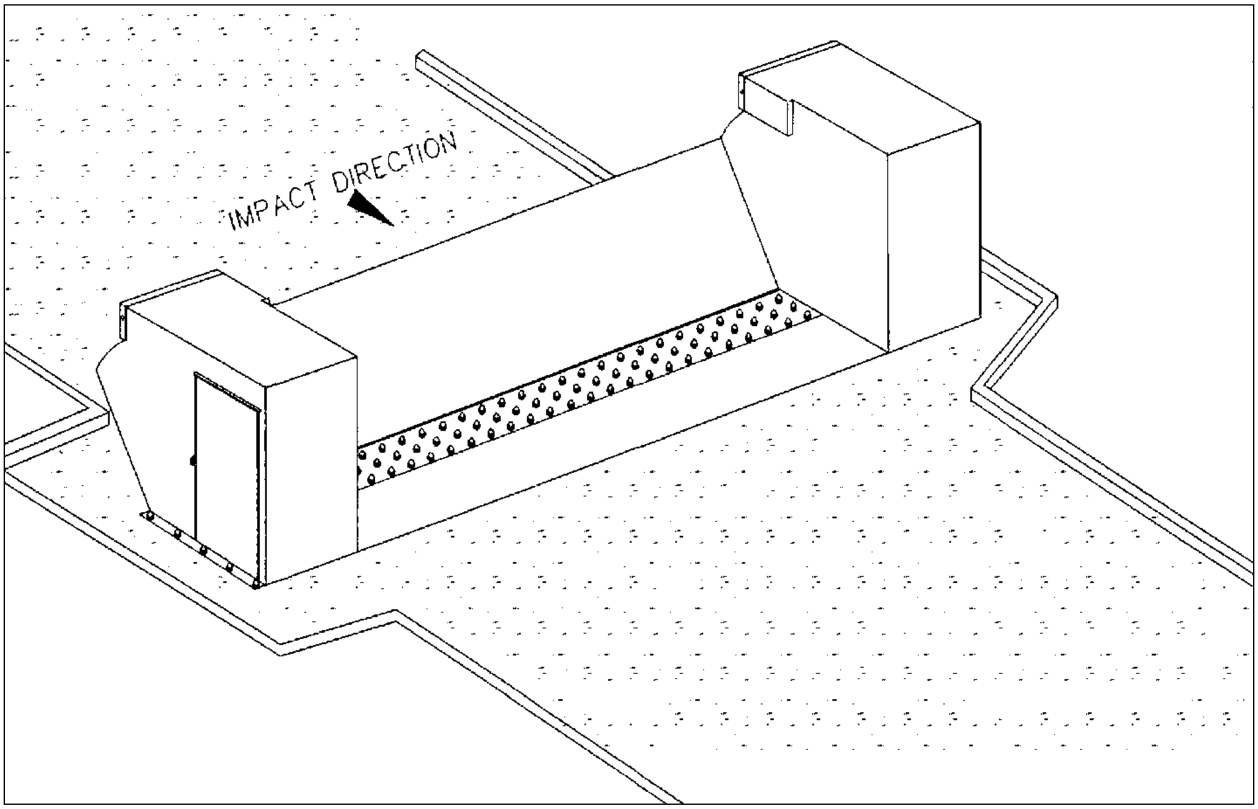

Figure 6-11 Second Example MSB Vehicle Barrier

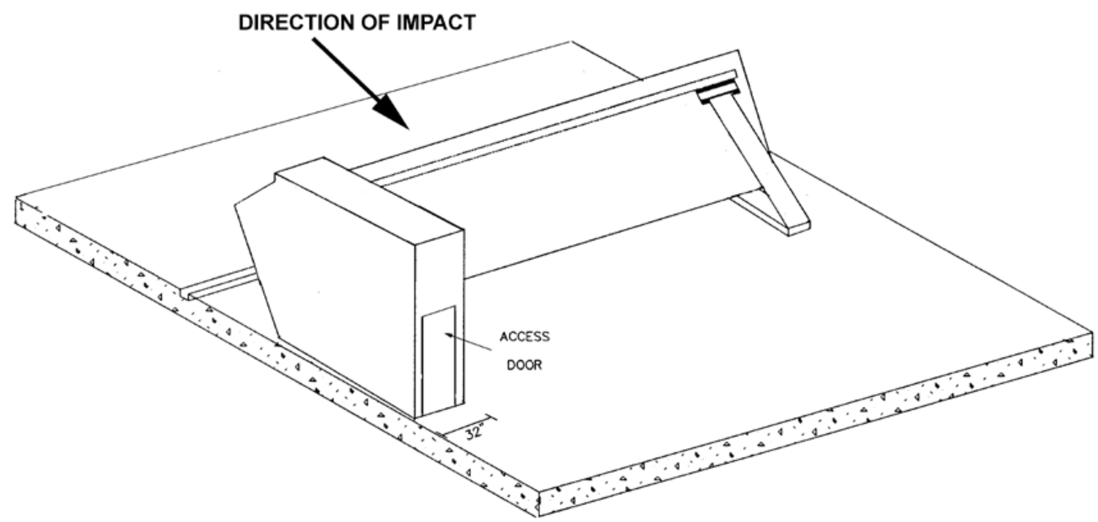

Table 6-6 Performance Data for MSB Vehicle Barriers

	Example 1*	Example 2*
Height, in. (cm)	31 (79)	33 (84)
Width, in. (cm)	168 (427) 10 ft (3m) clear	168 (427) 10 ft (3m) clear
Normal operating cycle (seconds)	3 to 5	3 to 5
Emergency operating cycle (seconds)	1	1
Kinetic energy absorbed in impact testing, ft-lbf (kgf-m) x one million	1.2 (0.16)	1.2 (0.16)

*Not DoS certified

6-1.7.2 **Testing**.

The Example 1 barrier was tested by NFESC in conjunction with DoS. A 14,980-lb (6,809-kg) vehicle at 50.3 mph (81 kph) failed to penetrate.

6-2 **PASSIVE BARRIER SYSTEMS**.

The following is a compilation of passive vehicle barrier systems used at DOD facilities. Included are generic systems that can be constructed with the aid of self-help manuals, using standard, and locally available materials. Some of the systems have not been formally tested, but should inflict substantial damage on a vehicle if impacted. A consolidated list of passive barriers, kinetic energy, and penetration data is provided in Appendix \1\ C /1/. See paragraph 5.3 h Additional Design Considerations, for handicap accessibility requirements.

6-2.1 **Concrete-Filled Bollard**.

6-2.1.1 **Description**.

Passive steel bollards can be constructed locally and are an effective means of enhancing security against vehicular bomb attacks. Approved bollards are constructed of structural steel pipe filled with concrete. The steel pipe should have a minimum outside diameter of 8-in. (20-cm), 1/2-in. (1.2-cm) wall, and be a minimum of 7-ft (2.1-m) in length. The bollards should extend 3 ft (0.9 m) above the ground level from a continuous footing with minimum width of 2 ft (0.6 m), as shown in Figure 6-12 and Figure 6-13. The bollards should be positioned 3 ft (0.9 m) ft apart on center (see example layout in Figure 6-13 and Figure 6-14. Bollards should never be placed on the un-secure side (outside) of a fence where they can be used as a climbing aid.

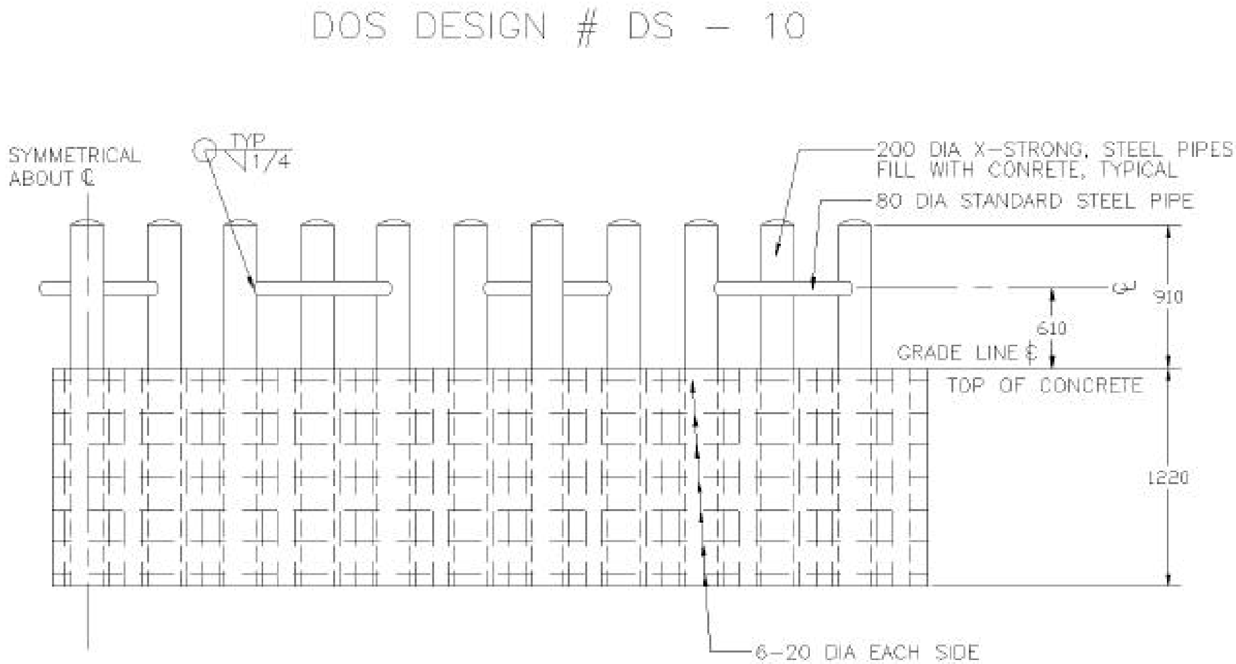

Figure 6-14 Bollard Design Example Layout in Plan View

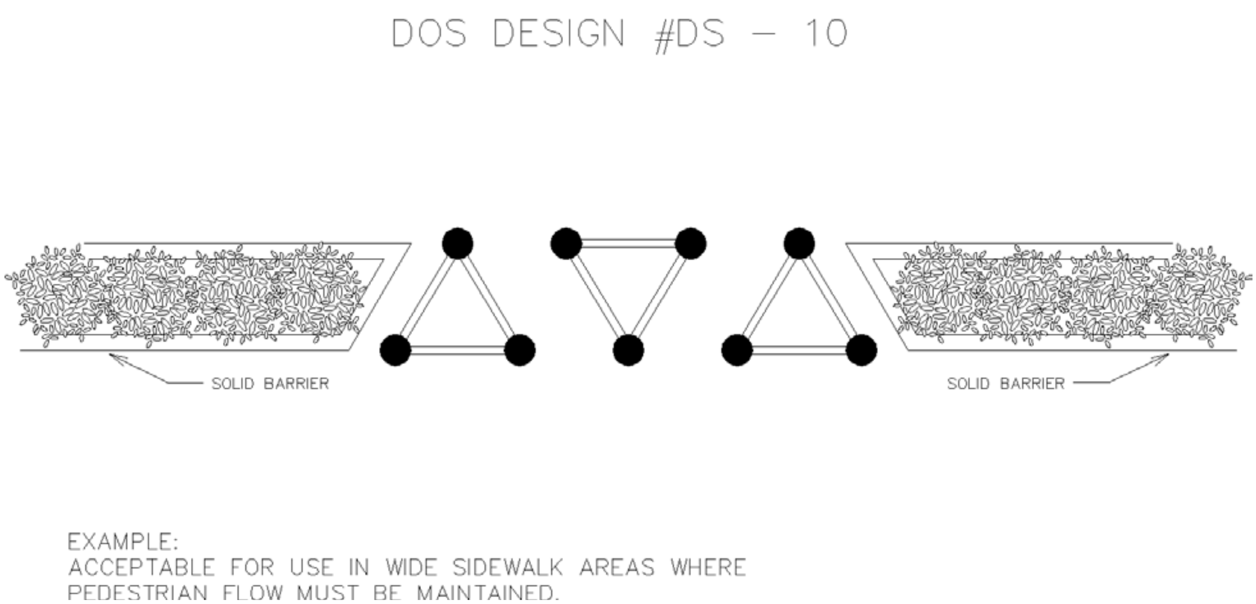


6-2.2 **Concrete Median**.

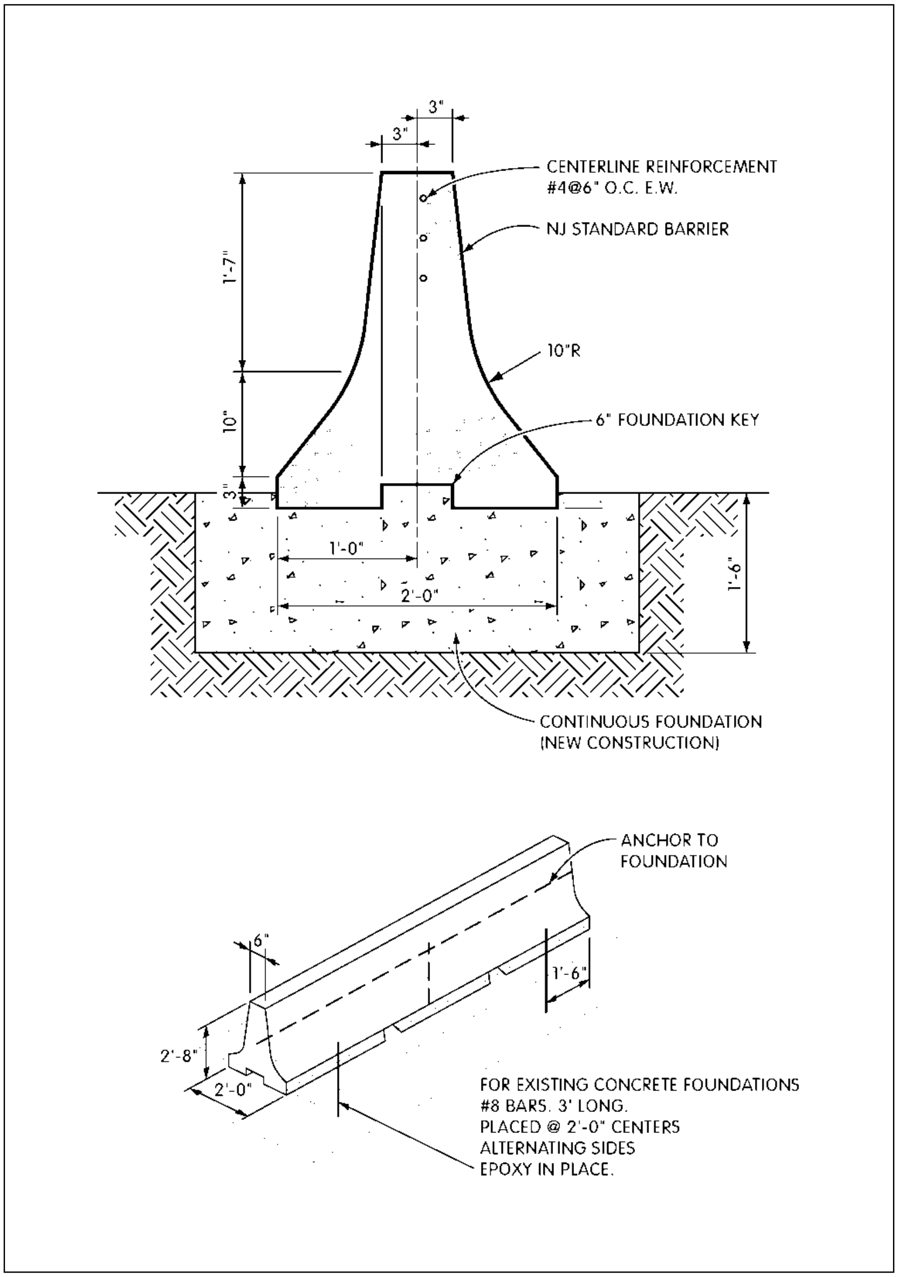
6-2.2.1 **Description**.

A concrete highway median (also known as a Jersey Bounce or Jersey Barrier) can be effectively used as a perimeter vehicle barrier, but only if the medians are securely fastened together. It can either be erected from pre-cast tongue-and-groove sections or cast in place with special concrete-forming equipment. It is especially effective for impact angles less than 30 degrees and is appropriate for locations where access roads are parallel to the barrier. Complete penetration is possible with light vehicles; however, damage to the vehicle will be extensive. If the potential impact angle from threat vehicle is expected to exceed 30 degrees, anchor barrier to foundation. These barriers should be set in a concrete foundation, as shown in Figure 6-15. Also barriers need to be securely connected with a minimum of one 3/4 inch steel cable tying them together to be effective.

6-2.2.2 **Testing**.

A non-reinforced, anchored, concrete median barrier was tested with a 4,000-lb (1,818-kg) vehicle at 50 mph (81 kph). The vehicle penetrated the barrier 20 ft (6 m). The vehicle had extensive front-end damage, and the occupants would have received serious to critical injuries. During the impact, a section of the barrier was broken and overturned. These barriers should be set in a concrete foundation, as shown in Figure 6-15, for applications where the impact angle exceeds 30 degrees. The barriers need to be securely tied together to be effective.

Figure 6-15 Precast Non-Reinforced Concrete Median



6-2.3 **King Tut Blocks**.

6-2.3.1 **Description**.

Non-reinforced concrete blocks can be used effectively as vehicle barriers or to slow the speed of oncoming vehicles, as shown in Figure 6-16. The placement of the blocks is shown in Table 6-7. These blocks can be cast in place and should be anchored to the ground so that movement or removal is difficult. Both Figure 6-16 and Table 6-7 are for passenger vehicles only. If trucks are considered, the ability to control POV speeds is lost. Thus, POV and truck traffic must be separated for optimum serpentine use.

Figure 6-16 Concrete Blocks

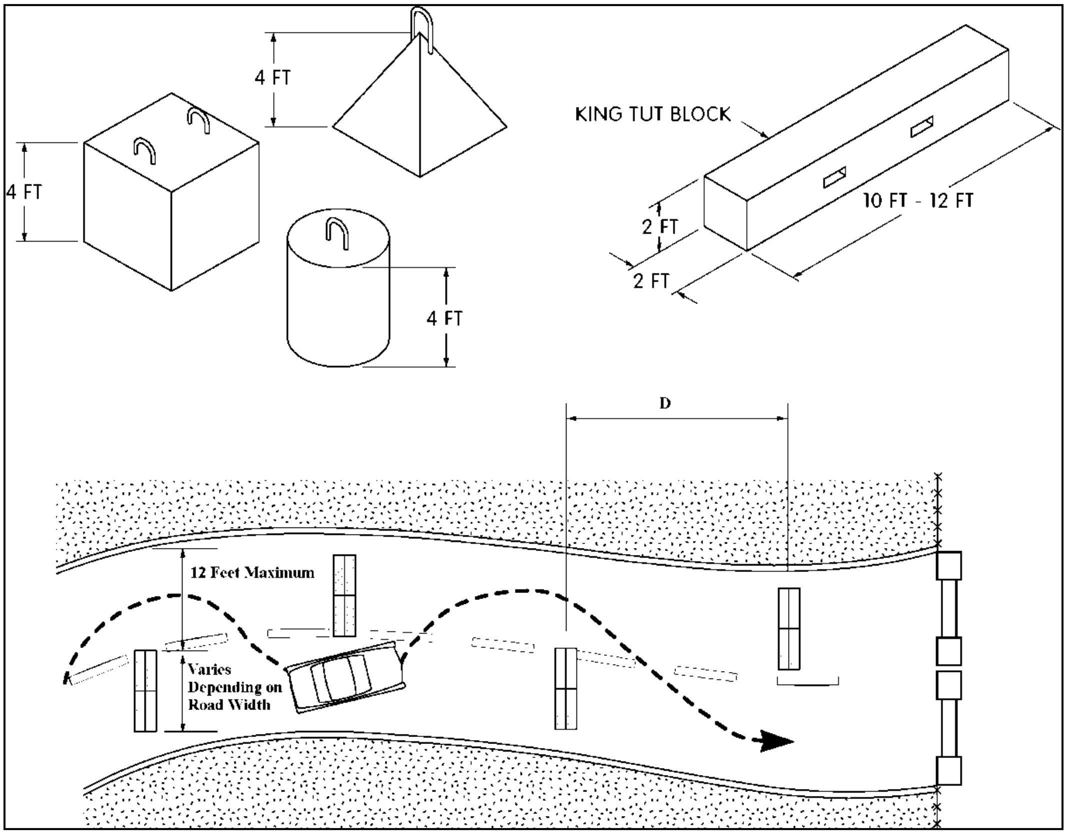


Table 6-7 Separation Distance (D)* for Barriers to Reduce Speed on a Straight Path in Ft (m)

Achievable Speed of Vehicle on a Curve in mph (kph)→ Road Width in ft (m) ↓	**20 (32)**	**30 (48)**	**40 (64)**	**50 (80)**	**60 (97)**
20 (6.1)	28 (8.5)	43 (13.1)	58 (17.7)	73 (22.2)	87 (26.5)
30 (9.1)	40 (12.2)	63 (19.2)	86 (26.2)	108 (32.9)	130 (39.6)
40 (12.2)	47 (14.3)	77 (23.5)	106 (32.3)	134 (40.8)	161 (49.1)
50 (15.2)	51 (15.5)	87 (26.5)	122 (37.2)	155 (47.2)	187 (57.0)
60 (18.3)	54 (16.5)	96 (29.3)	135 (41.1)	172 (52.4)	209 (63.7)

*Based on f=1.0

6-2.3.2 **Testing**.

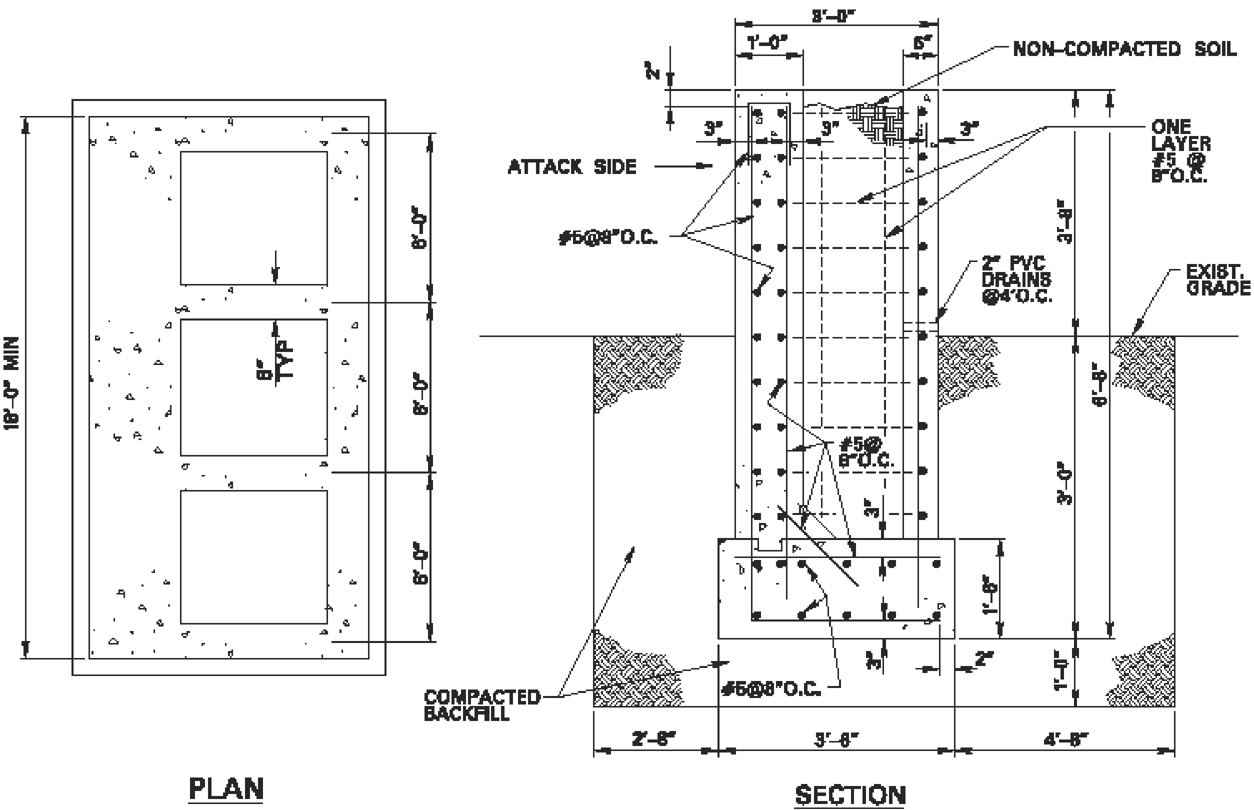
No formal crash testing has been conducted; however, the mass of this type of concrete construction should perform at least as well as a concrete median (Figure 6-15).

6-2.4 **Concrete Planter**.

6-2.4.1 **Description**.

A concrete planter barrier (Figure 6-17) offers permanent protection from vehicle penetration and can also be aesthetically pleasing.

Figure 6-17 Reinforced Concrete Planter



6-2.4.2 **Testing**.

This barrier was tested with a 15,000-lb (6,818-kg) vehicle traveling at 47 mph. The vehicle did not penetrate the barrier. The planter is DoS K12 certified.

6-2.5 **Excavations and Ditches**.

Ditches offer a simple method of rapidly securing a lengthy perimeter against a moving vehicle tactic. They can function as permanent anti-vehicle barriers if the required ditch profile is well maintained, or they can provide a temporary barrier before another permanent vehicle barrier system is installed. The ditch profile, including the approach slope, is critical to its ability to function as a vehicle barrier.

There are two vehicle attack methods against a ditch; 1) a slow covert attack where the vehicle attempts to cross the ditch by approaching at a oblique angle almost parallel to the ditch and going down and then up along the profile of the ditch, and 2) a fast attack where the vehicle approaches perpendicular to the ditch at high speed and attempts to jump the ditch. In the latter case, the flexibility in the vehicle suspension system and inertia of the vehicle can allow the front wheels to roll over the far edge of the ditch even if they do not fully clear the ditch. Also ditches are vulnerable to coordinated attacks, where the ditch profile is modified in the initial attack and then a moving vehicle attack is mounted across the ditch before it can be repaired.

Soil berms adjacent to the protected side of the ditch provide additional resistance to vehicle attack but they also can make the ditch a more effective hiding place for attackers on foot. This negative aspect of berms is less significant when there are elevated observation positions near the ditch. Soil berms and placement of spoil from ditch excavation on the attack side of the ditch should not be used because they provide a ramp effect, or launch angle over the ditch for a fast vehicle attack, increasing the capability of a vehicle to jump the ditch.

Numerous profiles for anti-vehicular ditches have been proposed in previous DoD documents, that were based on ditches used primarily to slow tank attacks. These profiles were not tested against simulated moving terrorist vehicle bombs until recently when similar ditches, tested in the United Kingdom. The following conclusions were determined from the United Kingdom tests:

a. Asymmetric V-shaped ditches with an inclined angle greater than 65 degrees and a total width and depth equal or greater than 5 m and 1.2 m, respectively, were able to stop the test vehicle.

b. The approach terrain on the attack side of the ditch should not have any incline or spoil and preferably should have a slight decline.

c. Ditches will stop a fast vehicle attack provided the vehicle drops more than 75% of its wheel diameter in the space provided.

d. Trapezoidal ditches should be avoided in general due to a concern that a vehicle can drive in and out of the ditch in a slow attack

The United Kingdom tests were not part of a comprehensive design project for anti-vehicular ditches that allowed the ditch profile to be optimized based on both resistance to moving vehicle attack and practical construction considerations. A study by NAVFAC was conducted to use observations from the United Kingdom tests, simple analyses of moving vehicle trajectories over various ditch profiles, and a survey of large commercial vehicle geometry information to design the three anti-vehicular ditches shown in Figures 6-18, 6-19 and 6-20. In all three figures, the protected side of the ditch is on the left.

Figure 6-18 Anti-Vehicular Ditch Profile with Incline Slope Requiring Stabilization

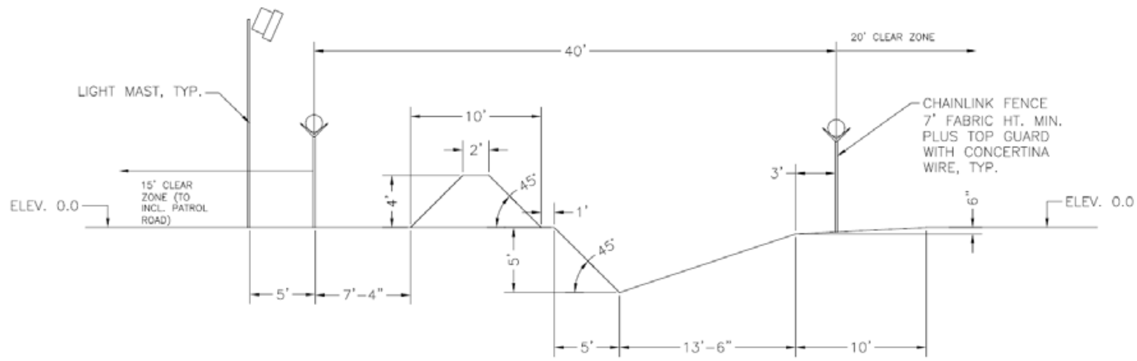


Figure 6-19 Anti-Vehicular Ditch Profile with Maximum Incline Slope Not Requiring Stabilization

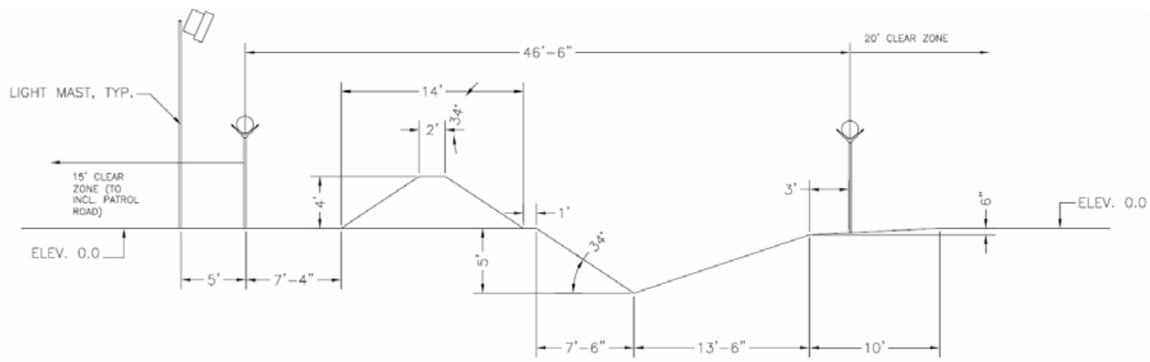

Figure 6-20 Anti-Vehicular Ditch Profile with Maximum Incline Slope Not Requiring Stabilization or Berm

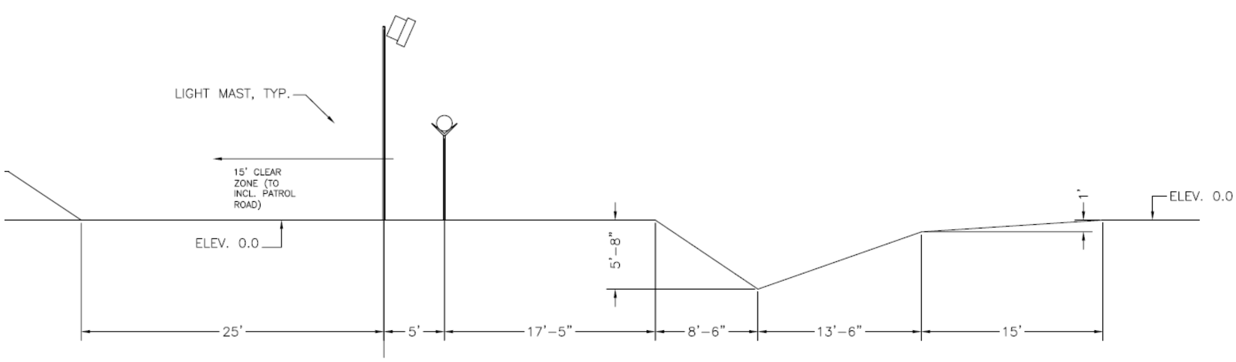
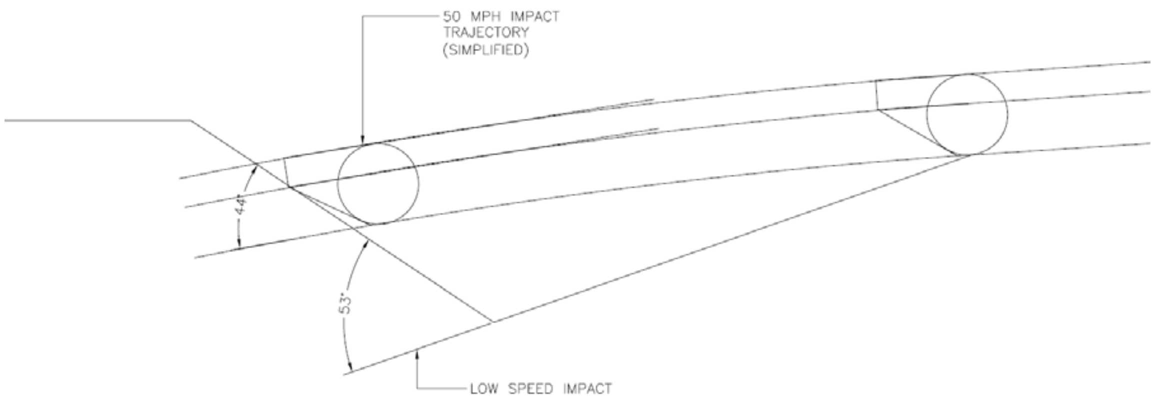


Trajectory simulations of \1\ medium sized SUV's /1/ at velocities up to 50 mph showed that the vehicle impact angle relative to the inclined slope on the far side of the ditch was at least 43 degrees for all the ditch profiles in Figure 6-18 through

The trajectory simulations were based on a simple physics derivation that ignored air resistance and specific vehicle geometry characteristics. Figure 6-21 shows a trajectory analysis where the approach angle at impact for the vehicle at 50 mph is 43 degrees. This approach angle is sufficient to prevent the front bumper from clearing the top edge of ditch for a range of commercial utility vehicles including Jeeps, Land Rovers, SUV's, and Hummers (except a Hummer 1) based on a limited survey of the geometry of these vehicles by NAVFAC Atlantic. This survey also indicated that a 42 degree side slope or greater was sufficient to cause all the surveyed vehicles to tip if they were trying to make a cross the ditch at an oblique angle in a covert attack.

Figure 6-21 Simulated Trajectory Path and Impact Angle with Ditch Incline Slope for Vehicle at Two Speeds



The most vehicle survey focused on the lower bumper reference line height of the vehicles, which affects the maximum approach impact angle that could allow a vehicle to clear the ditch, and the maximum side slope angle. The approach angle and lower bumper reference line are illustrated in Figure 6-22 from the International Organization of Motor Vehicle Manufacturer's (OICA). Based on a limited survey of SUVs by the OICA, the lower bumper reference height ranged from 340 mm (13.4") to 500 mm (19.7"). This information was used with a survey of SUV vehicle specifications to determine maximum vehicle approach angles and side slope angles shown in Tables 6-18, 6-19 and 6-20. The side slope in Table 6-8 is the transverse angle the vehicle can be at without tipping over.

Figure 6-22 Lower Bumper Reference Line and Vehicle Approach Angle

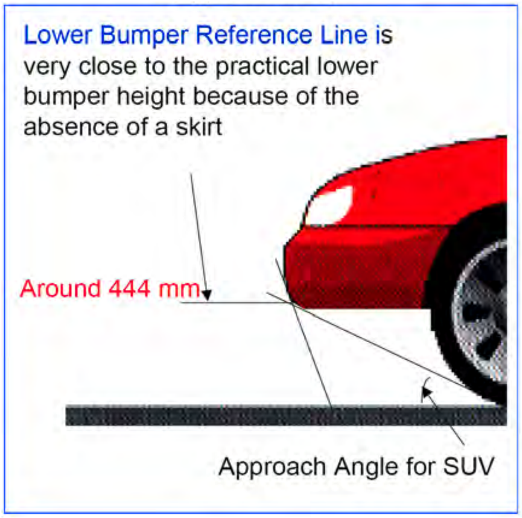


Table 6-8 Maximum Vehicle Approach Angles and Side Slope Angles

Vehicle	Maximum Approach Angle (degrees)	Maximum Side Slope Angle (degrees)
Jeep Liberty	38.1	
Jeep Commander	34	
Hummer H3	39.4	
Hummer H1	72	40
Hummer H2	41	40
Land Rover LR3	37	35
Toyota FJ Cruiser	34	41
Land Rover Range Rover	34	
Jeep Grand Cherokee	34	
Mercedes G-Class	36	28.4
Toyota 4 Runner	31	

The berms in Figure 6-18 and Figure 6-19 are essentially safety factors and they are recommended given the approximations in the analyses used to design the ditch profiles. The profile in Figure 6-18 provides the highest amount of resistance against a moving vehicle threat, but it requires a stabilized slope, such as concrete riprap or sand-bag cover, since natural soil cannot maintain a 45 degree slope. The profile in Figure 6-19 provides less resistance against a moving vehicle threat, but sandy soil can theoretically maintain a 34 degree slope. Finally, the profile in Figure 6-20 is similar to Figure 6-19 except that it does not have the additional safety factor of a berm for stopping a moving vehicle threat. As mentioned previously, the berm may be considered unacceptable because it may provide a potential hiding place for attackers on foot. The declined approach slope helps to some effect, to offset the reduced resistance to a moving vehicle threat caused by deletion of the berm.

6-2.6 **Guardrails**.

6-2.6.1 **Description**.

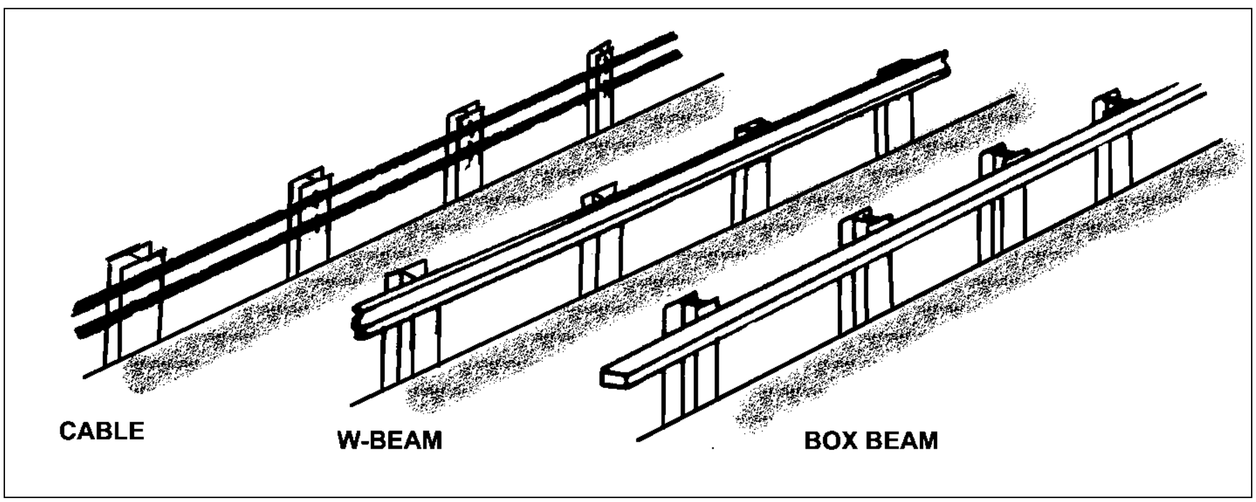
Standard highway guardrails or median barriers can be used as perimeter vehicle barriers (Figure 6-23). Guardrail design procedures can be found in the AASHTO Roadside Design Guide and AASHTO Geometric Design of Highways and Streets and in many state DOT standard drawings. Guardrails are normally designed to redirect vehicles approaching at angles less than or equal to 25 degrees and are not recommended as perimeter vehicle barrier for approach angles greater than 25 degrees..

A cable guardrail (AASHTO type G1) consists of three ¾-inch diameter steel cables, spaced 3 inches apart. The posts used are S3x5.7 steel, spaced at 16-ft intervals. The height, measured from the surface to the top rail, is 30 inches. From the end post, all three cables are turned down at a 45-degree angle and anchored to buried concrete deadmen.

A W-beam flexible guardrail (AASHTO type G2) consists of a 12 gauge "W" section bolted to S3x5.7 steel posts, spaced at 12 ft 6 in. intervals. A Blocked-Out W beam (AASHTO type G4) guardrail system uses a 12 gauge "W" section bolted to W6x8.5 posts, spaced at 6 ft 3 in. intervals. The AASHTO Guide for Selecting, Locating and Designing Traffic Barriers provides four post and blocking alternatives for this guardrail system. A thrie beam (AASHTO type G9) guardrail system consists of a steel thrie beam bolted to W6x8.5 steel posts at 6 ft 3 in. intervals.

A box-beam guardrail (AASHTO type G3) system consists of a 6 in. x 6 in. x 0.180 in. steel tube bolted to S3x5.7 steel posts, spaced at 6 ft 4 in. intervals.

Figure 6-23 Guardrails



6-2.6.2 **Testing**.

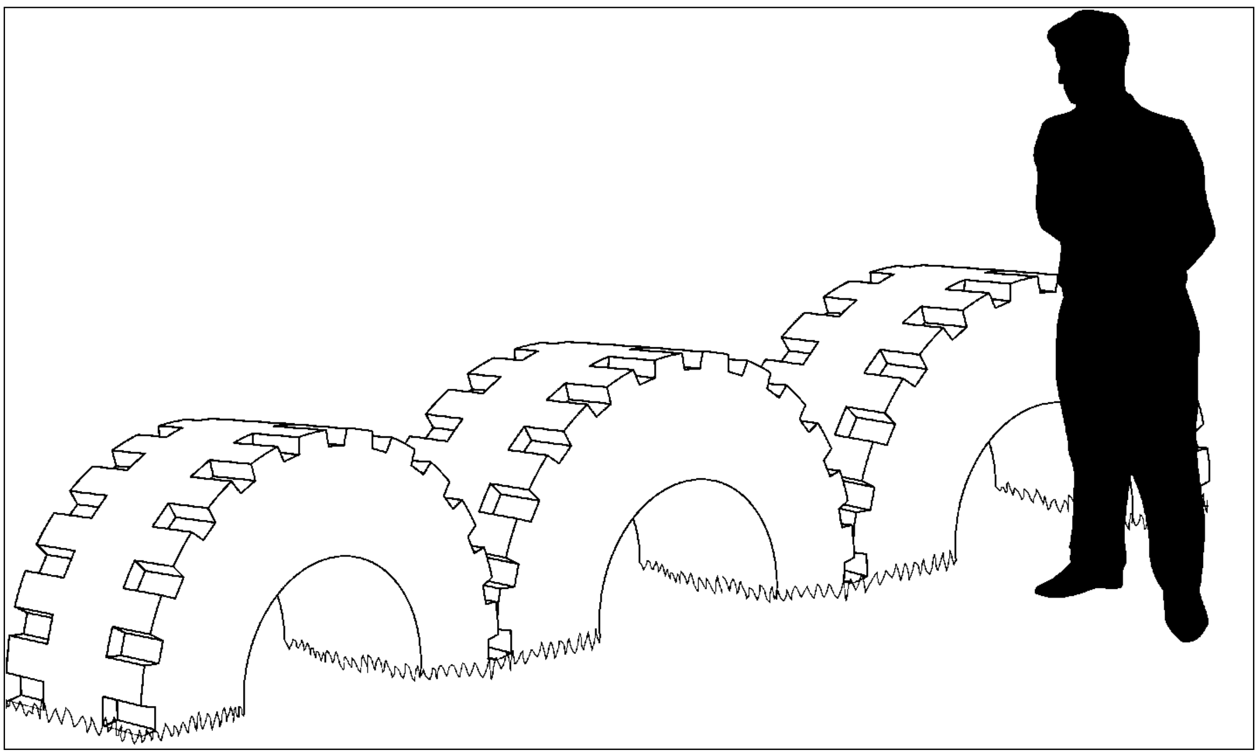
The cable guardrail system successfully redirected both low profile 3,500 lb (1,587 kg) vehicles and a 4,100 lb (1,850 kg) van, as well as other 4,000 lb (1,814 kg) vehicles, during testing for impact angles of 25 degrees or less. Tests of the W beam system resulted in redirection of a vehicle with an impact angle of 25 degrees, but the redirected vehicle was airborne for a distance of 50 ft. During testing of the Blocked-Out W beam system, the barrier successfully redirected low profile vehicles with impact angles of equal to or less than 25 degrees. This system caused several vans and other vehicles with high centers of gravity to overturn after impact. Tests of the thrie beam system provided a smooth redirection of vehicles when the impact angle was 25 degrees or less. The box beam guardrail system tested provided excellent redirection of the vehicle.

6-2.7 **Heavy Equipment Tires**.

6-2.7.1 **Description**.

Heavy equipment tires, half-buried in the ground and tamped to hold them rigid, can be effective vehicle barriers (Figure 6-24). Use tires that are 7 to 8 ft (2.1 to 2.4 m) in diameter. Heavy equipment tires can usually be obtained locally from salvage operations for the cost of hauling them away.

Figure 6-24 Heavy Equipment Tire Barrier



6-2.7.2 **Testing**.

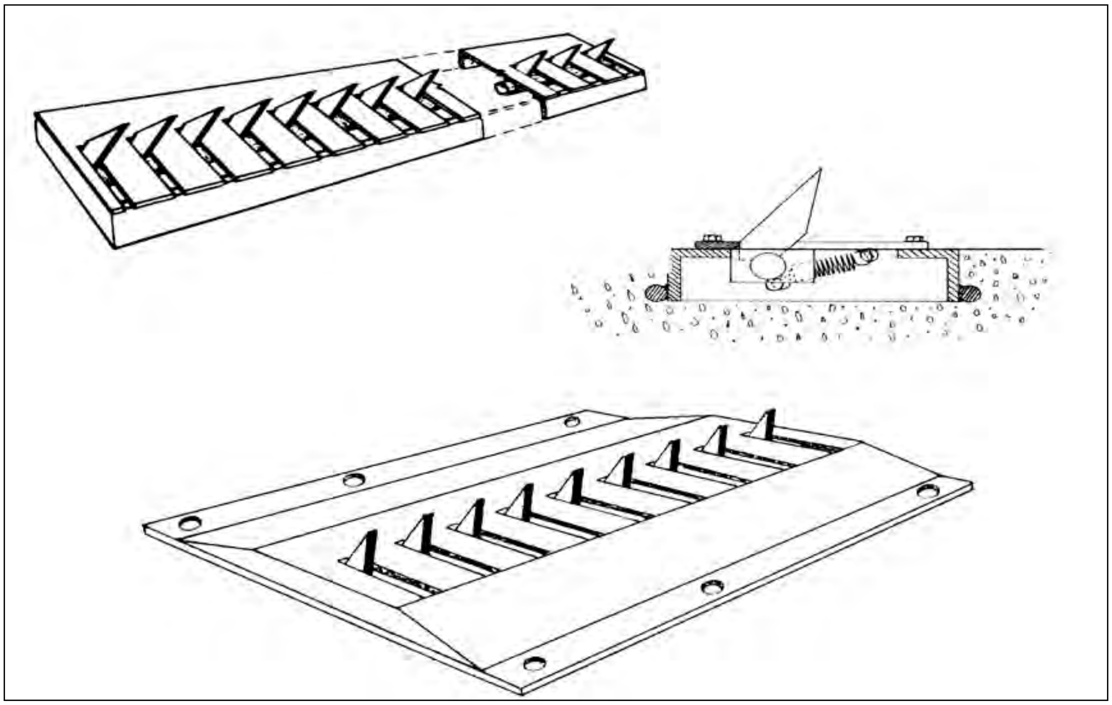
Buried equipment tires were tested using a 3,350-lb (1,523-kg) vehicle traveling at 51 mph (82 kph). The vehicle penetrated the barrier 1-ft (0.3-m). The tires used were 36 ply, 8 ft in diameter (2.4 m), and weighed 2,000 lbs (909 kg) each.

6-2.8 **Tire Shredders**.

6-2.8.1 **Description**.

Tire shredders can be either surface-mounted or imbedded, as shown in Figure 6-25. These devices are normally used for traffic control purposes and are designed to slow or stop a vehicle by deflating their pneumatic tires. These units are available from a number of commercial manufacturers. Delta Scientific Corporation manufactures the unit shown in Figure 6-25. When a vehicle drives over the mechanism in the wrong direction, the spikes penetrate the tire casing, which quickly deflates the tires, making the vehicle difficult to operate for extended periods. These systems should not be considered vehicle barriers. Tire shredders are not recommended where vehicle traffic drives over these devices at speeds exceeding 5 mph. These systems may also not be effective against modern "run flat" tires, heavy-duty truck tires, or extra-wide tires that can bridge over two or more spikes. Tire shredders have a very limited capability to stop a vehicle.

Figure 6-25 Tire Shredders



6-2.8.2 **Testing**.

These systems have not been formally tested, and as indicated above are not considered a vehicle barrier.

6-2.9 **Steel Cable Barriers**.

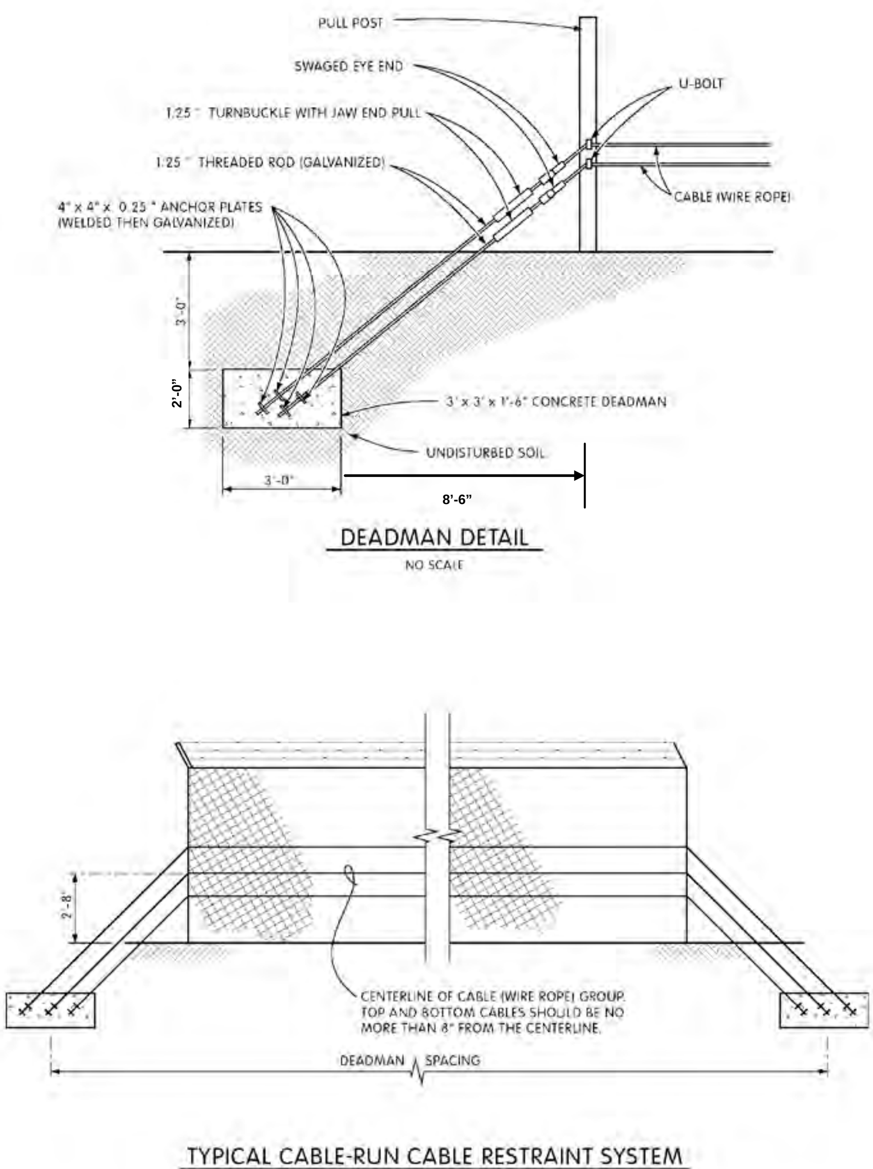
6-2.9.1 **Description**.

As shown in Figure 6-26, there are several configurations for steel cable barriers. Site requirements, configuration, and environment must be carefully considered prior to selecting a cable system for a particular application.

6-2.9.2 **Testing**.

Systems such as those shown in Figure 6-26 have not been formally tested. However, two 3/4-in. (1.9-cm) diameter cables attached to a 200-ft section of fence, minus fabric, with deadman anchors at both ends were tested with a 4,000-lb (1,818-kg) vehicle at 52 mph (84 kph). The vehicle was stopped within 13 ft (4 m) and then pushed back to the impact point. For additional considerations, details, and design guidance relating to the use of steel cables in fencing and gates, refer to UFC 4-022-03.

Figure 6-26 Steel Cable Barriers

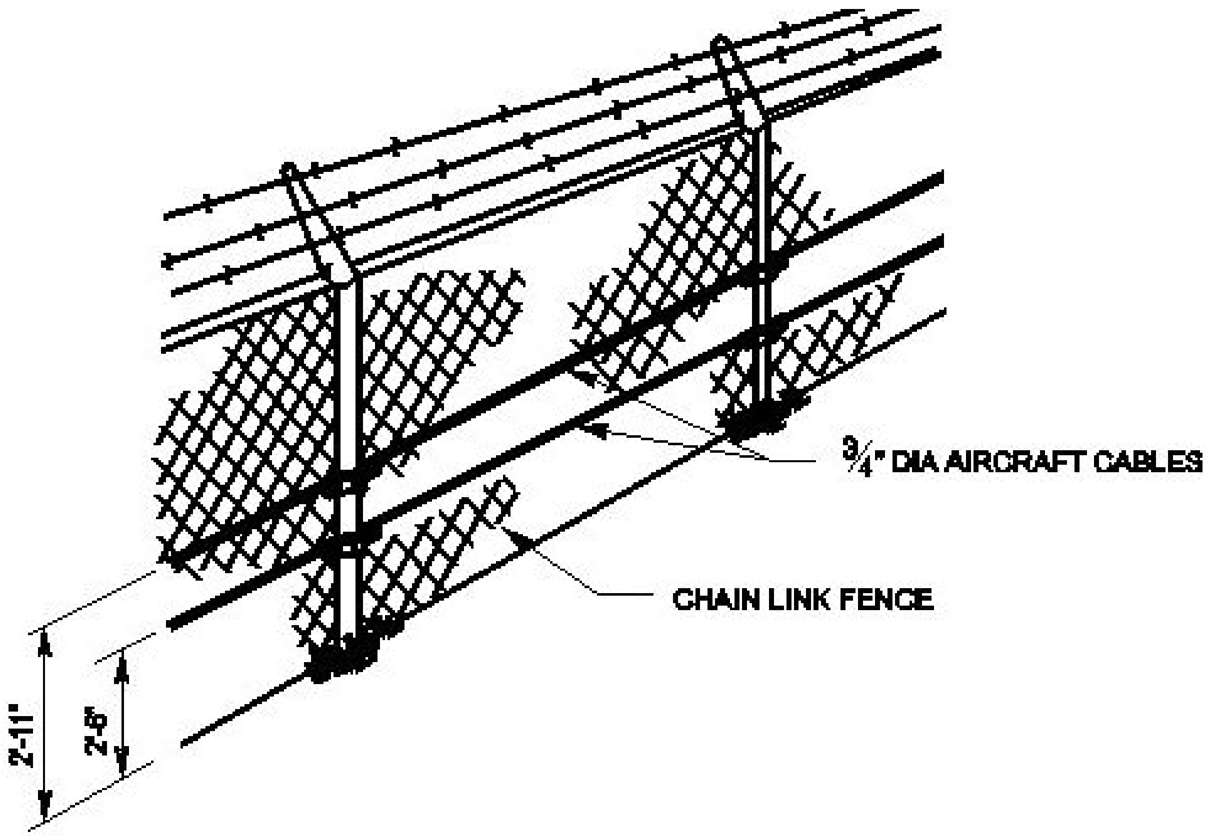


6-2.10 **Steel Cable-Reinforced Chain Link Fencing**.

6-2.10.1 **Description**.

Without some reinforcement, a standard chain-link fence can be penetrated easily by a light vehicle with little or no damage. However, standard fencing can be reinforced to provide a cost-effective method to protect against the threat of penetration by light vehicles, as in Figure 6-26 and Figure 6-27. Although no required pre-tension is specified for the cable, it is generally considered acceptable that it should be snug and not have significant sag. Routine (usually daily) perimeter inspection should include checking for visible sagging. At this time, there is no specific sag measurement benchmark, so checking for “visible” sag is a conservative approach. Regularly scheduled inspections should also check for corrosion of fittings, including the turnbuckles, anchor bolts, U-bolts, any swaged fittings, and cable clamps. Cable clamps should be inspected as well to insure no nuts have become loose. For additional considerations, details, and design guidance relating to the reinforcing of fencing and gates, refer to UFC 4-022-03.

Figure 6-27 Typical Steel Cable Reinforced Chain-Link Fencing



6-2.10.2 **Testing**.

Sandia National Laboratories tested a barrier consisting of a chain link fence reinforced with a 3/4-in. (1.9-cm) cable. In this test, a 3,350-lb (1,523-kg) vehicle traveling at 23.5 mph (38 kph) penetrated the barrier 7 ft (2.1 m). A 4,050-lb (1,841-kg) vehicle, traveling at 50.6 mph (82 kph), penetrated 26 ft (7.9 m), and the cable failed at the impact location. A test using two cables with no fabric was impacted by a 4,000-lb (1,814-kg) vehicle, traveling at 52 mph (84 kph), and the vehicle penetrated 13 ft (4 m) and then pushed back to the original fence line. Engineering analysis of various cable restraint configurations, using the BIRM computer model (PDC-TR90-2), is shown in Table 6-9.

Table 6-9 Performance of Cable Restraint Systems

Cable Barrier w/200-ft Anchorage Spacing	Kinetic Energy in ft-lbf x 1,000 (kgf-m)	Penetration in Ft (m)
1 Cable @ 3/4-in. dia.	100 (13.8)	40 (12.2)
2 Cables @ 3/4-in. dia.	200 (27.6)	40 (12.2)
3 Cables @ 3/4-in. dia.	338 (46.7)	40 (12.2)
4 Cables @ 3/4-in. dia.	418 (57.8)	40 (12.2)
1 Cable @ 1-in. dia.	150 (20.7)	40 (12.2)
2 Cables @ 1-in. dia.	340 (47.0)	40 (12.2)
3 Cables @ 1-in. dia.	506 (70.0)	40 (12.2)
4 Cables @ 1-in. dia.	706 (97.6)	40 (12.2)

6-2.11 **Reinforced Concrete Knee Walls**.

6-2.11.1 **Description**.

When a perimeter wall or fence line needs to also serve as a vehicle barrier, it must meet passive vehicle barrier standards. This can be achieved by using a reinforced concrete knee wall structure. A knee wall barrier is a wall resting on a footing. The entire footing and part of the wall are imbedded in the existing soil or in a crushed stone mix. Figures 6-28, 6-29 and 6-30 show representative cross sections of this type of barrier.

Figure 6-28 Anti-Ramming Foundation Wall

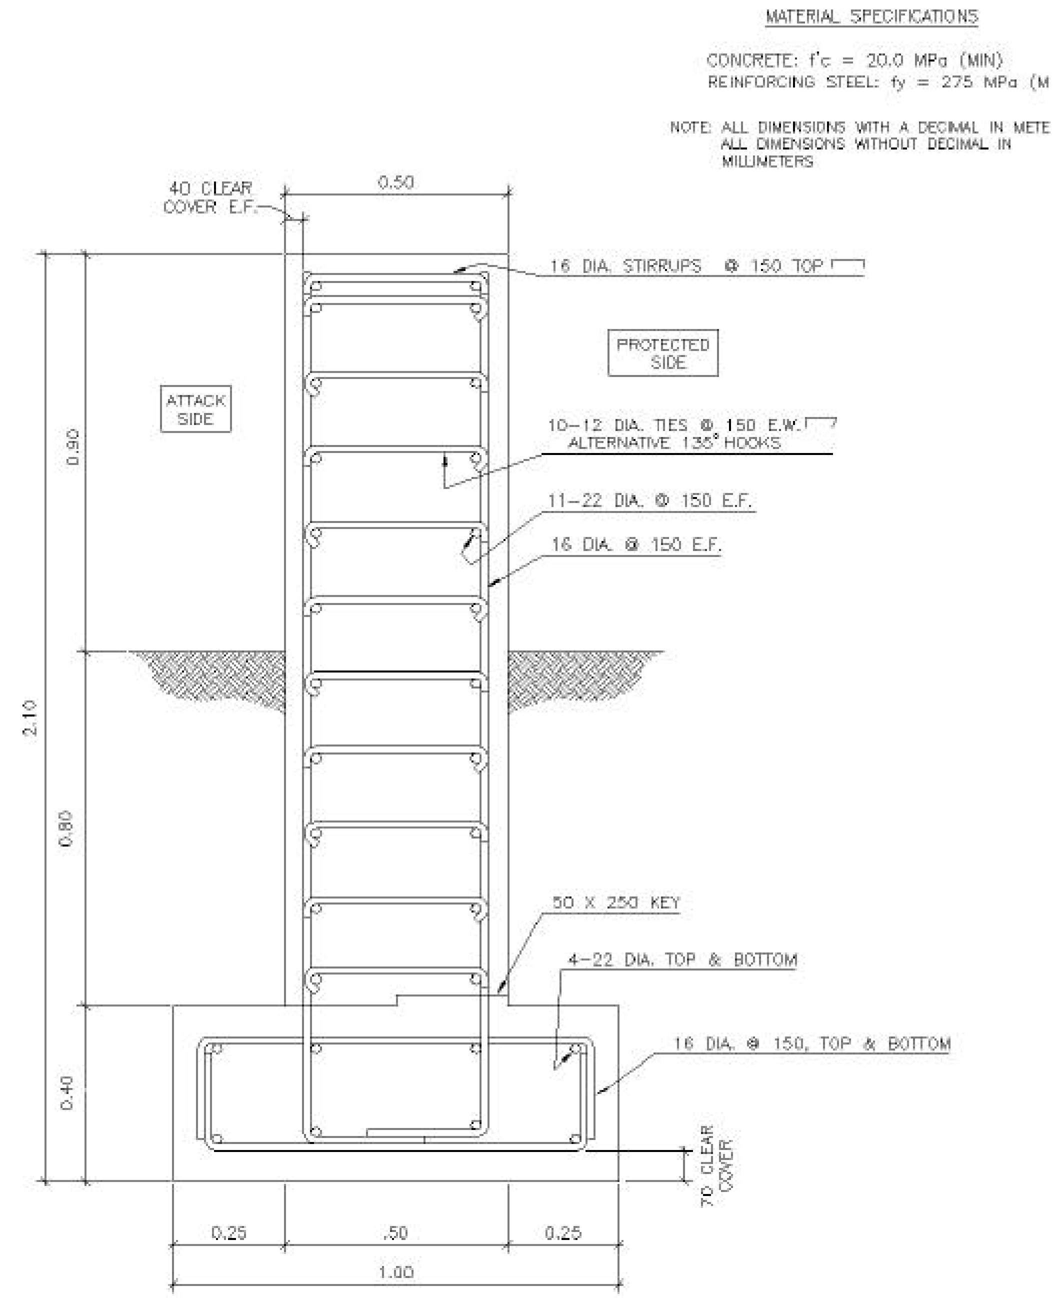


Figure 6-29 Anti-Ramming Knee Wall Section

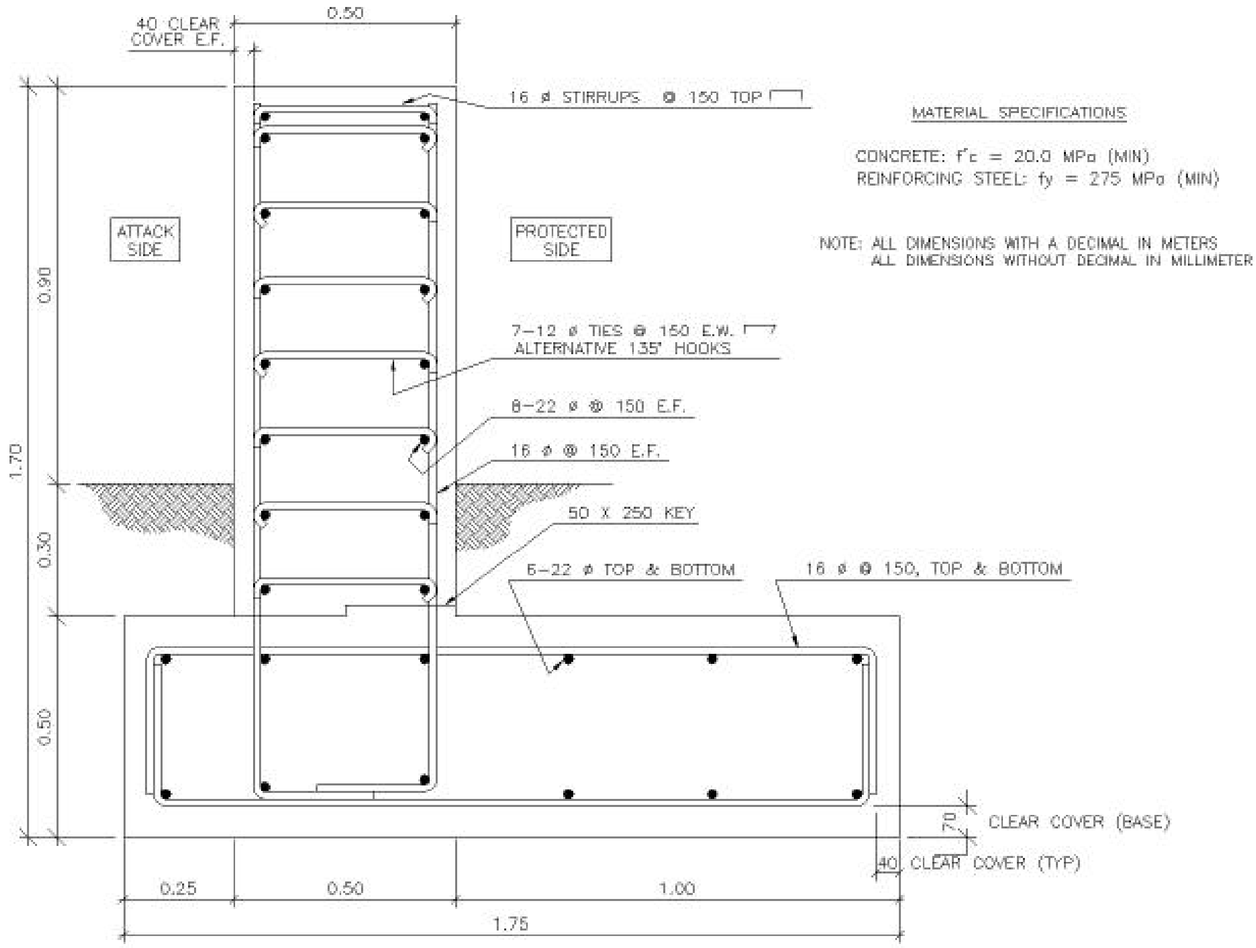

Figure 6-30 Reinforced Concrete Knee Wall Details

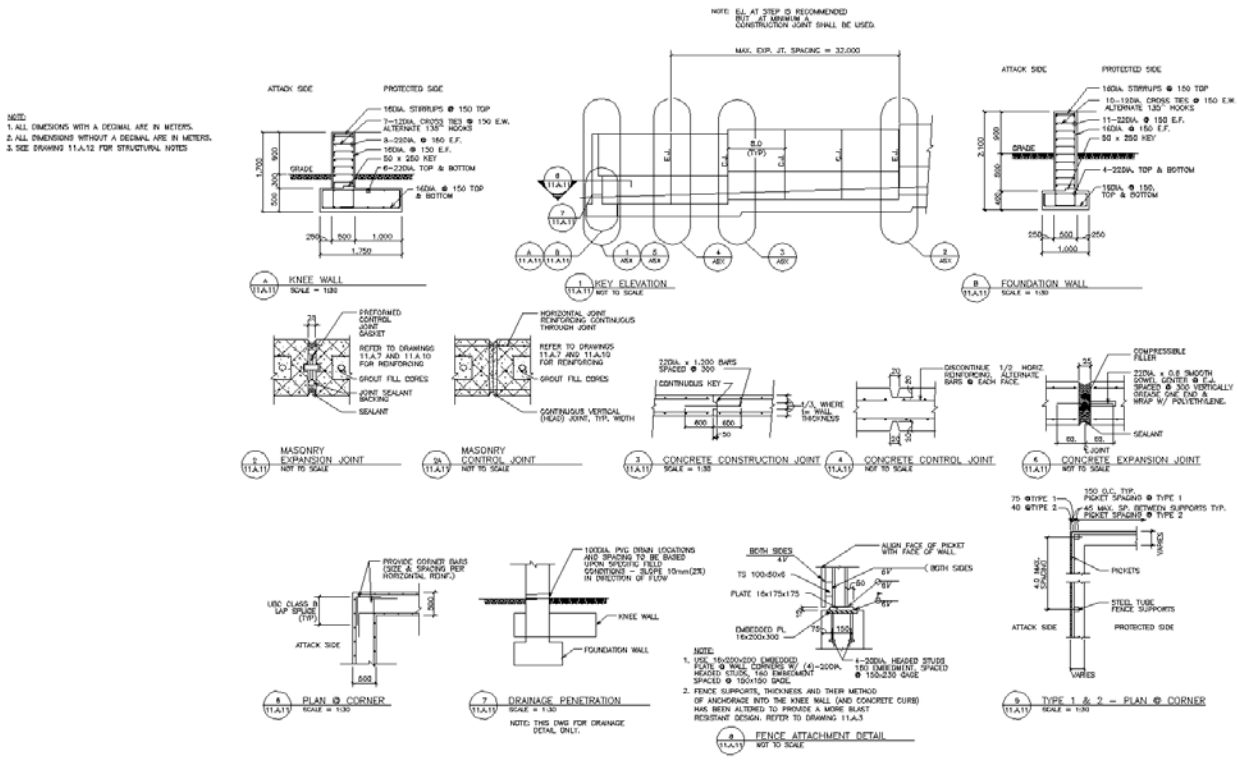


6-2.11.2 **Testing**.

Reinforced concrete knee walls have been formally tested. A configuration similar to Figure 6-28 was tested with a 15,000-lb (6,818-kg) vehicle traveling at 50 mph (80 kph). The wall effectively stopped the attack vehicle within 3.28 ft (1 m).

6-2.12 **Plastic Barrier Systems**.

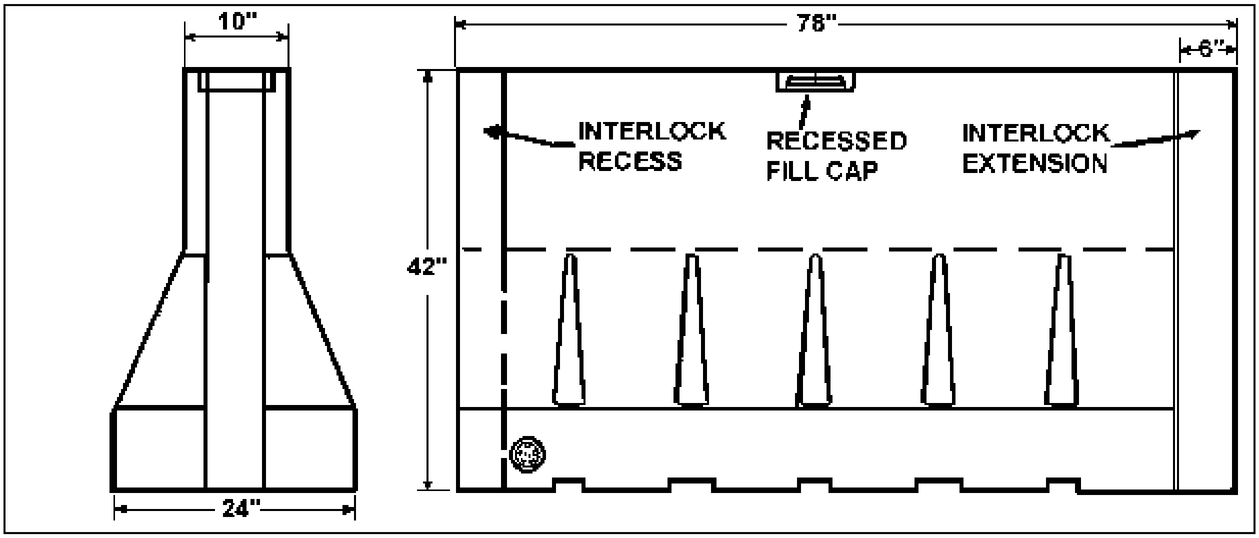
6-2.12.1 **Description**.

Plastic barrier systems (Figure 6-31) are available from several manufacturers.\1\ /1/ They are molded in a configuration similar to the Jersey Bounce or Barrier, shown in Figure 6-15. These barriers weigh approximately 130 lbs empty and 1,600 to 1,800 lbs when filled with water. The units are made from polyethylene plastic and come in six-ft sections that are easily transported. An interlocking section and steel pipe are used to link the sections together. Linking the sections is strongly recommended to provide added resistance to vehicle impact and reduce lateral movement. Surface mounting of these units limits their use as effective vehicle barriers, except for low-speed impacts (less than 15 mph) and angles less than 25 degrees.

6-2.12.2 **Testing**.

Example plastic barriers, filled with sand, have been crash tested, as described in Appendix \1\ C/1/, paragraph C-3.

Figure 6-31 Commercially Available Plastic Barrier System



6-2.13 **Expedient Barrier Systems**.

When barrier systems are required quickly with no time for ordering manufactured barriers, common construction items or available construction vehicles can be used as barriers. Materials such as large-diameter concrete and steel pipes can form makeshift barriers. Even large construction vehicles (e.g., dump trucks and earth moving equipment) that have heavy mass and size can be used, or modified for use, as expedient barrier systems. Some examples are:

a. Three-ft (0.9-m) sections of large-diameter, corrugated metal or reinforced concrete pipe can be placed on end and filled with sand or earth.

b. Steel pipe can be stacked and welded together in a pyramid.

c. Construction vehicles can be anchored together with cable or chain.

These expedient measures can provide effective protection against vehicle ramming attacks. Because no testing has been done on these systems, it is important that these barriers be stabilized and anchored to prevent displacement by a threat vehicle.

6-3 **VEHICLE BARRIER PERFORMANCE**.

Full-scale testing of vehicle barrier systems is only one way to obtain information on the performance capabilities of vehicle barriers. Testing provides evidence that the selected barrier will effectively absorb the impact of a threat vehicle. Tests may be conducted by independent testing laboratories, government agencies, or the manufacturer. Some tests are properly documented and/or witnessed by authorities, while others are not. Only tests conducted by independent laboratories or government agencies should be accepted.

It is important to correctly interpret the test results. For example, “full penetration” could mean that the vehicle passed through a barrier and was still capable of movement after penetration. Or, it could mean the vehicle payload penetrated through a barricade, but the vehicle was incapacitated. Whenever possible, carefully review the actual test report before selecting a barrier system. For commercially-available active barriers, these reports are usually accessible from the manufacturer. Such review may not always be possible

Selection of vehicle barriers can also be based on engineering analysis. Finite element analysis and computer models specifically designed to analyze barrier impact, such as the Barrier Impact Response Model 3 Dimension, have been successfully used and correlated to actual test results. Using this method is much more cost-effective than full-scale testing. Before accepting the results of an engineering analysis from a manufacturer, have the calculations carefully checked by a qualified structural engineer.

B-5 COST DATA FOR PASSIVE BARRIERS.

Table B-3 is a summary of cost data for selected passive vehicle barriers.

Table B-3 Cost for Passive Barriers

Barrier	Cost/Unit**
Anchored concrete Jersey barrier, non-reinforced (2007 Means double face, precast concrete median barrier; 34 71 13.26.2200)	$65/ft ($213.25/m)
Buried tires, 36-ply, 8-ft (2.4-m) diameter, weighing 2,000 lb (909 kg) each	$25.00/tire
Eight-in. (20.3-cm) diameter bollard system @ 3 ft (0.9 m) on center with 12-in. (30.5-cm) channel rail (2007 Means 8-in (0.2-m) bollard 34 71 13.17.2700, corrugated steel rail, 3 ft (0.9 m), 34 71 13.260012.)	$629/each
Standard chain link fence [7 ft (2.1 m), 9 ga w/ outrigger] and two 3/4-in. (1.9-cm) diameter cables (2007 Means 7-ft (2.1-m) chain link 32 31 13.53.0100 with cable guide rail assuming a ¾-in. (1.9-cm) cable 34 71 13.26.0600)	$61.30/ft ($201/m) (including fence)
Eight-in. (20.3-cm) diameter concrete-filled pipe (2007 Means 8-in. concrete-filled pipe bollards 34 71 13.17.2700)	$515.00/each
Concrete planter barrier (2007 Means for 48-in. (1.2-m) dia., 3-ft (0.9-m) high 34 71 13.17.0200)	$955/each
Cable barrier (2007 Means 34 71 13.26.0600 guide rail with steel posts; wire rope [6x19] adjusted per 05 15 16.50.0830 series rope costs)	
One cable @ 3/4-in. (1.9-cm) dia.	$12.90/ft ($42.32/m)
Two cables @ 3/4-in. (1.9-cm) dia.	$16.95/ft ($55.61/m)
Three cables @ 3/4-in. (1.9-cm) dia.	$21.05/ft ($69.06/m)
Four cables @ 3/4-in. (1.9-cm) dia.	$25.10/ft ($82.35/m)
One cable @ 1-in. (2.5-cm) dia.	$18.50/ft ($60.70/m)
Two cables @ 1-in. (2.5-cm) dia.	$26.75/ft ($87.76/m)
Three cables @ 1-in. (2.5-cm) dia.	$34.00/ft ($111.55/m)
Four cables @ 1-in. (2.5-cm) dia.	$43.25/ft ($141.90/m)
Reinforced concrete retaining or knee wall [2007 Means 03 30 53.40.6200 for cast-in-place concrete retaining walls, 4-ft (1.2-m) high]	$340/cu. yd ($445/cu. m)

C-3 **PASSIVE BARRIERS**.

Table C-4 is a summary of performance data for selected passive barriers.

Table C-4 Performance for Passive Barriers

Barrier	Kinetic Energy ft-lbf (kgf-m) x 1,000,000	Penetration ft (m)
Anchored concrete Jersey barrier, non-reinforced	0.3 (0.04)	20 (6.1)
Buried tires, 36-ply, 8-ft (2.4-m) diameter, weighing 2,000 lb (909 kg) each	0.3 (0.04)	1 (3.05)
Eight-in. (20.3-cm) diameter bollard system @ 3 ft (0.9 m) on center with 12-in. (30.5-cm) channel rail	1.1 (0.15)	None
12.75-in. (32.4-cm) to 13.25-in. (33.7-cm) diameter bollard system @ 3 ft (0.9 m) on center	0.8 (0.11) 1.2 (0.17)	3 (0.9) 3 (0.9)
Standard chain link fence [7 ft (2.1 m), 9 ga w/ outrigger] and one 3/4-in. (1.9-cm) diameter cable	0.06 (0.008) 0.35 (0.048)	7 (2.1) 26 (7.9)
Eight-in. (20.3-cm) diameter concrete-filled pipe	0.135 (0.019)	1.5 (0.46)
Concrete planter barrier	1.08 (0.15)	31.2 (9.5)
Cable barrier [200-ft (60.9-m) anchorage spacing]*		
One cable @ 3/4-in. (1.9-cm) dia.	0.1 (0.014)	40 (12)
Two cables @ 3/4-in. (1.9-cm) dia.	0.2 (0.028)	40 (12)
Three cables @ 3/4-in. (1.9-cm) dia.	0.338 (0.047)	40 (12)
Four cables @ 3/4-in. (1.9-cm) dia.	0.418 (0.058)	40 (12)
One cable @ 1-in. (2.5-cm) dia.	0.15 (0.021)	40 (12)
Two cables @ 1-in. (2.5-cm) dia.	0.34 (0.047)	40 (12)
Three cables @ 1-in. (2.5-cm) dia.	0.506 (0.07)	40 (12)
Four cables @ 1-in. (2.5-cm) dia.	0.706 (0.098)	40 (12)
Reinforced-concrete retaining wall** 10 in. (25.4 cm) thick 21 in. (53.3 cm) thick 3.28 ft (1 m) wall	0.157 (0.022)	None
Cable barrier – two 3/4-in. (1.9-cm)	0.36 (0.05)	13 (3.96)

* Based on analytical modeling, using BIRM 3D (PDC-TR90-2) or other finite element analysis process
**Of the wall designs, the shorter and thinner section 1 meter wall is the most efficient, based on K rating. /1/

Appendix D - EXAMPLES FOR PROTECTION AGAINST TERRORIST VEHICLE BOMBS

D-1 **SCOPE**.

This appendix contains examples for determining the design of vehicle barrier systems. The information contained herein is intended for informational purposes only.

D-2 **NON-GOVERNMENT PUBLICATIONS**.

Means, R.S., "Building Construction Cost Data", 65th Edition, 2007.

D-3 **DEFINITIONS**.

The definitions in Chapter 3 of this UFC apply to this appendix.

D-4 **EXAMPLES**.

D-4.1 **Example 1**.

Administrative Building 827 (Figure D-2) must be protected against a terrorist vehicle bomb. The structure is a single-story, reinforced-concrete building. The following factors apply:

a. A high threat level is considered. The design basis threat has been established as a moving vehicle with a gross weight of 15,000 lbs (6,818 kg), including 1,100 lbs (500 kg) of explosives, traveling at 50 mph (80 kph). This combination of vehicle size and speed will develop 1,253 ft-lbf (173 kgf-m) of energy on impact (Table 4-2).

b. Assume an asset value of 0.8 for Building 827. For a moving vehicle bomb as described above, this corresponds to a medium level of protection, according to UFC 4-020-01. The damage to the building will be repairable. No permanent deformation will occur in primary structural members.

c. For a medium level of protection, some injury from debris is anticipated, but serious injury or death is unlikely.

Referring to Figure D-2, the lines of approach are perimeter roads on the north and west sides of the building. Perimeter passive barriers and an active barrier on the west entrance to the facility will be required. A candidate active vehicle barrier system might be one of the example systems described in Table 6-2. For the perimeter fence, a candidate passive barrier could be the bollard system shown in Figure 6-1.

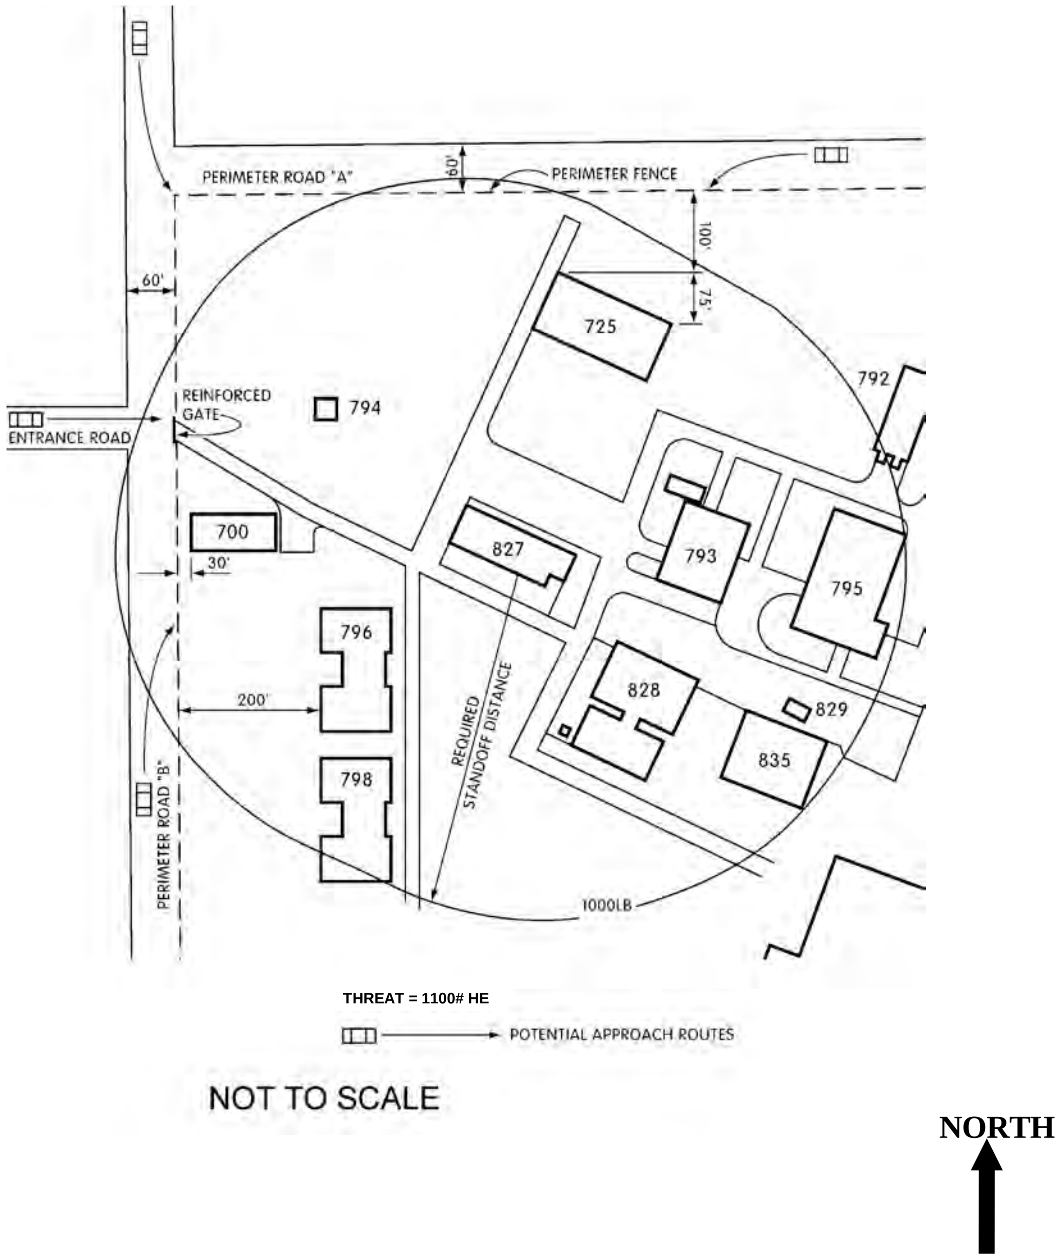
Using UFC 4-020-01, the required standoff distance for a minimal level of damage to the building from 1,100 lbs (500 kg) of explosives is 310 ft (95 m). Because there is about 320 ft (97 m) available for standoff at the location closest to the perimeter (at

Building 700), a medium level of protection can be secured. In this case, the asset value and high threat level indicate some injury is allowable, and minor damage to the structure is acceptable.

Based on the performance characteristics of the example barrier system, the penetration distance of the design threat vehicle is 27 ft (8 m). Adding this distance to the distance required for mitigating the explosive effects, the total standoff distance between the barrier and the building should be at least 337 ft (103 m). Because this standoff distance is not available for Building 827 under current site conditions, the next step would be facility hardening or the acceptance of more damage to the structure.

Passive barriers along the fence line should be designed to allow little or no penetration; the available standoff distance is already at the marginal level to protect personnel against death and injury. Selection of the concrete-filled bollard system (Figure 6-3) will provide adequate penetration resistance, because the approach is parallel to the barrier (77% of the impact load from Table 4-1).

Figure D-2 Site Plan for Examples



D-4.2 **Example 2**.

Referring to Figure D-2, the target buildings in this case are 796 and 798. Perimeter Road "B" has a 60-ft (18-m) offset (distance from the barrier to the restricting opposite curb). Using Table 4-1, a vehicle traveling at 50 mph (80 kph) can safely turn on a maximum 167-ft (51 m) radius curve without skidding. At this speed and angle of approach to the barrier, the vehicle will strike the barrier at an angle. Due to the angle of impact (Table 4-1), the speed directed at the barrier is 76.6 percent of the 50-mph (80-kph) speed, or 38 mph (61 m). Using Table 4-2 and rounding up to the next highest speed [40 mph (64 kph)], the kinetic energy transferred to the barrier will be 214,000 ft-lbf (29 kgf-m) if the design basis threat is a moving 4,000-lb (1,818-kg) vehicle, and 919,200 ft-lbf (111 kgf-m) if the design basis threat is a moving 15,000-lb (6,818-kg) vehicle.

> Note: Incorporate reduction due to angle of impact after calculation of kinetic energy.

Once the kinetic energy has been calculated, refer to Appendix\1\ C /1/ for a listing of passive barriers and penetration distances that can be used to select the most effective barrier. Anchored Jersey barriers could be used for the threat of a moving 4,000-lb (1,818-kg) vehicle, and a bollard system or concrete planter would be the only passive barriers that would be capable of stopping a 15,000-lb (6,818-kg) vehicle. For the larger threat, it would be appropriate to install concrete blocks as shown in Figure 6-16 and space them in accordance with the information from Table 6-7 to reduce the vehicle speed to 30 mph (48 kph) or less.

Appendix E - VEHICLE BARRIER DEBRIS MINIMIZATION AND EFFECTS ON COUNTER-MOBILITY

E-1 **GENERAL**.

Barriers are widely used in Entry Control Facilities/Access Control Points (ECF/ACP) and as perimeter boundaries to effectively control traffic. They can be successful in preventing entry of a suspected vehicle bomb into an installation; however, barriers may not prevent detonation of the bomb at the ECF/ACP. The barriers typically used in ECF/ACPs are designed to resist vehicle impact loads, not blast loads. The blast loading of a barrier wall can result in breakup of the barrier and subsequent throw of debris toward the facility being protected by the barrier. This debris has the potential of being thrown great distances, depending on the explosive quantity in the vehicle bomb. The debris can range in size from small, penetrating pieces to whole barrier sections, presenting a significant hazard to personnel, and possibly structures, near the detonation site. Control of this debris, as well as control of traffic, should be considered when selecting and installing a barrier system.

E-2 **BARRIER RESPONSE TO EXPLOSIVE LOAD TESTING**.

A large test program, Barrier Assessment for Safe Standoff (BASS), was conducted in 2001 for the USAF Force Protection Battlelab (FPB). Full-scale ECF/ACP vehicle barriers were subjected to detonations of bare explosives. The primary objectives of the effort were to analyze the secondary debris hazard for typical reinforced concrete ECF/ACP vehicle barriers and to identify barrier modifications that would minimize or eliminate this debris hazard.

Twelve barrier tests were conducted, with two barriers used per test. Various barrier, charge weight, and standoff distance configurations were tested. The tested barriers included:

- Jersey
- Jersey with soil revetment
- Bitburg
- Bitburg with soil revetment
- Jersey with polymer liner applied
- Cellular Jersey with polymer liner applied
- Jersey with rock/gravel fill revetment

- Back-to-back Bitburgs
- Texas
- Plastic, sand-filled barrier

Data collection included barrier debris pickup in designated areas behind each barrier, high-speed video of debris flight to aid in measuring debris velocities, documentation of the barrier response to the blast load, and free-field pressure measurements at specific locations in the debris fields.

Based on the barrier debris collected and analyzed in this study, some barrier systems are more effective than others at reducing the potential secondary debris hazard from a vehicle bomb detonating at an ECF/ACP. The addition of a soil revetment to common barrier configurations significantly reduces debris hazards. Depending on the amount of explosives and the standoff distance from the barrier to the charge, the barriers with a soil revetment either do not break up, or the debris are thrown considerably lesser distances than the same barrier configuration without soil revetment. A rock/gravel revetment presents only a slightly worse hazard than a soil revetment, if only the throw of the barrier debris is considered. Maximum debris distances measured from tests with Jersey reinforced concrete barriers backed by a rock/gravel revetment exceeded debris distances measured in tests of Jersey barriers backed by a soil revetment by less than 20%. It should be noted, however, that debris from the rock/gravel revetment could also be thrown and could cause damage (such as window breakage) to buildings within the installation.

The polymer liner applied to a Jersey barrier does not offer any improvement to the debris hazard from a Jersey barrier. Lightweight concrete and sand-filled plastic barriers produce significantly reduced debris hazards. This may seem attractive in selecting a barrier system to minimize barrier debris throw upon detonation of a vehicle bomb. However, subsequent counter-mobility testing of these barriers showed failure in stopping the vehicle and preventing access through an ECF/ACP, making them undesirable for use at an ECF/ACP.

The tests also showed that the vehicle-to-barrier standoff used at an ECF/ACP is equally important. Generally, using terminology from UFC 4-022-01, this standoff distance refers to the distance between the access control zone (inspection site) and the final debris barriers in the response zone. The larger 35-ft (10.7-m) standoff decreased debris hazards for all barrier systems tested. It was recommended that the standoff distances be increased from 10 ft (3.05 m) to 35 ft (10.7 m) at ECF/ACPs, where possible. It is recognized that a vehicle could potentially move through the access control zone without stopping and through the response zone to impact a barrier. If the vehicle bomb detonates while in direct contact with the barrier, the debris throw is obviously greater than if the bomb detonates 10 ft (3.05 m) or 35 ft (10.7 m) away from the barrier. The use of low-debris barriers in this case is even more attractive.

E-3 **LOW-DEBRIS BARRIER COUNTER-MOBILITY EVALUATION**.

Barriers qualified as low-debris producing barriers when exposed to detonations of typical vehicle bombs do not necessarily meet counter-mobility criteria. Barriers that have been proven to minimize, or eliminate, debris hazards from an explosive threat must still be validated for entry control capabilities. Both detonation response and counter-mobility issues should be addressed when selecting a barrier system for a particular base function, such as in an ECF/ACP.

For instance, the lightweight concrete and sand-filled plastic barriers proven to be low-debris barriers in the 2001 BASS tests did not perform well in subsequent crash tests. The Barriers for Reduced-debris and Counter-mobility Effects (BRACE) test program involved testing of these barrier types for counter-mobility. A baseline performance test was first conducted on a line of ten standard, reinforced concrete Jersey barriers tied together with steel cables. A 15,000-lb (6,820-kg) truck impacted the center of the line of barriers at 30 mph (48 kph). While the line of Jersey barriers successfully stopped the vehicle, neither the lightweight concrete nor the sand-filled plastic barrier was able to stop the vehicle. Two new low-debris vehicle barrier concepts were later devised and tested in another FPB-funded test series, Vehicle Impact Performance Evaluation of Reduced-debris, Counter-mobility Barriers (VIPER-CB).

The low-debris barriers tested in the later program were Hesco bastion concertainers (typically used as perimeter barriers and to provide ballistic and fragment protection) and a modification of the lightweight concrete Jersey barrier with polymer coating. The lightweight concrete, polymer-coated barriers and the steel gate successfully defeated the threat of a 15,000-lb (6,820-kg) truck traveling at 30 mph (48 kph). The depth of penetration of the truck was 16 ft (4.9 m) for the lightweight concrete, polymer-coated barriers. The Hesco bastion concertainers were tested with a 15,000-lb (6,820-kg) truck traveling at 50 mph (80 kph). The concertainers successfully stopped the truck in approximately 5 ft (1.5 m), with no penetration of the payload. Contact HESCO for proper configuration tested as indicated above.

The recommendations from the tests described in this section are to use both low-debris, counter-mobility barriers (Hesco bastion and lightweight concrete, polymer-coated barriers). The low-debris systems adequately protect against the standard threat of a 15,000-lb (6,820-kg) vehicle impacting at 30 mph (48 kph). The Hesco bastion barriers do not require any anchoring. They are simply stacked in layers. To defeat the standard threat above, two rows of barriers on the bottom with a staggered row of barriers on top are sufficient, as shown in Figure E-3. Concrete anchors to existing thick roadways or to specially placed foundations should be used with the polymer-coated, lightweight concrete barrier system.

Figure E-4 shows the cabling and anchor system used to test this system. For the test, the polymer-coated, lightweight concrete Jersey barriers were placed in a line and connected with three 1-in steel cables, as shown in Figure E-4. The cable was 1-in diameter, 6 x 36 extra improved plow steel, with independent wire rope center. A 4-ft long loop was created in the cables at the right end of the line of barriers. The purpose of this loop is to allow some slack in the cable; this reduces the peak tensile force but allows additional penetration of the truck Steel shackles were used to connect the cables to the anchor plate and 1-in cable clips at a 6-in spacing were used to tie the ends of the cables. For this example, the barrier anchoring system was designed to meet a load of 75,000 lb of force in each cable. Anchoring for a similar barrier system should at least meet the same anchoring requirement.

Figure E-3 Hesco Bastion Concertainer Barrier, Oblique View

Figure E-4 Polymer-Coated, Lightweight Concrete Barrier System

E-4 RESTORATION OF DAMAGED BARRIERS.

Another critical consideration in selection of vehicle barriers for use in an ECF/ACP or in other perimeter protection is the amount of time required to restore the barrier system to 100% capability after it has been damaged by exposure to a vehicle bomb detonation. Some barriers can be fully restored to their original protection capability within minutes after the removal of the vehicle debris. Other barrier types may take months to repair and restore to 100%.

Restoration time depends on the type of barrier, whether or not it has a revetment, the size of the vehicle bomb, and the standoff distance between the bomb and the barrier at the time of detonation. Concrete barriers exposed to low design basis threats will have minimal breakup and may just topple over or be slightly displaced. In such a case, the barriers could be reused and re-anchored back into the barrier system. Other barrier types may need to be completely replaced with new barriers. If a revetment was being used, it will have to be rebuilt when the barriers are replaced. Estimates of time required to restore the barrier system to 100% capability is critical information to consider in vehicle barrier selection.

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	Date	Location

This UFC supersedes NAVFAC Military Handbook 1013/10, *Design Guidelines for Security Fencing, Gates, Barriers, and Guard Facilities.*

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects.

Unified Facilities Criteria (UFC)
New Document Summary Sheet

Document: UFC 4-022-03, *Security Fences and Gates.*

Superseding: NAVFAC Military Handbook 1013/10, *Design Guidelines for Security Fencing, Gates, Barriers, and Guard Facilities*.

Document Description and Need:

Purpose: This document is to provide a unified approach for the design, selection, and installation of security fences and gates. The examples provided in the UFC are for illustration only and must be modified and adapted to satisfy service and installation specific constraints. This document is not intended to address procedural issues such as threat level determination and security operations or to provide specific design criteria such as impact forces.

This UFC was developed by consolidating and refining criteria from USACE Protective Design Center, Naval Facilities Engineering Command (NAVFACENGCOM), and available military, government, and commercial sources that are listed in Appendix A of this document.

Application and Use: Commanders, security personnel, planners, designers, architects, and engineers must use this UFC when evaluating existing and providing new security fences and gates.

Need: Fences and gates are primarily used to define perimeters; however, Department of Defense (DoD) and Service regulations require fencing to be provided for certain protected/restricted areas. DoD and Service policies address certain fencing requirements. This UFC focuses on the requirements for security fences, however, the information and design details presented within may also be used for general or perimeter fencing. Modifications to existing fencing are not required to meet this new UFC.

Impact: The following direct benefits will result:

- This document does not set the requirement for security operations at the installation perimeter.
- No additional cost impacts are anticipated by the publication of this document.
- This document does not have any adverse impacts on environmental, sustainability, or constructability policies or practices.

Unification Issues

There are no unification issues.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE

This document provides a unified approach for the design, selection, and installation of security fences and gates for Department of Defense (DoD).

1-2 APPLICABILITY

This document applies to all construction, renovation, and repair projects including expeditionary or temporary construction that include security fencing and gates for DoD. Consult with current Service policies, location of facility, and threat level for specific requirements.

1-3 SECURITY FENCES AND GATES

Security fences and gates are installed and used primarily to define the perimeter of protected areas, such as restricted areas, controlled areas, entry control/access control points, installation perimeters, and to provide a physical and psychological deterrent to entry and preventing unauthorized personnel from entering a protected area.

1-4 SCOPE AND GUIDANCE

Commanders, security personnel, planners, designers, architects, and engineers must use this UFC when evaluating existing and providing new security fences and gates. Technical information considered generally known to security professionals and engineers, or readily available in technical references (Unified Facility Criteria, Military Handbooks, Technical Manuals, etc.) has not been included. This document is not intended to address procedural issues such as threat levels or to provide specific design criteria such as vehicle impact forces.

1-4.1 Drawings

The notional examples provided in the body of this UFC are for illustration and must be modified for the specific application, environmental conditions, and local constraints. The details and drawings identified in Appendix C provide the minimum mandatory requirements and must be modified for the specific application, environmental conditions, and local/project constraints. See paragraph titled ‘Integration With Other Requirements’ for additional direction.

1-5 GENERAL BUILDING REQUIREMENTS

Comply with UFC 1-200-01, *General Building Requirements*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

This UFC is one of a series of unified facilities criteria documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used by a diverse audience to facilitate development of projects throughout the design cycle.

1-5.1 UFC Application

The application of the security and antiterrorism UFCs is illustrated in Figure 1-1. UFC 4-020-01 is intended to be the starting point for any project that is likely to have security or antiterrorism requirements. By beginning with UFC 4-020-01, *DoD Security Engineering Facilities Planning Manual*, the design criteria will be developed that establishes which of the other UFCs in the series will need to be applied. The design criteria may indicate that only the minimum standards need to be incorporated, or it may include additional requirements, resulting in the need for application of additional UFCs. Applying this series of UFCs in the manner illustrated in Figure 1-1 will result in the most efficient use of resources for protecting assets against security and antiterrorism related threats.

1-5.2 Requirements Determination

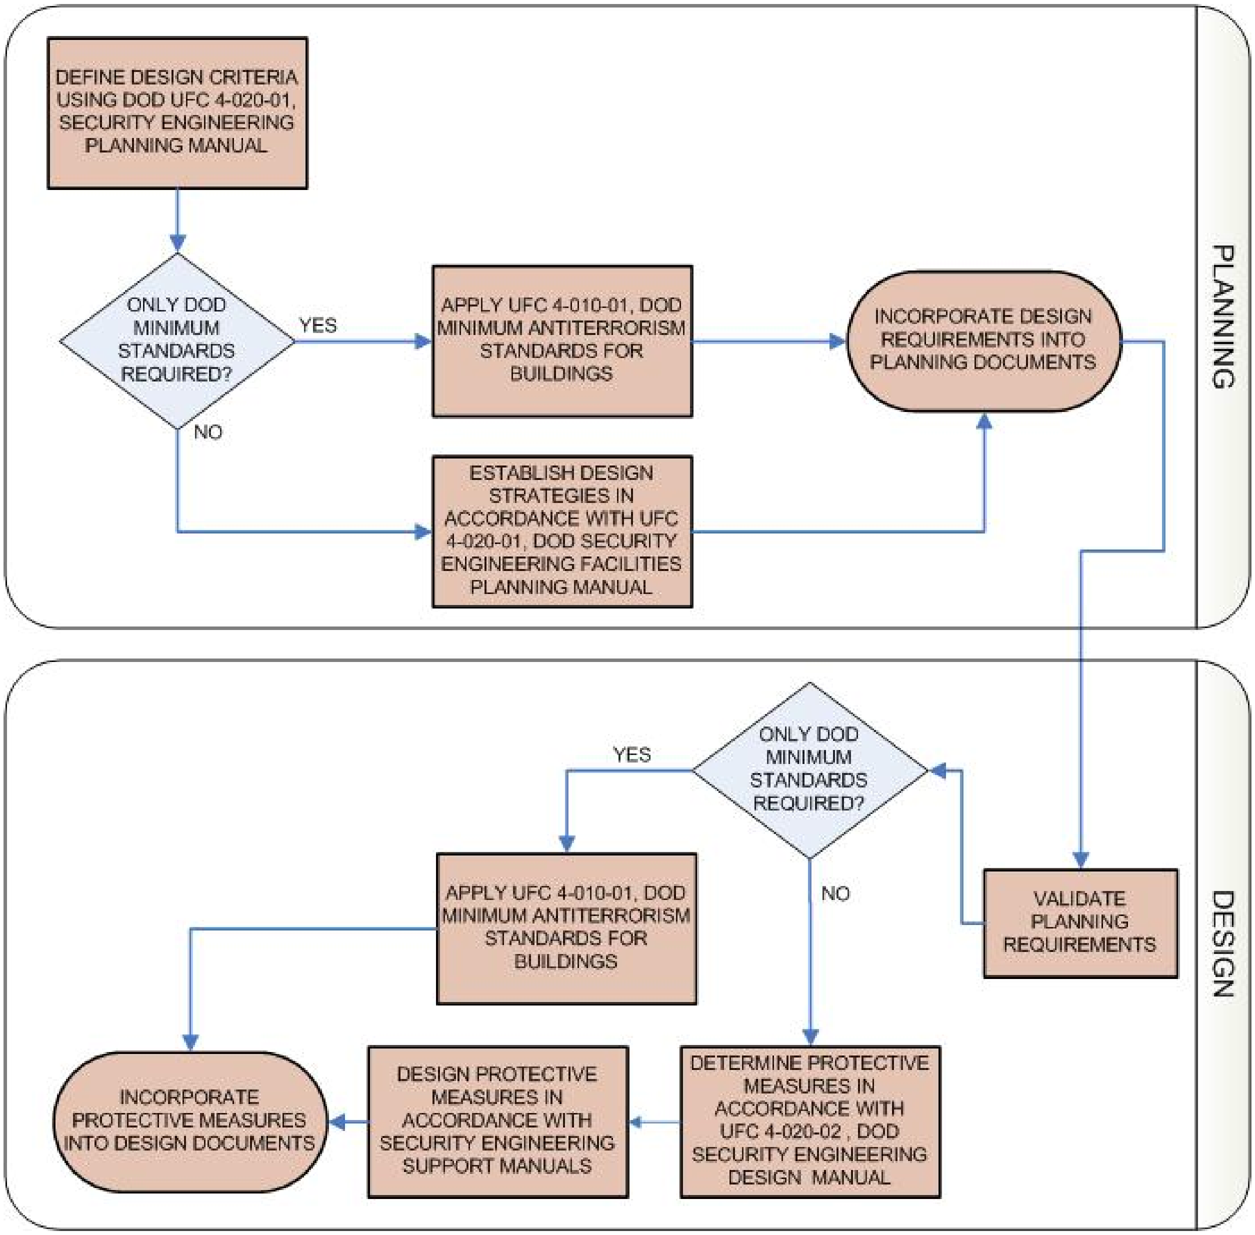
UFC 4-020-01 includes a process for defining the design criteria for a protective system that protects important assets associated with a permanent facility or one in an expeditionary environment. The design criteria will consist of the assets to be protected, the threats to those assets, the degree to which those assets will be protected against the threat, and any constraints that might be imposed on a design. The design criteria may be limited to that defined in minimum standards or it may go beyond those requirements.

Establishing the design criteria for security and antiterrorism is not something that can be done effectively by any one person. It requires a team of people to ensure that the varied interests relating to a project are considered appropriately. The specific membership of a planning team will be based on local considerations, but in general, the following functions should be represented - Facility User, Antiterrorism, Intelligence, Operations, Security, Logistics, Engineering, and Resource Management. Based on local considerations, there may be others who should be consulted for input into the design criteria. They might include Fire Marshals, communications people, environmental people, and historic preservation officers.

1-5.3 Integration With Other Requirements

Security and antiterrorism requirements will never be the only requirements associated with a project. Even where a project is specifically for security and antiterrorism upgrades, there will still be other requirements that must be considered. There will be times where one criterion is more stringent than another, in which case the more stringent one must be applied. In some cases, criteria may conflict. In those cases, those conflicts must be resolved, which may require compromise or adjustment to one or the other criteria. Many security regulations specify protective measures, policies, and operations related to security. This UFC is intended to complement those existing regulations, not to contradict or supersede them. Regulatory requirements must be accommodated and coordinated.

Figure 1-1 Security and Antiterrorism UFC Application



1-6 VULNERABILITY AND RISK ASSESSMENT

In accordance with DoD O-2000.12H Antiterrorism Handbook, a vulnerability and risk assessment must be conducted prior to beginning any security project. Upon identifying facility or asset vulnerabilities to threats, physical security measures such as security fences, gates, and Electronic Security Systems (ESS) may be deployed to reduce vulnerabilities. In summary, this UFC assumes the pre-design phases, including the risk analysis, are complete prior to beginning design. For information on Security

Engineering Planning and Design process, refer to UFC 4-020-01 and UFC 4-020-02. The engineering risk analysis conducted as part of UFC 4-020-01 must be consistent with the terrorism risk analysis conducted by the installation security/AT staff.

1-7 POLICY REQUIREMENTS

The requirement to protect installation assets comes from DoD Instruction/Directives, Geographic Combatant Commander (GCC) Instructions, Service Instruction/Directives, and Regional or Installation requirements. Consult Headquarters, Major Command, Regional, and Installation personnel to established installation asset protection requirements.

1-7.1 Department of Defense (DoD)

There are several instructions and publications within the Department of Defense that establish requirements for access control and physical security for installation perimeter, restricted access areas and other secure areas.

1-7.1.1 DoD Physical Security Program

DoD 5200.8-R: Requires DOD Components to determine the necessary access control based on the requirements of a developed physical security program. Emergency planning is specified to include establishment of a system for positive identification of personnel and equipment authorized to enter and exit the installation and maintenance of adequate physical barriers (i.e. security fences and gates) that will be employed to control access to the installation.

1-7.1.2 Physical Security of Sensitive Conventional Arms, Ammunition, and Explosives (AA&E)

DoD 5100.76-M prescribes minimum standards and criteria for the physical security of DoD sensitive conventional AA&E. This Manual establishes the requirements to protect sensitive AA&E including perimeters, openings, and security fences.

1-7.1.3 Nuclear Facilities

DoD S-5210.41-M Vols. 1-3, AFMAN 31-108, OPNAVINST 5210.16, and AR 190-54 prescribe policy, responsibilities, procedures, and minimum standards for the security and safeguarding of DoD nuclear reactors, special nuclear materials and weapons including perimeters, openings, and security fences.

1-7.1.4 DoD Antiterrorism Program

DoDI 2000.12: Provides DoD policies for ATFP and assigns responsibilities for implementing physical security systems as part of the DoD ATFP Program. It authorized the publication of DODI 2000.16 Antiterrorism Standards as the DoD standards for ATFP and DoD O-2000.12-H DoD Antiterrorism Handbook as guidance for the DoD standards.

1-7.1.5 DoD Antiterrorism Handbook

DoD O-2000.12H: Defines the DoD Force Protection Condition (FPCON) System, which describes the potential threat levels and the applicable FPCON measures to be enacted for each level. FPCON measures in the 12-H were modified in DoDI 2000.16, Change 2 of 08 Dec 2006. DoD O-2000.12H also requires Commanders to develop and implement Random Antiterrorism Measures (RAM) as an integral part of their AT Program. This handbook provides a detailed discussion on physical security functional requirements of which physical barriers (security fences and gates) are integral.

1-7.1.6 DoD Antiterrorism Standards

DoD I 2000.16: This instruction requires the installation or activity Commanding Officer to define the access control measures at installations. Additionally, DoDI 2000.16 requires Commanders at all levels to develop as part of the physical security program and implement a comprehensive Antiterrorism (AT) Program, which must define the necessary action sets, including identification and inspection procedures, barrier requirements at each of the potential Force Protection Condition (FPCON) levels and lists the most current approved FPCONS.

1-7.2 Geographic Combatant Commander (GCC) Requirements

GCC issue requirements for Antiterrorism and physical security for installations within their area of responsibility. Ensure any such requirements are incorporated in addition to the requirements found in DoD and Service Directives/Instructions. Resolve any differences in the requirements for the design of perimeter security by applying the most stringent requirement.

1-7.3 Service Requirements

1-7.3.1 Department of Air Force

1-7.3.1.1 AFI 31-101 – Integrated Defense (ID)(FOUO)

This Instruction provides the tools to plan and execute ID. It guides personnel through a familiar 7-step risk assessment process. Furthermore, working groups that are focused on mutually-supporting components of ID, such as the antiterrorism (AT) program and resource protection program (RPP), may be combined and streamlined. This Instruction provides flexible planning and execution opportunities that allow owners/users of various Air Force assets to become actively involved in the defense of their areas; however, some assets must remain secured in accordance with higher headquarters (HHQ) directives, such as nuclear weapons; arms, ammunition and explosives (AA&E); classified information and Defense Critical Infrastructure Program (DCIP) assets.

1-7.3.1.2 AFMAN 32-1084 Civil Engineering: Facility Requirements

This Manual is a tool to assist commanders, their management, and technical staff in programming the acquisition of facilities and in managing the inventory of real property facilities and provides additional guidance for fencing/barrier requirements.

1-7.3.2 Department of the Army

1-7.3.2.1 AR 190-13 The Army Physical Security Program

Implements DOD 5200.08–R. It prescribes policies, procedures, and guidance to plan and implement the Department of the Army Physical Security Program.

1-7.3.2.2 AR 190-16 Physical Security

Establishes standard policies on physical security systems planning, threat statements, control of access to installations, security of aircraft, bulk petroleum assets, and critical communications facilities.

1-7.3.2.3 AR 190-11 Physical Security of Arms, Ammunition and Explosives

Refer to AR 190-11 for physical security criteria for conventional arms, ammunition, and explosives (AA&E) for additional guidance on fencing requirements.

1-7.3.2.4 ATTP 3-39.32 Physical Security: Army Tactics, Techniques, and Procedures (ATTP)

Provides doctrinal guidance for personnel who are responsible for planning and executing physical security programs. It is the basic reference for training security personnel and is intended to be used in conjunction with the Army Regulation (AR) 190 series (Military Police), Security and Antiterrorism Unified Facilities Criteria (UFC) publications, Department of Defense (DOD) directives, and other Department of the Army (DA) publications.

1-7.3.3 Department of the Navy including Marine Corps

1-7.3.3.1 OPNAVINST 5530.14 Navy Physical Security and Law Enforcement

The intent of this instruction is to identify responsibilities and provide guidance for the protection of people and assets throughout the Navy.

1-7.3.3.2 Physical Security of Arms, Ammunition and Explosives

Refer to OPNAVINST 5530.13 for physical security criteria for conventional arms, ammunition, and explosives (AA&E) and additional fencing requirements.

1-7.3.3.3 NTTP 3-07.2.3 Law Enforcement and Physical Security

Provides guidance for the physical security for Naval Installations to include perimeter security and restricted areas.

1-7.3.3.4 MCO 5530.14 Marine Corps Physical Security Program Manual

Provides requirements for physical security for Marine Corps installations and organizations including additional barrier/security fence requirements.

1-7.4 Installation Specific Requirements

As required by DODI 2000.16 and service directives, each installation must have an Antiterrorism Plan. The plan provides procedures and recommendations for reducing risk and vulnerability of DOD personnel, their family members, facilities, and assets from acts of terrorism. As such, the installation AT plan reflects the foundation for requirements determination. Installation specific requirements need to be factored into all capital improvement initiatives.

1-7.5 Airfield Requirements

For Air National Guard (ANG) and Air Force Reserve Command (AFRC) units that are co-located with civilian airports, the airfield side of the restricted areas does not require fencing installation as it is prohibited by the Federal Aviation Agency (FAA) safety requirements. Fencing requirements for airports and heliports are provided in UFC 4-141-10N and UFC 3-260-01.

1-8 PHYSICAL SECURITY

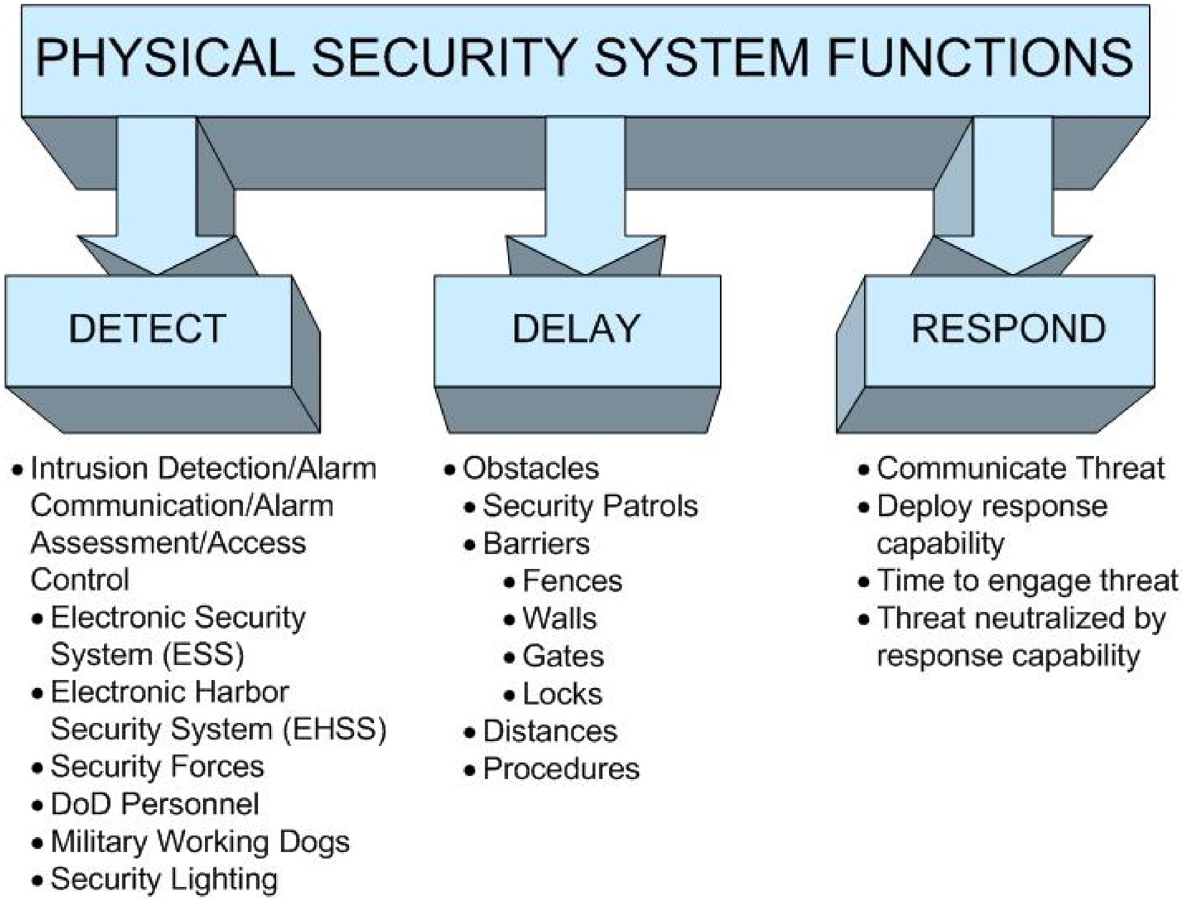
That part of security concerned with physical measures designed to safeguard personnel; to prevent or delay unauthorized access to equipment, installations, material, and documents; and to safeguard them against espionage, sabotage, damage, and theft.

1-8.1 Physical Security System

A system comprised of people, equipment, and operational procedures that control access to critical facilities or assets. Fences are but one of many elements that comprise the equipment component of a physical security system. Figure 1-2 diagrams some of the additional components of a physical security system.

From Figure 1-2, fencing is considered part of the delay function of the overall Physical Security System. However, standard chain-link fencing provides approximately 7- 15 seconds of delay.

Figure 1-2 Diagram of Physical Security System Functions



1-9 EMERGENCY ACCESS

Locate security fence as to not impede emergency vehicle or emergency personnel access to fire hydrants or other fire protection features. Coordinate with installation fire department regarding security fence location as it applies to fire hydrants and other fire protection features. See UFC 3-600-01, Fire Protection Engineering for Facilities for additional information.

1-10 CORROSION PREVENTION CONTROL

Design strategies for installation security structures and equipment must consider corrosion prevention and control (CPC) preservation techniques for long term maintainability throughout their life cycle. Trade-off decisions involving cost, useful service life, and effectiveness must address corrosion prevention and mitigation.

1-10.1 Material Selection and Coatings

Local environments must be considered during the selection of material for the fencing components as well as the required coatings to provide protection against corrosion. Color polymer and other coatings on fencing fabric, fittings, framework, and gates must be applied to enhance visibility and provide greater corrosion resistance, especially in corrosive or salt laden environment. Appendix B defines this environment.

Coating on any fasteners or ties must be electrolytically compatible with fencing fabric to inhibit corrosion. All security fence fittings must be electrolytically compatible with all fence components. Regarding drainage openings (ditches, culverts, vents, metal ducts/pipes, and other opening) consideration must be given to the materials used (smaller metal pipe, metal/steel grillage) in securing such openings. One of the most important corrosion issues is the chemical reaction between dissimilar metals. When dissimilar metals are in contact with one another in the presence of an electrolyte, galvanic action occurs, resulting in the deterioration. The electrolyte may be rain water running from one surface to another, or moisture from the air containing enough acid to cause it to act as an electrolyte. See Appendix A for material specifications.

1-11 REFERENCES

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-12 GLOSSARY

Appendix B contains definitions of terms.

This Page Intentionally Left Blank

CHAPTER 2 FENCING

2-1 FUNCTION

The physical security barrier provided by a security fence provides one or more of the following functions:

- Gives notice of legal boundary of the outermost limits of the protected area.
- Assists in controlling and screening authorized entries into secured/protected areas by channeling vehicles and personnel to access control points.
- Supports surveillance, detection, assessment, and other security functions by providing a platform for installing intrusion detection equipment.
- Deters casual intruders from penetrating a secured/protected area by presenting a barrier that requires an overt action to enter.
- Causes a delay to obtain access to a installation/facility, thereby increasing the probability of detection.

2-2 CHAIN LINK FENCING

Chain link fence is a fencing material made from wire helically wound and interwoven in such a manner as to provide a continuous mesh without knots or ties. See Figure 2-1 below for standard chain link fence details identifying all of the components.

Chain link fences and gates must comply with specification requirements in UFGS 32 31 13, *Chain Link Fences and Gates* and UFGS 32 31 13.53, *High-Security Chain Link Fences and Gates*. Consult with ASTM F2611 and ASTM F1712 for additional guidance (fabric, post, framework, fittings, and other accessories) regarding chain link fencing. Refer also to the Chain Link Manufacturers Institute's Security Fencing Recommendations (CLF-SFR0111) and Product Manual (CLF0PM0610) for additional information.

2-2.1 Chain Link Fencing Fabric

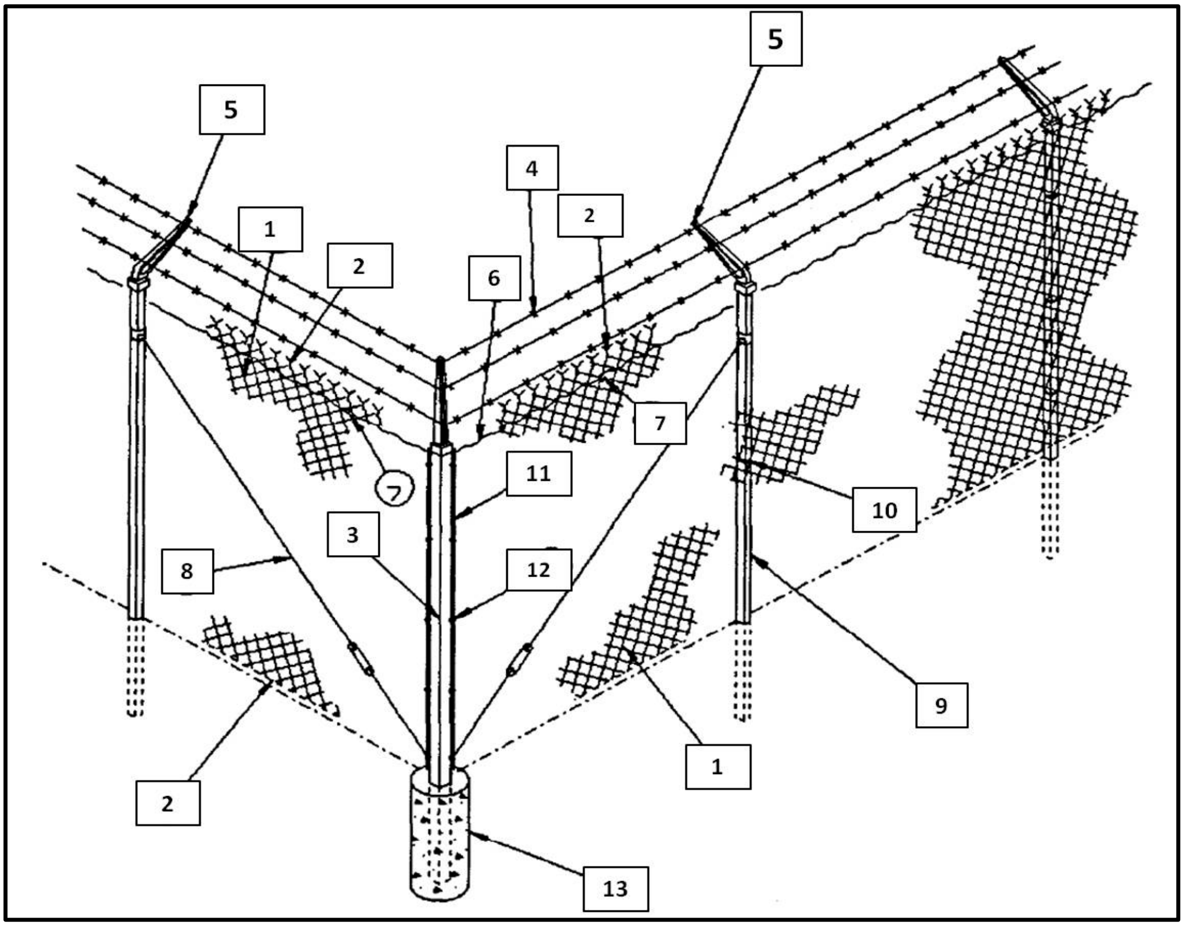
Fencing fabric must be minimum 9-gage wire mesh and mesh openings must be not be greater than 2-inches (51 mm) per side. Fence fabric material will be galvanized steel, PVC coated steel fabric (use PVC coated if located in corrosive environment or where aesthetics are of prime importance), or aluminum coated steel fabric (use aluminum coated if located in corrosive environment). See Corrosion Prevention Control for additional information regarding material selection.

2-2.1.1 Additional Fencing Fabric Requirements

The fencing fabric must be extended to within 2 inches (51 mm) of firm ground and anchored, if required by service requirements, using horizontal bottom rails, tension wires, concrete curbs, sills, sheet piling, piping, or other inexpensive materials. For additional security burying the fabric 12 inches (305 mm) may also be considered; however, corrosion of the buried fabric must be monitored. This anchoring will prevent the fencing fabric from being able to be lifted by hand more than 5 inches (125 mm) in height. Horizontal bottom rails, concrete curbs, or sills can assist in mitigating an intruder from lifting the fence fabric beyond the requirement above. Mesh openings in chain link fencing are intended to not be covered, blocked, or laced with material which would prevent a clear view of personnel, vehicles, or material in outer clear zones.

Locate all posts, rails, bracing and tension wires on the secure/protected side, i.e. inner side, of the fencing fabric. Select the framework components and material from ASTM F626, ASTM F1043, and ASTM F1083.

Figure 2-1: General Chain-Link Fence Components



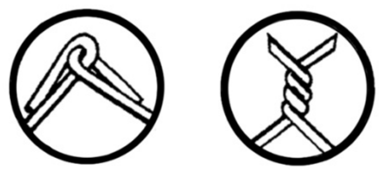
1	Fabric
2	Selvage
3	Corner Post
4	Barbed Wire/Barbed Tape
5	Outrigger/Barbed Wire Arm
6	Tension Wire (Top and Bottom)
7	Hog Ring
8	Truss Rod
9	Line Post
10	Tie Wire
11	Tension Bar
12	Tension Clip
13	Concrete Footing

2-2.1.2 Top and Bottom Selvages

Selvage is the edge finish on woven chain link fabric joining pairs of pickets. The selvage may be knuckled or twisted depending on application. Knuckled selvage is defined as the type of selvage obtained by interlocking adjacent pairs of wire ends and bending the wire back into a loop. Twisted is obtained by twisting adjacent pairs of wire ends together in a close helix of 1 1⁄2 machine turns, which is equivalent to three full twists. See Figure 2-2 for selvage examples.

Twisted selvage must be provided on the top of the fence fabric to deter climbing. Twisted selvage must be provided at the bottom of the fence fabric to deter borrowing unless the fence has a bottom rail, is buried, or encased in concrete. In these applications the selvage may be knuckled.

Figure 2-2 Selvage



2-2.1.3 Fence Posts

Fencing fabric must be mounted on steel posts that are set in concrete with additional bracing at corners and gate openings, as necessary. If steel posts are not available, reinforced concrete posts will be used. Posts, bracing, and all other structural members must be placed on the secure-side of the fencing fabric.

Posts must be vertical within plus or minus 2 degrees in each direction. Determine the embedment depth of the fence posts and associated footings considering wind load, local soil conditions, and the potential for wind and water erosion. Posts for security fencing must be embedded and encased in concrete according to the design details in Appendix C.

2-2.1.4 Fence Bracing

Steel truss rods used for bracing must have a minimum nominal diameter of 5/16 inch (8 mm) and provided with turnbuckles for tensioning. Provide bracing for each gate, terminal and end post. Install truss rods diagonally from near ground level of the gate, terminal or end post to within 6 inches (152 mm) from the top of the fabric at the adjacent line post. Fencing fabric can be securely fastened to tension wires on the top and bottom with 9 gage (3.76 mm) galvanized tie wires incorporating at least three full twists, 9 gage (3.76 mm) round wire galvanized hog rings, or in a manner that provides a tensile strength equal to or greater than the strength of the fencing fabric. Consider securing all fastening and hinge hardware by peening or welding to prevent disassembly of fencing and gate components where warranted by the required level of protection.

See Appendix C for design details of chain link fencing posts, rails, braces, and tension wires.

2-3 ORNAMENTAL FENCES

Ornamental (also known as tubular) fencing provides a greater resistance to climbing as well as providing aesthetic qualities in comparison to chain link fencing. Ornamental fencing systems are constructed of either steel or aluminum components. Install ornamental fence pickets plumb and provide a minimum of 2 inches (51 mm) or maximum of 6 inches (152 mm) between the fence and the ground. See ASTM F2408 for additional guidance for ornamental fence systems. See Appendix C for design details of ornamental fence.

2-4 WELDED WIRE MESH FABRIC FENCING

Welded wire mesh fabric fencing material is composed of a series of longitudinal and transverse steel wires arranged substantially at right angles to each other, and welded together. In comparison to chain link fencing has a greater deterrence to intrusion by climbing and cutting. Welded wire mesh fabric fence openings are relatively small to prevent toe or finger hold. Although the mesh sizes are small, visibility through the fence may be higher than chain link fencing even at sight angles near parallel to the fence line. See ASTM F2453/F2453M for material requirements. Maximum vertical/horizontal opening dimension must be 2 inches (51 mm). Minimum thickness – 9 gage (3.76 mm).

Welded wire mesh fabric fencing construction costs in non-urban environments may be approximately one half of ornamental security grade fencing. See Figure 2-3 for an example of a welded wire mesh fence.

2-4.1 Fence Components, Fittings, and Accessories

Provide welded wire mesh posts in accordance with ASTM F626, ASTM F1083, ASTM F1043, or ASTM A500/A500M. Posts and rails must be designed to resist specified loading and be spaced per manufacturer’s guidance. Connect fencing fabric with a minimum of 9 gage (3.76 mm) tie wires or other connection per manufacturer providing equal or greater capacity and resistance to tampering. If using welded wire mesh fence panels, attach to line and terminal posts and gate frames with post brackets.

Figure 2-3: Welded Wire Mesh Fence

2-5 EXPANDED METAL FENCING

Similar to welded wire mesh fabric fencing, expanded metal fencing is ideal for medium and high security applications. The diamond shaped mesh's small openings and wide strands deter climbing, cutting, and tunneling. Panels are constructed of steel sheets, simultaneously slit, and stretched into a rigid, open mesh design making continuous sheets that prohibit unraveling at the strands. Maximum vertical/horizontal opening dimension must be 2 inches (51 mm). Minimum strand width must be 0.150 inches (9 gage) (3.81 mm).

- In lieu of installing a fence topping, an expended metal fabric cap sheet can be installed at a 45-degree angle extending outside of the secured perimeter and terminating with a turned up vertical section. If additional protection measures are required, barbed tape can be applied to the back of the vertical portion of the cap sheet.

See ASTM F2548 and ASTM F2780 for design, construction, and application of expanded metal fencing systems. Available fence patterns can provide the architectural aesthetics of ornamental fencing. See Figure 2-4 for an example of an expanded metal fence.

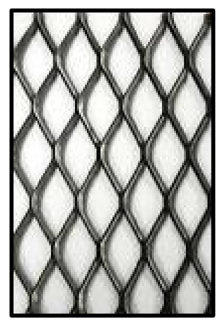
2-5.1 Retrofit Existing Fence

Expanded metal fencing can be applied as a retrofit to existing chain link fencing and gates to provide additional protection, strength, and durability. Expanded metal fencing should be installed directly to the existing fence utilizing the installed chain link fence fabric and framework.

2-5.2 Fence Components, Fittings, and Accessories

Line and terminal posts must be hot-dip galvanized in accordance with ASTM F626, ASTM F1043, and ASTM F1083. The manufacturer's recommendation must be considered when spacing line posts. Top, middle, and bottom rails must be hot-dip galvanized. Rails can be fastened to posts using clamps. Standard weight piping must be used for the posts and rails of expanded metal fencing. Fittings such as line rail clamps, post caps, tension bands, and panel clamps must be galvanized, heavy pressed steel or malleable iron.

Figure 2-4: Expanded Metal Fence



2-6 FARM STYLE FENCES

Farm style fences are constructed of wood and/or metal posts and wire. Farm style fences, barb wire, and woven wire must comply with specification requirements in UFGS 32 31 26, *Wire Fences and Gates* and the drawings in Appendix C. Pressure treat all wood posts and metal posts must be zinc coated and conform to ASTM A702. Steel post conforming to ASTM F1043 must be used in conjunction with T-section or U-section line post. The gates are constructed of 1 5/8 inch (41.3 mm) minimum diameter tubular steel, and secured with a chain and padlock.

See Appendix C for design details of farm-style fence.

2-7 EXPEDITIONARY PERIMETER FENCING

Refer to GTA 90-01-011, Joint Forward Operations Base (JFOB) Survivability and Protective Construction Handbook for perimeter security requirements.

2-8 FENCE FABRIC HEIGHT

Unless otherwise directed all security and perimeter fencing must have a minimum fence fabric height of 7 feet (2.13m), excluding the top guard. Fence height including outriggers must be a minimum of 8 feet (2.44m). Modifications to existing fences are not required to meet this new UFC.

Consult with current Service policies on specific requirements regarding fence height and assets that may require a higher level of protection.

2-9 TOP GUARDS

When required, install outriggers (support arms) at 45-degree angles in a single arm (towards the threat side) or “Y”/”V” configuration, constructed of a single or double outrigger consisting of 18-inch (457 mm) arm(s), each having three strands of barbed wire at regular intervals along the top of the fence.

The outriggers must provide a minimum of an additional 12 inches (305 mm) to the fence height. The top guard fencing adjoining gates may range from a vertical height of 18 inches (457 mm) to the normal 45 degree outward protection, but for a limited distance along the fence line to adequately open the gates. Outriggers must be permanently affixed to the fence posts with screws or by spot welding. Screws used to affix outriggers to posts must be made tamper-proof either by design, peening, or welding.

2-9.1 Outrigger/Barbed Wire Arm Material Specifications

Top guards must be constructed of the same material as the other fencing components in accordance to ASTM F626. See Appendix C for details.

2-9.2 Barbed Wire and Barbed Tape Concertina

Barbed wire is a fabricated wire product consisting of two line wires twisted to form a two-wire strand, into which 2–point or 4–point barbs are tightly wrapped and locked into place at specific intervals.

Barbed tape concertina is a strip of metal, machined to produce clusters of sharp points. Provide three strands of barbed wire, equally spaced, on outrigger/support arms where barbed tape/concertina is mounted.

2-9.2.1 Barbed Wire

Fences requiring barbed wire must use a minimum of 3 strands of barbed wire equally spaced. Additional strands may be added as required. Barbed wire must consist of two 12.5 -gage /0.099-inch (2.5 mm) (+0. 005- inch (.127 mm)) twisted line wires with 15-gage /0.080- inch (2 mm)(+0, 005-inch (.127 mm)) round barbs. Barbed wire must be zinc-coated steel, aluminum coated steel, aluminum alloy, or PVC over zinc-coated steel as specified. All barbs must consist of four points and spacing of barbs must be at 5- inch (127 mm) (+1- inch (25.4 mm)) centers.

2-9.2.1.1 Barbed Wire Material Specifications

Barbed wire must be in accordance to ASTM A121 and ASTM F1665. See Appendix C for barbed wire support configurations.

2-9.2.2 Barbed Tape/Concertina

Barbed-tape concertina is a commercially manufactured wire coil constructed of high-strength-steel barbed wire that is clipped together at intervals to form a single coil or double coil. The single coil must be a minimum of 2 feet (610 mm) in diameter and extend at least 50 feet (15.2 m) without permanent distortion. Double coil must be 24/30 inch (610 mm/762 mm) and extend at least 50 feet (15.2 m) without permanent distortion.

Barbed tape concertina may be added to the top and, in some cases, to the bottom to increase the level of protection. Barbed tape concertina must be secured at a minimum interval of 18 inches (457 mm) along the fence fabric to the top barbed wire strand and a maximum gap of 2 inches (51 mm) must be maintained between the bottom barbed wire and the top of the chain-link fabric. After use, barbed tape concertina may be recoiled and reused without distortion. For additional protection, barbed tape concertina may be installed between the “Y” configuration of the outriggers.

2-9.2.2.1 Barbed Tape/Concertina Material Specifications

Barbed tape concertina must be in accordance to ASTM F1911 and ASTM F1910. See Appendix C barbed tape configurations.

2-9.2.3 Specific Barb Requirements

2-9.2.3.1 Farm Style Fence

Any barbs used with farm fencing must be a minimum of 15.5 gage wire. Barbed clusters must have a minimum width of 1.2 inches (30.7 mm). The distance between these strands is intended not to exceed 6 inches (152 mm) and at least one wire must be interlaced vertically and midway between posts. The ends of the barbed wire strands may be staggered or fastened together, and the base wire may be picketed to the ground. See Appendix C for barbed wire details.

2-9.2.3.2 Barb Wire Fencing

3, 4, or 5-strand barbed wire fencing, 4 feet (1.2 m) high, should be used for extensions of flight-line area barriers, perimeter boundary for isolated portions of installations, livestock barrier, and area boundary for on-base bulk material storage areas. Barbed wire fastened on wooden posts may use a minimum of 1.5 inch (38 mm) staples made from the same metal as the wire for fastening. See Appendix C for barbed wire details.

2-9.2.3.3 Temporary Usage

When used for temporary purposes (not used as fence topper), concertina wire should be used in multiple stacked coils. Stacked concertina wire on perimeter barriers may be laid between poles with one roll on top of another or in a pyramid arrangement (minimum of 3 rolls). Concertina blades must have a minimum length of 1.2 inches (30.7 mm).

Barbed tape concertina as an expedient measure for short-term use, pending the erection of permanent fencing, can be non-reinforced. Reinforce all barbed tape concertina used for permanent security applications.

2-10 GROUNDING

Grounding and bonding of the perimeter systems must be in accordance with the National Electric Safety Code (NESC) - IEEE C2. Fences that are required to be grounded by NESC must be designed to limit touch, step, and transferred voltages in accordance with industry practices. IEEE Std 80™-2000 - IEEE Guide for Safety in AC Substation Grounding is one source that may be utilized to provide guidance in meeting these requirements.

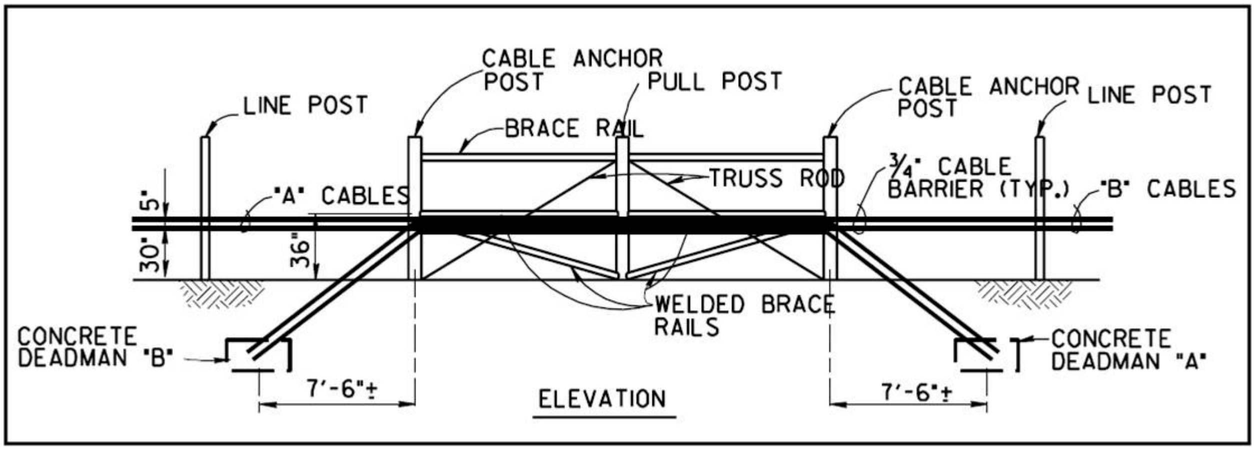
The grounding connections must be made either to the grounding system of the enclosed equipment or to a separate ground.

1. Fences must be grounded at each side of a gate or other opening.
2. Gates must be bonded to the grounding conductor, jumper, or fence.
3. A buried bonding jumper must be used to bond across a gate or other opening in the fence, unless a nonconducting fence section is used.
4. If barbed wire strands are used above the fence fabric, the barbed wire strands must be bonded to the grounding conductor, jumper, or fence.
5. When fence posts are of conducting material, the grounding conductor must be connected to the fence post or posts, as required, with suitable connecting means
6. When fence posts are of nonconducting material, suitable bonding connection must be made to the fence mesh strands and the barbed wire strands at each grounding conductor point.

2-11 REINFORCEMENT FOR FENCING

Refer to UFC 4-022-01 and 4-022-02 for additional guidance and requirements (number and size of cables) on fence reinforcement for identified moving vehicle threat. For fabric type fences install fence reinforcement between fence fabric and fence post. For both fabric type and ornamental fences reinforcement must be installed on exterior side of fence post. If located in a corrosive environment, coated or sheathed cable may be used; however, the sheathing must be removed at the connections. See Figures 2-5/2-6 and Appendix C for design details of fence reinforcement. See Appendix A for material specifications.

Figure 2-5 Steel Cable-Reinforced Chain Link Fence



2-11.1 Deadman Anchor

Reinforcing cables must be terminated to concrete deadman anchors. Anchors are to be placed at intervals of 200 feet (61 m) on the secure/protected side of the perimeter fencing. Offset deadman anchors from fence at the minimum distance required to avoid interference with post and to allow maintenance access to the turnbuckles, clamps, and other accessories.

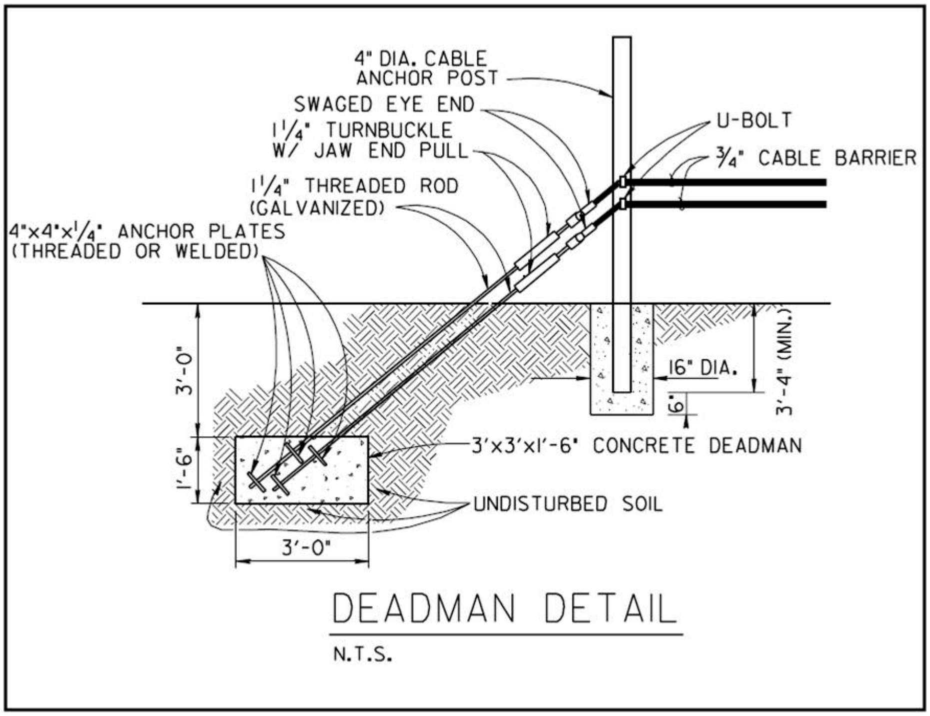
The anchoring system: deadman dimensions or other anchoring systems and burial depth, eyebolt embedment depth, etc. must be designed for local soil conditions and the anticipated impact force established by the threat parameters defined in UFC 4-022-02. See Appendix C for design details of deadman anchors.

2-11.1.1 Cable Connection

Eyebolts embedded in the concrete deadman anchors may have either a welded “T” or “L” end. The eyebolt can either be in-line with the attached cable or flush against the deadman surface. When used, eyebolts should be welded and galvanized to the anchor rods. The top side of the deadman can either be placed flush with or below the ground surface with the eye of the eyebolt above ground. Threaded rods may also be used as an alternative to the eye bolt when securing the cables to the deadman anchor. When using threaded rods, the threaded rod and wire rope connection must be visible above ground like the eyebolt previously described.

Figure 2-6 and details in Appendix C show the deadman position using a cable clamp and turnbuckle to secure the cable rather than a swaged on clamp. This turnbuckle adds the advantage of being able to adjust the tension of the cable.

Figure 2-6: Deadman Anchor Detail



2-12 SPECIAL SECURITY FEATURES

2-12.1 Clear Zones

Clear zones are areas established around the fence to provide and unobstructed view to enhance detection and assessment around fences. When required, dimensions of clears zones vary depending on asset being protected and level of protection. For example, outer clear zones may be 30 feet (9 m) wide and inner clear zones may be 20 feet (6 m) wide. Consult with Service policies for assets being protected to determine if clear zones are required and what dimensions are required.

2-12.2 Double Fence Lines

Assets that require Electronic Security Systems (ESS) for perimeter security may require a double fence line. Perimeter ESS and double fence lines typically associated with assets that require a high level of protection for the force or covert entry tactic. This system is intended to increase the probability of detection, decrease nuisance alarms, and prevent access to ESS. The typical configuration is outer clear zone, outer fence, isolation zone, inner fence, and inner clear zone. See Figure 2-7a/b below.

2-12.2.1 Outer Fence Line

Outer fence line acts to reduce the Nuisance Alarm Rate (NAR) by keeping animals, people, vehicles, and windblown debris out of the isolation zone. No sensors should be placed on the outer fence of a double fence line system. In some instances the outer fence line may define a protected or restricted area boundary. In the case where the outer fence line defines a protected or restricted area boundary, the outer fence must meet the minimum requirements as set forth in this UFC.

2-12.2.2 Isolation Zone

The isolation zone is the area between the inner and outer fence lines sometimes referred to as the detection zone and must meet clear zone requirements indicated above. The area must be free of all vegetation and above ground obstructions except for the ESS and its supporting infrastructure. The isolation zone is typically light colored gravel or crushed stone bed sloped to prevent standing water. This reduces maintenance, increases probability of detection, and enhances the assessment capability within the fence lines.

2-12.2.3 Inner Fence Line

The Inner fence line provides the inner boundary for the isolation zone and defines the protected or restricted area boundary. It may be used for mounting of fence line detection systems such as taut wire, Time Domain Reflectometry (TDR), or fiber-optic strain-sensitive cable systems, refer to UFC 4-021-02 for sensor types and applications. When used as a foundation for fence line detection systems, the fence meet the following minimum requirements.

2-12.2.3.1 Inner Fence Fabric

Fence fabric material must be in accordance with ASTM A491 and must comply with minimum requirements set forth in this UFC.

2-12.2.3.2 Inner Fence Components, Fittings, and Accessories

Select the framework components and material from ASTM F626, ASTM F1043, ASTM F1083, and ASTM F1712 in addition to the following:

1. End, corner, and pull posts will be concrete filled.
2. Gateposts must be minimum of 4-inch (102 mm) outside diameter (O.D.) and be sized according to Table 2-1.
3. Three (3) tension bands must be used. Top tension wire must be 7.5-inches (191 mm) below top of fabric with the other two (2) bands located approximately 31(787) and 56.5 (1435) inches (mm) down respectively from the top of fence fabric.

Table 2-1 Fence Type Components

PIPE	SIZE
Bottom or Brace Rails	1 5/8 in (41mm)
Line Posts	2 ½ in (63.5mm)
Corner, end and pull posts)	4 in (102mm)
Single Gate Posts – equal or less than 12ft (3.7m) Width	4 in (102mm)
Double Gate Posts – equal or less than 24ft (7.3m) Width	4 in (102mm)
Single Gate Posts – greater than 12ft (3.7m and less than 18ft (5.5m) Width	6 5/8 in (168 mm)
Double Gate Posts – greater than 24ft (7.3m) and less than 36ft (11m) Width	6 5/8 in (168 mm)
Single Gate Posts – over 18ft (5.5m) Width	8 5/8 in (219 mm)
Double Gate Posts – over 36ft (11m) Width	8 5/8 in (219 mm)

Figure 2-7a: Double Fence Line

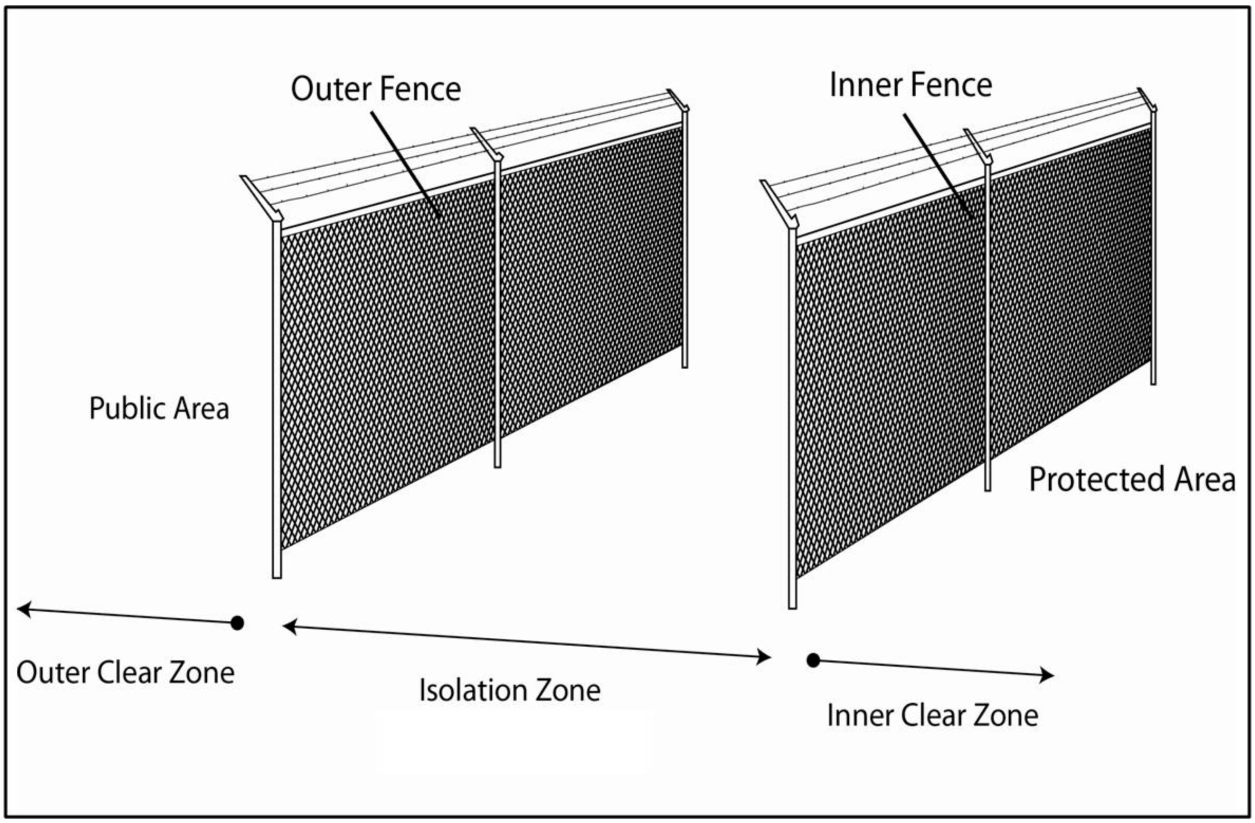


Figure 2-7b: Double Fence Line

2-12.3 Fence Line Electronic Security Systems

Electronic Security Systems (ESS) may be used to increase the probability of detection and the assessment of intruders attempting to enter restricted areas. ESS includes Intrusion Detection Systems (IDS), Access Control Systems (ACS), and Closed Circuit Television (CCTV) for assessment of alarm conditions. The design of fences and gates must support the site specific design of the ESS as required. Further information on Electronic Security Systems can be found in UFC 4-021-02.

2-12.4 Security Lighting

Security lighting or protective lighting provides illumination during periods of darkness or in areas of low visibility to aid in the detection, delay, and respond functions of a physical security system. Coordinate security lighting requirements with security personnel. Refer to UFC 3-530-01 for lighting design criteria.

2-12.5 Patrol Roads

When required provide an interior, all-weather perimeter road in all areas not affected by impassable terrain features for security-patrol vehicles. Drainage ditches parallel to patrol roads should be designed to utilize shallow or low angle side slopes to prevent obscuring the observation from a 4-foot (1.2 m) high line of sight above the road surface. Where patrol roads pass through clear zones, precautions must be taken in roadway design to preclude concealment for intruders.

2-12.6 Drainage Culverts and Utility Openings

Provide protective measures for culverts, storm drains, sewers, air intakes, exhaust tunnels, and utility openings, that have a cross-section area of 96 square inches (61,939 square mm) or greater, with the smallest dimension being more than 6 inches (152.4 mm) and :

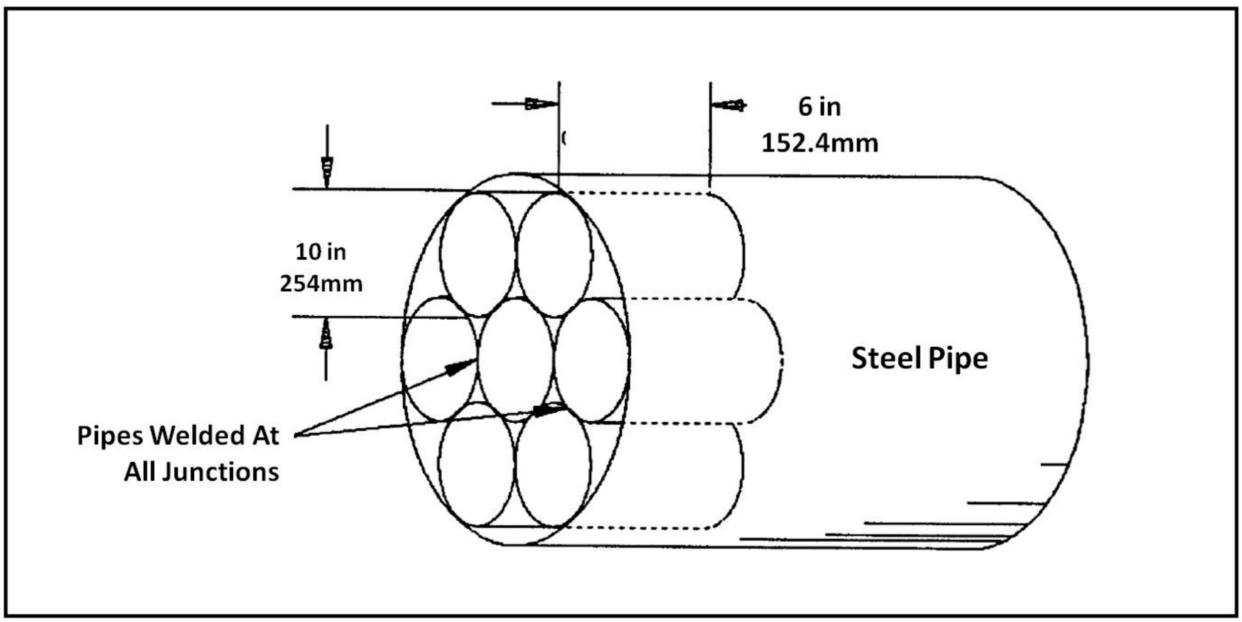
1. Pass through clear zones.
2. Traverse under or through security fences.

Such openings and barrier penetrations will be protected by securely fastened grills, locked manhole covers, or equivalent means to prevent entry or provide forced entry penetration resistance equal that of the fence. Regarding material selection for securing openings/penetrations see Material Selection and Coatings.

2-12.6.1 Large Diameter Pipes – Multiple Pipes

If drainage conditions require large diameter pipes, or if it is a more economical approach to provide security protection, drainage openings may be constructed of multiple pipes having individual diameters of 10 inches (250 mm) or less Extend multiple pipes through the entire conduit, secured to each other and to the large opening. As an economical alternative, reduce the pipe lengths to short segments approximately 6-inches (152 mm) long. Place the short segments at the attack side of the opening and secure them to the welded bar grill. See Figure 2-8.

Figure 2-8: Large Culvert with Short Pipes



2-12.6.2 Large Diameter Pipes – Grilled Configuration

Steel pipes that pass under fences must have grills welded to the pipe as shown in Figure 2-9. For concrete pipes that pass under fences, the grill ends must be welded to a steel rim that fits snugly over the concrete pipe. The rim and grillwork will be fastened over the concrete pipe and bolted or pinned to the rim of the concrete pipe as shown in Figure 2-10. Grill ends may be embedded in a concrete headwall that encapsulates the concrete pipe. Grills must be placed on attack side of the fence. Care must be taken during design to assure that bars and grills across culverts are not susceptible to clogging. All utility openings are intended to be designed with a debris catcher to permit either rapid clearing or removal of grating for cleaning when required. Steel used for grill must be in accordance with ASTM A529 and the corrosion prevention control section of this UFC.

Figure 2-9: Steel Culvert Grill

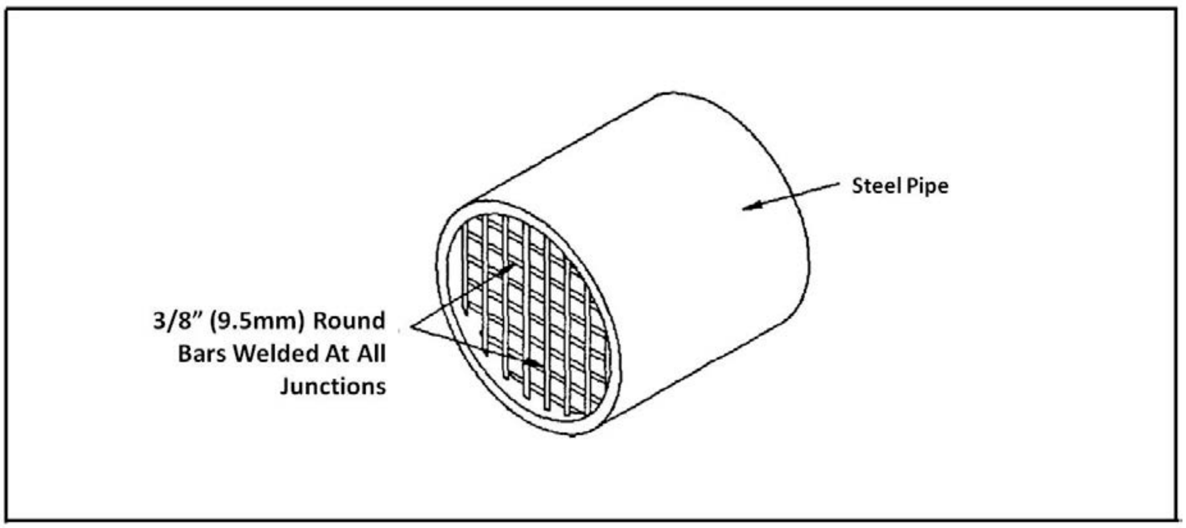


Figure 2-10: Concrete Culvert Grill

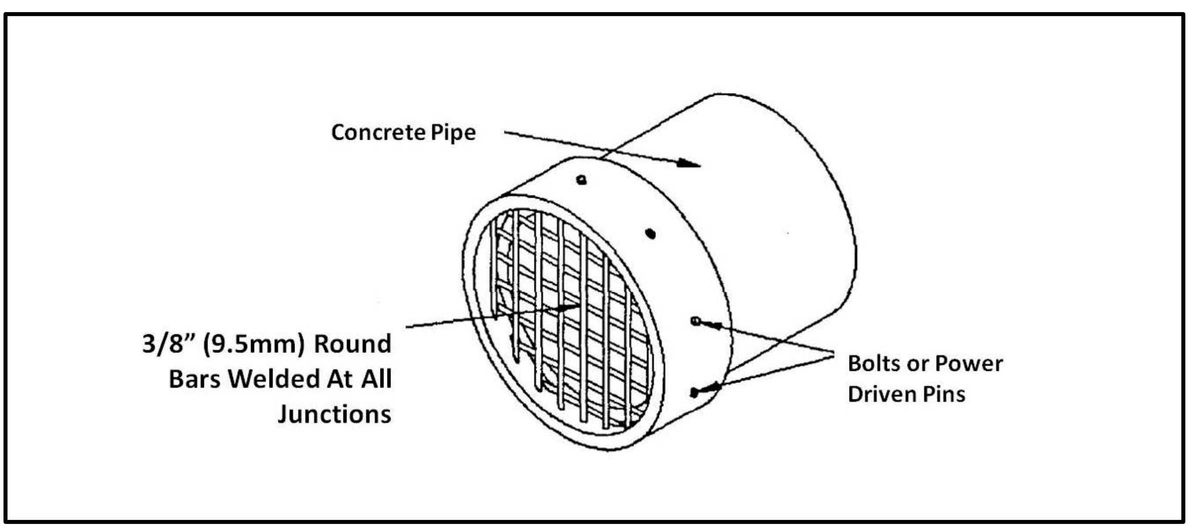

2-12.6.3 Utility Openings

Inlets for utility openings that are outside of the fence line must have a debris catcher with grating. As shown in Figure 2-11a/b below, inlets for utility openings that are outside of fence line must have a debris catcher (i.e. chain link fabric) with the grating on the inlet side. Caution must be taken when using debris catchers to ensure that plugging and flooding of the area surrounding the headwall do not occur.

2-12.6.4 Additional Considerations

In lieu of installing a grill in the utility pipe itself, provide manhole covers, 10 inches (254 mm) or more in diameter, covering a utility which passes through security perimeter fencing of a restricted access area and secure with locks and hasps or by welding them shut or by bolting them to their frame, or by using keyed bolts. Hasps, locks, and bolts must all be made of materials that resist corrosion.

Figure 2-11a: Utility Openings

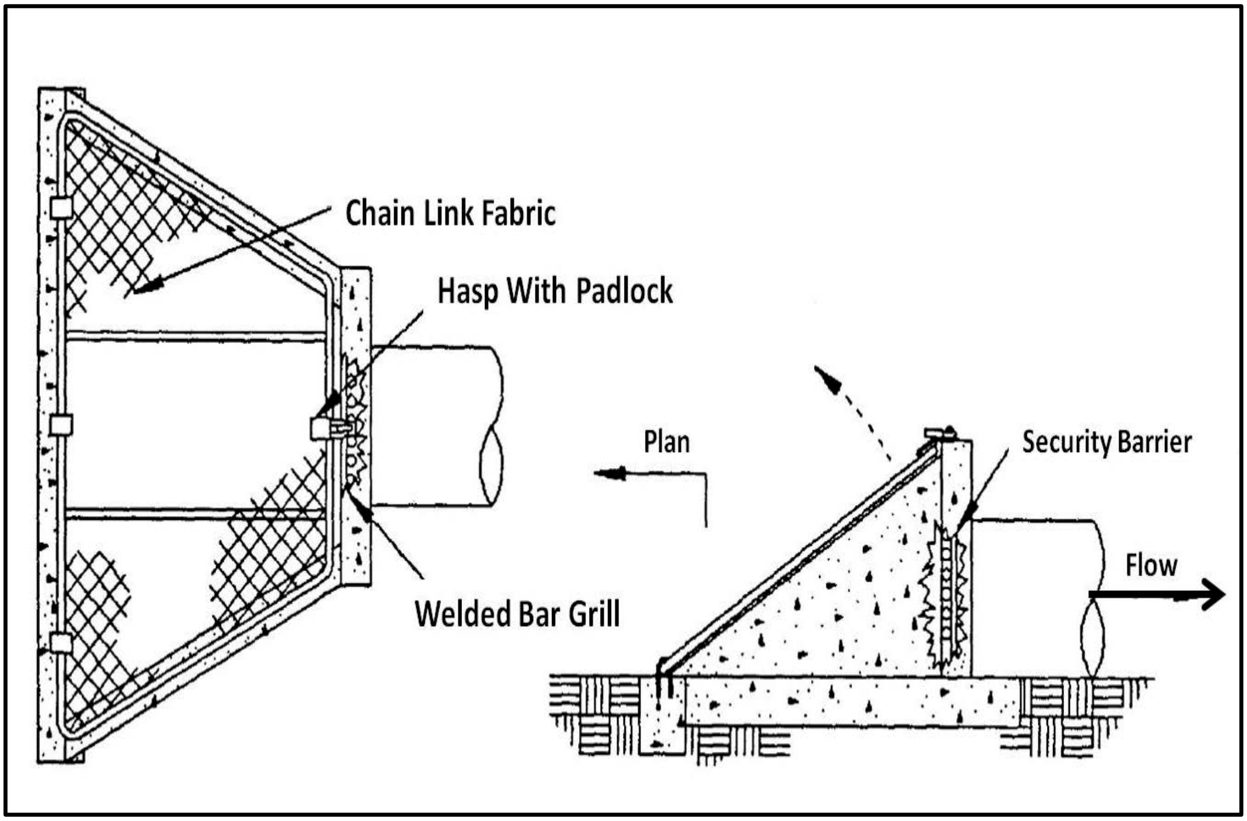

Figure 2-11b: Utility Openings

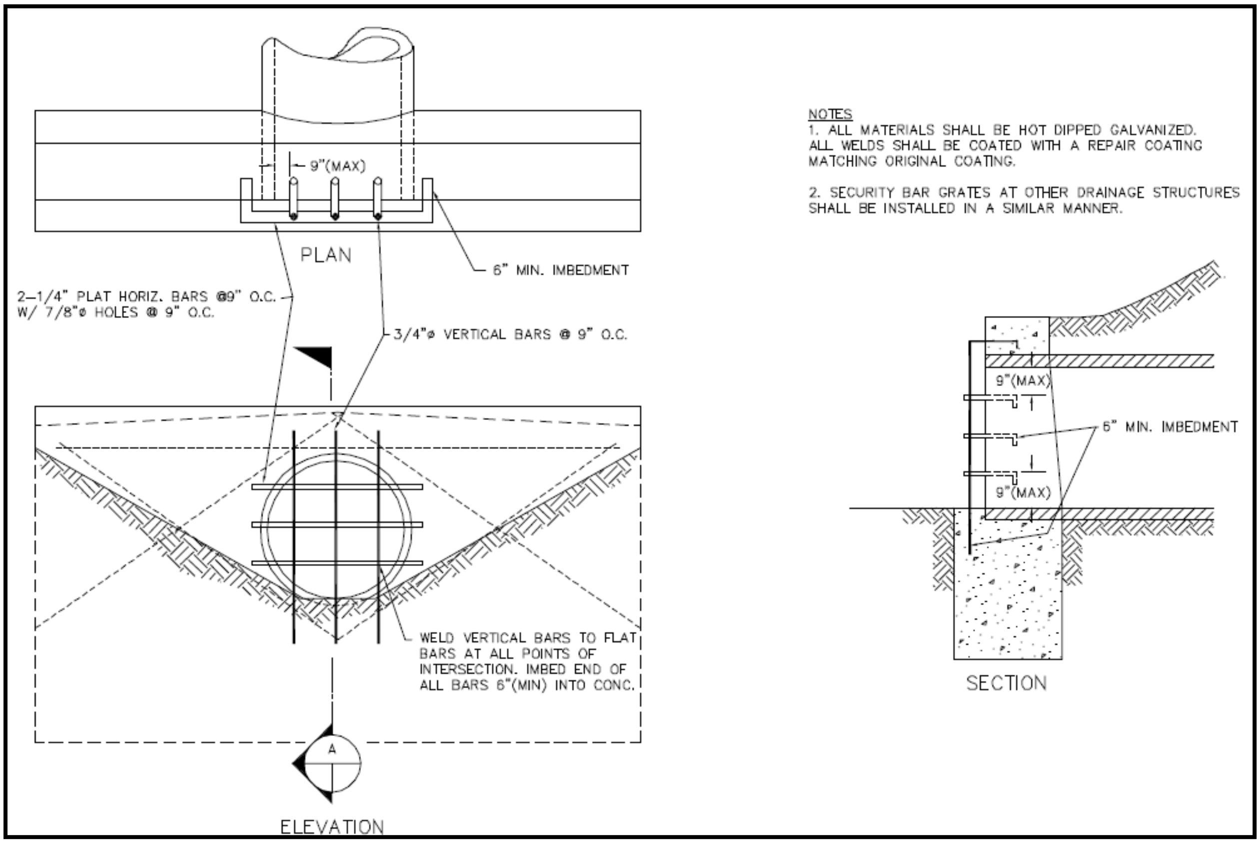

2-12.7 Drainage Crossing

Fencing passing over ditches or swales is intended to provide protection to prevent unauthorized entry. Ditches and swales that do not receive frequent water flow must provide additional fencing below, suspending from the lower rail of the main fence to the auxiliary frame and around the sides of the ditch. See Figure 2-15. The added fence must be attached every 2 inches (51 mm) along the intersection of the two fence sections and either attached to a series of ground stakes secured to the sides and bottom of the ditch, or embedded in a concrete sill in the ditch or swale as shown in Figures 2-12 and 2-13. Concrete curbing must be used to fill areas between fencing and ground surface.

Provide a screen arrangement below fencing using vertical and/or horizontal steel bars or pipes for ditches and swales receiving frequent water flow. Provide a maximum spacing of 9 inches (229 mm) between either vertical or horizontal bars. Possible debris must be considered when designing the spacing between bars. Crossing bars must be welded at each intersection, with bars embedded 6 inches (152 mm) into concrete and fastened to the bottom rail of the crossing fence. See Figures 2-14a/b/c/. Analyze the hydraulic capacity of ditches, swales, and culverts to verify the bar grills will not decrease the channel flow capacity below the maximum expected design flow.

Steel used for grill must be in accordance with ASTM A529 and the corrosion prevention control section of this UFC.

2-12.8 Tunneling Prevention

Soil under fence must provide a minimum of 15 seconds of tunneling resistance using hand tools. Tunneling prevention must be used in areas containing “soft” soils. UFC 3-220-10N describes “very soft” and “soft” soils as those that can be extruded between fingers when squeezed and/or molded by light finger pressure. Classification of soils must be in accordance with ASTM D2487, Standard Practice for Classification of Soils for Engineering Purposes (Unified Soil Classification System), and ASTM D2488, Standard Practice for Description and Identification of Soils (Visual-Manual Procedure). Areas with a soil analysis indicating that “soft” soils are present must embed fencing in a continuous concrete curb. The recommended depth of the curb will be determined from the soil analysis and the frost depth at the facility. The frost depth for the subject areas must be considered to assure that heaving of posts and curb cannot occur during the winter. If the soil analysis does not indicate tunneling may occur quickly, continuous concrete curbing may still be considered as an added protective measure. Nuclear sites with very sandy terrain are directed to have a soils engineering analysis to determine the recommended depth of the concrete curb. Restricted access facilities with a risk of tunneling may provide IDS for tunneling protection. Welded wire mesh fence systems may incorporate additional fence panels for burial on the secure-side of the perimeter and tie-wired to the vertical panels to deter tunneling.

CHAPTER 3 GATES

3-1 GATES OVERVIEW

3-1.1 Access Control

Access Control is a primary design consideration for gate systems. The design of gates must consider and address the following items to ensure proper specification of power-operator accessories and controls. See Appendix C for details of standard gates.

- Pedestrian traffic
- Reversing devices to keep gates from closing on vehicles
- Traffic flow
- Number of open and close cycles
- Type of vehicles
- Operational site security plan
- Provide lighting in accordance with UFC 3-530-01, *Design: Interior and Exterior Lighting and Controls.*

Gates, as part of perimeter fences, must be as effective as their associated fence to provide an equivalent deterrent. Gates will normally require additional hardening features due to their location across entrance roads and the inherent vulnerability of their hinges and latches. Gates are known to be the weakest point in the perimeter security fence and as such, attention must be paid to their requirements when designing security fencing. Materials used in fabricating and erecting chain-link gates must be the same as the materials used for the associated chain-link fence. A primary concern for gate design associated with security fences is to assure that the bottom of the gate fabric extends within 2 inches (51mm) of the roadbed or firm soil when closed. Where possible, pedestrian and vehicular gates should be clearly separated and defined.

3-2 PERSONNEL GATES

Personnel gates are intended to be designed to permit only one person to approach the guard at any time. Turnstile gates may be considered to control personnel entry.

Gates must conform to the Architectural Barrier Act (ABA) Accessibility Standard for Department of Defense Facilities as adopted by the Deputy Secretary of Defense memorandum dated October 31, 2008.

3-2.1 Single Swing Gates

Design single swing gates to match fence fabric height, with an additional 1 ft (305 mm) of three strand barbed wire added to the height if barb wire is part of the fence structure. The gate opening should not exceed a width of 14 ft (4.3 m). See ASTM F900 for additional gate requirements.

For pedestrian use, single swing gates may be considered as the second alternative to turnstile gates. See Figure 3-1 for a fixed and welded single swing gate example

3-2.2 Turnstile (Rotational) Gates

Turnstile gates are manufactured as single or tandem and are available for ABA access. Tandem turnstile gates should be considered where high volumes of pedestrian traffic are exchanged from both sides of the perimeter such as shift work. Only full height turnstile gates are permitted for access through security fencing. Automated access control systems such as card readers, push button, and wireless remote can be incorporated to access turnstile gates. Metal detectors and counters are also available as accessories. Movement of travel can be set for clockwise, counterclockwise, or bi-directional. Arms and barrier tubing are 1-3/4 in (44.5) diameter, 14 gage. Overall exterior height is 91 in (2.31 m) with a pedestrian walk through height of 84 in (2.13 m).

Provide canopy or barbed wire/barbed tape over top channel between adjacent fence posts. Provide Barbed wire/tape in accordance with Chapter 2. See Figure 3-2 for a turnstile gate example. See Appendix C for design details of turnstile (rotational) gates.

Figure 3-1: Single Swing Gate

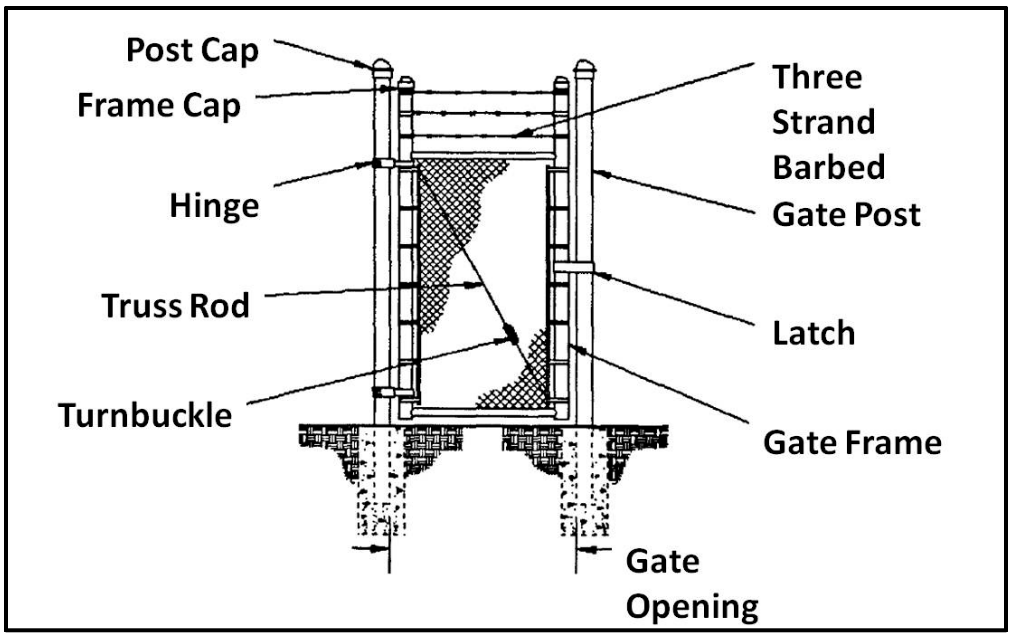

Figure 3-2: Turnstile/Turnstile with Barbed Wire

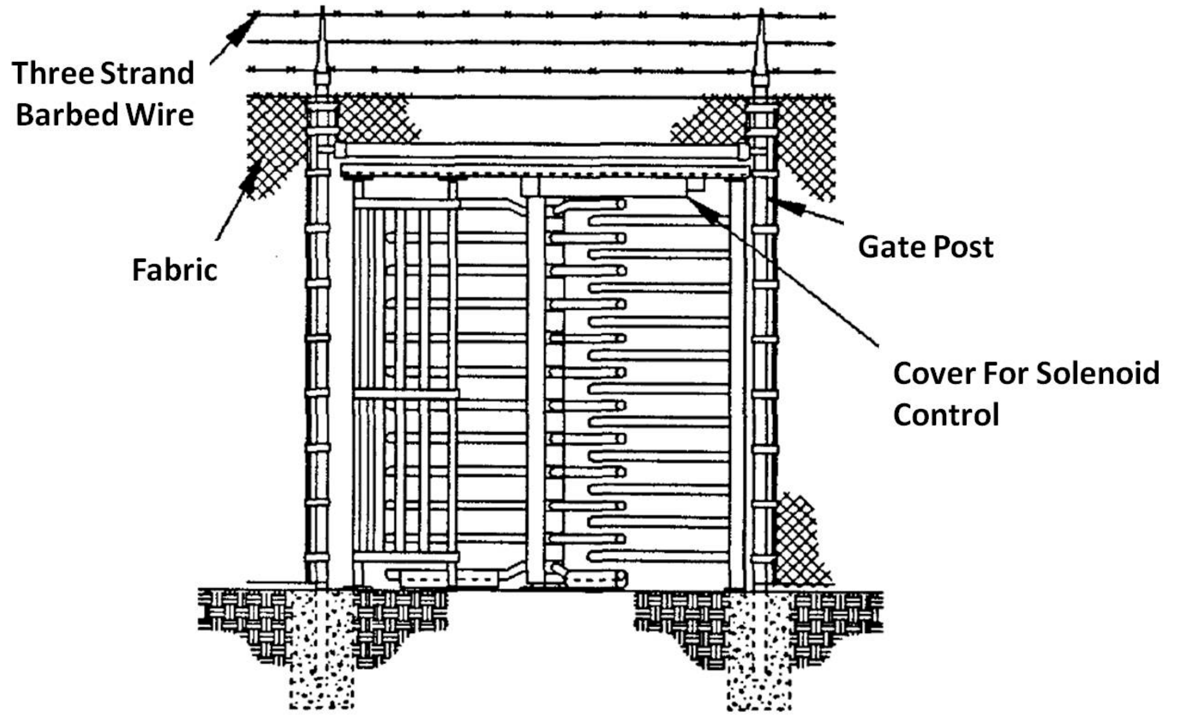

3-3 VEHICULAR GATES

Vehicular gates should limit opening sizes when possible to decrease open/close cycle time. There is no maximum height for vehicular gates. Coordinate gate height with surrounding/adjacent security fencing and the width will be at least as wide as the road entering the gate. The operational requirements for the gate must be evaluated to determine which gate type is most suitable. Analysis for all vehicular gates must consider daily peak of vehicular traffic and the operational access control requirements for the secured area to determine opening size, gate type, and whether an automatic operator is needed. Follow the requirements of ASTM F2200 for gates used for vehicular traffic that are to be automated. Cantilevered, sliding or wheel supported gates are considered the best selection for vehicle security gates followed by overhead sliding gates, swing gates, vertical tilt and overhead “guillotine” gates. Areas where snow and ice are prevalent may consider using cantilever or swing gates instead of tracked sliding gates. However, if sliding gates are used, consideration should be given to adding internal heating for gate mechanisms. Areas where real estate is tight vertical tilt gates are recommended.

3-3.1 Sliding Gates

Sliding gates must have all entry-exit points secured with a heavy duty sliding steel, iron, or heavily braced chain link gate equipped with a heavy locking device. The cross-slope of the road surface must be sloped at a constant grade for the full length of the gate path to permit proper drainage while maintaining smooth operation of the gate opening and closing. Where a sliding gate is installed at an existing paved entrance, the pavement may be filled or leveled where the gate will be installed. Follow the requirement of ASTM F1184 for sliding gates.

3-3.1.1 Single Wheel-Supported (V-groove) Sliding Gate

A guide rail or trough across the roadbed is utilized by this type of gate. The trough provides a smoother surface for vehicular traffic, but is not recommended due to debris buildup. Single wheel supported sliding gates do not have an opening distance restriction, but are limited by the power requirements of the gate operator. Wheel supported gates require 1/3 less straight level storage space along adjacent fence than cantilevered.

3-3.2 Cantilevered Gates

3-3.2.1 Single Cantilevered Gate

All single cantilevered gates should use full support and suspension of gate frame by four rollers secured to two posts inside the restricted area. Single cantilevered gates are not recommended for openings exceeding 24 ft (7.3 m). When an opened gate rests parallel to existing fence, a straight and level fence line 1.5 times the size of the opening should be made to accommodate when the gate is fully open. See Figure 3-3 and Appendix C for an example of single cantilevered gates.

3-3.2.2 Double Cantilevered Gate

Double cantilevered gates are not recommended for openings greater than 48 feet (14.6 m) and should be constructed in a similar manner as described for single cantilevered gates as shown in Figure 3-4.

3-3.3 Double Swing Gates

All double swing vehicular gates must be designed to swing inward, toward secured area. A 2 inch (51 mm) maximum clearance must be maintained between the bottom of fence and the road surface when gate is in closed position. The road surface may be leveled or sloped downward in the direction the gate opens. Recommend gate openings for double swing gates are not greater than 28 feet (8.5 m). Table 3-1 provides recommended concrete foundation diameters for swing gate posts. A minimum of 3 feet (915 mm) deep concrete foundation must be used for swing gate posts. Gate swings greater than 90 degrees must be designed with a large arc space for proper operation. See Figure 3-5 for double swing gates.

Table 3-1: Gate Post Foundations

Steel Post Diameter	Foundation Hole Diameter	Gate Leaf Length
2.875 in (73 mm)	18 in (450 mm)	0 - 6 ft (0 - 1.8 m)
4.000 in (101.6 mm)	24 in (609.6 mm)	6 - 12 ft (1.8 - 3.7 m)
6.625 in (168.3 mm)	36 in (914.4 mm)	12 - 18 ft (3.7 - 5.5 m)
8.625 in (219 mm)	40 in (1016 mm)	18 - 24 ft (5.5 - 7.3 m)

Figure 3-3: Single Cantilevered Gate

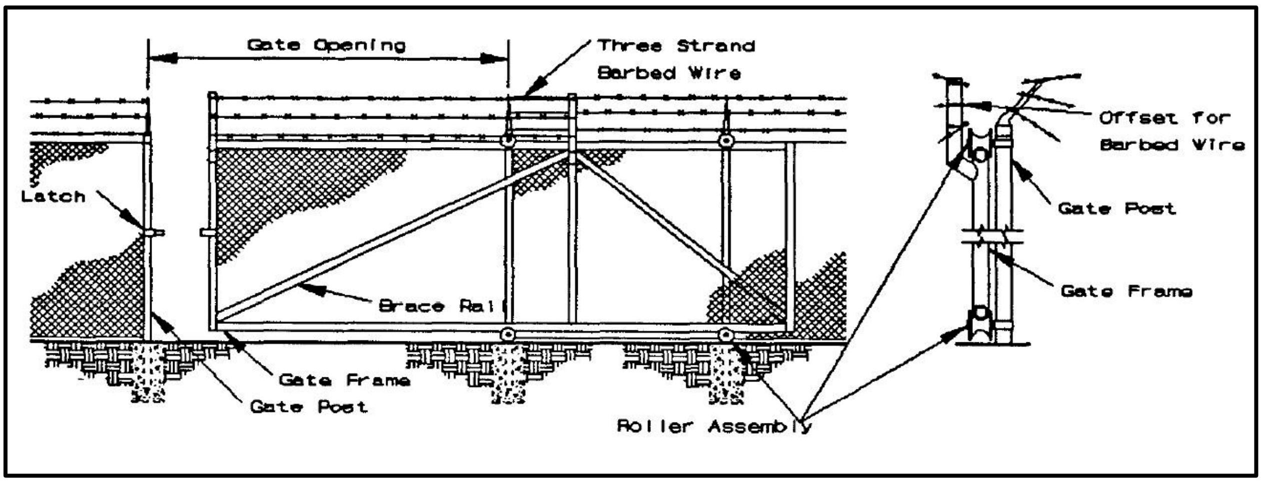

Figure 3-4: Double Cantilevered Gate

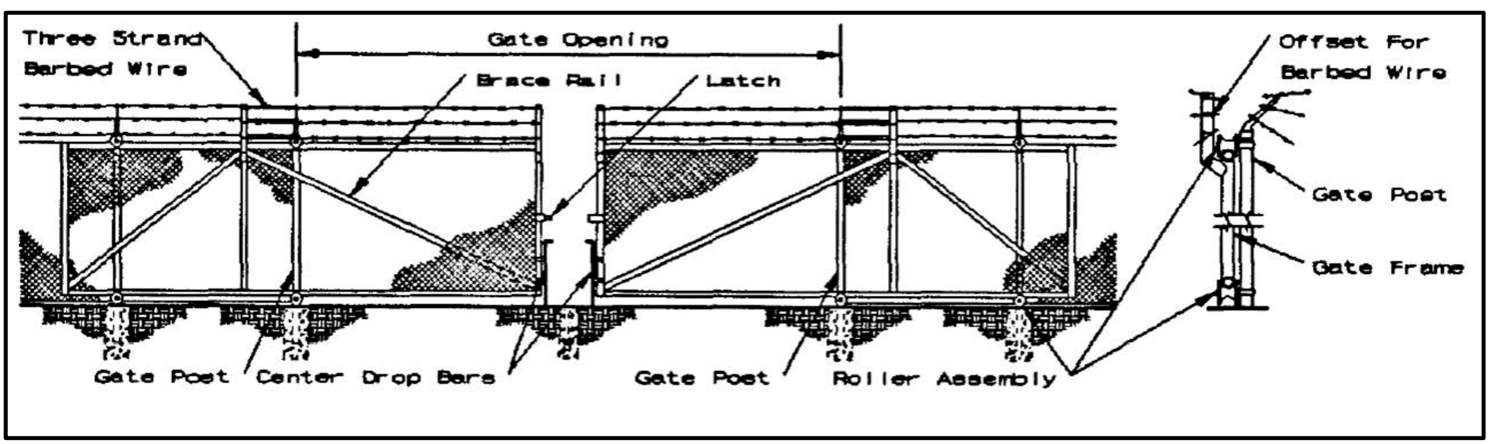

Figure 3-5: Double Swing Gate

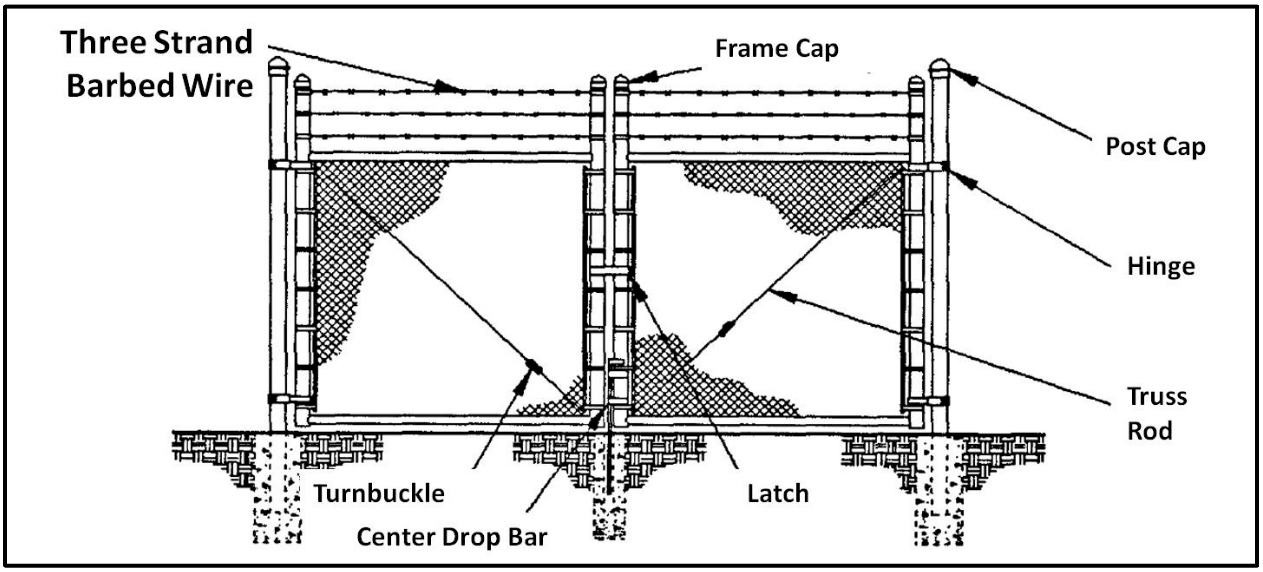

3-3.4 Vertical Pivot Gate

Vertical pivot gates can be manufactured with chain link fabric, expanded metal, ornamental, or similar materials as indicated within this document. A 2 inch (51 mm) maximum clearance must be maintained between the bottom of fence and the road surface when gate is in closed position. Recommend gate openings are not greater than 24 feet (7.3 m). For openings greater than 24 feet (7.3 m), consult with the manufacturer. See specific manufacturer requirements for gate foundation.

3-3.5 Overhead (Sliding) Gates

An overhead gate is a horizontal slide gate supported by an I-beam or enclosed track that is suspended above the opening. The support must extend at least the full opening width on one side of the opening to support storing the gate parallel to the adjacent fence line when the gate is opened. The gate storage area must be in line with the gate opening and either be level or have a decreasing grade to accommodate the gate when it is fully opened. Gates may be suspended from the I-beam or enclosed track by rollers attached to posts extending upward from the leading and trailing edge of the gate. The overhead beam or track height is intended to allow room for the largest possible vehicle going through the gate. Gates should be suspended above ground from the overhead beam or track and supported laterally near the ground by vertical rollers. The I-beam may be applied to strengthen the gate for peak hour traffic, large opening sizes, and heavy gate construction. More posts extending upward from the center of the gate to the tracks may be added to carry heavier loads. Overhead gates must conform to ASTM F1184.

3-3.4.1 Single Overhead Supported Gate

See Appendix C for design details of single overhead supported gates.

3-3.4.2 Double Overhead Supported Gate (Biparting) Gate

See Appendix C for design details of double overhead supported gates.

3-3.6 Vertical Lift Gate

The vertical lift gate, or "guillotine" gate, should be used where the topography does not provide enough room to store the gate adjacent to the fence line. Vertical lift gates should have a counterweight with a continuous drive chain on each side.

3-4 GATE REINFORCEMENT

The gates discussed under the 'Vehicular Gates' paragraph above are non-reinforced gates and not considered to resist impact by vehicles. Standard non-reinforced gates can be fitted with cables, chains, and anchors to increase their resistance to penetration by vehicles. In addition, there are proprietary, rated active vehicle barrier gate systems that are designed to resist penetration by vehicles. See UFC 4-022-02 for additional information on active and passive vehicle barriers. Provide cables at a minimum 3/4 inch (19 mm) wire rope in accordance with ASTM A1023/A1023M. Welded alloy steel chains must be minimum 1/2 inch (13 mm) diameter. These wire ropes must then be chained together and fastened with padlocks to create a continuous barrier. Padlocks used with this system must be medium security padlocks. The wire ropes must be positioned as to not interfere with gate operations when the chain is removed. Figures 3-6 through 3-8 and details in the drawings of Appendix C provide illustrations for reinforced gates.

Application of deadman anchors must be in accordance with the provisions of Chapter 2. See Appendix C for additional reinforcement details for gates.

3-4.1 Swing Gates

For swing gates, the cable must be looped around the gatepost, the gate frame upright, and through the fence cable loop. Cable must be strung across the inside of the gate leaf and fastened around the vertical gate frame upright and fabric tension bar midway above the road surface. The cable must be terminated with a swaged loop or wire rope clamp around the gatepost to interconnect with the gate cable barrier system. All cable ends must be looped and terminated with either four wire rope clamps or hydraulically swaged wire rope fittings. Remove sheathing on covered cables at connections so that the connections can be properly made and rated.

Figure 3-6: Locking Assembly for Reinforced Swing Gate

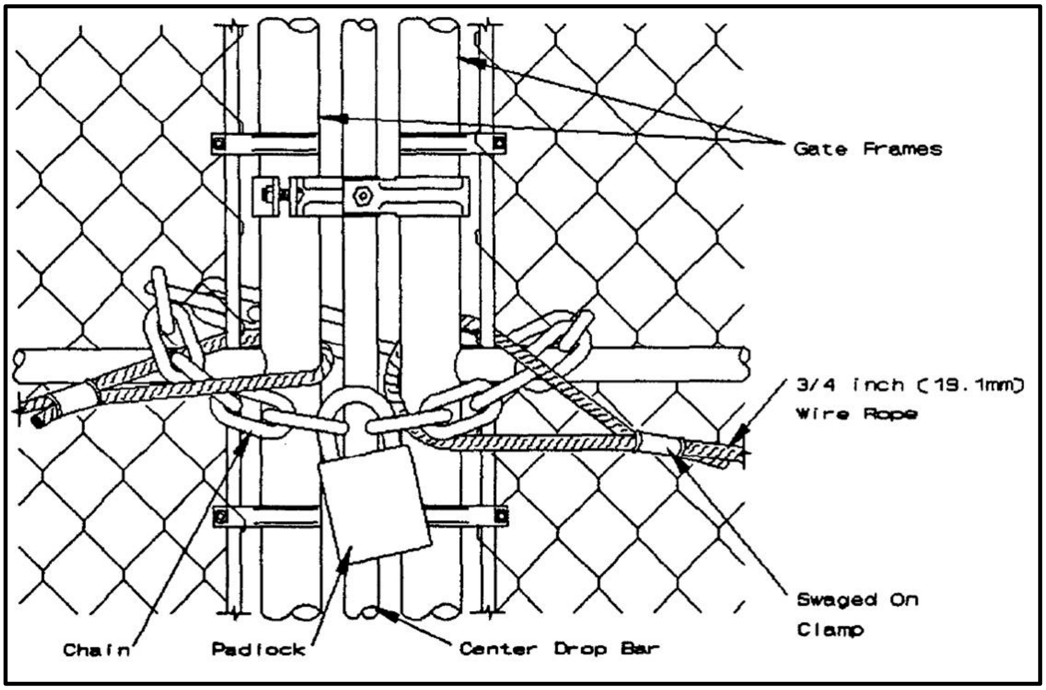

Figure 3-7: Locking Assembly for Reinforced Sliding Gate

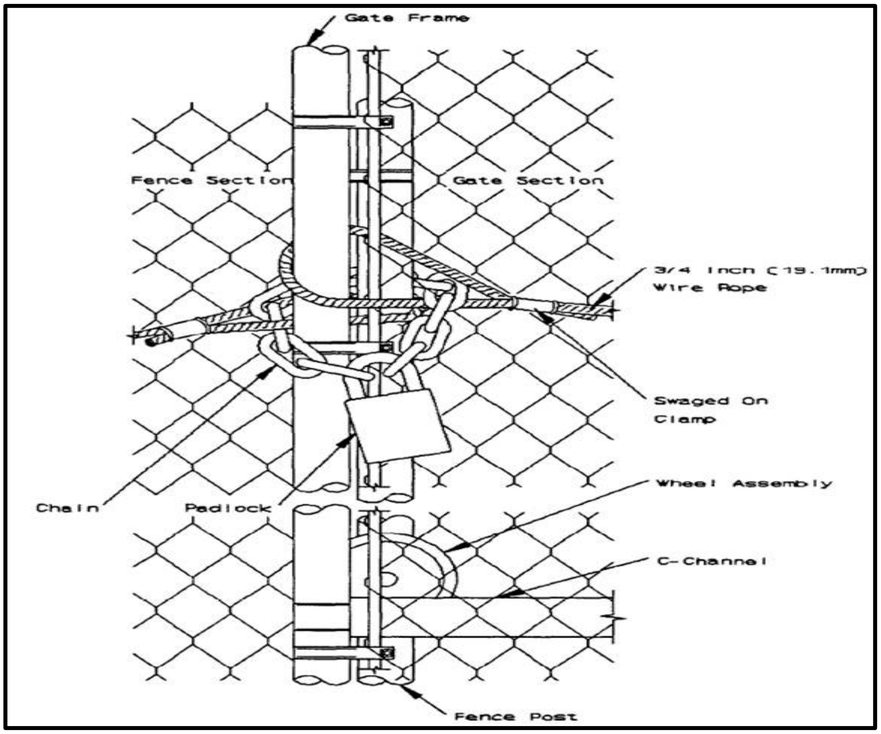

Figure 3-8: Locking Assembly for Reinforced Vertical Lift Gate

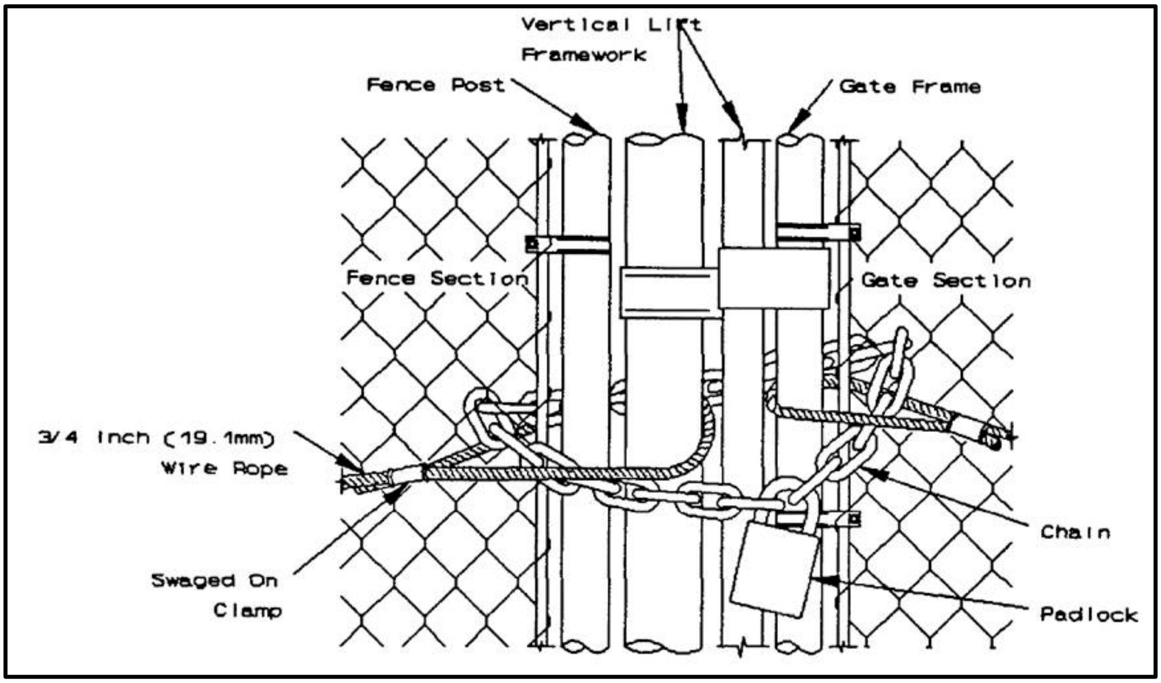

3-4.2 Sliding Gates

For sliding and vertical lift gates, the same materials must be used for reinforcement; however, the cable placement may vary. These gates must have the cable running along the length of the gate in the inside and looped around the frame in an appropriate place. The cable must be terminated and fastened as described previously in this section.

There are times when a gate reinforcement cable barrier system is desired but a cable reinforcement system for the adjoining fence is not necessary since terrain, natural barriers, structures, or other passive barrier features provide vehicle crash protection adjacent to the gate. In such cases, the gate cable system can be terminated directly on each side of the gate with the deadman anchors.

3-5 LATCHES AND HINGES

Hinge selection must consider size of the gate and frequency of use. Weld hinges to the gate post and gate frame if increased resistance against tampering is desirable. In addition, hinges may incorporate welded security top plates, reverse the direction of hinge pins, or have the hinge pins spot welded to provide increased tamper resistance and displacement during an incident.

3-6 LOCKING SYSTEM

As a minimum any locking system must provide penetration resistance equal to an approved general field service padlock. Where sally-port gates include automatic latches and the gate provides access for emergency vehicles or other special situations, the gatehouse must have an emergency override. The padlocked bolt or plunger arrangement must not be easily accessible from outside the barrier. Padlocks used must be medium security padlocks.

See Appendix C for design details of chain and wire rope locking systems.

3-7 GATE POWER OPERATORS

Locate all gate operators to prevent tampering from outside the fence. Coordinate design of gate operating systems with the Command Safety Officer to ensure consideration of site particular operating accessories, warning devices, and safety systems. Coordinate gate operation safety with guidance provided in UFC 4-022-01, *Security Engineering: Entry Control Facilities/Access Control Points.*

Provide powered gate operators for vertical lift gates unless use is infrequent and manual operation is reasonable. Powered gate operators with automatic latching systems must be provided at nuclear storage facilities.

3-7.1 Sliding Gate Power Operators

Automated sliding gates at restricted areas should use positive drive rail gate power-operators.

3-7.2 Swing Gate Power Operators

Swing gate power operators may be either positive drive or electromechanical swing.

3-7.3 Linear Induction Gate Operators

A linear induction gate operator incorporates electromagnetic Linear Induction Motor (LIM) technology, eliminating moving drive components, hydraulic fluids and lubricants and their environmental risks. This technology combines unprecedented speed and reliability and without moving drive components, making it efficient in operation and less costly to maintain. This technology is compatible with existing access control devices and can be specified for new construction or easily retro-fitted to accommodate existing gates. No requirement for any connecting mechanisms such as chains, gear boxes, or belts. Can work in the most rugged environment and has flexible settings that allow for variable and differentiate speeds for open and close mode. LIM technology can reach gate operating speeds of up to 8 feet (2.44m) per second – a significant improvement over existing designs that operate at approximately 1 foot (0.305 meter) per second.

APPENDIX A REFERENCES

ASTM F1345	*Standard Specification for Zinc-5% Aluminum-Mischmetal Alloy-Coated Steel Chain- Link Fence Fabric*	Chain Link/Fence Fabric
ASTM F1183	*Standard Specification for Aluminum Alloy Chain Link Fence Fabric*	Chain Link/Fence Fabric
***ASTM F626**	***Standard Specification for Fence Fittings***	**Chain Link/Post & Line Caps; Rail & Brace ends; Tie wires; Tension bars; Barbed Wire arms**
ASTM F2814	*Standard Guide for Design and Construction of Ornamental Steel Picket Fence Systems for Security Purposes*	Ornamental/Design & Construction
***ASTM F2408**	***Standard Specification for Ornamental Fences Employing Galvanized Steel Tubular Pickets***	**Ornamental/Pickets**
ASTM F2589	*Standard Specification for Ornamental Fences Employing Steel Tubular Pickets*	Ornamental/Pickets
ASTM B221	*Standard Specification for Aluminum and Aluminum- Alloy Extruded Bars, Rods, Wire, Profiles, and Tubes*	Ornamental/All
***ASTM A121**	***Standard Specification for Metallic- Coated Carbon Steel Barbed Wire***	**All/Barbed Wire**
ASTM F1379	*Standard Terminology Relating to Barbed Tape*	All/Barbed Tape a.k.a Concertina
***ASTM F1910**	***Standard Specification for Long Barbed Tape Obstacles***	**All/Barbed Tape a.k.a Concertina**
***ASTM F1911**	***Standard Practice for Installation of Barbed Tape***	**All/Barbed Tape a.k.a Concertina**

ASTM FOR FENCING [1]		
DOCUMENT NUMBER	**TITLE**	**FENCE TYPE - COMPONENT**
***ASTM F1665**	***Standard Specification for Poly(Vinyl Chloride) (PVC) and Other Conforming Organic Polymer- Coated Steel Barbed Wire Used with Chain-Link Fence***	**Chain Link/Barbed Wire**
***ASTM F1043**	***Standard Specification for Strength and Protective Coatings on Steel Industrial Fence Framework***	**Chain Link/Post; Rail**
***ASTM A702**	***Standard Specification for Steel Fence Posts and Assemblies, Hot Wrought***	**Taut Wire, Wood/Post**
***ASTM F1083**	***Standard Specification for Pipe, Steel, Hot Dipped Zinc-Coated (Galvanized) Welded, for Fence Structures***	**Chain Link/Post; Rail**
***ASTM A500/A500M**	***Standard Specification for Cold-Formed Welded and Seamless Carbon Steel Structural Tubing in Rounds and Shapes***	**Chain Link; Ornamental/Post; Rail**
ASTM A501	*Standard Specification for Hot-Formed Welded and Seamless Carbon Steel Structural Tubing*	Chain Link; Ornamental/Post; Rail
ASTM B429/B429M	*Standard Specification for Aluminum-Alloy Extruded Structural Pipe and Tube*	Chain Link; Ornamental/Post; Rail
***ASTM F2453/F2453M**	***Standard Specification for Welded Wire Mesh Fence Fabric (Metallic-Coated or Polymer Coated) for Meshes of 6 in^2 [3871mm^2] or Less, in Panels or Rolls, with Uniform Meshes***	**Welded Wire Mesh/Fabric**
ASTM F2919/F2919M	*Standard Specification for Welded Wire Mesh Fence Fabric (Metallic-Coated or Polymer Coated) with Variable Mesh Patterns or Meshes Greater than 6 in^2* ***[3871mm^2]*** *in Panels*	Welded Wire Mesh/Fabric
ASTM F1267	*Standard Specification for Metal, Expanded, Steel*	Expanded Metal/Design & Construction

ASTM FOR FENCING [1]		
DOCUMENT NUMBER	**TITLE**	**FENCE TYPE - COMPONENT**
***ASTM F2780**	***Standard Guide for Design and Construction of Expanded Metal Security Fences and Barriers***	**Expanded Metal/Design & Construction**
***ASTM F2548**	***Standard Specification for Expanded Metal Fence Systems for Security Purposes***	**Expanded Metal/All**
***ASTM F900**	***Standard Specification for Industrial and Commercial Steel Swing Gates***	**All/Gate**
***ASTM F1184**	***Standard Specification for Industrial and Commercial Horizontal Slide Gates***	**All/Gate**
***ASTM F2200**	***Standard Specification for Automated Vehicular Gate Construction***	**All/Gate**
ASTM F537	*Standard Specification for Design Fabrication, and Installation of Fences Constructed of Wood and Related Materials*	Wood/All
***ASTM A1023/A1023M**	***Standard Specification for Stranded Carbon Steel Wire Ropes for General Purpose***	**All/Reinforcing**
ASTM F1145	*Standard Specification for Turnbuckles, Swaged, Welded, Forged*	All/Reinforcing

NOTES:

1. This portion of the table, ASTM FOR FENCING, provides the ASTM Standard Specification/Standard Design and Construction specifications and requirements for the different fence systems indicated in this UFC. Not all are specifically referenced in this UFC. These specifications are provided for information and reference. Those specifically referenced in this UFC are indicated with an asterisk (*) and are in **bold** type.

MISCELLANEOUS ASTM		
DOCMENT NUMBER	TITLE	FENCE TYPE - COMPONENT
***ASTM A529**	***Standard Specification for High-Strength Carbon-Manganese Steel of Structural Quality***	**Steel, Grill**
***ASTM D2487**	***Standard Practice for Classification of Soils for Engineering Purposes (Unified Soil Classification System)***	**All/none**
***ASTM D2488**	***Standard Practice for Description and Identification of Soils (Visual-Manual Procedure)***	**All/none**

Note: Those specifically referenced in this UFC are indicated with an asterisk (*) and are in **bold** type.

This Page Left Intentionally Blank

APPENDIX B GLOSSARY

B-1 DEFINITION OF TERMS

Active Sensors: A sensor that can receive signals from either itself or other devices.

Attack Side: The outer side of the perimeter fence for a protected area. The side from which to expect attacks or forced entry.

Bollards: Reinforced concrete shapes or sleeves, or steel pipe filled with concrete, used to slow down vehicles and/or deny vehicle access.

Clear Zone: Area free of obstacles, topographical features and vegetation which reduce the effectiveness of the physical barrier, impede observation or provide cover and concealment of an intruder.

Color Polymer Coating: A coating on chain link fences to further protect and add color.

Concrete Sill or Curb: A concrete section to create a non-passable connection between a fence and the existing ground.

Corrosive or Salt Laden Environment/Atmosphere: Atmosphere which contains enough salt or corrosive elements to corrode a fence enough to decrease the intended strength. These areas are typically bordering oceans or other water bodies. For the application of coating requirements in this UFC, the corrosive atmosphere is considered 10 miles (16 kilometers) from coastal mean high water line.

Deadman Anchor : An anchor for fence or gate reinforcement cables which transfer the force from the fencing or gate fabric/surface to the ground. Deadman anchors are typically concrete blocks buried in the ground.

Electronic Security System (ESS): The integrated electronic system that encompasses interior and exterior Intrusion Detection Systems (IDS), Closed Circuit Television (CCTV) systems for assessment of alarm conditions, Automated Access Control Systems (ACS), Data Transmission Media (DTM) and alarm reporting systems for monitoring, control and display.

Eye Ends: Center space created when looping a wire for termination or reinforcement.

Fabric Diamonds: The opening formed by the woven wires in chain link fence fabric.

Fabric Tension Bar: A bar that the fencing fabric is attached to and it serves to hold the fabric tight to decrease ability to deform.

Fencing Accessories: Any fasteners, ties, wires or other objects used to attaching the fencing fabric, posts or top guards.

Fence Fabric: As used in this document means (chain link, ornamental, welded wire mesh, expanded metal).

Gate Leaf: A panel of a gate (There is one gate leaf for single fences and two for double fences).

Gates Openings: In the barrier system to allow authorized entry and exit.

Intrusion Detection System (IDS): A system consisting of interior and exterior sensors, surveillance devices, and associated communication subsystems that collectively detect an intrusion of a specified site, facility or perimeter and annunciate an alarm.

Line Posts: intermediate posts spaced a maximum of 10 feet (3 m) apart and considered the backbone of the fence line.

Mesh Openings: The opening formed by the woven wires.

Moving Vehicle Bomb Tactic: A forced entry tactic to place an explosive or other damaging terrorist device in a moving vehicle to create a mobile vehicular weapon.

Natural Boundaries: Natural formations such as bodies of water, rough terrain, or densely wooded areas that may act as a barrier to define and protect the restricted area's perimeter.

Outriggers: Metal top guards which are placed on the top of the barrier and may consist of at least one vertical arm, angled arm facing inside, angles arm facing outside or two angles arms facing both inside and outside. In addition, there may be more than one arm on each side if desired. The number and direction of arms depends on the nature of the barrier.

Passive Barriers: A passive barrier has no moving parts. Passive barrier effectiveness relies on its ability to absorb energy and transmit the energy to its foundation. Highway medians (Jersey), bollards or posts, tires, guardrails, ditches and reinforced fences are examples of passive barriers.

Passive Sensors: A sensor that receives signals through light or radio waves.

Protected Side: The inside of the fence that is being protected through various security measures.

Sally Ports: Sally ports are used to control entry into highly protected and restricted areas and used as part of an entry control facility/access control point for vehicle inspection.

Secure Side: The inside of the fence that is being protected through various security measures.

Special Nuclear Material (SNM): Nuclear material that requires extensive protection.

Swaged Loop: A loop created by looping a wire and fastening the loop with a swaged on clamp.

Swing Gates: Gates for entrance or exit that swing open either manually or automatically when controlled either electronically or manually.

Taut Wire: Wire that is continuously under tension through a series of spring connections.

Tension Bar: The bar that is threaded through the last vertical link of fabric. It attaches the fabric to the terminal post.

Top Guard: Additional protection of fences or other barriers that are placed on top of the barrier to prevent climbing or jumping. Possible top guards include, but are not limited to, outriggers with barbed wire, concertina wire, or barbed tape.

Truss Rods: A rod used in brace assemblies to draw and hold the line post firmly to the brace rail. The truss rod uses an adjustable turnbuckle to maintain proper tension. Truss rod details can be seen in the "Non Reinforced Chain-Link Fence" drawings in Appendix C.

Turnbuckles: A metal coupling device consisting of an oblong piece internally threaded at both ends into which the corresponding sections of two threaded rods are screwed in order to form a unit that can be adjusted for tension or length.

Turnstile Gates: Pedestrian gates which rotate around a central pole to allow only one entrance at a time.

Welded Bar Grill: A series of vertical and horizontal bars that are placed over an opening and welded at all bar crossing points.

Additional Terms relating to fences are found in:

- ASTM F552 - Standard Terminology Relating to Chain Link Fencing
- ASTM F2814 - Standard Guide for Design and Construction of Ornamental Steel Picket Fence Systems for Security Purposes
- ASTM F2780 - Standard Guide for Design and Construction of Expanded Metal Security Fences and Barriers
- ASTM F1379 - Standard Terminology Relating to Barbed Tape

- ASTM F537 - Standard Specification for Design, Fabrication, and Installation of Fences Constructed of Wood and Related Materials

APPENDIX C FENCE AND GATE DESIGN DETAILS

The details in this appendix illustrate general layouts for each type of fence or gate. These illustrations are not intended to depict the importance or size of each element. Sizes and dimensions indicated are the minimum requirement that must be modified per service policy and for the specific application, environmental conditions, and local constraints.

CHAIN LINK FENCING NOTES

1. FABRIC: THE STANDARD FENCE FABRIC SHALL BE VINYL, ZINC OR ALUMINUM-COATED STEEL WIRE CHAIN LINK WITH MESH OPENINGS NOT LARGER THAN TWO INCHES PER SIDE AND A TWISTED AND BARBED SELVAGE AT TOP AND BOTTOM IN ACCORDANCE WITH THE SPECIFICATIONS. UTILIZE 6-GAUGE FOR BASE PERIMETER OR HEIGHTENED SECURITY ZONES AND 9-GAUGE FOR BASE INTERIOR OR WHEN JOINING AN EXISTING FENCE WHICH IS ALREADY 9-GAUGE.

2. FABRIC TIES: ONLY 12-GAUGE STEEL TIES SHALL BE USED. COATING OR PLATING WILL BE ELECTROLYTICALLY COMPATIBLE WITH THE FENCE FABRIC TO INHIBIT CORROSION.

3. REINFORCEMENT: TENSION WIRES SHALL BE INSTALLED AND INTERWOVEN (OR AFFIXED WITH FABRIC TIES) ALONG THE TOP & BOTTOM OF THE FENCE FOR STABILIZATION OF THE FENCE FABRIC.

4. FENCE HEIGHT: CHAIN LINK FABRIC SHALL BE 7' HIGH WITH AN ADDITIONAL 1' IN HEIGHT COMPOSED OF 3 STRANDS OF BARBED WIRE AS REQUIRED. THE TOTAL FENCE HEIGHT SHALL BE 8'.

5. GROUND CLEARANCE: BOTTOM OF THE FENCE FABRIC SHALL BE WITHIN TWO INCHES OF FIRM SOIL.

6. TOP GUARDS: A TOP GUARD IS AN OVERHANG OF BARBED WIRED ALONG THE TOP OF A FENCE, FACING OUTWARD (AWAY FROM PROTECTED SITE) AND UPWARD AT APPROX. 45 ANGLE. TOP GUARD SUPPORTING ARMS WILL BE PERMANENTLY AFFIXED TO THE TOP OF FENCE POSTS TO INCREASE THE OVERALL HEIGHT OF THE FENCE AT LEAST 1 FOOT. THREE STRANDS OF 12-GAUGE BARBED WIRE, EQUALLY SPACED, SHALL BE INSTALLED ON THE SUPPORTING ARMS.

7. FENCE POSTS: SHALL BE ASTM F1043 OR F1083 ROUND PIPE OR SQUARE TUBE AND SHALL BE GALVANIZED IN ACCORDANCE WITH THE SPECIFICATIONS. FENCE POST SPACING AND SIZE (DIAMETER) SHALL BE DETERMINED IN ACCORDANCE WITH CHAIN LINK FENCE MANUFACTURERS' INSTITUTE (WLG 2445). SPACING SHALL NOT EXCEED 10'-0" OC. SIZE (DIAMETER) SHALL NOT BE LESS THAN THAT SPECIFIED.

GENERAL NOTES

1. THE GATE SHOWN IS TYPICAL. ANY STANDARD COMMERCIAL GATE THAT VARIES ONLY IN NON-ESSENTIAL DETAILS SHALL BE ACCEPTABLE SUBJECT TO APPROVAL.
2. GATE SHALL CONFORM TO ASTM F 1184, TYPE 1, EXCEPT AS EXCEEDED BY THIS DRAWING.
3. GATES SHALL SLIDE ON THE SECURE SIDE.
4. GATES SHALL BE CONSTRUCTED WIT A TROLLEY SYSTEM THAT WILL PREVENT THE GATE FROM BEING ELEVATED OVER 2 INCHES ABOVE THE PAVEMENT.
5. ALL GATE GLIDE DEFLECTORS SHALL BE COMPATIBLE WITH THE MANUFACTURED ELECTRO-MECHANICAL LOCK. THE GUIDE DEFLECTIOR SHALL BE DESIGNED FOR THE WIND CONDITIONS WITH 3/8" PLATE AND GALVANIZED.
6. GUARD POSTS SHALL BE NPS 6 STD WEIGHT, GRADE B, STEEL PIPE FILLED WITH CONCRTE. STEEL PIPE SHALL CONFORM TO ASTM A53/53M, TYPE E OR S, GALVANIZED, MINIMUM WALL THICKNESS .312 INCHES.
7. ALL STEEL PLATES, SHAPES AND ACCESSORIES SHLL BE GALVANIZED IN ACCORDANCE WITH ASTM A123.
8. ELECTRIC SLIDE GATE OPERATOR SHALL HAVE A MINIMUM 1 HP, PHASE MOTOR.
9. UNLESS OTHERWISE NOTED, ALL BOLTS SHALL BE 3/8" DIAMETER, ASTM A307, GALVANIZED BOLTS.

1 1/2" = 1'-0" 0 4" 8" 1'-4"

TURNSTILE NOTES:

1. TURNSTILE SHALL BE COMPOSED OF CARBON STEEL. ALL MATERIALS SHALL BE HOT-DIPPED GALVANIZED IN ACCORDANCE WITH ASTM A123.
2. TURNSTILE SHALL HAVE BI-DIRECTIONAL CONTROLS: IN THE CASE OF A POWER FAILURE, OUTBOUND TRAFFIC SHALL BE SET TO "FAIL SAFE"; THE INBOUND TRAFFIC WILL HAVE A "FAIL LOCK" MECHANISM (UNLESS OTHERWISE DIRECTED BY THE ACTIVITY VIA THE CONTRACTING OFFICER).
3. PROVIDE CARD READER MOUNTING PLATES FOR BOTH SIDES (INBOUND & OUTBOUND) OF TURNSTILE. CARD READER WILL BE INSTALLED BY THE ACTIVITY AT A LATER DATE.
4. BRACE BARRIER POST AT TOP TO ADJACENT VERTICAL SURFACE.
5. ALLOW 5 INCH CLEARANCE ABOVE TOP OF TURNSTILE TO REMOVE LIFT-OFF TYPE TOP COVER.
6. CONCRETE MOUNTING SLAB MUST BE LEVEL WITHIN 1/4". SEE DETAIL C2 THIS SHEET FOR CONC MOUNTING PAD.
7. CONTRACTOR SHALL PROVIDE AN ELECTRICAL 3-ROTOR FULL HEIGHT TURNSTILE AS MANUFACTURED BY TOMSED, MODEL THT-100ECP(3), OR APPROVED EQUAL.
8. TURNSTILE SHALL HAVE FINISH TO MATCH ADJACENT FENCEWORK: POWDER COATED BLACK FOR ORNAMENTAL FENCE AND GALVANIZED FOR CHAIN-LINK.
9. INSTALL 3 STRANDS BARBED WIRE OR CONCERTINA WIRE OVER TOP CHANNEL OF TURNSTILE (BETWEEN ADJACENT FENCE POSTS) TO HINDER SCALING UNIT.

LAYOUT OF REINFORCING

DESIGNER OF RECORD TO LOCATE DEADMEN ON SITE PLANS, SATISFYING SPACING CRITERIA, OVERLAPS, AND FENCE CORNERS / TURNING POINTS. AT GATES IT IS DESIRABLE TO HAVE TRAFFIC ON EITHER SIDE OF A MEDIAN TO OPERATE AND PROTECT INDEPENDENTLY (NOT UTILIZING THE SAME DEADMAN SYSTEMS). THEREFORE DEADMEN SHOULD BE PLACED IN THE MEDIAN TO ANCHOR THE GATE REINFORCING FOR EACH SIDE OF THE ROAD. IF THERE IS NO PHYSICAL MEDIAN (MERELY PAINTED LINES), LIMITED ROOM, OR UTILITY CONFLICTS THAT DO NOT ALLOW FOR DEADMEN PLACEMENT BETWEEN THE GATES, ENSURE THAT THE CABLING FOR BOTH GATES ARE CONNECTED-- EITHER DIRECTLY OR VIA AN INTERMEDIATE CABLE WHICH CREATES AN INTEGRAL CABLE SYSTEM ACROSS THE ENTIRE GATE AREA.

MODIFICATIONS TO TYPICAL DESIGN

NOTE FOR CONTRACTOR: IF LARGER DESIGN THREATS OR CUSTOMER REQUESTS INDICATE A NEED FOR GREATER SECURITY, MORE 3/4" ø CABLES CAN BE UTILIZED OR THE CABLES CAN BE UPGRADED TO 1" ø. BOTH SCENARIOS REQUIRE THE DEADMAN (WHICH WILL NEED TO BE LARGER) TO BE DESIGNED BY A PROFESSIONAL ENGINEER TO SATISFY THE CRITERIA OUTLINED IN REINF NOTE 18 ON THIS SHEET. FOR BIDDING PURPOSES, ESTABLISH A UNIT COST FOR ADDITIONAL EXCAVATION AND NEW CONCRETE PER CUBIC FOOT.

IF 1" ø CABLE IS USED, SPECIFICATIONS SHALL MATCH REINF NOTE 1 ON THIS SHEET, EXCEPT THE CABLE SHALL HAVE A MINIMUM BREAKING STRENGTH OF 70,000 POUNDS (35 TONS). OTHER COMPONENTS, SUCH AS EYEBOLTS, U-BOLTS, ROPE CLIPS, THIMBLES, AND OTHER ASSOCIATED HARDWARE SHALL BE SIZED ACCORDINGLY.

GRAPHIC SCALES

1/2" = 1'-0" — 0 1' 2' 4'

REINFORCING NOTES

1. REINFORCING CABLES SHALL BE U.S. DOMESTIC MINIMUM 3/4" ø 6x19 CLASS WIRE ROPE, REGULAR LAY, EXTRA IMPROVED PLOW STEEL (EIP), INDEPENDENT WIRE ROPE CORE (IWRC), CONFORMING TO ASTM A1023 AND GALVANIZED IN ACCORDANCE WITH ASTM A475 CLASS A, & HAVE A MINIMUM BREAKING STRENGTH OF 40,000 POUNDS (20 TONS). CABLES WITH A BLACK VINYL COATING, SHALL NOT BE IMPREGNATED.
2. CABLES SHALL BE CONTINUOUS FROM DEADMAN TO DEADMAN. NO SPLICES IN CABLE SHALL BE ALLOWED. CABLE BARRIER SHALL BE INSTALLED BETWEEN FENCE POST AND FENCE FABRIC AS PER PLANS. U-BOLTS SHALL BE INSTALLED PERPENDICULAR TO THE LAY OF THE STRANDS OF THE WIRE ROPE AND SHALL BE TIGHTENED AFTER SAG IN CABLE BARRIER HAS BEEN REMOVED. UNLESS INDICATED OTHERWISE, CONCRETE DEADMAN SPACING SHALL BE AT MAXIMUM 200' INTERVALS & TURNING POINTS (EXTERNAL CORNERS).
3. WIRE ROPE ENDS SHALL TERMINATE AROUND TURNBUCKLES, GATE POSTS OR EXTRA HEAVY-DUTY WIRE ROPE THIMBLES (AT GATES). THESE TERMINATIONS REQUIRE 18" MINIMUM OF ROPE FOR TURN BACK AND A MINIMUM OF (4)- CLIPS EACH (EQUAL SPACING).
4. CONTRACTOR SHALL FIELD VERIFY ALL DIMENSIONS PRIOR TO ORDERING MATERIALS.
5. DEADMEN SHALL BE INSTALLED ON THE SECURED SIDE (INTERIOR) OF THE FENCE; WHILE CABLES SHALL BE INSTALLED ON THE EXTERIOR SIDE OF POST.
6. PROVIDE NECESSARY SLACK IN CABLES (GATES ONLY) TO ALLOW FOR FULL SWING OF ALL GATE LEAVES.
7. OFFSET DEADMAN SYSTEMS FROM FENCELINE (PLAN VIEW) TO AVOID CONFLICT WITH EXISTING FENCE POSTS.
8. ALLOW EPOXY ANCHOR BOLTS (MIN 2 DAYS) & CONCRETE DEADMEN (MIN 7 DAYS) TO CURE, PRIOR TO APPLYING LOADS (INSTALLING TURNBUCKLES & STRAIGHTENING CABLES).
9. ALL WELDING SHALL BE DONE IN ACCORDANCE WITH AWS D1.1. ALL WELD MATERIAL SHALL BE E70XX ELECTRODES.
10. STRUCTURAL STEEL CONSTRUCTION SHALL BE IN ACCORDANCE WITH THE NINTH EDITION OF THE AISC "MANUAL OF STEEL CONSTRUCTION FOR ALLOWABLE STRESS DESIGN.
11. STRUCTURAL STEEL SHALL CONFORM TO ASTM A36 AND SHALL HAVE A MINIMUM YIELD STRESS OF 36,000 PSI.
12. ALL STRUCTURAL STEEL MEMBERS AND HARDWARE USED IN CABLE ANCHORING SYSTEM SHALL BE HOT-DIPPED GALVANIZED. ANY AREAS WHERE COATING IS DAMAGED OR REMOVED SHALL BE COVERED WITH A ZINC RICH COMPOUND.
13. TURNBUCKLES SHALL BE 1¼"x18", TYPE I, GALVANIZED IN ACCORDANCE WITH ASTM F1145.
14. WIRE ROPE CLAMPS SHALL BE TYPE I, GALVANIZED, AND CONFORM TO FS FF-C-450.
15. ALL THREADED RODS, U-BOLTS, AND BOLTS SHALL CONFORM TO ASTM A307 AND SHALL BE INSTALLED WITH F844 WASHERS AND A563 NUTS. ENTIRE BOLT ASSEMBLY SHALL BE GALVANIZED IN ACCORDANCE WITH ASTM A153. INSTALL PER MANUFACTURER'S RECOMMENDATIONS.
16. ZINC RICH COMPOUND FOR REPAIRS SHALL BE 95% METALLIC ZINC, BY WEIGHT IN DRIED FILM; INSTALL AT LEAST TWO COATS, 4 MILS MIN TOTAL THICKNESS.
17. ALL CONCRETE WORK SHALL BE IN ACCORDANCE WITH THE LATEST EDITION OF ACI 318. CONCRETE SHALL HAVE A MINIMUM 28-DAY COMPRESSIVE STRENGTH OF 4000 PSI. THE MINIMUM CONCRETE COVER SHALL BE 3", UNLESS OTHERWISE NOTED.
18. DESIGN CRITERIA:
    UFC 4-022-03 "Security Engineering: Fences and Gates
    UFC 4-022-02 "SELECTION AND APPLICATION OF VEHICLE BARRIERS"
19. AT CABLE REINFORCING GATES, PROVIDE TWIST-OFF METAL TIES TO SECURE CABLE TO GATE FABRIC @ 24" OC & U-BOLTS TO SECURE TO GATE UPRIGHTS. MODIFY AS NEEDED TO FACILITATE OPERATION OF GATE.

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	27 January 2010	Changed all references from UFC 3-310-01 "Structural Load Data" to UFC 3-301-01 "Structural Engineering"
2	1 June 2013	Revised tie force equations; removed 0.9 factor and lateral loads from alternate path load combination; clarified definition of controlled public access; clarified live load reduction requirements; revised reinforced concrete and structural steel examples; added cold-formed steel example.
3	1 November 2016	Changed organization name to Air Force Civil Engineer Center (AFCEC), updated ASCE 41-13 references, changed all reference from “Occupancy Category” to “Risk Category”, added a footnote “A” for Risk Category IV & V in Table 2-2, added section 1-8 for Design Submittals and section 1-9 for Recommendations for Specification, updated Chapter 17 section numbering. Editorial changes throughout.
4	10 June 2024	Removed inconsistent language with UFC-4-010-01.

This UFC supersedes UFC 4-023-03, dated 25 January, 2005. The format of this document does not conform to UFC 1-300-01.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD(AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and, \3\Air Force Civil Engineer Center (AFCEC)/3/ are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request (CCR). The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

Whole Building Design Guide website https://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Subject: UFC 4-023-03, Design of Structures to Resist Progressive Collapse

Cancels: UFC 4-023-03, Design of Structures to Resist Progressive Collapse, Dated 25 January 2005

Reasons for Change. UFC 4-023-03 was updated for the following reasons:

- Removed inconsistent language within UFC \4\ 4-010-01 /4/.

Description of Changes. This update to UFC 4-023-03 is a \4\ minor /4/ revision to the 25 January 2005 version. The \4\ /4/ changes include:

- \4\ Review use of modifiers “new” and “existing”
- Revise Section 1-2, APPLICABILITY to match information from the Security DWG
- Revised Section 1-2.1, Building Type and Story Height for clarity. /4/

Impact. The impact of this updated UFC 4-023-03 will vary depending upon the particular structure, structure type, location, and function. \4\ Retrofitting of existing buildings to resist progressive collapse is no longer mandatory, which aligns UFC 4-023-03 with UFC 4-010-01. /4/

Non-Unified Issues. Document content is unified and consistent for all services and agencies of the Department of Defense.

TABLE OF CONTENTS

CHAPTER 1 INTRODUCTION 1

1-1 PURPOSE AND SCOPE. 1
1-2 APPLICABILITY. 1
1-2.1 Building Type and Story Height. 1
1-2.2 Clarification for Partial Occupancy. 1
1-2.3 Clarification for Controlled Public Access. 1
1-2.4 Application by Other Organizations. 2
1-3 GENERAL. 2
1-3.1 Significance of Progressive Collapse. 2
1-3.2 Hardening of Structures to Resist Initial Damage. 3
1-3.3 Risk Considerations. 3
1-3.4 Design Approaches. 3
1-3.4.1 Direct Design Approaches. 3
1-3.4.2 Indirect Design Approaches. 4
1-4 SUMMARY OF THE PROGRESSIVE COLLAPSE DESIGN PROCEDURE. 4
1-5 REFERENCES. 4
1-6 INSPECTION REQUIREMENTS. 5
1-7 SECURITY ENGINEERING UFC SERIES. 5
1-8 DESIGN SUBMITTALS. 6
1-9 RECOMMENDATIONS for SPECIFICATION. 6

CHAPTER 2 PROGRESSIVE COLLAPSE DESIGN REQUIREMENTS FOR NEW AND EXISTING CONSTRUCTION 7

2-1 \3\RISK CATEGORY/3/ DETERMINATION. 7
2-2 DESIGN REQUIREMENTS 8
2-2.1 \3\ Risk Category /3/ I Design Requirement. 8
2-2.2 \3\ Risk Category /3/ II Design Requirement. 8
2-2.2.1 Option 1 for \3\ Risk Category /3/ II: Tie Force and Enhanced Local Resistance. 9
2-2.2.2 Option 2 for \3\ Risk Category /3/ II: Alternate Path. 9
2-2.3 \3\ Risk Category /3/ III Design Requirement. 10
2-2.3.1 Alternate Path Requirement for \3\ Risk Category /3/ III. 10
2-2.3.2 Enhanced Local Resistance Requirement for \3\ Risk Category /3/ III. 10
2-2.4 \3\ Risk Category /3/ IV Design Requirement. 10
2-2.4.1 Tie Force Requirement for \3\ Risk Category /3/ IV. 10
2-2.4.2 Alternate Path Requirement for \3\ Risk Category /3/ IV. 11
2-2.4.3 Enhanced Local Resistance Requirement for \3\ Risk Category /3/ IV. 11

CHAPTER 3 DESIGN PROCEDURES 13

3-1 TIE FORCES. 13
3-1.1 Minimum Structural Requirements for Tie Force Application. 13
3-1.2 Load and Resistance Factor Design for Tie Forces. 14
3-1.3 Floor Loads. 15
3-1.3.1 Uniform Floor Load. 15
3-1.3.2 Consideration for Non-Uniform Load Over Floor Area. 16
3-1.3.3 Cladding and Façade Loads. 17
3-1.4 Required Tie Strength, Distribution, and Location. 17
3-1.4.1 Longitudinal and Transverse Ties. 17
3-1.4.2 Peripheral Ties. 23
3-1.4.3 Vertical Ties. 25
3-1.5 Continuity of Ties. 25
3-1.6 Splices, Anchorage, and Development of Ties. 26
3-1.6.1 Cast-in-Place Reinforced Concrete Floor and Roof Systems. 26
3-1.6.2 Precast Concrete Floor and Roof Systems. 28
3-1.6.3 Composite Construction Floor and Roof Systems. 28
3-1.6.4 Other Floor and Roof Systems and Structural Elements. 28
3-1.7 Structural Elements and Connections With Inadequate Tie Strength 28
3-2 ALTERNATE PATH METHOD 28
3-2.1 General. 29
3-2.2 Alternative Rational Analysis. 29
3-2.3 Load and Resistance Factor Design for Alternate Path Method. 30
3-2.4 Primary and Secondary Components. 31
3-2.5 Force- and Deformation Controlled Actions. 31
3-2.6 Expected and Lower Bound Strength. 32
3-2.7 Material Properties. 32
3-2.8 Component Force and Deformation Capacities. 33
3-2.8.1 Component Capacities for Nonlinear Procedures. 34
3-2.8.2 Component Capacities for the Linear Static Procedure. 34
3-2.9 Removal of Load-Bearing Elements for the Alternate Path Method. 35
3-2.9.1 Extent of Removed Load-Bearing Elements. 36
3-2.9.2 Location of Removed Load-Bearing Elements. 36
3-2.10 Structure Acceptance Criteria. 41
3-2.11 Linear Static Procedure. 41
3-2.11.1 Limitations on the Use of LSP. 41
3-2.11.2 Analytical Modeling. 43
3-2.11.3 Stability/P-Δ Effects. 44
3-2.11.4 Loading. 44
3-2.11.5 Load Increase Factor. 45
3-2.11.6 Design Forces and Deformations. 49
3-2.11.7 Component and Element Acceptance Criteria. 49
3-2.12 Nonlinear Static Procedure. 50

3-2.12.1 Limitations on the Use of NSP. 50
3-2.12.2 Analytical Modeling. 50
3-2.12.3 \2\Stability/P-Δ Effects. 51
3-2.12.4 Loading 51
3-2.12.5 Dynamic Increase Factor for NSP. 52
3-2.12.6 Design Forces and Deformations. 53
3-2.12.7 Component and Element Acceptance Criteria. 53
3-2.13 Nonlinear Dynamic Procedure. 53
3-2.13.1 Limitations on the Use of NDP. 53
3-2.13.2 Analytical Modeling. 54
3-2.13.3 Lateral Stability and P- Δ Effects. 54
3-2.13.4 Loading 54
3-2.13.5 Design Forces and Deformations. 55
3-2.13.6 Component and Element Acceptance Criteria. 55
3-3 ENHANCED lOCAL RESISTANCE 56
3-3.1 Load and Resistance Factor Design for Enhanced Local Resistance. 56
3-3.1.1 Flexural Demand. 57
3-3.1.2 Shear Demand. 57
3-3.2 ELR Location and Extent Requirements. 57
3-3.2.1 RC II Option 1. 57
3-3.2.2 RC III. 57
3-3.2.3 RC IV. 58
3-3.3 RC II Option 1 Shear and Flexural Requirements 58
3-3.4 RC III Shear and Flexural Requirements. 58
3-3.5 RC IV Shear and Flexural Requirements. 58
3-3.5.1 RC IV Flexural Requirements. 58
3-3.5.2 RC IV Shear Requirements. 59
3-3.6 Connection Design for Rebound Reaction Forces. 59
3-3.7 Conflicts Between ELR and Other Design Requirements. 59

CHAPTER 4 REINFORCED CONCRETE 61

4-1 MATERIAL PROPERTIES FOR REINFORCED CONCRETE. 61
4-2 STRENGTH REDUCTION FACTOR Φ FOR REINFORCED CONCRETE. 61
4-3 TIE FORCE REQUIREMENTS FOR REINFORCED CONCRETE. 61
4-4 ALTERNATE PATH REquirements FOR REINFORCED CONCRETE. 62
4-4.1 General. 62
4-4.2 Flexural Members and Joints. 62
4-4.3 Modeling and Acceptance Criteria for Reinforced Concrete. 62
4-5 ENHANCED LOCAL RESISTANCE REQUIREMENTS FOR REINFORCED CONCRETE. 62

CHAPTER 5 STRUCTURAL STEEL 67

5-1 MATERIAL PROPERTIES FOR STRUCTURAL STEEL. 67
5-2 STRENGTH REDUCTION FACTOR Φ FOR STRUCTURAL STEEL. 67
5-3 TIE FORCE REQUIREMENTS FOR STEEL. 67
5-4 ALTERNATE PATH METHOD FOR STEEL. 67
5-4.1 General. 67
5-4.2 Connection Rotational Capacity. 67
5-4.3 Modeling and Acceptance Criteria for Structural Steel. 68
5-5 ENHANCED LOCAL RESISTANCE REQUIREMENTS FOR STEEL. 68

CHAPTER 6 MASONRY 71

6-1 MATERIAL PROPERTIES FOR MASONRY. 71
6-2 STRENGTH REDUCTION FACTOR Φ FOR MASONRY. 71
6-3 TIE FORCE REQUIREMENTS FOR MASONRY. 71
6-4 ALTERNATE PATH METHOD FOR MASONRY. 71
6-4.1 General. 71
6-4.2 Modeling and Acceptance Criteria for Masonry. 71
6-5 ENHANCED LOCAL RESISTANCE REQUIREMENTS FOR MASONRY 72

CHAPTER 7 WOOD 73

7-1 MATERIAL PROPERTIES FOR WOOD. 73
7-2 STRENGTH REDUCTION FACTOR Φ FOR WOOD. 73
7-3 TIME EFFECT FACTOR λ FOR WOOD. 73
7-4 TIE FORCE REQUIREMENTS FOR WOOD. 73
7-5 ALTERNATE PATH METHOD FOR WOOD. 74
7-5.1 General. 74
7-5.2 Modeling and Acceptance Criteria for Wood. 74
7-6 ENHANCED LOCAL RESISTANCE REQUIREMENTS FOR WOOD. 74

CHAPTER 8 COLD-FORMED STEEL 75

8-1 MATERIAL PROPERTIES FOR COLD-FORMED STEEL. 75
8-2 STRENGTH REDUCTION FACTOR Φ FOR COLD-FORMED STEEL. 75
8-3 TIE FORCE REQUIREMENTS FOR COLD-FORMED STEEL. 75
8-4 ALTERNATE PATH METHOD FOR COLD-FORMED STEEL. 75
8-4.1 General. 75
8-4.2 Modeling and Acceptance Criteria for Cold-Formed Steel. 75

8-5 ENHANCED LOCAL RESISTANCE REQUIREMENTS FOR COLD-FORMED STEEL. 76

APPENDIX A REFERENCES 77

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC) provides the design requirements necessary to reduce the potential of progressive collapse for \4\ /4/ facilities that experience localized structural damage through normally unforeseeable events.

1-2 APPLICABILITY.

\4\ The requirements outlined in this UFC are mandatory for all new construction of buildings three or more stories. For existing buildings, these requirements may be applied as required by the project proponents or AHJ. /4/

1-2.1 Building Type and Story Height.

\4\ ~~/4/~~ For this UFC, penthouse structures and floors below grade (i.e., single and multiple level basements) will be considered a story if there is any space that is designed for human occupancy and that is equipped with means of egress as well as light and ventilation facilities that meet the local building code requirements. If any story will not be occupied, perhaps due to mechanical equipment or storage, that story will be omitted from the calculation of the number of stories.

At changes in building elevation from a one or two story section to a section with three or more stories, the appropriate progressive collapse design requirements from Section 2-2 shall be applied to the section with three or more stories. Special attention shall be given to potential deleterious effects associated with the attachment of the short building section to the building section with three or more stories.

1-2.2 Clarification for Partial Occupancy.

When DoD personnel occupy 25% or more of the net interior useable space, the requirements of this UFC are applicable to the entire structure, not just the portion of the building occupied by DoD personnel; this requirement supersedes that given in UFC 4-010-01 *DoD Minimum Antiterrorism Standards for Buildings.*

\2\

1-2.3 Clarification for Controlled Public Access.

Per UFC 4-010-01 *DoD Minimum Antiterrorism Standards for Buildings*, controlled public access will be considered to include (but not be limited to) electronic access control devices or mechanical locks on all exterior doors. Where visitor processing makes locking visitor entrances during building operating hours impractical, providing personnel to control visitor access can be considered positive control at those entrances.

/2/

1-2.4 Application by Other Organizations.

This UFC may be employed by other federal and state government agencies as well as organizations that create and implement building codes (e.g. International Building Code) and material specific design codes (e.g., American Institute of Steel Construction, American Concrete Institute, The Masonry Society, American Iron and Steel Institute, American Forest and Paper Association). The responsibility for determining applicability rests with the specifying agency.

The material contained herein is not intended as a warranty on the part of DoD that this information is suitable for any general or particular use. The user of this information assumes all liability arising from such use. This information should not be used or relied upon for any specific application without competent professional examination and verification.

1-3 GENERAL.

Progressive collapse is defined in the commentary of the American Society of Civil Engineers Standard 7 *Minimum Design Loads for Buildings and Other Structures* (ASCE 7) as "the spread of an initial local failure from element to element, eventually resulting in the collapse of an entire structure or a disproportionately large part of it." The standard further states that buildings should be designed "to sustain local damage with the structural system as a whole remaining stable and not being damaged to an extent disproportionate to the original local damage." As discussed in the commentary of ASCE 7, "except for specially designed protective systems, it is usually impractical for a structure to be designed to resist general collapse caused by severe abnormal loads acting directly on a large portion of it. However, structures can be designed to limit the effects of local collapse and to prevent or minimize progressive collapse." The structural design requirements presented herein were developed to ensure prudent precautions are taken when the event causing the initial local damage is undefined and the extent of the initial damage is unknown.

1-3.1 Significance of Progressive Collapse.

Progressive collapse is a relatively rare event, in the United States and other Western nations, as it requires both an abnormal loading to initiate the local damage and a structure that lacks adequate continuity, ductility, and redundancy to resist the spread of damage. However, significant casualties can result when collapse occurs. This is illustrated by the April 19, 1995 bombing of the Alfred P. Murrah building in Oklahoma City, in which the majority of the 168 fatalities were due to the partial collapse of the structure and not to direct blast effects. The recent escalation of the domestic and international terrorist threat has increased the probability that other US government structures will be attacked with explosives or other violent means.

1-3.2 Hardening of Structures to Resist Initial Damage.

As the initiating event is unknown, the requirements in this UFC are not intended to directly limit or eliminate the initial damage. This is consistent with UFC 4-010-01, which applies where there is a known risk of terrorist attack, but no specific terrorist threat is defined; in this case, the goal is to reduce the risk of mass casualties in the event of an attack. For cases where specific explosive threats against a building have been identified, the designer shall employ the appropriate design methodology for hardening the building. However, even though a structure is designed to resist an identified explosive threat, the progressive collapse design requirements herein shall still apply.

1-3.3 Risk Considerations.

Hazards and consequences are addressed in a typical risk assessment. Due to the limited database of progressive collapse events (from deliberate attack, vehicle impact, natural causes, etc), it is not possible to reasonably assess the probability of occurrence for a specific hazard or group of hazards. Therefore, the risk assessment reduces to a consideration of consequences. In general, consequences are measured in terms of human casualties and, therefore, the \3\ risk category /3/ of a building or structure is often the most critical issue. The progressive collapse design approaches in this UFC are primarily a function of the \3\ risk category /3/ of the building, although the structure's function is also considered. In Section 2-1, guidance is provided on choosing the \3\ Risk Category /3/ of a building, using the occupancy tables contained in UFC 3-301-01 *Structural Engineering*.

1-3.4 Design Approaches.

ASCE 7 defines two general approaches for reducing the possibility of progressive collapse: Direct Design and Indirect Design.

1-3.4.1 Direct Design Approaches.

Direct Design approaches include "explicit consideration of resistance to progressive collapse during the design process…" These include: 1) the Alternate Path (AP) method, which requires that the structure be capable of bridging over a missing structural element, with the resulting extent of damage being localized, and 2) the Specific Local Resistance (SLR) method, which requires that the building, or parts of the building, provide sufficient strength to resist a specific load or threat.

1-3.4.2 Indirect Design Approaches.

With Indirect Design, resistance to progressive collapse is considered implicitly "through the provision of minimum levels of strength, continuity and ductility". The commentary in ASCE 7 goes on to present general design guidelines and suggestions for improving structural integrity. These include: 1) good plan layout, 2) integrated system of ties, 3) returns on walls, 4) changing span directions of floor slabs, 5) load-bearing interior partitions, 6) catenary action of the floor slab, 7) beam action of the walls, 8) redundant structural systems, 9) ductile detailing, 10) additional reinforcement for blast and load reversal, if the designer must consider explosive loads, and 11) compartmentalized construction. However, no quantitative requirements for either direct or indirect design to resist progressive collapse are provided in ASCE 7.

In this UFC, Tie Forces (TF) are used to enhance continuity, ductility, and structural redundancy by specifying minimum tensile forces that must be used to tie the structure together. This approach is similar to that employed by the British after the Ronan Point apartment building collapse in 1968 and currently used in the Eurocode.

1-4 SUMMARY OF THE PROGRESSIVE COLLAPSE DESIGN PROCEDURE.

For \4\ /4/ the level of progressive collapse design for a structure is correlated to the \3\ risk category /3/ (RC). The RC will either be assessed per Section 2-1.

The design requirements in this UFC were developed such that varying levels of resistance to progressive collapse are specified, depending upon the RC as discussed in Chapter 2. These levels of progressive collapse design employ:

- Tie Forces, which prescribe a tensile force strength of the floor or roof system, to allow the transfer of load from the damaged portion of the structure to the undamaged portion,
- Alternate Path method, in which the building must bridge across a removed element, and
- Enhanced Local Resistance, in which the shear and flexural strength of the perimeter columns and walls are increased to provide additional protection by reducing the probability and extent of initial damage.

1-5 REFERENCES.

This UFC incorporates provisions from other publications by dated or undated reference. These references are cited at the appropriate places in the text and the citations for the publications are listed in Appendix A References. For dated references, subsequent amendments to, or revisions of, any of these publications apply to this UFC only when incorporated in it by amendment or revision. For undated references, the latest edition of the referenced publication applies (including amendments).

1-6 INSPECTION REQUIREMENTS.

Inspection requirements to verify conformance with this UFC are provided in Appendix H. These inspection requirements are modifications to the provisions of the International Building Code (IBC), which cover construction documents, structural tests and special inspections for buildings that have been designed to resist progressive collapse.

1-7 SECURITY ENGINEERING UFC SERIES.

This UFC is one of a series of security engineering Unified Facilities Criteria that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include the following:

DoD Minimum Antiterrorism Standards for Buildings. UFC 4-010-01 *DoD Minimum Antiterrorism Standards for Buildings* and UFC 4-010-02 *DoD Minimum Standoff Distances for Buildings* establish standards that provide minimum levels of protection against terrorist attacks for the occupants of all DoD inhabited buildings. These UFC are intended to be used by security and antiterrorism personnel and design teams to identify the minimum requirements that must be incorporated into the design of all new construction and major renovations of inhabited DoD buildings. They also include recommendations that should be, but are not required to be, incorporated into all such buildings.

Security Engineering Facility Planning Manual. UFC 4-020-01*Security Engineering Facility Planning Manual* presents processes for developing the design criteria necessary to incorporate security and antiterrorism features into DoD facilities and for identifying the cost implications of applying those design criteria. Those design criteria may be limited to the requirements of the minimum standards, or they may include protection of assets other than those addressed in the minimum standards (people), aggressor tactics that are not addressed in the minimum standards, or levels of protection beyond those required by the minimum standards. The cost implications for security and antiterrorism are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they represent only representative construction that will meet the requirements of the design criteria. The manual also includes a means to assess the tradeoffs between cost and risk. The Security Engineering Facility Planning Manual is intended to be used by planners as well as security and antiterrorism personnel with support from planning team members.

Security Engineering Facility Design Manual. UFC 4-020-02 *Security Engineering Facility Design Manual* provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established using UFC 4-020-01. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them all work as a system. The information in UFC 4-020-02 is in sufficient detail to support concept level project development, and as such can provide a good basis for a more detailed design. The manual also provides a process for assessing the impact of protective measures on risk. The primary audience for the Security Engineering Facility Design Manual is the design team, but security and antiterrorism personnel can also use it.

Security Engineering Support Manuals. In addition to the standards, planning, and design UFC mentioned above, there is a series of additional UFC that provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02. These support manuals provide specialized, discipline specific design guidance. Some address specific tactics such as direct fire weapons, forced entry, or airborne contamination. Others address limited aspects of design such as resistance to progressive collapse or design of portions of buildings such as mailrooms. Still others address details of designs for specific protective measures such as vehicle barriers or fences. The Security Engineering Support Manuals are intended to be used by the design team during the development of final design packages.

\3\

1-8 DESIGN SUBMITTALS.

Design submittals for DoD projects requiring compliance with these criteria will include the following elements as a minimum;

- Narratives of the design includes the Risk Category, Design Approach (Tie Forces (TF) or Alternate Path (AP), and Design Method (Linear Static, Nonlinear Static or Nonlinear Dynamic),
- A list of the design software used to perform the progressive collapse mitigation, and
- The electronic input files for all phases of the design review.

1-9 RECOMMENDATIONS FOR SPECIFICATION.

Additional recommended specification language for new and existing buildings is included in Appendix C-11. The recommendations in this document include the sample paragraphs for the Request-For-Proposal (RFP) specification.

/3/

CHAPTER 2 PROGRESSIVE COLLAPSE DESIGN REQUIREMENTS FOR NEW AND EXISTING CONSTRUCTION

For both new and existing buildings, the level of progressive collapse design will be based on the \3\ risk category /3/ (RC) of the structure. The \3\ risk category /3/ will be determined per Section 2-1. The RC is used to define the corresponding level of progressive collapse design for new and existing construction as detailed in Section 2-2.

Chapter 3 Design Procedures provides the approaches and requirements for applying Tie Forces (TF), Alternate Path (AP), and Enhanced Local Resistance (ELR). The overall techniques for these three approaches are the same for each construction type, but the details may vary with material type. Chapters 4 through 8 provide the material specific design requirements. Finally, Appendix C provides insight into the development of these approaches.

2-1 \3\RISK CATEGORY/3/ DETERMINATION.

Determine the \3\Risk Category (RC) /3/ of a particular structure by using Table 2-1 for the situation that most closely matches the building. The Risk Category is taken from the risk category definitions in \1\ UFC 3-301-01 *Structural Engineering* /1/*;* the RC level can be considered as a measure of the consequences of a progressive collapse event and is based on two main factors: level of occupancy and building function or criticality.

Table 2-1. Risk Categories

Nature of Occupancy	\3\Risk Category/3/ [C]
• Buildings in Risk Category I in \1\ Table 2-2 of UFC 3-301-01. /1/ • Low Occupancy Buildings[A]	I
• Buildings in Risk Category II in \1\ Table 2-2 of UFC 3-301-01. /1/ • Inhabited buildings with less than 50 personnel, primary gathering buildings, billeting, and high occupancy family housing[A,B]	II
• Buildings in Risk Category III in \1\ Table 2-2 of UFC 3-301-01. /1/	III
• Buildings in Risk Category IV in \1\ Table 2-2 of UFC 3-301-01. /1/ • Buildings in Risk Category V in \1\ Table 2-2 of UFC 3-301-01. /1/	IV

[A] As defined by UFC 4-010-01 *DoD Minimum Antiterrorism Standards for Buildings*
[B] Risk Category II is the minimum occupancy category for these buildings, as their population or function may require designation as Risk Category III, IV, or V.
\2\ [C] Section 1604.5.1 Multiple occupancies of the International Building Code (IBC) is applicable for determination of the Risk Category including the provisions for structurally separated structures. /2/

2-2 DESIGN REQUIREMENTS \4\./4/.

The design requirements for each \3\ risk category /3/ (RC) are shown in Table 2-2. The details are provided in the following sections.

Table 2-2. Risk Categories and Design Requirements

\3\ Risk Category /3/	Design Requirement
I	No specific requirements
II	Option 1: Tie Forces (TF) for the entire structure and Enhanced Local Resistance (ELR) for the corner and penultimate columns or walls at the first story. **OR** Option 2: Alternate Path (AP) for specified column and wall removal locations.
III	Alternate Path for specified column and wall removal locations and Enhanced Local Resistance (ELR) for all perimeter first story columns or walls.
IV[A]	Tie Forces and Alternate Path for specified column and wall removal locations and Enhanced Local Resistance for all perimeter first story columns or walls.

\3\ [A] For buildings in Risk Category IV in Table 2-2 of UFC 3-301-01, the minimum structural requirements for Tie Force application in Section 3-1.1 can be exempted. The minimum structural requirements shall remain for buildings in Risk Category V. /3/

2-2.1 \3\ Risk Category /3/ I Design Requirement.

Progressive collapse design is not required for these structures.

2-2.2 \3\ Risk Category /3/ II Design Requirement.

For RC II structures, one of two options may be chosen. In the first, the designer shall incorporate the Tie Force requirement for the entire structure and Enhanced Local Resistance for the first story corner and penultimate columns and walls (a penultimate column or wall is the closest column or wall to the corner). In the second option, the designer shall design or analyze the building with the Alternate Path method to show that the structure can bridge over the removal of columns, load-bearing walls, or beams supporting columns or walls at specified locations.

2-2.2.1 Option 1 for \3\ Risk Category /3/ II: Tie Force and Enhanced Local Resistance.

The requirements in 2-2.2.1.1 and 2-2.2.1.2 for Tie Forces and Enhanced Local Resistance shall be satisfied, if this option is chosen.

2-2.2.1.1 Tie Force Requirement for RC II Option 1.

The procedure and requirements for Tie Forces for framed and load-bearing wall structures are presented in Section 3-1.

If a vertical structural member cannot provide the required vertical tie force strength, either re-design the member or use the AP method to prove that the structure can bridge over the element when it is removed.

For elements with inadequate horizontal tie force strength, the designer shall re-design the element in the case of new construction or retrofit the element in the case of existing construction. The AP method cannot be used as an alternative for inadequate horizontal ties.

2-2.2.1.2 Enhanced Local Resistance Requirement for RC II Option 1.

The Enhanced Local Resistance requirement is applied to the first story corner and penultimate columns and walls only. For this requirement for RC II Option 1, the flexural demand of the column or wall is not increased; however, the design shear strength of the column or wall and the connections to the slabs, floor system or other lateral load resisting elements shall be greater than the shear demand associated with the flexural demand of the component. The procedure is presented in Section 3-3.

2-2.2.2 Option 2 for \3\ Risk Category /3/ II: Alternate Path.

If the Alternate Path requirement is chosen, then the structure shall be able to bridge over vertical load-bearing elements that are notionally removed one at a time from the structure at specific plan and elevation locations, as required in Section 3-2. The procedures and general requirements for the Alternate Path method are provided in Section 3-2 with specific requirements for each material given in Chapters 4 through 8. If bridging cannot be demonstrated for one of the removed load-bearing elements, the structure shall be re-designed or retrofitted to increase the bridging capacity.

If the results of the analyses are similar for multiple locations due to the redundancy of the building, a formal analysis is not required for every location, provided that one typical analysis is performed, and that this observation is annotated in the design documents.

Note: for load-bearing wall structures, the Alternate Path approach will often be the most practical choice.

2-2.3 \3\ Risk Category /3/ III Design Requirement.

For \3\ Risk Category /3/ III, two requirements shall be satisfied: Alternate Path and Enhanced Local Resistance as discussed in the following sections.

2-2.3.1 Alternate Path Requirement for \3\ Risk Category /3/ III.

The structure shall be able to bridge over vertical load-bearing elements that are notionally removed one at a time from the structure at specific plan and elevation locations, as required in Section 3-2. If bridging cannot be demonstrated for one of the removed load-bearing elements, the structure shall be re-designed or retrofitted to increase the bridging capacity. Note that the structural re-design or retrofit is not applied to just the deficient element, i.e., if a structure cannot be shown to bridge over a removed typical column at the center of the long side, the engineer shall develop suitable or similar re-designs or retrofits for that column and other similar columns.

The procedures and general requirements for the Alternate Path method are provided in Section 3-2 with specific requirements for each material given in Chapters 4 through 8.

2-2.3.2 Enhanced Local Resistance Requirement for \3\ Risk Category /3/ III.

The Enhanced Local Resistance requirement is applied to all first story perimeter columns and walls. For this requirement, for RC III, the flexural demand of the column or wall need not be increased; however, the design shear strength of the column or wall and the connections to the slabs, floor system or other lateral load resisting elements shall be greater than the shear demand associated with the flexural demand of the component. The procedure is presented in Section 3-3.

2-2.4 \3\ Risk Category /3/ IV Design Requirement.

The design requirements for \3\ Risk Category /3/ IV include Alternate Path, Tie Forces and Enhanced Local Resistance as discussed in the following paragraphs.

2-2.4.1 Tie Force Requirement for \3\ Risk Category /3/ IV.

For RC IV, the designer shall provide adequate internal, peripheral and vertical Tie Force strengths. The procedure and requirements for applying the Tie Force approach are provided in Section 3-1.

If a structural member cannot provide the required vertical tie force strength, the designer shall either re-design the member or use the Alternate Path method to prove that the structure can bridge over the element when it is removed. For elements with inadequate horizontal tie force strength, the Alternate Path method cannot be used. In this case, the designer shall re-design the element in the case of new construction or retrofit the element for existing construction.

The minimum structural requirements for Tie Force application in Section 3-1.1 can be exempted for \3\ Risk Category /3/ IV, however, for \3\ Risk Category /3/ V, the minimum structural requirements shall remain.

2-2.4.2 Alternate Path Requirement for \3\ Risk Category /3/ IV.

For RC IV, use the same AP requirement as for RC III; see Section 2-2.3.1.

2-2.4.3 Enhanced Local Resistance Requirement for \3\ Risk Category /3/ IV.

The Enhanced Local Resistance requirement is applied to all first story perimeter columns and walls. The flexural demand of the columns and walls for a design with only gravity loads meeting the AP requirements shall be increased respectively by a factor of 2 and a factor of 1.5 and compared to the flexural demands for the building as designed to meet the AP requirements and all other building code requirements; the larger of these two flexural demands is used to determine the shear demand. The design shear strength of the column or wall and the connections to the slabs, floor system or other lateral load resisting elements shall be greater than this shear demand. Procedures for Enhanced Local Resistance are given in Section 3-3.

THIS PAGE INTENTIONALLY LEFT BLANK

CHAPTER 3 DESIGN PROCEDURES

The progressive collapse design requirements employ three design/analysis approaches: Tie Forces (TF), Alternate Path (AP), and Enhanced Local Resistance (ELR). This chapter discusses the required procedures for these approaches.

3-1 TIE FORCES.

In the Tie Force approach, the building is mechanically tied together, enhancing continuity, ductility, and development of alternate load paths. Tie forces can be provided by the existing structural elements that have been designed using conventional design methods to carry the standard loads imposed upon the structure. There are three horizontal ties that must be provided: longitudinal, transverse, and peripheral. Vertical ties are required in columns and load-bearing walls. Figure 3-1 illustrates these ties for frame construction. Note that these “tie forces” are different from “reinforcement ties” as defined in ACI 318 *Building Code Requirements for Structural Concrete*.

Unless the structural members (beams, girders, spandrels) and their connections can be shown capable of carrying the required longitudinal, transverse, or peripheral tie force magnitudes while undergoing rotations of 0.20-rad (11.3-deg), the longitudinal, transverse, and peripheral tie forces are to be carried by the floor and roof system. Acceptable floor and roof systems include cast-in-place concrete, composite decks, and precast concrete floor planks with concrete topping, reinforcement, and mechanical anchorage that meet the requirements of Sections 3-1.4 through 3-1.6. Other floor or roof systems may be used, provided that the ability to carry the required tie strength while undergoing rotations of 0.20-rad (11.3-deg) is adequately demonstrated to and approved by an independent third-party engineer or by an authorized representative of the facility owner.

\2\ Note: The use of structural composites such as fiber reinforced polymer (FRP) to provide the tie forces is not acceptable unless the designer can prove that the FRP is capable of meeting the rotation requirement of 0.20-rad (11.3-deg) specified in the previous paragraph. Also, the tie force design must not allow portions of the structure to break free and fall to the floor above, i.e., positive mechanical anchorage or connection must be provided between the tie force members and the other structural elements (floors, beams, etc). /2/

\2\

3-1.1 Minimum Structural Requirements for Tie Force Application.

To apply the Tie Force method, the structure must meet the requirements listed in the following paragraphs.

For framed and two-way load-bearing wall structures, the number of bays in both directions must be four or greater. A bay is defined as the square or rectangular floor area with boundaries demarked by vertical load-bearing elements, such as columns at the corners or load-bearing walls along the edges.

For one-way load-bearing wall structures, the number of bays in the one-way span direction must be four or greater. The length of the load-bearing walls (or width of the building) must be at least $4\ h_w$ where h_w is the clear story height.

/2/

3-1.2 Load and Resistance Factor Design for Tie Forces.

Following the Load and Resistance Factor Design (LRFD) approach, the design tie strength is taken as the product of the strength reduction factor, Φ, and the nominal tie strength R_n calculated in accordance with the requirements and assumptions of applicable material specific codes. Include any over-strength factors provided in Chapters 9 to 11 of ASCE 41, where these over-strength factors are referred to as "factors to translate lower bound material properties to expected strength material properties" and are given in Tables 9-3 (structural steel), 10-4 (reinforced concrete), and 11-2 (masonry). For wood and cold-formed steel, Chapter 12 of ASCE 41 provides default expected strength values; note that for wood construction, a time effect factor λ is also included. Per the LRFD approach, the design tie strength must be greater than or equal to the required tie strength:

$$\Phi R_n \geq R_u \qquad \text{Equation (3-1)}$$

where
- ΦR_n = Design tie strength
- Φ = Strength reduction factor
- R_n = Nominal tie strength calculated with the appropriate material specific code, **including the over-strength factors from Chapters 5 to 8 of ASCE 41.**
- R_u = $\Sigma \gamma_i Q_i$ = Required tie strength
- γ_i = Load factor
- Q_i = Load effect

The required tie strengths are provided in the following sub-sections for framed and load-bearing wall structures.
\2\/2/

3-1.3 Floor Loads.

3-1.3.1 Uniform Floor Load.

Use the floor load in Equation 3-2 to determine the required tie strengths:

$$w_F = 1.2D + 0.5L \qquad \text{Equation (3-2)}$$

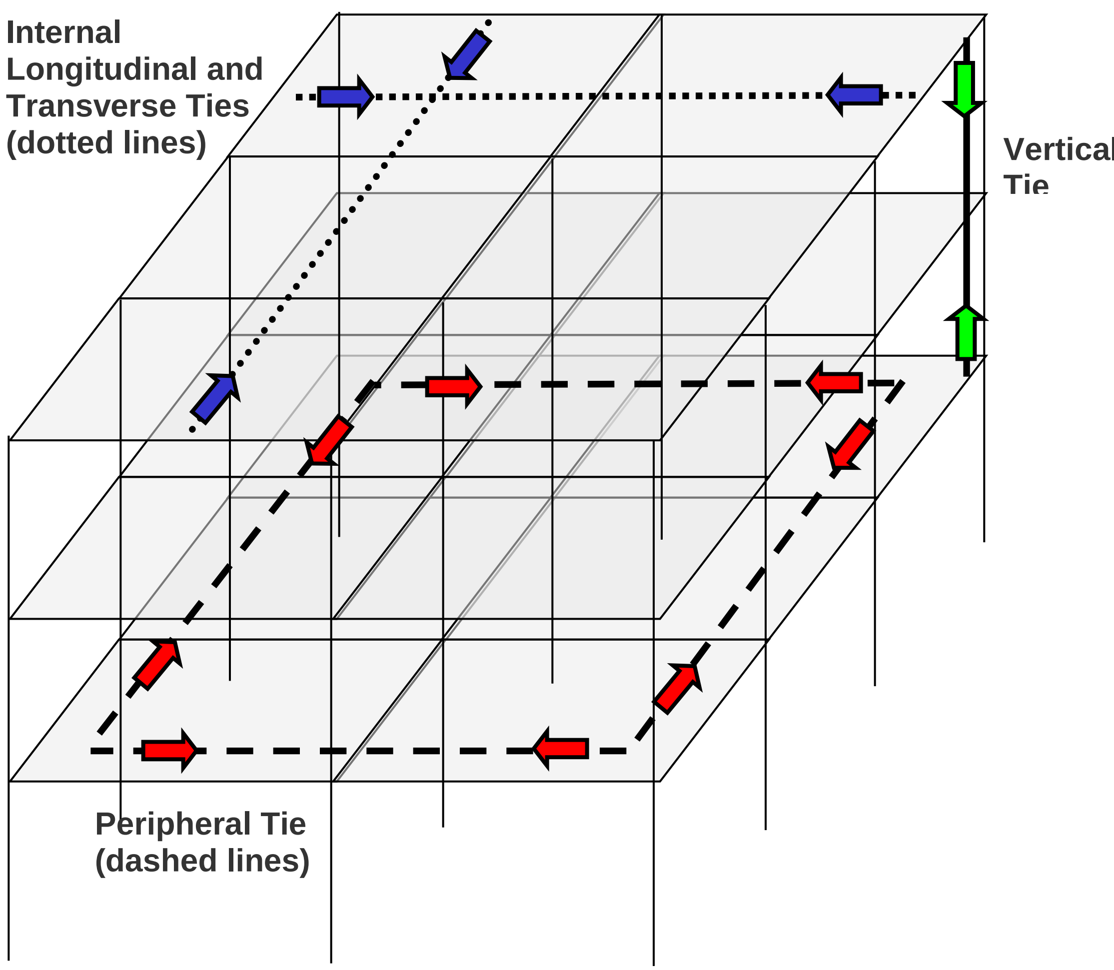
Where w_F = Floor Load (lb/ft^2 or kN/m^2)

D = Dead Load (lb/ft^2 or kN/m^2)
L = Live Load (lb/ft^2 or kN/m^2)

If the Dead Load or Live Load vary over the plan of the floor, use the procedure in Section 3-1.3.2 to determine the effective w_F.

\2

Figure 3-1. Tie Forces in a Frame Structure



NOTE: 1. Peripheral, longitudinal and transverse ties are not required in floors above crawlspaces if public access control is provided.
2. Vertical ties are not required to extend to the foundation and shall be straight. /2/

3-1.3.2 Consideration for Non-Uniform Load Over Floor Area.

3-1.3.2.1 Concentrated Loads.

If a concentrated load is located within a bay or one portion of the bay has a different loading than the rest of the bay, distribute the load evenly over the bay area and include in the dead or live load, as appropriate, in Equation 3-2.

3-1.3.2.2 Load Variations.

The load magnitude may vary significantly over the plan area of a given story, e.g. manufacturing activities may be located in one section of the floor and office space in another; see Figure 3-2. Calculate the floor load for each bay using Equation 3-2. Determine the effective floor load that will be used to determine the longitudinal, transverse, and peripheral Tie Forces, as follows:

1) If the difference between the minimum and maximum floor load in the bays on the floor plan is less than or equal to 25% of the minimum floor load and the area associated with the maximum floor load is

   a. Less than or equal to 25% of the total floor plan area, use an effective w_F, calculated by computing the total force acting on the floor and dividing by the total plan area.

   b. Greater than 25% of the floor plan, use the maximum floor load as the effective w_F.

2) If the difference between the minimum and maximum floor load in the bays on the floor plan is greater than 25% of the minimum floor load, either:

   a. Use the maximum floor load as the effective w_F, or,

   b. Divide the floor plan into sub-areas, where a sub-area is a region composed of contiguous or adjacent bays that have the same floor load. Each sub-area shall have its own longitudinal and transverse ties and peripheral ties. In addition, a peripheral tie will be placed in the boundary between the sub-areas, as shown in Figure 3-2. The required strength of the peripheral tie between the sub-areas shall be equal to the sum of the required peripheral tie force on the heavily loaded sub-area and the required peripheral tie force on the lightly loaded sub-area. In this case, the internal ties are not required to be continuous from one side of the structure to the other but may be interrupted at the sub-area peripheral tie, providing that the internal ties from both sub-areas are properly anchored with seismic hooks to the sub-area peripheral tie. If desired, the longitudinal and transverse internal ties on the lightly loaded sub-area may be continued across the heavily loaded sub-area as part of the longitudinal and transverse internal ties of the heavily loaded side. Note that sufficient embedment or anchoring must be provided to develop the strength of all peripheral ties, at the sub-area boundary and at the exterior of the building.

c. Note that the peripheral tie between the sub-areas may be omitted if the transverse and longitudinal ties from the heavily loaded sub-area continue across the lightly loaded sub-area and are anchored to the exterior peripheral ties. For instance, in Figure 3-2, the longitudinal ties from the heavily loaded sub-area could extend the full length of the floor plan, the transverse ties from the heavily loaded sub-area in the three left bays could extend the full width of the floor plan and transverse ties from the lightly loaded sub-area in the right two bays could extend the full width of the floor plan.

3-1.3.3 Cladding and Façade Loads.

Cladding and façade loads are used for the calculation of the peripheral and vertical tie forces and are omitted for the transverse and longitudinal tie calculations.

3-1.4 Required Tie Strength, Distribution, and Location.

The required tie strength, distribution, and location for longitudinal, transverse, peripheral, and vertical ties are defined in the following sub-sections for framed and load-bearing wall structures.

The design tie strengths are considered separately from the forces that are typically carried by each structural element due to live load, dead load, wind load, etc In other words, the design tie strength of a slab, beam, column, rebar, or connection **with no other loads acting** must be greater than or equal to the required tie strength. In addition, the tie member itself, its splices and its connections only resist the calculated tensile forces. There are no structural strength or stiffness requirements to be applied to the structural members that are anchoring these horizontal tie forces.
\2\ /2/

3-1.4.1 Longitudinal and Transverse Ties.

Use the floor and roof system to provide the required longitudinal and transverse tie resistance. The structural members (beams, girders, spandrels, etc) may be used to provide some or all of the required tie forces, if they and their connections can be shown capable of carrying the total internal tie force acting over the structural member spacing while undergoing a 0.20-rad (11.3-deg) rotation, i.e., if the required longitudinal tie force is 10-k/ft (146-kN/m) and the beams are located at 10-ft (3.05-m) on center, the designer must show that the beam can carry a tensile force of 100-k (445-kN) with rotations of 0.20-rad (11.3-deg).

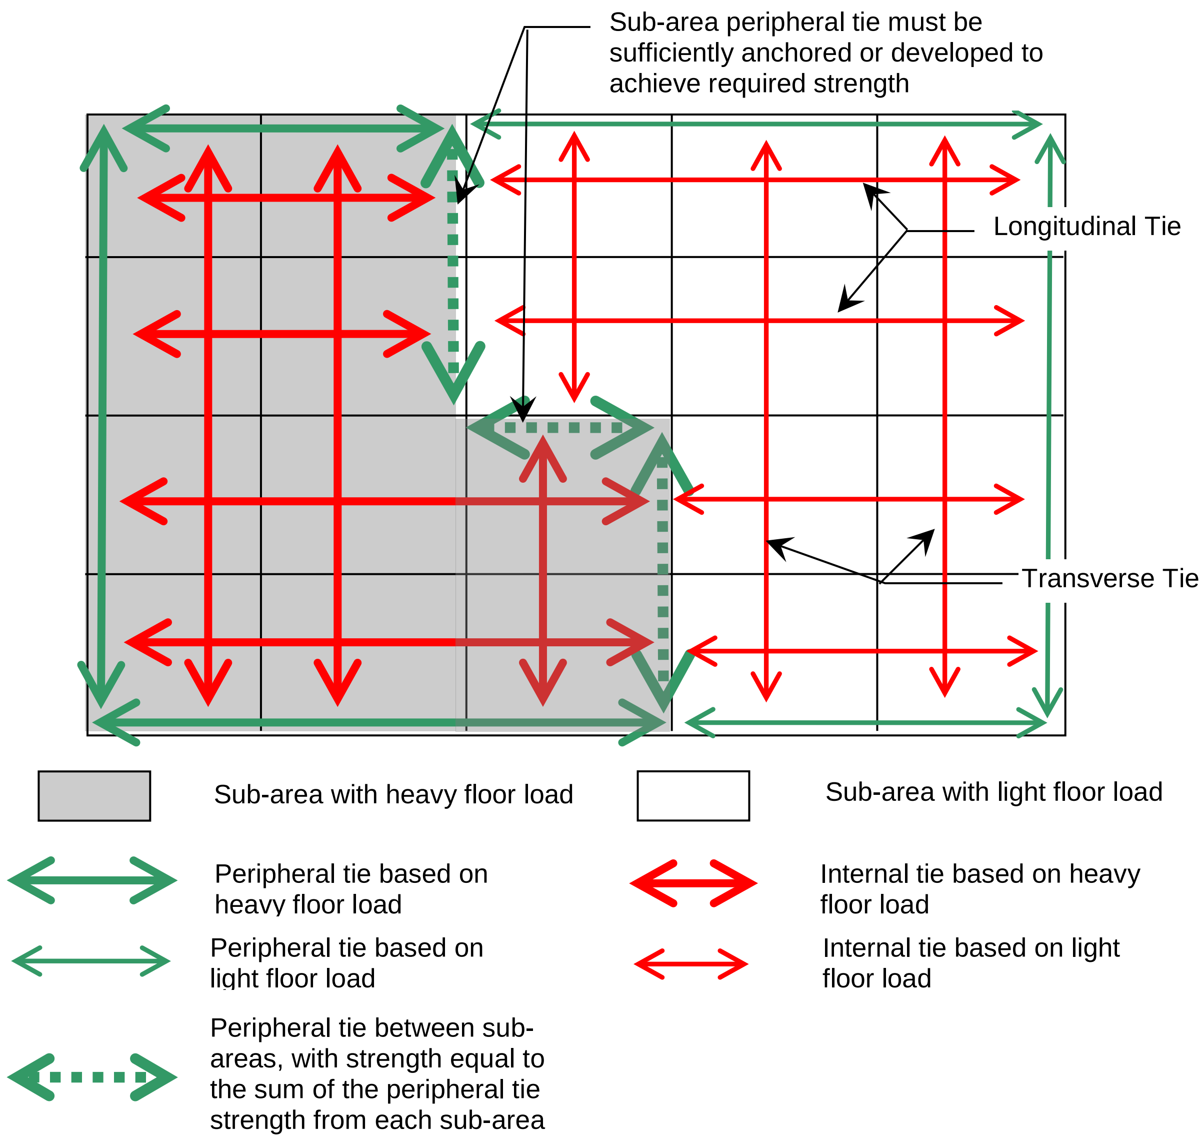
/2/ Note that longitudinal and transverse ties are not required in floors above crawlspaces if public access control is provided. See Section 1-2.3 for definition of public access control. /2/

3-1.4.1.1 Framed Structures, Including Flat Plate and Flat Slab.

Longitudinal and transverse tie forces shall be distributed orthogonally to each other throughout the floor and roof system. The longitudinal and transverse ties must be anchored to peripheral ties at each end. Spacing must not be greater than ***0.2*** L_T, or ***0.2*** L_L where L_T and L_L are the greater of the distances between the centers of the columns, frames, or walls supporting any two adjacent floor spaces in the transverse and longitudinal directions, respectively.

\2\

Figure 3-2. Sub-areas, Peripheral and Internal Ties for Non-uniform Floor Loads



/2/

For flat plate and flat slab structures without internal beams, girders, or spandrels, place no more than twice the required tie strength (force per unit length) in the column area, which is the column strip ***0.2 L_L*** or ***0.2 L_T*** wide that is centered on the column lines and runs in the direction of the tie under consideration, as shown in Figure 3-3. For instance, if the required longitudinal tie force ***F_L*** is 10-k/ft (146-kN/m), and ***L_T*** is 20-ft (6.1-m), then the width of the column area is ***0.2 L_T*** or 4-ft (1.22-m) and the maximum total tie force allowed in the column area is 2 x 10-k/ft x 0.2 x 20-ft or 80-k (356-kN). The remainder of the required total tie force is distributed in the floor or roof system.

For framed buildings with internal beams, girders, or spandrels, internal ties may cross over these elements, but are not to be placed parallel to these members and within the member or within the area directly above the member, unless the member can be shown capable of a 0.20-rad (11.3-deg) rotation. The internal ties that would fall within this area must be placed on either side of the beam, so that the total required tie strength for the adjacent bays is maintained. An illustration of this restriction is shown in Figure 3-4.

The required tie strength $\boldsymbol{F_i}$ (lb/ft or kN/m) in the longitudinal or transverse direction is:

$$F_i = 3\, w_F\, L_1 \qquad \text{Equation (3-3)}$$

Where w_F = Floor load, determined per Section 3-1.3, in (lb/ft^2 or kN/m^2)

L_1 = Greater of the distances between the centers of the columns, frames, or walls supporting any two adjacent floor spaces in the direction under consideration (ft or m)

\2\

Figure 3-3. Determination of L_1 and Column Area for Frame and Two-way Span Load-bearing Wall Construction

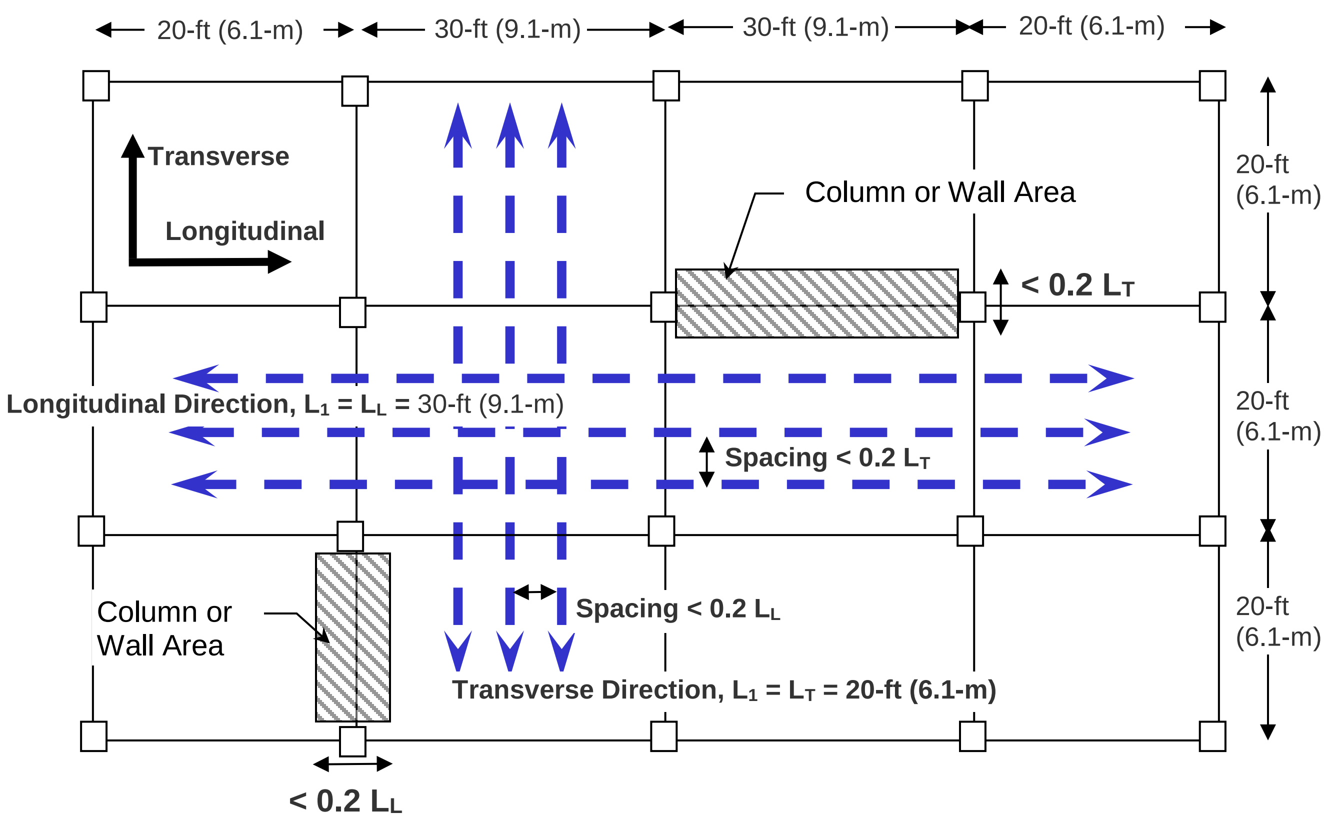


Figure 3-4. Location Restrictions for Internal and Peripheral Ties that are Parallel to the Long Axis of a Beam, Girder or Spandrel

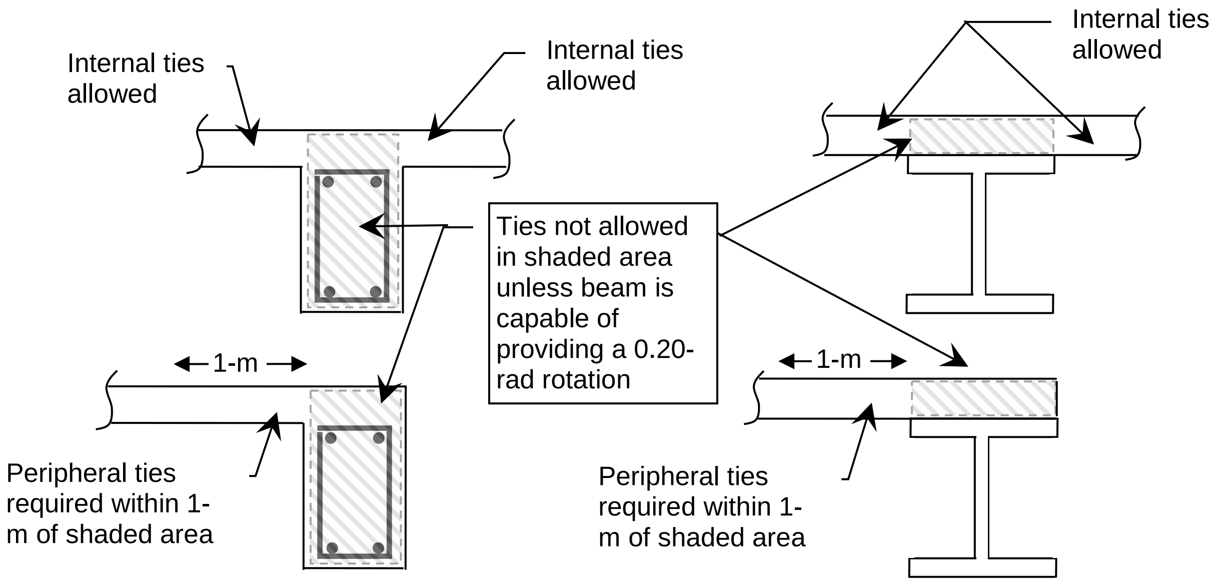


/2/

3-1.4.1.2 Load-bearing Wall Structures.

A longitudinal and a transverse tie force shall be distributed orthogonally to each other throughout the floor and roof system. These ties must be anchored to peripheral ties at each end.

For two-way spans, spacing must not be greater than $0.2\ L_T$, or $0.2\ L_L$ where L_T and L_L are the greatest of the distances between the centers of the walls supporting any two adjacent floor spaces in the transverse and longitudinal directions, respectively; see Figure 3-3. No more than twice the required tie strength shall be placed in the wall area, which is defined as the area bounded by the centers of the columns, frames, or walls supporting any two adjacent floor spaces in the direction of the tie under consideration and within $0.1\ L_T$ or $0.1\ L_L$ of the wall line, as appropriate, as shown in Figure 3-3. For two-way spans, the required tie strength F_i (lb/ft or kN/m) in the longitudinal or transverse direction is:

$$F_i = 3\ w_F\ L_1 \qquad \text{Equation (3-4)}$$

Where w_F = Floor load, determined per Section 3-1.3, (lb/ft^2 or kN/m^2)

L_1 = Greater of the distances between the centers of the columns, frames, or walls supporting any two adjacent floor spaces in the direction under consideration (ft or m)

For one-way spans, spacing of the longitudinal and transverse ties must not be greater than $0.2\ L_L$, where L_L is the greatest of the distances between the centers of the walls supporting any two adjacent floor spaces in the longitudinal direction; see Figure 3-5. A maximum of twice the required tie strength shall be placed in the wall area, which is defined as the area within $0.1\ L_L$ of the wall line, as shown in Figure 3-5. For one-way spans, L_L is the greater of the distances between the centers of the wall in the one-way span direction, as shown in Figure 3-5. In the transverse direction L_T is $5\ h_w$, where h_w is the clear story height. The required tie strength F_i (lb/ft or kN/m) in the longitudinal or transverse direction is

$$F_i = 3\ w_F\ L_1 \qquad \text{Equation (3-5)}$$

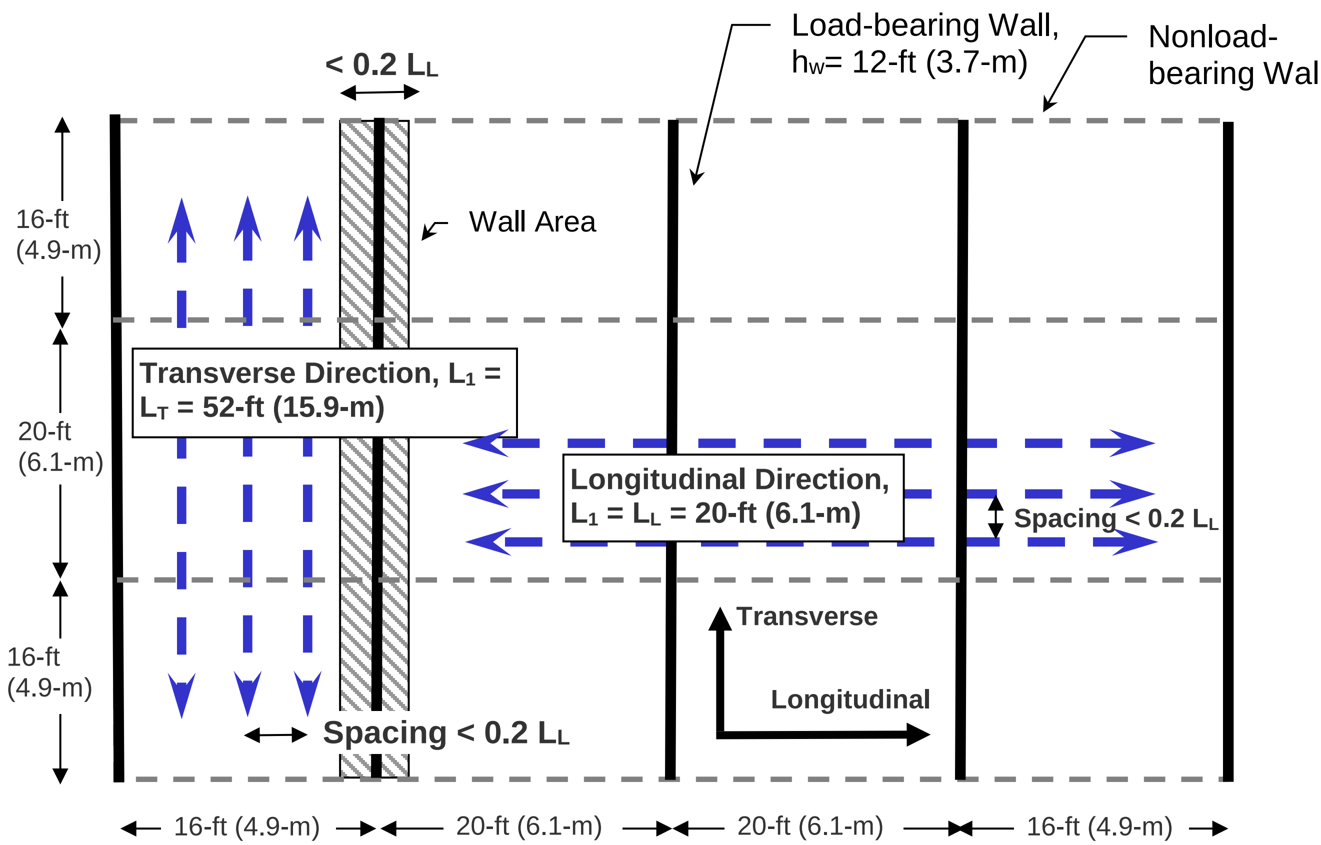
Where w_F = Floor load, determined per Section 3-1.3, ((lb/ft^2 or kN/m^2)

L_1 = Either L_L = the greater of the distances between the centers of the walls supporting any two adjacent floor spaces in the longitudinal direction or L_T = lesser of 5 h_w or the building width in the transverse direction (ft or m)

h_w = Clear story height (ft or m)

\2\ /2/

Figure 3-5. Determination of L_1 and Column Area for One-way Load-bearing Wall Construction with h_w = 12-ft (3.7-m)



3-1.4.2 Peripheral Ties.

Use the floor and roof system to carry the required peripheral tie strength. The structural members (beams, girders, spandrels, etc) may be used instead, if they can be proven capable of carrying the peripheral tie force while undergoing a 0.20-rad (11.3-deg) rotation.

\2\ Note that peripheral ties are not required in floors above crawlspaces if public access control is provided. See Sections 1-2.1 and 1-2.3 for definitions of occupied space and public access control, respectively.

For buildings with one- and two-story sections attached to a section with three or more stories, peripheral ties shall be placed in any contiguous floors at the boundary between the short and tall sections. /2/

Place peripheral ties within 3.3-ft (1.0-m) of the edge of a floor or roof and provide adequate development or anchors at corners, re-entrant corners or changes of construction. For framed buildings with perimeter beams, girders, or spandrels, peripheral ties may not be placed parallel to these members and within the member or

within the area directly above the member, unless the member can be shown capable of a 0.20-rad (11.3-deg) rotation. If perimeter beams, girders, or spandrels are present, the 3.3-ft (1.0-m) shall be measured from the interior edge of the beam, girder or spandrel. An illustration of this restriction is shown in Figure 3-4.
\2\

3-1.4.2.1 Framed and Two-way Load-Bearing Wall Buildings.

For framed and two-way load-bearing wall buildings, the required peripheral tie strength F_p (lb or kN) is

$$F_p = 6\, w_F\, L_1\, L_p + 3\, W_C \qquad \text{Equation (3-6)}$$

Where
- w_F = Floor load, determined per Section 3-1.3, (lb/ft^2 or kN/m^2)
- W_C = 1.2 x Dead load of cladding over the length of L_1, (lb or kN), where 1.2 is the LRFD dead load factor
- L_1 = For peripheral ties at the edge of the building: The greater of the distances between the centers of the columns, frames, or walls, at the perimeter of the building in the direction under consideration (ft or m).
  = For peripheral ties at openings (see Figure 3-6), the length of the bay in which the opening is located, in the direction under consideration.
- h_w = Clear story height (ft or m)
- L_p = 3.3-ft (1.0-m)

Note that the dead load includes the self-weight of the members and superimposed dead loads.

3-1.4.2.2 One-way Load-Bearing Wall Buildings.

For one-way load-bearing wall buildings, the required peripheral tie strength F_p (lb or kN) is

$$F_p = 6\, w_F\, L_1\, L_p + 3\, W_C + 3\, W_W \qquad \text{Equation (3-7)}$$

Where
- w_F = Floor load, determined per Section 3-1.3, (lb/ft^2 or kN/m^2)
- W_C = 1.2 x Dead load of cladding over the length of L_1, (lb or kN), where 1.2 is the LRFD dead load factor,
- W_W = 1.2 x Dead load of wall over the length of h_w, where 1.2 is the LRFD dead load factor,
- h_w = Clear story height (ft or m)

L_1 = For exterior peripheral ties perpendicular to the load-bearing walls (longitudinal direction in Figure 3-5), the greatest of the distances between the centers of the walls in the direction under consideration (m or ft).
= For exterior peripheral ties parallel to the load-bearing walls (transverse direction in Figure 3-5), 2 h_W (m or ft).
= For peripheral ties at openings (see Figure 3-6), the length of the bay in which the opening is located, in the direction under consideration (ft or m)
L_p = 3.3-ft (1.0-m)

Notes: 1) For the end load-bearing walls, only the wall load is acting, as the end wall is the façade, and W_C = 0.; 2) The dead load includes the self-weight of the members and superimposed dead loads; 3) See Commentary C-5.4.2 for additional information.
/2/

3-1.4.3 Vertical Ties.

\2\ Use the columns and load-bearing walls to carry the required vertical tie strength. Each column and load-bearing wall shall be tied continuously from the roof level down to the first column- or wall-supported floor above the foundation, i.e., the vertical ties are not required to extend to the foundation. Vertical ties shall be straight. /2/

The vertical tie must have a design strength in tension equal to the largest vertical load received by the column or wall from any one story, using the tributary area and the floor load w_F as determined in Section 3-1.3.

3-1.5 Continuity of Ties.

\2\ The load path for peripheral ties must be continuous between building corners and edge of openings. /2/ For internal longitudinal and transverse ties, the path must be continuous from one edge to the other. However, interruptions due to courtyards, mezzanines, elevator/stairwell cores, etc, are allowed, as shown in Figure 3-6, when a peripheral tie is placed at the interruption; \2\ note that peripheral ties around an opening are not required if the opening fits between the longitudinal and transverse ties that meet the spacing requirements of Sections 3-1.4.1.1 and 3-1.4.1.2./2/ Insure that sufficient embedment or anchoring is provided to develop the strength of the peripheral ties placed at the interruption; anchor the longitudinal and transverse ties to the peripheral ties with seismic hooks. Along a particular load path, different structural elements may be used to provide the required tie strength, providing that they are adequately connected.

\2\Each column and load-bearing wall shall be tied continuously from the roof level down to the first column- or wall-supported floor above the foundation, i.e., the vertical ties are not required to extend to the foundation. /2/

Re-entrant corners are allowed for all types of construction, providing that the transverse, longitudinal, and peripheral ties are adequately developed and anchored, per Section 3-1.6.
\2\/2/

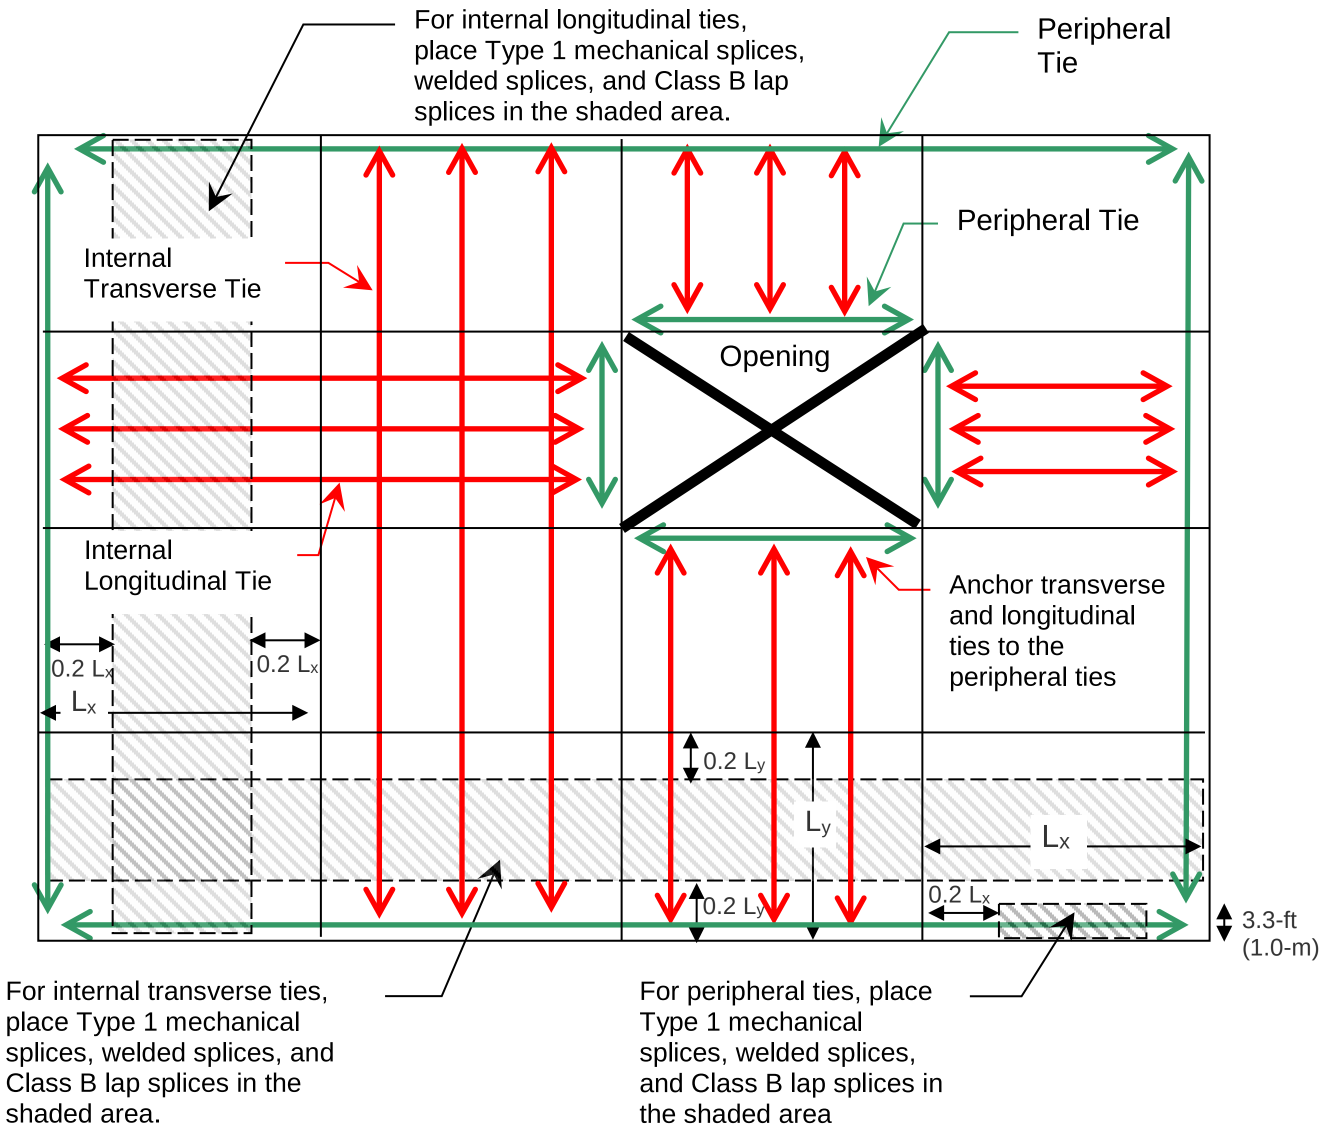
3-1.6 Splices, Anchorage, and Development of Ties.

3-1.6.1 Cast-in-Place Reinforced Concrete Floor and Roof Systems.

For cast-in-place construction, including composite construction with sheet metal decks and reinforced concrete topping, and, for precast floor systems with a concrete topping and reinforcement, splices in steel reinforcement used to provide the design tie strength shall be lapped with Class B lap splices, welded, or mechanically joined with Type 1 or Type 2 mechanical splices, per ACI 318. Splices shall be staggered within the allowable shaded areas shown in Figure 3-6.

Type 2 mechanical splices may be used at any location in the slab. For internal longitudinal and transverse ties, Type 1 mechanical splices, welded splices, and Class B lap splices shall be located no closer than 20% of the bay spacing in the direction of the tie to any vertical load carrying elements (i.e., these splices must be within the middle 60% of the slab or floor or roof system bay, in the direction of the tie); see Figure 3-6. For peripheral ties, Type 1 mechanical splices, welded splices, and Class B lap splices shall be placed no closer than 20% of the span distance in the peripheral tie direction; see Figure 3-6. Note that noncontact splices are not allowed.
\2\

Figure 3-6. Splice Locations and Interruptions in Internal Tie Forces



Use seismic hooks as defined in ACI 318 to anchor and connect internal longitudinal and transverse ties to the peripheral ties; when multiple rebar are used as the peripheral tie, the seismic hooks on the longitudinal and transverse ties shall engage the furthest peripheral tie rebar (the rebar closest to the edge of the structure). The strength of the peripheral ties shall be developed within the 3.3-ft (1.0-m) wide area at the edge of the floor or roof, using development lengths from Chapter 12 of ACI 318. At re-entrant corners or at substantial changes in construction, take care to insure that the transverse, longitudinal, and peripheral ties are adequately anchored and developed. /2/

3-1.6.2 Precast Concrete Floor and Roof Systems.

For precast concrete floor and roof systems, the rebar within the precast planks may be used to provide the internal tie forces, providing the rebar is continuous across the structure and properly anchored; this may be difficult to accomplish in the short direction of the plank. Also, the rebar may be placed within a concrete topping; in this case, provide positive mechanical engagement between the reinforcement and the precast floor system, with sufficient strength to insure that the precast units do not separate from the topping and fall to the space below. Do not rely on the bond strength between the topping and precast units, as the bond can be disrupted by the large deformations associated with catenary behavior. This attachment between the rebar in the concrete topping and the precast planks may be accomplished with hooks, loops or other mechanical attachments that are embedded in the precast floor units.

3-1.6.3 Composite Construction Floor and Roof Systems.

If composite construction with steel decks and concrete topping is employed, provide sufficient connection between the steel beam and the composite floor such that the beam will not fall to the space below.

3-1.6.4 Other Floor and Roof Systems and Structural Elements.

If other floor and roof systems and structural elements can be shown capable of carrying the tie forces required in Sections 3-1.4.1 and 3-1.4.2 while undergoing a rotation of 0.20-rad (11.3-deg) and while meeting the continuity requirement of Section 3-1.5, provide adequate splicing and anchorage that allows development of the transverse, longitudinal, and peripheral tie forces required in Section 3-1.6.

3-1.7 Structural Elements and Connections with Inadequate Tie Strength

If the vertical design tie strength of any structural element or connection is less than the vertical required tie strength, the designer must either: 1) revise the design to meet the tie force requirements or 2) use the Alternate Path method to prove that the structure is capable of bridging over this deficient element.

The AP method shall not be applied to structural elements or connections that cannot provide the required longitudinal, transverse, or peripheral tie strength; in this case, the designer must redesign or retrofit the element and connection such that a sufficient design tie strength is developed.

3-2 ALTERNATE PATH METHOD.

The Alternate Path method is used in two situations: 1) for Option 1 of \3\ Risk Category /3/ II and for \3\ Risk Category /3/ IV, when a vertical structural element cannot provide the required tie strength, the designer may use the AP method to determine if the structure can bridge over the deficient element after it has been notionally removed, and 2) for \3\ Risk Category /3/ II Option 2, \3\ Risk Category /3/ III, and \3\ Risk

Category /3/ IV, the AP method must be applied for the removal of specific vertical load-bearing elements which are prescribed in Section 3-2.9.

3-2.1 General.

This method follows the general LRFD philosophy by employing a modified version of the ASCE 7 load factor combination for extraordinary events and resistance factors to define design strengths. Three analysis procedures are employed: Linear Static (LSP), Nonlinear Static (NSP) and Nonlinear Dynamic (NDP). These procedures follow the general approach in ASCE 41 with modifications to accommodate the particular issues associated with progressive collapse. Much of the material-specific criteria from Chapters 9 to 12 of ASCE 41 are explicitly adopted in Chapters 4 to 8 of this document. The topics of each ASCE 41 Chapter are:

- Steel or cast iron, ASCE 41 Chapter 9,
- Reinforced concrete, ASCE 41 Chapter 10,
- Reinforced or un-reinforced masonry, ASCE 41 Chapter 11,
- Timber, light metal studs, gypsum, or plaster products, ASCE 41 Chapter 12.

Note that some of the deformation and strength criteria in ASCE 41 Chapters 9 to 12 have been superseded by requirements that are specified in the material specific Chapters 4 to 8 in this UFC.

3-2.2 Alternative Rational Analysis.

For the performance of the Alternate Path analysis and design, nothing in this document shall be interpreted as preventing the use of any alternative analysis procedure that is rational and based on fundamental principles of engineering mechanics and dynamics. For example, simplified analytical methods employing hand calculations or spreadsheets may be appropriate and more efficient for some types of buildings, such as load-bearing wall structures.

The results of any alternative rational analyses shall meet the acceptance criteria contained in Section 3-2.10 and in Chapters 4 through 8. The analyses shall include the specified locations for removal of columns and load-bearing walls in Section 3-2.9 and the ASCE 7 extreme event load combination, with the load increase factors in Sections 3-2.11.5 and 3-2.12.5 for linear static and nonlinear static analyses, respectively. The designer shall verify that these criteria are applicable to the alternative rational analyses. If a Linear Static approach is employed, the requirements of Section 3-2.11.1 must be met. All projects using alternative rational analysis procedures shall be reviewed and approved by an independent third-party engineer or by an authorized representative of the facility owner.

3-2.3 Load and Resistance Factor Design for Alternate Path Method.

\2\The Alternate Path method employed in this UFC follows the general philosophy of the standard LRFD approach but with modifications to facilitate the integration of the ASCE 41 procedures, which are not LRFD. /2/ For LRFD, the design strength is taken as the product of the strength reduction factor $\boldsymbol{\Phi}$ and the nominal strength $\boldsymbol{R_n}$ calculated in accordance with the requirements and assumptions of applicable material specific codes. The design strength must be greater than or equal to the required strength:

$$\Phi R_n \geq R_u \qquad \text{Equation (3-8)}$$

where
- ΦR_n = Design strength
- Φ = Strength reduction factor
- R_n = Nominal strength
- $R_u = \Sigma \gamma_i Q_i$ = Required strength
- γ_i = Load factor
- Q_i = Load effect

Items to note relative to the integration of the LRFD and the ASCE 41 approaches: /2/

- While ASCE 41 requires that all Φ factors be taken as unity, this UFC requires that strength reduction factors, Φ, be used as specified in the appropriate material specific code, for the action or limit state under consideration.

- \2\ASCE 41 uses the term “action” in the way LRFD defines “required strength”. ASCE 41 further differentiates actions into “deformation-controlled” and “force-controlled”. These terms are defined later.

- In this UFC, the LRFD “nominal strength” is defined as either the “expected strength” when deformation actions are being considered or the “lower-bound strength” for force-controlled actions; ASCE 41 sets all Φ factors to 1 and therefore, the expected and lower bound strengths are the nominal strengths in this document.

- This UFC and ASCE 41 both employ the same “over-strength factors” to translate lower bound material properties to expected strength material properties. The over-strength factors are provided in ASCE 41 Tables 9-3 (structural steel), 10-4 (reinforced concrete), and 11-2 (masonry). For wood and cold-formed steel, Chapter 12 of ASCE 41 provides default expected strength values; note that for wood construction, a time effect factor λ is also included.

Note that live load reductions (LLRs) per ASCE 7 are permitted for all live loads used in Alternate Path analysis and design. For framed structures, where the floor slab is supported by beams and girders, the analyst may use the LLR for each beam individually or may use the same LLR for the entire structure. In the latter case, the LLR shall be equal to the smallest LLR (greatest live load) for any beam in the bays above the column removal location. For flat-slab structures, load-bearing wall structures and other situations where the floor system transfers loads directly to the columns or walls, the LLR shall be computed for, and applied to, the floor in each bay. In all cases, the LLRs shall be based on the structural configuration before the column or load-bearing wall section is removed. /2/

3-2.4 Primary and Secondary Components.

Designate all structural elements and components as either primary or secondary. Classify structural elements and components that provide the capacity of the structure to resist collapse due to removal of a vertical load-bearing element as primary. Classify all other elements and components as secondary. For example, a steel gravity beam may be classified as secondary if it is assumed to be pinned at both ends to girders and the designer chooses to ignore any flexural strength at the connection; if the connection is modeled as partially restrained and thus contributes to the resistance of collapse, it is a primary member.

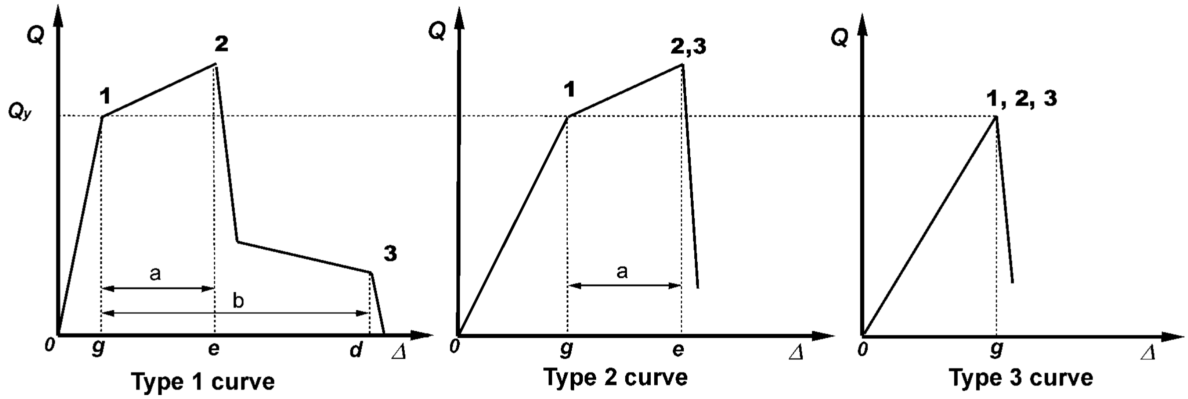
3-2.5 Force and Deformation Controlled Actions.

Classify all actions as either deformation controlled or force-controlled using the component force versus deformation curve shown in Figure 3-7. Examples of deformation and force controlled actions are listed in Table 3-1. Note that a component might have both force and deformation controlled actions. Further, classification as a force or deformation controlled action is not up to the discretion of the user and must follow the guidance presented here.

Define a primary component action as deformation controlled if it has a Type 1 curve and $e \geq 2g$, or, it has a Type 2 curve and $e \geq 2g$. Define a primary component action as force-controlled if it has a Type 1 or Type 2 curve and $e < 2g$, or, if it has a Type 3 curve.

Define a secondary component action as deformation controlled if it has a Type 1 curve for any e/g ratio or if it has a Type 2 curve and $e \geq 2g$. Define a secondary component action as force controlled if it has a Type 2 curve and $e < 2g$, or, if it has a Type 3 curve.

Figure 3-7. Definition of Force Controlled and Deformation Controlled Actions, from ASCE 41



3-2.6 Expected and Lower Bound Strength.

When evaluating the behavior of deformation controlled actions, use the expected strength, Q_{CE}. Q_{CE} is defined as the statistical mean value of the strength, Q (yield, tensile, compressive, etc, as appropriate), for a population of similar components, and includes consideration of the variability in material strengths as well as strain hardening and plastic section development. Note that Q_{CE} relates to any deformation-controlled action presented in Table 3-1, e.g., the expected strength for the moment in a deformation-controlled, laterally braced beam would be $Q_{CE} = M_{CE} = Z\,F_{YE}$, where Z is the plastic section modulus and F_{YE} is the expected yield strength. If a database to determine F_{YE} is not available, F_{YE} is obtained by multiplying the lower-bound strength F_{YL} (the nominal strength or strength specified in the construction documents) by the appropriate factor from Chapters 9 to 12 in ASCE 41, as discussed in Section 3-2.7.

When evaluating the behavior of force-controlled actions, use a lower bound estimate of the component strength, Q_{CL}. Q_{CL} is defined as the statistical mean minus one standard deviation of the strength, Q (yield, tensile, compressive, etc, as appropriate), for a population of similar components. Note that Q_{CL} relates to any force-controlled action presented in Table 3-1, e.g., the lower bound strength of a steel column under axial compression would be $Q_{CL} = P_{CL}$, where P_{CL} is based on the lowest value obtained for the limit states of column buckling, local flange buckling, or local web buckling, calculated with the lower bound strength, F_{YL}. Where data to determine the lower bound strength are not available, use the nominal strength or strength specified in the construction documents.

3-2.7 Material Properties.

Expected material properties such as yield strength, ultimate strength, weld strength, fracture toughness, elongation, etc, shall be based on mean values of tested material properties. Lower bound material properties shall be based on mean values of tested material properties minus one standard deviation.

If data to determine the lower bound and expected material properties do not exist, use nominal material properties, or properties specified in construction documents, as the lower bound material properties unless otherwise specified in Chapters 9 through 12 of ASCE 41. Calculate the corresponding expected material properties by multiplying lower bound values by appropriate factors specified in Chapters 9 through 12 of ASCE 41 to translate from lower bound material properties to expected material values. If factors for converting from a lower bound to expected material property are not specified, use the lower bound material property as the expected material property.

Table 3-1. Examples of Deformation Controlled and Force Controlled Actions, from ASCE 41

Component	Deformation Controlled Action	Force Controlled Action
Moment Frames • Beams • Columns • Joints	 Moment (M) M --	 Shear (V) Axial load (P), V V[1]
Shear Walls	M, V	P
Braced Frames • Braces • Beams • Columns • Shear Link	 P -- -- V	 -- P P P, M
Connections	P, V, M[2]	P, V, M

1. Shear may be a deformation controlled action in steel moment frame construction.
2. Axial, shear, and moment may be deformation controlled actions for certain steel and wood connections.

3-2.8 Component Force and Deformation Capacities.

\2\/2/Methods for calculation of individual component strengths and deformation capacities shall comply with the requirements in the individual ASCE 41 material chapters.

\2\As shown in the acceptance criteria given in Sections 3-2.11.7, 3-2.12.7 and 3-2.13.6, the expected and lower-bound strengths shall be multiplied by the strength reduction factors that are specified in the material specific design codes (i.e., the *Φ* factors in ACI 318, the AISC Steel Construction Manual, etc). Note that *Φ* factors are taken as 1.0 in ASCE 41. /2/

3-2.8.1 Component Capacities for Nonlinear Procedures.

For nonlinear procedures, component capacities for deformation controlled actions shall be taken as permissible inelastic deformation limits, and component capacities for force-controlled actions shall be taken as lower-bound strengths, Q_{CL}, multiplied by the appropriate strength reduction factor Φ, as summarized in Table 3-2.

Table 3-2. Calculation of Component Capacities for Nonlinear Static and Nonlinear Dynamic Procedures

Parameter	Deformation Controlled	Force Controlled
Deformation Capacity	Deformation limit	N/A
Strength Capacity	N/A	$\Phi\ Q_{CL}$

3-2.8.2 Component Capacities for the Linear Static Procedure.

For the linear static procedure, component capacities for deformation-controlled actions shall be defined as the product of ***m-factors*** and expected strengths, Q_{CE}, multiplied by the appropriate strength reduction factor Φ. Capacities for force-controlled actions shall be defined as lower-bound strengths, Q_{CL}, multiplied by the appropriate strength reduction factor Φ, as summarized in Table 3-3.

Table 3-3. Calculation of Component Capacities for the Linear Static Procedure

Parameter	Deformation Controlled	Force Controlled
Material Strength	Expected Material Strength	Lower Bound Strength
Strength Capacity	$\Phi\ m\ Q_{CE}$	$\Phi\ Q_{CL}$

3-2.9 Removal of Load-Bearing Elements for the Alternate Path Method.

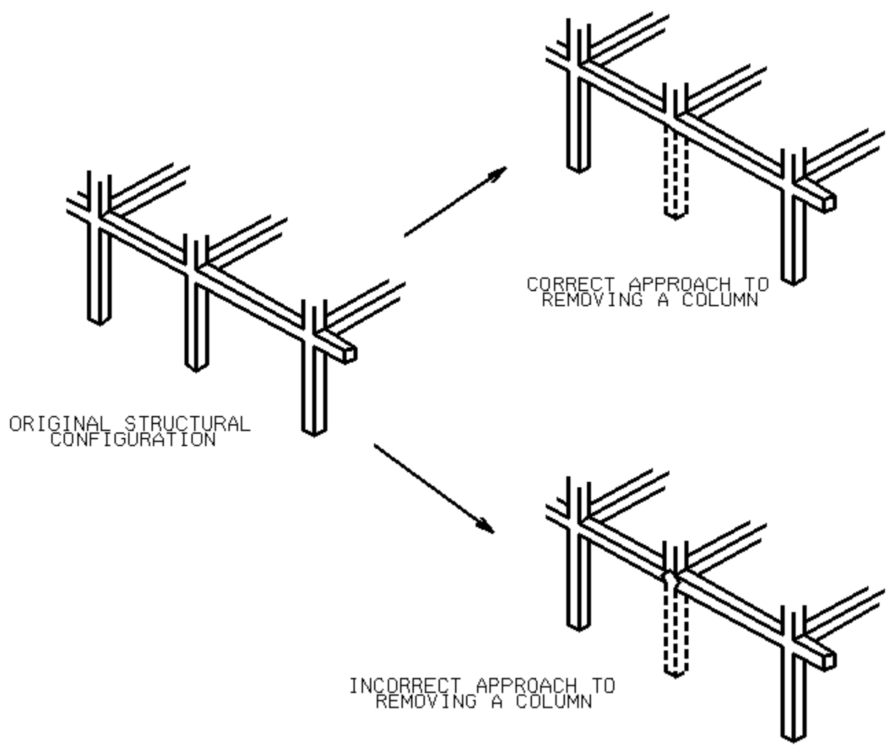
Load-bearing elements are removed for the following two cases:

1) For RC II Option 1 and RC IV structures, where an element cannot provide the required vertical tie strength,
2) For RC II Option 2, RC III, and RC IV structures, where AP is applied to elements for which the location and size are specified to verify that the structure has adequate flexural resistance to bridge over the missing element.

For both external and internal column removal, for the purposes of AP analysis, beam-to-beam continuity is assumed to be maintained across a removed column; see Figure 3-8.

The details of the size and location of the removed load-bearing elements are described in the following sub-paragraphs.

Figure 3-8. Removal of Column from Alternate Path Model



3-2.9.1 Extent of Removed Load-Bearing Elements.

3-2.9.1.1 RC II Option 1 (Deficient Vertical Tie Force).

For each column that cannot provide the required vertical tie force, remove the clear height between lateral restraints***.***

For each load-bearing wall that cannot provide the required vertical tie force, the length of the removed section of wall is twice the clear story height ***H***, if the length of the deficient wall is greater than ***2H***. If the length of the deficient wall is less than ***2H***, remove just that portion of deficient wall. In both instances, remove the clear height between lateral restraints. Note that discontinuities, such as joints, segmented walls, or openings for doors or windows, can be located within the ***2H*** length, providing that the loads above that discontinuity are carried by the remainder of the wall in the ***2H*** length.

3-2.9.1.2 RC II Option 2, RC III, and RC IV

For each column, remove the clear height between lateral restraints.

For each load-bearing wall, remove a length that is twice the clear story height ***H***. Remove the clear height between lateral restraints. Note that only planar sections of wall are removed, i.e., if a shear wall has a C-shaped cross-section in plan, only the flange or only the web are removed, but not both. However, for external corners, where one or both of the intersecting walls is load bearing, remove a length of wall equal to the clear story height ***H*** in each direction

3-2.9.2 Location of Removed Load-Bearing Elements.

3-2.9.2.1 RC II Option 1 (Deficient Vertical Tie Force).

Remove the column that cannot provide the required vertical tie force.

For a deficient load-bearing wall or section thereof that is longer than ***2H***, determine the location(s) for removal by using the guidance for wall removal locations provided in Sections 3-2.9.2.4 and 3-2.9.2.5. Additionally, use engineering judgment to shift the location of the removed ***2H*** section of wall within the length of deficient wall to evaluate worse case scenarios. If the length of the deficient load-bearing wall is less than ***2H***, remove just the section that is deficient.

3-2.9.2.2 RC II Option 2, RC III and IV External Columns.

For RC II Option 2, RC III and RC IV, as a minimum, remove external columns near the middle of the short side, near the middle of the long side, and at the corner of the building, as shown in Figure 3-9. Also remove columns at locations where the plan geometry of the structure changes significantly, such as abrupt decrease in bay size or re-entrant corners, or, at locations where adjacent columns are lightly loaded, the bays have different tributary sizes, and members frame in at different orientations or elevations. Use engineering judgment to identify these critical column locations.

\2\If any other column is within a distance of 30% of the largest dimension of the associated bay from the column removal location, it must be removed simultaneously. /2/

For each plan location defined for element removal, perform AP analyses for:

1. First story above grade
2. Story directly below roof
3. Story at mid-height
4. Story above the location of a column splice or change in column size

For example, if a corner column is specified as the removed element location in a ten story building with a column splice at the third story, one AP analysis is performed for removal of the ground story corner column; another AP analysis is performed for the removal of the corner column at the tenth story; another AP analysis is performed for the fifth story corner column (mid-height story) and one AP analysis is performed for the fourth story corner column (story above the column splice).

3-2.9.2.3 RC II Option 2, RC III and RC IV Internal Columns.

For RC II Option 2, RC III and RC IV structures with underground parking or areas of uncontrolled public access, remove internal columns near the middle of the short side, near the middle of the long side and at the corner of the uncontrolled space, as shown in Figure 3-10; see Section 1-2.3 for a definition of controlled public access. The removed column extends from the floor of the underground parking area or uncontrolled public floor area to the next floor (i.e., a one story height must be removed). Internal columns must also be removed at other critical locations within the uncontrolled public access area, as determined with engineering judgment. For each plan location, the AP analysis is only performed for the story with the parking or uncontrolled public area.

\2\If any other column is within a distance of 30% of the largest dimension of the associated bay from the column removal location, it must be simultaneously removed as well. /2/

3-2.9.2.4 RC II Option 2, RC III and RC IV External Load-Bearing Walls.

As a minimum, remove external load-bearing walls near the middle of the short side, near the middle of the long side and at the corner of the building, as shown in Figure 3-11. For external corners, where one or both of the intersecting walls is load bearing, remove a length of wall equal to the clear story height ***H*** in each direction. Also remove load-bearing walls at locations where the plan geometry of the structure changes significantly, such as at an abrupt decrease in bay size or at re-entrant corners, as well as at locations where adjacent walls are lightly loaded, the bays have different sizes, and members frame in at different orientations or elevations. Use engineering judgment to identify these critical locations. The length of the removed wall section is specified in Section 3-2.9.1. The designer must use engineering judgment to shift the location of the removed wall section by a maximum of the clear story height ***H*** if that creates a worst-case scenario.

For each plan location defined for element removal, perform AP analyses for the following stories:

1. First story above grade
2. Story directly below roof
3. Story at mid-height
4. Story above the location of a change in wall size

For example, if a wall section at the middle of the long side is specified as the removed element location in a six story wood building with a change in wall framing at the third story, one AP analysis is performed for removal of the ground story wall section; another AP analysis is performed for the removal of the wall section at the sixth story; another AP analysis is performed for the third story (mid-height story) and one AP analysis is performed for the fourth story (story above the change in wall framing).

If any other load-bearing element such as a column is within a distance of 30% of the clear story height (H) behind or in front of the wall removal location, it must be removed simultaneously.

Figure 3-9. Location of External Column Removal for RC II Option 2, RC III and IV Structures

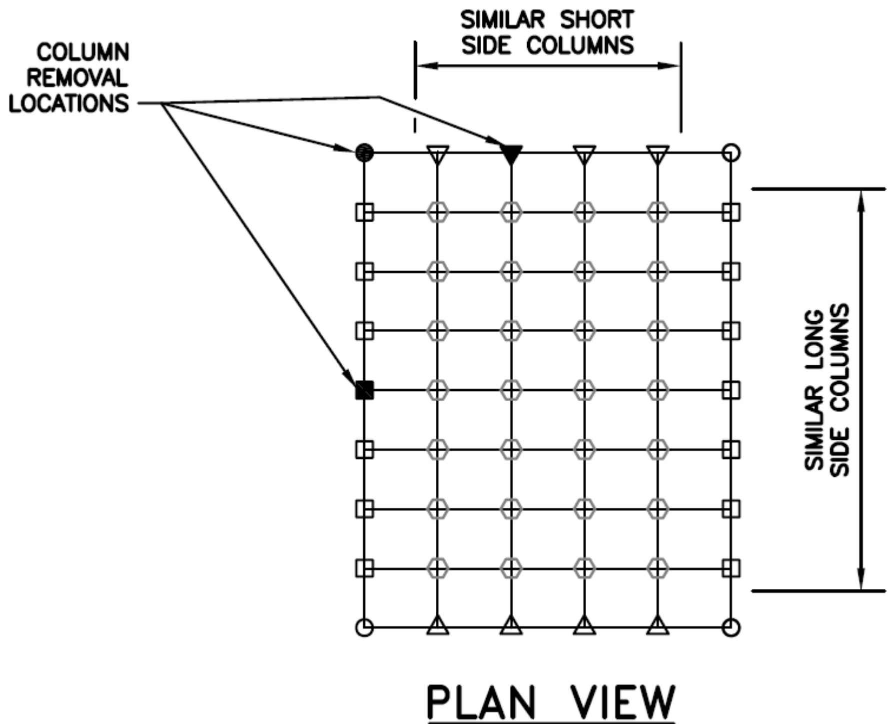


Figure 3-10. Location of Internal Column Removal for RC II Option 2, RC III and IV Structures

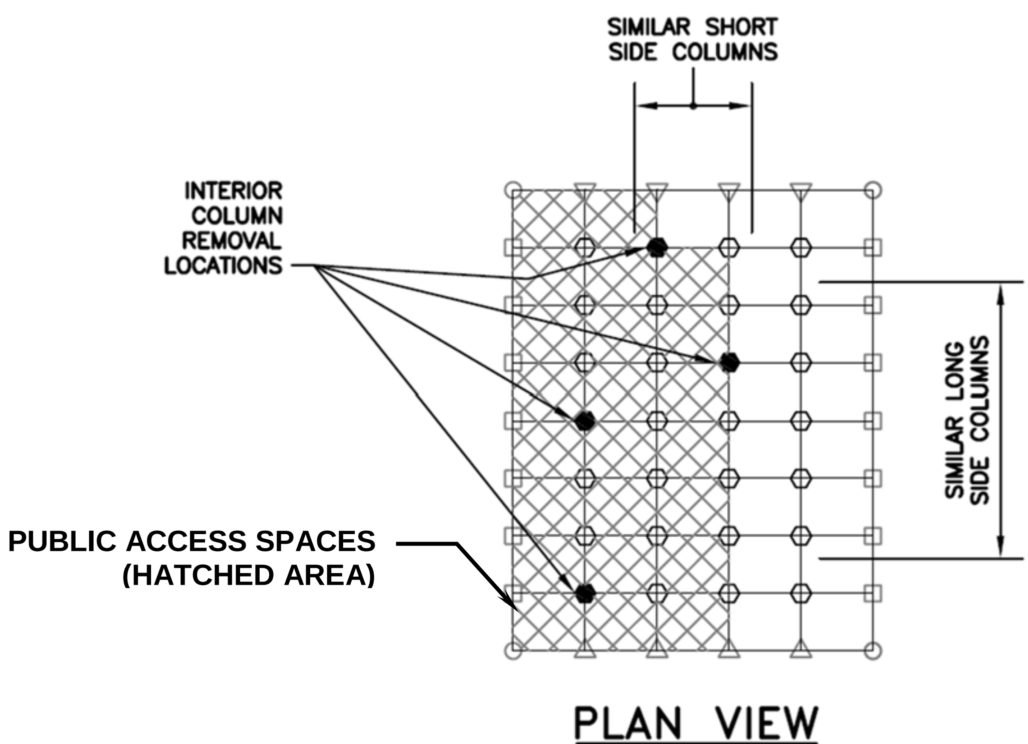

Figure 3-11. Location of External Load-Bearing Wall Removal for RC II Option 2, RC III and RC IV Structures

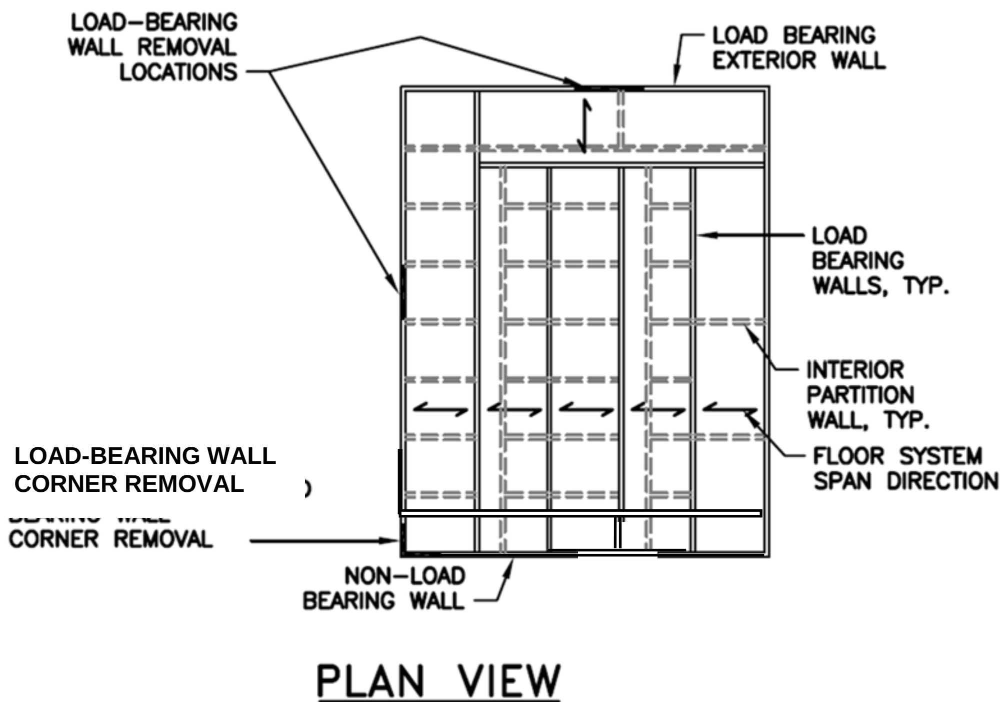

Figure 3-12. Location of Internal Load-Bearing Wall Removal for RC II Option 2, RC III and RC IV Structures

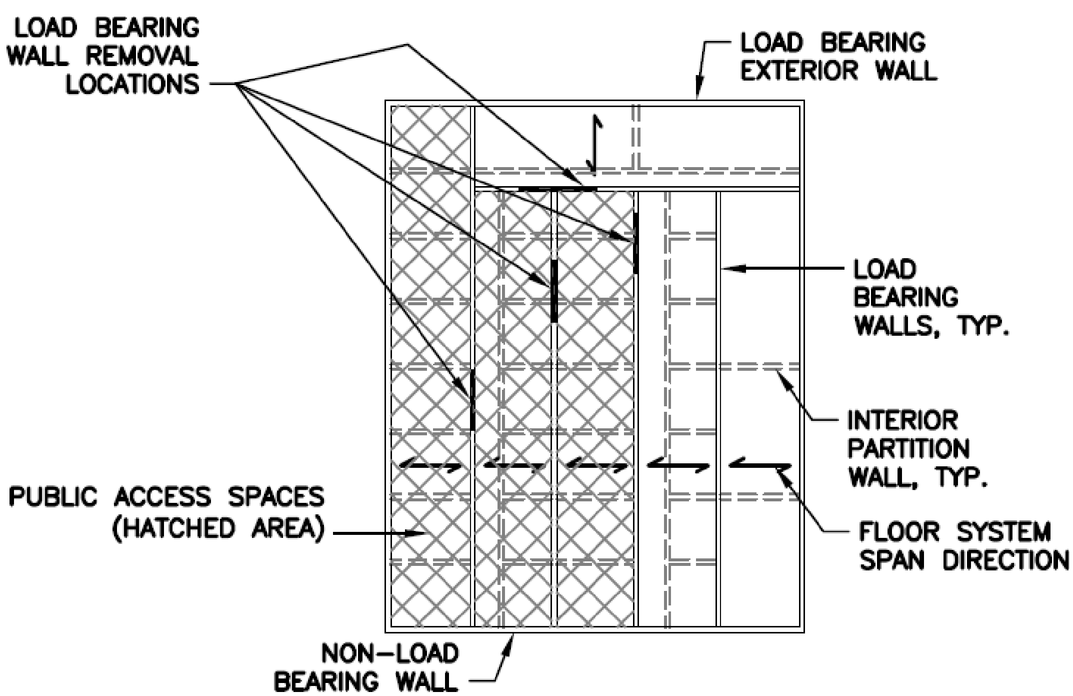

3-2.9.2.5 RC II Option 2, RC III and RC IV Internal Load-Bearing Walls.

For structures with underground parking or areas of uncontrolled public access, remove internal load-bearing walls near the middle of the short side, near the middle of the long side and at the corner of the uncontrolled space, as shown in Figure 3-12; see Section 1-2.3 for a definition of controlled public access. For internal corners, where one or both of the intersecting walls is load-bearing, remove a length of wall equal to the clear story height ***H*** in each direction. The removed wall extends from the floor of the underground parking area or uncontrolled public floor area to the next floor (i.e., a one story height must be removed). Also remove internal load-bearing walls at other critical locations within the uncontrolled public access area, as determined with engineering judgment. For each plan location, the AP analyses are only performed for the load-bearing walls at the story with parking area or uncontrolled public space, and not for all stories in the structure. The length of the removed wall section is specified in Section 3-2.9.1. The designer must use engineering judgment to shift the location of the removed wall section by a maximum of the wall height if that creates a worst-case scenario. If any other load-bearing element such as column is within a distance of 30% of the clear story height (H) behind or in front of the wall removal location, it must be removed simultaneously.

3-2.10 Structure Acceptance Criteria.

For all three analysis types (LS, NS, and ND), the building is structurally adequate if none of the primary and secondary elements, components, or connections exceeds the acceptance criteria, in Paragraphs 3-2.11.7, 3-2.12.7, and 3-2.13.6, as appropriate. If the analysis predicts that any element, component, or connection does not meet these acceptance criteria, the building does not satisfy the progressive collapse requirements and must be re-designed or retrofitted to eliminate the non-conforming element.

3-2.11 Linear Static Procedure.

The LSP and limitations to its use are provided in the following sub-sections.

3-2.11.1 Limitations on the Use of LSP.

The use of the LSP is limited to structures that meet the following requirements for irregularities and Demand-Capacity Ratios (DCRs).

If there are no structural irregularities as defined in Section 3-2.11.1.1, a linear static procedure may be performed and it is not necessary to calculate the DCRs defined in Section 3-2.11.1.2. If the structure is irregular, a linear static procedure may be performed if all of the component DCRs determined in the Section 3-2.11.1.1 are less than or equal to 2.0. If the structure is irregular and one or more of the DCRs exceed 2.0, then a linear static procedure cannot be used.

3-2.11.1.1 Irregularity Limitations.

A structure is considered irregular if any one of the following is true:

1. Significant discontinuities exist in the gravity-load carrying and lateral force-resisting systems of a building, including out-of-plane offsets of primary vertical elements, roof "belt-girders", and transfer girders (i.e., non-stacking primary columns or load-bearing elements). Stepped back stories are not considered an irregularity.
2. At any exterior column except at the corners, at each story in a framed structure, the ratios of bay stiffness and/or strength from one side of the column to the other are less than 50%. Three examples are; a) the lengths of adjacent bays vary significantly, b) the beams on either side of the column vary significantly in depth and/or strength, and c) connection strength and/or stiffness vary significantly on either side of the column (e.g., for a steel frame building, a shear tab connection on one side of a column and a fully rigid connection on the other side shall be considered irregular).
3. For all external load-bearing walls, except at the corners, and for each story in a load-bearing wall structure, the ratios of wall stiffness and/or strength from one side of an intersecting wall to the other are less than 50%.
4. The vertical lateral-load resisting elements are not parallel to the major orthogonal axes of the lateral force-resisting system, such as the case of skewed or curved moment frames and load-bearing walls.

3-2.11.1.2 DCR Limitation.

To calculate the DCRs for either framed or load-bearing structures, create a linear model of the building as described in Section 3-2.11.2.2. The model will have all primary components with the exception of the removed wall or column. The deformation-controlled load case in Section 3-2.11.4.1 shall be applied, with gravity dead and live loads increased by the load increase factor Ω_{LD} in Section 3-2.11.5. The resulting actions (internal forces and moments) are defined as Q_{UDLim}:

Use Q_{UDLim} to calculate the ***DCRs*** for the deformation controlled actions as:

$$DCR = Q_{UDLim}/Q_{CE} \qquad \text{Equation (3-9)}$$

where Q_{CE} = Expected strength of the component or element, as specified in Chapters 4 to 8.

3-2.11.2 Analytical Modeling.

To model, analyze, and evaluate a building, employ a three-dimensional assembly of elements and components. Two-dimensional models are not permitted. Note that hand or spreadsheet calculations can be used, as allowed in Section 3-2.2 Alternative Rational Analysis.

3-2.11.2.1 Loads.

Analyze the model with two separate load cases: 1) to calculate the deformation-controlled actions Q_{UD}, and 2) to calculate the force-controlled actions Q_{UF}. Apply the Gravity loads to the model using the load cases for deformation-controlled actions and force-controlled actions defined in Section 3-2.11.4.

3-2.11.2.2 Required Model Elements.

Include the stiffness and resistance of only the primary elements and components. Insure that the model includes a sufficient amount of structural detail to allow the correct transfer of vertical loads from the floor and roof system to the primary elements. Use the guidance of ASCE 41 Chapters 9 through 12 to create the model. Also, as discussed later, and after the analysis is performed, check the primary and secondary elements against the acceptance criteria for force-controlled and deformation-controlled actions. While secondary elements are not included in the model, their actions and deformations can either be estimated based on the deformations of the model with only primary elements or the model may be re-analyzed with the secondary components included. If the model is re-analyzed with the secondary components included, their stiffness and resistance must be set to zero, i.e., the advantage of including the secondary components is that the analyst may more easily check the secondary elements deformations rather than perform hand calculations of the original model.

If the building contains sections that are less than three stories and are attached to the sections with three or more stories, the designer shall perform an analysis to determine whether there is a possibility that the presence of the short section will affect the taller section in a negative manner; if so, then include the short section in the model.

3-2.11.2.3 Limitations on Connection Strength.

For models that incorporate connections between horizontal flexural elements (beams, slabs, girders, etc) and vertical load-bearing elements (columns and walls), the strength of the connection shall not be modeled as greater than the strength of the attached horizontal flexural element.

3-2.11.3 Stability/P-Δ Effects.

\2\Note that overall vertical and lateral stability as well as local stability (i.e., lateral torsional buckling) must be considered. However, a P-Δ analysis is not required for the Linear Static approach due to the small deformations. /2/

3-2.11.4 Loading.

Due to the different methods by which deformation-controlled and force-controlled actions are calculated, two load cases will be applied and analyzed: one for the deformation-controlled actions, and one for the force-controlled actions, as specified here.

Live load reduction is allowed, if the requirements in Section 3-2.3 are met.

3-2.11.4.1 Load Case for Deformation-Controlled Actions Q_{UD}.

To calculate the deformation-controlled actions, simultaneously apply the following combination of gravity loads:

Increased Gravity Loads for Floor Areas Above Removed Column or Wall. Apply the following increased gravity load combination to those bays immediately adjacent to the removed element and at all floors above the removed element; see Figures 3-13 and 3-14:

\2\ $G_{LD} = \Omega_{LD}\,[1.2\,D + (0.5\,L \text{ or } 0.2\,S)]$ /2/ Equation (3-10)

where

G_{LD} = Increased gravity loads for deformation-controlled actions for Linear Static Analysis
D = Dead load including façade loads (lb/ft^2 or kN/m^2)
L = Live load including live load reduction per Section 3-2.3 (lb/ft^2 or kN/m^2)
S = Snow load (lb/ft^2 or kN/m^2)
Ω_{LD} = Load increase factor for calculating deformation-controlled actions for Linear Static analysis; use appropriate value for framed or load-bearing wall structures; see Section 3-2.11.5

Gravity Loads for Floor Areas Away From Removed Column or Wall. Apply the following gravity load combination to those bays not loaded with G_{LD}; see Figures 3-13 and 3-14:

\2\ $G = 1.2\,D + (0.5\,L \text{ or } 0.2\,S)$ /2/ Equation (3-11)

where G = Gravity loads

\2\ /2/

3-2.11.4.2 Load Case for Force-Controlled Actions Q_{UF}.

To calculate the force-controlled actions, simultaneously apply the following combination of gravity loads.

Increased Gravity Loads for Floor Areas Above Removed Column or Wall. Apply the following increased gravity load combination to those bays immediately adjacent to the removed element and at all floors above the removed element; see Figures 3-13 and 3-14:

\2\ $G_{LF} = \Omega_{LF} [1.2 D + (0.5 L \text{ or } 0.2 S)]$ /2/ Equation (3-12)

where
- G_{LF} = Increased gravity loads for force-controlled actions for Linear Static analysis
- D = Dead load including façade loads (lb/ft^2 or kN/m^2)
- L = Live load including live load reduction per Section 3-2.3 (lb/ft^2 or kN/m^2)
- S = Snow load (lb/ft^2 or kN/m^2)
- Ω_{LF} = Load increase factor for calculating force-controlled actions for Linear Static analysis; use appropriate value for framed or load-bearing wall structures; see Section 3-2.11.5

Gravity Loads for Floor Areas Away From Removed Column or Wall. Use Equation 3-11 to determine the load ***G*** and apply as shown in Figures 3-13 and 3-14. \2\ /2/

3-2.11.5 Load Increase Factor.

The load increase factors for deformation-controlled and force-controlled actions for column and wall removal are provided in Table 3-4.

In Table 3-4, m_{LIF} is the smallest ***m*** of any primary beam, girder, spandrel or wall element that is directly connected to the columns or walls directly above the column or wall removal location. For each primary beam, girder, spandrel or wall element, ***m*** is the ***m***-factor defined in Chapters 4 to 8 of this UFC, where **m** is either explicitly provided in each chapter or reference is made to ASCE 41 and a corresponding performance level (Collapse Prevention or Life Safety). Columns are omitted from the determination of m_{LIF}. The method behind this procedure is explained in Appendix C.

Table 3-4. Load Increase Factors for Linear Static Analysis

Material	Structure Type	Ω_{LD}, Deformation controlled	Ω_{LF}, Force controlled
Steel	Framed	0.9 m_{LIF} + 1.1	2.0
Reinforced Concrete	Framed[A]	1.2 m_{LIF} + 0.80	2.0
	Load-bearing Wall	2.0 m_{LIF}	2.0
Masonry	Load-bearing Wall	2.0 m_{LIF}	2.0
Wood	Load-bearing Wall	2.0 m_{LIF}	2.0
Cold-formed Steel	Load-bearing Wall	2.0 m_{LIF}	2.0

[A] Note that, per ASCE 41, reinforced concrete beam-column joints are treated as force-controlled; however, the hinges that form in the beam near the column are deformation-controlled and the appropriate m-factor from Chapter 4 of this UFC shall be applied to the calculation of the deformation-controlled load increase factor Ω_{LD}.
\2\

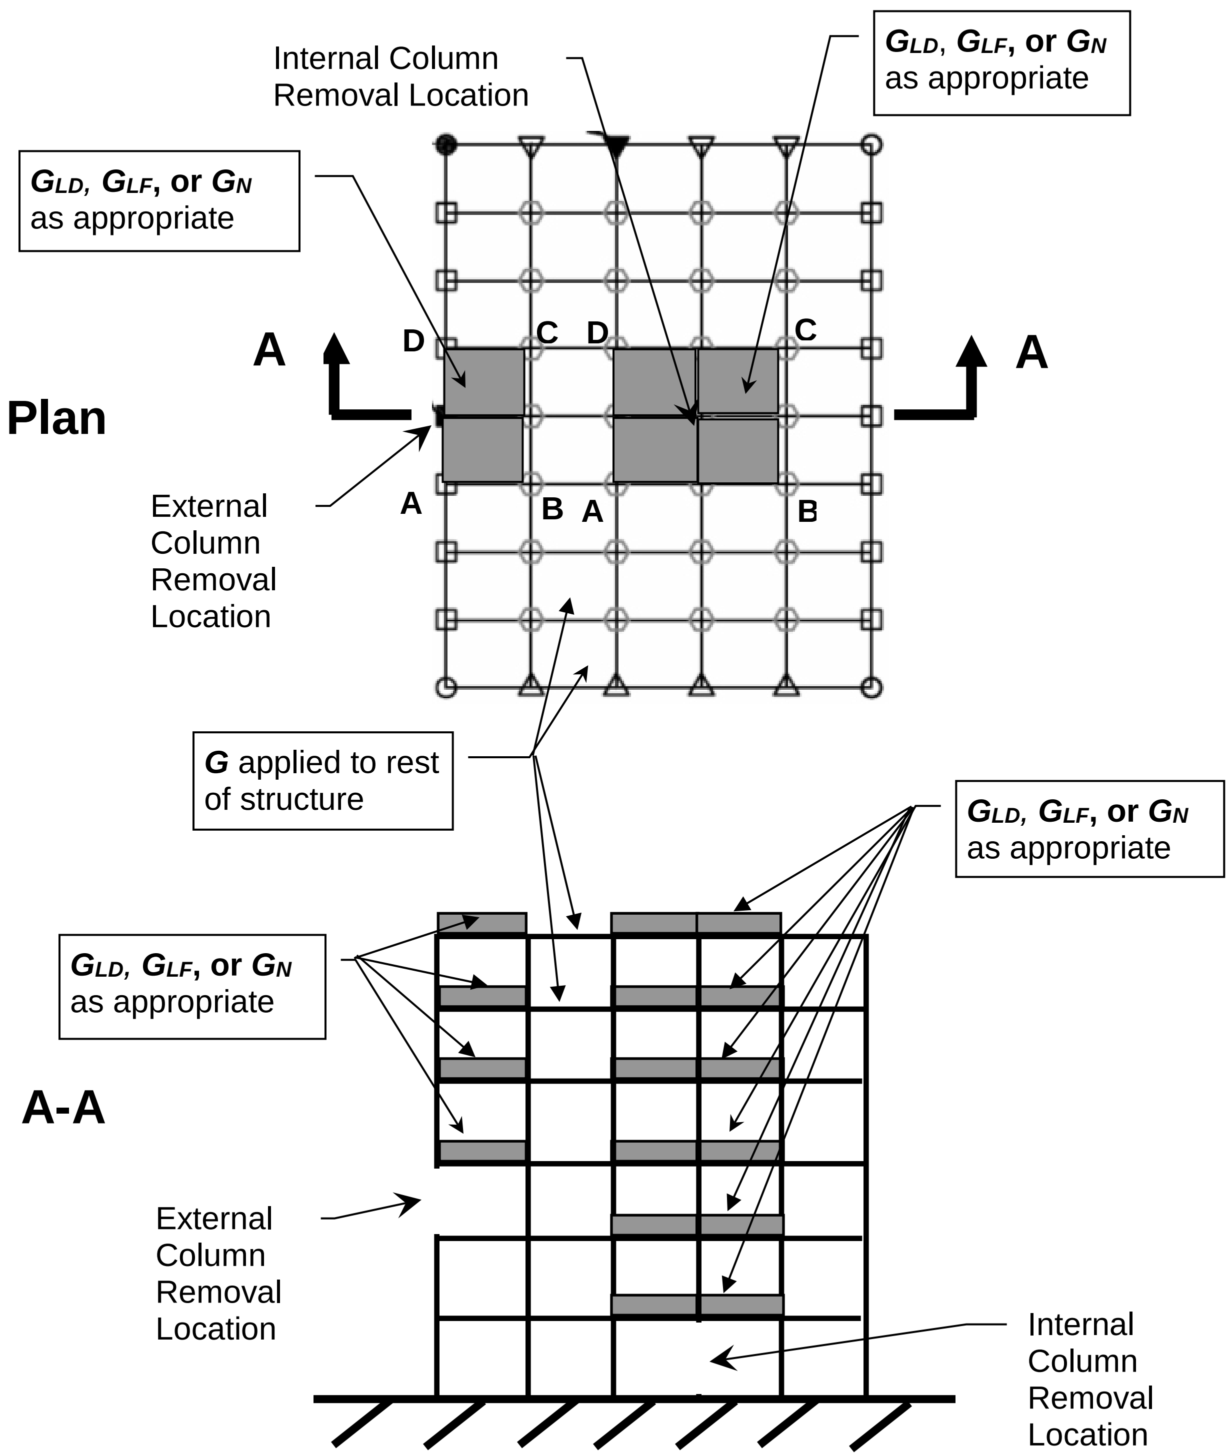

Figure 3-14. Loads and Load Locations for External and Internal Wall Removal for Linear and Nonlinear Static Models (Left Side Demonstrates External Wall Removal; Right Side Shows Internal Wall Removal)

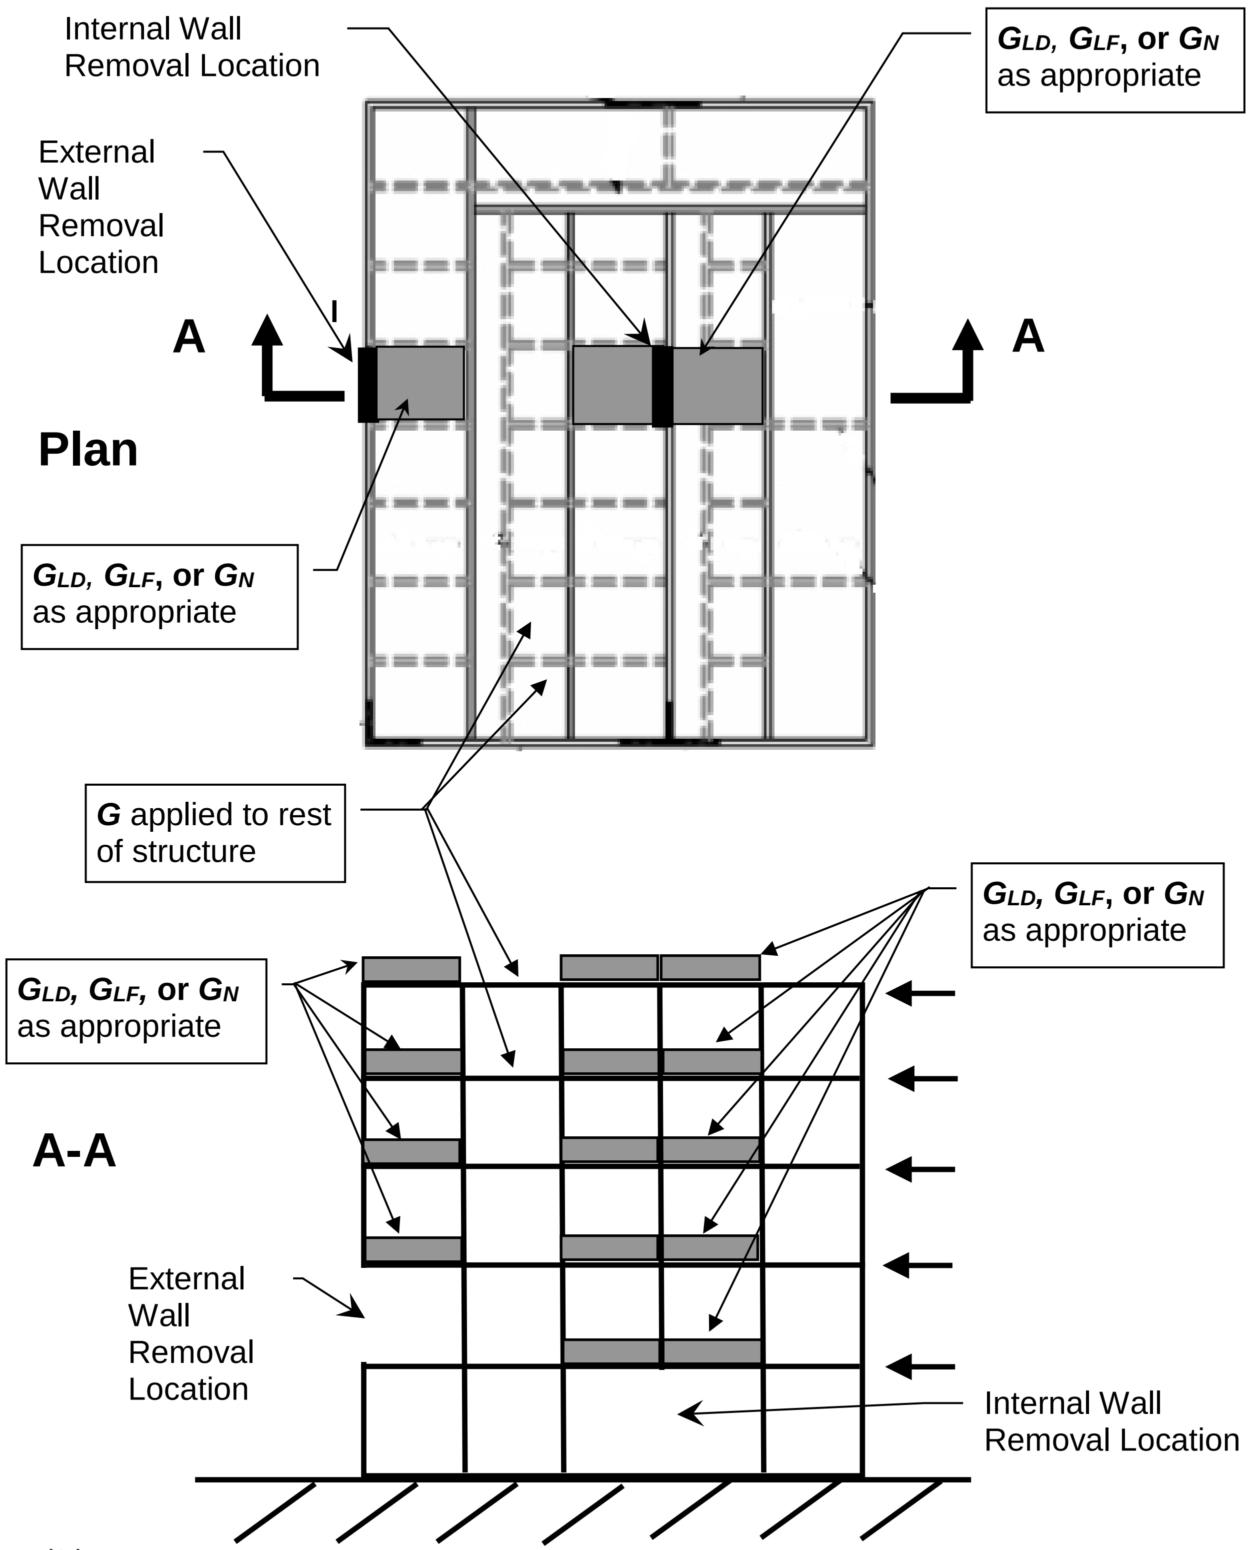

/2/

3-2.11.6 Design Forces and Deformations.

Calculate the deformation-controlled actions Q_{UD}, and force-controlled actions Q_{UF}, accordance with the linear analysis procedures of Sections 3-2.11.2 to 3-2.11.5.

3-2.11.7 Component and Element Acceptance Criteria.

Components and elements analyzed using the linear procedures of Section 3-2.11.2 to 3-2.11.5 shall satisfy the requirements of this section. Prior to selecting component acceptance criteria, classify components as primary or secondary, and classify actions as deformation-controlled or force-controlled, as defined in Section 3-2.5.

3-2.11.7.1 Deformation Controlled Actions.

For deformation-controlled actions in all primary **and** secondary components, check that:

$$\Phi\, m\, Q_{CE} \geq Q_{UD} \qquad \text{Equation (3-13)}$$

where
- Q_{UD} = Deformation-controlled action, from Linear Static model
- m = Component or element demand modifier (m-factor) as defined in Chapters 4 to 8 of this document.
- Φ = Strength reduction factor from the appropriate material specific code.
- Q_{CE} = Expected strength of the component or element for deformation-controlled actions.

Q_{CE}, the expected strength, shall be determined by considering all coexisting actions on the component under the design loading condition by procedures specified in ASCE 41 Chapters 9 through 12. Note that this includes interaction equations for shear, axial force, and moment and that these equations include force- and deformation-controlled actions, as well as expected and lower bound strengths.

Use the appropriate resistance factor for each action, as specified in the material specific design codes (i.e., the Φ factors in ACI 318, the AISC Steel Construction Manual, etc).

3-2.11.7.2 Force-Controlled Actions.

For force-controlled actions in all primary **and** secondary components:

$$\Phi\, Q_{CL} \geq Q_{UF} \qquad \text{Equation (3-14)}$$

where
- Q_{UF} = Force-controlled action, from Linear Static model
- Q_{CL} = Lower-bound strength of a component or element

for force-controlled actions

$\boldsymbol{\Phi}$ = Strength reduction factor from the appropriate material specific code.

Q_{CL}, the lower-bound strength, shall be determined by considering all coexisting actions on the component under the design loading condition by procedures specified in ASCE 41 Chapters 9 through 12. Use the appropriate resistance factor for each action, as specified in the material specific design codes (i.e., the $\boldsymbol{\Phi}$ factors in ACI 318, the AISC Steel Construction Manual, etc).

3-2.11.7.3 Secondary Elements and Components.

All secondary components and elements must be checked to ensure that they meet the acceptance criteria. Deformation-controlled actions are checked according to Equation 3-13 and force-controlled actions are checked according to Equation 3-14.

3-2.12 Nonlinear Static Procedure.

The NSP and limitations to its use are provided in the following sub-sections.

3-2.12.1 Limitations on the Use of NSP.

There are no DCR or geometric irregularity limitations on the use of the NSP.

3-2.12.2 Analytical Modeling.

To model, analyze, and evaluate a building, employ a three-dimensional assembly of elements and components. Two-dimensional models are not permitted. Create one model, as shown in Figures 3-13 and 3-14 for either framed or load-bearing wall structures, respectively. Inclusion of secondary components in the model is optional. However, if the secondary components are omitted, they must be checked after the analysis, against the allowable deformation-controlled criteria (e.g., to check the connections of gravity beams in a steel structure, compute the chord rotation and compare against the allowable plastic rotation angle for that connection). Include the stiffness and resistance of primary components. Note that the strength reduction factors are applied to the nonlinear strength models of the deformation controlled components (e.g., the nominal flexural strength of a beam or connection is multiplied by the appropriate $\boldsymbol{\Phi}$ factor). Analyze the model for the Nonlinear Static load case defined in Section 3-2.12.4

Use the stiffness requirements of ASCE 41 Chapters 9 through 12 to create the model. Discretize the load-deformation response of each component along its length to identify locations of inelastic action. The force-displacement behavior of all components shall be explicitly modeled, including strength degradation and residual strength, if any. Model a connection explicitly if the connection is weaker or has less ductility than the connected components, or the flexibility of the connection results in a change in the connection forces or deformations greater than 10%.

If the building contains sections that are less than three stories and are attached to the sections with three or more stories, the designer shall use engineering judgment to include some or all of the shorter section if there is any possibility that the presence of the short section will affect the taller section in a negative manner.

3-2.12.3 \2\Stability/P-Δ Effects.

Note that overall vertical and lateral stability as well as local stability (i.e., lateral torsional buckling) must be considered. /2/

3-2.12.4 Loading

\2\Live load reduction is allowed, if the requirements in Section 3-2.3 are met. /2/

3-2.12.4.1 Loads.

To calculate the deformation-controlled and force-controlled actions, simultaneously apply the following combination of gravity loads:

Increased Gravity Loads for Floor Areas Above Removed Column or Wall. Apply the following increased gravity load combination to those bays immediately adjacent to the removed element and at all floors above the removed element; see Figures 3-13 and 3-14:

\2\ $G_N = \Omega_N [1.2 D + (0.5 L \text{ or } 0.2 S)]$ /2/ Equation (3-15)

where
- G_N = Increased gravity loads for Nonlinear Static Analysis
- D = Dead load including façade loads (lb/ft^2 or kN/m^2)
- L = Live load including live load reduction per Section 3-2.3 (lb/ft^2 or kN/m^2)
- S = Snow load (lb/ft^2 or kN/m^2)
- Ω_N = Dynamic increase factor for calculating deformation-controlled and force-controlled actions for Nonlinear Static analysis, use appropriate value for framed or load-bearing wall structures. see Section 3-2.12.5

Gravity Loads for Floor Areas Away From Removed Column or Wall. Apply the following gravity load combination to those bays not loaded with G_N; see Figures 3-13 and 3-14.

\2\ $G = 1.2 D + (0.5 L \text{ or } 0.2 S)$ /2/ Equation (3-16)

where G = Gravity loads

\2\ /2/

3-2.12.4.2 Loading Procedure.

Apply the loads using a load history that starts at zero and is increased to the final values. Apply at least 10 load steps to reach the total load. The software must be capable of incrementally increasing the load and iteratively reaching convergence before proceeding to the next load increment.

3-2.12.5 Dynamic Increase Factor for NSP.

The Nonlinear Static dynamic increase factors are provided in Table 3-5.

In Table 3-5, θ_{pra} is the plastic rotation angle given in the acceptance criteria tables in ASCE 41 and this UFC for the appropriate structural response level (Collapse Prevention or Life Safety, as specified in Chapters 4 to 8 of this UFC) for the particular element, component or connection; θ_y is the yield rotation. For steel, θ_y is given in Equation 9-1 in ASCE 41. For reinforced concrete, θ_y is determined with the effective stiffness values provided in Table 10-5 in ASCE 41. Note that for connections, θ_y is the yield rotation angle of the structural element that is being connected (beam, slab, etc) and θ_{pra} is for the connection (determined from ASCE 41 and this UFC). Columns are omitted from the determination of the DIF.

To determine the DIF for the analysis of the entire structure, choose the smallest ratio of θ_{pra}/θ_y for any primary element, component, or connection in the model within or touching the area that is loaded with the increased gravity load, as shown in Figures 3-13 and 3-14. In other words, the DIF for every primary connection, beam, girder, wall element, etc that falls within or touches the perimeter marked as A-B-C-D must be determined and the largest value is used for the analysis. The method behind this procedure is explained in Appendix C.

Table 3-5. Dynamic Increase Factors for Nonlinear Static Analysis

Material	Structure Type	Ω_N
Steel	Framed	$1.08 + 0.76/(\theta_{pra}/\theta_y + 0.83)$
Reinforced Concrete	Framed	$1.04 + 0.45/(\theta_{pra}/\theta_y + 0.48)$
	Load-Bearing Wall	2
Masonry	Load-bearing Wall	2
Wood	Load-bearing Wall	2
Cold-formed Steel	Load-bearing Wall	2

3-2.12.6 Design Forces and Deformations.

Calculate component design forces and deformations in accordance with the nonlinear analysis procedure of Sections 3-2.12.2 to 3-2.12.5.

3-2.12.7 Component and Element Acceptance Criteria.

Components and elements analyzed using the nonlinear procedures of Sections 3-2.12.2 to 3-2.12.5 shall satisfy the requirements of this section.

3-2.12.7.1 Deformation-Controlled Actions.

Primary and secondary elements and components shall have expected deformation capacities greater than the maximum calculated deformation demands. Expected deformation capacities shall be determined considering all coexisting forces and deformations in accordance with Chapters 4 to 8 of this document.

3-2.12.7.2 Force-Controlled Actions.

For force-controlled actions in all primary **and** secondary elements and components:

$$\Phi \, Q_{CL} \geq Q_{UF} \qquad \text{Equation (3-17)}$$

where

- Q_{UF} = Force-controlled action, from Nonlinear Static model
- Q_{CL} = Lower-bound strength of a component or element.
- Φ = Strength reduction factor from the appropriate material specific code.

Q_{CL}, the lower-bound strength, shall be determined by considering all coexisting actions on the component under the design loading condition by procedures specified in ASCE 41 Chapters 9 through 12. Use the appropriate resistance factor for each action, as specified in the material specific design codes (i.e., the Φ factors in ACI 318, the AISC Steel Construction Manual, etc).

3-2.13 Nonlinear Dynamic Procedure.

The NDP and limitations to its use are provided in the following sub-sections.

3-2.13.1 Limitations on the Use of NDP.

There are no DCR or geometric irregularity limitations on the use of the NDP.

3-2.13.2 Analytical Modeling.

To model, analyze, and evaluate a building, employ a three-dimensional assembly of elements and components. Two-dimensional models are not permitted. Create a model of the entire structure, including the wall section and column that are to be removed during the analysis. Include the stiffness and resistance of primary components. Note that the strength reduction factors are applied to the nonlinear strength models of the deformation controlled components (e.g., the nominal flexural strength of a beam or connection is multiplied by the appropriate $\boldsymbol{\Phi}$ factor). Inclusion of secondary components in the model is optional. However, if the secondary components are omitted, they must be checked after the analysis, against the allowable deformation-controlled criteria (e.g., to check the connections of gravity beams in a steel structure, compute the chord rotation and compare against the allowable plastic rotation angle for that connection). Apply the loads per the loading procedure in Section 3-2.13.4.

Use the stiffness requirements of ASCE 41 Chapters 9 through 12 to create the model. Discretize the load-deformation response of each component along its length to identify locations of inelastic action. The force-displacement behavior of all components shall be explicitly modeled, including strength degradation and residual strength, if any. Model a connection explicitly if the connection is weaker or has less ductility than the connected components, or the flexibility of the connection results in a change in the connection forces or deformations greater than 10%.

If the building contains sections that are less than three stories and are attached to the sections with three or more stories, the designer shall use engineering judgment to include some or all of the shorter section if there is any possibility that the presence of the short section will affect the taller section in a negative manner.

3-2.13.3 Lateral Stability and P- Δ Effects.

\2\Note that overall vertical and lateral stability as well as local stability (i.e., lateral torsional buckling) must be considered./2/

3-2.13.4 Loading

\2\Live load reduction is allowed if the requirements in Section 3-2.3 are met. /2/

3-2.13.4.1 Loads.

To calculate the deformation-controlled and force-controlled actions, apply the following gravity load per the loading procedure given in Section 3-2.13.4.2:

Gravity Loads for Entire Structure. Apply the following gravity load combination to the entire structure.

\2\ $G_{ND} = 1.2\,D + (0.5\,L \text{ or } 0.2\,S)$ /2/ Equation (3-18)

where
G_{ND} = Gravity loads for Nonlinear Dynamic Analysis
D = Dead load including façade loads (lb/ft^2 or kN/m^2)
L = Live load including live load reduction per Section 3-2.3 (lb/ft^2 or kN/m^2)
S = Snow load (lb/ft^2 or kN/m^2)

\2\/2/

3-2.13.4.2 Loading Procedure.

Starting at zero load, monotonically and proportionately increase the gravity loads to the entire model (i.e., the column or wall section have not been removed yet) until equilibrium is reached.

After equilibrium is reached for the framed and load-bearing wall structures, remove the column or wall section. While it is preferable to remove the column or wall section instantaneously, the duration for removal must be less than one tenth of the period associated with the structural response mode for the vertical motion of the bays above the removed column, as determined from the analytical model with the column or wall section removed. The analysis shall continue until the maximum displacement is reached or one cycle of vertical motion occurs at the column or wall section removal location.

3-2.13.5 Design Forces and Deformations.

Calculate component design forces and deformations in accordance with the nonlinear analysis procedure of Sections 3-2.13.2 to 3-2.13.4.

3-2.13.6 Component and Element Acceptance Criteria.

Components and elements analyzed using the nonlinear procedures of Sections 3-2.13.2 to 3-2.13.4 shall satisfy the requirements of this section.

3-2.13.6.1 Deformation-Controlled Actions.

Primary and secondary elements and components shall have expected deformation capacities greater than the maximum calculated deformation demands. Expected deformation capacities shall be determined considering all coexisting forces and deformations in accordance with Chapters 4 to 8 of this document.

3-2.13.6.2 Force-Controlled Actions.

For force-controlled actions in all primary **and** secondary components,

$$\Phi Q_{CL} \geq Q_{UF} \quad \text{Equation (3-19)}$$

where Q_{UF} = Force-controlled action, from Nonlinear Dynamic model
Q_{CL} = Lower-bound strength of a component or element.
Φ = Strength reduction factor from the appropriate material specific code.

Q_{CL}, the lower-bound strength, shall be determined by considering all coexisting actions on the component under the design loading condition by procedures specified in ASCE 41 Chapters 9 through 12. Use the appropriate resistance factor for each action, as specified in the material specific design codes (i.e., the Φ factors in ACI 318, the AISC Steel Construction Manual, etc).

\2\

3-3 ENHANCED LOCAL RESISTANCE

Enhanced Local Resistance (ELR) is required in three cases: RC II Option 1 (Tie Forces and ELR), RC III (Alternate Path and ELR), and RC IV (Tie Forces, Alternate Path and ELR). All three cases contain the same objective, which is to insure that a ductile failure mechanism can form when the column or wall is loaded laterally to failure. To meet this objective, the column or wall must not fail in shear prior to the development of the maximum flexural strength.

Two components must meet the ELR requirement: 1. The column or wall, and 2. The connections between the end of the column or wall and the lateral supports (floor slab, base plate, etc).

Note that design for ELR is not required if the wall or column has been designed for a specific design basis threat, providing that the design basis threat was developed with a risk assessment approach that was approved by the building owner, government agency or other responsible entity.

3-3.1 Load and Resistance Factor Design for Enhanced Local Resistance.

The LRFD approach is used for ELR design,

$$\Phi R_n \geq R_u \quad \text{Equation (3-20)}$$

where ΦR_n = Design strength
Φ = Strength reduction factor

R_n = Nominal strength, including over-strength factors
R_u = Required strength

The design strength provided by a component is taken as the product of the strength reduction factor Φ and the nominal strength R_n. For ELR, all strength reduction factors Φ shall be 1.0. In addition, the material strengths for shear, flexure and all other actions shall be the expected material strength (i.e., with the appropriate over-strength factor applied to the lower bound material strength).

3-3.1.1 Flexural Demand.

The flexural demand is the nominal flexural strength **(R_n)** of a column or wall under the conditions specified in Sections 3-3.3, 3-3.4, and 3-3.5.

3-3.1.2 Shear Demand.

The shear demand is the required shear strength **(R_u)** of the column or wall that is necessary to achieve the required flexural demand of the component, i.e. at the formation of a three-hinge mechanism or similar failure mode in the component. In calculating the shear demand, consider any effects (axial load, end conditions, etc) that may act to increase the nominal flexural strength; in no case shall the shear demand be less than that of the column or wall with zero axial load acting. Include any applicable material over-strength factors. The shear demand shall be determined for the horizontal out-of-plane direction (i.e., perpendicular to the building perimeter façade). Columns at building corners or re-entrant corners shall be evaluated in both directions normal to the building perimeter façade. Examples of this procedure are provided in Appendices D and E.

3-3.2 ELR Location and Extent Requirements.

3-3.2.1 RC II Option 1.

For RC II Option 1 and framed and two-way load-bearing wall buildings, ELR is applied to the perimeter corner and penultimate columns and load-bearing walls of the first story above grade. For one-way load-bearing wall buildings, ELR shall be applied to the entire length of the end wall and penultimate wall; it is recognized that the majority of the penultimate wall may be interior to the structure, but it must still be designed for ELR.

3-3.2.2 RC III.

For RC III and framed and two-way load-bearing wall buildings, ELR is applied to all perimeter columns and load-bearing walls of the first story above grade. For one-way load-bearing wall buildings, ELR shall be applied to the entire length of the end wall and penultimate wall; it is recognized that the majority of the penultimate wall may be interior to the structure, but it must still be designed for ELR.

3-3.2.3 RC IV.

For RC IV and framed and two-way load-bearing wall buildings, ELR is applied to all perimeter columns and load-bearing walls of the first story above grade. For one-way load-bearing wall buildings, ELR shall be applied to the entire length of the end wall and penultimate wall; it is recognized that the majority of the penultimate wall may be interior to the structure, but it must still be designed for ELR.

3-3.3 RC II Option 1 Shear and Flexural Requirements.

For RC II Option 1, the flexural demand for the columns and walls is the nominal flexural strength **(R_n)** of the existing or as-designed structure and, therefore, no design modification is needed to meet the flexural requirement.

The shear demand is based on the flexural demand of the component as described above. Apply the procedure in Section 3-3.1.2 to the columns and walls to determine the shear demand. If Equation 3-20 is not satisfied, modify the column or wall design such that adequate design shear strength **(ΦR_n)** is achieved. If the flexural demand is increased as a result of meeting the shear requirement, check that the design shear strength still exceeds the shear demand associated with this new flexural demand.

3-3.4 RC III Shear and Flexural Requirements.

\4\ An RC III building /4/ must first meet the Alternate Path requirement. The flexural demand for the columns and walls is the nominal flexural strength **(R_n)** of the design after the Alternate Path requirement is applied and therefore, no design modification is needed to meet the flexural requirement.

The shear demand is based on the flexural demand of the component as described above. Apply the procedure in Section 3-3.1.2 to the columns and walls to determine the shear demand. If Equation 3-20 is not satisfied, modify the column or wall design such that adequate design shear strength **(ΦR_n)** is achieved. If the flexural demand is increased as a result of meeting the shear requirement, check that the design shear strength still exceeds the shear demand associated with this new flexural demand.

3-3.5 RC IV Shear and Flexural Requirements.

3-3.5.1 RC IV Flexural Requirements.

For RC IV, two nominal flexural strengths must first be determined and used to define the flexural demand. First, the **baseline** nominal flexural strength is determined using the design of the structure when only gravity loads are considered and after the AP procedure is applied. If such a design or analysis was not performed during the initial design and analysis of the new or existing structure, it must be performed to determine the column and load-bearing wall design.

Second, the **existing** nominal flexural strength is determined using the column and load-bearing wall design defined after the Alternate Path procedure was applied to the structural design that incorporated all applied loads (wind, earthquake, gravity, etc).

For columns in RC IV structures, the flexural demand is equal to the larger of: 1) the baseline nominal flexural strength multiplied by 2.0 and 2) the \4\ /4/ nominal flexural strength. If the flexural demand is controlled by condition 1), then redesign the column as required to meet the flexural demand of this controlling condition.

For load-bearing walls in RC IV structures, the flexural demand is equal to the larger of 1) the baseline nominal flexural strength multiplied by 1.5, and 2) the \4\ /4/ nominal flexural strength. If the flexural demand is controlled by condition 1), then redesign the wall as required to meet the flexural demand of this controlling condition.

3-3.5.2 RC IV Shear Requirements.

The shear demand for columns and walls is based on the flexural demand as calculated in the above section. Apply the procedure in Section 3-3.1.2 to the columns and walls to determine the shear demand. If Equation 3-20 is not satisfied, modify the column or wall design such that adequate design shear strength **(ΦR_n)** is achieved. If the flexural demand is increased as a result of meeting the shear requirement, check that the design shear strength still exceeds the shear demand associated with this new flexural demand.

3-3.6 Connection Design for Rebound Reaction Forces.

In some dynamic loading scenarios, the column or wall will initially be pushed into the building and then rebound back; the connections must be designed to prevent failure during both phases of loading. Connections at the top and bottom of the columns and walls shall be designed for a rebound reaction force equal to 50% of the inbound value.

3-3.7 Conflicts Between ELR and Other Design Requirements.

The ELR requirements may be satisfied in a number of ways and as the designer desires, providing the ELR-modified design does not violate the standard building and material-specific design codes. If there is a conflict with the ELR modifications, the building or material-specific design code has precedence and the ELR design must be altered. /2/

CHAPTER 4 REINFORCED CONCRETE

This chapter provides the specific requirements for designing a reinforced concrete building to resist progressive collapse. Appendix D demonstrates the application of the reinforced concrete design requirements for a 7-story building.

If composite construction with other materials is employed, use the design guidance from the appropriate material chapter in this UFC for those structural elements or portions of the structure.

Note that the combination of design requirements (TF, AP, and ELR) will depend upon the \3\ Risk Category /3/ of the buildings, as defined in Section 2-2.

4-1 MATERIAL PROPERTIES FOR REINFORCED CONCRETE.

Apply the appropriate over-strength factors to the calculation of the design strengths for both Tie Forces and the Alternate Path method. The over-strength factors are provided in ASCE 41 in Table 10-4 Factors to Translate Lower-Bound Material Properties to Expected Strength Material Properties.

4-2 STRENGTH REDUCTION FACTOR Φ FOR REINFORCED CONCRETE.

For the Alternate Path and Tie Force methods, use the appropriate strength reduction factor specified in ACI 318 *Building Code Requirements for Structural Concrete* for the component and behavior under consideration.

4-3 TIE FORCE REQUIREMENTS FOR REINFORCED CONCRETE.

Apply the Tie Force requirements in Section 3-1, when applicable, for concrete frame and load-bearing wall structural systems, mixed systems with concrete elements, and framed and load-bearing wall systems with precast concrete floors

The strength reduction factor Φ for properly anchored, embedded, or spliced steel reinforcement in tension shall be taken as 0.75 (based on ACI 318 for strut and tie models).

The structural integrity requirements of ACI 318 for cast-in-place and precast concrete construction must be satisfied, as well as the Tie Force requirements in this document. Use the largest or most stringent requirement when there is overlap between ACI 318 and this UFC.

4-4 ALTERNATE PATH REQUIREMENTS FOR REINFORCED CONCRETE.

4-4.1 General.

Use the Alternate Path method in Section 3-2 to verify that the structure can bridge over removed elements.

4-4.2 Flexural Members and Joints.

\4\ /4/The design strength and rotational capacities of the beams and beam-to-column joints shall be determined with the guidance found in ASCE 41, as modified with the acceptance criteria provided in Paragraph 4-4.3.

4-4.3 Modeling and Acceptance Criteria for Reinforced Concrete.

With the exception of Tables 10-7, 10-11, 10-14, and 10-15 in ASCE 41, use the modeling parameters, nonlinear acceptance criteria and linear m-factors for the Life Safety condition from Chapter 10 of ASCE 41 for primary and secondary components. Use the ASCE 41 modeling parameters and guidance, including definitions of stiffness, to create the analytical model.

Replace Table 10-7 of ASCE 41 with Table 4-1, which contains the nonlinear modeling parameters and acceptance criteria for reinforced concrete beams. Replace Table 10-11 of ASCE 41 with Table 4-2, which contains the acceptance criteria for linear modeling of reinforced concrete beams.

Replace Table 10-14 of ASCE 41 with Table 4-3, which contains the nonlinear modeling parameters and acceptance criteria for two-way slabs and slab-column connections. Replace Table 10-15 of ASCE 41 with Table 4-4, which contains the acceptance criteria for linear modeling of two-way slabs and slab-column connections.

4-5 ENHANCED LOCAL RESISTANCE REQUIREMENTS FOR REINFORCED CONCRETE.

Apply the Enhanced Local Resistance requirements in Section 3-3, where applicable, for framed and load-bearing wall reinforced concrete buildings.

Table 4-1. Nonlinear Modeling Parameters and Acceptance Criteria for Reinforced Concrete Beams (Replacement for Table 10-7 in ASCE 41)

			Modeling Parameters[1]			Acceptance Criteria[1,2]		
						Plastic Rotations Angle, radians		
			Plastic Rotations Angle, radians		Residual Strength Ratio		Component Type	
							Primary	Secondary
Conditions			a	b	c			
i. Beams controlled by flexure[3]								
$\frac{\rho-\rho'}{\rho_{bal}}$	Trans. Reinf.[4]	$\frac{V}{b_w d\sqrt{f'_c}}$						
≤ 0.0	C	≤ 3	0.063	0.10	0.2		0.063	0.10
≤ 0.0	C	≥ 6	0.05	0.08	0.2		0.05	0.08
≥ 0.5	C	≤ 3	0.05	0.06	0.2		0.05	0.06
≥ 0.5	C	≥ 6	0.038	0.04	0.2		0.038	0.04
≤ 0.0	NC	≤ 3	0.05	0.06	0.2		0.05	0.06
≤ 0.0	NC	≥ 6	0.025	0.03	0.2		0.025	0.03
≥ 0.5	NC	≤ 3	0.025	0.03	0.2		0.025	0.03
≥ 0.5	NC	≥ 6	0.013	0.02	0.2		0.013	0.02
ii. Beams controlled by shear[3]								
Stirrup spacing ≤ d /2			0.0030	0.02	0.2		0.002	0.01
Stirrup spacing > d /2			0.0030	0.01	0.2		0.002	0.005
iii. Beams controlled by inadequate development or splicing along the span[3]								
Stirrup spacing ≤ d /2			0.0030	0.02	0.0		0.002	0.01
Stirrup spacing > d /2			0.0030	0.01	0.0		0.002	0.005
iv. Beams controlled by inadequate embedment into beam-column joint[3]								
			0.015	0.03	0.2		0.01	0.02

1. Linear interpolation between values listed in the table shall be permitted. See Section 3-2.4 for definition of primary and secondary components and Figure 3-7 for definition of nonlinear modeling parameters *a, b,* and *c*
2. Primary and secondary component demands shall be within secondary component acceptance criteria where the full backbone curve is explicitly modeled including strength degradation and residual strength, in accordance with Section 7.4.3.2 of ASCE 41.
3. Where more than one of the conditions i, ii, iii, and iv occurs for a given component, use the minimum appropriate numerical value from the table.
4. "C" and "NC" are abbreviations for conforming and nonconforming transverse reinforcement. A component is conforming if, within the flexural plastic hinge region, hoops are spaced at ≤ *d/3*, and if, for components of moderate and high ductility demand, the strength provided by the hoops (V_s) is at least three-fourths of the design shear. Otherwise, the component is considered nonconforming.

Table 4-2. Acceptance Criteria for Linear Models of Reinforced Concrete Beams (Replacement for Table 10-11 in ASCE 41)

Conditions				*m*-factors[1]	
				Component Type	
				Primary	Secondary
i. Beams controlled by flexure[2]					
$\frac{\rho - \rho'}{\rho_{bal}}$	Trans. Reinf.[3]	$\frac{V}{b_w d \sqrt{f'_c}}$ [4]			
≤ 0.0	C	≤ 3		16	19
≤ 0.0	C	≥6		9	9
≥ 0.5	C	≤ 3		9	9
≥ 0.5	C	≥ 6		6	7
≤ 0.0	NC	≤ 3		9	9
≤ 0.0	NC	≥ 6		6	7
≥ 0.5	NC	≤ 3		6	7
≥ 0.5	NC	≥ 6		4	5
ii. Beams controlled by shear[2]					
Stirrup spacing ≤ d /2				1.5	3
Stirrup spacing > d /2				1.5	2
iii. Beams controlled by inadequate development or splicing along the span[2]					
Stirrup spacing ≤ d /2				1.5	3
Stirrup spacing > d /2				1.5	2
iv. Beams controlled by inadequate embedment into beam-column joint[2]					
				2	3

1. Linear interpolation between values listed in the table shall be permitted. See Section 3-2.4 for definition of primary and secondary components.
2. Where more than one of the conditions i, ii, iii, and iv occurs for a given component, use the minimum appropriate numerical value from the table.
3. "C" and "NC" are abbreviations for conforming and nonconforming transverse reinforcement. A component is conforming if, within the flexural plastic hinge region, hoops are spaced at ≤ *d/*3, and if, for components of moderate and high ductility demand, the strength provided by the hoops (V_s) is at least three-fourths of the design shear. Otherwise, the component is considered nonconforming.
4. V is the design shear force calculated using limit-state analysis procedures in accordance with Section 10.4.2.4.1 of ASCE 41.

Table 4-3. Modeling Parameters and Acceptance Criteria for Nonlinear Models of Two-Way Slabs and Slab-Column Connections (Replacement for Table 6-14 in ASCE 41)

		Modeling Parameters[1]			Acceptance Criteria[1,2]		
					Plastic Rotations Angle, radians		
						Component Type	
		Plastic Rotations Angle, radians		Residual Strength Ratio		Primary	Secondary
Conditions		a	b	c			
i. Slabs controlled by flexure, and slab-column connections[3]							
$\frac{V_g}{V_o}$ [2]	Continuity Reinforcement[3]						
≤ 0.2	Yes	0.05	0.10	0.2		0.05	0.10
≥ 0.4	Yes	0.0	0.04	0.2		0.0	0.08
≤ 0.2	No	0.02	0.02	-		0.015	0.015
≥ 0.4	No	0.0	0.0	-		0.0	0.0
ii. Slabs controlled by inadequate development or splicing along the span[3]							
		0.0	0.02	0.0		0.0	0.01
iii. Slabs controlled by inadequate embedment into slab-column joint[3]							
		0.015	0.03	0.2		0.01	0.02

1. Linear interpolation between values listed in the table shall be permitted. See Section 3-2.4 for definition of primary and secondary components and Figure 3-7 for definition of nonlinear modeling parameters *a*, *b*, and *c*.
2. Primary and secondary component demands shall be within secondary component acceptance criteria where the full backbone curve is explicitly modeled including strength degradation and residual strength, in accordance with Section 7.4.3.2 of ASCE 41.
3. Where more than one of the conditions i, ii, iii, and iv occurs for a given component, use the minimum appropriate numerical value from the table.
4. V_g = the gravity shear acting on the slab critical section as defined by ACI 318; V_o = the direct punching shear strength as defined by ACI 318.
5. Under the heading "Continuity Reinforcement," use "Yes" where at least one of the main bottom bars in each direction is effectively continuous through the column cage. Where the slab is post-tensioned, use "Yes" where at least one of the post-tensioning tendons in each direction passes through the column cage. Otherwise, use "No."

Table 4-4. Acceptance Criteria for Linear Models of Two-Way Slabs and Slab-Column Connections (Replacement for Table 6-15 in ASCE 41)

Conditions			*m*-factors[1]	
			Component Type	
			Primary	Secondary
i. Slabs controlled by flexure, and slab-column connections[2]

≤ 0.2	Yes		6	7
≥ 0.4	Yes		1	5
≤ 0.2	No		2	2
≥ 0.4	No		1	1
ii. Slabs controlled by inadequate development or splicing along the span[2]				
			-	4
iii. Slabs controlled by inadequate embedment into slab-column joint[2]				
			3	4

1. Linear interpolation between values listed in the table shall be permitted. See Section 3-2.4 for definition of primary and secondary components.
2. Where more than one of the conditions i, ii, and iii occurs for a given component, use the minimum appropriate numerical value from the table.
3. V_g = the gravity shear acting on the slab critical section as defined by ACI 318; V_o = the direct punching shear strength as defined by ACI 318.
4. Under the heading "Continuity Reinforcement," use "Yes" where at least one of the main bottom bars in each direction is effectively continuous through the column cage. Where the slab is post-tensioned, use "Yes" where at least one of the post-tensioning tendons in each direction passes through the column cage. Otherwise, use "No."

CHAPTER 5 STRUCTURAL STEEL

This chapter provides the specific requirements for designing a structural steel building to resist progressive collapse. Appendix E demonstrates the application of the structural steel design requirements for a 4-story building.

If composite construction with other materials is employed, use the design guidance from the appropriate material chapter in this UFC for those structural elements or portions of the structure.

Note that the combination of design requirements (TF, AP, and ELR) will depend upon the \3\ Risk Category /3/ of the buildings, as defined in Section 2-2.

5-1 MATERIAL PROPERTIES FOR STRUCTURAL STEEL.

Apply the appropriate over-strength factors to the calculation of the design strengths for both Tie Forces and the Alternate Path method. The over-strength factors are provided in ASCE 41 in Table 5-3 Factors to Translate Lower-Bound Steel Properties to Expected Strength Steel Properties.

5-2 STRENGTH REDUCTION FACTOR *Φ* FOR STRUCTURAL STEEL.

For Alternate Path and Tie Force methods, use the appropriate strength reduction factor ***Φ*** specified in ANSI/AISC 360 *Specifications for Structural Steel Buildings* for the component and behavior under consideration. If steel components can be proven capable of carrying the required longitudinal, transverse, and peripheral tie strength while undergoing rotations of 0.20-rad (11.3-deg), use the appropriate strength reduction factor ***Φ*** for each limit state considered.

5-3 TIE FORCE REQUIREMENTS FOR STEEL.

Apply the Tie Force requirements in Section 3-1, where applicable, for framed steel buildings.

5-4 ALTERNATE PATH METHOD FOR STEEL.

5-4.1 General.

Use the Alternate Path method in Section 3-2, where applicable, to verify that the structure can bridge over removed elements.

5-4.2 Connection Rotational Capacity.

\4\-/4/ The design strength and rotational capacities of the beams and beam-to-column connections shall be determined with the guidance found in ASCE 41, as modified with the acceptance criteria provided in Paragraph 5-4.3.

5-4.3 Modeling and Acceptance Criteria for Structural Steel.

With the exception of the connections and elements discussed later in this section, use the modeling parameters, nonlinear acceptance criteria and linear ***m***-factors for the Life Safety condition from Chapter 9 of ASCE 41 for primary and secondary components. Use the modeling parameters and guidance, including definitions of stiffness, to create the analytical model.

Columns under high axial load (P/P_{CL} > 0.5) shall be considered force-controlled, with the considered loads (***P*** and ***M***) equal to the maximum loads from the analysis. The ***P-M*** interaction equation shall not exceed unity. For $P/P_{CL} \leq 0.5$, the interaction equation shall be used with the moment considered as deformation-controlled and the axial force as force-controlled.

Nonlinear and linear acceptance criteria for structural steel components shall meet the Life Safety condition for primary and secondary elements provided in Tables 9-5, 9-6 and 9-7 of ASCE 41, except as follows:

1. For beams subjected to flexure or flexure plus axial tension, use the Collapse Prevention values for primary and secondary elements.

2. For the Fully Restrained (FR) and Partially Restrained (PR) connections listed in Tables 5-1 and 5-2 in this UFC, use the specified plastic rotations, modeling parameters and m-factors, as given.

For the Double Angles PR connection, the expected flexural strength shall be determined for each of the three limit states listed in Tables 5-1 and 5-2, using accepted analytical procedures. For the Simple Shear Tab, the expected flexural strength will be taken as the smallest flexural strength determined with limit state analysis for bolt shear, weld failure, block shear, bearing, plate flexure or other limit states as appropriate.

5-5 ENHANCED LOCAL RESISTANCE REQUIREMENTS FOR STEEL.

Apply the Enhanced Local Resistance requirements in Section 3-3, where applicable, for framed and load-bearing wall steel buildings.

Table 5-1. Acceptance Criteria for Linear Static Modeling of Steel Frame Connections

Connection Type	Linear Acceptance Criteria	
	m-factors	
	Primary[(1)]	Secondary[(1)]
Fully Restrained Moment Connections		
Improved WUF with Bolted Web	2.3 – 0.021d	4.9 – 0.048d

Simple Shear Tab	$0.0502 - 0.0015d_{bg}$	$0.1125 - 0.0027d_{bg}$	0.2	$0.0502 - 0.0015d_{bg}$	$0.1125 - 0.0027d_{bg}$

(1) Refer to Figure 3-7 for definition of nonlinear modeling parameters *a, b,* and *c*
(2) Refer to Section 3-2.4 for determination of Primary and Secondary classification
(3) d = depth of beam, inch
(4) d_{bg} = depth of bolt group, inch

CHAPTER 6 MASONRY

This chapter provides the specific requirements for designing a masonry building to resist progressive collapse.

If composite construction with other materials is employed, use the design guidance from the appropriate material chapter in this UFC for those structural elements or portions of the structure.

Note that the combination of design requirements (TF, AP, and ELR) will depend upon the \3\ Risk Category /3/ of the buildings, as defined in Section 2-2.

6-1 MATERIAL PROPERTIES FOR MASONRY.

Apply the appropriate over-strength factors to the calculation of the design strengths for both Tie Forces and the Alternate Path method. The over-strength factors are provided in ASCE 41 in Table 11-1 Factors to Translate Lower-Bound Masonry Properties to Expected Strength Masonry Properties.

6-2 STRENGTH REDUCTION FACTOR Φ FOR MASONRY.

For Tie Force and Alternate Path methods, use the appropriate strength reduction factor specified in ACI 530 *Building Code Requirements for Masonry Structures* for the component and behavior under consideration. If masonry components can be proven capable of carrying the required longitudinal, transverse, and peripheral tie strength while undergoing rotations of 0.20-rad (11.3-deg), use the appropriate strength reduction factor Φ for each limit state considered.

6-3 TIE FORCE REQUIREMENTS FOR MASONRY.

Apply the Tie Force requirements in Section 3-1, where applicable, for load-bearing masonry buildings.

6-4 ALTERNATE PATH METHOD FOR MASONRY.

6-4.1 General.

Use the Alternate Path method in Section 3-2, where applicable, to verify that the structure can bridge over removed elements.

6-4.2 Modeling and Acceptance Criteria for Masonry.

Use the modeling parameters, nonlinear acceptance criteria and linear m-factors for the Life Safety condition from Chapter 11 of ASCE 41 for primary and secondary components. Use the modeling parameters and guidance, including definitions of stiffness, to create the analytical model.

6-5 ENHANCED LOCAL RESISTANCE REQUIREMENTS FOR MASONRY.

Apply the Enhanced Local Resistance requirements in Section 3-3, where applicable, for framed and load-bearing wall masonry buildings.

CHAPTER 7 WOOD

This chapter provides the specific requirements for designing a wood building to resist progressive collapse. Appendix F demonstrates the application of the wood design requirements for a 3-story load-bearing wall building

Wood construction takes several forms in current practice. As described in the 1996 version of AF&PA/ASCE 16, *Load and Resistance Factor Design Manual for Engineered Wood Construction*, wood construction can be categorized as wood frame, noncombustible wall-wood joist, and heavy timber. As most wood construction used for DoD facilities falls under the wood frame category, this is the focus of these provisions. If composite construction with other materials is employed, use the design guidance from the appropriate material chapter in this UFC for those structural elements or portions of the structure.

Note that the combination of design requirements (TF, AP, and ELR) will depend upon the \3\ Risk Category /3/ of the buildings, as defined in Section 2-2.

7-1 MATERIAL PROPERTIES FOR WOOD.

Per ASCE 41, default expected strength values for wood materials shall be based on design resistance values from AF&PA/ASCE 16. In addition, ASCE 41 provides default expected strength values for shear walls and wood diaphragms. When default lower bound strength values are needed, multiply the expected strength values by 0.85.

7-2 STRENGTH REDUCTION FACTOR Φ FOR WOOD.

For Tie Force and Alternate Path methods, use the appropriate strength reduction factor specified in ANSI/AF&PA *National Design Specification for Wood Construction* for the component and behavior under consideration. If wood components can be proven capable of carrying the required longitudinal, transverse, and peripheral tie strength while undergoing rotations of 0.20-rad (11.3-deg), use the appropriate strength reduction factor Φ for each limit state considered.

7-3 TIME EFFECT FACTOR λ FOR WOOD.

The time effect factor λ for wood is 1.0.

7-4 TIE FORCE REQUIREMENTS FOR WOOD.

Apply the Tie Force requirements in Section 3-1, where applicable, for load-bearing wood buildings.

7-5 ALTERNATE PATH METHOD FOR WOOD.

7-5.1 General.

Use the Alternate Path method in Section 3-2, where applicable, to verify that the structure can bridge over removed elements.

7-5.2 Modeling and Acceptance Criteria for Wood.

Use the modeling parameters, nonlinear acceptance criteria and linear m-factors for the Life Safety condition from Chapter 12 of ASCE 41 for primary and secondary components. Use the modeling parameters and guidance, including definitions of stiffness, to create the analytical model.

7-6 ENHANCED LOCAL RESISTANCE REQUIREMENTS FOR WOOD.

Apply the Enhanced Local Resistance requirements in Section 3-3, where applicable, for framed and load-bearing wall wood buildings.

CHAPTER 8 COLD-FORMED STEEL

This chapter provides the specific requirements for designing a cold-formed steel building to resist progressive collapse.

If composite construction with other materials is employed, use the design guidance from the appropriate material chapter in this UFC for those structural elements or portions of the structure.

Note that the combination of design requirements (TF, AP, and ELR) will depend upon the \3\ Risk Category /3/ of the buildings, as defined in Section 2-2.

8-1 MATERIAL PROPERTIES FOR COLD-FORMED STEEL.

ASCE 41 provides default expected strength values for light metal framing shear walls. When default lower bound strength values are needed, multiply the expected strength values by 0.85.

8-2 STRENGTH REDUCTION FACTOR *Φ* FOR COLD-FORMED STEEL.

For Tie Force and Alternate Path methods, use the appropriate strength reduction factor specified in AISI/COS/NASPEC *AISI Standard North American Specification for the Design of Cold-Formed Steel Structural Members* for the component and behavior under consideration. If cold formed steel components can be proven capable of carrying the required longitudinal, transverse, and peripheral tie strength while undergoing rotations of 0.20-rad (11.3-deg), use the appropriate strength reduction factor ***Φ*** for each limit state considered.

8-3 TIE FORCE REQUIREMENTS FOR COLD-FORMED STEEL.

Apply the Tie Force requirements in Section 3-1, where applicable, for load-bearing cold-formed steel buildings.

8-4 ALTERNATE PATH METHOD FOR COLD-FORMED STEEL.

8-4.1 General.

Use the Alternate Path method in Section 3-2, where applicable, to verify that the structure can bridge over removed elements.

8-4.2 Modeling and Acceptance Criteria for Cold-Formed Steel.

Use the modeling parameters, nonlinear acceptance criteria and linear m-factors for the Life Safety condition from Chapter 12 of ASCE 41 for primary and secondary components. Use the modeling parameters and guidance, including definitions of stiffness, to create the analytical model.

8-5 ENHANCED LOCAL RESISTANCE REQUIREMENTS FOR COLD-FORMED STEEL.

Apply the Enhanced Local Resistance requirements in Section 3-3, where applicable, for framed and load-bearing wall cold-formed steel buildings.

APPENDIX B DEFINITIONS

B-1 INTRODUCTION.

Definitions for terminology and for structural analysis concepts are provided in this appendix. Many of the terms in this UFC are provided in other DoD UFCs, instructions, directives, standards, and manuals, as well as in typical non-government standards, such as ASCE 41, AISC Manual of Steel Construction, etc. Those terms of significance to this UFC are included in Section B-2. The definitions for structural analysis procedures are given in Section B-3.

B-2 TERMINOLOGY.

Deformation Controlled Action. A deformation controlled action provides a resistance that is proportional to the imposed deformation until the peak strength is reached, after which the resistance remains at a significant level, as the deformation increases. Classification as a deformation-controlled action is not based on engineering judgment and must follow the guidance presented in Section 3-2.5.

Expected Strength. The expected strength of a component is the statistical mean value of yield strengths for a population of similar components, and includes consideration of the variability in material strengths as well as strain hardening and plastic section development. If a statistically determined value for the expected strength is not available, the expected strength can be obtained by multiplying the lower bound strength (i.e., the nominal strength or strength specified in the construction documents) by the appropriate factor from Chapters 9 to 12 in ASCE 41.

Enhanced Local Resistance (ELR). ELR is an indirect design approach that provides a prescribed level of out-of-plane flexural and shear resistance of perimeter building columns (including their connections, splices and base plates) and load bearing wall elements, such that the shear resistance exceeds the shear associated with the required out-of-plane enhanced flexural resistance of the columns and wall elements. When the shear strength is reached before the flexural strength, the possibility exists of a sudden, non-ductile failure of the element, which may lead to progressive collapse.

Force Controlled Action. A force controlled action provides a resistance that is proportional to the imposed deformation until the peak strength is reached, after which the resistance drops to zero. Classification as a force-controlled action is not based on engineering judgment and must follow the guidance presented in Section 3-2.5.

Linear Static Procedure. In a linear static procedure, the structural analysis incorporates only linear elastic materials and small deformation theory; buckling phenomena are not included in the model but are assessed through examination of the output. Inertial forces are not considered. The analysis consists of a single step, in which the deformations and internal forces are solved based on the applied loads and geometry and materials.

Lower Bound Strength. The lower bound strength of a component is the statistical mean minus one standard deviation of the yield strengths for a population of similar components. If a statistically determined value for the lower bound strength is not available, the nominal strength or strength specified in the construction documents may be used.

Nonlinear Dynamic Procedure. In a nonlinear dynamic procedure, inertial effects and material and geometric nonlinearities are included. A time integration procedure is used to determine the structural response as a function of time.

Nonlinear Static Procedure. In a nonlinear static procedure, the structural model incorporates material and geometric nonlinearities. Inertial effects are not included. An incremental or iterative approach is typically used to solve for the structural response as a function of the applied loading.

Penultimate Column or Wall. The column or wall that is next to the corner column or corner wall on the exterior surface, i.e., the next-to-last wall or column along the exterior of the building.

Secondary Component. Any component that is not a primary component is classified as secondary.

Story. That portion of a building between the surface of any one floor and the surface of the floor above it or, if there is no floor above it, then that portion of the building included between the surface of any floor and the ceiling or roof above it.

Tie Forces. A tie force is the tensile resistance that is used to transfer the loads from the damaged region of the structure to the undamaged portion. Tie forces can be provided by the existing structural elements that have been designed using conventional design methods to carry the standard loads imposed upon the structure. If an existing structure or a new conventional structure design does not meet the tie force requirements, then new members must be added, or the structure must be redesigned.

B-3 DEFINITIONS FOR STRUCTURAL ANALYSIS PROCEDURES.

Joint and Joint Rotation. From ASCE 41, a joint is an area where ends, surfaces, or edges of two or more components are attached; categorized by type of fastener or weld used and method of force transfer. As shown in Figure B-1, a joint is the central region to which the structural members are attached. A joint possesses size, geometry, and material and, as such, the joint can rotate as a rigid body, as shown in Figure B-2. The joint in Figure B-2 is shown as a "+" shape, to facilitate visualization of the joint rotation, Γ.

Typically, deformations within the joint are ignored and only rigid body rotation is considered. However, shear deformations within the panel zone of structural steel and reinforced concrete joints can occur, as defined later.

Figure B-1. Joint and Connection Definition

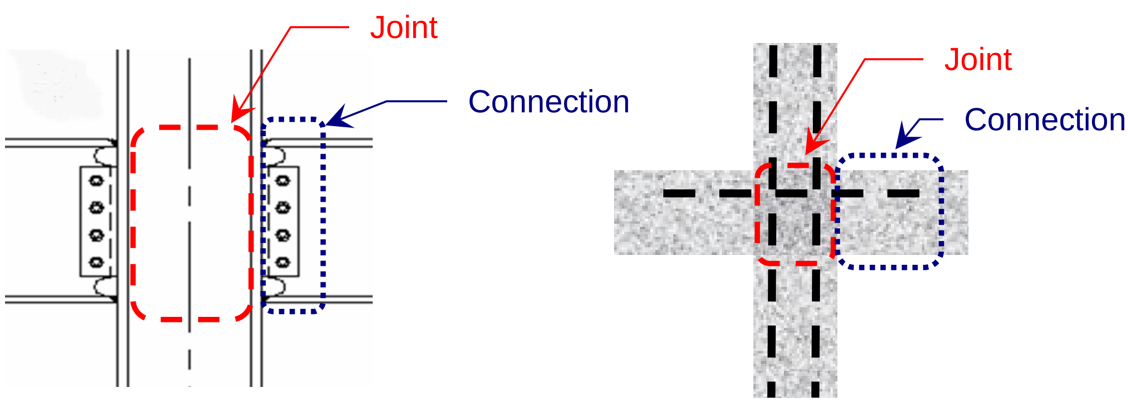

Figure B-2. Joint and Connection Rotations

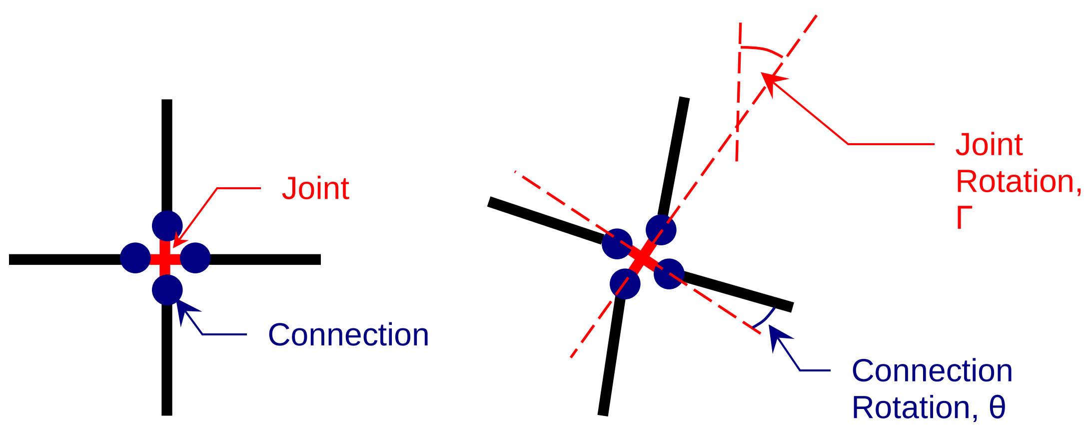
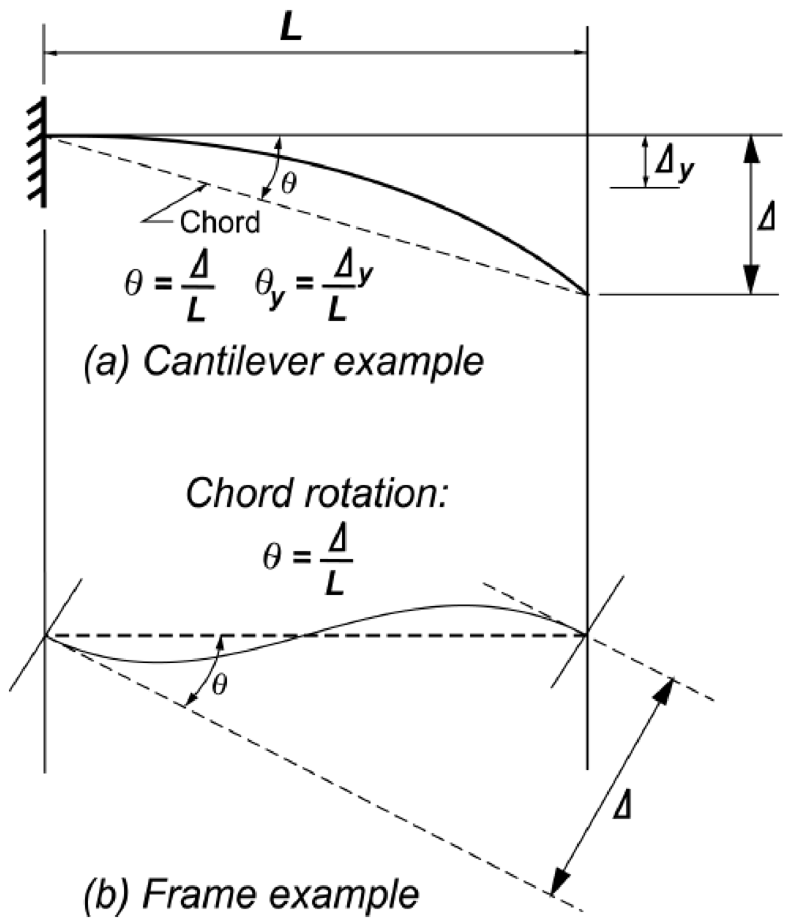


Connection and Connection Rotation. A connection is defined as a link that transmits actions from one component or element to another component or element, categorized by type of action (moment, shear, or axial) (ASCE 41). Steel moment and reinforced concrete connections are shown in Figure B-1. The rotation of the connection is shown in the sketches in Figure B-2. Rotation can occur through shear and flexural deformations in the connection and may be elastic (recoverable) or plastic (permanent). The connection rotation is measured relative to the rigid body rotation of the joint as shown in Figure B-2.

In a frame, calculation of the connection rotation is often determined via the chord rotation. In the case shown in Figure B-3, the chord rotation and connection rotation θ are identical; however, joint rotation must also be considered. The total connection rotation is the sum of the elastic and plastic rotations, defined later.

In numerical models and design software, connections are typically modeled with discrete “plastic hinges”, which exhibit a linear elastic behavior until the yield plateau is reached; in some models, the elastic rotations are ignored, due to their small value. In this case, the rotation of the discrete plastic hinge model is the connection rotation; care must be taken to insure that the rotation of the plastic hinge model only considers the connection rotation θ and does not also include the joint rotation Γ.

Figure B-3. Definition of Chord Rotation (from ASCE 41)



Yield Rotation. Many flexural elements will deform elastically until the extreme fibers of the element reach their yield capacity and the response becomes nonlinear. While the depth of the yielded material in the cross section will gradually increase as the moment is increased, this portion of the response is typically assumed as a finite change in the slope of the moment vs. rotation curve, as shown in Figure B-4. The yield rotation θ_y corresponds to the flexural rotation at which the extreme fibers of the structural elements reach their yield capacity f_y. This is also called the elastic rotation as it corresponds to the end of the elastic region.

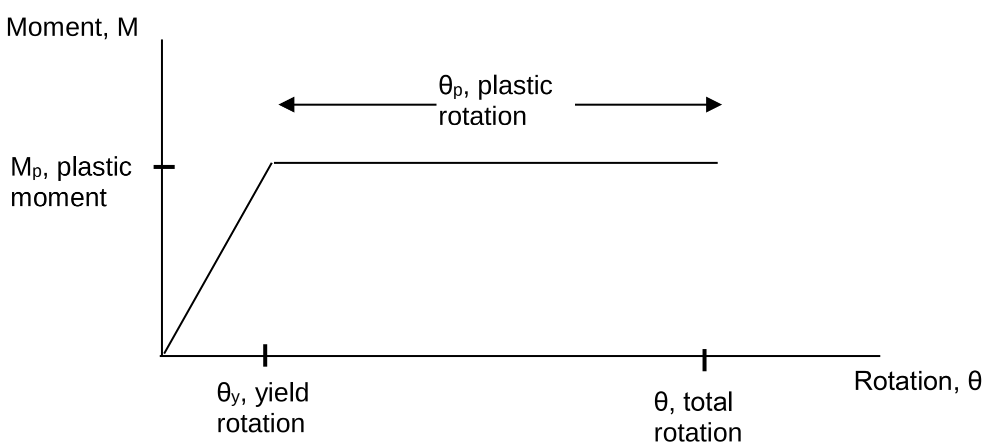
For steel beams and columns, ASCE 41 allows θ_y to be calculated as follows, where it has been assumed that the point of contraflexure occurs at the mid-length of the beam or column.

$$\text{Beams:} \quad \theta_y = \frac{ZF_{ye}l_b}{6EI_b}$$

$$\text{Columns:} \quad \theta_y = \frac{ZF_{ye}l_c}{6EI_c}\left(1 - \frac{P}{P_{ye}}\right)$$

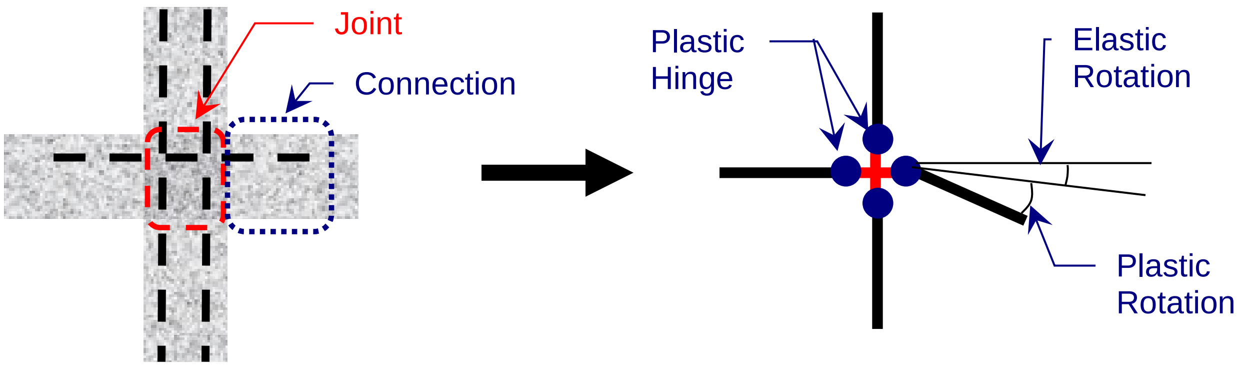
For steel structures, in ASCE 41, multiples of the yield rotation θ_y are used to define the acceptance criteria and modeling parameters in terms of plastic rotation for a number of elements (beams, columns, shear walls).

Figure B-4. Definition of Yield Rotation, Plastic Rotation, and Total Rotation



Plastic Rotation and Plastic Hinge. The plastic rotation θ_p is the inelastic or non-recoverable rotation that occurs after the yield rotation is reached and the entire cross section has yielded; see Figure B-4. The plastic rotation θ_p is typically associated with a discrete plastic hinge that is inserted into a numerical frame model, as shown in Figure B-5. The plastic hinge measures both elastic and plastic rotations, although for simplicity, the elastic portion is often ignored due to its small size.

Figure B-5. Plastic Hinge and Rotation



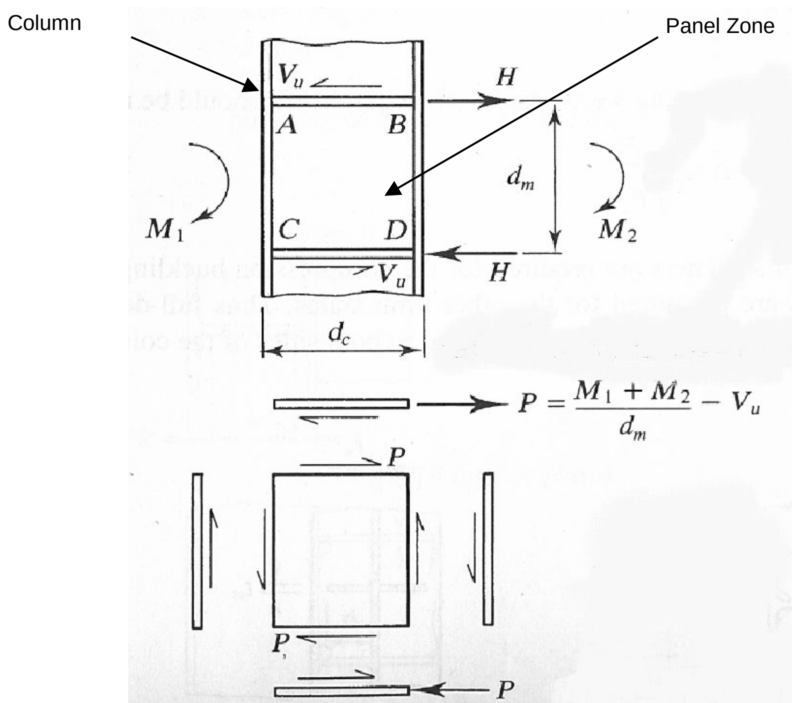
For both steel and concrete, ASCE 41 specifies the acceptance criteria and the modeling parameters in terms of plastic rotation. For some steel structural elements, the criteria parameters are given in terms of multiples of the yield rotation θ_y; for concrete and the remainder of the structural steel elements, a numerical value for the plastic rotation is given, in units of radians.

Total Rotation. The total rotation θ is the sum of the yield rotation θ_y and the plastic rotation θ_p.

Panel Zone. In steel frame structures, the panel zone is the region of high shear stress in the column web within the boundaries of the joint, which results from the large moment transferred to the column joint from a fully restrained connection; see Figure B-6. The panel zone is an integral part of the steel frame beam-to-column moment connection. The deformation measure is the plastic angular shear rotation. Guidance for including or excluding the panel zone in steel models is given in Sections 9.5.2.2.1 and 9.5.2.2.2 in ASCE 41.

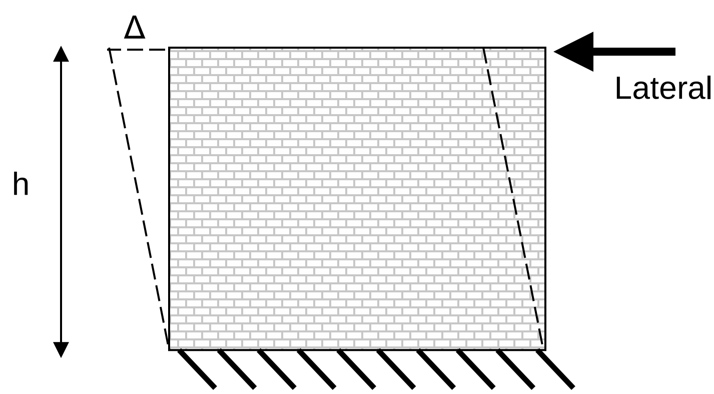
Similarly, for beam-column joints in reinforced concrete framed structures, the plastic shear rotation is the deformation parameter used in the acceptance criteria; in ASCE 41, only the secondary beam-column joints must be checked for shear rotation.

Figure B-6. Panel Zone



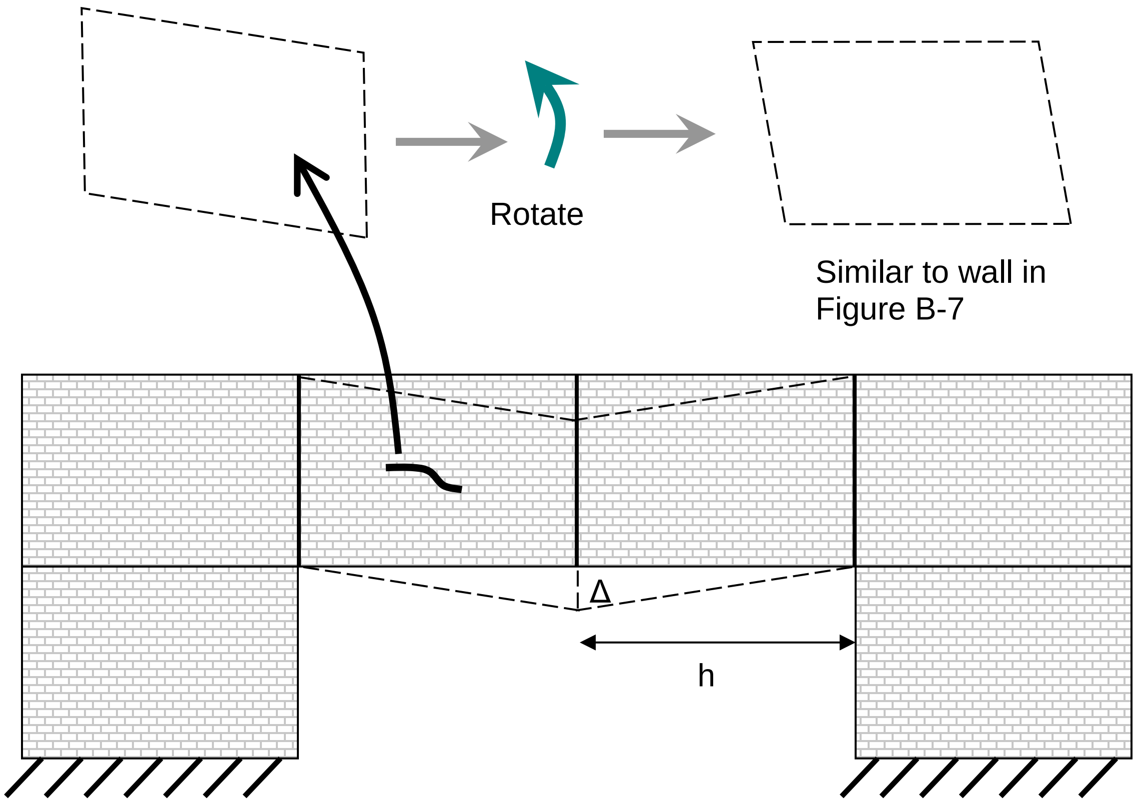
Story Drift (Wall Structures). In ASCE 41, story drift is used as the nonlinear deformation measure for load-bearing wall structures (masonry, wood, and cold formed steel). The story drift is defined as the ratio of the lateral deflection at the top of a wall segment Δ to the overall height of the wall segment, as shown in Figure B-7.

Figure B-7. Story Drift



While the story drift deformation criteria in ASCE 41 are applied to horizontal deformations due to lateral earthquake loads, this information can be used directly for progressive collapse analysis with vertical deformations due to removed wall sections, as shown in Figure B-8.

Figure B-8. Vertical Wall Deflection (Drift)



APPENDIX C COMMENTARY

C-1 INTRODUCTION.

The goal of these design requirements is to provide a rational and uniform level of resistance to progressive or disproportionate collapse. \4\ /4/ These requirements are threat-independent and are not intended to provide resistance to the local damage that may initiate the progressive collapse. Discussion and justification for the applicability requirements, design approaches, modeling techniques, and acceptance criteria are provided in this Appendix.

C-2 APPLICABILITY.

C-2.1 Three Story Requirement and Story Definition.

The required minimum height of 3 stories for progressive collapse design is taken from the original DoD guidance (DoD 2001). This requirement was based on a minimum threshold of 12 casualties in a progressive collapse event where it was assumed that the 2 bays on either side of a removed column or wall would collapse on each of 3 floors and that each bay/room would house 2 persons. Thus, the justification for setting the limit at 3 stories was determined by the level of casualties and not by the mechanics of progressive collapse as a function of structural characteristics.

As casualties are the key metric, a basement or penthouse structure is defined to be a story if it is occupied. The definition of "occupied" in the International Building Code (IBC) is: "A room or enclosed space designed for human occupancy in which individuals congregate for amusement, educational or similar purposes or in which occupants are engaged at labor, and which is equipped with means of egress and light and ventilation facilities." This definition was adopted in Section 1-2.1. Further, as noted in Section 1-2.1, any story that will not be occupied does not count towards the limit of 3 stories; this may include floors that house mechanical equipment or are used for storage.

Any portion of a building that is less than 3 stories is not required to meet the progressive collapse design requirements of this UFC. However, any deleterious effect from the attachment of a short section of the building to the 3 story or higher section must be considered. In particular, peripheral tie forces must be placed in the 3+ story section of the building, at the boundaries between the short section and 3+ story section. For Alternate Path, the structural elements of the short section must be considered in the analysis and design of the 3+ story section if there is any possibility that the presence of the short section will affect the 3+ story section in a negative manner.

C-2.2 Clarification for Partial Occupancy.

UFC 4-010-01 *DoD Minimum Antiterrorism Standards for Buildings* requires that: "These standards only apply where DoD personnel occupy leased or assigned space constituting at least 25% of the net interior useable area or the area as defined in the lease, and they only apply to that portion of the building that is occupied by DoD personnel." This 25% space threshold might be met by lease of entire stories in a multi-story building, e.g., DoD might lease the 3rd and 4th story in a 7-story building. As it is impractical to design or retrofit a building to resist collapse on only certain stories, this requirement from UFC 4-010-01 has been superseded by the requirement in Section 1-2-2.

C-3 RISK CATEGORIES.

In the 2005 UFC4-023-03, the level of progressive collapse design was based on the level of protection (LOP), which, in turn, was based on the asset value of the building, as calculated with UFC 4-020-01 *DoD Security Engineering Facilities Planning Manual*. The asset value was a function of different asset categories, including General Population, Critical Infrastructure and Operations and Activities, Sensitive Information, and All Other Assets, including Mission Critical Personnel. Thus, there was a strong dependence upon the level of occupancy and the criticality to the user. In essence, this is a "consequence approach" in that probability of occurrence and the associated risk for progressive collapse cannot be explicitly considered due to the very small database of progressive collapse events. Thus, the level of casualties and the degradation of function are the key considerations.

Beginning with the 2009 UFC 4-023-03, different levels of design requirements are specified, depending upon the \3\ Risk Category /3/ (RC). The RC is based on the Risk categories defined in Table 2-2 \3\ Risk Category /3/ of Buildings and Other Structures in UFC 3-301-01 *Structural Engineering*. The descriptions for "Nature of Occupancy" in Table 2-2 are very similar to those in ASCE 7 Minimum Design Loads for Buildings and Other Structures, however, some modifications specific to DoD have been made.

It is noted that the RC is independent of threat or initiating event, and, as with the previous LOP approach, this is consequence-based where Risk level and function are key parameters in defining the level of progressive collapse design.

C-4 DESIGN REQUIREMENTS.

The design requirements for RC I through RC IV are listed in Table 2-2 and briefly summarized in the following sections.

C-4.1 RC I Design Requirement.

These buildings present little risk to human life and no progressive collapse design is required providing the buildings were designed to the extant building code.

C-4.2 RC II Design Requirement.

For RC II structures, one of two options must be chosen: Option 1, Internal, peripheral and vertical Tie Forces with Enhanced Local Resistance for the corner and penultimate columns or walls at the first story **OR** Option 2, Alternate Path applied to specific locations. For load-bearing wall structures, the AP method may be the best choice, as the designer can take advantage of the building's inherent redundancy as well as the ability to develop deep beam or arching action.

In the 2005 UFC 4-023-03, only tie forces were used for LLOP (i.e., RC II) buildings. Tie Forces can be very difficult to implement in existing buildings and even for some new types of load-bearing wall construction. Since many load-bearing wall buildings are very redundant and may meet the Alternate Path requirements while staying elastic, Option 2 (as suggested in the Eurocode) was added. Thus, this provides some relief for existing buildings. For many load-bearing buildings, the walls are identical and a single set of calculations for a typical wall may be sufficient.

C-4.2.1 RC II Option 1, Tie Forces and Enhanced Local Resistance.

The goal of the Tie Force requirement is to enhance the structural integrity evenly throughout the structure, by prescriptively defining the magnitude, location, and distribution of the Tie Forces and without requiring significant design or analysis effort. While the Tie Forces are distributed uniformly throughout the structure, the response and performance of the structure varies with the location at which the initial damage occurs. As discussed in Stevens 2008, the removal of a corner column or wall or a penultimate corner or wall can lead to local collapse of a portion of the bay since the lateral support to anchor the Tie Forces has been removed or reduced. This damage will extend to the height of the building, but is unlikely to progress horizontally. While this damage is spatially limited and does not threaten the rest of the building, it is a limitation of the Tie Force approach. Therefore, to reduce the possibility that the corner or penultimate column or wall will be damaged, the Enhanced Local Resistance approach is applied to these elements at the first story above grade, as discussed in Section 3-3.

C-4.2.2 RC II Option 2, Alternate Path.

While the Tie Force requirement can be easily implemented in new construction for some material types, it can be difficult to apply to existing buildings and to non-ductile floor systems. The option to use the Alternate Path method provides another approach by which to evaluate an existing structure. It also allows the designer to account for the inherent and often substantial collapse resistance due to the natural redundancy and available load paths, commonly found in load-bearing wall structures. Many of the structures in RC II will be short (5 stories or less) load-bearing wall buildings with a uniform or regular layout. Hand calculations can be used to demonstrate bridging by deep beam action or arching over removed wall sections for a typical wall and those results applied to the similar walls in the structure.

C-4.3 RC III Design Requirement.

For RC III, two requirements must be satisfied: Alternate Path and Enhanced Local Resistance. The consequence of collapse is greater for this \3\ Risk Category /3/, which also increases the (unknown and unquantifiable) probability of a deliberate attack. Thus, a specified level of resistance to loss of a column or wall is provided by the Alternate Path method. Additional protection is provided by minimizing the likelihood of a non-ductile failure of the columns and walls at the building perimeter, in the first story above grade, through the Enhanced Local Resistance requirement.

For RC III (and IV), the buildings will tend to be large, framed structures, and the specified locations for column or wall removal are only the minimal locations that must be considered; the engineer must also consider locations where the geometry of the structure changes significantly. Since the regular portion of the structure should be covered by the minimum cases and all unusual portions of the structure should be identified by the engineer, this requirement applied to all columns or load-bearing walls in the structure. However, note that for RC III (and RC IV) structures without underground parking or other areas of uncontrolled public access, internal column removal does not need to be considered.

C-4.4 RC IV Design Requirement.

For RC IV, three requirements must be satisfied: Alternate Path, Tie Forces, and Enhanced Local Resistance. The addition of the Tie Force requirement to those of RC III provides another layer of resistance to collapse and will supplement the flexural resistance developed through the AP method. In addition, the ELR requirement is applied to all perimeter walls and columns, over the first story above grade and the level of flexural resistance is increased, to minimize the possibility that two columns or walls at the same level will be removed in the same event.

C-5 TIE FORCES.

C-5.1 General.

The Tie Force requirement is designed to enhance the structural integrity of the building by prescriptively defining tensile force strength of the members and connections, in terms of strength, location, and distribution. This prescriptive method is simple in that detailed or complicated models and analyses are not required, yet it must also be based on mechanical principles, such as equilibrium and deformation compatibility, as applied to a damaged structure.

C-5.2 Previous Requirements.

The Tie Force requirements in the 2005 UFC 4-023-03 were based on the British Building Standards (before the Eurocodes were introduced) for reinforced concrete, structural steel, and masonry. The previous Tie Force requirements were

material-specific, with limited similarity across the different materials in terms of location, distribution, magnitude, and other details. As discussed in the 2005 UFC 4-023-03, the Tie Forces for Reinforced Concrete could be related to an assumed catenary behavior of the floor system, but similar justification could not be found for the other materials.

One common and justified criticism of the previous Tie Force approach was that the great majority of steel connections as well as some RC connections are not capable of providing the magnitudes of rotation that are needed to develop the typically small Tie Forces that were specified. Thus, the connections would fail before the beams, girders, and spandrels could develop axial force. This is also true for Tie Forces distributed in floor systems with limited ductility, such as plywood on engineered I-joists or precast planks with limited continuity across connections.

C-5.3 New Tie Force Approach.

Due to the inability of many connections to sustain large rotations, a new approach was proposed and employed beginning with the 2009 UFC 4-023-03. In this new approach, the floor system now provides and carries the internal Tie Forces, thus removing these Tie Forces from the beams, girders, and spandrels. In essence, the floor system will transfer the vertical loads from the damaged section, via catenary or membrane action, to the undamaged horizontal members, which, in turn, will transfer the load into the vertical load carrying elements, as shown in Figure C-1.

While the internal and peripheral ties are now placed in the floor system, a designer is allowed to use the members and connections for steel, reinforced concrete and other materials, if it can be shown that the connections can carry the tensile forces due to a removed column/wall without failure due to large deformations and rotations.

Additional modifications from the previous UFC include:

- Requirements are now material-independent,
- Explicit tying to external and corner walls and columns is removed,
- Provisions to address openings in the floor system (stairwells, elevators, atria) are included,
- Provisions are added to account for large variations in floor loads over the plan geometry of a single floor.

C-5.4 Justification for the Tie Force Approach.

In the development of the 2009 UFC 4-023-03, analytical and numerical methods were used to derive reasonable tie force requirements that can be used for different column and wall loss locations for braced frames, moment frames, and load-bearing wall structures, with floor systems that are capable of developing membrane or catenary response; the details can be found in Stevens 2008. These floor systems include reinforced concrete (RC) floors with integral slabs, composite construction with

steel decks and RC, and floor systems that incorporate a grid of rebar or welded wire fabric.

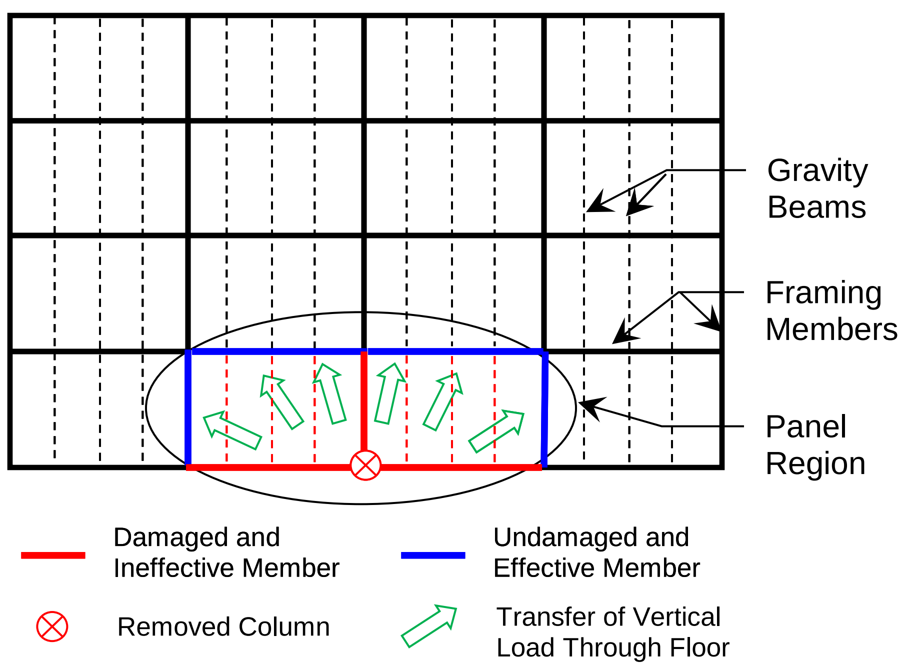


Figure C-1. Damaged and Undamaged Structural Elements

\2\

C-5.4.1 Tie Forces for Framed and Two-way Load-bearing Wall Buildings.

To develop the internal and peripheral tie force requirements for framed structures, 6 different column scenario removals were assessed, using simple catenary theory, membrane theory, and finite element analysis; see Stevens 2008. The removal locations included the corner column, penultimate column, internal column, near penultimate column, edge column, and near edge column, as shown in Figure C-2. In addition to assessing the tie force magnitudes required to carry the loads in catenary or membrane action, the transfer of the vertical force from the damaged panel to the undamaged structures was assessed. Finite element analyses were also performed to determine the dynamic effects created by the sudden loss of column support; the results of these analyses were used to modify the Tie Force equations. Load-bearing wall structures were also considered. As the floor system is the critical element for developing and supplying the internal and peripheral tie forces, many of the findings from the framed structure assessment are directly applicable to load-bearing wall structures.

The application of peripheral ties around the perimeter of openings was also investigated with numerical methods and the loads were shown to be adequately transferred from the damaged area to the peripheral ties and to the undamaged elements. Care must be taken to develop, lap or anchor the peripheral ties at openings

in the floor system (stairways, elevators, atria, etc), such that the strength can be developed. This same approach was used to develop the sub-areas and peripheral ties at the boundary between sub-areas with different floor loads.

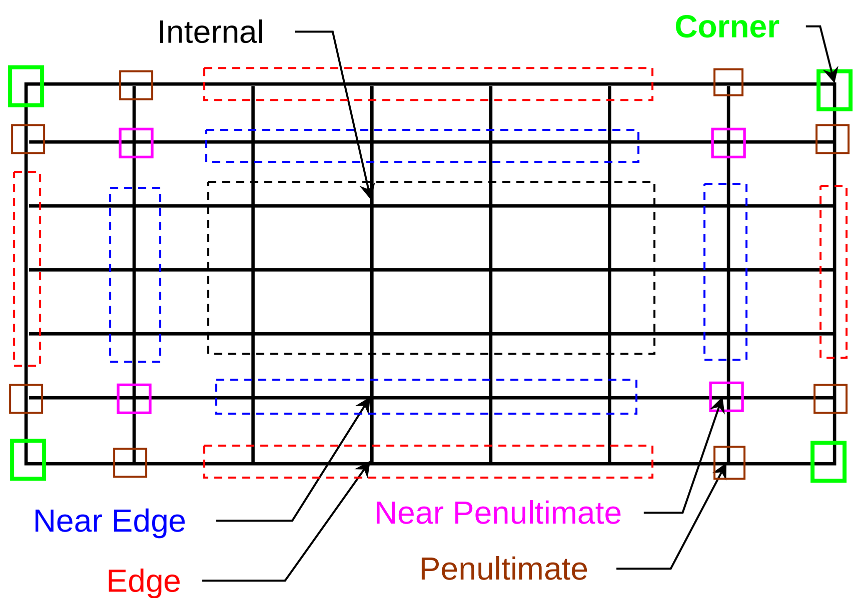

Figure C-2. Column Removal Locations

C-5.4.2 One-way Load-bearing Wall Buildings.

The internal tie force equations for one-way load-bearing wall structures in the 2009 version of UFC 4-023-03 were based on the Eurocode. A series of finite element analyses were subsequently performed to investigate 1) the use of 5h_w in determining the internal tie forces in the direction parallel to the load-bearing walls; and 2) the effect of loads from the removed section of the load-bearing wall on the internal and peripheral ties. As noted in Paragraph 2-2.2.2 design of this structural system to resist progressive collapse is often best addressed with the alternate path approach.

Figure C-3 shows the plan view of a one-way load-bearing wall building. To determine the required magnitude of the internal and peripheral tie forces, different wall removal locations must be analyzed; in all cases, the length of the removed wall is 2h_w

where ***h**_w_* is the clear story height. Four wall removal locations were considered, shown by the shaded boxes in Figure C-3: End wall--center; End wall--end; Interior wall--center; and, Interior wall--end. The results of the numerical simulations for the first two wall removal locations verified that tie forces are not an effective mechanism for resisting progressive collapse when the removed wall sections are at the end of the building. The end walls pull into the building and the wall and floor fail, as there is no means for resisting the lateral forces created by the tie force members; this fact was the motivation behind the requirement to apply Enhanced Local Resistance to the end and penultimate load-bearing walls for \3\ Risk Category /3/ 2 Option 1, in the 2009 version of UFC 4-023-03. A similar result will occur for the removal of the end and center wall sections for the penultimate load-bearing walls. Therefore, the numerical simulations were used to assess the second two cases: interior wall-center and interior wall-end.

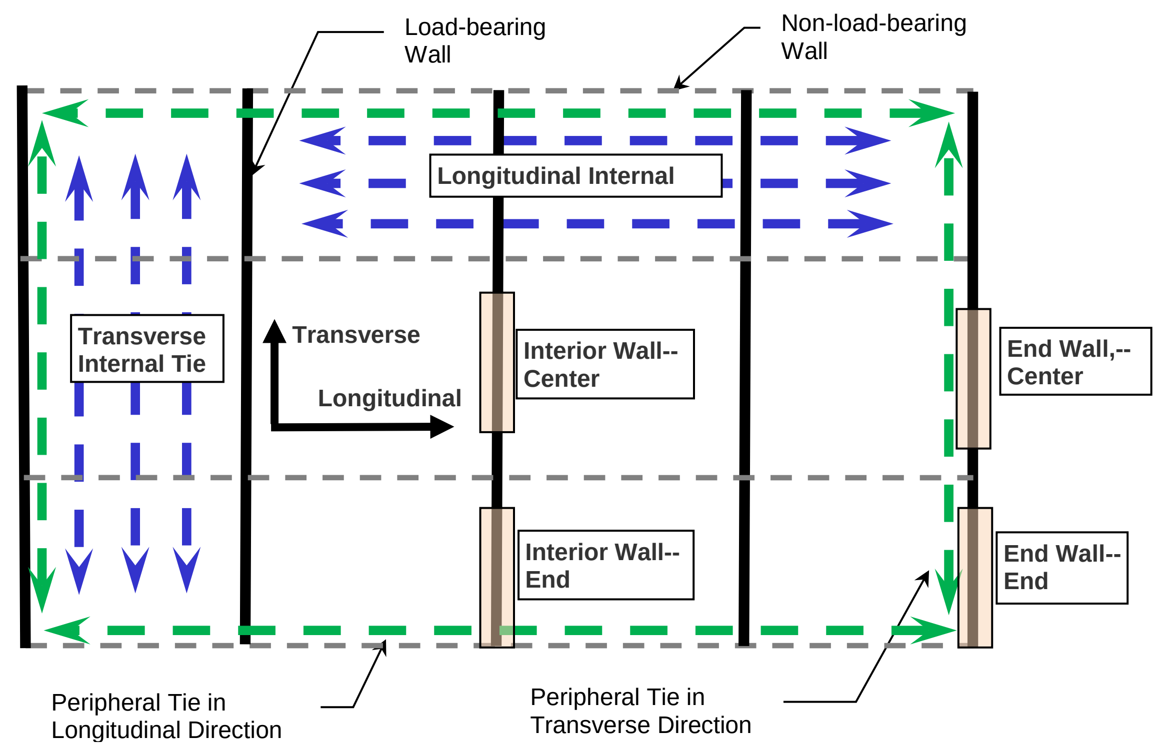

Figure C-3. Plan View of One-way Load-bearing Wall Structure

The purpose of the internal and peripheral tie forces is to transfer the loads of the floor section that is no longer vertically supported to the portions of the structure that are undamaged. For the case of framed structures, this means that each floor must carry its own dead and live load and, thus, each floor can be considered as a separate entity. This same approach holds for load-bearing wall structures, with the addition that the dead load must now include the weight of the walls above the removed wall sections as well as the façade load, if the façade is tied into the floor system. Thus, an idealized representation of the loads on a typical floor above the wall removal location is as shown in Figure C-4.

A series of finite element simulations were performed, using a similar approach as discussed for frame buildings. As reported in Stevens 2008, two levels of façade load (500-plf and 2000-plf) and two levels of wall loads (300-plf and 1500-plf) were considered. The deformation criteria were based on a 10% sag over a double span length; for these analyses, the double span length is in the longitudinal direction as shown in Figure C-4. The results of the analyses were used to create Equation (3-7); details can be found in Stevens 2008.

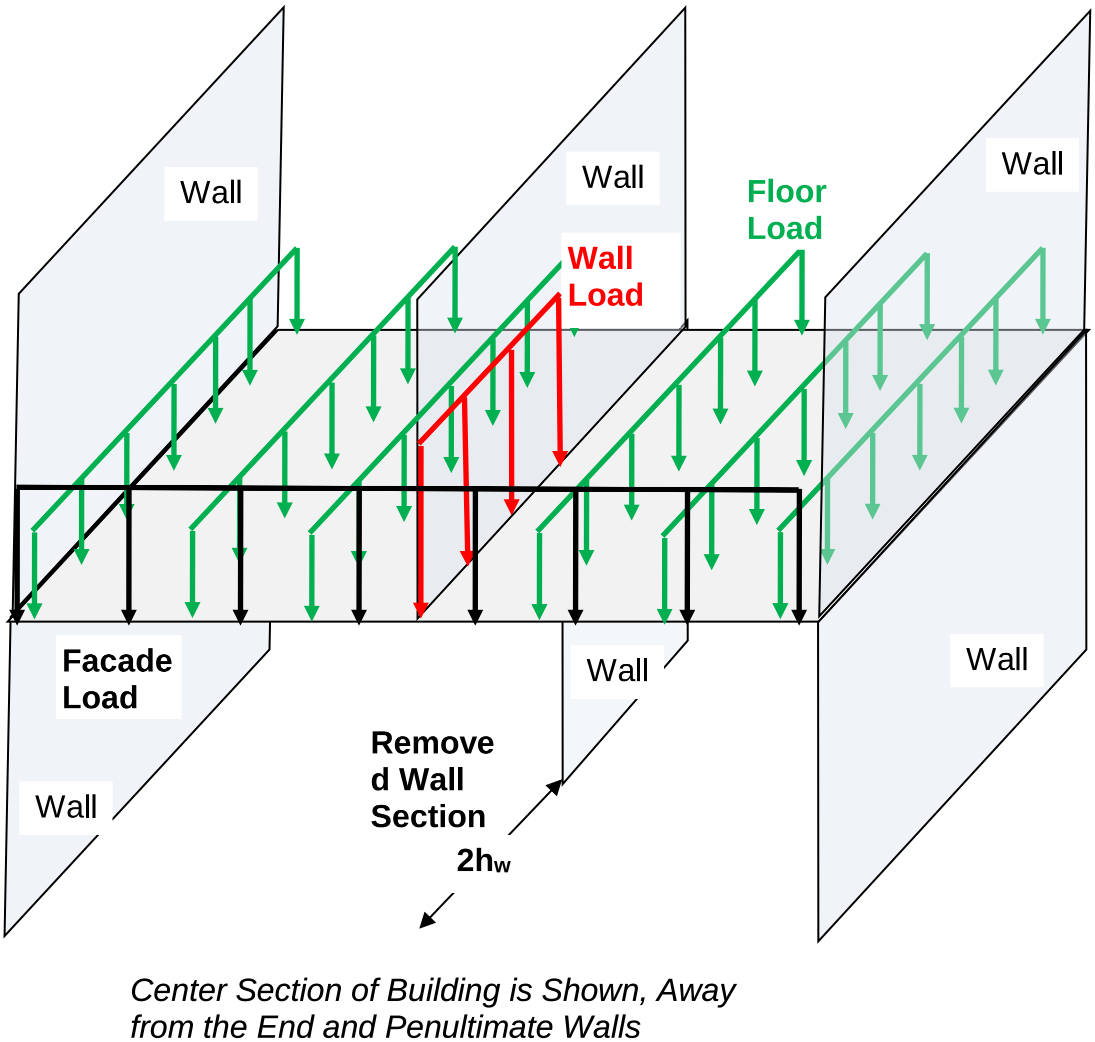

Figure C-4. Loads in a One-way Load-bearing Wall Structure

/2/

C-5.5 Tie Forces in Roof Systems

The roof system must meet the Tie Force requirements in Section 3-1. As with floor systems, these requirements will be more easily met with some types of roof systems, such as reinforced concrete slabs and composite decks.

For lightweight systems such as steel deck and joist roof systems, sufficient strength and ductility should be available in the direction of the joist, providing that the bottom chord of the joist does not connect to the column or beam; see Figure C-5. If so, then the top chord of the joist can be used to supply the Tie Force, providing that the load path is continuous across each vertical support. Two approaches can be used in the transverse direction. In the first, steel shapes (rods, angles, bars, etc.) could be placed through the open webs. Attachments of these internal ties to the peripheral ties must be capable of developing the longitudinal and transverse tie forces. Second, a steel deck that spans in the transverse direction to the joist could be used to supply the internal Tie Force provided that the welds or other connections between the steel deck sections are sufficient to develop the Tie Force. While there may be crushing of the steel deck where it crosses the joist or other vertical support, the upper surface of the deck should remain intact and capable of supplying tension up to 0.20-rad; see Figure C-6.

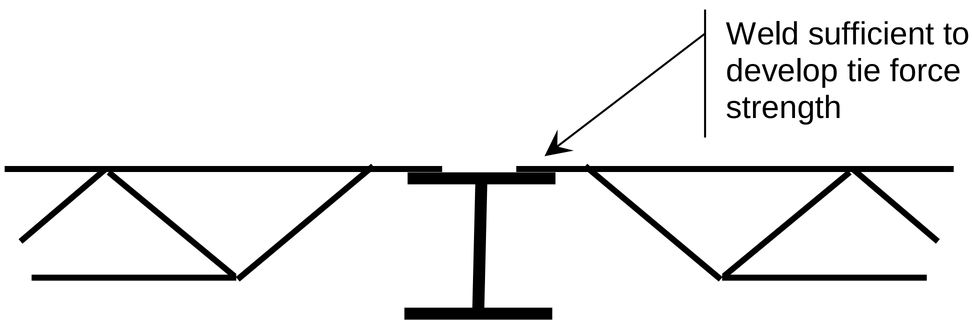

Figure C-5. Tie Force in Upper Chord of Roof Joist

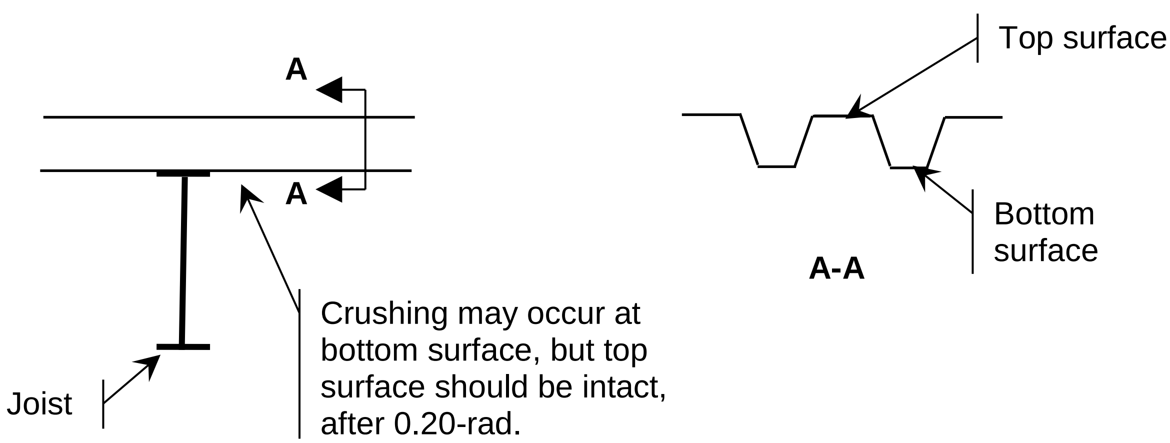

Figure C-6. Tie Force in Steel Deck

C-5.6 Location Restrictions on Internal and Peripheral Ties.

As mentioned, one goal of the revised Tie Force approach is to remove the Tie Forces from the flexural members, which typically are not capable of sustaining the large amount of deformation associated with catenary and diaphragm action. For example, if a peripheral tie was placed in a deep edge beam with limited ductility, the peripheral tie may be damaged or failed by the resulting motion of the edge beam after a column is removed. Within the floor plan, the internal ties can be shifted to either side of the beam, girder or spandrel for framed structures; for flat plate or flat slab structures without edge beams or internal beams, the tie forces can be placed on the column lines and pass through the columns. However, the peripheral ties also need to be close to the edge of the structure and therefore the peripheral ties are permitted to be close to the inner edge of the beam, girder or spandrel. While the portion of the slab/floor next to the beam may respond as a flange of the beam early in the deflection, at some point the beam and its action will be separated from the slab and the peripheral tie will function as intended.

C-5.7 Consideration for Non-Uniform Load Over Floor Area.

Since the load magnitude may vary significantly over the plan area of a given story, e.g. manufacturing activities may be located in one section of the floor and office space in another, the concept of sub-areas is used to accommodate the differences in longitudinal, transverse, and peripheral ties that result from the load variation.

The approach in Paragraph 3-1.3 is illustrated in Figure 3-2 for the case of two sub-areas. In principle, multiple sub-areas can be used across a floor system, but the designer is encouraged to minimize the number of sub-areas, to reduce the number of unique rebar layouts as well as the potential for errors in construction.

The peripheral ties between the sub-areas must be satisfactorily anchored or embedded such that the full tensile strength can be developed.

C-6 ALTERNATE PATH METHOD.

C-6.1 General.

In the Alternate Path (AP) method, the designer must show that the structure is capable of bridging over a removed column or section of wall and that the resulting deformations and internal actions do not exceed the acceptance criteria. Three analysis procedures are permitted: Linear Static, Nonlinear Static, and Nonlinear Dynamic.

These procedures were re-evaluated for the 2009 UFC 4-023-03. An assessment of analysis methods in the related field of seismic design revealed that the procedures specified in ASCE 41 *Seismic Rehabilitation of Existing Buildings* could be adopted and modified for application in the 2009 UFC 4-023-03. While progressive collapse design and seismic design are distinctly different, the general ASCE 41 approach was adopted for the following reasons:

- ASCE 41 and UFC 4-023-03 deal with extreme events that severely damage structures which must not collapse or otherwise imperil the occupants.
- The ASCE 41 methodology was developed and vetted by a panel of structural engineering experts over many years of effort and could be modified in a straightforward manner for progressive collapse design.
- Five materials are considered: steel, RC, masonry, wood, and cold formed steel, in ASCE 41 and UFC 4-023-03.
- Explicit requirements and guidance for analyzing and designing multiple building types for each material are provided in ASCE 41.
- Careful attention is given in ASCE 41 to deformation- and force-controlled actions, as well as primary and secondary components.
- The acceptance criteria and modeling parameters in ASCE 41 can be scaled for different structural performance levels.

The most significant differences between the physics, intent, and approaches underlying UFC 4-023-03 and ASCE 41 are:

- **Extent.** The seismic event involves the entire structure, whereas, for progressive collapse, the initial event is localized to the column/wall removal area.
- **Load Types**. Seismic loads are horizontal and temporary; for progressive collapse, the loads are vertical and permanent.
- **Damage Distribution**. For earthquake design, it is accepted that the damage will be distributed throughout the structure. For progressive collapse, the initial damage is localized and the goal is to keep the damage from progressing.
- **Connection and Member Response**. In typical tests to evaluate the seismic performance of connections and members, cyclic loads with increasing magnitude are applied, without axial loading, and the resulting curves are used to develop “backbone” curves. In progressive collapse, the connection and member experiences one half cycle of loading, often in conjunction with a significant axial load, due to large deformations and catenary response.

These differences have been accommodated in the adaptation of ASCE 41 procedures and criteria to Alternate Path modeling and design for progressive collapse. The significant elements of the Alternate Path method are presented in the following paragraphs.

C-6.2 Peer Review.

In the 2005 UFC 4-023-03, a peer review was required for Alternate Path design of medium and high level of protection buildings. In both the 2009 UFC 4-023-03 and in this UFC, a peer review is no longer required as this is a policy issue that is best addressed by the building owner. However, peer reviews are strongly recommended, for Alternate Path design in any \3\ Risk Category /3/.

C-6.3 Alternative Rational Analysis.

Any rational alternative analysis procedure that is based on fundamental principles of engineering mechanics and dynamics may be used. For load-bearing wall structures with uniform and regular wall layouts or simple frame structures, hand calculations or spreadsheet applications may be appropriate and more efficient. New software design and analysis tools, based on novel analytical formulations, may be used as well. However, any alternative rational analyses must incorporate or satisfy the following:

- the acceptance criteria contained in Section 3-2.10 and in Chapters 4 through 8.
- the specified locations and sizes of removed columns and load-bearing walls in Section 3-2.9.
- the ASCE 7 extreme event load combination.
- the load increase factors and dynamic increase factors in Sections 3-2.11.5 and 3-2.12.5 for linear static and nonlinear static analyses, respectively.
- the requirements of Section 3-2.11.1 must be met for a Linear Static analysis.

All projects using alternative rational analysis procedures shall be reviewed and approved by an independent third-party engineer or by an authorized representative of the facility owner.

C-6.4 Load and Resistance Factor Design.

Load and Resistance Factor Design (LRFD) continues to be used in this version of UFC 4-023-03 as well as the ASCE 7 extraordinary event load combination is employed. Also, unlike ASCE 41, strength reduction factors are employed in determining the design strength. The strength reduction factors account for deficient material strength, construction errors, design flaws and other uncertainties that can act to reduce the strength of the building; all of these uncertainties are “locked” into the building when it is constructed and will still be there when a progressive collapse event occurs. Therefore, the strength reduction factors, load factors, and the LRFD approach continue to be employed in this version of UFC 4-023-03.

C-6.5 Primary and Secondary Components.

The designation of elements, components and connections as primary or secondary is left to the judgment of the engineer; however, in all cases, the engineer must verify that the structure and its elements, components and connections are capable of meeting the structural acceptance criteria in Paragraph 3-2.10.

For evaluation of existing buildings, the engineer may wish to include elements that are typically considered secondary, i.e., gravity beams, slabs, infill walls, etc. If such elements are included as part of the system that resists the vertical loads and collapse, they become primary components by definition and must meet the primary component acceptance criteria.

C-6.5.1 Secondary Components.

While secondary components are designated by the engineer as not contributing to the resistance of gravity loads and progressive collapse, they are a critical part of the load path for the vertical loads and they pose a risk to the building occupants if they drop into the space below, potentially creating additional damage and collapse. As an example, the gravity beams in a bay supporting heavy mechanical equipment could be treated as secondary components; however, the shear tab connections with a deep bolt group could have reduced allowable rotations/m-factors such that the rotations from the column removal could be sufficient to fail the shear tab connections. Secondary components are not included as part of the models in the linear or nonlinear procedures but must be checked against the acceptance criteria given in this UFC and in ASCE 41.

\2\

C-6.5.2 Linear Static Secondary Component Acceptance Criteria.

While secondary components such as gravity beams and simple shear tab connections are not included in the linear static model, these members may fail if subjected to large dynamic loads and/or significant deflections due to column/wall removal and may pose a hazard to occupants or lead to additional structural failure if they detach and impact the floor below. These members must be checked with the same level of attention as the primary members. For linear procedures, the secondary component must meet the force- and deformation-controlled criteria of Equations 3-13 and 3-14.

Before the column or wall is removed, the secondary component will be initially stressed and deformed due to the deformation-controlled or force-controlled load combinations given in Equations 3-10 and 3-12, respectively. When the column or wall is removed, additional stresses and deformations are created. As a linear static procedure is being used, these two sets of demands can be directly added. Two steps are required. First, for each secondary component or connection, the force- or deformation controlled load case is applied to the secondary component in the un-deformed configuration and the demand (internal shear, moment, axial force) due to this load is calculated. Second, the displacements and rotations from the linear static model with the removed column/wall are then applied to the secondary component (without the gravity load) and the resulting demand is calculated. The two demands (due to load and due to deformed structure) are added together to determine the total demand. This approach is used in the steel example in Appendix E.

As Appendix E shows, acceptance checks of gravity beams and simple shear tab connections (secondary components) in steel frame structures present a unique challenge. While force- and deformation-controlled actions can be checked in a straight-forward manner with nonlinear procedures, the linear static procedure and criteria are based on m-factors applied to the moments and other deformation-controlled actions and thus moments must be determined to perform the checks, even at the simple connections and the ends of gravity beams which are often considered to be pinned. While allowable plastic rotations are available for nonlinear static and nonlinear dynamic procedures, they cannot be used for checks in the linear static method, as the analysis procedures are different, in terms of load adjustment factors, explicit consideration of hinges, fidelity of the nonlinear models, etc. Thus, the linear static acceptance criteria must be based on moments, shears, and other forces. As simple shear tab connections can be considered partially restrained (PR) connections, their flexural strength can be calculated with an approximate rotational stiffness and the overall rotations, for comparison to the flexural demand, as shown in Appendix E. Similar approaches must be devised and used for reinforced concrete, masonry, wood, and cold-formed steel structures./2/

C-6.6 Analysis Procedures.

C-6.6.1 Linear Static.

The Linear Static approach in the 2005 UFC 4-023-03 had been replaced with an “m-factor” procedure, very similar to that defined in ASCE 41. The two significant departures from the ASCE 41 procedure are in the definition of the “Irregularity Limitations” in Paragraph 3-2.11.1.1 and the use of a load increase factor appropriate for progressive collapse loading. The irregularity limitations have been adjusted due to the inherent difference between lateral/seismic loading and vertical/progressive collapse loading and the related criticality of different building geometric and strength features. As discussed in Section C-6.8, a new load increase factor to account for nonlinearity and dynamic effects has been implemented.

C-6.6.2 Nonlinear Static.

The Nonlinear Static procedure is similar to that specified in the 2005 UFC 4-023-03 and in ASCE 41. Two exceptions are the modeling parameters and the acceptance criteria, which are now taken from ASCE 41, unless specifically modified in Chapters 4 to 8 of this UFC. One advantage of ASCE 41 is that guidance is provided for the development of analytical and numerical models for a number of distinct structural systems, including the determination of connection and member properties

One significant difference from ASCE 41 and the 2005 UFC 4-023-03 is the specification of a dynamic increase factor that is applied to the loads on the bays above the removed column or wall location to account for dynamic effects. In the 2005 UFC 4-023-03 and in the 2003 *GSA Progressive Collapse Analysis and Design Guidelines for New Federal Office Buildings and Major Modernization Projects* (“GSA Guidelines”), the load factor was set at 2, as for the Linear Static analysis, despite the explicit incorporation of nonlinear effects in the Nonlinear Static procedure. The dynamic increase factor is discussed in Section C-6.8.

C-6.6.3 Nonlinear Dynamic.

The Nonlinear Dynamic procedure is essentially unchanged from the 2005 UFC 4-023-03, with the exception of the incorporation of the modeling parameters and acceptance criteria from ASCE 41.

C-6.7 Loads.

\2\The ASCE 7 extraordinary event load combination is employed, with the exception that the lateral load has been removed. In alternate path analyses, the initial and primary damage is limited to the column or removal location, with the rest of the structure being intact and providing the majority of its original lateral load resistance; the original lateral load resistance would be based on peak wind forces much higher than 0.2W, 0.002ΣP or seismic loads if present. It is highly unlikely that the loss of a column or 2H wall section would destabilize the building laterally and cases where applying the lateral load uncovered any instability of the building and motivated any changes to the building design are unknown. Therefore, the lateral load requirement has been removed. /2/

C-6.8 Load and Dynamic Increase Factors.

Three analytical procedures may be employed: Linear Static, Nonlinear Static, and Nonlinear Dynamic. As progressive collapse is a dynamic and nonlinear event, the applied load cases for the static procedures require the use of load increase factors or dynamic increase factors, which approximately account for inertial and nonlinear effects. For both Linear Static and Nonlinear Static, the 2005 UFC 4-023-03 and the GSA Guidelines use a load multiplier of 2.0, applied directly to the progressive collapse load combination.

Three issues with the use of a fixed factor of 2 have been identified. First, the same load multiplier is used for Linear Static and Nonlinear Static analyses, although the Nonlinear Static analysis incorporates nonlinearity. Second, an increase factor of 2.0 is not appropriate for the majority of LS and NS cases. The maximum dynamic displacement of an instantaneously applied and sustained load in a linear analysis is twice the displacement achieved when the load is applied statically. If a structure is designed to remain elastic, a factor of 2.0 would be appropriate. However, in extreme loading events, it is typical to design structures to respond in the nonlinear range. Thus, the dynamic increase factor (DIF) that allows a Nonlinear Static solution to approximate a Nonlinear Dynamic solution, is typically less than 2. On the other hand, the load increase factor (LIF) for a Linear Static analysis must be greater than 2, since dynamic and nonlinear effects are present. Third, the load enhancement factor did not vary with the structural performance level, i.e., a structure is assigned a load enhancement factor of 2.0 regardless of whether the designer wants to allow significant structural damage or very little damage.

A study was undertaken to investigate the factors needed to better match the results of the LS and NS static procedures to the ND results; see McKay et al. 2008. As in ASCE 41, structural deformation was considered to be the best metric for approximating structural damage. To match the ND deformation levels, SAP2000 models of reinforced concrete and steel multi-story models were developed and analyzed with LS, NS, and ND procedures. For the LS and ND models, the loads were varied until agreement with the NS model was reached. The ASCE 7 extreme event load case was used for all analyses.

The range of nonlinear structural deformations used in this study was based primarily on the acceptance criteria in ASCE 41, with some modifications for reinforced concrete, for which the Life Safety values were increased by a factor of 3.5. For reinforced concrete, the allowable deformation criteria in ASCE 41 are much smaller than indicated by test data from blast- and impact-loaded RC structural members. In addition, the conservative ASCE 41 RC criteria are based on backbone curves derived from cyclic testing of members and joints, whereas only one-half cycle is applied in a progressive collapse event.

As an example, the results of this procedure for the Dynamic Increase Factor (DIF), used for Nonlinear Static analyses of steel structures, are shown in Figure C-7, where the DIF is shown as a function of the normalized rotation (allowable plastic rotation divided by the rotation at yield of the cross section). The data points in this plot were obtained by analyzing a range of buildings with various heights, bay dimensions and structural details. With this plot the DIF can be chosen as a function of the level of nonlinear behavior (i.e., structural performance level) that the designer wishes to employ or, else, the level of nonlinear behavior can be assigned, resulting in a specific DIF. In this UFC, the designer must find the smallest normalized rotation for any structural component or connection within the region of the structure affected by the column removal and will use this value to determine the DIF from the recommended equation in Figure C-7.

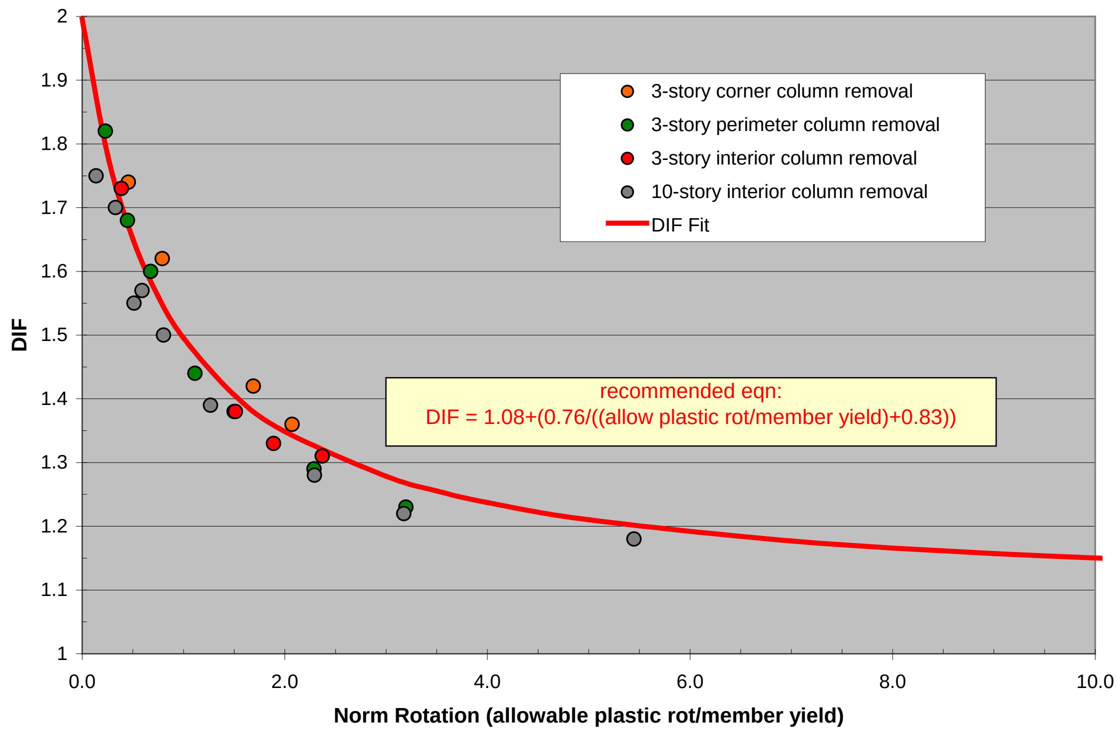

Figure C-7. Dynamic Increase Factor for Structural Steel

C-6.9 Structural Damage Limits.

In the previous UFC, the structural damage limits were set at 15% and 30% for the floor area above the removed column or wall at an external or internal column or wall, respectively. In this UFC, no damage to the floor is allowed and these criteria have been removed, as the floor system, beams, and girders in the bays directly above the removed column can be designed to not fail, as is done for the bays in the floors above the removed column location.

C-6.10 Modeling and Acceptance Criteria.

With a few notable exceptions, the acceptance criteria for linear and nonlinear approaches and the modeling criteria for nonlinear approaches from ASCE 41 are employed in the updated UFC 4-023-03. The ASCE 41 criteria are considered to be conservative when applied to progressive collapse design as they have been developed for repeated load cycles (i.e., backbone curves) whereas only one-half load cycle is applied in progressive collapse. As specified in each material specific chapter of this UFC, either the Collapse Prevention or Life Safety structural performance levels in ASCE 41 are used for many of the components; see Chapters 4 to 8.

The notable exceptions/modifications to the acceptance and modeling criteria include RC beams and slabs and a number of steel connections. These changes are motivated and justified by experimental data and numerical analysis results, as discussed later in this Appendix.

C-7 ENHANCED LOCAL RESISTANCE.

The second direct design approach is Specific Local Resistance (SLR) or structural hardening, in which key or critical elements of the structure are designed for a specific load, such as blast or vehicle impact. This approach reduces the likelihood or extent of the initial damage and can be effective, for those cases where the threat can be quantified through risk analysis or specified through prescriptive design requirements. SLR can be a cost-effective method for providing resistance to collapse prevention, particularly for existing structures. The main shortcoming to this method is the requirement to define the threat or design load, as this information could be used to plan a deliberate attack on the structure; because of this, the threat information may be considered classified, restricting its use by the general public. Also, philosophically, progressive collapse design is typically considered to be threat-independent and if a specific threat such as an explosive device is specified, separate design guidance for hardening buildings is available.

In the 2005 UFC 4-023-03, a version of SLR was implemented in the Additional Ductility Requirement (ADR), which specified that the shear strength of a ground story column or wall exceed the flexural strength. With this requirement, the columns or walls will fail in flexure, which provides a more ductile and controlled response than the sudden failure associated with shear. This requirement can be implemented cost-effectively in new construction and provides a significant benefit.

A modified or enhanced version of SLR is implemented in this UFC to provide a nominal level of protection for perimeter columns and walls. This procedure is also threat independent and is referred to as Enhanced Local Resistance (ELR) to differentiate it from SLR and ADR. As ELR is intended to provide resistance against severe dynamic loadings, the same philosophy as is used for blast resistant design is employed, wherein all strength reduction factors are set to 1.0 and the expected strength is employed for shear, flexure and all other actions. The development and design approach of this method is “tuned” to the inherent structural robustness of the system as discussed in Marchand and Stevens 2008. A charge weight that will destroy multiple columns or wall sections, depending upon standoff and location, was determined for a variety of representative structures. An analysis of the data resulted in required enhancement factors of 2 and 1.5 for the flexural and shear demands of columns and walls, respectively. The design shear strength of the column or wall and the connections to the lateral force resisting elements is also stipulated to be greater than the shear demand, which is based on the flexural demand, to provide a ductile and more controlled failure mode. \2\

C-7.1 ELR Design Requirements.

For RC II Option 1, the shear demand of the columns and walls is determined based on the existing or as-designed structure. For RC III, the shear demand is based on the structure design after the AP method has been applied.

A higher level of resistance is required for RC IV structures; in this case, two flexural demands are compared and used to determine the final shear demand. Because an RC IV building in a seismic region will have significantly larger columns than the same RC IV building in a non-seismic region, the seismic structure will also have significantly higher shear demand. However, both buildings should provide the same protection to the occupants. To accomplish this and to provide a reasonable shear demand, the design of the building based on only gravity loads and the AP requirements is used to define the baseline nominal flexural strength. If a gravity loads only design was not accomplished during the design effort, it must be performed. It is anticipated that mathematical models will be created for RC IV buildings and the effort to use them for a gravity loads only design and AP analysis should not be significant. After the baseline nominal flexural strength is determined with the column design from the gravity loads-only AP structural design, it is multiplied by 2.0 and compared to the existing nominal flexural strength. The existing nominal flexural strength is based on the column design after the Alternate Path method is applied to the final structure (i.e., the structural design based on wind, seismic, snow, and gravity loads). The larger of 2.0 times the baseline nominal flexural strength and the existing nominal flexural strength is defined as the flexural demand. If the flexural demand is greater than the existing nominal flexural strength, then the design of the column must be upgraded to match the flexural demand. The same procedure applies for load-bearing walls but in this case, the baseline flexural strength is multiplied by 1.5.

C-7.2 Connection Design for Rebound.

Rebound is most likely to occur for explosive loadings, not vehicle impact and the magnitude of the rebound reaction is a function of the column properties, end conditions, façade design, charge weight and standoff, etc Guidance for rebound forces can be found in Section 4-1.2.5 of PDC TR-06-01 *Methodology Manual for the Single-Degree-of-Freedom Blast Effects Design Spreadsheets (SBEDS)*, which states that “An equivalent static design load for rebound equal to one-half the inbound ultimate resistance is often used as a rule of thumb for blast design.” This is the basis for the requirement in Section 3-3.6 that the connection be designed for a rebound reaction equal to 50% of the inbound reaction force. It should be noted that this requirement is based on analytical modeling, engineering judgment, and qualitative observations. However, there is limited experimental evidence that neither supports nor discredits this requirement for the wide range of construction types and scenarios covered in this UFC. /2/

C-8 REINFORCED CONCRETE.

C-8.1 Reinforced Concrete Beams and Joints.

\4\ /4/ The design strength and rotational capacities of the beams and beam-to-column-to-beam joints shall be determined with the guidance found in ASCE 41, as modified with the acceptance criteria provided in Paragraph 4-4.3.

C-8.2 Structural Performance Levels.

To determine the appropriate structural performance level and the corresponding modeling and acceptance criteria from ASCE 41, the types of loading and resulting performance of reinforced concrete beams and beam-column joints were assessed. In seismic events, the structural elements and connections are subjected to primarily shear and bending with little axial tension. Under progressive collapse conditions, axial tension is developed in the beam, as they undergo large displacements in a double-span condition and the beam starts to behave as a catenary.

Conceptually, the damage states reflected in the Life Safety category make sense for progressive collapse. In seismic design, it is assumed that the primary components can sustain significant degradation to their lateral load resisting behavior as long as they can still support the gravity loads; for progressive collapse, the primary components must resist gravity loads during and after the event. As defined in ASCE 41, Collapse Prevention results in a damage state for which there is little additional deformation capacity and the stability of the system has been severely compromised. Life Safety provides a greater reserve in terms of nonlinear deformation and strength and thus is used for the majority of the steel acceptance criteria.

C-8.3 Modeling and Acceptance Criteria for Reinforced Concrete.

The majority of the modeling parameters, acceptance criteria and linear m-factors for reinforced concrete are chosen as the Life Safety values in Chapter 6 of ASCE 41 for primary and secondary components. Modifications to the modeling and acceptance criteria for beams and slabs were made based on data from blast- and impact-loaded beams and other flexural members. For RC beams and slabs controlled by flexure, the modeling and acceptance criteria values for Collapse Prevention were multiplied by a factor of 2.5 for primary members and 2.0 for secondary members. For all other conditions and cases of beams and slabs, the Life Safety values are used.

C-8.4 Best Practice Recommendation.

To insure ductile and energy absorbing response in new construction of reinforced concrete structures, it is recommended that the primary reinforced concrete beams and beam-to-column-to-beam joints comply with the provisions for special moment frames in ACI 318. These code provisions include ductile detailing requirements for longitudinal reinforcement, transverse reinforcement, required shear strength, and development length of bars in tension.

C-9 STRUCTURAL STEEL.

C-9.1 Structural Steel Connections.

A variety of steel frame connection types are listed in Table C-1 and illustrated in Figures C-8 through C-10. This list constitutes an inventory of connection types that have been used either in the past and/or present for standard building code design applications (gravity, wind, and earthquake loads).

Proprietary connections have been evaluated and found to be acceptable for specific projects and/or for general application. Inclusion of these connections in this UFC does not constitute an endorsement. The Kaiser Bolted Bracket®, SidePlate® and SlottedWeb™ are shown schematically in Figures C-11 through C-13, respectively. Details of the performance and geometry can be obtained from the vendors.

C-9.2 Steel Connection Requirements.

\4\/4/ The design strength and rotational capacities of the beams and beam-to-column connections shall be determined with the guidance found in ASCE 41, as modified with the acceptance criteria provided in Paragraph 5-4.3 in this UFC.

C-9.3 Structural Performance Levels.

To determine the appropriate structural performance level and the corresponding modeling and acceptance criteria from ASCE 41, the types of loading and resulting performance of structural steel connections were assessed as there is a fundamental difference between seismic and progressive collapse events. The seismic modeling and acceptance criteria in ASCE 41 are based upon cyclic tests in which the end of a cantilever beam is subjected to ever-increasing amplitudes; the beams and connections experience shear and bending moment with no axial tension. Under progressive collapse conditions, axial tension is developed as the beam experiences large displacements in a double-span condition and the beam starts to behave more like a cable than a beam.

Table C-1. Steel Frame Beam-to-Column Connection Types

Connection	Description	Type	Figure
Welded Unreinforced Flange (WUF)	Full-penetration welds between beams and columns, flanges, bolted or welded web, designed prior to code changes following the Northridge earthquake.	FR	C-8(a)
Welded Flange Plates (WFP)	Flange plate with full-penetration weld at column and fillet welded to beam flange	FR	C-8(b)
Welded Cover-Plated Flanges	Beam flange and cover-plate are welded to column flange	FR	C-8(c)
Bolted Flange Plates (BFP)	Flange plate with full-penetration weld at column and field bolted to beam flange	FR or PR	C-8(d)
Improved WUF-Bolted Web[(1)]	Full-penetration welds between beam and column flanges, bolted web, developed after Northridge Earthquake	FR	C-8(a)
Improved WUF-Welded Web	Full-penetration welds between beam and column flanges, welded web developed after Northridge Earthquake	FR	C-8(a)
Free Flange	Web is coped at ends of beam to separate flanges, welded web tab resists shear and bending moment due to eccentricity due to coped web developed after Northridge Earthquake	FR	C-8(e)
Welded Top and Bottom Haunches	Haunched connection at top and bottom flanges developed after Northridge Earthquake	FR	C-8(f)
Reduced Beam Section (RBS) [(2)]	Connection in which net area of beam flange is reduced to force plastic hinging away from column face developed after Northridge Earthquake	FR	C 8(g)
Top and Bottom Clip Angles	Clip angle bolted or riveted to beam flange and column flange	PR	C-9(a)

The rotational capacity values for connections in the 2005 UFC 4-023-03 were based upon the 2003 GSA Guidelines, and reasonably agree with those in ASCE 41 for primary elements and the Life Safety structural response level. Conceptually, the damage states reflected in the Life Safety category make sense for progressive collapse. The governing assumption for seismic design is that the primary components can sustain significant degradation to their lateral load resisting behavior as long as reserve capacity is maintained to support the gravity loads. For progressive collapse, the primary components must resist gravity loads during and after the event. Since gravity loads are constant, damage can result in instabilities and failure. Per the definitions of structural performance levels in ASCE 41, Collapse Prevention results in a damage state for which there is little additional deformation capacity and the stability of the system has been severely compromised. Life Safety provides a greater reserve in terms of nonlinear deformation and strength and thus is used for the majority of the steel acceptance criteria.

C-9.4 Modeling Parameters and Acceptance Criteria.

In developing the modeling procedures and acceptance criteria, a comparison was made between the deformation limits contained in ASCE 41, the Eurocode, and the 2005 UFC 4-023-03. These limits were also compared to the rotational capacities reported in the *GSA Steel Frame Bomb Blast & Progressive Collapse Test Program Report (2004-2007)* ("GSA Test Program Report") as summarized in Karns and Houghton 2008. The progressive collapse test configurations in the GSA Test Program were designed to capture both bending and axial tension to determine the effect of their interaction on the rotational capacity of the connection investigated.

Models and acceptance criteria in ASCE 41 are based upon cyclic loadings with bending moment only and rotational capacities are often limited because of degradation and premature loss of strength due to low cycle fatigue. In contrast, recent progressive collapse research with monotonic loading conditions has demonstrated that rotational capacities are most often higher than for cyclic loading. However, with the addition of axial loads, the progressive collapse rotational capacities may be limited, as some connections are unable to develop significant axial tension load upon reaching the

ultimate moment capacity of the beam. Thus, the majority of the modeling and acceptance criteria in Chapter 5 are specified either as Life Safety justified by the behavioral differences associated with the effects of loading (monotonic vs. cyclic) and the ultimate state of strain (moment only vs. moment-axial tension interaction).

Where appropriate, some modifications to the modeling parameters and acceptance criteria have been applied. In some cases, little or no criteria were available and new acceptance criteria were created, using the existing literature and recent tests and numerical simulations, as detailed in Karns and Houghton 2008. The results were used to determine the modeling and acceptance criteria provided in Tables 5-1 and 5-2 of this document.

C-9.5 Best Practice Recommendation.

For new construction, it is recommended that all primary steel frame beam-to-column moment connections be one of the special moment frame (SMF) connections identified in FEMA 350 under Section 3.5 (welded), Section 3.6 (bolted) or Section 3.8 (proprietary), and/or ANSI/AISC 358 (including Supplements), and/or prequalified under ICC-ES AC129. The use of an SMF connection type should not be construed to include the SMF seismic detailing provisions specified in national building codes for higher seismic regions, except for the case where a particular building design is subject to those code provisions.

The additional cost for SMF connections should be minimal, as the use of notch-tough weld wire, continuity plates, and high strength bolts, etc, is common practice. The primary reason for using an SMF connection is to secure the connection characteristics that provide a minimum threshold of rotational capacity. It is important to note that the “seismic detailing” provisions of the IBC Building Code are not required for progressive collapse design applications, unless the seismic region for a particular building design is subject to those earthquake code provisions anyway.

Acceptable SMF-type connections include:

- Welded Unreinforced Flanges with Welded Web (WUF-W)
- Bolted Flange Plate (BFP)
- Bolted Unstiffened End Plate (BUEP)
- Bolted Stiffened End Plate (BSEP)
- Reduced Beam section (RBS)
- Kaiser Bolted Bracket®
- SidePlate®

- Slotted Web™

Two common connections that do not meet the SMF requirements are:

- Double Split Tee (DST)
- Welded Unreinforced Flanges with Bolted Web (WUF-B).

For the WUF-B connection, welding of its bolted web-to-shear tab connection is all that is required for it to become a WUF-W connection, for which there is a significant improvement in rotational performance, including increased reliability.

C-10 MASONRY, WOOD, AND COLD-FORMED STEEL.

As discussed for steel and reinforced concrete, the modeling parameters, nonlinear acceptance criteria and linear m-factors for the Life Safety performance level in ASCE 41 are appropriate for Alternate Path analysis and design of masonry, wood, and cold-formed steel structures.

C-10.1 Time Effect Factor λ for Wood.

Note that for wood construction, the time effect factor λ must be included in the determination of strength for the Tie Force and Alternate Path requirements. As discussed in AFPA/AWC "LRFD Manual for Engineering Wood Construction", the time effect factors, λ, were derived based on reliability analysis that considered variability in strength properties, stochastic load process modeling and cumulative damage effects. The time effect factors are applied to the reference strengths used in the code, which are based on short-term loading test values. Time effect factors range in value from 1.25 for a load combination controlled by impact loading to 0.6 for a load combination controlled by permanent dead load. Common building applications will likely be designed for time effect factors of 0.80 for gravity load design and 1.0 for lateral load design. Further ANSI/ASCE 16-95 indicates time effect factors of 0.7 when the live load in the basic gravity load design combination is for storage, 0.8 when the live load is from occupancy, and 1.25 when the live load is from impact. It is desirable that the structure is stable following local damage to allow for rescue operations and the installation of temporary shoring, however stability in the damaged state is not a permanent condition. Therefore a time effect factor greater than that associated with permanent occupancy and less than that associated with impact is warranted. For this reason and to avoid overly conservative values for such an extreme loading, a time effect factor of 1.0, consistent with the time effect factors used for gravity-lateral load combinations, is specified.

\3\

C-11 RECOMMENDED ADDITIONAL SPECIFICATION PARAGRAPHS.

C-11.1 Recommendation 1. Work Experience.

The resume of the licensed Professional Engineer (P.E.) with a minimum of 3 years of experience with the Alternate Path Analysis per UFC 4-023-03 shall be submitted.

Reference projects.

Provide the list of projects involving progressive collapse design. Each reference project should include the design method used such as Tie Force Method or Alternate Path Method. For Alternate Path Method, specify the design procedure such as linear static, non-linear static or non-linear dynamic.

C-11.2 Resume for ATPF and Progressive Collapse Design Experience.

Specify the engineer(s) responsible for the progressive collapse design and/or the ATFP, blast design analysis for the project.

/3/

APPENDIX D REINFORCED CONCRETE EXAMPLE

D-1 INTRODUCTION.

A typical reinforced concrete frame commercial building design and analysis example has been prepared to illustrate tie force calculations. The structure is assumed to have an occupancy less than 500 people and is classified as \3\ Risk Category /3/ II per UFC 3-301-01.

The example has been prepared using tools and techniques commonly applied by structural engineering firms in the US. Computer software that is typical of that used for structural design was employed for preliminary design. Per the option given in the UFC, as specified in Section 2-2, tie forces and enhanced local resistance are applied to provide resistance to progressive collapse.

D-2 BASELINE PRELIMINARY DESIGN.

The structure is a seven-story concrete moment frame. The intended function of the building is office use, with occupancy of less than 500 people. See Figures D-1 and D-2 for drawings of the building. The preliminary design, shown in Figures D-1 and D-2, and described below, has been sized to meet the requirements of IBC2006.

D-2.1 Modeling Assumptions.

Systems:
- Gravity:
  - Floor system: Pan formed beams
  - Vertical support: Columns
- Lateral:
  - Moment frames
- Foundation:
  - Shallow spread footings

Elevation:

Foundation to L1:	16’-0”
Typical:	13’-0”
Roof:	14’-0”
Parapet:	4’-0”

Plan:

E-W dimension:	227’-0”
N-W dimension:	97’-0”

Concrete:
All concrete shall be normal weight concrete and shall have specified 28-day compressive strength as shown below:

f'c columns: 5000 psi
f'c floor: 4000 psi
f'c foundation: 4000 psi

Rebar:
A615 grade 60 ksi.

Details of pan formed beams and slab:
Slab thickness = 5" (fire rating)
Per ACI table 9.5 (a) for beams spanning 37.5' (clear span approximately 34.5') the required depth ~ 34.5X12/18.5 = 22.3". 20" deep beams with 5" slab (overall depth of 25") are provided. Rib width of 6" and spacing of 6'-0" utilizes pan form system that is very common.

Pans have 1" to 12" side slope.
Therefore Eq. thickness = (6" + 9.33")/2 X 20" / (72") = 2.13" + 5" slab = 7.13"
Therefore Eq. uniform weight = 89 psf

Details of girders:
Width of the beam: 36"
Depth of beam: 25"
Since the slab and pan formed beam weight is considered for the entire floor area, there is common area of concrete between girders and pan formed beams.
Eq. beam depth = 25 – 7.13" = 17.87"
There are 7 girders over the width of 227' in N-S direction and therefore eq. weight = (36 x 17.87) /144 x 150 x 7 /227 = 20.66 psf

There are 2 girders over the width of 97' in E-W direction and therefore eq. weight = (36 x 17.87) /144 x 150 x 2 / 97 = 13.82 psf

Therefore total weight of beams other than pan formed beams = 20.66 + 13.82 = 34.48 psf. Say 35 psf

Details of columns:
Typical interior column:
Pu = 1.2 (89 + 35 + 10) + 1.6 (50 + 10 + 20) = 288 psf
Pu = 0.288 x 37.5' x 37.5/2 x 7 = 1421 kips.
Axial stress = 1421/(24x24) = 2.46 ksi
For f'c of 5 ksi use 24' square column.

There are 28 columns at each floor.
Weight of column at typical floor = (24"x24")/144 x 13' x 28 x 150 / (97' x 227') = 9.91 psf say 10 psf.

D-2.2 Loading Assumptions.

Dead loads (equivalent uniform loads) (D):
- Self weight:
- Slab and pan formed beams→ 89 psf
- Beams → 35 psf
- Columns → 10 psf

Super imposed dead load (SDL):
- Ceiling, MEP → 10 psf
- Roofing → 20 psf

Cladding (CL) → 60 psf (wall area)

Live loads:
- Office floor area (LL) → 50 psf + 20 psf allowance for partitions
- Storage/Mechanical floor area (LL) → 125 psf
- Corridors → (LL) 80 psf
- Roof (Lr) → 20 psf

Wind Load (W) was determined per IBC 2006 using 110 mph with exposure = B and importance factor = 1.0

Earthquake Load (E) is assumed not to control the design because the building is in a non-seismic region.

Other Loads: Snow Loads (S), Rain Loads (R) are assumed to not control the design.

D-2.3 Design Information.

Column reinforcement at first level above grade:

Corner columns:	8-#8, 3 each face
Long side columns:	14-#11, 4X-5Y
Short side columns:	8-#8, 3 each face
Interior columns:	12-#10, 4 each face

Slab reinforcement at first level above grade:

Each direction:	#3 at 12”

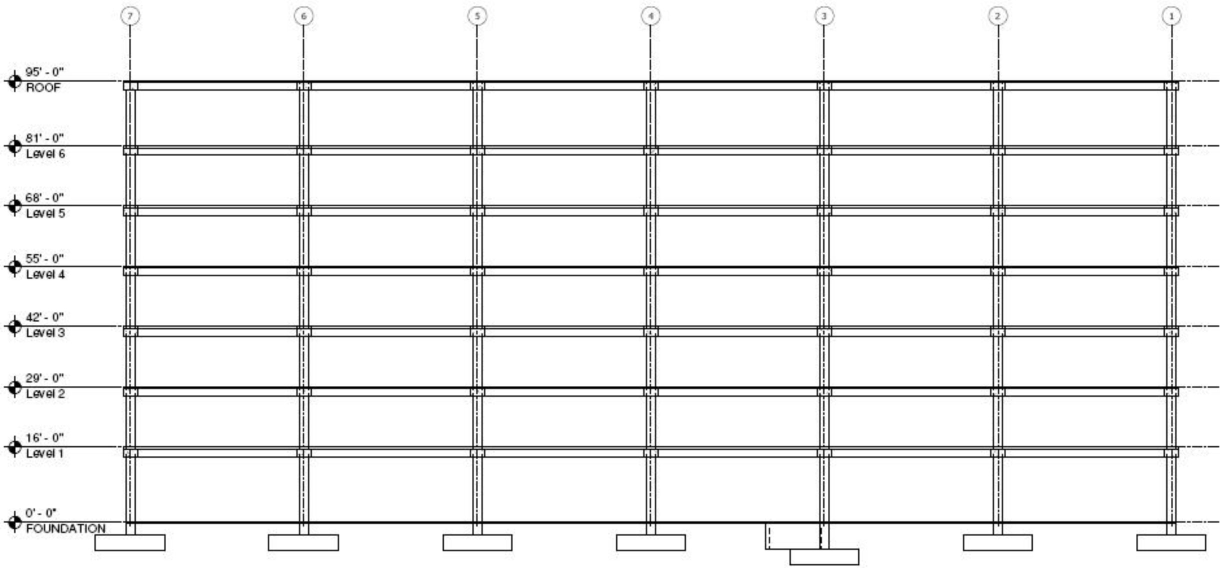

Figure D-1. Concrete Building Elevation

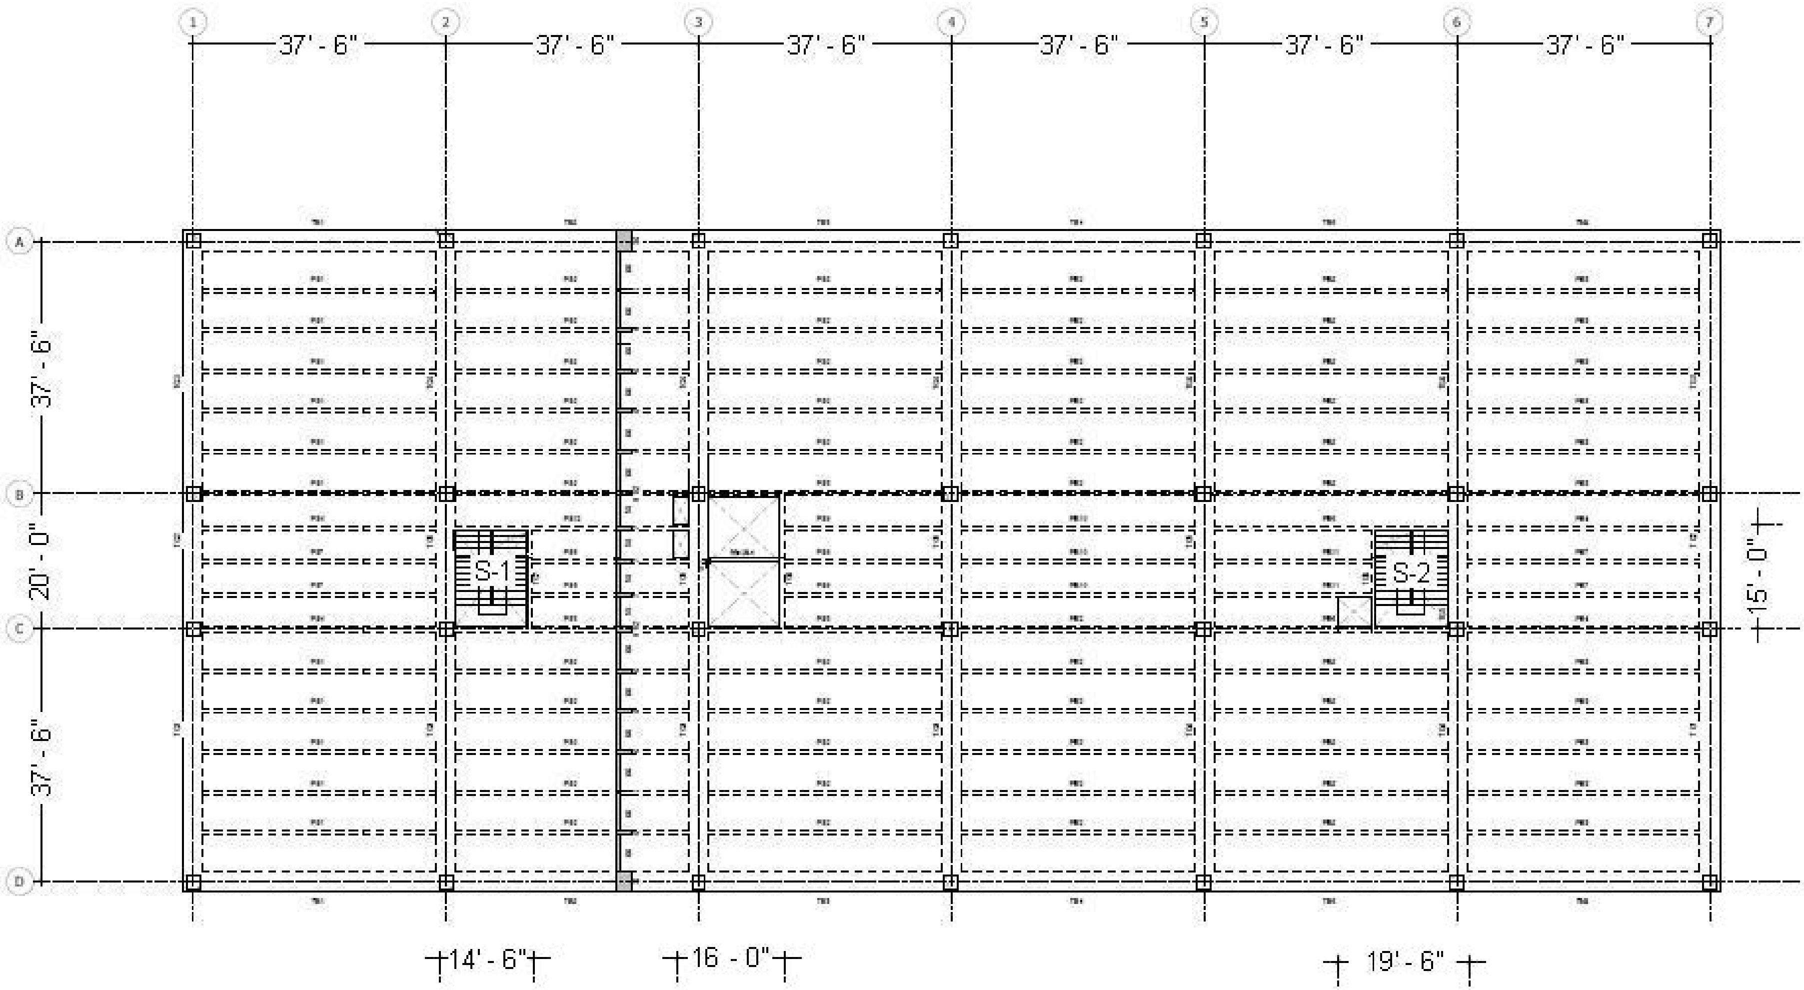

Figure D-2. Concrete Building Plan

D-3 \2\TIE FORCE DESIGN.

The procedure and requirements for Tie Forces for framed buildings are presented in Section 3-1. In the Tie Force approach, the building is mechanically tied together, enhancing continuity, ductility, and development of alternate load paths. There are three horizontal ties that must be provided: longitudinal, transverse, and peripheral. Vertical ties are required in columns. Figure 3-1 illustrates these ties for frame construction.

D-3.1 Calculating w_F.

Section 3-1.3 presents Equation 3-2 for determination of the floor load used in tie force calculations. The corridor load is applied over 25% of bay B-C and storage/mechanical load is provided over the 75% of bay B-C over the length of the building. Office live load is applied over the remainder of the floor. Based on these loads in combination with those presented in Section D-2.2, the effective w_F for transverse and longitudinal ties is 214.5-psf (from Section 3-1.3.2.2, with the difference between the minimum and maximum floor load in the bays on the floor plan being less than or equal to 25% of the minimum floor load and with the area associated with the maximum floor load less than or equal to 25% of the total floor plan area). The calculation is shown in Table D-1.

Table D-1. Load Calculations for w_F

Dead, psf	**Live, psf**			**w_F (1.2D+0.5L), psf**			
Slab and pan formed beams, beams, columns, ceiling, MEP	Office	Storage/ Mech	Corr.	Office		Storage/ Mech	Corr.
144	70	125	80	207.8		235.3	212.8
				Difference = 235.3-207.8 = 27.5 psf, less than 25% of smallest w_F			
Areas, sf	Office	Storage/ Mech	Corridor	Total			
	16875	3375	1125	21375			
	Storage/Mech area is less than 25% of total area						
Since max difference in w_F is less than 25% of smallest w_F and area of largest load is less than 25% of total area, use average w_F for the entire floor							
w_F, total load over total area, psf	= (16875 * 207.8 + 3375 * 235.3 + 1125 * 212.8)/(21375) = 214.5-psf						

The cladding load W_C is calculated as:

W_C = 1.2 * 60-psf * 13-ft height * 37.5-ft span = 35.1-kip

For vertical ties on the perimeter, the cladding load is averaged over the bays in which it is present and added to the floor distributed loading, to determine the effective w_F. For example, for column A1:

w_F = Floor distributed load + Cladding load/area
= 214.5-psf + 1.2 (18.75-ft + 18.75-ft) (13-ft) (60-psf)/(18.75-ft) ^2
= 314.3-psf

D-3.2 Tie Force Calculations.

The required tie forces and rebar area can be calculated with the loads from the previous section and the geometric properties of the building. As an example, the peripheral tie force in the transverse (N-S) direction is determined with Equation 3-6:

F_p = $6\ w_F\ L_1\ L_p + 3\ W_C$
= 6 (214.5-psf) 37.5-ft (3-ft) + 3 (35.1-kip)
= 250.1-kips

The required area is determined with Equation 3-1:

$\Phi\ R_n \geq \Sigma\ \gamma_i\ Q_i$
$0.75\ (1.25{*}60\text{-ksi})\ A_{s\ req'd} \geq 250.1\text{-kips}$
$A_{s\ req'd} = 4.45\text{-in}^2$

where 0.75 is the LRFD strength reduction factor per Section 4-3 of this document and 1.25 is the over-strength factor for rebar, per ASCE 41.

The data for tie force calculations and the resulting reinforcement are summarized in Table D-2.

Table D-2. Tie Force Calculations

Tie Type	Location	Length	w_F	W_C	F	$A_{s\ req'd}$	Reinfm't
		(ft)	(psf)	(kips)	(kips)	(sq in)[A]	
Peripheral	Transverse	37.5	214.5	35.1	250.1	4.45	8 - #7
Peripheral	Longitudinal	37.5	214.5	35.1	250.1	4.45	8 - #7
Peripheral	Stair 1 (S1) Transverse	15	214.5	0	57.9	1.03	6 - #4
Peripheral	Stair 1 (S1) Longitudinal	14.5	214.5	0	56.0	1.00	5 - #4
Peripheral	Stair 2 (S2) Transverse	15	214.5	0	57.9	1.03	6 - #4
Peripheral	Stair 2 (S2) Longitudinal	19.5	214.5	0	74.3	1.32	7 - #4
Peripheral	Elevator Transverse	21	214.5	0	81.08	1.44	8 - #4
Peripheral	Elevator Longitudinal	16	214.5	0	61.8	1.10	6 - #4
Tie Type	Location	Length	w_F		F	$A_{s\ req'd}$	Reinfm't
		(ft)	(psf)		(kips/ft)	(sq in/ ft)	
Transverse	Distributed	37.5	214.5		24.13	0.429	#5 @ 8" O.C.[B]
Longitudinal	Distributed	37.5	214.5		24.13	0.429	#5 @ 8" O.C.[B]
Tie Type	Location	Area	w_F		F	$A_{s\ req'd}$	Reinfm't
		(sq ft)	(psf)		(kips)	(sq in)	
Vertical	A1	351.6	314.3		110.5	1.96	No Additional
Vertical	A2	703.2	264.4		185.9	3.31	No Additional
Vertical	B1	539.1	264.4		142.5	2.53	No Additional
Vertical	B4	1078.2	214.5		231.3	4.11	No Additional

[A] The over-strength factor is 1.25, for rebar, per ASCE 41 and Φ is 0.75, per Section 4-3 of this UFC.
[B] Replace #3 at 12" O.C slab reinforcement with #5 at 8" O.C.

Reinforcement already present from the baseline design may be used to satisfy the tie force requirements in Table D-1 provided it is not within or directly above flexural members. Splices, development lengths and connections of reinforcement must be per Section 3-1.6. Note that the required tie forces at each of the stairs are different. This difference is to account for the additional MEP opening located immediately adjacent to Stair 2. In the case of Stair 2 and the adjacent MEP opening, these openings are separated by a flexural member. Since tie reinforcement cannot be located directly above a flexural member unless it can be shown to meet Section 3-1 rotation requirements, these openings were combined for the purposes of tie force calculation and placement of opening peripheral ties. A similar concept was used for the elevator and adjacent MEP openings. Note the dimension extents shown in Figure D-2.

Also note that the reinforcement shown in Table D-1 for internal longitudinal and transverse ties is to replace the preliminary #3 bars at 12”. A diagram of tie layout for an exterior bay is shown in Figure D-3. The internal ties may be connected to peripheral ties as shown in Figure D-4. Note that only the portion of the internal tie steel needed for the baseline design (the #3 bars at 12”) must extend to the beam top steel; the remainder of the internal ties may be directly connected to the peripheral tie (i.e., the supplemental hook is not needed for the internal ties that are directly connected to the peripheral tie).

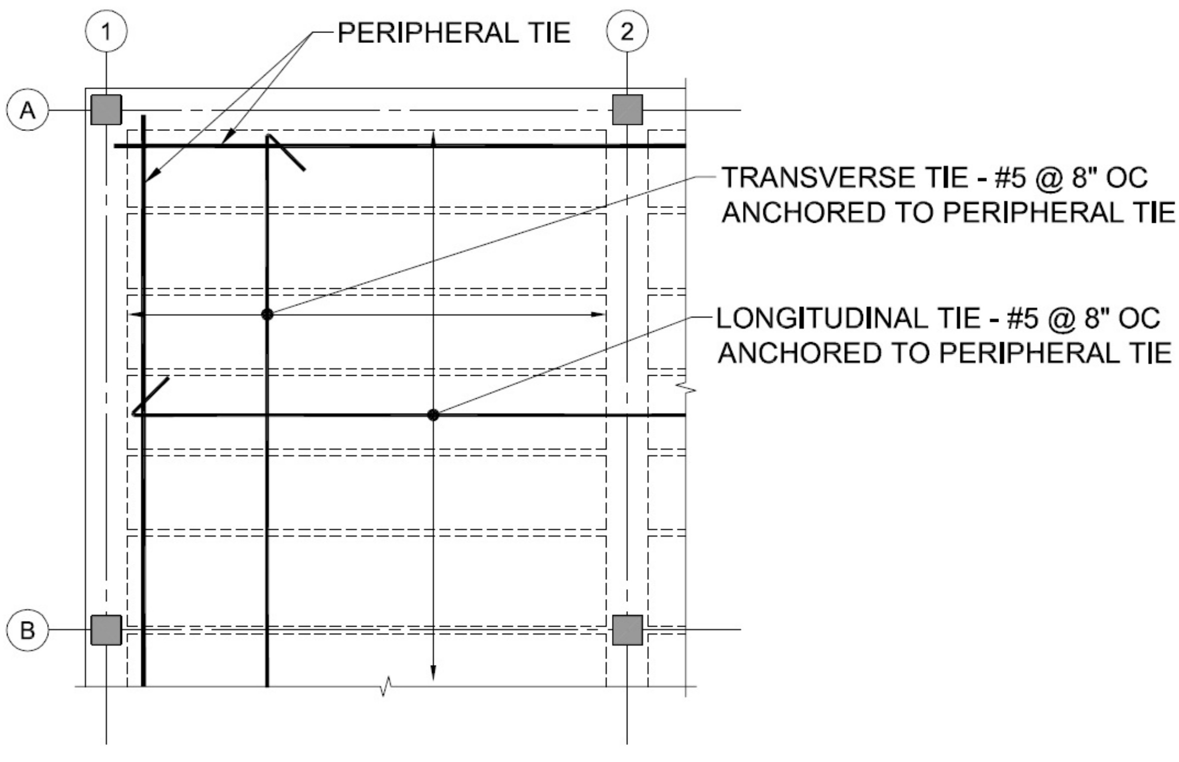

Figure D-3. Typical Layout of Internal Ties

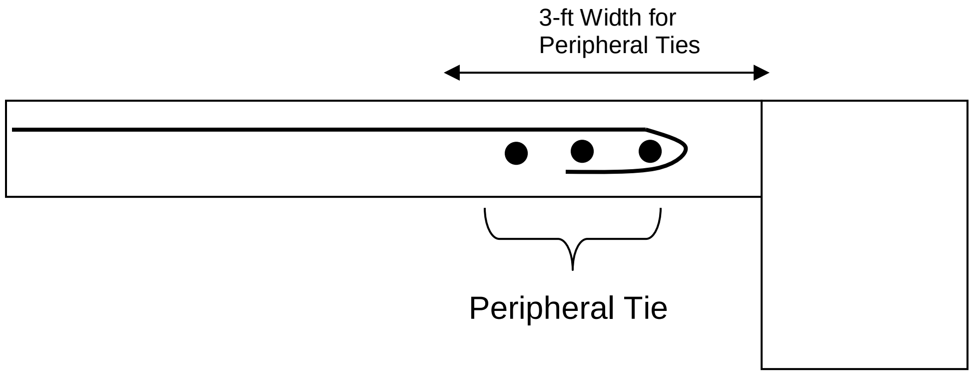

Figure D-4. Typical Anchorage of Internal Ties to Peripheral Ties

D-3.3 Enhanced Local Resistance.

ELR provisions for \3\ Risk Category /3/ II require that corner and penultimate perimeter columns at the first floor above grade achieve design shear strengths that exceed the shear demand associated with the flexural demands of the columns. For \3\ Risk Category /3/ II Option 1, the flexural demand is determined from the building design after it meets the TF requirements. For the purposes of ELR evaluation, the columns are considered fixed at the first level above grade due to continuity of the column above the first level and the rigid support provided by the floor diaphragm and pinned at the base. The flexural demand is based on the development of a three hinged mechanism in the column, with one hinge present as the pinned end of the column, a plastic hinge that develops at the fixed end at the first level above grade and a plastic hinge that develops within the column.

The required shear strength (i.e., the shear demand) can be found using methods in plastic structural design references or in Table 4-4 of PDC TR-06-01 *Methodology Manual for the Single-Degree-of-Freedom Blast Effects Design Spreadsheets (SBEDS)*. From PDC TR-06-01, the largest reaction/shear for a pinned-fixed, uniformly loaded beam is 5 r_u L/8, where r_u is the ultimate resistance and equal to 12 M_p/L^2. M_p is the plastic moment of the column cross-section and thus is the nominal flexural strength of the penultimate and corner columns, which incorporate vertical tie forces. Thus,

$V_u = 5\, r_u\, L/8$
$r_u = 12\, M_n/L^2$

and re-arranging yields

$$V_u = 7.5\, M_n / L \qquad \text{Equation (D-1)}$$

where V_u = Shear demand (maximum shear and reaction in the beam)
M_n = Nominal flexural strength, accounting for axial load

r_u = Ultimate resistance,
L = Column height

The corner column is considered in this example. The axial load on the corner column is based on the loads given in Section 3-2.2, bay sizes of 37.5-ft by 37.5-ft and the 7-story height.

P_{axial} = 7 [1.2D + 0.5L] 37.5-ft 37.5-ft/4
= 7 [1.2(89 + 35 + 10) + 0.5 (50 + 10 + 20)] 37.5-ft 37.5-ft/4
= 494-kip

With over-strength factors of 1.5 for concrete and 1.25 for steel (from ASCE 41), the concrete and steel strengths are 7500-psi and 75-ksi, respectively. For a 24-in x 24-in column with 8 #8s (3 each face) and an axial load of 494-kip, the interaction equation shows that M_n = 9,400-in-kip = 783-ft-kip.

V_u = 7.5 M_n/L = 7.5 (783-ft-kip)/16-ft
= 367-kip

The shear force carried by the concrete is

V_c = 2 (1 + N_u/2000A_g) $(f'_c)^{1/2}$ b_w d
= 2 [1 + 494,000-lb/2000(24-in x 24-in)] $(7500\text{-psi})^{1/2}$ 21.5-in 24-in
= 128-kip

The shear force carried by the steel is

$\Phi (V_n) = \Phi (V_c + V_s) \geq V_u$

V_s ≥ Vu/Φ - V_c
≥ 367-kip/1.0 – 128-kip
≥ 239-kip

Using s = 4 in, d = 21.5-in, fy = 75 ksi, the required area for shear steel is

V_s = A_v f_y d/s

A_v ≥ 0.59-in^2

Three #4 ties will work (0.2 in^2/tie) (3 ties) = 0.6 in^2

Note that Section 11.4.7.9 of ACI 318-11 states that "V_s shall not be taken greater than $8\,(f'_c)^{1/2}\,b_w\,d$".

$V_s = 8\,(f'_c)^{1/2}\,b_w\,d$
$= 8\,(5000)^{1/2}$ 21.5-in 24-in
= 291.8-kip > 239-kip. **OK**

/2/

D-3.4 Tie Force Evaluation Complete.

After provision of ties forces and additional stirrups as specified in D-3.2 and D-3.3, the tie force procedure is complete and the structure meets minimum requirements for progressive collapse resistance.

THIS PAGE INTENTIONALLY LEFT BLANK

APPENDIX E STRUCTURAL STEEL EXAMPLE

E-1 INTRODUCTION.

A typical steel frame health care facility design and analysis example has been prepared to illustrate alternate path calculations. The structure is assumed to be occupied by 50 or more resident patients; placing the structure in Risk category III per UFC 3-301-01. This RC requires the Alternate Path Method to be applied to select elements to demonstrate capacity to resist progressive collapse as specified in Section 2-2. The structure does not include underground parking. Enhanced local resistance for all perimeter first story columns will also be required for this building per Section 2-2.

The example was prepared using tools and techniques commonly applied by structural engineering firms in the US. Computer software that is typical of that used for structural design was employed for preliminary design and for the alternate path analysis. To illustrate the various options given in the UFC, the example is prepared using the linear static and nonlinear dynamic analysis procedures.

E-2 BASELINE PRELIMINARY DESIGN.

The structure is a four-story steel dual lateral system with a perimeter moment frame. The intended function of the building is health care, with occupancy of fifty or more resident patients. See Figures E-1 and E-2 for drawings of the building and the orientation of the members. The preliminary design, shown on the drawings below, has been sized to meet the requirements of IBC2006. In addition, the lateral drift of the frame has been evaluated for a performance limit of L/400 under a 10-year wind. Limited contribution of gravity framing due to partial restraint provided by simple connections was ignored for lateral load resistance (and stiffness).

E-2.1 Modeling Assumptions.

1) Members are represented by centerline elements (i.e. zero end offset to account for joint flexibility)
2) All moment connections are improved WUF.
3) Gravity framing connections are simple shear tabs, 3/8-in plate with 4 3/4-in A325N bolts and ¼” weld with a depth of bolt group = 9-in, assumed to be pinned except for secondary member checks when they are considered partially restrained (PR) moment connections
4) Column to foundation connections are considered pinned
5) Each floor was taken as a rigid diaphragm
6) Gravity framing was designed as composite sections
7) All steel shapes ASTM A992
8) Concrete 4000 psi NWC
9) Floor system: 3” composite steel deck + 4 ½” topping (total slab thickness = 7 ½”)
10) Roof system: metal deck only (no concrete fill)

E-2.2 Loading Assumptions.

Dead loads (D):
Self weight of members
Floor: 3 + 4½" normal weight composite slab with a weight of 75 psf + 3 psf allowance for deck
Roof: metal deck 5 psf (including secondary members not modeled)
Super imposed load (SDL):
15 psf for ceiling weight, and mechanical loads (including membrane/insulation at roof)
Cladding (CL):
15 psf x 14'- 8" → 220 plf on perimeter of the building
Live load:
Floor (LL): 80 psf + 20 psf allowance for partitions
Roof (Lr): 20 psf

Wind Load (W) was determined per IBC 2006 using 110 mph with exposure = B and importance factor = 1.15

Earthquake Load (E) is assumed not to control the design because the building is in a non-seismic region.

Other Loads: Snow Loads (S), Rain Loads (R) are assumed to not control the design.

E-2.3 Member Sizes.

Gravity floor design considers composite behavior and is identical for levels 2, 3 and 4. Roof gravity beams are non-composite with metal deck. Perimeter moment frames vary up the height of the building for drift control; see Figure E-1 for sizes.

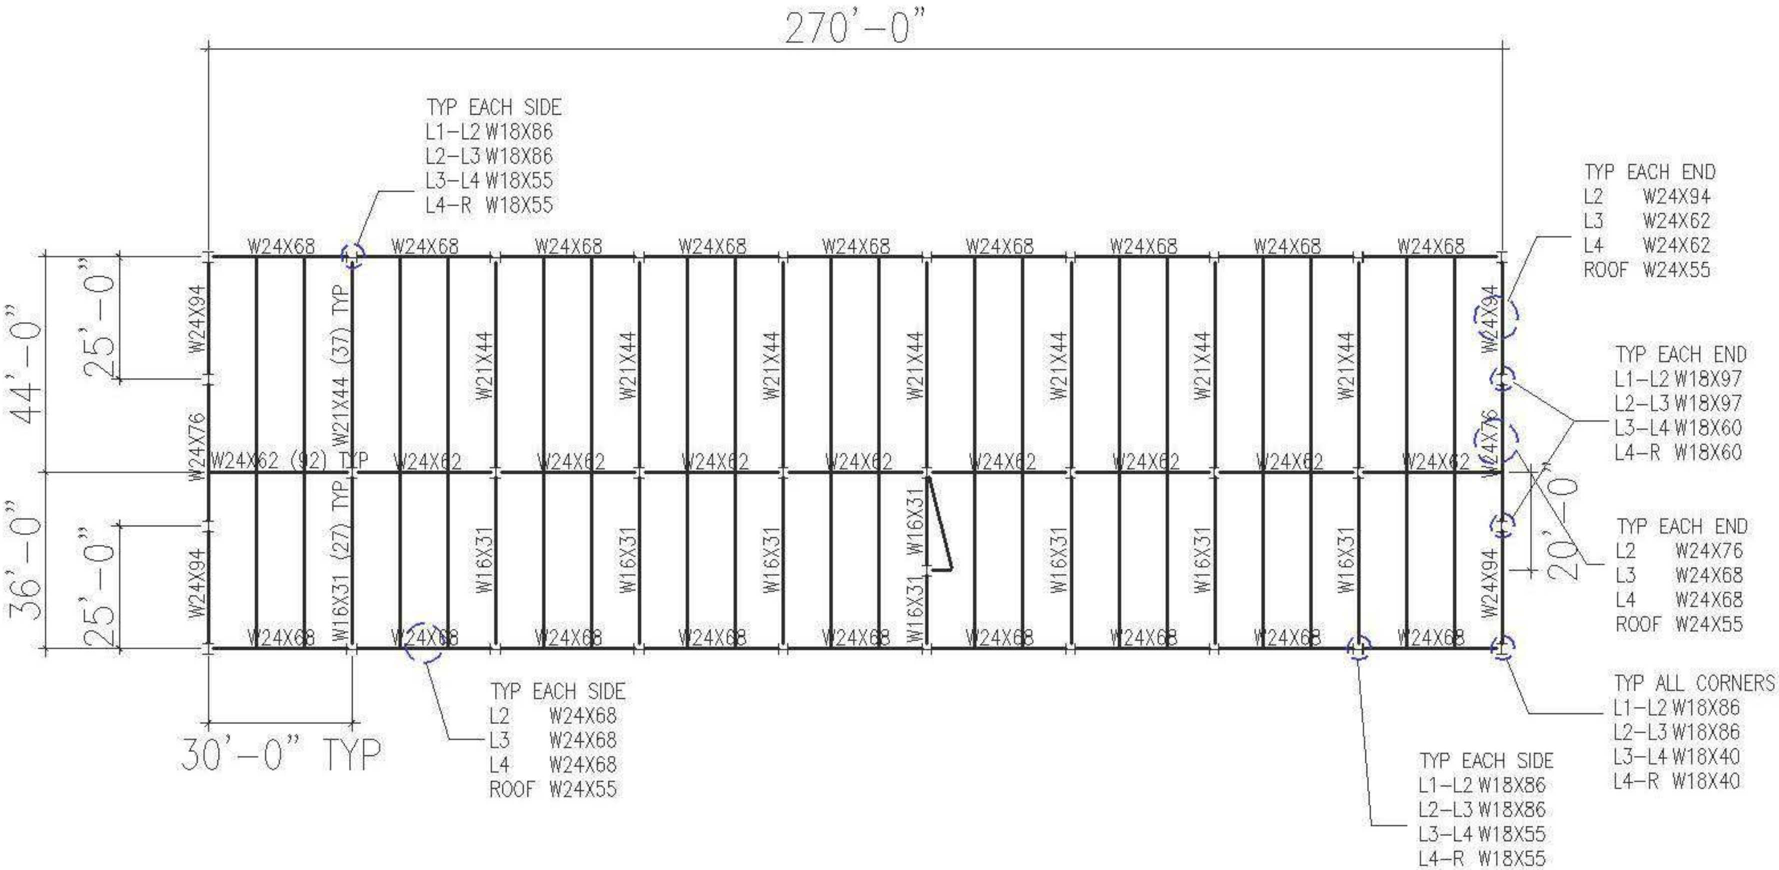

Figure E-1. Steel Building Plan

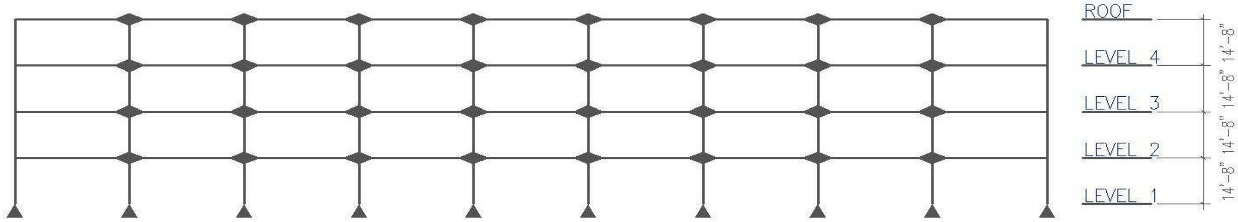

Figure E-2. Steel Building Elevation

E-3 LINEAR STATIC PROCEDURE.

Locations of required columns removals are illustrated in Figure E-3. Each removal is considered separately. For the purpose of this example, the column below level 2 is removed. Section 3-2 requires additional analyses for removals at other levels.

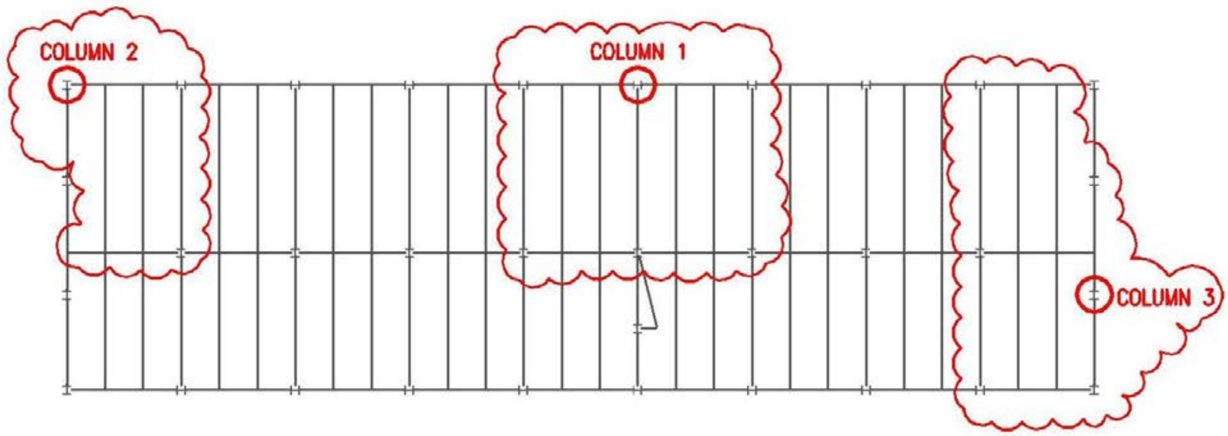

Figure E-3. Column Removal Locations

E-3.1 DCR and Irregularity Limitations.

The structure does not contain irregularities as defined by Section 3-2.11.1.1 and therefore DCR values are not limited for the use of the LSP.

E-3.2 Classification of Deformation Controlled and Force Controlled Actions.

Separate structural models are required to verify acceptability of components and actions which are deformation controlled and force controlled. Categorize these actions using the curves presented in Figure 3-7. A summary of classifications for this example is shown in Table E-1.

Table E-1. Deformation Controlled Column Calculations

Component	Deformation Controlled Action	Force Controlled Action
Moment Frames • Beams • Columns • Joints	 Moment (M) M, Axial Load (P)	 Shear (V) P, V V
Connections	M	V

E-3.3 Determination of m-Factors and Load Increase Factors.

Each component within the structure is assigned an **m** factor, or demand modifier which is determined from Table 5-1 and ASCE 41. Load increase factors (LIF) are applied to the area immediately affected by the removed column as required in Section 3-2.11. The LIF for the model to determine acceptability of force controlled actions is equal to 2. The LIF for the model to determine acceptability of deformation controlled actions is dependent on the lowest **m** factor for a component within the region of load increase. The **m** factors for each column removal location shown in Figure E-3 are summarized in Table E-2. The LIFs for deformation controlled actions based on these **m** factors are summarized in Table E-3.

Table E-2. Component m Factors for Primary Deformation Controlled Actions

Removed Column	Level	Beam/Girder	Beam/Girder **m** Factor	Simple Connection **m** Factor	Fixed Connection **m** Factor
1	2, 3, 4	W24x68	6.14	--	1.8
	2, 3, 4	W24x62	8	5.479	--
	2, 3	W24x146	8	--	1.79
	4	W24x117	6.52	--	1.79
	Roof	W24x55	8	--	1.8

	4	W24x117	6.52	5.479	1.79
	Roof	W24x55	8	5.479	1.8
	Roof	W24x62	8	5.479	--
	Roof	W24x76	8	5.479	1.8

Table E-3. Load Increase Factors

Removed Column	m_{LIF} (Smallest ***m-factor***)	Ω_{LD}, LIF for Deformation Controlled Actions	Ω_{LF}, LIF for Force Controlled Actions
1	1.8	2.72	2
2	1.79	2.71	2
3	1.79	2.71	2

E-3.4 Alternate Path Analysis.

The software used for this example was SAP 2000NL. The details of this example can be generally applied in any structural software capable of nonlinear static analysis. The “Staged Construction” option in SAP was used to ensure proper redistribution of loads upon member removal. Comparable software should also have the capability of load redistribution, or loads must be redistributed manually.

E-3.4.1 Develop Preliminary Model.

See Figure E-4 for a model developed in SAP2000. Gravity beams not on column lines are not modeled.

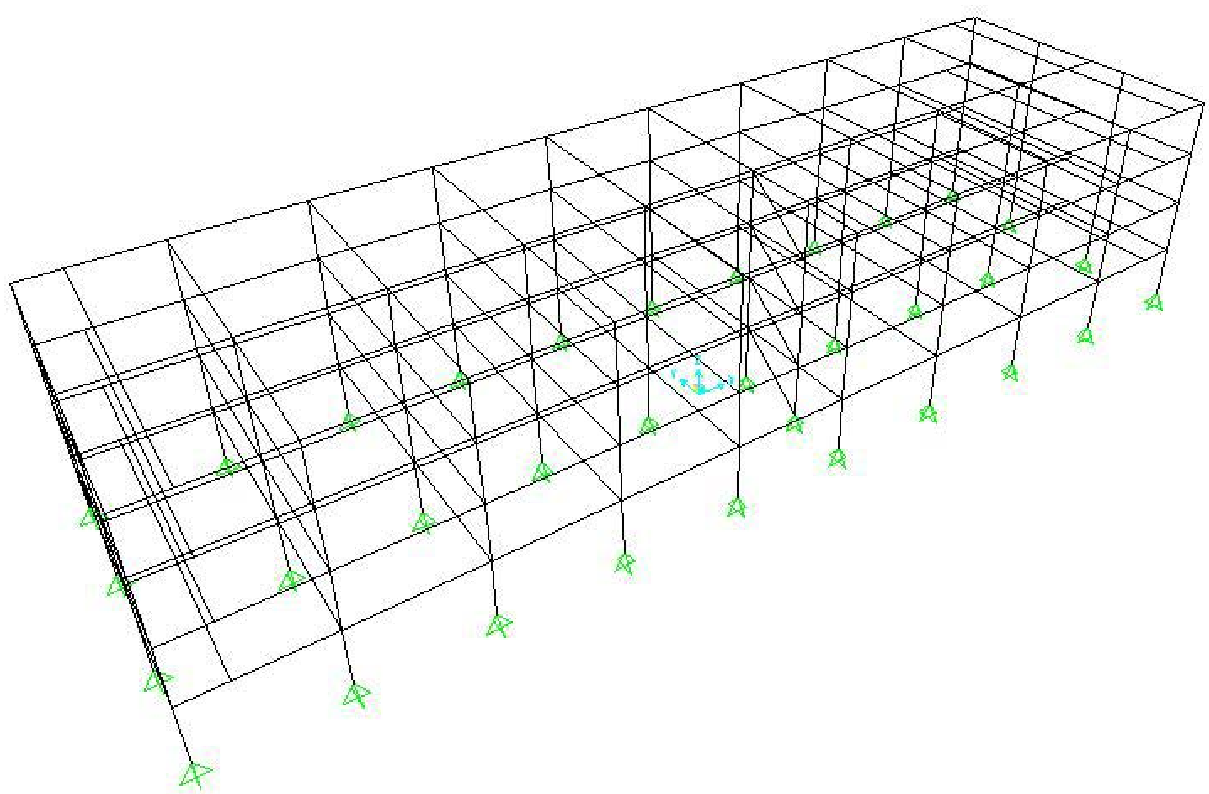

Figure E-4. Isometric View of SAP Model

E-3.4.2 Assign Groups.

Assign each column that is to be removed to a separate group. In this example, removal of three columns is demonstrated, each supporting the first elevated level. Columns are removed at three plan locations, one at a time.

E-3.4.3 Define Load Cases and Assign Loads.

Since increased loads are only applied over the location of the removed column, separate load cases are needed to assign the increased loading over each element to be removed. Separate models are needed to check force controlled actions and deformation controlled actions because of different LIFs.

E-3.4.4 Define Analysis Cases.

The "Staged Construction" option in SAP allows for the creation of separate analysis cases to automate the removal of columns. Create analysis cases which capture the stiffness for column removal. To do this, click Staged Construction button. In stage 1 add ALL, in stage 2 remove the column under investigation. Using these staged construction analysis cases as the initial stiffness, add a new analysis case for each column being removed. Within these analysis cases, assign all loads to be used in this analysis case per the load combinations in Equation 3-10 and 3-11. Click Nonlinear parameters button and choose P-delta option. It is possible to use P-delta + large displacements, but it is not necessarily needed for this analysis. Figure E-5 shows a screenshot of the interface for definition of analysis cases and their assigned loads.

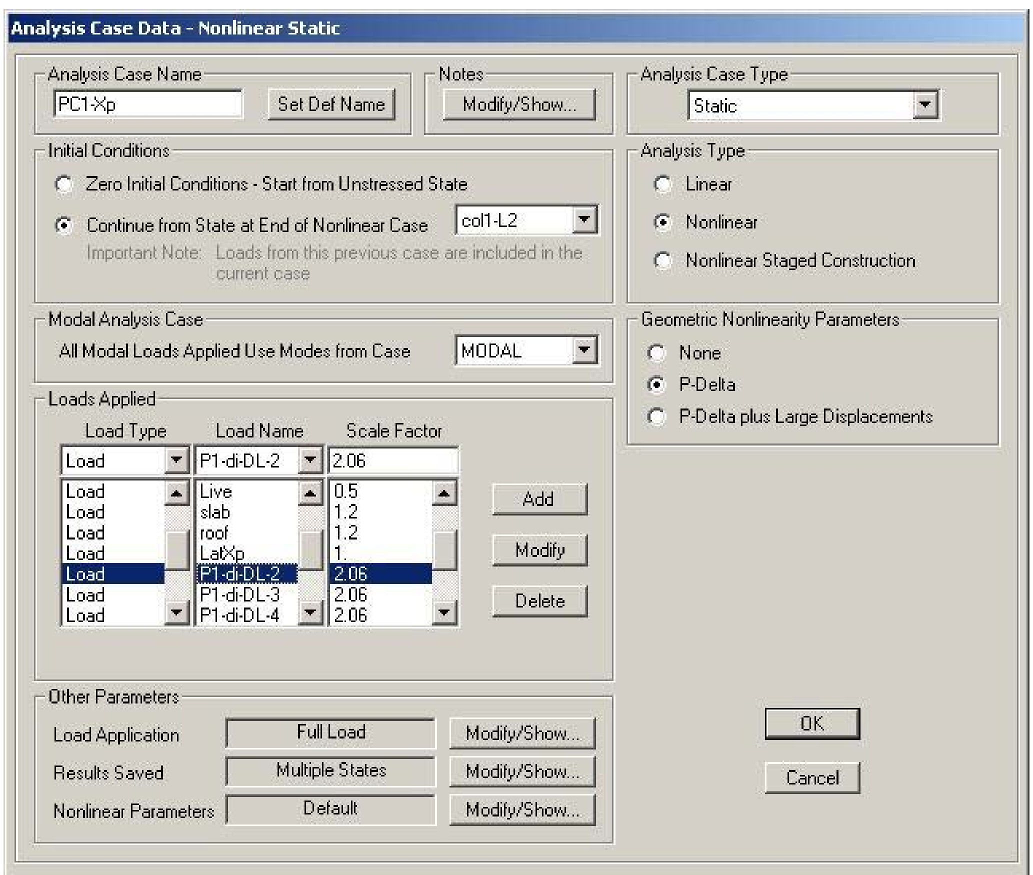

Figure E-5. Analysis Case Definition

E-3.4.5 Define Design Combinations.

In order to use the SAP design procedures to evaluate acceptance criteria design combinations must be defined. Create a design combination for each analysis case (12 total design cases created in this example, additional cases would be required for column removal at other elevations).

E-3.4.6 Run Analysis.

It is important to check that both stages of every analysis case converge. If the analysis does not converge, there is a problem with the model and it must be fixed.

E-3.4.7 Run Design and Compare to Acceptance Criteria.

After each analysis case converges, perform the SAP design. The design details allow for the comparison of each components **m** factor to the ratio of $Q_{UD}/\Phi Q_{CE}$ and comparison of $Q_{UF}/\Phi Q_{CL}$ to unity. In this example, the deformation controlled moment acceptance at beam ends is governed by the **m** factor for the improved WUF moment connections. By reviewing the moment diagrams of the design combinations for the progressive collapse cases it was determined that the moment at beam ends is greater than at other locations along its length. Based on this information the moment ratio provided by SAP within the deformation controlled model for the defined design load combinations can be compared directly to the connection **m** factor of 1.80. The design details can also be used to review the beam shear demand ratio within the force controlled model. Figure E-6 shows SAP screen captures of the moment ratios from the deformation controlled model for the removal of column 1 prior to any member upgrades. Figure E-7 and Figure E-8 show similar screen captures for removal of columns 2 and 3 respectively. Also pictured are the interaction ratios of columns in the vicinity of the removed members. Column upgrades are discussed below.

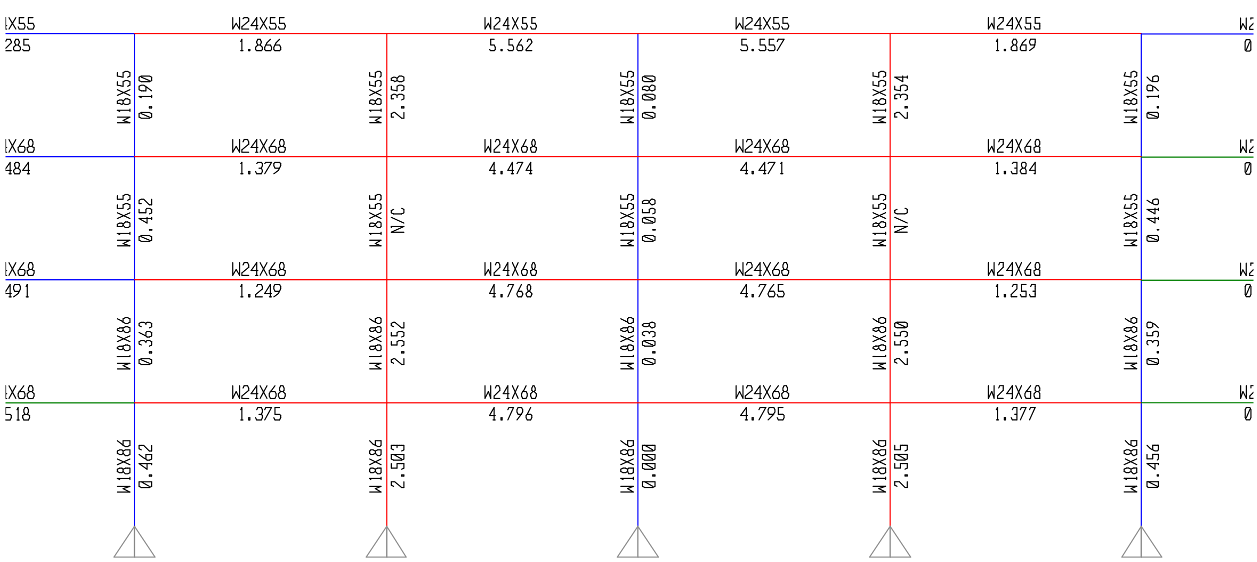

Figure E-6. Moment Ratios Due to Column 1 Removal with Original Design

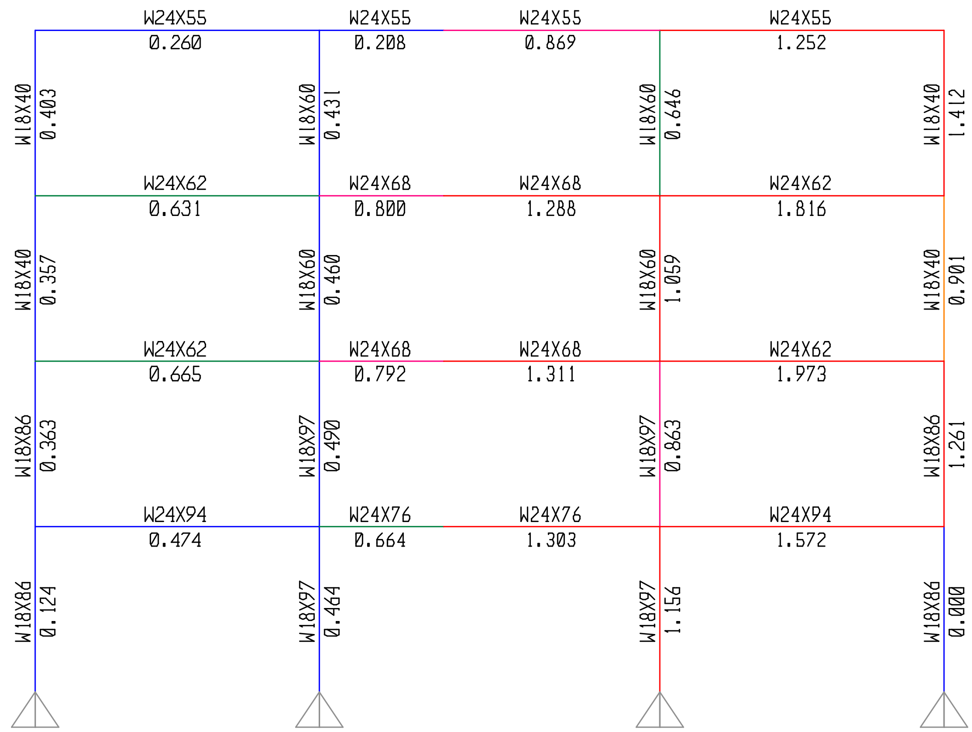

Figure E-7. Moment Ratios Due to Column 2 Removal with Original Design

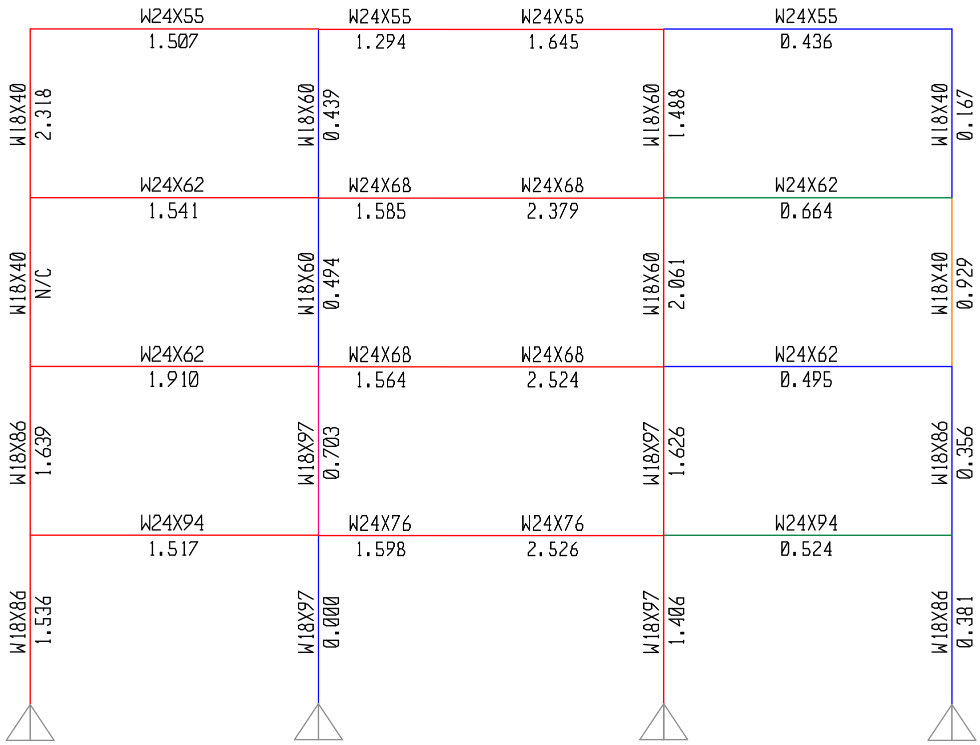

Figure E-8. Moment Ratios Due to Column 3 Removal with Original Design

Figures E-9 through E-11 show SAP screen captures of the moment ratios after member upgrade for the removal of columns 1 through 3 respectively.

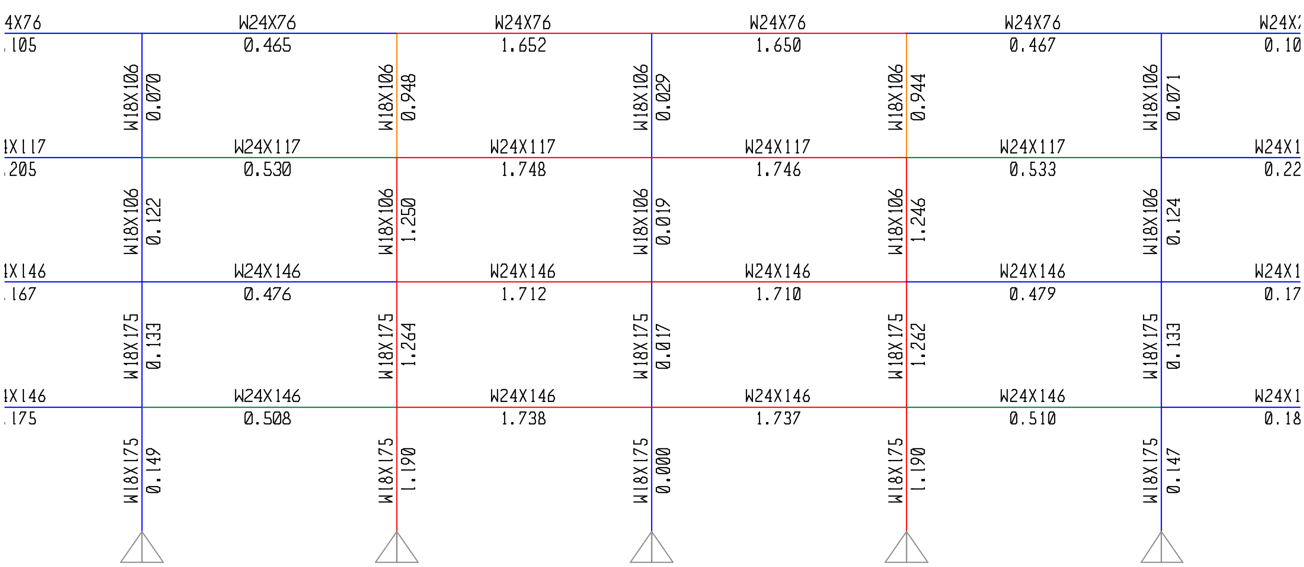

Figure E-9. Moment Ratios Due to Column 1 Removal with Redesign

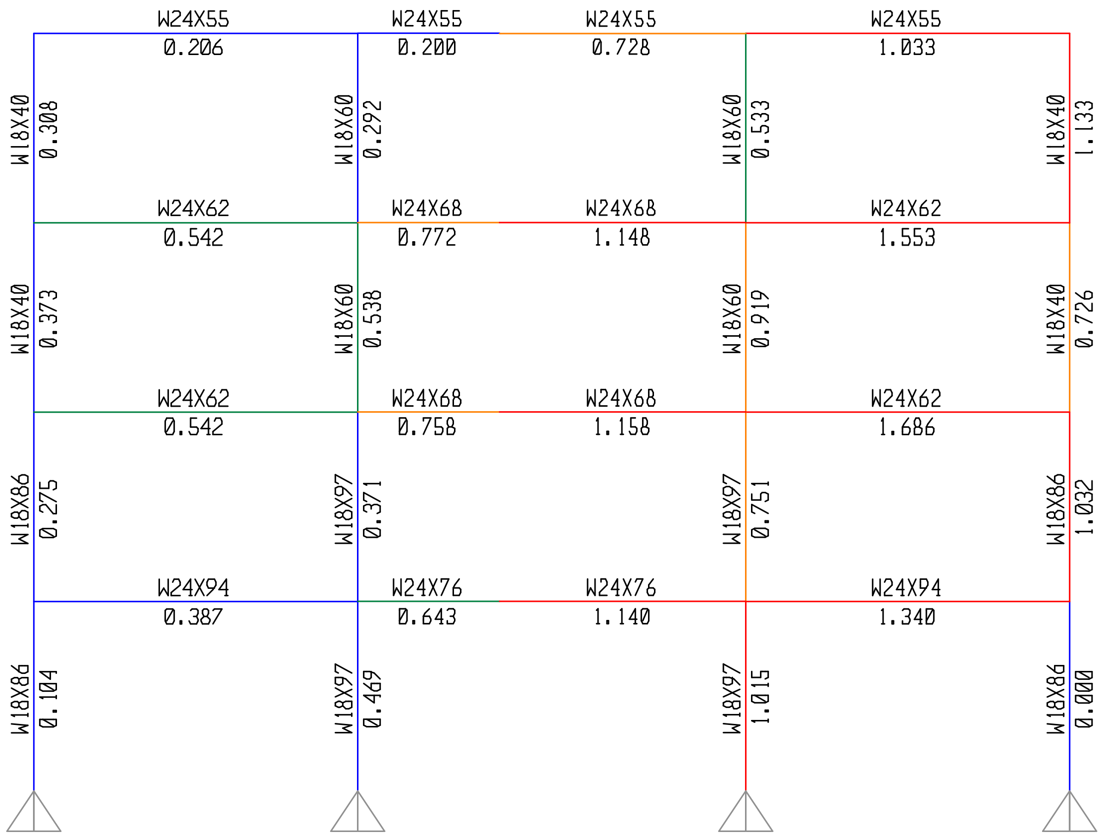

Figure E-10. Moment Ratios Due to Column 2 Removal with Redesign

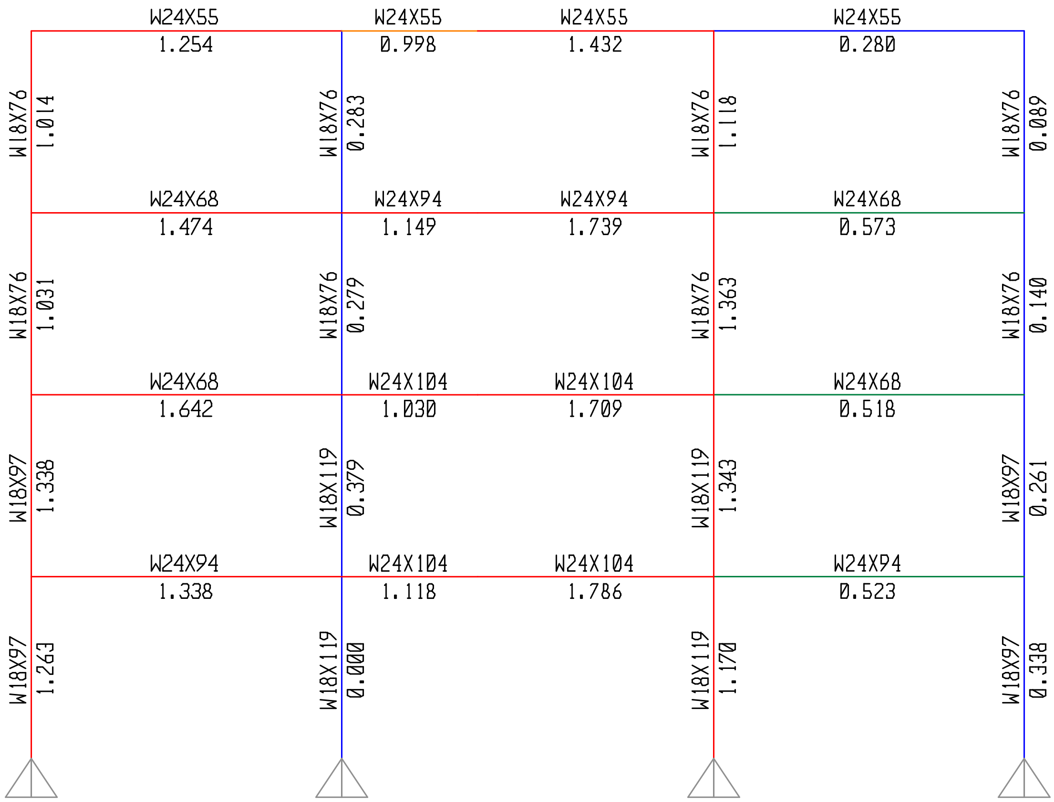

Figure E-11. Moment Ratios Due to Column 3 Removal with Redesign

To determine the acceptability of columns, the deformation-controlled model is reviewed to determine the level of axial load. In accordance with ASCE 41, any column with an axial load ratio of greater than or equal to 0.5 must be checked using the model for force controlled actions. These force controlled columns must have interaction values that do not exceed 1. Using the force controlled model, column sizes are increased to reduce interaction values less than unity or to reduce the axial demand in order to evaluate the column as deformation controlled.

Deformation controlled columns (axial load ratio less than 0.5) are checked using the acceptance criteria from ASCE 41. An example calculation for this verification of acceptance is shown in Table E-4.

Table E-4. Deformation Controlled Column Calculations

Removed Column	1
Column Size	W18x106
P/ΦPn	0.49
8/9 M/ΦMn	0.59
m = 9 (1-5/3 P/Pcl)	ASCE 41 Table 9-4
m = 9 (1-5/3 x 0.49 x 0.9)	2.385
Interaction = P/ΦPn + (8/9 M/ΦMn)/m	0.49 + 0.59/2.385 =0.73 **OK**

E-3.4.8 Secondary Component Checks.

\2\After verifying that all primary members satisfy the force- and deformation-controlled acceptance criteria, the secondary members must also be checked. The following calculations present the checks for the gravity beam and the interior connection of the gravity beam at removal location 1, where the closest secondary beam to the loss location is a W21x44 that spans 44-ft.

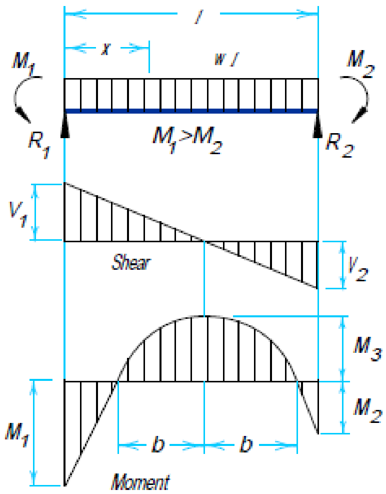
Acceptance checks of gravity beams in steel frame structures present a unique challenge within the framework of linear static analysis. Typically, gravity beams and simple shear tab connections are considered secondary members and not included in the linear static model. However, these members may fail if subjected to large dynamic loads and/or significant deflections due to column removal and may pose a hazard to occupants or lead to additional structural failure if they detach and impact the floor below. While force- and deformation-controlled actions can be checked in a straight-forward manner with nonlinear procedures, the linear static procedure and criteria are based on m-factors applied to the moments and other deformation-controlled actions and thus moments must be determined to perform the checks, even at the ends of gravity beams which are often considered to be pinned. While allowable plastic rotations are available for nonlinear static and nonlinear dynamic procedures, they cannot be used for checks in the linear static method, as the analysis procedures are different, in terms of load adjustment factors, explicit consideration of hinges, fidelity of the nonlinear models, etc. Thus, the linear static acceptance criteria must be based on moments, shears, and forces. As simple shear tab connections can be considered partially restrained (PR) connections, their flexural strength can be calculated with an approximate rotational stiffness and the overall rotations, for comparison to the flexural demand.

E-3.4-8.1 Deformation-Controlled Actions

For the gravity beam and the simple shear tab connection, the deformation controlled actions are the moments.

Gravity Beam

There are two contributions to the peak moment demand in the gravity beam. The first is due to the factored linear static load; while the gravity beam is not included in the linear static model, it will experience dynamic and nonlinear effects and the load must be increased accordingly. The second is the end moment created by the rotational stiffness of the simple shear tab connection and the displacements at the end of the beam, as determined from the linear static analysis for column removal at location 1, using the deformation-controlled load case. The combination of end moments and uniform load corresponds to the loading case shown in Figure E-12, which is taken from the AISC LRFD design manual.



$$R_1 = V_1 \quad \ldots\ldots\ldots\ldots \quad = \frac{wl}{2} + \frac{M_1 - M_2}{l}$$

$$R_2 = V_2 \quad \ldots\ldots\ldots\ldots \quad = \frac{wl}{2} - \frac{M_1 - M_2}{l}$$

$$V_x \quad \ldots\ldots\ldots\ldots\ldots \quad = w\left(\frac{l}{2} - x\right) + \frac{M_1 - M_2}{l}$$

$$M_3 \left(\text{at } x = \frac{l}{2} + \frac{M_1 - M_2}{wl}\right) \ldots = \frac{wl^2}{8} - \frac{M_1 + M_2}{2} + \frac{(M_1 - M_2)^2}{2wl^2}$$

$$M_x \quad \ldots\ldots\ldots\ldots\ldots \quad = \frac{wx}{2}(l - x) + \left(\frac{M_1 - M_2}{l}\right)x - M_1$$

$$b \quad \text{(to locate inflection points)} = \sqrt{\frac{l^2}{4} - \left(\frac{M_1 + M_2}{w}\right) + \left(\frac{M_1 - M_2}{wl}\right)^2}$$

$$\Delta_x = \frac{wx}{24EI}\left[x^3 - \left(2l + \frac{4M_1}{wl} - \frac{4M_2}{wl}\right)x^2 + \frac{12M_1}{w}x + l^2 - \frac{8M_1 l}{w} - \frac{4M_2 l}{w}\right]$$

Figure E-12. Shear and Moment in Simply Supported Beam with End Moments and Uniform Loading

The load w in Figure E-12 is the factored linear static load as calculated with Equation 3-10:

w $= G_{LD} = \Omega_{LD}$ [1.2 D + (0.5 L or 0.2 S)]

w $= G_{LD}$ = 2.7 [1.2 (SW + DL_{floor} + SDL) + 0.5 (LL_{floor})] = 4.5-kip/ft

where

Ω_{LD} = Load increase factor = 2.7 as discussed earlier for column removal location 1
SW = Self Weight = 44-lb/ft for W21/44
DL_{floor} = Dead Load of floor over tributary area of gravity beam = 78-psf * 10-ft
SDL = Superimposed Dead Load over tributary area = 15-psf * 10-ft
LL_{floor} = Live Load of floor over tributary area of gravity beam = 100-psf * 10-ft

The end moments in Figure E-12 are calculated from the rotations created by the relative displacement at the end of the beams, as calculated for the column removal at location 1 using the deformation-controlled load case. The rotation is calculated as:

θ = Δ/L = 4.09-in/528-in = 0.0077-rad

where

θ = Chord rotation
Δ = Relative displacement = 4.09-in
L = Beam length = 44-ft = 528-in

To determine the resulting end moments, the approximate stiffness for a partially restrained connection is calculated using Eq. 9-15 from ASCE 41:

K_o = M_{CE}/0.005

where

M_{CE} = Expected moment strength of the simple shear tab connection

The expected moment strength for the simple shear connection is based on the shear strength of the connection multiplied by the eccentricity of the bolt group, which is 3.5 inches in accordance with Figure 10-11 of the AISC Manual, 13th Edition. The shear strength from Table 10-9a of the AISC Manual is 63.6-k for 4 ¾-in A325N bolts. The expected moment strength and partially restrained connection stiffness are:

M_{CE} = 63.6-kip * 3.5-in = 22.6-in-kip
K_o = 222.6-in-kip/0.005 = 44.5 x 10^3-in-kip/rad

Thus, the end moment demands (M_1 and M_2 in Figure E-12) are

$M_1 = M_2 = K_o\,\theta$ = 44.5 x 10^3-in-kip/rad 0.0077-rad = 342.7.0-in-kip = 28.55-ft-kip

The maximum moment demand is found using the equation for M_3 in Figure E-12.

M_3 = $w\,L^2/8 – (M_1 + M_2)/2 + (M_1 – M_2)^2/2wL^2$
= 4.5-kip/ft [(44-ft) ^2]/ 8 - (28.55-ft-kip -28.55-ft-kip)/2 +
(28.55-ft-kip + 28.55-ft-kip)^2/ [2 (4.5-kip/ft) (44-ft)^2]
= 1089-ft-kip

This is the demand or Q_{UD} for the gravity beam. For a W21x44, the expected moment strength is

Q_{CE} = $\Omega\, F_y\, Z_x$ = 1.1*50-ksi*95.4-in^3 = 5247-in-kip = 437.3-ft-kip.

where

Ω = Overstrength factor = 1.1 from ASCE 41 Table 9-3
F_y = Yield strength = 50-ksi
Z_x = Plastic modulus, from AISC LRFD design manual = 95.4-in^3

Note that the unbraced length must be checked as part of the design.

Checking Equation 3-13 and with m = 12 for a secondary compact beam, per ASCE 41 Table 9.5,

$\Phi\ m\ Q_{CE} \geq Q_{UD}$
0.9 (12) (437.3-ft-kip) = 4723-ft-kip ≥ 1089-ft-kip **OK**

Simple Shear Tab Connection

A somewhat similar procedure is performed for the simple shear tab connection. In this case, there are two contributions to the moment demand at the connection. The first is the moment demand created by the shear reaction from the factored linear static load, multiplied by the eccentricity of 3.5-in. In this case, the factored linear static load is used to calculate the shear reaction and moment demand:

w = G_{LD} = 2.7 [1.2 (SW + DL_{floor} + SDL) + 0.5 (LL_{floor})] = 4.5-kip/ft
V = 0.5 w L + (M_1 - M_2)/L = 0.5 (4.5-kip/ft) 44-ft + (28.55-kip + 28.55-kip)/44-ft = 100.3-kip
M_{Dload} = V * 3.5-in = 351-in-kip

The second moment demand is generated by the relative displacements at the end of the gravity beam, as calculated from the linear static model for removal location 1 with the factored linear static load. The chord rotation is as before, θ = 0.0077-rad. The approximate stiffness for a partially restrained connection is calculated with Equation 9-15 of ASCE 41, or K_o = 44.5 x 10^3-in-kip/rad. This moment demand is

M_{Ddispl} = $K_o\ \theta$ = 44.5 x 10^3-in-kip/rad 0.0077-rad = 342.7-in-kip

The total demand is

M_{UD} = M_{Dload} + M_{Ddispl} = 351-in-kip + 342.7-in-kip = 693.7-in-kip

The strength of the simple shear tab connection was calculated earlier and is based on the design shear load for the connection times the eccentricity of the bolt group or

M_{CE} = 63.6-kip * 3.5-in = 222.6-in-kip

For the simple shear tab connection, Table 5-1 in Chapter 5 shows that the m-factor for secondary members is.

m = $8.7 - 0.161 d_{bg} = 7.25$

where

d_{bg} = Depth of bolt group or 9-in with 4 ¾-in A325N bolts.

Checking Equation 3-13 and with m = 7.25 for a simple shear tab connection, per Table 5.1,

$\Phi\ m\ Q_{CE} \geq Q_{UD}$

0.9 (7.725) (222.6-in-kip) = 1613.9-in-kip ≥ 693.7-in-kip **<u>OK</u>**

E-3.4-8.2 Force-Controlled Actions

For the gravity beam and the simple shear tab connection, the force-controlled action is the shear.

Gravity Beam

There are two contributions to the peak shear demand in the gravity beam. The first is due to the factored force-controlled linear static load; while the gravity beam is not included in the linear static model, it will experience dynamic and nonlinear effects and the load must be increased accordingly. The second is the end shear due to the end moments created by the displacements at the end of the beam (as determined from the linear static model with the force-controlled load case) and the rotational stiffness of the simple shear tab connection. The combination of end moments and uniform load corresponds to the loading case shown in Figure E-12.

The load w in Figure E-12 is the factored linear static load as calculated with Equation 3-12.

w = $G_{LF} = \Omega_{LF}$ [1.2 D + (0.5 L or 0.2 S)]

w = G_{LF} = 2.0 [1.2 (SW + DL_{floor} + SDL) + 0.5 (LL_{floor})] = 3.34-kip/ft

The end moments in Figure E-12 are calculated from the rotations created by the relative displacement at the end of the beams, as calculated for the column removal at location 1 using the force-controlled load case; this displacement is 3.03-in. The rotation is calculated as:

θ = Δ/L = 3.03-in/528-in = 0.0057-rad

To determine the resulting end moments, the approximate stiffness for a partially restrained connection is used, as calculated earlier.

K_o = $M_{CE}/0.005 = 44.5 \times 10^3$-in-kip/rad

Thus, the end moment demands (M_1 and M_2 in Figure E-12) are

$M_1 = M_2 = K_o\ \theta$ = 44.5 x 10^3-in-kip/rad 0.0057-rad = 253.7-in-kip = 21.1-ft-kip

The maximum shear demand is found using the equation for V_1 in Figure E-12.

V_1 = w L/2 + (M_1 - M_2)/L
= 3.34-kip/ft [(44-ft)]/2 + (21.1-ft-kip + 21.1-ft-kip)/44-ft+
= 74.4-kip

This is the demand or V_{UF} for the gravity beam. For a W21x44, the lower bound shear strength is

V_{CL} = 0.6 t_w d F_y = 0.6 (0.35-in) (20.66-in) (50-ksi) = 216.9-kip

where
t_w = Web thickness for W21x44 = 0.35-in
d = Depth of W21x44 = 20.66-in
F_y = Yield stress = 50-ksi

Checking Equation 3-13,

$\Phi\ Q_{CL} \geq Q_{UF}$
0.9 (216.9-kip) = 195.2-kip ≥ 74.4-kip **OK**

Simple Shear Tab Connection

A similar procedure is performed for the simple shear tab connection. In this case, there are two contributions to the shear demand at the connection. The first is the shear demand created by the shear reaction from the factored linear static load. In this case, the factored linear static load is used to calculate the shear demand:

w = G_{LD} = 2.0 [1.2 (SW + DL_{floor} + SDL) + 0.5 (LL_{floor})] = 3.338-kip/ft
V_{Dload} = 0.5 w L + (M_1 - M_2)/L = 0.5 (3.338-kip/ft) 44-ft + (21.1-ft-kip + 21.1-ft-kip)/44-ft
= 74.4-kip

The second shear demand is generated by the moment created by relative displacements at the end of the gravity beam, as calculated from the linear static model for removal location 1 with the factored force-controlled linear static load. The chord rotation and stiffness are as before, θ = 0.0057-rad and K_o = 44.5 x 10^3-in-kip/rad. This moment demand is

$M_{Ddispl} = K_o\ \theta$ = 44.5 x 10^3-in-kip/rad 0.0057-rad = 253.7-in-kip

From statics for a beam subjected to two end moments, the shear demand due to displacement is

V_{Ddispl} = 2 M_{Ddispl}/L = 2 (253.7-in-kip)/528-in = 0.96-kip

The total demand is

V_{UF} = V_{DLoad} + V_{Ddispl} = 74.4-kip + 0.96-kip = 75.4-kip

The shear strength of the simple shear tab connection is taken from Table 10-9a of the AISC Manual.

V_{CL} = 63.6-kip

Checking Equation 3-13,

$\Phi\ Q_{CL} \geq Q_{UF}$
0.9 (63.6-kip) = 57.2-kip ≥ 75.4-kip **NG**

Thus, the shear strength of the simple shear tab connection must be increased. Since the original design strength of the connection is based on the typical design load combination (1.2D + 1.6L) and the demand is based on the smaller load combination (1.2D + 0.5L) multiplied by the LIF of 2.0, this is not unexpected. Therefore, the strength of the simple shear tab must be increased to 75.4-kips and the deformation-controlled action (the moment) for the connection must be re-checked. For this example, the deformation controlled action is acceptable, by inspection.

Note that the axial force in these beams and connections are not checked, due to the small displacements at the ends of the beams. Similarly, the concrete slab is not checked, based on the small rotations and engineering judgment.

E-3.5 Enhanced Local Resistance.

ELR provisions for \3\ Risk Category /3/ III require that all perimeter columns at the first floor above grade achieve design shear strengths that exceed the shear demand associated with the flexural demand of the columns. For \3\ Risk Category /3/ III, the flexural demand is determined from the building design after it meets the AP requirements. For the purposes of ELR evaluation, the columns are considered fixed at the first level above grade due to continuity of the column above the first level and the rigid support provided by the floor diaphragm and pinned at the base. The flexural demand is based on the development of a 3-hinge mechanism in the column, with one hinge present as the pinned end of the column, a plastic hinge that develops at the fixed end at the first level above grade and a plastic hinge that develops within the column.

The required shear strength (i.e., the shear demand) can be found in plastic structural design references or in Table 4-4 of PDC TR-06-01 *Methodology Manual for the Single-Degree-of-Freedom Blast Effects Design Spreadsheets (SBEDS)*. From PDC

TR-06-01, the largest reaction/shear for a pinned-fixed, uniformly loaded beam is 5 r_u L/8, where r_u is the ultimate resistance and equal to 12 M_p/L^2. M_p is the plastic moment of the column cross-section and thus is the nominal flexural strength of the perimeter columns, which have been sized to meet the AP requirements as well as standard design requirements. Thus,

V_u = 5 r_u L/8
r_u = 12 M_p/L^2

and

V_u = 7.5 M_p / L   Equation (E-1)

where
- V_u = Shear demand (required shear strength)
- M_p = Nominal flexural strength, accounting for axial load; also, the plastic moment
- r_u = Ultimate resistance,
- L = Column height

In this example, the design shear strength for all columns other than corner columns exceeds the shear demand so no member size increases were required beyond those determined using the alternate path procedure. For corner columns, there is no W18 section that can provide adequate design shear strength to meet the shear demand. To satisfy these provisions, web doubler plates were added. At these corner locations the axial load is less than 10% of the column capacity and was ignored.

The corner column is a W18x97 with a strong axis plastic modulus of 211 in^3 per Figure E-11. The shear demand is calculated with Equation E-1 and using an over-strength factor of 1.1 (per Section 3-3.1) is

V_u = 7.5 M_p / L = 7.5 * 1.1 * 50-ksi * 211-in^3 / 174-in = 495-kips

The design shear strength (per AISC Chapter G) is:

ΦV_n = 1.0 * 0.6 * t_w * h * F_y= 0.6 * 0.535-in * 18.6-in * 50-ksi = 298-kips

The required additional design shear strength is achieved by adding a doubler plate to the web of the W18x97. The thickness is found by subtracting the design shear strength (298-kips) from the shear demand (495-kips) and using this difference to size a 14-in high plate. A 1/2" thick doubler plate is required for all corner columns. See Figure E-13 for a diagram of the doubler plate used to enhance strong axis shear strength.

/2/

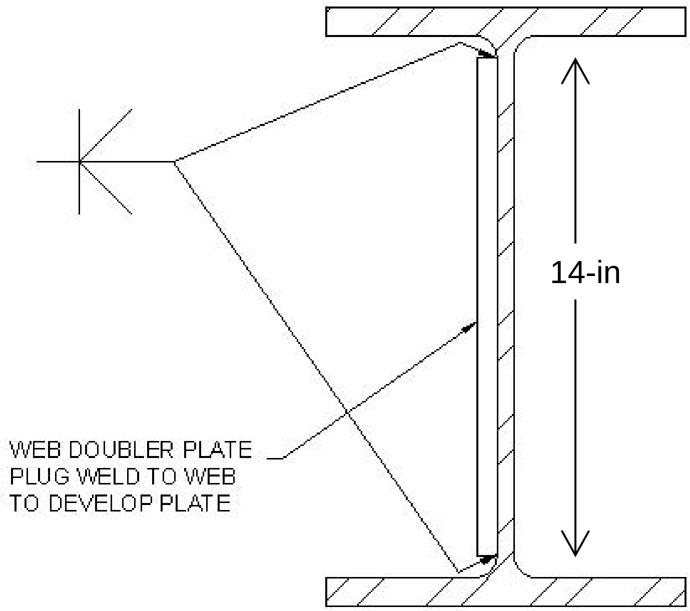


Figure E-13. Web Doubler Plate for ELR

E-3.6 Alternate Path Design Method Complete.

Once the model converges, all acceptance criteria have been met, and enhanced local resistance has been provided, the building has satisfied progressive collapse resistance requirements of this UFC.

E-4 NON LINEAR DYNAMIC PROCEDURE (NDP).

Locations of required columns removals are illustrated in Figure E-14. Each removal is considered separately. For the purpose of this example, the column below level 2 is removed, Section 3-2 requires additional analyses for removals at other levels.

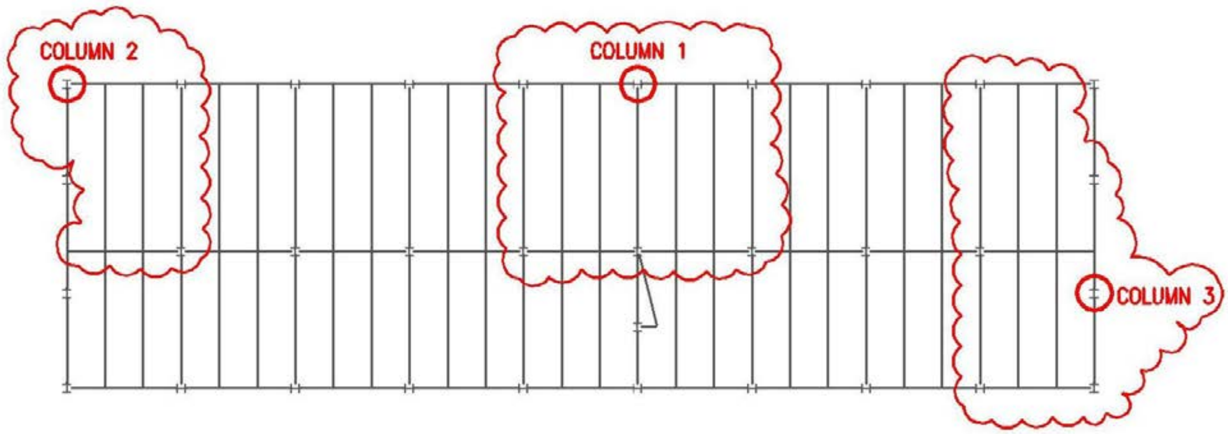

Figure E-14. Column Removal Locations

E-4.1 DCR and Irregularity Limitations.

There are no DCR or geometric irregularity limitations on the use of the NDP.

E-4.2 Alternate Path Analysis.

The software used and screen shots depicted for this example was SAP 2000NL. The details of this example can be generally applied in any structural software capable of nonlinear static analysis. The “Staged Construction” option in SAP was used to ensure proper redistribution of loads upon member removal. Comparable software should also have the capability of load redistribution, or loads must be redistributed manually.

E-4.2.1 Develop Preliminary Model.

See Figure E-15 for a model developed in SAP2000. All beams and columns are modeled including gravity beams.

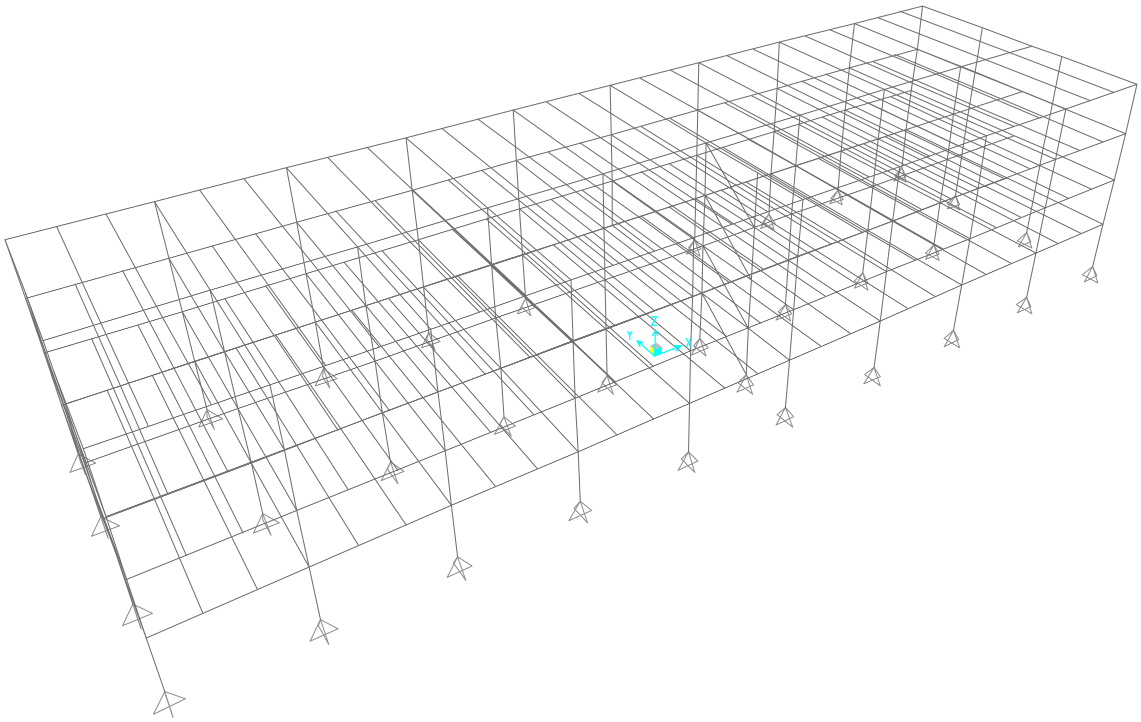

Figure E-15. Isometric View of SAP Model

E-4.2.2 Define Load Cases and Assign Loads.

The dynamic nature of this procedure does not require an increase factor to account for dynamic effects. No additional load cases are needed to account for dynamic load increase. For this reason, a single model may be used to verify acceptance of force controlled actions and deformation controlled actions.

E-4.2.3 Define Analysis Cases.

The nonlinear dynamic procedure requires one analysis case for each column removal. Analysis cases are created to determine the forces present at equilibrium in each column to be removed. For each column removal, the column member is deleted in the structural model and the internal forces determined from the equilibrium model are applied to the structure as a load case to the joint or joints at each column end. These static nonlinear analysis cases are used as the starting conditions for the column removals.

Within these analysis cases, assign all loads to be used in this analysis case per the load combination in Equation 3-18. Click Nonlinear parameters button and choose P-delta option. It is possible to use P-delta + large displacements, but it is not necessarily needed for this analysis. Figure E-16 shows a screenshot of the interface for definition of analysis cases and their assigned loads.

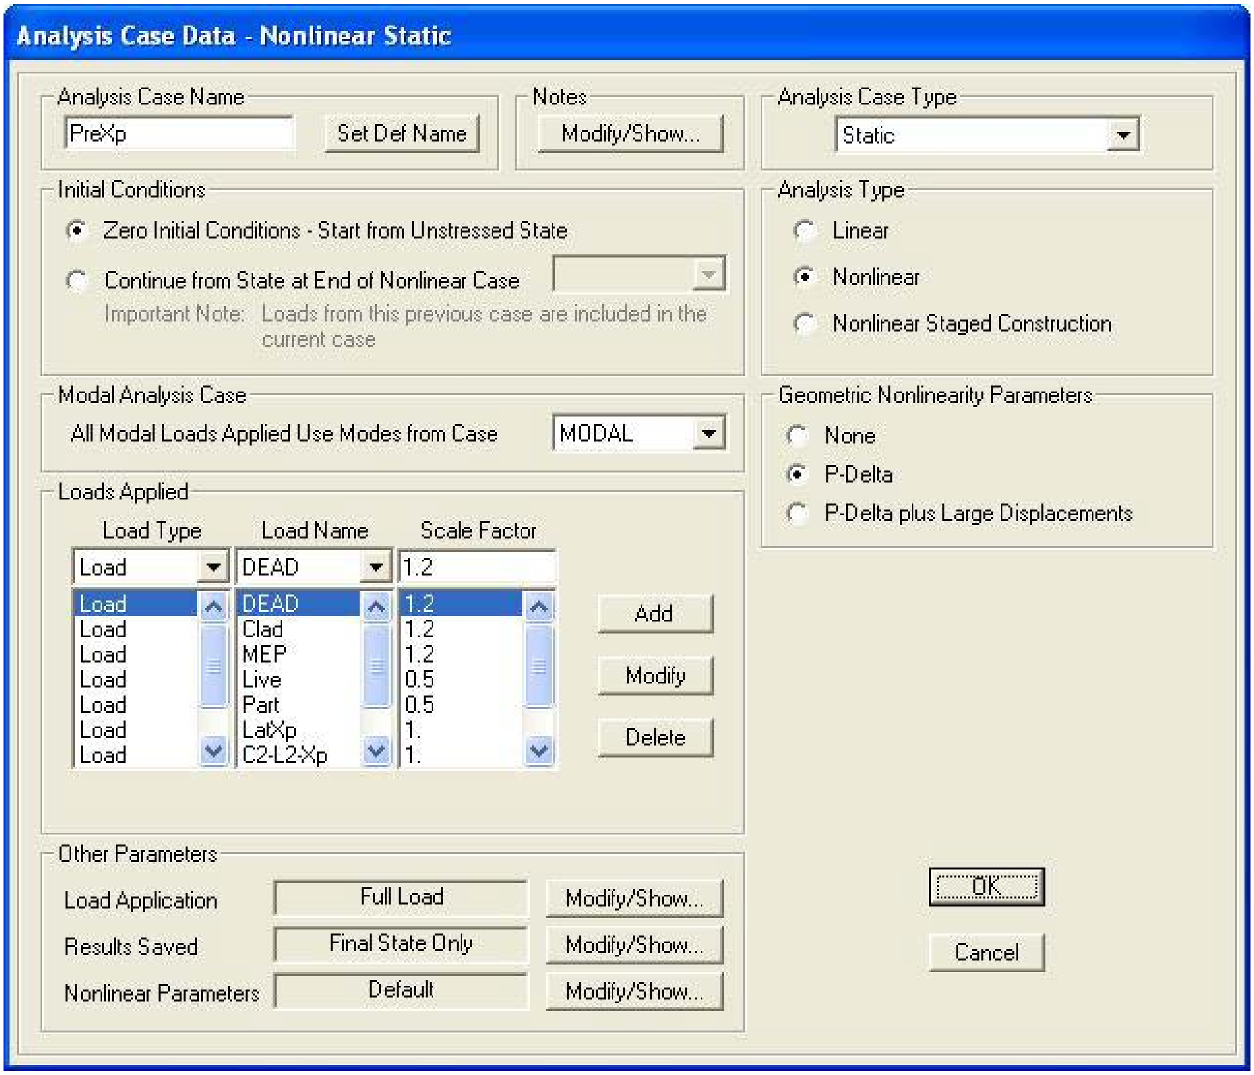

Figure E-16. Analysis Case Definition

After equilibrium is reached for the structure, remove the column by ramping down the column forces under a duration for removal of less than one tenth of the period associated with the structural response mode for the element removal. The analysis shall continue until the maximum displacement is reached or one cycle of vertical motion occurs at the column or wall section removal location. Figure E-17 shows a screen shot of the column removal analysis case definition.

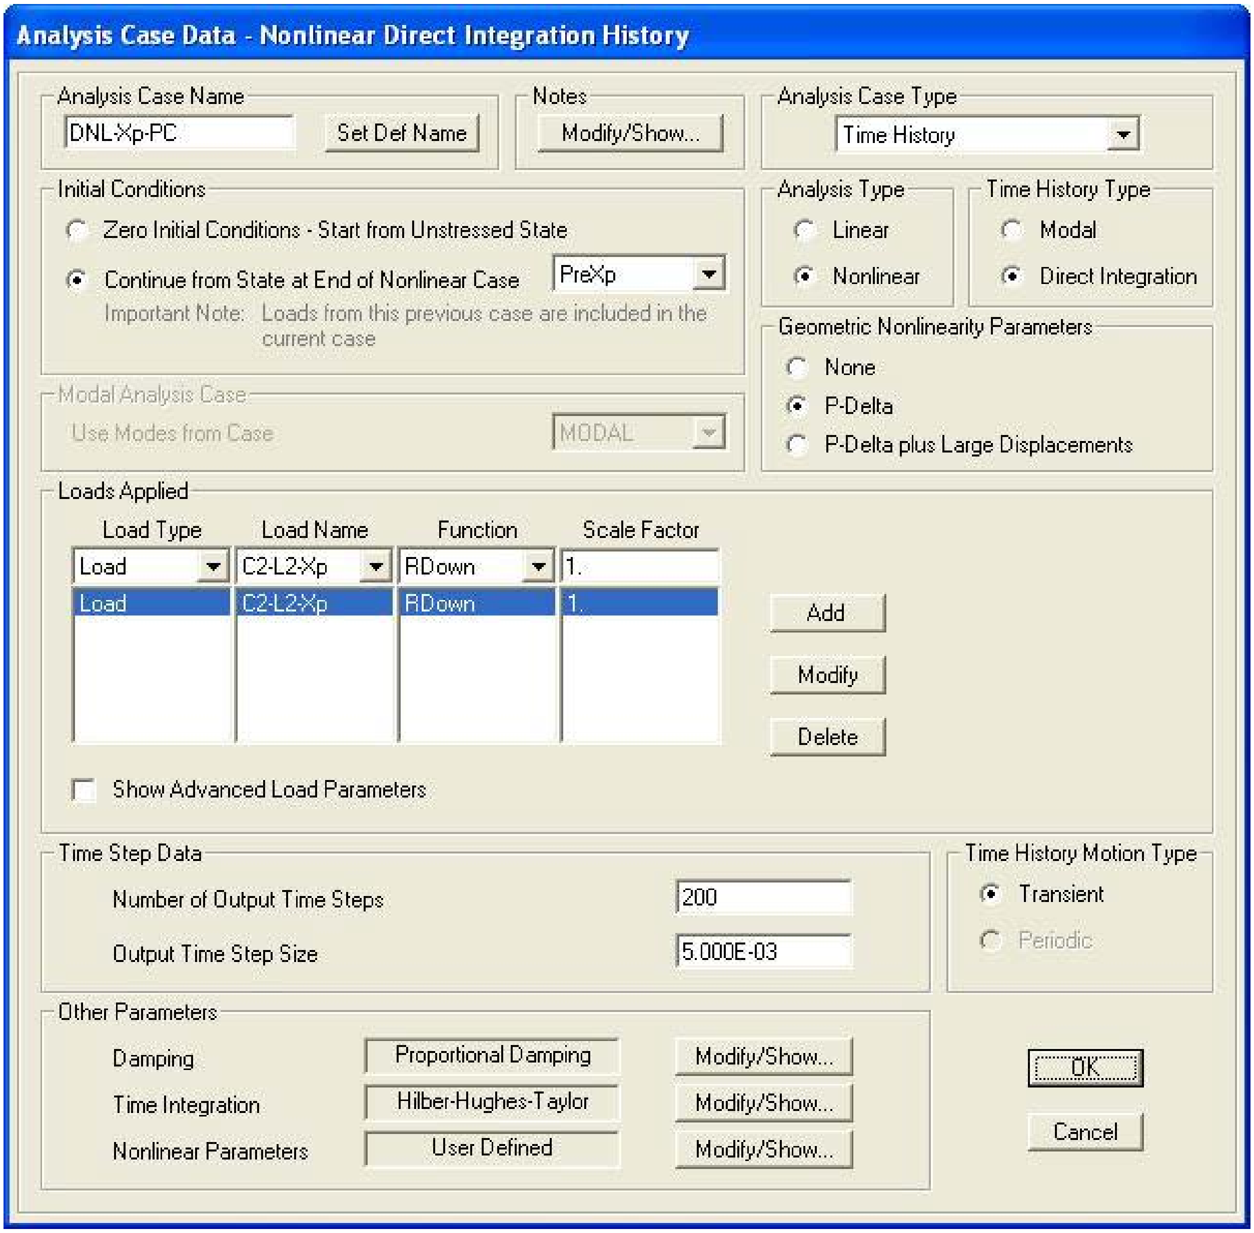

Figure E-17. Analysis Case Definition

E-4.2.4 Define Design Combinations.

SAP design procedures may be used to evaluate whether columns are deformation or force controlled. Design checks also aid in the definitions of column hinges by determining axial load demand and capacity. Create a design combination for each analysis case (12 total design cases created in this example, additional cases would be required for column removal at other elevations).

E-4.2.5 Run Dynamic Analysis.

It is important to check that both stages of every analysis case converge. If the analysis does not converge, there is a problem with the model and it must be fixed. The problem could be numerical with assumptions made in SAP, but the most likely reason is that the model has a plastic hinge that failed or a mechanism has formed. At this point, the model cannot support the load.

E-4.2.6 Plastic Hinges.

For the nonlinear alternate load path method, plastic hinges are allowed to form along the members. These hinges are based on maximum moment values calculated using phi factors and over-strength factors per the UFC. However, only flexural moments can cause a plastic hinge to form in beam members, and only the axial-moment interaction (PMM) can cause a plastic hinge to form in a column. Any shear or torsion values that would cause a hinge to form would result in an immediate failure.

E-4.2.7 Hinge Locations.

Theoretically hinges can occur anywhere along the beam. However, hinges are allowed to occur at the ends of each member and at the midspan of the flexural members. This simplifies the model by placing hinges in the most probable locations.

E-4.2.8 Hinge Properties.

Nonlinear acceptance criteria and component definitions are from Chapter 9 of ASCE 41 for the Life Safety condition for primary and secondary components. Use the modeling parameters and guidance, including definitions of stiffness, to create the analytical model. For beams subjected to flexure or flexure plus axial tension, use the Collapse Prevention values for primary and secondary elements. For the Fully Restrained (FR) and Partially Restrained (PR) connections listed in Tables 5-1 and 5-2 in this UFC, use the specified plastic rotations and modeling parameters as given. Figure E-18 shows the form of the plastic hinges for this model.

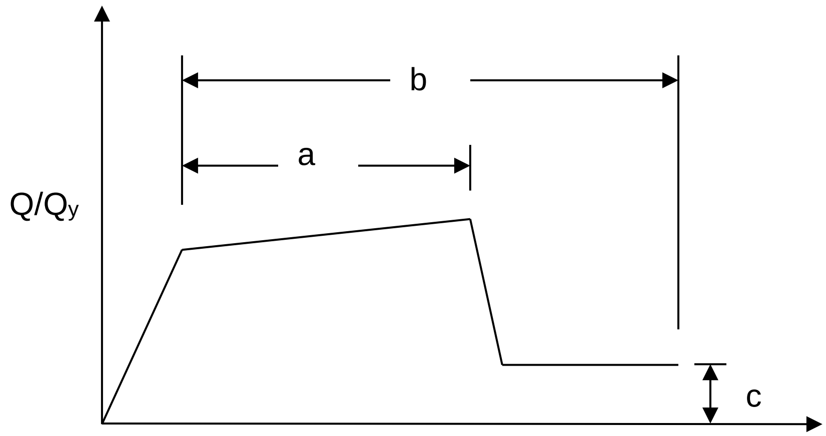

Figure E-18. Generalized Force-Deformation Hinge Definition

Beam and connection hinge properties are determined using ASCE 41 Table 9-6 and UFC Table 5-2. A summary of hinge properties and acceptance criteria for beams and connections corresponding to Figure E-18 are shown in Tables E-5, E-6 and E-7. When defining connection and beam hinges, be certain to include applicable strength reduction factors per AISC as required by this UFC.

Table E-5. Beam Hinge Properties

Column hinge properties are determined using ASCE 41 Table 9-6. These hinge definitions are dependent on the level of axial load present in the member. Because the hinge properties are based on the level of force present, they must be updated when the force level changes significantly. The initial model run was used for preliminary definitions of column hinges. A summary of hinge properties and acceptance criteria for columns used in this example corresponding to Figure E-18 are shown in Tables E-8, E-9 and E-10.

E-4.2.9 Iterate Dynamic Analysis.

It is important to check that both stages of every analysis case converge. If the analysis does not converge, there is a problem with the model and it must be fixed. The problem could be numerical with assumptions made in SAP, but the most likely reason is that the model has a plastic hinge that failed or a mechanism has formed. At this point, the model cannot support the load. If the analysis fails to converge,

1) Since the analysis did not converge, members must be redesigned. To determine which members must be redesigned, step through the incomplete progression of plastic hinge formations. The final steps saved by SAP will often give the best results on which beams or columns to redesign. See Figure E-18 for the final step in the hinge formations of an analysis that did not converge.

2) To view the plastic hinges, click Display – Deformed Shape. Choose an analysis case and click to the last step of that case. Any hinge that forms will "light up," and its color denotes the region the hinge has progressed (see Figure E-17). A hinge deformed in excess of the limit defined by its acceptance criteria, or is orange or red has failed.

3) Once members have been selected to be redesigned, re-run the analysis. Repeat this process until the structure converges. The engineer must check each analysis case to make sure that no hinge has failed. Once the analysis converges and no hinges fail, perform a shear check on each member. See Figures E-19 through E-21 for final deformed shapes and hinge formations and Figures E-22 through E-24 for final member sizes for each column removal location.

Figure E-22. Column 3 Removal Convergence After Redesign

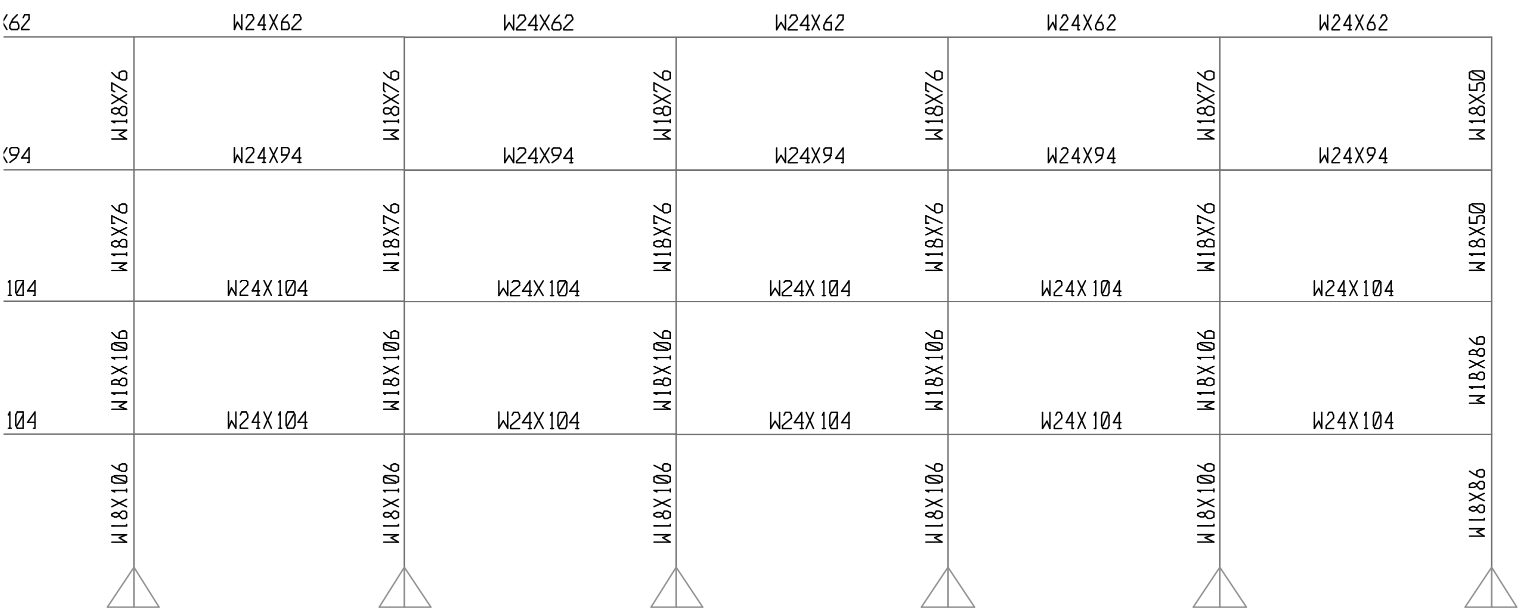

Figure E-23. Typical Member Sizes After Redesign for Column 1 Removal

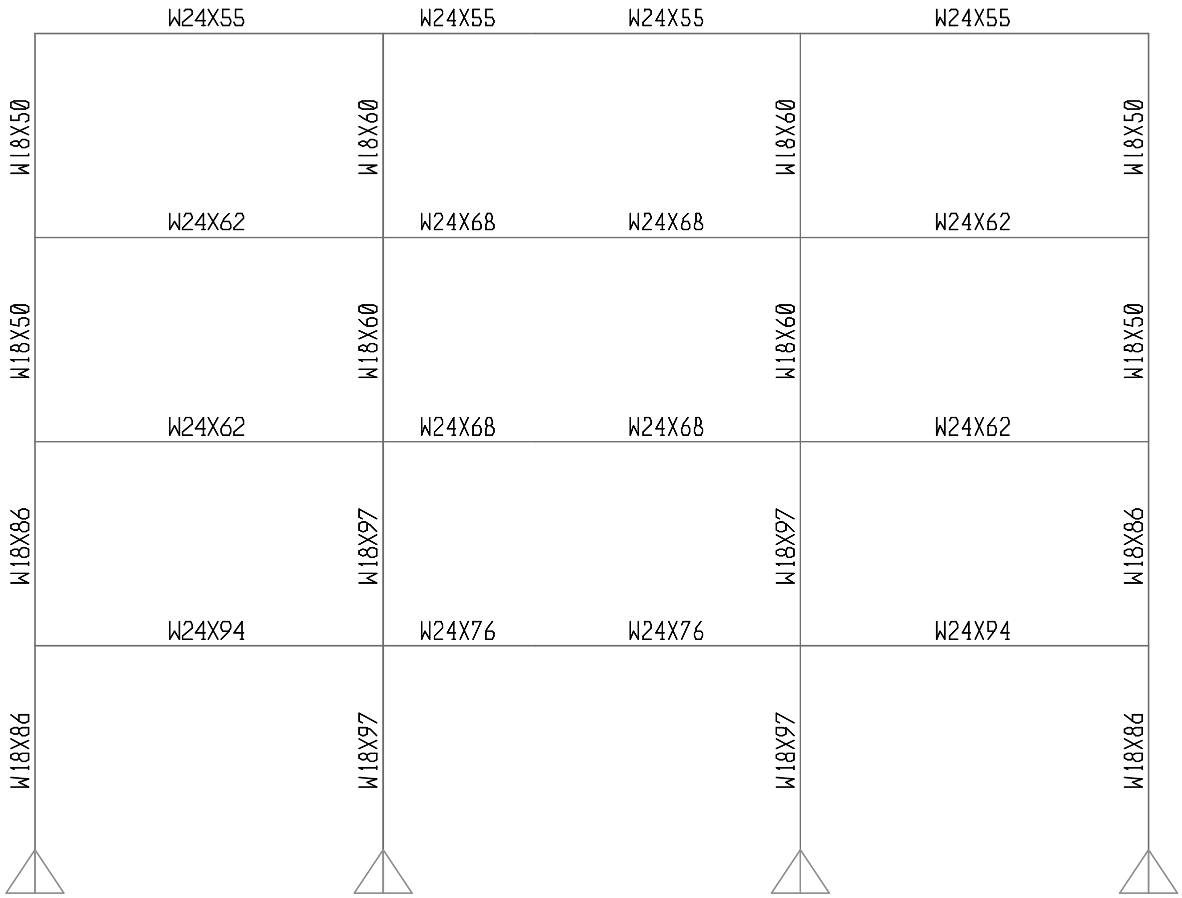

Figure E-24. Typical Member Sizes After Redesign for Column 2 or 3 Removal

E-4.2.10 Secondary Component Checks.

Because the gravity beams were explicitly included in the model, there are no secondary components to check. As with the Linear Static solution, the slab is adequate due to the small deformations and by engineering judgment.

E-4.3 Enhanced Local Resistance.

The provisions for \3\ Risk Category /3/ III require that all perimeter columns at the first floor above grade achieve design shear strengths that exceed the shear demand associated with the flexural demand of the columns. For \3\ Risk Category /3/ III, the nominal flexural strength is determined from the building design after it meets the AP requirements. The ELR design process for the Nonlinear Dynamic solution is similar to that used for the Linear Static solution in Section E-3.5.

In this example, the design shear strength for all columns other than corner columns exceeds the shear demand so no member size increases were required

beyond those determined using the alternate path procedure. For corner columns, there is no W18 section that can provide adequate design shear strength to meet the shear demand. In order to satisfy these provisions, web doubler plates were added. At these corner locations the axial load is less than 10% of the column capacity and was ignored.

The corner column is a W18x86 with a strong axis plastic modulus of 186 in^3. The shear demand is calculated with Equation E-1 and using an over-strength factor of 1.1 (per Section 3-3.1) is

V_u = 7.5 M_p / L = 7.5 * 1.1 * 50 ksi * 186 in^3 / 174 in = 441 kips

The design shear strength (per AISC Chapter G) is:

ΦV_n = 1.0 * 0.6 * t_w * h * F_y= 0.6 * 0.480 in * 18.4 in * 50 ksi = 265 kips

The required additional design shear strength is achieved by adding a doubler plate to the web of the W18x86. The thickness is found by subtracting the design shear strength (265-kips) from the shear demand (441-kips) and using this difference to size a 14-in high plate. A 7/16” thick doubler plate is required for all corner columns. See Figure E-13 for a diagram of the doubler plate used to enhance strong axis shear strength.

E-4.4 Alternate Path Design Method Complete.

Once the model converges, all acceptance criteria have been met, and enhanced local resistance has been provided, the building has satisfied progressive collapse resistance requirements of this UFC.

E-5 RESULTS COMPARISON.

Member size requirements determined from the linear static and nonlinear dynamic procedures are presented and compared to original size requirements in Tables E-11 and E-12.

Table E-11. Moment Frame Size Comparison

Location	Level	Original Size	LSP AP Size	NDP AP Size
Long Side	2	W24x68	W24x146	W24x104
Long Side	3	W24x68	W24x146	W24x104
Long Side	4	W24x68	W24x117	W24x94
Long Side	Roof	W24x55	W24x76	W24x62
Short Side – Exterior	2	W24x94	W24x94	W24x94
Short Side – Exterior	3	W24x62	W24x68	W24x62
Short Side – Exterior	4	W24x62	W24x68	W24x62
Short Side – Exterior	Roof	W24x55	W24x55	W24x55
Short Side – Central	2	W24x76	W24x104	W24x76
Short Side – Central	3	W24x68	W24x104	W24x68
Short Side – Central	4	W24x68	W24x94	W24x68
Short Side – Central	Roof	W24x55	W24x55	W24x55

Table E-12. Perimeter Column Size Comparison

Location	Level	Original Size	LSP AP Size	NDP AP Size
Long Side – Interior	1-3	W18x86	W18x175	W18x106
Long Side – Interior	3-Roof	W18x55	W18x106	W18x76
Short Side – Interior	1-3	W18x97	W18x119	W18x97
Short Side – Interior	3-Roof	W18x60	W18x76	W18x60
Corner	1-3	W18x86	W18x97	W18x86
Corner	3-Roof	W18x40	W18x76	W18x50

The frame size increases required for progressive collapse resistance are summarized by total weight in Table E-13. The weight of the exterior moment frames (girders and columns) are reported for the long side and short side for the baseline design, and after providing progressive collapse resistance using each of the linear static and nonlinear dynamic procedures.

Table E-13. Frame Weight Comparison

Frame	Original Weight	LSP AP Weight	NDP AP Weight
	(tons)	(tons)	(tons)
Long Side	58.2	108.7	78.2
Short Side	20.1	24.5	20.4

APPENDIX F WOOD EXAMPLE

F-1 INTRODUCTION

A wood load-bearing wall structure example has been prepared to illustrate Alternate Path analysis of a bearing wall type structure. The structure is assumed to have an occupancy of less than 100 people and is classified as \3\ Risk Category /3/ II per UFC 3-301-01.

The example has been prepared using tools and techniques commonly applied by structural engineering firms in the US. For wood design, this example relies primarily upon hand analysis supplemented with standard design tables published by various wood organizations. \3\ Risk Category /3/ II Option 2: Alternate Path has been selected from UFC Table 2-2 to evaluate resistance to progressive collapse.

F-2 BASELINE DESIGN

The example building is a 3-story wood structure, six bays long and two bays deep. The relevant design information is shown in Figures F-1 through F-4.

Platform construction is used. The internal shear walls are load bearing, with engineered I-joists (EIJ) running in the direction of the long length of the structure. One 4.5-foot x 6-foot window opening is present in each room. The footings are reinforced concrete with masonry. There are no internal partition walls.

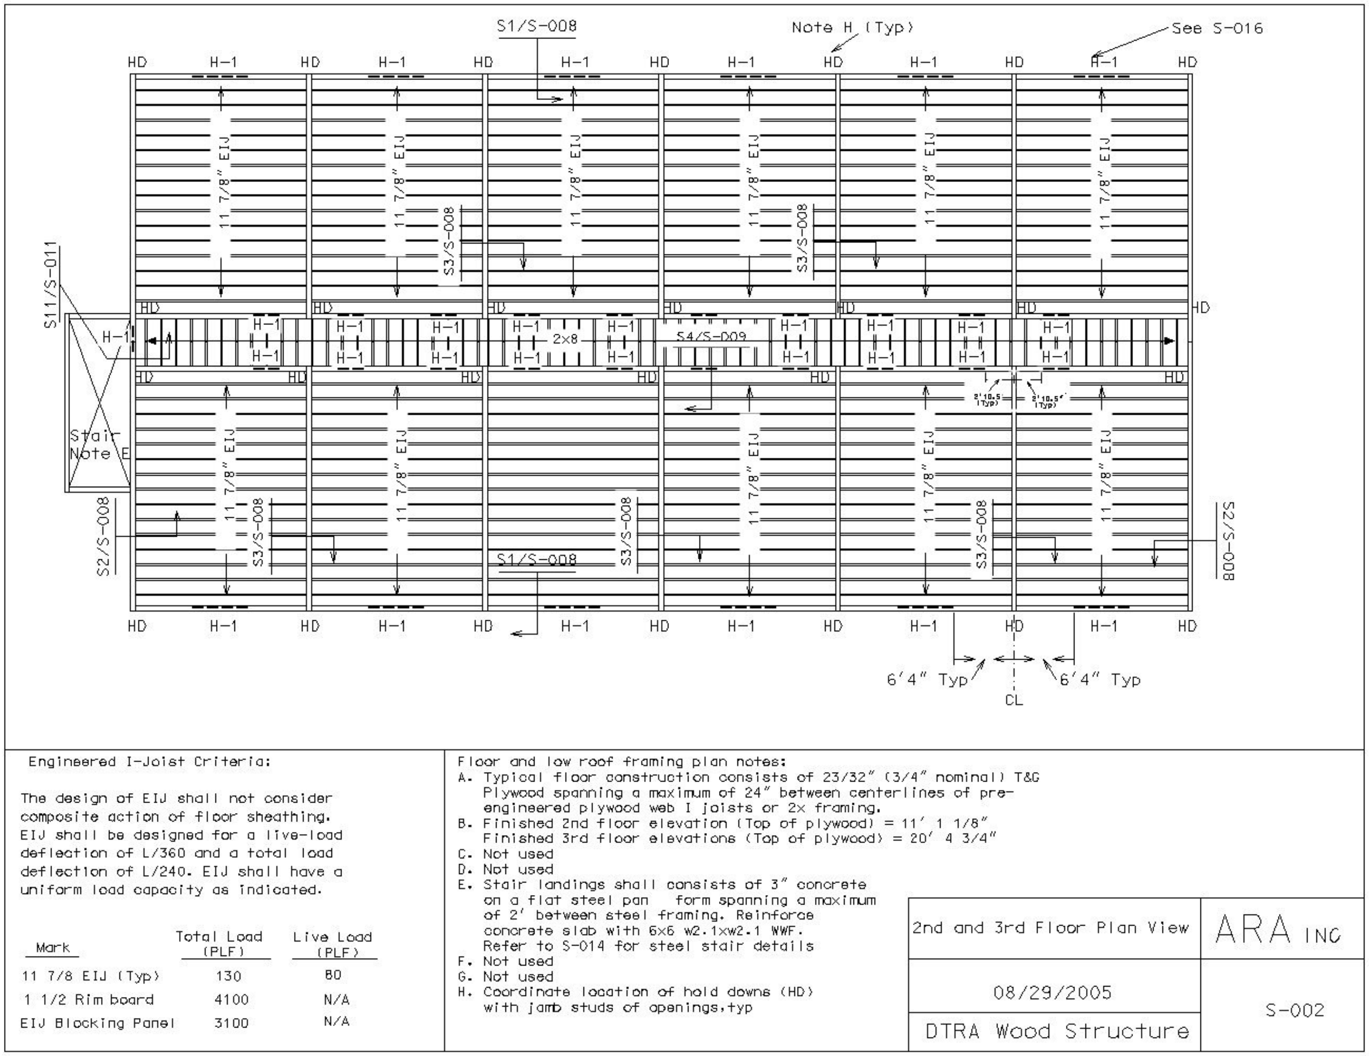

Figure F-1. Wood Frame Example Plan

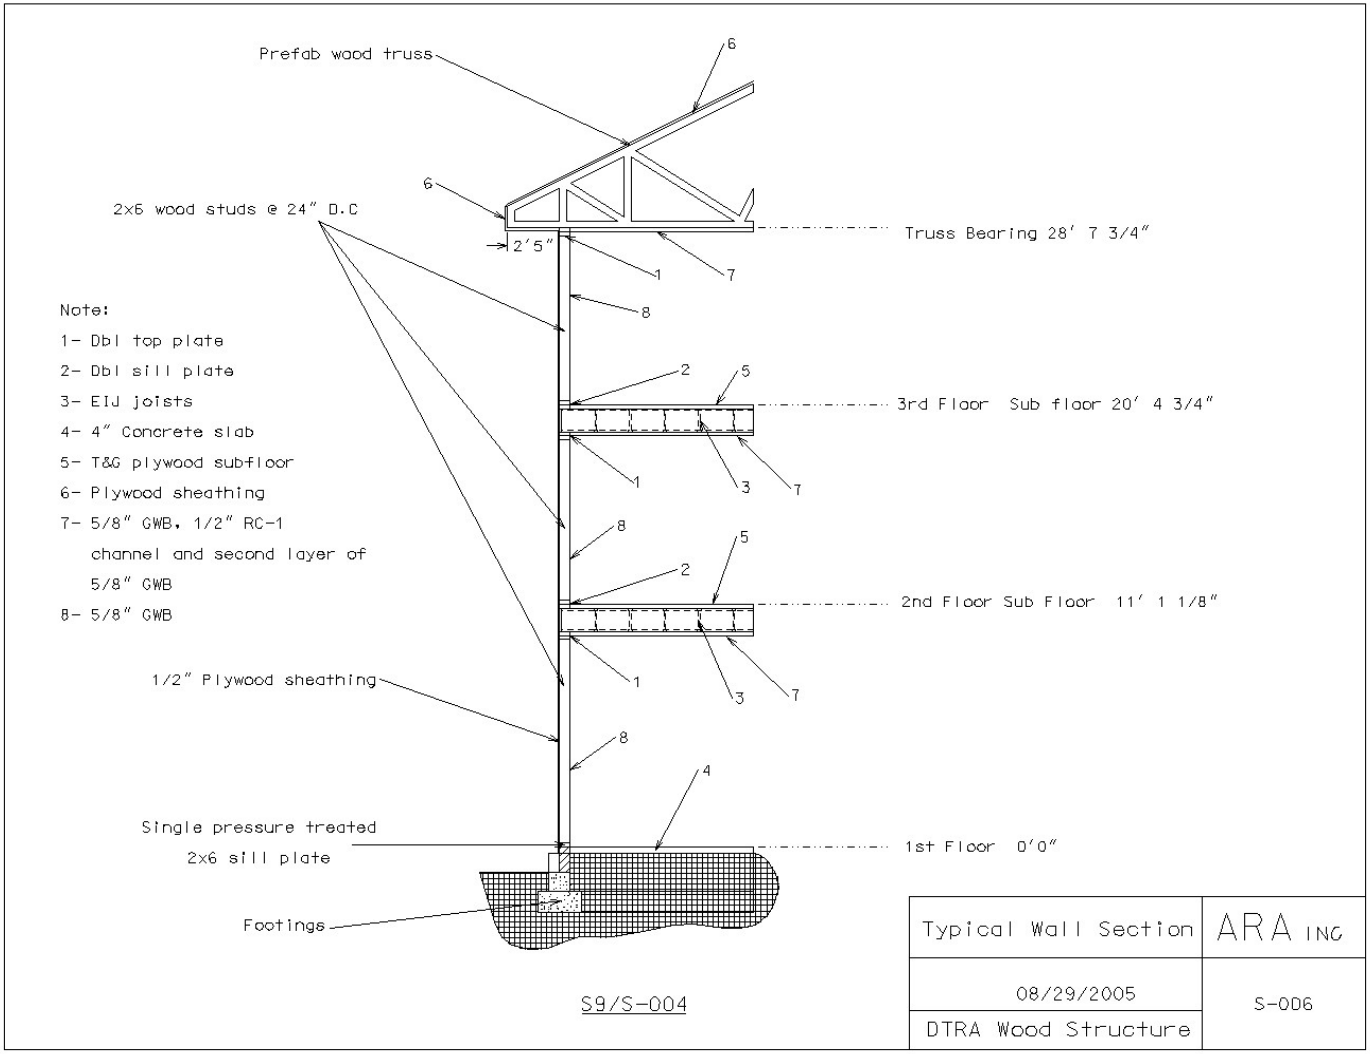

Figure F-2. Wood Frame Example Wall Section

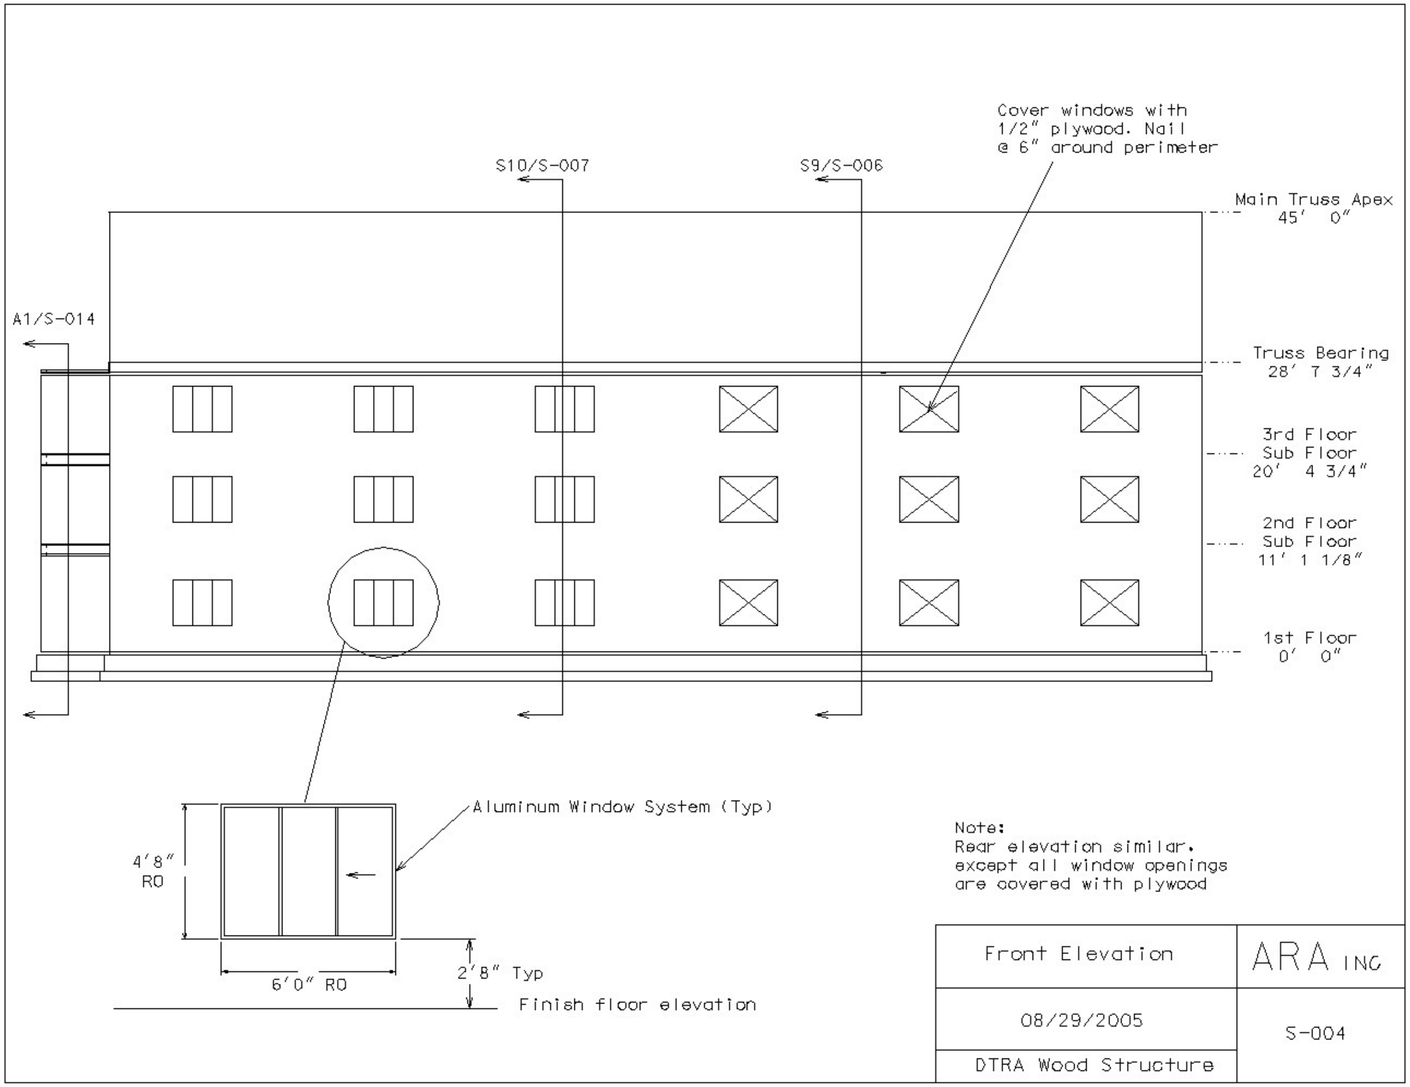

Figure F-3. Wood Frame Example Exterior Wall Elevation

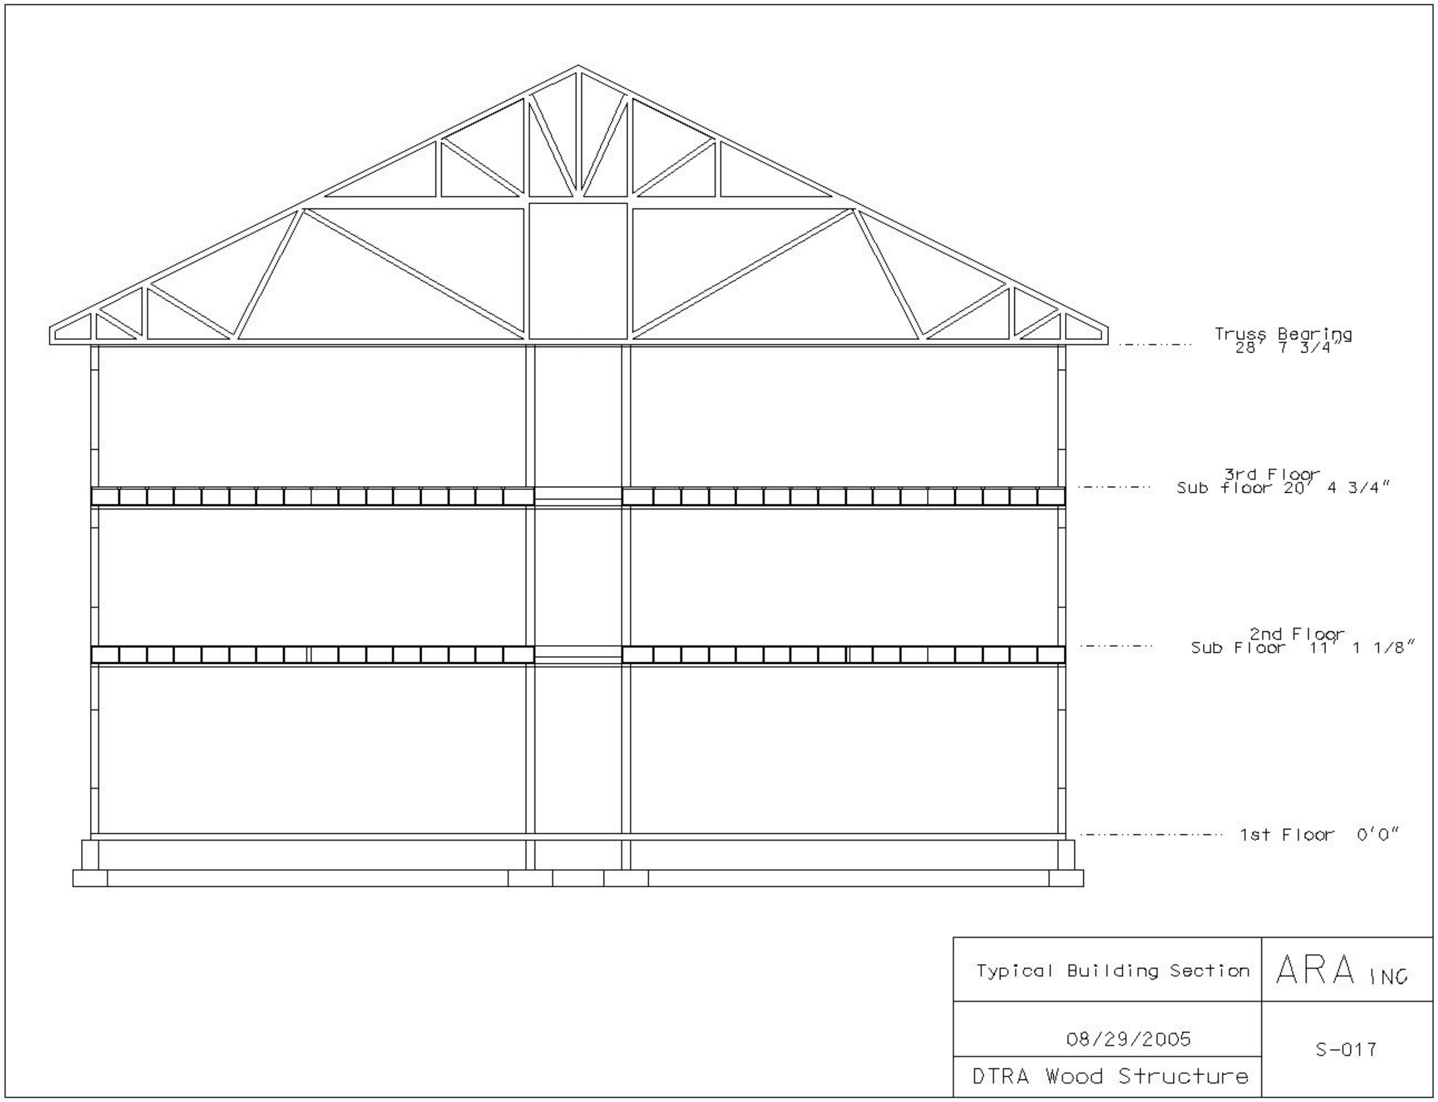

Figure F-4. Wood Frame Example Building Section

F-2.1 Construction and Materials

Wall Construction:
2x6 at 24 inches on center

Exterior Walls: 19/32” Plywood Sheathing Exterior Face, blocked; 5/8” Gypsum Wallboard, unblocked Interior Face

Interior Walls: 19/32” Plywood Sheathing both Faces, blocked

Floor Construction:
Engineered I-joists (EIJ) at 24 inches on center with 0.75-inch tongue and groove plywood sub-floor. Bottom surface 5/8” gypsum wallboard with a ½” channel separation for noise and fire suppression.

Roof Construction:
Engineered Trusses with ½” Plywood Sheathing

Material Grades:
Plywood: Voluntary Product Standard PS 1-07 Exposure 1; APA Rated

Wood Framing: Produced to American Softwood Lumber Standard Voluntary Product Standard PS 20.

- 19% maximum moisture content
- Grade 2 or better
- Southern Pine (SPIB)

F-2.2 Loading Assumptions

Typical loading relevant to AP Analysis:

Floors:
Dead Load: 25 psf including ceiling
Live Load: 40 psf

Roof:
Dead Load: 25 psf including roofing and bottom surface ceiling
Live Load: 20 psf
Snow Load: 7 psf (design, including all applicable ASCE 7-05 factors)

Walls:
Dead Load: 7 psf including sills and headers

Live loads reducible depending on tributary area considered.

F-2.3 Relevant Standards and Reference Documents

ANSI/AF&PA NDS-2005 National Design Specification for Wood Construction ASD/LRFD

ANSI/AF&PA SDPWS-2005 ASD/LRFD Special Design Provisions for Wind and Seismic With Commentary

International Building Code 2006

For design compatible with the UFC document LRFD is followed.

F-3 ALTERNATE PATH ANALYSIS

An alternate path (AP) analysis is conducted according to the requirements of Section 3-2. Removal scenarios are defined by 3-2.9.1 and 3-2.9.2. To bridge the wall removals, the remaining load bearing walls will be utilized as shear wall elements. The linear static AP analysis method will be followed.

F-3.1 Scope and Analysis Assumptions

Four scenarios of wall removal will be evaluated:

1. Removal of interior load-bearing wall (see Figure F-5) at first story
2. Removal of exterior long walls (see Figure F-6) at second story
3. Removal of exterior long walls (see Figure F-8) at second story (alternate location)
4. Removal of exterior long walls (see Figure F-9) at third story

General assumptions of the analysis are as follows:

- No wind or internal pressure acts on interior or exterior walls during wall removal scenario
- Contributions of EIJ and engineered roof trusses to the alternate path capacity are neglected due to uncertainty in specific properties during the design phase. At the designer's option, these elements could be included, provided that appropriate performance specifications including AP requirements are incorporated into the contract documents.

Per ASCE 41-13
C12.2.2.5:
"Actions associated with wood and light metal framing components generally are deformation controlled, and expected strength material properties will be used most often."

8.3.3:
"Demands on connectors, including nails, screws, lags, bolts, split rings, and shear plates used to link wood components to other wood or metal components shall be considered deformation controlled actions. Demands on bodies of connections, and bodies of connection hardware, shall be considered force-controlled actions."

For the AP analysis of this structure, wood shear wall assemblies and primary connections will be taken to be deformation controlled elements. Bodies of connectors will be checked as force controlled elements as required.

F-3.2 AP Analysis of Interior Load Bearing Wall Removal

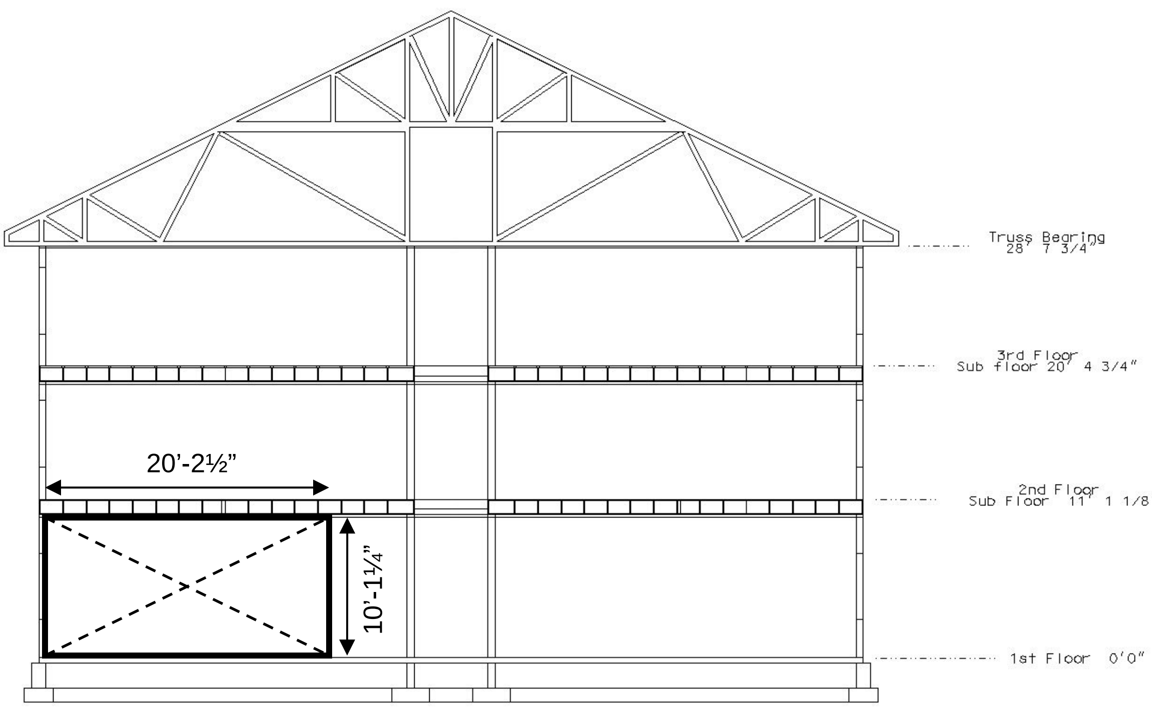

Figure F-5. Interior Load Bearing Wall Removal

As shown in Figure F-5, a segment of wall of length 2H is removed from the lower floor interior load bearing wall. H is taken as the distance between the 1st floor sub-floor elevation and the bottom of the 11-7/8" EIJ floor joists at the 2nd floor (=10'-1¼").

The remaining structure creates a shear wall element that must span the floor and wall loads from the 2nd and 3rd stories. The shear wall is taken to have an overall depth of 17'-6 5/8" (2nd floor to truss bearing). The boundary (chord) elements consist of (2) 2x6 plates provided at the top and bottom of each wall.

To bridge the removed section of wall, the shear wall panel must span from the exterior wall to a wall pier segment consisting of the remaining portion of the removed lower story interior wall. Note that no continuity action that might engage the right-hand wall panels in Figure F-5 is possible due to the corridor opening.

The structure contains no irregularities and therefore the linear static AP analysis is permitted per Section 3-2.11.1.1.

Loading:

Dead Load
Floors: 25 psf * 18'-8" * 2 floors = 934 plf
Wall: 7 psf * 18'-6 ½" = 130 plf

Live Load
40 psf * 18.67 * 2 floors = 1494 plf

Reduce live load in accordance with IBC 2006 1607.9.2:

A = 18.67'*20.21'*2 = 755 SF
R = 0.08 (A – 150) = 0.08 (755-150) = 48.4%
R_{max} = 60% or 23.1(1 + 25/40) = 37.5%

Live load used in AP check = 1494 plf (1-0.375) = 934 plf

Linear Static AP Load Case for Deformation Controlled Elements:

$\boldsymbol{G_{LD} = \Omega_{LD}\,[1.2D + 0.5\,L]}$

From ASCE 41-13 Table 12-3:

for "Wood Structural Panel Sheathing or Siding"
h/b = 17.55/20.21 = 0.87 < 2.0
m = 3.8 for Life Safety Primary Element

Assume all connections to be nailed:

m = 6.0 for "Nails – Wood to Wood"
m = 4.0 for "Nails – Wood to Metal"

m = 3.8 controls

Ω_{LD} = 2.0m = 7.6 (UFC Table 3-4)

G_{LD} = 7.6*(1.2*(934+130) + 0.5*(934)) = 7.6*(1744 plf) = 13,254 plf

Deformation controlled actions:

Shear: Q_{UD} = 13,254 plf * 20.21' / 2 / 17.55' = 7,631 plf in wall

Capacity checks of deformation controlled actions:

Shear in Wall:

Wall shear strength ϕQ_{CE} = 1.5 (ϕv_s)
where ϕv_s = LRFD shear strength of wall taken from ANSI/AFPA SDPWS-2005 and factor 1.5 for expected strength is taken from ASCE 41-13 12.4.9.2, but note that Section 3-2.11.7.1 requires inclusion of the material specific ϕ factor whereas ASCE 41-13 uses a ϕ of 1.0.

From ANSI/AFPA SDPWS-2005 Table 4.3A:

For "Wood Structural Panels – Sheathing", 19/32 with 10d nailing at 6" at edges:

v_{wc} = 950 plf (for one side of wall)
Note that value for wind is chosen rather than seismic per UFC Ch. 7.

Since the interior walls have plywood sheathing on both sides, strength of each individual side is additive per ANSI/AFPA SDPWS-2005 4.3.3.2.

ϕ = 0.8 for LRFD per ANSI/AFPA SDPWS-2005 4.3.3
ϕv_s = 0.8 (950) (2) = 1520 plf
ϕQ_{CE} = 1.5 (ϕv_s) = 1.5 (1520) = 2280 plf

Check UFC Equation 3-13:

$\phi m Q_{CE} \geq Q_{UD}$
2280 plf (3.8) = 8,664 plf > 7,631 plf **OK**

At the edge of the removed wall segment adjacent to the building exterior, the interior load bearing wall must transfer its reaction in shear to the exterior wall for distribution to an adequate length of exterior load bearing stud wall.

Exterior Wall Check:

Q_{UD} = 7,631 plf / 2 = 3,816 plf (half of reaction distributed each direction)

From ANSI/AFPA SDPWS-2005 Table 4.3A:

Exterior sheathing plywood 19/32 with 10d nailing at 6" at edges:

v_{WC} = 950 plf
ϕv_S = 0.8 (950) = 760 plf
ϕQ_{CE} = 1.5 (760) = 1140 plf

From ASCE 41-13 Table 12-3 m = 4.7 for Gypsum Wallboard with h/b ≤ 1.0. Assuming the shear reaction is spread over a length b less than 17.55', the m factor for wood structural panels controls.

Check UFC Equation 3-13:

$\phi m Q_{CE} \geq Q_{UD}$
1140 (3.8) = 4,322 plf > 3,816 plf **OK**

For force controlled actions:

$\boldsymbol{\Omega_{LD}}$ = 2.0 (UFC Table 3-4)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*(934+130) + 0.5*(934)) = 2.0*(1744 plf) = 3,488 plf

Force controlled actions:

Shear: Q_{UF} = 3,488 plf * 20.21' / 2 / 17.55' = 2,008 plf in wall
Chord Force: Q_{UF} = 3,488 plf * 20.21^2 / (8*17.55) = 10,147 pounds

Though ASCE 41 is somewhat ambiguous on the subject, consider the chord forces to be deformation controlled actions because ASCE 41 Table 12-3 designates "Frame Components Subject to Axial Compression" as force controlled. Treating both tension and compression chords as force controlled will be conservative.

From the NDS supplement for 2x6 #2 Southern Pine:

F_t = 825 psi
F_c = 1650 psi
$F_{c\perp}$ = 565 psi
E_{min} = 580,000 psi

Chord force limit will be governed by tension capacity since compression chord is fully braced in both directions:

Adjusted reference design value $F'_t = C_M C_t C_F C_i K_F \phi_t \lambda F_t$
All adjustment values are 1.0 except:
K_F = 2.16/ϕ_t
ϕ_t = 0.80

Note λ = 1.0 for short duration loading event
F'_t = 2.16*825 = 1782 psi

ϕQ_{CL} = 1782 psi (8.25 in^2) = 14,702 pounds for (1) 2x6 > Q_{UF} = 10,147 pounds

Note that by providing adequate strength for (1) 2x6 plate to act as a chord, the pair of 2x6's may be stagger spliced via nailing without the need for a direct metal plate splice of both plates. Nailing for splices should be sized for 10,147 pounds.

Check bearing transfer of bridged load to load bearing stud walls as force controlled action.

Q_{UF} = 3,488 plf * 20.21' / 2 = 35,246 pounds

\2\ 2x6 studs at 24" on center with in-plane bracing provided by sheathing. Check as columns for out-of-plane strength at lower story./2/

Adjusted reference design value $F'_c = C_M C_t C_F C_i C_P K_F \phi_c \lambda F_c$
All adjustment values are 1.0 except:

K_F = 2.16/ϕ_c
ϕ_c = 0.90
Note λ = 1.0 for short duration loading event

C_P calculation:
F_{c*} = $K_F \phi_c \lambda F_c$ = 2.16*1650 = 3564 psi
E'_{min} = $C_M C_t C_i C_T K_F \phi_s E_{min}$
All adjustment values are 1.0 except:
K_F = 1.5/ϕ_s
ϕ_c = 0.85
E'_{min} = 580,000*1.5 = 870,000 psi
l_e = 11'-1 1/8" – 4 ½" = 10'-8 5/8"
F_{cE} = 0.822*(870,000)/ (128.625/5.5)^2 = 1308 psi (NDS 3.7.1)
F_{cE}/ F_{c*} = 1308 / 3564 = 0.367
C_p = 0.334 per NDS Equation 3.7-1

ϕQ_{CL} = 0.334(3564 psi) (8.25 in^2) = 9820 pounds per stud

ϕQ_{CL} = 9820/2' = 4910 plf

Check bearing on plates:

Adjusted reference design value $F'_{c\perp} = C_M C_t C_i C_b K_F \phi_c \lambda\ F_{c\perp}$
All adjustment values are 1.0 except:
K_F = 1.875/ϕ_s

ϕ_c = 0.9
C_b = 1.25 for 1.5” wide member (NDS Table 3.10.4)
$F'_{c\perp}$ = 1.25*1.875*565 psi = 1324 psi

ϕQ_{CL} = (1324 psi)(8.25 in^2) = 10,923 pounds per stud

ϕQ_{CL} = 10,923/2’ = 5461 plf

ϕQ_{CL} = 4910 plf controls

Required width of wall = 35,246 pounds / 4910 plf = 7’-3”

Adequate width available at external wall

Available wall pier at interior wall = 25’-11” – 20’-2 ½” = 5’-8 ½” **NG**

Note that location of the removed section of wall could shift such that the situation on the interior side is similar to that considered in Figure F-5 for the exterior side. Therefore, the reaction must be transferred by shear into the interior corridor transverse load bearing walls. The wall construction is identical so shear capacity will be adequate.

Removal of a wall segment above the 2nd floor would produce a very similar analysis and results to those described above as the load resisted is roughly proportional to the available depth of remaining wall.

Similarly, removal of an exterior load bearing wall along the short side would produce results consistent with the interior removal as the tributary area of floor carried is roughly half that of an interior wall, and the provided capacity consists of one face plywood and one face drywall, giving larger than half the capacity of the interior wall.

/2/Secondary Component Check

EIJ joists span 18’-8” and are supported by the short direction load bearing walls. Removal of a load bearing wall will result in loss of support for EIJs.

Accordingly, all EIJs must be attached to the wall above to prevent collapse in the event of a bearing wall removal. The floor joists shall be hung from the wall above using a tension tie nailed to the 2x6 wall stud above which will include a threaded tension rod bolted through the top plate of the removed wall (See Figure F-6). The top plate of the removed wall shall be assumed to be held in place due by the tension rod.

Connection of each EIJ will consist of multiple connectors so it shall be considered force controlled:

Floor loadings:
DL = 25 psf * 18.67' * 2' = 934 lbs
LL = 40 psf * 18.67' * 2' = 1494 lbs (no live load reduction due to limited tributary area for each EIJ tension tie)

$\boldsymbol{\Omega_{LD}}$ = 2.0 (UFC Table 3-4)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*DL + 0.5*LL)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*(934 lbs) + 0.5*(1494)) = 3735 lbs

The tension tie capacity must be greater than 3735 lbs. Accordingly, provide one (1) Simpson HTT5 with 26-10dx1 ½" nails into the wall stud above with a capacity of 4350 lbs.

The head plate of the wall below consists of (2) 2x6 southern pine plates.

The shear in the 2x6 head plates will be a force controlled action.

For each 2x6 head plate:
$V' = 2/3\ F_V' * A$
$F_V' = 175$ psi
$A = 8.25\ in^2$

$F_V' = C_D C_M C_t C_i K_F \phi_v \lambda F_v$

All adjustment factors 1.0 except:
$K_F = 2.16/\phi_b$
$\phi_b = 0.75$
Note λ = 1.0 for short duration loading event

F_V'= 2.16/0.75 * 0.75* 175psi = 378psi

V' = 2/3 378psi * 8.25in^2 = 2079 lbs per head plate

ϕQ_{CL} = 2079 lbs * 2 = 4158 lbs > 3735 lbs **OK**

The flexure in the 2x6 head plates will be a deformation controlled action.

From ASCE 41-13 Table 12-3:
For "frame components subject to axial tension and/or bending":
m = 2.5 for Life Safety Secondary Element

$\boldsymbol{\Omega_{LD}}$ = 2.0m = 5.0 (UFC Table 3-4)

$\boldsymbol{G_{LD}}$ = 5.0*(1.2*(934 lbs) + 0.5*(1494 lbs)) = 5.0*(1868 lbs) = 9340 lbs

Since the head plate will be part of a continuous span the maximum moment will be:

Q_{UD} = $\boldsymbol{G_{LD}}$ * L / 8 = 9340 lb * 2 ft / 8 = 2335 lb-ft

Flexural capacity of each 2x6 head plate (weak axis bending):

$M' = F_b' * S$

S_y = 2.063 in^3
F_b = 1250 psi

$F_b' = C_D C_M C_t C_L C_F C_{fu} C_i C_r K_F \phi_b \lambda F_b$

All adjustment factors 1.0 except:
C_{fu} = 1.15
K_F = 2.16/ϕ_b
ϕ_b = 0.85
Note λ = 1.0 for short duration loading event

F_b' = 1.15*2.16/0.85 * 0.85 1250 psi = 3105 psi

M' = 3105 psi * 2.063 in^3 = 6406 lb-in = 534 lb-ft
$\phi m Q_{CE} \geq Q_{UD}$

$\phi m Q_{CE}$ = 2.5 * 534 lb-ft* 2 = 2670 lb-ft > 2335 lb-ft **OK**

Since the shear and flexural capacity of both 2x6 head plates is required to support secondary members, a 3rd 2x6 head plate must be provided in order to accommodate splicing. All splices shall be staggered. See Figure F-6 for a floor joist support detail.

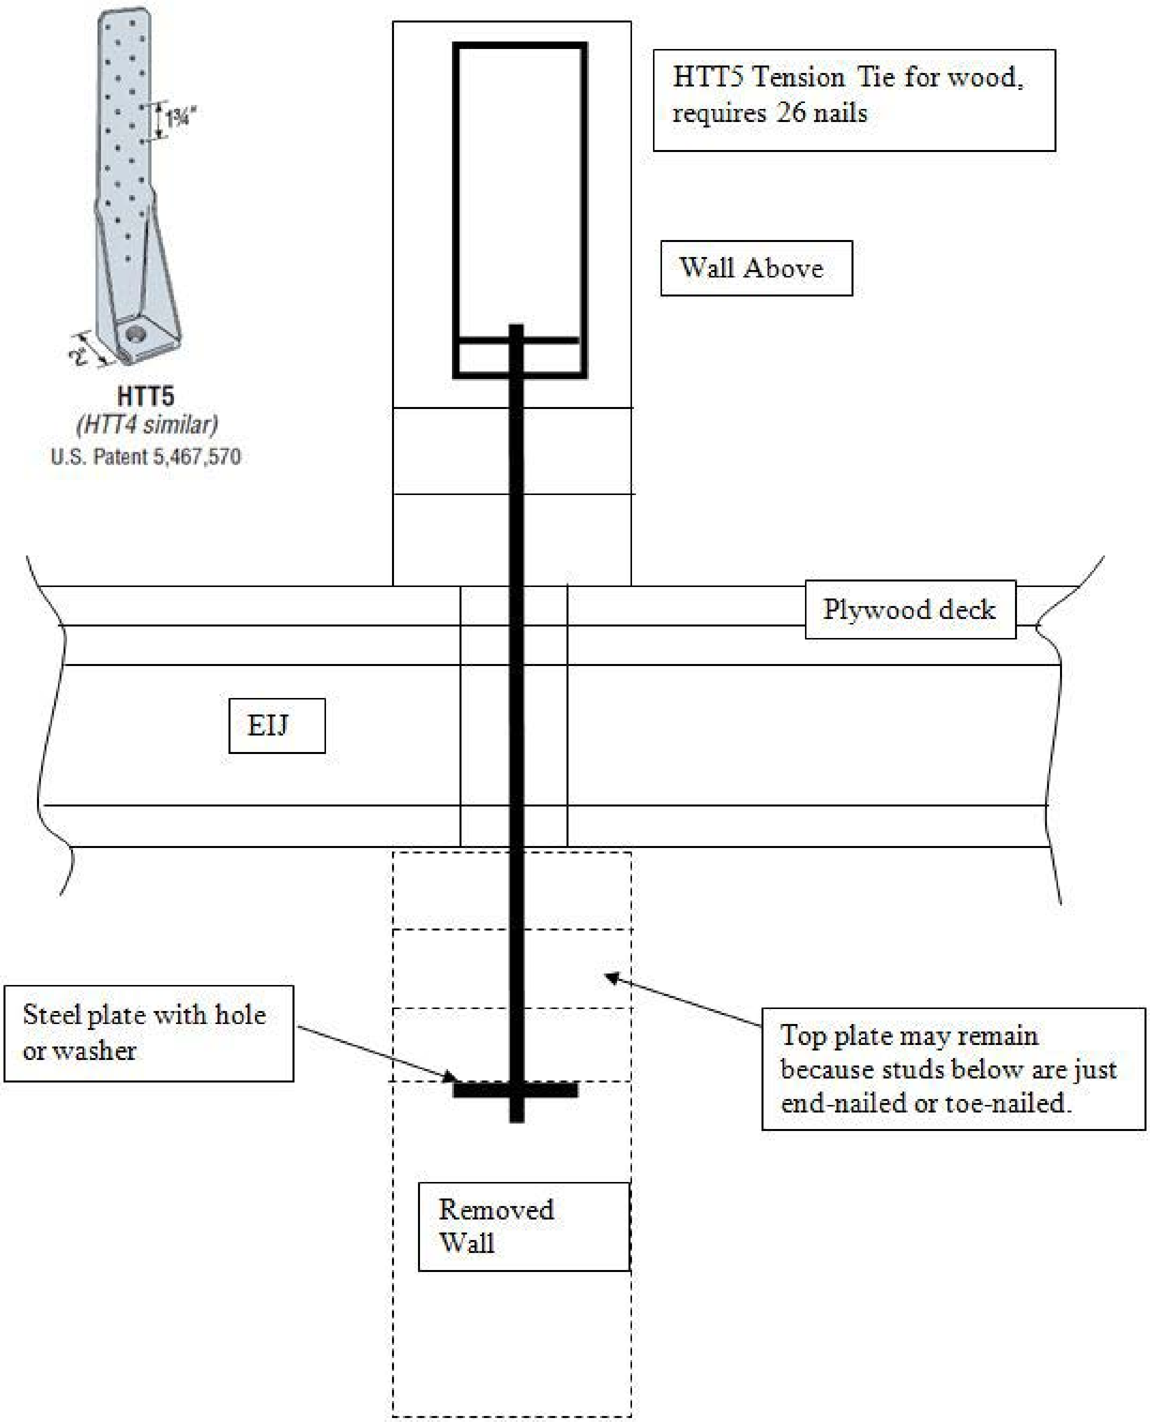

Figure F-6. Floor Joist Support Detail

/2/

F-3.3 AP Analysis of Removal of Exterior Load Bearing Walls (Long Direction)

As shown in Figure F-7, a segment of wall of length 2H is removed between the second and third floors. H is taken as the distance between the 2nd floor sub-floor elevation and the bottom of the 11-7/8" EIJ floor joists at the 3rd floor (=8'-3 1/8").

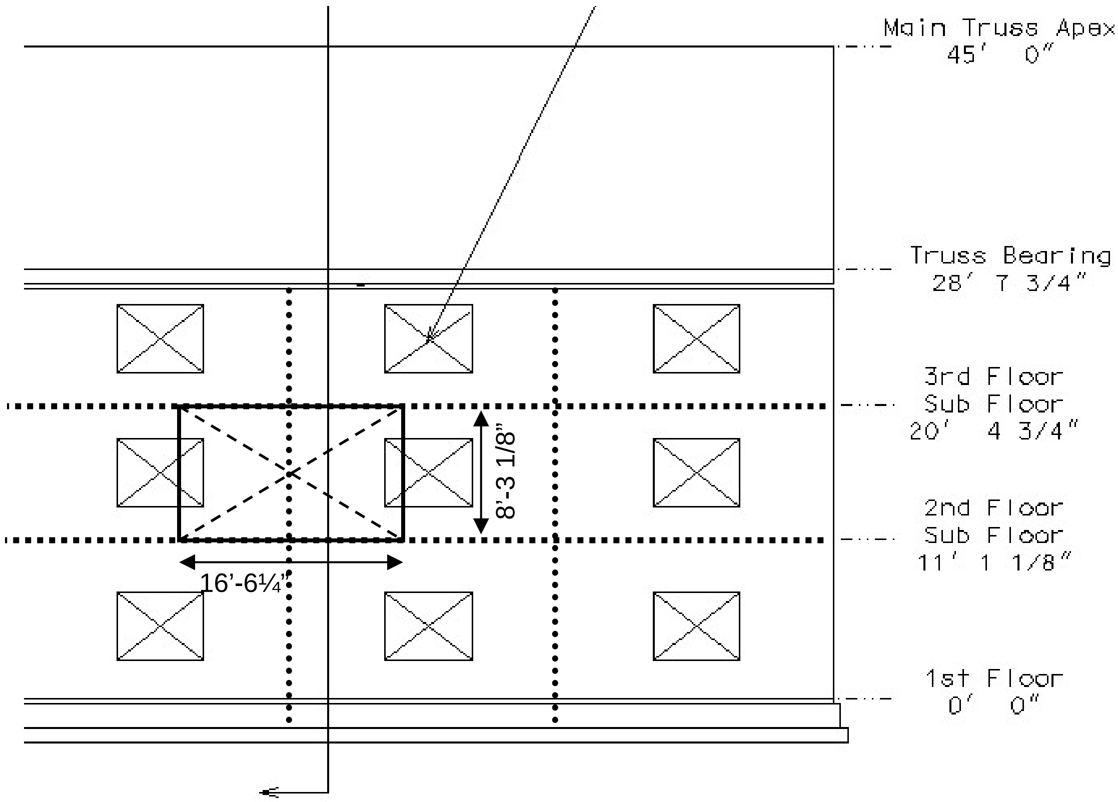

Figure F-7. Exterior Wall Removal

The chosen area of removal takes away the jamb and jack studs supporting the header of the window opening above the third floor. This header must now transfer its reaction via the remaining jack studs into the remaining wall above the 3rd floor. This remaining wall segment must then act as a cantilever from a vertical support provided by the crossing interior wall. Any unbalanced loads in the cantilever system must be resolved via drag forces in the 3rd floor and top of wall sill elements to adjacent intact wall segments. See Figure F-8.

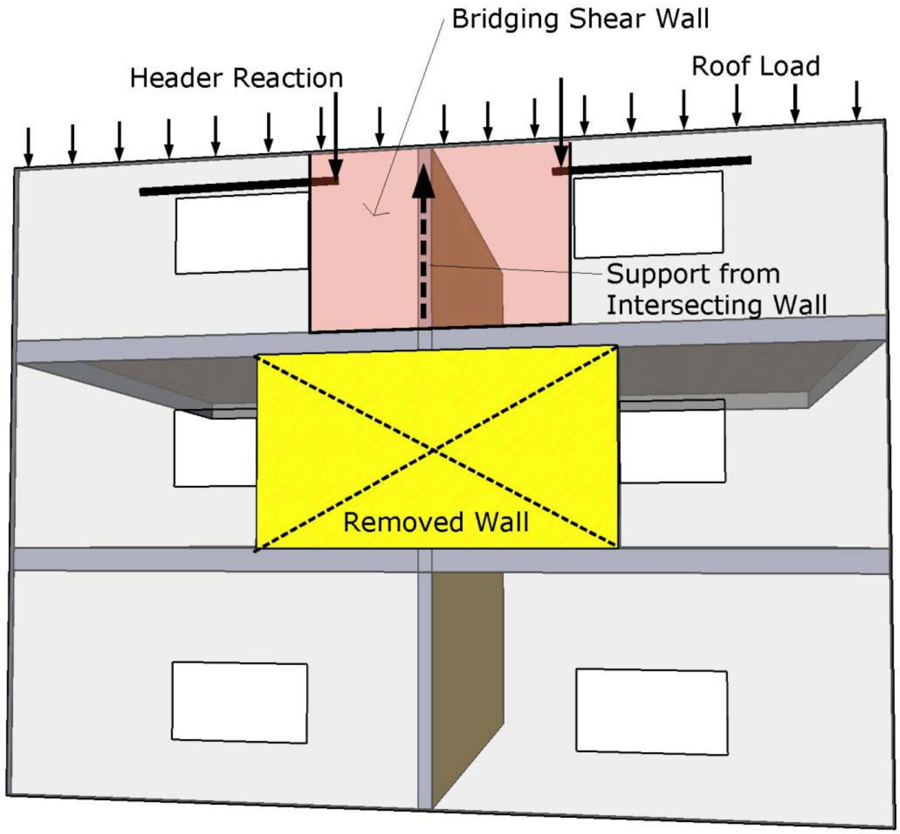

Figure F-8. Load Path for Exterior Wall Removal

The primary loading is that of the roof trusses:

Dead Load
Roof: 25 psf * 25'-11" / 2 = 324 plf
Wall: 7 psf * 8'-3" = 58 plf

Roof live load not applicable for UFC design combination

Snow Load
7 psf * 25'-11" / 2 = 91 plf

Linear Static AP Load Case for Deformation Controlled Elements:
$\boldsymbol{G_{LD} = \Omega_{LD}\ [1.2D + 0.2S]}$

From ASCE 41-13 Table 12-3:
for "Wood Structural Panel Sheathing or Siding"
h/b = 6.33/9.25 = 0.68 < 2.0
m = 3.8 for Life Safety Primary Element
m = 4.7 for Gypsum Wallboard with h/b ≤ 1.0 at interior face

Assume all connections to be nailed:
m = 6.0 for “Nails – Wood to Wood”
m = 4.0 for “Nails – Wood to Metal”

m = 3.8 controls

$\boldsymbol{\Omega_{LD}}$ = 2.0m = 7.6 (UFC Table 3-4)

$\boldsymbol{G_{LD}}$ = 7.6*(1.2*(324+58) + 0.2*(91)) = 7.6*(477 plf) = 3,622 plf

Header reaction = 3622 plf * 6’ / 2 = 10,866 pounds

Total shear in wall segment at intersection with interior wall
= 10,866 + 3622*(6’-4”) = 33,793 pounds

Unit shear = 33,793 / 8’-3” = 3528 plf

Wall strength ϕQ_{CE} = 1140 plf (established in wall analysis F-3.2)

Check UFC Equation 3-13:

$\phi m Q_{CE} \geq Q_{UD}$
1140 (3.8) = 4332 plf > 3,528 plf **OK**

For force controlled actions:

$\boldsymbol{\Omega_{LD}}$ = 2.0 (UFC Table 3-4)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*(324+58) + 0.2*(91)) = 2.0*(477 plf) = 954 plf

Header reaction = 954 plf * 6’ / 2 = 2,862 pounds

Chord force = [2862*6 + 954*$(6.33)^2$ / 2] / 8.25’ = 3,498 pounds = Q_{UF}

Chord tension ϕQ_{CL} = 14,702 pounds for (1) 2x6 (established in analysis F-3.2)

Total available strength = 14,702*2 = 29,404 pounds > 3,498 pounds OK

\2\The cantilever walls sections are to be supported by the interior load bearing wall that is perpendicular to cantilever wall sections.

Shear reaction from each side of the cantilever = 33,793 lbs
Total shear reaction from 2 cantilevers = 2*33793 lbs = 67,586 lbs

Interior load bearing shear walls with plywood at each side continue through the exterior wall to the exterior face of the building (see Figure F-1).

The exterior plywood sheathing of the long direction exterior walls must be nailed into the end 2x6's of the interior load bearing walls to allow for shear transfer. To carry the shear load from each side of the interior wall, two rows of 10d nails @6" will be required from the exterior sheathing into the end 2x6's.

Cantilever wall reaction then carried by shear in interior load bearing wall (between 3rd floor and truss bearing).

Interior load bearing wall has plywood sheathing on both sides.

ϕv_s = 0.8 * 2 * (950) = 1520 plf
ϕQ_{CE} = 1.5 (1520) = 2280 plf

8'-3" wall height for interior load bearing wall

Q_{UD} = 67,586 lbs / 8.25 ft = 8192 plf
$m\phi Q_{CE}$ = (3.8 * 2280 plf) = 8664 plf > 8192 plf **OK**

The interior wall below the 3rd floor supports the shear wall with compression in wall studs. Compression in studs is a force controlled action.

For force controlled actions:

$\boldsymbol{\Omega_{LD}}$ = 2.0 (UFC Table 3-4)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*(324+58) + 0.2*(91)) = 954 plf

Header reaction = 6 ft / 2 * 954 lb/ft = 2862 lbs

Reaction onto interior wall for each side:

954 plf * (6.33 ft) + 2862 lbs = 8900 lbs
Total reaction (from both sides) = 2 * 8900 lbs = 17,800 lbs (from exterior walls)

Bearing on interior wall studs (lowest level) will also include floor loading from 2 floors (18'-8" floor span)

DL = 25 psf each floor
Reduced LL = 40 psf (1-0.375) = 25 psf each floor

DL = 2 floors * 25 psf * 18.67 ft = 934 plf
LL = 2 floors * 25 psf * 18.67 ft = 934 plf

G_{LF} = 2.0*(1.2*(934) + 0.5*(934)) = 1587 plf

G_{LF} = 1587 plf * 2 ft stud spacing = 3174 lbs / stud

Bearing on interior wall (lower story) carried by 2x6 studs at 2’ on center with in-plane bracing provided by sheathing. Check as column for out-of-plane strength of lower story

Per F-3.2 Stud strength is 9820 lbs / stud

9820 lb / stud – 3174 lb / stud = 6646 lbs available per stud

17,800 lbs / 6646 lbs = 2.7 studs

3 studs available within 4 feet of interior wall **OK**

F-3.4 AP Analysis of Removal of Exterior Load Bearing Walls (Long Direction, Alternate Location)

As shown in Figure F-9, a segment of wall of length 2H is removed between the second and third floors. H is taken as the distance between the 2^{nd} floor sub-floor elevation and the bottom of the 11-7/8” EIJ floor joists at the 3^{rd} floor (=8’-3 1/8”).

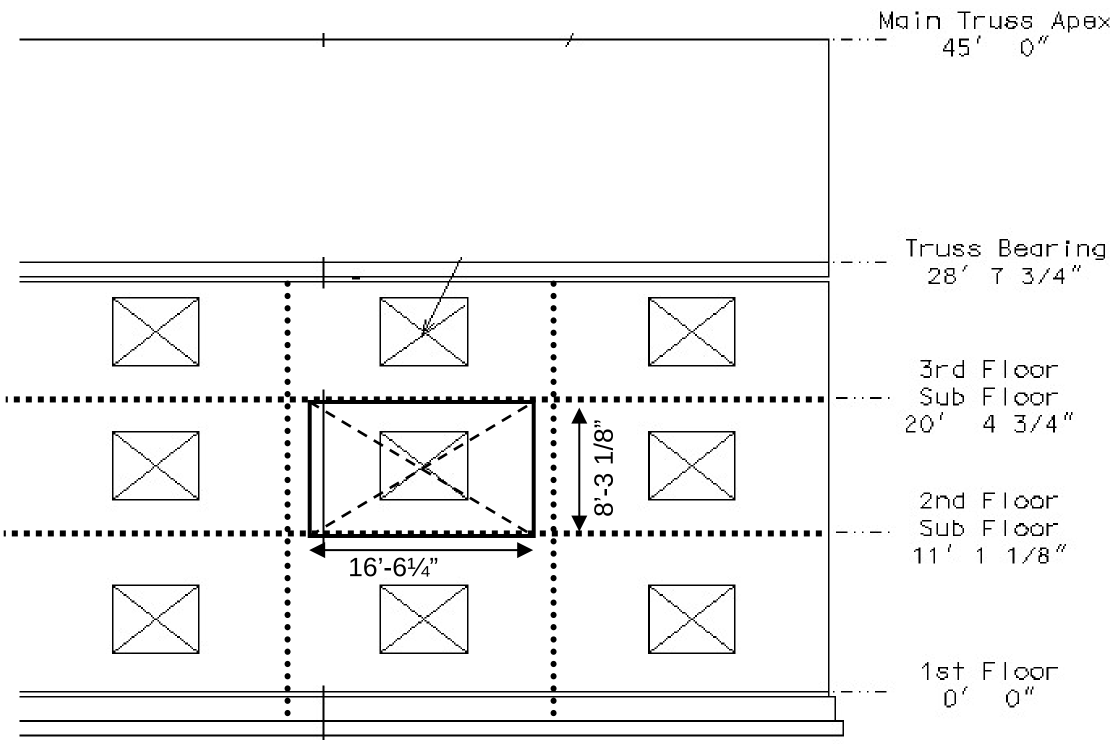

Figure F-9. Exterior Wall Removal

The chosen area of removal between the second and the third floor will allow for the shear wall above to span over and be supported on each side of the removed wall section. (Note, shifted removal locations could be addressed similar to F-3.3, however they will be less critical because additional cantilever shear wall sections could be engaged).

The primary loading is that of the roof trusses:

Dead Load
Roof: 25 psf * 25'-11" / 2 = 324 plf
Wall (including glazing): 7 psf * 8'-3" = 58 plf

Roof live load not applicable for UFC design combination

Snow Load
7 psf * 25'-11" / 2 = 91 plf

Linear Static AP Load Case for Deformation Controlled Elements:

$\boldsymbol{G_{LD} = \Omega_{LD} [1.2D + 0.2S]}$

From ASCE 41-13 Table 12-3:

for "Wood Structural Panel Sheathing or Siding"
h/b = 8.25/9.25 = 0.89 < 2.0
m = 3.8 for Life Safety Primary Element

m = 4.7 for Gypsum Wallboard with h/b ≤ 1.0 at interior face

Assume all connections to be nailed:
m = 6.0 for "Nails – Wood to Wood"
m = 4.0 for "Nails – Wood to Metal"

m = 3.8 controls

$\boldsymbol{\Omega_{LD}}$ = 2.0m = 7.6 (UFC Table 3-4)

$\boldsymbol{G_{LD}}$ = 7.6*(1.2*(324+58) + 0.2*(91)) = 7.6*(477 plf) = 3,622 plf

Total force onto the removed section
F = 3622 lb/ft * 16.5 ft = 59,763 lbs

Shear each side V = 59,763 lbs / 2 = 29,882 lbs

Unit shear = 29,882 lbs / 9.25' = 3230 plf

Wall strength ϕQ_{CE} = 1860 plf (established in wall analysis F-3.2)

Check UFC Equation 3-13:

$\phi m Q_{CE} \geq Q_{UD}$
1860 (3.8) = 7,068 plf > 3,230 plf **OK**

For force controlled actions:

$\boldsymbol{\Omega_{LD}}$ = 2.0 (UFC Table 3-4)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*(324+58) + 0.2*(91)) = 2.0*(477 plf) = 954 plf

Wall moment = $\boldsymbol{G_{LF}} * L^2 / 8$ = 954 plf * $(16.5')^2$ / 8 = 32,466 lb-ft

Chord force limit will be governed by tension strength since compression chord is fully braced in both directions

Chord force = M/d = [32,466 lb-ft] / 9.25' = 3,510 pounds = Q_{UF}

Chord tension ϕQ_{CL} = 14,702 pounds for (1) 2x6 (established in analysis F-3.2)

Total available capacity = 14,702*2 = 29,404 pounds > 3,923 pounds OK

End reactions of spanning wall will be carried by studs in compression between the 1st and 2nd floor. Compression of studs will be force controlled.

G_{LF} = 954 plf + additional wall load carried by each stud to the foundation

h = 28'-8" = 28.67' stud spacing = 2 ft wall DL = 7 psf

Additional wall load = 954 plf + 2.0 * (0.5* 7 psf * 28.67') = 201 lbs/ft

Q_{UD} = 954 lbs/ft * 0.5 * 16.5 feet + 201 lbs/ft * 2 ft = 8273 lbs/stud

Compression carried by 2x6 studs at 2' on center with in-plane bracing provided by sheathing and blocking. Check as column for out-of-plane capacity of lower story

Per F-3.2 Stud capacity is 9820 lbs / stud > 8273 lbs /stud **OK**

F-3.5 AP Analysis of Removal of Exterior Load Bearing Walls Below Third Floor (Long Direction)

As shown in Figure F-10, a segment of wall of length H is removed at exterior corners in each direction between the second and third floors. H is taken as the distance between the 3rd floor sub-floor elevation and the truss bearing location (=8'-3").

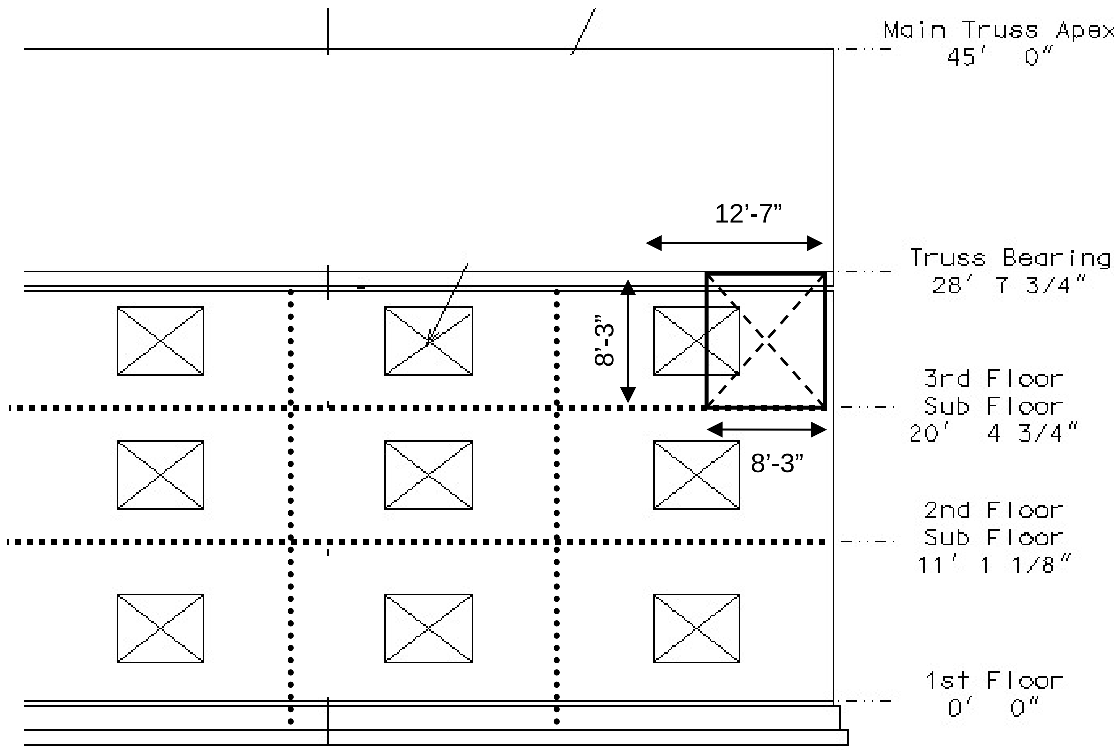

Figure F-10. Exterior Corner Wall Removal

The primary loading is that of the roof trusses:

Dead Load
Roof: 25 psf * 25'-11" / 2 = 324 plf

Roof live load not applicable for UFC design combination

Snow Load
7 psf * 25'-11" / 2 = 91 plf

Linear Static AP Load Case for Deformation Controlled Elements:
$\boldsymbol{G_{LD} = \Omega_{LD}\,[1.2D + 0.2S]}$

From ASCE 41-13 Table 12-3:
for "Frame Components Subjected to Axial Tension and/or Bending"
m = 2.5 for Life Safety Primary Element

Connections to include:
m = 6.0 for "Nails – Wood to Wood"

m = 2.8 for "Machine Bolts – Metal to Wood"

m = 2.5 controls

$\boldsymbol{\Omega_{LD}}$ = 2.0m = 5.0 (UFC Table 3-4)

$\boldsymbol{G_{LD}}$ = 5.0*(1.2*(324) + 0.2*(91)) = 5.0*(407 plf) = 2,035 plf

Provide new glulam beams at truss level, as shown in Figure F-11, to provide capacity for corner cantilever

Cantilever span = L = 12'-7"

Q_{UD} = $\boldsymbol{G_{LD}}$ * L^2 / 2 = 2,035 plf * $(12.6 \text{ ft})^2$ / 2 = 161,539 lb-ft

Try glulam 24F-V5 Southern Pine

ANSI/AFPA SDPWS-2005

Fb = 2400 psi

Volume factor Cv = $[(21 / L_o)^{(1/20)} * (12 / d)^{(1/20)} * (5.125 / b)^{(1/20)}] \leq 1$]
L_o = 2 * L for cantilever = 25.2 ft
Width = b = 3"
Depth = d = 12.375"

C_v = $[(21 / 12.6)^{(1/20)} * (12 / 12.375)^{(1/20)} * (5.125 / 3)^{(1/20)}] \leq 1]$
C_v = 1

S = $b*d^2/ 6 = 76.6 \text{ in}^3$

C_L = $(1 + Fbe/Fb) / 1.9 – \text{sqrt} (((1+ Fbe/Fb) / 1.9)^2 – (Fbe/Fb) / 0.95)$

Rb = $\text{sqrt} (Le * d / b^2)$

Beam supported against lateral and rotational displacement by nailing at each truss bearing post at 48" on center.

Lu = 48"
Le = 1.33 * Lu (uniformly distributed load on cantilever) = 63.8"

Rb = $\text{sqrt} (63.8 * 12.375 / 3^2)$

FbE = $1.2 \text{ Emin} / Rb^2 = 1.2 * 0.78 * 10^6 * (1.5/0.85) / 9.37 = 18817$
Fbe/Fb = 18817 / 2400 = 7.84

C_L = (1 + Fbe/Fb) / 1.9 – sqrt (((1+ Fbe/Fb) / 1.9)^2 – (Fbe/Fb) / 0.95)
C_L = (1 + 7.84) / 1.9 – sqrt (((1+ 7.84) / 1.9)^2 – (7.84) / 0.95) = 0.99

Lesser of C_L or C_v shall apply, C_L = 0.99

F'b = C_L C_{fu} K_f Φ_b λ Fb

All factors 1 except:
C_L = 0.99
Φ = 0.85
K_f = 2.16 / Φ
λ = 1 per UFC

ϕF'b = 0.99 * 2.16 * 2400 psi = 5146.7 psi

ϕQ_{CE} = M' = ϕF'b * S = 5146.7 psi * 76.6 in^3 = 394,084 lb-in = 32,840.3 lb-ft

$\phi m Q_{CE} \geq Q_{UD}$

$\phi m Q_{CE}$ = 32,840.3 lb-ft * 2.5 = 82,100.8 lb-ft
Q_{UD} = 161,539 lb-ft

Q_{UD} / $\phi m Q_{CE}$ = 1.97 therefore require two (2) 24F-V5 Southern Pine 12.375" x 3" beams

Provide one (1) 24F-V5 Southern Pine 12.375" x 3" beam at each side of roof truss vertical bearing post. Stagger the splice of these beams and provide a third identical beam between vertical truss posts at splice location.

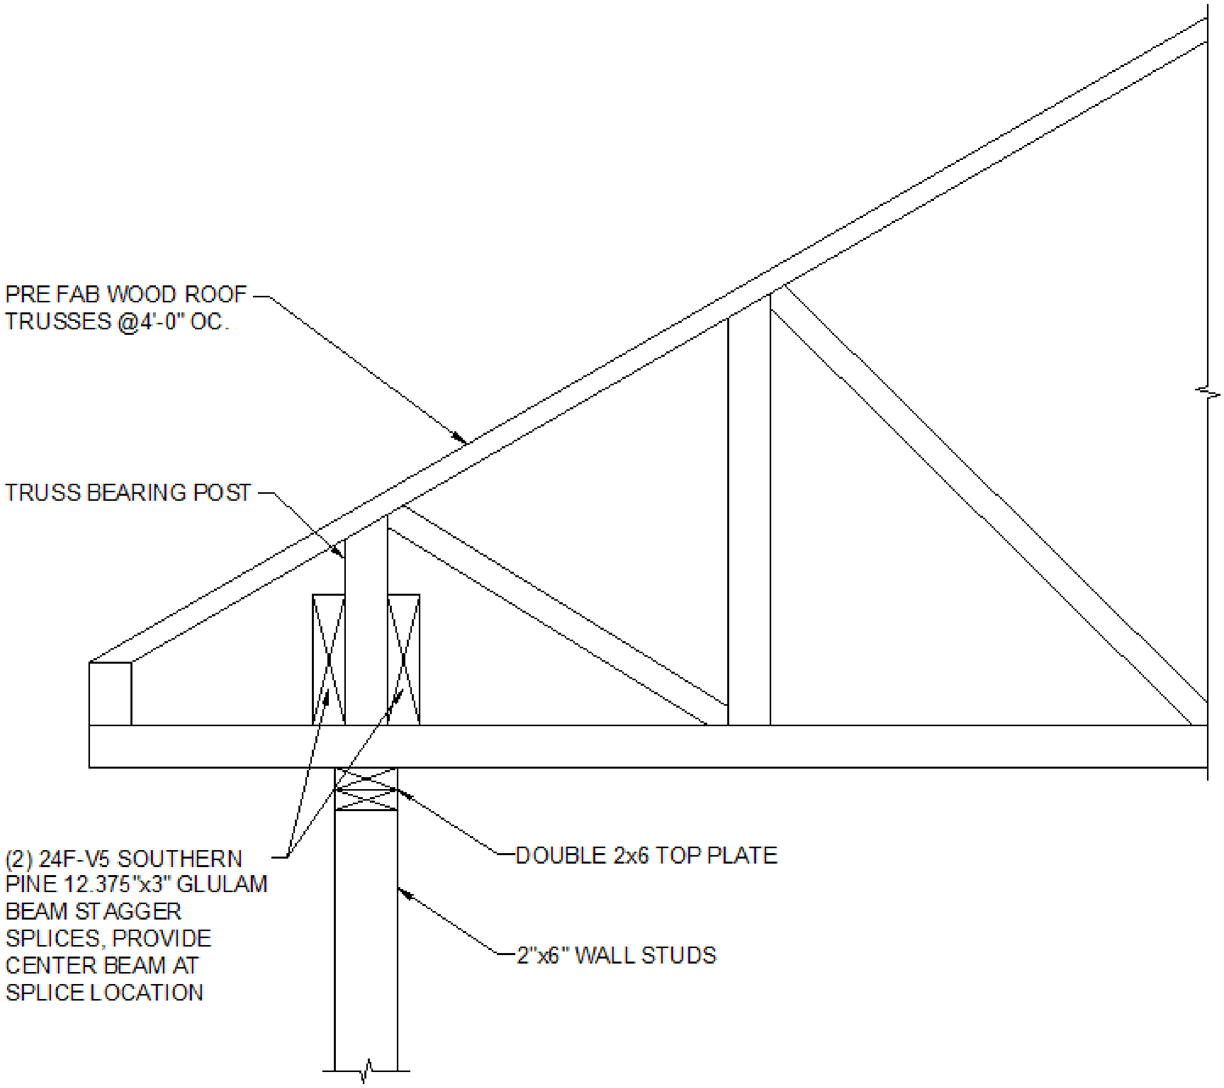

Figure F-11. Exterior Roof Beams

Anchorage of beams required to prevent uplift of the cantilever backspan. Nail Glulam to truss posts, and utilize hold-down anchors, such as Simpson HD9B at each side of truss post to resist uplift.

Two tie downs shall be used so in accordance with ASCE 41-13 section 12.3.3:
“demands on nails, screws, lags, bolts, split rings and shear plates used to link wood components to other wood or metal components shall be considered deformation controlled actions. Demands on bodies of connections and bodies of connection hardware shall be considered force controlled actions”

Accordingly, since 2 tie downs will be used, the action shall be considered force controlled.

$\boldsymbol{\Omega_{LD}}$ = 2.0 (UFC Table 3-4)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*(324) + 0.2*(91)) = 2.0*(407 plf) = 814 plf

Cantilever moment = $\boldsymbol{G_{LF}}$ * L^2 / 2 = 814 plf * $(12.6\text{ ft})^2$ / 2 = 64615.3 lb-ft
Backspan distance = 11'-5" = 11.4 ft
Uplift reaction = 64615.3 lb-ft / 11.4ft = 5668.8 lbs

Based on bolting into (2) 2x6 wall headers:
Capacity of Simpson HD9B = 7740 lbs

A single anchor would suffice; however provide 2 anchors to prevent connection eccentricity.

See Figure F-12 for tie down regions and Figure F-13 for anchorage configuration.

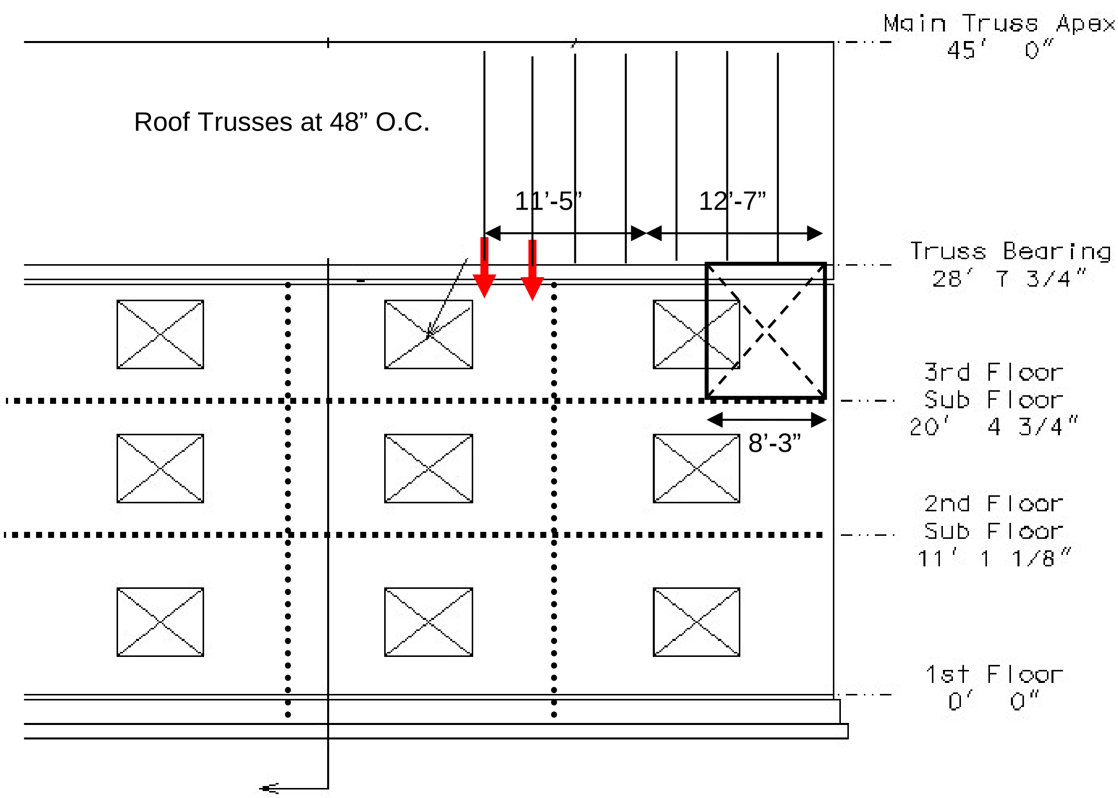

Figure F-12. Exterior Corner Wall Removal Tie Down Locations

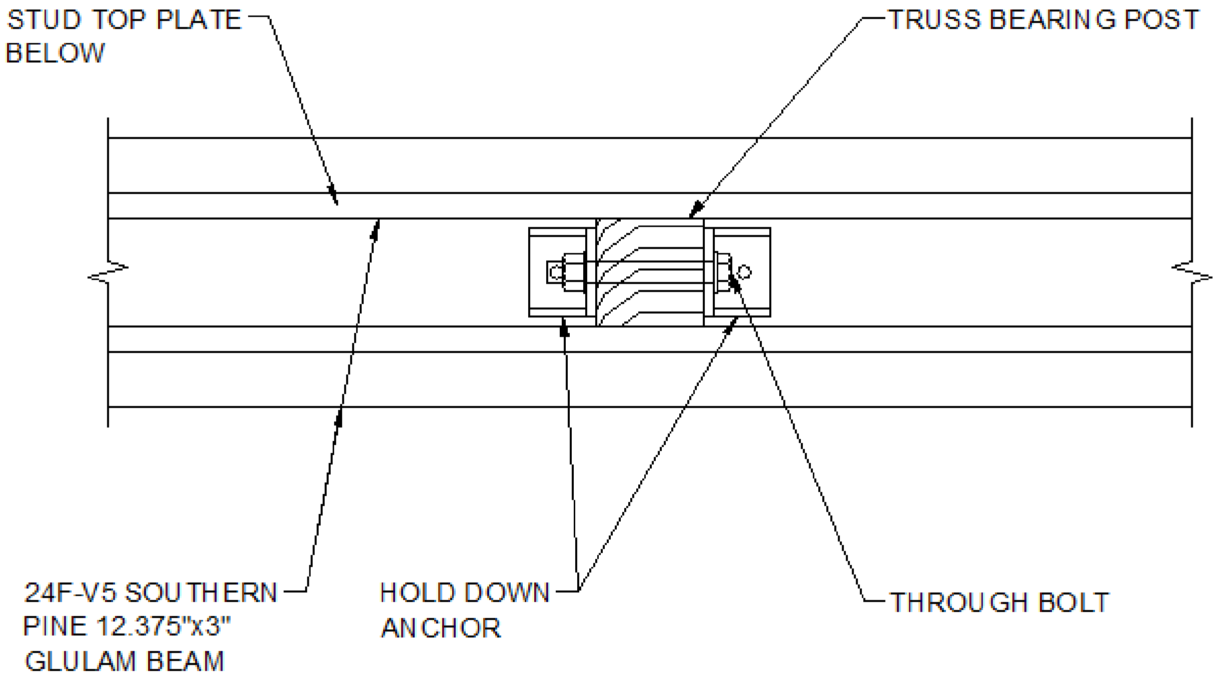

Figure F-13. Roof Beam Tie Down Anchorage, Plan View

For a stud bearing to support bridging, beam shall be force-controlled:

Stud compression in lowest level: QUF = G_{LF} * L + Uplift reaction + additional wall load

Additional wall load carried by each stud to the foundation

h = 28’-8” = 28.67’ stud spacing = 2 ft wall DL = 7 psf

Additional wall load = 2.0 * (0.5* 7 psf * 28.67’) = 201 lbs / ft * 2 ft = 402 lbs

Q_{UF} = 814 lb/ft * 12.6 ft + 5669 lbs + 402 lbs = 16,328 lbs

Compression carried by 2x6 studs at 2’ on center with in-plane bracing provided by sheathing and blocking. Check as column for out-of-plane strength of lower story

Per F-3.2 Stud strength is 9820 lbs / stud

16,328 lbs / 9,820 = 1.7 studs

2 studs available at each window jamb **OK**

/2/

Change 2

APPENDIX G COLD FORMED STEEL EXAMPLE

G-1 INTRODUCTION

A cold formed steel load-bearing wall structure example has been prepared to illustrate Alternate Path analysis of a cold formed steel structure. The structure is assumed to have an occupancy of less than 100 people and is classified as \3\ Risk Category /3/ II per UFC 3-301-01.

The example has been prepared using tools and techniques commonly applied by structural engineering firms in the US. For cold formed design, this example relies primarily upon hand analysis supplemented with publically available AISIWIN software and standard design tables published in the International Building Code. \3\ Risk Category /3/ II Option 2: Alternate Path has been selected from UFC Table 2-2 to evaluate resistance to progressive collapse.

G-2 BASELINE DESIGN

The example building is a 3-story cold formed steel structure, six bays long and two bays deep similar to the building considered in the Appendix F wood example. The relevant design information is shown in Figures G-1 through G-4.

Platform construction is used. The internal and end shear walls are load bearing, with a composite deck running in the direction of the long length of the structure. One 4.5-foot x 6-foot window opening is present in each room. The footings are reinforced concrete with masonry. There are no internal partition walls.

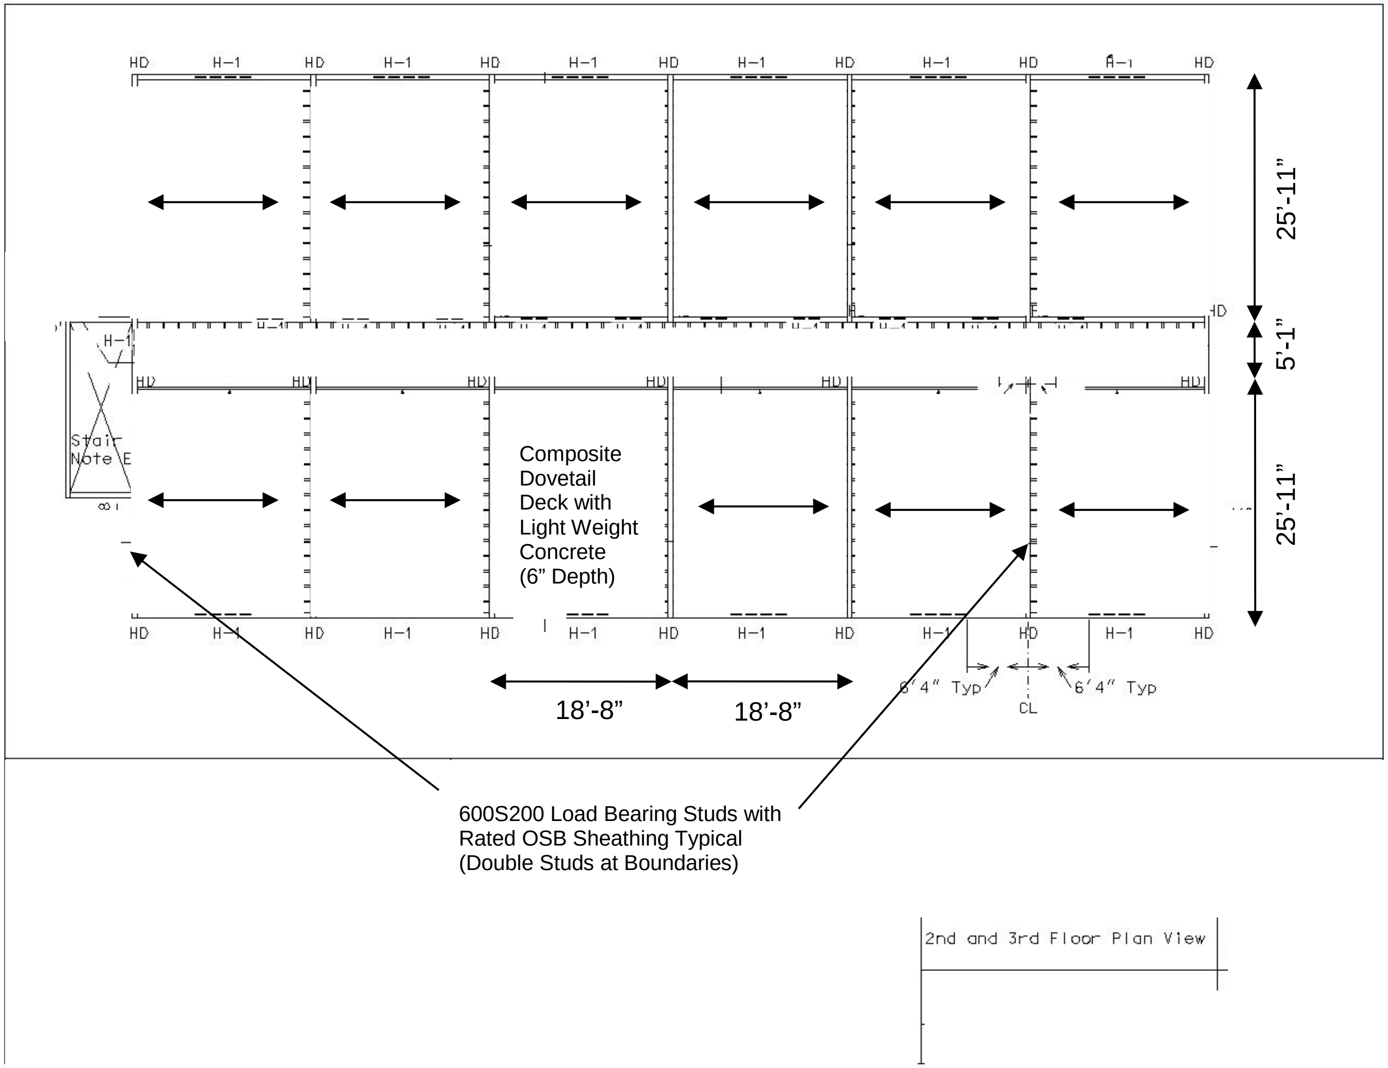

Figure G-1. Cold Formed Building Example Plan

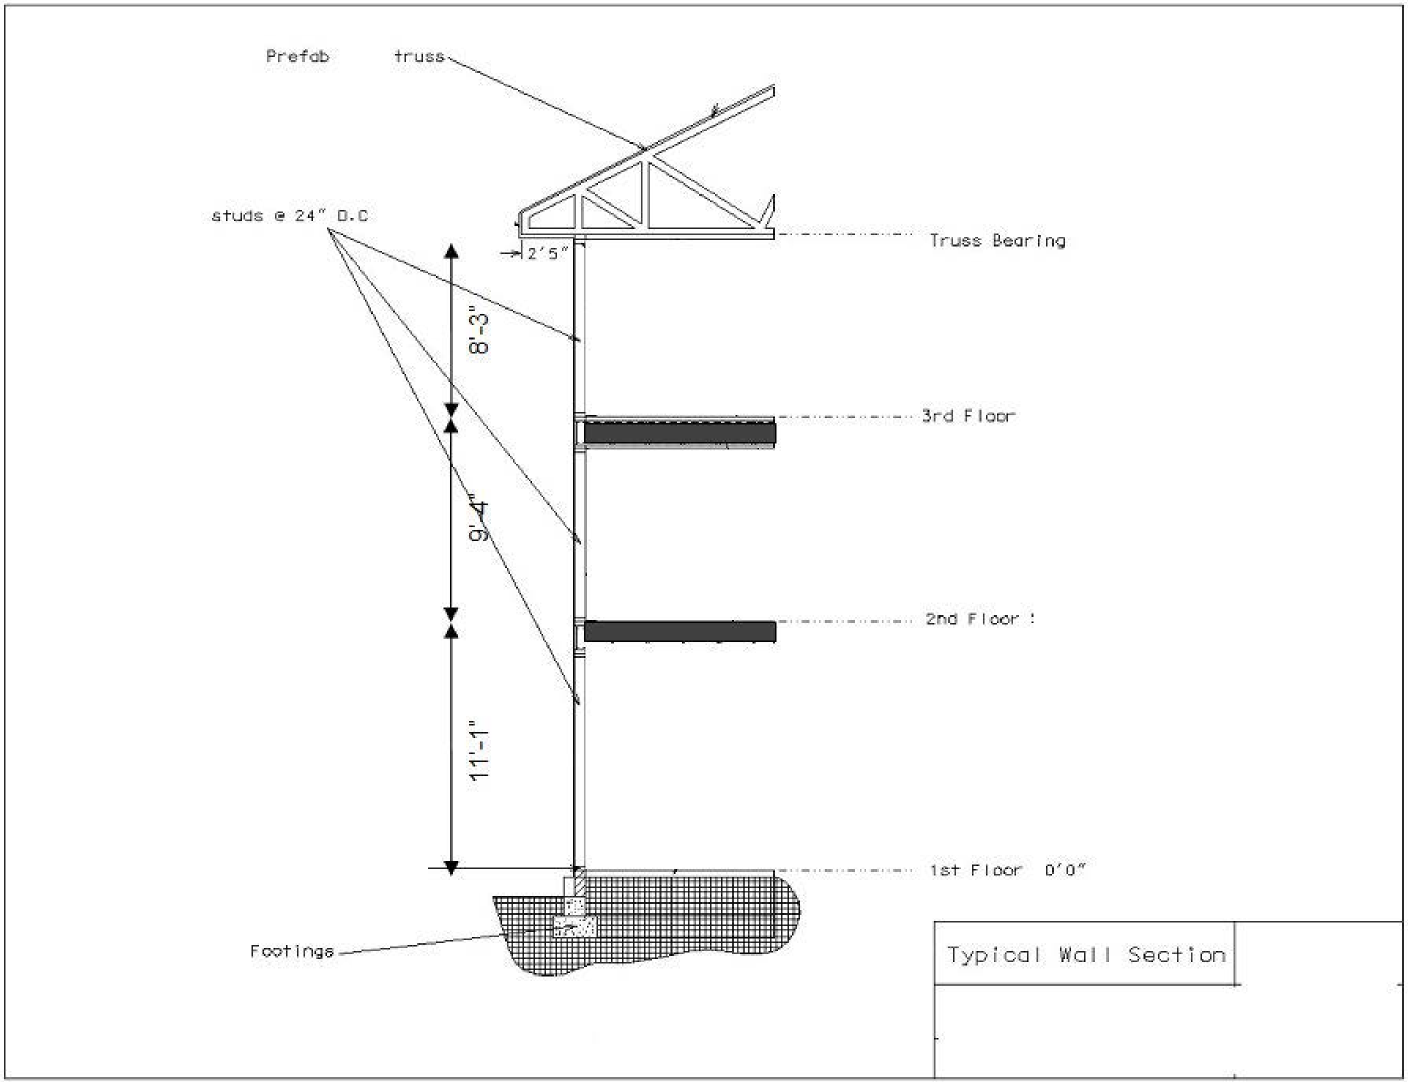

Figure G-2. Cold Formed Example Wall Section

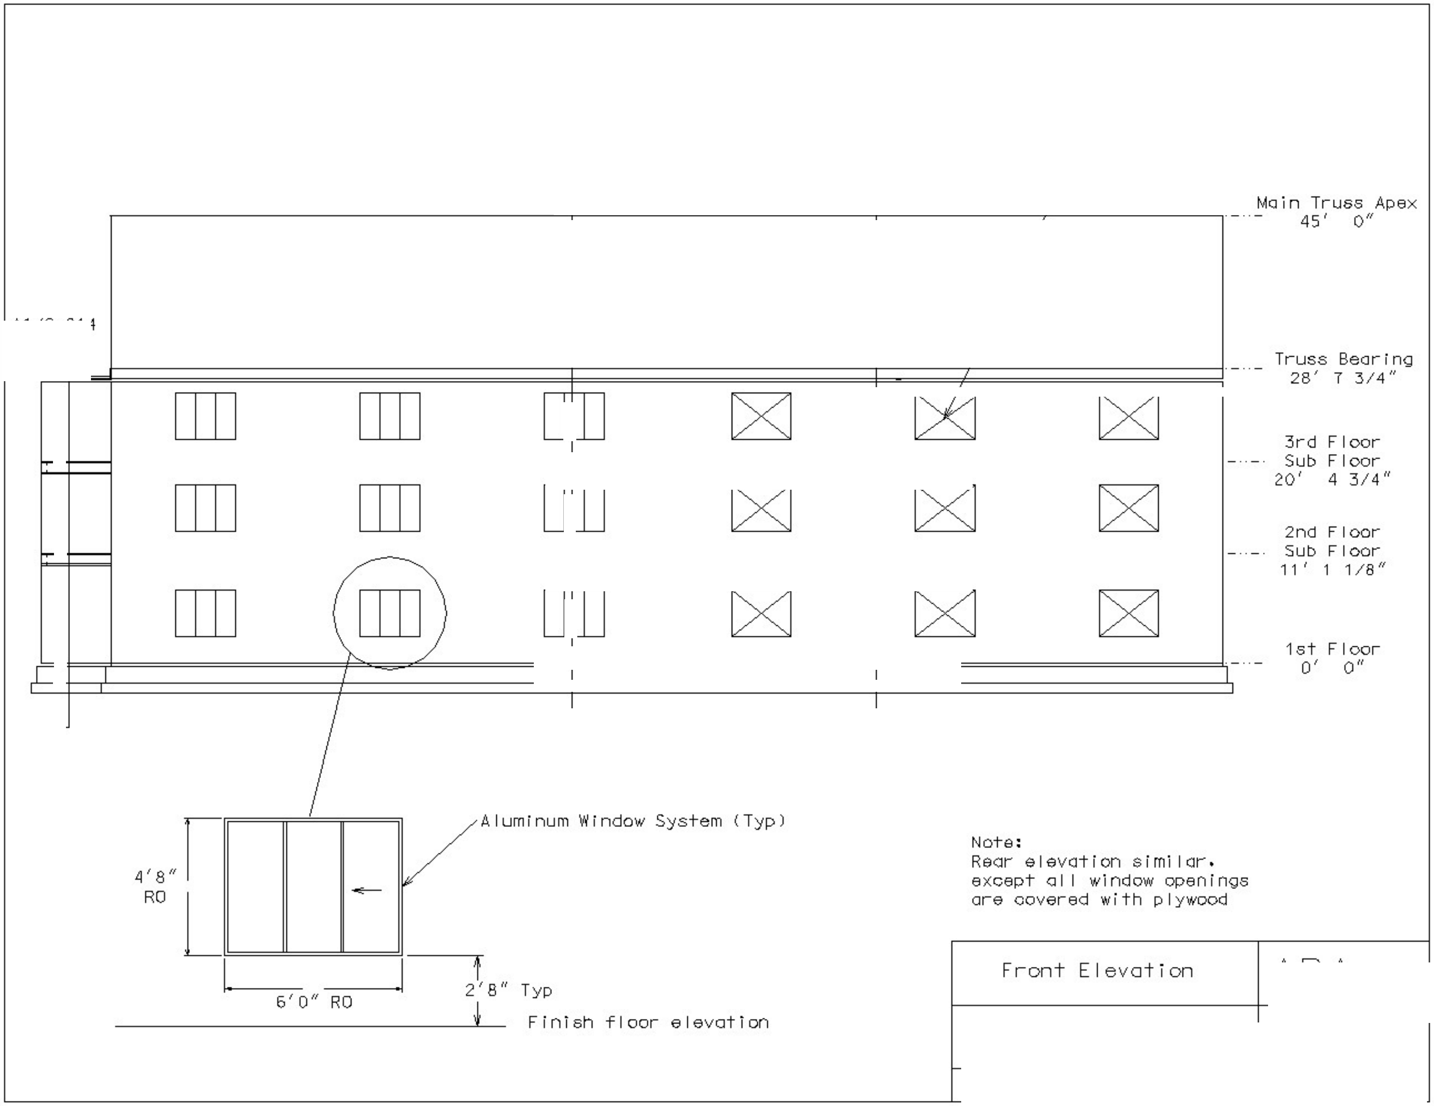

Figure G-3. Cold Formed Example Exterior Wall Elevation

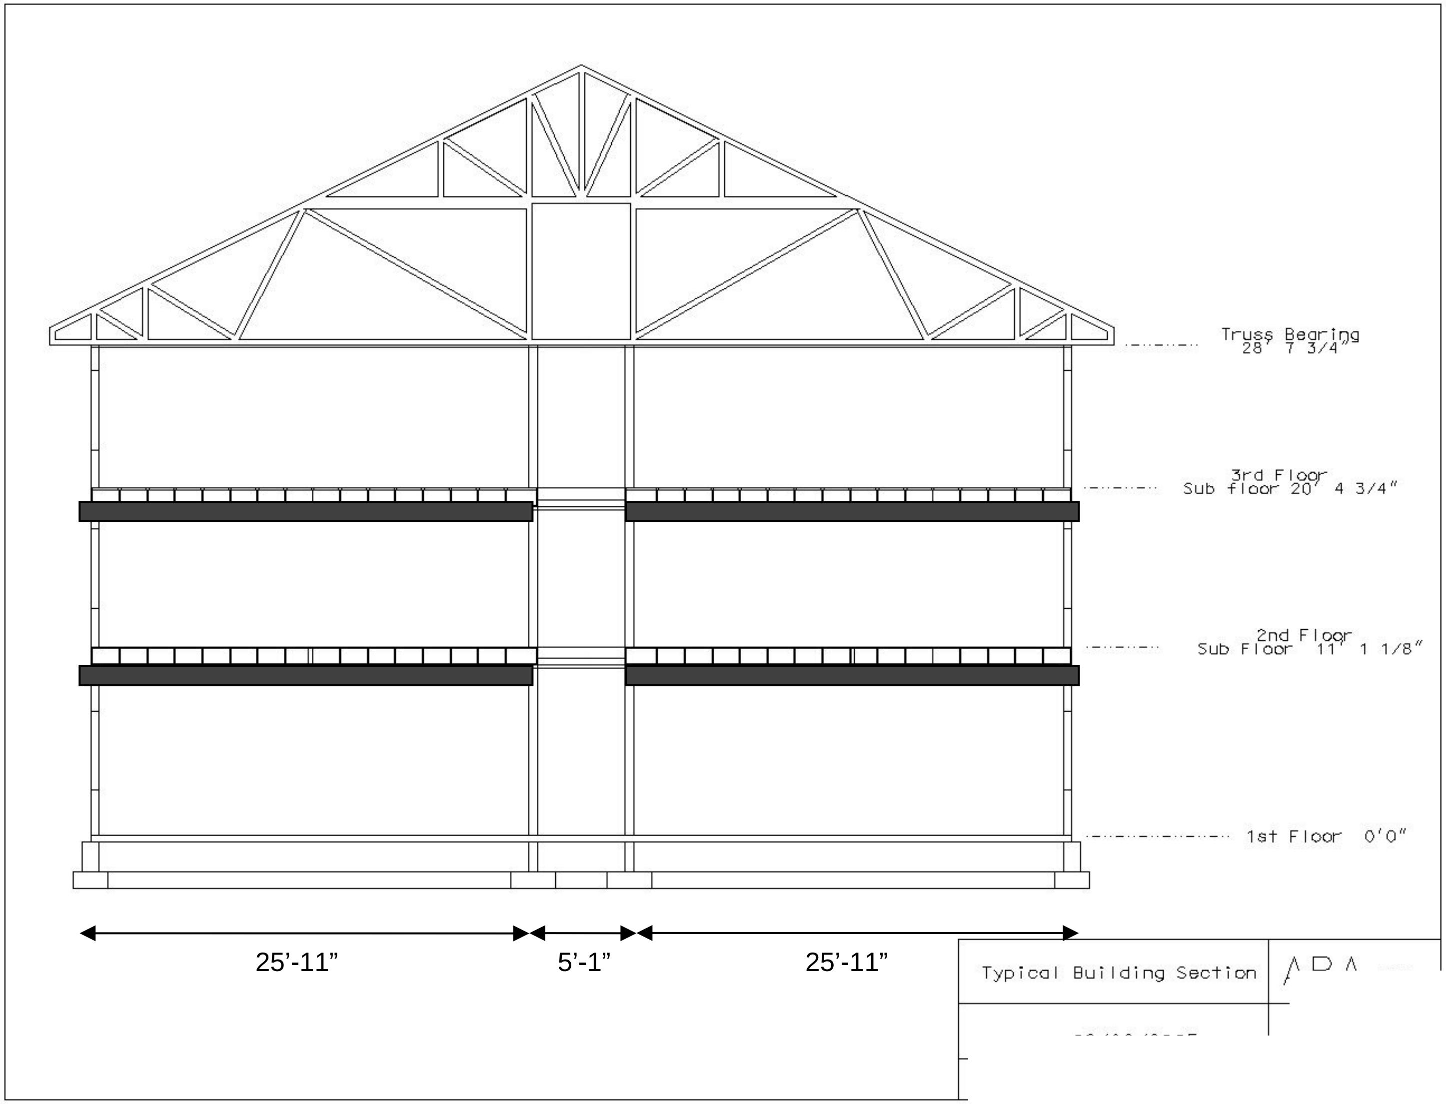

Figure G-4. Cold Formed Example Building Section

G-2.1 Construction and Materials

Wall Construction:
Interior Walls and Exterior End Walls: 7/16” rated OSB Sheathing both Faces, blocked
600S200-68 Gr50 studs at 24 inches on center
(2) 600S200-68 Gr50 studs stitched together at wall ends

Exterior Long Direction Walls: 7/16” rated OSB Sheathing exterior face, blocked
600S200-54 Gr50 studs at 24 inches on center
(2) 600S200-68 Gr50 studs stitched together at wall ends

Floor Construction:
Composite dovetail deck with light weight concrete (6” total depth) such as CSI Versa Deck or Vulcraft VLI.

Roof Construction:
Engineered Trusses with ½” Plywood Sheathing

Material Grades:
A653 Grade 50 cold formed steel

G-2.2 Loading Assumptions

Typical loading relevant to AP Analysis:

Floors:
Dead Load: 62 psf including concrete filled deck, MEP, ceiling
Live Load: 40 psf

Roof:
Dead Load: 25 psf including roofing and bottom surface ceiling
Live Load: 20 psf
Snow Load: 7 psf (design, including all applicable ASCE 7-05 factors)

Walls:
Dead Load: 7 psf including sills and headers

Live loads reducible depending on tributary area considered.

G-2.3 Relevant Standards and Reference Documents

American Iron and Steel Institute (AISI) North American Specification for Design of Cold-Formed Steel Structural Members

International Building Code 2006

For design compatibility with UFC 4-023-03, the LRFD approach is followed.

G-3 ALTERNATE PATH ANALYSIS

An alternate path (AP) analysis is conducted according to the requirements of Section 3-2. Removal scenarios are defined by 3-2.9. To bridge the wall removals, the remaining load bearing walls will be utilized as shear wall elements. The linear static AP analysis method will be followed.

G-3.1 Scope and Analysis Assumptions

Three scenarios of wall removal will be evaluated:

1. Removal of interior load-bearing wall (see Figure G-5) at first story
2. Removal of exterior long walls (see Figure G-6) at second story
3. Removal of exterior long walls (see Figure G-7) at third story

General assumptions of the analysis are as follows:

- No wind or internal pressure acts on interior or exterior walls during wall removal scenario
- Contributions of engineered roof trusses to the alternate path capacity are neglected due to uncertainty in specific properties during the design phase. At the designer's option, these elements could be included, provided that appropriate performance specifications including AP requirements are incorporated into the contract documents.

Per ASCE 41-13
C12.2.2.5:
"Actions associated with wood and light metal framing components generally are deformation controlled, and expected strength material properties will be used most often."

12.3.3:
"Demands on connectors, including nails, screws, lags, bolts, split rings, and shear plates used to link wood components to other wood or metal components shall be considered deformation controlled actions. Demands on bodies of connections, and bodies of connection hardware, shall be considered force-controlled actions."

For the AP analysis of this structure, wood shear wall assemblies and primary connections will be taken to be deformation controlled elements. Bodies of connectors will be checked as force controlled elements as required.

G-3.2 AP Analysis of Interior Load Bearing Wall Removal

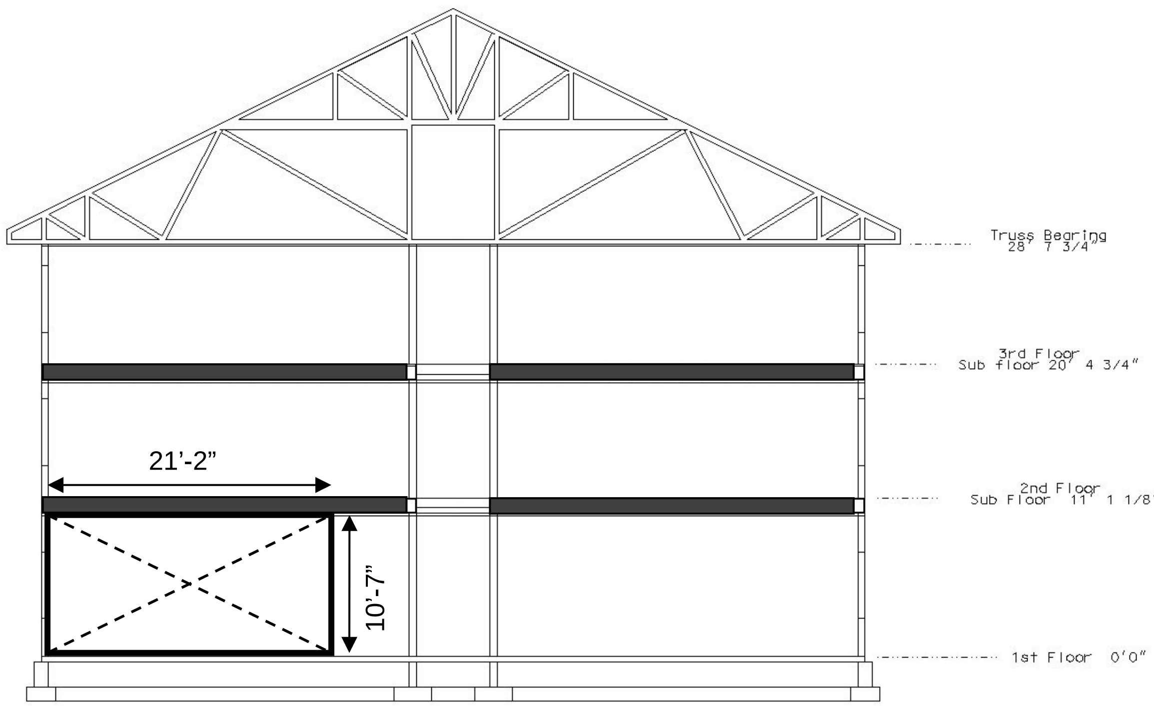

Figure G-5. Interior Load Bearing Wall Removal

As shown in Figure G-5, a segment of wall of length 2H is removed from the lower floor interior load bearing wall. H is taken as the distance between the 1st floor sub-floor elevation and the bottom of the 6-inch floor slab at the 2nd floor (=10'-7").

The remaining structure creates a shear wall element that must span the floor and wall loads from the 2nd and 3rd stories. The shear walls above will be divided by the floor slab at each level. The wall from level 2 to level 3 will have an overall depth of 8'-10" and the wall from level 3 to the roof level will have an overall depth of 8'-3". The boundary (chord) elements consist of 600T200 track provided at the top and bottom of each wall.

To bridge the removed section of wall, the shear wall panel must span from the exterior wall to a wall pier segment consisting of the remaining portion of the removed lower story interior wall. Note that no continuity action that might engage the right-hand wall panels in Figure G-5 is possible due to the corridor opening.

The structure contains no irregularities and therefore the linear static AP analysis is permitted per Section 3-2.11.1.1.

Loading:

Dead Load
Floors (each): 62 psf * 18'-8" = 1153 plf
Walls (each level): 7 psf * 9'-4" = 65 plf

Reduce live load in accordance with IBC 2006 1607.9.2:

A = 18.67'*25.91'*2 = 967.5 SF
R = 0.08 (A – 150) = 0.08 (967.5-150) = 65.4%
R_{max} = 60% or 23.1(1 + 62/40) = 58.9%

Live Load used in AP check (each level)
40 psf * 18.67' * (1-0.589) = 307 plf

Linear Static AP Load Case for Deformation Controlled Elements:

$G_{LD} = \Omega_{LD} [1.2D + 0.5 L]$

From ASCE 41-13 Table 12-3:
for "Wood Structural Panel Sheathing or Siding"
h = 21.17'/2 = 10.59'
b = 8.25'
h/b = 10.59'/8.25' = 1.28 < 2.0
m = 3.8 for Life Safety Primary Element

Connections to be screwed:
m = 1.8 for "Screws –Metal to Wood"

m = 1.8 controls

Ω_{LD} = 2.0m = 3.6 (UFC Table 3-4)

G_{LD} = 3.6*(1.2*(1153 +62) + 0.5*(307)) = 3.6*(1640 plf) = 5,802 plf (each level)

Deformation controlled actions:

Shear: Q_{UD} = 5,802 plf * 21.17' / 2 / 8.25' = 7,444 plf in wall

Capacity checks of deformation controlled actions:

Shear in Wall:

Wall shear strength $\phi Q_{CE} = 1.5 (\phi v_s)$
where ϕv_s = LRFD shear strength of wall taken from IBC

Factor 1.5 for expected strength is taken from ASCE 41-13 12.4.9.2 but note that Section 3-2.11.7.1 requires inclusion of the material specific ϕ factor whereas ASCE 41-13 uses a ϕ of 1.0.

From IBC Table 2306.2:

For "Wood Structural Panels – Sheathing", 7/16" rated OSB sheathing, fasteners at 4" O.C max at edges:
v_{WC} = 1410 plf (for one side of wall)
Note that value for wind is chosen rather than seismic per UFC Ch. 7.

Since the interior walls have identical plywood sheathing on both sides, capacity of each individual side is additive per IBC 2211.2.2.

ϕ = 0.55 for LRFD per IBC 2211.2.1
ϕv_S = 0.55 (1410 plf) (2) = 1551 plf
ϕQ_{CE} = 1.5 (ϕv_S) = 1.5 (1551) = 2327 plf

Check UFC Equation 3-13:

$\phi m Q_{CE} \geq Q_{UD}$
2327 plf (3.8) = 8,842.6 plf > 7,444 plf **OK**

For force controlled actions:

$\boldsymbol{\Omega_{LD}}$ = 2.0 (UFC Table 3-4)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*(1153 +62) + 0.5*(363)) = 2.0*(1640 plf) = 3,280 plf (each level)

Force controlled actions:

Moment in each wall above: Q_{UF} = 3,280 plf * 21.17' * 21.17' / 8 = 183,749 lb-ft
Chord Force: Q_{UF} = M/h = 183,749 lb-ft / 8.25 ft = 22,273 pounds

Though ASCE 41 is somewhat ambiguous on the subject, consider the chord forces to be forced controlled actions because ASCE 41 Table 12-3 designates "Frame Components Subject to Axial Compression" as force controlled. Treating both tension and compression chords as force controlled will be conservative.

Each chord and track element will be fully braced in both directions:

600T200-54
ASTM A653 Gr 50 Fy = 50ksi Fu = 65 ksi

Tension yield
ϕ_t = 0.9
T_n = A_g F_y
A_g = 0.5653 in^2
ϕ_t T_n = 0.9 * 0.5653 in^2 * 50,000 psi = 25,438 pounds

Tension fracture
ϕ_t = 0.75
T_n = A_n F_u
A_n = Ag – 3 * 3/16" * 0.054" = 0.535 in^2 (3 - #8 screws)
ϕ_t T_n = 0.75 * 0.535 in^2 * 65,000 psi = 26,078 pounds

Compression
ϕ_t = 0.85
P_n = A_g F_y
A_g = 0.5653
ϕ_t T_n = 0.85 * 0.5653 in^2 * 50,000 psi = 24,025 pounds

ϕQ_{CL} = 24,025 pounds for (1) 600T200-54 > Q_{UF} = 22,273 pounds

Track must be spliced with a minimum gross area of 0.56 in^2 or doubled across splice locations

At each edge of the removed wall segment, the shear present in the wall above must be transferred into the load bearing walls studs below. Compression in wall studs shall be considered force controlled.

$\boldsymbol{G_{LF}}$ = 3,280 plf (each level) 6,560 plf (2 levels) above

Wall shear: Q_{UF} = $\boldsymbol{G_{LF}}$ * L / 2

Q_{UF} = *6,560* * (21.17 ft) / 2 = 69,437 lbs each side of removal

Typical studs are 600S200-68 at 24" on center and are braced in-plane by rated sheathing and mid-height blocking and will be controlled by out-of-plane buckling.

Stud length at the lower level = (11' -1") – (0'-6") = 10' – 7" = 10.6 ft

Per American Iron and Steel Institute (AISI) North American Specification for Design of Cold-Formed Steel Structural Members

ϕ_c = 0.85
λ_c = $\sqrt{(Fy/Fe)}$
F_e = $\pi^2 E/(KL/r)^2$
F_y = 50 ksi

E = 29,000 ksi
KL_x = 127.2 in
r_x = 2.3162 in
A_e = 0.6574 in^2

KL/r_x = 127.2 in / 2.3162 in = 54.92
F_e = $\pi^2 E/(KL/r)^2 = \pi^2 * 29000 / (54.92)^2$ = 94.9 ksi
λ_c = $\sqrt{(50/94.9)}$ = 0.726

For λ_c =1.5 $\quad$ $Fn = (0.658^{(\lambda c)\,\wedge 2})\, F_y$

$F_n = 0.658^{0.726\wedge 2} * 50$ ksi = 27.23 ksi

$\phi_c P_n$ = $\phi_c * F_n * A_e$ = 0.85 * 27.23 ksi * 0.6574 in^2 = 15.2 kips per stud

Q_{UF} = 69.4 kips / 15.2 kips per stud = 4.6 studs

Studs at 24 in on center, therefore 5 studs available per 8 feet of wall

Removed wall section could be located at edge of exterior wall, or shifted toward the interior bearing walls, therefore 5 studs must be available at either exterior or interior long direction walls. A minimum of 6 studs will be available at the interior long direction walls, therefore the wall stud compression strength is adequate.

Bearing load will be transferred through concrete floor system to allow distribution to multiple studs.

Secondary Component Check

The composite floor deck consists of 4” light weight concrete over 2” dovetail deck and must span 18’-8” to be supported by the short direction load bearing walls. Removal of a load bearing wall will result in loss of support for deck. Accordingly, the deck shall be connected to the wall above to prevent collapse in the event of a bearing wall removal.

The floor joists shall be hung from the wall above using a tension tie screwed to the 600S200-68 wall stud above which will include a threaded tension rod through bolted to the deck (See Figure G-6) and including a plate washer to prevent the tension rod from pulling through the deck.

Connection of each floor slab will consist of multiple connectors so it shall be considered force controlled:

Floor loadings:
DL = 62 psf * 18.67’ * 2’ = 2315 lbs
LL = 40 psf * 18.67’ * 2’ = 1494 lbs (no live load reduction due to limited tributary area for each tension tie)

$\boldsymbol{\Omega_{LD}}$ = 2.0 (UFC Table 3-4)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*DL + 0.5*LL)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*(2315 lbs) + 0.5*(1494)) = 7050 lbs

The tension tie capacity must be greater than 7050 lbs. Accordingly, provide one (1) Simpson HTT5 with 26 #10 screws into the wall stud above with a capacity of 6505 lbs. Note that 6505 lbs is less than the required capacity, however the nominal tension capacity of the hanger is 11,585 lbs. This capacity, in conjunction with a phi factor of 0.6 will indicate sufficient strength. The 600S200-68 stud has sufficient strength and thickness to support this tension hanger. See Figure G-6 for a detail showing the floor system connection to the wall above.

In order to prevent the through bolt from tearing through the floor system, a plate washer shall be used. Grout packing will be needed at locations for which the washer must bear on the unfilled portion of the dovetail deck. Additionally, typical floor reinforcement in the direction of the deck span shall continue across load bearing wall supports and transverse reinforcement shall be provided above each interior load bearing wall to distribute forces horizontally between each tension hanger connection.

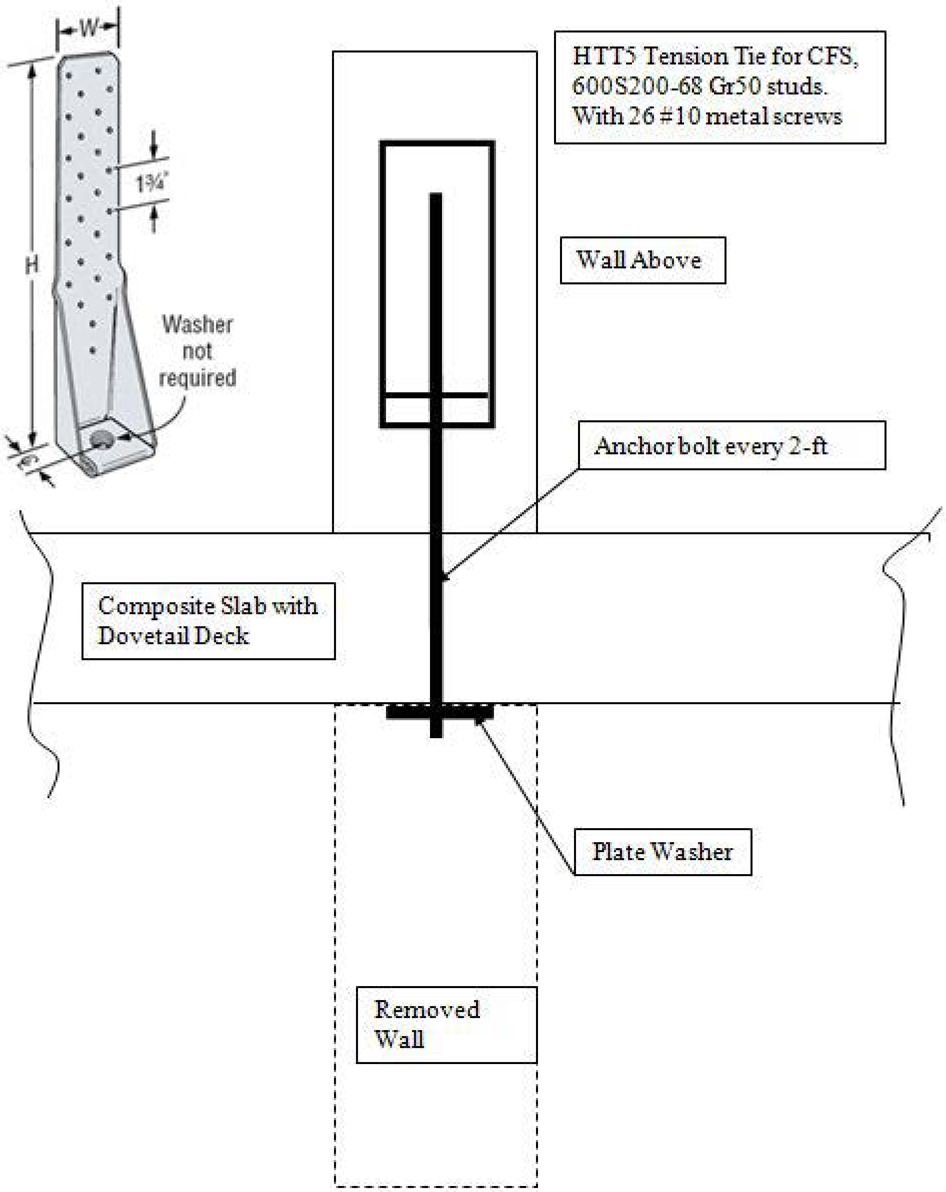

Figure G-6. Floor System Support Detail

Removal of a wall segment above the 2nd floor would produce similar analysis and results to those described above as the load resisted is roughly proportional to the available depth of remaining wall per level.

Similarly, removal of an exterior load bearing wall along the short side would produce results consistent with the interior removal as the tributary area of floor carried is roughly half that of an interior wall, and the provided capacity will be similar.

G-3.3 AP Analysis of Removal of Exterior Load Bearing Walls (Long Direction)

As shown in Figure G-7, a segment of wall of length 2H is removed between the second and third floors. H is taken as the distance between the 2nd floor sub-floor elevation and the bottom of the concrete deck at the 3rd floor (= 8'-10").

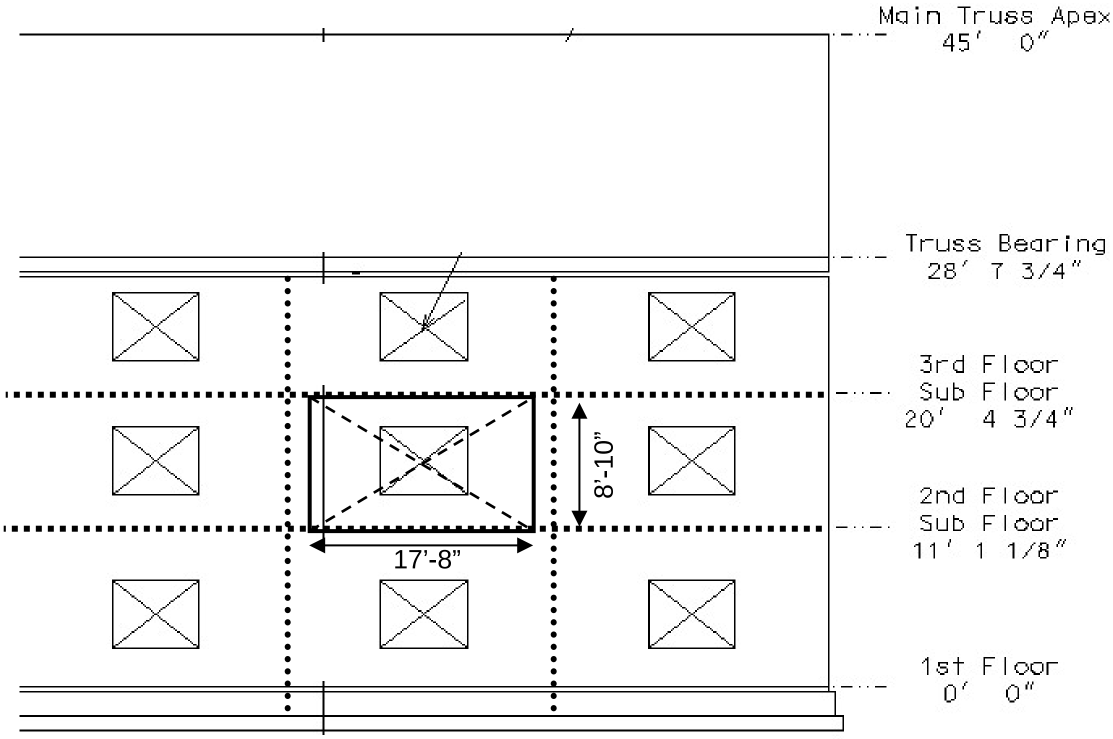

Figure G-7. Exterior Wall Removal

The chosen area of removal between the second and the third floor will allow for the shear wall above to span over and be supported on each side of the removed wall section. (Note: shifted removal locations could be addressed similar to the wood building examples of Appendix F).

The primary loading is that of the roof trusses:

Dead Load
Roof: 25 psf * 25'-11" / 2 = 324 plf
Wall: 7 psf * 8'-9" = 61 plf

Roof live load not applicable for UFC design combination

Snow Load
7 psf * 25'-11" / 2 = 91 plf

Linear Static AP Load Case for Deformation Controlled Elements:
G_{LD} = Ω_{LD} [1.2D + 0.2S]

From ASCE 41-13 Table 12-3:

for "Wood Structural Panel Sheathing or Siding"
h = 8'-10" b= 8'-9"
h/b = 8.83/8.75 = 1.0 < 2.0
m = 3.8 for Life Safety Primary Element

Connections to be screwed:
m = 1.8 for "Screws – Metal to Wood"

m = 1.8 controls

Ω_{LD} = 2.0m = 3.6 (UFC Table 3-4)

G_{LD} = 3.6*(1.2*(324+61) + 0.2*(91)) = 3.6*(480 plf) = 1,644 plf

Total force onto the removed section

F = 1644 lb/ft * 17.67 ft = 29,028 lbs

Shear each side V = 29,028 lbs / 2 = 14,514 lbs

Unit shear = 14,514 lbs / 8.83' = 1644 plf

For "Wood Structural Panels – Sheathing", 7/16" rated OSB sheathing, fasteners at 4" O.C max at edges:

v_{wc} = 1410 plf (for one side of wall)

Per IBC Table 2211.2, where gyp wall board is applied on opposite side of wall with fastener spacing less than 7" on center, shear strength may be increased by 30%.

ϕ = 0.55 for LRFD per IBC 2211.2.1
ϕv_s = 0.55 (1410 plf) (1.3) = 1008 plf
ϕQ_{CE} = 1.5 (ϕv_s) = 1.5 (1008) = 1512 plf

Check UFC Equation 3-13:

$\phi m Q_{CE} \geq Q_{UD}$
1512 plf (3.8) = 5746 plf > 1644 plf **OK**

For force controlled actions:

$\boldsymbol{\Omega_{LD}}$ = 2.0 (UFC Table 3-4)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*(324+61) + 0.2*(91)) = 2.0*(481 plf) = 961 plf

Wall moment = $\boldsymbol{G_{LF}}$ * L^2 / 8 = 961 plf * $(17.67')^2$ / 8 = 37,507 lb-ft

Chord force = M/d = 37,507 lbs / 8.25' = 4,546 pounds = Q_{UF}

ϕQ_{CL} = 24,025 pounds for (1) 600T200-54 as established in G-3.2 > 4,546 pounds OK

For stud bearing to support bridging walls:

Q_{UF} = $\boldsymbol{G_{LF}}$ * L / 2 = 961 lb/ft * 17.67 ft / 2 = 33,962 lbs at each side of removed wall

Similar to G-3.2, compression strength of bearing walls is adequate to support bridging wall.

G-3.4 AP Analysis of Removal of Exterior Load Bearing Walls Below Third Floor (Long Direction)

As shown in Figure G-8, a segment of wall of length H is removed at exterior corners in each direction between the second and third floors. H is taken as the distance between the 3rd floor sub-floor elevation and the truss bearing location (=8'-3").

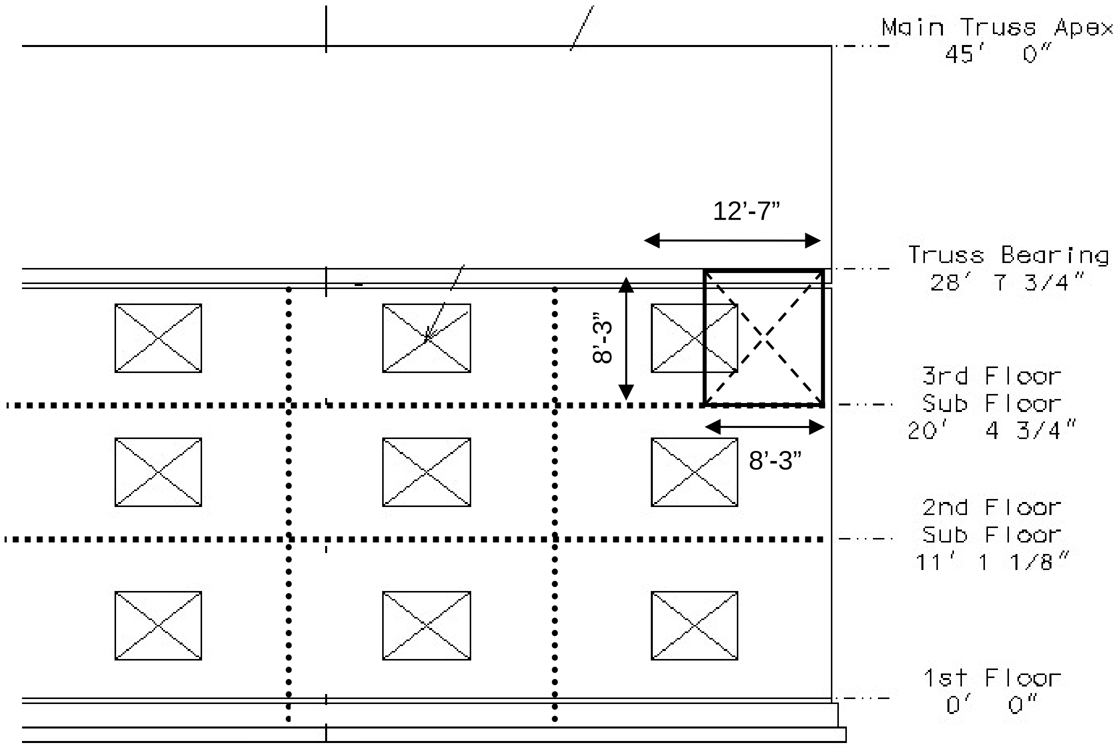

Figure G-8. Exterior Corner Wall Removal

The primary loading is that of the roof trusses:

Dead Load
Roof: 25 psf * 25'-11" / 2 = 324 plf

Roof live load not applicable for UFC design combination

Snow Load
7 psf * 25'-11" / 2 = 91 plf

Linear Static AP Load Case for Deformation Controlled Elements:
$G_{LD} = \Omega_{LD} [1.2D + 0.2S]$

Resistance will be provided by steel beam(s) at roof level braced at each roof truss at 4'-0" on center as shown in Figure G-9.

From ASCE 41-13 Table 9-5:

for "Frame Components Subjected to Axial Tension and/or Bending"
m = 8 for Collapse Prevention Primary Element

Connection for backspan to be similar to double angle shear tab
Per UFC Table 5-1
m = $5.8 - 0.107\ d_{bg}$ d_{bg} = 3”
m = 5.8 – 0.107 * 3 = 5.5

m = 5.5 controls

$\boldsymbol{\Omega_{LD}}$ = 0.9 m + 1.1 = 6.0 (UFC Table 3-4)

$\boldsymbol{G_{LD}}$ = 6.0*(1.2*(324) + 0.2*(91)) = 2,463 plf

Cantilever span = L = 12’-7”

Q_{UD} = $\boldsymbol{G_{LD}}$ * L^2 / 2 = 2,463 plf * $(12.6\ ft)^2$ / 2 = 195,513 lb-ft (2347 k-in)

Use Steel HSS beam Fye = 1.1 * 46ksi = 50.6 ksi

Beam supported against lateral and rotational displacement by bolting at each truss bearing post at 48” on center as shown in Figure G-9).

$\phi mQ_{CE} \geq Q_{UD}$
$\phi\ m\ F_{ye}\ Z$ = 0.9 * 8 * 50.6 ksi 8 Z ≥ 2347 k-in

$Z \geq 6.5\ in^3$ Use (2) HSS3x3x3/8” $Z_x = 3.25\ in^3$
Q_{UD} = 161,539 lb-ft

$Q_{UD} / \phi mQ_{CE}$ = 1.97 therefore require two (2) HSS3x3x3/8”

Provide (1) HSS3x3x3/8 beam at each side of roof truss vertical bearing post. Stagger the splice of these beams and provide a third identical beam between vertical truss posts at splice location or use a full moment splice at any splice locations.

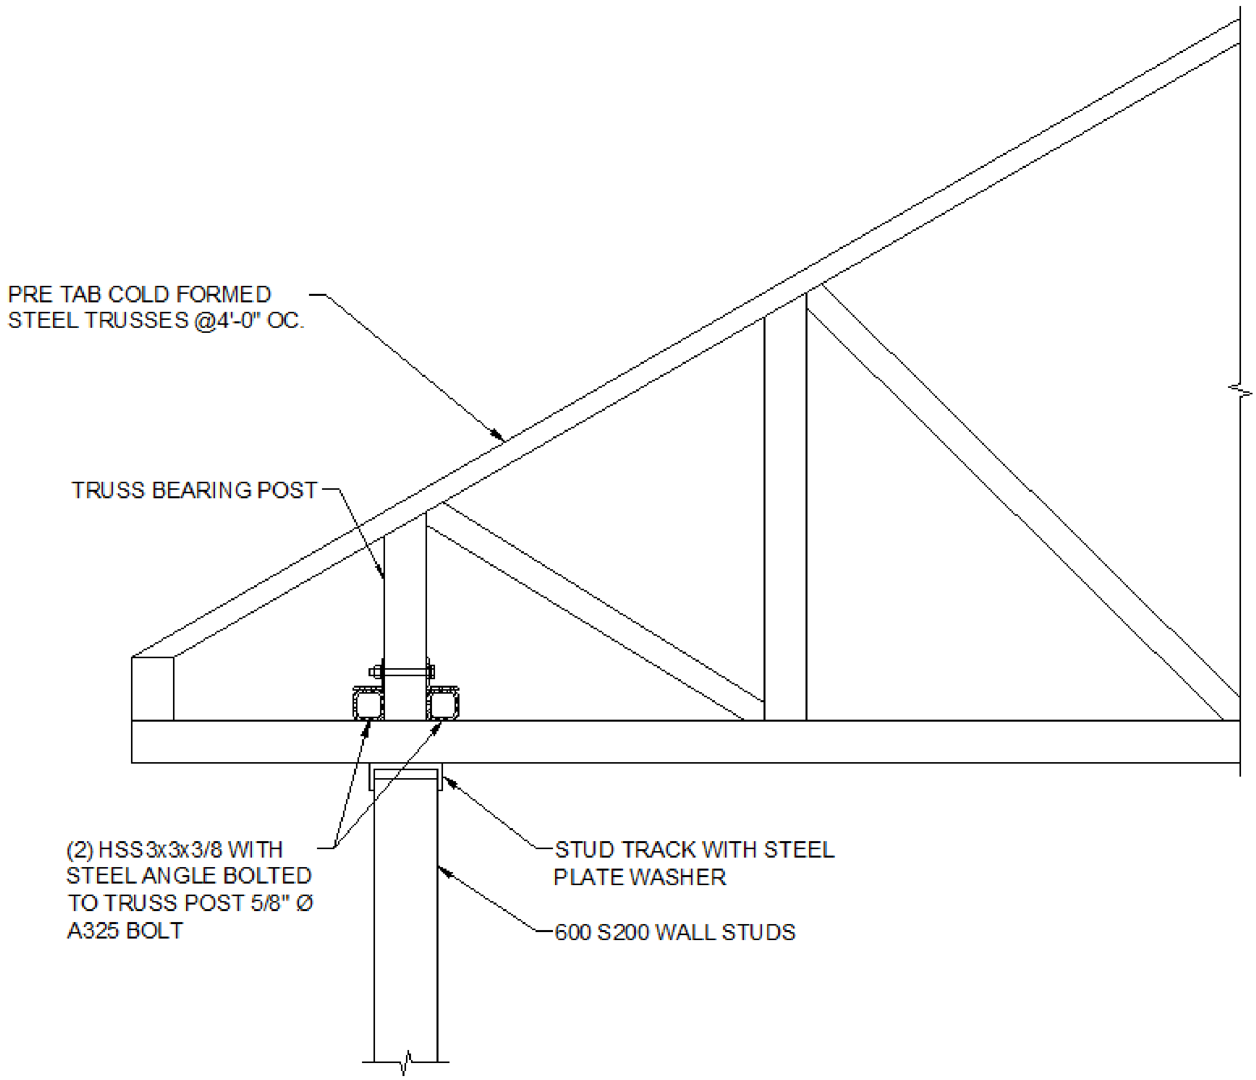

Figure G-9. Exterior Roof Beams

Anchorage of beams required to prevent uplift of the cantilever backspan at 11.4'. Attach beams using double angle connection to truss posts, and utilize hold-down anchors, such as Simpson HD7B at each side of truss post to resist uplift.

Double angle connection between HSS beams and truss shall be deformation controlled with m = 6

M_{LD} = 195,513 lb-ft
Vuplift = 195,513 lb-ft / 11.4' = 17,150 lbs
Bolt in double shear – 5/8" diameter A325 bolt
Per AISC table 7-1 ϕr_n = 11 kips
$m\phi r_n$ = 6 * 11 kips = 66 kips ≥ 17.15 kips

Two tie downs shall be used so in accordance with ASCE 41-13 section 12.3.3:
"demands on nails, screws, lags, bolts, split rings and shear plates used to link wood components to other wood or metal components shall be considered deformation controlled actions. Demands on bodies of connections and bodies of connection hardware shall be considered force controlled actions"

Accordingly, since 2 tie downs will be used, the action shall be considered force controlled.

$\boldsymbol{\Omega_{LD}}$ = 2.0 (UFC Table 3-4)

$\boldsymbol{G_{LF}}$ = 2.0*(1.2*(324) + 0.2*(91)) = 2.0*(407 plf) = 814 plf

Cantilever moment = $\boldsymbol{G_{LF}} * L^2 / 2$ = 814 plf * $(12.6\text{ ft})^2$ / 2 = 64615.3 lb-ft
Backspan distance = 11'-5" = 11.4 ft
Uplift reaction = 64615.3 lb-ft / 11.4ft = 5668.8 lbs

Capacity of Simpson HD7B = 6645 lbs

A single anchor would suffice; however provide 2 anchors to prevent connection eccentricity. Include a steel plate washer at wall header track to prevent anchor tension pullout.

See Figure G-10 for tie down regions and Figure G-11 for anchorage configuration.

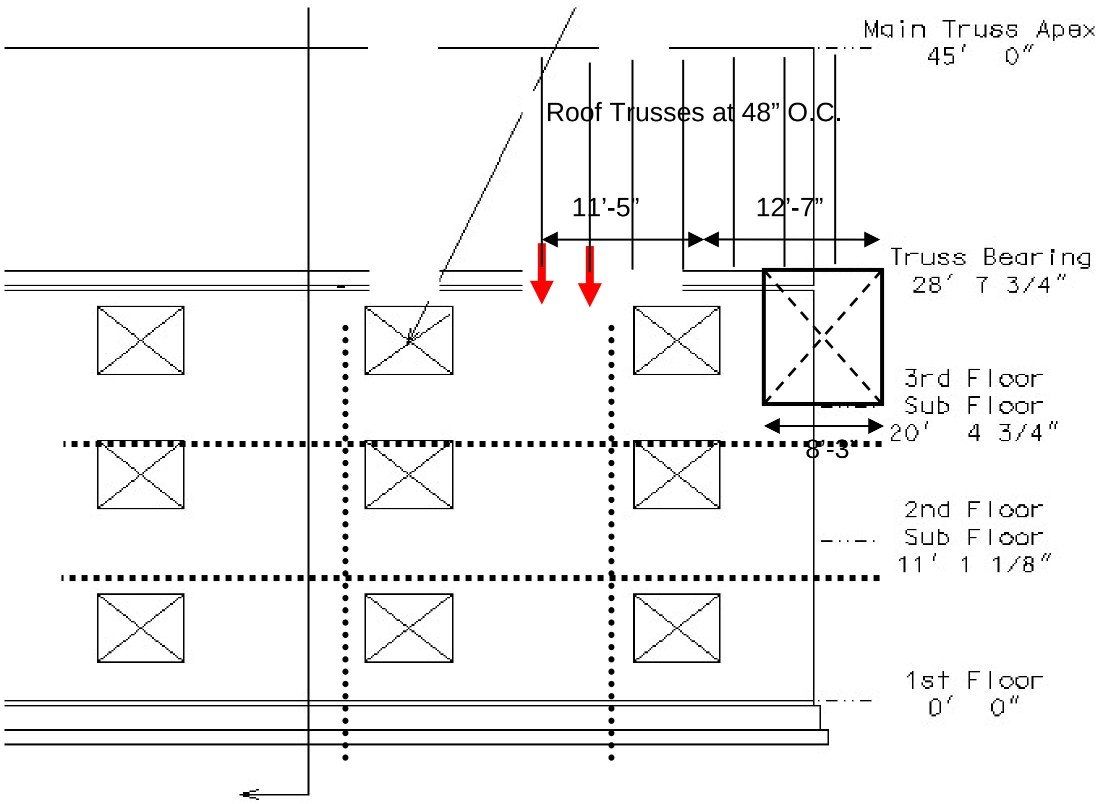

Figure G-10. Exterior Corner Wall Removal Tie Down Locations

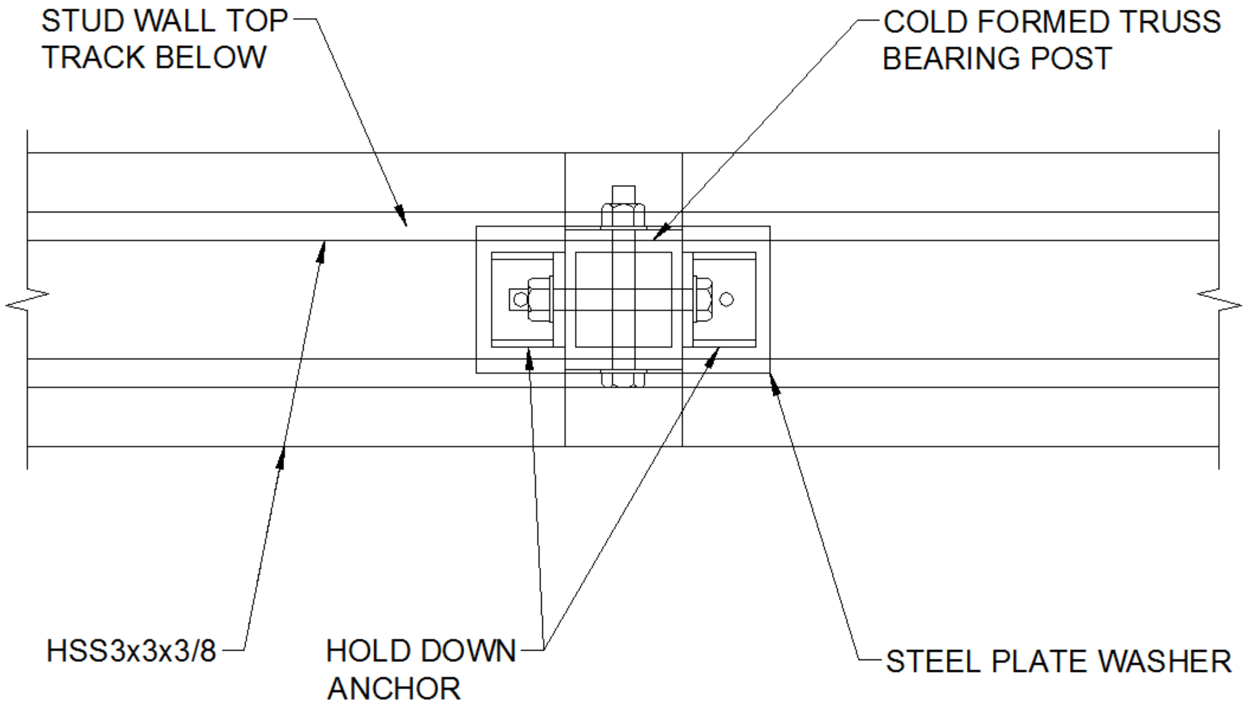

Figure G-11. Roof Beam Tie Down Anchorage, Plan View

Stud bearing to support bridging beam shall be force controlled:

Stud compression in lowest level:

Q_{UF} = $\boldsymbol{G_{LF}}$ * L + Uplift reaction + additional wall load

Additional wall load carried by each stud to the foundation

h = 28'-8" = 28.67' stud spacing = 2 ft wall DL = 7 psf

Additional wall load = 2.0 * (0.5* 7 psf * 28.67') = 201 lbs / ft * 2 ft = 402 lbs

Q_{UF} = 814 lb/ft * 12.6 ft + 5669 lbs + 402 lbs = 16,328 lbs

Compression carried by 600S200-68 studs at studs at 2' on center with in-plane bracing provided by sheathing and blocking. Check as column for out-of-plane strength of lower story

Per G-3.2 Stud strength is 15,200 lbs / stud

16,328 lbs / 15,200 = 1.1 studs

2 studs available at each window jamb **OK**

APPENDIX H /2/INTERNATIONAL BUILDING CODE MODIFICATIONS FOR CONSTRUCTION OF BUILDINGS TO RESIST PROGRESSIVE COLLAPSE

The following narrative identifies required modifications to the provisions of the *International Building Code* (IBC 2015) addressing construction documents, structural tests and special inspections for buildings that have been designed to resist progressive collapse. The modifications reference specific sections in the IBC that require modification. Apply IBC requirements except as modified herein. The required IBC modifications are one of two actions, according to the following legend:

LEGEND FOR ACTIONS

[Addition] -- New section added, includes new section number not shown in IBC.

[Replacement] -- Delete referenced IBC section and replace it with the narrative shown.

Chapter 16 Structural Design

1603 Construction Documents

1603.1.9 [Addition] Progressive Collapse design data. The following information shall be indicated on the construction documents:

1. General note stating the follow:

    Design of the building is in accordance with UFC 4-023-03, DD/MM/YYYY. Future additions or alterations to this structure shall not jeopardize the requirements for progressive collapse resistance.

2. \3\ Risk Category /3/ II, III or IV.

3. Method of progressive collapse resistance (Tie Force, Alternate Path, Enhanced Local Resistance or combinations thereof).

1603.1.10 [Addition] Systems and components requiring special inspections for progressive collapse resistance. Construction documents or specifications shall be prepared for those systems and components requiring special inspection for progressive collapse resistance and shall be submitted for approval as specified in section 1705.11 by the registered design professional responsible for their design on 107.1.

Chapter 17 Structural Tests and Special Inspections

1701.1 [Replacement] Scope The provisions of this chapter shall govern the quality, workmanship and requirements for materials covered. Materials of construction and tests shall conform to the applicable standards listed in this code.

1710 [Addition] QUALITY ASSURANCE FOR PROGRESSIVE COLLAPSE REQUIREMENTS

1710.1 [Addition] Scope A quality assurance plan shall be provided in accordance with Section 1710.1.1.

1710.1.1 [Addition] When required. A quality assurance plan for progressive collapse requirements shall be provided for the following structures designed for various Risk categories as follows:

1. Structures designed for \3\ Risk Category /3/ II, where either 1) structural elements provide horizontal and vertical tie force capacity as well as additional ductility requirements in which the shear resistance of the corner and penultimate first story walls and columns is greater than the flexural resistance for lateral loads, or, 2) the alternate path method is used to provide bridging over the deficient elements.

2. Structures designed for \3\ Risk Category /3/ III, with horizontal and vertical tie forces, alternate path design, and enhanced local resistance where the columns or walls in the first two perimeter stories are designed for increased flexural and shear resistance.

3. Structures designed to \3\ Risk Category /3/ IV, which requires a design based on the results of a systematic risk assessment of the building.

1710.1.2 [Addition] Detailed requirements. When required by Section 1710.1.1, a quality assurance plan shall provide for the following:

1. Horizontal and vertical tie force connections as required based on material type.

2. Roof and floor diaphragm systems including transverse, longitudinal, and peripheral ties.

3. Vertical progressive collapse resisting systems including vertical ties and bridging connections.

4. Perimeter ground floor columns and walls with enhanced ductility requirements to ensure shear strength is greater than the flexural strength

1710.2 [Addition] Quality assurance plan preparation. The design of each designated progressive collapse resisting system shall include a quality assurance plan prepared by the registered design professional. The quality assurance plan shall identify the following:

1. The designated progressive collapse resisting systems and elements that are subject to quality assurance in accordance with 1710.1.

2. The special inspections and testing to be provided as required by sections 1704 and other applicable sections of this code, including the applicable standards reference by this code.

3. The type and frequency of testing required.

4. The type and frequency of special inspections required.

5. The required frequency and distribution of testing and special inspection reports.

6. The structural observations to be performed.

7. The required frequency and distribution of structural observation reports.

1710.3 [Addition] Contractor responsibility. Each contractor responsible for the construction of the progressive collapse resisting system or progressive collapse component listed in the quality assurance plan shall submit a written contractor's statement of responsibility to the contracting officer prior to the commencement of work on the system or component. The contractor's statement of responsibility shall contain the following.

1. Acknowledgement of awareness of the special requirements contained in the quality assurance plan;

2. Acknowledgement that control will be exercised to obtain conformance with the construction documents approved by the building official;

3. Procedures for exercising control within the contractors organization, the method and frequency of reporting the distribution of reports; and

4. Identification and qualification of the person(s) exercising such control and their position(s) in the organization.

1711 [Addition] SPECIAL INSPECTIONS FOR PROGRESSIVE COLLAPSE RESISTANCE

1711.1 [Addition] General. Special inspections for progressive collapse resistance shall follow the requirements of Section 1704.1. Special inspections itemized in Sections 1717.2 through 1717.4 are required for the following:

1. Structures designed for Occupancy Category II, where either 1) structural elements provide horizontal and vertical tie force strength as well as additional ductility requirements in which the shear resistance of the corner and penultimate ground floor walls and columns is greater than the flexural resistance for lateral loads, or, 2) the alternate path method is used to provide bridging over the deficient elements.

2. Structures designed for Occupancy Category III, with horizontal and vertical tie forces, alternate path design, and enhanced local resistance where the columns or walls in the first two perimeter stories are designed for increased flexural and shear resistance.

3. Structures designed to Occupancy Category IV, which requires a design based on the results of a systematic risk assessment of the building.

1711.2 [Addition] Structural steel. Continuous special inspection for structural welding in accordance with AWS D1.1, including floor and roof deck welding.

Exemptions:

1. Single pass fillet welds not exceeding 5/16” (7.9mm) in size.

1711.3 [Addition] Structural Wood. Periodic special inspections during nailing, bolting, anchoring and other fastening of components within the progressive collapse resisting system, including horizontal tie force elements, vertical tie force elements and bridging elements.

1711.4 [Addition] Cold–formed steel framing. Periodic special inspections during welding operations, screw attachment, bolting, anchoring and other fastening of components within the progressive collapse resisting system, including horizontal tie force elements, vertical tie force elements and bridging elements.

1711.5 [Addition] Cast-in-place concrete. Continuous special inspection for reinforcing steel placement with a particular emphasis on reinforcing steel anchorages, laps and other details within the progressive collapse resisting system, including horizontal tie force elements, vertical tie force elements and bridging elements.

1712 STRUCTURAL OBSERVATIONS

1712.1 [Addition] Structural observations. Structural observations shall be provided for the progressive collapse resisting systems as follows:

1. When the contracting officer requires such observation.

2. In structures designed to \3\ Risk Category /3/ IV

This UFC supersedes UFC 4-023-07, dated Jul 2008.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force \ Civil Engineer Center (AFCEC) \ are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

\ Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects. \

UNIFIED FACILITIES CRITERIA (UFC)
REVISIONSUMMARY SHEET

Document: UFC 4-023-07, *Design to Resist Direct Fire Weapons Effects, Change 1*

Superseding: UFC 4-023-07, *Design to Resist Direct Fire Weapons Effects*

Description: This change updated the document’s format, incorporated multiple Criteria Change Requests and updated references.

Reasons for Document:

This UFC presents unified engineering guidance for designing facilities to protect assets within them from the effects of direct fire weapons, which include small arms and shoulder fired antitank weapons for the purposes of this UFC. It includes guidance to be applied to new construction and to apply in developing retrofits to existing buildings. This UFC is one in a series of security engineering Unified Facilities Criteria that address minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in the security engineering series include the following:

- UFC 4-010-01: DoD Minimum Antiterrorism Standards for Buildings
- UFC 4-020-01: DoD Security Engineering Facilities Planning Manual
- UFC 4-020-02: DoD Security Engineering Facilities Design Manual
- Security Engineering Support Manuals

This UFC is one of the security engineering support manuals, and as such is intended to be used to refine preliminary designs developed using UFC 4-020-02.

Impact:

The following will result from publication of this UFC:

- The approach to designing to resist direct fire weapons effects will be standardized among the Services.
- Use of this manual will not result in any adverse impacts on environmental, sustainability, or constructability policies or practices.

Unification Issues

No unification issues.

CHAPTER 1 INTRODUCTION

1-1 INTRODUCTION.

Attacks against facilities and other assets using direct fire weapons have always been a threat to U.S. Government operations. A direct fire attack requires an unobstructed line-of-sight to the asset being attacked within the effective range of the weapon being used. Aggressors often fire these weapons from vantage points outside the controlled perimeter of an installation or facility, which makes these threats difficult to prevent or to detect before they occur. The aggressors' goals are to damage the facility, to injure or kill its occupants, or to damage or destroy assets.

1-2 PURPOSE.

The purpose of this UFC is to present engineering guidelines and cost effective solutions for protecting assets within fixed facilities against direct fire (antitank weapons and small arms) attacks. Those solutions will vary according to the applicable level of protection, which must be provided to designers as part of the design criteria. This UFC is intended to be used to refine preliminary countermeasures designs and protective strategies developed using UFC 4-020-02.

1-3 SCOPE.

This document provides guidance for design of new buildings and for retrofits of existing buildings against the effects of direct fire weapons. Direct fire weapons, for the purposes of this UFC, are limited to small arms and shoulder fired antitank weapons. Small arms include ballistic weapons such as pistols, rifles, shotguns, and submachine guns up to 12.7 mm (0.50 caliber). Anti-tank weapons are limited to shoulder fired rockets such as the Russian RPG-7, RPG-18, and RPG-22 and the U.S. M-72 Light Antitank Weapon (LAW). For guidance on protecting against weapons outside of this scope, refer to UFC 3-340-01.

The ballistic weapons in this UFC are described in terms of ballistic standards developed by Underwriter's Laboratories (UL) for testing the resistance of building elements or assemblies to the ballistics effects. Those standards indicate the weapon to be used in the test, the ammunition, the muzzle velocity, the number of rounds to be fired, and the acceptance criteria for the targets. Coverage of the ballistic threat in this UFC includes the penetration mechanics of the ammunition, threat mitigation measures, and the use of ballistic resistant materials that prevent penetration. Countermeasures vary with level of protection and include blocking sight lines to facilities or assets, facility siting strategies, obscuration techniques, and facility hardening to resist the weapons effects. While there are more effective anti-tank weapons and missiles than those listed above, only weapons of the class described above will be considered in this UFC due to their wide availability and their frequent use. In addition, constructing conventional buildings to resist more effective weapons is impractical. The countermeasures described in this document are based on protecting against single hits, not volleys, since protecting against multiple hits is also impractical and since the accuracy of these weapons is such that firing two rounds through the same hole is difficult. Protection against multiple stage and delayed fuse warheads is also not addressed in this UFC. Strategies to mitigate the effects of these antitank weapons include obscuring assets from lines-of-sight and hardening building components for either pre-detonated rounds or direct hits depending on the level of protection. **\1**

1-4 APPLICABILITY.

This document provides design criteria for DoD components and participating organizations. This document applies to all construction, renovation, and repair projects requiring mitigation for direct fire weapons effects.

1-5 VULNERABILITY AND RISK ASSESSMENT.

A vulnerability and risk assessment must be conducted prior to beginning any security project. Upon identifying facility or asset vulnerabilities to threats, protection measures such as mitigation for direct fire weapons effects may be deployed to reduce vulnerabilities. In summary, this document assumes the pre-design phases, including the risk analysis, are complete prior to beginning design. For information on Security Engineering Planning and Design process, refer to UFC 4-020-01 and UFC 4-020-02 (described in the section “Security Engineering UFC Series” in this chapter). The engineering risk analysis conducted as part of UFC 4-020-01 should be consistent with the terrorism risk analysis conducted by the installation security/antiterrorism (AT) staff.

1-6 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, General Building Requirements. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-7 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-8 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

1-9 SECURITY ENGINEERING UFC SERIES.

This UFC is one of a series of security engineering unified facilities criteria documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include the following:

1-9.1 DoD Minimum Antiterrorism Standards for Buildings.

This UFC 4-010-01 and 4-010-02 establish standards that provide minimum levels of protection against terrorist attacks for the occupants of all DoD inhabited buildings. These UFCs are intended to be used by security and antiterrorism personnel and design teams to identify the minimum requirements that must be incorporated into the design of all new construction and major renovations of inhabited DoD buildings. They also include recommendations that should be, but are not required to be incorporated into all such buildings.

1-9.2 Security Engineering Facilities Planning Manual.

UFC 4-020-01 presents processes for developing the design criteria necessary to incorporate security and antiterrorism into DoD facilities and for identifying the cost implications of applying those design criteria. Those design criteria may be limited to the requirements of the minimum standards, or they may include protection of assets other than those addressed in the minimum standards (people), aggressor tactics that are not addressed in the minimum standards or levels of protection beyond those required by the minimum standards. The cost implications for security and antiterrorism are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they represent only representative construction that will meet the requirements of the design criteria. The manual also addresses the tradeoffs between cost and risk. The Security Engineering Facilities Planning Manual is intended to be used by planners as well as security and antiterrorism personnel with support from planning team members.

1-9.3 DoD Security Engineering Facilities Design Manual.

UFC 4-020-02 provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established using UFC 4-020-01. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them all work as a system. The information in UFC 4-020-02 is in sufficient detail to support concept level project development, and as such can provide a good basis for a more detailed design. The manual also provides a process for assessing the impact of protective measures on risk. The primary audience for the Security Engineering Design Manual is the design team, but it can also be used by security and antiterrorism personnel.

1-9.4 Security Engineering Support Manuals.

In addition to the standards, planning, and design UFCs mentioned above, there is a series of additional UFCs that provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02. These support manuals provide specialized, discipline specific design guidance. Some address specific tactics such as direct fire weapons, forced entry, or airborne contamination. Others address limited aspects of design such as resistance to progressive collapse or design of portions of buildings such as mail rooms. Still others address details of designs for specific protective measures such as vehicle barriers or fences. The Security Engineering Support Manuals are intended to be used by the design team during the development of final design packages.

1-9.5 Security Engineering UFC Application.

The application of the security engineering series of UFCs is illustrated in Figure 1-1. UFC 4-020-01 is intended to be the starting point for any project that is likely to have security or antiterrorism requirements. By beginning with UFC 4-020-01, the design criteria will be developed that establishes which of the other UFCs in the series will need to be applied. The design criteria may indicate that only the minimum standards need to be incorporated, or it may include additional requirements, resulting in the need for application of additional UFCs. Even if only the minimum standards are required other UFCs may need to be applied if sufficient standoff distances are unavailable. Applying this series of UFCs in the manner illustrated in Figure 1-3 will result in the most efficient use of resources for protecting assets against security and antiterrorism related threats.

CHAPTER 2 DIRECT FIRE WEAPONS PROPERTIES

2-1 INTRODUCTION.

Direct fire weapons threats involve weapons that require an unobstructed line-of-¬sight from the weapon to a target, for the shooter to acquire a target, and for the projectile to arrive at a target. Direct fire threat weapons include both ballistic and rocket propelled munitions. In a ballistic threat, the aggressor fires small arms such as pistols, submachine guns, shotguns, or rifles. Anti-tank (AT) weapons are military weapons or similar improvised weapons originally designed to penetrate the armor on armored vehicles. They can also be fired at facilities, which are the focus of this UFC.

2-2 THREAT LEVELS.

Table 2-1 shows the four threat severity levels associated with the direct fire weapons tactic in UFC 4-020-01. These threats provide representative weapons and munitions to the variety of direct fire weapons that can be expected to be used against people and facilities in criminal and terrorist attacks. There are more severe threats, but they are considered at this time to be less likely to be used by criminals and terrorists. The effective ranges of the weapons at which aggressors could be expected to accurately target person sized targets are entered for use in identifying relevant vantage points as described in Chapter 4.

2-2.1 Threat Severity.

Of the ballistic threats in Table 2-1, the weapon associated with the low threat severity level is a handgun. The weapons for **\1** medium, high and very high threat severity levels include rifles **/1/**. Rounds include ball type and armor piercing ammunition. Refer to **\1** Appendix C **/1/** for specific rounds.

The anti-tank weapon **\1** is associated with very high threat severity **/1/** and representative of a range of shoulder fired rocket propelled projectile weapons including the United States M-72 and the Russian RPG-7, RPG-18, and RPG-22.

Table 2-1 Threat Parameters

Design Basis Threat	Weapons / Standards	Effective Range
Very High	Anti-tank weapons ANSI/UL 752 Level 10 (12.7 mm / .50 caliber)	AT Weapon: 300 meters .50 Caliber: 2000 meters
High	ANSI/UL 752 Level 9 (.30 caliber Armor Piercing)	800 meters
Medium	ANSI/UL 752 Level 5 (7.62 mm / .30 caliber)	1000 meters
Low	ANSI/UL 752 Level 3 (.44 caliber Magnum)	100 meters

2-3 BALLISTIC THREATS.

Ballistic threats are described in terms of ballistic standards developed for testing the resistance of building components to ballistic threats. These standards provide criteria to evaluate the performance of materials or systems. Test standards specify caliber, weight, projectile composition, muzzle velocity of the round, number of impacts, and spacing of impacts. They also define what constitutes failure of the building component.

2-3.1 U.S Standards.

There are several recognized ballistic standards in the United States and other countries. There are many similarities among the standards, but their differences make them so they are not interchangeable. The most common commercial standards in the United States are American National Standards Institute (ANSI) / Underwriters Laboratories (UL) 752 and National Institute of Justice (NIJ) 0108.01. Additionally, there is the ASTM International F 1233 standard, although it is limited to security glazing materials and systems. The three standards are mostly based on the same weapons and rounds. The ballistic threats referenced in this UFC are from the ANSI/UL 752. Two additional U.S. standards are by the U.S. Department of State and H.P. White Laboratories. Those standards are not widely used commercially. **\1** Appendix C **/1/** lists all of the major national and international standards and their most common parameters. For a more detailed listing of the parameters of the standards in Table 2-1, refer to Table X1.1 in ASTM F 1233.

2-3.2 Non-U.S. Standards.

There are several standards available from other countries. They include Australian, British, European, and German standards. All are summarized in **\1** Appendix C **/1/** and are covered in more detail in Table X1.1 in ASTM F 1233.

2-4 ANTI-TANK WEAPONS AND MUNITIONS.

The anti-tank weapon threats addressed in this document are shoulder-fired weapons consisting of two components, the launcher and projectile. The projectile consists of an explosive warhead affixed to a solid fuel rocket motor. There are several types of warheads used in these weapons, but this document only addresses the armor penetrating warheads. They are the most common and represent the greatest challenge in designing countermeasures to mitigate this threat. This document also will not address multiple stage or delayed fuse warheads that are available for these weapons due to their limited availability. While the details of the specific projectiles and weapons differ, they all have similar operating mechanisms, which are summarized below.

2-4.1 Projectile.

The projectile (rocket motor and warhead) is fired from a light hand-held, shoulder fired launcher. When fired, the projectile leaves the launch tube and is propelled to the target by the rocket motor. When the projectile impacts the target, a fuse sends a signal to the detonator, which detonates the warhead.

2-4.2 Warhead.

The warhead incorporates a conical metal shaped charge (often copper lined) with high explosive packed behind it. See figure 2-1. On detonation, the material of the inner lining of the cone of the shaped charge collapses and forms a molten metallic "slug". The explosive gasses and the molten metallic slug together form a high velocity jet (on the order of 10,000 meters per second or 33,000 feet per second). As the gas and molten metallic jet begin to penetrate a target material, the pressure exerted by the jet tip pushes the material away in all directions, eventually driving through the target material. In addition, the force of the penetration of the jet causes the inside face of the target to fracture, and it is propelled into the protected space at high velocity. That effect is called "spall." The penetration effect of a conical shaped charge is illustrated in Figure 2-2. The kinetic energy of the warhead will allow it to penetrate 24 to 32 inches of reinforced concrete, depending on the weapon. Note that anti-tank weapons are designed to "poke" holes in armor, and they have similar narrowly focused effects on buildings as shown in Figure 2-3. Once the jet passes through a wall, it maintains its narrowly focused effects

Figure 2-1. Representative Anti-tank Round Cross-Section

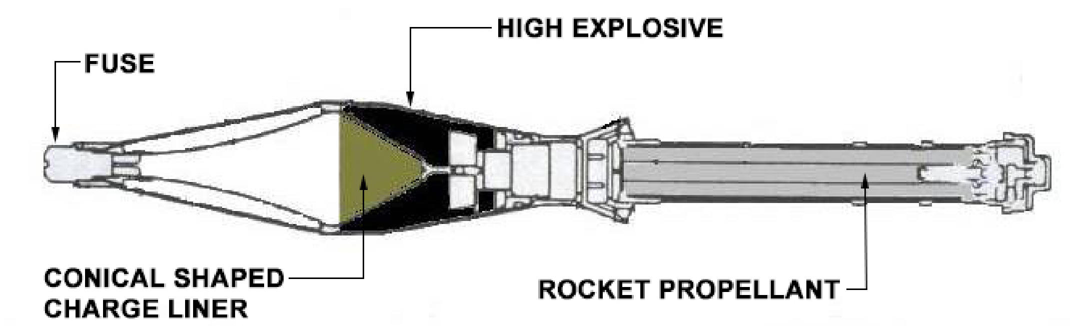

Figure 2-2. Shaped Charge Penetration

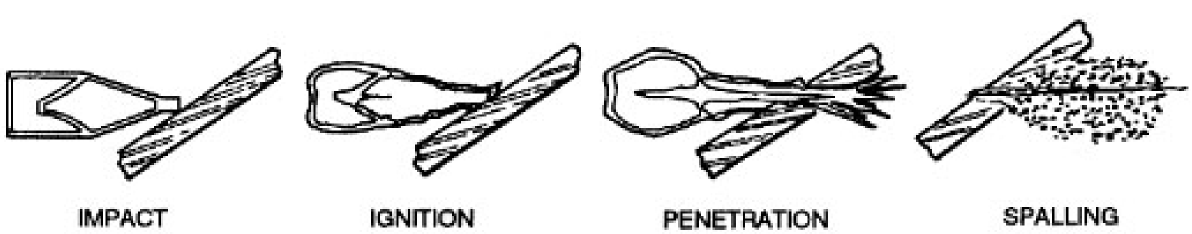

Figure 2-3. Shaped Charge Penetration of Masonry

2-4.3 Older Warheads.

Some older warheads for some of the commonly available shoulder fired anti-tank weapons had design configurations in which the wires extending from the fuses to the detonators could be severed when the warheads were forced through a wire mesh or a chain-link fence. That resulted in the warhead being rendered inert, which is often called “dudding.” Because there are available warheads that do not have that design vulnerability and because the process described above is not very reliable, the whole issue of dudding anti-tank rounds will not be addressed in this UFC.

CHAPTER 3 DESIGN APPROACH

3-1 INTRODUCTION.

This chapter describes the approach to developing systems of countermeasures to mitigate the effects of direct fire weapons attacks.

3-2 DESIGN STRATEGIES.

In approaching solutions to any security engineering related threat, there are two applicable strategies, the general design strategy and the specific design strategy. The general design strategy is the basic approach to developing a protective system to mitigate the effects a given tactic. It governs the general application of construction, building support systems, equipment, manpower, and procedures. The specific design strategy governs how the general design strategy is applied for different levels of protection. The specific design strategies address the different performances required by the levels of protection. The general design strategy and the specific design strategies for direct fire weapons will be described below.

3-2.1 General Design Strategy.

The general design strategy involves identifying vantage points from which direct fire weapons can be launched and, depending on the level of protection, either blocking sight lines to assets and building occupants or hardening the building elements to resist the direct fire weapons effects.

3-2.2 Specific Design Strategies.

Because this tactic includes both small arms and antitank weapons, and because the effects of those weapons vary significantly, the specific design strategies will not apply equally to all threat severity levels. Specifically, the medium level of protection applies only to the high threat severity level, which includes antitank weapons and high caliber small arms (12.7 mm or .50 caliber). When the medium level of protection applies for lower threat severity levels, use the design strategy for high level of protection.

3-2.2.1 Very Low Level of Protection.

The very low level of protection is limited to incorporating the standards of UFC 4-010-01, the DoD Minimum Antiterrorism Standards for Buildings. Those requirements will be described in this UFC, but detailed coverage will be left to UFC 4-010-01.

3-2.2.2 Low Level of Protection.

For all threat severity levels (involving both small arms and antitank weapons), the design strategy for this level of protection is to block sight lines to building occupants or assets. The assumption behind that strategy is that aggressors will not shoot at what they cannot see. Blocking sight lines may be accomplished by applying both building and sitework elements.

3-2.2.3 Medium Level of Protection.

The medium level of protection may be applied to all threat severity levels, but is only practical in the case of large caliber small arms (12.5 mm or .50 caliber) and antitank weapons. It includes the installation of predetonation screens that detonate antitank rounds at a specific distance from a target and/or energy absorption screens that reduce the energy of the small arms rounds before they impact the target. In both cases, the combination of screen material, standoff distance, and building element construction will prevent the small arms and antitank rounds from breaching the building envelope.

3-2.2.4 High Level of Protection.

For all threat severity levels (involving both small arms and antitank weapons), the design strategy for this level of protection is to harden building elements such that they resist the direct effects of the threat weapon.

3-3 THE PROTECTIVE SYSTEM.

The system of countermeasures that is provided to mitigate the effects of any tactic is referred to as the protective system. Develop the countermeasures that are parts of that system based on the general and specific design strategies associated with levels of protection and then evaluate them to ensure they are integrated so they act as part of a system. Countermeasures are divided into five major categories. Those categories are explained below.

3-3.1 Sitework Elements.

These include all countermeasures that are associated with areas surrounding buildings beyond 1.5 m (5 ft) from the building. They are addressed in Chapter 4.

3-3.2 Building Elements.

These include all countermeasures directly associated with buildings such as walls, doors, windows, roofs, and building layout. They are addressed in Chapter 5.

3-3.3 Building Support Systems.

Building support systems are systems such as utilities and heating, ventilating, and air conditioning (HVAC) systems. There are no significant issues relating to such systems in relation to mitigating the effects of direct fire weapons tactics, so they will not be addressed in this UFC.

3-3.4 Equipment.

Equipment as a category of countermeasures includes such things as electronic security systems and explosives detection equipment. Because there are no opportunities to detect direct fire weapons attacks and because they can be launched from a distance, equipment is not considered in protective system development for this tactic and will not be addressed in this UFC.

3-3.5 Manpower and Procedures.

Because there are no opportunities to detect direct fire weapons attacks prior to shots being fired and because they can be launched from a distance, manpower and procedures are only issues associated with response to attacks; therefore, they do not have facility implications, and they will not be addressed in this UFC. Similarly, activities such as patrolling areas from which attacks could be launched to deter or prevent attacks are also not addressed in this UFC.

This Page Intentionally Left Blank

CHAPTER 4 SITE WORK ELEMENTS

4-1 INTRODUCTION.

Sitework elements commonly play a limited role in mitigating direct fire weapons attacks, including both ballistics and anti-tank weapons. The primary reason for that limited role is that it is generally less expensive to build protection into buildings than to shield buildings using sitework elements. That may not be the case, however, for some existing buildings of lightweight construction, where there are limited areas of buildings that require protection, or where assets are not located in buildings. Sitework elements are used either to obscure assets from lines-of-sight to assets or to shield assets from direct fire weapons. How they are used with respect to those two functions varies by level of protection, and they are therefore addressed in the contexts of the applicable specific design strategies. In addition, there are sitework related issues that drive site selection and facility location, which are covered separately.

4-2 FACILITY LOCATION.

Before determining the location of new facilities, site planners should evaluate the site to identify vantage points from which aggressors could launch direct fire attacks. Look for vantage points that will permit an unobstructed line-of-sight to the facility or to areas within the facility where assets that are potential targets may be located. Consider the following in site planning to avoid such vantage points:

4-2.1 Locating Away from Vantage Points.

Locate buildings in areas of installations that are beyond the maximum range of the applicable weapons from identified vantage points where possible. Those vantage points may be either inside or outside the perimeter of the installation. An example would be tall buildings outside the secured perimeter from which an aggressor could establish a direct line-of-sight to facilities within the secured perimeter. That leads to the general recommendation to locate buildings that require protection closer to the interiors of installations. The DoD Minimum Antiterrorism Standards for Buildings (UFC 4-010-01) specifically address this issue in a recommendation.

4-2.2 Locating on High Points of Land.

Consider locating buildings on high points of land. If buildings are situated higher than the surrounding area there will be fewer potential vantage points from which to target the buildings. Locating the “castle on the hill” will also cause ballistic projectiles fired from a lower elevation to strike at an oblique angle, reducing their effectiveness slightly. That advantage is minimal for anti-tank weapons, however. One disadvantage of locating buildings on high points is that doing so may make the building more noticeable and easier to target.

4-2.3 Locating Near Existing Landforms.

Look for landforms that may block sight lines from vantage points. Consider locating buildings to take advantage of those landforms. Avoid locating near natural features that can be used as vantage points, however, unless they are within controlled areas. Also avoid locating buildings adjacent to drainage channels, ditches, ridges, or culverts that can provide concealment to aggressors and from which they could target buildings.

4-2.4 Locating Near Other Buildings.

Consider locating buildings near parking garages, warehouses, and other structures that may block sight lines from vantage points. Also take advantage of structures that house less critical assets and use those structures to block lines-of-sight. This could also be a strategy for placing multiple new buildings on a site. In that case, less critical buildings could be sited to block sightlines from vantage points to critical buildings.

4-3 COUNTERMEASURES FOR VERY LOW LEVEL OF PROTECTION.

The design strategy for the very low level of protection is limited to incorporating the minimum standards of UFC 4-010-01, the DoD Minimum Antiterrorism Standards for Buildings, into the protective system. There are no site work oriented requirements among those standards that are related to mitigating any effects of direct fire weapons.

4-4 COUNTERMEASURES FOR LOW LEVEL OF PROTECTION.

As stated in Chapter 3, the design strategy for the low level of protection is based on blocking lines-of-sight between vantage points and potential targets. This strategy assumes that aggressors will not fire at what they cannot see. Sitework elements that can be used effectively in implementing this strategy include vegetation, fences, land forms, and walls placed to interrupt sight lines. **\1**Consult a Landscape Architect to determine the appropriate site elements and plants for use in specific areas. **/1/** Recognize that vegetation used to block sight lines may not be effective until it matures, which may take years, and that plants that do not retain their foliage year-round will have periods when they are ineffective.

4-4.1 Planting and the Unobstructed Space.

The DOD Minimum Antiterrorism Standards for Buildings (UFC 4-010-01) require inhabited buildings to be surrounded by unobstructed spaces that extend **\1\/1/**outside of the buildings. Unobstructed spaces cannot have obstructions within them that would allow for concealment from observation of explosive devices 150 mm (6 inches) in height. Any **\1** shrubs or trees **/1/** planted to block sight lines, therefore, must either be planted outside the unobstructed space or should be kept trimmed to a height of 1.2 meters (4 feet) above the ground to preclude concealing explosives under them. Figure 4-1 illustrates the placement of trees in the vicinity of the unobstructed space. **\1**

4-4.2 Hedges.

/1/ Hedges can be effective at blocking sight lines, but their feasibility and the species available vary by region. **\1\/1/** Optimally select plants for hedges that retain their **\1** form and **/1/** foliage year-round and that are typically used for hedges. Where plants that are not evergreen varieties are used, alternative means to block sight lines will have to be provided during the periods of the year when the plants do not have leaves. Use caution when selecting shrubs or trees for planting in temperate or colder zones. Some shrubs or trees that are evergreen in warm climates may not be evergreen in cold climates. **\1**

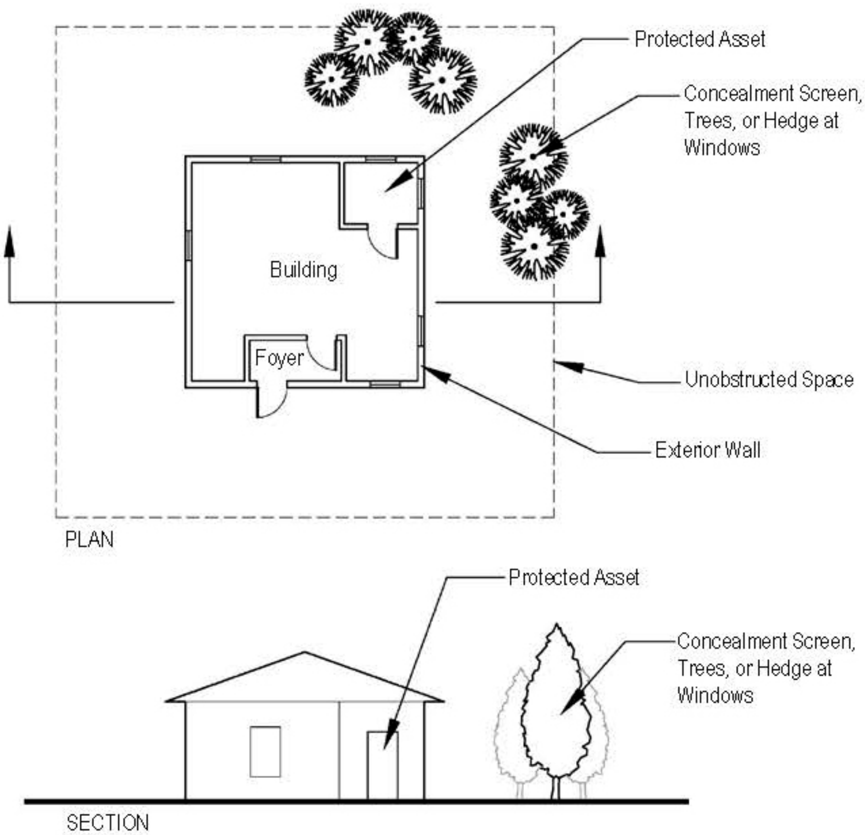
4-4.2.1 Shrubs for Hedges.

Utilize native and naturalized plants that are adapted to the local regional climate and natural aesthetic. Select plant species that are hardy, disease resistant, drought-tolerant, and low maintenance. Select plant species by ultimate size and form to maintain the natural shape and not require extensive maintenance or pruning. Place hedges a minimum of two-thirds of the radius of the ultimate growth of the shrub from hardscape, walls, fences, or buildings. Provide plant materials of sufficient size and spacing to achieve the desired screening effect. Confirm plant species with the appropriate Base Exterior Architecture Plan (BEAP), Installation Appearance Plan (IAP), Public Works Department or the reviewing Government Landscape Architect.

4-4.2.2 Shrubs to Avoid.

Avoid plants that are invasive, poisonous, or have excessive leaf, flower, seed or cone litter. Avoid plants that are short-lived or that have surface-rooting tendencies. Provide 100% native or naturalized plant materials on projects that are immediately adjacent to designated open space or sensitive environments. Provide plant materials that are fire-resistant on projects in regions prone to wild-fire. Refer to the appropriate Base Exterior Architecture Plan (BEAP), Installation Appearance Plan (IAP), Public Works Department or the reviewing Government Landscape Architect. **/1/ \1**

Figure 4-1. Trees and the Unobstructed Space



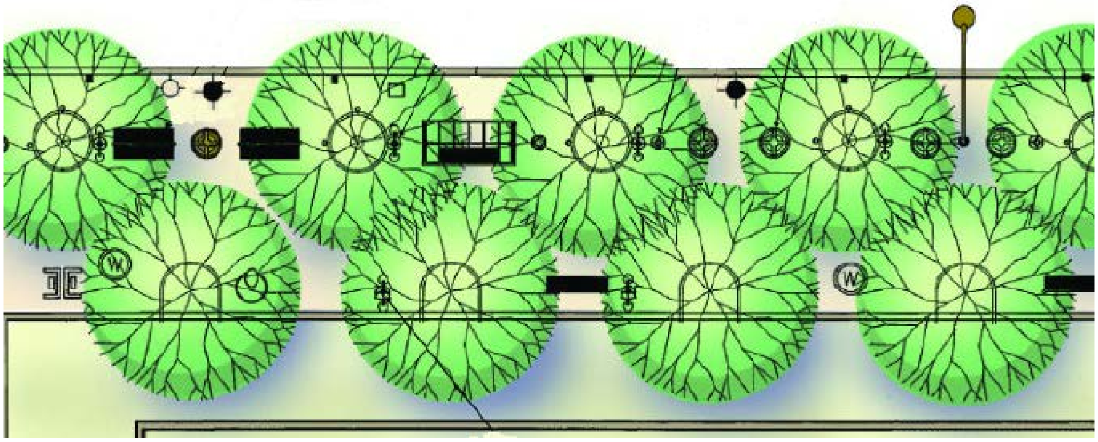
/1/ \1

4-4.3 Trees for Screening.

Select trees that retain their foliage year-round. Utilize native and naturalized trees that are adapted to the local regional climate and natural aesthetic. Select tree species that are hardy, disease resistant, drought-tolerant, and low maintenance. Select tree species by ultimate size and form to maintain the natural shape and not require extensive maintenance or pruning. In addition, ensure that trees overlap such that there are no visible gaps between them as shown in Figure 4-2. Note in the elevation view of Figure 4-2 that only the upper floors would be shielded, so only non-critical areas could be located on lower floors. Refer to the appropriate Base Exterior Architecture Plan (BEAP), Installation Appearance Plan (IAP), Public Works Department or the reviewing Government Landscape Architect. ***/1/***

Some varieties such as Douglas Fir can grow very tall and in areas with heavy snows will lose most of their lower branches. That may diminish their effectiveness for obscuration. Blue spruce will retain its branches even in heavy snows, but can be very slow growing. Magnolia trees will work well for warm climates and some of the new varieties will stay a nice medium height. Ficus is fast growing and will provide a good screen, but it can develop a massive root system, so it should be planted at least 3 meters (10 feet) away from paved areas.

Figure 4-2. Overlapping Trees for Obscuration



Plan

Elevation

\1 Utilize trees species that are "fanlike" (wide but not deep) for narrow areas such as between unobstructed spaces and paved areas where space for planting trees is limited. **/1/**

4-4.4 Fences and Walls.

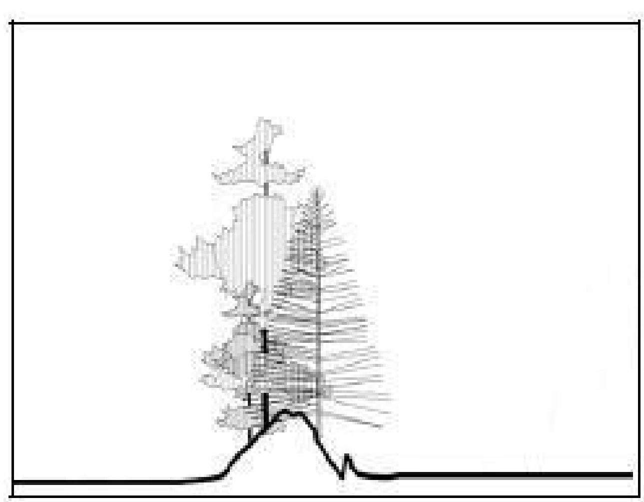
Perimeter barriers such as fences and walls can be used to block lines-of-sight. Walls, due to the fact that they are generally opaque and can be built to almost any height are very effective at blocking sight lines. Fences can be either solid, such as wood slat fences, or they can be transparent, such as chain-link or expanded metal. The solid fences are quite effective at blocking sightlines, but transparent fences require some form of obscuration material to be added to them for them to be effective at blocking sight lines. There are many such materials available for use with chain-link fencing. Some of the most common are wood, light gauge steel, or aluminum slats. The slats are woven in between the chain links. One significant issue in adding obscuration to fences is that they must be designed to resist the additional wind load that will result from adding the obscuration material. Figure 4-3 shows a chain link fence that failed due to the increased wind loading resulting from the addition of plastic obscuration material.

Figure 4-3. Failed Chain Link Fence with Obscuration Material Added

4-4.5 Using Landforms to Increase the Height.

Landforms can be built to raise fence-lines or to increase the height of newly planted trees or shrubs. Shrubbery can also be raised using individual or continuous planter boxes. Raising shrubs or tree lines for new plantings can obstruct lines-of-sight sooner than if the shrubs or trees are planted at ground level. Figure 4-4 shows a tree line elevated on a berm. The disadvantage to using landforms in this manner is that such landforms can create areas for intruder concealment or for the hiding of explosive devices. Due to such considerations, landforms should not be located within the **\1\/1/**unobstructed spaces required by UFC 4-010-01.

Figure 4-4. Tree Line Elevated on Berm



4-4.6 Berms and Landforms.

Berms and other such landforms can be used by themselves to block sightlines. Building them tall enough to be effective is generally impractical for all but the lowest of buildings, however. The berm in Figure 4-4, for example, would only potentially shield the lower floor of the building behind it. Berms can also provide opportunities for concealment, so they should be kept outside of unobstructed spaces.

4-5 COUNTERMEASURES FOR MEDIUM LEVEL OF PROTECTION.

The primary design strategy for the medium level of protection is to place a screen in front of portions of targeted buildings where there are assets identified as requiring protection against direct fire weapons. The screens intercept incoming direct fire rounds. In the case of ballistics, the screen will serve to absorb energy from the incoming round. In the case of anti-tank weapons, the screen will predetonate the incoming warhead. Both applications will be described below. Note that a screen can serve the purposes of both an energy absorption screen and a predetonation screen, but differences in construction will have to be evaluated to determine which controls.

4-5.1 Energy Absorption Screen.

The energy absorption screen serves to reduce the energy of incoming rounds, which allows for savings in the construction of building components behind them that are provided to resist penetration of the rounds. This strategy is only practical for the .50 caliber (12.7 mm) threat. For lesser threats it is more cost effective to build the full bullet resistance into the building construction. To be effective, the screen has to be solid and must have enough mass to reduce the velocity of the incoming round. That requires a minimum of 12 mm (1/2 inch) thick wood fence, reinforced concrete, or brick. The distance from the screen to the target is not a critical design parameter, but such screens should not be located within the 10 meter (33 feet) unobstructed space. Design guidance on screen thickness and material is provided in the wall design section of Chapter 5.

4-5.2 Predetonation Screen.

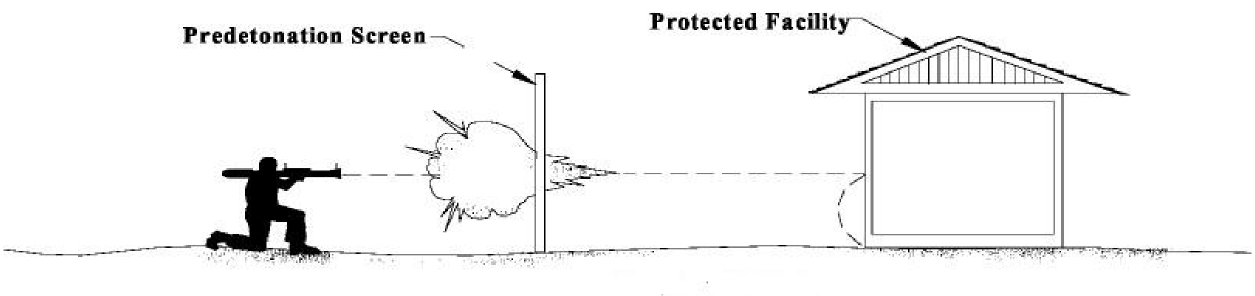
The effects of anti-tank warheads can be reduced by detonating the warheads at a distance from their targets. When the charges are detonated farther from the targets than their optimum standoffs (technically, the distance from the conical shaped charge to the tip of the warhead), the jets tend to break up and lose energy before striking the targets. This design strategy is called predetonation. It is accomplished by building a predetonation screen.

4-5.2.1 Predetonation Screen Location.

Predetonation screens generally will be located in front of portions of buildings that must provide protection against anti-tank weapons or areas that are vulnerable to an attack. In some cases a screen could surround an entire building. The standoff distance between the predetonation screen and the building is governed by the building construction. Those distances are discussed in the wall design section of Chapter 5.

For a range of common conventionally constructed walls the standoff distances range from 2 to 15 meters (7 to 49 feet), but the screens should not be located within the 10 meter (33 feet) unobstructed space. Figures 4-5 and 4-6 illustrate the placement and function of a predetonation screen.

Figure 4-5. Predetonation Screen



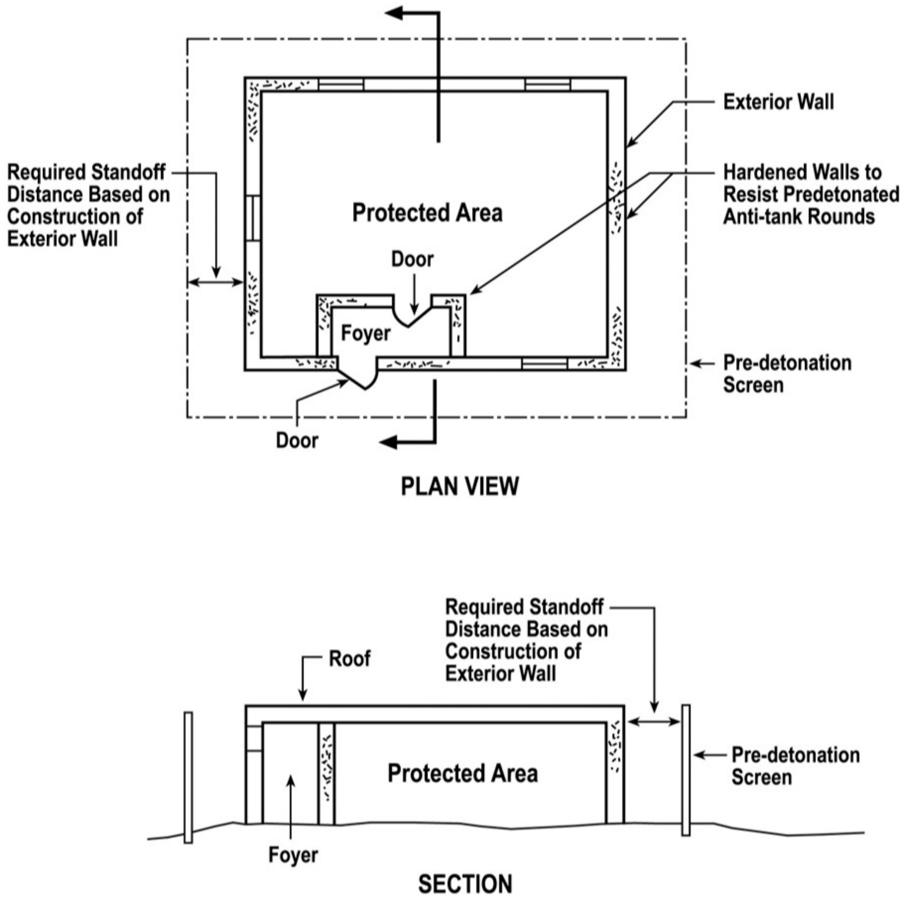
4-5.2.2 Predetonation Screen Height.

Predetonation screens need to be as high as the portions of buildings they are intended to protect. They may only be practical, therefore, for intercepting anti-tank rounds fired at the lower stories of buildings. Where building predetonation screens high enough to protect upper stories of buildings is not practical, design to a different level of protection for those portions of the building that are not shielded by the predetonation screen. Either use obscuration (low level protection) or harden the building to resist the direct impact of the anti-tank round. Note that in the case of designing for the low level of protection, building users are accepting the additional risk that goes along with that level of protection; therefore, the design team should not make that decision without consulting with the user or the planning team.

4-5.2.3 Building Exterior Envelope.

The exterior envelope of the building could be used as a predetonation screen if the assets that require protection are in interior rooms. In that case, the building exterior could be used as a predetonation screen and the interior walls would be designed to resist the predetonated round as described in Chapter 5.

Figure 4-6. Predetonation Screen Location



4-5.2.4 Predetonation Screen Material.

Predetonation screens can be constructed of concrete, masonry, or wood. If wood is used for the predetonation screen, construct it in sections so that if one section is damaged, it can easily be replaced. Wood predetonation screens thicknesses vary with wood species used. The minimum thicknesses required for some common wood species are listed below. The other requirement for the wood fences is that if wood slat fencing is used, the slats should be spaced no more than 6.4 mm (1/4 inch) apart.

- Cedar: 9 mm (3/8 inch)
- Douglas Fir or Pine: 25 mm (1 inch)
- Plywood: 18 mm (3/4 inch) (including Oriented Strand Board)

The thickness of concrete or masonry predetonation screens does not need to be greater than 25 mm (1 inch); therefore, they are limited only by what is required for structural stability. Another constraint is that a structural wall made of concrete or masonry could amplify the effects of a pressure wave created by a bomb blast by reflecting it back to the facility. If that is a concern blast resistance will have to be taken into account during the design of the predetonation screen. In addition, concrete or masonry predetonation screens could break up and produce hazardous flying debris in the event of an explosive detonation. The blast amplification and debris considerations are outside the scope of this UFC. See the DoD Security Engineering Facilities Design Manual (UFC 4-020-02).

4-6 COUNTERMEASURES FOR HIGH LEVEL OF PROTECTION.

The design strategy for the high level of protection depends on the shell of the building protecting the targeted assets to provide all of the resistance to the direct fire weapons. Because that strategy relies only on building components, sitework elements do not enter into the design strategy for this level of protection.

CHAPTER 5 BUILDING ELEMENTS

5-1 INTRODUCTION.

Building elements are the predominant components of protective systems to mitigate direct fire weapons effects. The exterior shells of buildings are commonly what provide the protection for assets within them, whether or not shielding has been provided using site work elements. This chapter will provide guidance for designing walls, windows, doors, vent covers, grilles, and roofs to implement the design strategies for the four applicable levels of protection. It will also address how building layout may be affected by the design strategies for mitigating direct fire weapons.

5-2 BUILDING LAYOUT.

Building layout can provide significant opportunities for mitigating the effects of direct fire weapons. How the design strategies for building layout vary for the different levels of protection is described below. Note, however, that applying the layout principles for the low and very low levels of protection can simplify protection at the higher levels of protection; therefore, always apply those principles where possible.

5-2.1 Very Low Level of Protection.

There is a requirement in UFC 4-010-01 that is predicated on consideration of direct fire weapons threats. Standard 11 requires main entrances to buildings not to face installation perimeters or other uncontrolled vantage points or to provide some means to block those lines-of-sight. The latter is addressed later in this chapter where the low level of protection for doors is discussed. For existing buildings, this requirement may lead to reorganization of building circulation to accommodate moving the main building entrance. Note, however, that the standards of UFC 4-010-01 are only triggered for existing buildings that are undergoing major modifications or conversions of use. Refer to UFC 4-010-01 for descriptions of those triggers. This main entrance requirement accounts for the facts that there is little control over what happens off installations and that building main entrances are especially vulnerable due to the level of traffic into and out of buildings at those locations.

5-2.2 Low level of protection.

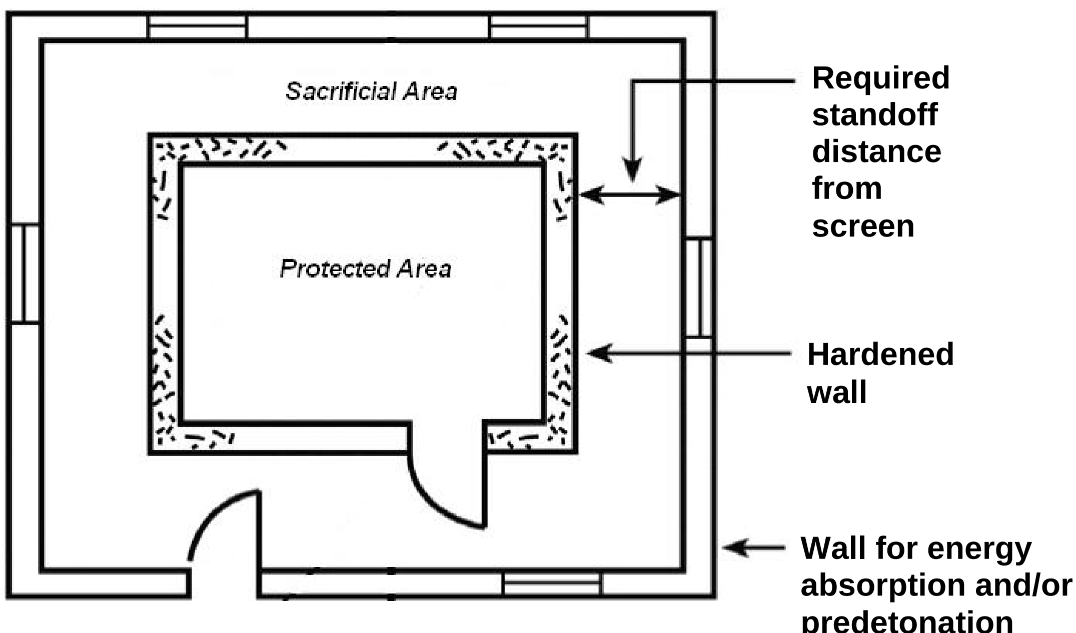
Building layout for the low level of protection is focused on minimizing lines-of-sight to targeted assets. Consider designing interior layouts of buildings to locate critical assets as far as possible into the interior of the building to make them easier to protect. Unoccupied areas or areas in which non-critical functions will be performed can be located along the exterior of the facility. Any such layout considerations must take into account whether or not issues such as building occupant operations will constrain where assets or functions are located. Interior room layout can also limit asset exposure. In designing room layouts locate furniture and activity areas to minimize visibility through windows and doors.

Building orientation can also be used to minimize asset exposure. Where possible, orient buildings so critical areas do not face known vantage points or installation perimeters. Storerooms or other uninhabited areas can be located on those sides of buildings.

5-2.3 Medium Level of Protection.

The design strategy for the medium level of protection includes employment of energy absorption and/or predetonation screens. Where targeted assets can be located in interior areas of buildings, the building shell can be used for energy absorption or predetonation. In those cases lay out interior walls between the building exterior and the assets and design the interior walls to resist the weapons effects remaining after energy dissipation and/or predetonation as described in the section in this chapter on walls. Figure 5-1 illustrates such a building layout. In addition, lay out buildings to minimize windows and doors leading to targeted assets. Refer to the section in this chapter on windows for more guidance on window layout.

Figure 5-1. Sacrificial Area Layout



5-2.4 High Level of Protection.

Because the design strategy for the high level of protection is based on building exteriors resisting the direct impacts of direct fire munitions, there are minimal layout issues to be considered. The only significant one relates to windows and doors. It is often not practical to design windows and doors to provide the high level of protection, especially for the higher threat severity levels, so a more practical approach for those cases is to avoid exposing targeted assets to windows and doors through effective building layout. Refer to the sections in this chapter on windows and doors for more guidance on window and door layout.

5-3 WALLS.

5-3.1 Very Low Level of Protection.

Because the design strategy for the very low level of protection is limited to incorporating the minimum standards of UFC 4-010-01, the DoD Minimum Antiterrorism Standards for Buildings, and since there are no minimum standards related to mitigating direct fire weapons effects against walls, there are no requirements for walls at this level of protection.

5-3.2 Low Level of Protection.

Because the design strategy for the low level of protection is limited to blocking lines-of-sight to targeted assets and because walls are commonly opaque, there are no additional requirements for walls at this level of protection. If, however, glass block are used for walls, ensure they are translucent or figured so assets cannot be targeted through them.

5-3.3 Medium Level of Protection.

The design strategy for the medium level of protection is predicated on either predetonating anti-tank rounds and/or reducing the energy of large caliber ballistics. Design of walls will differ based on whether they are designed for ballistics threats, anti-tank weapon threats, or both.

5-3.3.1 Ballistics Threats.

Table 5-1 covers wall design where an energy absorption screen is employed to mitigate the effects of high caliber ballistics (.50 caliber or 12.7 mm). Select a material and thickness for the energy absorption screen and find the reinforced concrete or masonry wall necessary to resist the residual velocity of the round after it impacts the screen. Masonry walls are either fully grouted concrete masonry units or solid clay brick masonry units. The distances from screens to targets are unimportant, but they cannot be located within the **\1\/1/** unobstructed space required by UFC 4-010-01.

For concrete and masonry materials, the design condition of the wall is for no spalling from the inside face. Spalling is a phenomenon in which the impact of a projectile propagates a shock wave through the material. That wave is reflected from the rear face of the wall as a tensile wave. When that tensile wave exceeds the limited tensile capacity of the material, the material is ejected from the spalled region, potentially at hazardous velocities. Spalling is illustrated in Figure 2-3. For more options, use the equations in the section on the high level of protection. Calculate the residual velocity of the round after it perforates the energy absorption screen and then design the target wall to resist that residual velocity.

5-3.3.2 Anti-tank Weapon Threats.

Table 5-2 covers wall design where a predetonation screen is employed to mitigate the effects of anti-tank weapons. The table includes 8 different common wall constructions, their total thicknesses, and the standoff distances from those walls at which predetonation screens must be located for the target wall to resist the predetonated round. The values in Table 5-2 were obtained through testing, and they represent walls that will resist the “family” of anti-tank weapons that were described in Chapter 2. Note that where Table 5-2 shows a predetonation screen standoff of less than the standoff associated with the unobstructed space, screens should not be located within the **\1\/1/** unobstructed space unobstructed space required by UFC 4-010-01.

Figures 5-2 and 5-3 illustrate techniques for retrofitting existing reinforced concrete walls to resist predetonated anti-tank rounds. Both techniques employ sand against the outside of the wall. The configuration in Figure 5-3 also includes the installation of steel plate on the interior face of the wall to prevent spall. There are many ways that sand in the thicknesses shown can be placed against walls, such as light retaining walls, sand bags, or sand grids. Aesthetics and maintainability issues are left up to designers.

Table 5-1 Wall Construction with Energy Absorption Screen [1]

Energy Absorption Screen Material and Thickness [2, 3]	Reinforced Concrete Wall Thickness [2]	Masonry Wall Thickness [2,3]
No screen	22 inch (560mm)	30 inch (760 mm)
½ inch (12 mm) wood	18 inch (460mm)	30 inch (760 mm)
¾ inch (19 mm) wood	18 inch (460mm)	28 inch (710 mm)
1 inch (25 mm) wood	18 inch (460mm)	28 inch (710 mm)
2 inch (50 mm) reinforced concrete	18 inch (460mm)	26 inch (660 mm)
4 inch (100 mm) reinforced concrete	16 inch (400mm)	26 inch (660mm)
6 inch (150 mm) reinforced concrete	15 inch (380 mm)	22 inch (560 mm)
8 inch (200 mm) reinforced concrete	14 inch (350 mm)	20 inch (500 mm)
12 inch (300 mm) reinforced concrete	10 inch (250 mm)	16 inch (400 mm)
Ungrouted CMU (1.5 inch or 40 mm total face shell thickness)	18 inch (460mm)	28 inch (710 mm)
4 inch (100 mm) masonry	16 inch (400mm)	26 inch (660 mm)
6 inch (150 mm) masonry	15 inch (380 mm)	22 inch (560 mm)
8 inch (200 mm) masonry	14 inch (350 mm)	20 inch (500 mm)
12 inch (300 mm) masonry	10 inch (250 mm)	16 inch (400 mm)

1. For .50 caliber (12.7 mm) round
2. All thicknesses are nominal thicknesses.
3. Masonry walls can either be fully grouted CMU or solid clay brick. Reinforcement ratio is not a significant factor in bullet resistance.

Table 5-2 Wall Construction with Anti-Tank Round Predetonation Screens

Material	Total Wall Thickness [1]	Standoff Distance to Predetonation Screen
4 inch (100 mm) brick / 2 inch (50 mm) air gap / 8 inch (200 mm) hollow CMU	14 inches (356 mm)	49 feet (15 meters)
8 inch (200 mm) grout filled CMU	8 inches (200 mm)	36 feet (11 meters)
8 inch (200 mm) solid brick	8 inches (200 mm)	36 feet (11 meters)
4 inch (100 mm) brick / 2 inch (50 mm) air gap / 4 inch (100 mm) brick	10 inches (254 mm)	36 feet (11 meters)
4 inch (100 mm) brick / 4 inch (100 mm) air gap / 4 inch (100 mm) brick	11.5 inches (292 mm)	36 feet (11 meters)
6 inch (150 mm) reinforced concrete	6 inch (150 mm)	25 feet (7.6 meters) [2]
8 inch (200 mm) reinforced concrete	8 inch (200 mm)	11 feet (3.4 meters) [2]
12 inch (300 mm) reinforced concrete	12 inch (300 mm)	7 feet (2.1 meters) [2]

1. Nominal thicknesses.

2. Do not locate closer than the edge of the unobstructed space where unobstructed space is required in accordance with UFC 4-010-01.

Figure 5-2. Anti-tank Weapon Wall Retrofit Using Sand

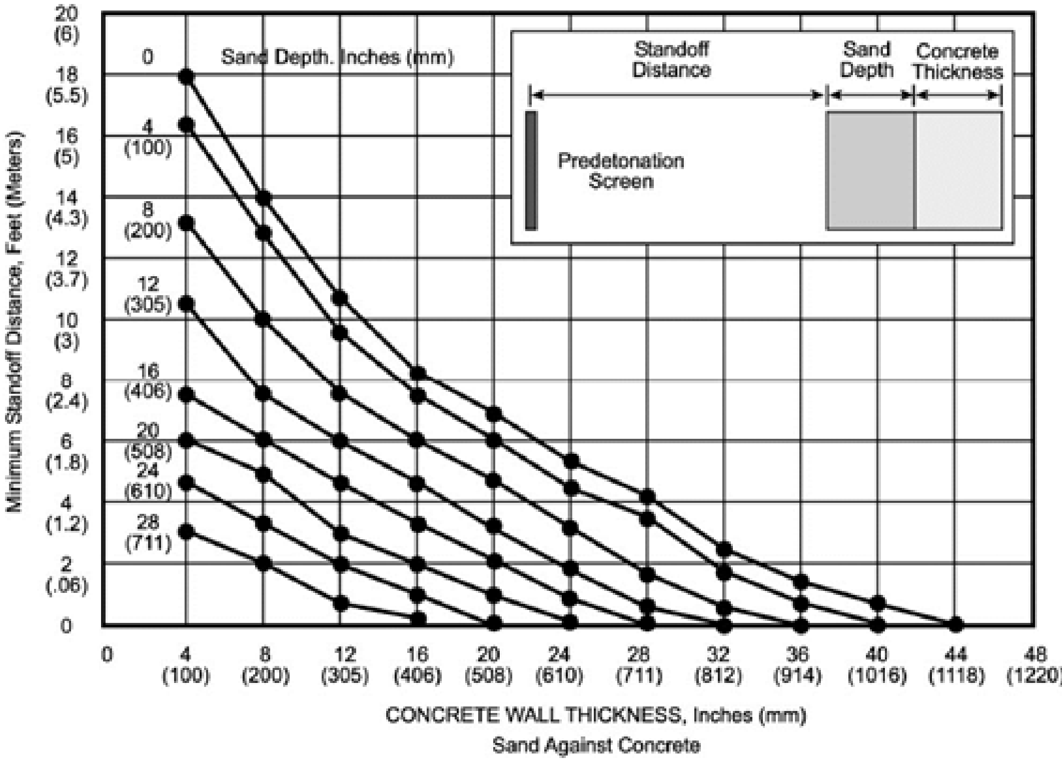


Figure 5-3. Anti-Tank Weapon Retrofit Using Sand and Spall Plate

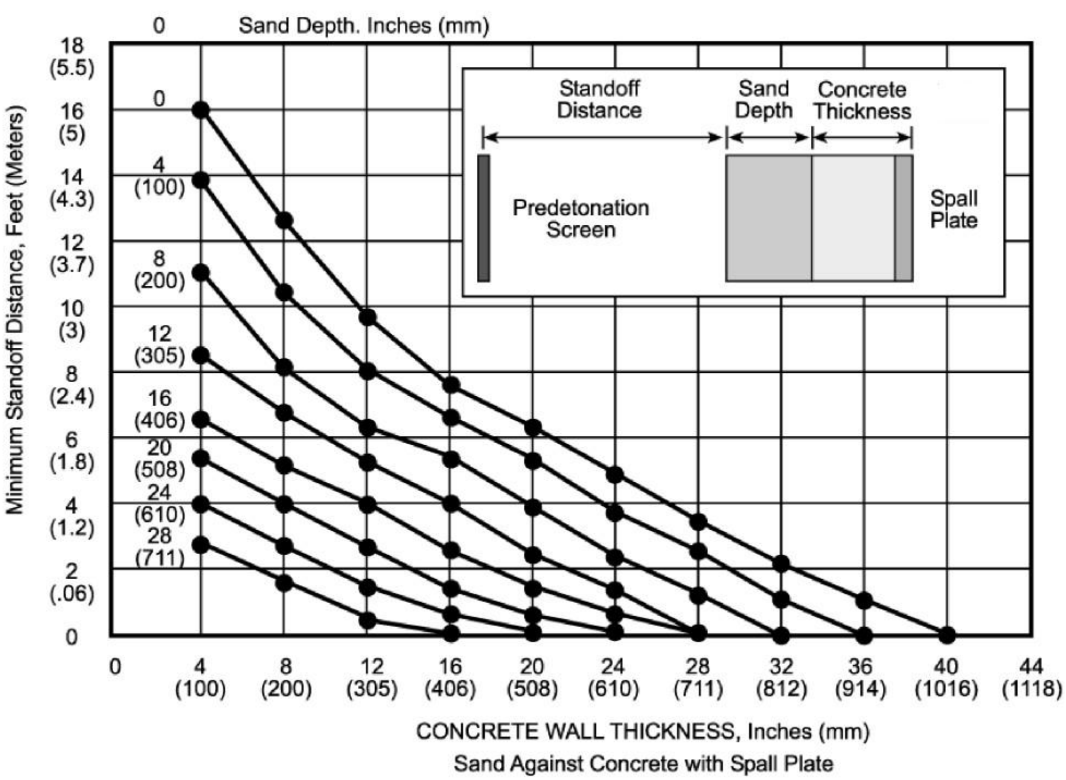


5-3.3.3 Ballistic and Anti-tank Weapon Threats.

The very high threat severity level is shown in Table 2-1 to include both high caliber ballistics and anti-tank weapons. In designing against both of those threats, apply both Tables 5-1 and 5-2 and use whichever construction is heaviest.

5-3.4 High Level of Protection.

The design strategy for the high level of protection is predicated on resisting the full effects of the ballistic or anti-tank rounds without any energy reduction or predetonation. That strategy results in hardened construction for all building components to which there are lines-of-sight and behind or under which there are assets that require protection. It can result in an entire building envelope or portions thereof being hardened depending on building layout and asset location. Walls constructed to resist ballistics or antitank weapons will commonly need to be constructed of reinforced concrete or masonry. Steel plate can also be added to existing wall construction as a retrofit.

5-3.4.1 Design Using Tables.

5-3.4.1.1 Ballistics Threat.

Table 5-3 provides construction that will resist the effects of direct hits by ballistics for all four threat severity levels. Some of the entries are from tests; others are from calculations. It includes reinforced concrete and concrete and clay brick masonry. Note that where concrete masonry unit construction is used, all cells must be grouted full.

Table 5-3 also includes steel plate and bullet resisting fiberglass, both of which can be used to retrofit existing walls that do not provide the necessary ballistic resistance. The steel plate includes both mild steel, which is common structural steel plate, and rolled homogeneous armor. The Brinnell Hardness Numbers for the two steel plate types are specified in the notes to Table 5-3. The bullet resistant fiberglass thicknesses are commercially available thicknesses that are based on tests. To design for other threats or to explore other options use the computational procedures later in this section.

5-3.4.1.2 Anti-tank Weapon Threat.

Table 5-4 provides the necessary thicknesses for a variety of potential construction materials to resist direct hits by anti-tank warheads. While the practicality of some of them is questionable, the results tabulated are provided for reference and to allow designers as much flexibility as possible.

Table 5-3 Ballistics Resistant Construction

Threat Level	Reinforced Concrete [1]	CMU [2] or Brick [1]	Steel Plate [1]		Bullet Resistant Fiberglass [1]
			Mild [3]	Armor [4]	
Low	2-1/2 inches (64 mm)	4 inches (100 mm)	5/16 inches (8mm)	1/4 inches (6mm)	7/16 inches (14mm)
Medium	4 inches (100 mm)	8 inches (200 mm)	9/16 inches (14 mm)	7/16 inches (11 mm)	1-1/8 inches (28.4mm)
High	6-1/2 inches (165 mm)	8 inches (200 mm)	13/16 inches (21 mm)	11/16 inches (18 mm)	Note 5
Very High	22 inches[6] (560 mm) 12 inches[7] (305 mm)	30 inches (760 mm)	1-1/4 inches (32 mm)	1 in. (25 mm)	Note 5

1. All thicknesses are nominal thicknesses. Reinforcement ration is not a significant factor in bullet resistance
2. For concrete masonry unit construction, all cells must be grouted full.
3. Brinnell Hardness Number for mild steel is 110 to 160
4. Brinnell Hardness Number for rolled homogeneous armor is 220 to 350
5. Bullet resisting fiberglass is not commonly available for bullets of these calibers or compositions.
6. Minimum compressive strength of 3000 psi (21 MPa).
7. Minimum compressive strength of 5000 psi (35 MPa).

Table 5-4 Anti-Tank Weapon Resistant Construction

Material	Thickness
Rolled Homogeneous Armor	22 inches (560 mm)
Mild Steel	28 inches (710 mm)
Aluminum	39 inches (990 mm)
Lead	20 inches (280 mm)
Copper	21 inches (530 mm)
Concrete	40 inches (1016 mm)
Concrete Masonry	44 inches (1118 mm)
Clay Brick Masonry	46 inches (1168 mm)
Granite	38 inches (965 mm)
Rock	39 inches (990 mm)
Soil	55 inches (1400 mm)
Water	62 inches (1575 mm)
Green wood	66 inches (1676 mm)

5-3.4.2 Design Using Computations.

Where threats are different than those in Table 2-1, where designers wish to explore options not included in the tables, or where they want to explore multiple materials or layers, the design tables above will fall short and designers will need to apply computational methods. Examples of evaluating multiple layers or materials include determining the required thickness of an inner wythe of a cavity wall after a bullet passes through the outer wythe and determining the effect of a steel plate mounted on the interior surface of a masonry wall. Note in the latter case that application of those equations is conservative where the two materials are in contact. Computational methods are presented separately for various materials for the ballistics threats, but there is only one computational method for the anti-tank weapons threat.

5-3.4.2.1 Ballistics Threats.

There are multiple ways to apply computational methods for designing building components to resist penetration by ballistics rounds. Complex finite element models can be used, but they are very expensive and seldom warrant the effort. There are also equations. The equations in this UFC come from the penetration chapter of UFC 3-340-01. In some cases, they have been modified slightly to compute the desired quantity, which is commonly the thickness of the material needed to resist perforation by a particular round. Applying the equations requires detailed knowledge of both the round and the material. Material properties that are not commonly known are provided. Projectile properties, including mass, velocity, and ratios needed to evaluate nose performance coefficients can be found in **\1** Appendix C **/1/**. All velocities in **\1**Appendix C **/1/** are muzzle velocities. Using those velocities is conservative because bullets will lose some velocity over distance due to drag.

Note that some of the equations are in metric units and some are in English units. Because the equations are largely curve fits of actual data, they are left in their original form rather than attempting to convert them to metric or English units.

5-3.4.2.1.1 Wood.

Equation 5.1 gives the thickness of wood necessary to resist perforation. Values for density and hardness for various species of wood can be found in Table 5-5. Where the thickness of wood target is less than that given by Equation 5-1, use Equation 5-2 to determine the residual velocity that the round will have after passing through the wood. Note that the latter case is how energy absorption screens can be designed. That residual velocity could then be applied to another material layer. In doing so, it is commonly assumed (conservatively) that the bullet retains all of its mass.

Equation 5-1. Wood Thickness to Prevent Projectile Perforation

$$T_W = 9837\left(\frac{v^{0.4113}w^{1.4897}}{\rho\left(\frac{\pi D^2}{4}\right)^{1.3596} H^{0.5414}}\right)$$

Where:
T_W = thickness of wood necessary to prevent perforation (in)
v = projectile impact velocity (ft/s) (conservatively use muzzle velocity in Appendix C)
w = projectile weight (lbs) (see Appendix C)
D = projectile diameter (in2)
ρ= wood density (lbs/ft3) (see Table 5-5)
H = wood hardness (lbs) (see Table 5-5)

Table 5-5 Wood Properties

Species		Density (lbs./ft^3)	Hardness (pounds)
Pine	Dry	23.5	38.7
	Wet	30	51.1
Maple	Dry	35	76.9
	Wet	40	72
Green Oak	Dry	55	88.1
	Wet	55	72.1
Marine plywood	Dry	37	68.7
	Wet	37	58.8
Balsa	Dry	6	21
	Wet	6	61.5
Fir plywood	Dry	30	75
	Wet	30	68.9
Hickory	Dry	50	74.3
	Wet	55	63.5

Equation 5-2. Residual Velocity from Wood Target

$$v_r = v\left[1.0 - \left(\frac{t}{T_w}\right)^{0.5735}\right]$$

Where:
v_r = residual velocity (ft/s)
t = actual target thickness (in)

5-3.4.2.1.2 Steel Plate.

The projectile velocity at which a given type and thickness of steel plate can prevent perforation is commonly referred to as the limit velocity. Equation 5-3 is a manipulation of the limit velocity equation for steel to give plate thickness. Note that the thickness reported by Equation 5-3 is what is necessary to stop complete perforation (the projectile passing completely through the plate and emerging with zero velocity). That represents a safe condition for most applications, although there are times when ensuring that there is no rear face spalling is necessary. In those cases, add two bullet diameters to the plate thickness determined from Equation 5-3. Note that Equation 5-3 is only valid for calibers of 0.50 (12.7 mm) or less. For larger calibers, refer to UFC 3-340-01.

If the plate thickness is less than that given in Equation 5-3, the bullet will pass through the plate with a residual velocity, which can be predicted using Equation 5-4. That residual velocity could then be applied to another material layer. In doing so, it is commonly assumed (conservatively) that the bullet retains all of its mass. In that equation, impact velocity can initially (conservatively) be taken to be muzzle velocity. Where the equation is used to evaluate multiple protective layers, the residual velocity would be used as the impact velocity in equations 5-3 or 5-4 or in other similar equations for other materials.

Equation 5-3. Steel Thickness to Prevent Projectile Perforation

$$T_S = D\left(\frac{vm^{0.5}\cos^{0.8}\theta}{1.125D^{1.5}\log_{10}BHN}\right)^{1.25}$$

Where:
v = impact velocity (m/s) (initially use maximum muzzle velocity from Appendix C.)
D = projectile diameter (mm) (see Appendix C)
T_S = thickness of steel plate to prevent perforation (mm)
θ = angle of obliquity (degrees)(see glossary)
m = mass of projectile (kg) (see Appendix C)
BHN = Brinnell Hardness Number (see Table 5-3)

Equation 5-4. Residual Velocity from Steel Plate Target

$$v_r = \left\{v^2 - \left[\frac{1.1275\left(\frac{t}{D}\right)^{0.8} D^{1.5}\log_{10}BHN}{m^{0.5}\cos^{0.8}\theta}\right]^2\right\}^{0.5}$$

Where:
t = thickness of steel plate (mm)
v_r = residual velocity (m/s)
v = impact velocity (m/s)

5-3.4.2.1.3 Concrete.

Concrete is the most common construction material used to provide bullet resistance. Calculating the thickness of concrete needed to stop projectiles requires the application of two equations. Use Equation 5-5 to determine projectile penetration into concrete for an air backed slab. If the wall is soil backed rather than air backed, see UFC 3-340-01. Determine the minimum thickness of concrete to prevent perforation of the wall slab by entering the results of Equation 5-5 into Equation 5-7, which provides the thickness at which the nose of the projectile reaches the back face of the slab, but with zero velocity. That is sufficiently safe for most applications in that any concrete that "spalls" off the back face is likely to represent a minimal hazard. Where that is not considered acceptable, use Equation 5-8, which provides the thickness required to prevent spall. These equations can also reasonably be used to estimate behavior of masonry. To do so, enter the lower of the compressive strength of the grout, the mortar, and that of the blocks or bricks themselves in Equation 5-5 for $f_c^{'}$.

If the concrete thickness is less than that calculated in Equation 5-7, the bullet will pass through the wall with a residual velocity, which can be predicted using Equation 5-9. That residual velocity could then be applied to another material layer as the impact velocity. In doing so, it is commonly assumed (conservatively) that the bullet retains all of its mass.

Equation 5-5. Penetration into Concrete (air backed)

$$P_C = \frac{56.6\left(\frac{m}{D^3}\right)^{0.075} \overline{N} m v^{1.8}}{D^2 \sqrt{f_{C'}^{'}}} \left(\frac{D}{c}\right)^{0.15} f_{age} + D$$

Where:
P_C = Maximum penetration into concrete (mm)
D = projectile diameter (mm) (see Appendix C)
m = projectile mass (kg) (see Appendix C)
c = maximum gravel size in concrete (mm)
(assume to be 19 mm for most concrete and 4 mm for concrete masonry)
v = impact velocity (m/s) (conservatively use muzzle velocity in Appendix C)
$f_C^{'}$ *= concrete compression strength (MPa)*
$\overline{N}$ *= nose performance coefficient (see equation 5-6)*

- *= 0.91 for low threat severity level*
- *= 1.26 for medium threat severity level*
- *= 1.39 for high threat severity level*
- *= 1.31 for very high threat severity level*

f_{age}*= concrete age factor*

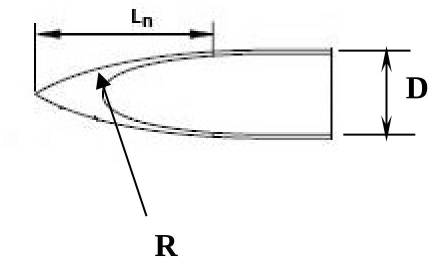
f_{age}	Concrete age (days)
1.0	≥ 360
1.01	180
1.02	66
1.05	≤ 28

Equation 5-6. Nose performance coefficient

$\overline{N} = 0.72 + 0.25\left(\frac{L_N}{D}\right)$ *(values for* $\overline{N}$ *are tabulated in Table C-1 for common bullets)*

$\frac{L_N}{D}$ *can also be calculated as* $\left(\frac{R}{D} - 0.25\right)^{0.5}$

$\frac{R}{D}$ *is tabulated in some publications as CRH (caliber radius head)*



Note: If the tangent ogive is truncated, use the actual L_N of the truncated nose in equation 5-6. If the nose shape does not conform to a tangent ogive, select an equivalent ogive with a similar length-to-diameter ratio using engineering judgment

L_N = nose length of projectile
R = tangent ogive radius

Equation 5-7. Perforation Limit Thickness for Air Backed Concrete Slabs

$$T_{BD} = D\left[1.375\left(\frac{P_C}{D}\right) + 2\right]$$

T_{BD} = thickness to prevent back face damage (mm)

Equation 5-9. Residual Velocity Equation from Concrete Slab Target

$$v_r = v\left(1 - \frac{\frac{t}{D}}{\frac{T_{PL}}{D}}\right)^{0.733}$$

Where:
v_r = residual velocity (m/s)
v = impact velocity (m/s)
t = slab thickness (mm)

5-3.4.2.2 Anti-tank Weapon Threat.

Anti-tank weapon penetration of building materials is not as well understood as ballistics penetration, but Equation 5-10 can be used to estimate common building material thicknesses necessary to resist perforation by anti-tank warheads for weapons within the family of antitank weapons covered by the UFC. The equation is a function of warhead diameter and is based on the required thicknesses of rolled homogeneous armor. The material multiplication factor "corrects" the thickness for armor to that for other materials. The following are common warhead diameters for the weapons discussed in Chapter 2 that can be used in applying Equation 5-9.

- Russian RPG 7 (and similar copies): 70 mm
- Russian RPG 18 (and similar copies): 64 mm
- Russian RPG 22 (and similar copies): 72.5 mm
- US M 72: 66 mm

Equation 5-10. Building Material Thickness to Resist Anti-tank Weapons

$$T = 7.79\ D\ M$$

Where:
T = thickness of the building material to resist perforation (in)
D = warhead diameter (in)
M = Material Multiplication Factor (see Table 5-6)

Table 5-6 Material Multiplication Factors for Antitank Weapon Resistance

Target Material	Material Multiplication Factor (M)	Material Density
Rolled Homogeneous Armor	1.00	7850 Kg/m^3 (490 $lb/ft^{3)}$
Mild steel	1.25	7850 Kg/m^3 (490 $lb/ft^{3)}$
Aluminum	1.75	2600 Kg/m^3 (160 $lb/ft^{3)}$
Lead	0.88	10,600 Kg/m^3 (660 $lb/ft^{3)}$
Copper	0.94	8900 Kg/m^3 (556 $lb/ft^{3)}$
Concrete	1.82	2400 Kg/m^3 (150 $lb/ft^{3)}$
Concrete Masonry	1.98	2000 Kg/m^3 125 lb/ft^3
Clay Brick Masonry	2.02	1920 Kg/m^3 120 lb/ft^3
Granite	1.68	2800 Kg/m^3 (170 $lb/ft^{3)}$
Rock	1.75	2600 Kg/m^3 (160 $lb/ft^{3)}$
Earth	2.47	1300 Kg/m^3 (80 $lb/ft^{3)}$
Water	2.80	1000 Kg/m^3 (60 $lb/ft^{3)}$
Green wood	2.97	900 Kg/m^3 (60 $lb/ft^{3)}$
Note: For other materials $M = \sqrt{\frac{\rho_s}{\rho_t}}$ ρ_s = density of steel; ρ_t = density of target material		

5-3.4.3 Design Based on Testing.

For ballistics threats there are a number of testing standards that can be used to test building components against a range of different ballistics rounds. Those test standards specify how the test specimens will be set up, the mass and velocity of the bullets to be used in the test, the number and positioning of the shots, and the criteria for “passing” the test. Testing can be used to test complex material interactions, to evaluate materials for which there are no computational methods and in cases where manufacturers wish to optimize designs. Refer to the test standards tabulated in **\1** Appendix C **/1/** for detailed information. There are no standardized tests for antitank weapons, but tests can be conducted using similar failure criteria to those of the ballistics tests.

5-4 WINDOWS.

5-4.1 Very Low Level of Protection.

Because the design strategy for the very low level of protection is limited to incorporating the minimum standards of UFC 4-010-01, the DoD Minimum Antiterrorism Standards for Buildings, and since there are no minimum standards related to mitigating direct fire weapons effects against windows, there are no requirements for windows at this level of protection.

5-4.2 Low Level of Protection.

Because the design strategy for the low level of protection is limited to blocking lines-of-sight to targeted assets, window requirements are focused on obscuration. This level of protection applies to all ballistics and anti-tank weapon threats. Obscuration can be accomplished by controlling sight lines to assets through window layout and placement, window design, window treatment application, or shielding. In addition, consider minimizing the number and size of windows to decrease visible window area and limit available targets. In addressing window layout and placement, consider layouts and placements that do not allow sight lines to assets from outside the building using window configurations such as those shown in Figures 5-4 and 5-5. Alternatively, arrange rooms to ensure that potentially targeted assets cannot be seen through the windows or block sight lines through windows using screening materials such as fences or vegetation as described in Chapter 4.

Figure 5-4. Narrow Obliquely Recessed Windows

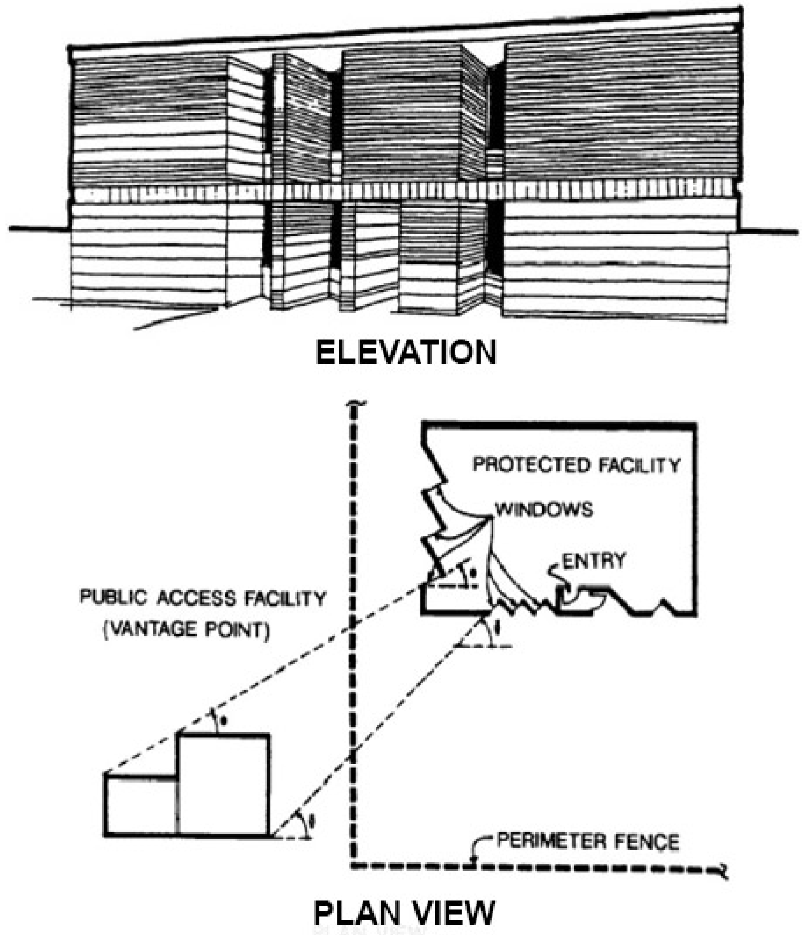


Figure 5-5. Elevated Windows

5-4.2.1 Low Level of Protection Alternatives.

An alternate approach is to design windows to limit sight lines through them by using translucent or figured glazing that allows light in but is not sufficiently transparent for people to be able to see anything through them.

Windows can also be treated with reflective films or glazing tints to limit views into buildings from outside. This is particularly useful for windows in existing buildings where there is little opportunity for reconfiguration. Reflective films are made by applying a thin metallic layer to a polyester or similar film to limit how much light passes through the film, a characteristic referred to as “visible transmittance”. When one side of the film is brighter than the other side, a relatively large amount of light is reflected off the bright side of the film. The reflection of that light results in an observer on the bright side seeing a mirror –like image while an observer on the darker side can see through the window. At night when the outside of the window becomes darker than the inside, more light is transmitted from the lit rooms inside of the building to the outside and an observer outside will see through the window while people inside the room will see a reflective surface. That suggests that drapes or blinds may need to be provided to obscure assets at night.

5-4.3 Medium Level of Protection.

The design strategy for this level of protection is to employ energy absorption or predetonation screens to limit the energy with which the projectiles impact the target and to provide hardened construction to prevent the projectiles from penetrating the protective envelope. In general, is not practical to apply that strategy to window designs to resist high caliber ballistics (12.7 mm or .50 caliber) and anti-tank weapons. Windows cannot be practically designed to resist predetonated anti-tank rounds, and while it may be feasible to design windows for reduced energy ballistics, most windows are designed and tested to meet particular ballistic standards, none of which address reduced energy ballistics. Developing window designs for that situation would therefore be impractical. One approach that can be used for both anti-tank weapons and high caliber ballistics is to use Tables 5-1 or 5-2 or Figures 5-2 or 5-3 to locate energy absorption or predetonation screens and to locate walls constructed to resist reduced energy or predetonated rounds a short distance in front of windows to shield them. Where such options are employed, ensure that the walls and screens do not provide opportunities for concealment with in the unobstructed space required by UFC 4-010-01. A more common approach to addressing this level of protection for the high caliber ballistics and antitank weapons is to minimize the number and size of windows to decrease visible window area and limit available targets. While that does not fully provide the medium level of protection to the same extent that it is provided for walls or other building components, doing anything else has limited practicality.

5-4.4 High Level of Protection.

The design strategy for the high level of protection applies similarly to all threat severity levels. It entails providing windows that resist the direct impact of the ballistic or anti-tank rounds. Designing windows to resist antitank rounds is impractical, however. The only practical approaches to addressing this level of protection against anti-tank weapons are to either eliminate windows or to take the reduced window area and layout approaches described in the low level of protection paragraph above. The latter will not fully mitigate the vulnerabilities associated with this tactic, which will require assumption of some risk on the part of the building occupants.

Ballistic resistant windows are commonly designed based on testing to standards such as those tabulated in Appendix C. It is important to note that window designs to meet those standards must include entire window assemblies including glazing, frames, and connections assembled as they would be in the field. Testing assemblies ensures that all potential impact points on a window provide ballistics resistance. Window designs will usually be proprietary and may use a variety of glazing and frame materials. Manufacturers certify their compliance with the standards, usually through independent testing laboratories. Window designs for non-armor piercing rounds of 7.62 mm (.30 caliber) and below are commonly available from most bullet resistant window manufacturers. Designs to resist armor piercing rounds are less common. That makes it important that designers review the actual test reports to ensure the tests follow procedures similar to those in national standards and that the results appear to be reasonable.

5-5 DOORS.

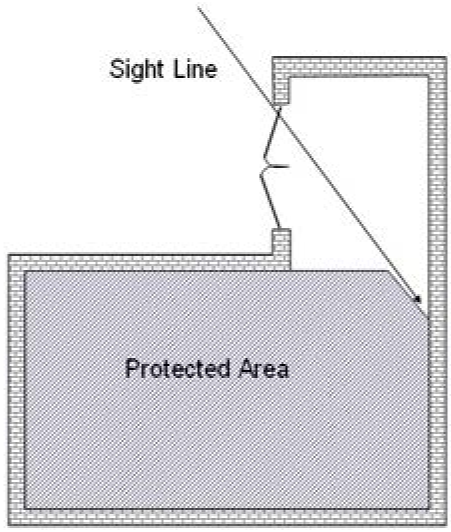
5-5.1 Very Low Level of Protection.

While the design strategy for the very low level of protection is limited to incorporating the minimum standards of UFC 4-010-01, the DoD Minimum Antiterrorism Standards for Buildings, there is a minimum standard that involves doors. It requires main entrances to inhabited buildings to be oriented such that they do not face installation perimeters or uncontrolled vantage points to minimize vulnerabilities to people entering or leaving buildings. Where such orientations are not an option, the standard allows for providing means to block lines of sight. Means to block lines of sight are described in the following paragraph. In existing buildings changing entrance orientation may require significant changes in building operations, such as using an alternate entrance as a main entrance. The option of blocking sight lines is often the most practical for existing buildings.

5-5.2 Low Level of Protection.

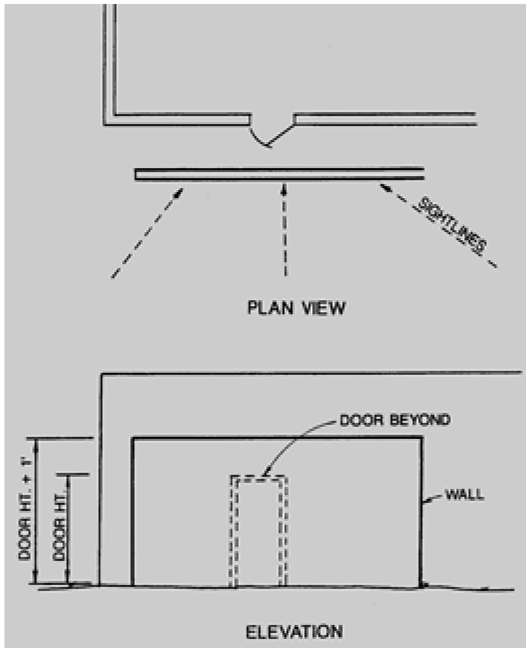
Because the design strategy for the low level of protection is limited to blocking lines-of-sight to targeted assets, door requirements are focused on obscuration. This level of protection applies to all ballistics and anti-tank weapon threats. Obscuration can be accomplished by controlling sight lines through door layout, door design, or shielding. In addressing door layout, consider door arrangements that do not allow sight lines to assets from outside the building such as the layout shown in Figure 5-6 or through the use of foyers in front of doors. Alternatively, arrange rooms to ensure that potentially targeted assets cannot be seen through the doors.

Figure 5-6. Entrance Layout to Limit Sight Lines



Doors can also be designed to limit sight lines through them by making them opaque (as wood or metal doors would be) or by using translucent or figured glazing for vision panels that allow light in but are not sufficiently transparent for people to be able to see anything through them. Vision panels in doors can also be treated with reflective films or glazing tints to limit views into buildings from outside as described above for windows. Note that drapes or blinds need to be provided to obscure assets at night as described previously. Drapes or blinds cannot be used for egress doors, however, unless they are built into the doors' vision panels or the doors will violate the requirements of NFPA 101, the Life Safety Code. Sight lines to doors can also be blocked by shielding the door from vantage points using walls or other screening materials as illustrated in Figure 5-7. This is a particularly useful option for limiting sightlines through existing doors. For the low level of protection, the screening material only needs to be sufficient to limit vision through it. Design the shield to be wider than the door by a distance established by extending a line from the door frame to the end of the wall at a 45^0 angle from the building on both sides of the door as shown in Figure 5-7. Design the shield to be higher than the door by at least the distance shown in Figure 5-7. Ensure the shield does not interfere with the requirements in NFPA 101 for egress and egress discharge. Doing so may require the shield to be moved away from the door, which may make it necessary to extend the wall.

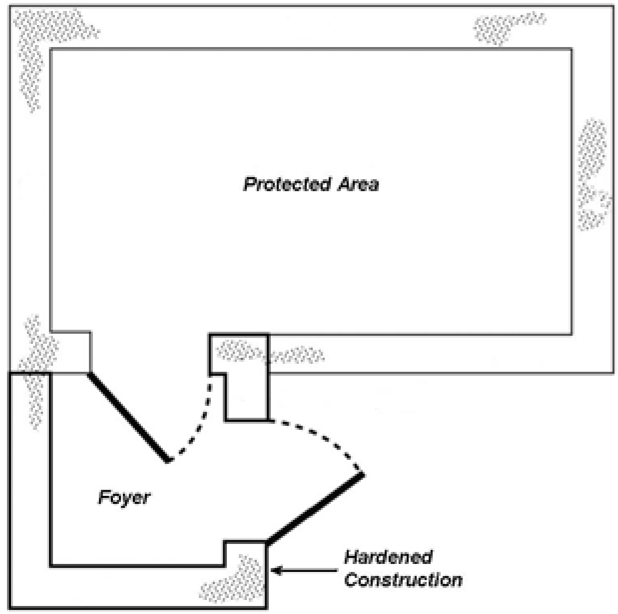
Figure 5-7. Door Shielding



5-5.3 Medium Level of Protection.

In general, the medium level of protection is only practical for high caliber ballistics (.50 caliber or 12.7 mm) or anti-tank weapons. The applicable design strategy is to employ energy absorption or predetonation screens to limit the energy with which the projectiles impact the target and to provide hardened construction to prevent the projectiles from penetrating the protective envelope. It is not practical to design doors to resist predetonated anti-tank rounds. While it may be possible to design doors for reduced energy ballistics, most doors are designed and tested to meet a particular ballistic standard and the reduced energy ballistics would not be reflected by any of those standards. Developing door designs for that situation would be impractical. The approach used, therefore, is to use Tables 5-1 or 5-2 or Figures 5-2 or 5-3 to locate energy absorption or predetonation screens and to select wall construction to resist reduced energy or predetonated rounds. Such walls should be configured in foyer arrangements as illustrated in Figure 5-8 or in shielding configurations as in Figure 5-7. In either case, the walls would provide all the necessary resistance to the threat and the doors could be of any material.

Figure 5-8. Hardened Foyer Configuration



5-5.4 High Level of Protection.

The design strategy for the high level of protection is to provide construction that resists the direct impact of ballistics or anti-tank rounds. Approaches to applying that strategy for doors are different for high caliber ballistics and anti-tank rounds and smaller caliber ballistics.

5-5.4.1 Small caliber ballistics.

For ballistics below 0.50 caliber (12.7 mm) the design approach is to use bullet resistant door assemblies. Those assemblies are tested in accordance with standards such as those in Appendix C. Note that, as for windows, tested door designs to meet those standards must include entire door assemblies including, frames, hardware, vision panels, and connections assembled as they would be in the field. Testing assemblies ensures that all potential impact points on a door provide ballistics resistance. Doors are available from multiple manufacturers to meet the various standards, although not all manufacturers provide doors to meet all the standards.

Door designs will commonly be proprietary and may use a variety of different door and frame materials. Manufacturers certify their compliance with the standards, usually through independent testing laboratories. Ballistics resistant doors will often be of the same approximate dimensions and outward appearance as conventional doors, but their cores may include other materials such as steel or bullet resistant fiberglass as shown in Figure 5-9. Note that bullet resistant doors may be significantly heavier than conventional doors, which may make them more difficult to operate and may require heavier duty door operators where they are necessary. Egress doors must meet the requirements of NFPA 101 for maximum allowable door operating force.

Figure 5-9. Bullet Resistant Fiberglass Door Core

5-5.4.2 High Caliber Ballistics and Anti-tank Weapons.

Doors designed to resist direct impacts from anti-tank rounds are not practical; therefore, the approach to providing the high level of protection for that threat for doors is to design foyers in front of the doors as shown in Figure 5-8. The exterior foyer wall would be designed to provide the full resistance to the anti-tank round. Door designs to resist .50 caliber (12.7 mm) rounds are available, but at the time this UFC is being written none were tested to any nationally approved standards because such a standard was only recently developed. That makes it important that designers review the actual test reports to ensure the tests follow procedures similar to those in national standards and that the results appear to be reasonable. Alternatively, application of hardened foyers as described above is a good option for protecting doors against high caliber ballistics.

5-6 VENT COVERS AND GRILLES.

Where there are potential sight lines to assets through vents or other building openings they should be protected similarly to windows and doors.

5-6.1 Very Low Level of Protection.

Because the design strategy for the very low level of protection is limited to incorporating the minimum standards of UFC 4-010-01, and since there are no minimum standards related to mitigating direct fire weapons effects against vent covers or grills, there are no requirements for vents or grills at this level of protection.

5-6.2 Low Level of Protection.

Because the design strategy for the low level of protection involves obscuration, ensure that any vent covers or grilles through which there are potential sight lines to assets are designed such that aggressors cannot see through them. Alternatively, shield them or block sightlines to them using opaque materials or vegetation or ensure through room arrangement that there is nothing that could be targeted through them. Any shielding using site furnishings or vegetation must avoid providing opportunities for concealment within the **\1\/1/** unobstructed space required by UFC 4-010-01.

5-6.3 Medium Level of Protection.

The design strategy for the medium level of protection is to employ energy absorption or predetonation screens to limit the energy with which the projectiles impact the target and to provide hardened construction to prevent the projectiles from penetrating the protective envelope. That approach is only practical for high caliber ballistics (.50 caliber or 12.7 mm) or anti-tank weapons. Designing vent covers or grilles to resist predetonated anti-tank rounds is not practical; therefore, the vents should be shielded by a wall designed to resist the predetonated round as described in the sections above on walls and doors. Vent covers or grilles could be designed to resist reduced energy ballistics or they could be shielded with walls designed to resist the reduced energy rounds. To design vent covers and grilles to resist the reduced energy rounds locate an energy absorption screen in accordance with the section above on walls and use Equations 5-3 and 5-4 to design steel louvers. Where shielding walls are used, ensure that their location and configuration are communicated to the mechanical engineers to ensure that their heating, ventilation, and air conditioning designs take the potential for reduced air flow into account.

5-6.4 High Level of Protection.

Because the design strategy for this level of protection requires protective elements to resist the direct impact of rounds and because resistance of vent and grill materials to anti-tank weapons and low and high caliber ballistics are so different, each of those applications will be discussed separately.

5-6.4.1 Low Caliber Ballistics.

Design vent covers or grilles with steel plate using equation 5-3 or use vent covers and grilles that have been tested for ballistics resistance to an appropriate standard.

5-6.4.2 High Caliber Ballistics and Antitank Weapons.

Designing vent covers and grilles to resist the direct impact of 12.7 mm (.50 caliber) bullets or anti-tank rounds would be impractical. Use shielding walls to resist the rounds or orient the openings so they cannot be targeted. Where shielding walls are provided, ensure that their location and configuration are communicated to the mechanical engineers to ensure that their heating, ventilation, and air conditioning designs take the potential for reduced air flow into account.

5-7 ROOFS.

Designing roofs to resist direct fire weapons is only an issue where there are sightlines to roofs. Where that is the case, design the roof similarly to walls.

5-7.1 Very Low Level of Protection.

Because the design strategy for the very low level of protection is limited to incorporating the minimum standards of UFC 4-010-01, and since there are no minimum standards related to mitigating direct fire weapons effects against roofs, there are no requirements for roofs at this level of protection.

5-7.2 Low Level of Protection.

Because the low level of protection is predicated on blocking sightlines to assets, ensure the roof is opaque or translucent and treat any skylights like windows using the guidance in the window section above.

5-7.3 Medium Level of Protection.

Because the design strategy for this level of protection involves erecting energy absorption or predetonation screens and designing to resist the reduced energy or predetonated rounds it is only practical for high caliber (12.7 mm or .50 caliber) or anti-tank rounds. Designing for this level of protection will require erecting an energy absorption or predetonation screen above the roof by the appropriate distance and of the appropriate material and designing the roof to resist the reduced energy or predetonated round. Follow the guidance in the wall section above in designing for this condition. That design will be conservative because it is predicated on perpendicular impacts and roof impacts will most likely be at oblique angles. The steel penetration equations for ballistics do take angle of obliquity into account, however.

5-7.4 High Level of Protection.

Because the design strategy for the high level of protection depends on building components resisting the direct impact of incoming rounds, where there are direct sight lines to roofs the roofs will have to be designed using materials such as reinforced concrete or steel to provide the necessary resistance.

Use the guidance in the wall section of this chapter to design roofs to resist either ballistics or anti-tank threats. Note that impacts on roofs will commonly be at oblique angles, so the tabulated material thicknesses in Tables 5-1 and 5-2 will be conservative as will most of the equations in this chapter. The exception to that is Equation 5-4 for steel, which includes angles of obliquity. Another option is to provide high parapets that block sightlines to the roof. For this level of protection those parapets would either be sufficiently constructed to provide all the penetration resistance necessary or the combination of the parapet and the roof material would have to provide the resistance. Refer to the wall section of this chapter to design the parapets. Figure 5-10 shows a raised parapet configuration.

Figure 5-10. Raised Parapets

APPENDIX B GLOSSARY

B-1 ACRONYMS

ANSI	American National Standards Institute
AP	Armor piercing
ASTM	Not an acronym. Formerly American Society for Testing and Materials
AT	Anti-tank
CNSC	Conical nosed soft core
CRH	Caliber Radius Head
DoD	Department of Defense
FCJ	Full copper jacket
FMCJ	Full metal copper jacket
FMJ	Full metal jacket
FSJ	Full steel jacket
ft/s	Feet per second
g	Grams
gr.	Grains
JSP	Jacketed soft point
lbs	Pounds
LAW	Light anti-tank weapon
mm	Millimeters
m/s	Meters per second
NATO	North Atlantic Treaty Organization
NIJ	National Institute of Justice
RN	Round nosed
RNL	Round nosed lead
RNSC	Round nosed soft core

RPG	Rocket propelled grenade
SHC	Steel hard core
SWC	Semi - wadcutter
UL	Underwriters Laboratories

B-2 DEFINITION OF TERMS:

Ammunition. One or more loaded cartridges consisting of a primed case, propellant and with or without one or more projectiles.

Angle of obliquity. The vertical angle from the perpendicular at which a projectile strikes a target.

Armor piercing. The characteristics of bullets that allow them to penetrate armor, relying on the design characteristics of the projectile, such as the shape of the tip and materials used in the bullet, rather than upon increased muzzle energy. The effects of armor piercing rounds differ from other rounds only in their ability to penetrate greater material thicknesses, especially of hardened or armored materials such as steel or composite assemblies including multiple layers of steel.

Ball. In ballistics, a general term used to describe military bullets which are entirely inert and intended for antipersonnel and general use. The term is used to distinguish them from specialized bullets such as tracers.

Ballistic Limit Velocity. That velocity for which there is a 50% probability of target perforation.

Buckshot. The coarse lead-alloy spherical pellets loaded in shotgun shells as projectiles. Buckshot is manufactured in sizes up to 1/3-inch diameter.

Building elements. Components of buildings and countermeasures associated directly with building interiors and exterior surface features.

Bullet resistant. A descriptive term for a material designed to prevent injury to persons or damage to objects positioned behind it when subjected to a ballistics attack.

Caliber. The caliber of a bullet refers to its diameter and is expressed either in decimals of an inch or in millimeters. Typical examples include the 9mm (.38 caliber), 5.56mm **\1** (.22 caliber) and 7.62mm (.30 caliber) **/1/** ammunition for military arms.

Controlled perimeter. For the purposes of this UFC, a physical boundary at which vehicle access is controlled with sufficient means to channel vehicles to the access control points. At a minimum, access control at a controlled perimeter requires the demonstrated capability to search for and detect explosives. Where the controlled perimeter includes a shoreline and there is no defined perimeter beyond the shoreline, the boundary for measuring standoff distances will be at the mean high water mark or the elevation associated with top of bank (associated with a flood recurrence interval of 1.2 years). (UFC 4-010-01)

Countermeasure. Any protective element put in place to mitigate the effects of a threat. Countermeasures may include building elements, sitework elements, building support systems, equipment, and manpower and procedures.

Design Strategy. The approach for developing a protective system to mitigate the effects of an attack. There are both general design strategies and specific design strategies (specific to levels of protection) associated with each tactic.

Dudding. Rendering a live round inert.

Effective range. The maximum distance at which a weapon may be expected to be accurate and achieve the desired effect.

Energy absorption screen. A solid surface that causes the energy of a projectile to be reduced as the projectile passes through the screen with a residual velocity.

Full metal jacketed. A bullet made of lead and completely covered, except for the base, with a copper alloy jacket (approximately 90 percent copper and 10 percent zinc). Most military bullets are full metal jacketed.

Gas checked. In ballistics, a method for preventing the lead buildup in high velocity handguns. A lead buildup occurs when an uncased soft lead bullet is propelled through a gun barrel by a column of gas, causing enough friction to melt the edges of the base of the lead bullet and subsequently causing a deposit of molten lead on the inner barrel of the gun. To prevent this, a shallow copper cup is placed on the base of the bullet to insulate it from the heat of the powder gases and to prevent lead buildup along the rifle bore.

Gauge. In ballistics, the size of a shotgun expressed as the number in a pound of round lead balls of a size to just fit into the barrel.

Grain. In ballistics, a measure of weight which is 1/7,000th of an English pound. Grains are used to express the weight of bullets used for all ballistics standards.

Jacketed soft point. A bullet made of lead and completely covered, except for the point, with copper alloy (approximately 90 percent copper and 10 percent zinc). The absence of jacketing at the point of the bullet enhances its deformation upon impact.

Level of Protection. The degree to which an asset (person, equipment, object, etc.) is protected against injury or damage from an attack. (UFC 4-010-01)

Lines of sight. Unobstructed direct views from vantage points to targets.

Magnum. A load or cartridge having greater power than other cartridges of the same caliber. A magnum case is generally longer than a common case. For example, a .44 Magnum is approximately 1/8 inch longer than the .44 Special. A .44 Magnum revolver will chamber either round, but a .44 Special revolver will chamber only the .44 Special cartridge. Another variation of the magnum is a cartridge with an exceptionally large propellant capacity in relation to the bore diameter, such as the .300 Winchester Magnum.

Muzzle velocity. The velocity of a projectile as it exits the muzzle of a firearm.

Obscuration. Blocking sightlines using any form of screening, vegetation, or building treatment.

Parabellum. Cartridges and pistols originating with Deutsche Waffen and Munitions Fabrik, Berlin; a term derived from their telegraphic address and trademark.

Penetration. Intrusion of a projectile beyond the strike face of a material without emerging from the protected face.

Perforation. Complete penetration through a material creating an opening in both the threat (target) face and the protected face.

Predetonation screen. A solid surface that causes an antitank round to detonate before it reaches its target. When placed at the proper distance for the facility construction, the screen will prevent penetration of the facility exterior by the antitank round.

Residual velocity. In ballistics, the velocity a projectile has after it has perforated a layer of material.

Round Nosed Lead. A lead bullet with a blunt, rounded tip.

Semi wadcutter. Intermediate bullet shape between round-nose and wadcutter (flat point).

Sitework elements. Countermeasures that are applied beyond 1.5 meters (5 feet) from a building, excluding countermeasures categorized under equipment.

Small arms. describes any number of smaller infantry weapons, such as firearms that an individual soldier can carry. It is usually limited to revolvers, pistols, submachine guns, shotguns, carbines, assault rifles, rifles, squad automatic weapons, light machine guns.

Spall. The condition in which pieces of a material are broken loose from the inner surface of a wall, roof, or similar element by tensile forces that are created when a compression shock wave travels through the body and reflects from the surface.

Temperate zone. Either of two middle latitude zones of the Earth; the Northern Temperate Zone and the Southern Temperate Zone, lying between 23-1/2 degrees and 66-1/2 degrees north and south.

Unobstructed space. Space around inhabited buildings in which there are no opportunities for concealment from observation of explosive devices 6 inches (150 mm) or greater in height or width. (UFC 4-010-01)

Witness panel. In ballistics, a material such as aluminum foil or corrugated cardboard that is positioned behind and parallel to a test target. Witness panels are used to provide evidence of penetration and spall created during impact of a test sample.

AP = armor piercing
CNSC = Conical Nosed Soft Core
FCJ = Full Copper Jacket
FMCJ = Full Metal Copper Jacket
FMJ = Full Metal Jacket
FSJ = Full Steel Jacket

JSP = Jacketed Soft Point
RN = Round Nosed
RNL = Round Nosed Lead
RNSC = Rounds Nosed Soft Core (lead)
SHC = Steel Hard Core
SWC = Semi Wad Cutter

$\overline{N}$ = Nose Shape Coefficient
n/a = not applicable
ft/s = feet per second
m/s = meters per second
gr. = grains
g = grams

in = inches
mm = millimeters

C-2 UL LEVELS

LEVEL 1: Protection against hand guns of medium power, such as the 9 mm, Super 38 Automatic, and the like, with muzzle energy of 380 – 460 foot-pounds (515 – 624 J).

LEVEL 2: Protection against hand guns of high power, such as the .357 Magnum, and the like, with muzzle energy of 548 – 663 foot-pounds (743 – 899 J).

LEVEL 3: Protection against hand guns of super power, such as the .44 Magnum, and the like, with muzzle energy of 971 – 1175 foot-pounds (1317 – 1593 J).

LEVEL 4: Protection against high-power hunting and sporting rifles, such as the 30-06, and the like, with muzzle energy of 2580 – 3120 foot-pounds (3498 – 4929 J).

LEVEL 5: Protection against military ball full metal copper jacket ammunition fired from a hunting rifle such as the 308 Winchester or a military rifle with muzzle energy of 2519 – 3048 foot-pounds (3416 – 4133 J).

LEVEL 6: Protection against multiple shots from a submachine-gun, such as a 9 mm Uzi, and the like, with muzzle energy of 540 – 653 foot-pounds (732 – 885 J).

LEVEL 7: Protection against multiple shots from a military assault rifle, such as an M-16, and the like, with muzzle energy of 1158 – 1402 foot-pounds (1570 – 1901 J).

LEVEL 8: Protection against multiple shots from a military assault rifle, such as an M-14, and the like, with muzzle energy of 2519 – 3048 foot-pounds (3416 – 4133 J).

LEVEL 9: Protection against armor piercing rounds fired from an M1 Garand rifle or the like, or high-power hunting and sporting rifles with muzzle energy of 2717 to 2777 foot-pounds (3683 – 4457 J). The bullet will be a .30-06 armor piercing round such as the US Military APM2.

LEVEL 10: Protect against one shot from a military sniper rifle, such as the Barrett M82 A1 (XM 107), with a muzzle energy of 12,439 – 12. 706 foot-pounds (16, 863 – 20,404 J). The bullet will be a .50 caliber round such as the US Military M2.

SUPPLEMENTARY SHOTGUN: A supplementary test using a rifled lead slug with a muzzle energy of 2438 – 2950 foot-pounds (3306 – 4000 J) and 00 lead buckshot with a muzzle energy of 2078 – 2415 foot-pounds (2818 – 3275 J), fired from a 12-gauge shotgun. Products shall be tested with both loads. Products complying with this test may have the suffix ²-SG² added to the rating designation.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most **stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.**

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://DoD.wbdg.org/.

Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
NEW DOCUMENT SUMMARY SHEET

Subject: UFC 4-023-10, Safe Havens

Supersedes: None

Document Description and Need:

- **Purpose:** In some DoD facilities, a safe haven may be required to provide additional protection to DoD personnel and their dependents for man-made and natural threats. This UFC specifies the development of design criteria for these threats and provides guidance for satisfying those criteria when designing a safe haven.

- **Application and Use:** This UFC applies to the design of a safe haven for all DoD buildings and facilities that require additional protection from man-made and natural threats. The safe haven may also be used as a fallback position for the destruction of classified information during an attack. This UFC will be employed when the project planning team (as defined in UFC 4-020-01) and/or the facility owner require that a safe haven be incorporated into the building or facility. The primary use of this UFC is to design the safe haven for man-made threats and that the guidance provided herein for natural threats is for information purposes and the planner/designer shall design the facility for the natural threats as necessary in accordance with UFC 1-200-01, General Building Requirements.

- **Need:** No guidance previously existed for the design of safe havens within the DoD or any of its components.

Impact: The following benefits will result from publication of UFC 4-023-10.

- Consistency in the planning and design of safe havens will be implemented across DoD.

- Safe haven design will be based on careful consideration, identification, and evaluation of man-made and natural threats.

- The design of a safe haven will employ the best existing design guidance for man-made and natural threats.

- The safety of DoD personnel and dependents will be increased, for both CONUS and OCONUS applications.

Unification Issues
There are no unification issues.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides planning and design requirements and guidance for a safe haven. It is not intended to create the requirement for a safe haven, but to assist in meeting the planning and design criteria requirements. The requirement for a safe haven may come from Department of Defense (DoD) policy, service policy, installation requirements, or user requirements when supported by policy.

1-2 APPLICABILITY.

This UFC provides planning and design criteria and guidance for DoD components and participating organizations. The primary use of this UFC is to design the safe haven for man-made threats and that the guidance provided herein for natural threats is for information purposes and the planner/designer shall design the facility for the natural threats as necessary in accordance with UFC 1-200-01, General Building Requirements. This document applies to all construction, renovation, and repair projects for safe havens.

For some applications, specific design or facility type criteria may be available, in those applications; the more stringent criteria will apply.

1-3 DEFINITION OF SAFE HAVEN.

A safe haven is a structure, or protected area within a structure, that provides protection from man-made threats, natural threats, or combination for short durations and infrequent intervals.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *General Building Requirements*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 VULNERABILITY AND RISK ASSESSMENT.

1-5.1 Man Made Threat.

Manmade threats range from focused attacks by trained aggressors using explosives, direct and indirect fire weapons, forced entry tools, and chemical or biological agents, to haphazard attempts to disrupt or occupy a facility by protestors with political or social motivations.

In accordance with DoD security and antiterrorism (AT) policies, a vulnerability and risk assessment must be conducted prior to beginning any security project. Upon identifying facility or asset vulnerabilities to threats, physical security measures such as a safe haven, a hardened and secure facility, fences, gates, and Electronic Security Systems (ESS) may be deployed to reduce vulnerabilities. In summary, this document assumes the planning phases, including the risk analysis, are complete prior to beginning design. For information on Security Engineering Planning and Design process, refer to UFC 4-020-01 and UFC 4-020-02FA (described in the section “Security Engineering UFC Series” in this chapter). The engineering risk analysis conducted as part of UFC 4-020-01 should be consistent with the terrorism risk analysis conducted by the installation security/AT staff.

1-5.2 Natural Threat.

For natural threats such as hurricanes, tornadoes, typhoons, earthquakes, and tsunamis, refer to UFC 3-301-01 *Structural Engineering,* and American Society of Civil Engineers (ASCE), Federal Emergency Management Agency (FEMA), and International Code Council (ICC) criteria referenced herein for guidance for assessing natural threats.

1-6 POLICY REQUIREMENTS.

The requirement to provide a safe haven comes from DoD Instruction/Directives, Geographic Combatant Commander (GCC) Instructions, Service Instruction/Directives, and Regional or Installation requirements. Consult Headquarters, Major Command, Regional, and Installation personnel to establish project requirements.

1-6.1 Department of Defense.

- DoD policy provides guidance to ensure individuals designated as High Risk Personnel (HRP) or serving in a designated High Risk Billet (HRB) are provided an appropriate level of protection.

- Department of Defense Instruction O-2000.22 *Designation and Physical Protection of DoD High-risk Personnel (HRP)*: The Protection-Providing Organization (PPO) will conduct a Personal Security Vulnerability Assessment (PSVA) for each HRP. The resulting PSVA will provide recommendations for the protection of the HRP which may include a safe haven. The PPO refers to the U.S. Army Criminal Investigative Command, the Naval Criminal Investigative Service, the U.S. Air Force Office of Special Investigations, the Defense Criminal Investigative Service, the Pentagon Force Protection Agency, and the National Security Agency. For additional information on HRP, refer to UFC 4-010-03, *Security Engineering: Physical Security Measures for High-Risk Personnel.*

1-6.2 Geographic Combatant Commander (GCC) Requirements.

GCCs issue requirements for antiterrorism and physical security for installations within their area of responsibility. Ensure any such requirements are incorporated in addition to the requirements found in DoD and Service Directive/Instructions. Resolve any differences in the requirements by applying the most stringent requirement.

1-7 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. The most recent edition of referenced publications applies, unless otherwise specified.

1-8 DOD SECURITY ENGINEERING UFC SERIES.

This UFC is one of a series of security engineering Unified Facilities Criteria documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include the following, and the intended process for applying them is illustrated in Figure 1-1.

1-8.1 DoD Minimum Antiterrorism (AT) Standards for Buildings.

UFC 4-010-01 establishes standards that provide minimum levels of protection against terrorist attacks for the occupants of all DoD inhabited buildings. UFC 4-010-01 is intended to be used by security and antiterrorism personnel and design teams to identify the minimum AT requirements that must be incorporated into the design of all new construction and major renovations of inhabited DoD buildings. UFC 4-010-01 also includes recommendations that should be, but are not required to be incorporated into all such buildings.

1-8.2 Security Engineering Facilities Planning Manual.

UFC 4-020-01 outlines the processes for developing the design criteria necessary to incorporate security and antiterrorism design criteria into DoD facilities and for identifying the cost implications of applying those design criteria. Those design criteria may be limited to the requirements of the minimum AT standards, or they may include protection of assets other than those addressed in the minimum AT standards (people), aggressor tactics that are not addressed in the minimum AT standards or levels of protection beyond those required by the minimum AT standards.

The cost implications for security and AT are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they only represent construction that will meet the requirements of the design criteria. The manual also addresses the tradeoffs between cost and risk. The Security Engineering Facilities Planning Manual is intended to be used by planners as well as security and AT personnel with support from planning team members.

1-8.3 Security Engineering Facilities Design Manual.

UFC 4-020-02FA provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established using UFC 4-020-01. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them all work as a system. The information in UFC 4-020-02FA is in sufficient detail to support concept level project development, and as such can provide a good basis for a more detailed design. The manual also provides a process for assessing the impact of protective measures on risk. The primary audience for the Security Engineering Design Manual is the design team, but security and antiterrorism personnel can also use it.

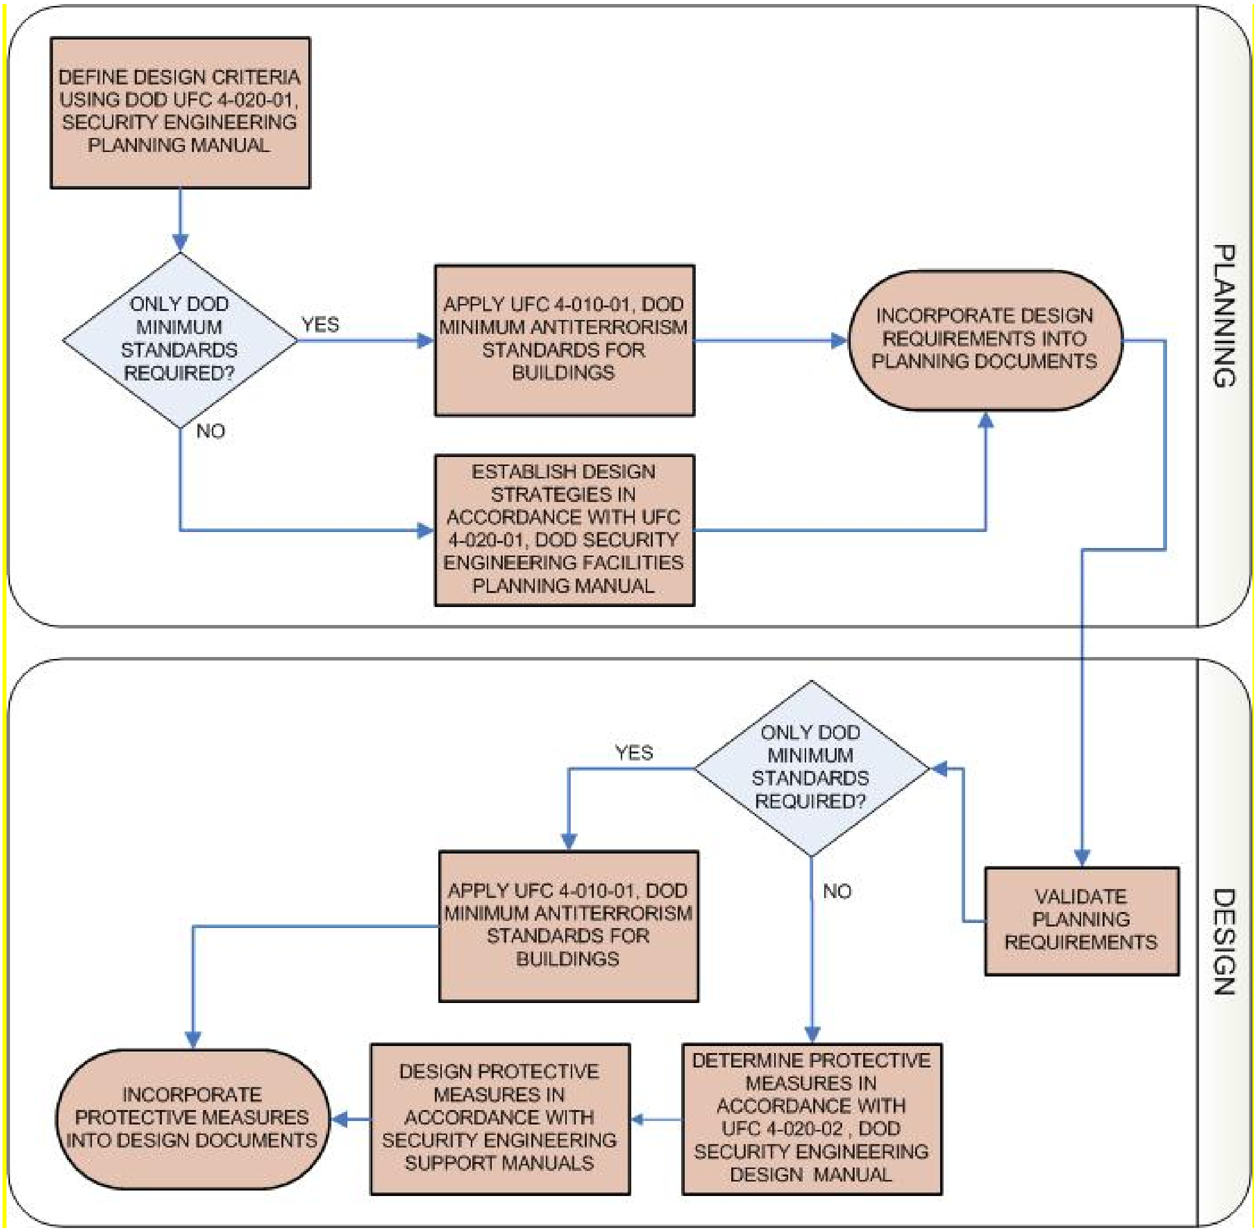
1-8.4 Security Engineering Support Manuals.

In addition to the standards, planning, and design UFC mentioned above, there is a series of additional UFCs that provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02FA. These support manuals provide specialized, discipline specific design guidance. Some address specific tactics such as direct fire weapons, forced entry, or airborne contamination. Others address limited aspects of design such as resistance to progressive collapse or design of portions of buildings such as mail rooms. Still others address details of designs for specific protective measures such as vehicle barriers or fences. The Security Engineering Support Manuals are intended to be used by the design team during the development of final design packages.

1-8.5 Security Engineering UFC Applications.

The application of the security engineering series of UFCs is illustrated in Figure 1-1. UFC 4-020-01 is intended to be the starting point for any project that is likely to have security or AT requirements. By beginning with UFC 4-020-01, the design criteria will be developed that establishes which of the other UFCs in the series will need to be applied. The design criteria may indicate that only the minimum AT standards need to be incorporated, or it may include additional requirements, resulting in the need for application of additional UFCs. Even if only the minimum AT standards are required, other UFCs may need to be applied if sufficient standoff distances are unavailable. Applying this series of UFCs in the manner illustrated in Figure 1-1 will result in the most efficient use of resources for protecting assets against security and AT related threats.

Figure 1-1 Application of UFC Documents for Planning and Design



This Page Intentionally Left Blank

CHAPTER 2 DESIGN CRITERIA DEVELOPMENT

2-1 INTRODUCTION.

Each safe haven must be sized, configured, and outfitted based on the project requirements. This section is intended to make planners aware of safe haven requirements that may affect the facility scope and budget. It is not intended to document the standard planning processes related to project development.

2-2 OVERVIEW OF PLANNING AND DESIGN PROCESS.

Determining the requirements for a safe haven requires an interdisciplinary team knowledgeable of local considerations. The interdisciplinary team must work together to determine project requirements. The team must consider cost, user constraints such as operations, manpower requirements or limitations, and sustainment costs when determining the requirements for the overall solution. The planning team should include the following:

- Supported Command
- Protection Providing Organization (PPO) representative (If for HRP)
- Security
- Safety
- Logistics
- Engineering (Planning and Design)
- Cultural resources/historic preservation officers (if historical building)

The process for determining the requirements for man-made and natural threats is provided further in this chapter. Physical security and structural design requirements and procedures required to meet these criteria are provided in Chapter 3.

2-3 PLANNING CONSIDERATIONS.

To define the design criteria for the safe haven, a preliminary determination of some of the physical attributes of its facility must be known.

2-3.1 Time

The location of a safe haven is an important part of the planning and design process, especially for natural threats such as tornados and some man-made threats that are presented in a relatively short time after the threat is annunciated.

2-3.1.1 Transit Time.

The planner and designer shall consider the time required for all occupants of a building or facility to reach the safe haven. The National Weather Service (NWS) has made great strides in predicting tornadoes and hurricanes and providing warnings that allow time to seek shelter. For tornadoes, the time span is often short between the NWS warning and the onset of the tornado. It is recommended that a safe haven for a natural threat be designed and located in such a way that the following access criteria are met. All potential users of the safe haven should be able to reach it within 5 minutes per FEMA P-361 *Safe Rooms for Tornadoes and Hurricanes: Guidance for Community and Residential Safe Rooms*. For hurricanes, these restrictions do not apply, because warnings are issued much earlier, allowing more time for preparation. Note that the typical walking speed is 3 to 4 ft/s (0.9 to 1.2 m/s) per Manual on Uniform Traffic Control Devices (MUTCD). For man-made threats, discuss transit time to the safe haven with the security professional based on the design basis threat.

Transit time may be especially important when safe haven users have disabilities that impair their mobility. Those with special needs may require assistance from others to reach the safe haven; wheelchair users may require a particular route that accommodates the wheelchair.

2-3.2 Travel Route.

The designer must consider the time factors above to provide the shortest possible access time and most accessible route for all potential safe haven occupants. To ensure that personnel are able to reach the safe haven within the required amount of time and that all personnel are provided a safe haven, it may be necessary to construct multiple safe havens at a given facility.

The route to the safe haven must be free from obstruction. If it is necessary for personnel to reach the safe haven by motorized conveyance, such as by automobile or shuttle, space around the safe haven must be provided for drop-off and parking.

2-3.3 Duration of Occupancy.

As specified in FEMA P-361, for short-duration natural events (tornadoes and earthquakes), the duration of occupancy is 2 hours. For the design of a safe haven that must protect against hurricanes, typhoons, and the airborne contamination tactic of a medium or high threat severity level, the duration of occupancy is a minimum of 24 hours. For all other man-made threats, the duration of occupancy is equal to the response time of the security forces. For instance, if 1 hour is required for security forces to respond and there are no natural threats or threat of airborne contamination, the duration of occupancy is 1 hour.

2-3.4 Occupancy Level.

The occupancy level for a safe haven is based on the maximum number of personnel required to occupy the safe haven. In the case of a HRP, the occupancy would be one. In the case of a Sensitive Compartmented Information Facility (SCIF), the occupancy would be the occupancy of the SCIF.

2-3.5 Floor Area.

2-3.5.1 Occupants.

The amount of required floor space depends upon the design threat, event duration, and the number and types of occupants. Natural events, such as hurricanes, or man-made threats, such as the air contamination tactic, may require longer occupancy times and therefore more floor area per person. For additional discussion on occupancy, means of egress, access, and accessibility see FEMA P-361.

If the building/facility in which the safe haven will reside must be designed for a hurricane or typhoon or if the threat severity level for the airborne contamination in accordance with UFC 4-020-01 is Medium or High, then use the floor area for long duration occupation in Table 2-1 to calculate the total required floor area. Otherwise, use the floor area for short duration occupation in Table 2-2.

Table 2-1 Floor Area for Long Duration (adapted from FEMA P-361)

Type of Person	Floor Area per Person, ft^2 (m^2)
Adult standing	20 (1.9)
Adult seated	20 (1.9)
Children under age 10	20 (1.9)
Wheelchair users	20 (1.9)
Bedridden persons	40 (3.8)

Table 2-2 Floor Area for Short Duration (adapted from FEMA P-361)

Type of Person	Floor Area per Person, ft^2 (m^2)
Adult standing	5 (0.46)
Adult seated	5 (0.46)
Children under age 10	5 (0.46)
Wheelchair users	10 (0.93)
Bedridden persons	30 (2.8)

2-3.5.2 Equipment for Destruction of Classified Materials.

If the safe haven will be used for destruction of classified materials, contact the responsible security office or the Facility Security Officer (FSO) to identify the equipment and procedure that is required to destroy or neutralize the classified materials and sensitive information. Determine the floor area and power requirements for this equipment. Check that the equipment can be safely used in a closed environment and that the generated waste can be accommodated within the space.

Note, for a SCIF or top secret open storage area that has been designated as a safe haven, the safe haven must be designed to provide sufficient space and delay time for the occupants to destroy documents. The occupants for such a safe haven must be limited to those personnel already occupying the space and those who are cleared and necessary for the destruction of the sensitive information. Additional safe havens may be required within the building to accommodate additional personnel.

2-3.5.3 Floor Area.

Calculate the required floor area by adding the floor area for occupants from the previous section on floor area to the floor area for the equipment used to destroy classified materials from Section on equipment for destruction of classified materials. The floor area must also include sufficient area for operational supplies for the safe haven, discussed in Chapter 4 on additional safe haven supplies.

2-3.6 Height.

For all safe havens, the minimum distance from the floor to ceiling is 7.5 feet (2.3 meters), as prescribed in NFPA 101 *Life Safety Code*.

2-3.7 Location, Type, and Number of Safe Havens.

Identify candidate safe haven locations with the guidance on site selection presented in siting section of Chapter 3, including maximum transit time to reach the safe haven as discussed previously. Note that a safe haven may serve multiple purposes, such as a conference room, cafeteria, gymnasium, restroom, classroom, or temporary lodging, and this possibility should be considered in the preliminary site selection.

After identification of the candidate safe haven types and locations, consider the issues of accessibility, power, ventilation (including special filtration for airborne contaminants, if necessary), water, communications, and waste storage. If the candidate safe haven location is still valid, proceed with the requirement determination of the design criteria in the following sections.

2-4 DESIGN CRITERIA FOR MAN-MADE THREATS.

To create the design criteria for man-made threats, employ the processes in UFC 4-020-01 to determine the level of protection (LOP) and the design basis threat (DBT). The man-made tactics relevant to safe haven design and discussed in UFC 4-020-01 include the following:

- Moving vehicle bomb
- Stationary vehicle bomb
- Hand delivered device
- Indirect fire weapons
- Direct fire weapons
- Forced entry
- Visual surveillance
- Airborne contamination
- Waterborne contamination
- Waterfront attack

The covert entry, acoustic eavesdropping, and electronic emanations eavesdropping tactics are not typically threats to a safe haven and need not be considered. In the event of retreat to a safe haven, personnel are alerted to the presence of a threat, and covert entry is unlikely to be employed by an aggressor. Per UFC 4-020-01, the acoustic eavesdropping and electronic emanations eavesdropping tactics are assumed to be employed by foreign intelligence services. As safe havens will only be used for destruction of classified material and not for creation or transmission, these two threats are removed from further consideration. In the event of a SCIF or classified conference room being designated as a multi-use safe haven, the creation and transmission of classified information will only be done during normal operations when the room is not being used as a safe haven. When such a room is being utilized as a safe haven, classified material will only be destroyed, not created or transmitted. Further, for the purposes of applying the UFC 4-020-01 procedures, the aggressors will not include unsophisticated criminals, sophisticated criminals, organized criminal groups, and vandals. For the Forced Entry tactic, specify the required protection time based on the response time of the security forces determined in security forces evaluation in addition to the DBT and the LOP.

2-5 DESIGN CRITERIA FOR NATURAL THREATS.

Natural threats include hurricanes, tornados, tsunamis, and earthquakes. Design to resist loads created by natural phenomena is discussed in design procedures for natural threats in Chapter 3.

2-5.1 Hurricane and Typhoon.

Hurricanes and typhoons are tropical cyclones in the western hemisphere and in the western North Pacific Ocean, respectively. In this UFC, the term hurricane also encompasses typhoons, for simplicity.

Hurricanes create three types of loads on a building. Wind-induced forces, high speed debris impact, and hydrodynamic forces from either flooding or storm surge. Ensure compliance with the most stringent of UFC 3-301-01 and FEMA P-361 for wind-speed data.

2-5.2 Tornado.

A tornado is a violently rotating column of air, in contact with the ground. According to FEMA P-361, tornados may load a structure in three ways: wind-induced forces, debris impact, and forces induced by change in atmospheric pressure. Forces induced by change in atmospheric pressure result from the large pressure gradient between the atmospheric pressure and the air pressure within the funnel of a tornado. As the tornado passes over a structure, it can cause outward pressures on a structure, due to the instantaneous pressure differences between the structure interior and exterior.

ICC 500-2014*ICC/National Storm Shelter Association (NSSA) Standard for the Design and Construction of Storm Shelters* provides design guidance for community shelters and residential safe rooms including wind speeds and other design criteria. Regarding wind speed and other structural design criteria ensure compliance with the most stringent of the UFC 3-301-01, FEMA P-361, and ICC 500-2014.

2-5.3 Earthquake.

Structures in earthquake regions are subjected to ground motions that generate inertial forces on the structure. Therefore, the ground motion is the critical parameter for seismic design. Use UFC 3-301-01 and 3-310-04 *Seismic Design for Buildings* to obtain data for ground motion data.

2-5.4 Tsunami.

A tsunami consists of waves generated by seismic activity, including sudden displacements of the seafloor or volcanic activity. When these waves reach shore, they can cause dramatic flooding in coastal areas. The result is that structures in affected areas can be subjected to hydrodynamic forces.

If tsunamis are a design threat, the building/facility in which the safe haven will reside must be designed in accordance with the guidance presented in UFC 3-310-04 and FEMA P-646 *Guidelines for Design of Structures for Vertical Evacuation from Tsunami.*

2-6 OTHER APPLICABLE DESIGN REQUIREMENTS.

Depending upon the location of the safe haven, additional design requirements may be imposed by the American Embassy Chief of Mission, the host nation’s military and police, and host nation agreements. Work with the Planning Team to identify these additional requirements.

Geographic combatant commanders may also establish additional guidance to ensure uniform and consistent application of these standards within their areas of operations or to account for any special circumstances.

2-7 FINAL DESIGN CRITERIA.

The design criteria developed in previous sections and the other applicable design requirements above must be combined such that the maximum criteria controls for all cases of overlap. Develop a final design criteria requirement that includes, as a minimum, the following items:

- Relevant man-made tactics, and corresponding DBT and LOP
- Required response time for Forced Entry tactic
- Identification of natural threats and all corresponding load criteria (such as maximum wind speed, earthquake load cases, debris impact, and hydrodynamic forces)
- Other applicable design requirements as described above

This Page Intentionally Left Blank

CHAPTER 3 DESIGN PROCESS

3-1 INTRODUCTION.

The design of a safe haven must meet the criteria that were developed in Chapter 2. Note that design to resist a given threat may provide protection against some other threat. For example, walls designed to resist a forced entry tactic for a high LOP will be more than sufficient to resist a hand-delivered weapon tactic at a low LOP. After examining the DBTs and LOPs for all applicable tactics, the tactic requiring the most stringent design will govern. Different tactics may govern various components of the safe haven, and each component must be validated to handle all applicable tactics. In addition, there are often multiple ways by which to satisfy the design criteria. Any method that is rational, based on fundamental principles of engineering mechanics and dynamics, and/or validated with experimental data is permissible. Any design approach that is not specified or referenced in this document must be approved by the Planning Team or by an authorized representative of the facility owner.

3-2 INITIAL CONSIDERATIONS.

3-2.1 Siting.

3-2.1.1 General Conditions.

A safe haven can be defined as standalone, such as a buried shelter or the entire structure, or internal, such as a protected area within a building. Specific guidance for standalone and internal safe havens is discussed in the following section on structural integration. The location of the safe haven must permit personnel to reach the safe haven from their work areas within 5 minutes after annunciation of a threat. Personnel will follow signage to reach the appropriate safe haven. The safe haven must also provide sufficient space for the protected assets, such as personnel and associated supplies or classified material. Furthermore, the site must provide a sufficient number of entry points into the safe haven, with appropriate access control. Finally, to facilitate egress of occupants from the safe haven once the threat has passed, site elevation must not be greater than an elevation that can be accessed by ladders available to the local fire department.

It is recommended that a standalone safe haven, as described in this document not be located near multi-story buildings or other relatively large structures, if possible, since collapse of these structures could damage the safe haven.

3-2.1.2 Natural Threat.

To prevent flooding, see FEMA P-361 and ICC 500 for siting facility with regards to Special Flood Hazard Area (SFHA). FEMA P-361 notes that smaller structures, such as poles for light fixtures and power lines, antenna towers, and satellite dishes, and roof mounted mechanical equipment should not be located near a safe haven. Smaller structures, trees, and waste receptacles can become hazardous debris in extreme weather events.

3-2.1.3 Explosives Tactics.

For explosives tactics, it is recommended that smaller structures, trees, and waste receptacles not be located near an internal or standalone safe haven, to prevent hazardous debris. Also, positioning a safe haven below ground provides protection against explosives tactics. To impede delivery of a vehicle-borne explosive, it is recommended that the building/facility in which the safe haven will reside be located at an appropriate standoff distance from railways, roadways, and parking facilities based on the DBT and required LOP.

Finally, the structural design of the building/facility in which the safe haven will reside must provide the required LOP for the DBTs for the assets that will occupy the safe haven at the available standoff distances. If at a given location the LOP requirements cannot be satisfied, the safe haven may be moved to satisfy them, or the building/facility in which the safe haven will reside can be hardened to provide the required LOP. Vehicle barriers may also be installed to increase standoff distance. Note that the construction of vehicle barriers will vary significantly, depending on whether the DBT includes moving vehicle bombs or is limited to stationary vehicle bombs.

3-2.1.4 Standoff Weapons.

To impede aggressor use of direct fire weapon threats, a safe haven must be located to minimize the number of vantage points for attack, such that an aggressor is denied line of sight. This objective can be accomplished by placing obstructions between the vantage points and the safe haven, or by providing an internal safe haven with no external windows. As with the explosives tactics, below-grade placement of the safe haven provides protection against ballistic tactics. However, if the safe haven is at a high elevation, an aggressor must shoot upwards at the position, causing the projectile to strike the structure at less than 90 degrees, diminishing its penetration into the structure.

Indirect fire weapons, such as mortars and small rockets, can be fired over obstacles to reach a target. These weapons do not require a direct line of sight to a target, but they do need a clear line of flight. While a safe haven may be located to minimize clear flight lines from these weapons, the best way to protect the safe haven from indirect fire is to harden its structure. The building/facility in which the safe haven will reside must be designed to protect the assets inside it from the detonation of the threat weapon at standoff distances that vary by level of protection. Per UFC 4-020-01, the structure must be designed to provide protection from the blast pressure from the exploding rounds and from warhead casing fragment penetration.

3-2.1.5 Airborne Contamination Tactic.

Trees, shrubberies, and any other vegetation must not be located within 10 feet (3 meters) of a standalone or internal safe haven, as vegetation can retain airborne contaminant agents. In addition, a below-grade safe haven is more vulnerable to the air contamination tactic. UFC 4-020-01 notes that aerosolized materials used for the air contamination tactic are heavier than air and tend to settle in the low-lying areas.

3-2.2 Structural Integration.

Depending on the facility, a standalone or an internal safe haven may be more effective. A standalone safe haven is physically separate from any other building. An internal safe haven is physically connected to another building but may be structurally independent.

3-2.2.1 Standalone Safe Haven.

Although a standalone safe haven is unlikely to be suitable for multi-use, as described in this document, the standalone safe haven does have several advantages:

- The safe haven may be sited away from likely targets, which can serve as potential debris hazards.
- The construction process of the safe haven can be simplified since it need not be integrated with another structure.
- It may be easier to implement at an existing facility.
- It may be concealed or camouflaged.
- An attack on the primary facility will likely not compromise the structural integrity of the safe haven.
- Physical separation from other buildings may prevent damage by the possible collapse of those buildings.
- Its ventilation and power systems are separate from the main facility.

3-2.2.2 Internal Safe Haven.

An internal safe haven has a different set of advantages:

- The design may only need to satisfy man-made threats, if the surrounding structure has been adequately designed for natural threats.
- Because it is within another structure, it is partially shielded from debris caused by either a man-made or a natural threat.
- Personnel do not have to be exposed when accessing the safe haven.
- An internal safe haven can likely be reached more quickly by building occupants, since they need not exit the building to enter the safe haven.
- With adequate planning, an internal safe haven may more readily serve two or more purposes such as a conference room, cafeteria, gymnasium, restroom, classroom, or temporary lodging.
- A separate air handling system can be included in the design of the safe haven for new construction to protect occupants from airborne contamination, without the expense of providing a special air handling system for the entire building to withstand the airborne contamination tactic if required.

For internal safe havens, use the available structure as much as possible to meet the required LOPs and DBTs. Existing walls can provide protection from forced entry, direct and indirect weapons, explosive devices, and potentially the airborne contamination tactic, if adequately sealed. Note that there will be an added delay for an internal safe haven, since the aggressors would have to penetrate the building first to reach the safe haven. The available structure should also be used as part of the design for natural threats.

3-2.3 Use of Safe Haven.

3-2.3.1 Single Use Safe Haven.

A single-use safe haven is used only in emergencies to provide protection in the event of an attack or natural event, and it has two advantages:

- Its restricted use can also permit it to have simplified electrical and mechanical systems, which can reduce construction costs.
- In addition, a single-use safe haven is always ready for occupants and will not be cluttered with furnishings and storage items.

The primary disadvantage of a single-use shelter is that it remains unused most of its design life.

3-2.3.2 Multi-Use Safe Haven.

A multi-use safe haven is designed to provide protection in an emergency but is also used as for other purposes in the absence of an emergency, such as a conference room, cafeteria, gymnasium, restroom, classroom, or temporary lodging. As noted in FEMA P-361 and FEMA 453, *Design Guidance for Shelter and Safe Rooms*, in contrast to single-use shelters, multi-use shelters can provide an immediate return on the financial investment required to construct them, because they can be used for non-emergency events.

A Sensitive Compartmented Information Facility (SCIF) is one example of a multi-use area that could be designed as an internal safe haven. If a SCIF is also designed to be a safe haven, SCI documents would not have to be transferred outside the SCIF and could be destroyed in place. Consult with UFC 4-010-05 *Sensitive Compartmented Information Facilities Planning, Design, and Construction,* ICS 705-1 and the IC Tech Spec-for ICD/ICS 705 that provide the standards for the physical and technical security standards that apply to a SCIF.

3-2.3.2.1 Multi-Use Signage.

Both the routine maximum occupancy and safe haven maximum occupancy must be posted in a multi-use structure.

3-2.4 System Integration.

The safe haven is part of the overall physical security scheme for the facility and must be coordinated with other physical security elements. For instance, communication equipment in the safe haven must be compatible with the other facility communications. The power source, backup power, and communications should be shared, if these resources are sufficiently protected against the DBTs.

3-3 ADJUSTMENTS IN SAFE HAVEN DESIGN.

During the application of the design procedures laid out in the following sections, the designer may decide to modify key physical parameters, such as size, location, or type of safe haven. For every modification and for each iteration through the design process, the engineer must revisit Chapter 2 to determine if these changes affect any of the final design criteria defined in Chapter 2.

3-4 DESIGN PROCEDURE FOR MAN-MADE THREATS.

The following paragraphs contain specific design procedures and design resources to be employed for the selected tactics determined by UFC 4-020-01. The following paragraphs may not applicable. UFC 4-020-01 is a planning tool and as such contains general design strategies to address these tactics. Some of the approaches from UFC 4-020-01 are incorporated in the following paragraphs.

Specific DoD design approaches for the tactics are available in UFC 4-020-02FA and Security Engineering Support Manuals as applicable. Any conflicts between this UFC and UFC 4-020-02FA and support manuals must be resolved by the project Planning Team.

3-4.1 Moving Vehicle.

When required, the building/facility in which the safe haven will reside must be designed to resist the pressure and impulse from the explosive weight associated with the DBT, and associated standoff of the moving vehicle threat. Employ standard blast design methods for the analysis and design of the building/facility in which the safe haven will reside and its components, including doors and windows, to resist the pressure and impulse. Blast design and analysis methods can be found in UFC 3-340-01, *Design and Analysis of Hardened Structures to Conventional Weapons Effects* and ASCE 59-11, *Blast Protection of Buildings.* Use the structural response limits specified in PDC-TR 06-08 *Single Degree of Freedom Structural Response Limits for Antiterrorism Design*. Approved design tools such as the *Single-degree-of-freedom Blast Effects Design Spreadsheet* (SBEDS) and *Single degree of freedom Blast Effects Design Spreadsheet for Windows* (SBEDS-W) both available from the US Army Corps of Engineers Protective Design Center may be employed if approved by the project planning team.

3-4.2 Stationary Vehicle.

The DBT for stationary vehicle bombs will be used to establish the design explosive weight. The standoff will be the distance from the building/facility in which the safe haven will reside to possible vehicle locations, as determined by a review of the site layout and the presence of components such as vehicle barriers, parking lots, and roadways. Note that multiple locations and standoff distances may need to be required for the design, depending upon the shielding provided by the terrain, buildings, and other obstructions between the vehicle bomb and the safe haven.

Use the same approach and response criteria as specified in the previous section to design the building/facility in which the safe haven will reside for a stationary vehicle bomb threat.

3-4.3 Hand Delivered Devices.

The DBT for hand delivered devices as determined with UFC 4-020-01 will be used to establish the design incendiary device or explosive type and weight. The standoff will be the shortest possible distance from the building/facility in which the safe haven will reside to the likely placement locations for the hand-delivered device; this could include direct contact with the structure.

Use the same approach and response criteria as specified above in moving vehicle bomb threat to design the building/facility in which the safe haven will reside for a hand delivered device.

3-4.4 Indirect Fire Weapons.

Consult UFC 4-020-01 for the general design approach and employ UFC 4-020-02FA as required for specific guidance to design the safe haven for the DBT and LOP.

3-4.5 Direct Fire Weapons.

Employ UFC 4-023-07 *Design to Resist Direct Fire Weapon Effects* as required to design the safe haven for the DBT and LOP.

3-4.6 Forced Entry.

Consult UFC 4-020-01 for the general design approach to design the safe haven to resist the design basis threat for the period of time determined in security forces evaluation. Use the procedures and guidance in UFC 4-020-02FA and UFC 4-020-03FA, *DoD Security Engineering: Final Design* to design the physical components of the safe haven, including walls, floors, ceilings, windows, doors, and other components.

3-4.7 Visual Surveillance.

UFC 4-020-01 recommends the following in the design against the visual surveillance threat when required; the safe haven is positioned, concealed, or camouflaged such that an aggressor cannot see it. In particular, safe haven entrances must be placed in locations that are not easily seen. If windows are used, window blinds or curtains must be installed to prevent aggressors from being able to observe activity inside the safe haven.

This guidance may conflict with other design guidance, such as design for natural threats, for which signage will be needed to assist personnel in finding the safe haven. In this case, the Planning Team will resolve the conflicts.

3-4.8 Airborne Contamination.

Employ UFC 4-024-01 *Security Engineering: Procedures for Designing Airborne Chemical, Biological, and Radiological Protection for Buildings* to design the safe haven for the DBT and LOP.

3-4.9 Waterborne Contamination.

Employ the guidance in Chapter 4 of UFC 4-020-02FA to design the safe haven for the DBT and LOP.

3-4.10 Waterfront Attack.

When required employ the guidance in Chapter 4 of UFC 4-020-01 and UFC 4-025-01, *Security Engineering: Waterfront Security* to design the building/facility in which the safe haven will reside for the DBT and LOP appropriate for waterfront attacks. Use the same approach and response criteria as specified in the previous section on moving vehicles regarding blast design and analysis.

3-5 DESIGN PROCEDURE FOR NATURAL THREATS.

Natural threats, as discussed in Chapter 2, must be identified for both standalone and internal safe havens. If an internal safe haven is placed within a building which has the capacity to resist relevant natural threats, then only elements of the safe haven that are exposed to natural threats must be considered. In the case of standalone safe havens, all relevant natural threats must be considered. For both standalone and internal safe havens with exposed elements, employ the procedures in the following four sections. For regions where wind speeds and loads from hurricanes/typhoons and tornados overlap ensure the most stringent threat is used in design and construction of the required shelter.

3-5.1 Hurricane and Typhoon.

As discussed in Chapter 2, hurricanes and typhoons can apply wind-induced forces, debris impact, and hydrodynamic forces. To resist wind-induced forces and debris impact, the building/facility in which the safe haven will reside must be designed according to FEMA P-361, ICC 500 and UFC 3-301-01. Wind speed data for building sites outside the US must be obtained from Appendix E of UFC 3-301-01. Ensure compliance with the more stringent criteria in design and construction.

To resist hydrodynamic forces associated with flooding, the building/facility in which the safe haven will reside must be designed according to UFC 3-301-01 and Chapter 5 of ASCE 7-10. If the safe haven is built in a location that lacks a US Flood Hazard Map or the equivalent in the host nation, available flood data from local agencies must be used for design. See United States Geological Survey (USGS) website for additional flood information: http://water.usgs.gov/floods/

3-5.2 Tornado.

As discussed in Chapter 2, a tornado subjects a building to wind-induced forces, debris impact, and forces induced by change in atmospheric pressure. ICC 500-2014 provides minimum design and construction requirements for storm shelters that provide a safe refuge from storms that produce high winds, hurricanes, and tornadoes. Chapter C26 of ASCE 7-10 also provides references pertaining to tornadic design and these references should be consulted. Regarding wind speed and other structural design criteria ensure compliance with the most stringent of the UFC 3-301-01, FEMA P-361, and ICC 500-2014. Ensure compliance with the more stringent criteria in the design and construction of the shelter.

3-5.3 Earthquake.

The building/facility in which the safe haven will reside must be designed in accordance with the seismic provisions presented in UFC 3-301-01 and UFC 3-310-04. Seismic ground motion data for buildings/facilities built outside of the US must be obtained from UFC 3-301-01. See USGS Earthquake Hazard Program website for additional seismic information: http://earthquake.usgs.gov/hazards/

It should be noted that the objective in designing the building/facility in which the safe haven will reside to resist seismic loading is not for the building/facility to serve as an earthquake shelter, though it could serve as a shelter for aftershocks. Rather, the objective is to ensure that the building/facility survives likely seismic events. In this way, the safe haven as part of the overall building structure is designed, like any other building in a seismic zone, to continue functioning despite the occurrence of a seismic event.

3-5.4 Tsunami.

If required the building/facility in which the safe haven will reside must be designed to resist hydrodynamic forces caused by a tsunami according to UFC 3-310-04. If the building/facility in which the safe haven will reside is built in a location that lacks a US Flood Hazard Map or the equivalent in the host nation, available flood data from local agencies must be used for design. See United States Geologic Survey (USGS): http://walrus.wr.usgs.gov/tsunami and National Oceanic and Atmospheric Administration (NOAA): http://www.tsunami.noaa.gov/ websites for additional Tsunami information.

CHAPTER 4 OTHER DESIGN GUIDANCE

4-1 EMERGENCY ROUTE MARKING.

For natural threats, proper route marking is essential to personnel reaching the safe haven within the required time. Therefore, the facility must incorporate signage demarcating routes to the safe haven. The signage should also indicate the threats for which the safe haven was designed. Entry points to the safe haven must be clearly identified. Route marking may be accomplished by powered lighting, or more recently developed photo luminescent path marking. Maps illustrating routes to the safe haven must be posted in appropriate locations in the facility. Any written content on the maps must be in a language intelligible to all personnel in the facility. Signage must comply with ADA requirements, including those for the blind. If this guidance conflicts with other guidance, such as the need to camouflage the safe haven to prevent visual surveillance, the Planning Team will resolve the conflict. For additional guidance on route marking and signage see UFC 3-600-01, *Fire Protection Engineering for Facilities.*

Vehicle parking can be a problem, either from the standpoint of insufficient number of parking spaces or due to traffic congestion in reaching a safe haven. Thus, a sufficient number of safe havens must be provided so personnel can reach a safe haven on foot within the required 5 minutes timeframe.

4-2 EMERGENCY POWER.

4-2.1 Backup Power Source.

Follow Service guidance for approval of backup power authorization and design. When required, provide at least one independent backup power source that will be available to a safe haven such that loss of the primary power source does not cause the safe haven(s) to lose power. The backup power source of a safe haven must be protected from the identified threats and consequently must be independent of the conventional power grid. Potential backup power sources include the building's backup power supply, electric cells, and standalone internal-combustion generators. The type of power source and quantity of power required for a safe haven must be determined from its power use in emergency operating conditions. When multiple safe havens are provided within the same building, one backup power source can be shared by all the safe havens.

4-2.2 Duration.

Sufficient power must be available for a safe haven to operate for the duration of the controlling event, whether that controlling event is the moving vehicle bomb tactic, waterborne contamination tactic, tornado, hurricane, or some other threat. For example, if the controlling event is a tornado, a safe haven must be provided with sufficient energy to operate at its required power for 2 hours. If the controlling event is a hurricane, there must be sufficient power for 24 hours of operation.

4-2.3 Supported Systems.

The following systems must be supported by the power source for the duration of the controlling event, as a minimum:

- Lighting
- Ventilation
- Communication

Safe havens equipped to destroy classified information must have sufficient power to support the necessary equipment. Per UFC 4-020-01, power to these systems must be resistant to interruption due to a natural event or deliberate attack. The equipment required to destroy the classified material must be determined in conjunction with the responsible security office or the FSO.

4-2.4 Signage.

UFC 4-020-01 recommends that the possibility of sabotage be minimized by limiting signage identifying the location of the power source.

4-3 EMERGENCY LIGHTING.

4-3.1 Internal Lighting.

Primary lighting must be provided within the safe haven for personnel to perform essential tasks, such as tending to injured personnel and destroying classified materials. Reliable primary lighting can also serve to calm personnel within a safe haven. All lighting must conform to UFC 3-530-01 *Design: Interior and Exterior Lighting and Controls.*

Primary lighting must be supported by fixtures that are designed to resist the motions from the identified threats, such as earthquakes and blast. The motions that the fixtures must withstand must be determined from analysis of safe haven structural response to the threat. All safe havens must meet the minimum requirements for bracing, as discussed in UFC 4-010-01. Furthermore, the electrical wiring joining the primary lighting to the power source must be resistant to sabotage and attack.

4-3.2 Lighting of Entry Points.

To expedite ingress into the safe haven, all entry points must be illuminated. As a minimum, lighting at entry points must conform to UFC 3-530-01.

4-4 COMMUNICATION.

The following means of communication may be provided for a safe haven, depending on its particular requirements (FEMA P-361 and FEMA 453 *Design Guidance for Shelter and Safe Rooms*):

- Handheld or emergency radios connected to the security force, police, or fire and rescue
- Cellular or satellite telephones (may not operate during certain events and may require signal amplifier to function within the safe haven)
- Standard telephones
- Battery-powered radio transmitters or signal-emitting devices for signaling emergency personnel
- Duress alarm
- Audible sounding device (e.g. canned air horn) to signal rescue personnel
- Megaphone
- Public address system
- Portable computers with modem and internet capabilities
- Fax machine, copier, and scanner
- Signal flares
- National Oceanic Atmospheric Administration (NOAA) weather radios or receivers for commercial broadcast

4-5 ENTRY POINT MONITORING.

Depending on operational requirements, an audible cue may be required at the entry points of the safe haven for access control. The audible cue would sound any time that the doors at the entry point are opened. In addition, a guard may be stationed at each entry point. For multi-use safe havens having such operational requirements, the cue should be activated and guards should be posted once the threat exists.

4-6 FIRE SAFETY.

Safe havens must comply with all fire and life-safety code requirements per UFC 3-600-01 and the following minimum requirements. The fire and life safety system inside the safe haven must remain operational, if determined by the level of protection and design basis threat, and provide life-safety protection after an incident and allow for safe evacuation of the building when appropriate for the required occupancy level. See Chapter 2, Occupancy Level for discussion on occupancy level and square footage requirements of the safe haven.

4-6.1 Fire Suppression Systems.

Facilities that are multi-use safe havens or contain a multi-use safe haven must be protected with an automatic sprinkler system.

Any fire suppression systems specified for use within the safe haven must be appropriate for use in an enclosed environment with human occupancy.

Provide fire extinguishers for safe havens. Fire extinguishers must be flush mounted on the surface of the safe haven wall.

Based on the LOP and DBT, the fire protection water system for the safe haven must be protected from single-point failure in case of an event.

4-6.2 Additional Guidance.

In no case will a standpipe cabinet or fire extinguisher cabinet/enclosure be recessed into the interior face of the exterior wall of the safe haven. This requirement is necessary to ensure that the integrity of the safe haven wall is not compromised by the installation of standpipes and fire extinguishers.

Maintain a positive pressure in the safe haven. Duct openings must be protected by a Class A, 2-hr fire and smoke dampener.

The enclosure of the safe haven must have a 2-hour fire resistance rating.

4-7 PLUMBING.

If the plumbing system includes faucets that discharge into the safe haven, it must be protected against the waterborne contamination tactic, as discussed in Chapter 3. To eliminate vulnerability to the waterborne contamination tactic, it is recommended that bottled water be provided to the occupants.

4-8 SANITATION MANAGEMENT.

Normal design procedures and code requirements will prevail for management of sanitation within the safe haven. See FEMA P-361 and ICC 500 for guidance on the number and type of toilets and associated plumbing requirements.

4-9 ADDITIONAL SAFE HAVEN SUPPLIES.

The agency operating the safe haven will identify appropriate supplies based on items listed in Table 4-1 of FEMA 453 with additional discussion in P-361 and ICC 500, including food and water, if required. Any design requirements for storing these supplies must be considered in the safe haven design.

APPENDIX B EXAMPLE PROBLEM

B-1 SCENARIO.

- 7-story reinforced concrete Navy operations building in Casablanca, Morocco (Figure B-1 and Figure B-2)
- Design is 40% complete
- No controlled perimeter
- Primarily military occupants
- Heavy winds, seismic; no tornado or tsunami
- Top Secret information exists and must be destroyed
- Internal safe haven, so classified material does not have to be transported outside the facility

NOTE: The scenarios, requirements and mitigating measures presented in this example may not be typical for a safe haven and are used to navigate the reader through the process (occupancy, asset needing protection, design basis threat, level of protection required, mitigating measures employed) of planning and designing a safe haven. In reality, the threat may be minimal; requiring minimum mitigating measures for a minimum number of occupants i.e. the occupancy of a safe haven for high risk executive may require the protection of just one person. The primary use of this UFC is to design the safe haven for man-made threats and that the guidance provided herein for natural threats is for information purposes and the planner/designer shall design the facility for the natural threats as necessary in accordance with UFC 1-200-01, General Building Requirements.

Figure B-1 Overall Building Elevation

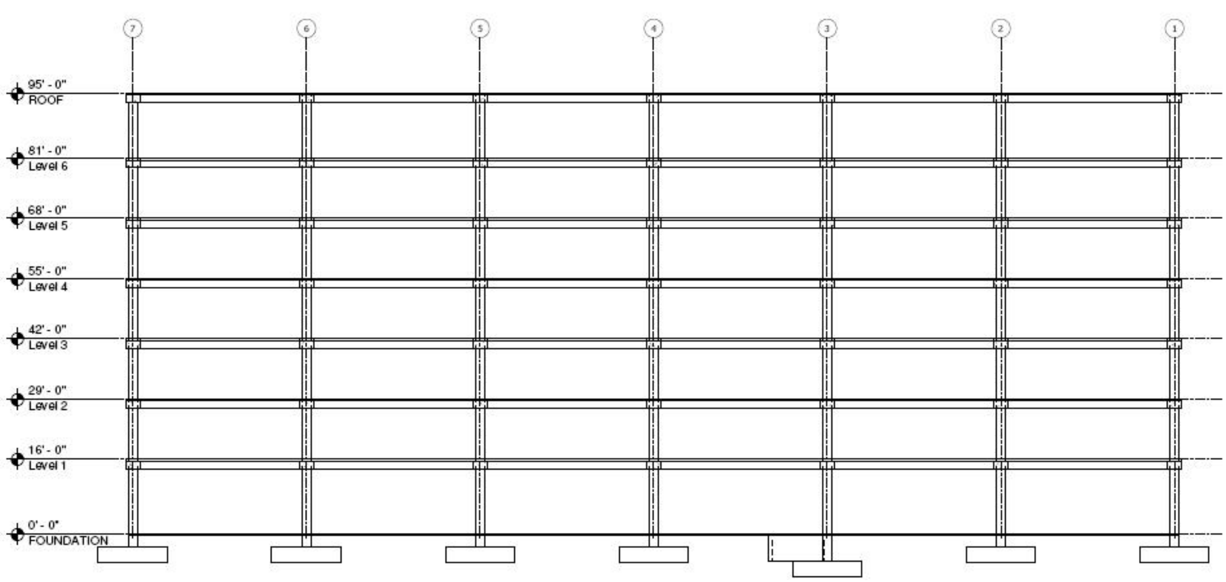

Figure B-2 Overall Building Plan

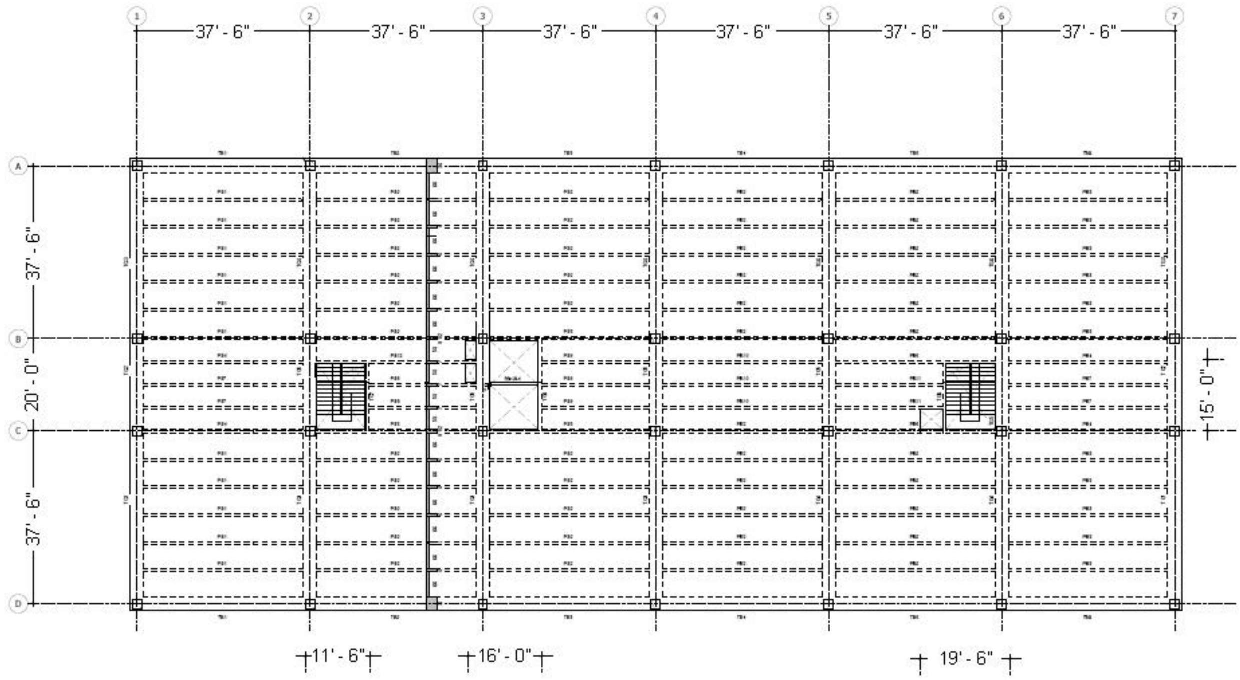

B-2 DESIGN CRITERIA DEVELOPMENT.

B-2.1 Procedures.

Follow procedure outlined in UFC 4-023-10.

B-2.2 Data Collection.

- Facility/Building Type: Headquarters and Operations
- Presence and Type of Classified Material and Sensitive Information:
  - Top Secret information storage
- Security Forces Evaluation: Security forces response time = 2 minutes

B-2.3 Planning Considerations.

Transit time: The distance from the furthest corner office on the 7th floor to the safe haven is approximately 204 feet (62 meter), based on the following distances: building corner to the stair well = ~56 feet (17 meter), 6 flights of stairs = 18 feet (5.5 meter) based on a 45-degree stair and a 13 feet (4 meter) story height and from the stairwell to the safe haven = ~40 feet (12 meter). The average distance from the parking area to the safe haven is approximately 288 feet (88 meter) based on the following distances: from parking lot to building entrance = 148 feet (45 meter) and from the building entrance to the safe haven = 140 feet (43 meter). Thus, the transit time will be less than 2 minutes, based on the longest distance from the parking area to safe haven and an estimated travel speed of 3 to 4 ft/s (0.9 to 1.2 m/s).

Duration of Occupancy: 2hrs- Short duration requirement based on the DBT and the security forces response time and evaluation of the situation.

Occupancy Level: Based on the distances involved, all occupants will be able to reach the safe haven in less than 5 minutes.

Floor Area:

Occupants:	135 adults standing	=	675 ft^2 (62.7 m^2)
	200 adults sitting	=	1000 ft^2 (93 m^2)
	5 wheelchair users	=	50 ft^2 (4.6 m^2)
	Total floor area	=	1725 ft^2 (160 m^2)

Equipment for destruction of classified materials, as specified by the building occupant and Facility Security Officer (FSO):

Storage safes	=	18 ft^2 (1.7 m^2)
Approved shredders	=	24 ft^2 (2.2 m^2)
Waste receptacles	=	50 ft^2 (4.6 m^2)
Work space	=	100 ft^2 (9.3 m^2)
Total floor area	=	192 ft^2 (17.8 m^2)

There are approved classified material shredders available with sheet capacity up to 16 sheets and speeds up to 44 ft/min (13 meters/min). The FSO will select the appropriate type and number of shredders based on the amount of sensitive information to destroy within the safe haven in the event of an emergency. In this example, the FSO has determined that six shredders are necessary in the safe haven, each taking up 4 ft^2 (0.37 m^2). All equipment listed above for the destruction of classified materials will be located in a separate secure room within the safe haven to prevent tampering or accidental damage.

Area for Operational supplies= 12 ft^2 (1.1 m^2)

Preliminary floor area:

Total floor area = 1725+192+12 = 1929 ft^2 (179 m^2)

Height: 13-ft (4-m) per drawings (minimum is 7.5-ft [2.3 m])

Preliminary Location, Type and Number of Safe Havens: The 75 ft x 50 ft (23 m x 15 m), 3750 ft^2 (348 m^2) cafeteria on the second floor, interior of the building will be the designated safe haven, as shown in Figure B-3 and Figure B-4. The design of the cafeteria will meet all criteria in UFC 4-023-10. This will be an internal, multi-use safe haven -- one for the complete building. There are four entrances/exits for the cafeteria, all of which satisfy ADA and life safety requirements.

Figure B-3 Elevation Showing Second Floor Cafeteria as Safe Haven

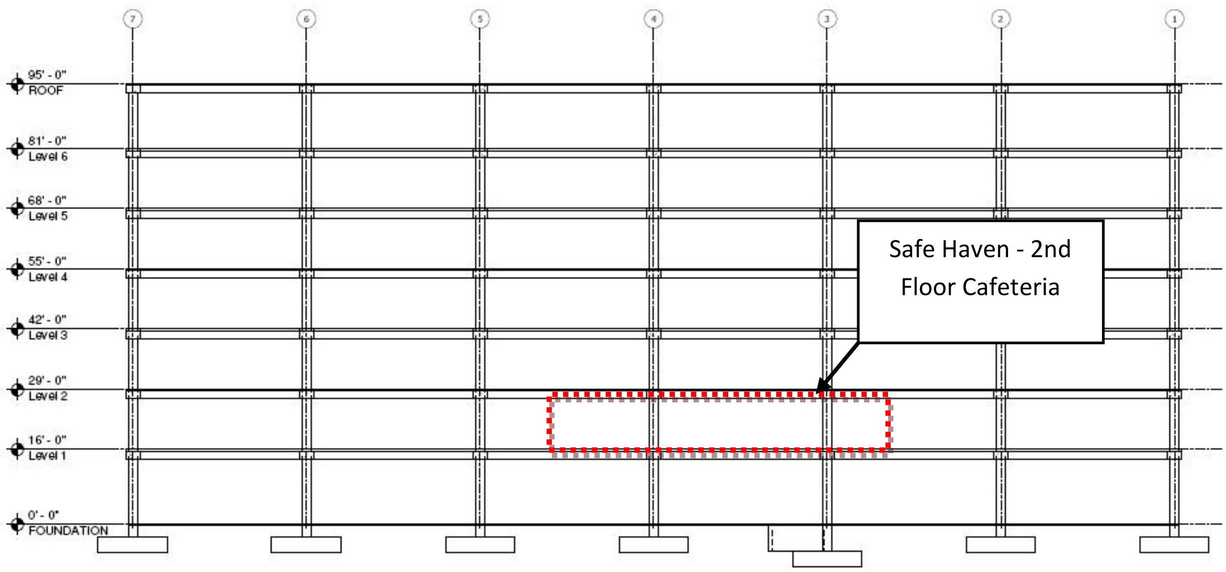

Figure B-4 Plan View of Second Floor with Cafeteria as Safe Haven

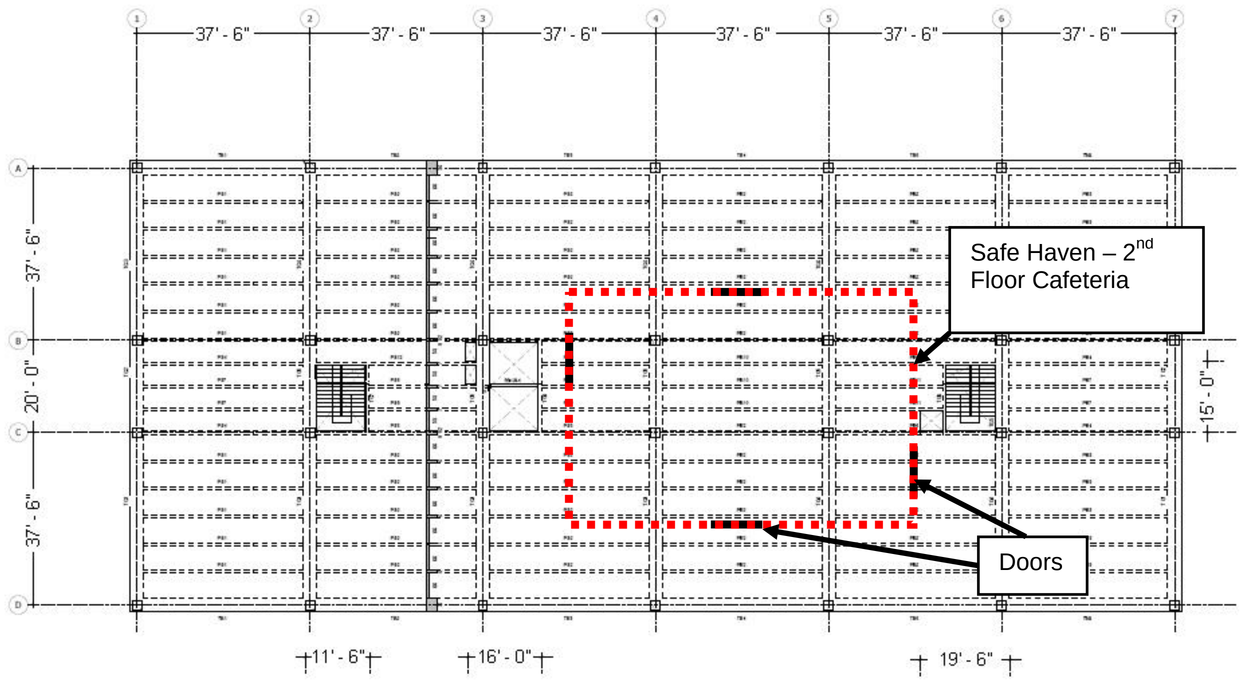

B-2.4 Design Criteria Development for Manmade Threats.

Use the processes in UFC 4-020-01 to determine the required LOP and DBTs for the safe haven design. Based on the worksheets prepared using UFC 4-020-01 (summary worksheet shown in Figure B-5), the calculated DBTs and LOPs are summarized in Table B-1 with an indication of the asset controlling the result. The weapons and tools associated with each threat and its corresponding DBT are also listed in the table.

Table B-1 DBTs and LOPs Determined Using UFC 4_020-01

Tactic	DBT, Controlling Asset*	LOP, Controlling Asset*	Weapons/Tools
Hand Delivered Devices	Medium, P	Low, P	IID, IED up to 2.2 lb. (1 kg) TNT, hand grenades
Indirect Fire Weapons	Low, P	Low, P	IID
Direct Fire Weapons	Low, P	Low, P	UL752 Level 3 (.44 magnum)
Forced Entry	Medium, P	High, SI	Unlimited hand tools, limited battery-powered tools
Airborne Contamination	Low, P	Low, P	Biological & radiological particulates release, chemicals/toxic industrials

P = Population; SI = Sensitive Information
IID = Improvised Incendiary Device, IED = Improvised Explosive Device

Figure B-5 UFC 4-020-01 Design Criteria Summary Worksheet

DESIGN CRITERIA SUMMARY WORKSHEET

Project or Building: Safe Haven Example	Analyst: Bowles	Date: 12/2/08

Assets	Asset Category	Asset Value Rating	Tactics: Explosive and Incendiary Devices						Standoff Weapons				Entry Tactics				Surveillance and Eavesdropping						Contamination Tactics					
			Moving Vehicle Devices		Stationary Vehicle Devices		Hand Delivered Devices		Indirect Fire Weapons		Direct fire weapons		Forced Entry		Covert Entry		Visual Surveillance		Acoustic Eavesdropping		Electronic Emanations Eavesdropping		Airborne Contamination		Waterborne Contamination		Waterfront Attack	
			DBT	LOP	DBT	LOP	DBT	LOP	DBT	LOP	DBT	LOP	DBT	LOP	DBT	LOP	DBT	LOP	DBT	LOP	DBT	LOP	DBT	LOP	DBT	LOP	DBT	LOP
Population	A	.7	L	L	L	L	M	L	L	L	L	L	M	L									L	L				
Sensitive Info	Q	.95											L	H														

DBT = Design Basis Threat severity level   LOP = Level of Protection

B-2.5 Design Criteria Development for Natural Threats.

Winds

Wind load of 130 mph (210 kph) based on FEMA P-361

Exposure = B, assumed

Importance factor = 1.15, based on UFC 3-301-01.

Earthquake

Magnitude = 6.4, based on historic data (earthquakes in Morocco)

Peak accelerations = 1.3 – 2.6 ft/sec^2 (0.4 – 0.8 m/sec^2)

The building/facility in which the safe haven will reside must be designed as Risk Category IV.

B-2.6 Other Applicable Design Requirements.

No additional design requirements.

B-2.7 Final Design Criteria.

Table B-2 Final Design Criteria Summary

Manmade			
Tactic	**DBT, Controlling Asset***	**LOP, Controlling Asset***	**Weapons/Tools**
Hand Delivered Devices	**Medium, P**	**Low, P**	**IID, IED up to 2.2 lb. (1 kg) TNT, hand grenades**
Indirect Fire Weapons	**Low, P**	**Low, P**	**IID**
Direct Fire Weapons	**Low, P**	**Low, P**	**UL752 Level 3 (.44 magnum)**
Forced Entry	**Medium, P**	**High, SI**	**Unlimited hand tools, limited battery-powered tools**
Airborne Contamination	**Low, P**	**Low, P**	**Biological & radiological particulates release, chemicals/toxic industrials**
Natural			
Threat	**Magnitude**		
Earthquake	**6.4**		

*P = Population, SI = Sensitive Information
IID = Improvised Incendiary Device, IED = Improvised Explosive Device

B-3 DESIGN PROCESS.

B-3.1 Procedure.

Follow procedure in UFC 4-023-10.

B-3.2 Initial Considerations.

Building Code: UFC 1-200-01

Siting: Use of the second floor cafeteria makes it internal and multi-use. There will be a separate room within the cafeteria for sensitive material storage or destruction.

Structural Integration: The safe haven is within the building, which has been designed to withstand external bombs, required wind loads, and designated earthquake loads. Thus, the internal safe haven automatically has protection against these loads (except for non-structural items). It also is partially shielded from debris threats. Personnel can reach the safe haven quickly and not be exposed to external threats while in transit. Since the safe haven is to contain GSA-rated safes for storage of classified material, the weight of this equipment must be taken into account when designing the floor system.

Use of Safe Haven: The cafeteria will be used on a daily basis in the absence of an emergency. The routine and maximum occupancy and required evacuation diagram will be posted according to UFC 3-600-01 and NFPA 101.

System Integration: All security elements, communication equipment, and power sources will be shared and/or compatible with the other facility resources and equipment.

B-3.3 Adjustments in Design.

Any design adjustments made during the design process will be rechecked against the criteria in UFC 4-023-10 Chapter 2.

B-3.4 Design for Manmade Threats.

The relevant man-made tactics include

- moving vehicle devices
- stationary vehicle devices
- hand delivered devices
- indirect fire weapons
- direct fire weapons
- forced entry
- airborne contamination
- forced entry

- airborne contamination

However, the building is already designed for applicable moving vehicle and stationary vehicle device threats, so the internal safe haven design does not need to consider these two threats. Use the DBTs summarized in Table B-2 as the design charge weight or load.

B-3.4.1 Hand Delivered Devices.

Per UFC 4-020-01, the general design strategy for this tactic is to detect the device at building entry points, before the device can reach the safe haven, and ensure that any assets inside the building are protected in accordance with the low LOP identified for this tactic in Table B-2. For low LOP, detection is only provided through operational procedures. For exterior attacks on the building, detection is based on visual observation of the unobstructed space surrounding the building. For attacks at building entry points, detection is provided using operational safeguards to prevent the device from proceeding past trained personnel dedicated to detection of such devices. Personnel qualified to respond to detection of an explosive or incendiary device, such as an explosive ordnance disposal team, must also be available.

The 2.2 lb. (1 kg) improvised explosive device (IED) threat will be used as the DBT. Per UFC 4-020-01, for a medium threat level and low LOP (Table B-2), conventional construction with no special requirements can be used for the exterior building walls and roof. Conventional hollow metal doors and ¼-inch (6-mm) laminated glass windows suffice. The interior cafeteria walls must be at least 6-inch (100-mm) thick, moderately reinforced concrete.

B-3.4.2 Indirect Fire Weapons.

Methods provided in UFC 4-020-01, and UFC 4-020-02FA, *DoD Security Engineering: Concept Design and* UFC 4-020-03FA, *DoD Security Engineering: Final Design*, will be used to design the safe haven for a DBT of an improvised incendiary device (IID) at a low LOP. The general design strategy for the indirect fire weapon tactic is to protect assets inside by hardening the structure to resist the effects of the DBT. At a low LOP; this requires fire resistant construction sufficient to prevent an IID from penetrating the structure shell. Materials used within the hallways and rooms surrounding the cafeteria must be selected to resist burning, flame spread, and smoke development. For low LOP, conventional construction can be used for the walls, roof, and doors. Windows are required to be ¼-inch (6-mm) plus 2 x1/8-inch (3-mm) glass with 0.03-inch (0.75-mm) PVB in narrow elevated windows.

B-3.4.3 Direct Fire Weapons.

UFC 4-023-07 *Design to Resist Direct Fire Weapon Effects* will be used to design the safe haven to resist the DBT for a low LOP of an UL752 Level 3 (.44 magnum) handgun. The effective distance for this weapon is 328 feet (100 meters).

The design strategy for low LOP is to block sight lines to building occupants or assets. The philosophy of that strategy is that aggressors will not shoot at what they cannot see. For an external or stand-alone safe haven, this strategy can be met using barriers of vegetation, fences, landforms, and walls placed to interrupt sight lines. For this internal safe haven example, blocking lines-of-sight will be accomplished using type A requirements for the walls, windows, and doors for the cafeteria, per UFC 4-020-01. The walls just need to be opaque for this requirement. The windows will be elevated per the requirement for indirect fire weapons tactic therefore providing no direct sight lines. Standard hollow metal doors are acceptable. There are no special design requirements for the roof since the safe haven is on the second floor of a 7-story building, and there are no direct sightlines to the roof.

B-3.4.4 Forced Entry.

The safe haven will be designed to resist the DBT of unlimited hand tools and limited battery-operated tools for a period of 2 minutes, the response time of the security forces provided in Section B-2.2 above. The guidance in UFC 4-020-02FA and UFC 4-020-03FA, will be used to design walls, doors, floors, and other necessary components.

Per UFC 4-020-01 for a medium threat severity level and a high LOP, the walls and roof will be designed as type E. The walls will be 8-inch (200-mm) reinforced concrete with #4 bars at 6 inches (150 mm) on center each way. Per UFC 4-020-02FA/ UFC 4-020-03FA, the required delay time for forced entry for this example would be 2 minutes. The roof will be 8-inch (200-mm) reinforced concrete with #4 bars at 6 inches (150 mm) on center each way on steel decking and with a built-up roofing system. The doors will be 10-inch steel clad solid wood (254-mm) swinging doors with ½-inch (13-mm) plate inside and out. There are no windows available to meet the requirements of this tactic, at the medium threat severity level and high LOP. Thus, either the cafeteria should be designed without windows, or the window openings must be limited to 96 sq. inches (0.06 sq. meters).

B-3.4.5 Airborne Contamination.

The methods and guidance in UFC 4-010-01, UFC 4-020-01 and UFC 4-024-01 *Security Engineering: Procedures for Designing Airborne Chemical, Biological, and Radiological Protection for Buildings* can be used to design the safe haven for the DBT specified in Table B-2. The design criteria summary worksheet (Figure B-5) indicates a low DBT and low LOP.

Limited chemical, biological, and radiological (CBR) protection is required in accordance with UFC 4-010-01 for all new inhabited facilities to provide very low and low levels of protection. Specific design strategies are to minimize air infiltration and to be able to limit dispersal of any agents that infiltrate the building. The very low and low levels of protection incorporate passive building component features at little or no additional cost when included in new facility designs and major retrofits. Protection measures that are recommended for all buildings and are required for new inhabited facility designs and major retrofits are a mass notification, public address, or alarm system; air distribution emergency shutoff; sealed mailrooms with separate, dedicated ventilation systems and exhaust fans; elevated outside air intakes; and restricted roof access. High efficiency particulate air (HEPA) filters will be used at air intakes, as required for the low LOP per

UFC 4-020-01. The HEPA filters will be installed in the central air-handling unit, filtering both the outside and recirculated air. A slight positive over pressurization of the building (Class II overpressure) will be maintained. The perimeter around the cafeteria/Safe Haven will be sealed with insulating foam.

Per UFC 4-024-01, a low design basis threat for airborne contamination is the threat of external release of biological particulates and toxic industrial chemicals (TICs). No toxic military chemical or radiological threat is expected.

If the presence of an airborne hazard is detected, there are four possible protective courses of actions: evacuation, sheltering in place, ventilation and purging, and the use of protective masks.

These actions do not provide protection on a continuous basis, of course, but are implemented singly or in combination for relatively short periods when a hazard is present or known to be imminent.

The use of protective masks in conjunction with evacuation is the most cost effective, efficient use of resources. New models of universal-fit escape masks have been developed for protection against chemical and biological agents. Such masks form a seal at the wearer’s neck and therefore fit a wider range of sizes than traditional masks that seal around the face. These masks do not require special fitting techniques or multiple sizes and can be used by people with facial hair. They are designed to store compactly and are practical to store at employees’ desks. Employees can also carry them on their belt. These masks have excellent protective capability and have a 5-year shelf life.

Sheltering in place for longer duration may require a collective protection (ColPro) strategy defined in UFC 4-020-01 and UFC 4-024-01 that can be used to ensure that agents introduced at entry points are kept out of the building and the safe haven. However with initial costs being high and the high expense to operate and maintain such as system makes this course of action not cost effective for the short duration required.

Designing to protect against a lower threat level equates to a higher risk of exposure and greater likelihood of defeat but entails lower costs. Designing to meet a higher threat level equates to a lower likelihood that the building will be compromised if attacked but entails high initial and operating costs.

The safe haven will be designed for the low LOP as required by UFC 4-010-01 and UFC 4-024-01 as described above. Protective masks will be provided to each employee, stored at their desks.

B-3.5 Design for Natural Threats.

The relevant natural threat is an earthquake, and typical wind loads must be considered as well. However, since the building structure is already designed for wind and seismic loads, these requirements have been met.

All non-structural components within the safe haven must be designed for seismic loads, per UFC 3-301-04, *Seismic Design of Buildings*.

B-4 OTHER DESIGN REQUIREMENTS.

B-4.1 Emergency Power.

If required, one internal-combustion generator in the cafeteria can provide backup power for the 2-hour duration, supporting lighting, ventilation, and communication systems. The generator must be vented to the outside without allowing airborne contamination to enter the safe haven. In general follow service guidance for approval of generator authorization and design.

B-4.2 Communication.

Hand-held radios and battery-powered radio transmitters for signaling emergency personnel will be provided in the safe haven. All communication devices will be tested at regular intervals defined by the Planning Team to ensure they are kept in working order, as described in FEMA P-361. A canned air horn will be in the safe haven to signal rescue personnel. Portable computers with internet capability, a fax machine, a copier, and a scanner are available in the cafeteria manager’s office, inside the safe haven.

B-4.3 Entry Point Monitoring.

An audible cue device will be mounted at all four entrances. When turned on, the cue should sound any time the doors are opened.

B-4.4 Fire Safety.

Safe havens must comply with all fire and life-safety code requirements per UFC 3-600-01. The fire and life safety system inside the safe haven must remain operational and provide life-safety protection after an incident and allow for safe evacuation of the building when appropriate for the required occupancy level. “The routine and maximum occupancy and required evacuation diagram will be posted according to UFC 3-600-01 and NFPA 101.”

B-4.5 Sanitation Management.

The cafeteria has 6 toilets, 3 each in one men’s and one women’s restroom, which more than meets the requirement of one toilet for every 75 occupants in the safe haven.

B-4.6 Additional Safe Haven Supplies.

The agency operating the safe haven will identify appropriate supplies based on items listed in Table 4-1 of FEMA 453, including food and water, if required. Any design requirements for storing these supplies must be considered in the safe haven design.

B-5 INTEGRATION.

Using the general population and sensitive information as the two main assets for the safe haven and considering all required tactics resulting from the design criteria analysis per UFC 4-020-01, the safe haven design is summarized in Table B-3.

Table B-3 Safe Haven Design Summary

Component	Governing Tactic	Construction Description
Walls	Forced Entry	8-inch (200-mm) reinforced concrete with #4 bars at 6 inches (150 mm) o.c. each way
Roof	Forced Entry	8-inch (200-mm) reinforced concrete with #4 bars at 6 inches (150 mm) o.c. each way, on steel decking, with a built-up roofing system
Doors	Forced Entry	10-inch (250-mm) steel clad solid wood swinging doors with ½-inch (13-mm) plate inside and out
Windows	Forced Entry	Limited to 96 sq. inches (0.06 sq. meters)
Non-structural	Earthquake	Peak acceleration of 2.6 ft/sec^2 (0.8 m/sec^2)

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

UNIFIED FACILITIES CRITERIA (UFC)
NEW DOCUMENT SUMMARY SHEET

Document: UFC 4-025-01 *Security Engineering: Waterfront Security*

Superseding: None

Description: Provide a unified approach to the development of waterfront protective measures intended to protect waterside assets.

Reasons for Document:

- This document is one of a series of security engineering criteria documents covering physical countermeasures for the current threat environment.

- The design of physical security measures is a specialized technical area that does not fall in the normal skill record and resume of commanders, architects, engineers, and project managers. This document provides guidance to those parties tasked with implementing existing and emerging physical protection system requirements for waterside assets.

Impact:

- This document does not set the requirement for protection measures for the waterfront. No additional cost impacts are anticipated by the publication of this document. This document should reduce the design and coordination efforts for waterfront design.

Unification Issues

There are no unification issues.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

Terrorist attacks on waterside assets such as the USS Cole emphasize the need for increased antiterrorism (AT) and physical security protective measures for waterfront assets.

1-2 PURPOSE.

Present a unified approach for AT and physical security systems that protect waterfront assets. Commanders, security personnel, planners, designers, architects, and engineers shall use this document when considering AT and physical security systems that protect waterfront assets.

1-3 APPLICABILITY.

This document provides planning and design criteria for DoD components and participating organizations. This document applies to all construction, renovation, and repair projects including expeditionary or temporary construction of waterfront facilities associated with waterfront assets onboard DoD installations. This document does not apply to ports of call.

1-4 SCOPE.

This document provides a methodology to design AT and physical security systems required to protect waterfront assets. It focuses on the protection of military warships and support vessels but the concepts within may be adopted for the protection of all DoD waterfront assets such as airfields, shore facilities, or other structures immediately adjacent to water.

The examples provided are for illustration only and should be modified and adapted to satisfy installation specific constraints. Issues such as tactics, techniques, and operational procedures are not addressed. However, a well-designed physical security system should not hinder operations and capabilities.

1-5 VULNERABILITY AND RISK ASSESSMENT.

In accordance with DOD O-2000.12H Antiterrorism handbook, a vulnerability and risk assessment must be conducted prior to beginning any security project. Upon identifying facility or asset vulnerabilities to threats, physical security measures such as fences, gates, and Electronic Security Systems (ESS) may be deployed to reduce vulnerabilities. In summary, this document assumes the pre-design phases, including the risk analysis, are complete prior to beginning design. For information on Security Engineering Planning and Design process, refer to UFC 4-020-01 and UFC 4-020-02 (described in the section “Security Engineering UFC Series” in this chapter). The engineering risk analysis conducted as part of UFC 4-020-01 should be consistent with the terrorism risk analysis conducted by the installation security/AT staff.

1-6 POLICY REQUIREMENTS.

The requirement to protect waterfront assets comes from DoD Instruction/Directives, Geographic Combatant Commander (GCC) Instructions, Service Instruction/Directives, and Regional or Installation requirements. Consult Headquarters, Major Command, Regional, and Installation personnel to established waterfront asset protection requirements.

1-6.1 Department of Defense.

There are several instructions and publications within the Department of Defense that establish requirements for access control and physical security for waterfront assets.

- DOD 5200.8-R: Requires DOD Components to determine the necessary access control based on the requirements of a developed physical security program. Emergency planning is specified to include establishment of a system for positive identification of personnel and equipment authorized to enter and exit the installation and maintenance of adequate physical barriers that will be deployed to control access to the installation. Planning will also include increasing vigilance and access restrictions during higher force protection conditions.

- DODD 2000.12: Provides DOD policies for ATFP and assigns responsibilities for implementing the procedures for the DOD ATFP Program. It authorized the publication of DOD 2000.16 Antiterrorism Standards as the DOD standards for ATFP and DOD O-2000.12-H DOD Antiterrorism Handbook as guidance for the DOD standards.

- DOD O-2000.12H: Defines the DOD Force Protection Condition (FPCON) System, which describes the potential threat levels and the applicable FPCON measures to be enacted for each level. FOCON measures in the 12-H were modified in DoDI 2000.16, Change 2 of 08 Dec 2006. DOD O-2000.12H also requires Commanders to develop and implement Random Antiterrorism Measures (RAM) as an integral part of their AT Program.

- DODI 2000.16: This instruction requires the installation or activity Commanding Officer to define the access control measures at installations. Additionally, DOD 2000.16 requires Commanders at all levels to develop and implement a comprehensive Antiterrorism (AT) Program, which should define the necessary action sets, including identification and inspection procedures, at each of the potential Force Protection Condition (FPCON) levels and lists the most current approved FPCONS.

1-6.2 Geographic Combatant Commander (GCC) Requirements.

GCC issue requirements for Antiterrorism and physical security for installations within their area of responsibility. Ensure any such requirements are incorporated in addition to the requirements found in DoD and Service Directive/Instructions. Resolve any differences in the requirements for the design of a waterfront security by applying the most stringent requirement.

1-6.3 Service Requirements.

Department of Navy.

- OPNAVINST 5530.14, Chapter 10 identifies the requirements for installation and restricted area access control. APPENDIX VIII identifies Waterside and Waterfront physical security requirements.

- NTTP 3-07.2.3 provides guidance for the physical security for Naval Installations to include Restricted Areas and Waterfront Security.

1-6.4 Installation Specific Requirements.

As required by DODI 2000.16 and service directives, each installation must have an Antiterrorism Plan. The plan provides procedures and recommendations for reducing risk and vulnerability of DOD personnel, their family members, facilities, and assets from acts of terrorism. As such, the installation AT plan reflects the foundation for requirements determination. Installation specific requirements need to be factored into all capital improvement initiatives.

1-7 CONSIDERATIONS.

The objective of waterfront security system is to secure the waterfront from unauthorized access and to detect and neutralize threats while minimizing impacts to port operations and the environment. Design considerations are:

- Security
- Port Operations
- Safety
- Appearance
- Environmental impact

1-7.1 Security.

Installations should focus first on threats at the first line of defense – the installation perimeter. Consideration of the waterfront is extremely important to defense-in-depth and effective risk mitigation.

The first priority of a waterside security system is to maintain perimeter security. The waterfront:

- is a part of the installation perimeter and a legal line of demarcation

- must be able to accommodate Random Antiterrorism Measures (RAMS) employment for sustained operations in order to validate installation's ability to affect directed security posture.

- must be able to operate at all FPCONs; and must have security features that protect against landside and waterside threats and unauthorized entry

1-7.2 Port Operations.

Design the waterfront security systems to maximize security while minimizing the impact on port operations. Ships must be able to sortie effectively without compromising safety, security, or causing undue delays that may affect port or fleet operations.

1-7.3 Safety.

Waterfronts must have a working environment that is both safe and effective for security forces and personnel working in the waterfront area. Safety includes provisions for personal protection against attack and mishaps.

1-7.4 Appearance.

Design waterfront security systems to impart an immediate impression of professionalism and convey the DOD's commitment to the security of DOD personnel and its mission critical assets, facilities, and resources.

1-7.5 Environmental Impact.

Design waterfront security systems to minimize environmental impact on the adjacent waterway. Include environmental representatives in the initial planning, design and construction of applicable projects to ensure there are no compliance issues, and that all regulatory approvals are received in a timely manner.

1-8 CORROSION PREVENTION AND CONTROL.

Design strategies for waterfront security structures and equipment shall consider corrosion prevention and control (CPC) preservation techniques for long term maintainability throughout their life cycle. Trade-off decisions involving cost, useful service life, and effectiveness shall address corrosion prevention and mitigation.

1-9 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-10 GLOSSARY.

Appendix B contains acronyms, abbreviations, and definitions of terms.

1-11 GENERAL BUILDING REQUIREMENTS.

UFC 1-200-01, "General Building Requirements", provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, sustainability, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-12 SECURITY ENGINEERING UFC SERIES.

This UFC is one of a series of security engineering unified facilities criteria documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include the following:

1-12.1 DoD Minimum Antiterrorism Standards for Buildings.

UFC 4-010-01and 4-010-02 establish standards that provide minimum levels of protection against terrorist attacks for the occupants of all DoD inhabited buildings. These UFCs are intended to be used by security and antiterrorism personnel and design teams to identify the minimum requirements that must be incorporated into the design of all new construction and major renovations of inhabited DoD buildings. They also include recommendations that should be, but are not required to be incorporated into all such buildings.

1-12.2 DoD Security Engineering Facilities Planning Manual.

UFC 4-020-01 presents processes for developing the design criteria necessary to incorporate security and antiterrorism into DoD facilities and for identifying the cost implications of applying those design criteria. Those design criteria may be limited to the requirements of the minimum standards, or they may include protection of assets other than those addressed in the minimum standards (people), aggressor tactics that are not addressed in the minimum standards or levels of protection beyond those required by the minimum standards. The cost implications for security and antiterrorism are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they represent only representative construction that will meet the requirements of the design criteria. The manual also addresses the tradeoffs between cost and risk. The Security Engineering Facilities Planning Manual is intended to be used by planners as well as security and antiterrorism personnel with support from planning team members.

1-12.3 DoD Security Engineering Facilities Design Manual.

UFC 4-020-02 provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established using UFC 4-020-01. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them all work as a system. The information in UFC 4-020-02 is in sufficient detail to support concept level project development, and as such can provide a good basis for a more detailed design.

The manual also provides a process for assessing the impact of protective measures on risk. The primary audience for the Security Engineering Design Manual is the design team, but it can also be used by security and antiterrorism personnel.

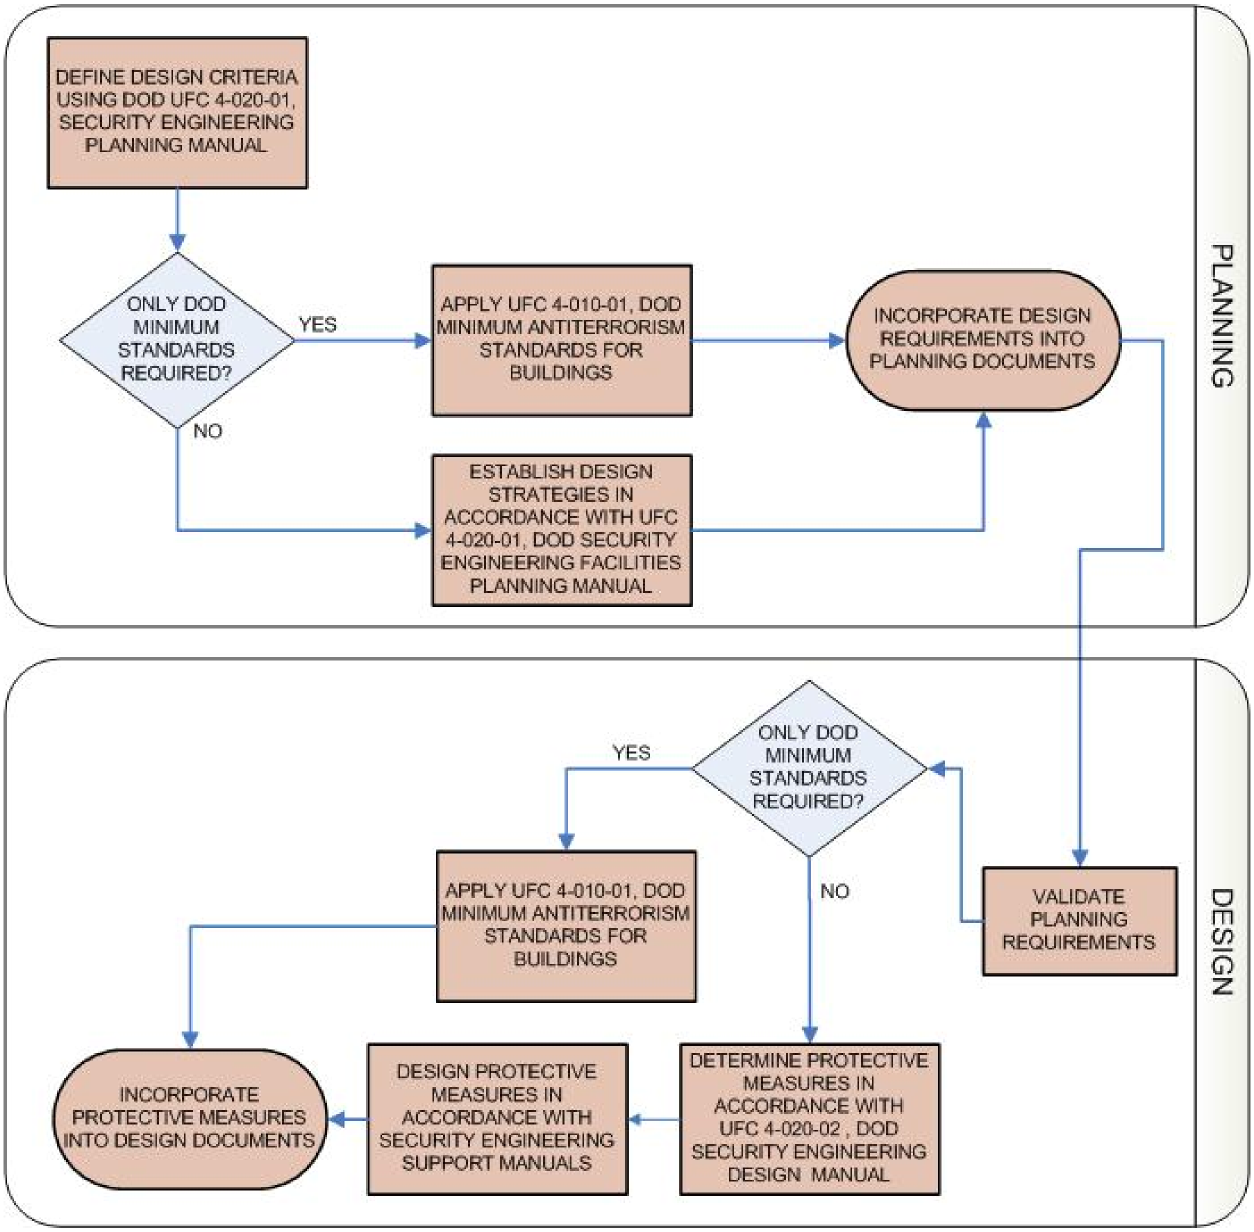
1-12.4 Security Engineering Support Manuals.

In addition to the standards, planning, and design UFCs mentioned above, there is a series of additional UFCs that provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02. These support manuals provide specialized, discipline specific design guidance. Some address specific tactics such as direct fire weapons, forced entry, or airborne contamination. Others address limited aspects of design such as resistance to progressive collapse or design of portions of buildings such as mail rooms. Still others address details of designs for specific protective measures such as vehicle barriers or fences. The Security Engineering Support Manuals are intended to be used by the design team during the development of final design packages.

1-12.5 Security Engineering UFC Application.

The application of the security engineering series of UFCs is illustrated in Figure 1-1. UFC 4-020-01 is intended to be the starting point for any project that is likely to have security or antiterrorism requirements. By beginning with UFC 4-020-01, the design criteria will be developed that establishes which of the other UFCs in the series will need to be applied. The design criteria may indicate that only the minimum standards need to be incorporated, or it may include additional requirements, resulting in the need for application of additional UFCs. Even if only the minimum standards are required other UFCs may need to be applied if sufficient standoff distances are unavailable. Applying this series of UFCs in the manner illustrated in Figure 1-1 will result in the most efficient use of resources for protecting assets against security and antiterrorism related threats.

Figure 1-1 Security Engineering UFC Application



This Page Intentionally Left Blank

CHAPTER 2 OVERVIEW

2-1 OVERVIEW.

DoD installations located adjacent to bodies of water face all the threats of land –locked installations. In addition, waterfront installations must defend against the waterside threat. Waterside attacks pose additional challenges for security forces and the installation's overall physical security system and include either surface (boat or swimmer) or subsurface (scuba diver or submersible) threats. Physical security systems protecting waterfront assets must enable/facilitate threat detection, assessment, delay, response, and threat neutralization for both waterside and landside threats.

2-2 WATERFRONT SECURITY SYSTEM.

Waterfront security system is that subset of an Installation's physical security system specifically designed to safeguard waterfront assets against espionage, sabotage, damage, or theft.

2-2.1 Waterfront Assets.

Waterfront assets are vessels, personnel, and facilities such as piers, wharves, docks or similar structures used to berth vessels.

2-2.2 Waterfront.

The area of the DoD installation adjacent to a body of water. This area comprises waterfront assets and the surrounding area including the adjacent waterway, land, facilities, parking, and roadways. This area may be designated as a restricted or controlled areas per DoD 5200.8-R. Within the controlled or restricted area, the waterfront is divided into the two areas of waterside and landside. See Figure 2-1.

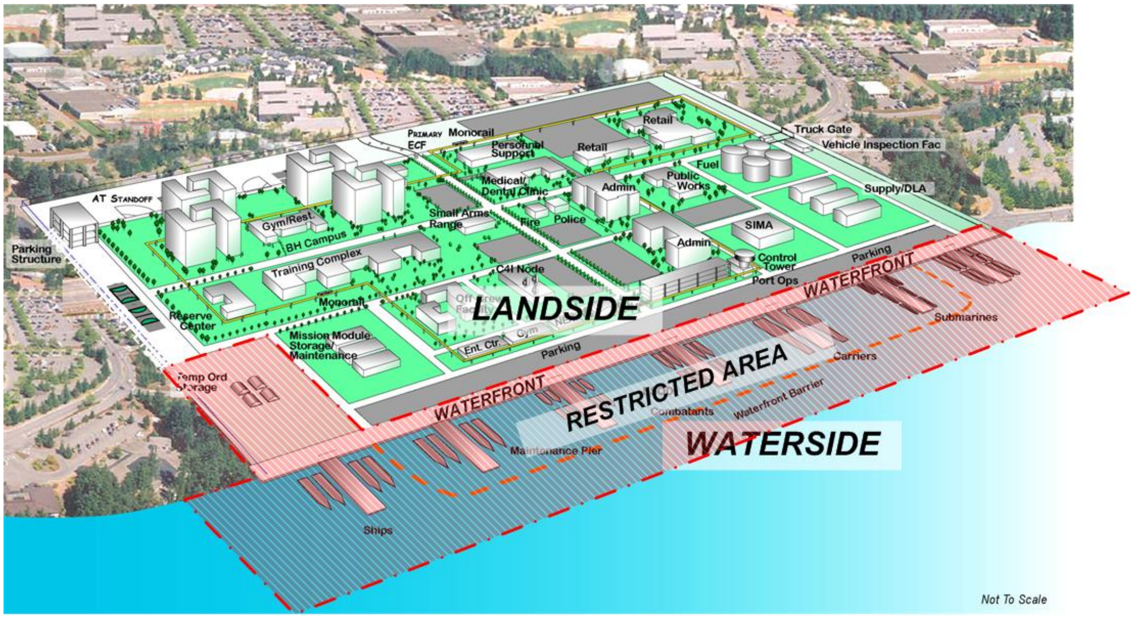
2-2.2.1 Waterside.

The body of water (waterway) adjacent to the DoD installation that is monitored and or controlled by the Installation. The waterside includes the piers and similar structures built out into the water.

2-2.2.2 Landside.

The land within the controlled or restricted area adjacent to the body of water. This includes facilities such as wharves or similar structures and includes the adjacent, facilities, parking and roadways.

Figure 2-1 Waterfront



2-2.3 Physical Security System.

A system of integrated protective measures comprised of people, equipment, and operational procedures that control access to facilities or assets.

Design physical security systems to ensure protective measures work as an integrated system rather than separate elements. The system must detect threats, delay threats, and then respond to threats. This concept is referred to as of detect, delay, and respond or detect, delay, and defend. To create an effective system, the time between detection and response by response capability must be less than the time it takes the threat to compromise the asset. Physical security systems accomplish this by detecting threats at the farthest possible distance from the asset and providing delays between the detection points and the asset giving the response capability time neutralize threat. This presents a challenge on the waterside due to limited distances between waterfront assets and unrestricted waterways.

Figure 2-2 diagrams the functions of a physical security system. Table 2-1 depicts the physical security protection measures of a waterfront security system.

Figure 2-2 Diagram of Physical Security System Functions

2-3 PLANNING.

2-3.1 Establish Requirements.

For some waterfront assets, the minimum security measures are established by policy or regulation. See OPNAVINST 5530.14 for security measures associated with waterfront assets in U.S. Navy controlled ports. Always determine requirements for waterfront asset protection early in the project planning process.

Establish an interdisciplinary planning team with local considerations to include the following:

- Supported Command
- Security forces
- Port Operations
- Installation/Regional Anti-terrorism Officer (ATO)
- Communications Officers
- Safety Officers
- Engineering
- Environmental
- Planning
- Local, state, Federal, or host nation officials to ensure integrity of restrictive access to the installation and reduce the potential adverse effects on surrounding communities.

The interdisciplinary planning team will use the process in UFC 4-020-01 to identify the design criteria, which includes the assets to be protected, the threats to those assets, and the levels of protection required for the assets against the identified threats. The planning team may also consider user constraints such as appearance, operations, manpower requirements or limitations, and sustainment costs when determining the requirements for asset protection and components of the overall security solution.

2-3.2 Design Basis Threat (DBT).

The DBT links aggressor with tactic. It includes the aggressor tactics and the associated weapons such as explosives, tools, and agents. The DBT must be determined to plan and design the protective measures required to protect the assets from compromise.

The waterfront should have a DBT for the landside protection measures, and a different DBT for the waterside. For example, the landside may be a stationary vehicle bomb consisting of a 4,000 lb (1814 kg) vehicle containing a Type II explosive. The waterside may be a 2,000 lb (907 kg) powerboat containing a Type I explosive.

2-3.3 Level of Protection (LOP).

Defines the degree to which an asset is protected against DBT.

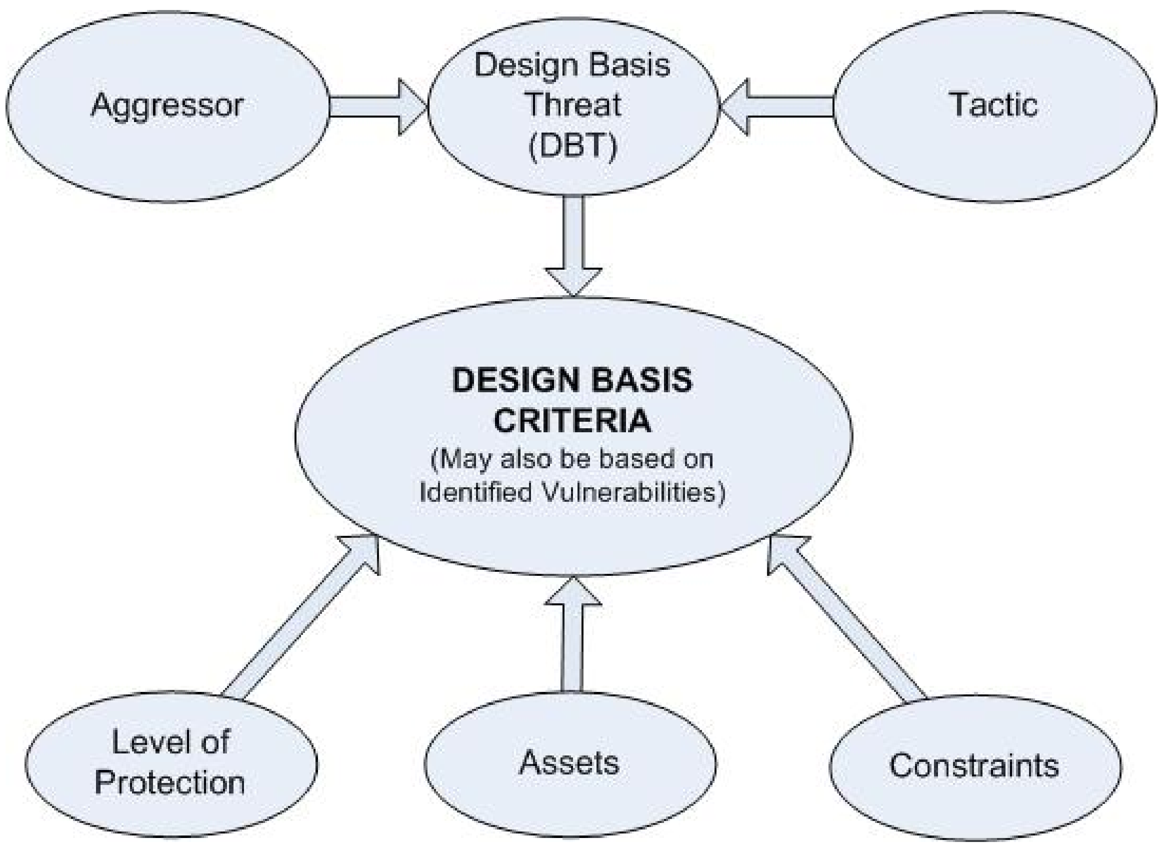
2-3.4 Future Development Plans.

The planning team must carefully evaluate future development plans for the installation and the surrounding community. All waterfront security development plans should accommodate future modifications necessitated by increased demand, additional assets, additional facilities, or revised security measures.

2-3.5 Document Requirements.

Document the planning requirements for endorsement by the Installation ATO and Port Ops Officers to ensure protective measures support the installation's physical security system, AT plan, and waterfront operations. Figure 2-3 provides a simplified flow chart of the overall process.

Figure 2-3 Project Process



This Page Intentionally Left Blank

CHAPTER 3 DESIGN STRATEGY

3-1 INTRODUCTION.

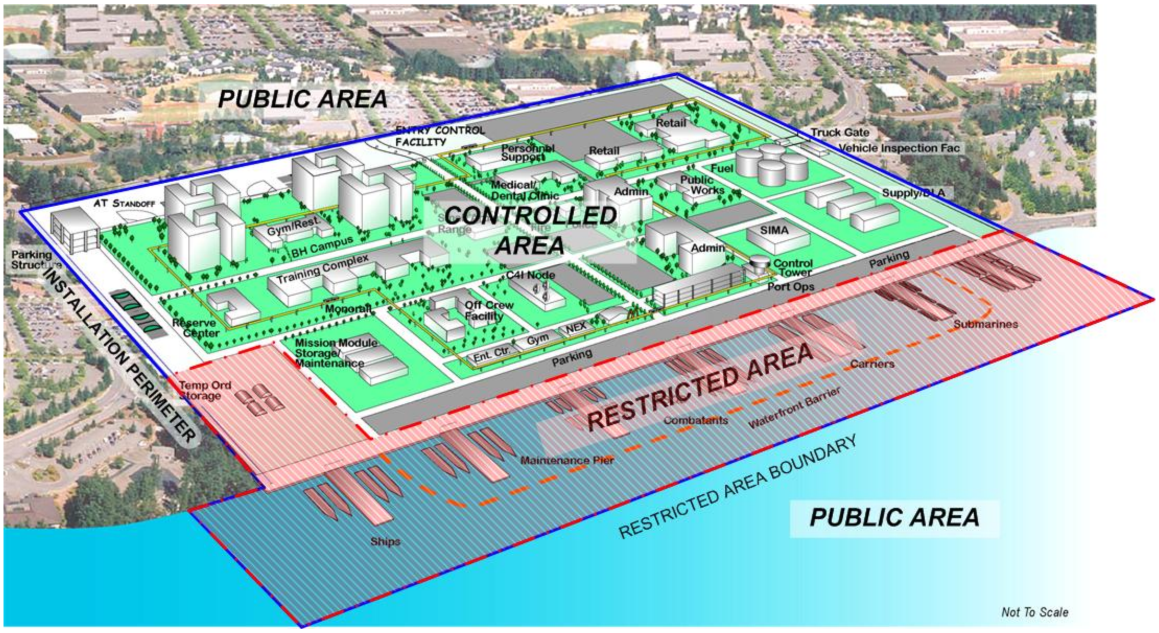
This chapter presents information to design a system of protective measures deployed on an installation that protect the waterfront from unauthorized access using the processes in UFC 4-020-01 and UFC 4-020-02 (delineated in Figure 2-3) to identify the design requirements. It assumes the waterfront is a controlled or restricted area (enclave), onboard a DoD installation with protective measures deployed on the installation and at the entry control points. It also does not address protective measures outside the waterfront area.

3-2 DESIGN STRATEGY.

All protective measures must support the concept of detect, delay and respond and facilitate security force's ability to determine capability, opportunity, and intent of would be aggressors. When possible, physical security systems shall use a defense-in-depth approach, which effectively employs human and other physical security measures throughout the installation to create a layered defense against potential threats. Defense-in-depth insures that no single point of failure would render assets vulnerable to compromise. This strategy utilizes a zone concept that establishes areas within the installation and their associated security measures. An installation must establish clearly defined sequence of boundaries through which personnel must pass to reach the restricted area. Security measures and access controls must increase as personnel transition from lower to higher security areas and personnel must understand the consequences associated with entering the restricted area. Figure 3-1 graphically describes this concept. This document will focus on the restricted area of the waterfront sometimes referred to as the waterfront enclave.

In the case of waterfront security, the first layer of defense is the Installation's perimeter including the Access Control Points (ACPs). For the landside, the installation's ACPs provide the first opportunity to detect and engage threats away from the critical assets. Access control at the installation's perimeter is extremely important to the defense-in-depth concept and effective risk mitigation. For the waterside, the first layer of defense may be the restricted area (waterway) boundary. The waterside restricted area should be visibly delineated in order to facilitate security force's ability to determine the intent of would be aggressor.

Figure 3-1 Zone Concept



- **Public Area:** Area outside an installation or controlled perimeter where the public has unrestricted access.

- **Access Control Area:** The installation's entry control points where authorized personnel transition from public zone to the DoD installation.

- **Controlled Area:** The area within the installation's controlled perimeter where authorized personnel have access. Installations are considered controlled areas for the purposes of national defense.

- **Restricted Area:** A defined area established to protect critical assets by providing a higher level of security than that afforded elsewhere on the installation.

3-2.1 Detect, Delay, and Respond.

A physical security system must operate on the principle of Detect, Delay, and Respond. To be effective, the time between detection of an intrusion and response by security forces must be less than the time it takes to damage or compromise the protected asset.

3-2.1.1 Detect.

Detection and assessment of the potential threats may be accomplished through ESS, electronic harbor security system (EHSS), security lighting, security forces, DoD personnel, military working dogs. Training and operational procedures are critical to detection and assessment as they improve personnel capabilities and support application of consistent concepts and practices. Security lighting, ESS and EHSS greatly enhance the probability of detection, reduce the time it takes to assess the threat, improve classification of potential threats, and may reduce the manpower required to accomplish these functions.

3-2.1.2 Delay.

Delay is the time it takes for the aggressor to get from the point of detection to compromising the protected asset. Physical security systems may deploy roving security patrols, barriers, or increase standoff distance to create obstacles to increase delay. The time delay that a physical security system provides is critical to asset security. The time delay of the system must be synchronized with security force response time to ensure that maximum security is afforded to critical assets.

3-2.1.3 Response.

Response is the time it takes for the response capability to interrupt or neutralize a threat. This includes communication, mobilization, travel time, and tactics.

3-3 SYSTEM EFFECTIVENESS.

A well designed physical security system will:

- Provide defense-in-depth
- Provide continuous protection
- Enhance detect, delay, and response function

Effective waterfront security systems must be compatible with the installation's operational and security procedures. Measures that are excessive, inappropriate may eventually be eliminated or bypassed. Poorly placed fencing or barriers can reroute cranes, forklifts or container carriers to pavement areas not designed for heavy loads. Forklift tines and crane hooks can damage security equipment rendering the system inoperable. Minimize impediments to waterfront operations and security hardware by placement and consolidation.

3-4 ESTABLISH PERIMETER.

To protect waterfront assets from unauthorized access, it is important to establish and maintain a defined perimeter. Before a person proceeds into the waterfront restricted area, they must perceive the area boundary and understand the consequences associated with crossing it. The use of ESS on the landside and EHSS on the waterside enhance:

- Detection of unauthorized access with an intrusion detection system (IDS)
- Improve the validation of credentials with access control systems (ACS)
- Threat detection, alarm assessment, surveillance, and archiving with video imaging.

The easiest and least costly opportunity for achieving the appropriate levels of protection against terrorist threats is to incorporate sufficient standoff distance to mitigate the defined threat. While sufficient standoff distance is not always available, maximizing the available standoff distance always results in the most cost-effective solution.

3-4.1 Landside Perimeter.

The landside perimeter of the enclave may consist of fences, walls, signage, natural barriers, and ACPs for authorized vehicles and pedestrians. In addition, a final denial boundary may be established at the foot of a pier creating defense-in-depth. See chapter 4 for Landside protection measures.

3-4.2 Waterside Perimeter.

The waterside boundary of the enclave may consist of channel markers, buoys, float lines, signage, or boat barriers. The transition from the public area to the restricted area may not go through additional areas or zones. Therefore, the boundary on the waterside may have to provide a higher LOP (delay) for critical assets than the landside counterparts to ensure critical assets are not compromised. See chapter 5 for Waterside protection measures.

3-5 SECURITY LIGHTING.

Security lighting or protective lighting provides illumination during periods of darkness or in areas of low visibility to aid in the detection, delay, and respond functions of a physical security system. Coordinate security lighting requirements with security personnel. Refer to UFC 3-530-01 for lighting design criteria and the Landside and Waterside Chapters of this UFC for specific security lighting guidance.

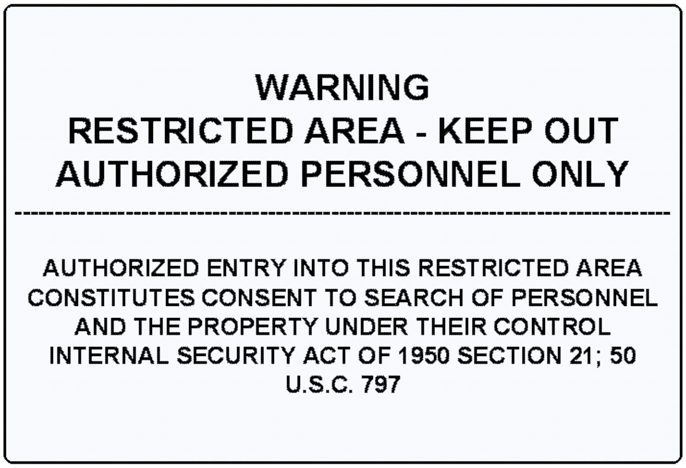
3-6 SIGNAGE.

Coordinate size, placement, wording, and use with security personnel. Signage should be consistent with applicable DoD/Service specific requirements. Any language in addition to English should be appropriate for the stated purpose.

3-6.1 Access Control Point (ACP) Signage.

Post reflective signs at all waterfront vehicle and pedestrian ACPs. For example see Figure 3-2.

Figure 3-2 ACP Sign Example



3-6.2 Restricted area signage.

Post reflective signs at intervals no greater than 100 feet (30.5 m) along the entire perimeter of the restricted area and where boundaries make abrupt changes in direction. For example see Figure 3-3.

3-6.3 Boat Barrier Signage.

Post reflective signs at intervals no greater than 100 feet (30.5 m) along the entire boat barrier perimeter and on moorings. For example see Figure 3-3.

Figure 3-3 Restricted Area Sign Example

This Page Intentionally Left Blank

CHAPTER 4 LANDSIDE

4-1 INTRODUCTION.

This chapter presents information to design a system of protective measures deployed on the landside of an installation intended to protect waterfront assets.

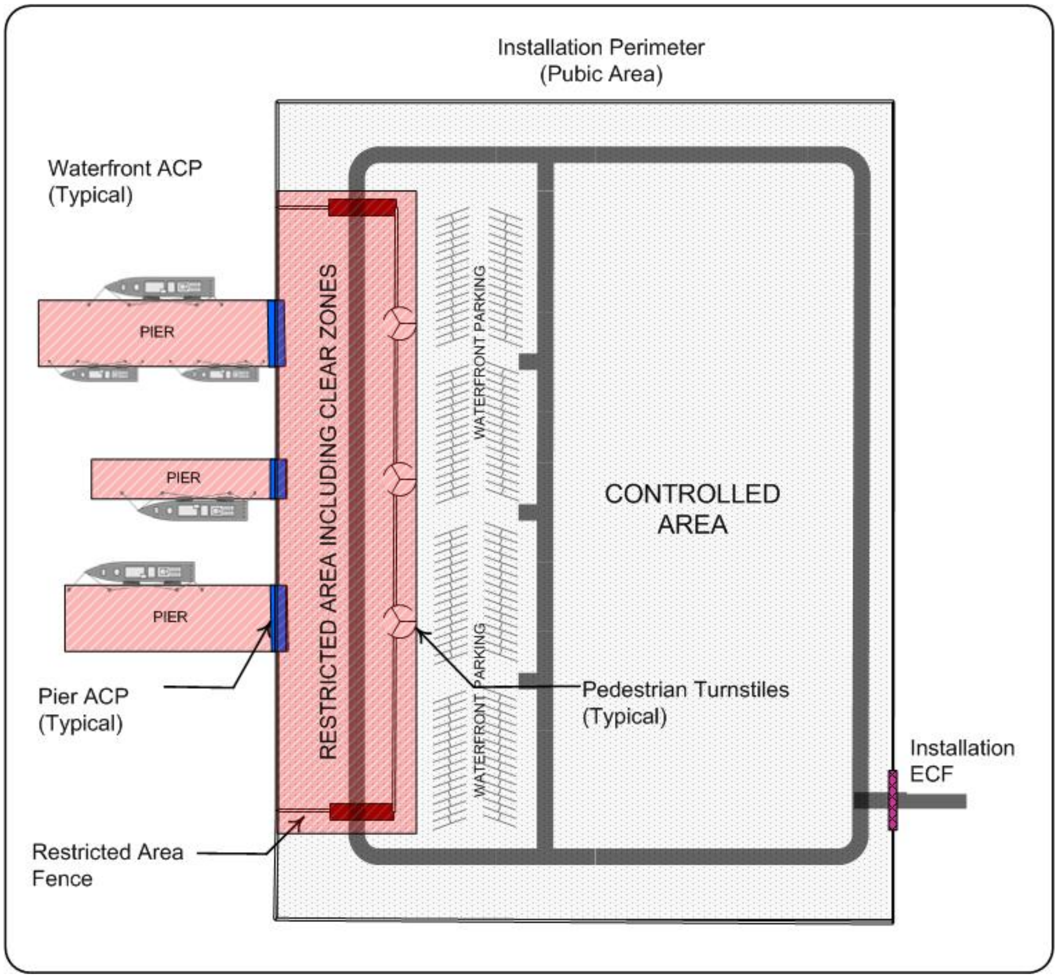
4-2 GENERAL DESIGN STRATEGY.

For the purposes of this chapter, threats are from the landside. The design strategy for the landside must be based on the concept of defense-in-depth. Establish multiple perimeters, boundaries, or zones through which unauthorized personnel must pass to access protected assets. Configuration of the physical perimeter and the LOP are dependent on assets to be protected and the DBT. In the case of the landside security, the Installation's controlled perimeter may be the first layer of defense.

The general design strategy for the landside is to establish and maintain defense in depth through the application of standoff, barriers, access control, operational procedures, and security zones, see Figure 4-1. The security zones or areas are defined as follows:

- **Asset location:** The area where the protected asset is located. For vessels, this would be a pier, wharf or dry dock.
- **Waterfront Restricted Area (enclave):** A defined waterfront area in which there are special measures employed to prevent unauthorized entry. Restricted areas may be of different types depending on the nature and varying degree of importance of the protected asset and may extend beyond the piers or wharfs to the surrounding areas. Restricted areas must be authorized by the installation commander, properly posted, and employ physical security measures.
- **Controlled Area:** The area within the installation's controlled perimeter where authorized personnel have access.

Figure 4-1 Landside Security Zones Adjacent to Piers



4-3 LANDSIDE ACCESS CONTROL.

Access control is established to prevent unauthorized access to restricted areas. As with any element of a physical security system, design must be based on the concepts of defense-in-depth. Design of the access control system begins at the Installation's perimeter and ACPs. Vehicles and personnel travel from one zone to another through the system to reach the restricted area. Physical security measures, including access control must increase from lower to higher security areas. The pier or wharf where critical assets are berthed are considered the final denial and should have the highest access control measures in the system, see Figures 4-2 and 4-3.

Figure 4-2 Landside Access Control Transitions

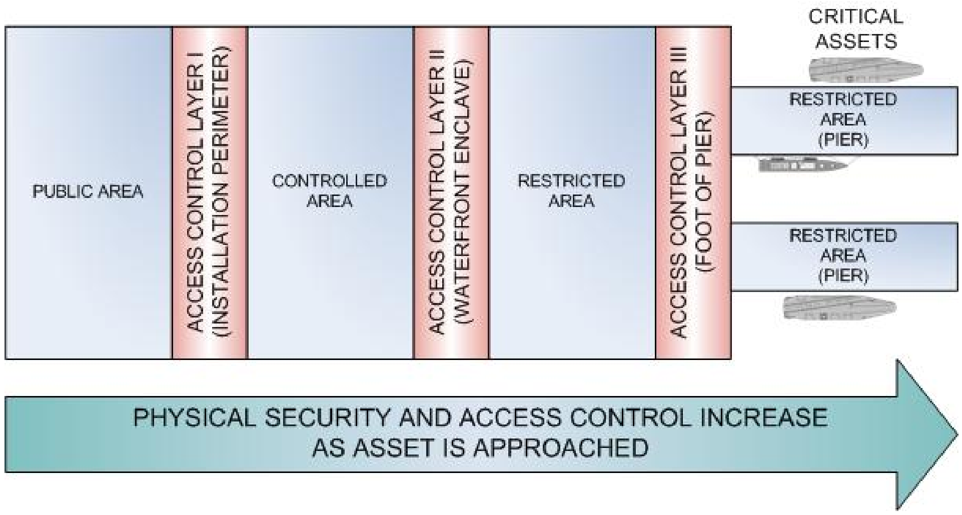


Figure 4-3 Waterfront Access Control

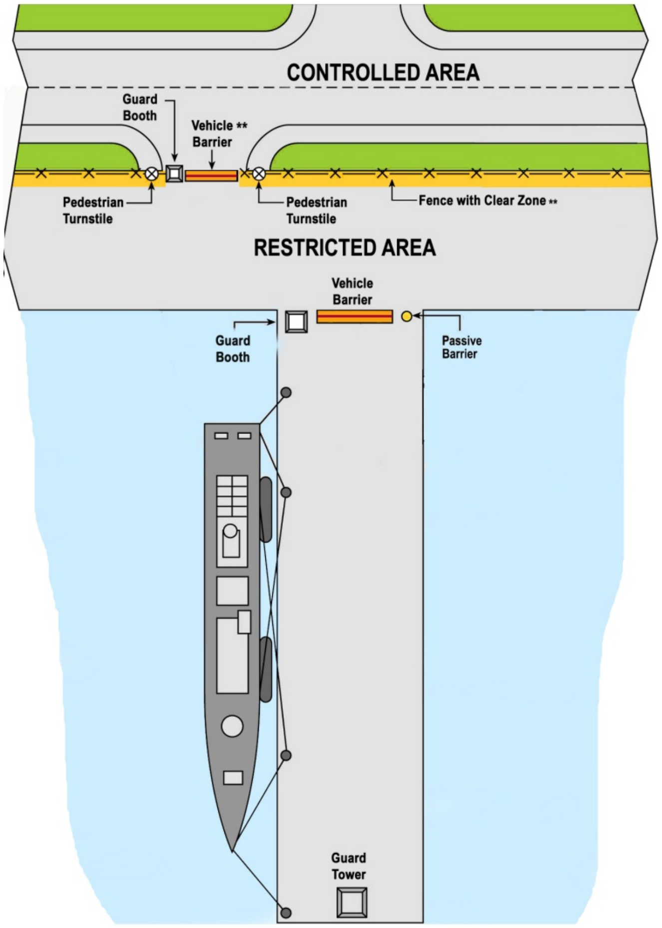


** If standoff from the asset is achieved at the foot of pier for the DBT, vehicle rated barriers at the restricted area boundary may not be required.

4-4 LANDSIDE STANDOFF.

While sufficient distance is not always available to provide the standoff required for a high LOP, maximizing the available standoff distance always results in the most cost-effective solution and also ensures that there is opportunity in the future to upgrade to meet increased threats or to accommodate higher force protection conditions (FPCON).

4-5 ACCESS CONTROL LAYER I: INSTALLATION PERIMETER.

The Installation's controlled perimeter and its related entry control points are not within the scope for this document. However, the Installation controlled perimeter, ACPs, and the related security procedures must be considered when determining the DBT and the resulting protective measures for the waterfront.

4-6 ACCESS CONTROL LAYER II: WATERFRONT ENCLAVE.

The access control and protection features for Layer II should be determined based on asset to be protected, DBT, and desired LOP. Coordinate requirements with supported command, ATO, and security personnel. To protect waterfront assets from unauthorized access, it is important to establish and maintain a defined perimeter. Before a person or vehicle proceeds into the waterfront restricted area (enclave), there must be a perceived perimeter boundary and an understanding of the consequences associated with crossing it. Design ACPs in accordance with UFC 4-022-01.

4-6.1 Layer II: Vehicle ACPs.

Minimize the number of vehicle ACPs into the waterfront to reduce operational requirement. However, provide a minimum of two gates for flexibility.

4-6.2 Layer II: Pedestrian ACPs.

Some waterfronts enclaves are very large and have a significant amount of pedestrian traffic. When pedestrian access control is required, ensure that proper sidewalk and safety provisions direct pedestrian traffic to the ACP separate from vehicular traffic. For pedestrian ACP at vehicular ACP, design pedestrian access to ensure security personnel maintain visual contact with the pedestrians as they approach the vehicular ACPs. If passive barriers are required, breaks in the passive barrier system for pedestrian access to the waterfront should not exceed 3.3 feet (1 m) in width for traffic having a 90-degree approach and 4.1 feet (1.25 m) in width for traffic paralleling the barrier.

Where warranted by pedestrian usage and size of the waterfront, incorporate turnstiles or similar devices in areas of high pedestrian traffic that can be automated to facilitate access control system. Provide infrastructure required to support automation to include a card reader, intercom, and video monitoring at each turnstile. Other considerations in the selection of turnstiles or similar access control devices include the control of potential tailgating and the likelihood that personnel will have equipment or luggage, which may require additional space in the turnstile. Consider if pedestrian inspection areas will be required based on pedestrian demand and any requirement to search personnel and packages. Design elements for pedestrians should be compliant with *ABA Accessibility Standard for Department of Defense Facilities*.

4-6.3 Layer II: Fence.

Fences, clear zones, signage, or other lines of demarcation shall delineate the waterfront restricted area. When required, design the fence and associated gates in accordance with UFC 4-022-03. Buildings, structures, and other barriers may be used as a part of a security fence line as long as they provide equivalent protection to the fencing enclosing the restricted area.

4-6.4 Layer II: Vehicle Barriers.

Vehicle rated barriers are only required for the moving vehicle threat. Consider the regional threat environment and coordinate with installation Antiterrorism Officer (ATO) to determine DBT. Depending on the DBT, reinforcement of the waterfront enclave may not be required if the standoff provided by the final denial barrier at the foot of the pier is adequate to meet the LOP. If vehicle rated barriers are required, conduct a site survey to determine where reinforcement of the waterfront enclave is required. Some areas may not require reinforcement due to existing site elements such as ditches, bio swales, or retaining walls. Design barriers in accordance with UFC 4-022-02.

4-7 ACP LAYER III: FOOT OF PIER.

The access control and protection features for Layer III should be determined based on assets to be protected, DBT, and desired LOP. Coordinate requirements with supported command, ATO, and security personnel. For high value assets, the ACP for a pier shall have a guard booth, barriers, security lighting, and signage.

4-7.1 Layer III: Vehicle Barriers.

Barriers may consist of either passive or active barriers designed to prevent vehicles or personnel from accessing the protected area. Active barrier systems are not recommended due to the extreme environmental conditions at the waterfront. For double deck piers, access for both the upper and lower decks must be controlled. See Figure 4-4 for an example of a double deck pier ACP.

Figure 4-4 Pier ACP

4-7.2 Layer III: Guard Booth.

A guard booth is a structure that provides a protected position to facilitate surveillance, assessment, and response to threats. It may be fixed or temporary/portable. Manning of the watch position will be in accordance with the installation physical security and AT plans. Location and elevation of the guard booth must enhance the ability of security personnel to process vehicles and personnel, observe and determine capability, opportunity, and intent of threats, initiate alarms, coordinate response, and attack with force if necessary and authorized. Coordinate the manning requirements of the guard booth with security personnel. Design the guard booth to provide maximum visibility of the approach to the guard position and pier deck from the interior. Provide overhangs sized to reduce glare on glazing, facilitate mounting of exterior lighting, and provide cover from the elements for security personnel. Refer to UFC 4-023-02 for ballistic design and other requirements. See Figure 4-4 for an example of a guard house at the foot of a double deck pier.

4-7.2.1 Communication and Information Technology.

Each guard booth should have at least two means of communication to a central monitoring point, e.g. installation emergency control center, central dispatch, or similar designated location. Coordinate the communication requirements with the installation. Provide a minimum of two 1 inch (2.54 cm) empty conduit raceways from the watch position to the roof to facilitate future roof mounted communication equipment.

4-7.2.2 Central Duress Alarm.

Provide a central duress alarm, which signals other guard positions and the central monitor point. Provide an enunciator in the guard tower to alert security personnel of alarm triggered at any other waterfront guard position or tower.

4-7.2.3 Guard Booth Lighting.

Lighting inside the guard booth must not degrade security personnel’s nighttime vision. All luminaires must be dimmable and should be mounted at or near desk level. Switch task and general lighting separately. When colors are not used to distinguished tasks (colored lights or controls for alarm annunciations), consider red light sources for task lighting to reduce adaptation problems. Lighting controls must be under the direct control of security personnel.

4-8 ELECTRONIC SECURITY SYSTEMS (ESS).

The need for an intrusion detection system (IDS) and video monitoring for the landside perimeter will be based on assets to be protected, threat environment, desired LOP, and defense-in-depth. Coordinate requirements with supported command, ATO, and security personnel. Design systems in accordance with UFC 4-021-02NF.

When turnstiles are provided for pedestrian access control, provide infrastructure required to support automation of turnstiles. Include lighting, card reader, intercom, and video monitoring at each turnstile.

4-9 SECURITY LIGHTING.

Security lighting aids in the detection of aggressors and assists personnel in the assessment and response to potential threats. The type of site lighting system provided depends on the installation environment and intended use. Provide full cut-off or fully shielded fixtures to limit glare. In general, high mast lighting provided for waterfront operations supply adequate illuminance for security requirements. Design lighting in accordance with UFC 3-530-01.

4-9.1 Perimeter Lighting.

The need for lighting for the landside perimeter will be based on assets to be protected, threat environment, desired LOP, and defense-in-depth. Coordinate requirements with supported command, ATO, and security personnel. Illumination of a restricted area perimeter includes the exterior and interior clear zones adjacent to the fence or, in some applications, the area between multiple fences. Provide poles, power circuits, and transformers within the protected area. Coordinate pole locations with the user to ensure that the applicable egress requirements and patrol routes of the clear zone are not violated. The distance of poles from the fence shall not be less than 5 feet.

4-9.2 Vehicle ACP Lighting.

For most of the ACPs (access zone), full cutoff or fully shielded luminaires will provide adequate lighting for most visual tasks. However, vertical illuminance on motorists' faces can be improved with the use of low brightness light sources (less than 3500 lumen lamp output). Luminaires mounted to the side and behind security personnel will improve identification tasks.

4-9.3 Pedestrian ACP Lighting.

Illuminate pedestrian zones for both pedestrians and security personnel. Pedestrians must have a clear view of gates and card access readers and security personnel must be able to see pedestrians approaching the ACP. Provide full cutoff or fully shielded luminaires mounted in the horizontal plane to minimize glare.

This Page Intentionally Left Blank

CHAPTER 5 WATERSIDE

5-1 INTRODUCTION.

This chapter presents information to design a system of protective measures deployed on the waterside of an installation.

5-2 DESIGN STRATEGY.

For this chapter, threats are from the waterside. As with Landside, the design strategy for the waterside must be based on the concept of defense-in-depth by establishing multiple boundaries or zones in which unauthorized watercraft or personnel (i.e. diver or swimmer) must pass to access protected assets. Configuration of the physical perimeter and the LOP are dependent on assets to be protected and the DBT. The primary protective measure is maintaining stand-off through detection and delay of surface and subsurface threats.

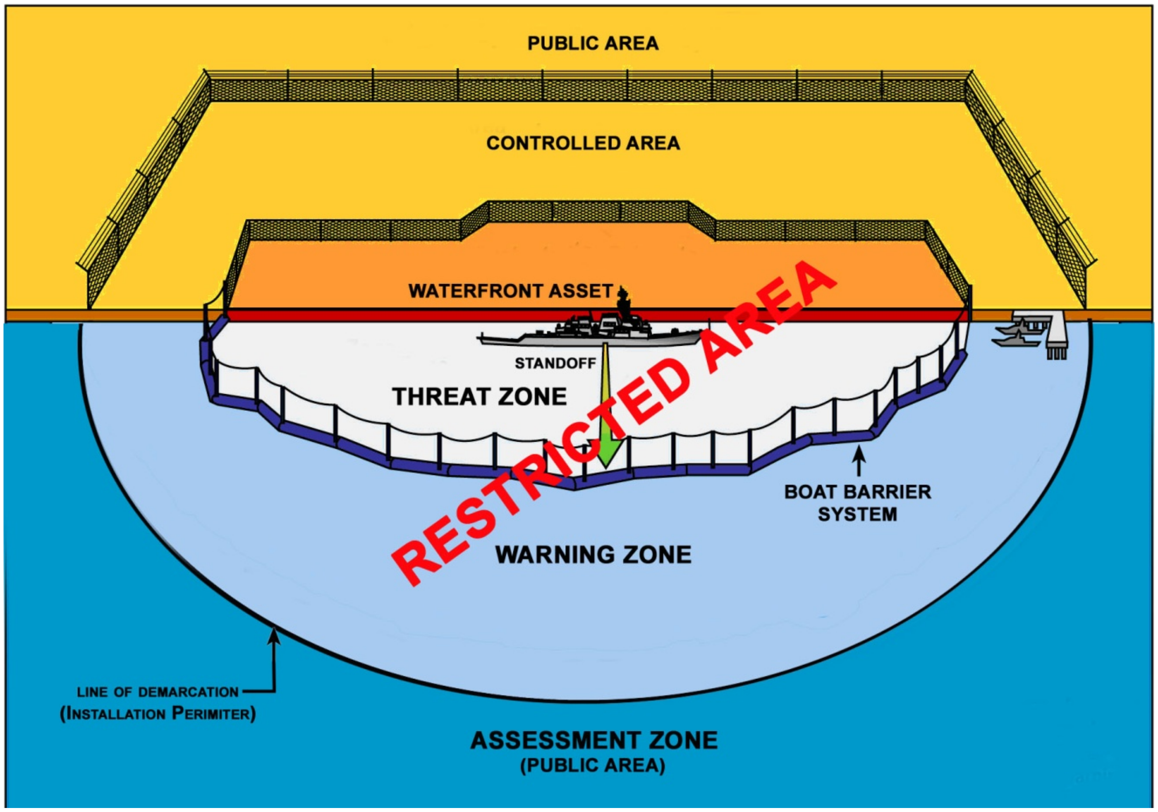
5-2.1 General Design Strategy.

Prevent waterfront attack by creating standoff and applying the defense in depth concept. Establish security zones with barriers, electronic harbor security systems (EHSS), and operational procedures from the high water mark to the waterside, installation perimeter. The security zones are defined as follows:

- **Waterside Assessment Zone:** An area beyond the DoD's property line from where surface and subsurface threats approaching the waterside warning zone may be detected, monitored, and tracked.
- **Waterside Warning Zone:** The area just outside the Threat Zone and within the waterside installation perimeter. In some locations a large warning zone is not feasible due to channel constraints.
- **Waterside Threat Zone:** The area between a line of floating barriers and an asset.

The Threat and Warning zones are determined by the Installation Commander.

Figure 5-1 Waterside Security Zones



Note: Restricted Area may extend out to the installation perimeter at some locations.

5-3 WATERSIDE STANDOFF.

Establish waterside standoff based on DBT. Ideally, this standoff distance extends from the protected assets to the maximum range of anticipated DBT (25 meters for small explosives to several thousand meters for portable anti-tank weapons). Security forces should endeavor to prevent the entry of surface and subsurface threats into the waterside standoff.

5-4 PERIMETER.

Establishing a perimeter is an important protective measure meant to deter and prevent unauthorized personnel from entering a DoD installation.

5-4.1 Waterside Perimeter.

Delineate the waterside perimeter by issuing a notice to mariners and with floating signage, signs on piles or other lines of demarcation to prevent innocent vessels from entering the Warning Zone. Methods of demarcation depend on the waterfront geography and the relation between installation and the navigational channel.

5-4.2 Waterside Restricted Area.

This is the designated restricted area in which special measures are employed to prevent unauthorized entry. The waterside restricted area may be the waterside perimeter or an enclave within that perimeter (Threat Zone). Identify waterside restricted area(s) with buoys and signs. Consider using a floating line of demarcation (LOD) to identify the waterside restricted area.

5-4.3 Line of demarcation (LOD).

A LOD is a system used to identify restricted waters, standoff distance, or an installation's waterside perimeter. It must be clearly visible to vessel operators in most weather conditions and be interspersed with signage indicating access control measures. LOD may be located at the perimeter of the Threat or Warning Zone. Coordinate location and requirement on floating LOD with installation. Figure 5-1 illustrates basic floating LOD.

5-4.4 Boat Barrier System.

A boat barrier system is a continuous, modular LOD intended to stop and/or delay waterborne threats. When required by DOD, GCC, or Service Instruction, provide boat barriers at the Threat Zone perimeter to prevent direct unchallenged access to waterfront assets. The boat barrier system's capability and configuration will depend upon the assets to be protected, DBT, port configuration, operations tempo, environmental constraints, and response capability. Attempting to cross a boat barrier establishes intent and provides time for security forces to arrive and escort the threat out of the area. Many DoD controlled waterfronts do not allow comprehensive waterside security layering due to proximity of waterfront restricted area to shipping channels. Therefore, the delay time afforded by the barrier system should be synchronized with other physical security system capabilities to ensure a comprehensive security. Figure 5-2 illustrates a boat barrier system. For more information on boat barrier systems and related products contact:

Waterfront Security Manager
Naval Facilities Engineering Service Center, Code 55
720 Kennon St SE Suite 333
Washington Navy Yard DC 20374-5063

Figure 5-1 Floating Line of Demarcation

Figure 5-2 Boat Barrier System (Port Security Barrier)

5-5 GUARD TOWERS.

Guard towers provide an elevated protected position to facilitate surveillance, assessment, and response to waterside threats. This position may be fixed or temporary/portable. Guard towers are not required at all locations. When required, there should be enough guard towers on the waterfront to ensure complete overlapping coverage of the protected area. Coverage should be such that the elimination of one guard tower does not preclude complete coverage.

Manning of the watch position will be in accordance with the installation physical security and AT plans. Locate and set the elevation of the guard tower to enhance the ability of security personnel to observe and assess threats, initiate alarms, coordinate response, and attack with force, if necessary and authorized. Coordinate the number and location guard towers with security personnel, waterfront operations, and EHSS infrastructure. Ensure towers have proper line of sight, are suitable for port operations, account for variations in port loading, and are suitable for port operations. In most cases, locate the guard tower at or near the end of the pier (head) to maximize visibility of the waterside restricted area. Provide 360-degree visibility from the interior of the guard tower and an open observation deck with overhang to facilitate assessment and engagement of threat, maintenance of watch position glazing, and access to roof mounted equipment. Size the overhang to reduce glare on glazing and provide cover from the elements for security personnel. Refer to UFC 4-023-02 for ballistic design and other requirements. See Figure 5-3 for an example of a guard tower at the head of a pier.

5-5.1 Communication and Information Technology.

Each guard tower should have at least two means of communication to a central monitoring point, e.g. installation emergency control center, central dispatch, or similar designated location. Coordinate the communication requirements with the installation. Provide a minimum of two 1 inch (2.54 cm) empty conduit raceways from the watch position to the roof to facilitate future roof mounted communication equipment.

5-5.2 Central Duress Alarm.

Provide a central duress alarm, which signals other guard towers and the central monitor point. Provide an enunciator in the guard tower to alert security personnel of alarm triggered at any other waterfront guard facility or towers.

5-5.3 Guard Tower Lighting.

Lighting inside the guard towers must not degrade security personnel’s nighttime vision. All luminaires must be dimmable and should be mounted at or near desk level. Switch task and general lighting separately. When colors are not used to distinguished tasks (colored lights or controls for alarm annunciations), consider red light sources for task lighting to reduce adaptation problems. A manually operated roof mounted searchlight may be required to assist security personnel to locate and assess waterside threats. Lighting controls must be under the direct control of security personnel.

Figure 5-3 Guard Tower on Pier

5-6 WATERFRONT SECURITY LIGHTING.

Provide full cut-off or fully shielded fixtures to limit glare. In general, high mast lighting provided for waterfront operations supply adequate illuminance for security requirements. Coordinate number, height, and location of poles and the associated concrete pedestals to minimize obstructions to pier and wharf operations. Refer to UFC 4-152-01 for Pier and Wharf operational lighting requirements and UFC 3-530-01 for lighting design criteria. Additional lighting (fully shielded or full cutoff) may be required on guard tower (below observation deck) to illuminate egress and the area on the opposite side from high mast lighting. Coordinate security lighting requirements with security personnel.

5-6.1 Water surface Lighting.

High mast lighting on piers and wharfs provide adequate illumination for security requirements. Glare, poor distribution, and excessive light levels reduce security personnel's ability to assess surface and subsurface threats.

5-6.2 Underwater Lighting.

Underwater lighting is not normally required for detection of subsurface threats and is discouraged due to limited benefit, high installation cost, and maintenance issues.

5-6.3 Under deck Lighting.

Dedicated luminaires located beneath the pier are not normally required and are discouraged due to limited benefit, high installation cost, and maintenance issues.

5-6.4 Lighting Interference.

Security lighting can visually interfere with lighting used as aids to navigation (ATON) by ships. Lighting ashore can camouflage, outshine, or otherwise conceal ATON. Ensure that lighting ashore and in the waterfront restricted area does not conflict with or otherwise conceal the ATON lights. Coordinate security lighting requirements with Port Operations

5-7 ELECTRONIC HARBOR SECURITY SYSTEMS (EHSS).

EHSS is provided when required by DOD, GCC, or Service Instruction. EHSS integrates electronic sensors and video systems to detect, assess, track, and archive capabilities for waterside surface and subsurface threats. The type of system utilized shall be based on assts to be protected and risk.

The EHSS can be configured to integrate all sensor and video information to provide a graphical display of all threats within waterside security zones to be protected (protected area). The waterside security zones may be programmed to generate alarm conditions dependant on location of threat relative to protected assets. As with all protection measures, the capability and configuration of the EHSS is dependent on the assets to be protected, DBT, port configuration, operations tempo, environmental constraints, and response capability. For more information on related products contact:

(619) 553-6553 fax

5-7.1 Surface Detection and Assessment.

Radar and video equipment are used to detect, track and assess surface threats within the protected area. Radar and video systems should be located based on site specific conditions such as landside and waterside operations, landside and waterside terrain, climate, available power and communications, and technology capabilities. When available, equipment should be roof mounted on the guard towers to provide a solid elevated mounting platform and enclosed space for the related equipment.

5-7.1.1 Radar.

The radar element is the primary means for detecting surface threat. Systems include a radar set, tracking processor, and display. The tracking processor has acquisition zones that can be configured for each site based on local geography, port activity, and the installation’s security protocols. The radar element should utilize multiple radar transponders installed at various locations to provide a complete picture of the protected zone. See Figure 5-4.

5-7.1.2 Identification Friend or Foe (IFF).

This system provides the capability identify “friend” vessels authorized to be in the area and assists in determining bearing and range when vessels are equipped with IFF transponder.

Figure 5-4 Radar Antenna

5-7.1.3 Video Imaging.

The imaging system is a collection of cameras, recorders, switches, keyboards, and monitors that allow assessment and recording of security events. The imaging system is normally integrated into the overall EHSS and monitored at operator workstation. Capabilities of the imaging systems include assessment of alarm conditions, surveillance of the protected area, and archiving of events. The imaging system must have a minimum of 30 days storage capacity. When integrated with video analytics the imaging system can have a detection capability. Refer to UFC 4-021-02NF for the design of imaging systems.

For EHSS, the basic imaging element consists of two cameras. Provide one low light color; pan, tilt, zoom (PTZ) camera for daytime assessment and one PTZ night vision camera or imaging device at each location. Multiple technologies must be deployed to ensure adequate coverage of the waterside area. Available technologies include low-light cameras, infrared cameras, thermal imagers, and near infrared laser-camera systems. Table 5-2 provides a summary the various technologies.

Table 5-2 Visual-Imaging Element Technologies

Technology	Range (Nominal)	Light Source	Support	Cost	Advantages	Disadvantages
Low-light camera	Short 100 to 300 yards (90 to 275 m)	Visible light (sunlight, moonlight, artificial light)	Camera power, video cable	$3k to $5k	Low cost Uses available light	Unable to provide coverage in new moon (no moon) and dark or cloudy conditions
Infrared camera (camera with infrared illuminators)	Short 100 to 300 yards (90 to 275 m)	Infrared illuminators	Power for camera and illuminator, video cable Illuminators	$3k to $5k camera $1k per illuminator	100 percent night vision capable Low total cost of ownership	Limited to the range of the associated infrared illuminators Short range
Near-infrared system	Medium 1,000 to 3,000 yards 900 to 2700 m)	Near-infrared laser	Composite system of laser and camera	$50k to $90k	No interference from heat and visible light Natural-contrast night image	Performs best as synchronized system
Thermal camera (uncooled)	Long 1,000 to 5,000 yards (900 to 4500 m) (height of eye)	Heat energy emitted from object/scene	Camera power Internal temperature-adjusting controls	$7k to $20k	Autonomous system; does not require visible light or supporting illumination system	Non-natural image Requires trained operator to interpret thermal images
Thermal camera (cooled)	Long 1,000 to 10,000 yards (900 to 9000 m) (height of eye)	Heat energy emitted from object/scene	Camera power Internal refrigerant system	$100k plus	Highest detection sensitivity Autonomous system	High cost Periodic maintenance of coolant system Non-natural image

5-7.2 Subsurface Detection and Assessment.

The subsurface element detects an underwater threat. Current designs make use of underwater soundheads connected to signal processors for eventual display. Ensure proper EV permitting has been obtained to ensure conformance with the “Marine Mammal Protection Act (MMPA).

5-7.2.1 Sonar.

The sonar transponders are the primary means for detecting subsurface targets. Submerged non-visual elements include the use of sonar transponders installed at various underwater locations feeding their inputs to a central display (operator workstation). The soundhead can be bottom-mounted, side-mounted, or moored, See Figure 5-5. The sonar track processor evaluates contacts and assigns tracks to those exceeding preset levels. The use of multiple transponders helps eliminate holes and shadows in the non-visual submerged surveillance picture. Locate the devices so that they are not shrouded by berthed ships, and provide adequate coverage of the underwater approaches. Poorly placed devices can create hazards to shipping, interfere with dredging operations and can be difficult to maintain. An environmental assessment must be completed prior to the deployment of any sonar transponders.

Figure 5-5 Sound Transducer Being Lowered into the Water

5-7.3 Command, Control, Communication and Display (C3D).

The C3D element provides a situational display of the waterside. Multiple displays provide an overview of the waterside and include display of EHSS subsystem elements for surface and subsurface detection, assessment, and tracking.

5-7.4 Infrastructure.

Infrastructure includes the permanent facilities necessary to support the EHSS including mounting structures, power, communication cabling (connectivity), pathways, and space for workstations and rack mounted equipment.

Vehicles including forklifts and container carriers operate in all areas of a pier. Electrical gear located on pier decks have suffered casualty due to forklift tines and crane hooks. Minimize equipment mounted on the operational pier deck. Any deck mounted equipment must be approved by the Port Ops Officer.

5-7.4.1 Location.

For double deck piers, the generator and electronic equipment enclosure shall be located to the lower deck, within the guard tower, or located on the offshore side of the guard tower to minimize the total footprint, and enable the guard tower walls to be used for mounting the conduit system.

Do not mount equipment or conduits near cleats or bollards. Crews must haul mooring lines past these deck fittings in order to secure the ship. Equipment located in close proximity to these deck fittings create safety hazards for the crew and is subject to damage by the lines.

5-7.4.2 Space.

Space must be reserved in multiple locations to support the equipment and operation of the EHSS. This includes locations such as guard towers, piers, wharfs, and a central monitoring location.

5-7.4.3 Guard Towers.

Provide space for roof mounted equipment and weather tight pathways from the roof to the sensor equipment cabinet for associated communication and power cabling, See Figure 5-6. Provide a minimum of two 2 inch (50 mm) conduit per element (imaging, radar, and/or sonar) from sensor equipment cabinet to element location.

Provide space for a 19 inch (48 cm) telecommunications cabinet (sensor equipment cabinet) sized for the associated EHSS equipment. Consider providing space on first floor of guard tower for EHSS generator and controls. If the generator is located in guard tower, provide ventilation, vibration, an acoustic isolation from guard position.

Figure 5-6 Roof Mounted Equipment

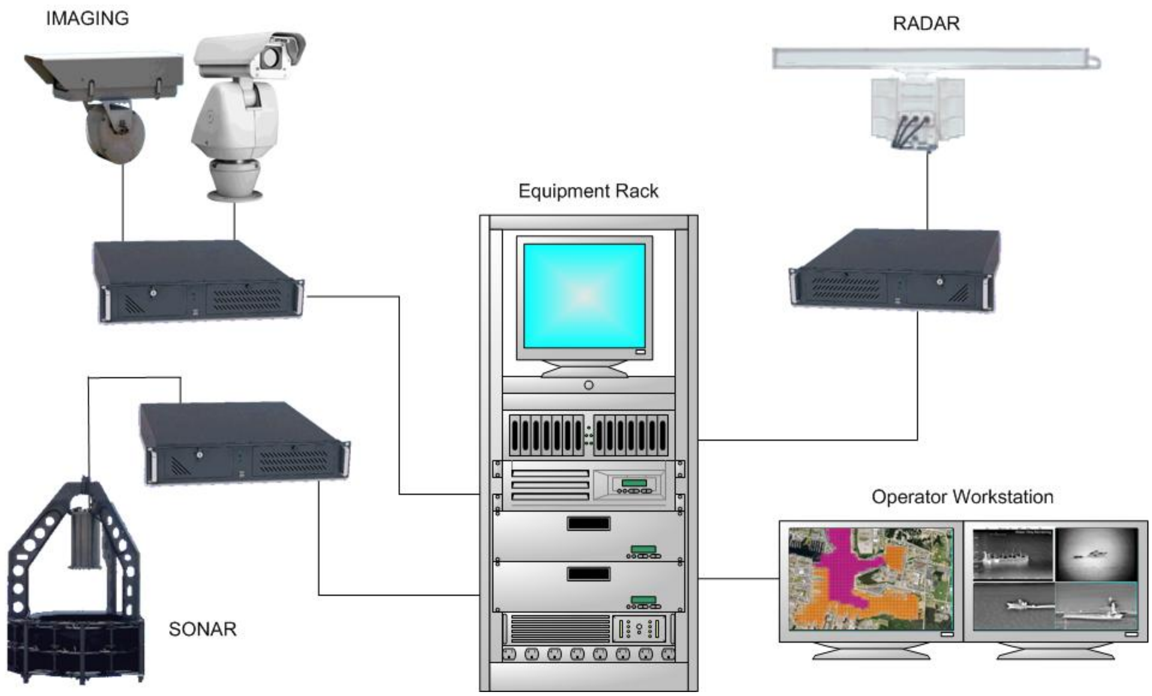
5-7.4.4 Piers and Wharfs.

Provide a dry location for a sensor equipment cabinet (19 inch (48 cm) telecommunications cabinet) sized for the EHSS equipment deployed. The preferred location is directly underneath or adjacent to the surface detection and assessment equipment mounting structure.

5-7.4.5 Central Monitoring Location.

Provide space for a full height freestanding 19 inch (48 cm) telecommunications cabinet, operator workstation, and multiple displays. Provide space, connectivity, and power receptacles for operator workstation including multiple desktop displays. Provide wall space, connectivity, and power receptacles for EHSS multiple large format flat panel displays EHSS subsystems monitoring. Reserve additional wall space for nautical chart displays. See Figure 5-7 for a notional configuration of the equipment associated with an EHSS.

Figure 5-7 EHSS Configuration



5-7.4.6 Backup Power.

EHSS systems require a backup generator. The supporting generator is normally located pierside in a weather-protected location or enclosure. Reserve a minimum of 8 foot 6 inch (259 cm) space x 3 foot 6 inch (107 cm) space for generator and associated controls. Coordinate actual space requirements with equipment provider. Do not locate generators on the upper (operational) deck of a double deck pier unless they are located on the offshore side of the guard tower.

5-7.4.7 Conduit Infrastructure.

Coordinate conduit requirements with equipment provider. At a minimum, provide one conduit per element (imaging, radar, and/or sonar) from sensor equipment cabinet to element location.

5-7.4.8 Communication and Information Technology.

Connectivity is required from each sensor equipment cabinet to the central monitoring location. Provide a minimum of one 12-strand, single mode, optical fiber cable from sensor equipment cabinet to the central monitoring station. Coordinate point of service with installation.

APPENDIX B GLOSSARY

ACRONYMS

ACP	Access Control Point
AT	Antiterrorism
ATON	Aids to Navigation
CCTV	Closed Circuit Television
DBT	Design Basis Threat
EHSS	Electronic Harbor Security System
ESS	Electronic Security System
ESSC	Electronic Security System Console
FP	Force Protection
FPCON	Force Protection Condition
GCC	Geographic Combatant Commander
IDS	Intrusion Detection System
LOD	Line of Demarcation
LOP	Level of Protection
RAM	Random Antiterrorism Measures

DEFINITION OF TERMS

Controlled Area. A space extending upward and outward from a specified point. This area is typically designated by a commander or director, wherein sensitive information or operations occur and requires limitations of access.

Design basis threat (DBT) The threat against which an asset must be protected and upon which the protective system's design is based. It is the baseline type and size of threat that buildings or other structures are designed to withstand. The DBT includes the tactics aggressors will use against the asset and the tools, weapons, and explosives employed in these tactics.

Dispatch Center. The space that serves as a central monitoring and assessment facility for the ACS, CCTV, and IDS systems. The key components of a Dispatch Center include consoles, monitors, and printers. Normally, the Dispatch Center is staffed 24 hours a day, seven days a week by trained personnel. Other names for the Dispatch Center include Regional Dispatch Center (RDC), Security Operations Center (SOC), Security Command Center and Security Control Center (SCC), Central Monitoring Station, Data Transmission Center (DTC), and Alarm Control Center (ATC).

Electronic Harbor Security System (EHSS). An electronic system that integrates surface detection, subsurface detection, and video systems to detect, assess, track, and archive waterside threats.

Electronic Security System (ESS). The integrated electronic system that encompasses interior and exterior Intrusion Detection Systems (IDS), Closed Circuit Television (CCTV) systems for assessment of alarm conditions, Automated Access Control Systems (ACS), Data Transmission Media (DTM), and alarm reporting systems for monitoring, control, and display.

Electronic Security System Console (ESSC). While not always specifically referred to as the ESSC, most security systems have a console that houses monitoring and server interface equipment. Generally, this console is located in the Dispatch Center.

Foot of pier. The landside end of the pier

Force Protection (FP). Actions taken to prevent or mitigate hostile actions against DoD personnel (including family members), resources, facilities, and critical information.

Force Protection Condition (FPCON). A DoD-approved system standardizing the Department's identification, recommended preventive actions, and responses to terrorist threats against U.S. personnel and facilities.

Head of pier. The waterside end of the pier sometimes referred to as the pier head.

Installations. Real DoD properties including bases, stations, forts (including National Guard and Federal Reserve Centers), depots, arsenals, plants (both contractor and Government operated), hospitals, terminals, and other special mission facilities, used primarily for military purposes.

Level of protection. The degree to which an asset is protected against compromise.

Physical Security. That part of security concerned with physical measures designed to safeguard personnel; to prevent unauthorized access to equipment, installations, material, and documents; and to safeguard them against espionage, sabotage, damage, and theft.

Ports of Call. A port not located on a DoD installation where ships dock in the course of deployment to load or unload cargo, obtain supplies, liberty, or undergo repairs.

Restricted Area. An area under military jurisdiction in which special security measures are employed to prevent unauthorized entry.

Waterside Security. Measures or actions taken to prevent or guard against the use of a waterside approach to a waterfront facility or vessel by persons or vessels intent on theft, sabotage, terrorism, and/or belligerent acts

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
NEW DOCUMENT SUMMARY SHEET

Document: UFC 4-026-01, *Design to Resist Forced Entry*

Superseding: MIL-HDBK-1013/1A, *Design Guidelines for Physical Security of Facilities,* dated 15 December 1993.

Description: Provide a unified approach to the development of protective measures intended to protected assets from a forced entry attack.

Reasons for Document:

- This document is one of a series of security engineering criteria documents covering physical countermeasures for the current threat environment.
- The design of physical security measures is a specialized technical area that does not fall in the normal skill record and resume of commanders, architects, engineers, and project managers. This document provides guidance to those parties tasked with implementing existing and emerging physical protection system requirements for assets.

Impact:

- No additional cost impacts are anticipated by the publication of this document. This document should reduce the design and coordination efforts for design of systems that protect against forced entry.

Unification Issues

There are no unification issues.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

1-1.1 Purpose.

The purpose of this document is to present engineering guidelines and cost-effective designs to protect assets in fixed facilities against a forced entry and providing egress in compliance with NFPA 101.

1-1.2 Scope.

Project leaders, architects, and engineers must use this UFC when designing facilities to resist aggressor forced entry. Technical information considered generally known to professional designers, architects, or engineers or readily available in existing technical references has not been included.

Designs to resist forced entry must be based on protecting specific assets, the applicable asset values, threat severity, and level of protection, which will be provided to designers as part of the design criteria developed during the security engineering planning and preliminary design phases.

1-2 APPLICABILITY.

This document provides design requirements for only fixed facilities that require forced entry threat mitigation. This UFC applies to all facilities either owned, leased, privatized, or otherwise occupied, managed, or controlled by or for DoD containing assets that required force entry protection pursuant to DOD policy.

1-3 SECURITY ENGINEERING UFC SERIES.

This UFC is one of a series of security engineering unified facilities criteria documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. Figure 1-1 illustrates the process from initial planning to the development of facility design requirements. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include the following:

1-3.1 DoD Minimum Antiterrorism Standards for Buildings.

UFC 4-010-01 establishes standards that provide minimum protection against terrorist attacks for the occupants of all DoD inhabited buildings. This UFC is intended to be used by security and antiterrorism personnel and design teams to identify the minimum requirements that must be incorporated into the design of all new construction and major renovations of inhabited DoD buildings. It also includes recommendations that should be but are not required to be incorporated into all such buildings.

1-3.2 DoD Security Engineering Facilities Planning Manual.

UFC 4-020-01 presents processes for developing the design criteria necessary to incorporate security and antiterrorism into DoD facilities and for identifying the cost implications of applying those design criteria. Those design criteria may be limited to the requirements of the minimum standards, or they may include protection of assets other than those addressed in the minimum standards (people), aggressor tactics that are not addressed in the minimum standards or levels of protection beyond those required by the minimum standards. The cost implications for security and antiterrorism are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they represent only representative construction that will meet the requirements of the design criteria. The manual also addresses the tradeoffs between cost and risk. The Security Engineering Facilities Planning Manual is intended to be used by planners as well as security and antiterrorism personnel with support from planning team members.

1-3.3 DoD Security Engineering Facilities Design Manual.

UFC 4-020-02 provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established using UFC 4-020-01. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them all work as a system. The information in UFC 4-020-02 is in sufficient detail to support concept level project development, and as such can provide a good basis for a more detailed design. The manual also provides a process for assessing the impact of protective measures on risk. The primary audience for the Security Engineering Design Manual is the design team, but it can also be used by security and antiterrorism personnel.

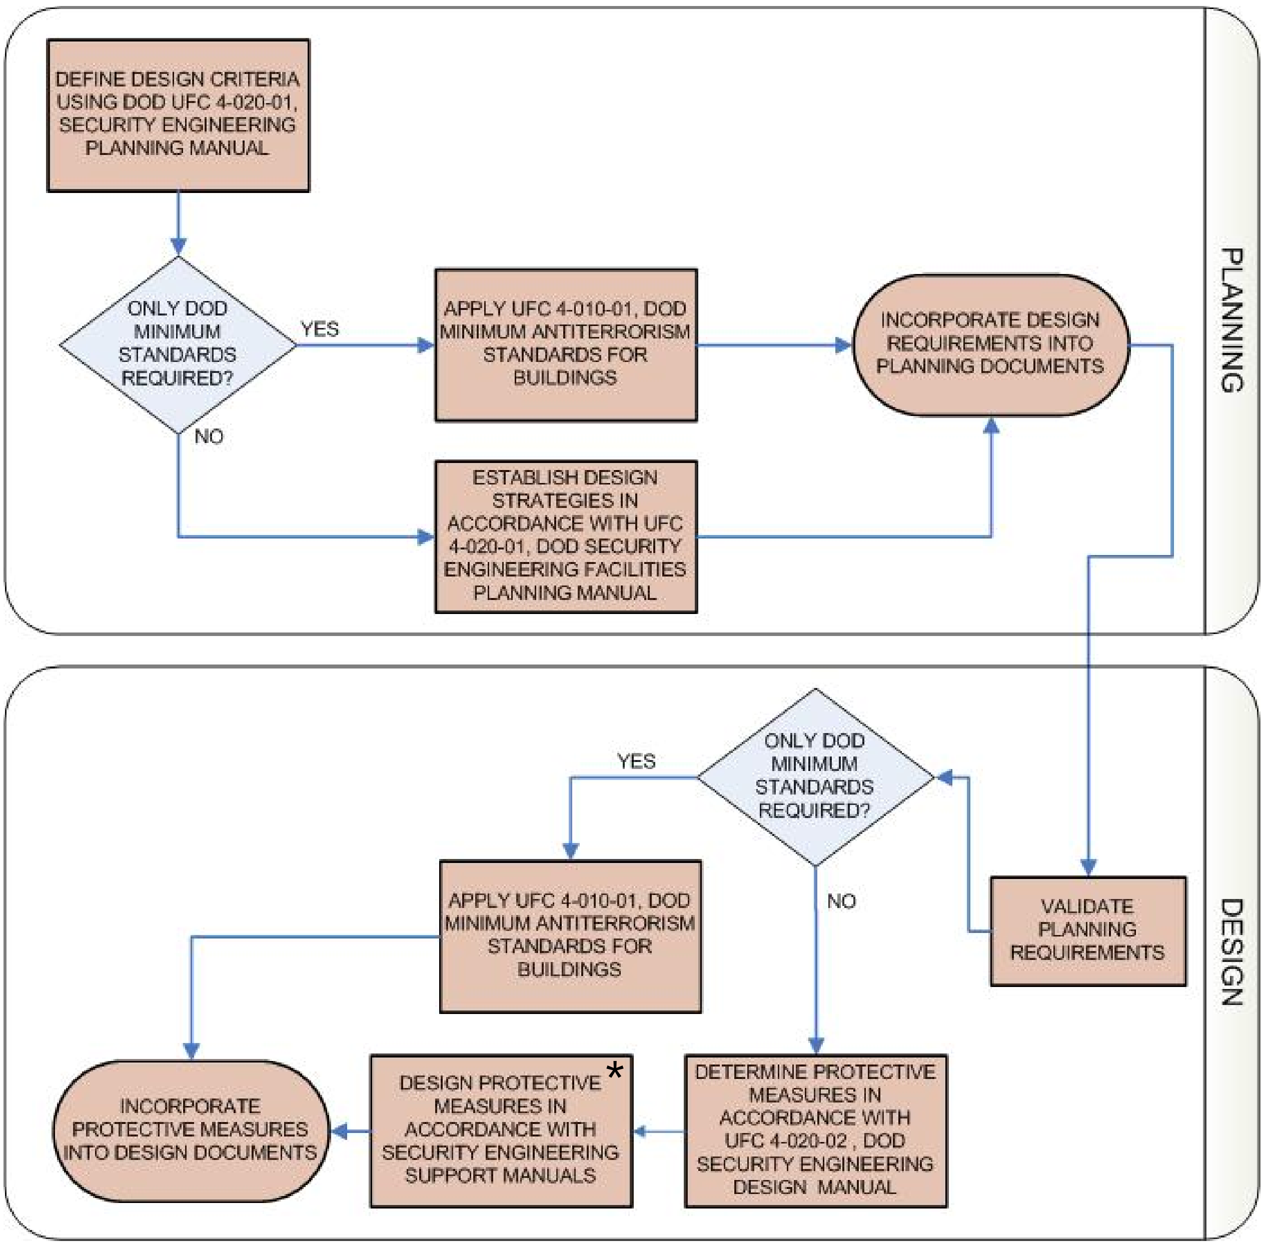
1-3.4 Security Engineering Support Manuals.

In addition to the standards, planning, and design UFCs mentioned above, there is a series of additional UFCs that provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02. These support manuals provide specialized, discipline specific design guidance. Some address specific tactics such as direct fire weapons, vehicle borne improvised explosive devices, or airborne contamination. Others address limited aspects of design such as resistance to progressive collapse or design of portions of buildings such as mail rooms. Still others address details of designs for specific protective measures such as vehicle barriers or fences. The Security Engineering Support Manuals are intended to be used by the design team during the development of final design packages.

1-3.5 Security Engineering UFC Application.

The application of the security engineering series of UFCs is illustrated in Figure 1-1. UFC 4-020-01 is intended to be the starting point for any project that is likely to have security or antiterrorism requirements. By beginning with UFC 4-020-01, the design criteria will be developed that establishes which of the other UFCs in the series will need to be applied. The design criteria may indicate that only the minimum standards need to be incorporated, or it may include additional requirements, resulting in the need for application of additional UFCs. Applying this series of UFCs in the manner illustrated in Figure 1-1 will result in the most efficient use of resources for protecting assets against security and antiterrorism related threats.

Figure 1-1 Security Engineering UFC Application



* **NOTE: UFC 4-026-01 is one of the Security Engineering Support Manuals.**

1-4 VULNERABILITY AND RISK ASSESSMENT.

During the pre-design phase of forced entry upgrade projects for existing facilities, a multi-functional security and antiterrorism planning team conducts a vulnerability assessment and develops risk mitigating protection requirements to a level that is both acceptable and cost effective. This document presumes risk analyses are complete prior to beginning the design phase.

For new forced entry projects, a criteria development analysis which addresses risk versus cost is conducted as part of the UFC 4-020-01 planning process.

1-5 PRESCRIPTIVE VS. RISK-BASED DESIGN REQUIREMENTS.

Dynamic conditions drive both vulnerability and risk assessments. Changes in forced entry tactics, technology, and tools of the trade affect residual risk levels. This document and other documents in the UFC series are designed to provide a method of balancing protection, budget, and risk.

The design to resist forced entry may be based on both prescriptive and risk-based requirements that together provide a solution to mitigate risk to an acceptable level.

1-5.1 Prescriptive Design Requirements.

The design for the protection of some assets may require the application of prescriptive measures contained in, or derived from, other non-UFC government regulations. For example, DoDM 5100.76 *Physical Security of Sensitive Conventional Arms, Ammunition, and Explosives (AA&E)* contains prescriptive requirements for facility design where arms, ammunition, or explosives are stored. Additionally, UFC 4-010-05 *Sensitive Compartmented Information Facilities Planning, Design, and Construction* contains design criteria for the construction of facilities to protect Sensitive Compartmented Information that is derived from DODM 5105.21, Vol 2, *Sensitive Compartmented Information (SCI) Administrative Security Manual: Administration of Physical Security, Visitor Control, and Technical Security;* and from the IC Tech Spec for ICD/ICS 705, *Technical Specifications for Construction and Management of Sensitive Compartmented Information Facilities.* (See CHAPTER 6 for further information on Protected Areas.)

1-5.2 Risk-Based Requirements.

Risk-based requirements are developed during the planning phase of the project using the procedures in UFC 4-020-01 and become a part of the project design criteria. When conditions subsequently change the risk level, designers should revisit the design criteria for methods to change or augment how protection is achieved. Not all solutions are sustainable or durable, but those based on current conditions can provide acceptable interventions for a shorter period. At end state, assessments reflect current conditions and protection is achieved at an acceptable risk level.

1-6 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code (General Building Requirements)*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-7 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-8 HISTORIC PRESERVATION COMPLIANCE.

1-8.1 Security and Stewardship.

The Department of Defense remains the lead federal agency in balancing security threats with the protection of historic properties. The Department of Defense abides by federal legislation on protecting cultural resources and issues its own complementary policies for stewardship.

1-8.2 Compliance with Laws.

Implementation of these standards will not supersede DoD’s obligation to comply with federal laws regarding cultural resources to include the National Historic Preservation Act and the Archaeological Resources Protection Act. Installation personnel must determine possible adverse effects to historic structures and archaeological resources during project development and consult accordingly. Personnel at installations outside the United States should coordinate with the applicable host nation regarding possible adverse effects to cultural resources.

1-8.3 Compliance with DoD Standards.

Conversely, historic preservation compliance does not negate the requirement to implement other Department of Defense policy. Federal agencies are always the decision-maker in the Section 106 process of the National Historic Preservation Act. An agency should seek to avoid prolonged consultations that conflict with the imminent need to implement security requirements. Preservation considerations and antiterrorism standards are not mutually exclusive, and any compliance conflicts should be quickly and effectively resolved in consultation with appropriate stakeholders.

1-9 GLOSSARY.

APPENDIX A contains acronyms, abbreviations, and terms.

1-10 REFERENCES.

APPENDIX B contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 DESIGN CRITERIA

2-1 INTRODUCTION.

This chapter describes the forced entry tactic and the design criteria to be used to develop a protective system to address that threat.

2-2 FORCED ENTRY TACTIC.

Forced Entry is a tactic whereby aggressors penetrate a facility through the application of tools, explosives and small arms; then, generate a passageway to operate within the target. Aggressors steal or destroy assets, compromise information, injure or kill occupants, or disrupt operations. Access passageways include walls, roofs, floors, ceilings, doors, windows, and utility portals.

2-2.1 Tools and Effects.

Forced entry tools include hand, power, and thermal tools and explosives that can be carried by one or two aggressors. Categories of forced entry tools are based on levels of sophistication, required skills and risk of detection (observability). Refer to UFC 4-020-01 for the maximum tools and explosives that each threat severity level is projected to employ. When one threat severity level is contained in the design criteria, the threat also includes the tools in all lower threat severity levels. For the purposes of this UFC, weapons are not a tool to breach construction. They are potentially used to overpower guards. (See Table 2-1 for the tools that the aggressor can use for each threat severity level.)

Table 2-1 Forced Entry Tool Sets

<table>
<tr><th>THREAT SEVERITY LEVEL</th><th>WEAPONS</th><th>TOOLS</th></tr>
<tr><td>V</td><td rowspan="2">Handguns and sub-machine guns (up to UL 752 Level 3 to overpower guards)</td><td>Bulk explosives (up to 20 lbs. /9 kg TNT); linear shaped charges (up to 10,500 grains per foot); unlimited hand, power, and thermal tools</td></tr>
<tr><td>IV</td><td>Unlimited hand, power, and thermal tools</td></tr>
<tr><td>III</td><td rowspan="2">None</td><td>Unlimited hand tools - limited power tools</td></tr>
<tr><td>II</td><td>Limited hand tools - low observables</td></tr>
</table>

NOTE: For convenience, this table has been derived from information contained in UFC 4-020-01. Information in the current version of that document takes precedence over information in this table.

2-2.2 Employment of Tools.

Forced entry can involve a combination of tools used by different group sizes for varying lengths of time. Six is the maximum number of attackers able to work together effectively when concentrated on a single opening. The high number of possible combinations of factors makes it impossible to completely predict the actual effects of a forced entry attack. Forced entry attacks must be simulated by laboratories experienced in forced entry testing to predict the resistance of specific construction components and assemblies; therefore, the effects of forced entry tool attacks are discussed not in terms of loads on building components, but in terms of the predictable effects of various individual tools.

2-2.3 Hand Tools.

Hand tools include commonly available hand-held tools requiring only manual manipulation and human strength as sources of power. These tools are used for prying, screwing, pulling, shearing, pounding, cutting, sawing, drilling, and wedging. Hand tool effects include disassembly, breaking, deformation, notching, shaving, puncturing, moving, or spalling of components and the removal of fasteners or debris. Hand tools are used for attacks in which the aggressor manipulates either an operable component (prying open a locked door) or stationary components at their intersection or seams (popping metal wall panels away from their anchors). Attacks using hand tools generate relatively less noise than powered tools, but the motion of the aggressor and vibration of the building materials, as well as the noise, might all be detectable. Hand tools can be used to create holes in lighter weight components, such as by breaking glass with a hammer or by smashing plywood or concrete block assemblies with a sledgehammer. Hand tools can also be used in combination with other tools. For example, a bolt cutter can sever steel reinforcing bars after the encasing concrete has been demolished with explosives, or wrecking bars can be used to remove materials crushed but not displaced by more sophisticated tools.

- Limited hand tools carry a low observation profile when employed due to the noise associated with using them and include claw hooks, carpenter saws, hacksaws, bolt cutters, pliers, spanner wrenches, tin snips, and wire cutters. Limited hand tools are readily available and require little skill.
- Unlimited hand tools carry a high observation profile when employed. These include, but are not limited to Kelly tools, Halligan bars, sledgehammers, cutting mauls, shovels, and axes. These tools are less common than limited hand tools and are normally part of a firefighter equipment kit.

2-2.4 Power Tools.

Power tools include electrically powered or gasoline fueled cutting and drilling tools; portable power impact tools; and hydraulic cutting, ramming, and spreading tools. Effects of power tools are breaking (including cutting of anchors and fasteners), deformation, material weakening, notching, spalling, and removal of debris. Attacks using power tools generate detectable evidence during the actual attack that includes noise, motion, vibration of the construction assembly, smoke, heat, dust, and debris. Because these tools require fuel or a power source such as a battery, they are heavier and more awkward to transport than most hand tools. Many power tools also require adequate space in which to effectively manipulate the tools. Aggressors might use power tools to sever the anchors of components, to cut locks or closing devices, or to cut or pry openings through construction materials. Power tools can be used in combination with other tools. For example, a saw might be used to cut through a concrete wall and then a ramming device can be used to displace the severed material to create an opening.

- Limited power tools operate from a self-contained power source like batteries and hydraulics. The hydraulic jack is a self-contained manually operated spreading device that works quietly.
- Unlimited power tools operate from external electric, gasoline, hydraulic pump, or compressed air power sources.

2-2.5 Thermal Tools.

Thermal tools generate flames capable of burning through steel and concrete. They include thermal cutting devices such as an oxyacetylene torch, oxygen-fueled devices such as the Kerie Cable, and the burn bar (thermal lance). Oxygen-fueled cutting devices are used to swiftly cut openings in materials, including reinforced concrete or masonry. Effects of thermal tools include material weakening, breaking, burning, cutting, and melting. Different effects are obtained depending upon the composition of the materials attacked. For example, fiberglass might melt or deform, glass might shatter due to thermal stresses, and flame-resistant materials might resist actual destruction, but the fumes or smoke produced can inhibit further efforts to destroy the assembly. Materials likely to yield to thermal attack, such as wood or plywood assemblies, might resist oxygen-fueled cutting tools longer than other assemblies. Detectable evidence yielded by thermal tools during attacks includes heat, smoke, and light. Some of these tools require oxygen and acetylene fuel tanks, which contributes to the total weight of the tool kit, and they require adequate space and ventilation. In some instances, aggressors would need to use protective safety clothing or other gear to execute an attack with these tools.

2-2.6 Explosives.

Explosives are used as forced entry tools to breach obstacles. Explosive tools include linear shape charges (LSC) and untamped and tamped breaching charges. Refer to UFC 4-020-01 for limits imposed on explosives used as forced entry tools. LSC focus energy from the explosion directly underneath the strip. The practice of backing up a charge with mass to direct the explosive effect is tamping the charge.

Explosive weights are expressed as weights that have the equivalent explosive effect as the expressed weight of trinitrotoluene (TNT). The actual explosive compound may be but is unlikely to actually be TNT.

2-2.6.1 Linear Shaped Charges.

An LSC consists of a copper v-shaped liner embedded in a similarly shaped high-explosives charge. The purpose of an LSC is to sever material. Upon detonation of the explosives, the liner collapses and a high-velocity metallic linear jet is formed. Because of its high kinetic energy, the jet can cut through materials upon impact. Typically, four lengths of LSC are placed in a picture frame arrangement on the element to be breached. Commercially available LSC have explosive weights ranging from 100 to 30,000 grains of TNT per linear foot of charge.

2-2.6.1.1 Homogeneous Materials.

Experimental data shows that the thickness of mild steel that can be severed by an LSC can be reasonably estimated by using Equation 2-1.

Equation 2-1. LSC Delay Calculation Based on Weight of Explosives

$$t = 0.027 * W^{0.547}$$

Where:
t = the thickness in inches of mild steel that can be severed by a given charge weight.
W = the weight of explosives charge in grains per foot (gpf) (linear).

To obtain the severance capability of a linear shape charge against material other than mild steel, multiply the result of Equation 2-1 by the appropriate factor from Table 2-2. The thickness given by Equation 2-1 is the limit for complete severance. If a section is only slightly thicker than the thickness given by the equation and modification factors, it can probably be severed with only minimal effort using hand tools. Because the LSC is a very debilitating tool, it is in the threat severity level V tool kit. When combined with the other tools at this severity level, custom components or materials may need to be developed and tested for the project. Example: Applying the formula to the 10,500 gpf design charge results in a 4.3-inch (109-mm) severance capability for mild steel.

Table 2-2 Mild Steel Severance Factors for Various Materials

MATERIAL	FACTOR
Mild Steel	1.00
Lead	0.67
Steel Armor	0.80
Granite	1.20
Aluminum	1.40
Rock	1.40
Concrete	1.60
Water	2.24
Green Wood	2.88
Earth	4.80
Kiln-Dried White Oak (12% moisture)	5.36

2-2.6.1.2 Composite Construction.

The adequacy of an assembly made of layers of different materials can be determined by converting the thickness of each layer to an equivalent thickness of mild steel. Divide the actual thickness of each material by the appropriate factor from Table 2-2 and sum the results for all materials in the assembly. This total equivalent mild steel thickness is then compared to the result of Equation 2-1 for the given charge weight to determine the adequacy of the composite element.

2-2.6.2 Breaching Charges.

A breaching charge is an explosive placed in direct contact with an element and detonated. The explosive materials used are typically dynamite or plastic explosives such as composition C-4 (U.S.) or Semtex (Czech Republic). Breaching charges are very effective against concrete, masonry, and thin steel elements; however, steel reinforcing bars, if present in concrete or masonry elements, usually remain intact and must be removed with bolt cutters, saws, or thermal tools after the explosion.

Tamped breaching charges are placed on the surface of the target. They are tamped by covering explosives with tightly packed sand, clay, or other dense material.

2-2.6.3 Platter Charges.

Platter charges are not included in this UFC and not identified as a forced entry tool by UFC 4-020-01. A platter charge is a sheet of explosive (either rubberized sheet explosive or a thin sheet of plastic explosive) backed by a plate of copper or steel. When the explosive detonates, the blast wave is largely projected away from the backing plate. If another lighter weight plate or disk is placed on the opposite face of the explosive charge, it will be projected like a missile in the opposite direction.

A platter charge used as a breaching tool may cut and remove most or all the reinforcing material, depending on its configuration. This will minimize the need to cut reinforcing bars with hand, power, or thermal tools after the explosive attack. A platter charge requires more explosives by weight than would be required if a regular explosive charge were used to remove the same mass of concrete. Also, size and weight of the platter, material (copper or steel), size and type of the explosive charge, and the barrier design all play critical roles in how a platter charge will perform against a specific barrier cross section. These factors plus the technical complexity, the possibility of destroying the entire structure or target, and the potential risk to the adversary, makes the use of platter charges for forced entry penetration questionable. Consequently, the following designs in this UFC are based on the use of bulk explosives in combination with hand, power, and thermal tools.

2-3 PROJECT DESIGN CRITERIA.

The project design criteria that was produced by the procedures in UFC 4-020-01 include the assets to be protected, the threat severity level, and the level of protection to be achieved in the final design of the project. These criteria dictate the elements of the protective system that must be provided in the final design.

2-3.1 Assets.

A protective system is designed to protect specific assets within a facility rather than the facility itself. Forced entry assets are those to which the aggressor must gain access for the purpose of stealing, damaging / destroying, or otherwise compromising them; examples include sensitive information, funds, controlled substances, arms, ammunition, and explosives (AA&E). The project design criteria will list the assets to be protected against a forced entry.

2-3.2 Threat Severity Level.

A threat severity level defines the composition of an aggressor team and the tools, weapons, or explosives that the team can potentially use against a facility. Threat severity levels are designated as I, II, III, IV, and V with V being the most severe. Resistance to forced entry does not require protection against threat severity level I. The project design criteria will assign one threat severity level to each asset requiring protection. When the project design criteria contain more than one asset, the facility design can protect all assets at the highest threat severity level; but, protection of each asset at the assigned threat severity level will commonly result in the most cost-effective solution.

2-3.3 Level of Protection.

The level of protection is the degree to which the protective system must defend an asset against the threat severity level. Levels of protection can be designated as very low, low, medium, high, or very high. The higher the level of protection, the lower the risk of asset compromise. The project design criteria specify the level of protection to be provided for each asset. Since the associated cost increases as the level of protection increases, the level of protection must balance risk at a reasonable cost.

Levels of protection for the forced entry tactic relate to the probability that the aggressors will be intercepted by a response force before the assets are compromised. The probability of the intercept is composed of the probability of detecting the aggressors and the probability of the response force arriving in time. The probability of intercept is increased by increasing the number of detection layers, or by increasing the delay time provided by protection measures between the point of detection and the asset. Delay that occurs prior to a detection layer may provide a deterrent to low level aggressors but does little to improve the probability of intercept. The response time that must be met with delay elements varies from the minimum to the maximum expected time depending on the level of protection. Refer to UFC 4-020-01 for the levels of protection for the forced entry tactic. The probability of intercept is also a function of the sophistication and design of the detection system.

2-3.4 Design Constraints.

The project design criteria may include constraints on the protective system design based on the project user’s operational or functional considerations and constraints imposed by regulations.

This Page Intentionally Left Blank

CHAPTER 3 DESIGN GUIDANCE TO RESIST FORCED ENTRY

3-1 GENERAL DESIGN STRATEGY.

The general design strategy for the forced entry tactic is to detect aggressors either prior to their reaching barriers or as they attempt to breach them and then to provide sufficient delay to forced entry in the construction of those barriers to allow responding forces to arrive and defeat the aggressors before they can compromise assets. Inherent in this strategy, therefore, is that there is an intrusion detection system that provides an alarm to a monitoring station in response to intrusion and that there is a response force that can respond to an alarm and reach its location before aggressors are able to breach the barriers between that point and the assets being protected.

3-2 SPECIFIC DESIGN STRATEGIES.

The specific design strategies associated with the different levels of protection vary by the amount of delay provided and the sophistication of the intrusion detection. Note that the levels of protection have specific delay times associated with them. Those delay times are generalized goals, but if the planning team is confident that response times are either more or less than those associated with the applicable levels of protection, the applicable delay times may have to be adjusted. All building elements in the protective envelope that provides the delay time must provide at least the minimum delay time associated with the applicable level of protection based on the assumption that aggressors will always be able to identify the weakest element in the envelope. That protective envelope may be all in one layer, such as the shell of a room or the exterior of a building, or it may encompass multiple layers such as the building exterior and multiple rooms arrayed in rings around the asset. The detection element of the protective system may also include closed circuit television (CCTV) to assess the validity of alarms. The criteria associated with the levels of protection are summarized in Table 3-1 and described below.

Table 3-1 Forced Entry Levels of Protection Summary

LEVEL OF PROTECTION	PERFORMANCE
Low	Provide construction that provides at least 1 minute of delay and provide intrusion detection sensors at all operational openings.
Medium	Provide construction that provides at least 5 minutes of delay and provide a complete ring of intrusion detection sensors
High	Provide construction that provides at least 15 minutes of delay and provide a complete ring of intrusion detection sensors with two different sensor phenomenologies
Very High	Provide construction that provides at least 30 minutes of delay and provide a complete ring of intrusion detection sensors with two different sensor phenomenologies

3-2.1 Low Level of Protection.

The specific design strategy associated with this level of protection incorporates an envelope of building elements (walls, roofs, floors, ceilings, doors, windows) surrounding an asset that provides a delay time to the specified threat tools of at least 1 minute. In addition, the protective system incorporates intrusion detection sensors at all operable openings. Entry though other building elements would be detected through operational procedures, such as roving patrols.

3-2.2 Medium Level of Protection.

The specific design strategy associated with this level of protection incorporates an envelope of building elements (walls, roofs, floors, ceilings, doors, windows) surrounding an asset that provides a delay time to the specified threat tools of at least 5 minutes. It also incorporates a complete ring of detection covering all possible approaches through the protective envelope.

3-2.3 High Level of Protection.

The specific design strategy associated with this level of protection incorporates an envelope of building elements (walls, roofs, floors, ceilings, doors, windows) surrounding an asset that provides a delay time to the specified threat tools of at least 15 minutes. It also incorporates a complete ring of detection covering all possible approaches to the asset. That ring must include two different sensor phenomenologies covering each approach.

3-2.4 Very High Level of Protection.

The specific design strategy associated with this level of protection incorporates the same delay and detection elements as the high level of protection, but the delay time is at least 30 minutes.

3-3 DESIGN PROCEDURES.

If the project is for new construction, review Paragraph 3-4 through Paragraph 3-8 of this document; then, use Chapters 4 through 7 to develop preliminary layout and design of the facility. Following preliminary layout and design, follow the procedures for calculating system delay starting in Paragraph 3-9. If the project is for an existing facility, review Paragraph 3-4 through Paragraph 3-8; then, follow the procedures for delay calculations starting in Paragraph 3-9.

3-4 PROTECTIVE SYSTEM.

Provide an integrated and layered protective system for the facility that is designed to deter, and if that fails, provide detection and physical barriers that provide enough delay time for a response force to defend/defeat the aggressor.

The protective system must operate on the principles of deter, detect, delay, deny, defend/defeat as defined in UFC 4-020-01.

- Deter is the prevention of an action by the existence of a credible threat of unacceptable counteraction or belief that the cost of action outweighs the perceived benefits.
- Detect is to assess possible aggressor action, or sensor/alert transmission that an event has occurred.
- Delay is the capability to interrupt or neutralize an aggressor’s activities.
- Deny prevents an aggressor from access, theft or generating casualties.
- Defend / defeat prevents unauthorized access and safeguards assets.

3-5 SECURITY IN DEPTH.

Security in Depth (SID) is a combination of layered and complementary security controls sufficient to deter, detect, and document unauthorized entry and movement within the installation and/or facility and the ability to delay and respond with force. Refer to UFC 4-020-01 for additional information on SID.

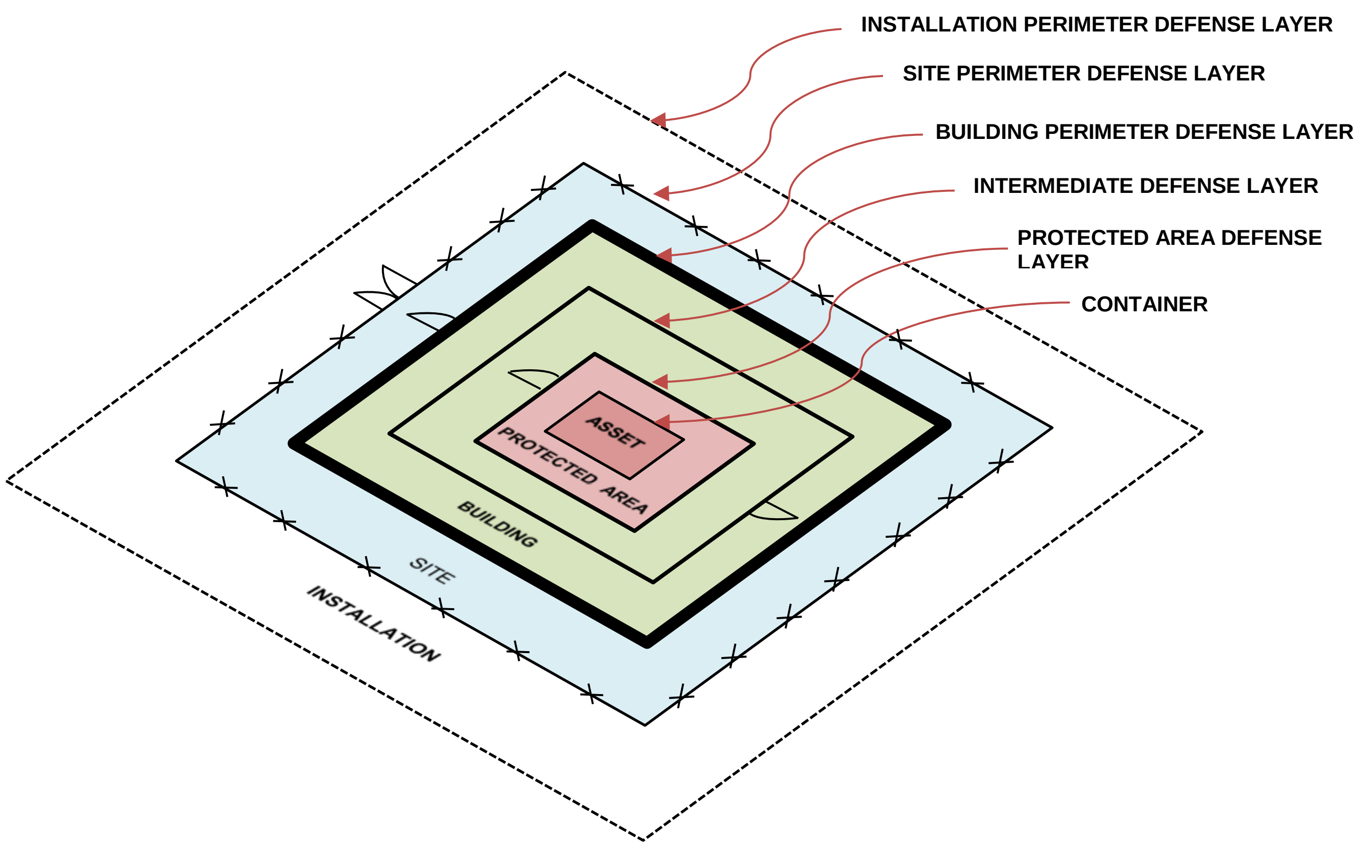
The project protective system should provide SID; and, when possible, consist of multiple defense layers and complementary control zones. If the project is being located within a larger installation, SID begins at the installation boundary.

3-6 DEFENSE LAYERS.

Each defense layer must consist of physical barriers that will delay the aggressor attempt to penetrate the layer and detection measures to provide early warning of the aggressor attempt. Detection measures may use electronic security systems (ESS) to provide the early warning or rely on visual observation by installation personnel or roving guards.

Figure 3-1 illustrates a protective system with multiple defense layers. Defense layers in the illustration are identified as installation perimeter, site perimeter, building perimeter, intermediate, protected area, and container.

Figure 3-1 Defense Layers

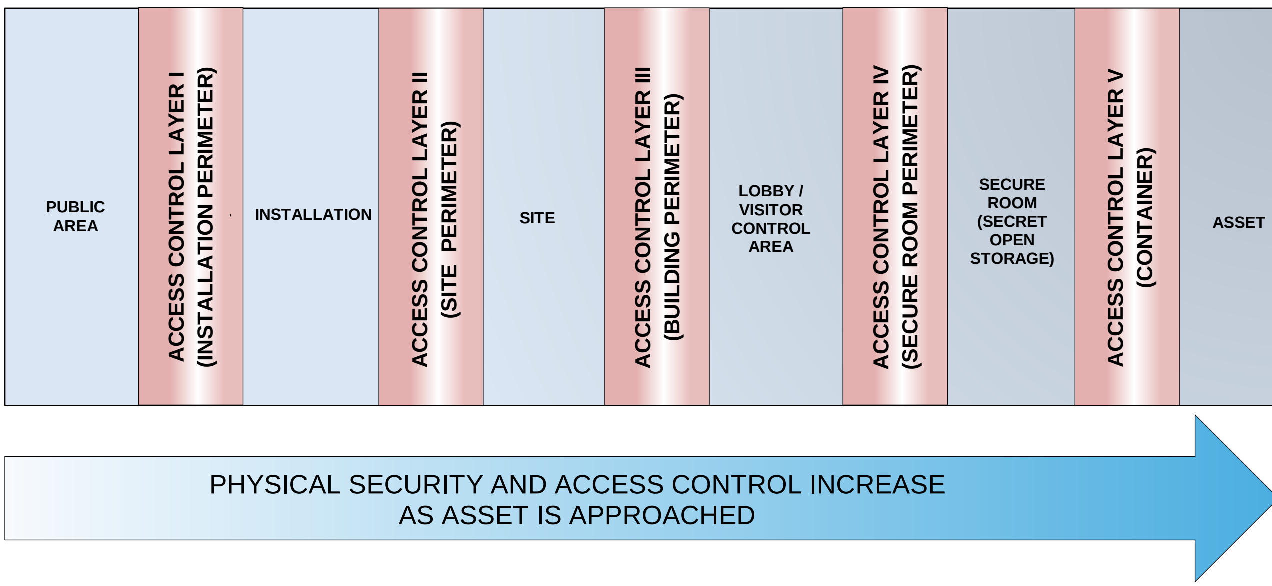


3-7 CONTROL ZONES.

Control zones are groupings of functional areas where access to a zone is restricted to site or building inhabitants who are required to work in the zone. If configured correctly, having multiple access control layers within an installation or facility can enhance the security of the higher security zones. This is accomplished by requiring personnel to transition through increasingly secure access control layers prior to accessing the protected area with the high value asset. Control zones may include installation access, site access, building access, restricted access, or protected area access.

Figure 3-2 illustrates a model for establishing control zones within a layered defense using an installation perimeter, site perimeter, building perimeter, secure room (protected area), and container.

Figure 3-2 Control Zones

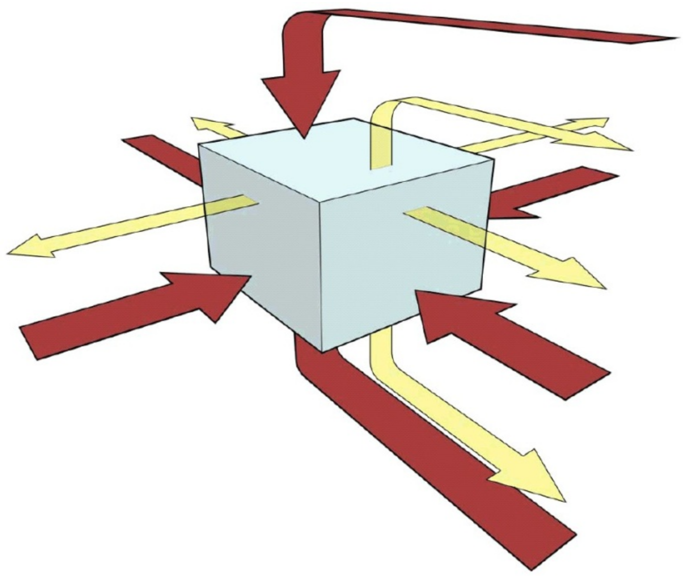


3-8 LAYOUT CONSIDERATIONS.

Except for a site perimeter, use a six-sided approach when designing each defense layer. The walls, floor, roof or ceiling, and any penetrations of the defense layer must be designed so that all elements meet the delay rating for the layer. See Figure 3-3 for a diagram of the six-sided approach.

Chapter 4 describes detailed site layout and design. Chapter 5 describes detailed building layout and design.

Figure 3-3 Six-Sided Approach



3-8.1 Multiple Assets.

Since the design basis threat is focused on assets, not all assets will require the same threat severity level and levels of protection. If there are multiple assets, evaluate each asset and the design criteria associated with it and factor that into how the building is laid out.

When the design criteria contain multiple assets to be protected, consider grouping the protected areas containing those assets together unless prohibited by prescriptive requirements such as a minimum interspatial distance required for explosives.

3-8.2 Multiple Buildings in Project.

When the design project contains more than one building, consider locating assets in a building near the center of the complex.

3-8.3 Multiple Aggressor Tactics.

When the design criteria contain multiple aggressor tactics, each tactic will have a threat severity level and an associated level of protection. Provide design features that protect the assets against the forced entry tactic and associated level of protection, enhanced by requirements to protect against other aggressor tactics and associated levels of protection.

When there are multiple applicable tactics, each tactic will have to be addressed separately and the resulting protective measures will have to be integrated into a comprehensive solution that addresses all tactics. In doing so, the tactics should be addressed in order from the one that has the greatest potential impact on building construction to the tactic with the least impact. For example, construction to protect against explosives related tactics may require heavy construction that may be a greater requirement than the forced entry resistance but may prove to be advantageous to forced entry resistance.

3-8.4 Multiple Defense Layers with Common Roofs or Ceilings.

Some forced entry projects may necessitate that two or more defense layers have common roofs or ceilings. The pathway to the asset may be through the roof and ceiling, the floor or through the walls and doors. Either pathway must meet the required system delay.

3-9 ESTABLISHING REQUIRED PROTECTIVE SYSTEM DELAY TIME.

An effective protective system requires that any aggressor attempt to attack the facility must be detected so that response forces can interrupt and neutralize the aggressor's attack before his goal can be achieved. Since it is usually not feasible to maintain a response force to provide immediate protection for all assets, a comprehensive aggressor detection and delay plan is needed.

3-9.1 Delays for Multiple Assets.

When the design criteria list multiple assets to be protected, each with an applicable level of protection, delay can be provided for the protection of all assets at the highest level of protection, but a more cost effective design may entail providing delay for each asset listed according to the level of protection assigned to that asset.

3-9.2 Establish Minimum and Maximum Response Times.

Minimum or maximum response time refers to the minimum or maximum possible time in which the response force can reach an engagement area. Consult with facility operations personnel, facility security personnel, and the base Facility Antiterrorism Officer to establish response force tactics including potential engagement areas and the minimum and maximum response times for each asset. For some assets, such as Sensitive Compartmented Information, response time is dictated by policy.

3-9.3 Establish Required Protective System Delay Times.

Defense layers surrounding an asset must collectively provide detection and enough physical delay for a response force to intercept the aggressors, either before the asset is compromised or before the aggressor escapes.

Calculate the required collective protective system delay time based on the minimum or maximum response times using the requirements in Table 3-2.

Table 3-2 Level of Protection Delay Times for Forced Entry

LEVEL OF PROTECTION	REQUIRED DELAY TIME
Very Low	Delay does not apply to this level of protection.
Low	The required delay time is greater than the minimum possible response time.
Medium	The required delay time is greater than the minimum possible response time.
High	The required delay time is greater than the maximum possible response time.
Very High	The required delay time is 25% greater than the maximum possible response time.

3-10 EVALUATING SYSTEM DELAY IN PRELIMINARY DESIGN.

Use the Forced Entry Design Worksheet, Figure 3-4, to document the delay times included in the preliminary design for each asset. Enter the project and asset descriptions; date; minimum/maximum response times, level of protection, and threat severity level assigned to the asset in boxes 1 through 5b.

Enter the protective system delay time calculated in Paragraph 3-9 in Box 5c of the Forced Entry Design Worksheet.

Figure 3-4 Forced Entry Design Worksheet

1. PROJECT / BUILDING IDENTIFICATION	2. ASSET IDENTIFICATION		3. DATE

4a. MINIMUM RESPONSE TIME	4b. MAXIMUM RESPONSE TIME	5a. LEVEL OF PROTECTION	5b. THREAT SEVERITY LEVEL	5C. REQUIRED DELAY

CONTAINER				
PROTECTED AREA				
INTERMEDIATE LAYER				
BUILDING PERIMETER				
SITE				

ESTIMATED AGRESSOR ESCAPE TIME	12.	SYSTEM DELAY RATING	11.	

3-10.1 Physical Delay Ratings.

The physical delay rating for a defense layer (construction) element is the time it takes for the aggressor to breach and pass through the element. This rating will include the attack time, the tool penalty, and the skill penalty, as applicable. For traditional elements such as walls, door, and windows used in both new and retrofit construction design, these delay ratings, based on threat severity levels can be found in Chapters 5 and 6.

Additionally, Chapter 7 discusses the use of dispensable barrier and shuttering systems that can be used to further delay a forced entry attempt. For use of these systems, consult with subject matter experts in coordination with facility operations and security personnel.

3-10.1.1 Defense Layer Element Physical Delay Ratings.

Enter the construction elements for each defense layer used in the preliminary design in the appropriate spaces in column 7. For example, building perimeter elements might include walls, roofs, floors, ceilings, doors, windows, and utility openings.

Enter the corresponding delay rating for each element in column 8. If there is no entry in Chapters 5 or 6 for a design element at the required threat severity level, use the delay time for the next lower threat severity level for which data is available.

3-10.1.2 Layer Physical Delay Ratings.

Ideally, all element delay ratings within a layer will be equal, providing a consistent defense; however, aggressors will exploit the weakest element in a defense layer. Thus, the layer delay rating for a given defense layer equals the least delay time among the elements of that layer. Determine the layer delay rating for each defense layer and enter that rating in the appropriate space in column 9.

3-10.1.3 System Delay Rating.

The total system delay is the sum of the defense layer delay ratings in Column 9. Enter the total system delay time in box 11.

3-10.1.4 Aggressor Escape Time.

If the goal in protecting an asset is to keep it from being removed from the facility rather than to deny access to the asset, enter an estimate of the time necessary for an aggressor to escape from the facility in box 12. Note that the escape delay time through each layer will likely be significantly shorter than for entry because of use of emergency exits or use of penetrations created during initial breaching of the layer.

3-10.2 Outermost Defense Layer.

The outermost defense layer is the layer at which the sum of the delay ratings for that layer and layers interior to it is equal to or greater than the required delay time (box 5c). Column 10 of the Forced Entry Design Worksheet is used to indicate the calculated outermost defense layer. The outermost defense layer is the point at which detection is achieved. Where electronic security systems (ESS) are used as part of the protective system, it is the point at which sensors will be placed. Refer to UFC 4-021-02 for design of ESS.

3-11 DESIGN ADJUSTMENT.

If the system delay rating (box 11 of the Forced Entry Design Worksheet) is less than the required delay time (box 5c) or if the outermost defense layer is at an unacceptable location, add defense layers or upgrade layer components. It is usually more efficient to upgrade layers closer to the asset because the size of the inner layers is smaller as is the resulting protected area volume. To upgrade existing defense layers, start with the component with the least delay rating. Select different construction components if the facility is new construction. Replace or retrofit vulnerable existing construction components. Fill out a new Forced Entry Design Worksheet if significant changes are made to the initial defensive system.

This Page Intentionally Left Blank

CHAPTER 4 SITEWORK

4-1 INTRODUCTION.

This chapter applies when the design criteria require that the project establish a building compound with a dedicated site perimeter and open areas between the site perimeter and the building housing the asset to be protected. When required, the building compound may provide the first opportunity for forced entry delay.

a. Not all resistance to forced entry projects will require the establishment of a building compound. In that case, the building perimeter provides the first defense layer; refer to Chapter 5 for building designs.

b. Not all resistance to forced entry projects will be located on an existing Government installation. When the establishment of a building compound is required by the design criteria, this UFC is applicable for both a site located on an existing installation and a stand-alone site.

c. This UFC does not address the design of installation perimeters.

4-2 SITEWORK ELEMENTS.

Sitework elements such as chain-link fences, gates, and entry portals are not likely to delay a small group of well-equipped and dedicated aggressors; however, managing the site perimeter and open areas external to buildings:

- assists in building access control,
- minimizes hidden spots and concealed avenues of approach for an aggressor,
- provides opportunities for observation and detection, and
- may provide a platform for sensors (such as fence mounted sensors).

4-3 CRIME PREVENTION THROUGH ENVIRONMENTAL DESIGN.

Crime prevention through environmental design (CPTED) is the proper design and effective use of the built environment that can lead to a reduction in the fear and incidence of crime, and an improvement in the quality of life. Consider using CPTED concepts in the design of the projects to make the facility less attractive to aggressors considering forced entry. The main features of CPTED are natural access control, natural surveillance, and territorial reinforcement.

For further information on CPTED, See:

- Publications by the National Institute of Law Enforcement and Criminal Justice.
- Crowe, Timothy D., *Crime Prevention Through Environmental Design*. National Crime Prevention Institute (1991).

4-3.1 Natural Access Control.

Natural access control includes design features that clearly indicate public routes and discourage access to private structural elements. These features decrease an opportunity for crime by creating in an offender a perception of unacceptable risk when attempting access to private areas, which marks the stranger as a possible aggressor. Such design features include placement of entrances and exits, fencing, and landscaping to control traffic flow.

4-3.2 Natural Surveillance.

Natural surveillance includes design features that increase the visibility of a property. These features maximize the ability of persons in the area to see persons in the vicinity and avoid trouble and allow external activities to be seen from adjacent building structures by persons who could call for help. Such design features include landscaping, lighting, window and stairway placement, and building entrance and garage layouts.

4-3.3 Territorial Reinforcement.

Territorial reinforcement includes design features that clearly indicate public and private structural elements of a property. An individual will develop a sense of territoriality for a space with frequent activities in an area, a sense of ownership. With this feeling of ownership, the individual will want to defend his environment. This ownership does not necessarily mean legal ownership; it maybe a perceived ownership, such as the sense of ownership that employees feel for the office in which they work. The sense of territory and ownership by an individual is reinforced through regularly scheduled activities, inspections, and maintenance.

4-4 SITE LAYOUT CONSIDERATIONS.

To optimize the site layout for security and function, architects, engineers and security personnel must work together to understand the layout of operational spaces within the site such as parking, landscape and drainage features, lighting, and trash collection areas in addition to visitor and vehicle access and escort requirements. This takes an integrated design approach that balances the site's operational and space requirements. If space permits, the site layout should be designed to provide early detection of aggressor movement toward the building. See Paragraph 4-6 for application of clear zones and unobstructed space.

The following are site-related layout considerations:

- Establish a well-defined perimeter using fences, walls, or a combination of both.
- Provide an intrusion detection system (IDS) at site perimeter to detect aggressor attempt to penetrate site.
- Provide only one personnel entry control point (ECP) and one vehicle ECP into the site.

- Locate facility within view of other occupied facilities.
- Locate assets stored outside of the facility within view of occupied rooms of the facility.
- Eliminate potential hiding places for aggressors.
- Minimize or eliminate signs or other indicators of asset location.
- Illuminate building exterior or exterior sites where assets are located.

4-5 SECURITY FENCING.

Security fencing is effective at delineating a boundary and at keeping honest people honest, but ineffective for preventing a forced entry. The design strategy for forced entry is based on delaying the aggressor, and any serious aggressor could climb a fence in less than four seconds or can cut through a fence in less than ten seconds; however, fences can provide an important role in the early detection of an aggressor's forced entry attempt. An aggressor must make an overt action to breach the fence, which allows them to be intercepted in accordance to the rules of engagement. Refer to UFC 4-022-03 for the functions and design of security fences.

4-5.1 Gates for Fences.

Gates control authorized pedestrian and vehicular traffic and flow. They establish entry and exit points into an area defined by fences. They are a component of the perimeter fence and must be as effective as the associated fence in order to provide an equivalent deterrent. Gates normally require additional hardening features for hinges and locking mechanisms due to their operation and inherent vulnerability. Use designs in UFC 4-022-03 for gates and hardware. When required, design ESS in accordance with UFC 4-021-02 for associated alarms.

4-5.2 Utility Openings in Fence Lines.

Drainage ditches and culverts may pass through or under a perimeter fence. If those openings create a cross-sectional area greater than 96 square inches (619 cm^2) and a smallest dimension greater than 6 inches (150 mm), they must be protected using designs in UFC 4-022-03. Ensure that any addition of grilles or pipes to culverts or other drainage structures is coordinated with civil engineers so that they can compensate for the diminished flow capacity and additional maintenance that will result from the installation.

4-5.3 Walls in Fence Lines.

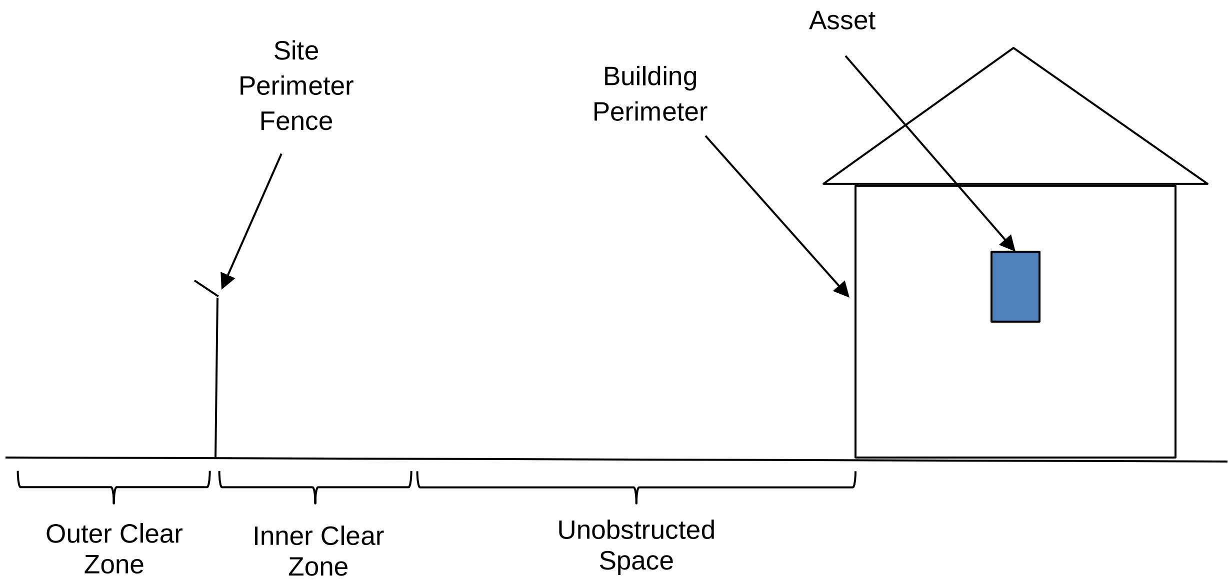
Walls can be used to replace part, or all, of a security fence in the site perimeter. Alternatively, a short wall topped by a fence can be used in the site perimeter.

Walls and walls topped with a fence should provide security features equivalent to that of a security fence. Refer to UFC 4-022-03 for the functions and design of security fences.

4-6 CLEAR ZONES AND UNOBSTRUCTED SPACE.

The space between the site perimeter (security fence) and the facility buildings consists of an inner clear zone and an unobstructed space (Figure 4-1). Additionally, there may be an outer clear zone that is outside of the site perimeter.

Figure 4-1 Site Areas



4-6.1 Clear Zones.

When a site perimeter fence is required, clear zones are areas established on both outer and inner sides of a security fence to provide an unobstructed view to enhance detection and assessment. Refer to UFC 4-022-03 for application of clear zones at fence lines and UFC 4-010-01 for application of clear zones around inhabited buildings.

4-6.2 Unobstructed Space.

Unobstructed Space is an area around inhabited buildings in which there are no opportunities for concealment from observation of explosive devices 6 inches (150 mm) or greater in height or width. Refer to UFC 4-010-01 for minimum requirements for unobstructed space.

4-7 SITE PERIMETER ENTRY CONTROL.

Depending on the project, entry control points may be required in the site perimeter. Consult with facility operations personnel and facility security personnel for entry control requirements for the project perimeter.

4-8 DETECTION.

For forces to respond to an attempted forced entry, the threat must be detected. This may be accomplished by visual observation, IDS, or CCTV. Initial threat detection should occur at the outermost defense layer, either at the site perimeter or at the building perimeter. Refer to UFC 4-021-02 for additional information and designs for IDS and CCTV employment at the outermost defense layer.

4-9 SECURITY LIGHTING.

Security lighting provides illumination during periods of darkness or in areas of low visibility to aid in the detection, assessment, and interdiction of aggressors by security forces. Lighting may also be a deterrent to some aggressors.

Consult with facility operations and facility security personnel, including ESS specialists, for security lighting requirements. When required, design lighting in accordance with UFC 3-530-01.

This Page Intentionally Left Blank

CHAPTER 5 BUILDING ELEMENTS

5-1 INTRODUCTION.

Building elements include the building layout, walls, roofs, ceilings, floors, doors, windows, and utility openings. Designs for each element type are presented in separate sections within this chapter.

5-2 BUILDING LAYOUT.

Effective building layout enhances resistance to forced entry by making assets harder to find and more time-consuming to reach, by making escape more difficult, and by taking advantage of inherent monitoring opportunities by occupants. Some related considerations also influence building layout. Several defense layers surrounding an asset may be more cost-effective than a single layer that provides the total delay time. Minimizing the actual protective volume (all sides of a space must be considered) around an asset reduces construction and detection system costs and surveillance requirements. Deciding whether to consider delay time in terms of the aggressor's ingress time only (time required from detection until the aggressor reaches an asset) or ingress plus egress time (including escape time after compromising or stealing an asset) can also influence building arrangement. Finally, design the building such that interior signage, which may indicate an asset's existence or location is unnecessary.

To optimize the building layout for security and function, the designer must understand the various secure spaces in the facility, the security clearances of the occupants, visitor access and escort requirements and the separations or adjacencies required. This takes an integrated design approach that balances the occupant's operational and space requirements, visitor control requirements, security-in-depth and the concept of control zoning. If building operations permit, the building layout should be designed to complicate aggressors' movement toward the asset by requiring that they be forced to take complicated routes and be equipped with a number of different tools and skills. In developing the building layout:

- Maximize the vertical and horizontal separation between the lowest and highest security areas.
- Maximize grouping of secure areas to enhance floor/ceiling security and to minimize locations of secure elements.
- In large facilities, locate the highest security area in the building center, on an upper floor, or in the basement.
- When a facility has multiple security levels and functionally compatible missions, access to the highest security area should be through the area with the next lower security level.

5-3 BUILDING COMPONENTS.

Defense layers consist of construction components and assemblies including walls, roofs, floors and ceilings, doors, windows, and utility openings, which delay an aggressor from reaching an asset. Consider building components that may be attacked horizontally or vertically from all sides of a space. The penetration delay time for any layer equals the least penetration delay time for any single component of that layer.

The materials from one type of component can be used for another type of component; for example, wall materials can be used for ceilings or window materials can be used for skylights. When making these substitutions, penetration delay times must be adjusted since horizontal and vertical attacks on the same materials yield different penetration delay times; for example, the penetration delay time for a downward attack on a 6-inch (150-mm) concrete roof slab is lower than a similar attack on a 6-inch (150-mm) concrete wall.

5-4 FORCED ENTRY RESISTANT BUILDING COMPONENT TABLES.

This Chapter provides a series of tables containing forced entry resistant building components and the delay times they provide against the four possible threat severity levels for the forced entry tactic. There are separate tables for walls, doors, windows, roofs, floors, and utility openings. Each component table is located within the paragraph of this chapter devoted to the respective component.

5-4.1 Data Formulation.

The tables contain only components which have been tested or otherwise analyzed for forced entry resistance. Although the components in the tables are representative, they are not the only components available. New technology is used to develop improved components, and testing may have been performed that is not reflected in the tables. Users of this manual must therefore supplement it with whatever other data is available to them; however, only data based on actual testing or formal analysis should be used. Manufacturers' data may be based on limited testing or assumptions and may not accurately reflect the tools associated with the threat severity levels discussed in this manual.

The data in these tables was derived from actual tests and on estimates based on such tests. The total delay time consists of three elements: (1) the attack time, (2) the tool penalty, and (3) the skill penalty.

5-4.1.1 Attack Time.

The attack time is the actual time that it took the person or persons performing the test to make a man-passable opening of 96 square inches (619 cm^2) in the designated building component under laboratory conditions. Some data is based on estimates or delay times based on tests of similar materials with the same tools.

5-4.1.2 Tool Penalty.

The tool penalty is an additional delay time added to the attack time to account for difficulties associated with using some tools. It does not apply for all tools.

5-4.1.3 Skill Penalty.

The skill penalty is an additional delay time added to the attack time and tool penalty to reflect an unskilled user's inefficiency in using the tools. Again, the skill penalty does not apply to all tools.

5-4.2 Advantages of Composite Components.

A composite construction component such as a wall, floor, ceiling, or door built with two or more types of materials such as wood, metal, concrete, or foam provides significant delay over a component built with a single material since it requires aggressors to use multiple tools to breach the component.

Thermal tools can cut through metal but do not work well on wood, and power tools commonly get fouled up by foams. Explosives can blast holes in concrete but generally leave the reinforcing bars intact, requiring the aggressors to switch to cutting tools to complete the breach. Note that many of the entries in the tables in this chapter include such cross sections.

5-4.3 Data Application.

The attack time and the tool and skill penalties are already incorporated into the total delay times shown in the tables. All three quantities are applied to arrive at the total delay time for the threat severity levels II and III. The skill penalty is not applied for the threat severity level IV because aggressors operating at that threat severity level are assumed to be skillful at using the tools they select; they may still select tools which are difficult to use, and they are therefore still assigned a tool penalty. The aggressors to whom the threat severity level V applies are assumed to be skillful at using the tools they select and to select only tools which are not too difficult for them to use; therefore, no penalties are associated with the threat severity level V.

5-4.4 Using the Tables.

The tables provide the delay times for building components for the four possible threat severity levels applicable to the forced entry tactic. The second column in each table provides a description of each component with which a delay time is associated. Components may be used as a stand-alone application in new construction or as a retrofit. The third through sixth columns on the tables indicate the total delay times in minutes for various threat severity levels. Each identified building component resists the tools associated with the forced entry threat severity level for the time indicated. Where there are no entries under a given threat severity level, no testing or analysis has been done for that component for that level. In those cases, either select another component or use the next higher threat severity level for which data is available. Using higher threat severity levels will always be conservative.

5-4.5 References to Explosives Use.

The threat severity level V includes the potential for the use of explosives. The delay times associated with explosives are indicated by an asterisk (*). Where testing was done on a building component at threat severity level V without using explosives, that value is also indicated. In such cases the delay time entry will appear as two numbers, such as 10/<1*. The 10 refers to the delay without explosives and the <1* refers to the delay assuming the use of explosives. If the aggressor is unlikely to use explosives due to their noise, their potential for damaging the asset, or for any other reason the planning team establishes, use the value which does not include explosives.

5-5 NEW CONSTRUCTION.

This section provides design options for hardening a new building against forced entry penetration. The objective is to identify construction choices that assure a balanced security design between all building components; approximately equal penetration delays against a given threat severity level.

5-5.1 Walls.

Solid plywood or expanded metal construction can be used to resist a low severity threat. For threat severity levels III and IV, the choices are limited to grout-filled and reinforced concrete-masonry unit (CMU) for lower delay time requirements, and conventional or steel-fiber-reinforced (SFR) concrete for higher delay time requirements. Protection against threat severity level V will require sacrificial areas, multiple barriers, or reinforced concrete barriers.

5-5.1.1 Walls to Resist Threat Severity Level II.

Since conventional wall construction such as stud-girt construction using less than 3/4-inch (19-mm) plywood, stucco, gypsum, composite, light sheet metal, and conventional masonry provides a delay of less than one minute against threat severity level II, use one of the wall types shown in Table 5-4.

5-5.1.2 Walls to Resist Threat Severity Levels III and IV.

Use solid-filled and reinforced CMU; conventional reinforced concrete; SFR concrete; or masonry, wood, metal, and plastic composite walls.

Solid core, filled, and reinforced CMU, conventional, SFR concrete wall construction options and corresponding minimum penetration delay for threat severity levels III and IV are shown in Figure 5-1 through Figure 5-3. Note in Figure 5-1 through Figure 5-3 that the minimum penetration delay times are presented as a function of the thickness of the cross section and the size and spacing of reinforcing bars. Different combinations of reinforcing bar size and spacing are identified by capital letters from Table 5-1 for masonry and in Table 5-2 for reinforced concrete. In general, a required penetration delay time can be achieved either by providing a thicker cross section or by adding more reinforcement. Table 5-4 provides options that can be considered based on structural and cost considerations.

5-5.1.2.1 Security Threat Level III.

a. CMU walls: As shown in Figure 5-1 and Table 5-1, penetration delay times up to about 5.5 minutes are achievable using mortar filled CMU. The use of reinforcing bars in the core is required for higher penetration delay times.

b. Conventional Reinforced Concrete. As shown in Figure 5-2 and Table 5-2, penetration delay times up to 7.5 minutes are achievable with 6 inches (150 mm) of reinforced concrete with the B-curve reinforcing bar combination.

c. SFR Concrete. As shown in Figure 5-3 and Table 5-2, penetration delay times up to about 11 minutes are achievable with 6 inches (150 mm) of SFR concrete with the B-curve conventional reinforcing bar combination. The steel fiber is at least 5 percent by volume of the concrete mix.

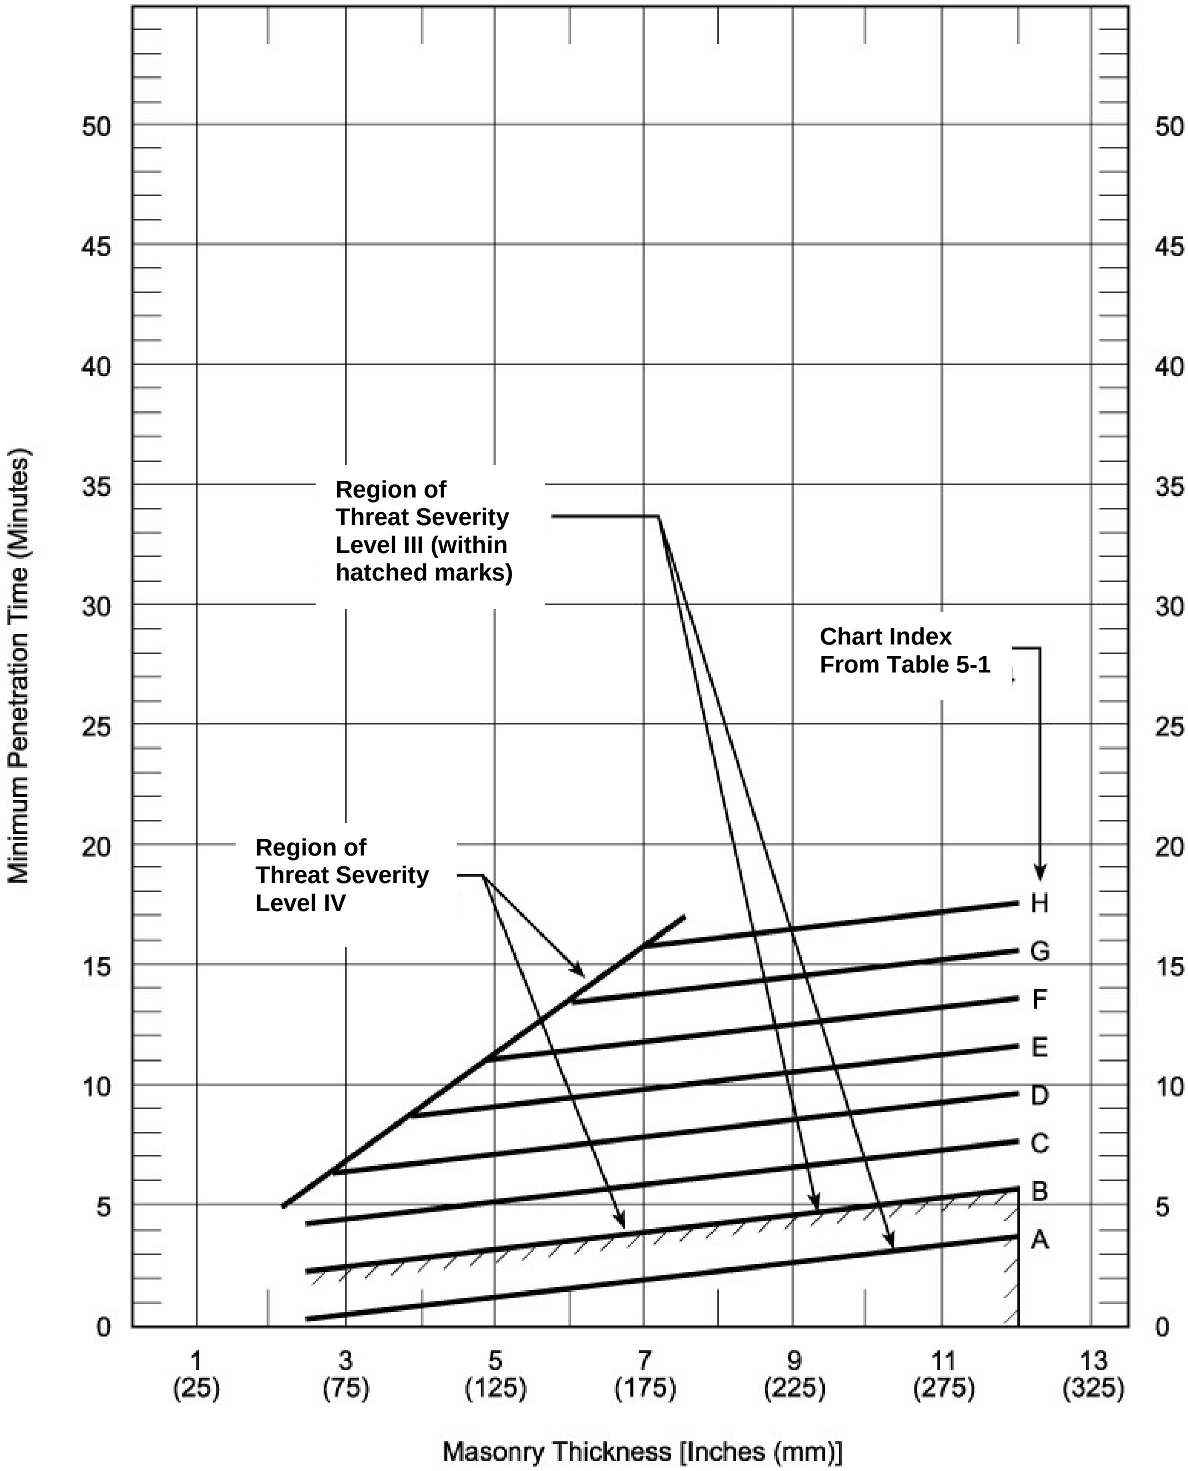
5-5.1.2.2 Security Threat Level IV.

a. CMU walls: Figure 5-1 with Table 5-1, gives CMU and reinforcing bar combinations that can provide penetration delay times up to 18 minutes.

b. Conventional Reinforced Concrete. Figure 5-2 with Table 5-2, gives conventional concrete thickness and reinforcing bar combinations that can provide penetration delay times up to 35 minutes.

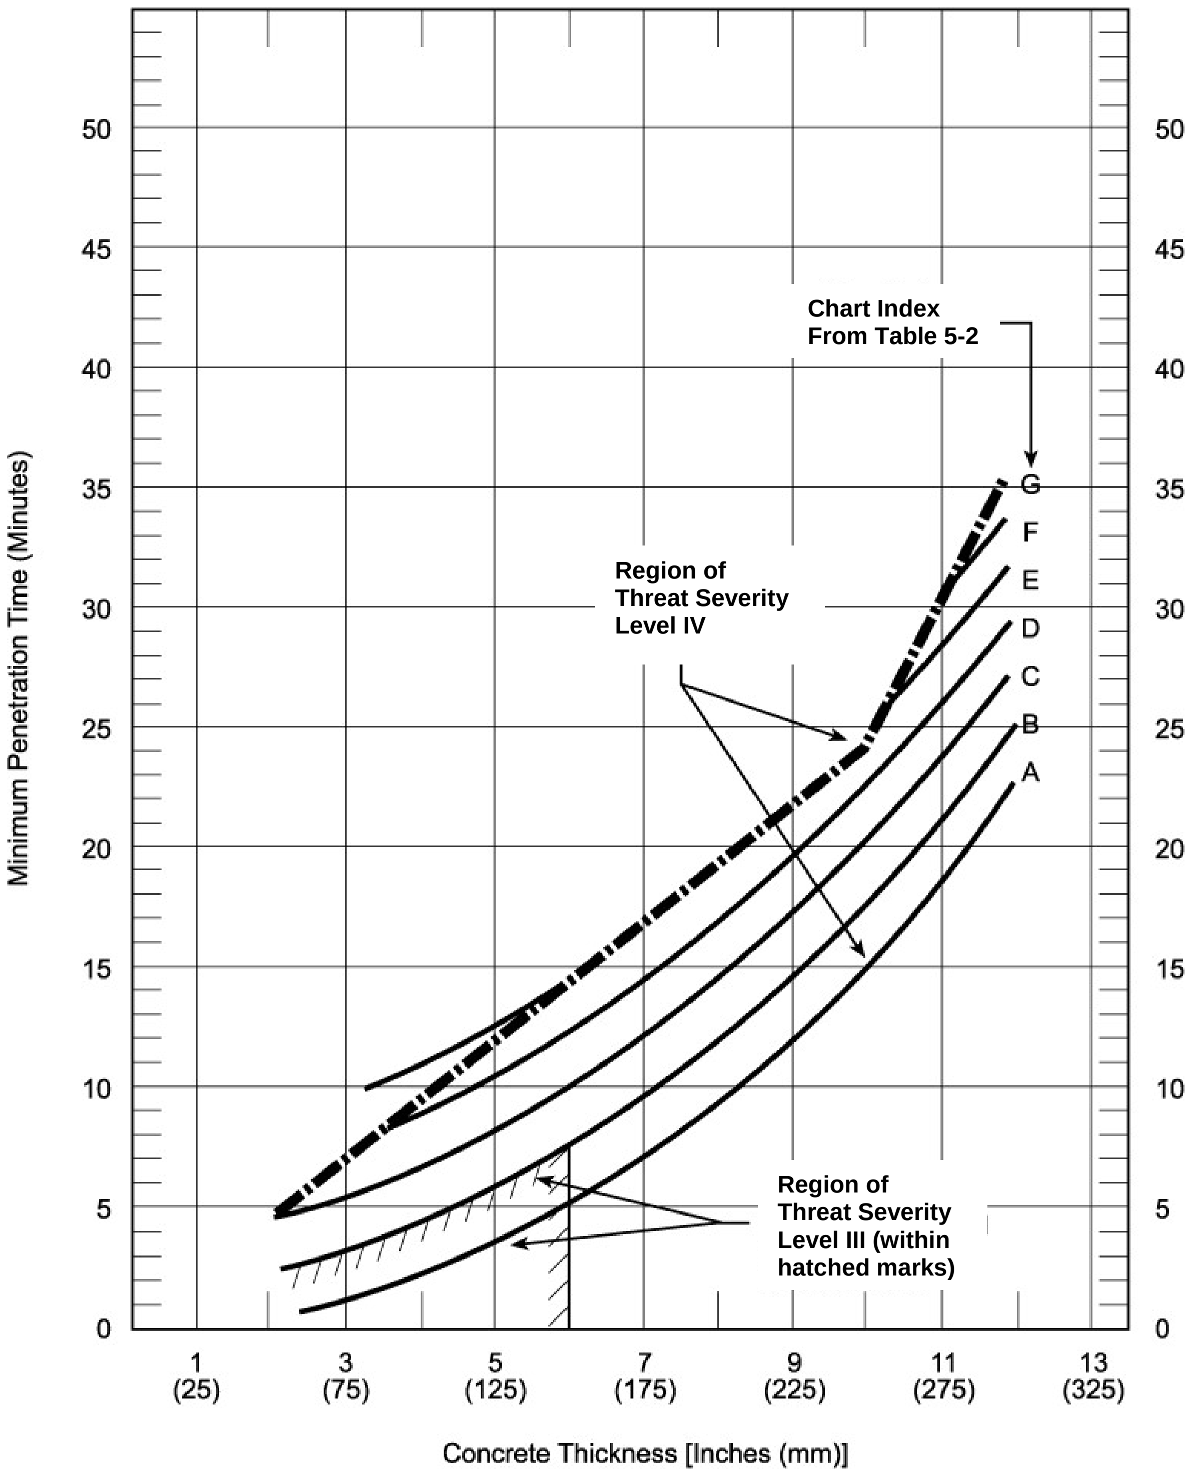
c. SFR Concrete: Figure 5-3 with Table 5-2, gives SFR concrete thickness and conventional reinforcing bar combinations that can provide penetration delay times up to 50 minutes.

Figure 5-1 Delay times for Solid Core Filled and Reinforced CMU Walls



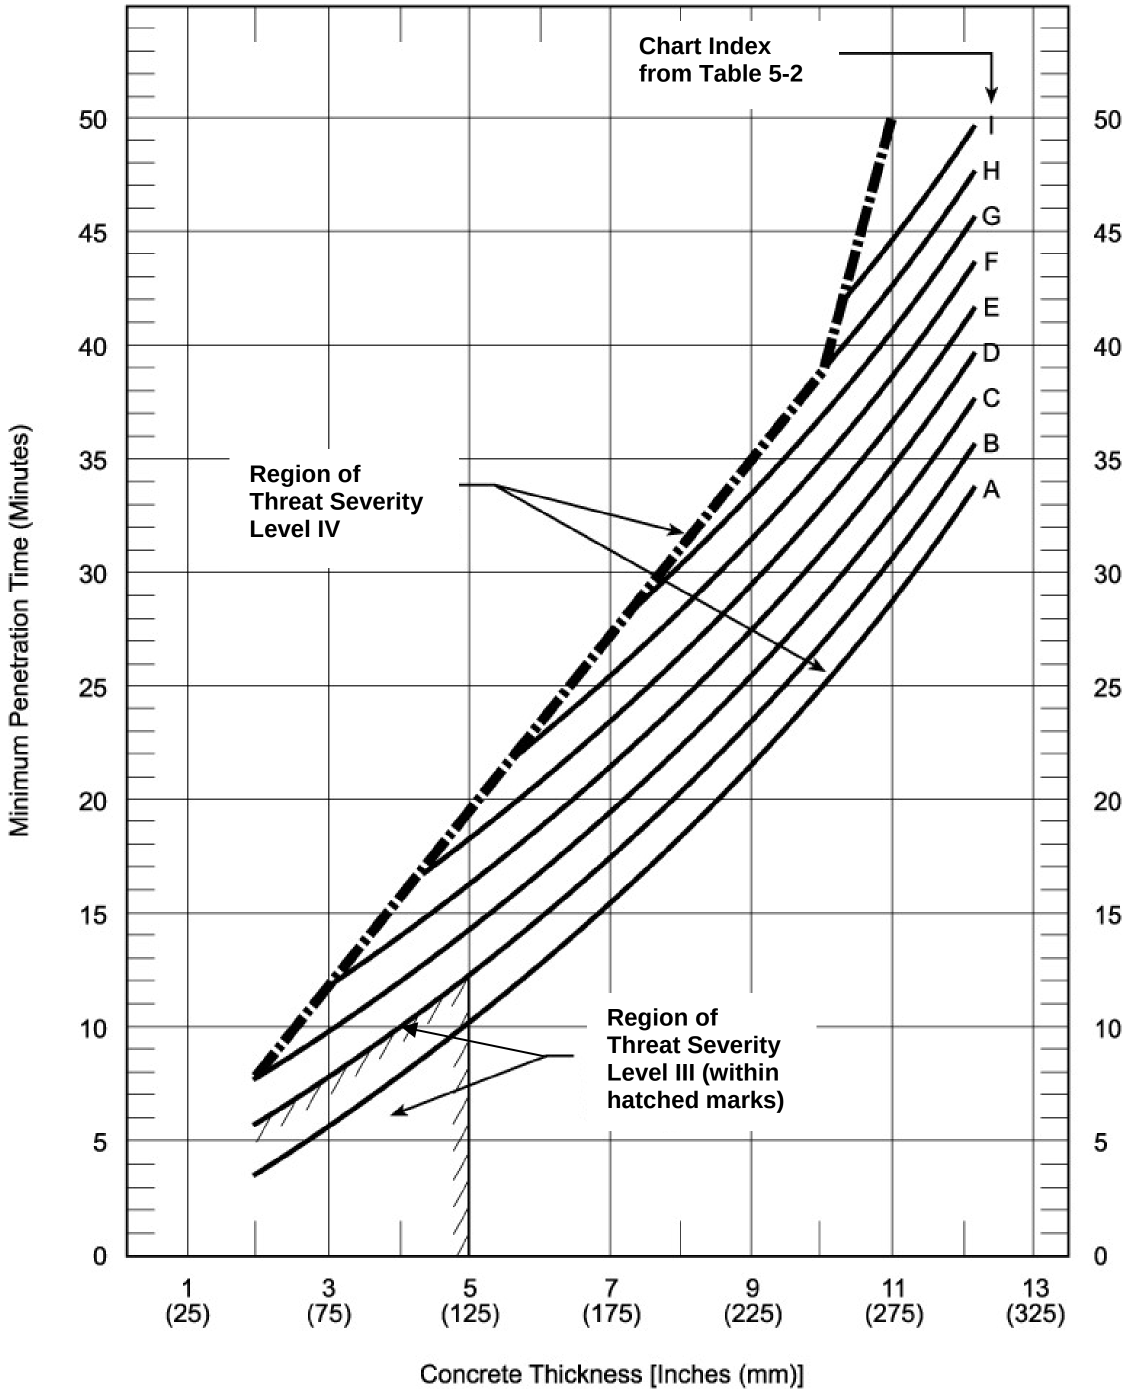
Note: the penetration times are minimum values based on the proper selection and optimal use of the attack tools. In this figure, the regions identified as threat severity level III assumes that only hand powered tools and some limited battery powered tools are used. For these cases, the thickness and/or reinforcing bar combination required is less than for the threat severity level IV where power and thermal tools also may be used.

Figure 5-2 Delay times for Conventional Reinforced Concrete Walls



Note: the penetration times are minimum values based on the proper selection and optimal use of the attack tools. In this figure, the regions identified as threat severity level III assumes that only hand powered tools and some limited battery powered tools are used. For these cases, the thickness and/or reinforcing bar combination required is less than for the threat severity level IV where power and thermal tools also may be used.

Figure 5-3 Delay times for SFR Concrete Walls



Note: the penetration times are minimum values based on the proper selection and optimal use of the attack tools. In this figure, the regions identified as threat severity level III assumes that only hand powered tools and some limited battery powered tools are used. For these cases, the thickness and/or reinforcing bar combination required is less than for the threat severity level IV where power and thermal tools also may be used.

>10 (250)	A	A	A	A	A	A	A

5-5.1.3 Walls to Resist Severity Level V.

The only two ways to harden a structure against these types of threats are to construct massive reinforced concrete or sacrificial barrier walls.

The use of bulk explosives or LSCs designed to direct energy, can be especially effective in breaching barriers and producing holes large enough for an aggressor to crawl through. While bulk explosives can produce large holes, even in thick concrete walls, they will not cut internal reinforcing material. The shock waves produced by an explosion propagate throughout the concrete, resulting in internal fragmentation and spalling (breaking off) of the inner and outer surfaces. The pressure of the explosive will force concrete fragments out of a wall creating a relatively clean hole. Cutting and removing the reinforcing material to create a crawl hole creates most of the delay.

a. Thick, heavily reinforced concrete walls can provide significant penetration resistance. Use reinforced concrete 18 to 48 inches (0.46 to 1.2 m) thick. Table 5-3 presents the estimated minimum penetration delay times provided by varied thicknesses of reinforced concrete that has a compressive strength of at least 5,000 psi (35,500 kPa).

   Table 5-4 provides options that can be considered based on structural and cost considerations.

Table 5-3 Reinforced Concrete Designs for Threat Severity Level V

CONCRETE THICKNESS, INCH (M)	REINFORCING BAR LAYERS – NO. 6 (19 MM) ON 6-INCH (150-MM) CENTERS	MINIMUM PENETRATION DELAY TIME (MINUTES)[a]
≤8 (≤0.2)	1	≤1
12 (0.3)	2	2
18 (0.46)	3	3
24 (0.6)	4	4.5
36 (0.9)	6	8
48 (1.2)	8	13

[a] Use of bulk explosives to remove the concrete and using power and thermal tools to cut the reinforcing bars.

b. Sacrificial barriers can be employed above, below, and around the critical area in the building. The walls, doors, and other features of this sacrificial area may be damaged but will provide cumulative delay created by the necessity to breach multiple barriers, transport breaching tools through each barrier, and retreat to a safe distance before the next barrier is breached. In general, the critical area should be internal to the building, and away from exterior walls and roofs.

55	8-INCH, SOLID-CORE, FILLED CONCRETE MASONRY WITH #6 BARS AT 4 INCHES OC VERTICALLY AND 8 INCHES OC HORIZONTALLY			5	
56	12-INCH, REINFORCED CONCRETE WITH # 5 BARS AT 6 INCHES OC EW			15	
57	12-INCH, REINFORCED CONCRETE WITH 2 LAYERS OF # 7 BARS AT 4 INCHES OC EW		30		
58	12-INCH, REINFORCED CONCRETE WITH 5/16 EXPANDED METAL 2½ INCHES OC (4 LAYERS)				5
59	12-INCH, REINFORCED CONCRETE WITH 5/16-INCH, EXPANDED, METAL MESH AT 2½ INCHES OC AND A ¼-INCH BACKING PLATE			30	15
60	18-INCH-THICK REINFORCED CONCRETE WITH 5/16-INCH EXPANDED METAL AT 2- 1/2 INCHES OC AND A 1/4-INCH BACKING PLATE				30

NOTES: For the use of the above table, refer to Paragraph 5-4.
Where not specified in the table, use 3000 psi concrete.

5-5.2 Roofs.

Conventional roof construction offers little resistance to downward forced entry attack, except where reinforced concrete slabs form the structure.

5-5.2.1 Roofs to Resist Threat Severity Level II.

Solid plywood roof construction provides a delay of less than one minute against threat severity level II. Since greater delay is required, use one of the roof types shown in Table 5-5.

5-5.2.2 Roofs to Resist Threat Severity Levels III and IV.

Protection against threat severity levels III and IV requires the use of conventional or fiber reinforced concrete. Use one of the concrete thickness options in Figure 5-2 and Figure 5-3 combined with the reinforcing bar options in Table 5-2 for roof designs; however, for a downward attack on a roof, penetration delay times are lower for a similar attack on a wall; therefore, to achieve the same delay rating, use an additional thickness of 1-inch (25-mm) concrete, or the same concrete thickness and increase the reinforcement by 2 bar sizes.

Table 5-5 contains several additional design options that provide delays from 2 to 30 minutes.

5-5.2.3 Roofs to Resist Threat Severity Level V.

Threat severity level V requires sacrificial areas, multiple barriers, or massive reinforced concrete. For the reinforced concrete design, use one of the options in Table 5-5 with entries for the threat severity level V.

Sacrificial barriers can be employed above the protected area in the building. The features of these sacrificial areas may be damaged but will provide cumulative delay created by the necessity to breach multiple barriers, transport breaching tools through each barrier, and retreat to a safe distance before the next barrier is breached. Any type of construction for the sacrificial barrier is acceptable if the barrier provides an equivalent level of penetration resistance to lower threat severity levels.

Table 5-5 Roof Materials

ITEM NUMBER	ROOF MATERIAL DESCRIPTION	THREAT SEVERITY LEVEL			
		II	III	IV	V
1	GRAVEL ON ASPHALT, 2" INSULATION ON 2-1/2" CONCRETE	3

ITEM NUMBER	ROOF MATERIAL DESCRIPTION	THREAT SEVERITY LEVEL			
		II	III	IV	V
28	12-INCH-THICK, REINFORCED CONCRETE WITH 5/16-INCH EXPANDED METAL AT 2½ INCHES ON CENTER, ¼-INCH STEEL DECKING, AND BUILT-UP ROOFING				30*

NOTES: For the use of the above table, refer to Paragraph 5-4.
Where not specified in the table, use 3000 psi concrete.

5-5.2.4 Roof-Mounted Equipment.

Roof-mounted equipment, such as air-supply fans, exhaust fans, gravity ventilators, and filter banks, are usually welded or bolted to an equipment curb, duct system, or foundation and can be removed with simple hand tools. Openings uncovered when equipment is removed can provide entry to the interior of the building. In many installations, the removal of a small number of bolts, plus the removal of the equipment, can provide access. For protection of an exposed opening consider on the following alternatives:

- When possible, limit the exposed opening to less than 96 square inches (619 cm^2) with no dimension greater than 6 inches (150 mm).
- Provide grilles constructed of metal bars to provide delay. See Table 5-21 for the size and spacing of bars for the defense layer penetration delay time.
- Provide a hardened equipment cover to house the machinery. Equipment cover penetration delay time will depend on structural components, doors, and other openings. Specific penetration delay times can be estimated by the same methods described for structures throughout this manual. The use of the equipment cover option must be weighed against the probability, likelihood, and logistics involved with removal of the roof-mounted equipment.

5-5.2.5 Structural Openings.

Structural openings, such as skylights, roof hatches, scuttles, elevator shafts, ash dumps, rubbish chutes, fire escapes, and roof access ladders, offer access to aggressors and should be considered in hardening plans. The approach to upgrading miscellaneous openings is dictated by the structural elements involved (design of walls, roofs, doors, and locking mechanisms).

5-5.2.6 Other Openings.

Secure all hatches, penthouses, and exterior ladders.

5-5.2.7 Roof Styles and Railings.

Use steeply pitched roof structures where possible to make movement difficult and to minimize concealment opportunities provided by flat roofs.

For flat roofs, use railings instead of solid parapets to minimize concealment opportunities.

5-5.3 Ceilings and Floors.

Floor and ceiling assemblies are the horizontal (top and bottom) components of the 6-sided intermediate defense layers. Floors may be exposed to exterior forced entry if the asset is in the space above the floor and the aggressors gain access to the space below; and, ceilings may be exposed to forced entry if the asset is in the space below the ceiling and the aggressors gain access to the space above. Select floor and ceiling construction which provides the required delay time where applicable.

5-5.3.1 Ceilings and Floors to Resist Threat Severity Level II.

Conventional construction of 3/4 inch (19 mm) plywood on wood joists for ceilings and floors can be used to provide the required one minute of penetration delay.

5-5.3.2 Ceilings and Floors to Resist Threat Severity Levels III and IV.

Threat severity levels III and IV necessitate the use of conventional or fiber reinforced concrete. Use one of the concrete thickness options in Figure 5-2 and Figure 5-3 combined with the reinforcing bar options in Table 5-2 for ceiling and floor designs. Table 5-6 contains several additional design options that provide delays from 2 to 30 minutes.

In general, for reinforced concrete walls less than 12 inches (30 cm) thick, the following rules of thumb for companion ceilings will apply. Penetration delay times for an upward attack on a ceiling (floor of upper level) will be higher than the same attack on a wall; therefore, use the next lowest thickness of 1-inch (25-mm) concrete or use the same concrete thickness and decrease the reinforcement by 2 bar sizes. For a downward attack on a roof, penetration delay times are lower for a similar attack on a wall; therefore, to achieve the same delay rating, use an additional thickness of 1-inch (25-mm) concrete, or the same concrete thickness and increase the reinforcement by 2 bar sizes.

5-5.3.3 Ceilings and Floors to Resist Threat Severity Level V.

Thick, heavily reinforced concrete ceilings and floors can provide significant penetration resistance. Use reinforced concrete 18 to 48 inches (0.46 to 1.2 m) thick. Table 5-3 presents the estimated minimum penetration delay times provided by varied thicknesses of reinforced concrete that has a compressive strength of at least 5,000 psi (507,000 kPa). Table 5-6 provides options that can be considered based on structural and cost considerations.

Table 5-6 Floor or Ceiling Materials

ITEM NUMBER	FLOOR OR CEILING MATERIAL DESCRIPTION	THREAT SEVERITY LEVEL			
		II	III	IV	V
1	PLYWOOD ON WOOD JOISTS	1	1	1	1
2	PLYWOOD ON WOOD JOISTS W/INSULATION	1		1	<1*
3	4-1/2" REINFORCED CONCRETE (#4 BARS @ 18" EW) AND 16 GA SHEET METAL	6			2*
4	5-1/2" REINFORCED CONCRETE (10 GA STEEL MESH)	6			
5	8" REINFORCED CONCRETE (#4 BARS @ 9" EW)			12	11/<2*
6	12" REINFORCED CONCRETE (#5 BARS @ 6" EW, EF)			23	22/<3*
7	3" CONCRETE, #10 6" STEEL MESH, 2-1/2" CONCRETE PLANK	6		2	
8	CARPET, 1-1/2" PLYWOOD, 3" SILICATE INSULATION		5	1	<1*

NOTES: For the use of the above table, refer to Paragraph 5-4.
Where not specified in the table, use 3000 psi concrete.

5-5.3.4 Slabs on Grade.

Use minimum 6-inch thick reinforced concrete with #4 bars (1/2-inch, 13 mm) reinforcing bars spaced at 6 inches OC, EW.

5-5.4 Personnel Entrances.

The number of entrances to a defense layer should be limited to one personnel entrance and the minimum number of emergency exit doors required for life safety per National Fire Protection Association (NFPA) 101.

5-5.4.1 Specifying Door Assemblies.

When specifying door assemblies, ensure that the threat severity level and required penetration delay time is included. Refer to UFGS-08 34 63 for design and installation requirements.

5-5.4.2 Personnel Entrances to Resist Threat Severity Level II.

Use doors and frames that are built and installed according to National Association of Architectural Metal Manufacturers/ Hollow Metal Manufacturers Association (NAAMM/HMMA) Hollow Metal Manual standards. Doors and frames meeting these requirements will provide at least a 1-minute penetration delay time against a threat severity level II. If more delay time is needed, use multiple doors placed in series.

Personnel door and frame details for severity threat level II are shown in Table 5-7 and Table 5-8. The frame is designed for installation in a wood-stud frame wall. Hinge-side protection should be provided as shown in Figure 5-4.

Table 5-7 Personnel Door Panel/Edge Details, Threat Severity Level II

COMPONENT	REQUIREMENT
Size	3 feet by 80 inches by 1-3/4 inches (0.9 m by 2 m by 44 mm).
Applicable Specifications	NAAMM/HMMA, Hollow Metal Manual – 1995., UFGS-08 34 01.
Type	Type A, full-flush with continuous welded-edge seams. Design F, full-panel flush door.
Panel	Steel-stiffened.
Face Sheet	16-gauge (1.6 mm) steel.
Stiffeners	Hat section, 16-gauge (1.6 mm) steel; maximum distance between stiffeners 4 inches (100 mm) OC.
Edge Construction	14-gauge (1.9 mm) steel channel, recessed.

Table 5-8 Personnel Doorframe Details, Threat Severity Level II

COMPONENT	REQUIREMENT
Applicable Specifications	Construct per NAAMM/HMMA, Hollow Metal Manual – 1995 except as noted, UFGS-08 34 01.
Frame Design	Single door, butt-type, double-rabbet type; 14-gauge (1.9 mm) steel, fully welded.
Jamb Depth	4 inches (100 mm).
Special Features	(See Figure 5-4 for hinge side protection.)
Frame Installation	Install per NAAMM/HMMA, Hollow Metal Manual – 1995. Install frame into a wood-stud frame wall.
Hardware Preparation	Prepare hardware per NAAMM/HMMA, Hollow Metal Manual – 1995.

Table 5-9 Door Hardware for Threat Severity Levels II and III

COMPONENT	REQUIREMENT
Mortise Lock	American National Standards Institute/Building Hardware Manufacturers Association (ANSI/BHMA) A156.13 Series 1000 Security Grade, with dead bolt and latch bolt.
Auxiliary Rim Lock	ANSI/BHMA A156.5, Security Grade drop bolt lock operated by key from inside and outside. Lock selected must conform to mounting bolt tensile test [12,000 pounds (5,450 kg)]. This lock should be used in conjunction with anti-wedge and anti-drill plates. To comply with life safety requirements, this lock should only be used during those hours when the space is unoccupied.
Hinges	ANSI/BHMA A156.1. Heavy Weight. Note: security door systems for threat severity level III require some form of hinge side protection. Some hinge manufacturers provide this type of protection in the form of shear plugs incorporated into the hinge or hinge pins that are not removable. If these types of hinges are not used, then some form of hinge side protection should be engineered into the door system. For added protection against door sag, surface-mounted continuous hinges can be used.
Panic Hardware	American Society for Testing and Materials (ASTM) F571, Grade 1, Mortise exit device. Use panic type exit devices as required by life safety codes in lieu of this mortise lock; however, to ensure resistance to threat severity level III, use in conjunction with an auxiliary rim lock.
Other Hardware	If the use of additional hardware such as closing devices and electric strikes, among others, is required, ensure that the hardware selected meets ANSI/BHMA requirements, and does not interfere with the security devices on the door systems. Consult with the DoD Lock Program, NAVFAC Engineering and Expeditionary Warfare Center, Toll Free: (800) 290-7607 Comm: (805) 982-1212, if there are any questions.

5-5.4.3 Personnel Entrances to Resist Threat Severity Level III.

Use doors and frames that are built and installed according to ANSI/NAAMM HMMA 863-14. Doors and frames meeting these requirements will provide at least a 4-minute penetration delay time against threat severity level III. If more delay time is needed, use multiple doors placed in series.

Personnel door and frame details for threat severity level III are shown in Table 5-10 and Table 5-11. The frame is designed for installation in a reinforced CMU wall. Hinge-side protection should be provided as shown in Figure 5-4.

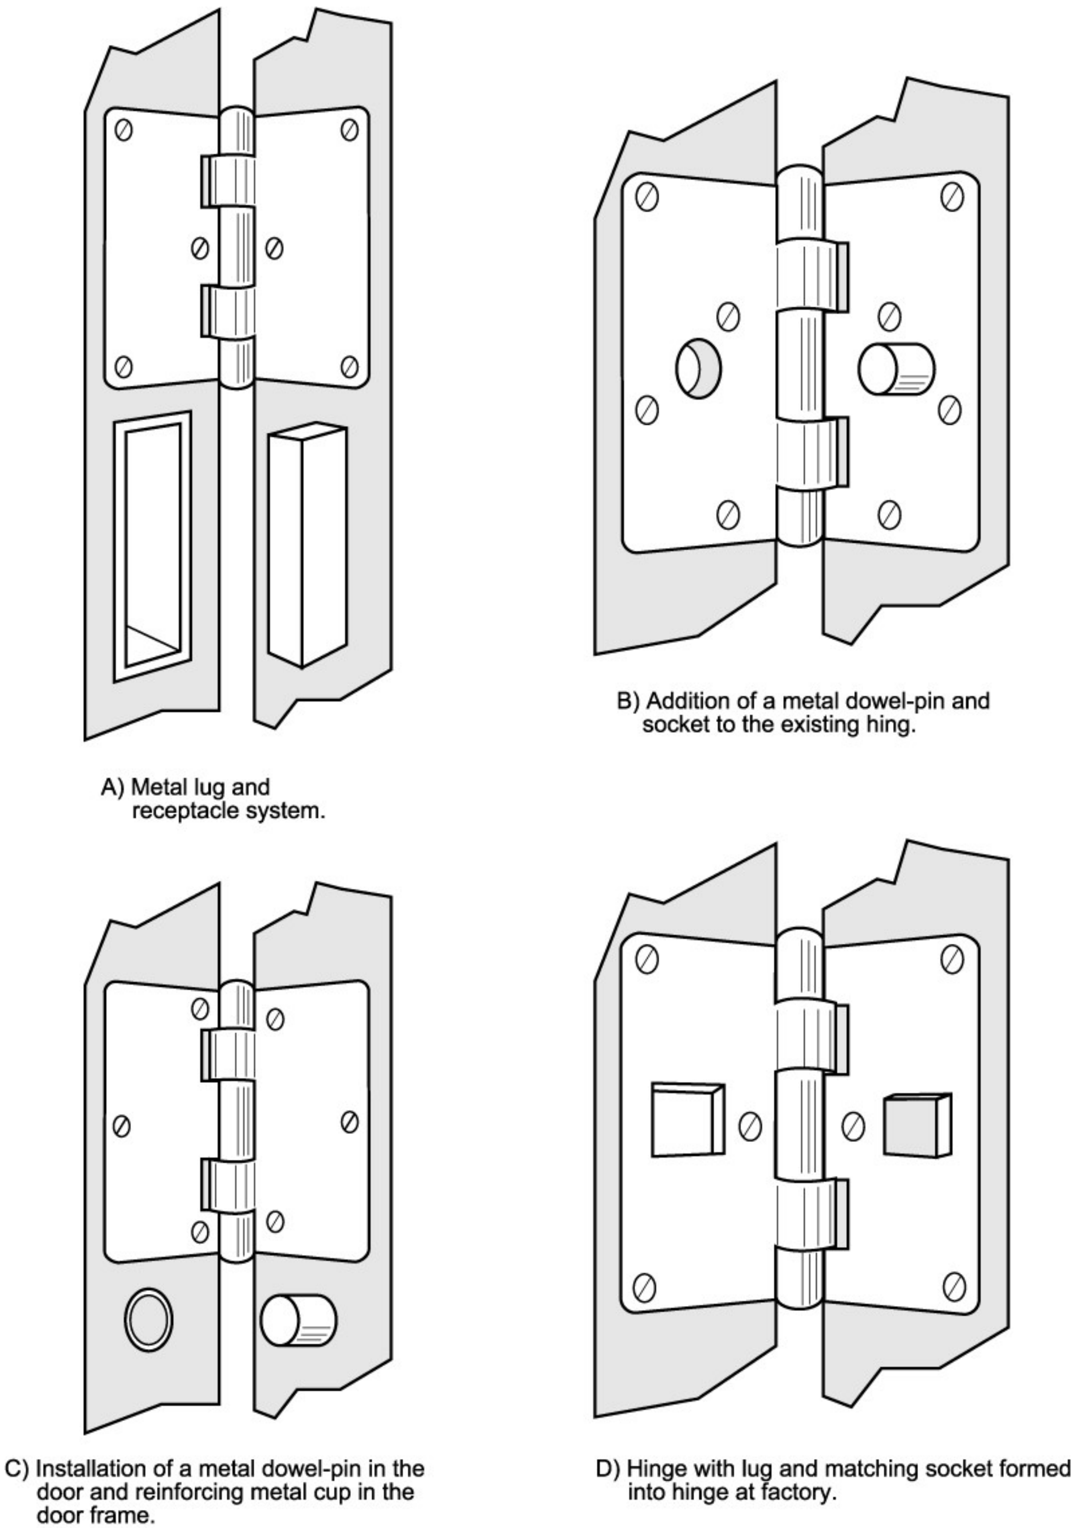
Table 5-10 Door Panel/Edge Details for Threat Severity Level III

COMPONENT	REQUIREMENT
Size	3 feet by 80 inches by 1-3/4 inches (0.9 m by 2 m by 44 mm).
Applicable Specifications	ANSI/NAAMM HMMA 863-14.
Type	Type A, full flush with continuous welded-edge seams. Design F, full-panel flush door.
Panel	Steel-stiffened.
Face Sheet	14-gauge (1.9 mm) steel.
Stiffeners	Hat section, 14-gauge (1.9 mm) steel; maximum distance between stiffeners 4 inches (100 mm) OC.
Edge Construction	12-gauge (2.7 mm) recessed steel channel.
Special Features	(See Figure 5-4 for the hinge side protection configuration and Figure 5-5 for the 7-gauge (4.5 mm) anti-pry strips).

Table 5-11 Doorframe Details for Threat Severity Level III

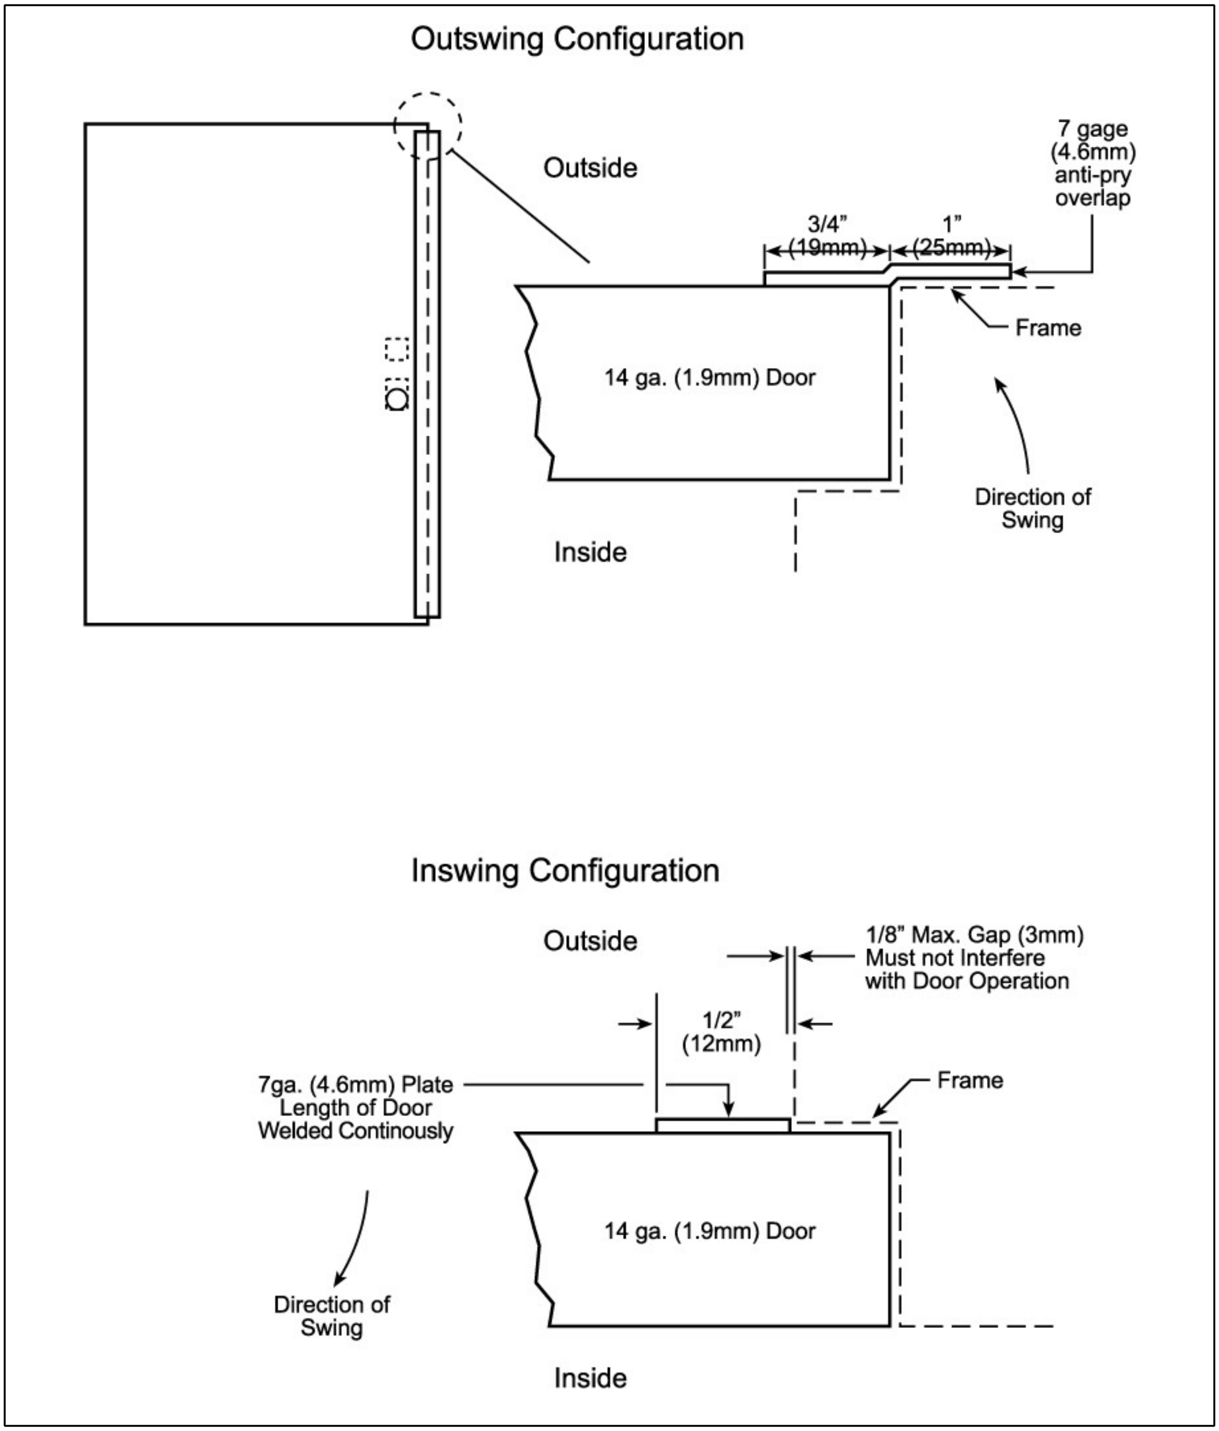
COMPONENT	REQUIREMENT
Frame Thickness	12 gauge (2.7 mm)
Applicable Specifications	Construct per HMMA 863-14 except as noted.
Frame Design	Single door, butt-type, double-rabbet type; 10-gauge (3.4 mm) steel, fully welded.
Jamb Depth	8 inches (200 mm)
Special Features	(See Figure 5-4 for details on hinge-side protection.)
Frame Installation	Install per HMMA 863-14 and NAAMM HMMA, Hollow Metal Manual
Hardware Preparation	Prepare for hardware per HMMA 863-14. Use one of the two cases below for selecting installation hardware: Frame to be installed in a CMU wall with the frame installed and the wall built to the frame. Provide adjustable 2- by 10-inch (50- by 254-mm) corrugated 12-gauge (2.7 mm) frame side. Ensure that the reinforcing bars of the CMU wall tie into the interior of the frame. Fill frame with a grout of compressive strength not less than 3,000 psi (21,000 kPa). Frame is to be installed in a prepared opening in a CMU wall. Frame must be punched and countersunk for expansion bolt anchors (four per side) and provided with 12-gauge (2.7 mm) hat shaped reinforcements secured in place with at least four spot welds each. Fill frame with a pour type grout with a compressive strength of not less than 3,000 psi (21,000 kPa).

Figure 5-4 Door Hinge-Side Protection Threat Severity Levels II and III



Note: Lugs, dowel-pins, etc. should be 1-inch-diameter (25.4mm) minimum.

Figure 5-5 Door Anti-Pry Strips for Threat Severity Level III



5-5.4.4 Personnel Entrances to Resist Threat Severity Levels IV and V.

There are no personnel doors rated to resist threat severity levels IV and V. Use multiple threat severity level III personnel doors mounted in series or use a vault door. Consider using a day gate during daytime operations.

5-5.5 Doors (Non-Entry).

The number of doors needed to secure a defense layer should be minimized. In cases where more than one door exists, only one (personnel entrance) should be provided with exterior mounted locks. All other non-entry doors to the defense layer must present blank, flush surfaces to the outside and have internal locking or bolting mechanisms to reduce the vulnerability to attack.

5-5.5.1 Door Panel Construction (Non-Entry).

Table 5-12 shows options for door panel construction to resist all threat severity levels. Although the penetration delay time through the door surface can usually be increased by use of thicker or composite materials, such hardening may be constrained by weight, functional requirements (disability access requirements or safety), mounting hardware, or locking system vulnerability. There is no value in hardening a door surface beyond the attack resistance of the available mounting hardware and locking system technology.

Table 5-12 Door Materials

ITEM NUMBER	DOOR MATERIAL DESCRIPTION	THREAT SEVERITY LEVEL			
		II	III	IV	V
1	2 LAYERS 10 GA HOT-ROLLED STEEL, 1 LAYER 3/4" EXTERIOR PLYWOOD	6			
2	3 LAYERS 10 GA HOT-ROLLED STEEL, 2 LAYERS 3/4" EXTERIOR PLYWOOD	12

36	SWINGING DOOR (6 INCHES THICK) WITH 1/2-INCH PLATE INSIDE AND OUT, LIGHTWEIGHT CONCRETE FILL, AND AN INTERNAL LOCKING SYSTEM		30		

ITEM NUMBER	DOOR MATERIAL DESCRIPTION	THREAT SEVERITY LEVEL			
		II	III	IV	V
37	SLIDING DOOR (6 INCHES THICK) FILLED WITH LIGHTWEIGHT CONCRETE THAT HAS BEEN REINFORCED WITH EXPANDED METAL MESH WITH A 3/4-INCH STEEL FRONT PLATE, 1/4–INCH BACK PLATE, AND AN INTERNAL LOCKING SYSTEM				5
38	SWINGING DOOR (10 INCHES THICK) WITH 1/2-INCH PLATE INSIDE AND OUT INTERNAL LOCK		15		
39	SWINGING DOOR (10 INCHES THICK) WITH 1/2-INCH PLATE INSIDE AND OUT, LIGHTWEIGHT CONCRETE FILL, AND AN INTERNAL LOCKING SYSTEM			15	
40	SWINGING DOOR (10 INCHES THICK) WITH 1/2-INCH PLATE INSIDE AND OUT, LIGHTWEIGHT CONCRETE FILL REINFORCED WITH EXPANDED METAL MESH, AND AN INTERNAL LOCKING SYSTEM			30	15
41	SWINGING DOOR (10 INCHES THICK) WITH 1/2-INCH PLATE INSIDE AND OUT, LIGHTWEIGHT CONCRETE FILL REINFORCED WITH EXPANDED METAL MESH, AND AN INTERNAL LOCKING SYSTEM WITH A WELDED C-STEEL GRATING VESTIBULE AROUND THE DOOR FOR STANDOFF PROTECTION				30

NOTE: For the use of the above table, refer to Paragraph 5-4.

5-5.6 Emergency Exit Hardware.

When the area is to be occupied and emergency exit hardware is required for fire protection requirements, use a light industrial door with an intrusion sensor and provide forced entry resistance interior to the door.

Since drilling a small hole large enough to pass a wire hook through is all that is required to trip emergency exit hardware, for unoccupied areas, auxiliary rim locks or mortise locks can be used to secure the doors.

5-5.7 Vehicle Access Doors.

Table 5-13 provides a summary of the door construction choices applicable to vehicle access doors for the threat severity levels II and III. There are no commercial vehicle access doors available that will provide penetration resistance equivalent to wall systems designed for threat severity threat level IV or V. If used for threat severity level IV or V, consider separating vehicle access areas from the protected asset. In this configuration delay time calculations may be layered beginning at the barrier system beyond the vehicle storage area and the vehicle storage area can be used as a detection buffer for the secure area.

5-5.7.1 Threat Severity Level II.

For threat severity level II, use a standard 18-gauge (1.2-mm) galvanized steel overhead coiling door with interlocking slats. Refer to UFGS-08 33 23 for installation details.

5-5.7.2 Threat Severity Level III.

For threat severity level III, use a 1-3/4-inch (44-mm) thick hollow metal door with 12-gauge (2.7-mm) skins and stiffeners on 6-inch (150-mm) vertical spacing similar to a sliding magazine door. Refer to UFC 4-420-01 for designs.

The trailing edge of the sliding magazine door must be restrained using a 4-foot (1.2-m) high, 8-inch (20-cm) diameter concrete filled steel bollard along the outside trailing edge to prevent wedging attacks that move doors away from walls.

Table 5-13 Vehicle Access Door Construction

THREAT SEVERITY LEVEL	CONSTRUCTION	PENETRATION DELAY TIME (MINUTES)
II	18-gauge (1.2-mm) galvanized steel with interlocking slats.	1
III	1-3/4-inch (44-mm) thick hollow metal door with 12-gauge (2.7-mm) skins and stiffeners on 6-inch (150-mm) vertical spacing.	4

5-5.8 Windows.

Because forced entry resistant window enhancements are costly, minimize windows where possible in defense layers that are counted on for penetration delay. Security glazing systems are commercially available that will meet the requirements for threat severity levels II, III, and IV (up to 5 minutes of delay). There are no cost-effective glazing cross sections available for threat severity levels V. For commercially available windows use the anchoring method prescribed by the window certification.

Consider the placement of windows in relation to doors. Even a small window in or next to a door could allow an aggressor to reach through and unlock the door. Use obscured glazing materials, blinds, shutters, or drapes to eliminate asset visibility.

5-5.8.1 Specifying Window Assemblies.

When specifying window assemblies, ensure that the threat severity level and required penetration delay time is included.

5-5.8.2 Windows to Resist Threat Severity Level II.

Glazing, frame, and anchor designs for windows to resist threat severity level II are provided in Table 5-14 through Table 5-16 for one minute of penetration delay. These designs are for installation in a wood frame wall. Other options for window components are available in Table 5-20.

Table 5-14 Glazing Specifications - Threat Severity Level II

TYPE	MINIMUM THICKNESS	CROSS-SECTION
Air Gap	1 inch (25 mm)	1/4 inch (6 mm) Laminated Annealed Glass, 1/4 inch (6 mm) AIR, 1/2 inch (13 mm) Laminated Polycarbonate
Extruded Ionomer	13/16 inch (20 mm)	3/16 inch (5 mm) Annealed Glass, 1/2 inch (13 mm) extruded IONOMER, 1/8 inch (3 mm) Annealed Glass
Glass-Clad Polycarbonate	11/16 inch (17 mm)	3/16 inch (5 mm) Annealed Glass, 3/8 inch (10 mm) Polycarbonate, 3/16 inch (5 mm) Annealed Glass
Monolithic Polycarbonate	3/8 inch (10 mm)	3/8 inch (10 mm) Polycarbonate

5-5.8.4 Windows to Resist Threat Severity Level IV.

There are few commercially available glazing systems that provide forced entry resistance against threat severity level IV. See Table 5-20 for window component options.

5-5.8.5 Windows to Resist Threat Severity Level V.

There are no commercially available glazing systems that provide forced entry resistance against threat severity level V. When the threat severity is established at level V, windows should be eliminated, sized below the man-passable threshold, or designed as slat windows (long narrow windows less than 6 inches (150 mm) wide).

Table 5-20 Window Materials

ITEM NUMBER	WINDOW MATERIAL DESCRIPTION	THREAT SEVERITY LEVEL			
		II	III	IV	V
1	1/2" POLYCARBONATE GLAZING	3	1

NOTE: For the use of the above table, refer to Paragraph 5-4.

5-5.8.6 Grilles and Grates.

Alternatives to the use of glazing systems may be grilles or gratings over the window openings. Combinations of glazing and grilles can also be used to increase delay time. Note that the use of grilles or grates over windows that can be used as fire exits must comply with the Life Safety Code.

Table 5-21 shows that penetration delay time is directly related to the diameter and spacing of the protective bars. If, for example, No. 5 (16mm) bars are spaced 3 inches (75 mm) apart (both vertically and horizontally) to form a grille, a penetration delay time of about 2.5 minutes can be achieved. When bars are used to delay penetration, properly anchoring them to the wall is critical, since it may be easier to break them loose than to cut them. Bar type grills should only be used with concrete walls, ceilings, roofs, slabs, or CMU walls. They must be embedded at least 6 inches (150 mm) into the wall, welded to a steel frame with concrete anchors, and cast in place during construction.

Table 5-21 Time Required for Making a Man-Passable Opening in Grilles

BAR SIZE	3/8 INCH (10 MM)	1/2 INCH (13 MM)	5/8 INCH (16 MM)	3/4 INCH (19 MM)
SEVERITY THREAT LEVELS II and III			SEVERITY THREAT LEVEL IV	
SPACING	TIME (MINUTES)	TIME (MINUTES)	TIME (MINUTES)	TIME (MINUTES)
3 inches (75 mm)	1.2	1.7	2.5	3.5
3.5 inches (90 mm)	0.8	1.2	1.6	2.3
4 inches (100 mm)	0.8	1.2	1.6	2.3
4.5 inches (115 mm)	0.8	1.2	1.6	2.3
5-9 inches (125-225 mm)	0.4	0.6	0.8	1.2

NOTES: Estimated times are for a single-layer grille composed of steel bars of the diameter shown, equally spaced both horizontally and vertically.

Times shown are total time measured in minutes required to provide a man-passable opening of at least 96-square-inch (619 cm^2) or with a single rectangular dimension greater than 6 inches (15 cm).

All reinforcing bar should be embedded at least 6 inches (15 cm) into the surrounding concrete wall and welded at intersections.

5-5.9 Utility Openings.

Utility openings, manholes, tunnels, air conditioning ducts, filters, or equipment access panels can provide aggressors with an easily accessible entrance or exit route. These passages can also circumvent existing IDS. Such openings must be eliminated or kept below the man-passable 96 square inches (619 cm^2) threshold. For long utility conduits, it is not always necessary to hold to the minimum man-passable threshold. For these cases, the threshold can be increased to 144 square inches (930 cm^2) depending on the configuration of the conduit. Bends in long utility runs effectively impede movement through the conduit. Where exits from a utility conduit (manholes and junction boxes, among others) can be effectively sealed from the secure side, the size of the conduit is immaterial unless direct access to the secure space and bypass of the IDS is possible. Ensure that mechanical designers are aware of any restrictions of utility openings being designed so they can adjust air flow designs to accommodate the restrictions; this is particularly import for HVAC designers.

5-5.9.1 Utility Opening Treatments to Resist Threat Severity Levels II and III.

When it is not feasible to hold to the minimum man-passable 96 square inches (619 cm^2) threshold, use single or multiple gratings or grilles for threat severity levels II and III. Protect man-passable openings with the treatments shown in Table 5-21 and Table 5-22 to provide the indicated delay times. Delay times in the tables are for a single layer.

Table 5-22 Utility Opening Materials

Item Number	Utility Opening Material Description	Threat Severity Level			
		II	III	IV	V

NOTE: For the use of the above table, refer to Paragraph 5-4.

5-5.9.2 Utility Opening Treatments to Resist Threat Severity Level IV.

Use grilles constructed with larger size bars (No. 5 (16 mm) or greater) and various constrictive barrier designs for threat severity level IV. Options are shown in Table 5-21.

5-5.9.3 Utility Opening Treatments to Resist Threat Severity Level V.

Threat severity level V requires sacrificial enclosing structures around openings.

5-5.9.4 Special Treatments for Utility Openings.

The following describes typical utility openings and protective design options for hardening them when they cannot be eliminated or sized below the man-passable threshold.

5-5.9.4.1 Sewers and Manholes.

Providing multiple pipes, each less than the man-passable opening threshold, is more desirable than a single large pipe. If a large passageway is required, structural walls, floors, and foundations that are accessible from underground passageways should provide penetration delay times equivalent to the basic structure. Access points from sewer lines into secure structures should be equipped with IDS that can detect intrusion activities. The use of grilles in storm and sanitation systems should be avoided because of the operation and maintenance problems caused by such structures. Where grilles are required on storm sewers, inlet filter screens are highly recommended to prevent clogging.

5-5.9.4.2 Pipe Chases.

Pipe chases are horizontal or vertical framed-in passageways that vary in size. They are typically constructed of studs and gypsum board. If unprotected, vertical chases connecting adjacent floors or horizontal chases running through walls may provide access to secure areas. Horizontal chases may provide little resistance to movement except obstacles such as internal equipment, piping, cable, and the entrance door(s). Chases provide entrance and exit points to overhead crawl spaces. Pipe chases that provide man-passable access to HVAC ducts and maintenance crawl spaces larger than the man-passable opening threshold should be alarmed or barriers inserted to prevent free movement through the pipe chase.

5-5.9.4.3 Exhaust Vents.

Exhaust vents through roofs and walls are usually protected by the associated equipment. Because the ductwork and dampers are usually constructed of light sheet metal, penetration can be easily accomplished with a low severity threat tool mix. Typical exhaust ducts range in size up to 4 by 8 feet (1,200 by 2,400 mm). The discussion of hardening techniques under gravity vents, ventilation ducts, and air distribution fixtures generally applies in the case of exhaust vents.

5-5.9.4.4 HVAC Ductwork and Vent Pipes.

If maintenance access is not required, filling duct openings with a 2-foot (0.6-m) length (minimum) of steel pipe, welded together and anchored securely in place by a welded steel plate on the inside (secure side) of the structure as shown in Figure 5-6 is an option. The honeycomb material should be made of steel. For this barrier system, penetration delay time will result from the length of the honeycomb and the necessity for multiple long cuts and debris removal in the relatively restricted space of the duct. If possible, such a barrier should be located at a sharp turn to further restrict the use of cutting tools. This arrangement can also be used for tunnels with electrical lines, since maintenance personnel can have access to both sides of the impediment (constriction), and cables can be threaded through the relatively short constriction.

An alternative option is to weld the steel pipes front and back at least 3 inches (75mm) on each end and at each point where the steel pipes intersect. No steel pipe diameter inside the pipe should be greater than the man-passable threshold opening. A second approach is to eliminate the center steel pipe and to connect the remaining pipes inside the tunnel with continuous welds; however, if this approach is taken, the designer should be careful to ensure that the area in the center, which would have been filled by the seventh center pipe, as shown in Figure 5-7, is not a man-passable opening. These constrictions should be located at secure walls with equivalent penetration resistance. The length of the constriction will force an aggressor to attack and remove each barrier separately. The confined working space and the necessity for debris removal further add to penetration delay time.

Figure 5-6 Vent and Duct Hardening Barriers

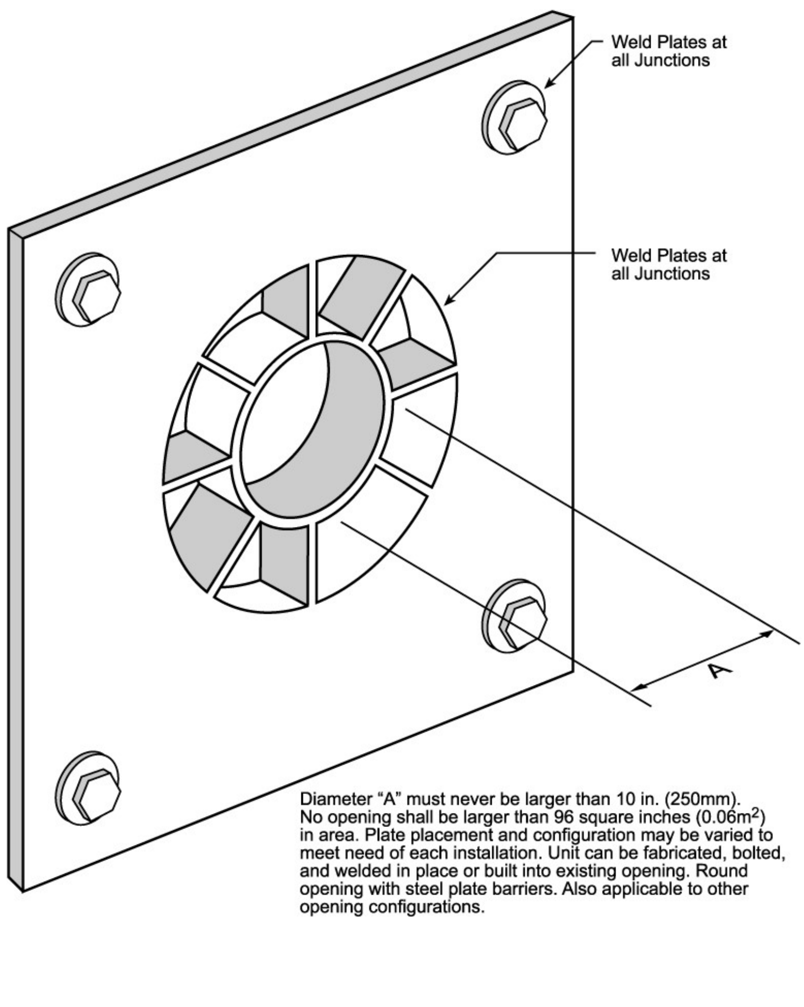

Figure 5-7 Vent Pipe and Chase Protection

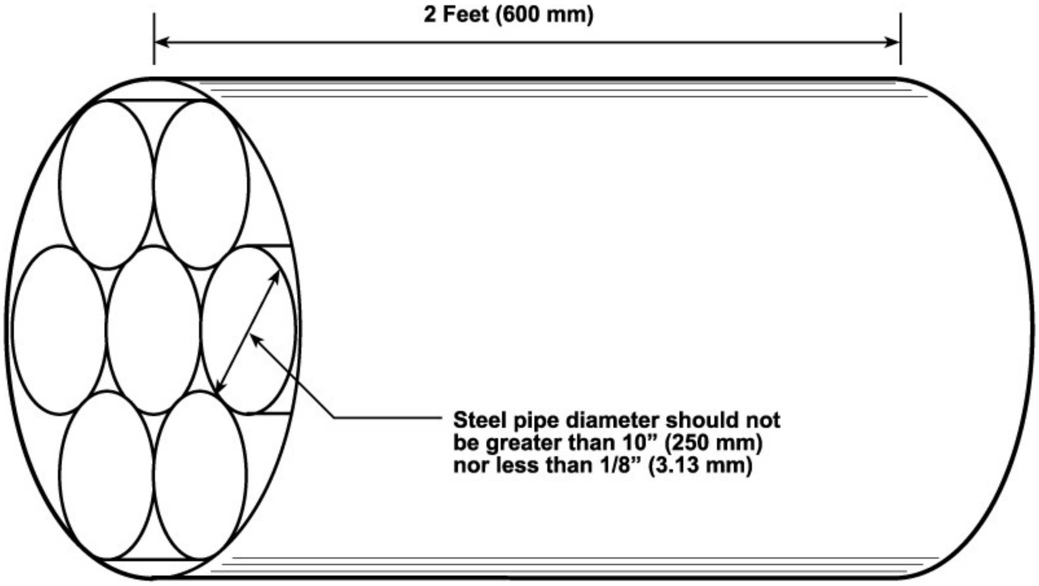

5-5.9.4.5 Sleeves and Trays.

Sleeves are pipe penetrations through walls, roofs, and ceilings. Trays are removable, sheet-metal-covered conduits. Sleeves and trays that penetrate security walls should be less than the man-passable opening threshold. Penetrations should be angled upward and, to the extent practical, contain sharp turns to prevent the easy introduction of hooks, cables, or explosive devices. Penetration resistant barriers are similar to those used to protect pipe chases.

5-5.9.4.6 Ducts.

Ducts are round or square sheet metal or fiberglass conduits that may vary in size. Ducts constructed of sheet metal, usually 28 gauge (0.4 mm) through 14 gauge (1.9 mm), can readily be cut with hand tools and light power tools. These ducts do not present a significant barrier to penetration. Penetration resistance is, however, sometimes enhanced using ducts of less than man-sized cross section and the inclusion of required apparatus, such as turning vanes, dampers, pressure plates, and final air distribution fixtures. Duct dimensions should be kept at less than a man-passable cross section. Penetration resistant barriers are similar to those used to protect pipe chases.

5-5.9.4.7 Filter Banks.

Filter banks are unlikely to offer any significant penetration delay time. A hardened enclosure, with one of the vent or duct-hardening techniques should be used to prevent aggressor entry.

5-6 RETROFIT CONSTRUCTION.

This section provides design options for retrofitting an existing building against forced entry attack. The objective of the design is to increase the penetration resistance of the existing building using retrofit options that provide the required penetration delay against the threat severity level for the building. The design should also provide a balanced design between all building components. The following paragraphs provide forced entry delay expected from the existing construction followed by the penetration delay time enhancement of various retrofit options.

5-6.1 General.

Determine if the existing structure and foundations will support the additional weight of the enhanced construction. If not, the use of additional defense layers may be an alternative to retrofit.

5-6.2 Walls.

Solid plywood construction can be used to resist a low severity threat. For severity threat levels III and IV, the choices are limited to grout-filled and reinforced CMUs for lower delay time requirements, and conventional or SFR concrete for higher delay time requirements. Threat severity level V will require sacrificial areas, multiple barriers, or reinforced concrete barriers.

The following paragraphs provide information for estimating the penetration delay times for walls in existing facilities and retrofit options for hardening these walls if additional delay time is required.

5-6.2.1 Penetration Delay Times for Existing Walls.

Table 5-23 shows the maximum penetration delay times for representative stud-girt walls. If existing wall types are not represented in the table, either take credit for the closest type or take no credit.

For conventional concrete materials, the penetration delay times range from about 2 minutes to greater than 60 minutes.

5-6.2.2 Walls to Resist Threat Severity Level II.

If an existing stud-girt wall construction uses a combination of plywood, stucco, or gypsum that meets, or exceeds, 3/4-inch (19-mm) in thickness; light sheet metal; or conventional masonry, it will provide the required one minute penetration delay time against a threat severity level II attack. Otherwise, add materials to the inside of the wall to achieve the one minute penetration delay time or take no credit for delay.

Note that in cases where materials such as expanded metal are applied to a wall, it is common practice to cover those materials with gypsum wallboard for aesthetic purposes.

5-6.2.3 Walls to Resist Threat Severity Level III.

5-6.2.3.1 Stud-Girt Walls.

Table 5-23 shows recommended treatments for existing stud-girt walls to provide resistance to threat severity level III.

Table 5-23 Stud-Girt Construction Retrofit Options for Threat Level III

CONSTRUCTION		PENETRATION DELAY TIME (MINUTES)
1	2- by 4-inch (50- by 100-mm) wood stud frame at 16 inches (400 mm) on center w/bevel siding at 1.5-inch (37.5-mm) lap joints. One-layer No. 15 felt paper, and 1- by 6-inch (25- by 150-mm) sheathing diagonally and 3/8-inch (10-mm) GWB. Attach the following to secure side (opposite from attack side): • 3/4-inch (19-mm) plywood, No. 9 expanded metal and 3/4-inch (19-mm) plywood.	5.0
2	1-inch (25-mm) tongue-and-groove layered with 1/2-inch (13-mm) plywood. Attach either of the following to secure side (opposite from attack side): • 9-gauge (3.8-mm) chain-link fence fabric nailed to wall • 3/16-inch (4.7-mm) steel plate attached to wall with lag bolts.	1.8 1.9

5-6.2.3.2 Masonry Walls.

Several techniques for hardening both hollow and mortar-filled 8-inch (200-mm) CMU block are illustrated in Figure 5-8 through Figure 5-12. Note that the retrofit hardening layers are applied to the interior (secure side) of the cross section. These options were specifically designed and tested to provide enhanced attack resistance. The CMU sections vary in the type of retrofit materials used.

	3	3

5-6.2.3.3 Reinforced Concrete Walls.

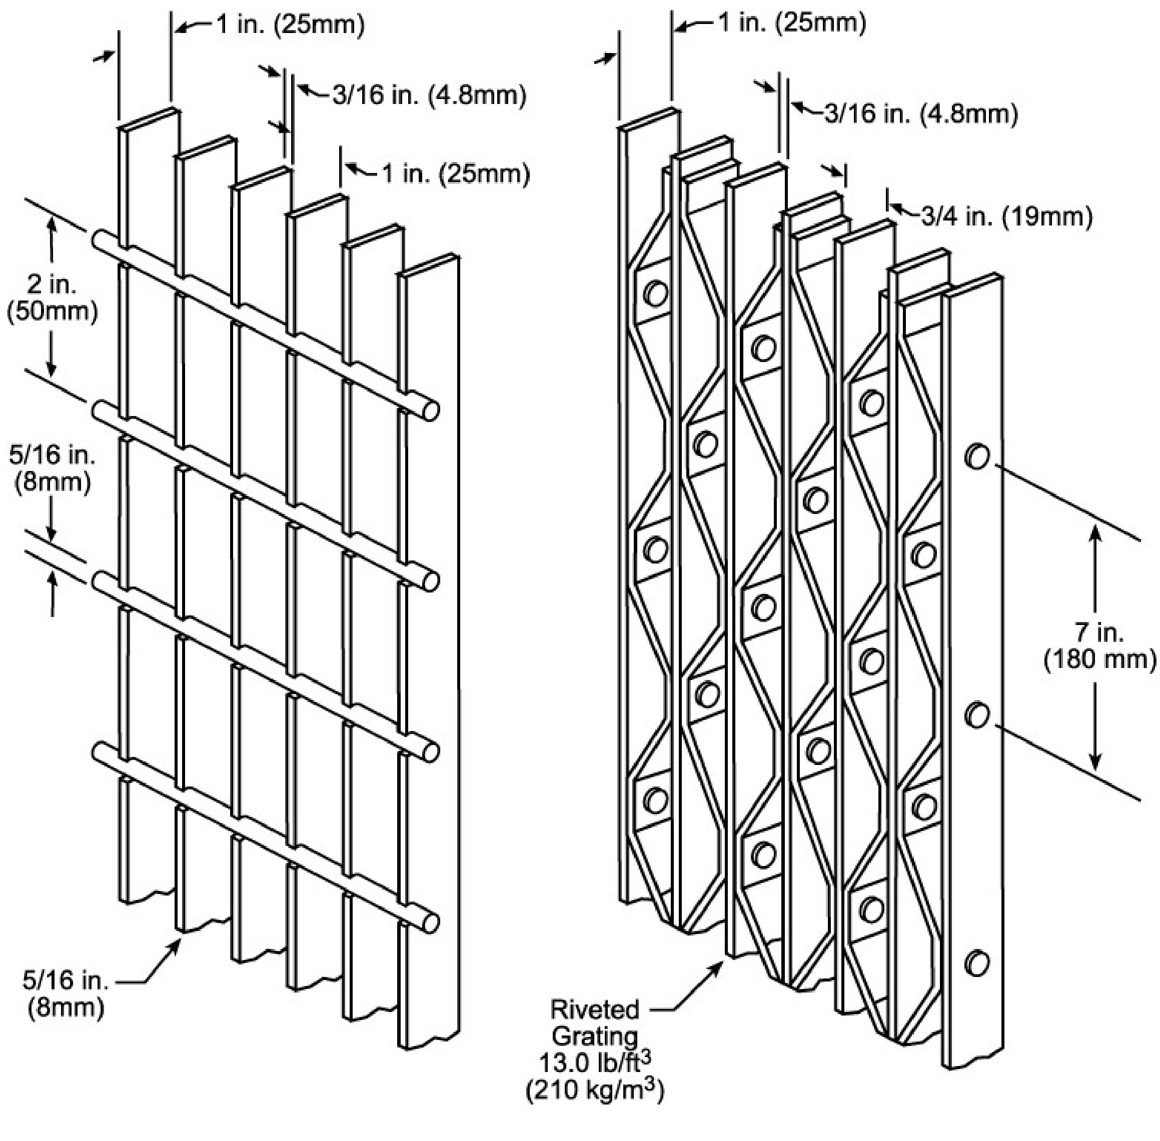
Reinforced concrete 6 inches (150 mm) thick with the “B” reinforcing bar combination (Table 5-2) provides minimum penetration delay times up to about 7.5 minutes for threat severity level III. If the concrete thickness and reinforcing bar combination is outside the threat severity level III region shown in Figure 5-2, using hand-held attack tools alone is not practical. In this case, the existing wall will provide penetration resistance. If the delay time provided by existing concrete construction is inadequate, penetration delay time can be doubled from the values shown in Figure 5-2 by bolting 10-gauge (3.4-mm) standard sheet steel to the interior surface of the wall using taper bolts or expansion sleeve anchors. This effect is gained by preventing internal spalling of the concrete.

5-6.2.4 Walls to Resist Threat Severity Level IV.

5-6.2.4.1 Stud-Girt Walls.

The riveted or welded steel grating shown in Figure 5-13 can be attached to the interior of a stud-girt wall with lag or through bolts to increase the delay time. Additional penetration times against threat severity level IV are approximately 2 minutes minimum for the riveted and 1 minute minimum for welded grating.

Figure 5-13 Welded and Riveted Steel Grating



5-6.2.4.2 Masonry Walls.

The retrofit designs in Figure 5-8 through Figure 5-10 can be used for resistance to threat severity level IV. In addition, the penetration delay times for solid core CMU block walls can be doubled by attaching 10-gauge (3.4-mm) sheet steel to the interior surface with taper bolts or expansion sleeve anchors.

If the penetration delay time is still not adequate, steel-plywood options can be used. Use a layer of 3/4-inch (19-mm) plywood sandwiched between two layers of 10 gauge (3.4-mm) hot-rolled steel to provide about 6 minutes of additional penetration delay time. The penetration delay time can be increased by about five minutes with the addition of another wood and steel layer. This rule of thumb can be applied to the addition of more layers until the desired penetration delay time is reached. Penetration delay time for steel-plywood systems can be increased by changing the steel material to 9-gauge (3.8-mm) ASTM A1008, Class 2, high-strength, low-alloy steel. One layer of 3/4-inch (19-mm) plywood sandwiched between two layers of this steel will provide 14 minutes of penetration delay time. Adding layers of 90-pound (200-kg) gravel finish roofing paper between the plywood and steel further increases the penetration delay time to about 20 minutes. These times are added to the increased penetration delay time provided by preventing internal spalling of the concrete (approximately double the initial penetration delay time).

5-6.2.4.3 Reinforced Concrete Walls.

If the delay time provided by existing concrete construction is inadequate, penetration delay time can be doubled by bolting (taper bolts or expansion sleeve anchor) 10-gauge (3.4-mm) standard sheet steel to the interior surface of the wall. This effect is gained by preventing internal spalling of the concrete.

If the penetration delay time is still not adequate, steel-plywood options as described in Paragraph 5-6.2.4.2 can be used. Standard welded and riveted steel grating can also be used to provide additional delay time. This grating is available in standard 2- by 10-foot (0.6- by 3-m) panels and can be attached to the secure side concrete walls with taper bolts or expansion sleeve anchors. They can also be assembled in a variety of free-standing configurations of any length (in 2-foot (0.6-m) increments). Additional penetration delay times against threat severity level IV are approximately two minutes minimum for the riveted and one minute minimum for welded grating, plus additional time gained by preventing spallation if attached to the secure side of the wall (approximately double the initial penetration delay time).

5-6.2.5 Walls to Resist Threat Severity Level V.

The use of bulk explosives can be effective in quickly producing man-passable openings. Only a reinforced concrete structure 12 inches (305 mm) or more in thickness can provide penetration delay times greater than one minute. In general, the options that will protect existing construction from an explosive penetration attack are retrofit prohibitive because of the weight restrictions and cost implications of retrofitting existing facilities. The only choice is to move the critical asset being protected away from exterior walls and roofs and develop one or more intermediate defense layers. The exterior of the building will then serve as a sacrificial barrier that will force the aggressor to penetrate multiple barriers and limit the use of explosives inside the structure.

5-6.3 Roofs.

Conventional roof construction offers little resistance to downward forced entry attack, except where reinforced concrete slabs form the structure.

5-6.3.1 Roofs to Resist Threat Severity Level II.

Since solid plywood or metal roof construction provides a delay of less than one minute against threat severity level II, replace the existing roof with one of the roof types shown in Table 5-5.

5-6.3.2 Roofs to Resist Threat Severity Levels III and IV.

Conventional or fiber reinforced concrete roofs are required to resist threat severity levels III and IV. If the existing roof is of stud-girt construction, the only choice is to move the critical asset being protected away from exterior walls and roofs and develop one or more intermediate defense layers. The exterior of the building will then serve as a sacrificial barrier that will force the aggressor to penetrate multiple barriers. Figure 5-2, Figure 5-3, and Table 5-2 can be used to estimate penetration times for existing reinforced concrete construction of roofs. In general, for reinforced concrete walls less than 12 inches (30 cm) thick, penetration delay times for a downward attack on a roof will be lower than a similar attack on a wall; therefore, use the next lowest thickness 1 inch (2.5 cm) of concrete in Figure 5-2 to determine the existing penetration delay rating.

If the penetration delay rating for the existing roof is not adequate, add a layer of 3/4-inch (19-mm) plywood sandwiched between two layers of 10 gauge (3.4-mm) hot-rolled steel to provide about 6 minutes of additional penetration delay time. The penetration delay time can be increased by about five minutes with the addition of another wood and steel layer. This rule of thumb can be applied to the addition of more layers until the desired penetration delay time is reached. Penetration delay time for steel-plywood systems can be increased by changing the steel material to 9-gauge (3.8-mm) ASTM A1008, Class 2, high-strength, low-alloy steel. One layer of 3/4-inch (19-mm) plywood sandwiched between two layers of this steel will provide 14 minutes of penetration delay time. Adding layers of 90-pound (200-kg) gravel finish roofing paper between the plywood and steel further increases the penetration delay time to about 20 minutes. These times are added to the increased penetration delay time provided by preventing internal spalling of the concrete (approximately double the initial penetration delay time).

5-6.3.3 Roofs to Resist Threat Severity Level V.

The use of bulk explosives or platter charges can be effective in quickly producing man-passable openings. Only a reinforced concrete structure 12 inches (305 mm) or more in thickness can provide penetration delay times greater than one minute.

In general, the options that will protect existing construction from an explosive penetration attack are retrofit prohibitive because of the weight restrictions and cost implications of retrofitting existing facilities. The only choice is to move the critical asset being protected away from exterior walls and roofs and develop one or more intermediate defense layers. The exterior of the building will then serve as a sacrificial barrier that will force the aggressor to penetrate multiple barriers and limit the use of explosives inside the structure.

5-6.3.4 Roof Equipment and Openings.

For retrofit projects, use the designs in Paragraphs 5-5.2.4 through 5-5.2.6. to secure roof-mounted equipment and utility openings. Eliminate skylights or use tested grille arrangements shown in Figure 5-13 to protect openings where required. Secure all hatches, penthouses, exterior ladders, and fire escapes.

5-6.4 Ceilings and Floors.

Floor and ceiling assemblies are the horizontal (top and bottom) components of the 6-sided intermediate defense layers. Floors may be exposed to exterior forced entry if the asset is in the space below; and, ceilings may be exposed to forced entry if the asset is in the space above. Select floor and ceiling construction which provides the required delay time where applicable.

5-6.4.1 Ceilings and Floors to Resist Threat Severity Level II.

Existing conventional floor and ceiling assemblies of 3/4-inch (19-mm) plywood on wood joists provide at least one minute of penetration delay, they are adequate for resistance to the threat severity level II.

5-6.4.2 Ceilings and Floors to Resist Threat Severity Levels III and IV.

Reinforced stud-girt or reinforced concrete ceilings and floors are required to resist threat severity levels III and IV. Figure 5-2, Figure 5-3, and Table 5-2 can be used to estimate penetration times for existing reinforced concrete construction of ceilings and floors. Penetration delay times for an upward attack on a ceiling (floor of upper level) will be higher than the same attack on a wall; therefore, use the next lowest thickness of concrete 1 inch (2.54 cm) or use a less compact configuration of reinforcing bar size and spacing. For a downward attack on a floor (ceiling of lower level), penetration delay times are lower for a similar attack on a wall; therefore, use the next highest thickness of concrete 1 inch (2.54 cm) or use a configuration with more layers of reinforcing bar size and spacing.

If the existing ceiling or floor is of stud-girt construction, the existing reinforced concrete ceiling or floor cannot provide an adequate penetration delay time, and supporting walls can bear the additional weight, use a layer of 3/4-inch (19-mm) plywood sandwiched between two layers of 10 gauge (3.4-mm) hot-rolled steel to provide about 6 minutes of additional penetration delay time. The penetration delay time can be increased by about 5 minutes with the addition of another wood and steel layer. This rule of thumb can be applied to the addition of more layers until the desired penetration delay time is reached. Penetration delay time for steel-plywood systems can be increased by changing the steel material to 9-gauge (3.8-mm) ASTM A1008, Class 2, high-strength, low-alloy steel. One layer of 3/4-inch (19-mm) plywood sandwiched between two layers of this steel will provide 14 minutes of penetration delay time. Adding layers of 90-pound (200-kg) gravel finish roofing paper between the plywood and steel further increases the penetration delay time to about 20 minutes. These times are added to the increased penetration delay time provided by preventing internal spalling of the concrete (approximately double the initial penetration delay time).

5-6.4.3 Ceilings and Floors to Resist Threat Severity Level V.

The use of bulk explosives or platter charges can be effective in quickly producing man-passable openings. Only a reinforced concrete structure 12 inches (305 mm) or more in thickness can provide penetration delay times greater than one minute. In general, the options that will protect existing construction from an explosive penetration attack are retrofit prohibitive because of the weight restrictions and cost implications of retrofitting existing facilities. The only choice is to move the critical asset being protected away from exterior walls and roofs and develop one or more intermediate defense layers. The exterior of the building will then serve as a sacrificial barrier that will force the aggressor to penetrate multiple barriers and limit the use of explosives inside the structure.

5-6.5 Personnel Entrances.

Existing personnel entrances should provide the same penetration delay times as the other components of the defense layer.

Refer to Table 5-7 through Table 5-12 for evaluating the penetration delay times for existing personnel entry doors. Where existing doors do not provide adequate penetration delay times, they must be upgraded or replaced. As an alternative, additional doors can be added in a vestibule layout to force aggressors to attack multiple doors in sequence before they can penetrate the defense layer.

5-6.6 Doors, Frames and Locks (Non-Entry).

If the existing building or intermediate defense layer perimeters have non-entry doors, perform a life safety evaluation to determine if any non-entry doors can be eliminated. If non-entry doors can be eliminated, fill in the walls to match existing materials.

Refer to Table 5-7 through Table 5-12 for evaluating the penetration delay times for existing doors. Where existing non-entry doors do not provide adequate penetration delay times, they must be upgraded or replaced.

5-6.7 Windows.

Conventional windows provide little resistance to even the lowest threat severity levels of the forced entry tactic. With special glazing materials and frame and anchorage design, forced entry resistant windows can resist the threat severity level II. With specially constructed grille or shutter enhancements, window openings can resist the threat severity levels III and IV. Refer to Table 5-14 through Table 5-20 for evaluating penetration delay times for existing windows. If existing window types are not in the tables, assume they offer no protection against attempted forced entry. Where existing windows do not provide adequate penetration delay times, they must be upgraded; replaced; or, because forced entry resistant window enhancements are costly, eliminated. Removal of existing windows will provide enhanced penetration delay time if the retrofit is accomplished properly. The most straightforward method is to seal the window opening with the same construction used in the wall where it is mounted.

Do not design man-passable window openings in defense layers where the threat severity level V applies. Also consider the placement of windows in relation to doors. Even a small window in or next to a door could allow an aggressor to reach through and unlock the door. Use obscured glazing materials or blinds, shutters, or drapes to eliminate asset visibility.

5-6.8 Utility Openings.

In conventional building designs, utility openings, manholes, tunnels, HVAC ducts, filters, and equipment access panels with openings greater than a man-passable 96 square inches (619 cm^2) provide aggressors with fast ingress and egress routes and provide no penetration delay time. Such openings must be eliminated, or their penetration delay times increased significantly to provide a consistent level of delay for a defense layer.

Methods for hardening man-passable utility openings are described in Paragraph 5-5.9.

CHAPTER 6 PROTECTED AREAS

6-1 INTRODUCTION.

Protected Areas contain the assets; their perimeters are the innermost defense layer and the last layer to provide delay to the aggressors' attempt to reach the assets. Paragraph 6-2 identifies protected asset types and the type of structure to be used to protect them. Construction design requirements for each type of structure is either covered in detail in this UFC; or, when other UFCs or DoD documents exist that contain those requirements, they are summarized, and references provided for the other documents. Paragraphs 6-3 through 6-11 provide the design requirements for structures not covered in other documents.

This UFC does not supersede any of the guidance in other regulatory publications. This UFC is intended to summarize the construction requirements in those documents and provide guidance if additional construction measures are required to protect the assets. If there are any inconsistencies between this UFC and any of the applicable references, the most stringent requirements will control.

6-2 PROTECTED ASSET TYPES.

The following asset types are those most likely to be identified as forced entry targets. Where an asset is identified in the design criteria that is not listed here, use the prescriptive protection requirements from the DoD regulatory documents that govern that asset.

6-2.1 High-Risk Personnel.

High-Risk Personnel (HRP) are DoD personnel who are likely to be terrorist or criminal targets based on their grade, assignment, symbolic value, criticality, and threat and vulnerability assessment. DoDI O-2000.22 defines High Risk Billets and HRP levels; assigns responsibilities; and establishes policy, processes, and procedures for the designation and protection of DoD HRP.

The project design criteria will identify if there are requirements for the protection of HRP including any need for safe havens. UFC 4-010-03 contains the minimum design requirements for the protection of HRP. UFC 4-023-10 contains the design requirements for safe havens.

6-2.2 Classified Information and Material.

The protection of classified information, which is governed by DoDM 5200.01, Volume 3 requires that classified information be secured under conditions adequate to prevent access by unauthorized persons. The storage requirements in DoDM 5200.01 are the same for all classification levels. Classified information and materials can be stored in General Services Agency (GSA)-approved storage containers, secure rooms, or vaults. For service specific regulatory requirements refer to AFI 31-101, AFI 16-1404, AR 380-5, and SECNAVINST M-5510.36.

(See Paragraph 6-11 for Class 5 GSA Storage Cabinets, Paragraph 6-3 for Secure Room design, and Paragraph 6-7 for Class A Vault design.)

6-2.3 Sensitive Compartmented Information.

Sensitive Compartmented Information is classified information concerning or derived from intelligence sources, methods, or analytical processes, which is required to be handled exclusively within formal control systems. The handling and storage of Sensitive Compartmented Information must be confined to a Sensitive Compartmented Information Facility (SCIF). Physical security standards for the construction and protection of SCIFs is governed by DoDM 5105.21, Volume 2.

Use the physical design requirements in UFC 4-010-05 as the minimum requirements for construction of a SCIF.

6-2.4 Special Access Program Information and Equipment.

A Special Access Program is established for a specific class of classified information that imposes safeguarding and access requirements that exceed those normally required for information at the same classification level. Physical security standards for the construction and protection of a Special Access Program Facility (SAPF) is governed by DoDM 5205.07, Volume 3.

Use the physical design requirements in UFC 4-010-05 as the minimum requirements for construction of a SAPF.

6-2.5 Communications Security (COMSEC) Materials.

COMSEC materials are used to secure or authenticate sensitive telecommunications. The protection of COMSEC materials is governed by DoDI 8523.01. COMSEC materials can be stored in security containers, secure rooms, or vaults in accordance with DoDM 5200.01 to the appropriate classification level.

(See Paragraph 6-11 for Class 5 GSA Storage Cabinets, Paragraph 6-3 for Secure Room design, and Paragraph 6-7 for Class A Vault design.)

6-2.6 Arms, Ammunition, and Explosives.

Security of AA&E is governed by DoD 5100.76-M. Storage requirements include security containers, arms rooms, modular vaults, or magazines. Classified AA&E are stored in accordance with DoDM 5200.01. For service specific regulatory requirements refer to AFI 31-101, AR 190-11, MCO 5530.14, and OPNAVINST 5530.13.

UFC 4-215-01 contains minimum design requirements for armories and arms rooms. For forced entry protection of AA&E, use design requirements in Paragraph 6-10.

6-2.7 Chemical Agents.

Chemical weapons storage is governed by DoDI 5210.65. In general, chemical agents are stored within Chemical Exclusion Areas in magazines or rooms constructed to vault standards and with an IDS. The Chemical Exclusion Area needs to be fenced with a perimeter IDS. Research and development level quantities of chemical agents can be stored in security containers within vaults or secure rooms. Classified agents are stored in accordance with DoDM 5200.01. AR 190-59 provides additional Army guidance.

For magazines to store chemical weapons, use the design requirements in UFC 4-420-01. For forced entry protection of research and development level quantities of chemical agents, use the design requirements in Paragraph 6-7.

6-2.8 Biological Agents.

Biological agent security is governed by DoDI 5210.88. That instruction requires agents to be stored in secure containers, including refrigerators, freezers, or other approved storage devices secured with GSA-approved locking devices located within Biological Restricted Areas. Those Biological Restricted Areas must be equipped with an IDS, at least two access control devices, and the entrance must be under constant surveillance.

For forced entry protection of biological agents, use the design requirements in Paragraph 6-7.

6-2.9 Nuclear Weapons.

Nuclear weapons physical security is governed by DoDD 5210.41/AFMAN 31-108. The weapons are stored similarly to chemical weapons within fenced weapons storage areas with a perimeter IDS. Storage is in magazines or rooms constructed to vault standards and with IDS.

6-2.10 Controlled Substances.

Controlled substance storage is governed by 21 CFR 1301.72 for all DoD components except for the Army. Army storage of controlled substances is governed by AR 190-51. In all cases, small quantities of controlled substances can be stored in safes or security containers as described in Paragraph 6-11. Greater quantities of controlled substances need to be stored in vaults. Pharmacy construction standards are in AR 190-51 and AFI 31-101.

For forced entry protection of large quantities of controlled substances, use the design requirements in Paragraph 6-7.

6-2.11 Funds.

The security of DoD funds is governed by DoDR 7000.14. Storage of funds in excess of $100,000 requires special construction for rooms in which funds storage containers are stored. Requirements for the Air Force are reflected in AFI 31-101.

For forced entry protection of funds in excess of $100,000, use the design requirements in Paragraph 6-4.

6-3 SECURE ROOMS.

Secure rooms are options for the storage of classified information and lower levels of COMSEC materials. Secure room construction can also be used for the storage of sensitive items such as funds, and small quantities of controlled substances; however, a secure room cannot be used to simultaneously store both classified information and sensitive items. Their construction is governed by DoDM 5200.01, Volume 3, which includes requirements for all the building elements associated with the perimeter of the room. A secure room may require an IDS if the area is not occupied on a twenty four-hour/seven-day basis; consult with facility security personnel for guidance.

The following paragraphs contain the minimum design requirements for a secure room; they provide little resistance to forced entry. If the secure room requires resistance to forced entry, use construction components from Chapter 5.

6-3.1 Walls, Floor, and Roof.

The walls, floor, and roof construction of secure rooms must be of permanent construction materials such as plaster, GWB, metal panels, hardboard, wood, plywood, or other materials offering resistance to, and evidence of, unauthorized entry into the area. Walls must be extended from the true floor to the true ceiling; and, if not, attached with permanent construction materials, mesh, or 18-gauge (1.2 mm) expanded steel screen.

6-3.2 Ceiling.

The ceiling must be constructed of plaster, GWB, hardboard or other acceptable material.

6-3.3 Door and Frame.

All doors in the secure room perimeter must be substantially constructed of wood or metal. The hinge pins of outswing doors must be peened, brazed, or spot-welded to prevent removal.

6-3.4 Locks.

The access door must be equipped with a built-in GSA-approved combination lock meeting FS FF-L-2740. Emergency exit doors should not have any external hardware installed.

6-3.5 Windows.

Windows that are less than 18 feet above the ground measured from the bottom of the window or are easily accessible by means of objects placed beneath the windows, must be constructed from or covered with materials that will provide protection from forced entry. The protection provided to the windows must provide the same penetration delay time as the contiguous walls.

Secure rooms which are located within a controlled compound or equivalent may eliminate the requirement for forced entry protection if the windows are made inoperable either by permanently sealing them or equipping them on the inside with a locking mechanism and they are covered by an IDS (either independently or by motion detection sensors within the area). This must be approved by the secure room's Security Manager.

6-4 FUNDS STORAGE ROOMS.

A funds storage room is a space specifically selected for containing a funds storage container during non-duty hours. The following construction requirements apply.

6-4.1 Walls, Floors, and Ceilings.

Walls, floors, and ceilings must be constructed or reinforced to provide protection equal to or greater than that of doors and windows. Effectively, most permanent construction will provide protection equal to or greater than that provided by the required windows and doors. Consider any concrete or masonry construction to be at least equivalent. Lightweight construction such as Exterior Insulating Finishing System may not provide equivalent protection, however. Add 5/16-inch expanded metal mesh to at least the walls of such construction. Add it to the floors and ceilings as well if they are constructed of something other than concrete.

6-4.2 Doors.

Doors should be constructed of 1-3/4 inch (44 mm) solid or laminated wood with US 12-gauge (2.7 mm) steel plate on the outside face; or standard 1-3/4 inch (44 mm) hollow metal, industrial type construction with minimum US 14-gauge (1.9 mm) skin plate thickness, internally reinforced vertically with continuous steel stiffeners spaced 6 inches maximum on center. A class 5 steel vault door with a changeable combination may be used instead of other doors and locks.

6-4.3 Door Frames and Hardware.

Door bucks, frames, and keepers should be rigidly anchored and provided with anti-spread space filler reinforcement to prevent disengagement of the lock bolt by prying or jacking the door frame. Also, the frames and locks for both interior and exterior doors should be designed and installed to prevent removal of the frame which faces the built-in locking mechanism. Frames should also be designed to prevent spreading sufficiently to disengage the lock bolt from outside the protected room when the door is closed and locked. Construction requirements for door frames and thresholds must be exacting as those for the door. For example, where metal doors are used, the frame and thresholds must also be metal.

When choosing the proper type of hinge for secure area doors, apply the following criteria:

- The hinge must be strong enough to withstand the rigors of constant use and the unusual weight of the door.
- Hinges should have fixed pins.
- Exposed hinges should be peened, or spot welded, or otherwise protected to prevent removal.
- Hinge mounting screws should not be exposed to the outside unless they are spot welded or peened to prevent removal.

6-4.4 Windows and Other Openings.

Windows should be filled in and sealed with material comparable to that forming the adjacent walls and otherwise limited to the essential minimum. Windows, ducts, vents, or similar openings large enough to permit entry [96-square-inch (619 cm^2) or with a single rectangular dimension greater than 6 inches (150 mm)] must be equipped with bars or mesh of one of the types below. Bars and steel mesh should be securely embedded in the structure of the building or welded to a steel frame that will be securely attached to the wall with fastenings inaccessible from the exterior of the facility.

- 3/8 inch (10 mm) or larger hardened steel bars, if the vertical bars are no more than 4 inches (100 mm) apart with horizontal bars welded to the vertical bars so that the openings do not exceed 32 square inches (206 cm^2).
- High carbon manganese steel mesh [US Number 8-gauge (4.0 mm)] with 2-inch (50-mm) diamond grid. (US Number 6-gauge (5.0 mm) steel mesh may be used if 8 gauge is unavailable.)

6-4.5 Security Lighting.

Interior and exterior security lighting is required for all government funds facilities and encouraged for all other funds facilities. The lighting must be bright enough to allow persons observing the structure or facility to recognize illegal acts. The following additional criteria apply.

- Locate switches for exterior lights so they are not accessible to unauthorized persons.
- Motion sensor lights may be installed to save energy.

Refer to UFC 3-530-01 for security lighting designs.

6-4.6 Locks and Keys.

Equip doors used for entry to funds storage rooms with, as a minimum, key actuated deadbolt locks with at least a 1-inch (25-mm) throw.

6-4.7 Intrusion Detection Systems.

AFI 31-101 requires accounting and finance offices and facilities storing $100,000 or more to have an IDS.

6-5 SECURE STORAGE STRUCTURES.

Army Regulation 190-51 identifies a class of storage facilities referred to as secure storage structures. They may be used to store a variety of asset types but cannot be used to store classified information or AA&E. The regulation has requirements for all building components in the perimeter of the space. The requirements vary by risk level as determined using DA Pamphlet 190-51.

6-5.1 Walls.

6-5.1.1 Risk Level I.

Walls should be constructed of at least 1/2–inch (13-mm) plywood, 1–inch (25-mm) tongue–in–groove wall boards, or 26–gauge (0.45 mm) steel siding.

6-5.1.2 Risk Level II.

Walls should be constructed of 4–inch (100-mm) minimum thickness brick and stud construction or of 8–inch (200-mm) minimum thickness concrete masonry (unreinforced). Alternatively, walls may be designed to provide delay equal to or greater than the actual response time.

6-5.1.3 Risk Level III.

Walls should be constructed of 8–inch (200-mm) minimum thickness core-filled concrete masonry reinforced with #6 (19 mm) reinforcing bars at 4 inches OC vertically and 8 inches (200 mm) OC horizontally, or 4–inch (100-mm) minimum thickness concrete reinforced with #5 (16 mm) reinforcing bars at 5 inches (125 mm) OC EW. Alternatively, walls may be designed to provide delay equal to or greater than the actual response time.

6-5.2 Floor and Ceiling.

The following requirements do not apply to slab on grade floors. No special requirements apply for such floors.

6-5.2.1 Risk Level I.

Floors and ceilings should be constructed of at least 1/2–inch (13 mm) plywood, 1–inch (25-mm) tongue–in–groove wall boards, or 24–gauge (0.6 mm) steel deck.

6-5.2.2 Risk Level II.

Floors and ceilings should be constructed as for Risk Level I with the addition of 5/16–inch (8 mm) expanded metal mesh or 10–gauge (3.4 mm) 6 inch by 6 inch (150 mm by 150 mm) woven wire fabric. Alternatively, floors and ceilings may be designed to provide delay equal to or greater than the actual response time.

6-5.2.3 Risk Level III.

Floors and ceilings should be constructed of 4–inch (100 mm) minimum thickness concrete reinforced with #5 (16 mm) reinforcing bars at 5 inches OC EW. Alternatively, floors and ceilings may be designed to provide delay equal to or greater than the actual response time.

6-5.3 Doors.

6-5.3.1 Risk Level I.

Doors should be a minimum of 1 3/4–inch (44 mm) thick solid core wood or hollow steel. Hollow steel doors will be industrial type construction with at least 20–gauge (0.88 mm) skin plate thickness and will be internally reinforced with continuously spaced stiffeners.

Door frames should be constructed of a minimum of 18–gauge steel. Doors with locking systems exposed to the outside should be kept to the absolute minimum number needed based on operational considerations. In addition, the doors should meet the following installation requirements:

- Door hinge mounting screws should not be exposed to the exterior of the facility. If screws are exposed, they should be spot welded, peened, covered, or filled with material in a way to prevent easy removal. Nails should not be used to mount hinges or any other door hardware.
- Door hinge pins should not be exposed to the exterior of the facility. If they are, they should be spot welded, covered, filled, or otherwise secured to prevent easy removal.
- Doors secured from the inside should be secured with a deadbolt locking device, crossbar, or similar locking device resistant to jimmying and manipulation from the outside. Latch style door locks should not be used.

6-5.3.2 Risk Level II.

Doors should be a minimum of 16–gauge (1.6 mm) hollow steel construction with a minimum of frame construction of 16–gauge (1.6 mm) steel. Installation requirements for Risk Level I also apply. Alternatively, doors or pairs of doors may provide delay time equal to or greater than the actual response time.

6-5.3.3 Risk Level III.

Doors should be a minimum of 1 3/4–inch (44 mm) solid core wood with wood block cores and 12–gauge (2.7 mm) minimum thickness steel plate on both sides or doors should be 12–gauge (2.7 mm) minimum thickness hollow steel doors reinforced with vertical stiffeners at 6 inches (150 mm) on center. Door frames should be constructed of 16–gauge (1.6 mm) steel minimum and be grouted full. Alternatively, doors or pairs of doors may provide delay time equal to or greater than the actual response time.

6-5.4 Windows.

The following apply to all first-floor openings, except doors, in excess of 96 square inches (619 cm^2) that are located less than 12 feet (3.7 m) from the ground level and to similar openings above the first floor which can be reached from an elevated portion of the structure or from an adjacent structure which provides ground level access. Long narrow openings with the shortest dimension measuring less than 6 inches (150 mm) are exempt from these requirements. If window air conditioning is used, bar, mesh, or fence fabric assemblies should completely enclose the air–conditioning unit protruding from the building or storage room exterior. If the window air conditioner is mounted through the wall, measures should be taken to ensure that it cannot be removed from the outside.

6-5.4.1 Risk Level I.

Operable windows should have adequate individual locking devices. Windows should also be covered with 1/2–inch (13 mm) diameter bars spaced at 6 inches (150 mm) on center each way, with 5/16–inch (8 mm) expanded metal mesh, or with 9–gauge (3.8 mm) chain link fabric.

6-5.4.2 Risk Level II.

Windows should be inoperable. They should be covered with bars or mesh as for Risk Level I and the glass should be covered with 4–mil (0.1 mm) fragment retention film or they should have 1/2–inch (13 mm) thick laminated glass or plastic security glazing. Alternatively, windows may provide delay time equal to or greater than the actual response time.

6-5.4.3 Risk Level III.

Windows should be inoperable, and they should be covered with bars or mesh as for Risk Level I and have 1/2–inch (13 mm) thick laminated glass or plastic security glazing. Alternatively, windows may provide delay time equal to or greater than the actual response time.

6-6 VAULTS.

Federal Standard 832 provides requirements for three classes of vaults for the storage of classified material and equipment: A, B, and C.

- Class A vaults provide penetration delay against threat severity levels II to IV. (See Paragraph 6-7 for the minimum construction requirements for Class A vaults.)
- Class B vaults provide penetration delay against threat severity levels II and III. Construction of a Class B vault must be in accordance with FS AA-V-2737. The door and frame of a Class B vault must conform to Federal Specification AA-D-600.
- Class C vaults offer no protection against a forced entry but may be used where unique structural circumstances do not permit concrete wall construction. They cannot be used as a defense layer unless substantially upgraded with designs from Chapter 5. (See Paragraph 6-8 for the minimum construction requirements for Class C vaults.)
- A lightweight, portable modular vault equivalent to a Class B vault that meets FS AA-V-2737 may also be used to store classified material and equipment. (See Paragraph 6-9 for modular vault design requirements).

DoD instructions on the protection of classified information and weapons systems require that vaults used to protect these assets must be cast-in-place reinforced concrete with a GSA-approved vault door that meets the requirements of FS AA-D-600. As alternatives within existing buildings where the use cast-in-place reinforced concrete is not structurally feasible, either a Class C vault or a GSA-approved modular vault can be used in place of a reinforced concrete structure.

6-7 CLASS A VAULTS.

This paragraph contains the minimum construction requirements for Class A vaults. (See Table 6-1 for penetration delay times provided by Class A vaults.)

Table 6-1 Penetration Ratings for Class A Vaults

MINIMUM CONSTRUCTION REQUIREMENT		MINIMUM PENETRATION DELAY TIME (MINUTES)			
		II	III	IV	V
Walls	8-inch (200-mm) Reinforced Concrete	(a)	(a)	12	<1
Floors	8-inch (200-mm) Reinforced Concrete	(a)	(a)	18 (b)	<1
Roof / Ceiling	8-inch (200-mm) Reinforced Concrete	(a)	(a)	10 (c)	<1
Door / Frame	Class 5 (FS AA-D-600)	(a)	10	2	<1

(a) Not practical to attack at this threat severity level.
(b) Penetration delay time is for an upward attack for other than floors on grade. Floors on grade not practical to attack.
(c) Penetration delay time is for a downward attack.

6-7.1 Walls.

Use 8-inch (200-mm) thick reinforced concrete with a minimum 28-day compressive strength of 3,000 psi (20.7 MPa). Reinforce concrete with 5/8-inch (16-mm) reinforcing bars, 6 inches (150 mm) on center each way, staggered each frame. Extend the reinforcement to the underside of the roof or ceiling slab above. Tie wall reinforcement into floor and ceiling or roof. When vault walls are part of the exterior walls, set the vault wall back from the exterior part of the exterior wall to allow 4 inches (100mm) for the normal wall facing to cover the vault wall.

6-7.2 Floor.

Use 8-inch (200-mm) thick reinforced concrete with a minimum 28-day compressive strength of 3,000 psi (20.7 MPa). Reinforce concrete with 5/8-inch (16-mm) reinforcing bars, 6 inches (150 mm) on center each way, staggered each frame. These requirements do not apply to slab on grade floors because these are not practical to attack; no special requirements apply for such floors.

6-7.3 Roof and Ceiling.

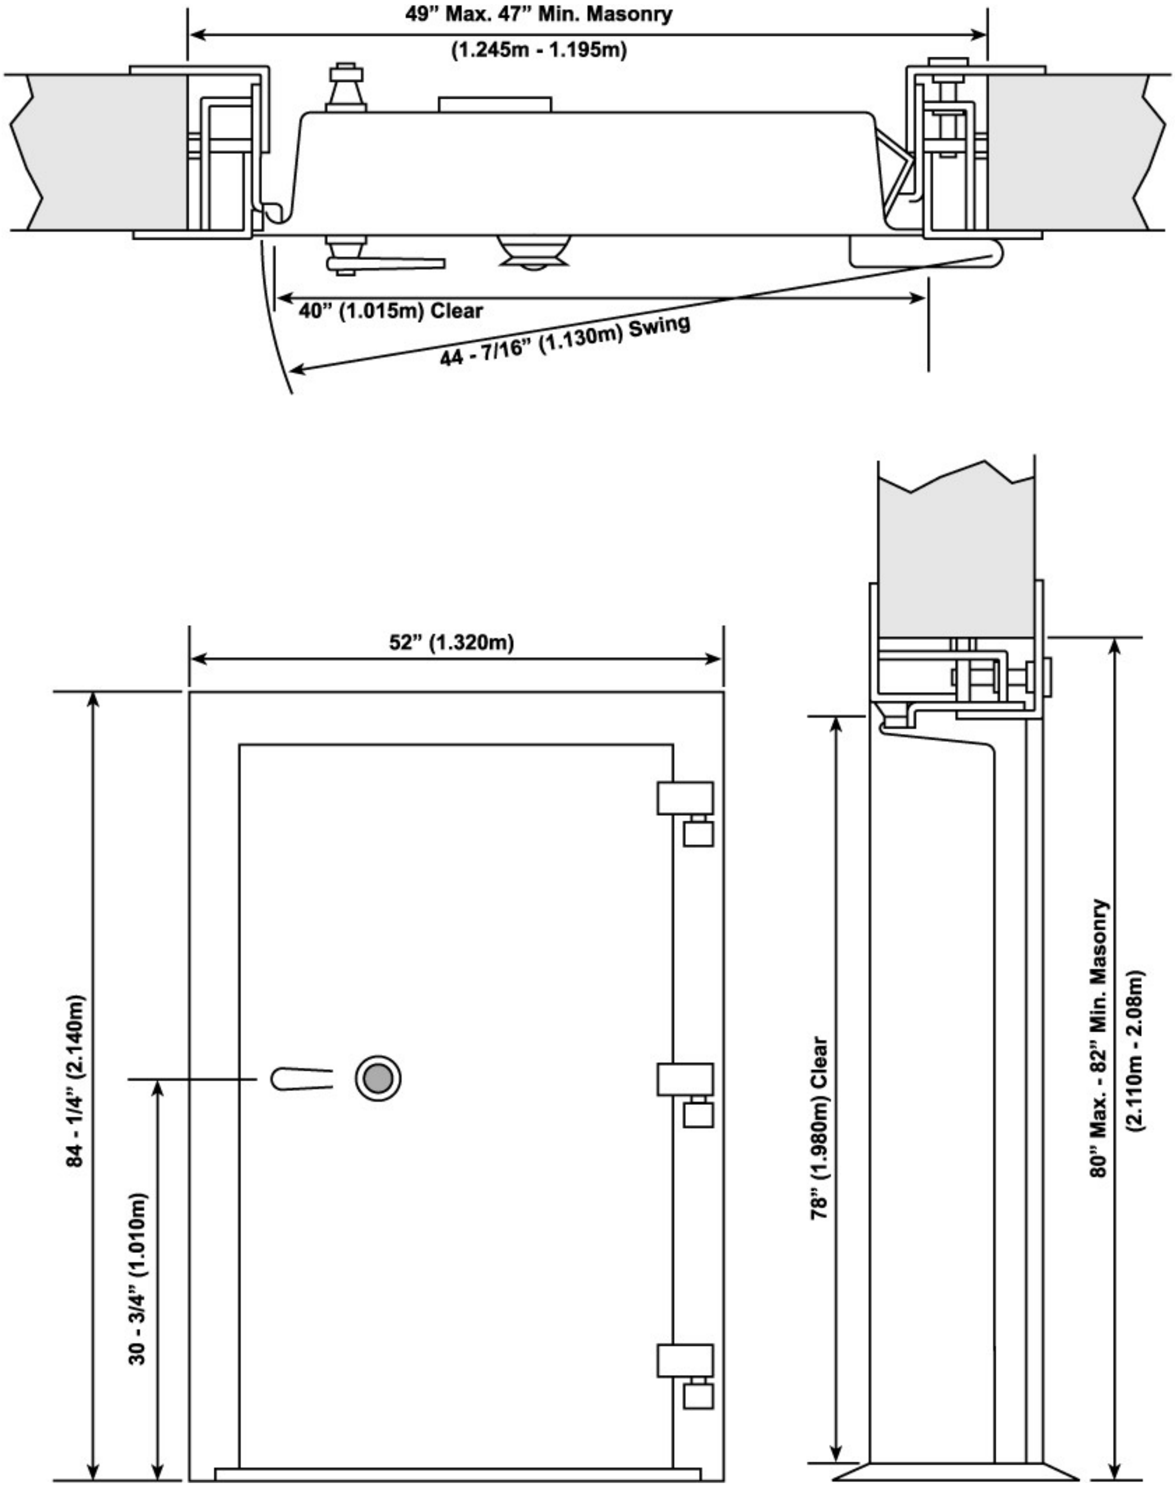
Use 8-inch (200-mm) thick reinforced concrete with a minimum 28-day compressive strength of 3,000 psi (20.7 MPa). Reinforce concrete with 5/8-inch (16-mm) reinforcing bars, 6 inches (150 mm) on center each way, staggered each frame.

6-7.4 Door and Frame.

Since vault doors are more vulnerable to attack than the vault enclosure itself, there should be only one entrance into a vault area. When a vault exceeds 1,000 square feet (93 $m^{2)}$ in floor space, or will have more than eight occupants, it should have a minimum of two exits for safety purposes. When more than one entrance is required, each must be equipped with an approved vault door with only one used for normal access. Where continued use of an entry barrier is required at a vault door, a day gate may be provided for the primary entrance to preclude undue wear of the door during operating hours.

Vault doors, frames, and locks must conform to FS AA-D-600. Doors other than those secured with locks meeting FF-L-2740 must be secured from the inside with deadbolt emergency egress hardware, a deadbolt, or a rigid wood or metal bar that extends across the width of the door. Figure 6-1 shows the dimensional requirements for a Class 5 vault door.

Figure 6-1 Class 5 Vault Door



6-7.5 Locks.

Use vault door locks that meet the requirements of FS FF-L-2740.

6-7.6 Miscellaneous Openings.

Install barriers in any miscellaneous openings, open ducts, pipes, register, sewers in excess of 96 square inches (619 cm^2) in area and over 6 inches (150 mm) in its smallest dimension. Acceptable barriers are 9 gauge expanded metal mesh, or rigid (steel) bars at least 1/2-inch (13-mm) in diameter, welded vertically and horizontally 6 inches (150 mm) on center. Securely fasten the rigid metal bars at both ends to preclude removal. Use crossbars to prevent spreading of the bars.

6-8 CLASS C VAULTS.

Class C vaults may be used in existing buildings where unique structural circumstances do not permit construction of a Class A concrete vault.

6-8.1 Walls.

Use 1/4-inch (6-mm) thick steel alloy-type metal plates having characteristics of high yield and tensile strength. The metal plates are to be continuously welded to load-bearing steel members of a thickness equal to that of the plates. If the load-bearing steel members are being placed in a continuous floor or ceiling of reinforced concrete, they must be firmly affixed to a depth of one-half the thickness of the floor and ceiling.

6-8.2 Floor and Ceiling.

If the floor and/or ceiling construction is less than six inches of reinforced concrete, use a steel liner with the same characteristics as the walls to form the floor and ceiling of the vault. Weld seams together where the steel plates meet horizontally and vertically.

6-8.3 Door and Frame.

Use a vault door and frame that conforms to F S AA-D-600.

6-8.4 Locks.

Use vault door locks that meet the requirements of FS FF-L-2740.

6-8.5 Miscellaneous Openings.

Equip any miscellaneous openings, open ducts, pipes, registers, sewers in excess of 96 square inches (619 cm^2) in area and over 6 inches (150 mm) in its smallest dimension with barriers. Acceptable barriers are 9-gauge (3.8-mm) expanded metal mesh, or rigid metal (steel) bars at least 1/2 inch (13 mm) in diameter, welded vertically and horizontally 6 inches (150 mm) on center. Securely fasten the rigid metal bars at both ends to preclude removal. Use crossbars to prevent spreading of the bars.

6-9 MODULAR VAULTS.

Modular vaults provide a minimum of 15 minutes of forced entry resistance against a multilevel tool attack up to threat severity level III. Modular vaults provide only minimal delay to threat severity levels IV and V.

An advantage of modular construction is that a modular vault can be reconfigured or disassembled and relocated as needed.

6-9.1 Advantages of Modular Vaults.

Advantages of using modular vaults instead of poured in place reinforced concrete vaults include:

- Ability to construct a new vault in a few hours rather than days or months.
- Ability to construct a new vault without the use of concrete forms and resulting construction debris.
- Lighter weight (up to 70 percent less) depending on the class of vault.
- Lower cost (up to 50 percent less) depending on the extent of structural modifications that would be required.
- Flexibility for installing a vault in or removing a vault from an existing operational building (depending on the extent of structural modifications required).
- Reduction in space required because the walls are up to 70 percent thinner.

6-9.2 Construction.

Vaults are made of modular panels, which are assembled to form a six-sided structure. The floor may be the concrete slab of the building, or it may consist of modular panels. Figure 6-2 shows a representative configuration of a modular vault.

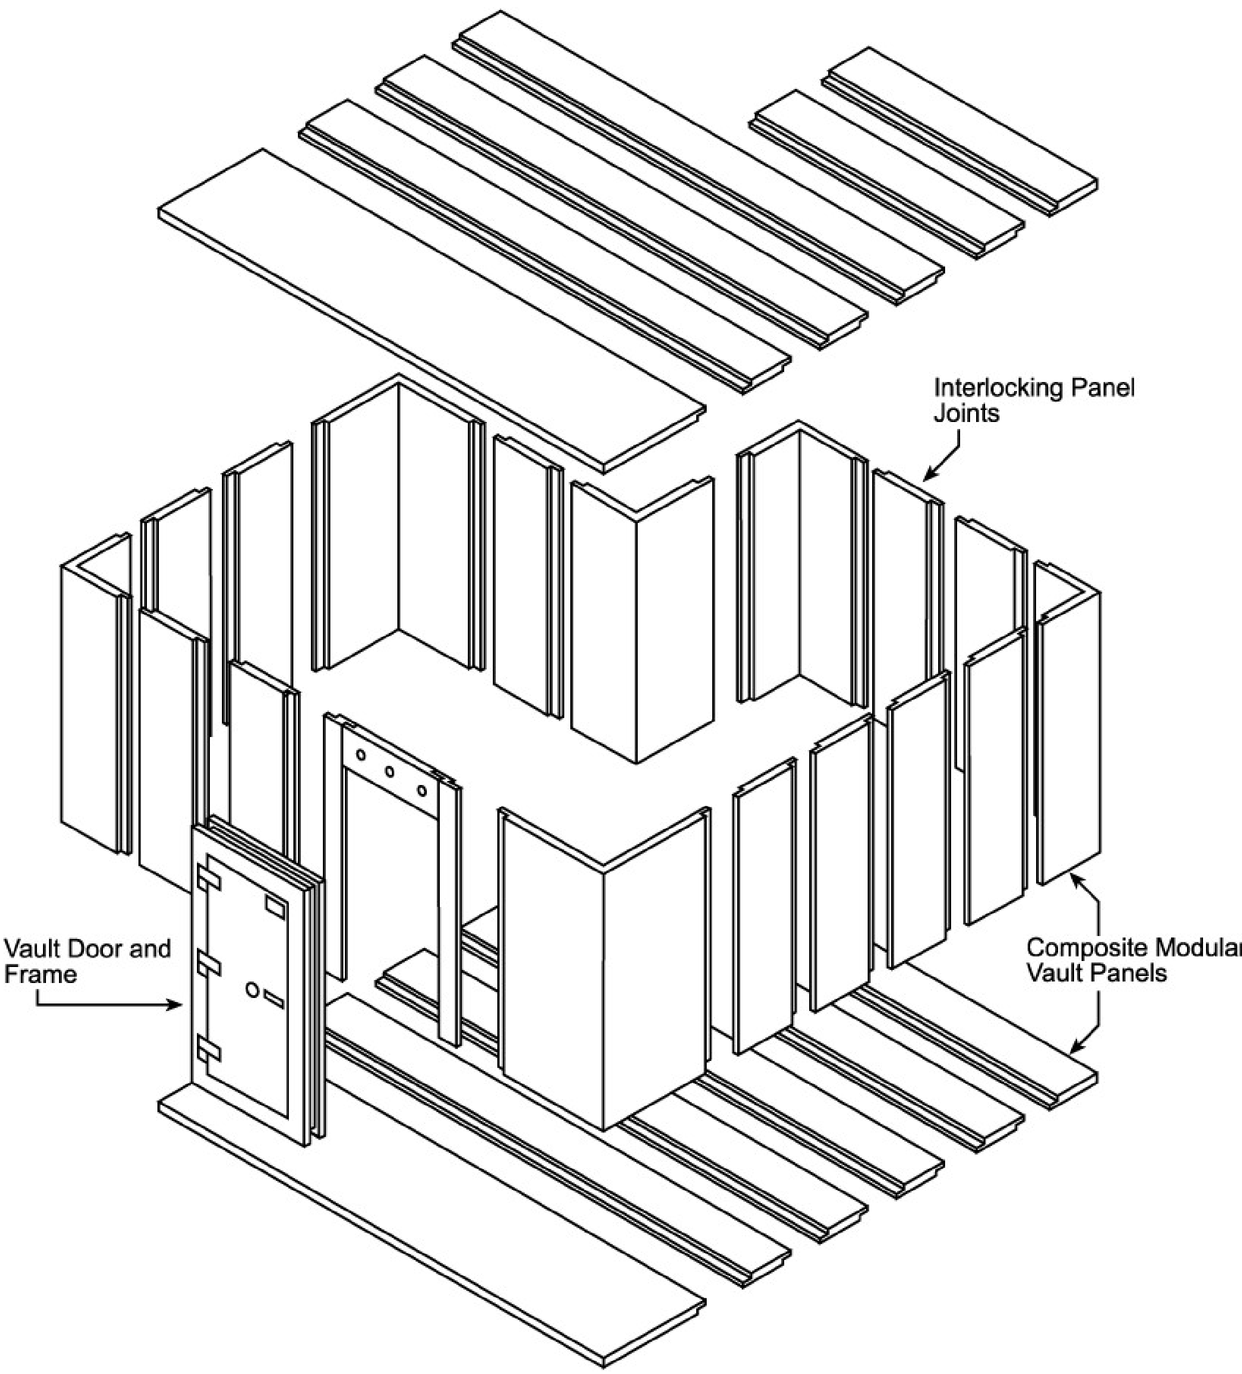
FS AA-V-2737 covers panels that may be assembled to form a GSA-approved modular vault. The vault must use a Class 5 GSA-approved vault door meeting requirements of FS AA-D-600.

Modular vault panels are either lightweight (less than 30 pounds per square foot) or heavyweight (unlimited weight). Lightweight panels are laminated of various materials which together provide the forced entry resistance time of at least 15 minutes against threat severity level IV. Heavyweight panels are typically made of concrete.

6-9.3 Availability.

Modular vaults are available from a variety of American manufacturers. Additional information is available from the Naval Facilities Engineering and Expeditionary Warfare Center (EXWC) Code CI8 Port Hueneme, CA, 93043 and from GSA.

Figure 6-2 Simple Modular Vault Panel and Door Arrangement



6-10 ARMS, AMMUNITION, AND EXPLOSIVES AREAS.

AA&E can be stored in magazines, arms rooms, or vaults depending on the risk category and quantities and use of the AA&E.

Table 6-2 lists AA&E Risk Categories and their application.

- All Risk Category I AA&E must be stored in standard magazines.
- AA&E Risk Categories II through IV must be stored in a structure with a minimum forced entry resistance of 10 minutes against threat severity level III including arms rooms or permanent and modular vaults with a Class 5 approved vault door.

Table 6-2 Security Risk Categories for AA&E (DODM 5100.76)

CATEGORY	WEAPONS	AMMUNITION & EXPLOSIVES
I	Nonnuclear man-portable missiles and rockets in a ready to fire configuration; for example, Redeye, Stinger, Dragon, Javelin, light antitank weapon (66mm), shoulder–launched multi–purpose assault weapon rocket (83 mm), and AT–4 anti–armor launcher and cartridge (84 mm). Also included are the tube–launched, optically tracked, wire–guided missile (TOW) weapon and the Hellfire missile.	Explosive complete rounds for Category I missiles and rockets
II	Light automatic weapons up to and including 0.50 caliber (13 mm), M16A2 rifle, M4 rifle, Squad Automatic Weapon, M60 machine gun, and 40mm MK 19 grenade launcher. Silencers, mufflers and noise suppression devices.	High explosive hand or rifle grenades and white phosphorous. Mines, antitank or antipersonnel with an unpacked weight of 50 pounds (23 kg) or less. Explosives used in demolition operations, C-4, military dynamite and TNT with an unpacked weight of 100 pounds (45 kg) or less. Critical binary munitions components containing “DF “and “QL” when stored separately from each other and from the binary chemical munition bodies in which they are intended to be employed.

CATEGORY	WEAPONS	AMMUNITION & EXPLOSIVES
III	Launch tube and grip stock for the Stinger missile. Launch tube, sight assembly and grip stock for Redeye missiles. Tracker for the Dragon missile. Mortar tubes up to and including 3.2 inch (81 mm). Grenade launchers. Rocket and missile launchers (unpacked weight of 100 pounds (45 kg) or less). Flame throwers. Launcher, missile guidance, or the optical sight for TOW.	Ammunition, .50 caliber (12.7 mm) and larger, with explosive filled projectile (unpacked weight of 100 pounds or less each). Grenades, incendiary, and fuses for high explosive grenades. Blasting caps. Supplementary charges (uninstalled or installed in projectiles in a manner allowing easy removal without special tools or equipment). Bulk explosives. Detonating cord.
IV	Shoulder-fired weapons other than grenade launchers, not fully automatic. Handguns. Recoilless rifles up to and including 4.2 inches (106 mm).	Ammunition with non–explosive projectile (unpacked weight of 100 pounds or less each). Fuses, except for those in Category III. Grenades, illumination, smoke, and tear gas (CS)/chloroacetophenone (CN) (tear–producing). Incendiary destroyers. Riot control agents, 100-pound package or less. Ammunition for weapons in Category III.

6-10.1 Magazines.

Refer to UFC 4-420-01 for construction requirements for ammunition and explosives storage magazines.

6-10.2 Arms Rooms.

Arms rooms are governed by DoDM 5100.76; they are similar in construction to vaults. They are treated as six-sided rooms, but there are door options in addition to vault doors. Unlike vaults, however, arms rooms must both meet minimum construction requirements and provide a minimum of 10 minutes of forced entry resistance against threat severity level III.

- Army arms rooms are constructed according to the requirements of AR 190-11; these are facilities, similar in function to the weapons storage spaces of armories, with very limited maintenance and repair facilities.
- Air Force arms rooms are governed by AFI 31-101 and AFMAN 32-1084. Air Force weapons repair and maintenance facilities are normally located in a Combat Arms Facility.
- Navy arms rooms must comply with OPNAVINST 5530.13.
- Marine Corps arms rooms must comply with MCO 5530.14.

6-10.3 General.

Permanently constructed arms rooms are normally cast-in-place concrete. Precast concrete of similar construction may be used, but it would have to be tested to ensure that the joints and connections meet the required delay time. Alternatively, precast panels meeting the requirements in Paragraph 6-10.4, and in which there are cast-in-place segments between panels, may be allowed if the continuity of reinforcement between panels and between floors or foundations and roofs or ceilings is maintained. In all cases, the construction in the paragraph below constitutes minimum requirements.

Structural requirements may require greater thicknesses and reinforcement. Use concrete in walls, floors, ceilings, and roofs with 3000 psi (20.7 MPa) minimum compressive strength. Use ASTM A615, Grade 60 for reinforcing bars and comply with ASTM A1064 for welded wire fabric. Reinforcement should be installed in accordance with ACI 318. Note that the reinforcing bars outside the United States may not be of the same dimensions or yield strengths as those in ASTM A615 and ASTM A1064. In those cases, use the closest greater diameter and tensile strength.

6-10.4 Walls.

Use a minimum of 8-inches (200 mm) thick concrete with a minimum 28-day compressive strength of 3,000 psi (20.7 MPa) reinforced with a minimum of #4 (1/2-inch, 13 mm) reinforcing bars in both directions on each face, spaced at 9 inches (225 mm), and staggered each face such that they form a projected grid approximately 4-1/2 inches (115 mm) square. Thinner cross sections can be used if heavier reinforcing is selected. For example, a 6-inch (150-mm) cross section could be used if there are two layers of #5 (16-mm) reinforcing bar spaced at 4-1/2 inches (115 mm) each way. Tie reinforcement in walls into ceilings and floors.

6-10.5 Roofs and Ceilings.

For roofs and ceilings, use a minimum of 8-inches (200-mm) thick concrete with a minimum 28-day compressive strength of 3,000 psi (20.7 MPa) reinforced with a minimum of #4 (1/2-inch, 13-mm) reinforcing bars in both directions spaced such that they form a grid such that the areas of any openings between bars will not exceed 96 square inches (619 cm^2). If the ceiling or roof must be pan-joist construction, the thinnest part may not be less than 6-inches (150-mm) and the clear space between joists may not exceed 20-inches (500-mm).

6-10.6 Floors.

Floors, if on grade, must be a minimum of 6-inches (150 mm) thick reinforced concrete with a minimum 28-day compressive strength of 3,000 psi (20.7 MPa) reinforced with minimum of 6-inch x 6-inch (150-mm x 150-mm) W4 x W4 welded wire fabric. Alternatively, use a minimum of #4 (1/2-inch, 12.5 mm) reinforcing bars in both directions spaced such that they form a grid such that the areas of any openings between bars will not exceed 96 square inches (619 cm^2). Bar spacings in each direction of 10 inches (254 mm) would result in a clear area between bars less than the minimum area.

Where floors of arms rooms are ceilings of spaces below them, follow the ceiling standard.

6-10.7 Existing Wall, Ceiling, Roof, and Floor Reinforcement.

Where existing construction is not up to the standards above, use any of the reinforcing methods listed below. When any of these are applied, fasten them to the existing structure so that destruction of the existing and reinforcing materials is required to remove them.

- Steel bars: Use 3/8-inch (10 mm) steel bars, 4 inches (100 mm) apart with bars in one direction welded to the bars in the opposite direction so that the openings do not exceed 32 square inches (0.02 m2). Ends of the steel bars must be embedded securely in the structure of the building or welded to a steel frame securely fastened to the building.
- Steel landing mat: Use Marsten, Irving, or pierced steel planking.

- Expanded metal: Use 3/16-inch (5 mm) thick expanded metal with a maximum grid opening of 1 inch by 3 inches (25 mm by 75 mm) and weighing a minimum of 4.27 pounds per square foot (20.8 kg/m2).
- Steel plate: Use 1/4-inch (6.4 mm) steel plate.
- Steel mesh: Use Number 8–gauge (4.1 mm) high carbon manganese steel, or for existing facilities, number 6–gauge (4.1 mm) cold drawn steel wire with a grid of not more than 2 inches (50 mm) center to center. The number 6–gauge (4.1 mm) wire is not authorized for future upgrading.
- Sheet metal: For existing facilities, use 16–gauge (1.6 mm) steel sheets or plates securely fastened together. This material is not authorized for future upgrading.

6-10.8 Doors.

Only the GSA-approved Class 5 Armory Door provides the required 10 minutes of delay; therefore, only that door is allowed for new construction. The Class 5 Armory Door is specified using FS AA-D-600.

The following doors are authorized for existing construction by DoDM 5100.76:

- 1-3/4-inch (44 mm) solid or laminated wood with 12-gauge (2.7 mm) steel plate on the exterior face.
- 1-3/4-inch (44 mm) hollow metal, industrial type construction with minimum 14-gauge (1.9 mm) skin plate thickness, internally reinforce vertically with continuous steel stiffeners spaced 6-inches maximum on-center.
- Solid hardwood or laminated wood of at least 2 inches (50 mm) thickness with a 1/4-inch (6 mm) thick steel plate on the outside face.
- A door constructed with a 3/8-inch (10 mm) thick steel plate or combines thickness of outside and inside surfaces of at least 3/8-inch (10 mm) steel.

6-10.9 Door Frames and Hardware.

For doors other than the Class 5 Armory Doors, door bucks, frames, and keepers must be rigidly anchored and provided with anti-spread filler reinforcement to prevent disengagement of the lock bolt by prying or jacking of the door frame. Door frames must be designed and installed in a manner that prevents removal of the frame facing. Their construction requirements must be as exacting as those for the doors themselves. For example, where metal doors are used, the frame and thresholds must also be metal. Door hinges must be located on the inside and must be of the fixed-pin security type or equivalent. Figure 6-3, Figure 6-4, Figure 6-5, and Figure 6-6 show designs of acceptable hinge side protection.

Figure 6-3 Hinge Side Protection Using a Pin-in Socket

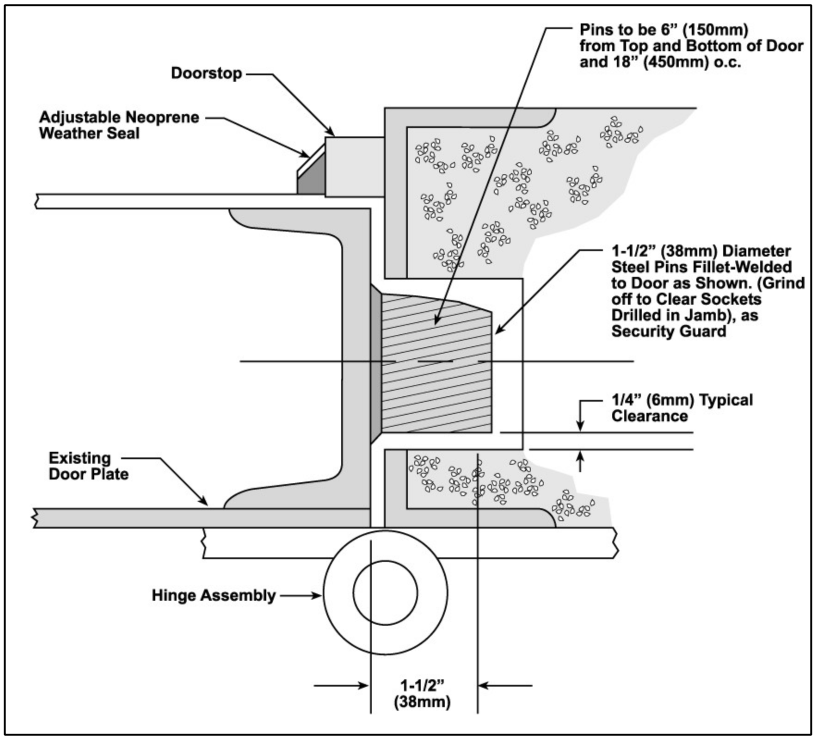


Figure 6-4 Hinge Side Protection Using a Forward Doorstop with Steel Angle

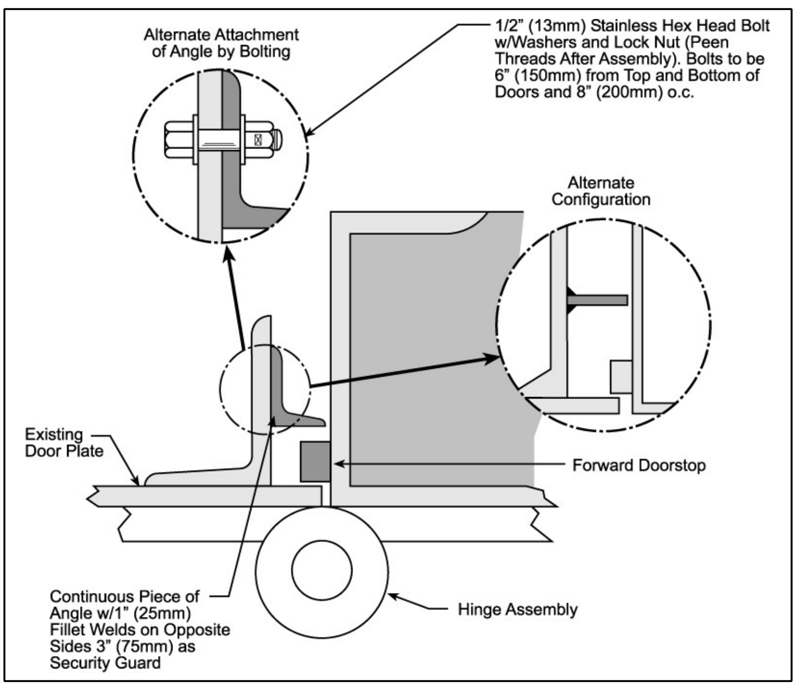

Figure 6-5 Hinge Side Protection Using an Angle Stop

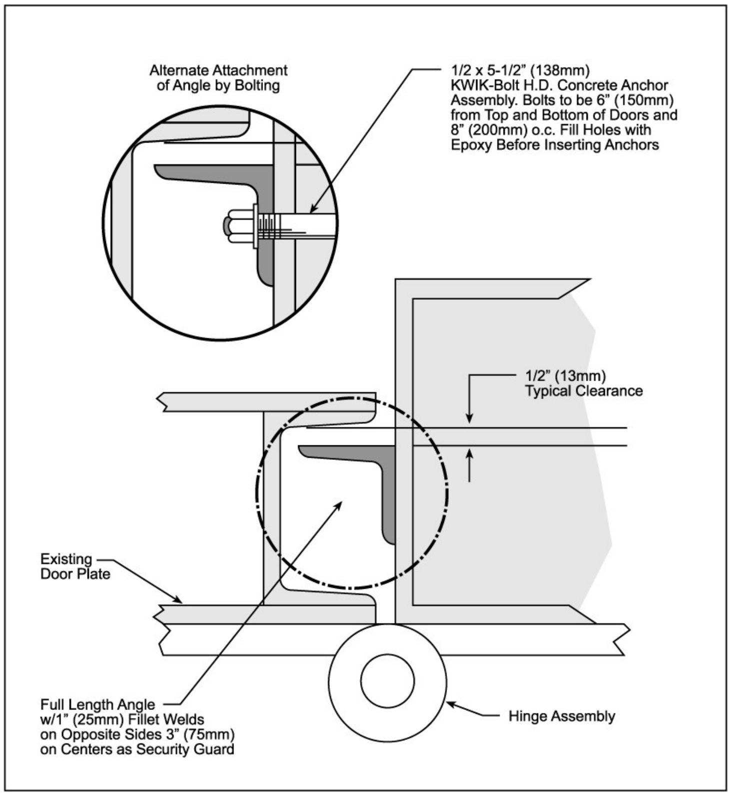

Figure 6-6 Hinge Side Protection Using a Bar Stop

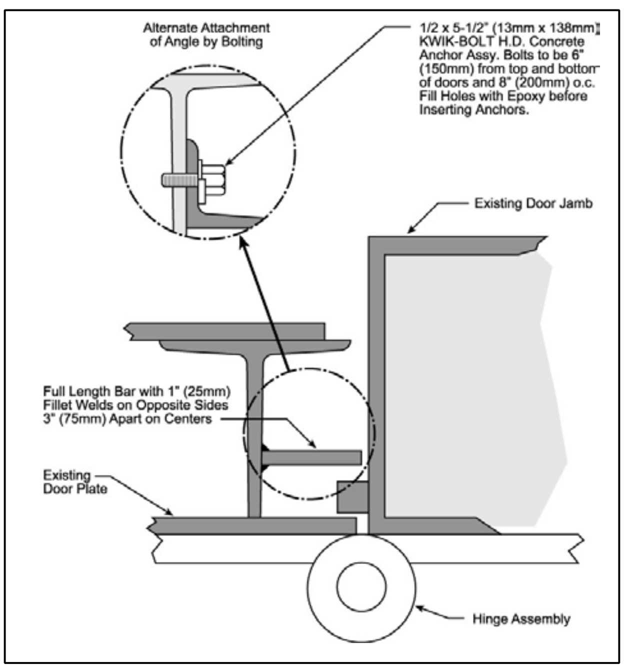
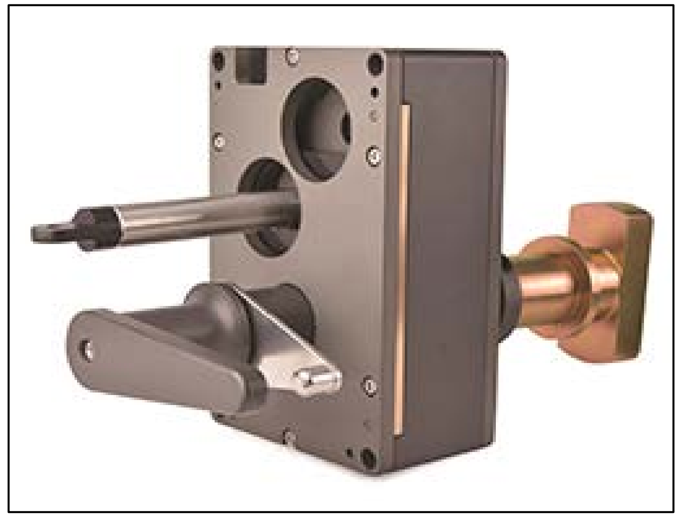


6-10.10 Locks.

Locks for Class 5 Armory Doors are covered in FS AA-D-600. They are combination locks that are listed in accordance with Group 1 of UL 768. Locks for new construction and upgrades of Category I and II AA&E areas must be the Internal Locking Device (See Figure 6-7 for all doors except for Class 5 Armory Doors.)

Figure 6-7 Internal Locking Devices

ILD Gen I



ILD Gen II

6-10.11 Miscellaneous Openings.

In general, windows and other openings must be kept to a minimum. Windows are not authorized for new construction for Army arms rooms. Where any openings are greater than 96 square inches (619 cm^2) with a least dimension greater than 6-inches (150 mm) one of the following can be used to secure them:

- Minimum 3/8-inch (10 mm) hardened steel rods with a maximum spacing of 4-inches (100 mm) and with horizontal bars attached to no openings exceed 32 square inches (0.02 square meters).
- Riveted steel grating weighing 13.2 lbs/square foot (64.4 kg/m^2) or welded steel grating weighing 8.1 lbs/square foot (39.6 kg/m^2) with 1 by 3/16-inch (25 by 5 mm) bearing bars.

6-10.12 Other Storage Options.

A vault that meets the requirements for arms rooms can be used to store all categories of Risk Category II, III and IV arms and ammunition depending on explosive safety restrictions. Modular vaults can also be used.

Security containers that meet the requirements of Federal Specification AA-F-363, Class 5, or Federal Specification AA-C-2859, can be used to store small quantities of Risk Category II, III and IV arms.

6-10.13 Other Requirements.

Unless a weapons storage site is continuously guarded, an IDS is required for Risk Category I and II AA&E storage areas. Refer to UFC 4-021-02 for IDS designs. Risk Category I and II AA&E must be fenced separately. Refer to UFC 4-022-03 for fencing and gate designs. Exterior lighting is required for Risk Category I and II AA&E only.

6-10.14 Retrofit of Existing Arms Rooms.

Existing facilities can be effectively upgraded to meet the AA&E storage requirement for ten minutes of penetration resistance against threat severity level III. To upgrade these facilities, reinforce walls, ceilings and floors as necessary using a layer of 3/4-inch (19-mm) plywood sandwiched between two layers of 10 gauge (3.4-mm) hot-rolled steel to provide about 6 minutes of additional penetration delay time. The penetration delay time can be increased by about five minutes with the addition of another wood and steel layer. This rule of thumb can be applied to the addition of more layers until the desired penetration delay time is reached. Penetration delay time for steel-plywood systems can be increased by changing the steel material to 9-gauge (3.8-mm) ASTM A1008, Class 2, high-strength, low-alloy steel. One layer of 3/4-inch (19-mm) plywood sandwiched between two layers of this steel will provide 14 minutes of penetration delay time. Adding layers of 90-pound (200-kg) gravel finish roofing paper between the plywood and steel further increases the penetration delay time to about 20 minutes. These times are added to the increased penetration delay time provided by preventing internal spalling of the concrete (approximately double the initial penetration delay time).

6-11 STORAGE CONTAINERS.

Class 5 storage containers are allowed as options for the storage of many of the assets that are governed by the regulatory documents described in Paragraph 6-2. They are not considered to be parts of facilities; however, they can provide resistance to forced entry at threat severity level II. Class 5 storage containers provide 10 man-minutes of delay against threat severity level II; they provide no delay against higher threat severity levels. See Figure 6-8 for storage container examples.

Storage containers must be approved by GSA. They are specified using one of the following Federal Specifications (FS) based on what is being stored inside them. The Federal Specifications include container construction and testing requirements as well as locking device specifications.

- FS AA-F-358, Filing Cabinet, Letter and Legal Size, Uninsulated, Security
- FS AA-F-363, Filing Cabinet, Security, Maps and Plans, General Filing and Storage
- FS AA-C-2859, Cabinet, Security, Weapons Storage
- FS AA-C-2786, Cabinet, Security, Information Processing System Storage, Class 5.

CHAPTER 7 EQUIPMENT AND SYSTEMS

7-1 INTRODUCTION.

This chapter contains information on systems that can be considered to supplement the barrier designs in Chapter 5 for high and very high levels of protection combined with threat severity levels IV and V.

7-2 DISPENSABLE BARRIER SYSTEMS.

Dispensable barriers are activated manually or automatically in response to attack. Such systems include sticky foam and cold smoke. Sticky foam is an aggressively tacky thermoplastic resin stored under pressure in canisters or wall panels. When punctured by tools or bullets, or when the system's detectors are tripped, the foam shoots out of the panels. The foam expands and adheres to whatever it contacts. Aggressors must be extricated from the foam with a solvent. The foam must also be cleaned off surfaces with the solvent. Because sticky foam may result in the death of the aggressor or anyone else who accidentally triggers it, apply it only where the use of deadly force is authorized. This system provides a minimum delay time of 15 minutes against motivated aggressors (according to the manufacturer). It is most effective when used in hallways. Cold smoke is a particulate material, which fills a room with a persistent dense cloud when activated. Aggressors cannot see in the cloud and therefore have difficulty locating assets. To be effective, both activated barrier systems must by sized for the volume of the protected space.

Dispensable barriers can, on command, stop or delay aggressors from accomplishing their objective. Several types are being developed and tested. This section identifies the major components of a dispensable barrier system and describes some of the attributes of dispensable materials. The information in this paragraph was developed by Sandia National Laboratories, Albuquerque, NM.

7-2.1 Typical Dispensable Barrier System.

A typical dispensable barrier system includes:

- A process for decision making to determine when the dispensable barrier is to be activated.
- Command and control hardware to implement this decision.
- The material that is deployed to physically deny access.
- The dispensing mechanism.
- A response force located on site.

7-2.2 Barrier Activation.

The dispensable barrier may be activated by a member of the response force, some form of intrusion sensing, or by the combined action of both the security force and sensors.

The major compromise is between assurance that activation can and will occur in an aggressor attack (reliability) and assurance that the probability of inadvertent activation is low (premature activation). Hardware design and effective operational procedures can reduce the probability of inadvertent activation to as low a value as required.

7-2.3 Command and Control Hardware.

The command and control hardware accepts the activation decision and operates the dispensing hardware. Command and control hardware stands between the decision mechanism and the dispensing hardware. Because the activation decision mechanism and the dispensing hardware may be separated by large distances, electromagnetic radiation, lightning, earthquakes, power surges, and other possible severe environments must be considered in the design. The command and control hardware improves personnel safety and assures that, if inadvertent activation occurs, authorized personnel in the area have time to exit.

7-2.4 Dispensable System.

7-2.4.1 Types of Dispensable Barriers.

Specific dispensable materials and associated dispensing hardware that are being developed and tested include:

- Rigid polyurethane foam.
- Stabilized aqueous foam.
- Obscurants smoke.
- Sticky thermoplastic foam.
- Various entanglement devices.
- Irritants.

7-2.4.2 Compact Storage and Rapid Expansion.

The dispensable material is normally stored in a compact form, and through a chemical or physical reaction, is expanded to provide additional delay. These properties that permit compact storage and rapid expansion make activated delay systems attractive in applications where operational considerations are dominant or where there are weight issues in the protective system design. For example, pyrotechnic and chemical obscurants have an expansion ratio of approximately 50,000 to 1, whereas most foams range from 50 to 1 to 500 to 1 for aqueous foams.

7-2.5 Dispensing Hardware.

Dispensing hardware consists of storage tanks, activation valves, pressure regulators, safety valves, filters, power sources, and plumbing hardware. The specific hardware design is unique for each material and application, but many of the components are similar. This uniqueness of design and limited application are factors that increase the cost of the dispensing hardware.

7-2.6 Response Force Time.

Dispensable barrier systems will only delay an adversary for a finite time. At some point in time, the aggressor will defeat any delay mechanism; therefore, either guards or the response force must respond and achieve control in a shorter time than the barrier delay time.

An effective dispensable barrier can reduce the critical need for an immediate reaction by the response force. This may allow the use of response personnel who are not always dedicated to security and therefore reduce overall protection system costs. In addition, the dispensing hardware requires that the adversary must be capable of doing more than just neutralizing the response force. This increased requirement on the aggressor can significantly increase the probability that the overall physical protection system will perform as desired.

7-3 SHUTTERING SYSTEMS.

Shuttering systems are doors, screens, or other barriers that can be used to supplement defense layer protection of assets. While these barriers provide only limited delay to a forced entry attempt, they do cause the aggressor to take time to breach them, thereby allowing additional time for a response force to deploy.

7-3.1 Automated Shuttering Systems.

Shuttering systems such as fire barrier doors and security shutters can be automatically deployed in response to detection devices such as smoke detectors, heat detectors, or intrusion detection sensors. They can also be deployed though commands from a guard or monitoring station.

During normal operations, fire barrier doors can be held open by magnetic door holders but released by remote command from fire alarm panels (automatic) or from a security command center. The doors also close upon loss of power. Security shutters are normally open until a command is received from the ACS (in response to sensor activation) or from a security command center. Shutters would remain open during loss of power.

7-3.2 Use of Automated Shuttering Systems.

Automated shuttering systems can be used to delay aggressors along predicable paths from building entrances to the protected areas containing the asset. Consider using them at personnel entrances and in hallways for high and very high levels of protection combined with threat severity levels IV and V.

A-2 DEFINITION OF TERMS.

Access Control: For the purposes of this document, any combination of barriers, gates, electronic security equipment, and/or guards that can deny entry to unauthorized personnel or vehicles.

Aggressor: Any person seeking to compromise an asset. Aggressor categories include protesters, criminals, terrorists, and subversives.

Antiterrorism: Defensive measures used to reduce the vulnerability of individuals and property to terrorist acts, to include limited response and containment by local military and civilian forces.

Assessment: Visual verification of the validity of an alarm from an electronic security system.

Asset: A resource requiring protection.

Biological Agents: Pathogens and toxins that can be used to contaminate air or water.

Breaching: Making a hole completely through a building surface using tools or explosives.

Building: A structure, usually enclosed by walls and a roof, constructed to provide support or shelter for an intended occupancy. Note that other structures, such as canopies, are not considered buildings for the purposes of this UFC.

Building Compound: A controlled area established around a building or group of building that has a perimeter defined by fences or walls, and an open area between the perimeter and the buildings.

Building Elements: Components of buildings and countermeasures associated directly with building interiors and exterior surface features.

Building Hardening: Enhanced conventional construction that mitigates threat hazards where standoff distance is limited. Building hardening may also be considered to include the prohibition of certain building materials and construction techniques.

Chemical Agents: Chemicals, including toxic industrial chemicals, toxic industrial materials, and military chemical agents that can be used to contaminate air or water.

Controlled Perimeter: A physical boundary at which vehicle access is controlled at the perimeter of an installation, an area within an installation, or another area with restricted access. A physical boundary will be considered as a sufficient means to channel vehicles to the access control points. At a minimum, access control at a controlled perimeter requires the demonstrated capability to search for and detect explosives. Where the controlled perimeter includes a shoreline and there is no defined perimeter beyond the shoreline, the boundary will be at the mean high-water mark.

Critical Asset: Any facility, equipment, service or resource considered essential to DoD operations in peace, crisis, and war and warranting measures and precautions to ensure its continued efficient operation, protection from disruption, degradation, or destruction, and timely restoration. Critical assets may be DoD assets or other government, or private assets Critical assets include traditional physical facilities and equipment, non-physical assets (such as software systems), or “assets” that are distributed in nature (such as command and control networks, wide area networks or similar computer-based networks).

Critical Infrastructure: Infrastructure deemed essential to DoD operations or the functioning of a Critical Asset.

Delay Time. The time an adversary must work to breach a security barrier to gain access to a secured resource. Total delay time is the sum of penetration and ingress times by one or more barriers separating an aggressor from a secured asset required to breach and travel between barriers. Total delay time can include egress time required to load the asset and exit the facility.

Design Basis Threat: The threat upon which a system of countermeasures protecting assets is based. The design basis threat includes the aggressor tactics and the associated weapons, explosives, tools, and agents.

Design Criteria: For the purposes of this document, the basis for defining a protective system that mitigates vulnerabilities to assets. Design criteria include assets, threats, levels of protection, and design constraints.

DoD Building: Any building or portion of a building (permanent, temporary, or expeditionary) owned, leased, privatized, or otherwise occupied, managed, or controlled by or for DoD. DoD buildings other than leased buildings are categorized within these standards as low occupancy, inhabited, primary gathering, high occupancy family housing, and billeting.

DoD Personnel: Any U.S. military, DoD civilian, or family member thereof, host-nation employees working for DoD, or contractors occupying DoD buildings. For the purposes of these standards, non-DoD visitors to DoD owned or controlled visitor centers, visitor control centers, museums, and similar facilities will be included in DoD personnel populations of those facilities. Visitor counts will be based on routine visitor levels.

Egress Time: The interval required for an aggressor to load and carry stolen assets when theft is the purpose of the penetration. The egress time varies depending upon the interior layout of the facility; the availability of doors, windows, and utility ports that can be opened; and the weight and volume of the assets being stolen. In general, egress time increases with layout complexity and any limitation on the number of doors, windows, and utility openings available as exits.

Entry Control Point. A continuously or intermittently manned station at which entry through a perimeter is controlled.

Equipment: As part of a protective system, countermeasures such an electronic security system elements and other devices used by personnel for detection and assessment of threats or weapons, tools, explosives, or chemical, biological, or radiological agents.

Explosive Safety: The practice of providing the maximum possible protection to personnel and property, both inside and outside the installation, from the damaging effects of potential accidents involving DoD ammunition and explosives.

Ferrocement or **ferro-cement:** Also called thin-shell concrete or ferro-concrete; is a system of reinforced mortar or plaster (lime or cement, sand and water) applied over layer of metal mesh, woven expanded-metal or metal-fibers and closely spaced thin steel rods such as reinforcing bars.

Forced Entry Penetration Delay Time: Barrier penetration time is defined as the time interval during which an aggressor can create a man-passable opening through a barrier (such as a wall, roof, floor, door, or window) by forced entry. The penetration delay time is based on working time rather than elapsed time. Working time accounts for the interval that an attack tool is used to attack the barrier. Working time excludes the time required to change tools, change operators, rest, and transfer tools, and for personnel to pass through the barrier. In not accounting for these interruptions, the penetration delay time is inherently conservative. In the case of multiple barriers, the total penetration delay time is the sum of the individual penetration delay times provided by all barriers.

Fragment: For the purposes of developing protective systems, pieces of the materials surrounding an explosive that may be propelled at high velocity toward a building or other target as a result of an explosion of a bomb or a warhead.

Gravity Vent: Strategically placed opening in the building to take advantage of prevailing winds and thermal buoyancy or stack effect to remove heat from a building.

Halligan Bar: A tool used in fire and rescue service for forcible entry and other prying and striking tasks.

Historic Preservation: Protection afforded to districts, sites, buildings, structures, or objects listed on or eligible for inclusion on the National Register of Historic Places in accordance with the National Historic Preservation Act.

Incendiary Devices: Devices designed to spread fire.

Ingress Time: The sum of all-time intervals required for an aggressor to traverse from barrier to barrier within a site or facility. This includes the time required to climb (up or down) through horizontal barriers (for example, roofs or floors) and the time to traverse between vertical barriers (for example, walls or fences). In general, ingress time increases with increasing site or facility size, number of barriers separating the secured area from the exterior, and size and types of tools and equipment that must be transported between barriers. The designer can increase ingress time by properly laying out the exterior and interior of the facility.

Inhabited Facilities: Buildings or portions of buildings routinely occupied by 11 or more DoD personnel and with a population density of greater than one person per 430 gross square feet (40 gross m^2). This density generally excludes industrial, maintenance, and storage facilities, except for more densely populated portions of those buildings such as administrative areas. The inhabited building designation also applies to expeditionary and temporary structures with similar population densities. In a building that meets the criterion of having 11 or more personnel, with portions that do not have sufficient population densities to qualify as inhabited buildings, those portions that have sufficient population densities will be considered inhabited buildings while the remainder of the building may be considered uninhabited, subject to provisions of these standards. An example would be a hangar with an administrative area within it. The administrative area would be treated as an inhabited building while the remainder of the hangar could be treated as uninhabited.

Kerie Cable: A long flexible spiral cable with the center strand pulled out to allow for oxygen passage used as an exothermic cutting tool.

Kelly Tool: A tool used in fire and rescue service for forcible entry and other prying and striking tasks. The predecessor of the Halligan bar, it has largely been superseded by the latter, but still sees some use.

Level of Protection: The degree to which an is protected against injury or damage from an attack.

Man-Passable Opening: A man-passable opening is defined as the minimum area required for an aggressor to physically pass through a barrier and enter a secured area. DoDM 5100.76 defines man-passable as an opening of 96 square inches (619 cm^2), which is at least 6 inches (150 mm) wide or high. These values have been established to standardize laboratory test procedures and provide a built-in level of conservatism for the final test results. The forced entry test data presented in this UFC are based on tests and are conservative. The conservative nature of this approach is even more evident where the avenue of physical entry involves passage through a thick barrier, such as an 18-inch (450-mm) reinforced concrete wall, or a long passageway, such as a 20-foot (6-m) ventilation duct.

Manpower: Countermeasures that relate to the use of guards or other personnel necessary to implement or operate elements of the protective system.

Passive Perimeter Barriers: Vehicle barriers that are permanently deployed and do not require a response to be effective and fences, walls, screens, landforms, and lines of vegetation applied along an exterior perimeter used to obscure vision, hinder personnel access, or hinder or prevent vehicle access.

Penetration: Relating to bullets or fragments, entry into a material without passing all the way through.

Planning Team: A team of people with responsibilities relating to a project that is formed to develop design criteria and review material from all phases of the design process.

Protected Asset: An asset identified in the project design criteria that requires protection against a forced entry attack.

Protective System: An integrated system of countermeasures designed to protect assets against threats to specific levels of protection. Protective systems include building elements, sitework elements, equipment, and manpower and procedures.

Procedures: Countermeasures that relate to actions taken by people, including guards and building occupants, to implement or operate elements of the protective system.

Risk: A means to quantify the combined issues of the value of an asset or the impact of its loss, the likelihood of the asset being attacked, and the effectiveness of the protection afforded the asset that can be used as a tool in making decisions about asset protection.

Risk Analysis: The process of determining risk levels for assets.

Risk Management: The process of evaluating how changes in countermeasures application affect risk levels and costs for the purpose of decision making.

Sitework Elements: Countermeasures that are applied beyond 1.5 meters (5 feet) from a building, excluding countermeasures categorized under equipment.

Spall: The condition in which pieces of a material are broken loose from the inner surface of a wall, roof, or similar element by tensile forces that are created when a compression shock wave travels through the body and reflects from the surface.

Specific Design Strategy: The approach to applying general design strategies based on the applicable levels of protection.

Tactics: The specific methods of achieving the aggressor's goals to injure personnel, destroy assets, or steal materiel or information.

TNT Equivalent Weight: The weight of TNT (trinitrotoluene) that has an equivalent energetic output to that of a different weight of another explosive compound.

Unobstructed Space: Space within 10 meters (33 feet) of an inhabited building that does not allow for concealment from observation of explosive devices 150 mm (6 inches) or greater in height.

Vulnerability: Any weakness in the design or operation of a protective system for an asset that can be exploited by an aggressor to disrupt, damage, destroy, injure, or otherwise compromise the asset.

UFC 4-027-01 contains Controlled Unclassified Information (CUI). Direct inquiries regarding this UFC to:

Air Force: Mr. Jeffrey Nielsen (AFCEC/COSC), jeffrey.nielsen@us.af.mil, DSN 523-6119, or commercial 850-283-6119.

Navy: Ms. Julie Heup (NAVFACSYSCOM – PDCC), julie.m.heup.civ@us.navy.mil , DSN 262-4447, commercial 757-322-4447

Army: Mr. Ryan Murphy (HQUSACE), ryan.r.murphy@usace.army.mil , commercial 202-236-0670

OVERVIEW

This UFC supports physical security and force protection planning and design of deployed operational bases to protect personnel, assets, and infrastructure from terrorism and other deliberate man-made threats. The intended users of this UFC are engineers and planners responsible for project development and force bed down in the deployed environment. This UFC provides appropriate, effective, and economical protective designs to a level appropriate for project programming and provides commanders with the information they need to allocate resources. It covers minimum protection requirements and best practices applicable for temporary to semi-permanent facilities and infrastructure. The summary outline below is intended to guide potential inquiries regarding its scope.

SUMMARY OUTLINE

INTRODUCTION
- *Applicability*
- *Regulatory or functional authorities*
- *General building requirements*
- *Cybersecurity*
- *Security engineering UFC series*

PLANNING AND REQUIREMENTS DEVELOPMENT

Change No.	**Date**	**Location**
1	December 2017	Revised UFC Summary Sheet and Para. 1-3 Army Applicability
2	June 2019	Changed references to USACE Mobile District to Savannah District on Pages 2, 3, and 5

This UFC supersedes UFC 4-133-01N, dated July 2007.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

UNIFIED FACILITIES CRITERIA (UFC)
NEW SUMMARY SHEET

Document: UFC 4-133-01, *Air Traffic Control and Air Operations Facilities*

Superseding: *UFC 4-133-01N, Navy Air Traffic Control Facilities, 30 July 2007*; *UFC 4-141-10N, Design Aviation Support Facilities \1\ Section 6 and Section 8 and all other content relating to facility types in this UFC 4-133-01 /1/*, *United States Air Force Design Guide for Air Traffic Control Towers and Radar Approach Control Facilities, 15 November 2001.*

Description:

UFC 4-133-01 provides requirements for evaluating, planning, programming, and designing Air Traffic Control (ATC) and Air Operations Facilities. This UFC contains guidance for Army, Navy and Air Force planners, engineers, and architects on the planning, engineering, and design of Air Traffic Control Towers (ATCT), Radar Approach Control Facilities (ARAC/RATCF/RAPCON), and Air Operations Buildings (AOB). This UFC is intended as a source of basic architectural and engineering information for all individuals involved in the planning, design, or evaluation of ATC and Air Operations Facilities.

Reasons for Document:

This UFC was developed to provide design requirements to accomplish the following:

- Assist planners in understanding the facility requirements to ensure accurate space programs and budgets,
- Provide architects, engineers and construction surveillance personnel with the essential, minimum requirements for the design and construction of Air Traffic Control and Air Operations Facilities.

Impact:

The following will result from the publication of this UFC:

- There are negligible cost impacts; however, a greater degree of standardization among the Service Branches will result.

\1\ Change 1:

- UFC Summary Sheet. **Superseding** paragraph revised to reflect that this UFC supersedes only certain content of UFC 4-141-10N.
- Para 1-3. Revised to clarify required coordination with respective Army Centers of Aviation Standardization and Expertise and change in availability of definitive designs./1/

\2\ Change 2:

- Paragraph 1-3. Changed "Mobile District Center of Standardization of Army Vertical Aviation Facilities (CESAM-AVN-COS-V)" to "Savannah District Center of Standardization for Air Traffic Control/Air Operations Facilities (CESAS-ATCT-COS)"
- Paragraph 1-6. Changed "Aviation Center of Standardization-Vertical (CESAM-AVN-COS-V), Mobile District" to " Air Traffic Control/Air Operations Facilities Center of Standardization (CESAS-ATCT-COS), Savannah District,"
- Paragraph 2-1. Changed "AVN COS-V" to "ATCT-COS" /2/

Unification Issues

The following table identifies items that are not unified among the services:

Section	Topic	Issue
3-9.1	Physical Security General Requirements	The Navy provides additional operational security requirements for ATC facilities.
4-1.2.20	Cab Consoles	Cab consoles are procured differently by each service.
4-1.7.7	Airfield Lighting Control Panel	Each Service branch has unique requirements for the Airfield Lighting Control Panel based on operational standards and interaction with established ATC systems.
4-2.7.7.4	Back-Up Radio Poles and Communications Antennas	The Air Force maintains a requirement for poles for mounting back-up radio antennas.
4-2.7.8.1	Operations/IFR Lighting	The Navy requires colored lights to provide continuity between shore and shipboard operations. The Army and Air Force do not have a requirement for colored lights in the Operations/IFR Room.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND

This Unified Facilities Criteria (UFC), UFC 4-133-01, provides requirements for evaluating, planning, programming, and designing Air Traffic Control (ATC) and Air Operations Facilities. The requirements contained in this UFC apply to Army, Navy, and Air Force facilities unless specifically referenced to a single service. This UFC is not intended as a substitution for thorough review during design by individual Program Managers and Operations Staff in the appropriate service.

The desired goal of this UFC is to maintain consistency in ATC and Air Operations Facility requirements across the Army, Navy and Air Force. This UFC is not intended as an operational manual.

Each service has unique requirements to fulfill specific missions. This document will highlight any key differences that impact the overall facility program, layout and design. Where one Service's criteria vary from the other Services' criteria, it is noted in the text.

1-2 PURPOSE AND SCOPE.

This UFC contains guidance for Army, Navy and Air Force planners, engineers, and architects on the planning, engineering, and design of ATC and Air Operations Facilities, which include three facility types:

- <u>Air Traffic Control Tower</u> (ATCT) – Houses equipment and personnel for control of aircraft approaching, departing, and transiting the terminal area or airport and aircraft and vehicular movement on the runways, taxiways and all other movement areas.

- <u>Radar Approach Control Facility</u> (RACF), referred to as the Army Radar Approach Control Facility (ARAC); the Navy Radar Air Traffic Control Facility (RATCF); or the Air Force Radar Approach Control Facility (RAPCON) – Enables the radar branch to provide radar ATC services to instrument flight rules (IFR) and visual flight rules (VFR) air traffic within assigned airspace.

- <u>Air Operations Building</u> (AOB), referred to as the Navy Air Operations Building; the Air Force Airfield Management Operations (AMOPS) Building; or the Army Airfield Headquarters Building/Airfield Operations Facility - Houses the central command, control, services, and management center of an air installation complex. It provides the management center for flight operations, services, and movement control for the entire air installation complex.

1-3 APPLICABILITY.

This UFC is intended as a source of basic architectural and engineering information for all individuals involved in the planning, design, construction or evaluation of ATC and Air Operations Facilities. Architects and engineers (A/Es) that provide design services will use this UFC under the direction of the Service design agencies. Installation and facility planning personnel will use this UFC, in conjunction with other required planning documents, for programming new or replacement facilities, pre-design planning, or assessing the extent of improvements required in an existing ATC or Air Operations Facility in order to achieve the standard established herein.

Refer to UFC 3-260-01, Sec. 1-4, for additional applicability description.

For more information, refer to the following **Service-specific** governing documents:

- **Army**: \1\ This UFC must be used in coordination with the \2\Savannah District Center of Standardization for Air Traffic Control/Air Operations Facilities (CESAS-ATCT-COS)/2/, and the Omaha District, Army Mandatory Center of Expertise for Horizontal Aviation (CENWO-MCX-Horizontal AVN) by authorities granted under ER 1110-345-100 and ER 1110-3-109. /1/
- **Navy**: This UFC is the primary guidance to be used in conjunction with Facility Requirements Documents (FRD), Facility Requirements Supplements (FRS), Intrusion Detection Systems Engineering Plans (IDSEP), Base Exterior Architecture Plans (BEAP), and other DoD and Department of Transportation (DOT) material for the planning and construction of ATCFs and the preparation of DD 1391 MILCON and Step II Special Project Submissions.
- **Air Force**: This UFC must be used in coordination with AF Project Manager Guide for Construction and AFMAN 32-1084, *Facilities Requirements*.

1-4 GENERAL BUILDING REQUIREMENTS.

UFC 1-200-01, "General Building Requirements", provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, sustainability, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein, including the core UFCs listed in UFC 1-200-01.

1-5 FACILITY PROJECT TEAM.

The planning and design team for ATC and Air Operations Facilities must include the standard architectural and engineering (including civil, structural, MEP, and fire protection) disciplines along with the following representatives:

- Airfield or Heliport Operations
- Airfield or Heliport Maintenance Operations
- Environmental Quality and Protection

- Safety
- Fire Emergency Services
- Facility Maintenance
- Energy Management
- Flightline and AT/FP Security
- Space and Naval Warfare Systems Command (SPAWAR) - Navy only

1-6 PROGRAM AUTHORITIES.

Prior to project development, confirm the acquisition methodology and coordinate facility requirements with the appropriate Service. The functional proponent to justify the need, scope (size), and utilization of an ATC or Air Operations Facility is described below. Engineers and planners should assist operations personnel with the planning and programming, definition and scope, site selection, and design of the facility. The functional proponents for each Service are:

- **Army**: Coordinated effort of Air Traffic Services Command (ATSCOM), U.S. Army Aeronautical Services Agency (USAAA), the \2\Air Traffic Control/Air Operations Facilities Center of Standardization (CESAS-ATCT-COS), Savannah District,/2/ and the Transportation Systems Center (TSC), Omaha District.
- **Navy and Marine Corps**: Coordinated effort of the Station, SPAWAR, NAVAIR and NAVFAC
- **Air Force**: Air Force Final Authority A30-BAA, HQ AFFSA (operations) and AFCEC (technical).

1-7 APPENDICES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

Appendix B contains a list of background information, “lessons learned,” and other current, good design practices. The designer is expected to review and interpret this guidance and apply the information according to the needs of the project.

Appendix C contains an outline of the Site Selection Process.

Appendix D contains acronyms, abbreviations, and terms.

This Page Intentionally Left Blank

CHAPTER 2 PLANNING AND LAYOUT

This chapter describes the technical requirements that should be addressed during the planning and layout phase in order to understand the unique requirements of Air Traffic Control (ATC) and Air Operations Facilities.

2-1 SPACE CRITERIA.

ATC and Air Operations Facility space needs are site and mission specific and must be individually programmed based on a facility study. Space program development guidance is provided in the following documents:

- **Army**: Actual size must be determined from the definitive standard design and criteria documents in conjunction with unique site requirements shown in the Design-Build Request for Proposals (DB RFP) documents for new ATCFs. Space modules, criteria, or components of the Airfield HQ/ATC Facility must be used to develop space allowances and/or requirements before consideration for development of unique or specialized space allowances from those set forth in this definitive standard design. When space standards and criteria and/or components are not used, the Functional Proponent, in accordance with the Aviation FDT, AVN \2\ATCT-COS/2/ (buildings), and AVN COS-H (siting), will review and validate functional or operational requirements prior to the development of any unique or specialized space allowance(s) and before incorporating into a project programming document or facility design.

- **Navy**: Actual size must be determined during the planning phase using UFC 2-000-05N, *Facility Planning Criteria for Navy and Marine Corps Shore Installations* and UFC 3-101-01, *Architecture*. Consult SPAWAR for the space requirements of the required ATC equipment.

- **Air Force**: Actual size must be determined during the planning process using AFMAN 32-1084, *Facility Requirements*.

Certain spaces are not defined specifically in space programming criteria, such as the Control Cab and Simulator Classroom. These spaces should be considered and added to the space criteria during the planning/DD 1391 development phase.

2-2 COLLATERAL EQUIPMENT.

ESD workbenches, storage cabinets, and shelving are usually procured with the rest of the facility furniture. The work benches, storage cabinets, and shelving are not “built in” during construction. Special ESD chairs are also required.

2-3 PROJECT PHASING AND COORDINATION.

If continuous operations are required, then ensure that project construction phasing does not interrupt ATC operations.

FAA and ATC equipment will need to be relocated from existing facilities, or procured and installed in a new ATC facility. Coordinate requirements and appropriate funding during the planning phase. Refer to Appendix B-20 of this UFC for more information.

2-4 FACILITY TYPES.

Design the ATC and Air Operations Facilities to provide space and equipment for the specific functions required by the project mission. In general, there are two (2) types of ATC Facilities and one (1) type of Air Operations Facility:

1. Air Traffic Control Tower (ATCT)
2. Radar Approach Control Facility (RACF) and
3. Air Operations Building (AOB)

2-4.1 Air Traffic Control Tower (ATCT).

2-4.1.1 Function

The Air Traffic Control Tower (ATCT) houses equipment and personnel for control of aircraft approaching and departing the terminal area and aircraft and vehicular movement on the runways, taxiways, and all other movement areas. It is an elevated structure having an unobstructed line-of-sight to the airfield approach areas, runways, taxiways, aircraft parking areas, and all other operational areas over which aircraft movements must be controlled. The ATCT may be an independent facility or combined with a Radar Approach Control Facility (RACF) or an Airfield Operations Building (AOB). If at all possible, the control tower should be an integral facility with the RACF, thus providing a complete, integrated air traffic control facility.

The ATCT is the nerve center for an air installation complex. All air movement within the Class D airspace and all ground movement are controlled via the ATCT when operational. In some locations, control is relinquished as an advisory service to Flight Operations during extended hours of operation. All aviation electronics (e.g. radios), navigational aids, and landing/approach systems are controlled and operated by ATC personnel. Hence, redundant capabilities in controlling lighting, communications, and data must exist at both the ATCT and Flight Operations. During emergency conditions, (e.g., severe weather), ATC activities may displace to Flight Operations when occupying a tall, narrow building becomes hazardous to ATC personnel.

2-4.1.2 Tower Location and Height.

Each Service branch maintains a Site Selection process that establishes overall Tower location and height. Siting is dependent on a Siting Report. Refer to Section 2-6 for more information.

2-4.1.3 Space Allowance.

Each Service branch maintains a program approval process that establishes overall ATCT size.

- **Army**: The tower gross square foot (GSF) area is a function of the required height for observation of aircraft. This is validated by G-3/5/7 (USAASA). The tower can be a single structure composed of a Control Cab and the tower vertical shaft, which accommodates the structure, functional areas, and provides a code compliant stairwell and elevator. In addition, a tower can be a single structure co-located with another facility structure, but separated seismically for force protection measures.
- **Navy**: The minimum installation is a basic tower containing an entrance level, five (5) intermediate levels, and the Control Cab. Towers of increased height can be provided by adding incremental levels. Cab dimensions are determined during the design phase. Reference UFC 2-000-05N.
- **Air Force**: Refer to Air Force Manual (AFMAN) 32-1084. Space requirements are generally dictated by the site survey and Statement of Intent (SOI) that defines some site specific design parameters. AF Operations (AOF, CCTLR, and AFFSA) will determine the Control Cab occupancy in the site survey.

Table 2-1 outlines the various ATCT Cab level controller and space allowances, either in net square feet (NSF) or gross square feet (GSF). The number of positions and total square footage for each service are based on current average standards. Additional Cab area may be required based on higher controller levels.

Table 2-1 ATCT Cab Controller and Space Allowances

ATCT Service Criteria	Typical ATC Controller Positions[1]	Cab Area (SF)	
Army			
Standard Cab 3 positions and 1 supervisor	4	600 Max NSF[2]	Based on AR 420-01 and TC 3-04.81
Navy			
Standard Small Cab 2 positions and 1 supervisor	3	370 GSF[3]	Based on NAVAIR 80-T-114
Standard Medium Activity Cab 3 positions and 1 supervisor	4	500 GSF	
Standard Large Cab 4 positions and 1 supervisor	5	620 GSF	
Air Force			
Standard Cab 3 positions and 2 supervisors (including SOF – Supervisor of Flying)	5	540 NSF + 64 NSF for each additional position	Based on AFMAN 32-1084

[1] Positions include space for trainees. Additional special positions may be required based on survey results.
[2] NSF = Net Square Feet
[3] GSF = Gross Square Feet

2-4.1.4 Functional Program Areas.

Typical functional program areas are listed and described briefly in Table 2-2 and described in greater detail in Chapter 5.

Note: Not all ATCT's contain all of the areas listed in the table. The functional areas required are dependent on operational requirements, and the functions required are determined by the user during the planning/DD 1391 development phase.

Table 2-2 ATCT Functional Program Areas

Functional Program Area	Description
Main Entrance Lobby/Vestibule (Table 5-1.1)	Main entrance to the ATCT. Include vestibule in cold weather climates.
Elevator and Elevator Lobby (Table 5-1.2)	One (1) elevator must be provided to service the ATCT. Elevator service is not required to serve the Control Cab and the floor immediately below the Control Cab. However, if a hydraulic elevator is used, the elevator can serve all floors including the one immediately below the Control Cab.
Elevator Machine Room (Table 5-1.3)	A room housing elevator machine equipment.
Tower Shaft Mechanical Room (Table 5-1.4)	A room housing mechanical equipment servicing the Tower Segment with a lockable door.
Tower Shaft Electrical Room (Table 5-1.5)	A room housing electrical equipment servicing the Tower Segment with a lockable door.
Telecommunications Room (Table 5-1.6)	Telephone / Data Communications Frame Room housing the communications distribution plant.
Fire Pump Room (Table 5-1.7)	A room housing the fire pump.
ATCT Simulator Room (Table 5-1.8)	A Simulator Room may be required in the ATCT or the RACF. Refer to description of Simulator Room in Table 2-3.
Administration Area (Table 5-1.9)	An area for the Facility Administrative Work Space.
Private Offices	Provide private offices for the following:

Functional Program Area	Description
(Table 5-1.10)	1. An office for the Chief Controller with a lockable door. The Chief Controller controls all operations of the ATCT and reports back to the AOF/CC. All personnel within the ATCT report to the Chief Controller.
	2. An office for the Chief of Airspace Information Center (Army only)
	3. An office for the Chief of Ground Controlled Approach (Army only)
Training Room (Table 5-1.11)	A room for mandatory training with a lockable door. May be combined with Break Room for space and budgetary constraints.
Toilet Rooms (Table 5-1.12)	Provide a minimum of two (2) toilet rooms, both unisex, one near ground level and one on the level directly below the Control Cab. If the ATCT is attached to a support building that has toilet rooms, then the First and Second floors of the Tower are not required to have a toilet room for those floors. Toilet rooms are only required for the Third floor and above.
Janitor Closet (Table 5-1.13)	A room for janitorial supplies and equipment.
Stairwell (Table 5-1.14)	Pressurized fire-rated stairwell providing emergency egress from the floor below the Control Cab to the ground floor
Lower Electronic Equipment Room (Table 5-1.15)	A room housing ATC electronic equipment with a lockable door. Divide electronic equipment room into two rooms on different floors only if equipment will not fit on one floor due to Occupational Safety and Health Administration (OSHA) standards (e.g. equipment rack spacing). Some stand-alone ATCTs could require three equipment rooms on different floors to accommodate additional equipment (such as a voice switch, recorder, etc.)

Functional Program Area	Description
Upper Electronic Equipment Room (Table 5-1.16)	Preferred location for communication equipment, equipment with antennas, and back-up radio systems.
UPS Room (Table 5-1.17)	A room housing batteries and the UPS system, with a lockable door. May be combined with the ATCT Electronic Equipment Room.
Ready/Break Room (Table 5-1.18)	A room with a small kitchenette and seating for mandatory controller breaks on a separate level from the ATCT Control Cab.
Control Cab Mechanical Room (Table 5-1.19)	A mechanical room providing HVAC service for the ATCT Control Cab separately.
Control Cab Electrical/ Telecommunications Room (Table 5-1.20)	A room housing electrical power and telecommunications equipment for the Control Cab.
Control Cab (Table 5-1.21)	A room with windows on all sides with minimal window framing to maximize view of the airfield.
Electronic Equipment Room (Table 5-1.22)	Additional room housing additional ATC Electronic Equipment, such as the Voice Communications Switching System (VCSS).
Catwalk	An exterior platform surrounding the Control Cab, providing exterior access for cleaning the Cab glass.
Mechanical Chase	A fire rated chase, open from the ground floor to the concrete sub-floor of the ATCT Cab that serves as a pathway for HVAC and plumbing utilities from the Tower Shaft Mechanical Room to the ATCT Mechanical Room.
Vertical Cable Chase	A fire rated chase, open from the ground floor to the concrete sub-floor of the ATCT Cab that serves as a pathway for communications cables from the first floor Telecommunications Room to the Lower Equipment Room, Upper Equipment Room, and the Control Cab.

Functional Program Area	Description
Antenna Cable Chase	Ducts or conduits located within or adjacent to the Control Cab structural columns that serve as pathways for antenna cables from the Equipment Room containing radios to the ATCT Roof.
Ground Controlled Approach (Table 5-1.23)	An office-type open work area for Ground Controlled Approach operations.
Airspace Information Center (Table 5-1.24)	An office-type open work area for Airspace Information Center operations.
ATC Equipment Maintenance (Table 5-1.25)	A building/room for ATC electronic equipment maintenance, including an area for soldering and storage, when an ATCT is located remotely from the Airfield Operations Building.
Mechanical Yard	A screened maintenance yard must be provided for the chiller, back-up generator fuel tank, transformer, etc. In cold-weather climates, the generator may be located in an enclosed generator room. Coordinate with AT/FP requirements.

2-4.1.5 Functional vs. Non-Functional Tower Shaft.

ATCTs may have a functional or a non-functional tower shaft supporting the Control Cab. The key programmatic differences between a functional and a non-functional tower shaft include the following:

- Functional Tower Shaft: Typically pertains to low and intermediate activity ATCTs where operations support functions can be located on most floors in the tower shaft. This eliminates the need for an administrative support building.
- Non-functional Tower Shaft: Typically pertains to major activity ATCTs where operations support functions cannot fill up all the floors in the tower shaft. The shaft includes only unoccupied spaces (i.e. egress stair, elevator and service shafts, etc.) to reduce the floor footprint for cost efficiency. Two to three floors immediately below the cab can be used for administrative support and equipment spaces (these floors can have a wider footprint).

In either case, the preferred layout for the tower shaft is rectangular or square to maximize the efficiency of the layout of the internal spaces.

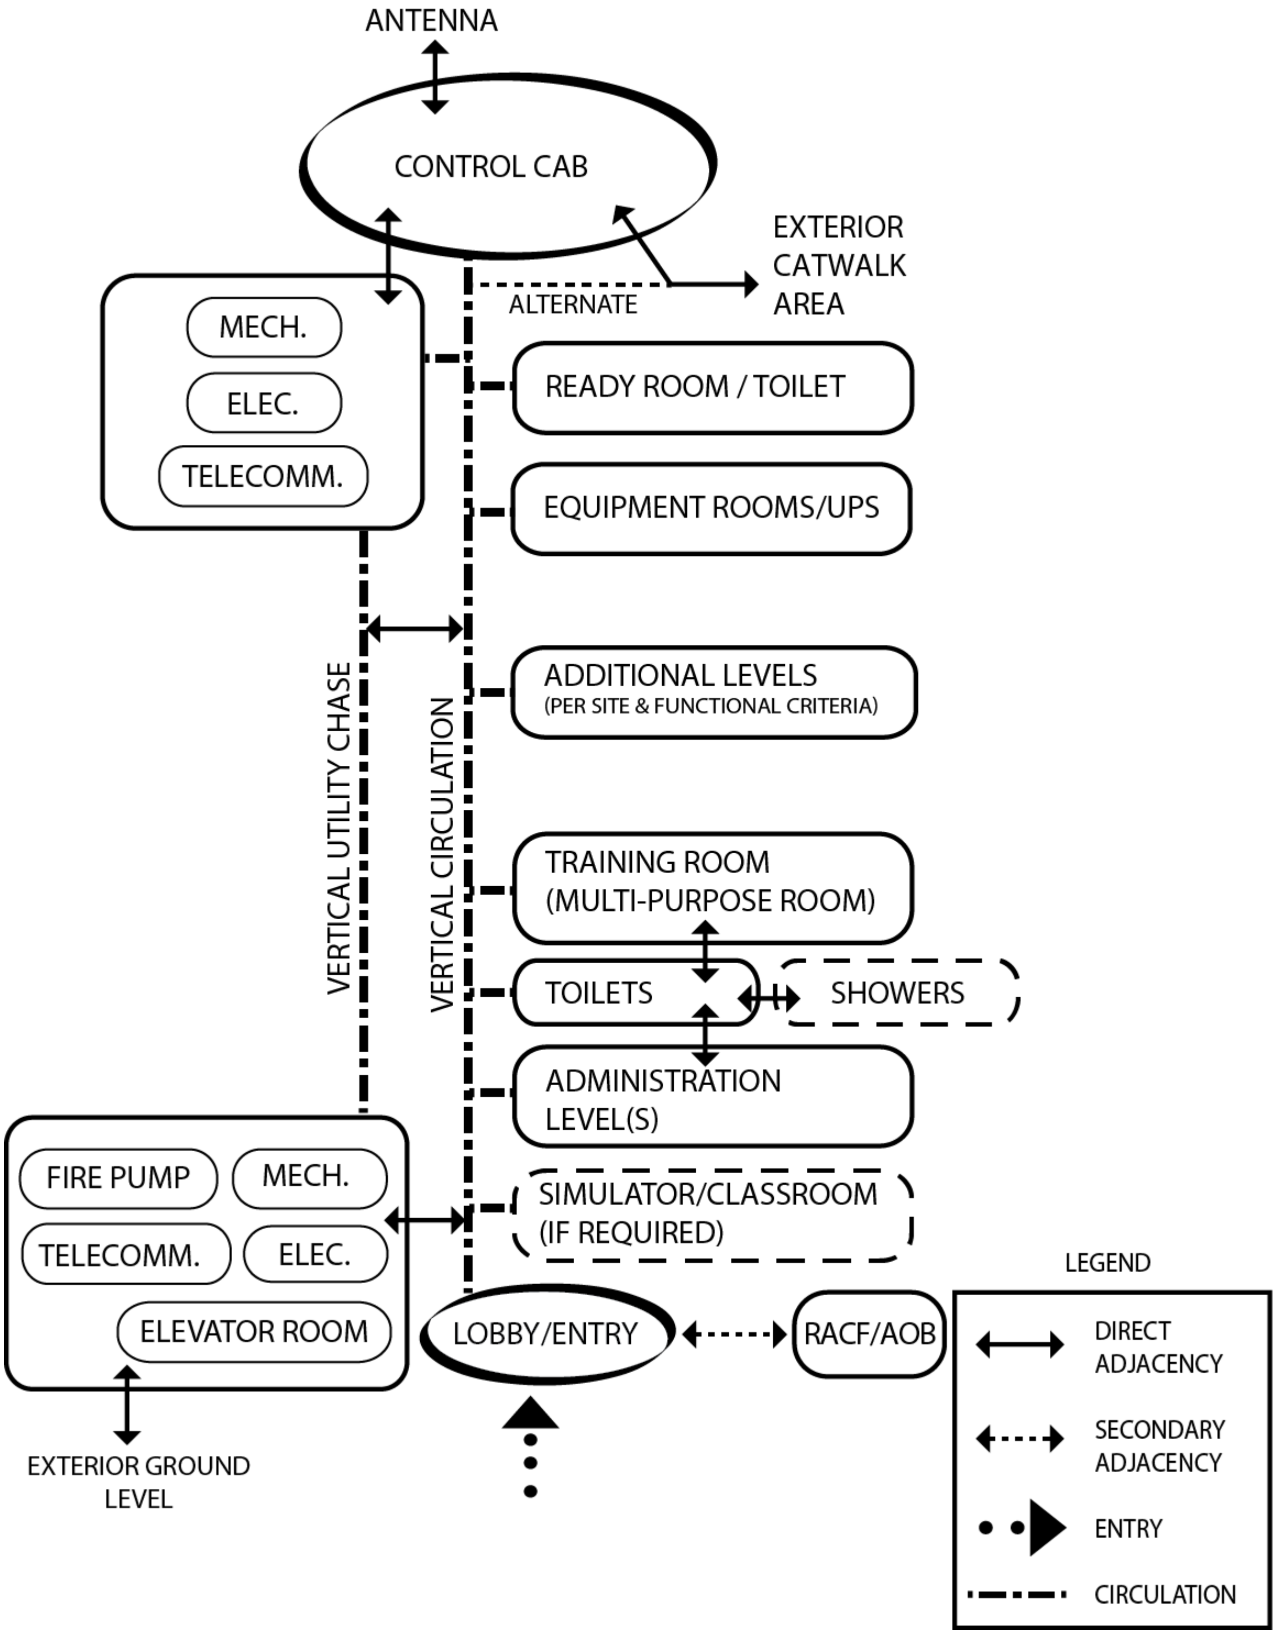
2-4.1.6 Adjacencies and Layout.

Figure 2-1 represents the vertical adjacencies in an ATCT. This diagram does not convey a building shape, but represents the required adjacencies in a typical ATCT. Figures 2-2 and 2-3 represent a notional Control Cab plan and Section Diagram, respectively.

Important adjacency requirements include the following:

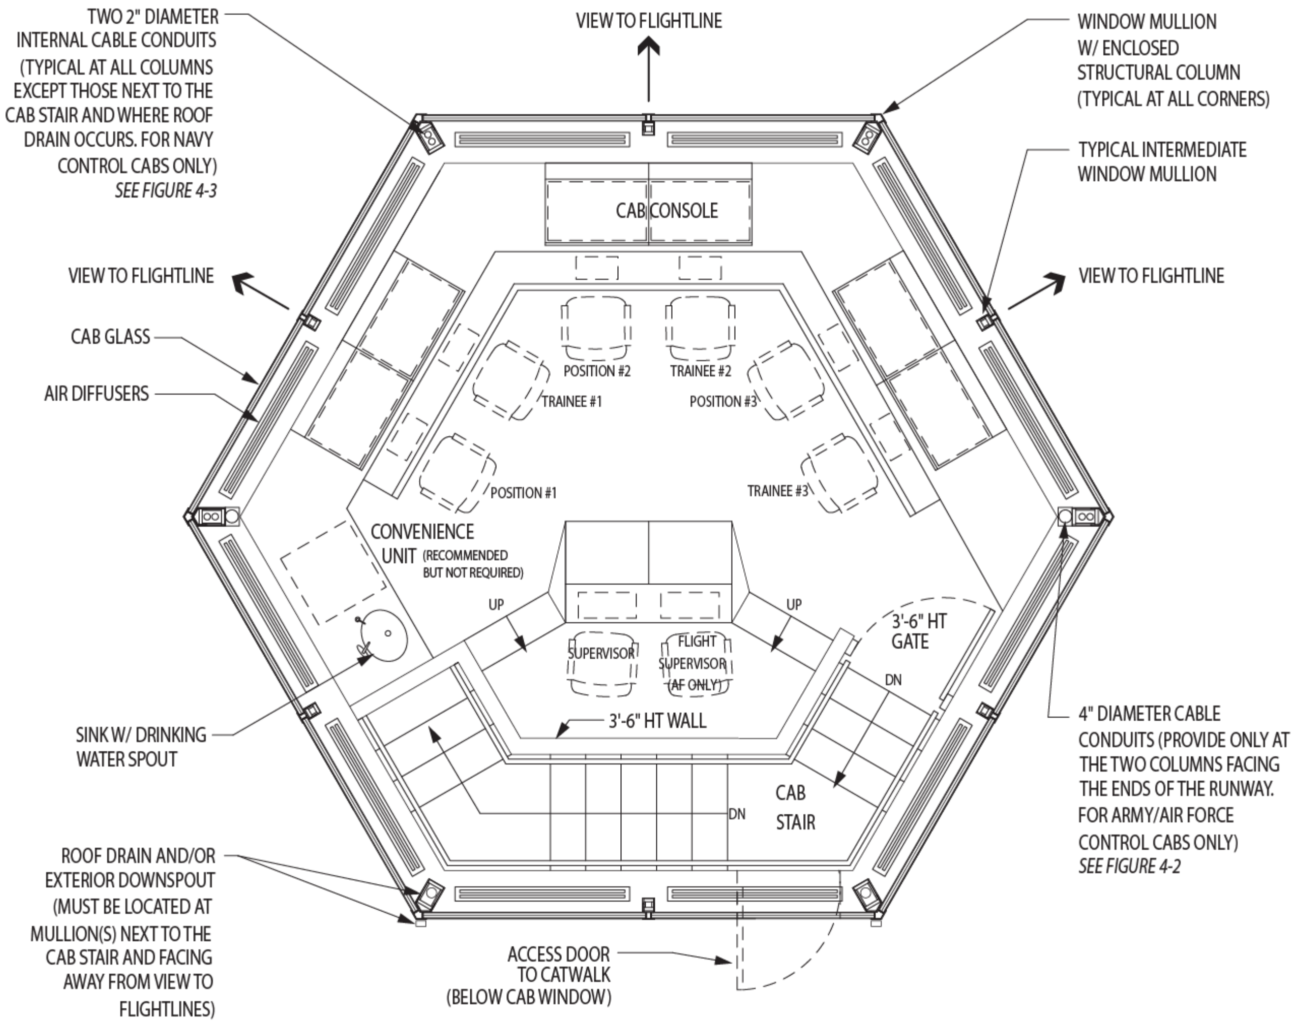
- ATC personnel normally request that a bathroom and break room be located on the floor directly below the ATCT Cab.
- The ATCT electronic equipment space(s) must be located on the uppermost available floor(s) below the Ready/Break Room to ensure that RF cable runs and communication signal losses are minimized. The exact arrangement of the electronic equipment will depend on the specific design of the ATCT and will be determined during design.
- Support functions such as training rooms may be housed separately in a RACF or AOB when the facilities are collocated.

Figure 2-1 ATCT Functional Shaft Vertical Adjacency Diagram



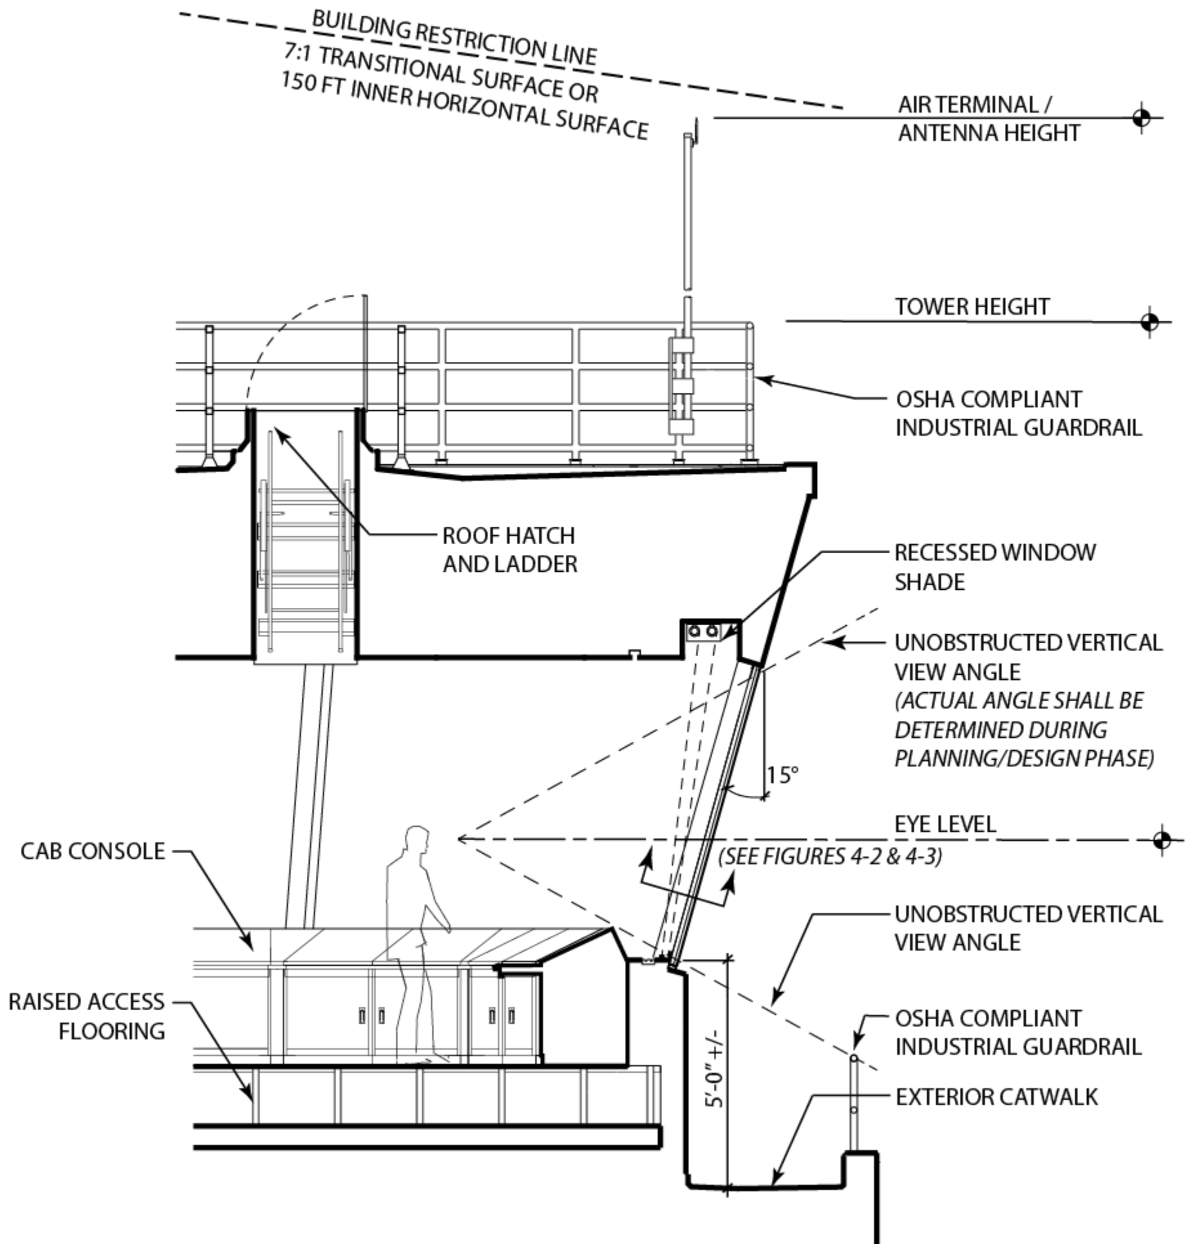
Note: The ATCT Functional Shaft Vertical Adjacency Diagram on the previous page is only illustrative, and is intended to demonstrate typical relationships between programmed spaces. It does not exclude other floor plan geometry, building configurations, or additional spaces required. More refined floor layouts should be developed during the design phase.

Figure 2-2 ATCT Control Cab Notional Floor Plan Diagram



Note: The ATCT Control Cab notional floor plan on this page is diagrammatic and intended to illustrate typical configurations. It does not exclude other tower geometry, Cab configurations, or additional spaces required. More refined floor layouts and should be developed during the design phase.

Figure 2-3 ATCT Control Cab Section Diagram



Note: The ATCT Control Cab section is diagrammatic and intended to illustrate typical configurations. It does not exclude other tower geometry and Cab configurations. More refined floor layouts should be developed during the design phase.

Height from exterior catwalk to top of window sill is typical per FAA standards. Maximum distance should allow for simultaneous Control Cab viewing and window washing.

Figure 2-4 ATCT Non-Functional Shaft with Support Building

Figure 2-5 ATCT Functional Shaft without Support Building

Figure 2-6 ATCT Functional Shaft with Support Building

Figure 2-7 ATCT Functional Shaft - Standalone

2-4.2 Radar Approach Control Facility (RACF).

2-4.2.1 Function.

A Radar Approach Control Facility (RACF) controls aircraft by using installed radar to provide ATC services to Instrument Flight Rules (IFR) and Visual Flight Rules (VFR) air traffic within a certain assigned airspace. RACFs offer ATC services to aircraft arriving, departing, or transiting the airspace controlled by the facility.

The RACF contains equipment used for controlling air traffic and is staffed by air traffic controllers and air operations, administrative and maintenance support personnel. The scope of radar services provided will vary according to equipment installed and the delegated airspace. The scope and complexity of the services are the significant design drivers. The RACF contains an IFR control room that includes the radar display consoles and communications control equipment. An adjacent terminal equipment room houses all automation central (or terminal) equipment, maintenance positions and audio/video tape recorders.

Based on current practices and policies, each Service maintains unique names for its Radar Approach Control Facilities as follows:

- **Army**: Army Radar Approach Control (ARAC) facilities are located at U.S. Army installations that use surveillance radar (normally collocated with Precision Approach Radar (PAR) facilities) and air/ground communications equipment. ARAC facilities offer air traffic control services to aircraft arriving, departing, or transiting the airspace controlled by the facility. Service is available to both civil and military airports located within approach control airspace.

- **Navy**: Radar Air Traffic Control Facilities (RATCF) are located at U.S. Navy installations. The ASR, PAR, Precision Approach Landing System (PALS), Transmitting and Receiving Sites, and other NAVAIDS, all of which are remotely located, are monitored and controlled in the RATCF. Local agreements may dictate that an FAA air traffic representative be provided office space in the air traffic control facility. An office for the FAA liaison officer is required at joint-operated Navy/FAA terminal radar approach control (TRACON) facilities.

- **Air Force**: Radar Approach Control (RAPCON) facilities are located at U.S. Air Force installations.

2-4.2.2 Location.

RACFs can be sited anywhere within the range of the radar providing radar assisted approach control. The RACF functions well in a single-story facility, making it a candidate for siting near airfields where building heights are restricted by airport conical or imaginary surfaces.

It is preferable to locate the Radar Approach Control Facility (RACF) adjacent to the Air Traffic Control Tower (ATCT). However, the RACF is not required to be adjacent to the ATCT.

Provide drive-up service access to service entries, including the IFR Equipment Room, the Operations/IFR Room (through the IFR Equipment Room), and the Mechanical Room. Refer to Section 2-2 for more information.

2-4.2.3 Functional Program Areas.

Typical functional program areas are listed and described briefly in Table 2-3 and described in greater detail in Chapter 5.

Note: Not all RACFs contain all of the areas listed in the table. The functional areas required are dependent on operational requirements, and the functions required are determined by the user during the planning/DD 1391 development phase.

Table 2-3 RACF Functional Program Areas

Functional Program Area	Description
Lobby/Entry Vestibule (Table 5-2.1)	Main entrance to the RACF. Include vestibule in cold weather climates.
Administrative Offices (Table 5-2.2)	An open office area with freestanding systems furniture workstations for administrative personnel.
Private Offices (Table 5-2.3)	Provide private offices for the following:
	1. Airfield Operations Flight Commander's Office (AOF/CC). The AOF/CC office may or may not be included in the RACF design. This officer is responsible for the overall management of flight operations, which includes the ATCT, RACF, Airfield Management, and Base Operations. If possible, this office should be located in another facility other than the RACF so that flying customers can meet with them at a facility that is not in a controlled area.
Private Offices (cont'd)	2. Chief Controller. The Chief Controller controls all operations of the RACF and reports back to the AOF/CC. All personnel within the RACF report to the Chief Controller.

Functional Program Area	Description
	3. Chief, Air Traffic Control & Training (Air Force: NCOIC, Air Traffic Control Training). This individual is responsible for keeping all training materials up to date as well as for ensuring the training of new personnel and continuing education of current controllers.
	4. Chief, Standardization & Evaluation (Air Force: NCOIC, Standardization and Evaluation). This individual maintains the currency of the RACF, ensures compliance with Service standards, and evaluates procedures that are in operation.
	CBI (Computer-Based Instruction).
Toilet Rooms with Lockers and Showers (Table 5-2.4)	If space and budget allow, there should be toilet rooms available adjacent to the Operations/IFR Room and the Break Room. Toilet rooms for administrative personnel and visitors should be provided in the administrative area.
Janitor (Table 5-2.5)	A separate storage room for janitorial supplies and equipment, located near the toilet rooms.
Mechanical Room (Table 5-2.6)	A room housing mechanical equipment servicing the RACF with a lockable door.
Electrical Room (Table 5-2.7)	A room housing electrical equipment servicing the RACF with a lockable door.
Telecommunications Room (Table 5-2.8)	This room is the first termination point for all copper cabling and fiber optic entering the facility. All incoming lines will be surge-suppressed in this room.

Functional Program Area	Description
Terminal Instrument Procedures (TERPS)/Data System Specialist (DSS) Office (Table 5-2.9)	This area is the largest office requirement in the administrative area. The TERPS office is responsible for actual planning and plotting of approach and procedures, revising procedures that are in place, updating procedures based on new criteria such as airfield mishaps, new aircraft controls, etc. **Air Force**: TERPS Room is required only when the TERPS function is performed at the unit level. Many MAJCOMS have consolidated TERPS offices to control CONUS locations. The A/E must consult the MAJCOM to confirm the location of TERPS. **Navy**: TERPS/DSS Office not required.
Operations/Instrument Flight Rules (IFR) Room (Table 5-2.10)	This is the primary functional area of the RACF. This space should be located within the facility and never exit directly to the outside. All radar-controlled approaches are handled from this room.
Radar Simulator Room (Table 5-2.11)	A room housing radar simulators for Standard Terminal Automation Replacement System (STARS) simulators and the IPARTS (PAR Trainer).
ATCT Simulator Room (Table 5-2.12)	A room housing simulators for ATCT simulator operations. The ATCT Simulator Room contains the tower simulator.
Training Room (Table 5-2.13)	A room housing the Computer-Based Instruction (CBI) component of RACF training.
Briefing/Conference Room (Table 5-2.14)	This room should be sized to house the entire RACF shift, plus the AOF/CC and the shift Watch Supervisor. The Briefing Room should be sized to accommodate an adequately-sized conference table.
IFR Equipment Room (Table 5-2.15)	A room housing the communications racks that are the termination points for all lines entering and departing the RACF that provide data to and from the scopes in the Operations/IFR Room.

Functional Program Area	Description
UPS Room (Table 5-2.16)	A room housing the UPS system and its batteries. May be combined with the IFR Equipment Room or the Electrical Room.
Storage Room (Table 5-2.17)	An interior storage area for miscellaneous supplies for the office and operational functions of the RACF.
Flight Planning (Table 5-2.18)	Open office area containing flight dispatch and flight planning operations
Pilot Flight Planning (Table 5-2.19)	Open office area containing flight planning operations
ATC Equipment Maintenance Admin Area (Table 5-2.20)	An open office area for administrative functions required for ATC equipment maintenance.
ATC Equipment Maintenance Area (Table 5-2.21)	An area for ATC equipment maintenance, including space for soldering and storage.
Break Room (Table 5-2.22)	A room containing a wet sink, coffee service, refrigerator, microwave, and vending machines.
2M Room (Table 5-2.23)	A room for Micro-Maintenance repair. Refer to NAVAIR 01-1A-23 for additional requirements.
Secret Internet Protocol Router Network (SIPRNet) Room (if required)	For certain facilities, a room for SIPR equipment must be provided. Discuss space requirements with facility user.
Ground Electronics Maintenance Division Area	Provide an area for Ground Electronics Maintenance Division, including: 1. GEMO Office 2. ET Chief Office 3. GEMD Admin/LPO Area
Mechanical Yard	A screened maintenance yard must be provided for the chiller, back-up generator fuel tank, garbage dumpster with a separate screen wall enclosure, generator, transformer, etc.

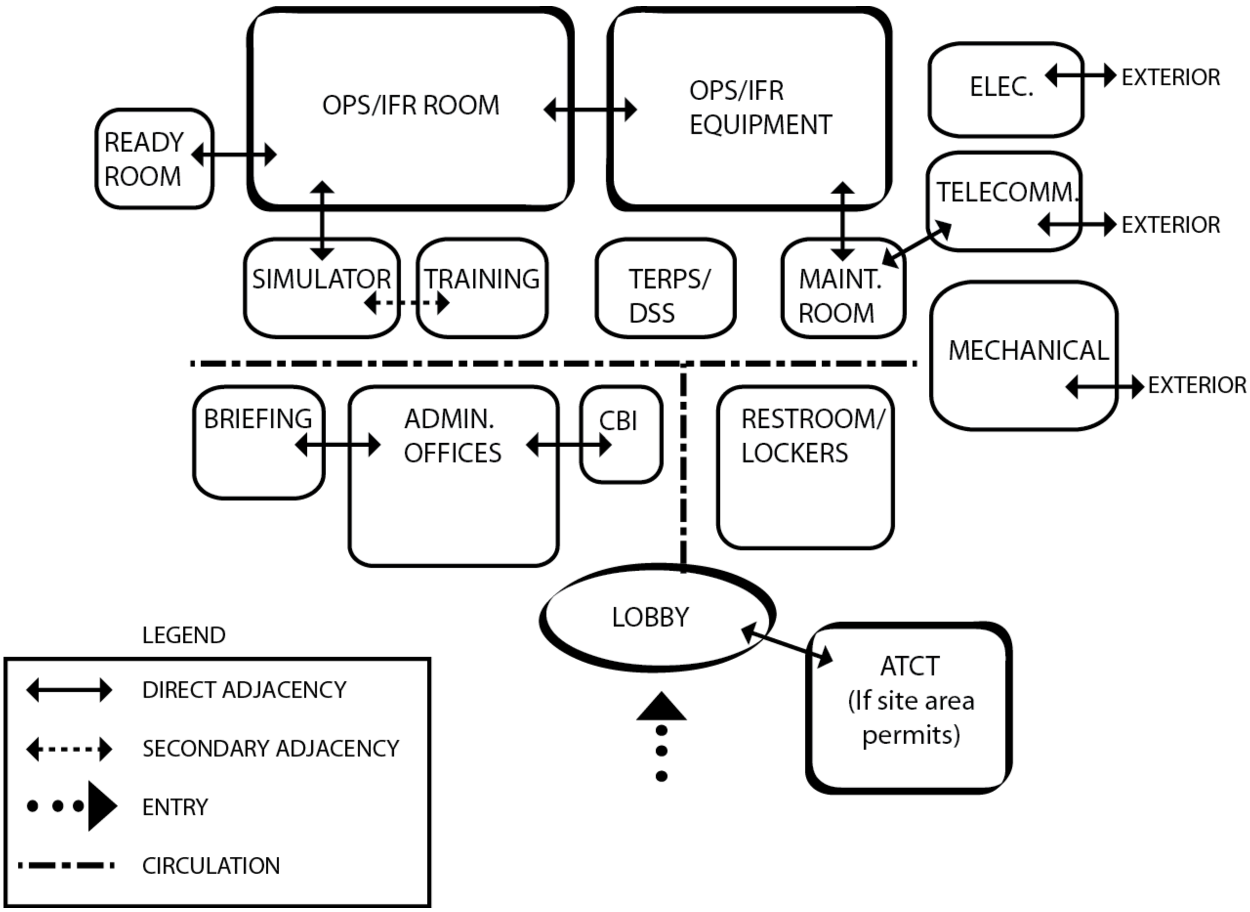
2-4.2.4 Adjacencies and Layout.

Appropriate building adjacencies are illustrated in Figure 2-8. This diagram does not convey a building shape, but represents the required adjacencies in a typical Radar Approach Control facility.

Important adjacency requirements include the following:

- ATC personnel normally request that an ATC/Simulator/Training Room be located adjacent to the Operations/IFR Room.
- Maintenance personnel normally request that the IFR Equipment Room be located adjacent to the Main Distribution Frame (MDF) Room.

Figure 2-8 RACF Adjacency Diagram



Note: The RACF Adjacency Diagram is only illustrative, and is intended to demonstrate typical relationships between programmed spaces. It does not exclude other floor plan geometry, building configurations or additional spaces required. More refined floor layouts should be developed during the design phase.

Figure 2-9 RACF IFR Room

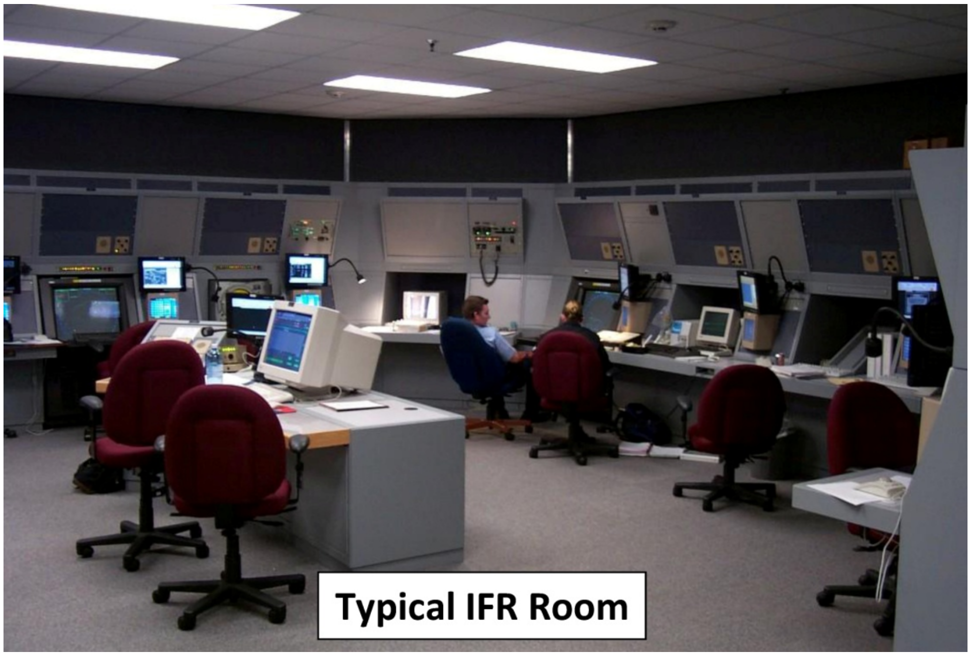


Figure 2-10 RACF IFR Equipment Room

2-4.3 Airfield Operations Building (AOB).

2-4.3.1 Function.

The Airfield Operations Building (AOB) is required to house flight operational and administrative functions of the airfield headquarters. The AOB includes all the functions of flight planning, flight personnel equipment and support rooms, passenger support facilities, and the communications, operations and weather services. Also included, unless otherwise provided in other permanent facilities, are an in-flight kitchen and/or snack bar, and a conference and/or briefing room which may also serve as a personnel training room or classroom. Because of differences in the aviation missions and the requirements of the facility commanders, the components for an AOB may vary considerably. The existence of available permanent facilities will also affect overall space requirements.

Certain airfield installations may enlarge the AOB to include the Airfield Headquarters (HQ). The Airfield HQ includes administrative space for the commander, military personnel, safety officer, and others.

2-4.3.2 Location.

The AOB adjoins the ATCT and RACF where site conditions permit. The AOB may be housed in a separate building or may be combined into a single structure with the ATCT.

The Air Operations Building must be located with direct access by personnel outside the airfield restricted area boundary.

2-4.3.3 Functional Program Areas.

Typical functional program areas are listed and described briefly in Table 2-4 and described in greater detail in Chapter 5.

Note: Not all AOBs contain all of the areas listed in the table. The functional areas required are dependent on operational requirements, and the functions required are determined by the user during the planning/DD 1391 development phase.

Table 2-4 Airfield Operations Building Functional Program Areas

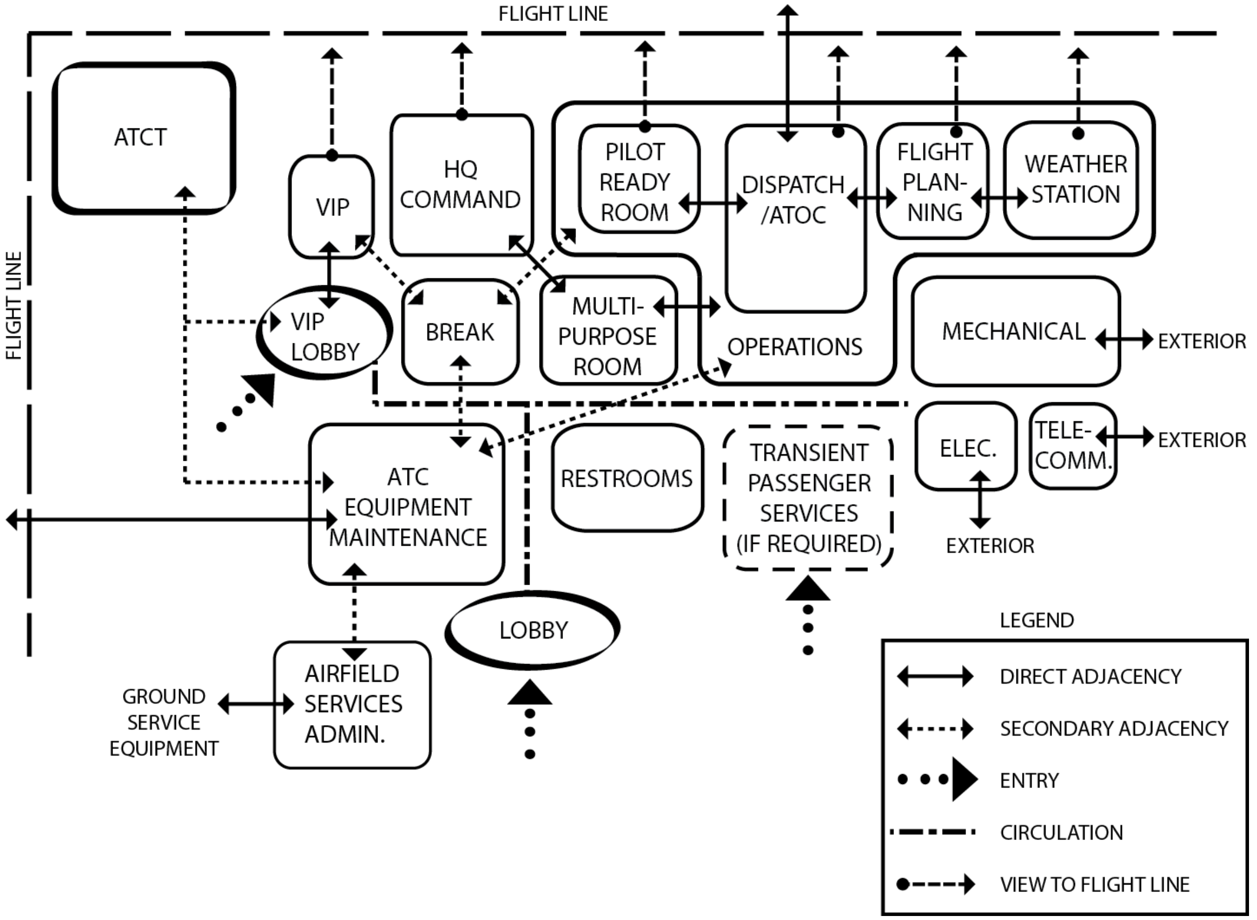
Functional Program Area	Description
Lobby/Vestibule (Table 5-3.1)	Main entrance to the AOB. Include vestibule in cold weather climates.
HQ / Command Suite	The HQ/Command Suite must be tailored to the specific requirements of each command echelon.
HQ/Command Suite - Reception Area (Table 5-3.2)	Controls access to the HQ/Command suite. Include receptionist workstation, visitor seating area, coat closet, and supply closet.
HQ/Command Suite – Private Offices (Table 5-3.3)	Provide Private Offices for: 1. Airfield Manager/Commander 2. Chief Controller (CCTLR) or Airfield Operations Flight Commander (AOF/CC) 3. Operations Officer 4. Airfield Safety Officer
Airfield Operations (Tables 5-3.4 – 5-3.8)	This space is comprised of several functional areas, including: 1. Air Operations Duty Officer 2. Airfield Management/Flight Planning 3. Pilot Flight Planning 4. Weather Station 5. Pilot Ready Room
Airfield Services (Tables 5-3.9 – 5-3.13)	Provide an area for Airfield Services consisting of: 1. General Purpose Workstations 2. Printer/Copier Station (non-secure data only) 3. Non-Sensitive Secure Storage Room 4. General Purpose Storage Room 5. File Storage Area 6. Fuel Handlers
ATC Equipment Maintenance Admin Area (Table 5-3.14)	An open office area with freestanding systems furniture workstations for administrative personnel.
ATC Equipment Maintenance Area (Table 5-3.15)	A room for ATC electronic equipment maintenance, including an area for soldering and storage.

Functional Program Area	Description
Break Area (Table 5-3.16)	A room containing a wet sink, coffee service, refrigerator, microwave, and vending machines.
Multipurpose Room (Table 5-3.17)	Briefings, conferences, press releases, and consolidated training.
Male and Female Toilet Rooms (Table 5-3.18)	Toilet rooms for administrative personnel and visitors should be provided near the main entrance.
Janitor (Table 5-3.19)	A separate room for janitorial supplies and equipment, located near the toilet rooms.
Mechanical Room (Table 5-3.20)	A room housing mechanical equipment servicing the AOB with a lockable door.
Electrical Room (Table 5-3.21)	A room housing electrical equipment servicing the AOB with a lockable door.
Telecommunications Room (Table 5-3.22)	This room is the first termination point for all copper and fiber optic cabling and fiber optic entering the facility. All incoming lines must be surge-suppressed in this room.
SIPR Room (if required) (Table 5-3.23)	For certain facilities, a room for SIPR equipment must be provided. Discuss space requirements with facility user.
Outside Covered Storage Area (Table 5-3.24)	One (1) outside storage building and one (1) outside covered storage area with fence and 10' wide lockable gate. The storage area is used to store airfield services related equipment and must have direct access to the parking aprons
Transient Passenger Services (Table 5-3.25)	Waiting area for transient passengers.
VIP Passenger Services (Table 5-3.26)	Waiting area for VIPs.

2-4.3.4 Adjacencies and Layout.

Appropriate building adjacencies are illustrated in Figure 2-11. This diagram does not convey a building shape, but represents the required adjacencies in an Airfield Operations Building.

Figure 2-11 AOB Adjacency Diagram



Note: The AOB Adjacency Diagram is only illustrative, and is intended to demonstrate typical relationships between programmed spaces. It does not exclude other floor plan geometry, building configurations, or additional spaces required. More refined floor layouts should be developed during the design phase.

2-5 COMBINING AIR TRAFFIC CONTROL AND AIR OPERATIONS FACILITY TYPES.

ATC and Air Operations Facilities may be provided in separate structures or combined into one structure. Locate the ATCT adjacent to the RACF where siting requirements permit. However, the ATCT may be separated from the RACF and the AOB in order to facilitate visual observation and control of aircraft movement.

2-6 SITE SELECTION AND APPROVAL PROCESS.

2-6.1 Site Location Requirements.

The location and height of the ATC and Air Operations Facilities must be based on a Siting Report that recommends the optimum location and relative orientation of all structures, including the optimum size and height of the ATCT.

Selection of a site within 1,000 meters (m) of a station Tactical Air Navigation (TACAN) system will require an analysis of impacts to the TACAN.

2-6.1.1 Air Traffic Control Tower.

The Air Traffic Control Tower (ATCT) must be sited in accordance with UFC 3-260-01, *Airfield and Heliport Planning and Design*. The ATCT must be physically oriented relative to the primary runways so as to obtain the best unobstructed view of the air installation complex and aircraft primary movement areas (i.e. runways and taxiways), their associated VFR and IFR approach paths, traffic pattern entry points, traffic patterns, ground routes, parking areas, and VFR and IFR departure paths. Consider planned runway and taxiway construction when siting the ATCT, as well as expected vegetation growth that cannot be cultivated due to various factors.

The ATCT itself should not be an obstruction or affect IFR operations. Care must be taken not to site the ATCT close to and/or under a flight path. When computing the height of the ATCT, the height of the antennas being installed (after construction is completed) must be included. The design of the antenna supports, installed as part of the construction, will affect the final antenna height. When computing the total ATCT height, the height of the tallest antenna must be added to the height of the top of the parapet wall or railing. The height of the lightning protection installed during construction must also be included in the total ATCT height if the lightning protection is designed to be higher than the antennas mentioned above. The total height of the ATCT, including antennas and lightning protection, must be shown on the design elevation drawings.

Other considerations for final siting include utility availability (water, sewer, storm, power, and gas), site access, security, and relationship to existing ATC Facilities and existing ATCTs. If an area directly below the ATCT requires controlling, consideration for relocating the ATCT to allow proper visual access to that area should be of prime importance.

All ATCTs have transmitting antennas on the roof. The site approval process requires that all projects having explosives safety, airfield safety, or electromagnetic safety implications, require a "Safety Certification." Also, consider the existing location of the airfield beacon during the site selection process. If the beacon will cause visibility problems for ATCT controllers, it will require relocation or a change in height, and should be included in the DD 1391 for the ATCT. The rotating beacon must not be located on top of the ATCT.

2-6.1.2 Radar Approach Control Facility.

The Radar Approach Control Facility (RACF) can be sited anywhere within the range of the equipment providing radar-assisted approach control. The RACF functions well in a single-story facility, making it a candidate for siting near airfields where building heights are restricted by airfield conical or imaginary surfaces.

Provide drive-up service access to service entries in the RACF, including the IFR Equipment Room, the Operations/IFR Room (through equipment room), and the Mechanical Room. Screen chillers, back-up generator fuel tanks, and dumpsters in maintenance/service yards.

2-6.1.3 Air Operations Building.

The Airfield Operations Building (AOB) can be sited anywhere within the air installation complex as long as it complies with the requirements of UFC 3-260-01. Preferred adjacencies are described above in Section 2-4.3.2.

2-6.2 Site Radiation Hazards.

Hazards of Electromagnetic Radiation to Personnel (HERP), Ordnance (HERO), and Fuel (HERF) surveys are crucial to the siting process. Radiating radio frequency (RF) antennas must be installed on top of the ATCT and a radiation hazard (RADHAZ) study to support their installation should be conducted during the site approval process. Facility siting criteria must consider radiating fields of existing antennas, such as the Airport Surveillance Radar (ASR), that support ATC operations.

Define the specific concerns with aiming of radar and various antennas so there is no interference from electrical propagation in the form of electromagnetic and RF waves.

2-6.3 Site Selection and Approval Process.

- **Army**: ATSCOM, through a site survey and in coordination with the USACE Transportation System Center selects the ATCT location. The IMCOM Regional Director, for the specific region approves the site location. The Headquarters, Department of the Army validates the project as part of the established Army process. Refer to project review requirements contained in AR 95-2.

  Army National Guard Bureau: The Director, Army National Guard, through the State Adjutant General, approves the location and project. As is appropriate, the State Adjutant General may be the final approval for the site location and project.

- **Navy**: NAVFAC Asset Management and SPAWAR are responsible to conduct the siting study. When a tower siting study is performed, the TSAR analyzes multiple sites and recommends one.

  Final site approval must be from the Base/Station Commanding Officer per current NAVFACINST 11010.45. A letter from the ATC Officer or Base/Station Commanding Officer selecting a particular site should be required.

- **Air Force**: The MAJCOM Programming and Requirements Manager requests a site survey from Headquarters Air Force Flight Standards Agency. HQ AFFSA will recommend a site selected for ATCF based on the survey results. Concurrence with the Base/Wing Commander signifies acceptance of the site recommendations.

Refer to Appendix C for an outline of a typical Site Selection Process.

This Page Intentionally Left Blank

CHAPTER 3 GENERAL REQUIREMENTS

This chapter describes the general design criteria shared by all Air Traffic Control (ATC) and Air Operations Facilities.

3-1 AIRFIELD SAFETY.

Federal Regulation 14 CFR Part 157, section 77.13 requires FAA notification for anyone proposing to construct, alter, or deactivate a civil, military, or joint-use (civil/military) airport. Provide obstruction marking or lighting for facilities located in or near aviation operational areas in accordance with UFC 3-535-01, *Visual Air Navigation Facilities* and FAA Advisory Circular AC 70/7460, *Obstruction Marking and Lighting*.

3-2 ARCHITECTURAL.

3-2.1 Future Expansion Capability.

Discuss future expansion potential with local ATC operations personnel. If required, plan for building design that permits incremental additions. Future expansion capability should be carefully planned into the overall design. Future growth must be assumed to be horizontal and not vertical.

3-2.2 Acoustics/Noise Control.

Sound attenuation is necessary for all ATC and Air Operations Facilities in order to control disturbance from high energy noise levels and to minimize disturbance from intrusive speech. Acoustical control is required around toilet rooms, conference/training rooms, and private offices, as well as specialized spaces required in each facility type. Refer to Chapter 5, Functional Data Sheets, for specific sound level criteria for all rooms.

3-2.3 Accessibility for the Disabled.

Comply with the DoD Architectural Barriers Act Accessibility Standards (ABAAS), and provide barrier-free access to civilian workspaces and other spaces intended for public access.

3-2.4 Exterior Materials.

During design, a TACAN Subject Matter Expert must review the facility's proposed exterior materials and their possible impact on TACAN operations. Depending upon the materials used for the outside of an ATC or Air Operations Facility, the impacts can vary for the same location. Some exterior wall materials may interfere with TACAN operations. An example would be that corrugated steel siding would scatter the signal vice acting as a standard reflector and could degrade the signal enough to make the TACAN unusable.

3-2.5 Reflective Surfaces.

To prevent mirror-like reflections from building surfaces to aircraft in flight and air traffic controllers, provide roofs and other external surfaces with a specular reflectance compatible with the location of the building on the airfield. If the building is so located that glare may be an operational hazard, provide the critical surfaces of that building with a light reflectance of not more than 10, measured at an angle of 85 degrees in accordance with the ASTM D 523, *Standard Test Method for Specular Gloss*.

3-2.6 Windows.

Windows in ATC and Air Operations Facilities must comply with UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings*. In addition, windows must meet EPAct-2005 and EISA-2007 energy requirements.

Consider windows for administrative and break areas, but do not provide windows in electronic equipment rooms, the RACF Operations/IFR Room, storage rooms, or mechanical and electrical rooms.

3-2.7 Raised Access Flooring.

Where required, provide Raised Access Flooring (RAF) to meet the requirements of NFPA 75, *Standard for the Protection of Information Technology Equipment*. RAF must be supported around the entire perimeter. Provide a bolted grid (stringer) or a rigid grid system. Utilize 24-inch (610 mm) stringer supports throughout (larger supports are not acceptable). Pedestal support systems without horizontal stringers must not be used.

The space between the concrete sub-floor and all raised access flooring will be used to route ATC system cabling to the electronic equipment. Ensure that there is no structural steel in these areas, including any additional seismic bracing that may be required. Keep all air supply panels and similar inserts flush with the flooring surface. Specify installation procedures to conform to FAA-STD-019e and FAA-STD-020b. Provide depressed structural framing and slabs in areas where access flooring occurs to result in uniform, continuous finish floor levels between adjacent floor spaces. Provide a RAF installation above a level permanent floor when it is not economical or practical to depress the structural framing and slab.

3-2.7.1 Bonding and Grounding of RAF.

RAF must be electrically continuous, properly bonded and grounded. Both systems must be connected to the below-floor signal reference grid system and to the perimeter ground cable with copper straps or cable that meets FAA-STD-019e. Stringers of the bolted grid must also be bonded per FAA-STD-019e.

3-2.7.2 Design Loads for RAF Installations.

Use the following Design Loads for RAF installations:

- Rolling: 400 lb min.

- Impact: 100 lb min.
- Concentrated: 1,000 lb. min.

3-2.7.3 RAF Floor Tiles.

Provide filled or unfilled floor tiles with integral, static dissipative carpet or vinyl coverings. The use of filled or unfilled floor tiles must be determined during the planning/DD 1391 development.

If carpeted floor tiles are required, carpet squares must be factory glued or glued to the tiles using adhesive provided by the manufacturer of the floor tile and per the manufacturer's instructions. Carpet squares must have the same dimensions as the RAF panels, instead of tiles with vinyl trim. Spare carpeted tiles (25% of installed area) and one quart of the same adhesive used must be provided and turned over to local ATC personnel upon completion of construction. The adhesive must be provided from the floor manufacturer.

3-2.8 Floor Finishes.

All exposed concrete floors or sub-floors without floor or carpet finish must be cleaned and sealed or painted with an appropriate type of concrete sealer or paint. Floors must be sealed prior to the installation of any conduits, piping, ventilation ducts or RAF.

3-2.8.1 Electronic Equipment Area Floor Finishes.

All areas housing electronic equipment must have static dissipative floor finish materials with a surface resistance between 2.5 x 104 and 1.0 x 108 Ω (ohms) measured in accordance with the ANSI ESD S7.1. Electronic equipment spaces must be provided with static dissipative carpet or laminate or vinyl tile. Cut pile carpeting with a performance factor of less than 2.0 (kV) static generation under worst possible conditions should be required for high traffic areas.

3-2.9 Building Signage.

Building directory, bulletin boards and interior signs must be in accordance with UFC 3-120-01, *Air Force Sign Standard*, unless directed to use installation standards. Confirm final details including size and location for all building signage with user group during the design phase.

- Provide a suitably sized building directory located near the main entrance of each ATC or Air Operations Facility. The directory case must be constructed of extruded aluminum with an architectural finish. It should have a changeable letter board with insertable letters and a sliding glass front.
- A bulletin board is required in the entrance. The bulletin board must be similar in construction to the building directory, except with a cork backboard.

3-2.10 Locker Area.

The locker area provides a space for ATC and Technical Operations personnel to secure their personal belongings while on duty, and serves as a place to store work equipment while off duty. All facets of locker rooms must comply with DoD ABAAS requirements. Include showers with changing rooms and half-height lockers (60% male/40% female). In overseas locations, full-height lockers must be provided.

3-3 STRUCTURAL.

3-3.1 Structural Design.

Except as indicated herein, use the model codes with modifications specified in UFC 1-301-01 along with other applicable UFC documents to develop design documents. Special design requirements for each facility type are provided in Chapter 4.

3-4 MECHANICAL.

3-4.1 Indoor Design Conditions.

The mechanical systems serving ATC and Air Operations Facilities must be based on maintaining the following temperature and humidity requirements:

<u>Critical Spaces</u>: Certain spaces in all ATC facilities are considered Critical and must have the capability to maintain certain temperature/humidity sound level design conditions. Normally, Critical spaces include the Control Cab, Communications Equipment Room, RACF Operations/IFR Room, UPS/Battery Room and all ATC Electronic Equipment Rooms.

- Temperature: 73° F stable ± 2° F
- Humidity: 35% to 60% R.H
- Control Cab and RACF Operations/IFR Room Sound: Maximum NC 35
- Equipment Room Sound: Maximum NC 45

Refer to Chapter 5, Functional Data Sheets, for information on program areas identified as Critical Areas.

3-4.2 Air Conditioning Loads.

Equipment heat loads must be provided during the planning/DD 1391 development process. Loads must be calculated using normal air conditioning load calculation procedures. Do not consider heat loads from electronic equipment when calculating heating requirements. Loads must be based upon personnel occupancy. Loads due to electronic equipment must be verified during design.

3-4.3 Acoustics/Noise Control.

HVAC system noise control is required for ATC facilities and electrical and mechanical rooms must be designed to control sound attenuation. Sound traps must be used, as required, on the supply and/or return air duct openings and where return air passes through sound treated walls. To minimize HVAC noise, equipment must be mounted on vibration isolators. All rooftop mounted air-handling systems and packaged air conditioning systems must be strategically mounted to alleviate noise attenuation.

3-4.4 General HVAC Requirements.

Detailed descriptions of required spaces and HVAC system requirements are as follows:

3-4.4.1 Radar, Communication, and Telecommunications Rooms.

These spaces house solid state electronic equipment and require complete heating and air conditioning. Cooling and humidity control is required for reliable equipment operation and cooling loads are generally constant, 24 hours per day, except during additions or equipment modifications. Humidification is required to prevent electrostatic charges from derogating equipment performance.

Multiple units designed for computer room environments must supply each equipment room. Two air handling units must house humidifiers and each must be sized for the maximum load for redundancy. Ventilation requirements are based on occupancy and the designer must collect information about room personnel occupancy during the planning process. Specialized computer room HVAC systems with air distribution through the RAF must be installed, and high efficiency air filtration must be integrated into the systems to minimize dust and contaminants.

3-4.4.2 Administrative Spaces.

These spaces require normal office environment cooling, humidification, and heating systems. Heating and cooling loads are variable. Administrative spaces are not normally occupied more than eight (8) hours a day and must be zoned by occupancy hours and similarities in comfort control requirements. Use night setback thermostats in areas occupied for eight (8) hours per day. HVAC systems with VAV are preferred and zones must be determined from building size and layout.

3-4.4.3 Break Rooms.

Provide HVAC capacity for 24-hour per day operation to handle the heat generated by existing and planned vending machine, cooking equipment, refrigeration compressor associated with under-the-counter refrigerators, and drinking water remote chillers when provided. The kitchen area must have its own exhaust fan ducted to the outside which is activated by a switch located near the cook-top or microwave oven.

3-4.4.4 Toilet, Shower, and Locker Rooms.

Provide tempered conditioned supply air ducted directly to toilet room ceilings in the amounts only as required to compensate for heating or cooling thermal envelope loads. Louvered door makeup air must not be used if toilet room entrance walls are fire-rated. Door louvers or undercuts must not be considered if requirements exceed 100 cfm (47.2

lps). Where appropriate, the exhaust fans serving toilets (and adjoining janitor closets) must be interlocked with the building HVAC fan(s). In low activity buildings without central HVAC systems, toilet rooms may be equipped with an exhaust vent fan operated with the room lighting switch.

3-4.4.5 Emergency Generator (E/G) Rooms (if required).

For summer conditions, provide an exhaust fan that is mounted to the side or on the building roof and is weatherproof for space ventilation, activated by an adjustable thermostat. Provisions must be considered to maintain room temperatures a maximum of 10° F above ambient conditions. Design must preclude drawing outside air that could be contaminated by the battery room exhaust. An additional high volume fan is required for simultaneous operation with the generator set. This fan must be sized to draw air through the E/G space at a rate sufficient to provide the necessary heat removal for the specified E/G. Alternatively, a two-speed thermostatically activated fan with activation set-points, sized as noted above, to operate with E/G operation, may be considered. Air intake for both normal ventilation and high-volume exhaust fans must be via low efficiency filtered storm-proof outdoor air louvers or intake hoods with multi-blade (sectioned) low-leakage motorized control dampers (insulated airfoil dampers or similar type preferred for all heating climate zone I through III inclusive). Dampers on fan intake throats must be of similar type, motorized, and interlocked with either fan operation or barometric backdraft.

For installation in colder northern regions, a low ambient thermostatic damper control to interlock intake damper blade sections for high volume exhaust fan to preclude the full damper area from opening on E/G start-up when outdoor ambient is below freezing. Other design options can be considered. For E/G sets equipped with bed-rail mounted integral radiators, the high volume exhaust fan is not typically required as air is drawn over the engine and discharged to the atmosphere via the integral radiator fan (requirements must be verified individually for such installations). E/G space must be provided with a thermostatically-activated unit heater to maintain this space at no less than 50° F.

3-4.4.6 UPS/Battery Equipment Rooms.

This room must be served with two 100% redundant cooling-only constant volume air conditioning systems with minimum MERV 11 filtration. Air-cooled direct refrigerant expansion condensing units, geothermal, and variable refrigerant volume systems are permitted when chilled water is not selected as a primary cooling source. Automatic switchover must be provided in the event of failure of the primary unit. Air distribution must be via an overhead or low sidewall supply directed toward the UPS gear base (integral) ventilation intakes. The UPS gear cooling load is continuous, 24-hours per day, year round, and is approximately constant. Consider the option of incorporating a hydronic run-around-loop heat recovery system or air-to-air heat exchanger for preheating winter ventilation air when justified by life cycle cost analysis. Outside air economizers must not be used due to dust and/or humidity exposure to the sensitive equipment within this room.

3-4.5 Energy Conservation.

The designer must use UFC 1-200-02, *High Performance and Sustainable Building Requirements (August 2012)* for guidance in developing an energy efficient design for ATC and Air Operations Facilities.

The use of alternate sources of energy, such as wind or solar, should be checked carefully to ensure any equipment required will not cause interference issues with the ATC equipment. System maintenance by local personnel should also be considered.

3-4.5.1 Solar Photovoltaic, Solar Lighting, and Heating.

The location of solar collectors should not create a sun reflection problem for aircraft or ground movement on the airfield.

3-4.5.2 Economizer Cycles.

Economizers should be provided as required by ASHRAE 90.1 except for the HVAC systems serving rooms with ATC electronic equipment, such as the ATCT Control Cab, the RACF Operations/IFR Room, all ATC electronic equipment rooms, all UPS Rooms, and all telecommunications rooms.

3-4.6 HVAC System Selection and Location.

HVAC systems should be located on the floor above or below the level housing the equipment. This allows better maintenance access to the mechanical equipment and the likelihood of an HVAC water leak causing damage to electronic equipment is reduced. Locating HVAC and related equipment above the ceilings in occupied Critical areas must be avoided to eliminate problems associated with noise, vibration, and access. Air conditioning equipment serving Critical spaces must be provided with low ambient control to allow cooling in the winter season. ATC Electronic Equipment Rooms with Raised Access Flooring (RAF) must be cooled by multiple floor-mounted Computer Room Air Conditioner (CRAC) units due to anticipated ceiling height restrictions. Rooms without raised access flooring may be served by CRAC units or overhead distribution from adjacent air handling units. The space required for CRAC units and other equipment, including ATC equipment and building systems, must be considered. CRAC units designed for RAF systems must only be used in rooms with RAF systems.

3-4.7 Critical Space Redundancy.

All Critical spaces in ATC and Air Operations Facilities must be provided with 100% redundancy so that if one unit goes down another unit must be capable of handling the entire load. Also, electronic equipment rooms typically need cooling, even when other rooms need heat. Consider having electronic equipment rooms on a dedicated, redundant unit with both humidifying and dehumidifying capabilities.

All cooling systems (central air handling units, DX package units, DX split systems, chillers, pumps, etc.) serving Critical spaces must have 100 percent redundancy and preclude any single-point failure. Include in commissioning requirements to confirm that all equipment serving critical spaces is connected to a power source that is backed up by the E/G.

If chilled water systems are selected, the systems should be sized for 75% (60% allowable with approval) of peak load for the entire facility. The chillers should share the entire load with the primary and secondary units alternating on a user programmable schedule. In the event of a chiller failure, control must be such that the non-Critical loads (all areas other than control cab and electronic equipment rooms) can be dropped. Alternate use of chillers and equalize run time to lengthen life span and improve efficiency. VRV systems must not be used. The use of dedicated Outside Air Units must be considered.

3-4.8 Air Filtration.

The inclusion of highly sensitive electronic equipment in ATC and Air Operations Facilities requires the use of high-quality air filtration systems. High-efficiency filters must be installed in equipment serving Critical areas. In addition, a minimum of 2-inch (50-mm) thick disposable MERV 7 pre-filters must be used in all units. If severe fuel/exhaust odor problems are anticipated due to site location, charcoal filters may be used for outside air intakes serving Critical areas.

Careful consideration must be made for specification of these systems due to the size and high maintenance cost of these filters. High-efficiency filters must be rated at a minimum of MERV 11. Electrostatic air filters may be considered for the Critical spaces in locations with high ambient dust levels such as airports in desert areas. During design, care must be taken to ensure that these filters will not produce electronic feedback or allow harmonics back into the system.

3-4.9 Equipment.

Computer rooms and electrical equipment rooms produce predominantly sensible heat and require specially designed HVAC equipment for optimal performance. Ensure mechanical systems do not interfere with electronic equipment or radiated signals. Provide adequate clear heights in MEP rooms for maintenance personnel throughout ATC and Air Operations Facilities.

Ensure that the locations of mechanical devices in ATC Facilities do not interfere with electronic systems to be installed or the support devices installed in conjunction with ATC equipment. In addition, ensure that mechanical assemblies do not interfere with post-construction access to power panels, cable chases, equipment hatches, or roof hatches.

Provide a snorkel type localized stand-alone exhaust system with timer and 100 fpm capture velocity for any spaces where soldering occurs.

3-4.10 Thermostats.

Remote and local control of thermostats can be allowed in spaces with ATC equipment but must be restricted to the temperature limits as defined in paragraph 3-4.1.

3-4.11 Batteries.

Wet cell lead acid or nickel-cadmium batteries must not be designed for use in the ATC Facilities, except as approved for emergency lighting.

3-5 PLUMBING.

3-5.1 Design Criteria.

Consult with the electrical and architectural design engineers to ensure that plumbing does not interfere with the cable tray installation.

Plumbing design must use UFC, 1-200-02, *High Performance and Sustainable Building Requirements* (August 2012).

3-5.2 Restrooms.

Vitreous china fixtures must be used in all restrooms. Flush valves must be used on ground or second floor only. Tank-type fixtures must be used above the second-floor elevation. Wall-mounted fixtures must be used whenever possible. Provide accessible fixtures required by DoD ABAAS for disabled access. Consider in-line hot water heaters for ATCT restrooms.

3-5.3 Emergency Generator (E/G) Rooms (if required).

An emergency eyewash station must be provided within the E/G Room. A floor drain should not be provided because of the potential for contamination of the sanitary sewer system with diesel fuel.

3-6 FIRE PROTECTION AND LIFE SAFETY.

3-6.1 Type of Construction.

Construction type must be in accordance with UFC 1-200-01.

3-6.2 Definitions:

- Control Cab: That portion of a building or structure used for the control of aircraft by visual observation, radio communication, and/or radar by Air Traffic Control specialists.
- Tower Shaft: That portion of a building, facility, or tower that structurally supports a control cab used for housing minimum mechanical, electrical power, and electronic equipment.
- Base Building: Buildings used for housing support equipment and personnel for ATC activities.

3-6.3 Floor and Wall Penetrations.

All ducts and chases must be fire/smoke-stopped by an approved and listed method. Through-penetration assemblies must be provided in cable duct wall penetrations in accordance with NFPA standards after installation of cables.

Openings in rated walls and floors for cabling, whether installed at the time of construction or for later use, must be completely filled and fireproofed, with a listed assembly. The fire rated assembly must permit repeated removal and replacement, without special tools, as necessary for the installation of cables and to support changing requirements.

3-6.4 Raised Access Flooring Areas.

Raised Access Flooring (RAF) areas may be used as supply air plenums only. Return air plenum use is not allowed.

All cabling and conductors installed in RAF areas must be plenum rated or installed in metal conduit or EMT.

3-6.5 Fire Suppression Systems.

For the purposes of the design and installation of suppression systems only, ATC and Air Operations Facilities are not to be considered “mission critical.”

All areas of ATC and Air Operations Facilities must be protected with wet pipe fire-suppression sprinkler systems. A single fire suppression system may serve an ATCT and an attached adjacent RACF provided that separate water flow indicators are provided for each.

Provide for concealed mounted sprinklers where suspended ceilings are installed.

3-6.6 Fire Alarm and Detection Systems.

Provide intelligent addressable fire alarm, detection and mass notification systems in all ATC and Air Operations Facilities. Audible notification shall be voice messages via speakers. The fire alarm and mass notification systems shall share speaker circuits and notification appliances.

Carbon Monoxide detection, in accordance with NFPA 720, is required in any facility provided with fossil-fueled equipment, such as a generator, boilers, hot water heaters, etc.

A single fire detection and notification system may serve an ATCT and attached adjacent RACF provided separate notification zones are provided for the ATCT and the RACF to prevent simultaneous evacuation of both technical areas.

3-6.7 Electronic Equipment Spaces.

3-6.7.1 Separation.

Provide separation from other areas of the facility with one-hour fire resistance-rated assemblies.

3-6.7.2 Automatic Sprinkler System.

Provide a wet pipe sprinkler system in Electronic Equipment Spaces (EES).

- Provide guards for sprinklers in EES's without ceilings. Provide concealed sprinklers for EES's with drop ceilings.
- Provide a single fire suppression line supplying the sprinklers in EES. This supply must be provided with a supervised shut off valve, check valve, flow switch, and test valve.
- Actuation of the flow switch must remove power to the electronic equipment.

3-6.7.3 Fire Alarm System.

For the EES:

- Provide smoke detection at ceilings, connected to the building fire alarm system to transmit local and remote signal as well as to activate the extinguishing system where provided.
- Provide manual fire alarm stations at all doors from the EES.
- Smoke detector(s) shall be spot type utilizing a laser light source technology. It shall be able to recognize and transmit at least two separate alarm threshold signals.
- Provide local audible alarm notification in each EES. The fire alarm system must be configured such that the first threshold smoke detection signal shall annunciate an alarm at the Fire Alarm Control Panel (FACP) and all remote annunciators, if provided, and initiate alarm notification from the local audible alarms, but will not initiate evacuation alarms throughout the facility.
- A signal indicating second threshold smoke detection, or a detection signal from a second detector, if provided in the EES, will silence the local alarm and initiate the facility evacuation system.
- Do not install heat/smoke detectors directly above ATC equipment cabinets. Equipment locations will be determined during design.

3-6.8 Seismic Restraint.

Fire protection systems and components shall be braced against damage from movement such as from seismic activity, regardless of the probability of such activity. Design and installation of system bracing shall be in accordance with the applicable design standards such as NFPA 13, NFPA 14, NFPA 70 and NFPA 72.

3-7 ELECTRICAL.

The criterion set forth in this section includes the minimum functional and design requirements of interior and exterior electrical systems for ATC and Air Operations Facilities. The power distribution system and components must meet overall power system and Critical system reliability requirements.

3-7.1 Emergency Electrical Power.

3-7.1.1 Emergency Generator.

All electrical power provided to ATC and Air Operations Facilities is considered "Essential", requiring back-up by an Emergency Generator (E/G). This Essential power must be supplied on a split-bus system, which is herein denoted as Critical and "Non-Critical". Equipment to be supplied from the Critical bus is limited to the ATC electronic equipment, the signal light guns, and select non-ATC computers, LAN, or other technical equipment that may be required. Non-Critical circuits include the facility mechanical and building systems, such as the HVAC, lighting, and fire protection systems.

To ensure equipment operation during extended power outages, the HVAC systems serving Critical spaces must be on E/G power. If an ATCT is located adjacent to an RACF or AOB, a common emergency generator must be considered.

3-7.1.2 Emergency Generator Location.

Consider an outdoor unit with a weatherproof enclosure in mild climate conditions. Where the E/G is located in a cold climate, the emergency generator must have an in-block heater to facilitate rapid start-up during cold winter snaps. If the cold weather is extreme, utilize a crankcase engine lubricating oil heater to reduce the oil's viscosity and facilitate an easier and faster start. Consider the use of a battery heat jacket in extreme frigid weather to facilitate full battery cranking power. An ether injection system for direct injection into the engine's intake manifold will enhance starting capability during very frigid weather.

Consider a below-ground generator vault for units which must be sited within airfield clear zones or primary surfaces.

3-7.1.3 Emergency Generator Fuel Storage.

- Design fuel storage for diesel or jet fuel powered generators in accordance with:
- UFC 3-460-01, *Design: Petroleum Fuel Facilities*, state and local regulations, and the following:

- Title 40, CFR Part 112, *Oil Pollution Prevention*
- Title 40, CFR Part 113, Liability Limits for Small Onshore Storage Facilities, Subpart A "Oil Storage Facilities"

Provide fuel storage capacity for a minimum of 36 hours of continuous generator operation. This will account for periodic engine testing while ensuring at least 24 hours of fuel supply for the full required load during an actual electrical emergency. Provide separation between fuel storage tanks and adjacent buildings, parking aprons and property lines in accordance with UFC 3-460-01. Provide double wall storage tanks and piping. The screen wall surrounding an exterior fuel storage tank must be at least 6 inches (150 mm) taller than the tank. Underground fuel storage tanks are not allowed for ATC Facilities.

3-7.1.4 Emergency Lighting.

Emergency lighting must be connected to the emergency bus and will have 100% backup power from the E/G. Stairways, exit corridors and vestibules must have sufficient general building luminaries connected to the emergency system to provide emergency exit illumination. Also provide emergency lighting at the UPS and backup generator systems for reading any operating instructions.

In addition, each continuously occupied room and each ATC Electronic Equipment Room must be supplied with at least one (1) light from circuits powered by the E/G. Consider providing additional emergency fixtures (conventional with battery back-up or inverter/rectifier located in the fixture ballast) in other locations if determined by local ATC personnel.

3-7.1.5 Emergency Power-Off Switch.

Per NFPA 70, a means to immediately secure all incoming Critical power is required in the ATC electronic equipment spaces and the Facility MDF. These Emergency Power-Off (EPO) switches must cause a main breaker trip (by activating a shunt trip) in the Critical power panel feeding the associated room. Under-voltage type devices must not be used. Circuit breaker number one of the associated power panel must be reserved for shunt trip power. (Local regulations must be consulted for deactivating each facility UPS via an EPO switch. Deactivation is required if over 600 VAC).

The EPO switch must be conveniently located in a conspicuous location near the room entrance(s), readily visible, and protected from accidental activation by means of a protective hinged cover. The EPO switch must have a label stating "Emergency Power-Off." Resetting after activation does not have to be controlled from within the space. An audible alarm on the EPO switch cover is not required.

3-7.1.6 Uninterruptible Power Supply (UPS).

Provide an Uninterruptible Power Supply (UPS) system in ATC and Air Operations Facilities for all Critical technical loads and the specific requirements of the Program Authorities. Install the UPS system in accordance with MIL-HDBK-1012/1, *Electronic*

Facilities Engineering. The UPS system must feed all Critical power panels. UPS sizing calculations are the responsibility of the Designer of Record.

- By design, UPS units must be physically near the load to be served. The UPS must be sized to provide the critical loads with power (plus a 25% spare capacity) for a minimum of 15 minutes to allow the E/G to start, stabilize, and assume the load. Provide remote monitoring of the UPS from a location determined by local ATC personnel.
- Connect the UPS so that the E/G provides input to the UPS during facility power outages. The UPS must be "double conversion" type. UPS output converters must include an isolation transformer. Size and install grounding electrode/bonding separately for derived neutral in accordance with the National Electrical Code (NEC). The UPS must be provided with dual inputs (one Normal UPS input and one Bypass input).
- The UPS is not normally located in the electronic equipment rooms due to space limitations, but must be located in a room serviced by the redundant HVAC system. The electronic equipment cabinets (to be installed after construction) will occupy most of the area in these spaces. If the UPS is to be located in any of these spaces, additional square footage will be required.

UPS systems that are built in are included in the MILCON construction and funding. Rack-mounted UPS systems for telecommunications, instrumentation or similar electronic equipment are not MILCON funded.

- **Navy:** Refer to OPNAVINST 11010.20 for updated guidance on UPS funding.
- **Army:** Refer to AR 415-15 for guidance on funding sources for UPS equipment.

3-7.2 400-Hz Power.

When required by the Program Authority, provide 400-Hz solid-state converter in accordance with UFGS 26 35 43, *400-Hz Solid State Frequency Converter*. Design in accordance with UFC 3-555-01N, *400 Hertz Medium Voltage Conversion/Distribution and Low Voltage Utilization Systems*. De-rate all 400-Hz cables and locate in separate non-magnetic raceway system. Also refer to MIL-HDBK-1012/1.

3-7.3 Grounding, Bonding, Lightning and Surge Protection.

Grounding, bonding, lightning protection, transient voltage protection, and shielding must be designed and installed in accordance with the requirements of NEC Article 250 and as specified in FAA-STD-019e, FAA-STD-020b, NFPA 780, Underwriters Laboratory (UL) 96A, Installation of Lightning Protection Systems, FAA-C-1217, and FAA Order 6950.19a. Specifically, ATC and Air Operations Facilities must have grounding electrode systems and safety grounding systems plus lightning protection, signal reference systems, and multipoint grounding systems. Designers should be aware that FAA requirements dramatically exceed those of the NEC. Special note: unless otherwise noted, there is no requirement for a single point ground system for ATC Facilities.

Lightning protection and grounding are crucial elements to an ATC Facility. Improper grounding and lightning protection can be the cause of many system failures and equipment damage. Any interruption of ATC services can cause severe flight safety issues.

3-7.3.1 Grounding.

Provide a grounding grid on all raised access flooring systems and isolated grounds for each piece of electronic equipment and equipment racks. Provide Equipotential Grounding Plane connections in the areas where equipment racks will be installed. Racks must be directly grounded for maintenance and should operate on a grounded power supply

3-7.3.2 Bonding.

Bonding of all metallic components in a facility is part of the complete facility grounding. Bonding of all metallic components in ATC Facilities is required per FAA-STD-019e. Special attention must be paid to the bonding of items that will be concealed upon completion of the construction effort, such as reinforcing bar.

3-7.3.3 Lightning Protection.

Due to the increased use of jointly procured (FAA/Department of Defense [DoD]) electronic systems for the National Airspace System Modernization (NAS Mod) Program, the lightning protection system requires that the structure be designed and installed per FAA-STD-019e.

Care must be taken to ensure lightning down conductors do not run within the building structure, take the shortest route possible, and are properly terminated to an earth ground. As specified in FAA-STD-019e, all down conductors are required to be connected to the earth electrodes by exothermic welds. This requirement must include the connection of any down conductors to the ground rod in the access well. The Government will ensure that all rooftop antennas installed by the Government are adequately bonded to the lightning protection system, and that all ATC antenna and ATC signal cables installed by the Government are adequately protected from lightning induced transients.

3-7.3.4 Transient Voltage Protection.

Transient voltage protection is required per FAA-STD-019e. Transient Voltage Surge Suppressors (TVSS) will help to prevent incoming surges from damaging any UPS installed. Additionally, the design must include TVSS on all critical power panels to prevent surge transmission between electronic equipment. TVSS is also required on any non-critical panels providing power to general-purpose outlets in any electronic equipment space. TVSS is optional on all other non-critical panels in the remainder of the facility. The lowest set of breakers (either right or left, according to which provides the shortest cable length) must be used in connecting the TVSS. Consult with local ATC personnel for additional non-critical power panel requirements.

The TVSS should be in a separate enclosure adjacent to the switchboard or panel board and be nippled with it. The nipple should be sealed with Oakum or duct seal.

3-7.3.5 Electronic Multipoint Ground System

An electronic multipoint ground system, per FAA-STD-019e, is required. This system must facilitate the interconnection of all non-current-carrying metal objects in the ATC Facility structure to the Earth Electrode System (EES). It is essential that no power grounds utilize this system.

- Electronic multipoint ground plates are required in ATC equipment spaces for the exclusive use of the ATC electronic equipment. One multipoint ground plate is required in the vicinity of the power panels in each of the ATC equipment spaces. A multipoint ground plate is not required in the Operations/IFR Room, IFR Equipment Room, ATC Simulator Room, or the ATCT Control Cab. The Signal Reference Grid (SRG) under the Raised Access Flooring (RAF) will be used to provide the grounding connection. Other multipoint ground plates may be installed as dictated by the facility design.
- All multipoint ground plates provided for ATC electronic equipment must be constructed of 4-inch (100-mm) wide x 20-inch (500-mm) long x 0.25-inch (6-mm) thick copper plate, mounted on standoff brackets. (NOTE: FAA-STD-019e states ground plates must be a minimum of 4 inches (100 mm) wide x 6 inches (150 mm) long). One half of each plate must have an evenly distributed pattern of holes, clear drilled for 0.375-inch (10-mm) hardware, on 1-inch (25-mm) centers. The other half must have a similar pattern of holes clear drilled for 0.125-inch (3-mm) hardware on 0.75-inch (20-mm) centers. All electronic multipoint ground plates in ATC Facilities must be mounted, have covers, and be labeled per FAA-STD-019e.
- To aid future testing of each facility grounding system, a Main Ground Plate must be installed in each facility, which must be easily accessible. The Main Ground Plate can be located in the IFR Equipment Room or in the ATCT Vertical Cable Chase on the ground floor. The Main Ground Plate must be identified by a predominantly green, permanently attached, plastic or metal label bearing the caption “MAIN GROUND PLATE” in black letters.

3-7.3.6 Electrostatic Discharge Prevention.

The electronic equipment to be installed in ATC Facilities will primarily consist of commercial off-the-shelf equipment containing circuit cards similar to those used in computer systems. This electronic equipment is highly susceptible to damage by electrostatic discharge (ESD). It is vital that design efforts concentrate on minimizing the potential for generating static electricity

All floors in rooms containing ATC electronic equipment have static dissipative surfaces connected to the electronic multipoint ground system and that floor coverings meet the requirements of ANSI-A148.1 (UL 779), *Electrically Conductive Floorings*. All chairs in rooms with ATC electronic equipment must have metal frames with conductive casters and chair-covering materials must have a low propensity to store static electricity.

Coordination with local Maintenance personnel is necessary to determine the requirements for any electronic repair or maintenance stations in ATC and Air Operations Facilities. If such work areas are requested, suitable ESD protection is required per FAA-STD-019e.

3-7.3.7 Earth Electrode System.

An EES is required for ATC Facilities per FAA-STD-019e. A survey to gather information concerning the subsurface conditions and soil resistance of the site is required per FAA-STD-019e. One access well is required per FAA-STD-019e so that periodic checks of the EES can be made.

At facilities that have two or more structures, the EES may be required to be interconnected per FAA-STD-019e. Additional guidelines are provided in FAA Orders 6950.19a and 6950.20.

3-7.4 Critical Power Distribution System.

All ATC and Air Operations Facilities require a Critical Power Distribution System (CPDS). Only 480 volt, three-phase, wye, three-wire distribution systems must be used, based on their superior harmonic resolution capability. This capability is applicable to all ATC and Air Operations Facilities unless 480 volt, three-phase utility power is not available.

ATC electronic equipment requires 120/208-volt service, and will generally be supplied from transformers 30 kVA to maximum 75 kVA (480 volt delta, 208Y/120 volt). The designer must follow guidelines in IEEE STD 1100, the Federal Information Processing Standard (FIPS PUB 94) power distribution publication for electronic equipment, and actual equipment loads to size transformer.

3-7.4.1 Main Distribution Panel Essential.

The Main Distribution Panel Essential (MDPE) will normally be rated 480 volt, 60 Hertz, three-phase, three-wire. This panel must be designed with a minimum spare capacity of 25 percent. All breakers 1000 ampere three-phase and higher must be installed in accordance with the NEC, have ground fault interruption protection option, and be rated to provide interrupting capacity in accordance with the short circuit study.

Provide an option to use 208 volt or 480 volt power. On smaller ATC Facilities, it could be more beneficial to use 208 volt power to eliminate the use of dry-type transformers.

3-7.4.2 Critical Power Panels.

Critical power panels are required for ATC Facilities. The critical power panels must be connected to the UPS and designated for ATC electronic equipment use. The combined equipment characteristics, estimated power panel loads, and proposed circuit designations should be identified during the planning/DD 1391 development process. Unless indicated otherwise, each critical panel in ATC Facilities must be 3-phase, 100 Amperes (A) with a 100A 3-phase shunt trip main breaker.

Flush mount panels in the ATC equipment spaces are required, except on masonry walls. Provide six (6) 3/4-inch (20-mm) empty spare conduits to a NEMA 3 enclosure below the RAF at each panel. These spare conduits will facilitate adding circuits in the future without exposing the bottom of the panel.

Each of the Critical power panels must be fed individually from the CPDS. The feeder to each 100 A critical panel must be designed for 100A 3-phase of load at rated voltage. The desired locations of the Critical power panels will be determined during design. Power panels must retain sufficient access for the future installation of additional conduits.

3-7.5 Non-Critical Power Panels.

Non-critical panels are required in ATC Facilities to support general facility requirements, such as overhead lighting and general-use duplex outlets. Desired locations for these power panels will be identified during design.

Non-critical power panels are typically located adjacent to the critical power panels.

3-7.6 Power Panel Access.

The individual room designs must ensure that there are no objects or equipment mounted above or below power panels. This will ensure nothing impairs the installation of conduit runs to support equipment being installed after construction.

Post-construction access to power panels must be designed into the facility. When a power panel is located above the RAF, there must be sufficient cable paths (conduit or 4-inch (100-mm) x 4-inch (100-mm) metal duct) to facilitate cable installation. When power panels are located in adjacent rooms to where the service is required, an adequate number of conduits must be installed from the panel to the room(s) serviced. Quantities and termination of additional cable paths should be specified during the planning process.

3-7.7 Critical Power Circuits

ATC equipment power circuits must be installed during construction. The circuits terminate in junction boxes below the RAF. During the equipment installation, the circuits are extended to the equipment. Everything installed under the RAF (except ATC circuit cables) is installed during construction. This places the burden of overcoming interference issues on the construction contractor.

Note: Not all junction boxes will require an individual conduit path to the Critical power panel. However, conduit sizes and junction boxes must conform to the NEC with respect to the fill requirements. Wiring and junction boxes must be labeled with the power panel designation and circuit number. Spare and unused circuits may be used in the future.

3-7.8 Exterior Electrical Outlets.

Any requirements for vehicle heater outlets or golf cart charging stations should be determined during the planning process. Watertight outlets may be provided for vehicle heaters in parking lots at cold weather sites or for golf cart charging stations when authorized by the local installation.

3-7.9 Neutral Conductor.

Every circuit should consist of one phase conductor, one neutral and one equipment ground. Up to three (3) circuits may be run in one raceway.

3-8 TELECOMMUNICATIONS.

3-8.1 General.

Administrative telephone wiring/cabling must be installed under the MILCON project and funded with MILCON appropriations. In addition, specialized communication wiring/cabling between facilities (e.g., cabling which extends from the ATCT to the RACF, navigation aids, remote transmitters and receivers, etc.) and all raceways, conduits, pullboxes, duct banks, etc., are considered permanent and must be installed as part of the construction contract.

The construction contractor must provide all Inside Plant (ISP) and Outside Plant (OSP) equipment for the facility. ISP includes outlets, jacks, cabling, conduit, cable trays, racks, cabinets, building protector assemblies, and passive termination devices such as patch panels and connector blocks. OSP includes exterior cabling, ductbanks, manholes and utility poles.

3-8.2 Operational Telephone Lines.

Administrative telephone service, not related to ATC, will be required in the ATC and Air Operations Facilities. Typically, this service includes dedicated lines for point-to-point communications (e.g. Crash Phone). Consult with local ATC personnel for guidance. As a preliminary recommendation, each room should have a minimum of one administrative telephone line.

3-8.3 Data Communication Lines.

Communications networking cable should be installed in each space and must be of a type consistent with current station or networking systems. Consult with local ATC personnel for guidance. As a preliminary recommendation, two network lines should be available in each space.

Two data ports are generally required at each location, one for a computer and one for a printer. Four outlet panels (Type RJ-45) are recommended for network and telephone services in each room. Exact requirements must be coordinated with local Facilities, Communications and Information Technology personnel.

3-8.4 Telecommunications Room.

Telecommunications Rooms for Telephone/Data communications systems must be provided for all ATC and Air Operations Facilities. This room is configured with termination blocks and patching hardware and serves as the communications distribution plant for the building supported. This room may require temperature and humidity control. The design must be coordinated with local Facilities personnel, and designed to accommodate all telecommunications and networking equipment.

Provide fireproof 3/4-inch (20-mm) thick plywood from floor to ceiling for telecommunication mounted equipment. Paint plywood to match the other walls in the facility. Provide Building Entrance Terminals (BETs) for the primary lightning protection at their entry point into this room and as necessary to meet the NEC. The BETs may be mounted horizontally or vertically. If mounted vertically, there must be 12 inches (300 mm) minimum between each BET. This will allow external cabling to be connected properly.

A cable management system must be used to create a neat, professional cable installation. Attention to detail is critical. Organize space on walls for each cable type and service. Provide space as necessary in the MDF for other services controlled by other factions (such as CATV and fire alarm systems). It may be necessary to design alternate security for each faction in this room.

3-8.5 Facility Main Distribution Frame.

The facility Main Distribution Frame (MDF) is the location in the facility where all exterior signal cabling (not power) is terminated and surge suppressed before being distributed throughout the facility. The types of conductors include (but are not limited to) telecommunications copper, communications fiber, control circuits for airfield lighting, CATV coaxial cabling, and ATC equipment circuits. The contractor is required to remove all waterproofing from exposed conductors. There must not be another room or communications closet within the ATC Facility for termination of outside plant services. This room may require temperature and humidity control. Coordinate with Mechanical Engineer on HVAC requirements for this room.

The MDF must be located in the Telecommunication Room and must be designed with a minimum spare capacity of 25 percent. A short circuit calculation and protective device coordination analysis for the entire facility must be accomplished to determine the appropriate available interrupting current capacity (AIC) requirement for all facility panels and breakers. This analysis must be performed in accordance with FAA Order 6950.27, *Short Circuit Analysis and Protective Device Coordination Study*. The design must allow only the over-current device closest to the fault to operate.

An elevation drawing of the MDF area must be included in the design showing the location of all installed components in this area, to include (but are not limited to): BETs, inter-site conduits, fiber and copper terminations.

3-8.6 Data Cable Tray.

All cable trays must be the dual flange type with a fill depth of at least 4 inches (100 mm) for electronic and telephone cabling and equipment. The cable trays must be designed to provide shielding consistent with equipment cabling requirements, FAA-STD-019e, and must be UL listed. The system design must be coordinated with specific equipment layouts as directed by the designated Electronics Engineer. Cable trays must not be located in fire rated corridors. Cable trays must be easily accessible for maintenance. Where feasible, cable tray installations must provide one foot of access between trays and three feet of access around trays. Cable trays must be bonded in accordance with FAA-STD-019e.

Design engineers must consult with each other to ensure that the cable tray does not interfere with other requirements. Designs for cable tray routing must ensure that the tray lies horizontally flat and is not mounted sideways on the tray edge.

3-8.7 Communications Outlets.

One Quad communications outlet is required every 100 square feet. A minimum of one outlet per quad is used for voice circuit.

Multiple outlets should be installed in every room. Installing wiring and multiple outlets within a room adds flexibility for future requirements.

Printers, fax machines and other similar electronics require a separate, dedicated communications outlet.

3-8.8 Telephone Outlets.

Telephone outlets are required in the offices of the facility. Provide a minimum of four (4) each (one per wall) "quad" jacks, two each CAT 6 data and two each CAT 6 telephone at each room. Conduit for telephones can be stubbed, with bushings provided, above the ceiling where suspended ceilings are used. A cable tray should run from the Telephone Terminal Backboard (TTB) to and along the centerline of the facility when this method of installation is used. Conduit is only necessary for areas where there is no ceiling or there is no access above the ceiling. When conduit is used, it must be prewired.

3-8.9 Internal Facility Connectivity.

Careful attention must be applied when designing cable access runs within ATC and Air Operations Facilities to ensure pathways are uninterrupted, provide accessibility along the routes, and provide enough clearance for feeding the cables from point of origin to point of terminations using industry standards.

3-8.10 Inter-Site Connectivity.

ATC remote facilities (navigational aids) are located on and off the airfield, and most require hard-wire connectivity back to the ATC and Air Operations Facilities. These inter-site conduits can be expensive to install, especially if the path is under runways, taxiways, or parking aprons. All conduits entering the facility must comply with FAA STD-019e.

- All inter-site cabling must be terminated utilizing the Western Electric color code. Provide detectable warning tape above any new duct banks installed for electronic detection.
- Where new facilities are proposed to replace existing ATC Facilities, the new ATC Facilities will require connectivity to the same remote sites as the existing ATC Facilities. This new connectivity must terminate at the RACF MDF. If existing facilities are to be demolished, the design must reroute any "through" cabling prior to the entry into these facilities. Splicing and burying cables beneath the demolished structures is not acceptable. There must be direct and unobstructed access between the vertical cable ladder and the inter-site cable trays/ducts, which provide connectivity to ATC systems in the other ATC facilities.
- If flooding is a possible issue, the conduits may require extensions so that water will not discharge into the ATCF. The penetration in the ATCF must be near the location of the MDF. Nylon pull-cords are required in all conduits. Manhole or conduit access requirements must be determined when the ATCF locations are finalized. A combination of copper, fiber optic, and coaxial cables, with sufficient spares for future use, must be installed. A dedicated ATC-related inter-site trunk cable (minimum 300 pair) is required between the new RACF and ATCT and the existing ATC facility.
- Existing inter-site connectivity may be utilized. However, any existing connectivity cannot be removed or interrupted.
- Every attempt must be made to minimize splices in all new copper and fiber inter-site cabling. Any splices required in the inter-site cabling must be installed by properly trained personnel. All fiber cables must be fusion spliced. All splices, copper and fiber, must be the direct bury, encapsulated, re-enterable type.
- All conduits must penetrate the RACF and ATCT so that installed communications cables can transition easily to their associated termination area or enclosure. The exact termination of the conduits will be determined during design.
- Any connectivity requirements to Flight Planning, the Weather Office, or Airfield Lighting Vaults should be identified during the planning/DD 1391 development process.
- LAN or telephone cabling must not be placed in the same cable tray or conduits as ATC circuits.

Site specific requirements for communication ducts, conduits, manholes, and stub-outs should be identified during the planning/DD 1391 development process.

3-9 PHYSICAL SECURITY.

Physical Security is defined as that part of security concerned with physical measures designed to safeguard personnel, to prevent unauthorized access to equipment, installations, material, and documents, and to safeguard them against espionage, sabotage, damage, and theft.

3-9.1 General Requirements.

In the context of these requirements, facilities may be sited within a restricted or controlled area (airfield enclave) or may be designated as a controlled or restricted area. Controlled and restricted areas are defined areas in which there are special restrictive measures employed to prevent unauthorized entry. Restrictive areas may be of different types depending on the nature and varying degree of importance of the protected asset. Restricted areas must be authorized by the installation commander, and properly posted, and shall employ physical security measures.

3-9.2 Specific Requirements.

All planned security design and installation must be coordinated in advance with the Base Antiterrorism Office (ATO), Security Officer, and Air Operations to determine the area or building designation (controlled or restricted), threat environment, design basis threat (DBT), level of protection, and access control or other ESS requirements. Use the process in UFC 4-020-01 to identify the design criteria, which includes the assets to be protected, the DBT, and the levels of protection. The engineering risk analysis conducted as part of UFC 4-020-01 should be consistent with the terrorism risk analysis conducted by the installation security/AT staff.

3-9.3 Electronic Security Systems.

Design electronic security systems (ESS) when required in UFC 4-021-02, *Security Engineering: Electronic Security Systems*.

3-9.4 Security Lighting.

Design all security lighting to meet the requirements as stated in UFC 3-530-01, *Design: Interior Exterior Lighting and Controls*.

3-10 SITE WORK.

3-10.1 Parking.

Provide parking spaces for staff on shift, plus accessible spaces required by ABAAS, two visitor spaces, and government vehicles as needed. Many airfields have alternative vehicles for Government use. Provisions for these vehicles including charging stations must be considered. Additional parking should be considered for shift changes. Specific criteria are given in UFC 3-210-02, *POV Site Circulation and Parking*.

3-10.2 Pavement Design.

Exterior paved areas include aircraft, pedestrian and vehicle access and parking. Vehicle access and parking should be in accordance with UFC 3-250-01FA, *Pavement Design for Roads, Streets, Walks, and Open Storage Areas*.

3-10.3 Site Utilities.

Reference UFC 3-210-01A, *Area Planning, Site Planning and Design*; UFC 3-210-06A, *Site Planning and Design*; and UFC 3-230-04A, *Water Distribution*.

3-10.4 Site Lighting.

Orient exterior fixtures to minimize glare on ramps and taxiways. Use full cut-off type fixtures. Refer to UFC 3-260-01, *Airfield and Heliport Planning and Design* for clearance requirements, obstruction lighting requirements, and airfield utility lighting information.

3-11 SAFETY AND HEALTH.

3-11.1 General Requirements.

Design occupied buildings with maximum consideration given to safety and health, with particular emphasis on noise control for hearing conservation.

3-11.2 Human Engineering.

Consider safety in relation to operational function, accessibility for maintenance and repair, physical layout for traffic, interface with other equipment, and environmental factors, such as lighting, temperature, and humidity. See MIL-STD-882, *Standard Practice for System Safety*, and MIL-STD-1472, *Human Engineering*.

3-11.3 Electromagnetic Hazards.

ATC and Air Operations facilities contain equipment that radiates an electromagnetic signal. Consider the effect of electromagnetic radiation (EMR) on personnel (HERP), ordnance (HERO) and fuel (HERF) when planning and designing facilities housing EMR emitting equipment. Provide safety measures to eliminate or reduce hazardous conditions. Refer to Section 2-6.2 and MIL-HDBK-1012/1, *Electronic Facilities Engineering*.

3-11.4 Life Safety.

All drawings must be reviewed by the Regional Safety Manager for safety issues such as lockout points, anchor points, confined spaces, fall hazards, noise hazard areas, and areas where eyewash stations or emergency showers may be necessary. These issues must be addressed at the design level to minimize hazards involved with the day-to-day activities and maintenance of the facility.

This Page Intentionally Left Blank

CHAPTER 4 SPECIAL DESIGN REQUIREMENTS

This chapter describes the special design requirements that only apply to each type of Air Traffic Control and Air Operations Facility, including:

- Air Traffic Control Tower (ATCT). Section 4-1
- Radar Approach Control Facility (RACF, referred to as ARAC (Army), RATCF (Navy) and RAPCON (Air Force)). Section 4-2
- Air Operations Building (AOB, referred to as Air Operations Building (Navy), Airfield Management Operations (AMOPS) Building (Air Force) or Airfield Headquarters Facility (Army)). Section 4-3

4-1 AIR TRAFFIC CONTROL TOWER (ATCT).

Design the Air Traffic Control Tower (ATCT) to be generally consistent with FAA Order 6480.7e, *Airport Traffic Control and Terminal Radar Approach Control Facility Design Guidelines.* If a conflict exists between this UFC and FAA Order 6480.7e, this UFC governs. Sizing of Control Cab window mullions, Cab glazing and electrical grounding are examples of where most recent FAA criteria should be considered.

4-1.1 General Requirements.

4-1.1.1 Risk Category.

For Risk Category, see Table 2-2, UFC 3-301-01. This classification has an impact on the design of most design disciplines involved with an ATCT, including architecture and structural, mechanical, electrical and fire protection engineering. Ensure that non-structural components (e.g. raised access flooring, architectural components, utilities, etc.) are laterally braced as required for seismic load stability in accordance with UFC and building code provisions. Careful analysis of these requirements must be addressed in the planning/DD 1391 development phase. Coordinate additional bracing requirements to avoid interference with items to be installed post construction, such as cabling, conduit raceways and other infrastructure for electronic equipment.

4-1.1.2 Airfield and Ramp Blind Spot Monitoring.

If any portion of the airfield surface is actively used for aircraft movement or parking and the visibility from the ATCT is limited, Closed Circuit Television (CCTV) may be required to provide remote viewing of the area. Consult with the local ATC operations personnel for specific requirements. The entire runway surface must be visible. CCTV cameras must not be used for remote viewing of runways.

4-1.2 Architectural Requirements.

4-1.2.1 Accessibility for the Disabled.

In air traffic control towers, an accessible route is not required to serve the cab and the floor immediately below the cab. See ABAAS F206.2.3.

4-1.2.2 Raised Access Flooring.

Provide Raised Access Flooring (RAF) in the Control Cab with 18 inches (450 mm) of clearance between the floor panels and sub floor to accommodate wiring and insulated piping. The use of RAF in the ATCT Cab area is required to facilitate the periodic rearranging and upgrading of equipment and cables.

The RAF in the Cab must be supported around the perimeter in addition to the normal stringer support. Due to the shape of the Cab, some pieces of RAF can be small, odd shapes. These small pieces must be securely supported so that when stepped on, they do not create a safety hazard.

4-1.2.3 Floor Finishes.

Provide floor tiles with integral, static dissipative carpet coverings in the Control Cab. The use of carpet aids in sound dampening.

4-1.2.4 Interior Walls.

Use wall materials that will help with sound attenuation in the Control Cab and Cab access stairway.

The finish of any interior exposed wall surface in the Cab must be a dark, flat, non-reflective color to reduce night glare. Consult with local ATC personnel for color preferences.

4-1.2.5 Control Cab Walls.

The exposed Control Cab wall above the window and below the window sill must be finished with acoustical material, such as a heavy-gauge insulated metal panel with noise absorbent backing. Design decibel level no greater than 65 dB. Use of floor carpet on walls is not allowed.

4-1.2.6 Ceiling Finishes.

The Control Cab ceiling must be accessible acoustical ceiling tiles with low light reflectance in a suspended grid system. Use dark colored tiles with textured surface, and high acoustic damping. Flat black color is preferred to prevent reflections on the Cab windows. Suspended ceiling grids must be painted flat black.

Ceiling tiles must be constructed of material which is dyed black, so that the ceiling tiles are black throughout the entire tile. The grid system should not be painted black on site. The grid should be ordered from the manufacturer as black.

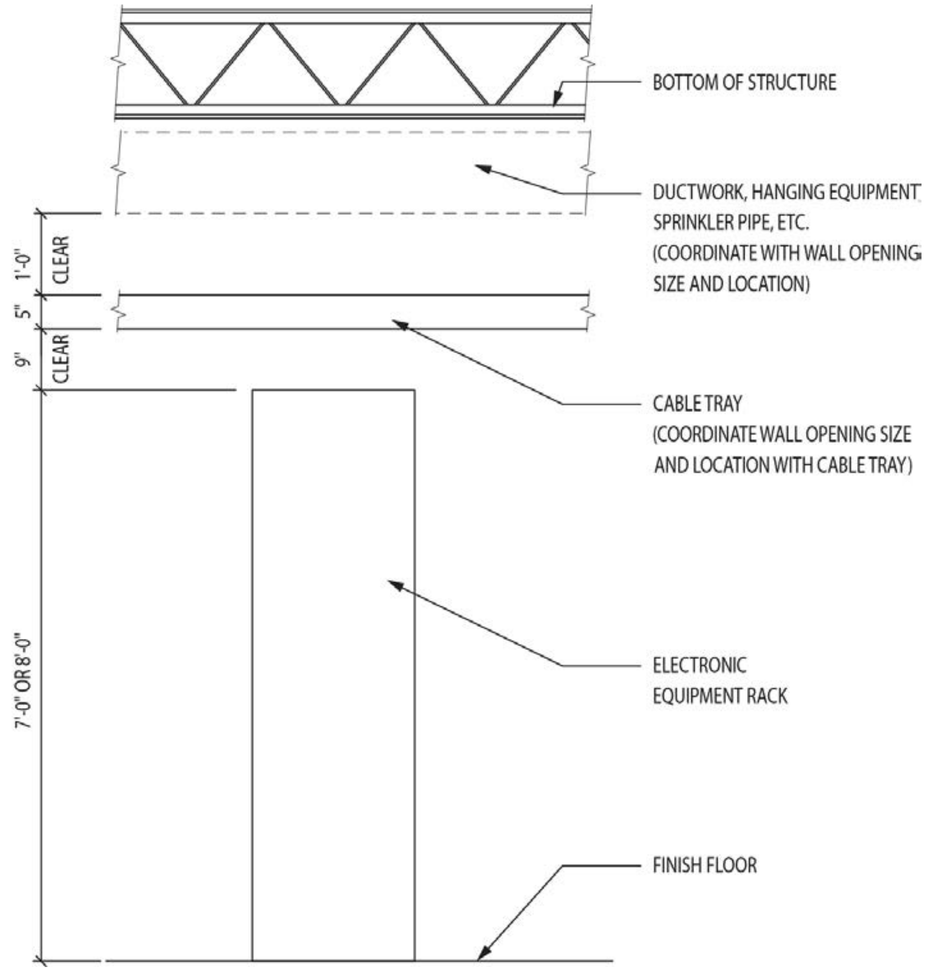
4-1.2.7 Ceiling/Clearance Heights.

The minimum clear height in the ATCT from the finished floor to the bottom of a finished ceiling must be 8’-0”, except for the following conditions:

- Control Cab must have a clear ceiling height of 10’-0” above worker floor (not the raised supervisor level).

- Electronic Equipment Rooms must have a minimum clear unobstructed area from the finished floor to any overhead obstruction of 9'-2". These rooms do not typically have a finished ceiling installed. Refer to Figure 4-1 below for more information.

Figure 4-1 Electronic Equipment Room Clearance Detail



The structural height (floor-to-floor) of each level should be enough to allow HVAC, sprinklers, and electrical equipment be installed without interference.

4-1.2.8 Windows.

Windows must be provided on all sides of the Control Cab, and may also be required in other spaces in the tower.

Window ledges in the Cab must be designed so as not to hinder an air traffic controller's ability to see aircraft movement areas. Deep window ledges extend control consoles away from windows and prevent controllers from viewing aircraft movement areas below and in close proximity to the ATCT. For this reason, the window sill wall thickness/depth must be as narrow as possible (no more than 18" deep).

- The ATCT window sill must be coordinated with the Cab consoles so that the sill and the consoles are the same height. The window sill height must be consistent at the entire Cab perimeter where the consoles will be installed. Refer to Figure 2-3 for window sill height and Cab console height details.
- The window sill must be capable of supporting a 250 lb point load for personnel standing on the sill for maintenance and repair purposes. All window sills and mullions must be covered with a laminate or other material to provide a durable, non-reflective surface. Materials such as gypsum board, plywood, or stained or painted wood are not acceptable.
- The length of the screws used to secure the cab window frames to the structure must be kept as short as possible. If the screws are too long, installing flexible non-metallic tubing or cables inside the tubular column is difficult.
- At a minimum, provide a single window on the runway side of the shaft tower in Training/Briefing Rooms and in the Chief Controller's office. Provide more windows if structurally feasible.

4-1.2.9 Control Cab Glass.

Control Cab glass is the glass in the windows of the Cab for observation of aircraft. Cab glass must be low-iron glass to optimize visible light transmittance. Tinted glass or heat strengthened glass must not be used for the Cab glass.

- Low-E coated glass may be used with the understanding that the coating may reduce visible transmittance. Coordination with HVAC design must take place during planning and design phases to determine the acceptable heat transmission for the low-E coated glass.
- The Cab glass must slope at an outward angle of 15 degrees from vertical.
- Use double pane glazing unless design conditions dictate otherwise.
- Window units must be constructed with a metal or composite plastic perimeter or a unitized extruded aluminum system frame. The frame must be bonded to the glass to provide an airtight, waterproof, and vapor proof seal.
- Cab glass must meet site-specific wind load and seismic requirements.
- Cab glass must allow light gun red, white and green light from inside the ATCT to the outside.

Coordinate with mechanical engineer on HVAC design to minimize condensation forming on Cab glazing, using humidity controls and attention to return air ducts adjacent to each side of the Cab. Cab glass must meet the requirements of the UFGS 08 88 58, *Air Traffic Control Tower Cab Glazing*.

4-1.2.10 Control Cab Window Mullions.

Minimize Control Cab window mullions for air traffic controller visibility. Window mullions should not be directly in the line of sight to critical aircraft movement areas such as the approach ends of the runways.

- If located in a high-wind zone, additional intermediate window mullions may be required to transfer glazing loads to the structure. These mullions, used to resist wind and seismic forces, may be considered only as a last resort.
- Cab window mullions are not limited to aluminum. There are innovations in steel mullion systems that are commercially available. The steel system has better design load properties than aluminum. Also, the coefficient of expansion is less (stainless steel has less thermal conductance than aluminum).
- To minimize sun reflections and hindrance of night vision, Cab window mullion and column finishes must be a non-reflective dark color, and must incorporate a high performance anti-corrosion protection coating. Particular attention must be paid to prevent sunlight reflections from the window sills and mullions. Consider butt glazing in place of non-load bearing mullions.

4-1.2.11 Control Cab Window Shades.

Provide manually-operated window shades for the Control Cab windows. Refer to FAA-E-2470b, *Transparent Plastic Window Shades* and FAA-ANI-300-380, *Transparent Plastic Window Shades.* The Cab shades must be at least 0.125 mm thick, color smoke gray, body dyed, supported by rollers with constant tension. Follow slope of windows and match size and shape of Cab windows. Manual operation is preferred - electric rollers are not encouraged. “Mini-blinds” or opaque, semi-opaque, or mesh type shades are prohibited. Design suspended ceiling so window shade roller is recessed in ceiling.

Local ATC personnel must determine if dual shades are required. If required, use a dual shade system with F-72 SR as the primary shade material and DS 8 SR as the secondary shade material.

4-1.2.12 Roof.

- The Control Cab roof must be sloped to drain away from the center; however, the slope must be kept to a minimum as maintenance personnel will be walking and working on the roof to maintain antennas. Walking pads are required on the Cab roof to protect the roofing material. These pads must provide a walking surface around the perimeter of the roof as well as a path from the perimeter to the roof hatch. Provide a place on the Cab roof to stand while safely shoveling snow away.

- It is recommended that the Cab roof be a flat thermoplastic roof with a Solar Reflective Index (SRI) of 78 or better to meet LEED "cool roof" requirements. Use a light color roof membrane to help achieve LEED criteria. No shingles are allowed. Minimize roof dripping at Cab windows to the greatest extent practicable.
- An OSHA-compliant industrial type safety railing (top rail, middle rail & kick plate) or a parapet wall with height to meet OSHA requirements is required on the roof. The 4-inch (100-mm) sphere rule does not apply to the railing system on the Cab roof because it is considered a "maintenance area" and the railing should comply with the regulations for maintenance areas. Coordinate railing shape and size with antenna mounting requirements.
- Antennas will be mounted to the railing and it shall be designed to carry the weight of the antennas. If a parapet wall is provided, a railing system is still required on the inside of the parapet wall for mounting antennas.

4-1.2.13 Roof Access Hatch.

A personnel access hatch and ladder/stairs is required to transit from the Control Cab to the roof. The opening between the suspended ceiling and the roof is required to be enclosed around the hatch opening and painted flat black on the inside. The portion of the hatch which is visible when stowed must also be painted flat black.

The access hatch must be provided with a concealed pull-down/retractable ladder with integral grab rail. Include OSHA-compliant railing and gate at roof access hatch.

The location of the roof hatch and ladder must not be over the controller position cabinetry. Additionally, it is essential that the location of where the roof ladder will bear on the raised access flooring be shown on the design drawings. This will confirm that the extended ladder does not interfere with the controller position cabinetry. The bearing feet of the ladder must rest on the finished floor when the ladder is fully extended.

4-1.2.14 Catwalk.

Provide safe access for walking around the exterior of the Control Cab to facilitate exterior observations, window washing, and general maintenance. The width of the catwalk must be selected to ensure that it does not interfere with the air traffic controller's visibility of the runway, taxiway, or apron areas. Locate the catwalk at a sufficient elevation below the Cab to permit the controllers a view of the field unobstructed by any railing. A concrete catwalk is preferred. The exterior catwalk can be a galvanized metal or aluminum grate that allows snow to melt directly through without building up at the edge. Corrosion issues must be taken into account if metal grating is used. Care must be taken during the design to eliminate the possibility of falling snow or ice from the catwalk.

Provide a weather-sealed access door to the catwalk from the ATCT Stairwell. The door must be a minimum of 32 inches (810 mm) wide and 36 inches (910 mm) high. The head of the door must not extend above the cab sill and the base of the door must not extend below the cab walkway extension. The height of this door is limited due to the Cab structure, but must be as tall as possible. Personnel access to the ATCT catwalk is required to allow washing of the exterior glass of the Cab without the need for a safety harness. Consult with the local ATC staff to discuss window cleaning methods and requirements.

The catwalk must be designed to meet ANSI and OSHA requirements, and should be wide enough to allow the windows to be washed without having to lean backwards over the railing. Catwalk guardrails must also meet ANSI and OSHA requirements, but are not designed to support antennas or other equipment.

4-1.2.15 Elevator.

For Army and Navy projects, comply with NAVFAC ITG 2013-01 *NAVFAC Elevator Design Guide* in addition to requirements below.

Provide an elevator in the ATCT. The elevator must operate from the ground floor to the floor below the floor directly below the Control Cab, or the floor below the Cab if possible.

A hydraulic elevator is acceptable if the Tower Control Cab floor level is less than 60 feet above grade. Otherwise, provide an electric traction elevator. Electric traction elevators must have elevator machine room with elevator machine and controller in a machine room. Elevator machine room may be located above or adjacent to the elevator hoistway.

- Elevator speed must be 150 feet per minute (fpm) if hydraulic, and 350 fpm if electric traction. Minimum rated load for a typical elevator must be 3500 lbs. Elevator capacity must be sufficient to transport equipment to be installed above the ground floor.
- Elevators must conform to ASME/ANSI A17.1, *Safety Code for Elevators and Escalators,* as well as the International Building Code (IBC), NFPA 101, and NEC. The ATCT elevator must be available for use on standby power.
- The elevator car must be sized to accommodate the stretcher requirements of IBC Chapter 30 (24 inches x 84 inches or 610 mm x 2130 mm). The recommended interior size of the elevator car must be 60 inches (1520 mm) wide x 84 inches (2130 mm) deep x 108 inches (2740 mm) high.
- The elevator car door opening must be at least 42 inches (1060 mm) wide and 84 inches (2130 mm) high. The elevator car door must be the single-speed, side-opening, horizontal sliding type. The elevator car must have retractable covers.
- Provide a ventilated elevator shaft.
- Elevator doors must not open directly to the ATCT Stairwell enclosure.
- Hydraulic elevators must be equipped with elevator car safeties and an overspeed governor. Position of the overspeed governor in the elevator hoistway must allow for a governor access door accessible inside the ATCT. Governor access must include a working platform with a platform height of 4 ft. below the bottom of the access door.

4-1.2.16 ATCT Stairwell and Control Cab Stairway.

A pressurized stairwell is required from the floor below the Control Cab to the ground floor. Stair width must be 44 inches (1120 mm) minimum.

A stairway from the floor below the Cab leading up into the Cab must be provided. This stairway must not be a ship's ladder-type stair, but must be a regular stairway meeting all applicable design codes. Code-compliant stairs are required from the Cab subfloor to the RAF. Care must be taken so that the stairwell does not take up a large portion of the Cab floor area.

4-1.2.17 Vertical Utility Chase.

4-1.2.17.1 Ground-to-Cab Mechanical Chase.

A fire-rated chase, open from the ground floor to the concrete sub-floor of the Control Cab that serves as a pathway for HVAC and plumbing utilities from the Tower Shaft Mechanical Room to the ATCT Mechanical Room.

4-1.2.17.2 Ground-to-Cab Vertical Cable Chase.

The ATCT Vertical Cable Chase is typically a 4-foot wide x 2-foot deep (clear inside dimensions) fire-rated chase, open from the ground floor to the concrete sub-floor of the Control Cab.

- A vertical ladder-type cable tray is required for ATC equipment cabling. This vertical cable tray must be accessible from all floors and must provide cable access from the first floor to the open area beneath the ATCT Cab RAF. The ladder must be centered on the chase access door. A minimum 18 inches (450 mm) wide x 4 inches (100 mm) deep (fill depth) ladder-type cable tray is required to provide a cable management system surface. Additional information for the vertical tray shall be provided during design.
- All power cables in the chase must be located in rigid metal conduit instead of the cable tray.
- Access between the top of the vertical cable chase and the Cab is provided as conduit stubs through the Cab sub-floor. Six stubs of 4-inch (100-mm) inside diameter (ID) conduit are required for the exclusive use of ATC equipment cabling. These stubs must be furnished with anti-chafing bushings on each end and must extend at least 4 inches (100 mm), but no more than 6 inches (150 mm), above and below the sub-floor. Additional conduit may be required for telephone and Local Area Network (LAN) cabling. Consult with local ATC operations personnel to confirm final requirements.
- Lockable access to the vertical cable chase must be designed into each floor of the structure. The design must provide sufficient opening to allow personnel to reach and dress cabling runs on the tray. Signs/labels stating "Cable Chase" must be provided for each cable chase access and match in style and size the other facility labels/signage.

- A full size door is not required at each level of the tower for access. A full size door is required on the ground floor and the equipment room floors. Access on the other floors can be via a 24-inch (610-mm) wide X 36-inch (910-mm) high fire-rated access panel/door. If there is no floor at a particular level of the ATCT, an access walkway is required from the stairwell to the front of the cable chase. Final door size will be determined during design.
- A wall opening 5 inches (125 mm) high x 14 inches (350 mm) wide must be provided for the cable tray that will connect the vertical cable tray to the suspended tray systems in the ATC Electronic Equipment Room(s). This opening must be centered above the lockable access door. The bottom of the opening must be a minimum of 110 inches (2790 mm) above the finished floor. Ensure openings comply with fire codes. The final location of this opening will be identified during design. The opening must be finished with smooth edges on both sides of the opening between the chase and equipment space and on the sides of the opening. This opening must be finished to match other openings in the walls, such as sheetrock, paint, and trim.
- Cable Separation. Power and communication cables must be physically separated by distance or by barrier to preclude power cables from coming into contact with communication cables in accordance with the NEC. Cable ladders must be provided. Vertical shafts must be provided with fire separation assemblies in accordance with the other paragraphs in this section.
- The vertical cable chase must be located so as to minimize cable distance to the ATC equipment space(s).

4-1.2.17.1 Control Cab-to-Roof Vertical Chase.

The path for all the RF cables to the roof must be through or adjacent to the tubular steel columns supporting the Control Cab roof. These cableways provide the means to run signal and antenna cables from beneath the Cab RAF to the area above the suspended ceiling and/or to the roof. Power cables for obstruction lights and any building system wiring (electrical and telecommunications) located above the ceiling or on the roof must pass through only the two (2) cableways at the back of the Cab near the Cab stairway. The cableways near the stairs are typically not accessible after construction is complete. All remaining cableways must be reserved for the ATC antenna and signal cabling.

These cableways must be free of obstructions. Cableways must be provided with nylon pull-cords and pull boxes on each floor, sized per the NEC. Pull boxes must be large enough to meet the minimum bending radius specifications of any transmission lines running to the roof. All cable paths must be free of burrs and sharp edges that would damage cables.

- **Army and Air Force**: Provide ducts within the Cab for ATC equipment cabling. Two (2) 4-inch (100 mm) Inside Diameter (ID) ducts must be provided for antenna cables between the ATC Equipment Room and the roof. These ducts are installed adjacent to the roof support columns and terminate in weatherheads on the roof. Ducts from the ATC Equipment Room extend to the floor just below the Cab. A ladder-type cable tray connects these ducts to two (2) 4-inch (100 mm) ID ducts that continue the run up to the weatherheads required at each of the Cab roof corners. Refer to Figure 4-2 for Plan Detail at Control Cab Window Mullion/Structural Column (Army and Air Force only).

- **Navy**: Access cutouts in the vertical columns are required below the Cab RAF and above the suspended ceiling area. These cutouts are typically slots of at least 2-1/2 inches (62 mm) x 6 inches (150 mm), opening directly into the columns. Reinforcement of these access holes may be required to maintain the structural integrity of the columns. The bottom of the slots below the RAF must be 2 inches (50 mm) to 6 inches (150 mm) above the sub-floor.
- The preferred location of the openings is on the surface of the column that faces the inside of the Cab. However, access holes on the sides of the column are acceptable. The primary requirement is for the access holes to accommodate two sleeves for antenna cables with a bend radius of up to 10 inches (250 mm). Clear access to these openings must be maintained. Nothing must be allowed to block access to these openings, such as HVAC ductwork.

A minimum of two (2) 2-inch (50-mm) ID smooth-walled, non-metallic, flexible sleeves/conduits must be installed in each of the mullions with enclosed structural column to provide a continuous path through the columns. These sleeves are for the exclusive use by SPAWAR Atlantic. One end of each sleeve must be terminated three (3) feet into the cable tray beneath the RAF and secured to the tray. The other end of each sleeve must terminate in the space above the suspended ceiling, within 6 inches (150 mm) of the weatherhead conduits in the same column area, and the ends secured. In addition to the two sleeves described above, one (1) 2-inch (50-mm) ID flexible sleeve must be installed in the column closest to the position labeled as "Local" in the FRS. One end of this sleeve must lay three (3) feet into the cable tray beneath the RAF. The other end must terminate in the area above the ceiling. Each end must be secured to prevent accidental movement into inaccessible areas. The column location for this sleeve will be identified in the FRS.

An ATCT with two local positions will require one conduit for each local position. The requirement for two sleeves or tubing will be identified in the FRS.

After the finished wall is installed in the Cab, access to the cutouts in the column below the RAF must be provided. Where drywall or other wall covering is installed, there must be approximately 6-inch (150-mm) x 6-inch (150-mm) openings provided to permit reaching the access holes in the columns. Protective flashing must be installed to prevent chipping the wall material during post-construction cable installation.

One (1) 4-inch (100-mm) ID galvanized conduit and weather head is required at each of the Cab roof corners. These conduits must be welded to the roof structure and must extend 18 inches (450 mm) to 24 inches (610 mm) above the roof and 8 inches (200 mm) below the roof structure into the space above the suspended ceiling. Anti-chafing bushings area required on the end of the conduit below the roof. The weatherhead must be galvanized with stainless steel hardware, and sized to accommodate cables with a minimum bending radius of 11-1/4 inches (285 mm). Refer to Figure 4-3 for Plan Detail at Control Cab Window Mullion/Structural Column (Navy only).

Figure 4-2 Plan Detail at Control Cab Window Mullion and Structural Column (Army and Air Force only)

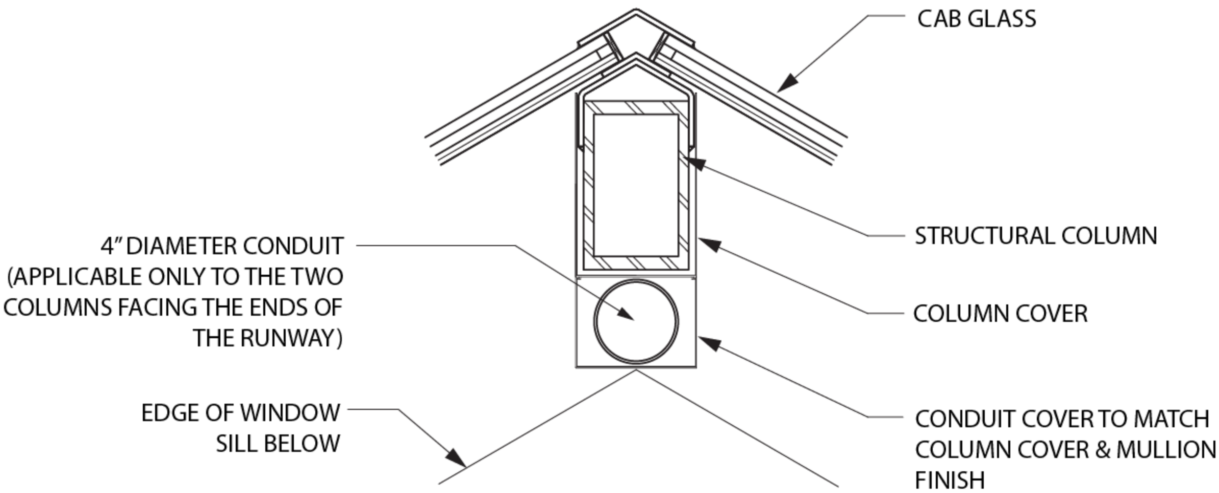


Figure 4-3 Plan Detail at Control Cab Window Mullion and Structural Column (Navy)

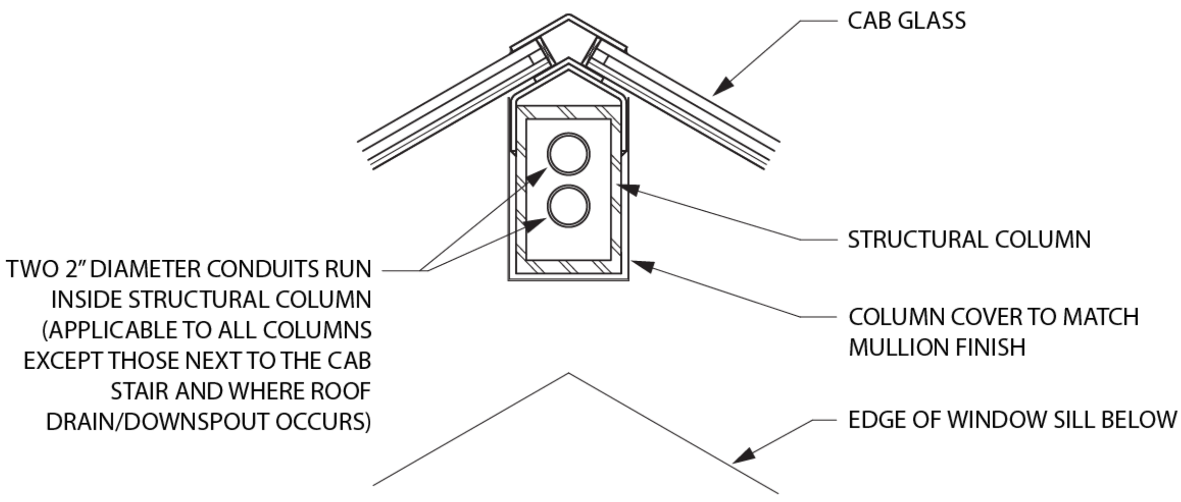


4-1.2.18 Cable Tray System.

In the Control Cab, an aluminum or steel ladder-type cable tray is required beneath the RAF, near the controller consoles, and connected to the vertical cable chase. The consoles will be located flush against the Cab wall. This cable tray must be 12 inches (300 mm) wide and 4 inches (100 mm) high (fill depth), with 6-inch (150-mm) on-center rung spacing, and must be installed flush with the front edge of the controller position cabinets. The tray must run continuously around the front of the ATCT Cab and mounted on 1-5/8 inch (40 mm) struts, secured to the concrete floor. The exact location of this cable tray will be determined during design.

In the ATCT Electronic Equipment Rooms, an aluminum or steel ladder-type suspended cable tray system is required. This cable tray must be 12 inches (300 mm) wide and 4 inches (100 mm) high (fill depth), with 6-inch (150-mm) on-center rung spacing. This tray must start at the opening above the access door to the vertical cable ladder and extend into the room above the electronic equipment cabinets. The bottom of the cable tray system must be at least 110 inches (9'-2" or 2790 mm) above the finished floor. If a suspended ceiling is installed, a minimum clearance of 12 inches (300 mm) must be provided between the top of the cable tray and the ceiling. Cable tray dividers, sized to fit the tray, must be provided. The dividers must be MILCON provided and installed by the Government. The location dimensions of the cable tray must be shown on the electrical design drawings to ensure the tray is installed in the correct location.

- NOTE: The specific design of the ATCT Electronic Equipment Rooms will determine the exact layout of the cable tray. The exact location of the electronic equipment cabinets and the cable tray must be determined during design.

4-1.2.19 Doors.

ATCT ground level entrance requires a minimum 42" (1070 mm) wide opening.

The doors to the ATCT Electronic Equipment Rooms must be a minimum of 36 inches (910 mm) wide x 80 inches (2030 mm) high to allow for the movement of electronic equipment racks and other ATC equipment. Equipment room doors must have closers and be lockable.

4-1.2.20 Control Cab Consoles.

- **Navy**: The Cab position consoles will be designed, procured and installed by SPAWAR Atlantic during the equipment installation.

- **Army/Air Force:** Use prefabricated modular consoles, vented type with flat top and/or slope top capability with solid surface extended shelf. Provide "spacers" of specific widths to allow the consoles to be installed from corner-to-corner with no gaps. Provide positions for local control, ground control, flight data, and airfield light controls. Provide supervisor overwatch position.

  In the Cab, ATC equipment is installed from the front of the consoles so there is no need to have access to the rear of the cabinets. Upgrading or replacing equipment is done from the front of the cabinets. Cabling comes from below the floor into the bottom of the cabinets.

Cab consoles must not obstruct the controller's visibility and must contain all necessary equipment. Consoles must be constructed as modules sized to permit removal from the Cab. Cab console colors, equipment location and surface configuration design will be coordinated with local ATCT staff.

The contractor must provide and install the airfield lighting panel, power outage indicator lights, door ajar indicator light, dimmer switch for overhead lights, and the master control for the intercom system in the Cab console. Place single "strip bays" at the Local Control Flight Data and Ground Control positions, in addition to the dual "strip bay" provided for the Flight Data position. All other equipment will be provided and installed by the Government. Government installers will accomplish console cut-outs for Government-installed equipment.

- **Army:** Cab consoles are CFCI.
- **Air Force:** Coordinate and validate the Cab console design through E&I, AFFSA, MAJCOM, and the station Air Operations Department to ensure the design accommodates the required equipment.

  The location of the Supervisor of Flying (SOF), where required, will be coordinated with the Operations Group (OG) Commander, or designated representative. Provide a sketch of the Cab layout to the ATC staff during design in order to finalize the operational requirements, positions, and equipment layouts.

4-1.2.21 Restrooms.

Provide a minimum of two unisex restrooms. Additional restrooms may be required, depending on functions located in the ATCT shaft. Provide one shower and locker area in towers with more than one restroom where the program requirements reflect a 24-hour work shift.

Restroom doors must be provided with a bathroom door lockset. Restrooms must have one water closet and one lavatory with mirror. Plumbing fixtures should be wall hung to facilitate cleaning and maintenance. Fully or partially recessed (depending on wall depth) towel dispensers with integral waste receptacles should be used. Dispenser/receptacle should have standard stainless steel architectural finish with a removable stainless steel waste container in the bottom receptacle portion. No sanitary napkin dispenser must be installed in unisex restrooms. A sign depicting "In Use" should be included and installed to aid in occupancy notification.

4-1.2.22 Building Signage.

Signage stating “Cell phone use not permitted” is required at the entrance to the Control Cab, IFR Equipment Room and Flight Planning Room. Signage style must match that used throughout the remainder of the facility.

4-1.3 Structural Requirements.

4-1.3.1 Basic Requirements.

It is desirable to provide flexibility for future modifications to occupancy and usage. The minimum floor live load specified below was selected to facilitate future modifications. The Control Cab perimeter walkway live load is required to allow for potential loads related to removal and replacement of window panels.

When a Base Building is required adjacent to the ATCT, design the two to be structurally independent when feasible. This approach is recommended to reduce structural complexity and to facilitate future modification to either structure.

Depending on geometry and stiffness, ATCT structures can be more sensitive to wind and seismic loads than typical buildings due to the slender geometry of the shaft and Cab. Follow procedures provided in applicable UFC documents and national standards for wind and seismic load analysis. Ensure the serviceability limits indicated below are met.

4-1.3.2 Design Live Loads.

Unless a larger load is required, design the structure to withstand the following minimum uniform live loads.

Table 4-1 Design Live Loads

Occupancy or Use	Uniform Load Psf (kPa)
All Floor Levels	150 (7.2)
Cab Perimeter Walkway	60 (2.9)

4-1.3.3 Serviceability.

Serviceability of Control Cab windows is particularly important. In addition to serviceability requirements indicated in UFC 3-301-01 for various components of the structure, take special care to ensure serviceability of window panels at the Cab level. Limit the drift ratio (story lateral deflection/story height) to 0.002 due to design wind loading. Coordinate and review window and mullion details to ensure that windows are designed for the required wind loads, seismic loads, and thermal effects. Coordinate with architectural discipline to provide davits (when required) to facilitate window washing.

Discuss drift requirements for seismic loads with the Government during the design phase. A reasonable approach may be to limit drift ratio to 0.002 for a seismic event less than the maximum considered earthquake.

4-1.3.4 Antenna Support.

Railing at the Control Cab roof is required to withstand the forces imposed by the antennas. Unless more stringent criteria are provided on a project basis, design the railing based on the following parameters in addition to model code criteria:

- Antennas spacing of 24 inches (610 mm) on center for the full length of the railing.
- Antenna size: 3 inch (75 mm) diameter x 17 feet (5180 mm) tall
- Antenna weight: 16 pounds (71 N) each.
- Railing is required to withstand forces imposed by the antennas with 1/2-inch (13 mm) of radial ice and with wind speeds as required by UFC 3-301-01.

4-1.3.5 Support of Control Cab Electronic Monitors.

There are three methods to accommodate electronic monitors used by controllers: Desktop monitors, ceiling tracks, and ceiling track support plates.

4-1.3.5.1 Desktop Monitors.

Due to recent improvements in computer technology, large and heavy television-like monitors are being replaced with lighter flat screens. Typical system monitors weigh an estimated 85lbs. These devices can be placed or mounted to the top of the Cab Consoles. Coordinate requirements with the design of the Cab Consoles.

4-1.3.5.2 Ceiling Tracks.

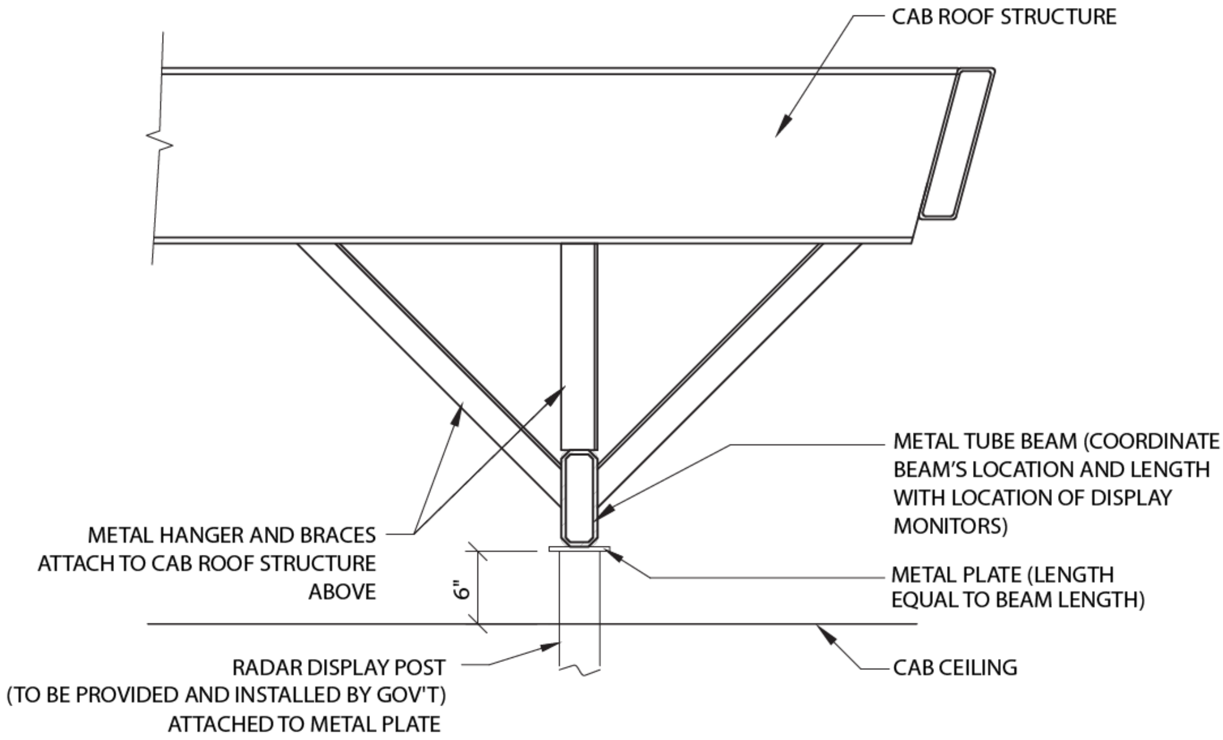
Some electronic monitors require mounting devices incorporated into suspended ceiling systems. Consult with local ATC personnel for preferences for ceiling track systems.

4-1.3.5.3 Ceiling Support Plate.

Some ATC personnel require a ceiling support plate for their electronic monitors. In this case, the ATCT structure must be designed to include secondary framing that runs directly over the controller position cabinetry of the ATCT Cab. This secondary framing beam should be suspended from the Cab roof structure and braced appropriately. The bottom surface of the suspended beam must be 6 inches (150 mm) clear distance above the suspended ceiling tiles. Align the beam with the interior Cab wall where the controller cabinets are installed. The beam will be used to support either a ceiling track or a mounting plate.

Coordinate the design such that no utilities (e.g. sprinkler system piping) are within 3 inches (75 mm) on either side of the beam. This will ensure that there is adequate clearance for the mounting bracket to be installed. See Figure 4-4 for ceiling track support plate detail.

Figure 4-4 Ceiling Support Plate Section Detail



4-1.3.6 Progressive Collapse.

Population density calculation of an ATC tower may not be used to designate a tower with 11 or more personnel as low occupancy. All ATC towers exceeding two stories and routinely occupied by 11 or more personnel must be designed to resist progressive collapse using the UFC 4-023-03 excluding the Tie Force method. Progressive collapse mitigation allows for only safe egress of the facility. Some ATC towers may require continued operation after an event which would require a higher level of protection. Therefore, ATC towers must be evaluated to determine if a higher level of protection is required. Use the process in UFC 4-020-01 to identify the design criteria, which includes the assets to be protected, the DBT, and the levels of protection.

4-1.3.7 Control Cab Roof and Columns.

The Control Cab must use a clear span roof structure so that controllers have 360 degrees of clear view.

Cab columns must be hollow structural shapes. Typically, the columns are sloped in order to provide support of windows with the required downward angle of view. Coordinate column sizes with local ATC personnel to maximize visibility of the airfield. The goal is to minimize the dimensions of the Cab columns in order to minimize obstructed views. Structural shapes should not exceed a width of 6 inches (150mm). Refer to Figure 2-2.

4-1.4 Mechanical Requirements.

4-1.4.1 HVAC Criteria.

The primary HVAC system design objective is to provide environmental control for ATC electronic equipment and personnel. In electronic equipment areas, provisions for temperature and humidity control within the room and under the Raised Access Flooring (RAF) must be installed. Special attention must be given to factors involving installation, maintenance, operation, and reliability with consideration given to diversity and economics. HVAC system design simplicity must be a design goal. HVAC equipment must be limited to serving one or two floors.

- The Control Cab and the supporting electronics equipment areas are considered Critical spaces. Refer to Indoor Design Conditions, General HVAC Requirements, and other information described in Chapter 3-4, *Mechanical*.
- Testing, balancing, adjusting, and commissioning of the HVAC system must take place prior to Government acceptance. This is critical because the heat load varies on each floor because of the different heat output of the equipment.
- Provide an Emergency Air Distribution Shutoff Switch on each floor. Activation of the Shutoff Switch shall shutdown ventilation to the entire building but shall not shut down critical space cooling. Activation of the Emergency Air Distribution Shutoff Switch shall close the outdoor air damper for the Cab Air Handling Unit but the unit shall continue to run on full return air.

4-1.4.2 HVAC Requirements.

Detailed descriptions of required spaces and HVAC system requirements are as follows:

4-1.4.2.1 Control Cab.

The Control Cab is a poorly insulated glass box subject to the maximum effects of changes in atmospheric conditions. Solar gain, greenhouse effect, humidity, conductive heat loss, and convection are forces that influence the design of a specialized Cab HVAC system. Proper air distribution must be controlled to maximize comfort in the Cab. When necessary, ceiling fans must be considered to improve air distribution throughout the space. Supply air must be equally distributed around the perimeter of the Cab and operated continuously at constant volume. Air distribution must be provided along the perimeter of the Cab to prevent glass fogging. Return air must be collected from registers located near the floor or down the stairway and designed to minimize noise transmission from the air handlers. Economizer cycles for the HVAC system must not be utilized, avoiding exposure of critical electronic equipment to wide fluctuations in humidity. The Cab HVAC system must be designed as multiple units in parallel to provide 100 percent cooling redundancy. The Cab HVAC system must serve only the Cab and adjoining spaces within the same fire area. Failure of one unit must allow continuing operation of the second unit. Cabs may be equipped with more than one temperature sensor to allow averaging temperatures throughout the Cab.

4-1.4.2.2 Control Cab HVAC Distribution.

The air distribution system must follow configurations and patterns that are standard to the industry (SMACNA standards). Low and medium pressure ductwork systems must be used where possible. Duct sections with inherently high airflow resistance must be avoided. The number of sharp turns and branching patterns that create airflow turbulence must be minimized. Ductwork must be thermal/noise insulated and must be free of obstruction from auxiliary hardware. Design ductwork to utilize minimum fan horsepower. Exterior insulation must be considered in lieu of duct lining material when required to reduce possible long-term moisture build-up that may lead to growth of mold.

Air distribution must be continuous under the window diffuser system. The duct system must be low noise with a maximum static resistance of 21.17 Pa per 30.5 m (0.085 in of water per 100 linear ft). The duct routing must be under the RAF and coordinated with electrical and equipment wiring routes. Access in the base of the structural columns is critical for installing antenna cables. Diffusers must be floor-grade, linear type, and located at the base of the windows, providing an even coverage of glazing preventing condensation and drafts. Duct system must be coordinated with the structure, electrical, control cabinet sizes, and proximity to the window.

4-1.4.2.3 Sill Area.

The Control Cab window sill area is often used to support the weight of a person cleaning the interior surface of the windows. The design must ensure the air vents located in the Cab window sill and the sills themselves are strong enough to support a 250lb point load for personnel standing on the sills and diffusers.

4-1.4.2.4 Control Cab HVAC System Location.

HVAC systems are located directly below the Control Cab, either on a mezzanine level in the overhead of the floor below the Cab, or on a full floor. Locating HVAC systems on a mezzanine level works well, provided enough space is allocated, including space for maintenance. Provide redundancy for the Cab air handling unit.

- Provide a ducted supply from the air handlers on the floor below the Cab to the diffusers in the Cab sills. HVAC units are not permitted on the Cab roof.
- HVAC ductwork, which may be installed inside the Control Cab wall, must be designed to be as narrow as practical to keep the wall as narrow as possible. HVAC ductwork installed in this wall must not interfere with access to the column cableways or the routing of cables into the cableway.
- It is preferred not to have HVAC systems in overhead spaces because of maintenance difficulty with the limited space available.
- Electrical rooms may require cooling due to the UPS batteries.
- HVAC ducting under the RAF must be routed such that the area along the Cab wall is not used entirely for ducting. Ducts running around the perimeter of the Cab blocks access to the concrete sub floor to secure the position cabinetry. Ducts should exit the Cab wall perpendicular to the wall.

During design, the locations of the duct work and floor penetrations must be reviewed to ensure that they will not interfere with the position consoles.

4-1.4.2.5 Utility and Elevator Shafts.

These spaces usually require natural ventilation only. Storm-proof louvers must be provided to the outside at the top portion of each shaft. Air intake at lower levels may be via passage door, space under doors, or louvers at the base level. Utility chase spaces containing water pipes and drain lines must be heated to maintain a minimum temperature of 40° F.

4-1.4.2.6 Stairwell.

Space conditioning for ATCT Tower Stairwell is not required. However, the stairwell must be controlled to mechanical room standards. Stair sections must be heated above the top elevator landing which leads to the Cab. Heating may be required in some locations due to extreme winter temperatures. Special attention may be required for high humidity areas to prevent condensation in the Stairwell.

4-1.4.2.7 Pipe Chase.

The pipe chase must be fire-stopped at every floor. To prevent freezing, the chase must be opened with louvers, one high and one low between each floor.

4-1.4.2.8 Smoke Dampers.

An elevator shaft smoke damper must be provided to meet life-safety criteria.

4-1.4.2.9 Energy Management and Control System (EMCS).

All new and altered ATCTs must be designed so they can be monitored by an Energy Management and Control System (EMCS). The EMCS must have the capability to monitor lighting systems, security systems, and other systems. Consult the base EMCS office for the design requirements since each base is different.

Due to “Mission Essential” staffing requirements and flight safety considerations, the ATCT occupants, must have direct control of the thermostat to regulate appropriate heating and cooling levels. Configure thermostats so Base EMCS can monitor but not control temperature levels.

Zone the HVAC system so that Control Cab occupants can control the temperature in the Cab. Electronic equipment rooms must be treated as separate zones with their own thermostats. Other floors must be controlled by thermostats zoned to those floors.

4-1.5 Plumbing Requirements.

4-1.5.1 Plumbing Fixtures and Equipment.

Any floor above ATCT Electronic Equipment Rooms must be provided with a floor drain to prevent flooding in case of a water leak. All floor drains must be provided with selfpriming traps or another means to maintain the water level in the traps, which will prevent sewage gasses from entering the ATCT spaces.

- Provide drainage from the elevator pit.
- The ATCT will likely need a water pressure booster system to get water to the Control Cab. Provide a duplex pump system and tanks to provide ample pressure for the domestic water system if the system does not have adequate pressure.
- In the Mechanical Room, provide floor sink for maintenance. Provide floor drains for all mechanical equipment with condensate drains. If ultrasonic humidifiers are used in the Electronic Equipment Rooms or the Cab, provide de-ionized water system to supply the humidifiers.
- In the Fire Pump Room, provide floor sink for system maintenance and back flow preventer drainage.
- In the Janitors Closet, provide floor-mounted mop sink and floor drain.
- Small instant type water heaters are required at each lavatory/sink. A larger instant type heater to serve multiple points of use can be considered if the fixtures are located close together.

4-1.5.2 Catwalk.

Provide freeze-proof hose bib at the exterior door to the Cab catwalk and at the exterior of the ground floor of the ATCT.

Area drains may be provided on the catwalk or the catwalk may be sloped to the exterior for positive drainage.

4-1.5.3 Control Cab Roof.

Provide roof drain and overflow roof drains or scuppers. Minimize exterior downspouts because roof drain pipes interfere with views from the Control Cab. All pipe routings between the roof and the Cab floor, including roof drainage and sprinkler piping, must be routed within or adjacent to the structural columns or mullions at the back of the Cab adjacent to the Cab stairway (away from the primary viewing areas).

In cold weather climates, roof drain hubs and downspout piping must be insulated. The insulation, for the downspout pipe within the Cab roof support column must be 1/2-inch (12-mm) thick foam rubber with the remaining tube void filled with foam insulation. It should be noted that the Cab structure tube configuration produces a significant interior space limitation. Provide electrical heat tapes and insulation for water pipes where required. Heat tapes shall include thermostat control with visual indicator for "ON" condition. Where possible, provide 18 inches (450 mm) heat tape clearance access all around. Heat tape shall not be used on fire protection piping.

4-1.5.4 Convenience Unit.

A convenience unit is required to allow the air traffic controllers on watch in the Control Cab to prepare light meals without leaving their duty station. These units typically contain a sink with hot (on-demand) and cold water, a drinking fountain, a frost-free refrigerator, and a microwave oven. Coordination with the local ATC personnel is required to determine the specific features desired.

4-1.6 Fire Protection and Life Safety Requirements.

4-1.6.1 Fire Alarm and Detection Systems.

All audible and visual notification devices must be "private mode" devices. Private mode audible devices in the Control Cab will sound for at least 180 seconds (required by NFPA 72 18.4.2.3). Provide a textural private mode device above each exit door for visual text alarm and notification messages.

Audible devices in the Cab must be capable of being manually acknowledged in the Cab, which will interrupt (silence) the audible devices in the Cab before 180 seconds (permitted by NFPA 72 18.4.2.3). Visual devices shall include a blue flashing incandescent light instead of a strobe fixture. Red lights are not allowed.

4-1.6.2 Sprinkler Head Cover Plates.

The cover plates for the sprinkler heads in the Control Cab must be flat black in color.

4-1.6.3 Standpipes.

Class 1 standpipe systems shall be installed in all ATCTs with a Control Cab floor more than 30 feet above the level of Fire Emergency Services (FES) access. Fire hose valves (FHV) shall be located in every stair at each landing serving an occupied or service area level.

4-1.6.4 Smoke Detectors.

Smoke detectors installed in the Control Cab ceiling must be flat black in color.

4-1.6.5 Remote Alarm Panel.

A remote annunciator panel with a local audible alarm is required to be installed in the Control Cab to allow air traffic controllers to monitor alarms. Provisions must be made to allow controllers to silence the local audible alarm generated by the annunciator panel, but not the fire alarm indication.

4-1.7 Electrical Requirements.

4-1.7.1 Critical Power Panels.

4-1.7.1.1 Control Cab.

One Critical power panel is required in the Control Cab, or the uppermost floor directly below the Cab, to provide the Critical power requirements. The preferred location of this power panel is near the stairwell for easy access in case of an emergency.

Note: Flush mounting is the preferred method of installation for the Cab power panels. An access gutter or spare conduits are required between the bottom of the flush-mounted panels and the void below the RAF. This provision will allow installation of branch circuits at a later time.

4-1.7.1.2 Electronic Equipment Spaces.

At least one Critical panel is required in the electronic equipment spaces of the ATCT to provide the power for electronic equipment installed in these spaces. The design of the ATCT will dictate the number of spaces required and therefore the number of Critical panels.

At least one Critical power panel is required in the space housing the Emergency Communications System (ECS) in order to provide the power for Voice Communications Switching System (VCSS) electronic equipment.

Note: Surface mounting is the preferred method of installation for the power panels in the electronic equipment spaces. The location of these panels must provide sufficient safety clearances for maintenance personnel per the NEC. Do not mount power panels directly below the cable tray penetration in ATCT Electronic Equipment Rooms.

4-1.7.2 Critical Power Circuits.

4-1.7.2.1 Control Cab.

Critical power circuits are required below the RAF in the Control Cab. Two Critical power circuits, with dedicated neutral conductors, are required to each controller position and must terminate in a 4-inch (100-mm) x 4-inch (100-mm) junction box under each controller position in the Cab. Provide a 24-inch (610-mm) service loop at each junction box. The quantity of circuits, the number of junction boxes, and the exact location of the junction boxes will be determined during design.

4-1.7.2.2 Control Cab Ceiling.

The Control Cab ceiling requires one or two pairs of ceiling junction boxes, each pair connected to a corresponding pair below the RAF. Each junction box must be 4-inch (100-mm) x 4-inch (100-mm) x 1-1/2-inch (38-mm). These junction boxes must be connected with flexible metal conduit, with one 3/4-inch (20-mm) conduit and one 1-1/4-inch (30-mm) for each pair. The conduit routing must be inside the window mullion. The exact quantity and location of the junction boxes will be identified during design.

Note: Additional wired outlets may be required in the ceiling area for relocated signal light guns. Consult with local ATC personnel for specific requirements.

4-1.7.2.3 Roof.

The ATCT roof will require Critical power service. This service must provide power to obstruction lights installed as part of construction. Any additional critical power required on the roof should be identified during design.

4-1.7.3 Non-Critical Power Circuits.

The ATCT roof requires non-critical power service, consisting of two weatherproof duplex 20A outlet boxes, which must be placed on opposite sides of the roof. These are required for electronic maintenance use. This service must be Ground Fault Interrupt (GFI) protected.

The ATCT catwalk requires non-critical power service, including one weatherproof duplex 20A outlet box, which must be placed adjacent to the access door. This outlet is required for maintenance use.

Non-critical outlets must not be designed into the Control Cab wall areas where ATC equipment consoles will be located.

4-1.7.4 Emergency Electrical Power.

4-1.7.4.1 UPS.

Provide a UPS system for critical power near the Control Cab and all ATC electronic equipment areas. Use the anticipated load to determine the size of the UPS. For UPS units serving ATCTs, minimum size must not be less than 20KVA. ATC electronic equipment loads should be provided during the planning/DD 1391 development process.

4-1.7.4.2 Remote Monitoring of Emergency Generator.

Remote monitoring of the ATCT generator must be provided. Personnel in the ATCT Control Cab may be unaware if the generator is running. Locate the monitor in the ATCT Cab.

4-1.7.4.3 Emergency Lighting.

Emergency lighting must be provided in the Control Cab. Provide additional emergency fixtures (conventional with battery-backup or inverter/rectifier located in the fixture ballast) in the Stairwell and ATC equipment rooms.

4-1.7.4.4 Emergency Power-Off Switch.

The electronic equipment space(s) in the ATCT require one Emergency Power-Off (EPO) switch in each room. A typical location for the Control Cab EPO switch is immediately adjacent to the top of the Cab stairway. The exact location of the EPO switches will be determined during design.

4-1.7.5 Lighting.

All fluorescent lighting fixtures require Radio Frequency Interference (RFI) suppression-type ballasts. All lighting controls in the facility, when more than one exists, should be labeled with which lights they control.

4-1.7.5.1 Control Cab.

Lighting in the Control Cab is divided into two groups: focused and non-focused. The first group is focused and is required to illuminate the controller positions. The second group is non-focused and is designed for general housekeeping usage. Each group requires independent controls and must be capable of variable intensity. The local ATC personnel must determine the location for all wall-mounted ceiling light variable intensity controls. All dimmer switches for controlling the lights in the Cab and Cab Stairwell must be located in the Cab.

Lighting should be compatible with night vision goggle requirements.

All lighting trim rings on ceiling lights shall be flat black.

- Focused Lighting

  The focused lighting group is required to illuminate the controller positions. The design must plan for pairs of focused white lights, with each pair illuminating one ATC controller position with its own intensity control. Focused lighting controls (dimmer switches) must be within easy reach of the person sitting in the controller position. Each pair must be recessed into the ceiling to prevent reflections on the window glass and positioned to cancel shadows at the controller console.

  After testing, the lighting intensity controls must be coiled and stored under the Raised Access Flooring (RAF) with sufficient cable length to permit mounting the controls on each controller console, which will be installed after construction is completed.

  Spotlights must be recessed pinhole lights with non-reflective grooved baffles, dimmer controlled, with approximately 2.5 inch (64 mm) opening and a 100-watt bulb.

- Non-Focused Lighting

  Separate, non-focused lighting is required for general use. Recessed white ceiling lights are required for general housekeeping purposes. A single, wall-mounted, variable intensity control is required. This light control must have a protective cover to prevent accidental activation of these lights during night operations.

  Additional non-focused lighting is required to properly illuminate the stairs leading to the Cab. The stairwell lighting must include variable intensity, white floor illumination (theater-style) lights as well as general purpose lighting. Ensure light fixtures do not create a hazard to personnel or restrict movement of equipment on the stairs.

  Overhead lighting must not be used above controller positions. Consider the use of desk-mounted gooseneck lamps to illuminate each position. The gooseneck lamp must be fully dimmable and controlled from each position.

4-1.7.5.2 Electronic Equipment Room(s) and Other Spaces.

Lighting in ATCT Electronic Equipment Room(s) must be consistent with that required in electronic maintenance and administrative spaces. Fluorescent-type lighting is acceptable and there is no requirement for variable intensity control. Light fixtures in the ATCT Equipment Rooms must not be located directly above proposed cabinet installations. To prevent interference with overhead-mounted cable tray, lights must be mounted at least 110 inches (9’-2” or 2790 mm) above the finished floor. Proposed cable tray and cabinet locations will be determined during design. See Figure 4-1 for minimum clearance height details.

Consult with the local ATC personnel for any specific requirements in administrative spaces.

4-1.7.5.3 Roof Obstruction Lights.

Per FAA Advisory Circular AC 70/7460, provide obstruction lighting on the ATCT during and after construction. Although some antennas have lights, the ATCT must have obstruction lighting as part of the structure. Lights that are part of the antennas may be removed at a later date if the communication requirements or communication system design changes.

4-1.7.5.4 Signal Light Guns.

Electrical design must include light gun mounting and power. Local ATC personnel must be consulted to determine if new light guns are required as part of the construction project.

Light gun outlet locations must be determined during design. Eye bolts for hanging the light guns must be installed by the Contractor.

4-1.7.5.5 Exterior Lighting.

Building entrances should be lit to 21.5 lx (2 foot-candles) by High Pressure Sodium (HPS) units. Specify the use of solar powered luminaries when they meet lighting requirements and are cost-effective.

4-1.7.6 Lightning Protection.

Air terminals on an ATCT roof must provide a zone of protection for all antennas to be installed by the Government except for those antennas with built-in lightning protection. These antennas have integral air terminals that must be connected to the lightning protection down conductors during installation. The down conductors on the ATCT roof must be accessible for the later connection of the ECS antennas.

4-1.7.7 Airfield Lighting Control Panel.

Provide an Airfield Lighting Control Panel (ALCP), with connections and interface to the airfield lighting vault. Request review with the local ATC staff to determine if the ALCP is required. If required, connectivity to the vault or other lighting sites would be installed by the construction contractor.

- **Army:** Where available, integrate ALCP with the Army Airfield Automation System.

- **Navy:** An ALCP is not required, but a connection to the airfield lighting vault may be required. Refer to FRS for specific connectivity requirements.

- **Air Force**: If required, include installation of the conduit and wiring for the ALCP. The size and number of conduit and conductors must be determined on a case-by-case basis. Provide and install the ALCP in the ATCT Control Cab console. -The Contractor should make the physical connection (including underground ducting) from the airfield lighting vault to the ALCP. Provide one 4-inch (10-cm) empty square duct between power panel and the space below the RAF in the ATCT Cab. The ALCP must conform to minimum requirements of FAA Advisory Circular AC 150/5345-3, *Specification of L 821 Panels for Remote Control of Airport Lighting*. Updated, improved controls are encouraged but must be approved by the MAJCOM.

  ALCPs in the Control Cab should be designed and programmed for ATC use. Specifically, Sequenced Flashing Lights must be programmed to work in concert with the settings of the Approach Lighting System. (For example, when ALS settings are adjusted, the SFL settings must be coupled to the ALS settings which means they must act as one system without requiring independent setting adjustments by ATC personnel.)

4-1.8 Telecommunications Requirements.

4-1.8.1 Main Distribution Frame (MDF)

An ATCT Main Distribution Frame (MDF) is not required if the ATCT is attached to the RACF.

If the ATCT is not attached to the RACF, provide an MDF in the Telecommunications Room on the ground floor of the ATCT for terminating all outside communications conductors. At this location, all outside plant communications and control conductors must terminate, be protected, cross connected, and distributed throughout the rest of the ATCT. This includes all cables between the RACF and ATCT if the buildings are not connected.

4-1.8.2 ATC Circuit Intermediate Distribution Frame (IDF).

An ATC Circuit Intermediate Distribution Frame (IDF) is where circuits are separated and routed to the ATC equipment. This IDF contains both copper and fiber cables. If required, the ATC Circuit IDF may be located in the ATCT Electronic Equipment Room or the Control Cab. The ATC IDF located in the ATCT must be located on 3/4-inch (20-mm) thick fire-rated plywood, at least 4 feet wide, from floor to ceiling.

4-1.8.3 Internal Facility Connectivity.

Two (2) 4-inch (100-mm) conduits are required between the ATCT MDF and ATCT cable chase exclusively for ATC circuit cabling. Conduits must terminate in the bottom of the ATCT MDF and the bottom of the ATCT cable chase. Bushings must be installed at each end. Nylon pull-cords are required in each conduit.

Any additional connectivity requirements should be addressed during the planning/DD 1391 development phase.

4-1.8.4 Primary Crash Alarm System.

One of the phone lines in the Control Cab will be uniquely identified as the "Crash Phone" line. This circuit will be terminated in a junction box under the raised access floor. The junction box shall have one CAT 6 telephone jack. The exact location of this circuit will be identified during design.

4-1.9 Safety and Security.

ATCTs are normally located within restricted areas that meet the minimum security measures for external security. If the facility is located within a restricted area of a lower level of security, provide additional measures to meet the minimum security requirements for the level of security assigned to the facility.

When the ATCT is outside the Security Zone perimeter, a 10-foot-high fence with single razor wire will completely enclose the tower structure. The fence must be not less than 15 feet from the structure exterior and include a lockable personnel gate not less than 40 inches (1015 mm) wide, and a vehicle lockable access gate not less than 15 feet wide.

4-1.9.1 Doors and Cipher Locks.

The exterior entry doors must be equipped with non-removable hinges and locking hardware including cipher locks. Doors equipped with electronic cipher locks are required to be powered from a critical power circuit (Uninterruptible Power Supply [UPS]).

Provide and install cipher locks, door closers, and electric strikes on the ground floor main entrance door to the ATCT and the door entering the stairs going to the Control Cab. The lock on the main entry and cab doors must have a remote control override switch, controlled from the Cab.

Provide a light in the Cab console which indicates when either of these doors is not closed. Any indicator lights for doors not closed should be wall mounted on the stair wall or other location.

To allow selective access to personnel who do not have the combination, ATCT doors with cipher locks must be releasable from inside the ATCT Cab via a door release switch. This switch must be provided with an electric strike for remote release from the Cab. Doors equipped with electronic cipher locks are required to be powered from a Critical power circuit (UPS).

The small door from the Cab to the catwalk should not be automatically lockable. A manually activated deadbolt engaged from the inside is acceptable. If an outside ladder or stair is provided from the catwalk to the pressurized stairwell, the door leading into the stairwell must not be capable of locking. This door serves as the secondary egress from the Cab.

ATCT electronic equipment spaces require doors with locking hardware. The locking hardware must comply with the requirements of NFPA 101. Standard commercial-grade key locks will suffice for the equipment spaces.

If the ATCT elevator design utilizes an elevator with a door that opens directly into the electronic equipment space(s), a means to "lock out" the elevator from stopping at these space(s) is required. This lockout capability must be activated from inside the elevator cab.

4-1.9.2 Access Control System.

Provide an intercom station and a video camera system to monitor the ATCT doors equipped with cipher locks such as the ATCT ground floor entrance and the final stairs leading to the Control Cab. This system allows the controllers in the Cab to identify, communicate if needed, and grant access to individuals not having pre-approved access. If the intercom station is located on the exterior of the ATCT, it must be installed in a weatherproof box. Consider including a canopy in the design if the main entry is not under the roof.

Typically, the video camera monitors are located in the Cab. The video from these cameras does not go anywhere but to the controllers' point of use.

The video cameras and monitors must be provided as part of MILCON construction. These cameras are used for access control only, and should not be classified as "security" cameras. Without these cameras, someone needing access could potentially wait for an extended length of time before gaining access, because the controllers can't always leave their position to open a door.

4-1.9.3 Airfield Monitoring Cameras.

Provide a video camera system for the monitoring of obstructed airfield areas, if necessary, for 100% visibility of all airfield traffic surfaces. Cameras cannot be used to view any runway surface, only taxiways, parking areas, loading areas, etc. Cameras are also used to monitor weapons loading areas if they are obstructed from view. Additional cameras are added as needed for each area that is obstructed. The obstructed areas must be identified during the Site Selection process.

4-1.9.4 Voice Communications.

Doors with cipher locks in the ATCT require two-way communications between personnel in the Control Cab and personnel not having the combination but needing access. Consult with the local Air Operations Department for specific requirements.

Provide and install an intercom station at the main entrance to the ATCT and at the entrance to the Cab. The intercom station located on the exterior of the ATCT must be installed in a weatherproof box.

An intercom system must be provided and installed to allow audible communication between all floors and stations. The intercom system must be simple and allow the Cab to do an "All-Call" to every floor, including the Simulator Classroom (if provided). Master control must be located in the Cab. The intercom system is purchased and installed by the Contractor.

Connect exterior intercom system to the base telephone system in case of emergency.

4-2 RADAR APPROACH CONTROL FACILITY (RACF).

4-2.1 General Requirements.

4-2.1.1 Risk Category.

For Risk Category, see Table 2-2, UFC 3-301-01. This classification has an impact on the design of most design disciplines involved with a RACF, including architecture and structural, mechanical, electrical and fire protection engineering. Ensure that non-structural components (e.g. raised access flooring, architectural components, utilities, etc.) are laterally braced as required for seismic load stability in accordance with UFC and building code provisions. Careful analysis of these requirements must be addressed in the planning/DD 1391 development phase. Coordinate additional bracing requirements to avoid interference with items to be installed post construction, such as cabling, conduit raceways and other infrastructure for electronic equipment.

4-2.2 Architectural Requirements.

4-2.2.1 Raised Access Flooring.

Provide Raised Access Flooring (RAF) in the Operations/IFR Room, the IFR Equipment Room, and the STARS and ATCT Simulator Room with 18 inches (450 mm) of clearance provided between the floor panels and sub floor to accommodate wiring and insulated piping.

4-2.2.2 Floor Finishes.

The Operations/IFR Room and Simulator Rooms must be provided with integral, static-dissipative carpet. The IFR Equipment Room must be provided with vinyl or laminate floor tiles or carpet with integral static dissipative coverings. Consult with local ATC personnel for preferred floor finishes.

4-2.2.3 Interior Walls.

Sound attenuating wall panels for the Operations/IFR Room are required to absorb noise generated from within the room.

All interior exposed surface treatments in the Operations/IFR Room must be non-glare and non-reflective.

4-2.2.4 Ceiling Finishes.

A black or white ceiling is required in the Operations/IFR room and the Simulator Rooms. Black tiles should be the same as the ceiling in the ATCT Control Cab. Consult with local ATC personnel for preferred ceiling color.

4-2.2.5 Ceiling Heights.

The minimum clear height in the RACF from the finished floor to the bottom of a finished ceiling must be 9'-0", except for the following conditions:

- The RACF Operations/IFR Room and the IFR Equipment Room must have a clear ceiling height of 10'-0" above the RAF.

Final floor-to-floor heights will be determined during design.

4-2.2.6 Acoustical Treatment.

Provide full height 3-1/2" (90-mm) thick sound attenuation batt. insulation in all walls surrounding the Operations/IFR Room:

- Partitions must be constructed to provide a minimum STC rating of 45. Consider increasing this requirement if the RACF if located adjacent to a runway.
- Operations/IFR Room doors must be solid core and rated STC 35 or higher.
- As a minimum, doors should have acoustical seals around all frames.
- An acoustical sill may be provided between Operations/IFR Room and external rooms. Do not provide a sill between the Operations/IFR Room and the IFR Equipment Room since it may obstruct movement of equipment.

4-2.2.7 Roof Access.

A personnel access hatch and ladder/stairs is required to transit from inside the RACF to the roof to maintain antennas mounted on the roof. Any requirement for roof walking pads must be identified during the planning/DD 1391 development phase.

4-2.2.8 Antenna Mounting.

An area for miscellaneous antenna mounting on the RACF roof may be required. If required, the system must consist of a 10 to 20 foot long railing with weather head(s) and conduit to an inside cable path, and must include lightning protection and grounding per FAA standards.

Any requirements for this antenna mounting area must be identified during the planning/DD 1391 development phase.

4-2.2.9 Roof Cable Access for GPS Antenna Infrastructure.

A cable path is required from the space below the RAF in the IFR Equipment Room to the roof of the RACF. One 2-inch (50-mm) rigid conduit is required. This conduit will be used to route antenna cabling to the roof.

- An enclosure with a back panel, mounted to the conduit, is required. The enclosure must be a 16-inch (400-mm) wide by 12-inch (300-mm) high by 8-inch (200-mm) deep, stainless steel, Hoffman-style enclosure.
- All conduits must utilize sweep bends.
- Anti-chafing bushings are required at both ends.
- The interior end of the conduit must be connected to the IFR Equipment Room cable tray or terminate within 6 inches (150 mm) of the cable tray.
- The conduit must protrude 18 inches (450 mm) above the roof and be bonded to the lightning protection system. The location of this conduit must be on the portion of the RACF roof that has a southern exposure. The exact location must be determined during design.

4-2.2.10 Doors.

- Double door access is required between the Operations/IFR Room and the IFR Equipment Room. In addition, double door access is required between the IFR Equipment Room and the outside loading area. At least one leaf of double-door sets must be 48 inches (1220 mm) wide, if the center support is not removable. Doors from the IFR Equipment Room to the Maintenance Room and from the Operations/IFR Room (if directly connected) to the Maintenance Room must be a minimum of 48 inches (1220 mm) to allow passage of equipment being maintained.
- All other doors in equipment areas must be a minimum of 42 inches (1050 mm) wide. All other doors (office, toilet, etc.) must be a minimum of 36 inches (910 mm) wide.
- The primary building entry door should be steel with a wire-glass vision lite and cipher lock. All exterior doors must be steel.
- Provide a small, narrow wire-glass lite in the Operations/IFR Room door.

4-2.2.11 Vertical Cable Chase.

If connectivity with the ATCT utilizes an overhead cable tray, a short vertical cable chase may be required in the IFR Equipment Room. Specific requirements will be identified during design.

4-2.2.12 Cable Tray System.

Connectivity of the cable tray between the Operations/IFR Room, the IFR Equipment Room, and the ATC/STARS Simulator Rooms is required. If bulkheads or walls are installed below the RAF between these rooms, two (2) penetrations will be required to connect the cable tray between the Operations/IFR Room and the IFR Equipment Room.

One (1) penetration is required for all other rooms. If required, cable tray penetrations connecting adjacent rooms must be located below the door access between those rooms. All cable tray penetrations between spaces must comply with applicable fire protection codes.

- A 12-inch (300-mm) or 18-inch (450-mm) wide by 4-inch (100-mm) high (fill depth) ladder-type cable tray is required below the RAF in the Operations/IFR Room. The exact size and location of this cable tray will be determined during design.
- A 12-inch (300-mm) or 18-inch (450-mm) wide by 4-inch (100-mm) high (fill depth) ladder-type cable tray is required below the RAF in the IFR Equipment Room. The exact size and location of this cable tray will be determined during design. Connectivity of this tray to the ATCT vertical cable chase is required utilizing either conduit or cable tray.
- A 12-inch (300-mm) wide by 4-inch (100-mm) high (fill depth) ladder-type cable tray is required below the RAF in the ATC Simulator and STARS Simulator Rooms. The exact location of this cable tray will be determined during design.

See Section 3-8.10 for connectivity requirements between the ATC MDF Enclosure and the IFR Equipment Room.

4-2.2.13 Building Signage.

Signage stating “Cell phone use not permitted” is required at certain ATC Facility operational spaces such as the entrance to the IFR Equipment Room, and the IFR Room. Signage style must match that used throughout the remainder of the facility.

4-2.2.14 Building Loading Area.

Provide an exterior building loading area adjacent to the double doors to the IFR Equipment Room. The driveway leading to this loading area must be at least 15 feet (4570 mm) wide.

4-2.3 Structural Requirements.

4-2.3.1 Design Live Loads.

Unless a larger load is required, design the structure to withstand the following minimum uniform live loads:

Table 4-2 Design Live Loads

Occupancy or Use	Uniform Load Psf (kPa)
RACF Operations/IFR Room	150 (4.8)
Loading Docks	200 (9.6)

Locker Rooms	50 (2.4)

4-2.4 Mechanical Requirements.

4-2.4.1 General HVAC Requirements.

Detailed descriptions of required spaces and HVAC system requirements are as follows:

4-2.4.2 RACF Operations/IFR Room.

RAF grilles must be sized and located to provide proper air distribution. Where RAF is not utilized or where two separate equipment and people conditioning systems are used, dampers in an overhead system must control proper air distribution. Either system designed for use in the RACF must provide a comfortable working environment. Economizer cycles for the HVAC system must not be utilized, avoiding exposure of critical electronic equipment to wide fluctuations in humidity. Under-floor pressure and air volumetric delivery, measured in cubic feet per minute (cfm) or liters per second (lps), must initially be balanced for the design load. The system must be re-balanced to take advantage of additional design capacity when future equipment is added. Where required by local environmental conditions, the outside air must be carbon filtered at the make-up air intakes for the RACF Operations/IFR Room.

4-2.4.3 Energy Management and Control System (EMCS).

The RACF must be connected to the installation's Energy Management and Control System (EMCS). The EMCS must have the capability to monitor lighting systems, security systems, and other systems. Consult the base EMCS office for the design requirements since each base is different.

Due to “Mission Essential” staffing requirements and flight safety considerations, the RACF occupants, not the base EMCS office, must have direct control of the thermostat to regulate appropriate heating and cooling levels for ATC electronic equipment spaces.

4-2.5 Plumbing Requirements.

No special plumbing requirements have been identified for the RACF.

4-2.6 Fire Protection and Life Safety Requirements.

4-2.6.1 Fire Alarm and Detection Systems.

Audible alarms must not be installed in the Operations/IFR Room. Provide a textural private mode device above each exit door for visual text alarm and notification messages. Two white strobes are required behind the controller position cabinets and two red strobes are required in front of the cabinets in the controller area.

Audible and visual notification devices in operational and technical areas must be 'private mode' devices. Audible and visual notification devices in public areas must be 'public mode' devices.

4-2.6.2 Light Blocking Curtain in Operations/IFR Room.

The Operations/IFR Room may include features such as a light blocking curtain installed over the controller position cabinetry. This curtain will extend from the top of the cabinets to the ceiling. The curtain on the ends of the cabinets will extend from the floor to the ceiling. This curtain must be considered when designing the placement of the recessed sprinklers. The specific location of the curtain will be identified during design.

4-2.7 Electrical Requirements.

4-2.7.1 Space Requirements.

Consult the Systems Integration Engineer (SIE) for power support requirements and panel locations. The SIE will provide a comprehensive list of equipment including their electrical requirements and significant watt or BTU output. Similarly, consult the equipment manufacturers for accurate power requirements, including requirements for power or frequency filters.

4-2.7.1.1 Operations/IFR and IFR Equipment Rooms.

Power distribution panels for the Operations/IFR Room and the IFR Equipment Room must be located in the IFR Equipment Room or adjacent Maintenance Room. These spaces must be supplied separately from the rest of the building.

Provide dedicated circuits for each piece of equipment in the Operations/IFR Room and for each rack in the IFR Equipment Room so that removal for maintenance of any piece of equipment has no effect on the balance of the RACF. Circuits in the Operations/IFR Room should be “clean” to eliminate electrical interference from any other equipment.

4-2.7.1.2 Electrical Room.

The Electrical Room must have exterior access as well as access from within the RACF. A pad-mounted transformer must be provided.

4-2.7.1.3 TERPS.

The TERPS office, if provided, has multiple equipment requirements (computers, scanners, plotters, etc.). Consider replacing standard office duplex locations with fourplex outlets. If practical, provide integral surge protection for these outlets.

4-2.7.1.4 Simulator Room.

Typically, the simulator will require a minimum of 10 each, single pole, 120 VAC, 20 amp circuit breakers and 2 each, single pole, 120 VAC, 30 amp circuit breakers from a 120/208VAC, 60 Hz, three-phase source designed to comply with ANSI C84.1. The total connected load will not exceed 100 amps. Design dedicated circuit breakers for the proposed tower simulator equipment and separate convenience outlets distributed throughout the classroom.

4-2.7.1.5 Other Building Areas.

Power distribution panels for the spaces outside the Operations/IFR Room and the IFR Equipment Room must be in an electrical closet accessible to base Maintenance personnel. All hallways must have at least one duplex outlet for janitorial personnel. Office spaces must have at least one duplex outlet located for the convenience of janitorial personnel in addition to the standard requirements for an office space.

4-2.7.2 Critical Power Panels.

4-2.7.2.1 Operations/IFR Room.

Two 100 amp critical power panels are required in the Operations/IFR Room. Proposed locations of these power panels will be identified during design.

4-2.7.2.2 IFR Equipment Room.

Two 100 amp critical power panels are required in the IFR Equipment Room. Proposed locations of these power panels will be identified during design.

4-2.7.2.3 ATC Simulator Room.

In lieu of a separate ATC Simulator/Training Room critical power panel, critical power circuits for this room will be provided by the panels located in the Operations/IFR Room.

4-2.7.3 Critical Power Circuits.

4-2.7.3.1 Operations/IFR Room.

Critical power circuits are required below the Raised Access Flooring (RAF) in the Operations/IFR Room. The critical circuits must terminate in a 6-inch (150-mm) by 6-inch (150-mm) by 4-inch (100-mm) deep junction box under the RAF directly below each controller position in the Operations/IFR Room. Each box must contain between one and four circuits. Provide a 24-inch (600-mm) service loop at each junction box.

4-2.7.3.2 IFR Equipment Room.

Critical power circuits are required below the RAF in the IFR Equipment Room. The critical circuits must terminate in a 6-inch (150-mm) by 6-inch (150-mm) by 4-inch (100-mm) deep junction box under the RAF directly below each electronic cabinet or rack in the IFR Equipment Room. Provide a 24-inch (600-mm) service loop at each junction box.

4-2.7.3.3 ATC Simulator/Training Room.

Critical power circuits are required either below the RAF or on the wall in the ATC Simulator/Training Room. The critical circuits must terminate in a standard duplex outlet under the RAF directly below each trainer position or on the wall. In lieu of a separate ATC Simulator/Training Room critical power panel, these junction boxes can be fed from the Operations/IFR Room critical power panel.

The quantity of circuits, the number of outlets, and the exact location of the outlets must be determined during design.

4-2.7.4 Non-Critical Power Circuits.

There are no specific requirements for the RACF non-critical power circuits.

4-2.7.5 Grounding.

In addition to the RACF grounding requirements in the IFR Equipment Room, Operations/IFR Room, and Simulator Room, a single point ground connected to the Equipotential Grounding Plane is required on the plywood panel for the telephone cable breakout. If the ETVS is on a separate rack, provide a grounding connection for this rack.

4-2.7.6 Transient Voltage Surge Suppressors (TVSS).

The power bus for other rooms must be isolated from technical power and critical-technical loads in the Operations/IFR, IFR Equipment and Simulator Rooms to protect such loads from transient voltage variations. Surge protection must reduce lightning and switching surges to within acceptable quality power limits.

4-2.7.7 Emergency Electrical Power.

4-2.7.7.1 Uninterruptible Power Supply (UPS).

Provide a UPS system for critical power near the IFR Equipment Room and all ATC electronic equipment areas. Use the anticipated load to determine the size of the UPS. ATC electronic equipment loads should be provided during the planning/DD 1391 development process.

4-2.7.7.2 Emergency Lighting.

Emergency lighting must be provided in the Operations/IFR Room (spots and floor lights only). In the Operations/IFR Room, emergency lighting should activate only when there is a power failure.

Exit lighting in the Operations/IFR Room must be screened so the lighting will not reflect or cause glare on operational positions. Use LED non-glare exit lighting design.

4-2.7.7.3 Emergency Power-Off Switch.

The IFR Room and IFR Equipment Room require two EPO switches in each. The exact location of the EPO switches will be determined during design.

4-2.7.7.4 Backup Radio Poles and Communications Antennas.

- **Air Force Only**: Provide a minimum of two poles at 25-50 feet (7.5 m – 15 m) from the building and 50 feet from each other for mounting back-up radio antennas. The type and construction of the poles should be verified with the installation's communications squadron. Provide a dedicated panel for troubleshooting lines.

4-2.7.8 Lighting.

All fluorescent lighting fixtures require Radio Frequency Interference (RFI) suppression-type ballasts. All lighting controls in the facility, when more than one exists, should be labeled with which lights they control. Additional guidance is as follows:

4-2.7.8.1 Operations/IFR Room.

Lighting in the Operations/IFR Room will be divided into four functional uses within each operational area ("horseshoe"): blue or red lights inside the horseshoe, white lights inside the horseshoe, theater wall lights inside the horseshoe, and white lights behind the horseshoe. Wall-mounted lighting controls must be installed with a safety switch cover to prevent accidental activation. Blue or red light controls must be readily distinguishable from white light controls. Consult with the local ATC personnel for preference of either red or blue lights. Location of the lighting fixtures with respect to the light blocking curtain will be identified during design.

- Blue or red operation area lights (white fluorescent lights with blue or red, semi-opaque tube covers that are often the center bank of two lights on a four-tube light fixture) must be variable and separately controlled from all other lights. One variable intensity control must be located near the room main entrance; a second variable intensity control must be located near the door to the IFR Equipment Room. If multiple operational areas are planned, each horseshoe must have an independent light control.

- White operations area lights, which are often the outer bank of two lights on a four-tube light fixture, must be variable and separately controlled from all other lights. One on/off switch with variable intensity control must be located near the room entrance; a second on/off switch with variable intensity control must be run under the RAF with sufficient cable so that the control can be mounted in the supervisor's console or near the entrance to the IFR Equipment Room. If multiple operational areas are planned, each horseshoe must have independent light control.
- Theater-type wall lighting to illuminate the walking area near the walls is required inside or between the horseshoes. One on/off switch with variable intensity control must be located near the room entrance. A second on/off switch with variable intensity control must be centrally located on the wall where the theater lights are installed.
- The area behind each horseshoe requires variable intensity white fluorescent lighting. These lights can be subdivided into left and right side controls. The double set of on/off switches with variable intensity control must be located at each entrance to the IFR Equipment Room. A second set of on/off switches with variable intensity control must be located near the other room entrance. If multiple operational areas are planned, each horseshoe must have independent light control.
- **Army and Air Force**: The Army and Air Force do not have a requirement for colored lights in the IFR Room. However, lights must be 0-100% dimmable in the Operations/IFR Room and 50% dimmable in immediate adjacent areas.

4-2.7.8.2 IFR Equipment Room.

Lighting in IFR Equipment Room must be consistent with that required in electronic maintenance and administrative spaces. Fluorescent-type lighting is acceptable and there is no requirement for variable intensity control. Light fixtures in the IFR Equipment Room must not be located directly above proposed cabinet installations. Lighting must be placed to ensure that the areas between equipment rows are illuminated. Proposed cabinet locations will be determined during design.

4-2.7.8.3 ATCT and STARS Simulator Rooms.

Lights in the ATCT and STARS Simulator Classrooms must be white and must be capable of variable intensity (fully dimmable).

4-2.7.8.4 Other Spaces.

Consult with the local ATC personnel for any specific requirements in administrative spaces.

4-2.8 Telecommunications Requirements.

4-2.8.1 RACF Main Distribution Frame (MDF).

Provide an MDF within the RACF for terminating all outside communications conductors. At this location, all outside plant communications and control conductors must terminate, be protected, cross-connected, and distributed throughout the rest of the RACF. This includes all cables between the RACF and the ATCT if the buildings are not connected.

If the RACF MDF and the IFR Equipment Room are adjacent to each other, RAF can be installed in both rooms and a cable tray must be used for the connectivity. If the two rooms are not adjacent (separated by other rooms or hallways), 4-inch (100-mm) conduits are used to provide the connectivity.

4-2.8.2 ATC MDF Enclosure.

The ATC MDF Enclosure is located within the RACF MDF and is exclusively where all ATC circuits are terminated before being distributed to the ATC equipment spaces. Trunk cables are utilized for the ATC circuits going to the IFR Equipment Room.

A Hoffman-style enclosure (Type 1, 48 inches (1220 mm) high by 36 inches (910 mm) wide by 11 inches (275 mm) deep), including a back panel, is required for termination of all operational ATC circuit inter-site cabling. This enclosure must be wall-mounted in close proximity to the RACF MDF. The bottom of the enclosure must be 24 inches (600 mm) above the finished floor. The door of the enclosure must incorporate a “T” handle latch. A closure accepting a padlock is required.

4-2.8.3 ATC Circuit Intermediate Distribution Frame (IDF).

The ATC Circuit Intermediate Distribution Frame (IDF) is located in the IFR Equipment Room and is where circuits are separated and routed to the ATC equipment and from the equipment to the ATCT. This MDF contains both copper and fiber cables. The IDF in the IFR Equipment Room is inside a prefabricated enclosure.

4-2.8.4 RACF to ATCT Connectivity.

4-2.8.4.1 Attached ATCT.

Four (4) 4-inch (100-mm) conduits or one (1) 12-inch (300-mm) wide and 4-inch (100-mm) deep (fill depth) cable tray is required from the RACF MDF to the ATCT cable chase exclusively for ATC circuit cabling. Conduits must terminate in the bottom of the RACF MDF and the bottom of the ATCT cable chase. Conduits must stub up 4 inches (100 mm) from the concrete floor. Bushings must be installed at each end. Nylon pull-cords are required in each conduit.

Four (4) 4-inch (100-mm) conduits or one (1) 12-inch (300-mm) wide and 4-inch (100-mm) deep (fill depth) cable tray is required from the ATC MDF to the ATCT cable chase exclusively for ATC circuit cabling. Conduits must terminate in the bottom of the ATC MDF and the bottom of the ATCT cable chase. Conduits must stub up 4 inches (100mm) from the concrete floor. Bushings must be installed at each end. Nylon pull-cords are required in each conduit.

4-2.8.4.2 Detached ATCT.

If the ATCT and the RACF are not attached, connectivity is required between the two.

- Four (4) 4-inch (100-mm) conduits are required from the RACF MDF to the ATCT MDF exclusively for ATC circuit cabling. Conduits must terminate in the bottom of each MDF. Conduits must stub up 4 inches (100 mm) from the concrete floor. Bushings must be installed at each end. Nylon pull-cords are required in each conduit.
- Four (4) 4-inch (100-mm) conduits or one (1) 12-inch (300-mm) wide and 4-inch (100-mm) deep (fill depth) cable tray is required from the ATC MDF to the ATCT cable chase exclusively for ATC circuit cabling. Conduits must terminate in the bottom of the ATC MDF and the bottom of the ATCT cable chase. Conduits must stub up 4 inches (100 mm) from the concrete floor. Bushings must be installed at each end. Nylon pull-cords are required in each conduit.

Any additional connectivity requirements should be addressed during the planning/DD 1391 development phase.

4-2.8.5 Internal Facility Connectivity.

Four (4) 4-inch (100-mm) conduits or one (1) 12-inch (300-mm) wide and 4-inch (100-mm) deep (fill depth) cable tray is required between the RACF MDF and ATC MDF exclusively for ATC circuit cabling. Conduits must terminate in the bottom of the RATCF MDF and the bottom of the ATC MDF enclosure. Bushings must be installed at each end. Nylon pull-cords are required in each conduit.

Three (3) 4-inch (100-mm) conduits or one (1) 12-inch (300-mm) wide and 4-inch (100-mm) deep (fill depth) cable tray is required from ATC MDF to the IFR Equipment Room. Conduits must stub up 4 inches (100 mm) from the concrete floor. Bushings must be installed at each end. Nylon pull-cords are required in each conduit. Exact location will be determined during design. This cable tray must be connected to the cable tray in the IFR Equipment Room.

Any additional connectivity requirements should be addressed during the planning/DD 1391 development phase.

4-2.9 Safety and Security.

The RACF is normally located within restricted areas that meet the minimum security measures for external security. If the facility is located within a restricted area of a lower level of security, or is located remote and outside of an established restricted area, provide additional measures to meet the minimum security requirements for the level of security assigned to the facility. Security at the main entrance to the RACF requires a single entry point with visitor control.

Remote locks, video cameras, card readers, and/or keypads may be required as components of the IDS. The level of security and the designer's responsibility for particular security elements will be designated by the User command.

4-2.9.1 Doors and Cipher Locks.

The exterior entry doors must be equipped with non-removable hinges and locking hardware including cipher locks. Doors equipped with electronic cipher locks are required to be powered from a critical power circuit (Uninterruptible Power Supply [UPS]).

Provide and install cipher locks, cameras, intercoms, door closers, and electric strikes on any outside or inside entrance doors to the Operations/IFR Room. This approach allows the controllers in the Operations/IFR Room to identify, communicate if needed, and grant access to individuals not having pre-approved access. Cameras are not required on the doors to the IFR Equipment Room. The exterior door into the IFR Equipment Room is required to have entry hardware. This door must be equipped with a cipher lock or standard locking hardware. The Maintenance division will determine the type of lock.

If exterior doors are provided out of the Operations/IFR Room, these doors must not have access hardware on the outside.

4-2.9.2 Access Control System.

Provide and install intercom stations with video camera system at the main entry door of the RACF and the entrance to the Operations/IFR Room to monitor RACF doors equipped with cipher locks. This system will allow for personnel identification, visitor check-in, and to monitor ingress and egress. Adequate space for the video monitor must be provided in the Watch Supervisor's area and in the entry vestibule.

If the intercom station is located on the exterior of the RACF, it must be installed in a weatherproof box. Consider including a canopy in the design if the main entry is not under the roof.

Additional video monitoring may be required at security fencing and guard post for facilities located outside the secure area of the installation. Consult with the local ATC personnel for specific CCTV requirements.

4-2.9.3 Voice Communications.

Provide communication between the main entry door into the Operations/IFR Room and the supervisor position in the Operations/IFR Room.

4-3 AIR OPERATIONS BUILDING (AOB).

4-3.1 General Requirements.

4-3.1.1 Risk Category.

For Risk Category, see Table 2-2, UFC 3-301-01. This classification has an impact on the design of most design disciplines involved with an AOB, including architecture and structural, mechanical, electrical and fire protection engineering. Ensure that non-structural components (e.g. raised access flooring, architectural components, utilities, etc.) are laterally braced as required for seismic load stability in accordance with UFC and building code provisions. Careful analysis of these requirements must be addressed in the planning/DD 1391 development phase.

4-3.2 Architectural.

4-3.2.1 Ceiling Heights.

The minimum clear height in the AOB from the finished floor to the bottom of a finished ceiling must be 9'-0".

Final floor-to-floor heights will be determined during design.

4-3.2.2 Floor Finishes.

The Operations-Airfield Management/Fight Planning Room must be provided with integral, static-dissipative carpet.

4-3.2.3 Roof Access.

A personnel access hatch and ladder/stairs is required to transit from inside the AOB to the roof to maintain antennas mounted on the roof. Any requirement for roof walking pads must be identified during the planning/DD 1391 development phase.

4-3.2.4 Antenna Mounting.

An area for miscellaneous antenna mounting on the AOB roof may be required. If required, the system must consist of a 10 to 20-foot (3 m – 6 m) long railing with weather head(s) and conduit to an inside cable path, and must include lightning protection and grounding per FAA standards.

Any requirements for this antenna mounting area must be identified during the planning/DD 1391 development phase.

4-3.3 Structural.

4-3.3.1 Structural Isolation.

If located adjacent to the ATCT, the AOB must be structurally isolated from the ATCT to prevent pounding during a seismic event.

4-3.4 Mechanical.

4-3.4.1 Energy Management and Control System (EMCS).

The AOB must be connected to the installation's Energy Management and Control System (EMCS). The EMCS must have the capability to monitor lighting systems, security systems, and other systems. Consult the base EMCS office for the design requirements since each base is different.

Due to "Mission Essential" staffing requirements and flight safety considerations, the AOB occupants, not the base EMCS office, must have direct control of the thermostat to regulate appropriate heating and cooling levels for ATC electronic equipment spaces.

4-3.5 Plumbing.

No unique plumbing requirements have been identified for the AOB.

4-3.6 Fire Protection and Life Safety.

No unique fire protection requirements have been identified for the AOB.

4-3.7 Electrical.

4-3.7.1 Space Requirements.

Consult the Systems Integration Engineer (SIE) for power support requirements and panel locations. The SIE will provide a comprehensive list of equipment including their electrical requirements and significant watt or BTU output. Similarly, consult the equipment manufacturers for accurate power requirements, including requirements for power or frequency filters.

4-3.7.2 Electrical Room.

The Electrical Room must have exterior access as well as access from within the AOB. A pad-mounted transformer must be provided.

4-3.7.3 Power Distribution.

Power distribution panels for the spaces in the AOB must be in an electrical closet accessible to base Maintenance personnel. All hallways must have at least one duplex outlet for janitorial personnel. Office spaces must have at least one duplex outlet located for the convenience of janitorial personnel in addition to the standard requirements for an office space.

4-3.7.4 Critical Power Panels.

4-3.7.4.1 Operations – Airfield Management/Flight Planning Room and Weather Station.

Critical power panels are required in the Operations – Airfield Management/Flight Planning Room and Weather Station. Proposed locations of these power panels will be identified during design.

4-3.7.5 Non-Critical Power Circuits.

There are no specific requirements for the AOB non-critical power circuits.

4-3.7.6 Grounding.

In addition to the grounding requirements in the Operations-Airfield Management/Flight Planning Room and the Weather Station, a single point ground connected to the Equipotential Grounding Plane is required on the plywood panel for the telephone cable breakout. If the ETVS is on a separate rack, provide a grounding connection for this rack.

4-3.7.7 Transient Voltage Surge Suppressors (TVSS).

The power bus for other rooms must be isolated from technical power and critical-technical loads in the Operations – Weather Station to protect such loads from transient voltage variations. Surge protection must reduce lightning and switching surges to within acceptable quality power limits.

4-3.7.8 Emergency Electrical Power.

4-3.7.8.1 Uninterruptible Power Supply (UPS).

Provide a UPS system for critical power near all ATC electronic equipment areas. Use the anticipated load to determine the size of the UPS. ATC electronic equipment loads should be provided during the planning/DD 1391 development process.

4-3.7.9 Lighting.

All fluorescent lighting fixtures require Radio Frequency Interference (RFI) suppression-type ballasts. All lighting controls in the facility, when more than one exists, should be labeled with which lights they control.

Consult with the local ATC personnel for any specific requirements in administrative spaces.

4-3.8 Telecommunications.

4-3.8.1 AOB Main Distribution Frame (MDF).

Provide an MDF within the AOB for terminating all outside communications conductors. At this location, all outside plant communications and control conductors must terminate, be protected, cross-connected, and distributed throughout the rest of the AOB.

4-3.8.2 ATC MDF Enclosure.

The ATC MDF Enclosure is located within the AOB MDF and is exclusively where all ATC circuits are terminated before being distributed to the ATC equipment spaces.

A Hoffman-style enclosure (Type 1, 48 inches (1220 mm) high by 36 inches (910 mm) wide by 11 inches (275 mm) deep), including a back panel, is required for termination of all operational ATC circuit inter-site cabling. This enclosure must be wall-mounted in close proximity to the AOB MDF. The bottom of the enclosure must be 24 inches (600 mm) above the finished floor. The door of the enclosure must incorporate a "T" handle latch. A closure accepting a padlock is required.

4-3.8.3 AOB to RACF Connectivity.

Connectivity between the RACF IFR Equipment Room and the AOB Operations-Airfield Management/Flight Planning Room is required. This and any additional connectivity requirements should be addressed during the planning/DD 1391 development phase.

4-3.9 Safety and Security.

The AOB is normally located within restricted areas that meet the minimum security measures for external security. If the facility is located within a restricted area of a lower level of security, or is located remote and outside of an established restricted area, provide additional measures to meet the minimum security requirements for the level of security assigned to the facility. Security at the main entrance to the AOB requires a single entry point with visitor control.

Remote locks, video cameras, card readers, and/or keypads may be required as components of the IDS. The level of security and the designer's responsibility for particular security elements will be designated by the User command during the planning/DD 1391 development process.

4-3.9.1 Doors and Cipher Locks.

The exterior entry doors must be equipped with non-removable hinges and locking hardware including cipher locks. Doors equipped with electronic cipher locks are required to be powered from a critical power circuit (Uninterruptible Power Supply [UPS]).

4-3.9.2 Access Control System.

Provide and install intercom stations with video camera system at the main entry door of the AOB to monitor AOB doors equipped with cipher locks. This system will allow for personnel identification, visitor check-in, and to monitor ingress and egress. Adequate space for the video monitor must be provided in the Command Suite or Airfield Operations area.

If the intercom station is located on the exterior of the AOB, it must be installed in a weatherproof box. Consider including a canopy in the design if the main entry is not under the roof.

Additional video monitoring may be required at security fencing and guard post for facilities located outside the secure area of the installation. Consult with the local ATC personnel for specific CCTV requirements.

4-3.9.3 Voice Communications.

Provide communication between the main entry door into the AOB and the Command Suite or Airfield Operations area.

This Page Intentionally Left Blank

CHAPTER 5 FUNCTIONAL DATA SHEETS

5-1 INTRODUCTION.

This chapter identifies the specific design needs for the individual spaces within Air Traffic Control (ATC) and Air Operations Facilities. Building design criteria are provided in a standard Functional Data Sheet (FDS) table format that generally follows the Uniformat II / Work Breakdown Structure (WBS). The Interior Construction/Built-In Equipment category includes anything physically attached or plumbed to the building such as counters, cabinets, casework, toilet accessories, window treatments, and retractable overhead screens. The Furnishings and Equipment category includes loose or moveable items.

The Functional Data Sheets are presented as a guide for the designer, planner, or RFP preparer. It is intended that the information in them are the minimum requirements for the respective rooms and spaces. These minimum requirements apply in addition to all other requirements of this UFC and other referenced documents. In the event of a mutually exclusive conflict or where both requirements cannot be satisfied, the Functional Data Sheets take precedence. However, if in the best judgment of the designer, a more restrictive requirement is appropriate, the more restrictive requirement may be applied after consulting with the user.

Not all ATCT's contain all of the areas listed in the following tables. The functional areas required are dependent on operational requirements, and the functions required are determined by the user during the planning/DD 1391 development phase.

Table 5-1.1 ATCT – Main Entrance Lobby/Vestibule

Description / Usage	Main entrance to ATCT	
Ceiling Height	8'-0" minimum	
Windows	Not required	
Doors	Minimum 42" W x 96" H opening – provide vestibule in cold weather areas	
Interior Construction / Built-In Equipment	Building directory and bulletin board	
Finishes	**Walls**	Plaster or GWB - painted
	Floor	Hard surface (terrazzo, VCT, etc.)
	Base	Terrazzo, rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and Cooling (heating only in vestibule)	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office-type areas	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	As required for access control system
	CATV	
	Security	Intercom station and access control system in vestibule – cipher lock, door closer and electric strike on secured door between vestibule (or exterior) and lobby
Acoustics	NC 40	
Furnishings and Equipment		
Special Requirements	A covered or recessed entrance or vestibule is recommended.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.2 ATCT – Elevator and Elevator Lobby

Description / Usage	Provide one (1) elevator to service all floors of the ATCT from the ground floor to the floor below the floor directly below the Control Cab, or the floor below the Cab if possible. Provide an elevator meeting all IBC requirements on each floor.	
Ceiling Height	8'-0" minimum	
Windows		
Doors	Minimum 42"W x 84"H – single-speed, side-opening, horizontal sliding type	
Interior Construction / Built-In Equipment	Standard elevator cab with stainless steel retractable covers.	
Finishes	**Walls**	Standard elevator cab with plastic laminate panels
	Floor	Hard surface (terrazzo, VCT, etc.)
	Base	
	Ceiling	Standard elevator ceiling
Plumbing	Floor drain in elevator pit	
HVAC	Ventilate elevator shaft – air enters low and exits high	
Fire Protection and Life Safety	Conform to UFC 3-600-01 and ASME/ANSI A17.1, *Safety Code for Elevators and Escalators.* Provide smoke detection. For Army and Navy comply additionally with NAVFAC ITG 2013-01 *NAVFAC Elevator Design Guide.*	
Power		
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	Emergency telephone
	Data	
	CCTV	
	CATV	
	Security	
Acoustics		
Furnishings and Equipment		
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff/Other**	
Min. net ft^2 (m^2)		

Table 5-1.3 ATCT – Elevator Machine Room

Description / Usage	Room housing elevator equipment	
Ceiling Height	Exposed structure. Provide 8'-0" minimum clear height	
Windows	Not required.	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC	Heating and cooling for elevator equipment, based on manufacturer's requirements	
Fire Protection and Life Safety	Conform to UFC 3-600-01 and ASME/ANSI A17.1, *Safety Code for Elevators and Escalators.* Provide smoke detection. For Army and Navy comply additionally with NAVFAC ITG 2013-01 *NAVFAC Elevator Design Guide.*	
Power	As required for elevator equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Elevator equipment, as required	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.4 ATCT – Tower Shaft Mechanical Room

Description / Usage	Room housing HVAC equipment for the lower levels of the ATCT.	
Ceiling Height	Exposed structure. Minimum 8'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing	Floor drain required if located above an ATC Electronic Equipment Room	
HVAC	Heating/cooling based on manufacturer's requirements	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for mechanical equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Mechanical HVAC equipment, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.5 ATCT – Tower Shaft Electrical Room

Description / Usage	Room housing electrical equipment for the lower levels of the ATCT.	
Ceiling Height	Exposed structure. Minimum 8'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC	Heating and cooling as required for electrical equipment	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for electrical equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Electrical equipment, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-1.6 ATCT – Telecommunications Room

Description / Usage	Telephone/Data Communications Frame Room housing the communications distribution plant for the ATCT. Room only required if the ATCT is a standalone facility.	
Ceiling Height	Exposed structure. Minimum 8'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Painted 3/4-inch fire-rated plywood, floor to ceiling, all walls
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC	Heating and cooling as required for telecommunications equipment	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system. Provide smoke detection.	
Power	Critical and non-critical power as required for telecommunications equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	As required for telecommunications equipment
	Data	As required for telecommunications and networking equipment
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Telecommunications and networking equipment, as required.	
Special Requirements	Multipoint ground system	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.7 ATCT – Fire Pump Room

Description / Usage	Room housing fire pump for the ATCT.	
Ceiling Height	Exposed structure. Minimum 8'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 84" H door; coordinate with fire pump equipment.	
Interior Construction / Built-In Equipment	Provide duplex pump system and tanks to provide ample pressure for the domestic water system. If an ATCT is deemed "mission critical," a redundant fire pump must be provided in accordance with UFC 3-600-01.	
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing	Provide floor sink and reduced pressure backflow preventer	
HVAC	Heating and ventilation only	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for fire pump(s) and related equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Fire pump(s) and related equipment, as required.	
Special Requirements	May be combined with Mechanical Room	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.8 ATCT – ATCT Simulator Room

Description / Usage	Room housing ATCT simulator for controller training.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system. Provide smoke detection.	
Power	Critical power as required for simulator equipment and standard power for office area	
Lighting	As required by UFC 3-530-01, with dimmable capability	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 30	
Furnishings and Equipment	Simulator equipment, as required and ESD chairs on casters for controllers.	
Special Requirements	Multipoint ground system	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.9 ATCT – Administration Area

Description / Usage	Open office area containing systems furniture workstations.	
Ceiling Height	8'-0" minimum	
Windows	Not required	
Doors		
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-1.10 ATCT – Chief Controller's Office, Chief AIC Office, Chief GCA Office

Description / Usage	Private office for Chief Controller, Chief AIC and/or Chief GCA.	
Ceiling Height	8'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet
	Data	Two outlets (computer and printer)
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 35	
Furnishings and Equipment	Desk, chair, credenza/bookcase, filing cabinets and two (2) visitor chairs	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.11 ATCT – Training Room

Description / Usage	Room for mandatory training.	
Ceiling Height	8'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	As required
	Security	Intercom and lockable door with standard commercial-grade key lock
Acoustics	NC 30	
Furnishings and Equipment	Freestanding furniture, as required	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-1.12 ATCT – Toilet Rooms

Description / Usage	Unisex restroom	
Ceiling Height	8'-0" minimum	
Windows		
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Include recessed towel dispensers with integral waste receptacles. No sanitary napkin dispenser shall be provided.	
Finishes	**Walls**	Ceramic tile on moisture resistant GWB – full height
	Floor	Ceramic tile
	Base	Ceramic tile
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing	One (1) water closet and one (1) lavatory with mirror in each restroom. Include a shower and changing area in at least one toilet room.	
HVAC	Exhaust fan only.	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power at lavatory with GFI outlets	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with bathroom lockset
Acoustics	NC 45	
Furnishings and Equipment		
Special Requirements	Locate one restroom at the ground level and one at the level directly below the Control Cab. Provide sign indicating "In Use".	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.13 ATCT – Janitor Closet

Description / Usage	Space for custodial supplies and equipment	
Ceiling Height	Exposed structure. Provide 8-0" minimum clear height.	
Windows		
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Include mop rack and storage shelving	
Finishes	**Walls**	48"H ceramic tile wainscot on moisture resistant GWB – painted GWB above
	Floor	Ceramic tile or sealed concrete
	Base	Ceramic tile
	Ceiling	No ceiling required
Plumbing	One (1) custodial-style floor sink and floor drain	
HVAC	Exhaust fan only	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power with GFI outlets	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment		
Special Requirements	Provide elevator access to the janitor mop sink	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.14 ATCT – Stairwell

Description / Usage	Pressurized fire-rated stairwell providing emergency egress from the floor below the Control Cab to the ground floor. Minimum stair width must be 44”.	
Ceiling Height	Exposed structure. Provide minimum clear height as required by code.	
Windows		
Doors	Minimum 36” W x 80” H, fire-rated as required	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	CMU, plaster or GWB - painted
	Floor	Sealed concrete
	Base	Rubber or vinyl
	Ceiling	No ceiling required
Plumbing		
HVAC	Stairwell must be pressurized. Heating and/or cooling, to be determined during the planning process	
Fire Protection and Life Safety	Fire-rated enclosure as required by code. Sprinklers as required by NFPA 13. Provide	
Power	Standard power at each landing	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Intercom and access control system – cipher lock, door closer and electric strike at upper door providing access to Control Cab
Acoustics	NC 50	
Furnishings and Equipment		
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft2 (m2)		

Table 5-1.15 ATCT – Lower Electronic Equipment Room

Description / Usage	Room for ATC Electronic Equipment	
Ceiling Height	Exposed structure. Provide 110 inches (9'-2") minimum clear height below any obstruction.	
Windows		
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Overhead cable tray system.	
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Static dissipative carpet or tile
	Base	Rubber or vinyl
	Ceiling	No ceiling required
Plumbing		
HVAC	CRITICAL AREA: Requires redundant heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system. Provide smoke detection.	
Power	Critical and non-critical power as required for ATC electronic equipment	
Lighting	Standard fixtures with RF shielding and suppression filters	
Communication	**Telephone**	One outlet
	Data	As required for ATC electronic equipment
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	ATC electronic equipment as required. ESD bench and chairs on casters if required.	
Special Requirements	Multipoint ground system. Elevator access is required for this room.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.16 ATCT – Upper Electronic Equipment Room

Description / Usage	Room for ATC Electronic Equipment. Preferred location for communications equipment, equipment with antennas, and back-up radio systems.	
Ceiling Height	Exposed structure. Provide 110 inches (9'-2") minimum clear height below any obstruction.	
Windows		
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Overhead cable tray system.	
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Static dissipative carpet or tile
	Base	Rubber or vinyl
	Ceiling	No ceiling required
Plumbing		
HVAC	CRITICAL AREA: Requires redundant heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system. Provide smoke detection.	
Power	Critical and non-critical power as required for ATC electronic equipment	
Lighting	Standard fixtures with RF shielding and suppression filters	
Communication	**Telephone**	One outlet
	Data	As required for ATC electronic equipment
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	ATC electronic equipment, as required. ESD bench and chairs on casters if required.	
Special Requirements	Multipoint ground system. Elevator access is required for this room. Locate room as high in the ATCT as possible to reduce RF loss in the antenna cables going to the roof.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.17 ATCT – UPS Room

Description / Usage	Room housing the UPS system for the ATCT.	
Ceiling Height	Exposed structure. Minimum 8'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC	CRITICAL AREA: Requires redundant heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for UPS system equipment, include grounding per FAA Standard. Include EPO switch.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	UPS system equipment, as required.	
Special Requirements	May be combined with the Upper ATCT Electronic Equipment Room or the Electrical Room.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.18 ATCT – Ready/Break Room

Description / Usage	Room for mandatory controllers breaks on the level directly below the ATCT Control Cab	
Ceiling Height	8'-0" minimum	
Windows	Optional	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Base cabinets with plastic laminate countertop and wall cabinets above. Accommodate a wet sink.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	VCT or carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing	Sink (and floor drain, if located above an ATC electronic equipment room)	
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power with GFI outlets	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet
	Data	Yes
	CCTV	
	CATV	Yes
	Security	Intercom
Acoustics	NC 40	
Furnishings and Equipment	Coffee service, refrigerator, microwave, as well as one table with seating.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.19 ATCT – Control Cab Mechanical Room

Description / Usage	Room housing HVAC equipment serving the Control Cab. May be provided as a mezzanine space above the Ready/Break Room.	
Ceiling Height	Exposed structure. Minimum 8'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing	Floor drain required if located above an Electronic Equipment Room	
HVAC	Heating and ventilation only.	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for mechanical equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Mechanical HVAC equipment, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-1.20 ATCT – Control Cab Electrical/Communications Room

Description / Usage	Room housing equipment for electrical power and telecommunications service to the Control Cab. Locate near the Control Cab level.	
Ceiling Height	Exposed structure. Minimum 8'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	UPS system is required	
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC	Heating and cooling as required for electrical and telecommunications equipment	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for electrical and telecommunications equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Electrical and telecommunications equipment, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.21 ATCT – Control Cab

Description / Usage	Elevated space having an unobstructed line of sight to the entire airfield and areas over which aircraft movements must be controlled. If required, provide a raised platform for the ATCT Supervisor.	
Ceiling Height	10'-0" ceiling height at controller positions	
Windows	360 degree view – minimize structural supports and window mullions to maximize view from Control Cab to airfield	
Doors	Minimum 36" W x 80" H Cab entrance door and minimum 36" x 42" access door to Catwalk.	
Interior Construction / Built-In Equipment	Raised Access Flooring (RAF), fully grounded and bonded – Data cable tray installed below RAF. Accommodate a convenience unit, if required.	
Finishes	**Walls**	Plaster or GWB – painted flat black – acoustical panels on exposed walls above windows and below windowsill
	Floor	Static dissipative carpet on RAF
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile – flat black tile and suspended grid – flat black trim on all lighting
Plumbing	(Optional) Convenience unit– floor drain at subfloor below RAF	
HVAC	CRITICAL AREA: Requires redundant heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system – special audible and visual alarm requirements – see Section 4-1.6. Provide smoke detection. Provide flat black sprinkler cover plates and flat black smoke detectors.	
Power	Critical and non-critical power as required for ATC electronic equipment	
Lighting	Focused and non-focused lighting with dimmable capability. Low level "theater" style lighting at treads in Cab stairway.	
Communication	**Telephone**	3 total. Refer to Sec. 4-1.8.4
	Data	As required
	CCTV	Access control monitors in Cab
	CATV	
	Security	Cipher lock, door closer and electric strike at door to Cab. Intercom and access control video camera at door to Cab
Acoustics	NC 25	
Furnishings and Equipment	Modular consoles for each controller position – provide ESD chairs that have metal frames with conductive casters and chair-covering material for controllers and supervisor – light guns as required	
Special Requirements	Multipoint ground system. Provide a stairway from the Cab level down to the entrance to the ATCT stairwell. Refer to Table 5-1.14 for ATCT stairwell security requirements.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-1.22 ATCT – Electronic Equipment Room for VCSS

Description / Usage	Additional Room for ATC Electronic Equipment (if required) for VCSS.	
Ceiling Height	Exposed structure. Provide 110 inches (9'-2") minimum clear height below any obstruction.	
Windows		
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Overhead cable tray system.	
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Static dissipating carpet or tile
	Base	Rubber or vinyl
	Ceiling	No ceiling required
Plumbing		
HVAC	CRITICAL AREA: Requires redundant heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system. Provide smoke detection.	
Power	Critical and non-critical power as required for ATC electronic equipment.	
Lighting	Standard fixtures with RF shielding and suppression filters.	
Communication	**Telephone**	One outlet
	Data	As required for ATC electronic equipment
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	ATC electronic equipment, as required. ESD bench and chairs on casters if required.	
Special Requirements	Multipoint Ground System	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-1.23 ATCT – Ground Controlled Approach

Description / Usage	Room housing Ground Controlled Approach (GCA) operations.	
Ceiling Height	8'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Static dissipative carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	Intercom speaker for monitoring ATCT access, lockable door with cipher lock access.
Acoustics	NC 30	
Furnishings and Equipment	Freestanding furniture, as required	
Special Requirements	Overhead cable tray	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-1.24 ATCT – Airspace Information Center

Description / Usage	Room housing Airspace Information Center (AIC) operations.	
Ceiling Height	8'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Static dissipative carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	Intercom speaker for monitoring ATCT access, lockable door with cipher lock access.
Acoustics	NC 30	
Furnishings and Equipment	Freestanding furniture, as required	
Special Requirements	Raised access floor	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-1.25 ATCT – ATC Equipment Maintenance Building

Description / Usage	When a standalone ATCT is remote and not attached to an Airfield Operations Building, a separate building with office/work bench space for technicians will be provided for ATC equipment maintenance. Refer to specific Army requirements in the COS Standard Design.	
Ceiling Height	Minimum 9'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H and 72" W x 84" H double door for receiving ATC equipment.	
Interior Construction / Built-In Equipment	Snorkel-type localized standalone exhaust system, as required.	
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Static dissipative VCT or carpet
	Base	
	Ceiling	Acoustical ceiling tile
Plumbing		
HVAC	Heating and ventilation as required	
Fire Protection and Life Safety	Wet pipe, automatic fire suppression sprinkler system	
Power	As required for maintenance equipment, including grounding per FAA Standard. TVSS required on the panel feeding this room.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	Two outlets (computer and printer) minimum
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics		
Furnishings and Equipment	ESD chairs on casters, ESD storage shelving, ESD cabinets, and ESD workbenches, as required.	
Special Requirements	Multipoint ground system.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.1 RACF – Lobby/Entry Vestibule

Description / Usage	Main entrance to RACF	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors	Minimum 42" W x 96" H opening – provide vestibule in cold weather areas	
Interior Construction / Built-In Equipment	Building directory and bulletin board	
Finishes	**Walls**	Plaster or GWB - painted
	Floor	Hard surface (terrazzo, VCT, etc.)
	Base	Terrazzo, rubber or vinyl
	Ceiling	Acoustical Ceiling Tile or Painted GWB
Plumbing		
HVAC	Heating and Cooling (heating only in vestibule)	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office-type areas	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	Yes
	Data	
	CCTV	Access Control System
	CATV	
	Security	Intercom station and access control system in vestibule – cipher lock, door closer and electric strike on secured door between vestibule (or exterior) and lobby
Acoustics	NC 40	
Furnishings and Equipment		
Special Requirements	A covered or recessed entrance or vestibule is recommended. Provide a one-way reinforced window and a slot for passing of ID cards in the primary building entry door.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.2 RACF – ATC Administration Area

Description / Usage	Open office area containing systems furniture workstations	
Ceiling Height	9’-0” minimum	
Windows	Not required	
Doors		
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.3 RACF – Private Offices

Description / Usage	Private office for select RACF positions.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet
	Data	Two outlets (computer and printer)
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 35	
Furnishings and Equipment	Desk, chair, credenza/bookcase, filing cabinets and two (2) visitor chairs	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.4 RACF – Toilet Rooms with Lockers and Showers

Description / Usage	Men's and Women's Toilet Rooms	
Ceiling Height	9'-0" minimum	
Windows		
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Include lockers and recessed towel dispensers with integral waste receptacles. Provide half-height lockers (60% male, 40% female). In overseas locations, full-height must be provided.	
Finishes	**Walls**	Ceramic tile on moisture resistant GWB – full height
	Floor	Ceramic tile
	Base	Ceramic tile
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing	Water closets, urinals and lavatories with mirror. Include at least one shower and changing area in each toilet room.	
HVAC	Exhaust fan only.	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power at lavatory with GFI outlets	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with bathroom lockset
Acoustics	NC 45	
Furnishings and Equipment		
Special Requirements	Provide separate restrooms adjacent to the Operations/IFR Room and the Break Room if space and budget allow.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.5 RACF – Janitor Closet

Description / Usage	Space for custodial supplies and equipment	
Ceiling Height	Exposed structure. Provide 9'-0" minimum clear height.	
Windows		
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Include mop rack and storage shelving	
Finishes	Walls	48" H Ceramic tile wainscot on moisture resistant GWB – painted GWB above
	Floor	Ceramic tile or sealed concrete
	Base	Ceramic tile
	Ceiling	No ceiling required
Plumbing	One (1) custodial-style floor sink and floor drain	
HVAC	Exhaust fan only	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power with GFI outlets	
Lighting	As required by UFC 3-530-01	
Communication	Telephone	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment		
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	Staff	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.6 RACF – Mechanical Room

Description / Usage	Room housing HVAC equipment for the RACF.	
Ceiling Height	Exposed structure. Minimum 7'-6" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing	Floor sink required.	
HVAC	Heating and ventilation only.	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for mechanical equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Mechanical HVAC equipment, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.7 RACF – Electrical Room

Description / Usage	Room housing electrical equipment for RACF.	
Ceiling Height	Exposed structure. Minimum 9'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H – interior and exterior access required	
Interior Construction / Built-In Equipment	UPS system is required	
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC	Heating and ventilation as required for electrical equipment	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for electrical equipment. Include UPS system if required. Include grounding per FAA standard.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Electrical equipment, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft2 (m2)		

Table 5-2.8 RACF – Telecommunications Room

Description / Usage	Telecommunications Frame Room housing the communications distribution plant for the RACF.	
Ceiling Height	Exposed structure. Minimum 9'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Painted 3/4- inch fire-rated plywood, floor to ceiling, all walls.
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC	Heating and cooling as required for telecommunications equipment	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system. Provide smoke detection.	
Power	Critical and non-critical power as required for telecommunications equipment. Include grounding per FAA standard.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	As required for telecommunications equipment
	Data	As required for telecommunications equipment
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Telecommunications equipment, as required.	
Special Requirements	Multipoint ground system. Location of Main Distribution Frame (MDF) and ATC MDF enclosure.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.9 RACF – TERPS/DSS Office

Description / Usage	Office responsible for actual planning and plotting of aircraft approach and ATC procedures	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors		
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture for employee workstations. Also provide space for a large format plotter, drafting table, computer workstation, map storage drawers, and shelving for active Technical Orders.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.10 RACF – Operations/Instrument Flight Rules (IFR) Room

Description / Usage	Room for controlling radar approach by aircraft, including a station for the Watch Supervisor, who oversees all scope activity. The Operations/IFR Room requires a considerable amount of circulation space.	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors	36" W x 80" H minimum – double door access (48" W x 80" H) is required to the IFR Equipment Room – include narrow wire-glass lite in all doors	
Interior Construction / Built-In Equipment	Raised Access Flooring (RAF), fully grounded and bonded – Data cable tray installed below RAF	
Finishes	**Walls**	Plaster or GWB – painted with acoustical wall panels
	Floor	Static dissipative carpet
	Base	Rubber or vinyl
	Ceiling	Black (dyed) or white acoustical ceiling tile
Plumbing		
HVAC	CRITICAL AREA: Requires redundant heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system – special audible and visual alarm requirements – see Section 4-2.6. Provide smoke detection.	
Power	Critical power as required for ATC equipment and standard power for office area	
Lighting	Special requirements, see Paragraph 4-2.7.8	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	Outside or inside entrance doors require cipher locks, cameras, intercoms, and electric door strikes
Acoustics	NC 40	
Furnishings and Equipment	Modular consoles for each controller position – provide ESD chairs that have metal frames with conductive casters and chair-covering material for controllers and supervisor – light curtain installed over cabinetry	
Special Requirements	Multipoint ground system. Doors between the Operations/IFR Room and the IFR Equipment Room must not be lockable.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.11 RACF – Radar Simulator Room

Description / Usage	Room housing Radar simulators for controller training.	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Raised Access Flooring (RAF), fully grounded and bonded – Data cable tray installed below RAF	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Static dissipative carpet
	Base	Rubber or vinyl
	Ceiling	Black (dyed) or white acoustical ceiling tile
Plumbing		
HVAC	CRITICAL AREA: Requires redundant heating and cooling. May be on same system as Operations/IFR Room	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Critical power as required for simulator equipment and standard power for office area.	
Lighting	As required by UFC 3-530-01, with dimmable capability.	
Communication	**Telephone**	One outlet per simulator
	Data	Two outlets per simulator (computer and printer)
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 30	
Furnishings and Equipment	Simulator equipment, as required – provide ESD chairs that have metal frames with conductive casters and chair-covering material	
Special Requirements	Multipoint ground system.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.12 RACF – ATCT Simulator Room

Description / Usage	Room housing ATCT simulator for controller training.	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Raised Access Flooring (RAF), fully grounded and bonded – Data cable tray installed below RAF	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Static dissipative carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	CRITICAL AREA: Requires redundant heating and cooling. May be on same system as Operations/IFR Room	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Critical power as required for simulator equipment and standard power for office area	
Lighting	As required by UFC 3-530-01, with dimmable capability	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 30	
Furnishings and Equipment	Simulator equipment, as required - provide ESD chairs that have metal frames with conductive casters and chair-covering material	
Special Requirements	Multipoint ground system.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.13 RACF – Training Room

Description / Usage	Room housing the Computer-Based Instruction (CBI) component of RACF training. Locate adjacent to or near the Operations/IFR Room.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	White board, projector and motorized recessed projection screen. If a single large room is provided, consider a moveable partition to subdivide the space, allowing two individual sessions to be held at the same time.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for multiple computer workstations	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 30	
Furnishings and Equipment	Freestanding furniture, as required. Typically contains between two and five computer workstations – provide ESD chairs that have metal frames with conductive casters and chair-covering material	
Special Requirements	May be combined with the RACF Briefing / Conference Room to reduce overall space requirements.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.14 RACF – Briefing/Conference Room

Description / Usage	Room sized to house the entire RACF shift, plus the AOF/CC and the shift Watch Supervisor, for joint briefings and conferences. This space will be used by ATC and Maintenance personnel.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	White board, projector and motorized recessed projection screen. If a single large room is provided, consider a moveable partition to subdivide the space, allowing two individual sessions to be held at the same time.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office-type areas	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	Two outlets (computer and printer) minimum
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 35	
Furnishings and Equipment	Conference Table(s) and chairs on casters as required	
Special Requirements	May be combined with the RACF Training Room to reduce overall space requirements.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.15 RACF – IFR Equipment Room

Description / Usage	Room housing communication racks that are the termination points for all lines entering and departing the RACF that provide data to and from the scopes in the Operations/IFR Room. Locate immediately adjacent to the Operations/IFR Room.	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors	36" W x 80" H minimum – provide double door access (48" W x 80" H minimum) to the Operations/IFR Room(include narrow wire-glass lite in both doors) – provide double door access (48" W x 80" H minimum) to the exterior.	
Interior Construction / Built-In Equipment	Raised Access Flooring (RAF), fully grounded and bonded – Data cable tray installed below RAF.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Static dissipative carpet or vinyl tile
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	CRITICAL AREA: Requires redundant heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system. Provide smoke detection.	
Power	Critical power as required for ATC equipment and standard power for office area.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet
	Data	As required for ATC equipment
	CCTV	
	CATV	
	Security	Outside or inside entrance doors require cipher locks, door closers, and electric door strikes
Acoustics	NC 45	
Furnishings and Equipment	Communications racks and support equipment as required, including ESD workbenches, storage cabinets, shelving and chairs on casters.	
Special Requirements	Multipoint ground system. Doors between the Operations/IFR Room and the IFR Equipment Room must not be lockable. Location of ATC Circuit Intermediate Distribution Frame (IDF).	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-2.16 RACF – UPS Room

Description / Usage	Room housing the UPS system for the RACF.	
Ceiling Height	Exposed structure. Minimum 9'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H interior access door and a double door for exterior access as required	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC	CRITICAL AREA: Requires redundant heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for UPS system equipment, include grounding per FAA Standard. Include EPO switch.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	UPS system equipment, as required.	
Special Requirements	Multipoint ground system. May be combined with the IFR Equipment Room or Electrical Room.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.17 RACF – Storage Room

Description / Usage	Room for storage of general purpose materials.	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Full height walls for secure storage.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	VCT
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for storage areas	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key locks
Acoustics	NC 40	
Furnishings and Equipment	Shelving and storage cabinets as required by user.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.18 RACF – Flight Planning Room

Description / Usage	Open office area containing flight dispatch and flight planning operations.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Provide eight (8) linear feet of counter open to hall or lobby. If required, provide Raised Access Flooring (RAF), fully grounded and bonded, with data cable tray installed below RAF.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Static dissipative carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Critical power (UPS) as required for ATC electronic equipment and standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	As required
	CATV	As required
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required. ESD chairs on casters for operations personnel.	
Special Requirements	Multipoint ground system. Connectivity to IFR Equipment Room required.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-2.19 RACF – Pilot Flight Planning Room

Description / Usage	Open office area containing flight planning operations.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet.
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-2.20 RACF – ATC Equipment Maintenance Administration Area

Description / Usage	An open office area for administrative functions required for ATC equipment maintenance.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.21 RACF – ATC Equipment Maintenance Area

Description / Usage	Room for maintenance of ATC equipment. Locate adjacent to the IFR Equipment Room with direct access to the Telecommunications Room.	
Ceiling Height	Minimum 9'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Snorkel-type localized stand-alone exhaust system, as required.	
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Static dissipative VCT or carpet
	Base	
	Ceiling	Acoustical ceiling tile
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for maintenance equipment, include grounding per FAA Standard. TVSS required on the panel feeding this room.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	Two outlets (computer and printer) minimum
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 45	
Furnishings and Equipment	ESD Chairs on casters, ESD storage shelving, ESD cabinets, and ESD workbenches, as required.	
Special Requirements	Multipoint ground system. Locate adjacent to the IFR Equipment Room with direct access to the Telecommunications Room.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-2.22 RACF – Break Room

Description / Usage	Room with a small kitchenette and seating accessible to trainees and RACF maintenance personnel as well as the on-duty controllers and administrative offices. Locate immediately adjacent to the Operations/IFR Room. Should also be accessible from the administrative office area.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 40" W x 80" H to provide access for vending machines.	
Interior Construction / Built-In Equipment	Base cabinets with plastic laminate countertop and wall cabinets above. Accommodate a wet sink.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	VCT
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing	Sink with hot and cold water	
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power with GFI outlets – provide outlet for wall-mounted television (if provided).	
Lighting	As required by UFC 3-530-01. Provide fully dimmable fixtures if located adjacent to the Operations/IFR Room.	
Communication	**Telephone**	One outlet
	Data	Yes
	CCTV	
	CATV	As required
	Security	Intercom
Acoustics	NC 40	
Furnishings and Equipment	Coffee service, refrigerator, microwave, a stove/range unit, and vending machines, along with seating and tables.	
Special Requirements	If a small break area, adjacent to the Operations/IFR Room, is provided for the controllers, another larger break room is required for the remainder of the facility. If approved, provide a stove/range unit with a filtered hood vented to the exterior.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-2.23 RACF – 2M (Micro Miniature) Electronic Repair Room

Description / Usage	A room for Micro-Maintenance repair. Refer to NAVAIR 01-1A-23 for additional requirements.	
Ceiling Height	Minimum 9'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Snorkel-type localized stand-alone exhaust system, as required.	
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Static dissipative VCT or carpet
	Base	
	Ceiling	Acoustical ceiling tile
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for maintenance equipment, include grounding per FAA Standard. TVSS required on the panel feeding this room.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	Two outlets (computer and printer) minimum
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 45	
Furnishings and Equipment	ESD Chairs on casters, ESD storage shelving, ESD cabinets, and ESD workbenches, as required.	
Special Requirements	Multipoint ground system. Locate adjacent to the IFR Equipment Room with direct access to the Telecommunications Room.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.1 AOB – Lobby/Entry Vestibule

Description / Usage	Main entrance to AOB.	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors	Minimum 36" W x 84" H opening, or as required by code – provide vestibule in cold weather areas	
Interior Construction / Built-In Equipment	Building directory and bulletin board	
Finishes	**Walls**	Plaster or GWB - painted
	Floor	Hard surface (terrazzo, VCT, etc.)
	Base	Terrazzo, rubber or vinyl
	Ceiling	Acoustical Ceiling Tile or Painted GWB
Plumbing		
HVAC	Heating and Cooling (heating only in vestibule)	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office-type areas	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Cipher lock and door closer at main entry door
Acoustics	NC 40	
Furnishings and Equipment		
Special Requirements	A covered or recessed entrance or vestibule is recommended.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.2 AOB – HQ / Command Suite - Reception Area

Description / Usage	Open office area containing reception area for HQ / Command.	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Include visitor seating and coat closet	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.3 AOB – HQ / Command Suite - Private Offices

Description / Usage	Private office for select HQ / Command positions.	
Ceiling Height	9’-0” minimum	
Windows	Recommended but not required	
Doors	Minimum 36” W x 80” H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet
	Data	Two outlets (computer and printer)
	CCTV	
	CATV	As required
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 35	
Furnishings and Equipment	Desk, chair, credenza/bookcase, filing cabinets and two (2) visitor chairs	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-3.4 AOB – Air Operations Duty Officer

Description / Usage	Reception area with counter.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.5 AOB – Operations - Airfield Management/Flight Planning

Description / Usage	Open office area containing flight dispatch and flight planning operations.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Provide eight (8) linear feet of counter open to hall or lobby. If required, provide Raised Access Flooring (RAF), fully grounded and bonded, with data cable tray installed below RAF.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Static dissipative carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Critical power (UPS) as required for ATC electronic equipment and standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	As required
	CATV	As required
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required. ESD chairs on casters for operations personnel.	
Special Requirements	Multipoint ground system. Connectivity to IFR Equipment Room required.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.6 AOB – Operations – Pilot Flight Planning Room

Description / Usage	Open office area containing flight planning operations.	
Ceiling Height	9’-0” minimum	
Windows	Recommended but not required	
Doors	Minimum 36” W x 80” H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet.
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.7 AOB – Operations – Weather Station

Description / Usage	Open office area containing weather station operations.	
Ceiling Height	9’-0” minimum	
Windows	Recommended but not required	
Doors	Minimum 36” W x 80” H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Static dissipative carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Critical power is required for the Weather electronic equipment and standard power for office area. TVSS required on the panel feeding this room.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required.	
Special Requirements	Multipoint ground system.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.8 AOB – Operations – Pilot Ready Room

Description / Usage	Open office area containing pilot ready room.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-3.9 AOB – Airfield Services – Open Office Area

Description / Usage	Open office area containing airfield services operations.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.10 AOB – Airfield Services – Printer/Copier Station

Description / Usage	Room containing shared printers and copiers for airfield services.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Base cabinets with plastic laminate countertop and wall cabinets above.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet or VCT
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for printers and copiers. Provide standard outlets along countertop for portable equipment.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	As required for printers and copiers
	CCTV	
	CATV	
	Security	Lockable cabinets
Acoustics	NC 45	
Furnishings and Equipment		
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.11 AOB – Non-Sensitive Secure Storage Room

Description / Usage	Room for storage of non-sensitive materials.	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Full height walls for secure storage. Room construction must comply with service specific requirements.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	VCT
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for storage areas	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Shelving and storage cabinets as required by user.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-3.12 AOB – General Purpose Storage Room

Description / Usage	Room for storage of general purpose materials.	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Full height walls for secure storage.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	VCT
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for storage areas	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key locks
Acoustics	NC 40	
Furnishings and Equipment	Shelving and storage cabinets as required by user.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.13 AOB – File Storage Area

Description / Usage	Room for file storage.	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Full height walls for secure storage.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	VCT
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for storage areas	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key locks
Acoustics	NC 40	
Furnishings and Equipment	Shelving and storage cabinets as required by user.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.14 AOB – ATC Equipment Maintenance Administration Area

Description / Usage	Open office area containing systems furniture workstations	
Ceiling Height	9'-0" minimum	
Windows	Not required	
Doors		
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office area	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet per workstation
	Data	Two outlets per workstation (computer and printer)
	CCTV	
	CATV	
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Freestanding systems furniture, as required	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.15 AOB – ATC Equipment Maintenance Area

Description / Usage	Room for maintenance of ATC electronic equipment. Include general purpose storage room, non-sensitive secure storage room, and file storage area.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H – interior; minimum 36" W x 80" H exterior door access; confirm opening requirement with local ATC equipment maintenance personnel.	
Interior Construction / Built-In Equipment	Snorkel-type localized stand-alone exhaust system, as required.	
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Static dissipative VCT or carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing	Plumbed emergency eye wash station, as required.	
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for maintenance equipment, include grounding per FAA Standard. TVSS required on the panel feeding this room.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	Two outlets (computer and printer) minimum
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 45	
Furnishings and Equipment	General purpose workstations, ESD Chairs on casters, ESD storage shelving, ESD cabinets, and ESD workbenches, as required.	
Special Requirements	Multipoint ground system.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-3.16 AOB – Break Area

Description / Usage	Room with a small kitchenette and seating accessible to all occupants of the AOB.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 42" W x 80" H for vending machine access. Coordinate vending machine installation route.	
Interior Construction / Built-In Equipment	Base cabinets with plastic laminate countertop and wall cabinets above. Accommodate a wet sink.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	VCT or ceramic tile
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing	Sink with hot and cold water	
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power with GFI outlets – provide outlet for wall-mounted television (if provided).	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet
	Data	
	CCTV	
	CATV	
	Security	Lockable cabinets
Acoustics	NC 40	
Furnishings and Equipment	Coffee service, refrigerator, microwave, and vending machines, as well as seating and tables	
Special Requirements	If approved, provide a stove/range unit with a filtered hood vented to the exterior.	
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.17 AOB – Multipurpose Room

Description / Usage	Multipurpose room for conferences and training sessions.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H (provide two if a moveable partition is provided)	
Interior Construction / Built-In Equipment	White board, projector and motorized recessed projection screen. If a single large room is provided, consider a moveable partition to subdivide the space, allowing two individual sessions to be held at the same time.	
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office-type areas	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum (two if a moveable partition is provided)
	Data	Two outlets (computer and printer) minimum (four if a moveable partition is provided)
	CCTV	
	CATV	As required
	Security	Lockable door(s) with standard commercial-grade key lock
Acoustics	NC 35	
Furnishings and Equipment	Conference table(s) and chairs on casters, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft² (m²)		

Table 5-3.18 AOB – Male and Female Toilet Rooms

Description / Usage	Men's and Women's Toilet Rooms	
Ceiling Height	9'-0" minimum	
Windows		
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Include lockers and recessed towel dispensers with integral waste receptacles.	
Finishes	**Walls**	Ceramic Tile on moisture resistant GWB – full height
	Floor	Ceramic Tile
	Base	Ceramic Tile
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing	Water closets, urinals and lavatories with mirror. Include at least one shower and changing area in each toilet room.	
HVAC	Exhaust fan only	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power at lavatory with GFI outlets	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with bathroom lockset
Acoustics	NC 45	
Furnishings and Equipment		
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft2 (m2)		

Table 5-3.19 AOB – Janitor Closet

Description / Usage	Room for custodial supplies and equipment.	
Ceiling Height	Exposed structure. Provide 9'-0" minimum clear height.	
Windows		
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment	Include mop rack and storage shelving	
Finishes	**Walls**	48"H Ceramic Tile wainscot on moisture resistant GWB – painted GWB above
	Floor	Ceramic Tile or Sealed Concrete
	Base	Ceramic Tile
	Ceiling	No ceiling required
Plumbing	One (1) custodial-style floor sink	
HVAC	Exhaust fan only	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power with GFI outlets	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment		
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft2 (m2)		

Table 5-3.20 AOB – Mechanical Room

Description / Usage	Room housing HVAC equipment for the AOB.	
Ceiling Height	Exposed structure. Minimum 9'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing	Floor sink required.	
HVAC	Heating and ventilation only	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for mechanical equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Mechanical HVAC equipment, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft2 (m2)		

Table 5-3.21 AOB – Electrical Room

Description / Usage	Room housing electrical equipment for AOB.	
Ceiling Height	Exposed structure. Minimum 9'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H – interior and exterior access required	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	CMU, plaster or GWB – painted
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC	Heating and cooling as required for electrical equipment	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for electrical equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Electrical equipment, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft2 (m2)		

Table 5-3.22 AOB – Telecommunications Room

Description / Usage	Telephone / Data Communications Frame Room housing the communications distribution plant for the AOB.	
Ceiling Height	Exposed structure. Minimum 9'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Painted 3/4 inch fire rated plywood, floor to ceiling, all walls
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC	Heating and cooling as required for telecommunications equipment	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system. Provide smoke detection.	
Power	As required for telecommunications equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	As required for telecommunications equipment
	Data	As required for telecommunications equipment
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	Telecommunications equipment, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.23 AOB – SIPR Room

Description / Usage	For certain facilities, a room for SIPR equipment must be provided.	
Ceiling Height	Exposed structure. Minimum 9'-0" clear height	
Windows	Not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Painted 3/4 inch fire rated plywood, floor to ceiling, all walls
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC	Heating and cooling as required for SIPR equipment	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	As required for SIPR equipment	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	As required
	Data	As required
	CCTV	
	CATV	
	Security	Lockable door with standard commercial-grade key lock
Acoustics	NC 50	
Furnishings and Equipment	SIPR equipment, as required.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.24 AOB – Outside Covered Storage Area

Description / Usage	One (1) outside storage building and one (1) outside covered storage area with fence and lockable gate. The storage area is used to store airfield services related equipment and must have direct access to the parking aprons	
Ceiling Height	Exposed structure. Minimum 12'-0" clear height	
Windows		
Doors		
Interior Construction / Built-In Equipment		
Finishes	**Walls**	
	Floor	Sealed concrete
	Base	
	Ceiling	No ceiling required
Plumbing		
HVAC		
Fire Protection and Life Safety		
Power	As required for overhead lighting and convenience power	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	
	Data	
	CCTV	
	CATV	
	Security	
Acoustics		
Furnishings and Equipment		
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.25 AOB – Transient Passenger Services

Description / Usage	Waiting area for transient passengers.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system.	
Power	Standard power for office-type areas. Provide adequate USB charging outlets.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	Wireless internet access
	CCTV	
	CATV	Yes
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Seating as required by program.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)		

Table 5-3.26 AOB – VIP Passenger Services

Description / Usage	Waiting area for VIPs.	
Ceiling Height	9'-0" minimum	
Windows	Recommended but not required	
Doors	Minimum 36" W x 80" H	
Interior Construction / Built-In Equipment		
Finishes	**Walls**	Plaster or GWB – painted
	Floor	Carpet
	Base	Rubber or vinyl
	Ceiling	Acoustical ceiling tile or painted GWB
Plumbing		
HVAC	Heating and cooling	
Fire Protection and Life Safety	Wet-pipe, automatic fire suppression sprinkler system	
Power	Standard power for office-type areas. Provide adequate USB charging outlets.	
Lighting	As required by UFC 3-530-01	
Communication	**Telephone**	One outlet minimum
	Data	Yes
	CCTV	
	CATV	Yes
	Security	
Acoustics	NC 40	
Furnishings and Equipment	Seating as required by program.	
Special Requirements		
	For use during project execution by the appropriate Service agency	
Occupancy	**Staff**	
	Other	
Min. net ft^2 (m^2)

APPENDIX B BEST PRACTICES

B-1 DEVELOPMENT OF REQUIRED BUILDING AREA AND LAYOUT.

During the planning/DD 1391 development process, the planner should contact appropriate local personnel to discuss and finalize specific space requirements. Confirm area requirements for electronic equipment areas with the requirements developer. In addition, there are unique mechanical/electrical requirements for ATCFs.

For the ATCT, the circulation factor is greater than normal due to limited building footprint.

B-2 ATCT HEIGHT DETERMINATION.

After site selection and issuance of siting report, the planner can determine the tower height and consequently, the number of floors in the ATCT.

B-3 USE OF DIMENSIONS ON FLOOR PLAN DIAGRAMS.

The use of floor plan diagrams is generally helpful to communicate the overall layout and adjacencies in each facility type.

B-4 PROJECT EXPERIENCE.

Require the use of experienced A/E, designers and builders.

B-5 AT/FP REQUIREMENTS.

Reduce the impact of AT/FP requirements.

B-6 TEMPORARY MOBILE ATCT.

During the planning/DD 1391 development phase, the need for a temporary mobile ATCT should be determined to avoid interruptions of continuous ATC operations.

B-7 ACCESSIBILITY VS. FUNCTIONALITY.

Improve accessibility without affecting functionality.

B-8 ELEVATOR MACHINE ROOM.

A room housing elevator machine equipment.

B-9 EXTERIOR CATWALK ACCESS.

The catwalk must be accessible directly from the Cab stair via an access door hatch. Using the Catwalk to provide secondary egress from the Cab is optional, not mandatory; the final decision on the requirement for secondary egress shall be determined by the local Authority Having Jurisdiction (AHJ).

B-10 CATWALK SCAFFOLD.

Consider a means to attach scaffolding to the catwalk for regular maintenance of the tower shaft. Reinforced holes may be designed into the catwalk on all four sides of the shaft to allow scaffolding cables to be routed through the holes and secured.

B-11 EXTERIOR OBSERVATION AREA GRATES.

There are corrosion concerns with the metal grates, especially ATCTs near the coast. The salt in the air helps speed up the corrosion process. Even if the grating is galvanized, some corrosion will still occur. Implement detailed solutions during the design and siting phase.

B-12 OVERALL TOWER SHAFT.

A rectangular tower shaft floor plan often provides an economical use of space. Electronic equipment racks, stairwells and elevators are rectangular in shape and fit more efficiently in a rectangular tower to reduce materials and cost.

B-13 ATCT POWER SHADES.

Recommend not using power shades in the tower Cab due to maintenance issues. If the electric motors fail, replacements may not be readily available and the shades remain broken.

B-14 CABLE TRAY LAYOUT/ROUTING.

Cable tray routing should be planned and designed to provide direct routing between equipment served. The preference is that cable tray routing should be confined within the operational spaces where possible, and avoid corridors especially in multi-occupancy buildings. Routing should minimize penetration of fire-rated walls and floors. Depending on facility configuration and required path between equipment, the cable trays may have to be routed through corridors.

B-15 ATCT CABLE LENGTH.

Minimizing the cable distance is of extreme importance and should not be sacrificed for other design considerations. An example would be offsetting the cable path to facilitate HVAC duct. Interdisciplinary coordination early in the design is very important in reducing cable length. Additionally, the cable chase is meant to be a straight vertical shaft with no horizontal jogs from one location to another. Coaxial cable connecting the radios to the antennas is very stiff and cannot easily be routed through offsets.

B-16 DESIGN SPECIAL LOADS.

The structural designer will provide for the support of communication, future ceiling track, and other special equipment.

Before undertaking unique antenna support designs, consider the use of existing commercial products suitable for the purpose.

B-17 LANDSCAPING AND BIRD ISSUES.

Contractor should be aware of bird issues when creating landscaping plan. For example, retention ponds tend to also attract birds, especially if there is water present all the time.

B-18 FOAM INSULATION.

Consider spray on foam in equipment and mechanical areas for sound attenuation that meets smoke development and flame spread criteria.

B-19 PARKING.

The ATC electronic equipment maintenance division typically has numerous Government vehicles used to travel on the airfield. If the facility is part of the airfield perimeter security fence, consider parking some of the Government vehicles used on the airfield on the airfield side.

B-20 WORK NOT INCLUDED IN CONSTRUCTION CONTRACT.

The following items, except as noted, are Government-Furnished Equipment (GFE) and will be installed by others during construction or upon completion of the construction contract.

1. Antennas. Antennas will be Government installed. All required safety features and lightning protection will be incorporated to protect property and personnel. Lightning protection is provided and installed by the Contractor, and must protect any antennas without integral lightning protection. The antenna mast must withstand wind loads based on the maximum gust conditions and take into consideration the projected heights of antennas to be mounted on the ATCT as well as being capable of resisting lateral loads required by the applicable safety codes. Also consider ice loads and wind-borne salt spray, and how it corrodes and affects radio inter-mod vulnerability.

2. Light Guns. Install eyebolts in the ceiling to hang light guns. These should be located adjacent to light gun outlets. If desired, the battery-operated desk mount type light gun may be installed in lieu of the ceiling mount type. The light gun(s) must be purchased with local Operations and Maintenance (O&M) funds. If battery-powered light guns are used, a 115 +/- 10 VAC outlet must be installed on the console within three feet of each proposed light gun location. Coordinate the location of the light guns with the user during the planning process. Consult with the local Air Operations Department to determine if any existing hard-wired light guns require relocation. If required, the Contractor is responsible for relocating any existing light guns.

3. CCTV Security System. The CCTV security system is Government furnished and installed (GFGI). The Contractor provides rough-in and conduits with pull wires as required.

4. Tower Radar Display Monitor. The Tower Radar Display monitor is GFGI.

5. ATC data or communications cabling internal to the facility, other than office telephone systems and local area network (LAN) cabling to desktop computers, is GFGI.

6. ATC Electronic Equipment Room communications racks, communications equipment, and radar/radar housing are GFGI. Wall-mounted data or telecommunications cabinets or related conduit are furnished and installed by the Contractor.

7. FAA Coordination. Coordinate relocation of existing equipment and connectivity with the FAA.

- **Army**: ATC equipment: radios, STARS, communication and recording equipment, Voice Communications Switching System (VCSS), etc. is installed by separate contract and is procured through Product Manager Air Traffic Control (PM ATC) at the Army Aviation and Missile Command (AMCOM) Redstone Arsenal, AL. Requirements and Technical oversight is a function of USAISEC Fort Detrick, MD. The Contractor is responsible for providing conduit and pull strings for installation. Console cut-out locations and instrument locations must be determined during design. Items to be transferred over from existing facilities must be identified. Weather station equipment and locations must be coordinated with the organization responsible for weather status on the installation.

- **Air Force**: ATC equipment: radios, STARS and RADAR consoles, communication and recording equipment, Enhanced Terminal Voice Switch (ETVS) etc. is installed by separate contract and is procured through UNK due to 38 EIG stepping away. Requirements and Technical oversight is a function of HQ AFFSA. The Contractor is responsible for providing conduit and pull strings for installation. Console cut-out locations and instrument locations must be determined during design. Items to be transferred over from existing facilities must be identified. Weather station equipment and locations must be coordinated with the organization responsible for weather status on the installation.

  Refer to ETL 02-12, *Communications and Information System Criteria for Air Force Facilities*, which delineates programming responsibilities for Real Property versus equipment.

APPENDIX C OUTLINE OF TYPICAL SITE SELECTION PROCESS

The air traffic control tower site selection process is a collaborative effort amongst the planner, Air Ops/Customer, and the representative performing the site evaluation study.

C-1 Establish Tower Siting Study Representative/Methodology (Government/Consultant, etc.)

- See Site Selection and Approval Process in Chapter 2.

C-2 Establish authority for tower site approval.

- See Site Selection and Approval Process in Chapter 2.

C-3 Base/authority recommends potential site(s) for consideration.

- Planner coordinates tower siting study.
- Perform preliminary desktop study:
- Use GIS and other basic available tools to evaluate proposed sites

C-4 Establish site viability and basic geometry compliance.

- Safety zones/clearances
- Site angle to critical areas
- Obstruction avoidance
- Establish preliminary tower height
- Re-work proposed options and results from preliminary study with feedback/input from Air Ops and Planner. Revise and establish new viable options as required.

C-5 Basic considerations in site selection.

- Clear Zone conflicts (existing and future – consider impact of planned/future projects)
- Existing infrastructure
- Future development
- Environmental/Archaeological Issues
- Anti-Terrorism/Force Protection (AT/FP)
- Exact site variance – consider that exact placement of tower on proposed site may vary during actual design for various reasons. Evaluate envelope of reasonable exact locations at a specified site.
- Other special design considerations (Light vault locations, special seismic design, special foundation design, etc.)
- Terminal Approach Procedures (TERPS)

- Existing equipment relocation – consider if space is required for relocation of existing equipment

C-6 Narrow recommended viable site(s) based on considerations.

- Visual tower site evaluation and validation study: (use recommended or equivalent process below)
- Visually validate Tower cab vantage point Height Options
- Perform physical site survey
- Utilize vertical man-lift and accurate GPS on proposed site location/cab vantage point
- Film 360-degree video from tower cab vantage point
- Validate control points
- Consider/evaluate alternate vantage points/elevations

C-7 Re-Evaluate and Rank viable tower sites.

- Assess visual vantage point study results
- Consider optimal visual vantage point
- Consider operational requirements

C-8 Prepare Final Report (forward to planner).

- Summary of viable tower sites
- Plan to resolve visual obstructions
- Maps, flight paths, and other relevant data
- Pros/Cons for viable sites
- Recommended site selection

C-9 Final Site Selection.

- Conduct meeting with selecting authority
- Review final study/recommendations

C-10 Begin formal site approval process.

- See Site Selection and Approval Process in Chapter 2.

C-11 Prepare activity 1391 (use worst case height).

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

This UFC provides criteria for new and renovated C5ISR facilities to adopt and align industry best practices for critical facility redundancy and Resilience with the Core UFCs and other DoD criteria for data centers. Industry best practices such as Uptime Institute's *Data Center Site Infrastructure Tier Standard; Topology*, ANSI/TIA-942-B *Telecommunications Infrastructure Standard for Data Centers*, and ANSI/BICSI 002 *Data Center Design and Implementation Best Practices* provide multiple paths to achieve a redundant and resilient facility. These best practices do not always align with the Core UFCs or provide a complete set of criteria to allow for prescriptive designs that can be executed with a degree of commonality across the DoD.

The planners, designers, and Functional Authorities must use this UFC in conjunction with service-specific requirements for planning to develop the program for the facility. The planning and design process must include development of the sponsor and user operational requirements statement and technical description of the infrastructure required to support the mission. Refer to Paragraph 2-3 for additional requirements for developing the Mission Engineering Systems Execution Plan (MESEP).

1-2 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC) provides requirements for evaluating, planning, programming, and designing new construction and renovations of existing Command, Control, Computers, Communications, Cyber-Defense, Intelligence, Surveillance, and Reconnaissance (C5ISR) Facilities. This UFC provides prescriptive criteria to achieve the required redundancy and Resilience for C5ISR facilities.

1-3 APPLICABILITY.

This UFC follows the same applicability as UFC 1-200-01, paragraph 1-3 Applicability for C5ISR facilities.

1-3.1 Facility Types.

This UFC applies to the following DoD facility types and provides prescriptive criteria for the facility to meet the required reliability and availability:

- DoD Real Property Categorization System (RPCS) Basic Category Code 131: Communications Buildings
- DoD RPCS Facility Analysis Category (FAC) Code 1444: Miscellaneous Operations Support Buildings with C5ISR missions
- DoD RPCS FAC Code 1452: Missile Guidance Facility
- DoD RPCS FAC Code 6104: Automated Data Processing Center

Refer to the DoDI 4165.03 RPCS for cross reference between the three-digit DoD Basic Category Code, four-digit FAC Code, and the five- or six-digit Military Department Category Codes.

1-3.2 Users of this Document.

1-3.2.1 Planning/Programming Personnel.

Planning and programming personnel must use this UFC in conjunction with the applicable Service-specific governing document for pre-design planning or to assess the extent of improvements required in an existing facility to achieve the standard established herein.

1-3.2.2 Assessment of Existing Facilities.

Use UFC 3-520-02 to assess existing facilities' reliability and availability.

1-3.2.3 Design Services.

Professional architects, engineers, and interior designers must provide design services under the direction of the individual design agencies and this UFC.

1-3.2.4 Service-specific Users and Distribution of Responsibilities.

When Service criteria vary from standard criteria, it is noted in the text as a "Service Exception" or a "Service-specific" criteria. Since numerous and different program offices and functions may be housed in C5ISR Facilities, refer to the appropriate overseeing program office for the specific users and distribution of responsibilities to be housed in the facility. For more general planning questions, refer to the following Service-specific governing documents:

- Army — AR 405-70, IMCOM Space Planning And Criteria Manual
- Navy and Marine Corps — FC 2-000-05N
- Air Force — DAFMAN 32-1084

1-4 FUNCTIONAL AUTHORITIES.

Each facility user or service must appoint a Component Technical Representative (CTR). The CTR represents the project sponsor or customers and exercises authority to establish project requirements on behalf of the user or facility owner as described in UFC 1-200-01. The CTR must identify additional criteria above these requirements during the planning process and MESEP development.

Where Sensitive Compartmented Information Facilities (SCIFs) and Special Access Program Facilities (SAPFs) are included in the C5ISR facility space program, the planning, design, and construction teams must work closely with the supported command, designated Site Security Manager (SSM), and the Certified TEMPEST Technical Authority (CTTA) to determine the requirements for each SCIF. Refer to UFC 4-010-05 for additional requirements.

1-4.1 Planning Process and Facility Grading.

All C5ISR facilities must be at least Grade 3 (concurrently maintainable facility) and can be elevated to Grade 4 (fault-tolerant facility) or lowered to Grade 2 (Redundant Component) based on the mission. During the planning/1391 development phase, the CTR must validate the facility Grade. Justification for facility grades other than Grade 3 must be captured in the planning documents to pass along to the designers. Justification for other than Grade 3 is a service- and mission-specific determination. DoD IEA DC RA requires DoD Core Data Centers (CDCs) to target ANSI/TIA 942-B III Data Center requirements for availability which is equivalent to Grade 3 in this UFC. Refer to DoD IEA DC RA for requirements for other types of DoD Data Centers such as Component Enterprise Data Centers (CEDCs), Installation Processing Nodes (IPNs), Special Purpose Processing Nodes (SPPNs), Installation Services Node (ISN), Geographically Separated Unit (GSU), and Tactical Processing Nodes (TPNs). Refer to Paragraph 2-2 for description of Facility Grading.

Table 1-1 Grade Criteria Based on DoD IEA DC RA

	Data Centers					Other Nodes	
	CDC	CEDC	IPN	SPPN	TPN	ISN	GSU
Grade 1[1]	N/A	N/A	N/A	N/A	N/A	N/A	N/A
Grade 2	N/A	N/A	●[2]	●[2]	N/A	●[2]	●[2]
Grade 3	●	●	●	●	●	●	N/A
Grade 4	●	●	●	●	●	●	N/A

Notes:
1. Grade 1 is not acceptable for any DoD Communication Facility
2. Grade 2 is acceptable as minimum with exception.
N/A = Not Applicable

1-5 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-6 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-7 INFORMATION SECURITY.

Where SCIFs and SAPFs are included in the C5ISR facility space program, refer to UFC 4-010-05 for planning, design, and construction requirements. In accordance with ICS 705-1, the designated SSM must develop a Construction Security Plan (CSP). Construction plans and all related documents must be handled and protected following the CSP.

1-8 GLOSSARY.

APPENDIX B contains acronyms, abbreviations, and terms.

1-9 REFERENCES.

APPENDIX C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 PLANNING AND LAYOUT

2-1 RESILIENCE AND REDUNDANCY.

The continued operation of the facility is contingent upon the systems that maintain the operations. Systems must be reliable and provide both Resilience and redundancy. Refer to Table 1-1 for Grading criteria. C5ISR facilities are to have a minimum facility Grade of 3. Facilities that can operate at a decreased availability and reliability may be designed to have an infrastructure Grading of 2. Facilities that require increased mission availability and reliability may be designed to have an infrastructure Grading of 4. The decision to design a facility for Grade 2 or 4 must be made during the planning/DD1391 development phase. Data Center Infrastructure ratings are driven by the Resilience and redundancy of the systems as defined by Appendix A-2. Refer to UFC 3-520-02 for further definition and descriptions of Resilience.

2-1.1 Resilience.

Systems must be able to continue to support critical equipment in the event of unforeseen circumstances. System Resilience includes maintainability, survivability, and adaptability. Conceptually straightforward systems are easier to operate and maintain. Consider proximity to skilled labor and replacement parts. Systems must be designed to survive natural disasters and other unforeseen circumstances. Systems must be designed for the appropriate risk category to withstand seismic events and wind loads from storms common to their location. Design must comply with the antiterrorism requirements and consider other physical security preventive measures. Identify any other facility requirements with the mission owner, including but not limited to Chemical, Biological, Radiological, Nuclear, and Explosives, or electromagnetic shielding during the planning/DD1391 development phase.

Resilient systems provide an ability to adapt or recover from an event quickly. Work with mission owner engineering and maintenance personnel during the planning/DD1391 development and design process to incorporate resilient features. Resilient features may require higher first cost and increased maintenance. Carefully weigh and discuss resilient features, understanding that no facility can be designed for all unforeseen events.

2-1.2 Redundancy.

Redundancy in a facility is the ability to have multiple paths of system operation allowing for a component or components to be inoperable, while maintaining system function. For mission critical systems, it is important for the mechanical & electrical systems to allow facility operators to maintain equipment or replace faulty equipment while maintaining the mission operations with minimal or no downtime. Both mechanical and electrical can be configured with multiple redundant system architectures ranging from simplistic to more complex. More complex systems feature more components and equipment and may be less reliable. Simpler systems often feature fewer components and less equipment but may suffer from the ability to provide adequate support paths.

See mechanical and electrical discussions of redundancy in Chapter 3 for further discussion. Redundancy must focus on providing highly reliable operations.

System redundancy must be outlined during the planning/DD1391 development phase. Redundancy requirements carry a significant cost. If costs are not accounted for in the development phase, the project cost may be significantly larger than the enacted DD1391 cost.

2-2 FACILITY MISSION CLASSIFICATION (GRADING).

Command, Control, Communications, Computers, Cyber, Intelligence, Surveillance, and Reconnaissance (C5ISR) facilities are mission critical facilities for multiple branches of the Department of Defense. They support the reception, processing, distribution, and/or transmission of classified and unclassified voice, data, and video communications. Refer to the individual services applicable policies and regulations for space types within these facilities based on their Military Department Category Code. Due to the redundancy and Resilience requirements for the C5ISR missions, non-mission space and users should be minimized and limited to the space and users required to execute the C5ISR mission. This requirement to limit space types and users in the C5ISR facility is to reduce risk to the mission (outside and insider threats), facility construction, and facility maintenance costs. The CTR identifies any spaces that must be part of the facility, but do not have the highest level of mission criticality. The CTR can allow these spaces to have a lower infrastructure Grade than the rest of the C5ISR facility.

All C5ISR facilities must be at least Grade 3. Facilities that can operate at a decreased availability and reliability may be designed to have an infrastructure Grading of 2. Facilities that require increased mission availability and reliability may be designed to have an infrastructure Grading of 4. The decision to design a facility for Grade 2 or 4 must be made during the planning/DD1391 development phase. During the planning phase, the CTR must validate the facility Grade. Grades are defined as the following:

2-2.1 Grade 1.

Not applicable to C5ISR facilities. A facility that has no redundant capacity components and no redundant distribution pathways. Maintenance or failures result in facility down time. For cross reference, this Grade 1 definition is a DoD specific definition that is similar in scope to Uptime Institute’s Tier I Data Center, ANSI/TIA-942-B I Data Center, and ANSI/BICSI 002 Class F1.

2-2.2 Grade 2.

A facility that contains single path(s) to critical loads while having some component redundancy. Component redundancy includes added equipment to exceed N requirements but not system level redundancy. This type of system would be vulnerable to component level faults with no added path around failures. It is possible to have planned component level maintenance but only on those components with the added redundancy. In most cases, maintenance or failures would cause downtime to the critical loads supporting the mission. For cross reference, this Grade 2 definition is a DoD specific definition that is similar in scope to Uptime Institute's Tier II Data Center Topology, ANSI/TIA-942-B II Data Center, and ANSI/BICSI 002 Class F2.

2-2.3 Grade 3.

A concurrently maintainable facility with redundant components to service critical operations. The facility must maintain operations for any scheduled maintenance routine without loss in availability. Major features of these facilities include mechanical and electrical systems with N+1 design architectures at a minimum. These architectures may be 50 percent higher in cost compared to a similar-sized facility with no redundancy. For cross reference, this Grade 3 definition is a DoD specific definition that is similar in scope to Uptime Institute's Tier III Data Center Topology, ANSI/TIA-942-B III Data Center, and ANSI/BICSI 002 Class F3.

2-2.4 Grade 4.

A fault-tolerant facility with independent systems that provide redundant paths to critical operations of the facility and automatic response to faults. Equipment associated with redundant paths are physically isolated to prevent catastrophic events from impacting the operations. This facility can maintain availability during a single component, system, or infrastructure failure by initiating an automatic sequence of operations. It may suffer from loss of operations if a component fails during a scheduled maintenance event. Major features of these facilities include mechanical and electrical systems with 2N design architectures at a minimum. These architectures may cost 100-300 percent more than a similar-sized facility with no redundancy. Cost will increase significantly with additional full capacity (N) redundant paths. For cross reference, this Grade 4 definition is a DoD specific definition that is similar in scope to Uptime Institute's Tier IV Data Center Topology, ANSI/TIA-942-B IV Data Center, and ANSI/BICSI 002 Class F4.

2-3 ENGINEERING SYSTEMS GRADING CHECKLIST.

The following checklist is adopted from ANSI/TIA-942-B, Annex F and aligned to DoD-specific requirements. Discipline designations reflect ANSI/TIA-942-B, Annex F and do not necessarily align with the discipline alignments of Chapter 3.

Engineering Systems Grading Checklist			
	Grade 2	**Grade 3**	**Grade 4**
TELECOMMUNICATIONS			
General			
Cabling, racks, cabinets, & pathways meet TIA specs.	IAW UFC 3-580-01	IAW UFC 3-580-01	IAW UFC 3-580-01
Racks & Cabinets	IAW UFC 3-580-01	IAW UFC 3-580-01	IAW UFC 3-580-01
Diversely routed access provider entrances and maintenance holes with minimum 20 m separation	Required	Required	Required
Redundant access provider services – multiple access providers, central offices, access provider rights-of-way	Not Required	Required	Required
Redundant Entrance Room	Not Required	Required	Required
Redundant Distribution Area	Not Required	Not Required	Optional
Redundant Backbone Pathways	Not Required	Required	Required
Redundant Horizontal Cabling	Not Required	Not Required	Optional
Routers and switches have redundant hot-swappable power supplies and processors	Required	Required	Required
Multiple routers and switches for redundancy	Not Required	Required	Required

	Grade 2	Grade 3	Grade 4
Patch panels, outlets, and cabling to be labeled per ANSI/TIA-606-D. Cabinets and racks to be labeled on front and rear.	Required	Required	Required
Patch cords and jumpers to be labeled on both ends with the name of the connection at both ends of the cable	Required	Required	Required
Patch panel and patch cable documentation compliant with ANSI/TIA-606-D.	Not Required	Required	Required
ARCHITECTURAL			
Parking			
Separate visitor and employee parking areas	IAW UFC 3-201-01	IAW UFC 3-201-01	IAW UFC 3-201-01
Separate from loading docks	IAW UFC 3-201-01	IAW UFC 3-201-01	IAW UFC 3-201-01
Proximity of visitor parking to data center perimeter building walls	IAW UFC 4-020-01	IAW UFC 4-020-01	IAW UFC 4-020-01
Multi-tenant occupancy within building	IAW UFC 4-020-01	IAW UFC 4-020-01	IAW UFC 4-020-01

	Grade 2	Grade 3	Grade 4
Fire Resistive Requirements			
Exterior bearing walls	IAW UFC 1-200-01. Minimum Type II construction.	IAW UFC 1-200-01. Minimum Type II construction.	IAW UFC 1-200-01. Minimum Type II construction.
Interior bearing walls	IAW UFC 1-200-01. Minimum Type II construction.	IAW UFC 1-200-01. Minimum Type II construction.	IAW UFC 1-200-01. Minimum Type II construction.
Exterior nonbearing walls	IAW UFC 1-200-01. Minimum Type II construction.	IAW UFC 1-200-01. Minimum Type II construction.	IAW UFC 1-200-01. Minimum Type II construction.
Structural frame	IAW UFC 1-200-01. Minimum Type II construction.	IAW UFC 1-200-01. Minimum Type II construction.	IAW UFC 1-200-01. Minimum Type II construction.

Output Power Distribution	Distribution equipment incorporating removable circuit breakers. For equipment main circuit breakers larger than 225 amps provide adjustable long time, short time and instantaneous functions with provision to turn off instantaneous function.	Distribution equipment incorporating removable circuit breakers. For equipment main circuit breakers larger than 225 amps provide adjustable long time, short time and instantaneous functions with provision to turn off instantaneous function.	Distribution equipment incorporating removable circuit breakers. For equipment main circuit breakers larger than 225 amps provide adjustable long time, short time and instantaneous functions with provision to turn off instantaneous function.
Dedicated Battery String for each module	Single or common string for multiple modules modular UPS. Dedicated string for standalone modules	Required	Required
Battery Type	IAW UFC 3-520-05	IAW UFC 3-520-05	IAW UFC 3-520-05
Battery minimum backup time with design load at end of battery life	IAW with MESEP.	IAW with MESEP.	IAW with MESEP.
Battery Monitoring System	String level by UPS system	String level by UPS system	Centralized automated system to check each cell for voltage and impedance or resistance
Power Distribution Unit			
Transformer	Harmonic cancelling, high efficiency	Harmonic cancelling, high efficiency	Harmonic cancelling, high efficiency
Surge Suppression	Required	Required	Required

	Grade 2	Grade 3	Grade 4
Static Transfer Switch (STS)			
Over-current Device	Not Required	Circuit Breaker	Circuit Breaker
Maintenance Bypass Procedure	Not Required	Manual guided with mechanical interlock	Automatic operation
Grounding			
Lightning protection system	Required	Required	Required
Lightning fixtures neutral isolated from service entrance derived from lighting transformer for ground fault isolation	IAW with UFC 3-520-01	IAW with UFC 3-520-01	IAW with UFC 3-520-01
Data center grounding infrastructure in computer room as required by ANSI/TIA-607-D	As required by ANSI/TIA-607-D	IAW MIL-STD-188-124B	IAW MIL-STD-188-124B

	Grade 2	Grade 3	Grade 4
Computer Room Emergency Power Off (EPO) Systems			
Installation	Army and Navy: Provide manual means for electronic equipment EPO as permitted by UFC 3-600-01. Air Force: Automatic EPO is permitted upon sprinkler water flow as guided by TSFPEWG G 3-600-01.01-18. Where provided, provide IAW with NEC 645. A minimum circuit reliability of Performance Level d (PLd) in accordance with ANSI B11.26.	Army and Navy: Provide manual means for electronic equipment EPO as permitted by UFC 3-600-01. Air Force: Automatic EPO is permitted upon sprinkler water flow as guided by TSFPEWG G 3-600-01.01-18. Where provided, provide IAW with NEC 645. A minimum circuit reliability of Performance Level d (PLd) in accordance with ANSI B11.26.	Army and Navy: Provide manual means for electronic equipment EPO as permitted by UFC 3-600-01. Air Force: Automatic EPO is permitted upon sprinkler water flow as guided by TSFPEWG G 3-600-01.01-18. Where provided, provide IAW with NEC 645. A minimum circuit reliability of Performance Level d (PLd) in accordance with ANSI B11.26.
Test Mode	Required	Required	Required
Alarm	Required	Required	Required
Abort Switch	As required by the MESEP	As required by the MESEP	As required by the MESEP

	Grade 2	Grade 3	Grade 4
Central Power Monitoring			
Monitored points	Utility, main transformer, UPS, generator, feeder circuit breakers, automatic static transfer switch, PDU, automatic transfer switches. Limited to circuit breakers 800A or greater.	Utility, main transformer, UPS, generator, feeder circuit breakers, automatic static transfer switch, PDU, automatic transfer switches. Limited to circuit breakers 800A or greater.	Utility, main transformer, UPS, generator, feeder circuit breakers, automatic static transfer switch, PDU, automatic transfer switches. Limited to circuit breakers 800A or greater.
Notification Method	Control Room Console	Engineer of the Watch Workstation via Windows based software.	Engineer of the Watch Workstation via Windows based software.
Battery Room			
Separate from UPS/Switchgear Equipment Rooms	Not Required	Required	Required
Individual Battery Strings contained within their own enclosure.	Not Required	Required	Required
Shatterproof Viewing Glass in Battery Room Door	Not Required	Not required	Required
Standby Generator System			
Generator Sizing	Sized for UPS and mechanical system without redundancy	Sized for station load with N+1 distributed redundancy	Sized for total station load with 2N distributed redundancy. N+1 can be considered if 2N utility is provided.
Generator Configuration	N	N+1 or better	2N on redundant busses

	Grade 2	Grade 3	Grade 4
Loadbank			
Installation	Provision for portable	Provision for portable	IAW with MESEP.
Equipment Tested	Generator	Generator, UPS	IAW with MESEP.
Auto Shutdown	Not Required	Automatic upon failure of utility	IAW with MESEP.
UPS Switchgear	Not Required	Not Required	IAW with MESEP.
Permanently Installed	No - Rental	No - Rental	IAW with MESEP.
Testing			
Factory Accepting Testing	Switchboards, Switchgear, UPS and generator systems, generator controls, STS. Primary injection and contact resistance test of all circuit breakers in critical and essential paths, 225 A and higher IAW UFC 3-560-01	Switchboards, Switchgear, UPS and generator systems, generator controls, STS. Primary injection and contact resistance test of all circuit breakers in critical and essential paths, 225 A and higher IAW UFC 3-560-01	Switchboards, Switchgear, UPS and generator systems, generator controls, STS. Site Circuit Breaker Testing	Primary injection and contact resistance test of all circuit breakers in critical and essential paths, 225 A and higher IAW UFC 3-560-01	Primary injection and contact resistance test of all circuit breakers in critical and essential paths, 225 A and higher IAW UFC 3-560-01	Primary injection and contact resistance test of all circuit breakers in critical and essential paths, 225 A and higher IAW UFC 3-560-01
Commissioning	Component level, system level, and integrated system including Black Start testing	Component level, system level, and integrated system including Black Start testing	Component level, system level, and integrated system including Black Start testing

	Grade 2	Grade 3	Grade 4
Equipment Maintenance			
Operation and Maintenance Staff	Onsite Day Shift only. On-call at other times	Onsite 24 hrs M-F, on-call on weekends	Onsite 24/7
Preventative Maintenance	Comprehensive preventative maintenance program to include but not limited to Switchgear, switchboards, generators, ATS, STS, automatic sequence exercises and UPS.	Comprehensive preventative maintenance program to include but not limited to Switchgear, switchboards, generators, ATS, STS, automatic sequence exercises and UPS.	Comprehensive preventative maintenance program to include but not limited to Switchgear, switchboards, generators, ATS, STS, automatic sequence exercises and UPS.
Facility Training Programs	Comprehensive training program for normal operation of equipment	Comprehensive training program for normal and emergency operation of equipment.	Comprehensive training program for normal operation of equipment and manual operation of equipment during emergency operation
MECHANICAL			
General			
Redundancy for mechanical equipment (e.g., air conditioning units, coolers, pumps, cooling towers, condensers)	N+1 redundancy for mechanical equipment. Loss of electrical supply path or water supply (where applicable) could lead to loss of cooling	N+1 redundancy for mechanical equipment. Temporary loss of electrical power will not cause loss of cooling, but may cause temperature to elevate within operational range of critical equipment	2N or N+2 redundancy for mechanical equipment. Extended loss of electrical power will not cause loss of cooling outside operational range of critical equipment

	Grade 2	Grade 3	Grade 4
Routing of water or drain piping not associated with the data center equipment in data center spaces	Not permitted	Not permitted	Not permitted
Positive pressure in computer room and associated spaces relative to outdoors and non-data center spaces	Required	Required	Required
Floor drains in computer room for condensate drain water, humidifier flush water, and sprinkler discharge water	Required	Required	Required
Mechanical systems on standby generator	Required	Required	Required
Preventive Maintenance for critical equipment and sensor calibration	Required	Required	Required

	Grade 2	Grade 3	Grade 4
Water-Cooled System			
Indoor Terminal Air Conditioning Units	One redundant air conditioning unit per critical area	Qty. of AC Units sufficient to maintain critical area during loss of one source of electrical power	Qty. of AC Units sufficient to maintain critical area during loss of one source of electrical power. N+1 redundancy is required following loss of one unit.
Humidity Control for Computer Room	De-humidification/humidification, where applicable, provided	De-humidification/humidification, where applicable, provided	De-humidification/humidification, where applicable, provided
Electrical Service to Mechanical Equipment	Single path of electrical power to AC equipment	Multiple paths of electrical power to AC equipment. Connected in checkerboard fashion for cooling redundancy	Multiple paths of electrical power to AC equipment. Provided with ATS/MTS at each piece of equipment.
Heat Rejection			
Piping System	Single path	Headered parallel piped chilled water/ condenser water system or dedicated cooling piping system to ensure concurrent maintainability	Dual path condenser water system
Chilled Water Piping System	Single path	Dual path ladder loop chilled water system with isolation valves	Dual path chilled water system
Condenser Water Piping System	Single path	Headered parallel piped condenser water system	Dual path condenser water system

	Grade 2	Grade 3	Grade 4
Chilled Water System			
Humidity Control for Computer Room	De-humidification/ humidification, where applicable, provided	De-humidification/ humidification, where applicable, provided	De-humidification/ humidification, where applicable, provided
Electrical Service to Mechanical Equipment	Single path of electrical power to AC equipment	Multiple paths of electrical power to AC equipment	Multiple paths of electrical power to AC equipment
Air-Cooled System			
Electrical Service to Mechanical Equipment	Single path of electrical power to AC equipment	Multiple paths of electrical power to AC equipment	Multiple paths of electrical power to AC equipment
Humidity Control for Computer Room	De-humidification/ humidification, where applicable, provided	De-humidification/ humidification, where applicable, provided	De-humidification/ humidification, where applicable, provided
HVAC Control System			
HVAC Control System	Control system failure will not interrupt cooling to critical areas	Control system failure will not interrupt cooling to critical areas	Control system failure will not interrupt cooling to critical areas
Power Source to HVAC Control System	Single path of electrical power to HVAC control system	Redundant, UPS electrical power to BMS control	Redundant, UPS electrical power to BMS control
Plumbing (for Water-Cooled Heat Rejection)			
Dual Sources of Make-up Water	Dual sources of water, or one source + on-site storage with a minimum equal to duration of generator fuel supply	Dual sources of water, or one source + on-site storage with a minimum equal to duration of generator fuel supply	Dual sources of water, or one source + on-site storage with a minimum equal to duration of generator fuel supply
Points of Connection to Condenser Water System	Single point of connection	Two points of connection	Two points of connection

	Grade 2	Grade 3	Grade 4
Fuel Oil System			
Bulk Storage Tanks	Single storage tanks	Multiple storage tanks	Multiple storage tanks
Storage Tank Pumps and Piping	Multiple pumps, single supply pipes, redundant power for fuel control panel.	Multiple pumps, multiple supply pipes, redundant power for fuel control panel.	Multiple pumps, multiple supply pipes, redundant power for fuel control panel.
Fire Suppression			
Fire detection system	Required	Required	Required
Fire sprinkler system	Wet-pipe for Army and Navy. Preaction allowed in certain instances for Air Force per TSFPEWG G 3-600-01.01-18	Wet-pipe for Army and Navy. Preaction allowed in certain instances for Air Force per TSFPEWG G 3-600-01.01-18	Wet-pipe for Army and Navy. Preaction allowed in certain instances for Air Force per TSFPEWG G 3-600-01.01-18
Gaseous suppression system	Clean agent required.	Clean agent required.	Clean agent required.
Early Warning Smoke Detection System	Required	Required	Required
Water Leak Detection System	Required	Required	Required

2-4 MISSION ENGINEERING SYSTEMS EXECUTION PLAN (MESEP).

The MESEP translates the sponsor and user operational requirement statement into a technical description of command, control, communications and intelligence and IT systems and facility infrastructure required to provide the required command, control, communications, and intelligence mission capability. The MESEP must include mission-specific engineering and architecture requirements. The MESEP must include the space planning documents and the electronic equipment engineering requirements document. The requirements of the space planning documents are outlined in the applicable Service-specific governing document.

2-4.1 Minimum MESEP Requirements.

The electronic equipment engineering requirements document must include:

- Technical details related to the station orientation or layout
- Telecommunications equipment rack layouts and rack counts
- Power density per rack
- Network list
- Network Security Requirements (Black/Red/Special Red)
- Preliminary electrical distribution and sizing
- Preliminary mechanical system concept and sizing
- Preliminary fire protection systems (fire alarm, detection, suppression) concepts
- Facility physical security requirements
- Facility cybersecurity requirements
- Systems to be Commissioned.

Rack layouts must include every space that includes telecommunications racks or cabinets. Power density per rack must be provided in a kW per rack unit. The network list must be complete and thorough, giving thought to future networks. Network security must be provided, and verbiage aligned with CNSSAM TEMPEST 1-13. The preliminary mechanical plan is anticipated to assist the Architecture/Engineering (A/E) team in designing the mechanical system. The design process must determine the final mechanical and electrical systems, but it is important to coordinate the electronic equipment engineer’s expectations before design begins. The facility security requirements must be coordinated with the mission and security assessment provided in accordance with UFC 4-020-01. Cybersecurity requirements must be coordinated with mission requirements. At a minimum, include the required C-I-A ratings. This document must be completed during the planning/DD1391 development phase or preliminary project development process to capture required funding.

Navy Facilities: This document is equivalent to the Base Electronic System Engineering Plan (BESEP) for Navy projects, refer to OPNAVINST 11010.20J.

2-5 SITE CONSIDERATIONS.

The primary consideration in selecting a site is its technical adequacy for meeting performance objectives. Generally, the primary considerations are maximum signal-to-noise ratios at the receivers and maximum effective power radiated in the desired direction from the transmitters. Additional considerations include suitability for construction at a reasonable cost, link requirements between components of the communication station, land costs, and logistic support requirements. Other site-specific factors for consideration are the availability of utilities, climate, foundation stability, survivability, physical security, and expansion potential. Although other factors enter into the selection of a site, compromises for the sake of economy or logistics convenience must not interfere with performance.

2-5.1 Relationship to Design.

The designer does not select the site, but the considerations leading to its selection must be understood and incorporated into the design. The resulting findings must be incorporated into the final design for the project.

Navy Facilities: Before the designer begins work, the Field Technical Authority of Naval Information Warfare Systems Command (COMNAVWARSYSCOM) conducts a site selection survey and an Electromagnetic Compatibility (EMC) evaluation as part of the preparation of the MESEP.

2-5.2 Site Selection Survey and Risk Assessment.

Perform a site selection survey and risk analysis to determine the suitability of a site.

2-5.3 Natural and Man-Made Site Factors and Constraints.

Do not select project sites with the following site factors and constraints:

- Sites within 5 miles (8.1 km) of a commercial airport or the aircraft takeoff and landing paths.
- Sites within ¼ mile (0.4 km) of a chemical plant, landfill, river, coastline, or dam.
- Sites within one mile (1.6 km) of a nuclear, munitions, or defense plant.

Where feasible, avoid project locations with the following site factors and constraints during the site selection process:

- Sites near a geologic fault, on a hill subject to slide risk, or downstream from a dam or water tower.
- Sites that are within 300 feet (91.5 m) of the 500-year flood hazard area or less than 10 feet (3.1 m) above the highest known flood level.
- Sites within current or future flood hazard areas as defined by UFC 3-201-01. Unless otherwise stipulated in project-specific guidance provided by the using agency or Authority Having Jurisdiction (AHJ), assume that the

C5ISR facility is classified as Flood Design Class 4 (high risk, essential facilities).

- Sites with wetlands and protected habitats.
- Sites with unstable geotechnical conditions, such as expansive soils, subsurface contamination, or potential for sinkholes.
- Sites adjacent to properties with the potential for any development that could interfere with facility operations.
- Sites that may be impacted by vibrations from railroads or that may have access restrictions due to railroad crossings.

Refer to Appendix A-3 – Data Center Facility Grading Requirements for additional site factors based on the facility grade.

2-5.4 Site Accessibility and Infrastructure.

Consider the following site accessibility and infrastructure factors during the site selection process:

- Availability of electrical utility capacity at the site. Electrical utility capacity must be available at the project site to meet the facility's current and projected future needs. Coordinate with the Electrical Engineer to determine the project-specific electrical demands and projected future needs.
- Availability and economics of redundant utility feeders from separate utility substations.
- Availability and economics of redundant telecommunications pathways from separate telecommunications providers.
- Accessibility of the site from major roadway infrastructure. Where feasible, select a site with multiple access roads to the facility from existing major arterial roadways.
- The site's proximity to emergency services such as hospitals, fire stations, and police stations.

2-5.5 Electromagnetic Compatibility (EMC) Evaluation.

Any factor that prevents or degrades the reception of signals also degrades the ability of the site to perform its mission. Locate the receiving and direction-finding site where signal reception is known to be good. All pertinent information must be outlined in the MESEP.

2-5.6 Isolation.

Optimum radio communications depend largely on the site's isolation from sources of interference and the proper dispersion of structures within the site. Minimum separation distances for electromagnetic interference protection of receiver sites are provided in Table 2-1. Tabulated sources interference applies to Direction Finder (DF) stations of any frequency. Specific requirements for each project, including variations required by local conditions, are developed in the MESEP.

Table 2-1 Minimum Separation Distances for Receiver Sites

Facility	Source of Interference	Minimum Distance
Radio Receiver Station	High-power transmitter stations: Very low frequency	25 miles (40 km)
	Low frequency/high frequency	15 miles (24 km)
	Other transmitter stations not under DoD control	5 miles (8 km)
	Airfields and guide paths: general communications transmitting	5 miles (8 km)
	Airfields and guide paths: aeronautical receiving at air stations	1,500 feet (457 m)
	Teletype and other electromechanical systems installed in shielded rooms or level signaling and keying modified	No requirement
	Teletype and other electromechanical systems installed in unshielded rooms or high level signaling and keying operation: Large installation (communication center)	2 miles (3.2 km) from nearest antenna
	Teletype and other electromechanical systems installed in unshielded rooms or high signaling and keying operation: Small installation (one to six instruments)	200 feet (61 m) from nearest antenna
	Main highways	3,000 feet (914 m)
	High-tension overhead power-lines-receiver station feeders	1,000 feet (305 m) from nearest antenna
	Habitable areas (beyond limits of restriction)	1 mile (1.6 km)
	Areas capable of industrialization (beyond limits of restriction) – Light industry	3 miles (4.8 km)
	Areas capable of industrialization (beyond limits of restriction) – Heavy industry	5 miles (8 km)
	Radar installation	1,500 feet (457 m)
Radio Transmitter Stations	Airfield and glide paths: general communications transmitting	3 miles (8 km)
	Airfields and glide paths: aerological transmitting at air stations	1,500 feet (457 m)
	Main highways	1,000 feet (305 m)
	High-tension overhead power lines	1,000 feet (305 m) from nearest antenna

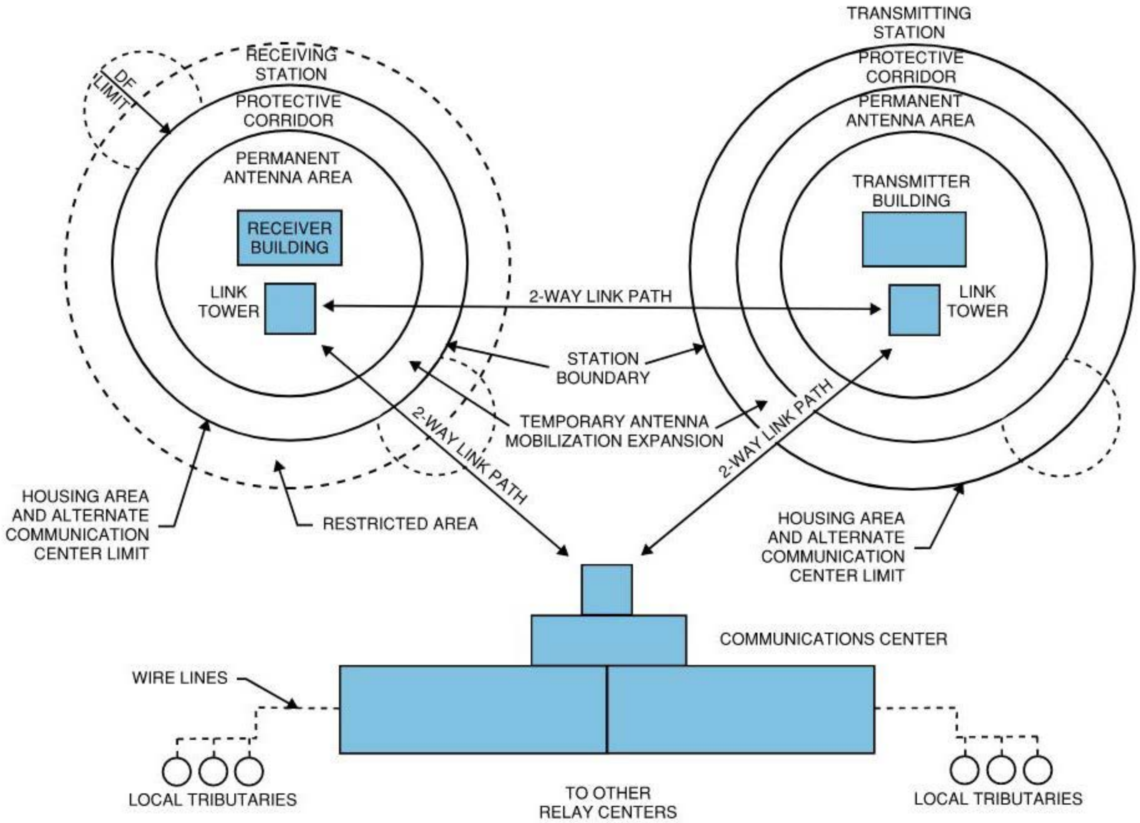
Facility	Source of Interference	Minimum Distance
Direction Finder (DF) Stations (other than Wullenweber type)	Elevated horizontal conductors	Must not subtend a vertical angle exceeding 3° at base of DF antenna
	Railroads	1/4 mile (0.4 km) from antenna
	Rivers and streams	No effect
	Major radio transmitter stations	10 miles (16 km)
	Minor or emergency radio transmitter stations	1 mile (1.6 km)
	Housing areas	1,500 feet (457 m) from DF site
Direction Finder (DF) Stations (other than Wullenweber type)	Ambient interference	Less than 3µV/meter throughout desired frequency range
Communications centers and terminal equipment building	Conform to the minimum separations from Receiver Station as given above	
Control Link Facilities	Separation between RF building and antennas	Max distance 300 feet (91 m)
	Separation between RF building and operations building	Max distance 1,500 feet (457 m)

2-5.7 Layout.

Technical details relating to the location and orientation of buildings are provided in the MESEP and furnished to the designer for adaptation to the site. The arrangement of facilities at a communication station varies according to the mission. Consider the functions of each facility in planning the layout. The locations of buildings are determined in relation to the antenna locations.

Site operating buildings, such as transmitter and receiver buildings, and the terminal point of transmission lines as close to the center of the station or antenna field as possible. Locate support buildings near the station boundary. Where radio interference is a problem, locate roads and parking areas to not have traffic interfere with reception at receiver stations. Orient buildings to provide maximum economy in heating and cooling and to keep paving to a minimum. Site the facility such that adjacent roadway traffic does not result in vehicular contact with the facility perimeter security fence or any external component of the mechanical or electrical systems. Figure 2-1 is a schematic representation of a typical major communication station system.

Figure 2-1 Typical Major Communication Station



2-6 BLACK START SYSTEMS CAPABILITIES.

Black Start capability as defined by National Renewable Energy Laboratory:

> *"Black start is the ability of generation to restart parts of the power system to recover from a blackout. This entails isolated power stations being started individually and gradually reconnected to one another to form an interconnected system again. It is used when the grid experiences a blackout and must be restarted from scratch. As such, black start is a critical resource for maintaining the reliability and resilience of the electric power system and is central to system restoration and recovery plans for system operators."*

For C5ISR facilities, this pertains not only to electrical systems but mechanical systems. The building must be able to be disconnected from its main utility power supply and provide independent power to emergency power system controls, mechanical system controls and start standby power systems. This requirement includes standby generators and UPS systems. Quantity and complexity of systems would be dependent on the Grade required by the mission.

This Page Intentionally Left Blank

CHAPTER 3 GENERAL REQUIREMENTS

3-1 PHYSICAL SECURITY AND ANTITERRORISM.

Unless otherwise stipulated in project-specific guidance provided by the using agency or AHJ, assume that the C5ISR facility is an inhabited building in accordance with UFC 4-010-01. For any additional protective design requirements, the installation must establish explicit project-specific Design Basis Threats and Levels of Protection in accordance with UFC 4-020-01.

3-1.1 C5ISR Facilities Enhancements.

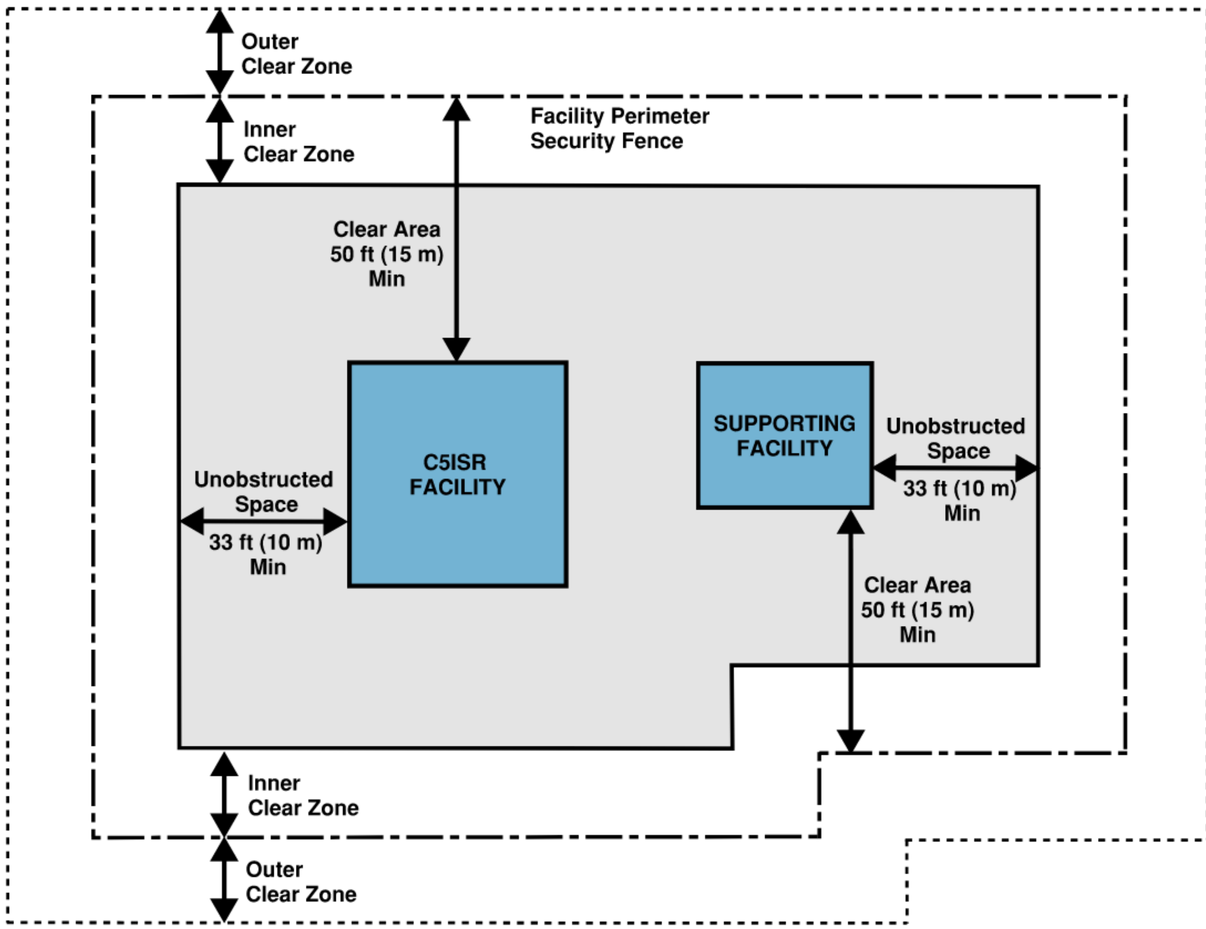
C5ISR facilities contain assets that are critical to the facility’s mission and personnel. The Design Basis Threat analysis must consider the criticality of the facility's assets to the success of the facility’s mission, including equipment located exterior to the facility, such as transformers and generators. When assets such as transformers or generators are in a standalone supporting facility structure, such as a central utility plant, the standalone structure must meet the same standards as the primary facility.

Due to the enhanced security requirements for C5ISR facilities, establish a minimum clear area around the facility and supporting structures. Clear areas must be free of all obstacles, topographical features, and vegetation exceeding 8 in. (200 mm) in height that could impede observations or provide cover and concealment of an aggressor. Provide a minimum of 50 feet (15 m) from the structures to the facility perimeter security fence. Regardless of the installation’s level of security, this requirement provides enhanced detection and assessment of potential threats. This also serves to protect the facility in the case of an insider threat as it establishes a minimum separation between the facility and the remainder of the installation. Provide a minimum unobstructed space of 33 feet (10 m) around the facility in accordance with UFC 4-010-01, Standard 2. Establish requirements for minimum clear zones on the inner and outer perimeter of the security fence in accordance with DoD and Service policy. Refer to Paragraph 3-3.5 for additional information on the perimeter security fence. See Figure 3-1 below.

3-1.2 Secure Facility Requirements.

Facilities with secure requirements must comply with UFC 4-010-05.

Figure 3-1 Facility Clear Zone and Perimeter Fence Requirements



3-2 ARCHITECTURE.

3-2.1

3-2.2 Space Planning.

3-2.2.1 General.

Provide in accordance with MESEP or as required by the individual services applicable policies and regulations.

A computer or equipment room can be defined as any room within the facility where data routing and switching equipment are installed and/or room where cable management is performed to facilitate the mission. When selecting the computer or equipment room site, avoid locations restricted by building components that limit expansion, such as elevators, building cores, outside walls, or other fixed building walls. Provide accessibility, including but not limited to pathways, corridors, and clear door openings for the delivery of large equipment to the equipment room for initial delivery, anticipated service, or replacement (see ANSI/TIA-569-D).

3-2.2.2 Equipment Spaces.

Provide in accordance with MESEP or as required by the individual services applicable policies and regulations.

3-2.2.3 Telecommunications Spaces.

Co-locate telecommunications spaces within the common secure boundaries for the areas being served to the greatest extent practicable.

3-2.3 Basic Construction Criteria.

3-2.3.1 Type of Construction.

Provide minimum Type II Construction for new C5ISR facilities.

Note: The mission can dictate a higher construction type if necessary. Also, depending on location (Outside Continental United States [OCONUS] or expeditionary structures) and for renovations of existing facilities, a lower construction type may be the only option available.

3-2.3.2 Exterior Construction.

3-2.3.2.1 Construction Type.

Facility construction type must be in accordance with Appendix A-3 – Data Center Facility Grading Requirements and the Facility Grade. Reference Section 3-5 STRUCTURAL ENGINEERING for additional requirements.

3-2.3.2.2 Roofs.

Provide Class A roofing as a minimum. Roof penetrations are not permitted in C5ISR mission spaces and telecommunications, mechanical, and electrical rooms that support the C5ISR mission. Antenna doghouses are considered an extension of the facility roof.

Design antenna platforms to be located at a height above the roof to facilitate replacement or repair of roof system without removal of antenna platform structure.

3-2.3.3 Interior Construction.

3-2.3.3.1 Partitions.

At the perimeter of computer rooms and at walls separating computer rooms, provide walls which span from floor slab (true floor) to underside of floor above or roof deck (true ceiling). Coordinate thicknesses to accommodate fully recessed electrical, mechanical and fire safety items (for example, switches, outlets, controllers, fire extinguisher cabinets, piping). Where partitions touch a deck or vertical structural members, provide a joint isolator to prevent the transfer of vibration and structural loads. Design walls and other structural elements for minimum deflection and securely fastened with isolation from all mechanical units and isolation pads or caulking at the top of the partitions.

Coordinate thermal insulation and vapor retarders required for interior partitions with humidity control requirements. Refer to Paragraph 3-6.5.8. Wood stud or other combustible interior framing is prohibited.

3-2.3.3.2 Permanent (Fixed) Flooring.

Provide in accordance with UFC 1-200-01 and UFC 3-101-01 requirements.

3-2.3.3.3 Raised Flooring - Construction.

Raised flooring must conform to the requirements of NFPA 75 and ANSI/TIA-569-D. The flooring system must be a rigid grid bolted grid (stringer) of computer-grade, all steel construction, or as required by the MESEP. Steel or concrete-filled steel flooring panels are acceptable. Galvanized steel components are not permitted. All air supply panels, and similar inserts, must be flush with the flooring surface. Install in accordance with MIL-HDBK-419A, Volumes 1 and 2.

Where under floor cooling is utilized, use floor tile cuts only to accommodate cabinet vents, cooling systems, or route cables from under floor to above floor. In all cases, design floor tile openings to seal, as tight as possible, against the penetrations to minimize loss of under floor air pressure. Use brushes, flaps, or other methods to contain static air pressure. Place floor tile cuts for cabinets under the cabinets or in other locations where the floor tile cut will not create a tripping hazard. Place floor tile cuts for racks either under the vertical cable managers between the racks or under the rack (at the opening between the bottom angles). Generally, placing the floor tile cut under the vertical cable managers is preferable as it allows equipment to be located at the bottom of the rack. Provide access floor tile cuts with edging or grommets along all cut edges. If the edging or grommets are higher than the surface of the access floor, install them so as not to interfere with the placement of racks and cabinets. Do not place the edging or grommets where the racks and cabinets normally contact the surface of the access floor. In the case of down-flow air conditioning (AC) systems where the access flooring is being used as an air distribution plenum, limit floor tile cuts in both size and quantity to ensure proper airflow. In addition, floor tiles with cement cores must have their exposed cut edges sealed to prevent core material from being blown into the computer room. Complete floor installation before mechanical testing and balancing, including all cuts and subsequent sealing.

3-2.3.3.4 Raised Flooring – Depth.

Raised access floor depth must consider future flexibility, with space for future re-configuration and addition of cabling and conduits. The design must ensure ample space is reserved for air distribution if underfloor air distribution is used.

Air Force Facilities: Provide a minimum raised access floor height of 24 in. (610 mm) where underfloor air distribution is utilized.

3-2.3.3.5 Ceilings.

Ceiling design must be consistent with lighting, air conditioning, ventilation, cable tray layout, acoustical treatment, and fire protection requirements. The minimum height of the room is 8.5 feet (2.6 m) from the finished floor to any obstruction, such as sprinklers, lighting fixtures, overhead cable trays, or cameras. Cooling requirements or racks/cabinets taller than 7 feet (2.1 m) may dictate higher ceiling heights. Maintain a minimum of 18 in. (460 mm) vertical and horizontal clearance from sprinklers. In the uninterruptible power supply, transmitter, and similar equipment spaces where heat dissipation is a design factor, a clear height of 10 feet (3 m) is required.

If suspended ceilings are installed, provide clean room tile in all computer rooms. To support the items hanging below the suspended ceiling, provide a structural ceiling grid with a hanging capacity of 25 lb/square foot (1197 N/m^2) and a point load capacity of 132 lb. (60 kg) at a minimum. Structural requirements and systems to be supported off the ceiling grid may require a higher hanging and point load capacity.

3-2.3.3.6 Doors.

For computer rooms and entrance rooms, doors must meet the minimum dimensions of the Engineering Systems Grading Checklist and must be sized to accommodate the largest expected equipment. The door must have no door sills and be hinged to open outward (code permitting). Doors must be fitted with locks and have either no fixed center posts / mullions or be provided with removable center posts / mullions to facilitate access for large equipment.

For computer rooms and entrance rooms, doors and frames must be acoustically treated to provide acoustic separation between computer rooms and program spaces, as required by the MESEP.

3-2.3.3.7 Windows.

No exterior windows are permitted in computer rooms, entrance rooms, equipment rooms, watch floors, or in other spaces defined by the MESEP or applicable security criteria.

3-2.3.3.8 Finishes.

Where wall terminations are to be used for protectors and termination hardware, cover adequate wall space for all anticipated protectors and termination hardware with 3/4 in. (19 mm) fire-retardant-treated plywood. The backboard must be 48 in. (1200 mm) x 96 in. (2400 mm) sheets, mounted vertically, and with the bottom of the plywood mounted 6 in. (150 mm) above finished floor (AFF) with the best side toward the room with markings visible. Plywood must be permanently fastened to the wall using wall anchors utilizing galvanized, zinc-plated, or stainless-steel hardware with a flat head. The finished installation must have a flush appearance with countersunk screw heads to prevent the splitting of the plywood. Drywall screws are not acceptable. Plywood must not be painted, stained, or otherwise finished so that the rating markings remain visible. Finish equipment rooms and related walls with a particulate-free, water-based epoxy paint finish, smooth finish. Before painting, the drywall board must be sealed with a compatible sealing primer.

Completely seal all penetrations in perimeter walls where the wall meets the deck (structure) above, following all security, acoustic, and fire protection requirements. All penetrations in the perimeter walls must be completely sealed, following all security, acoustic, and fire protection requirements.

3-2.3.4 Special Space Requirements.

3-2.3.4.1 Clearances.

Equipment paths from exterior doors and loading areas to computer rooms and equipment spaces must be sized to accommodate the movement of the largest anticipated piece of equipment.

3-2.3.4.2 Acoustical Treatment.

Provide as required by the MESEP.

For Army facilities: Meet the noise abatement requirements of DA PAM 40-501. The noise level must not expose the occupants to sound levels above those shown in MIL-STD-1472, MIL-STD-1474, and DA PAM 40-501. Sound pressure levels within the computer room must not exceed 60 dBA. The facility design and materials must interrelate and optimize the following factors: arrangement and spacing of the engines; acoustical insulation and design of exhaust and intake systems; and acoustical characteristics of the building construction.

3-2.3.4.3 Firestopping.

Provide in accordance with UFC 3-600-01.

3-2.3.4.4 Shielding.

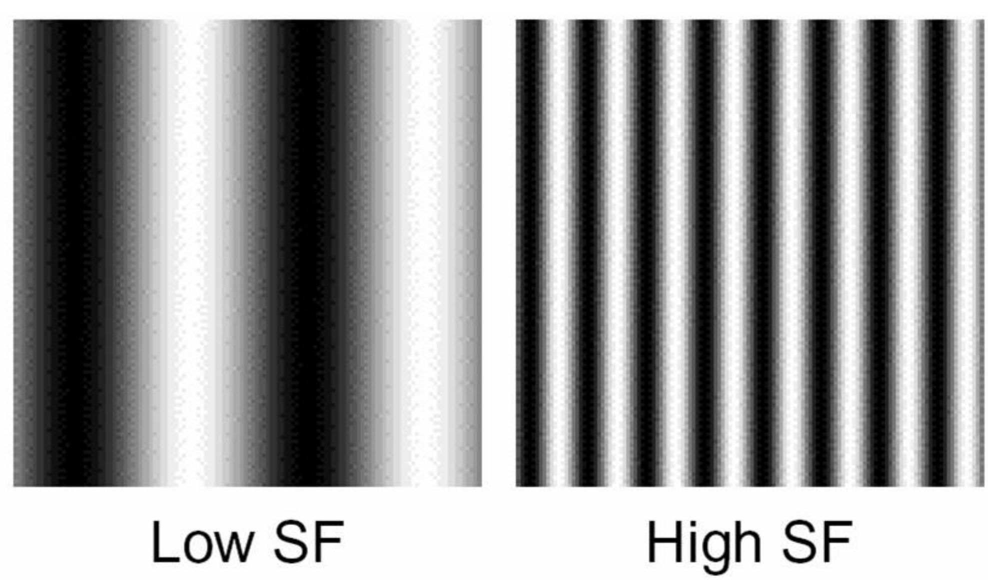
Provide in accordance with TEMPEST Countermeasures Review or as required by the MESEP.

3-2.3.4.5 Windowless Operating Environments (Command and Control / Operations Centers)

C5ISR facilities are mission critical facilities that maintain operations during severe weather and, in worst case, war. Some facilities may be operated and occupied 24 hours a day, 7 days a week. Some facilities support remote wartime operations with operators transitioning from wartime environments (remotely) to a peacetime environment (in person) once they leave the facility. The continuous operation of the facility and transitioning from wartime to peacetime environments makes them a high stress work environment. Many spaces within a C5ISR facility contain sensitive information, and, therefore, may not include windows. This type of environment can be stressful given its claustrophobic nature. Consider providing large frame TVs within the spaces with a continuous, scanning camera feed of the outside. This will allow occupants to maintain their bearings, observe the weather and reduce the stress caused by a confined environment. Visual relief in the form of views of nature may not be possible in the operations area but is highly effective in break areas. Every few hours, analysts need to reset their visual system with long distance viewing (relaxes the eye muscles) ideally with fractal patterns, best provided by views of nature. Visual relaxation is as important as mental relaxation for this high stress visual environment.

For spaces with continuous operation special consideration of interior patterns must be considered to reduce stress. Avoid the use of carpets, art, wall finishes or systems furniture with high spatial frequencies. High spatial frequencies have been associated with exacerbating stress and reducing cognitive functions.

Figure 3-2 Spatial Frequency Example



3-3 CIVIL ENGINEERING.

3-3.1 Siting Procedure.

Developing the optimum site configuration requires civil and electronic equipment engineering coordination. The designer must be provided with preliminary site layouts developed by the electronic system engineering activity showing the site dimensions, schematic building layout, utility requirements, access road layout, direction and number of transmission paths, size, and layout of supporting structures, and unique design considerations for optimum performance of the electronic system.

Provide for future expansion as required by the MESEP. If there are no specific requirements, plan for expansion as a matter of course. Locate support facilities near the boundary of the station to permit expansion without impacting the antenna area. Construction of separate structures or self-contained elements is preferred to expansion by extension of existing facilities.

3-3.2 Site Plan Components.

The designer is responsible for preparing a final site plan using the preliminary site layout prepared by the electronic system engineering activity, information from the site survey, and the criteria herein. In addition to the location of facility components, incorporate the following site components into the final plan as applicable:

- Site boundary and property lines
- Survey base line and benchmarks
- Access roads and parking areas
- Elevation, azimuth, and coordinates for the center of each antenna
- Underground utilities and services
- Existing buildings and facilities

In general, electronic facilities (structures) are similar to other shore facilities, and the criteria in UFC design manuals are applicable.

3-3.3 Surface and Subsurface Drainage.

Utilize surface drainage, such as swales, to the greatest extent possible. Design swales for minimal velocity to avoid erosion to swales or downstream receiving channels. Design storm sewer systems and stormwater management infrastructure based on a storm with a 50-year design frequency. Metallic pipe and reinforced concrete pipe may not be permitted at some sites. Restrictions on pipe material will be indicated in project MESEP. Storm drain piping may not be routed through an antenna ground plane.

Consider water table conditions at the site in the building design. Design the lowest level of the building and any utility piping above the water table. If the building has one or more subgrade floors, additional efforts may be required to protect it from water infiltration or the effects of seasonal variations in the water table.

3-3.4 Vehicular and Pedestrian Circulation.

Provide access roads, parking areas, pedestrian walks, and other traffic areas adjacent to buildings with bituminous concrete (asphalt) or Portland cement concrete surface. Design access roads from the nearest major arterial road to the site having a minimum height clearance of 14 feet (4.3 m). Design access roads to the site to allow for deliveries such as heavy components of the technical building systems, including mobile cranes, in any weather conditions. Avoid using curb and gutter unless necessary based on project or site-specific design constraints.

Provide guardrail where the work area is 4 feet (1.2 m) or more above a lower level.

3-3.5 Site Security Considerations.

Provide a facility layout that is compatible with an overall installation security plan and considers the location of guard posts, patrols, and security response forces; the location and characteristics of intrusion detection systems; facility access control; and natural factors.

External security requirements, in most cases, depend on the internal security measures provided in the facility design and the type of protection required. Normally, external considerations, including building location, orientation, and use of protective barriers and lighting, are developed as part of the facility's security plan and specified in the MESEP. The mode of operation, level of security, and designer's responsibility for particular security elements must be designated in the MESEP.

3-3.5.1 Perimeter Fencing.

Generally, chain-link fencing is used for permanent areas. General-purpose barbed tape and concertina wire are used for temporary installations or where the terrain does not allow the construction of chain-link fencing. The following requirements are the minimum for normal protection:

- Establish clear zones, clear areas, and locate the facility perimeter security fence in accordance with Paragraph 3-1.
- Provide chain-link fence fabric a minimum of 7 feet (1.9 m) high unless project-specific requirements dictate otherwise. Provide a fence topped by a 45-degree outrigger that is 15 to 18 in. (380 to 460 cm) long. Provide three evenly spaced strands of barbed wire strands attached to the outriggers. Provide grounding for all fence fabric and barbed wire strands.

- Protect utility openings, covers, sewers, culverts, tunnels, and other subsurface routes penetrating the fence line.

- Provided the minimum number of gates and perimeter entrances required for safe and efficient operation.

- Where security fencing is adjacent to vehicular travel lanes or parking areas, provide wheel stops, curbs, bollards, or guardrails as required.

- Provide guard shelters where required by the MESEP.

3-3.5.2 Exterior Equipment.

Locate all mechanical equipment, generators, fuel tanks, or other exterior equipment within the perimeter security fence and secure from public access.

3-3.6 Utility Services.

Refer to the MESEP for project-specific restrictions on the use of metallic pipe and reinforced concrete pipe. Refer to Section 3-6.12 for plumbing requirements.

3-4 LANDSCAPE ARCHITECTURE.

Provide landscaping and ground cover only to the extent that they reduce site maintenance. Vegetation must not interfere with antennas and ground mats. Some site areas must be kept free of vegetation. Maintain clear zones free of vegetation on either side of perimeter security fencing in accordance with Paragraph 3-3.1. Consult the electronic system engineering activity for additional restrictions.

Do not provide permanent irrigation for lawn areas or plantings.

3-5 STRUCTURAL ENGINEERING.

3-5.1 Risk Category.

Unless otherwise stipulated in project-specific guidance provided by the using agency or AHJ, assume that the C5ISR facility is a building or other structure having DoD mission-essential command, control, primary communications, data handling, and intelligence functions that are not duplicated at geographically separate locations, as designated by the using agency, and therefore classified as Risk Category IV, as defined by UFC 3-301-01.

3-5.2 Live Loads.

Use a minimum design floor uniform live load of 250 psf (12 kPa). For elevated floors, assume an additional uniform live load of 50 psf (2.4 kPa) minimum to account for the weight of overhead hanging equipment in spaces below. Coordinate with the user to determine if the actual anticipated equipment exceeds these minimum uniform live loads and design the floors accordingly.

3-5.3 Seismic Criteria.

Ensure that non-structural components are laterally braced as required for seismic load stability in accordance with UFC, building code provisions, and as described in this standard. Careful analysis of these requirements must be addressed in the planning/DD1391 development phase. Coordinate additional bracing requirements to avoid interference with items to be installed post construction, such as cabling, conduit raceways, and other infrastructure for electronic equipment.

Assign components required to support and sustain continued operations of the C5ISR mission a component Importance Factor of I_p = 1.5. Refer to UFC 3-301-01 for additional information.

3-5.4 Minimum Concrete Thicknesses.

Provide a minimum concrete thickness of 5 in. (127 mm) for slabs-on-grade. Coordinate minimum concrete thickness with any project security noise reduction requirements. Coordinate minimum concrete thickness with Paragraph 3-7.8 Grounding and Bonding requirements.

For elevated floor construction using a concrete-filled metal deck structure, provide a minimum 4 in. (102 mm) concrete thickness above the flutes of the metal deck to allow equipment anchorage using post-installed anchors.

3-5.5 Raised Flooring Minimum Loading Requirements.

Minimum loading and allowable deflection requirements for raised access flooring are as follows:

- Rolling load (access floor tile): 1,500 lb (680 kg). Local surface deformation 0.02 in. (0.5 mm). Total permanent set 0.04 in. (1 mm).
- Impact Load (access floor tile): 175 lb (80 kg). Drop weight, dropped from 12 in. (305 mm) height on 1 in^2 (645 mm^2) local surface with maximum deformation 0.06 in. (1.5 mm).
- Concentrated Load (access floor tile): 1500 lb (680 kg). Load on 1 in^2 (645 mm^2) point with maximum deflection 0.08 in. (2 mm) anywhere on the panel.
- Uniform Load (access floor system): 250 psf (12 kPa). Load rating of the access floor system, including panels, pedestals, and stringers.

3-5.6 Raised Flooring Seismic Requirements.

Design raised access floors for seismic considerations in accordance with UFC 3-301-01 or UFC 3-301-02 as applicable or ASCE/SEI 7 special access floor requirements, whichever is more stringent. Additionally, perform an in-structure response analysis to compute the coupled response of a raised access floor, then use it to develop response spectra for equipment mounted on the raised access floor. Compute the overturning of equipment mounted on the computer room floor, and if required, provide restraints for Seismic Design Categories C through F. Provide positive mechanical attachments as required to prevent overturning using direct fasteners or adhesive to the substrate. Treat raised access floors as Designated Seismic Systems.

3-6 MECHANICAL ENGINEERING.

All mechanical criteria from UFC 3-401-01 that apply to DoD facilities also apply to C5ISR facilities. Only items specifically applicable to C5ISR facilities are covered in this section.

3-6.1 Outside Design Conditions.

C5ISR spaces must utilize outside design temperature criteria for Specialized Technical Requirements.

3-6.2 Indoor Design Conditions.

C5ISR facilities have spaces with stringent indoor air temperature and humidity requirements.

3-6.2.1 C5ISR Space Temperatures.

C5ISR spaces with data equipment must always comply with ASHRAE Thermal Guidelines for Data Processing Environments. Air temperature and humidity must comply with the “Recommended” requirement. Liquid cooling temperature must comply with Class W17/W27. Heating, Ventilating, and Air-Conditioning (HVAC) systems and controls must account for temperature rise during primary power loss.

Comply with user criteria and MESEP requirements where more stringent.

3-6.2.2 Battery and UPS Space Temperatures.

Temperatures for battery and UPS rooms with batteries must be in accordance with the requirements of UFC 3-520-05.

3-6.2.3 Generator Room Temperatures.

Temperatures for generator rooms must be in accordance with UFC 3-540-01.

3-6.3 Redundancy and Resilience.

Mechanical systems serving C5ISR functions must meet the Facility-required Grade to provide the required level of redundancy and Resilience. Systems that do not serve C5ISR functions are not required to comply with the facilities mission classification.

To increase redundancy in the mechanical plant, use automatic transfer switches (ATS), manual transfer switches (MTS) or static transfer switches (STS) on individual mechanical equipment to provide a dual power path. Dual power feed mechanical equipment is an acceptable solution to reduce the required square footage. An ATS or STS must be provided for Grade 4 facilities to meet the fault tolerant requirements. An MTS is acceptable for Grade 3 facilities.

Air Force Facilities: Manual transfer switches are not allowed.

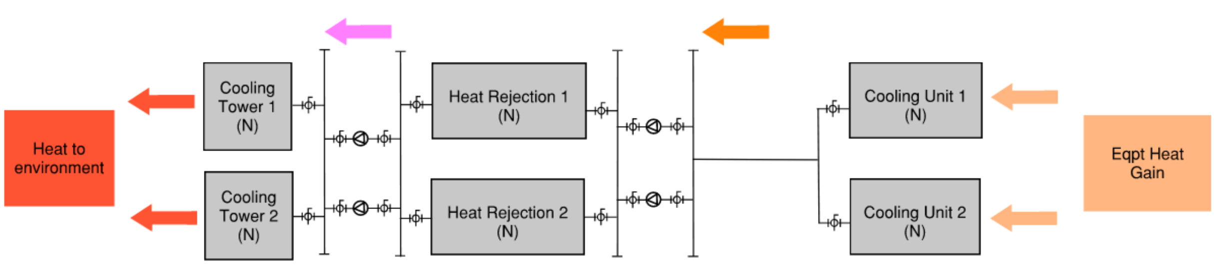
3-6.3.1 Grade 1 Mechanical Systems.

Not applicable.

3-6.3.2 Grade 2 Mechanical Systems.

Grade 2 systems provide critical equipment redundancy. Equipment serving a critical space must feature equipment N+1 redundancy. Redundancy must allow for routine maintenance to any piece of equipment without affecting the critical services being provided with cooling. Refer to Figure 3-3 for a Grade 2 common cooling heat rejection schematic and Figure 3-4 for a Grade 2 dedicated cooling heat rejection schematic. The size of equipment (% of N) can vary, but the system must maintain a minimum of N+1 redundancy. The systems mentioned represent typical cooling approaches but are not an exhaustive list of possible systems. For Grade 2 systems, utilize N+20% redundancy where N is met by five or more components.

Figure 3-3 Grade 2 Common Cooling Heat Rejection Schematic (N+1)



Cooling Tower / Condenser Water (N+1)	Heat Rejection (N+1)	Piping w/ headed pumps*	Cooling Unit (N+1)
Cooling Tower w/ headered pumps	Water Cooled Chiller Plant	Chilled Water	CRAH/Fan Coils
NA	Air Cooled Chiller Plant	Chilled Water	CRAH/Fan Coils
NA	Closed Circuit Cooling Tower	Condenser Water	CRAC/Water Source Heat Pumps
NA	Drycoolers	Cooling Water	CRAC/Water Source Heat Pumps
NA	Drycoolers	Cooling Water	Liquid Cooling

*Figure does not show both supply and return piping for clarity. System requires both supply and return piping.

Availability at Critical Technical Load	
System	Availability
Grade 2 Common Heat Rejection - Water Cooled Chiller (Cooling Tower) w/ CRAH/FCU	0.999999
Grade 2 Common Heat Rejection - Air-Cooled Chiller w/ CRAH/FCU	0.999999
Grade 2 Common Heat Rejection - Evaporatively Cooled w/ CRAC/WSHP	0.999999
Grade 2 Common Heat Rejection - Drycooler w/ CRAC/WSHP	0.999999
Grade 2 Common Heat Rejection - Drycooler w/ Liquid Cooling	0.999999

1. Availability equations are taken from UFC 3-520-02. Calculator utilizes the "block diagram" model.
2. Availability values are taken from IEEE 493-2007, Table 10-4.

2. Availability values are taken from IEEE 493-2007, Table 10-4.

3-6.3.3 Grade 3 Mechanical Systems.

Grade 3 systems are concurrently maintainable. Concurrently maintainable mechanical systems must maintain critical space temperature and humidity at design conditions while allowing for active maintenance of any unit or utility path. Redundancy must enable the isolation of any item of equipment as required for essential maintenance without affecting the services being provided with cooling. Refer to Figure 3-5 for a Grade 3 common cooling heat rejection schematic and Figure 3-6 for a Grade 3 dedicated cooling heat rejection schematic. The size of equipment (% of N) can vary, but the system must maintain a minimum of N+1 redundancy. The systems mentioned represent typical cooling approaches but are not an exhaustive list of possible systems. For Grade 3 systems, utilize N+20% redundancy where N is met by five or more components.

2. Availability values are taken from IEEE 493-2007, Table 10-4.

3-6.3.4 Grade 4 Mechanical Systems.

Grade 4 systems are fault tolerant. Fault-tolerant mechanical systems must maintain critical space temperature and humidity at design conditions while allowing failure of / or service to one electrical switchboard. Redundancy must enable the isolation of any item of equipment as required for essential maintenance or failure without affecting the services being provided with cooling. Refer to Figure 3-7 for a Grade 4 common cooling heat rejection schematic with 2N redundancy, Figure 3-8 for a Grade 4 common cooling heat rejection schematic with N+2 redundancy, Figure 3-9 for a Grade 4 dual path heat rejection schematic, and Figure 3-10 for a Grade 4 dedicated cooling heat rejection schematic. The size of equipment (% of N) can vary, but the system must have a minimum of N+2 redundancy. N+1 redundancy must be maintained if any unit is lost. The systems mentioned represent typical cooling approaches but are not an exhaustive list of possible systems.

For Grade 4 systems with N+2 redundancy, utilize N+40% redundancy where N is met by five or more components.

3-6.4 Air Conditioning Loads.

Equipment heat loads must be established during the planning/DD1391 development process. When a MESEP is available, use it for equipment loads. When a MESEP is not provided, the mission owner must verify, document, and approve electrical equipment loads during design.

3-6.5 HVAC System Design.

HVAC systems selected for C5ISR facilities must consider proximity to service organizations and be maintainable. Equipment requirements must consider the installed environment. Utilize the most life cycle cost effective system considering available utilities, energy consumption, first cost, and maintenance cost over the life of the system. HVAC systems must be capable of meeting the specialized requirements of electronic equipment rooms. Systems must provide air filtration, positive pressurization, and humidity control.

Central utility plants are often used at larger facilities as they are typically more efficient and centralize maintenance. See paragraph 3-6.6 for Central Cooling Equipment. Smaller facilities often utilize packaged/unitary equipment. See paragraph 3-6.7 on Packaged/Unitary Cooling Equipment.

3-6.5.1 Proximity to Service Organizations.

Mechanical equipment must account for facility location and local support resources. Match the level of sophistication with regionally available service personnel expertise and procurement ability. Ensure factory certified service organizations can support the selected systems and equipment to provide regular and emergency service. Organizations must be close to the facility and be able to render service in under 8 hours. Organizations must be capable of obtaining standard replacement parts within 24 hours.

3-6.5.2 Installed Environment.

Mechanical equipment must be configured for the installed environment. Corrosive-prone locations must feature corrosion-resistant materials and coatings in accordance with UFC 1-200-01 and UFC 3-410-01. Equipment in coastal conditions must be rated for wind loads and potential damage from tropical storm wind-borne debris. Equipment in cold environments must be capable of operation in mean extreme winter temperatures and must have features to prevent freezing. Heat rejection equipment must be capable of operating at site specific humidity and dry bulb design temperatures.

3-6.5.3 HVAC System Life Cycle Cost Analysis.

Work with mission owner engineering and service design review engineer to develop three proposed systems. Systems must comply with UFC 3-410-01. Perform Life Cycle Cost Analysis (LCCA) in accordance with UFC 1-200-02 and UFC 3-410-01 of the proposed systems. Utilize system that is life cycle cost effective.

3-6.5.4 Specialized Equipment Room Characteristics.

Equipment rooms typically have high sensible heat gain and require specialized cooling equipment selection. Utilize mechanical equipment capable of operating efficiently with high sensible heat ratios. Also, consider tight temperature and humidity environmental requirements when selecting equipment and controls. Computer Room Air Conditioning Units (CRACs) and Computer Room Air Handling Units (CRAHs) offer a solution, as they are designed to meet stringent equipment room requirements. Units serving electronic equipment rooms must be dedicated to equipment rooms. Units also cannot serve both electronic equipment rooms and non-critical climate cooled rooms, as the sensible heat ratios vary significantly between them.

The use of air-side economizers is not permitted for the primary system serving equipment rooms as they make precise humidity control difficult. Economizers may be allowed for emergency cooling when approved by the mission owner and design authority review engineer.

Air Force Facilities: Economizers for emergency cooling are not allowed.

3-6.5.5 Equipment Room Cooling.

Air distribution and heat management can result in significant energy savings and improved thermal performance of equipment rooms. The design must provide good air distribution across the entire data center or equipment room and must comply with ASHRAE Thermal Guidelines for Data Processing Environments.

Equipment rooms larger than 1000 square feet (92 sm) or with cooling design loads greater than 100kW must be validated using computational fluid dynamics (CFD) modeling. The model must validate all rack inlet temperatures conform with ASHRAE Thermal Guidelines for Data Processing Environments at design load with N capacity components. The model must be submitted for review with the initial design submission or prior to the 50% design completion, whichever is soonest.

3-6.5.5.1 Traditional Equipment Room Cooling Methods.

Below-grade air distribution in the raised access floor and ducted overhead conditioned supply air have traditionally been used. While convenient, both distribution methods have challenges. Unless the equipment is specifically designed to receive raw supply air, avoid the direct connection between the air plenum and the equipment. Instead, supply air to the room through relocatable floor registers and configure equipment to draw tempered air from the room. If overhead distribution is provided, low velocity/low-pressure ductwork is desirable. Systems with overhead and underfloor air distribution air terminal devices must be located to allow the air to reach the area of the loads. When underfloor power distribution is implemented, ensure floor register air flow is not constricted due to power/network cabling. Overhead network and power distribution is preferred when using an underfloor air plenum. When electronic equipment is in a high-bay area with an overhead cable grid network, air outlets must not be located directly above electrical equipment, cabling, or power networks to facilitate good air distribution. Poor air distribution results in thermal hot spots within the space.

Underfloor air distribution with ducted return utilizes traditional underfloor plenum supply air distribution but utilizes a ducted return to eliminate hot spots that develop away from air conditioning units or at high-density racks. This method utilizes cold aisles for rack intake and hot aisles at the discharge of the racks. Locate return inlets over the hot aisles. Air returns must not be located directly above electrical equipment, cabling, or power networks to facilitate good air distribution. The use of containment structures can increase efficiency and thermal performance.

3-6.5.5.2 Alternative Equipment Room Cooling Methods.

Flooded room cool air distribution with rack containment can be used to increase energy efficiency. Flooded rooms utilize a cool air discharge of 60-68°F (15.5-20°C). The equipment room remains cool (65-72°F, [18.3-22.2°C]); air is drawn into racks by server fans which discharge to a hot aisle or directly to the return duct via rack chimneys.

Other cooling strategies, including in-row cooling units and equipment-based cooling, are also used. In-row cooling benefits from dedicated hot and cold aisles and is effective at preventing thermal hot spots caused by uneven rack loading. Equipment or rack-based cooling is gaining more attention due to its ability to remove heat from the source, increasing cooling efficiency and preventing thermal hot spots. Both in-row and equipment-based cooling may result in security concerns if secure networks are present. Secure networks require a physical separation between unsecure and secure networks. The separation requirements for in-row or equipment-based cooling may be overcome by designating the unit control system as a secure network. Secure cooling controls require approval by the mission owner, as the system cannot be tied into a non-secure building Direct Digital Control (DDC) system. All critical controls must be continuously monitored.

3-6.5.5.3 Equipment Room Cooling Coordination.

Rack location must be coordinated with the mission owner, electrical engineer, and telecommunications engineer. Where cold aisles are used, front of racks/cabinets must face each other. The rear of cabinets/racks must face each other to create a hot aisle. Where underfloor supply air is utilized, floor registers/tiles must be installed only in the cold aisles. Utilize blanking plates racks to prevent re-circulation of hot air within racks.

Air Force Facilities: Provide hot or cold aisle containment. Do not duct CRAC/CRAH units; return air chimneys are allowed.

3-6.5.5.4 Clean Agent Fire Suppression Considerations.

Equipment rooms with clean agent systems must be protected with overpressure relief dampers as required and have an exhaust system in accordance with UFC 3-600-01. See Fire Protection and Life Safety Section for smoke exhaust requirements.

3-6.5.6 Air Filtration.

Filter all outside and recirculated air. Equipment providing outside air must have a minimum of Minimum Efficiency Reporting Value (MERV) 8 prefilter with a MERV 13 final filter. Provide equipment room air conditioning units with a minimum of MERV 8 filters. Provide high-performing filters as required by the mission owner or specific equipment requirements. Utilize replaceable media filters. To extend the life of high-performing filters, use prefilters of lower efficiency upstream of higher-efficiency filters. All filter banks must have pressure switches with a dirty filter maintenance alarm when the pressure drop exceeds the maximum recommended loading.

3-6.5.7 Pressurization

Equipment rooms must be slightly positively pressurized relative to the outdoors and surrounding rooms/areas. Positive pressurization limits particulate and moisture infiltration into the equipment room.

3-6.5.8 Humidity Control.

Systems must be capable of maintaining space temperature and humidity. Work closely with the architect during the preliminary design phase to conduct a vapor barrier analysis. The vapor barrier analysis must ensure condensation does not occur in interior partitions or exterior walls.

3-6.5.8.1 Dehumidification.

A Dedicated Outdoor Air System (DOAS) is an acceptable solution to provide filtered dehumidified air to the space in accordance with UFC 3-410-01. Where outside air requirements are not large enough to justify a DOAS, outside air and space latent loads can be met by a dehumidifier controlled by a local humidistat. Do not rely on equipment room cooling units to meet the latent cooling load of outside air. Dehumidification must not rely on full load capacity of equipment as equipment rooms typically operate at part load and are built-out with racks and equipment over several years following construction completion. Avoid reheat where possible and, if required, utilize waste heat.

3-6.5.8.2 Humidification.

Electronic equipment areas require less humidification per thousand British Thermal Units (BTUs) per hour (MBH) of heating than comfort applications. Humidification needs are higher if excessive fresh air is admitted to the space, dehumidification during the cooling process is excessive, or if the humidity ratio of the outside ventilation air is less than the desired humidity ratio. When needed, consider humidifiers mounted integral to the cooling equipment or standalone wall-mounted humidifiers. Humidifiers must have automated controls and report alarms to the building control and automation system. UFC 3-410-01 does not permit atomized water and evaporative humidifiers. Protect domestic water connections to humidifiers with backflow prevention devices.

3-6.6 Central Cooling.

Central cooling is often used at C5ISR facilities. Central cooling equipment has higher efficiencies and centralized maintenance. Since cooling is required year-round, evaluate the life cycle cost effectiveness of condenser heat recovery. Condenser heat recovery can prevent simultaneous heating and cooling, resulting in significant energy savings.

Central cooling plants must include provisions to keep space temperatures within ASHRAE Thermal Guideline “Recommended” requirements for allowable temperature and humidity. Liquid cooling temperature must comply with Class W17/W27. In addition to placing cooling equipment on backup power systems, consider using thermal storage, controls on UPS power, and rapid restart chillers. If space and liquid cooling temperatures cannot be maintained within allowable ranges after primary power is lost and backup power is established, pumps can be placed on the UPS system.

3-6.6.1 Water-Cooled Chiller Plants.

Water-cooled chiller plants often result in the most energy savings. However, water-cooled plants may have a higher overall cost of ownership due to the cost of makeup water, chemical treatment, and replacement cost. Water-cooled plants also require more maintenance. Locate water-cooled chillers and pumps indoors. Consider physical separation of chillers with fire-rated walls to safeguard against the loss of all cooling in the event of a fire in one of the chiller rooms. Chiller rooms must comply with ASHRAE Standard 15 and protective provisions required for Class A2L refrigerants, where used. Chilled water pumps must be headered and match the plant's redundancy scheme. Condenser water pumps must also be headered to allow any pump combination to operate any cooling tower combination. Condenser water cleanliness is critical to the efficiency and reliability of a water-cooled plant. In addition to chemical treatment, a side stream condensing water filter is an acceptable solution to minimize condenser piping and chiller condenser tube fouling. Cooling towers must be specified to conform with NFPA 214 or have a self-extinguishing fill with a flame spread index of 5 or less when tested by ASTM E84.

3-6.6.2 Air-Cooled Chiller Plants.

Air-cooled chiller plants often use more energy than water-cooled plants but often have lower life cycle costs. The cost of makeup water, backup makeup water, reduced maintenance, and replacement can result in air-cooled chiller plants with a lower total cost of ownership than water-cooled plants. Air-cooled chillers are typically located outside, while their pumps can be mounted on the chiller frame or inside a mechanical room. Chilled water pumps must be headered to allow any pump to operate with any chiller. If unit-mounted pumps are used, redundant pumps on each chiller can be used. Redundant pumps cannot share a motor as a shared motor has a single point of failure.

3-6.6.3 Piping and Valves.

Piping must support facility redundancy grade, see Appendix A. Valves on critical Grade 3 and 4 hydronic systems must be installed to allow isolation for maintenance or repairs without disrupting critical loads. Valving must allow isolation of any cooling component.

3-6.7 Packaged/Unitary Cooling.

Packaged/unitary cooling is often used at smaller C5ISR facilities and outlying equipment buildings. Packaged/unitary equipment tends to have lower efficiencies and requires maintenance at the unit. Packaged/unitary equipment includes packaged direct expansion (DX)-cooled floor-mounted or roof-mounted equipment, split system DX, variable refrigerant flow/volume (VRF/VRV), water source heat pumps (WSHPs), and CRACs with a remote condenser or drycooler. Packaged units may have a lower first cost than centralized cooling but are often more expensive over the system's life. Packaged units typically have a shorter service life and a higher overall maintenance burden as they are not centralized. Packaged units are also very dependent on refrigerant and often require factory-trained technicians to maintain refrigerant circuits.

If space temperature cannot be maintained within “Recommended” requirements for temperature range after primary power is lost and backup power is established, unitary equipment can be placed on the UPS system.

3-6.7.1 Packaged/Unitary Design Considerations.

Packaged units can be configured to allow for redundancy and support concurrently maintainable and fault-tolerant configurations. The design must account for dehumidification and part loading, as packaged units may cycle at lower loading and provide inadequate dehumidification.

3-6.8 Controls and Automation Systems.

Mechanical controls and automation systems must be robust and capable of maintaining the equipment room environment within ASHRAE Thermal Guideline “Recommended” temperature and humidity range. Powering the control system from the UPS system allows the system to remain online if main power is lost. Controls must resume programmed operations if power is lost and must be capable of standalone operation if connection to controls is lost.

3-6.8.1 Facility Central Control System.

Central DDC controls systems allow mission owner engineers and maintenance teams to continuously monitor systems from a dedicated engineer watch station. Control systems must report critical and maintenance alarms and be capable of trending data. Work with the mission owner engineering and maintenance team to establish critical control overrides or initiate critical procedures from the watch station. DDC control systems must be in accordance with UFC 3-410-02.

Provide an automated central Power and Environmental Monitoring and Control System (PEMCS). The system must be capable of continuously monitoring the following systems where utilized: utility transformers, main distribution switchboard, switchgear, UPS, batteries, generator, generator fuel tanks, ATS, PDUs, STSs, CRAHs, AHUs, central cooling plant, central heating plant, dampers, fans, and control devices. The system must be capable of providing an external alarm by phone, text, and email. The system must continuously poll using non-proprietary industry standard protocols. Grade 3 PEMCS may utilize a single central processing unit, while Grade 4 PEMCS must have a 2N redundancy.

Army and Navy Facilities: When required by CTR the PEMCS and associated controllers must be on central mission UPS system power, with Grade 4 provided with dual path UPS power.

Air Force Facilities: The PEMCS and associated controllers must be on central mission UPS system power, with Grade 4 provided with dual path UPS power.

3-6.8.2 Cybersecurity.

The controls system must be provided with cybersecurity protections in accordance with UFC 4-010-06. Standalone control networks may be utilized where central DDC controls pose a risk to secure networks. Standalone controls are required to comply with cybersecurity requirements and must be capable of being continuously monitored. Ethernet switches provided in the controls architecture must be an Open Source Interconnection (OSI) layer 2/3 managed switch.

Identify Confidentiality, Integrity, and Availability (C-I-A) rating of controls system during the planning/DD1391 development process.

Air Force Facilities: Controls system must not tie into a non-Classified base wide network.

3-6.8.3 Leak Detection.

Equipment rooms served by hydronic systems must be provided with leak detection. Utilize leak detection at cooling units and floor drains, where provided. Raised Access Floor where utilized, must be provided with leak detection.

3-6.9 UPS/Battery Rooms.

Mechanical systems serving UPS rooms must consider the loss of primary power. Systems must be designed to prevent the temperature in the UPS room from exceeding 104°F (40°C) or manufacturer maximum temperature, whichever is less, when primary power is lost. Mechanical systems serving battery rooms must consider the loss of primary power. Systems must be designed to prevent the temperature in the battery rooms from exceeding UFC 3-520-05 maximum or manufacturer maximum temperature, whichever is less, when primary power is lost. If UPS and/or battery room temperature cannot be maintained within allowable range after primary power is lost and backup power is established, work with CTR to determine which components of the cooling system will be placed on the UPS system.

Army and Navy Facilities: A ventilation fan on UPS power is allowed to serve as a backup system where the outside air temperature and air quality are suitable when acceptable to CTR.

Air Force Facilities: Provide redundant cooling system for UPS rooms. Backup mechanical ventilation of the UPS room is not acceptable.

3-6.10 Physical Security.

Locate critical exterior equipment within the secure perimeter. Facilities with secure requirements must comply with UFC 4-010-05.

3-6.11 Backup Power and Generators.

Mechanical systems serving equipment rooms must be on backup power. Work with the mission owner to identify mechanical equipment and controls that require UPS power.

Design systems supporting generators in accordance with UFC 3-540-01.

3-6.11.1 Fuel Storage and Piping.

Fuel storage systems serving backup power generators must be in accordance with UFC 3-460-01 and meet Environmental Protection Agency (EPA), state, and local environmental requirements.

3-6.11.1.1 Fuel Storage Capacity.

Indoor fuel storage volume must comply with NFPA 30. Grade 2 facilities must have a minimum of 24 hours of fuel storage. Grade 3 facilities must have a minimum of 72 hours of onsite fuel storage with a confirmed delivery source. Grade 4 requires a minimum of 96 hours of onsite fuel storage with a confirmed delivery source. Storage must be based upon full load fuel consumption. The need for additional fuel storage capacity must be established with the mission owner during the planning/DD1391 development process.

Grade 2 facilities may utilize a single storage tank, while Grade 3 and 4 facilities must utilize multiple storage tanks. Grade 3 systems must be concurrently maintainable, while Grade 4 systems must be fault tolerant.

Air Force Facilities: Provide a minimum of 7 days of fuel storage. The Air Force allows Grade 2 and 3 facilities to utilize a fueling agreement provided there is 24 hours of integral/day tank fuel storage. Grade 4 facilities must be provided with N+1 storage tanks.

3-6.11.1.2 Fuel Controls.

The fuel controls must tie into the building control system. The fuel controls must alarm on high fuel level, low fuel levels, and upon leak detection. The fuel system must provide N+1 transfer pump redundancy.

3-6.11.1.3 Fuel Maintenance.

Design for maintenance in accordance with UFC 3-460-03.

3-6.12 Plumbing.

Where plumbing services feed critical systems (cooling tower makeup water or once-through cooling), redundant sources are required.

3-6.12.1 Backup Cooling Water.

Facilities using evaporative heat rejection must be provided with a minimum of 24 hours of makeup water for Grade 2, 72 hours of makeup water for Grade 3, and 96 hours of makeup water for Grade 4. Once through cooling systems can be used as a backup cooling source, but often have drawbacks. Cooling systems typically have high flow requirements. Municipal water is often dependent on electric pumps and may not be reliable if primary electrical power is unavailable. A well can be used to provide backup cooling water. Wells have a higher first cost and recurring maintenance costs. Sustained use of a well for backup cooling may negatively impact the aquifer. Carefully weigh the use of once-through cooling systems. A closed-circuit heat rejection source is an acceptable alternative. When a combination of evaporative cooling and closed-circuit cooling is utilized, a backup water source is not required, provided the heat rejection component has N capacity.

Where water storage is used as a backup cooling source, this water is considered non-potable water and must meet EPA Guidelines for Water Reuse and AWWA M24.

3-7 ELECTRICAL ENGINEERING.

The core UFCs define the minimums for electrical systems. The requirements set forth in this document are more stringent requirements above the core UFCs and are the minimums for C5ISR facilities. If more stringent requirements are presented, beyond the scope of this document by the end users, then the most stringent requirement must be implemented. Analyze stricter user requirements with minimums to determine a cost delta and determine if the implementation is feasible.

C5ISR facilities come in many different types with a large range of electrical requirements. There may be small projects under 250 kVA, medium projects up to 2,500 kVA, and large capacity projects greater than 2,500 kVA. Projects may also contain multi-site facilities that can be as large as 10 MVA with multiple buildings and primary power circuits from a commercial power company. Appropriate electrical distribution architecture must be implemented to meet the facility Grade requirement determined by the mission. For Army projects, refer to TM 5-691 Utility Systems Design Requirements for guidance. Refer to MESEP for more stringent and specific engineering requirements.

3-7.1 Utility Requirements.

Grade 2 and 3 facilities must be provided with independent utility power sources supplied by a commercial power company when available and economically feasible. Grade 4 facilities must be provided with two independent utility power sources supplied by a commercial power company. Investigate the independence of commercial power company feeds; each should originate from an independent substation. Provide a cost for an added utility feeder to assess its economic feasibility to the project overall costs. An added feeder is not economically feasible if it exceeds 10 percent of the total construction budget. Common substation utility feeders for Grade 4 are only acceptable when unavoidable. Each utility feed to the building must be maintained within its own pathway, separate from each other. For new utilities, maintain a 66-foot (20.2 m) separation between feeders along the route and maintain a minimum separation of 4 feet (1.2 m) between other utilities. Redundant feeders must not share duct banks or maintenance holes. When separation requirements cannot be met due to existing utilities and conditions, document the process to resolution in the basis of design narrative. When commercial power is not readily available, an on-station primary power plant must be provided. Generation systems must meet the requirements as outlined in UFC 3-540-01. Utility capacity requirements must be for 100 percent of the station demand load.

3-7.2 Load Categories.

The facility Grade is to be determined in accordance with MESEP. Load categories during design must be labeled and referred to as indicated:

3-7.2.1 Station Load.

Total power requirement of the facility.

3-7.2.2 Operational.

Loads required to maintain continuous operation of the facility.

3-7.2.3 Non-Technical.

Part of the total operational load used for the administration of the facility. Non-technical loads include general lighting, convenience outlets, HVAC, and other normal operation functions and do not require emergency power. These types of loads can be load shed to maintain synchronous operation of the critical technical load.

3-7.2.4 Technical.

Part of the operational load required for the critical technical load and the utilities serving this equipment. Technical load is essential to the facility's mission and must be on emergency power. The project’s electronic equipment engineers must determine this load.

3-7.2.5 Non-critical Technical Load.

Load that is a portion of the technical load not required for synchronous operation. This includes nonsynchronous electronic equipment, test equipment, emergency lighting, and HVAC for critical technical load. The outage time tolerance for specific facilities will vary based on the facility Grade and end user.

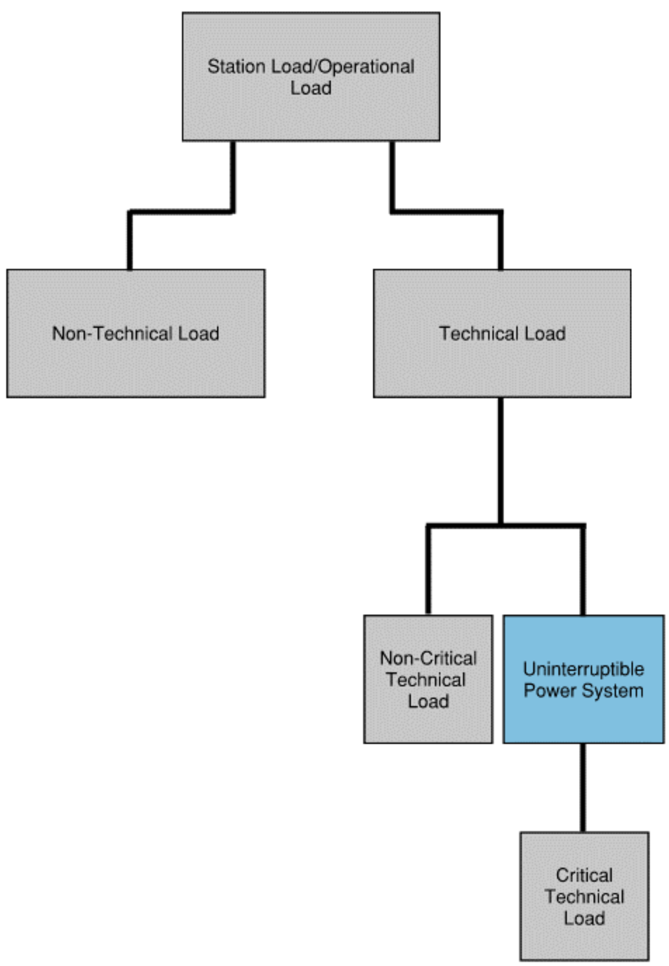
- HVAC Equipment/distribution components supporting critical loads.
- Point-of-use UPS equipment
- Elevators

3-7.2.6 Critical Technical Load.

Part of the total technical load required for continuous synchronous operation of electronic equipment. This includes any equipment malfunctioning during a momentary power dropout and causing additional outages after power is restored due to the need to resynchronize, loss of real-time count by master time sources, or loss of data in Automatic Data Processing (ADP) systems. These loads must be served from a UPS. Some examples of critical technical load include but not limited to:

- Rack-mounted IT Equipment
- Mission communications equipment
- Network equipment
- Facility Related Control Systems
- Key components of security systems

Figure 3-11 Load Categories



3-7.3 Redundancy and Resilience.

Figures associated with Grades are only examples to demonstrate a possible topology. Intent is to show limitations of each grade and help easily navigate pathing to critical loads. Engineered solutions are to be included in the drawing set one-line or riser diagram and demonstrated to meet their intended grade during design development.

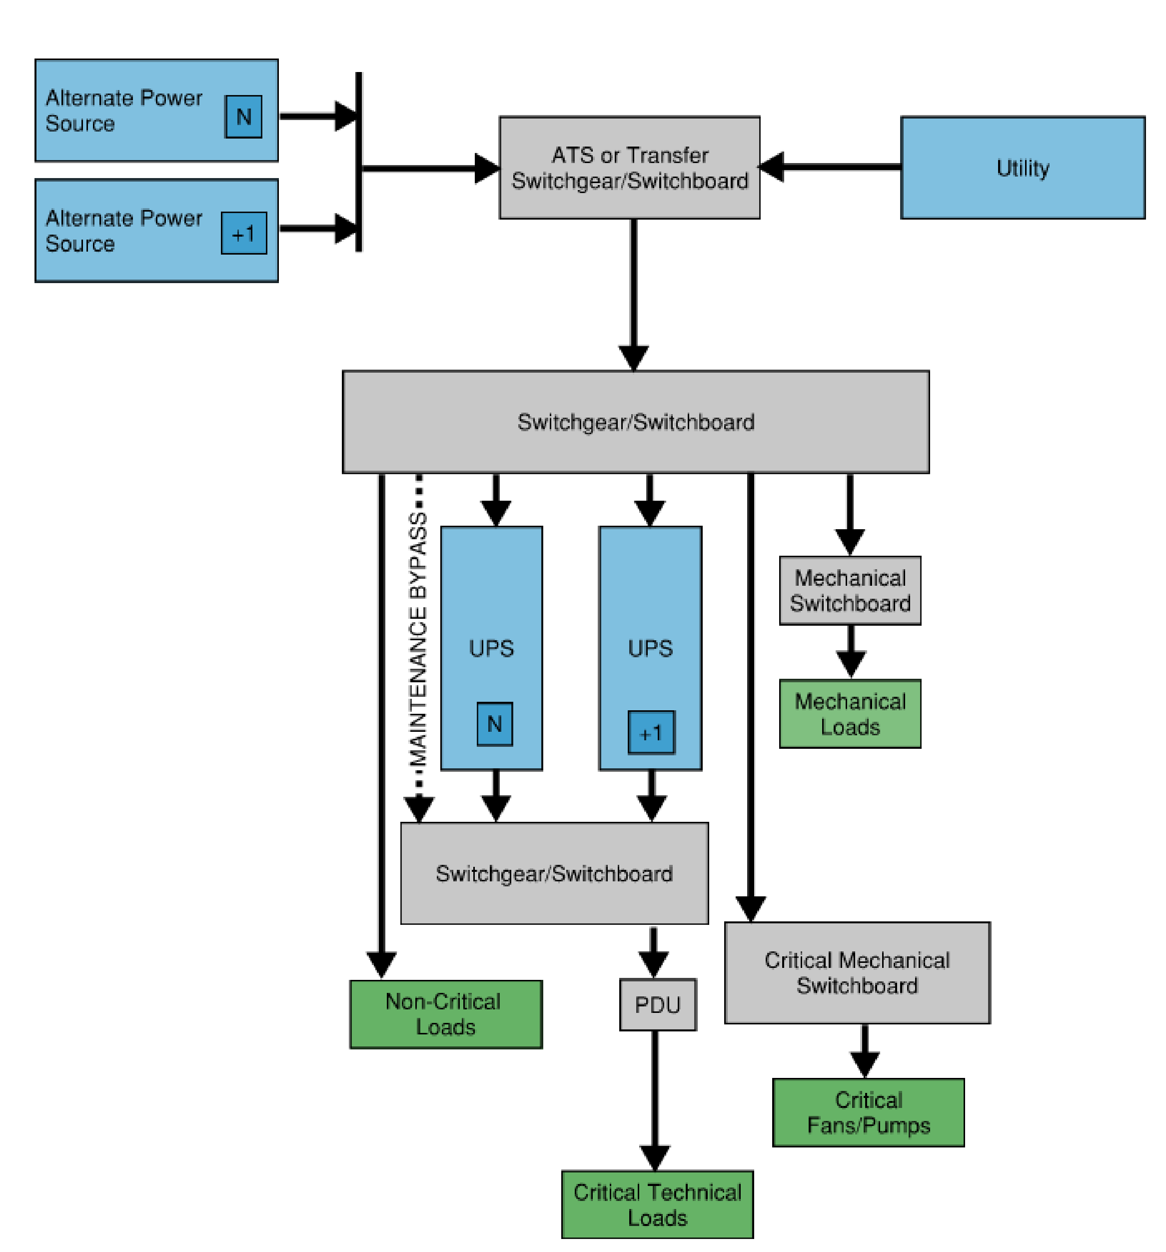
3-7.3.1 Grade 1 Electrical Systems.

Not applicable.

3-7.3.2 Grade 2 Electrical Systems

An electrical system that contains a single path to critical loads while having component redundancy. Component redundancy includes added equipment to exceed N requirements but not system level redundancy. This type of system would be vulnerable to component level faults with no added path around failures. It is possible to have planned component level maintenance but only on those components with the added redundancy. In most cases maintenance or failures would cause downtime to the critical loads supporting the mission. Figure 3-12 is an example of Grade 2 distribution architecture. One-line figures are example solutions only; the final electrical distribution system must meet or exceed the Grade 2 definition.

Figure 3-12 Grade 2 Single Utility with Alternate Power Sources



Availability at Critical Technical Load
0.9999

1. Availability equations are taken from UFC 3-520-02. Calculator utilizes the "block diagram" model.
2. Availability values are taken from IEEE 493-2007, Table 10-4.

3-7.3.3 Grade 3 Electrical Systems

An electrical system that is concurrently maintainable with a minimum redundancy of N+1. Concurrently maintainable systems can effectively maintain power during maintenance operations; it is not fault tolerant. It is common for Grade 3 mechanical systems architecture to push electrical into a 2N architecture similar to Grade 4. Analyze requirements with minimums to determine a cost delta and determine if the implementation is feasible. Figure 3-13 and Figure 3-14 are both examples of Grade 3 distribution architectures. One-line figures are example solutions only; the final electrical distribution system must meet or exceed the Grade 3 definition.

Redundant equipment must be physically separated in a redundant architecture to avoid damage due to catastrophic failures. Maintain 3-ft between redundant equipment or the NFPA 70 working clearance; whichever is greater.

2. Availability values are taken from IEEE 493-2007, Table 10-4.

3-7.3.4 Grade 4 Electrical Systems

An electrical system that is tolerant to faults or unexpected failures of both mechanical and electrical equipment within the distribution system. The electrical distribution network must have a 2N redundancy architecture including two separate utility feeds from independent substations. If 2N utility is provided, an N+1 generator power source may be considered to reduce cost. Provide a 2N uninterruptible alternate power source for critical technical loads.

When multi-path architecture is utilized, all equipment associated with the path is considered a subsystem and must be separated. Electrical subsystems must be separated by a minimum 1-hour fire-rated wall or structure. The critical technical power subsystem must be separated from other subsystems that do not support the data center. If a multi-path architecture is utilized, all equipment associated with the path is considered a subsystem and must be separated. Pathways serving subsystems must be separated by 3 feet (910 mm) when routed in a common space. A reduction to the 3 feet (910 mm) requirement is acceptable when not obtainable. For reference, Figure 3-15 would be considered dual path (2N), Figure 3-16 would be considered dual path (2(N+1)), and Figure 3-17 has three paths (3N). One-line figures are example solutions only; the final electrical distribution system must meet or exceed the Grade 4 definition.

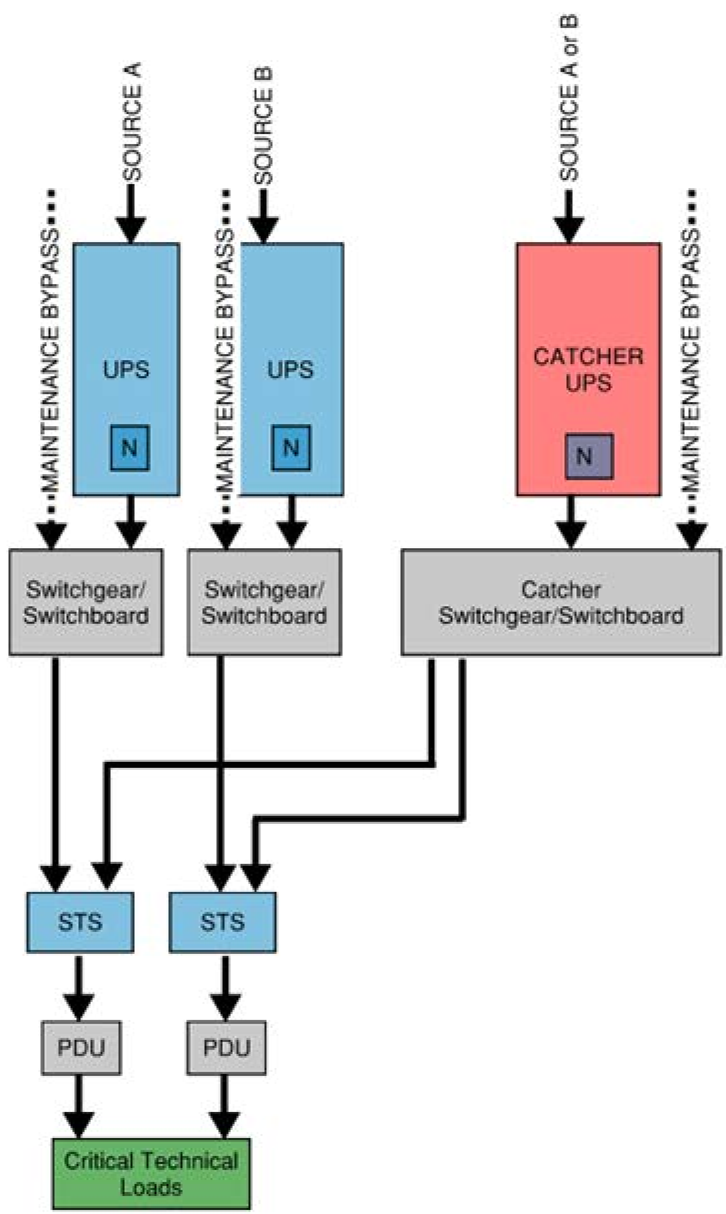
3-7.3.5 Architectures with Uninterrupted Transfer of Loads

It is possible to provide additional flexibility in the system by utilizing a “catcher” topology. This is when a redundant UPS feeds the static bypass inputs of the normal UPSs (“N” or Need). By having the static bypass feed from the catcher UPS, the normal UPSs sync their outputs with the input from the redundant UPS. This allows switching in the downstream system to be completed much easier and simplifies syncing of UPS outputs. The “catcher” must seamlessly assume the load of a single normal UPS failure. The outputs of the redundant and normal UPSs are tied together allowing for a manual switching between the two sources for maintenance of the normal UPSs. This can be utilized on any distribution paths with UPSs.

Figure 3-18 UPS “Catcher” Topology



3-7.4 Electrical Power Characteristics.

3-7.4.1 Voltage.

Steady-state voltage variation must not exceed plus or minus five percent of the nominal voltage level. The preferred voltage is 480Y/277V for systems above 300 kVA. For systems below 300 kVA, provide 208Y/120V systems.

3-7.4.2 Frequency.

Steady-state variations must not exceed plus or minus 0.5 percent of the nominal frequency. The preferred frequency is 60 hertz (Hz). If 60 Hz is not available overseas, the use of 50 Hz is acceptable. If frequency conversion is required, a synchronous generator or solid-state converter is required. Provide calculations for conversion equipment. Consult UFC 3-510-01 Foreign Voltages and Frequency Guide.

3-7.4.3 Availability.

Availability is the ability for a utility to be ready for use or to maintain its state. Not to be confused with reliability which is the measure of failures of a system or product over a period of time. A system can have poor reliability products in its network, but a given network architecture may provide high availability. Critical loads for C5ISR facilities require high availability to maintain mission operations. Different electrical architectures provide differing levels of availability.

3-7.4.4 Dynamic or Transient Variation.

This is the change of electrical conditions at the operational bus due to system operations, for example, motor starting. Voltage must not exceed minus 15 percent or plus 10 percent. Identify large motors and utilize reduced voltage starters or select a variable speed drive starting operation that reduces voltage requirements. Systems upstream of the Operational load bus may exceed these tolerances.

3-7.4.5 Power Factor.

Provide power factor correction when required. Minimum power factor must not exceed 0.85 lagging.

3-7.5 Medium Voltage (1kV-35.4kV).

Utilize medium voltage distribution within the facility when low voltage service requirements exceed 5 MW or 6000 A at lower utilization voltages (<600V). One-for-one replacement of existing equipment must match existing equipment and not be subject to this requirement.

Where increased safety and reduced footprint are desired, evaluate the use of Gas or Solid Insulated Switchgear (GIS or SIS). Provide all medium voltage circuit breakers with an electronic trip protective relay and when control is required, provide means to open and close the circuit breaker remotely. Protective relays must have the ability to network for advanced control schemes. Protective relays must be compatible with the selected DDC controls or Building Automation System (BAS). Provide connection into the DDC/BAS and monitor relay status at the facility control room. Review available protective relay control points with mission engineering and integrate those into the DDC/BAS.

3-7.5.1 Medium Voltage Controls.

Controls for switchgear operations must be integral to the equipment and have black start capabilities. Black start systems can maintain operations with no external power, carrying their own power supply to regain either primary or standby power. Allocate space for a DC battery supply for operating controls and circuit breakers in the switchgear lineup when located exterior of the facility. Batteries are to be provided in accordance with UFC 3-520-05. Mission central Uninterruptible Power Supply (UPS) circuits to provide power to controls is required. Control operations must be remote from the facility control room.

3-7.6 Low Voltage Electrical Distribution (<1000V).

3-7.6.1 Switchgear, Switchboards, Motor Control Centers, and Panelboards.

For Grade 3 and Grade 4 facilities provide switchgear with the following:

- Overhead lifting means for removing draw out circuit breakers.
- An arc-resistant switchgear assembly tested and certified to IEEE C37.20.7.
- Draw out compartment shutters to protect operators during hot operations.
- Infrared viewing windows for thermal imaging bus and connections without opening equipment doors or access panels.

For main service entrance switchgear and switchboards, consider using 4-pole circuit breakers that can alleviate the use of complicated ground fault schemes. With 4-pole circuit breakers, residual ground fault protection may be utilized in lieu of a modified differential ground fault scheme since the system switches neutrals between sources. When equipment is separated and requires communications connections for proper operation, provide two 4 in. (102 mm) conduits between the equipment to support these communications. When double ended switchgear or switchboards are utilized, they must be configured as Main-Tie-Tie-Main (M-T-T-M). When the utility owns the outdoor transformer, provide disconnecting means ahead of the main service entrance equipment to test black start capabilities.

3-7.6.2 Remote Power Panels (RPP).

Remote power panels (RPPs) can extend a large power capacity into the data center in a small footprint. RPPs have similar footprints to data racks, with some fitting entirely onto a 24in. by 24 in. (610 mm by 610 mm) tile while having the ability to contain four 42-pole panelboards. Consider using RPPs to remove transformers and PDUs, which increase the heat load on the data center floor. When desired, provide branch circuit monitoring capabilities compliant with paragraph 3-7.6.5 for branch circuits less than 800 A.

3-7.6.3 Circuit Breakers and Relays.

The use of low voltage protective relays may be used for better selective coordination on large drawout power circuit breakers over 800 A. For selective coordination purposes, all circuit breakers 225 A or larger must have adjustable long-time, short-time, and instantaneous (LSI) trip settings. Molded case thermal magnetic fixed trip circuit breakers are acceptable up to 225 A.

3-7.6.4 Low Voltage Controls (<600V).

Controls for switchgear and switchboard operations must be integral to the equipment and have black start capabilities. Control operations must also be remote from the facility control room. Black start systems can maintain operations with no external power, carrying their own power supply to regain either primary or standby power. A mission central Uninterruptible Power Supply (UPS) circuits to provide power to controls is required in a 2N configuration with separation of independent pathways. For Grade 3 and above, provide redundant controls with a physical separation, for example, control sections at opposite ends of the gear lineup or in a separate lineup. For Grade 4 provide controllers within separate rooms with 1hr fire barrier. For example, if switchgear A and B are located in different rooms but function together to maintain operations, switchgear A may have the primary controller while switchgear B contains the redundant controls. All controls are to be completely 2N, having automatic failover to the redundant controls system. No controls equipment can be shared for independent operation. Provide a 2N communication path between primary and redundant controls. Provide separate pathways/conduits for each communication link provided. The controls must be provided with cybersecurity protections in accordance with UFC 4-010-06. Ethernet switches provided in the controls’ architecture must be an OSI layer 2/3 managed switch.

3-7.6.5 Metering.

Metering is to be provided for all circuit breakers 800 A and above. All digital metering systems must be networked and consolidated at a single Electrical Power Monitoring System (EPMS). Connect consolidation location to DDC/BAS. Provide points to DDC/BAS to monitor phase current, voltage, frequency, crest factor, total harmonic distortion (THD), transient capture, Power (kW, kVA, kVAR), power factor, and energy consumption (kWh) per individual circuit breaker. Ethernet switches provided in the metering architecture must be an OSI layer 2/3 managed switch.

3-7.6.6 Transformers.

Transformers that directly serve critical technical loads must be harmonic mitigating type. Harmonic Analysis must identify which harmonics are the largest in the system and assist in selecting transformer harmonic mitigation techniques. Transformers must have a winding temperature sensor connected to a local and remote alarm system. Local alarms must be visual and audible. Provide connection and integration into the DDC/BAS and monitor the over temperature alarm.

3-7.6.7 Emergency Power/Alternate Power Source.

Categorize loads in accordance with NFPA 70 for Emergency, Legally Required Standby and Optional Standby. Provide a detailed Sequence of Operations (SoO) for generator operations. SoO must include dry contacts or input/output (I/O) blocks for generator running signals to initiate a sequence of operations for other systems. For outdoor generator units 1 MVA and larger, walk-in enclosures are required for ease of maintenance during adverse weather conditions. Size generator sets to their manufactured prime rating in lieu of standby rating to increase generator longevity in extended outages. Provide generators with a nameplate that states “Emergency Standby Use Only.”

Consider providing generator set(s) indoors when space is available. Provide when dictated by the design basis threat analysis. When considered, provide an LCCA comparing indoor and outdoor costs. The LCCA must account for building costs, including architecture, structure, mechanical, and electrical versus outdoor installation costs. The generator transient performance class must be G3 or better.

3-7.6.7.1 Emergency Power System Monitoring (EPSM).

Emergency power system monitoring must be compatible with the selected DDC controls or Building Automation System (BAS). Provide connection into the DDC/BAS and monitor the required Safety Indications and Shutdowns as indicated in NFPA 110 per level type. It is recommended to review optional points with end users for incorporation into the Safety Indications and Shutdowns list. If the EPSM is powered from the generators 12V starting system provide the controls with a power supply buffer that can maintain operating voltages above 9V for a minimum of 0.3 seconds. Multiple buffers can be placed in parallel to increase the duration beyond 0.3 seconds to cover cranking time. It is common during starting to have a large voltage drop which can lead to power issues at the controls. Monitoring system must have a 2N power supply.

3-7.6.7.2 Emergency Power Controls.

Controls for generator operations must be integral to the equipment and have black start capabilities. Allocate space for a DC battery supply for operating controls. If the controls are powered from the generators 12V starting system, provide with a power supply buffer that can maintain operating voltages above 9V for a minimum of 0.3 seconds. Multiple buffers can be placed in parallel to increase the duration beyond 0.3 seconds. It is common during starting to have a large voltage drop which can lead to power issues at the controls. The controls must be provided with cybersecurity protections in accordance with UFC 4-010-06.

3-7.6.7.3 Uninterruptible Power Supplies (UPS).

Provide batteries in accordance with UFC 3-520-05. Provide to meet the transient voltage requirements indicated in 3-7.4.4. Provide monitoring system capable of recording and trending individual battery voltage and impedance. Temperature must be monitored. UPS and monitoring systems must be compatible with the selected DDC controls or BAS. All alarms must be visible at the control room central monitoring station via the DDC or BAS. The use of small DIN rail mounted UPS and batteries is allowable for mechanical and electrical controls and monitoring equipment for ride through until main emergency power is initiated. When calculating runtimes use battery system end-of-life (EOL) runtime. Assume battery system EOL is 80% of initial capacity.

Air Force Only: UPS minimum runtime must be 15 minutes.

3-7.6.8 Loadbanks.

To provide an adequate load to maintain generator(s), provide a loadbank sized at 50 percent minimum of the generator nameplate rating. Loadbanks sized for less than 100 percent of a single generator must be able to be paralleled with the facility loads for full load testing. In facilities with multiple paralleled generator sets, provide a sequence of operations to test each generator set individually to keep the required loadbank size to a minimum. This sequence of operations must be activated via the paralleling switchgear human machine interface (HMI).

For Level 1 generators as defined by NFPA 110, provide a loadbank sized at 75 percent minimum of the generator nameplate rating with the ability to step from 25 percent to 50 percent to 75 percent. This will allow the yearly NFPA 110 required testing to be performed. This will also reduce annual maintenance costs and minimize the logistics of providing a third-party tester onto a secure site.

3-7.6.9 Busway.

The use of continuous open channel busway systems with modular plug-in units is acceptable for providing power to operational racks and cabinets. Coordinate plug-in unit circuit breaker and receptacle types with the facility’s electronic equipment engineer. Provide plug-in units with intelligence to monitor the following points: phase current, voltage, frequency, crest factor, THD, Power (kW, kVA, kVAR), Power factor, and energy consumption (kWh) per individual plug-in circuit breaker. Data protocols must be compatible with DDC/BAS system. All points must be integrated into the DDC/BAS and visible at a central monitoring station.

3-7.6.10 Pathways.

For Grade 3 and 4, at a minimum, redundant circuits must not be routed in common duct banks, maintenance holes, conduits, pathways, raceways, or cable trays.

3-7.6.11 Wiring and Wiring Devices.

Coordinate specific wiring device requirements with the facility's electronic equipment engineer. All receptacles other than general purpose, 120V, 20A receptacles must be marked with amperage, voltage, phase, and frequency.

3-7.7 Motors and Motor Control.

Adjustable speed drives must have an Insulated-Gate Bipolar Transistor (IGBT) rectifier or “active front end.” Active front end drives have reduced harmonics that affect the sensitive electronics within the system. Provide adjustable speed drives with three contactor bypasses to allow power to be completely disconnected from the drive during replacement. Locate redundant motor control circuits within their own pathway separate from primary control circuits. Faults on the primary control circuits must not inhibit the operation of the redundant motor.

Modern HVAC equipment utilizes electronically commutated (EC) motors. These motors use a built-in inverter for operation. Inverters add harmonics to the system and therefore include EC motors as non-linear loads in the harmonic analysis.

3-7.8 Grounding and Bonding.

Provide in accordance with NFPA 70, TIA-607-D, and MIL-STD-188-124B. TIA-607 grounding is not required in spaces where MIL-STD-188-124B apply. MIL-STD-188-124B grounding includes an equipotential ground plane (copper mesh) imbedded in the concrete floors/slab which will increase the design thickness. Provide the TIA-607 excluded spaces within the MESEP. Radio equipment with manufacturer warranties require specialized grounding. Provide grounding in accordance with Motorola R56 for Motorola equipment and AE/LZT 123 4618/1 R3A for Harris equipment. Earth electrode subsystem must not exceed 5 ohms.

3-7.8.1 Neutrals.

All neutrals must be fully rated. Coordinate systems furniture circuiting requirements with interiors implementing the built-in electrical through specifications.

3-7.8.2 Screen Rooms and Shielded Enclosures.

Screen rooms/shielding enclosures must be grounded and bonded in accordance with MIL-HDBK-1195.

3-7.8.3 Lightning Protection.

Provide lightning protection for all facilities to include antenna platforms.

3-7.9 Static Transfer Switches (STS).

Static transfer switches are provided to switch power sources with little to no interruption in service. Provide rack-mounted STSs (rSTS) for single-corded network equipment to provide a dual power path. Distribution STSs can be provided for serving mission critical work areas. Distribution level STSs must be provided when required by the MESEP. Do not provide the rSTS with intelligence/ metering capabilities via ethernet.

3-7.10 Power Distribution Units (PDU).

3-7.10.1 Distribution Level PDU.

A distribution level PDU is a single piece of equipment that integrates power distribution and transformer to reduce installation times and costs. When utilized, PDUs must have harmonic mitigating transformers (HMT). PDU must have a main input circuit breaker on the transformer primary. Provide PDUs with sub-feed output sections on the secondary of the transformer. A fully configured HMI display must be provided. Provide with surge suppression device.

3-7.10.2 Rack Level PDU (rPDU).

A rack power distribution unit distributes power to the rack loads and is typically either vertically or horizontally mounted within the rack or cabinet. Provide rPDUs in each rack and coordinate input and output receptacle types with the electronic equipment engineer. Utilize basic non-metered rPDUs unless increased metering is required at the local rPDU level. If remote monitoring is required, provide a monitored rPDU. Monitored rPDUs must be connected to the metering network. Discuss if the facility Operational Technology (OT) network can reside within the cabinet with the mission network(s). Switched rPDUs are an industry option that can remotely switch on/off rPDUs. Switched rPDUs must not be utilized unless specifically required by the electronic equipment engineer. Most rPDUs do not include surge protection; therefore, it is not required at the rPDU level. Coordinate rPDU amperage, voltage and phase requirements with electronics engineer to include in the facility MESEP.

Air Force Only: Provide two 3-phase rPDUs per rack/cabinet with power monitoring in data centers.

3-7.11 Transient Voltage and Surge Protection.

Voltage transient protection must be installed on both transient sources and power distribution equipment serving electronic equipment.

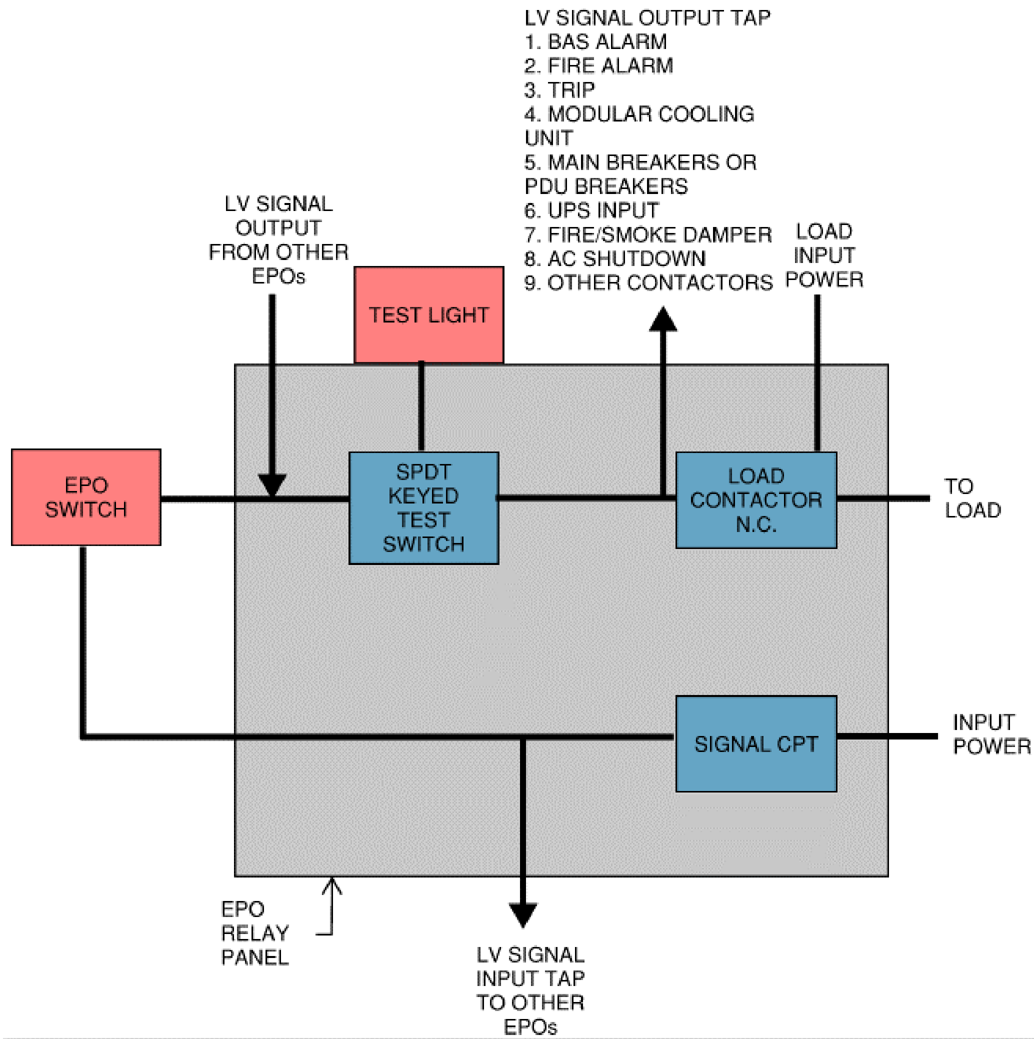
3-7.12 Selective Coordination.

Selective coordination must be provided to 0.1 seconds at a minimum. For instantaneous regions, provide manufacturer test documentation that circuit breakers must operate to open the nearest circuit breaker to the fault based on the calculated fault current. Proper coordination may lead to the deactivation of larger upstream circuit breaker instantaneous operations or instantaneous delay settings above 3 cycles (0.05s). Where this occurs, circuit breakers must be provided within a UL 1558 switchgear designed for a 30-cycle withstand rating. To properly coordinate molded case circuit breakers, consider maintaining a 2:1 or 3:1 ratio of the largest branch to the main rating. Properly document all miscoordinations in the power system study in accordance with UFC 3-501-01.

3-7.13 Emergency Power Off (EPO).

When provided, emergency power off buttons and circuits must have a Performance Level d (PLd) in accordance with ANSI B11.26. This implies structure Category 4 in accordance with ISO 13849-1, adding high diagnostic coverage and common cause failure avoidance techniques. Monitor circuit power at the Fire Alarm Control Unit (FACU) for circuit power failure and EPO activation. EPO system must have a means to test the signal pathway that deactivates the signal to the load contactors and activates a test light.

Figure 3-19 EPO Diagram



3-7.14 Lighting and Lighting Controls.

3-7.14.1 Lighting for Windowless Operating Environments (Command and Control / Operations Centers)

C5ISR facilities are high stress work environments, refer to paragraph 3-2.2.4.5. These high stress work environments are illuminated with two different scenarios; a high and low light environment. For areas of the facility that have high stress associated with them such as Command and Control Operations, Watch Floors, Operations Centers, or War Rooms refer to UFC 3-530-01 section on Command and Control/Operations Centers for the high light environment. The high light scenario will be used for housekeeping of the spaces. The users of these spaces operate in a low light environment much like a movie theater. Therefore, consideration must be given to the amount of light given off by computer screens which adds a measurable amount of usable light to the space. Provide lighting of the low light environment as follows:

- Horizontal Foot-Candles: 1.5 fc at desk
- Vertical Foot-Candles: 6 fc at 6'-0" on walls. 2 fc MAX at screen.
- Correlated Color Temperature: 2700-5500K
- Lighting Orientation: Uplight ON. Downlight OFF.

Use a mixture of direct, indirect and wall washers to meet the requirements and provide flexibility for user comfort. Provide spectral tuning luminaires to enhance operator quality of life in Command and Control/Operations spaces that mimic the natural circadian rhythm of a 24/7 schedule. For additional information refer to U. S. Air Force Lighting for Stressful Environments Report.

3-7.14.2 Lighting Controls

If automatic lighting controls are desired in the data center, provide automatic controls on a per row basis. When a networked system is utilized, integrate it into the DDC/BAS in accordance with UFC 3-530-01. Provide a SoO for lighting controls. SoO must include dry contacts or I/O blocks for outgoing or incoming signals to integrate other systems. Wireless controls are prohibited. The controls must be provided with cybersecurity protections in accordance with UFC 4-010-06. Ethernet switches provided in the lighting controls architecture must be an OSI layer 2/3 managed switch.

When applying lighting controls to secure spaces be mindful of using microphonics due to the microphone used to listen to activity in the space. Secure spaces do not allow the installation of active microphones. Obtain documentation that the sensor is passive and does not transmit intelligible voice data beyond the device. A proper passive device must utilize an op-amp comparator. Provide a lighting control network or lighting control panel inside all common secure areas and connect using fiber optics. For example, if there are multiple compartmentalized secure areas, provide one for each area. Provide location and specifications of all required media conversion equipment to connect control panels by fiber.

3-7.14.2.1 Mission Lighting Controls

Spaces that have continuous 24/7 operations must be provided with a separate control system capable of adjusting individual luminaire spectral color and color shift to meet circadian rhythm requirements. This control system must control the low light scenario of the environment. To meet the low light scenario requirement, provide addressable luminaires and control devices. The color shift must happen over a duration that corresponds to the time of the year of the facility's geographical location. The intent is to maintain the natural circadian rhythm of the operators in 24/7, high stress environments which has shown to reduce stress. The color shift must be adjusted from 2700k as a minimum to 5500K maximum.

3-7.14.3 Security Lighting.

Security lighting for facilities must be provided. Lighting must be installed inside the perimeter security fence to illuminate the fence completely and prevent an intruder from using the light poles and guy wires to gain access to the area. Illuminate areas shadowed by structures. Ensure that the failure of one lamp in a circuit does not affect other lamps in the same circuit. Provide overlapping light distribution to minimize reductions in illumination levels upon lamp failure. Protect all components of the system from vandalism. Provide lights on buildings. The emergency power source must be adequate to sustain security lighting of all critical areas and structures for 8 hours and must go into operation automatically when the primary power fails. The facility must have battery-powered lights at key control points if a failure disables the alternate power supply. Install special-purpose lighting (such as for fog penetration) when climatic or other local factors dictate. Provide additional lighting for (CCTV) security surveillance, as necessary. Vapor type lighting must not be used within 0.5 miles (0.8 km) of antenna receiving areas.

3-7.15 Telecommunications.

Similar to the electrical system, the telecommunications system can be determined using a small, medium, and large scale. Regardless of scale, C5ISR facilities contain large amounts of data processing equipment, typically in a central room or multiple rooms within the facility called data centers. These data centers may process information for multiple missions and must be properly networked for redundancy and flexibility. C5ISR facilities rooms/spaces/areas must be labeled as indicated when applicable:

3-7.15.1 Entrance Facility (EF).

The room or area where the outside plant cabling terminates inside the facility. In some cases, this room will be the same as the main distribution area if the facility provider owns the OSP cabling. When there is an outside service provider, provide a demarcation room to allow separate access for provider cable termination and equipment.

3-7.15.2 Main Distribution Area (MDA).

The room or area that supports customer-owned core equipment, including routers, core switches, firewalls, load balancers, DNS, and possibly core SAN fabric switches. This area is typically found in support of the core data center. MDAs may serve one or more HDAs, IDAs, EDAs, or TRs within a facility. May also be called data center.

3-7.15.3 Intermediate Distribution Area (IDA).

The room or area that supports the intermediate cross connect. Typically used in large facilities when the number of connections between MDAs and HDAs is large and cannot be supported by these rooms or areas. This area is typically found in support of the core data center. IDAs are optional spaces dependent on networking demand.

3-7.15.4 Horizontal Distribution Area (HDA).

The room or area that supports horizontal cabling to ZDAs, EDAs, IT equipment, or equipment outlets. This area is typically found in support of the core data center. HDAs are optional areas that assist with cable decongestion in medium to large scale data centers.

3-7.15.5 Equipment Distribution Area (EDA).

Area that houses IT processing equipment.

3-7.15.6 Zone Distribution Area (ZDA).

An optional interconnection point within the horizontal cabling located between the HDA and the EDA to allow frequent reconfiguration and added flexibility.

3-7.15.7 Telecommunications Room (TR).

A room that supports operations outside of the data center or mission directly serving the data center. This room may also extend the core data center service outside the data center room or area and into the facility for mission use.

In small data centers, a single MDA is required with no supporting area, such as HDAs or IDAs, to provide necessary connections. Provide HDAs and IDAs for larger data centers to support the increased number of cross connects and horizontal cabling. Close coordination with the facility's electronic equipment engineer is required to determine networking requirements and needs for these specific areas.

3-7.16 Telecommunications Infrastructure Grade.

The Grade is to be determined in accordance with MESEP.

3-7.16.1 Grade 1 Telecommunications System.

Not applicable.

3-7.16.2 Grade 2 Telecommunications System.

The incoming outside plant cabling to the facility must be redundant via two separate paths and maintenance holes. Redundant feeds terminate in a single entrance facility room. Telecommunications equipment for supporting services are to have redundant components such as processors and power supplies. Backbone cabling between telecommunications rooms must have redundant stands or pairs which can be shared within the same sheath of a single cable; independent cabling is not required. It is acceptable to incorporate ring or mesh topologies along with the required star topology.

3-7.16.3 Grade 3 Telecommunications System.

Two separate feeds from separate buildings should serve the facility. Cabling should be separated by 66 feet (20 m) along their entire routes when possible. Document any restrictions of feed separation in the Basis of Design. The facility must have two entrance rooms at preferably opposing ends of the building. A separation distance of 66 feet (20 m) between the two rooms is acceptable if opposing ends are not viable. Sharing entrance feed equipment, fire protection zones, power distribution, and air conditioning equipment between the two entrance rooms is prohibited. The equipment in each entrance room must be able to maintain the mission if the equipment in the opposing entrance room is undergoing planned maintenance. Redundant backbone pathways must be between the entrance rooms, MDA, IDAs, and HDAs. The redundant connections must be in separate pathways or by separate cables.

3-7.16.4 Grade 4 Telecommunications System.

Grade 4 facility must meet all the provisions of Grade 3 plus the following: Backbone cabling and distributor rooms/area must be redundant. Backbones and horizontal cabling between two spaces must be separate paths, with common paths only inside the termination rooms/areas. There should be an automatic backup for all critical telecommunications equipment. The facility must have redundant MDAs. A separation distance of 66 feet (20 m) between the two rooms is acceptable if opposing ends are not viable. Sharing fire protection zones, power distribution units, and air conditioning equipment between MDAs is prohibited. The MDAs must have separate pathways to each entrance room. There must be a telecommunications cabling pathway between the facility MDAs. HDAs must be provided with connections to two different IDAs or MDAs. When provided, each IDA must be provided with connections to both MDAs. Critical systems should have connections to two HDAs.

3-7.17 Telecommunications Cabling, Topology, and Installation.

This section outlines the architecture and product performance requirements of the telecommunications system.

3-7.17.1 Backbone Cabling and Topology.

Maintain backbone cabling outside of horizontal cabling cable trays. When backbones are routed within a large data center space, cabling may be routed inside cable trays or conduits. Backbone topologies will vary based on facility Grade. Refer to project MESEP and Appendix A for exact requirements.

Figure 3-20 Grade 3 Concept Topology

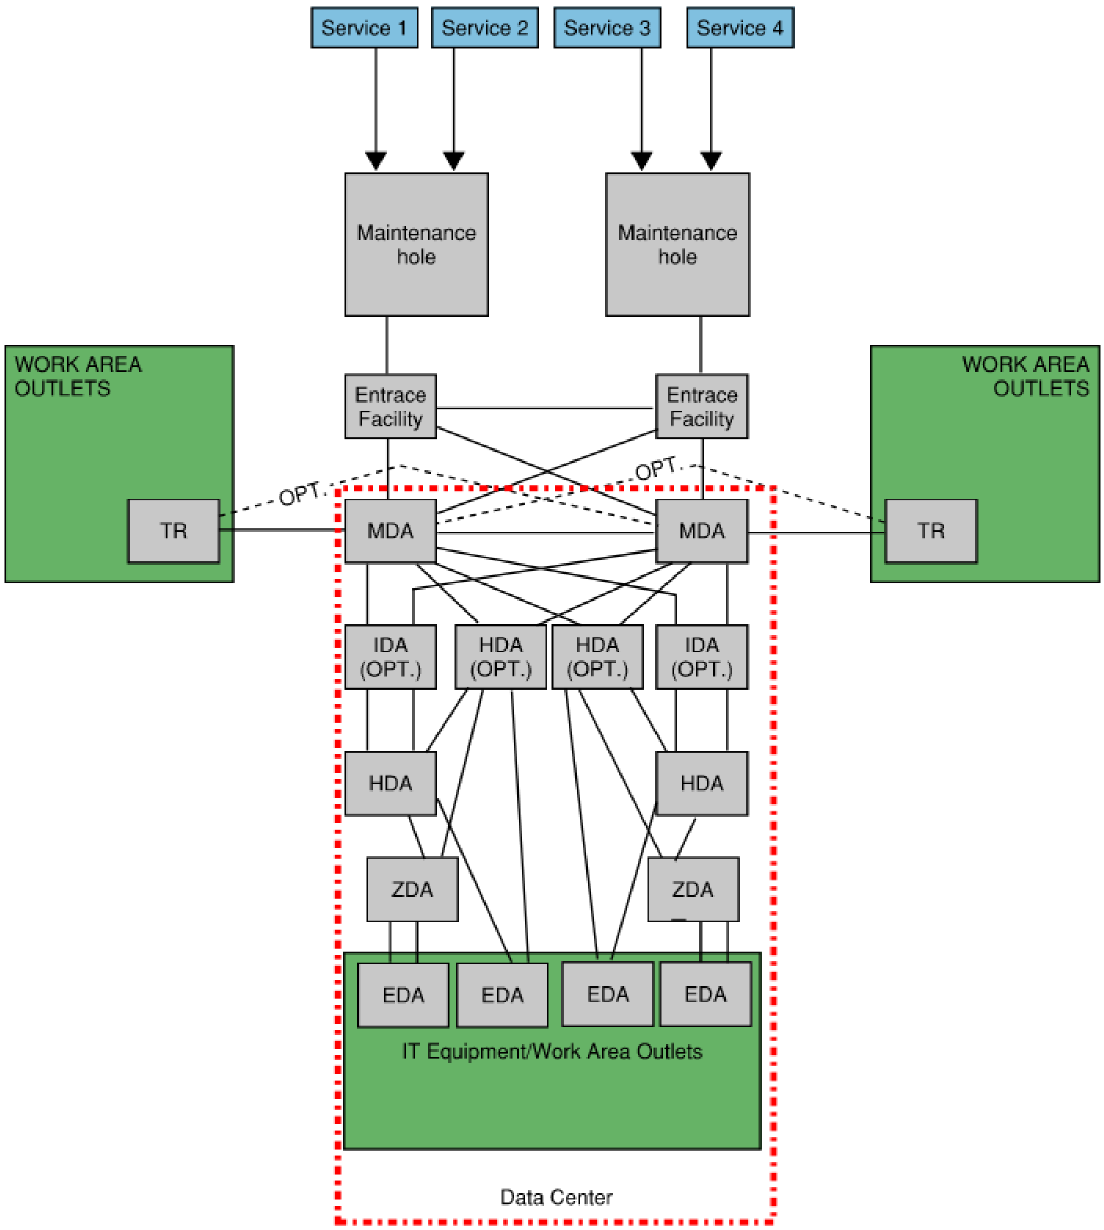


Figure 3-21 Grade 4 Concept Topology

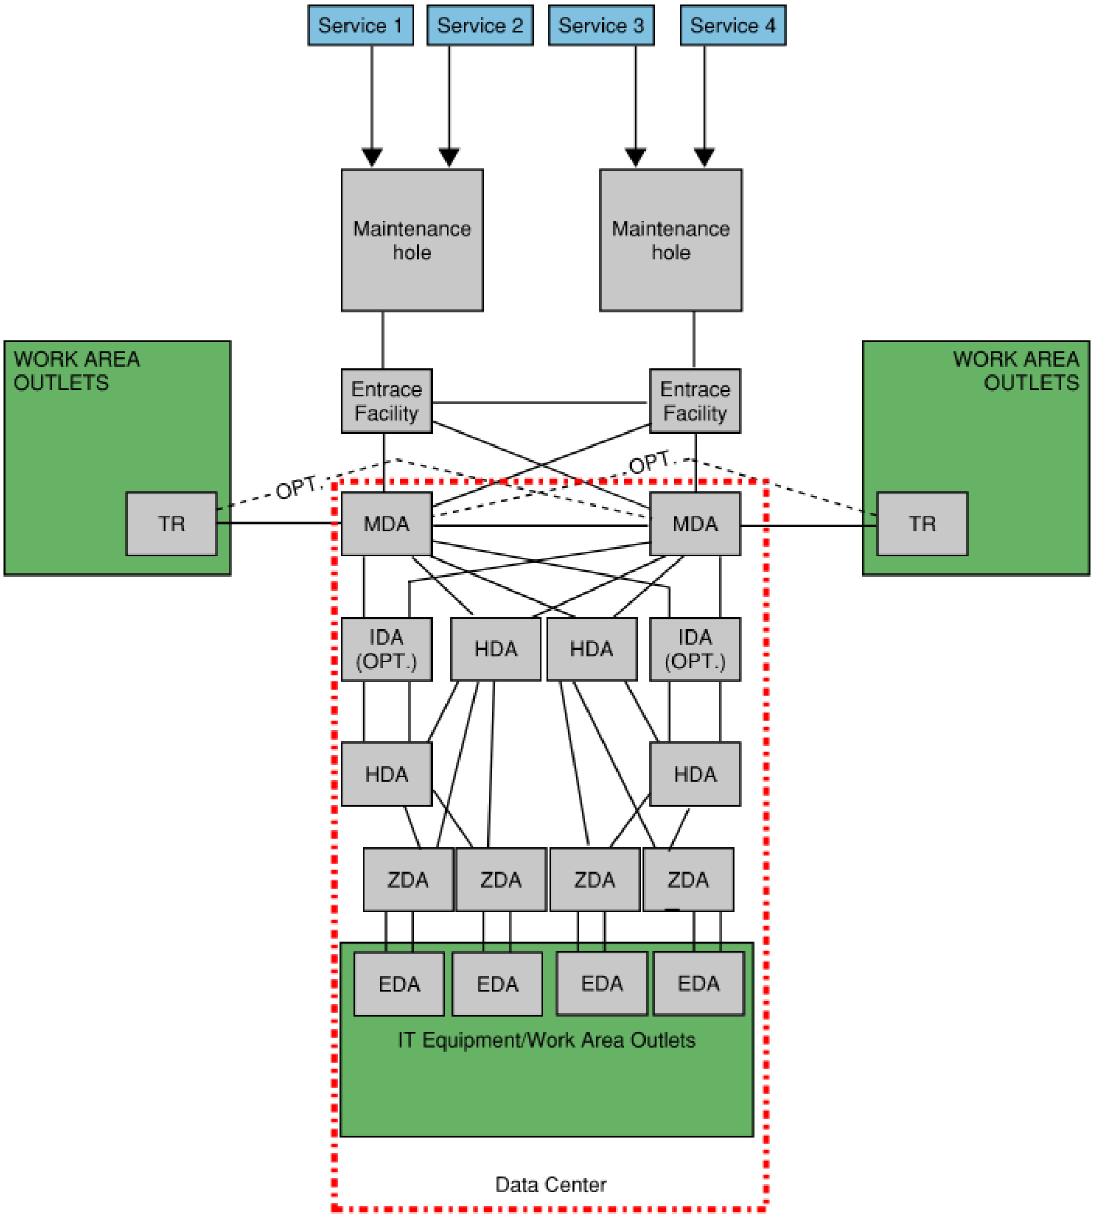

3-7.17.2 Horizontal Cabling and Topology.

Horizontal cabling must be provided in a star topology. Refer to project MESEP and Appendix A for exact requirements. If workstations require redundant horizontal cabling, provide from two separate spaces/rooms. If not possible, route from separate rack/cabinets and provide a cable tray divider between the primary and redundant cabling. Redundant horizontal cabling is not required for workstations serving Grade 3 or 4 facilities. Secure and unsecure networks must maintain separation in accordance with CNSSAM TEMPEST 1-13. The use of cable tray dividers to maintain separation of networks sharing a cable tray is acceptable but not required. This will minimize cable trays within the building reducing overall space required. If dividers are not acceptable special networks with higher security than Red networks must be in their own cable trays.

3-7.18 Telecommunications Spaces and Pathway.

TR spaces should be provided with no ceiling. In facilities with a high structure, a hard ceiling is acceptable 24” above the highest infrastructure within the room.

Data center rooms and areas must be sized for the equipment and mission. Secure and unsecure networks must maintain separation in accordance with CNSSAM TEMPEST 1-13; add square footage for separation requirements. Consider the use of structural grid ceilings in data centers for equipment mounting. Include preferred space sizes in the project MESEP.

For Navy Only: Refer to FC 2-000-05N for guidelines for sizing spaces per rack/cabinet quantities.

3-7.18.1.1 Protected Distribution System (PDS).

Minimize the amount of PDS within the facility as much as possible. Verify with electronics engineer or base communications officer the strategy for decryption within secure spaces. It is not uncommon to have multiple secure areas but a single decryption device provided to support them. PDS is required in this situation to route secure backbones between secure areas. If a decryption device can be located in each secure area, then no PDS would be required between those spaces.

3-7.18.2 Telecommunications Cabinets and Racks.

Coordinate cabinet requirements with the selected mechanical system provided within the data center/equipment room space. Provide blanking panels for empty rack unit spaces when air control is required to maintain hot and cold aisles. If a containment system is required, coordinate the cabinet size/type to maintain proper containment/sealing of the system. Refer to project MESEP for exact requirements.

3-7.18.3 Outside Plant Cabling Infrastructure.

Refer to project MESEP for exact requirements.

3-7.18.3.1 Underground Pathways.

Concrete encase all duct banks providing incoming services to the facility.

3-7.18.3.2 Aerial Pathways.

Do not provide overhead services unless necessary.

3-7.19 Television Systems (CATV).

Provide copper to fiber to copper media conversion for CATV traversing secure boundaries when required.

3-7.20 Electronic Security Systems (ESS).

Provide in accordance with UFC 4-021-02 and coordinate with the security assessment per the design basis threat analysis. Coordinate exact requirements with stakeholders. Provide copper to fiber to copper media conversion for ESS traversing secure boundaries when required. Refer to project MESEP for exact requirements. Ethernet switches in the ESS architecture must be an OSI layer 2/3 managed.

3-7.21 Audio Visual (A/V)

Provide space in accordance with TIA-569 within the telecommunications rooms or local served spaces for A/V equipment.

3-8 FIRE PROTECTION AND LIFE SAFETY.

Provide buildings and systems in accordance with UFC 3-600-01 except where requirements are added/modified by this UFC. Electronic Equipment Areas, as defined by UFC 3-600-01, must follow UFC 3-600-01 requirements except as modified herein.

3-8.1 Physical Security.

For buildings requiring locking arrangements for security purposes, comply with NFPA 101, Life Safety Code locking requirements.

3-8.2 Areas Not Containing Electronic Equipment and Incidental Electronic Equipment Areas.

Comply with UFC 3-600-01.

3-8.3 Electronic Equipment Areas.

3-8.3.1 Electronic Equipment Area Separation.

Provide minimum 2-hour fire barriers to separate Electronic Equipment Areas from the rest of the facility.

3-8.3.2 Vaults, Other Electrical/Telecom Rooms Supplying Electronic Equipment Areas.

All vaults and other telecom and/or electrical rooms within C5ISR facilities that contain communication/data and/or electrical equipment that serve the Electronic Equipment Areas must be protected the same as the Electronic Equipment Areas in the facility and comply with all requirements in 3-8.3. Follow NFPA 70 Article 110. Provide clean agent fire extinguisher(s) sized and spaced in accordance with NFPA 10 in all vaults.

3-8.3.3 Fire Suppression Systems.

3-8.3.3.1 Classification of Hazard.

Follow UFC 3-600-01.

Army Facilities: Minimum sprinkler hazard classification for Electronic Equipment Areas must be Ordinary Hazard.

3-8.3.3.2 Automatic Sprinkler Protection for Electronic Equipment Areas.

Label and identify valves controlling water to Electronic Equipment Areas to indicate the Electronic Equipment Areas they serve.

Army and Navy Facilities: Provide wet-pipe automatic sprinkler protection in these areas of the facility where the facility is fully sprinkled. Use of preaction sprinkler systems is not permitted.

Air Force Facilities: Refer to UFC 3-600-01 and the use of TSFPEWG G 3-600-01.01-18 for automatic sprinkler system guidance, including areas permitting preaction sprinkler systems.

For areas with hot aisle and cold aisle containment, provide sprinklers inside the compartments to comply with NFPA 13 obstruction requirements.

3-8.3.3.3 Clean Agent Systems.

Provide total-flooding clean agent systems in addition to automatic sprinkler protection for all Electronic Equipment Areas in C5ISR facilities regardless of Grade. Comply with UFC 3-600-01 and activate system by a Very Early Warning Fire Detection System (VEWFD).

Note: Additional preventative maintenance requirements are incurred when using a total-flooding clean agent system such as maintaining the enclosure integrity. See UFC 3-601-02 for the required annual, 2-year, 5-year, and other Inspection, Testing, Maintenance requirements.

3-8.3.3.4 Portable Fire Extinguishers

Provide clean agent fire extinguisher(s) sized and spaced in accordance with NFPA 10 in all Electronic Equipment Areas.

3-8.3.4 Fire Alarm Systems.

Provide addressable fire alarm system in accordance with UFC 3-600-01.

3-8.3.4.1 Very Early Warning Fire Detection.

Provide VEWFD port spacing in accordance with NFPA 76 VEWFD port installation requirements. Design system using manufacturer-provided listed criteria, which includes the pipe air pressure, airflow rate through sampling port, percentage of total pipe flow through sampling port, and transport time required for a smoke sample to be drawn from the sampling port to the detector. For areas with hot aisle and cold aisle containment, provide detection inside the compartments. Utilize cross-zoned detection or an equivalent method to minimize potential for false discharges of the clean agent system.

Provide supervisory alert level notification (at lowest smoke obscuration level) with silence switch outside of the protected area in a readily apparent location to notify building occupants. If building occupants do not have access to the protected area, provide signage indicating contact information of personnel who have access to space. Where the protected area is always occupied, outside the space notification is not required.

3-8.3.5 Electronic Equipment Power Disconnect.

Must meet the requirements set forth in section 3-7.13.

Army and Navy Facilities: Provide manual means for electronic equipment EPO as permitted by UFC 3-600-01.

Air Force Facilities: Automatic EPO is permitted upon sprinkler water flow as guided by TSFPEWG G 3-600-01.01-18.

3-8.3.6 Air Handling Equipment Shutdown.

CRAC and CRAH units must not automatically shut down if electronic equipment remains energized and heat generated in the room will be sufficient to activate sprinkler heads. Duct smoke detectors and automatic shutdown are not required where air distribution systems are incapable of spreading smoke beyond the enclosing walls, floors, and ceilings of the room or space in which the smoke is generated.

Clean agent system activation must shut down any equipment cooling system where the airflow passes outside of the clean agent discharge envelope/volume. Equipment cooling systems with airflow completely within the discharge envelope/volume must continue to operate.

3-8.3.7 Smoke Exhaust Systems.

Army and Navy: Smoke exhaust of Electronic Equipment areas is not required in accordance with UFC 3-600-01.

Air Force: Refer to TSFPEWG G 3-600-01.01-18 for smoke exhaust guidance.

CHAPTER 4 SPECIAL REQUIREMENTS

4-1 MAINTENANCE AND COMMISSIONING REQUIREMENTS.

4-1.1 Maintenance.

Design for accessibility and maintenance. Provide egress pathways for all critical equipment to allow removal/replacement without interrupting service. Include in design package drawings indicating travel pathway for equipment removal. Ensure all equipment is readily accessible for inspection and ease of maintenance.

4-1.2 Commissioning.

Provide commissioning in accordance with UFC 1-200-02 and ANSI/NETA ECS. A third party must provide Integrated Systems Testing (IST) for all systems within the facility. Introduce mission critical events that initiate all emergency systems' sequence of operations. Verify that all mechanical, fire protection, and electrical systems operate per the designed sequence of operations and maintain the mission.

For Army only: Provide commissioning in accordance with ER 1110-345-723 and UFC 1-200-02.

4-1.2.1 Grade 1 Facility Scheduled Maintenance Event Test Requirements.

Not applicable.

4-1.2.2 Grade 2 Facility Scheduled Maintenance Event Test Requirements.

Initiate a mission critical scheduled maintenance event by removing equipment from the path of operation that has redundant components. Verify the mission's planned operating procedures by manually shutting down a single piece of equipment requiring maintenance and initiating the redundant mode of operation. Test must be repeated for each piece of equipment in the path of operation for each redundant component. Components are to be tested independently.

4-1.2.3 Grade 3 Facility Scheduled Maintenance Event Test Requirements.

Initiate a mission critical scheduled maintenance event by removing equipment from the intended path of operation. Verify the mission's planned operating procedures by manually shutting down a single piece of equipment requiring maintenance and initiating the redundant mode of operation. Test must be repeated for each piece of equipment in the intended path of operation and each path of operation.

4-1.2.4 Grade 4 Facility Critical Failure Event Test Requirements.

In addition, for Grade 4 facilities, initiate a simulated mission critical failure event by removing equipment from the intended path of operation without a planned procedure. Verify automatic operations of the system to the redundant path equipment for maintaining the critical load. Verify the intended redundant path is operating. Test must be repeated for each piece of equipment or system in the intended path of operation and each path of operation.

4-1.2.5 Systems Manual Requirements.

The Designer of Record (DOR) must incorporate the SM requirements into the construction documents via UFGS 01 91 00.15 Building Commissioning.

For Army only: Provide Systems Manual (SM) for all C5ISR facilities in accordance with ER 1110-345-723 and ER 25-345-1.

4-1.3 Staff Training.

Training of systems must cover the project system Sequence of Operations. It must demonstrate how to maintain facility operations during maintenance or fault conditions.

For Army only: Provide staff training for all C5ISR facilities in accordance with ER 1110-345-723.

4-2 ELECTRICAL.

4-2.1 400 Hz Power.

When 400 Hz is required, provide using either a motor generator or static converter. Provide calculations for conversion equipment in accordance with UFC 3-501-01. Consideration should be given to standby requirements when selecting and locating frequency converters. Both types of converters must be adequately grounded to prevent electromagnetic interference. Power at 400 Hz requires that the distribution system be carefully engineered. Consider using larger conductors, parallel feeders, non-magnetic conduits, and load drop compensators. All cables carrying 400-Hz power must be run in separate raceway systems.

4-2.2 Direct Current (DC) Power Systems.

Electronic facilities often require direct-current power supplies and distribution systems. These power systems utilize 24 to 48-volts DC. The facility’s electronic equipment engineer must provide these systems. Coordinate with the facility’s electronic equipment engineer to support equipment requirements. If others are not providing these systems, determine their impact on project cost and implementation if economically feasible for the project.

4-2.3 Data Center Infrastructure Management (DCIM).

Provide DCIM software integrated with the building's DDC/BAS computer. Integration of Information Technology (IT) and facility management disciplines centralizes monitoring, management, and intelligent capacity planning of a data center's critical systems. It is achieved by implementing specialized software, hardware, and sensors. DCIM enables common, real-time monitoring and management platform for all interdependent systems across IT and facility infrastructures. DCIM allows the user to record equipment installation dates and set maintenance intervals that alarm the user to perform preventative maintenance. The software can also integrate with more advanced sensors to address equipment on the verge of failure due to abnormal operating parameters. For example, a server cabinet operating at a higher temperature may require more frequent replacements of active equipment. DCIM can also track maintenance work orders and perform audits for compliance.

4-2.4 Power Conditioning.

For secure areas requiring filtering or conditioning of power refer to UFC 4-010-05. Any power conditioning equipment must meet the electrical power characteristics stated in Section 3-7.

4-2.5 Antenna Systems.

Size cable entry ports into facilities as required based on quantity and size. Cable boots must be provided and sized according to the cables to enter the entry port. Multi-cable modular-based compression-type transit systems are acceptable. Provide power to exterior antenna systems by underground cable trench with removable covers. Fluorescent and LED lighting can cause interference in radio systems. Consider using incandescent lighting for radio systems easily influenced by EMI. Discuss lighting with radio operators to verify EMI impact on systems.

4-2.6 Audio Visual.

Provide audio visual equipment as required. A/V equipment must utilize all hardwired connections; wireless operability is prohibited.

This Page Intentionally Left Blank

APPENDIX A BEST PRACTICES

A-1 GENERAL.

A-1.1 Antiterrorism (AT).

Incorporate AT issues at the initial phase of the design. Coordinate all protection features with the current standards and any additional requirements in place at the time of the design. Ascertain the requirements for protection based on a site-specific survey, or lacking one, and provide the minimum protection standards outlined in the standards. Coordinate all AT issues with the base that may be a part of another project or impact adjacent facilities, such as security fencing and parking.

Design basis threat must consider both the occupants of the building and the equipment within the building necessary for the mission's success.

A-2 ENGINEERING SYSTEMS GRADING.

A-2.1 Grade 1.

Not applicable.

A-2.2 Grade 2.

These facilities have redundant componentry but not system level redundancy. Some maintenance activities will interrupt or impede the performance of the mission.

A-2.3 Grade 3.

These facilities can have any capacity component or distribution element serviced or repaired on a planned basis without interrupting or impeding the performance of the computer equipment.

A-2.4 Grade 4.

The facilities systems can continue operations uninterrupted despite the failure of one or more components.

APPENDIX B GLOSSARY

B-1 ACRONYMS

A/E	Architecture/Engineering
AC	Air Conditioning
AFCEC	Air Force Civil Engineer Center
AFF	Above Finish Floor
ADP	Automatic Data Processing
AHJ	Authority Having Jurisdiction (See MIL-STD 3007, Change 2, Nov 2018)
ASCE	American Society of Civil Engineers
AT	Antiterrorism
ATS	Automatic Transfer Switch
A/V	Audio/Visual
BAS	Building Automation System
BESEP	Base Electronic System Engineering Plan
BIA	Bilateral Infrastructure Agreement
BTUs	British Thermal Units
C5ISR	Command, Control, Communications, Computers, Cyber, Intelligence, Surveillance, and Reconnaissance
CATV	Television Systems
CDC	Core Data Center
CEDC	Component Enterprise Data Center
CFD	Computational Fluid Dynamics
C-I-A	Confidentiality, Integrity, and Availability
COMNAVWARSYSCOM	Naval Information Warfare Systems Command
CRAC	Computer Room Air Conditioning Units

CRAH	Computer Room Air Handling Units
CSP	Construction Security Plan
CTTA	Certified TEMPEST Technical Authority
CTR	Component Technical Representative
DC	Direct Current
DCIM	Data Center Infrastructure Management
DDC	Direct Digital Control
DF	Direction Finder
DOAS	Dedicated Outdoor Air System
DoD	Department of Defense
DOR	Designer of Record
DX	Direct Expansion
EC	Electronically Commutated
EDA	Equipment Distribution Area
EF	Entrance Facility
EMC	Electromagnetic Compatibility
EPA	Environmental Protection Agency
EPSM	Electrical Power System Monitoring
EPO	Emergency Power Off
ESS	Electronic Security Systems
FAC	Facility Analysis Category
FACU	Fire Alarm Control Unit
GIS	Gas Insulated Switchgear
GSU	Geographically Separated Unit
HDA	Horizontal Distribution Area

HMI	Human Machine Interface
HMT	Harmonic Mitigating Transformers
HNFA	Host Nation Funded Construction Agreements
HQUSACE	Headquarters, U.S. Army Corps of Engineers
HVAC	Heating, Ventilating, and Air-Conditioning
Hz	hertz
in.	Inches
in^2	Square Inches
I/O	Input/Output
IDA	Intermediate Distribution Area
IGBT	Isolated Gate Bipolar Transistor
IPN	Installation Processing Node
ISN	Installation Services Node
IST	Integrated Systems Testing
IT	Information Technology
kg	Kilogram
kPa	Kilopascal
lb	Pounds
LCCA	Life Cycle Cost Analysis
LSI	Long-time, Short-time, and Instantaneous
mm	Millimeter
mm^2	Square Millimeter
MBH	**T**housand BTU per Hour
MDA	Main Distribution Area
MERV	Minimum Efficiency Reporting Value

MESEP	Mission Engineering Systems Execution Plan
MTS	Manual Transfer Switch
M-T-T-M	Main-Tie-Tie-Main
NAVFAC	Naval Facilities Engineering Systems Command
OCONUS	Outside Continental U.S.
OSI	Open Source Interconnection
PDS	Protected Distribution System
PDU	Power Distribution Unit
PEMCS	Power and Environmental Monitoring and Control System
PLd	Performance Level d
psf	Pounds per Square Foot
RPCS	Real Property Categorization System
RPP	Remote Power Panel
rPDU	Rack Mounted PDU
rSTS	Rack Mounted STS
SAPF(s)	Special Access Program Facility(ies)
SCIF(s)	Sensitive Compartmented Information Facility(ies)
SEI	Structural Engineering Institute
SIS	Solid Insulated Switchgear
SM	Systems Manual
SOFA	Status of Forces Agreements
SoO	Sequence of Operations
SPPN	Special Purpose Processing Node
SSM	Site Security Manager
STS	Static Transfer Switch

THD	Total Harmonic Distortion
TPN	Tactical Processing Node
TR	Telecommunication Room
UFC	Unified Facilities Criteria
UPS	Uninterruptible Power Supply
USACE	U.S. Army Corps of Engineers
U.S.	United States
VRF/VRV	Variable Refrigerant Flow/Volume
VEWFD	Very Early Warning Fire Detection
ZDA	Zone Distribution Area

B-2 DEFINITION OF TERMS.

Electronics Engineer: Person(s) responsible for the active equipment design of the mission systems to be contained within the facility.

Equipment Rooms: Rooms containing mission active data processing equipment.

Grade: A DoD specific term that is similar to Uptime Institute's Tiering, ANSI/TIA 942 Data Centers, and ANSI/BICSI 002 Class models.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC S), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

This Unified Facilities Criteria (UFC), UFC 4-141-10, *Airfield Operations Support Facilities* provides requirements for evaluating, planning, programming, and designing Airfield Operations Support Facilities. The requirements contained in this UFC apply to Army, Navy, and Air Force facilities unless specifically referenced to a single service. This UFC is not intended as a substitution for thorough review during design by individual Program Managers and Operations Staff in the appropriate service.

The desired goal of this UFC is to maintain consistency in Air Operations Support Facility requirements across the Army, Navy and Air Force. This UFC is not intended as an operational manual.

Each service has unique requirements to fulfill specific missions. This document highlights any key differences that impact the overall facility program, layout and design. Where one Service's criteria vary from the other Services' criteria, it is noted in the text.

1-2 INCORPORATES AND CANCELS.

UFC 4-141-10N, *Design: Aviation Operation and Support Facilities*, 16 January 2004.

1-3 PURPOSE AND SCOPE.

This UFC is organized with general requirements for several different categories of airfield operations support facilities included in separate chapters. Within each chapter, the planning and design requirements for one or more system are described, with differences between Service requirements identified.

1-4 APPLICABILITY.

The information in this UFC applies to the design of all new construction projects, to include additions, alterations, and renovation projects within the United States and its territories and possessions outside of the United States.

1-5 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5.1 Facility Requirements Document (FRD)

The airfield operations support facility manufacturer's FRD or equivalent document is an integral requirement of facility design that contains additional specific facilities requirements that must be considered and satisfied in addition to this UFC.

FRDs are typically authored by the system manufacturer and contain many specific details, are often quite voluminous and difficult to obtain. The FRD may have additional technical facility requirements, special maintenance procedures, systems, data or other items that may impact the airfield operations support facility design. This UFC is not a substitute for the FRD of the support facility.

1-6 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, *Cybersecurity of Facility-Related Control Systems*, and as required by individual Service Implementation Policy.

Cybersecurity is implemented to mitigate vulnerabilities to all DoD real property facility related control systems to a level that is acceptable to the System Owner and Authorizing Official. UFC 4-010-06 provides requirements for integrating cybersecurity into the design and construction of control systems.

1-7 GLOSSARY.

APPENDIX B contains acronyms, abbreviations, and terms.

1-8 REFERENCES.

APPENDIX C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 GENERAL PLANNING AND DESIGN CONSIDERATIONS

2-1 INTRODUCTION.

2-2 SERVICE CONTACT AGENCIES.

For additional information and guidance on the topics covered in this UFC, contact the following agencies within each Service. These agencies were instrumental in providing the contents of this UFC.

2-2.1 Army.

Fixed Base Division
Air Traffic Services Command (ATSCOM)
Ft Rucker, AL
Email: usarmy.rucker.forscom.mbx.afat-ats-cb@mail.mil

2-2.2 Navy.

a. Instrument Landing System and Shore Instrument Carrier Landing System Facilities

   Naval Air Warfare Center Aircraft Division – Webster Outlying Field (NAWCAD WOLF)
   17464 Webster Field Road, Building 8131
   St. Inigoes, MD 20684
   Email: shore_ls@us.navy.mil

b. Shore Based Airport Surveillance Radar (ASR), ATC Communications Facilities, and Automated Surface Observing System (ASOS)

   Naval Information Warfare Center (NIWC) – Atlantic
   ATC Engineering Division
   P.O. Box 190022
   North Charleston, SC 29419
   Email: atcweb@navy.mil

c. TACAN & PAR Facilities

   Naval Information Warfare Center (NIWC) – Pacific
   Code 41110 Tactical Air Navigation Branch
   53560 Hull Street
   San Diego, CA 92152-5001
   Email: tacan@navy.mil, NIWC_4110_TACAN_ISEA@us.navy.mil

2-2.3 Air Force.

ATCALS Maintenance Division
Air Force Flight Standards Agency
HQ AFFSA/XM
Oklahoma City, OK
Email: HQAFFSA.XM.ATCALS.1@us.af.mil

2-3 GENERAL PLANNING CONSIDERATIONS.

2-3.1 Key Planning Documents.

UFC 2-000-05N	*Facility Planning for Navy and Marine Corps Shore Installations*
UFC 2-100-01	*Installation Master Planning*
UFC 3-201-01	*Civil Engineering*
UFC 3-260-01	*Airfield and Heliport Planning and Design*
NAVFACINST 11010.45A	*Site Approval Request Process*

2-3.2 Planning Process.

The planning process is used to define and consolidate requirements for a new facility and then select a site that meets those requirements while also fitting within site constraints. Each Service has their own defined process for site selection that must be followed for every facility project. The planning process ensure that the full range of factors that may influence site selection are considered before site approval is achieved.

Factors that must be considered include:

- Installation Master Plan
- Land Use Compatibility (AICUZ)
- Topography and Flood Protection
- Airfield Clearances
- Airspace Clearances
- Roadway Access
- Environmental Constraints
- Natural, Historic and Cultural Resources
- Future Development
- Explosive Safety Quantity-Distance Arcs

- Security
- Connections to other Facilities

All new construction must be evaluated for potential environmental impacts following the requirements of the National Environmental Policy Act (NEPA). See Service-specific guidance for implementation of this process.

Ensure the Lead Service Agencies are consulted early in the planning and programming process to explore all viable options and make the best possible site selection.

In most cases, the facilities described in this UFC must be sited in a particular location to properly function. However, site-specific conditions might require a non-standard installation. Where a non-standard installation is required and conflicts with the airfield clearances described in UFC 3-260-01, follow the Service-specific waiver processing procedures outlined in UFC 3-260-01, Appendix B, Section 1 during site selection and approval, before detailed design or construction has begun.

2-4 GENERAL DESIGN CONSIDERATIONS.

2-4.1 Key Design Documents.

These are a partial list of key design documents that contain additional requirements for the respective subjects. Requirements in this UFC related to those subjects are additive and intended to conservatively supplement these documents and references. See Section 1-4 for General Building Requirements.

UFC 1-200-01	*General Building Requirements*
UFC 2-000-05N	*Facility Planning Criteria for Navy/Marine Corps Shore Installations*
UFC 3-101-01	*Architecture*
UFC 3-110-03	*Roofing*
UFC 3-201-01	*Civil Engineering*
UFC 3-220-01	*Geotechnical Engineering*
UFC 3-250-01	*Pavement Design for Roads and Parking Areas*
UFC 3-260-01	*Airfield and Heliport Planning and Design*
UFC 3-260-04	Airfield and Heliport Marking
UFC 3-301-01	*Structural Engineering*
UFC 4-010-01	*DoD Minimum Antiterrorism Standards for Buildings*

UFC 4-022-03	*Security Fences and Gates*
UFC 3-401-01	*Mechanical Engineering*
UFC 3-410-01	*Heating, Ventilating and Air Conditioning Systems*
UFC 3-420-01	*Plumbing Systems*
UFC 3-450-01	*Noise and Vibration Control*
UFC 3-460-01	*Design: Petroleum Fuel Facilities*
UFC 3-501-01	*Electrical Engineering*
UFC 3-520-01	*Interior Electrical Systems*
UFC 3-530-01	*Design: Interior and Exterior Lighting and Controls*
UFC 3-535-01	*Visual Air Navigation Facilities*
UFC 3-540-01	*Engine-Driven Generator Systems for Prime and Standby Power Applications*
UFC 3-575-01	*Lightning and Static Electricity Protection Systems*
UFC 3-580-01	*Telecommunications Building Cabling Systems Planning and Design*
UFC 3-600-01	*Fire Protection Engineering for Facilities*
UFC 4-133-01	*Air Traffic Control and Air Operations Facilities*
TSEWG TP-19	*Static Uninterruptible Power Supply (UPS)*
FAA AC 70/7460-1	*Obstruction Marking and Lighting*
FAA AC 150/5220-23	*Frangible Connections*
FAA AC 150/5320-5	*Surface Drainage Design*
SDDCTEA Pamphlet 55-17	*Traffic and Safety Engineering for Better Entry Control Facilities*

2-4.2 Site Selection.

In addition to the following paragraphs, site facilities in accordance with UFC 3-260-01. For Navy and Marine Corps, also check UFC 2-000-05N for airfield safety clearances.

2-4.2.1 Siting Criteria/Land Requirements.

For each Airfield Operations Support Facility there are specific criteria that must be met to allow the device to function properly. These requirements are described in the chapters for each system. The optimum location of the device relative to the runway/taxiway or airport varies by the function of the device. There are tolerances to the ideal device siting location, which allow some flexibility to fit existing facilities.

2-4.2.2 Separation/Clearance.

In addition to the location of the facility and the land needed, there are specific separation and clearance standards for each device for it to function properly and provide a safe environment for aircraft operations. Each device has allowable height and separation distances for above-ground objects around the device so that the electronic or light signal is not impacted. The size, shape, mass and material nature of the object can impact the function of a device that transmits an electronic signal. For communications and surveillance antennas, including some NAVAID antennas, there is a critical area immediately around the device that must be kept clear of all above-ground objects. Once a NAVAID is installed, it is essential to maintain the separation and clearance standards as future construction is considered in the vicinity of the facility. A Notice of Proposed Construction or Alteration (FAA Form 7460-1) must be submitted to the FAA to allow an evaluation of the potential impact of any proposed construction in the vicinity of a NAVAID. Sometimes the nature of construction activity will by itself mean that the NAVAID must be temporarily turned off, to prevent a false signal from being transmitted.

2-4.2.3 Critical Areas.

Many NAVAIDs and ATC facilities have a defined critical area that must be protected to ensure adequate performance.

a. <u>Geometry</u>. Each critical area extends a certain distance out in all or select directions. It can be circular-, rectangular- or wedge-shaped. The dimensions may vary based on the aircraft and terminal operations the NAVAID and ATC facility is designed to serve and the precision of the device in use.

b. <u>Grading</u>. There are standards for grading the ground around each of the NAVAIDs. In general, grade the immediate area around the device relatively smooth, level and well drained.

c. <u>Protection</u>. Coordinate maintenance activities, such as mowing or the use of service vehicles, within the critical area with the tower and airfield management offices to prevent a degradation of the function of the NAVAID during Instrument Flight Rules (IFR) conditions when the operation of the NAVAID is critical. Proposed construction in the vicinity of any NAVAID must be reviewed and analyzed by the Lead Service Agency to determine any potential impacts to the function of the NAVAID. For off-airport NAVAIDs, installation of fencing or guardrails along the perimeter of the critical area is needed to keep these areas clear. For certain systems, due to false reflective targets or poor accuracy, exercise care when a decision to fence around a critical area is made.

2-4.2.4 Jet Blast/Exhaust.

Locate NAVAIDs, monitoring devices, and equipment shelters at least 600 feet (183 m) behind the source of jet blast to minimize the accumulation of exhaust deposits on antennas.

2-4.3 NAVAIDs as Obstacles.

Any object, including NAVAIDs, that are located near an active runway can present an increased risk to aircraft operations. In particular, UFC 3-260-01 recognizes the need to limit NAVAIDs except those required to be in a certain location to perform their function and may fall within the Primary Surface or penetrate Imaginary Surfaces. Any NAVAID object that remains inside the Primary Surface must be supported by frangible structures that minimize damage to any aircraft that might strike the object.

2-4.3.1 Permissible Deviations (Army and Air Force) and Standard Exceptions (Navy and Marine Corps).

While it is desirable not to have any objects in areas that could be a hazard to aircraft, some properly sited NAVAIDs have been classified as being Permissible Deviations (Army and Air Force per UFC 3-260-01, Appendix B, Section 13) or Standard Exceptions (Navy and Marine Corps per UFC 3-260-01, Chapter 2). In other words, the NAVAID location is critical for its proper functioning and the safety benefit derived from the operation of the NAVAID outweighs the potential risk of an aircraft striking the NAVAID. A permissible deviation or standard exception determination allows NAVAIDs to be in the Primary Surface. However, the power and control equipment and shelters associated with certain NAVAIDs are not considered to be a permissible deviation or standard exception in regard to the Primary Surface, unless operational requirements require them to be near the NAVAID.

2-4.3.2 Frangibility.

NAVAID objects located within operational areas on the airport are generally mounted with frangible couplings, with the point of frangibility no higher than 3 inches (75 mm) above the ground on the mounting legs, which are designed to break away upon impact. This reduces the potential damage to an aircraft that inadvertently leaves the paved surfaces. FAA AC 150/5220-23 provides guidance on frangible connections to meet frangibility requirements.

2-4.3.3 Non-Standard Installations.

Any NAVAID or associated equipment that remains inside the Primary Surface and is not a permissible deviation or standard exception and does not meet frangibility requirements is a non-standard installation. The NAVAID must be removed from the Primary Surface if practicable.

2-4.3.4 Marking and Lighting.

NAVAIDs that penetrate the Imaginary Surfaces defined in UFC 3-260-01 are marked with international orange and white paint and lights, with red obstruction lights placed on the highest point. This makes the NAVAID and other ATC Facilities more visible to the pilot. See UFC 3-260-04 for marking requirements. See UFC 3-535-01 for obstruction lighting requirements.

2-4.4 Site Considerations.

2-4.4.1 Site Suitability.

Basic considerations for site selection include terrain characteristics and meteorological conditions. Locate facilities requiring technical adequacy for radiation, reception, visibility, etc., following the requirements established by the governing agency or command responsible for the project. Ensure site selection considerations are fully understood and incorporated into the design. Site considerations for electronic facilities are generally contained in facility-specific FAA Orders or FRDs referenced in the following chapters. Ensure new systems do not encroach on Compass Calibration Pads. See UFC 3-260-01, Chapter 6 for specific requirements.

2-4.4.2 Separation of Structures.

Comply with UFC 3-600-01.

2-4.4.3 Access and Parking.

Provide paved access drives and parking lots for attended facilities. Access drives and parking facilities for <u>unattended</u> facilities may be unpaved except where access to the facility is directly from runways and taxiways. In these cases, pave minimum 300 feet (100 m) prior to connecting to an airfield operations surface (runway, taxiway, apron) to avoid the scattering of debris onto the operational surfaces. At facilities adjacent to runways and taxiways, provide parking space off the operational surface for a maintenance vehicle. Locate the parking space to avoid interference with the operation of any facilities in the area (e.g., provide adequate wingtip clearances). Ensure roadway and vehicle parking surfaces within the airfield operations area are flush with the surrounding ground surface. See UFC 3-250-01 for roadway design procedures. Grade unpaved access roads and parking areas to rapidly drain surface water and constructed with materials that remain stable to support maintenance vehicles in all local environmental conditions.

2-4.4.3.1 Parking.

The number of parking stalls required at each facility varies dependent upon the function, location, and size of the user command. Consider double work shifts and shift changes when determining the required number of parking stalls. Criteria for establishing the required number of parking stalls based on the type of facility and size of the work force are provided in SDDCTEA Pamphlet 55-17. In addition to requirements established in the reference document, conform to the following restrictions:

2-4.4.4 Access for Fire Department Vehicles.

Consult local authorities having jurisdiction for criteria regarding access to the area and clearance around the buildings for fire apparatus maneuvering. The equipment expected to respond to an emergency will control these decisions. See National Fire Protection Association (NFPA) 1141, Fire Protection in Planned Building Groups.

2-4.4.5 Site Drainage.

Provide drainage design in accordance with UFC 3-201-01. Metallic pipe and reinforced concrete pipe are inappropriate at some sites. Establish requirements for use of metallic pipe and reinforced concrete pipe early in facility planning. Consider drainage swales with minimal velocities to avoid erosion. See also FAA AC 150/5320-5 for surface drainage on airfields.

2-4.4.6 Protection of Fixed Objects.

In areas where frangibility is not a concern, provide barriers or bollards to protect non-frangible fixed objects (electrical transformers, generators, fuel tanks, fire hydrants, etc.) outside the primary surface from damage due to vehicles and moving equipment.

2-4.4.7 Airfield Safety.

Consider safety clearances listed in UFC 3-260-01 when siting facilities in or near aviation operational areas. For Navy and Marine Corps, also check UFC 2-000-05N for airfield safety clearances. Fabricate objects located within the Primary Surface for low impact resistance in accordance with FAA AC 150/5220-23. Provide obstruction marking or lighting for facilities located in or near aviation operational areas in accordance with UFC 3-260-04 and UFC 3-535-01.

2-4.5 Architectural Requirements.

Comply with requirements of UFC 3-101-01. Place design emphasis on fire resistance, minimal maintenance and repair cost, and ease of facility expansion or modification. Electronic communications equipment housed in the building varies with the mission of the installation. Design facility exterior in accordance with the base architectural compatibility guidance or local command architectural guidance.

2-4.5.1 ADA Requirements.

Provide barrier-free access to civilian workspaces and other spaces intended for public access. Design facilities to locate handicapped access spaces on first floor only unless the size of the facility's administration and other accessible areas requires a second floor. Areas hazardous to handicapped persons need not be accessible. Comply with current criteria in Uniform Federal Accessibility Standards (UFAS). Refer to UFC 3-101-01.

2-4.6 Structural Requirements.

Design in accordance with UFC 3-301-01. Base an economical structural system on facility size, projected load requirements, quality of local available materials, local labor and construction materials, and local wind, snow, seismic, geologic, and permafrost conditions. Design structural systems to support roof-mounted and/or suspended loads, when required.

2-4.7 Construction Materials.

Design attended facility buildings using styles and materials as approved by the ordering authority. Unless otherwise directed, design unattended facility buildings using concrete, concrete masonry, pre-engineered metal, or premanufactured metal or fiberglass-reinforced plastic. Use construction methods that provide maximum overall economy consistent with functional and aesthetic requirements, reasonable comfort, and sound architectural and engineering practices. Select materials, equipment, and methods to result in low costs consistent with economic maintenance for the required use and life expectancy of the facility. Refer to UFC 1-200-01.

2-4.7.1.1 Reflective Surfaces.

To prevent mirrorlike reflections from building surfaces to aircraft in flight, provide roofs and other external surfaces with a specular reflectance compatible with the location of the building on the airfield. If the building is located such that glare may be an operational hazard, provide the critical surfaces of that building with a light reflectance of not more than 10, measured at an angle of 85 degrees in accordance with American Society for Testing and Materials (ASTM) D 523, Standard Test Method for Specular Gloss.

2-4.7.2 Floors and Foundations.

Construct antenna foundations, equipment pads and building floors with reinforced concrete on a compacted subbase or subgrade in accordance with UFC 1-200-01, UFC 3-220-01, and UFC 3-301-01. Site-specific design is required for all foundations and floors, considering the local soils, climate and environmental loads.

Unless otherwise indicated in this UFC or in specific system FRDs, provide equipment pads for prefabricated or modular shelters minimum 12-inches larger than the supported equipment on all sides.

For foundations on airfields, construct foundations or equipment pads 2 inches (50 mm) +/- 1 inch (25 mm) above the surrounding grade. When the foundation is surrounded by airfield pavement or shoulder pavement, construct the foundation flush with surrounding pavement.

2-4.7.3 Roofing.

Provide roof system and insulation to meet the requirements of UFC 3-110-03. Determine thermal resistance of roof insulation by design criteria and life cycle costs.

2-4.8 Mechanical Requirements.

Comply with the requirements of UFC 3-401-01.

2-4.8.1 Energy Conservation.

Design climate-controlled facilities for energy efficiency. Consider isolated ventilation or air conditioning systems for equipment with high heat loads or that require more critical temperature or humidity control than would otherwise be required for the remainder of the occupancy.

2-4.8.2 Equipment Selection.

Select adequately sized air conditioning equipment for personnel comfort applications to remove the sensible and latent heat loads generated within these areas. Computer rooms and electrical equipment rooms produce predominantly sensible heat and require specially designed units. Ensure mechanical systems do not interfere with electronic equipment or radiated signals.

2-4.8.3 Heating and Air Conditioning.

Provide heating and air conditioning in accordance with UFC 3-401-01 and UFC 3-410-01. Provide duct smoke detectors and controls in accordance with UFC 3-600-01.

2-4.8.4 Plumbing.

Provide plumbing for facilities in accordance with UFC 3-420-01. Ensure that plumbing work not covered by UFC criteria meets the requirements of the National Plumbing Code Handbook.

2-4.8.4.1 Water and Sanitation.

Unattended facilities are not normally provided with water and sanitation facilities (sink and toilets). However, provide water and sanitary facilities at unattended facilities where a significant amount of maintenance is anticipated, and sanitary facilities are not available in the vicinity. Consider the use of chemical toilets and bottled water.

2-4.8.5 Fire Protection.

Design fire protection systems in accordance with UFC 3-600-01.

2-4.8.6 Noise and Vibration Control.

Design mechanical systems and equipment to limit noise and vibration in accordance with UFC 3-450-01.

2-4.9 Electrical Systems.

Design electrical systems in accordance with UFC 3-501-01.

2-4.9.1 Lighting.

Design interior lighting in accordance with UFC 3-530-01.

2-4.9.2 Lightning Protection.

Design facilities for lightning protection. Refer to NFPA 78, *Lightning Protection Code*, and UFC 3-575-01 for minimum standards.

2-4.9.3 Emergency Electrical Power.

2-4.9.3.1 Emergency Generator.

Provide emergency generators with electronic line monitoring equipment and automatic starting and switching capability. Design in accordance with UFC 3-540-01. When used in conjunction with an UPS, provide generator output at least 1.5 times the output rating of the UPS. Provide the following for emergency generators:

a. Unless otherwise noted, provide automatic starting and switching capable of supplying the rated load within 15 seconds of a power failure, except where Category II instrument operations are conducted.
b. During Category II instrument operations, a 1-second power transfer is required. This is normally accomplished by providing a remote start capability which permits operation of the systems on the generator during Category II weather conditions. Standby power is then subject only to switching time. The actual procedure must be locally coordinated.
c. An isolation switch to bypass the emergency generator during generator maintenance.
d. An automatic battery charger for maintenance of generator starting batteries.
e. An isolated mounting slab for the generator to reduce noise and vibration transmission.
f. Provide the following when an indoor emergency generator is required:
    - A separate generator room with an independent ventilation system.

- An engine exhaust system connected to the exterior of the facility with an exterior muffler. Configure the exhaust system to prevent rainwater or condensation from entering the engine manifold.
- Adequate engine cooling by a radiator duct or externally mounted radiator.

g. Consider a premanufactured building to house an indoor generator. Consider an outdoor unit in mild climate conditions. Consider a below ground generator vault for units which must be sited within airfield clear zones or primary surfaces.

2-4.9.3.2 Emergency Generator Fuel Storage.

Design fuel storage for generators in accordance with UFC 3-460-01 and UFC 3-540-01 as well as state and local regulations. Provide fuel storage capacity for 24 hours of continuous generator operation, unless otherwise noted in subsequent chapters. Provide double wall storage tanks and piping.

2-4.9.4 Uninterrupted Power Supply (UPS)

Provide an UPS in electronic facilities and air traffic control installations for critical technical loads and the specific requirements of the ordering authority. Install the UPS in accordance with UFC 3-501-01, UFC 3-520-01 and TSEWG TP-19.

2-4.10 Communications Systems.

Provide voice, data, and equipment control communications systems in accordance with UFC 3-580-01. Consider fiber optic systems in facilities requiring extensive internal communications systems for electronic cable protection.

Bury communication cables minimum 24 inches (610 mm) below ground. Install cables in concrete-encased conduit or duct bank beneath runways, taxiways, aprons, roadways and parking areas with regularly spaced manholes or handholes. Concrete-encase conduits where appropriate to protect critical communications systems from accidental damage during digging.

2-4.10.1 Cable Loop System.

For the benefit of redundancy and uninterrupted service, provide a cable loop system. FAA Order 6950.23 addresses control/monitor, digital data, voice/voice frequency and radar video/trigger signals.

2-4.11 Physical Security.

Comply with UFC 4-010-01. Where fences are required, comply with UFC 4-022-03.

2-4.12 Air Traffic Control Towers.

This UFC does not apply to Air Traffic Control Towers. See UFC 4-133-01.

2-5 STORMWATER MANAGEMENT.

Determine whether on-site stormwater management to address the added impervious surfacing associated with the concrete pads and gravel surfacing is required. If thresholds are exceeded, implement stormwater management strategies to meet the local, state, or federal guidelines for stormwater treatment. Typical strategies used include bioretention swales or cells, dispersing stormwater through existing or new vegetation, and infiltration facilities. See UFC 3-260-01, Chapter 2 for precautions and prohibitions regarding stormwater management facilities on or near airfields.

2-6 EROSION AND SEDIMENT CONTROL.

Install erosion control measures to prevent construction stormwater from leaving the project site and entering any adjacent storm system or critical areas. Measures must meet local, state, and federal guidelines. Typical erosion control measures that may be used include filter fabric fencing, silt sock fabric, and catch basin filter inserts.

2-7 FRANGIBILITY REQUIREMENTS.

Army and Air Force: Comply with frangibility requirements included in UFC 3-260-01, Appendix B, Section 13.

Navy and Marine Corps: Comply with frangibility requirements described in FAA AC 150/5220-23.

This Page Intentionally Left Blank

CHAPTER 3 AIR NAVIGATION AIDS

3-1 GENERAL INFORMATION.

Air Navigation Aid facilities are fixed ground station electronic equipment which transmit bearing, identification, and distance information to properly equipped aircraft. These facilities are unattended.

3-1.1 Function.

Air Navigation Aid facilities may consist of the following types of facilities.

Table 3-1 Types of Air Navigation Aid Facilities

Designation	Type of Facility
VOR	VHF navigational facility, omnidirectional azimuth only
DME	UHF navigational facility, distance only
TACAN	UHF navigational facility, omnidirectional azimuth and distance
VOR/DME	Associated VOR and DME navigational facilities
VORTAC	Associated VOR and TACAN navigational facilities

3-1.1.2 Very High Frequency (VHF) Omni-Directional Range (VOR) Systems.

The VOR facility is a VHF, fixed ground-based station which continuously transmits bearing, identification, and with proper equipment (DME), distance information to properly equipped aircraft. Figure 3-1 illustrates a typical VOR facility. See FAA AC 150/5300-13 and FAA Order 6820.10 for a detailed description of the features and different types of VOR facilities.

Figure 3-1 VOR (VOR) Facility

3-1.1.3 Distance Measuring Equipment (DME).

The DME provides pilots with a measurement of distance to the runway in nautical miles. The DME is a terminal area or en route navigation facility that provides the pilot with a direct readout indication of aircraft distance from the identified DME. It can be co-located with a VOR and/or a Localizer shelter. Figure 3-2 illustrates a typical DME antenna located adjacent to a Localizer Shelter.

Figure 3-2 Omni-Directional Distance Measuring Equipment (DME) Antenna

3-1.1.4 Tactical Air Navigation (TACAN) Systems.

The TACAN facility is an ultra-high frequency (UHF) ground-based station, developed by the military, which continuously transmits bearing, identification, and distance information to properly equipped aircraft when interrogated. Figure 3-3 illustrates a typical TACAN facility.

Figure 3-3 Typical TACAN Facility

3-1.1.5 Very High Frequency (VHF) Omni-Directional Range/Tactical Air Navigation (VORTAC).

The VORTAC facility is a VHF/UHF fixed ground-based station which continuously transmits bearing, identification, and distance information to properly equipped aircraft when distance measuring equipment (DME) is installed. It combines a VOR and TACAN into one facility. Figure 3-4 illustrates a typical VORTAC.

Figure 3-4 VORTAC Facility

3-2 VERY HIGH FREQUENCY (VHF) OMNI-DIRECTIONAL RANGE (VOR) SYSTEMS.

3-2.1 Key Documents.

UFC 3-260-01	*Airfield and Heliport Planning and Design*
FAA AC 150/5300-13	*Airport Design*
FAA Order 6780.5	*DME Installation Standards Handbook Type FA-96-39 (Request from Lead Service Agency)*
FAA Order 6780.8	*Distance Measuring Equipment (DME) Installation Standards Handbook Type FA-9783 (Request from Lead Service Agency)*
FAA Order 6820.10	*VOR, VOR/DME, and VORTAC Siting Criteria*
AF T.O. 31Z3-822-2	*Air Traffic Control Landing Systems (ATCALS) Site Requirements 404L*

3-2.2 Siting.

If possible, locate the VOR in an area adjacent to the intersection of the primary runways. Locate the facility at the minimum distances from the centerline of runways and taxiways according to Table 3-2 and Figure 3-5. When the facility is located off the airfield, consider selecting a site with one or more flight path courses providing an approach to the primary runway. When sited outside these distances, include obstruction lighting if the VOR is within the primary surface or penetrates the imaginary surfaces defined in UFC 3-260-01. See UFC 3-260-01 and FAA Order 6820.10 for more details about siting considerations.

Table 3-2 VOR Siting Dimensions

Item		Legend in Figures	Requirement		Remarks
No.	Description				
1	Distance to Runway Centerline	A	Army	250 ft (76 m)	Source: UFC 3-260-01, App. B, Section 13
			Navy	750 ft (229 m)	Source: UFC 4-141-10N (Jan 2004)
			Air Force	500 ft (152 m)	Source: UFC 3-260-01, App. B, Section 13
2	Distance to Taxiway Centerline	B	Army	150 ft (46 m)	Source: UFC 3-260-01, App. B, Section 13
			Navy	250 ft (76 m)	Source: UFC 4-141-10N (Jan 2004)
			Air Force	200 ft (61 m)	Source: UFC 3-260-01, App. B, Section 13

The area around the VOR must be clear and reasonably smooth. Per FAA Order 6820.10, all obstructions within 1,000 feet (305 m) of the antenna are to be removed except as noted below. See Figure 3-6 for airspace clearances surrounding the VOR.

- Trees and Forests. Trees close to the VOR antenna can cause severe scalloping. Single trees of moderate height (up to 30 feet (9 m)) may be tolerated beyond 500 feet (152 m), but no closer. Groups of trees are not allowed within a 1,000-ft (305 m) radius or subtend a vertical angle of more than 2 degrees.
- Wire Fences. Ordinary farm-type wire fences about 4-feet (1 m) high are not permitted within 200 feet (61 m) of the antenna; fences of the chain type 6 feet (1.8 m) or more in height are not permitted within 500 feet (152 m) of the antenna; beyond these distances wire fence is not permitted to extend more than 0.5 degrees above the horizontal, measured from the antenna.
- Power and Control Lines. Install power and control line extensions underground for a minimum distance of 600 feet (183 m) from the antenna. Overhead power and control lines may be installed beyond 600 feet (183 m) if they are essentially radial to the antenna for a minimum distance of 1,200 feet (366 m).
- Structures. Structures are not allowed within 1,000 feet (305 m) of the antenna, except for buildings such as the transmitter building at a mountain top site located on a slope below the ground level of the antenna so that they are not visible from the antenna.

3-2.2.1 Army and Air Force.

When used as a terminal navigational aid, the VOR facility may be sited not less than 500 feet (152 m) from the centerline of any runway to the edge of the facilities, provided the elevation of the antenna does not exceed 50 feet (15 m) above the highest point of the adjacent runway centerline. For an on-base installation, the maximum angle of convergence between the final approach course and the runway centerline is 30 degrees. Align the final approach course to intersect the extended runway centerline 3,000 feet (914 m) outward from the runway threshold. When an operational advantage can be achieved, this point of intersect may be established at any point between the threshold and a point 5,200 feet (1,585 m) outward from the runway threshold. Also, where an operational advantage can be achieved, a final approach course which does not intersect the runway centerline or intersects at a point greater than 5,200 feet (1,585 m) outward from the runway threshold may be established, provided that such a course lies within 500 feet (152 m) laterally of the extended runway centerline at a point 3,000 feet (914 m) outward from the runway threshold.

3-2.3 Security.

VOR facilities are normally located within the airfield restricted area. This siting typically meets the minimum security measures for external security. When the facility is located within a restricted area of a lower level of security or is located remote and outside of an established restricted area, provide additional measures to meet the minimum security requirements for the level of security assigned to the facility.

3-2.4 Facility Design Guidance.

Provide an equipment building with roof-mounted antenna. See Figures 3-7 and 3-8 for typical site plan and building layout. See Figure 3-9 for a typical building section. See service-specific guidance for allowable building size. Typical building size is 300 square feet (28 square meters) to house the electronic equipment, monitoring and test equipment, and mechanical equipment.

3-2.4.1 Site Work.

Provide an access road to allow maintenance vehicles access to the VOR. Provide parking space for two maintenance vehicles. See Chapter 2, paragraph “Access and Parking” for roadway and parking area design requirements.

3-2.4.2 Architectural Requirements.

Provide the following:

- Adequate space for equipment and equipment maintenance.
- Clear ceiling height of 10 feet (3 m).
- Work bench.

Do not provide a restroom.

Do not provide windows.

Consider the use of a premanufactured building.

3-2.4.3 Structural Requirements.

Provide sufficient roof area to accommodate the VOR roof mounted antenna and counterpoise. Consider an extended roof overhang or an antenna tower to accommodate a large antenna counterpoise.

3-2.4.3.1 Concrete Pad.

For a shelterized unit, provide a minimum 15’ x 20’ (5 m x 6 m) concrete pad, minimum 6” (150 m) thick with welded wire mesh, and minimum 10” (250 mm) thick at the edges tapering to 6” (150 mm) thick at 2’ (0.6 m) from all edges. In the 10” (250 mm) thick region, place reinforced steel bars (rebar) under the mesh at mid-depth. These requirements for thickness and reinforcement are for optimal soil conditions.

Size of concrete pad may be designed to be larger, as determined by the site-specific requirements.

3-2.5 Mechanical Requirements.

Provide HVAC system to maintain shelter temperature between 65° and 80° F (18° and 27°C). Provide humidity control to maintain humidity between 0 and 95%, with no condensation.

Air Force: See Environmental Control Unit requirements (e.g., allowable temperature and humidity ranges) in AF T.O. 31Z3-822-2, Chapter 3.

3-2.6 Electrical Power.

To avoid potential interference with radar transmissions, locate power, communications, and control cables underground within 1,000 feet (305 m) from the facility. Ensure electrical systems do not interfere with radar transmissions.

Provide 120/240V, 100A, single-phase, 60 HZ commercial power service to the VOR facility.

Air Force: See Commercial Power, Uninterruptible Power Supply, and Backup Power, in AF T.O. 31Z-822-2, Chapter 1. See Grounding, Bonding Shielding and Lightning Protection requirements in AF T.O. 31Z-822-2, Chapter 2.

3-2.6.1 Emergency Electrical Power.

Provide an emergency generator with automatic starting and switching capability as described in Chapter 2. Provide emergency power to the entire facility.

3-2.6.2 Grounding and Bonding.

Install two (2) ground rods, one on each 20' (6 m) side of the concrete pad. Provide separate ground cables, one for the shelter and one for a direct path to ground from the antenna lightning arrestor.

3-2.7 Communications.

Provide 12-strand single mode fiber optic cable or 25 twisted pair communications line to provide required connectivity for data and telephone.

- Data connectivity from the VOR Shelter to Remote Unit located in the ATC Tower.
- Data connectivity from the VOR Shelter Fire Alarm to external monitoring system.
- Telephone line for distance support to troubleshoot system.

Air Force: See fiber optic cable and modem requirements in AF T.O. 31Z-822-2, Chapter 4.

3-2.8 Connection/Interrelation to other Facilities.

Connect a dedicated DSN-capable telephone connection through to the VOR to facilitate distant support, troubleshooting, and corrective maintenance due to the remote location. Connect the VOR to the ATC Tower via fiber optic cable for remote monitoring.

AF T.O. 31Z3-822-2	*Air Traffic Control Landing Systems (ATCALS) Site Requirements 404L*

3-3.2 Siting.

If possible, locate the TACAN in an area adjacent to the intersection of the primary runways. Locate the facility at the minimum distances from the centerline of runways and taxiways according to Table 3-3 and Figure 3-10. When the facility is located off the airfield, consider selecting a site with one or more flight path courses providing an approach to the primary runway. When sited outside these distances, include obstruction lighting if the VOR is within the primary surface or penetrates the imaginary surfaces defined in UFC 3-260-01. See FAA Order 6820.10 for more details about siting considerations.

Table 3-3 TACAN Siting Dimensions

Item		Legend in Figures	Requirement		Remarks
No.	Description				
1	Distance to Runway Centerline	A	Army	250 ft (76 m)	Source: UFC 3-260-01, App. B, Section 13
			Navy	750 ft (229 m)	Source: UFC 4-141-10N (Jan 2004)
			Air Force	500 ft (152 m)	Source: UFC 3-260-01, App. B, Section 13
2	Distance to Taxiway Centerline	B	Army	150 ft (46 m)	Source: UFC 3-260-01, App. B, Section 13
			Navy	250 ft (76 m)	Source: UFC 4-141-10N (Jan 2004)
			Air Force	200 ft (61 m)	Source: UFC 3-260-01, App. B, Section 13

The area around the TACAN must be clear and reasonably smooth. Per FAA Order 6820.10, all obstructions within 1,000 feet (305 m) of the antenna are to be removed except as noted below.

- Trees and Forests. Trees close to the TACAN antenna can cause severe scalloping. Single trees of moderate height (up to 30 feet (9 m)) can be tolerated beyond 500 feet (152 m), but no closer. Groups of trees are not allowed within a 1,000-ft (305 m) radius or subtend a vertical angle of more than 2 degrees.
- Wire Fences. Ordinary farm-type wire fences about 4-feet (1.2 m) high are not permitted within 200 feet of the antenna; fences of the chain type 6 feet (1.8 m) or more in height) are not permitted within 500 feet (152 m) of the antenna; beyond these distances wire fence is not permitted to extend more than 0.5 degrees above the horizontal, measured from the antenna.
- Power and Control Lines. Install power and control line extensions underground for a minimum distance of 600 feet (183 m) from the antenna. Overhead power and control lines may be installed beyond 600 feet (183 m) if they are essentially radial to the antenna for a minimum distance of 1,200 feet (366 m).
- Structures. Structures are not allowed within 1,000 feet (305 m) of the antenna, except for buildings such as the transmitter building at a mountain top site located on a slope below the ground level of the antenna so that they are not visible from the antenna.

3-3.2.1 Army and Air Force.

When used as a terminal navigational aid, the TACAN facility may be sited not less than 500 feet (152 m) from the centerline of any runway to the edge of the facilities, provided the elevation of the antenna does not exceed 50 feet (15 m) above the highest point of the adjacent runway centerline. For an on-base installation, the maximum angle of convergence between the final approach course and the runway centerline is 30 degrees. Align the final approach course to intersect the extended runway centerline 3,000 feet (914 m) outward from the runway threshold. When an operational advantage can be achieved, this point of intersect may be established at any point between the threshold and a point 5,200 feet (1,585 m) outward from the runway threshold. Also, where an operational advantage can be achieved, a final approach course which does not intersect the runway centerline or intersects at a point greater than 5,200 feet (1,585 m) outward from the runway threshold may be established, provided that such a course lies within 500 feet (152 m) laterally of the extended runway centerline at a point 3,000 feet (914 m) outward from the runway threshold.

3-3.3 Security.

TACAN facilities are normally located within the airfield restricted area. This siting typically meets the minimum security measures for external security. When the facility is located within a restricted area of a lower level of security or is located remote and outside of an established restricted area, provide additional measures to meet the minimum security requirements for the level of security assigned to the facility.

3-3.4 Facility Design Guidance.

Provide an equipment building with roof-mounted antenna. See Figures 3-11 and 3-12 for typical site plan and building layout. See Figure 3-13 for a typical building section. See service-specific guidance for allowable building size. Typical building size is 300 square feet (28 square meters) to house the electronic equipment, monitoring and test equipment, and mechanical equipment.

Alternatively, a standard configured shelterized TACAN is a self-contained unit. If this type of facility is selected, provide a 20’ x 15’ (6 m x 4.6 m) concrete pad capable of supporting 12,000 lbs (5,443 kg) on four (4) 12” (300 mm) by 12” (300 mm) support feet.

A typical shelterized TACAN consists of the following items:

- Concrete Pad
- TACAN Shelter/ roof mounted TACAN Antenna
- Backup power (Generator) with associated power transfer equipment
- Electrical conduits/ Ground points (not specifically shown)
- Equipment shelter for the electrical transfer switch, electric main cutoff, and communications enclosures to minimize their exposure to the elements

3-3.4.1 Site Work.

Provide an access road to allow maintenance vehicles access to the TACAN. Provide parking space for two maintenance vehicles. See Chapter 2, paragraph “Access and Parking” for roadway and parking area design requirements.

3-3.4.2 Architectural Requirements.

Provide the following:

- Adequate space for equipment and equipment maintenance.
- Clear ceiling height of 10 feet (3 m).
- Work bench.

Do not provide a restroom.

Do not provide windows.

Consider the use of a premanufactured building.

3-3.4.3 Structural Requirements.

If not using a shelterized unit, provide sufficient roof area to accommodate the TACAN roof-mounted antenna and counterpoise. Consider an extended roof overhang or an antenna tower to accommodate a large antenna counterpoise.

3-3.4.3.1 Concrete Pad.

For a shelterized unit, provide a minimum 15’ x 20’ (4.6 m x 6 m) concrete pad, minimum 6” (152 mm) thick with welded wire mesh, and minimum 10” (250 mm) thick at the edges tapering to 6” (150 mm) thick at 2’ (0.6 m) from all edges. In the 10” (250 mm) thick region, place reinforced steel bars (rebar) under the mesh at mid-depth. These requirements for thickness and reinforcement are for optimal soil conditions.

Size of concrete pad may be designed to be larger, as determined by the site-specific requirements.

Construct the concrete pad above the 100-year flood plain.

3-3.4.3.2 Equipment Shed Requirements.

For a shelterized unit, provide a shed enclosure large enough to house the electrical and communication panels/enclosures. It may be three sided as shown in Figure 3-14 or completely enclosed.

3-3.5 Mechanical Requirements.

Provide HVAC system to maintain shelter temperature between 65° and 80° F (18° and 27°C). Provide humidity control to maintain humidity between 0 and 95%, with no condensation.

Air Force: See Environmental Control Unit requirements (e.g., allowable temperature and humidity ranges) in AF T.O. 31Z3-822-2, Chapter 3.

For a shelterized unit, the AN/FRN-48(V)3 TACAN is a self-contained unit with internal power distribution, emergency lighting, smoke detection equipment, thermostatically controlled environmental control unit with humidity controls, aircraft obstruction and exterior lighting. This equipment is designed, built, tested, and configuration managed by each Service. No additional mechanical systems are required.

3-3.6 Electrical Requirements.

To avoid potential interference with radar transmissions, locate power, communications, and control cables underground within 1,000 feet (305 m) from the facility. Ensure electrical systems do not interfere with radar transmissions.

Provide 120/240V, 100A, single-phase, 60 HZ commercial power service to the TACAN facility.

Air Force: See Commercial Power, Uninterruptible Power Supply, and Backup Power, in AF T.O. 31Z-822-2, Chapter 1. See Grounding, Bonding Shielding and Lightning Protection requirements in AF T.O. 31Z-822-2, Chapter 2.

3-3.6.1 Emergency Electrical Power.

Provide an emergency generator with automatic starting and switching capability as described in Chapter 2. Provide emergency power to the entire facility.

3-3.6.2 Grounding and Bonding.

Install two (2) ground rods, one on each 20’ (6 m) side of the concrete pad. Provide separate ground cables, one for the shelter and one for a direct path to ground from the antenna lightning arrestor.

3-3.6.3 Lighting.

The TACAN shelter comes equipped with an external red filtered door light and obstruction light. Provide additional lighting for the external electrical shed, but include features (aiming, shielding) not to interfere with night-time flight operations.

3-3.7 Communications.

Provide 12-strand single mode fiber optic cable or 25 twisted pair communications line to provide required connectivity for data and telephone.

- Data connectivity from the TACAN Shelter to Remote Unit located in the ATC Tower.
- Data connectivity from the TACAN Shelter Fire Alarm to external monitoring system.
- Telephone line for distance support to troubleshoot system.

Air Force: See fiber optic cable and modem requirements in AF T.O. 31Z-822-2, Chapter 4.

3-3.8 Connection/Interrelation to other Facilities.

Connect a dedicated DSN-capable telephone connection through to the TACAN to facilitate distant support, troubleshooting, and corrective maintenance due to the remote location. Connect the TACAN to the ATC Tower via fiber optic cable for remote monitoring.

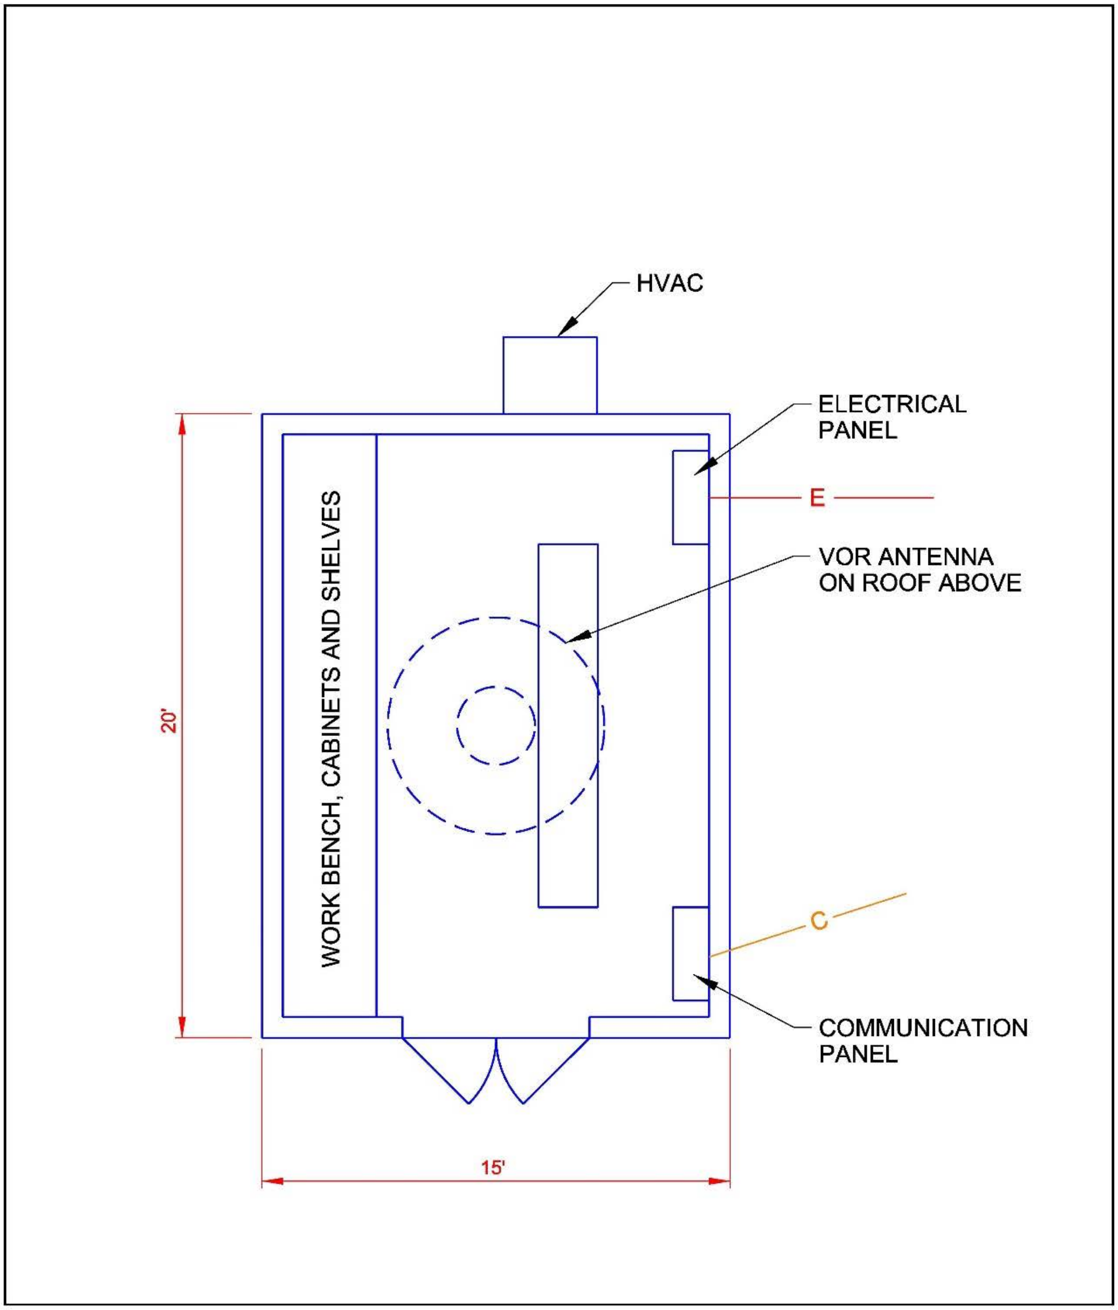

Figure 3-13 Typical TACAN Building Section

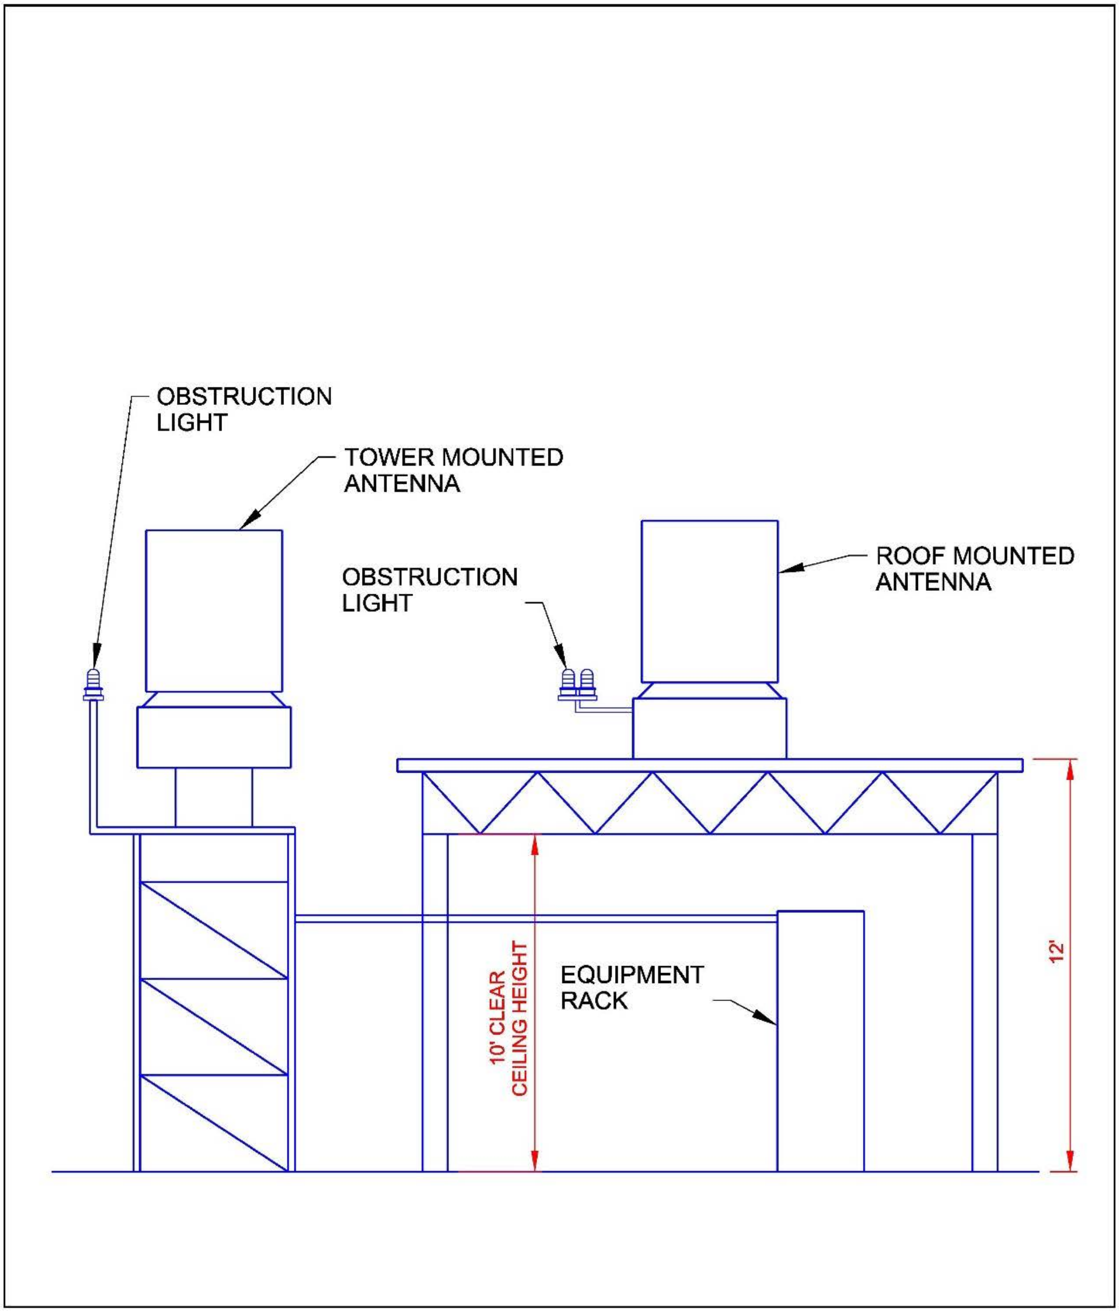

Figure 3-14 Typical Shelterized TACAN Antenna with Adjacent Electrical Shed

3-4 VERY HIGH FREQUENCY (VHF) OMNI-DIRECTIONAL RANGE/ TACTICAL AIR NAVIGATION (VORTAC).

3-4.1 Key Documents.

UFC 3-260-01 — *Airfield and Heliport Planning and Design*

FAA AC 150/5300-13 — *Airport Design*

FAA Order 6780.5 — *DME Installation Standards Handbook Type FA-96-39 (Request from Lead Service Agency)*

FAA Order 6780.8 — *Distance Measuring Equipment (DME) Installation Standards Handbook Type FA-9783 (Request from Lead Service Agency)*

FAA Order 6820.10 — *VOR, VOR/DME, and VORTAC Siting Criteria*

AF T.O. 31Z3-822-2 — *Air Traffic Control Landing Systems (ATCALS) Site Requirements 404L*

3-4.2 Siting.

If possible, locate the VORTAC in an area adjacent to the intersection of the primary runways. Locate the facility at the minimum distances from the centerline of runways and taxiways according to Table 3-4 and Figure 3-15. When the facility is located off the airfield, consider selecting a site with one or more flight path courses providing an approach to the primary runway. When sited outside these distances, include obstruction lighting if the VORTAC is within the primary surface or penetrates the imaginary surfaces defined in UFC 3-260-01. See FAA Order 6820.10 for more details about siting considerations.

Table 3-4 VORTAC Siting Dimensions

Item		Legend in Figures	Requirement		Remarks
No.	Description				
1	Distance to Runway Centerline	A	Army	250 ft (76 m)	Source: UFC 3-260-01, App. B, Section 13
			Navy	750 ft (229 m)	Source: UFC 4-141-10N (Jan 2004)
			Air Force	500 ft (152 m)	Source: UFC 3-260-01, App. B, Section 13
2	Distance to Taxiway Centerline	B	Army	150 ft (46 m)	Source: UFC 3-260-01, App. B, Section 13
			Navy	250 ft (76 m)	Source: UFC 4-141-10N (Jan 2004)
			Air Force	200 ft (61 m)	Source: UFC 3-260-01, App. B, Section 13

The area around the VORTAC must be clear and reasonably smooth. Per FAA Order 6820.10, all obstructions within 1,000 feet (305 m) of the antenna are to be removed except as noted below.

- Trees and Forests. Trees close to the VORTAC antenna can cause severe scalloping. Single trees of moderate height (up to 30 feet (9 m) may be tolerated beyond 500 feet (152 m), but no closer. Groups of trees are not allowed within a 1,000-ft (305 m) radius or subtend a vertical angle of more than 2 degrees.
- Wire Fences. Ordinary farm-type wire fences about 4-feet (1.2 m) high are not permitted within 200 feet (61 m) of the antenna; fences of the chain type 6 feet (1.8 m) or more in height) are not permitted within 500 feet (152 m) of the antenna; beyond these distances wire fence is not permitted to extend more than 0.5 degrees above the horizontal, measured from the antenna.
- Power and Control Lines. Install power and control line extensions underground for a minimum distance of 600 feet (183 m) from the antenna. Overhead power and control lines may be installed beyond 600 feet (183 m) if they are essentially radial to the antenna for a minimum distance of 1,200 feet (366 m).
- Structures. Structures are not allowed within 1,000 feet (305 m) of the antenna, except for buildings such as the transmitter building at a mountain top site located on a slope below the ground level of the antenna so that they are not visible from the antenna.

3-4.2.1 Army and Air Force.

When used as a terminal navigational aid, the VORTAC facility may be sited not less than 500 feet (152 m) from the centerline of any runway to the edge of the facilities, provided the elevation of the antenna does not exceed 50 feet (15 m) above the highest point of the adjacent runway centerline. For an on-base installation, the maximum angle of convergence between the final approach course and the runway centerline is 30 degrees. Align the final approach course to intersect the extended runway centerline 3,000 feet (914 m) outward from the runway threshold. When an operational advantage can be achieved, this point of intersect may be established at any point between the threshold and a point 5,200 feet (1,585 m) outward from the runway threshold. Also, where an operational advantage can be achieved, a final approach course which does not intersect the runway centerline or intersects at a point greater than 5,200 feet (1585 m) outward from the runway threshold may be established, provided that such a course lies within 500 feet (152 m) laterally of the extended runway centerline at a point 3,000 feet (914 m) outward from the runway threshold.

3-4.3 Security.

VORTAC facilities are normally located within the airfield restricted area. This siting typically meets the minimum security measures for external security. When the facility is located within a restricted area of a lower level of security or is located remote and outside of an established restricted area, provide additional measures to meet the minimum security requirements for the level of security assigned to the facility.

3-4.4 Facility Design Guidance.

Provide an equipment building with roof-mounted antenna. See Figures 3-16 and 3-17 for typical site plan and building layout. See Figure 3-18 for a typical building section. See service-specific guidance for allowable building size. Typical building size is 300 square feet (28 square meters) to house the electronic equipment, monitoring and test equipment, and mechanical equipment.

3-4.4.1 Site Work.

Provide an access road to allow maintenance vehicles access to the VORTAC. Provide parking space for two maintenance vehicles. See Chapter 2, paragraph “Access and Parking” for roadway and parking area design requirements.

3-4.4.2 Architectural Requirements.

Provide the following:

- Adequate space for equipment and equipment maintenance.
- Clear ceiling height of 10 feet (3 m).
- Work bench.

Do not provide a restroom.

Do not provide windows.

Consider the use of a premanufactured building.

3-4.4.3 Structural Requirements.

Provide sufficient roof area to accommodate the VORTAC roof mounted antenna and counterpoise. Consider an extended roof overhang or an antenna tower to accommodate a large antenna counterpoise.

3-4.4.3.1 Concrete Pad.

For a shelterized unit, provide a minimum 15’ x 20’ (4.6 x 6 m) concrete pad, minimum 6” (150 mm) thick with welded wire mesh, and minimum 10” (250 mm) thick at the edges tapering to 6” (150 mm) thick at 2’ (0.6 m) from all edges. In the 10” (250 mm) thick region, place reinforced steel bars (rebar) under the mesh at mid-depth. These requirements for thickness and reinforcement are for optimal soil conditions.

Size of concrete pad may be designed to be larger, as determined by the site-specific requirements.

Construct the concrete pad above the 100-year flood plain.

3-4.5 Mechanical Requirements.

Provide HVAC system to maintain shelter temperature between 65° and 80° F (18° and 27°C). Provide humidity control to maintain humidity between 0 and 95%, with no condensation.

Air Force: See Environmental Control Unit requirements (e.g., allowable temperature and humidity ranges) in AF T.O. 31Z3-822-2, Chapter 3.

3-4.6 Electrical Power.

To avoid potential interference with radar transmissions, locate power, communications, and control cables underground within 1,000 feet (305 m) from the facility. Ensure electrical systems do not interfere with radar transmissions.

Provide 120/240V, 100A, single-phase, 60 HZ commercial power service to the VORTAC facility.

Air Force: See Commercial Power, Uninterruptible Power Supply, and Backup Power, in AF T.O. 31Z-822-2, Chapter 1. See Grounding, Bonding Shielding and Lightning Protection requirements in AF T.O. 31Z-822-2, Chapter 2.

3-4.6.1 Emergency Electrical Power.

Provide an emergency generator with automatic starting and switching capability as described in Chapter 2. Provide emergency power to the entire facility.

3-4.6.2 Grounding and Bonding.

Install two (2) ground rods, one on each 20’ (6 m) side of the concrete pad. Provide separate ground cables, one for the shelter and one for a direct path to ground from the antenna lightning arrestor.

3-4.6.3 Lighting.

The VORTAC shelter comes equipped with an external red filtered door light and obstruction light.

3-4.7 Communications.

Provide 12-strand single mode fiber optic cable or 25 twisted pair communications line to provide required connectivity for data and telephone.

- Data connectivity from the VORTAC Shelter to Remote Unit located in the ATC Tower.

- Data connectivity from the VORTAC Shelter Fire Alarm to external monitoring system.
- Telephone line for distance support to troubleshoot system.

Air Force: See fiber optic cable and modem requirements in AF T.O. 31Z-822-2, Chapter 4.

3-4.8 Connection/Interrelation to other Facilities.

Connect a dedicated DSN-capable telephone connection through to the VORTAC to facilitate distant support, troubleshooting, and corrective maintenance due to the remote location. Connect the VORTAC to the ATC Tower via fiber optic cable for remote monitoring.

Figure 3-15 VORTAC Facility Siting Criteria

	MINIMUM DISTANCE	
	A	B
ARMY	250'	150'
NAVY	750'	250'
AIR FORCE	500'	200'

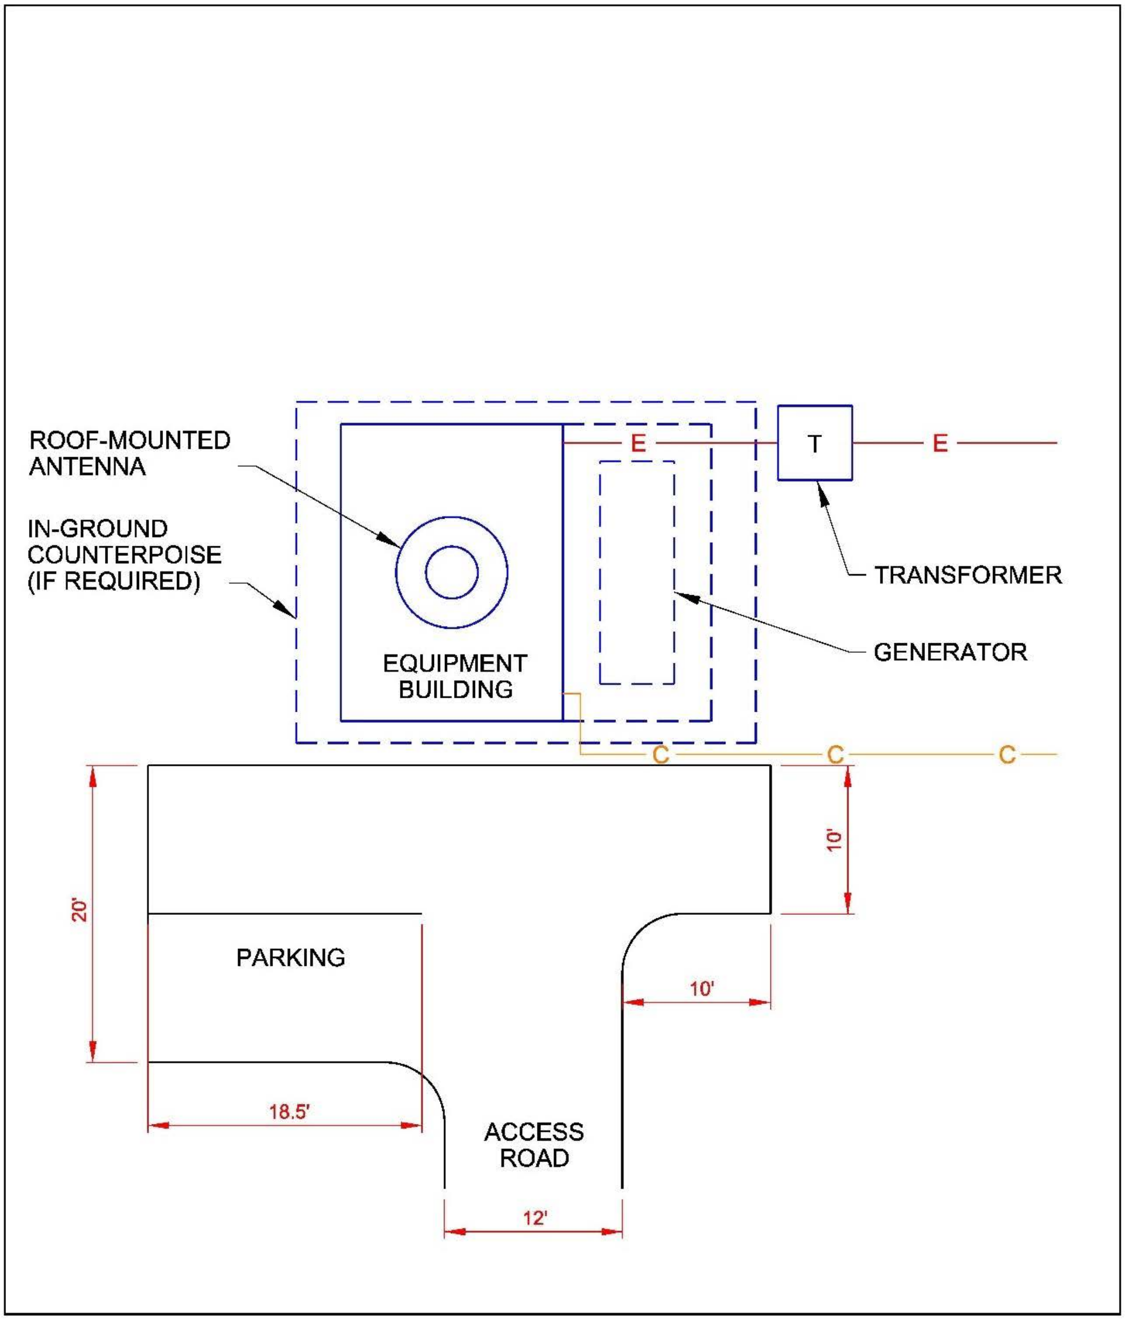

Figure 3-17 VORTAC Building Layout

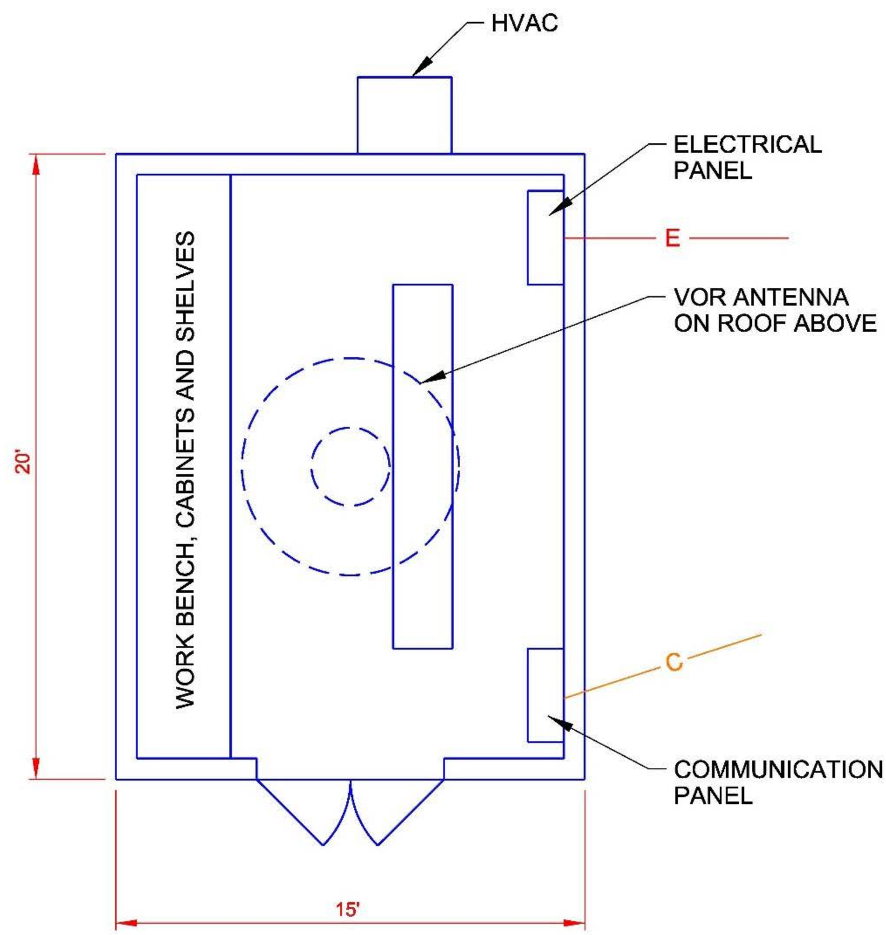

Figure 3-18 VORTAC Building Section

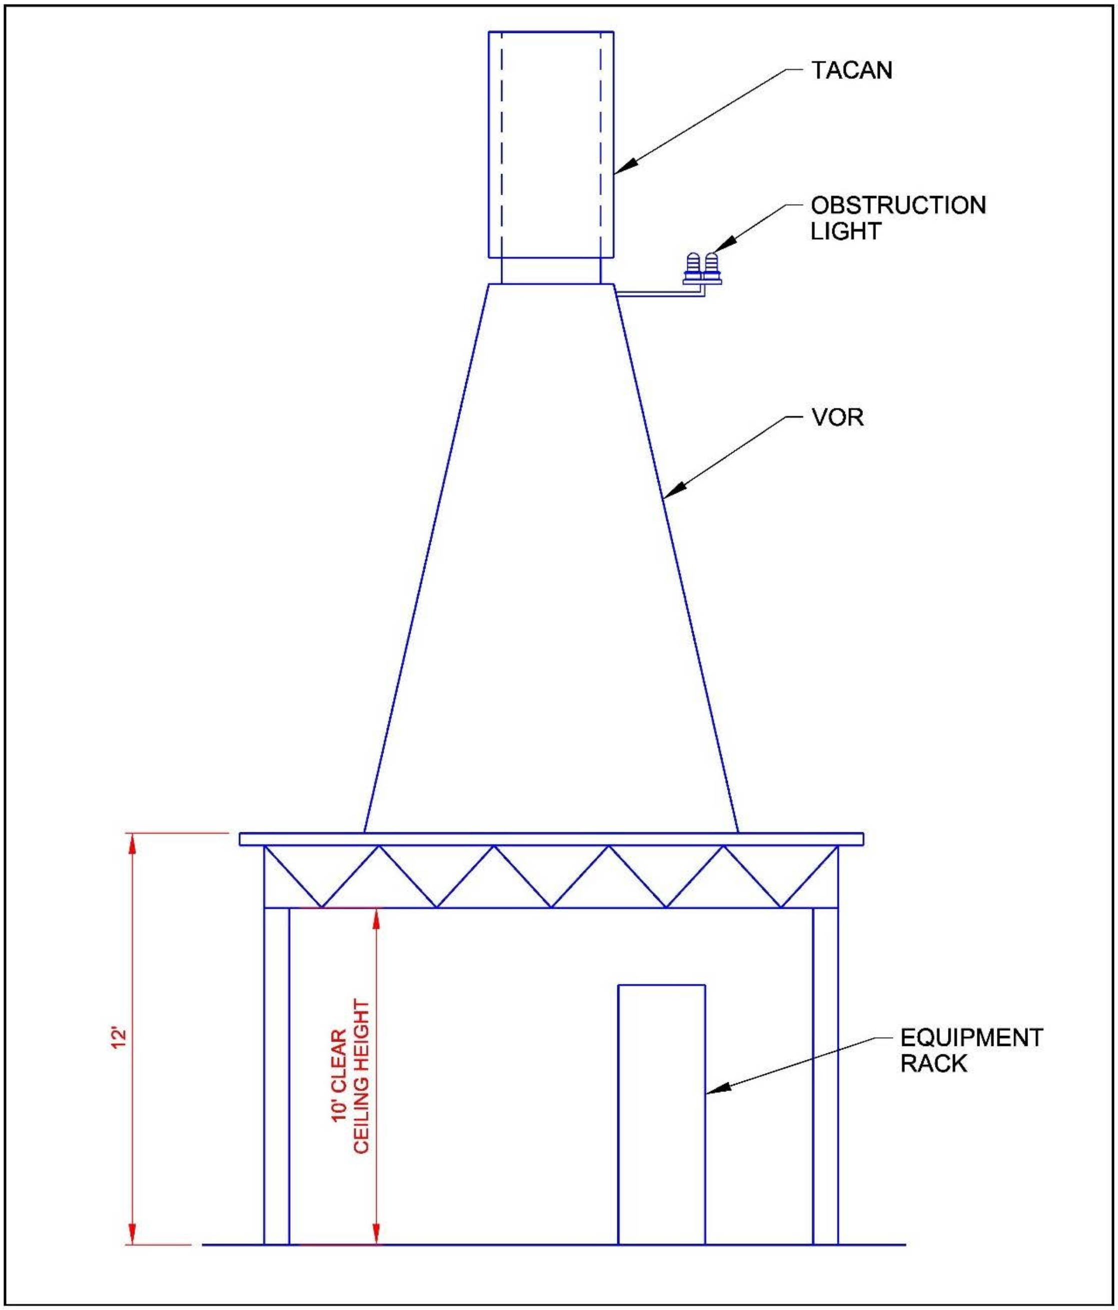

CHAPTER 4 AIRCRAFT LANDING SYSTEMS

4-1 GENERAL INFORMATION.

4-1.1 Function.

The MLS, SBICLS, ILS and PAR facilities contain electronic equipment used in precision instrument approaches. These facilities are unattended.

4-1.1.1 Microwave Landing System (MLS).

The MLS provides azimuth, distance, elevation, and glide path position to aircraft on a precision approach to the MLS instrumented runway. The MLS operates in a narrow band microwave frequency. Figure 4-1 shows a typical MLS antenna and shelter.

4-1.1.2 Shore-Based Instrument Carrier Landing System (SBICLS).

The SBICLS is a microwave-based precision instrument landing aid that provides guidance to appropriately equipped Navy or Marine Corps carrier-based aircraft. The system can be used for conducting carrier-controlled approach training, field carrier landing practice (FBLP), or as a stand-alone instrument landing system. The system is comprised of the identical transmitter equipment used for shipboard aircraft landing operations but in a shore-based configuration. As of 2021, the AN/FRN-49(V) is the current equipment package being installed and replacing the older AN/TRN-28 system. Figure 4-2 shows a typical SBICLS Elevation Transmitter system.

4-1.1.3 Instrument Landing System (ILS).

The ILS provides azimuth, distance, elevation, and glide path position to aircraft on a precision approach to the ILS instrumented runway. The ILS operates in the VHF and UHF radio bands. The ILS consists of two different antennas – Localizer (LOC) and Glide Slope (GS). Figures 4-3 and 4-4 show typical ILS antennas.

4-1.1.3.1 Far Field Monitor (FFM).

ILS monitor systems are of three basic types: integral/aperture, near field and far field, which attempt to predict localizer and glide slope guidance quality on the glide path. A full-fledged Far Field Monitor provides the most complete response of the ILS system to effects which cause degradation to the glide path guidance.

The FFM is not required for CAT I ILS systems; however, it is required for CAT II and above systems. The FFM is considered part of the localizer system. However, it is sited at the opposite end of the runway from the localizer antenna array. Figure 4-5 illustrates a typical FFM antenna.

4-1.1.4 Precision Approach Radar (PAR).

The PAR is an unattended self-contained radar system. The PAR detects azimuth, elevation, and range information of aircraft on final landing approach to PAR instrumented runways. This information is displayed in the Military Terminal Radar Approach Control Facility (MTRACON). The PAR can be mounted on a fixed base or on a turntable. Figure 4-6 illustrates a typical PAR.

Figure 4-1 Typical MLS Facility

Figure 4-5 Typical Far Field Monitor

Figure 4-6 Typical PAR-2000/AN/FPN-68 PAR

4-2 MICROWAVE LANDING SYSTEM (MLS)

4-2.1 Key Documents.

UFC 3-260-01	*Airfield and Heliport Planning and Design*
FAA Order 6830.5	*Criteria for Siting Microwave Landing Systems*
FAA-STD-019f	*FAA Standard, Lightning and Surge Protection, Grounding, Bonding and Shielding Requirements for Facilities*
AF T.O. 31Z3-822-2	*Air Traffic Control Landing Systems (ATCALS) Site Requirements 404L*

4-2.2 Siting.

Locate the azimuth transmitter on the extended runway centerline, 700 to 1,200 feet (213 to 366 m) from the end of runway. Locate the elevation transmitter 600 to 900 feet (183 to 274 m) set back from the runway approach threshold and offset 250 to 600 feet (76 to 183 m) from runway centerline on the runway side opposite of taxiways. See Figure 4-7 for an illustration of the general siting criteria.

4-2.2.1 MLS Obstacle Free Zones.

The MLS obstacle free zones shown in Figures 4-8 and 4-9 must always remain clear of fixed objects as well as moving aircraft and vehicles.

4-2.3 Security.

MLS facilities are normally located within the airfield restricted area which would typically meet the minimum security measures for external security. When the facility is located within a restricted area of a lower level of security or is located remote and outside of an established restricted area, determine the additional measures required to meet the minimum security requirements for the level of security assigned to the facility.

4-2.4 Facility Design Guidance.

4-2.4.1 Site Work.

The MLS consists of two stations, an azimuth station and an elevation station.

Provide an access road to allow access to both MLS stations. Provide parking space for two maintenance vehicles. Typical site layouts are illustrated in Figures 4-8 and 4-9. See Chapter 2, paragraph “Access and Parking” for roadway and parking area design requirements.

4-2.4.2 Architectural Requirements.

There are no architectural requirements for the MLS.

4-2.4.3 Structural Requirements.

MLS transmitter equipment is provided in a self-contained structure by the system supplier. Provide concrete foundations flush with surrounding grade to mount equipment structures. Ensure MLS structures are frangible.

4-2.5 Mechanical Requirements.

Mechanical systems for the shelter system supporting the MLS are self-contained within the shelter and provided as part of the equipment package.

4-2.6 Electrical Power.

To avoid signal interference, install power, communications, and control cables underground within 1,000 feet (305 m) from the facility. Locate electrical equipment which is not frangible, such as transformers, outside the runway clear zone or primary surface. Ensure electrical systems do not interfere with radio transmissions.

Provide 120/240V, 100A, single-phase, 60 HZ commercial power service to the MLS equipment shelter.

4-2.6.1 Emergency Electrical Power.

MLS equipment is supplied with backup battery power. No emergency generator is required.

4-2.6.2 Lighting.

No site lighting is required. Obstruction lighting is provided with the equipment.

4-2.6.3 Grounding and Bonding.

Provide grounding and bonding systems in accordance with FAA STD-019f.

4-2.7 Communications.

Provide 12-strand single mode fiber optic cable or 25 twisted pair communications line to provide required connectivity for data and telephone.

- Data connectivity from the MLS Shelter to Remote Unit located in the ATC Tower.
- Data connectivity from the MLS Shelter Fire Alarm to external monitoring system.
- Telephone line for distance support to troubleshoot system.

Air Force: See fiber optic cable and modem requirements in AF T.O. 31Z-822-2, Chapter 4.

4-2.8 Connection/Interrelation to other Facilities.

Connect the MLS to the ATC Tower via fiber optic cable for remote monitoring.

Figure 4-7 MLS Facility: Site Plan

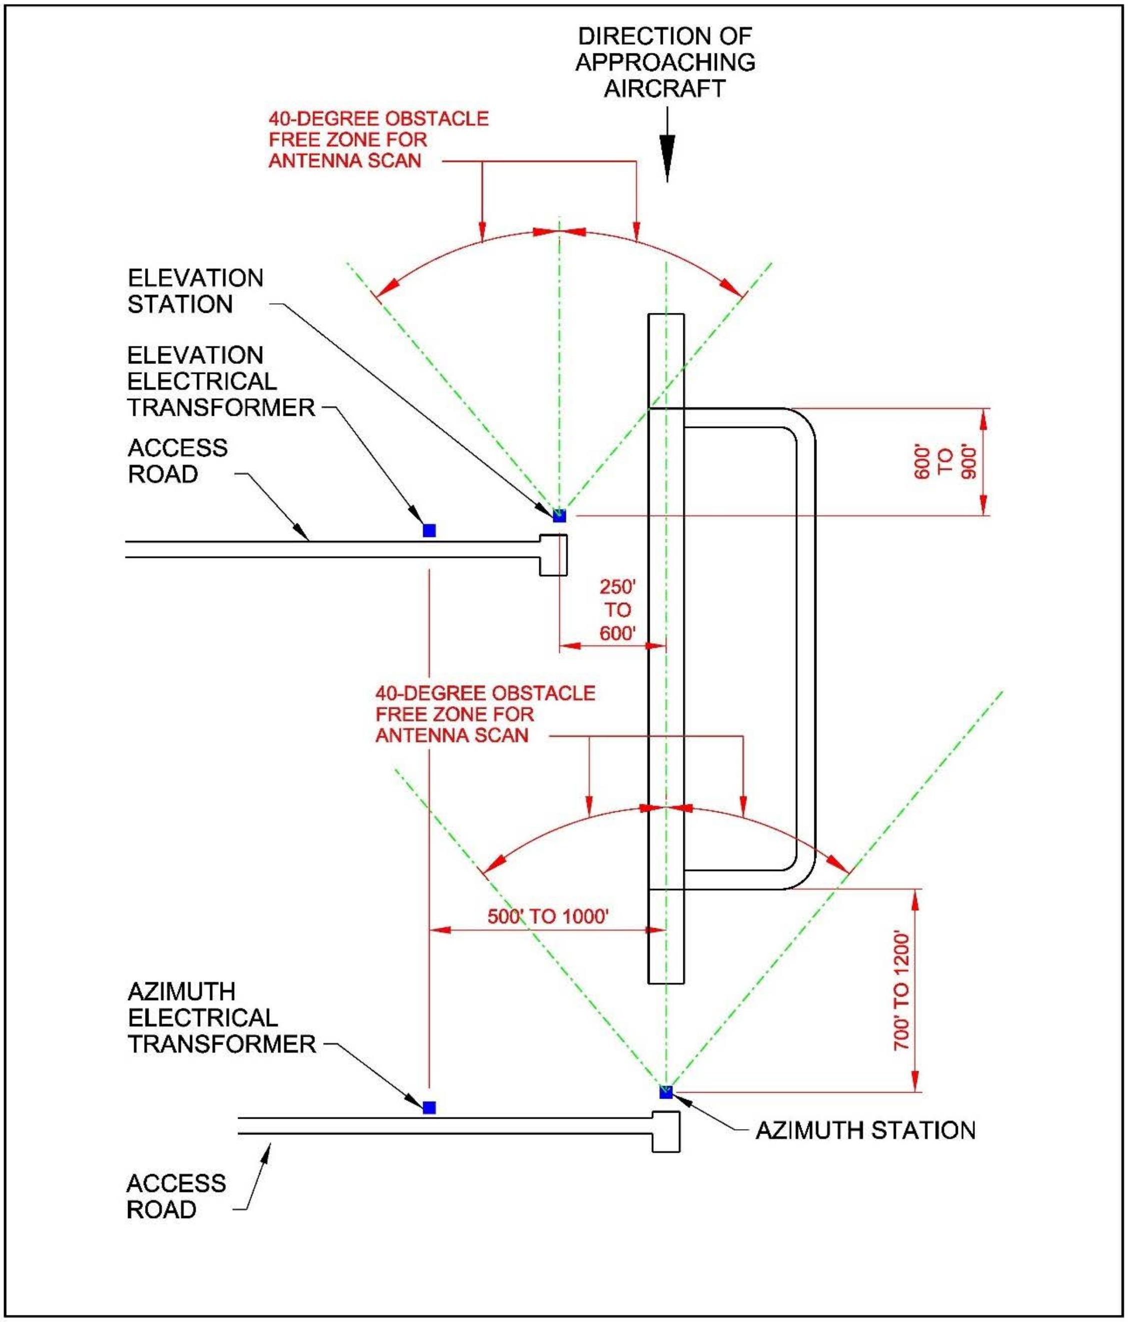

Figure 4-8 MLS Facility: Azimuth Station Site Plan

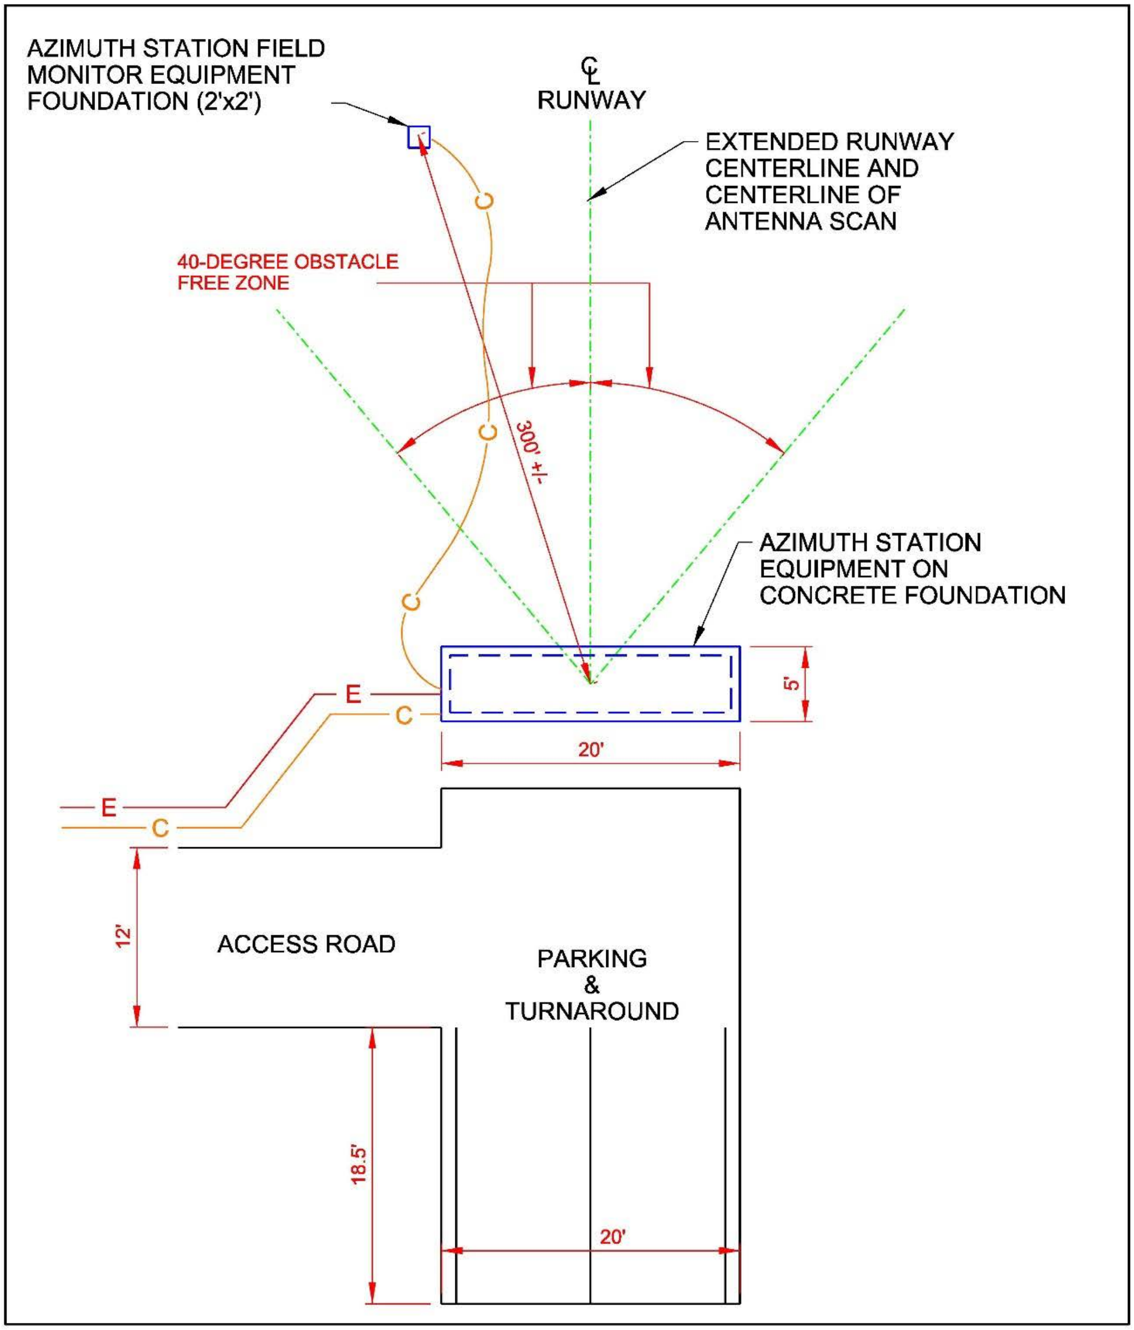

Figure 4-9 MLS Facility: Elevation Station Site Plan

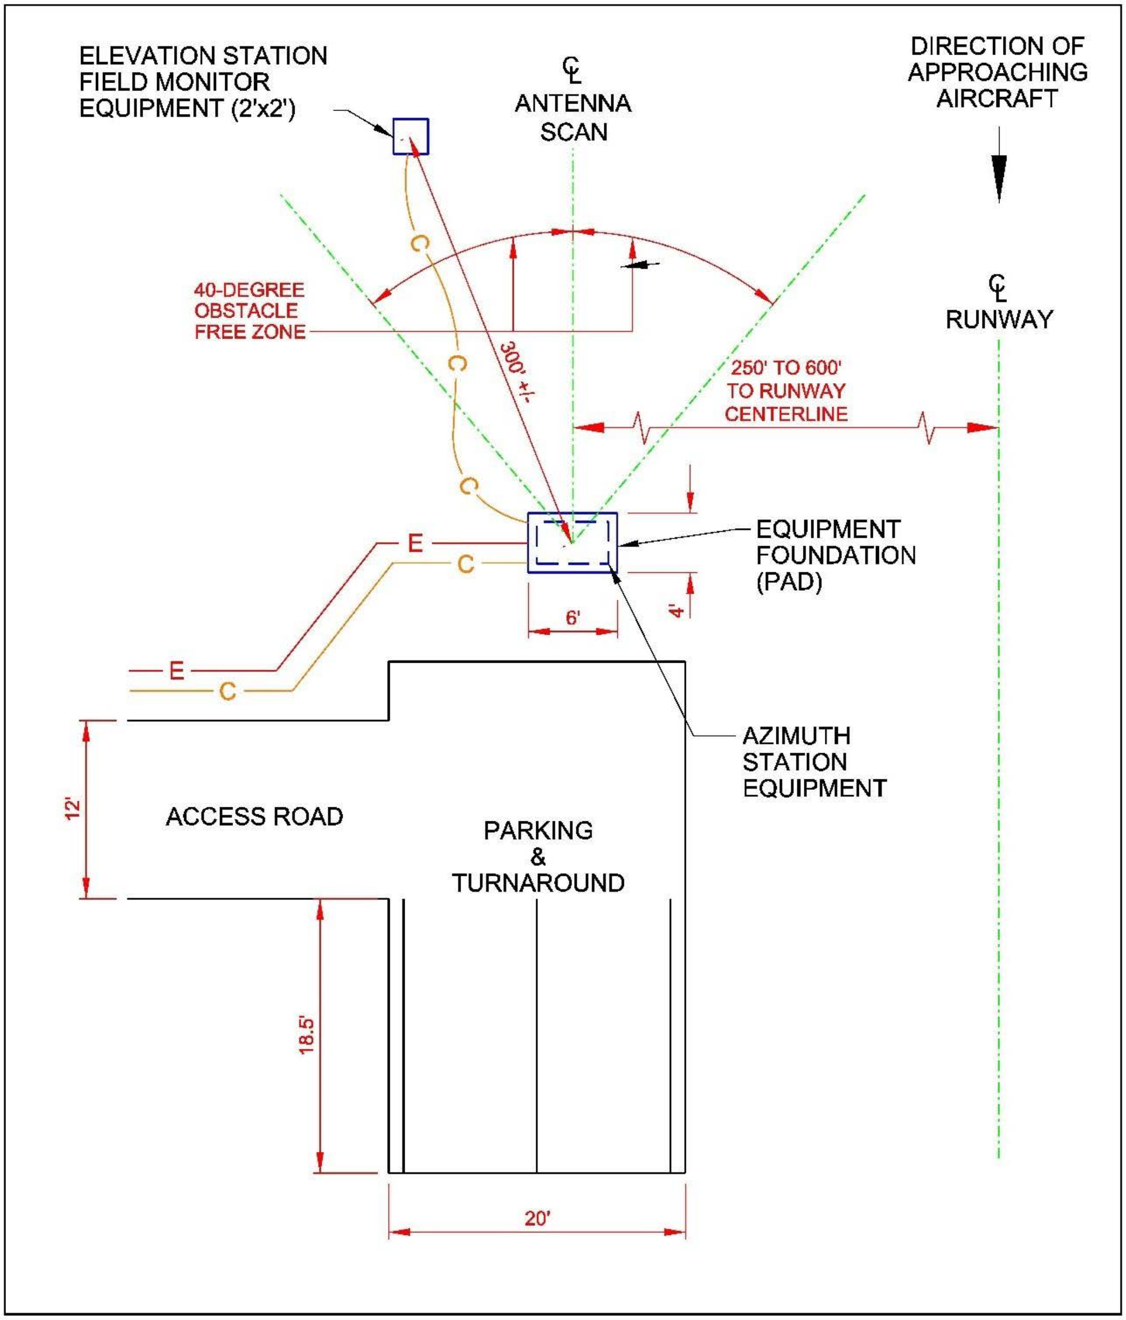

4-3 SHORE-BASED INSTRUMENT CARRIER LANDING SYSTEMS.

4-3.1 Key Documents.

4K73-D2018-011	*Facility Requirements Document (FRD) for the Shore Instrument Carrier Landing System (ICLS) AN/FRN-49(V)*
FAA AC 70/7460-1M	*Obstruction Marking and Lighting*

4-3.2 Siting.

Locate the azimuth transmitter on the extended runway centerline. Locate the elevation transmitter adjacent to the runway, preferably 400-ft to 500-ft (122 to 152 m) from the runway centerline. See the FRD for specific distances. General siting requirements are illustrated in Figure 4-10.

Do not install the SBICLS if a Fresnel Lens Optical Landing System (FLOLS)/Improved Fresnel Lens Optical Landing System (IFLOLS) is not installed to the landing runway or a marked simulated carrier deck on a runway.

The SBICLS consists of three sites, as described below.

4-3.2.1 Elevation Station Site.

This site consists of the elevation transmitter and its associated waveguide (W/G) horn which provides vertical guidance. The elevation transmitter group is located adjacent to the runway near the touchdown point associated with the simulated carrier deck markings. The elevation transmitter group may also be sited to provide for traditional vertical guidance to a runway touchdown point similar to an ILS glide slope antenna.

4-3.2.2 Azimuth Station Site.

This site consists of the azimuth transmitter and its associated W/G horn, and it provides lateral guidance similar to an ILS localizer antenna array. The signal is provided through a transmitter located along the extended centerline or simulated carrier deck centerline at the far end of a runway approach.

4-3.2.3 Operations Station Site.

This site consists of the transmitter control group and the transmitter control unit. The purpose of this site is to provide a graphical user interface, controls, system status and alerts, synchronization, and built-in test to maintenance personnel and operators.

4-3.2.4 SBICLS Critical Areas.

The SBICLS critical areas shown in Figures 4-11 and 4-12 must always remain clear of fixed objects as well as moving aircraft and vehicles.

4-3.3 Security.

SBICLS facilities are normally located within the airfield restricted area which would typically meet the minimum security measures for external security.

4-3.4 Facility Design Guidance.

4-3.4.1 Site Work.

Provide an access road to allow access to both SBICLS stations. Provide parking space for two maintenance vehicles. See Chapter 2, paragraph “Access and Parking” for roadway and parking area design requirements. Typical site layouts are illustrated in Figures 4-11 and 4-12.

4-3.4.2 Architectural Requirements.

There are no architectural requirements for the SBICLS.

4-3.4.3 Structural Requirements.

SBICLS transmitter equipment is provided in a self-contained structure by the system supplier. Provide concrete foundations flush with the surrounding grade to mount equipment structures. See FRD for additional requirements and foundation details.

4-3.5 Mechanical Requirements.

Mechanical systems for the shelter system supporting the SBICLS are self-contained within the shelter and provided as part of the equipment package.

4-3.6 Electrical Power.

To avoid signal interference, install power, communications, and control cables underground within 1,000 feet (305 m) from the facility.

Provide 120/240V, 100A, single-phase, 60 HZ commercial power service to each SBICLS equipment shelter. The minimum required transformer size for each SBICLS shelter is 15 kVA, in a pad-mounted configuration.

4-3.6.1 Emergency Electrical Power.

Emergency generators are not supplied with the ICLS equipment and are not required for IFR approach certification. The requirements for individual generators at the equipment shelter sites are a base-level determination. If required, the base will provide the generator.

An integrated battery backup UPS will be supplied as part of each ICLS transmitter shelter. The UPS is rated for 4 hours at full load and meets the requirements for IFR certification.

4-3.6.2 Lighting.

No site lighting is required. Provide obstruction lights in accordance with FAA AC 70/7460-1 on transmitter shelters.

4-3.7 Communications.

Provide a minimum 12-strand single-mode fiber optic cable to each system (elevation and azimuth) through underground conduits and handholes.

4-3.8 Connection/Interrelation to other Facilities.

Each SBICLS system must be connected to the remote monitoring site (usually the Air Traffic Control Tower) with fiber optic cables. See the FRD for additional details.

Figure 4-10 SBICLS Facility: Site Plan

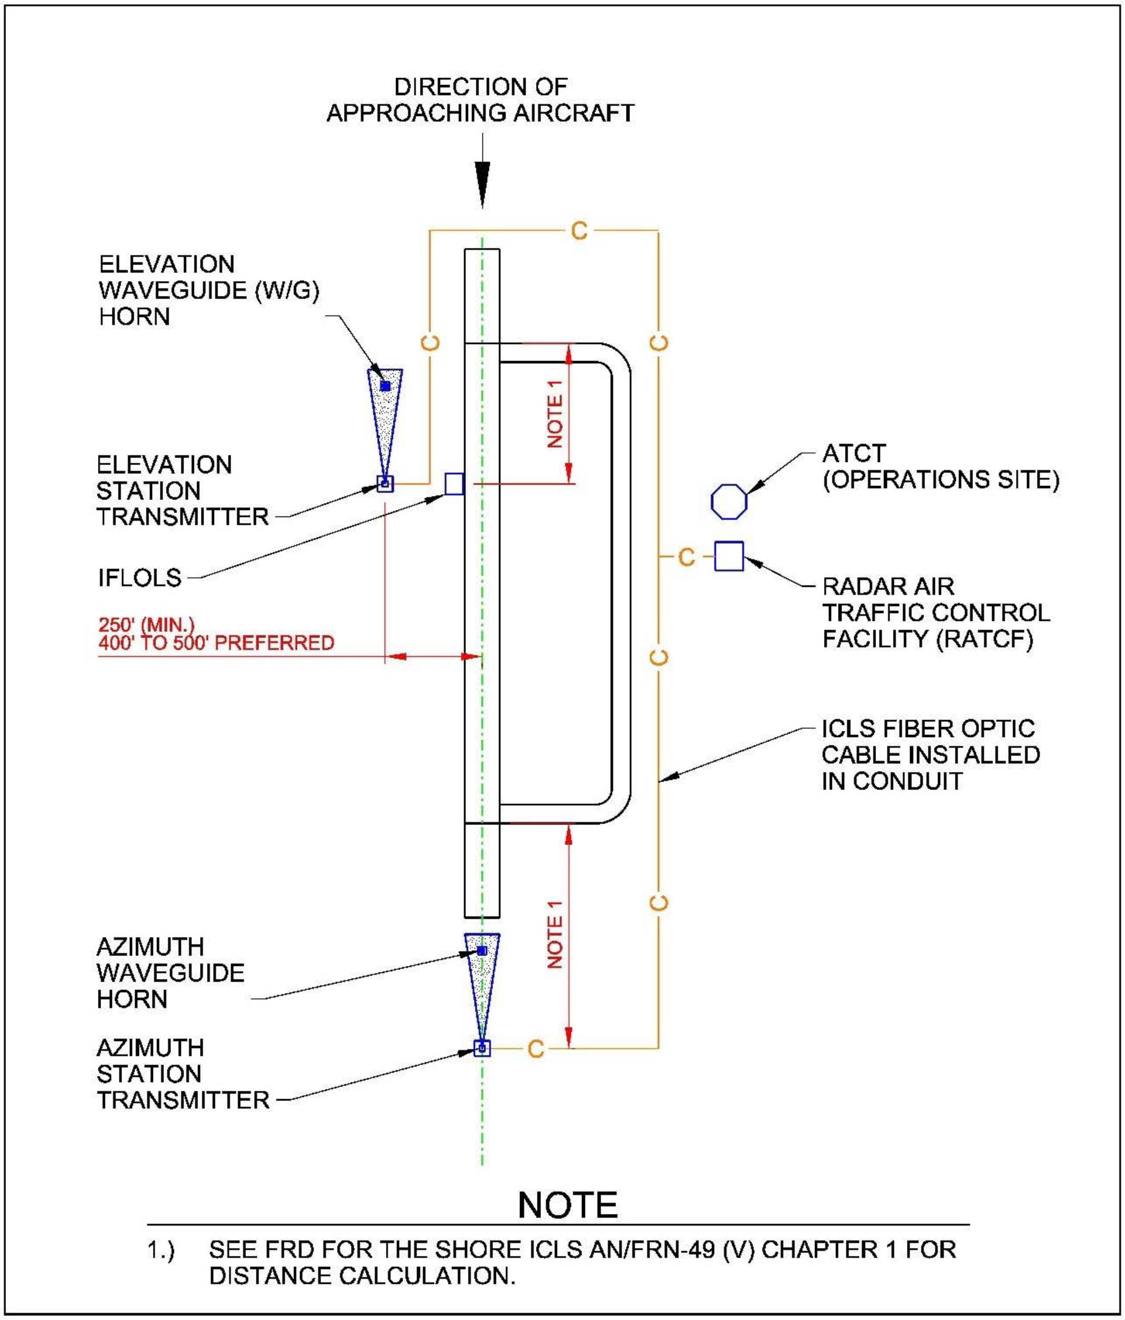

Figure 4-11 SBICLS: Azimuth Station Site Plan

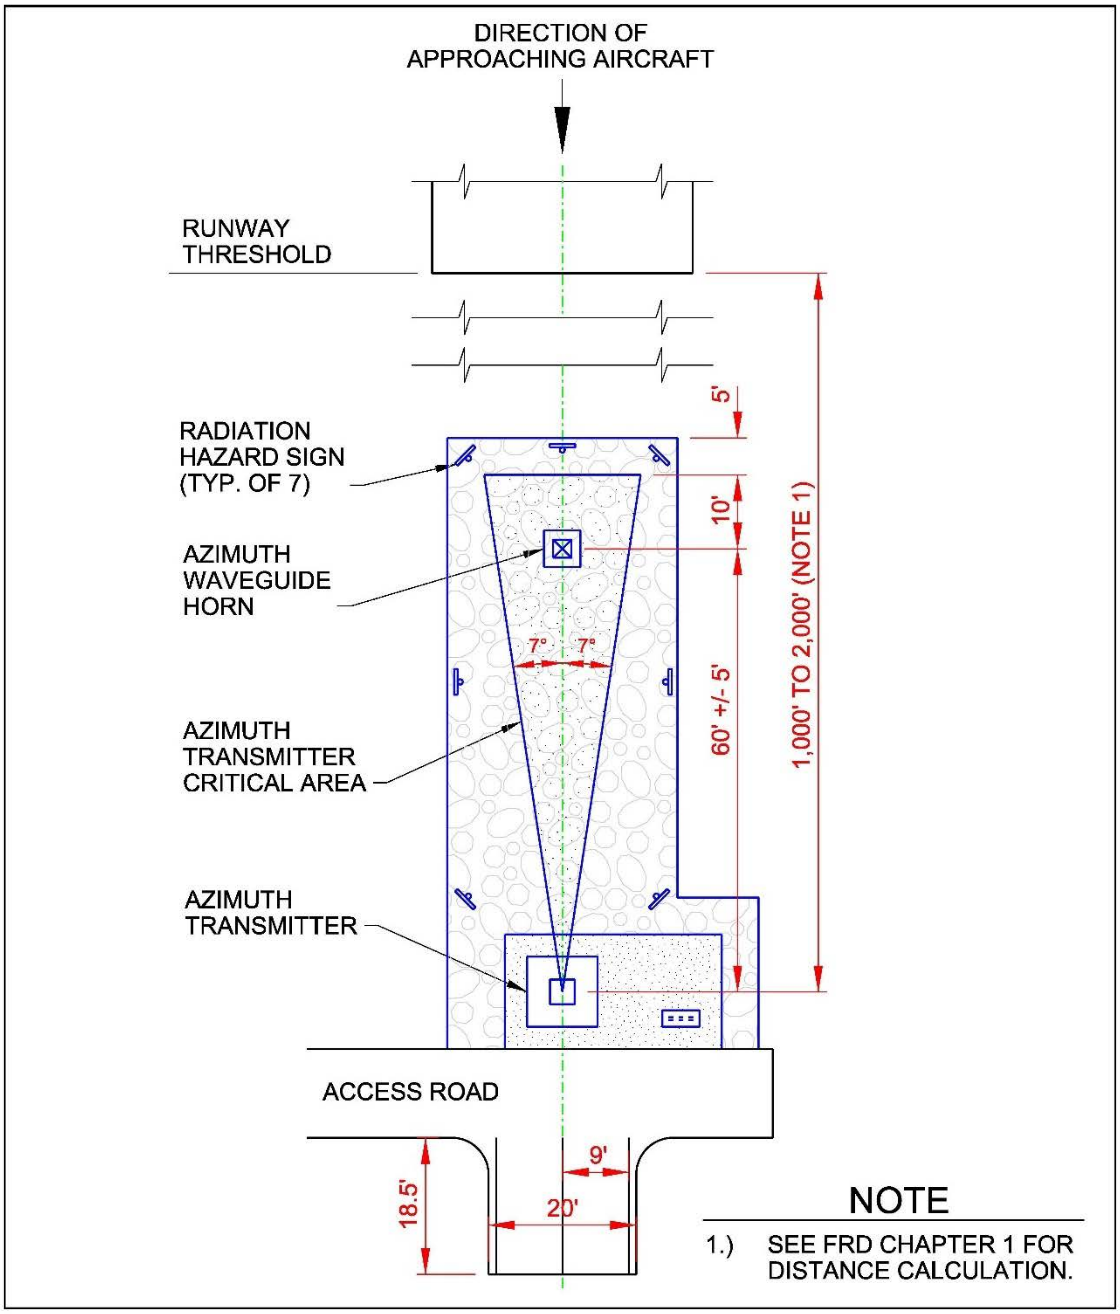

Figure 4-12 SBICLS Facility: Elevation Station Site Plan

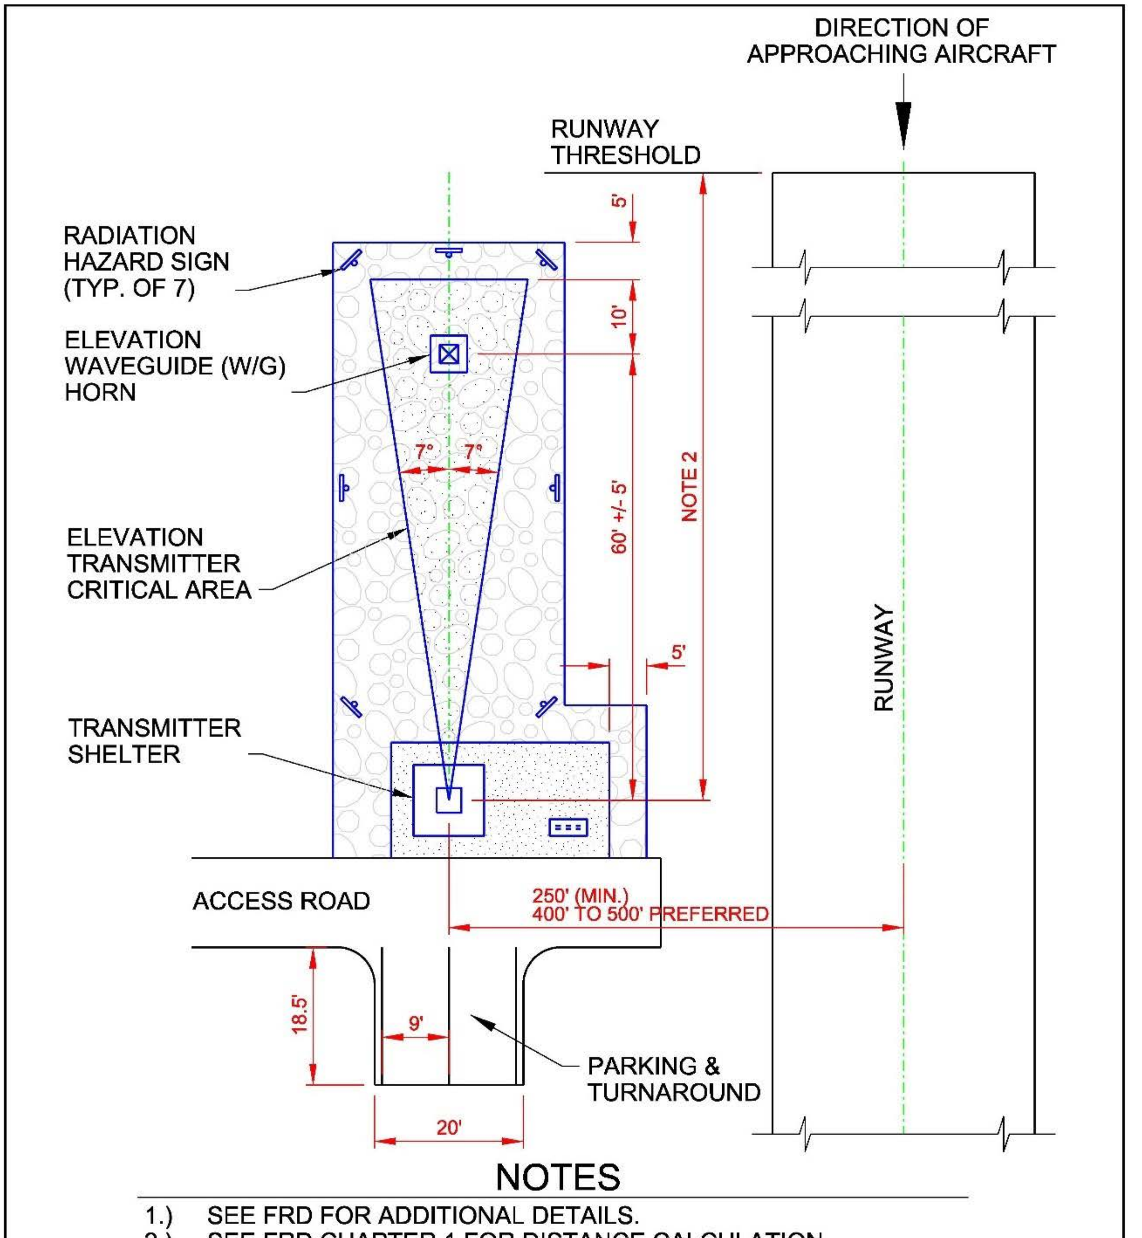

NOTES

1.) SEE FRD FOR ADDITIONAL DETAILS.
2.) SEE FRD CHAPTER 1 FOR DISTANCE CALCULATION.
3.) MINIMUM DISTANCE BETWEEN ELEVATION TRANSMITTER AND NEAREST TAXIWAY CENTERLINE IS 150 FEET.

4-4 INSTRUMENT LANDING SYSTEM (ILS).

4-4.1 Key Documents.

UFC 3-260-01	Airfield and Heliport Planning and Design
AF T.O. 31Z3-822-2	Air Traffic Control Landing Systems (ATCALS) Site Requirements 404L
AF T.O. 31R4-2GRN30-32	*Combined Maintenance Operating Instructions: Radio Transmitting Set (Localizer Station)*
FAA AC 150/5300-13	*Airport Design*
FAA Order 6750.16	*Siting Criteria for Instrument Landing Systems*

4-4.2 Siting.

Provide separate facilities for glide slope (GS) antenna transmitter equipment, for localizer (LOC) antenna transmitter equipment and for Far Field Monitor (FFM) antenna equipment. Refer to FAA Order 6750.16 and FAA AC 150/5300-13. See Figure 4-13 for general layout requirements.

4-4.2.1 General.

The ILS uses a line-of-sight signal from the LOC antenna and marker beacons and a reflected signal from the ground plane in front of the GS antenna.

a. ILS antenna systems are susceptible to signal interference sources such as power lines, fences, metal buildings, cell phones, etc.

b. Since ILS uses the ground in front of the GS antenna to develop the signal, this area must be free of high-growth vegetation and graded to remove surface irregularities.

c. GS and LOC equipment shelters are located near, but are not a physical part of, the antenna installation.

d. The FFM is considered part of the localizer system. However, it is sited at the opposite end of the runway from the localizer antenna array.

4-4.2.2 ILS Localizer Antennas (Frangible).

Site the LOC antenna array between 1,000 feet and 2,000 feet (305 and 610 m) beyond the stop end of the runway. Siting must conform to approach-departure clearance surface criteria discussed in UFC 3-260-01, Chapters 3 and 4. Refer to FAA Order 6750.16 if standard localizer antenna placement is not an option. See Figure 4-16 for a typical LOC site plan.

a. The critical area depicted in Figure 4-14 surrounding the LOC antenna and extending toward and overlying the stop end of the runway must be clear of objects and high growth of vegetation.

b. The critical area must be smoothly graded. A constant +1.0% to -1.50% longitudinal grade with respect to the antenna is recommended. Allowable transverse grades from -0.5 percent to -3.0 percent, with smooth transitions between grade changes. Antenna supports are frangible and foundations must be flush with the ground.

c. Place the LOC equipment shelter at least 250 feet (76 m) to either side of the antenna array and within 30 degrees of the extended longitudinal axis of the antenna array.

4-4.2.2.1 ILS Localizer Transmitter Shelter (Non-Frangible).

The ILS localizer transmitter shelter is sited adjacent to the localizer antenna array. It must be located at least 250 feet (76 m) from the extended runway centerline, or a waiver is required.

4-4.2.3 ILS Glide Slope Antenna (Non-Frangible).

Locate the antenna mast or monitor a minimum distance of 400 feet (122 m) from the runway centerline to the centerline of the antenna, and not exceeding 55 feet (17 m) in height above the nearest runway centerline elevation. A mast height of over 55 feet (17 m) is permitted if the minimum distance from the runway centerline is increased by 10 feet (3 m) for each 1 foot (0.3 m) the mast exceeds 55 feet (17 m). When the mast cannot, for technical or economic reasons, be located at a minimum distance of 400 feet (122 m) from the runway centerline, the minimum distance may be reduced to not less than 250 feet (76 m) from the centerline, provided the basic mast height of 55 feet is reduced 1 foot (0.3 m) for each 5 feet (1.5 m) it is moved toward the runway from the 400-foot (122 m) point. Glide slope monitor units are considered part of the parent equipment. Emergency power generators must be as close to the facilities they support as practical, but no closer than the glideslope main facility. See Figure 4-17 for a typical GS site plan.

a. The GS antenna may be located on either side of the runway. The most reliable operation is obtained when the GS is located on the side of the runway offering the least possibility of signal reflections from buildings, power lines, vehicles, aircraft, etc. The GS critical area is illustrated in Figure 4-15.

b. The critical area must be smoothly graded. A constant +1.0 percent to -1.50 percent longitudinal grade with respect to the antenna is recommended. Allowable transverse grades range from -0.5 percent to -3.0 percent, with smooth transitions between grade changes. Antenna supports are frangible and foundations must be flush with the ground.

c. Signal quality is dependent upon the type of antenna used and the extent of reasonably level ground immediately in front of the antenna.

d. The GS equipment shelter is located behind the antenna and a minimum of 400 feet (122 m) from the runway centerline.

4-4.2.3.1 ILS End Fire Glide Slope Antenna (Frangible).

Site in accordance with FAA Order 6750.16. For the end-fire glide slope, the antenna array typically extends to 25 feet (7.6 m) from the runway edge. This is allowed due to antenna frangibility.

4-4.2.4 Far Field Monitor (FFM).

The FFM is not required for CAT I ILS systems; however, it is required for CAT II and above systems. The FFM is considered part of the localizer system. However, it is sited at the opposite end of the runway from the localizer antenna array. Typical locations are 365.8 meters (1,200 feet) to 914.4 meters (3,000 feet) prior to the landing threshold. FFM antenna height is determined by line of sight to the localizer antenna array. The line-of-sight requirement can be relaxed if satisfactory localizer signal reception is proven with a portable ILS receiver at the proposed lower height of the FFM site. Just as with the localizer antenna array, the FFM antenna must not penetrate the approach-departure clearance surface criteria discussed in UFC 3-260-01, Chapters 3 and 4. Army siting requirements are contained in FAA Order 6750.16.

4-4.3 Security.

ILS facilities are normally located within the airfield restricted area which would typically meet the minimum security measures for external security. When the facility is located within a restricted area of a lower level of security or is located remote and outside of an established restricted area, determine the additional measures required to meet the minimum security requirements for the level of security assigned to the facility.

4-4.4 Facility Design Guidance.

4-4.4.1 Site Work.

The ILS consists of two stations, a localizer and antenna station, and a glide slope equipment station.

Provide a roadway to allow access to the LOC and GS antennas. Provide parking space for two maintenance vehicles.

When included, the FFM also requires an access road and a parking space for one maintenance vehicle.

See Chapter 2, paragraph “Access and Parking” for roadway and parking area design requirements.

4-4.4.2 Architectural Requirements.

There are no architectural requirements for the ILS. Localizer and Glide Slope shelters are prefabricated units.

4-4.4.3 Structural Requirements.

ILS transmitter equipment is provided in a self-contained structure by the system supplier. Provide concrete foundations flush with grade that extend below the frost depth to mount equipment structures. Ensure ILS structures are frangible.

The LOC station requires an 18 by 20-foot (5.5 by 6 m) concrete pad for the localizer equipment shelter and a 12 by 18-foot (3.7 by 5.5 m) concrete pad for the glide slope equipment shelter.

The FFM requires pier foundations flush with grade that extend below the frost depth.

4-4.5 Mechanical Requirements.

Localizer and Glide Slope shelters are prefabricated units that include HVAC systems.

Air Force: See Environmental Control Unit requirements (e.g., allowable temperature and humidity ranges) in AF T.O. 31Z3-822-2, Chapter 3.

4-4.6 Electrical Power.

To avoid potential interference with antenna transmissions, install power, communications, and control cables underground within 1,000 ft (305 m) of each facility. Locate electrical equipment which is not frangible, such as transformers, outside the runway clear zone or primary surface. Ensure electrical systems do not interfere with radio transmissions.

Provide 120/240V, 100A, single-phase, 60 HZ commercial power service to the LOC and GS facility shelters.

Air Force: See Commercial Power, Uninterruptible Power Supply, and Backup Power, in AF T.O. 31Z-822-2, Chapter 1. See Grounding, Bonding Shielding and Lightning Protection requirements in AF T.O. 31Z-822-2, Chapter 2.

4-4.6.1 Emergency Electrical Power.

ILS equipment is supplied with backup battery power. No emergency generator is required. Backup power is not required for the FFM.

4-4.6.2 Lighting.

No site lighting is required. Obstruction lighting is provided with the equipment.

4-4.7 Communications.

Provide a minimum 12-strand single-mode fiber optic cable to each system (elevation and azimuth) through underground conduits and handholes.

Air Force: See fiber optic cable and modem requirements in AF T.O. 31Z-822-2, Chapter 4.

4-4.8 Connection/Interrelation to other Facilities.

Each ILS system must be connected to the remote monitoring site (usually the Air Traffic Control Tower) with fiber optic cables.

Figure 4-13 ILS Facility: Site Plan

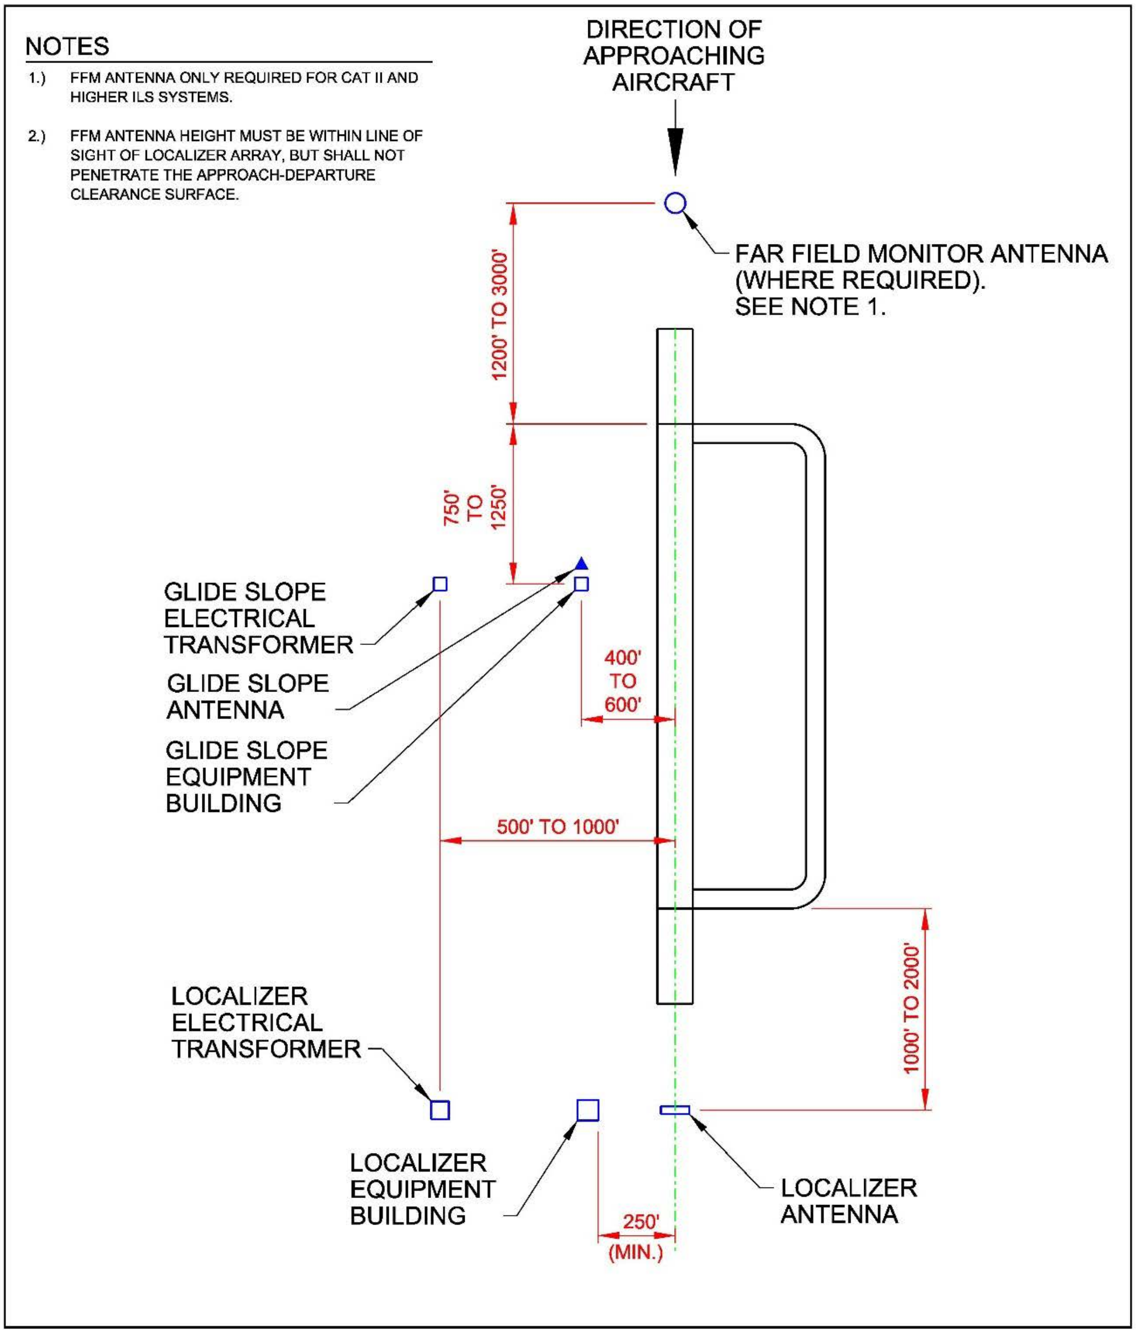

Figure 4-14 ILS Facility: Localizer Antenna Siting and Critical Area

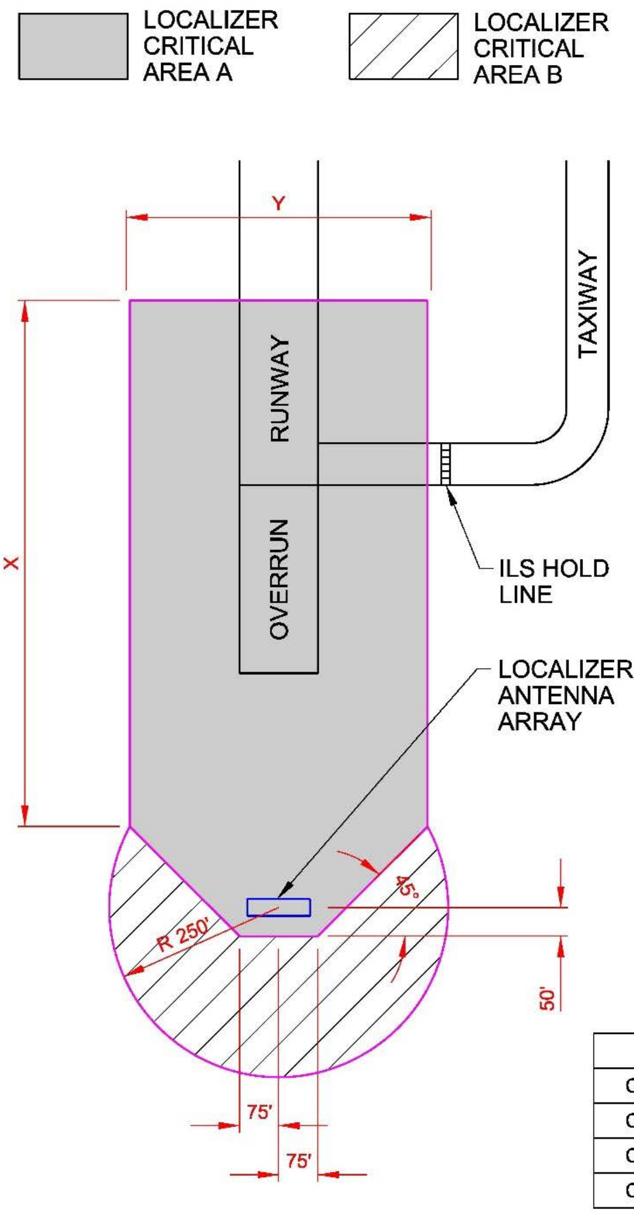

NOTES

1.) CRITICAL AREA IS INDICATED BY SHADED ZONES.

2.) HOLD LINES/SIGNS INDICATE THE POSITION BEYOND WHICH AIRCRAFT/VEHICLES WILL REQUIRE ATCT AUTHORIZATION BEFORE PROCEEDING ON OR ACROSS RUNWAY.

3.) AREA B IS DELETED FROM THE CRITICAL AREA WHEN A UNIDIRECTIONAL LOCALIZER ANTENNA IS INSTALLED. THE STANDARD LOG PERIODIC DIPOLE ANTENNA IS IN THIS CATEGORY.

4.) FOR 8-ELEMENT LOCALIZER ARRAY WITH COURSE WIDTHS LESS THEN 4' AND RUNWAYS WHICH OPERATE B-747 SIZE AND LARGER AIRCRAFT THE "Y" DIMENSION IS 600' [183 M].

5.) THESE DIMENIONS APPLY WHERE AIRCRAFT SIZE IS EQUAL TO OR LESS THAN 135' [41 M] IN LENGTH OR 42' [13M] IN HEIGHT, E.G. B-737.

6.) CRITICAL AREA FOR LDA, SDF AND OFFSET LOCALIZER FACILITIES ARE THE SAME AS FOR CATEGORY I, BUT ARE CENTERED ABOUT THE COURSE LINE.

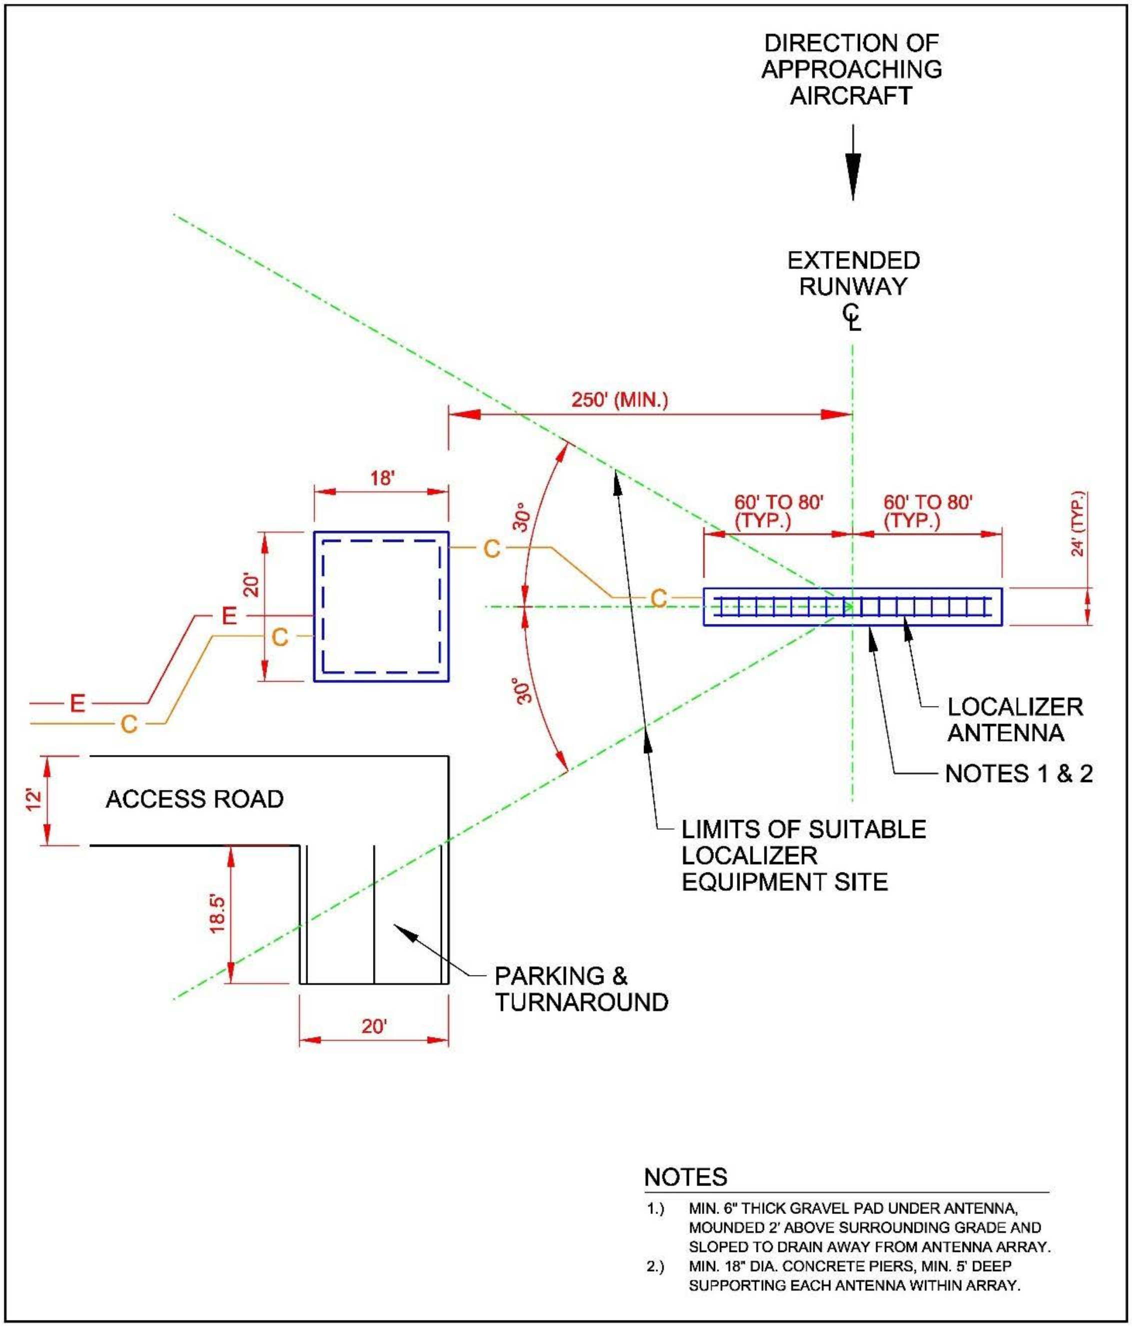

Figure 4-17 ILS Glide Slope Equipment and Antenna Site Plan

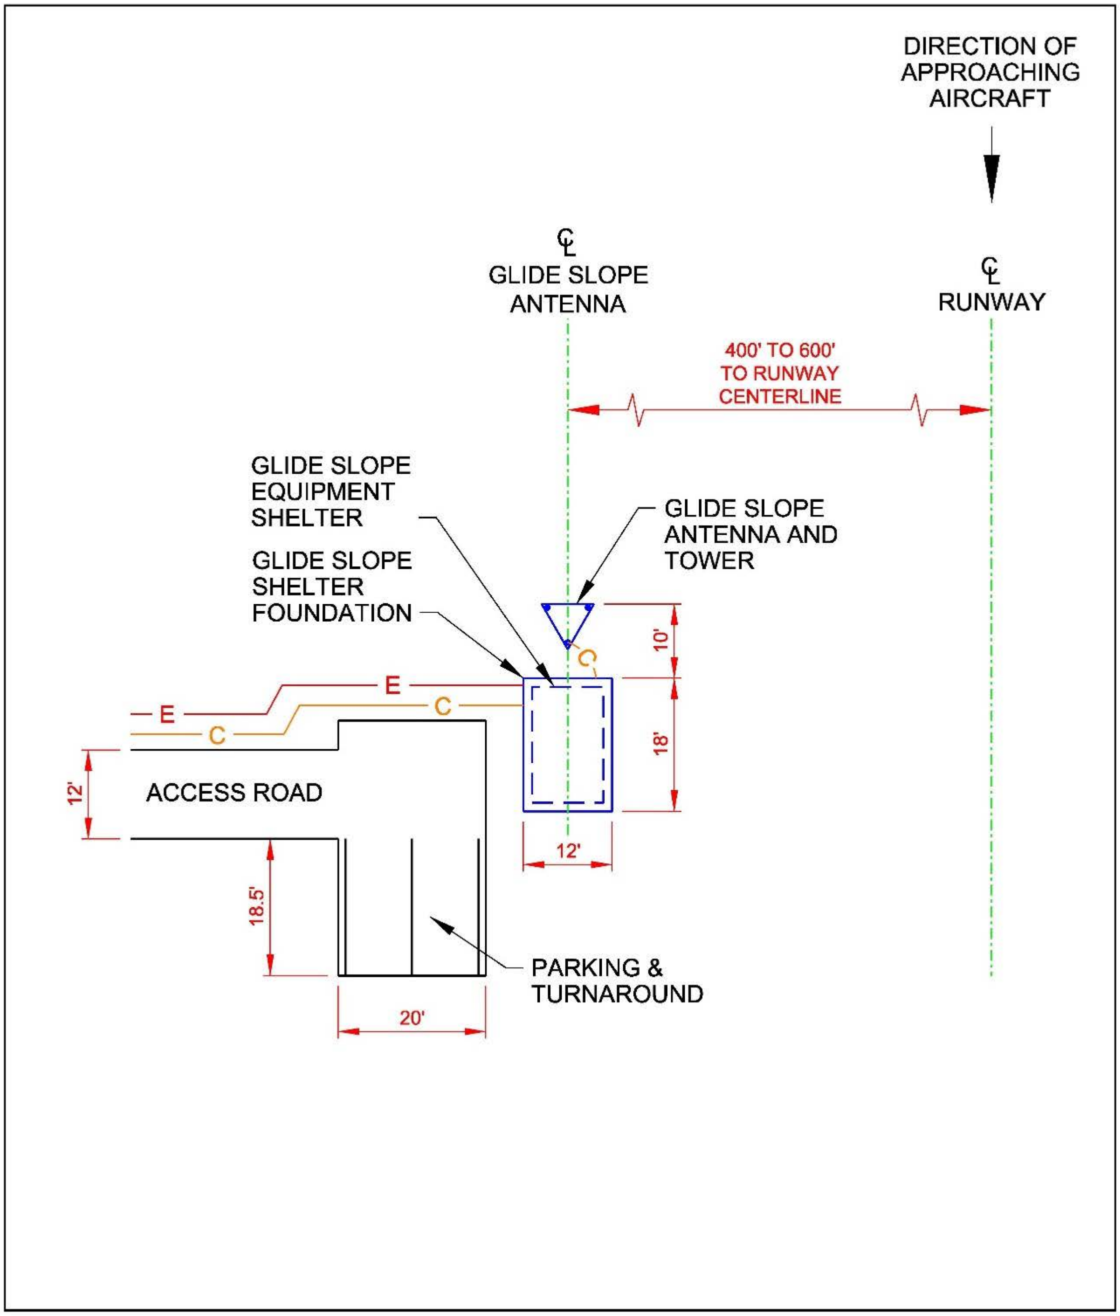

4-5 PRECISION APPROACH RADAR (PAR).

4-5.1 Key Documents.

UFC 3-260-01	*Airfield and Heliport Planning and Design*
UFC 3-301-01	*Structural Engineering*
AF T.O. 31Z3-822-2	*Air Traffic Control Landing Systems (ATCALS) Site Requirements 404L*
AF T.O. 31P5-2GPN22-12	*Facility Manual – Radar Set Group, Type AN/GPN-22(V)*
SSC PAC PAR SPSPP	*SPAWARSYSCEN Pacific (SSC PAC) Precision Approach Radar (PAR) Site Preparation Standard Plan Package*

4-5.2 Siting.

4-5.2.1 Navy PAR Siting.

Locate PAR sites adjacent to the instrumented runway or runway intersection. See the SSC PAC PAR Site Preparation Standard Plan Package for additional information.

4-5.2.2 Army and Air Force Siting for GPM-22 PAR.

PAR systems (AN/GPN-22) must be sited not less than 512 feet (156 meters) from the centerline of a runway to the near edge of the equipment. The reference reflector must be positioned so that the reflector and the radar antenna are parallel with the runway centerline (± 0.005°), be in clear and unobstructed view of the radar antenna and be located in an area where there are no large reflecting objects. Specific siting criteria for this system is provided in AF T.O. 31P5-2GPN22-12. When it is necessary to place units between parallel runways with insufficient distance to allow a 512-foot (156-meter) clearance to each runway centerline, site the system to provide the minimum distance to the centerline of the primary instrument runway and the lesser clearance to the centerline of the other runway. While it is desirable, from a safety standpoint, to keep these units as low as possible, AFFSA ATCALS will determine the final elevation for the units. The elevation is dependent on the necessary lines of sight between the unit and calibration reflectors and the touchdown areas of the runways. If it is necessary to change the existing ground elevation to provide a proper height for these units, follow grading requirements discussed in UFC 3-260-01, Chapter 3. These systems are non-frangible.

4-5.2.3 AN/FPN-67 or FBPAR (Fixed Base Precision Approach Radar).

The AN/FPN-67 is a modern, solid-state, reliable, ground-based, precision approach radar in a fixed-shelter (or integrated with the ATNAVICS system). AN/FPN-67 systems must be sited not less than 512 feet (156 meters) from the centerline of a runway to the near edge of the equipment.

4-5.2.4 PAR Reflectors (Frangible and Non-Frangible).

4-5.2.4.1 Air Force.

Site moving target indicator (MTI) reflectors, or “target simulators,” not less than 150 feet (46 meters) from the near edge of a runway nor less than 125 feet (38 meters) from the near edge of a taxiway or apron boundary marking to the centerline of the equipment. The height of these reflectors must be held to a minimum consistent with the operational requirements of the system. MTI reflectors sited less than 500 feet (152 meters) from the centerline of any runway must be of frangible construction, using breakaway sections in reflector masts. Tracking reference reflectors must not be installed closer than 500 feet (152 meters) to the centerline of any runway, nor exceed 60 feet (18 meters) in height above the centerline elevation of the nearest runway at the intersection of the equipment centerline perpendicular with the runway centerline.

4-5.2.4.2 Army.

Site MTI reflectors not less than 250 feet (76 meters) from the near edge of a runway nor less than 125 feet (38 meters) from the near edge of a taxiway or apron boundary marking to the centerline of the equipment.

4-5.2.5 Airborne Radar Approach Reflectors (Non-Frangible).

Place airborne radar approach reflectors not less than 325 feet (99 meters) from the runway edge and not less than 400 feet (122 meters) nor more than 750 feet (229 meters) from the runway centerline to the edge of the equipment in a pattern parallel to the runway.

4-5.2.5.1 Army.

Locate at least one reflector within the AN/FPN67/AN/TPN-31 PAR azimuth angle coverage area in order to provide a horizontal reference point. Reflectors may not be sited less than 150 feet (46 meters) from the near edge of a runway nor less than 125 feet (38 meters) from the near edge of a taxiway or apron boundary marking to the centerline of the equipment. Reflectors sited less than 250 feet (76 meters) from the runway centerline must be of frangible construction, using breakaway sections of reflector masts, nor exceed 10 feet (3 meters) in height above the centerline elevation of the nearest runway at the intersection of the equipment centerline perpendicular with the runway centerline.

4-5.3 Security.

PAR facilities are normally located within the airfield restricted area which typically meets the minimum security measures for external security. When the facility is located within a restricted area of a lower level of security or is located remote and outside of an established restricted area, provide additional measures to meet the minimum level of security assigned to the facility.

4-5.4 Facility Design Guidance.

4-5.4.1 Site Work.

Provide a roadway to allow access to the PAR system. Provide parking space for two maintenance vehicles. Include access roads located around the COTS PAR concrete pad and from any nearby access road. See Chapter 2, paragraph "Access and Parking" for roadway and parking area design requirements. The use of asphalt pavement for access routes is not allowed. Slope the access roads and concrete pads to provide positive drainage away from the COTS PAR equipment and toward any stormwater management facility or existing vegetation.

Provide a reinforced concrete pad approximately 20' x 40' (6 x 12 m) to accommodate the main PAR facility equipment. A site-specific concrete pad may be installed to accommodate a generator, transformer, or fuel tank. Install additional concrete pads to accommodate reflector towers and guy wire anchor pads. The number of reflector towers required is site specific.

4-5.4.2 Architectural Requirements.

There are no architectural requirements for the PAR. The building is a prefabricated shelter.

4-5.4.3 Structural Requirements.

The PAR system is housed in a transportable shelter provided by the system manufacturer. Provide a reinforced concrete pad for the fixed mounted PAR and reinforced concrete foundations to support the turntable-mounted PAR frame. Provide concrete anchor blocks for turntable stop anchor bolts.

4-5.4.3.1 Design Criteria and Loads.

Base the structural design on a Risk Category of IV, as noted in UFC 3-301-01, Structural Engineering, Table 2-2. See the SSC PAC PAR SPSPP for additional structural design criteria.

Place the PAR and associated infrastructure on a minimum 6-inch (150 mm) thick 40' x 20' (12 m x 6 m) concrete slab on grade. Provide a slab with a thickened footing at the edge with a minimum embedment below the finished grade of 12 inches (300 mm). Provide a thickened footing at the edge a minimum of 15 inches (380 mm) thick and 12 inches (300 mm) wide. Adjust the dimensions of this footing based on the frost depth penetration at each site and based on the findings of the site-specific geotechnical investigation.

Place the PAR Sensor on a 4-ft (1.2 m) tall, 6’ x 6’ (1.8 m x 1.8 m) cast-in-place concrete pedestal. Support the cast-in-place concrete pedestal with a foundation of variable size, designed based on the wind category applicable to the facility location. Install the Antenna Mounting assembly within the concrete pedestal. This assembly consists of two mounting plates and 12 anchor bolts, nuts, and washers.

4-5.5 Mechanical Requirements.

Air Force: See Environmental Control Unit requirements (e.g., allowable temperature and humidity ranges) in AF T.O. 31Z3-822-2, Chapter 3.

4-5.6 Electrical Power.

To avoid potential interference with antenna transmissions, install power, communications, and control cables underground within 1,000 ft (305 m) of the PAR facility. Ensure electrical systems do not interfere with radio and radar transmissions.

Provide commercial power service to the PAR. Provide service maximum 25kVA, 208Y/120V, 3 Phase, 4-wire, 60Hz.

Provide the PAR site with a new 100-amp electrical panelboard: 208Y/120V, 3 Phase, 4-wire, 60Hz. Provide a panelboard with a 100A, 3-Pole, ground fault protected main circuit breaker. Mount the panelboard on two concrete imbedded stainless steel channel stanchions, minimum 5 feet exposed above grade. Install the panelboard at a location aligned with the corner of the PAR power/electronics equipment shelter where the enclosure-provided disconnect is positioned.

Air Force: See Commercial Power, Uninterruptible Power Supply, and Backup Power, in AF T.O. 31Z-822-2, Chapter 1. See Grounding, Bonding Shielding and Lightning Protection requirements in AF T.O. 31Z-822-2, Chapter 2.

4-5.6.1 Emergency Electrical Power.

Provide a backup power generator, minimum 30 kVA. See Chapter 2 for additional requirements.

4-5.6.2 Grounding and Bonding.

Install four perimeter ground rods with an interconnecting below grade #2/0 Bare Copper ground conductor. Install one of the corner ground rod locations in a round test handhole with H20 traffic rated cover. Place the ground loop 6.5 feet from the edge of the PAR Site concrete pad. Bond the grounding systems for the generator and transformer below grade to the ground loop. Install a 12' x 12' (3.7 m x 3.7 m) copper ground mesh 2 feet below grade between the PAR power/electronics shelter and the PAR Sensor. Install three additional ground rods in a triangular pattern with the tops exposed, bonded to the mesh, the perimeter ground loop, and bonded together above grade. Connect two of the exposed ground rods to the PAR power/electronics shelter and the PAR Sensor. Connect the third exposed ground rod below grade to the electrical panelboard ground bus and a communication termination box ground bus. Configure the placement of the three triangular pattern grounds to allow for installation of an above ground cable tray between the power/electronics shelter and the PAR Sensor.

Install a separate isolated ground rod exposed a minimum of 6 inches (15 cm) above grade at a maximum distance of 1 foot (31 cm) from the edge of the concrete pad to support connection from a lightning protection tower cable.

The ground impedance at all locations of the grounding system must not exceed 10 ohms. Ideal ground impedance is less than 1 ohm.

4-5.6.3 Lighting.

No site lighting is required. Obstruction lighting is provided with the equipment.

4-5.7 Communications.

Provide a minimum 12-strand single-mode fiber optic cable to each system (elevation and azimuth) through underground conduits and handholes.

Air Force: See fiber optic cable and modem requirements in AF T.O. 31Z-822-2, Chapter 4.

4-5.8 Connection/Interrelation to other Facilities.

The PAR system must be connected to the remote monitoring site (usually the Air Traffic Control Tower) with fiber optic cables.

Figure 4-18 PAR Facility Siting Criteria

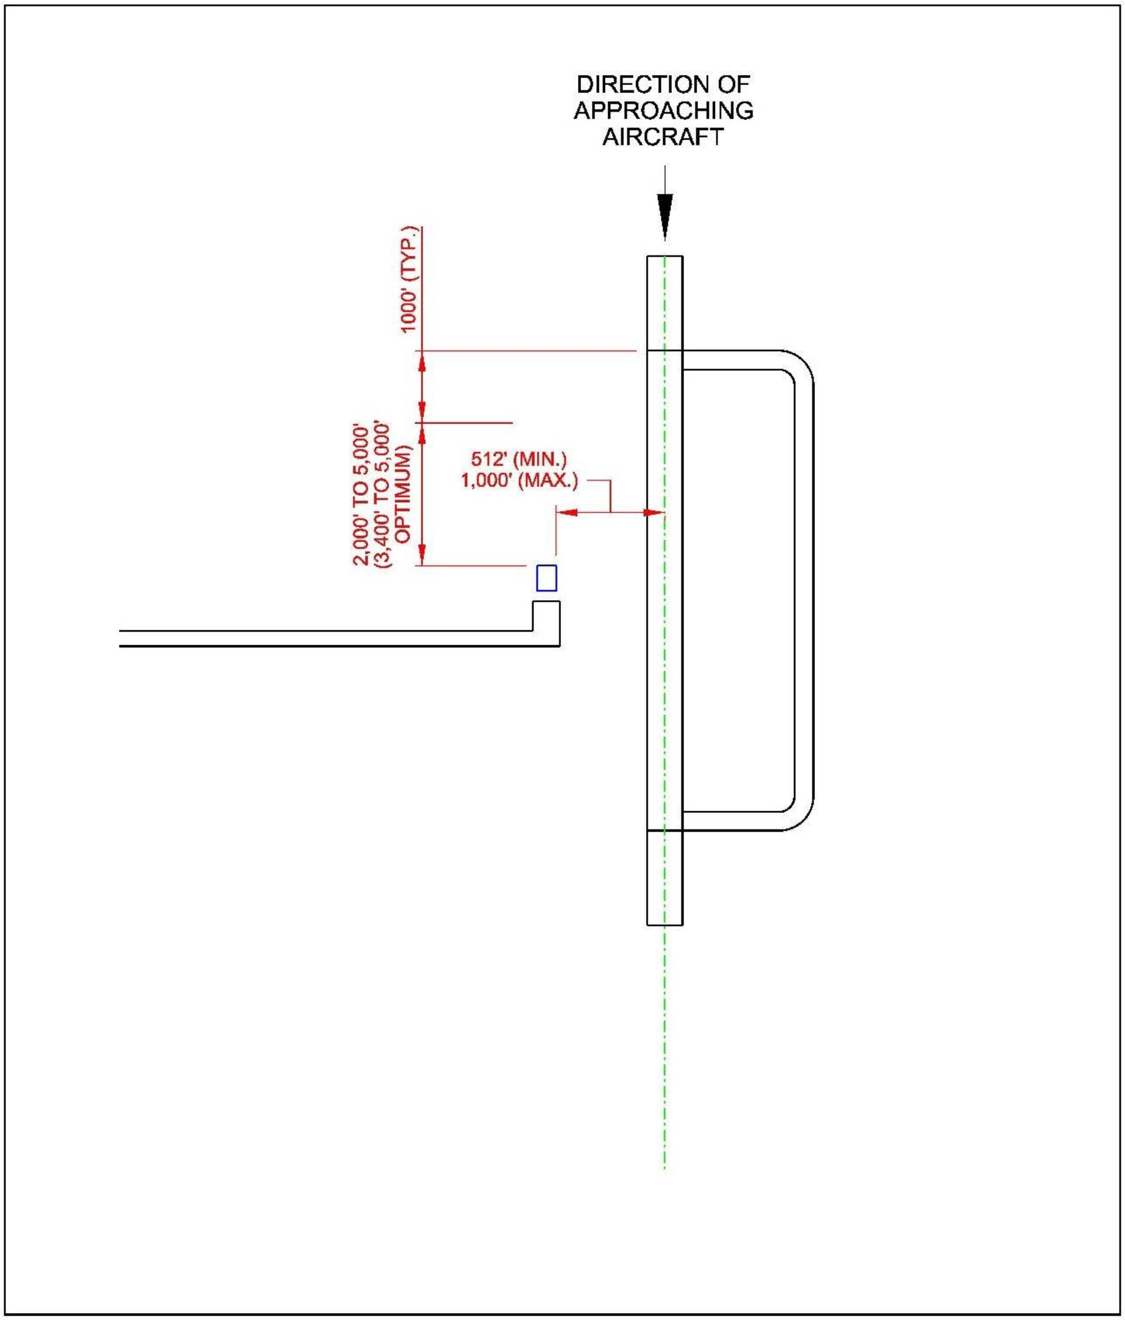

Figure 4-19 PAR Facility Site Plan

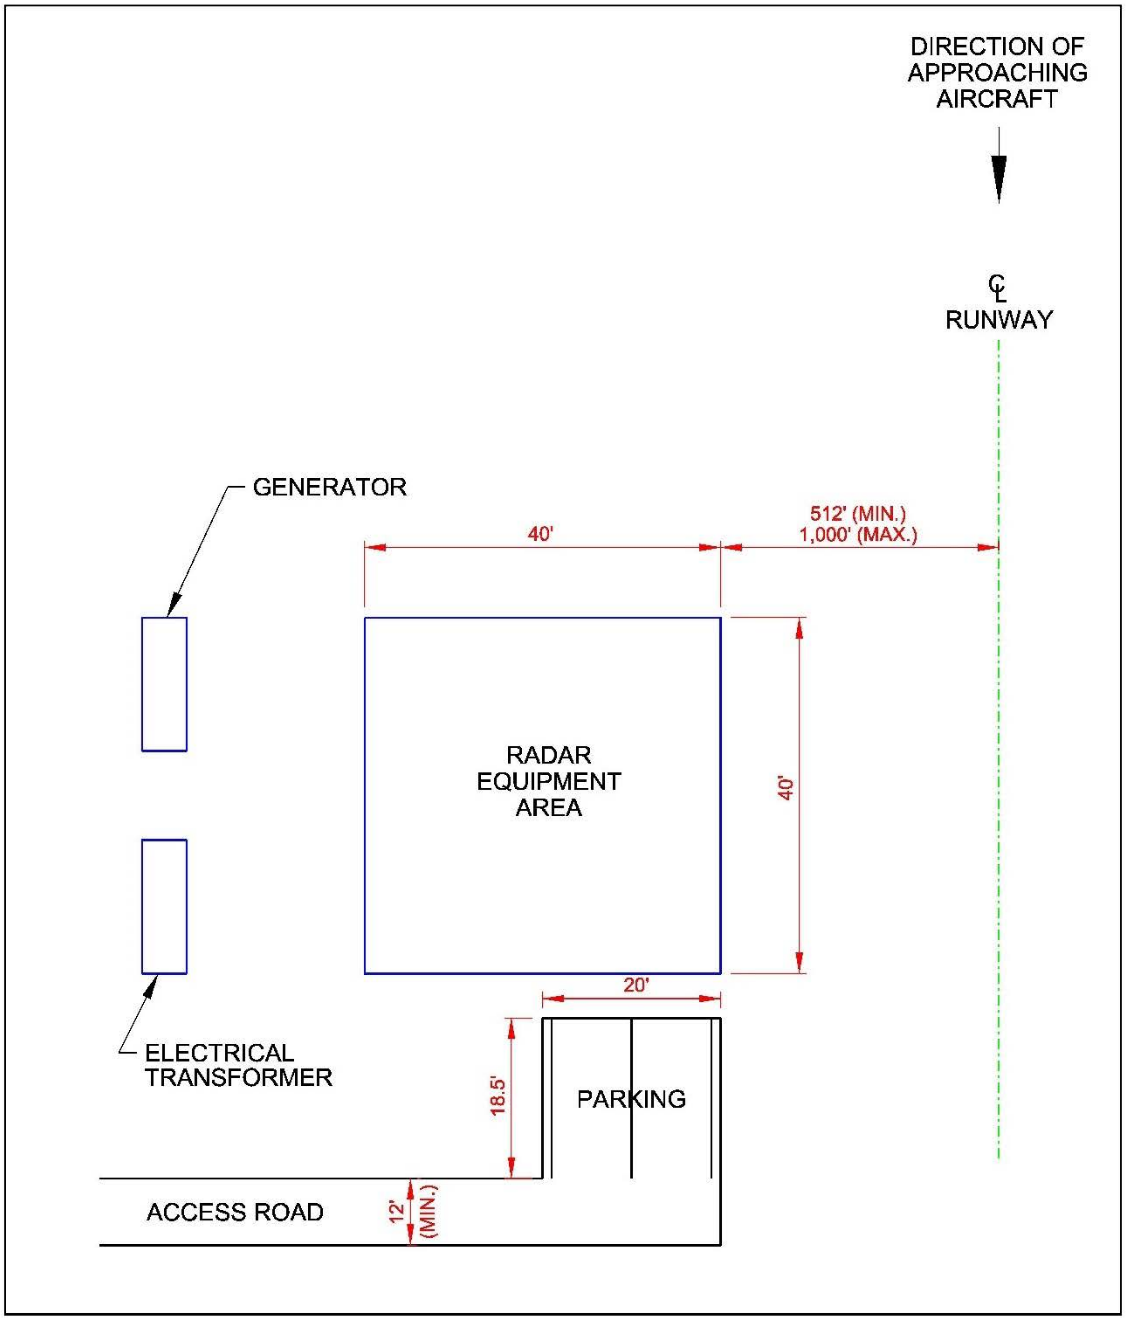

Figure 4-20 PAR Facility: Turntable Mounted Radar Plan and Elevation

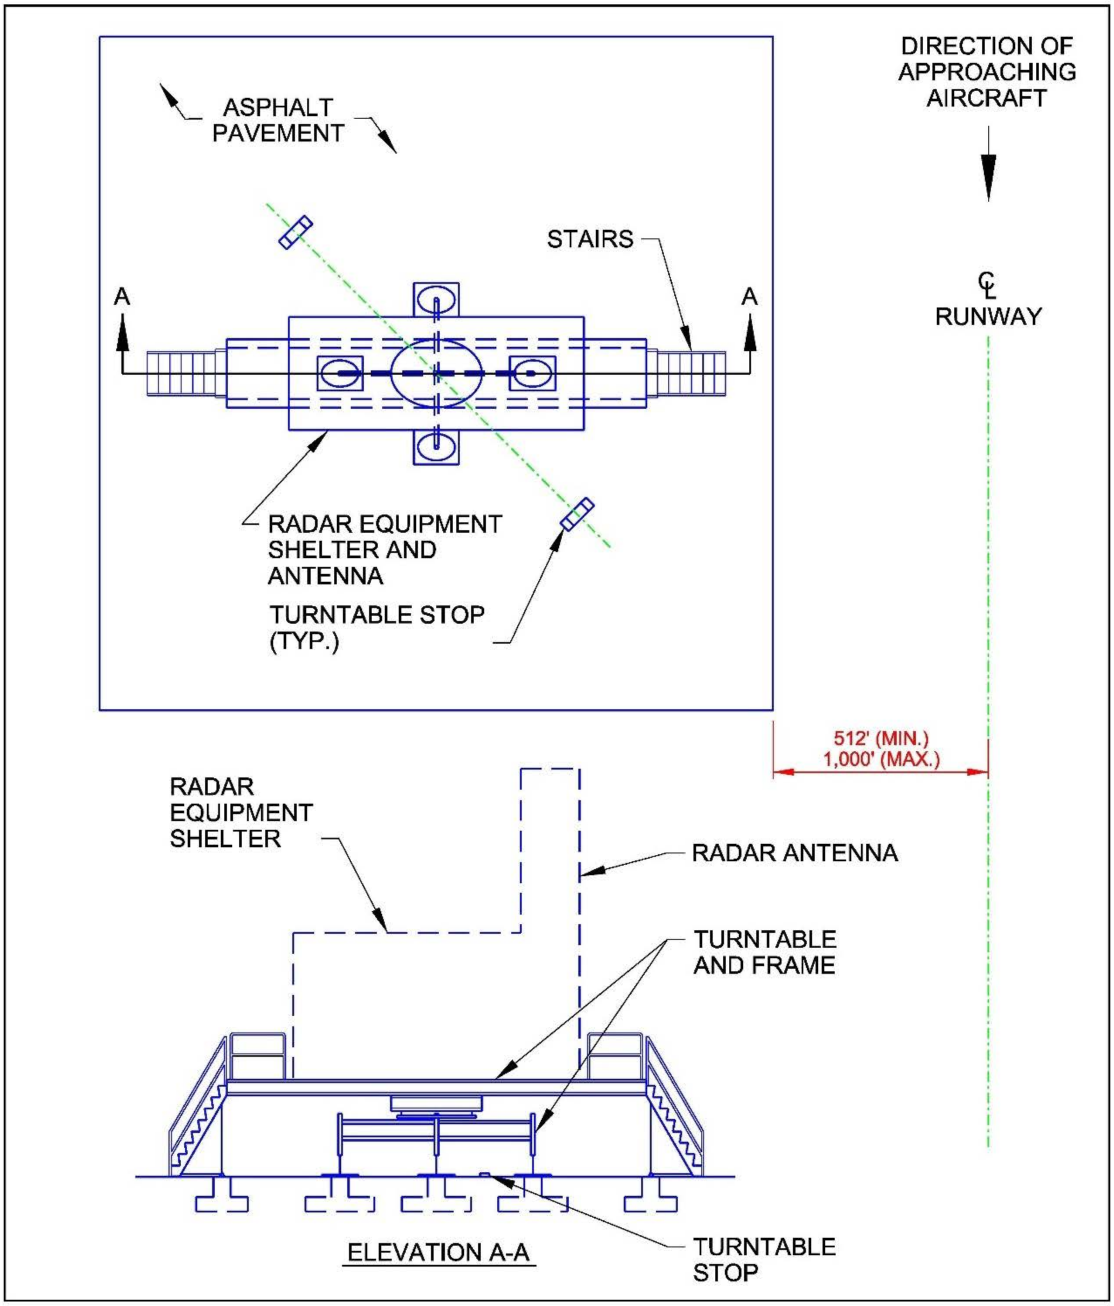

Figure 4-21 PAR Facility: Fixed Mounted Radar Plan and Elevation

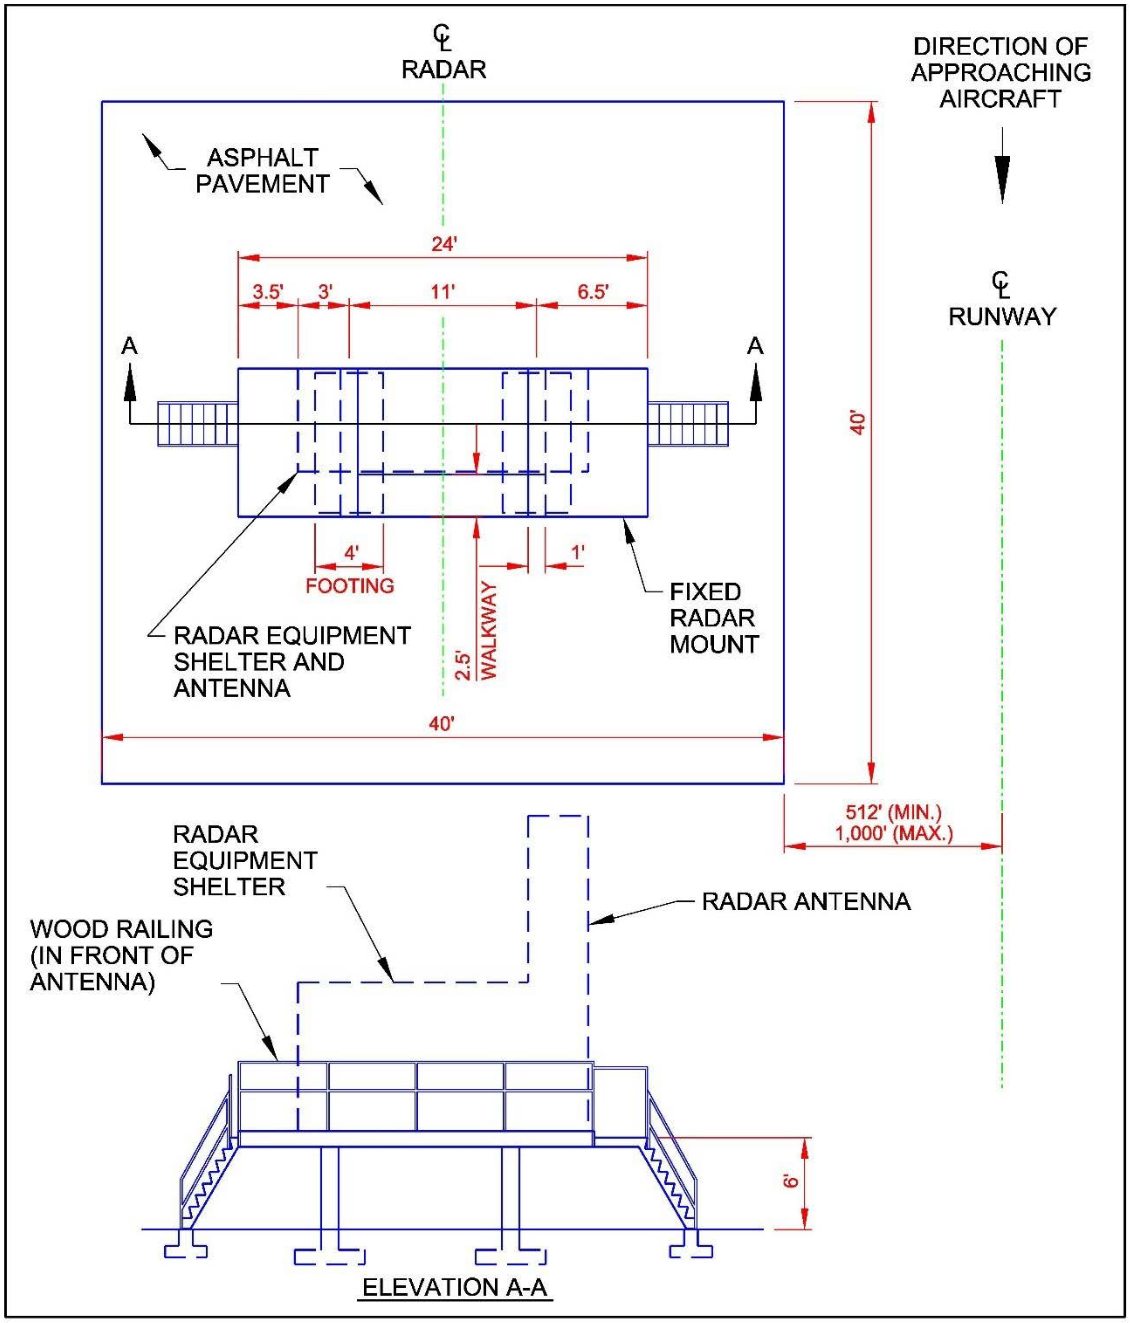

CHAPTER 5 AIR SURVEILLANCE RADAR SYSTEMS

5-1 GENERAL INFORMATION.

5-1.1 Function.

Air Surveillance Radar (ASR) facility buildings provide housing for electronic radar equipment used to detect and display location information about in-flight aircraft. These facilities are unattended.

5-1.1.1 Air Surveillance Radar (ASR).

The ASR is an electronic radar system used to obtain the range and azimuth of an aircraft. When equipped with an Air Traffic Control Radar Beacon System (ATCRBS), the ASR obtains altitude and azimuth of an aircraft. When equipped with an ATCRBS, the ASR obtains altitude and identification of the aircraft. Information obtained by the ASR and ATCRBS is displayed in the Military Terminal Radar Approach Control Facility (MTRACON), the air traffic control tower with ground-controlled approach or a Joint Control Facility (JCF). The ASR is used to control aircraft on overflight, approach, and departure flight paths at a terminal facility. Figures 5-1 through 5-3 show a typical ASR.

5-1.1.2 Air Route Surveillance Radar (ARSR).

The ARSR is an electronic radar system used to obtain the range and azimuth of an aircraft. These systems are only owned and operated by the FAA, and therefore are not included in this UFC.

Figure 5-1 Typical Airport Surveillance Radar (ASR) Steel Tower

Figure 5-2 Typical Digital Airport Surveillance Radar (DASR) (Army)

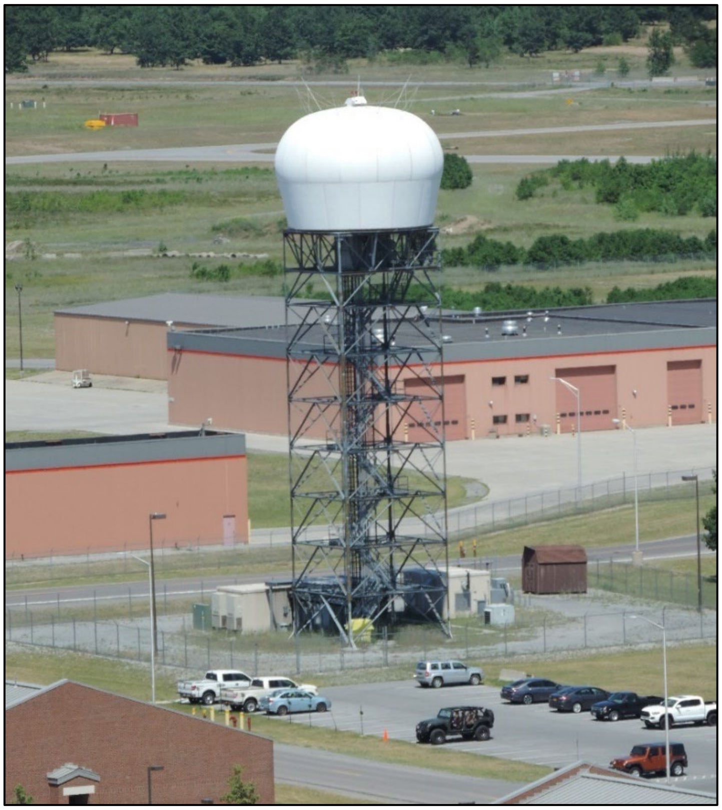

Figure 5-3 Typical DASR without Antenna Cover (Army)

5-2 AIRPORT SURVEILLANCE RADAR (ASR).

5-2.1 Key Documents.

FAA Order 6310.6	*Primary/Secondary Terminal Radar Siting Handbook*
FAA Order 6340.15	*Primary/Secondary En Route Radar Siting Handbook*
AF T.O. 31Z3-822-2	*Air Traffic Control Landing Systems (ATCALS) Site Requirements 404L*

5-2.2 Siting.

Locate the ASR adjacent to the radar facility antenna tower. Locate the ASR facility radar no closer than 0.5 nautical miles from the approach and departure ends of the runway. Do not locate the radar below the approach/departure paths or ground-controlled approach patterns. Care should be exercised in the placement of the ASR in relation to the Air Traffic Control tower as it can create a screening object for the radar. The only limit to the radar's distance from the airfield for ASR approaches is 20 nautical miles as defined in the 8200.1D United States Standard Flight Inspection Manual. This is based upon current radar accuracy to place an aircraft target on a standard runway width. The ASR facility at Range Airspace Surveillance Sites (RASS) may be located further away. Locate the facility to minimize obstruction to radar transmissions. Refer to FAA Order 6310.6 and FAA Order 6340.15. See Figure 5-4 for general siting requirements.

Clearances: Prior to determining final antenna placement, conduct an analysis as part of the site approval process for transmitters of electromagnetic radiation. Electromagnetic Environmental Effects (E3) analysis will determine Hazards to Personnel (HERP), Hazards to Ordinance (HERO), Hazards to Fuel (HERF), and Electromagnetic Interference (EMI).

Produce a Radar Siting Analysis (RSA), using FAA order 6310.6 as a guide, to analyze operational requirements and facilitate final site selection. Radar siting analysis is typically conducted by the Program Office deploying the radar asset in conjunction with the local Air Traffic Control Facilities Officers. ASR antennas may be elevated to obtain line-of-sight clearance. Typical ASRs (antenna platform heights – mezzanine level) range from 17 to 77 feet (5 to 23.5 m) above ground level (AGL). The antenna tower is a standard 24 feet × 24 feet (7 m × 7 m) galvanized steel structure. Additional ten-foot (3 m) sections are usually added incrementally until the radar platform reaches the desired elevation. Trees and other structures must always stay below the mezzanine level. Carefully evaluate the presence of wind turbines in the vicinity of an airport while siting the location of a radar antenna system as such objects do cause reflectivity issues and are the cause of false targets.

5-2.3 Security.

Air surveillance radar facilities are normally located within restricted area which typically meets the minimum security measures for external security. When the facility is located within a restricted area of a lower level of security or is located remote and outside of an established restricted area, provide additional measures to meet the minimum security requirements for the level of security assigned to the facility.

5-2.4 Facility Design Guidance.

See Figures 5-5 and 5-6 for typical ASR site plan and building layout. See service-specific guidance for allowable building size. Typical building size is 1,400 square feet (130 square meters) to house the electronic equipment, monitoring and test equipment, and mechanical equipment.

5-2.4.1 Site Work.

Provide an access road to allow maintenance vehicles access to the ASR. Provide parking space for four maintenance vehicles. See Chapter 2, paragraph “Access and Parking” for roadway and parking area design requirements.

5-2.4.2 Architectural Requirements.

Provide the following:

- Adequate space for equipment and equipment maintenance.
- Clear ceiling height of 10 feet (3 m).
- Work bench.
- Vinyl tile flooring in equipment room.

Do not provide a restroom.

Do not provide windows.

Consider the use of a premanufactured building.

5-2.4.3 Structural Requirements.

Design roof structural system to support cable trays and radar equipment wave guides.

5-2.5 Mechanical Requirements.

Design mechanical systems to meet the general criteria in Chapter 2. Ensure mechanical systems do not interfere with radar transmissions.

Air Force: See Environmental Control Unit requirements (e.g., allowable temperature and humidity ranges) in AF T.O. 31Z3-822-2, Chapter 3.

5-2.5.1.1 Heating.

Provide a minimum temperature of 70 degrees F (21°C).

5-2.5.1.2 Air Conditioning.

Provide two separate air conditioning systems, each capable of handling the entire load independently. One unit functions as a secondary backup unit if the primary unit fails. Provide the following:

- Separate thermostat controls for each unit.
- Interlocked primary and secondary units to prevent simultaneous operation.

5-2.6 Electrical Power.

To avoid potential interference with radar transmissions, install power, communications, and control cables underground within 1,000 ft (305 m) of each facility. Ensure electrical systems do not interfere with radio transmissions.

Provide 120/240V, 100A, single-phase, 60 HZ commercial power service to the ASR.

5-2.6.1 Emergency Electrical Power.

Provide an emergency generator with automatic starting and switching capability as described in Chapter 2. Provide emergency power to the entire radar facility.

5-2.6.2 Uninterrupted Power Supply (UPS).

Provide non-redundant UPS in accordance with Chapter 2. Use the anticipated load to determine the size of the UPS.

5-2.6.3 Lighting.

Reserved.

5-2.7 Communications.

Provide 12-strand single mode fiber optic cable or 25 twisted pair communications line to provide required connectivity for data and telephone.

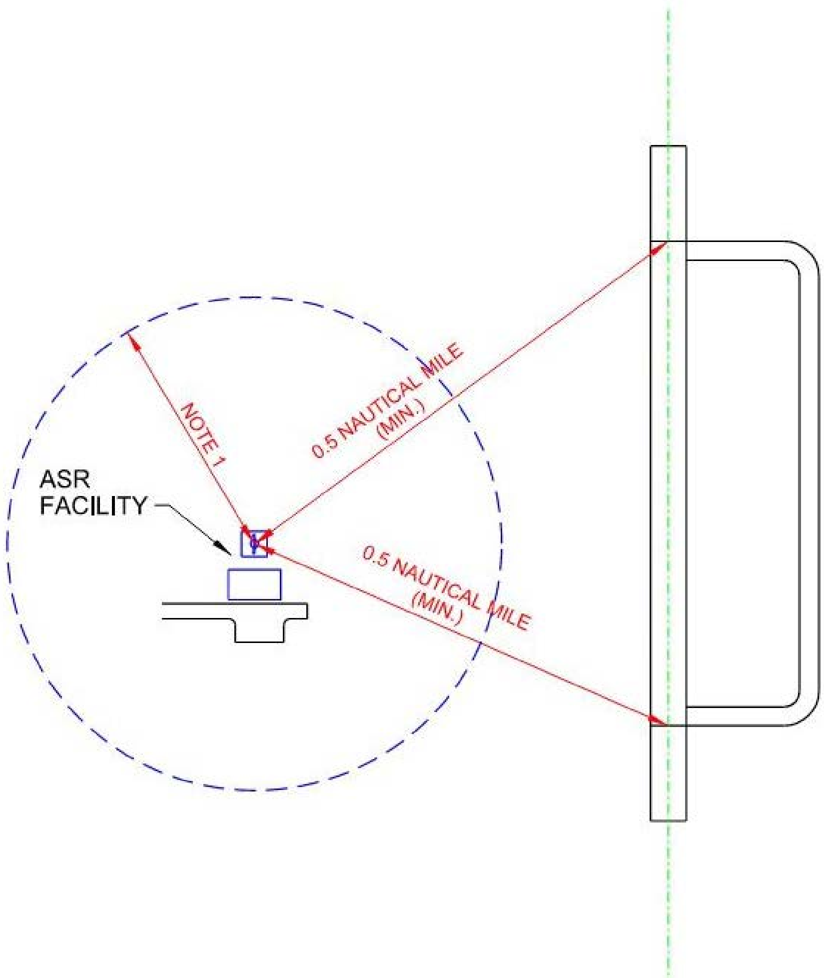
- Data connectivity from the ASR to Remote Unit located in the ATC Tower. (Dedicated pair)
- Data connectivity from the ASR Fire Alarm to external monitoring system. (Dedicated pair)
- Telephone line for distance support to troubleshoot system.

Air Force: See fiber optic cable and modem requirements in AF T.O. 31Z-822-2, Chapter 4.

5-2.8 Connection/Interrelation to other Facilities.

Connect a dedicated DSN-capable telephone connection through to the ASR to facilitate distant support, troubleshooting, and corrective maintenance due to the remote location. Connect the ASR to the ATC Tower via fiber optic cable for remote monitoring.

Figure 5-4 ASR Facility Siting Criteria



NOTE

1.) LOCATE ASR AT LEAST 1,500 FEET FROM ANY BUILDING OR OBJECT THAT MAY CAUSE SIGNAL REFLECTIONS AND 0.5 MILE FROM OTHER ELECTRONIC EQUIPMENT.

Figure 5-5 ASR Site Plan

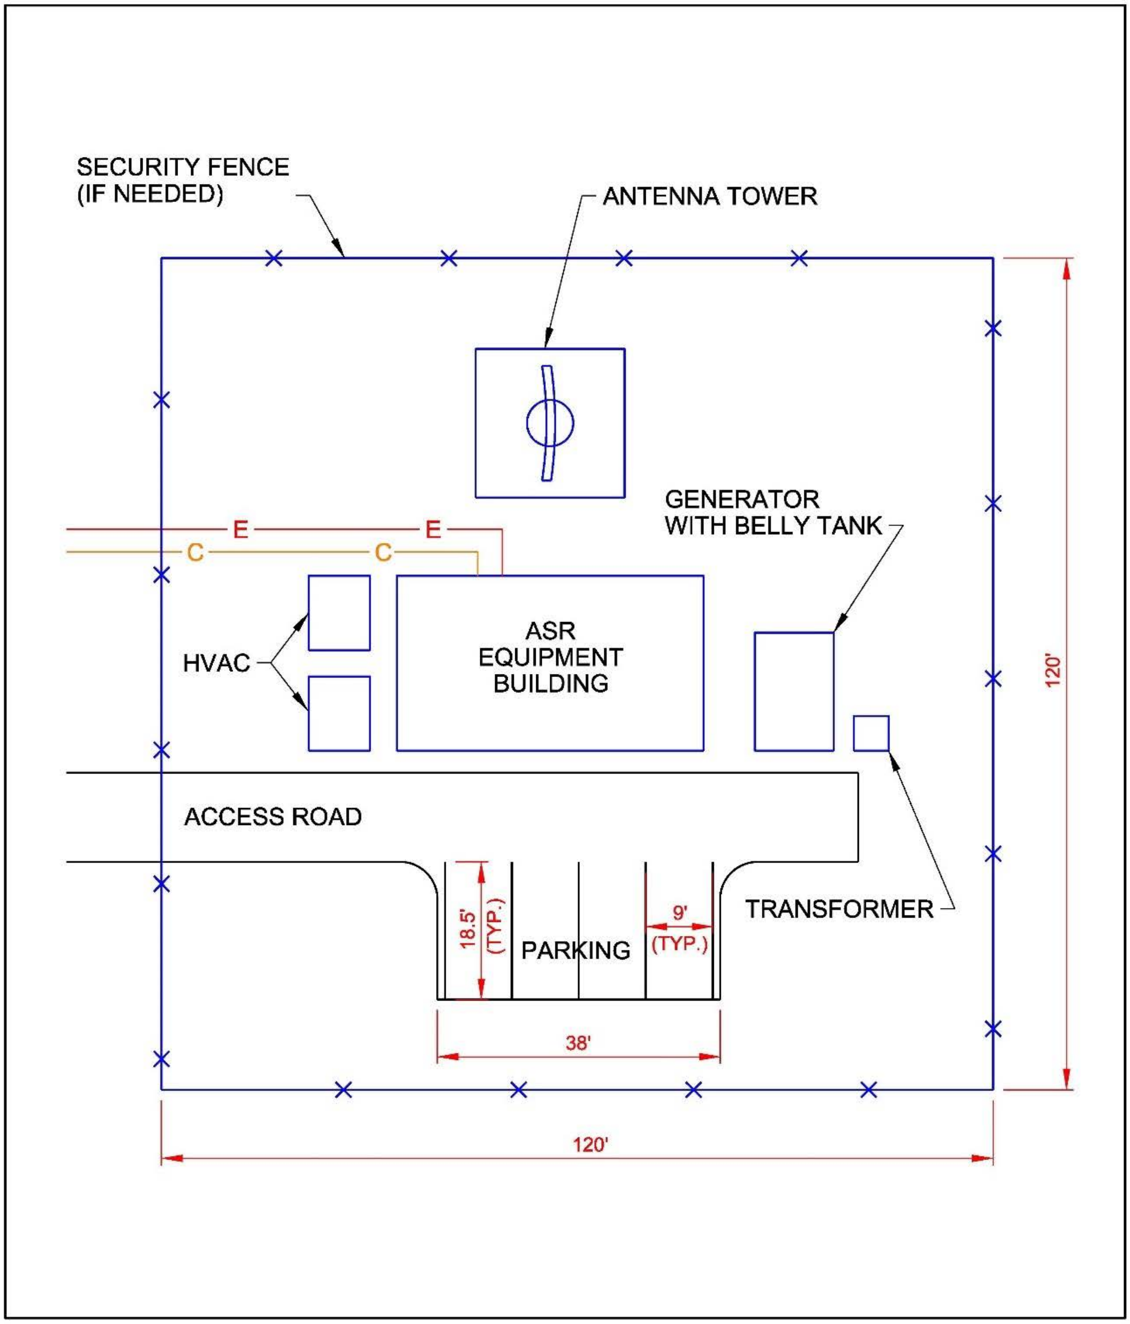


Figure 5-6 ASR Building Layout

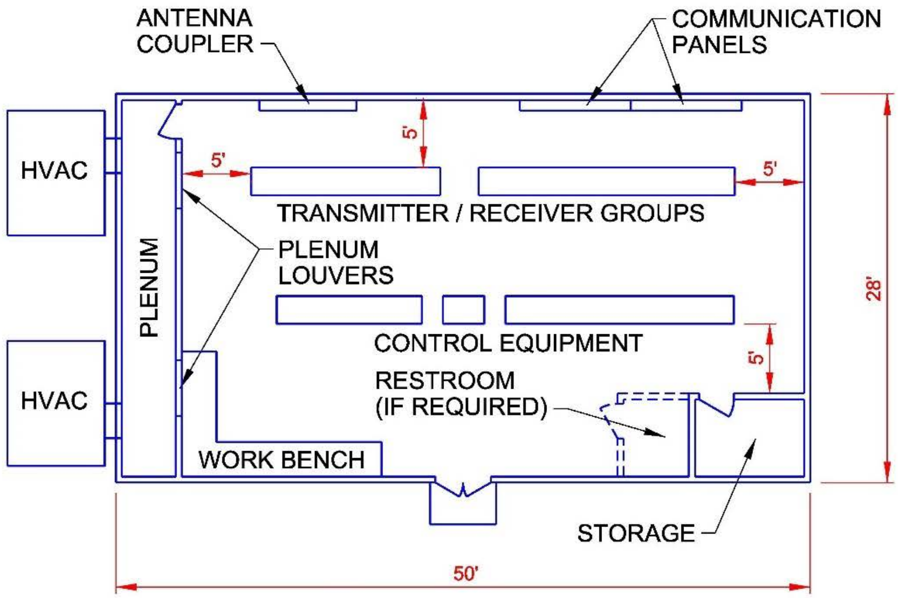

This Page Intentionally Left Blank

CHAPTER 6 COMMUNICATIONS FACILITIES SUPPORTING AIRFIELDS

6-1 GENERAL INFORMATION.

6-1.1 Function.

Air Traffic Control (ATC) communications facilities provide environmentally controlled spaces that house radio frequency (RF) Transmitter (Tx) and/or Receiver (Rx) equipment used to communicate with aircraft for ATC operations and for regulating all types of aircraft on an airfield.

ATC communications facilities contain remote electronic communications and linking equipment used for ground-to-air (G/A) communications with tactical and transient aircraft, to control aircraft departures and arrivals, and to communicate with other agencies involved in ATC or aviation support.

There are three types of ATC Communications Facilities:

- Transmitter Facilities (Tx)
- Receiver Facilities (Rx)
- Collocated Transmitter/Receiver (Tx/Rx) Facilities

Figure 6-1 Remote Transmitter/Receiver (RTR) Communication Facility

6-1.1.2 Transmitter (Tx) Facility.

The transmitter building contains transmitting equipment, antenna coupling equipment, and maintenance and test equipment.

6-1.1.3 Receiver (Rx) Facility.

The receiver building contains receiver and repeater equipment, antenna coupling equipment, and maintenance and test equipment.

6-1.1.4 Collocated Transmitter and Receiver (Tx/Rx) Facility.

The collocated Rx/Tx facility contains both Rx and Tx equipment, antenna coupling equipment, and maintenance and test equipment.

6-1.1.5 Remote Data Link Building.

The remote data link building provides housing for a suite of communications linking equipment. Equipment suites typically include satellite communications, radio, and television microwave.

6-1.1.6 Continuity of Operations.

6-1.1.6.1 Coordination

Normal air traffic control (ATC) operations may be affected by construction, renovation, and/or repair of the ATC communications facility. Give careful consideration to the operational impact of a proposed facility design/specification; the goal is to minimize these impacts. Coordinate any design that results in construction that has the potential to affect safety of flight (SOF) with the Airfield Manager. Coordinate any construction that affects structures currently housing electronic equipment required to support air operations through each Service’s subject matter expert.

6-1.1.6.2 Temporary Facilities

If existing facility demolition or repair efforts are required prior to construction of the new ATC communications facility, demolition/repair efforts must not start until all communications functions have been fully transferred to a temporary facility and the temporary facility has been certified fully operational by the Air Traffic Control function. This stipulation is vital to maintaining ATC operations and SOF.

6-2 ATC COMMUNICATIONS FACILITY.

Whether constructing a Tx, Rx or collocated Tx/Rx facility, the components and requirements are the same, with the exception of the space required for a collocated facility. Collocated facilities require more space inside the building to house additional radio equipment and may require more parking space outside the facility.

6-2.1 Key Documents.

FAA Order 6580.6A	*Remote Communications Facilities Siting Process* (not accessible outside FAA)
FAA-STD-019f	*FAA Standard, Lightning and Surge Protection, Grounding, Bonding and Shielding Requirements for Facilities*
AF T.O. 31Z3-822-2	*Air Traffic Control Landing Systems (ATCALS) Site Requirements 404L*

6-2.2 Siting.

Locate radio communications buildings within the antenna field to provide minimum length of cable from antenna to radio communications equipment. Refer to the Base Master Plan and consider planned expansion of airfield systems when locating communications facilities. See FAA Order 6580.2 for additional details. Figure 6-2 illustrates general siting requirements.

6-2.2.1 Site Selection.

a. Use a coordinated effort between Air Operations, Air Traffic Control, and the service-specific engineering and equipment maintenance organizations to select potential facility sites. Site selection must consider the requirements listed in this document, UFC 3-260-01, and current service-specific publications.

b. Select construction sites to account for an antenna field next to or surrounding the ATC communications facility. The facility's antenna field typically has up to 10 antenna towers, with six to eight antennas on each tower. A minimum separation of 80 feet (24 m) is required between antenna towers; a separation of 120 feet (37 m) is preferred. See Figure 6-3 for a typical ATC communications facility site plan. See Figure 6-5 for a typical antenna tower. Towers can be a maximum of 350 feet (107 m) from the ATC communications facility.

c. The size (diameter) of the RF cable is dependent on the total length of the cable path from the antennas to the radios. Determine the exact RF cable diameter during design. Note: The diameter of RF cable can be as large as 1-5/8". Typically, 7/8" (22 mm) cable is used for exterior runs exceeding 100 ft (30 m).

d. Antennas mounted on towers require an unobstructed Line of Sight (LOS) to all runways, taxiways, ramps, and parking aprons. The service-specific electronics maintenance office (e.g., NIWC Atlantic) is required to perform an RF coverage/propagation analysis to select the optimal site locations to ensure the locations and tower heights provide operational coverage for ATC communications.

6-2.2.2 Radiation Hazards

Hazards of Electromagnetic Radiation to Personnel (HERP), Ordnance (HERO), and Fuel (HERF) surveys are crucial to the siting process. Contact service-specific offices to conduct these surveys (e.g., NIWC Atlantic, NSWC Dahlgren Division, etc.) NIWC Atlantic and the facility Air Operations Department can assist with information concerning the electronic equipment to be installed in the facility to support ATC operations. Radiating RF antennas are installed on the antenna towers; therefore, a radiation hazard (RADHAZ) study to support the antenna installation must be conducted during the siting process. Facility siting criteria must consider the radiating fields of existing antennas supporting ATC operations, such as the Airport Surveillance Radar

(ASR). NAVSEA OP 3565, Vol. 2 provides detailed information concerning HERP, HERO, and HERF.

6-2.2.3 Site Approval.

Navy: Final site approval must comply with current NAVFACINST 11010.45A requirements.

6-2.3 Security.

Communications facilities are normally located within restricted areas which would typically meet the minimum security measures for external security. When the facility is located within a restricted area of a lower level of security or is located remote and outside of an established restricted area, provide additional measures to meet the minimum security requirements for the level of security assigned to the facility.

6-2.3.1 Fencing

Chain link fences are required around the facility and antenna tower field. Provide fences 8 ft. high and include three strands of barbed wire at the top. Ground all fences in accordance with FAA STD-19f. Provide one motorized or manual vehicle gate and one personnel gate. Determine the exact locations of these items during the design process.

Note: A minimum distance of 30 ft (9 m). is required between the communications building and the fence on all sides.

6-2.4 Facility Design Guidance.

6-2.4.1 General.

6-2.4.1.1 This section is divided into engineering disciplines associated with the design effort in order to consolidate requirements and simplify distribution. Designers for each discipline must consult with each other to verify that design conflicts do not exist and that all aspects of the design support a suitable final product.

6-2.4.1.2 Tx and Rx buildings are composed of interlaced engineered systems. The design of the facility does not lend itself to late involvement by engineering disciplines (e.g., mechanical and electrical). All engineering disciplines must be actively involved during floor plan inception. At the 35% design submittal, develop all engineered facility systems that affect ATC communications equipment to a level such that the minimum required square footages identified in the FRS are assured.

6-2.4.1.3 Contact Service-specific agencies (e.g., NIWC Atlantic) to obtain drawings of the electronic equipment cabinet layout during the design process. See Figure 6-3 for a typical layout of facility equipment.

6-2.4.1.4 Paragraphs in this section identify requirements to support electronic equipment or construction recommendations for general use. Specific details of some requirements identified in this section must be obtained from the facility Air Operations Department. These paragraphs serve as reminders to ensure requirements are not overlooked. Consider the following design details:

a. Provide water and sanitation at unmanned facilities where sanitation is not available in the vicinity.
b. Place ATC electronic equipment in a dedicated space not shared with mechanical rooms or administrative offices.
c. Clean and seal all unfinished concrete floors, to include concrete sub floors under raised access flooring.
d. Provide any mechanical, electrical, or other facility systems in the electronic equipment space(s) in direct support of ATC communications equipment and strictly abide by working clearance definitions in the latest NEC.
e. Determine the exact locations of ATC communications equipment with input by the service-specific agencies that operate the facility (e.g., NIWC Atlantic and the Air Operations Department) as the initial design plan is developed. Note that depending upon the airfield's ATC requirements, the amount of equipment installed may vary. However, all facilities must adhere to the service-specific agency's clearance, installation, physical security, and location requirements for ATC communications equipment, which are based on the type of equipment to be installed, regulatory codes, and Service policies.
f. Do not include windows in ATC communications equipment spaces.
g. If electronic component repair involving soldering will be performed in the ATC communications facility, a designated work area is required. Navy: This work area must meet the requirements of NAVAIR 01-1A-23.

6-2.4.1.5 Due to the increased use of electronic systems procured jointly by the FAA and Department of Defense (DOD), the facility grounding system must be designed and installed in accordance with FAA standards (FAA-STD-019f).

6-2.4.2 Site Work.

Provide an access road to allow maintenance vehicles access to the ATC Communications Facility. Provide parking space for two maintenance vehicles. See Chapter 2, paragraph "Access and Parking" for roadway and parking area design requirements.

6-2.4.2.1 Sidewalks/Ramp

Provide an 8 ft (2.4 m). wide sidewalk/ramp from the main facility driveway to the main facility entrance. Provide a sidewalk that can support the weight of a small truck. If the finished floor is above grade, a small loading dock and a ramp from the sidewalk to the main entrance are required. If the finished floor is at grade, a loading dock and ramp are not required.

6-2.4.3 Architectural Requirements.

Provide the following:

- Adequate space for equipment and equipment maintenance.
- Clear ceiling height of 10 feet (3 m).
- Work bench.
- Provide water and sanitation at unmanned facilities where sanitation is not available in the vicinity.
- Raised access floor or suspended cable trays.

Do not provide windows.

See NIWC – ATC Remote Communications Facility – FRD for more specific requirements.

6-2.4.3.1 Critical Dimensions.

Provide a facility with an equipment room with minimum interior dimensions of 36 ft x 22 ft (11 m x 6.7 m)

6-2.4.3.2 Equipment and Personnel Space Requirements.

The ATC communications facility must include space for the following:

a. Equipment
b. Lavatory (only if sanitation facilities not available in the vicinity).
c. Electrical (including uninterruptible power supply)
d. Mechanical
e. Emergency generator (E/G) space (can be outside on pad)
f. Data Communications Frame Area/Main Distribution Frame (MDF)
g. Antenna Towers

6-2.4.3.3 Access Flooring.

An 18 in (450 mm) raised access floor system is required in ATC communications equipment spaces in lieu of floor trenches. See NIWC – ATC Remote Communications Facility – FRD for more specific requirements.

6-2.4.4 Structural Requirements.

Design and install foundations for each ATC communications facility antenna tower. Follow structural design requirements of UFC 3-301-01. Foundation design is dependent upon antenna tower height and soil conditions.

6-2.4.5 Pre-manufactured Buildings.

Consider using a pre-manufactured building as described in Chapter 2.

6-2.5 Mechanical Design Requirements.

a. Refer to UFC 4-133-01 for general and specific mechanical design requirements for ATC-related facilities. See also NIWC – ATC Remote Communications Facility – FRD for more specific requirements.

b. A chiller, boiler, and four-pipe distribution system with separate air handlers for each zone is not required if suitable Direct Expansion (DX) units can be used.

c. Do not use HVAC systems specifically designed for use with raised floors in facilities without raised floors.

6-2.5.1 Fire Protection Requirements.

Design and install fire protection and alarm systems in accordance UFC 3-600-01.

6-2.6 Electrical Requirements.

To avoid potential interferences with radar communications, locate power, communications, and control cables underground within 1,000 feet (305 m) of the antenna site. Ensure facility electrical systems do not interfere with radio communications.

Provide 120/208V, 100A, three-phase, 60 HZ commercial power service for the ATC Communcations Facility with a minimum 30-circuit power panel.

All electrical power provided to the facility requires backup by an emergency generator. Power must be supplied on a split-bus system, which is herein denoted as “critical” and “non-critical.”

See NIWC – ATC Remote Communications Facility – FRD for more specific requirements.

6-2.6.1 National Electrical Code Compliance.

Provide ATC communications facility electrical grounding that comply with the requirements outlined in NEC Article 250, and FAA-STD-019f. Specifically, provide the ATC communications facility with grounding electrode systems and safety grounding systems in accordance with the NEC plus lightning protection, signal reference systems, and multipoint grounding systems. Be aware that FAA requirements exceed those of the NEC.

6-2.6.2 Emergency Electrical Power.

Provide an emergency generator with automatic starting and switching capability as described in Chapter 2. Provide emergency power to the entire communications facility.

a. A minimum of 24 hours of emergency backup power is required for the ATC communications facility. Obtain ATC equipment loads from the service-specific agency that operates the facility. To ensure equipment operation during extended power outages, HVAC systems serving electronic equipment spaces must be supported by emergency generator (E/G) power. Consult with the facility users for E/G fuel storage capacity requirements above 24 hours.

b. Provide remote electronic monitoring and control of the E/G. Provide electronic control with the capability to monitor power status and fuel level as well as starting and stopping the generator. Coordinate the location of the remote monitoring equipment with the facility users.

6-2.6.3 Uninterruptible Power Supply.

a. A Facility UPS is required for the ATC communications facility.

b. The Facility UPS must be sized to provide the critical loads with power (plus a 25% spare capacity) for a minimum of 30 minutes to allow the emergency generator (E/G) to start, stabilize, and assume the load. See NIWC – ATC Remote Communications Facility – FRD for more specific requirements.

6-2.6.4 Facility Lightning Protection.

a. Design the lightning protection system to meet FAA-STD-019f requirements.

b. Take care to ensure lightning down-conductors do not run within the building structure, take the shortest route possible, and are properly terminated to an earth ground.

c. As specified in FAA-STD-019f, all lightning protection down-conductors must be connected to the EES via exothermic welds, including the connection of any down-conductors to the ground rod in the access well.

d. In accordance with the NEC, protect signal cables entering the ATC communications facility against lightning-induced transient voltage at the building entrance.

e. Air terminals on the facility roof are required to provide a zone of protection for any miscellaneous antennas mounted on the roof, such as the fire alarm antenna.

6-2.6.5 Grounding and Bonding.

In the design of the grounding and bonding system unless otherwise noted, FAA-STD-019f takes precedence. See NIWC – ATC Remote Communications Facility – FRD for more specific requirements.

6-2.6.6 Lighting.

LED lighting must meet the requirements of CFR 47, Part 15 (B), but is preferred and acceptable. Fluorescent lighting requires radio frequency interference (RFI) suppression ballasts. See NIWC – ATC Remote Communications Facility – FRD for more specific requirements.

6-2.7 Communications.

Provide 12-strand single mode fiber optic cable or 25 twisted pair communications line to provide required connectivity for data and telephone.

- Data connectivity from the Communications Facility to the Remote Unit located in the ATC Tower. (Dedicated pair)
- Data connectivity from the Communications Facility Shelter Fire Alarm to external monitoring system. (Dedicated pair)
- Telephone line for distance support to troubleshoot system.

Air Force: See fiber optic cable and modem requirements in AF T.O. 31Z-822-2, Chapter 4.

6-2.8 Safety Considerations.

6-2.8.1 Eyewash Station.

Provide an Occupational Safety and Health Administration (OSHA)-approved eyewash station in each equipment space.

6-2.8.2 Fire Extinguisher.

Provide at least one OSHA-approved fire extinguisher in the ATC communications facility.

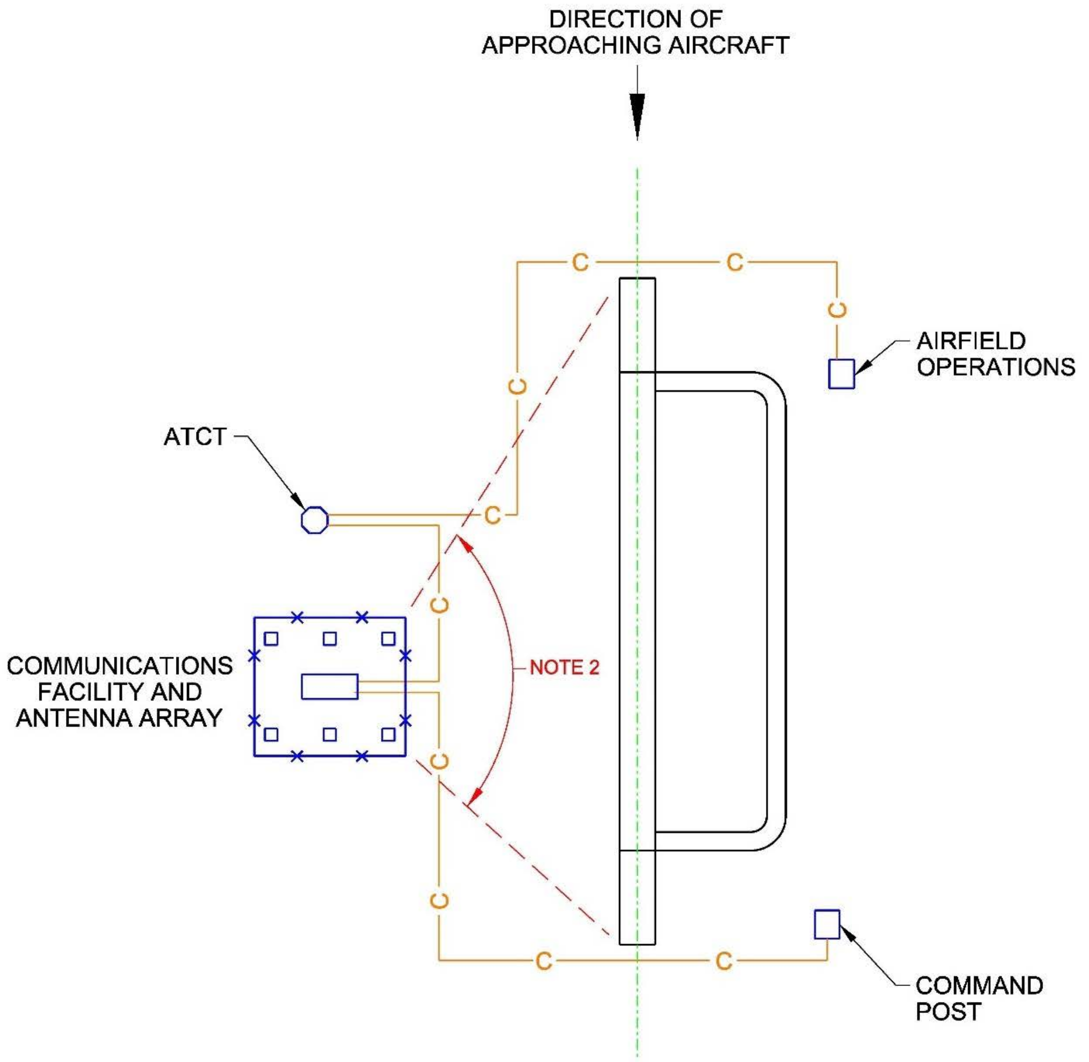
6-2.8.3 First Aid Kits and Safety Gear.

The facility GEMD/ATCMD is responsible for providing any first aid kits and safety gear required for the ATC communications facility.

6-2.9 Connection/Interrelation to other Facilities.

Connect a dedicated DSN-capable telephone connection through to the proposed Communications Facility to facilitate distant support, troubleshooting, and corrective maintenance due to the remote location. Connect the Communications Facility to the ATC Tower via fiber optic cable for remote monitoring.

Figure 6-2 Typical ATC Communications Facility Siting Criteria



GENERAL SITING REQUIREMENTS

1.) COORDINATE SITE WITH BASE MASTER PLAN AND CONSIDER PLANNED EXPANSION OF AIRFIELD SYSTEMS.

2.) ANTENNAS ON TOWER REQUIRE UNOBSTRUCTED LINE OF SIGHT TO ALL RUNWAYS, TAXIWAYS, RAMPS AND PARKING APRONS.

Figure 6-3 Typical Communications Facility Site Plan

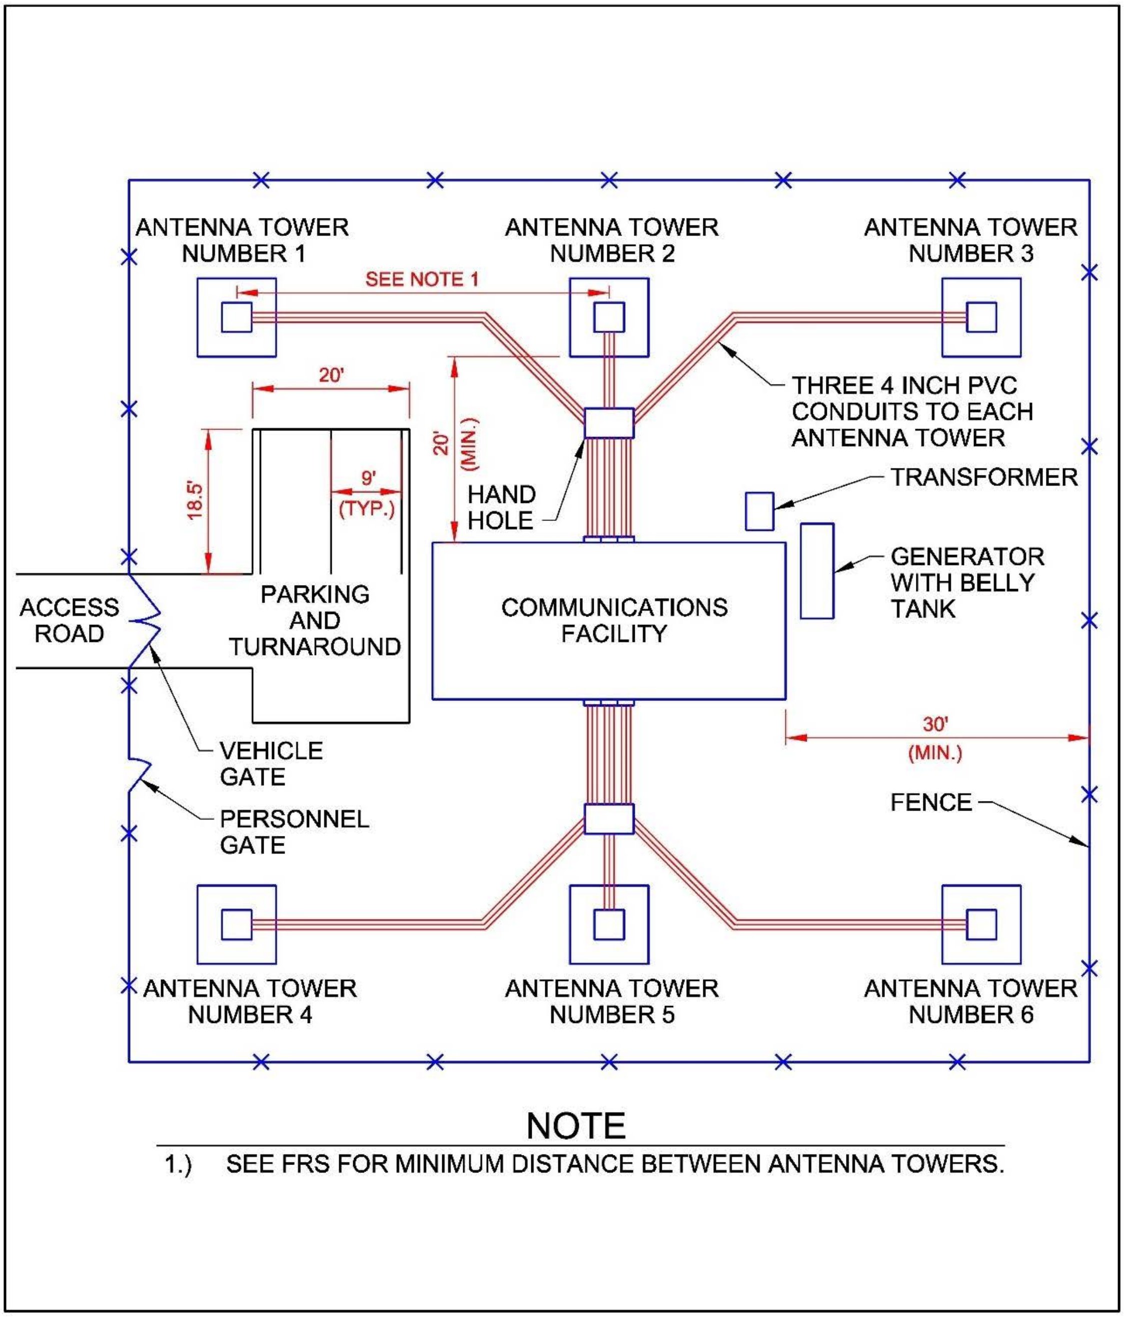


Figure 6-4 Typical Communications Equipment Building Layout

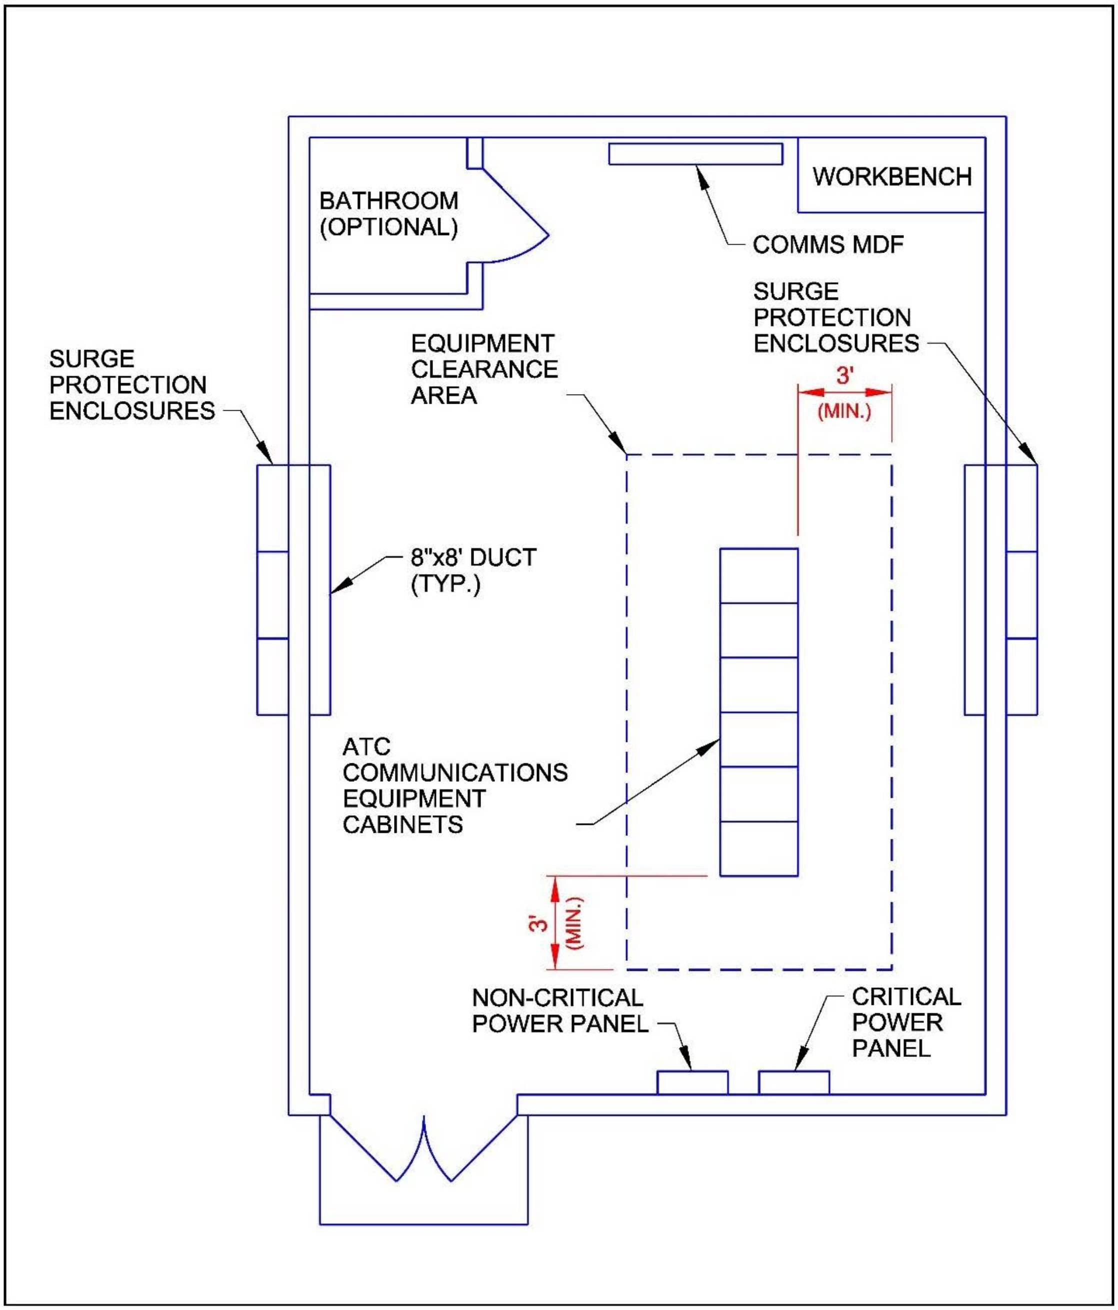

Figure 6-5 Typical Communications Antenna Tower

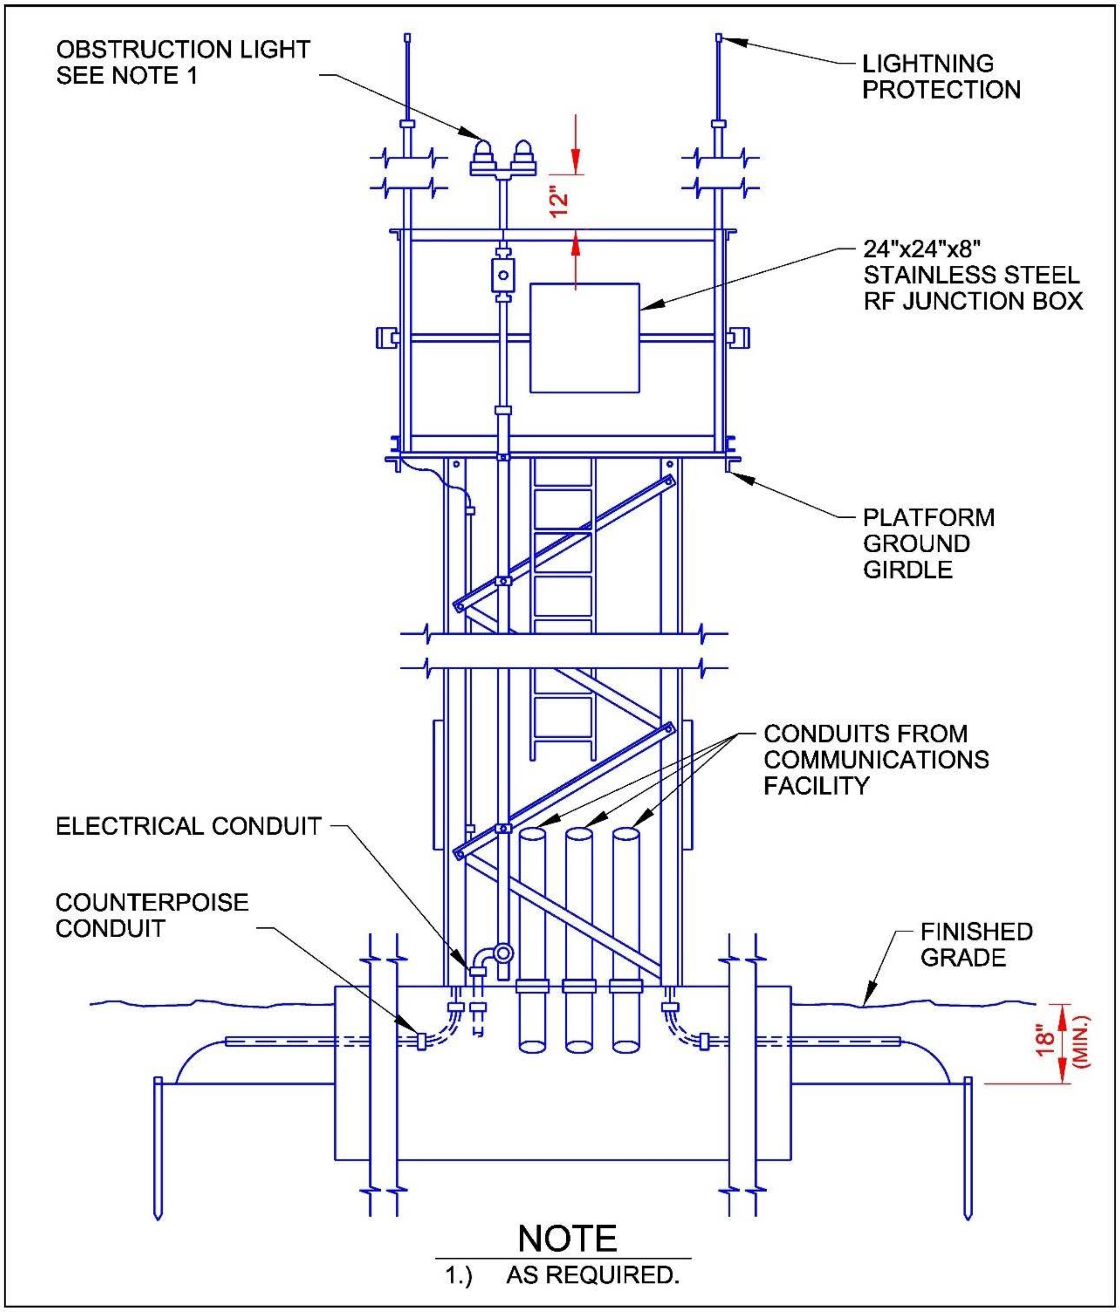


This Page Intentionally Left Blank

CHAPTER 7 WEATHER EQUIPMENT SUPPORTING AIRFIELDS

7-1 GENERAL INFORMATION.

7-1.1 Function.

The office where weather is recorded, analyzed and forecasted goes by different names within the Services and within different organizational structures. The equipment used to collect weather information on airfields are more common among the Services.

7-1.1.1 Weather Office.

The Weather Office is most often located within a building, adjacent to Airfield Management or Air Operations. In some cases, the Weather Office may even be located at another installation. For those reasons, no facility requirements for a Weather Office are included in this UFC.

7-1.1.2 Automated Surface Observing System (ASOS) and Fixed Base Weather Observing System (FBWOS).

A permanently installed automated ASOS or FBWOS (e.g., AN/FMQ-19, AN/FMQ-22, AN/FMQ-23) consists of a suite of weather sensors and processors capable of collecting, measuring or calculating and reporting a myriad of weather elements. These elements include, but are not limited to, wind direction and speed, prevailing visibility, present weather and visibility obstructions, cloud coverage and cloud base height, temperature, dew point, atmospheric pressure, lightning, and precipitation amounts. The observing system's primary sensor suite contains the majority of the sensors. Many locations also have additional discontinuity sensor suites. The discontinuity suite contains fewer sensors than the primary suite and is sited at the runway's roll out, midfield, or in the case of a multi-runway configuration, at an adjacent site along a parallel or intersecting runway to provide critical weather element readings that are representative of the respective location.

ASOS or FBWOS are automated stations operated and controlled by the DoD, National Weather Service, and FAA. They help the national weather system compile data on the entire United States and OCONUS sites, and not just for aviation purposes. ASOS reports are issued hourly with special reports issued more frequently when conditions change rapidly. The system went into operation in the early 1990s.

AWOS are automated stations generally operated and controlled by the FAA for aviation purposes. New reports are generated and transmitted every minute. The AWOS was the original aviation weather reporting system and AWOS stations are located solely at airports.

7-1.2 Certification and Commissioning.

To provide confidence in the quality of the meteorological data that the ASOS and FBWOS provides to users in the aviation community, the FAA has initiated a three-part

ASOS and FBWOS quality assurance process consisting of type certification, site-specific commissioning and annual revalidation.

For ASOS and FBWOS installed on military bases, follow the certification, commissioning and annual revalidation process described in FAA AC 150/5220-16, Chapter 2.

Figure 7-1 ASOS Combined Sensor Group (CSG)

7-2 AUTOMATED SURFACE OBSERVING SYSTEM (ASOS) OR FIXED BASE WEATHER OBSERVING SYSTEM (FBWOS).

The ASOS or FBWOS is a modular system consisting of two general components at two separate locations.

The sensor group (Combined Sensor Group (CSG) and discontinuity sensor groups for ASOS or primary and discontinuity sensor groups for FBWOS) is located near the runway and collects a variety of weather sensors. The ASOS Data Collection Package (DCP) or FBWOS Field Data Collection Unit (FDCU) in the sensor group then formats and transmits the data to the ASOS Acquisition Control Unit (ACU) or FBWOS Terminal Data Acquisition Unit (TDAU).

The ACU or TDAU is typically located in close proximity to the Air Traffic Control equipment (e.g., ATCT equipment room). The ACU or TDAU receives data from the sensor group (via radio frequency modem link or via a direct line link) and performs the algorithmic functions to produce weather products. The weather data is provided via local displays, remote dial-in, voice phone, and one way transport via modem to an Advanced Weather Interactive Processing System (AWIPS) hub. Then the weather data is transported to the NWS gateway.

Potential sensors included in an ASOS or FBWOS are listed below.

- Surface Wind Speed and Direction
- Ambient Air Temperature
- Dew Point Temperature
- Atmospheric Pressure
- Visibility
- Sky Condition
- Precipitation Type Discrimination (rain, snow, drizzle, etc.)
- Precipitation Occurrence (Yes/No)
- Freezing precipitation detection
- Precipitation Accumulation
- Lightning detection

7-2.1 Key Documents.

UFC 3-260-01	*Airfield and Heliport Planning and Design*
FCM-S4-2019	*Federal Standard for Siting Meteorological Sensors at Airports, Office of the Federal Coordinator for Meteorological Services and Supporting Research*
FAA AC 70/7460-1M	*Obstruction Marking and Lighting*
FAA AC 150/5220-16	*Automated Weather Observing Systems (AWOS) for Non-Federal Applications*
FAA Order JO 6560.20C	*Siting Criteria for Automated Weather Observing Systems (AWOS)*
FAA-STD-019f	*Lightning and Surge Protection, Grounding, Bonding and Shielding Requirements for Facilities and Electronic Equipment*

7-2.2 Siting.

Site ASOS or FBWOS equipment on DoD airfields and heliports using the guidance included in FCM-S4-2019. Special care is necessary in selecting appropriate locations for installation of sensors to assure that the resultant observations are representative of the meteorological conditions affecting aviation operations. When applying these criteria, consider future plans for the airport that could impact placement of sensors, e.g., installation of an Instrument Landing System (ILS), Microwave Landing System (MLS), runway construction, etc.

Figure 7-2 illustrates the typical position of weather sensors relative to the runway. Figure 7-3 illustrates the typical position of weather sensors relative to the Glide Slope antenna and shelter. Figure 7-4 shows one arrangement for multiple items in a Combined Sensors Group.

<u>Navy</u>: Site ASOS equipment on DoD airfields and heliports using the guidance included in FCM-S4-2019.

- For airports with only Visual or Non-Precision Runways, site the ASOS minimum 500 feet (152 m) and maximum 1,000 feet (305 m) from the centerline of the runway.
- For airports with Precision Instrument Runways without RVR instrumentation, there are two options for siting from centerline: a) minimum 750 feet (229 m) and maximum 1,000 feet (305 m); or b) locate the ASOS behind the Glide Slope shelter or MLS elevation station.
- For airports with Precision Instrument Runways with RVR instrumentation, site the ASOS minimum 400 feet (122 m) from the centerline of the runway and in accordance with FCM-S4-2019.
- For all runways, site the ASOS longitudinally as close as possible to the touchdown point (between 1,000 and 3,000 feet (305 and 914 m) from the runway threshold).

<u>Army and Air Force</u>: Align the FBWOS primary and discontinuity sensor groups parallel to the runway and not less than 300 feet (91 m) (Class A/Rotary-Wing Runways) or 400 feet (122 m) (Class B Runways) from centerline of the runway, as close as possible to the touchdown point (between 1,000 and 3,000 feet (305 and 914 m) from the runway threshold). For siting criteria of a FBWOS near taxiways and parking aprons on airfields and heliports, use Tables 5-1, 5- 2, and 6-1 of UFC 3-260-01 to provide appropriate clearances between aircraft and the weather equipment. Selecting appropriate locations to install sensor groups is a critical consideration for flight operations safety as well as to ensure the weather elements collected are representative of the meteorological conditions affecting flight operations.

See FCM-S4-2019 for clearance and mounting height requirements for individual sensors in the sensor group.

7-2.3 Security.

ASOS and FBWOS facilities are normally located within the airfield restricted area. This siting typically meets the minimum security measures for external security. When the facility is located within a restricted area of a lower level of security or is located remote and outside of an established restricted area, provide additional measures to meet the minimum security requirements for the level of security assigned to the facility.

7-2.4 Facility Design Guidance.

7-2.4.1 Site Work.

Provide an access road to allow maintenance vehicles access to the sensor group(s) on the airfield. Provide parking space for one maintenance vehicle. See Chapter 2, paragraph “Access and Parking” for roadway and parking area design requirements.

7-2.4.2 Architectural Requirements.

There are no architectural requirements for the ASOS or FBWOS equipment.

7-2.4.3 Structural Requirements.

The wind sensor tower is mounted on a concrete foundation and may vary in dimension depending on type of system suite. Other sensors are mounted on metal posts set into the 12” diameter concrete foundations minimum 24” into the ground (or extending below frost line) with gravel around the posts. Install the top surface of these concrete foundations flush with the surrounding surface grade. See Figure 7-5 and 7-6 for typical concrete foundations for a ASOS CSG. Site adapt the minimum size and depth for local environmental conditions and soils.

7-2.5 Mechanical Requirements.

There are no mechanical facility requirements for the ASOS or FBWOS.

7-2.6 Electrical Power.

Provide 120V, 30A, single-phase, 60 Hz commercial power service to the sensor group. Provide 120V, 20A single-phase, 60Hz commercial power service to the ACU or TDAU.

7-2.6.1 Emergency Electrical Power.

The ASOS system is designed to return to normal operation without human intervention after a power outage. The system is equipped with UPS battery back up to allow for orderly shutdown of the system in the event of source power loss. When power is restored, the system automatically returns to service and begins outputting sensor data only after internal sensor diagnostics allow data to pass, preventing dissemination of erroneous data.

7-2.6.2 Lighting.

If a separate tower is used for the wind sensor, provide daytime marking and nighttime lighting in accordance with the guidelines set forth in the latest edition of FAA AC 70/7460-1.

7-2.6.3 Lightning Protection, Grounding and Bonding.

Install lightning protection systems in accordance with FAA-STD-019f.

7-2.7 Communications.

Provide 12-strand single mode fiber optic cable, 25 twisted pair communications line or RF antenna signal between the DCP and ACU or FDCU and TDAU. Provide required data connectivity (fiber optic preferred) to receiving units located in the ATC Tower, Base Operations and Weather Office.

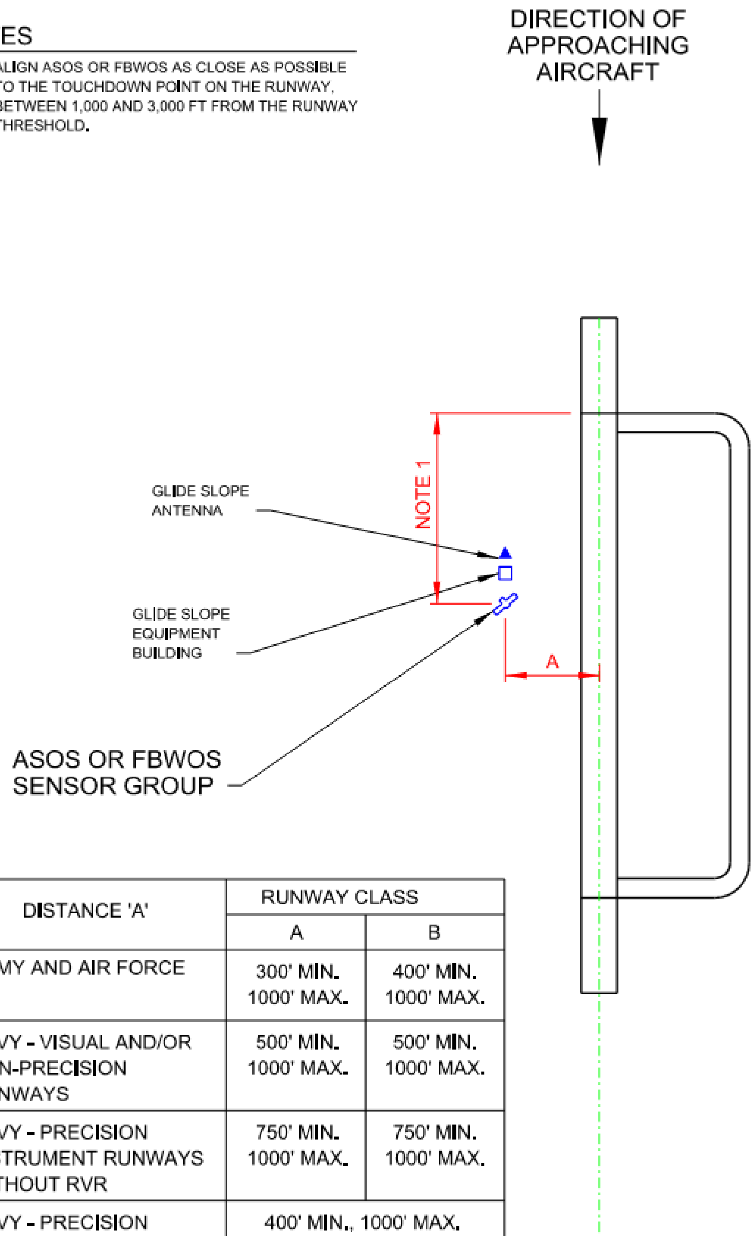
7-2.8 Connection/Interrelation to other Facilities.

Connect the ASOS ACU or FBWOS TDAU to the ATC Tower, Base Operations and Weather Office via fiber optic cable or twisted pair communications cable for remote monitoring.

Figure 7-2 ASOS or FBWOS Siting

NOTES

1.) ALIGN ASOS OR FBWOS AS CLOSE AS POSSIBLE TO THE TOUCHDOWN POINT ON THE RUNWAY, BETWEEN 1,000 AND 3,000 FT FROM THE RUNWAY THRESHOLD.



DISTANCE 'A'	RUNWAY CLASS	
	A	B
ARMY AND AIR FORCE	300' MIN. 1000' MAX.	400' MIN. 1000' MAX.
NAVY - VISUAL AND/OR NON-PRECISION RUNWAYS	500' MIN. 1000' MAX.	500' MIN. 1000' MAX.
NAVY - PRECISION INSTRUMENT RUNWAYS WITHOUT RVR	750' MIN. 1000' MAX.	750' MIN. 1000' MAX.
NAVY - PRECISION INSTRUMENT RUNWAYS WITH RVR	400' MIN., 1000' MAX. SEE ALSO FCM-S4-2019

APPENDIX A BEST PRACTICES

A-1 SUBJECT MATTER EXPERTS (SMEs).

The facilities described in this UFC are unique and not routinely constructed. Contact Service Specific SMEs for guidance early in the programming, siting and design processes to obtain the most up-to-date guidance.

A-2 FACILITIES REQUIREMENTS DOCUMENTS (FRDs).

Many of the facilities described in this UFC support specialized equipment that may have been purchased in large quantities and then distributed to individual airfields. Whenever possible, obtain the FRD associated with the specific equipment to be installed for more detailed installation guidance.

A-3 UFC COORDINATION.

Coordinate all design elements with the Core Discipline requirements listed in UFC 1-200-01.

A-4 WAIVERS/EXEMPTIONS.

Site the facility to be compatible with the requirements of UFC 3-260-01. Where unusual circumstances require a non-standard installation, consult UFC 3-260-01, Appendix B, Section 1 for waiver processing procedures. For standard exceptions from waivers, consult UFC 3-260-01, Appendix B, Section 13 (Army and Air Force) or UFC 3-260-01, Chapter 2 (Navy and Marine Corps).

Record of Changes (changes are indicated by **\1** ... /**1**/)

Change No.	Date	Location

This UFC supersedes UFC 4-150-02, dated May 2003, with Change 5, 1 Sept 2012.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

REVISION SUMMARY SHEET

Document: UFC 4-150-02, *Dockside Utilities for Ship Service*

Superseding: UFC 4-150-02, dated 13 May 2003, With Change 5, 1 September 2012

Description: This document provides a reference for the utility requirements of DoD and Coast Guard vessels and best practices for the design and maintenance of those utilities.

Reasons for Document:

- This document provides facility managers and engineers with a consolidated reference of utility requirements for active duty vessels.
- Revision includes updates to ship utility requirements.

Impact:

- There are no cost impacts.

Unification Issues:

- There are no unification issues.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

This UFC has been developed from an evaluation of facilities in the shore establishment, from surveys of the availability of new materials and construction methods, and from selection of the best design practices of the Naval Facilities Engineering Command (NAVFACENGCOM), other Government agencies, and the private sector. This UFC was prepared using, to the maximum extent feasible, national professional society, association, and institute standards. Deviations from this criteria, in the planning, engineering, design, and construction of DoD shore facilities, cannot be made without prior approval of the cognizant Service.

1-2 PURPOSE AND SCOPE.

This UFC provides design criteria and guidance in the design of utility systems for piers, wharves, and dry docks. Criteria are given for Type I Piers (Fueling, Ammunition, and Supply); Type II Piers (General Purpose Piers); and Type III Piers (Repair Piers). Utilities covered include steam, compressed air, salt or non-potable water, potable water, oily waste/waste oil (OWWO) or petroleum, oil and lubricants (POL), Collection-Holding-Transfer (CHT), electric power, and telecommunications.

1-3 APPLICABILITY.

This document applies to all service elements and contractors designing dockside utilities for ship service construction, repair, and maintenance projects.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, *Cybersecurity of Facility-Related Control Systems* and as required by individual Service Implementation Policy.

1-6 GLOSSARY.

APPENDIX E contains acronyms, abbreviations, and definition of terms.

1-7 REFERENCES.

APPENDIX F contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 GENERAL UTILITY REQUIREMENTS

2-1 SHIPS UTILITY REQUIREMENTS.

Ships utility demands and other pertinent data for individual ships utilities are available from APPENDIX A. Planners and designers must access this information in order to obtain design data regarding dockside utilities for all ship services. Data provided in APPENDIX A is the best available at the time of publication of this document. Data is incomplete, may not be completely accurate, and must be verified by planning and design team. In general, ship utility demands for active berthing are based on the ship's complement without deployed forces such as air wings or marine troops. Diversity factors are provided for use in determining demand in multiple berthing. If the designer is basing the project design on a specific ship that is not included in APPENDIX A, use data from a similar ship, or obtain the expected demand from the cognizant Service. For graving dry docks, refer to UFC 4-213-10*, Graving Dry Docks*. This information is for use at new facilities and for use in additions, modifications, and replacements at existing facilities. While means of diversification are provided for multiple ships and multiple piers by these diversity factors, metered data from existing facilities and ships should be used for planning and design whenever such data are available.

2-2 UTILITY-CONNECTION LAYOUT.

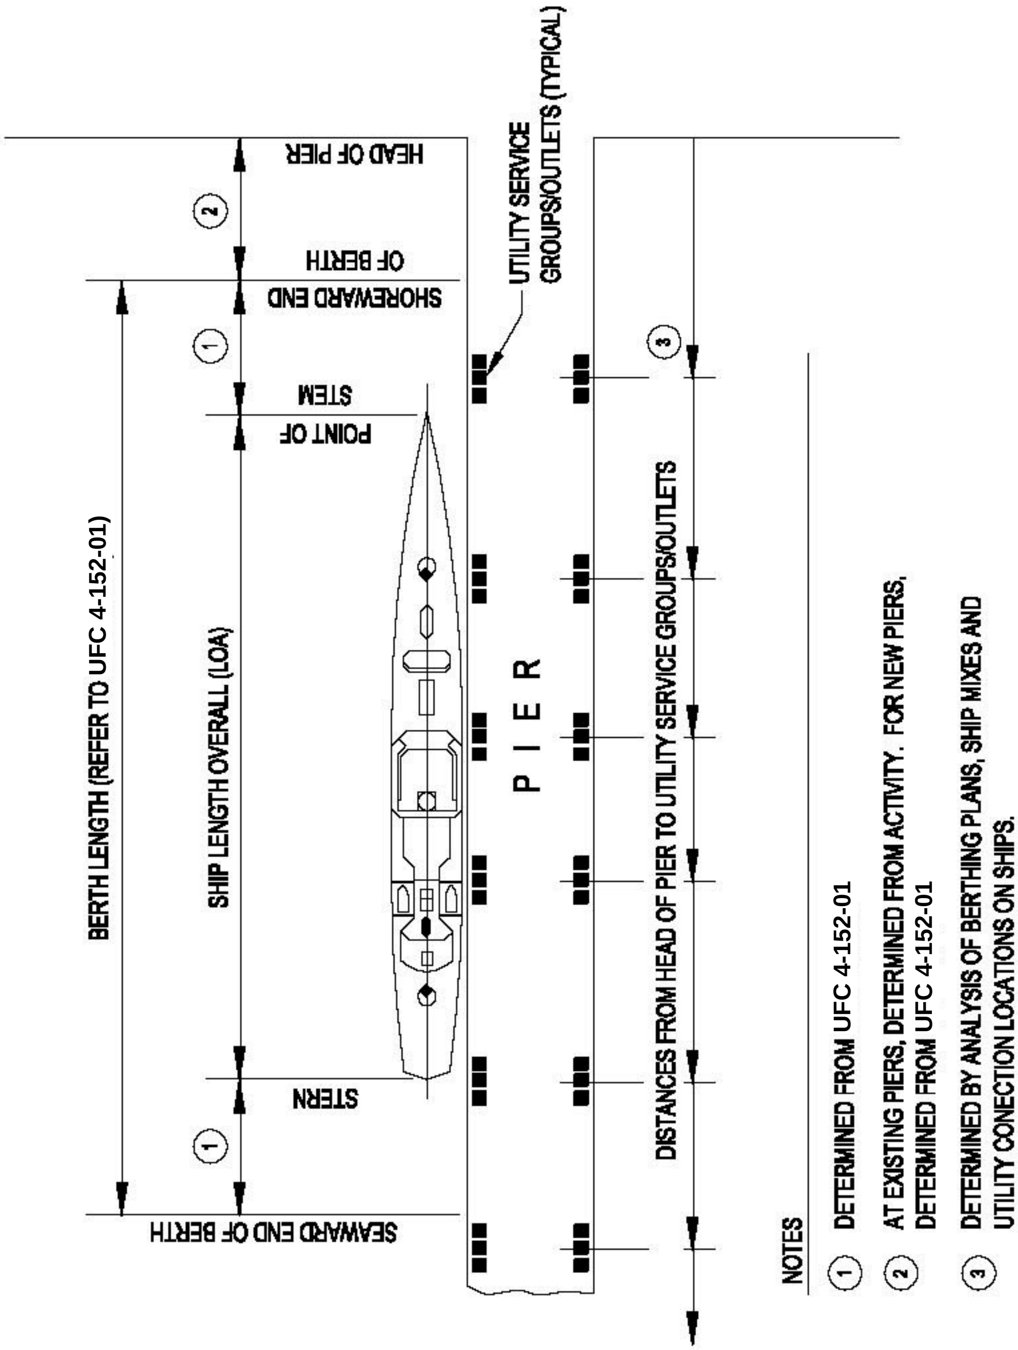
Figure 2-1 shows the dimensional relationships normally encountered in placement of shore utility connections. APPENDIX A provides size/shape data for typical ship hulls and dimensioned reference points that define the ship's utility connection locations. Ideally, the locations of shore utility connections for a given berth would simply correspond to their respective connection locations on the ship to be berthed. In practice, however, utility connection locations can never be ideal, due to largely nondedicated berthing, interference with other pier or wharf activities, other deck equipment, and the grouping of connections. The designer must optimize the location of all utility outlet assemblies based upon the projected berthing mix.

2-2.1 Connection Grouping.

Utility connections should be confined to specific locations along a shore facility so that interference with line handling and other facility operations is reduced. Connections may be in large groups to encompass all utilities, or may be in subgroups, such as the following:

- Freshwater, saltwater (if required), steam, and compressed air;
- Electrical power and communications;
- Sewer and oily waste; and
- POL, when required.

Figure 2-1 Typical Ship-Berth-Pier-Utilities Relationships



Regardless of the variations in utility groups that may be necessary to accommodate deck fittings and pier construction, sewer and oily waste connections must always be located 10 ft (3.1 m) or more from domestic water connections. Electrical outlet assemblies must be separated from other utility outlets by at least 10 ft (3.1 m) whenever possible. Additionally, where fueling is required, separation between such connections and electrical equipment is mandatory. See UFC 3-460-01, *Design: Petroleum Fuel Facilities* and consult with the cognizant Fire Protection Engineer to ascertain the minimum separation distances. Separation distances will vary depending upon the type of fuel or fuels.

2-2.2 Hose and Cable Lengths.

Experience has shown that if utilities are to be grouped, not all of the shore connections can be placed optimally in regard to their respective ship connections, even at a dedicated berth. This being the case, the location of connections for certain utilities should be given preference in order to minimize required hose lengths. Preference should be given, in order of importance, to electrical power, fire protection water (if required), steam, sewage, oily waste collection, and potable water. Excessive hose and cable lengths have significant disadvantages as defined below.

2-2.2.1 Electrical Power.

Excessive lengths of power cable increase the possibilities of accident, fire, and excessive voltage drop.

2-2.2.2 Fire Protection Water.

Losses in the fire protection system hoses could be critical in the event of fire, particularly when ship's pumps are under repair. Coordinate with NAVSEA or cognizant Service to determine how much hose is required to ensure proper flow and pressure.

2-2.2.3 Steam.

Steam hoses have a very short life, are expensive, and usually have high-pressure losses from shore to ship.

2-2.2.4 Sewage.

Although added hose pressure loss is not normally a problem, sewage hose is heavy, difficult to support, and must be disinfected when the ship's connection is broken.

2-2.3 Group Locations and Spacing.

The locating dimensions for shipboard utility connections of various ship classes are presented in APPENDIX A. These dimensions, when used with the ships configuration drawings and the parameters given in this UFC, provide guidance in spacing determinations for the shore connections. The locations of required deck equipment (capstans, bollards, cleats, ladders, and railings) and deck operations (brows, cranes, dumpsters, etc.) must always be coordinated with locations of utility connections. Pier berthing plans (graphic plots) must be made for the most likely ship mixes, and should consider local berthing practices as defined by the Activity. The berthing plans provide the basis for the design and operations of the pier's utility systems and must be included in the construction contract drawings when included under the design contract. Suitable shore connection spacing for the range of possible ships must be provided. Individual utilities within groups for mixed berthing should generally not be more than 200 ft (66 m) apart. Whenever possible, shore utility connection spacing should be such that connections are not offset more than 50 ft (15 m) from corresponding ships connections when other ship types occupy their prescribed berths.

2-3 UTILITY CONNECTION GROUP DESIGN.

2-3.1 Configurations to Avoid Interference.

Utility outlet groups should be designed for minimum interference of hoses and cables with each other, with deck equipment, and with deck operations. Check weights of hose lengths and cables with crane's lifting capability. Outlet groups may be placed above deck or in deck pits. They may also be placed in open galleries below the main deck where the pier has sufficient elevation to avoid submergence of the utility connections. An example is a double-deck pier system such as Pier 6 at Naval Station Norfolk as shown in Figure 2-2.

The type of connector at outlets must be compatible with hoses in use, or intended for use, at a given site. It is noted that the profile presented by utility groups above deck is dependent upon the height of the pier and the type of ship at berth. This is an important consideration in the design of dockside utilities for ship service. Required hose or cable connection types and sizes are given in individual utility descriptions in the following chapters. Provide for future expansion of utilities by the appropriate sizing of valve pits, pipe trenches, electrical vaults, and electrical duct banks. Likewise, a specific project may require the immediate design for future utility services. Lastly, always design for proper and safe access and maintenance of all utility systems.

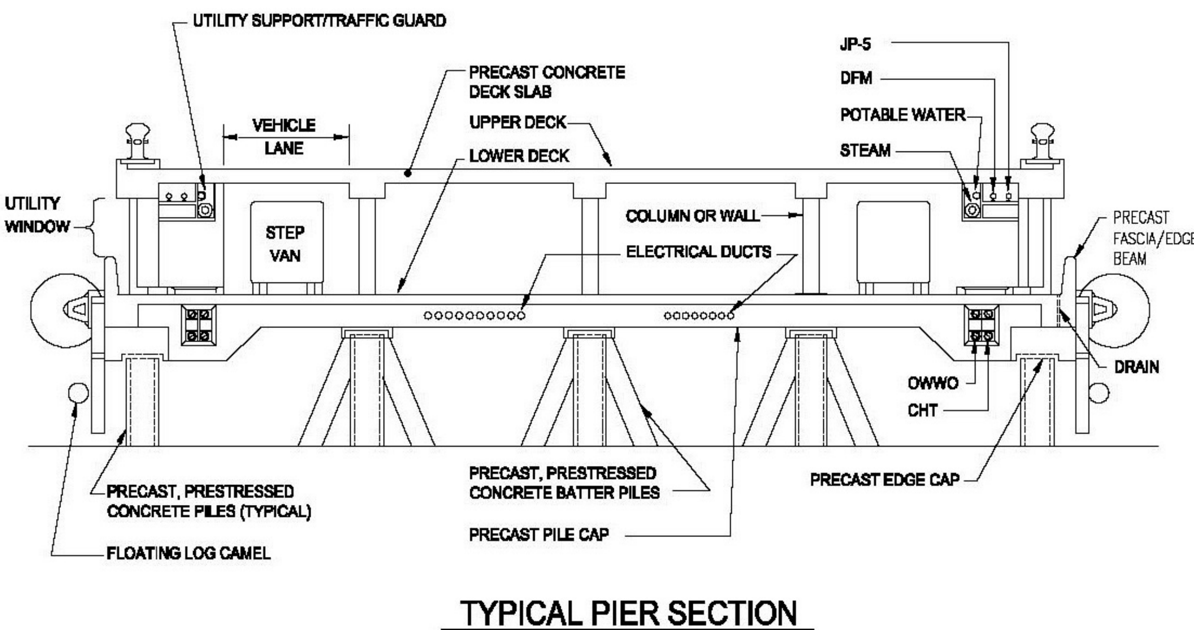
2-3.1.1 Layout.

In order to avoid hose-connection difficulties and interferences with pier traffic, outlet connections should have centerlines parallel with berths or at not more than a 30-degree angle. The distance of connections from the pier face should be as short as is consistent with structural restraints and with convenience. However, on some aircraft carrier berths such as those using narrow breasting camels, locate the utilities to clear ship elevators.

2-3.1.2 Mooring Lines.

Mooring lines for ships such as destroyers are relatively low and present a greater hazard to utility connections. Low-profile utility outlet arrangements are usually preferred. Whenever possible, mooring line patterns for the specific ships to be berthed should be observed at a similar berth before utility group design is commenced. The berthing plans are to include mooring line patterns and must uncover conflicts with utility outlets. Some typical above-deck utility connection details are shown in figures in subsequent chapters. Other arrangements are also possible and may be acceptable. A specific arrangement may be required by the cognizant Service to match existing outlet designs.

Figure 2-2 Double-Deck Pier Example



2-3.2 Design for Nesting of Ships.
