Where berthing plans include the nesting of ships, provide a sufficient quantity of adequately sized services and connections. Design according to the number of ships that may simultaneously use each such berth. Unless instructed otherwise, provide internal shipboard port-to-starboard utility headers for all utilities except for potable water. For potable water, use dual connections with individual backflow devices to provide separately protected supplies to two ships at each group location.

2-4 PROTECTION.

2-4.1 Protection of Mains and Laterals.

Mains and laterals serving utility connections must be protected from damage by waves, wind, floating debris or ice, and tidal immersion. Where these lines could be subjected to such damage, they must be placed in the utility corridor of a double deck pier, placed in the trenches or tunnels of a single deck pier, or special construction techniques must be used to provide a barrier. Electrical conduits may be embedded in new concrete structures. It is preferable to place electrical duct banks, manholes, and pull boxes such that they are cast integrally with the pier deck and at least 2 ft (0.6 m) above the mean high water level.

There are cases where conduit and piping mains and laterals (except for POL systems) may be hung exposed from the bottom of pier decks in protected locations. This is not a preferred situation and is discouraged. In such cases, it is necessary to coordinate with the structural design to secure inspection ladders and deck inserts, and to facilitate installation of access platforms for maintenance purposes. New mains placed on existing piers may be placed on top of the pier deck if other construction techniques are impractical and if approved by the cognizant Service.

Corrosion protection requirements are defined in the following paragraphs. Requirements for POL systems are defined in Section 3-5 entitled “POL Systems” and refer to UFC 3-460-01, *Design: Petroleum Fuel Facilities*.

2-4.1.1 Utility Trenches.

The use of utility trenches is highly preferred. Trench covers may be concrete, steel plate, grating, or a combination of these, and as dictated by structural loading, maintenance, and cost considerations. Coordinate design with structural requirements. Note that permanently fixed covers (concrete and steel) create confined workspaces. This is a significant operational problem (regarding inspection and maintenance) that is generally undesirable and should be avoided if possible. Identifiable markings should be located on the trench entrances.

2-4.1.2 Above-deck Lines.

At most types of berthing facilities, clear deck space is at a premium, rendering above-deck mounting of utility services inappropriate, operationally difficult, and generally unacceptable. A notable exception to this general rule applies to dedicated fueling facilities. In these cases, above-deck mounting of fuel lines is often the most functional solution because it allows for the proper and safe access and maintenance of the fuel lines. See UFC 3-460-01 for additional information and criteria.

2-4.1.3 Under-deck Lines.

Except as noted above, utility service pipelines should not be located on the operating deck. At single deck piers, utilities should be contained in trench structures, shielding the enclosed pipes from exposure to saltwater and spray. Utility trench covers are of three basic types: solid, solid with personnel access, and open gratings. Solid covers are generally used over most of the trench length. Solid covers with 30 inch (760 mm) diameter manhole covers should be located over those portions of utility trenches containing valves, expansion mechanisms, or branch connections which require easy access for inspection, maintenance, and repair. Gratings may be substituted for solid trench covers with personnel access wherever ready visibility of the respective utilities is required or where ventilation of trench is advisable (steam line drip assemblies). Unless specifically curbed against vehicular traffic, covers must be designed for the same uniform loads and wheel loads as the nominal pier deck with the exception that crane outrigger reactions need not be addressed. It is therefore necessary that utility trenches not be located within the pier cross-section where mobile cranes are likely to position their outriggers.

2-4.1.4 Hangers and Support Assemblies.

Hangers, bolts and specially fabricated supports and braces steel must be hot-dip galvanized after fabrication or stainless steel. Many Activities prefer the state-of-the-art fiberglass hangers containing ultraviolet inhibitors and polyester resin (NEC type RTRC in article 355). Consult with the Activity and the cognizant Service. Where salt spray exposure is severe, incorporate appropriate additional anticorrosion measures for hangers. This includes the application of epoxy coatings, the use of stainless steel or monel bolting. Lastly, hangers must be designed based upon the maximum potential weight of the utility system. For example, for steam piping, allow the piping to be full of water.

2-4.2 Protection of Utility Connections.

Means to protect utility connections, hoses, and cables from damage due to traffic and snagging by mooring lines are essential. Conventional protection schemes consist of curbs, pits, concrete structures, or railings. Where pier width is sufficient, consider the use of continuous curbs located at sufficient distance from the edge of the pier. The design should exclude pier traffic from the areas containing utility connections, hoses, and cables. Where utility pits are used, sufficient pit length must be incorporated to ensure that hoses may be connected and led from pits to ships without kinking or chafing.

2-4.2.1 Outlets, Connections, and Access Hatches.

Access hatches in decks should have flush-mounted covers and must be designed to eliminate any danger of tripping. Where outlets and connections must appropriately protrude above the deck level, shield them in a manner that will ensure personnel safety and prevent mooring lines from being snagged on the piping and equipment. Certain utility connections such as sanitary sewer, fuels, oily waste, and waste oil must be contained within a curb or vault. Provide a drainage system to an appropriate collection system. Additionally, fuel hoses must be provided with a curbed lay-down area for the collection of drippings. Also, refer to UFC 4-152-01, *Piers and Wharves*, for other typical details.

2-4.3 Seismic Protection.

2-4.3.1 Performance of Utility Lines.

Provide special and detailed considerations for seismic protection. This applies to pierside utility systems and the associated landside utility systems. Specific details are required for storage structures and the interface transition between the landside systems and the pierside systems. Except POL lines, design all piping and utility lines as "essential" construction. See UFC 4-152-01. (The design requirements for POL lines are defined in the following paragraph.) In general, essential construction is expected to:

- Resist the maximum probable earthquake likely to occur one or more times during the life of the structure (50% probability of exceedance in 50 years) with minor damage, without loss of function, and the structural system to remain essentially linear.
- Resist the maximum theoretical earthquake with a low probability of being exceeded during the life of the structure (10% probability of exceedance in 100 years) without catastrophic failure and a repairable level of damage.

2-4.3.2 Performance of POL and Hazardous Utilities.

Design lifeline service associated with construction categorized as containing "hazardous materials" with the same levels of service. In general, hazardous material containment construction is expected to:

- Conform with criteria for essential construction.
- Resist pollution and release of hazardous materials for an extreme event (10% probability of exceedance in 250 years).

2-4.3.3 Liquefaction.

Design of structures should include provisions to evaluate and resist liquefaction of the foundation and account for expected potential settlements and lateral spread deformation. Refer to UFC 3-220-10N, *Soil Mechanics*. Special care must be given to buried pipelines in areas subject to liquefaction to preclude breaks resulting in release of hazardous materials. It is imperative to avoid areas of landslide and lateral spread. The presence of any potentially liquefiable materials in foundation or backfill areas should be fully analyzed and expected settlements computed.

2-4.3.4 Pipelines.

Design pipelines to resist the expected earthquake induced deformations and stresses. In general, permissible tensile strains are on the order of 1 to 2% for modern steel pipe. To accommodate differential motion between pipelines and storage tanks, it is recommended that a length of pipeline greater than 15 pipe diameters extend radially from the tank before allowing bends and anchorage and that subsequent segments be of length not less than 15 diameters. Flexible couplings should be used on long pipelines. In general, pipes should not be fastened to differentially moving components; rather, a pipe should move with the support structure without additional stress. Unbraced systems are subject to unpredictable sway whose amplitude is based on the system fundamental frequency, damping, and amplitude of excitation. For piping internal to a structure, bracing should be used for system components. Additional seismic protection considerations are as follows.

- In potentially active seismic areas, no section of pipe should be held fixed while an adjoining section is free to move, without provisions being made to relieve strains resulting from differential movement unless the pipe is shown to have sufficient stress capacity.
- Flexible connections should be used between valves and lines for valve installation on pipes 3 in (76 mm) or larger in diameter.
- Flexibility should be provided by use of flexible joints or couplings on a buried pipe passing through different soils with widely different degrees of consolidation immediately adjacent to both sides of the surface separating the different soils.
- Flexibility should be provided by use of flexible joints or couplings at all points that can be considered to act as anchors, at all points of abrupt change in direction, and at all tees.
- Piping containing hazardous materials should contain numerous shutoff valves and check valves to minimize release of materials if there is a break. Seismic shutoff valves should be used where necessary to control a system or process. A secondary containment system should be incorporated where feasible.
- When piping is connected to equipment or tanks, use of braided flexible hoses is preferable to bellow-type flexible connectors. Bellow-type flexible connectors have been noted to fail from metal fatigue. Welded joints are preferable to threaded or flanged joints. If flanged joints cannot be avoided, the use of self-energizing or spiral wound gaskets can allow a bolt to relax while continuing to provide a seal. (Reference: *Association of Bay Area Governments*, 1990.)

2-4.3.5 Supports.

Piers may contain pipelines for freshwater, saltwater, steam, compressed air, waste oil, sewer, and fuels systems; and may also contain electrical power and communication lines. Ship demands dictate the utility system configurations. In general, design of these lines follows the general provisions discussed herein. It is essential that the lines be attached to the supporting structure with sufficient rigidity that the lines are restrained against independent movement. Attachments to a pier may be analyzed as simple two-degree-of-freedom systems. Resonance amplification can occur when the natural period of the supported pipe is close to the fundamental period of the pier structure.

Flexible connections/sections should be used to bridge across expansion joints or other locations where needed.

2-4.4 Cathodic Protection Systems (CPS).

Provide special and detailed considerations for cathodic protection systems (CPS). This applies to pierside utility systems and the associated landside utility systems. Specific details are required for storage structures and the interface transition between the landside systems and the pierside systems. The services of a qualified corrosion engineer must be provided unless defined otherwise by the cognizant Service. For additional information and requirements see UFC 3-570-01, *Cathodic Protection* and guide specifications: UFGS 26 42 13.00 20, *Cathodic Protection by Galvanic Anodes*; UFGS 26 42 17.00 10, *Cathodic Protection System (Impressed Current)*; and UFGS 26 42 15.00 10, *Cathodic Protection System (Steel Water Tanks)*. Specific requirements are as follows:

- Provide CPS and protective coatings for the following buried or submerged metallic utility systems regardless of soil or water corrosivity:
  - Petroleum, Oil and Lubricant (POL) pipelines.
  - Oxygen pipelines.
  - Underground POL and gasoline storage tanks.
  - Underground hazardous substance storage tanks.
  - All water storage tanks interiors.
  - Other systems defined by the cognizant Service's Corrosion Control Coordinator.
- Provide a CPS and bonded protective coatings on other buried or submerged new steel, ductile iron, or cast-iron utility pipelines not mentioned above when the resistivity is below 30,000 Ohms at the installation depth at any point along the installation. Do not use unbonded protective coatings such as loose polyethylene wraps. Provide joint bonding on all ductile iron installations.
- When an existing CPS is being modified or extended, the new CPS must be compatible with the existing CPS system. When plastic pipe is selected to replace or extend existing metallic pipe, thermal weld an insulated No. 8 AWG copper wire to the existing pipe and run the full length of the plastic pipe for continuity and locator tracing purposes.
- The CPS must provide protective potentials according to the requirements of the National Association of Corrosion Engineer (NACE) Standard RP0169 (latest revision), *Control of External Corrosion on Underground or Submerged Metallic Piping Systems* and NACE Standard RP0285 (latest revision), *Standard Recommended Practice – Corrosion Control of Underground Storage Tank Systems by Cathodic Protection*.

- Unless instructed otherwise by the cognizant Service, provide an engineering life-cycle cost (LCC) analysis for the CPS. Coordinate with the cognizant Service's Corrosion Control Coordinator to establish design efforts and field test efforts. Obtain preliminary approval from the Corrosion Control Coordinator prior to accomplishing the LCC analysis. Define the proposed elements of the LCC analysis and a general description of the proposed CPS design.
- Unless instructed otherwise, Architect-Engineer (A/E) CPS surveys and designs must be accomplished under the supervision of one of the following individuals:
    - Registered Professional Corrosion Engineer.
    - Registered Professional Engineer who is also a NACE certified corrosion protection specialist or cathodic protection specialist or has a minimum of five years of experience in the applicable CPS.
    - NACE certified corrosion protection specialist or cathodic protection specialist with a minimum of five years of experience in the applicable CPS.
- Unless instructed otherwise by the cognizant Service, perform field tests (resistivity, pH, current requirements, etc.) at the proposed installation to evaluate, as a minimum, soil and/or water corrosivity. The tests are used to design the CPS and assumptions must be supported by the field test data. Design the CPS for overall system maintainability.
- Project Managers must contact the cognizant Service's Corrosion Control Coordinator regarding the CPS design and, upon request, will forward the design documents to the Coordinator for review. Design submittals must include, as a minimum, the following:
    - Preliminary Engineering Plan (PEP): soil and/or water corrosivity data, current requirements test data (if applicable), and all design calculations.
    - Final drawings: the CPS one-line diagrams, locations of all cathodic protection equipment (anodes, rectifiers, test stations, etc.), interference test points, installation details, insulating fittings, and bond connections.
    - Final specifications: acceptance testing procedures including static (native) potentials, initial and final system potentials, and interference tests.

2-5 METERING.

In general, all utilities should be metered unless instructed otherwise by the cognizant Service. Metering actual utility usage provides accurate data for billing and historical purposes. Install meters in accessible vaults or in above-grade enclosures ashore or on piers. Specify state-of-the-art electronic meters unless instructed otherwise. Consult with the Activity to determine if there is an existing metering program and integrate new meters into such existing programs. Where metering is not initially provided, then include provisions for the easy future addition of meters. This may include providing concrete meter vaults or access covers in pipe trenches. Consult with the cognizant Service for specific instructions.

2-6 PAINT AND FINISH REQUIREMENTS.

Evaluate the requirements for paint and finish systems. Final requirements will be based upon geographical location, the respective utility system, Station standards and preferences, and the guidance defined in UFC 3-190-06, *Protective Coatings and Paints*. The designer must confer with the Activity and the cognizant Service. Final designs must be based upon the paint manufacturers written instructions, especially with respect to surface preparation and paint/finish application.

2-7 UTILITY CONNECTIONS COLOR CODES.

To ensure safety, shore-to-ship utility service connections use the standardized federal color codes as an identification system on wharf and pierside connections and hose assemblies. The primary identifiers should be plain language tags, nameplates, or labels. Special emphasis should be applied to potable water, nonpotable water and the sewer system. The color code system is defined in CHAPTER 5.

2-8 DEPERMING PIERS AND FACILITIES.

Deperming piers and magnetic silencing facilities require special design consideration because of the magnetic operations. As a result, non-magnetic piping and conduit materials are required. This includes materials such as PVC, fiberglass and aluminum.

CHAPTER 3 ACTIVE AND REPAIR BERTHING

3-1 STEAM SYSTEMS.

Provide steam service at 150 psi (1,034 kPa) (saturated) along all piers and other waterfront structures used for active berthing and ship repair, and at the perimeter of graving dry docks. Provide 125 psi (862 kPa) only if approved by the Activity and the cognizant Service. Laundries on many vessels use the highest pressure at 100 psi (689 kPa). Provisions for returning condensate from ships will not be required except in special cases, and as directed by the cognizant Service. Newer ships do not require steam services. Contact the cognizant Service to waive the mandatory steam requirement.

3-1.1 Demands.

Steam requirements for selected ship classes are given in APPENDIX A. Generally, steam demand is considerably less in port than at sea. Loads must be selected for the appropriate local climate as indicated in Table 3-1. For ships not included in APPENDIX A, use data from a similar ship, or obtain the expected demand from the cognizant Service. For graving dry docks, refer to UFC 4-213-10.

3-1.2 Sizes of Piping.

Size the piping for single berths to meet the demands indicated. Include nested ships that are indicated on berthing plans. For multiple berthing, use diversity factors determined from Table 3-1. Branch steam lines from main to outlet locations should be sized for the full demands and should be no smaller than the outlet riser pipe. For ships that require two connection locations, assume 75% of the demand for sizing each branch. Refer to Section 3-1.5 entitled “Outlet Design” for minimum outlet and riser sizes. Determination of pipe sizes should be in accordance with UFC 3-430-09, *Exterior Mechanical Utility Distribution*.

3-1.3 Piping System Design Criteria.

For steam piping and condensate return piping design requirements, refer to UFC 3-430-09 subject to the following exceptions and additions. It is noted that steam piping on piers and wharves is often specified to be ASTM A53 steel.

3-1.3.1 Pitch.

For steam piping on or under a pier, the pitch of piping required by UFC 3-430-09 may be impractical due to elevation limitations or structural interference. In such cases, the designer must compensate by proper sizing of piping and by provision for adequate condensate removal. Tidal submergence of piping should be avoided by whatever means are practical.

Table 3-1 Diversity Factors (DF) for Steam Usage [a]

Ship Type	Outdoor Temperature Range (°F)	Diversity Factor (DF) [b] for: 1 Ship	3 Ships	5 Ships	9 Ships
Surface Combatants	0 - 20	1	0.97	0.96	0.94
	20 - 40	1	0.93	0.89	0.86
	40 - 60	1	0.86	0.80	0.76
	> 60	1	0.80	0.73	0.68
Aircraft Carriers	0 - 20	1	0.97	0.96	0.95
	20 - 40	1	0.96	0.94	0.91
	40 - 60	1	0.93	0.90	0.86
	> 60	1	0.82	0.76	0.74
Amphibious	0 - 20	1	0.95	0.96	0.95
	20 - 40	1	0.87	0.94	0.91
	40 - 60	1	0.80	0.90	0.86
	> 60	1	0.78	0.76	0.74
Auxiliary	0 - 60	1	0.91	0.87	0.84
Aggregate	0 - 20	1	0.96	0.93	0.92
	20 - 40	1	0.93	0.90	0.88
	40 - 60	1	0.90	0.86	0.83
	> 60	1	0.86	0.81	0.78

Note:

[a] Use of Diversity Factors (DF):
If the total number of ships in aggregate is greater than nine:
- Group the ships by types.
- Determine the maximum demand of each ship from the utility data. (See Appendix)
- Sum the individual demands within each type of ship.
- Multiply the total demand of each ship type by the appropriate DF, relative to the number of ships and temperature range.
- Total the demands obtained for the different ship type groups.

If the total number of ships in aggregate is nine or less:
- Determine the maximum demand for each ship from the utility data.
- Sum the individual demands of each ship.
- Obtain the aggregate DF from Table 3-1.
- Multiply the total demand by the "aggregate" DF in Table 3-1.

[b] Linear interpolation is permissible for actual ship quantities.

3-1.3.2 Protection.

For steam and condensate piping under a pier or wharf, or in a dry dock where submergence may occur, piping should be encased in a pressure-testable, prefabricated conduit system. Corrosion-resistant conduit coatings should be selected, and polyethylene heat-shrinkable sleeves and/or high temperature tape wrapping must be used at joints and fittings. Provide pipe hangers and associated support assemblies in accordance with Section 2-4.1.4 entitled “Hangers and Support Assemblies”. Hangers should be designed based upon the maximum potential weight of the steam system; that is, the piping is full of water. Identify piping and outlets and color-code in accordance with CHAPTER 5.

3-1.4 Location and Arrangement of Piping Mains and Branches.

As a general rule, for all active berthing piers, provide a single main with cross-branch piping to outlets. For repair piers, provide a main on each side of the pier and a cross connection at the outboard end of the pier (loop configuration). It is normally more desirable operationally to provide a looped main rather than an equivalent single main. Provide isolation valves at appropriate locations for reliability of service during emergency repairs. Coordinate piping with structural conditions and arrange mains for the best combination of versatility, security, and overall cost. For graving dry docks, refer to UFC 4-213-10. The location of ships steam connections may be found in APPENDIX A. For discussion of methods to be used to establish shore utility-station spacing on piers and wharves, refer to CHAPTER 2.

3-1.5 Outlet Design.

See Figure 3-1. Naval facilities use 2 inch (51 mm) hoses (from 1 to 10 per ship) almost exclusively for ship-to-shore steam connections. At locations where 1-1/2 inch (38 mm) and 1 inch (25 mm) hoses are used, design for 2 inch (51 mm) hoses and utilize reducing fittings at hose connections. Total numbers of shipboard steam connections are found in APPENDIX A. The number of hoses actually connected to shore per ship varies with the severity of the climate. For facilities in the coldest climates (see APPENDIX B, Figure B-1, Regions I and II), assume that all ships connections will be connected to shore. For warmer climates, obtain the demand for the appropriate design temperature; divide by 2,500 for 2 inch (51 mm) hose and by 1,250 for 1-1/2 inch (38 mm) hose. For existing facilities, the maximum number of hose connections actually made for the ships to be berthed may be obtained from the cognizant Service. Refer to CHAPTER 2 for a general description of the arrangement and spacing of utility outlets.

3-1.5.1 Steam Outlet Assemblies.

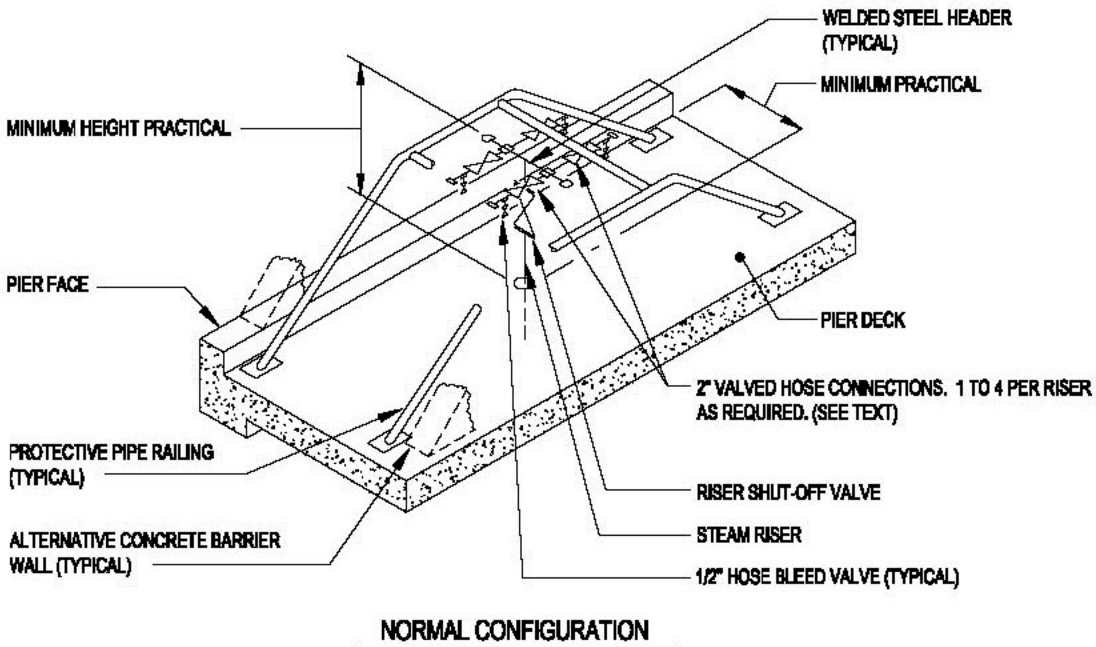
The design of steam outlet assemblies is to include the following conditions.

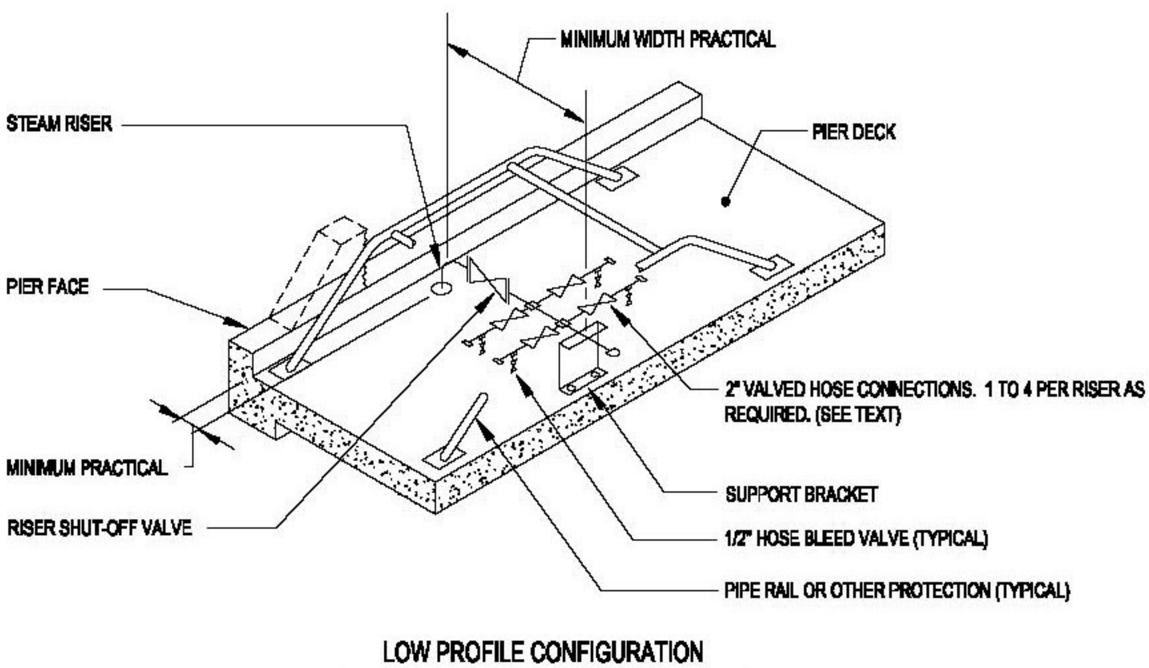
- Provide a shut-off valve for each riser assembly. The valve must be easily accessible.

- Provide a welded steel header after the riser shut-off valve. The header must serve the hose connections.
- The designer is responsible for determining the number of hose connections required at each outlet assembly.
- Hose connections must be 2 inch (51 mm) unless instructed otherwise.
- Each hose connection must include a shut-off valve, a 1/2 inch (13 mm) hose bleeder valve, and a hose connector. Threaded connections are to be avoided in order to prevent loosening of joints due to hose tension.
- Minimum pipe size of each rise assembly must be as follows:

Number of Hoses Connected to Riser	**Riser Size inch (mm)**
1	2-1/2 (64)
2	3 (76)
3 or 4	4 (102)

Figure 3-1 Typical Steam Outlet Assembly





3-1.6 Specific Ship Requirements.

3-1.6.1 CVN Ship Requirements (All Classes).

These ships are normally berthed starboard side-to. Steam is provided to CVNs certified pure at 150 psi (1,034 kPa). Galley and hot water requirements should be increased by 50% where it is reasonable to assume that the ship's air wing may be on board.

3-1.6.2 Nuclear-Powered Submarine Requirements.

Steam supply for nuclear-powered submarines is not required at operational berths. For ship construction or major repair activities, high-pressure steam at 2,000 to 4,000 psi (13.8 to 27.6 MPa) may be required for test purposes. This supply may be from a permanent plant or from a portable steam generator. The proper selection is dependent upon local weather conditions. Evaluate each location on an individual basis. The cognizant Service will approve.

3-1.6.3 Troop Carrier Special Requirements (LHA, LHD, LPD, and LSD).

Provide steam service at 150 psi (1,034 kPa) certified pure. For LHA, LHD, LPD, and LSD increase galley and hot water requirements by 100% if it is probable that troops will be aboard while at active berths.

3-1.6.4 Nested Ships.

Maximum nested ships demand at shore connections is 17,950 lb/h (8142 kg/h) based on the requirements of nested CG 47s.

3-1.7 Shore-to-Ship Steam and Feedwater Requirements.

3-1.7.1 Quality.

Naval Sea Systems Command (NAVSEA) shore-to-ship steam and feedwater quality standards are provided in NAVSEA S9086-AB-ROM-010, *Naval Ship's Technical Manual (NSTM)*, Chapter 220, *Boiler Water/Feedwater - Test and Treatment*, paragraphs entitled: “Shore Steam and Condensed Shore Steam Used as Feedwater”; “Navy and Commercial Facility Shore Steam Certification Requirements”; “Shore Processed Feedwater (Demineralizers, Reverse Osmosis)”; “Shore Source Feedwater Requirements”; and “Makeup Feedwater Demineralizer System”. These standards are given in Table 3-2 and Table 3-3.

Table 3-2 Shore Steam and Condensed Shore Steam Quality Requirements [a]

Constituent or Property	Requirement
pH	8.0 to 9.5
Conductivity	15 µ S/cm maximum [b]
Dissolved Silica	0.2 ppm maximum
Hardness	0.10 ppm max or 5 ppm as $CaCO_3$ total hardness
Total Suspended Solids	0.10 ppm maximum

Note:

[a] Steam must be generated from feedwater which is either treated with a chemical oxygen scavenger or mechanically deaerated to a maximum dissolved oxygen content of 15 parts per billion. Shore steam and condensed shore steam used as feedwater must meet the above standards. The use of filming amines is prohibited.

[b] µS/cm = micro-Siemens/centimeter = micro-mho/centimeter. The lowest reading on the shipboard conductivity meter is 40.

Table 3-3 Bulk Shore Feedwater Quality Requirements [a]

Constituent or Property	Requirement
pH	5.4 to 8.2 (process effluent)
Conductivity	2.5 µS/cm maximum (at point of delivery) [b]
Silica	0.2 ppm maximum

Note:

[a] Produced by method other than condensed steam.
[b] µS/cm = micro-Siemens/centimeter = micro-mho/centimeter.

3-1.7.2 Use of Steam Separators.

Provide steam separators as required to meet the NAVSEA criteria for the purity of shore-to-ship steam in Navy ports. Properly selected steam separators may be installed in steam mains at piers, wharves, and dry docks. (See S9086-AB-ROM-010 NSTM Chapter 220). These will provide additional protection against condensate carryover and the resultant steam contamination where such problems are known to exist. Normally, steam separators are not required on piers, wharves, or dry docks if adequate condensate removal is provided at the boiler plant and in shore mains. Steam separators should be used only when necessary and as based upon a case-by-case evaluation of local conditions. If a steam separator should be necessary, then Figure 3-2 provides a typical installation detail that should be used in conjunction with the guidelines of NFESC Test Report No. TN 1586, *Steam Separator Test and Evaluation*.

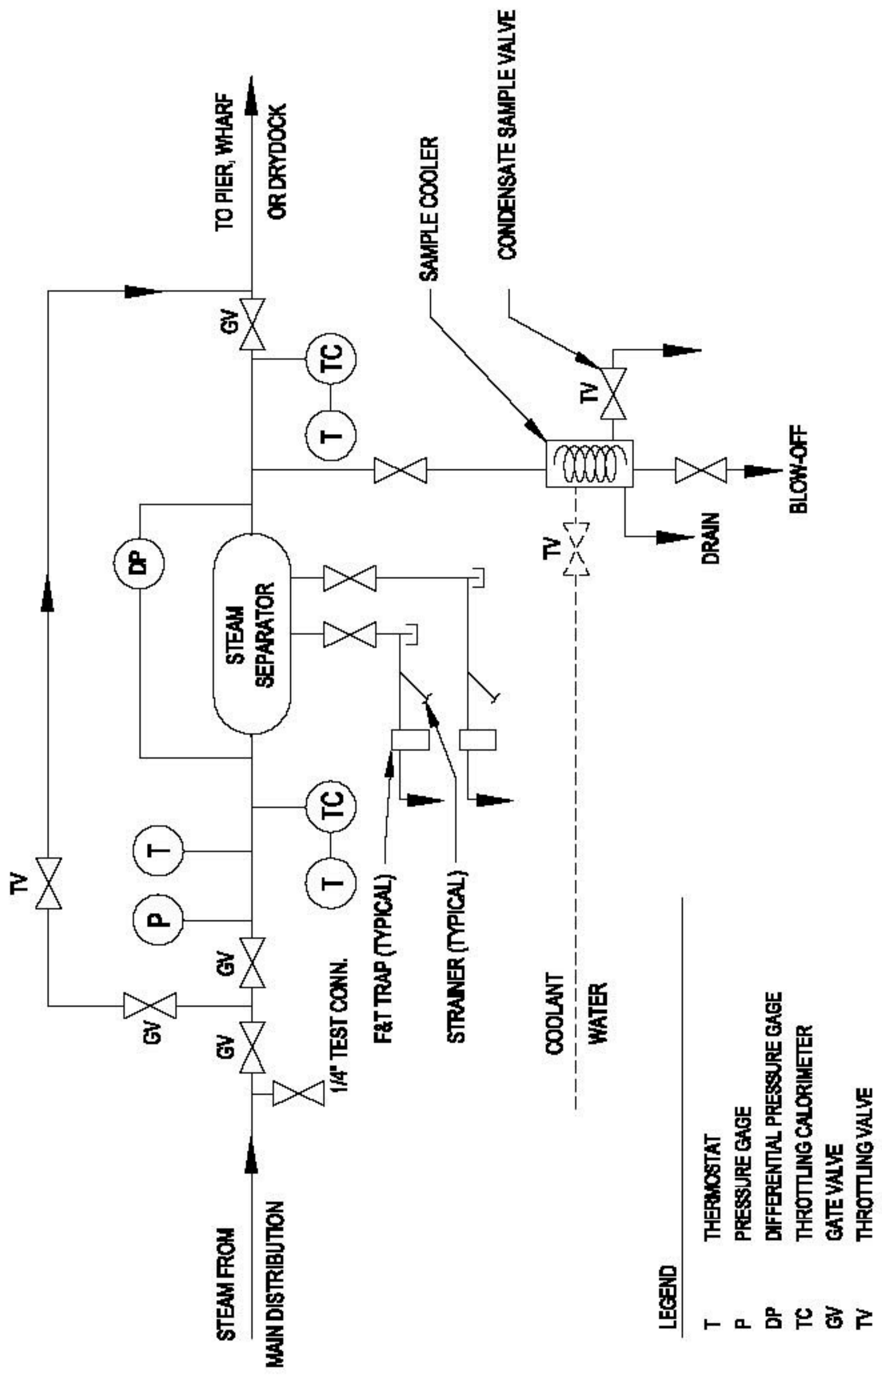
3-1.7.3 Sampling.

Due to the harsh marine environment, conductivity and pH meters should not be installed permanently on piers or wharves. Condensate sampling stations should be provided at piers and at steam plants. Figure 3-2 also shows a typical installation of a sampling station.

3-1.8 Metering.

Where monitoring of usage is required, provide metering of steam flows to piers, groups of piers, or dry docks. Install meters in accessible vaults or in above grade enclosures ashore or on piers. At individual piers or dry docks, use pressure and/or temperature compensated electronic microprocessor type flow meters for good mass flow accuracy and range. Consult with the cognizant Service to determine if a steam meter installation and maintenance program exists at the Activity. Consult the Activity steam meter program coordinator to integrate the flow meter type selection into any existing meter program. Where metering is not initially required, make provision for ease of future installation by means of concrete vaults or pier access covers.

Figure 3-2 Schematic Steam Separator and Sampling Station



3-2 COMPRESSED AIR SYSTEMS.

In general, a compressed air system (low pressure) is required at all active and repair berths. However, final needs and requirements vary on a pier-by-pier basis. Consult with the Activity for actual requirements, existing construction standards, and preferences. Requirements for graving dry docks are given in UFC 4-213-10. See Section 3-2.7 for high pressure compressed air requirements.

3-2.1 Demands.

Compressed air requirements for selected ship classes are defined in APPENDIX A. For ships not included in APPENDIX A, use data from a similar ship, or obtain the expected demand from the cognizant Service.

3-2.2 Piping System Design Criteria.

Design compressed air piping to conform to commercially available standard practices. Also, the designer may consult UFC 3-430-09, *Exterior Mechanical Utility Distribution*. In addition, provide corrosion protection of steel pipes. Consider an extruded polyethylene or polypropylene exterior coating. Extruded plastic coatings must contain an ultraviolet inhibitor. For coated pipe, use polyethylene, heat-shrinkable sleeves and/or tape wrapping at joints and fittings. Provide pipe hangers and associated support assemblies in accordance with the Section 2-4.1.4 entitled “Hangers and Support Assemblies”. Identify piping and outlets and color-code in accordance with CHAPTER 5.

3-2.3 Quality.

Compressed air should normally be "commercial" quality. Where breathing quality air and/or an oil-free system is necessary use an oil-free source and/or purification systems. Compressed breathing air compressors must meet the requirements of 29 CFR 1910.134 and the requirements for Grade D breathing air described in ANSI/CGA G-7.1, *Commodity Specification for Air*. Locate compressors used to supply breathing air so as to prevent entry of contaminated air into the air supply system and breathing air couplings are incompatible with outlets for nonrespirable worksite air or other gas systems.

3-2.4 Size of Piping.

For single berths, size the mains in accordance with air quantity per ship data given in APPENDIX A. Multiple pier demand data for use in design of new compressed air plants and at new facilities should be obtained by evaluating demands at operating Naval berthing and repair facilities which are similar to the proposed facility. The designer should consult with the cognizant Service. For multiple berthing at a single pier or wharf, including nested ships, use the following diversity factors:

Number of Ships	Diversity Factor
1	1.0
2	0.8
3	0.7
4	0.6
5 or more	0.5

3-2.4.1 Branches.

Branch-pipe sizes should be in accordance with the ships' usage data defined in APPENDIX A. Where a variable mixture of ships is probable at a given pier, all branch lines should be 3 inch (76 mm) minimum. However, where carriers may be berthed, branch lines should be 4 inch (102 mm) minimum.

3-2.4.2 Sizing Method.

Determination of pipe size should be in accordance with available friction loss tables. Size mains for a pressure drop of not greater than 5 psi (34.5 kPa) total friction loss from pier or wharf entrance to farthest outlet, and as based upon the designed flow rates. For looped mains, assume flow in both legs of the loop. In all cases, mains should be sized to supply the most outboard ship with 100% of the quantity defined in APPENDIX A, and then adjusted for its full-diversified demand.

3-2.5 Location and Arrangement of Piping Mains and Branches.

As a general rule, for all active berthing piers, provide a single compressed air main with cross branch piping to outlets. For repair and submarine piers, provide a piping main on both sides of the pier and provide a cross connection at the outboard end of the pier (loop configuration), unless not feasible or practical on a submarine pier. It is normally more desirable operationally to provide a looped compressed air main rather than an equivalent single main. Provide isolation valves at appropriate locations for reliability of service during emergency repairs. Coordinate piping with structural conditions and arrange mains for the best combination of versatility, security, and overall cost. The number of shore compressed air outlets and risers for various ship types is defined in APPENDIX A. Specific ships connection locations (one or two per ship) are also defined. However, compressed air may be required at many locations both on and alongside a ship during maintenance or repair operations. The number of outlets and risers per berth should therefore be integrated within utility groups designed and spaced as discussed in CHAPTER 2.

3-2.6 Outlet Design.

See Figure 3-3. The size of outlet risers should be the same as that of branch piping. Provide a full-sized accessible shut-off valve in each branch near the outlet riser. Hose couplers for maintenance and repair connections should be quick coupler type and must match those used by the Activity. When the site is an existing facility, the number and size of maintenance and repair hose connections required to match a facility standard may be used in lieu of those given in the following table. Shore couplings for 2-1/2 inch (64 mm) ship-to-shore connections should be male cam-locking connector with cap which complies with Commercial Item Description (CID) A-A-59326, *Coupling Halves, Quick-Disconnect, Cam-Locking Type* (with supplements). Shore couplings for 4 inch (102 mm) ship-to-shore connections should be 150-pound flanges with blind flange covers. Refer to CHAPTER 2 for general description of the arrangement and spacing of utility outlets. Provide a header at the outlet riser, with hose connections (valved outlets and hose couplers) sized as follows:

Size of Riser inch (mm)	Maintenance and Repair Connections Number, inch (mm)	Ship-to-Shore Connection inch (mm)
2 (50.8)	Four 3/4 (19.1)	None
3 (76.2)	Two 3/4 (19.1) & Two 1-3/4 (44.5)	4 (102)
4 (102)	Two 3/4 (19.1) & Two 1-1/4 (31.8)	4 (102)

3-2.7 Requirements for High Pressure Compressed Air.

Submarines and aircraft carriers (CVN 68 class and higher) (ref NSTM Chapter 9490) require a high pressure compressed air (HPA) supply in addition to the customary low pressure compressed air (LPA) requirements. This service may be provided by tapping an available 3,000 psi (21 MPa) or 4,500 psi (31 MPa) source, or by utilizing portable compressors. Required ships service size is normally 1/2 inch (13 mm) or 3/4 inch (19 mm). The ship's compressors will be used for top off under emergency conditions. Air quality should be in accordance with NAVSEA S9086-AB-ROM-010, *Naval Ship's Technical Manual (NSTM)*, Chapter 551, *Compressed Air Plants and Systems*. This chapter requires air to be oil free and dehumidified by a desiccant type dehydrator to a dew point (at atmospheric pressure) of -60 °F (-51 °C). High pressure compressed air service is normally portable and provided by the Activity, but the need must be determined on an individual site basis.

3-2.8 Submarine Pier Requirements.

Submarine and UUV piers/berths require both LPA and HPA. Provide permanently installed LPA and HPA systems at submarine and UUV piers/berths. However, this must be determined on a case-by-case basis.

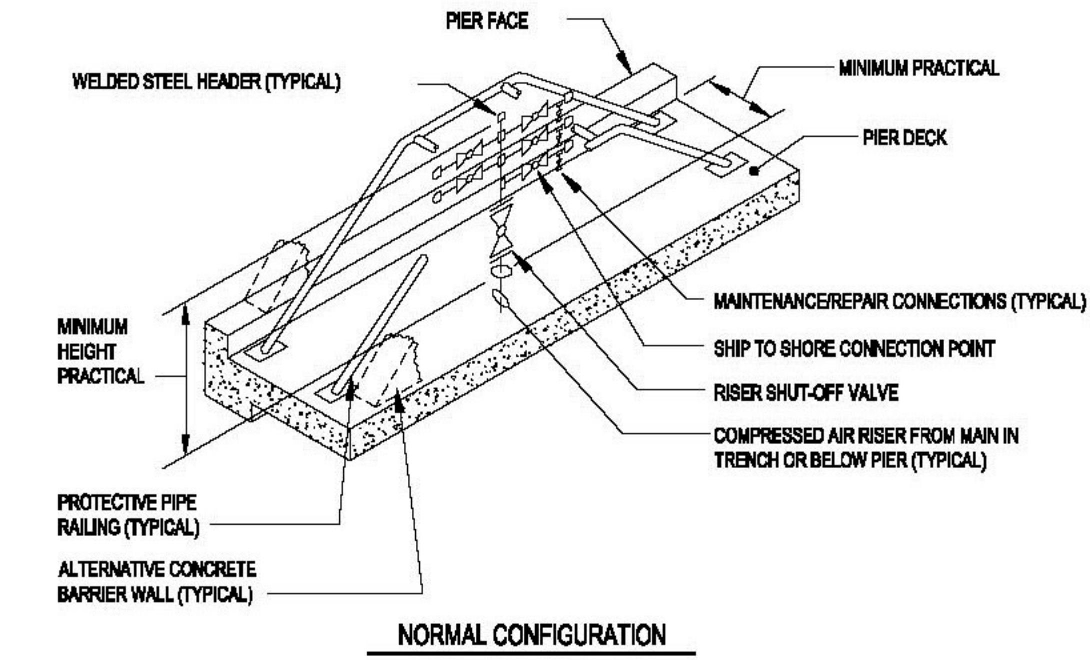
Where not feasible or practical to provide a permanently installed utility systems, a suitable solution that limits operational impacts must be developed and fully vetted through the various stakeholders to meet this utility requirement. Project team must document the variation in providing the utility, alternatives, mitigation measures, and resolution.

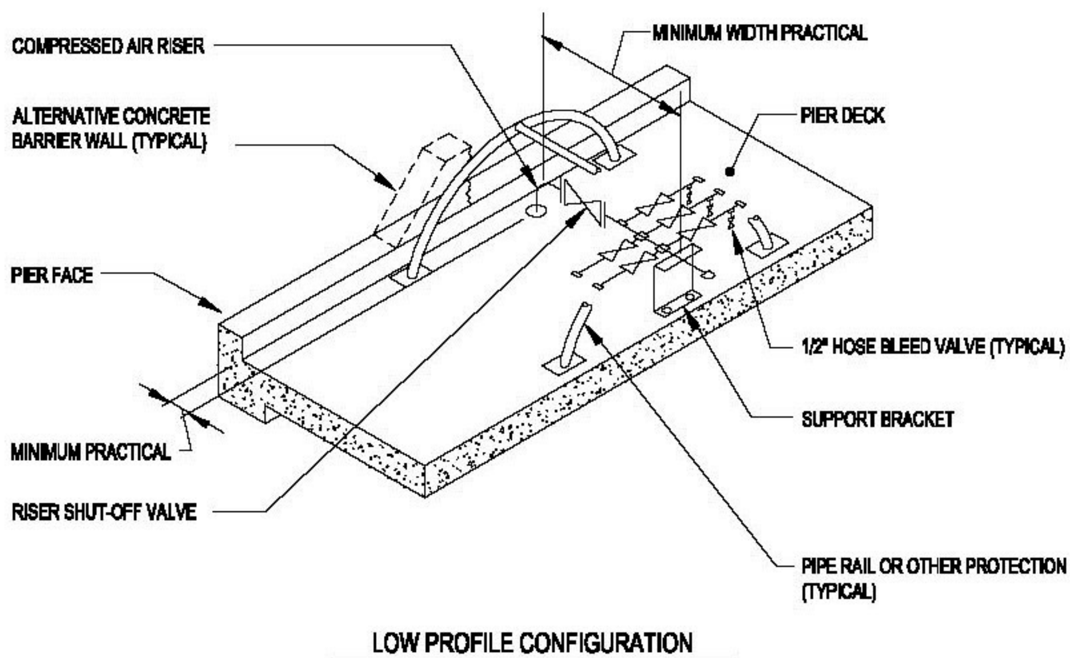
Permanently installed systems are preferred. But, require adequate pier width, deck space, shoreside space, and/or a remote facility for supply. Permanently installed piping with connections for temporary/portable equipment is an option, but is not preferred. This requires a location for portable equipment that limits impacts to operational areas. It is less desirable to provide portable compressors with hoses since they will impact pier deck space and interfere with operations.

3-2.9 Metering.

Provide metering of LPA and HPA supply to piers or groups of piers unless instructed otherwise. See Section 2-5 entitled “Metering” in CHAPTER 2.

Figure 3-3 Typical Compressed Air Outlet Assembly





3-3 SALTWATER OR NONPOTABLE WATER SYSTEMS.

Do not provide shore-supplied saltwater or nonpotable water to active berthing piers and wharves unless instructed by the cognizant Service. Refer to the paragraphs below for guidance regarding justification for the use of permanent salt or nonpotable water systems. For dry docks, refer to UFC 4-213-10. For pier and wharf fire protection requirements, refer to UFC 3-600-01, *Fire Protection Engineering for Facilities*, as well as the criteria in this UFC. Also, refer to NAVSEA 8010, *Industrial Ship Safety Manual for Fire Prevention and Response* for requirements for any industrial work being performed pierside on in a dry dock. Consult with the cognizant fire protection engineer, both at the local level and at the cognizant Service level.

3-3.1 Justification.

The use of permanent salt or nonpotable water systems must be justified and approved in advance by the cognizant Service. Use the following criteria to establish approval requirements for these systems.

3-3.1.1 Repair Piers and Dry Docks.

At facilities used for major ship repair in which the repaired ships do not have use of their own pumping capabilities, permanent shore salt or nonpotable water systems are normally utilized. These types of installations do not require prior approval. Design such systems in accordance with applicable requirements defined herein and beginning with Section 3-3.2 entitled “Demands and Pressure Requirements”.

3-3.1.2 Active Berthing.

Permanent salt or nonpotable water systems must not be provided at active berthing facilities unless instructed otherwise. It is the Navy's intent that ships at active berth will normally rely upon their own pumping capabilities to supply saltwater for flushing/cooling and firefighting. In the event of a major fire or other emergency, shore-based portable pumps and other available station fire apparatus would be utilized to augment the ship's saltwater pumping capability.

Generally, fixed fire protection systems are not required for active berthing piers when the level of the pier is low enough to the waterline such that the responding fire crews can perform drafting operations from the pier. However, with the development of the double-decker type piers, normal fire department operations are restricted due to the elevation of the pier above the water level. Provide dry standpipe systems for piers where construction features restrict fire department vehicle access and/or prevent the fire department from performing drafting evolutions from the pier. The system consists of multiple inlet, or pumper, connections and multiple outlet (standpipe) connections located on both levels of the pier.

3-3.1.2.1 Connections.

Locate inlet connections on both sides of the access ramp and size to support flows of 3,000 gpm (190 L/s). Pumper connection type should be as preferred by the base fire department, but typically will consist of both 5 inch (127 mm) Storz and 2-1/2 inch (64 mm) connections. This configuration will permit the fire department to obtain water from adjacent fire hydrants, drafting operations from the relieving platform, or a combination of both.

Outlet connections consist of the following:

- Upper level connections consist of a single 5 inch (127 mm) Storz outlet and valve or four (4) 2-1/2 inch (64 mm) hose valves. Locate connections at each stair access point to the lower level and at the top of the pier access ramp.
- Lower level standpipe or hose stations consist of two (2) 2-1/2 inch (64 mm) hose valves. Locate hose stations along both sides of the pier, spaced so that all portions of the lower level are within 150 ft (45 m) of a hose connection. Measure distances along a path of travel originating at the hose connection.

3-3.1.2.2 Identification.

Identify locations of the lower level connections on the upper level by color coordinated reflective markers located on the curb along the pier edge. Provide reflective markers to identify all fire protection and ship service connections. Identify locations of lower level connections on the lower level by painting the adjacent pier structural column (bent) red in color.

3-3.1.2.3 Piping.

Main distribution piping on the pier must be a minimum 8 inch (203 mm) diameter, Schedule 40-Galvanized. Loop piping to supply hose stations along both sides. Piping must not infringe on vehicle lanes with respect to clear height requirements.

3-3.1.3 Justification Requirements.

At locations where special conditions or hazards exist, permanent salt or nonpotable water systems will be allowed for active berthing and inactive berthing facilities on a case-by-case basis provided: (1) it is adequately justified by the Activity; and (2) it is approved in advance by the cognizant Service Chief Fire Protection Engineer. Each pier or wharf at a given facility must be considered separately unless the usage of two or more piers is identical. The Station/Activity should submit the following when requesting approval for these systems.

- Identify the type of facility and activities, and describe the special condition(s) or hazard(s) peculiar to this facility upon which this request is based.
- Establish the required pier or facility demand and pressure parameters based on the methods given in Section 3-3.2 entitled “Demands and Pressure Requirements”.
- Provide description and analysis of the options available to provide the required protection such as: (1) permanent system to supply the entire demand; (2) portable pumping systems(s) dedicated or otherwise; and (3) combinations of items (1) and (2). All existing Navy assets must be included in the analysis including any existing permanent systems.
- Provide a life cycle cost analysis for all viable options on a site-specific basis. Perform the analysis in accordance with the cognizant Service P-442, *Economic Analysis Handbook*. The analysis must take into consideration the costs of owning and operating all pertinent plants, both on ships and ashore.
- Make recommendations for the best system to meet the required demand as based on consideration of the special conditions(s) or hazards(s) and on the life cycle cost analysis.
- The demands and pressure parameters of an approved permanent salt or nonpotable water system should be designed as described in Section 3-3.2 entitled “Demands and Pressure Requirements” and all subparagraphs.

3-3.2 Demands and Pressure Requirements.

Berthing facilities should conform to the requirements specified below. Note that the requirements differ for overhaul and dry dock berthing versus those for active berthing.

3-3.2.1 Dry Dock, Repair and Inactive Berthing.

Nonpotable or saltwater supply should be furnished at dry docks, piers, and wharves as described below. Requirements for selected ship classes are defined in APPENDIX A. For ships not included in APPENDIX A, use data from a similar ship, or obtain the expected demand from the cognizant Service. The following criteria should also apply.

- Dry dock: Provide sufficient saltwater to meet the requirement of the ship with the highest saltwater demand anticipated to be docked at the dry dock. Use the "Total Demand" quantity listed in APPENDIX A. Refer to UFC 4-213-10 and NAVSEA 8010 for additional requirements at dry docks.
- Repair Berthing: Provide sufficient saltwater to meet the "Total Demand" requirement defined in APPENDIX A for the largest ship to be berthed at the pier plus the aggregate cooling/flushing demand of all remaining ships

at the pier, and then multiplied by the diversity factors given below. In general, allow 1,000 gpm (63 L/s) minimum for piers serving frigate ships and larger and 500 gpm (32 L/s) minimum for piers serving ships smaller than frigates. Also, do not include nested ships.

Number of Ships	Diversity Factor
1	1.0
2	0.9
3	0.8
4	0.7
Over 4	0.6

- Total System Demand: Where a system serves more than one pier, assume only one ship fire will occur for the group of repair piers. The multiple pier supply system should be designed to meet the requirement of the pier with the highest demand plus the aggregate cooling/flushing demand from ships at all remaining piers, and then adjusted by the same diversity factors defined above. To obtain an overall demand that includes dry docks, add the sum of all dry dock demands to the multiple pier demand as described herein.
- Pressure Requirement: The saltwater pressure should be 150 psi (1,034 kPa) residual pressure (for all ships except submarines) at the most remote outlet. Submarines require only 40 psi (276 kPa). These pressure requirements should be available within 3 minutes of system activation.

3-3.2.2 Active Berthing (Single or Multiple Berths).

As stated previously in Section 3-3 entitled “Saltwater or Nonpotable Water Systems”, shore supplied saltwater or nonpotable water should not be provided to active berthing piers or wharves. However, there are instances where this occurs. In the criteria given below for saltwater or nonpotable water demands, one of the following conditions of flow governs. (Note: Either the fire protection demand or the cooling/flushing demand may govern. Use whichever is greater.)

- Base fire demand on a fire occurring aboard the ship with the largest fire protection demand plus the cooling/flushing ratings of all other ships connected to the fire protection water systems, and then adjusted for diversity.
- Base cooling/flushing demand on the aggregate of connected ships and then adjusted for diversity.

Requirements for selected ship classes are defined in APPENDIX A. For ships not included in APPENDIX A, use data from a similar ship, or obtain the expected demand from the cognizant Service. For aircraft carriers (CVN 68 class and higher) include saltwater for firefighting and cooling/flushing when potential exists for ship to be in cold iron status. Total demand equals firefighting plus cooling/flushing flow.

3-3.3 Pumping Equipment.

Pumps may be permanent, portable or mobile as justified and approved under the requirements defined in Section 3-3.1 entitled “Justification”. In general, pump capacities and heads should be selected to provide for both fire protection and cooling/flushing requirements. Use separate pumps for the two requirements only when specifically allowed or when upgrading an existing system as defined in Section 3-3.5.2 entitled “Upgrading”. Refer to UFC 3-600-01 for requirements of fire pumps and associated equipment. Centrifugal fire pumps should comply with NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection*.

3-3.3.1 Drives.

As defined by NFPA 20, fire pumps may be driven entirely by electric motors if either a single reliable power source is available, or if two independent power sources are available. Single reliable power sources need not include dual substations or starting equipment. If the above conditions for use of "electric drive only" cannot be met, design the system such that a minimum of 50% of pumping capacity is driven by approved alternative drives such as diesel engines. Portable or mobile pumping equipment is normally driven by remote-starting electric motors (when appropriate) or by diesel or gas-turbine engines.

3-3.3.2 Pressure Control.

Pressure must be controlled under varying demands by staging of pumps and by incorporation of surge tanks and/or other suitable equipment. It is imperative to prevent excessive surges due to starting and stopping of pumps. Use a small pressure-maintenance pump to handle low flows. Fire pumps must be equipped for automatic startup upon pressure drop, manual stop, and provision for "manual override startup".

3-3.3.3 Alternative Pump Drive.

When a separate cooling/flushing water system is used, a variable speed electric drive may be used to control pressure. Variable speed equipment may also be used for combined fire protection and cooling/flushing systems when approved by the cognizant Service. Variable speed drive equipment should be selected from types that have been proven by successful use. Adjustable frequency type variable speed systems are preferred because of their higher efficiency. See UFC 3-520-01, *Interior Electrical Systems*, for additional requirements regarding variable speed systems.

3-3.3.4 Location.

Permanent pumping equipment for individual piers, wharves, or dry docks should be located ashore and as near as possible to the pier, wharf or dry dock. It is highly preferred to provide vertical pumps with wet sump/intake configuration. Where this is impractical, then the pumps may be placed in an enclosure on or alongside a pier or wharf. The pump columns must be adequately protected from wave action and floating debris. Portable or mobile pumping equipment may also be placed on pier decks or on floating platforms moored to the pier.

3-3.3.5 Materials.

Care must be taken when specifying pump materials for nonpotable water service. Where salt or brackish waters are present, the potential for galvanic and crevice corrosion is severe. Steel and cast iron, ordinary brass and bronze, and most stainless steels are not suitable for these corrosive water sources. Specially coated steel and cast iron as well as 400 series stainless steel have proven to be ineffective. Material selection should be based on a thorough investigation of the site and operational conditions. The construction specifications should be explicit as to materials required for each major part, indicating appropriate ASTM designation and Unified Numbering System (UNS) number per ASTM E527, Numbering Metals and Alloys in the Unified Numbering System (UNS). Since it is impractical to list all parts, a sentence such as the following should be included:

"Minor parts not listed should be of comparable materials with equivalent corrosion resistance to the materials listed."

Submittals for Government approval, including material lists, should be required for pumps. Materials generally considered appropriate for salt and brackish waters are as follows:

Application	Material	ASTM	UNS
All wetted parts	316 SS, or	A276	S31600
	316L SS	A276	S31603
Shafts/Couplings	Nickel-Copper	B164 [a] and	N04400
	(Monel)	B165 [a]	N04499
All wetted parts,	Alum Bronze, or	B148 [a]	C95200
except shafts/couplings	Ni-Alum Bronze	B148 [a]	C95500

Note:

[a] Full titles for ASTM Standards can be found in APPENDIX F.

In salt water it is important to avoid dissimilarity of parts. Pumps constructed of type 316L stainless steel or nickel aluminum bronze with monel shafts are preferred. In brackish water, cost savings can be realized by allowing acceptably small dissimilarities. Aluminum bronze pumps with type 316 stainless steel shafts are a reasonable alternative. The presence of sand/grit must also be considered. Pumps constructed of stainless steels handle sand/grit better than pumps constructed of bronze and other copper alloys. However, saline waters corrosion concerns are still paramount.

3-3.4 Piping and Outlets.

3-3.4.1 Size of Mains.

Piping systems must be designed to provide the required residual pressure at the rated design flows to the berths farthest from the pumping location. Where a common shore pumping and distribution system feeds several piers or dry docks, the shore distribution system must be sized to deliver the design firefighting flow to any one of the piers or dry docks while cooling/flushing flows continue to all other locations.

3-3.4.2 Location and Arrangement of Mains.

As a general rule, provide a permanent main on both sides of a pier with a cross connection at the outboard end of the pier (loop configuration). When permanent mains are placed on piers 50 ft (15 m) or less in width or in unique situations, provide a single main with branch lateral pipes for outlets on both sides of the pier. It is normally more desirable operationally to provide a looped main than an equivalent single main. Provide isolation valves at appropriate locations for reliability of service during emergency repairs. Coordinate piping with structural conditions and arrange mains for the best combination of versatility, security, and overall cost. Segregation valve should be placed in the fire main loop so that the maximum distance between any two adjoining valves does not exceed 200 ft (61 m).

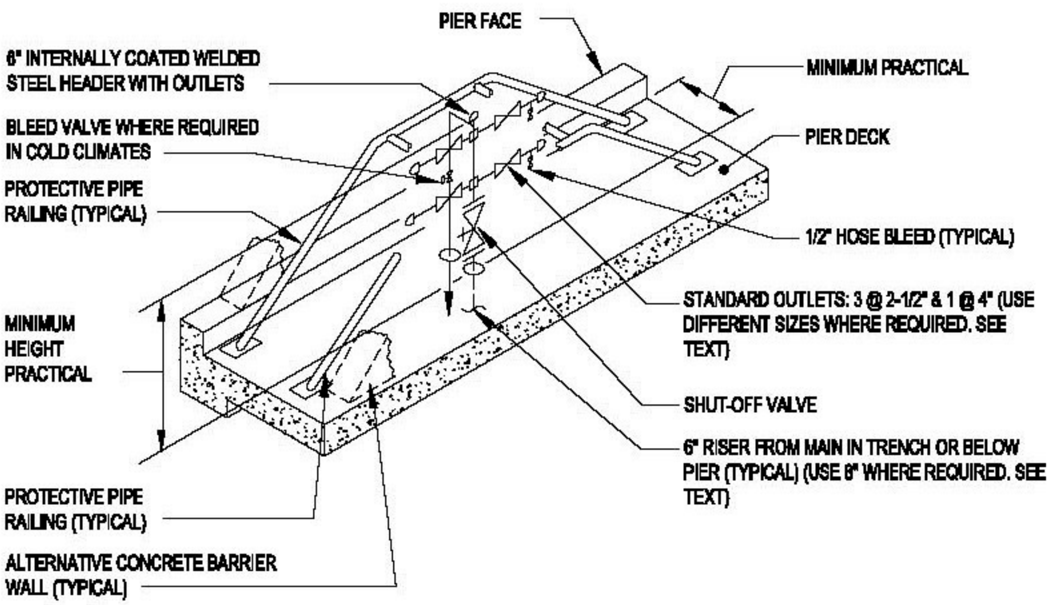
3-3.4.3 Location and Spacing of Outlets.

The pier location of ships' saltwater connections are defined in APPENDIX A. Refer to CHAPTER 2 for a description of the methods to be used in establishing shore utility-station spacing on piers and wharves. Hose valve manifolds should be provided in sufficient numbers such that all parts of the ship can be reached by at least two 100 ft (31 m) hoses. For spacing in dry docks, refer to UFC 4-213-10.

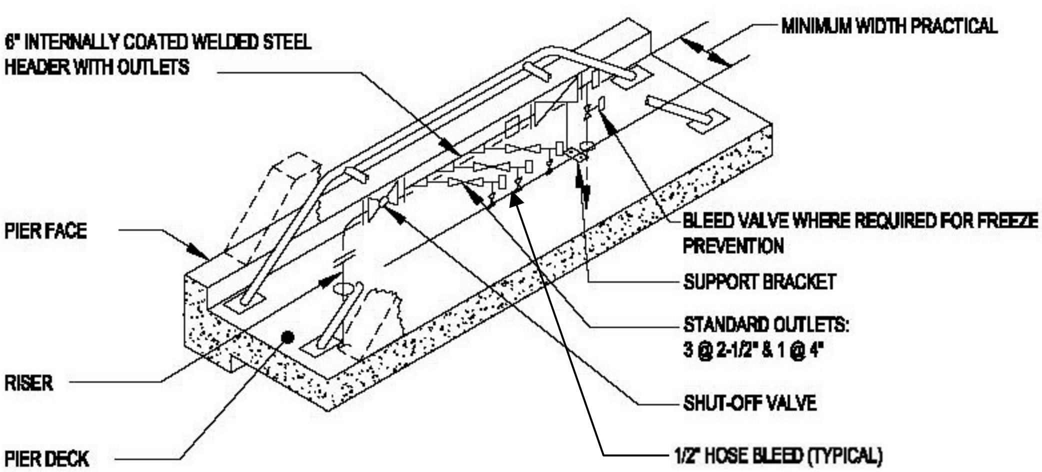
3-3.4.4 Outlet Design.

See Figure 3-4. The typical outlet should consist of a 6 inch (152 mm) branch main and riser feeding a manifold arrangement of three 2-1/2 inch (64 mm) and one 4 inch (102 mm) valved hose connections. Where portable pumping systems are used, standpipe connections may be provided on some (or each) of the outlet risers for connection to the portable pumping system discharge hose. For certain large ships, the above outlet requirements should be modified as defined in Section 3-1.6.1 entitled “CVN, LHA, and LHD Requirements (All Classes)”. Provide four 4 inch (102 mm) valved hose connections in a manifold arrangement at the outboard end of large piers. These outlets are to serve fireboat or large-volume portable-pump connections. Where berthing is designed exclusively for tugboats, work boats, or other small craft having a "Salt Water From Shore" requirement of not more than 625 gpm (39 L/s), properly spaced 4 inch (102 mm) risers having two to three 2-1/2 inch (64 mm) connections may be used in lieu of the above. All connections should be protected by a corrosion resistant chained cap, sized to properly support the weight of the cap on the chain for extended periods of time. At each designated pier in each naval station where oceangoing U.S. merchant and foreign ships are expected, provide two international shore connections. See Figure 3-5.

Figure 3-4 Typical Salt or Nonpotable Water Outlet Assembly

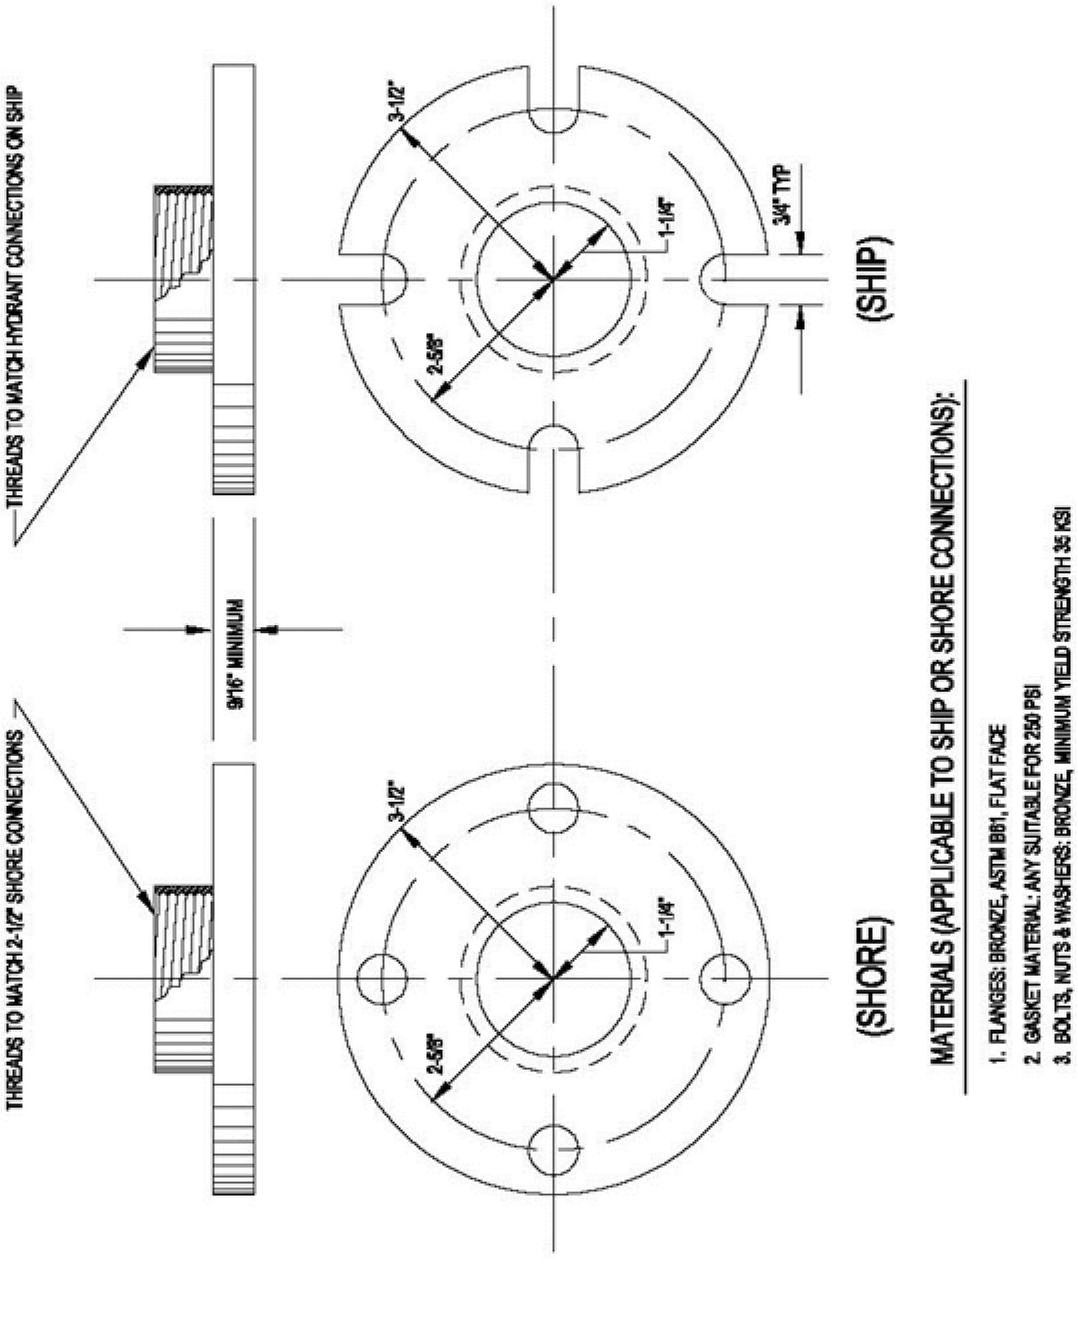


NORMAL CONFIGURATION



LOW PROFILE CONFIGURATION

Figure 3-5 International Shore Connection for Ship Fire Mains



3-3.4.5 Materials and Installation Criteria.

Pipe and fittings should conform to UFC 3-230-01, *Water Storage and Distribution*, as applicable to piers and wharves. Use pipe, fittings and valves pressure-rated at 250 psi (1,724 kPa) minimum. Hose threads should be National Standard hose-coupling threads, 7-1/2 threads/inch, or as approved by the cognizant Fire Protection Engineer. Materials for valves should conform to requirements for pumps as defined in Section 3-3.3.5 entitled “Materials”. For piping on a pier or wharf, evaluate the relative advantages of cement-lined ductile iron versus cement-lined steel pipe with an extruded polyethylene or polypropylene exterior coating. An ultra violet inhibitor must be used in polyethylene coatings that will be exposed to sunlight. For coated pipe, use polyethylene heat-shrinkable sleeves and/or tape wrapping at joints and fittings. Provide pipe hangers and associated support assemblies in accordance with Section 2-4.1.4 entitled “Hangers and Support Assemblies”. Provide means of pipe movement due to thermal expansion, preferably by the use of expansion loops and offsets. Also, provide for differential movement of piping at pier expansion joints. Piping and outlets must be identified and color-coded in accordance with CHAPTER 5.

3-3.5 CVN, LHA, and LHD Requirements (All Classes).

At existing installations where insufficient saltwater pressure exists, the pressure should be increased to provide 150 psi (1034 kPa) residual pressure at the pier outlets. Pump-discharge pressure must be sufficient to provide the required residual at the rated design flow. The following special requirements apply to these large class ships:

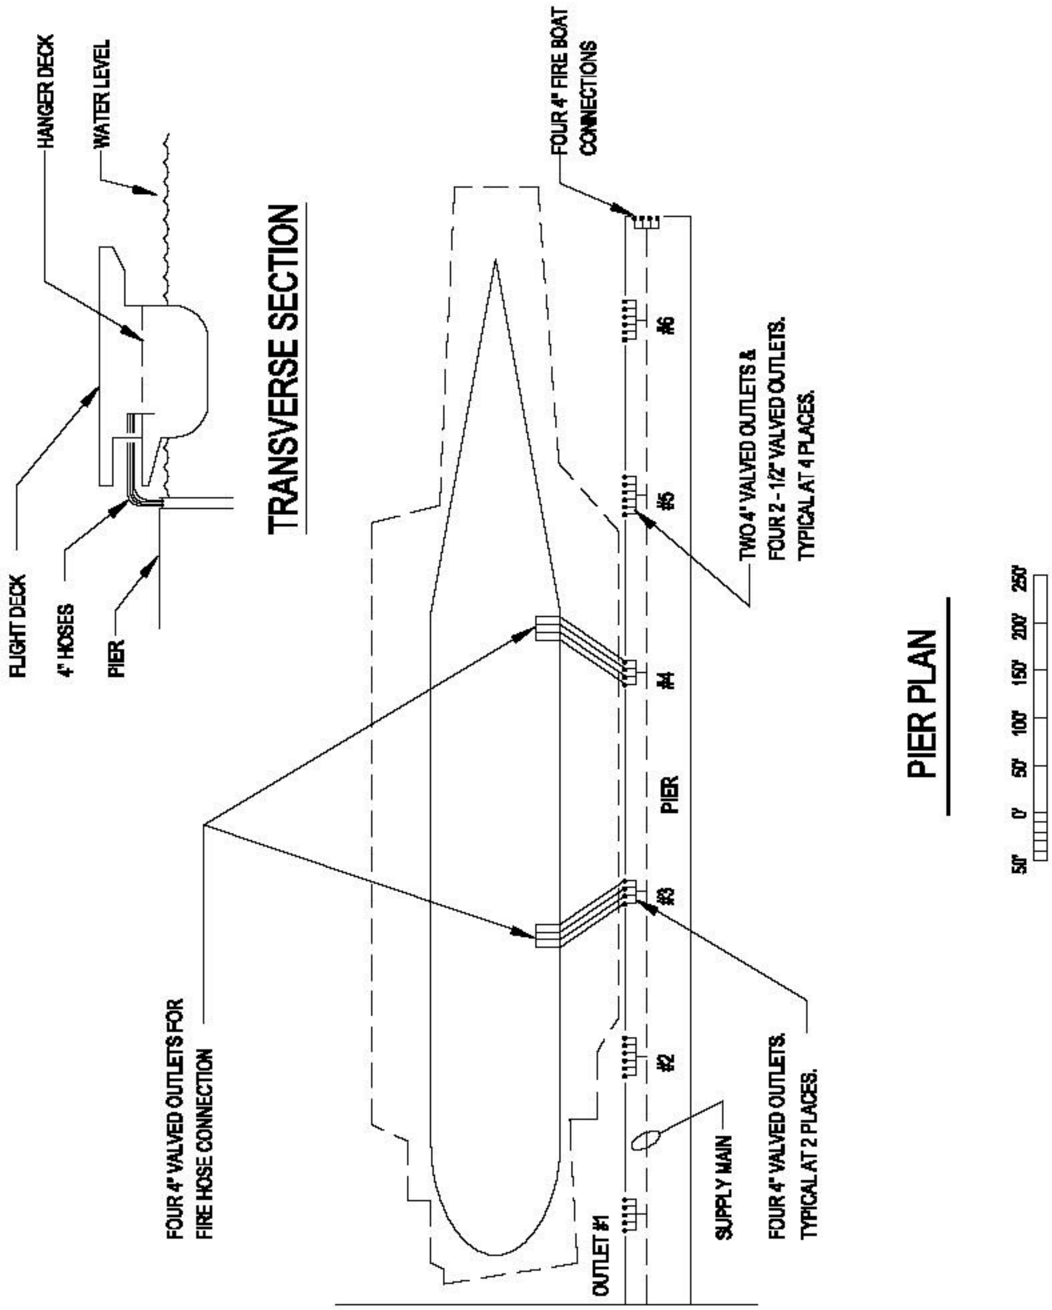
3-3.5.1 Special Outlets.

In lieu of the typical outlet assembly, provide four 4 inch (102 mm) gate valve hose connections in an 8 inch (203 mm) manifold arrangement with an 8 inch (203 mm) riser at each of two locations. Approximate locations of outlets for aircraft carriers are indicated on Figure 3-6. For LHA and LHD ships, determine locations from NAVSEA or from the Activity. Except for the riser size, outlet design and configuration should be similar to outlets at other locations and which serve the smaller ships.

3-3.5.2 Upgrading.

Permanent changes to existing pier systems for upgrading of the fire protection system (where permanent system has been justified) should be a separate high-pressure system. Provide pipes, fittings, and valves with a pressure rating of 250 psi (1,724 kPa) minimum. Existing low-pressure saltwater systems may remain in place for cooling/flushing and for fighting fires on piers when handheld hose lines are required.

Figure 3-6 Salt or Nonpotable Water for CVN Classes at Pier



3-3.5.3 Portable or Mobile Pumps.

Supplemental large-volume portable or mobile pumps may be utilized to augment the salt-water supply from a permanent system. Existing systems that can supply a portion of the requirement at 150 psi (1,034 kPa) residual pressure may remain unchanged. However, when portable or mobile systems are used at dry docks or repair facilities, the capacity of the permanent system should be no less than 5,000 gpm (18,925 L/min).

3-3.6 Other Nuclear-Powered Ship Requirements.

For active and repair berthing or docking, the requirements are the same as those for conventionally powered ships of similar type.

3-4 POTABLE WATER SYSTEMS.

Provide potable water via a permanently installed fixed piping system to all berthing spaces. For graving dry docks, refer to UFC 4-213-10. Supplemental utility data as well as specialized technical data and specific ship requirements are provided at the end of this chapter. See Section 3-4.6.3 entitled “Additional Requirements for Nuclear-Powered Ships” for pure water requirements.

3-4.1 Quantity and Pressure Requirements.

3-4.1.1 Active Berthing (Single or Multiple Berths).

For single berths, provide a potable water supply of 1,000 gpm (63 L/s) for all berth lengths up to 2,000 ft (610 m). Design for a minimum residual pressure of 40 psi (276 kPa) downstream of an RP2 backflow preventer located at the most remote outlet on the pier. Where the pier length accommodates more than one berth, provide a potable water supply of 1,000 gpm (63 L/s) for the first 2,000 ft (610 m) of berth, plus 500 gpm (32 L/s) for each additional 2,000 ft (610 m), up to a maximum of 2,000 gpm (126 L/s), and with a minimum pressure of 40 psi (276 kPa) downstream of an RP2 backflow preventer located at the most remote outlet. Potable water requirements for selected ship classes are defined in APPENDIX A. For ships not included in APPENDIX A use data from a similar ship or obtain the expected data from the cognizant Service.

3-4.1.2 Repair Berthing.

The potable water requirements are defined in APPENDIX A. Add the quantities indicated for each ship (including nested ships) and that total available on the pier. Base the peak rate of flow for sizing the main on providing the entire daily flow requirements defined in APPENDIX A, applied to all ships on a pier or wharf, at a constant flow rate, within an 8 hour period, and at a residual pressure of 40 psi (276 kPa) minimum at the furthest shore connections. It is noted that this data is based on 30 gpd/person (114 L/d/person).

3-4.1.3 Multiple Piers.

Determine total usage for multiple piers by summing daily flows for all ships at all piers or wharves assuming 30 gpd/person (114 L/d/person). Determine the peak-flow rate for multiple piers by summing peak-flow rates for all piers or wharves as determined by the method described above and then multiplied by a diversity factor of 0.75.

3-4.2 Piping System Design Criteria.

For piping materials and installation requirements, refer to UFC 3-230-01. Ductile iron is typically used for the main lines while PVC or copper is used for branch lines. For piping under a pier or wharf, evaluate the relative advantages of cement-lined ductile iron versus cement- lined steel pipe with an extruded polyethylene or polypropylene exterior coating. Provide an ultra violet inhibitor in polyethylene or polypropylene coatings exposed to sunlight. For coated pipe, use polyethylene, heat-shrinkable sleeves and/or tape wrapping at joints and fittings. Type of joint requires particular consideration. Provide pipe hangers and associated support assemblies in accordance with Section 2-4.1.4 entitled “Hangers and Support Assemblies”. Provide means of pipe movement due to thermal expansion, preferably by use of expansion loops or offsets. Also, provide for differential movement of piping at pier expansion joints. Consider effects of transients from water hammer.

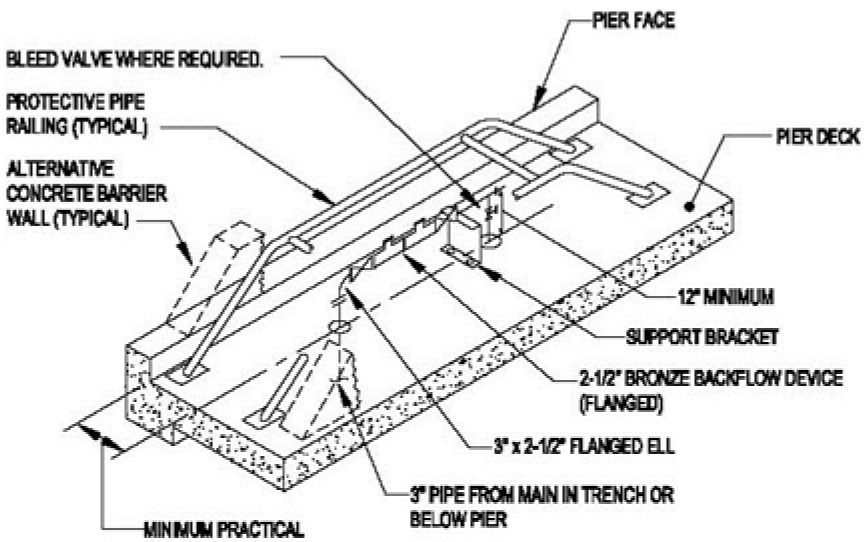
3-4.3 Location and Arrangement of Piping Mains.

As a general rule, provide a single water main with cross-branch piping to outlets for active berthing piers. For repair and submarine piers, provide piping mains on both sides of the pier with a cross connection at the outboard end of the pier (loop configuration), unless not feasible or practical on a submarine pier. Normally, it is more desirable to provide a looped main rather than an equivalent single main. Provide isolation valves at appropriate locations for reliability of service during emergency repairs. Coordinate piping with structural conditions and arrange mains for the best combination of versatility, security, and overall cost.

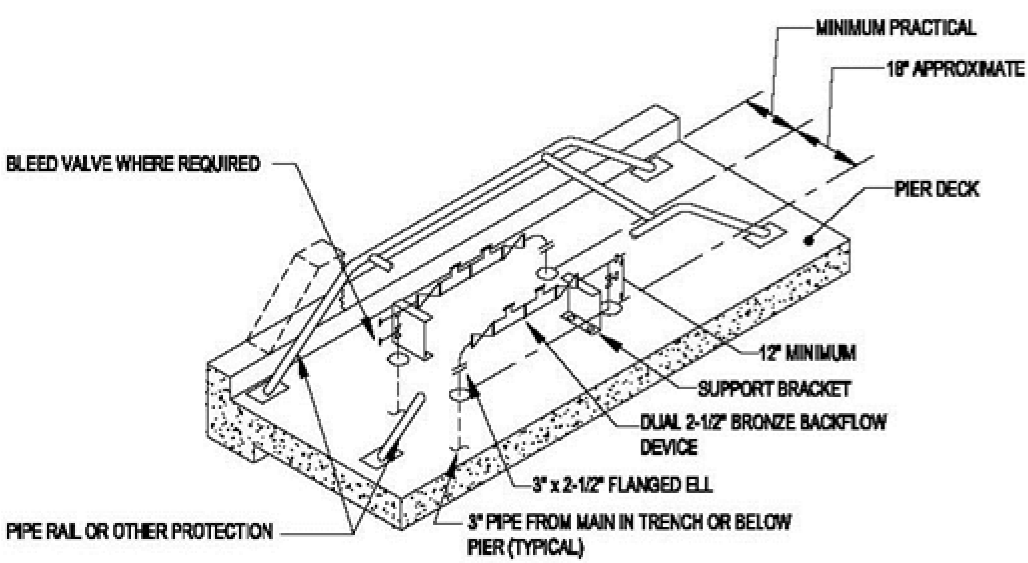
3-4.4 Piping and Outlets.

See Figure 3-7. Provide at least one 2-1/2 inch (64 mm) connection at each service outlet except as specified in Section 3-4.6 entitled “Specific Ship Requirements” for large ship requirements or where nesting is anticipated. Branch piping from mains to outlet risers should be not less than 2-1/2 inches (64 mm), and not less than 4 inches (102 mm) where dual 2-1/2 inch (64 mm) connections are fed by a common branch. Terminate shore connections with a 2-1/2 inch (64 mm) gate valve with hose threads (national hose threads) and a chained cap. Provide a reduced-pressure type backflow prevention device in accordance with UFC 3-230-01. Identify and color-code potable water outlets on piers and wharves in accordance with CHAPTER 5. If static pressure in supply mains is greater than 80 psi (552 kPa) for any portion of the day, then provide regulators set at 80 psi (552 kPa) maximum. All connections should be protected by a corrosion resistant chained cap, sized to properly support the weight of the cap on the chain for extended periods of time.

Figure 3-7 Typical Potable Water Outlet Assembly



SINGLE OUTLET



DUAL OUTLET

3-4.5 Location and Spacing of Outlets.

The pier locations of ships potable water connections may be determined by the data defined in APPENDIX A. Refer to CHAPTER 2 for a description of methods to be used in establishing shore-utility station spacing on piers and wharves.

3-4.6 Specific Ship Requirements.

3-4.6.1 CVN Ship Requirements (All Classes).

Design systems as specified above except provide a 4 inch (102 mm) branch line, a 4 inches (102 mm) reduced pressure backflow prevention device, and an outlet assembly at outlet locations 3 and 4 of Figure 3-6. Provide a 4 inch to 2-1/2 inch (102 mm to 64 mm) reducer for each location to allow the use of these outlets by ships other than carriers.

3-4.6.2 LHA and LHD.

Design systems as specified for CVN class ships except provide dual outlets at each utility connection group, one 4 inch (102 mm) reduced-pressure backflow prevention device, and an outlet assembly near the center of the berth. Provide a 4 to 2-1/2 inch (102 to 64 mm) reducer to allow use of the 4 inch (102 mm) outlet with other ships.

3-4.6.3 Additional Requirement for Nuclear Powered Ships.

A "pure" water supply as defined by NAVSEA is required for all nuclear-powered ships. Quantities for CVNs and submarines are 20,000 gpd (75,708 Lpd) and 10,000 gpd (37,854 Lpd) respectively. Applicable reference documents include MIL-STD-767, *Control of Hardware Cleanliness (NOFORN)* and MIL-STD-2041, *Control of Detrimental Materials (NOFORN)*. A project team will be established for pure water delivery systems for new projects. The project team (consisting of at least the cognizant Service project manager and a Shipyard pure water engineering representative) will agree on the pure water delivery system for new projects with NAVSEA 08 concurrence. Viable options include:

- At locations where there is an existing remote demineralized water plant of sufficient capacity, pure water can be produced from the demineralized water plant and processed through a polishing unit for either direct delivery to the ship via permanent piping system or delivered via pure water tanker delivery trailer.*
- At locations where there is neither an existing demineralized water plant nor one of sufficient capacity, pure water can be produced from a portable demineralizer unit processed through a portable polishing trailer for either direct delivery to the ship or delivered via pure water tanker delivery trailer.*

- At locations where usage quantities or berth arrangements dictate, design and construction of a pure water production plant and/or permanent piping delivery system may be considered.*

* NOTE: Final connections to the ship from either the trailers or the permanent piping system are made with hoses.

3-4.6.4 Submarine Pier Requirements.

Submarine piers/berths require both potable water and pure water. Provide permanently installed potable water system and pure water system at submarine piers/berths. See Section 3-4.6.3 entitled “Additional Requirement for Nuclear Powered Ships” for pure water requirements.

Where not feasible or practical to provide a permanently installed “pure” water system, a suitable solution that limits operational impacts must be developed and fully vetted through the various stakeholders to meet this utility requirement. Project team must document the variation in providing the utility, alternatives, mitigation measures, and resolution.

Preferred option is a permanently installed pure water system with an on-site pure water plant. But, this requires space for the production plant shoreside or remotely. Water quality and O&M are a concerns with this option. A less preferred option is permanently installed piping with connections for temporary pure water supply. But, this will require portable equipment or tanker truck. The least preferred option is to provide pure water directly to ship via pure water tanker. But, tanks and hoses take up deck space and interfere with operations.

3-4.7 Quality.

Refer to UFC 3-230-01. The quality of water must meet or exceed the requirements of 40 CFR, Part 141, *U.S. Environmental Protection Agency's National Primary Drinking Water Regulations*.

3-4.8 Metering.

Provide metering of potable water supply to piers or groups of piers unless instructed otherwise. See Section 2-5 entitled “Metering” in CHAPTER 2. Use compound-disc or magnetic-flow meters to achieve a high range of registration.

3-5 POL SYSTEMS.

Refer to UFC 3-460-01, *Design: Petroleum Fuel Facilities*. Fuel and lube oil connection locations on various ships are defined in APPENDIX A. Pier fueling connections and hoses must be kept a minimum of 25 ft (8 m) away from any possible ignition sources, such as pier power outlets, telephone terminal panels, and fire alarm equipment. Required POL connection sizes must be obtained from specific ship data available from NAVSEA. General requirements for pipe hangers and support assemblies (see Section

2-4.1.4 entitled "Hangers and Support Assemblies") and for metering (Section 2-5) are applicable. Identify POL outlets on piers and wharves and color-code in accordance with CHAPTER 5. POL piping systems also require special consideration for protective coatings and cathodic protection systems. See Section 2-4.4 entitled "Cathodic Protection Systems (CPS)". Refer to military specifications MIL-C-52404, *Connection Hose, Fire and Water* and MIL-S-12165, *Strainer Suction, Fire Hose, and Strainers, Suction, Hose* for POL connection types. Consult with the cognizant fire protection engineer, both at the local level and at the cognizant Service level.

3-6 OILY WASTE SYSTEMS.

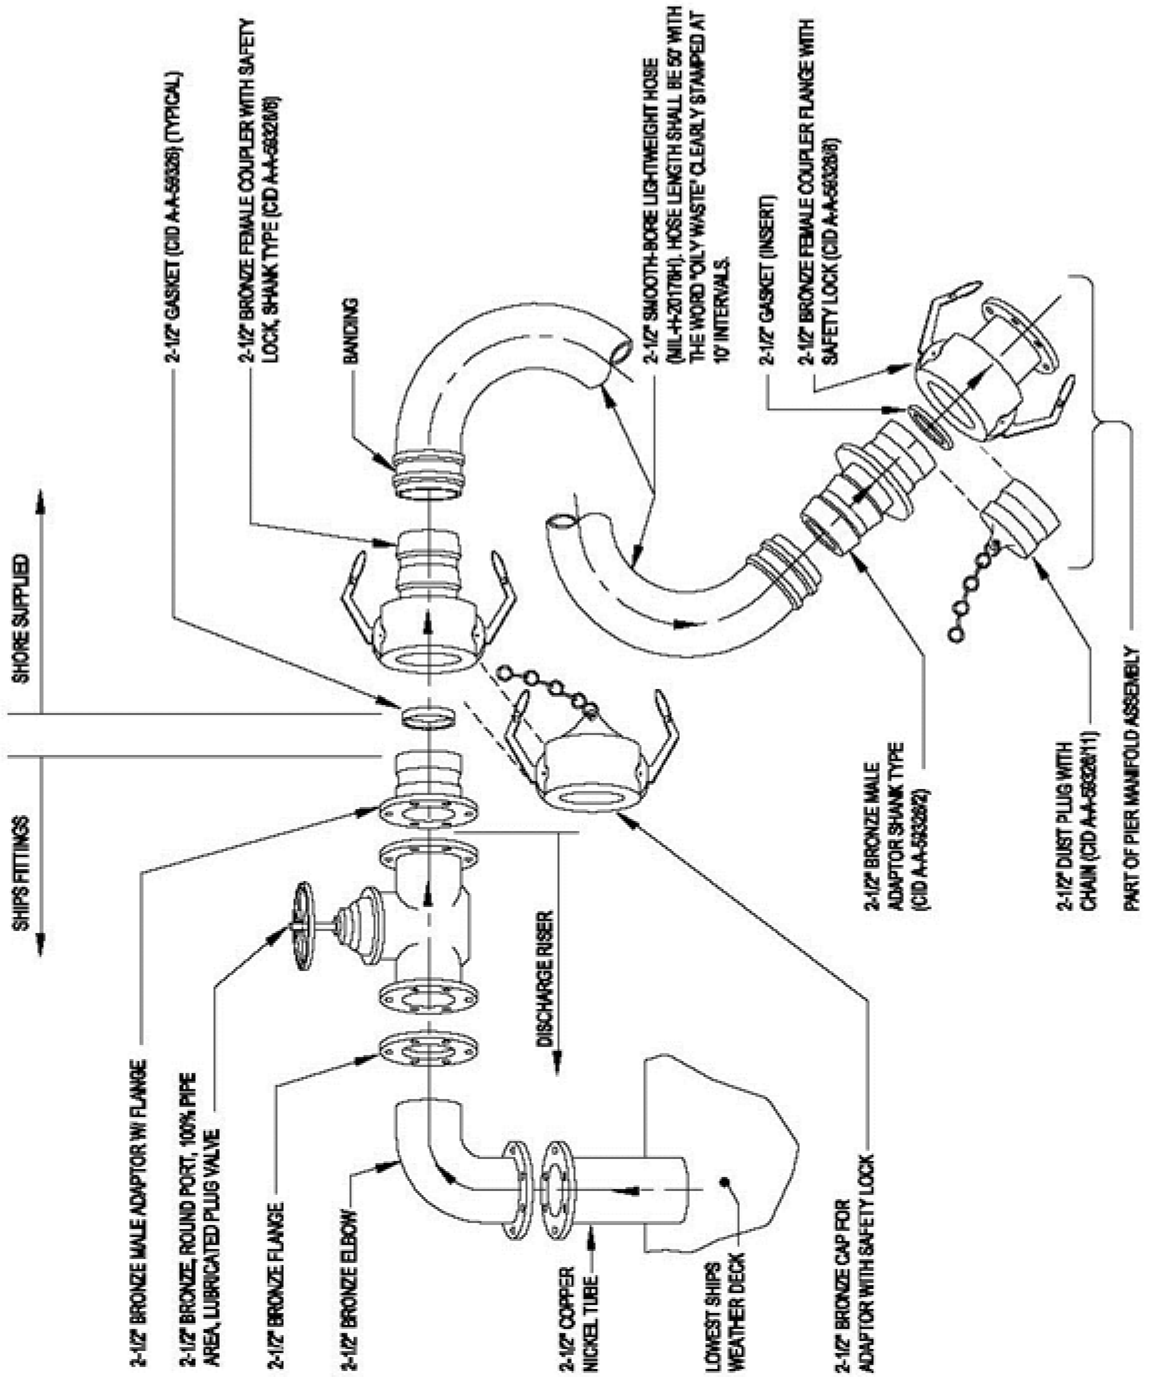
For typical ship-to-shore connection requirements, see Figure 3-8. Oily waste collection must be provided at all berths for 100 gpm (6.3 L/s). Oily waste system requirements for selected ship classes are defined in APPENDIX A. For ships not included in APPENDIX A, use data from a similar ship or obtain the expected demand from the cognizant Service.

The system is usually a fixed piping system. However, tanker truck or barges may be used for transient berths if allowed by the Activity. Ship waste oily barges (SWOB) should not be used at submarine berths due to potential hull damage. Provide a permanently installed oily waste collection system at submarine piers, see Section 3-6.6. Design ships oily waste (bilge water) systems in accordance with UFC 4-832-01N, *Industrial and Oily Wastewater Control*. Also, refer to *40 CFR, Part 1700, Uniform National Discharge Standards for Vessels of the Armed Forces*, and to *NAVSEA S9593-BF-DDT-010, Oil Pollution Abatement System* for ship design. Connection locations for ships oily waste are defined in APPENDIX A. Refer to CHAPTER 2 for a description of utility spacing requirements. In climates subject to freezing temperatures, oily waste lines must be properly protected. Refer to CHAPTER 5.

3-6.1 Pierside and Barge Collection of Shipboard Oily Waste.

Shipboard oily waste must not be directly discharged to public waters. In many cases it is unsuitable for discharge to a publicly owned treatment works (POTW). Requirements are: (1) provide full treatment to direct discharge standards; or (2) provide pretreatment to reduce pollutants to acceptable levels for municipal sewer discharge. Bilge wastes are normally the primary influent (both in volume and contaminant concentration) to an oily waste treatment system. Occasionally, compensating ballast water is discharged from ships and barges directly overboard. As of this writing, Puget Sound, Washington, activities are required by the local regulatory agencies to collect compensating ballast water during ship's refueling operations. This waste contains lower contaminant levels than bilge wastes but usually requires treatment before disposal. Lastly, the designer should refer to the Naval Facilities Engineering Service Center's (NFESC), *Bilge and Oily Wastewater Treatment System* as an alternative system for pollution prevention. Every project must be evaluated on a project-by-project basis. The designer must consult with the cognizant Service, the Activity, and the responsible Environmental Engineers, both at the local level and at the cognizant Service level.

Figure 3-8 Ship-to-Shore Oily Waste Hose Connection



3-6.2 Ship Oily Waste Generation.

Collection may take the form of transfer systems to trucks or barges, or a facility pipeline system. Coordinate with environmental requirements to provide an environmentally acceptable collection system with the most economical life cycle cost.

3-6.2.1 Oil Content.

Primary sources of ship-generated oily wastewater are bilges, oily waste holding tanks for collecting lubricating oils and water contaminated fuel, condensate lines, and tank cleaning water. Sonar dome pumping water is not normally collected as part of the oily waste collection system. The oil content in the bilge water normally varies from 100 ppm (0.01%) to 10,000 ppm (1.0%). The rest is mostly saltwater of unknown chloride content. The oil content of ship discharges overboard is limited to 20 ppm or less within 12 nautical miles of the nearest land. In ports that restrict the direct discharge of ballast water, the ballast water can be discharged from most ships (other than tankers) through a large diameter piping system to a ship waste oily barge (SWOB) or a YON Fuel Oil Barge. Compensating ballast water can also be discharged directly to a pier collection system provided the liquid can discharged by gravity flow (from ship to pier connection) and the back pressure can be kept to a minimum. The Navy policy on classification of oily wastewater is that the oily waste and waste oil (OWWO) become a waste only upon removal from the ship. In general, bilge water should be treated like any other waste.

3-6.3 Pumping Equipment.

Provide basket or bar type screens on a pump inlet that can be easily removed and cleaned from an easily accessible and safe location.

Determine pump capacity and operating cycle. In order to reduce mechanical formation of emulsion at oily waste treatment plants, use positive displacement pumps (in lieu of centrifugal pumps) with pressure relief valves. Pumps should pass solids having a diameter 0.125 inch (3 mm).

Provide controls suitable for Class I, Division 1, Group D hazardous classification. Use float or sonic type level controllers for pump control and alarm. Air bubbler type controllers must not be used. Provide a discharge pump control valve to minimize surge effects on equalization basins located at oily waste treatment plants. (This requirement is not applicable for positive displacement pumps.) Provide an alarm system for overflow or power failure. Provide manual override of automatic pump controllers. Low-level alarm conditions must lock out all pumps and must require manual resetting.

3-6.4 Piping Systems.

Piping requirements are similar to requirements for sewage systems. See Section 3-7 entitled “Sewage Systems” and the associated subparagraphs. Piping material is typically galvanized steel. However, some local environmental regulations require double-wall piping systems. Consult with the Activity and the cognizant Service.

Provide pipe hangers and associated support assemblies in accordance with Section 2-4.1.4 entitled “Hangers and Support Assemblies”. Identify oily waste outlets on piers and wharves and color-code in accordance with Chapter 6.

3-6.5 Metering.

Unless instructed otherwise, specify the following to monitor the system: (1) accumulating flow meter; (2) elapsed time meter for pumps and ventilator; and (3) pump suction and discharge pressure gages. Provide gages with oil-filled diaphragm and cutoff valves. Consult with the cognizant Service for any additional requirements. See Section 2-5 entitled “Metering” in CHAPTER 2 for additional metering requirements.

3-6.6 Submarine Pier Requirements.

Submarine piers/berths require an OWWO collection system. Provide a permanently installed OWWO system at submarine piers/berths.

Where not feasible or practical to provide a permanently installed OWWO utility system, a suitable solution that limits operational impacts must be developed and fully vetted through the various stakeholders to meet this utility requirement. Project team must document the variation in providing the utility, alternatives, mitigation measures, and resolution.

Preferred option is a permanently installed system connected to an on-base collection system. But, this requires a base treatment or collection and transfer facility. A less preferred option is permanently installed piping with connections for tanker truck transfer. But, this may infringe on deck and shoreside space. The least preferred option is to provide OWWO collection directly from pier to a tanker truck, but tanker truck and hoses will take up deck space and interfere with operations.

3-7 SEWAGE SYSTEMS.

3-7.1 Introduction.

Design information on wastewater collection and transmission systems is extensively covered in Water Environment Federation (WEF) MOP FD-5, *Gravity Sanitary Sewer Design and Construction*. This section addresses two wastewater collection and transmission topics that are not addressed in WEF MOP FD-5: (1) pier and wharf facilities; and (2) dry dock facilities.

3-7.2 Specialized Shipboard Sewage Characteristics and Parameters.

Designing sewage collection systems for shipboard wastewater requires special and unique conditions that the designer must take into account. All of these special issues must be addressed and resolved.

3-7.2.1 Characteristics of Ship Holding Tank Discharges.

Ship holding tank discharges can be a major source of wastewater. These wastewaters have the following general characteristics.

- A ship's wastewater is primarily domestic wastewater but may also contain industrial wastewater depending on the ship operations.
- A ship's wastewater is more concentrated than typical domestic wastewater, a result of specific design features of the ship's wastewater collection systems.
- A ship's wastewater may contain high concentrations of dissolved solids, chloride, sulfates, and sodium if seawater flushing or ballast systems are used.

3-7.2.2 Ship Discharge Values.

APPENDIX A defines the maximum sewage discharge values of a ship's complement, daily flow, maximum discharge, number of pumping stations, total number of pumps, and number and location of discharge connections. Where destroyers or submarines are nested next to a tender berthed at a pier, the nested ships will discharge into the tender. The tender will then discharge to the pier's sewage collection system at the rate listed for the tender. For nested ships, it is suggested to provide a pressure manifold to reduce peak demand flow.

3-7.2.3 Flow Rate Variations.

Domestic wastewater flows at piers, wharves, and dry docks can be expected to exhibit seasonal and other weather-influenced flow variations. In addition, the effect of industrial and ship discharge flows as well as the variable nature of military operations may significantly affect flow variations. To minimize flow variations, flow equalization should be considered. Equalization can be applied to specific flows (such as industrial flows or other specialized flow types) that exhibit wide variations to the entire wastewater flow. When calculating flows, consider the following.

- Industrial flows, such as vehicle and aircraft wash facilities. If these flows coincide with peak domestic flows, then they should be added to the peak flows.
- Ship holding tank discharge flows. Flow rates will depend on the total volume of flow and the time required to convey the wastewater to the treatment facility. Design equalization systems to equalize the flows in order to minimize their effects on peak flows. Consider conveying the ship wastewaters to the treatment facility at night when domestic flows are low.
- Intermittent flows due to military functions. Periods of increased sewage flows will occur because of training activities or other personnel mobilization exercises common to military installations. Training activities

or other mobilization exercises will create short-term increases in domestic wastewater and possibly industrial flows. These intermittent activities may create the peak wastewater flow rate. Design the sewage collection system to handle routine variations in flow resulting from training and other routine military exercises. The design must ensure acceptable performance with reasonable operational costs. (For example, an equalization system may provide flow and load dampening to accommodate these significant variations.) However, do not design facilities to accommodate peak surges resulting from emergency military mobilizations.

- Intermittent periods of reduced use. Low flows can also be a problem. Therefore, design the wastewater facility to operate efficiently over a range of flows. (For example, provide parallel trains that can be taken out of service.)
- Changes in requirements or military mission. Designs should include provisions for the system's expansion and contraction as well as system modifications due to more stringent effluent requirements or military mission changes. In general, maximize operational flexibility.

3-7.2.4 Wastewater Loadings.

Wastewater loadings are typically calculated based on the projected flows and wastewater pollutant concentrations and are expressed in pounds per day (lb/d) (kilograms per day (kg/d)). Where possible, determine loadings by analyzing the wastewater to be treated. Consult with the Activity and the cognizant Service to obtain collected data and specific instructions.

3-7.2.5 Ship Sewage.

Ship sewage settles well and is amenable to biological treatment, but it may be septic. Table 3-4, "Typical Ship Sewage Concentrations", define typical concentration values. Wastes from shipboard industrial activities are not included. High dissolved solids, chloride, sulfates, and sodium concentrations apply when seawater flushing or ballast systems are used. For more information on ship sewage, refer to *NAVSEA S9086-AB-ROM-010, Naval Ship's Technical Manual (NSTM), Chapter 593, Pollution Control*.

3-7.2.6 Effect of Wastewaters with High Seawater Content.

- <u>Performance:</u> High concentrations of seawater tend to inhibit biological treatment. Process inhibition is related to the chloride concentration of the wastewater.
    - o For new designs: Currently, there is an absence of pilot plant data or treatment data from similar wastewaters. Consequently, compensate for high seawater content according to the data presented in Table 3-4.

- In analyzing the capacity of existing treatment facilities to receive ship's wastewater, use figures defined in Table 3-5. If these indicate overloading solely because of chloride inhibition, conduct pilot plant tests before planning any expansion. Consult with the Activity and the cognizant Service for instructions.
- Sudden changes in chloride concentration may upset biological processes. Consider equalization storage to limit chloride variation at the wastewater facility. For chloride concentrations in excess of 5,000 mg/L, provide design limitations of 200 mg/L/h.

- Maintenance: High seawater content in wastewater will aggravate incrustation problems. Avoid fine bubble air diffusion systems and design orifices to facilitate periodic cleaning of mineral deposits. This is especially applicable to orifices in trickling filter flow distributors or in aeration devices. Use care in selecting construction and equipment materials.

Table 3-4 Typical Ship Sewage Concentrations

Characteristic	Concentration (mg/L)
Total suspended solids	600
Total dissolved solids	20,000
Chlorides	11,000
Sulfates	1,500
Sodium	6,200
Other dissolved solids	1,300
Biochemical oxygen demand (BOD)	400

Table 3-5 Chloride Inhibition of Biological Nitrification

Process	Maximum Chloride Concentration for No Inhibition (mg/L)	Concentration for Chlorides in Excess of Maximum Level [a]
Trickling filters and rotating biological contactors	5,000	Referring to appropriate design loading curve, decrease loading an amount corresponding to one percentage point of removal efficiency per 1,000 mg/L of chlorides in excess of 5,000 mg/L
Activated sludge	5,000	Decrease loading by 2% per 1,000 mg/L chlorides in excess of 5,000 mg/L
Aerobic and facultative lagoons	8,000	Increase detention time by 2% per 1,000 mg/L chlorides in excess of 8,000 mg/L

Note:

[a] Highest average chloride concentration expected over 24 hours.

3-7.3 Pier and Wharf Systems.

Provide a permanently installed sewage collection system at all active berths. Design the ship sewage collection system for the peak flow from the maximum planned berthing with sewer flowing full. Base the design on maximum discharge of ship pumps. Provide a gravity flow system unless approved otherwise.

3-7.3.1 Layout/Location.

See Figure 3-9. Provide a single (1) 4 inch (102 mm) pressure rated manifold assembly at each berth. Each manifold assembly should have four (4) single (1) 4 inch (102 mm) diameter pressure sewer connectors. This layout has the following advantages:

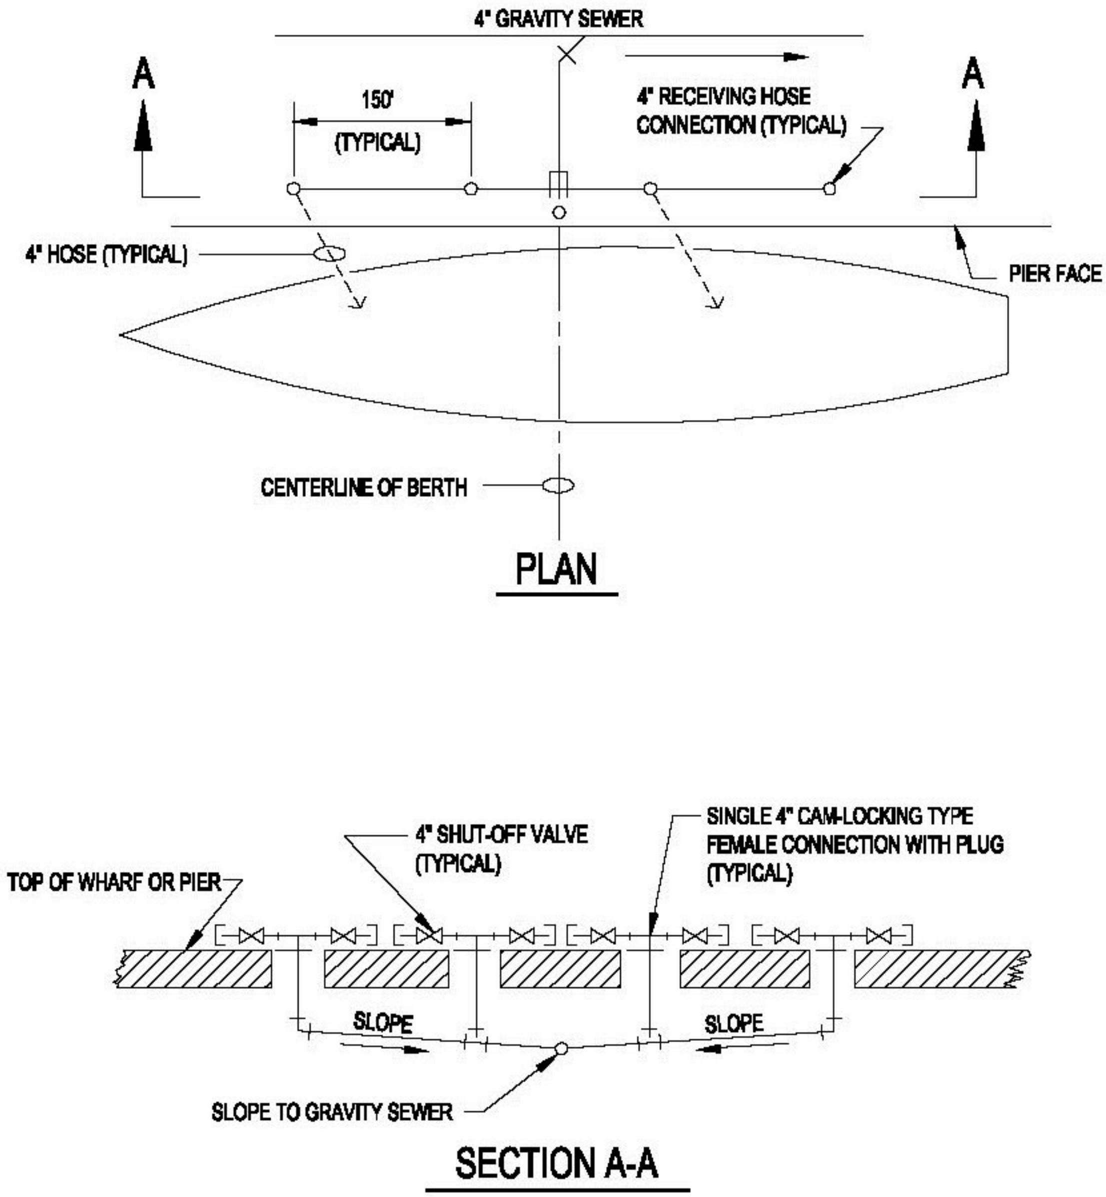
- It provides large reduction in peak flows by combining multiple discharges from a ship (or nested ships) into a single stream, thereby increasing the head on the ship's pumps.
- By reducing peak flow, it allows berthing of other ship types included in the berthing plan.
- It is self-regulating and self-cleaning plus avoids failure or maintenance problems inherent in regulating valves or other similar devices.

3-7.3.2 Additional Requirements.

See Figure 3-10 for typical collection sewer layouts on different pier types. Properly isolate each berthing space in order to prevent pumping from one berth into another and to allow ships with lower head pumps to discharge into the pier sewer.

Isolate the berths by providing one separate manifold assembly at each berth and then connect the manifold assembly directly to the pier's gravity sewer system. Where the berthing space is less than 600 ft (183 m), the number of manifold assemblies should be reduced to fit the space available. In such cases, it may be necessary to reduce the 150 ft (46 m) spacing between the assemblies. For carrier berths, two (2) standard manifold assemblies each with four (4) 4 inch (102 mm) outlet connectors should be provided.

Figure 3-9 Pressure Manifold Schematic for Pier and Wharf Systems



NOTE: DESIGN RECEIVING HOSE CONNECTIONS FOR 3000LB PULL IN ANY DIRECTION.

Figure 3-10 (a) Sewer Layout for Alternative Pier Types (1 of 2)

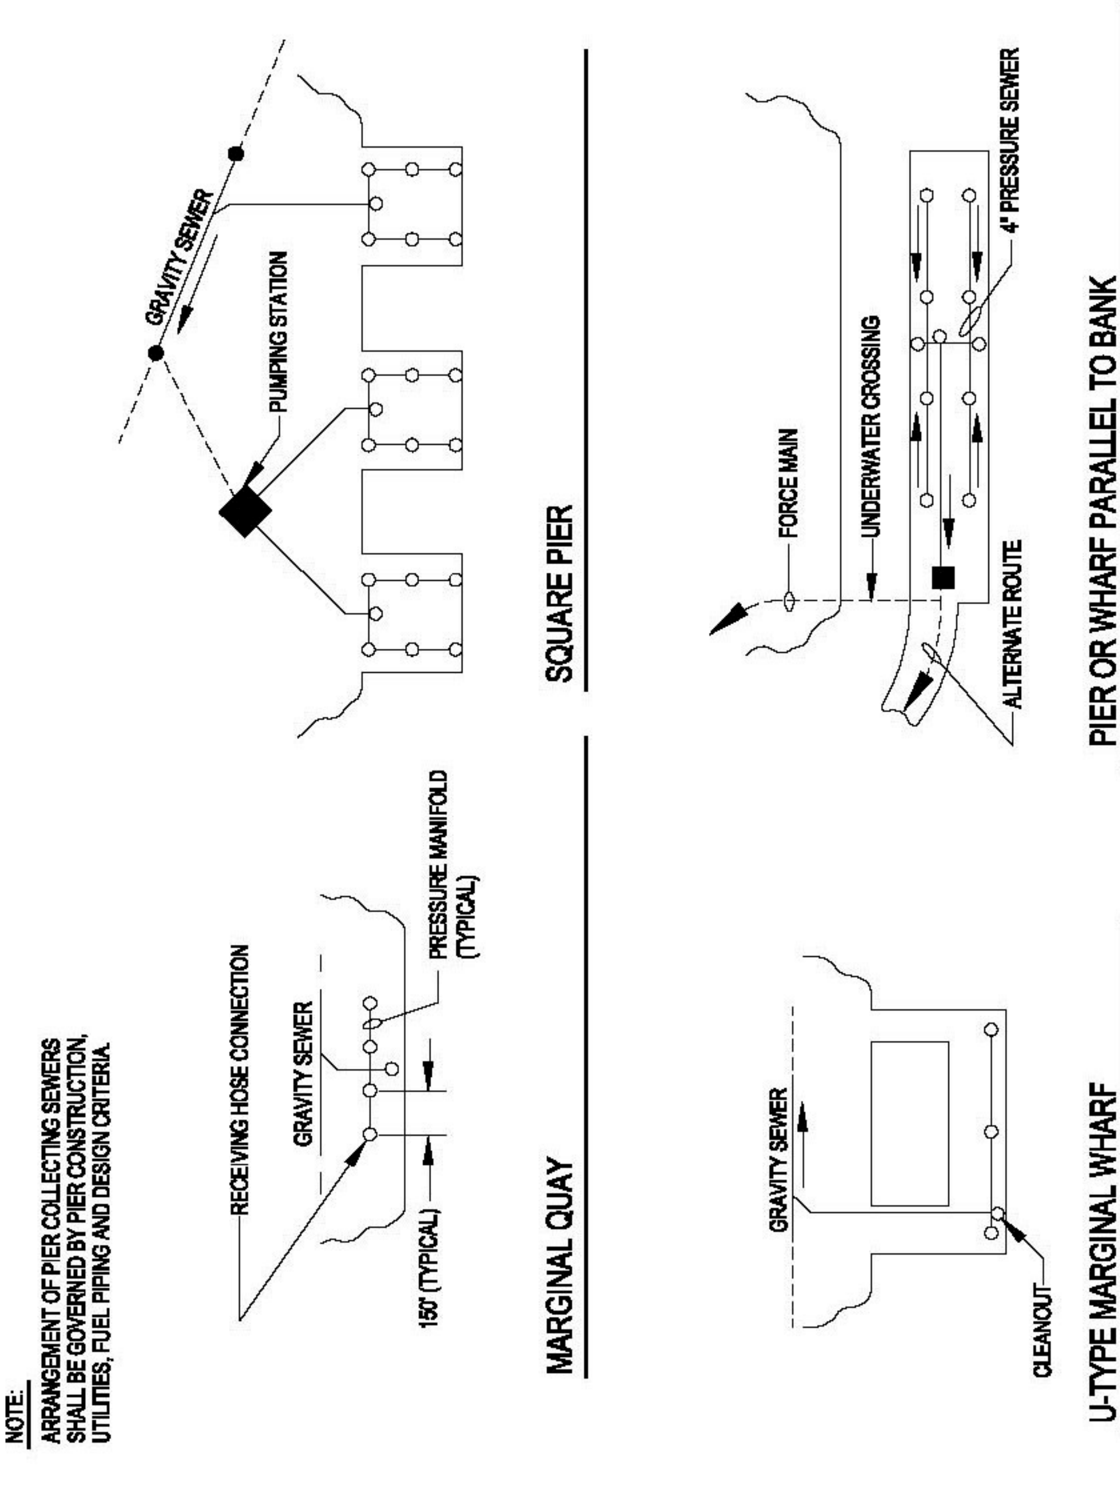


Figure 3-10 (b) Sewer Layout for Alternative Pier Types (2 of 2)

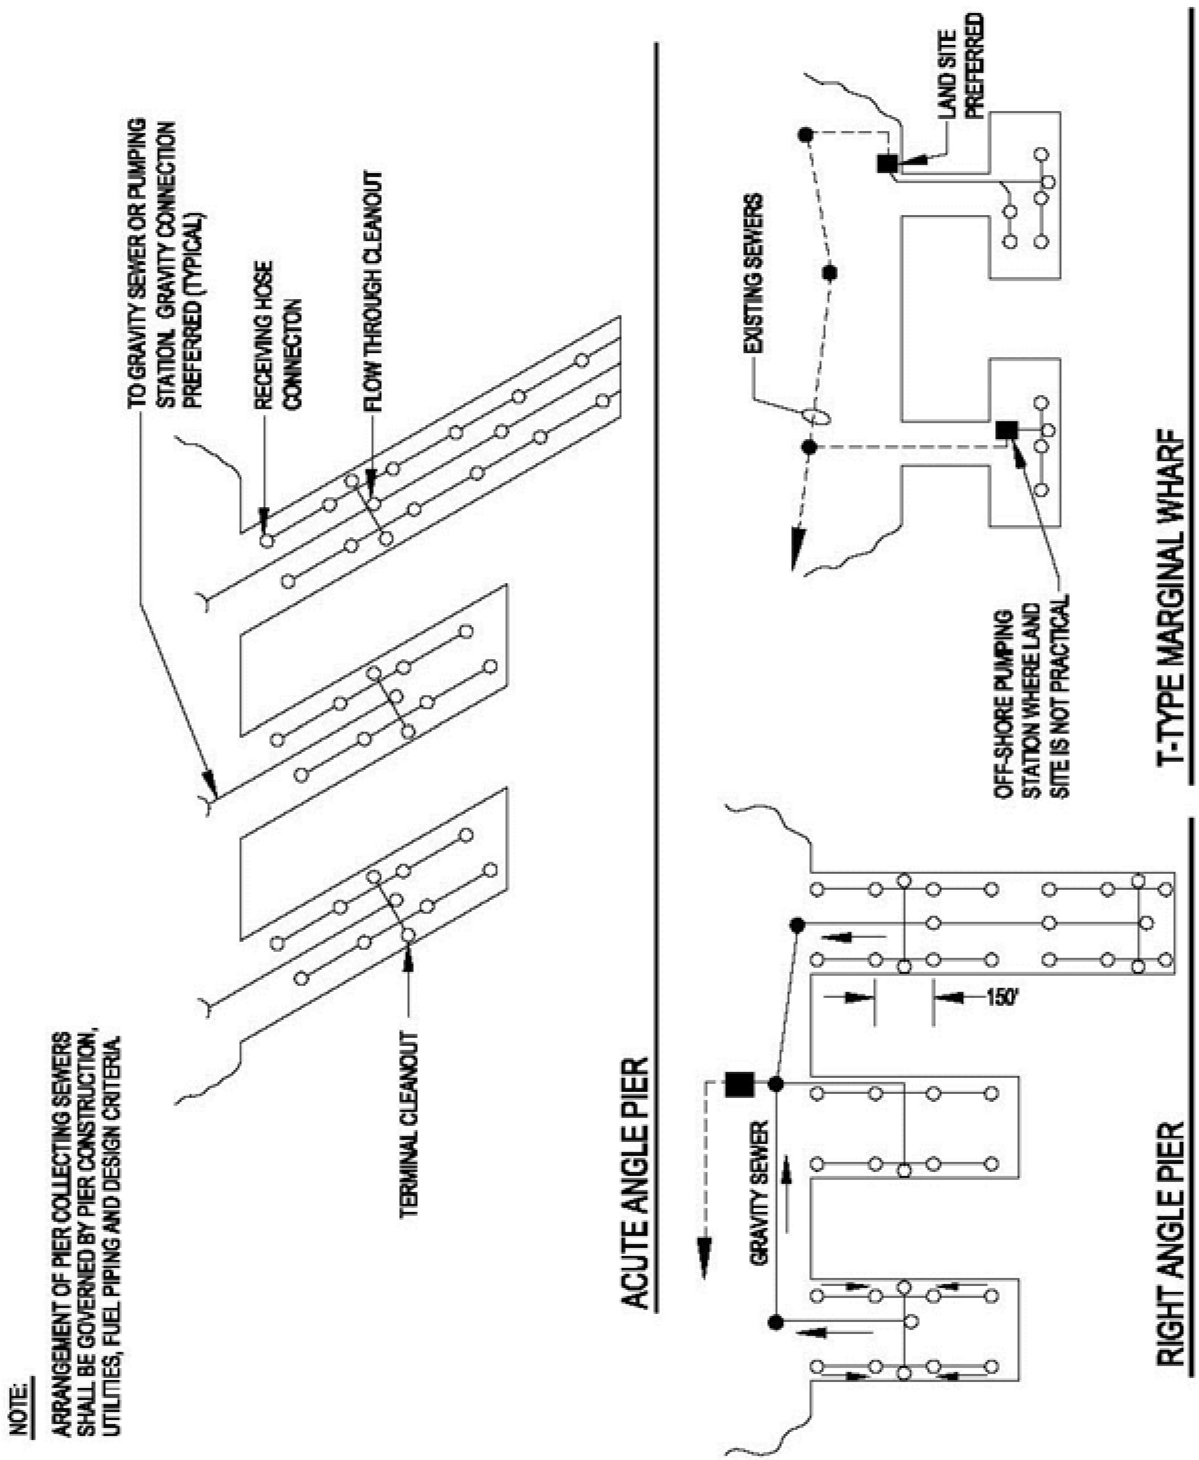

3-7.3.3 Location Details.

See Figure 3-11 and Figure 3-12 for typical installation on piers and quay walls. Locate all collecting sewers behind the permanent wharf or pier construction and away from the fender systems. Locate pump stations off the pier and behind the bulkhead lines. If location along the pier deck is required, then do not restrict working area on the pier. Lines behind wharves should always be buried. For design of new piers and quay walls, consider locating sewers in utility tunnels. This arrangement will reduce external corrosion and improved maintainability of the sewer lines, and thus may offset higher construction costs.

3-7.3.4 Environmental Considerations (Corrosion and Freeze Protection).

- Evaluate paint and finish requirements. See Section 2-6 entitled “Paint and Finish Requirements”. For ship to shore sewer connections (including ductile iron sewer pipe and all exposed metal such as steel support members, gratings, angles, pipe support hangers, fastening devices, and other appurtenances) it is generally recommended to provide a two coat, coal tar epoxy coating, conforming to Steel Structures Painting Council (SSPC) Paint No. 16. Specify a total dry film thickness of 16 mils (0.4 mm) minimum.
- Evaluate freeze protection requirements. See Figure 3-13. Pipes installed under piers or wharves in any geographic location must be protected from wave action and floating objects. Provide protective jacketing of the insulation using aluminum, stainless steel, or coal tar epoxy coated steel where freeze protection is required. Provide structural protection for the entire length of pipe run in addition to jacketing. Use steel cage of fabricated shapes or consider the use of a catwalk system that would provide both access and piping protection. Specialized freeze protection features are defined in CHAPTER 5.

3-7.3.5 Odor/Septicity Control.

Slope sewer pipes as much as possible to minimize detention time. Provide aeration in accordance with sound engineering practices. Holding tanks must be aerated unless detention time is less than 3 hours at average 24-hour flow. Keep force mains as short as possible and avoid sulfide generation. Control sulfide generation by using an injection of oxidizing chemicals such as chlorine, permanganate, or hydrogen peroxide. Consult suppliers of chemicals feed equipment regarding costs and expected performance. Refer to WEF MOP FD 5, Gravity Sanitary Sewer Design and Construction, for rational methods to predict sulfide generation rates and methods of control. Maintain minimum flow velocity of 3 ft/s (0.9 m/s). Provide cleanouts and air relief valves at strategic and accessible locations. Provide check valves at pump stations.

NOTE:

FOR TERMINAL CLEANOUT USE 90° ELBOW IN PLACE OF LATERAL.

Figure 3-13 (a) Piping Details for Sewage Collection Facilities (1 of 2)

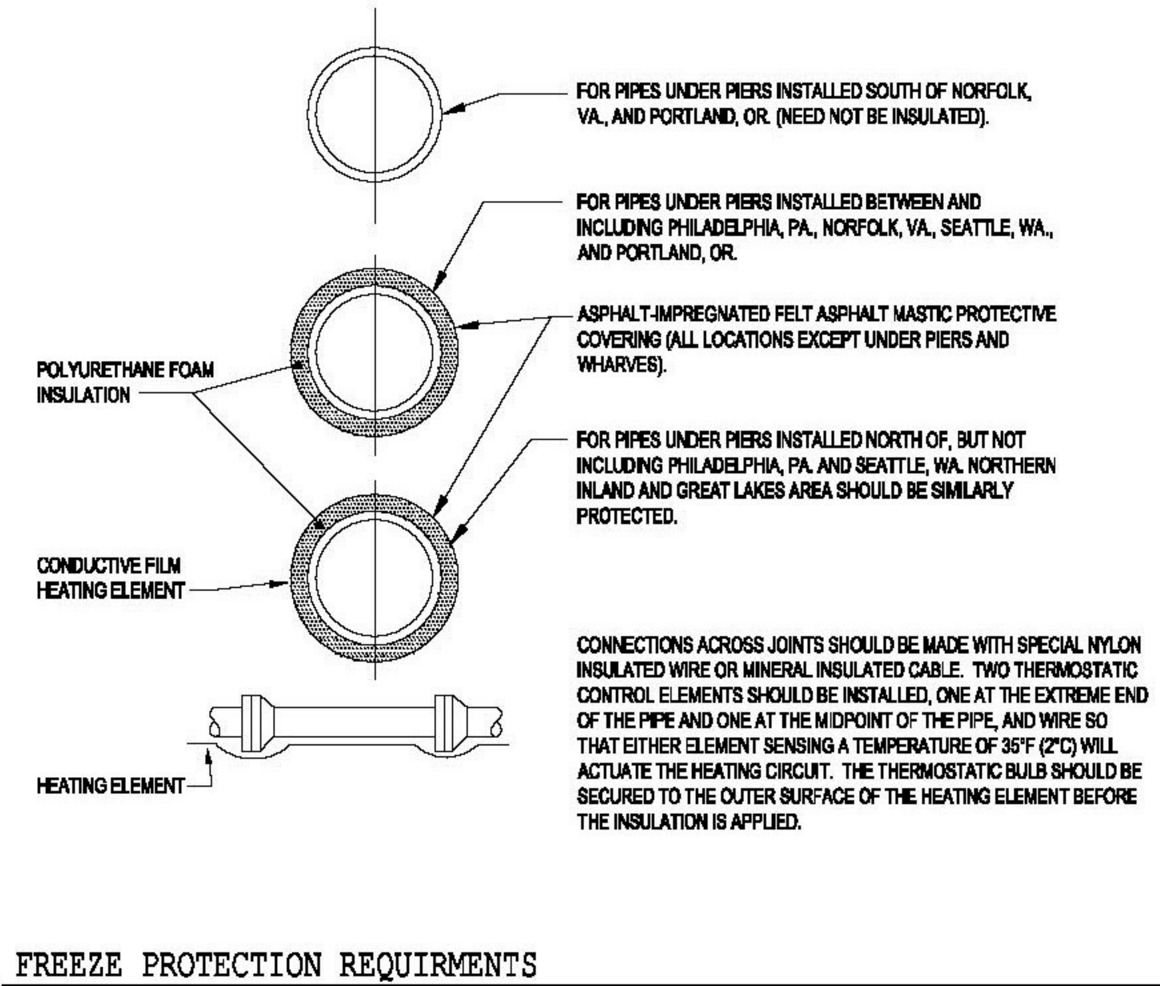

Figure 3-13 (b) Piping Details for Sewage Collection Facilities (2 of 2)

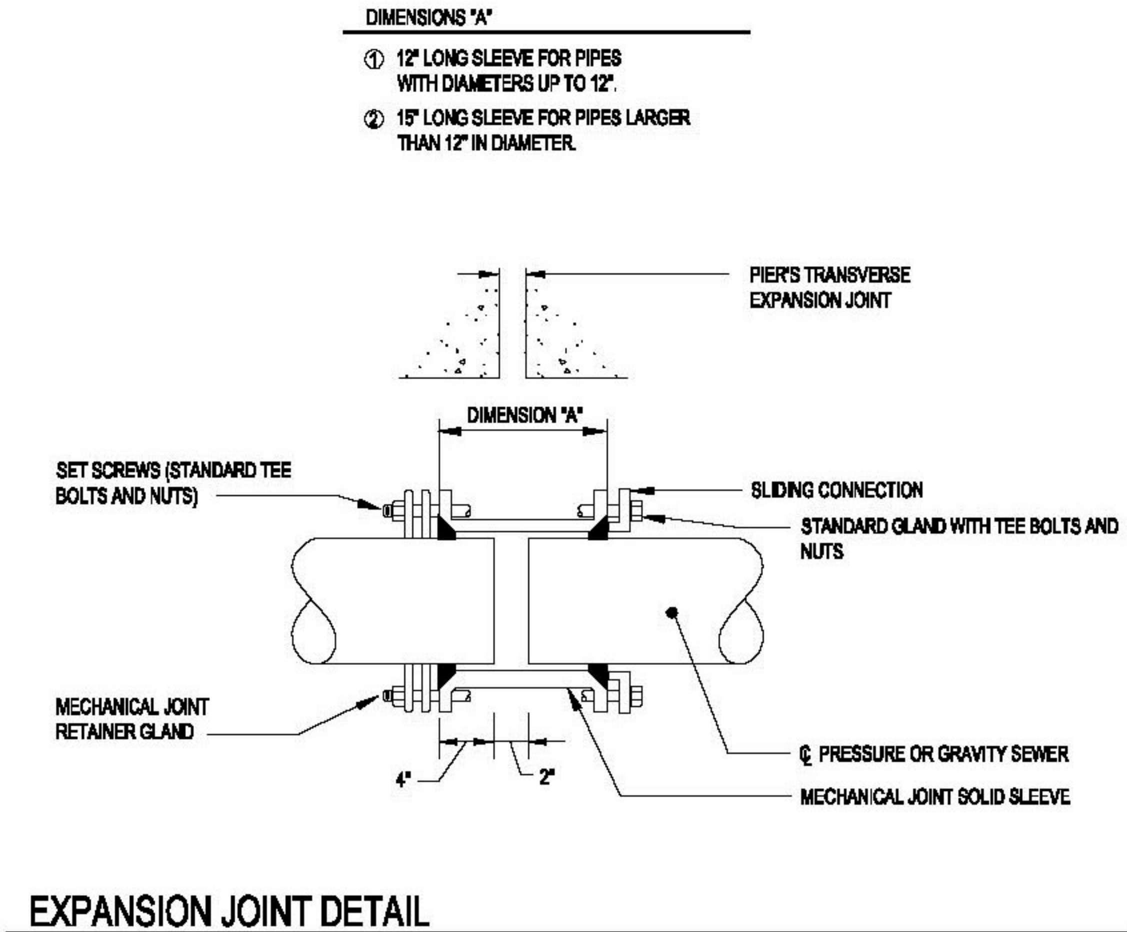

3-7.3.6 Structures and Appurtenances.

Some sewer structures and appurtenances have already been defined in Figure 3-11, Figure 3-12, and Figure 3-13. Additional features are defined in Figure 3-14, and Figure 3-15. Also, see Table 3-6.

3-7.3.7 Pump Stations.

The design of sewage pump stations at waterfront facilities requires the careful consideration of all associated parameters including the premium value of real estate. The system must account for all ship flows and the connection to the station's central sewage distribution system. Careful coordination is required with the Activity and the cognizant Service. It is imperative to provide a properly operational system at minimum construction cost and operational cost while optimizing the use of waterfront property.

3-7.3.8 Pipe.

A variety of pipe materials may be acceptable to specify and will vary on a pier-by-pier basis. Consult with the Activity and the cognizant Service for the final material selection. In general, PVC pipe may be used for gravity systems. Ductile iron pipe is preferred for pressurized systems. However, PVC pipe and HDPE pipe has been specified for pressurized systems at some pier facilities. Lined ductile iron with mechanical joints should be used for exposed locations and where high impact resistance is important. Support exposed pipe in accordance with manufacturer’s recommendations. In other exposed locations where corrosion resistance is a major concern, consider specifying thermoplastic (high density polyethylene) pressure pipe with butt fusion joints. Plastic piping on pier and wharf systems should be protected from impact by floating debris and other hazards. In these cases, consider a specially designed utility trench. For buried lines, apply general sewer pipe selection guidelines.

Figure 3-14 Ship-to-Shore Sewage Hose Components

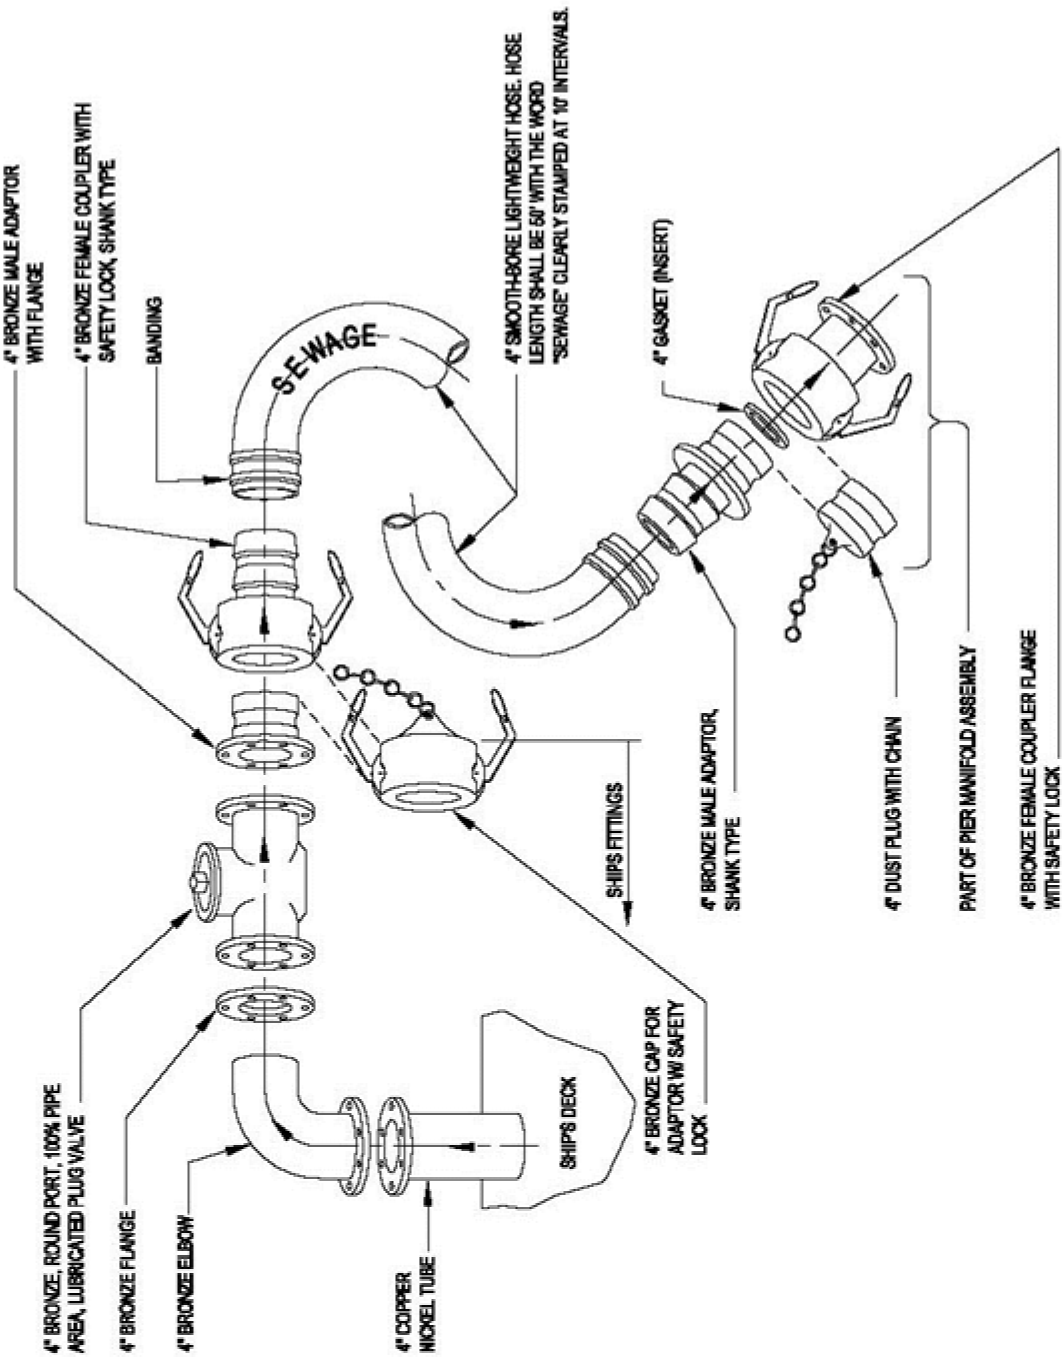

Figure 3-15 Above Pier Hose Connection

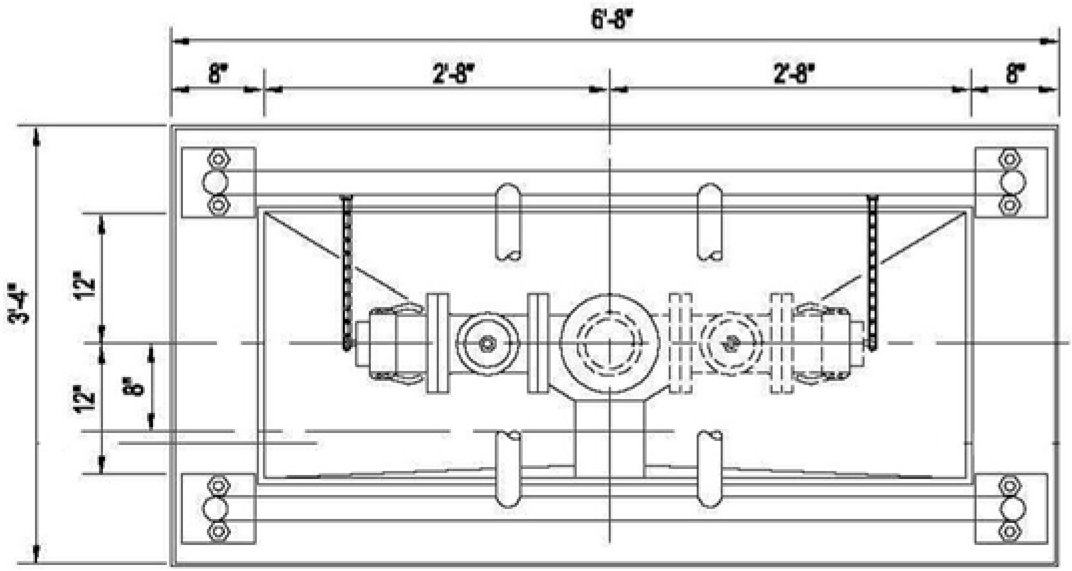

Table 3-6 Special Pier Structures and Appurtenances

Structure or Appurtenance	Where To Use	Details	Requirements
In-line Cleanout	Note 1	See Figure 3-12	
Regular Manhole	Note 2	Refer to UFGS 33 30 00, *Sanitary Sewerage*	Note 3
Drop Manhole	Note 4	Refer to UFGS 33 30 00, *Sanitary Sewerage*	Note 5
Siphons	Note 6	Note 7	Note 8
Intercepting Sewers	Note 9		Note 10
Traps and Interceptors	Note 11	Note 12	
Terminal Cleanout	Note 13	See Figure 3-12	Note 14
Receiving Hose Connections		See Figure 3-14 & Figure 3-15	Note 15
Sewer Pipe Supports	Note 16	See Figure 3-11 & Figure 3-13	

Note:

1. Use in-line cleanout at junctions and changes of direction and when required according to spacing shown in details under regular manhole below.
2. Use regular manhole: terminally on all lines; at all junctions and changes of direction; at changes in invert elevation or slope. Otherwise, according to spacing shown below:

Pipe Size inch (mm)	Maximum Spacing ft (m)
18 (450) or less	400 (120)
18-48 (450-1200)	500 (150)
48 (1200) and greater	600 (180)

3. Requirements for regular manholes: lower invert through manhole a distance equal to expected loss of head in manhole, plus 0.8 times any change in sewer size. For junction manholes, check which upstream invert is critical in determining outlet invert. Raise top of manhole above possible flooding level.
4. Use drop manhole when difference between inlet and outlet inverts exceed 2 ft (0.6 m).
5. Requirements for drop manholes: for difference less than 2 ft (0.6 m), increase upstream sewer slope to eliminate drop.
6. Use siphons for carrying sewers under obstructions or waterways.
7. For siphons: maintain velocity of 3 fps (0.9 m/s). Use no less than two barrels with minimum pipe size of 6 inches (150 mm). Provide for convenient flushing and maintenance.
8. Requirements for siphons: use WEF MOP FD-5 for hydraulic design.
9. Use intercepting sewers where discharge of existing sewers must be brought to a new concentration point.

10. Requirements for intercepting sewers: take special care against infiltration due to depth or proximity of surface water.
11. Use traps and interceptors on all outlets from subsistence buildings, garages, mechanical shops, wash pits, and other points where grease or oil can enter the system.
12. For traps and interceptors: use a displacement velocity of 0.05 fps (0.015 m/s). Grease removal: in absence of other data use 300 to 400 mg/L. Provide for storage of 1 week's grease production (1 day if continuous removal is provided). Length = twice depth.
13. Use terminal cleanouts terminally on all pier collection systems.
14. Requirements for terminal cleanouts: locate where it will not interfere with other operations on the pier or other utilities.
15. Requirements for receiving hose connections: design connections to receive the discharge from ships.
16. Properly support all sewer pipes, especially pipes located under the pier. See Section 2-4.1.3 entitled “Hangers and Support Assemblies”.

3-7.3.9 Sewage Transfer Hoses.

See Figure 3-14 and Figure 3-15. Provide a washing facility for washing the end couplings and the exterior of the hose. The facility should include hot potable water and a standard stock detergent. Hose washing/storage facilities must be designed so that manual lifting or pulling of hoses is minimized through the use of mechanical devices and/or arrangement of the area. Caps for each end of the hose should be provided and installed after washing. The clean hose should be stored in drying racks.   For further information, refer to NAVFAC MO-340, *Ship-to-Shore Hose Handling Operations Manual*.

3-7.4 Dry Dock Facilities.

For dry dock facilities, design the sewage collection system for the maximum planned docking pattern and the designed peak flow conditions. Consider the following when designing dry dock collection systems.

- Separation of hydrostatic leakage from dry dock wastewater: The dry dock wastewater is generally not contaminated and can be discharged directly to storm sewers or open water depending on regulatory conditions.
- Separation of ship's domestic wastes from the industrial wastes generated by dry dock activities: These industrial wastes include leakage, precipitation runoff, and washdown that carries sandblasting residue and paint.

3-7.4.2 Layout.

Ships fitted with collection-holding-transfer (CHT) should be connected to dockside sanitary sewers for CHT discharge. Ships without CHT should use scuppers and manifold connections to the ship's discharge points and then transfer to the sanitary sewer system. See Figure 3-16 for typical collection system layouts in dry dock facilities.

3-7.4.3 Pump Station Features.

Make capacity equal to that of maximum combined ship's discharge rate of ships in dry dock. Furnish portable auxiliary pumping facilities when required. Refer to UFC 4-213-10.

3-7.4.4 Sewage Receiving Connections and Transfer Hoses.

See Figure 3-17 for underground dry dock receiving hose connections. Figure 3-15 is also applicable for aboveground dry dock receiving hose connections. Aboveground receiving hose connections should be used whenever possible. See Section 3-7.3.9 entitled "Sewage Transfer Hoses" regarding transfer hoses.

3-7.4.5 Special Structures and Appurtenances.

See Figure 3-16 for typical cleanout locations for dry dock sewers. Locate cleanouts in main sewer at a maximum spacing of 300 ft (91 m).

Figure 3-16 (a) Typical Sewage System Layouts for Dry Dock Facilities (1 of 2)

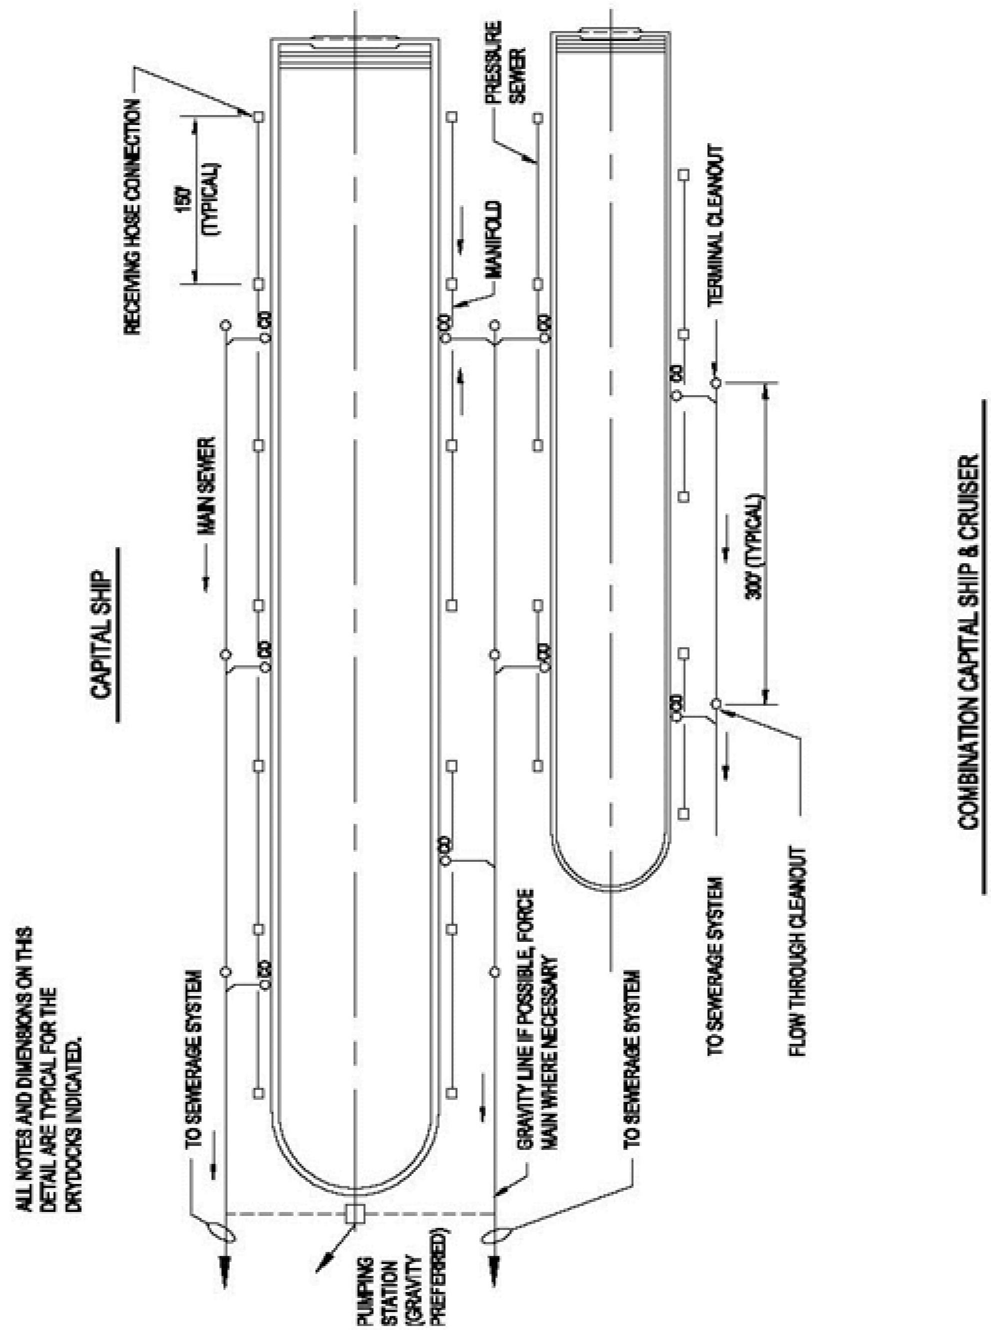

Figure 3-17 (a) Underground Hose Connection (1 of 2)

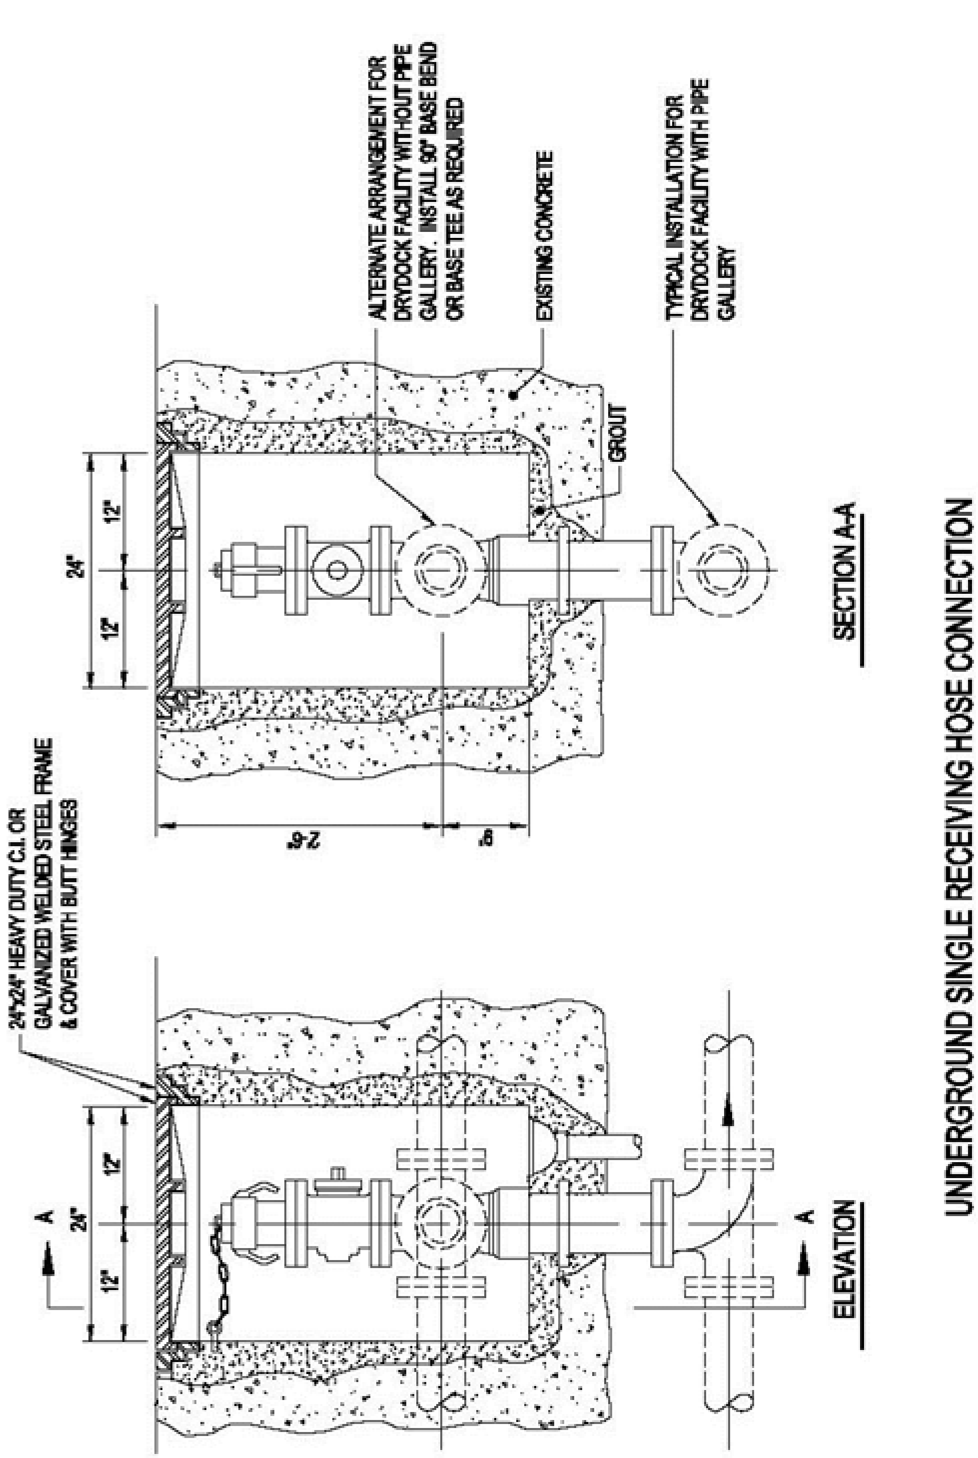

Figure 3-17 (b) Underground Hose Connection (2 of 2)

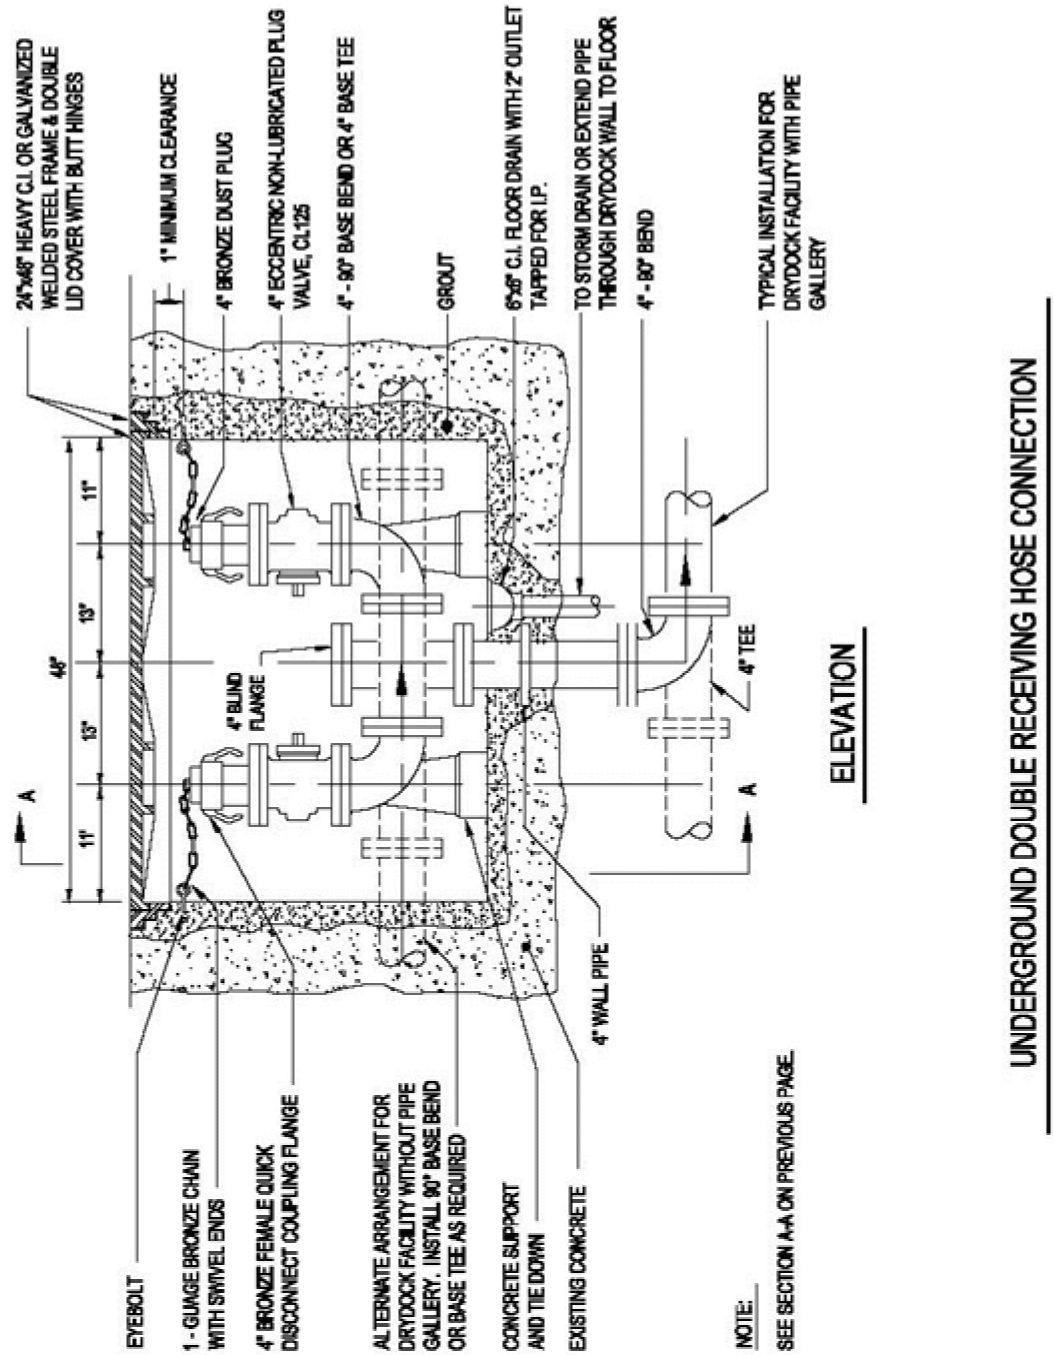


3-8 ELECTRICAL SYSTEMS.

Electrical power is required on piers, wharves, and at dry docks for ships services. This includes hotel service (shore-to-ship power), ship repair (industrial power), ships systems testing, pier weight-handling equipment, cathodic protection systems, pier lighting, and miscellaneous pier electrical systems. Materials and installation must conform to the requirements given in UFC 3-501-01, *Electrical Engineering*, and in NFPA 70, *National Electrical Code*. For dry docks, refer to additional criteria in UFC 4-213-10. Utility data and specialized technical data is available in APPENDIX A or it may be obtained directly from the cognizant Service. In addition to the design criteria provided in this particular section, operation and maintenance guidance for electrical systems is provided in APPENDIX C.

3-8.1 Types of Electrical Services.

Design electrical services for piers, wharves, and dry docks for one of the two types of service listed below, as directed by the cognizant Service.

3-8.1.1 Permanent Service.

At naval stations, shipyards, repair piers, dry docks, and other continuously occupied waterfront facilities, provide electrical substations and associated facilities to accommodate the normal, maximum electrical demand load. The design may include the use of portable substations. The electrical design must include: (1) ships power requirements (hotel services) on a dedicated un-grounded power system; and (2) other facility loads on a separate grounded power system that includes loads such as lighting, weight-handling equipment, cranes, pumps, general utilization power, and the industrial power system (dedicated for ship's repair work while berthed) when required. There are three basic types of substation installations: (1) the substation is installed on the lower deck of a double-deck pier; (2) the substation is installed on the pier deck of a single-deck pier or at grade level adjacent to the pier or associated waterfront facility, and (3) the substation is installed in an electrical vault located below the pier deck. The vault system has been used on many existing piers, however it is not recommended for new installations and requires approval of the cognizant Service. See APPENDIX C and Section 3-8.4.1 entitled "Substations" for additional information.

3-8.1.2 Temporary Service.

Provide temporary electrical service at waterfront facilities not continuously occupied, or at any facility where a substantial portion of the peak load will be occasional or intermittent. Provide primary feeders and high voltage outlet assemblies (5 kV and 15 kV) for connections to portable substations. Examples of high temporary loads include: (1) power for testing certain ships weapons systems; and (2) power for testing ships plant nuclear systems. That portion of the load serving basic pier, wharf, or dry dock functions (lighting, weight-handling equipment, and receptacles not related to ship service or repair service) must be fed from the permanent service.

3-8.2 Primary Power System.

The primary distribution system on the pier or other waterfront facility normally operates in the medium-voltage range between 5 kV and 35 kV and will depend upon the shore-side utility voltage(s) available. The shore-side utility system is normally already in existence. It may have to be expanded or upgraded to support a new or increased capacity pier, but will rarely require a completely new electrical utility service point. Upgrades to the system should provide the pier with a dedicated normal circuit and provisions for switching to a backup circuit. The Activity is responsible for providing justification for alternate primary feeders and standby power services required for essential operations. Special electrical primary systems may be required for certain classes of ships. These specific requirements are included in APPENDIX A. Provide selective coordination between system equipment components to ensure minimized downtime of ships systems due to external or internal electrical system faults. Refer to UFC 3-501-01, *Electrical Engineering*, for a description of the different types of distribution systems.

3-8.2.1 Pier, Wharf, or Dry Dock Primary Systems.

For permanent service, provide dual primary feeders from the shore primary system to the switching stations or substations serving the ships' hotel services and industrial loads. For temporary service, provide dual primary feeders from the shore primary system to strategic locations that serve portable substations. Conduits, ductbanks, and manholes cast integrally with the pier structure are preferred for new piers. Conduits on piers may also be installed in dedicated electrical trenches or in piping trenches that serve other utilities, or hung from above on double deck piers. To avoid damage to the conductor's insulation, electrical conduits should not be placed in close proximity to high temperature systems such as steam piping. Refer to CHAPTER 2 for general protection requirements.

3-8.3 Secondary Power Systems.

The secondary electrical distribution system is evolving to higher voltages as the power demand on the ships continues to increase. It must be designed with the flexibility to serve the various classes and categories of ships that are anticipated to utilize the facility.

3-8.3.1 Ships Power.

Historically, the electrical system providing power for most ships has been a dedicated 480 V (nominal), three-phase, 60 Hz, ungrounded system. This system has been supplied from substations located on piers (or at the head of the pier for shorter piers), and connected through dedicated receptacles located at the perimeter of the pier, wharf, or dry dock. Currently, 4,160 V (nominal), three-phase, three-wires, 60 Hz power is required for nuclear aircraft carriers (CVN 68 class and higher). These carriers are sometimes capable of accepting 480 V power as well. Future classes of ships (surface combatants and amphibious assault) will require 4,160 V (nominal), three-phase, three-wires, 60 Hz power. CVN 78 class ships will require 13,800 V (nominal), three phase, three wires, 60 Hz power. The pier electrical distribution system must be designed to limit the fault current contribution from the shore power, at the ship's bus, to 100,000 A (rms) for 480 V distribution, 35,000 A for 4,160 V distribution, and 15,000 A (rms) for 13,800 V distribution. The use of UL listed current limiting breakers is recommended to limit the let-thru I^2t energy during a fault to not more than the available energy during a half-cycle of the prospective symmetrical short circuit current.

3-8.3.2 Other Ships Power Requirements.

When required, provide direct current (DC) power and 400 Hz power for ships service. These systems must be derived from portable rectifiers or conversion equipment provided by the Activity. Provide an electrical power connection system that is supplied from the pier's permanent / industrial power system rated 277/480 V, three-phase, four-wires, grounded, 60 Hz. These special power systems must not be connected to the ships' dedicated shore power service(s). Conduit for 400-Hz systems requires the use of non-magnetic conduit such as aluminum conduit. This is due to the higher reactive inductances at 400 Hz which occurs in magnetic conduit resulting in large voltage drop issues (such as when using rigid galvanized steel conduit).

3-8.3.3 Permanent Pier Loads and Industrial Power.

Other electrical requirements such as pier lighting, receptacles, weight-handling equipment and industrial power must be supplied from dedicated 480Y/277 V transformers. A delta primary winding for transformers prevents 3^{rd} harmonics from being transmitted to the primary line and limits voltage distortion impacts to the electrical distribution system whereas a wye-wye wound transformer does not. Industrial power is defined as power specifically for equipment utilized for the repair and overhaul of ships at berth and is normally only required in naval shipyards. Do not provide permanent pier load power or industrial power from the same transformers providing shore to ship hotel power.

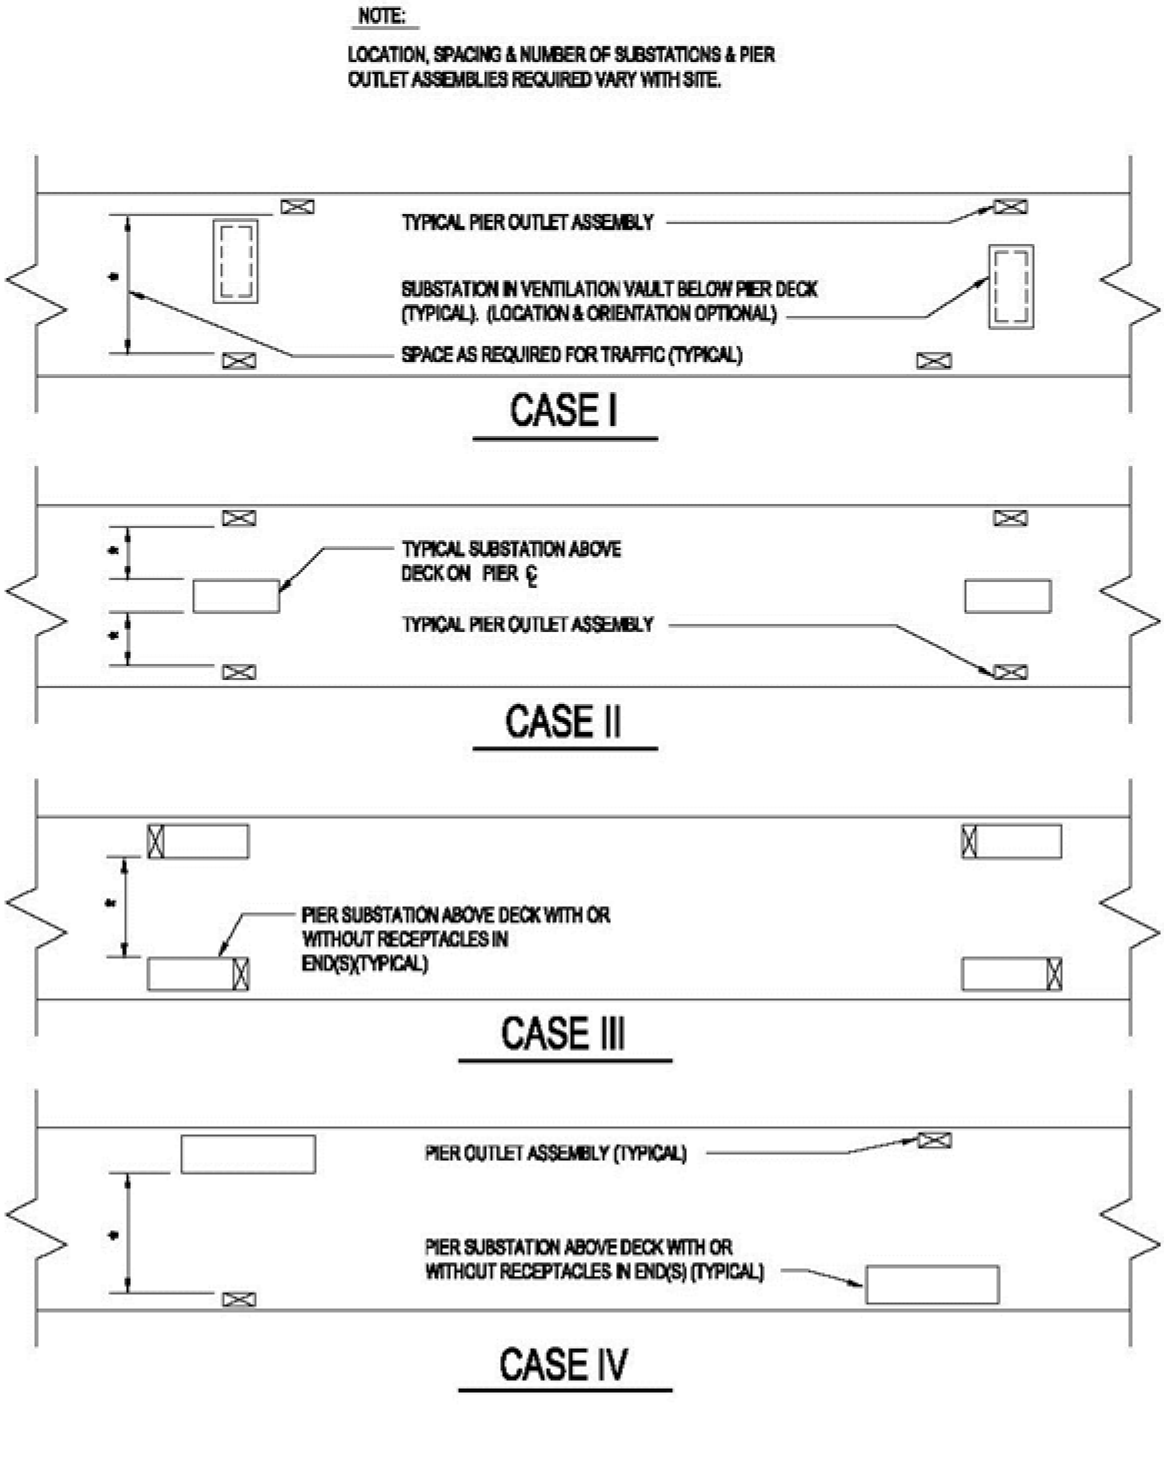
3-8.4 Location and Arrangement of Equipment.

Final locations of equipment must be made on a pier-by-pier basis in concurrence with the Activity and the cognizant Service. Selection must be coordinated with the pier design type, other pier utilities and the pier's operational requirements. In general, provide as much clear space for cranes and vehicular traffic on the pier deck as possible. Examples of pier equipment arrangements are shown in Figure 3-18.

3-8.4.1 Substations.

The three main types of arrangements for substations are discussed in the following subparagraphs with an example of their use, where appropriate. The unit substations should be outdoor construction.

Figure 3-18 Typical Alternative Pier Electrical Equipment Arrangements



3-8.4.1.1 Double-Deck Pier Substations.

On a double-deck pier, the upper deck is used for conventional pier functions while the lower deck serves utility systems and utility connections. The electrical service for a double deck pier should be a permanent service. The substations should be located on the lower deck and may be symmetrically arranged around the pier centerline. Cross sections of a double-deck pier are shown in Figure 2-2. One recent example of substation arrangement and power distribution system is Pier 6 at the NS Norfolk (NSN). It consists of two electrical service clusters with each service cluster consisting of four 4,000 kVA unit substations, totaling 32 MVA. The output of these substations serves fixed low voltage outlet assemblies. These outlets are defined on the Pier 6 project drawings as “shore power stations” (SPS). Each SPS contains 12 sets of three (3), single pole, low voltage cable connectors (36 connectors total) that in turn serve the shore-to-ship service cables. Illustrations of the electrical system for the NSN double-deck Pier 6 are shown in Figure D-1. (Note the one-line drawing in Figure D-1(a) the nominal medium voltage is 34.6 kV and the distribution conductors are 750 MCM EPR copper.) Pier 6 was designed as a general berthing pier to support all ship classes except SSN and CVN, and may not be directly applicable for double-deck SSN and CVN piers or piers designed for specific ships. See Appendix C-5 “Cable Connectors” for additional information on the various types of connectors currently being used.

3-8.4.1.2 Single Deck Pier Substation.

On a single deck pier the substation can be deck mounted or at grade level adjacent to the pier. The unit substation illustrated in the vault system in Figure D-2 could also be utilized in the pier deck mounted or grade level installation system. The deck mounted/grade level substations may include walk-in aisle features, however they are not recommended when located on the pier due to the significant increase in size.

3-8.4.1.3 Existing Pier Vaults.

Many existing piers utilize the electrical vault system. This system is described in Figure D-2. This type of electrical service, commonly used on many existing piers, is not authorized for the design of new piers. It was based upon electrical vaults located below the pier deck that were designed as an integral part of the pier’s structural system. The vaults house secondary unit substations and may also contain primary switching equipment. The vaults require proper ventilation, pumping systems, and an access system integrally designed into the pier’s deck. This type of electrical system has four significant disadvantages: (1) the vaults are considered to be a “confined space”; (2) the vaults are subject to flooding; (3) the vault’s environment is excessively corrosive to the electrical equipment, even under normal conditions; and (4) replacement of a unit substation creates significant interference to pier operations and results in deck pavement removal and replacement.

When a vault system is used, the substation vaults must be ventilated and flood resistant for protection of the electrical equipment. Prevent flooding with dual sump pumps that discharge at a point above highest tide. Provide a "float switch and alarm system" to alert personnel of sump pump failure and high water level. The sump pump power must be connected to a source other than the vault substation. That source must remain energized when the pier electrical hotel service power and permanent / industrial power systems are turned off. Freeze protection must be provided in climates where any element of the pumping system could freeze. Ventilation cooling must be provided with air quantity based upon the highest site temperature and the highest vault temperature that can be tolerated by the electrical equipment. One approved method of vault ventilation is shown in Figure D-2. Separate ventilation air intake and exhaust louvers by as much distance as possible. They may be on opposite sides of the pier if the ventilation ducts are above high tide. Provide an access system for the electrical vault that includes personnel access and equipment replacement access. Personnel access usually consists of manhole frame with cover and vertical ladder. Equipment access systems are a significant structural element that are required to withstand vehicular traffic and must be designed as an integral part of the pier deck.

3-8.4.2 Outlet Assemblies.

The number of electrical shore service stations, their location aboard ship, the per station ampacity, and appropriate voltage for each ship are defined in APPENDIX A. For a general discussion of methods to be used to establish shore utility station spacing on piers and wharves, refer to CHAPTER 2. For spacing at dry docks, refer to UFC 4-213-10.

3-8.4.3 Cable Lengths.

Most ships have to be served from multiple 400 Amp circuits. Design the electrical system to maintain balanced impedances and reduce unbalanced phase currents. Route cable from the substation to the outlet assemblies in the parallel circuits to achieve approximately equal cable lengths (within 10%). When routing shore power feeder conduits through concrete decks, avoid routing individual shore power PVC conduits through closed rebar loops due to possible inductive coupling causing current unbalance with feeder PVC conduits not routed through the same rebar loop(s). Where single phase connections and cabling are used for ship to shore connections, care must be taken to bundle phases of each circuit to maintain balanced impedances and reduce unbalanced phase currents.

3-8.4.4 Combined Equipment.

Electrical substations and outlets may be consolidated in an integral package, with the receptacles placed in the side (or sides) of the substation enclosure. These consolidated outlet assemblies may be spaced as necessary along the pier or dry dock perimeter. See Figure 3-18, Cases III and IV.

3-8.4.5 Outlet Assemblies for Portable Equipment.

When supplying ships loads from portable substations, locate primary outlet assemblies in the same manner as required for regular outlet assemblies. Primary outlet assemblies, provided for temporary services that supplement permanent substations, should be placed in the vicinity of their intended use. Coordinate these locations with the Activity and the cognizant Service.

3-8.5 Distribution System Equipment and Materials.

Equipment and materials selected for waterfront electrical systems must be coordinated with the cognizant Service and the standards and preferences of the Activity. Since significant technical information for many of the distribution system components is available in the Unified Facilities Guide Specifications (UFGS) Sections UFGS 26 11 16, *Secondary Unit Substations*, UFGS 26 13 00, *SF6/High-Firepoint Fluids Insulated Pad-mounted Switchgear*, and UFGS 26 23 00.00 40, *Switchboards and Switchgear*, the nomenclature and requirements for the equipment must be thoroughly coordinated in the project documentation (plans and specifications).

3-8.5.1 Fixed Substations for 480 Volts Service.

There are several methods for providing substations for permanent 480 V services on piers. Based on the overall system design, the substation should contain primary, secondary, auxiliary, and transformer sections. See APPENDIX C. The primary section would either contain the primary overcurrent protection features, a disconnect switch, and a service circuit selector switch if the system includes multiple primary circuits, or it would be limited to the primary circuit terminations if separate pad-mounted primary switchgear is used. Where transformer differential relays are used, the primary section should contain a circuit breaker instead of fused disconnects to allow disconnecting primary side power to the transformer via a trip circuit connection to the breaker from the differential relay. There must be separate 480 V secondary unit substations designated for the ships hotel loads and for the other pier loads including industrial power (if required). The main transformers should be of the liquid-cooled type, standard three-phase, 480 V, with four (4) full-capacity, 2-1/2-percent taps, two above and two below the nominal primary voltage rating unless actual operational conditions require other tap settings. Maximum transformer rating should be 4,000 kVA. Substations, including transformers should be stainless steel with a paint coating system in compliance with ANSI/NEMA C57.12.29. If specific operational conditions require parallel operation with the shipboard generators, coordinate with the cognizant Service to determine the additional features that must be added to the equipment. In these cases, the shipboard generator and other equipment ratings are available upon request from NAVSEA.

Substation must be designed with maintainability in mind and provisions and/or clearance for removing the circuit breakers must be factored into the design.

3-8.5.1.1 Shore Power Circuit Breakers.

The equipment should provide 480 V (nominal), three-phase, 60 Hz power, as defined in ANSI/NEMA C84.1, *Voltage Ratings for Electrical Power Systems and Equipment (60 Hz)*, voltage range "A." via low voltage power circuit breakers. The power circuit breakers shall be electrically operated, drawout-type, with adjustable electronic trip features. Feeder circuit breakers shall provide circuit protection up to a maximum overcurrent setting of 480 Amps and interrupting ratings up to 100 kA at 480 VAC without fuses. Provide a circuit breaker for each individual shore power service receptacle. The adjustable trip module long time pick-up (LT setting) for submarine shore power circuit breakers shall be adjusted per APPENDIX C, C-4.1.

3-8.5.1.2 Shunt Trip Interlocks.

- Provide a shunt trip interlock circuit to open all possible paralleled circuit breakers in the event that any shore power circuit breaker trips due to an overcurrent operation.
- For existing installations, provide a shunt trip interlocking scheme on all ship power service circuit breakers for submarines.
- For new construction a remote trip capability shall be provided on all ship power services for submarines.

3-8.5.1.3 Space Heaters.

Space heaters should be incorporated within individual substation sections in order to prevent condensation.

3-8.5.2 Substations for 4,160 or 13,800 Volts Service.

Provide substations with a secondary voltage of 4,160 V or 13,800 V (nominal, as defined in ANSI/NEMA C84.1, voltage range "A), when required by APPENDIX A for the classes of ships to be berthed. Design of primary unit substations is similar to fixed 480 V substations except for voltage classifications and outlet assembly provisions. Circuit breakers should be 5 kV or 15 kV vacuum drawout type, with interrupting current rating based on available fault.

3-8.5.3 Portable Substations.

See Figure D-3. The pier design must include space allocation for the portable substations and provide the electrical primary distribution system required to energize the portable substations. This includes primary circuits, their disconnect switches, and the primary outlet assemblies. Design is similar to fixed substations except for portability provisions.

3-8.5.4 480 Volt Outlet Assemblies.

480 V outlet assemblies (receptacles and cable connections) vary with Activities but should be standardized on a Station-by-Station basis. Additional information on the outlet assemblies and the actual operational procedures used on the piers is available in UFC 3-560-01, *Electrical Safety O&M*, Section 9, “Shore-to-Ship Electrical Power Connections”. Detailed specifications for the outlet assemblies are also included in guide specification UFGS 26 05 33, *Dockside Power Connection Stations*.

3-8.5.4.1 Receptacles.

Ships hotel service receptacles must be provided in weatherproof, corrosion-resistant pier outlet assemblies, or combined with the substations. Provide the number of receptacles required to serve the specific ship types and classes in accordance with APPENDIX A.

There are currently two types of ship hotel service receptacles being used, a three-pole receptacle and a single-pole receptacle. Existing facilities and NATO, Army, and USCG ships utilize a three-pole, 500 Amp receptacle in accordance with Mil Spec MIL-C-24368/1, *Connector Assemblies; Plug, Power Transfer, Shore-to-Ship and Ship-to-Ship*. A typical MIL-C, three-pole outlet assembly is illustrated in Figure D-4. Other facilities and the Navy utilize a single-pole, 500 Amp receptacle, grouped in a cluster of three. Typical details of the single-pole receptacle system are shown in Figure D-5. The preferred connection is the single-pole receptacle which must be used for new construction for the Navy.

3-8.5.5 Primary Outlet Assemblies.

Primary voltage outlet assemblies must have weatherproof, corrosion-resistant enclosures and high voltage connectors. Connectors must match the standard primary voltage coupler in use by the Activity and as required by the cognizant Service. Disconnects should have an interlocking key which can only be removed when the switch is opened. Design should be such that, after the disconnect has been opened, the interlocking key must be used to unlock and make possible the insertion or removal of the corresponding primary voltage pier coupler plug. Provide 500 Amp coupler receptacles at each 4,160 and 13,800 V pier outlet assembly. Incorporate outlet assemblies into substations as applicable. See Figure D-6 for typical 15 kV details.

3-8.5.6 Coordination of Shipboard Phase Rotation.

Shipboard alternating current systems have a standard phase rotation. To minimize the phasing procedure and to reduce the time required to connect shore-to-ship power cables, shore power connectors should be phased so that they are compatible with the shipboard system. Refer to *NAVSEA 59300-AW-EDG-010/EPISM*, Section 2, Group E, Sheets 14 and 15, to determine phase rotation required for shore power connections.

3-8.5.7 Conduit Systems.

For electrical conduit exposed under or on a pier, wharf, or dry dock, evaluate the relative advantages of Schedule 80 PVC, and Reinforced Thermosetting Resin Conduit (RTRC). Avoid the use of PVC where it will be exposed to sunlight and moving objects. Although PVC Coated steel conduits have been used on many piers, the alternatives are more attractive from an economic and durability standpoint. The potential exists for loss of integrity of the PVC Coating systems in the harsh and corrosive environment. Fiberglass cable trays may be used in lieu of conduit where adequately protected from physical damage and the elements. Coordinate hangers with the requirements in Section 2-4.1.4 entitled “Hangers and Support Assemblies”.

3-8.6 Ships’ Shore Power Requirements.

APPENDIX A provides a listing of shore electrical loads of ships while homeported or undergoing alteration and repair. Substation and feeder sizing on piers and wharves must be based upon the electrical loads given in the "Design Load" for the largest ship (or largest number of ships) of all classes which could be berthed at the pier. The minimum number of receptacles provided in a secondary outlet assembly should match the number of receptacles in the ship’s respective receptacle stations. Nested ships must also be considered in the electrical outlet assembly design where indicated by the facility berthing plan or where conceivable at a future date.

3-8.6.1 Alternating Current (AC) Power.

Hotel service loads include the ship's electronics, weapons systems, cargo booms, galley equipment, space heating, and miscellaneous lighting and power loads. The number of circuits shall be as requested by ship’s force. These loads are supplied with either 480 V (nominal) or 4,160 V (nominal) ungrounded power, or 13,800 V (nominal) ungrounded power. The 480 V system shall supply approximately 480 V at no load and 450 V (plus or minus 5%) under loaded conditions and at the ship's load center. The 4,160 V system shall supply approximately 4,160 V plus or minus 5% under loaded conditions and at the ship's load center. The 13,800 V system shall supply approximately 13,800 V plus or minus 1% with up to 60 seconds time delay under loaded conditions. Cable ratings must be sized to exceed the ships’ loading requirements of APPENDIX A and the associated circuit breaker trip settings. System design must be coordinated with the planned nesting requirements of the pier to maintain the voltage within the allowable tolerances at outboard ships.

3-8.6.2 Direct Current (DC) Power.

When required, DC power should be provided for certain ships in accordance with instructions provided by the Activity. Portable rectifier units will be provided by the Activity. Provide sufficient AC power and receptacles to serve such equipment. Coordinate connection requirements with the Activity.

3-8.6.3 400-Hz Power.

400-Hz power for ship service may be supplied from the 480 V system utilizing portable generating equipment furnished either by the Activity or by the ship. Provide 60 Hz power and receptacles to serve such equipment. Coordinate connection requirements with the Activity.

3-8.6.4 Shipboard Equipment Ratings.

Most ship distribution circuit breakers operate at 440 V and are protected with 100,000-Amp interrupting current, current-limiting fuses in series with the breakers. In most cases, these circuit breakers are type AQB-LF400 as described in NAVSHIPS Publication 362-2333, *Air Circuit Breakers (Fused), Navy Type* AQB LF400. The main breaker for the shipboard system on nuclear carriers is an air-type breaker rated at 250,000 Amps asymmetrical interrupting capacity, and without current-limiting fuses. The shore distribution system must be designed in accordance with UFC 3-501-01, *Electrical Engineering*, to ensure that available fault is within the capability of the ship's distribution system. Contact the cognizant Service for information on shoreside fault current data to determine the required interrupting capacities and equipment design characteristics.

3-8.7 Supplemental Requirements for Nuclear Submarines (SSN, SSBN, SSGN) and UUVs.

Nuclear submarine (SSN, SSBN, SSGN) and Unmanned Underwater Vehicles (UUVs) piers and berths should conform to the following shore power requirements.

3-8.7.1 Substations for 480 Volts Service.

Substations serving hotel loads at submarine piers must be designed in accordance with Section 3-8.5.1 entitled "Fixed Substations for 480 Volts Service" for fixed substations, or Section 3-8.5.3 entitled "Portable Substations" for portable substations, and in accordance with the supplemental requirements below. The substation's primary section should be built with dual primary feeders. Switchgear and breaker equipment should be designed so that automatic reset and restoration of power to submarine services will be delayed a minimum of 5 to 10 seconds after loss of commercial power. This is required in order to prevent damage to the submarine's electric plant equipment. The maximum time to restore power should be 5 minutes. Provide undervoltage and underfrequency relays at substations. Relay types and set points for undervoltage and underfrequency should be evaluated separately for each installation and coordinated with the cognizant Service.

3-8.7.2 Standby Power.

Power requirements for normal operation are given in APPENDIX A. Standby backup power to the normal shore supply is required. A standby backup electrical power source for the reactor plant is required which is capable of providing 450 V, 3 Phase 60 Hz power with a capacity of at least 850 kW with the ability to start a 260 hp induction motor with an initial load of 650 kW. The standby backup power source should use the normal ship's shore power connections. This source of standby power will only be required to be available when power from the ship's battery or diesel generator are not available. The standby backup power source can be, for example, a portable generator set, or separate power sources to the facility, provided that the loss of one source will not result in a long duration power outage.

3-8.7.3 Maximum Downtime.

For the shore facility and overhaul yard dry dock permissible outage time allowed is 5 minutes. System downtime is defined as: (1) the time required to restore power to the pier when maintenance or repair activities are required; or (2) the time required to transfer from one power source to another after system disturbances. This includes the time required for protective devices to operate and the time to start standby generators.

3-8.7.4 Super Shore Power.

APPENDIX A lists “super shore power” requirements for nuclear submarines. Super power is required for the ship's testing, checkout, and refueling operations. These super shore power requirements are in addition to the normal power requirements. Provide super power from a separate substation that supplies no other loads. Portable substations connected to temporary service outlets are recommended for this service. Extend primary service and provide connections for these portable substations. The special requirements for submarine piers given in subparagraphs 3-8.7.1, 3-8.7.2, and 3-8.7.3 entitled “Substations for 480 Volts Service,” “Standby Power,” and “Maximum Downtime” above do not apply to super shore power.

3-8.7.5 Shorepower Booms.

Provide permanently installed shorepower booms at submarine/UUV piers and berths. See UFC 4-152-01, *Piers and Wharves*, for additional submarine/UUV pier/berth configuration, construction, berthing, fendering, access, and utility infrastructure requirements.

3-8.7.6 UUV Requirements.

Special considerations must be given to ensure all power and infrastructure requirements for current and future UUVs are met.

3-8.8 Ground System.

Provide a ground system at piers, wharves, quay walls, and other waterfront structures that measures not more than 5 Ohms for all permanent electrical equipment. Ground systems should be in accordance with NFPA 70. Stranded-copper-wire ground conductors, sized in accordance with NFPA 70, should be used to interconnect equipment enclosures and the ground system.

3-8.9 Pier Lighting.

Information on pier lighting is available in UFC 4-152-01, *Piers & Wharves*.

3-8.10 Lightning Protection.

Provide lightning protection systems when required. Coordinate with the cognizant Service. Design in accordance with UFC 3-575-01, *Lightning and Static Electricity*

Protection Systems, and NFPA 780, Standard for the Installation of Lightning Protection Systems. Consider the protection of cranes, above deck substations, pier mounted buildings, and lighting system masts.

3-9 TELECOMMUNICATION SYSTEMS.

The purpose of this section is to provide requirements for Base Level Information Infrastructure (BLII) Pier Connectivity Specifications, telephone service, and other telecommunications systems.

3-9.1 BLII Pier Connectivity.

These guidelines are provided for planning, designing, engineering, and constructing new or repairing existing Navy piers. Figure 3-19 illustrates the three major components that are required to provide end-to-end connectivity to IT-21 compatible ships. They are the Pier Head ITN Building Node; the Pier Fiber Distribution Center, and the Fiber Optic Riser Panels.

3-9.1.1 Pier Head ITN Building Node.

The Pier Head ITN Building Node is connected to the Base Area Network (BAN) and becomes the interface for adding additional piers to the infrastructure for SIPRNET/NIPRNET connectivity. A 144-strand hybrid fiber optic cable (72 multi-mode and 72 single mode) is required between the Pier Head ITN Building Node and the Pier Fiber Distribution Center. Where a hybrid cable is not readily available and the designer deems it appropriate, two individual cables, one 72 strand single-mode and one 72 strand multi-mode, are permitted for use in lieu of the hybrid cable. The fiber optic cable may already exist if the pier is being repaired; however, for new pier construction, the cable will need to be installed. The designer should coordinate with the local Information Technology (IT) group to ensure that the proper Pier Head ITN Building Node has been identified. All cabling and interconnections inside the Pier Head ITN Building Node are the responsibility of the local IT group unless other prior arrangements have been made.

3-9.1.2 Pier Fiber Distribution Center.

The Pier Fiber Distribution Center provides a breakout point for the 144-strand hybrid fiber optic cable coming from the Pier Head ITN Building Node and the Fiber Optic Riser Panels. Figure 3-20 shows the fiber optic cable entering into the splice can from the Pier Head ITN Building Node. The fiber is spliced onto another 144-strand fiber optic cable (72MM/72SM) for submarine piers or 96-strand fiber optic cable (48MM/48SM) for surface ship piers. This is routed to the Environmental Distribution Center 1 (EDC 1) patch panel. Using internal patch cables, EDC 1 is patched to EDC 2. From EDC 2, a 144 or 96 strand hybrid fiber optic cable is routed to a second splice can where it is spliced to several 24-strand hybrid fiber optic cables (12MM/12SM) that run to the Fiber Optic Riser Panels. Figure 3-21 through Figure 3-24 provide detailed information on the EDC 1 and EDC 2 patch panels located inside the Pier Fiber Distribution Center and their interconnections. (Note that the patch panels are shown for both surface ship piers and submarine piers).

Submarine piers/berths require validation that the hardware supports or exceeds the requirements of data throughput and cyber security as mandated by CTF 10, NAVIFOR, and PMW 160.

3-9.1.3 Fiber Optic Riser Panel.

The Fiber Optic Riser Panel is the interface for the ship to shore connectivity. The panel is provided with a 24-strand hybrid fiber optic cable (12MM/12SM) coming from the Pier Fiber Distribution Center. This provides a fiber optic receptacle, J1, to interface with the umbilical cable assembly that goes to the ship (note that details on the J1 pigtail assembly may be found on NAVSEA drawing 7325760D). Figure 3-25 shows the Fiber Optic Riser Panel. Figure 3-26 and Figure 3-27 show the patch panel connections inside the EDC for a surface ship and submarine respectively. Figure 3-28 and Figure 3-29 show the rubber gasket cutouts for a surface ship and submarine respectively.

3-9.2 Telephone Systems.

Provide a voice telephone distribution system to each berth on piers and at dry docks unless specifically instructed otherwise. Provision should be made for the telephone cable to be terminated in a telecommunications outlet assembly adjacent to each berth. Provide a Main Distribution Frame (MDF) at the shore end of the pier for the cross-connect devices. The assembly must include connectors mounted to the exterior of the enclosure. These connectors will be connected to the shore end of the ship-to-shore telephone cable. Commercial "dial tone" services and the telephone switching system is the responsibility of the Station's Communications Officer. Figure 3-30 provides a typical telephone connection with surge protector module.

3-9.2.1 Ships Demand.

APPENDIX A identifies the number of telephone pair shorelines required by each ship type. Cable sizes include the ship requirement, the appropriate embarked-staff requirement, and an allowance for spare pairs. Cable sizes have been rounded up to the next larger standard telephone cable. The pier telephone distribution cable system should be designed using the pier's berthing plan. Provide cable sizes based upon the worst case at each berth. Berths designed for nested ships should be provided with the total number of cables indicated for all ships in the nest.

3-9.2.2 Other Demand.

Provide telephone service to security checkpoints and watchstand stations. These requirements may occur at the head and end of the pier, and at intermediate points along the pier. Coordinate with the Activity's security representatives.

3-9.2.3 Location and Arrangement of Pier Telephone Distribution System.

Each berth should be served by an independent run of conduit. The telecommunications outlet assembly must be an independent, freestanding structure. Outlet assemblies must be designed to prevent damage by ships lines and by traffic on the pier.

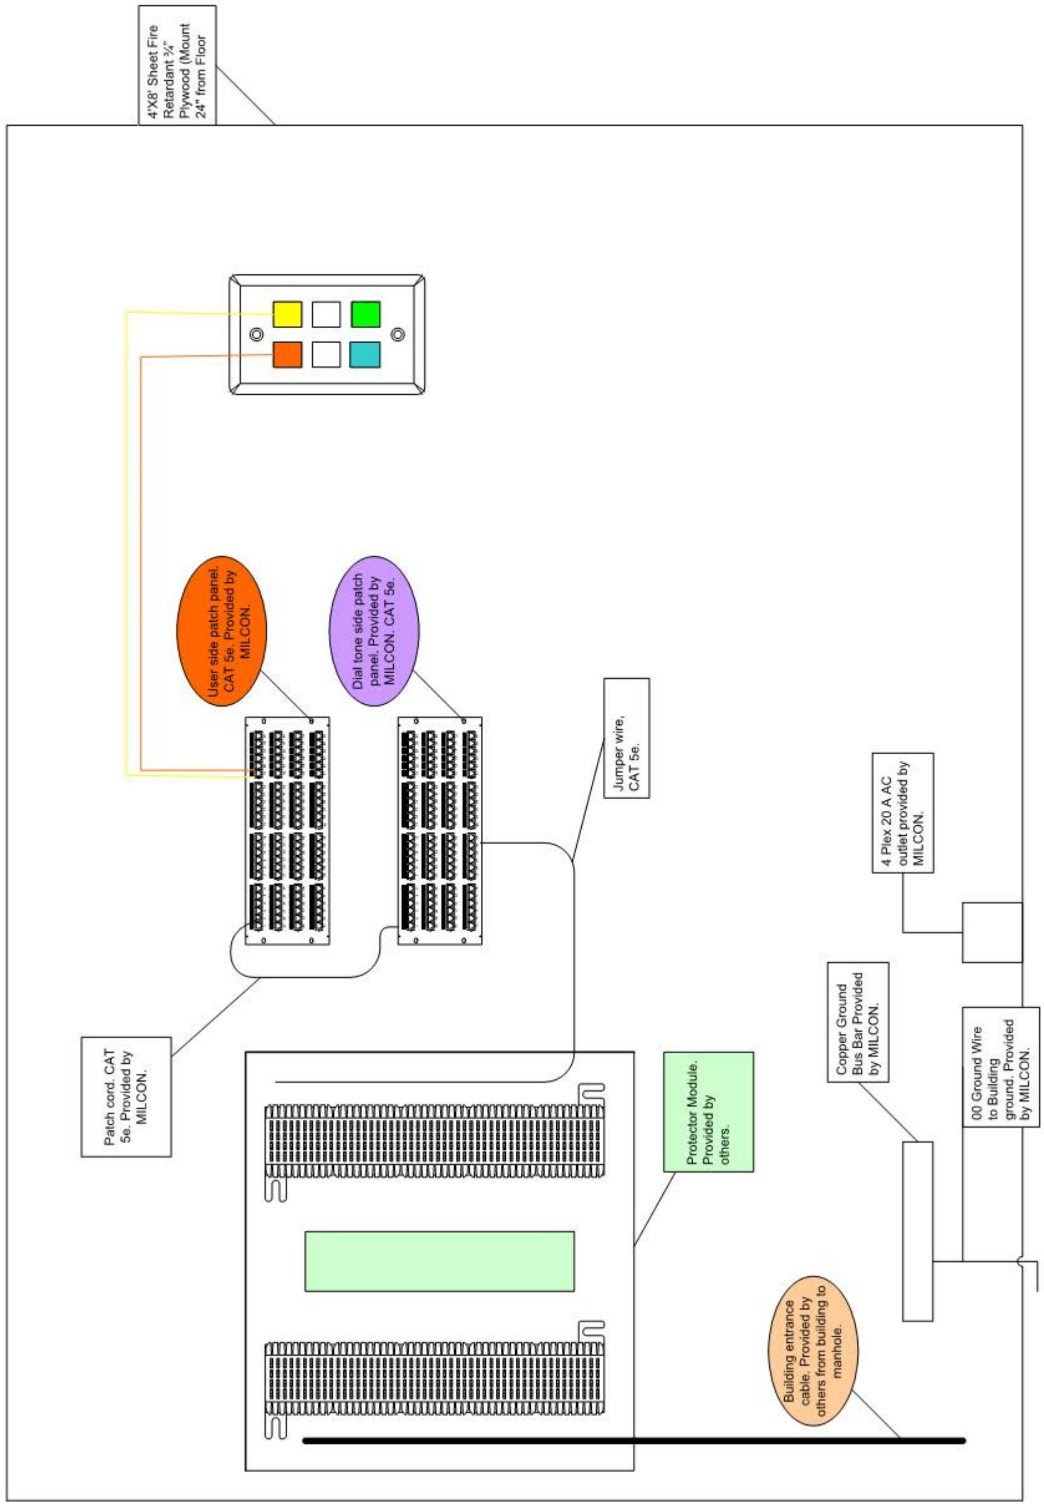
3-9.3 Other Telecommunications Systems.

The need for the systems described below should be evaluated on a site-by-site basis. Provide these systems as directed by the Activity and the cognizant Service.

3-9.3.1 Dedicated Communication Circuits.

Provide one (1) 2 inch (51 mm) conduit from the manhole or cross-connect cabinet at the head of the pier to each telecommunications outlet assembly. This conduit must be dedicated for communication circuits that cannot use the telephone system.

Figure 3-30 Typical Telephone Connection Detail with Surge Protector Module



3-9.3.2 Cable Television.

Provide a conduit system (from the manhole at the head of the pier to each telecommunications outlet assembly) to support cable television requirements. Unless instructed otherwise, the cable television system will be provided by a commercial vendor. The designer must coordinate with the vendor and provide a complete raceway system.

3-9.3.3 Alarm and Signal Circuits.

Provide two (2) 1-1/4 inch (32 mm) conduits (from the manhole at the head of the pier to each telecommunications outlet assembly) to serve alarm and signal circuits that cannot use the telephone system. Provide all conductors to serve these systems unless instructed otherwise. Coordinate with the Activity and the cognizant Service.

3-10 PIER POWER METERING SYSTEMS.

Naval ships connected to shore power utilize a large percentage of the Navy's infrastructure electricity. Many bases are now requiring the electricity usage to be measured and recorded. Since multiple circuits are normally used to provide the required capacity to the ships, often in a "nested" configuration, standard metering/ monitoring equipment may not be appropriate. There are however, commercial and government developed systems, including hardware and software that are available. Coordinate with the cognizant Service to determine if the Activity has a desired or required system that must be utilized.

3-10.1 Pier Power Monitoring System (PPMS).

One of the power measurement systems available has been developed by the NAVFAC Engineering and Expeditionary Warfare Center (EXWC, formerly NFESC). The system is defined as the Pier Power Monitoring System (PPMS) and consists of specialized embedded computer circuit boards, embedded software, and personal computer (PC) software that enable the Activity to measure, record, and study the electricity consumption and usage patterns of the connected ships. The PPMS was developed to be cost effective and to be easily installed. It involves the simple utilization of a conventional utility metering system. Typically, each monitored electrical outlet assembly will have one set of circuit boards. Battery backup features ensure that no data or operating software is lost when electrical power is disconnected. The data are sent to a central PC station. The PC can program the circuit boards and retrieve data. Parameters available on the PC are megawatt-hours and instantaneous values of Amps, Volts, power factor, and megawatts. Time-of-use (TOU) data are also available for the present 24-hour period. The PPMS correctly identifies the receptacles allocated to each ship and the total power consumed. Both the ship (customer) and the Activity (provider) can easily track shore supplied ship electricity. Software can be easily tailored to send the data directly from the PPMS to a master data collection and billing system. By providing complete energy use pattern information and consumption data, the PPMS enables Navy managers to educate, monitor, and encourage energy conservation for ships using shore supplied electricity. An operating PPMS demonstration system is presently installed on Pier 1 at Naval Station San Diego, CA.

3-11 ADDITIONAL SUBMARINE AND UUV REQUIREMENTS.

Submarines and UUVs have specific pier requirements to meet berthing needs. These differ from other platforms and have specific needs to support surge requirements. Additional requirements will be provided as they are identified. Coordinate with the Activity on other unique requirements for these platforms.

See UFC 4-152-01, Piers and Wharves, for additional submarine/UUV pier/berth configuration, construction, berthing, fendering, access, and utility infrastructure requirements.

3-12 OTHER SERVICES.

Although their design is not covered by this UFC other services will occasionally be required at active and repair berthing facilities. Such systems include: jet fuel, chilled water, pure water, oxygen, acetylene, MAPP gas, and inert gases. These services may be permanent or temporary (tank truck, gas containers or similar means) depending upon required quantity, location and economic considerations. The designer must consult with the Activity and the cognizant Service for specific instructions.

CHAPTER 4 SUPPLY AND AMMUNITION PIERS

4-1 STEAM AND COMPRESSED AIR.

In general, steam and compressed air services are not required on supply and ammunition piers. However, ammunition piers that serve ballistic submarines require special considerations.

4-2 SALTWATER AND NONPOTABLE WATER.

Provide fire protection water as required for active berthing facilities. However, consult with the Activity and the cognizant Service regarding ammunition piers that are in an isolated area and are far removed from mobile fire apparatus. For remote ammunition piers, design a pumping station to supply between 2,500 and 3,500 gpm (9,463 and 13,248 L/min) at sufficient pressure to provide 75 psig (517 kPa) residual pressure at the most remote outlet. Outlet connection threads must be national standard male hose threads unless required otherwise to serve an existing system.

4-3 POTABLE WATER, SEWER, AND OILY WASTE.

For supply piers, requirements are the same as those for active berthing facilities. For ammunition piers, provide potable water only when indicated in the project directive. However, oily waste and sewer collection systems should always be provided. For all three systems, see the requirements defined in CHAPTER 3.

4-4 ELECTRICAL SERVICE.

Shore power for ships hotel service, lighting, and power for industrial services (as required) will be provided on ammunition piers and wharves that load missiles for nuclear powered vessels. This provision lengthens the life of vessel reactors and decreases manpower requirements during the loading / unloading operation. Electrical systems provided on ammunition piers must be designed for the hazardous rating actually encountered and in accordance with NFPA 70.

4-5 TELECOMMUNICATION SYSTEMS.

Both supply piers and ammunition piers require telecommunication systems. However, full services that are defined for active and repair berths are not required except for ammunition piers that serve ballistic submarines. Consult with the Activity and the cognizant Service for specific requirements. In general, the design guides for active and repair berths are applicable. The systems required are to be evaluated on a project-by-project basis. Lastly, comply with all hazardous requirements associated with ammunition piers.

This Page Intentionally Left Blank

CHAPTER 5 FUELING PIERS

5-1 STEAM AND COMPRESSED AIR.

In general, steam and compressed air services are not required on fueling piers.

5-2 SALTWATER AND NONPOTABLE WATER.

Ships loading or unloading POL products at fueling piers will never be cold iron and will therefore not require a shore-to-ship fire protection water connection.

5-3 POTABLE WATER, SEWER, AND OILY WASTE.

Supply potable water systems at locations where connections may be made to existing systems. Maximum potable water requirements are 1,000 gpm (3,785 L/min) with 40 psi (276 kPa) residual pressure at the most remote outlet. Design outlets as for active berthing and space about 200 ft (61 m) apart. Provide oily waste and sewage collection systems at all fueling piers unless instructed otherwise. Consult with the Activity and the cognizant Service. Provide all three systems in accordance with the criteria defined in CHAPTER 3.

5-4 POL SYSTEMS.

Refer to UFC 3-460-01, *Design: Petroleum Fuel Facilities* for information on piping and other appurtenances, including manifolds, hoses and shelters, connections and adapters, hose handling equipment, bilge and ballast lines, stripper pumps, environmental protection, and other equipment. In general, ships use a 6 inch (152 mm) commercial flanged connection. Verify before commencing design of shore connections.

5-5 ELECTRICAL SERVICE.

Ships service, temporary lighting, and ships industrial power are not required for fueling piers and quay walls. Consult with the Activity and the cognizant Service regarding electrical systems that directly serve the pier. Evaluate all hazardous requirements and preferences that may be encountered.

5-6 TELECOMMUNICATION SYSTEMS.

Fueling piers require telecommunication systems. However, full services that are defined for active and repair berths are not required. Consult with the Activity and the cognizant Service for specific requirements. In general, the design guides for active and repair berths are applicable. The systems required are to be evaluated on a project-by-project basis. Lastly, comply with all hazardous requirements associated with fueling piers.

5-7 ADDITIONAL REQUIREMENTS.

Refer to UFC 3-460-01, *Design: Petroleum Fuel Facilities* for additional requirements.

5-8 FIRE PROTECTION.

Refer to UFC 3-600-01, *Fire Protection Engineering for Facilities*. Consult with the Fire Protection Engineering Departments, both at the local level and at the cognizant Service level.

CHAPTER 6 MISCELLANEOUS PROVISIONS

6-1 FREEZE PROTECTION.

6-1.1 Where Required.

Provide freeze protection for saltwater, fresh-water, sanitary-waste (sewage), and oily-waste (bilge) pipes exposed on piers and wharves and in dry docks when located in freezing climates.

6-1.2 Regional Weather Differences.

See Figure B-1 and Table B-1. For design purposes, coastlines within the United States can be divided into the five regions listed below. Table B-1 lists average historical weather data for the five regions. For freeze protection systems at locations outside of the United States, match weather data (insofar as possible) to one of the regions in Table B-1 and design accordingly. The five weather regions are defined as follows:

Region I: "Severe": Alaska, Maine, New Hampshire, Great Lakes and inland locations.

Region II: "Cold": Connecticut, Massachusetts, Rhode Island, and New York.

Region III: "Moderate": Pennsylvania, New Jersey, Delaware, Maryland, and Washington, DC.

Region IV: "Mild": Washington, Oregon, Virginia, and North Carolina.

Region V: "Very Mild": California, South Carolina, Georgia, Texas, Mississippi, Louisiana, Alabama, and Florida.

6-1.3 Methods.

The methods described below vary with climate. Use the methods recommended below when the relative costs of electricity, sewage disposal, and freshwater are not abnormally high. Where the cost of electricity, sewage disposal, or water is abnormally high, then modify the freeze protection system and use an approved method that minimizes operating cost. Use approved life cycle cost procedures and submit analysis.

6-1.4 Protection in Regions I and II.

6-1.4.1 Water Lines.

For water lines, provide freeze protection by using a combination of electric heat tape and pipe insulation. The suggested combinations of insulation thickness and heating (Watt density) for various pipe sizes are shown in Table B-2. Heat tape should be controlled by remote thermostats having sensors taped to the surface of pipes and under the insulation. Consult with the Activity and the cognizant Service regarding preferred heat tape systems and methods. Several sections of heat tape may be required due to overall pipe length. Provide each section of heat tape with a dedicated thermostat. Thermostats must be in a protected location that is also accessible. The heating requirement given in Table B-2 (6 Watts/ft) is the Watt density available for a typical electric heat tape. Any Watt density from 4 to 10 Watts/ft would be suitable, but insulation thicknesses must be adjusted to compensate. Insulation thicknesses given in Table B-2 are based upon polyurethane. Adjust thickness for other insulation materials as based upon their rated thermal conductivity values. Protect backflow devices, valves, and risers with electric heat tape and preformed polyurethane insulation kits. Heat tape systems must be maintainable to be successfully used for the system's expected life span. To improve maintainability, use multiple sections of heat tape instead of extended single circuits. The designer may need to consider special heating systems in which heating elements are placed in channels alongside the pipe. These systems periodically terminate in accessible junction boxes. Maintenance personnel can then easily replace an inoperable section. It is also much easier to troubleshoot when the heating system is divided into reasonable segments with accessible test points.

6-1.4.2 Sewer and Oily Waste Lines.

A combination of electric heat tape and pipe insulation should be used in accordance with Table B-2 for: (1) exposed gravity sewer piping which drains fixtures directly; (2) exposed oily waste piping; and (3) for those portions of exposed pressure lines (sewage and oily waste) which will not completely drain upon cessation of pumping. Heat tape may not be required (insulation only) for exposed pressure and gravity sewer and oily waste piping (or portions thereof) which receive material intermittently and which drain well when pumping stops. Neither heat tape nor insulation may be required for pipe risers and valves above pier decks and in dry dock galleries.

6-1.5 Protection in Regions III and IV.

6-1.5.1 Fresh Water Lines.

For water lines, the preferred method of freeze protection in these regions is to use a combination of insulation and a flushing of water through the pipes. Insulation thickness for various pipe sizes, and pipe sizes for which flushing is necessary, are defined in APPENDIX B Table B-3. Insulation thicknesses are such that for expected durations of subfreezing temperatures less than 50 percent of pipe contents will freeze. Where flushing is indicated, use thermostatically actuated solenoid valves. Size each valve for a rate at which the entire contents of exposed piping can bleed in 8 to 12 hours. Thermostats should be in protected locations and sensors are to be taped to the surface of pipes and under the insulation. Thermostats should be factory set to open the flushing valves at 30 °F (-1 °C) and to close the valves at approximately 35 °F (2 °C). Flushing valves (freeze protection valve) and associated thermostats should be located at each ship's connection and at any other line extremity to protect the most remote valve component in the system. Insulation thicknesses given in Table B-3 are based upon polyurethane. Adjust thickness for other insulation materials as based upon their rated thermal conductivity values. Insulation must also be applied to backflow devices and valves. Special care must be taken to prevent the freezing of flushing valves and associated pipe connections. If water is scarce, or if the winter temperature of buried water mains is below 45 °F (7.2 °C), heat tape should be used in lieu of flushing. In this event, the design should be based upon the data defined in Table B-4.

6-1.5.2 Sewer and Oily Waste Lines.

A combination of electric heat tape and pipe insulation should be used in accordance with Table B-4 for: (1) exposed gravity sewer piping which drains fixtures directly; (2) exposed oily waste piping; and (3) those portions of exposed pressure lines (sewage and oily waste) which will not drain completely upon cessation of pumping. Neither insulation nor heating is required for exposed sewer and oily waste piping (or portions thereof) which receive material intermittently and which drain well when pumping stops. This applies to both pressure lines and gravity lines.

6-1.6 Protection in Region V.

In portions of Region V in which the temperature can drop below 25 °F (-4 °C), use a properly sized flushing valve, atmospheric thermostat, and timer to bleed approximately 35 gallons per inch (132.5 L per 25 mm) of pipe diameter for each 100 ft (30.5 m) of fresh water pipe. This flushing is to be applied over an 8 to 12 hour period on each day that the ambient temperature drops below 25 °F (-4 °C). Pipes need not be insulated, but flushing valves and connections must be located at system extremities and must be protected from freezing.

6-1.7 Modification of Requirements for Saltwater.

Because seawater freezes at a temperature approximately 4.5 °F (-15.3 °C) lower than that at which freshwater freezes, make the following adjustments when designing freeze protection for exposed saltwater mains:

- In Regions I and II, treat saltwater the same as required for freshwater.
- In Region III, design as for region IV.
- In Region IV, design as for region V.
- In Region V, no freeze protection is necessary for saltwater at any location.

6-1.8 Materials.

6-1.8.1 Pipe.

Piping materials must be metallic where heat tape is required. Where a flushing system is utilized, any approved piping material may be used.

6-1.8.2 Heat Tape.

Flat style electric heat tape is recommended. Heat tape should be easy to splice and repair and must be waterproof. A low Watt density (4 to 10 Watts per lineal foot (13 to 33 W/m) of pipe) is recommended, and the ability to lap the tape without damage should be required. When heat tape is used with the insulation thicknesses listed in Table B-2 and Table B-4, they will cycle 30 to 60% of the time on the coldest days.

6-1.8.3 Insulation and Covering.

Closed-cell foam-type insulations (such as cellular glass) having low moisture absorption qualities should be used for Regions I and II due to the destructive effect of freezing on wet insulations. Use closed-cell foam-type insulation for Regions III and IV if wave action and/or immersion are possible. Cover all insulation with a watertight metallic or plastic system.

6-1.8.4 Valves and Thermostats.

Select single-seated solenoid valve shaving flow constants suitable for bleeding proper quantities of water in the prescribed interval. Temperature sensors should be ambient air temperature sensing type. Thermostats may be bimetallic, thermistor, or Resistance Temperature Detector (RTD) type, having differentials of 2 to 5 °F (-16.6 to -15 °C).

6-2 PIPING IDENTIFICATION.

6-2.1 Primary Identification.

Identify each valve on a pier, wharf, or dry dock by a plain language brass tag, and labeled. (Example: "potable water" or "sewer".) Additionally, at each shore-to-ship utility connection, name plates or stenciled letters near the connection must identify the utility in plain language.

6-2.2 Color Coding.

Two sources of design requirements govern color-coding for pier, wharf, and dry dock piping.

6-2.2.1 Distribution Piping On or Under Deck and Ashore.

Such piping, exclusive of shore-to-ship utility connections, must be color coded in accordance with MIL-STD-101, *Color Code for Pipelines and for Compressed Gas Cylinders*. Applicable requirements must be specified in the design documents.

6-2.2.2 Shore-to-Ship Utility Connections.

Such piping (including valves, operating levers, ends of hose assemblies, risers, and adjacent piping) must be specified to be color-coded in accordance with Table 6-1. Color-coding may also extend to adjacent curbs, protective rails, posts, and walls.

6-3 OPERATIONAL NOTICES.

Provide the following operational notices. Consult with the Activity and the cognizant Service regarding other desired notices, nameplates, warning signs, and so forth.

- Bleed systems must be marked with the following warning:

  ”Freeze protection valve.
  Water will flow below 35 °F.
  Do not close.”

- Heat tape systems must be marked with the following warning:

  “Heat tape system (self-limiting).
  Do not disconnect power.”

Table 6-1 Color Code for Shore-to-Ship Utility Connections [a, d]

Shore Service [b]	Color	Reference Number [c]
Potable Water 40-81 psi (276-558 kPa)	Blue, Dark	15044
Nonpotable Water for Fire/Flushing/Cooling 100-175 psi (689-1207 kPa)	Red	11105
Chilled Water	Stripped Blue/White	11044/17886
Oily Waste Discharge	Striped Yellow/Black	13538/17038
Sewer	Gold	17043
Steam and condensate 150 psig (1,034 kPa)	White	17886
Compressed Air 100-125 psi (689-862 kPa)	Tan	10324
High Pressure Air 3,000 psi (20.7 MPa)	Stripped Yellow/Gray	13538/16081
Fuel	Yellow	13538

Note:

[a] If additional information is needed on color-coding systems, contact the cognizant Service.
[b] Pressures shown are nominal pressures and represent average conditions.
[c] The reference numbers refer to Federal Standard 595B, Colors Used in Government Procurement.
[d] Also, see “General Specifications for Ships of the U.S. Navy”, COMNAVSEASYSCOM, 1991.

This Page Intentionally Left Blank

CHAPTER 7 U.S. ARMY REQUIREMENTS

7-1 APPLICABILITY.

This chapter is applicable for waterfront facilities designed for U.S. Army vessels.

7-2 POTABLE WATER.

Provide potable water in sufficient capacity to permit the filing of a vessel's tank in such time as to avoid delays in the operation of the vessel.

7-2.1 Quantity and Pressure Requirement.

Provide a minimum flow of 100 gpm (6.3 L/s) with a minimum residual pressure of 25 psi (173 kPa) at the most remote outlet.

7-2.2 Piping and Outlets.

Install one (1) 2-1/2 inch (64 mm) connection at each service outlet. Potable water outlets on piers and wharves should have a reduced pressure-type backflow prevention device. The piping must be insulated and provided with electrical heat tape if the lines are normally full of water and subject to freezing temperatures. Where thermal expansion is a problem, provision should be made for expansion joints or loops. Figure 7-1 shows a typical potable water connection in the pier deck.

7-3 ELECTRIC POWER.

7-3.1 Electrical System Characteristics.

The main electrical system providing power to ships will be nominal 480 V, three-phase, 60-Hz, supplied from substations preferably located on the piers. For lighting service, a 120 V, 60-cycle, single-phase power may be provided.

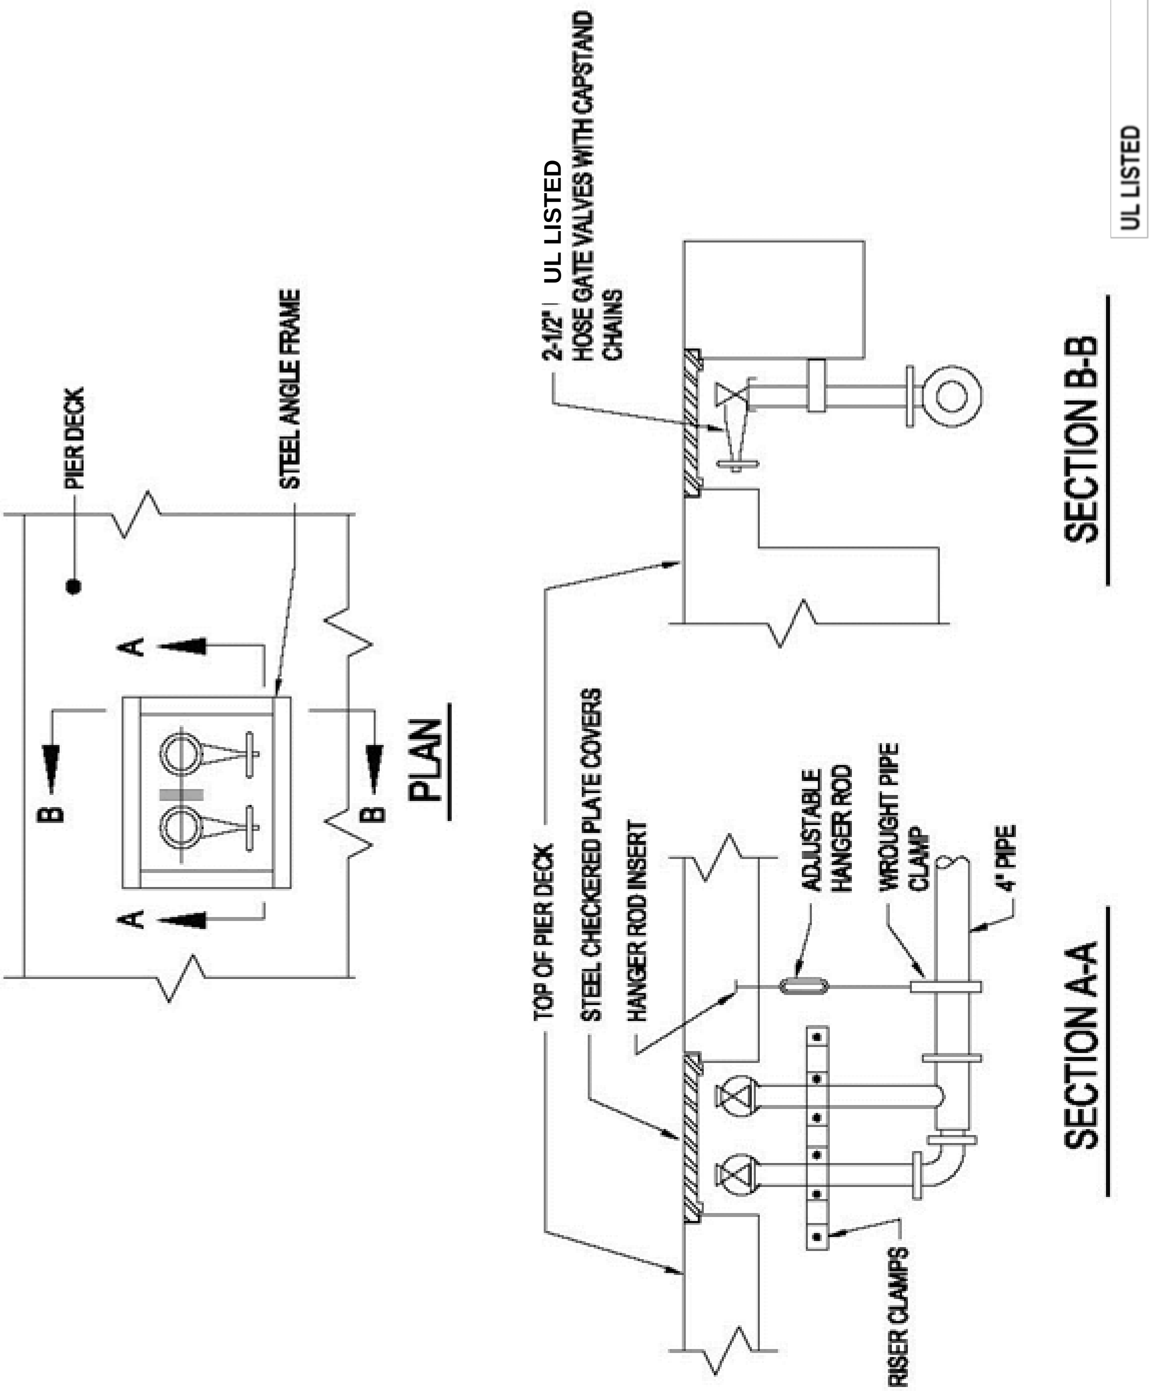
7-3.2 Ground System.

At piers, wharves, and other waterfront structures, a ground system that will measure not more than 3 ohms must be provided for permanent electrical equipment.

7-4 LOCATION AND NUMBERS OF SERVICE POINTS.

A minimum of two service points will be provided for each berth and located for the convenience of the using vessels. Each service point must supply electric power and water service as outlined above. Depending upon the physical site conditions of each specific installation, the point of connection for each service may be located in a single service box, or may be placed in separate but closely grouped boxes. Boxes should be located as close as practicable to the berthing face of the structure so that connected hoses and electric cables are not subject to vehicular traffic damage.

Figure 7-1 Typical Water Supply Connection for an Army Pier



7-5 MISCELLANEOUS.

7-5.1 Telephone Service.

Provide telephone service and outlet connectors for each berth. Locate for the convenience of the using vessels.

7-5.2 Lighting.

Satisfactory illumination shall be ensured for night operations. For open watering areas on the pier where ship loading or unloading occurs, a lighting intensity of at least 5 footcandles (54 lux) should be maintained. The illumination level of 5 footcandles (54 lux) should also be provided for areas of warehouses or storage buildings.

7-5.3 Fire Protection.

Refer to UFC 3-600-01, *Fire Protection Engineering for Facilities*.

7-5.4 Sanitary Facilities and Sewage Disposal.

A dockside connection to a sewage disposal system must be provided for the disposal of sewage and oily wastes from vessels.

APPENDIX A SHIP UTILITY REQUIREMENTS

Table A-1 Shore Services - Steam

Table A-2 Shore Services - Compressed Air

Table A-3 Shore Services - Salt or Nonpotable Water - Overhaul and Dry Dock

Table A-4 Shore Services - Potable Water

Table A-5 Shore Services - Oily Waste/Waste Oil (OWWO) Discharge

Table A-6 Shore Services - Sanitary (CHT) Discharge

Table A-7 Shore Services - Electrical

Table A-8 Shore Services -Telecommunications

Note:

* Data provided in this appendix is for general informational and basic planning purposes only. It is the best data available at the time of publication of this document. Data is incomplete and may not be completely accurate. Ship utility requirements shown are for various classes of ships and may not include all ships, modifications, flights, blocks, and other variants between ships in a class. Information is for ship demands only and may not reflect the full requirements at a berth/pier/facility. If additional shore side utilities are necessary, coordinate with the installation and/or Activity on the requirements.

Designer/Planner needs to verify ship utility requirements with specific ship(s) being berthed, Activity, Facilities Planning Criteria (FPC), PEO, Port Ops, and/or cognizant Command or Service.

Submit any updates, changes, or additions directly to the NAVFAC Engineering and Criteria Program Office or by submitting a CCR (http://www.wbdg.org/ffc/dod).

Notes to Table A-1:

* See note (*) at beginning of APPENDIX A; information provided in this table is for general reference purposes only; information is incomplete and may not be accurate; verify utility requirements with ships/program office(s). Blanks in table indicate information is missing or unavailable at this time.

** Designations of locations of ship connections are as follows:

- L is the distance (in feet) of the connection aft of the stem of the ship.
- H is the height (in feet) of the connection above the design waterline.
- P, S, C, CL refer to Port side, Starboard side, and Center/Centerline of a ship respectively.
- P/S indicates one connection on each side of ship at distance L.
- N is the number of shipboard connections at given location(s).
- Where more than one connection exists, all locations are shown.

[a] Loads based on ship's peacetime complement (no air wing or troops).

[b] Maximum single ship demand at shore connections is column (a) plus column (b).

[c] For multiple ships, see Steam Service Diversity Factors.

[d] Steam quantity required to achieve normal environmental temperature in ship spaces relative to the outdoor temperatures shown. Interpolation between temperature columns is permissible. Determine specific site design temperature from UFC 3-400-02, Design: Engineering Weather Data, 99 percent 4 basis, whenever available. Design temperatures for sites not listed may be obtained from the American Society of Heating, Refrigerating and Air-Conditioning Engineers, Inc., ASHRAE Handbook, 97-1/2 percent basis.

[e] Galley, laundry, hot water, etc.

[f] Not required. '---'

[g] Loads based on absolute, worst case condition. Upon completion of ShipAlt CG47-00588K (All Electric), there will no longer be a requirement for steam.

[h] Information contained in NAVSEA Dwg 6726570 Rev C (NOFORN)

[i] Information contained in NAVSEA Dwg 4639983 Rev E (NOFORN)

[j] Figure based on normal supply to ship when berthed at NNSY.

[k] Steam used for hot water and ship services not significantly affected by outside temperatures. Mid-Life electrical upgrades will remove steam from these ships.

[l] Shore steam not expected for commissioned vessels; required only during dry dock periods; if needed, use 5 NPS ANSI B.16.5 flange 600.

Notes to Table A-2:

- * See note (*) at beginning of APPENDIX A; information provided in this table is for general reference purposes only; information is incomplete and may not be accurate; verify utility requirements with ships/program office(s). Blanks in table indicate information is missing or unavailable at this time.

- ** Designations of locations of ship connections are as follows:
  - L is the distance (in feet) of the connection aft of the stem of the ship.
  - H is the height (in feet) of the connection above the design waterline.
  - P, S, C, CL refer to Port side, Starboard side, and Center/Centerline of a ship respectively.
  - P/S indicates one connection on each side of ship at distance L.
  - N is the number of shipboard connections at given location(s).
  - Where more than one connection exists, all locations are shown.

[a] Low pressure compressed air requirements shown.

[b] For multiple ships, use diversity factor.

[c] Minimum required at connections. Higher pressures may be necessary where specifically directed by the cognizant Service or the using agency.

[d] This is size of pipe from main to (and including) outlet riser.

[e] No shore connection; normal procedure is for ship's force to identify valve in system to be pulled and temporary hoses are attached where valve was pulled

[f] FPC for CVN 78 Class from PMS 378 (Rev 4, May 2015) states, High pressure air: none. Low pressure air, nitrogen, oxygen, and divers air: portable only. NAVSEA 05V3 states the values listed are required.

[g] DDG 51 Arleigh Burke class is currently comprised of three separate variants or “Flights”: DDG 51-71 represent the original design and are designated Flight I ships; DDG 72-78 are Flight II ships; DDG 79 through DDG 123 are or will be built to the Flight IIA design.

[h] Not required. ‘---‘

[i] Submarine and UUV piers/berths require low pressure and high pressure compressed air.

[j] For SSN 774, 1.750 – 12UN-3A X 0.500 NPS adapter assembly at aft charging station. Limited charging flow rate at 150 scfm.

[k] Information contained in NAVSEA Dwg 4639983 Rev E (NOFORN).

[l] No designated shore air connections on board.

[m] Not required at normal pier tie up.

<u>Notes to Table A-3:</u>

* See note (*) at beginning of APPENDIX A; information provided in this table is for general reference purposes only; information is incomplete and may not be accurate; verify utility requirements with ships/program office(s). Blanks in table indicate information is missing or unavailable at this time.

** Designations of locations of ship connections are as follows:

- L is the distance (in feet) of the connection aft of the stem of the ship.
- H is the height (in feet) of the connection above the design waterline.
- P, S, C, CL refer to Port side, Starboard side, and Center/Centerline of a ship respectively.
- P/S indicates one connection on each side of ship at distance L.
- N is the number of shipboard connections at given location(s).
- Where more than one connection exists, all locations are shown.

[a] Not required. '---'

[b] Provide 600 gpm @ 65 psi for cooling (inboard connection in engine room) and 336 gpm @ 100 psi for flushing and firefighting.

Inboard connections fore and aft.

[c] Provide 2,000 gpm @ 40 psi; also provide 600 gpm @ 40 psi from separate, but simultaneous source as emergency backup.

Dry dock provides (F10) steel bolted fire hose connection (male) for standard fire hose.

Dry dock also provides connection for 12" ASW hull valves.

[d] For cooling/flushing; only flushing value is provided.

[e] Information contained in NAVSEA Dwg 4639983 Rev E (NOFORN).

[f] Planning Yard (NNSY) advises no shore connections; use 15 hose connections to ships fire plugs.

[g] DDG 51 Arleigh Burke class is currently comprised of three separate variants or "Flights": DDG 51-71 represent the original design and are designated Flight I ships; DDG 72-78 are Flight II ships; DDG 79 through DDG 123 are or will be built to the Flight IIA design.

[h] NAVSEA calculated total minimum 'critical load' saltwater flow is 17,620 gpm. Total (minimum + habitability/testing) saltwater required calculated by NNSY for all ship and dock systems is 29,000 (rounded from 28,072) gpm. Pressure at ship is 150 psi and pressure at shoreside manifold is 175 psi.

[i] NAVSEA letter Ser 14-0452, *Norfolk Naval Shipyard Request for CVN 78 Class Drydock Seawater Flow Requirements*;

NAVSEA Response of 09 May 14; NNSY letter C240 Ser 240-008-17, *Norfolk Naval Shipyard Request for CVN 78 Drydock Seawater Flow Requirements, Follow Up*, 14 Nove 2017 (NOFORN)

Notes to Table A-4:

* See note (*) at beginning of APPENDIX A; information provided in this table is for general reference purposes only; information is incomplete and may not be accurate; verify utility requirements with ships/program office(s). Blanks in table indicate information is missing or unavailable at this time.

** Designations of locations of ship connections are as follows:

- L is the distance (in feet) of the connection aft of the stem of the ship.
- H is the height (in feet) of the connection above the design waterline.
- P, S, C, CL refer to Port side, Starboard side, and Center/Centerline of a ship respectively.
- P/S indicates one connection on each side of ship at distance L.
- N is the number of shipboard connections at given location(s).
- Where more than one connection exists, all locations are shown.

[a] Reduce requirement by 35% if airwing is not embarked.

[b] DDG 51 Arleigh Burke class is currently comprised of three separate variants or “Flights”: DDG 51-71 represent the original design and are designated Flight I ships; DDG 72-78 are Flight II ships; DDG 79 through DDG 123 are or will be built to the Flight IIA design.

[c] Connection is PW-8; 1.5" NPS globe valve w/hose connection; silver-bronze union end (MIL-F-1183) w/adaptor for Hose 'B' thread size; 1.5" male x 11.5 fem.

[d] Includes additional capacity to fill technical (flushing) water system. Technical water system is not dependent on shore potable water and may be filled using dedicated onboard water generating equipment if required.

[e] LCC-20 Potable water connections are configurable to either 2 x 1.5” or 1 x 2.5” Hose Connections.

Notes to Table A-5:

* See note (*) at beginning of APPENDIX A; information provided in this table is for general reference purposes only; information is incomplete and may not be accurate; verify utility requirements with ships/program office(s). Blanks in table indicate information is missing or unavailable at this time.

** Designations of locations of ship connections are as follows:

- L is the distance (in feet) of the connection aft of the stem of the ship.
- H is the height (in feet) of the connection above the design waterline.
- P, S, C, CL refer to Port side, Starboard side, and Center/Centerline of a ship respectively.

- P/S indicates one connection on each side of ship at distance L.
- N is the number of shipboard connections at given location(s).
- Where more than one connection exists, all locations are shown.

[a] Oily Water 8,000 gpd (45,000 gal); Waste Oil 40,000 gal/offload; Aircraft Waste Fuel 9,400 gal/offload. All use same 2.5” deck connection.

Ship OWWO system has two 90 gpm pumps and is capable of discharging 90-180 gpm. Shipboard standard operating procedure while pierside is to operate with only one pump and discharge at the lower rate of 90 gpm.

[b] Oily waste requirement to be determined; Synthetic oily waste = 54 gpm.

[c] DDG 51 Arleigh Burke class is currently comprised of three separate variants or “Flights”: DDG 51-71 represent the original design and are designated Flight I ships; DDG 72-78 are Flight II ships; DDG 79 through DDG 123 are or will be built to the Flight IIA design.

Notes to Table A-6:

* See note (*) at beginning of APPENDIX A; information provided in this table is for general reference purposes only; information is incomplete and may not be accurate; verify utility requirements with ships/program office(s). Blanks in table indicate information is missing or unavailable at this time.

** Designations of locations of ship connections are as follows:

- L is the distance (in feet) of the connection aft of the stem of the ship.
- H is the height (in feet) of the connection above the design waterline.

- P, S, C, CL refer to Port side, Starboard side, and Center/Centerline of a ship respectively.
- P/S indicates one connection on each side of ship at distance L.
- N is the number of shipboard connections at given location(s).
- Where more than one connection exists, all locations are shown.

[a] CVN 78 utilizes a Type III Vacuum CHT (VCHT) system (50,000 gal tank forward and 100,000 gal tank aft). CHT transfer (discharge) pumps come on and empty tanks at ratings indicated. CHT tanks are only opened when there is maintenance/repair required in the tank. HMR 104 and HMR 104 Rev 1 authorized the change to a Type III VCHT system from a Type II (treatment).

[b] CHT fwd and aft systems are independent and must both be hooked up for shore discharge of sewage.

[c] DDG 51 Arleigh Burke class is currently comprised of three separate variants or “Flights”: DDG 51-71 represent the original design and are designated Flight I ships; DDG 72-78 are Flight II ships; DDG 79 through DDG 123 are or will be built to the Flight IIA design.

** Designations of locations of ship connections are as follows:

- L is the distance (in feet) of the connection aft of the stem of the ship.
- H is the height (in feet) of the connection above the design waterline.
- P, S, C, CL refer to Port side, Starboard side, and Center/Centerline of a ship respectively.
- P/S indicates one connection on each side of ship at distance L. Two station locations, one port and one starboard, at an equal distance from the bow, of which only one may be used at a time to receive power, one half of the total number of stations given are on port side, one half are on starboard.
- ST is stern station location; if power is delivered to the stern station, the port and starboard stations would normally not be used for receiving power.
- N is the number of service points - number of cables per service point (ex: 1 – 4, one service point with four cables).
- Where more than one connection exists, all locations are shown.

[a] Capacity is given in amperes. Unless otherwise indicated, power to load center is 450 V, 3-phase, three-wire, 60 Hz, ungrounded. Power factor is approximately 0.8. The number of receptacles per station may be obtained by dividing per station ampacity by 400.

[b] Required ampacity of shore power service is the maximum power that the ship will demand from the shore power system. The shore power service transformer shall be sized to provide the "Required ampacity of shore power service" for the ship moored at the respective berth. Note that the shore power service transformer is not necessarily sized to provide the ampacity equivalent to the product of the required number of shore power circuits and the rating (400 A) of the shore power circuits.

[c] Power is 4,160 V, 3-phase, three wire, 60 Hz, ungrounded. .

[d] CVN 70 and higher will not require any 480 V electrical services.

[e] Power to load center is 13,800 V, 3-phase, three wire, 60 Hz, ungrounded; 1307/1569 correspond to 25 MW load (without air wing) and 30MW load (with air wing). For additional information regarding the shore-to-ship interface, refer to *NAVSEA Drawing 802-7094558*, CVN Class Aircraft Carrier Electrical Interface Characteristics (NOFORN).

[f] CG 47 through CG 51: A total of 26 shore power receptacles are provided, 13 at each port and starboard station. Three receptacles (1,200 A) are used for a feed-through circuit to a tended ship and 10 receptacles (4,000 A) are used for the ships shore power station. CG 52 and following have no feed-through circuits.

[g] DDG 51 Arleigh Burke class is currently comprised of three separate variants or “Flights”: DDG 51-71 represent the original design and are designated Flight I ships; DDG 72-78 are Flight II ships; DDG 79 through DDG 123 are or will be built to the Flight IIA design.

[h] Normal hotel service load is 1,600 Amps.

Special testing of submarines, usually conducted at shipyards, requires an increased level of shore power (super shore power). Depending upon local operating policies, either additional circuits from the same service(s) are connected in conjunction with the normal "hotel" circuits to provide a combined increased level of shore power or additional circuits from completely separate service(s) are provided in addition to the normal "hotel" service. Note that for both modes of operation, the additional circuits are connected directly to the ship's switchboard bus.

[i] It is required that the shunt interlock circuits for the three SSN 774 Class services be independent of each other and the interlock should insure that all of the breakers for a given service (e.g. port) trip open at the same time in the event of an overcurrent condition.

[j] Only SSN 774 Block V (with VPM) requires a total of 6 circuits (cables) to the aft service points, 3 Port and 3 Starboard. One additional circuit (cable) is required to the Port bus for Block V (with VPM). Block V (w/o VPM) does not require an additional circuit. SSN 774 Block V (w/o VPM) – 2,400 A total. SSN 774 Block V (with VPM) – 2,800 A total.

[k] Between FY08 & FY14 LSD Class goes through a Mid Service Life Electrical Upgrade.

- LSD 41-48 goes from 6 cables (2,400 A) to 10 cables (4,000 A).
- LSD 49-52 goes from 8 cables (3,200 A) to 12 cables (4,800 A).

[l] T-AKE 1 requires that shore power be delivered at 505 to 515 V.

T-AKE 1 uses its own DC system to detect grounds, whereas shoreside facility uses an AC system to detect grounds. Prior to arrival at berth, shoreside facility must disable its ground detection system for that particular berth and rely upon the T-AKE 1 ground detection system.

[m] A = Requirement shown represents the demand of the tender while not tending.

B = Requirement shown represents the demand of the tender while tending; this includes the requirements of the tender plus the maximum requirements of the ships being tended.

Notes to Table A-8:

* See note (*) at beginning of APPENDIX A; information provided in this table is for general reference purposes only; information is incomplete and may not be accurate; verify utility requirements with ships/program office(s). Blanks in table indicate information is missing or unavailable at this time.

** Designations of locations of ship connections are as follows:

- L is the distance (in feet) of the connection aft of the stem of the ship.
- H is the height (in feet) of the connection above the design waterline.
- P, S, C, CL refer to Port side, Starboard side, and Center/Centerline of a ship respectively.
- P/S indicates one connection on each side of ship at distance L.
- N is the number of shipboard connections at given location(s).
- Where more than one connection exists, all locations are shown.

[a] Total number of active lines required for any ship is sum of column for "active lines" for the ship class and the embarked staff requirements necessary where specifically directed by the cognizant Service or the using agency.

[b] Column "cable size at berth" lists the size of cable to be provided at berths designated for various ship types. Cable sizes given in column "cable size at berth" include the ship requirement, the appropriate embarked staff requirement, and an allowance for spare pairs.

[c] Also requires Internet T-1, T-100, ISDN, SIPRNET/NIPRNET Digital T-1/ISDN type, 2 lines.

[d] Also requires fiber optic LAN connectivity.

[e] Also requires (1) Internet T-1, T-100, ISDN Digital T-1/ISDN - 1 line; (2) SIPRNET/NIPRENET BL II 1 connection.

[f] Also requires 2 fiber optic connections for IT21/ISNS and BFTT.

[g] Embarked staff requirements.

APPENDIX C OPERATION AND MAINTENANCE CRITERIA FOR SHORE-TO-SHIP POWER

C-1 CRITICAL COMPONENTS.

All electrical components whose failure could affect the reliability of the electrical distribution system supplying power to ships are identified as critical components of the shore to ship power system and are placed under the maintenance program defined in this enclosure. Critical components are the shore power primary circuit breaker, step down transformer, secondary circuit breakers, the permanently installed cables between the shore power circuit breakers and the power connection station (turtleback), the power connection station receptacles, and the portable power cable assemblies used for supplying shore power services to ships. Each portable power cable assembly is defined to consist of two electrical connectors and the cable in between.

C-1.1 Critical Component Inventory Records.

A history record will be established and maintained covering each shore to ship power system critical component. The record will document via inspection checklists all work completed and by whom. Cable and connections shall be tagged in accordance with the Shore Power Cable Assembly Nomenclature Detail, as shown in Figure C-6 and entered into Single Platform MAXIMO and other appropriate maintenance planning databases.

- **One-line diagram:** One-line diagrams, illustrating the equipment ratings and system configuration from the utility point of service, are prepared and kept current by the activities in accordance with the cognizant Service Manual MO-201, Electric Power Distribution Systems. Plot plans will be annotated to show the location of all shore to ship power system components.
- **Power System Study:** An activity power system study, including load flow, fault current analysis, coordination of protective devices, and arc flash is prepared in accordance with MO-201, Electric Power Distribution Systems.

C-2 PARALLELING TRANSFORMERS.

If a ship is supplied by two or more shore transformers, the ship's force will be directed, through standard ship operating procedures, not to parallel the transformers through the ship's bus unless the senior ship's electrician verifies correct phase orientation between power sources, and the supplying activity authorizes the parallel operation. If shore transformers are paralleled through the ship's bus, short circuit currents may be increased to unsafe levels and circulating currents may overheat and destroy cables, transformers, and switchgear on board ship or on shore.

C-2.1 Paralleling Shipboard Generation with the Shore Power System.

Paralleling of ship's service generators with the shore power system is prohibited except for the shortest time necessary to transfer load to or from shore power.

C-3 CABLES FOR SHORE-TO-SHIP SERVICE.

Shore-to-ship cables are normally provided by the Activity. For 480 V, three-phase, three-wire service, cables should be ungrounded, standardized lengths of single cable with three conductors, Type THOF-500, conforming to military spec MIL-DTL-915, Cable, Electrical, for Shipboard Use, and should be used for loads not exceeding 400 A. For 4,160 V, three-phase service to nuclear aircraft carriers, cables should be SHD350GC 8 kV, non-shielded insulated, PVC-jacketed cable, in accordance with Insulated Cable Engineers Association (ICEA) S 66 524, Cross-Linked-Thermosetting Polyethylene Insulated Wire and Cables.

C-3.1 Low Voltage Cables.

- Existing portable cables used for 480 V shore to ship power service may be MIL-DTL-915 type THOF-500 or type SHOF-500 in accordance with MIL-DTL-915. Low smoke cable specified by MIL-DTL-24643 which is for use on ships, shall not be used for shore-to-ship power applications. Its softer jacket is susceptible to damage.
- New portable cables used for 480 V shore to ship power service shall be three conductor type "Enhanced THOF-500" or "Enhanced Plus THOF-500" as shown in Figure C-6, Figure C-6, Figure C-6. Equivalent or better cables from other sources may be considered as approved by Navy technical authority.

C-3.2 Medium Voltage Cables.

The portable cables used for 4,160 V and 13,800 V shore to ship power service shall be three conductor, 350 kcmil type SHD-GC with Chlorinated Polyethylene (CPE) jacket. Insulation and jacket shall conform to ICEA S-75-381. Cables for 4,160 V service shall be 8 kV or 15 kV. Cables for 13,800 V service shall be 15 kV. However, cable sizes larger than 350 kcmil may be used with approval by Navy technical authority.

C-3.3 Standard Cable Lengths.

Activities will maintain an inventory of portable shore to ship electric power cables in lengths required for the ships. Lengths will be selected and constructed to service ships without the use of in-line connectors. Approval by Navy technical authority is required for an exception allowing the use of in-line connectors for specific conditions. All cable runs will be of equal length to minimize unequal load sharing.

C-3.4 Cable Storage.

Cables not in use should be stored appropriately. Covered off pier storage locations are highly desirable.

C-4 SHORE POWER CIRCUIT BREAKERS.

C-4.1 Low Voltage Cable Overcurrent Protection for Submarines.

The long-time pickup settings of the 450 V shore to ship power service circuit breakers for submarines shall be adjusted so that they match nominal ratings of equipment on the submarine. (Currently, the limiting ratings for equipment on the submarine is 435 A. If the 435 A setting is not a standard setting on the existing equipment, then the next higher setting is acceptable up to 480 A. Circuit breaker settings in excess of 435 A shall be documented and submitted to the cognizant Service with sufficient technical justification of the setting. Shore activities shall provide written notification to the submarines prior to connection focusing on the load requirements and load monitoring, breaker settings, and safety impacts. The instantaneous pickup setting shall be coordinated with the available short circuit amperes and associated system devices.

C-4.2 Low Voltage Cable Overcurrent Protection for Surface Ships.

The long-time pickup settings of the 450 V shore to ship power service circuit breakers for surface ships shall be adjusted to 430 A. If the 430 A setting is not a standard setting on the existing equipment, then the next higher setting is acceptable up to 480 A. Circuit breaker settings in excess of 430 A shall be documented and submitted to the cognizant Service with sufficient technical justification of the setting. The instantaneous pickup setting shall be coordinated with the available short circuit amperes and associated system devices.

C-4.3 Medium Voltage Cable Overcurrent Protection.

The long-time pickup setting of the shore to ship power service circuit breakers shall be adjusted to 400 A. If the 400 A setting is not a standard setting on the existing equipment, then the next higher setting is acceptable. The cable overcurrent protection will be based on the lowest rated service system device which is usually the fixed cables (normally 350 kcmil 105C conductors rated 440 A in conduit in air) between the substations and the receptacles for the portable cables, therefore the service rating could be as high as 440 A. Metal-clad switchgear with vacuum power circuit breakers will be equipped with programmable microprocessor relays which will allow the over current pickup to be set precisely to the desired setting. Circuit breaker settings in excess of 400 A shall be documented and submitted to the cognizant Service with sufficient technical justification of the setting. The instantaneous pickup setting shall be coordinated with the available short circuit amperes and associated system devices.

C-5 CABLE CONNECTORS.

Connectors. Cable connectors are available in two types: (1) one single, multiple conductor type (1-3/c cable); and (2) single conductor type grouped in a cluster of three (3-1/c cables). A typical three-conductor outlet assembly is illustrated in Figure D-4. Figure D-5 illustrates the single-conductor type connector.

- Low Voltage Terminations:
  - All low voltage portable power cables will be terminated with a MIL-C-24368/1 (procured from vendors on the Qualified Products List (QPL)) plug at the ship end of the cable for surface ships.
  - All low voltage portable power cables will be terminated with a MIL-C-24368/5 (procured from vendors on the QPL) plug at the ship end of the cable for submarines.
  - The termination device at the service end of the cable must be compatible with the design of the dockside power connection station (turtleback) and may be terminated with one of the following:
    - a MIL-C-24368/1 plug, for existing installations
    - a single pole connector which meets the environmental and test requirements of the MIL-C-24368 and the additional requirements identified is shown in Figure D-5
    - a UL 486A listed plug
    - an equivalent or better connector as approved by Navy technical authority
  - Install terminations in accordance with manufacturer's recommendations.
- Low Voltage In-line Connections: In-line single pole connectors and lug to lug connections shall meet the same requirements as identified above. Male and female cable mount in-line connectors may be used to connect shorter cable segments together to make longer cable circuits as necessary.
- Medium Voltage Terminations: All medium voltage portable power cables will be terminated at the ship end of the cable with a heat shrinkable termination (Institute of Electrical and Electronics Engineers standard IEEE-48 class 1) specifically designed for SHD-GC cables. Medium Voltage portable power cables for CVN 78 will be terminated at the ship end of the cable with a 15 KV Patton & Cooke cable coupler specifically designed for SHD-GC cables. The termination device at the service end of the cable must be compatible with the design of the dockside power connection station (turtleback) and may be terminated the same as the ship end of the cable or with a coupler plug that is compatible with the receptacle at the dockside power connection station. The termination devices shall be assembled on to the cable per the manufacturer's instructions. Terminate the SHD-GC cable ground and check

conductors within the cable breakout boot or to the appropriate termination pin integral with the coupler plug.

C-6 MAINTENANCE OF PORTABLE POWER CABLE ASSEMBLIES.

C-6.1 Tests and Inspections for Submarine Portable Power Cable Assemblies.

Electrical tests and inspections shall be in accordance with Maintenance Standard (MS) Number 3420-08 1-089. These tests and inspections shall be conducted annually. Results of the contact tightness checks, conducted in accordance with paragraph 1.g of Maintenance Standard (MS) Number 3420-081-089, shall be included on the written notification provided to ships forces prior to each shore power service connection to the submarine, identified in Section C-4.1 above entitled “Low Voltage Cable Overcurrent Protection for Submarines”.

C-6.2 Tests and Inspections for Surface Ship Portable Power Cable Assemblies.

Electrical tests and inspections shall be in accordance with ANSI/NETA MTS Maintenance Testing Specifications for Electrical Power Distribution Equipment and Systems (most recent edition) for cables and the manufacturer's instructions for connectors. Over potential tests are not required, but may be performed on the cable assemblies that fail insulation-resistance tests as a means to locate cable faults and to verify cable integrity. These tests and inspections shall be conducted annually.

C-6.3 Cable Repair.

Cables with damage other than to the outer jacket shall be removed from service permanently. Repair jackets using a heat shrinkable wrap around mining cable repair sleeve, cold repair elastomeric strips for mining cables, or a similar product. Repair of the coupler plugs and receptacles shall be performed in accordance with the manufacturers' instructions of these cable repair products or shall be in accordance with reference (b) MS NO.3420-08 1-089.

C-6.4 Connector Repairs.

Repairs to MIL-C-24368/5 connectors shall be in accordance with reference (b) MS NO. 3420-08 1-089 Repairs to MIL-C-24368/1 and MIL-C-24368/4 connectors, and medium voltage coupler plugs shall be in accordance with manufacturer's instructions.

C-6.5 Splicing.

Splicing of portable shore to ship power cables is not recommended for 480V shore power cables. Medium voltage portable power cables shall not be spliced under any conditions.

C-7 MAINTENANCE OF SHORE TO SHIP POWER PERMANENT COMPONENTS.

C-7.1 Electrical Tests and Inspections.

Electrical tests and inspections for shore power circuit breakers and associated protective relaying and the permanently installed cables between the shore power circuit breaker and the power connection station (turtleback) shall be performed in accordance with the latest edition of ANSI/NETA Maintenance Testing Specifications (MTS).

Note: Complete visual inspection of inaccessible components is not required.

For low voltage power air circuit breakers, Visual and Mechanical Inspections and Electrical tests shall follow ANSI/NETA MTS recommendations and be performed every two years, with the exception of primary current injection testing. Primary current injection testing shall be performed every 3rd breaker maintenance cycle (6 years) unless a problem is suspected, in which case the test shall be done immediately. Secondary current injection testing with primary current verification to verify proper operation of the current transformers and remaining connection points shall be a substitute for primary current injection testing every 1st and 2nd breaker maintenance cycle (2 and 4 years respectively).These intervals may be reduced, as required, based upon equipment condition or operating environment.

For medium voltage circuit breakers, Visual and Mechanical Inspections and Electrical tests shall follow ANSI/NETA MTS recommendations and be performed every two years. This interval may be reduced, as required, based upon equipment condition or operating environment.

All new low and medium voltage circuits breakers shall follow acceptance testing requirements set forth in ANSI/NETA Acceptance Testing Specification (ATS).

Electrical tests and inspections for the power connection station receptacles shall be in accordance with the manufacturer's instructions. Over potential tests are not required, but may be performed on the cable assemblies that fail insulation-resistance tests as a means to locate cable faults and to verify cable integrity.

C-7.2 Repair.

Repair of permanent components shall be performed in accordance with the manufacturer's instructions.

C-7.3 Breaker Operation.

Whenever shore power circuit breakers operate on instantaneous trip, do not re-energize associated shore power circuits until the cause of the fault has been cleared and the circuit breaker has been inspected for damage to contacts, arc chutes, frame and operating mechanism. Whenever shore power circuit breakers operate because of an over current, the ships forces shall be notified and the associated shore power circuits may be reenergized per local SOPS with concurrence from the ships forces.

3/C ENHANCED PLUS THOF

REVISED: CIEE	MARCH 24, 2006	ATTACHMENT 2-1.2

Figure C-3 3/C Enhanced & Enhanced Plus THOF Cable Specification

CONDUCTOR – CLASS I, UNIDIRECTIONAL LAY-UP, MAXIMUM RESISTANCE: 0.0238 OHMS/1000FT AT 25°C.

CONDUCTOR INSULATION – EPR PER ICEA S-75-381.
ABRASION RESISTANCE TEST IN ACCORDANCE WITH ISO 4649 – INDEX OF 50 MINIMUM.
PHYSICAL AND AGING TESTS IN ACCORDANCE WITH ICEA S-75-381.
TEAR RESISTANCE, MINIMUM, 20LB/IN.
UN-AGED VALUES.
TENSILE STRENGTH, MINIMUM – 1200 PSI.
ELONGATION AT RUPTURE, MINIMUM % – 150.
AFTER AGING IN AIR 168 HOURS AT 121 ± 1°C.
TENSILE STRENGTH, MINIMUM % OF UN-AGED VALUE – 75.
ELONGATION AT RUPTURE, MINIMUM % OF UN-AGED VALUE – 75.
LONG TERM INSULATION RESISTANCE IN 75°C WATER SHALL BE IN ACCORDANCE WITH UL 44.

CONDUCTOR JACKET (ENHANCED PLUS ONLY) – CPE OR HYPALON – COMPOSITE, TYPE RHH/RHW-2.
ABRASION RESISTANCE IN ACCORDANCE WITH ISO 4649 – INDEX OF 50 MINIMUM.
PHYSICAL AND AGING TESTS IN ACCORDANCE WITH ICEA S-75-381.
TEAR RESISTANCE, MINIMUM, 30 LB/IN.
UN-AGED VALUES.
TENSILE STRENGTH, MINIMUM – 2000 PSI.
ELONGATION AT RUPTURE, MINIMUM % – 400.

OVERALL JACKET – MOLD CURED, TWO LAYER REINFORCED JACKET FILLING THE CABLE INTERSTICES.
INNER WALL – HEAVY DUTY CPE.
PHYSICAL AND AGING TESTS IN ACCORDANCE WITH ICEA S-75-381.
UN-AGED VALUES.
TENSILE STRENGTH, MINIMUM – 1800 PSI.
ELONGATION AT RUPTURE, MINIMUM % – 300.
AFTER AGING IN AIR 168 HOURS AT 100 ± 1°C.
TENSILE STRENGTH, MINIMUM % OF UN-AGED VALUE – 85.
ELONGATION AT RUPTURE, MINIMUM % OF UN-AGED VALUE – 55.
OUTER WALL– EXTRA HEAVY DUTY CPE.
ABRASION RESISTANCE IN ACCORDANCE WITH ISO 4649 – INDEX OF 75 MINIMUM.
PHYSICAL AND AGING TESTS IN ACCORDANCE WITH ICEA S-75-381.
TEAR RESISTANCE, MINIMUM, 50 LB/IN.
UN-AGED VALUES.
TENSILE STRENGTH, MINIMUM – 2400 PSI.
ELONGATION AT RUPTURE, MINIMUM % – 300.
AFTER AGING IN AIR 168 HOURS AT 100 ± 1°C.
TENSILE STRENGTH, MINIMUM % OF UN-AGED VALUE – 70.
ELONGATION AT RUPTURE, MINIMUM % OF UN-AGED VALUE – 55.

ENHANCED & ENHANCED PLUS THOF SPECIFICATION

REVISED: CIEE JANUARY 31, 2007 ATTACHMENT 2-1.3

Figure C-4 3/C Enhanced & Enhanced Plus THOF Cable Specification

ASSEMBLY

ENHANCED THOF CABLE SHALL HAVE INSULATED CONDUCTORS.
ENHANCED PLUS THOF CABLE SHALL HAVE INSULATED AND JACKETED CONDUCTORS.
SEE DRAWINGS FOR DIMENSIONS AND SUPPLEMENTAL INFORMATION.

THREE CONDUCTORS SHALL BE CABLED WITH A MAXIMUM LAY LENGTH OF 26 INCHES. EXCEPT FOR A CENTER EXTRUDED RUBBER ROD FILLER, NO OTHER FILLERS ARE PERMITTED. NO ASSEMBLY BINDER TAPE IS TO BE USED. MOLD RELEASE AGENTS, IF USED SHALL NOT CONTAIN SILICONE OR WAX.

FUNCTIONAL TESTS

THE GOVERNMENT RESERVES THE RIGHT TO WITNESS ANY OR ALL CABLE TESTS. ONCE FUNCTIONAL TESTING HAS BEGUN, ALL TESTS MUST BE COMPLETED IN NO MORE THAN 36 HOURS. FUNCTIONAL TESTS ARE REQUIRED USING A TEST CABLE AS DESCRIBED BELOW. TESTS SHALL BE CONDUCTED AFTER THE CABLE HAS BEEN EXPOSED TO THE SPECIFIED TEST TEMPERATURE FOR AT LEAST 8 HOURS. THE FUNCTIONAL TESTS SHALL BE PERFORMED IN THE FOLLOWING ORDER USING THE SAME PIECE OF CABLE:

1. DIELECTRIC PRE–FLEX TEST.
2. SUMMER FLEXIBILITY WITH NATURAL BEND.
3. SUMMER FLEXIBILITY AGAINST NATURAL BEND.
4. WINTER FLEXIBILITY WITH NATURAL BEND.
5. WINTER FLEXIBILITY AGAINST NATURAL BEND.
6. CUT–BACK.
7. DIELECTRIC POST–FLEX TEST.

TEST CABLE DESCRIPTION

THE TEST CABLE WILL BE 12 FEET IN LENGTH CUT FROM A CABLE WITH A MINIMUM LENGTH OF 100 FEET, ROLLED ONTO A CABLE REEL FOR AT LEAST 168 HOURS WHOSE SPOOL DIAMETER DOES NOT EXCEED 3 FEET. THE TEST CABLE WILL BE CUT FROM THE LAYER OF CABLE IN CONTACT WITH THE SPOOL. AFTER THE DIELECTRIC PRE–TEST EACH END WILL BE SEALED TO PREVENT MOISTURE INFILTRATION.

ENHANCED & ENHANCED PLUS THOF SPECIFICATION (CONT'D)

REVISED: CIEE	MARCH 24, 2006	ATTACHMENT 2–1.4

Figure C-5 3/C Enhanced & Enhanced Plus THOF Cable Specification

FLEXIBILITY TEST

ALL FLEXIBILITY TESTS WILL BE PERFORMED BY LAYING THE TEST CABLE ON A 20 INCH DIAMETER SHEAVE OR DRUM (IE WHEEL) AND LIFTING IT VERTICALLY UNTIL THE CABLE HANGS FREE IN AIR. THE PLACEMENT OF THE CABLE ONTO THE WHEEL WILL ALLOW APPROXIMATELY ONE-HALF OF THE CABLE TO HANG DOWN ON EACH SIDE. AS THE CABLE HANGS FREE, ATTACH 80 POUNDS TO EACH END AND MEASURE TANGENTIALLY (IE PERPENDICULAR TO VERTICAL) THE SHORTEST DISTANCE BETWEEN THE CABLE MEASURED AT THE BOTTOM OF THE WHEEL. THE CABLE SHALL HANG FOR NO MORE THAN 30 SECONDS BEFORE THE MEASUREMENT IS TAKEN. NO FORCE TENDING TO BRING THE CABLE ON EACH SIDE OF THE WHEEL CLOSER TOGETHER WILL BE PERMITTED. ONLY THE WEIGHT OF THE CABLE AND THE TEST WEIGHTS WILL BEND IT AROUND THE TOP OF THE WHEEL.

DIMENSIONS BETWEEN CABLE AT BOTTOM OF WHEEL.
SUMMER: 25 INCHES MAXIMUM AT 25°C, ± 2°C.
WINTER: 28 INCHES MAXIMUM AT 5°C, ± 2°C.

CUT-BACK TEST

NOT LESS THAN 24 INCHES OF THE CABLE JACKET WILL BE REMOVED FROM BOTH ENDS OF THE TEST CABLE USING A KNIFE, 10 INCH CHANNEL LOCK OR VICE GRIP TYPE PLIERS, AND 8 INCH NEEDLE NOSE PLIERS. REMOVAL OF THE JACKET SHALL BE ACCOMPLISHED WITHOUT THE APPLICATION OF HEAT TO THE JACKET AT ROOM TEMPERATURE OF 20°C ±2°C. VERIFY THE FOLLOWING:

NO BONDING OF CONDUCTOR INSULATION (OR CONDUCTOR JACKET) TO CABLE JACKET
NO REMOVAL OF CONDUCTOR INSULATION (OR CONDUCTOR JACKET) BY TEARING
BOND BETWEEN INNER WALL AND OUTER WALL OF OVERALL JACKET SHALL BE STOCK TEARING.

DIELECTRIC TESTS

DIELECTRIC TESTS (BOTH PRE AND POST FLEXIBILITY TESTING), PER ICEA T-27-581.
AC HI POT; 9.5 KV FOR 5 MINUTES.
INSULATION RESISTANCE: NOT LESS THAN 100 MEG-OHMS.

NOTES

1. DRAWING IS FOR REFERENCE, PLANNING AND ESTIMATING PURPOSES ONLY.
2. DRAWING IS DESIGNED FOR A 3 PHASE, 13.2KV GROUNDED NEUTRAL SYSTEM. THE CONNECTORS ARE NOT AVAILABLE FOR UNGROUNDED NEUTRAL SYSTEMS ABOVE 8.32KV.
3. THE NUMBER OF CIRCUIT BREAKERS AND RECEPTACLES AND THE LENGTH AND WEIGHT OF THE SUBSTATION WILL VARY DEPENDING ON THE TRANSFORMER KVA SIZE. THE TRANSFORMER SIZE WILL NORMALLY VARY FROM 1000KVA TO 2500KVA, THE NUMBER OF CIRCUIT BREAKERS AND RECEPTACLES FROM 6 TO 12, THE SUBSTATION LENGTH FROM 22' TO 28', AND THE SUBSTATION WEIGHT FROM APPROXIMATELY 22,500 POUNDS TO 33,500 POUNDS.

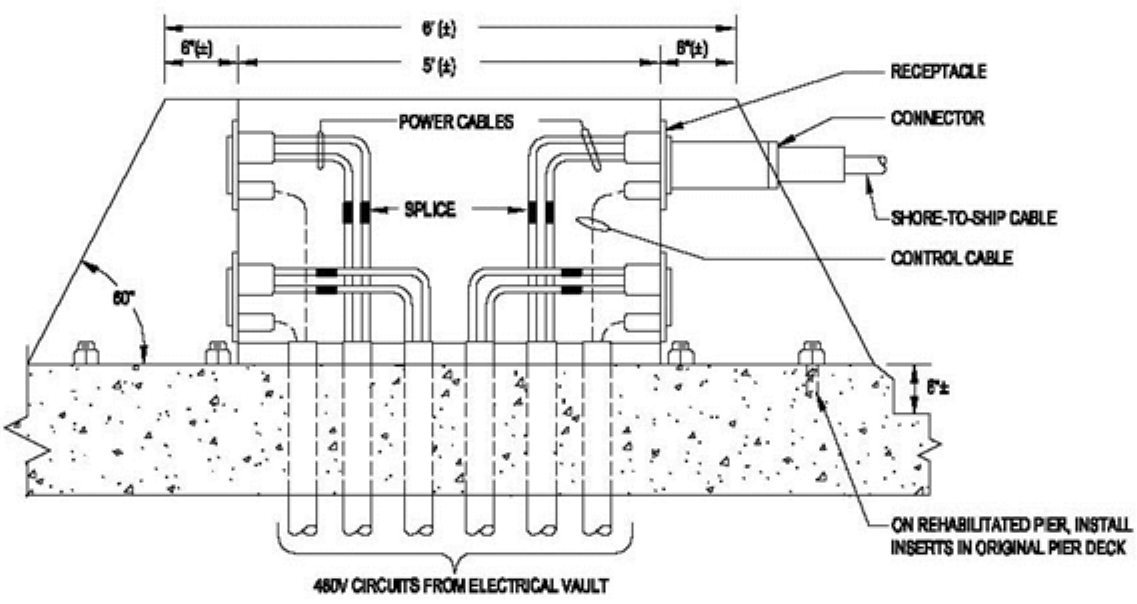
SECTION A



SECTION B

Figure D-5 (a) Single Pole Connector Details

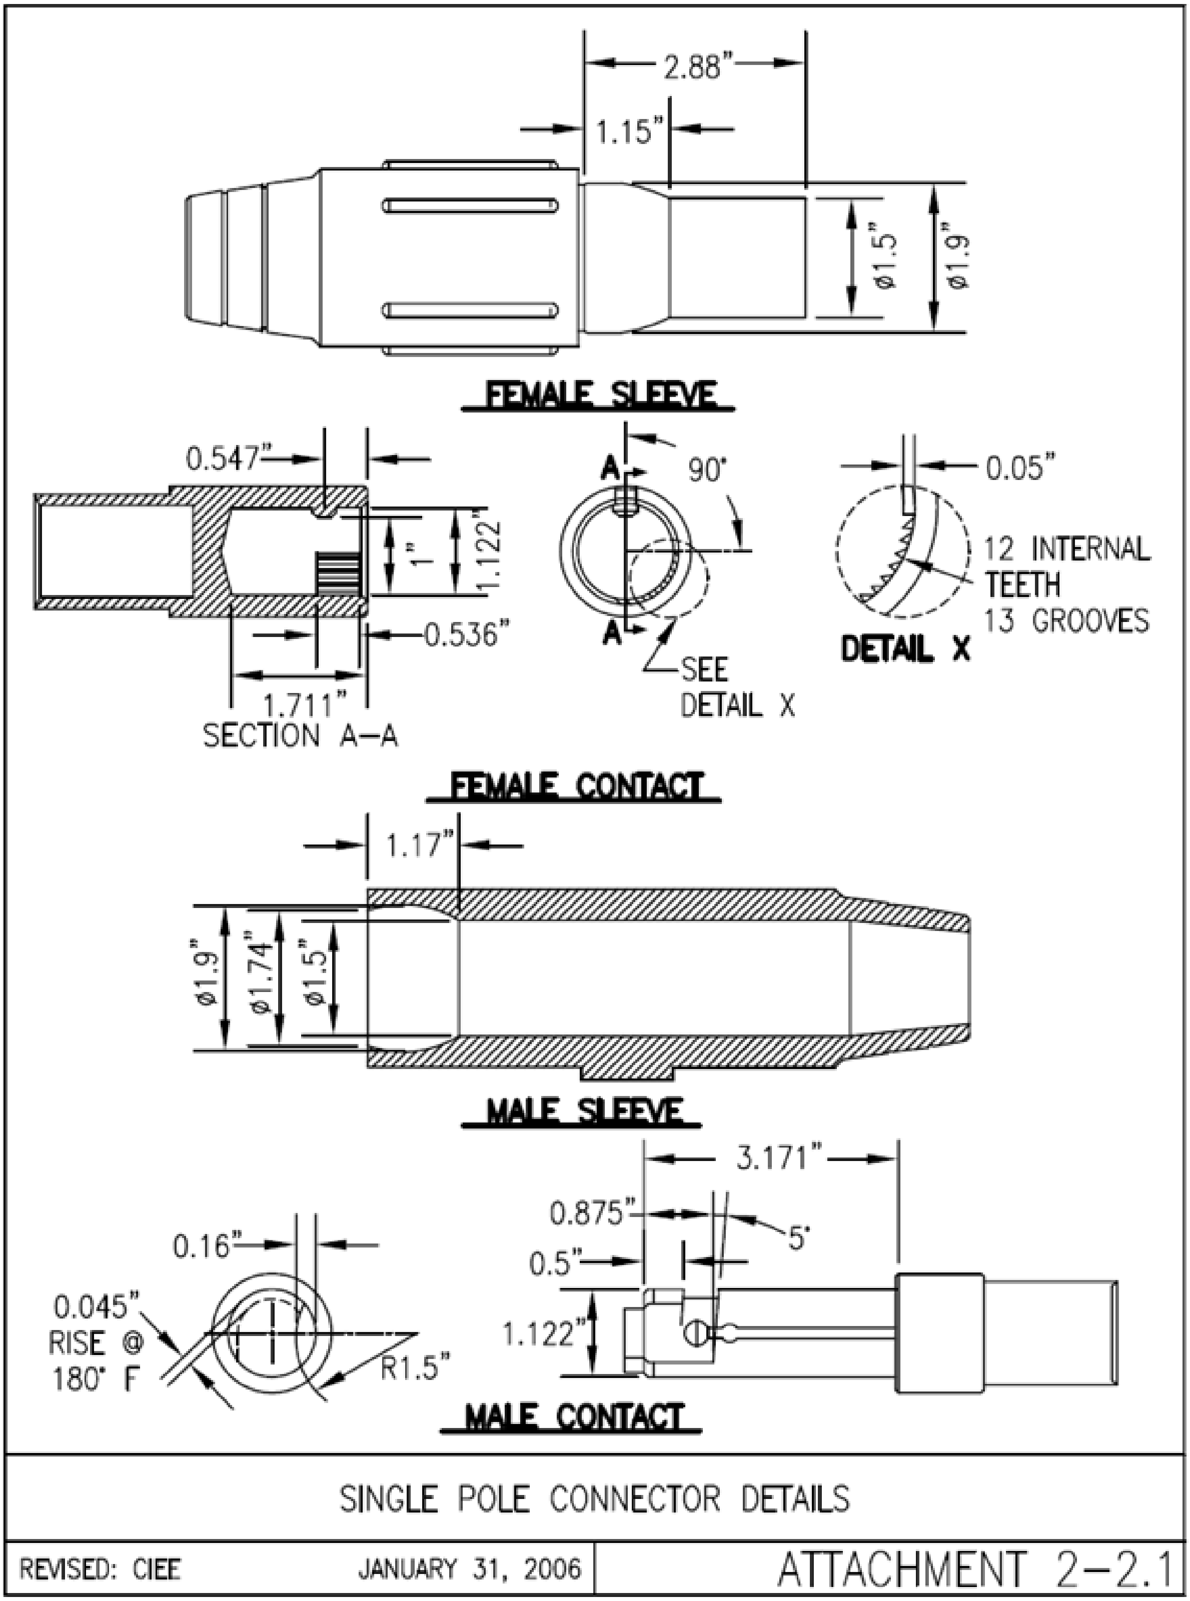


Figure D-5 (b) Single Pole Connector Specification

1. RATED FOR 600 VOLTS, 690 AMPERE MAX, 60 HERTZ, SINGLE POLE CAM, CONTINUOUS DUTY OPERATION.
2. INLINE CONNECTORS SHALL LOCK TOGETHER SO THAT THEY CAN NOT TWIST OR TURN LOOSE UNLESS A PUSH-BUTTON RELEASE MECHANISM IS ENGAGED.
3. POWER CABLE TERMINATION TO THE CONNECTOR CONTACTS SHALL BE VIA A CRIMP CONNECTOR.
4. THE INSULATED SLEEVES SHALL BE MECHANICALLY SECURED TO THE CONNECTOR CONTACTS TO GIVE A MINIMUM OF 700 LBS SHEAR FORCE.
5. BALL NOSE INSULATED SLEEVES SHALL BE MOLDED OF AN ETHYLENE PROPYLENE THERMOPLASTIC RUBBER (EPTR) COLORED BLACK PHASE A, WHITE PHASE B, AND RED PHASE C.
6. THE EPTR SLEEVES SHALL HAVE THE FOLLOWING MINIMUM REQUIREMENTS:
   - CONSTANT SERVICE TEMPERATURE RANGE: −60°C TO +135°C (−81°F TO +275°F)
   - FLAMMABILITY: UL 94 HB RATED
   - ELECTRICAL: UL RELATIVE THERMAL INDEX (RTI): 100°C (212°F)

psi	pound per square inch
psig	pound per square inch gauge
S	starboard side (right side of vessel when facing forward)
scfm	standard cubic feet per minute
V	volt
VAC	volt alternating current
W/ft	watts per foot
W/m	watts per meter
w/o	without
WL	waterline

E-3 DEFINITIONS OF TERMS

Active Berthing: A pier or wharf with berths used for homeport or light repair purposes, usually with a full or partial crew aboard, and always with ships in active status.

Activity: The organization (or organizations) that is responsible for the daily and routine operation and maintenance of the associated waterfront facility.

APTS: Activity providing telephone service. The organization responsible for the daily and routine operation and maintenance of the waterfront's telecommunication system (or systems).

Berth: A specific, marked-off length, along a pier or wharf, containing ships services appropriate for the ship classes which may be assigned to it.

Berthing Pier: A general term for a pier with berths and ships services.

Berthing Plan: A plan devised by each facility showing all berthing areas with ships assignments. May be permanent or temporary, depending upon the type of facility.

Bollard: A single-post fitting to which mooring lines from vessels are attached.

Capstan: A motorized, vertical-drum device used to tension lines for positioning ships, usually in dry dock.

Cleat: A mooring fitting having two diverging horizontal arms to which mooring lines from vessels are attached.

Cold Iron: Used to describe the condition of a ship when all shipboard boilers, engines, and generators are inoperative during repairs and can furnish none of the required ships services.

Cooling/Flushing Water: Water (usually nonpotable or salt) supplied to ships for condenser-cooling, fixture-flushing and other miscellaneous uses.

Dedicated Berth: A berth having required services for, and dedicated to use by, a specific ship for an extended period of time.

Graving Dry Dock: A permanent concrete drydocking structure requiring the use of caisson and dewatering pumps.

Hotel Services: Dockside utilities provided for a ship at berth (also called ships services, utility services, and cold iron services).

Inactive Berthing: Permanent or semi-permanent berthing areas for ships out of service, with crew normally not aboard.

Nested Ships: Two or more ships berthed side by side, with utility services supplied from berth side to the outer ships via ships header systems or hoses and cables strung across decks.

Oily Waste: Water (usually salt) from ships bilge which has been contaminated with petroleum products (fuel or lube oils) and which cannot discharge either to surface waters or to sanitary sewer.

Overhaul Facility: Generally used interchangeably with Repair Facility.

Pier: A dock, built from the shore out into the harbor, which is used for berthing and mooring vessels.

POL: Petroleum, oil and lubricants. An acronym used to describe petroleum products, and the facilities used in their storage and handling. As used herein, applies to marine fuels, jet fuels and lubricants.

Quay Wall: A heavy gravity or platform structure fronting on navigable water, behind which earth fill is placed to a level grade along its length.

Repair Facility: Locations where ship repair activities take place, such as at a shipyard or ship-repair facility. Facilities may utilize repair piers, dry docks, or both. (Also, Overhaul Facility.)

Telecommunications: Systems of communicating speech or impulses via wire or cable over distances, such as telephone, data transmission, coded transmission, cable TV and signal or alarm circuits.

Wharf: A dock, oriented approximately parallel to shore, with more than one access connection with the shore; a wharf is used for berthing or mooring vessels. May also be as above, except with continuous connection to shore.

With Change 1, 19 October 2010

UNIFIED FACILITIES CRITERIA (UFC)

MILITARY HARBORS AND COASTAL FACILITIES

UNIFIED FACILITIES CRITERIA (UFC)

MILITARY HARBORS AND COASTAL FACILITIES

U.S. ARMY CORPS OF ENGINEERS
NAVAL FACILITIES ENGINEERING COMMAND (Preparing Activity)
AIR FORCE CIVIL ENGINEER SUPPORT AGENCY

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
	June 2006	Forward Change
1	19 October 2010	Replaced cover page; replaced section 5-6 in its entirety; Appendices A, B and C were combined into Appendix B; renumbered Appendix E to C and Appendix F to D; other minor changes throughout

This UFC supersedes DESIGN MANUAL 26.1, 26.2 and 26.3.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD(AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Center for Engineering and the Environment (AFCEE) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request (CCR). The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

CHAPTER 1 INTRODUCTION

1-1 SCOPE.

The objective of this document is to cite and supplement existing government and commercial standards for design and construction of harbor and coastal facilities. It serves as planning, engineering and design guidance for professional facility planners, designers, constructors, and maintainers, including Navy personnel and Government contractors. Designers and planners will use this handbook for individual project planning, for preparing engineering documentation, and for preparing contract documents for construction and repair. This document extensively references the U.S. Army Corps of Engineers (USACE) *Coastal Engineering Manual* (CEM). The CEM is in the final stages of development and can be accessed at http://chl.erdc.usace.army.mil/chl.aspx?p=s&a=ARTICLES;101.
For sections not currently available contact the NAVFAC LANT Engineering Criteria and Programs Office.

1-2 PURPOSE.

The purpose of UFC 4-150-06 is to provide adequate harbor and dredging project criteria, design and maintenance guidance, and relevant lessons learned with respect to shore infrastructure. This document also provides the complete criteria and guidance package needed by appropriate end users. To the extent practical, it addresses the range of harbor and dredging criteria needed at stateside and overseas military installations. **Note**: This document does not include overseas data.

1-3 ORGANIZATION.

The majority of the information for subjects of this handbook is introduced as references to the applicable government and consensus standards in which the original information resides. Where other documents are not available or are inadequate, additional narrative information regarding Navy-specific issues has been developed and inserted, as appropriate.

1-4 CANCELLATION.

UFC 4-150-06 cancels and supersedes NAVFAC Design Manual 26.1, *Harbors*, dated 1 December 1984, NAVFAC Design Manual 26.2, *Coastal Protection* and NAVFAC Design Manual 26.3, *Coastal Sedimentation and Dredging*, dated 1 September 1986.

CHAPTER 2 HYDRODYNAMICS

2-1 INTRODUCTION.

This chapter covers design considerations related to the physical effects on structures caused by various types of water movement, such as tides, currents, and wave action along the open shore line and those occurring within restricted bodies of water. This subject is thoroughly covered by the *Coastal Engineering Manual* (CEM) but is outlined below by subjects of interest to Navy coastal facilities designers and then cross-referenced to the appropriate section of the CEM and other applicable references. Note that references made to sections in the draft CEM may change once the final version is published. The most current version of the CEM at the time of this publication can be found on the web at http://chl.erdc.usace.army.mil/chl.aspx?p=s&a=ARTICLES;101

Port, harbor and facility issues, such as trends in port and harbor development, deep versus shallow draft projects and motivation, are discussed in CEM, Section V-5. These issues are discussed as explanations and justifications for harbor needs. For example, the motivation for developing new or existing port and harbor facilities is the importance of overseas trade to the U.S. economy and government.

Development of local design criteria is essential in many cases due to the variation in meteorological and geological conditions at different geographical sites. These criteria are based upon raw and hindcast environmental information and the forecasting of data with analytical descriptor models.

2-2 WATER WAVE MECHANICS.

The very complex phenomenon of wave action on the sea surface, and how it affects structures, is a primary concern in design of coastal facilities. An extensive study to characterize regular and irregular waves is contained in Section II-1 of the CEM.

2-2.1 Selection of Design Waves.

The selection of design waves should be related to the economics of construction, maintenance, and repairs. The selection of design conditions for larger structures requires more detailed consideration of the economics of the design. Wave analysis yields the recurrence interval of a given wave height. The economics of increasing the initial cost versus making occasional repairs must be evaluated. Furthermore, the cost and extent of damages to areas that the structure is designed to protect must also be considered. Physical and economic factors, such as design wave height versus annual costs, must be optimized. For small projects, a 20- to 25-year design wave, coupled with an annual extreme water level, is appropriate. In addition to the general design parameters for determining cost-benefit relationships, specific local design criteria must be determined and applied. For example, Norfolk, VA would not use a 50-year hurricane, although it may be an appropriate criterion for other locations. Refer to the CEM, Section II-8: Coastal Hydrodynamics, for further details.

2-3 METEOROLOGY AND WAVE CLIMATE.

A basic understanding of marine and coastal meteorology and the relationship between meteorological processes and wave generation is important to coastal design and planning. Section II-2 of the CEM contains an analysis of this subject.

2-4 ESTIMATION OF NEARSHORE WAVES.

The size and directions of nearshore waves that impact coastal design are strongly influenced by underlying seafloor geometry and currents. While overestimating wave height can inflate the price of a project, underestimating can result in catastrophic loss. Section II-3 of the CEM evaluates wave transformation analyses methods and provides guidance for selecting a reasonable approach for making wave transformation calculations.

2-5 SURF ZONE HYDRODYNAMICS.

Breaking waves, and the resulting dissipation of energy, induce nearshore currents and other hydrodynamic processes that make the surf zone the most dynamic coastal region. Section II-4 of the CEM describes shallow-water wave breaking and associated hydrodynamic processes that affect shoreline and beach profile, which impact the design of coastal structures and beach fills.

2-5.1 Coastal Bottom Boundary Layers.

The severe interaction between the slowly varying current boundary layer and the turbulent wave bottom boundary layer during severe storm events plays a significant role in sediment transport. This interaction, which occurs primarily in the area just outside the surf zone, in water depth ranging between 6.6 to 9.8 ft (2 or 3 m) up to 65.6 to 98.4 ft (20 to 30 m), affects sediment that is not usually suspended under normal wave conditions. The fate of the sediments in this zone is a complex question for coastal engineers. The factors and complexities that make analysis of this activity so difficult are discussed in Section III-6 of the CEM. An extensive analysis of this process is contained in *Coastal Bottom Boundary Layers and Sediment Transport* by Peter Nielsen.

2-6 WATER LEVELS AND LONG WAVES.

A significant component of coastal design is protection of structures from some predefined water surface elevation. The following sections, the scope of which is summarized in Section II-5, of the CEM, classify the various types of surface elevation variation generated by long waves and guidance for developing a preliminary study approach and applicable design procedure. A discussion of the geological effects of wave action is contained in Section IV-2 of the CEM.

2-6.1 Water Wave Classification.

Section II-5-2 of the CEM gives a brief review of wave classification criteria and a summary of long wave properties.

2-6.2 Astronomical Tides.

Astronomical tides represent an important example of long waves. Section II-5-3 of the CEM describes tidal processes and effects.

2-6.3 Water Surface Elevation Datums.
Section II-5-4 of the CEM describes the various means of defining water surface elevation datums and the relationship between tidal observation-based datums, which account for spatial variability of sea level and vary according to locale, and the National Geodetic Vertical Datum (NGVD), which does not. It also discusses several processes that result in long-term changes in relative mean sea level. An additional discussion of datums and relationship to coastal geology is contained in Section IV-2-4 of the CEM. The selected datum and a rationale for its choice should be stated specifically in the design documentation.

2-6.4 Storm Surge.
High-wind systems and low barometric pressures over shoaling water will create a temporary water-level rise along shorelines. Especially susceptible are areas where large cyclonic storm systems (such as hurricanes and typhoons) track across relatively shallow offshore water. A relatively short-duration water-level rise (setup) will occur along coastlines during episodes of high-wave attacks. The rise in water level is caused by breaking waves trapping a water mass along the shoreline. This water rise can increase water heights in protected water areas hydraulically linked to the coast, shoreward of the breaker line. This phenomenon, and generated currents associated with it, can be significant in harbor sites located behind reefs or large shoals. Section II-5-5 of the CEM discusses the effect of tropical and extra-tropical storm activity on water surface elevation.

2-6.5 Seiche.
Defined as a standing-wave oscillation of an enclosed body of water that continues, pendulum fashion, after the cessation of the originating force, seiche may be either seismic or atmospheric in origin. Seiche is a phenomenon associated with ocean waves having periods in excess of those of normal sea swell. Such waves, commonly known as "long waves," have periods ranging from 20 seconds to several hours. Long waves exhibit relatively low heights, on the order of 0.1 to 0.4 foot (0.03 to 0.12 meters). They are highly reflective, even off flat-slope beaches, and will pass virtually unimpeded through porous breakwaters. Seiche occurs within a basin, harbor, or bay during certain critical wave periods when the period of incident long-wave energy matches the resonating period of the basin. The result is a standing wave system comprising reinforced wave heights greater than those of the incident wave. The water surface exhibits a series of nodes and antinodes with respect to the water column. Antinodes are regions where the vertical motion is a maximum and the horizontal velocities are minimum. Where wavelength is sufficiently greater than ship length, a ship berthed at the antinode will experience a gentle rise and fall with the standing-wave period. At the node, the ship will be subject to a periodic horizontal surging action due to currents. A ship in combination with its mooring lines behaves as a spring-mass system which, when excited, can resonate at certain critical frequency ranges. During seiching action,

the horizontal surging motion of a vessel located near a node can interfere with loading operations and, in severe cases, can cause the mooring lines to part. Section II-5-6 of the CEM discusses further details of this phenomenon.

2-6.6 Tsunamis.
In certain ocean regions, waves generated by seismic disturbances or landslides occur. From event history, some shoreline locations are more susceptible to damage from tsunamis than others. Probability approximations of water-level height exist for some coastal locations. These are included in reports by the U.S. Army Corps of Engineers (USACE) and licensing studies by Public Utility Commissions. If warranted, a site-specific risk analysis can be performed, which relies heavily upon probability parameters for specifics of the underwater seismic movement. Contact the NAVFAC LANT Engineering Criteria and Programs Office regarding when to perform such site-specific risk analyses. This is coupled with a three-dimensional numerical analysis of ocean-basin propagation and near-shore site shoaling of the resulting long wave.

2-6.7 River Discharge and Flood Control Channel Discharge.
Where a harbor site is hydraulically influenced by river discharge, present as well as future river flood discharge effects on water levels need to be considered. Effects of river discharge on harbor hydrodynamics are discussed briefly in Section II-7-6 of the CEM. Deltaic processes, river mouth flow, and sediment disposition, and inlet processes and dynamics are discussed in Section IV-3.

2-6.8 Extreme Water Levels.
The estimation of extreme water levels is discussed in Section II-8-6-e of the CEM.

2-6.9 Numerical Modeling of Long Wave Hydrodynamics.
Due to the complexity of most natural flow systems, engineering analyses for coastal engineering design projects often require numerical modeling of the hydrodynamic processes. Methods for applying this analytical tool are described in Section II-5-7 of the CEM. NAVFAC LANT Engineering Criteria and Programs Office should be contacted when contemplating using numerical modeling.

2-7 HARBORS.
Because harbors are, by nature and design, protected from short wave effects, long wave processes primarily drive their hydrodynamic environment. Specific information on these processes is examined in the sections on tides, seiche, storm surge and other long wave phenomenon. Section II-7 of the CEM covers the hydrodynamics of harbors, including effects of wave action, flushing/circulation, and vessel interaction. The discussion of inlet hydrodynamics contained in Section II-6 of the CEM also adds insight into the processes that take place at the entrance of a harbor and impact its overall hydrodynamic environment. The impact of these processes on moored ships and criteria for acceptable ship motions in safe working conditions is contained in the Permanent International Association of Navigation Congresses (PIANC) report titled *Criteria for Movements of Moored Ships in Harbours - A Practical Guide*.

2-7.1 General Function.
A harbor is described as a water area that is bounded by natural features or manmade structures or a combination of both. As such, it provides refuge and safe moorings and protection for vessels during storms or accommodations for such water to water or water to land activities as resupply, refueling, repairs, or transferring cargo and personnel. In such cases when a harbor is used to transfer commercial cargo or passengers, it is designated as a “port”. More specifically, when military services use a harbor or portions thereof, the facility is referred to as a “military harbor”. The landside areas adjacent to military harbors are also included under this designation because they support various waterborne naval activities. Additional terms such as naval base, naval station, naval depot, and naval shipyard are also used depending upon the appropriate support activity.

2-7.2 Purpose of Harbor Construction.
The intended goals in designing and constructing a harbor are twofold: to obtain a relatively large area of water, with adequate depth during all tidal stages that will provide shelter for ships and to provide a means by which to transfer cargo and passengers between ships and shore locations and facilities.

2-7.3 Harbor Features.
Though it may not be feasible to provide all of the desirable characteristics of an ideal harbor at any one location, the ideal waterside harbor would include the following features:

- shelter from open-sea waves,
- minimum tidal range and moderate currents,
- freedom from troublesome long-wave agitation (seiche),
- freedom from fog and ice,
- access through one or more safe navigational channels under all weather conditions,
- adequate room and depth to maneuver ships within the sheltered area,
- space for an adequate number of fixed moorings,
- shelter from strong winds from all directions,
- minimum maintenance dredging, and
- room for future expansion.

The following landside features provide accommodation for naval ship activities:

- layout of quays, piers, and wharves to accommodate ships of varying lengths and drafts,
- waterfront structures of dimensions and strength to accommodate weight-handling equipment and cargo-hauling vehicles, including both road and rail,
- utility services at berth
- covered and uncovered transit storage in the immediate area of the berth, with additional long-term and depot storage at a more remote location where required,
- space for adequate road and rail transportation linkage between the waterside area and inland distribution,
- provisions for the transfer and accommodation of passengers,
- provisions for small craft, shore boats, lighters, and tugs,
- safety from fire hazards,
- minimum general maintenance,
- proximity to labor and material sources,
- proximity to air-transport facilities,
- adaptability of shore installations for alternate uses, and
- room for expansion.

2-7.4 Types of Harbors.

The locations for constructing harbors range from open coastlines requiring artificial impoundments to natural bays, estuaries, and navigable rivers that need a minimum of manmade structures for the necessary storm protection. Within limits, harbors may be built wherever suitable water depth exists or can be provided and maintained with dredging operations. The degree of artificial works necessary to construct a viable harbor varies with the site's natural features. Examples of various siting classifications are shown in Figure 2-1. The characteristics of harbor location types are given in Table 2-1.

Figure 2-1 Examples of Harbor Siting Classifications

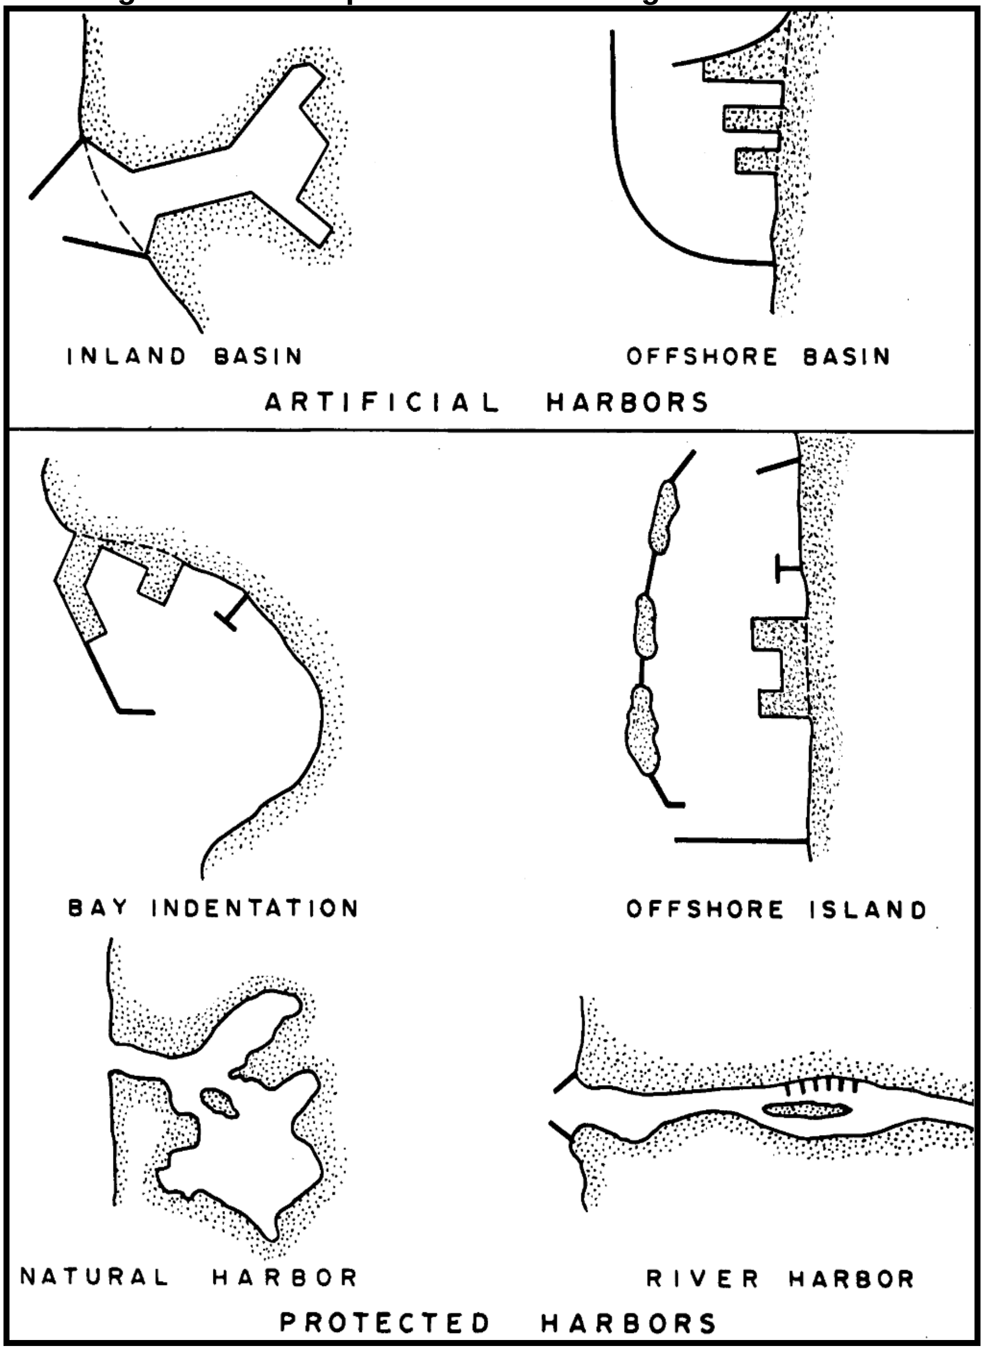

Table 2-1 Characteristics of Harbor Location Types

Type		Characteristics
Artificial – inland basin	Needs:	Low elevation; economical excavation.
	Advantages:	Less breakwater costs; feasibility of expansion.
	Concerns:	Low ground may contain poor soils; potential of flooding and sedimentation from upland sources; distance to offshore navigational water depth; littoral drift; silting.
Artificial – offshore basin	Needs:	Adequate sources for extensive breakwater construction material.
	Advantages:	Normally good foundation conditions can be developed with minimal dredging.
	Concerns:	Construction costs relatively high for harbor size; minimum expansion capability; littoral drift; shoaling.
Protected	Needs:	Shoreline relief features help to reduce storm-wave exposure.
	Advantages:	Less breakwater development cost.
	Concerns:	Can be same as other locations.
Natural	Needs:	Natural ocean access passage of adequate dimensions leading to embayment protected from storm waves.
	Advantages:	Minimal effort required for developing protected water area.
	Concerns:	If not historically used as ship refuge area, ascertain reason (example: Lituga Bay, Alaska, which is subject to landslides and massive waves); natural sediment regime should be thoroughly investigated if extensive deepening of natural depths is proposed.
River	Needs:	Historically stable river of adequate natural depths and widths to accommodate proposed vessel sizes.
	Advantages:	Minimal effort required for developing protected water area.
	Concerns:	Currents and water-level fluctuations due to variation in river stages; effects of new works on river’s natural alluvial regime require thorough analysis, including effects of salinity changes; extensive basin dredging and channel deepening should be avoided where possible.

2-7.5 Open Coastlines.

When harbors are situated on open coastlines, a high degree of artificial work is required to provide shelter. Consequently, as the coastline itself becomes more winding and offshore islands appear, the degree of natural shelter provided in turn reduces the harbor's exposure to wind and waves. Thus a corresponding decrease in the amount of artificial protection is required.

2-7.6 Bays, Estuaries, and Navigable Rivers.

When the harbor is situated entirely within an enclosed bay or estuary having a narrow opening into the sea, an environment of total natural protection results. Depending on the orientation of the naturally occurring protective features, these harbor sites need little or no additional protection. Nonetheless, a degree of entrance improvement is usually required to ensure safety during storms and as the entrance widens, the degree of protection required increases as well.

2-7.7 Hydraulic Impoundments.

Hydraulic impoundments are defined as harbor basins in which the vessel mooring depth is constantly maintained behind locks, versus the case in harbors where free-flowing water linkages to the sea or other large bodies of water exposed to storms exist. Since harbors are not located in bays, estuaries, and rivers, the hydraulic-impoundment harbors are not influenced by tidal fluctuations. Either admitting or releasing water through the locks maintains water levels. Though constructed worldwide economically efficient for commercial port facilities, the constricted access of hydraulic impoundments makes then generally undesirable for military purposes.

2-7.8 Roadsteads.

In cases when protection is provided only as a moored-ship refuge, the protected harbor area is referred to as a "roadstead." Roadsteads need a bottom in the protected area in the protected area that is suitable for sufficient anchor holding power. Examples of roadstead anchorages in a natural bay and a protected harbor are shown in Figure 2-2.

2-8 HYDRODYNAMIC INVESTIGATIONS.

Effective coastal engineering studies require appropriate understanding of the hydrodynamics of the project area and its impact on design parameters. A summary of the considerations and procedures for hydrodynamic investigations is contained in Section II-8 of the CEM.

2-9 SHIP DYNAMICS IN CHANNELS.

Ships moving in shallow or restricted waterways experience dynamic behavior different from that exhibited in open water that can significantly affect control of the ship. The width and depth of the channel, if insufficient, can interfere with the normal passage of water around the hull of the ship and inhibit steering control. The sinkage and trim of a vessel in a navigation channel depend primarily on vessel speed, the ratio of the channel cross section area to the vessel wetted cross section area, and the ratio of the water depth to the vessel draft. The maximum vessel draft is determined through consideration of the effects on vessel draft by such factors as squat, variation in salinity, effects of wave motion, and loading. In addition, some judgment needs to be exercised in considering the conditions that could realistically be expected to occur. For example, it wouldn't be practical to design a ship channel for extremes of vessel draft during a hurricane, because the ships probably will not attempt to transit the channel during the storm. The effect of these and other factors on design parameters are discussed in the CEM, Section II-7-7-b(4). Additional analysis of this subject is contained in *Principles of Naval Architecture, Vol. 3* (Lewis, 1990).

2-10 SOURCES OF HYDRODYNAMIC INFORMATION.

Because coastal engineering design requires considerable knowledge of many physical sciences and engineering disciplines, the CEM contains a summary of sources for available information in Section II-8.

2-11 COMBINING DESIGN EVENTS.

Consideration of specific event extremes is the first step toward determination of design requirements. However, there are situations where the probability of coincident events is significant enough to warrant a further analysis of the combined effects of those events. As stated in the CEM, Section II-5-5-a(3), the importance of the timing of a storm event with tide phase cannot be over-emphasized because the resulting combined effect can be catastrophic. Methods for determining the frequency of occurrence for a 25- or 50-year storm are discussed in Section II-5-5-b of the CEM.

2-11.1 Earthquake and Low Tide.

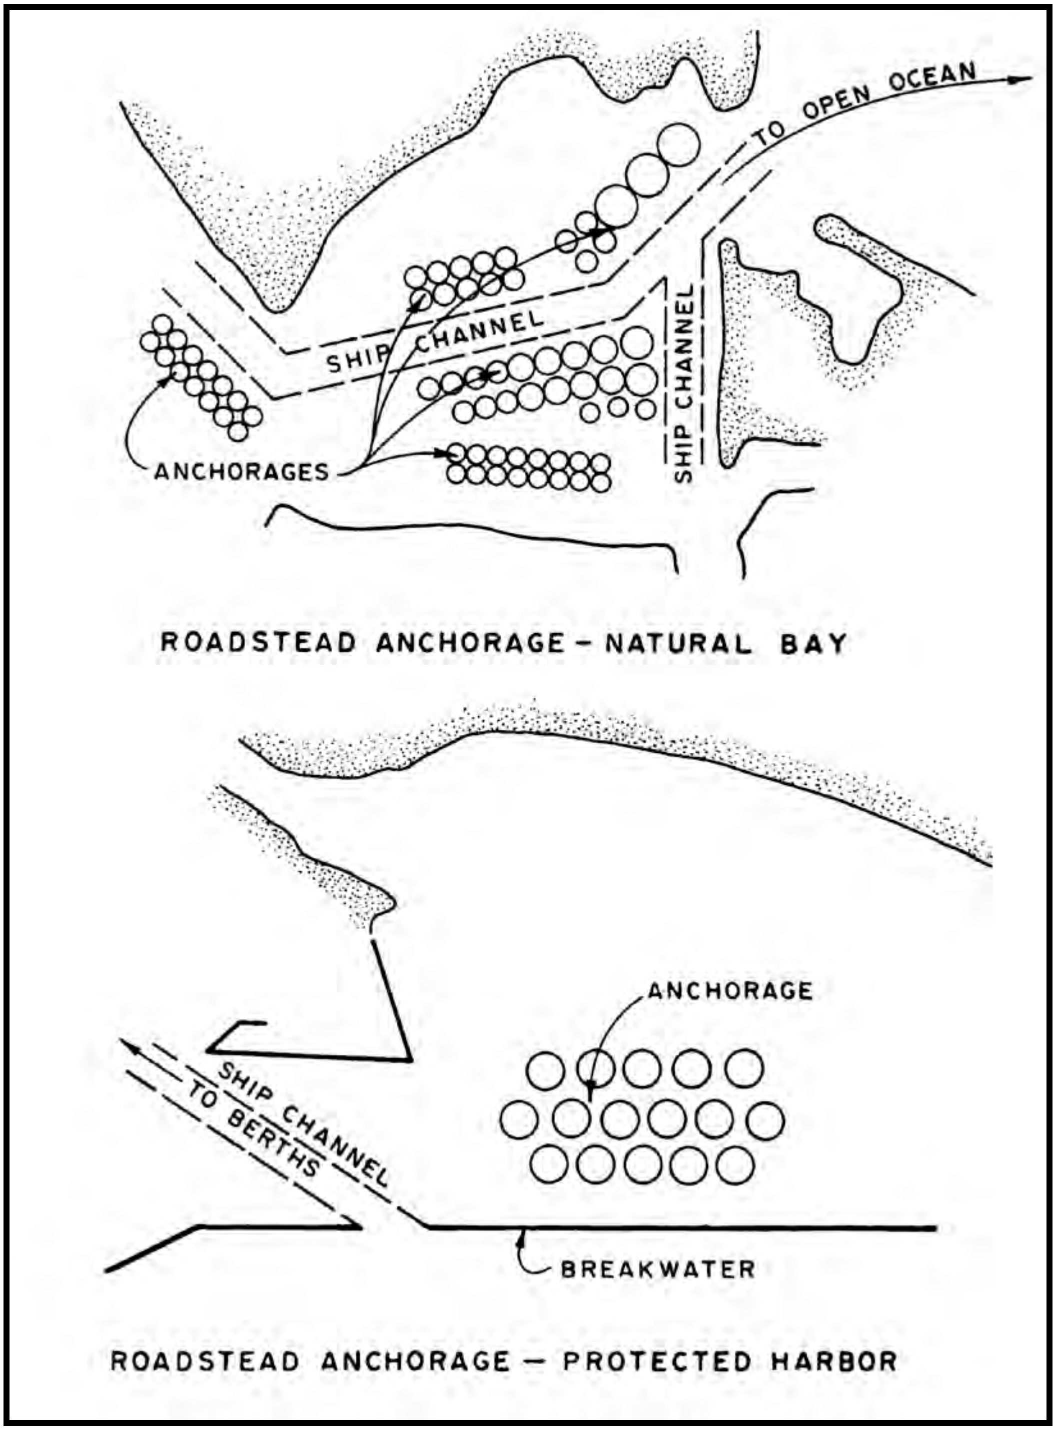
Coastal projects in areas with a high probability of seismic activity need to consider potential impacts related to ground deformation and severe liquefaction. The decision to allow for seismic loading in a coastal project design may hinge on such factors as estimated repair costs versus replacement costs, if loss of life and interruption of vital services are not considerations. Flexibility of the structure is a consideration in areas where rubble mound structures tend to be less affected by seismic activity than monolithic structures. Although not discussed in available texts, there is the potential that the stability of bluffs and coastal structures can be catastrophically affected if that activity occurs at a time of extreme low tide.

2-11.2 Storm Surge and High Tide.

Coastal areas are susceptible at certain times of the year to the effects of storm surge associated with high surf, which, if combined with an extreme high tide, can cause disastrous erosion of the shoreline. The importance of considering this interaction in coastal design is discussed in Section II-5-5-a(3) of the CEM.

The majority of coastal structures are designed to provide a level of protection to the beach and the surrounding population and supporting structures. This level of protection is generally based on a determination of the frequency-of-occurrence of a storm surge of a specified maximum elevation selected through an assessment of the risks of structural failure or consequences of overtopping versus project design costs. Consequently, it is important to determine stage frequency or frequency-of-occurrence relationships for the area in question. The designer must investigate and determine such factors as how to define high tide (2 min per day or 2 hours per day) and the probability of this happening with an extreme event such as a 25- or 50-year hurricane. Essentially, the phasing of the storm and tide both impact the design of the structure and the probability analysis of the design.

Figure 2-2 Examples of Roadstead Moorings



2-11.3 Storm Water Runoff and High Tide or Storm Surge.
The orientation, magnitude, and thickness of storm water runoff plumes are functions of the amount of river discharge, wind speed, direction, and duration, local ocean currents due to tides and surge, and local bathymetry. The runoff plume generally spreads out in a thin-layer over a large area as it mixes with ambient seawater. As a river discharges along the coast, the storm water runoff plume tends to spread in a longshore direction, parallel to the coast.

It is unclear as to whether or not dissolved and suspended plume components spread similarly throughout the water column. Thus, sufficient turbulence caused by river eddies or strong winds can cause particles to remain in suspension. With time, as turbulence decreases, particles will come out of suspension and deposit on the seafloor.

Coastal engineers should be aware that a coupling action between storm water runoff dynamics coincident with high tide or storm surge would undoubtedly have an effect on coastal project designs.

A lack of information covering this topic in the literature indicates that a need exists to more closely study these phenomena by conducting *in situ* observation and combining this data with analytical models to simulate the coupled effects. We solicit any comments and information regarding this phenomenon.

CHAPTER 3 SEDIMENT DYNAMICS

3-1 INTRODUCTION.

This chapter describes the important physical processes related to the movement of sediment around and in harbors and coastal facilities. An understanding of sediment movement is required for the proper design and maintenance of coastal facilities, such as siltation in harbors, shoreline erosion near structures, scour and burial of cables and pipelines, or anchoring in the nearshore. Much of the information related to these topics is contained in the CEM and the draft American Society of Civil Engineers (ASCE) “Standard for Shore Protection Systems". These and other applicable references are cross-referenced below by subject. The development of local criteria is essential in many cases due to the variation in meteorological and geological conditions at different geographical sites. If there are specific additional criteria to be considered, recommendations should be provided to Naval Facilities Engineering Service Center, Code 51, Port Hueneme, CA 93043, telephone (805) 982-1170.

3-2 SEDIMENT TRANSPORT PROCESSES.

Sediment transport in the nearshore zone is generally a result of the combination of breaking waves and various patterns of nearshore currents, characterized as a vector with both longshore and cross-shore components. Analysis of these two components has historically been performed separately because one or the other tends to dominate in a particular scenario. A discussion of the components of sediment transport and methods of analysis is found in Section III of the CEM, starting with a discussion of sediment classification by size and properties, followed by transport processes of cohesionless and cohesive sediments, and concluding with a discussion of sediment transport outside the surf zone.

3-2.1 Sediment Transport Rates.

Estimates of sediment transport rates can be derived either from calculations or through analysis of historical data. Although analysis of historical shoreline changes may provide a higher level of confidence, underestimation of the transport rate has not been uncommon in past practice. Where accuracy is critical to project development, construction and monitoring of a test groin to verify the estimate should be considered. However, the test groin must extend seaward far enough to trap all the littoral material. Representative examples of historical data for various coastal locations are shown in Table 3-1.

Sediment transport and deposition occur on open coasts, in tidal inlets, estuaries, harbors, and rivers. Sedimentation problems occurring in locations such as these are a function of soil type, continuity of materials, and the potential for fluid motion to transport material.

3-2.2 Harbor Siting.

Assess sedimentation processes when siting a harbor or an open-coastal littoral system, in an inlet system, or in a river-mouth estuary system. In each of these systems, transport capacity and sediment supply factors must be taken into account. A state of natural equilibrium may be due to unchanging channel depths or stable shoreline positions; alternatively, gradual and long-term sedimentation or erosion processes may be occurring. Refer to Sections III and V-6 of the CEM.

Table 3-1 Longshore-Transport Rates at Selected U.S. Coastal Locations

Location	Predominant Direction of Transport	Longshore Transport[a] cu yd/yr (m^3/yr)	Date of Record
Atlantic Coast			
Suffolk County NY	W	200,000 (152,920)	1946-55
Sandy Hook, NY	N	493,000 (376,948)	1885-1933
Sandy Hook, NY	N	436,000 (333,366)	1933-51
Asbury Park, NJ	N	200,000 (152,920)	1922-25
Shark River, NJ	N	300,000 (229,380)	1947-53
Manasquan, NJ	N	360,000 (275,256)	1930-31
Barneget Inlet, NJ	S	250,000 (191,150)	1939-41
Absecon, Inlet, NJ[b]	S	400,000 (305,840)	1935-46
Ocean City, NJ[b]	S	400,000 (305,840)	1935-46
Cold Spring Inlet, NJ	S	200,000 (152,920)	-
Ocean City, MD	S	150,000 (114,690)	1934-36
Atlantic Beach, NC	E	29,500 (22,556)	1850-1908
Hillsboro Inlet, FL	S	75,000 (57,345)	1850-1908
Palm Beach, FL	S	1150,000-225,000 (114,690 to 172,035)	1925-30
Gulf of Mexico			
Pinellas County, FL	S	50,000 (38,230)	1922-50
Perdido Pass, AL	W	200,000 (152,920)	1934-53
Pacific Coast			
Santa Barbara, CA	E	280,000 (214,088)	1932-51
Oxnard Plain Shore, CA	S	1,000,000 (746,600)	1938-48
Port Hueneme, CA[c]	S	1,000,000 (746,600)	-
Santa Monica, CA	S	270,000 (206,442)	1936-40
El Segundo, CA	S	162,000 (123,865)	1936-40
Redondo Beach, CA	S	30,000 (22,938)	-
Anaheim Bay, CA[b]	E	150,000 (114,690)	1937-48
Camp Pendleton, CA	S	100,000 (76,460)	1950-52
Great Lakes			
Milwaukee County, WI	S	8,000 (6117)	1894-1912
Racine County, WI	S	40,000 (30,584)	1912-49
Kenosha, WI	S	15,000 (11,469)	1872-1909
IL State Line to Waukegan	S	90,000 (68,814)	-
Waukegan to Evanston, IL	S	57,000 (43,582)	-
South of Evanston, IL	S	40,000 (30,584)	-
Hawaii			
Waikiki Beach, HI[b]	-	10,000 (7646)	-

[a]Transport rates are estimated net transport rates. In some cases, these approximate the gross transport rates.
[b]Method of measurement is by accretion except for Absecon Inlet, NJ, Ocean City, NJ, and Anaheim Bay, CA (by erosion) and Waikiki Beach, HI (by suspended load samples).
[c]Reference for Port Hueneme, CA, is U.S. Army (1980).

3-3 COASTAL GEOLOGIC MORPHOLOGY.

Classification of coastal geology and geologic character is of great importance to coastal engineers because of the complexity and diversity of the coastal environment. Section IV-3 of the CEM describes the historical emergence of coastal geologic classifications and summarizes the current preferred classifications and their influence on contemporary coastal design.

3-4 COASTAL MORPHODYNAMICS.

The discussion of coastal morphodynamics in Section IV-4 of the CEM states that coastal landforms are the result of the interactions of many physical processes, man-made influences, global tectonics, local underlying geology, and biology. Significant to the coastal designer is the fact that the physical conditions along the coast are constantly changing in response to many processes and often, in a relatively limited area, influence the formation of a combination of the four types of coastal environments: deltas, inlets, sandy shores, and cohesive shores (CEM, Section IV-4).

3-5 FOUNDATIONS AND ANCHORING.

Seafloor conditions and materials must be considered when placing structures and establishing an area for anchorage. Considerations for seafloor foundation design are discussed in Section VI-3-1 of the CEM. “Scour” occurs where sediment is eroded from beneath or around a structure’s foundation making it susceptible to failure. A summary of this process and its effects is found in the *Handbook for Marine Geotechnical Engineering*, edited by K. Rocker (Naval Civil Engineering Laboratory (NCEL), 1985). Additional design considerations regarding sediment transport are discussed in Section III-1-1 of the CEM.

3-5.1 Anchoring.

Selection of anchor type is based on bottom conditions. Information on this subject is also contained in the “Handbook for Marine Geotechnical Engineering” (Rocker, 1985). Where possible, locate the anchorage over a bottom of loose sand or gravel, clay, or soft coral. Avoid locations where the bottom consists of rock, hard gravel, deep mud, and deep silt.

3-6 SEDIMENT BUDGET.

Sediment budget is based on the principle of continuity or conservation of mass as applied to coastal sediments. A discussion of the processes and methods of evaluation are found in Section III-2-3-g of the CEM. Related information concerning windblown sediment transport is contained in Section III-4-5-c of the CEM.

3-7 EFFECTS OF STRUCTURES ON SEDIMENT TRANSPORT.

Man-made structures have a significant influence of sediment transport mechanisms. Groins, seawalls, jetties, breakwaters and piers all affect sediment transport and deposition processes. Numerous examples given in Sections III-2 and III-3 of the CEM indicate that the effect of these man-made structures on sediment deposition is significant in coastal engineering design. These effects can often be a source of technical data when investigating sediment transport.

3-8 MATERIAL PROPERTIES.

Sediment transport and deposition occur on open coasts, in tidal inlets, in estuaries, in harbors, and in rivers. The types of sedimentation problems that occur at each of these locations depend, in part, on the soil type. Properties and composition of coastal sediments are discussed in Section III-1 of the CEM. Additional information can be found in *Technical Notes, Technical Area 2: Material Properties Related to Navigation Dredging, published by the USACE Waterways Experiment Station (WES) for the Dredging Research Program (DRP)*. The Dredging Research Program Bibliography can be found on the web at http://wesda.org/related_links.htm#.

3-9 OPEN WATER DISPOSAL.

Disposal of project-removed sediment in open water can be an appropriate alternative where transportation costs for land disposal become prohibitive. In some cases, it is also useful for replenishment of shoreline where erosion is a problem. However, when foreign sediment is introduced into the marine environment, associated environmental issues arise. Whether from dredging operations or any other construction activity that affects the natural sediment environment, the coastal engineer needs to evaluate the impact on bottom dwelling and water column organisms due to such factors as blockage of light or toxicity of the sediment. Additional information is contained in Technical Notes published by the U.S. Army Engineer Waterways Experiment Station (WES) for the Dredging Research Program (DRP).

3-9.1 Contaminated Sediment Risk Assessment.

The sediment property of most environmental consequence is grain size. Turbidity in the water column depends on the fall velocity of the sediment particles, which is largely a function of the grain size. Turbid waters can be carried away by currents from the immediate project site, blocking the light to organisms over a wide area. As the sediments settle out, they blanket the bottom at a rate faster than the organisms can accommodate. Fine sediments (silts and clays) get greater scrutiny under environmental regulation because they produce greater and longer-lasting turbidity, which will impact larger areas of the seafloor than will coarser, sand-sized material. The dredging of sand usually encounters less severe environmental objection, provided that there are few fine sediments mixed with it and that the site has no prior toxic chemical history. Environmental regulation is changing, and many regulatory questions are outside the usual experience of coastal engineers. However, a basic coastal engineering contribution to facilitating the progress of a project through regulatory review is the early collection of relevant sediment samples from the site and obtaining accurate data on their size, composition, and toxicity. These issues are discussed in Sections III-1-1-b(2) and V-6-1-d of the CEM. Environmental requirements are discussed further in the paragraph titled “Regulatory Requirements” of this handbook.

3-10 GEOLOGICAL INVESTIGATIONS.

Effective coastal engineering studies require appropriate understanding of the geology of the project area and its impact on design parameters. A presentation of the considerations and procedures for coastal geological investigations is contained in Section IV of the CEM.

3-11 SOURCES OF SEDIMENT PROCESS INFORMATION.

A summary of sources of available coastal information and data can be found in Section IV of the CEM.

CHAPTER 4 CONSTRUCTION MATERIALS

4-1 INTRODUCTION.

The majority of materials utilized in coastal construction are quite similar to those used in dry-land construction. However, their introduction into the marine environment results in a need for the designer to expand his view of material degradation methods. In addition to the increased corrosive environment and possible freeze-thaw cycles, they must withstand relentless wave pounding and marine organisms that can attack most materials in a variety of ways. Primary material selection criteria are physical properties and strength, durability, adaptability, cost, availability, handling requirements, maintenance requirements, and environmental impact. Much of the information related to this topic is contained in Section VI-4 of the CEM.

4-2 CONSTRUCTION MATERIALS CONSIDERED, ANALYZED, OR COMMONLY USED.

The primary materials used in construction of coastal projects are stone, concrete, beach sand, steel, timber, composites, and geotextiles. These materials are critically important to the success and longevity of the project. Knowledge of past material performance on similar coastal projects is an important consideration for the design engineer. Detailed information on the materials discussed below and their selection criteria can be found in Section VI-4 of the CEM.

4-2.1 Availability.

In addition to the technical considerations for material selection, local availability of materials plays a big role in cost, both for initial construction and for future maintenance and repair planning. A summary of this and other material availability issues is contained in Section VI-3-7 and VI-4-1 of the CEM.

4-3 EARTH AND SAND.

Coastal projects tend to be fairly large and require a significant volume of construction materials. When feasible, structures are designed to use earth or sand as an economic filler material, and in many cases the mechanical strength properties of the soil are an integral part of the design. Some varieties, properties, and common uses of earth and sand in coastal construction are described in Section VI-4-2 and VI-4-3 of the CEM.

4-4 STONE.

Used extensively to construct coastal structures, stone is by far the most common material used in the United States for breakwaters, jetties, groins, revetments, and seawalls. A description of types of stone and their uses for coastal projects is contained in Section VI-4-1 and VI-4-3 of the CEM.

4-5 CONCRETE.

Concrete is the predominant construction material for waterfront facilities due to its durability, strength, and economy as a bulk construction material, and the basic components to make concrete are readily available at most locations. To optimally design a breakwater, for example, it is important to budget for minimum capital cost without excessive maintenance costs over the lifetime of the structure. Common breakwater designs based on an inner mound of small rocks or rubble provide stability, while an outer armor of large boulders protects the structure from wave action. Outer armoring designs range from simple concrete cubics or rectangulars, dense natural rock, and four-legged tetrapods (with each leg projecting from the center at an angle of 109 1/2° from each of the other three), to solid breakwaters made of concrete or masonry. Section VI-4-4 of the CEM summarizes specific applications of concrete in coastal construction.

4-6 STEEL.

Use of steel and considerations for appropriate applications are discussed in Section VI-4-5 of the CEM.

4-7 WOOD AND TIMBER.

Wood and timber members are widely used for the construction and maintenance of waterfront facilities due to availability, economy, and ease of handling relative to other construction materials. Wood can be used in coastal projects such as seawalls, revetments, bulkheads, piers, wharves, sand fences, and floating platforms. It's also used for temporary constructions such as formwork, bracing, and blocking. Uses of wood and timber and applicable properties, benefits, and drawbacks are described in Section VI-4-6 of the CEM.

4-8 COMPOSITES.

Though the subject of composite materials is applicable to the design of piers and wharves, this relatively new field is not addressed in the CEM. Nonetheless, many of the nation's leading academic institutions are investigating the use of fiber reinforced composite materials for concrete reinforcement.

The use of fiber reinforced plastics as an outside shell has been found to increase the load capacity and durability of piers, wharves, and bridges. These materials offer particular advantages over traditional reinforcements, though an understanding of their long term performance characteristics in aggressive environments is necessary before their use is widely accepted.

4-9 GEOTEXTILES.

As strong fabrics consisting of strong woven plastic filaments, geotextiles are predominantly used as filter cloth and are sometimes called filter fabrics, construction fabrics, plastic filter cloth, or engineering fabrics. The most frequent use of geotextiles in coastal construction is as a filter between fine granular sands or soils and overlying gravel or small stones that forms the first under layer of a coastal structure such as a revetment. A discussion of their properties and design considerations for their application is contained in Section VI-4-7 of the CEM.

CHAPTER 5 PROJECT PLANNING

5-1 INTRODUCTION.

In order to properly plan a project, a basic sequence of tasks should be considered as a basis for project planning:

- Problem Definition
- Initial Site Characterization
- Criteria Development (Functional, Accepted Damage Level, Performance)
- Define Without Project Condition
- Formulate Alternatives
- Detailed Site Characterization
- Refine Alternatives
- Evaluate/compare Alternatives
- Select Plan
- Final Design
- Plans and Specifications
- Cost Assessment/bid and Award
- Construction
- Quality Assurance
- Post Construction Inspection and Monitoring
- Operation and Maintenance
- Modifications to Existing Elements.

This process is discussed in detail in Section V-1 of the CEM.

5-2 DESIGN DATA.

Factors to be considered in general harbor site selection are listed in Table 5-1. Some sources of site data information are listed in Table 5-2.

Table 5-1 Principal Factors in Harbor Siting

Factor	Considerations
External Access	1. Vessel access to harbor site contains adequate depths and clearance for safe navigability. 2. Land access to harbor site is or can be reasonably developed to provide required land transportation linkage.
Size and Depth	1. Protected water depth and space adequate to accommodate intended vessel traffic in the following areas: (a) entrance and turning basins, (b) mooring areas, and (c) berthing areas. 2. Land areas of sufficient size and elevation to accommodate support needs free from flooding or inundation. 3. Potential for future enlargement or change in harbor use.
Physical and Topographic	1. Sheltering from winds and ocean waves; natural sheltering features such as headlands, offshore reefs, and islands will reduce both artificial sheltering requirements (breakwaters) and costs. 2. Limited fetch. The protected water area shall not contain segments of sufficient fetch to act as a generating area for waves that would cause difficulties within the harbor. 3. Bottom. Heavy, stiff, or overconsolidated clays furnish the best holding ground for anchors. Sands will provide acceptable holding ground. Sites should be avoided where the bottom consists of extremely hard clays, rocks, or very soft clays. If this is not possible, costly provisions (such as mooring islands) must be made to secure ships. Similarly, the costs of breakwaters, piers, and shore side structures will also depend upon the underlying soil conditions. Location of extensive structural systems in areas of deep, soft clays should be avoided. 4. Dredging. Avoid locations involving dredging of large quantities of rock or other hard bottoms. 5. Shoreline relief. Land adjacent to shoreline should gradually slope away from beach. Avoid locations with pronounced topographic relief (cliffs) adjacent to shoreline. 6. Upland drainage. Preferably, the upland area should be naturally well drained. Evaluate occurrence of health hazards due to local conditions.
Hydrographic and Hydrological	1. Variations in water level. The range between water level extremes due to cumulative effects of astronomical and storm tides as well as flood flows in river-affected harbors should be minimized as far as practicable. 2. Currents. Current velocity should be minimum and, except for localized areas and/or special considerations, should not exceed 4 knots. 3. Fouling rate. Desirable factor is a low fouling rate and relative freedom from marine borers, hydroids, and other biofouling organisms, which can be drawn into the cooling systems of ships. 4. Water circulation. Water basins should have sufficient natural circulation. 5. Sedimentation. The effect of the harbor site on natural regimes of coastal and riverine sediment transport and supply must be thoroughly evaluated. It is desirable not to interfere with the natural regime of sediment movements. The effects of harbor development on the sediment system may require maintenance dredging and/or shore-stabilization needs that must be considered as part of the overall development effort.
Meteorological	1. Storm. Avoid locations subject to the direct effects of pronounced, severe, and frequent storms. 2. Fog. Consider local variation in fog intensity and avoid the more severe sites where practicable. 3. Ice. Avoid locations that might be ice-locked for several months a year.
Other	1. Availability of construction material. In particular, rock for breakwater and jetty construction. 2. Fresh water availability. In particular, water for potable water supply.

Table 5-2 Informational Sources for Harbor Site Selections

Data Required	Sources
Underwater Bathymetry	**\1\ National Geospatial-Intelligence Agency – NGIA /1/** (https://www1.nga.mil/Pages/Default.aspx), NOAA's National Ocean Service - NOS (http://www.nos.noaa.gov), U.S. Naval Oceanography Portal - NAVO (http://www.navo.navy.mil), U.S. Army Corps of Engineers - USACE (http://www.usace.army.mil/), local Government Public Works and/or Hydrographic Survey Offices; where such is not available, survey is required.
Upland Topography	U.S. Geological Survey – USGS (http://www.usgs.gov), **\1\ National Geospatial-Intelligence Agency – NGIA /1/** (https://www1.nga.mil/Pages/Default.aspx); local Government Public Works mapping offices.
Subsoil Characteristics	Borings, probings or seismic survey; use diver for preliminary reconnaissance.
Astronomical Tides	NOAA's National Ocean Service – NOS (http://www.nos.noaa.gov), U.S. Naval Oceanography Portal - NAVO (http://www.navo.navy.mil; observation at site.
Storm Surge/Tsunamis	Site history. Probability forecasts for some areas have been prepared by U.S. Army Corps of Engineers – USACE (www.usace.army.mil) and Federal Emergency Management Agency, Storm Watch (http://www.fema.gov/plan/prevent/nhp/stormwatch.shtm); review available tide records (marigrams) to compare predicted astronomical tide to measured water levels during storm or tsunami occurrences.
Seiche	Historic experience in general area including marigram inspection can provide some indication of potential activity; long-term observations at site are desirable.
Currents	U.S. Naval Oceanography Portal - NAVO (http://www.navo.navy.mil), NOAA's National Ocean Service - NOS (http://www.nos.noaa.gov), Pilot Manuals, U.S. Geological Survey – USGS, for riverine currents (http://www.usgs.gov).
Meteorological Characteristics	Weather Bureau - National Oceanic and Atmospheric Administration (NOAA), (http://www.noaa.gov); Fleet Numerical Meteorology and Oceanography Center (http://www.usno.navy.mil/FNMOC).
Waves	National Oceanic and Atmospheric Administration, (http://www.noaa.gov); National Climatic Data Center, http://www.ncdc.noaa.gov/oa/ncdc.html; Fleet Numerical Meteorology and Oceanography Center (http://www.usno.navy.mil/FNMOC), U.S. Army Corps of Engineers (http://usace.army.mil); WIS Reports – see references.
Sedimentation/Erosion	U.S. Army Corps of Engineers, (http://www.usace.army.mil), U.S. Geological Survey, (http://www.usgs.gov); analysis of shoreline and hydrographic changes in comparison of successive surveys from initial to present conditions.
Fouling Conditions	Observations at site; consultation with local residents and authorities.

5-3 COASTAL PROJECT PLANNING AND DESIGN.

The type of structure required for a particular design situation depends upon the protection required, such as harbor protection, beach erosion control, and stabilization of an entrance channel. The primary types of coastal structures and methods of marine improvement and shore protection are breakwaters, jetties, revetments, bulkheads, seawalls, groins, headlands, and beach restoration and nourishment. The paragraph of this document titled "Navigation Aids" provides introductory descriptions and figures showing each of these. In many cases, more than one type of structure may provide a possible solution. Studies of alternative solutions, including consideration of first and annual costs, maintenance, construction methods, and environmental impacts, should be conducted to select the most appropriate one. Selection of the structure type requires that the foundation condition, availability of construction materials and equipment, and probable impacts on the adjacent shores be considered.

5-3.1 Planning and Design Process.

The CEM, Section V-1, discusses this topic at length. It emphasizes function of components, concepts, non-structural, dynamic and static structures. It offers information regarding coastal zone management, coastal armoring, sediment issues, temporary solutions, and others.

5-4 REGULATORY REQUIREMENTS.

Permitting, inspection, and enforcement activities are conducted by various organizations.

5-4.1 USACE.

The responsibilities of USACE are outlined below:

5-4.1.1 Jurisdiction.

All works located in the waters of the United States and its territories are under the jurisdiction of the USACE. This zone is generally located seaward from the mean high water line. A USACE permit is required for all dredging, filling, construction, or maintenance works. The permit must be approved prior to commencement of work. Therefore, processing of permits should be initiated well in advance of the date work is scheduled to begin because of the lead time required to obtain USACE permits. The USACE's jurisdiction also includes interior wetlands, rivers, and lakes. Questions regarding the extent of the jurisdiction for specific areas inland of the high-tide line should be addressed to the local USACE District Office.

5-4.1.2 Review Procedure.

In reviewing permit applications for works in U.S. waters, the USACE circulates the application to other Federal and local agencies. In accordance with various executive actions, the USACE cannot, at a local level, override the permit objections of the following:

- Department of the Interior, U.S. Fish and Wildlife

- Environmental Protection Agency (EPA)
- Department of Commerce, Bureau of Commercial Fisheries

In addition to input by Federal agencies, input by State or regional agencies are considered. To date, most concerns address changes in water quality and loss of marine habitat. In specific cases critical to national defense, regulations and procedures can be modified through the Office of the Secretary of the Navy. However, most Navy facility projects are subject to the concerns and regulations of other authorities, which have jurisdiction. Specific contact should be made at project inception with the agencies affected. Liaison is particularly important where harbor works involve:

- dredging and disposal of dredged materials,
- work in or around existing marshes, and
- significant reduction of existing intertidal or shallow-water areas.

5-4.2 U.S. Coast Guard.
All aids to navigation for U.S. waters are prescribed and installed under the jurisdiction of the U.S. Coast Guard (USCG). In addition, USCG jurisdiction extends to drawbridges and encompasses construction clearances for new drawbridges, modifications of existing drawbridges, and drawbridge operations.

Prior to construction of any coastal project that may impact navigation or interrupt any existing aids to navigation, complete project information should be provided to local authorities (USCG district commander). This information should include details about project authorization, proposed construction schedule, and detailed drawing showing the project location relative to existing feature. Local authorities may require a set of “as-built” plans after the project has been completed, and it may be necessary to include new aids to navigation as part of the project design (CEM, Section VI-3-8).

5-4.3 Harbor Control Lines.
USACE, through the Secretary of the Army, establishes harbor control lines for all U.S. ports. Control lines include:

- bulkhead lines – seaward limit of solid-fill structures;
- pierhead lines – seaward limit of open waterfront structure; and
- channel lines – extent of channel limits usually maintained by the Federal Government.

5-4.4 Jurisdiction.

USACE has jurisdiction over construction and dredging in the navigable waters of the United States and of its territories and possessions. EPA has jurisdiction over water quality relating to dredging, disposal of dredged material, and fill activities. Dredging activities and equipment must comply with USCG regulations. Consultation with the district office of the USCG is recommended before dredging projects are started.

5-4.4.1 Federal Permits.
A USACE permit is required to locate a structure, excavate, or discharge dredged or fill material in waters of the United States. A USACE permit is also necessary for transport of dredged materials into ocean waters for the purpose of dumping. Application for Federal permits can be made through the local district office of the USACE. Applications must be accompanied by drawings of the dredge and disposal areas and a description of the proposed work. Although there are general guidelines established for the permit process, each district is somewhat autonomous and has the authority to amend the requirements for each particular project. These requirements include explanatory documentation of existing data, supplementary chemical and biological testing, and additional environmental surveys. The extent of each requirement is dependent upon the quantity and quality of the dredged material, the proposed form of disposal, and the environmental sensitivity of the area. To expedite permit application processing, appropriate regulatory agencies (e.g., USACE and EPA) should be contacted early in project planning. In extreme cases, early notification can expedite processing emergency dredging permits by the USACE.

5-4.4.2 State Permits.
Federal law assures the right of any state or interstate agencies to control the discharge of dredged or fill material in any portion of the navigable waters of any state jurisdiction. Typically, a water-quality certificate, a hydraulic-fill permit, or both, are required at the state level.

5-4.4.3 Local Permits.
In certain areas, a local permit may be required. Most states have federally endorsed coastal development and water quality plans. Many consider the operation and maintenance of existing Navy facilities as consistent with, and part of, their planning documentation. Direct authority over new Navy construction works does not presently extend to local State agencies; however, for consistency with local plans, notification of new works is desirable. Notification of concerned local agencies may be through circulation of an environmental impact statement for new works, public notice in the case of operation or maintenance projects, or directly through an exchange of memoranda.

5-4.5 Disposal of Dredged Material.
Dredging may be required to gain access to the project site, for entrenching toe materials, for backfilling higher quality foundation material, or for other reasons. When dredging is to occur, dredging volume should be estimated, and the method of dredged material transport and disposal should be determined. Beneficial uses of the dredged

material should be considered, particularly if the displaced material consists primarily of beach-quality sediment. Some dredged sediments may be disposed offshore in a designated and permitted Ocean Dredged Material Disposal Site (ODMDS); note that management of an ODMDS requires predicting the response of the sediment mound to wave and current forces with the aid of validated numerical models for the region in question. Guidance on dredging disposal and beneficial uses of dredging material can be found in Engineer Manuals (EM) 1110-2-5025 (USACE, 1983) and 1110-2-5026 (USACE, 1987). Also, papers from technical specialty conferences, e.g., Dredging '94 (American Society of Civil Engineers, 1994), provide useful information; for additional information, see Section VI-3-8 of the CEM.

5-4.6 Environmental Considerations.

Understanding and mitigating environmental impacts of coastal projects are key considerations throughout the planning, design, construction, and maintenance phases of all projects. Refer to CEM Sections V and VI-3-6.

5-4.6.1 Discussion.

The Coastal Zone Management (CZMA) Act of 1972, PL 92-583, establishes a national policy to preserve, protect, develop, and, where possible, restore and enhance the resources of the coastal zone of the United States. DoD Implementation of the Coastal Zone Management Act, DOD Instruction 4165.59 of 29 December 1975, authorized the Navy to implement programs to achieve the objectives of PL 92-583. The Navy will cooperate and provide information on Navy programs within the coastal zone to states responsible for developing state CZMA plans. Naval operations, activities, projects, or programs affecting coastal lands or waters shall insure that such undertakings, to the maximum extent practicable, comply with state-approved coastal-zone programs.

5-4.6.2 Guidelines and Standards.

All natural resources management programs on naval installations in the coastal zone have potential effects on the coastal zone and should be reviewed for consistency with approved state Coastal Zone Management plans. The Navy shall develop, in cooperation with a designated state agency, a set of criteria and standards for judging the consistency of natural resource management programs with respect to approved state management programs. Consistency determinations shall be made in accordance with provisions of PL 92-583.

Agricultural out lease of real property affecting land or water uses in the coastal zone shall provide a certification that the proposed use complies with the coastal state's approved program and that such usage will be conducted in a manner consistent with the program.

Technical assistance requested by the states to assist their implementation of CZMA will be provided to the extent practicable. Data collected by the Navy on subjects such as beach erosion, hydrology, meteorology, and navigation may be useful for coastal-zone planning and shall be made available.

5-4.7 Natural Resource Protection Criteria.

In recognition of the intrinsic value of natural resources, the National Environmental Policy Act (NEPA) of 1969, amended in 1970, 1975, and 1982, provides a vehicle for arresting any rapid degradation and destruction of critical natural resources. Appropriate permitting procedures shall be followed by the design team prior to beginning any activity that will be located in, on, or over any protected natural resource or is located adjacent to an activity that will cause material or soil to impact coastal wildlife habitats, among others. The importance of working to conserve and restore endangered and threatened species and the ecosystems upon which they depend on for survival is also recognized via the Endangered Species Act (ESA) of 1973 and the Marine Mammal Protection Act of 1972. The attendant dredging, displacement, and filling of soil during construction projects in the coastal zone underlines the necessity for the Navy to address natural resource protection issues early in the planning process.

5-5 SITE CHARACTERIZATION AND DESIGN CRITERIA.

Many coastal failures can be traced back to inadequate site characterization analysis. Site characterization involves identifying distinguishing qualities and features of a region that have a direct and indirect impact on the conception, design, economics, aesthetics, construction and maintenance of a coastal project. The coastal environment varies spatially and temporally and therefore a design that is functionally, economically, and environmentally appropriate at one location may be inappropriate at another. Physical, biological, and cultural attributes need to be delineated so that an acceptable project is adopted and potential effects of the project are determined. Sections V-2 and VI-3 of the CEM cover this topic in detail.

5-5.1 Hydrographic Surveys and Subbottom Profiling.

It is important to perform surveys to identify bottom conditions and to determine if any structures are present which need to removed or avoided. This knowledge pertains to both construction efforts and dredging. Table 5-2 provides information on some of the bathymetric, Differential Global Positioning System (DGPS), and sidescan sonar sources available to the design engineer.

\1\

5-6 PORT AND HARBOR PROJECT DESIGN - DREDGING AND NAVIGATION PROJECTS.

Planning efforts must consider environmental policies such as the National Environmental Policy Act (NEPA), the Environmental Assessment (EA), and the Environmental Impact Statement (EIS). Project Assessment and Alternative Selection, and Development of a Navigation Project, are addressed in the following sections.

5-6.1 Project Assessment and Alternative Selection.

This information is readily available from the CEM, Section V-5, which acts as a complement to EM 1110-2-1613, *Hydraulic Design Guidance for Deep-Draft Navigation Projects* and EM 1110-2-1615, *Hydraulic Design of Small Boat Harbors*.

5-6.1.1 General Harbor and Port Facility Issues.
Within limits, any site may be modified to accommodate the required vessel use. Ideally, the minimum and maximum area requirements must be estimated in order to properly evaluate a proposed location. For military purposes, it is desirable to allow for unrestricted operation of all vessels at all times. However, it is not always practical to design for statistically infrequent low-water conditions or an all-weather navigable entrance at locations exposed to extreme wave climates. Before proceeding with the design, trade-offs based upon the probabilities of occurrences should be discussed with the using agency.

5-6.1.1.1 Major Water-Area Elements.
Figure 5-1 illustrates the arrangement of major water-area elements associated with a harbor facility. Depending upon siting, a harbor facility may include all of, or portions of, these elements. Functionally, approach- and entrance-channel elements provide the transition between open-sea and protected water environments. Further, channels are differentiated between open and restricted types as shown in Figure 5-2. The protected interior channel serves as a navigational linkage; in riverine situations, this channel length can become of increasing importance. Turning basins provide area for a ship to maneuver while approaching its final terminus, either alongside berths or in open mooring areas. In some harbors, special water areas are required for vessel electronic and navigation calibration. Sizing of water-area dimensions is related to both capacity and operational requirements.

Figure 5-1 Water-Area Elements

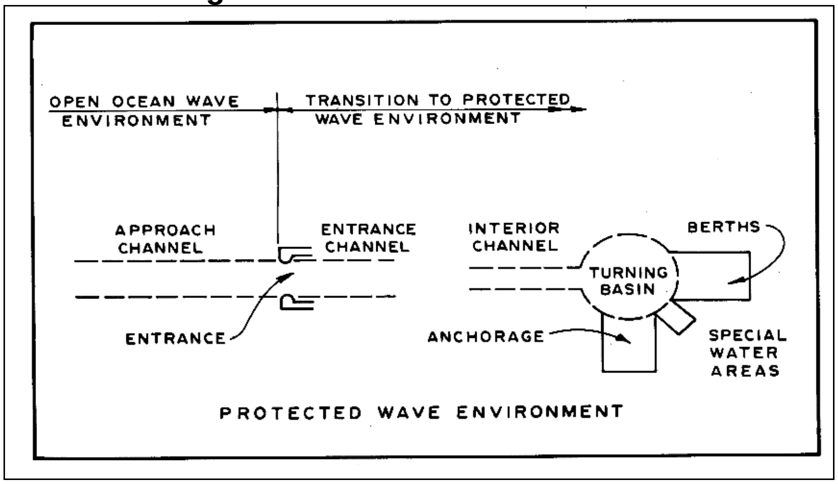


Figure 5-2 Channel Types

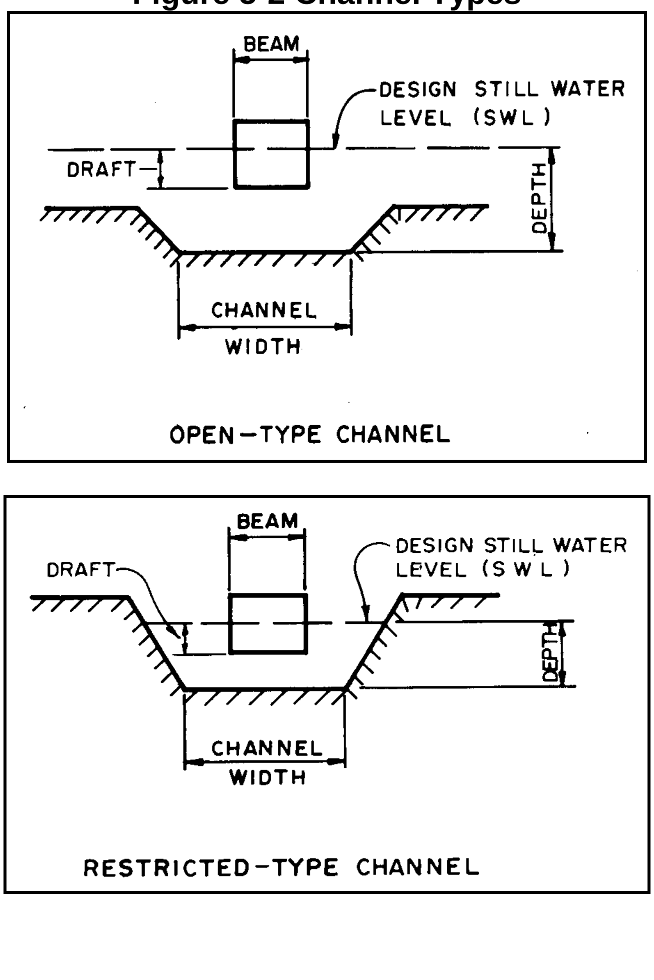

5-6.1.1.2 Capacity.
Ascertain the approximate anticipated capacity requirement from the using agency in terms of numbers, types, and sizes of vessels expected to simultaneously anchor within the harbor limits. Also estimate the number of these vessels that must be simultaneously accommodated at pier or wharf berths and determine the needs for special water areas for ship calibration.

5-6.1.1.3 Operation.
Proposed vessel-handling methods and navigational minimums need to be defined. Included in this assessment is the use of pilots and tugs for ship handling and berthing. Tolerances for ship movement restrictions in cases of extreme tide or weather conditions need to be defined.

5-6.1.1.4 Dimensioning.
Guidelines for dimensioning harbor water-area elements, and spatial and water-depth values are provided below. Alternative evaluations may be made through comparison using existing operating Navy facilities. However, caution should be exercised in making such operational comparisons in that, to do so, the wind, wave, and current environments must also be similar.

5-6.1.1.5 Economics.
Economic considerations must be weighed against depth requirements. In harbors where tidal range is very large and, particularly, where an entrance channel is long, consider the possibility of restricting the entrance of the largest draft ships using the harbor to the higher tidal stages. Where hard bottoms prevail and excavation costs are high, consider the exclusion of certain classes of deep-draft vessels, with provision of lighter service between deep-water anchorage and docks.

5-6.1.2 General Depth Requirements.
In general, the depth of harbor areas vary. Certain areas are reserved for small craft usage while larger areas are set aside for larger ships. Additionally, channel depth requirements differ from those at anchorages and berths. Depending upon the specific area under consideration, it is imperative to provide for adequate depths at all anticipated water levels. Project depths shall be determined for each of the following harbor elements:

- Berth
- Turning Basin
- Inner Channel
- Outer Channel

Additionally, when determining project depth, there are a number of factors/parameters that must be considered (see Figure 5-3):

5-6.1.2.1 Maximum Static Draft.
Maximum static drafts for vessels currently in use by the U.S. Navy and Military Sealift Command are provided in Table 5-3. Values shown include static trim and appendages and are based upon saltwater condition. For areas where freshwater, brackish, or significant freshwater inlets exist, draft will be greater and should be properly accounted for. If vessel list is a consideration, that should be accounted for as well.

Figure 5-3 Factors Affecting Maximum Vessel Draft

5-6.1.2.2 Squat.
When a vessel is underway in shallow water or situated in a restricted channel, the water surface near the quarter point of the vessel drops below the normal level and the vessel tends to settle itself or squat in the depression (Figure 5-4). The amount of squat depends upon the:

- Speed of the vessel through the water
- Distance between the keel and the bottom
- Trim of the vessel
- Cross-sectional area of the channel
- Presence of other vessels in the channel passing or overtaking the subject vessel, and
- Location of the vessel relative to the channel's centerline.

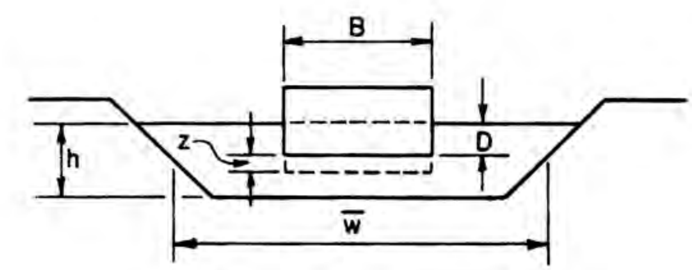
The following procedure is recommended for performing preliminary estimations of squat:

1. Compute $S = \frac{A}{\overline{w}h}$.
2. Using Figure 5-5, obtain F; compute V_L using $F = \frac{V_L}{\sqrt{gh}}$.
3. Compute $\frac{V}{V_L}$ and $\frac{h}{D}$; obtain $\frac{z}{h}$ using Figure 5-6.
4. Multiply by h to obtain z_{max}, valid for $\frac{\overline{w}}{B} = 6$.
5. For other values of $\frac{\overline{w}}{B}$, find $\frac{\Delta z}{z_{max}}$ from Figure 5-7.
6. Compute z using $z = z_{max} + \Delta z$.

The amount of squat will increase when vessels travel near one side of the channel. This effect has been shown in a model test for a 32-ft (9.8 m) draft by 113-ft (34.4 m) beam vessel in a 500-ft (152.4 m) wide by 45-ft (13.7 m) deep channel with 1-on-1 side slopes. The results of this test, given in Figure 5-8, show that the additional squat due to a vessel traveling near the side of a channel is small for slower velocities. For higher velocities, additional squat due to a vessel traveling near the side of the channel may be 50 percent greater than if the vessel were in the center of the channel.

Squat will also increase if there are two or more vessels passing one another, side by side. A vessel will normally travel near the side of a channel when it is passing alongside another vessel. In this case, the effective cross-sectional area of the channel will be reduced by the cross-sectional area of the vessel being passed. The total squat for a vessel can be approximated by first calculating the centerline squat with the reduced effective cross-sectional area of the channel. To this centerline squat is added the additional squat resulting from the vessel being off the centerline of the channel.

Figure 5-4 Factors Affecting Squat



where:

z	=	depth of squat [ft]
h	=	channel depth [ft]
$\overline{w}$	=	average channel width [ft]
A	=	underwater midship cross section [ft^2] = DB
D	=	vessel draft [ft]
B	=	vessel beam [ft]
V	=	vessel speed through water [ft/sec]
V_L	=	theoretical limiting vessel speed [ft/sec]
g	=	gravitational acceleration [32.2 ft/sec^2]
S	=	ratio of underwater midship cross section to the channel cross section $= \frac{A}{\overline{w}h}$
F	=	Froude number $= \frac{V_L}{\sqrt{gh}}$

Figure 5-5 Sogreah Laboratory Squat Curve (Wicker, 1965)

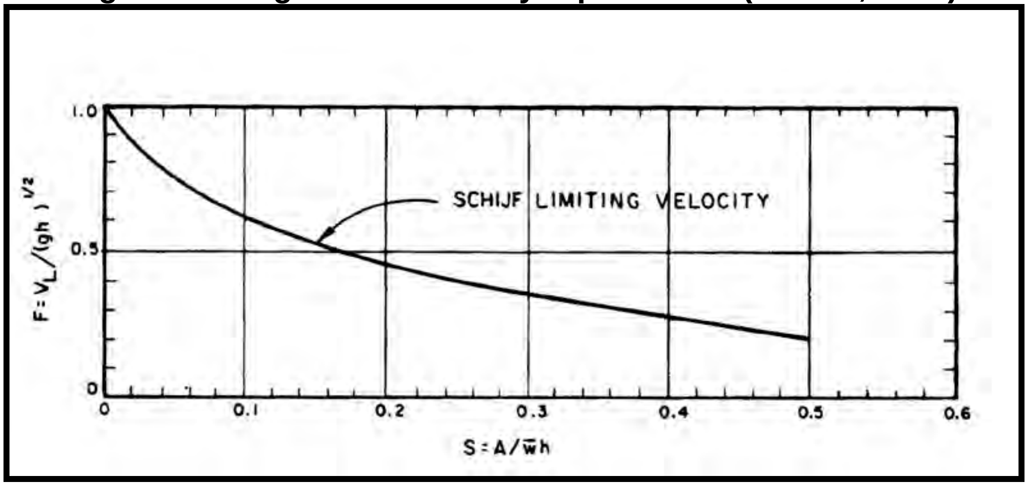


Figure 5-6 Sogreah Laboratory Squat Curves (Wicker, 1965

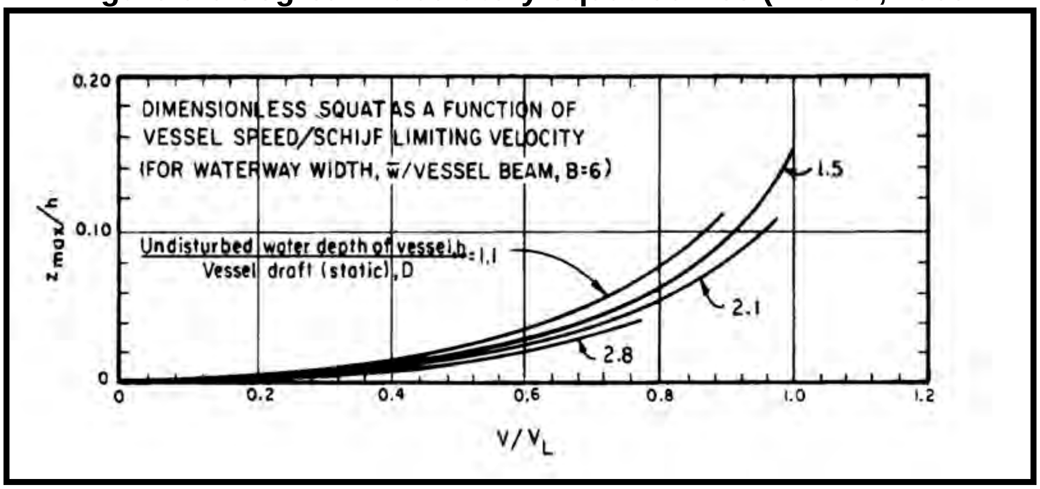

Figure 5-7 Sogreah Laboratory Squat Curves (Wicker, 1965)

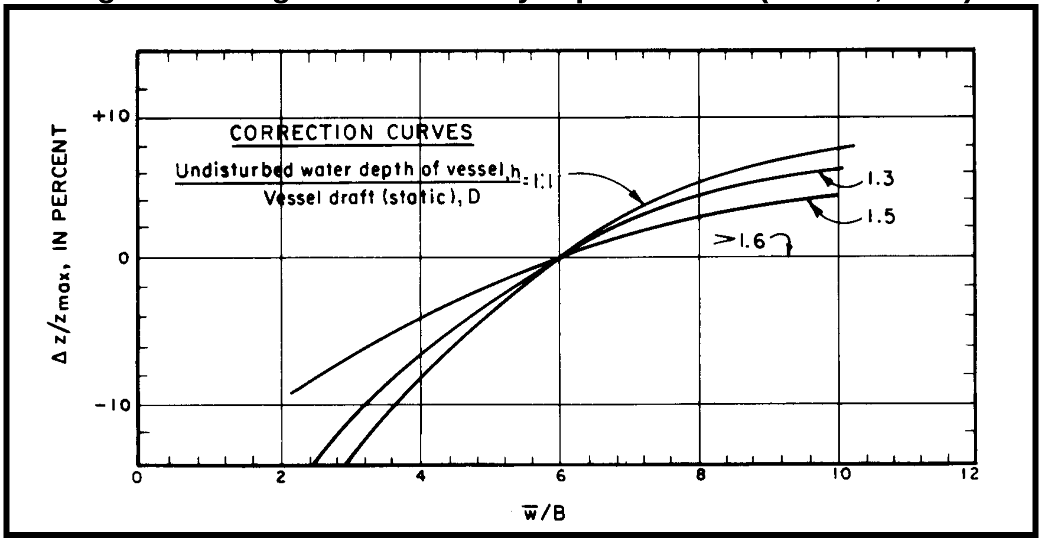

Figure 5-8 Effect of Ship's Location in Channel on Squat

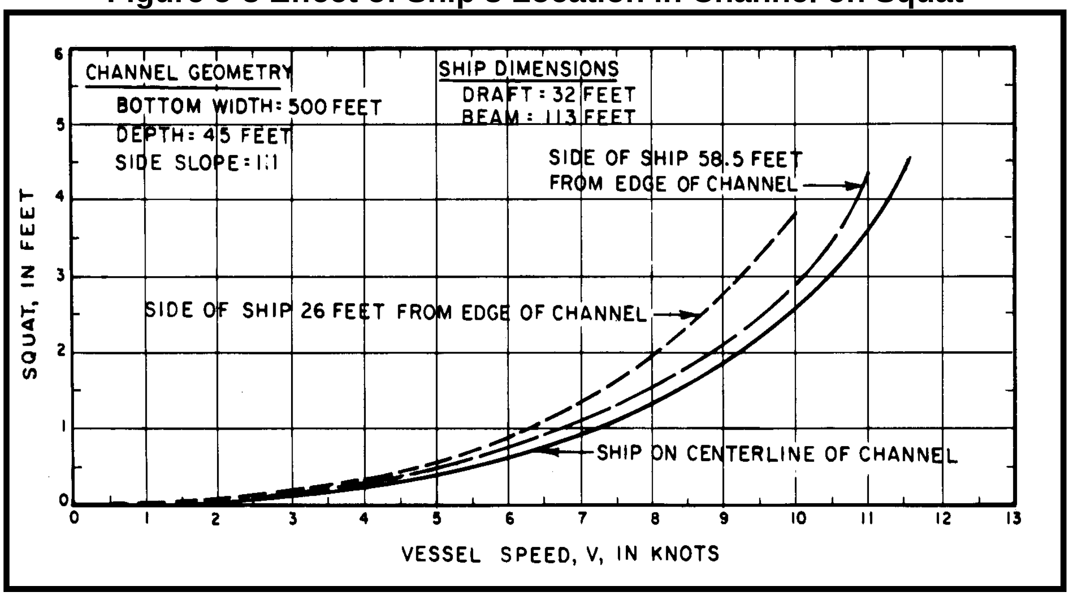

In considering U.S. Navy and Military Sealift Command vessels transiting at speeds of 5 knots, 10 knots and 15 knots, Tables 5-4, 5-5, and 5-6 have been prepared to show the dynamic (underway) draft. Values came from *Dredge Depths for Active US Navy Combatants and Military Sealift Ship Classes – Update,* NSWCCD-50-TR-2008/048, October 2008

5-6.1.2.3 Wave Motion.
In cases where a vessel is in a water area that is subject to wave action, vertical motions will increase the extreme draft relative to the still water level. Rotational motions of pitch and roll, as well as vertical displacement through heaving motion, will take place. The motion of the ship subjected to steep waves requires that a dynamic analysis take into account the physical property of the ship modeled in the sea condition. Under certain critical ratios of vessel length to relative wavelength, the added vertical sinkage of the vessel can be appreciably greater than the water-level displacement at the wave trough. Generally, these critical ratios are generally believed to lie within the 0.3 to 0.6 range. This situation is normally critical where the unprotected harbor-entrance approach is situated in shoaling water. A recent harbor site selection at a particularly stormy site suggests that an overdepth in the approach and entrance channels on the order of 35 percent of the draft is required. In semi-protected water areas, such as when a ship is subjected to swell, but not to local seas, the increased displacement of the vessel due to pitch and heave can be determined by placing two points of the vessel on a trochoidal wave surface at two-thirds the vessel waterline-length normal to the wave crests, as is shown in Figure 5-9. Semi-protected water areas are shown in Figure 5-10. Dynamic draft increase due to wave motion is a highly specialized analysis that is normally applicable to the outer channel area of a project.

Figure 5-9 Increase in Vertical Sinkage Due to Wave Action

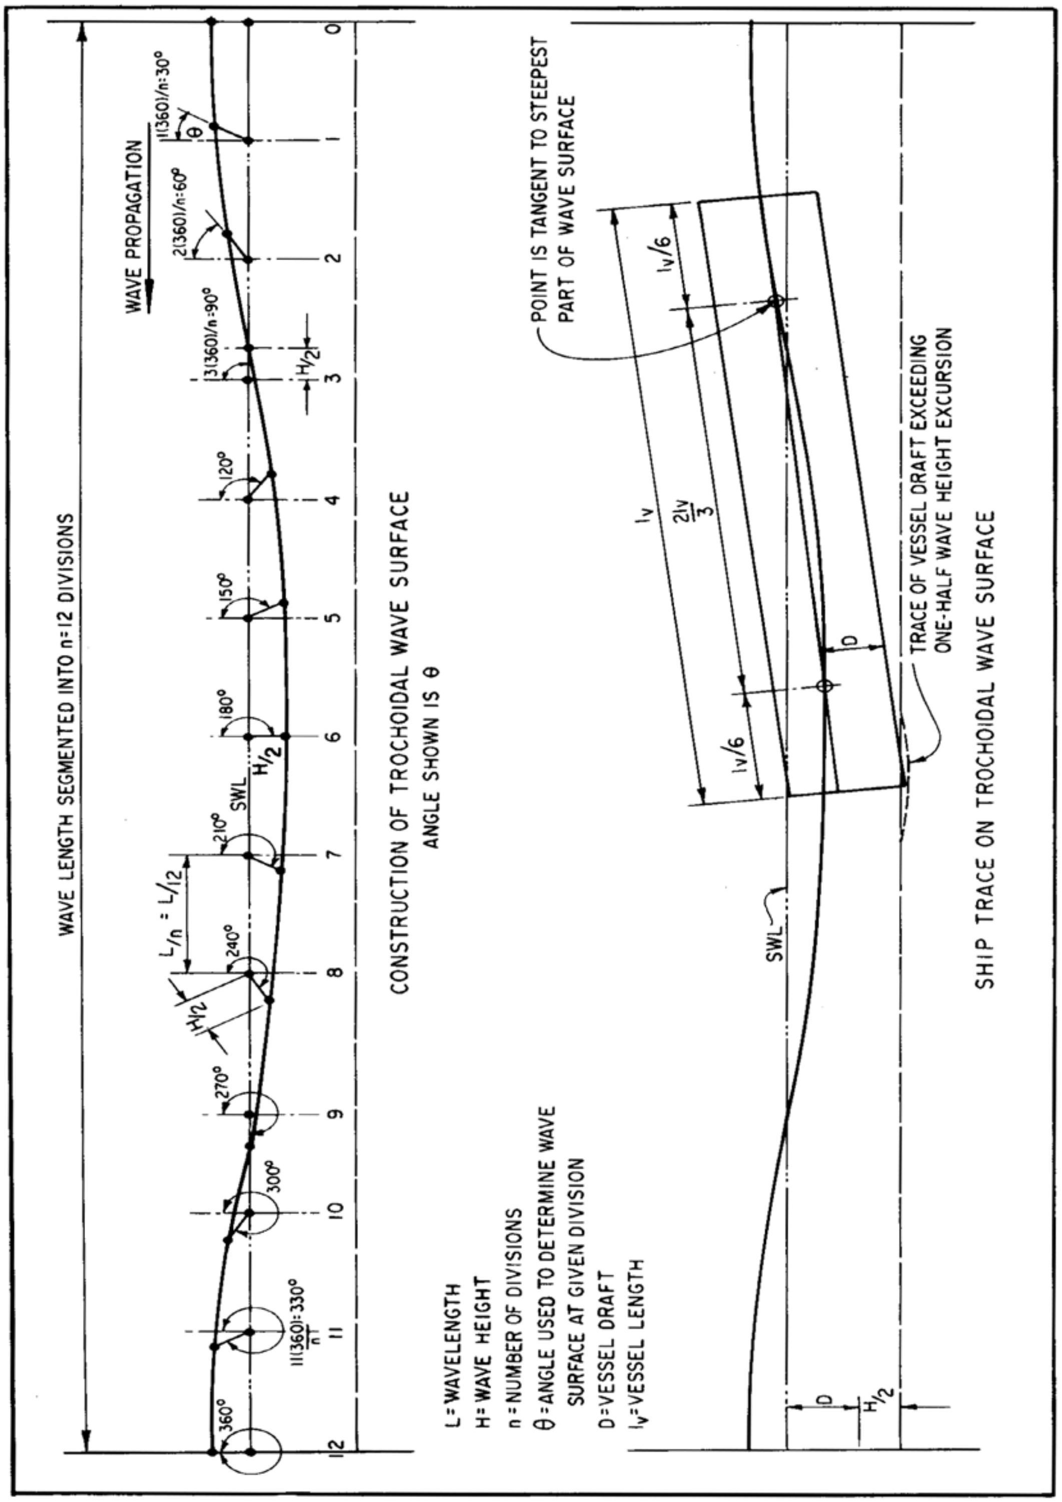

Figure 5-10 Example of Semi-Protected Water Area

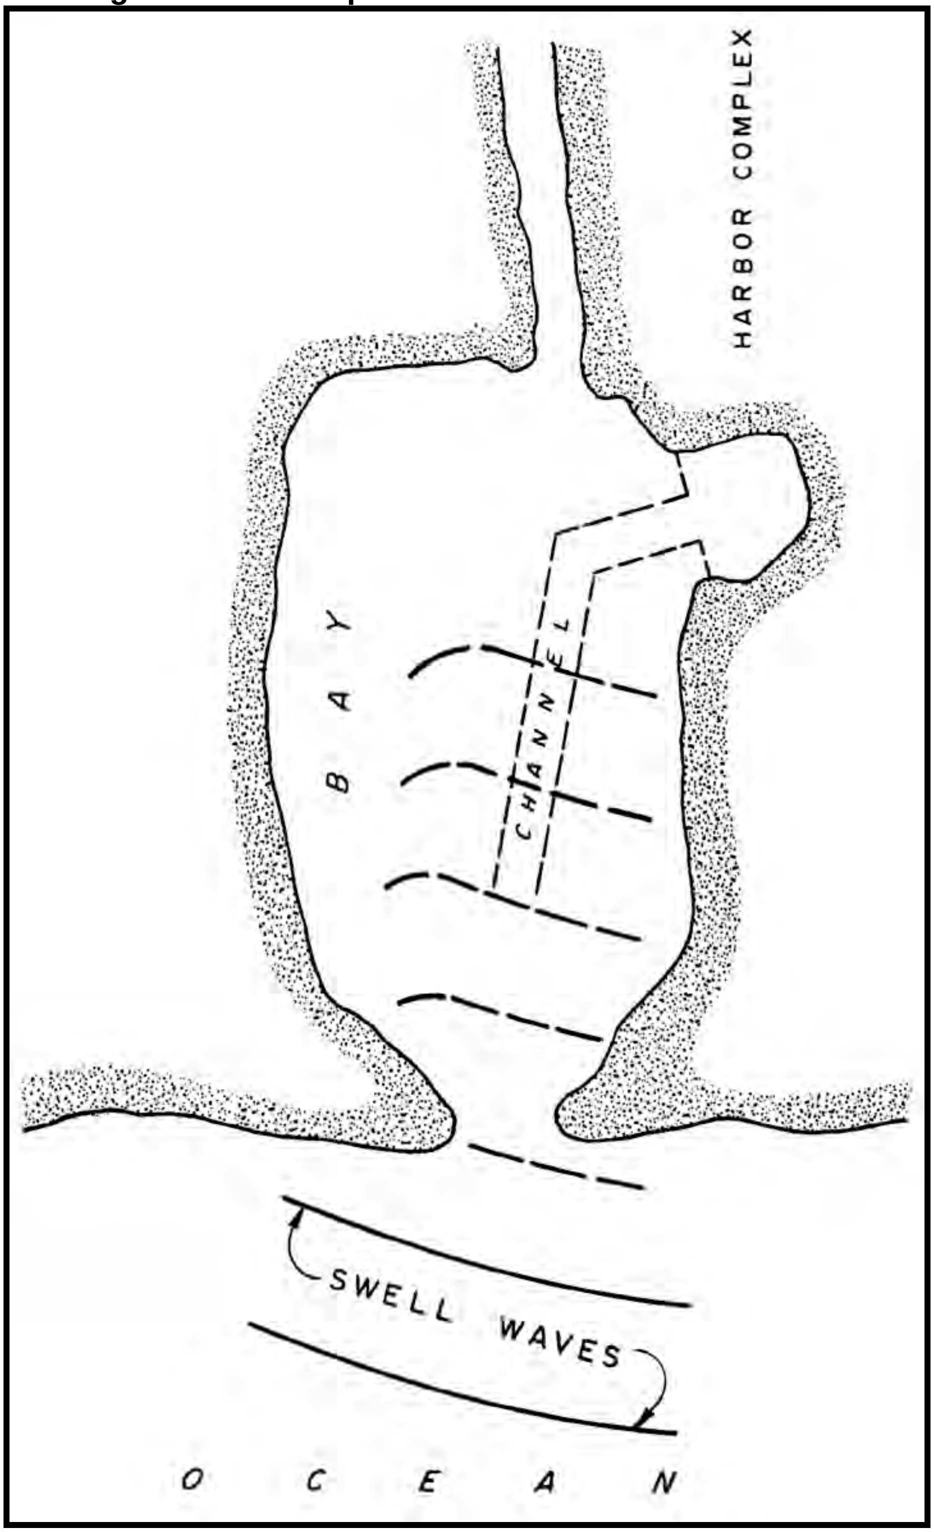

5-6.1.2.4 Underkeel Clearance.

Factors in addition to those presented above that must be considered in determining the clearance between the maximum vessel draft and the bottom are vessel operation, type of bottom material, and a factor of safety. Bottom material is an important consideration when accounting for underkeel clearance. Soft bottom material can be displaced and shoaled by passing vessel propeller action. Hard bottoms with sharp outcroppings can cause severe damage to vessels upon grounding. In active sedimentation areas, bottom shoals can also occur during relatively short periods of storm activities. The following shall be used for underkeel clearance:

Table 5-7 Underkeel Clearance

Vessel Type	Berth Soft/Hard	Turning Basin Soft/Hard	Inner Channel Soft/Hard
Submarine[1]	2'/3'[3]	2'/3'	2'/3'
Surface Ship[2]	6'/6'[4]	2'/'3'	2'/3'
MSC Ship[2]	6'/6'[4]	3'/3'	3'/3'

[1] PEO-SUB ltr Ser 07T236/0436 of 4 Oct 2007
[2] NAVSEA ltr Ser 05D/058 of 5 Feb 09
[3] "X'/X' represents soft/hard bottom typical
[4] Underkeel clearance at berth for Surface Ship and MSC Ship is based upon Mean Low Water (MLW) datum

5-6.1.2.5 Depth Determination.

In all cases, with the exception of the instance noted in Table 5-7, project depth shall be determined with respect to Mean Lower Low Water (MLLW) datum Based upon the foregoing, project depth shall be determined by selecting the "controlling" design vessel for the project location and using the following procedure:

- Obtain maximum static draft (Table 5-3)
- Provide additional draft due to freshwater if applicable (See Figure 5-3)
- Provide additional draft due to ship list if applicable (See Figure 5-3)
- Provide additional draft due to squat if applicable (Tables 5-4,5,6)
- Provide additional draft due to heel (experienced) during ship turn if applicable
- Provide additional draft due to wave motion if applicable
- Provide underkeel clearance (Table 5-7)

Above procedure shall be followed for each harbor element under consideration, i.e. berth, turning basin, inner channel, and outer channel. The following examples are provided:

Example 1:

Determine project depth for DDG-51 class ship at a berth at Navsta Norfolk
Maximum static draft = 33.64 feet
Freshwater inlet = 0.5 feet (additional draft due to freshwater inlet)
List, squat, heel, wave motion not applicable.
Soft bottom – underkeel clearance = 6 feet

Project Depth:	Maximum Static Draft	33.64 feet	(Table 5-3)
	Salinity	0.5 feet	(Estimated)
	Underkeel Clearance	+ 6.00 feet	(Table 5-7)
		40.14 feet MLW	

Example 2:

Determine project depth for LHA-1 class ship in a turning basin at Navsta San Diego
Maximum static draft = 28.65 feet
Freshwater, list, squat, heel, wave motion not applicable.
Soft bottom – underkeel clearance = 2 feet

Project Depth:	Maximum Static Draft	28.65 feet	(Table 5-3)
	Underkeel Clearance	+ 2.00 feet	(Table 5-7)
		30.65 feet MLLW	

Example 3:

Determine project depth for T-AKE1 class ship transiting inner channel at 5 knots at Navsta San Diego
Underway draft @ 5 knots = 32.46 feet (Table 5-4, includes maximum static draft and squat)
Freshwater, list, heel, wave motion not applicable.
Soft bottom – underkeel clearance = 2 feet

Project Depth:	Underway Draft @ 5 knots	32.46 feet	(Table 5-4)
	Underkeel Clearance	+ 2.00 feet	(Table 5-7)
		34.46 feet MLLW	

5-6.1.3 Aircraft Carrier Facility Special Requirements.
Dredge depth requirements for Nimitz Class Aircraft Carriers are summarized below.

5-6.1.3.1 Water Depth Requirements
Water depth requirements for Nimitz Class Aircraft Carriers transiting to and moored at homeports, ports of call, and shipyards are delineated in COMNAVSEASYSCOM ltr 4790PMS312 Ser 05-045 dtd 11 Jan 05, included as Appendix B. It specifies the minimum water depth required while the ship is in the waterway; however, it does not specify dredge depth requirements. The minimum water depth required to operate carriers in inner channels and turning basins on the way to and at piers at home ports is between 49 and 50 ft (14.9 and 15.24 m) depending on harbor salinity. These numbers

are similar for ports of call. Due to the reduced draft when visiting shipyards, the minimum water depth required to operate carriers in inner channels and turning basins on the way to and at piers at shipyards is between 46 and 47 ft (14 and 14.3 m) depending on harbor salinity. Applying these requirements to determine dredge depths requires additional port specific information. Appendix B specifies the following:

- “The dredging project depth can be traded off with tides to obtain the necessary water depth in inner channels and turning basins with the corresponding operational conditions." Therefore, planners should consider channel accessibility and operational restrictions imposed when selecting a design water level above the extreme low water. To facilitate uniform application of the minimum water depth requirement in referenced letter, formal criteria guidance is required.

- “Shallower and/or narrow channels and/or higher speeds will require greater allowance for squat.” Since narrow channel widths and greater speeds result in greater ship sinkage during transit (squat), and thus deeper water, planners should also include these effects.

- “Port specific fouling clearance studies can be performed if requested and funded” to possibly reduce the 6.0 ft (1.83 m) fouling clearance criteria. The clearance criteria was derived from condenser fouling studies on stationary ships berthed at NAVSTA Norfolk, VA in 1980. Locations that exhibit more or less potential for fouling may require more or less clearance to prevent it.

- “Ship motions analyses of the remaining home ports and shipyards will be completed...after receipt of funding.” The motion analyses that NAVFAC prepared for Mayport and San Diego predicted days of access and generated nomographs for other locations. For channels subjected to significant waves, engineers and planners must evaluate these wave effects on ship motions.

- Therefore, as provided for in Appendix B, facility engineers and planners should determine dredge depth requirements by including the additional considerations of design water level, channel width and ship speed impacts, dynamic effects of sea chest intake fouling, and wave effects. Additionally, they should include effects from sedimentation and dredging tolerances.

5-6.1.3.2 Consistency

The requirements provide consistency and reliability in the determination of acceptable dredge depths for channels and berths used by active Nimitz class aircraft carriers. The NAVFAC LANT Engineering Criteria and Programs Office will address reserve status condition of CVNs when required. Deviation from minimum criteria requires a waiver from the NAVFAC LANT Engineering Criteria and Programs Office which will be coordinated with cognizant Major Claimants, Naval Sea Systems Command, and Chief of Naval Operations.

5-6.1.3.3 Waterway Type

Ideally, engineers and planners should base ship channel designs on physical model testing, risk analysis, and ship simulator analysis. However, time and funding constraints may prevent this process. In any event, the requesting activity should determine the required dredge depths for Military Construction Projects. Dredge depth requirements for Nimitz class aircraft carriers depend on the type of waterway to be dredged. Four categories exist based on the magnitude of wave-induced and speed-induced ship movement:

- Outer channels – entrance channels or waterways subject to significant wave action, that is, wave energy resulting in vertical ship motions greater than 0.5 ft (0.15m) under design conditions.

- Inner channels – interior protected channels or waterways subject to minimal wave action, that is, wave energy resulting in vertical ship motions less than 0.5 ft (0.15m) under design conditions.

- Berths – water areas where ship velocity approaches zero, such as anchorages, slips, and pier and wharf berths that are subject to minimal wave action under design conditions; generally includes turning basins except as noted below.

- Special berths – defined as berths subject to significant wave action under design conditions.

5-6.1.3.4 Definitions

The following definitions apply:

- Datum – the horizontal plane from which the dredge depth requirement is referred, normally the local tidal datum of Mean Lower Low Water (MLLW).

- Design depth – the distance below the datum that must be maintained for safe navigation and berthing, also called the advertised, nominal, or project depth. This depth usually appears on Navigational Charts.

- Contract depth – the distance below the datum that is initially dredged by the contract and includes advanced maintenance dredging requirements but not the dredging tolerance (allowable overdepth). Also called the required depth, it is the depth noted on the DD-1391 Project Documentation and indicates the minimum depth required under the dredging contract.

- Permitted depth – the distance below datum to the lowest depth authorized by the regulatory agencies and normally includes the dredging tolerance (allowable overdepth). Planners and engineers should use this depth to determine estimated dredging quantities.

5-6.1.3.5 Parameters

Determine required dredge depths using sound engineering practice. The design depth is determined by summing the following parameters:

- Minimum water depth requirement – the minimum water depth that must be available for safe operation. For existing locations, use Appendix B implemented as follows for design water level, squat, ship motions, and underkeel clearances. For locations not addressed in the Appendices, contact the NAVFAC LANT Engineering Criteria and Programs Office for assistance.

- Design water level – the distance above the datum from which the dredge depth is calculated. For outer channels – use 0 f (0 m). The design water level should equal the datum to provide enough water depth and ensure that the ship can transit at all times. For inner channels and turning basins – use a water level that ensures safe passage to the berth or basin. This water level should be selected by the Activity based on optimizing cost and operation. Ship operators generally accept some minor operational restrictions and transit shallow channels at mid to high tide levels. Therefore, the design water level should be selected so that the carrier can transit from deep water to the berth, or vice versa, as frequently as expected without encroaching on the minimum water depth requirement noted in Appendix B. The user should identify for the planner the expected ship transit speed and desired days of accessibility, realizing that slow transits at low tide levels result in excessive dredge depths.

An example of this procedure is as follows:

- Determine level of accessibility; e.g. minimum of 339 days per year of access to homeports and 300 days per year of access to shipyards and ports of call. These accessibility levels equate to operational restrictions of approximately 2 consecutive days per month of encroachment on the underkeel clearance for homeports and 5 consecutive days per month for shipyards and ports of call, respectively.

- Based on local traffic and regulations, assume an average ship speed through channel; e.g. 5 knots.

- Using assumed transit speed and navigational charts, calculate the time required to accomplish the transit from the outer channel to the turning basin or berth.

- Using the calculated transit time, days of accessibility, and the charts in the Appendices, determine the channel depth requirement.

- Subtract the water depth requirement from the channel depth requirement to obtain the design water level. This number will usually be negative and thus result in a design water level above MLLW.

For all berths, except turning basins – use 0 ft (0 m). Since 6 ft (1.83 m) of clearance is provided, as noted later, the design water level may equal the datum (MLLW)

- Squat – the downward displacement of a vessel while underway. Assume no squat in berths. Appendix B incorporates squat for infinitely wide channels with ship speeds equal to or less than 10 knots. Ship squat greatly increases when CVNs transit channels less than 600 ft (182.88 m) in width or move at speeds faster than 10 knots. To determine squat for conditions other than those addressed in Appendix B, use the method contained in the paragraph titled “Squat” of this manual. All channels used by aircraft carriers in the United States, except the Southern Branch, Lower Reach, of the Elizabeth River, Norfolk, VA (450 ft (137.2 m)) at narrowest point) and the Entrance Channel, Mayport, FL (500 ft (152.4m) at narrowest point), are wide enough to be considered infinitely wide. For these narrow channels, the squat increases by 2 ft (0.6 m) The water depth requirement determined above should be modified to incorporate any difference in calculated squat.

For outer channels, assume ship speed of 15 knots. For inner channels, base on local traffic and regulations, but as a minimum, assume an average ship speed through channel of 10 knots and include the effects of narrow channels as noted above. For berths and special cases, assume ship speed of zero.

- Ship motion -- vertical excursion of vessel from waves. Appendix C addresses ship motions only for San Diego and Mayport. For other locations, use nomographs in Appendix D. H_S is defined as the significant wave height. Each set of nomographs reflects the direction of the significant wave relative to the direction of the CVN in transit; i.e., Following Seas are collinear with and in the same direction of ship movement, Quartering Seas are those that approach the aft quarter of the ship at 45 degrees, Beam Seas impact broadside to the ship, Bow Seas are those that approach the forward quarter of the ship at 45 degrees, and Head Seas are collinear with but opposite to the ship movement. The wave height and period should be transformed to and through the channel entrance using local wave data or Army Corps of Engineers reports entitled, *Wave Information Studies of U.S. Coastlines*.

For outer channels, use H_s for periods greater than 10 seconds with a 6 days/month recurrence interval. Exclude hurricane waves. Here is an example: Determine the wave climatology using available data determine the significant wave height, direction, and period. Transform waves into harbor based on shoaling, refraction, and diffraction, etc. Then based on local traffic and regulations, assume an average ship speed through channel; e.g. 14 knots. Using the calculated wave climatology, assumed ship speed and the charts in Appendix C, determine the predicted vertical ship motion for all applicable directions. For inner channels and berths, use $H_s = 0$. For special cases, use H_s for periods greater than 10 seconds with a 25 yr recurrence interval, unless directed differently by the Activity. Include hurricane waves if the berth is expected to be occupied during that extreme event.

- Clearance – distance from the lowest point on the vessel to the design depth. For berths, turning basins, and inner channels, Appendix B incorporates a 6 ft (1.83 m) clearance to prevent ingestion of benthic biota. This clearance when combined with installed discharge diffusers reduces the possibility of condenser fouling. Additional studies may reduce the requirement and can be performed if funded. The planner must collect all historical data available regarding fouling of condensers to ascertain the extent of the problem. The NAVFAC LANT Engineering Criteria and Programs Office is available to assist in analyzing this data. Notwithstanding, at berths the planner must ensure that a minimum of 2 ft (0.6 m) of clearance is provided at Extreme Low Water. See Table 5-8 for other categories:

Table 5-8 Required Clearances

LOCATION CATEGORY	SOFT BOTTOM	HARD BOTTOM
1. Outer channel	3.0 ft (0.9 m) for 50 ft (15.24m) depth	4.0 ft (1.22 m) for < 52 ft (15.85 m) depth
	4.4 ft (1.34 m) for 54 ft (16.46 m) depth	
	5.5 ft (1.68 m) for > 58 ft (17.68 m) depth	5.5 ft (1.68 m) for > 58 ft (17.68 m) depth
2. Special berths	6 ft (1.82 m) (min.) coupled with discharge diffusers	6 ft. (1.82 m) (min.) coupled with discharge diffusers

5-6.1.3.6 Contract Depth

Determine the contract depth by adding the advanced maintenance dredging requirement to the design depth requirement. The advanced maintenance dredging is the additional depth to reduce life-cycle maintenance costs by decreasing the frequency of dredging. Base the quantity on the anticipated local channel sedimentation rates corresponding to the anticipated dredging cycle. Use a dredging frequency of not less than 3 years, but based on local conditions. Include a minimum of 1 ft advanced maintenance dredging to prevent contractor change orders for differing site conditions on future maintenance dredging contracts. This minimum also provides the Contracting Officer field flexibility if the contractor does not achieve the contract depth in spot locations. The dredging tolerance, or overdredge, is the additional depth below the contract depth paid for by the dredging contract. The contract permits this additional depth because of inaccuracies in the dredging process. It is normally either +1 or +2 feet (+.3 or +.6 m). Local conditions and anticipated dredging equipment may warrant a different value.

5-6.1.3.7 Permitted Depth

Determine the permitted depth by adding the dredging tolerance, or overdredge, to the contract depth. Material samples for environmental testing should be accomplished at least to this depth.

5-6.1.3.8 Responsibilities

OPNAVINST 11010.20E, Part 5 designates responsibilities of the Chief of Naval Operations, Lead Activities, Shore Activities having assigned water areas, Public Works Centers and Public Works Lead Activities, Naval Facilities Engineering Command and Engineering Field Divisions, and Major Claimants regarding dredging coordination.

- Lead Activities and Shore Activities having assigned water areas – determine dredge depth requirements for Nimitz class aircraft carriers following procedures contained herein.

- NAVFAC Headquarters NAVFAC LANT, NAVFAC PACand FECs

    - Provide technical advice and assistance to lead activities and shore activities having assigned water areas.

    - Plan, design, and construct channels in compliance with the guidance stated herein.

- NAVFAC LANT Engineering Criteria and Programs Office will provide technical advice and assistance to: lead activities, shore activities having assigned water areas and FECs.

5-6.1.4 Currents.

The influence of entrance widths on the magnitude of the current also influence harbor site selection. Entrance widths should be adequate to reduce currents to acceptable values. The maximum allowable current in an entrance channel is a function of the type of ship or ships to be accommodated. It is only under special circumstances that the current exceed 4 knots.

5-6.1.4.1 Nonconstricted Entrance

If the entrance is not constrictive, as is shown in Figure 5-11 and the following conditions are met:

- the basin is relatively short and deep; that is

$$\frac{l_b}{\left(\sqrt{gd}\right)(T)} \leq 0.05 \qquad (5\text{-}1)$$

where l_b = basin length [ft]
d = average basin depth [ft]

- the bay water area is relatively constant
- freshwater inflow is minimal, and
- the ocean tide is approximately sinusoidal, then a good approximation for the current velocity is

$$\overline{V}_m = \frac{2\pi a_s A_b}{A_c T} \qquad (5\text{-}2)$$

where $\overline{V}_m$ = average cross-section velocity at maximum tidal flow [ft/sec]
T = period of tide [sec]
A_b = surface area of basin [ft2]
A_c = cross section of opening at mean tide level [ft2]
a_s = ½ range of the ocean tide [ft]

The circumstance that the entrance is not constrictive, together with the condition in Equation 5-1, implies that the water surface in the bay fluctuates uniformly and equals the ocean tide.

5-6-1.4.2 Constricted Entrance

If the entrance is constrictive, as shown in Figure 5-12, it reduces the tide range in the bay, so the above expression will overestimate the tidal currents. If conditions outlined in the paragraph titled "Nonconstricted Entrance" are satisfied, the maximum current in the entrance can be determined from this equation:

$$\overline{V}_m = \frac{2\pi\, a_s\, A_b\, e}{A_c\, T} \qquad (5\text{-}3)$$

where $\overline{V}_m$ = average cross-section velocity at maximum tidal flow [ft/sec]
A_c = cross section of opening at mean tide level [ft^2]
T = period of tide [sec]
a_s = ½ range of the ocean tide [ft]
e = dimensionless factor which depends on coefficients K_1 and K_2; see Figure 5-13.

The coefficients K_1 and K_2 are defined as follows:

$$K_1 = \frac{a_s\, A_b\, F_c}{2\, l_b\, A_c} \qquad (5\text{-}4)$$

$$K_2 = \frac{2\,\pi}{T}\sqrt{\frac{l_c\, A_b}{g\, A_c}} \qquad (5\text{-}5)$$

where l_c = channel length [ft]
F_c = $k_{en} + k_{ex} + \left(\frac{f\, l_c}{4\,R}\right)$
k_{en} = entrance-loss coefficient (≈ 0.1)
k_{ex} = exit-loss coefficient (≈ 1.0)
f = Darcy-Weisbach friction factor (≈ 0.03)
R = hydraulic radius of inlet channel [ft]

K_l represents the ratio of the magnitude of the friction forces and inertia forces. K_2 is a measure of the magnitude of the inertia forces relative to the magnitude of the pressure (water-level) gradient.

Since the entrance is constrictive, the amplitude of the bay tide will differ from the amplitude of the tide range in the ocean. The bay-tide amplitude can be determined from the following relationship:

$$\frac{a_b}{a_s} = \varepsilon \qquad (5\text{-}6)$$

where ε = dimensionless factor which depends on the coefficients K_1 and K_2 (see Figure 5-14))
a_b = ½ range of bay tide [ft]

Note that for small values of K_1, which denotes large inertia forces, the value of ε is greater than one.

For irregular entrance channels, an effective channel length, l_c', can be used in place of l_c.

$$l_c' = \sum_{i}^{n} \left(\frac{\overline{R}}{R_n} \right) \left(\frac{\overline{A}_c}{A_n} \right)^2 \Delta X_n \qquad (5\text{-}7)$$

where:

$\overline{R}$ = average hydraulic radius of channel [ft]
$\overline{A}_c$ = average cross section of channel at mean tide level [ft^2]
R_n = hydraulic radius at each of n sections of equal length, ΔX_n, [ft]
A_n = cross section of channel at each of n sections of length, ΔX_n, [ft^2]

This analysis provides an estimate of the channel-inlet hydraulics applicable to design situations. However, if the conditions in paragraph the paragraph titled “Nonconstricted Entrance” are not satisfied, or if the current velocities are critical to the channel design, a more detailed analysis to include mathematical or physical-model simulation is necessary.

5-6.1.5 New Facilities in Existing Harbors.

Where new facilities are to be developed in an existing port, these facilities are subject to the same criteria as the development of a new port. Although some information is contained in CEM, additional information is required. Further topics worthy of consideration are basin depth, Navy ship size and draft, ordnance issues, and new types of Electronic Counter Measures (ECM), such as deperming and degaussing.

5-6.1.6 Submarine Facility Special Requirements.

The following submarine-specific requirements are provided:

5-6.1.6.1 Special Considerations.

Harbors designed to accommodate naval submarines of the various classes require special attention during the planning stage. Since surfaced submarines are relatively unwieldy deep-draft vessels with low freeboards, channels and other water areas to be used by submarines must be wide and deep enough for safe maneuvering.

5-6.1.6.2 Entrances and Channels.

Surfaced submarines are susceptible to wave action, surge and currents. Submarines require still water not only during docking and mooring operations, but also especially while negotiating the entrance and channels. Where moorings are located in estuaries and rivers subject to strong currents, or where entrances are subject to moderate to strong wave action, protection in the form of jetties or breakwaters should be provided.

5-6.1.6.3 Moorings.

Because of its “barrel” cross-section, a submarine’s beam underwater exceeds the width of its above-water superstructure. Thus, to safely moor submarines, an underwater fendering system is mandatory. Either submarine camels or hydropneumatic fenders are used to buffer the widest point of the vessel. The depth required depends upon the specific submarine. For example, if the draft of the submarine is 33 ft (10.1 m) the separator must extend a minimum of 18 ft (5.5 m) below the surface. Separators are normally between 30 and 50 ft (9.1 and 15.2 m) in length. Facilities for docking submarines and the design of deep draft separators are described in UFC 4-152-01. However, it should be remembered when designing harbors to accommodate submarines that ample storage area is needed for camels/fenders when not in use. Further, consideration should be given to water-area docking or mooring requirements for small craft servicing camels/fenders and other support structures.

5-6.1.6.4 Piers and Wharves.

Special requirements for the design of piers and wharves to accommodate submarines are contained in UFC 4-152-01. It is noted that in the absence of tug assist, the water approaches to submarine docking facilities should be designed to accommodate the largest vessel anticipated.

5-6.1.7 Dangerous Cargo Requirements.
Anchorages for tankers and similar vessels should be at least 500 ft (152.4 m) from adjacent berths, and located so that prevailing winds and currents carry spillage away from general anchorage and berthing areas.

Anchorages for vessels carrying explosives should be separated in accordance with quantity-distance relationships established in Ammunition and Explosives Safety Standards, DOD 5154.45 (DOD, 1978), which was superseded by DOD 6055.9 (DOD, 1997), and Ammunition and Explosives Ashore, NAVSEA OP 5 Vol 1, 6^{th} edition (NAVSEA, 1999).

5-6.1.8 Shipyard Special Requirements.
The following information is provided:

5-6.1.8.1 Mission and Requirements.
Harbors or sections of harbors designed as shipyards require special facilities and designs. Shipyard facilities consist of navigation basins, piers, drydocks, and backland. Outfitting or repair piers are generally arranged as in Figure 5-15c or f. Less commonly, where space permits, repair stations could be arranged along a marginal quay, as in i. Drydocks may be either the floating or graving type.

5-6.1.8.2 Waterways.
he shipyard portion of the harbor requires a channel sufficiently large to accommodate the largest vessel to be served by the shipyard. The water area fronting the shipyard should be a navigable basin in which the largest vessel is capable of maneuvering to and between repair facilities. It is essential that the shipyard has quiet water and be free of strong currents. Ships at repair are frequently in “hotel” status and short of the operating personnel needed to operate them in case currents should tear them loose from their moorings.

5-6.1.8.3 Piers.
Special considerations for repair and outfitting piers include crane rails for portal cranes, railroad tracks between crane rails, and special service piping to shipside galleries or service boxes. For pier design, refer to UFC 4-152-01.

5-6.1.8.4 Drydocks.
Drydocks are of two basic types: floating and graving. Floating drydocks may be moved from place to place and are suitable for servicing smaller ships and submarines. A floating drydock must be moored or anchored in a location where the water is considerably deeper than the draft of the ships it serves, and it must have access to the shore for supplies and utilities. A staging and laydown area alongside the drydock is required to provide operational support.

A graving drydock is a permanently placed facility dug into the embankment. Such drydocks are usually equipped with portal cranes that travel around the perimeter of the dock and are surrounded by service and laydown areas for large ship parts and equipment. Space along the quay near the drydock or other moorage and clear of vessels maneuvering into the dock is required for storage of the drydock's caisson gate. For all types of drydocks, keel blocks for the various vessels served must be stored nearby.

5-6.1.8.5 Ancillary Facilities.
Additional facilities and water area should be allocated for anchorage or moorage of ships awaiting repair service and for tugboats and fireboats. These facilities and areas may not be required within the shipyard limits if they are available nearby in the harbor.

5-6.1.8.6 Land Needs.
Land area should be allocated to shipyard use in sufficient quantity to provide for rail or highway access, including onsite storage of vehicles and goods required for shipyard operations. Shop and office buildings, storage areas, and laydown spaces should be arranged to provide the most efficient flow of work and personnel within the facility consistent with the available space and mission of the shipyard. Figure 5-16 is an example of the space allocation and arrangement of a sample shipyard.

5-6.1.9 Degaussing and Deperming Requirements.
NAVORD OP 2706, Introduction to Degaussing (NAVORD, 1960) and NAVSEASYSCOM SS475-AD-MMD-010/MAG FAC, Magnetic Silencing Facilities Description and Installation of Permanent and Portable Equipment (NAVSEASYSCOM, 1980) cover the two methods used in magnetic silencing: magnetic compensation (degaussing coils) and magnetic treatment (deperming). Deperming which reduces the permanent magnetization accumulated by a ship during construction and operation complements the use of opposing magnetic fields in degaussing.

Figure 5-15 Types of Berthing Layouts

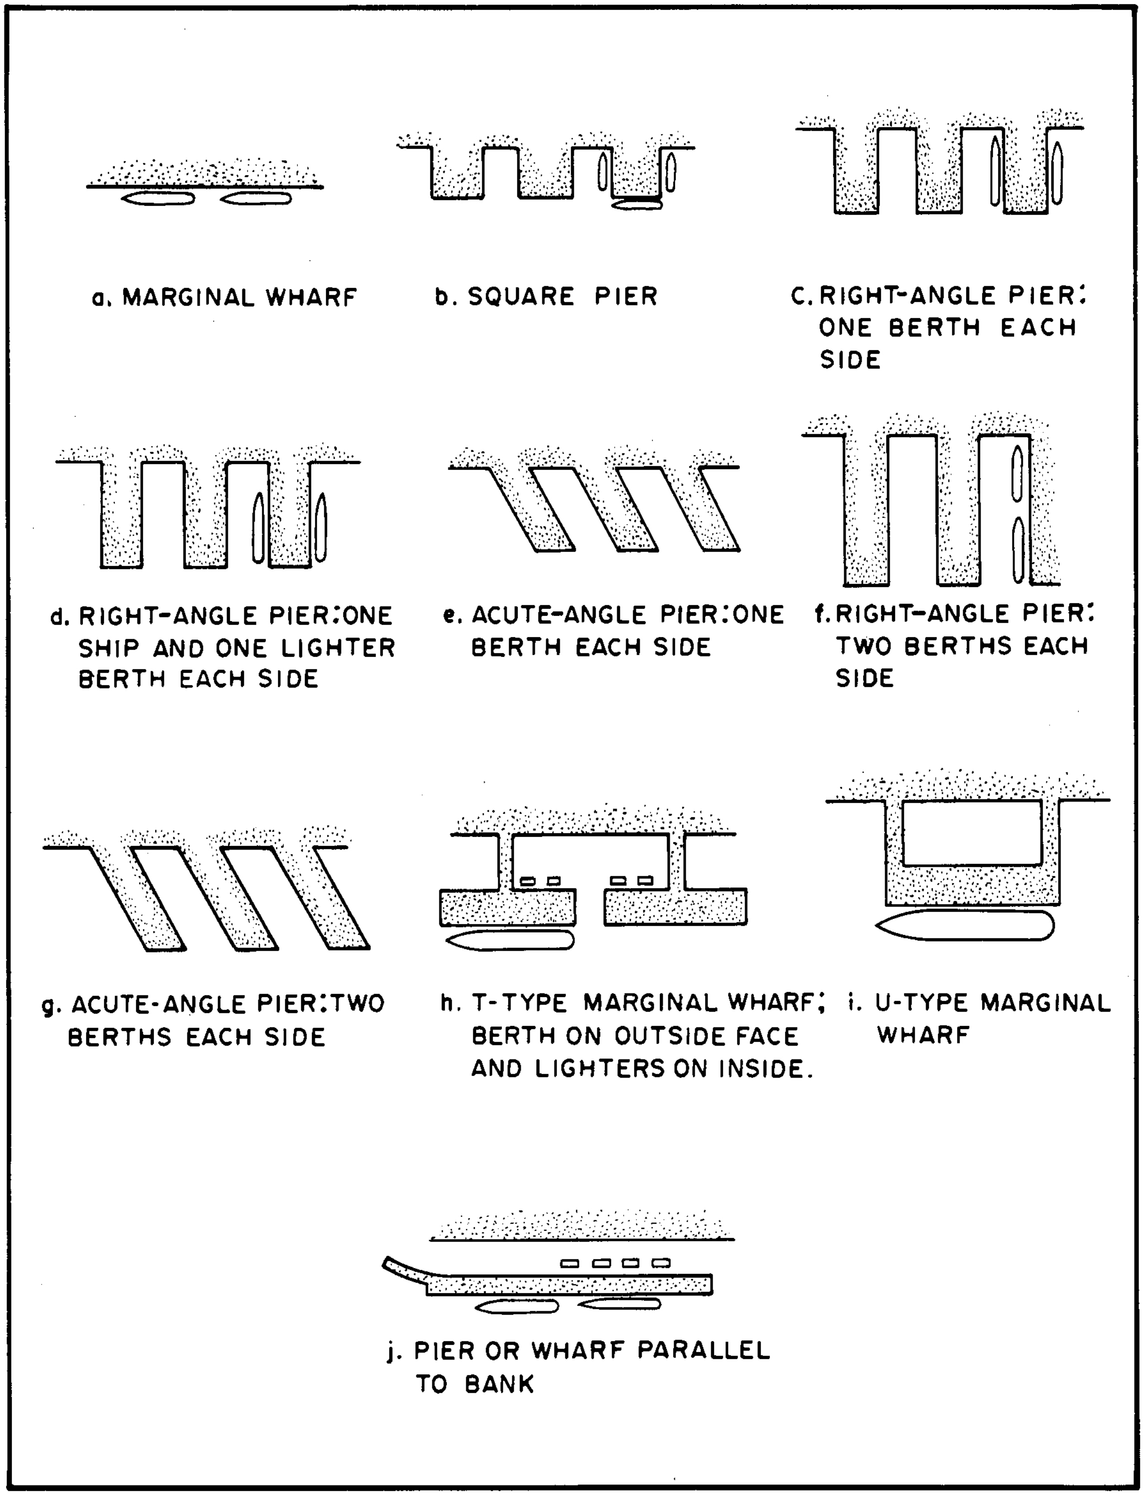

Figure 5-16 Sample Shipyard Layout

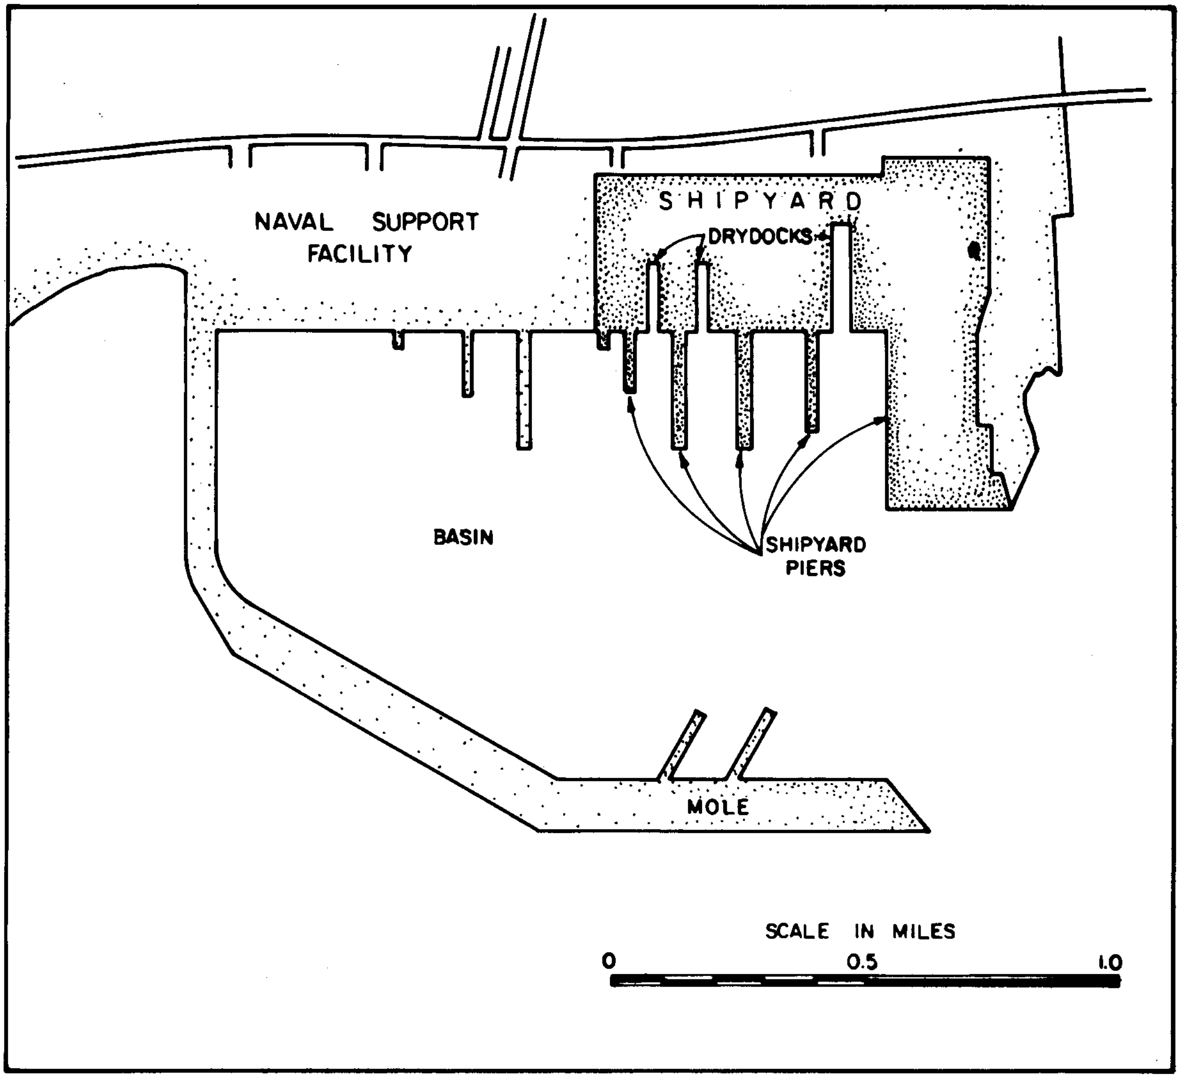

5-6.1.9.1 A steel object under the magnetic forces of the earth will itself become polarized and set up a magnetic field of its own. A steel-hulled ship will become a huge floating magnet itself. In addition, there are induced magnetic signatures caused by inside electronics and motors. This magnetic field makes the ship vulnerable to magnetically sensitive mines or other magnetic influence detecting devices.

5-6.1.9.2 The science of degaussing deals with reducing the ship's magnetic field, or signature. Normal deperming techniques based on alternate reversals of ship polarity are used to reduce the ship's permanent structural hull signature whereas equipment induced signatures are controlled by interior degaussing cables. In order to determine the characteristics of a ship's magnetic field it is necessary to make periodic measurements of the field, referred to as "ranging". The primary type of degaussing/magnetic silencer range consists of a linear pattern of instrumentation tubes containing magnetometers embedded in the channel bottom.

5-6.1.9.3 There are three depth classifications of check ranges based on class of ship:

- Minesweeper – shallow (30 ft (9.1 m))
- Medium depth (55 ft (16.8 m)); and
- Deep (85 ft (25.9 m))

There are now 6 Forward Area Combined Degaussing and Acoustic Ranges (FACDAR) for forward deployed areas where no permanent ranges are available.

5-6.1.9.4 In order to deal with magnetic silencing facilities for degaussing and deperming purposes, it is necessary to design with dredging in mind. If the facilities are already in place, a dredging method, which will not impact the facilities, must be chosen.

5-6.1.10 Seismic Loading.

Coastal projects constructed in regions known to experience seismic activity may need to consider potential impacts related to ground deformation and severe liquefaction. Seismic loading may also be a concern in design of confined dredge material berms (subaerial) and caps (subaqueous) where liquefaction could release contaminated sediments. CEM Section VI-3-4 provides further guidance. Areas of seismic activity may produce tsunamis. Designs should also consider the potential for tsunamis and their assoiciated effects, i.e. extreme tide ranges and surges.

5-6.1.11 Ice Loading.

At some latitudes, fresh water lakes and coastal regions experience annual ice formation during portions of the year. Thus, in project planning stages, it is important to determine if the presence of ice adversely impacts the project functionality; furthermore, during design, it is important to consider the effect that ice loads and impacts might have on individual coastal project elements. CEM Sections VI-3-5, and EM 1110-2-1612, Ice Engineering**,** provide further guidance. Chapter 10 of the Report on Ship Channel Design provides a cursory view of design of channels with ice cover, locks, erosion and sediment movement, and vibration and mitigation of ice problems in channels (ASCE, 1993).

5-6.1.12 Debris Entering Harbors.
Marine debris entering harbors is composed of a broad range of materials, which include litter (e.g., aluminum cans, plastic pieces, glass pieces, and cigarette butts), waste (e.g., medical, galley, operational, and sewage), and wood from branches from trees and other inland vegetation. As such, it can interfere with harbor operations. Assessment and strategies to reduce marine debris in the coastal and ocean environment can be accomplished by managing uses and activities that contribute to the entry of such debris. Existing regulations include, but are not limited to, prohibiting littering and dumping of debris and discharging pollutants in near shore waters. Harbor activities are also subject to the same rules and statutes relating to debris control.

5-6.1.13 Drydocks.
This subject is covered in detail in UFC 4-213-10.

5-6.2 Development of a Navigation Project.
Often a navigation project requires one or more engineered structures to accomplish its objectives. Structures can serve a variety of purposes. However, their presence also establishes a major hazard for vessels. Hence, a navigation structure must be designed with regard to several functional concerns. Basic types of structures and functions involved in navigation projects are briefly discussed in CEM Section V-5. Sediment processes and management at inlets and harbors are discussed in CEM Section V-6. Detailed guidance on structure design is given in CEM Section VI.

5-6.2.1 Defining Fleet Requirements.

- All dredging activities must be coordinated with the NAVFAC Criteria Office.
- The activity should coordinate the following issues with the major claimant: classes of ships used at the facility, access frequency, days of harbor access required, and function performed in the harbor,
- Most harbors cannot design for 100 percent accessibility, so the amount of risk the claimancy wants to take on should be addressed.
- Seakeeping issues in the channel shall also be addressed.
- Check for criteria of thickness of ice; refer to paragraph titled “Ice Loading” for references.

5-6.2.2 Entrance Channel Configuration.
Designing approach-channel and entrance-channel widths for harbors located in exposed ocean-wave environments is largely accomplished by comparing presently operating harbors. The forces of waves and currents acting on a vessel in exposed locations induce excursions of the vessel from its intended path of travel. For example, to pass in the lee of an entrance structure, a vessel needs maneuvering room in order to adjust to the rapid changes in sea conditions.

Where naval activities share common entrance approaches with commercial port activities, entrance-channel widths greater than 1,000 ft (304.8 m) are common. Table 5-9 gives entrance-channel dimensions for several typical harbors. Table 5-10 provides typical harbor entrances serving naval facilities.

For new entrance designs, preliminary width approximations can be made as given in paragraph titled “Entrance Channels”, by adjusting ship beam with yaw angle increase and then proceeding as for an interior-channel design. In the case where the hydraulic environment at the entrance is unique and without precedent, navigational studies involving suitable-scale physical model methods are recommended.

5-6.2.2.1 Interior Channels.
The dimensioning of interior channels protected from open sea waves and strong cross currents is shown in Figure 5-17 , where B = beam of vessel.

- Ship-Lane Widths. Where good operating conditions (that is, a maximum ship speed of 10 knots, currents less than 3 knots, good visibility, and wind less than 15 knots) exist, the following ship-lane widths should be used:

Vessel Maneuvering Characteristics	Lane Width as a Multiple of Beam
Excellent – CG and DD	1.6
Good – FFG, CV, AOE, and LSD 36	1.8
Poor – Submarines, Tenders, AE, and AS	2.0

- Ship Clearance. Ship clearance is normally assumed to be equal to the beam at waterline of the largest vessel. Where a channel is to be frequently used by aircraft carriers having large overhanging decks, increase the clearance between ship lanes to maximum vessel breadth.

- Bank Clearance. Vessels traveling in restricted waterways experience hydrodynamic suction from the banks. This is offset by rudder-angle adjustment. Results of limited model studies are shown in Figure 5-18.

For sustained travel by a naval vessel in a restricted channel, a 5-degree rudder angle is a desired maximum.

Figure 5-17 Dimensioning Protected Interior Channels

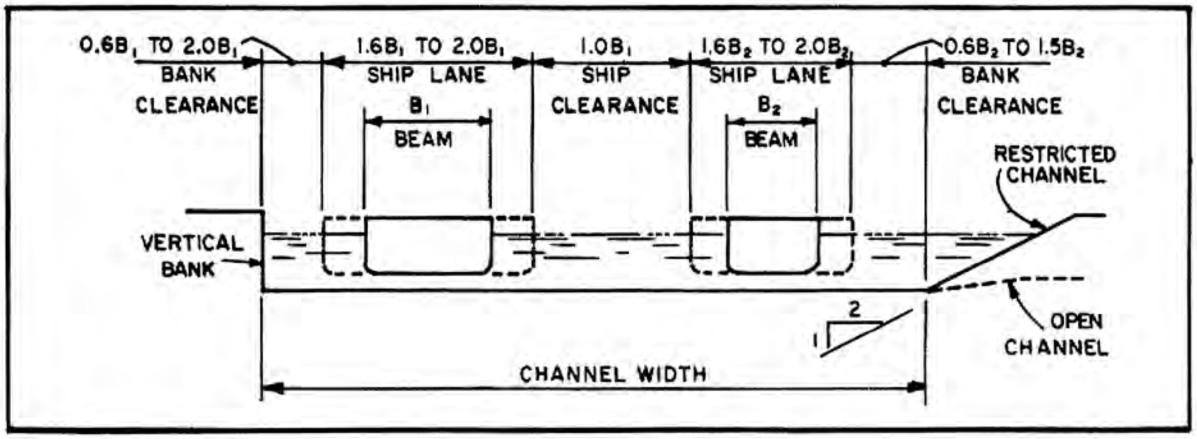

Figure 5-18 Bank Clearance versus Rudder Angle

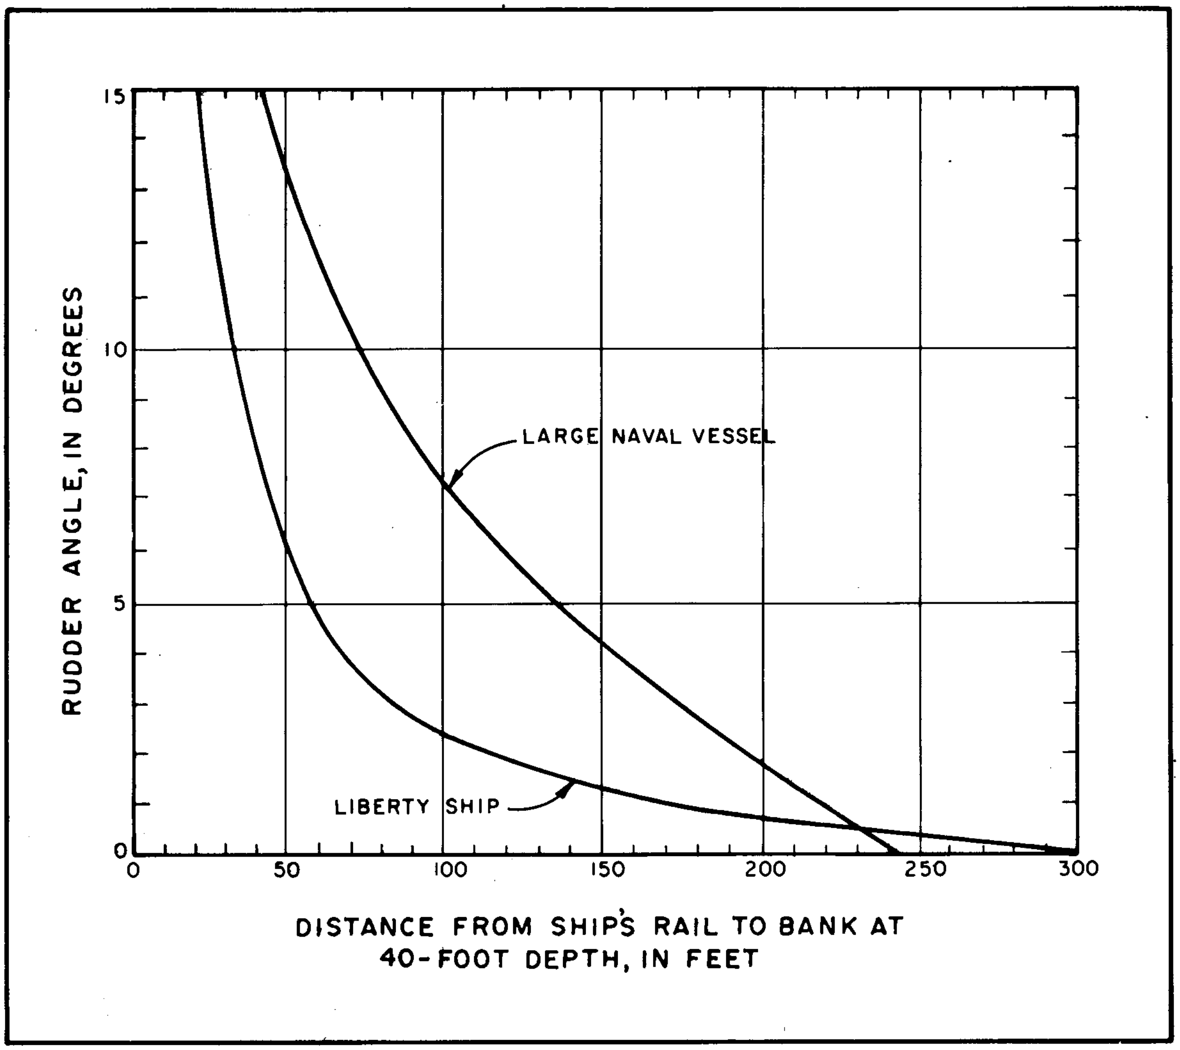

Table 5-9 Typical Entrance-Channel Dimensions

Harbor	Width (ft (fm))	Depth (m (ft))	Remarks
Boston, MA	1,100 (335.3)	40 (12.2)	Access to port entrance
New York, NY	1,800 (548.6)	44 (13.4)	Access to port entrance
Charleston, SC	1,500 (457.2)	35 (10.7)	Non-restricted outlet for three rivers
Columbia River, OR	2,640 (804.7)	48 (14.6)	River bar crossing in severe wave environment – closed during certain storms
Long Beach, CA	1,800 (548.6)	60 (18.3)	Breakwater gap
San Diego, CA	800 (243.8)	41 (12.5)	Entrance channel through parallel jetties
Apra Harbor – Guam	1,350 (411.5)	120 (36.6)	Entrance between breakwater head and shore

Table 5-10 Typical Harbor Entrances Serving Naval Facilities

Harbor	Width (ft (m))	Depth (ft (m))	Largest Naval Vessel – Normal Use	Remarks
Mayport, FL	900 (274.3)	42 (12.8)	Unrestricted	Entrance through parallel jetties
Port Hueneme, CA	600 (182.9)	39 (11.9)	Destroyer	Entrance through non-parallel jetties
Pearl Harbor, HI	1,580 (481.6)	60 (18.3)	Unrestricted	Broad, ill-defined entrance
Seal Beach, CA	600 (182.9)	38 (11.6)	Destroyer	Entrance through non-parallel jetties

In addition to rudder-angle and vessel-handling criteria, overall vessel safety must be considered in determining bank-clearance distance. In an open channel, the markings of the channel limits may not be as fully defined as in a restricted channel. This can be compounded in times of poor visibility. Similarly, where there exists a high damage probability for grounding, as in the case of an underwater rock ledge, additional bank-clearance margins should be considered. Extra allowance should also be made where the channel is subject to siltation from the side slopes. Under conditions such as those mentioned above, the minimum desired bank clearance for design purposes should be equal to the beam of the largest vessel frequenting the harbor. For open channels with steeper than 1-on-3 side slopes, this minimum clearance should be 1.2 times the beam. Examples of existing interior channels are given in Table 5-11.

5-6.2.2.2 Channel Bends.

Bends in channels should be avoided if possible. If channel bends are unavoidable, the channel should be widened to account for the fact that the path of a ship in a bend is wider than in straight sections. The criteria for designing channel bends depend upon:

- The angle of deflection, defined as the angle between the two straight sections of the channel,
- The speed of travel of and the properties of the vessel,
- The characteristics of the channel,
- The visibility, obstructions, and aids to navigation in the vicinity of the bend, and
- Human elements.

Table 5-11 Examples of Existing Interior Channels

Harbor	Width		Depth		Remarks
	m	ft	m	ft	
Baltimore-Fort McHenry Channel	121.9	400	10.7	35	Open-type channel
Norfolk- Thimble Shoal	469.4	1540	13.7	45	Open-type channel
Charleston-Naval Weapons Annex, Kingston	152.4	500	10.7	35	Riverine, open-type channel
Columbia River-Astoria Range	182.9	600	12.2	40	Riverine, open-type channel
Oakland-Bar Channel	91.4	300	10.7	35	Open-type channel
San Pablo Bay-Pinhole Shoal	182.9	600	10.7	35	Open-type channel
Long Beach	304.8	1000	10.4	34	Restricted-type channel
San Diego	213.4	700	12.5	41	Open-type channel

- Open-Type Channels. A change from one direction of the channel into another can be accomplished for an open-type channel without the introduction of a curved bend, provided the vessels encountering the bend are highly maneuverable and the change in direction is not too large. Such a bend is called a straight-line bend and is shown with alternative methods of widening the channel in Figure 5-19.

- Restricted-Type Channels. If the bend occurs in a restricted-type channel, the change of direction is large, or the maneuvering characteristics of the vessels frequently using the channel are poor, introduction of a curve in the channel becomes necessary. In designing a channel curve, the critical factor is determination of the radius of the curve. The criteria upon which the radius, R, is based are the length, l_v, of the ship entering the channel and the angle of deflection, α, of the channel bend. The general rules governing determination of the radius are as follows:

    - Minimum R = 3,000 ft (914.4 m) for a ship under its own power.

    - R = 1,200 to 2,000 ft (365.8 to 609.6 m) for tug assistance.

    - If the angle of deflection is greater than 10 degrees, the curve should be widened at the inside curve.

    - The tangent length between consecutive curves where there are no obstructions should be 1,000 ft (304.8 m) or 2 l_v (where l_v = length of the largest ship using the channel), whichever is larger.

- Reverse curves should not be used except in special situations.

Rules governing the radius, based on angle of deflection, are:

$R = 3\ l_v$ minimum for $\alpha < 25$ deg.

$R = 5\ l_v$ minimum for 25 deg. $< \alpha <$ 35 deg.

$R = 10\ l_v$ minimum for $\alpha > 35$ deg.

Rules governing the radius, based on vessel length, are:

R = 1219.2 m (4,000-ft) minimum for $l_v <$ 152.4 m (500 ft)

R = 2133.6 m (7,000-ft) minimum for $l_v =$ 152.4 m (500 ft)

R = 2133.6 to 3048 m (7,000 to 10,000 ft) for (152.4 m (500 ft) $< l_v <$ 213.4 m (700 ft)

The radius of the curve must fulfill the above criteria. Once R has been determined, the channel-bend geometry must be determined. This consists of widening the channel at the bend and providing a smooth transition from the straight portions of the channel through the curve. This can be done in several ways, as shown in Figures 20 to 24. The entire amount of widening in the channel could be added to the inside of the channel, as shown with curved transitions in Figure 21 and straight transitions in Figure 22. The widening could also be split on the inside and outside of the curves equally, as shown in Figure 23, or unequally, as shown in Figure 24. For final design, an investigation considering local conditions and dredging costs is required to optimize bend geometry. If widening the channel cannot be achieved due to existing soil conditions or structures, tugs must be used to assist ships.

5-6.2.2.3 Entrance Channels.

- Entrance Channel Widths

  - Breakwater gaps. In practice, vessels transit gaps between breakwaters one at a time. Observations reveal that in practice a second vessel will normally standoff and allow the first vessel to complete its passage through the gap to and from protected water. A minimum entrance gap width of 0.8 to 1.0 times the length of the vessel appears to be adequate for most sea conditions.

  - Channel entrances. Vessels require more room to maneuver in and out of channels leading to protected harbor waters. Therefore, prescribed widths for interior channels must be increased to allow for additional channel width at the entrance. By utilizing vessel beam and its length, the increase in vessel beam can be approximated by the following equation:

$$B' = B + l_v \tan \theta \qquad (5\text{-}8)$$

where: B' = adjusted vessel beam

B = vessel beam

l_v = vessel length

θ = yaw angle

Yaw angle should be assumed to range from 5 to 15 degrees, depending upon entrance exposure. The adjusted vessel width, B', is used in ship lane width determinations with ratio factors similar to those used in interior-channel design (see Figure 5-17).

- Entrance Channel Length. In order to safely negotiate the entrance channel, vessels normally must maintain a higher rate of speed than is required or permitted within a harbor. Thus, the entrance channel should be of a length sufficient to allow vessels to reduce velocity before entering the harbor proper. For vessels entering with speeds in the range of 5 to 10 knots, allow one vessel length of slowing distance per knot of entering speed between the entrance and the turning basin. For medium-sized vessels with no tug-assisted speed arrestment, a minimum of 3,500 ft (1066.8 m) should be provided. CEM Section V-5 deals with the crucial elements of channel design: width, depth and alignment. In addition, the special requirements of entrance channels are discussed.

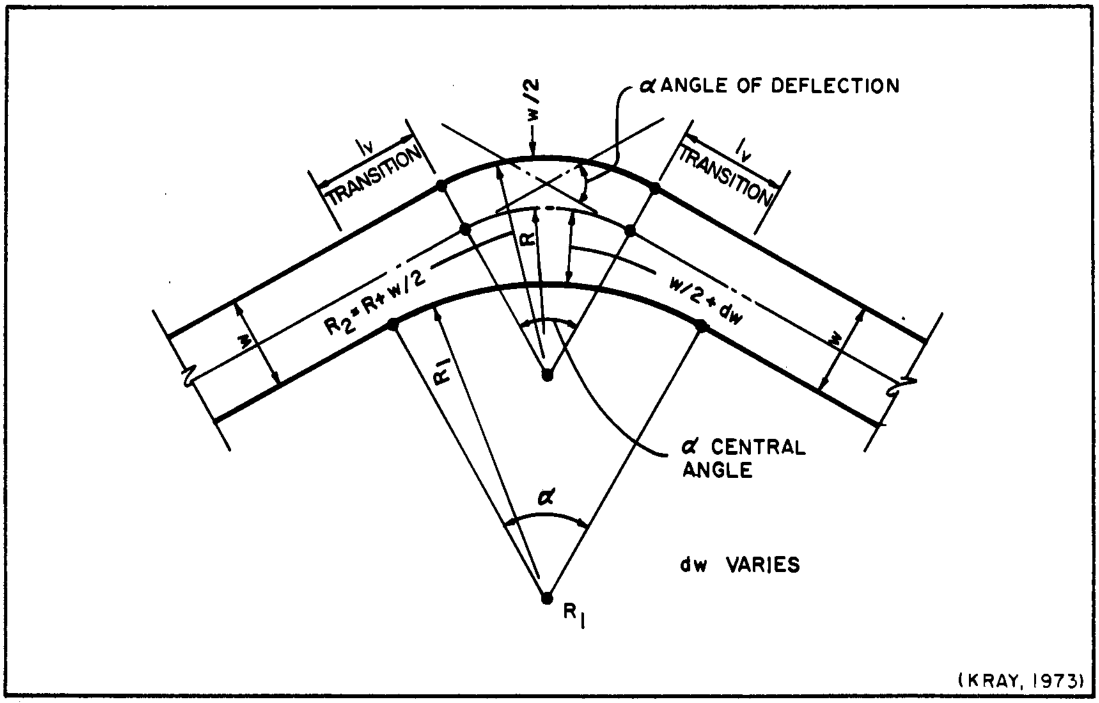

Figure 5-22 Unsymmetrically Widened Turn With Straight Transitions

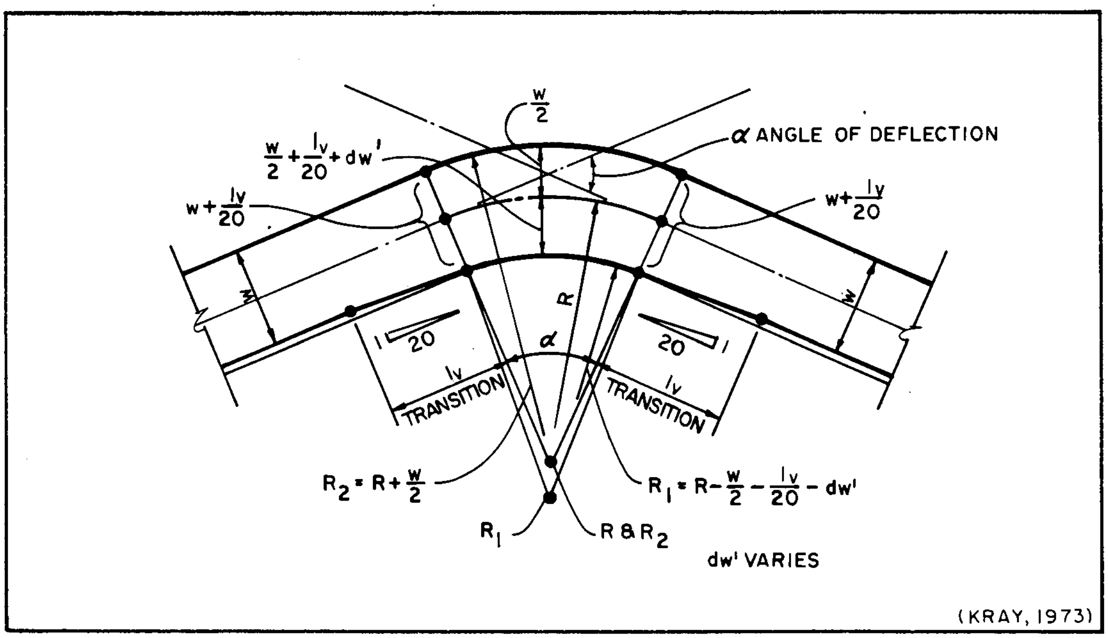

Figure 5-23 Parallel Widened Turn in Channel

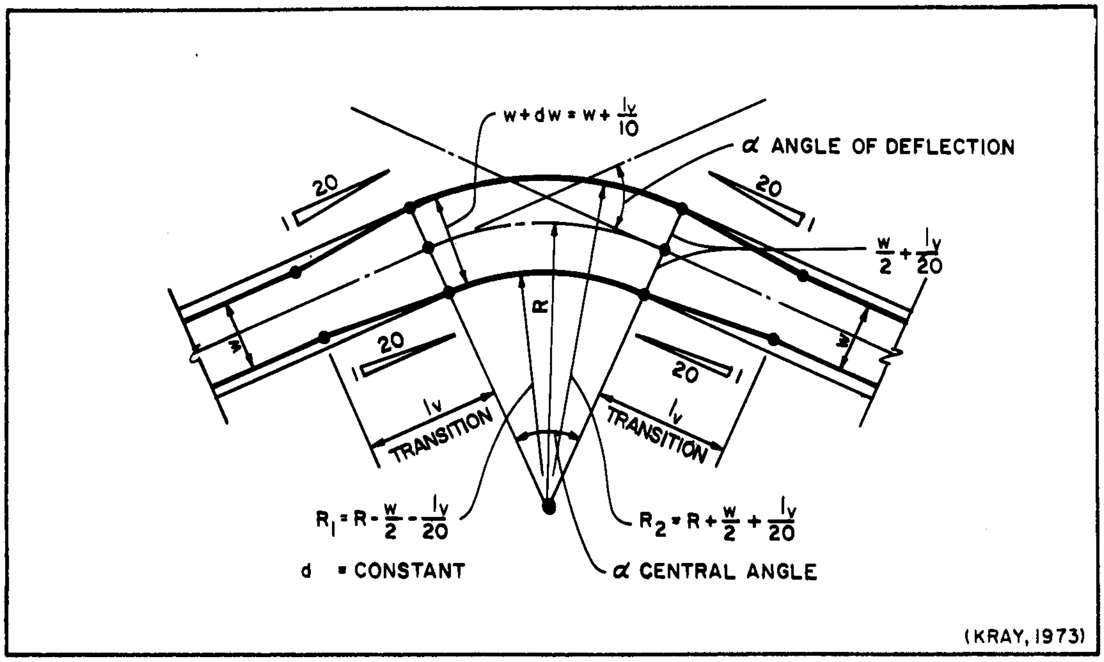

Figure 5-24 Symmetrically Widened Turn With Straight Transitions

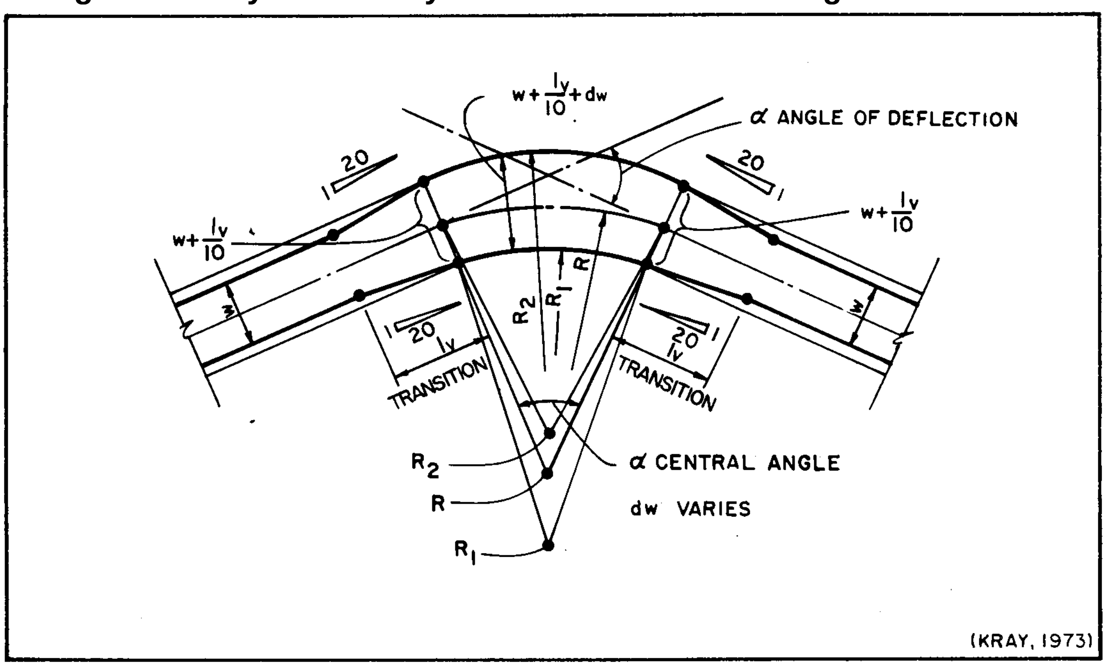


5-6.2.3 Berths and Berthing Basins.

Figure 5-15 showed types of berth arrangements. Table 5-12 lists factors affecting the selection of the location of berthing basins. A rule of thumb is that the wave height in the berthing basin should not exceed 2 ft (0.6 m) for comfortable berthing, but in no case shall the wave height exceed 4 ft (1.2 m).

5-6.2.3.1 Quayage Required.

Quayage requirements of piers and wharves for the various classes of vessel may be estimated from tabulated data in UFC 4-152-01. Consult with the using agency for data on the maximum number of ships of various classes (including lighters) to be simultaneously accommodated.

5-6.2.3.2 Arrangement of Berths.

- Selection. The arrangement of berths must fit the proposed site without encroaching on pierhead or bulkhead lines. For steeply sloping subgrades, the berths must fit within the depth contour below which the driving of piles is impractical. In selecting the berthing arrangement, consider the factors relating to economics and utility (see Table 5-13).

- Relative Berthing Capacities. Table 5-14 shows linear feet of berthing space per 1,000 ft (304.8 m) of shorefront.

5-6.2.3.3 Size and Depth of Basin and Berths.

For the general depth requirements for the basin, see paragraph titled “General Depth Requirements”.

- Berthing Area. For berthing-area requirements for piers, see 5-15. For ships berthed at marginal wharves or quay walls, provide twice the total area requirement shown in Table 5-15 for pier berthing. Allow additional area within the harbor limits for channels, special berths, turning basins, and other facilities.

- Depth. Except where heavy silting conditions require greater depth at individual berths at low water, the depth should equal the maximum navigational draft of the largest vessel to be accommodated plus 10 percent. On mud or silt bottoms, consider increasing depth requirements if investigation indicates probable fouling of condensers on the vessel due to the proximity of the mudline to intake pipes of the condenser system. Where vessels to be accommodated are not specifically known, the values in Table 5-16 may be used.

- Clear Width of Slips Between Piers; see UFC 4-152-01.

- Length of Berth; see UFC 4-152-01.

- Width of Piers.

  - Square pier systems. Width should be capable of berthing the longest expected ship. The net area of the pier should be three times that required for a single berth terminal.

  - Finger pier system. Pier width varies. Width requirements may be estimated from data in UFC 4-152-01.

- Special Berths.

  - Fueling vessels. Berths should be at least 500 ft (152.4 m) from adjacent berths.

  - Explosives. Berths should be separated in accordance with the quantity-distance relationships established in DOD 5154.45 and NAVSEA OP 5.

5-6.2.4 Turning Basins.
Where space is available, providing turning basins will minimize tug usage. However, where space is restricted, tugs may be used to turn vessels, thereby eliminating the need for turning basins.

5-6.2.4.1 Location.
The following location requirements must be met:

- locate one turning basin at the head of navigation

- locate a second turning basin just inside the breakwater

- in areas where especially heavy traffic is anticipated, provide intermediate basins to reduce congestion and save time

- where feasible, use an area of the harbor, which in its natural state has the required size and depth.

- it is frequently advantageous for a turning basin to be located at the entrance to drydocks or at the interior or landward end of long piers or wharves that provide multiple-length berthing.

5-6.2.4.2 Size and Form.
As a rule of thumb, a vessel can be turned comfortably in a radius of twice the vessel length, or, where ease of maneuver is not an issue, in a radius equal to the vessel length. For shorter turning radii, tug assistance for the vessel is necessary. Also in this case, where wind and current effects are not critical, naval vessels can be turned in a

circle with a diameter of 1.5 times the vessel length. Table 5-17 provides dimensions of typical turning basins in existence.

5-6.2.5 Anchorage Basins

5-6.2.5.1 Siting Factors.

Table 5-18 lists factors affecting location, size, and depth of anchorage basins.

- Free-Swinging Moorings and Standard Fleet Moorings.
  For the diameter of the swing circle and the area requirements per vessel, see Tables 5-19, 5-20, and 5-21. For size of berth for floating drydocks, spread-moored, see Tables 5-22 and 5-23. Additional area allowance should be made for maneuvering vessels into and out of berths and for waste space between adjacent berths.

a) Demarcation. Anchorage areas should be marked.

b) Dangerous Cargo.

- Tankers. Anchorages for tankers and similar vessels should be at least 500 ft (152.4 m) from adjacent berths, and located so that prevailing winds and currents carry spillage away from general anchorage and berthing areas.

- Explosives. Anchorages for vessels carrying explosives should be separated in accordance with quantity-distance relationships established in DOD 5154.45 (DOD, 1978), which has since been superceded by DOD 6055.9 (DOD, 1997), and NAVSEA OP 5 (NAVSEA, 1999).

CEM Section V-5 discusses the details of inner harbor elements.

Table 5-12 Factors Affecting Location of Berthing Basins

Factor	Requirement and Comment
Protection	Locate berthing basins in harbor areas that are best protected from wind and wave disturbances and/or in areas remote from the disturbances incident upon the harbor entrance.
Orientation	Orient berths for ease of navigation to and from entrance and channel.
Offshore Area	Provide sufficient area offshore of berths for turning ships, preferably without use of tugs.
Quayage adequacy	Adequate quayage shall be provided for expected traffic.
Expansion	Provide area for future expansion.
Fouling and Borers	Where possible, locate berthing basin in area of harbor with minimum fouling conditions and minimum incidence of marine borers. Elliott, Tressler, and Meyers (1952) indicate some advantages for locations in the ebb side of an estuary harbor. The ebb side of an estuary in the Northern Hemisphere is the right side looking seaward.
Foundations	Where feasible, locate in area of favorable subsoil conditions, in order to minimize cost of berthing structures.
Supporting shore facilities	Locate supporting shore facilities in proximity to their respective berths. Adequate space and access for upland road and railroad facilities are essential. In general, it is desirable to have a wide marginal street at the inshore ends of the piers or wharves and a wide street on the pier axis. Annual capacity per terminal is based on commercial throughput values obtained from Hockney (1979).

Single Berth Terminal by Cargo Class	Cargo Throughput (tons per year)
Break-bulk general	66,000
Neo-bulk general cargo	130,000
Containerized general cargo	360,000
Dry bulk – silo storage	1,000,000
Dry bulk – open storage – low density	500,000
Dry bulk – open storage – high density	1,000,000
Liquid bulk – other than petroleum	80,000
Petroleum bulk – up to 50,000 dwt ships	1,500,000
Petroleum bulk – 30,000 to 200,000 dwt ships	6,000,000

Table 5-13 Selection Factors for Berthing Arrangements

Berthing System	Advantages	Disadvantages
Marginal Wharf (Figure 5-15a)	Solid fill supports deck loads without expensive framing. Accessibility of entire upshore area for working space, storage space, laydown operations, and traffic circulation adds to the utility of the wharf as compared to pier or offshore wharf systems. Permits utilization of surplus fill material. Suitable for sites where pier cannot be projected out from shore and where dredging of a recessed basin for piers would be expensive. Also suitable where the navigation channel is too narrow to permit maneuvering into finger piers.	Costs per berth greater than for pier systems. Ratio of berthing space to length of waterfront is low. Berthing length is limited to length of face of wharf, unless mooring dolphins are used to extend usable length.
Square Pier (Figure 5-15b)	Solid fill supports deck loads without expensive framing. Upshore area is accessible for storage and traffic circulation. Side-berth accommodations add to linear feet of berthing accommodations. Permits utilization of surplus fill material.	Economy depends on availability of inexpensive fill. The requirements for fill or piling are great compared to the usable space provided on the deck.
Rectangular Pier and Slip (Figures 5-15c, 15d, and 15f)	Length of accommodation for a given length of shoreline is great. In general, this system has the lowest relative cost per berth.	In some bottom formations, any considerable later dredging of slips may be hazardous. Space between slips is limited, and adds to the density of navigation traffic. Reduces width of navigation channel. Cargo handling is restricted unless pier has at least 6 acres per berth.
Angle Pier and Slip (Figures 5-15e and 5-15g)	Layout is advantageous compared to rectangular pier-and-slip system where navigation channel is too narrow for perpendicular pier layout. Currents or prevailing winds may also dictate the use of angle piers.	Construction is more difficult and expensive than that for rectangular pier-and-slip system. Corners of the pier are waste space where cargo-handling equipment cannot work.
Offshore Marginal Wharves (Figures 5-15h, 5-15i, and 5-15j)	Layout adaptable to many types of construction methods, including floating wharfage. Moorings for shallow-draft craft may be provided along the sides of the causeway. When multiple causeways are used, a movable section can be provided to give access to space between causeways. Suitable along rocky shores. Suitable where water of adequate depth is located at large distance offshore.	When a single causeway is used, craft along the causeway create loading and unloading and traffic problems. Usually requires separate moorings, supported by the wharf structure, because a relatively large area of the wharf structure is not tied to shore anchorages.
Floating Wharves	Floating wharves can be moored in water too deep for pile driving. Pontoon or prefabricated sections can be used. Equipment can be quickly assembled, moved, and replaced.	Maintenance is high. (Maintenance of steel floating wharves is higher than that of concrete floating wharves.) Not suitable for heavy craft nor in exposed locations without heavy anchorage requirements. Difficult to maintain alignment in heavy tide range. Restricted cargo-handling capability.

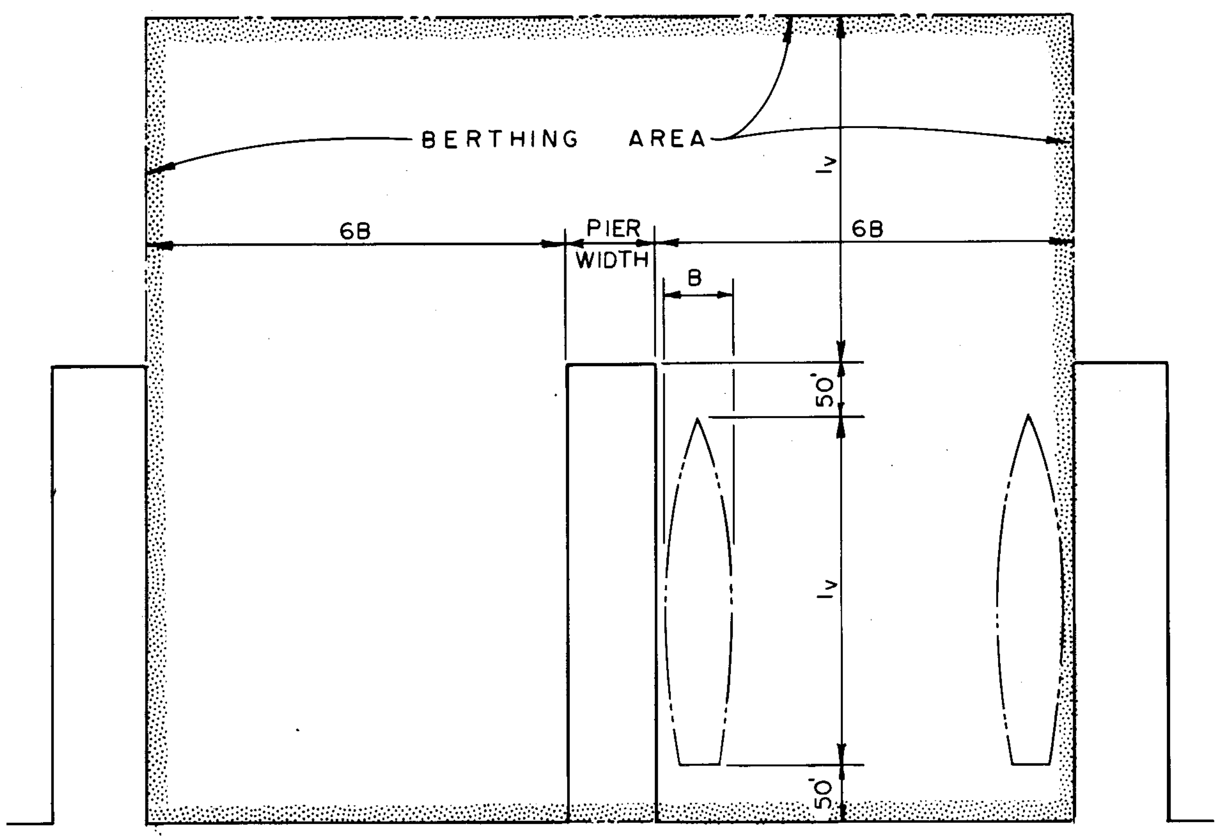
Table 5-14 Linear Feet of Berthing Space per 1,000 ft (305 m) of Shore Front

Type of Layout	Freighter[a]	Lighter[a]	Total[a]
Marginal wharf	1,000 (305)	-	1,000 (305)
Square pier	2,143 (653)	-	2,143 (653
Right-angle pier for one freighter on each side	3,120 (951)	313 (95)	3,433 (1046)
Right-angle pier for one freighter plus one lighter on each side	3,120 (951)	1,250 (381)	4,370 (1332)
Acute-angle pier for one freighter on each side	2,690 (820)	270 (82)	2,960 (902)
Right-angle pier for two freighters on each side	4,160 (1268)	208 (63)	4,368 (1331)
Acute-angle pier for two freighters on each side	3,600 (1097)	180 (55)	3,780 (1152)
T-type marginal wharf for freighter on outside face and lighters on inside face	770 (235)	1,380 (421)[b]	2,150 (655) [b]
U-type marginal wharf	1,000 (305) or less	-	1,000 (305) or less
Pier or wharf parallel to bank	2,000 (610)	-	2,000 (610)

[a]These figures are for purposes of comparison only.
[b] 1,682 ft (513 m) and 2,452 ft (747 m), respectively, if traffic conditions are such that lighters can be worked along the faces of the causeway.

Table 5-15 Approximate Berthing Area Requirements for Single-Berth Piers[a]

Class of Ship	Sizes of Piers (ft (m))	Spacing of Piers (ft (m))	Total Area Required in Harbor (acres (hectares))
Submarines	60 x 520 (18 x 159)	330 (101)[b]	16 (6.48)[b]
Destroyers	80 x 670 (24 x 204)	330 (101)	21 (8.50)
Auxiliaries	80 x 900 (24 x 274)	640 (195)	53 (21.45)
Aircraft Carrier	100 x 1,250 (30 x 381)	780 (238)	88 (35.61)



[a]Area = [2 1_v + (2) (50*)] [^{2}12B + pier width]. (See diagram.) Values for 1_v, B, and pier width are from UFC 4-152-01 for purposes of this table.
[b]At submarine slips, pier spacing should be increased by at least four vessel beams.
*100 ft (30 m) for aircraft carrier.

Table 5-16 Berthing Depths for Typical Naval Vessels

Vessel	Depth[a] (ft (m)
Small boats	8 to 15 (2.4 to 4.6)
Minesweepers	18 (5.5)
Landing ships	24(7.3)
Frigates	30 (9.1)
Tenders, cargo, and transport ships	34 (10.3)
Guided missile cruisers, destroyers, and medium submarines	36 (11)
Carriers and fast combat support ships[b]	45 (13.7)

[a]These depths are referenced to mean low water (MLW) or mean lower low water (MLLW) statistics for the area under study.
[b]To obtain optimum berthing depth for CVN, AOE, and CV vessels, refer to *Underkeel Clearance Study,* Hydro Research Science, Inc., Project Report No. 092-81, 21 Mar 1981.

Table 5-17 Dimensions of Typical Existing Turning Basins

Location	Depth Below MLW (ft (m))	Dimensions (ft (m))	Area (acres (hectares))
Port Arthur, East Turning Basin	36 (11)	420 x 1,800 (128 x 549)	17.35 (7.02)
Port Arthur, West Turning Basin	36 (11)	600 x 1,700 (183 x 519)	18.12 (7.33)
Brazosport Turning Basin	32 (9.8)	700 x 700 (213 x 213)	11.25 (4.55)
Norfolk Harbor, Virginia South Branch Project	35 (10.7)	600 x 600 (183 x 183)	8.25 (3.34)
Wilmington Harbor	32 (9.8)	1,000 x 800 (305 x 244)	18.36 (7.43)
Miami Harbor	30 (9.1)	1,350 x 1,400 (411 x 427)	20.43 (8.27)
Tampa Harbor	30 (9.1)	700 x 1,200 (213 x 266)	19.38 (7.84)
Alameda Naval Air Station	42 (12.8)	4,000 x 2,500 (1219 x 762)	230.00 (93.08)
San Diego Harbor	40 (12.2)	2,400 x 3,000 (732 x 914)	165.29 (66.89)

Table 5-18 Factors Affecting Location, Size, and Depth of Anchorage Basins

Consideration	Factor	Requirement and Comment
Location	Isolation	Locate near entrance, away from channels, out of traffic, and in shelter. The area should be isolated, insofar as possible, from attack by surface or subsurface craft.
	Depth	Locate in area of sufficient natural depth to avoid dredging.
	Currents	Area should be free from strong currents.
	Accessibility of shore facilities	The area should be accessible to fresh water, fuel, and fleet recreation facilities. Shore facilities shall be provided to accommodate liberty parties, mail, light freight, and baggage.
	Foundation conditions	Where possible, locate over a bottom of loose sand or gravel, clay, or soft coral. Avoid locations where the bottom consists of rock, hard gravel, deep mud, and deep silt.
	Subaqueous structures	Anchorage areas should be free of cables and pipelines and cleared of wrecks and obstructions.
	Expansion	Leave provision for future expansion.
Size and Depth		Sizes of individual free-swinging moorings and of spread moorings for floating drydocks are contained in Tables 5-17, 5-18, and 5-19. Use free-swinging moorings where available area will permit. Where available area is limited, use fixed moorings or moorings in which the swing of the vessel is restricted. Various types of restricted moorings are described in DM 26.5.

61	914	965	1038	1093	1148	1221

[a]For shallower water depths, the swing radii implied by this table are based on the following
assumptions:

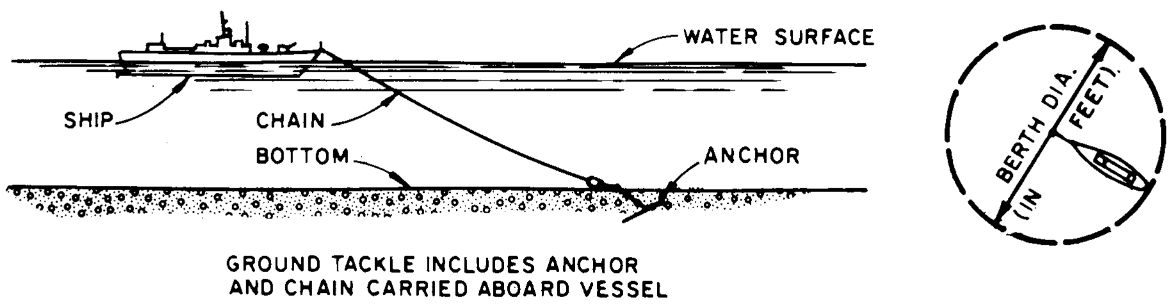
a) Scope = 6 x depth
b) Anchor rode has no sag
c) Allowance for anchor drag = 27.4 m

For depths greater than about 21.3 m, the 6:1 scope is excessive, and swing radii are based on the computed horizontal length of the anchor chain under heavy load. Typical ship characteristics and chain sizes have been selected for each ship length category.

Assumed load conditions are as follows:

a) Wind speed = 50 knots
b) Current = 4 knots, aligned with wind direction
c) Vertical projection of anchor chain = depth + height of hawse hole
d) Vertical angle of chain at anchor = 0 degrees

Table 5-20 Diameter of Berth, in Feet, Using Ship's Anchor and Chain[a]



Overall Vessel Length, In Feet	100	200	300	400	500	600

[a]For shallower water depths, the swing radii implied by this table are based on the following
assumptions:

d) Scope = 6 x depth
e) Anchor rode has no sag
f) Allowance for anchor drag = 90 ft

For depths greater than about 70 ft, the 6:1 scope is excessive, and swing radii are based on the computed horizontal length of the anchor chain under heavy load. Typical ship characteristics and chain sizes have been selected for each ship length category.

Assumed load conditions are as follows:

e) Wind speed = 50 knots
f) Current = 4 knots, aligned with wind direction
g) Vertical projection of anchor chain = depth + height of hawse hole
h) Vertical angle of chain at anchor = 0 degrees

[a]This table is based on the following assumptions:

(a) Length of riser chain is equal to depth of water at mean high water.
(b) Ground chains are of length called for by drawings and are pulled taut when installed.
(c) Anchor drags 90 ft (27 m) from initial position.
(d) 55 m (180 ft) of ship's chain used between vessel and buoy.
(e) Basic formula $b = (2/3)(d + 1_v + C_1)$

Where: b = diameter of berth, in feet
d = depth of water, in feet at MHW
l_v = length overall of vessel, in feet
C_1 = 300 ft (91 m) (includes 30 ft (9 m) allowance for increase in radius of berth for drop in waterline due to fall of tide, 180 ft (55 m) from buoy to ship, and 90 ft (27 m) allowance for drag of anchor

[a]The width and length of berths for floating drydocks include out to out of anchors, assuming that anchors are placed in accordance with the diagram. Berth diameter for free-swinging floating drydocks may be obtained from Tables 5-19, 5-20, 5-21; in addition to that for drydock length, allowance must be made for vessel entering dock.
Berth types are as follows:

ARD = Auxiliary Repair Drydock
AFDL = Small Auxiliary Floating Drydock
AFDB = Large Auxiliary Floating Drydock
YFD = Floating Drydock

5-7 NAVIGATION AIDS.

Aids to navigation are the markers and signals vessels require to safely use a navigation project. The navigation safety of a project is directly related to the clarity and visibility of aids to navigation. Channel design must be planned so that the layout, dimensions, and alignment facilitate clear marking. A reduced width may be possible in a well-marked channel as compared to a poorly marked channel, so a tradeoff between channel widening cost and aids to navigation costs should be considered in design; additional information is available in CEM Section VI-3.

5-7.1 Jurisdiction.

Where aids to navigation, such as lights, daybeacons, or buoys, are required, consult the District Office of the USCG or, in the case of areas where no district office has jurisdiction, the Commandant, USCG. This organization will advise as to requirements for aids to navigation. The aids, which conform to USCG specifications, may be purchased from the USCG. Structures for supporting the aids (towers for lights or daybeacons and moorings for buoys) shall be provided by or under the cognizance of the NAVFAC. The USCG has specific jurisdiction over all aids to navigation in the continental United States and in all outlying territories and possessions. Refer to Code of Federal Regulations, Title 33, for information relating to establishing aids to navigation. In foreign countries, the regulations of local agencies, where such agencies exist, govern in lieu of the USCG, but the USCG will assist, when requested, in establishing aids to navigation, even in foreign countries.

5-7.2 Types of Aids.

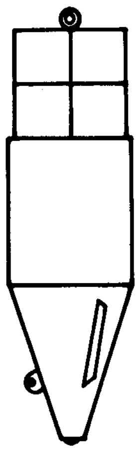
The following general data on aids to navigation are given to assist in preliminary layouts and as a basis to discuss requirements with the regulating agency. Aids to navigation include, but are not limited to, lighthouses (light stations), range lights, directional lights, minor lights, lighted and unlighted buoys, daybeacons, and sound signals. Other types of aids to navigation that are not under the primary cognizance of the NAVFAC include lightships, radio beacons, radar beacons, and loran stations. Several types of navigational aids are illustrated in Figure 5-25 through Figure 5-29.

5-7.2.1 Lighted Aids.

The placing of lights is a function of local navigation requirements and topography. General rules are not applicable. Height of the lantern and type and candlepower of illuminant shall be specified. For daytime use, light structures shall be distinctively marked or painted in order to provide easy identification.

- Primary Seacoast Lights. These lights, which may be attended or automatic, are established on seacoasts, bays, sounds, and lakes for the purpose of marking landfalls and coastwise passages from headland to headland, and in harbors where powerful candlepower is necessary. The light source is designed to obtain the maximum geographic range.

Figure 5-25 The 2 CR Buoy



1952 TYPE STANDARD

FUNCTION

THE 2 CR BUOY IS DESIGNED AND CONSTRUCTED FOR EXPOSED OR SEMIEXPOSED LOCATIONS WHERE AN UNLIGHTED BUOY IS REQUIRED.

PHYSICAL CHARACTERISTICS

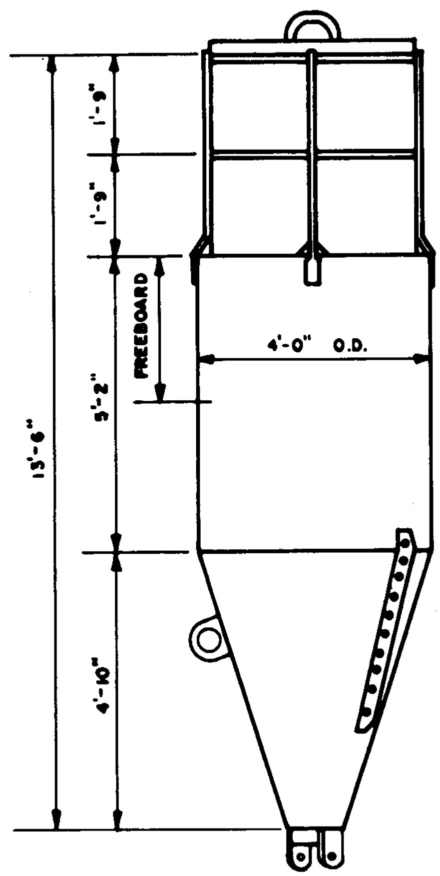
BUOY WEIGHT	2,700 LB
BUOY DRAFT (NO MOORING)	6 FT - 1 IN
FREEBOARD (NO MOORING)	3 FT - 11 IN
MINIMUM FREEBOARD	1 FT - 0 IN
POUNDS PER INCH OF IMMERSION	67

RELATED EQUIPMENT

MOORING CHAIN SIZE	7/8 IN
SINKER SIZE	4,000 LB

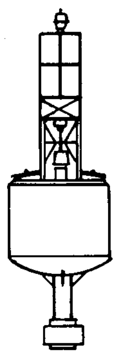
OPERATIONAL CHARACTERISTICS

NOMINAL VISUAL RANGE OF DAYMARK	2.8 NMI
RADAR RANGE	2.5 NMI
MAXIMUM CURRENT	6 K
MINIMUM MOORING DEPTH	15 FT
MAXIMUM MOORING DEPTH	200 FT



DIMENSIONS OF THE 2 CR

Figure 5-26 The 8 x 26 LBR Buoy



1962 TYPE STANDARD

FUNCTION

THE 8x26 LBR BUOY IS DESIGNED AND CONSTRUCTED FOR EXPOSED OR SEMIEXPOSED LOCATIONS. THIS BUOY CONFIGURATION IS USED WITH A 225-LB BELL, WAVE-ACTUATED SOUND SIGNAL. THE BASIC BUOY IS THE SAME AS THE 8x26 LR.

PHYSICAL CHARACTERISTICS

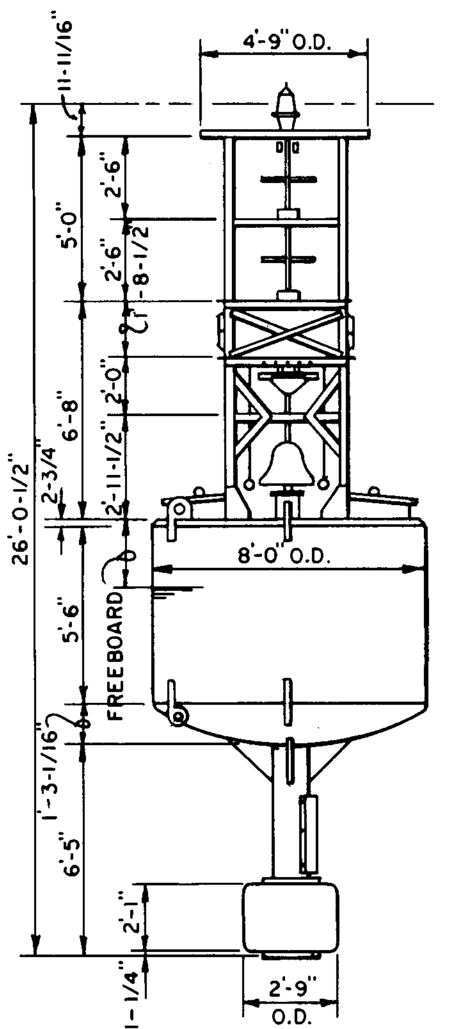
BUOY WEIGHT	11,917 LB
BUOY DRAFT (NO MOORING)	10 FT-3 IN
FOCAL HEIGHT OF LIGHT (NO MOORING)	15 FT.-8 IN
FREEBOARD (NO MOORING)	3 FT-1 IN
MINIMUM FREEBOARD	1 FT-3 IN
POUNDS PER INCH OF IMMERSION	270

RELATED EQUIPMENT

POWER UNITS (MAXIMUM NUMBER AND SIZE)	2-B30
SOUND EQUIPMENT	225-LB BELL
BRIDLE SIZE (CHAIN DIAMETER AND LENGTH)	1-1/4 IN x 15 FT
MOORING CHAIN SIZE	1-1/4 IN
SINKER SIZE	8,500 LB

OPERATIONAL CHARACTERISTICS

NOMINAL VISUAL RANGE OF DAYMARK	3.2 NMI
RADAR RANGE	3.7 NMI
MAXIMUM CURRENT	4 K
MAXIMUM MOORING DEPTH	25 FT
MAXIMUM MOORING DEPTH (B10)	220 FT
(B30)	190 FT



DIMENSIONS OF 8x26 LBR.

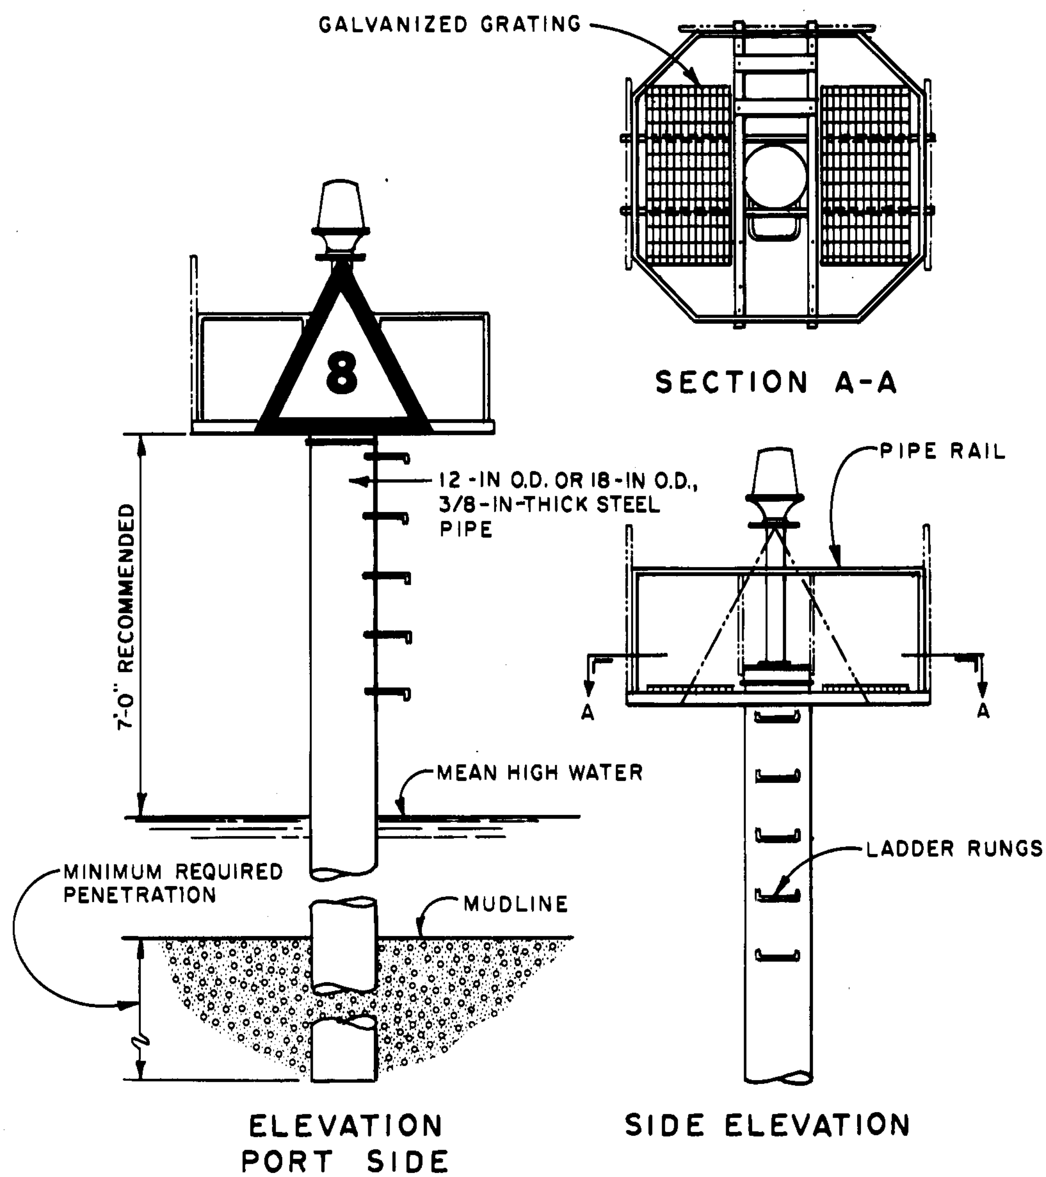

Figure 5-28 Lateral Daymarks

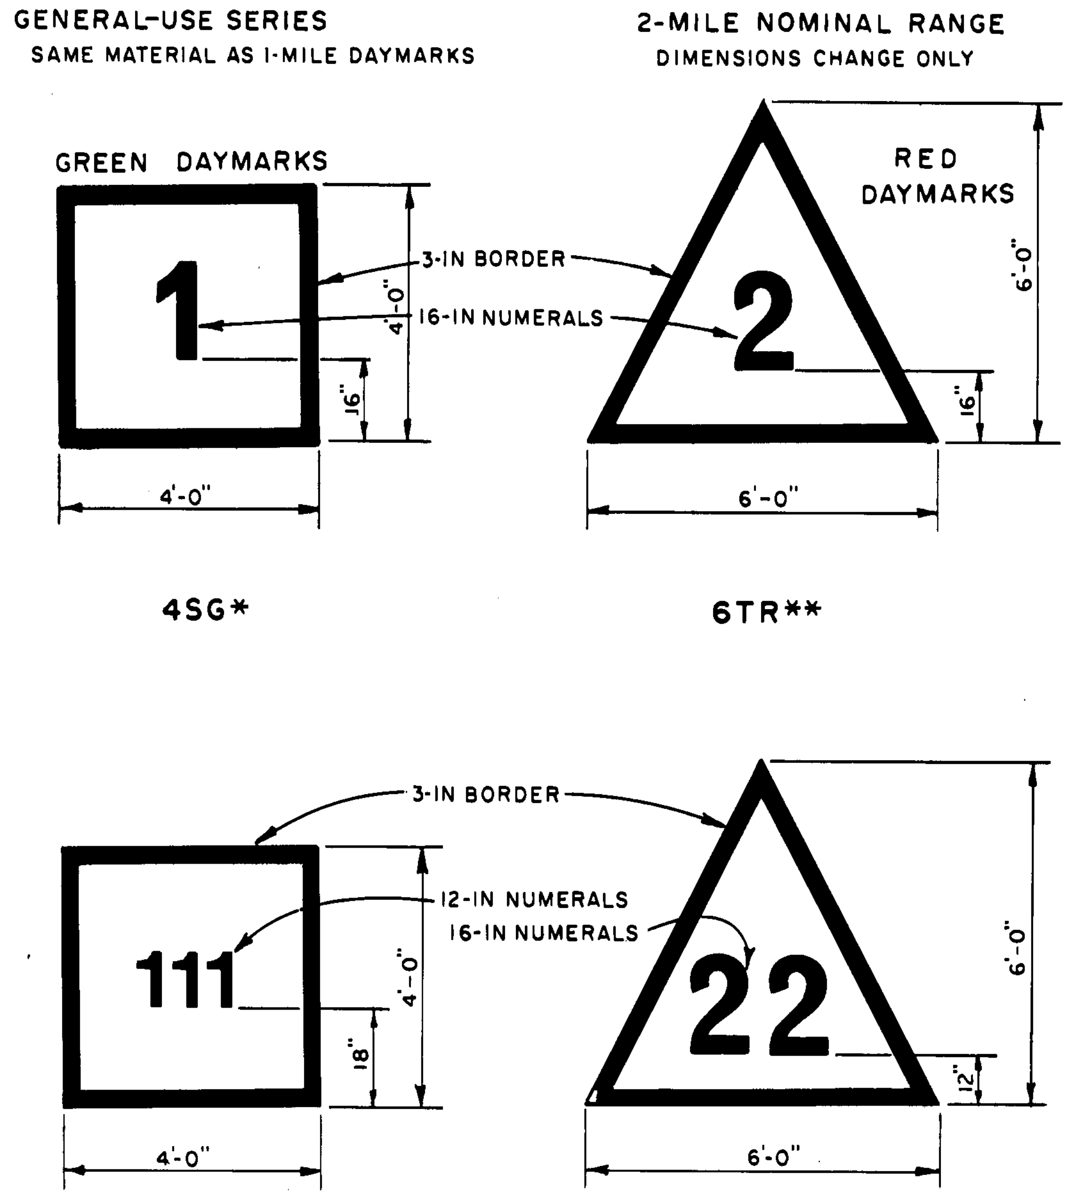
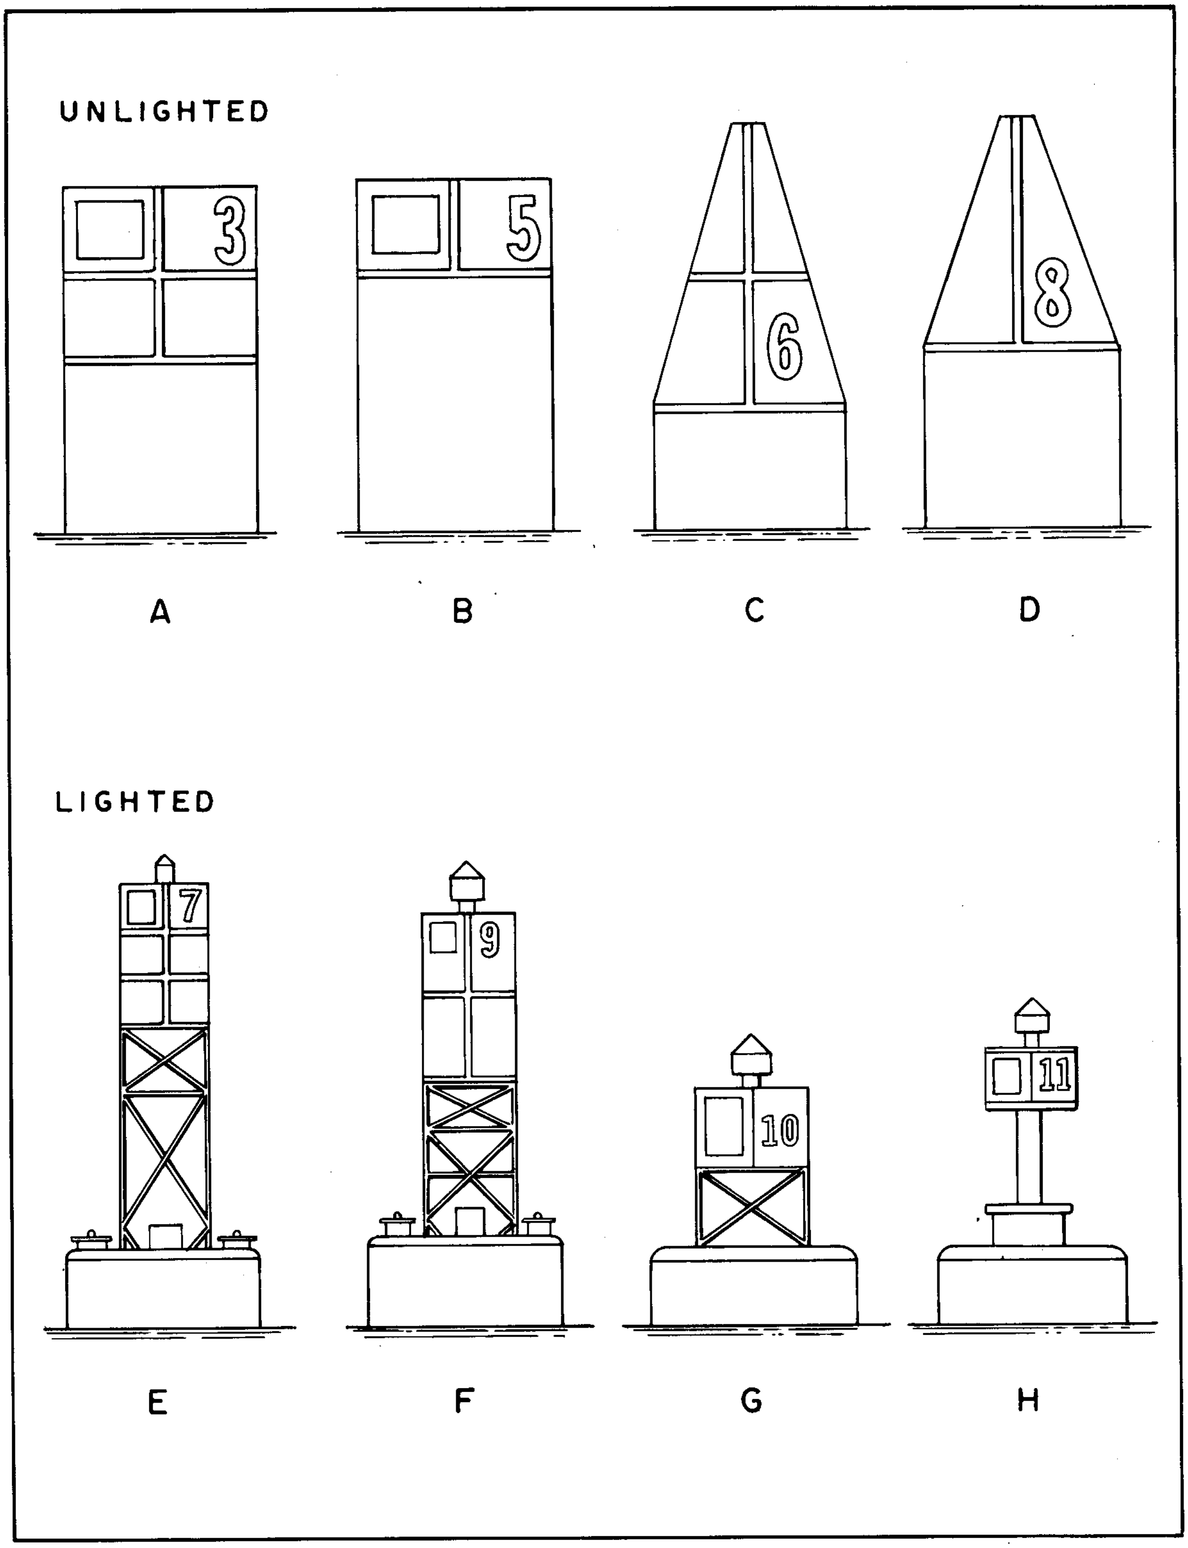


* FOR 2 NUMERALS USE 16-IN NUMERALS AT HEIGHT OF 16 IN OFF BASE
** FOR 3 NUMERALS USE 12-IN NUMERALS AT HEIGHT OF 12 IN OFF BASE
NOTE: DAYMARKS CONSIST OF RETROREFLECTIVE BORDERS AND NUMERALS ON A FLUORESCENT BACKGROUND.

Figure 5-29 General Use Series Buoys, Radar Reflector Type



- Secondary Lights. These lights, which also may be attended or automatic, are established at harbor entrances and other locations where the needs for high candlepower and long range are less necessary, and on large inland waterways as intermediate aids in harbor channels and in other inshore channels where the requirements of navigation indicate that the range and candlepower of this class are necessary.

- Range Lights. These are pairs of lights located to form a range in line with the center of a channel or entrance to a harbor. The rear light is higher than the front light and a considerable distance in back of it. The length of the range and width of the channel govern the height and distance of separation necessary between the lights. Range-light structures shall be equipped with daymarks for ordinary daytime use. Ranges may be used either ahead or over the stern.

- Directional Lights. A directional light is a single light which will project a beam of high intensity, separate color, or other special characteristic, in a given direction. It has limited use in those cases where a two-light range may not be practicable or necessary, and for other special applications. The directional light is essentially a narrow-sector light with or without adjacent sectors which give information as to the direction of and relative displacement from the narrow sector.

- Minor Lights. These are lights of relatively low candlepower usually established in harbors, along channels, along rivers, and in isolated locations. They are generally unattended and unwatched and should operate automatically. Depending upon circumstances, these lights may be displayed from towers, skeleton structures, or from a group of piles. They shall be colored to distinguish them from the surrounding background and from adjacent structures.

- Lighted Buoys. These are floating aids showing from the upper of their structures an automatically operated, low-candlepower light. Colors and characteristics vary. Lighted buoys are established for the purpose of definitely identifying spots. These include the entrance and side limits of natural and dredged channels, centers of fairways, obstructions and wrecks, isolated natural dangers in offshore or restricted waters, and for special purposes such as quarantine or general anchorages. These lights are powered by batteries.

5-7.2.2 Unlighted Aids.

- Unlighted Buoys. These are floating aids of varying size, shape, and color. They serve the same general purposes as lighted buoys. They are used in areas of lesser importance or as intermediate aids to supplement lighted buoys in the more important areas.

- Daybeacons. Although all aids, whether lighted or unlighted, serve as a daymark to the mariner, daybeacons are specifically designed as unlighted structures used to mark isolated dangers, channels, edges, or alignment.

5-7.2.3 Sound Signals.

Sound signals are sound-producing devices operated mechanically or by the action of the sea, consisting of horns, sirens, diaphones, bells, gongs, and whistles. They are installed on shore structures and on buoys.

- Operation. Most sound signals on structures are attended. Sound signals on a few minor shore structures or on buoys shall be automatically operated. Other signals on buoys shall be operated by action of the sea.

- Purpose. Sound signals are intended to warn of danger and provide the mariner with the best practicable means of determining his position. This is in relation to the sound signal station at such times as the station, or any light that it might display, is obscured from view by fog, haze, smoke, or generally poor visibility.

- Range. To be effective, sound signals must be capable of a useful range, and they must be of such characteristic duration as to permit their direction to be judged with reasonable accuracy by ear. It must be remembered that due to the uncertainty of passage of sound through the atmosphere, the range of sound signals cannot be depended upon or specifically fixed. Major fog signals shall have a minimum range of 1-1/2 miles (2.4 km).

5-7.3 Lights.

Due to the increase in shore illumination along navigable waters, the usefulness of fixed white lights is limited to areas where the usable range is short or where the natural background includes few other lights.

5-7.3.1 Length of Period.

The period of a flashing or occulting light is the time required to go through a full set of changes. The limiting basis for the period of light characteristics is 60 seconds, since it is considered that the mariner cannot always safely watch the light to the exclusion of everything else for a longer period. Light characteristics that are so similar as to require careful timing in order to differentiate between them should not be established in close proximity to one another.

5-7.3.2 Colors.

White, red, yellow, and green are used for navigational lights. Other colors are not used.

- Means of Obtaining Color. The light source in all illuminating apparatus is white. Color is produced by the addition of colored-glass shades or screens.

- Alternating Colors. In certain instances, light characteristics consist of alternations of colors, with either two or three colors being used in combination. Where an alternating white and red or white and green light is desired, the candlepower of the colors shall be equalized by selection of the lens panels.

5-7.3.3 Visibility.

The distances at which lights may be seen in clear weather are computed for a height of the observer's eye of 15 feet (4.6 m) above sea level. Table 5-20 gives the approximate geographical range of visibility for objects of varying elevations that may be seen by an observer whose eye is at sea level. To determine the distance of visibility for an observer whose eye is at an elevation other than sea level, add to the distance of visibility (determined from Table 5-20) the distance of visibility from Table 5-20 which corresponds to the elevation of the observer's eye above sea level.

5-7.3.4 Suppliers.

Lights built to USCG specifications may be purchased from the USCG or from a manufacturer.

Table 5-24 Distances of Visibility for Objects of Various Elevations above Sea Level

Elevation (f (m))	Distance (nmi)	Elevation (ft (m))	Distance (nmi)	Elevation (ft (m))	Distance (nmi)
5 (1.5)	2.5	70 (21.3)	9.6	250 (76.2)	18.2
10 (3.0)	3.6	75 (22.9)	9.9	300 (91.4)	19.9
15 (4.6)	4.4	80 (24.4)	10.3	350 (106.7)	21.5
2020 (6.1)	5.1	85 (25.9)	10.6	400 (121.9)	22.9
25 (7.6)	5.7	90 (27.4)	10.9	450 (137.2)	24.3
30 (9.1)	6.3	95 (29)	11.2	500 (152.4)	25.6
35 (10.7)	6.8	100 (30.5)	11.5	550 (167.6)	26.8
401 (12.2)	7.2	110 (33.5)	12.0	600 (182.69)	28.0
45 (13.7)	7.7	120 (36.6)	12.6	650 (198.1)	29.1
50 (15.2)	8.1	130 (39.6)	13.1	700 (213.4)	30.3
55 (16.8)	8.5	140 (42.7)	13.6	800 (243.8)	32.4
60 (18.3)	8.9	150 (45.7)	14.1	900 (274.3)	34.4
65 (19.8)	9.2	200 (61)	16.2	1,000 (304.8)	36.2

5-7.4 Buoys.

Buoys are used for lateral identification for channels in navigable waters. Demarcation of the channel is accomplished by arranging the colors, shapes, numbers, and light characteristics of the buoys. The standard coding system of the USCG should be followed, where possible, and shall be obtained from that organization. Special buoys, having no lateral significance, should be used for marking anchorages, nets, and dredging and other special-purpose areas. For characteristics of buoys, consult the USCG.

5-7.5 Daybeacons.

Daybeacons shall be constructed and painted in order to be distinct and conspicuous. Only white, green, or red color shall be used, either separately or in combination. Where a number of daybeacons are to be used within a limited area, use different types of construction to assist in distinguishing among them. Daybeacons should be reflectorized for night use.

5-7.6 Fog Signals.

Design fog signals at stations, where a continuous watch is maintained, to be sounded both when the visibility decreases to 5 miles (8.1 km) and when the fog whistle of a passing vessel is heard. Design fog signals at locations where no watch is maintained to operate continuously or automatically. Fog signals on buoys generally should be operated by the motion of the sea and should operate continuously.

5-7.6.1 Sound Intervals.

Time blasts for a minimum 2 seconds in length, occurring at intervals not exceeding 60 seconds; preferable interval length is 15 seconds.

5-7.6.2 Suppliers.

Fog signals built to USCG specifications may be purchased from the USCG or from a manufacturer.

5-7.7 Ranges.

Height, distance apart, size of daymark, and color marking are dependent on local conditions, and general rules are not applicable. There are no rules as to shape of the daymark, except that it should be the most distinctive possible shape in the range system.

5-7.8 Design of Support Structures.

Design dolphins, towers, and similar supports for lights, daybeacons, and similar aids in accordance with requirements for the same or similar structures established elsewhere in this manual.

5-7.9 Moorings.

Design moorings for buoys according to the requirements of \1 UFC 4-159-03 /1/.

5-7.10 Buoy Systems.

The U.S. and most Western-Hemisphere countries use a buoy system based on green daymarks/black buoys for port hand and red daymarks/red buoys for starboard hand when returning from sea. Many Eastern-Hemisphere countries use green for starboard and red for port hand. The system that is used in the local area is an important consideration when designing a new aid system.

5-7.11 Environmental Monitoring and Operator Guidance System.
As an operational underkeel clearance (UKC) forecasting system, the Environmental Monitoring and Operator Guidance System (EMOGS) was developed to provide safe transit of deep draft vessels through shallow entrance channels. A risk-based system used to avoid vessel grounding and to minimize channel depth requirements, EMOGS can predict the estimated UKC during a specified transit through a shallow water channel for the vessel in question. Silver et al.'s David Taylor Research Center (DTRC) publication, Environmental Monitoring and Operator Guidance System (EMOGS) Overall Technical Description, DTRC Report SHD-1283-16, provides for further details.

- The EMOGS, as installed at Kings Bay to protect OHIO class submarines, is used because it is not economically feasible to dredge the channel to provide safe transits of the vessels in all weather conditions. EMOGS provides the clearance between the vessel hull and the bottom in near real time. EMOGS software uses bottom survey data, statistical and measured wave and tidal data, and calculated ship motions to assess the risk of the submarine touching the channel bottom. Where the MicroVAX computer is not available, there is a manual procedure for carrying out the calculations; refer to the EMOGS User Handbook by Silver et al. (DTRC Report SHD-1283-02).

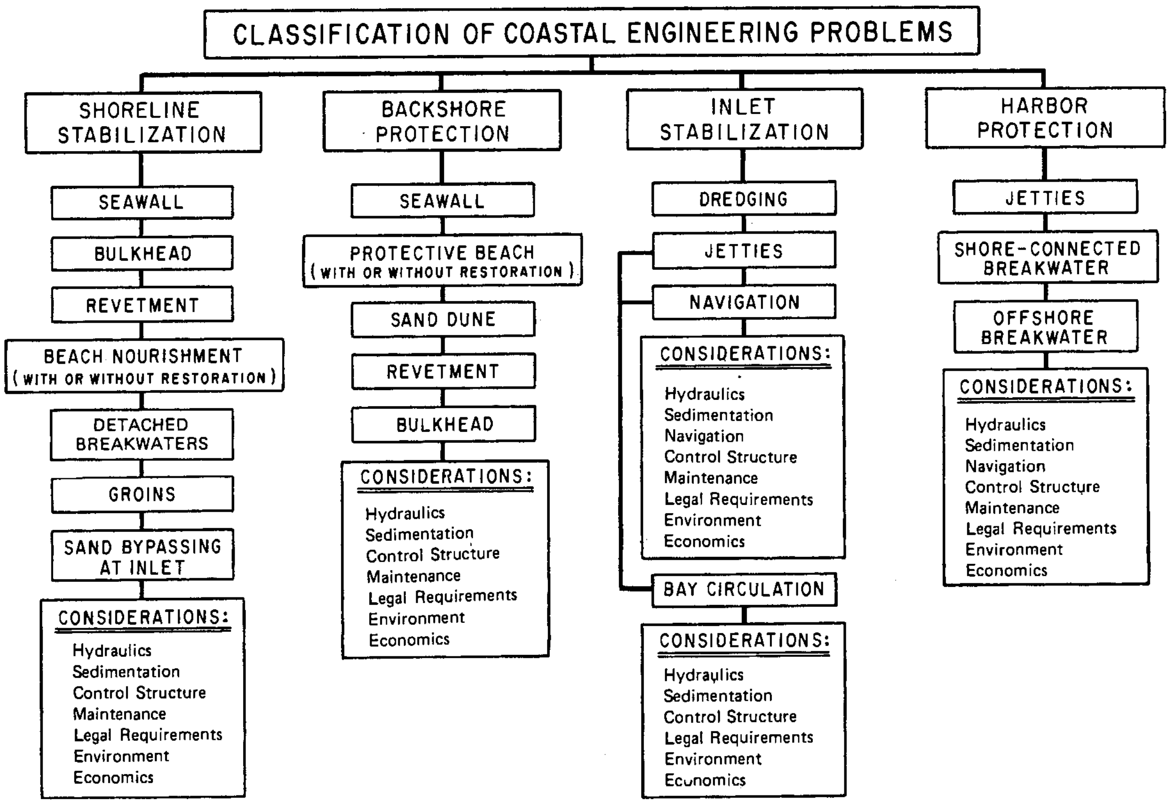
- The level of risk is sensitive to sedimentation rates and dredging activities, and any change in environmental conditions must be represented in the predictions.

5-7.12 Carrier Channel Guidance System.
A guidance system was developed to reduce the risk of aircraft carriers touching the channel bottom while transiting entrance channels at Norfolk, Mayport, Pensacola, San Diego, and Pearl Harbor. This system is used by the navigation officer to determine the advisability of transiting the channel at a scheduled date and time. The system is PC based and is set up in the Meteorological Office aboard ship. The system provides the predicted clearance between the vessel hull and the bottom in near real time using bottom survey data, statistical and measured meteorological data, water depth measurements and calculated ship motions.

5-8 MARINE IMPROVEMENT AND SHORE PROTECTION.
Coastal engineering problems may be classified into four general categories: shoreline stabilization, backshore protection (from waves and surge), and inlet stabilization and harbor protection (Figure 5-30). A coastal problem may fall into more than one

category. Once classified, various solutions are available to the coastal engineer. Some of the solutions are structural; however, other techniques may be employed such as zoning and land-use management. The primary types of coastal structures and methods of marine improvement and shore protection are discussed in Chapter 7.

Figure 5-30 General Classification of Coastal Engineering Problems (USACE, 1984b).



5-9 SEDIMENT MANAGEMENT PROJECTS.

The development of sediment management projects is available in CEM Section V-5. Discussions are presented on the use of weir jetties, sediment traps, and training dikes to interrupt longshore sand movement, to accumulate sand on the shore, or to retard sand losses. Maintenance in existing channels, berthing areas, and the expansion of coastal facilities requires dredging in areas that may contain elevated levels of heavy metals, pesticides, and other contaminants. Though concentrations of these contaminants may not always approach hazardous levels, contaminated sediments are not suitable for unconfined ocean disposal. Remediation of these sites may require dredging and disposal of contaminated dredged materials, which requires special management. Material may be placed in a confined, aquatic disposal site, capped, disposed in an upland site, or possibly treated and then undergo beneficial re-use. Management alternatives, cumulative impacts, and long-term solutions to prevent re-contamination of sediment are issues that need to be addressed with respect to the ecological and health implications of contaminated dredged material disposal. All project areas are to be evaluated for environmental risks early in the planning stages of a project. Subsequently, if a hazardous substance is suspected at a project site, the sediment should be left undisturbed and the appropriate Environmental Department or Regional Environmental Coordinator of the appropriate activity be notified.

5-10 PHYSICAL SECURITY.

The physical security of harbor and coastal facilities must be addressed in the early stages of project planning. The NAVFAC LANT Engineering Criteria and Programs Office is presently developing Anti-Terrorism, Force Protection (AT/FP) design and construction criteria for the programming, planning, design, and construction of AT/FP systems for waterfront facilities. Interim Technical Guidance on Anti-Terrorism, Force Protection and Physical Security of Waterfront Facilities and Installation can be obtained by contacting the NAVFAC LANT Engineering Criteria and Programs Office at 757-322-4202.

CHAPTER 6 DESIGN OF DREDGING PROJECTS

6-1 INTRODUCTION.

Dredging is generally carried out either to increase the depth of a body of water, or to replace, re-configure or mine for *in situ* sediments. It may involve new construction (Capital dredging), such as excavation for harbors or canals, the construction of stable bases for tunnels or reclamation of submerged land. Maintenance dredging on the other hand is used for such purposes as maintaining waterway utility and restoring the hydraulic efficiency of reservoirs. Section V-5-3 of the CEM contains information on dredging. Additional extensive detailed information on dredging project design can be found in the Handbook of Dredging Engineering by J.B. Herbich; Dredging: A Handbook for Engineers by Bray, Bates and Land and the ASCE Engineering Practice #80, “Report on Ship Channel Design (Herbich, 1992; Bray et al., 1997; ASCE, 1993).

6-2 ACCOMPLISHMENT OF WORK.

Government-owned dredges should be used to the maximum extent consistent with economy. When the only suitable dredging equipment is in private ownership, or when the workload exceeds the capability of available government dredging facilities, private contractors may accomplish dredging. Some of the factors to be considered in planning a dredging project are:

- Marine environment, including water depths, waves, tides, currents;
- Nature and character of the sediments;
- Dredged quantities and disposal areas;
- Social, biological, regulatory and institutional factors;
- Long term dredging and disposal problems.

More detailed information on dredging project implementation is found in Chapter 2 of Dredging: A Handbook for Engineers (Bray, 1997).

6-3 TERMINOLOGY.

Some common terminology is provided in the section below. For additional information on this subject, refer to the Dredging Desk Reference (Verna and Maciejewski, 1994).

Centrifugal Pump. A pump operated by centrifugal force, the force outward exerted by a body moving in a curved path.

Clamshell. A dredging bucket made of two similar pieces hinged together at one end.

Drag Head. A device placed on the end of a suction pipe (connected to a dredge) used for loosening or cutting away the bottom material that is to be dredged.

Dredge. (1) To excavate or move soil or rock underwater. (2) A vessel, or item of floating plant, equipped with means to move or excavate soil or rock underwater.

Hopper. A funnel-shaped chamber in which materials are stored temporarily and later discharged through the bottom.

6-4 CURRENT DREDGING DESIGN PRACTICE.

Dredging practice and plant equipment is determined based on whether one is dealing with river dredging, estuary or coastal dredging, ocean dredging, beach replenishment, etc. Preliminary investigations must first be conducted to provide data to confirm that dredging will be necessary and that environmental regulations can be satisfied. A preliminary study will provide estimates of the sedimentation regimes, disposal areas, and the type of dredging plant that will be employed.

6-4.1 Navy Harbors.

The dredging of Navy harbors may involve the dredging of clay and silt from estuarine harbors or the dredging of sand from harbors on open coasts. By 1980, 87 percent of the Navy's total annual maintenance-dredging volume consisted of cohesive sediments, while 13 percent consisted of sand. A large part of the total dredging in naval harbors consists of removing shoaled material from under berthing piers. Other dredging activities include dredging of navigation channels and turning basins, as well as channel-entrance bypassing.

6-4.2 Dredging Research Program.

The USACE Dredging Research Program (DRP) conducts studies to develop up-to-date information on dredging technology. The results of these studies are compiled in technical reports that may be obtained from WES. Additional information can be found on the USACE web site.

6-4.3 Methods.

Extensive discussion of current practices, including agitation dredging, barrier curtains, water injection dredging, sediment bypassing, and jet scour arrays, can be found in Chapter 7 of Dredging: A Handbook for Engineers (Bray et al., 1997) and the Handbook of Dredging Engineering (Herbich, 1992).

6-5 PROJECT DEPTH.

According to the Permanent International Association of Navigational Congresses (PIANC), the required dredge depth for ship channels is determined by summing up the following components:

- Reference Water level minus lowest low water level
- Admissible ship draft, including trim and density change allowances
- Vertical ship motions, including squat, pitch and roll

- Net required under-keel clearance
- Depth sounding precision
- Sediment deposition thickness between scheduled dredgings
- Dredging accuracy tolerances

Discussions of this subject are contained in various sources including the joint PIANC and IAPH Final Report entitled, "Approach Channels - A Guide for Design," PTC II-30, dated June 1997; the Report of Ship Channel Design (ASCE, 1993); Chapters 3.2.1 and 8.3.1 in Dredging: A Handbook for Engineers (Bray et al., 1997).

6-5.1 Overdepth Dredging.
Previous studies have shown up to 20 percent of over excavation on typical dredging projects. In addition to the additional dredging costs encountered, this can also result in premature filling of scarce disposal areas. Two factors that control overdepth dredging are dredge control and dredge survey. Modern dredge control is achieved by instrumentation, which provides real time knowledge of cutterhead depth and velocity and density of the slurry being pumped (Herbich, 1992). However, in some situations, it is less expensive to overdredge an area by 1 or 2 feet (0.3 or 0.6 m) than to pay for the careful manipulation of dredging equipment and for the extra time involved in dredging to the exact depth required. Overdepth dredging also allows for some additional shoaling before dredging is required again. Overdepth dredging should be investigated for each specific site as it cannot be used in every situation. For example, it may jeopardize stability of nearby structures.

6-5.2 Advanced Maintenance Dredging.
It is advantageous to minimize maintenance costs by performing advanced maintenance dredging to increase the interval between dredgings. The channel is dredged deeper and/or wider than its original design or authorized depth, thereby allowing for shoaling to occur while the channel can still be navigable. Advance maintenance dredging can also greatly increase the time intervals between maintenance dredging operations, which can reduce the number of mobilization and demobilization tasks and the costs associated with them. This method is economically feasible if the money saved through a reduced dredging frequency schedule is greater than the cost of removing any additional sediment that may have been deposited as a result of the deeper and wider channel.

To determine whether or not advanced maintenance dredging is economically feasible, the design engineer must analyze and extrapolate shoaling data for "prior to dredging" depths of the channel and use numerical models to simulate site-specific estuarine hydrodynamics and sediment transport mechanisms. If appropriate data are unavailable for performing analytical studies, and numerical modeling studies are cost prohibitive, a minimal advance maintenance effort can be put into effect and the results evaluated. Thus, if money is saved, advanced maintenance dredging efforts can be stepped up and, conversely, if money is lost, the efforts can be abandoned (Sedimentation Control To Reduce Maintenance Dredging of Navigational Facilities in Estuaries, 1987).

6-5.3 Disposal Areas.
The selection of an appropriate disposal area depends upon the physical characteristics of the dredged material, potential environmental impacts, size of the project and social, political, economic and regulatory considerations. Dredged material disposal sites may be offshore or onshore sites, confined by levees or containment dikes, or unconfined. Because of environmental considerations, confined upland sites are generally preferred unless the dredge spoil is being used to create wetlands. Selection of an upland site requires consideration of return of effluent water to the waterway. Unnecessary entrapment of water that may cause flooding must be avoided. It must be assured that effluent water does not pick up additional turbidity or toxic chemicals as it returns to the waterway. A more thorough discussion of these options is contained in the Handbook of Dredging Engineering (Herbich, 1992), Chapter 8, and in Chapter 5 of Dredging: A Handbook for Engineers (Bray et al., 1997). Bray also discusses the various types of sites for disposal as well as various processes of disposal and cleaning of dredged material and the decision making process for disposal (Bray et al., 1997). The PIANC bulletin, Management of Dredged Material From Inland Waterways (PIANC, 1990) and USACE EMs 1110-2-5026 and 1110-2-5027 are also useful and recommended sources of information.

6-5.3.1 Upland Open Site.
This disposal location is generally used for placement of coarse, cohesionless sediments. Material placement is controlled with small berms constructed by a bulldozer or similar land-construction equipment.

6-5.3.2 Upland Diked Site.
This type of disposal location is generally used for the confined placement of fine-grained sediments. Dikes constructed prior to sediment placement typically have overflow weirs to minimize turbidity in receiving waters. Dikes may be constructed of existing soil or may be built up with hydraulically placed fill. Soil embankments should have a maximum slope of 1 vertical to 2 horizontal on the exterior face and 1 vertical to 3 horizontal on the interior face. Hydraulic fill must be placed at the natural angle of repose. Care should be taken to provide a cross-sectional area sufficient to withstand the water depths in the fill. A minimum freeboard of 2 feet is typical. Placement of dredged material at an upland diked site may cause ground-water contamination; investigations should be made to determine if this possibility exists. Certain situations require that the diked site be lined with filter cloth or a layer of clay to prevent penetration of pollutants into the ground-water system.

6-5.3.3 Open-Water Site.

With this type of disposal location, materials are generally limited to coarse sediments due to environmental considerations. EPA regulations and designated disposal areas should be investigated.

6-5.3.4 Contained-Water Site.
For this type of disposal location, earthen dikes are usually constructed prior to dredging. The use of silt curtains instead of earthen dikes is possible under certain combinations of sediment, tides, currents, and environmental considerations.

6-5.4 Downtime Criteria for Projects and Water Level Extremes.
An acceptable method for determining the design basis for water level extremes, such as the frequency and duration of low and high water levels should be determined from the historical record and used to define the maximum level of planned and unplanned downtime with respect to project scheduling.

6-6 ECONOMIC FACTORS.
The economic factors affecting the dredging of Navy harbors are the following.

6-6.1 Amount of Material to be Dredged.
The mobilization and demobilization costs will constitute a significant portion of the total project cost for small-volume dredging projects. For large-volume dredging projects, the mobilization and demobilization costs will only increase the cost per cubic yard by a relatively small amount.

6-6.2 Distance From the Dredging Site to the Disposal Site.
This distance depends on the availability of disposal sites, the volume, and the environmental mental quality of the dredged material. If the sediment is contaminated, regulatory agencies may require dumping at a "contained" land disposal site. In many areas these sites are limited. Ocean disposal sites are attractive alternatives because of their unlimited capacity and general proximity to Navy harbors. In either case, additional costs and time delays may be incurred because the dredged material must be proven environmentally clean prior to issuance of a dredging permit. Regardless of where the material is dumped, cost is a function of distance to the disposal site and mode of transport.

6-6.3 Environmental Considerations.
Some form of environmental documentation is required for every dredging project, which can add substantially to project costs. The minimum requirement is a Preliminary Environmental Assessment. Additional chemical or biological testing may be required to supplement this documentation. If ocean disposal is proposed, it is likely that bioassays will be required at an additional cost. Most costly of all are environmental surveys of the dredge site and the disposal site which may be required in environmentally sensitive areas or cases of critical contamination. It is recommended to involve the local environmental office in the planning discussions from the inception of the project.

6-6.4 New Work versus Maintenance Dredging.
Where an area has not been dredged before, the bottom sediments may be consolidated and difficult to dredge. The added time required to dredge new material may incur additional costs.

6-6.5 Other Factors.
Other factors include the cost of fuel, competition between private and public dredgers, and the configuration and use of the naval harbor to be dredged. Refer to either Chapter 8 of The Handbook of Dredging Engineering (Herbich, 1992) for an Economic Analysis for Disposal or Chapter 10 in Dredging: A Handbook for Engineers (Bray et al., 1997) for a discussion of Dredging Costs and Prices.

6-7 GEOTECHNICAL FACTORS.
Soil investigations and testing techniques are generally similar to terrestrial procedures except that trial dredging may be resorted to where conditions for a particular type of dredge are marginal. Soil classifications generally refer to the PIANC adopted system.

6-7.1 Sediment Analysis.
Sediment samples from the dredge area should be obtained and analyzed.

- *Grab samples*. Samples for maintenance dredging are often not necessary as review of historical records reveals sediment characteristics. If samples are necessary for maintenance projects they are usually grab sampled taken from the bed surface.

- *Subsurface investigation*. New-work dredging requires subsurface investigation. Recoverable cores are recommended where consolidated sediments may be encountered.

- *Probing or sonar profiling*. If rock pinnacles or debris are detected by grab or core samples, extensive probing or sonar profiling of the dredging area should be accomplished to locate and quantify rock and debris.

- *Sediment testing*. To evaluate dredging-plant requirements and disposal procedure, cohesionless samples should undergo mechanical sieve analysis. A chemical analysis is necessary for cohesive sediments. Bioassays may be necessary for cohesive sediments, depending on results of chemical analysis and proposed disposal action. If the project involves dredging of new sediments, a principal element of interest may be the density (or consistency) of material and, for cohesive sediments, the shear strength.

6-8 UNEXPLODED ORDNANCE.
Currently the Navy has embarked on a number of efforts to locate and dispose of unexploded ordnance (UXO). Where there is a past history indicating potential

existence of such ordnance, it must first be located so that care can be exercised to avoid injury to individuals or property damage.

6-9 MAGNETIC SILENCING FACILITIES.

In order to deal with magnetic silencing facilities (for degaussing and deperming), the facility should be designed with future dredging requirements in mind. If the facilities are already in place, a dredging method that will not impact the facilities must be chosen.

6-10 DREDGING EQUIPMENT.

A comprehensive summary of descriptions and optimum uses for various types of dredging equipment is found in Chapter 7 of The Handbook of Dredging (Herbich, 1992) and in Chapter 7 of Dredging: A Handbook for Engineers (Bray et al., 1997).

6-10.1 Mechanical Dredges.

Mechanical dredges dislodge and raise sediment by mechanical means. Mechanical-dredging methods are generally used in protected waters, but because the equipment is relatively mobile, some mechanical dredging may be accomplished in open water during short-term, calm-water conditions. Mechanically dredged sediments may be disposed alongside the dredge at a dumpsite or may be transferred to scows which transport the sediments to a dump site. The production rate by means of mechanical dredging is relatively low. Mechanical dredges produce a more irregular bottom than hydraulic dredges.

6-10.1.1 Types of Mechanical Dredges.

- *Clamshell, grab, or bucket dredge*. This system consists of a crane, or derrick, mounted on a floating barge, with a clamshell, orange peel, or dragline bucket used to pick up sediment and transfer it to an adjacent scow or barge. This dredge may be a specially built machine or may consist of land equipment on a suitable floating platform. This form of dredging can remove loose, unconsolidated sediments ranging in size from silts and clays to blasted rock. The dredge can be used in moderate-swell conditions. The system is not exceedingly efficient but has the advantage of high mobility. This mobility enables dredging at the base of bulkheads, piers, and fender piles without damaging these structures or the dredge equipment.

- *Ladder, or bucket-ladder, dredge*. This dredge consists of a floating dredge that has a continuous chain of buckets on a frame which is called a ladder. Each of the buckets possesses a cutting edge for digging into the sediment. The ladder is lowered to the bed so that the buckets can reach and cut sediments to be dredged. The buckets dump the dredged sediment by gravity at the opposite end of the ladder onto a conveyor system or an adjacent open barge. The barge may then transport the material to the disposal site. This dredging system is effective in hardpan and cemented sediments, but is ineffective in firm rock. The system cannot be used in swell conditions. This system is not often used in the United States.

- *Dipper-barge dredge*. This dredge consists of a backhoe mounted on a barge equipped with a trapdoor shovel. Sediment is removed from the bed and deposited alongside the dredge, in another barge, in the water, or onshore. Where the sediment is deposited depends on the length of backhoe reach. Spuds, which penetrate the bottom, are usually used to keep the barge from moving during a dredging activity. This dredging method is effective for hardpan and cemented sediments, as well as for firm rock that has been blasted. The effectiveness of this type of dredging system is limited in moderate-swell conditions.

6-10.2 Hydraulic Dredges.
Hydraulic dredges lift sediment from the bottom and transport it by means of a centrifugal pump. Hydraulic dredges can be used in either open or protected waters, depending on the type of dredge. The dredged material is transported in a slurry and is generally discharged by a pipeline in the hull of the dredge; the slurry is discharged alongside the dredge, or it may be pumped ashore. The rate of production depends on sediment type, depth of cut, and dredge size and power; it generally exceeds that of mechanical dredges.

6-10.2.1 Types of Hydraulic Dredges.

6-10.2.1.1 Pipeline, or suction, dredge.
This dredge consists of a barge-mounted centrifugal pump. A suction line, or pipe, extends from the pump beyond the bow and is lowered to the bed by means of an "A" frame and ladder. At the end of this ladder, the pipe moves along the bottom dislodging the material. The material is then pumped in a slurry to a discharge line extending beyond the stern of the dredge. The material may then be pumped to the disposal site through a discharge line. Using booster pumps can extend the distance through which the material may be pumped. Sweeping the suction pipe over an area at constant depth will result in the excavation of the channel bottom. Pipeline dredges are not self-propelled, but move by forward-mounted swing wires and aft-mounted walking spuds or wires. This type of dredge can be operated safely only in the absence of moderate to high swell; it can excavate material ranging from clays and silts to blasted rocks. The dredge is generally capable of dredging large volumes of material. Pipeline dredges are usually limited to excavation depths of approximately 60 feet (18.3 m). The rate of production will decrease with increased length of discharge line, increased lift, and increased bed-sediment compaction.

6-10.2.1.2 Cutterhead dredge.

This dredge consists of a pipeline dredge equipped with a rotary cutter at the end of the ladder. The cutter is used to dislodge bed sediments.

6-10.2.1.3 Dustpan dredge.
This dredge consists of a pipeline dredge with a dustpan-shaped head at the end of the ladder. The head is equipped with water jets that are used to dislodge bed sediments.

6-10.2.1.4 Bucket-wheel excavator.
This dredge consists of a pipeline dredge with a bucket wheel rotating (on a horizontal axis) at end of the ladder.

6-10.2.1.5 Trailing suction dredge.
This dredge consists of a self-propelled or tug-assisted vessel. The hull of the vessel contains a hopper and the dredge is equipped with one or two suction pipes (normally fitted with drag heads) extending below the hull to the bed. This dredge usually operates while underway, drawing slurry by centrifugal pumps to the hopper, where excess water is overflowed back to the waterway. Sediment is discharged at the disposal site by opening doors located on the hopper bottom or by pumping out the hopper. This dredge is a self-contained unit and is capable of operating in higher swell conditions. Because the dredge is self-propelled, it is capable of dredging material from sites which are large distances from the point of disposal.

6-10.2.1.6 Hopper Dredge.
This dredge consists of a trailing suction dredge with a ship shaped hull, a bridge, an engine room, and crew quarters. This dredge is typically used for the dredging of estuary and river-mouth bars that are prone to ocean-swell conditions.

6-10.3 Special Equipment.

6-10.3.1 High Solids-Content Dredge.
This dredge consists of a floating system capable of pumping high concentrations of solids through the use of compressed air. It is primarily used for removal of industrial wastes from rivers and harbors. The production rates are generally low and the distance over which the material may be pumped is limited. This type of dredge is not generally available.

6-10.3.2 Elevated-Platform Dredge.
This system consists of a pipeline dredge that incorporates a "jack-up" barge to elevate the equipment above the surface swells. The system incorporates a submerged discharge pipeline. Availability of this type of dredge is very limited.

6-10.4 Selection of Dredging Equipment.
Principal considerations upon which equipment selection is made include:

- exposure of dredging site

- volume and distribution of materials to be dredged
- type of material to be dredged
- location of disposal area
- distance to disposal area
- time available for work
- vessel traffic
- availability of equipment.

The US ACE DRP Technical Areas 3 and 4 contain numerous reports on the types of mechanical dredges listed in this chapter.

6-11 DISPOSAL OPTIONS.

Disposal of dredged material generally presents problems, particularly when there is a lack of candidate disposal sites. The beneficial use of dredged materials should be investigated.

6-11.1 Landfill.

Dredged sediments may be used as a landfill for commercial, industrial, and recreational purposes.

6-11.2 Construction Materials.

Coarse sediments are often suitable for use as construction aggregate. These sediments may be stockpiled for present and future use.

6-11.3 Marshland Wetland Habitat.

After intertidal- and submerged-fill operations are completed, shellfish larvae, wetland vegetation, or other organisms indigenous to the locale may be placed in the area to create a productive marshland.

6-11.4 Upland Wildlife Habitat.

During and after completion of above-water fills, seeding and contouring of sediments can provide a habitat indigenous to wildlife; this procedure may also prevent erosion.

6-11.5 Beach Nourishment.

Placement of suitable fill in water or on beaches can help to replenish losses of material caused by seasonal storms, washouts, currents, and other natural phenomena.

CHAPTER 7 DESIGN OF MARINE IMPROVEMENT PROJECTS

7-1 INTRODUCTION TO COASTAL PROJECT ELEMENT DESIGN.

The CEM Section VI-2 contains sections on the introduction to coastal project element design, types and functions of coastal structures, site specific design conditions, materials and construction aspects, fundamentals of design, reliability based design of coastal structures, design of specific project elements, and designing for repair, rehabilitation, and modification.

7-2 TYPES AND FUNCTIONS OF COASTAL STRUCTURES.

Coastal structures are used in coastal defense schemes with the objective of preventing shoreline erosion and flooding of the hinterland. Other objectives include sheltering of harbor basins and harbor entrances against waves, stabilization of navigation channels at inlets, and protection of water intakes and outfalls. An overview of the various types of coastal structures and their application is given in CEM Section VI-2. Overall planning and development of coastal projects is covered in CEM Section V.

7-2.1 Breakwaters.

Primary applications of breakwaters are to provide protection against waves for shore areas, harbors, anchorages, and basins, and to enable maintenance-dredging operations. A secondary purpose is beach erosion control.

7-2.2 Jetties.

Jetties are devices parallel to a navigation channel used to protect the channel from shoaling with littoral drift and to stabilize the entrance to a tidal inlet. They may also provide wave and wind protection and direct or confine the flow of river or tidal currents. Sand bypassing of jettied inlets is often necessary to preclude erosion of the downdrift coast.

7-2.3 Revetments, Bulkheads, and Seawalls.

These structures are used to protect embankments or shore structures from eroding or from damage due to wave attack or currents and to retain or prevent sliding of land. Revetments are generally rubble construction. Seawalls and bulkheads are generally more rigid structures constructed of steel, concrete, or timber. Another design for seawalls is to use Igloos, patented by Nippon Tetrapod (
Figure 7-1). Igloos can be used as space-saving wave absorbers or breakwaters. Prefabricated concrete units have been used successfully as wave-dissipating walls in harbors.

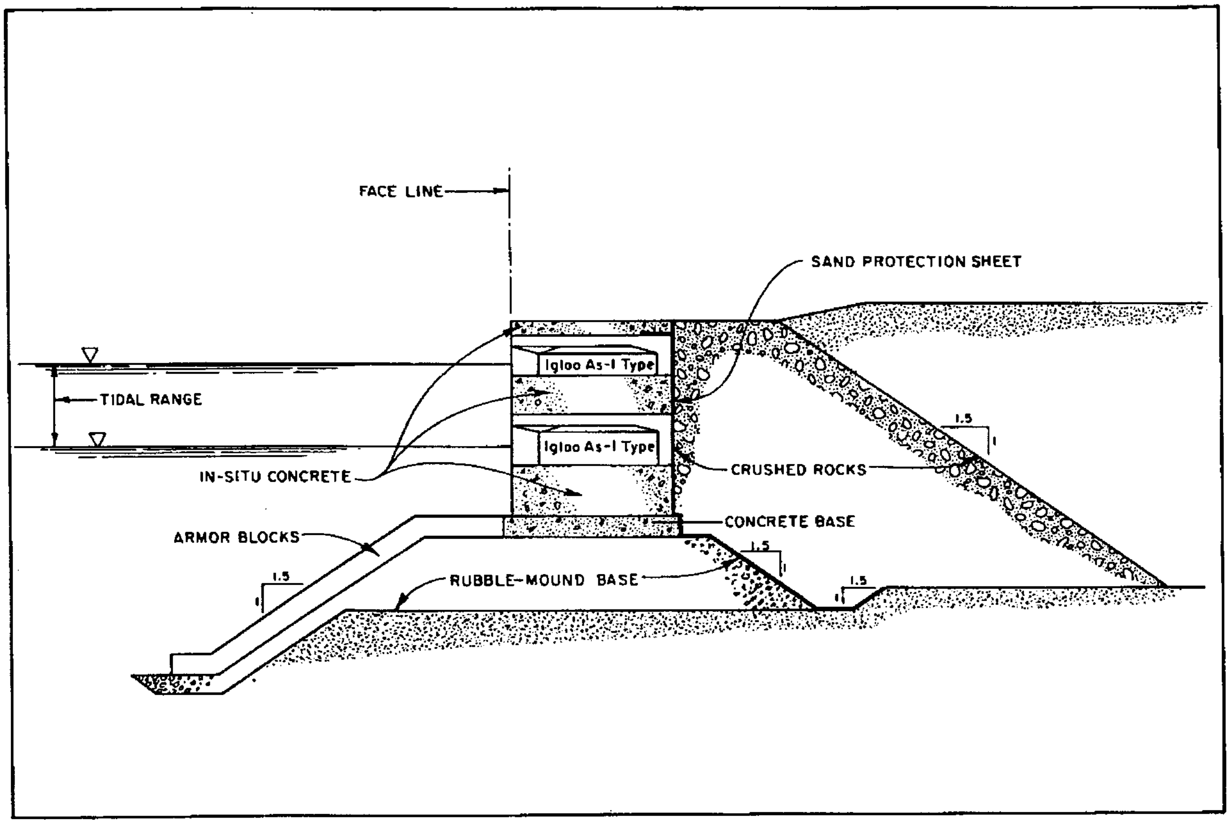
7-2.4 Groins.

Groins are used to protect the coast from erosion and to retard or control littoral transport to stabilize a beach. Groin fields should generally be filled with imported material to preclude erosion of the downdrift coast.

7-2.5 Headlands.

Headlands are high, steep-faced border points of land extending into the ocean or other body of water. Large segments of shorelines can be stabilized by construction of artificial headlands.

Figure 7-1 Typical Igloo Seawall



7-2.6 Beach Restoration and Nourishment.

Beaches that are eroding due to an interrupted or inadequate sand source can be stabilized by deposition of sand brought from a source on land or of dredged materials.

7-3 SITE SPECIFIC DESIGN CONDITIONS.

When developing a harbor or other coastal project, much of the information that is required is site specific. This requires the engineer to pursue various methods of field testing or existing data regarding a site. The various types of information that are typically required are foundation/geotechnical requirements, seasonal profile variation, flanking possibility, seismic activity, ice, environmental considerations, construction considerations and other design considerations (including regulatory, maintenance, etc.). CEM Section VI-3 presents an overview of these subjects.

7-4 RELIABILITY OF DESIGN.

CEM Section VI-6 discusses reliability in design in depth. First, the engineer must decide on what design life is desired and/or permitted by the budget. The level of protection must then be considered.

The CEM also provides information on the factors to be considered in a complete design, necessary baseline data (field surveys, etc.) and concept of risk/reliability in project design. Finally, the CEM discusses overall performance criteria.

7-5 FUNDAMENTALS OF DESIGN.

Planning and design procedures for coastal projects are described in CEM Section V-1. The engineering design steps related to a specific type of coastal structure can be schematized as follows:

- Specification of functional requirements and structure service life time.
- Establishment of the statistics of local short-term and long-term sea states as well as estimation of possible geomorphological changes.
- Selection of design levels for the hydraulic response: wave runup, overtopping, wave transmission, and wave reflection.
- Consideration of construction equipment and procedures, and of availability and durability of materials (e.g., only land based equipment operational and available at reasonable costs, rock of sufficient size easily available).
- Selection of alternative structure geometries to be further investigated (e.g., composite caisson structures, rubble structures with and without crown walls).
- Identification of all possible failure modes for the selected structure (e.g., armor layer displacement).
- Selection of design damage levels for the identified failure modes (e.g., 50 percent probability of displacement of 5 percent of the armor units within 50 years).
- Conceptual design of the structural parts based on the chosen design levels for failure mode damage and hydraulic responses (e.g., determination of armor layer block size and crest height for a breakwater).
- Evaluation of costs of the alternative structures and selection of preferred design(s) for more detailed analysis and optimization.
- Detailed design including economical optimization and evaluation of the overall safety of the structure. This stage will involve scale model tests

and/or advanced computational analyses for non-standard and major structures.

7-6 DESIGN OF SPECIFIC PROJECT ELEMENTS.

The design of specific coastal project elements is outlined below. For additional information and case studies, see CEM Section VI-7-1.

7-6.1 Sloping-Front Structures.

The types of structures discussed here are armor units, one-sided shoreline sloping and two-sided sloped structures. Refer to CEM Part VI-7-2 for further information regarding this subject.

Rubble-mound structures generally have a core covered with one to several quarry stone underlayers that are protected with armor units of stone or specially shaped concrete units. Breakwaters have a core material of randomly dumped, well-graded quarry run, sand or coral. This material is generally impermeable. Successive underlayers cover the core; the material in each successive layer is carefully increased in size to prevent loss of the smaller-sized core material. Armor units are placed on the outer surface to hold to core and the underlayers in place against wave attack. Rubblemound revetments, groins, and jetties are similarly built in that armor units hold the underlying material in place. Rubble-mound structures are well suited to the coastal zone because they can absorb the forces of waves with relatively minor damage even when design conditions are exceeded to a moderate degree.

7-6.2 Vertical Front Structures.

The types of structures of concern in this chapter are gravity structures and sheet-pile structures. CEM Section VI-7-3 is the nominal source.

7-6.3 Beach Fill Systems.

Adding fill to a beach is an economical and effective method to replace lost beach materials or to increase the size of an existing beach. The added fill increases the backshore width and moves the high water line farther offshore. The choice of fill type should resemble the original beach material and the slope of the beach should also match the original slope as closely as possible. Note that the cost and ease of beach fill as an erosion control method depends on the rate of material loss from the beach. If fill is readily available from a nearby location, the initial cost of refilling the beach would be low. However, regular refilling translates into recurrent maintenance costs. See CEM Section VI-7-4 for information on beach fill systems.

7-6.4 Floating Structures.

Floating breakwaters are a special classification of breakwater. A floating breakwater comprises a float, of sufficient size relative to the wavelength, held in place by mooring lines fixed to anchors or to guide piles. Floating breakwaters can be constructed of barges, pontoons, floating docs, or rubber tires, or one can be specifically designed. The recommended source for more information on this subject is CEM Section VI-7-5.

7-6.5 Pile Structures.

As the most common type of deep foundation, piles are used to transmit loads through upper weak and/or compressible soil strata to underlying competent zones. These include driven piles, drilled piles, drilled piers/caissons, sheet piles (for containing fills), and fender piles for docking. Piles also provide support in areas where shallow foundations are impractical, such as underwater, in close proximity to existing structures, and other conditions, and to provide uplift resistance and/or lateral load capacity. The performance of a deep foundation is highly dependent on the installation procedures and quality of workmanship. Forces on piles and piers and pile design are addressed in the recommended source for information on this subject, CEM Section VI-7-6.

7-6.6 Pipelines and Outfalls and Submarine Cables.

Pipelines, outfalls and submarine cable systems that cross a shoreline, harbor, river or other bodies of water are exposed to many hazards. Fishing activity, anchors, wave action, currents, ice scour, and vandalism are just a few of the causes of damage to these systems. A variety of methods are used for protection and stabilization including, armor, split pipe, rock riprap, concrete encasement, mechanical anchoring, trenching and horizontal direction drilling. The recommended source for information on this subject is CEM Section VI-7-7.

7-6.7 Miscellaneous Structure Examples.

Examples of low-cost shore protection, sand-filled beach structures, low-energy shore protection, and beach draining are provided in CEM Section VI-7-8.

7-7 DESIGNING FOR REPAIR, REHABILITATION, AND MODIFICATION.

CEM Section VI-8 provides information on this topic with emphasis on the reliability of existing structures, sloping-front structures, vertical-front structures and monitoring of structures.

Chapter 8 HARBOR AND COASTAL MAINTENANCE

8-1 INTRODUCTION.

After a navigation project has been designed and constructed, operation and maintenance are required to sustain safe and efficient use of the project. Operation and maintenance requirements and costs can be substantial. They are typically estimated with care and optimized against initial construction costs in planning and designing a navigation project. Anticipated maintenance costs are based on predictions of physical changes after the project is constructed.

A completed navigation project must be monitored to insure safe operation and to plan for maintenance activities as needed; see CEM Section V-2-1-q. Monitoring typically includes hydrographic surveys, beach profile surveys, tide and wave data collection, and navigation structure condition surveys. Surveys are typically done on a planned schedule, such as annually, and before and after periods of maintenance and repair. Surveys should be analyzed comparatively to determine rates of erosion, shoaling, and structure deterioration. The recommended source for information on this subject is CEM Section V-4-3.

8-2 HARBOR AND CHANNEL SEDIMENTATION AND MAINTENANCE.

Often periodic dredging to maintain project depths is the major maintenance need (CEM, Appendix VII-4). Maintenance dredging intervals are dependent on factors such as shoaling rate, dredge availability, and dredge mobilization costs. Typical maintenance intervals are on the order of 1-3 years at some projects. However, environmental forces impacting a navigation project are highly variable. The number and intensity of storms affecting a project each year can only be predicted in terms of probabilities. Maintenance needs are often strongly influenced by storm events. A single severe storm can cause major shoaling and structure damage. Consequently, monitoring and maintenance activities may occasionally need to respond quickly to maintain project integrity. See CEM Section V-4-3 for further information.

8-2.1 Navigation Aids.

Information on Navigation Aids can be found in the Code of Federal Regulations: 33 CFR Part 62 and 33 CFR Part 209.325.

8-3 INSPECTION AND REPAIR OF MARINE IMPROVEMENTS.

The recommended source for information on this topic is the “ASCE Standard for Shore Protection Systems - Draft,” August 20, 1997.

8-3.1 Revetments.

The recommended source for information on this topic is the “ASCE Standard for Shore Protection Systems - Draft” (ASCE, 1997).

8-3.2 Beach Nourishment.

The recommended sources for information on this topic are the CEM Chapter V-3-3-a(1) and "ASCE Standard for Shore Protection Systems – Draft," August 20, 1997.

8-3.3 Sedimentation Around Piers and Basins.
Deepening harbors to provide for deeper draft ships and the installation of piers can increase the rate of sedimentation, in those cases where the entire sediment supply isn't already depositing itself. The ramifications of siltation around piers, for example, can induce localized changes; silt or microorganisms can be picked up through a ship's saltwater intakes, thereby causing significant damage to vessels and high repair costs.

Since sedimentation control is a site-specific phenomenon, each location must be accessed and the best method chosen for the area. Modeling sites can provide valuable information, but all sites cannot be modeled at full scale due to cost limitations; additionally, scaling can be problematic. Research and development into sediment limitation by way of stopping the sediment from reaching the site, keeping the material in suspension through the site, or diverting the sediment flow from critical areas has produced ideas for several different systems and methods: the venting canal, the scour jet array, the vortex foil array, the barrier curtain, and the maintenance trench (Sedimentation Control to Reduce Maintenance Dredging of Navigational Facilities in Estuaries, 1987).

Subj: AIRCRAFT CARRIER WATER DEPTH REQUIREMENTS

Ref: (a) NAVSEA ltr 11460 Ser 03D/242 of 3 Jan 95

Encl: (1) Aircraft Carrier Home Port Water Depth Requirements
(2) Aircraft Carrier Shipyard Water Depth Requirements

1. Purpose. The purpose of this letter is to update the information in reference (a) to current requirements. This letter also states the requirement for a minimum water depth of six feet beneath the keel of aircraft carriers for all transits in homeports, ports of call, and shipyards.

2. Background. In reference (a), NAVSEA provided the pier and channel water depth requirements for CVN 68 Class aircraft carriers in homeports, ports of call, and shipyards.

3. Discussion.

a. The requirements previously provided in reference (a) for CVN 68 Class aircraft carriers have been updated and reference (a) is hereby superceded. These updates are summarized as follows:

(1) The requirements have been extended to all aircraft carriers.

(2) The requirements have been extended to apply to "dead stick" (towed) conditions.

(3) References to Long Beach Naval Shipyard have been deleted.

(4) Enclosure (3) of reference (a) has been deleted. This enclosure described plans for aircraft carriers to improve

shallow water navigation aids that predict ship's motions provide real time channel condition measurement, improve ship's draft and attitude indication and provide a load management system.

(5) Minor changes to displacements and drafts have been made to the charts in the enclosures.

(6) Estimates of the impact of water depth from ship motions in the outer channel for Pearl Harbor Naval Shipyard and Norfolk area facilities have been included.

b. Enclosures (1) and (2) provide water depth requirements for all aircraft carriers in under power or "dead stick" (towed) conditions. "Dead stick" is defined as propulsion plants shut down, emergency diesel generators operating on high suction, all other ship and reactor plant cooling loads (8000 to 10,000 gpm) supplied by the firemain system and no main injection or SSTG/CTG cooling requirements.

(1) Enclosure (1) provides aircraft carrier water depth requirements for homeports. Attachment (1) of enclosure (1) also applies to ports of call. The ship's mean draft used for homeports corresponds to the limiting displacement and is considered the proper basis for determining the appropriate channel, turning basin and pier water depths since it will permit operations of a fully loaded ship.

(2) Enclosure (2) provides water depth requirements for shipyards. The ship's mean draft used for shipyards was reduced based on the assumption that only 55% of the ship's loads (aircraft, fuel, personnel stores, etc.) would be onboard. Each enclosure describes and quantifies the components that contribute to aircraft carrier draft and clearance:

(a) the governing depth requirements for the pier, turning basin, inner channel, and outer channel for each homeport and shipyard

(b) general tide information for each homeport and shipyard

(c) a graphical representation of the relationship between the number of days of access to the turning basin and inner channel, the length of the tide window, and the dredging project depth for the governing depth requirement of each homeport and shipyard.

c. Water Depths. While at the pier, in the turning basin, or in the inner channel of a homeport or a port of call, it is recommended that there be a minimum of 50 feet of water depth. While at the pier, in the turning basin, or in the inner channel of a shipyard, it is recommended that there be a minimum of 47 feet of water depth. Entering a shipyard without offloading should be treated as a port of call.

Clearance. These water depth requirements are governed by the sea chest fouling clearance criterion established as a result of sea chest fouling problems experienced at Norfolk. Note that this criterion also provides clearance for divers (5 feet) while at the pier.

Dredging Project Depths. The dredging project depth can be traded off with tides to obtain the necessary water depth in inner channels and turning basins with the corresponding operational restrictions; however, tide tradeoffs cannot be used at piers. Localized pier dredging in way of sea chests can save 2 feet of dredging cost outside of the sea chest area; however, operational restrictions may result (e.g., less transit time in tide window and limited diver access).

d. In the outer channel, wave action usually dominates the depth requirements and can have a large variance. A ship motions analysis was performed for the outer channels of San Diego and Mayport to account for the statistical nature of the tides and wave action. The ship motions analyses of Pearl Harbor and Norfolk outer channels have been estimated based on wave height data for these areas and compared to San Diego wave data and previously accomplished ship motions analysis. The ship draft changes are derived relative to these analyses.

4. Action. Many of the factors that affect channel transit are operational issues, such as operating schedule and contingencies, port operations, ship displacement, trim, list, and speed as well as weather and tides. Actual transit situations will vary and will involve different combinations of these factors. Consequently, a given transit could require more or less water depth. However, to minimize the risk of fouling heat exchangers for either operational or "dead stick" (towed)

Subj: AIRCRAFT CARRIER WATER DEPTH REQUIREMENTS

transits in restricted waters for all aircraft carriers, a water depth beneath the keel of at least 6 feet should be maintained.

5. The NAVSEA point of contact is Mr. F.E. Horacek, NAVSEA 05N25, (202) 781-0649, DSN 326-0649, e-mail: franklin.horacek@navy.mil.

Aircraft Carrier Home Port and Ports of Call
Draft and Clearance Requirements

Static Draft					
Mean	40.9 ft 103,800 tons (CVN 68-75) 104,300 tons (CVN 76)				- Accounts for: Actual operating condition (+2000 tons) Service life weight growth (+70 tons/year) Unreported weight - Assumes weight is added in best location. - Assumes good ship weight control.
Trim	0.25 degrees		Bow	2.3 ft	- Based on operational experience. Instances of greater trim do occur, but rarely when the ship is at or near the limiting displacement.
			Sea Chest	0.8 ft	
			Rudder	2.1 ft	
List	Pier	2 degrees	Bilge Keel	2.3 ft	- Based on operational experience. Instances of greater list do occur, but rarely when the ship is at the limiting displacement.
			Sea Chest	1.4 ft	
	Channel	0 degrees			- Assumed ship is leveled prior to transit. TYCOM confirmation is needed.
Appendages	9 inches				- All of the CVN 68 Class except CVN 70 have discharge sea chest diffusers. - Assumed to be overshadowed by trim.
Salinity & Temperature	0.5 feet (50% salinity reduction & 10° temperature rise)				- This calculation is port, season, and tide specific. - Assumed constant.
Dynamic Draft					
Wind & Waves	Outer Channel			See Note	- This calculation is port specific. - See indiv. port summary sheet for details.
	Inner Channel			0 ft	- Protected harbor.
	Pier & Turning Basin				
Squat	10 kts		Forward	0.9 ft	- Based on wide channel that is 50 ft deep. - Shallower and/or narrower channels and/or higher speeds will require a greater allowance for squat.
			Aft	1.3 ft	
			Sea Chest	1.0 ft	
Heel	1.4 degrees		Bilge Keel	1.6 ft	- Based on operational experience, 10 kts and 10 degrees rudder.
			Sea Chest	0.8 ft	
Clearance					
Fouling	6 ft				- Based on operational experience at NOB and NAVFAC study and applies to soft bottoms and bottoms with loose sea growth. - Assumes diffusers are installed.
Grounding	Soft Bottom			2 ft	- NAVFAC deterministic standard.
	Hard Bottom			3 ft	
	1/100				- Proposed probabilistic standard.

Aircraft Carrier Water Depth Requirements for Norfolk Operating Base

APPENDIX C - Appendix C CVN68 Class Shallow Water Navigation Improvements

CVN 68 CLASS SHALLOW WATER NAVIGATION IMPROVEMENTS

Due to the deep draft of the CVN 68 Class aircraft carriers, port and shipyard access can be restricted, in order to minimize the cost and environmental impacts of deep dredging, actual ship loading, tides, and favorable weather conditions can be used. Utilizing these factors affects operational issues such as operating schedule and contingencies as well as ship loading and speed. Actual transit situations will vary and will involve different combinations of these factors. Current dredging plans will not provide unrestricted access to CVN 68 Class home ports and shipyards. To reduce the risk of grounding, it is recommended that shallow water navigation aids be improved.

The wave and motion determination process in shallow water is complex. Wave conditions are port dependent; each port must be individually studied for an accurate assessment. The most extreme CVN motions are generated from seal swells originating from storms hundreds of miles away; consequently, they are difficult to detect. Waves and swells are predicted from the Fleet Numerical Oceanographic Center or observed by the crew. Waves seen in or predicted for the open ocean may not be that which are experienced at any given port. Local land and bottom effects and changes due to wind, tides, and currents are not included.

This plan improves onboard shallow water navigation aids by:

(a) Providing a channel guidance system.
(b) Providing real time channel condition measurement.
(c) Improving ship's draft and attitude indication.
(d) Providing a load management system.

These systems and other supporting systems would be integrated as appropriate to facilitate overall functionality and minimize cost.

<u>Channel Guidance System</u>

NAVSEA has developed and tested an onboard CV Channel Guidance System (CVCGS). This system aids in the determination of under keel clearances and the probability of grounding while operating in ports. It is a PC computer program which calculates depth requirements based on data from the ship's force concerning load and trim conditions. Environmental conditions are down loaded from Fleet Numerical or input from the ship's navigator. Ship motions, under keel clearance, and probability of grounding predictions are then calculated for channel transits. The CVCGS has been validated by ship model tests and full scale wave measurements. This system will be sent to all CVs by the and of FY95.

Channel Condition Measurement

The Environmental Monitoring and Operator Guidance System {EMOGS) incorporates analysis capabilities of the CVCGS. However, instead of using predicted information from Fleet Numerical and the navigator, EMOGS uses real time wave and tide data from sensors installed in the channel. Because this is a far more accurate prediction of waves and variable water levels, substantial risk reductions are realized. The following table shows the accessibility levels of CVCGS and EMOGS associated with different dredge depths for San Diego and Mayport. An EMOGS type system is successfully being used by SUBLANT at Kings Bay, Georgia for SSBN 726 Class transits. EMOGS is recommended for channels not dredged for unrestricted operations and are subject to wave action, particularly swells. EMOGS is a facilities improvement cost tradeoff with dredging.

OUTER CHANNEL ACCESSIBILITY
FOR A RISK OF EXCEEDING DREDGE DEPTH 1 IN 100 TIMES

CHANNEL DEPTH (feet)	DAYS PER YEAR	
	CVCGS	EMOGS
SAN DIEGO:		
55	227	333
59	295	355
MAYPORT:		
47	254	262
50	362	363

Without guidance of any sort in avoiding extreme wave conditions, risk may increase to 1 in 2.

Draft and Attitude Indication

Currently, the CVN 68 Class only has one Remote Draft Indicator and list and trim inclinometers. The Profile Draft Indicator has been removed because it contained about a pint of mercury. Consequently, the ship does not have the ability to accurately determine the ship's draft, list, and trim. Installation of two more Remote Draft Indicators would provide the ability to triangulate accurate draft, list, and trim values. Based on simple geometry, the ship could then accurately determine the extreme draft point. A JCF and ECPs are being prepared to add two Remote Draft Indicators.

Load Management System

The CVN 68 Class carries roughly 20,000 tons of loads (aircraft, fuel, personnel, stores, etc.). There are some 415 tanks and voids and some 245 storerooms and magazines. The amount of material continuously being brought onboard, moved, and being consumed is large. Aircraft carrier operations require the flight deck to be as level as possible. There is a list control system to account for aircraft movement. A system similar to those used on tankers (commercial and AOEs) would provide the ship with a tool to better track and manage loads. This would enable the crew to minimize displacement list, and trim; thereby, minimize operational restrictions. A load Management system is being investigated by the CVN 76 IC effort.

APPENDIX D - Appendix D Nomographs of CVN68 Motion in Shallow Water

APPENDIX D   NOMOGRAPHS OF CVN 68 MOTION IN SHALLOW WATER

Background

Shallow water motion transfer functions where developed for the CVN 68 class ship to aid in predicting the ship's underkeel clearance for a variety of different entrance channels. The motion transfer functions were validated by model tests conducted at the US Army Corps of Engineers Waterways Experiment Station.

Description

The nomographs of CVN 68 motion in shallow water were developed by combining the shallow water motion transfer functions with a variety of wave and ship operating conditions. The waves used in calculating ship motions were developed to simulate the shallow water environments. The modal wave periods ranged from 6 to 14 seconds and the significant wave height ranged from 1 to 10 feet. The wave energy was spread using the idealized JONSWAP spectrum which is consistent with fetch limited conditions generally found in shallow water, and the energy was spread +/- 90^{o} to simulate shortcrested seas.

The ship operating conditions used for these nomographs were the following. The ship speeds were 6, 10, and 14 knots which covers most transit conditions for CVN 68 class ships. The ship-to-wave heading on the nomographs are head, bow, beam, quartering and following seas. Defining these headings, head seas are directly at the bow of the ship, bow seas are 45 ^{o} off the bow, beam seas are directly at the beam or side of the ship, quartering seas are 45 ^{o} off the stern, and following seas are directly off the stem.

The vertical motion and velocity at the bow and stern of the ship is calculated for each of these conditions. The extreme motion expected in 100 transits is then calculated from the vertical motion and velocity using a statistical formula generated by Ochi (1973). The largest resulting vertical motion is then used in the nomographs.

AIR FORCE CIVIL ENGINEER SUPPORT AGENCY

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	1 Sept 2012	Various updates and editorial changes throughout.

This UFC supersedes MIL-HDBK-1104, DATED 10 December 1999.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Center for Engineering and the Environment (AFCEE) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

CHAPTER 1

INTRODUCTION

1-1 **SCOPE**. UFC 4-150-07 is a guide for the inspection, maintenance, and repair of waterfront structures and related facilities. It is a source of reference for planning, estimating, and performing technical maintenance and repair work; and may serve as a training manual for waterfront facilities maintenance personnel.

1-2 **PURPOSE**. This document provides guidance for maintenance and repair of waterfront facilities to retain them in continuous readiness for use by the Fleet and in support of military marine operations.

1-3. **APPLICATION**. The types of waterfront facilities covered include:

- Berthing facilities for mooring and for providing support to ships and craft.
- Drydocks used for modification, inspection, maintenance and repair of ships.
- Components of waterfront structures such as piling, dolphins, bulkheads, and decks.

Fender systems are briefly considered. Refer to MO-104.1, *Maintenance of Fender Systems and Camels*, for detailed coverage.

Not specifically considered in this document are:

- Coastal protection structures designed to protect shorelines or harbors.
- Components of waterfront structures such as utility distribution systems and fleet moorings.

The maintenance and repair of coastal protection structures is included in the Army Corps of Engineers, *Shore Protection Manual*, Volumes I and II. Repair of coastal structures is covered in more detail in USACE, *Coastal Engineering Technical Notes and Repair, Evaluation, Maintenance, and Rehabilitation Technical Notes*. The maintenance of utility distribution systems is covered by various service manuals and commercial publications. NAVFAC MO-124, *Mooring Maintenance Manual*, provides details on the maintenance of fleet mooring systems.

These documents, and all Government documents referenced in this document, provide additional guidance primarily to DOD and U.S. Coast Guard activities.

They may also be useful, however, to commercial firms that provide waterfront repair for these activities. \1\ /1/

1-4 **TECHNICAL SECTIONS**. The technical sections following this introduction include:

MAINTENANCE PLANNING AND TYPES OF FACILITIES (Chapter 2):

- Joint service responsibilities, maintenance policies, and the basic elements of maintenance planning.
- Overview of waterfront facilities.

MATERIALS AND PREVENTIVE MAINTENANCE (Chapter 3):

- Describes materials at the waterfront and the types of deterioration likely to be encountered.
- Describes preventive maintenance measures for each type of material.

SAFETY AND ENVIRONMENTAL CONSIDERATIONS (Chapter 4):

- Guidelines for personnel and work site safety.
- Guidelines for assuring compliance with environmental policies and regulations.

INSPECTION (Chapter 5):

- Overview of inspection levels, methods, planning, equipment and documentation.
- Guidance and checklists for above and underwater inspection of timber, concrete, steel, synthetics, and rubble-mound structures.

REPAIR (Chapters 6, 7, 8, 9, and 10):

- Describes and illustrates repair methods and techniques for the problems encountered.
- Guidance for selecting material along with pertinent references and standards.

CHAPTER 2

MAINTENANCE PLANNING AND TYPES OF FACILITIES

2-1 MAINTENANCE PLANNING

2-1.1 Cooperation and Coordination

2-1.1.1 **Intraservice Functions**. Cooperation and coordination of waterfront maintenance activities among the installation departments concerned should be continuous. Properly planned and executed maintenance programs prevent undesirable interruption of operations on military installations. Supply officers, through normal channels, provide standard items of materials and equipment for waterfront maintenance.

2-1.1.2 **Interservice and Interdepartmental Functions**. Cooperation and coordination in conducting waterfront maintenance are encouraged at all levels of command. Appropriate liaison should be established and maintained between major commands and installations in a geographical area. Cross-service assistance should be provided as necessary in the interests of economy and maximum utilization of manpower and equipment. Technology transfer of improved maintenance methods and materials should be continuously encouraged.

2-1.1.3 **Fleet Requirements**. All maintenance and repair activities should be scheduled and coordinated to minimize pier down time for the fleet. Direct communication with the fleet command is vital for ensuring fleet requirements are considered when planning pier maintenance or repair.

2-1.2 **Joint Service Responsibility**. The responsibility for inspection, maintenance, and repair of waterfront structures and related facilities rests with each service. Because of the quantity of waterfront facilities in inventory, the Navy retains a strong technology base in design, construction, and maintenance of waterfront structures: such as piers, wharves, quaywalls, dry-docks, dolphin assemblies, and moorings. The Army maintains a similar capability for coastal harbor facilities, such as breakwaters, jetties, groins, and seawalls.

2-1.2.1 **Army**. Staff, command, and technical responsibility for maintenance and repair of waterfront structures at Army installations will conform to assignments set forth in AR 415 and 420-10 series. Policy and standards for the maintenance of shore protection works are contained in ER-1110-2-2902, *Prescribed Procedures for the Maintenance and Operation of Shore Protection Works*.

U.S. Army Engineer divisions and districts provide specialized expertise in evaluation of coastal erosion, and design and maintenance of coastal and harbor facilities.

\1\ /1/2-1.2.2 **Navy**. The Naval Facilities Engineering Command (NAVFAC), \1\ is /1/ responsible for organizing and performing waterfront inspection, maintenance, repair, and minor construction programs to support the Commanding Officer at each Naval shore installation. NAVFAC MO-322, *Inspection of Shore Facilities*, (Volumes 1 and 2) contains Navy guidelines for shore facilities inspection and preventive maintenance programs.

\1\ NAVFAC provides design, maintenance, and repair management expertise to assist the shore activities in carrying out their mission of maintaining waterfront facilities. Requests for assistance should be directed to the appropriate local NAVFAC office. /1/

Specialized expertise in waterfront materials, structures, and related topics can be provided to DOD and other Federal activities by the Naval Facilities Engineering Service Center (NFESC), Port Hueneme, California. Current criteria documents for maintenance and repair of waterfront facilities are developed and maintained by \1\ NAVFAC LANT CI1. /1/

The Navy's underwater construction teams (UCT) provide military responsive capability for construction, installation, inspection, repair, and removal of ocean facilities. \1\ NTRP 4-04.2.8, *Conventional Underwater Construction and Repair Techniques* and NTRP 4-04.2.9*, Expedient Underwater Construction and Repair Techniques*, provide guidelines /1/ for UCT teams in underwater inspection and repair techniques that may be useful to facilities maintenance personnel. UCT ONE is located in Norfolk, Virginia; UCT TWO is located in Port Hueneme, California.

2-1.2.3 **Air Force**. Policy and standards for the maintenance, repair, and minor construction of Air Force facilities are set forth in Air Force Instruction \1\ 32-1023, *Design and Constructing Military Construction Projects*. /1/

The installation commander, assisted by the Base Civil Engineer (BCE) and others on the staff, is responsible for identifying, planning, and programming all real property maintenance, repair, and minor construction requirements necessary to properly support assigned missions and people (including tenants) and to care for and preserve Air Force real property. Major commands provide oversight to ensure compliance with law, Department of Defense (DOD) and Air Force policies and are responsible for establishing quality standards. The Civil Engineer, HQ USAF/ILE provides programming guidance, oversight, and policy as required. The Air Force Civil Engineer Support Agency (AFCESA) and Air Force Center for Environmental Excellence (AFCEE) provide technical engineering guidance.

2-1.3 **Maintenance Standards and Criteria**.

2-1.3.1 **Engineering**. The need for and accomplishment of major repairs and rehabilitation of existing waterfront facilities will be based on experience, judgment, and engineering evaluation. The services of qualified technical personnel will be used to assist in the establishment of waterfront maintenance programs.

2-1.3.2 **Related Published Material**. \1\ Navy requirements for the design and construction of waterfront facilities are found in UFC 4-152-01, *Design: Piers and Wharves* and UFC 4-151-10, *General Criteria for Waterfront Construction*. These documents provide guidance and recommendations on port design and construction and port maintenance primarily for Navy activities. MO-322, NTRP 4-04.2.8, and NTRP 4-04.2.9 /1/ are especially important relative to inspection of waterfront structures. Maintenance of fendering systems and camels are described in MO-104.1. Reference to other published materials, which provide related or more extensive information on specific areas of waterfront maintenance, is made where appropriate throughout this handbook. A Glossary of waterfront terms is provided in this handbook.

2-1.4 **Maintenance Program**. The maintenance program shall be designed to include prevention of deterioration and damage, prompt detection of deficiencies, and early accomplishment of maintenance and repairs to prevent interruptions to operations or limiting full use of a facility. The Navy's principal guide for maintenance management is NAVFAC MO-321, *Facilities Management.*

2-1.4.1 **Planning and Economic Considerations**. In maintenance planning and execution, consider future expected use of each facility, the life expectancy of the facility, and the life cycle cost of periodic repairs versus replacing a facility or major components. The level of maintenance and programming of major repairs should be planned in consonance with the future requirement for the facility and planned replacement. When waterfront structures are in an inactive status, the maintenance policies will be in accordance with the inactivation plan.

2-1.4.2 **Inspection**. Periodic, rigorous inspections are necessary for an effective maintenance program. Types of inspections and detailed procedures for waterfront facilities are described in Chapter 5.

2-1.4.3 **Maintenance**. Maintenance is the recurrent day-to-day, periodic, or scheduled work that is required for a facility to be used for its designed purpose. It includes routine work undertaken to prevent damage or deterioration of a facility that otherwise would be more costly to restore. The more common concerns in maintenance of waterfront facilities are:

- Painting and protective coating.

- Routine replacement or mending of fender components (e.g., rub strips) to prevent damage to ships and the pier.
- Maintenance of utility systems to prevent outages.
- Routine mending of protective plastic wraps.
- Routine patching of small concrete spalls and cracks.
- Maintenance of the cathodic protection system.

Chapter 3 provides details of maintenance procedures in addition to descriptions of waterfront materials and deterioration causes.

2-1.4.4 **Repair**. Repair is the restoration of a facility to such a condition that it can be used for its designed purpose. The repair is done by overhaul, reconstruction, or replacement of deteriorated constituent parts or materials that have not been accomplished through maintenance. The more common repair projects for waterfront facilities are:

- Replacement or reconstruction of fender systems.
- Repair of eroded or failing quaywalls.
- Repair and resurfacing of pier decks.
- Reconstruction of major concrete spalls and cracks.

Chapters 6 through 10 provide details of repair options for waterfront structures. These sections are organized to guide engineering and maintenance personnel in selecting repairs to waterfront facilities. Each repair procedure is a stand alone document, with the repair description on the left and the illustration on the right hand page. In Sections 6, 7 and 8, repair procedures are numbered (for example, TR-1; timber repair number one) to permit identification and reference. For many of the repair procedures, problem definition and application constraints are also provided to guide the user in selecting the proper repair technique to match the problem.

2-2 **TYPES OF FACILITIES**. The types of waterfront facilities include:

- Berthing facilities for mooring and for providing support to ships and craft.
- Drydocks used for construction of ships and to expose the underwater portion of the ship for repair, modification, inspection, or maintenance.

- Coastal protection structures designed to protect shorelines or harbors.

- Components of waterfront structures such as fender systems, piling, dolphins, utility distribution systems, deck and mooring hardware, and fleet moorings.

2-2.1 **Berthing Facilities**. The basic facilities to provide berthing support for ships and craft are piers and wharves. These facilities provide a safe space for ships to moor and receive shore utilities and other hotel services. They provide a platform for loading and unloading cargo and personnel, transferring ordnance, receiving fuel, and performing ship maintenance; repair; and fitting out. Berthing facilities are also provided for tugboats, small craft, barges, and harbor support equipment.

2-2.2 **Piers**. Piers are berthing facilities that extend outward from the shore into the water. Piers may be used for berthing on one or both sides of their length. There are three types of pier structures with distinct differences in configuration: open, closed, and floating piers. Combination piers combine open and closed configurations.

Open piers are pile-supported platform structures that allow water to flow underneath. Pile supported piers can be single-deck or double-deck structures. Figures 2-1 and 2-2 show schematics of a single- and double-deck, open piers.

Figure 2-1 Single-Deck, Open Pier

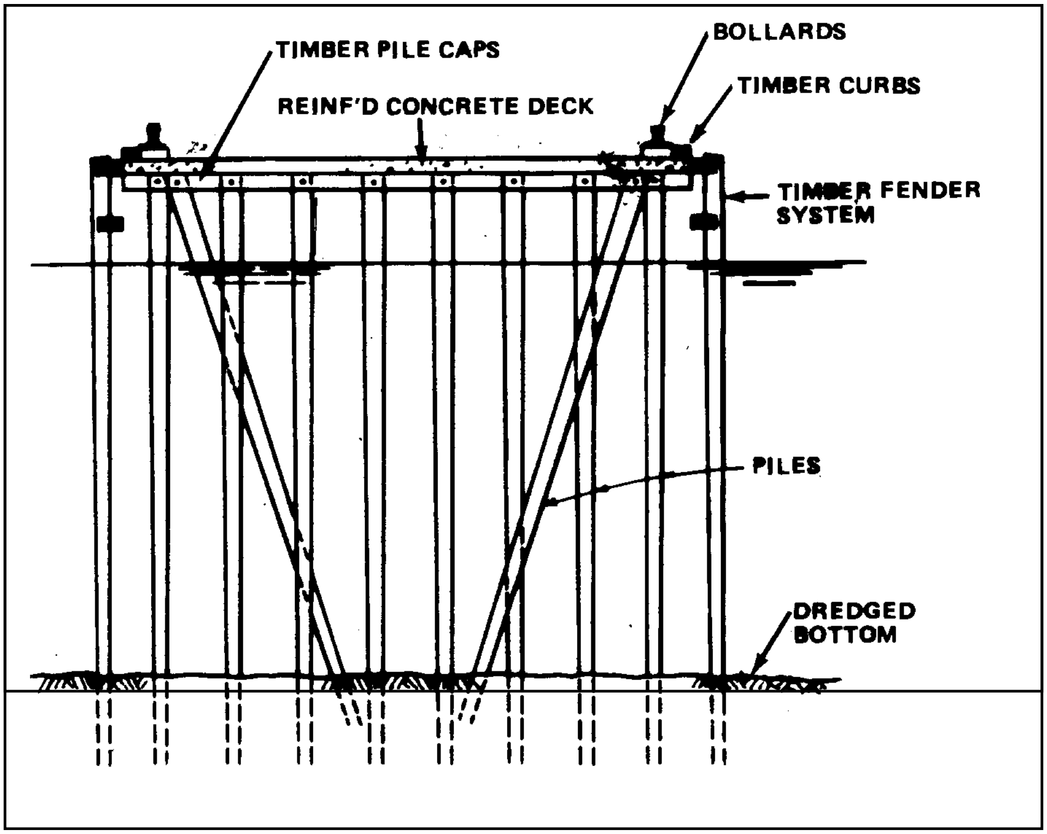

Figure 2-2 Double-Deck, Open Pier

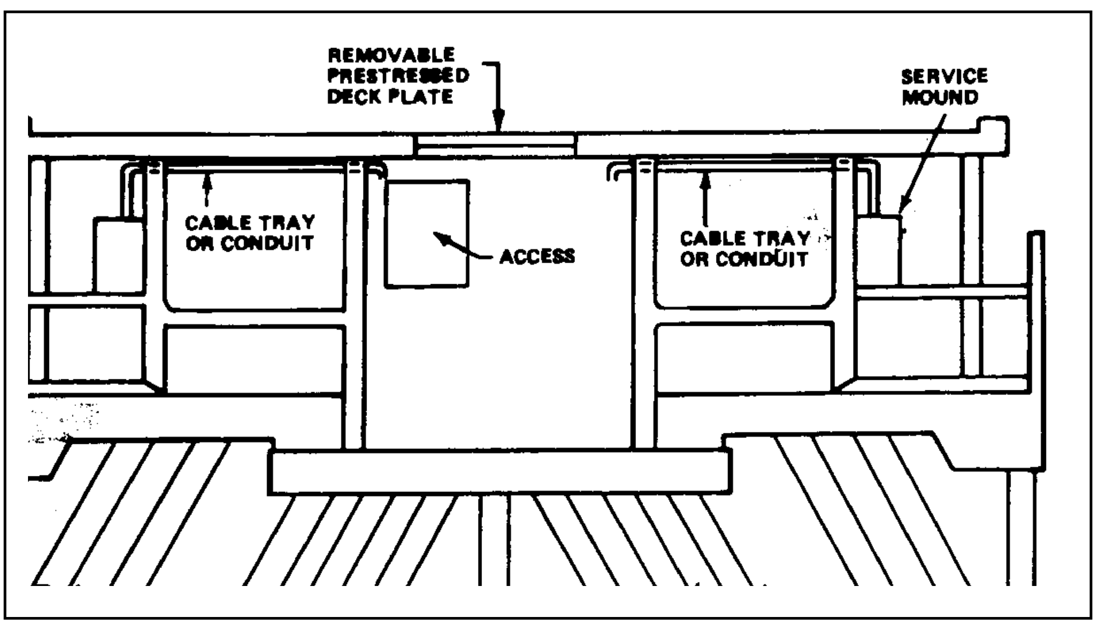

Closed piers, or solid fill piers, are constructed so that water is prevented from flowing underneath. The solid fill pier is surrounded along the perimeter by a bulkhead to hold back fill. Figure 2-3 shows a schematic of a solid fill pier. A special type of solid fill pier is a mole pier. Mole piers are earthen structures that extend outward from the shore. The sides and offshore end of the pier are retained and protected by sheet piles, circular cells or walls of either masonry or concrete. If the water is deep, the pier can be used to berth ships.

Floating piers are constructed of steel or concrete and are connected to the shore with access ramps. Guide piles in the center of the pier, or a chain anchorage system, prevent lateral movement and allow the pier to move up and down with the tide. The floating pier may be a single-deck or a double-deck structure. A floating pier design concept developed by the Navy is shown in Figure 2-4.

A more detailed discussion of the design and configuration of piers is documented in \1\ UFC 4-152-01 /1/, *Design: Piers and Wharves*.

2-2.3 **Wharves and Quaywalls**. Wharves are berthing facilities that are parallel to the shore. They are normally connected to the shore along their full length, and a retaining structure is used to contain earth or stone placed behind the wharf. This retaining structure is often referred to as the quaywall or bulkhead. Ships are moored along the outshore face of the wharf. The wharf types are the same as the basic pier types and include open and closed (or solid fill) configurations. Figure 2-3 shows a solid-fill pier with a configuration similar to a closed wharf.

2-2.4 **Drydocking Facilities**. Navy drydocking facilities are used to expose the underwater portion of ships for repair, modification, inspection, or maintenance. Several different types of drydocks exist, including graving drydocks, floating drydocks, marine railways, and vertical ship lifts.

- Graving drydocks are fixed basins adjacent to the water's edge and are constructed of stone masonry, concrete, or sheet pile cells. They can be closed off from the waterway by a movable watertight barrier (entrance caisson or flap gate). After closing the barrier, the basin is pumped dry, which allows the ship to settle on blocking set on the dock floor. Figure 2-5 shows a schematic of a graving drydock.

Figure 2-3 Solid-Fill Pier

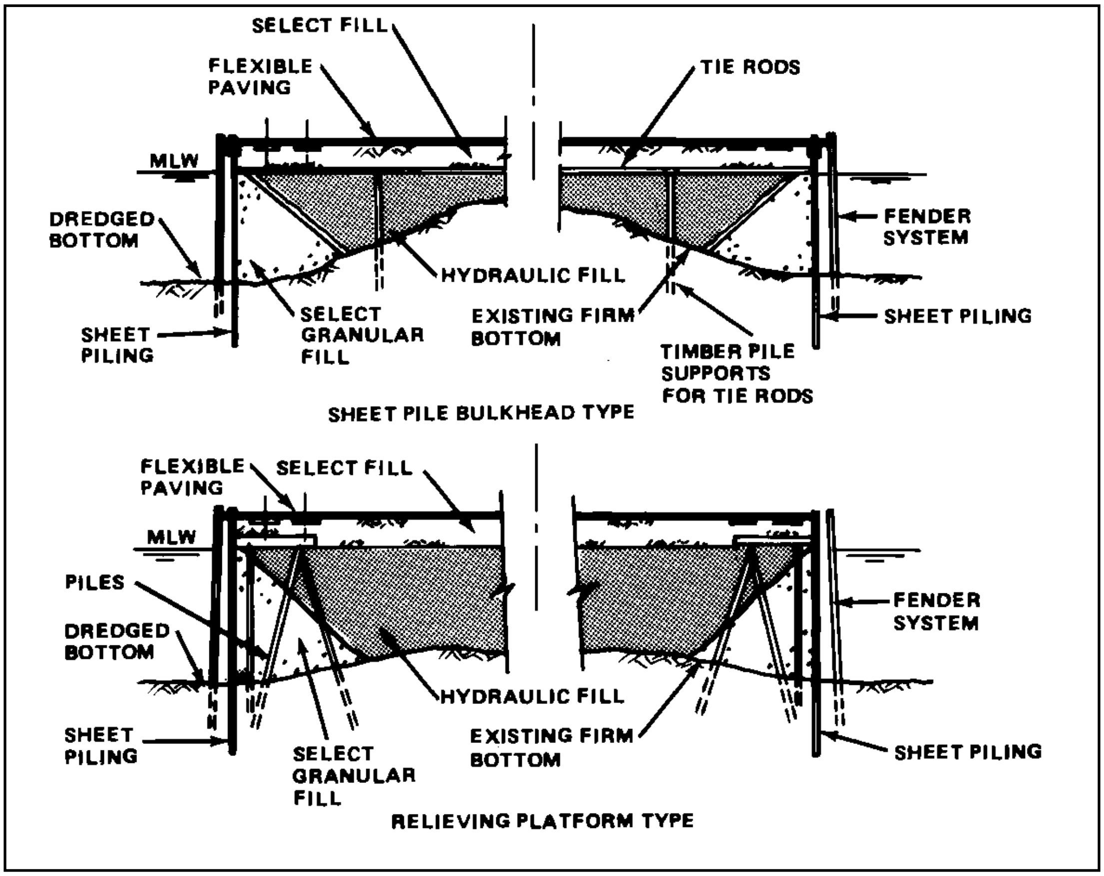

Figure 2-4 Floating Pier Design Concept

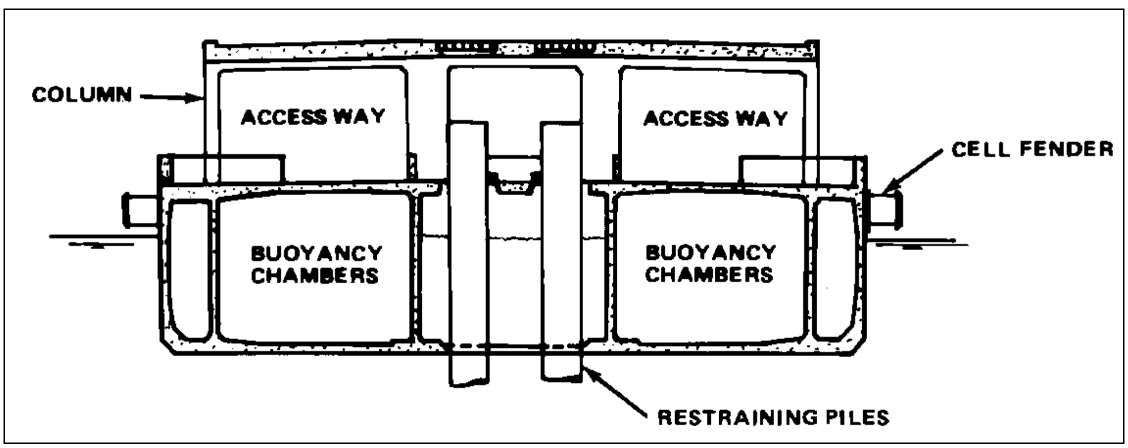

Figure 2-5 Drydocking Facilities

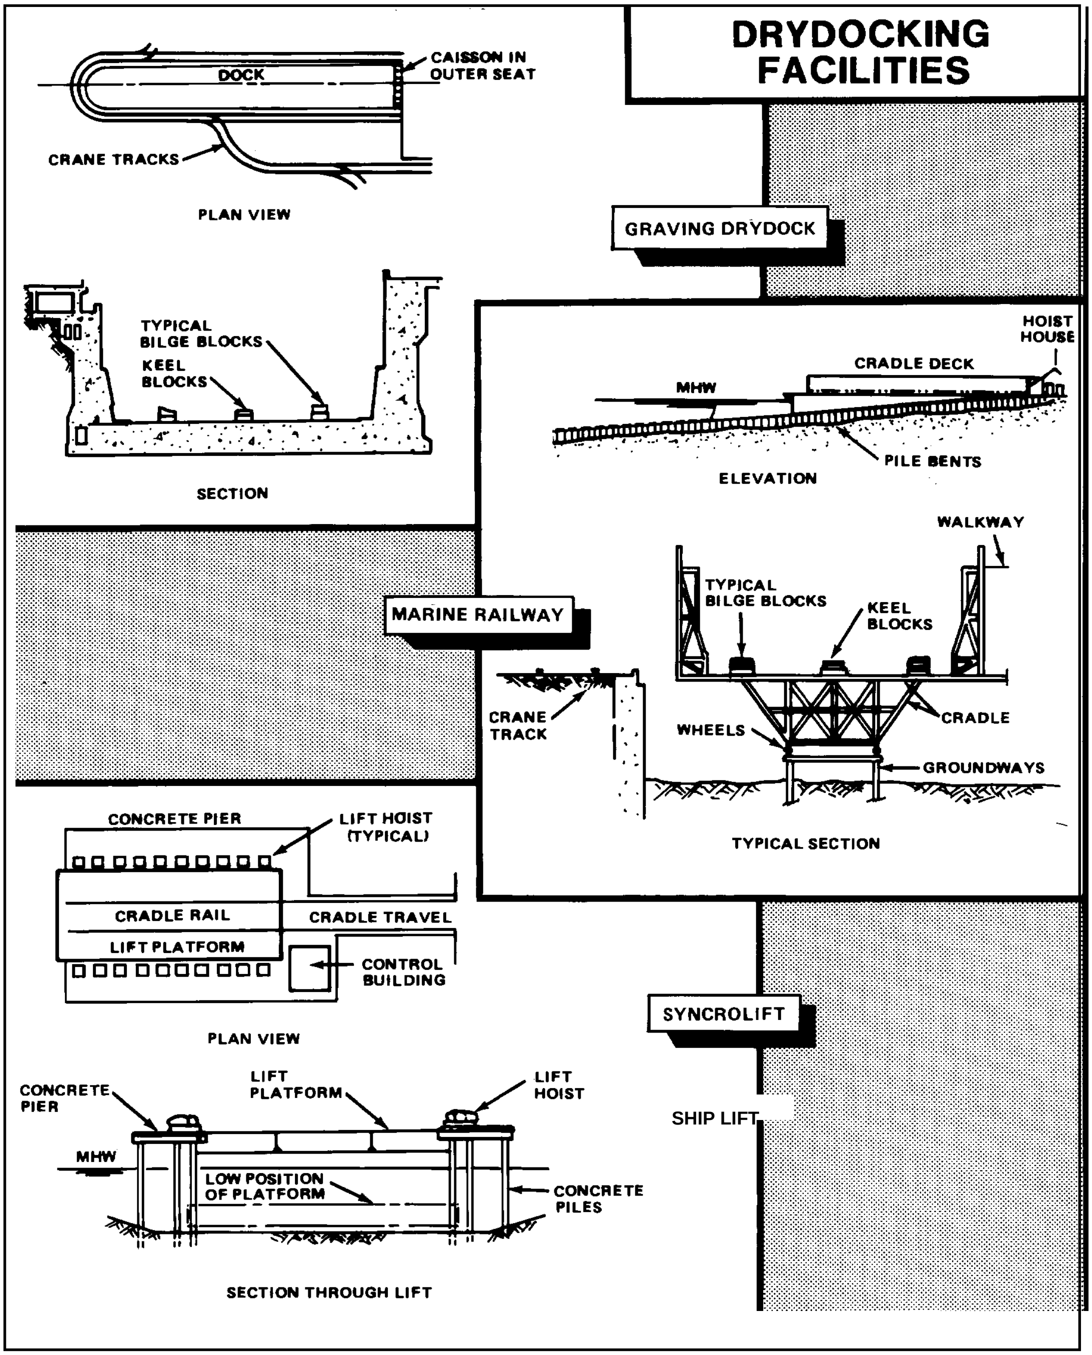


- Floating drydocks are ship or U-shaped structures that are submerged by flooding to permit a vessel to enter and then pumped dry to raise the vessel out of the water.

- Marine railways consist of a ramp extending into the water, a mobile ship cradle on wheels or rollers, groundway ship cradle tracks, hoisting machinery, and chains or cables for hauling the ship cradle endwise or sidewise. Figure 2-5 shows a marine railway.

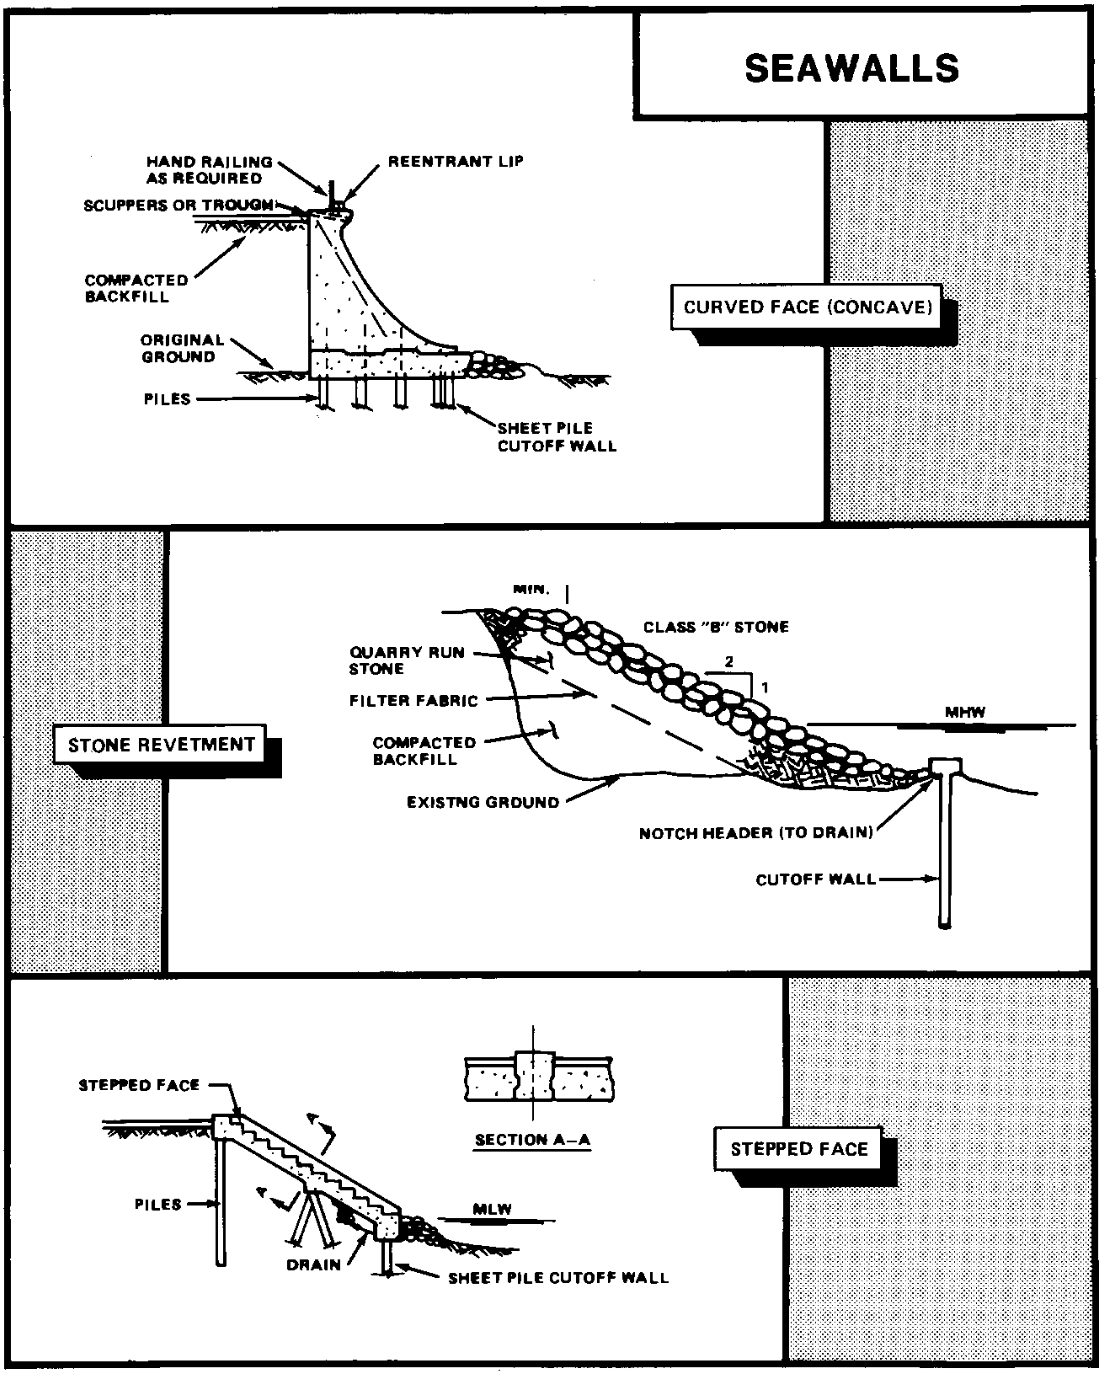
- Ship lifts consist of platforms that are lowered into the water to receive ships. The ship is then lifted out of the water on the platform by electrical powered hoist equipment. Figure 2-5 shows a vertical ship lift drydocking system.

More detailed discussions of drydocking and marine railway facilities can be found in \1\ UFC 4-213-10, *Design: Graving Drydocks* and UFC 4-213-12, *Drydocking Facilities Characteristics. /1/* Maintenance of drydocking facilities is not specifically covered in this manual.

2-2.5 **Coastal Protection Structures**. Structures designed to reduce the erosive effects of wave action, or to protect harbors from excessive wave action and the formation of sandbars, are classified as coastal protection structures. The common coastal protection structures are seawalls, groins, jetties, and breakwaters. \1\ The U. S. Army Corps of Engineers, *Shore Protection Manual* provides /1/ additional information on the design and configuration of coastal protection structures. Maintenance of coastal protection structures is not specifically covered in this handbook. Bulkheads are included, however, because they are an integral part of solid fill piers.

2-2.5.1 **Seawalls**. Seawalls are massive coastal structures built along the shoreline to protect coastal areas from erosion caused by waves and flooding during heavy seas. Seawalls are constructed of a variety of materials including rubble-mounds, granite masonry, or reinforced concrete. They are usually supplemented by steel or concrete sheet pile driven into the soil and are strengthened by wales and brace-type piles. Figure 2-6 shows three seawall configurations.

Figure 2-6 Seawall Configurations



2-2.5.2 **Groins**. Groins are structures designed to control the rate of shifting sand by influencing offshore currents and waves so that erosion of the shoreline is minimized. Groins project outward, perpendicular to the shoreline, and are constructed of large rocks, pre-cast concrete units, reinforced or prestressed concrete piles, steel sheet piles, or timber cribbing filled with rock. Figure 2-7 is an example of a groin.

2-2.5.3 **Jetties**. Jetties are structures that extend from the shore into deeper water to prevent the formation of sandbars and to direct and confine the flow of water due to currents and tides. These structures are normally located at the entrance to a harbor or a river estuary. Jetties are usually constructed of mounds of large rubble about a meter above the high tide mark. Figure 2-8 shows the position of jetties at a harbor entrance.

Figure 2-7 Groin

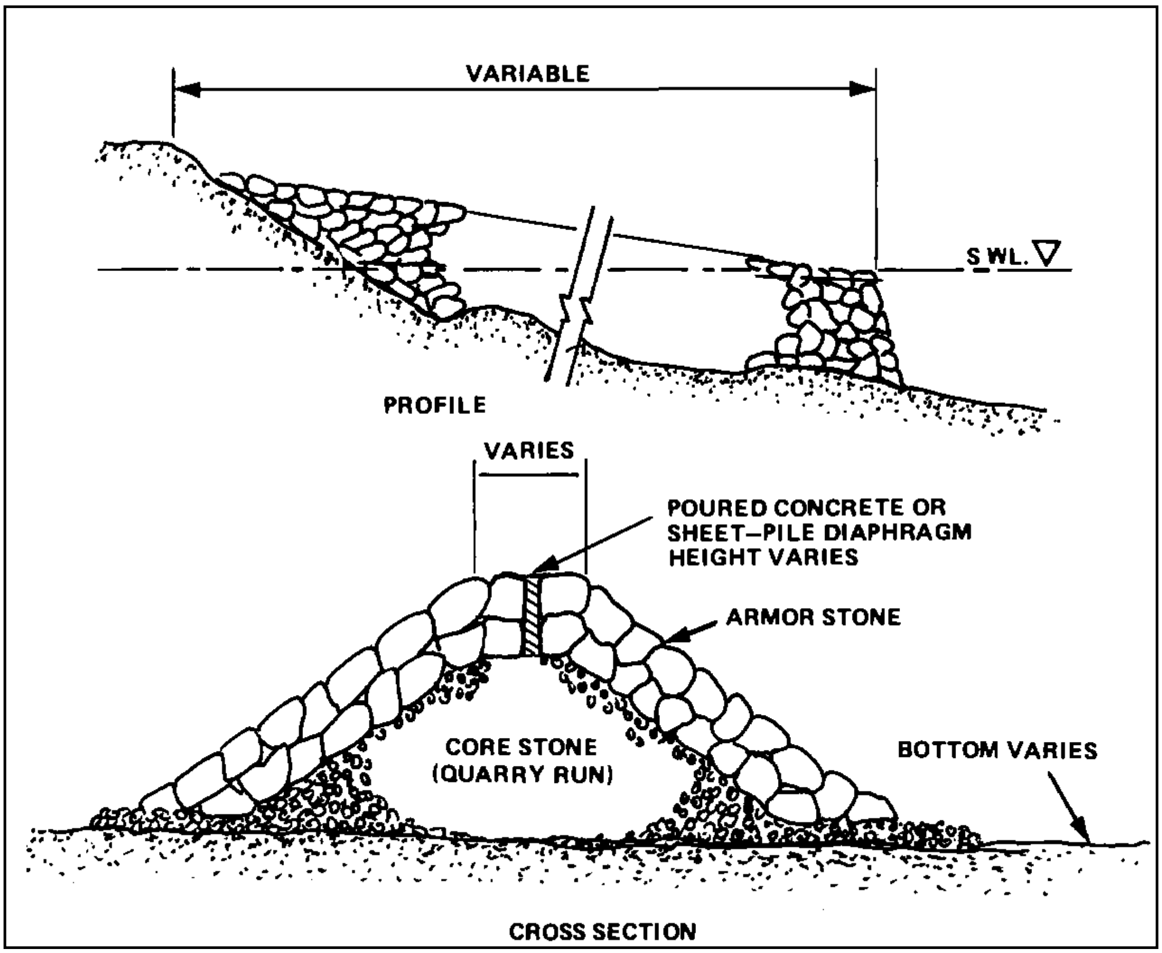


Figure 2-8 Typical Location of Jetties

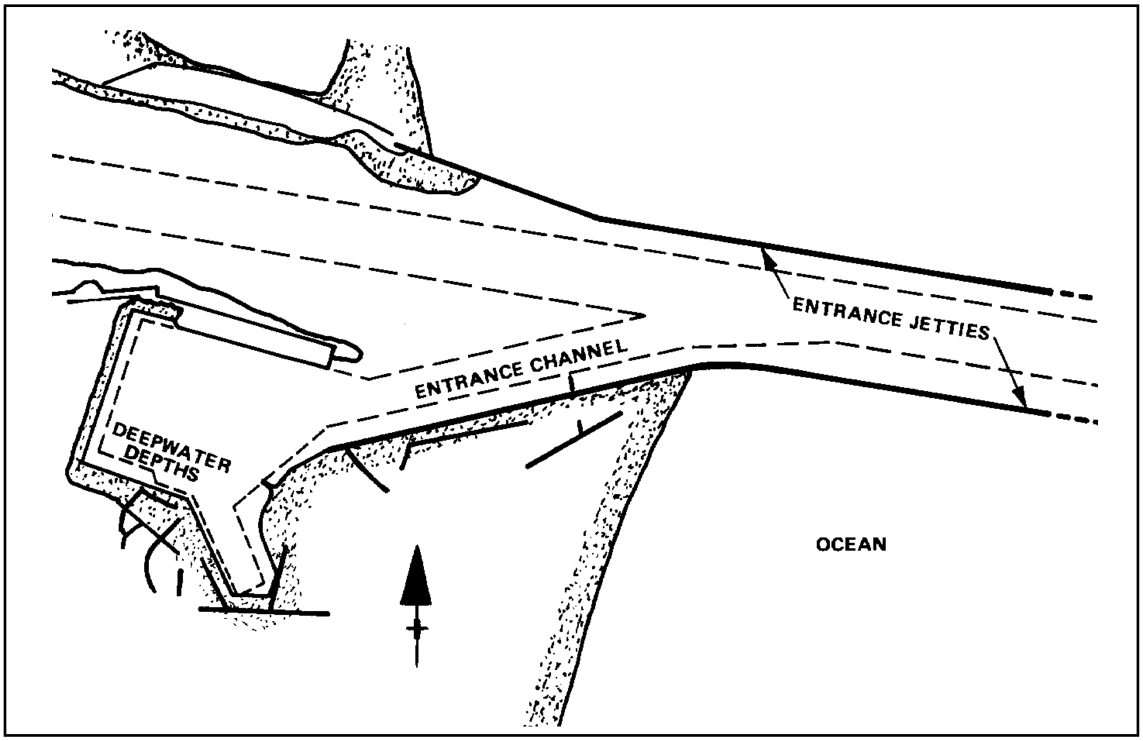
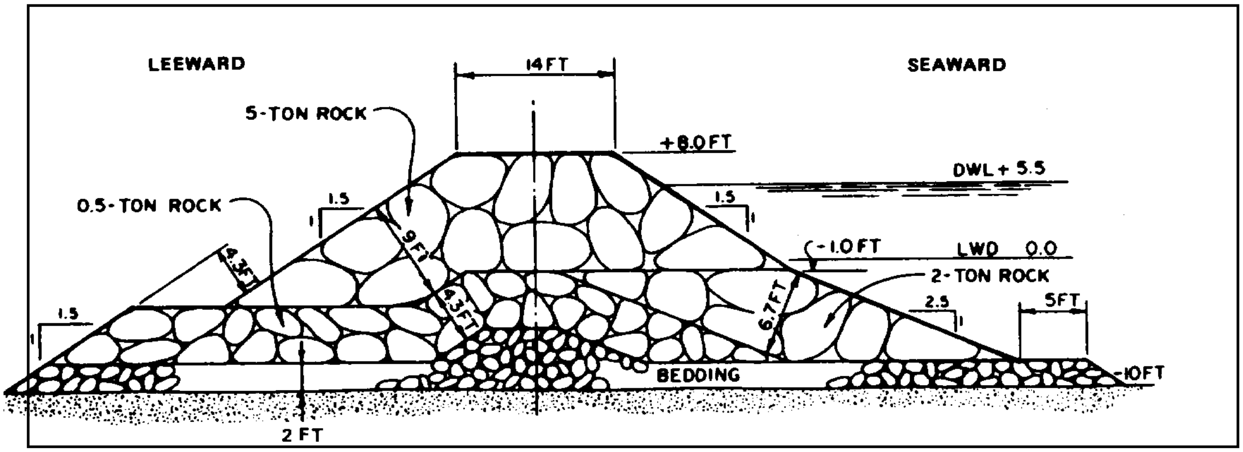


2-2.5.4 **Breakwaters**. Breakwaters are large rubble-mound structures located outside of a harbor, anchorage, or coastline to protect the inner waters and shoreline from the effects of heavy seas. These barriers help to ensure safe mooring, operating, loading, or unloading of ships within the harbor. Breakwaters may be connected to the shore or detached from the shore. There are three general types of breakwaters, depending on the type of exposed face. The exposed face may be vertical, partly vertical and partly inclined, or inclined. Figure 2-9 shows a section of a breakwater.

2-3 **COMPONENTS OF WATERFRONT STRUCTURES**. Numerous components of basic facilities are present at the waterfront to aid in port operations. These components are integral parts of piers and wharves and include fender systems, piling, dolphins, deck and mooring hardware, and utility distribution systems, or they may be offshore systems vital to ship operations, such as fleet moorings. Utility distribution systems and offshore systems are not specifically covered in this manual.

Figure 2-9 Breakwater Section



2-3.1 **Fender Systems**. Fender systems are used on piers to protect the ship and the pier during berthing operations and while the ship is moored. The most widely used fender system consists of timber fender piles, timber wales, and chocks, with rubber compression fender units between the system and the pier to absorb berthing impacts. This type of system is the highest maintenance cost portion of the pier. The trend is toward using longer lasting and more resilient fender systems with less reliance on treated timber because of environmental concerns.

The main types of fenders, and their components, that may be found installed in ports are:

- Fender pile systems: timber, steel, concrete, or composite piles.

- Fenders fixed to the pier ("rubber" refers to various elastomeric plastic materials):

  a. Rubber-in-compression units: cylindrical, rectangular, trapezoidal, wing-type, and D-shaped units.

  b. Rubber-in-shear fenders: rectangular rubber column and Raykin fender.

  c. Buckling fender: buckling column fender and cylindrical cell fender.

- Resilient, floating pneumatic and foam-filled fenders connected or suspended from the pier or backed up by closely driven steel or concrete fender piles. \1\ UFC 4-152-01 /1/ gives more in-depth descriptions of types of fender systems. The maintenance of fender systems is covered in MO-104.1.

2-3.2 **Piling**. Piling is an integral part of all open piers and wharves. The exposure of piling makes it susceptible to severe environmental attack: corrosion, marine borers, and erosion. Piling is made from concrete, wood, steel, or composite materials and requires protective coatings, preservatives, or wraps to ensure a long life.

There are four functional types of piling: vertical bearing piles, batter piles, fender piles, and sheet piles. Bearing piles are used to support the weight of the pier and loads on the pier. Batter piles provide lateral and longitudinal stability. Fender piles are used to absorb the impact of berthing ships. Sheet piling is used for various waterfront structures, e.g., quaywalls to retain fill.

2-3.3 **Dolphins**. A dolphin is a group of piles placed near piers and wharves, or in turning basins and ship channels. These structures are used to guide vessels into their moorings, to mark underwater structures (shoals or shore), and to support navigational aids.

2-3.4 **Fleet Mooring**. A fleet mooring is an offshore anchoring system that consists of various hardware items: chain, cable, sinkers, anchors, and buoys. The offshore anchoring system is placed in a fixed location so that vessels, when entering the port, can anchor to the buoys. NAVFAC MO-124, *Mooring Maintenance Manual* provides details on the maintenance of fleet mooring systems, therefore, they are not covered in this handbook.

2-3.5 **Deck and Mooring Hardware**. Various deck and mooring hardware, such as gratings, handrails, bollards, bitts, cleats, chocks and rings, are used on piers and wharves. These items require inspection and maintenance to ensure personnel safety and adequate mooring facilities for ships.

2-3.6 **Utility Distribution Systems**. Utility distribution systems are provided on most piers and wharves to service the ships. Utilities available at most piers and wharves include:

- Steam
- Potable water
- Saltwater
- Sewage and oily waste collection
- Compressed air

- Electricity
- Fuel
- Telephone service
- Fire alarm systems

These utility systems require maintenance of conduit, piping, valves, expansion joints, drains, regulators, and insulation. The maintenance of utility systems and their components is covered by various service manuals and commercial publications, and is not included in this manual.

CHAPTER 3

MATERIALS AND PREVENTIVE MAINTENANCE

3-1 **GENERAL.** Common structural materials used for construction and repair in waterfront areas are: wood, reinforced concrete, steel, and plastic. Selecting the proper materials and systems can reduce maintenance costs and increase the life of facilities. Wood preservatives, coatings, quality control of the reinforced concrete materials, cathodic protection, and carefully selecting alloys and synthetic materials help extend the life of the materials and structures.

This Section describes types of materials used in the construction and repair of waterfront facilities; types of deterioration, corrosion, and other problems that may be encountered; and preventive maintenance (PM) actions that should be taken. Table 3-1 summarizes PM actions that should be a part of all waterfront maintenance programs.

Table 3-1. Summary of Preventive Maintenance Actions

PREVENTIVE MAINTENANCE ACTION	PARAGRAPH TITLE
Wood and Timber – General	
Use pressure-treated member	Pressure Treatment
Treat exposed areas: cuts, bolt holes, pile tops	Field Treating Exposed Areas of Wood Before Installation
Embed fumigant in pile top	Encasements and Retardants
Use pile top bonnet and preservative	Encasements and Retardants
Timber Piles	
Install plastic wrapping or jacket	Protection of Timber Piles
Concrete - General	
Use Type II or V cement	Cement
Avoid marine aggregates	Aggregates
Provide adequate cover over reinforcing steel	Reinforcing Steel
Use coating on concrete above splash zone	Preventive Maintenance for Concrete
Treat cracks with a flexible elastomeric or with polyurethane injection	Treatment of Cracks
Steel – General	
Design Actions	
Select proper protective coating for immersed steel	Protective Coatings for Steel
Provide cathodic protection system	Cathodic Protection of Steel
Substitute corrosion resistant metals for steel	Nonferrous Metals and Alloys
Increase thickness to allow for corrosion over life cycle	
Minimize galvanic corrosion:	Preventive Maintenance for Nonferrous Metals and Alloys

Minimize use of different metals	Preventive Maintenance for Nonferrous Metals and Alloys
Insulate different metals from each other	Preventive Maintenance for Nonferrous Metals and Alloys
Maintain protective coatings	Preventive Maintenance for Nonferrous Metals and Alloys
Keep cathodic area small relative to active metal	

3-2 **WOOD AND TIMBER**. Wood and timber members have been used for construction and maintenance of waterfront facilities due to availability, economy, and ease of handling relative to other construction materials.

Common wood products used include: dimension lumber, timber, piles, and poles. Engineered wood products such as glued and laminated timbers (glulam) are common and, if, properly preserved or protected, may be used. Plastics and composites can be used as substitute materials for non-load bearing wood members. The primary applications at the waterfront include:

- Older piers, wharves, bulkheads, and quaywalls built from timber piles.
- Fender systems built from timber and round timber piles.
- Pile dolphins built from round timber piles.
- Floats and camels built from logs, timber, dimension lumber, glued and laminated wood, or miscellaneous forms.
- Groins built from timber and round timber piles.

\1\ One critical aspect of timber construction is connection hardware. Typcially, bolts are used. Problems observed from hardware misalignment and corrosion are exhibited in terms of: “necking down” of bolt shank, distortion/enlargement of washer holes, and bolt heads popping off or being drawn through the washer. /1/

3-2.1 **Maintenance.** Maintenance of wooden structures involves replacing decayed or damaged wood with properly treated wood or other suitable material. If repairs are to be reduced in the future, exposed wood and pile caps must be treated with an effective preservative to retain its strength and longevity against destructive fungi, marine organisms, insects, and bacteria attack.

Many wood species are used for treated dimension lumber and timber in the United States. Primarily, Douglas fir is used on the West Coast and southern pine is used on the East Coast due to availability. See Unified Facilities Guide Specification \1\ UFGS-06 13 33, *Pier Timberwork* /1/ for proper Navy procurement and product inspection criteria of pier timber work. Round timber piles for marine use are also usually made from Douglas fir or southern pine according to availability and size requirements for piling. For Navy use, these piles must conform to \1\ UFGS 31 62 19.13, *Wood Marine Piles*. /1/

All wood products, including treated wood, must be inspected by agencies certified by the American Lumber Standards Committee (ALSC) and must be properly graded and marked before acceptance. General Navy criteria for accepting wood products are well described in NAVFAC MO-312.2, *A Field Guide for the Receipt and Inspection of Treated Wood Products by Installation Personnel.*

3-2.2 **Wood Deterioration**. Biological and physical deterioration of wood can bring about rapid destruction of waterfront facilities. Improper design and construction procedures that lead to biological deterioration include:

- Inadequate preservative treatment.
- Improper handling of treated wood.
- A design that promotes retention of water.
- A design that unnecessarily places wood timbers below water.

Major design deficiencies, which promote physical deterioration, include:

- Insufficient strength of piles resulting in overloading (loss of strength and embrittlement caused by treatment with salts and other preservatives are an important design considerations).
- Improper connection hardware or pile connections that restrict load transfer to other parts of the structure.
- Inability of sheet pile walls to retain backfill or insufficient strength in the soil foundation that results in sheet pile movement.

3-2.2.1 **Biological Deterioration**. Wood-destroying organisms infest wood structures both above and below the waterline. Marine borers are the principle cause of deterioration in the immersed zones and are found in harbors and estuaries worldwide. Marine fouling organisms found on the wood surface do not cause wood deterioration and may even serve to retard marine borer damage. Insects and fungi are the main wood-destroying organisms above the waterline.

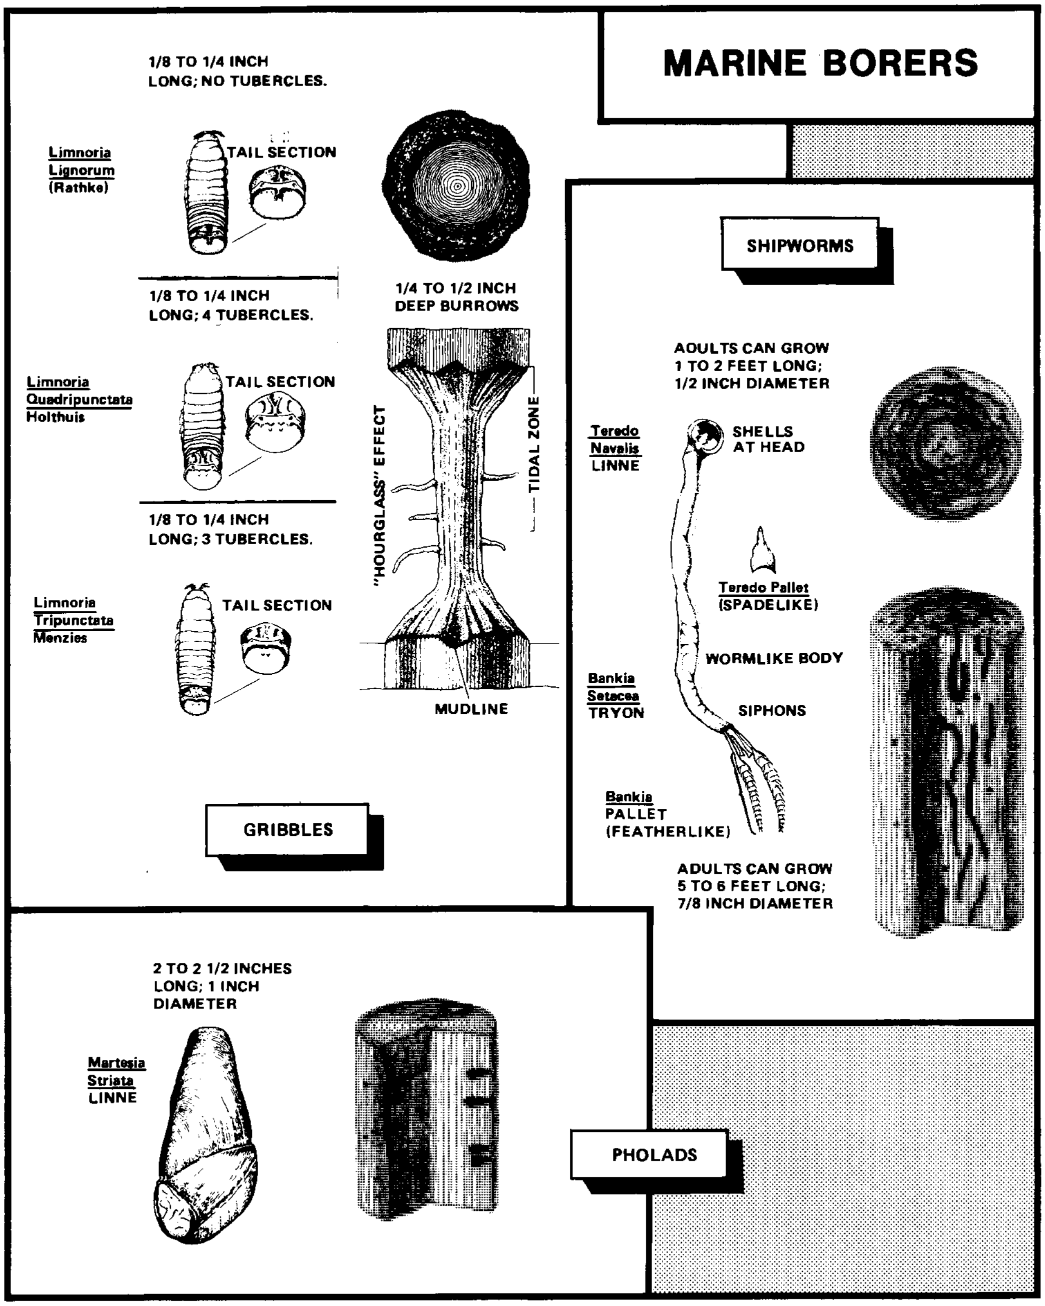
3-2.2.1.1 **Marine Borers**. There are two general types of marine borers that attack marine timbers: crustaceans and mollusks. The major wood-boring crustaceans are the Limnorians; the principle wood-destroying mollusks are the Teredines (Teredo and Bankia) and the Pholads (Martesia). See Figure 3-1.

- Crustaceans. Of the three common crustacean wood borers - Limnoria, Sphaeroma, and Chelura - Limnoria is considered to be the most economically important. These borers burrow just below the wood surface forming a network of interlacing tunnels. The weakened wood is easily eroded by wave action often resulting in a characteristic "hourglass" shape. Limnoria tripunctata is of particular importance because it can attack creosoted wood.

- Teredines. The Teredines are commonly referred to as "shipworms" because of their wormlike appearance. Penetration of the wood occurs during the microscopic larval stage. As the shipworms grow, their tunnels increase in diameter and length while the entrance holes remain about the same size. Attacked piles may appear sound on the surface, yet be completely riddled.

- Pholads. Pholads bore into wood, soft rock, or concrete for protection. These clams have pear-shaped shells that can reach 6 cm in length. Like the Teredines, Martesia can cause considerable structural damage to wood, but both of these mollusks can be more effectively controlled by creosote preservative treatment than the Limnorians.

Figure 3-1. Three groups of Marine Borers.[1]



•

NOTE: Gribbles are 1/8 to ¼ inch (3mm to 6mm) in length; Shipworms are 1 to 2 feet (30 to 60 cm) in length, 1/2 inch (12.7mm) in diameter; and Pholads are 2 to 21/2 inches (51mm to 63.5mm) in length.

[1] From *Oregon State Research Bulletin 48*, October 1984.

3-2.2.1.2 **Insects**. Termites are the most destructive wood-destroying insects found on waterfront structures. Other insect pests include: wood-boring beetles, ants, and bees. An insect frequently associated with damage to piers and docks is the wharf-borer, Nacerda, a beetle about 0.32 inch (8 mm) long, yellowish-brown to dark red in color. Some insects, such as termites, require wood for food and shelter; others, such as carpenter ants, require wood for nesting only. Most wood-destroying insects thrive under damp conditions.

3-2.2.1.3 **Fungi**. Three categories of wood-decay fungi are: white rot, which tends to bleach the affected wood; brown rot, often termed "dry rot," which produces a brown, crumbling type of decay; and soft rot, which softens the wood. Slight strength reduction of infected wood can be caused by stain fungi, which produce bluish black to steel gray or brownish discoloration of the wood. Molds also produce a discoloration of the wood surface and are regarded as merely a blemish, but their presence indicates that conditions may be favorable for decay organisms. Most wood-destroying fungi require damp conditions for growth.

3-2.2.2 **Physical Deterioration**. Physical deterioration of timber piles and other wood structures is generally due to the following causes:

3-2.2.2.1 **Abrasion**. Abrasion of timber piles occurs principally in the intertidal zone. The rate at which piles are destroyed by abrasion depends on the amount of floating debris in the harbor, the velocity of water moving past the piles, ice in the harbor, and the action of marine borers. Fender piles are also abraded by camels and ships.

3-2.2.2.2 **Overload**. Overloading of piles may result from a continuous heavy load or infrequent, severe loads. Overloading may be caused by vertical and horizontal loads. Failure of one pile requires the adjacent piling to carry the extra load. Continual overloading can lead to collapse of the entire structure.

3-2.2.2.3 **Connection Failure**. When a timber pile connection fails, the structure is free to move and will eventually fail. If untreated wood is exposed, connection failure may first allow the entry of marine borers if below the waterline, or insects and fungi if above the waterline.

3-2.2.2.4 **Timber Wall Movement**. Outward wall movement can result from horizontal loading of the backfill material caused by excessive loading behind the structure or failure of tie-backs. Loss of backfill material can result in movement in the opposite direction. If either condition continues, the structure will fail.

3-2.2.2.5 **Single Timber Piles.** Single timber piles or those used in light structures may be lifted by ice freezing to the pile and pulling it as the ice moves with the tide.

3-2.3 **Preventive Maintenance for Wood and Timber.** The primary preventive maintenance (PM) measure at the waterfront is to select the type of wood best suited for the particular use and to purchase wood products and timber piles that have been treated with quality preservatives and methods. Field techniques should be used to eliminate or minimize cuts and holes made in the members at the site, particularly for those members to be placed below water. If cuts and holes must be made, special field PM preservative treatment is required. In addition, there are other PM measures applicable to timber piles using encasements and retardants. The most important field PM for the exposed wood of waterfront buildings and related structures is the application of paint and other coatings. Preventive maintenance measures discussed in this section are summarized in Table 3-1.

3-2.3.1 **Pressure Treatment**. Pressure treatment of the outer sapwood of timbers with preservatives is the most important and effective method of protecting wood. Using pressure treatment allows the preservative to uniformly penetrate deeper and allows closer control of retention levels. The preservative penetrates the wood from .39 to 3.93 inches (1 cm to 10 cm), depending on the type of wood, and provides protection from fungi, marine borers, insects and bacteria. \1\ American Wood Protection Association (AWPA) /1/ Standards govern the treatment processes that must be performed on wood used in waterfront areas. MO-312.2, *A Field Guide for the Receipt and Inspection of Treated Wood Products by Installation Personnel,* is a field guide for acceptance of treated wood products and must be consulted by Navy activities and followed whenever treated wood is used.

The choice of preservative treatment depends on how and where the wood is to be used. Wood preservatives are classified in three categories: creosote preservatives, oil-borne preservatives, and water-borne preservatives.

3-2.3.1.1 **Creosote.** Creosote preservatives have been the most commonly used preservatives at the waterfront because they are not easily leached from the wood and are not corrosive to metals. Creosote and creosote-coal tar solutions, both derived from bituminous coal, can be used for immersed wood. Creosote is commonly diluted with petroleum oil for treatment of wood not subject to immersion. An important disadvantage of creosoted piling, however, is that it is readily attacked by the marine borer, Limnoria tripunctata. In addition, creosote and creosote solutions cannot be used where it may come in contact with people or where local environmental concerns have restricted its use in the marine environment. Consult your environmental office for the latest policies and regulations regarding its use.

3-2.3.1.2 **Oil-Borne.** Oil-borne preservatives are dissolved in a petroleum solvent and include pentachlorophenol, copper naphthenate, tributyl tin oxide, and copper-8-quinolinolate. Oil-borne preservatives are suitable for wood members out of the water for protection against insects and fungi but does not provide adequate protection against marine borers and, thus, cannot be used for immersed wood. Treated wood can be painted, does not swell and distort, is easily handled, and will not corrode metal. Before the solvent evaporates, it is more flammable than untreated wood. Pentachlorophenol is the most effective of these preservatives but is also highly toxic. Consult the Consumer Information Sheet and your safety and environmental office before you consider using it.

3-2.3.1.3 **Water-Borne.** Water-borne preservatives are toxic metallic salts dissolved in water for easier application. The water-borne preservatives include chromated copper arsenate (CCA), ammoniacal copper zinc arsenate (ACZA), and ammoniacal copper arsenate (ACA). Wood treated with one of these water-borne preservatives can be used either above or below the waterline (wood used below the waterline is treated at higher retention levels). In addition, these salts in combination with creosote (dual treatment) are more effective in preventing marine borer damage than any single treatment. Other water-borne preservatives for use above the waterline include acid copper chromate (ACC), ammoniacal copper citrate (CC), and ammoniacal copper quat (ACQ)-Type B.

3-2.3.1.4 **Negative Aspects**. All preservative treatments have drawbacks that should be considered. Metallic salts, for example, will seriously embrittle wood. More importantly, these toxic chemicals present environmental and personnel safety concerns. All treated wood should be supplied with a Consumer Information Sheet that provides use, handling, and disposal precautions. Proper safety procedures should be carefully followed.

Plans for handling pressure-treated wood removed from service should be carefully considered, especially in areas where the disposal of treated wood may be restricted. Alternatives to landfilling include reuse as landscape timbers, recycled as fuel, etc. Wood treated with CCA should never be used as a fuel, and treated wood should not be recycled as mulch. Other restrictions may apply; Consult with your environmental office.

3-2.3.2 **Field Treating Exposed Areas of Wood Before Installation**. Cut surfaces of wood members, pile cutoffs, bolt holes, and any other exposed surfaces of treated wood members must be treated in the field before installation. All exposed, untreated wood should be treated in accordance with \1\ American Wood Protectors Association, Standard U1, *Use Category System: User Specification for Treated Wood* /1/. Treat holes for bolts and wood plugs inserted in piles and timbers with the same general type of wood preservative originally used for the member. Bolt holes should be treated under pressure with a mechanical bolt hole treater, if available, or thoroughly saturated. Wood preservatives are restricted use pesticides and must be applied in compliance with applicable standards. Consult your safety office or nearest EFD applied biologist.

Timber pile tops, cut off after the pile is driven, expose the untreated heartwood of the pile to rapid decay. AWPA Standard \1\ U1 /1/ provides recommendations for preservative treatments for pile tops. Creosoted piles may be field treated with creosote solutions, or where particularly heavy coatings are required, a coal-tar roof cement meeting ASTM D4022/D4022M, *Specification for Coal Tar Roof Cement, Asbestos Containing*. Piles treated with ACA, ACZA, or CCA can be field treated with any of these water-borne preservatives. After field treatment, the pile top must be covered with a cap or bonnet consisting of two layers of tar saturated fabric, tar paper, or fiberglass cloth, which shall overlap the side of the pile at least 2 inch (5 cm) and securely fastened.

3-2.3.3 **Remedial Treatment of Wood**

3-2.3.3.1 **Fumigants.** Fumigants are used to prevent or eradicate fungal decay of large (6 by 6 inch (15 by 15 cm) or greater cross-sectional area) wood members. These products may be an available option in your area for waterfront structures. They are highly toxic, restricted use pesticides, and can be handled only by certified personnel. The most widely available product currently available is applied only by the manufacturer. Generally, an inspection of the prospective treatment site and a treatment plan is carried out by the contractor prior to actual treatments. Consult your environmental and safety offices before using these products.

3-2.3.3.2 **Brush On.** Brush on preservative pastes and bandages are commonly used as a remedial groundline treatment for southern pine utility poles. They may have some application to waterfront timbers. Diffusion of the preservative ingredients into the decayed portion of the wood depends on the moisture in the wood. Typically, the level of preservative penetration and long-term efficacy of these products is less than that of fumigants.

3-2.3.3.3 **Liquid Internal.** Liquid internal treatments are sometimes used when voids and cavities are present in wood. This treatment is not generally recommended for waterfront timbers. If voids and cavities are present, replacing the wood member is advisable.

3-2.3.3.4 **Solid Rod.** Solid rod treatments commercially available today are fused borate rods available in a variety of sizes. They are relatively easy and safe to handle. Like brush on pastes and preservative bandages, diffusion of the borate in these rods depends on wood moisture and the level of preservative penetration and long-term efficacy of these products is less than that of fumigants.

3-2.3.3.5 **Encasements and Retardants.** Two methods are available to protect timber pile tops by using encasements and retardants. They include:

- Remedial Treatment with Fumigant Vials. Commercial fumigant vials are embedded in the cut top of timber piles and slowly leach into the pile to retard and prevent rot. Holes are bored in the top of the pile, vials inserted, and the holes plugged with hardwood. See Figure 3-2. A pile cap can be installed (see following bulleted paragraph) after fumigants are applied. This method is useful where the pile top is accessible and subject to wetting by rain or spray. These are restricted use pesticides; application of fumigants over water is restricted in California and other areas. Consult your environmental or safety office before using.

- Pile Top Bonnet. This method uses liquid preservative in the pile top and a protective bonnet or cap fabricated of two layers of tar saturated fabric or tar paper or fiberglass. Formation of reservoir is optional. See the Paragraph entitled, “Field Treating Exposed Areas of Wood Before Installation” for selecting a preservative. This method can be used to repair a rotted pile top, as shown in Figure 3-3, or as a preventive measure on a sound pile.

Figure 3-2. Fumigant Vials for Timber Piles

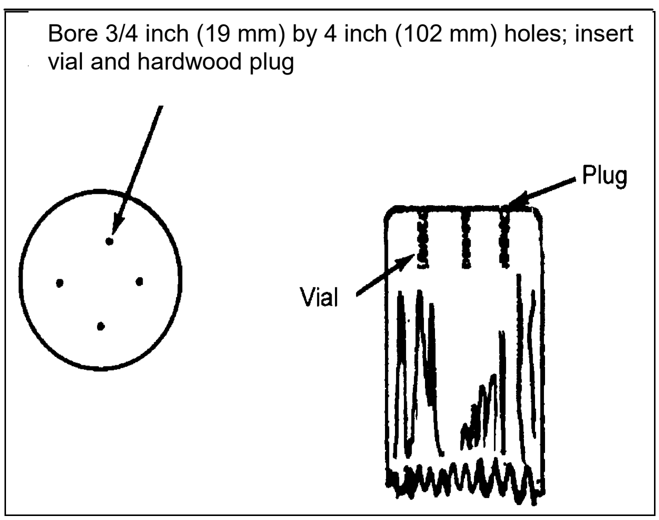


Figure 3-3. Pile Top Bonnet for Timber Piles

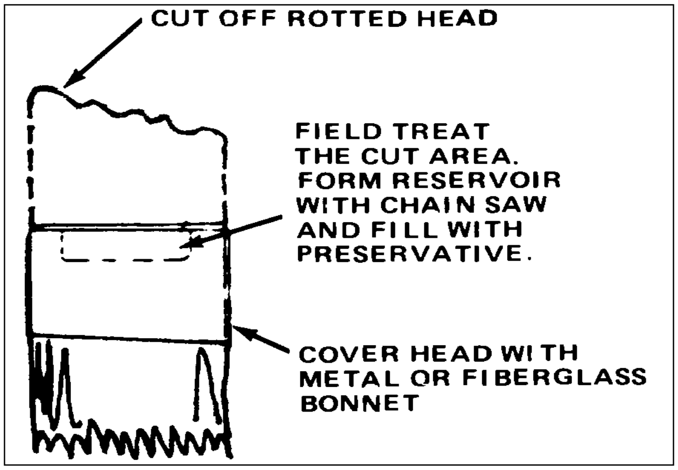


3-2.3.4 **Coatings for Wood Buildings.** Wooden structures continuously immersed in seawater or subject to immersion during tidal changes are not usually painted except for marking identification or location. In general, coating wood is confined to structures such as buildings located in waterfront areas to protect the wood from weathering and for appearance. Surface preparation of either previously coated wood or uncoated wood may consist of the following procedures:

- 100% removal of biological growth,
- removal of unsound coatings,
- removal of surface contamination such as oil, grease, dirt,
- light sanding of sound coatings and exposed wood.

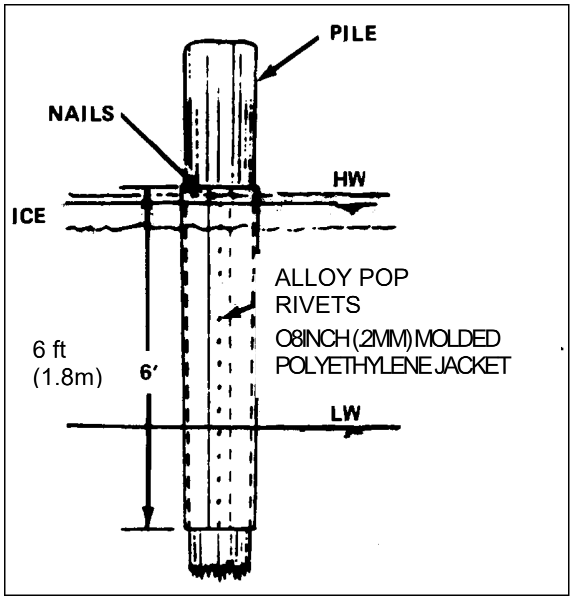
Two coating systems may be used for either previously coated wood or uncoated wood as follows:

- 40% volume solids, exterior latex (water-based): 1 or 2 coats at 1.97 to 5.9 mils (0.05 to 0.15 mm) dry film thickness (DFT)
- 55% volume solids, flexible acrylic waterborne (water-based): 1 or 2 coats at 3.94 to 11.81 mils (0.1 to 0.3 mm) DFT.

3-2.3.5. **Protection of Timber Piles.** All timber piling in the marine environment, including piling properly treated, are eventually attacked by wood destroying organisms. Pilings are also commonly subjected to ice lift and abrasion. As a result, protection with plastic wraps is often required, in order to minimize the impact of these environmental factors. In tropical environments, such as Roosevelt Roads, Puerto Rico, even dual-treated pilling should be wrapped.

The use of plastic wrapping to protect piling against marine borer damage, at and below the waterline, does offer considerable economic benefit by effectively eliminating borer damage, reducing future repair costs. The polyvinyl chloride (PVC) or polyethylene wrapping smothers borers already in the wood and prevents the entry of more borers. Installation of barrier wraps are described in repair technique TR-3 in Chapter 6. Fender piles pre-wrapped with a thick, heat-shrink polyethylene provides a slippery surface that prevents exposure of untreated wood due to wear from camels. An example of a molded polyethylene jacket used for ice protection is shown in Figure 3-4.

Figure 3-4. Timber Pile Jacket for Ice Protection



3-3 **CONCRETE**. Reinforced concrete is the predominant construction material for waterfront facilities due to its durability, strength, and economy as a bulk construction material. Steel and wood do not have the bulk properties and adaptability of concrete. In addition, basic components to make reinforced concrete are readily available at most locations. Applications of reinforced concrete at the waterfront include:

- Seawalls, bulkheads (quaywalls), and revetments use reinforced concrete as the dominant material of construction. It is used as the facing material to absorb wave impact, retain fill, and reduce the erosive effects of wave action. Concrete is used in piles, curved-faces, sheet piling, and other forms.

- Piers and wharves are usually built with reinforced concrete. Concrete is also used to protect wood or steel from corrosion, weathering, fungal decay, or marine organism attack. Prestressed concrete fender piles are effective and long lasting.

- Groins are built from concrete sheet piles and panels. The piles or panels are usually prestressed units and are tied in place with a concrete cap.

- Breakwaters use various shapes of precast concrete. These interlocking building blocks can be assembled in various shapes.

- Submerged structures use reinforced concrete that are cast in place or precast and used to support pilings and structures.

- Floating structures use reinforced concrete for pontoons, quays, wharves, piers, and facilities for small boats.

- Drydocks are made of reinforced concrete.

3-3.1 **Deterioration.** Deterioration of reinforced concrete near or in seawater is due to corrosion of the reinforcement. This corrosion can be accelerated due to improper concrete mix, insufficient concrete cover (thickness of concrete over the reinforcing steel), improper curing, operational loads, chemical attack, and volume changes. Using well established mix designs and construction practices, however, will enhance reinforced concrete durability.

Reinforced concrete in waterfront facilities must meet the criteria set by the American Concrete Institute (ACI) Standard 318, *Building Code Requirements for \1\ Structural /1/ Concrete*. This standard covers the building code requirements for concrete with and without reinforcing. Additional design information, with emphasis on waterfront facilities, is included in \1\ UFC 4-151-10, *General Criteria for Waterfront Construction*. /1/ These manuals provide general design and application data for a variety of waterfront structures. Unified Facilities Guide Specification UFGS 03 31 29, *Marine Concrete*, provides guidance for cast-in-place concrete subject to exposure to the marine environment. Unified Facilities Guide Specifications \1\ UFGS 31 62 13.13, *Cast-in-Place Concrete Piles*, UFGS 35 59 13.13, *Prestressed Concrete Fender Piling*, and UFGS 31 62 13.20, *Precast/Prestressed Concrete Piles*, provide guidelines on concrete piling. /1/

3-3.2 **Components of Concrete**. Concrete is a mixture of Portland cement, coarse and fine aggregate, and water. Various admixtures, and pozzolans may be used to improve the strength, workability, and service life. Preparation and proportioning of concrete mixtures should follow the recommendations of the Portland Cement Association's, *Principles of Quality Concrete*, and ACI 211, *Recommended Practice for Selecting Proportions for Concrete*.

3-3.2.1 **Cement**. Five types of Portland cement are described in \1\ ASTM C150 / C150M, Standard Specification for Portland Cement /1/. For concrete structures exposed to seawater, Types II and V should be used. Type II is a sulfate-resisting cement. Type V, however, is no longer being produced. Low alkali cements should be used with potentially reactive aggregates.

Do not use any product containing sodium or calcium, as it will likely accelerate the onset of rebar corrosion.

3-3.2.2 **Aggregates**. Aggregates are used in concrete mixtures to improve durability and reduce costs. They usually make up 60 to 80 percent of the volume of the concrete. The shape and size of the aggregate should meet the requirements specified in ASTM C330/C330M. Aggregates are a mixture of sand and rock. Marine aggregates, such as coral, should not be used. However, if marine aggregate is the only available material, it must be washed thoroughly with freshwater to remove the salt.

In some applications, special aggregates may be used to make lightweight concrete for lightweight structures. Most lightweight concretes have a density between 79.9 and 109.87 pounds/cubic foot (1,280 and 1,760 kg/m^3) compared to 149.83 pounds/cubic foot (2,400 kg/m^3) for normal weight concrete. Lightweight aggregate concrete is generally more durable in the marine environment than concrete made with normal weight aggregate.

3-3.2.3 **Water**. Water quantity and quality will affect the durability, strength, and workability of concrete. In practice, use water equal in quality to drinking water. The ratio of water to cement has a direct effect on the strength of the concrete and its permeability. A maximum water-to-cement ratio of 0.40 by weight is crucial for concrete used in a marine environment. Seawater should never be used for making concrete because the salts will dramatically increase the corrosion rate of reinforcing steel.

3-3.2.4 **Admixtures**. Various chemical admixtures are used to give specific properties to the concrete to improve durability, finishability or workability. If admixtures are required, they should meet the appropriate ASTM or ACI specifications.

3-3.2.4.1 **Water Reducing.** Water-reducing admixtures are available to allow a reduction in the water-to-cement ratio while maintaining a workable slump. Normal range water reducers and superplasticizers are admixtures that permit the reduction of the water-to-cement ratio.

3-3.2.4.2 **Air-Entraining.** Air-entraining admixtures are available to improve the concrete's ability to resist freeze-thaw conditions and enhance workability. Air-entraining agents should be used to incorporate from 5 to 7 percent of entrained air into the concrete. \1\ ASTM C233 / C233M, Test Method for Air Entraining Admixtures for Concrete /1/, covers the air-entraining agents. Air-entraining agents also improve the workability of the concrete.

3-3.2.4.3 **Accelerator.** Accelerator admixtures are available for rapid setting products. These increase the early strength of concrete but have little effect on the final strength. Accelerators containing excessive chloride should not be used since they increase corrosion of reinforcing steel.

3-3.2.4.4 **Pozzolan Minerals.** Pozzolan minerals (fly ash Class F) are highly recommended as a replacement of 25% of the Portland cement. The ash reduces permeability, eliminates alkali-silicon reactions, and improves workability. Silica fume can reduce permeability but may cause finishing problems and surface cracks. Avoid silica fume dosages about 5% by weight to concrete.

3-3.3 **Reinforcing Steel**. Reinforcing steel for concrete in waterfront facilities is the same as for conventional concrete structures and should conform to ASTM A615,*Specification for Deformed and Plain \1\ Carbon-Steel /1/ Bars for Concrete Reinforcement* \1\ or ASTM A996/A996M, *Specification for Rail-Steel and Axle-Steel Deformed Bars for Concrete Reinforcement* /1/. Place 3.15 inch (8 cm) concrete cover, which is critical for durability, over the plain steel. \1\ /1/

3-3.4 **Special Types of Concrete Mixtures**. Special concrete mixtures include polymer concrete and polymer-Portland cement concrete. Concrete mixtures containing polymers are useful for repairing concrete and may provide improvements over conventional concrete mixtures when used and applied correctly.

3-3.4.1 **Polymer .** Polymer concrete does not contain Portland cement. Epoxy concrete is one common type of polymer concrete that is readily available and possesses excellent bond and tensile strength qualities. Use extreme caution when using polymer concretes for structures subject to thermal resistance due to a high coefficient of thermal expansion that often results in repair failure.

3-3.4.2 **Fiber Reinforced.** Fiber reinforcements may improve the tensile strength, toughness, and ductility of concrete. In general, steel fibers should not be used in the marine environment. Polypropylene fibers avoid the corrosion problem of steel fibers and improve impact resistance. Fiber should not be considered as a replacement for the reinforcement.

3-3.5 **Causes of Concrete Deterioration**. Cracking and spalling of concrete are the results of chemical attack and rebar corrosion.

3-3.5.1 **Chemical Attack**. The most common chemical attack is from sulfates in seawater that cause a softening of cement paste. Other causes of chemical attack are poor quality aggregates reacting with alkali in the cement (alkali-aggregate reaction). The alkali-aggregate reaction expands the aggregate and results in cracking throughout the concrete in the presence of moisture. Use of 25% Class F fly ash is extremely effective in reducing chemical attack.

3-3.5.2 **Corrosion of Reinforcing Steel**. The high alkalinity of cement paste protects steel from corrosion. With improper mix designs, chloride contamination and carbonation eventually reduce the alkali film around the steel. Corrosion will then occur if sufficient moisture and oxygen are present. In the splash zone, the wet and dry cycles provide conditions for the chloride and oxygen to corrode the steel. Accordingly, steel corrosion in concrete is most severe directly above the mean low water (MLW).

When steel corrodes, the rust product increases in volume many times over its original volume. Expansion of the rust causes cracking of the concrete. These cracks run parallel to the reinforcement. Eventually, concrete covering the reinforcing steel spalls off.

3-3.5.3 **Cracking of Concrete**. As concrete dries it shrinks, which in turn, can cause cracks. These cracks may increase in size as the internal water is lost over time and the concrete cannot contract freely. Temperature changes can also cause cracking. In addition, freezing water in the concrete can lead to deterioration, cracking, and spalling. Overload conditions can cause cracks. Waterfront structures are subject to settlement conditions. When settlement is uneven, cracks usually result.

Shrinkage cracking can be minimized by proper curing and using a minimum amount of cement and water in the mix. Temperature cracking can be controlled in concrete by using expansion joints and temperature reinforcement. Air entrainment is critical to minimize freeze-thaw damage.

Prevention and control of cracking may be improved by proper design of the concrete structure and measures taken during construction. The measures that must be taken during repair of concrete structures are discussed in Chapter 7.

3-3.6 **Preventive Maintenance for Concrete**. Measures to minimize deterioration of reinforced concrete must be taken during design of the structure and during construction. Proper design for concrete is contained in ACI standards and service design manuals.

The main objectives of preventive maintenance are to:

- Keep water out of the concrete.
- Protect the reinforcing steel.
- Prevent and control cracking.
- Prevent chemical actions.

The primary PM measure that should be considered for existing reinforced concrete structures is the application of a surface coating. Coatings should be reapplied periodically to concrete that was coated when new. This measure can be applied to old concrete but rebar corrosion, the principal cause of concrete deterioration and the reason these PM measure are applied, will not likely be inhibited.

The treatment of cracks, described briefly in this Chapter, is best considered as a repair technique and is presented in detail in Chapter 7.

3-3.6.1 **Surface Coatings for Concrete Waterfront Structures**. Sound concrete piles and other waterfront concrete structures are generally left uncoated and provide years of excellent service. Existing concrete structures, above the splash zone, however, may be successfully coated for aesthetics, for marking purposes, and for protection against wind driven rain and sand, and salt spray. The application of a coating over a penetrating sealer is not recommended because the sealer reduces the bond strength of the coating to the concrete.

It is both difficult and labor intensive to coat immersed concrete and concrete in the splash zone. These areas require using either cofferdams or divers to apply "splash zone mastics," high performance coatings that cure underwater, and other specialty coatings. The benefit of applying these coatings, however, may not warrant the high cost.

3-3.6.2 **Coatings for Deck Marking**. For use in identifying walkways and traffic lines, the following marking paints may be applied to clean/dry concrete decks.

- 54% volume solids, solvent-based, chlorinated rubber: 1 coat at 7.87 to 9.84 mils (0.2 to 0.25 mm) DFT
- 50% volume solids, solvent-based alkyd: 1 coat at 7.87 to 9.84 mils (0.2 to 0.25mm) DFT
- 60% volume solids, waterborne acrylic (water-based): 1 coat at 7.87 to 9.84 mils (0.2 to 0.25mm) DFT

3-3.6.3 **Other Coatings**. Concrete buildings above the splash zone may be coated for aesthetics and protection against wind driven rain. Surface preparation of concrete surfaces may consist of the following sequential procedures:

- 100% removal of biological growth
- removal of unsound coatings
- removal of surface contamination such as oil, grease, dirt, and efflorescence
- removal of weak surface cement (laitance)
- removal of surface chloride contamination
- brush-off blasting of sound coatings
- light abrasive blasting of uncoated concrete

The below acrylic system may be used as an overcoat for sound coating systems whereas all three systems are acceptable for use on uncoated concrete.

- 55% volume solids, flexible acrylic waterborne (water-based): 1 to 2 coats at 3.94 to 15.75 mils (0.1 to 0.4 mm) DFT

- Two-component, epoxy polyamide primer followed by two coats of a flexible acrylic topcoat: 3 coats at 19.67 mils (0.5 mm) total DFT (5.9 mils (0.15 mm) primer, 7.87 mils (0.2 mm) topcoat

- Two-component, epoxy polyamide primer followed by two coats of a two-component, aliphatic urethane topcoat: 3 coats at 9.84 mils (0.25 mm) total DFT (5.9 mils (0.15 mm) primer, 3.94 mils (0.1 mm) topcoat, 3.94 mils (0.1 mm) topcoat)

3-3.6.4 **Treatment of Cracks**. Cracks in concrete are typically caused by shrinkage during curing, thermal expansion and contraction, rebar corrosion, operational loading, or structure settlement. Cracks are routed out and repaired using a flexible elastomer over bond-breaker tape. Hairline cracks may be repaired by pressure injecting polyurethane or methyl methacrylate through injection ports. Chapter 7 provides details of materials and procedures to use to repair both static and dynamic cracks in concrete.

3-4 **STEEL**. Steel is used extensively in construction and repair of water-front facilities due to availability, cost, ease of fabrication, physical and mechanical properties, and design experience. Structural steel and cast or fabricated steel are used in all areas of the waterfront. Typical applications include:

- Piers and wharves use steel H-piles or pipe piles to support or brace the structure. Structural steel shapes are used for framing.

- Bulkheads and quaywalls use interlocking steel sheet piling with tie rods and wales. Steel sheet piling is used to retain fill.

- Fender systems incorporate steel H-piles.

- Mooring hardware such as cleats, bollards, bitts, and chocks are made from cast or fabricated steel.

- Other items such as utility lines, grating, opening frames, manhole covers, fences, bolts and nuts, handrails, and concrete reinforcement are made of steel.

- Steel components are used in some camels.

Maintenance of steel structures and components will entail repair or replacement of damaged or corroded steel, periodic coating of steel surfaces for corrosion protection, and maintenance of cathodic protection systems. Although physical damage from impact or loading may occur, corrosion is the major cause of the deterioration of steel structures. The extent or severity of corrosion will vary with the exposure zone of the material; that is, whether it is in the atmospheric zone, the splash or tidal zone, or the submerged zone. The selection of materials for waterfront use must consider each of these varied conditions. \1\ Additionally, instances of failure of steel structures, i.e. sheet pile bulkheads with interior wales resulting from galvanic incompatibility have occurred. Consult NFESC metallurgist for proper selection of materials. /1/

The use of steel should follow design guidelines in \1\ UFC 4-151-10, *General Criteria for Waterfront Construction*; UFC 3-301-01, *Structural Engineering*, /1/ and the American Institute of Steel Construction's *Manual of Steel Construction*. The material specifications of ASTM and other organizations document chemical and physical characteristics of the various types of steel. Material selection and procurement should conform to these specifications.

3-4.1 **Steel for Waterfront Construction**. Carbon steel and carbon steel alloys are the most important types of metals used for construction of waterfront facilities. In general, only low carbon steels with a carbon content less than 0.35 percent by weight are used due to welding characteristics.

3-4.1.1 **Carbon Steel**. Carbon steel is an alloy of iron and carbon with a carbon content less than 2 percent. The requirements for structural carbon steel are contained in ASTM A36/A36M and this grade is suitable for welding.

Carbon steel will corrode in all exposure zones, but the most severe corrosion occurs in the splash zone and just below MLW. Coatings and cathodic protection are necessary to prevent excessive corrosion of steel in the waterfront environment. Coatings are covered in the Paragraph entitled, "Protective Coatings for Steel". Cathodic protection is covered in the Paragraph entitled "Cathodic Protection of Steel".

3-4.1.2 **Low-Alloy Carbon Steels**. Corrosion resistant, low-alloy carbon steel may be used instead of carbon steel if greater corrosion resistance is required. Low-alloy carbon steels contain small amounts of other elements such as copper, chromium, nickel, molybdenum, silicon, and manganese. Up to 1.5 percent of these elements is added for increased strength or heat treatment capability. These alloys have a better resistance to corrosion because the rust does not easily break away from the metal surface.

The common low-alloy steels include:

- ASTM A690/A690M, \1\ Specification for High-Strength Low-Alloy Nickel, Copper, Phosphorus Steel H-Piles and Sheet Piling with Atmospheric Corrosion Resistance for Use in Marine Environments /1/, (also called "Mariner steel").

- ASTM A572/A572M, *Specification for High-Strength, Low-Alloy Columbium-Vanadium \1\ Structural Steel /1/*.

- ASTM A242/A242M, *Specification for High-Strength, Low-Alloy Structural Steel*.

Steel conforming to ASTM A690/A690M is recommended for steel H-piles and sheet piling, because of its greater corrosion resistance over plain carbon steel in the splash zone. The low-alloy steels offer no more resistance to corrosion than ordinary carbon steel, however, when submerged. Under this condition, the low-alloy steels require coatings or cathodic protection, or both. Composite piles of ASTM A690/A690M and ASTM A36/A36M, *Specification for \1\ Carbon /1/ Structural Steel* may be used when more resistance in the splash zone is required. ASTM A242/A242M steels are not recommended for buried structures, submerged conditions, and marine atmospheres unless they are exposed to the wind, rain, and sun.

Coatings for, and cathodic protection of, low-alloy steels are the same as for plain carbon steel as discussed in the Paragraph entitled, “Preventive maintenance for Steel”.

3-4.1.3 **Stainless Steels**. Stainless steels have application in the marine environment under certain conditions. They do well when exposed to wind, rain, sun, or high-velocity conditions in seawater. In calm or stagnant waters, salt spray zones, or in buried conditions, corrosion is likely to occur. Stainless steels in the 300 series (302, 304, 316) are substantially more corrosion resistant than the 400 series stainless steels. Except in certain atmospheric environments, stainless steels should only be used for specialized applications where performance experience has been superior to more commonly used materials to justify the high cost.

3-4.2 **Deterioration of Steel**. Although exposure to the atmosphere, severe temperature changes, and wind erosion all contribute to the deterioration of steel in waterfront facilities, exposure to saltwater is the major concern. Corrosion rates of metals exposed to seawater are much higher than those of similar metals exposed to freshwater.

Biological fouling, the growth of marine organisms on the steel, also contributes to increased corrosion. This type of fouling can be decreased by using antifouling coatings.

The other major causes of deterioration are: wave and current effects, abrasion from objects, and elements in the seawater.

3-4.3 **Preventive Maintenance for Steel**. The primary preventive measures available to increase the life of steel are protective coatings and cathodic protection. The decision of which approach to use is a function of location on the waterfront structure (submerged or not) and economics. The use of cathodic protection is restricted to submerged or buried structures.

3-4.3.1 **Protective Coatings for Steel**. Steel in a marine environment will corrode freely if left unprotected and without a coating system. Coating systems are designed according to three marine zones:

- constantly submerged
- intertidal and splash zone
- above the splash zone

Steel in the submerged zone is best protected through a combination of a coating system and cathodic protection. Maintenance coating systems are employed as follows:

- Overcoats on sound coatings
- Repairs to coating systems with spot failing
- Complete reapplication where coating systems have failed

Surface preparation of previously coated steel may consist of the following sequential procedures:

- 100% removal of biological growth
- removal of unsound coatings and rust
- removal of surface contamination such as oil, grease, dirt
- removal of surface chloride contamination
- brush-off blasting of sound coatings
- abrasive blasting of uncoated steel to produce an angular anchor profile between 2 to 3 mils (0.05 to 0.08 mm)

3-4.3.2 **Coating Systems.** The below coating systems have displayed high performance and may be used for either spot repairs or complete reapplication. It is recommended that a coating specialist be contacted prior to specifying one of the below coating systems for overcoating sound coatings. DOD and other Federal activities may wish to contact an NFESC coating specialist.

3-4.3.2.1 **Submerged**

- Underwater cure, two-component, 100% solid liquid epoxy: 1 to 2 coats at 7.87 to 11.81 mils (0.2 to 0.3 mm) DFT
- Underwater cure, two-component, 100% solid epoxy putty: 1 coat at 118.1 to 236.22 mils (3 to 6 mm) DFT

3-4.3.2.2 **Intertidal/Splash Zone**

- Two-component, coal tar epoxy: 1 to 2 coats at 7.387 to 15.75 mils (0.2 to 0.4 mm) DFT
- Single-component, coal tar urethane: 1 to 2 coats at 3.94 to 11.81 mils (0.1 to 0.3 mm) DFT
- Three-component, aggregate-filled epoxy: 1 coat at 118.1 to 236.22 mils (3 to 6 mm) DFT
- Additional systems are presented in \1\ UFGS 09 97 13.26, *Coating of Steel Waterfront Structures. /1/*

3-4.3.2.3 **Above Splash Zone**

- Two-component epoxy polyamide primer followed by two coats of a two-component, aliphatic urethane topcoat: 3 coats at 9.84 mils (0.25 mm) DFT (5.9 mils (0.15 mm) primer, 3.94 mils (0.1 mm) topcoat, 3.94 mils (0.1 mm) topcoat)
- Single-component, zinc-rich urethane primer followed by two coats of a single-component, aliphatic urethane topcoat: 3 coats at 7.87 mils (0.2 mm) DFT (3.94 mils (0.1mm) primer, 3.94 mils (0.1 mm) topcoat, 3.94 mils (0.1 mm) topcoat)
- Two-component epoxy polyamide primer followed by two coats of a flexible acrylic topcoat: 3 coats at 19.67 mils (0.5 mm) DFT 5.9 mils (0.15 mm) primer, 7.87 mils (0.2 mm) topcoat, 7.87 mils (0.2 mm) topcoat)

3-4.3.3 **Cathodic Protection of Steel**. The natural corrosion of steel structures immersed in water or buried in soil can effectively be controlled by using anodes and direct current systems to minimize or stop the corrosion process, by establishing the steel as a cathode. Cathodic protection systems are best installed when the structure is constructed, but can be added to existing structures. They can effectively stop corrosion but cannot restore the material already lost by corrosion. Design and maintenance of cathodic protection systems can be found in \1\ UFC 3-570-02N, *Electrical Engineering Cathodic Protection*. /1/

3-4.3.3.1 **Galvanic Anode.** Galvanic anode cathodic protection systems rely on the corrosion of active metals such as zinc, magnesium or aluminum to generate the electrical current needed to protect buried or submerged steel structures. Since these anodes are sacrificed to protect the structure, they are known as sacrificial anodes. The anodes must be buried or submerged near the structure to be protected and electrically connected to it with a low resistance bond. As the anodes are consumed, they must be periodically monitored and replaced when over 80 percent of the metal is consumed, or when they will be consumed before the next scheduled inspection. The level of protection provided can be determined by measuring the potential of the structure being protected by comparison with a standard reference electrode.

3-4.3.3.2 **Impressed Current.** Impressed current cathodic protection systems use an external source of electrical alternating current, and a rectifier, to provide the protective direct current to be impressed across the system. This system also requires anodes buried or submerged in the vicinity of the structure being protected, but these anodes can last much longer than galvanic anodes, since they only conduct the protective current into the water or soil and are not the source of the current. Impressed current cathodic protection systems also require periodic inspection and maintenance to ensure effectiveness in controlling corrosion.

3-5 **NONFERROUS METALS AND ALLOYS.** A variety of materials are available that, if used properly, are more resistant to corrosion by seawater and marine atmosphere than steel. These materials are used for specialized applications and are not used as much as steel due to higher costs. The common nonferrous metals are aluminum, copper, nickel, titanium, and alloys of each.

3-5.1 **Aluminum**. Many alloys of aluminum are available for applications requiring high corrosion resistance to the marine atmosphere as well as good strength-to-weight ratios. The common uses of aluminum at the waterfront include: Brows and platforms, decking and catwalks, and light poles and bases.

Aluminum should not be used as a substitute for steel solely for its corrosion resistance quality. Aluminum and its alloys are subject to pitting and crevice corrosion in marine environments, especially in submerged conditions. If pitting can be tolerated and crevices eliminated, aluminum alloys may be used successfully where low weight and other unique properties are required.

ASTM specifications define compositions and mechanical properties of aluminum alloys. Alloys 5083, 5086, 5052 and 6061 are the most popular alloys for structures exposed to the marine atmosphere.

3-5.2 **Copper**. Copper and copper alloys are suitable for waterfront use because of their uniform, low corrosion rate. Copper is used for electrical conductors, pipe, sheathing, and many hidden uses on supporting equipment at the waterfront. The copper alloys usually selected for marine corrosion resistance are: copper, cupro-nickel 90-10, cupro-nickel 70-30, arsenical admiralty brass, and most true (zincless) bronzes. These alloys form films of corrosion products that provide protection even in flowing water.

3-5.3 **Nickel**. Nickel base alloys have good corrosion resistance to seawater and to cavitation damage. These materials are used for specialized applications in springs, cable connectors, expansion joints, rupture disks, valves, fasteners, heat exchangers, and piping. The high cost of these materials makes them unsuitable for bulk construction at the waterfront.

The most common nickel alloys used are: Inconel Alloy 625 (nickel-chrome alloy), Hastelloy Alloy "C" (nickel-chrome-molybdenum alloy), and Monel 400 (nickel-copper alloy). Inconel and Hastelloy "C" are essentially immune to corrosion in marine environments. Monel 400 has good corrosion resistance when it has been cathodically protected with a more active metal. If not protected, Monel will develop pitting and crevices.

3-5.4 **Deterioration of Nonferrous Metals and Alloys**. Nonferrous metals and alloys will corrode and develop pits and crevices under normal atmospheric conditions. In general, these metals are not given preservative coatings, but may be painted for color/appearance in certain uses. Corrosion rates can be greatly accelerated when two or more dissimilar metals are in contact with each other and exposed to a corrosive environment. Particularly when they are buried or submerged, accelerated corrosion of one of the metals can occur due to an electrochemical reaction called galvanic corrosion. Galvanic corrosion rates depend on the metals' electrical properties and the medium in which the metals are exposed. Galvanic series tables have been developed indicating lists of metals in order of decreasing corrodibility when exposed to a certain solution or medium. Generally, the closer one metal is to another in the galvanic series, the lower the corrosion rate with the more active metal, and conversely, the further apart, the greater will be the corrosion rate of this metal.

3-5.5 **Preventive Maintenance for Nonferrous Metals and Alloys**. PM measures depend on whether or not dissimilar materials are involved:

- Similar Nonferrous Metals and Alloys. The only formal PM measure is regular and careful inspection to determine the condition of the component. In the later part of a component’s life expectancy, it may prove economical to coat the metal to prevent further corrosion rather than to replace the component.

- Avoiding Galvanic Corrosion. Galvanic corrosion can effectively be eliminated by making the structure out of as much of the same metal as possible, placing a protective insulator between the two dissimilar metals, and by providing cathodic protection if buried or immersed. When galvanic corrosion cannot be effectively eliminated, it can be reduced by using appropriate protective coatings on the steel, ensuring not to coat the anodes. Detailed information on treatments of galvanic corrosion is given in MIL-STD-889B, *Dissimilar Metals* for metal exposed to the saltwater environment.

If dissimilar metals must be joined, the following preventive measures should be taken:

- Choose metals close together in the galvanic series.
- Keep the cathodic area small in relation to the anode area; for instance, bolts or screws of stainless steel for fastening aluminum sheets, but not the reverse.
- Provide a protective insulator between the two metals.
- Use special coatings on the metals.

3-6 **SYNTHETIC MATERIALS**. Numerous synthetic materials are used in waterfront facilities and components. They are extremely versatile in application and serve as a structural material, coating material, or buoyancy material. In general, these materials do not corrode in the marine environment, but deteriorate due to other reasons, such as water absorption and swelling and degradation by ultraviolet light. The common synthetic materials include:

- Fiber-reinforced plastics (FRP)
- Foams, rubbers, and elastomers
- Plastic pile wraps and piping
- Synthetic fibers
- Adhesives

Deterioration of these synthetics, other than physical damage, increases with aging; plastics crack or separate, some become brittle; foams crumble with age and lose resiliency; and elastomers stretch and deteriorate from the effects of sun and exposure. In general, no preventive maintenance measures are performed other than inspection. Certain materials and components can be economically repaired when damaged.

3-6.1 **Fiber-reinforced Plastics (FRP).** FRP are used for applications requiring high strength-to-weight ratios and resistance to deterioration, such as:

- Pile jackets for steel, concrete, and timber piling to reduce corrosion or erosion; for reinforcement; and to prevent marine borer attack.

- Lightweight, sandwich construction for small buildings and containers.

- Floating structures, such as buoys and landing floats, when used in combination with closed-cell foams.

- Deck hardware such as lighting posts, grating, utility line hangars, and handrails on piers.

- Filament wound piping for lightweight, low temperature pipelines transporting steam condensate, seawater, freshwater, sewage, oil, and potable water.

Carbon fiber sheets, strips, and rods are used to upgrade existing pier decks. The sheets and strips can be used by bonding them to the underside of the deck and the rods embedded into the top deck for negative reinforcement. These techniques can increase the shear capacity of the deck to permit greater loads. For more information see Chapter 7 on concrete.

FRP are a composite of resin and fibrous material. The common resins are polyester and epoxy. Polyester resins are general purpose resins that cost less than epoxy. Epoxy resins have superior strength properties, greater resistance to chemical and water degradation, and lower shrinkage during curing.

Materials used as reinforcement for FRP include: continuous strands, woven cloth, chopped fibers, and in some cases, glass flakes.

3-6.2 **Plastic and Fiberglass Piles**. Piles made primarily of plastic or fiberglass are being used as replacements for timber fender piles. Among the plastic piles are recycled plastic piles of which there are two basic types. One type uses a steel pipe core encapsulated in a mixture of high density and low density polyethylene. The second uses either steel or fiberglass rebar as the reinforcement in high-density polyethylene (HDPE). Early versions of the plastic piles had problems associated with cracking of the outer skin. Later editions of the plastic piles have had fewer cracking problems attributed to them. In addition to the plastic piles, there are fiberglass piles that consist of a fiberglass tube, which can be filled with concrete for increased strength. The fiberglass piles have performed extremely well as fender piles.

In general, the fiberglass tube type piles that are filled with concrete provide more stiffness than the plastic piles. However, the fiberglass piles are vulnerable to abrasion. High- density polyethylene or ultra high molecular weight polyethylene (UHMW) should be used as a rub strip on the fiberglass fender piles. Both the plastic and composite fender piles have been employed successfully at many Navy piers. Most of the plastic and composite piles have been used as part of the secondary fendering system. It is recommended that the plastic and composite piles not be used as the primary fendering system at this time. Furthermore, the plastic and composite piles are not recommended for use as bearing piles. Currently, there are no ASTM or other industry standards for these piles, but they are being developed.

3-6.3 **Foams.** Foams are used at the waterfront as filler material for sandwich construction, to provide buoyancy for buoys; landing floats; and floating brows, and in foam-filled fenders to absorb the energy of berthing ships. Foams are resistant to deterioration in the marine environment if encased in an impermeable, durable material.

The common foams are polyurethane, polystyrene, polyethylene, and foams formed of ionomer resins. Polyurethane foams can be foamed on-site. However, before the foam hardens it is unstable in direct sunlight and is flammable.

Polystyrene foams are relatively inexpensive compared to polyurethane. They can be purchased in large quantities and cut to shape. Polystyrene foams are used in decks for buoyancy of small boat moorings in marinas.

Closed cell cross-linked polyethylene foams are used in foam-filled fenders. The foam, encased in an elastomer cover, absorbs the impact energy of berthing ships. Ionomer foams have been used in buoys and fenders. The outer skin of the products is a denser version of the low-density encased foam.

3-6.4 **Rubber and Elastomers**. Numerous natural and synthetic rubbers and elastomers are used at the waterfront in hose lines, gaskets, fender system components, and other specialized applications. These materials are resistant to the marine environment provided the appropriate rubber or elastomer is used. The more common material is a urethane elastomer as used for the shell of foam-filled fenders. The elastomer ethylene propylene dimonomer (EPDM) is used in arch-type rubber fenders.

3-6.5 **Other Synthetic Materials**. Synthetic materials are also used at the waterfront for pile wraps, piping, and as adhesives. Pile wraps are made of flexible polyvinyl chloride (PVC) or polyethylene (PE) films and prevent growth of wood boring organisms. PVC piping is widely used for numerous applications, as it is lightweight and corrosion resistant. Some degradation of the piping will occur if exposed to sunlight and other weathering factors. Normally, PVC pipe becomes brittle as it ages.

Adhesives, coatings, and putties made from epoxy have been developed for bonding to damp and underwater surfaces. They are used to bond structures or components, connections, joints, and other metal configurations susceptible to corrosion; to fill voids; and to protect surfaces. They can also be used to patch holes above the water or underwater.

3-7 **SOIL FILL FOR QUAYWALLS AND MOLES**. Soil is the most common backfill material behind quaywalls, shoreline walls, and solid fill/mole piers; dikes; and levees. Refer to \1\ UFC 3-220-10N, , *Soil Mechanics*, and UFC 3-220-01N, *Geotechnical Engineering Procedures for Foundation Design of Buildings and Structures* /1/ for further information on geotechnical issues.

3.7.1 **Description**. A complete description of a soil includes classification, density, shear strength, moisture content, and mineralogic content. For soils used in waterfront structures, it is often sufficient to classify them according to size (clay, silt, sand, and gravel.) The density, plasticity, and moisture content are important for the finer-grained soils, while soundness and gradation are applicable to the coarser-grained soils and rock fills.

The particle size, which marks the boundary between the fine-grained, generally cohesive soils (silts and clays) and the coarse-grained, granular soils (sands and gravels), is approximately the minimum size retained on the No. 200 standard sieve. Organic soils, such as elastic silts and peats, are never used in the construction or repair of engineering structures.

Maintenance problems increase as the grain size of the soil gets smaller. Finer-grained soils in the cohesionless range are extremely susceptible to leaching and erosion, whereas fine-grained cohesive soils are difficult to compact satisfactorily and may undergo undesirable shrinkage or swelling.

With granular soils, gradation is important. Uniformly graded soils with a narrow range of particle sizes are difficult to compact, are extremely porous, and have lower densities and strengths than soils with a broader distribution of particle sizes. However, where compaction of sands and gravels is involved, large, oversize cobbles can interfere with the compaction of the finer materials present. Such large particles should be removed from the compacted fills and used as riprap or slope protection.

This page intentionally left blank.

CHAPTER 4

SAFETY AND ENVIRONMENTAL COMPLIANCE

4-1 **INTRODUCTION**. Diverse types of work are performed at the waterfront during maintenance and repair of facilities. Much of this work contains elements hazardous to personnel, equipment, and property, as well as to the environment. The purpose of this chapter is to familiarize the reader with the areas of safety and environment that must be addressed during the planning and execution of waterfront maintenance or repair projects.

This section is divided into two topics: Occupational Safety and Environmental Compliance. Responsibility for safety and environmental compliance lies with each individual during each phase of a maintenance and repair project. However, all safety and environmental issues must be considered during the planning stage and be adequately relayed to the work site employees through training and consultation by the appropriate work supervisor.

There are many references to safety and environmental compliance that can be applied to waterfront construction and operations. Several primary military references are:

- OPNAVINST 5100.23, *Navy Occupational Safety and Health Program Manual*, U. S. Department of the Navy Instruction.
- OPNAVINST 5090.1, *Environmental and Natural Resources Program Manual*, U. S. Department of the Navy Instruction.
- COE EM 385-1-1, *Safety and Health Requirements Manual*, U.S. Army Corps of Engineers Manual.
- AFPD 91-3, *Occupational Safety and Health*, U. S. Department of the Air Force Publications Document.
- 29 CFR 1910, *Occupational Safety and Health Standards for General Industry*
- 20 CFR 1915, *Occupational Safety and Health Standards for Shipyard Employment*
- 29 CFR 1917, *Occupational Safety and Health Standards for Marine Terminals*
- 29 CFR 1926, *Occupational Safety and Health Standards for Construction*

- NAVFAC P-307, *Management of Weight Handling Equipment Maintenance and Certification.*

4-2 **OCCUPATIONAL SAFETY**. At each Navy installation, a Safety Office exists to oversee all base operations for compliance with federal, state, and local occupational safety regulations. The Safety Office is the primary point of contact for information and assistance with project safety issues. It is their responsibility to give direction and guidance on what safety regulations are applicable for each project, and which safety measures are required for compliance. To adequately identify the hazards associated with this type of work operation, the Safety Office may require a safety plan for any new project. The safety plan is sometimes called an “accident prevention plan” or “job hazard analysis” and includes activity hazard analyses for each phase of the project. This plan identifies the sequence of work operations, hazards associated with each task and the recommended controls (engineering, elimination, isolation, substitution and/or personal protective equipment) to ensure safe work operations. This plan is submitted by the project planner(s) before the project begins. COE EM-385-1-1 recommends submitting the safety plan at least 15 calendar days before the work starts at the job site. However, individual Safety Offices may require longer review periods. The Safety Office reviews the plan and provides feedback to the project planner on safety requirements. Appendix A of \1\ USACOE EM-385-1-1 /1/ provides a minimum basic outline for Accident Prevention Plans. An example of a safety plan format is given in Figure 4-1. Project work for a new project is usually not allowed to proceed until the safety plan has been signed and approved.

Figure 4-1 Safety Plan Format

1. Proposed Project: ____
   a) Description: ____
   ____
   b) Project Site/Diagrams: ____
   c) Dates/Times of Operation: ______________________________________
   d) Project Personnel: ____
   e) Safety Coordinators: ____

2. Preliminary Hazard Analysis:
   a) List hazards, triggering events, and estimate seriousness:___________
   ____
   b) Assign Risk Assessment Code (based on hazard severity and mishap probability): ____
   c) Hazard Control Mechanisms/Safety Measures (attach SOPs): _______
   ____

3. Training and Medical Surveillance (list project personnel, their training, medical surveillance dates and signatures): ____________________________________
____

4. Hazardous Waste Operations and Emergency Response (describe applicable HW operations and emergency plans):_________________________________
____

5. Personal Protective Equipment (list all PPE to be used for each task): _
____

6. Medical surveillance (list personnel who have had the required medical surveillance exams for each task):____________________________________
____

7. Industrial hygiene (identify requirements for air, personnel and environmental monitoring):____

8. Site control measures (identify any site control measures instituted):____
____

9. General information:____

10. Phone contacts:____

11. Emergency contacts:____

4-3 **ENVIRONMENTAL COMPLIANCE**. Environmental compliance is a facility's or project's status with respect to a wide variety of federal, state, and local environmental regulations in existence to protect our environment. Environmental compliance involves aspects that affect the operation of a project, such as:

- Wastewater discharge
- Noise abatement
- Air quality attainment
- Hazardous waste (HW) and hazardous materials (HAZMAT) management

4-3.1 **Environmental Regulations.** Environmental regulations have increased exponentially in recent years due to a growing concern about the environment. All shore activities are now regulated by a number of federal, state, regional, and local agencies. Thus, compliance to all of the applicable regulations for a particular project can vary greatly depending on the project's nature and location.

Navy policies on environmental compliance are contained in OPNAVINST 5090.1. Although this instruction generally addresses the responsibilities of the facility's Commanding Officer and higher agencies, it should be reviewed for general policy and reference by all project personnel. OPNAVINST 5090.1 contains information on specific environmental topics including:

- Management of ozone-depleting substances
- Clean air ashore
- Clean water ashore
- Drinking water and water conservation
- Oil and hazardous substances contingency planning
- PCB management
- Pesticide compliance
- Noise prevention
- Installation restoration

- Natural resources management
- Solid waste management

4-3.1.1 **Other Services Documents.** The equivalent Army document is Army Regulation AR 200-1, *Environmental Protection and Enhancement*. The Air Force equivalent is the Air Force 32 Series instructions.

4-3.1.2 **Environmental Instructions.** In addition, most commands and activities have developed instructions that provide policy guidance for complying with regulatory requirements applicable to activity personnel. Consult with the Environmental Office to obtain relevant guidelines for that activity.

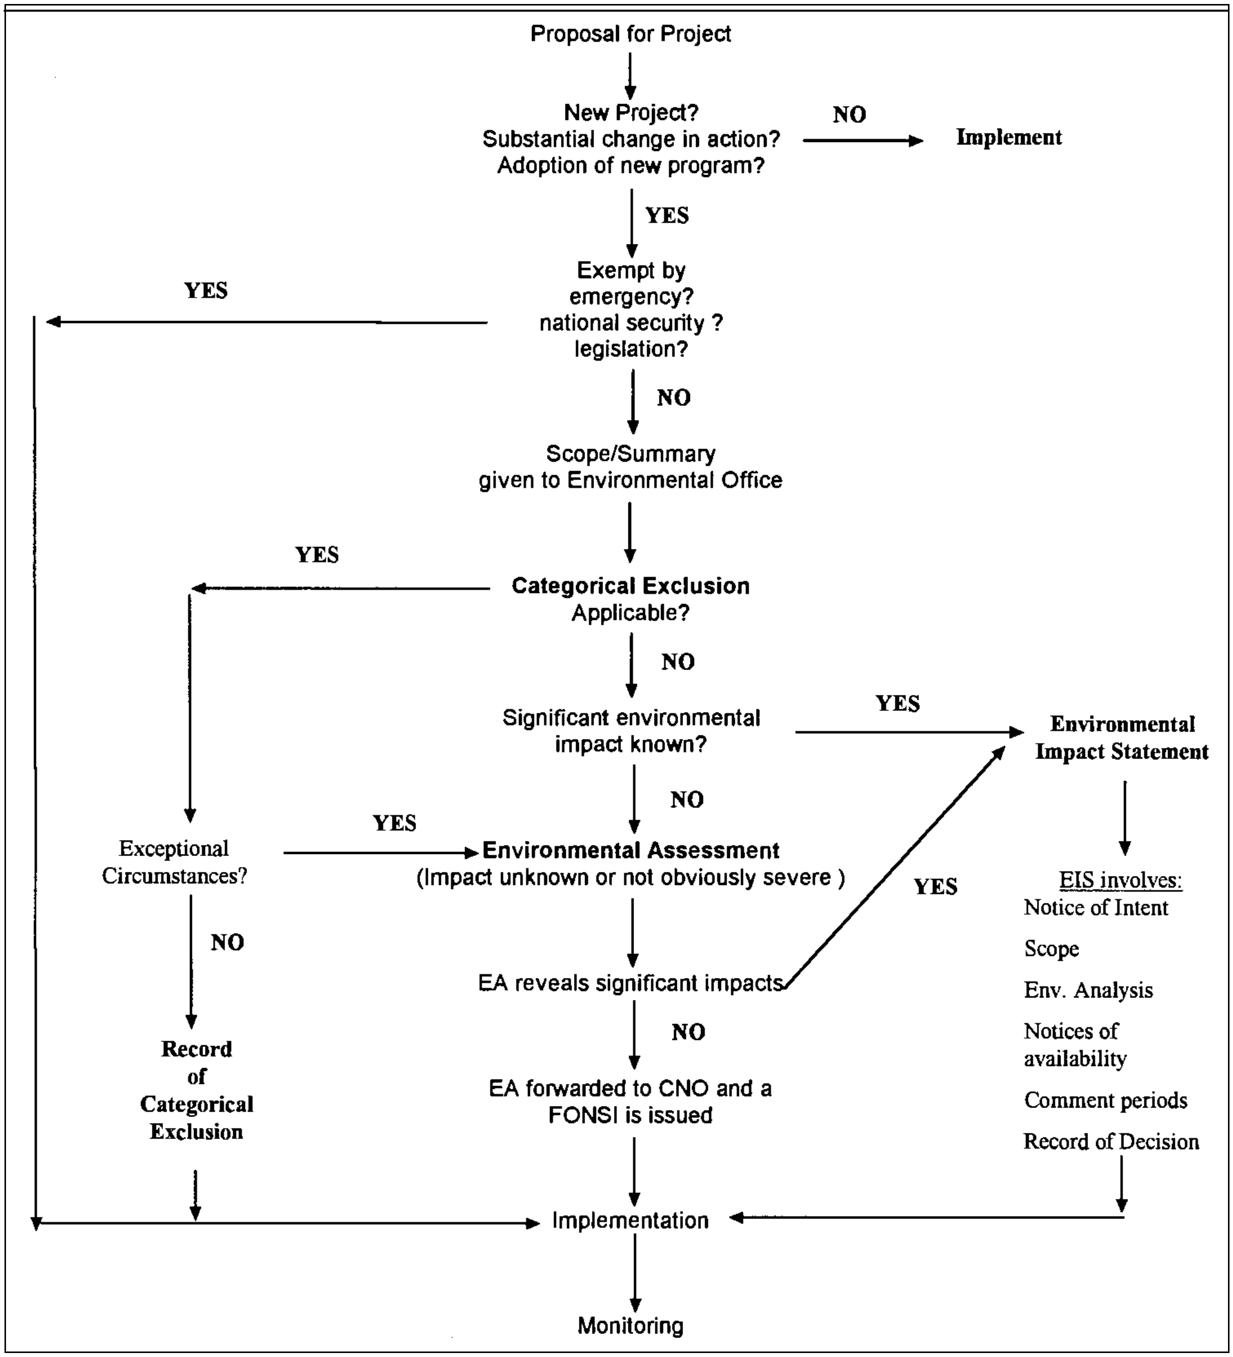
4-3.1.2.1 **Environmental Compliance Responsiblity.** Environmental compliance is everyone's responsibility, from the Commanding Officer of the activity to the people performing the actual tasks of a project. The Department of Defense is fully committed to strict compliance, not only to protect our environment and conserve our natural resources, but also for the overall benefit to the mission or project. In the long run, proper compliance prevents time delays and operational shutdowns, and improves public relations.

4-3.1.2.2 **Environmental Office.** Depending on the reader's role in a waterfront maintenance and repair project, whether a planner or estimator, or a member of the activity requesting waterfront maintenance and repair, involvement with environmental documentation will vary. In all cases, however, each activity should have an Environmental Office that is responsible for overseeing the environmental aspects of all projects at that facility. Environmental Office personnel are responsible for: developing and implementing activity instructions and providing guidance on procedures for ensuring environmental compliance for projects. Specific services provided by the Environmental Office include:

- Preparing categorical exclusions
- Obtaining any necessary local permits
- Issuing site-approvals
- Contacting \1\ local NAVFAC offices /1/ and contractors when an Environmental Assessment (EA) or Environmental Impact Statement (EIS) preparation is appropriate

The flow chart in Figure 4-2 shows a typical process of environmental documentation.

Figure 4-2 Environmental Documentation Process



4-3.1.3 **National Environmental Policy Act (NEPA).** The National Environmental Policy Act (NEPA), first enacted in 1969, is the national charter (within the United States and its territories) for protection of the environment. It establishes policy, sets goals, and provides a means for carrying out environmental policy within the United States and its territories. NEPA impacts a wide variety of existing environmental legislation including the:

- Clean Water Act (CWA)
- Clean Air Act (CAA)
- Pollution Prevention Act (PPA)
- Coastal Zone Management Act (CZMA)
- Endangered Species Act (ESA)
- Marine Protection Research and Sanctuaries Act (MPRSA)

4-3.2 **Environmental Documentation**. Under the NEPA Council on Environmental Quality (CEQ), a three-tiered approach of environmental consideration and documentation has been established:

- Categorical Exclusion (Cat. Ex)
- Environmental Assessment (EA)
- Environmental Impact Statement (EIS)

4-3.2.1 **Categorical Exclusion**. A categorical exclusion is a statement that the intended project work or action does not have, under normal circumstances, individually or cumulatively, a significant effect on the environment. If a categorical exclusion is allowed, an EA or EIS will not be required. The Environmental Office is generally responsible for deciding on and preparing a categorical exclusion. To do this, the Environmental Office will require from the project coordinator or planner(s) a summary or scope of the work to be performed. This summary does not need to be a lengthy document but must contain sufficient detail of the work to allow the EO to determine whether a categorical exclusion is appropriate. Categorical exclusions include:

- Routine repair and maintenance of facilities and equipment to maintain existing operations and activities, including maintenance of improved and semi-improved grounds.

- Alteration and additions of existing structures to conform or provide conforming use specifically required by new or existing applicable regulations.

- Routine actions normally conducted to operate, protect, and maintain military-owned or controlled properties.

- New construction that is consistent with existing land use and, when completed, complies with existing regulatory requirements.

- Routine movement, handling, and distribution of materials, including HAZMAT or HW that is moved, handled, or distributed under applicable regulations.

- Demolition, disposal, or improvements involving buildings or structures neither on nor eligible for listing on the National Register of Historic Places.

- Actions which require the concurrence or approval of another Federal agency, where the action is a categorical exclusion of the other Federal agency.

- Maintenance dredging and debris disposal where no new depths are required, applicable permits are secured, and disposal will be at an approved site.

Even though a proposal generally fits the definition of a categorical exclusion, the categorical exclusion will not be used if the proposed action affects public health and safety, or involves an action that is determined to have the potential for significant environmental effects on wetlands, endangered species, HW sites, or archeological resources.

When it is unknown beforehand whether or not the proposed action will significantly affect the human environment or be controversial with respect to environmental effects, a categorical exclusion cannot be used.

4-3-2.1.1 **Environmental Office Documentation.** The Environmental Office must document the categorical exclusion(s), the facts supporting their use, and specific considerations of whether the exceptions to the use of categorical exclusions are applicable. This Record of Categorical Exclusion need not be more than a page or two, but must be signed by the Commanding Officer or a designee. The signed Record of Categorical Exclusion must be retained within the project files and be available for review during environmental compliance evaluations. Additionally, many Environmental Officers will prepare an Environmental Review Document (ERD), an in-house document listing impacts, or lack thereof, of the project on several environmental areas.

Even though a categorical exclusion is granted, it does not mean the end of the environmental compliance process. Local, regional, state, and federal agencies may require permits for certain operations, or for a specific type of equipment. It is the Environmental Officer's responsibility to obtain these permits, using the technical input from the project team. When work is contracted out, the contractor is responsible for providing an environmental protection plan, along with applicable permits and reports via the Contracting Officer.

4-3.2.1.2 **Permits.** Waterfront maintenance projects usually do not require permits unless special construction is required. Additionally, they will not need a new categorical exclusion if the work has been previously reviewed by the Environmental Officer. However, the Environmental Officer needs to be informed of any work taking place at the waterfront to ensure that environmental procedures are being followed. Normally, maintenance projects evolve from an annual inspection of waterfront structures by the Public Works Centers. The repair and/or maintenance requirements are then relayed to the facility customers who then submit a summary of the proposed work to the Environmental Office.

4-3.2.2 **Environmental Assessment**. An environmental assessment (EA) is an analysis of the potential environmental impact of a proposed action. An EA is prepared for projects or actions that do not fall under one or more of the listed categorical exclusions and that have the potential for significant environmental impacts. If significant impacts are obvious, an Environmental Impact Statement is directly prepared.

The EA discusses the need for the action, alternatives, impacts, and any environmental monitoring required. Additional information may be required of the project coordinators and other project planners to complete the EA. The EO will likely turn the preparation of an EA over to \1\ a local NAVFAC office /1/ or a contractor.

If after completion of the EA, it is determined that the proposed project will not significantly impact the environment, a Finding of No Significant Impact (FONSI) will be prepared and the project implemented. If it is determined that the proposed project will significantly impact the environment, an EIS must be prepared.

4-3.2.3 **Environmental Impact Statement**. An EIS is a detailed document that provides a full discussion of significant environmental impacts and informs decision makers and the public of reasonable alternatives that would avoid or minimize adverse impact, or enhance the quality of the human environment. EIS can be lengthy and are frequently prepared by contractors who can provide an unbiased analysis, thus avoiding a conflict of interest. An EIS is completed with a Record of Decision (ROD) and signed by the Secretary of the Navy. The likelihood that an EIS would be required for a normal waterfront maintenance/repair project is small.

4-3.3 **Working in Compliance**. Once all permits for a project have been obtained and all documentation has been completed, the Environmental Officer will issue a “site-approval.” Generally, the Public Works Center performing the maintenance or repair will not start work until the site-approval has been issued.

Often, contact with the activity’s Environmental Office during planning and execution of waterfront maintenance and repair projects is all that will be required to assure compliance with environmental regulations. Project personnel in some circumstances, however, may need to establish direct contact with the various permitting and regulatory agencies concerned with the work. These might include but are not limited to:

- Port officials
- State Department of Health
- Department of Fish & Game
- State EPA office
- Coast Guard
- Army Corps of Engineers

Contact with these agencies should not be used to circumvent communication with the Environmental Office, but should be used to compliment it to help ensure environmental compliance and agency approval of the planned project tasks.

4-3.4 **Environmental Training**. All project personnel should be provided with formal training on the principles of environmental compliance and the regulations that govern them. Personnel working on projects that involve hazardous materials and wastes, operations which potentially could cause air, water, or noise pollution, or that may endanger the marine environment need more extensive training in these specific areas. OPNAVINST 5100.23 gives Navy requirements for training for hazardous materials handling and hazard communication.

The primary source of information concerning environmental training requirements is, again, the Environmental Office. They provide guidance on who must be trained, what training is required, and how often. They frequently conduct the training sessions themselves.

4-3.5 **Treated Wood - Environmental Issues**. Since there is extensive use of treated wood at waterfront facilities, and since wood preservatives likely constitute the greatest percentage of chemicals used on the waterfront, a special mention about the environmental issues is warranted. In recent years, using treated wood in the marine environment raised concerns about its effect on surrounding aquatic life. Currently, wood preservatives are registered by the EPA for use in the marine environment, and treated wood is not considered a hazardous waste nor banned from landfills, according to Federal law. However, local and state regulations are more restrictive. The Environmental Office should be consulted for applicable restrictions at the waterfront facility of interest. See Chapter 6 of this handbook for more information on the environmental concerns of treated wood.

This page intentionally left blank.

CHAPTER 5

INSPECTION

5-1 **GENERAL CONSIDERATIONS**. The fundamental purpose of any inspection is to provide the information necessary to assess the condition (capacity, safety, and rate of deterioration) of a structure. Waterfront structures to be inspected include: piers, pilings, wharves, quaywalls, fender systems, dolphins, and drydocks.

5-1.1 **Inspection Objectives**. Inspections are classified according to the objectives. These include:

- Baseline - to obtain data on a facility that has not been inspected. This inspection involves the greatest "pre-inspection" effort.
- Routine - to obtain data on general condition, confirm drawings, estimate repair costs, etc.
- Design Survey - to obtain data for specifications or for detailed cost estimates.
- Acceptance - to obtain data confirming that a repair has been completed according to plan or specification.
- Research - to obtain data on deterioration rates, etc.

The usefulness of an inspection depends on establishing a clear and complete record. Although the level of inspection will determine the extent of information to be provided, in general the inspection will address the:

- Identification and description of all major damage and deterioration of the facility.
- Description of facilities inspected including updated layouts of pile plans (which occasionally differ significantly from the drawings available at the activity).
- Documentation of types and extent of marine growth, if applicable.
- Water depth, visibility, tidal range, and water current.
- Assessment of general physical condition including projected load capacities.
- Recommendations for required maintenance and repair (M&R).

- Budgetary estimates of costs of this M&R, including examples of how estimates were derived.
- Identification of any problems associated with mobilization of equipment, personnel, and materials to accomplish repairs/maintenance.
- Estimate of expected life of each facility.
- Recommendations for types and frequencies of future underwater inspections.

5-1.2 **Information an Inspection Should Provide**. There are a number of reference documents dealing with waterfront inspections. The inspection procedures and planning factors outlined in this section have been taken from several of them. Two important references are:

\1\

- NAVFAC MO-322, *Inspection of Shore Facilities*
- NTRP 4-04.2.8, *Conventional Underwater Construction and Repair Techniques*
- NTRP 4-04.2.9, *Expedient Underwater Construction and Repair Techniques*

/1/

5-2 **LEVELS OF INSPECTION**. For any inspection objective, three levels of inspection effort are used for inspecting waterfront facilities:

5-2.1 **Level I - General Visual Inspection**. This inspection involves no cleaning of any structural elements and, therefore, is the most rapid of the three types of inspection. The purpose of the Level I inspection is to confirm as-built structural plans, provide initial input for an inspection strategy, and detect obvious major damage or deterioration due to overstress, impacts, severe corrosion, or extensive biological growth and attack.

5-2.2 **Level II - Close-Up Visual Inspection**. This inspection is directed toward detecting and identifying damaged or deteriorated areas that may be hidden by surface biofouling or deterioration and obtaining a limited amount of deterioration measurements. The data obtained should help estimate the facility's load capability. Level II inspections will often require cleaning the structural elements. Since cleaning is time consuming, it is generally restricted to areas that are critical or which may be representative of the entire structure. The amount and thoroughness of cleaning to be done is governed by what is necessary to determine the general condition of the overall facility.

5-2.3 **Level III - Highly Detailed Inspection**. It is recommended that a "Level III" above and under water inspection be performed on piers identified for mooring use during heavy weather conditions. This inspection normally includes underwater inspections, and will often require the use of nondestructive testing (NDT) techniques. It may also require using partially destructive techniques, such as core sampling of concrete and wood structures, physical material sampling, or surface hardness testing. The purpose of this type of inspection is to detect hidden or interior damage, loss in cross-sectional area, and material homogeneity. A Level III examination will normally require cleaning. The use of NDT techniques are usually limited to key structural areas, areas that may be suspect, or structural members that may be representative of the underwater structure. Level III inspections require more experience and training than Level I or Level II inspections, and should be done by qualified engineering or nondestructive testing personnel. This type of inspection is covered in MO-104.2.

Inspection of waterfront facilities is considered to be a specialized control inspection within the Navy. The underwater inspection should be done by a qualified, certified diver supervised by an engineer or a qualified engineering diver. The structural assessment must be done by an engineer with experience and skill in inspection procedures and techniques.

Table 5-1 lists the types of damage that are detectable with the three levels of inspection.

5-3 **PLANNING FOR INSPECTION**. The levels of inspection to be used for a particular task must be decided early in the planning phase. The inspection objectives (i.e., baseline, design survey, repair acceptance, research) should be clearly defined. A site survey of the facilities should be obtained, or conducted if doing a first-time inspection. A site survey for underwater inspections includes: bathymetric, oceanographic, and geological data, as well as information on nearby obstructions or activities. A site survey accelerates the planning process and will help determine the levels of inspection to be used.

The time and effort required to carry out the three different levels of inspection are quite different. The time required also depends on whether the inspection is surface or underwater; on environmental factors, such as visibility, currents, wave action, water depth, tides, severity of marine growth; and on the inspector's skill and experience.

Table 5-1. Capability of Each Level of Inspection for Detecting Damage to Waterfront Structures

Level	Purpose	Detectable Defects		
		Steel	Concrete	Wood
I	General visual to confirm as-built conditions and detect severe damage	Extensive corrosion Severe mechanical damage	Major spalling and cracking Severe reinforcement corrosion Broken piles	Major losses of wood due to marine borers \1\ (limnoria; see earlier section on Marine Borers) /1/ Broken piles and braces Severe abrasion or marine borer attack
II	Detect surface defects normally obscured by marine growth	Moderate mechanical damage Major pitting	Surface cracking and crumbling Rust staining Exposed rebar and/or pre-stressed strands	External pile diameter reduction due to marine borers Splintered piling Loss of bolts and fasteners Early borer and insect infestation
III	Detect hidden and imminent damage	Reduced thick-ness of material	Location of rebar Beginning corrosion of rebar Internal voids	Internal damage due to marine borers,\1\ internal voids (teredines and pholads; see earlier section on Marine Borers) /1/ Decrease in material strength \1\ (based upon section loss as determined by either nondestructive and/or destructive testing which are discussed in this chapter) /1/

Table 5-2 provides a guide for estimating the time required to conduct Level I and Level II surface and underwater inspections.

Level III inspections depend on the extent of existing damage, the type of inspection techniques, and the equipment used (ultrasonic thickness measurements, increment borings, caliper measurements). Therefore, estimates of time for Level III inspection are not included in Table 5-2.

Table 5-3 shows daily rates for underwater inspection of piles and bulkheads.

Table 5-2 Production Rate for Surface and Underwater Inspection of Structural Elements

Structural Element	Inspection time per Structural Element (minutes)			
	Level I		Level II	
	Surface	Underwater	Surface	Underwater
12 inch (30 cm) steel H-pile	2	5	15	30
12 inch (30 cm) wide strip of steel sheet pile	1	3	8	15
12 inch (30 cm) square concrete pile	2	4	12	25
12 inch (30 cm) wide strip of concrete sheet pile	1	3	8	15
12 inch (30 cm) diameter timber pile	2	4	10	20
12 inch (30 cm) wide strip of timber sheet pile	1	3	7	15

NOTE: This information is based on a 11 to 15 yard r (10 to 14 meter) water depth; 3.1 to 6.6 feet (1 to 2 meter) visibility; warm, calm water; moderate marine growth about2 inch (5 cm) thick; and an experienced engineering diver or diver supervised by an engineer. For the Level II inspection, it is assumed that 3.1 feet (1 meter) of the structural element is in the splash zone, 12 inch (30 cm) at mid-depth, and 12 inch (30 cm) at the bottom, and will be completely cleaned of marine growth. It is also assumed that the most efficient method of removing marine growth will be used.

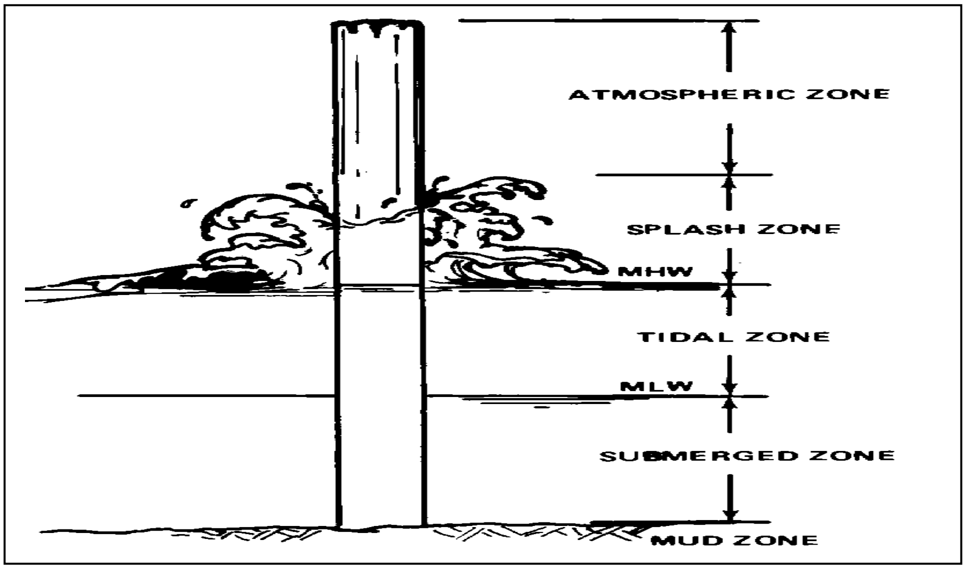
Table 5-3. Daily Rates for Underwater Inspection Tasks*

Inspection Task	Pile/Day	Bulkhead in Linear Meters Day
Swim by	300 to 600	150 to 450
Cleaning	30 to 70 at 3 to 15% of each pile	150 to 450 at 15 to 90meter (16 to 98 yard) intervals
Measurements	50 to 200 for wood at 5 to 15% of each pile 30 to 60 for steel at 3 to 10% of each pile 30 to 70 for concrete at 3 to 15% of each pile	150 to 450 at 15 to 90meter (16 to 98 yard) intervals

*Rates vary widely depending on the effects of many factors, such as: water visibility, facility size and age, marine growth, and construction.

5-3.1 **Inspection Frequency**. The frequency of routine or periodic inspections will depend on whether the inspection is on the surface or underwater, and the expected rate of deterioration and damage. An example of an area requiring more inspections is ships berthing, which deteriorates both fender and bearing piling. The frequency and level of inspection should, therefore, be closely tied to the historical deterioration rate of the facility. Statistical software has been developed that identifies inspection frequencies based on cost when known or estimated structural data. The frequencies obtained will be unique to the activity’s situation (from NCEL CR 87-005, *Inspection Frequency Criteria Models for Timber, Steel, and Concrete Pile Supported Waterfront Structures*, December 1986.) As a general guide, recommended frequencies of inspection for the different types of waterfront structures are:

Figure 5-1. Exposure zones on piling.



a. All superstructure and piling/sheet piling above the waterline, including the splash and tidal zones (Figure 5-1), should be inspected annually.

b. Concrete/steel structural members at the splash/tidal zones (Figure 5-1) and downward should be inspected at least every 6 years. As deterioration is discovered, the level of inspection and frequency needs to increase accordingly. For steel structures, the age of the structures is a primary factor since the rate of deterioration due to corrosion is fairly constant. Likewise, concrete in a saltwater environment deteriorates chemically with time, especially if cracks are present to allow the seawater to reach the structure's interior.

c. Timber members should be inspected at least every 3 years and, as above, more frequently and intently as deterioration is discovered. In areas where marine animal infestation is known to be a problem, increased inspections are especially important.

If it is not feasible to thoroughly inspect all elements of a structure (e.g., underwater inspection of a series of piers with many piles), selecting an optimum number of structural elements or members is crucial to obtaining accurate information representative of the overall condition of the structure. Development and validation of sampling criteria and procedures has been reported in Naval Civil Engineering Laboratory's TN-1762 *Sampling Criteria and Procedures for Inspection of Waterfront Facilities*, September 1988. Statistical sampling techniques using probability theory provide a method for determining condition parameters for the entire population based on information from the sample elements, with a calculated confidence level and precision.

5-3.2 **Inspectors.** Inspections may be by a variety of individuals at different times for different reasons. It should be notes that periodic comprehensive inspections are done as part of the Underwater Inspection Program administered by the \1\ Naval Facilities Engineering Service Center, East Coast Detachment. /1/

5-3.3 **Collecting Inspection Plan Data**. Before starting an inspection, all available information about the facility should be gathered. This includes prior maintenance and inspection records, facility drawings and site survey reports, general background information, and environmental data, including:

- Atmospheric temperature range
- Water temperature range
- Tidal range
- Water depths
- Water visibility
- Currents

Any condition could have a direct impact on the time required to perform an inspection, such as: the amount of biofouling growth on piles; ice; or seasonal flooding. Any other unique feature or special problems that may be encountered should also be noted.

The inspection plan should include CADD drawings showing individual piles and other structural members. The inspection could use pile numbering/designation systems often available on existing "as-built" drawings. Usually, combinations of numbers and letters are used with the number designating the bent and letter indicating the pile within the bent. CADD drawings should also be developed for the above and below deck portions of the pier. The existing positions of all topside bollards, bitts, cleats, capstans, utility covers, as well as any under deck utilities and fittings should be shown on the CADD drawings. A legend should be created to represent such things as the:

- Degree of deterioration of individual structural members
- Level of inspection given to designated portions of a facility
- Shape of individual piles

- Type of materials
- Condition of bollards and bitts

Pile plans should be prepared for piers showing the lengths, widths, and spacing of bents. The plans must also include the numbering system used in the inspection and in the report, and these must be correlated with existing drawings of the facility. Also include design live load data on all pile plans, if available. Load testing of the pier decking, if heavy equipment or vehicles are driven onto the pier, should be considered.

Particular attention should be paid to mooring hardware as it relates to safe mooring of naval vessels during heavy weather. A more thorough treatment of this topic is contained in \1\ UFC 4-150-08, *Inspection of Mooring Hardware.* /1/

5-3.3.1 **Developing Inspection Plan.** Once the information about the facility structure and environment has been collected, an inspection plan is developed. The plan should be based on the inspection objective and the level of inspection required to meet that objective. It is important to select enough inspection areas per structural member. The written plan should be similar to a statement of work (SOW) specifying the sampling criteria, tasks, schedules, equipment to be used, and any additional responsibilities. The inspection plan must be prepared by a qualified engineer who is familiar with the structure.

The plan must specify that a qualified diver supervised by a qualified engineering diver should conduct the underwater inspections and an experienced engineer must perform the structural assessment of the entire pier.

5-3.4 **Equipment and Tools**

5-3.4.1 **Surface Cleaning Tools**. To perform a Level II and Level III inspection, the marine growth on the structure must be removed. How this is done depends on the surface support available. For small sample areas, wire brushes, probes, and scrapers may be adequate. For larger areas or more detailed inspections underwater, a hydraulic grinder with barnacle buster attachment, or high-pressure water jet gun, may be used. Take care to prevent damage to pile wraps or coatings and to the preservative-treated layers of timber or deteriorating surfaces of concrete.

5-3.4.2 **Inspection Tools**. Inspection tools and equipment include:

5-3.4.2.1 **Hand-Held Tools.**

- Portable flashlight, ruler, and tape measure for documenting areas

- Small or large hammers or pick-axes for performing soundings of the structural member
- Calipers and scales for determining thickness of steel flanges, webs, and plates, or diameters of piling
- Increment borer and T-handles for extracting core samples from timbers
- Chipping tools for prodding the surface of the concrete to determine the depth of deterioration.

5-3.4.2.2 **Mechanical Devices.** Mechanical devices including a Schmidt test hammer for measuring concrete surface hardness and rotary coring equipment for taking core samples from concrete structures.

5-3.4.2.3 **Electrical Equipment.** This includes electrical equipment, such as an underwater voltmeter for determining the level of cathodic protection on steel structures and underwater sonic and ultrasonic equipment for detecting voids in \1\ /1/ concrete and thickness of structural steel. It also includes underwater magnetic particle testing to locate and define surface discontinuities in magnetic materials. Figure 5-2 shows typical equipment applications used in underwater inspections.

5.3.4.3 **Recording Tools**. Recording tools and equipment are required to provide a complete documentation of the condition of the structure. Simple tools such as a clipboard, forms, and cassette recorder for above water inspections; or Plexiglas® slate and grease pencil for underwater inspection, provide the basic documentation tools. More in-depth documentation may be obtained with above water or underwater photography using either colored still-frame cameras, colored video, or closed-circuit television. The latter may be very valuable in expediting major underwater inspections. For underwater inspections in turbid water, a clear-water box may be fitted to the lens of the photographic or video equipment to improve visibility between the lens and surface to be inspected.

5-3.5 **Preparing Inspection Documentation**. For the information to be useful, documentation must be clear and concise. Inspectors should maintain daily logs of inspection details including measurement data, locations of observation, and water depths, if relative. Fill out inspection forms as the inspection progresses, and complete the reports soon after the inspection has been finished. Standard forms and report formats facilitate the documentation procedure and are essential for comparing the results of the present inspection with past and future inspections. Figure 5-3 is a standard form that may be used for reporting the condition of piles; Figure 5-4 is an explanation of the condition ratings for concrete piles used on the form; and Figure 5-5 is an explanation of the condition ratings for timber piles. Steel pile inspection results are usually recorded in terms of remaining metal thickness.

Figure 5-2 Tools and Equipment Used for Waterfront Inspection

Figure 5-3 Standard Pile Inspection Report Form.

PILE INSPECTION RECORD

LOCATION		DATE	DIVERS

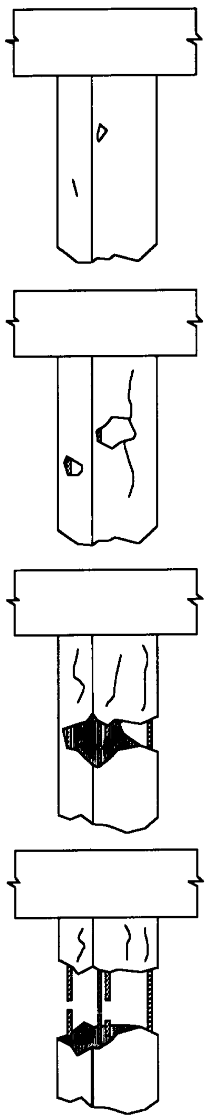
WATER DEPTH	TIME OF DAY	TIDE	DEPTH OF DAMAGE FROM DATUM=GAUGE DEPTH-TIDE

BENT NO	PILE NO	NI	PILE CONDITION					TYPE DAMAGE			GAUGE DEPTH DAMAGE	DIMENSIONS OF DAMAGE			COMMENTS
			ND	MN	MD	MJ	SV	MECH	BIO	FUNC		HGT	WIDTH	PENETR	

Figure 5-4 Pile Condition Ratings for Concrete Piles

CONCRETE PILES



CONCRETE PILE CONDITION RATING	EXPLANATION
NI	NOT INSPECTED, INACCESSIBLE OR PASSED BY
ND	NO DEFECTS: - hairline cracks - good original surface, hard material
MN	MINOR DEFECTS: - good original surface - minor cracks or pits - small chips or popouts - slight rust stains - hard material, sound - corrosion of the wires
MD	MODERATE DEFECTS: - limited spalling of concrete - minor corrosion of exposed re-bar - rust stains along re-bar - softening of concrete - reinforcing steel ties exposed - popouts or impact damage
MJ	MAJOR DEFECTS: - spalling of concrete results in (10-15%) loss - large spalls six inches or more in width or length - deep wide cracks along re-bar - major rust stains along rebar - wide spread surface disintegration
SV	SEVERE DEFECTS: - exposed rebar with 50% loss of steel section area - more than 15% loss of concrete

NOTE: Explanation of defect should be placed in the comments column.

Figure 5-5 Pile Condition Ratings for Timber Piles

TIMBER PILE CONDITION RATING	EXPLANATION
NI	NOT INSPECTED, INACCESSIBLE OR PASSED BY
ND	NO DEFECTS: - Less than 5% lost material - sound surface material - no evidence of borer damage
MN	MINOR DEFECTS: - 5% to 15% lost material - sound surface material - no evidence of borer damage - minor abrasion damage
MD	MODERATE DEFECTS: - 15% to 45% lost material - significant loss of outer shell material - evidence of borer damage - significant abrasion damage
MJ	MAJOR DEFECTS: - 45% to 75% lost material - significant loss of outer shell and interior material - evidence of severe borer damage - severe abrasion damage
SV	SEVERE DEFECTS: - more than 75% lost material - no remaining structural strength - severe borer damage

NOTE: Explanation of defect should be entered in the comments column.

When appropriate, visual inspection should be documented with still photography and closed-circuit television. Still photography provides the necessary high definition required for detailed analysis, while video provides a continuous view of the inspection. All photographs should be numbered and labeled with a brief description of the subject. A slate or other designation identifying the subject should appear in the photograph. Video tapes should be provided with a title and lead-in describing what is on the tape. The description should include the inspection method used, the nature and size of the structure being inspected, and any other pertinent information.

5-4 INSPECTION OF TIMBER STRUCTURES

5-4.1 **Scoping the Problem**. Timber damage is caused by:

- Fungal rot
- Marine borer and insect attack
- Shrinkage
- Overloading
- Connector Corrosion
- Abrasion
- Ice Lift

These are described in detail in Chapter 3. Typical damage found is illustrated in Figures 5-6, 5-7, 5-8, and 5-9.

Waterfront deterioration and damage is found by walking the pier, by inspecting dolphins and below pier decks in a small boat or barge, and by underwater inspections.

When inspecting above the water, the inspector should take maximum advantage of low tide conditions in order to visually inspect the overall condition of the piling. This may determine that an underwater inspection is necessary. The underwater inspection should, on the other hand, take advantage of high water conditions in order to compile the most comprehensive field data on existing conditions.

5-4.2 **Surface Inspections**. Use Figure 5-10, “Timber Structures and Attachments (Above Water) Checklist” to ensure that a thorough inspection of all timber structures and their attachments above water is done. Include annual load testing of the pier decking if heavy equipment or vehicles are driven onto the pier. Sampling equipment and inspection data to be compiled are in Table 5-4.

Figure 5-6 Damage Areas Involving Timber Members

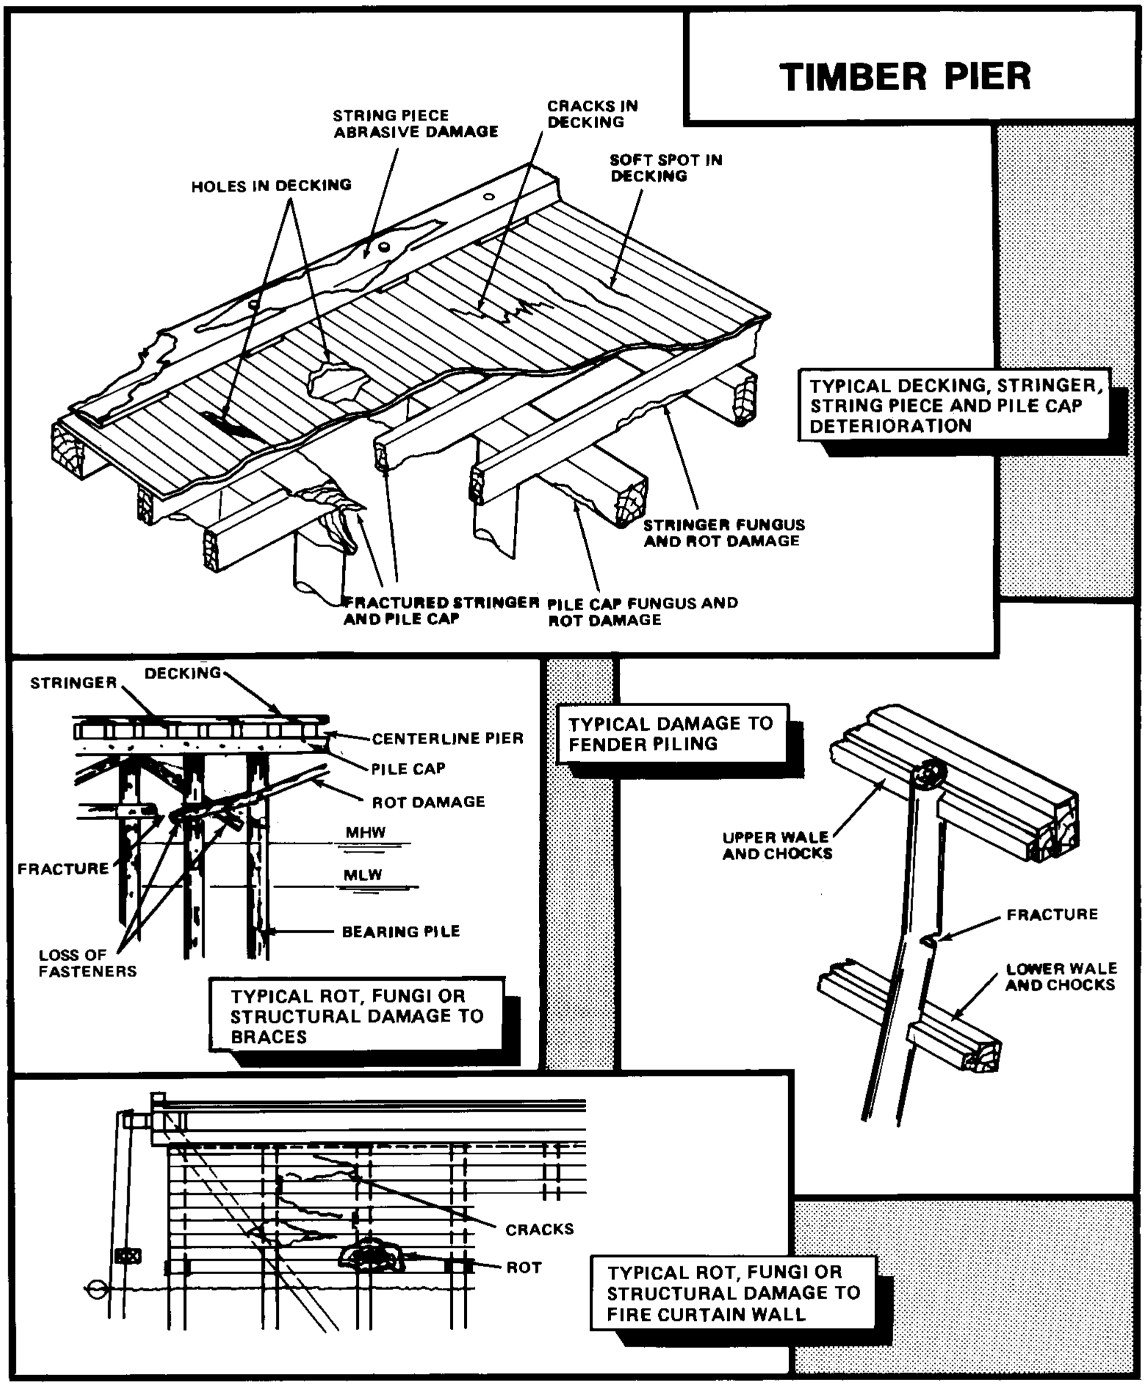


Figure 5-7 Damage to Timber Piles from Biological Sources

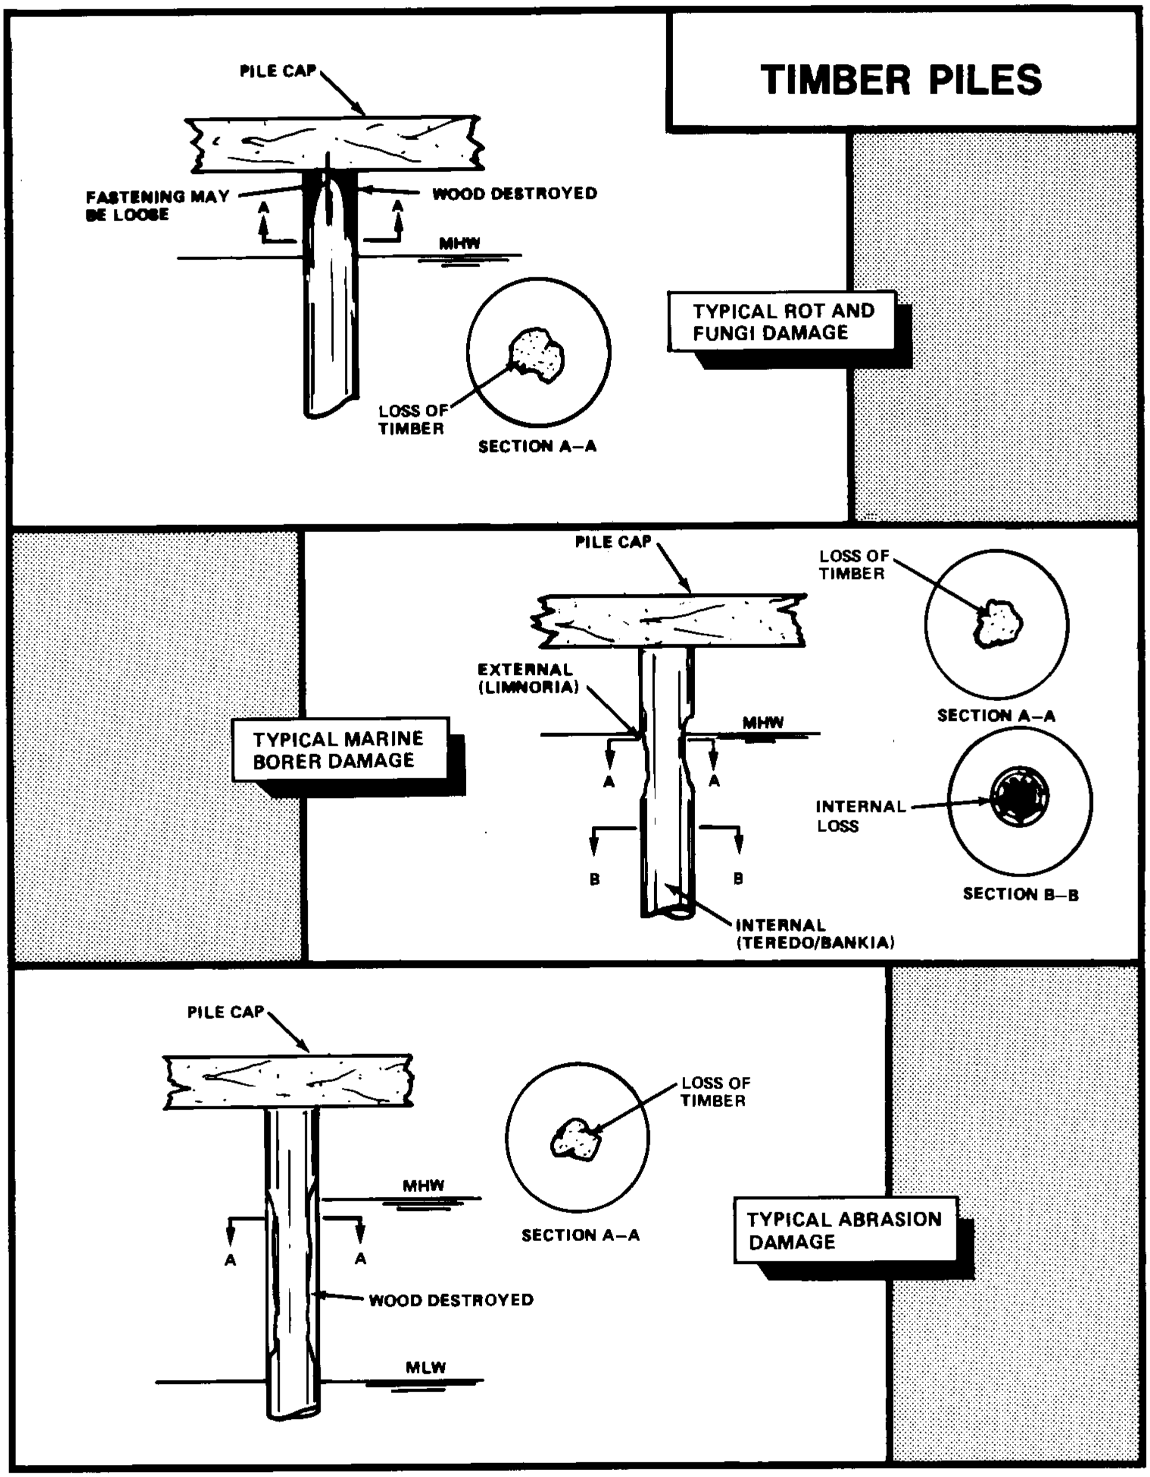

Figure 5-8 Damage to Timber Piles from Non-Biological Sources

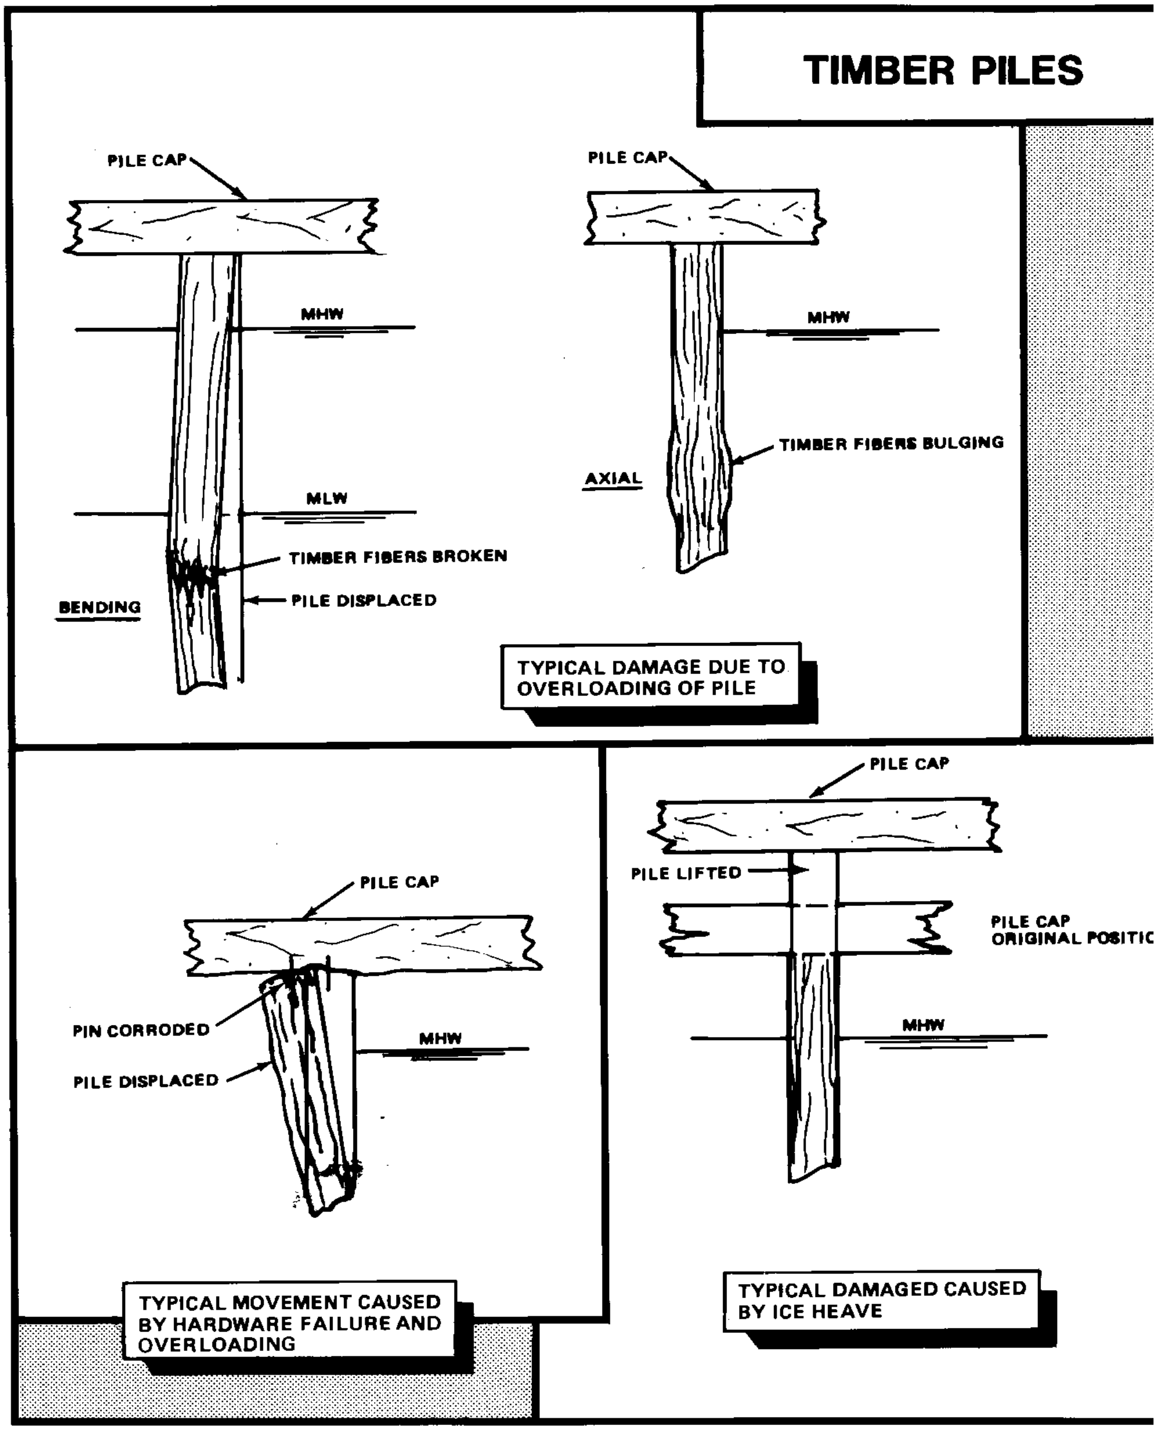

Figure 5-9 Damage to Timber Sheet Piling

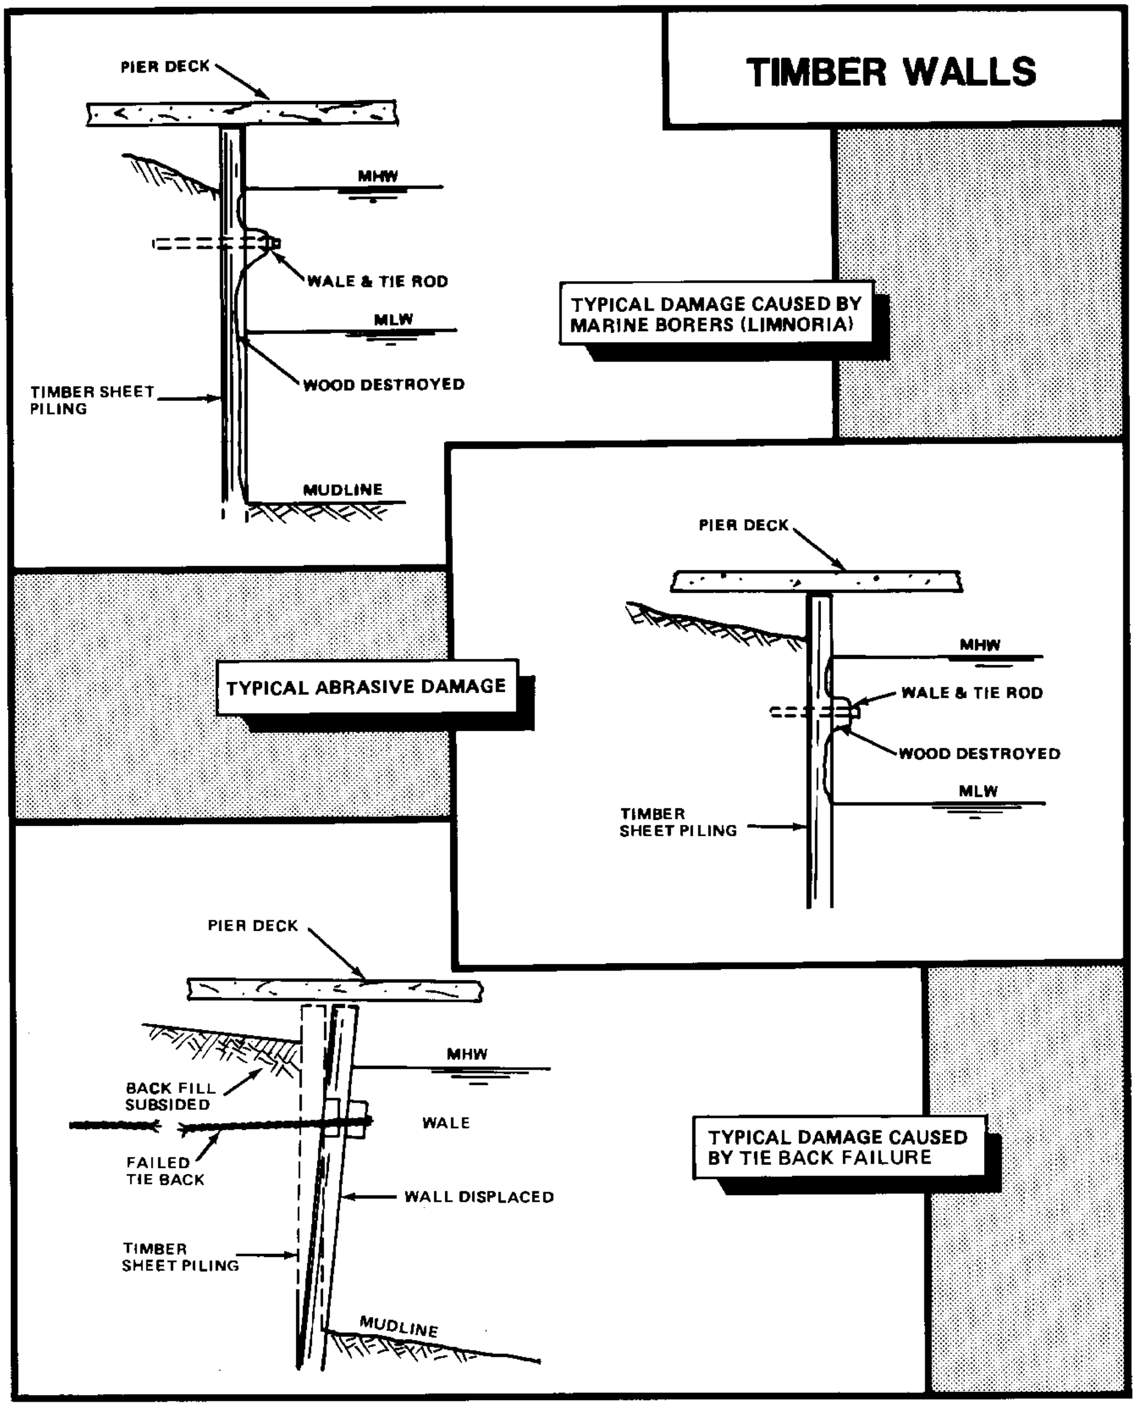

The inspector should be alert, specifically in the areas of stringers, pile caps and top of piles, for signs of discoloration and softening of the wood, accompanied by a fluffy or cotton appearance. This may be an early sign of fungi damage. More advanced deterioration may take on the appearance of fruiting bodies, such as mushrooms. Further down the pile, the inspector should look for burrows or hollows in the wood, surface trenches in the outer layers of the pile, and loss of pile diameter. This may be evidence of marine borer attack.

Table 5-4 Sampling Equipment, Measurements, and Ratings for Timber Structures

Special Sampling Equipment	Measurements or Ratings
Increment borer (Install Treated wooden plugs in holes left after boring)	Quality of preservative or soundness of piling
Calipers	Pile diameter; rating of piling condition
Sonic Equipment	Data from sonic equipment; detection of hollow areas in piling
Ice pick or other sharp probe	Location and size of damaged areas Depth of cracks and other damaged areas

5-4.3 **Underwater Inspection**. Use Figure 5-11 “Timber Structures and Attachments (Below Water) Checklist” to ensure that a thorough inspection of all timber structures and their attachments below water is done. An engineer should explain to the diver exactly what should be looked for: number and size of piles, type and depth of bulkheads, location of tiebacks, and cross bracing. The engineer shall evaluate the diver's observations and determine the degree of hazard.

\1\

Additionally, when observing damage from marine borers (teredos) precautions need to be taken. As the diver swims up to the pile, he may be able to see the cilia, “waving,” as the worm filters food from the water, Otherwise, the worm feels the disturbance and withdraws the feeding hairs (and closes the opening). The diver is unable to see anything because the opening is:

- Small
- Closed
- Obscured by marine growth and shellfish

/1/

Figure 5-10 Timber Structures and Attachments (Above Water) Checklist

	Deck Area
___	Check for cracked, rotted, loose or worn decking or string pieces, loose hardware, soft spots in decking (Figure 5-6), and termite or pest infestations.
___	Check the tops of fender piles and visible chocks and wales for physical damage, dry rot and termite or pest infestations.
___	Check horizontal and vertical alignment.
___	Check for missing, broken, or loose connections; obstructions; and other hazardous conditions of curbing, handrails, and catwalks.
___	Check bollards, bits, cleats and capstans for wear, breaks, rough or sharp surfaces or edges and missing or loose bolts.
___	Check deck drains and scuppers for loose, missing or broken screws, standing water, and other deficiencies.
___	Check manhole covers and grating for rust, corrosion, bent or worn hinge pins, and other damage.
___	Inspect asphalt deck coverings (if applicable) for cracks, holes, and other damage.
___	Check ladders for rust and corrosion, broken, bent or missing rungs, and rot, termite or pest infestations.
___	Check grounding connections for tightness.
	Exposed Area Under Pier or Along Wharf or Dolphin Assembly
___	Check wood stringers, pile caps, bearing, batter and fender piles, for missing or broken members and evidence of fungal decay and insect damage. Check for loose, fractured or missing wales and chocks.
___	Check dolphins for broken, worn or corroded cables and cable connectors; and corroded, loose, broken or missing wedge block, chafing strips and bands, or chock bolt hangers.
___	Check dolphins for poor vertical pile alignment.
___	Visually examine piling and other wood in the splash and tidal zones for marine borer damage.
___	Sound the pile areas with a hammer and carefully probe with a thin-pointed tool such as an ice pick.
___	Check for pile shrinkage, overloading damage, connector corrosion, abrasion, and ice heaving damage.
___	Take a small boring for laboratory analysis using and increment borer if an area of rot or marine borer damage is in question. Once the core is extracted, seal the hole with a creosote treated plug to prevent easy access of borers to the interior of the pile.

Figure 5-11 Timber Structures and Attachments (Below Water) Checklist

___	Start at the splash/tidal zones. Note: A Level I inspection should be done first to identify areas of mechanical damage, repair and new construction.
___	Clear a section of the structure of all marine growth and visually inspect it for surface deterioration. This is done at spot locations rather than cleaning the entire structure.
___	Sound the cleaned area with a hammer and carefully probe with a thin-pointed tool, such as an ice pick.
___	If an area is in question, take a small boring for laboratory analysis using an increment borer. Plug the hole with a creosote treated plug to prevent easy access for marine borers.
___	Descend down to the pile, sounding the structure with a hammer wherever there is minimal marine growth, as well as probing carefully with an ice pick.
___	At the bottom, note and record the depth of the water on a Plexiglas® slate with a grease pencil.
___	Record visual observations, i.e., the presence of marine borers, losses of cross-sectional area, organism-caused deterioration, location and extent of damage, alignment problems, and condition of fastenings. Use calipers and scales and required.
___	Use ultrasonic techniques if internal marine borer damage is suspected. Ultrasonic techniques are available to support the underwater inspection program.
___	After finishing the underwater work, return to the surface and record all data into the inspection log. Similar procedures would be followed for timber retaining walls.

5-5 INSPECTION OF CONCRETE STRUCTURES

5-5.1 **Scoping the Problem**. Concrete damage appears in the following forms:

- Corroded rebar
- Alkali-silica reaction
- Freeze/thaw deterioration
- Abrasion wear
- Chemical deterioration from saltwater
- Overloading deterioration
- Shrinkage

These forms of damage are described in detail in Chapter 3. As with timber structures, concrete damage is found by walking the pier deck, inspecting below the pier deck in a small boat or barge, and underwater inspections.

The primary method of inspecting concrete is visual observation and sounding with a hammer. Only after problems are detected should other inspection methods be used. These other methods may include chipping away loose concrete to reveal the steel, coring, or Schmidt hammer.

5-5.2 **Surface Inspections**. Use Figure 5-12 “Concrete Structures and Attachments (Above Water) Checklist” to do a thorough inspection of all concrete structures and their attachments above water. Include annual load testing of the pier decking if heavy equipment or vehicles are to be driven onto the pier. Sampling equipment and inspection data to be compiled are given in Table 5-5.

Areas where the inspector should be particularly watchful for signs of deterioration, include:

- Inside corners and areas where radical changes occur in size of deck sections, curbs, and bollards.
- Construction joints.
- Poorly designed scuppers, drips, and curb slots, and other areas where inadequate drainage exists.

- Joints between the deck and pile cap, expansion joints where insufficient gap is allowed, and rigid joints between precast piles and cast-in-place pile caps.

Table 5-5 Sampling Equipment, Measurements and Ratings for Concrete Structures

Special Sampling Equipment	Measurement, Ratings or Samplings
Half-cell potential measurements	Location and size of damaged area
Schmidt hammer	
Hammer	
Chipping tool	Depth of chips, cracks, spalls, etc. Powder samples for chloride contamination
Concrete-core rotary drill	Drilled concrete cores for laboratory analysis
Pachometer	Rebar locator

The inspector should be alert for any change in appearance of the concrete surface and any change in the sound from the hammer:

- Erosion of the surface material or by cracking on the surface are signs of chemical attack.
- Erosion of surface material is a sign of freeze-thaw deterioration.

Use a hammer or gad (sharp pointed tool) to chip or probe the surface to detect the depth of deterioration.

Corrosion of the reinforcement can be detected from rust stains on the surface. More advanced stages of corrosion is indicated by cracks that run parallel to the steel reinforcing bars. At times, corrosion is hidden from view, but will be indicated by a hollow sound from the hammer. This can occur on heavily reinforced slabs, such as pier decks, where the reinforcement has corroded enough to delaminate a layer of concrete at the level of the reinforcing mat.

Figure 5-12 Concrete Structures and Attachments (Above Water) Checklist

Deck Area	
___	Check horizontal and vertical alignment
___	Check for missing, broken, or loose connections, obstructions and other hazardous conditions of curbs, handrails and catwalks.
___	Check bollards, bits, cleats and capstans for wear, breaks, rough or sharp surfaces or edges, and missing or loose bolts.
___	Check deck drains and scuppers for loose, missing or broken screws, water ponding and other deficiencies.
___	Check manhole covers and grating fro rust, corrosion, bent or worn hinge pins, and other damage.
___	Inspect concrete deck surface, curbs, utility trenches and gallery areas for cracks, spalling, loose joint sealers, and other damage. Closely inspect for corrosion of reinforcing steel and visual signs of rust.
___	Check ladders for corrosion, and broken, bent or missing rungs.
___	Check grounding connections for security
Exposed Area Under Pile or Along Wharf or Dolphin Assembly	
___	Check pile caps and bearing, batter and fender piles for damaged or broken members, cracks and spalling of concrete, rust stains, and exposed reinforcing steel.
___	Check for efflorescence, and general disintegration of the underside of pier decking and pile caps (Figure 5-13).
___	Check bottom scouring or undermining.
___	Check for evidence of shrinkage, swelling, and chemical deterioration; freeze/thaw deterioration; abrasion wear; and overload damage of piles as shown in Figure 5-14.
___	Sound the piling or structure with a hammer to detect any loose layers of concrete or hollow spots. A sharp ringing noise indicates sound concrete. A soft surface will be detected, not only by a sound change, but also by the change in the rebound, or feel, of the hammer. A thud or hollow sound indicates a delaminated layer of concrete, most likely for corrosion of steel reinforcement.

Figure 5-13 Inspection Areas for Visual Indications of Concrete and Reinforcement Deterioration

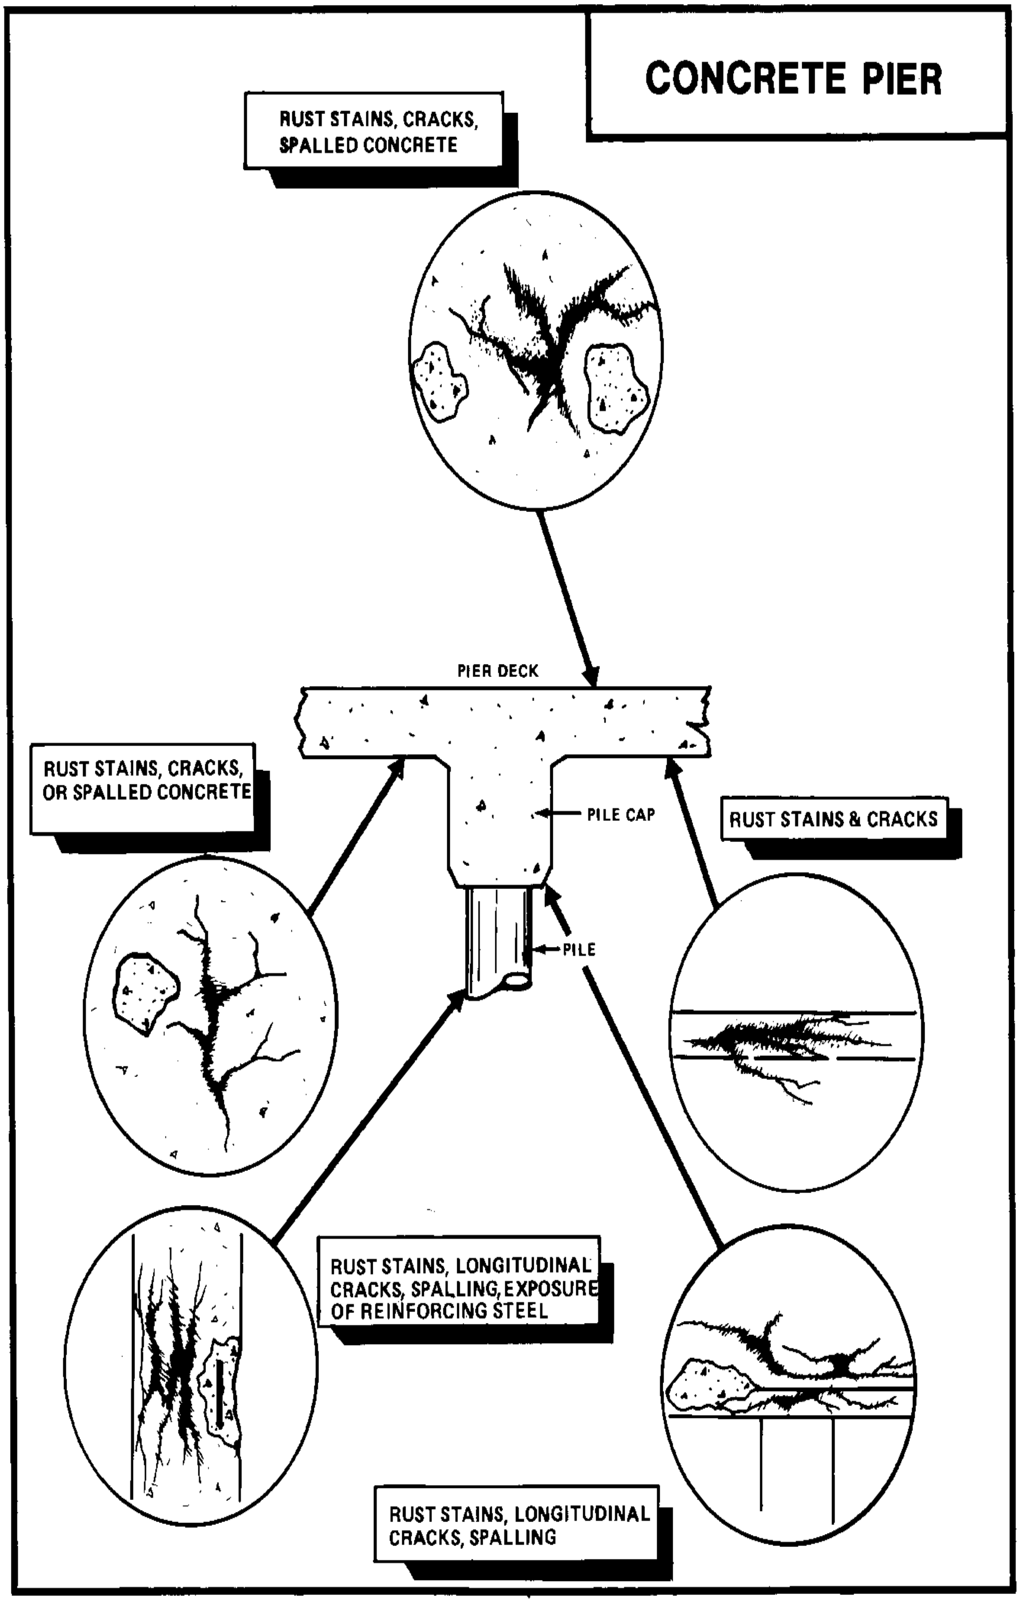

Figure 5-14 Typical Damage to Concrete Piles from Non-Biological Sources

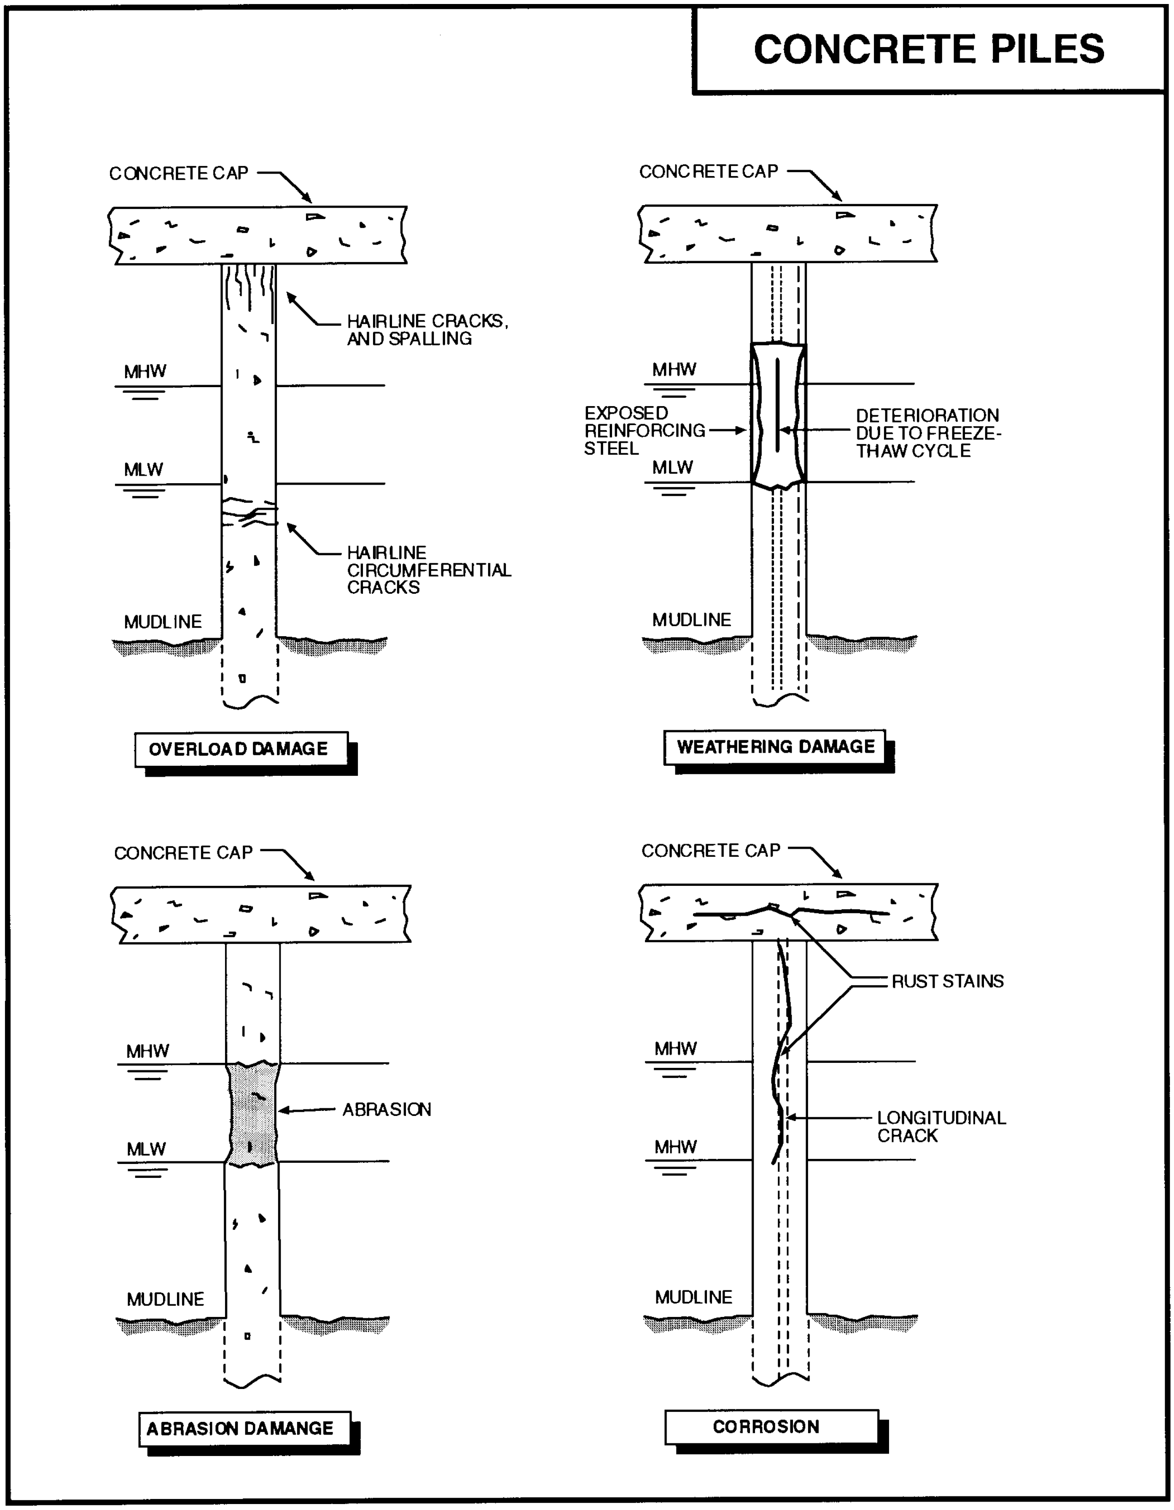

Give special attention to cracks found on the surface of a concrete structure. Make sketches that show the length and direction of the cracks. Overall cracking patterns and changes in crack length, width and direction with time are meaningful data to a structural engineer. Photographs are helpful, but only as a supplement to the sketches.

If there is evidence of significant deterioration, more detailed NDT techniques may be used in a scheduled Level III inspection. Refer to the Level III test procedures for concrete inspection for mechanical and electrical test methods in the Paragraph entitled, “Level III Test Precedures for Concrete Inspection”. The plan and sampling techniques shall be tailored to the specific areas of concern.

5-5.3 **Underwater Inspection**. Use Figure 5-15 “Concrete Structures and Attachments (Below Water) Checklist” to ensure that a thorough inspection of all concrete structures and their attachments below water is done. An engineer should explain to the diver exactly what should be looked for: number and size of piles, type and depth of bulkheads. The engineer will evaluate the diver’s observations and determine the degree of corrosion.

5-5.4 **Level III Test Procedures for Concrete Inspection**. If signs of deterioration or damage are found by Level I or II inspections then a Level III inspection, involving either nondestructive or destructive tests, may be required. Level III concrete inspections use mechanical and electrical test methods.

Mechanical and electrical test methods include:

- The Schmidt test hammer may be used in order to compare the relative surface quality of concrete at different locations on the same structure. The instrument measures the hardness of concrete surfaces by the extent of rebound of a spring-loaded steel plunger in a tubular frame. The relative surface quality of the concrete, which is also an indication of its compressive strength, can be obtained. Surface texture may reduce values obtained.

- Core samples are destructive in nature and should only be used if other techniques cannot satisfactorily define the damage. Core samples may be taken from selected areas in order to determine the cause and depth of deterioration, chloride, ion contamination for petrographic analyses, and the actual compressive strength. Take special care when setting up to drill a core, in order to avoid hitting steel reinforcement, especially prestressed steel. Steel reinforcement near the surface can be located by using a pachometer (rebar locator). The length of the core sample should be twice the diameter. After the core has been taken, patch the hole with non-shrink cementitious mortar.

Figure 5-15 Concrete Structures and Attachments (Below Water) Checklist

___	Inspect the structure beginning in the splash/tidal zone. This is where most mechanical and biological damage is normally found.
___	Clear a section about 16 to 24 inches (40 to 60 cm) in length of all marine growth.
___	Visually inspect this area for cracks with rust stain, spalling or impact damage, and exposed reinforcing steel.
___	Sound the cleaned area with a hammer to detect any loose layers of concrete or hollow spots in the pile or structure. A sharp ringing noise indicates sound concrete. A soft surface will be detected, not only by a sound change, but also by a change in the rebound, or feel, of the hammer. A thud or hollow sound indicates a delaminated layer of concrete, most likely from corrosion of steel reinforcement.
___	Visually inspect the pile or structure where marine growth is minimal, and sound with a hammer.
___	Inspect, in greater detail, the base of mass concrete structures, such as retaining walls and foundations. These structures are prone to undermining by wave and current action, which, if not rectified, could lead to failure of the structure.
___	At the bottom, record the water depth along with any observations of damage on a Plexiglas® slate.
___	After returning to the surface, immediately record all information into the inspection log.

- ASTM C876*, Corrosion Potentials of Uncoated Reinforcing Steel in Concrete* can be used to determine the extent of active corrosion and the degree of susceptibility of corrosion in other areas in the structure. Corrosion can be detected before visible signs appear. The method detects corrosion by measuring the electrical potential of the steel. An electrical connection is made from one side of a voltmeter to an embedded steel-reinforcing bar that has been exposed. The other side of the voltmeter is connected to a copper sulfate half-cell, which is then put in contact with the concrete surface at various locations. The magnitude and sign of the resulting voltage is an indication of corrosion activity.

- Ultrasonic methods are available to inspect concrete for voids that cannot be seen, such as honeycomb pockets, and for internal deterioration by cracking. Pulse velocities and fundamental frequencies are imposed in the concrete structure to search for imperfections. Sonic methods conducted at specific time intervals can monitor progressive deterioration. Interpretation of data is a highly specialized skill.

Before starting any of the above tests, a test plan must be prepared and the areas to be tested must be cleaned thoroughly.

5-6 INSPECTION OF STEEL STRUCTURES

5-6.1 **Scoping the Problem**. There are six major types of steel structure deterioration to watch for in the marine environment:

- Corrosion
- Abrasion
- Loosening of structural connections
- Fatigue
- Overloading
- Loss of foundation material

The causes and forms of steel deterioration are described in detail in Chapter 3.

5-6.2 **Surface Inspections**. Generally, visual inspections will detect most forms of deterioration of steel structures. Use Figure 5-16 “Inspection of Steel Structures (Above Water) Checklist” to ensure a thorough inspection of steel structures above water is done. In the event that more detailed NDT techniques are required under a Level III inspection, a plan and sampling techniques must be developed and tailored to the specific areas of concern.

Some types of corrosion, however, may not be detected by visual inspections. For example, inside steel pipe piling, anaerobic bacterial corrosion caused by sulfate-reducing bacteria (Figure 5-17) is difficult to detect by visual inspection. Fatigue distress can be recognized by a series of small hairline fractures perpendicular to the line of stress but these are difficult to locate by visual inspection. This type of problem, however, is more prevalent to offshore platforms with welded structural connections than to standard piers and wharves.

Cathodic protection systems need to be closely monitored both visually and electrically for signs of loss of anodes, wear of anodes, disconnected wires, damaged anode suspension systems, and low voltage.

Table 5-6 summarizes special sampling equipment, measurements required, and ratings used in the inspection of steel structures.

Table 5-6. Inspection Equipment, Measurements, and Ratings of Steel Structures

Special Sampling Equipment	Measurements, Ratings, or Samplings
Scale or calipers for deter-mining thickness	Metal thickness
Ultrasonic equipment for determining thickness	Deformation of structural members Cathodic protection potentials
Voltmeter and half-cell for measuring electronic potentials on cathodically protected steel	Location and size of damaged areas
Pit Gauge	Depth of pits and extent of their occurrence.
Scraper	Samples of corrosion products or damaged coatings

5-6.3 **Underwater Inspections**. Use Figure 5-19 “Under Water Steel Structures Checklist” to ensure that a thorough inspection of underwater steel structures is done. An engineer should explain to the diver exactly what to look for: number and size of piles, type and depth of bulkheads. The engineer shall evaluate the diver's observations and determine the degree of hazard.

Figure 5-16 Inspection of Steel Structures (Above Water) Checklist

	Deck Area
___	Refer to either Timber Structures (Figure 5-10) or Concrete Structures (Figure 5-12) Surface inspection Checklist, depending on construction.
	Exposed Area Under Pier or Along Wharf
___	Check for corrosion evidence: rust, scale and holes, in H-piles and sheet piling, especially in the splash zone and approximately 24 inches (60 cm) below mean water low water (Figure 5-17).
___	Sound the surface with a hammer to detect any scaled steel or hollow areas.
___	Indicate the location, extent and type of corrosion (density pitting, etc.) found.
___	Check for loosening of structural connections as indicated by misalignment of mating surfaces and by looseness or distortion of structural members
___	Check for deformation or distortion of a structural member in the form of a sharp crimp, or compression of a bearing or batter pile (Figure 5-18). This indicates possible overloading.
___	Check for deflection of steel sheet piling caused by failure of tiebacks or overload of backfill or live load.
___	Check for abrasion of steel structures as indicated by a worn, smooth, polished appearance.
___	Check for loss of foundation material caused by scour of materials from around the piles supporting the structural element (Figure 5-18). A loss of foundation material in front of a sheet pile bulkhead may cause kick-out of the toe of the wall and result in total failure.
___	Inspect welds for signs of corrosion, cracking or looseness.
___	Inspect coating or wraps for any peeling, blistering, erosion, tears, etc.
___	Inspect holes in steel sheeting for loss of backfill material through the opening and subsidence of adjacent ground surface.

Figure 5-17 Corrosion Damage to Steel Bearing and Sheet Piling

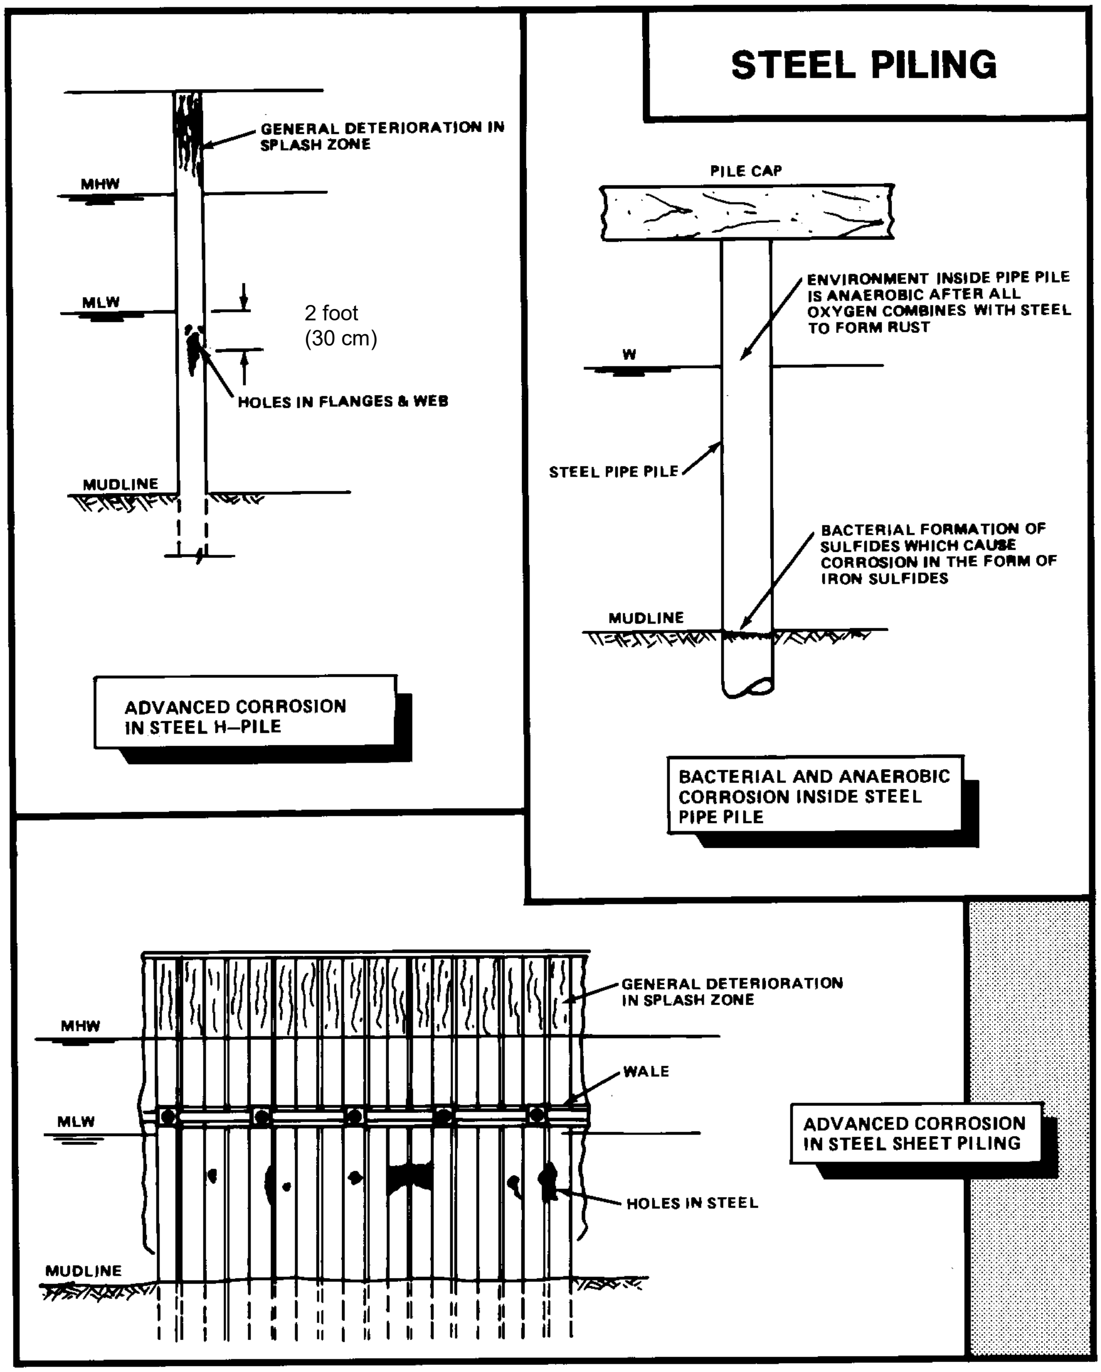

Figure 5-18 Damage to Steel Bearing and Sheet Piles from Overloading, Wall Movement or Scour.

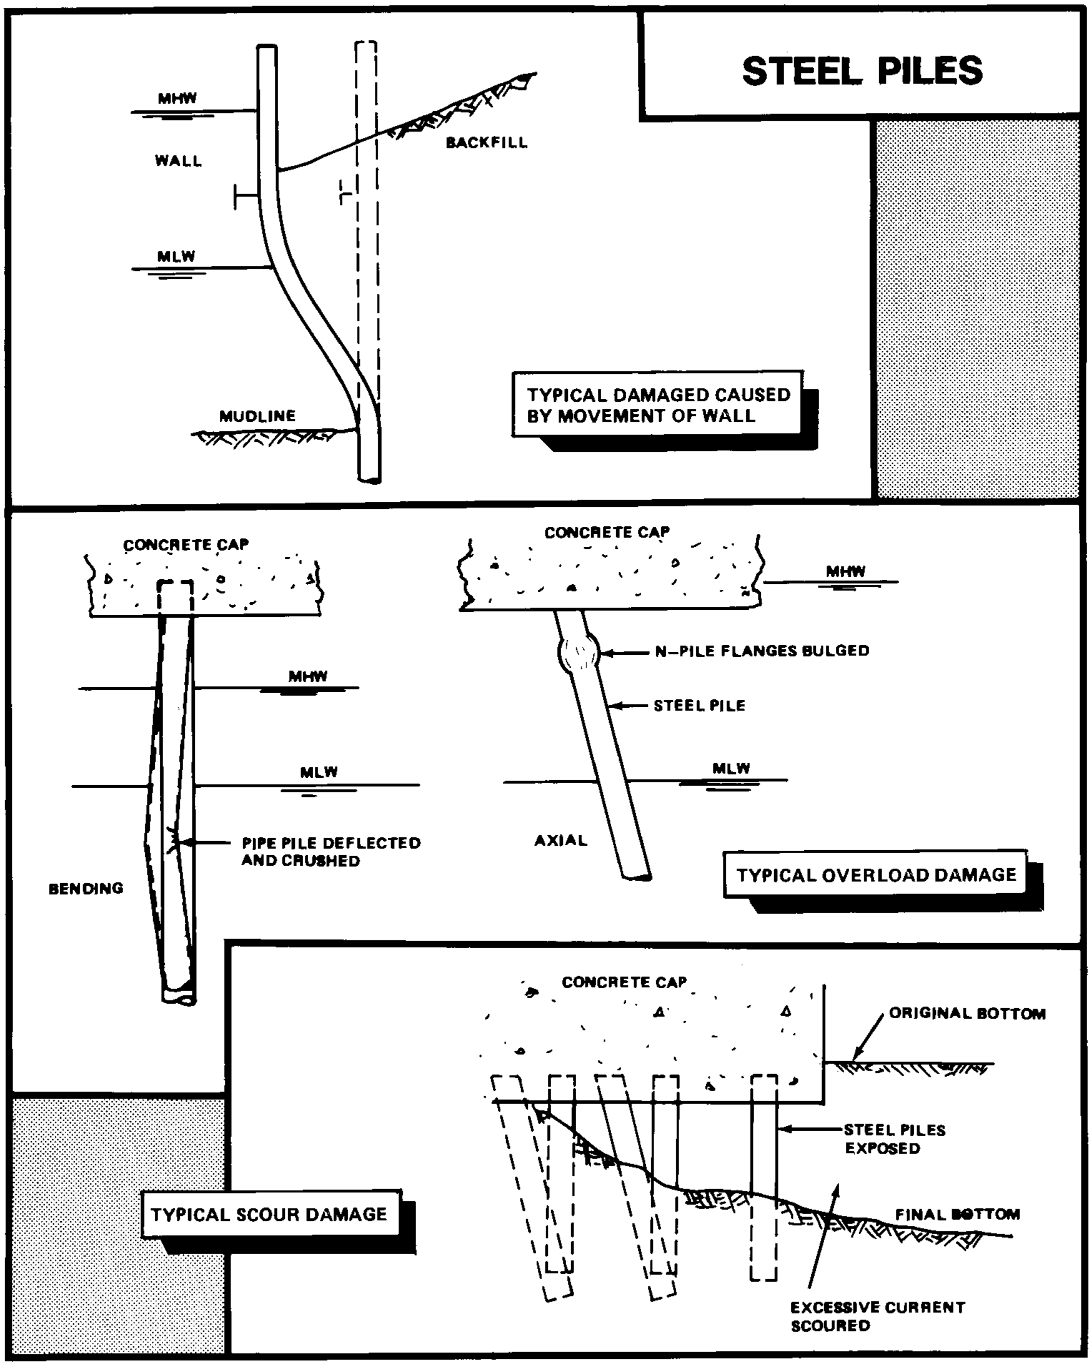

Figure 5-19 Underwater Steel structures Checklist

___	Start the inspection at the splash/tidal zones and at depth of about 24 inches (60 cm) below mean low water (MLW). This is where most mechanical and corrosion damage is found.
___	Clean all marine growth from a 12 inch (30 cm) square section of pile (clean a larger area if inspecting sheeting) and visually inspect for rust, scale and holes.
___	If the structure has a cathodic protection system, check the cleared area with an underwater voltmeter to determine its effectiveness. Acceptable levels of cathodic protection are between -0.80 to -0.90 volts when compared to a silver/silver chloride reference cell.
___	Sound the surface with a hammer to detect any scaled steel or hollow areas. Inspect holes in steel sheeting for loss of backfill material through the opening and subsidence of adjacent ground surface.
___	Visually inspect the structure and sound with a hammer where there is minimal marine growth.
___	At the bottom, record the water depth, using a wrist depth gauge, on a Plexiglas® slate with a grease pencil.
___	Record other visual observations, such as coating condition (peeling, blistering, erosion). Closely inspect splices for loss of weld materials and looseness of splices.
___	Record the condition of cathodic protection equipment (broken or corroded conduits, loose wires, consumed or lost anodes).
___	Record the extent and type of corrosion, structural damage, or any other significant observations, using calipers and scales to determine thickness of steel flanges, webs and plates.
___	Return to the surface and immediately record the observation data in the inspection log.
___	If more sophisticated means are required to evaluate the condition of steel piling, ultrasonic inspection is available for more complete thickness measurements. These measurements must be made in areas clear of all marine growth and scale. Using ultrasonic equipment in areas with corrosion pitting can give erroneous thickness measurements. Magnetic particle inspection may be used, particularly on welded connections, to detect cracks and small defects.

5-7 **INSPECTION OF SYNTHETIC MATERIALS AND COMPONENTS**. Inspection of synthetic materials and components is subdivided into the following three categories:

5-7.1 **Structural Members**. Structural members should be inspected annually. The inspection should detect:

- Cracked, worn, brittle, or deformed plastic railings, stanchions, gratings, light standards, or piping; loose or damaged fittings and connections; and exposed fiberglass.
- Cracked, worn, or deformed rubber resilient fender components, and/or loose or damaged fittings and connections.

Basic inspection procedures are the same as those outlined for timber or concrete structures.

5-7.2 **Coatings, Patches and Jackets**. Coatings, patches, and jackets should be inspected annually, or more frequently, depending on the failure rate of the application. The inspection should detect:

- Pits, cracks, scars, or abrasions in coatings.
- Cracked, loose, or dislodged epoxy patches.
- Punctures, brittleness, tears, rips, or abrasions in fabric, or unlocking of fabric seams in pile jackets.

Basic inspection procedures are the same as those outlined for timber, concrete, and steel structures.

5-7.3 **Foam-Filled Fenders**. Foam-filled fenders should be inspected more than normal pier inspections and should cover:

- Condition of the fender-to-pier connection hardware. Check for operability and signs of corrosion. Check to ensure that the fender is constrained horizontally so that it contacts the bearing surface for its full length. Ensure that the fender is free to vertically float with the tide and rotate around its long axis.
- Condition of the fender chain and tire net for net fenders. Check to see that the chain is symmetrical on the fender and that the end fittings are in good working order. Ensure that the chains are protected from the ship hull by the tires, and that the net is not loose.

- Condition of end fittings on netless fenders. Check to see that the fittings are in good working order, and corrosion is minimal. Check to see that the fender shell is not cracked or separated around end fittings.

- Condition of the fender elastomer shell. Check for cuts, tears, and punctures. Record the size and location of damage on a sketch.

- Measure or estimate the diameter of the fender at its smallest point to record permanent set.

Inspections will be done by walking the pier and using a small boat.

Record keeping for foam-filled fenders is very important. In this regard, the fenders should be treated as an item of high-cost equipment rather than an appurtenance to a fixed facility. Each fender should have a unique identification number with a history record that includes date of procurement, manufacturer, date of installation or when fender was put into service, and berth location if permanently installed.

5-8 **INSPECTION OF QUAYWALLS**. Quaywalls are an integral part of wharves and should be included when other pier components are inspected.

Deterioration of quaywalls is indicated by:

- Shifts in horizontal and vertical alignment of sheet piling.

- Damage or deterioration of the wood, concrete, or steel sheet piling.

- Wash-out of substrate under the sheet piling, particularly at the toe of the structure.

Alignment shifts can be detected by visual observation. A complete description of shifts and any apparent cause should be provided. Deterioration of wood is covered by the Paragraphs entitled, “Inspection of Timber Structures”, Inspection of Concrete Structures” and “Inspection of Steel Structures”. Wash-out may be detected by visual inspection in clear water at low tide. If not, then an underwater inspection is required. Figure 5-20 “Quaywall Surface and Underwater Inspection Checklist,” is a useful guide.

Figure 5-20 Quaywall Surface and Underwater Inspection Checklist

___	Swim around the base of the structure looking for weaknesses in the base of these structures, e.g., washout of small stones and core material.
___	Note signs of detrimental wave action, e.g., scouring and sloughing.
___	Record all pertinent information on a Plexiglas® slate and transfer the information to the inspection log.
___	Record the result of the above water inspection, which should include a description of the alignment and general condition of the seawall.

5-9 **THE INSPECTION REPORT**. For each inspection, a report is prepared. The report includes facility plans with updated descriptions, such as: size and pile arrangement, an evaluation of the assessed conditions, and recommendations for further action. The report should provide enough technical detail to support the assessments and recommendations. The Paragraph entitled, “Planning for Inspection” provides guidance for preparing inspection documentation to be used in preparing the report.

NAVFAC MO-322, *Inspection of Shore Facilities* calls for a three-part inspection report package for shore facilities consisting of a: facility inspection checklist, facility condition summary report sheet, and facility condition detailed deficiency list. Forms for these three sections are shown in Chapter 4, Volume 1 of MO-322. They are, however, geared more for inspecting buildings and are not specifically designed for waterfront structures.

Since waterfront inspections are specialized, a report format such as the one presented in Table 5-7 would be more appropriate. This format is used by NFESC \1\ /1/ when conducting underwater inspections and assessments at Naval waterfront facilities.

Table 5-7. Report Format of Underwater Inspections and Assessments

CHAPTER 6

REPAIR OF WOOD AND TIMBER STRUCTURES

6-1 **GENERAL.** The most common uses of wood and timber structures in waterfront facilities involve:

- Older piers, wharves, bulkheads, and quaywalls constructed from dimension lumber, beams and stringers, and round timber piles.
- Fender systems constructed from beams and stringers and round timber piles
- Pile dolphins constructed from round timber piles.
- Log floats and camels, glued and laminated wood, and miscellaneous forms.
- Degaussing facilities that require using nonmagnetic construction materials.
- Groins constructed from beams and stringers and round timber piles.

With the exception of fender systems, floats and camels, most systems have been installed for several decades, in many cases dating back to World War II.

The need to conduct an effective repair program for these facilities is essential if the facilities will continue to be used and if escalating costs of repairs are to be avoided. Postponing the repairs, particularly for bearing piles, can lead to costly replacement or downgrading of the structural capacity of the facility.

6-1.1 **Repair Methods.** Repair methods for wood and timber structures are generally directed at correcting one or more of the following problem areas: fungal decay, insect damage, marine borer deterioration, abrasion, and overload.

The repair methods to be used must consider the following elements.

- Facility mission and required life.
- Extent of damage and deterioration.
- Estimated life expectancy with and without repairs.
- Projected load capacities.

- Problems associated with mobilization of equipment, personnel, and materials to accomplish repairs/maintenance.

- Economic trade-offs.

6-2 **REFERENCES**. Materials used to develop repair techniques and planning factors outlined in this section have been taken, in part, from:

- Scheffer, T.C., *Observations and Recommendations Regarding Decay in Naval Waterfront Structures*, Forest Products Laboratory, September 1966.

- Morrell, J. J. and et. al, *Marine Wood Maintenance Manual: A Guide for Proper Use of Douglas-fir in Marine Exposures*, Forest Research Lab, Oregon State University Research Bulletin 48, October 1984.

- Childs Engineering Corp., *Survey of Techniques for Underwater Maintenance/Repair of Waterfront Structures*, Revision No. 1, for the Naval Civil Engineering Laboratory, December 1985.

- \1\ Southern Forest Products Association /1/, *Marine Construction Manual: A Guide to Using Pressure-Treated Southern Pine in Fresh and Saltwater Applications*, October 1994.

6-3 **PLANNING THE REPAIRS**. Repairing timber structures will be controlled by the availability of skilled personnel and equipment. In many cases structural repairs, particularly those involving bearing and sheetpiling, will be done by contract.

6-3.1 **Reviewing Inspection Reports**. The initial planning step must involve a review of prior inspection reports to determine the scope and rate of damage or deterioration, and specific operational constraints placed on the facilities because of the deterioration. Once the scope of repair requirements (including priorities) is established, determining how to do the repairs (whether in-house or by contract) must be determined.

6-3.2 **Engineering Considerations**. Any repair of structural members will require experienced design professionals with knowledge of local tidal conditions, building codes, materials, substrate analysis, and construction practices.

6-3.3 **Special Skill Requirements**. Surface repairs covering pier decking, string pieces, stringers, pile caps, braces, and fender piles require skills common to the wharf-building trade. Underwater repairs, however, require special skill levels that may not be available with in-house forces. This includes how to remove marine growth, jetting or air lifting procedures, underwater cutting and drilling techniques, and jacketing and wrapping materials used in underwater construction.

6-3.4 **Equipment Requirements**. Surface repairs to the pier superstructure and fender system require equipment common to in-house shop forces. Equipment for underwater repairs, however, may include:

- High-pressure water blaster
- Hydraulic grinders with barnacle buster attachment
- Hydraulic drill with bits
- Hydraulic power unit
- Hydraulic chain saw
- Concrete pump with hosing
- Jetting pump and hose
- Rigging equipment
- Float stage and scaffolding
- Clamping template for cutting piles
- Special clamping equipment
- Crane

6-4 **REPAIR PROCEDURES.** Repair procedures for waterfront wood and timber structures are summarized in Table 6-1. Using any of the repair techniques that follow should adhere to the preservation treatment requirements outlined for wood and timber structures in Chapter 3.

Every effort should be made in rafting and handling to prevent damage to treated piles and timbers, particularly in portions of the work exposed to marine borer attack. Care should also be taken in driving piles to prevent checking or splitting of the treated wood, and butts shall be trimmed and headed so that the hammer will strike only untreated wood. Piles and timbers should be inspected before and during the time they are driven or placed. Where the protective preservative shell is broken or damaged in any way, the holes or crevices should be repaired by drilling, and neatly and tightly plugged in accordance with AWPA Standard \1\ U1 /1/. Where abrasions or other damages cannot be sealed against marine borers, other protection must be provided in an approved manner. All piles shall be handled in accordance with AWPA Standard \1\ U1 /1/.

Repair No.	Description
PIER SUPERSTRUCTURE AND FENDER SYSTEMS	
TR-1	Repairing timber pier superstructure
TR-2	Repair by replacing timber fender pile and damaged chocks and wales
BEARING PILES	
TR-3	Protecting timber piles with Polyvinyl Chloride Polyethylene Wrapping
TR-4	Partial posting of damaged pile with concrete encasement
TR-5	Repairing timber piles with concrete encasement
TR-6	Repair of retrofit timber piles with an underwater curing epoxy and fiber-reinforced wrap
TR-7	Replacing damaged pile with new timber pile under timber pier deck
TR-8	Replacing damaged pile with new concrete pile under concrete deck
TIMBER SHEET PILING WALLS	
TR-9	Reinforcing tie-back system for timber sheet piling wall
TR-10	Installing a tie-back system on the top of a timber sheet piling wall
TR-11	Installing a concrete cap / face on a timber sheet piling wall
DOLPHINS	
TR-12	Repair of dolphins

6-5 **ENVIRONMENTAL CONCERNS**. Federal environmental regulations allow the use of treated wood in the marine environment. A possible exception is the sheen created when creosoted piling is driven but this can be mitigated. Wood preservatives are EPA-registered pesticides and treated wood products for the marine environment will be widely available for the foreseeable future. Treated wood removed from service is not a hazardous waste and is not banned by Federal law from landfills.

Local and state environmental regulations, especially along the west coast, have restricted the marine use of treated wood. In some cases, where there is cause for environmental concern, conduct a site-specific risk assessment before starting on a project that involves installing a large amount of treated wood in the marine environment.

The handling of treated wood removed from service should be considered as an important part of any repair project. Discarded treated wood may generally be disposed at municipal landfills approved to receive the material by the state or local authorities. Some non-hazardous waste landfills, however, may classify treated wood as a “special waste” and require documentation of its status. Reuse of treated wood is a preferred option and is not currently regulated by Federal law, provided such reuse is consistent with the intended end use. Examples of reuse include fence posts, retaining walls, landscaping, decking, bulkheads, general construction, etc. Energy recovery may be an option if there is a facility relatively near that uses treated wood waste as a fuel. Bioremediation is another option that is encouraged, but is not yet widely available.

Since potential restrictions can vary widely with locale and can change, contact your Environmental Office before using, recycling, or dispersing of treated wood.

6-6 **QUALITY ASSURANCE CONCERNS.** In the recent past, Navy activities have too often accepted and used treated wood products that did not meet industry standards. This has resulted in poor performance and costly premature failure of waterfront wood structures and the perception that wood products are inappropriate for modern facilities. It is imperative that industry best management practices (BMP) be used to avoid receiving unacceptable treated wood products. These BMP include:

- Specify the appropriate material in terms of performance as defined in the \1\ American WoodProtectors Association /1/ Standards. Specify that wood treatments and handling methods comply with current industry BMP.

- Specify that treated wood be inspected by an independent agency certified by the American Lumber Standards Committee. Specify an on-site inspection before installation to assure proper lumber grades, moisture contents, and treatment standards have been met. For environmental reasons, if the treated wood does not appear clean and dry, i.e., no surface deposits, it should be rejected.

TR-1: REPAIRING TIMBER PIER SUPERSTRUCTURE

Problem: Wood components are damaged and no longer fully serve intended purpose or present a safety risk.

Description of Repair:

Decking**.** Replace decking with properly treated quarter-sawn timber or other suitable material when its top surface becomes uneven, hazardous, or worn to a point of possible failure. Spacing between decking planks is normally provided for ventilation and drainage. Blacktopping of decking may not provide a completely protective cover against rain wetting beneath it because cracks often develop in the material. Limit washing decks with freshwater as this promotes wood decay.

Pile Caps**.** Replace decayed or damaged pile caps with properly treated wood (including glulam) or other suitable material. Replacement caps should be the same size and length as the original caps unless redesigned.

Curbs, Chocks, and Wales**.** Replace these members with properly treated lumber (including glulam) or other suitable material when decay or other damage renders them unfit for service. Make butt-type joints, not lap-type joints, in connecting wood curbs and wales to reduce decay damage potential. Replacement sections should be long enough to reach a minimum of two bents. Place new preservative-treated wood blocks or other suitable material, 2 to 3 inches (5 to 8 cm) thick, under each curb (upper string piece) replacement section at intervals of about 3.3 feet (1 meter) to provide for drainage (Figure 6-1).

Braces**.** Replace diagonal braces that are broken or attacked by fungi or marine borers with wood or other suitable material. Place pressure-treated wood braces well above high water and treat all bolt holes with a preservative. An alternative to using pretreated wood is plastic barriers, either polyethylene or polyvinyl chloride plastic wraps or polyurethane coatings. The braces, with bolt holes, can be fashioned to fit and the plastic applied before the braces are attached to the pier piling. Where braces are fastened to a piling, the pile should not be cut or dapped to obtain a flush fit. Where decking has been removed for repairs, it is often possible to drive diagonal brace piles to provide lateral stiffness. This procedure eliminates all bolt holes except those at the top of the structure immediately below the decking.

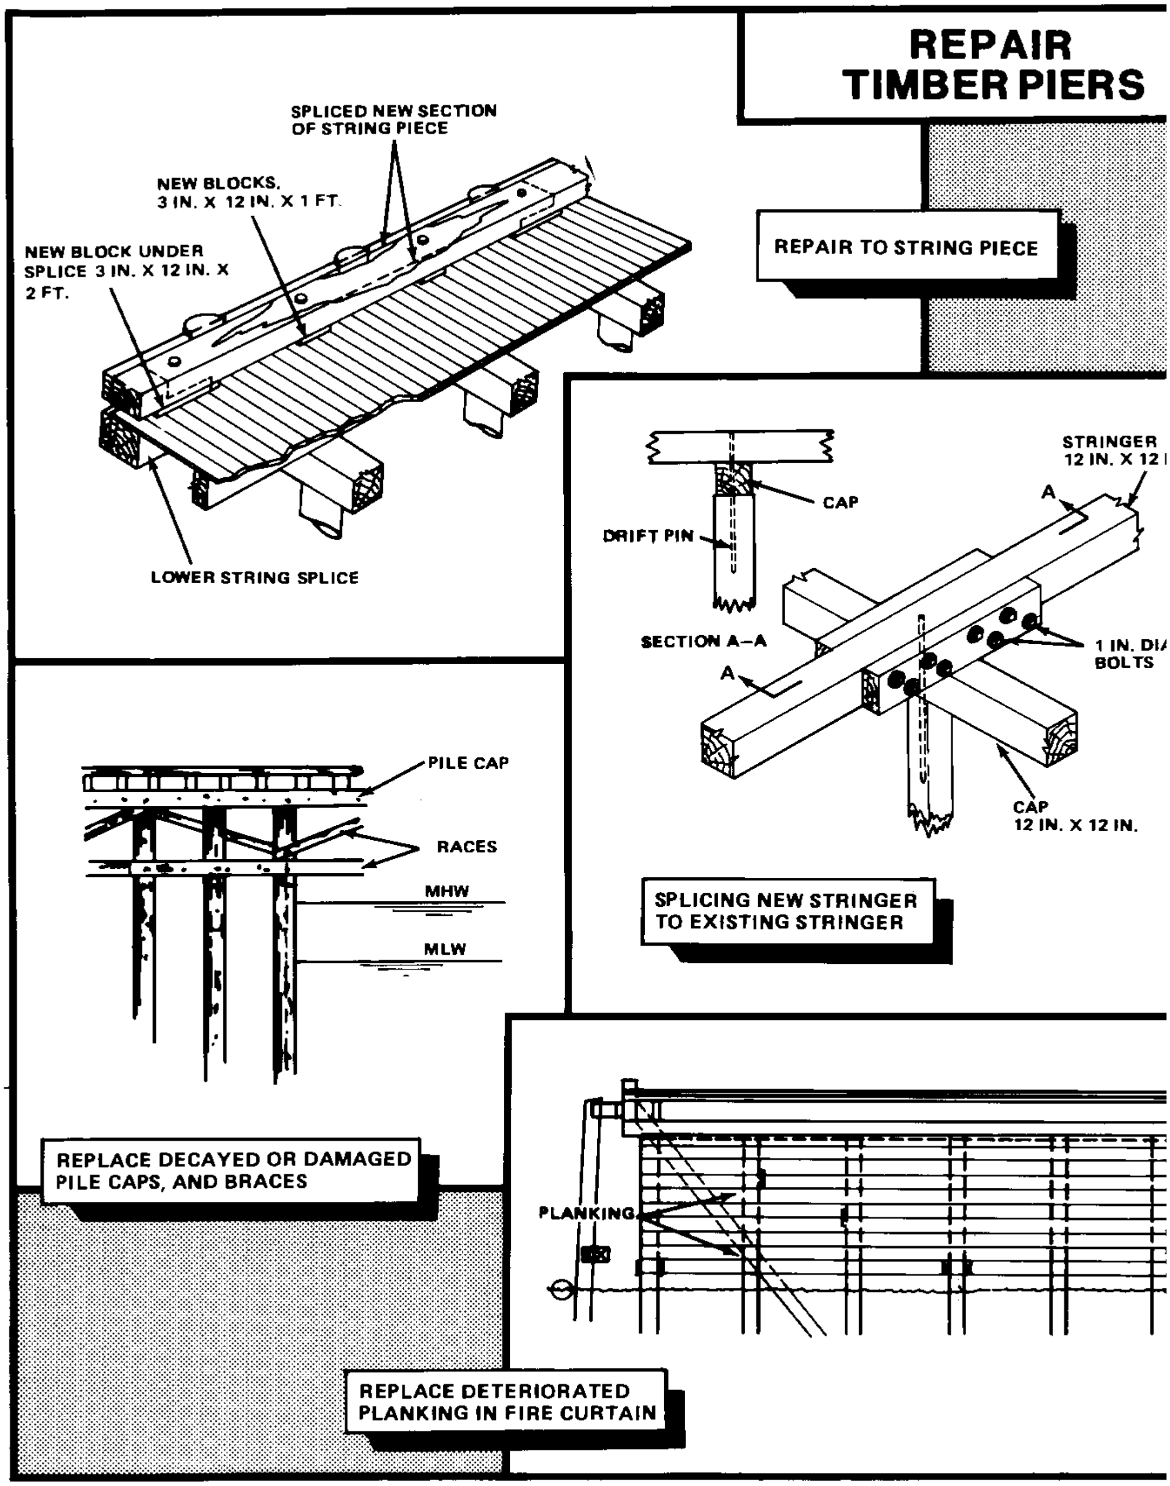
Stringers**.** Replace decayed or damaged short stringers with properly treated wood or other suitable material. Replace decayed or damaged areas of long stringers with new sections. Make connections between replacement and existing stringers directly over a pile cap and stringers. Tightly bolt or pin the stringers to the pile cap (Figure 6-1). Stagger the splices in adjacent stringers where possible. Avoid checks and splits, which promote decay, when driving deck spikes by pre-drilling small holes.

***Fire Curtain Walls*.** Wood fire curtain walls are usually made of two layers of planking that run diagonally to one another. Replace all deteriorated planks to restore the wall to its original condition - as watertight as possible. In addition, each side of the wall should be protected by automatic sprinklers or by nearby openings in the deck through which revolving nozzles or other devices can be used to form an effective water curtain.

Application: These methods are routinely used.

Future Inspection Requirements: Areas near replaced wood may be susceptible to similar damage and should receive special emphasis in future inspections.

Figure 6-1 Repairs to Timber Pier Structure



TR-2: REPAIR BY REPLACING TIMBER FENDER PILE AND DAMAGED CHOCKS AND WALES

Problem: Fender pile broken or damaged and no longer functional.

Description of Repair (see Figure 6-2): Pull and replace decayed, marine borer damaged, or broken fender piles with new piles. Consider using alternative materials instead of treated wood for the new piles. Recommend installing a steel shoe on the outer surface of each wooden fender pile.

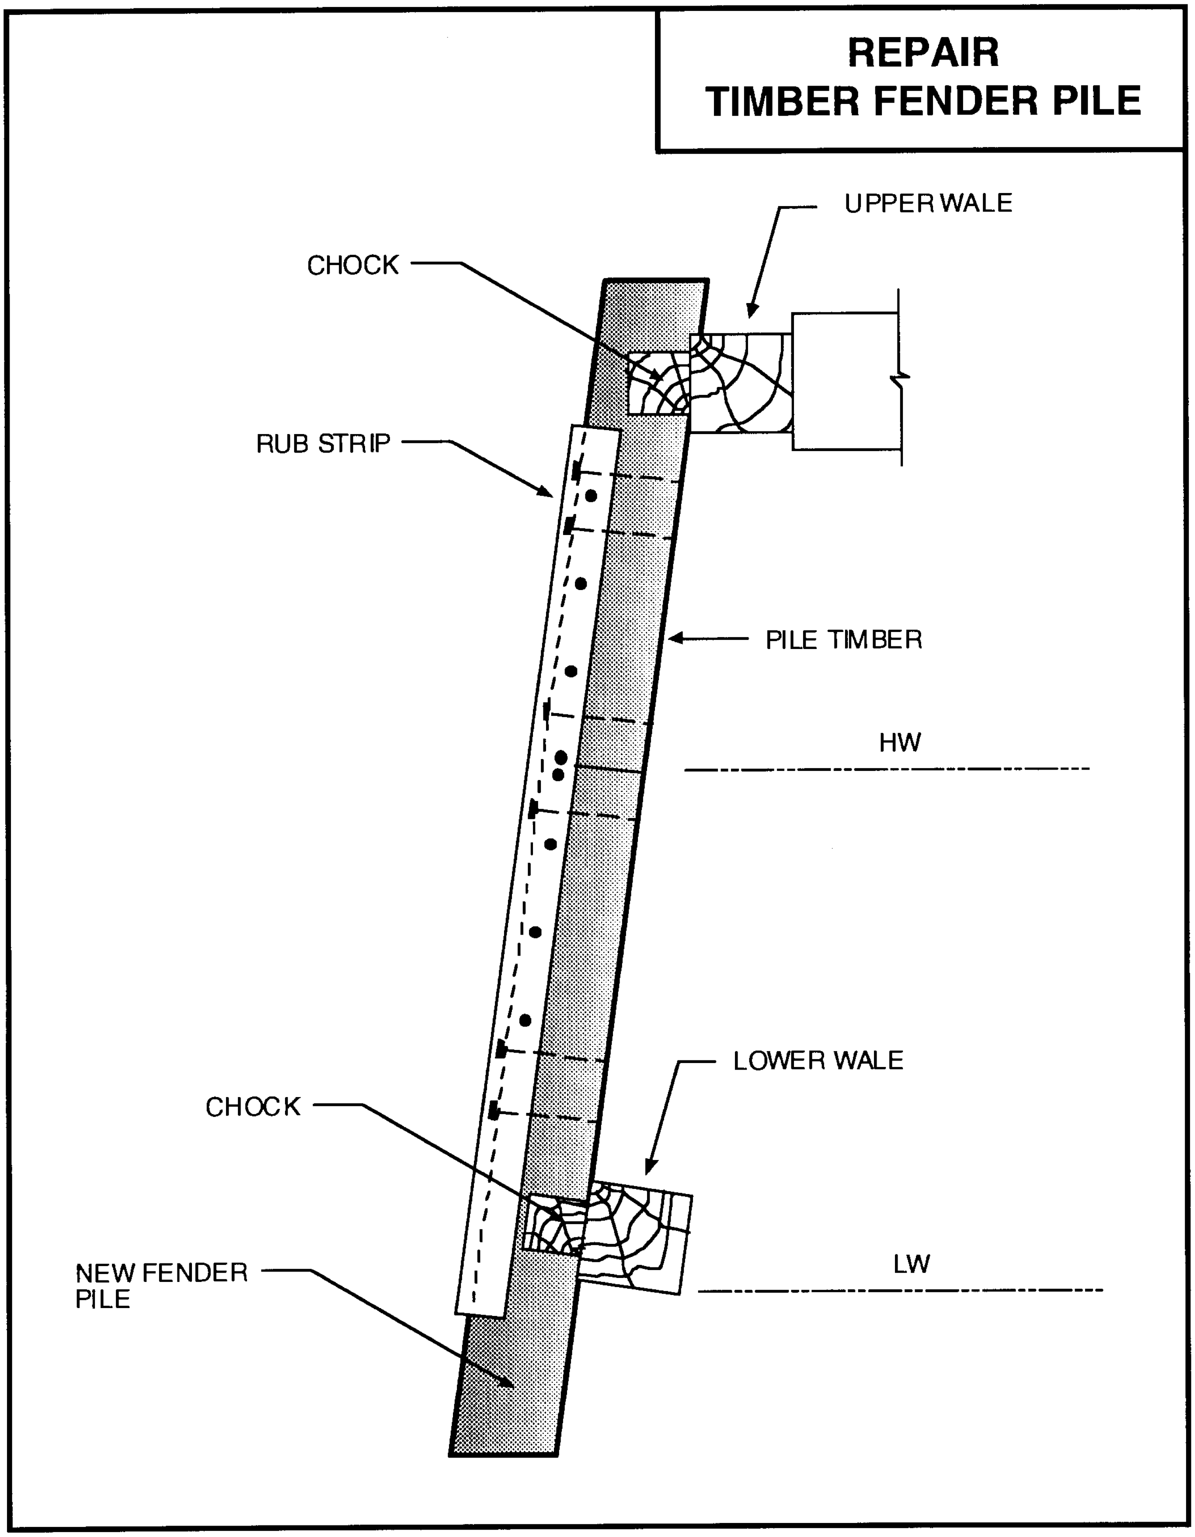
Replace deteriorated chocks with tightly fitting chocks that are bolted to one string piece or to a wale below the deck. Wood treatment requirements will be locally determined.

Replace deteriorated or damaged wales with the same size and length as the original wales unless redesigned. Wood treatment requirements for the wales will be locally determined.

Application: Repair by replacement is applicable to virtually all timber fender systems.

Future Inspection Requirement: Inspections should be based on historical records of fender pile damage.

Figure 6-2 Repair by Replacing Timber Fender Pile and Damaged Chocks and Wales



TR-3: PROTECTING TIMBER PILES WITH POLYVINYL CHLORIDE OR POLYETHYLENE WRAPPING

Problem: Either a new pile or pile butt is being installed that requires a protective covering or marine borer deterioration has been discovered in an existing pile, and further damage needs to be prevented. This method can also be used to protect untreated piling from marine borer damage.

Description of Repairs: \1\ /1/ Clean the surface of the pile to remove all sharp or protruding objects that would penetrate or deform the plastic wrapping on the pile.

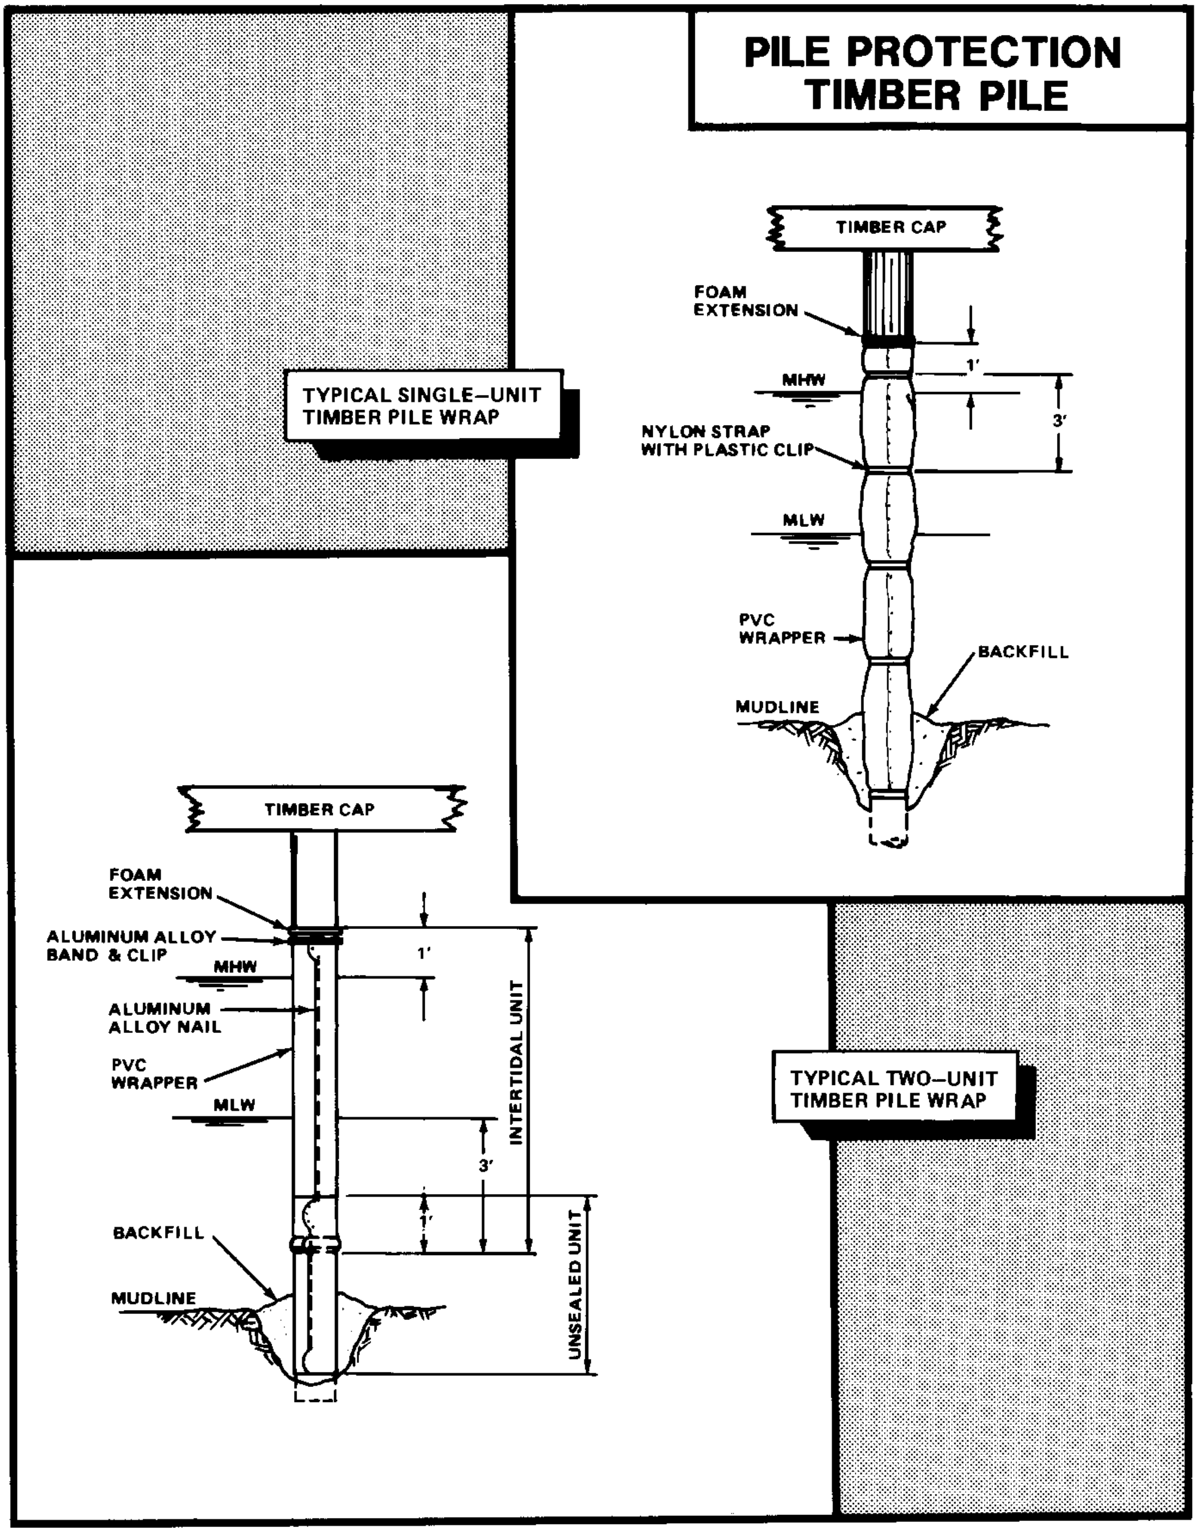
> "If a polyvinyl chloride (PVC) wrap is used on a relatively new creosoted piling, first wrap a 1.0 mm (4-mil) polyethylene sheet around the pile to protect the PVC wrap from the creosote. Install the PVC or polyethylene (PE) wrap starting with the upper intertidal unit at least 30 cm (1 foot) above mean high water (MHW). The lower units then overlap the upper units and extend below the mudline. Tighten the PVC wrap using wood poles and a ratchet wrench. Fasten the wrapper with aluminum alloy bands around the top and bottom and with aluminum alloy nails along the vertical joints (see Figure 6-3)."

Once the wrap is completed, backfill the area around the base of the pile.

Application: This method is widely used for preventing or arresting marine borer attack. It is more economical than concrete encasement or pile repair or replacement. Plastic wraps have been placed on creosoted piling in California to prevent the migration of creosote into the water, thus avoiding any environmental restrictions. Using a 150-mil (3.8 mm) polyethylene wrap in the intertidal area can provide protection against abrasion.

Future Inspection Requirement: Look for punctures or tears in the plastic wrap; any damage to wraps over untreated piles can result in rapid borer damage.

Figure 6-3 Wrapping Timber Piles with Polyvinyl Chloride



TR-4: PARTIAL POSTING OF DAMAGED PILE WITH NEW PILE BUTT

Problem: Top of pile has rotted or has major insect damage. No other major detectable deterioration of piling found.

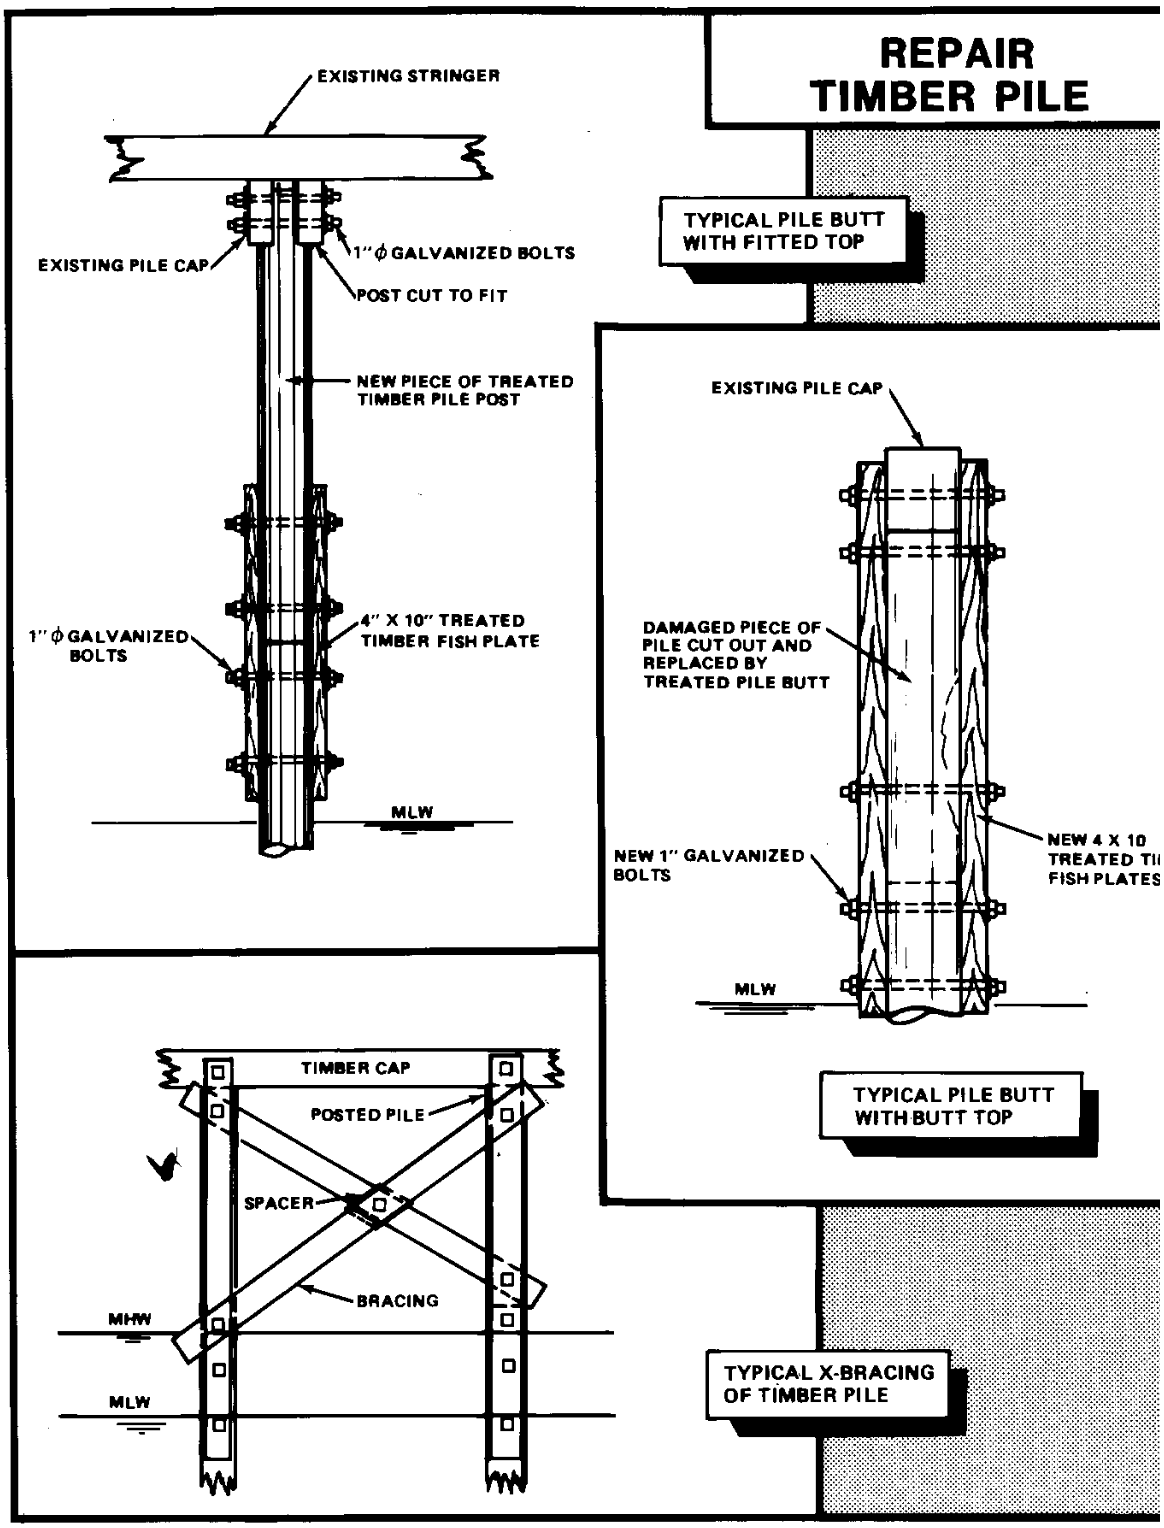
Description of Repairs: Cut the pile below the damaged, rotted, or insect infested area. Cut the pile butt to length and shape head to fit pile cap (if required). See Figure 6-4 for two methods of interfacing pile butt with pile cap. Make the joint with two pretreated timber fishplates bolted to existing pile and pile butt using 100 mil (2.55 mm) galvanized bolts. Treat the ends of all cuts with creosote. Treat bolt holes with the same wood preservative as used for the pile butt. Place shims between new pile butt head and pile cap. Bolt pile or fishplates, depending on the method selected, to pile cap.

When adjacent timber piles have been repaired using either posting or fishplating techniques, it is necessary to provide some resistance to lateral loads imposed on the structure. This can be done by installing X-bracing between piles, as illustrated in Figure 6-4. Treated timbers are fastened high on one pile and low on the adjacent pile, forming an X pattern. Where X-bracing crosses, a timber spacer should be bolted between the bracing pieces to shorten the unsupported length of span.

Application: This method works well where not many piles need repair. This method may be more expensive than replacing the pile. The cause of damage, e.g., water entrapment, must be remedied before using this method.

Future Inspection Requirement: Even with X-bracing, weak joints will exist where column buckling may occur. All splices and holes below MHW may be subject to accelerated marine borer attack. This may be offset by adding a PVC wrap around the splice. Above MHW these areas are subject to accelerated fungal attack.

Figure 6-4 Posting Timber Pile with Pile Butt and Fish Plates



TR-5: REPAIRING TIMBER PILES WITH CONCRETE ENCASEMENT

Problem: Approximately 10 to 50 percent of the cross-sectional area has been lost as a result of marine borer attack.

Description of Repairs: Clean the timber pile thoroughly from below the mudline to above MHW. Two types of forms are available:

- Flexible forms
- Split fiberboard forms

After piles have been thoroughly cleaned, place a 6- by 6-inch (15- by 15-cm) reinforcing mesh around the pile, using spacers to maintain clearance between pile, reinforcing, and fabric form. The fabric form should be placed around the pile.

For the flexible form, the zipper should be closed, and the form secured to the pile at top and bottom with mechanical fasteners (see Figure 6-5).

For the fiberboard form, straps are installed and secured every 1 foot (30 cm). Maintain a minimum of 1-9/16 inch (40 mm) spacing between pile and reinforcing and between reinforcing and form (see Figure 6-5).

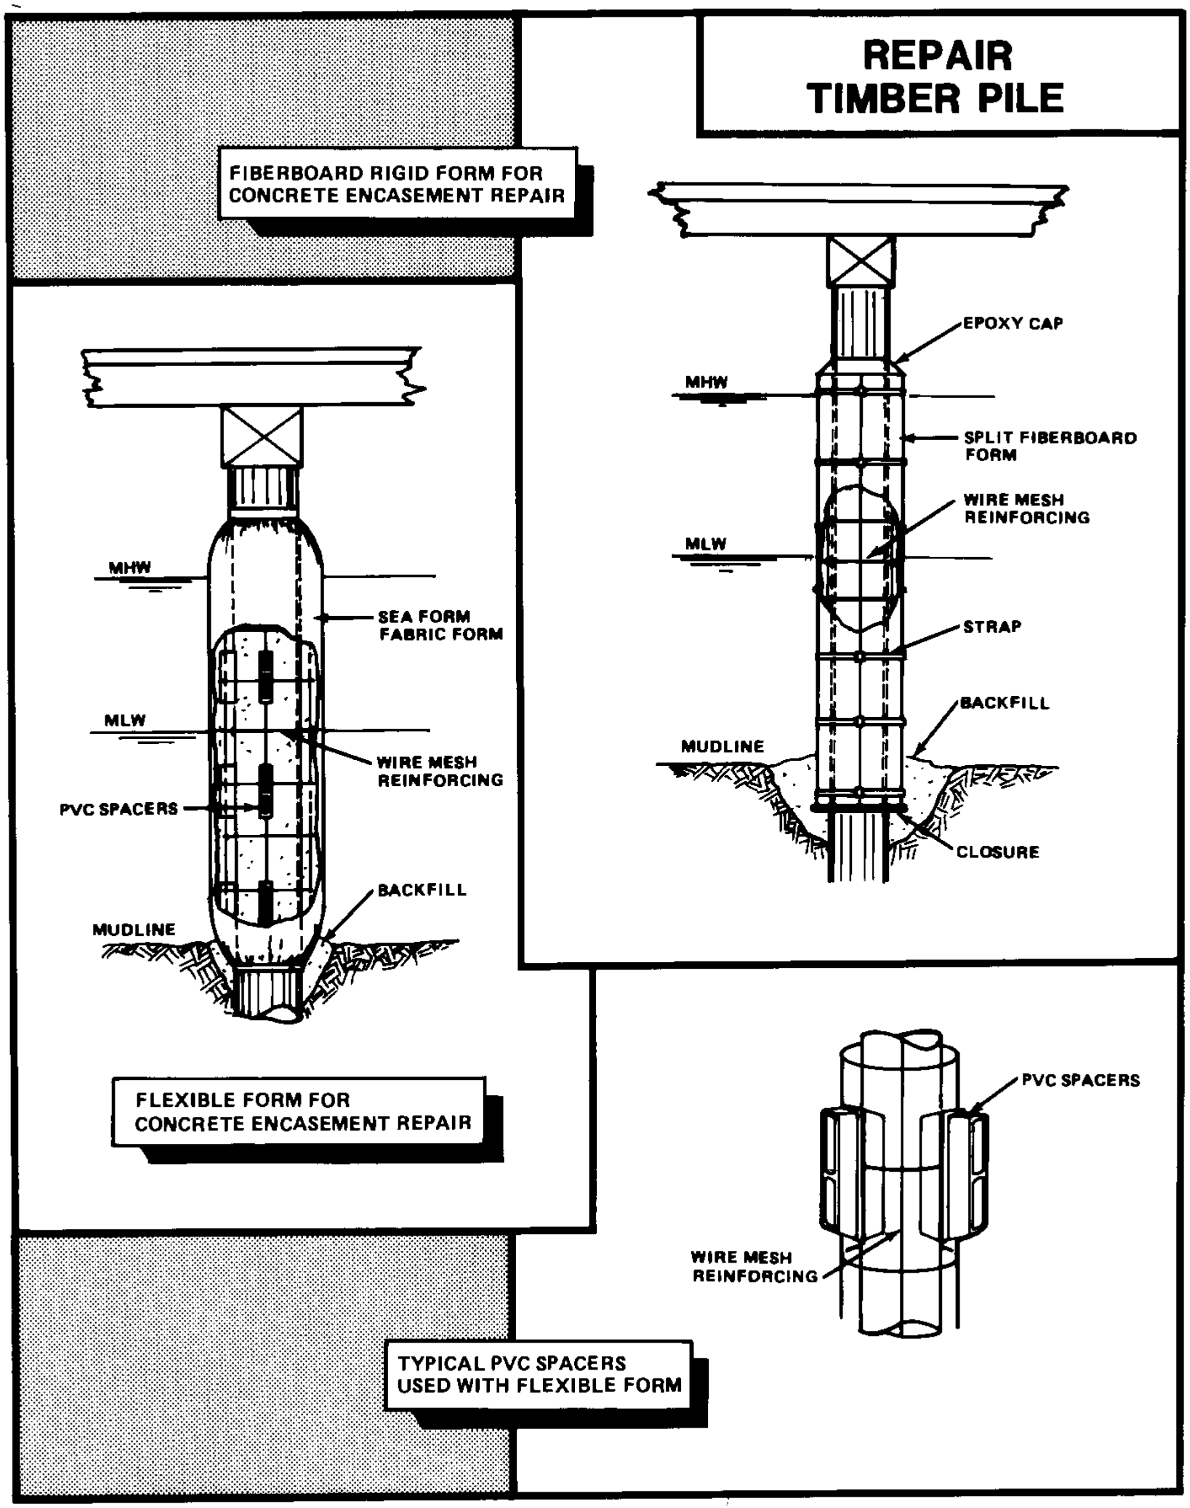
The space between pile and form is then filled to overflowing with concrete grout. Use a tube or hose extended to the lowest point of the form.

The form is left in place and the base is backfilled to above the concrete.

Application: This method can be used as a repair or as protection against marine borer attack and abrasion, and may be more expensive than replacing one or more timber piles. Economics will dictate decision.

Future Inspection Requirement: Increased inspections may be required to detect signs of ripped fabric forms, unzipped or locked form seams, or abrasion and failure of concrete encasement.

Figure 6-5 Concrete Encasement Repairs to Timber Pile



TR 6: REPAIR OR RETROFIT TIMBER PILES WITH

AN UNDERWATER CURING EPOXY AND FIBER-REINFORCED WRAP

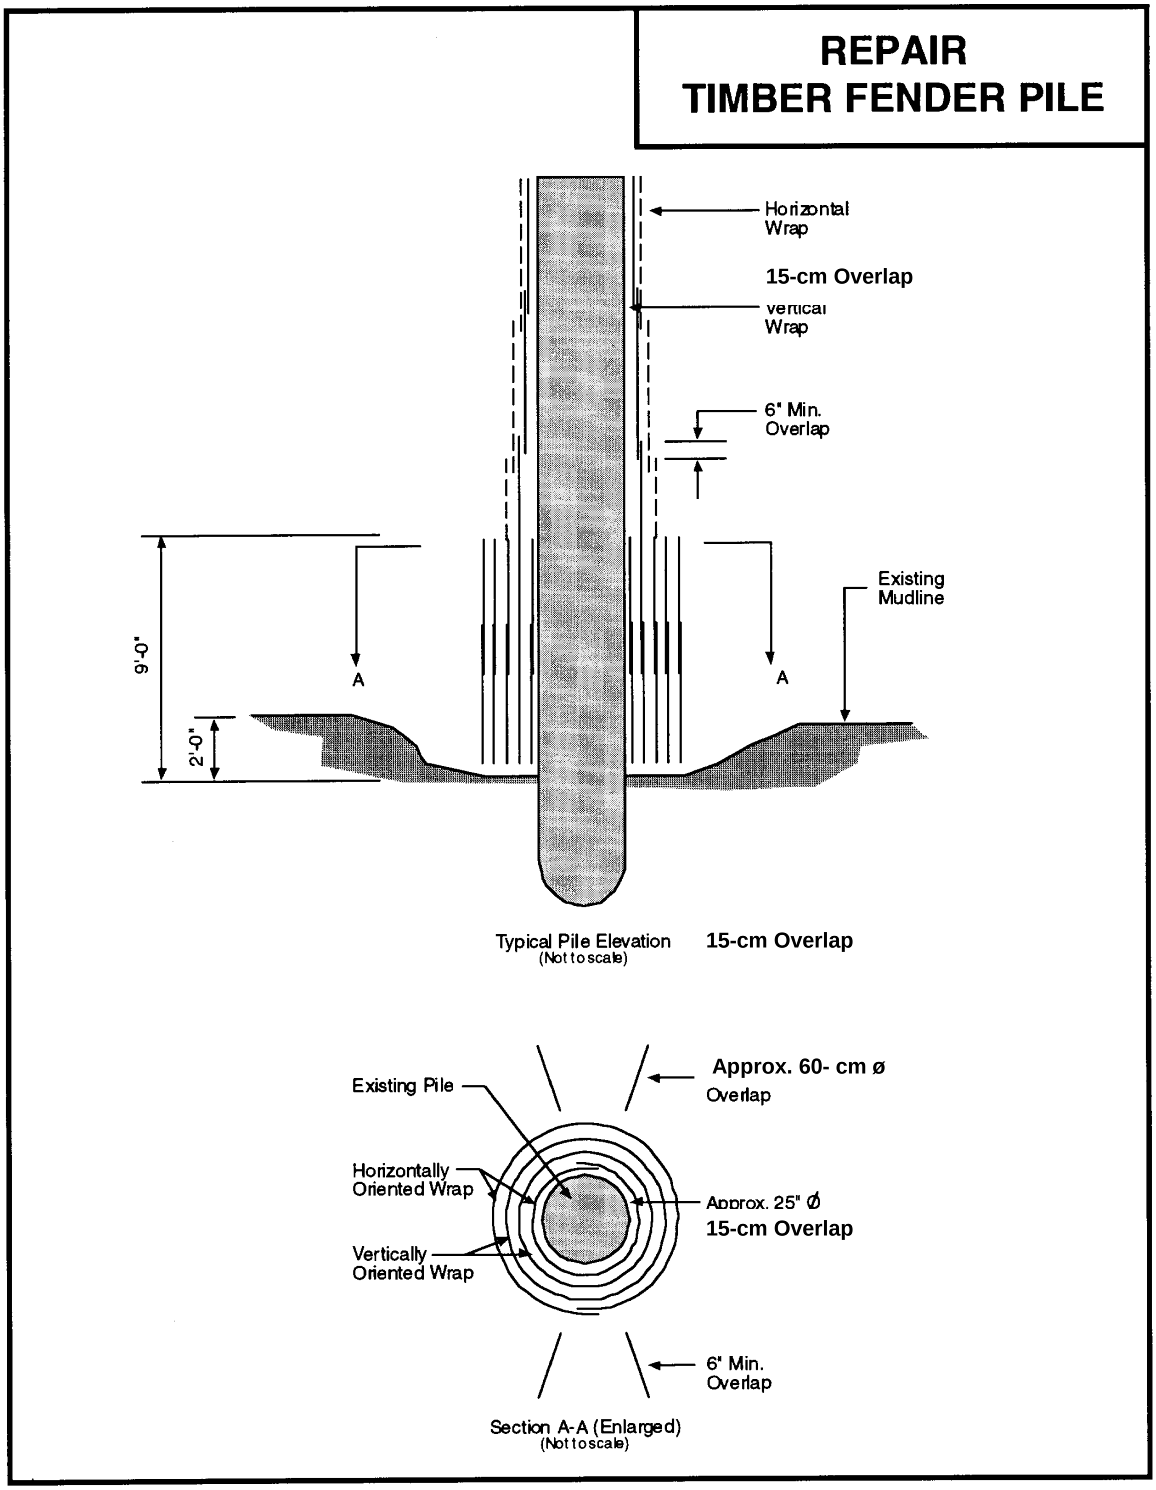
Problem: Pile deterioration by marine borers has occurred. Load requirements preclude resolving the problem by using PVC or PE wraps or an increase in strength (retrofitting) of intact piles is desired. In either case, deterioration cannot be so extensive as to require replacing the pile.

Description of Repair: Remove rotted or damaged wood and all sharp or protruding objects that could penetrate or deform the fiber wrap of the pile to be repaired or retrofitted (see Figure 6-6). Fill in any holes and gaps with material recommended by the system manufacturer. Saturate the wrap with the underwater curing epoxy before applying. Apply vertical layers of the fiber wrap with a 6-inch (15-cm) overlap. In most cases, it is advisable to wrap the fabric around the pile from below the mudline to above the high water mark. Apply horizontal layers of the fiber wrap with a 6-inch (5-cm) overlap. Additional vertical and horizontal wraps are applied as required for sufficient strength and as recommended by the manufacturer.

Application: This technology is designed to increase pile strength characteristics, but may be limited by cost and confidence levels. In most cases, PE or PVC wraps or pile replacement will be more cost effective for damaged piles. In addition, because this is a relatively new technology option, long-term performance has not yet been demonstrated. Environmental issues related to the use of underwater curing epoxies must be considered.

Future Inspection Requirement: Basically the same as for a PVC-wrapped pile. Any damage to the fiber wrap, however, could reduce the pile’s load bearing capacity.

Figure 6-6 Repair by Oriented Fiber Wraps



TR-7: REPLACING DAMAGED PILE WITH NEW TIMBER PILE

UNDER TIMBER PIER DECK

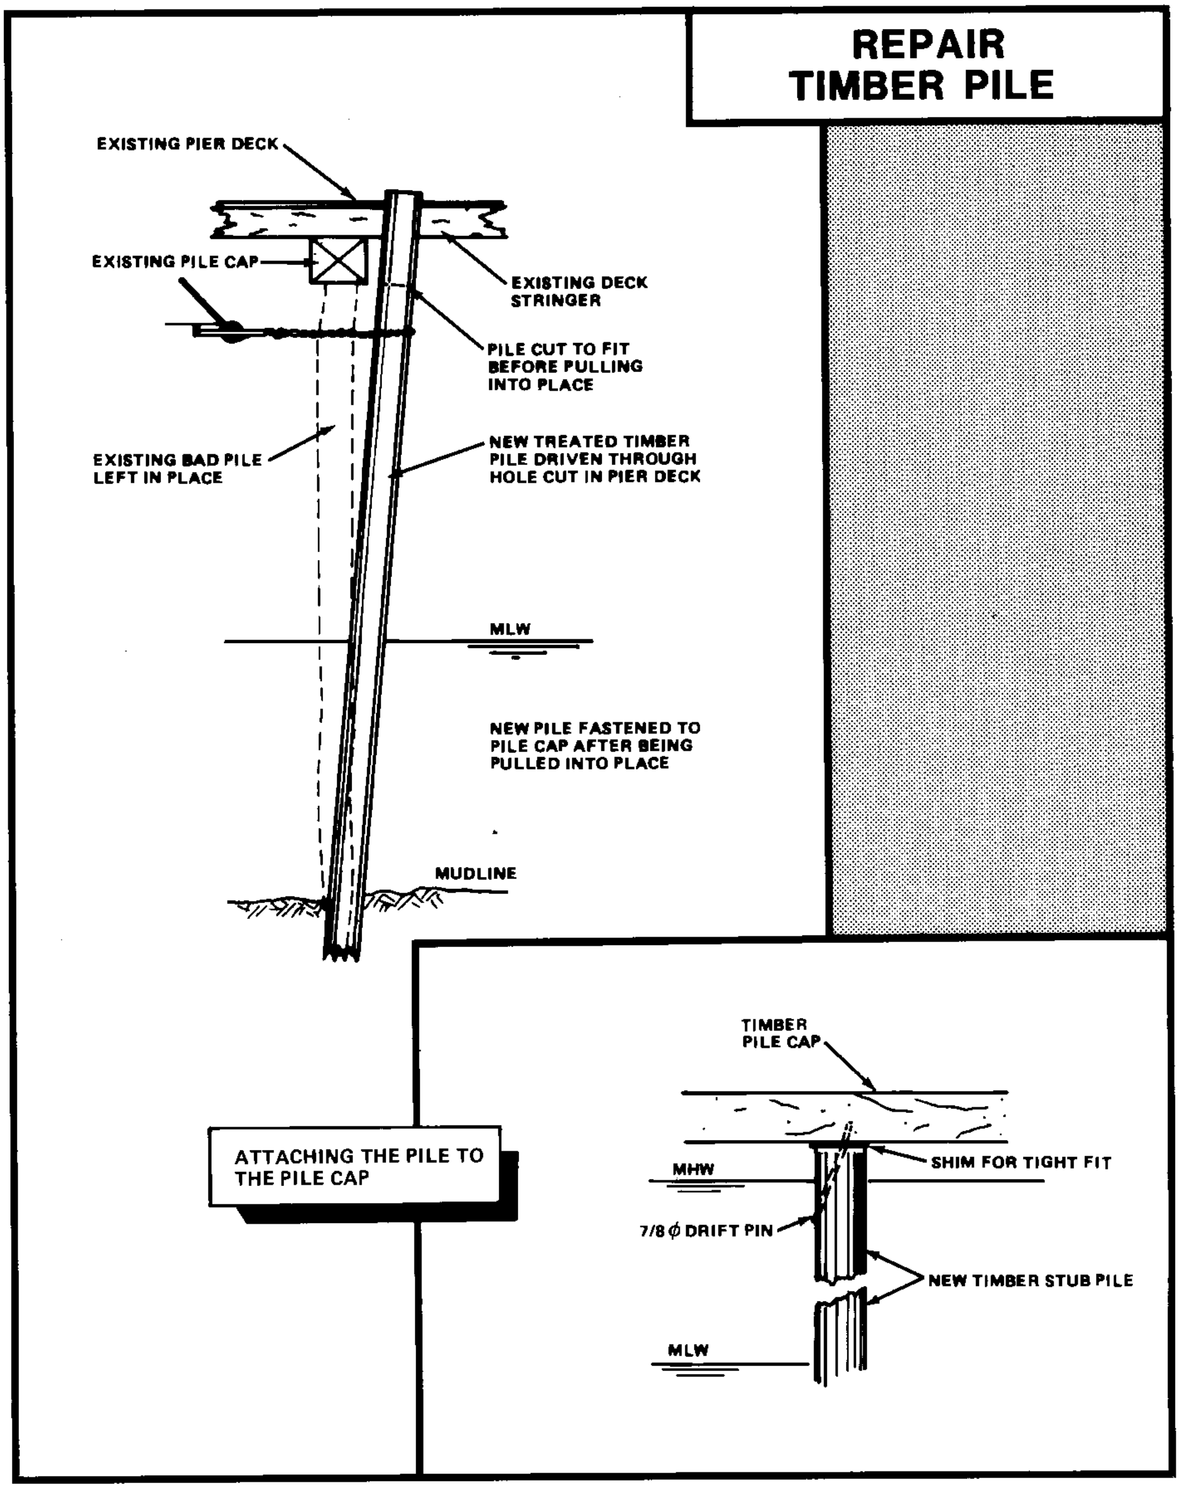
Problem: Physical damage or severe pile deterioration has been experienced below mudline, and/or a number of piles with severe deterioration (above mudline) is too extensive to maintain structural integrity with partial pile replacement.

Description of Repair: Cut an opening in the timber pier deck adjacent to the damaged pile. Drive the new pile and cut to fit under the pile cap. Spring the pile into place (see Figure 6-7). Place shims between the pile and pile cap, then fasten pile to pile cap with a 7/8-inch (22-mm) diameter drift pin.

Application: Limited mainly by cost. If fixed structures are on deck, this method may not be cost effective. If damage to the original pile(s) is due to marine borers, remove old pile(s) so that it does not provide bait to attract and nourish more borers. This application can also be used to replace damaged concrete or steel piles.

Future Inspection Requirement: Basically the same as for a new pretreated pile.

Figure 6-7 Replacing Damaged Pile with a New Timber Pile



TR-8: REPLACING DAMAGED PILE WITH NEW CONCRETE PILE UNDER CONCRETE DECK

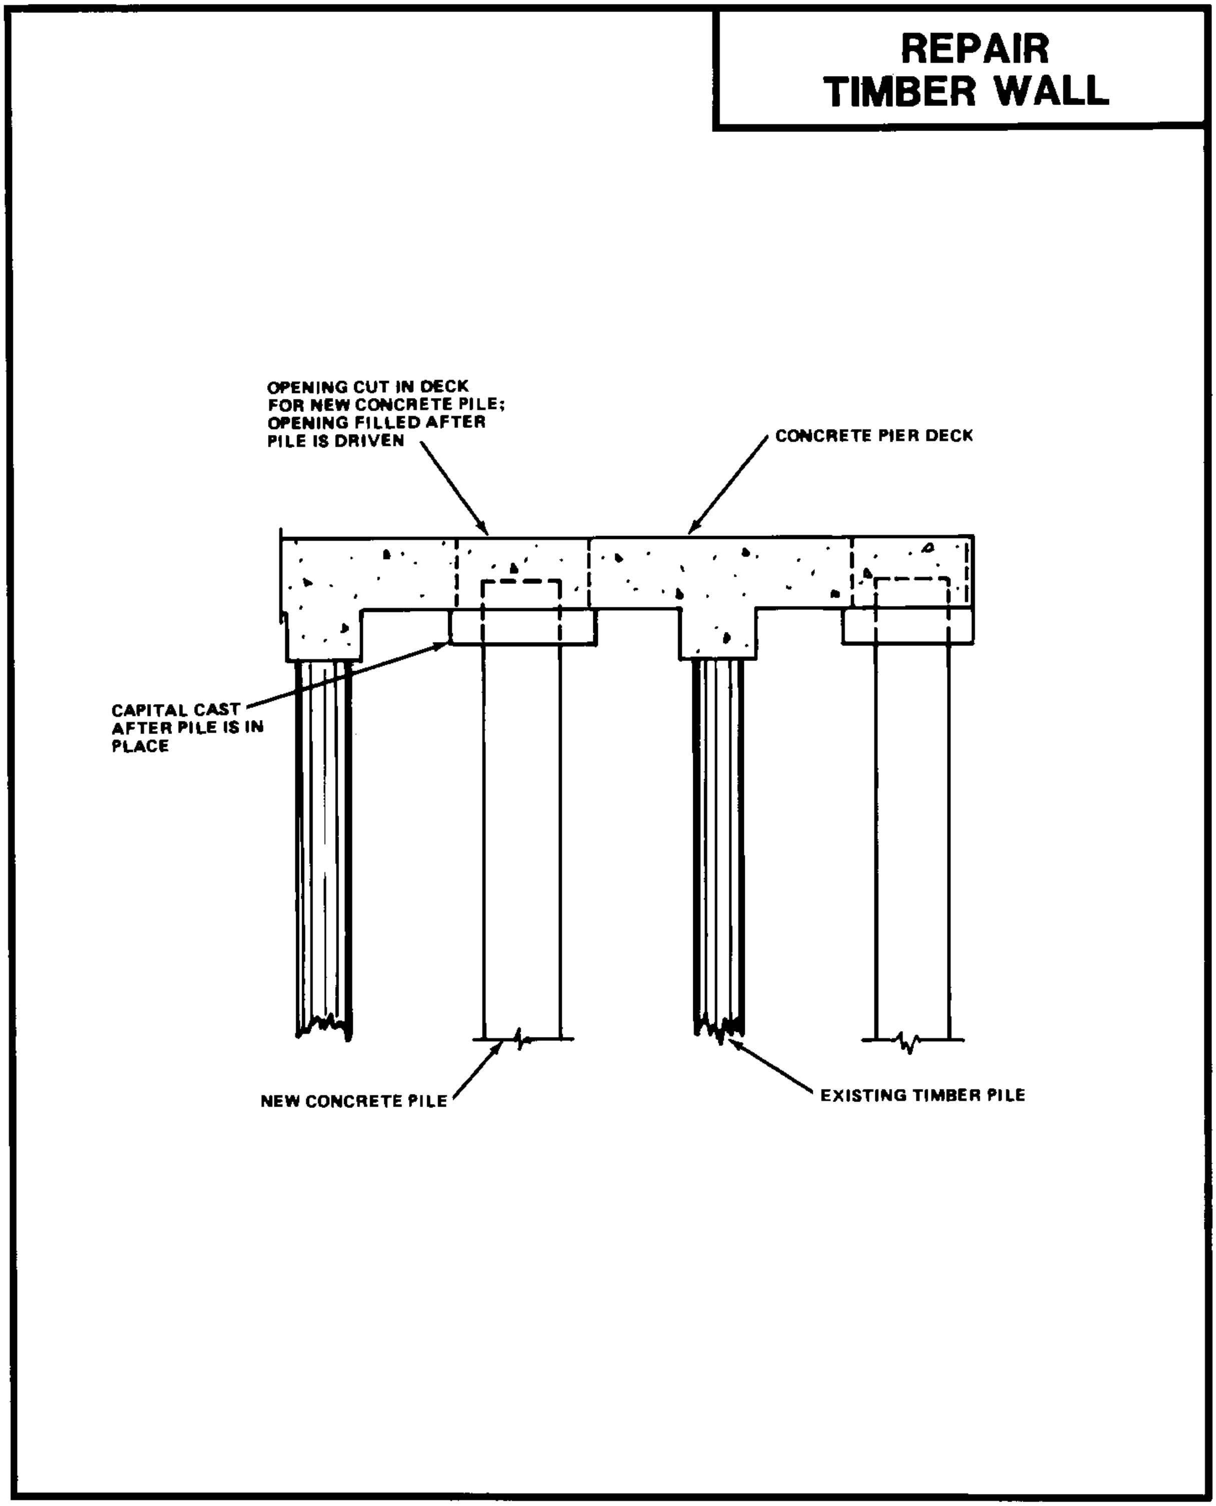
Problem: Pile deterioration or damage has been experienced to significantly reduce the structural integrity of the section of pier. Concrete pile cap and decking precludes replacing with timber pile.

Description of Repair: Cut a hole in the concrete deck between timber pile bents. Drive new concrete pile. Cut the pile below the top of the concrete deck. Form the capital under the deck, on top of the new pile. Cast the capital and the new section of concrete deck (see Figure 6-8) including splicing in new reinforcing bars. Epoxy coat bars where possible.

Application: Limited, mainly due to cost. If fixed structures are on deck, or if deterioration is wide spread, this approach may not be practical.

Future Inspection Requirement: Same as with new concrete piles and concrete deck areas.

Figure 6-8 Replacing a Damaged Timber Pile with a New Concrete Pile under a Concrete Deck



TR-9: REINFORCING TIE-BACK SYSTEM FOR TIMBER SHEET PILING WALL

Problem: Light to moderate movement of the top of the timber sheetpiling wall has occurred due to tie-back failure or excessive loading behind the wall. The area behind the wall is accessible to perform repairs.

Description of Repairs: Install a new wale slightly above the existing wale. Locate the new deadman anchors based on engineering calculations. Trench for the tie rods between the wall and the deadman anchors. Place the tie rods through the wale and sheet piles and secure in place to the deadman anchors (see Figure 6-9). Install zinc or magnesium packaged anodes to prevent further corrosion of the rods.

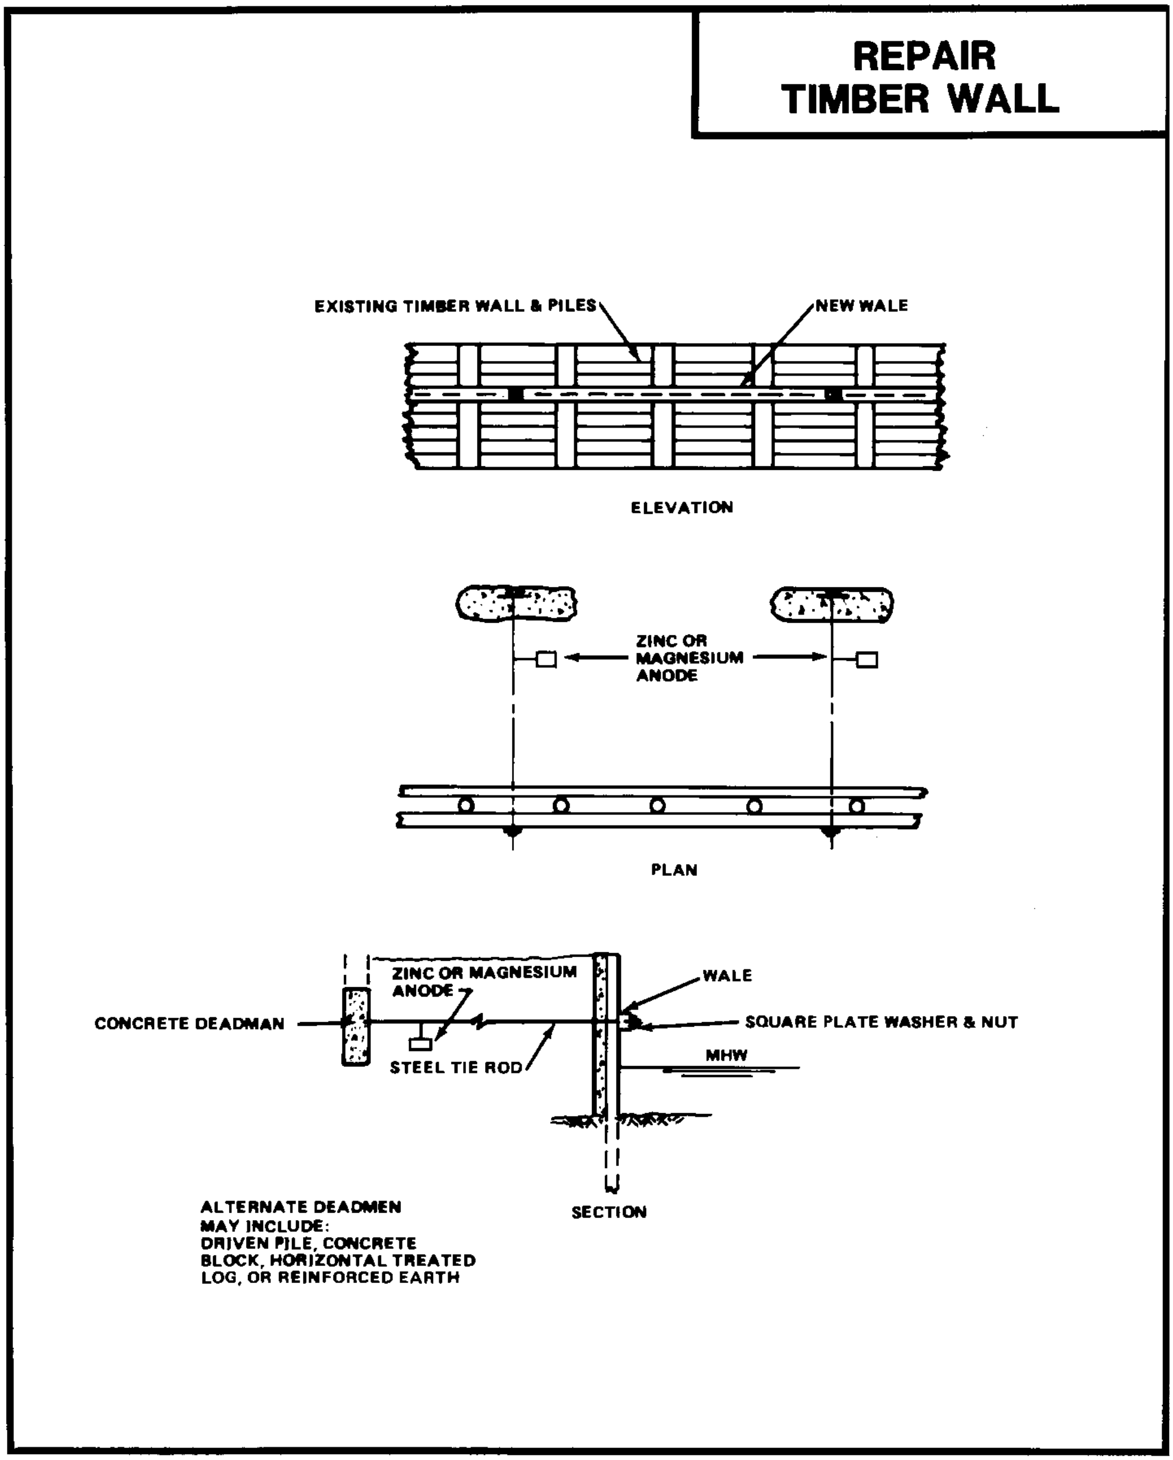
Replacing an existing tie-back system may involve replacing any or all of the existing components, depending on the amount of deterioration that has taken place.

Sheet pile wall movement can also be arrested by changing the soil load acting on the wall. For example, stone riprap dumped against the exterior toe of the wall will add resistance to the movement of the toe. Alternatively, or in addition, backfill can be removed from behind the wall and replaced with lightweight granular fill. This type of fill frees drains, which reduces the hydrostatic pressure behind the wall and allows the water level on both sides to balance.

Application: Reinforcing or replacing the tie-back system may be restricted to correct slight to moderate wall deflection. Excessive deflection may require replacing the wall or major restoration. With timber construction, it is unlikely that excavation and pulling the wall back into position can be done without high risk of failure of the timber members.

Future Inspection Requirement: Pay careful attention to wall inspection for further signs of continued deflection or timber member failure.

Figure 6-9 Installing or Replacing Tie-Back System for Timber Sheet Piling Wall



TR-10: INSTALLING A TIE-BACK SYSTEM ON THE TOP OF A TIMBER SHEET PILING WALL

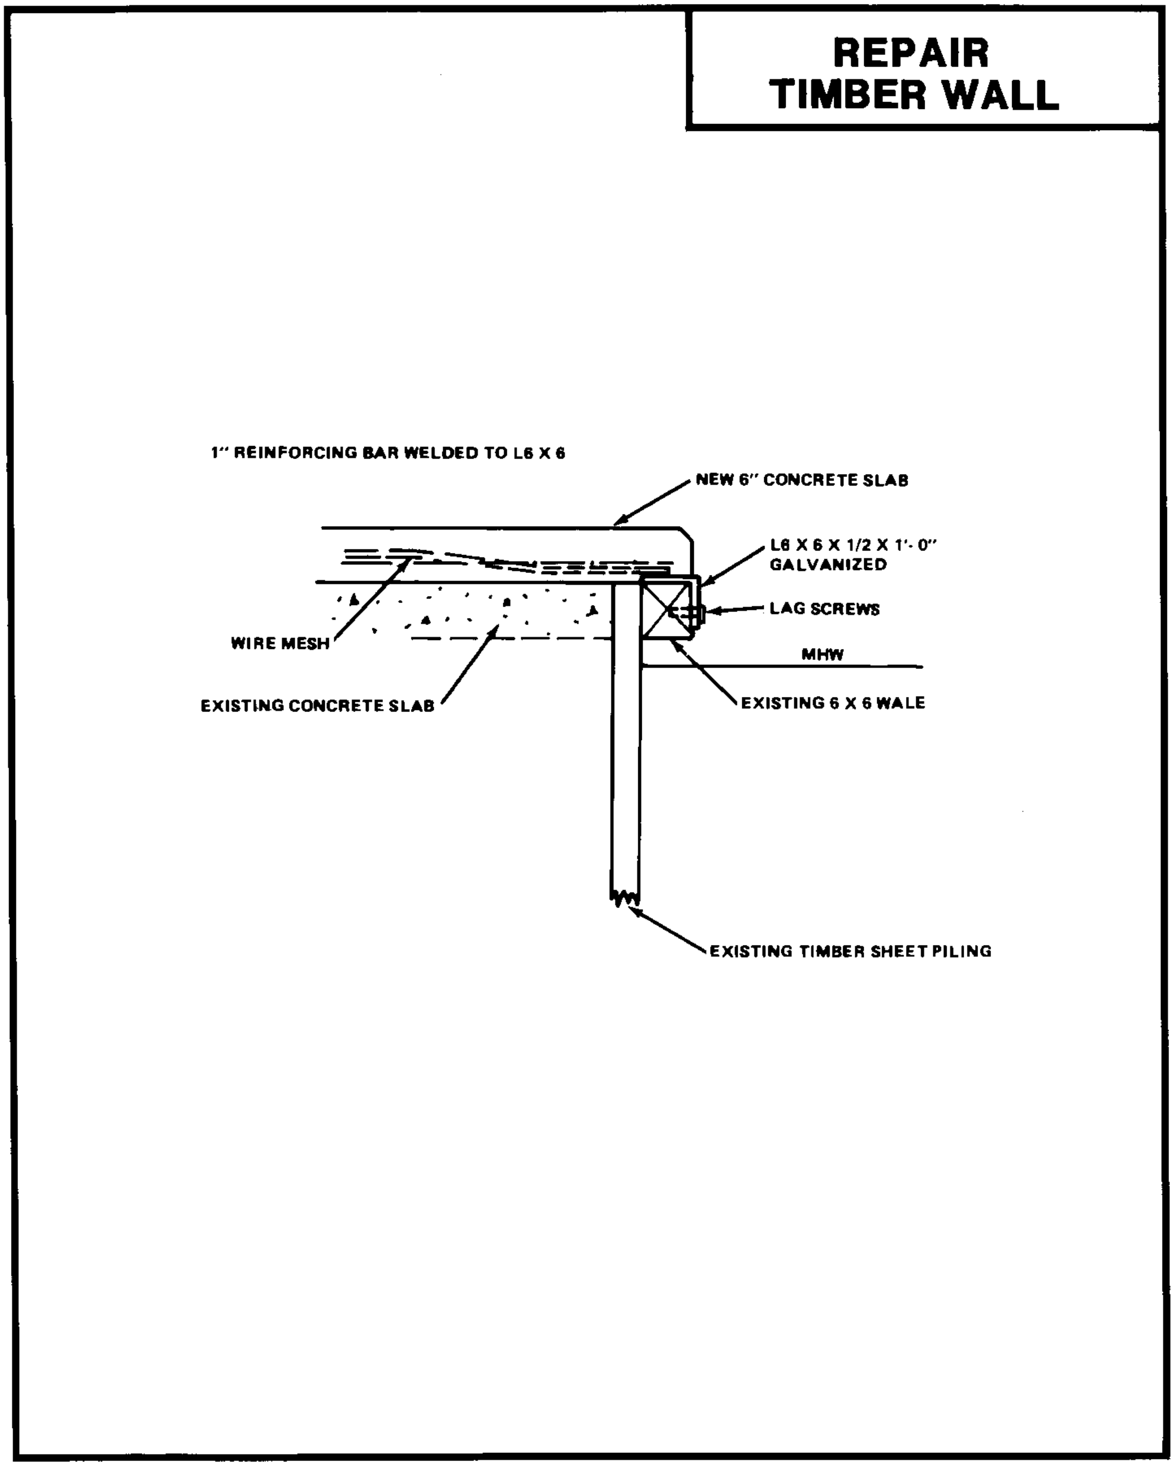
Problem: The top of the timber sheetpiling wall has moved, lightly to moderately, due to tie-back failure or excessive loading behind the wall. The area behind the wall is inaccessible for repairs.

Description of Repair: Cast a new concrete slab with extra reinforcing, from the face of the wall back behind the wall to the end of the existing slab. Tie the front edge of the new slab to wall through use of a steel angle (see Figure 6-10).

Application: Limited. Additional restraint is limited to top of sheetpiling. If excessive loading or loss of regular tie-back anchors are experienced, further failure, including shearing of sheetpiling tops, may occur.

Future Inspection Requirement: Pay careful attention to wall inspection for further signs of continued deflection or timber member failure.

Figure 6-10 Installing a Tie-Back System at Top of a Timber Sheet Piling Wall



TR-11: INSTALLING A CONCRETE CAP/FACE ON A TIMBER SHEET PILING WALL

Problem: Large-scale deterioration of the timber sheet pile structure has occurred precluding the use of patches for repairs.

Description of Repairs: Excavate the soil from behind the wall to a level required for the new concrete cap or attachment of form ties for a concrete face. Remove all marine growth and deteriorated wood, and clean the surfaces.

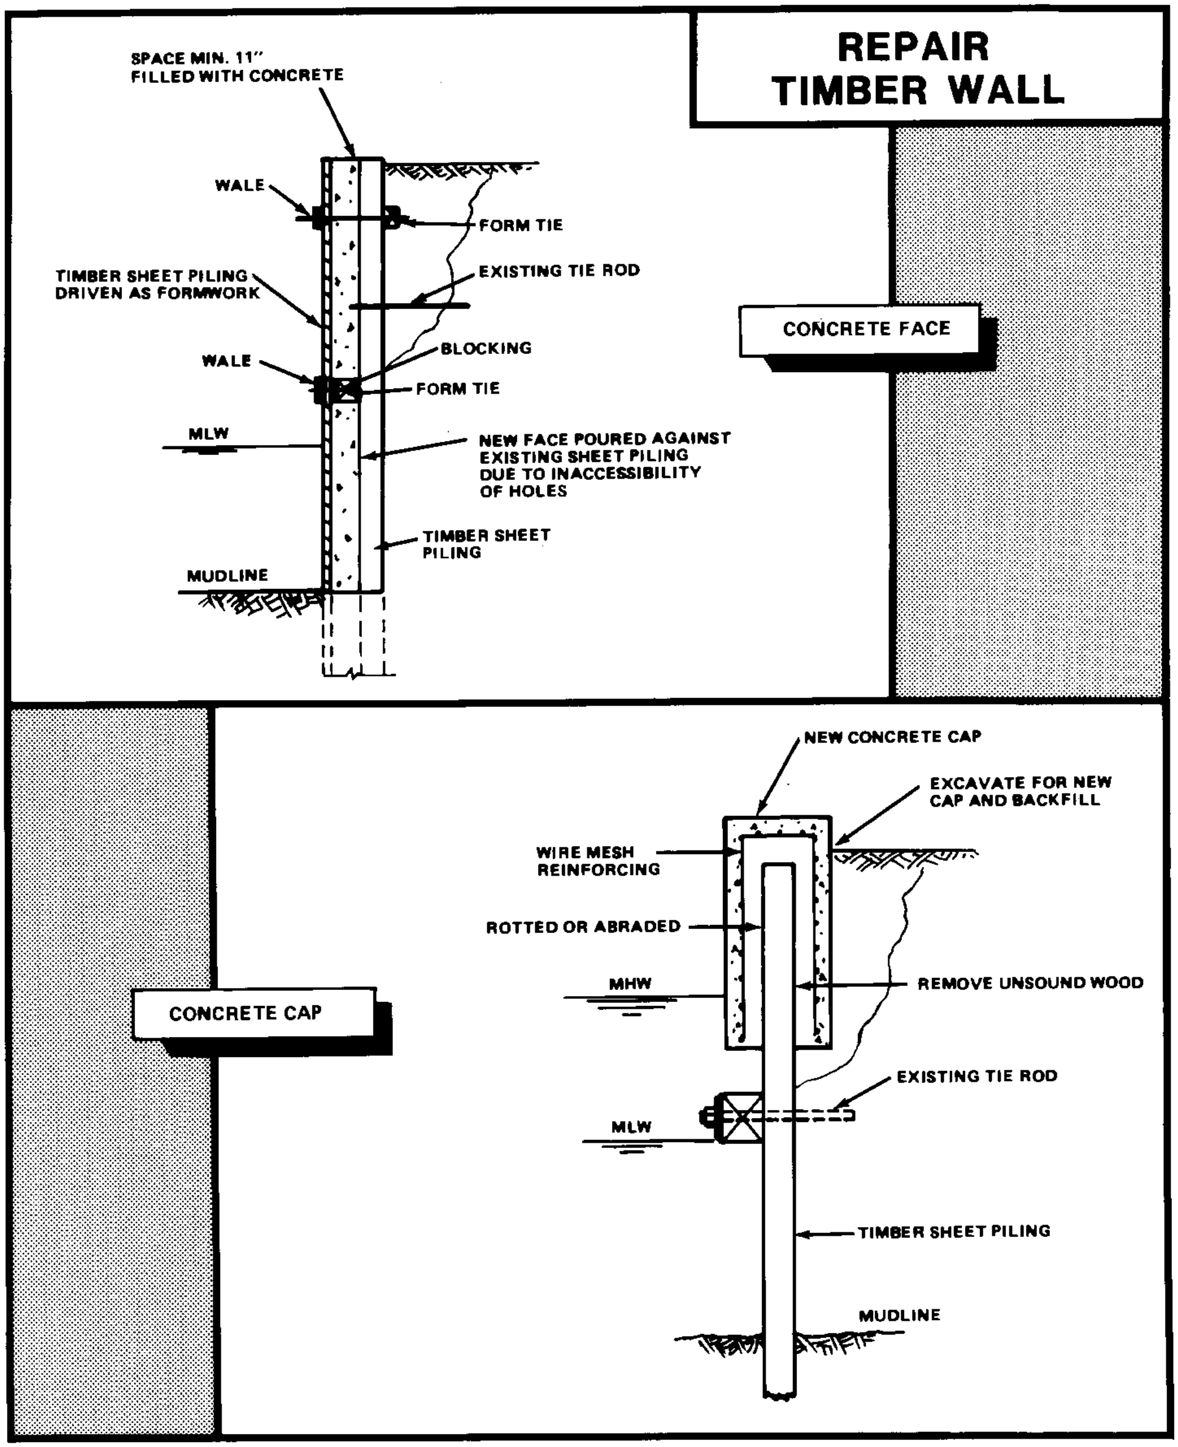
***To repair a concrete cap* –** Build forms, place reinforcing, and pour concrete at MLW. After curing, remove forms and backfill behind the wall (see Figure 6-11).

***To repair a concrete face* --** Place and fasten blocking and low wale against existing sheetpiling. Drive the timber sheet pile wall about 1 foot (30 cm) in front of existing sheetpiling using the wale as a guide. Attach outside wales to timber sheeting and place concrete by pumping or tremie. Leave timber sheet piling in place or remove as desired (see Figure 6-11).

Application: Used to restore structural strength at the top of the wall (cap) or prevent further loss of soil through holes in the sheetpiling (face). Does not restore bending moment capacity in wall. Provides protection against further deterioration.

Future Inspection Requirement: Do an annual inspection of sheetpiling areas immediately under the pile cap, in order to ensure that fungi, insect, or marine borer damage is not weakening the support for the concrete cap.

Figure 6-11 Installing a Concrete Cap and/or Face on a Timber Sheet Piling Wall



TR-12: REPLACING DAMAGED DOLPHIN PILE

Problem: One or more timber piles are broken or damaged by marine borers and the dolphin can no longer fully serve its purpose**.**

Description of Repair: Before replacing any piles, the fastenings should be removed only as far as is necessary to release the damaged piles. Take care to drive new piles at an angle so that they will not have to be pulled too far to fit them in place. Carefully note the size of piles to be replaced, particularly at the head or intermediate point where they are fitted together with other piles. Trouble cutting and fitting replacement piles can be avoided by selecting piles with the proper size head. Replace and drive all piles before any are brought together. After all the piles are driven, the center cluster should be brought together first, fitted, chocked, bolted, and pinned; when all rows have been properly fitted, etc., wrap with wire rope. All cuts in piles for fittings, bolts, and wrappings should be thoroughly field-treated with creosote. Avoid these cuts as much as possible because field treatment with creosote gives only marginal protection against marine borer attack.

Wrapping the dolphin with PVC may provide protection. See repair technique TR-3.

Application: This method is routinely used.

Future Application Requirements: Remaining piles should receive special attention.

This page intentionally left blank.

CHAPTER 7

REPAIR OF CONCRETE STRUCTURES

7-1 **CONCRETE FOR REPAIRS**. Quality, lasting concrete for repair of waterfront facilities depends on the quality of the concrete mix, and careful attention to preparation and construction techniques. Both factors are important in making and placing conventional Portland cement concrete and the special types of repair concretes.

Some of the information in this section was extracted from the following references:

- \1\ UFC 4-151-10, *General Criteria for Waterfront Construction*. /1/
- *Survey of Techniques for Underwater Maintenance/Repair of Waterfront Structures*, Revision No.1, Childs Engineering Corporation, December 1985.
- NCEL TM-43-85-01CR *UCT Conventional Inspection and Repair Techniques Manual*, October 1984.
- CEL CR 81.009, *Survey of Techniques for Underwater Maintenance/Repair of Waterfront Structures*, Childs Engineering Corporation, February 1981.

7-1.1 Portland Cement Concrete

7-1.1.1 Important Properties

- Durability. Concrete of low permeability is important for waterfront facilities. The objective is to keep salt and water out of the concrete to protect the reinforcing steel from corroding, which result in the concrete spalling. The most important factors are a low water-to-cement ratio (0.40) in the mix, use of 25% Class F fly ash, and proper curing of the concrete when placed.
- Strength. 5000 psi (35 MPa) concrete is recommended for most repairs. Design of the mix and proper curing will determine the final strength.
- Workability. Concrete must be easily handled and placed. A dense concrete is important. This workability must be obtained without increasing the water content beyond the mix design. Enhanced workability is obtained by using 25% Class F fly ash. Use of admixtures conforming to ASTM C494/C494M, *Standard*

Specification for Chemical Admixtures for Concrete; Types A, D, E, F and G are approved but not required.

7-1.1.2 **Preparation and Construction**. To obtain quality concrete repairs, the following basics are mandatory for all jobs:

- Properly prepare the surface of the old concrete to be adjoined.
- Ensure a good bond between the old and new concrete.
- Do not add more water than specified for the concrete mix.
- Do not patch across active cracks or joints.
- Cure the concrete properly.

7-1.1.2.1 **Surface Preparation**. All deteriorated concrete must be removed down to sound concrete. For some old concretes, exposed surfaces will soften after a few days of exposure; therefore, the surfaces should be checked closely before patching. Clean the old surface thoroughly just before placing new concrete.

Normally, when removing concrete hand tools or light duty hand-held power tools are used, particularly around the edges, to prevent damaging the remaining concrete. Do not use an impact hammer greater than 15 pound (67 Newtons). Edges should be square, preferably cut by sawing to about a 1 inch (25-mm) depth. Feathered edges must be absolutely avoided. Reinforcing bars should be exposed around their entire circumference by a 1 inch (25-mm) clearance.

Sandblasting surfaces removes loose concrete fragments and scaling rust from steel. Once the steel is clean, protect the coating with a slurry of Portland cement grout or latex modified Portland cement grout. This procedure improves the life of the repair.

7-1.1.2.2 **Bonding**. Before patching, the existing base concrete should be kept damp (except for epoxy concrete repair) for several hours, preferably overnight. Remove free water or shiny wet areas by vacuuming or with oil-free compressed air. Then scrub a bonding agent into the surface with a stiff brush. The bonding agent can be Portland cement mortar or a latex modified Portland cement mortar. Do not use epoxy bonding agents. The mortars should be one-part cement and 1 part sand passing the No. 30 sieve, and have a consistency of thick cream. In all cases, it is important to place the repaired concrete immediately after placing the bonding agent.

7-1.1.2.3 **Curing**. Concrete used in repairs must be protected and cured more carefully than usual. Curing should last for 7 days. The old concrete could absorb moisture too fast from the new concrete, or the temperature of the old concrete could be too low to permit early development of strength of a concrete patch. Shrinkage of the repair is the most common reason for delamination of the repair from the substrate.

Curing is important to allow strength development and minimize drying shrinkage. For Portland cement mixes, water curing by ponding with water, fog misting, or covering with wet burlap are the best methods. If continuous moisture curing is not possible, then use two applications of a liquid curing compound. The repaired concrete should be kept wet or moist for a minimum of 7 days. When water evaporates from the concrete, drying shrinkage occurs. Shrinkage of a repair patch can cause the patch to crack or partially debond.

Curing for epoxy concrete is to provide the correct temperature for the epoxy resin to develop full strength. Epoxy resins that use 100 percent solids and no solvents do not shrink. Epoxy resins do, however, have a much greater coefficient of expansion than concrete. This often leads to failure in large patches and in environments that experience large temperature differentials between day and night. Epoxy can be mixed with sand (1 part epoxy : 7 parts sand) to minimize the difference in the thermal expansion characteristics.

7-1.1.3 **Guidelines.** General guidelines for concrete used in waterfront repairs include:

- Use 5000 psi (35 MPa) concrete.
- Use only Type I or II.
- Use a minimum of 8.3 bags (360 kg) to a maximum of 10.4 bags (445 kg) of cement per cubic meter in the concrete mix.
- Use a maximum water-cement ratio of 17 L per bag of cement (0.40 by weight).
- For most small volume repairs, use aggregate no larger than 4/5 inch (2 cm).
- Make sure the concrete cover over reinforcing steel is at least 3-1/5 inches (8 cm).

\1\ /1/

- Pay particular to the use of admixtures: DO NOT use an admixture containing chloride.

- For concrete subject to freeze-thaw cycles, use air-entraining agent to obtain 5 to 7 percent air content.
- Use a water-reducing admixture (ASTM C494/C494M) when concrete is placed in area congested with reinforcing or in pours difficult to consolidate. This will decrease chance of voids and temptation to add water to the concrete.

Specific guidelines for underwater concrete include:

- Water-cement ratio must not exceed 0.40 (5 gallons (19 L) per bag of cement).
- Use a minimum of 10.4 bags (445 kg) to a maximum of 11.25 bags (556 kg) of cement per cubic meter.
- Use an air-entraining admixture to obtain 3 to 6 percent entrained air for improved workability.
- A water-reducing plasticizing admixture may be used to enhance placement and consolidation.

7-1.2 Special Types of Repair Concrete

7-1.2.1 **Fiber-Reinforced Concrete**. Concrete and mortar containing fibers of steel, glass or polypropylene are sometimes used in repair work. Fiber reinforcement provides improved tensile strength, toughness and ductility to concrete. The fibers reinforce crack repair material by distributing tensile strains.

Fiber-reinforced shotcrete is good to use in marine repair work. In some applications, the fibers can replace steel mesh. Although steel fibers corrode near the surface, in the interior sections they are protected from corrosion by the high alkali of the cement paste. Steel fibers are usually 1/100 to 1/5 inch (0.3 mm to 5 mm) in diameter and 1/2 to 1 3/5 inch (13 to 40 mm) long. The quantity of steel fibers used varies from 6.2 to 18.5 psf (30 to 90 kg/m^2).

Glass fibers in concrete can lose strength over periods of time in a wet environment and are not recommended. Synthetic fibers reduce crack size due to plastic shrinkage, but should not be the primary reinforcement.

7-1.2.2 **Latex Modified Portland Cement Concrete**. Latex modified Portland cement concrete should not be confused with epoxy or polymer concrete discussed in the Paragraph entitled, “Epoxy Concrete”. Latex modifiers improve the bond and tensile strength and reduce the permeability of Portland cement concrete. Latex formulations of acrylics, styrene-butadiene, and polyvinyl acetates are available. The first two latexes are suitable for wet environments.

Polyvinyl acetates should not be used in concrete for repairs exposed to water. Latex modified concrete is recommended for overhead and vertical repairs when placed in lifts less than 1-3/5 inch (4 cm).

Latex modified concrete, compared to epoxy concrete, is vapor permeable and lower in cost. Even though permeable to vapor, it is not very permeable to liquids. Repairs requiring thin sections, which will be exposed to the sun, should be breathable so that vapor pressure does not build up behind the patches or overlays. Vapor pressure can debond and cause a patch to spall off.

Recommended mix proportions for thin and medium thickness repairs are in Table 7-1.

Table 7-1 Recommended Mix Proportions

		Finished Thickness
	1/2 to 1 ¼ inch (13 mm to 32 mm)	1 ¼ inch and up (32 mm and up)
Latex to cement ratio	0.10 to 0.20	0.10 to 0.20
Water to cement ratio	0.30 to 0.40	0.30 to 0.40
Fine aggregate to 1 part cement	3.0 to 3.5 parts	2.5 to 3.1 parts
Coarse aggregate to 1 part cement	2.5 to 3.1 parts	1.4 to 2.0 parts

Prepackaged latex modified mortars, or just the liquid latex modifiers, are commercially available. The mortar mixes can be converted to concrete by adding coarse aggregate. Latex modified concretes are sensitive to improper placement techniques, and noted failures have occurred. Carefully follow the manufacturers' recommendations.

7-1.2.3 **Epoxy Concrete**. Epoxy concrete does not contain Portland cement. It is a mixture of an epoxy resin and aggregate. Epoxy concrete is the most popular polymer concrete used because of its many physical properties that can be obtained, good adhesion to existing concrete, and availability. Other commercially available polymers are acrylics, polyesters, polyurethanes, and polyvinyl acetate.

Epoxy resin, when mixed with a curing agent, forms a thermosetting plastic that rapidly develops adhesive strength. Epoxy mixes are used for several purposes:

- To repair cracks by injecting the resin.
- To make epoxy mortar or concrete by mixing the resin with fine and coarse aggregate.

Because the cost is high and the material is inflexible in thick layers, epoxy concrete is used mainly for thin section repairs. Proprietary, prepackaged systems should be used. Generally, the aggregate is a silica sand with little or no material passing the No. 100 sieve (dust). The aggregate must be clean and absolutely dry. Not all epoxy resins will bond to damp or wet concrete, so check the manufacturer's specifications.

Epoxy mortars consist of 1 part epoxy resin to 4 to 7 parts sand by weight. The resin is usually made up of two components that are batched by volume and thoroughly mixed before combined with the aggregate. Epoxy concrete contains 1 part epoxy resin to 6 to 10 parts aggregate by weight. Equal parts of the fine and coarse aggregate are used. Epoxy concrete should be placed in layers no more than 2 inches (5 cm) thick, so that excessive heat build up does not occur. Generally, one should avoid using epoxy mortars because of their high coefficient of thermal expansion that leads to early disbondment of the repair.

7-2 **PLANNING THE REPAIRS**. The first steps in planning a repair will be to:

- Conduct an inspection to determine the course and scope of damage or deterioration.
- Determine operational or functional constraints on the facility because of the needed repair.
- Establish a priority for the repair.

Based on these factors, planning will then proceed to determine if the job should be done in-house or on contract, the repair technique to be used, method of placing the concrete, special skills required, and unique equipment requirements. If underwater repairs are involved, give special attention to planning for the unique requirements, particularly involving safety.

7-2.1 **Seismic Impact of Repairs**. Any concrete repair that alters significantly the mass of a structure may increase seismic vulnerability. A structural analysis by a qualified structural engineer is required to ensure earthquake safety is not compromised by the repair.

7-2.2 **Special Skill Requirements**. Most concrete repair techniques and methods of placement require:

- Normal skills associated with concrete construction
- Building forms
- Setting reinforcing steel
- Mixing concrete
- Vibration
- Finishing
- Curing

Special skills and experience are required for placing shotcrete and for handling and placing concrete for underwater repairs. Shotcrete, in particular, requires a skilled nozzle operator to ensure quality results. Use experienced personnel when using epoxy components, epoxy injection, and sealing cracks and joints require experienced personnel.

Underwater repairs, depending on the complexity of the job, require special skills beyond placing the concrete, such as how to remove marine growth, underwater jetting and blasting, how to use underwater tools for cutting and drilling, and how to use certain materials for coating and caulking underwater.

7-2.3 **Special Equipment Requirements**. Unique equipment requirements exist on many jobs and often dictate the personnel skill requirements. Applying shotcrete requires a complete set of special equipment, as does pumped concrete. See the outlines in concrete placement methods (CPM) CPM-4 and CPM-6. Also, underwater work can require the same equipment listed in the Paragraph entitled, “Equipment Requirements”.

Above water repairs require conventional equipment for surface abrasive blasting and air-jet cleaning, form construction, and mixing, placing, and finishing concrete.

7-3 **METHODS OF PLACING CONCRETE AND MORTARS**. The seven most common methods for the placing concrete and mortars in waterfront repair are listed and describer in Table 7-2.

Table 7-2 Placement of Concrete and Mortar

No.	Description
CPM-1	Hand Placement
CPM-2	Dry Pack
CPM-3	Cast-in-Place
CPM-4	Shotcrete
CPM-5	Tremie
CPM-6	Pumped
CPM-7	Prepacked

CPM-1: HAND PLACEMENT

Description: Troweling a mortar into shallow, relatively small areas requiring patching.

Uses: Patching surface areas small enough for hand work and shallow cavities not suitable for dry pack.

Materials and Curing: Take careful measures to minimize drying shrinkage by selecting a material mix design with a maximum allowable shortage of 0.05 percent per ASTM C157/C157M modified and proper curing.

Preparation:

a. Remove all loose and unsound old concrete.

b. If reinforcing steel is exposed, ensure 1 inch (25 mm) clearance all around and wire brush steel bar.

c. Thoroughly clean repair area immediately before applying bonding coat.

Bonding: Vigorously brush coat repair area with sand-cement slurry: 1 part Type II cement; 1 part sand; and enough water or latex for a consistency of thick cream.

Mortar Mix: The proportions of the mix depend on the overall size and depth of the repair, accessibility, and whether the repair is large enough to require coarse aggregate. A typical cement-to-sand ratio is 1:2.5 to 1:3. The water-cement ratio should be no greater than 0.40.

Placement:

a. If repair is in direct sun or wind, build shade/wind break and leave in place during curing period.

b. Wet the surface of repair area for 24 hours. Do not leave any free water.

c. Brush coat repair area surface with cement slurry.

d. Immediately trowel on mortar mixture; completely fill voids and dense placement.

Curing: Use wet burlap for 7 days or use a curing compound.

CPM-2: DRY PACK

Description: Packing a stiff mortar into a confined hole or cavity.

Uses: Filling narrow slots cut during repair of dormant cracks, and filling cavities/small holes in cross-sectional area that are relatively deep.

Restrictions/Cautions:

a. Use for holes no larger than 35 inches^2 (225 cm^2) in cross-sectional area.

b. The depth of the cavity should be equal to or greater than the smallest surface dimension.

c. DO NOT use for:

1. Shallow depressions where lateral restraint is not obtained.
2. Filling behind exposed reinforcing steel.
3. Holes that extend through the structure.

d. Maintain water content of mortar carefully.

Preparation:

a. Thoroughly clean cavity.

b. Remove all loose or cracked aggregate.

c. Allow to dry at least 2 days before packing.

Bonding: Vigorously brush inside of cavity with a cement slurry: 1 part Type II Portland cement; 1 part clean, dry fine sand; and enough water for a consistency of thick cream.

Dry Pack Mix: 1 part cement, 2.5 parts sand passing No. 16 sieve, only enough water so mortar sticks together when squeezed with slight pressure. Take careful measures to minimize drying shrinkage by selecting a material mix design with a maximum allowable shortage of 0.05 percent and proper curing.

Placement:

a. Place and compact in layers 2/5 inches (10 mm) thick.

b. Scratch surface of each layer for good bond of next layer.

c. Fully compact each layer over entire surface with hardwood stick and hammer.

d. If a layer becomes rubbery, delay about 30 minutes for mortar to stiffen and then compact.

e. Finish surface with flat side of stick. Steel tools and water are not recommended.

f. Patch is usually darker than surrounding concrete. For appearance, use white cement in mix for outside layers.

Curing: Use wet burlap for 7 days or use a curing compound.

CPM-3: CAST-IN-PLACE CONCRETE

Description: Placing conventional concrete mix with a concrete mixer truck, chute, bucket, wheel barrows, concrete carts, or shovels.

Uses: Use in all repairs where the quantity of concrete required is too large for hand placement, and where special placement methods CPM-4 through CPM-7 are not required. Control of the concrete mix and strength of the completed repair is much better than with any other methods. Should be used when:

- The hole/cavity extends through the concrete section.
- The cavity in un-reinforced concrete is larger than 139 ½ in^2 (900 cm^2) in area and over 4 inches (10 cm) deep.
- The cavity in reinforced concrete is over 69 ¾ in^2 (450 cm^2) in area and deeper than the reinforcing steel.

Major concerns are quality of the mix, good bonding to old surfaces, keeping a low water-cement ratio, and proper curing.

Restrictions/Cautions:

a. Temperature shall be over 40 degrees F (4.5 degrees C) during placement.

b. Concrete settles after placement, therefore, proper consolidation is essential to prevent cracking

Preparation: See concrete repair (CR) procedure CR-3.

a. Delay several days after demolition of old, deteriorated concrete to confirm the soundness of remaining concrete and excavated surfaces.

b. Check forms for tightness and stability.

c. Ensure that old surfaces are cleaned before repairs begin.

d. Ensure that reinforcing steel is cleaned of rust and scale and exposed at least 1 inch (2.5 cm) all around.

Bonding: Usually, a sand-cement grout will suffice. See CR-3 for more information.

Concrete Mix: Give particular attention to:

a. Take careful measures to minimize drying shrinkage by selecting a material mix design with a maximum allowable shortage of 0.05 percent and proper curing.

b. Consider moisture in aggregate when calculating quantity of water.

c. Use a water-reducing plasticizer admixture wherever placement and consolidation are restricted, or slumps greater than 4 inches (10 cm) are required.

Placement: The equipment used depends on size of the pour, accessibility and working space, and availability of equipment. Concerns are placement speed and consolidation. In confined, hard to access locations, aid consolidation by using admixtures and mechanical vibrators and tampers. Elimination of voids and honeycombing is very important.

Curing: The most effective moist-curing method is using wet burlap for 7 days. Do not cut corners or try to economize. This is critical.

CPM-4: SHOTCRETE (GUNITE)

Description: Sprayed concrete applied directly by an air jet gun. Equipment includes a mechanical feeder, mixer, and compressor. If using a dry-mix, water is added at the nozzle.

Uses: Shotcrete is relatively economical where deterioration is shallow and area is large and irregular in shape. Shotcrete requires no form work and thin patches can be made that have a high strength, is an efficient method for vertical and overhead surfaces, and is also used for encasing timber and steel piling.

Restrictions/Cautions:

a. Must have enough repair work to justify the cost of equipment.

b. Normally restricted to a depth of 4 inches (10 cm) per lift.

c. Can have a high porosity if improperly applied.

d. Drying shrinkage rate and thermal expansion can be different than concrete being repaired.

e. Can have wide variation in application/composition. Quality depends almost entirely on the operator's skill. Follow ACI SP-14 guidelines.

Preparation:

a. Thoroughly remove all defective and loose concrete.

b. Clean all rust off exposed reinforcing steel.

c. Roughen all smooth surfaces.

d. Wire brush or abrasive blast exposed concrete surfaces to be covered.

Bonding: A bonding agent is not required.

Shotcrete Mix:

a. Cement-to-aggregate maximum ratio 1 to 3.5. This will result in an in-place mix of about 1 to 2.5 after rebound.

b. Minimize the water-to-cement ratio.

c. May use a non-chloride type admixture for rapid setting.

d. Fiber reinforcing may help minimize shrinkage cracks.

Placement:

a. Install reinforcing wire fabric to ensure the laps project no more than 4/5 inch (20 mm) from surface being covered.

b. Usually start work at bottom and move up; may follow the tide down.

c. Fix the profile.

d. Fill out the area to the original face.

e. Apply each coat at least 2 inches (5 cm) thick. The final coat should be at least 1/2 inch (13 mm) thick.

f. Ensure that rebound material is not trapped in corners or edges.

g. Ensure reinforcing bars are properly encased.

Curing: Use wet burlap for 7 days or use a curing compound.

CPM-5: TREMIE CONCRETE

Description: The primary method of placing concrete underwater when gravity flow is adequate. The tremie, a steel tube or rigid hose, runs from a hopper for filling its upper end into the form and is moved vertically as the concrete is placed.

Uses: All underwater pours at easily accessible locations that require a quantity of concrete to warrant the equipment set-up.

Restrictions/Cautions:

a. Do not use an aluminum alloy tremie to avoid reaction with the concrete mix.

b. Location, and space in the form, must be accessible for positioning and moving the tremie vertically and horizontally.

c. Slump of concrete mix must be carefully controlled within 6 to 8 inches (15 to 20 cm). Too wet a mix may segregate and too dry a mix will not flow properly in the form.

d. If practicable, place concrete when water temperature is above 50 degrees F (10 degrees C).

Preparation: Prepare the repair location in the same manner as cast-in-place concrete. Also, ensure that the tremie pipe is heavy enough to be negatively buoyant, and that the joints in the tremie are well gasketed and sealed. The diameter of the tremie should be at least eight times the largest size aggregate used.

Bonding: Not usually required.

Concrete Mix:

a. A typical mix proportion for cement, sand, aggregate, is 1:1.7:2.4 by weight with a water-cement ratio of 0.45.

b. Use air-entraining and water-reducing plasticizer admixtures as required for the underwater repair. Admixtures conforming to ASTM C494/C494M are acceptable.

c. Use a mineral admixture of pozzolan in thick sections to control heat buildup. This will reduce amount of cement in the mix.

Placement:

a. Once the tremie pipe is filled, carefully lift the bottom end from the bottom of the form not more than 6 inch (15 cm) to start the flow of concrete.

b. Placement should be as continuous as possible. The end of the tremie must remain embedded in the concrete by as much as 40 inches (1 meter).

c. If the tremie is lifted out and the seal is lost, remove it, reseal, and start again.

d. Move the tremie horizontally while concrete is flowing

Curing: Not applicable.

CPM-6: PUMPED CONCRETE

Description: Placing concrete through a pipe or hose using a concrete pump with attached hopper.

Uses: Often used for placement above water. May be used for underwater placement in locations with limited accessibility, where the tremie method is not efficient. The advantages for underwater repairs include:

- High quality concrete can be pumped. The mixture must be both workable and cohesive without blocking the pump.

- Workable mixtures containing relatively small coarse aggregate particles provide an easily placed and dense concrete.

- Concrete can be transferred from a barge directly into the forms.

- Pumped concrete fills forms from the bottom upwards, displacing the seawater as more concrete is added.

Restrictions/Cautions: See CPM-5, Tremie Concrete. Also:

a. Carefully control slump of concrete to 6 to 8 inches (15 to 20 cm).

b. Avoid inclines in the pipe whenever possible.

c. If delays are encountered, move concrete about 40 inches (1 meter) every 5 minutes. If concrete becomes stiff due to a long delay, discard the mix. Do not retemper by adding water.

d. Use rubber hose only for discharge end and short pumping distances.

Preparation: Prepare the repair location in the same manner as cast-in-place concrete. Also, carefully plan location of pump and routing of pipeline to minimize moves. The pipeline should be horizontal or vertical whenever possible.

Bonding: Not usually required underwater; for above water, see CPM-3: Cast-in-Place Concrete.

Concrete Mix:

a. A typical mix proportion is 1:3:1 by weight with a water-cement ratio of 0.45. Take careful measures to minimize drying shrinkage by selecting a material mix design with a maximum allowable shortage of 0.05 percent and proper curing.

b. Use rounded coarse (2/5 inch (10 mm) minimum) aggregate when possible.

c. Sand should have a higher proportion of finer sizes.

d. Avoid porous aggregates such as expanded clay, foamed slag, and pumice.

Placement: The principles of placing tremie concrete apply. Also:

a. Before filling hopper, lubricate the pipe with water, then a cement-water slurry.

b. Take all precautions to avoid separation of the mix.

c. Always keep discharge buried in the fresh concrete.

d. Control discharge to keep lateral flow of concrete within 0.7 to 1 meter.

Curing: Not applicable underwater. If above water, use wet burlap for 7 days or use a curing compound.

CPM-7: PREPACKED CONCRETE

Description: Placing coarse aggregate in the form and filling the voids with grout. It is used on large repair jobs, and usually grout is pumped through grout pipes from the bottom up.

Uses: Prepacked concrete is used where placement of cast-in-place concrete is not practical. It is also used underwater where the tremie or pumped methods are not practical due to inaccessibility. It is suitable for vertical surface repairs that have a minimum thickness of 3 to 4 inches (8 to 10 cm).

Restrictions/Cautions:

- Prior to injecting grout, be sure fines have not collected in the coarse aggregate. Fines in the aggregate can impede the flow of grout and create voids.
- Protect the aggregate from contamination after it is placed.

Preparation: Prepare the repair location in the same manner as for cast-in-place concrete. Also, ensure grout pipes are well installed and fixed to forms or reinforcing. A vent must be provided at the highest point.

Bonding: Not required.

Concrete Mix: Take careful measures to minimize drying shrinkage by selecting a material mix design with a maximum allowable shortage of 0.05 percent and proper curing. Coarse aggregate is sized to the size of repair. The sand-cement grout is usually richer than a 1:1 mix. Admixtures are used as required by the circumstances. Usually, a chemical admixture is used as an intrusion aid for the grout. This suspends solids and provides fluidity. An air-entraining admixture is used to obtain about 9 percent air in the grout.

Placement: Pump the grout soon after the aggregate is placed. Ensure that all voids are filled and that segregation in layers does not take place. When forms are filled, apply a closing pressure of about 14.5 psi (0.1 MPa) to drive out air and water through the vent.

Curing: Use wet burlap for 7 days or a curing compound.

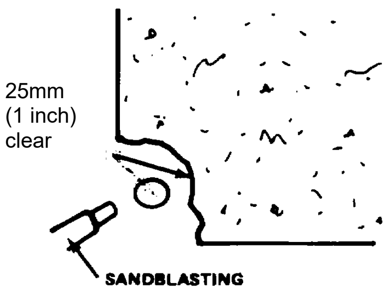
7-4 **CONCRETE REPAIR PROCEDURES**. Figure 7-1 summarizes the general steps taken in concrete repairs. The more standard repair procedures and techniques used for waterfront facilities are listed in Table 7-3 and included in the following pages. These repair techniques should be used in conjunction with the guidelines for concrete in the Paragraph entitled, “Concrete for Repairs”, the descriptions of methods of placement in the Paragraph entitled, “Methods of Placing Concrete and Mortars” and the preservation measures outlined in Chapter 3.

Table 7-3 Repair Techniques for Concrete Structures

No.	Description
CR-1	Repair Small to Medium Cracks by Epoxy Grout Injection
CR-2	Major Joint and Crack Repair
CR-3	Repairs to Concrete Seawall
CR-4	Miscellaneous Repairs to Concrete Piles
CR-5	Concrete Jacketing of Concrete Piles
CR-6	Typical Combination Repair: Cast-in-Place Concrete and Epoxy Grout Injection
CR-7	Typical Repair Using Polymer Concrete
CR-8	Typical Concrete Wall Repair

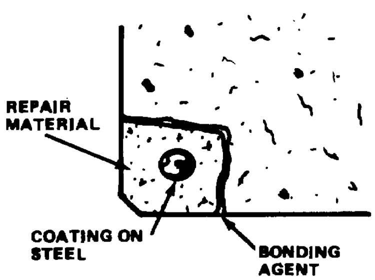
Figure 7-1 General Steps to Concrete Repair

REPAIR CONCRETE STRUCTURES



SURFACE PREPARATION

- Remove all deteriorated and loose concrete.
- Expose all uncovered reinforcing steel at least 1 inch clear all around.
- Sandblast/waterblast/wire brush concrete and steel as necessary to clean thoroughly.
- Keep concrete surface wet for several hours.
- Coat reinforcing steel with cement slurry.
- Just before placing repair material, apply cement slurry to old concrete.

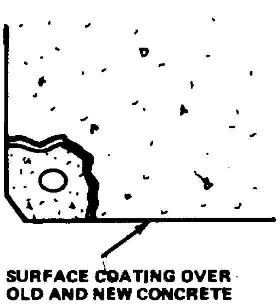


PLACE REPAIR MATERIAL

- Depending on size and type of repair, material may be a mortar or concrete, Portland cement concrete, or latex modified concrete.
- Above water placement: hand placement, dry pack, cast-in-place, or shotcrete.
- Underwater placement: tremie, pumped, or prepacked.

CURING

- Use most efficient moist curing for at least 7 days if practicable. Wet burlap is the best.
- Use two curing applications of compound. Wet burlap is not practical.



SURFACE COATING

- Determine if surface coating is required.
- Prepare surface by air/abrasive blasting.
- Apply coating applicable to location, exposure, and use of concrete.

CR-1: REPAIR SMALL TO MEDIUM CRACKS BY EPOXY GROUT INJECTION

Problem: Cracks caused by weathering, deterioration, or reinforcing steel corrosion allow water to penetrate the structure.

Description of Repairs: Filling and sealing small to medium cracks by injecting a low-viscosity urethane and sealing the outside with an epoxy paste. Routing and cleaning of cracks are performed with conventional hand and power tools. Injection for smaller jobs can be done with a hand-operated caulking gun. Large jobs are usually done with special equipment.

Materials:

a. Low-Viscosity Epoxy - Select a urethane suitable for wet surfaces and underwater application that is compatible with crack volume, crack movement, and equipment to be used for injection. \1\ /1/b. Sealing Epoxy - Use a quick-setting epoxy paste adhesive suitable for underwater application that has good bonding characteristics for concrete being repaired.

Preparation:

a. Rout out cracks to remove all deteriorated and loose concrete and aggregate. Clean area to receive sealing epoxy with wire brush, high-pressure water jet, or sandblasting.

b. Drill injection holes every 6 inches (15 cm) along the length of the crack for larger jobs with deep cracks. Install a tube or one-way polyethylene valve in the holes as injection ports.

c. Repair small and shallow cracks with a hand gun, injection ports may be openings left in the sealing epoxy every 6 inches (15 cm).

Repair Procedures: See Figure 7-2.

a. Perform repairs when ambient/water temperature is at least 50 degrees F (10 degrees C).

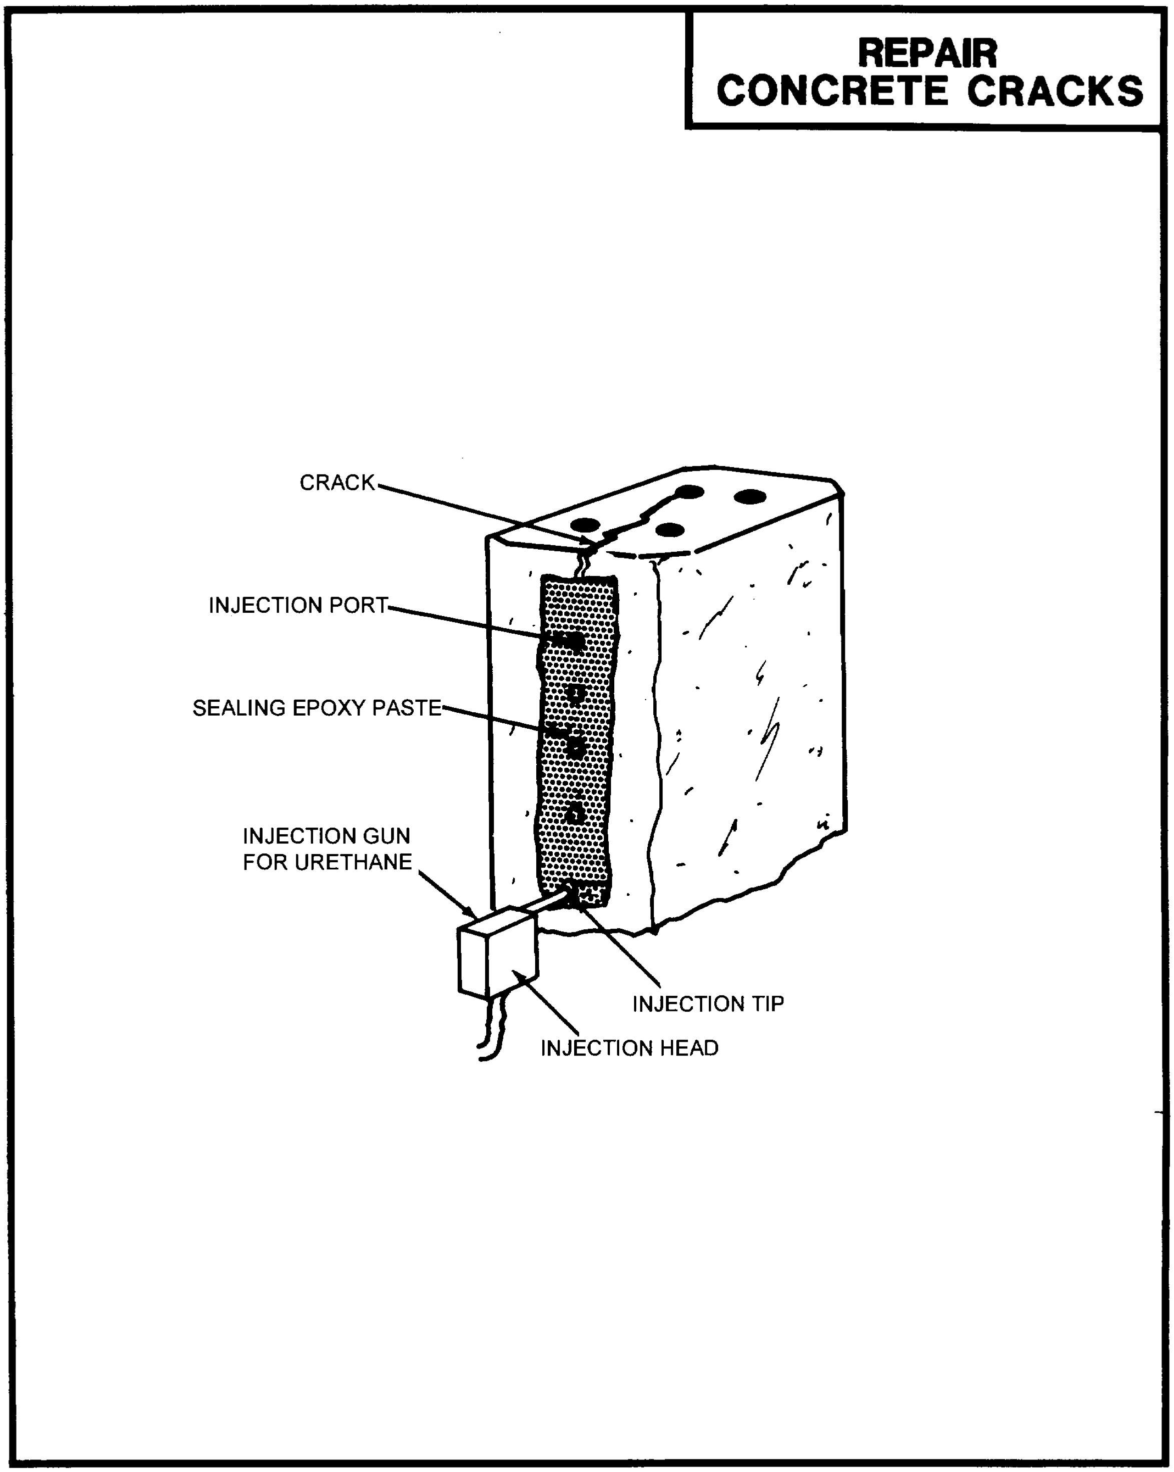
b. Seal the outside surface of the crack with the epoxy paste, carefully sealing around the injection ports.

c. After the surface seal has set, inject the urethane grout, starting at the bottom port for a vertical crack. Continue injection until grout shows in the next port then continue up the crack until the entire crack is filled.

d. Plug the port holes with the sealing epoxy paste.

Application: Epoxy grout injection does not stop spalling due to rebar corrosion. This method is most useful in making structural repairs of cracked concrete that is static only. Cured epoxy is rigid, therefore, epoxy injection is not recommended where there is any additional cracking or movement of concrete anticipated. Follow International Concrete Repair Institute (ICRI) Technical Guide \1\ No. 210.1, Guide for Verifying Field Performance of Epoxy Injection of Concrete Cracks (formerly No. 03734) /1/.

Figure 7-2 Typical Crack Repair with Epoxy Grout Injection



CR-2: MAJOR JOINT AND CRACK REPAIR

Problem: Large cracks or construction joints allow water to penetrate in or leak through the structure.

Description of Repairs: Sealing of cracks and construction joints to prevent leakage. This repair is performed after grouting of cracks is completed. Example given is for drainage and discharge tunnels, and should be modified for less demanding applications. Repair requires conventional hand and power tools and a heating bucket.

Materials:

a. Sealant No. 1 - Two-component epoxy coating system. See \1\ /1/ CR-4, Applications.

b. Sealant No. 2 - Non-meltable mastic of refined asphalts, resins, and plasticized compounds reinforced with non-asbestos fiber. Resistant to seawater, salts, acids, and dilute alkalis.

c. Primer for Sealant No. 2 - Asphaltic liquid primer compatible with sealant.

d. Sealant No. 3 - Two-component, moisture insensitive epoxy resin mortar; 1 part mixed epoxy to 7 parts aggregate by volume.

e. Copper Plate - 16 gauge conforming to ASTM B370, *Copper Sheet and Strip for Building Construction*.

Preparation: Chip out and saw cut concrete as shown on Figure 7-3. Clean all surfaces to receive sealants of all loose and deteriorated concrete and marine growth by chipping, scraping, and sandblasting. Provide clean, sound bond surfaces. Prepare surfaces to meet sealant manufacturer's requirements.

Repair Procedures:

a. Perform repairs when ambient or water temperature is at least 50 degrees F (10 degrees C), depending on whether structure is exposed or submerged.

b. Apply Sealant No. 1 with a brush to cleaned surfaces.

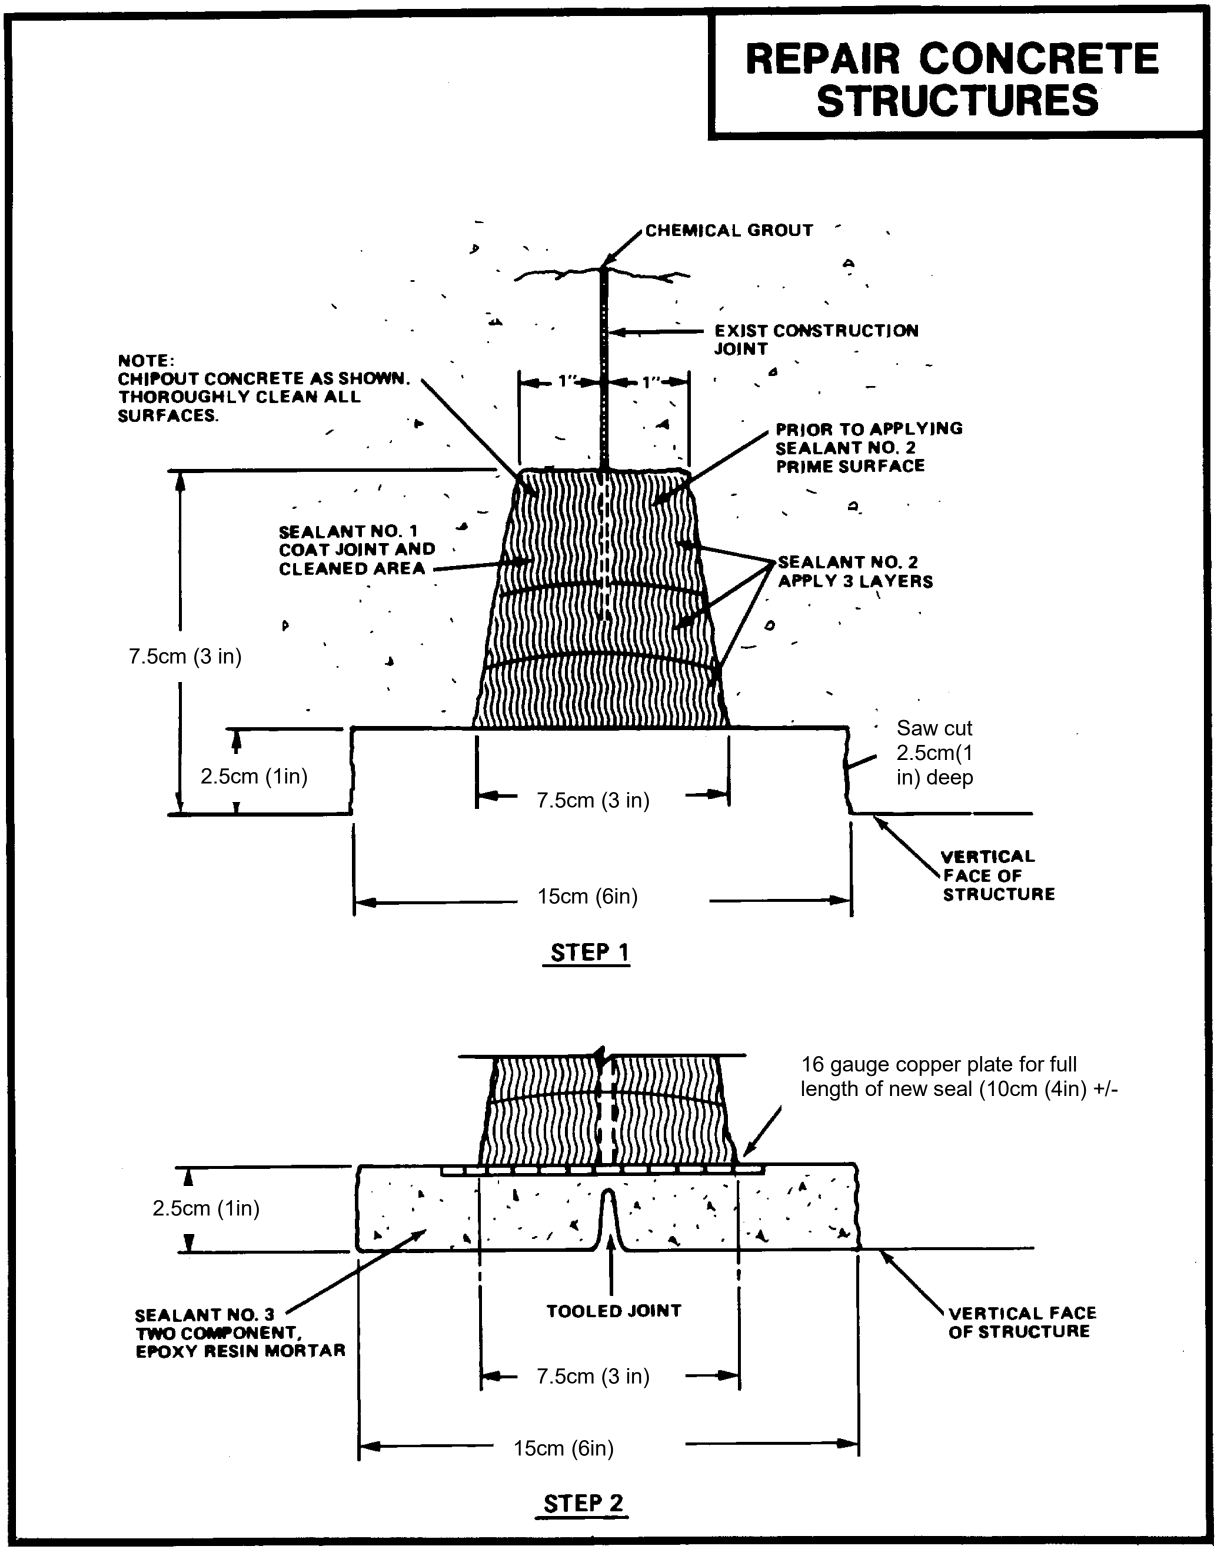
c. Prime all surfaces to receive sealant No. 2 with primer and let dry.

d. Apply three layers of Sealant No. 2 (heat sealant) as shown in Figure 7-3. Pound each layer during and after cooling.

e. Fasten copper strip in place for placement of sealant No. 3. Do not use fasteners of dissimilar metal.

f. Apply sealant No. 3 as shown and tool the joint as required.
Curing: Cure sealants per manufacturer's specifications.

Figure 7-3. Joint and crack repair



CR-3: REPAIRS TO CONCRETE SEAWALL

Problem: Sulphate attack has caused limited disintegration of the seawall within the tidal zone.

Description of Repairs: Contact between the existing concrete and seawater is eliminated by adding a repair layer of sulphate-resisting concrete. Old concrete is replaced only to the extent necessary to repair damage and to isolate the old concrete from the seawater reaction. See Figure 7-4.

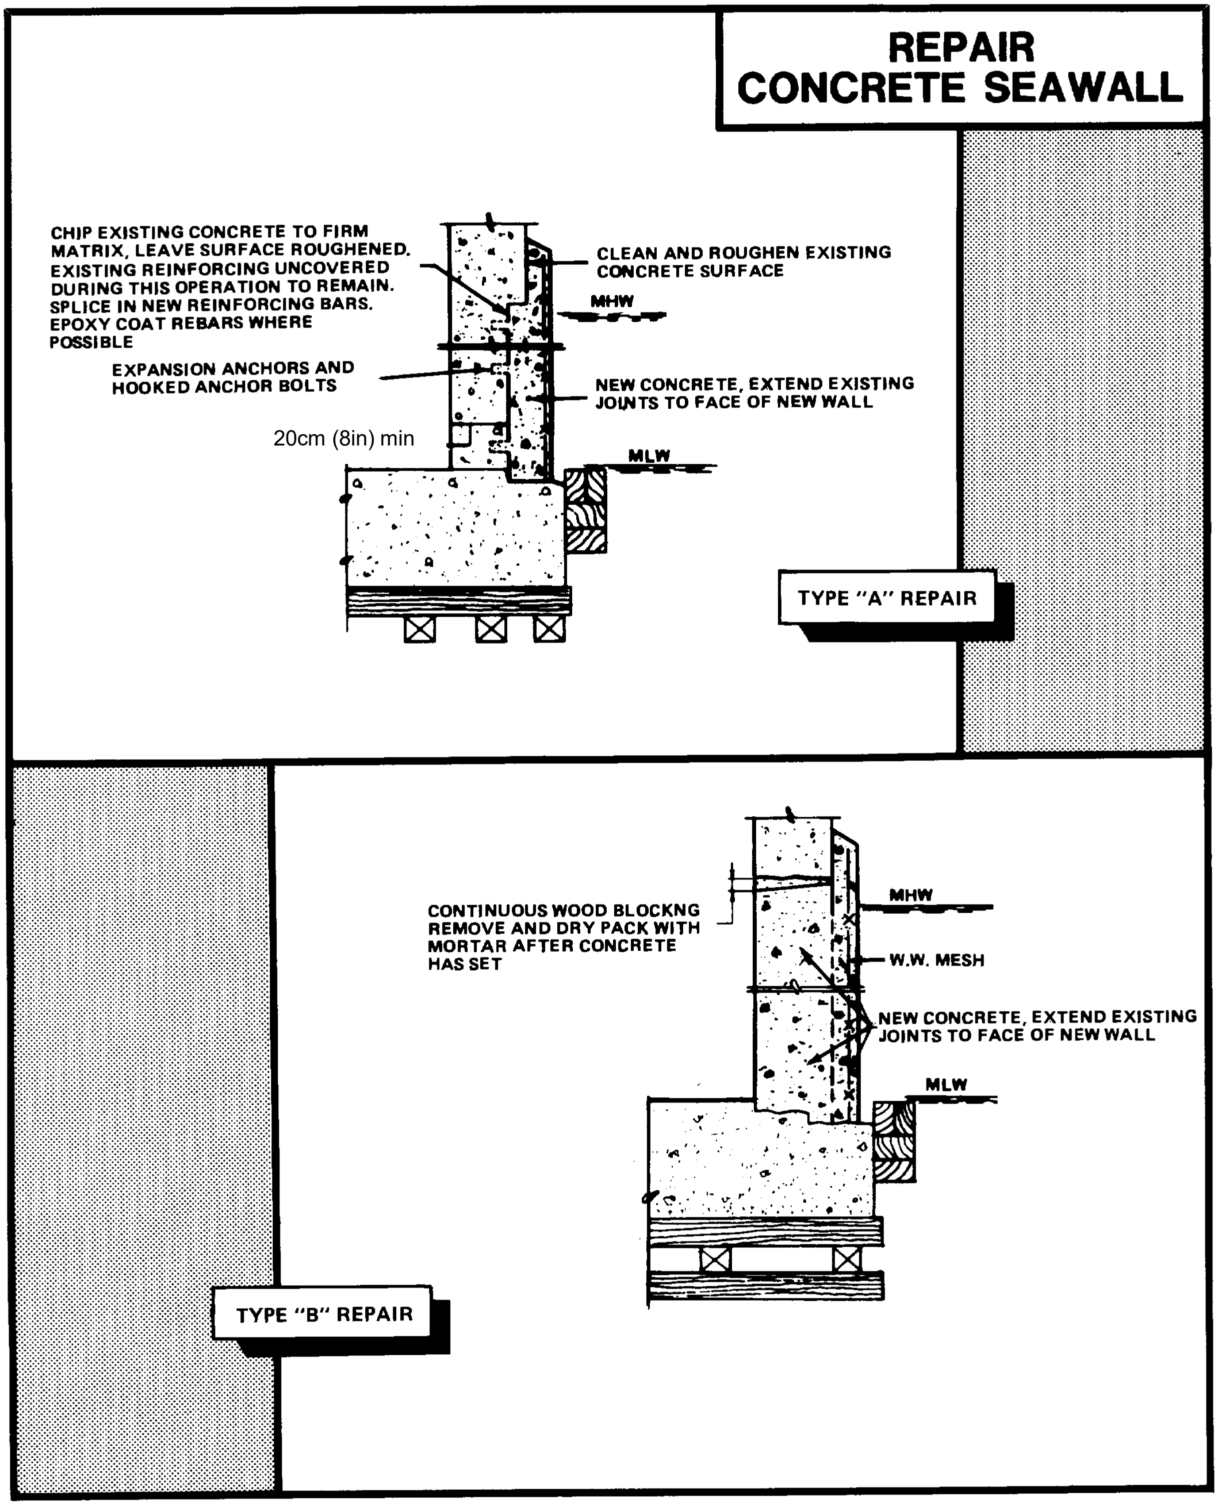
Repair procedures are as described in CPM-3 for cast-in-place concrete or CPM-5 if the tremie method is required. Also, see repair CR-8 for certain applicable procedures.

- Type "A" Repair: In this case, a minimum of 7 7/8 inch (20 cm) of the existing wall thickness must be sound concrete. A facia of new concrete is added, well anchored to the existing wall.

- Type "B" Repair: In this case, a section of the wall is replaced, through its entire width, which includes the facia on the water side. This type of repair uses the dry pack method, CPM-2, to close the gap between the top of the new concrete and the existing concrete. See CR-8 and Figure 7-7 for a similar wall repair.

Application: These types of repair are applicable where the extent of the deterioration is limited and is not threatening to the entire height of the seawall, and a partial repair from foundation to above high water will solve the problem. The wall foundation must be in good condition. Extensive deterioration along a length of the seawall would call for a complete demolition and replacement of a section of wall.

Figure 7-4 Repairs to Concrete Seawall



CR-4: MISCELLANEOUS REPAIRS TO CONCRETE PILES

Problem: Concrete pile is worn from abrasion at waterline; has spalled areas above the tidal zone; or is badly cracked.

Description of Repairs: In all cases, the repair area must be cleaned thoroughly of marine growth. All loose and deteriorated concrete must be removed. If reinforcing steel is exposed, it must be cleaned of all rust and scale and exposed at least 1 inch (2.5 cm) clear all around.

Figure 7-5 illustrates:

- Concrete Jacketing:

  a. Wrap pile with spiral reinforcing length of jacket.

  b. Place form around pile (metal, fiberglass, fiber, or other material).

  c. Fill form with 5000 psi (35 MPa) concrete, either pumped or placed with a tremie (see CPM-5 and CPM-6).

  d. Form may be removed or left in place.

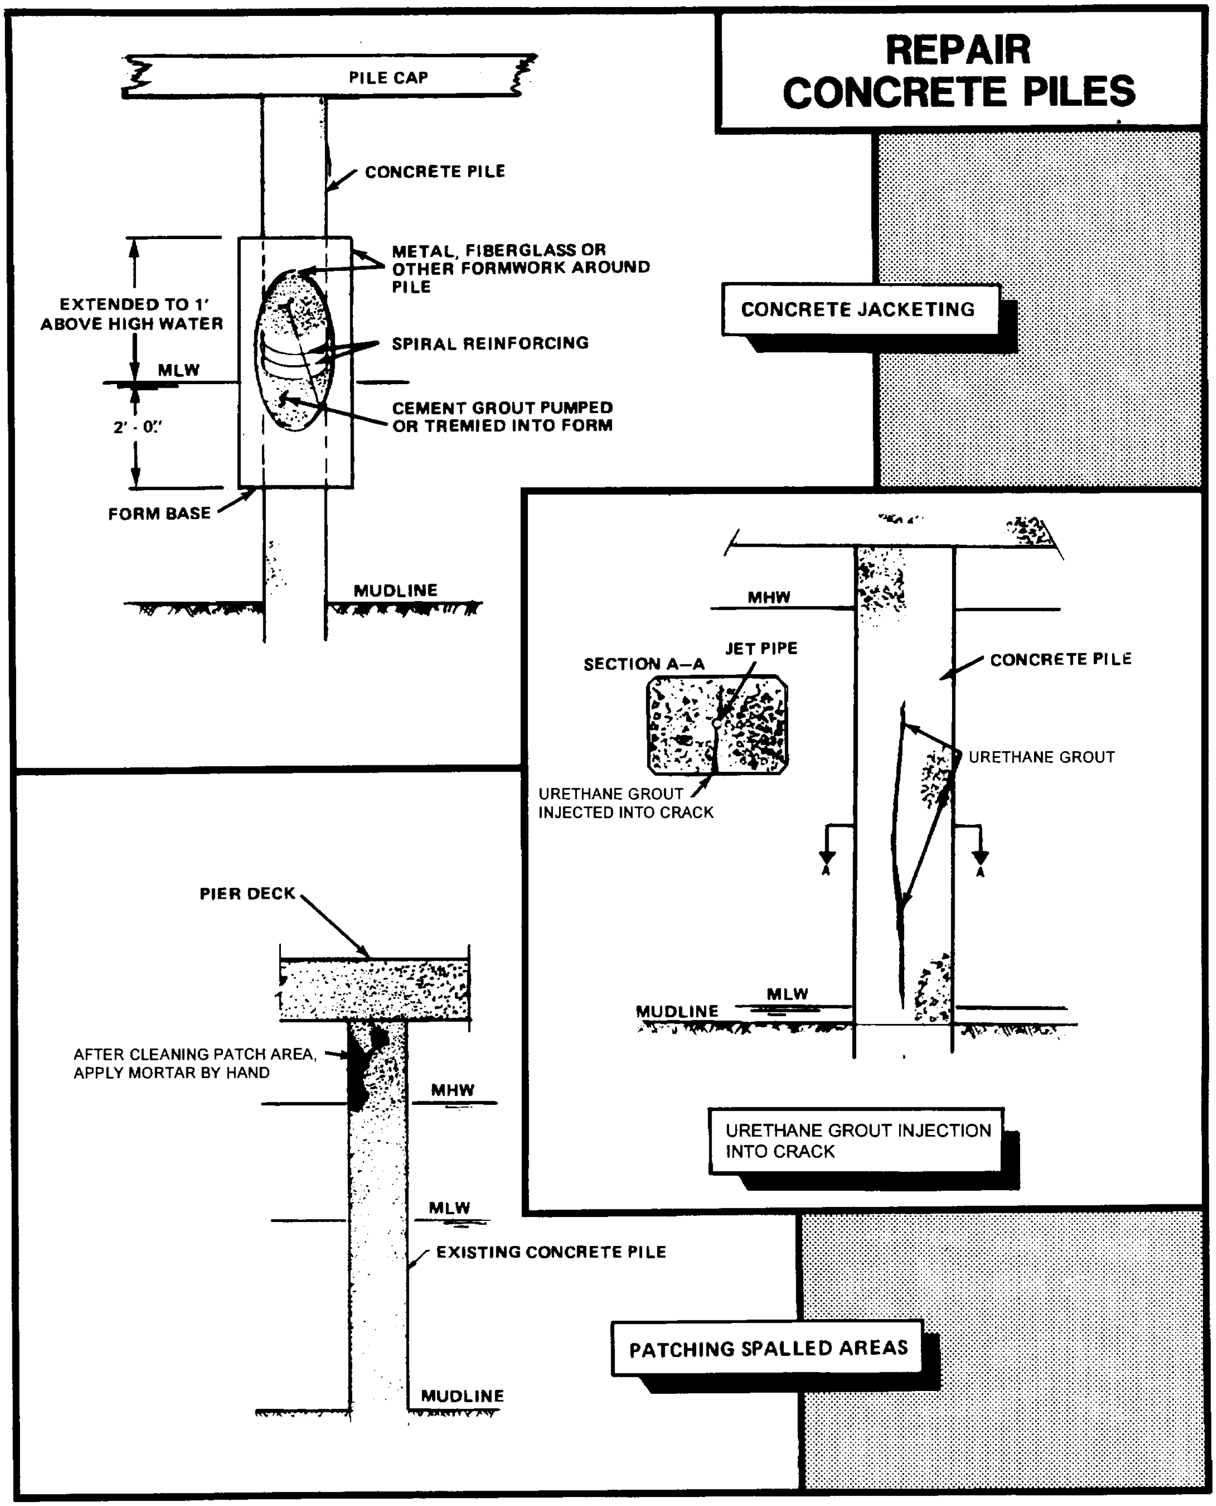
- Patch Spalled Areas: Repair the spalled areas by hand (see CPM-1) or form and pour.

- Fill Crack with Urethane Grout: See repair CR-1.

Applications: The concrete jacketing repair is a partial restoration when the pile is worn/deteriorated only in the tidal zone and sound below and above water. See repair CR-5 for more complete concrete pile restoration.

The spall patching and crack filling repairs are relatively minor, inexpensive techniques to protect the reinforcing steel from seawater. The effectiveness of the spall patches depend on the bond that is obtained with the old concrete and the corrosion activity on-going in the rebar in the substrate.

Figure7-5 Miscellaneous Repairs to Concrete Piles



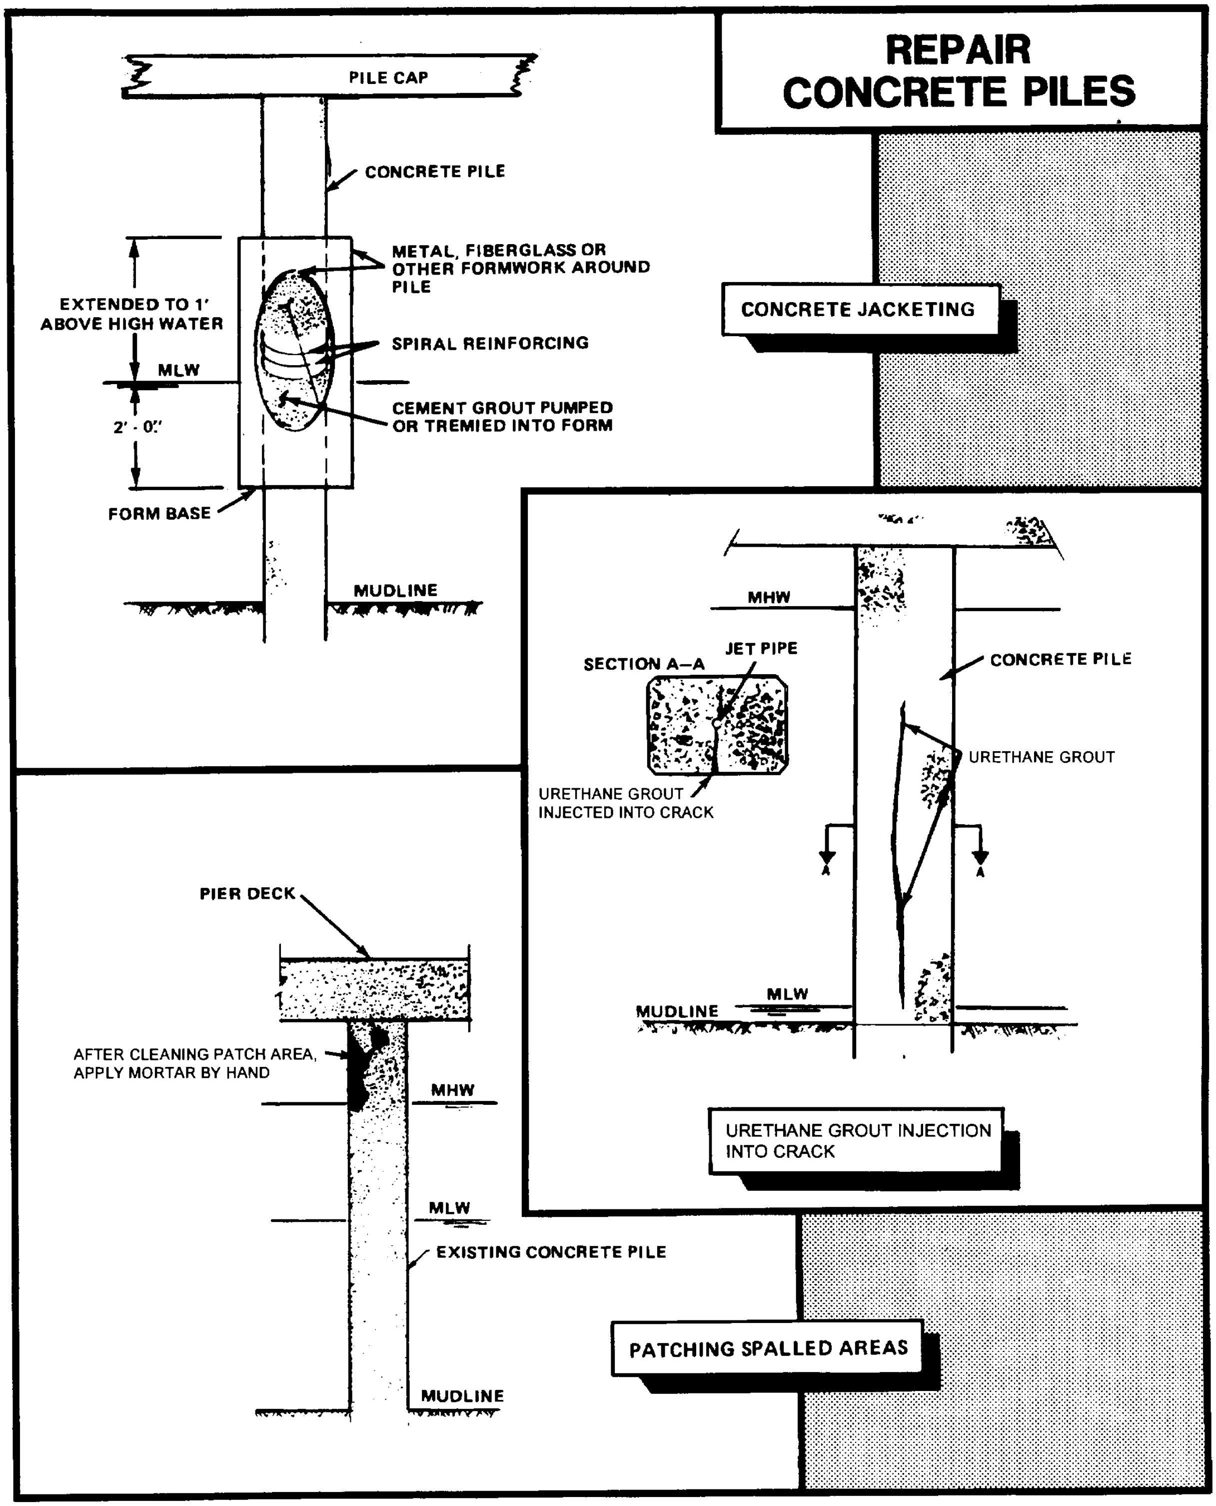
CR-5: CONCRETE JACKETING OF CONCRETE PILE

Problem: Precast concrete piles have major deterioration due to sulphate attack. Deterioration extends to the mud line.

Description of Repairs: See Figure 7-6. In this example, the original pile section was 15 ¾ inches (40 cm) square. The concrete jacket, as shown, is 30 inches (76 cm) in diameter. A timber encasement, with galvanized steel bands, is used in the tidal zone. A corrugated sheet metal form is used down below the mud line. See CPM-6 for the pumped concrete method of injecting the new concrete. Figure 7-6 shows the top portion of the pile encased with either a pneumatically placed (CPM-4) or hand-placed grout (CPM-1).

Applications: This method is applicable when the remaining section of pile is structurally sound and judged to be worth saving. Jacketing versus complete replacement is an economic decision.

Figure 7-6 Jacketing Concrete Piles



CR-6: COMBINATION REPAIR CAST-IN-PLACE CONCRETE AND EPOXY GROUT INJECTION

Problem: Concrete footings with many cracks with some spalling, scaling, and delaminated areas.

Description of Repairs: Repair footings using a combination of restoration with Portland cement concrete, and filling cracks and delaminated concrete by injecting urethane resin. Tools required: air hammer, conventional hand and power tools, and injection gun or pump for urethane.

Materials:

a. Portland cement concrete.

b. Urethane resin for injection.

Preparation:

a. Remove all unsound concrete.

b. Wire brush or sandblast all surfaces to receive bonding agent and clean thoroughly.

c. Thoroughly clean and coat any exposed reinforcing steel with cement slurry.

d. Sound concrete with metal rod to determine extent of delamination and outline the areas.

e. After restoration of concrete is completed, rout and clean racks to be filled with injected urethane.

Repair Procedures:

a. Place, cure, and finish concrete repairs to restore structure to its original shape (CPM-3).

b. Select epoxy injection points and drill holes if required. Insert injection tubes or valves if required. See repair CR-1.

c. Fill cracks 3.1 mils (0.08 mm) wide and larger, and delaminated areas, by injecting the low-viscosity urethane. For jobs with large areas of delamination and deep cracks, pressures up to 1,000 psi (6.9 MPa) may be required.

d. Plug the injection holes with epoxy paste.

CR-7: REPAIR USING POLYMER CONCRETE

Problem: Concrete roof deck spalling due to corrosion of reinforcing steel and cracks around support columns.

Description of Repairs: Patch spalled areas with PCC mortar. Coat roof deck. Reseal joints with polyurethane joint sealer. Requires conventional hand and power tools. May not be suitable for vehicle traffic areas.

Materials: Take careful measures to minimize drying shrinkage by selecting a material mix design with a maximum allowable shortage of 0.05 percent and proper curing.

a. Latex modified portland cement.

b. Polyurethane joint sealant that meets ASTM C920, *Specification for Elastomeric Joint Sealants*.

Preparation:

a. Remove all unsound concrete in the spalled areas. Expose reinforcing steel all around.

b. Clean the exposed reinforcing steel and entire deck area by sandblasting.

c. Thoroughly clean areas to receive new material immediately prior to placement.

Repair Procedures:

a. Patch spalled areas with Latex Modified Cconcrete.

b. Seal entire deck area with neat polyester resin.

c. Remove all joint sealant and reseal joints.

Limitations: The corrosion processes will continue to cause cracks and delaminations.

CR-8: TYPICAL CONCRETE WALL REPAIR

Problem: Holes or severely deteriorated areas require replacing the wall section with cast-in-place concrete.

Description of Repairs: Defective section of wall is removed, surfaces and reinforcing steel are prepared, form work built, and wall is restored with cast-in-place concrete. Repair may be an internal section, as shown in Figure 7-7, or may be the top of a wall or pier deck curb requiring an open-top form. Equipment used includes: sandblasting and air-water jet cleaning equipment, concrete saw, air chipping hammer, air-suction gun for mortar if available, power vibrator and tamper, and conventional concrete placement tools.

Materials: Portland cement concrete with maximum shrinkage of 0.05 percent.

Preparation:

a. Use air hammer or hand tools to remove all unsound concrete to the limits of the repair area.

b. Cut the top edge of the hole at the face of the structure to a fairly horizontal line (see Figure 7-7). Where a hole passes through a structural element, it may be necessary to fill the hole from both sides. In this case the slope of the top of the cut should be modified accordingly.

c. Cut the bottom and sides of the hole sharp and square with the face of the wall. When the hole goes entirely through the concrete section, spalling and feather edges can be avoided by having chippers work from both faces. All interior corners should be rounded to a minimum radius of 1 inch (25 mm).

d. Do not leave reinforcing steel partially embedded. Ensure there is a minimum of a 1 inch (25 mm) clearance around each exposed bar. Remove unnecessary tie wires.

e. Clean all surfaces to bond to new concrete with wet sandblasting and air-water jet. Clean exposed steel with abrasive blasting or wire brushing.

Repair Procedures:

a. Construct front forms for patches more than 18 inches (46 cm) high in horizontal sections so the concrete can be placed in lifts not more than 1 foot (30 cm) high. The back form can be built in one piece. Sections to be set as concreting progresses should be fitted before concrete placement is started. See Figure 7-7.

b. For irregularly shaped holes, chimneys (accesses) may be required at more than one level. In some cases, such as when beam connections are involved, a chimney may be needed on both sides of the wall or beam. In all cases, the chimney should extend the full width of the hole.

c. Ensure forms are constructed so that pressure can be applied to the chimney cap at the proper time.

d. Ensure forms are mortar tight at all joints between adjacent sections, between the forms and concrete, and at the tie-bolt holes to prevent the loss of mortar when pressure is applied to the concrete during the final states of placement. Place twisted or stranded caulking cotton, folded canvas strips, or similar material between the joints as the forms are built.

e. Keep concrete surfaces wet for several hours, preferably overnight, before placement.

f. Before placing the front section of form for each lift, coat the surface of the old concrete with a 118 mils (3-mm) thick layer of mortar. This mortar should have the same sand and cement content and the same water-cement ratio as the new concrete. The surface should be damp, but not wet. The mortar can be applied with an air-suction gun, brush, or rubbed into the surface by hand. (Be sure worker is wearing rubber gloves if doing by hand.)

g. Place concrete immediately. Ensure thorough compaction by vibration or pressure grouting to14.5 psi (0.1 MPa).

h. Remove forms the day after placement. If chimneys were used, remove the remaining projections the second day working up from the bottom.

i. Thoroughly moist-cure the new concrete.

j Finish with a wood float. Tool or chamfer edges and corners as required. Avoid using water in finishing.

Figure 7-7 Typical Concrete Wall Repair

CHAPTER 8

REPAIR OF STEEL STRUCTURES

8-1 **GENERAL**. Steel is used extensively in construction and repair of waterfront facilities due to availability, cost, ease of fabrication, physical and mechanical properties, and the design experience with its use. Structural steel and cast or fabricated steel are used in all areas of the waterfront. Typical applications requiring maintenance include:

- Piers, wharves, bulkheads, and quaywalls using steel H-piles or pipe piles to support or brace the structure; steel sheet piling used to retain fill; structural steel shapes used for framing.
- Fender systems incorporating steel H-piles.
- Mooring hardware such as cleats, bollards, bitts, and chocks made from cast or fabricated steel.
- Other items such as utility lines, grating, opening frames, space manhole covers, fences, bolts and nuts, handrails, and concrete reinforcement.
- Steel components of camels.

Corrosion is the major cause of deterioration of steel structures and components. The extent or severity of corrosion will vary with the exposure zone of the material; that is, whether it is in the atmospheric zone, the splash or tidal zone, or the submerged zone. Selection of the repair technique must consider each of these varied conditions and such other elements as:

- Facility mission and required life.
- Extent of damage and deterioration.
- Estimated life expectancy with repairs and without repairs.
- Projected load capacities.
- Problems associated with mobilization of equipment, personnel, and materials to accomplish repairs/maintenance.
- Tides and currents
- Economics and trade-offs.

Maintenance and repair of steel structures and components fall into five general categories: coating and wrapping, cathodic protection, concrete encasement, partial replacement, and complete replacement.

8-2 **PLANNING THE REPAIRS**. Repairing steel structures are often controlled by the availability of skilled personnel and equipment. In many cases, structural repairs, particularly of bearing piles and sheet piling, will be done by contract.

The initial planning step for establishing the repair approach must involve review of prior inspection reports to determine the scope of damage or deterioration, the rate of deterioration, and specific operational constraints placed upon the facilities because of the deterioration. Once the scope of repair requirements, including priorities, is established, how the work will be done, whether in-house or by contract, must be determined.

8-2.1 **Special Skill Requirements**. Repairing the pier decking and curbs, pile caps, fender system, and deck hardware involves having skills common to in-house shop forces. Underwater repairs require special skill levels that may not be available with in-house forces. These include general diving capability plus knowledge of:

- removing marine growth
- jetting or air lifting procedures
- underwater cutting, welding and drilling techniques
- underwater lifting procedures
- application techniques for underwater protection coatings
- wrapping materials used in underwater construction

8-2.2 **Equipment Requirements**. Repairing pier decking and curbs, pile caps, fender system and deck hardware requires equipment common to in-house shop forces. Equipment for bearing or sheet piling repairs, however, may include:

- high-pressure water blaster
- hydraulic grinders with barnacle buster attachment
- hydraulic drill with bits
- hydraulic power unit

- oxygen arc cutting and oxy-acetylene torch equipment
- protective clothing and gloves for personnel handling epoxy coatings for steel
- concrete pump with hose
- jetting pump and hose
- rigging equipment
- float stage and scaffolding
- cofferdams
- clamping template for cutting piles
- special clamping equipment
- crane

8-3 **REPAIR PROCEDURES**. Repair techniques for waterfront steel structures are summarized in Table 8-1. Selecting a technique must address both immediate repairs necessary to restore the structure to full (or other designated) usage and protective measures needed to prevent further corrosion. Selecting a means for restoring the structural capacity of the facility may be straightforward, being generally controlled by the level and rate of deterioration. Decisions on the level of protection needed to inhibit future corrosion may be more difficult. Generally, these decisions are economically driven.

Each repair decision must carefully weigh the long-term operational requirements and existing environmental factors (tides and currents) that can help accelerate corrosion before evaluating initial and life cycle costs. In many cases, combining cathodic protection and protective coating in the repair decision may be the most cost effective in the long term. Using any of the repair techniques that follow should fully adhere to the preservation treatment requirements outlined for steel structures in Chapter 3.

Damaged steel hardware such as cleats and bollards in general should be replaced in kind. Care should be taken that the engineer determine the cause of failure and that the replacement item conforms to NAVFAC Standard Details.

Table 8-1 Repair Techniques for Steel Structures

Repair No.	Description
Bearing Piles	
SR-1	Protecting Steel Piles by Coating
SR-1	Cathodic Protection for Steel Bearing Piles
SR-3	Partial Replacement of Steel Piles
SR-4	Repairing Steel Pile with Concrete Encasement
SR-5	Complete Replacement of Steel Pile
Sheet Piling Walls	
SR-6	Coating and Cathodic Protection for Steel Sheet Pile Wall
SR-7	Patching of Steel Sheet Pile Wall
SR-8	Reinforcing Tie-Back Systems for Steel Sheet Pile Wall
SR-9	Replacement of Existing Steel Sheet Pile Wall
SR-10	Installing a Concrete Cap or Face on a Steel Sheet Pile Wall
SR-11	Scour Protection for Steel Pile Supported Waterfront Structure

SR-1: PROTECTING STEEL PILES BY COATING OR JACKETING

Problem: A new steel pile has been installed or an existing pile has experienced slight deterioration (less than 15 percent) of the cross-sectional area at some point. Protection against further corrosion is required.

Description of Repairs: Clean steel above water with abrasive blasting equipment and underwater with water jet cleaning equipment.

Epoxy-Polyamide Coating: See the Paragraph entitled, "Protective Coatings for Steel" (see Figure 8-1).

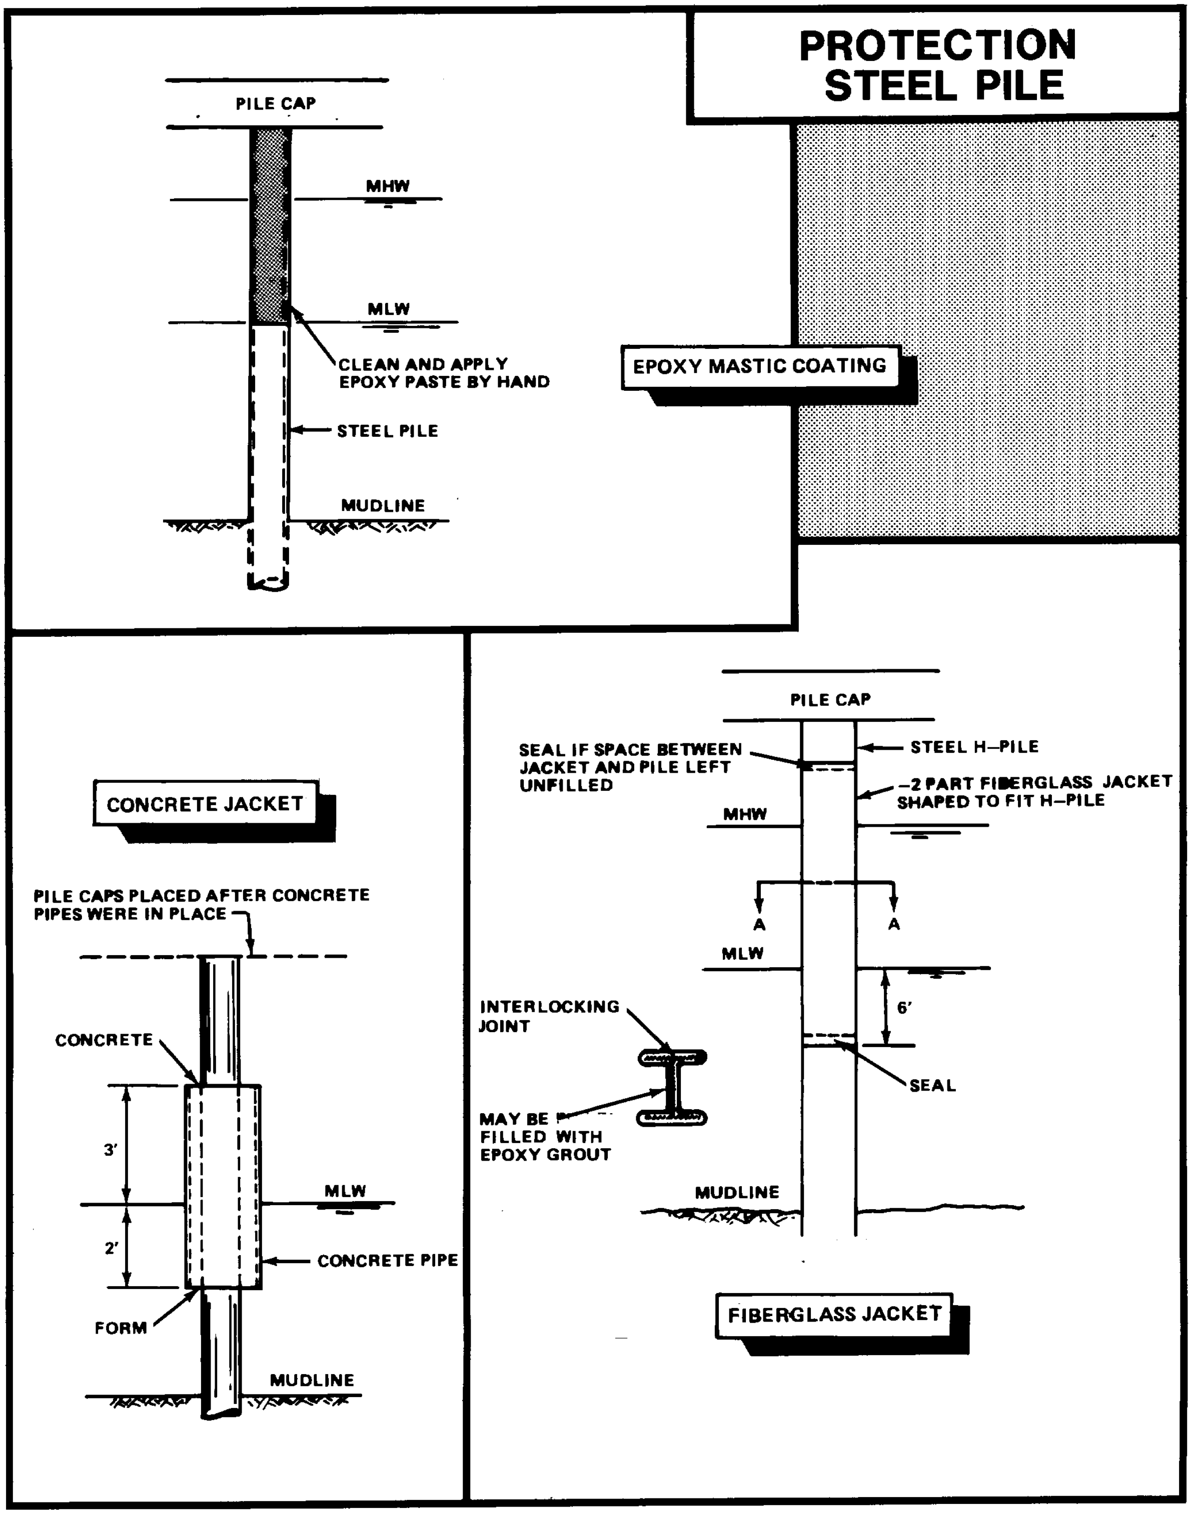
Fiberglass Jacket: Place jacketing around pile and secure. Pour epoxy grout inside sleeve if grout is used. Seal the top and bottom of the pile to prevent water entering inside jacket, if mortar is placed between pile and jacket (see Figure 8-1).

Concrete Jacket: During installation of steel pile, place a concrete pipe jacket around pile after it is driven. Fill the annular space between concrete jacket and pile with concrete (see Figure 8-1). The pile must be accessible from the top.

Application: These methods can be used to prevent further rusting. Economics will govern which method is used based on the extent of overall facility deterioration, access to pile, and availability of alternatives.

Future Inspection Requirement: Increased inspections may be required, particularly in areas where ice may be present, to detect signs of abrasion of the mastic or jacketing and renewed corrosion of the pile.

Figure 8-1 Protecting Steel Piles by Coating or Jacketing



SR-2: CATHODIC PROTECTION FOR STEEL BEARING PILES

Problem: New steel bearing piles have been installed or existing piles have experienced slight surface deterioration. Anticipated corrosion is high. Protection against further corrosion is required.

Description of Repairs: Two methods are available for providing cathodic protection for steel bearing piles:

Sacrificial Anode System: Secure sacrificial anodes below low water on steel by welding or bolting. Size, type, and spacing of anodes must be determined to suit structure and environment (see Figure 8-2). A good electrical connection between elements must be maintained.

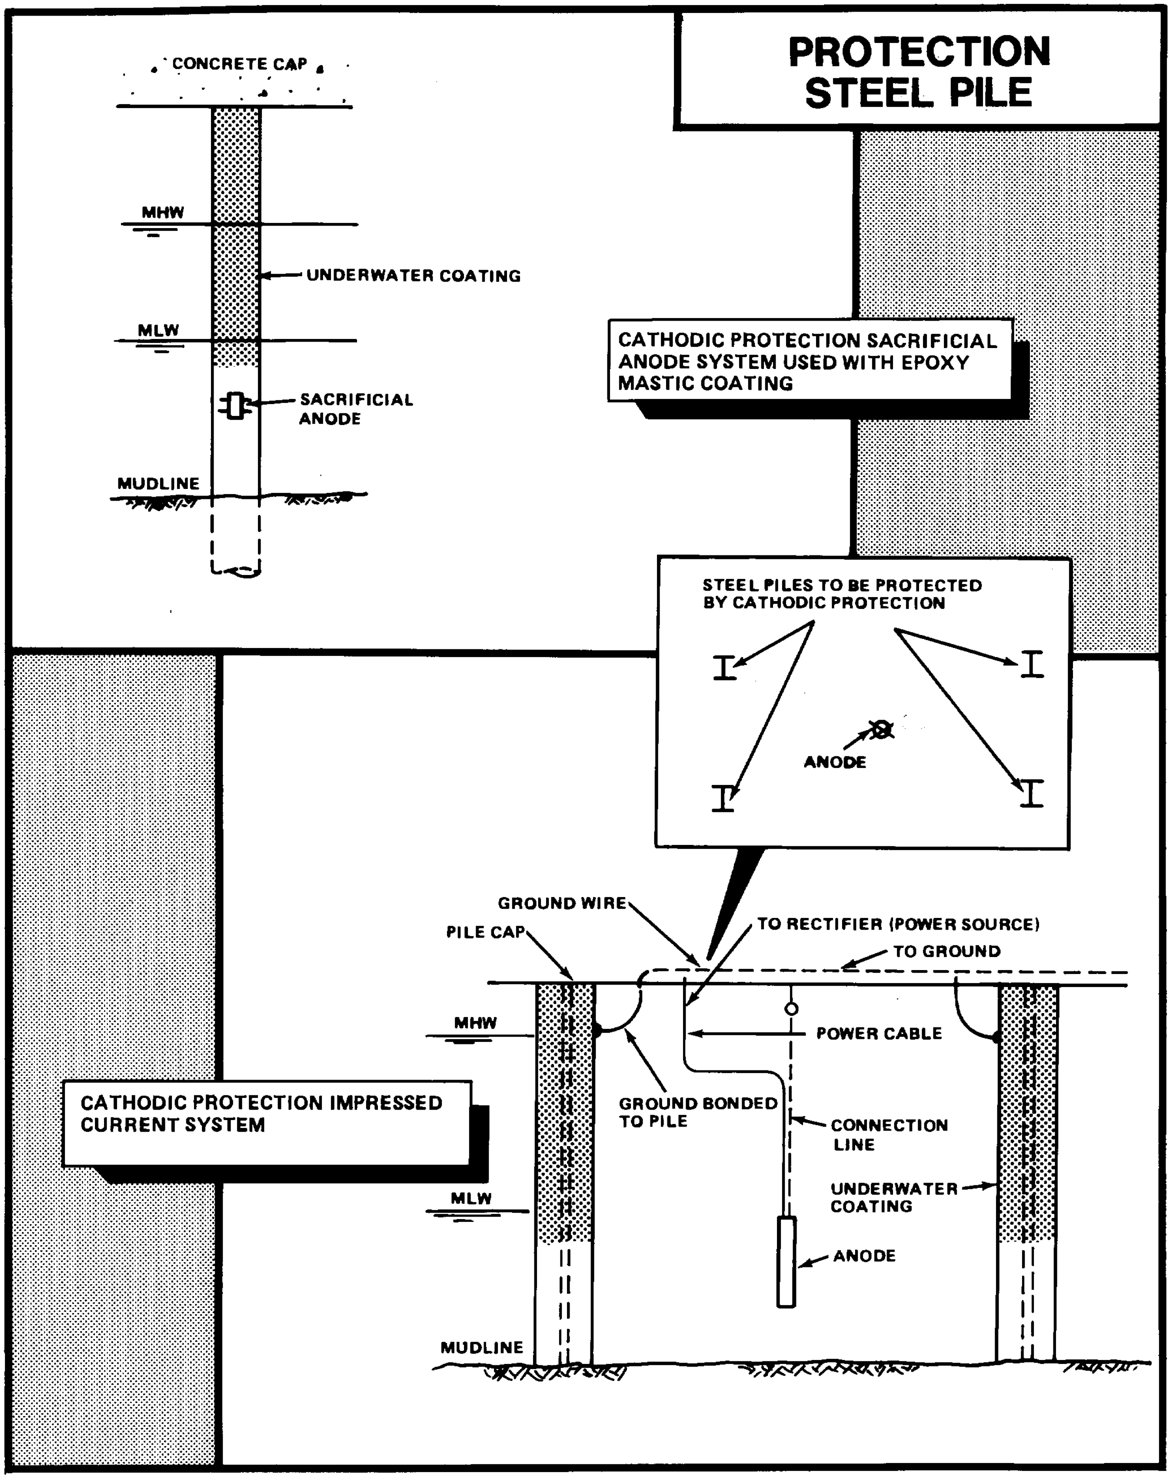
Impressed Current System: Install the cathodic protection system as shown in Figure 8-2. Basic components include:

- Anode: Material to be consumed over a long period of time.
- Electrical potential: Power source (rectifier) to provide constant electrical potential between anode and steel pile.
- Ground between piles and power source to provide closed cell.

Application: Requires careful design and installation. System is not effective for mitigating corrosion above mean low water.

Future Inspection Requirements: The cathodic protection system must be carefully monitored and maintained. If anodes for an impressed current system are placed between bents, special inspections must be made to ensure that floating debris has not damaged or removed the individual anodes.

Figure 8-2 Cathodic Protection for Steel Bearing Piles



SR-3: PARTIAL REPLACEMENT OF STEEL PILE

Problem: Moderate to heavy deterioration (greater than 35 percent) of the upper cross-sectional area of the H-pile has occurred.

Description of Repairs: Cut out the corroded section of pile; be sure that the bottom cut and top cut (if applicable) are square. Temporary supports may be needed to transfer the load from the pile being repaired to adjacent piles. Fabricate a welded assembly consisting of: a 1-inch (25 mm) steel bearing plate, two 2/5-inch (10 mm) steel side plates, and four steel angles. Place over the bottom cut. Drill and bolt the bearing assembly to the remaining lower steel pile using 1 ¼-inch (32 mm) galvanized steel bolts. Add cathodic protection to new the section.

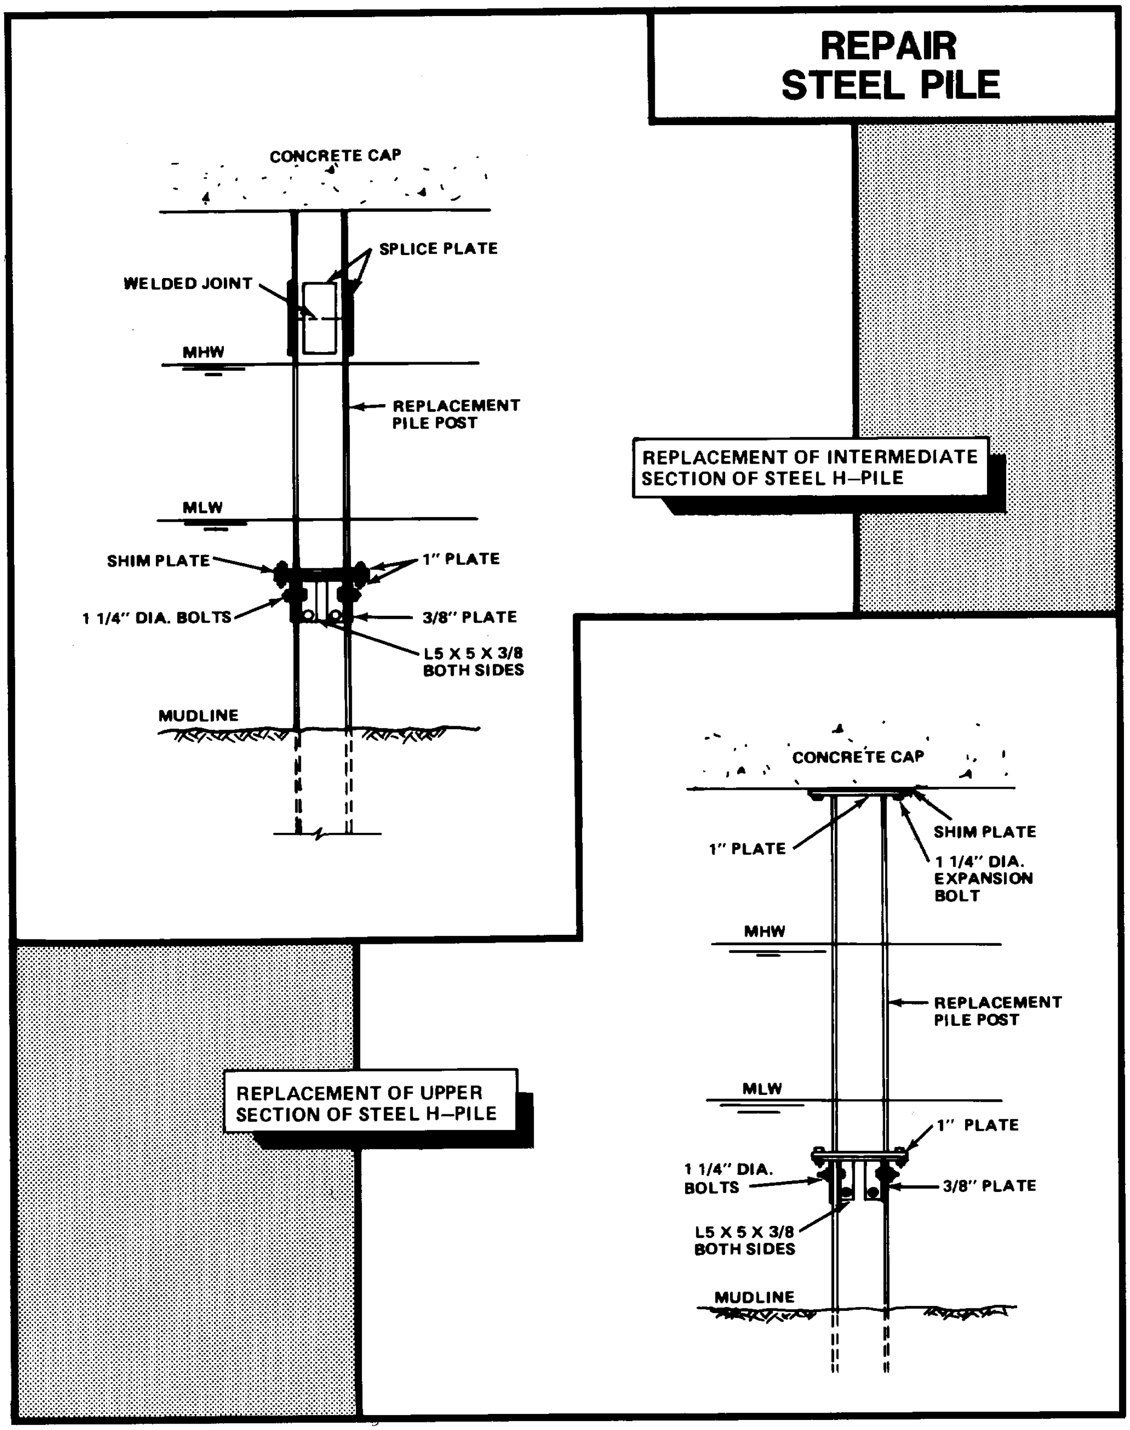
Intermediate Replacement (see Figure 8-3): Cut a section of new H-pile to fit the missing length of pile and weld a 1-inch (25 mm) steel bottom bearing plate to the new section. Place the intermediate section into position and bolt the bearing plates together. Weld the upper joint and four 5/8-inch (16 mm) steel splice plates to both old upper and new H-pile sections.

Total Upper Section Replacement (see Figure 8-3): Cut a new section similar to that required for intermediate replacement, except cut to fit under the concrete cap using a 1-inch (25 mm) steel bearing plate bolted to the cap. This arrangement is necessary when the steel has corroded extensively at the concrete-steel interface. All new metal should be cleaned and coated before installation. Welded joints should be cleaned and coated after welding. All welded joints should be watertight.

Application: This method restores the structural strength lost in the deteriorated upper section. Corrosion can again occur once the coating fails. Economics will govern approach.

Future Inspection Requirement: Same as for new steel pile sections.

Figure 8-3 Repair by Partially Replacing the Steel Pile



SR-4: REPAIRING STEEL PILE WITH CONCRETE ENCASEMENT

Problem: Slight to moderate deterioration (less than 35 percent) of the cross-sectional area has occurred; or protection against corrosion and abrasion is required.

Description of Repairs: Clean the steel pile of all marine growth and loose rust using a high-pressure water blaster. Two methods may be used to provide the concrete encasement: flexible and rigid form. In addition, steel angles may be used with the rigid form, to regain some of the reinforcement in the steel pile where greater levels of deterioration have occurred (see Figure 8-4). After the piles have been thoroughly cleaned, place a 6- by 6-inch (150- by 150-mm) reinforcing mesh around the pile, using spacers to maintain clearance between the pile, reinforcing, and fabric form. The fabric form should be placed around the pile.

For the flexible form, the zipper should be closed, and the form secured to the pile at the top and bottom with mechanical fasteners (see Figure 8-4).

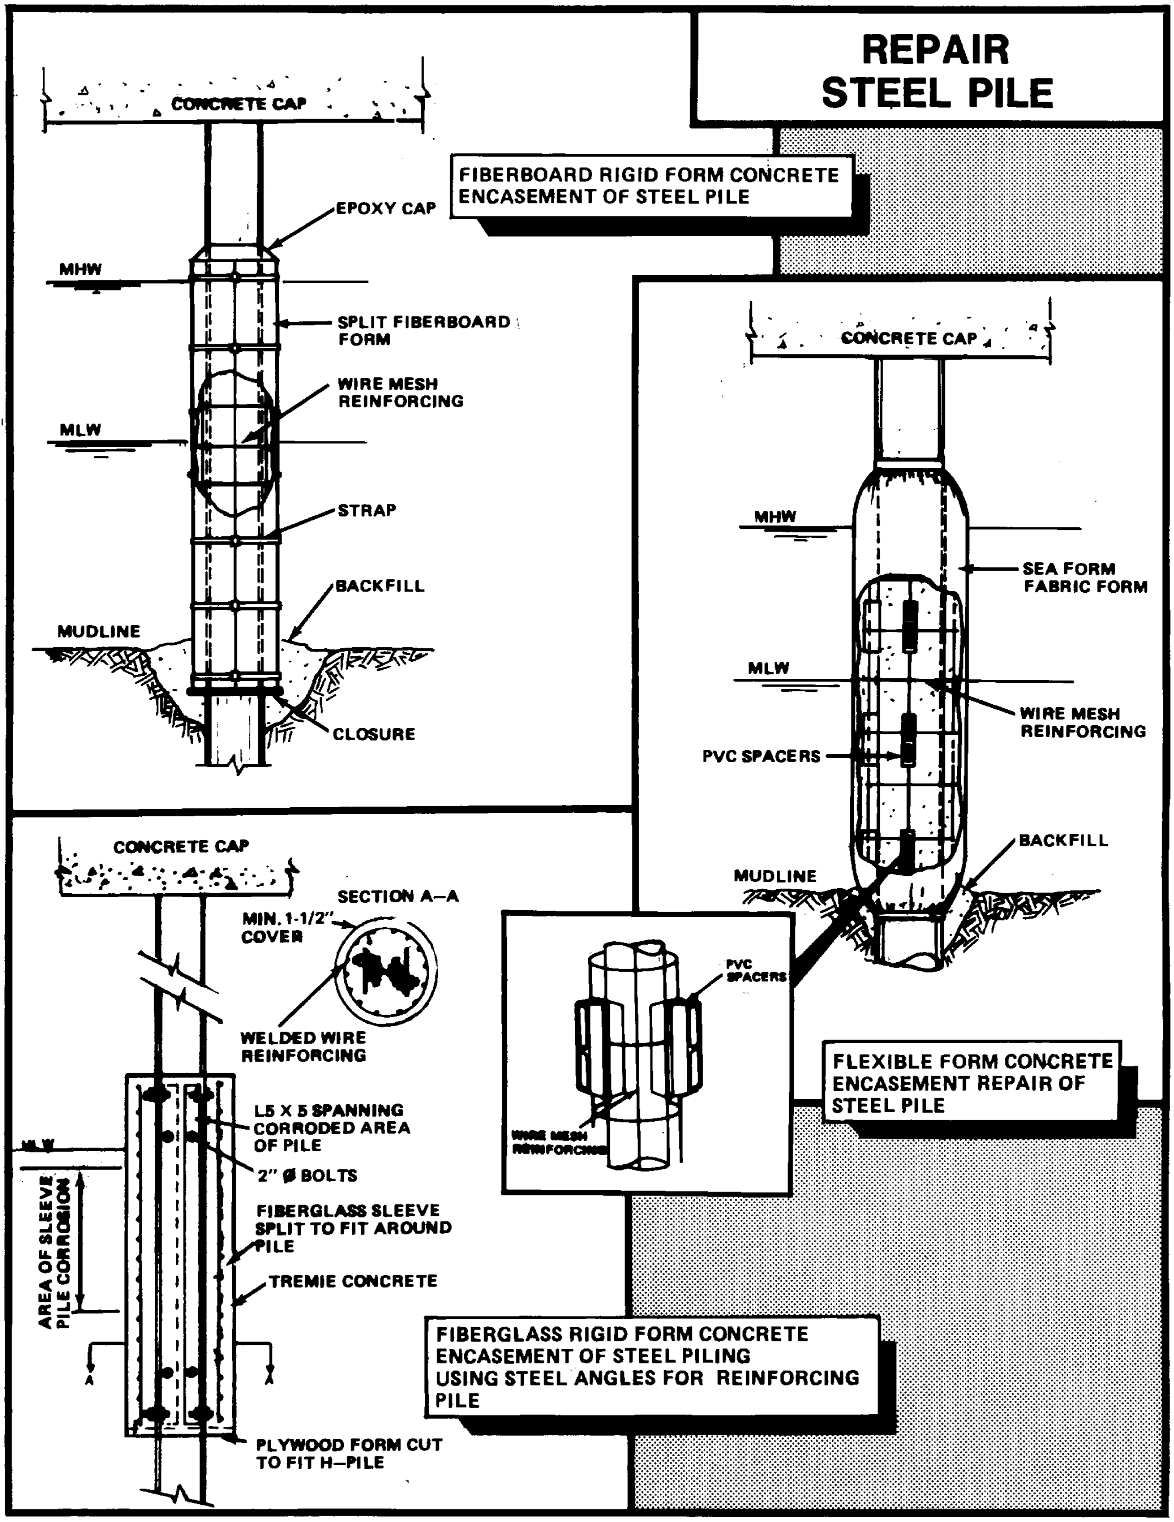
For the fiberboard form, the straps are installed and secured every 12-inch (300-mm). Maintain a 1 ½-inch (38-mm) space between the pile and reinforcing and between the reinforcing and form (see Figure 8-4).

The annular space between the pile and the form is then filled to overflowing with concrete grout using a tube or hose extending down to the lowest point of the form. The form is left in place and the base is backfilled to above the concrete.

Application: This method can be used as a repair or as a protection technique to prevent further rusting or abrasion. The method will not restore bearing capacity lost by the deterioration of the steel cross section. Partial restoration of compressive strength may be gained by the using steel angles with the concrete encasement. This is not a generally accepted practice, however, so care must be used to ensure that the connections are made to sound metal. Many times, posting the existing pile with a new H-pile section may be more cost effective. Economics would normally govern the decision.

Future Inspection Requirement: Increased inspections may be required to detect signs of potential failure of the repair.

Figure 8-4 Repair Steel Pile Using Concrete Encasement



SR-5: COMPLETE REPLACEMENT OF STEEL PILE

Problem: Moderate to heavy deterioration (greater than 35 percent) of the cross sectional area, or damage has occurred to a steel H-pile.

Description of Repairs:

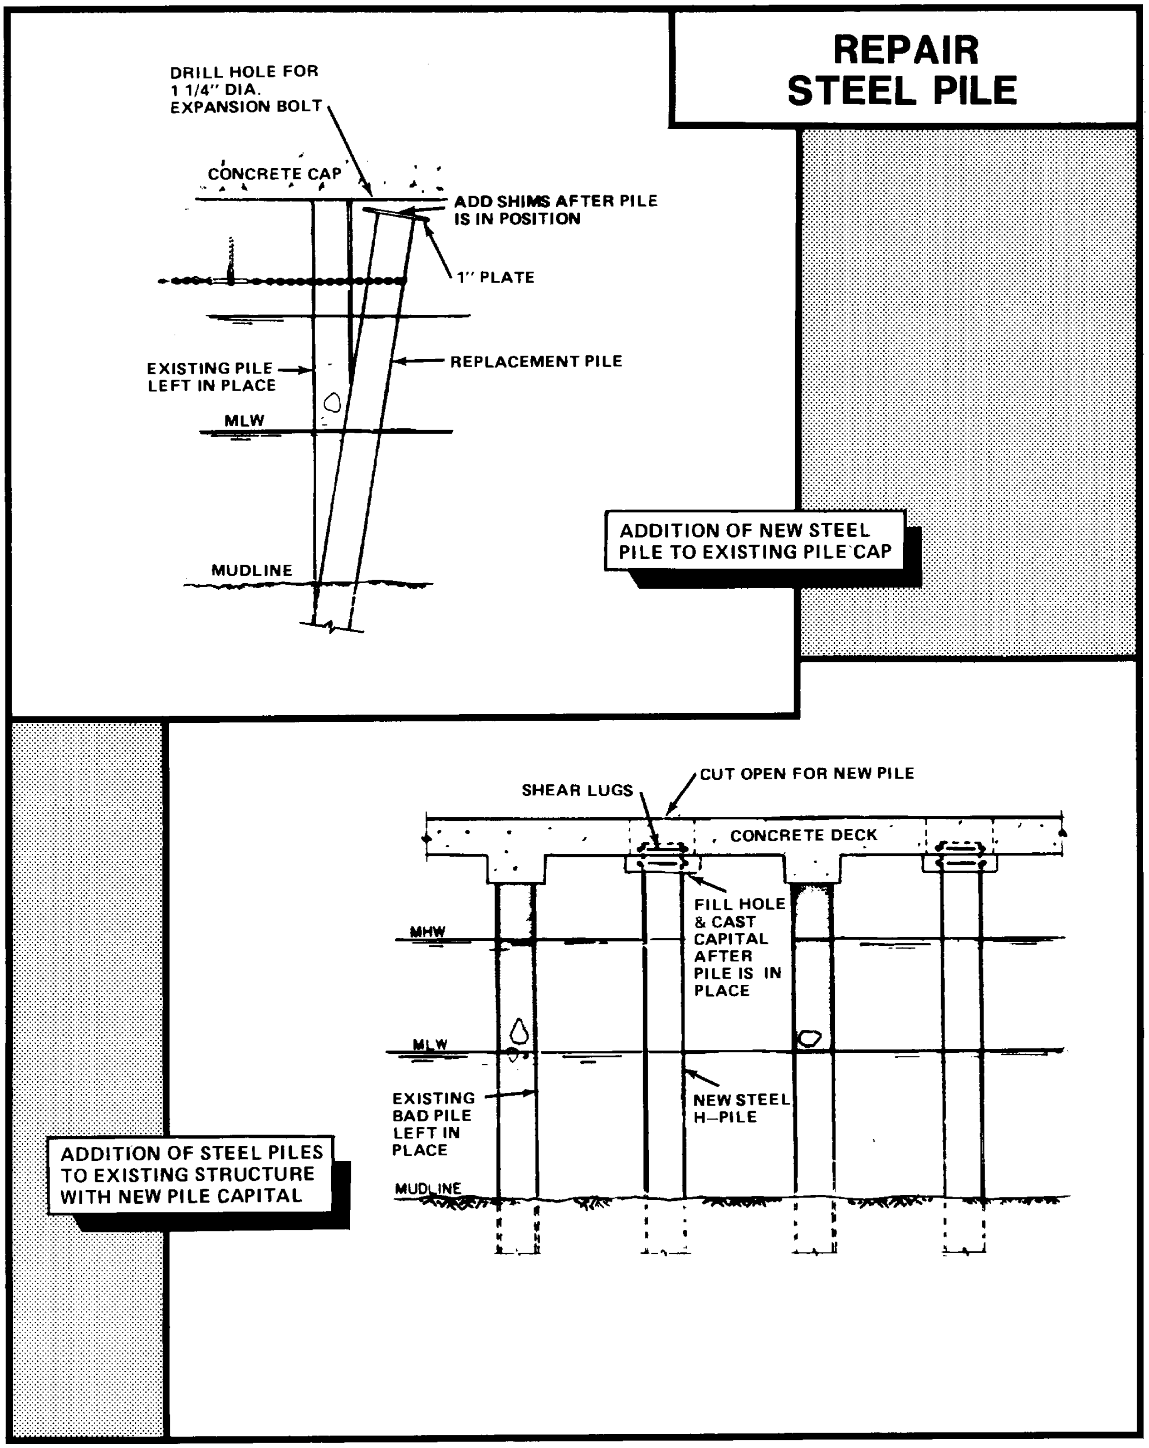
Using Existing Pile Cap. Cut an opening in the concrete deck adjacent to the damaged pile. Drive the new steel pile and cut to fit under the existing pile cap. Pull the pile laterally into place (see Figure 8-5). Shim between the pile and pile cap and secure the pile to the pile cap using 1 ¼-inch (32-mm) expansion bolts.

With New Pile Cap. Cut an opening in the concrete deck between existing pile locations. Drive the new steel pile through the hole cut in the deck and cut off below the top of the concrete deck (see Figure 8-5). Weld horizontal reinforcing bars to the top of the steel replacement pile or provide suitable reinforcing steel transitions with concrete piles, to ensure load transfer. Form the pile capital under the deck and around the new pile, and fill the form and deck space with concrete. Ensure that new and existing piles are electrically isolated otherwise accelerated corrosion may be experienced with the new piles.

Application: This method restores the structural strength lost with the deteriorated pile. The same corrosion can occur, however, with the new pile. Concrete encasement or cathodic protection can be used to extend life expectancy. Economics will govern approach.

Future Inspection Requirement: Same as for new steel or concrete pile sections.

Figure 8-5 Replacing Damaged or Deteriorated Steel Piles



SR-6: COATING/CATHODIC PROTECTION OF STEEL SHEET PILE WALL

Problem: Sheet pile wall has surface deterioration. Protection against further corrosion is required.

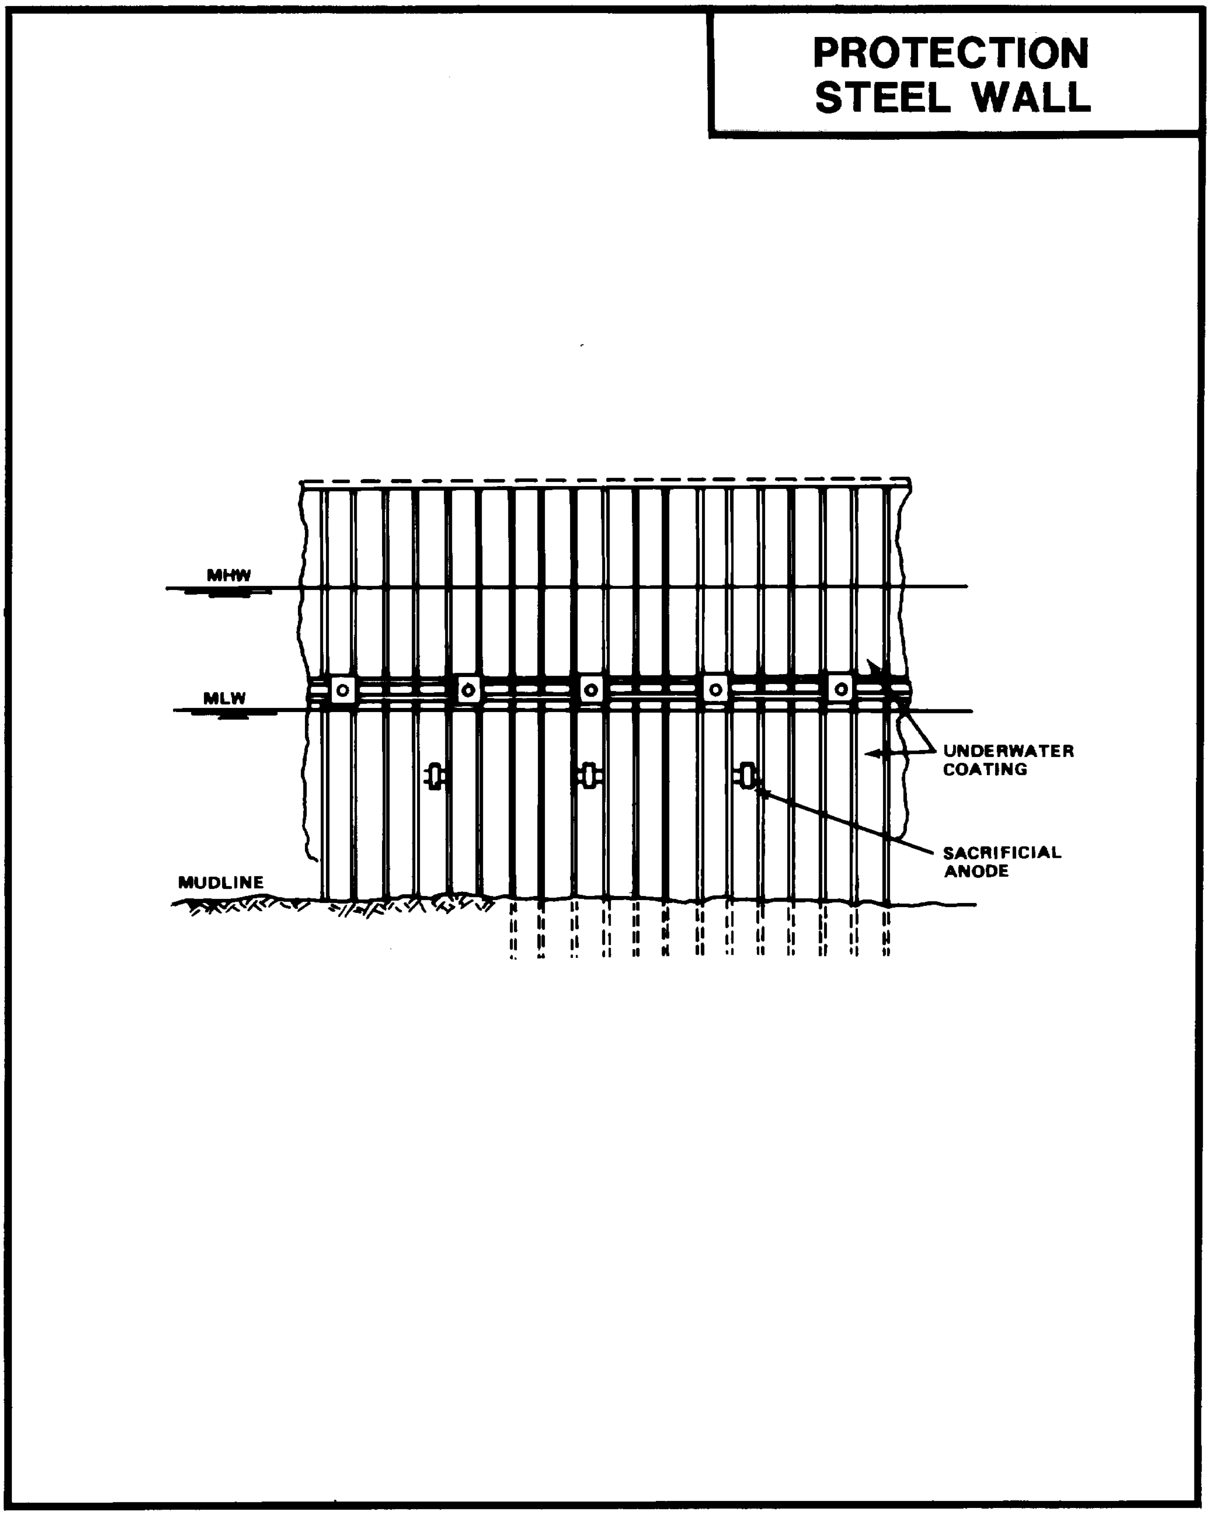
Description of Repairs: Two procedures provide corrosion protection for steel sheet piling:

Coatings. See the Paragraph entitled, “Protective Coatings for Steel” (Submerged and Splash Zone). See Figure 8-6.

Cathodic Protection: For sacrificial anode system, weld or bolt anodes below low water on the steel. Determine size, type, and spacing of anodes to suit structure and environment. A low resistance electrical connection between adjacent piling must be made (see Figure 8-6). For impressed current systems, place anodes off the face of the sheet pile wall.

Future Inspection Requirement: Increased inspection may be required, particularly in areas where ice may be present, in order to detect signs of abrasion of the mastic or removal of the anodes and renewed corrosion of the sheet piling.

Figure 8-6 Coating/Cathodic Protection of Steel Sheet Pile Wall



SR-7: PATCHING STEEL SHEET PILE WALL

Problem: Steel sheet pile wall has small to medium holes. General condition of sheet piling is otherwise sound with minimum signs of corrosion.

Description of Repairs: Clean around area to be patched. For larger holes using steel plate patches, clean sheet piling from 18-inch (460-mm) below holes to above mean low water.

Epoxy Patch: Weld wire mesh or bolt fabric mesh over holes and cover with epoxy-polyamide putty smeared on by hand (see Figure 8-7). Good for a limited number of small holes.

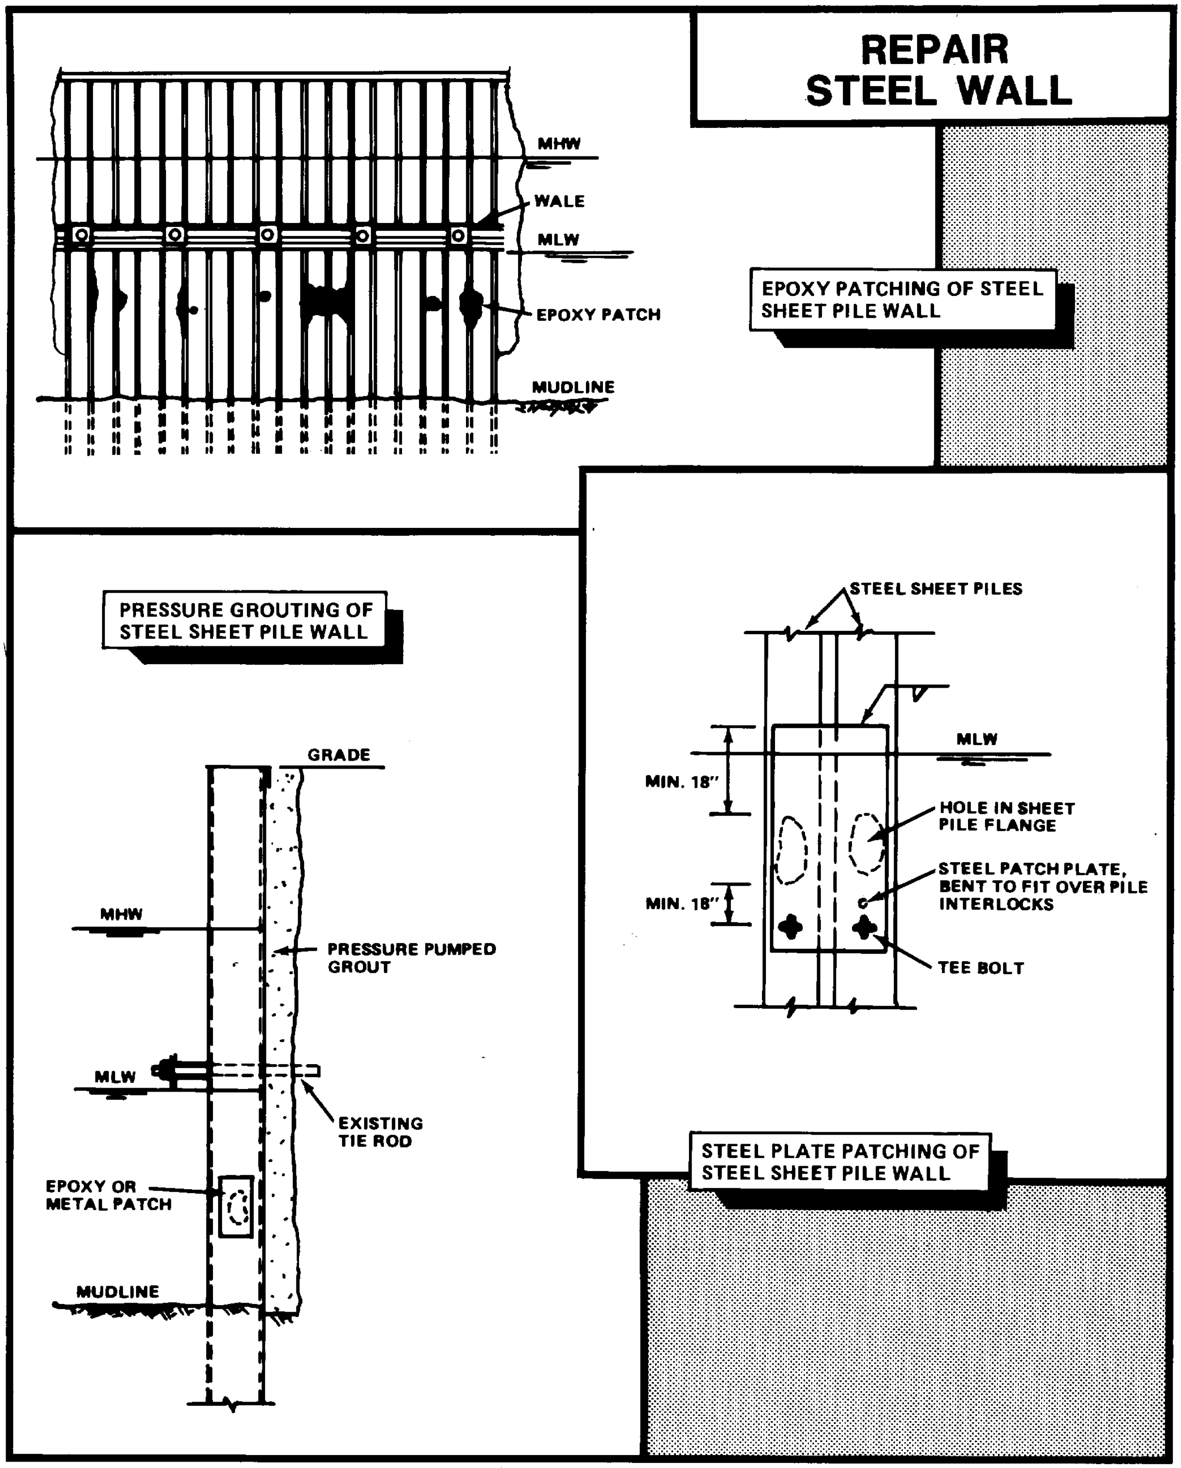
Steel Plate Patch: Determine size of patch plate needed. Cut plate to size and bend plate to fit over sheet pile interlocks. Weld plate in place at top, above low water. Cut holes for Tee bolts in sheet piling behind holes in plate; place and tighten Tee bolts (see Figure 8-7). Alternative is to weld plate all around, which is more appropriate for larger holes or several small holes.

Patch and Pressure Grouting: Where several small holes make pure patching cost expensive, a combination of patching and grouting may be a better solution. In this approach, cover the larger holes with epoxy or steel plate patches, then pressure grout the area behind the wall (see Figure 8-7).

Application: This approach will not prevent further corrosion and its success depends on the surrounding areas of sheet piling being relatively sound and free from rust. Continued deterioration of a weak structure, particularly near tiebacks, could lead to rapid failure and poor use of repair funds. Economics should govern final selection of the repair method.

Future Inspection Requirement: Increased inspection will be required at the patch areas to ensure that welds and bolted connections continue to hold.

Figure 8-7 Repairs to Steel Sheet Pile Walls Using Different Patching Methods



SR-8: REINFORCING TIE-BACK SYSTEMS FOR STEEL SHEET PILE WALL

Problem: Light to moderate movement of the top of the steel sheet pile wall has occurred due to tieback failure or excessive loading behind the wall. The area behind the wall is accessible to perform repairs.

Description of Repairs: Install a new wale slightly above the existing wale. Locate the new deadman anchors based on engineering calculations. Trench for the tie rods between the wall and the deadman anchors. Place the tie rods through the wale and sheet piles and secure in place to the deadman anchors (see Figure 8-8). Be sure that enough clearance is allowed through the sheet piles to electrically isolate the tie rods from the piling.

Install zinc or magnesium packaged anodes to prevent future corrosion of the rods.

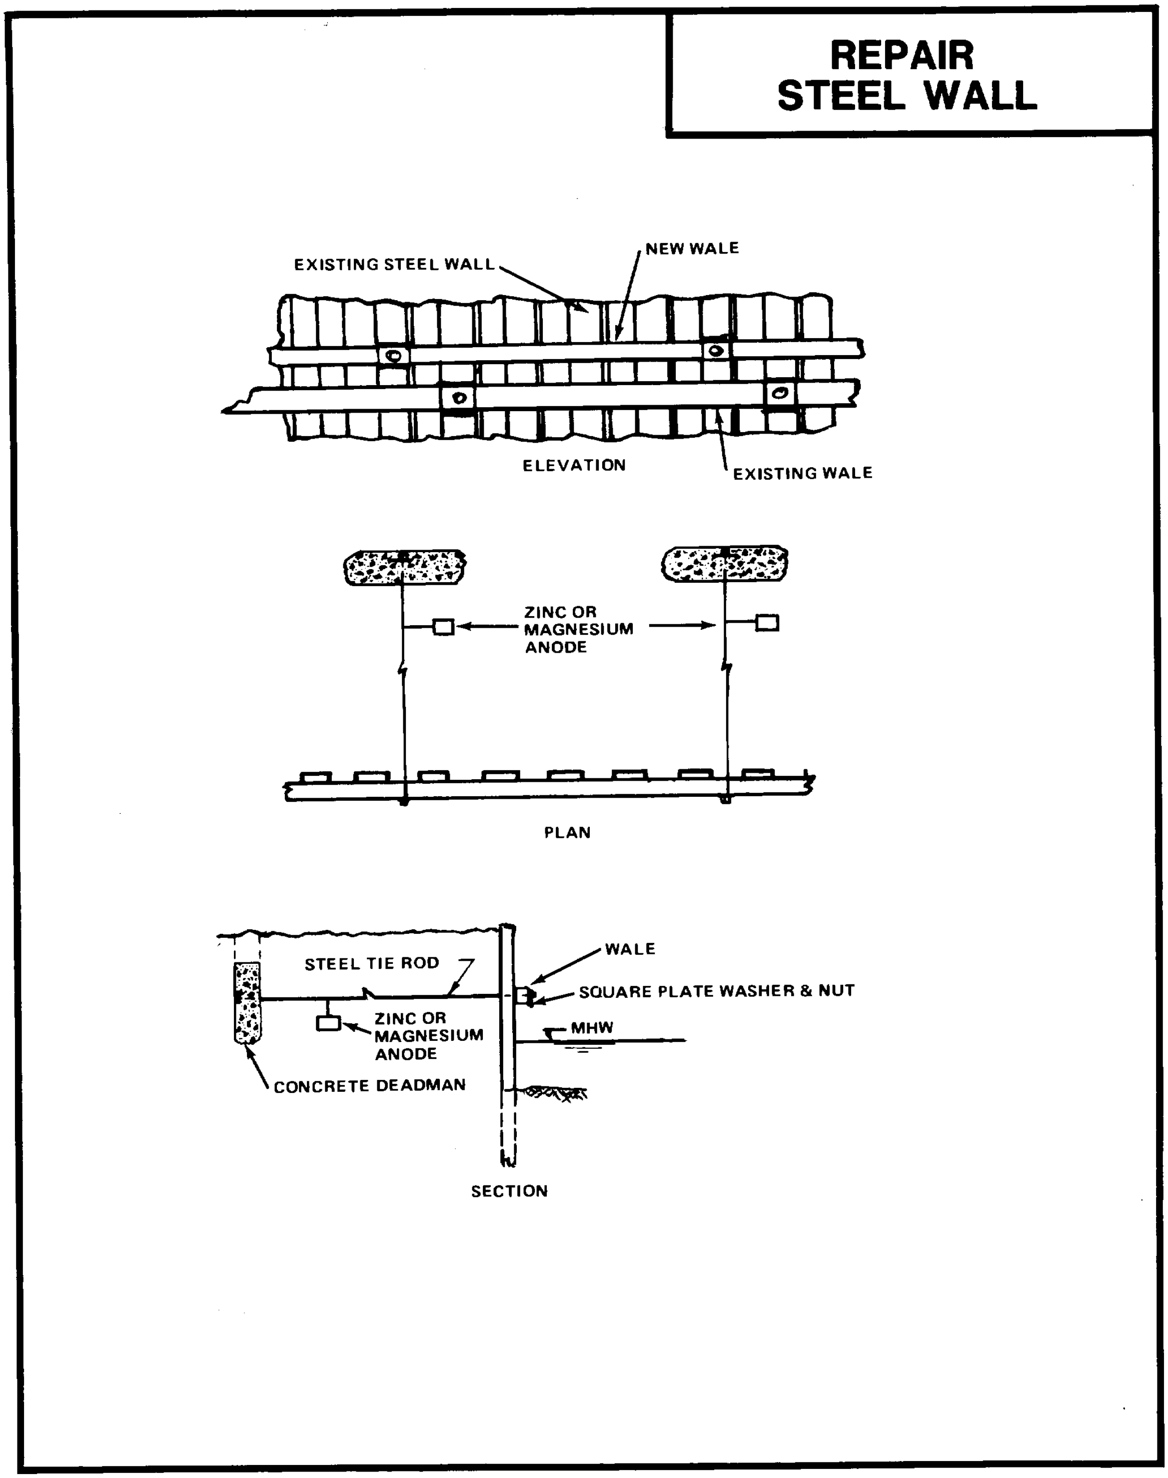
Replacing an existing tieback system may involve the replacing any or all of the existing components, depending on the amount of deterioration that has taken place.

Sheet pile wall movement can also be arrested by changing the soil loading acting on the wall. For example, stone riprap dumped against the exterior toe of the wall will add resistance to the movement of the toe. Alternatively, or in addition, backfill can be removed from behind the wall and replaced with lightweight granular fill. This type of fill is free draining, which reduces the hydrostatic pressure behind the wall and allows the water level on both sides to balance.

Application: Reinforcing or replacing the tieback system may be restricted to correcting slight to moderate wall deflection. Excessive deflection may require wall replacement or major restoration.

Future Inspection Requirement: Carefully inspect the wall for further signs of continued deflection or steel member failure.

Figure 8-8 Installing or Replacing Tieback Systems for Steel Sheet Pile Wall



SR-9: REPLACEMENT OF EXISTING STEEL SHEET PILE WALL

Problem: Serious deterioration of the steel sheet pile structure has occurred; patches cannot be used for repairs.

Description of Repairs: Two methods are available for replacing deteriorated steel sheet piling:

Timber Sheet Piling: Remove decking (if required) behind existing steel sheet pile wall to provide enough space to excavate and drive timber piling. Excavate to expose tie rods (usually these are above mean low water). Place new timber wales to act as template for driving timber sheeting. Drive timber sheeting (see Figure 8-9). Backfill may not be possible between steel sheeting and timber sheeting below wales. Replace decking (as applicable).

Steel Sheet Piling: Drive new steel sheet piling in front of existing sheet piling. Drill hole for tie rod and pipe casing through both walls into stiff clay, out of active zone behind old wall. Pressure grout inside casing forming bulb in clay at end of casing (see Figure 8-9). Fill space between old and new sheet piling with concrete. If stiff clay is not available, deadmen may need to be added to secure the tie rods. Ensure electrical isolation is maintained between the existing and new sheet piling, especially through tie rods.

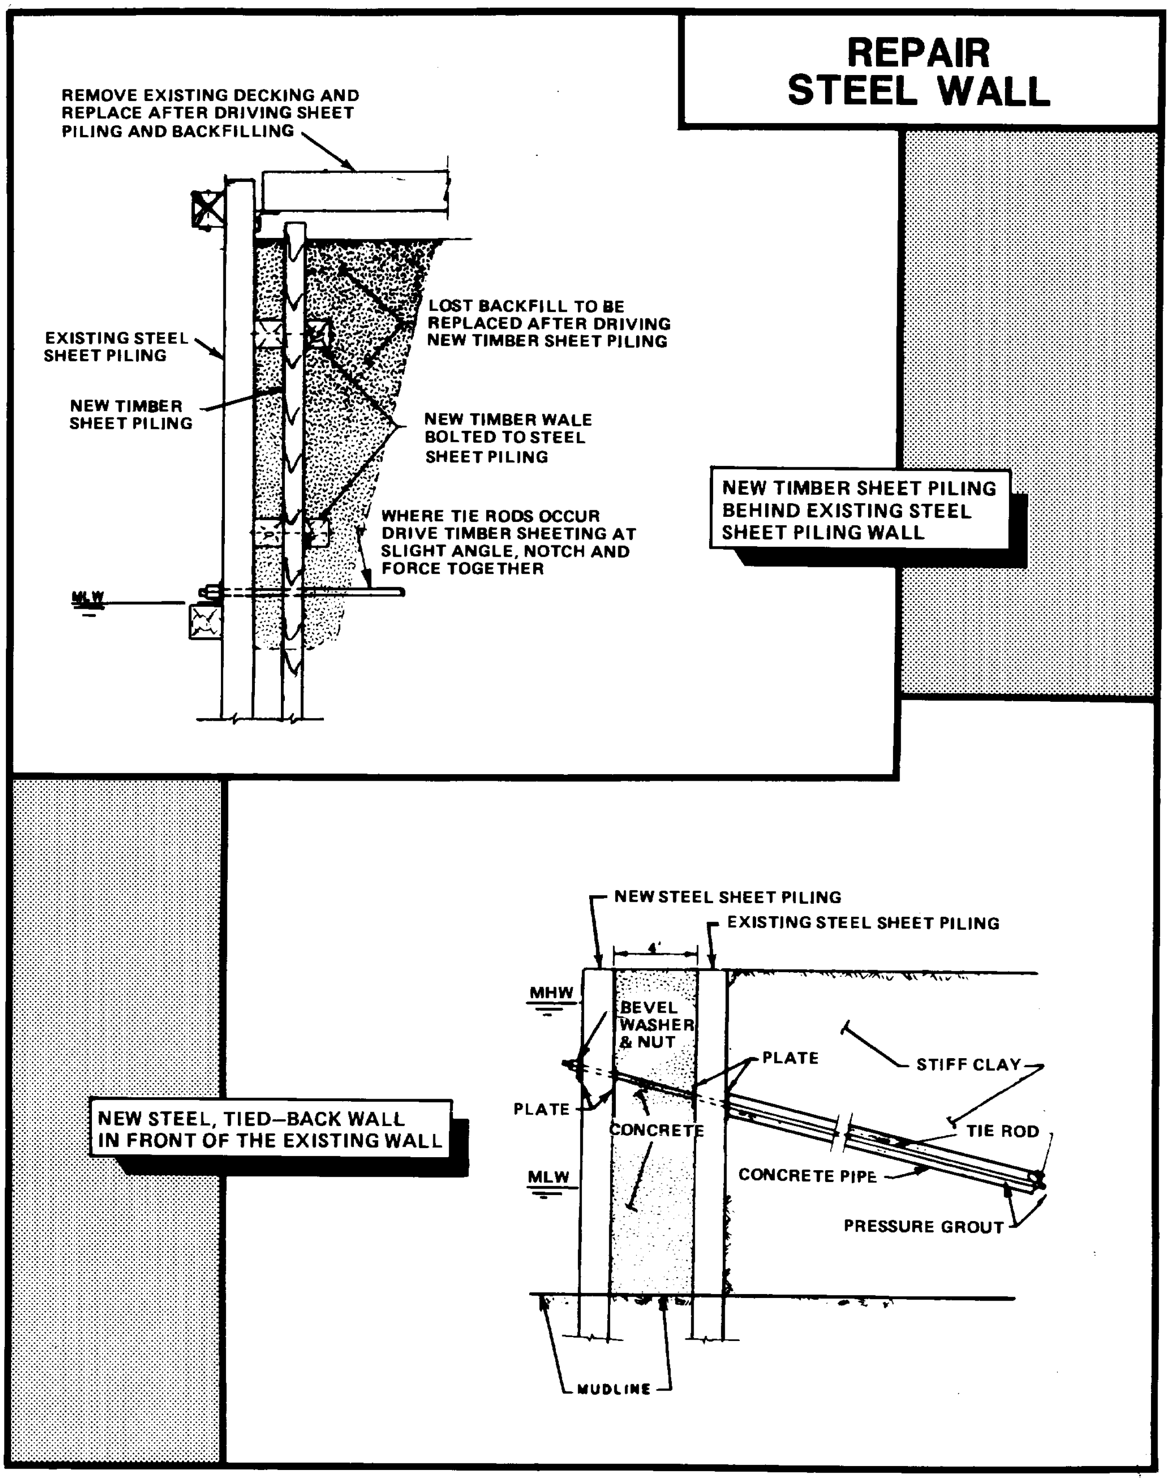
Application: Either solution should stop the loss of backfill through the existing steel sheetpiling wall.

The timber sheet piling should be less expensive than the new steel sheetpiling wall. However, the timber piling will require access behind the existing wall, and continued corrosion of the existing steel sheet piling can be expected.

The new steel sheet piling can provide a new wall with equal or greater strength; and construction can be done without excavating behind the existing wall. This approach does, however, require grouted tie rods be secured in existing soil. If stiff clay or other suitable soil is not available, this method may not be appropriate unless deadmen are added.

Future Inspection Requirement: Normal inspection requirements should suffice for the new steel sheet pile wall. If the timber piling approach is used, more extensive annual inspections may be required to watch for signs of timber piling deterioration and failure behind the existing wall.

Figure 8-9 Replacing Existing Steel Sheet Pile Wall With New Steel Sheetpiling Or Timber Sheet Pile Wall



SR-10: INSTALLING A CONCRETE CAP/FACE ON A STEEL SHEET PILE WALL

Problem: Large-scale deterioration of the steel sheet pile structure has occurred; patches can not be used for repairs.

Description of Repairs: Excavate the soil from behind the wall to a level required for the new concrete cap or attachment of form ties for a concrete face. Remove all marine growth and deteriorated steel and clean surfaces. Two methods are available for installing a concrete cap/face:

For Concrete Cap: Build forms, place reinforcing, and pour concrete at mean low water. After curing, remove forms and backfill behind wall (see Figure 8-10).

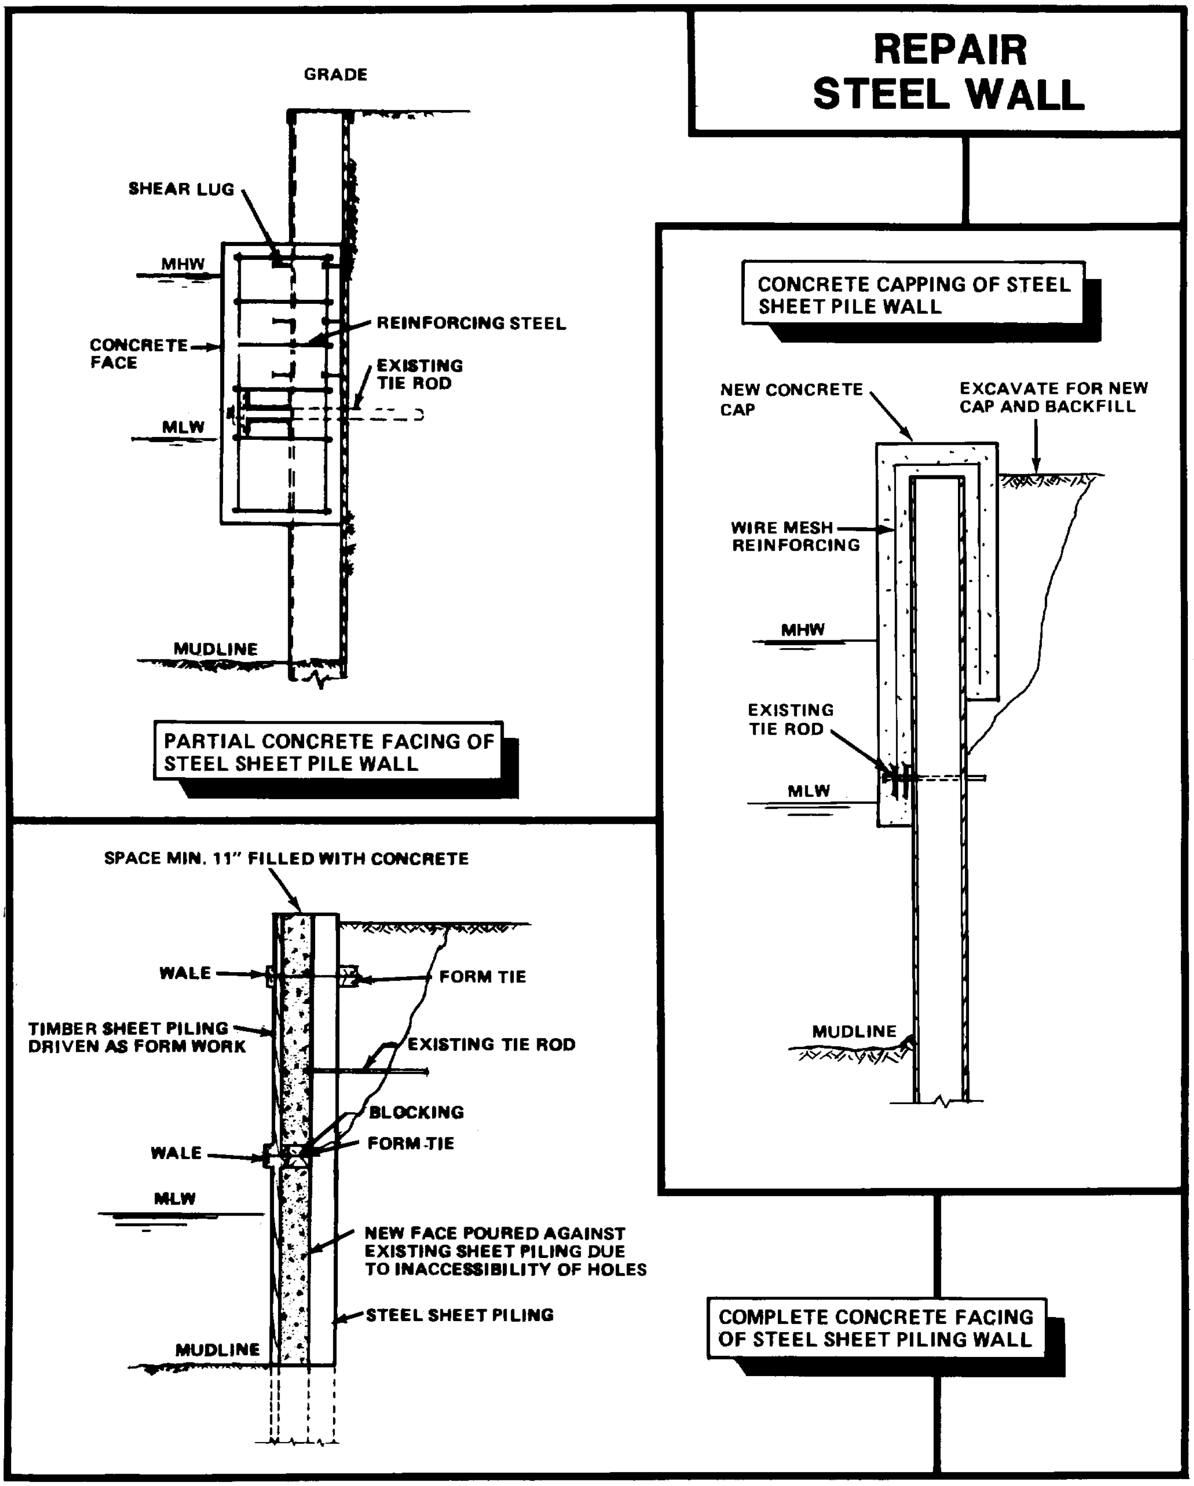
For Concrete Face: Place and fasten blocking and low wale against existing sheet piling. Drive the timber sheet pile wall about 12 inches (300 mm) in front of existing sheet piling using wale as a guide. Attach outside wales to timber sheeting and place concrete by pumping or tremie. Leave timber sheet piling in place or remove as desired (see Figure 8-10).

For partial concrete facing of steel sheet pile wall, techniques exist to repair a deteriorated wall from the exterior side without requiring excavating. One method uses timber formwork (see Figure 8-10), welding steel studs to the steel sheet pile at locations where the metal is sound. The shear lugs help to hold the concrete in place. A temporary steel frame, which supports the timber formwork, is suspended from the top and welded to the exterior of the wall above the waterline. Blocking is used to maintain a 12-inch (300-mm) minimum space, and reinforcing is placed in the center of the space. Concrete is placed by pumping or tremie method. The form work can be removed within a few days.

Application: Used to restore structural strength at the top of the wall (cap) or prevent further loss of soil through holes in the sheet piling (face). Does not restore bending moment capacity in wall. Provides protection against further deterioration.

Future Inspection Requirements: Annually inspect the sheet piling areas immediately under the pile cap to ensure that further corrosive damage is not being weakening the support for the concrete cap. Follow similar procedures for partial concrete faces. For complete concrete facing, follow normal inspection procedures.

Figure 8-10 Installing a Concrete Cap and/or Face on a Steel Sheetpiling Wall



SR-11: SCOUR PROTECTION FOR STEEL PILE SUPPORTED WATERFRONT STRUCTURE

Problem: Serious erosion of seabed material has occurred around a marine structure as a result of wave action and/or strong current.

Description of Repairs: Two methods are available for scour protection:

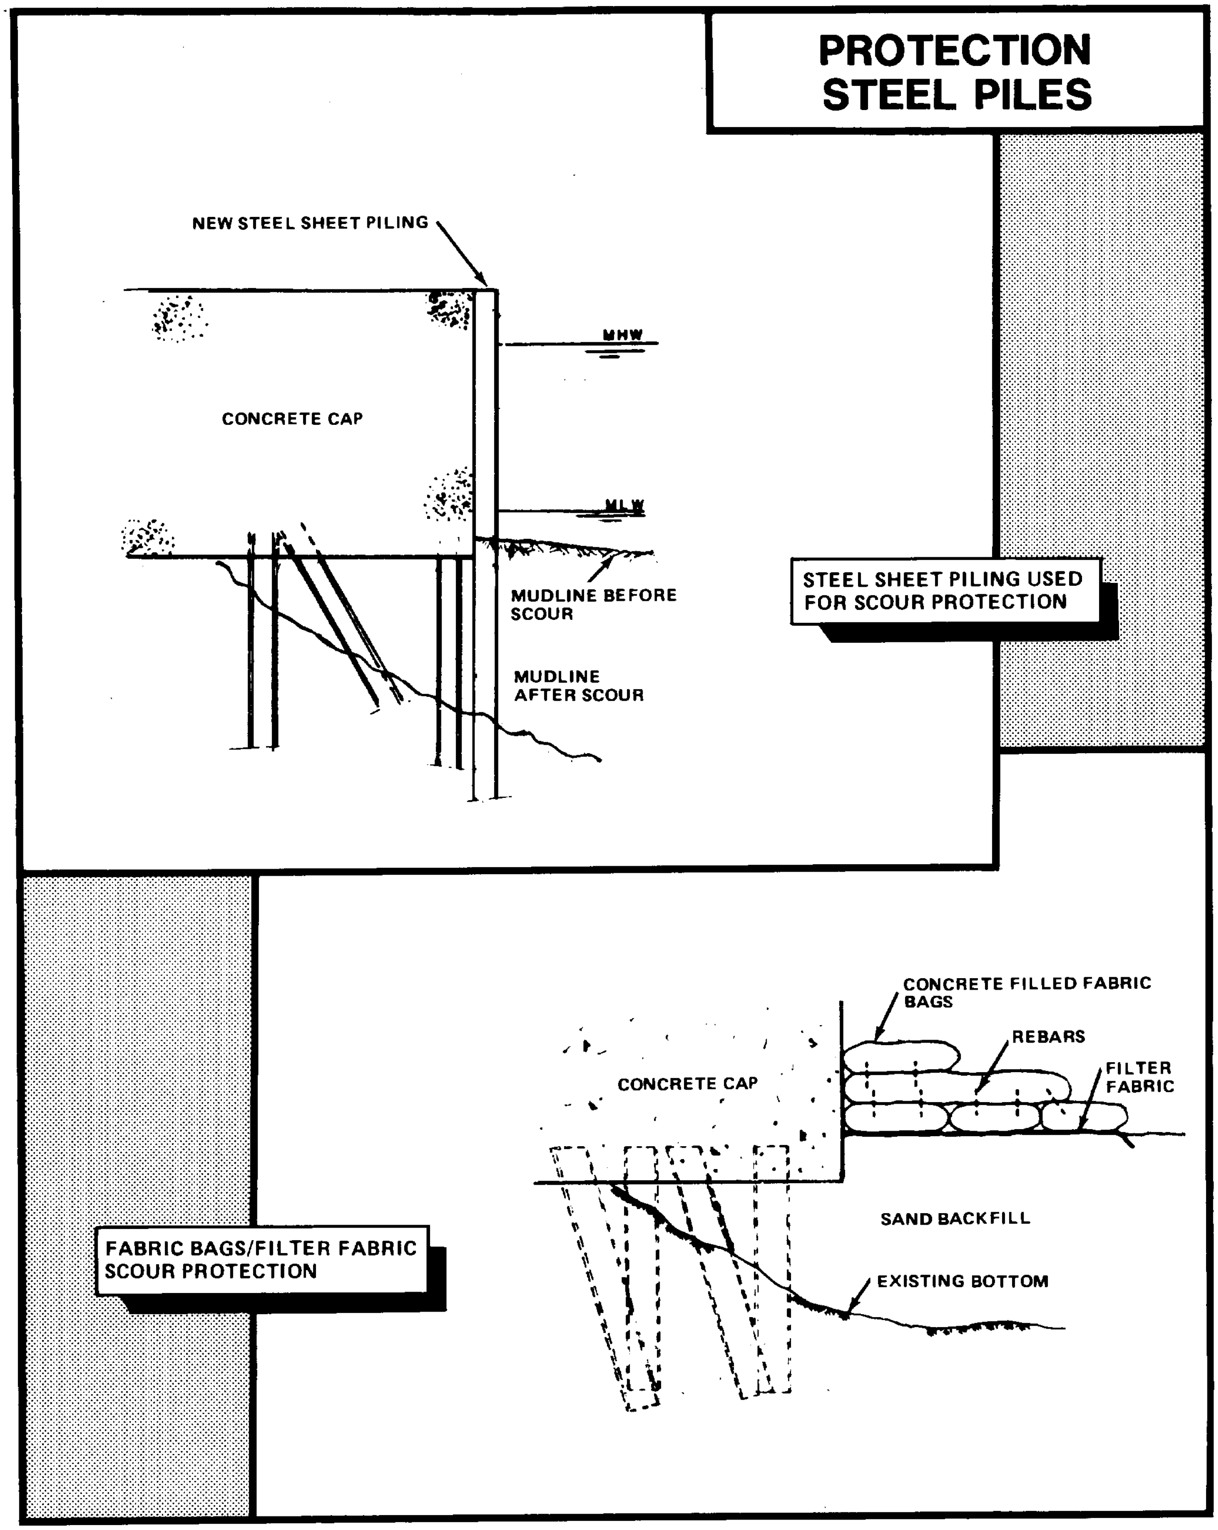
Riprap Placement: Replace the lost foundation material by dumping stones randomly into place. If stone riprap is not available, use bags of synthetic fiber woven water-permeable material filled with concrete. On sandy seabeds, a filter fabric may be required under the riprap or bags to prevent scour through the individual units (see Figure 8-11). The materials most commonly used are commercially available synthetic fiber, non-woven fabrics weighing between 8 and 12 ounces per square yard (269 and 405 grams per square meter) or woven fabrics weighing between 5 and 7 ounces per square yard (169 and 236 grams per square meter.)

Steel Sheet Piles: Drive steel sheet piling around structure to protect soil around the bearing piles (see Figure 8-11). The decision to replace the lost foundation material under the structure should be based on the strength of the exposed piles.

Application: A careful evaluation should be performed to determine if: (1) any settlement of the structure has occurred due to the scour, or (2) suitable bearing capacity exists within the remaining structural foundation to support the loading. Selecting either scour protection technique should ensure that suitable structural integrity exists before beginning the repairs.

Future Inspection Requirement: Normal inspection requirements will generally suffice. If riprap is used, annual underwater inspection will be required to ensure that material is not lost.

Figure 8-11 Scour Protection for Steel Pile Supported Waterfront Structure



CHAPTER 9

REPAIR OF SYNTHETIC MATERIALS

9-1 **GENERAL**. Synthetic materials used on waterfront structures include:

- Structural components such as railings and stanchions, resilient fenders, camels, chocks, wales, piles, light standards, gratings, and piping.
- Coatings, wraps, and jackets for piles and piping.
- Buoyancy materials used in buoys, floats and foam-filled and pneumatic fenders

Deterioration of synthetic materials results from physical damage, exposure to the environment, aging, or a combination of these factors. Physical damage is the most common type of deterioration for most waterfront synthetic components. Exposure results in plastics cracking, separating or becoming brittle; foams crumble with age and lose resilience; and elastomers stretch and deteriorate from the effects of sun and exposure.

9-2 **INSPECTION OF SYNTHETIC MATERIALS**. All synthetic materials should be inspected periodically to ensure that they are clean and in good working order. If any component is damaged then it should be repaired or replaced as necessary. Repairs to synthetic materials and components will normally be controlled by the position of the components (or material) within the waterfront structure. Components, such as: railings, stanchions, resilient rubber fenders, camels, wales, chocks, light standards, gratings, and piping, will normally be replaced and may be done by shop personnel. In general, small surface damage such as burns, scratches, chips, or small cracks can be repaired, but if the damage is structural then replacement is the recommended course of action. (Table 9-1.)

Table 9-1 Repair Techniques for Synthetic Materials

Repair No.	Description
Small Surface Damage	
PR-1	Repair of Fiberglass, Guard Rail
Repair by Replacement	
PR-2	Repair Dry Dock Caisson Seal (See Figure 9-1)

If damage to fiber-reinforced plastic (FRP) products, either fiberglass or carbon fiber, is detected then the manufacturer should be contacted to help determine if the product can be repaired or if it needs to be replaced. Repairing these products requires specialized expertise and will require contracting services.

Repairing coatings or jackets on piling involve skilled personnel and specialized equipment; repairs may have to be done by contract. Specialized skills and equipment for applying coatings, jackets, and patches on piling are covered in Chapters 6, 7 and 8.

Special instructions and equipment requirements for repairing foam-filled fenders are covered in NAVAFAC MO-104.1, *Maintenance of Fender Systems and Camels.*

PR-1: Repair of Fiberglass Guard Rail

Problem: Fiberglass guard rail is chipped and is a safety hazard.

Procedure: Sand and clean the damaged area and ensure it is dry. Apply epoxy or a catalyzed resin to the damaged area with a putty knife or spatula. Cover the repair with cellophane and secure it. Allow the repair to cure; then remove the cellophane and sand the area smooth.

Application: This procedure can be routinely used for any fiberglass component. Similar procedures can be used for other synthetic components.

Future Inspections: Basically the same as for other deck components.

PR-2: Repair of Drydock Caisson Seal by Replacement

Problem: Caisson wood or “rubber” seal is deteriorated or damaged and leaks.

Procedure: Move the caisson into the drydock and secure. Remove the existing wood or synthetic “rubber” seal assembly (see Figures 9-1 and 9-2.) Unless the old seal is “rubber” and the existing studs are still serviceable and in the correct configuration, remove the old mounting studs. Clean any wood or “rubber” remnants or any other obstruction on the caisson seal mounting surface. Repair surface flaws and irregularities in the caisson seal substructure to within an allowable tolerance as follows.

- Caisson seal mounting surface roughness profile should not deviate from the nominal profile by more than 98 mils (2.5 mm).
- Caisson seal mounting surface waviness profile should not deviate from its nominal profile by more than 12 mils (0.3 mm) over a waviness spacing of 12 inches (30 cm).
- Caisson seal mounting surface should be parallel to within at least 393 mils (10 mm) over the length of a span section (9 feet (2.75 meters)).

Install new mounting studs onto the caisson seal sub-structure if required. The stud material should be a MONEL alloy with the weld filler material and weld process conforming to the correct specifications for welding MONEL to carbon steel. A wood template duplicating the seal configuration hole pattern must be made for each type of seal configuration. These templates are used to properly position the new studs. Starting with the corner section, position and align the wood templates around the caisson. Mark the stud locations on the caisson using a center punch.

Mount a new isoprene “rubber” seal onto the caisson seal sub-structure. Use MONEL washers and nuts to mount the seal assemblies. Use the following procedure starting with the corner section. Be careful not to damage the assembly.

- Position the lifting fixture at the top end of the seal and lower the fixture retaining bar over the seal.
- Lift the seal out of the crate and position the bottom end of the seal over the corresponding mounting studs. The bottom of the seal should make contact with the caisson first.
- Apply a coating of rubber adhesive to mitered joints before mating.
- Install at least two nuts and washers onto the studs at the bottom to

hold the seal in place while the lifting fixture is removed.

- After the lifting fixture is removed, push the top of the seal against the caisson and install all remaining nuts and washers.
- Move the seal into position so that the mating surface at the mitered joint is aligned with the previously installed seal assembly. There should not be a gap or misalignment.
- Once the seal is in position, tighten all mounting nuts one and a half turns beyond the point where initial contact is made between the seal, caisson, nut, and washer.

Application: Caisson wood seals should be replaced as required by new "rubber" isoprene seals. Greenheart wood is NOT immune to marine borer attack; DO NOT USE in saltwater or brackish water.

Future Inspections: Caisson seals should be visually inspected before each use and if any leakage occurs.

Figure 9-1 Typical Caisson Wood Seal Assembly

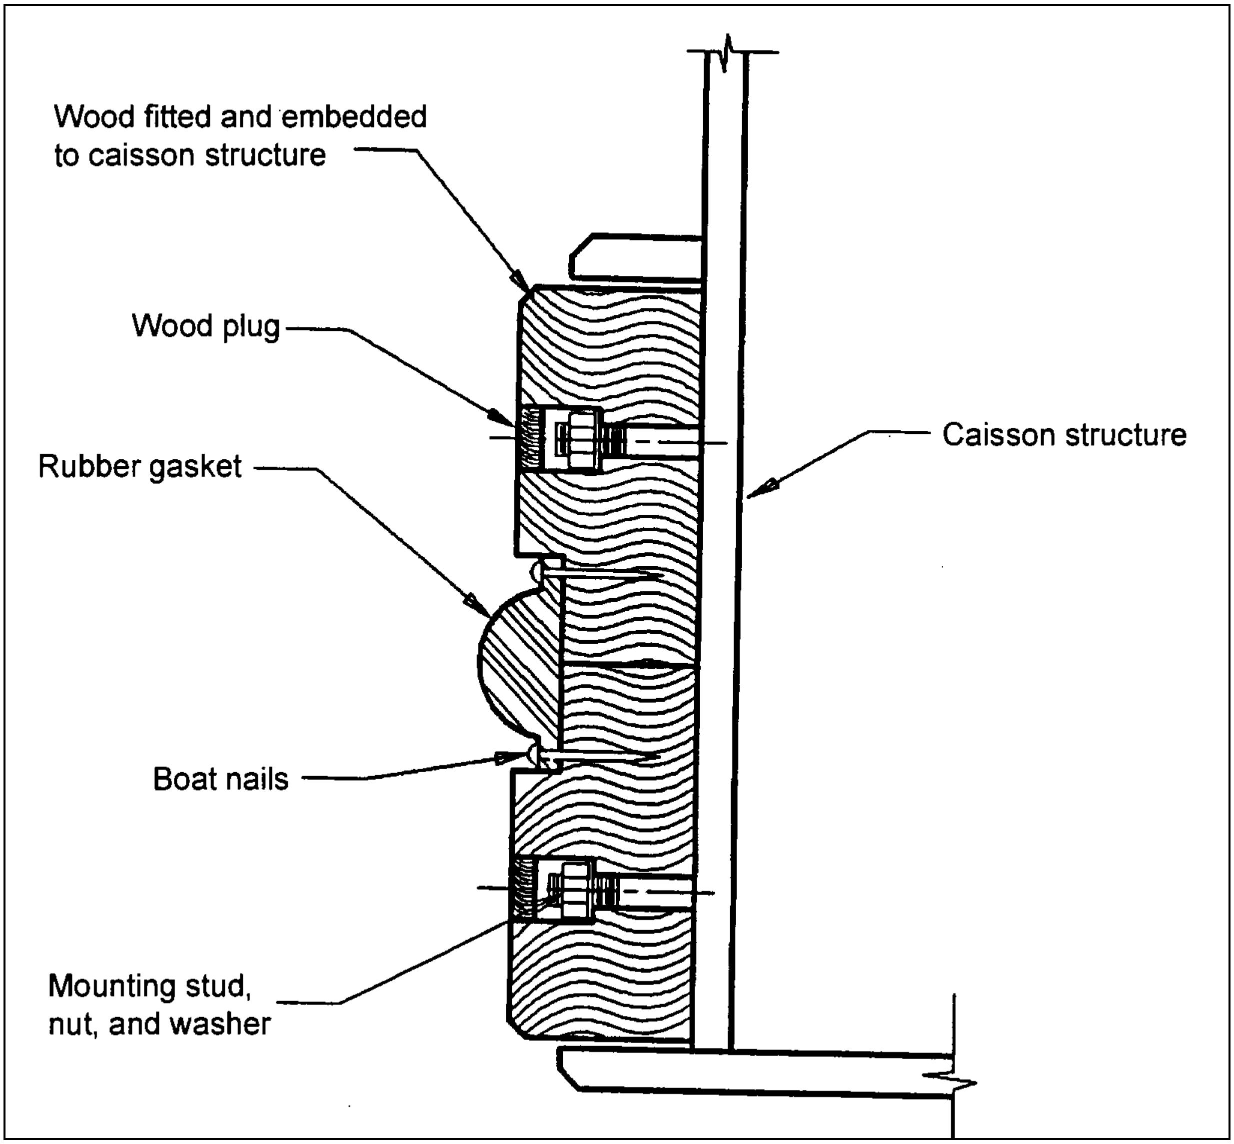


Figure 9-2 Steel Reinforced All-Rubber Caisson Seal Assembly

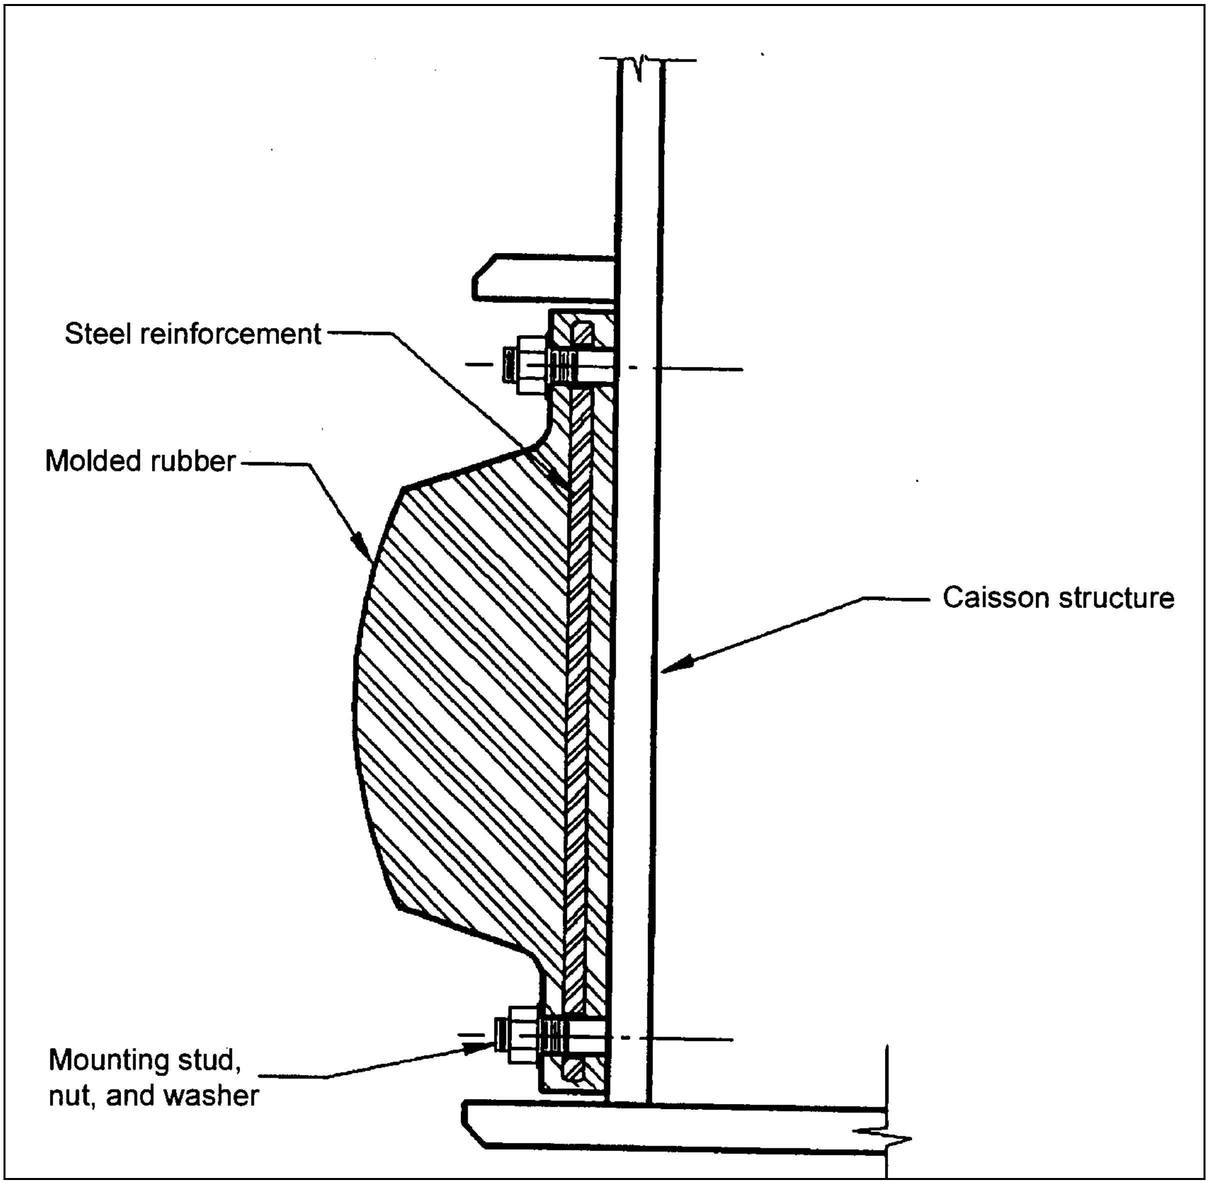

This page intentionally left blank.

CHAPTER 10

REPAIR OF BULKHEADS AND QUAYWALLS

10-1 **GENERAL**. Bulkheads and quaywalls are used as berthing facilities and thus are included in this handbook. Similar structures such as seawalls and breakwaters, designed primarily for coastal protection functions, are covered extensively in USACE manuals. \1\ /1/ Since the basic functions and designs of these structures overlap, there is considerable overlap in repair procedures.

Bulkheads and quaywalls are constructed primarily of sheet piling with soil fill overlaid with concrete or asphalt. Chapters 6 through 9 address the repair of sheetpiling. This section describes the repair of soil fill and overlay.

The common causes of damage to earth-filled structures are erosion by water and settlement due to undermining, washouts, etc. In addition, the sheet piling may deteriorate. Sheet piling repair procedures depend on the type of material used and are included in Chapter 8.

10-2 **PLANNING THE REPAIRS**. Before repairing earth-filled structures, consider the following:

- Scope of damage and/or deterioration.
- Rate of deterioration and overall age of the structure.
- Mission requirement for the structure.
- Operational constraints placed on the facility because of the deterioration.
- Changes to environmental conditions, such as currents, caused by other coastal or harbor changes.
- Alternatives for repairing the structure.

In many cases, usage requirements for the facility may have changed. Stone masonry bulkheads and earth-filled vertical bulkhead structures, as an example, may no longer be required for other than retaining the surrounding shoreline. The solutions may involve using riprap to shore up the structure or reduce seepage and loss of backfill, rather than performing expensive repairs to the structures.

Once the scope of repair requirements, including priorities, is established, then determine if the repairs should be done in-house or by contract.

10-3 **REPAIR PROCEDURES OF EARTH-FILLED STRUCTURES**. The procedures contained below describe the general approach involved in most repairs.

10-3.1 **Problem**. Erosion or settlement has occurred. Any breaching of, or impairment to, an earth structure exposed to moving water sharply increases its susceptibility to damage. For this reason it is critical that any required maintenance be identified and carried out as quickly as possible.

10-3.2 **Description of Repair/Maintenance**

10-3.2.1 **Replacing Soil**. Where there is evidence of erosion or loss of soil, protective coverings, such as rock fill or armor units, should be removed and the internal fill material inspected. Any necessary repairs in the form of replacement of properly compacted soil should be made, and the protective slope-covering replaced in a manner that ensures no further erosion. A series of soil layers of varying coarseness may be used to ensure that the finer, central materials cannot be washed out through the coarser, shell materials. The use of a geotextiles (see below) might be appropriate. In some cases, it may be economical to protect the side slopes with asphalt concrete, soil cement, or even reinforced Portland cement concrete. In cases where the side slopes are exposed only to atmospheric erosion, vegetation such as ice plant or grasses may be adequate.

10-3.2.2 **Geotextiles**. A rapidly emerging geotechnical engineering technology involves use of geotextiles for seepage and erosion control, and for soil strength reinforcement, see Koerner (Koerner, R. M. (1990), *Designing with Geosynthetics*, 2nd Edition, Prentice-Hall, Inc., Englewood Cliffs, NJ). Geotextiles are porous, flexible polymeric fabrics used for separating soil types, soil retention, and strength reinforcement. When used for soil retention, the fabric must meet permeability or permittivity requirements (ASTM D4491, *Test Methods for Water Permeability of Geotextiles by Permittivity*) relative to the permeability of the retained soil. Also the openings in the fabric must be small enough to impede loss of soil particles. This usually requires a fabric opening size not more than twice the 85% size of the soil (sieve size through which 85% of the soil grains will pass). Where a geotextile is used to provide drains for pressure relief, the transmissivity or flow capacity in the plane of the fabric is the important parameter.

Geotextile strength must also be considered in any design, see ASTM D4595, *Test Method for Tensile Properties of Geotextiles by the Wide Width Strip Method*\1\ /1/. In order to prevent excess creep under load, geotextiles should have design strength factors of safety in the range of 2 to 4. This is particularly important where soil grids are used for the express purpose of reinforcing or strengthening the soil mass.

10-3.2.3 **Compaction Control**. The performance of soil embankments improves with density, so fill materials should generally be placed at as high a density as is economically feasible, particularly with the finer-grained soils at a density of at least 90% Proctor (ASTM D698, see below). Where the soil will be subjected to heavy loads, or where settlement of the fill would be undesirable, soil density should be increased, even up to 100% modified Proctor (ASTM D1557, see below). There is a specific moisture content for each soil type at which the maximum density is obtained under a specific compaction effort. Therefore, moisture control is an important factor in efficient compaction techniques, particularly with silts, clays, and mixed soils.

10-3.2.3.1 **Compaction Control Standards**. The two most common standards for compaction control are the standard Proctor (ASTM D698, \1\ *Test Methods for Laboratory Compaction Characteristics of Soil Using Standard Effort (12 400 ft lbf/ft3 (600 kN m/m3)) /1/*) and the modified Proctor (ASTM D1557, \1\ *Test Methods for Laboratory Compaction Characteristics of Soil Using Modified Effort (56,000 ft lbf/ft3 (2,700 kN m/m3)) /1/*) tests. The latter method represents a larger compactive effort than the former and has been adopted to account for the higher compactive capability of modern construction equipment. However, the standard considered most pertinent for waterfront structures is still the standard Proctor. This is because the lower compactive effort results in a slightly higher optimum moisture content for maximum density, and the higher moisture content is more compatible with the expected in-service conditions of waterfront structures.

10-3.2.3.2 **Compaction Selection**. The type of compaction selected should be based on the soil type. Vibratory compaction is more efficient with granular soils, whereas kneading types of equipment, such as sheepsfoot rollers, are more applicable to cohesive soils. Vibratory rubber-tired compactors in the 24,250 to 30,865 pounds (11- to 14-metric ton) range are reasonably effective for all types of soil. Soil lifts should generally be limited to layers having a compacted thickness of no more than 5.9 inches (15 cm), except where it has been demonstrated that the compactors are capable of achieving the required densities throughout the full depth of thicker lifts. Such a situation might exist with a vibratory compactor on relatively clean, non-cohesive material. For backfilling sheet pile cofferdams or other structures with limited space, it may be necessary to use small hand-operated tampers or compactors. The difficulty of compaction generally increases with the decrease in grain size of the soil.

10-3.2.3.3 **Compaction Requirements**. A typical requirement for many waterfront structures is to specify a compacted density of 95 percent of standard Proctor, but this may vary with the type of structure and its present condition. It is desirable to place a soil material in a structure in as close to its long-term stable condition as possible. Although clean, granular materials should be placed in as saturated a condition as is practicable, fine-grained or mix-grained soils may require moisture contents to be maintained within a particular optimum range. Often, control of water content with respect to the optimum value is left up to the contractor, since he can elect to replace rigorous moisture control with increased compactive effort. Where excess compactive effort could result in damage to the structure, such as in quaywalls or cofferdams, the compactive effort should be minimized and the moisture content controlled as well as is practicable. For these latter types of structures, it is also very important that design densities not be exceeded. Excessive compaction might result in undesirable lateral stresses in structural members.

10-3.2.4 **Dewatering**. Where excavation and replacement of soil takes place below the water table, it may be necessary to dewater the site by using seepage barriers, such as sheet piles. Where soil permeability is high, subsurface drainage by well points or deep wells may be necessary. Prior to planning dewatering procedures, it is necessary to determine permeability and piezometric levels by field observations. The major concern is to avoid instability through piping or heaving by controlling the upward hydraulic gradient at the base of the excavation. Hydraulic gradients (head loss per unit length of flowpath) equal to the ratio of buoyant density of the soil divided by the density of water lead to immediate instability in all cases. This ratio varies from > 1 for dense soils to < 1 for loose soils. Exit gradients of 0.5 to 0.75 will cause unstable working conditions even in clean sands. Silty materials are even more critical.

10-3.2.5 **Sealing/Filling Voids**.

10-3.2.5.1 **Sealing**. The loss of soil from behind quaywalls, or from within sheet pile cofferdams, requires sealing the structure to prevent further loss of material before replacing with a suitable backfill. Coarser-grained materials and/or geotextile filters are preferred, since they are less subject to leaching or erosion. Fine-grained materials are desirable only where very low permeability is required, such as in the core of an earth dam. When fine materials are used, construction of inverted geotextile filters and/or sealing of structural joints are necessary to prevent erosion. Where materials consist of the very erodible silts or fine sands, the structure must be sealed to prevent influx of surface water.

10-3.2.5.2 **Grouting**. In some cases, it may be more expedient to either seal or repair a damaged structure by injecting grout. Grout may be used to reduce the permeability of the soil fill or its foundation and, thereby, minimize erosion or leaching. It may also be used to physically strengthen the structure to make it more resistant to wave or ship loading, and superimposed dead loads.

Cavities or voids in the soil structure may be grouted using sand/water mixtures, Portland cement, clay, chemical grouts, or a combination of these materials depending on the size of voids. Sand/water mixtures are applicable where large cavities are present and the paths of soil loss have been sealed off. Cement grout is not applicable if the effective grain size of the in-place soils, D (the sieve size through which only 10 percent of the soil would pass), is less than 19.7 mils (0.5 mm) for loose soils and 55.1 mils (1.4 mm) for dense soils. Portland cement grout is most applicable where the grout can be pumped directly into cavities.

An effective grouting procedure for sandy materials consists of injecting solutions of sodium silicate and calcium chloride. This procedure both solidifies the soil and makes it impermeable, but it is extremely expensive. Mixtures of cement and clay are also used, sometimes adding a chemical deflocculant.

One of the more recently developed chemical grouts polymerizes in the soil voids; however, it is also expensive. With fine-grained backfills, grouting is generally of no benefit except to fill cavities or to seal off paths of soil removal.

10-3.2.6 **Preventing Loss or Settlement of Soil**. Maintaining good surface drainage is the most important preventive maintenance measure for earthwork structures. Efficient runoff of rainfall and overflow water must be ensured. If subsurface drainage features exist, they must be kept clear (for example, periodic cleaning of weep holes). Hand-placed riprap can be added to the slope just behind the sheet piling, if storm runoff results in heavy soil loss.

10-3.3 **Future Inspection Requirements**. Where the rate of erosion or settlement has been increasing the structure must be closely monitored to provide early warning of impending failure. Where a major problem has been encountered and corrected, increased inspection may be necessary to ensure that the repair is effective.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 4-150-08, *Mooring Hardware Inspection*

Superseding: UFC 4-150-08 Change 1, dated 19 June 2001

Description: This UFC provides guidance for the specialized inspection and testing of mooring hardware at waterfront facilities and related facilities. Inspection levels, methods, and testing procedures are presented for the mooring hardware. The testing procedures presented herein are a precursor for a more detailed load capacity assessment of specified mooring hardware. The resulting findings of inspections of mooring hardware and fendering are to guide facility personnel in the selection of appropriate analysis, repair and replacement techniques, maintenance, inspection of fieldwork for acceptability, and planning the follow-on inspection requirements.

Reasons for Document:

- Document was due for revision.
- Provides coordination with ASCE MOP130, *Waterfront Facilities Inspection and Assessment*.
- Mooring condition ratings updated and coordinated with other UFCs. Mooring hardware testing procedures updated.
- Several references had been superseded and required updating.

Impact:

- This UFC is a guide for the inspection and evaluation of mooring hardware used at waterfront facilities that provide berthing for U.S. Military Ships.

Unification Issues:

- None.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

This UFC 4-150-08, is a guide for the inspection and evaluation of mooring hardware used at waterfront facilities that provide berthing for U.S. Military Ships. It is a source of reference for the planning, inspection, and reporting of mooring hardware conditions in a standardized format.

Initial chapters in this UFC provide a summary of responsibilities and policies, field inspection guidelines, and mooring hardware types. Inspection levels, methods, planning, and techniques and checklists are covered for above water inspection. General load capacity testing procedures are described and illustrated for general mooring hardware.

1-2 PURPOSE AND SCOPE.

This UFC provides guidance for the planning, inspection, assessment, and reporting of mooring hardware conditions. It should be used as a tool for helping personnel tasked with maintaining the readiness of shore side facilities for use by the fleet and in support of military marine operations. The Mooring Hardware Report has the following objectives:

- Establish adequacy of mooring facilities.
- Enable facility users to develop efficient berthing plans.
- Establish baseline data on existing mooring hardware and berthing capacity.
- Provide facility users with information sufficient to determine level of effort to maintain or upgrade existing capacity.

1-3 APPLICABILITY.

This UFC provides guidance for the specialized inspection and testing of mooring hardware at waterfront facilities and related facilities. Inspection levels, methods, and testing procedures are presented for the mooring hardware. The testing procedures presented herein are a precursor for a more detailed load capacity assessment of specified mooring hardware. The resulting findings of inspections of mooring hardware and fendering are to guide facility personnel in the selection of appropriate analysis, repair and replacement techniques, maintenance, inspection of fieldwork for acceptability, and planning the follow-on inspection requirements.

The standards and methods presented herein are a guide to the planning, inspection, assessment, and reporting of mooring hardware conditions. The standards and methods outlined have been developed from the best technical sources in industry and the military services.

1-3.1 Facilities Covered.

Types of facilities covered as related to mooring hardware include:

- Berthing facilities (piers, wharves, and dolphins) for mooring and for providing support to ships and craft.
- Dry docks used for modification, inspection maintenance, and repair of ships.

1-3.2 Facilities Not Covered.

Facilities not covered in this UFC are:

- Fleet moorings - which are covered in UFC 4-150-09, *Permanent Anchored Moorings: Operations and Maintenance*.
- Mechanical capstans.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 GLOSSARY.

APPENDIX B contains acronyms, abbreviations, and terms.

1-6 REFERENCES.

APPENDIX C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 PLANNING FACILITY INSPECTION

2-1 MAINTENANCE PLANNING.

Maintenance planning criteria can be found in Chapter 2 of UFC 4-150-07, *Waterfront Facilities Operations and Maintenance*. Development of a long-term inspection and maintenance program involving all aspects of waterfront facilities is covered in the above document. A long-term inspection program involving regular field inspection of mooring hardware at established intervals should be part of the overall facility maintenance program.

2-2 PLANNING.

2-2.1 General.

This section covers the planning required to conduct an inspection and assessment of mooring hardware. Critical aspects of planning an inspection of this nature include the establishment of a clear scope of work and gathering all available data. Figure 2-1 depicts the Mooring Hardware Inspection Process.

2-2.2 Scope of Work.

Planning the inspection of mooring hardware will begin with the establishment of a scope of work. The scope of work will define the facilities to be inspected and level of inspection. The scope of work should include:

- Number of hardware.
- Type of hardware.
- Type of support structure.
- Level of inspection required.
- Date of last inspection.
- Fender system type and quantity.
- List of ships that normally use hardware, (i.e. mission critical ships).

2-2.3 Existing Data.

All available relevant data on the facilities to be inspected and assessed should be gathered at the earliest possible date. This information should be provided to the persons responsible for planning and organizing the inspection and assessment effort such that the level of effort for inspecting a specific facility can be determined. Data and information may be available in many forms as listed below.

2-2.3.1 Drawings.

- As-Built Construction Drawings – Original construction drawings will often have vital information regarding mooring and berthing design loads. This information is usually the most accurate data available to the inspector. Caution should be taken to confirm that the data on the plans is accurate and changes to the structure have been investigated and confirmed.
- Repair and Maintenance Drawings – All modifications to the original structure should be investigated and analyzed as to their impact to the structure.
- Site Plans – Site plans can provide layout data and, in some cases, will have sufficient detail to show mooring hardware position. This data is often out dated and should be confirmed.
- Hydrographic Survey Plans – Hydrographic data is important to establish depth of water at the berth.

2-2.3.2 Calculations.

Design calculations to establish the capacity of the supporting structure. Calculations used to determine loads on hardware.

2-2.3.3 Existing Reports.

Previous inspection reports such as a Waterfront Facilities Inspection Report, Prior Mooring Hardware Condition report or Annual Inspection Summaries.

2-3 FIELD INSPECTION / DATA GATHERING.

2-3.1 General.

The purpose of any mooring hardware inspection is to gather information to assess the condition of the mooring hardware system inspected. The level of inspection will determine the amount and type of information gathered. The inspection will focus on gathering the following information:

- Identification of damage.
- Confirmation of available data.
- Changes in the known supporting structure.
- Identification of potential problems with interacting equipment and fixtures.
- Establishing the position of mooring hardware and fenders.
- General condition of fender system and hardware.
- Gather available background information at the site.

2-3.2 Field Inspection.

Personnel assigned to conduct a field inspection of mooring hardware should acquire the appropriate tools necessary to accomplish the work. The level of inspection will dictate the required tools. All levels require appropriate record keeping. Information should be recorded in logbooks. The time and level of effort required to conduct an inspection will depend on the amount of background information that is available, level of inspection required, site conditions, site access and activity, as well as the skill of the inspector.

2-3.2.1 Tools Required.

2-3.2.1.1 Hand Tools.

Various hand tools are required to accomplish the task of inspecting mooring hardware. Tape rules, folding rules, measuring wheels, and in some instances surveying equipment will be required to perform tasks such as: dimensioning structural components, finding the position of mooring hardware, and measuring distress within the structural system. Other tools such as wire brushes, chipping hammers, and scrapers can be used to clean and uncover structural components that are not readily visible. Marking devises such as paint stick, keel, paint, and ink pens can be used to establish identifying marks on each hardware unit for reference.

2-3.2.1.2 Equipment.

Heavy equipment may be required to conduct Level 3 Inspections. Equipment such as diving gear, compressions, jacks, hoists, rigging, load cells, and cranes should be used as necessary to accomplish the work.

2-3.2.1.3 Note Keeping.

Field inspection data and notes should be kept in a surveyor's field book or the Mooring Hardware Inspection Sheet (see Figure 2-2) and in an orderly and legible fashion. Photographic documentation of each piece or representative piece of mooring hardware should be taken and recorded in the field book. Notes can be kept in tabular form within the notebook. The following minimum data is required:

- <u>Hardware Number or Designation</u> – Each fitting should have a unique alphanumeric designation. If an existing system is in place it should be used. If there is no system for identifying hardware, unique designations should be assigned. For example, identifying systems such as "B1-C3" for Berth 1, Cleat Number 3 may be used.
- <u>Size and Type of Hardware</u> – Record the casting number or serial number that identifies each type of hardware. Standard U.S. Navy fittings can be found in Figure 2-3 (see Table 6-11 and Figure 6-3 in UFC 4-159-03). If the hardware number cannot be found or identified in the field, then the overall dimensions should be recorded.

Additional information concerning the sizes and working capacities of pier and wharf mooring fittings is found in UFC 4-159-03, *Moorings*. Further information on inspection can be found in ASCE MOP 130, *Waterfront Facilities Inspection and Assessment*.

- Position of hardware (X, Y, Z coordinates) – A coordinate system should be identified and established such that the location of each hardware can be established along the berth. The relationship between the hardware and the tidal datum should also be established.
- Reference position of coordinates – All coordinate systems should be referenced to a local system for each facility i.e. reference benchmark on site, or activity base map coordinates.
- Condition of the hardware – The condition of each piece of mooring hardware should be rated in the field. The rating system should be on a scale of 1 to 5, as described in Figure 2-4.
- Condition of the base structure – The base structure of each piece of hardware should be rated on a scale of 1 to 5, as described in Figure 2-5.
- Condition of the fender system should be noted and rated as described in UFC 4-150-07.
- Fasteners – The number, pattern and size of the fasteners on each piece of mooring hardware should be recorded.
- Additional remarks – Additional notes such as odd conditions, qualifying remarks, and other information that might be deemed useful should be recorded.
- Photo identification number and description.
- All sketches and other ancillary notes should be kept in the same notebook.

2-4 ENGINEERING EVALUATION.

An evaluation of the data can only be conducted once the inspection is complete. The field data as well as the existing data should be reviewed and analyzed to formulate allowable load criteria.

2-5 TYPE OF MOORING SERVICE.

The type of mooring service should be considered when planning the inspection frequency. For example, Berths with Mooring Service Type III should be considered high priority as ships moored at these berths may not have the ability to get under way in case of an approaching storm. See Table 3-4 in UFC 4-159-03, *Moorings* for an explanation of mooring service types (MST).

Figure 2-3 Typical Profiles of Mooring Hardware

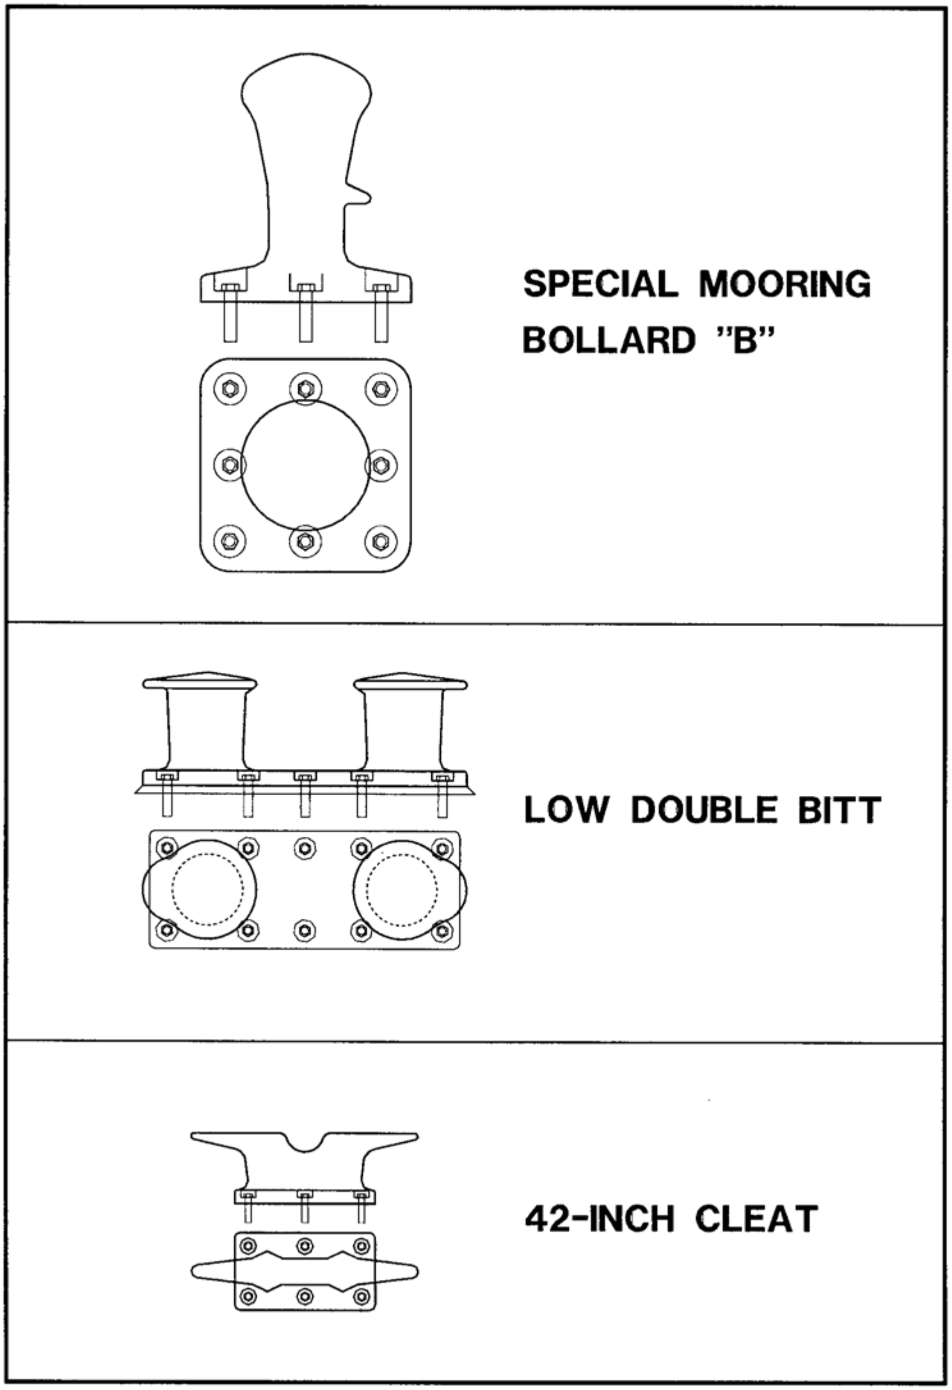

Figure 2-4 Condition Rating Scale for Mooring Hardware

Example of Condition | **Mooring Hardware Condition Rating**

#1 No Defects:
- Material and connections sound
- Less than 10% surface corrosion
- Surface coating in good condition
- Bolt countersinks grouted or sealed

#2 Minor Defects:
- Surface corrosion over 10-25% of area
- Minor wear marks or pitting are less than 1/8 in. (3.2 mm) deep
- Minor corrosion of fasteners with no significant section loss

#3 Moderate Defects:
- Surface corrosion with loose scale over 25-50% of its area
- Moderate wear marks or pitting are less than 1/4 in. (6.4 mm) deep
- Fasteners corroded with less than 25% section loss

#4 Major Defects:
- Surface corrosion with loose scale over 50% or more of its area and/or less than 25% section loss
- Significant wear marks or pitting are 1/4 in. (6.4 mm) deep or greater
- Fasteners corroded with loose scale or greater than 25% section loss

#5 Severe Defects:
- Heavy surface corrosion and loose scale with greater than 25% section loss at critical areas
- Movement, rotation, or deformation of fitting; components are broken, cracked, or delaminated
- Loose, missing, or broken fasteners

Figure 2-5 Condition Rating Scale for Base Structure

Example of Condition | **Mooring Foundation Condition Rating**

#1 <u>No Defects:</u>

- Good original sound condition with no visible defects

#2 <u>Minor Defects:</u>

- Hairline cracks in concrete from thermal expansion, mooring hardware corrosion, and/or age; no significant section loss
- Light surface corrosion of steel, no significant section loss, coating weathered
- Timber or composite weathered; presence of fungal decay; minor checks, splits, and gouges up to 1/4 in. (6.4 mm) wide

#3 <u>Moderate Defects:</u>

- Noticeable cracking of concrete without loss of interlock
- Steel corrosion with less than 10-25% section loss
- Timber or composite cracked or checked up to 1/2 in. (12.7 mm) wide, weathered surfaces, fungal decay with section loss up to 1 in. (25.4 mm)

#4 <u>Major Defects:</u>

- Noticeable cracking or spalling of concrete with loss of interlock
- Steel corrosion with 25-50% section loss
- Timber cracked or checked greater than 1/2 in. (12.7 mm) wide; fungal decay up to 3 in. (76.2 mm) deep; dry rot
- Composite elements cracked or split

#5 <u>Severe Defects:</u>

- Displacement or yielding; loss of full bearing
- Major cracking or spalling of concrete base under hardware
- Significant corrosion of steel members with greater than 50% section loss at any location
- Timber members broken or damaged or fungal decay greater than 3 in. (76.2 mm)
- Composite elements broken or damaged

This Page Intentionally Left Blank

CHAPTER 3 QUALIFICATIONS

3-1 PERSONNEL.

If a contract is used, the inspection of mooring hardware must be conducted under the supervision of a Registered Professional Engineer (P.E.) who has experience in the design and inspection of marine structures. At a minimum, the supervising engineer (P.E.) must be onsite and involved in the inspection to assess and record conditions encountered using standard engineering practice. Level 1 inspections may be conducted by technicians under the supervision of a Registered Professional Engineer. For Level 2 or Level 3 inspections, which may require underwater inspection as well as the operation of equipment, personnel must be fully qualified and should have adequate levels of support to accomplish the task. All work operations must be accomplished in accordance with the standards identified in APPENDIX C. Guidance for underwater inspections can be found in UFC 4-150-07, *Waterfront Facilities Operations and Maintenance.*

This Page Intentionally Left Blank

CHAPTER 4 INSPECTION FUNDAMENTALS

4-1 LEVELS OF INSPECTION.

4-1.1 Level 1 - Walk through Inspection.

This inspection is a walk-through inspection to assess damage following a storm event and to confirm any changed conditions. Gross deficiencies can be identified during this inspection. This level of inspection cannot provide sufficient data to assess the capabilities of a mooring system.

4-1.2 Level 2 - Visual Inspection.

This inspection will involve visual observation of the condition of exposed components of the mooring hardware and supporting structure. The hardware should be visually inspected for cracks or other anomalies. Hardware geometry should also be inspected to determine if displacement has occurred. Bolts, if exposed, can be inspected to determine their relative tightness. The general condition of the supporting base structure should be inspected for anomalies such as cracking and/or displacement. Under this level of inspection, the position of the hardware should be determined. The relative position in relation to the three principal axis coordinates (X, Y, Z) should be established to the nearest foot. The Level 2 visual inspection is required to establish baseline conditions.

4-1.3 Level 3 - Detailed Inspection.

This inspection is performed in addition to the inspection tasks performed under the Level 1 and Level 2 inspections. A detailed inspection will involve the observation of exposed components of the supporting structure such as the underside of the pier deck and piles.

In addition, a detailed inspection may involve partly destructive techniques related to dismantling and load testing mooring hardware. Removal of sealing material and fasteners for inspection and load testing will be accomplished as directed by the Scope of Work under this level of inspection. Individual fasteners may be load tested in tension by using a jacking apparatus. The entire hardware piece may be load tested using various methods. The method employed for load testing of hardware will be dependent upon the type of hardware piece and site conditions. Guidelines for load testing hardware and fasteners can be found in APPENDIX A of this document.

4-1.4 Fender System.

A Level 1 visual inspection of the fender system should be conducted concurrently with all levels of mooring hardware inspection. The type of fender system will be noted, and the general configuration will be established as it relates to the mooring hardware. Size and location of fender system components will be noted to determine the placement of ships.

4-2 FREQUENCY OF INSPECTION.

Under most circumstances, all mooring hardware in satisfactory or better condition should receive a Level 1 Inspection annually, and a Level 2 maximum inspection interval of 4 to 6 years, depending upon the aggressiveness of the environment and the level of hardware protection. The type of structure and the class of service will also dictate the inspection frequency and level of inspection. For timber structures that are susceptible to impact and severe environmental conditions the frequency of Level 2 inspections should be set at every 3 years. For structures that are high priority, the berthing officer will determine the level of inspection. In instances where extreme storm events have resulted in the potential overloading of mooring hardware, a Level 1 inspection should be conducted to determine post storm conditions. Level 3 Inspections involving load testing should be conducted as directed by the Berthing Officer or as described in APPENDIX A, based on hardware priority level.

4-3 INSPECTION METHODS.

4-3.1 Local Conditions.

4-3.1.1 Mooring Hardware Fittings.

Each piece of mooring hardware should be visually inspected for anomalies. Conditions that are commonly found include cracks, abrasion (due to wire rope), corrosion and displacement. Cracks are usually the result of impact loading or overloading the hardware under extreme conditions. Abrasion normally occurs when mooring lines are pulled around the hardware causing friction and erosion of the casting under the barrel or horn. If this condition is severe, it will weaken the casting through loss of cross sectional area. Documentation of the depth of abrasion, location, and area are required to establish loss of strength. The condition of the coating should be noted. Coatings that have mechanical damage, i.e., cracks, peeling, or abrasion, should be described. Coating systems that have failed or are worn out should also be described, as well as any resulting corrosion. Levels of corrosion can be described as rust stains, light scale, and heavy scale. The surface roughness of the steel should also be described. Corrosion of the casting should be assessed to determine the loss of section at critical points on the casting. Heavy corrosion will also affect the surface roughness of the hardware increasing the chafing and wearing of mooring lines. Observations of the mooring hardware plumbness and level should be made to determine prior overloading and failure of the surrounding soil or fasteners.

4-3.2 Fasteners.

Fasteners consisting of steel bolts are used to anchor the mooring hardware to the supporting structure. In some cases, mooring hardware is embedded directly in the supporting structure. Where fasteners are used, their function within the mooring system is critical and is almost always the crucial structural element. Fasteners are generally inaccessible because of typical mooring hardware details, calling for protection usually in the form of lead fill, bituminous fill or grout being placed in the bolt pockets. If the fasteners are not visible, then a Level 1 or 2 inspection will result in minimal fastener data. A Level 3 inspection is required to determine the condition of the fasteners. For newer structures, the fasteners may pass through blocking and terminate with nuts and washers bearing on heavy plates. This part of the structure is accessible and should be inspected for loss of section due to corrosion. If fasteners are embedded in the structure and the bolt pockets are filled, the only inspection technique available to the inspector is to remove the casting and observe the fastener for corrosion and loss of cross sectional area. Load testing of the fasteners can be conducted without removal of the casting and will result in the determination of an allowable load. See APPENDIX A for load testing criteria.

4-3.3 Supporting Structure.

4-3.3.1 Concrete.

The majority of heavy load mooring hardware is attached to concrete decks. Concrete acts well to resist the forces applied by mooring hardware. The compressive strength of concrete resists the shear forces generated as well as providing excellent distribution of load through the structure. Factors to consider when inspecting concrete that supports mooring hardware include cracking, disintegration and corrosion of reinforcing steel. Cracking occurs in all concrete through many processes both as a result of natural factors and from outside forces such as impact. The inspector must be able to determine the differences between the various types of cracks, their causes and the structural implications of those cracks. Cracks of a concerning nature include: shear cracks near the edge of the pier deck (running at 45 degrees through the corner); diagonal cracking on the deck surface running at 45 degrees from the hardware to the edge; and radial cracking around fasteners indicating cone failure. Gaps at the hardware base or crushing of bedding grout indicate movement or overloading and should be noted. General deterioration of the concrete should be observed and noted.

The mooring hardware should be founded on a solid concrete matrix and/or bedded in grout to provide full contact on the bottom and sides. The concrete should be solid and not exhibit any significant disintegration or spalling.

4-3.3.2 Timber.

Timber structures should be inspected for structural failures such as: crushing of the timber under the hardware or the fastener bearing plates, cracking or failed members, and displaced members. Timber also exhibits deterioration in several forms such as: dry rot or decay, marine borers, and termites or other insects. These conditions should be noted and assessed based on their impact to the structure and mooring hardware.

4-3.3.3 Steel.

Steel supporting structures exhibit conditions such as corrosion, buckling, and cracking. Steel members are generally fastened with either bolts or welds. Bolts should be inspected for tightness, loss of cross sectional area due to corrosion, and bearing. Welds should be inspected visually for cracking.

4-3.4 Fender System.

Visual observation of the fender system should be made in sufficient detail to establish the typical cross-section and to detail the energy absorbing characteristics of the system. Where timber fender systems are employed, the general condition of the timber components should be noted in terms of berthing capability. Where other types of fender systems are in place, the overall capacity of the system should be documented. Locations where damage has occurred should be noted. Missing fender units should be noted and identified.

4-3.5 Global Conditions.

Global conditions refer to the condition of the supporting pier, wharf, or dolphin structure. The inspection of these structures is closely related to the condition of the mooring hardware with respect to the capacity of the mooring system. For example, the sum of the capacities of the mooring hardware may exceed the total capacity of the structure to resist these loads. In this case the mooring hardware cannot be fully developed. Berthing plans are required to factor these limitations into the allowable berthing capacity for the facility. Inspection of pier facilities is addressed in UFC 4-150-07, *Waterfront Facilities Operations and Maintenance*.

4-3.5.1 Pier Structure.

The significant loading imposed on the pier structure by mooring hardware is in the lateral direction (horizontal "x" direction), which in most cases is resisted by batter piles or passive earth pressure. Piers vary in their construction and the methods employed to transmit these loads to the soil. Open pier structures generally have battered piles (piles at an angle) along with plumb piles (vertical piles,) as well as significant dead loads to resist the lateral and resulting uplift loads. Solid pier structures rely on their massive dead load for stability, as in cellular structures or in the resistance of deadman in the case of tied-back sheet pile bulkheads.

4-3.5.2 Structural Analysis.

The inspecting engineer must collect all available data to ascertain the capacity of the pier structure to resist lateral loads. Available information may include:

- Original design drawings and calculations.
- Modifications to the structure.
- Previous inspection reports.

4-3.5.2.1 Calculations.

When directed, a licensed professional engineer must calculate the lateral capacity of the facility based on available data and according to UFC 4-152-01, *Piers and Wharves*. For each ship that uses the facility, the analysis should provide the maximum wind speed for safe mooring. Caution should be exercised in using appropriate factors of safety based on the accuracy and scope of available data.

4-4 PHOTOGRAPHY.

Photography should be used to document the condition of each piece of hardware. This can be used in future assessments to determine the change in conditions. Photographs should include a general overview of the hardware piece and any significant conditions. The hardware should be identified within the photograph. An overview of each berth showing the fender system should be taken and included within the report.

This Page Intentionally Left Blank

CHAPTER 5 REPORT

5-1 REPORT PURPOSE AND OBJECTIVES.

The mooring hardware report should present the data acquired during the field investigation and the results of the analysis of that data for the use by Berthing Officers in the formulation of berthing plans, scheduling repairs, and instituting a mooring hardware load test program.

5-2 REPORT FORMAT.

For consistency, all reports should follow the Report Outline in Figure 5-1. The contents of each section are described below. Each report should be submitted in MS Word (.doc) and Adobe Acrobat (.pdf). The quantity of each submittal should be determined in the scope of work. The digital files should be submitted on CD-ROM media or other approved file transfer system.

5-3 REPORT STRUCTURE.

5-3.1 Outline.

See Figure 5-1.

5-3.2 Introduction.

This section is largely a descriptive overview with sections including:

1.1 Background/Objectives

1.2 Report Description

1.3 Condition Rating

1.4 Digital Model

5-3.3 Activity Description.

This section has subsections including:

2.1 Location

2.2 Existing Waterfront Facilities along with regional, area, and facility maps that are the same as in the Waterfront Facilities Inspection Report.

Additional subsections include:

2.3 Inspection Procedure and

2.4 Hardware Numbering System

In these subsections, the inspection procedure and hardware numbering system are explained in detail to the reader. In the inspection procedure subsection, the condition rating system is described as well as the method of locating the position of the mooring hardware. This will provide the reader with an understanding of the level of accuracy of the inspection and data. The subsection on the Hardware Numbering System will provide the reader with an understanding of the system used and why this system was employed, (i.e. whether the system was in place or developed for a specific inspection).

5-3.4 Facilities Inspected.

This section constitutes the body of the report and has the following subsections:

3.1.1 Description

3.1.2 Design Structural Capacity

3.1.3 Existing Condition

5-3.5 Facilities Description.

Includes a summary of the history of the facility structure including the date of original construction, type of structure, length of berth, deck elevation, depth of water (MLLW datum), and a description of the fender system. The intent of this section is to give the reader a solid background on the specifics of the structure while being concise. In addition to structure description, the current use of the facility should also be described. The types of vessel usage complement as well as the type of service (I, II, III, or IV) should be noted. See UFC 4-159-03, *Moorings*.

5-3.6 Design Structural Capacity.

This section consists of a table reviewing mooring hardware data associated with the facility. The data within this table includes: mooring hardware type and quantity, design load rating of the hardware, the calculated load capacity of the hardware if manufacturer's data is not available, and the design and/or calculated capacity of the base structure. This table is a structural summary intended to provide the reader with information required to determine berthing capacity.

5-3.7 Existing Condition.

This section provides a summary of the conditions found during the inspection. A discussion of hardware rated at #3 or #4 is included to highlight conditions that warrant attention. Following the existing condition text are photo pages that present a photographic example of each type of hardware found on the facility and photos of anomalous conditions. Following the photo page(s) is the figure showing the 3-D perspective view of the facility (when requested). Following this is the figure (drawing) showing the plan view of the facility with the condition of the fittings and fender system noted. Following this is the data table. The data table has all the information available about each piece of mooring hardware. This information includes; hardware #, node #, X-coord., Y-coord., Z-coord., type of hardware, line pull rating, and the condition of both the hardware and it's support structure.

5-3.8 Appendices.

5-3.8.1 Key Personnel.

Each report should have a list of key personnel responsible for organizing, conducting, and implementing the investigation.

5-3.8.2 Load Test Procedures.

This section will include a description of any load testing undertaken. The level of testing, quantity, and location of load tests will be described (see APPENDIX A).

5-3.8.3 Calculations.

All calculations to determine the load capacity of mooring hardware and/or supporting structures is presented in APPENDIX A.

5-3.8.4 Mooring Hardware Inspection Records.

The actual mooring hardware inspection records should be included in this section.

5-3.8.5 Deck Fitting Load Test Reports.

The load testing reports should be presented in this section.

5-3.8.6 References.

All references used in the body of the report should be identified in this section.

5-4 3D MODEL.

A three-dimensional model of each facility will be generated when requested for Level 2 inspections in AutoCAD 2010 or greater to assist facility users in the placement of ships and camels along the pier or wharf in conjunction with fender systems that are in place. At a minimum the model must include: all mooring hardware, main components of the permanent fender system, mudline representation, water level representation, and all fixtures and buildings within 50 feet (15.2 m) of the berth face or that would cause obstruction to berthing lines. A perspective view of the berth should be presented in the body of the report for each facility in the form of a figure in 8.5 in. x 11 in. (216 mm x 279 mm) format.

5-5 DRAWINGS.

The report will include plan views of each berth showing the location of each mooring hardware piece with the hardware identification number as well as its condition. The condition of the hardware should be color-coded to match the color-coding of the data tables. The condition of the fender system should also be noted with a color line running parallel to the face of the berth. The plans will be to scale such that laying out mooring lines can be planed and facilitated.

Obstructions to mooring lines will also be shown on the plan. The north arrow and direction of current ebb and flood will also be shown.

5-6 DATA TABLES.

Data tables will be included in the report and in spreadsheet format. At a minimum the data tables will include: X, Y, Z coordinates of each piece of hardware, its identification number, its node number, the condition of the hardware and its base, the type of hardware, and its allowable line pull rating. The hardware condition will be annotated both numerically and in color as noted in Table 5-1. The data table will be produced in Excel format as shown and should have the ability to be manipulated in to the EMOOR database (see UFC 4-159-03, *Moorings*) The node number, coordinates, and the line pull should be numbers (not labels) to facilitate import into a database in Excel format.

Table 5-1 Condition of Color Schemes

Condition Color Level	Color	AutoCAD 2010 Color Number
1 = Excellent	Green	90
2 = Satisfactory	Blue	160
3 = Marginal	Yellow	40
4 = Poor	Red	240

APPENDIX A MOORING HARDWARE TESTING

A-1 INTRODUCTION.

A-1.1 Scope.

This Appendix is a guide for the testing of mooring hardware at waterfront facilities. It is a source of reference for the planning, testing, and reporting of current load capacities of mooring hardware at waterfront facilities in a standard format.

A-1.2 Purpose.

This Appendix provides guidance for the planning, testing, and reporting of current mooring hardware load capacities. It should be used as a tool for assisting personnel tasked with maintaining the readiness of shoreside facilities for use by the fleet and in support of military marine operations.

The objectives of the Mooring Hardware Report are:

- To establish adequacy of mooring facilities.
- Enable facility users to develop efficient berthing plans.
- Establish baseline data on existing mooring hardware and berthing capacity.
- Provide facility users with information sufficient to determine the level of effort necessary to maintain or upgrade existing capacity.
- This UFC covers berthing facilities for mooring and providing support to ships and craft, as well as dry docks used for modification, inspection, maintenance, and repair of ships.

This UFC does not cover fleet moorings (covered in UFC 4-159-03, *Moorings*) or mechanical capstans.

A-2 PLANNING HARDWARE TESTING PROGRAM.

A-2.1 General Description.

This section covers the planning required to conduct the testing of mooring hardware. Critical aspects of planning testing of this nature include the establishment of a clear scope of work and gathering all available data as well as understanding the prioritization of berths and fittings.

A-2.2 Scope of Work.

Planning the testing of mooring hardware will begin with the establishment of a scope of work. The scope of work will define the mooring hardware to be tested and the level of testing to be conducted. The scope of work should be made following initial findings of the Level 2 Inspection and Report (covered in UFC 4-159-03). The scope of work should include:

- Hardware to be tested, by established designation.
- Type of hardware.
- Type of support structure.
- Level of testing required.
- Accessibility.
- Date of last inspection/testing.

A-2.3 Existing Data.

All available relevant data on the mooring hardware to be tested should be gathered at the earliest possible date. This information should be provided to the persons responsible for planning and organizing the testing effort such that the level of effort for testing a specific piece of hardware can be determined. Data and information may be available in many forms as listed below:

- Mooring Hardware Inspection report.
- Design plans.
- Berth priority ratings.
- Hardware priority ratings.

A-2.4 Site Conditions.

The portion of the waterfront facility surrounding the mooring hardware to be tested should be evaluated for accessibility. If there are no limitations to accessibility of the mooring hardware, all options for testing should be considered. This information assists in formulating accurate cost estimates for the testing.

A-2.5 Testing Plan.

Testing of fittings is relatively expensive and time consuming, so it is recommended that periodic testing is used on a statistical basis. Prioritize the tests based on the importance of the mooring facility.

Various levels of testing can be instituted to achieve the desired results. For example, if it is determined that the required level of accuracy is 100%, then all fittings will need to be tested. If 95% accuracy is required, then the number of tests can be reduced significantly. The sampling criteria can be based on statistical sampling techniques.

Statistical sampling provides an objective method for determining sample size for a desired confidence level and precision. The result of a statistical sampling program would determine the approximate number of fittings that are marginal or unacceptable; however, it would not be able to determine the location of those fittings. An estimation of the load carrying capacity and condition of the fittings in general could be made.

Testing of every fitting would be required for 100% accuracy. A statistical approach may be a reasonable cost effective method of initiating a testing program that would determine the overall adequacy of the berthing system.

Standard sampling plans are presented in ANSI/ASQ Z1.9, *Sampling Procedures and Tables for Inspection of Variables for Percent Nonconforming* or ANSI/ASQ Z1.4, *Sampling Procedures and Tables for Inspection by Attributes* based on choice of inspection methods; inspection by variables or by attributes. ANSI/ASQ Z1.4 may be well suited for a testing program where the fittings are either passing or failing the load test.

A-2.6 Facility Prioritization.

Review mooring facilities and prioritize each mooring hardware unit as ‘HIGH’, ‘MEDIUM’ or ‘LOW’ to determine the extent of testing required. Consider the following factors in assigning testing priorities.

- Visual inspections and non-destructive testing (such as ultrasonic) may find possible problems and indicate that certain mooring fittings need to be assigned the highest priority. Visual inspections should include the fasteners (nuts and bolts) including the under-deck connections if available. Some mooring fittings should be taken out of service and should not be tested if the fasteners are in poor condition.
- Berths providing Mooring Service Type III (Heavy Weather Mooring) are especially high priority, because the ships under repair at these piers and wharves cannot get under way in case of an approaching storm.
- High capacity fittings secure a larger portion of a mooring load at a given facility, and should be assigned higher priority (i.e. a Special Mooring Bollard 'A' holds more load than a 30-in. (76.2 cm) cleat, so the bollard is assigned a higher priority).
- Older facilities not previously pull tested are more likely to suffer from structural deterioration and should be assigned higher priority. Testing recommendations are shown in Table A-1.
- Facilities that do not know the rated load capacities of their mooring fittings should develop a test plan to first estimate the capacities using engineering tools and comparison to similar designs. Then test a sample set of mooring fittings to their estimated capacity by applying incremental loads while monitoring for deflection and other failure modes.

Table A-1 Pull Testing Interval Recommendations

Hardware Priority	Testing Interval	Minimum % of Hardware	Description
High	12 years	20%	For older and very important facilities, up to 100% of fittings can be tested. If any of the tested fittings fail, then testing should be expanded to include a higher percentage of fittings.
Medium	18 years	10%	For older or very important facilities, up to 50% or more of fittings can be tested. If any of the tested fittings fail, then testing should be expanded to include a higher percentage of fittings.
Low	TBD	TBD	A responsible authority should determine what level, if any, pull testing is required.
Mooring Anchors	During installation	100%	All anchors are pull tested during initial installation.

A-3 QUALIFICATIONS.

A-3.1 Personnel.

If contracted, the testing of mooring hardware must be conducted under the direct supervision of a Registered Professional Engineer (P.E.) who has experience in the design and inspection of marine structures. At a minimum, the supervising engineer (P.E.) should be on site and involved in the testing to assess and record conditions encountered using standard engineering practice. NAVFAC EXWC has the capability of providing mooring hardware analysis and testing on a reimbursable funding document for any U.S. government or military agency. All rules governing workplace safety should apply, and it is recommended to have a site safety supervisor available to review safety plans and oversee the work.

A-4 BACKGROUND.

A-4.1 General.

An understanding of the following information regarding the testing of mooring hardware is essential. Each test will consider the following:

- Orientation: The position (X, Y, Z coordinates) of the hardware should be based on the coordinate system established during the mooring hardware inspection. Direction of the forces applied should be established and recorded utilizing the same coordinate system.
- Magnitude: The load applied to the hardware should be 110% of its rated load capacity, applied incrementally while monitoring for deflection and other failure modes. The rated load capacity of the hardware can be gathered from existing data or estimated using engineering tools and comparison to similar designs.
- Duration: The duration that test loads are applied should be dependent upon the level of the test and the discretion of the supervising engineer (P.E.).

A-4.2 Load Path.

The load path followed by the mooring line load through the fitting into the supporting concrete slab can be considered the same for all the mooring fittings.

The mooring line load is applied under the horn or lip at the mooring fitting. The upward vertical load component from the mooring line causes a vertical shear at the base of the horn or lip for loads with nonzero vertical load components. The horizontal load component at the load point induces shear stresses in the cross section of the mooring fitting. The upward tensile force causes tensile stress in the cross section of the mooring fitting as well as a constant bending moment along the mooring fitting axis about a horizontal axis normal to the load. The horizontal load component induces a bending moment that increases with distance from the load point toward the base of the mooring fitting. This bending moment is a maximum at the base of the mooring fitting.

The axial and shear forces and bending moments at the base of the mooring fitting are resisted by the base plate through flexure and shear action. At the bottom of the base plate, the resulting forces and moments are resisted by the tensile and shear stresses in the anchor bolts. However, a small portion of these forces and moments is resisted by friction between the toe of the base plate and the concrete and by bearing of the vertical sides of the base plate against the adjacent concrete. The shear and tensile forces in the anchor bolts are resisted by the concrete base through bearing, shear and tensile stresses in the slab. The concrete slab transfers these loads from the anchor bolts to the pile cap through shear and tensile stresses and then to the support piles. In turn, the piles transfer the forces to the supporting soil.

A-4.2.1 Load Failure.

The failure of any component along the load path described above from the load point to the ground disrupts the flow of forces unless there are sufficiently strong adjacent parallel load paths to take up the load carried by the failed component. A disruption of the load path can lead to the failure of the load resisting system as a whole.

A-4.3 Supporting Structures.

Consideration of the supporting structure is a critical component of planning a hardware test. Personnel responsible for carrying out the testing program must determine the following:

- The structural adequacy of the system to support the test load.
- General condition of the supporting structure.

Once it is determined that the supporting structure was designed to handle the fitting and the condition of the structure is sound, the test can be carried out.

A-4.4 Failure Modes.

There are various modes of failure associated with mooring hardware. Most cases of failure under in-service conditions occur in the fasteners. When the fitting is embedded in concrete and does not utilize a bolted connection the fitting will generally fail by cracking in areas of high tensile stress or excessive bearing stress. It has been observed that some failures of mooring hardware do not result from mooring line loads. These failures result from overload due to vehicular impact, cranes accidentally setting loads upon the fitting, and other miscellaneous incidents. This type of failure should be observed prior to conducting a load test and should be grounds to abort the test. Mooring hardware with obvious distress must be taken out of service immediately.

Failure under load test is generally associated with corrosion of the fasteners or failure of the supporting structure. The following methods should be used for detection of failure:

- Visual observation of distress or movement.
- Measured permanent yielding or displacement following release of test loads.
- Observation of cracking.

A-5 METHODS.

A-5.1 General.

The purpose of a hardware test is to ensure that the mooring hardware is capable of holding its design load. If a mooring fitting fails, take out of service immediately and replace or repair as soon as possible. Several general methods exist to test fittings:

A-5.1.1 Pull Testing.

There are four methods of pull testing:

- Pull test with a test rig, which may include jacking equipment.
- Pull test with a land-based crane or winch.
- Pull test with a water-based crane or winch.
- Pull test similar mooring hardware one-against-the-other to test two pieces of mooring hardware at once using weight handling equipment to apply the load.

A-5.1.2 Bolt Testing.

Fasteners transmit the load to the structure and are often the critical component in many fittings. Therefore, consider testing the bolts in lieu of testing the entire hardware if the mooring fittings are in good condition. Bolts act in tension and shear to resist loads applied to mooring fitting. Since most mooring fittings are set in a grout or concrete base and have shear keys integral with the fitting, most of the shear stresses are resisted by the concrete or grout base. This is not the case on structures constructed of timber or steel where all loads are resisted by the fasteners. If the fitting is set in concrete, the fasteners need only to be tested in tension. In cases such as timber structures or steel structures, the fasteners are readily accessible and can be removed for inspection, eliminating the need for in-situ load test. Bolts that have their anchorage in concrete should be load tested in tension using the procedures outlined in ASTM E 488, S*tandard Test Methods for Strength of Anchors in Concrete and Masonry Elements*. Ultrasonic or other non-destructive testing may also be utilized before pull testing to detect voids, cracks, corrosion, and other discontinuities along the bolts. It should be noted that tension and testing of fasteners will not provide a comprehensive indication of load capacity of the system.

The bolt testing procedure is:

- Remove the grout and nuts from the bolts.
- Pull-test each bolt to 110% of its working load using a pull test rig. The pull test procedure must follow the procedure for testing anchors described in ASTM E 488, Standards Test Methods for Strength of Anchors in Concrete and Masonry Elements.
- If test is successful, reinstall the nuts and grout to the design condition.
- If bolt fails, take out of service and replace as soon as possible.

A-5.2 Results.

Load testing results are reported on the form provided in Figure A-1. Remove any mooring hardware that does not pass the pull test and plan and allocate resources for appropriate replacement.

A-5.3 Levels of Load Testing.

- Level I - Bolt pull test (tension). Bolts are tested individually to determine tensile strength of the bolt and anchorage.
- Level 2 - Indirect line load. Mooring fittings are pull-tested with actual line force but not in actual direction of mooring line due to cost and convenience, e.g., bollard-to-bollard pull. This level of testing will confirm the strength of the mooring hardware system including the casting, fasteners, and structure.
- Level 3 - Load applied in actual direction of mooring line force. This will confirm the working load of the entire system including base structure, anchor bolts, and fitting.

A-5.4 Testing Procedure.

A-5.4.1 Test Prerequisites.

Area adjacent to fitting to be tested should be open and clear of vehicles, vessels, or other equipment and associated personnel.

A-5.4.1.1 Prior to Testing.

Prior to testing, a review should be conducted of the test equipment by qualified personnel to determine its adequacy for the loads to be applied.

A-5.4.1.2 Fittings.

Fittings should not exhibit outward signs of distress or failure prior to conducting a load test.

A-5.4.2 Test Preparation – General.

A-5.4.2.1 Testing Personnel.

Testing personnel should provide test rigs, jacks, pumps, wire rope rigging, surveying instruments for measuring deflection and movement (such as an optical level or a total station), chain falls and dynamometer, and all subject matter expertise as required to perform the test.

A-5.4.2.2 Precautionary Measures.

Precautionary measures should be taken to prevent damage to the fitting, dock structure, or fender system. Lumber blocks, sheet copper, etc. should be provided to prevent chafing and rope burns as necessary. Where needed, rubber padding should be provided to absorb and distribute point loads on concrete.

A-5.4.2.3 Monitoring Points.

Monitoring points should be established on the fitting or fastener to track movement under load. Movement should be recorded in the three principal axes. A reference point independent of the fitting or fastener and its foundation should be established to find movement. Surveying methods can be employed to track movement from a safe distance. A target could be affixed to the fitting and readings taken (X, Y, Z) during the test.

A-5.4.2.4 Base.

The strip of concrete surrounding the base plate of each fitting and the surface of the free edge of the concrete in front of the fitting must be visually inspected for shear cracks. To aid in the detection of potential shear cracks, it is recommended that an approximately 1 ft (0.3 m) wide strip surrounding the base plate and the surface of the free edge of the concrete in front of the fitting, be painted with whitewash or light-colored brittle paint.

A-5.4.3 Test Precautions.

A-5.4.3.1 Standards.

Perform all work operations in accordance with the safety standards identified in APPENDIX C (such as U.S. Army Corps of Engineers EM-385-1-1 and OSHA Standards). Provide U.S. Coast Guard (USCG) approved life jackets or buoyant work vests to employees working over or near water, where the danger of falling into the water and/or drowning exists. Evaluate the requirement for the use of personal floatation devices (PFDs) on piers, taking into consideration falling/tripping hazards, proximity to edge, obstacles/obstructions, availability and placement of life rings with lines, access ladders, etc. Follow site specific weight handling equipment safety rules as required.

A-5.4.3.2 Provisions.

Provisions should be made for keeping personnel not involved in the test clear of the test site and any danger areas.

A-5.4.4 Test Procedure.

A-5.4.4.1 Horizontal Pull.

Using the test rig, chain falls, dynamometer, etc. and a wire rope pendant, begin by exerting a pull equivalent to 10% of the rated load capacity for the mooring fitting or fastener. Application of the load should be 4 in. (102 mm) below the lip, horn, or other line holding device on fittings. Increase the load incrementally, in 10% steps or as directed by the test engineer. Hold each incremental load for one minute or as directed by the test engineer, monitoring for deflection, movement, and other failure modes. Increase to a final load of 110% of the rated load capacity. The 110% load should be held for 10 minutes. At the end of 10 minutes, the fitting or fastener should be examined for any evidence of failure and any deformation, movement, or other failure modes recorded. Slowly remove the load from the fitting after recording all information.

The results should be recorded on the load test record sheet.

A-6 REPORTING.

All results of testing should be recorded on the deck fitting load test record shown in Figure A-1 or a similar record sheet. These records should be included in the report described in Section 5 of this document.

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	Date	Location

This UFC supersedes MO-124, dated August 1987.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
NEW SUMMARY SHEET

Document: UFC 4-150-09, *Permanent Anchored Moorings, Operations and Maintenance*

Superseding: MO-124, Mooring Maintenance Manual, August 1987
FPO-1-84(6), Fleet Mooring Inspection Guidelines, 1984
FPO-1-88(40), Fleet Mooring Buoy Surface Inspection Guidelines, December, 1988
NAVFAC P-1110, Fleet Mooring Handbook

Description: The UFC 4-150-09, *Permanent Anchored Mooring, Operations and Maintenance* represents another step in the joint Services effort to bring uniformity to the maintenance and operations of moorings. This UFC contains extensive modifications in the following areas:

- Inclusion of lessons learned from past operations
- The use of commercial, industrial and offshore industry standards where appropriate
- Updating, conversion and combining of several NAVFAC manuals and local command guidelines to a more uniform format and a document to be used by all services with general updates and revisions

Reasons for Document:

The existing guidance was inadequate for the following reasons:

- Need to convert to UFC format
- Incorporation of changes described above
- Update to referenced documents

Impact:

The following direct benefits will result from the update of UFC 4-150-09, *Permanent Anchored Moorings, Operations and Maintenance*

- Although primarily a U.S. Navy document, a single, comprehensive, up to date criteria document exists to cover mooring operations and maintenance.
- Eliminates misinterpretation and ambiguities that could lead to conflicts.
- Facilitates updates and revisions and promotes agreement and uniformity of design and construction between the Services.

Unification Issues:

- There are no unification issues.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

This UFC provides requirements, guidance and procedures for operation and maintenance of permanent anchored moorings for U.S. Department of Defense (DoD) vessels. This manual provides important technical data, information and recommended procedural guidelines for the operation, inspection, maintenance, repair, removal and refurbishment. This document will supersede all the documents and drafts of documents currently being used to conduct inspections, maintenance and repairs of fleet moorings, such as the NAVFAC P-1110 Fleet Mooring Handbook, FPO-1-84(6) Fleet Mooring Underwater Inspection Guidelines, NAVFAC MO-124, Mooring Maintenance Manual, etc. OPNAVINST 5450.348 states NAVFACENGCOM serves as the technical authority responsible for permanent anchored “fleet” moorings for the U.S. Navy.

1-2 PURPOSE AND SCOPE.

This UFC provides requirements, guidance and procedures for operation and maintenance of permanent anchor moorings for U.S. Department of Defense (DoD) vessels. This manual provides important technical data, information and recommended procedural guidelines for the operation, inspection, maintenance, repair, removal and refurbishment.

A mooring is any structure whose purpose is to restrain a ship’s movement and keep it in a relatively fixed location. A mooring is of two general types, fixed moorings and compliant anchor moorings. Fixed moorings are defined as a system that includes both tension and compression members. These systems include facilities like piers and wharves, the components that connect the vessel to the fixed facility (lines, chain, etc.) as well as the fendering used to protect the vessel from damage due to contact with the facility. Compliant anchor moorings are defined as a stationary system that includes primarily tension members with mooring loads transferred into the earth via anchors. Active ship’s anchor systems are excluded. This manual only addresses compliant anchor moorings, but many of the procedures described here are applicable to the inspection and maintenance of fixed mooring systems or their components.

This document standardizes mooring inspection procedures for both surface and underwater inspection and assist inspection personnel by describing the various typical permanent anchor mooring types and materials used and defining what should be accomplished before, during and after a mooring inspection. Also defined are the types of data and documentation that must be gathered and captured in the inspection report. The inspection’s Engineer-in-Charge (EIC) will evaluate the inspection data and provide an assessment of the mooring’s condition to meet its design requirements.

The document provides the inspector with a standard inspection template for the inspection of a mooring system, a sample preliminary inspection results email, a sample inspection report, inspection checklist, details of go no-go gauges and other inspection tools, and guidance on surveying of permanent anchor mooring buoys and anchors.

This document provides guidance for the maintenance and repair of the moorings based on the results of the inspection.

1-3 APPLICABILITY.

The information presented in this manual is applicable to planners, quality assurance and quality control personnel, supervisors and technicians who are involved in DoD mooring operations, inspections, and maintenance.

Planners can use this information to assist in developing budgetary input, inspection schedules and maintenance and repair schedules. The information will be useful in preparing specific plans for each major task and evolution in the life cycle of a mooring system.

In addition to safety, Quality Assurance (QA) and Quality Control (QC) must be the paramount consideration in the execution of every phase of the operation of a mooring system. The information will assist QA personnel in determining the number and type of checks and inspections that must be performed to ensure that the stringent quality control procedures are adhered to. QC personnel will find the information useful for identifying test equipment and procedures and personnel qualifications necessary to meet the requirements of the QC plan.

Supervisory personnel will use the information to assist in selection equipment and qualified personnel for each task and in executing each task in the safest and most efficient manner possible.

Technicians will find the manual useful as a training tool and a useful reference.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code (General Building Requirements)*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 BEST PRACTICES.

APPENDIX A provides documentation on Best Practices to be used during the operations, inspections, maintenance and repair of mooring systems. Included in this appendix is a section on Safety.

1-6 GLOSSARY.

APPENDIX M contains acronyms, abbreviations, and terms.

1-7 REFERENCES.

APPENDIX N contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

This Page Intentionally Left Blank

CHAPTER 2 TECHNICAL REQUIREMENTS

2-1 PERMANENT ANCHOR MOORINGS.

2-1.1 Compliant Anchor Mooring Systems.

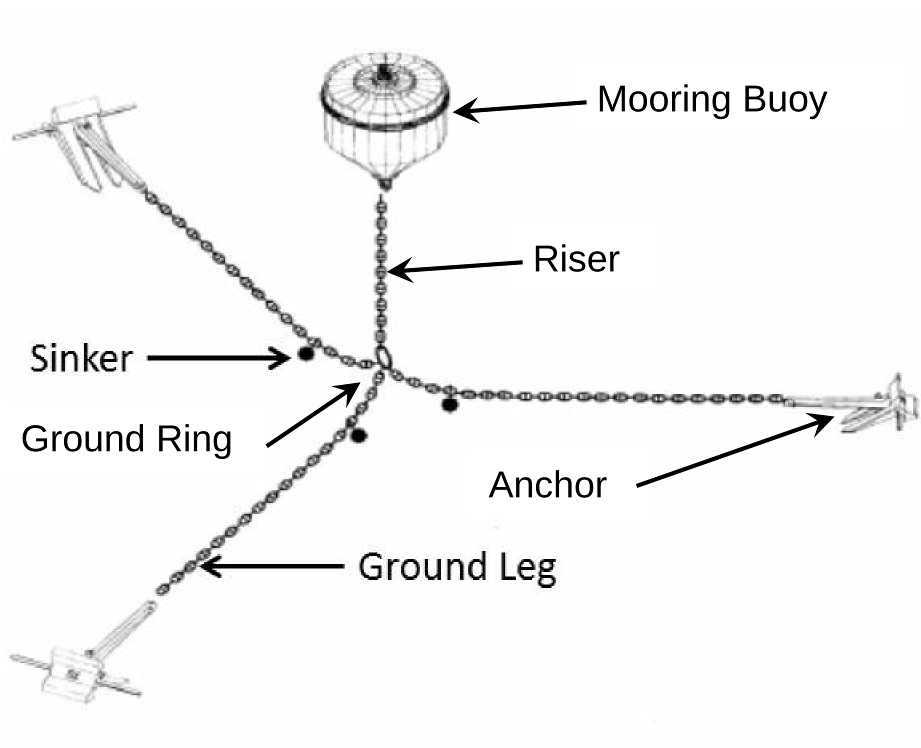
A compliant anchor mooring is used to provide temporary or permanent berthing for vessels in ports and harbors where pier space is limited or unavailable or in the open ocean. The most common moorings consist of one or more buoy systems. A buoy system includes the surface mooring buoy, the attendant chain, the anchor(s), the fittings, and the accessories. There are mooring systems that do not require a surface mooring buoy. Buoy and non-buoy mooring systems are described in subsequent paragraphs of this chapter. The complete mooring is defined by type and by classification, regardless of the existence of a surface mooring buoy. Type refers to the physical configuration of the mooring and classification refers to the holding capacity. There are several basic types of mooring systems, each serving a specific purpose and each offering advantages and disadvantages. The most commonly used mooring arrangements are discussed below.

2-1.1.1 Single Point (Free Swinging) Mooring System.

A single point mooring (SPM) system consists of a single buoy or attachment point to which a ship may moor. This single point of attachment permits the ship to swing freely and weathervane in response to environmental loading such as wind and currents. Single point moorings consist of an attachment point (in most cases a buoy), a riser assembly and either one or multiple ground leg assemblies. Most SPM systems used by the Navy have a buoy, a riser assembly with three ground legs attached to the riser by a ground ring and equally separated from each other (Figure 2-1). Ground legs can be secured to the seafloor by a variety of anchoring assemblies including gravity anchors, drag anchors, stake piles or embedded plate anchors. The single point mooring, having only one surface attachment point, minimizes material requirements, installation effort, and maintenance requirements.

The major disadvantages of this type of mooring are the large amount of real estate required by the moored vessel and the possibility of the vessel "fishtailing" or "horsing" about the buoy. A free-swinging mooring must be sufficiently clear of shoreline, shoal waters, structures, and other moorings. This will allow the moored ship to swing freely about the mooring, without interference, as it responds to the weather conditions.

Figure 2-1 Riser-Type Single Point Mooring



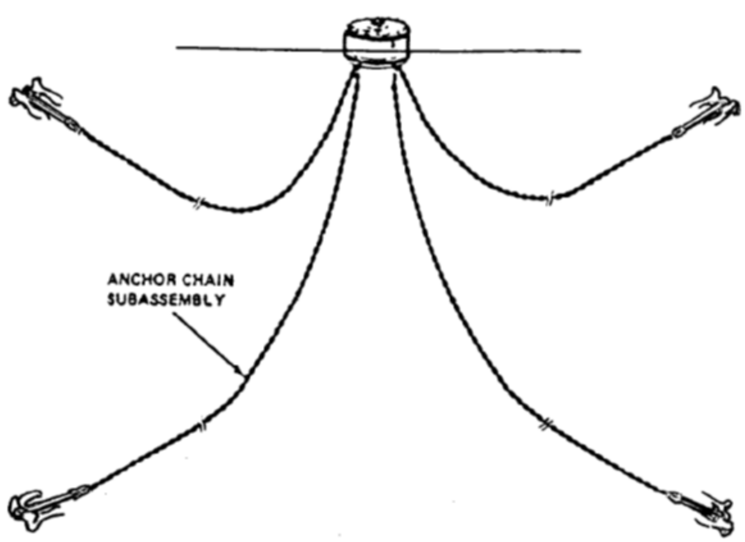
Single point moorings have three mooring configuration types. One type is the “Riser-Type” mooring with a buoy, a riser assembly and three ground legs attached to the riser by a ground ring, equally separated from each other as shown in Figure 2-1. Many single point moorings in the fleet mooring program are configured as a riser-type mooring. The riser-type mooring is preferred because it allows the ship to moor with a short hawser and not risk any damage to its hull by rubbing against a chain.

The second configuration type is the single riser-leg type mooring where a single chain assembly acts as both the riser and ground leg and is connected to either a plate anchor or in special cases, another type of anchor assembly. Figure 2-2 shows a Single Riser Leg Mooring. Most single riser-leg moorings in the Navy are secured to an embedded plate anchor and are used to create a spread moor (Paragraph 2-1.1.3 and Figure 2-5).

Figure 2-2 Single Riser Leg Mooring

The third configuration type is the “non-Riser” type mooring. In the non-Riser type mooring, the ground legs are attached directly to padeyes or chain capture devices on the buoy. These moorings do not permit the buoy to rotate and can be used to bring up electrical power or signal (telephone) cables or fuel lines to the ship. Although these moorings have the largest holding capacities, ships must be careful when mooring to them. A ship that is moored too closely, risks damaging its hull with the chain that is suspended in the catenary. There are some moorings within Department of Defense that utilize a non-riser type mooring. Figure 2-3 shows a Non-Riser Mooring.

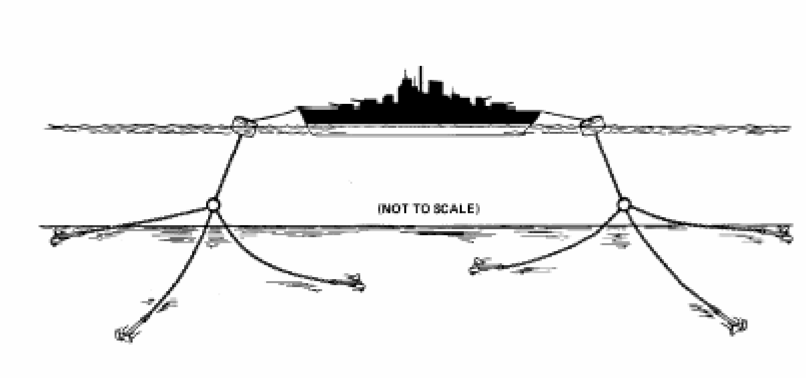
Figure 2-3 Non-Riser Mooring



2-1.1.2 Bow and Stern Mooring System.

A bow and stern mooring system provides two surface points to which a ship may attach its fore and aft mooring lines (Figure 2-4). Bow and stern moorings consist of two single point mooring systems. Most bow and stern moorings have two single point riser-type moorings consisting of a mooring buoy, a riser assembly and two ground leg assemblies.

Figure 2-4 Bow and Stern Mooring

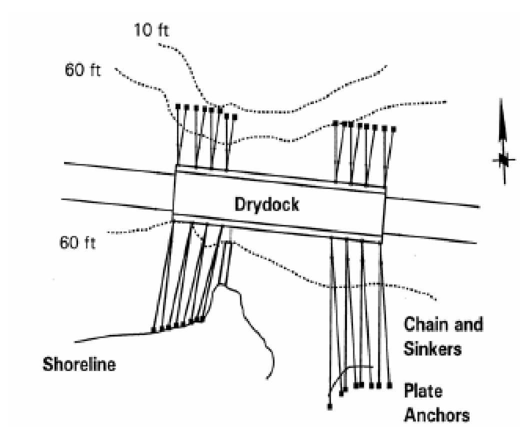


This type of mooring is designed to maintain the orientation of the moored ship into the prevailing currents and requires less area than a single point mooring. The major disadvantage of a bow and stern mooring is that each leg of the mooring usually must have a greater holding capacity than a single point mooring to resist strong loads imposed on the mooring legs by broadside winds.

2-1.1.3 Spread Mooring.

A spread mooring system (Figure 2-5) is installed to moor a single ship or cluster of ships in a fixed position for a long period of time. This system is used primarily to provide berthing for inactive ships or to moor floating dry-docks.

Figure 2-5 Spread Mooring



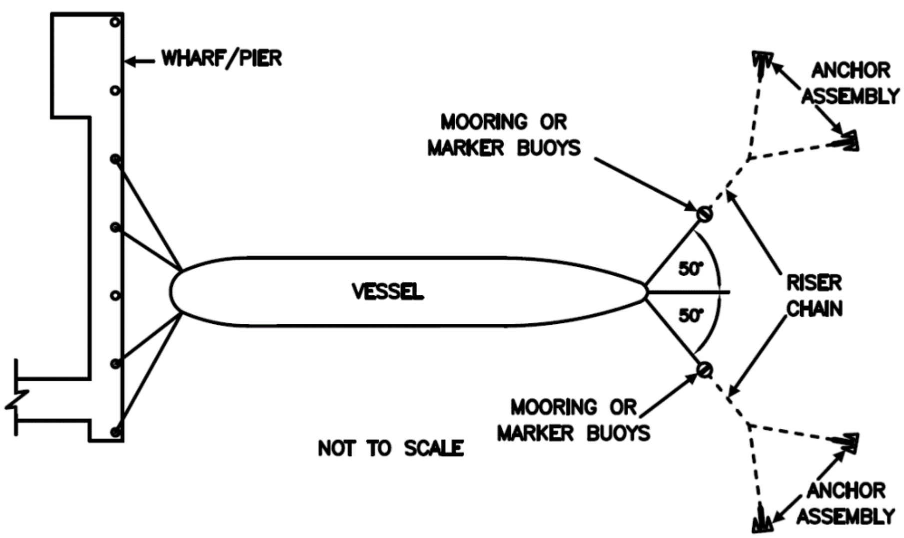
A spread mooring consists of four or more single point moorings installed in a specified pattern to provide multiple attachment points for the moored vessel(s). Single point moorings within a spread mooring may or may not have a buoy for an attachment point. Ship chains are either attached to the buoy or directly to the mooring's riser.

2-1.1.4 Mediterranean Mooring.

A Mediterranean mooring (Med-moor) is similar to a bow and stern mooring. The vessel is oriented perpendicular to a wharf or pier, or parallel, centered and in line with the end of a pier. The stern is generally secured to shore fittings on the pier or wharf. The bow of the vessel is secured using mooring chains to buoy attachment points provided on two single point moorings (Figure 2-6).

The moorings consist of a buoy, a riser-leg or multiple ground legs secured to a common riser with a ground ring. Under normal circumstances, ground legs for the bow moorings in a Med-moor are secured by either multiple drag anchors or a buried large deadweight anchor.

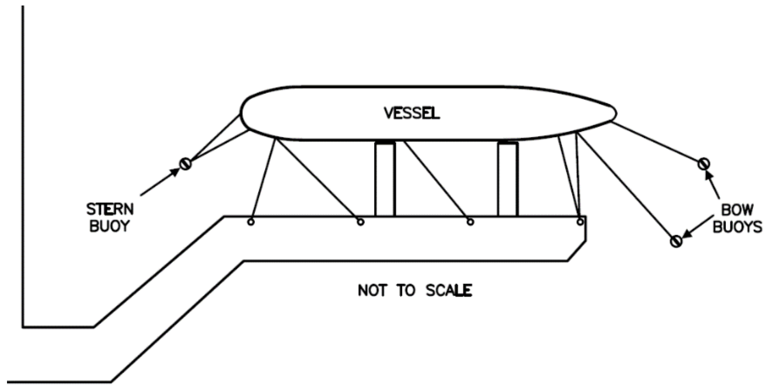
Figure 2-6 Mediterranean Mooring



2-1.1.5 Buoy Dolphins Mooring.

Single point moorings acting as mooring dolphins are installed to provide bow and stern attachment points for a ship moored alongside a short pier or to one or more finger piers (Figure 2-7). Single point moorings with buoy are used instead of permanent concrete or timber dolphins. The length of the ship that may moor to the buoy dolphins is limited by the distance between the buoys.

Figure 2-7 Buoy Dolphin Mooring System



2-1.2 Mooring Systems Assemblies.

2-1.2.1 Buoy Assembly.

The buoy assembly consists of the buoy and the top jewelry (to connect the vessel to the mooring buoy. See the descriptions of the various components in Section 2-2.

2-1.2.2 Riser Assembly.

The riser assembly connects the ground ring to the buoy. It consists of chain (or other tensile strength member) and all the connecting hardware used to connect the riser to the buoy (usually including a riser swivel shackle) as well as to connect the riser to single or multiple ground leg assemblies (usually an anchor joining link and a ground ring). See the descriptions of the various components in Section 2-2.

2-1.2.3 Ground Leg Assembly.

Ground leg assemblies consist of the chain (or other tensile strength member) and associated hardware to connect the anchor to the ground ring. Sinkers may also be used on the ground legs to help minimize or reduce the dynamic loads put on the mooring system by the moored vessel. See the descriptions of the various components in Section 2-2.

2-1.2.4 Riser Leg Assembly.

Riser leg assemblies consist of the chain (or other tensile strength member) and associated hardware to connect the buoy directly to the anchor assembly. Sinkers may be used on the ground legs to help minimize the dynamic loads put on the mooring system by the moored vessel. See the descriptions of the various components in Section 2-2.

2-1.2.5 Anchor Assembly.

The anchor assembly consists of the anchor that holds the system in place, and the hardware to connect the anchor to the ground leg or riser leg assembly. See the descriptions of the components in Section 2-2.

2-1.2.6 Cathodic Protection Assembly.

This assembly helps prevent corrosion of the mooring system by providing zinc anodes to corrode before the steel in the mooring system. Anodes are usually attached to each chain link as well as to the bottom of the buoy’s attachment padeye. See the descriptions of the components in Section 2-2.

2-2 MOORING COMPONENTS.

2-2.1 Mooring Buoys.

Mooring buoys are classified based on their shape and their construction. The type of buoy used in a mooring depends on the mooring's rated capacity and the method of attachment used by the serviced vessel. Buoys are generally equipped with a center tension bar which provides a lower padeye attachment for the mooring riser and an upper padeye attachment for an anchor bolt shackle where connecting hardware to secure the vessel is attached to. Buoys may also be equipped with a hawse pipe that allows the riser chain to pass through the center of the buoy and be the attachment point for connecting hardware to secure the vessel. Both of these two styles are designed for riser-type moorings.

Buoys may also be designed to attach directly to multiple ground legs. These buoys are prevented from rotating by the attached ground legs. These types of buoys are used when electrical power wires, communication wires or fuel hoses are being brought up to vessel from the sea floor. One would find this type of buoy on a non-riser type mooring system.

A buoy's size depends primarily on the weight of the mooring system it must support in the water column. The following types of buoys are utilized.

Peg-Top Buoys – Peg-Top buoys have bottoms that are conical in shape and upper vertical sides, similar to the drum buoy. The buoy serves to support a riser type system. They may have either a tension bar or a hawse pipe design. They may be coated with either a standard ship paint, a fiberglass coating or a polyurethane coating. Peg-Top buoys can be manufactured of steel or of foam encapsulating steel core and covered by an outer nylon reinforced urethane shell.

Drum Buoys – Drum buoys are so called because of their resemblance to the shape of a drum. Drum buoys are available in a variety of sizes and are used to support a riser type buoy system, having a hawse pipe or tension bar through them. They may be coated with either a standard ship paint, a fiberglass coating or a polyurethane coating.

Drum buoys can be manufactured of steel or of foam encapsulating steel core and covered by an outer nylon reinforced urethane shell.

Non-Riser Type Buoys – Non-riser type buoys are also shaped like a drum but have no hawse pipe or tension bar. Instead, they have padeyes or chain capture devices equally spaced around the bottom perimeter of the hull for attaching ground leg chains and have a swivel fitting on the top to support the top jewelry. These buoys are generally larger than riser-type buoys because of the added weight of the several chains they must support in the water column and because they are a load-bearing member of the mooring system. Non-riser buoys are also known as "telephone buoys".

Spherical Buoys – Spherical buoys are normally used only to mark and retrieve the riser chain of a mooring system. Ships attach their mooring hardware directly to the riser chain rather than to the buoy. The most commonly used spherical buoy is of steel construction, 54 inches (1.37 m) in diameter and may be foam filled.

2-2.1.1 Foam Buoys.

The foam buoy (Figure 2-8) is a buoy encased in rigid, closed-cell foam that is covered by a flexible crossed-linked polyethylene foam bonded to the rigid interior foam. The entire foam assembly is then encased in a urethane elastomer (Figure 2-9). Two sizes of foam peg-top buoys are primarily stocked in the Fleet Mooring Program; 8-foot (2.44 m) diameter (referred to as a small foam buoy) and 11.5-foot (3.51 m) diameter (referred to as a medium foam buoy). General data is provided in Table 2-1.

Figure 2-8 Foam Buoy

Figure 2-9 Foam Buoy Cross Section

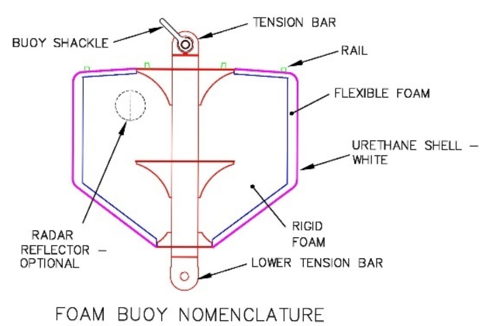


Table 2-1 Foam Buoy Data

PARAMETERS	8 ft BUOY	11.5 ft BUOY
Size	Small	Medium
Weight in Air	4,500 lbs (2,041 kg)	10,400 lbs (4,717 kg)
Net Buoyancy	15,000 lbs (6,804 kg)	39,000 lbs (17,690 kg)
Working Buoyancy (24 inch freeboard)	6,150 lbs (2,790 kg)	20,320 lbs (9,217 kg)
Reserve Buoyance (24 inch freeboard)	8,850 lbs (4,014 kg)	18,680 lbs (8,473 kg)
Proof Load on Tension Bar	300,000 lbs (1,334 kN)	600,000 lbs (2,669 kN)
Working Load on Tension Bar	150,000 lbs (667 kN)	300,000 lbs (1,334 kN)
Diameter Overall (w/fenders)	8 ft 6 in (2.591 m)	12 ft (3.658 m)
Diameter of Hull	8 ft (2.438 m)	11 ft 6 in (3.505 m)
Length of Hull Overall	7 ft 9 in (2.362 m)	8 ft 9 in (2.667 m)
Length of Tension Bar	11 ft 4 in (3.454 m)	13 ft 1 in (3.988 m)
Height of Cylindrical Portion	4 ft 4 in (1.321 m)	5 ft 7 in (1.702 m)
Height of Conical Portion	3 ft 5 in (1041 mm)	3 ft 2 in (9652 mm)
Bar Thickness (top/bottom)	4.5/3 in (114/76 mm)	5/3.5 in (127/89 mm)
Padeye ID (top/bottom)	3.5/3.5 in (89/89 mm)	4.5/5 in (114/127 mm)
Shackle on Top	3 in	4 in
Maximum Chain Size	2.75 in	4 in
Minimum Recommended Riser Weight	1,068 lbs (484 kg)	7,500 lbs (3402 kg)
Riser Weight for 24 inch Freeboard	8,850 lbs (4,014 kg)	18,680 lbs (8,473 kg)
Maximum Recommended Riser Weight	7,500 lbs (3,402 kg)	21,264 lbs (9,645 kg)
Moment to Heel 1 degree (Min Riser Wt)	108 ft-lbs (14.9 m-kg)	1,183 ft-lbs (163.6 m-kg)
Moment to Heel 1 degree (Max Riser Wt)	648 ft-lbs (89.6 m-kg)	2,910 ft-lbs (402.3 m-kg)

A foam buoy is superior to a steel buoy for a number of reasons:

- It will not flood or sink if the outer shell is punctured, see Figure 2-10;
- It is considerably lighter than the steel buoy that would be required to support the equivalent weight of chain in the water column;
- It requires significantly less preventive and corrective maintenance, resulting in lower projected operation and maintenance (O&M) costs than for a steel buoy;
- The resiliency of the foam greatly reduces the probability of damage to a vessel from a collision.

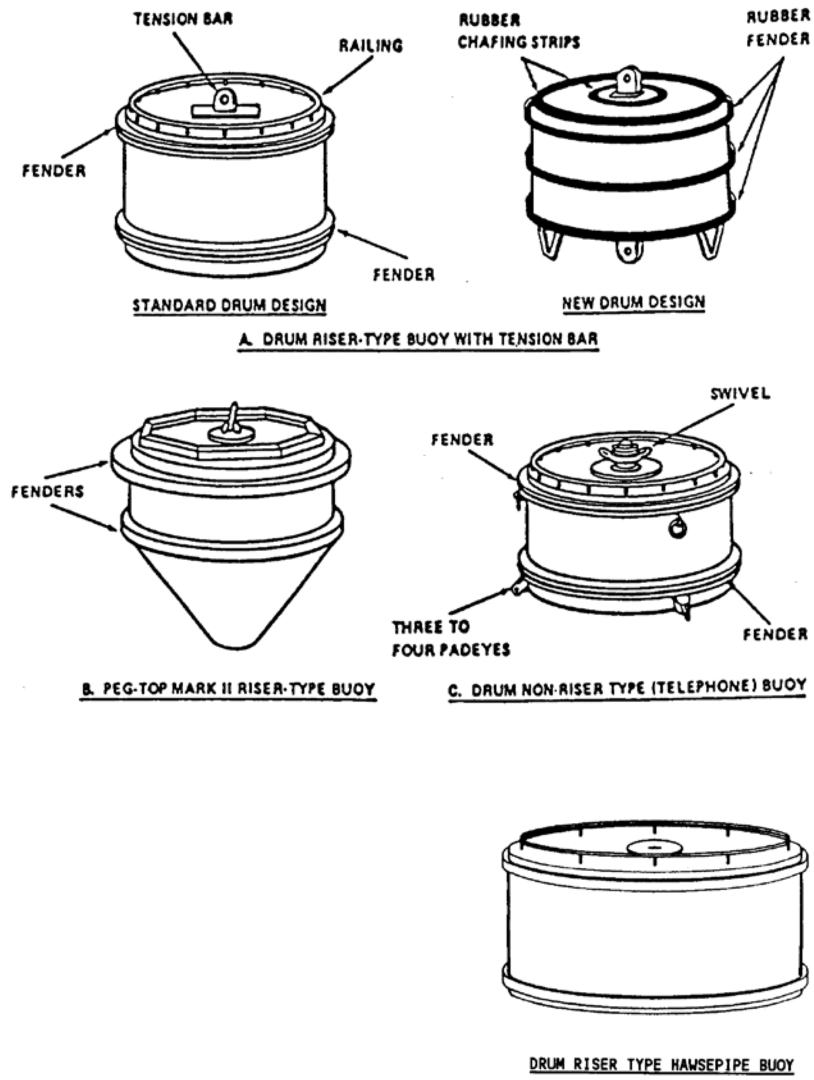
The working buoyancy is the amount of weight the buoy can support and still maintain a 2-foot freeboard above the deck line (when level). The deck line of a buoy is at the elevation on the buoy top shell where the top deck transitions to the buoy sides. For the buoys listed in Table 2-1, the deck line is at the bottom of the outer chafe rail.

Figure 2-10 Punctured Foam Buoy

2-2.1.2 Steel Buoys.

Older riser type buoys were fabricated out of steel. Like the foam buoys, most steel buoys have either a tension bar or a hawse pipe to bring the mooring load from the vessel to the chain/anchors. All non-riser buoys have been constructed of steel. See Figure 2-11 for various types of steel buoys.

Figure 2-11 Steel Buoys



Note:

All efforts should be made to replace steel buoys with foam buoys since steel buoys are much more difficult to inspect and maintain. Steel tension bar buoys can still be used, but hawse pipe buoys shall be taken out of service, disassembled and disposed of in accordance with local steel recycling programs.

2-2.1.3 Buoy Accessories.

2-2.1.3.1 Chafing Strips.

Chafing strips are heavy, molded rubber strips attached to the buoy at the top edge and around the top jewelry to prevent wear in the areas where the ship's mooring chain or hawser may drag against the buoy. Additionally, chafing strips provide both foot and hand hold points for operators. Not all buoys are equipped with chafing strips. Standard small and medium foam buoys have urethane chafing strips integrally casted as part of the outer shell or attached to the buoy's shell.

2-2.1.3.2 Rails.

Some steel buoys have rails attached to the outer perimeter of the top of the buoy to serve the same purpose as chafing strips. The rails are usually made of steel. Recent foam buoy procurements are using either D-rubber toe rails or cast elastomer toe rails in lieu of urethane chafing strips used for the standard Fleet Mooring foam buoy.

2-2.1.3.3 Fenders.

Fenders are installed in one or more rows around the circumference of the buoy's sides to absorb the shock of collision and prevent damage to the buoy hull. Fenders may be wood, rubber or a combination of the two materials. The fenders may be may be connected to steel buoy using studs, welded brackets (segmented or continuous) or metal retaining bands. Standard small and medium foam buoys have a single fender that is integrally casted as part of the outer shell (sometimes referred to as a rub rail).

2-2.1.3.4 Reflective Markings.

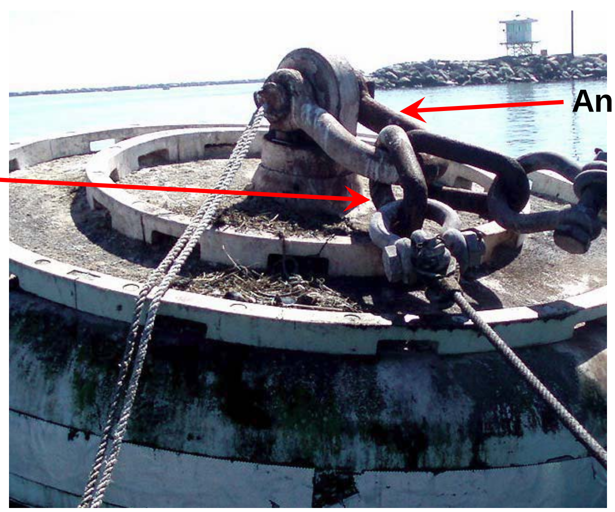
Mooring buoys are painted white or are coated with a white material. However, to make them more visible at night, one or more rows of reflective tape is bonded to the circumference of the buoy's sides. Mooring buoys within the Navy's restricted zone generally have white reflective tape. Mooring buoys in other locations will have reflective tape conforming to the cognizant USCG authority. Figure 2-12 illustrates a buoy with two strips of reflective tape.

Figure 2-12 Reflective Tape on Foam Buoy

2-2.1.3.5 Top Jewelry.

Top jewelry is the fitting or fittings attached to the chain or the tension bar padeye on top of the buoy. Top jewelry serves as the transition piece from the installed mooring system to the ship's mooring hawser or chain. Standard top jewelry has become an anchor bolt shackle and two pear links (Figure 2-13).

Figure 2-13 Top Jewelry on a Buoy



2-2.1.3.6 Buoy Lighting.

The lighting requirements will be specified by the United States Coast Guard (USCG) on the approved Aids to Navigation Application. If buoy lighting is required, it must be maintained by the custodian. See Figure 2-14.

Figure 2-14 Buoy Light

2-2.2 Anchors.

The most commonly used anchoring systems are either direct embedment anchors or drag-embedment anchors. Embedment anchors, by design, are installed below the seafloor and are not visible for inspection. The most common direct embedment anchors used by the Navy are plate anchors. Other direct embedment anchors include pile anchors and propellant embedment anchors (PEA). As of 2010, no PEA anchors are in service for U.S. Navy moorings.

The most common drag-embedment anchors found are either the Navy stockless anchor or the high capacity NAVMOOR anchor. Other types of drag embedment anchors that may be found include the NAVFAC STATO anchor and LWT anchor. Drag embedment anchors are generally not visible for inspection since they will tend to bury themselves during proof loading of the ground legs during installation. However, in hard rocky or even dense sand seafloors, they may be partially or completely visible for inspection.

Other anchor types that are found are deadweight or gravity anchors. Though they can be shaped to aid the anchor in digging into the soil and may be jetted into the seafloor during installation, they primarily resist mooring forces through their large submerged weight.

2-2.2.1 Direct-Embedment Anchors.

2-2.2.1.1 Plate Anchor.

Plate anchors can be used in place of the much larger and costlier pile anchor or a standard drag anchor. Like a pile anchor, installation equipment is composed of standard pile driving barges and hammers. The plates are driven into the soil using a follower that is removed when the anchor reaches proper depth. Plate anchors can be used in soils with poor engineering properties or where there is not enough room for the long legs of a typical drag anchor mooring. Plate anchors have been proven to hold well in soils that are not good candidates for drag anchors, such as coral limestone and hard glacial till. Figure 2-16 shows a picture of a plate anchor and Figure 2-15 provides a schematic of how to install a plate anchor.

Figure 2-15 Plate Anchor Installation Schematic

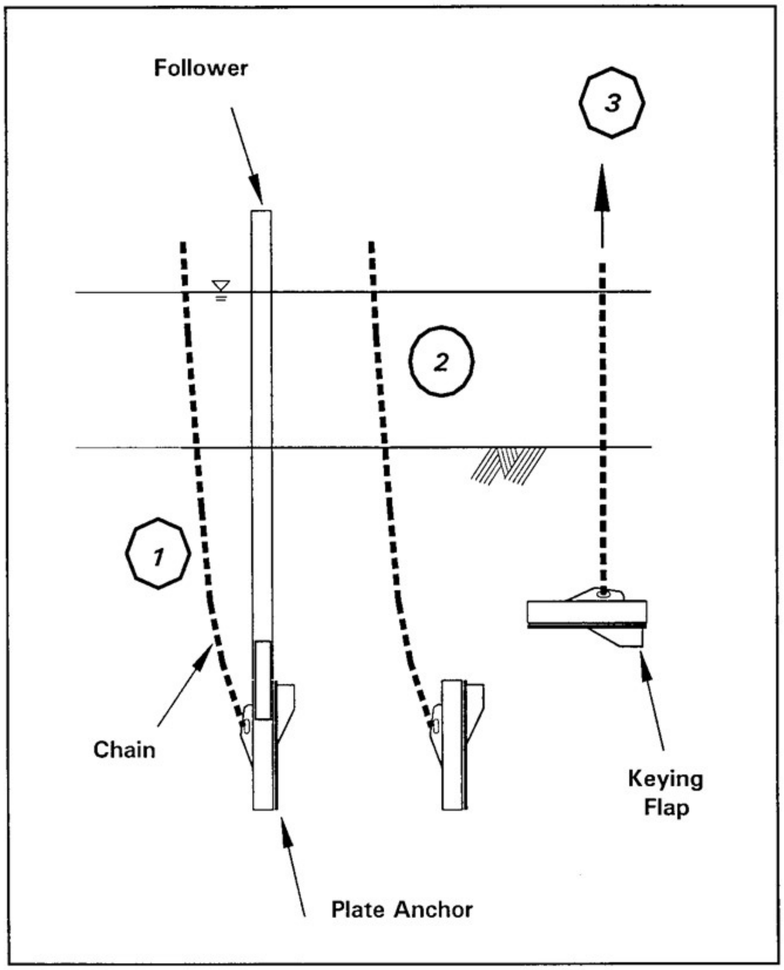


Figure 2-16 Plate Anchor

2-2.2.1.2 Pile Anchor.

Pile anchors are fabricated from structural steel shapes, such as H beams, or pipes with appropriate attachment points for connecting the ground leg chain. Pile anchors are installed by driving, drilling and grouting, or other underwater construction methods. Pile anchors can resist large uplift forces or horizontal forces from various directions and are generally installed in bottom soils characterized by stiff clays or medium to dense sands. Pile anchors develop holding power as a result of the surface friction of the soil in which they are driven.

2-2.2.1.3 Propellant-Embedment Anchor (PEA).

PEAs are composed of a plate anchor attached to wire rope pendants. During installation, the PEA fluke is fitted to a reaction vessel that houses a cannon barrel. When the reaction vessel touches the seafloor, the explosive charge in the barrel explodes, embedding the fluke into the bottom. PEAs usually have a wire rope to chain connector. Due to environmental concerns, life cycle of the wire pendant and training of operators, PEA anchors are no longer installed by the Navy. All existing Navy moorings utilizing PEA anchors have been either disestablished or replaced with mooring systems that utilize another type of anchoring system.

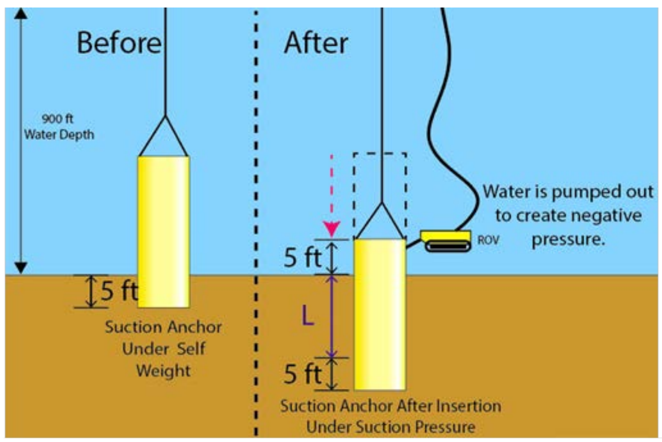
2-2.2.1.4 Suction Anchor.

A suction anchor can effectively be described as an upturned bucket that is embedded in the marine sediment. This embedment is achieved by creating a negative pressure inside the anchor skirt; securing the anchor into the seabed. The foundation can also be rapidly removed by reversing the installation process, applying an overpressure inside the anchor skirt.

The concept of suction technology was developed by the oil and gas industry for projects where gravity loading is not sufficient for pressing foundation skirts into the ground. The technology was also developed for anchors subject to large tension forces due to waves and stormy weather. The suction anchor technology functions very well in a seabed with soft clays or other low strength sediments. The suction anchors are in many cases easier to install than piles, which must be driven (hammered) into the seabed. Mooring lines are usually attached to the side of the suction anchor at the optimal load attachment point, which must be calculated for each anchor. Once installed, the anchor acts much like a short rigid pile and is capable of resisting both lateral and axial loads.

Suction anchors have not been used in Navy moorings but their existence should be recognized and they may be used in the future. See Figure 2-17.

Figure 2-17 Suction Anchor



2-2.2.2 Drag-Embedment Anchors.

There are many types of drag embedment anchors in existence. Navy Stockless and NAVMOOR anchors are the most common used in Navy moorings and are currently stockpiled by the Fleet Mooring Program. This document will limit its description to those two types of anchors.

2-2.2.2.1 Navy Stockless Anchor.

This type anchor is a drag-embedment anchor, ranging in size from 5,000 to 40,000 pounds (22 to 178 kN). Navy stockless anchors are used extensively in Navy applications, primarily because of the availability of the anchors. The Navy stockless anchor is prone to overturning, or rolling over to an upside-down orientation, during proof testing. The possibility of this type failure can be minimized by welding stabilizers to the anchor. Flukes are generally fixed at a specified angle based on the expected soil conditions at the site. Figure 2-18 shows a Navy stockless anchor with stabilizers and flukes fixed. Characteristics of the most common Navy stockless anchors used in fleet mooring are provided in Table 2-2.

Figure 2-18 Navy Stockless Anchor with Stabilizers

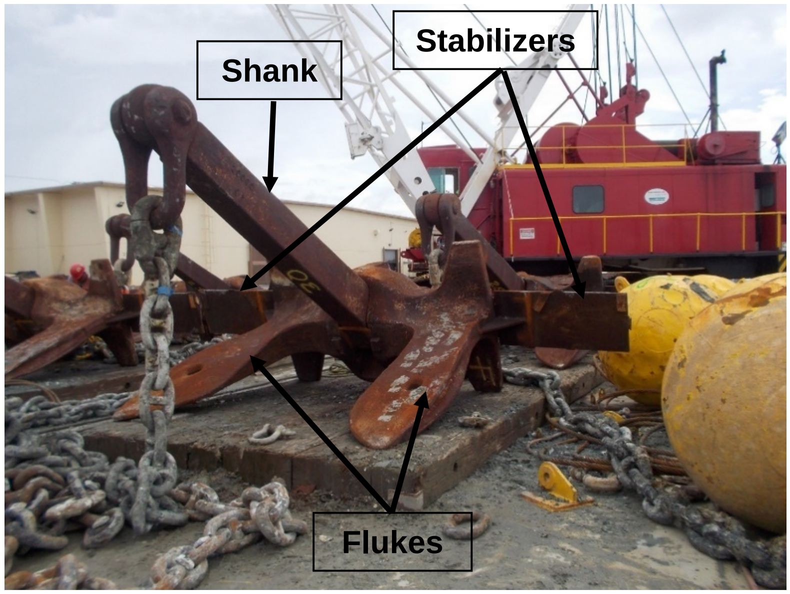


Table 2-2 Navy Stockless Anchor Characteristics

Anchor Nominal Size	20-kip	25-kip	30-kip
Anchor Wt. in Air, lbs (kg)	20,000 (9,072)	25,000 (11,340)	30,000 (13,608)
Length, inches (mm)	127.25 (3,232)	137 (3,479)	145.63 (3,699)
Stabilizer Extension, inches (mm)	45 (1,143)	48 (1,219)	50 (1,270)
Fluke Length, feet (mm)	7.65 (2,331)	8.24 (2,511)	8.94 (2,724)
Fluke Area, ft^2 (m^2)	35.1 (3.26)	40.7 (3.78)	46.9 (4.35)

2-2.2.2.2 NAVMOOR Anchor.

The NAVMOOR anchor is a high capacity drag-embedment anchor designed specifically for mooring use. The anchor's flukes are streamlined hollow shells which enable good penetration in hard soils. The large tripping palms are permanently affixed to the anchor to ensure reliable tripping in soft soils. Some designs are equipped with a 32-degree stopping wedge attached to one side to provide maximum holding power in sand or hard clay. Removing the wedge and welding the flukes open to 50 degrees provides maximum holding power in soft mud. NAVMOOR anchors can come in a number of sizes, but the most common sizes found in Navy moorings are 12,000 pounds (NAVMOOR10) and 18,000 pounds (NAVMOOR15). Figure 2-19 shows a NAVMOOR10 anchor. Characteristics of NAVMOOR anchors in use are provided in Table 2-3.

Figure 2-19 NAVMOOR10 Anchor

Table 2-3 NAVMOOR Anchor Characteristics

Anchor Size	NAVMOOR10	NAVMOOR15
In Air Weight, lbs (kg)	12,400 (5625)	19,200 (8709)
Overall Length, inches (m)	192 (4.9)	219 (2.6)
Stabilizer Width, inches (m)	192 (4.9)	219 (2.6)
Fluke Length, feet (m)	8.54 (2.60)	9.73 (2.97)
Fluke Area, ft^2 (m^2)	38.54 (3.58)	50.07 (4.65)
Proof Load, 1000 lbs (kN)	165 (734)	213.7 (950.6)
Tandem Link Padeye Diameter, inches (mm)	3.5 (88.9)	4 (101.6)
Shank Shackle Size, inches (mm)	3 (76.2)	3.5 (88.9)

2-2.2.3 Deadweight Anchors.

Any heavy object that can be placed on the seafloor can be used as a deadweight anchor if it can be shown that the anchor selected is capable of satisfying design requirements. Deadweight anchors can rest on the seafloor, be partially or completely buried, or dig into the bottom under load. The most common type of deadweight anchor encountered in fleet moorings is the Pearl Harbor anchor which is designed to dig into the soil to a limited extent as the anchor is dragged. The ultimate holding power of the deadweight anchor is the minimum force required to overturn, lift, or drag the large weight over the bottom. Resistance to uplift, or vertical force, is simply the submerged weight of the anchor plus the suction and friction effects of the bottom soil. Figure 2-20 shows a Pearl Harbor style deadweight anchor.

Figure 2-20 Pearl Harbor Style Deadweight Anchor

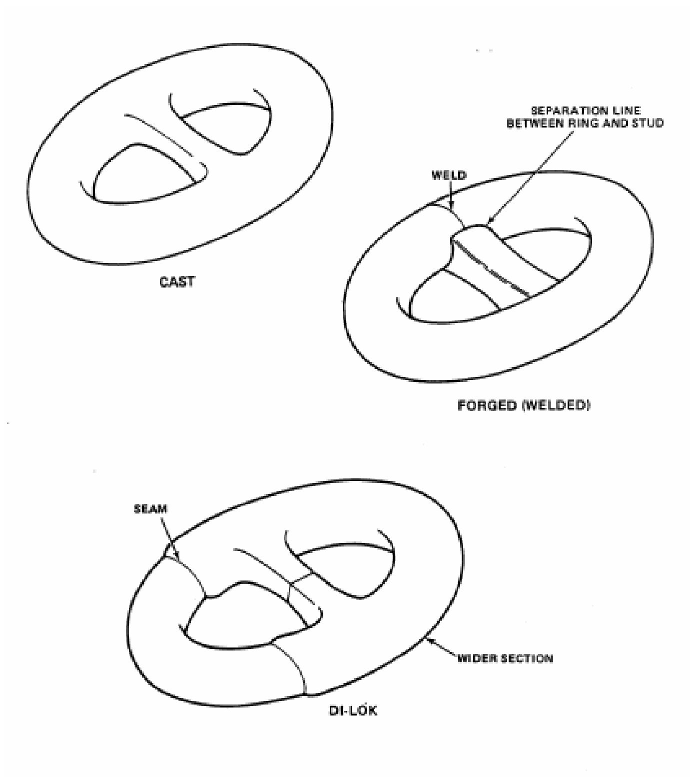
2-2.3 Chain.

2-2.3.1 Chain Grades and Types.

Chain grade is determined by the properties of the steel used to form the chain links. Chain manufactured to NAVFAC specifications for mooring purposes is similar in chemical content to that manufactured to commercial standards meeting the classification of American Bureau of Ships (ABS) Grade 3 (ABS3). Chain and chain accessories procured by the Navy for use in Fleet Moorings are classified as Fleet Mooring Grade 3 or FM3. FM3 chain and chain accessories have tighter mechanical property parameters imposed than those imposed on corresponding Grade 3 chain manufactured to commercial standards. Other commercially available chain grades use different steel alloys to have either higher or lower tensile strengths.

Chain type is identified by the manufacturing process used to form the links. The different chains that may be encountered in existing moorings include forged stud link, cast, and Dilok chain (Figure 2-21). The majority of installed Navy moorings utilize FM3 stud-link chain. Dilok and cast chains are no longer manufactured. However, since some of these types of chain may still remain in the system (in older moorings installed prior to 1990), they are described here for recognition purposes.

Figure 2-21 Types of Chain



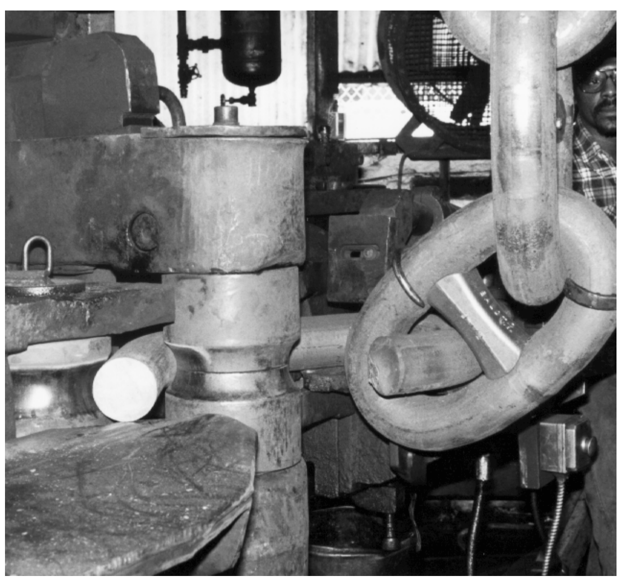
2-2.3.1.1 Stud-Link Chain.

Each link of stud-link chain is formed by bending a length of heated bar stock into the shape of a link and flash welding the ends together. A center crossbar, or stud, is inserted into the link while it is still hot and pressure is applied to both sides of the link to secure the stud in place. Stud-link chain is also referred to as flash-butt-welded chain. The stud in each link of FM3 chain is welded to the link on the end opposite the flash-butt weld. The welding of the stud is unique to FM3 chain as it is not required on ABS chains. The primary purpose of the weld is to provide a metallic path to the chain link for the sacrificial anode that is attached to the stud on FM3 stud-link chain. In addition to unique identification stamping requirements, the presence of this weld, along with a threaded hole attachment point on the stud for the zinc anode, is the primary method of identification of FM3 chain as opposed to commercial stud-link chain. Chain-stud zinc anodes are discussed in Section 2-2.6.2.2. Figure 2-22 shows the forming of a link of stud-link chain and Table 2-4 shows the characteristics of FM3 chain.

Table 2-4 FM3 Chain Characteristics

NOMINAL SIZE (inches)	**1.75**	**2**	**2.25**	**2.5**	**2.75**	**3.5**	**4**
NUMBER OF LINKS PER SHOT	153	133	119	107	97	77	67
LINK LENGTH *(avg.)*, inches (mm)	10.63 (270)	12.15 (309)	13.67 (347)	15.20 (386)	16.70 (424)	21.26 (540)	24.30 (617)
WEIGHT PER SHOT IN AIR *(min.)*, (lbs (kg)	2,525 (1,145)	3,276 (1,486)	4,143 (1,879)	5,138 (2,331)	6,250 (2,835)	10,258 (4,653)	13,358 (6,059)
BREAKING STRENGTH, 1,000 lbs (kN)	352 (1,556)	454 (2,019)	570 (2,535)	692 (3,078)	826 (3,674)	1,285 (5,716)	1,632 (7,259)
WORKING STRENGTH *(33% of break)*, 1,000 lbs (kN)	117.2 (521)	151.2 (672)	189.8 (844)	230.4 (1025)	275.1 (1224)	427.9 (1903)	543.5 (2418)

Figure 2-22 Formation of Stud-Link Chain



2-2.3.1.2 Cast Chain.

Cast chain, as the name suggests, is formed by a die-casting method. This type chain is easily recognizable as the stud is integral to the link and there is no link butt joint.

2-2.3.1.3 Dilok Chain.

Each link of Dilok chain is formed from two U-shaped sections, male and female. The male section has a forged, serrated, stem end while the female section has hollowed ends. The male ends are inserted into the heated female ends and drop forged. This results in the heated interior of the female section forming to the serrated stem on the male end and creating a lock. Use of Dilok chains are not recommended for mooring use due to the inability to inspect corrosion that may be present inside the “locked” ends.

2-2.3.2 Chain Markings.

The stud of the last link of each shot of FM3 chain bears a symbol or marking that shows the contract year and serial number of the shot. Additionally, the stud of each link bears permanent markings that denote chain size, manufacturer and “FM3”. The markings on the last link of each shot are stamped; the markings on the stud of each link are raised figures. Note that for ABS anchor chain, markings are on the end link body.

2-2.4 Chain Accessories.

2-2.4.1 Joining Links.

There are two main types of joining links, Chain Joining Links (CJL) and Anchor Joining Links (AJL) found in U.S. Navy mooring systems.

There are two different designs for joining links based on the manufacturer and how they are put together: the Baldt type and the Kenter type. The Baldt type can be distinguished by the two T-shaped plates that enclose the pin and make up the stud. The Kenter style has two C- shaped halves with a removable stud. The two C-shaped halves of a Kenter style link are similar.

CJLs are normally used to connect two shots of chain or chain to another chain component with a similar wire diameter and look similar to a normal chain link. Figure 2-23 and Figure 2-24 show the different types of CJLs.

It is important to not interchange parts between connecting links, especially the Kenter style or they may not properly be reassembled.

Figure 2-23 Baldt Style Chain Joining Link

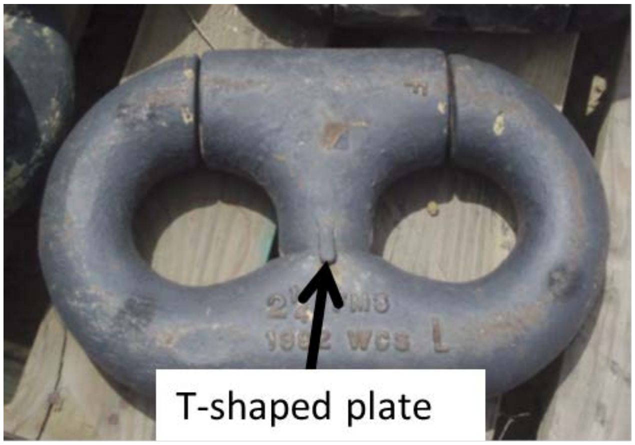


Figure 2-24 Kenter Style Chain Joining Link

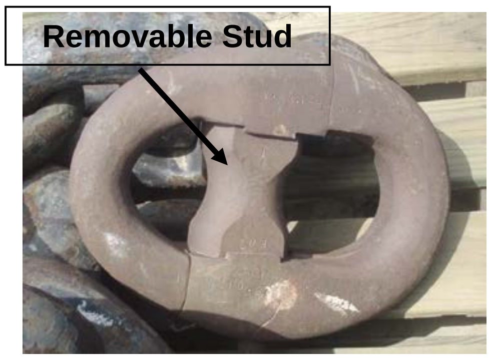
AJLs are used to connect chain to chain components with a larger diameter (ground rings, spider plates, shackles on anchors, etc.). It is larger on one end to accommodate the larger diameter wire of those components. Figure 2-25 and Figure 2-26 show the different types of AJLs.

Figure 2-25 Baldt Style Anchor Joining Link

Figure 2-26 Kenter Style Anchor Joining Link



When a connecting link is reassembled, the pieces are secured with a pin which is held in place by a lead plug. Lead plugs are either pounded into place using a heavy hammer or the lead is melted into the hole from a long lead bar. All joining links should have a visible lead plug (some cleaning may be required for joining links that are below the waterline to locate the lead plug) in the large pin hole (see Figure 2-27). Figure 2-28 shows a missing lead plug.

Figure 2-27 Lead Plug in CJL

Figure 2-28 Missing Lead Plug

Disassembled joining links should not be mixed with parts from other disassembled links as the tracking of serial number data on the installed link would be interrupted and the mixing of parts may result in the joining link not be able to be reassembled due to fit interferences among the mixed parts.

Safety Note

All personnel at or near a mooring component being secured by lead shall wear PPE commensurate with EM 385-1-1 (such as safety glasses, foot protection, floatation vest) and other required PPE for mooring operations.

2-2.4.2 Ground Ring.

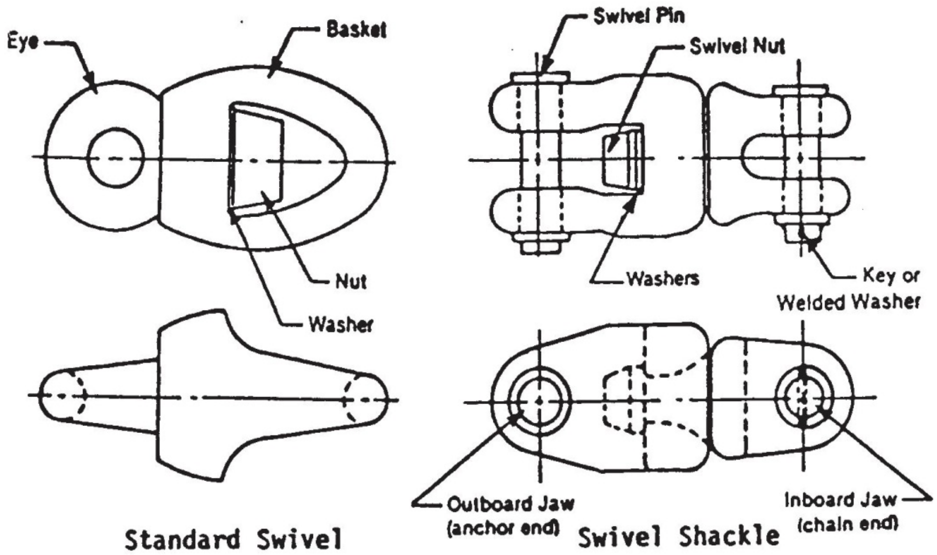
The ground ring is a steel ring used in a riser type mooring to connect multiple chain leg assemblies to the riser chain. Ground rings are classified by the size chain they support, and not the bar diameter of the ground ring. Figure 2-29 shows a ground ring.

Figure 2-29 Ground Ring

2-2.4.3 Swivel Fittings.

Swivel fittings are used in mooring systems to prevent twisting of the chain legs during installation and to prevent twisting of the riser chain during use. See Figure 2-30 shows the different types of swivels.

Figure 2-30 Swivel Fittings



2-2.4.3.2 Riser Swivel Shackle.

A riser chain subassembly should contain a riser swivel (Figure 2-31) that is attached to the lower tension bar padeye of a buoy before the riser chain starts. The purpose of the swivel is to permit a ship to swing 360 degrees around a buoy without twisting the riser chain. Swivel shackles are capable of rotating 360 degrees when supporting a full shot of chain of its rated size. The jaws on the riser swivel shackle are different sizes on each end, one end is designed to fit over a link of chain and the other end to fit over the padeye on the buoy. Pins on the riser swivel shackle are secured by tapered stainless pins which are then prevented from coming out with lead plugs (Figure 2-32) similar to joining links.

Figure 2-31 Riser Swivel Shackle

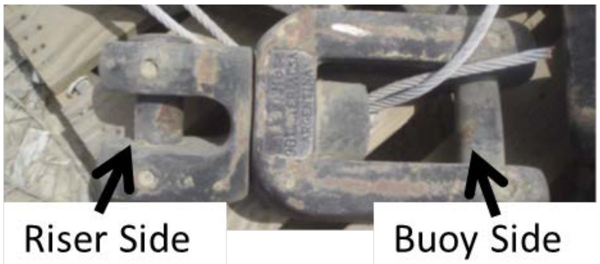


Figure 2-32 Lead Plugs Securing the Riser Swivel Shackle

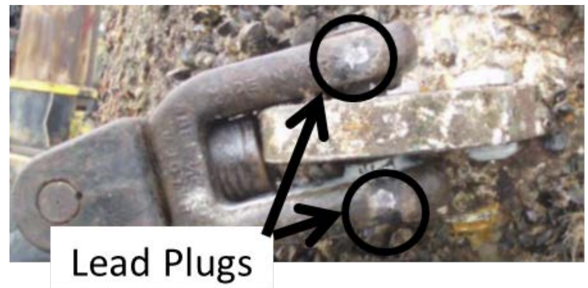


2-2.4.3.3 Chain Swivel Shackle.

The chain swivel shackle is a swivel fitting with jaws of equal size on both ends (as opposed to the Riser Swivel Shackle that has different size jaws). The jaw openings are sized to fit over a link of a specified size of chain. A chain swivel shackle is secured in the same manner that the riser swivel shackle is.

2-2.4.3.4 Standard Swivel.

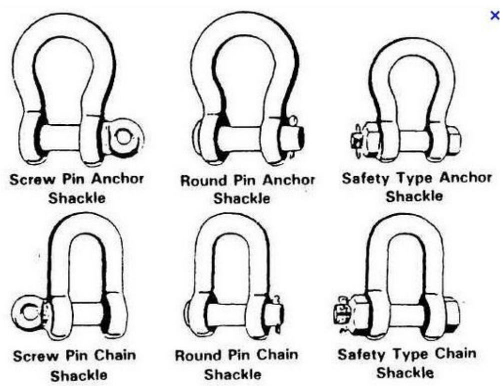
The standard swivel (Figure 2-33) has a fitting on each end to accommodate a standard link of chain. This fitting may be used on either a ground leg or the riser leg of a mooring system and are attached to the chain using a CJL.

Figure 2-33 Standard Swivel

2-2.4.4 Shackles.

Shackles come in three general types, depending on how the bolt is fastened to the body: Round Pin which uses a cotter pin to ensure that the pin doesn't slip out; Screw Pin, in which the pin screws directly into the body of the shackle; and Bolt Pin (sometimes called a Safety Type Shackle), which uses a bolt and nut/cotter pin combination. Figure 2-34 shows the various shackles. The primary shackle type used on mooring systems is the bolt pin.

Figure 2-34 Shackles



2-2.4.4.1 Anchor Shackle.

Anchor shackles (Figure 2-35) have also been referred to as bow shackles. With a large "O" shape to the bale, this shackle can take loads from many directions without developing as much side load. However, the larger, wider bale does reduce its overall strength when compared to a chain shackle. Anchor shackles are usually found on the top jewelry of a mooring tension bar foam buoy. Anchor shackles may also be found connecting the riser chain to the lower tension bar padeye on steel buoys or foam buoys as well. They may also be found as connecting hardware between ground leg assemblies and the riser assembly.

Anchor shackles used on the surface are equipped with a cotter pin or a safety bolt and nylok nut. Anchor bolt shackles used below the waterline, in addition to the cotter pin or safety bolt, will have a fillet weld between the outer perimeter of the nut and the shackle bolt (Figure 2-36).

Figure 2-35 Anchor Shackle

Figure 2-36 Anchor Shackle for Underwater Use

2-2.4.4.2 Chain Shackle.

Chain shackles, sometimes referred to as a D-Shackle, are narrow shackles whose bale has a similar shape as one end of a link of chain, with a threaded pin (bolt) and nut closure and the nut is secured with a cotter pin or safety bolt with a nylok nut although some are secured with a non-threaded pin held in place with a driven pin similar to a joining link. The shackle bale can take high loads primarily in line only as side and racking loads may twist or bend a chain shackle (Figure 2-37). Consequently, chain shackles are not generally used in mooring systems.

Figure 2-37 Chain Shackle

2-2.4.4.3 Sinker Shackle.

Sinker shackles (Figure 2-38) are similar to a chain shackle but have a longer and narrower bale. With their long and narrow bale, sinker shackles are used to attach a sinker to a ground leg or a suspended riser chain assembly by slipping over a chain link.

Figure 2-38 Sinker Shackle

2-2.4.4.4 Plate Shackle.

Plate shackles (Figure 2-39) consist of 2 plates in the shape of a “dog bone”, 2 bolts with nuts and are primarily used to attach a sinker to a ground leg assembly. After the plate shackle is attached to the sinker and ground leg, the nuts are also secured to the bolts with a fillet weld to the outside of the bolt. Plate shackles are not normally used on moorings to carry the mooring loads, due to their lack of strength and their susceptibility to bending.

Safety Note
Follow safe welding procedures per EM 385-1-1 and wear required PPE for welding operations.

Figure 2-39 Plate Shackle Attaching Sinker to Chain

2-2.4.5 Sinkers.

Sinkers, or clump weights, are attached to the chain legs in the water column to provide damping to a mooring system to reduce dynamic peak tensions. Sinkers are generally concrete clumps or modified stockless anchors that have their flukes welded close and an additional padeye welded at the anchor crown (Figure 2-40). Sinkers generally range in weight from 3,000 to over 25,000 pounds (13.3 to 111.2 kN) in air.

Figure 2-40 Navy Stockless Anchor Rigged as a Sinker

2-2.4.6 Pear Link.

A pear link (Figure 2-41) is an open link, wider at one end then at the other. It may also be called a pear-shaped link or pear-shaped ring. It is often used as top jewelry on a buoy, serving as the attachment point for the lines from the moored vessel.

Figure 2-41 Pear Link

2-2.4.7 Spider Plate.

The spider plate (Figure 2-42) is a steel plate or casting, triangular in shape, with a hole at each point of the triangle. It is most commonly used to connect the two chains of a paired-leg assembly to a single attachment to provide additional holding capacity. NAVFAC stocks a 4-inch (102 mm) and a 2.25-inch (57 mm) spider plate.

Figure 2-42 Spider Plate

2-2.4.8 Yoke Assembly.

The yoke assembly (See Figure 2-43) is specially configured to connect the two chains of a paired anchor installation to a single ground leg. The assembly generally consists of two modified (two cross plates are welded between end plates to form 1 assembly) plate shackles, a spider plate and a chain swivel shackle or it may consist of three modified plate shackles and a spider plate, eliminating the swivel shackle. They may be found on old mooring systems with tandem anchors installed in the 1980’s.

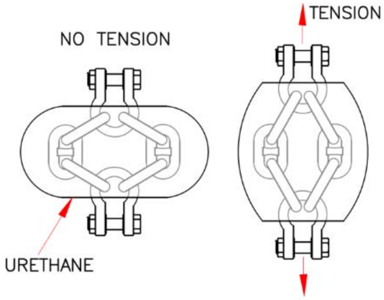
Figure 2-43 Yoke Assembly

2-2.4.9 Kinetic Links.

A Kinetic Link is a short open loop segment of chain links that is encased in polyurethane. A shackle is provided at both ends for attachment of the kinetic link within a mooring riser or ground leg. Like sinkers, they are used to provide a shock absorber to minimize dynamic loads. Figure 2-44 is a picture of kinetic links. Figure 2-45 is a drawing of the kinetic link details. There are some very specialized moorings that have single or multiple kinetic links within the mooring riser or ground leg assemblies. As attached sinkers provide similar damping of dynamic loads and are less expensive to construct, kinetic links are not generally used.

Figure 2-44 Kinetic Links

Figure 2-45 Kinetic Link Details



2-2.4.10 Chain Equalizer.

Chain equalizers are specialty hardware that can be used to moor large vessels to pier or wharf fittings or 2 ground legs to a single riser on a buoy (See Figure 2-46). Chain equalizers distribute the tension equally to both parts of chain as the vessel or buoy responds to environmental forces. Although equalizers contain no movable parts, they do resemble large pulleys. The chain is free to slide back and forth through the equalizer so that each end of the chain is under equal tension. Figure 2-47 shows a chain equalizer.

Figure 2-46 Chain Equalizer on a Mooring

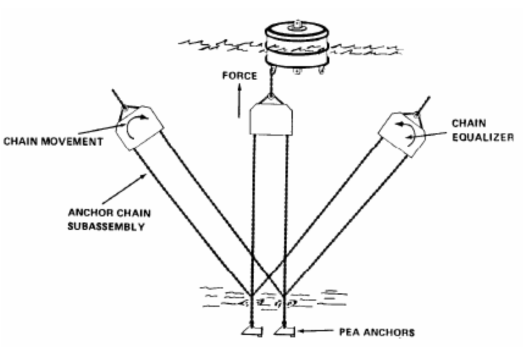


Figure 2-47 Chain Equalizer

2-2.5 Miscellaneous Special Links.

There are a variety of special links used in industry to connect chain and chain accessories that sometimes make their way into mooring systems. The PEAR LINK, described in Paragraph 2-2.4.6 is the only special link used in U.S. Navy mooring systems today. Other special links that may be encountered in older, existing fleet moorings are the ENLARGED LINK or B-LINK, the END LINK or E-LINK, and the C-LINK. The B-link is an adaptor used between the last common link of a chain and the E-link. The E-link is a studless link used as the last link in a shot of chain. The C-link is similar to the E-link but has an off-center stud. The use of these special links, other than the Pear link, should be avoided in mooring installations whenever possible.

Drawings for FM3 mooring components are provided in APPENDIX G.

2-2.6 Cathodic Protection System.

The galvanic action of seawater, acting electrolytically on the submerged portions of a mooring system, greatly increases the rate of corrosion on these components. This galvanic action can be inhibited by impressing a negative electrical potential on the exposed steel surfaces thus prolonging the useful life of the mooring system. The required electrical potential is provided by attaching sacrificial anodes to all steel surfaces with the water column.

2-2.6.1 Cathodic Protection for Buoys.

The submerged portion of a steel buoy must be cathodically protected. Buoy anodes, manufactured from a zinc composition in accordance with MIL-A-18001, are attached to the buoys in such a manner that the anodes are protected from impact or collision. They may be on the bottom of the buoy, in seachests built into the buoy, or attached to the sides of the buoy, depending on the type of buoy. The lower padeye of foam tension bar buoys is also protected by anodes (see Paragraph 2-2.6.2.2)

2-2.6.2 Cathodic Protection for Chain.

All chain in a mooring system that is between the mudline and the buoy must be cathodically protected. Protection is achieved by attaching anodes in such a manner that each link is protected. Several methods and several types of anodes have been used for this purpose. The preferred method is the chain-stud anode; however, since other methods may still be encountered on existing mooring systems, each method will be discussed below.

2-2.6.2.1 Clump Anodes.

A clump anode is simply a cast zinc shape attached to the chain assembly using a sinker shackle or other methods of attachment. Sometimes, approximately 500 pounds (2.2 kN) of zinc is cast over an elongated chain link and this is called a link anode. A wire rope, called a continuity cable, is attached to the clump anode and passed through every 4th link of the chain to provide continuity throughout the chain leg. Hose clamps are then used to secure the continuity wire to every 8th link.

Generally, one clump anode is used for every shot (90 feet (27.4 m)) of chain in the ground leg or riser. These methods are less effective than the stud link anode method discussed in section 2-2.6.2.2 for several reasons: (1) The continuity between links may be lost when the chain is not in tension and; (2) The contact area between the chain link and the continuity wire must be cleaned to bare metal to ensure conductivity and (3) No assurance is given that the connecting wire rope will remain in constant contact throughout the chain leg especially at locations where the chain leg is moving due to loading or tidal effects. Figure 2-48 shows clump anodes in storage.

Figure 2-48 Link and Clump Anodes

2-2.6.2.2 Chain-Stud Anodes.

This method of protecting chain consists of an anode attached to the stud of each link of FM3 mooring chain. Attaching an anode to each link ensures maximum protection as each link is in contact with an anode whether or not the system is in tension. Additionally, the anodes are easily replaced by divers and do not require removal of the mooring system for this routine maintenance task. Replacement of chain-stud anodes generally occurs during the fleet mooring underwater inspection. All FM3 chain links are manufactured with a tapped 0.375-16UNC-2B hole in each stud to accept an anode. Currently, chain-stud anodes are made from a zinc alloy.

Figure 2-49 provides details of the chain stud link anode assembly and Figure 2-50 shows the assembly on the stud of a chain link. Table 2-5 provides the characteristics of the chain-stud anodes. Though there is a specified chain-stud anode for each nominal size of FM3 chain, current maintenance practices are to replace chain-stud anodes with ones manufactured for a larger size of chain and to stockpile only a few sizes of zinc anodes. Two to four chain-stud anodes are also attached to the lower padeye on fleet mooring foam tension bar buoys (Figure 2-51).

Figure 2-49 Chain Stud Anode Assembly

Notes:

1. All screws are SAE .375-16UNC-2A, Grade 5, Hex Cap.
2. All screw heads are 9/16 inch.

2-2.7 Wire Rope.

In general, wire rope is not used by the Navy in mooring systems. The service loads for offshore mooring lines are extremely difficult to predict and, thus, difficult to maintain a safe working load. The permanent immersion of mooring lines in seawater poses problems with corrosion and corrosion-assisted fatigue and access to the rope for regular inspections. Wire ropes are used in commercial moorings, especially for semi-submersible platforms. Since this type of platform is typically used for exploratory drilling, the mooring lines are constantly being hauled in to permit the rig to be moved to another location. This permits a better inspection of the wire rope on a reasonable basis. New mooring designs are now using synthetic rope instead of wire rope.

Wire ropes may also be found in deep water moorings, such as tension leg platforms, where the weight of chain would be prohibitive.

Wire rope is a loosely applied term, referring to a multitude of different constructions. The general accepted terminology is:

- Wire – is a single wire filament.
- Strand – is a number of single wires wound helically around a central wire in a series of concentric layers
- Rope – a number of strands wound helically together around a core of other strands (or of synthetic or natural fiber materials). The core can be composed of fiber, another wire strand, or an independent wire rope (IWRC). See Figure 2-52 and Figure 2-53.
- Cable – a number of ropes wound helically together

Figure 2-52 Structure of Wire Rope

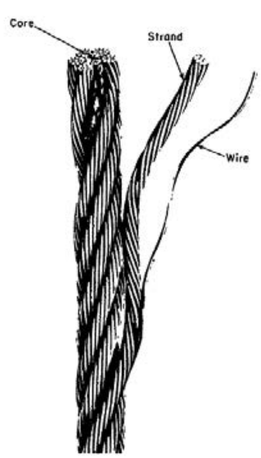

Figure 2-53 Wire Rope Structure

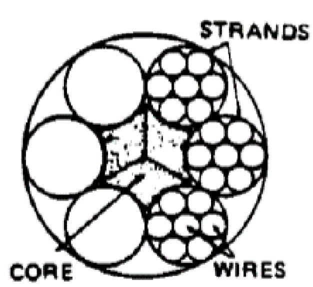
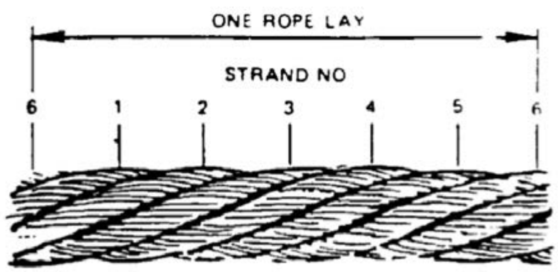


Most common construction of wire ropes are 6x19, 6x25 or 6x37, meaning there are six strands on the outside of the rope composed of 19, 25 or 37 wires respectively, with the six strands wrapped around either a fiber or a wire core. The more wires that are used to construct a strand, the more flexible the rope will be but the more susceptible the rope will be to physical damage or corrosion problems.

In addition to the rope diameter, other items to know in describing wire rope are:

- Lay length - distance parallel to the axis of the rope in which the outer strands make one complete turn (or helix) about the axis of the rope. See Figure 2-54.

Figure 2-54 Lay Measurement of Wire Rope



- Lay direction of strand – The direction of the lay of the outer layer of wires in relation to the longitudinal axis of the strand.
- Lay direction of rope – The direction of the lay of the outer strands in relation to the longitudinal axis of the rope
- Lay Type – Ordinary or regular lay has the lay direction of the strand in the opposite direction to the lay direction of the rope while Lang lay has the strand lay direction in the same direction as the rope lay. See Figure 2-55.
- Core Type – The core of the rope can be made from either natural fibers (fiber core usually hemp or sisal) or steel (IWRC – Independent Wire Rope Core). See Figure 2-56.

Figure 2-55 Wire Rope Lays

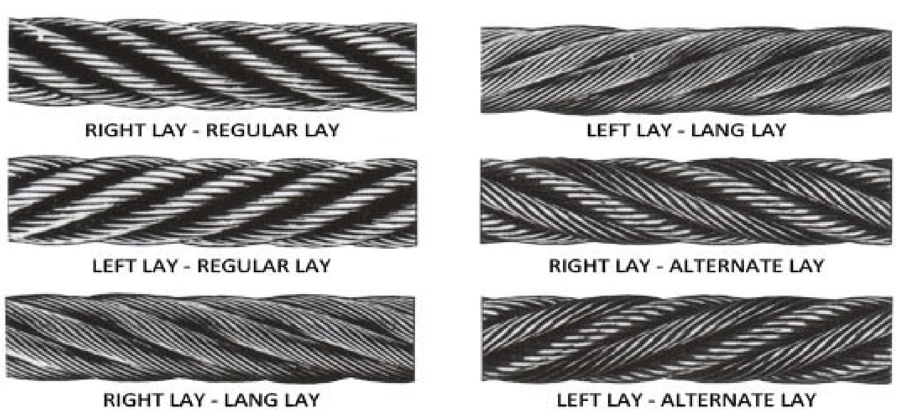


Figure 2-56 Wire Rope Cores

Safety Note

Wear appropriate gloves when handling wire rope.

2-2.8 Synthetic Line.

Natural fiber ropes (Manila, hemp, jute, sisal) have been in use since the beginnings of boating. For working lines, they have largely been replaced by synthetic lines. Synthetic lines come in two main types, low tenacity ropes composed of older synthetic fibers (polyester, polyethylene, polypropylene, nylon) or newer, high tenacity fibers such as: aramid (Kevlar); HMPE (High Modulus Polyethylene such as Spectra, Dyneema, Amsteel).

The use of synthetic lines for anything other than tying the vessel to the mooring is relatively uncommon. Commercially, the high tenacity synthetics might be used for extremely deep-water moorings, but for DoD uses, they are extremely uncommon.

Like wire ropes, synthetic lines are extremely difficult to inspect, if they cannot be removed from the mooring. In addition, damage to inner filaments may not be apparent.

Synthetic ropes are typically constructed in a 3-strand twisted rope, 8-strand or 12-strand braid, 8-strand plaited, double braid or a core-dependent braid. The difference between a double braided rope and a core-dependent braided rope is that with the double braid, the load is shared by both the inner rope and outer jacket while with a core-dependent braided rope, the outer jacket simply acts to provide abrasion protection and the load is take strictly by the inner rope.

CHAPTER 3 MOORING INSPECTION

Safety Warning:

Ensure all personnel have, maintain, and wear PPE (steel toed shoes, personal floatation vest, hard hat and other PPE for specific tasks i.e. leather gloves, safety glasses, etc.).

Daily safety briefs should emphasize everyone’s responsibility for applying risk management.

3-1 MOORING INSPECTION PLANNING.

This section describes the responsibilities and inspection planning tasks of each person involved in a mooring inspection as well as the equipment and material that will be needed to conduct a thorough inspection.

3-1.1 Mooring Program Manager.

The Program Manager is responsible for program management of the inspection portion of the mooring program. He will perform the following program tasks in support of planning for the mooring inspection:

- Reviews all available historical maintenance records and develops a list of those moorings which should be scheduled for underwater inspection during a particular fiscal year.
- Develops the planned mooring inspection schedule for the next three fiscal years.
- Submits mooring inspection requests to the Underwater Construction Teams (UCT).
- Designates a Mooring Inspection Engineer-in-Charge (Inspector) for each planned mooring underwater inspection during the current fiscal year.
- Maintains an archive of previous inspection reports, mooring configuration drawings, property records and mooring usage charts of current moorings.
- Maintains an adequate supply of chain-stud anodes at the mooring inventory to support changing out zinc anodes during inspections.
- Provides the inspector with a copy of the last underwater inspection report, mooring usage chart, and latest drawings of the moorings scheduled for inspection.
- Provides the inspector with catalog dimensional information for the mooring components to be inspected at the site.

- Allocates funding for the onsite inspection and post-inspection documentation.
- Ensures that the inspection report is provided to the custodian.
- Reviews and approves the inspection report to include its findings and recommended maintenance actions.
- Executes required maintenance actions on moorings in accordance with the inspection report.
- Funds local activity custodians to execute annual surface inspections or performs annual surface inspections using other in-house or contracted assets.
- Informs the local activity custodian of the planned fleet mooring inspections at their site.

3-1.2 Mooring Inspection Engineer-In-Charge (EIC or Inspector).

The Inspector is responsible for planning and monitoring the inspection. The Inspector is also responsible for collecting the inspection notes, the pictures, and the survey data. The inspector may execute portions of the mooring inspection such as the performing the surface inspection tasks and surveying the buoys. If the inspector is Navy dive certified, the inspector may become a part of a military dive inspection team. The Inspector, whether or not dive qualified, must interpret the results of the inspection before leaving the site to ensure that that the inspection is complete. Upon return, it is the Inspector’s responsibility to send out written preliminary inspection results within 14 calendar days and the completed inspection report within 60 calendar days, to include any supporting engineering documentation for inspection results.

The Inspector will establish a tentative schedule for the mooring inspection in conjunction with available dive support team. This schedule will be based on the maximum availability of station support, anticipated favorable weather conditions, vessel movement, and diver availability. The inspection may be required to meet deployment scheduling requirements of the supporting dive team. The dive team must be familiar with the project requirements in order to assist in inspection planning. Equipment requirements must be coordinated with the dive team. The Inspector shall perform the following program tasks in support of planning for the mooring inspection:

- The Inspector shall review the mooring drawings and previous inspection reports to determine the required amount of time that will be needed on site to perform the inspection, amount and size of chain-stud anodes required for the inspection, the size and quantity of go/no-go gauges and other inspection tools needed.
- The Inspector shall arrange for area clearances, camera clearances or passes, passport, and on-site transportation. If using a contractor dive team, he will coordinate the administrative requirements for the contractors with the local shore activity.

- The Inspector shall arrange for his (her) own travel requirements.
- The Inspector shall provide the mooring program manager a cost estimate for the inspection. This estimate will be reviewed by the program manager to verify adequate funding for the inspection is available.
- In conjunction with the inspection dive team, the Inspector shall plan the inspection procedures to be used on the inspection for surface and underwater inspection tasks, anode replacement and survey requirements.
- The Inspector or the dive team's designated representative shall coordinate any logistical requirements required at or by the shore activity to perform the inspection with the activity's mooring custodian.
- The Inspector shall contact the local activity's mooring custodian of the planned inspection schedule and brief the custodian on the goals of the inspection. Obtain, from the mooring custodian, any base operational requirements, Force Protection requirements, and vessel mooring requirements that may impact the inspection.
- The Inspector shall coordinate and arrange with the local activity's custodian, the assigned inspection dive team, and the mooring program manager for all required inspection tools to include survey equipment, go no-go gauges, calipers, etc.
- If the dive team has the responsibility to plan and execute the logistical requirements for the inspection, the Inspector should then coordinate with the dive detachment to ensure that all required tools and equipment are identified and arranged to be available for the inspection.
- If the inspection is being performed by a contractor dive team, the Inspector shall arrange for review and approval of the contractor's dive plan by a qualified District Diving Coordinator (DDC) at the location of the inspection or in accordance with command policy.
- The inspector shall arrange for base logistical support at the inspection location in accordance with established command policy.
- In conjunction with the project superintendent, the Inspector shall conduct an in-brief to the local activity's custodian going over the goals of the inspection, the inspection schedule, and communication and safety procedures to be followed during the inspection period.

3-1.2.1 Inspection Planning Information.

The Inspector should obtain the following information from the Mooring Program Manager (MPM) and the mooring custodian. This information should be thoroughly reviewed by the Inspector prior to departure for an inspection site:

- Class and type of moorings to be inspected.
- Latest "as-built" documentation, usage chart and property records of the moorings to be inspected.
- Copies of mooring configuration drawings.
- Last inspection report and installation report or latest mooring repair documentation report.
- Geographic positions of moorings, if not in previous installation or inspection reports.
- Type of cathodic protection system and its last reported condition.
- Environmental data; such as seasonal weather and potential for extreme weather, tides and currents during the inspection period at the site, water depth and type bottom at the moorings, and any potential diving hazards at the site (such as obstructions, ship movements, sonar operations, intakes, etc.).

3-1.2.2 Inspection Planning Equipment.

The Inspector should carry to, or make arrangements for, the following to be on the inspection site:

- Inspection data sheets and forms.
- Digital still camera and digital video camera.
- Tape measure (20-foot (6.1 m) minimum).
- Local nautical and tide charts.
- Calculator.
- Pre-inspection briefing data.
- Survey equipment when it is not available on site.
- Calipers. Tear drop (or outside) type calipers are recommended but dial and vernier type calipers will also work but it may be easier to maneuver the tear drop calipers into the tight places to take measurements. The calipers need to open large enough to fit over the pieces to be measured (such as 24-inch sized calipers). See Figure 3-1 and Figure 3-2.
- Go/No-Go gauges.
- Underwater voltmeters.
- Inclinometer (if necessary).
- Anodes with screws (if necessary).
- 9/16-inch hand wrench (to remove old anodes).
- Pneumatic wrench with 9/16-inch socket (for attaching anodes).
- Cleaning tools to remove growth and coating on selected chain links for inspection.

Figure 3-1 Diver Using Tear Drop Calipers

Figure 3-2 Tear Drop (Outside) Calipers

The dive team might be capable of providing some of this equipment. The Inspector should coordinate with the dive team supervisor or dive detachment OIC to ensure what equipment will be provided by the divers.

3-1.2.3 Anode Replacement Planning.

Most Fleet Moorings have been installed with FM3 chain which has a chain-stud anode attached to every link. Inspections generally include replacing these anodes. Subsequent to the initial installation, some fleet mooring’s original anode size has been replaced with larger anodes on subsequent inspections. It is the Inspector’s responsibility to determine the size and quantity of the anodes that will be installed.

Anodes are currently located at the Naval Construction Battalion Center (CBC) Gulfport, MS or CBC Port Hueneme, CA, the fleet mooring inventory sites, and can be shipped to either the project site or to the assigned dive team by submitting a DD1149 shipping document. A sample DD1149 is provided in APPENDIX C.

3-1.2.4 Survey Planning.

It is the Inspector's responsibility to ensure the surveying is conducted by qualified individuals and that the surveying is conducted correctly. It is the Inspector's responsibility to ensure the survey calculations are correct and that the results are transferred to the coordinate system required by the activity.

Initially, mooring surveying of the buoys utilized single or multiple transits, tripods, electronic distance measurement devices (EDM) and prism poles and surveying was done by surveying the buoys from single to multiple survey benchmarks using conventional surveying principles. These techniques are rarely used today.

Recent mooring surveying and inspections have been performed using commercial Global Positioning System (GPS) handheld receivers that are linked to either a nearby U.S. Coast Guard (USCG) beacon, FAA satellites (SBAS) or a commercial service such as OMNISTAR to receive corrections to provide sub-meter survey accuracy. GPS allows a more efficient method of obtaining the geographic location of the mooring. The GPS unit can be set up to provide the coordinates in the required coordinate system used by the shore activity. Programs such as CORPSCON or GeoGraphic Calculator are available for coordinate system conversions to other datum's such as World Geographic System 1984 (WGS84) latitudes and longitudes, Universal Transverse Mercator (UTM) Northings and Eastings (units in meters), or state plane coordinates, Northings and Eastings, in either North American Datum (NAD) 1927 (units in US Feet) or 1983 (units in meters). Figure 3-3 shows a hand-held GPS being used to survey the location of a buoy.

There are numerous commercial GPS devices available. Low cost units generally have limited coordinate systems to use as well as reduced levels of accuracy.

If practical, mooring buoys should be surveyed during periods of slack tide and with no attached vessels. For mooring systems secured by embedment anchors, a low-cost GPS is adequate. Mooring systems secured with drag embedment anchors should have the buoy and found anchors surveyed with a GPS having sub-meter accuracy.

Figure 3-3 Using a Handheld GPS to Survey a Mooring

3-1.2.5 Notes and Reports.

It is the Inspector's responsibility to collect the inspection notes, the survey data, the pictures, and the inspection results. It is recommended that the Inspector use waterproof paper and pens. The Inspector must make a preliminary assessment of the results before leaving the site in order to ensure the inspection is completed. Upon return from the site, the Inspector must write the inspection report within 60 days.

An inspection sheet template (APPENDIX D) and an inspection report template (APPENDIX E) that the inspector can utilize to help in planning for the inspection. Items, such as points of contact information, references, email addresses, mooring class, type and configuration, buoy sizes, riser and ground leg sizes, project site maps, etc., are information that is provided in the inspection report that are needed for the inspection planning process.

As section one and the majority of section two of the inspection report are standardized information, the Inspector can complete a good portion of the inspection report before arriving on site for the inspection.

3-1.3 Inspection Dive Team.

Dive teams can be provided through a variety of sources, as selected by the PM/EIC/Inspector and as dictated by the situation and based on the available schedules and funding. The dive team can be from the Navy UCTs, other DoD diving units, commercial divers, or AE divers. It is important that the Inspector understand the differences in using these different groups.

Much of the fleet mooring inspections are performed by a diving detachment from the UCTs. For inspections performed by the UCTs, a lot of the inspection planning will be executed by the detachment OIC and Project Superintendent as the inspection provides an opportunity to develop project planning and management skills. The EIC/Inspector should coordinate with the OIC or Project Superintendent ensuring all required logistical requirements are accounted for. The EIC/Inspector is still responsible for submitting the completed inspection report.

3-1.3.1 Dive Team Responsibilities.

The responsibilities of the assigned diving team or detachment include:

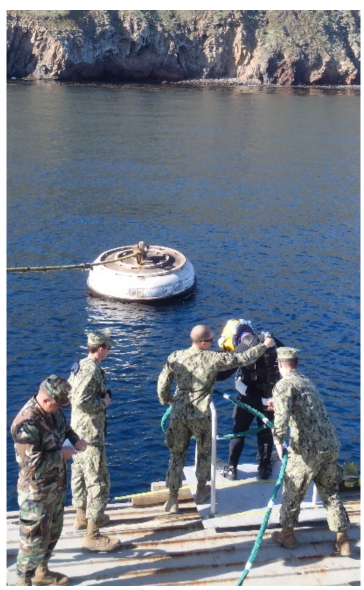
- Interface with the Inspector on all inspection planning matters to ensure that the Inspector is aware of the planned dates of the inspection, the type of diving that will be utilized, the estimated duration on site for the inspection, and any equipment requirements for the inspection that the dive team cannot provide.
- Coordinates with the Inspector to ensure that all logistical arrangements to perform the inspection are occurring; including diving equipment, inspection tools, shipping of anodes to the project site, and if necessary, arranging for local chamber support, dive platform support, forklift support, etc.
- Arranges for own travel orders, area clearances, camera clearances or passes, passports, and on-site transportation. If using a contractor dive team, the Inspector coordinates these administrative requirements for the contractors with the local shore activity.
- Based on the inspection requirements and site conditions, plans for either scuba or surface-supplied diving. A means of diver to surface communications should be incorporated into the selected diving procedures (Figure 3-4).

- Develops the inspection safety plan and diving emergency plans to include phone numbers and directions to the nearest hospital or urgent care center, nearest recompression chamber (Figure 3-5), etc.
- Plans dive operations in accordance with the US Navy Diving Manual, or if using non-DoD divers, diving regulations in accordance with EM 385-1-1.

Figure 3-4 Inspection Diver using SCUBA with Diver/Topside Communications Equipment

Figure 3-5 Portable Recompression Chamber at Dive Site

Figure 3-6 Surface Supplied Diver Entering Water



3-1.3.2 Dive Team Inspection Tools and Equipment.

In addition to inspection and anode replacement tools listed in paragraph 3-1.2.2 and 3-1.2.3, the dive team provides the following equipment and material required for the underwater inspection:

- Underwater digital camera or digital camera in a housing with a strobe and spare batteries.
- Underwater digital video camera system.
- Cleaning equipment (wire brushes, K-bars, chipping hammers, chisels, etc.).
- 100-foot (30.5 m) underwater tape measure.
- Marker tags (such as nylon zip ties) to relocate or mark links or accessories.
- Hand-held radios.
- Underwater compass.
- Underwater writing tablets and grease or underwater pencils.
- Binoculars.
- Surface marker buoys with lines to mark the location of anchors.
- All diving equipment and small boats as required.
- Tide tables and nautical charts of the project area.

The underwater writing tablets can be developed specifically for inspection of riser assemblies, ground leg assemblies, buoy assemblies or even specific mooring components (riser swivel shackles, joining links, etc.) that can aid the inspector. Example inspection sheets are provided in APPENDIX D.

3-1.4 Shore Activity Custodian.

The activity custodian, whose moorings are scheduled for inspection should provide support to EIC and the inspection team by forwarding, when requested, the following information:

- Copies of the latest local area harbor charts.
- Historical use and future plans for the existing moorings and future moorings.
- Clearances and passes for inspection team members and their cameras.
- Coordinates of known benchmarks and personnel cognizant of their location.
- Responses to requests for other pertinent inspection data.
- Information regarding protocol requirements to include force protection requirements.
- Information regarding ship movements or mooring usage that may impact the planned inspection schedule.

It is the responsibility of the Inspector to request the cooperation and support of the activity in matters related to the inspection.

3-1.5 Go/No-Go Gauges.

A list of inspection tools and equipment are presented in sections 3-1.2.2 and 3-1.3.2 One of the primary inspection tool used for underwater mooring inspections are Go/No-Go gauges. These gauges come in single link and double link sizes for nominal chain sizes ranging from 1.75 to 4 inches (44 to 102 mm). One side of the gauge has a jaw opening that is equal to 90% of the original wire diameter (OWD) while the other jaw on the gauge has an opening equal to 80% of the original wire diameter. For double link gauges, one jaw is equal to 2 x 0.9 x OWD of the nominal chain size with the other side equal to 2 x 0.8 x OWD of the nominal chain size.

Go/No-Go gauges should be made from stainless steel with a thickness of 1/4 inch (6 mm) minimum. Gauges can be made from aluminum but must be thick enough to avoid being bent during inspection operations. A hole on the gauge should be provided to attach a lanyard.

It is recommended that a white strip of electrical tape be wrapped around the middle of the jaws representing 90% of the OWD for easy identification by the divers.

A fabrication drawing for Go/No-Go gauges for common chain sizes is provided in APPENDIX H. Jaw gap dimensions for fleet mooring chain sizes are provided in Table 3-1. Figure 3-7 shows a double link Go/No-Go gauge for 2.5-inch (64 mm) nom FM3 chain.

Figure 3-7 Double Link Go/No-Go Gauge for 2.5" FM3 Chain

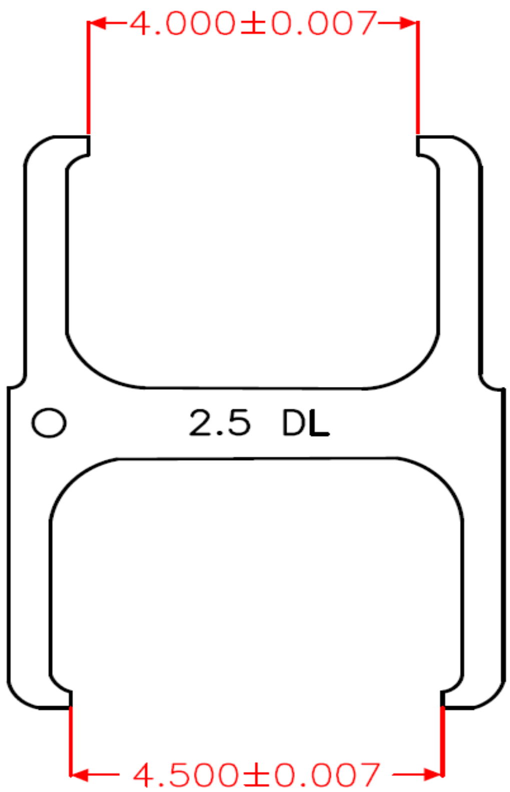


Table 3-1 Go/No-Go Gauges

Diameter	Single Link		Double Link	
	.90D	.80D	.90D	.80D
inches	inches	inches	inches	inches
4.0	3.60	3.20	7.20	6.40
3.5	3.15	2.80	6.30	5.60
3.0	2.70	2.40	5.40	4.80
2.75	2.475	2.20	4.95	4.40
2.5	2.25	2.00	4.50	4.00
2.25	2.025	1.80	4.05	3.60
2.0	1.80	1.60	3.60	3.20
1.75	1.575	1.40	3.15	2.80

3-2 MOORING INSPECTION.

3-2.1 Inspection Responsibilities.

3-2.1.1 Inspector Responsibilities.

The primary responsibility of the Inspector is Quality Assurance. The Inspector will ensure that all of the data collected is accurate and complete enough to make an informed evaluation of the condition of the mooring.

The assigned Inspector should arrive on site a minimum of one working day before the start of the inspection. This provides the opportunity to meet with appropriate station personnel in order to:

- Brief station personnel on the plans, techniques, and purpose of the inspection.
- Obtain any information concerning the moorings that was previously unavailable.
- Confirm mooring usage or ship movements during the inspection period in order to establish the order in which the moorings will be inspected.
- Obtain the latest weather forecast for the local area.
- Obtain other information from the shore activity custodian that may affect the inspection.

Prior to beginning diving operations, the Inspector shall brief the Dive Superintendent on the latest information obtained from station personnel and ensure that the Dive Superintendent is aware of any changes to the inspection procedures. As the lead of this inspection, the Inspector is authorized to modify inspection procedures on site as necessary, as long as modifications are acceptable to the Dive Superintendent in maintaining diver safety. In addition, the Inspector must:

- Interface with the Dive Superintendent in all matters related to the inspection.
- Report the status of the inspection and advise the program manager and the activity custodian of any schedule or procedural changes.
- Arrange with the Dive Superintendent to conduct the post dive briefing at the completion of each dive.
- Evaluate the inspection data as it is gathered and determine if additional data is required.
- Brief activity personnel on mooring conditions following completion of the inspection.

Prior to beginning diving operations, the Inspector shall brief the Dive Superintendent on the latest information obtained from station personnel and ensure that the Dive Superintendent is aware of any changes to the inspection procedures. As the lead of this inspection, the Inspector is authorized to modify inspection procedures on site as

necessary, as long as modifications are acceptable to the Dive Superintendent in maintaining diver safety. In addition, the Inspector must:

- Interface with the Dive Superintendent in all matters related to the inspection.
- Report the status of the inspection and advise the program manager and the activity custodian of any schedule or procedural changes.
- Arrange with the Dive Superintendent to conduct the post dive briefing at the completion of each dive.
- Evaluate the inspection data as it is gathered and determine if additional data is required.
- Brief activity personnel on mooring conditions following completion of the inspection.

3-2.1.2 Dive Team Responsibilities.

The Dive Superintendent is the interface between the Inspector and the inspecting divers. The Dive Superintendent is responsible to:

- Interface with the Inspector on all inspection-related matters.
- Ensure safe performance of the underwater portion of the inspection.
- Provide underwater photographs and video as required.
- Submit all inspection data, notes, and inspection-related film to the Inspector prior to departing the site.
- Accompany and assist the Inspector in briefing station personnel.

3-2.2 Inspection Limitations.

3-2.2.1 Mooring Inspection Limitations.

Moorings are inspected using underwater inspection procedures to the maximum extent possible to include riser assemblies, ground leg assemblies and anchor assemblies. The riser or ground leg is inspected as far as practicable until the riser or ground leg assembly is completely buried and unable to be inspected by the diver. The use of lift bags or other lifting devices to raise riser and ground leg assemblies out of the seafloor are not used during mooring inspections for diver safety. Most portions of the ground legs that are completely buried and unavailable for inspection are generally unaffected by tidal changes and have seen minimal movement. The inspection results obtained on the riser or ground leg that are in the moorings “thrash zone” (portion of the mooring riser and ground legs that are raised and lowered by tidal effects) will provide a good indication of the overall condition of the mooring riser or ground legs. Moorings that are in locations with a large tidal change (> 5 foot (1.5 m)) should be inspected during periods of high tides. As fleet moorings proof test drag-embedment anchors, these anchors will be buried and unable to be inspected unless they are in hard soil conditions. Embedment anchors are also not available for inspection.

3-2.2.2 Diving Limitations.

The majority of moorings are installed in harbor locations where the water depth is less than 50 feet (15.2 m), making them suitable for dive operations performed using either scuba or surface supplied diving within the no-decompression dive limits (though it may take more than 1 dive to fully inspect a mooring). A few moorings (i.e. outer Apra Harbor, Guam; and Wilson Cove, San Clemente Island, CA) are in water depths between 130 to over 190 feet (39.6 to 57.9 m) sea water (FSW) and may require restrictions, command approval, and decompression diving procedures. Portions of some moorings may have to be inspected using remotely operated vehicle (ROV) equipment. Moorings that are in water depths 100 feet (30.5 m) or greater should be identified early in the inspection planning phase to ensure proper diving procedures, equipment and command clearances are planned and obtained prior to arrival at the project site.

3-2.3 Mooring Rating Criteria.

3-2.3.1 Mooring Rated Condition.

Moorings are satisfactory or unsatisfactory for continued use based on an engineering assessment of all inspection data – buoy condition, chain measurements, anchor and buoy position, and other factors. The relationship between mooring condition and rating is summarized below and in Table 3-2.

- If the mooring chain wire diameter measures between 90% and 100% of its original wire diameter and surface components measure 90% to 100% of the original wire diameter, the mooring is considered as C1 (formerly referred to as Good).
- If the mooring chain wire diameter measures between 90% and 100% of its original wire diameter and only topside components measure 80% to 90% of their original wire diameter, the mooring is assessed as C2 (formerly referred to as Fair).
- If the mooring chain wire diameter measures between 80% and 90% of its original wire diameter and topside components measure at least greater than 80% of their original diameter, the mooring is assessed as C3 (also formerly referred to as Fair).
- If the mooring chain or surface components measure less than 80% of the original wire diameter for the required mooring class, the mooring is assessed as C4 and is not satisfactory for continued use (formerly referred to as Poor).

Table 3-2 Mooring Rating Criteria

FACLITY RATING	FACILITY IMPACT ON OPERATIONS	FACILITY CONDITION
C1- FACILITY OPERATIONAL	No impact on operations.	Condition of mooring is considered satisfactory for continued use.
C2 – FACILITY PARTIALLY OPERATIONAL AT A REDUCED CAPACITY	Mooring may be unable to be used at its full design capacity. An engineering assessment is required. Restrictions could impair operations. Vessels may have to find alternate facilities to moor.	Mooring inspection has revealed irregular or degraded surface materials and may no longer be able to hold rated capacity. Topside components or mooring buoy must be replaced or repaired to restore to original design condition
C3 – FACILITY PARTIALLY OPERATIONAL AT A REDUCED CAPACITY	Mooring may be unable to be used at its full design capacity. Restrictions could impair operations. An engineering assessment is required. Vessels may have to find alternate facilities to moor.	Mooring chain or underwater connecting jewelry is degraded and may no longer be able to hold rated capacity. Underwater components must be replaced or repaired to restore to original design condition.
C4 – FACILITY NOT OPERATIONAL	Mooring is restricted from use. Vessels must use alternate facilities. Failure of mooring is imminent.	Mooring must be replaced. Mooring chain or connecting jewelry has degraded below 80% of required Mooring Class.

3-2.3.2 Mooring Condition Readiness.

Mooring condition readiness is a numerical value assigned to a mooring that provides the mooring custodian or local Public Works Officer (PWO) an assessment of the mooring's readiness condition using the Infrastructure Condition Assessment Program (ICAP). It is similar to the Mooring Rated Condition described in paragraph 3-2.3.1 above, but through the assigned numerical value, provides additional information as to the condition of the mooring and sustainment requirements. The mooring condition readiness values and associated condition is shown in Table 3-3.

Table 3-3 Mooring Condition Readiness Scale

VALUE	CONDITION
90	All > 90%; minimal corrosion present.
80	All > 90%; moderate corrosion present or partial damage to fenders or chafe rails or reflective tape in need of replacement.
75	All > 90%; heavy corrosion present or fenders or chafe rails completely missing or top jewelry not secure.
70	All > 90%; buoy refurbishment required.
60	Topside < 90%; minimal to moderate corrosion present.
55	Topside < 90%; moderate to heavy corrosion present.
50	Below water connection assembly not secure.
40	Underwater < 90%; minimal to moderate corrosion present.
30	Underwater < 90%; moderate to heavy corrosion present.
20	Underwater < 80%; minimal corrosion present or legs dragged off location.
10	Underwater < 80%; moderate corrosion present.
0	Underwater < 80%; heavy corrosion present or a ground leg is detached.

3-2.4 Chain Wire Diameter Sampling.

The most common measurements performed in the mooring underwater inspection is selective sampling using Go/No-Go gauges. A selective sampling of chain wire diameter measurements is used to evaluate the condition of a mooring. See Appendix L-1 for a video link for the inspection of chain using double and single link Go/No-Go Gauges.

3-2.4.1 Selective Sampling Locations on the Riser Assembly.

For a riser assembly in water depths less than 90 feet (27.4 m), minimum selective sampling is performed at three locations; (1) One or two links below the buoy connection in the splash zone (area near the surface where it is rich in oxygen due to wave action and the presence of uniform corrosion may be present); (2) At mid-water depth; and (3) Just above the seafloor or the ground ring connection in the thrash zone (area where mechanical wear may be present due to mechanical wear by cyclical tidal action). If the riser is in water depths greater than 90 feet (27.4 m), then the amount of mid-water selective sampling should be increased by one for every 30 feet (9.1 m) the water depth is greater than 90 feet (27.4 m).

For example, if the water depth at the mooring site is 100 feet (30.5 m), minimum selective sampling should be performed in the splash zone just below the buoy connection, the thrash zone just above the seafloor or ground ring connection and two interior locations on the riser. These four locations should be approximately equally separated from themselves.

Since FM3 connecting links have a larger bar diameter than their corresponding nominal size FM3 chain, measurements are taken one to two links away to ensure that a connecting link is not part of the double link measurement.

3-2.4.2 Selective Sampling Locations on a Ground Leg Assembly.

For a ground leg assembly, minimum selective sampling is performed just past the ground leg's connection to the ground ring, at 30 feet (9.1 m) intervals, and one to two links from its connection to the anchor or where the ground leg disappears into the mud line and cannot be further inspected. The number of links for approximately 30 feet (9.1 m) of FM3 chain is provided in Table 3-4.

Table 3-4 Chain 30 Foot Length Link Count

CHAIN SIZE	LINK QTY	CHAIN SIZE	LINK QTY
1.75	51	2.75	32
2	43	3.5	26
2.25	40	4	22
2.5	36		

3-2.4.3 Double Link and Single Link Go/No-Go Gauges.

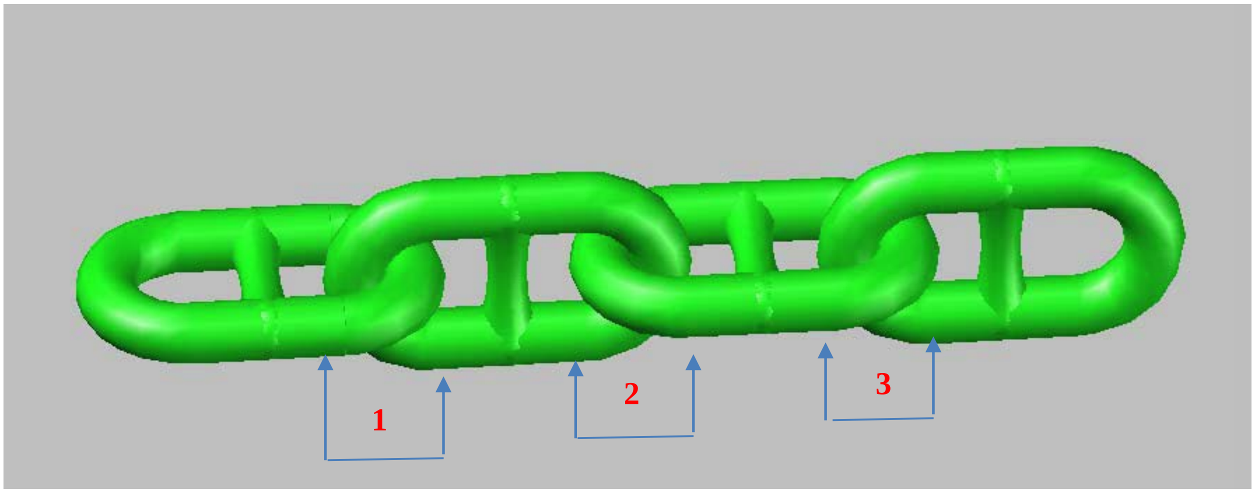
Go/No-Go gauges come in single link and double link sizes. Double link gauges are used to measure the combined bar diameter of two joined links where the two links connect under tension to detect the combined effects of corrosion and mechanical wear. Suspended portions of chain, particularly the riser, are in tension so double link Go/No-Go gauges are frequently used to inspect riser assemblies.

Single link gauges are used to measure the bar diameter of an individual chain link. Single link gauges are used on portions of the riser and ground legs that are not in tension or are slack. Portions of a ground leg or riser that is laying along the seafloor may be slack since its weight is being supported by the seafloor and chain tension is resisted by static friction between the chain links and the seafloor. Chain not in tension will have points of no contact between adjacent links and must be inspected using single link gauges procedures.

3-2.4.4 Measurement Set.

At each selective sampling location, a measurement set is taken using either the double link or the single link Go/No-Go gauges. A measurement set is defined as three consecutive measurements of a chain link joint. A chain link joint contains the connected ends of two adjacent chain links. A measurement set will contain both chain link connection points for 2 chain links and one chain link connection point for 2 other chain links. Therefore, one measurement set provides inspection data on 4 chain links. Figure 3-8 shows one measurement set with three consecutive measurements.

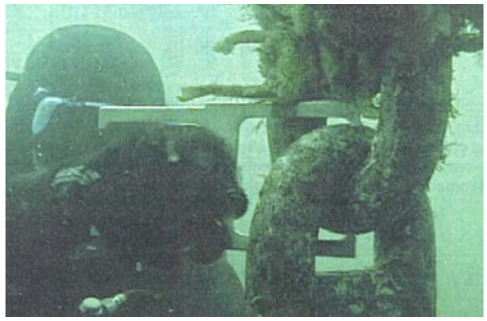
Figure 3-8 Measurement Set



3-2.4.5 Double Link Measurement Set.

Each of three consecutive measurements are taken using double link gauges as shown in Figure 3-9. At each measurement, both ends of a chain link joint are measured simultaneously with one measurement as the double link gauge is held approximately parallel to the plane bisecting the long axis of the joined chain links in performing the measurement.

Figure 3-9 Double Link Measurement at a Chain Link Joint

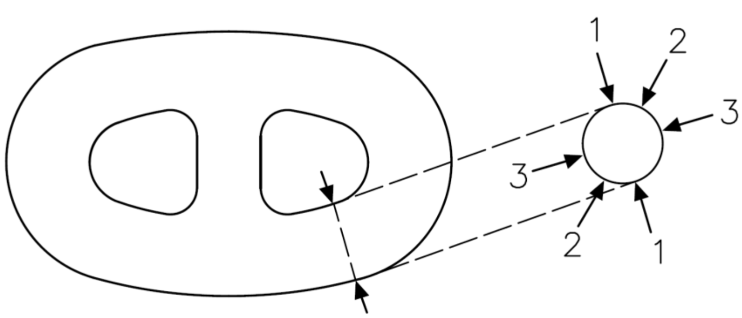


3-2.4.6 Single Link Measurement Set.

Single link measurements are more time consuming because one must take multiple single link measurements on both chain links in a single chain link joint. Since the links are slack or have a gap somewhere between them, one must measure the link from several (at least three) directions of approach around the link. Care must be taken to do these measurements as far as practical from the stud of the chain link, as this area is normally larger in diameter and generally not a contact point for wear. As the other joined link will tend to hinder taking single link measurements, several measurements are taken from different directions of approach as close as possible to where the chain contact points on the link are.

Once one chain link end is done, the same quantity of single link measurements is taken on the adjacent end of the other joined link. When both ends are inspected multiple times from different approach directions, that constitutes one measurement. This is repeated at the next two adjacent chain link joints to complete the measurement set at that location on the mooring assembly. Figure 3-10 shows single link gauge measurements on the end of one chain link.

Figure 3-10 Single Link Measurement



3-2.4.7 Using the Correct Go/No-Go Gauge Size.

Though one of the planning requirements is to review prior inspection reports and obtain a copy of the mooring configuration drawing, the inspector and inspecting divers should not take the information for granted and verify the chain size prior to performing chain measurements using the Go/No-Go gauges. This can be done in the field by fully cleaning the marine growth and excessive corrosive materials off one chain link a few feet below the buoy connection and measuring the overall outer length of a single link using a ruler. The length of the link divided by 6 will provide the nominal chain size. Chain link lengths for fleet mooring chain are provided in Table 3-5.

Table 3-5 Chain Link Lengths

CHAIN SIZE	LINK LENGTH (inches/centimeters)	CHAIN SIZE	LINK LENGTH (inches/centimeters)
1.75	10.5 (26.67)	2.75	16.5 (41.91)
2	12 (30.48)	3.5	21 (53.34)
2.25	13.5 (34.29)	4	24 (60.96)
2.5	15 (38.10)		

3-2.4.8 Cleaning of Chain Link Joint for Inspection.

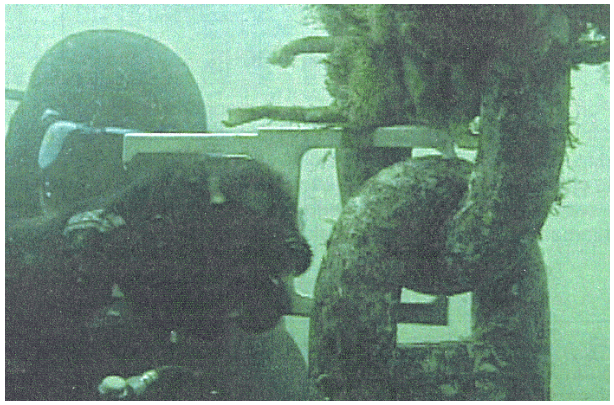
One of the important steps in the mooring inspection is the proper cleaning of the chain links for inspection. The portion of the chain links for inspection is cleaned to “bare metal”, i.e. all the marine growth is removed as well as heavy oxidation materials in the areas of the chain link where single or double link measurements are to be taken (Paragraph 3-2.4.1 and Paragraph 3-2.4.2). Note that the entire link doesn’t have to be cleaned, just the outer side of the ends of each link in a chain link joint where the gauge measurements will be taken. Note for single link measurements, a larger portion of the chain link ends will require cleaning. Due to the proximity of available light, increased presence of oxygen, less motion and sometimes warmer temperature, not to mention that the movement of the chain in the thrash zone can keep the links free of growth and corrosion, there will be more cleaning required in the splash zone than the thrash zone.

Safety Warnings:

Failure to properly clean the inspection area of the chain links may provide erroneous measurements leading the inspector, custodian, and users of the mooring system to an improper conclusion on the mooring condition that could result in an unsafe mooring condition for a moored vessel.

Divers should be aware of the potential movement of the chain, especially when working on the ground legs.

Figure 3-11 Chain Link End Cleaned for Inspection



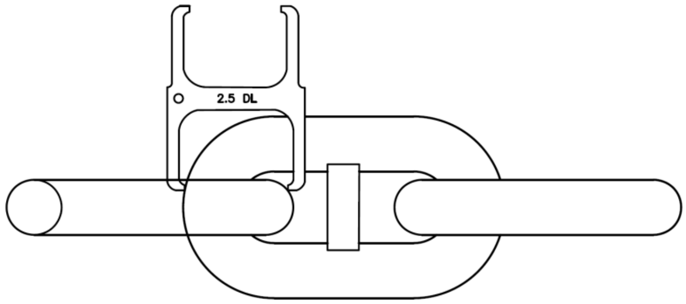
3-2.4.9 Go/No-Go Gauge Measurements.

Whether you are using double link or single link Go/No-Go gauges the procedural steps at each measurement location are the same. Once the inspecting divers have verified the chain size and have the correct set of gauges and the chain link areas have been cleaned, the following steps are performed:

(1) Note the water depth at the measurement set location on the riser or ground leg. When taking readings on a ground leg, note the distance from the ground ring to the measuring set location. On the riser, this measurement is less critical but the diver should still note the distance between the buoy shackle and the measurement set location.

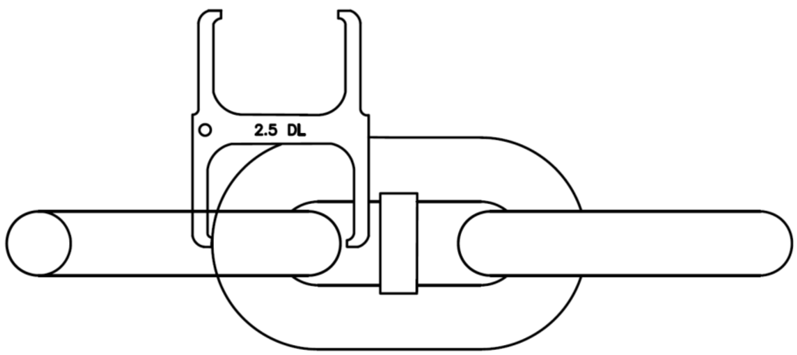
(2) Start with the 90% side (the larger of the two jaws) of the gauge. It is recommended that a single white strip of electrical tape be wrapped around the sides of the 90% jaw for easy recognition in low visibility conditions. Try to pass the 90% jaw over the end of the link (or the ends of both chain link ends at a chain joint if using double link gauges). If the gauge does not pass through, then the measurement is recorded as >90% of the chain's original wire diameter (OWD). See Figure 3-12. Then the inspecting diver would proceed onto the next consecutive measurement location. (Remember for using single link gauges one has to inspect the ends of both connected links individually from at least three angles of approach.)

Figure 3-12 Chain >90% of OWD Using Double Link Go/No-Go Gauges



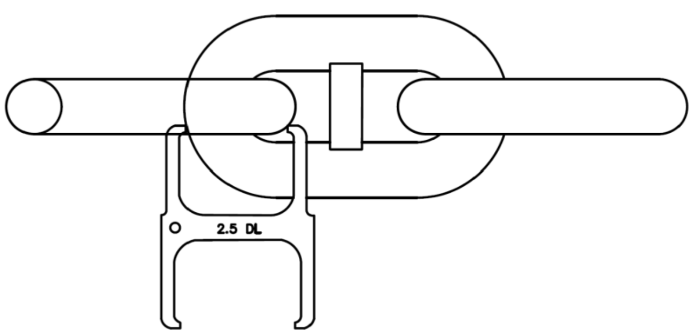
(3) If the >90% jaw does pass through (or if doing single link gauge measurements the 90% jaw passes through on at least one time), we know that the chain is <90% of OWD. See Figure 3-13.

Figure 3-13 Chain <90% of OWD Using Double Link Go/No-Go Gauges



(4) The diver then will flip the gauge so the 80% jaw (smaller of the two jaws on the gauge) and repeat the measurement process. If the 80% jaw does not pass through, then the measurement is recorded as >80% of OWD. See Figure 3-14. Then the inspecting diver would proceed on to the next measurement location.

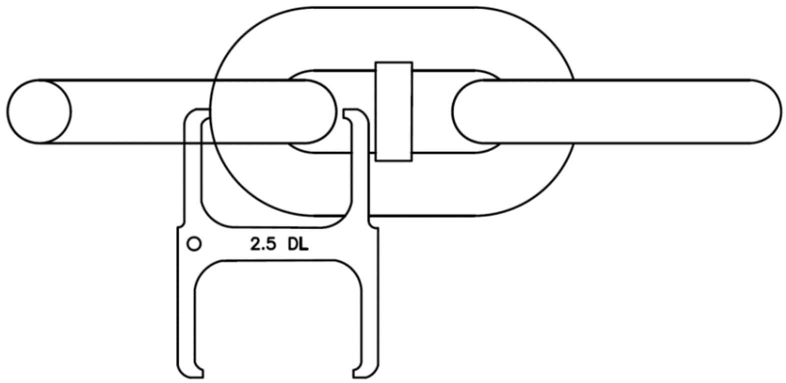
Figure 3-14 Chain >80% of OWD Using Double Link Go/No-Go Gauges



(5) If the >80% jaw does pass through (or if doing single link gauge measurements, the 80% jaw passes through on at least one time), then the

measurement is recorded as <80% of OWD. We don’t know the exact %, but we do know that it is <80% of OWD. See Figure 3-15.

Figure 3-15 Chain <80% of OWD Using Double Link Go/No-Go Gauges



(6) Attach a tie-wrap (zip tie) around the stud(s) on both links (for double measurements) or single link (for single link measurements) that were <90% of OWD. The inspecting divers should get a still photo showing the 90% or 80% jaw passing through the single link or link joint or a video recording of the measurement. Then the inspecting diver would proceed on to the next measurement location.

(7) The above sequence is repeated at each measurement location within a measurement set and at each selective sampling location on the riser and ground leg. For mooring risers and exposed portions of ground legs that are 9 links or less in length, perform single or double link measurements on all chain links as described in Paragraph 3-2.4.1 and 3-2.4.2.

Some moorings have oversized chain on the mooring riser and/or ground legs that are located in the thrash zone to extend the mooring’s operational use before sustainment operations are required. Oversized mooring chain that is found to be <80% OWD should be remeasured using calipers, to the maximum extent possible to determine its actual % remaining to allow for an engineering assessment on the continued use of the oversized mooring chain.

3-2.4.10 Go/No-Go Gauge Measurement Evaluation.

Measurements >90% of OWD indicate that the chain is still in “Good” condition. Measurements between 80% and 90% of OWD indicate that the chain is in “Fair” condition. Measurements <80% of OWD indicate that the chain is in “Poor” condition.

Once all ground leg assemblies and riser assemblies are fully inspected, the mooring is assigned an overall rating per section 3-2.3 based on the lowest condition found. As the mooring is only as good as the “weakest” link, only one measurement found to be between 80% and 90% of OWD will require the entire mooring system to be rated in C2 or C3 (Fair) condition. Likewise, all it takes is one measurement <80% of OWD for the entire mooring system to be rated in C4 (Poor) condition. It takes all measurements to be >90% of OWD for the mooring system to be rated in C1 (Good) condition.

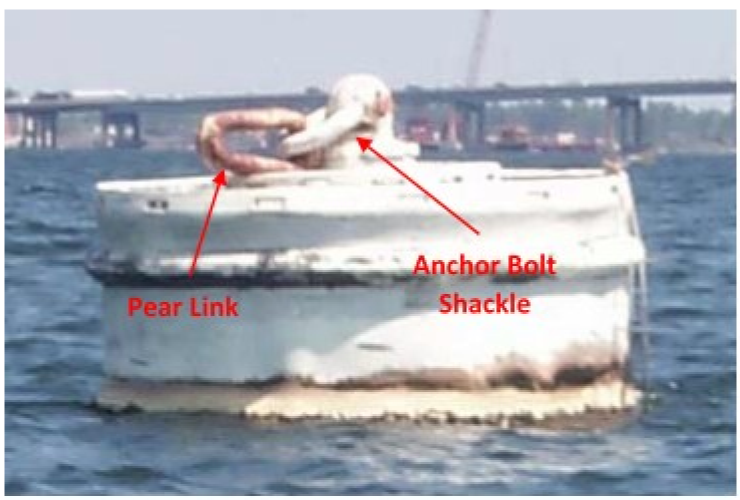
Locations where a measurement <80% of OWD is found should be verified by the dive superintendent, inspector or project superintendent. Additionally, still photo or video documentation should be performed at any location where measurements were found to be <90% of OWD to aid the mooring custodian to seek funding to repair the mooring.

3-2.5 Top Jewelry Inspection Requirements.

Standard top jewelry on fleet moorings include an anchor bolt shackle and two pear links (Figure 3-16). Inspection of top jewelry and surface inspection of mooring buoys should be done on an annual basis. See Appendix L-4 for a video showing the methods to inspect the top jewelry on the buoy.

Similar condition terms as “Good”, “Fair” and “Poor” as described in paragraph 3-2.4.10 will be used in evaluating top jewelry components. The inspection report should note the type and quantity of top jewelry present on the buoy.

Figure 3-16 Buoy Top Jewelry



3-2.5.1 Anchor Bolt Shackle.

Anchor bolt shackles are inspected by caliper measurements at their wear points, an assessment of its overall condition with regard to mechanical wear, corrosion, serviceability, and security of shackle components. See Table 3-6 for Anchor Bolt Shackle dimensions.

- Using calipers, measure the bar diameter of the shackle’s pin between the bale of the shackle and the tension bar padeye Figure 3-17).

Figure 3-17 Measure Pin Diameter Close to Tension Bar Padeye

- Using calipers, measure the bar thickness of the bale of the shackle by its connection points with other hardware (Figure 3-18 and Figure 3-19).

Figure 3-18 Measure Wear Point Using Calipers

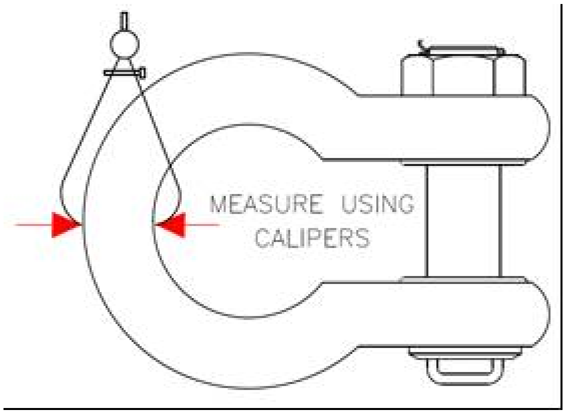


Figure 3-19 Measure Along Wear Point Axis

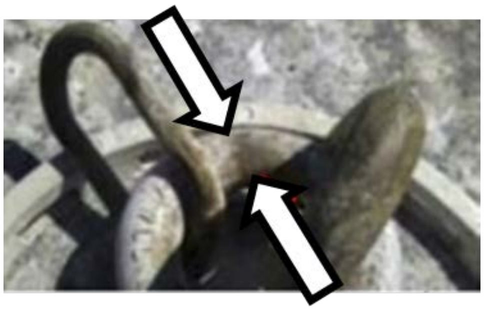
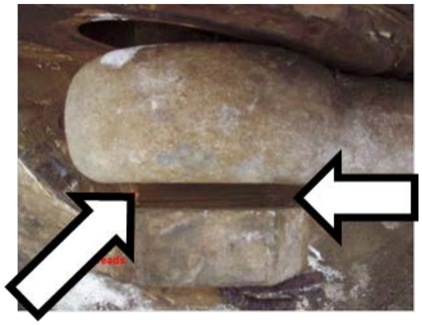


- Verify if the correct shackle size is on the buoy. Fleet mooring 8 foot (2.44 m) diameter (small) foam buoys have a 3-inch (76 mm) anchor bolt shackle. Fleet mooring 11.5-foot (3.51 m) diameter (medium) buoys have a 4-inch (102 mm) anchor bolt shackle (Figure 3-20).
- Verify if a cotter pin or safety bolt is present on the shackle nut. Note its condition with regard to corrosion.
- Check if the nut is tight on the shackle pin (Figure 3-21).

Figure 3-20 3-inch Shackle on Medium Foam Buoy

Figure 3-21 Nut on Shackle Pin Not Fully Seated



- Note the overall condition of the shackle with regard to corrosion (Figure 3-22 and Figure 3-23).

Figure 3-22 Minimal Corrosion

Figure 3-23 Heavy Corrosion

For mechanical wear at the pin and bale contact points, the buoy anchor bolt shackle is assessed as C1, C2 or C4 using similar criteria as done for chain measurements. Table 3-6 provides catalog dimensions for Fleet Mooring anchor bolt shackles and 90% and 80% levels. Rust products should be removed prior to performing caliper measurements to obtain accurate measurements at the wear points.

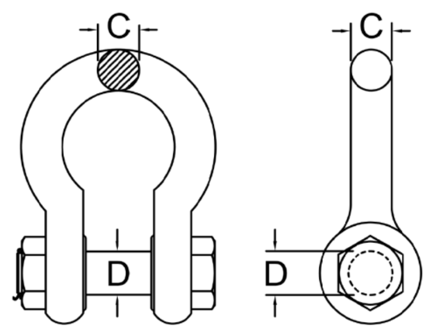
Assessment of the overall condition of the shackle is generally based on the judgment of the inspector. If the shackle shows excessive corrosion, it should be scheduled for replacement. Note that the safe working load of a 3-inch Crosby G-2140 anchor bolt shackle (smallest shackle found on fleet mooring foam buoys) is 110 tons (979 kN) and will be found on Class E moorings that are rated for 25 tons (222 kN). As the buoy shackle is significantly stronger than the mooring rating, moderate to heavy corrosion can be tolerated provided that caliper measurements are >90% of the design dimensional value. However, if the shackle is assessed to have excessive corrosion, it should be scheduled for replacement.

Shackles found without a safety bolt or cotter pin should be corrected by either the local custodian or the inspection team. The absence should be documented in the inspection report as well as the corrective action taken.

Loose nuts should be tightened up immediately by the local custodian or the inspection team. This finding should be documented in the inspection report as well as the corrective action taken.

Table 3-6 Anchor Bolt Shackle Dimensions

Size (inch)	Location	Catalog (inch)	90%	80%
3	Pin	Dim D – 3.25	2.93	2.60
3	Bale	Dim C – 3.62	3.26	2.90
4	Pin	Dim D – 4.25	3.83	3.4
4	Bale	Dim C – 4.56	4.10	3.65



3-2.5.2 Pear Links.

Pear links are inspected by caliper measurements at their wear points, as well as an assessment of its overall condition with regard to corrosion.

- Using a tape, measure the inside length of the pear link.
- Using a tape, measure the overall length of the pear link.
- Using calipers, measure the bar diameter of the pear link at both ends as close as possible to the contact points (Figure 3-24).
- Verify that the correct size pear links are on the buoy. The pear link size should be equal or greater in diameter than the required size chain for the design class rating for the mooring.
- Record the serial number, year of manufacture and manufacturer of the pear link. Typical serial number information on fleet mooring pear links are shown in Figure 3-25.

Figure 3-24 Wear Point & Direction On Fleet Mooring Pear Link

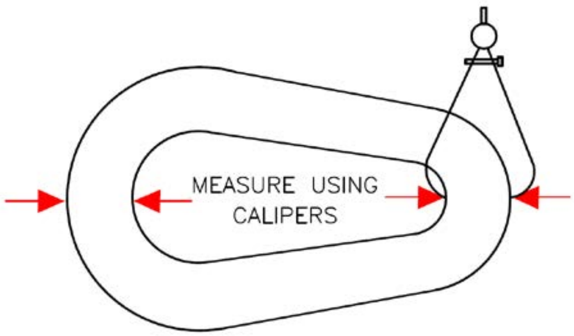


Figure 3-25 Pear Link Marking Data

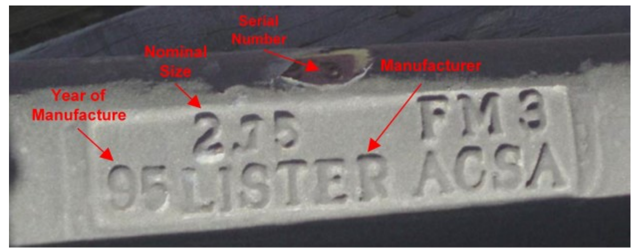


3-2.6 Mooring Buoy Inspection Requirements.

3-2.6.1 Surface Inspection of Mooring Buoys.

Surface inspection of the buoy includes freeboard measurements, damage assessment, tension bar padeye condition assessment, reflective tape, and chafing and fender rail damage assessment. If the buoy has a navigation light, it should be inspected for functionality and its attachment bracket inspected for condition assessment. See Appendix L-5 for a video showing the techniques for a surface inspection of a foam Buoy.

- For foam buoys, record the serial number, contract number, year of manufacture and manufacturer of the buoy. Typical serial number information on foam buoys are shown in Figure 3-26.

Figure 3-26 Foam Buoy Identification Plate

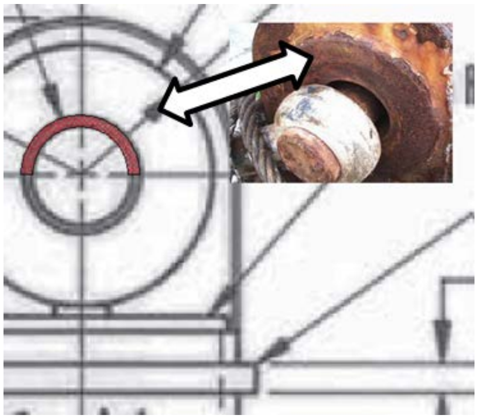
- Record the size (diameter), type (foam or steel), style (drum or peg top), method of connection (tension bar of hawse pipe) presence or absence of any attached vessels. If the identification plate is illegible, exclude the fenders when measuring the buoy diameter.
- Note the overall condition of the tension bar padeye with regard to corrosion (Figure 3-27 and Figure 3-28).

Figure 3-27 Minimal Corrosion on Tension Bar Padeye

Figure 3-28 Excessive Corrosion on Tension Bar Padeye

- Visually inspect the condition of the wear bushing inside the padeye along the upper half of the padeye hole in the direction of pull (Figure 3-29).

Figure 3-29 Location of Tension Bar Padeye Wear Bushing



- Record the freeboard of the buoy from the waterline to the deck line (the top flat surface of the buoy, not counting the rub rails) at the edge of the buoy. Measure from the top surface of the buoy. If the buoy has a severe list due to an attached vessel or excessive attached hardware, measure the high and low sides to obtain an average freeboard.
- Assess the buoy hull for damage, holes and or dents. On steel buoys, note level and type of corrosion (i.e. pitting, rust bleeding, level of corrosion) on buoy shell. If buoy has an outer fiberglass or urethane coating note any cracks, peeling or other damage (Figure 3-30).

Figure 3-30 Outer Coating Loss on Steel Buoy

- Visually inspect the upper chafing rails for damage. Remove debris from drainage holes on chafing rails. On a buoy, record the quantify of chafing strips, method of attachment and presence of any broken mounting brackets, bolts, etc.
- Visually inspect the fenders for damage. On a steel buoy, record the quantity of fenders, method of attachment and presence of any broken mounting brackets, bolts, etc.
- Assess the condition of the reflective tape and legibility and correctness of buoy identification markings.
- Note and record any significant listing not caused by a moored vessel, the moored diving platform or top jewelry.

Tension bar padeyes are made from mild A36 grade steel, which is a softer steel than that used for the shackle pin. Consequently, they are subject to elongation of the padeye in the direction of the load once the wear bushing has worn through. Dents to the outer buoy shell should be inspected closely, especially on steel buoys, to ensure that the water tightness of the buoy is not compromised. These buoys should be monitored in annual inspections as these points will form local points of corrosion that will spread over time.

Assessment of the overall condition of the buoy is generally based on the judgment of the inspector. Buoys with damaged fenders, chafing rails, reflective tape in need of replacement, minor dents to the hull on foam buoys, moderate corrosion on the tension bar padeye may still be satisfactory for continued fleet use as these are either minor repairs or do not affect the ability of the buoy to support the suspended portions of the mooring system or reduce its load carrying capacity.

Depending on the level of corrosion on the buoy tension bar padeye, the amount of outer hull damage, presence of an unexplained buoy list or excessively low freeboard (i.e. is the freeboard significantly less than from the last inspection?), condition of the padeye wear bushing, the buoy may be assessed as in C2 (Fair topside) or C4 (Poor topside) condition. Assessing the buoy in Poor condition indicates that there is sufficient damage or corrosion on the buoy indicating a significant reduction in buoyancy and/or mooring load capacity or its condition presents a risk of either loss of buoyancy, mooring load capacity or operational safety if not immediately replaced or repaired.

A rating of C4 (Poor) on a buoy will also cause the entire mooring system to be rated in C4 condition and unsatisfactory for continued fleet use. Lack of marine growth cover or the removal of the outer cover in one area of the buoy may be an indication of a vessel coming into contact with the buoy. Usually, impact damage will be seen above the waterline.

Note:

All efforts shall be made to replace steel buoys with foam buoys since steel buoys are much more difficult to inspect and maintain. Steel tension bar buoys can still be used, but hawse pipe buoys should be taken out of service.

3-2.6.2 Subsurface Inspection of Mooring Buoys.

While a surface inspection of a mooring buoy should be conducted on an annual basis, the subsurface buoy inspection will normally be conducted with the underwater inspection of the mooring system as a whole. Divers shall thoroughly inspect the buoy below the waterline.

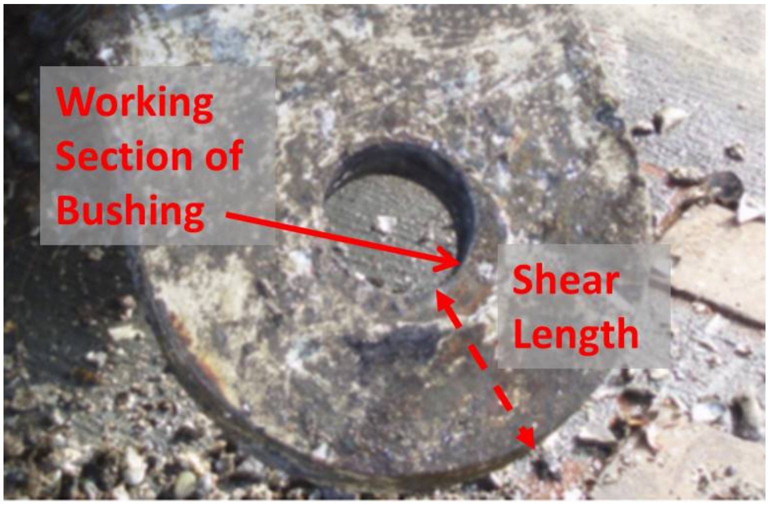
Safety Warning:

Divers should use extreme caution when working directly below a live/moving buoy.

- Record marine growth thickness. Care should be taken not to puncture the outer urethane shell on foam buoys or fiberglass/urethane coating on steel buoys.
- Lack of growth cover may be an indication of a vessel coming into contact with the buoy. In most cases, impact damage will also be seen above the waterline.
- Clean off the lower tension bar and visually inspect the condition of the lower tension bar zinc anodes. Replace zinc anodes if the remaining amount of zinc anode is >25% depleted.
- Visually inspect any submerged fenders for damage. On a steel buoy, record the quantity of fenders, method of attachment and presence of any broken mounting brackets, bolts, etc.
- Clean off the lower tension bar padeye and visually inspect the condition of the wear bushing inside the padeye along the lower half of the padeye hole in the direction of riser pull (Figure 3-31).

- Measure the tension bar thickness and shear length of the lower tension bar padeye (Figure 3-31). Divers should look for the bushing seam then trace it toward the wear direction. They should note if it thins out or if the base metal of the padeye is being penetrated. The measurement of the shear length is difficult with the swivel shackle in the way. It is suggested that divers use a thin metal rule to make that measurement.

Figure 3-31 Lower Tension Bar Padeye



Information from the underwater inspection of the buoy is combined with the inspection results from the above water inspection of the buoy to provide an overall buoy assessment as described in Paragraph 3-2.6.1

3-2.6.2.1 Bottom Buoy Jewelry Inspection Requirements.

The most common bottom buoy jewelry is the riser swivel shackle or the anchor bolt shackle.

3-2.6.2.2 Riser Swivel Shackle.

The riser swivel shackle is the most common connection of the mooring riser to the buoy. The inspection includes pin diameter caliper measurements, checking for full assembly and verification that tapered pins securing the swivel pins are secured by lead plugs. See Appendix L-2 for a video showing the techniques to inspect a Riser Swivel Shackle.

- Thoroughly clean off all marine growth on the swivel shackle at the swivel “gap” and along the front and back of the narrow sides of both the upper and lower jaw. Verify the presence of 2 lead plugs per side on both the upper and lower jaws (Figure 3-32).
- Using calipers, measure the bar diameter of the upper riser swivel shackle’s pin by the tension bar padeye. Measure the pin closest to the

buoy shackle or riser chain to not accidently measure the casted shim located on the inside of the swivel top and bottom bales.

- Using calipers, measure the bar diameter of the lower riser swivel shackle's pin by the end link on the mooring riser.

Figure 3-32 Riser Swivel Shackle Inspection Points

- Thoroughly clean off all marine growth by the swivel "gap" (Figure 3-32). Inspect the swivel gap for uniformity all around the swivel. The swivel "gap" should be less than 0.75-inch (19 mm). Gaps larger than 0.75-inch (19 mm), may indicate that the swivel shackle is in the process of coming apart. As shown in Figure 3-33, the outer sleeve is secured to the lower jaw extension with an all-around fillet weld. Larger gaps may indicate that this weld has failed and the lower portion of the swivel shackle is starting to unscrew itself from the upper jaw. If a gap >0.75-inch (19 mm) is measured, the divers should clean off the top of the jaw extension and inspect the condition of the weld as well as the level of the lower jaw extension to the locking tube. A failed weld or the lowering of the jaw extension in the locking tube is a sign that the swivel shackle is in need of immediate replacement. Moorings that have a "loose" riser swivel shackle are assessed as C4 and unsatisfactory for continued fleet use. Riser swivel measurement points are shown in Figure 3-34, Figure 3-35, Figure 3-36, and Figure 3-37.

Figure 3-33 Welding of Lower Jaw Extension

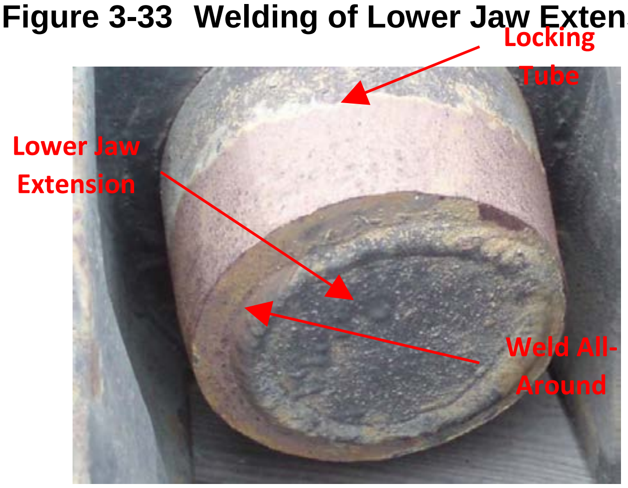


Figure 3-34 Top of Riser Swivel Shackle by Buoy

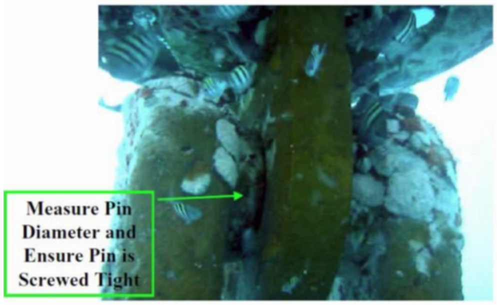

Figure 3-35 Cleaning and Inspection of Swivel Gap

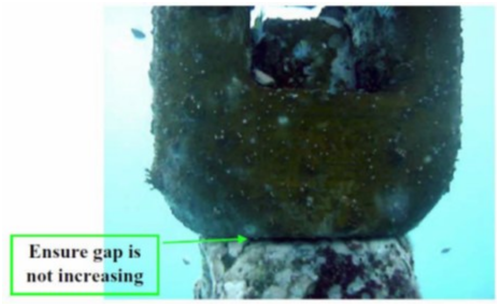

Figure 3-36 Bottom of Riser Swivel Shackle by Chain

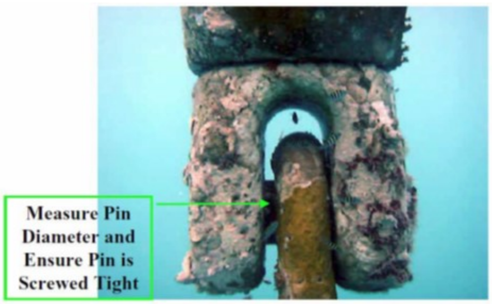

Figure 3-37 Lead Plugs in Riser Swivel Shackle Jaw

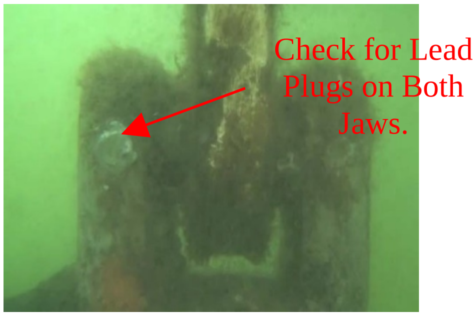


3-2.6.2.3 Anchor Bolt Shackle.

The anchor bolt shackle is inspected in a similar manner as stated in Paragraph 3-2.5.2.

- Clean the anchor bolt shackle.
- Using calipers, measure the bar diameter of the shackle’s pin between the bale of the shackle and the tension bar padeye (Figure 3-17).
- Using calipers, measure the bar thickness of the bale of the shackle by its connection points with other hardware (Figure 3-18 and Figure 3-19).
- Verify if a cotter pin or safety bolt is present on the shackle nut. Note its condition with regard to corrosion.
- Check if the nut is tight on the shackle pin (Figure 3-21).
- Check if the nut is secured to the anchor bolt with a fillet weld. Check the condition of the fillet weld.

3-2.7 Riser Chain Subassembly Inspection Requirements.

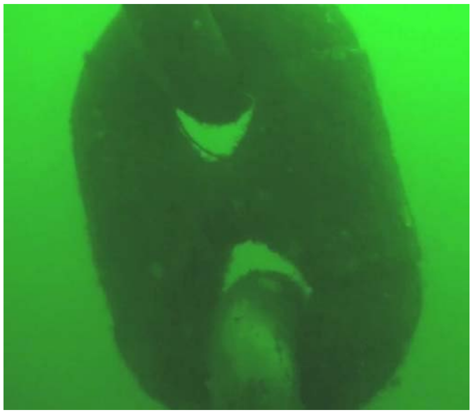
Inspection of the riser assembly includes verification of riser chain size, selective sampling and inspection of connecting hardware found along the mooring riser.

- Determine selective sampling locations in accordance with Paragraph 3-2.4.1. Clean one link near the buoy that will be the upper measurement set.
- Record type of chain found (i.e., forged, cast or Dilok).
- At the upper measurement set location, measure the overall outer length of a single link using procedures described in Paragraph 3-2.4.7
- At each measurement set, record water depth below the waterline. If the riser is laying along the seafloor, a link count referenced to the touchdown point on the seafloor or a connecting link may be used instead.
- At each measurement set, perform go/no-go gauge measurements per procedures as described in 3-2.4.5 (Figure 3-38). Record results.
- Note the presence of pitting found on any areas of links cleaned for measurements as well as on chain that is already “cleaned” in the thrash zone (Figure 3-40). Measure the diameter and depth of any pits found and record results. The length of the pits can be measured using the tape, while any probe that goes into the pit can be used to measure the depth of the pit.
- At chain joining link locations along the riser, clean off the connecting link, note type of CJL (Kenter, Baldt), report any broken, missing or loose parts and verify that a lead plug is secured in the large pin hole on top of the joining link

Figure 3-38 Double Link Go/No-Go Measurement

FM3 chain joining links are larger than the size chain they attach to (Figure 3-39). Therefore, they should look larger than the attached chain.

Figure 3-39 Chain Joining Link



Though chain joining links are the most common connection hardware found on a riser between the buoy connection and the ground ring or anchor connection, other connecting hardware may be found. They should be inspected in accordance with information provided throughout this manual.

Though most moorings have a riser made from a single size chain, some moorings use a larger size riser chain in the thrash zone. Therefore, mooring configuration drawings should be checked ahead of time and taking a link length measurement for each measurement set will prevent using the wrong size gauges.

Examples of worn chain found during inspections is shown in Figure 3-40, Figure 3-41, and Figure 3-42.

Figure 3-40 Pitting Corrosion on Chain in the Thrash Zone

Figure 3-41 Worn 3.5-inch Chain with Stud Missing

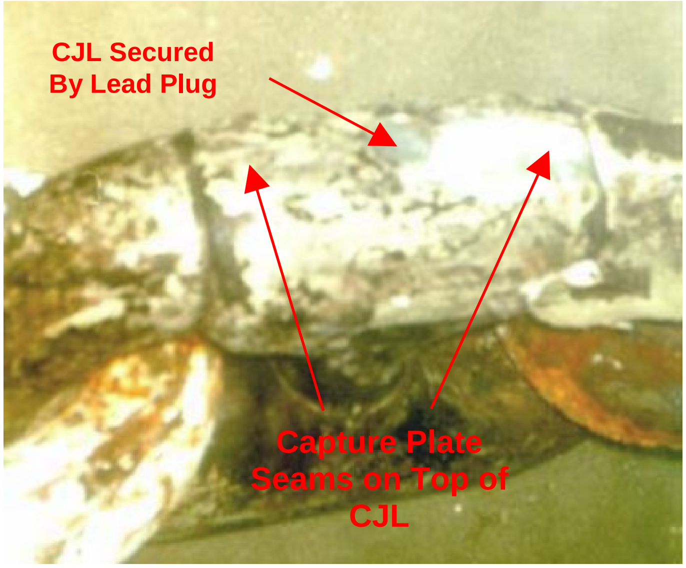
Figure 3-42 OWD <80% Chain in Mooring Thrash Zone

3-2.8 Connecting Hardware Inspection Requirements.

Chain joining links may be found along the riser and the riser is generally secured to a ground ring with an anchor joining link. The inspection process for both types of connecting links is the same. See Appendix L-3 for a video link showing the techniques to inspect chain and anchor joining links.

- Clean the connecting link of marine growth to identify the seams of the T-shaped capture plates (Baldt style-Figure 2-23 or Figure 2-25) or the link joints (Kenter-style-Figure 2-24 or Figure 2-26).
- Check the joining link for complete assembly.
- Check that the connecting link is at least equal or larger than the chain that is attached to it.
- Verify that the top pin hole on the connecting link is filled with lead (Figure 3-43). For the Kenter style joining link, there is no top or bottom pin hole. The larger hole is filled with lead while the other smaller hole is not. The large hole is located on top of the Baldt-style joining link where the T-shaped capture plate seams are located.

Figure 3-43 Lead Plug Present on CJL



3-2.9 Ground Ring Assembly Inspection Requirements.

The ground ring assembly consists of a ground ring and several anchor joining links (Figure 3-44) connecting the riser, ground legs and sometimes a sinker. Anchor joining links are inspected in accordance with the procedures outlined in Paragraph 3-2.4.8.

Figure 3-44 Ground Ring Assembly

- Check the ground ring for roundness (i.e. has it elongated in one direction?).
- Measure the inside diameter of the ground ring.
- Clean and measure the bar diameter of the ground ring near a connecting link (or at locations that show evidence of wear).

3-2.10 Sinker Connection Inspection Requirements.

Sinkers found on the riser are generally secured with a sinker shackle or a sinker hook. Sinkers found on the ground legs are generally secured with a plate shackle (Figure 3-45).

- Clean and check the plate shackle, sinker shackle or sinker hook for complete assembly.
- Check that the shackle nuts are tight on the shackle bolts.
- Check the integrity of the fillet welds that secure the plate shackle nut to the plate shackle bolt. For sinker shackles, check for the presence of a safety bolt or cotter pin.

Figure 3-45 Sinker and Plate Shackle

<u>Safety Note:</u>

Divers should inspect the connections of suspended sinkers with caution as motions imposed on the mooring system from surface weather conditions or attached vessels can cause the suspended sinker to move within the water column.

3-2.11 Ground Leg Chain Assembly Inspection Requirements.

3-2.11.1 Chain Measurements.

Ground legs are inspected using similar procedures performed for the riser chain assembly (Paragraph 3-2.7). The first measurement set is taken one to two links from the ground ring assembly. Subsequent measurement sets are performed along the ground leg every 30 feet (9.1 m) until reaching the anchor assembly or the ground leg buries into the seafloor and is no longer available for inspection. At the point of burial, a final measurement set is taken.

Connecting hardware such as chain joining links or sinker connections found along the ground ring are inspected using procedures outlined in Paragraphs 3-2.8 and 3-2.10.

Measurement sets on the ground leg will most likely include double link as well as single link measurements. As double link measurements are performed at locations where the chain is under tension, measurements taken on the suspended portions of the ground leg are usually done using double link Go/No-Go gauges. Measurements along portions of the ground leg that is lying on the seafloor may have to be performed using single link Go/No-Go gauges as the chain may be slack and gaps between the adjoining links may be present. The inspecting divers should carefully inspect the ground leg chain along the bottom to determine the correct type of Go/No-Go gauges to use.

Double and single link measurement procedures are addressed in Paragraph 3-2.4.

3-2.11.2 Compass Headings.

A compass heading should be taken for each ground leg. The compass heading should be referenced for the ground leg's direction from either ground ring to the anchor or vice-versa. The inspecting diver should record which reference was done during the inspection. Sometimes it is difficult to initially determine the ground leg direction (Figure 3-46) due to poor visibility, burial of the ground leg into the seafloor close to the ground ring, a minimal length of ground leg visible or excess slack in the mooring leg near the ground ring assembly. It is recommended that the diver swim out the leg until a consistent heading is obtained.

Figure 3-46 Ground Legs Just Below the Ground Ring

3-2.12 Anchor Assembly Inspection Requirements.

Anchors assemblies are generally buried and unable to be inspected. However, in locations having a hard bottom, embedment drag anchors may be partially buried or visible on the seafloor.

> **<u>Safety Note:</u>**
>
> While inspecting the anchors, divers should not go under the flukes or shank of the anchor.

Inspection of anchor assemblies include the following:

- Checking the connection hardware for presence of lead plugs on connecting hardware.
- Inspect the swivel gap for uniformity all around the swivel. The swivel "gap" should be minimal. For safety, the diver should not go under the anchor.
- Record whether the flukes are pointing into the seafloor or away from the seafloor. Record whether the flukes appear to be fixed or not fixed.
- Record the presence or absence of stabilizers. Check if the stabilizers are still welded along the back of the anchor crown.
- Referencing Figure 3-47, measure the width of the anchor's flukes along the backside (dimension B), the fluke length (dimension C) and the length of the anchor's shank (dimension A). This will aid in determining the size of the anchor.
- Record the presence of anchors found upside down or improperly installed (Figure 3-48 and Figure 3-49).
- Attach a plumbed surface float to the anchor crown. This can be used to obtain a location coordinate for the anchor as well as to verify the compass heading of the attached ground leg.

Figure 3-47 Stockless Anchor Nomenclature

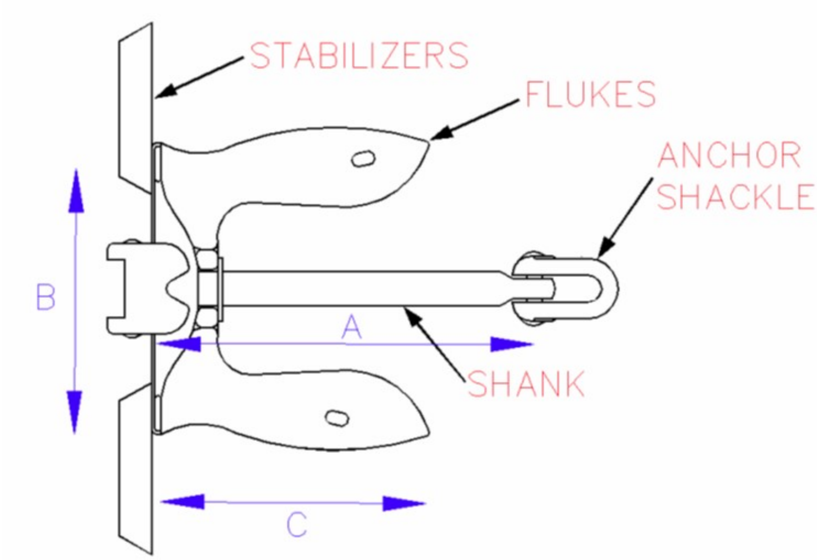


Figure 3-48 Upside Down Anchor

Figure 3-49 Upside Down Anchor and Incorrect Alignment

3-2.13 Cathodic Protection System Inspection Requirements.

3-2.13.1 Fleet Mooring Chain Link Zinc Anodes.

Records should be checked to determine if zinc anodes have been used on the mooring, but, it is pointed out that all chain used for fleet mooring ground legs and risers have been fabricated with a threaded hole in the chain link stud to attach a sacrificial zinc anode (Figure 3-50). As part of the mooring underwater inspection, zinc anodes, if present, should be inspected and replaced as required.

Figure 3-50 Zinc Anode Installed on a Chain Link

Existing zinc anodes are replaced when the anodes are less than 75% of their original size. Anodes that appear to be >75% of their original size should be tapped with a cleaning tool Figure 3-51 or a dive knife to see if the anode is actually solid or if it easily crumbles, indicating that it is spent and requires replacement. A representative anode from the riser and each ground leg should be brought to the surface and compared with a replacement anode to determine if the existing anodes require replacement.

Figure 3-51 Tapping the Zinc Anode

In addition to noting the reduction in volume of the existing anodes, divers should also check for the presence of the oxidation deposit on the zinc anodes. A whitish coating indicates that the anodes are working properly. A black coating, or no coating at all indicates that the anodes are not working properly, most likely due to a break in the metallic path (i.e. the zinc anode is not tight on the chain link, or there is some debris preventing metal-to-metal contact between the chain's stud and the anode's sleeve).

3-2.13.2 Assessment of the Chain's Cathodic Protection System.

Assessment of the chain's cathodic protection system is done either visually, or with a bathycorrometer, or both.

It is expected that zinc anodes installed previously will exhibit some degradation. This loss of individual link zinc anode material may be complete, leaving nothing more than the anode's sleeve and screw. This is common to moorings in areas with a strong tidal current and near the surface. In some cases, a good percentage of the anode will still be present. This may be found in moorings where tidal currents are relatively weak and the chain links are fully encrusted with soft coral growth.

The evidence of a white oxidation on the surface area of the individual anodes, in addition to having some percentage of depletion (remember to tap the anode with a knife or metal tool to determine its actual remaining size), will provide the inspector with an assessment of the chain's cathodic protection.

A diver-held bathycorrometer can also be used to provide a measure of the effectiveness of the cathodic protection system. (Figure 3-52).

Figure 3-52 Diver-Held Bathycorrometer

A diver held Bathycorrometer consists of a silver/silver chloride reference electrode, a self-cell, a digital voltmeter and a probe. The unit operates by measuring the potential difference between the reference electrode and the material being measured. The potential reading is displayed on a liquid crystal display.

The bathycorrometer should be soaked in water at the dive site for 20 to 30 minutes prior to initial use. In addition, the area of the chain that will be in contact with the bathycorrometer's probe must be cleaned to bare metal.

Readings between -0.80 to -0.90 Volt will indicate that the cathodic system is performing properly. After the attachment of new zinc anodes, a full day should be allowed for the cathodic protection system to set up before checking with the Bathycorrometer.

3-2.13.3 Oversize Chain Link Zinc Anodes.

When possible, oversized zincs are used to replace existing zincs to extend the cathodic protection to the next underwater inspection cycle. Table 2-5 provides recommended "oversized" zinc anodes per nominal chain size. As the length of the anode screw differs between various anode sizes, when replacing existing anodes with oversized anodes, be sure to use the screws that come with the new oversize anodes.

Note:

Regardless of using the design anode size or oversized anodes, the mounting hole must be free of debris and the anode tightened to the recommended torque for the anodes to work properly.

3-2.13.4 Replacement of Mooring Chain Link Zinc Anodes.

Mounting holes for anodes are on the same side of every other chain link in a shot as shown in Figure 3-53.

Replacement of zinc anodes is generally performed using the following procedures:

- Using an adjustable wrench or a 9/16-inch socket wrench, remove the existing anode screw and anode body from the chain link. For chain links that do not show an existing zinc anode, some cleaning of the chain link at the stud may be required to find the remaining anode. If all that is found is a screw inside a sleeve, that indicates that the anode material has been completely consumed. Pneumatic wrenches can be used as long as they are powered from a separate air source.
- Using a small brush, clean out the anode mounting hole of debris.
- Attach a new anode to the stud of the chain link using a new screw.
- Tighten the anode to the chain link by applying a torque approximately 20 to 30 foot-pounds (27 to 41 N-m).
- See Figure 3-54 for a picture of a diver attaching an anode to a chain link.

As the bolts are only 3/8-inch in diameter, applying too much torque could shear the screw. If the zinc feel's tight when grabbed by the diver's hand, it has sufficient torque to provide the necessary metallic path for the cathodic protection to properly perform.

Figure 3-53 Location of Anode Mounting Holes on FM3 Chain Links

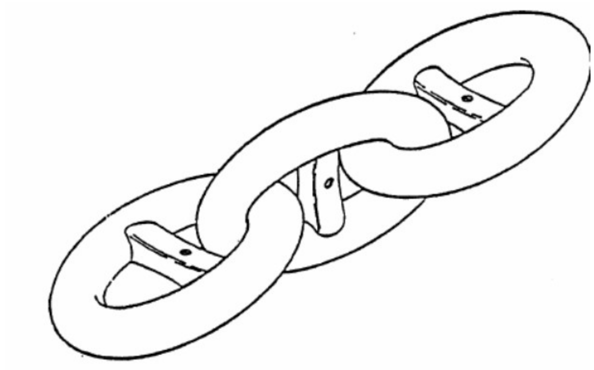

Figure 3-54 Diver Attaching Anode to Chain

Periodically, the diver will find chain links where the anode bolts were sheared at the stud during installation, preventing anodes to be attached to the chain link. The quantity of chain links unable to attach a zinc anode to should be recorded in the comment section of the mooring's inspection data sheet.

In addition to replacing the anodes on the chain, divers should replace the anodes on the bottom padeye of the buoy, see Figure 3-55.

Figure 3-55 Diver Installing a Zinc Anode on the Bottom Buoy Padeye

There are several methods that have been used on site to perform anode change out operations. Most methods involve the initial removal of the existing anodes, the initial loose attachment of new anodes followed by the tightening up of the new anodes. A supply of zincs is usually placed in a canvas bag positioned near the divers by topside support personnel. These tasks are usually divided among a dive buddy team based on diving conditions at the site, the quantity of zincs to be replaced and the direction of the dive supervisor. Divers should police up the area, removing zinc anodes and screws and all other materials.

CHAPTER 4 DOCUMENTATION OF MOORING INSPECTION RESULTS

4-1 RECORDING OF MEASUREMENTS IN THE FIELD.

Recording of measurements and observations in the field should be performed as soon as possible during the inspection to ensure that the data is not lost and that all required measurements are taken during the dive to minimize additional dives and the associated logistics to obtain the missing inspection data.

The data can be recorded by the diver using a dive slate. If topside communications are available, the information should be provided concurrently with the inspection process and recorded by topside personnel. Table 4-1 provides a list of necessary inspection data for type or mooring component to be recorded.

Table 4-1 Inspection Data

Component	Data Recorded	Comments
	Buoy Assembly Inspection Data	
Buoy Topside	Type and condition of buoy hull Diameter Freeboard Serial Plate Date (manufacturer, contract #, serial #, manufacture date) Buoy surveyed location Fender type and condition Chafe rail type and condition Reflective tape condition. Replacement of reflective tape if needed Tension bar padeye corrosion condition	Usually performed by the On-site Engineer Note type of survey system used, accuracy and datum of coordinates
Topside Jewelry	Pin diameter for shackles Pear Link measurements Assessment of cotter pins or safety bolts for shackles Wear assessment on shackles Wear assessment on pear links Serial number data on topside jewelry (spec, serial #, manufacturer) Top jewelry corrosion condition	Usually performed by the On-site Engineer
Buoy Below the Waterline	Condition of the buoy Marine growth assessment Tension bar padeye condition Wear bushing assessment	

Component	Data Recorded	Comments
Riser Assembly Inspection Data		
Riser Connecting Hardware Below the Waterline	Pin diameter for shackle or riser swivel shackle If riser swivel shackle, verify lead plugs and swivel gap measurement If anchor bolt shackle, assessment of cotter pins or safety bolt and bale measurement	
Riser	Water depth of all measurement sets Go/No-Go results for each measurement in a set Anode condition assessment (% depletion, oxidation coating) Type and amount of marine growth on riser	
Anodes	Percent remaining on existing anodes Size of replacement anodes Quantity of anodes replaced on the riser	25 – 30 ft-lbs (34 – 41 N-m) torque
Connecting Links	Type of connecting link Presence of lead plug on top of connecting link Assembly assessment of connecting link Wear assessment	Only the hole on top will be leaded
Sinkers	Assessment of attachment hardware of sinker to riser Condition of sinker	
Ground Ring	Inside diameter Bar thickness near connected components	

Component	Data Recorded	Comments
Ground Leg Inspection Data		
Ground Leg	Link distance of measurement sets from ground ring Go/No-Go results for each measurement in a set Anode condition assessment (% depletion, oxidation coating) Type and amount of marine growth on ground legs Leg compass headings to or from anchor and ground ring Location of legs along seafloor and assessment (buried or exposed, twisted, slackness, entanglement, etc.)	Single link go/no go gauges may be required
Anodes	Percent remaining on existing anodes Size of replacement anodes Quantity of anodes replaced on ground legs	25 – 30 ft-lbs (34 – 41 N-m) torque
Swivels	Presence of 4 lead plugs on open jaw swivels Gap assessment Wear assessment on pins	
Connecting Links	Type of connecting link Presence of lead plug on top of connecting link Assembly assessment of connecting link Wear assessment	Only the hole on top will be leaded
Shackles	Assessment of cotter pin and/or safety bolt Shackle nut to bolt weld assessment (except for topside shackles) Pin and bale wear assessment and measurements	
Sinkers	Assessment of attachment hardware of sinker to riser or ground leg Condition of sinker	

Component	Data Recorded	Comments
	Anchor Assembly Inspection Data	
Anchors	Type of Anchor Percentage of burial for anchors located Orientation of anchor Are the flukes fixed or free Are there stabilizers? If so, assess the condition of the weld along the anchor crown. Measure the anchor (fluke length, distance between flukes, shank length)	Note type of survey system used, accuracy and datum of coordinates
Shackles	Assessment of cotter pin and/or safety bolt Shackle nut to bolt weld assessment (except for topside shackles) Pin and bale wear assessment and measurements	
Anchor Joining Link	Type of AJL Presence of lead plug on top of connecting link Assembly assessment of AJL Wear assessment	Only the hole on top will be leaded
	Miscellaneous	
Water Conditions	Current condition Visibility Max water depth during inspection	
Seafloor	Type Presence of a crater caused by the ground ring	

An inspection form for each major component or subassembly that can be used to develop inspection slates is provided in APPENDIX D.

4-2 MOORING INSPECTION FORM.

Inspection results are recorded for each mooring using a mooring inspection form. Sample mooring inspection forms for both mooring surface inspections as well as mooring underwater inspections are provided in APPENDIX E.

The form is broken into 3 parts; (1) General Information; (2) Inspection Measurement Results; and (3) Inspection Comment Results.

4-2.1 General Information.

This section contains general information listing the following information:

- Mooring identification and report number
- Mooring assessment and condition ratings
- Mooring survey results
- Mooring zinc anode results
- Mooring buoy topside and top jewelry results

Provide both a geodetic location as well as Northing and Easting location for survey results. Provide the size and quantity of zinc anodes replaced. Provide caliper results of top jewelry measurements.

It is recommended that measurements found to be in C2 or C4 condition be highlighted in the inspection sheet.

4-2.2 Underwater Inspection Measurement Results.

This section is devoted primarily to recording the results of the Go No-Go gauge measurement sets or individual link measurements. If measuring the chain links using calipers, record these results in this section as well.

- If recording by measurement sets, record the condition % of the smallest of the 3 consecutive measurements. In the inspection comment results section, provide additional detail as to the actual measurements taken for the measurement set in the riser or ground leg block. If all measurements in a measurement set are identical, record this as “all 3 >90 (or >80 or <80)” in the condition % block.
- If recording each specific chain link measurement, then record the specific location and condition % result for each.

For riser swivel shackles and ground rings, catalog dimensions for measurement points, the nominal size of the component and the caliper measurement is recorded. Note that assessment of connecting components, presence of lead plugs, etc. are provided in the respective block on the Inspection Comment Results section.

Provide the location from waterline for riser measurements or from a well-defined reference hardware location for ground legs (i.e. the ground ring) either in feet (most commonly used for the riser) or in links (most commonly used for ground legs).

It is recommended that measurements found to be in C3 or C4 condition be highlighted in the inspection sheet.

4-2.3 Inspection Comment Results.

This section provides the inspector to record a more detailed and descriptive evaluation of the condition of the mooring for several different subjects. A minimum list of subject areas is provided in the APPENDIX F inspection forms. Additional subject areas may be added to the form as deemed necessary by the inspector. For example, a separate subject block may be provided for each specific ground leg, or inspection information on all the ground legs may just be provided under one block.

The following comment headings are provided in the basic inspection form.

General: State the final condition assessment of the mooring to include both its condition rating (i.e. C1-C4) and overall condition readiness (Maximo) value. If the mooring has been downgraded from its original design use, state the revised limitations to its usage. State what is required to return the mooring to a rating of C1 and its intended design use. Record vessel class moored to the vessel during the inspection. List marine conditions (i.e. currents, tide conditions) encountered during the inspection.

Buoy: List serial data found on the buoy. Provide supporting documentation to the buoy inspection results provided in section one.

Top Jewelry: List serial data found on top jewelry components. Provide supporting documentation to the top jewelry inspection results provided in section one. State presence or absence of cotter pins, safety bolts, lead plugs, etc. Provide any additional caliper measurements taken.

Riser: State the overall condition of the riser (i.e., good, fair, poor) and how measurements were taken (i.e. single or double link). Summarize the overall results of caliper measurements. If measurement sets have different results, then provide this detail in this section. Provide assessment to swivel shackles, connecting links and other attachments as to wear, assembly, presence/absence of lead plugs, caliper measurements, etc. State water depth of the ground ring recorded during the inspection.

Ground Legs: State the overall condition of the ground legs (i.e., good, fair, poor) and how measurements were taken (i.e. single or double link). Summarize the overall results of caliper measurements. If measurement sets have different results, then provide this detail in this section. Provide assessment to swivel shackles, connecting links and other attachments as to wear, assembly, presence/absence of lead plugs, etc. List the headings of the ground legs and the heading reference (i.e. from ground leg toward the anchor, or vice-versa). State if and when ground legs become buried and unable to be inspected. State tension condition and overall layout of the ground legs (i.e. are they slack or in tension; do they generally head in a straight line or have significant changes in headings; are they twisted with other legs, etc.). If sinkers are found, state their location and condition assessment of the sinker's attaching hardware. One may add additional blocks for each ground leg if needed.

Anchors: If anchors are found, state the overall condition of the anchors, whether they are buried and how deep, if the flukes are pointing up or down, if there are stabilizers. Record the percentage of anchors improperly installed or upside down. State the measurements of the anchors and verify the proper size. State if the anchors were surveyed (results though will be included in the survey paragraph below).

Anodes: State the size anode used for replacement. State the quantity of anodes replaced on the mooring system to include those installed on the buoy's lower tension bar padeye. State the overall assessment of the existing anodes found on the mooring system.

Marine Growth: Provide an overall condition assessment as to the type, hardness and amount of marine growth found on the bottom of the buoy, the top section of the riser, the bottom section of the riser and on the ground legs.

Survey: State whether the mooring buoy was surveyed or not. If the anchors are also surveyed, provide results in this block as well. State the type of survey equipment used and its reported accuracy. List the complete datum description used to record the survey and its surveyed reference measurements (i.e. U.S. feet or meters). State if a vessel was using the mooring during the survey. State software used for any coordinate conversions.

Bottom: State the type of soils found at the mooring.

Photo: Provide an identification photo of the mooring buoy. If the buoy identification is stenciled on the buoy, ensure that it is visible in the photo. Other specific photos from the underwater inspection of interest would be provided in section 3 of the body of the main report (Engineering Results).

It is recommended that supporting statements for C2, C3 or C4 conditions be highlighted in within the inspection comments.

4-3 INSPECTION FIELD OUT BRIEF.

A post-inspection out brief (debrief) should be performed by both the EIC and the project dive superintendent, providing initial results of the mooring inspection and any immediate revisions to the operational use of the mooring known at the time. The post-inspection debrief should be presented to the local activity custodian, but may include representatives from vessels, FEC or base tenants as local protocols dictate.

Ensure that the activity custodian knows that a preliminary inspection email providing initial inspection results will be sent out within 2 weeks and that the final inspection report will be provided within 90 calendar days.

4-4 PRELIMINARY INSPECTION EMAIL.

A preliminary inspection email is sent out by the EIC within 2 weeks of completion of the on-site inspection for underwater inspections only. The inspection message should be addressed to the local activity custodian's command as well as any activity that uses the moorings. Other commands whose responsibilities include base and mooring conditions should be included. The diving detachment's command (or private company) should also be included.

The preliminary inspection email should provide preliminary results of the inspection to include whether zinc anodes were changed out or not. The message should include contact information for the Inspector and when the detailed inspection report is expected to be released.

A sample preliminary inspection email is provided in APPENDIX E. This sample provides the body of the email.

4-5 DOWNGRADING OF FLEET MOORING SYSTEMS.

A mooring that is assessed to be in C2 or C3 condition (Fair) is downgraded to the next lower mooring class until repairs are performed to return the mooring system back to a C1 (Good) condition and satisfactory for continued fleet use.

Moorings that are assessed to be in C2 or C3 condition should be evaluated by a mooring engineer to determine what restrictions must be imposed on the mooring system until repairs can be performed to restore the mooring to its original design requirement. These restrictions can include reductions in environmental criteria before the vessel must vacate the mooring or a reduction in vessel class that can use the mooring under the original design criteria. The mooring capacity of the assessment must be within the downgraded class.

Sometimes the downgraded mooring class may not impact mooring operations at the site as the design vessel may have changed over the life of the mooring and current design requirements (i.e. a smaller class vessel) are lower than the original mooring design criteria (sometimes the inspector may find that the requirements for the mooring have increased requiring upgrades to the mooring as well as an engineering evaluation of the mooring for the new increased requirements). If the mooring was overdesigned for the design vessel (i.e. larger size components were used due to availability rather than what the design would call for) then the mooring in its interim class may still meet the original mooring requirement. Nevertheless, a full engineering evaluation of a downgraded mooring is required.

4-6 MOORING INSPECTION DOCUMENTATION REPORT.

A mooring inspection report is sent out by the EIC within 90 calendar days of completion of the on-site inspection. The inspection is provided to the local activity custodian's command as well as any activity that uses the moorings. In addition, the report should be sent to concerned higher commands as well as the inspecting organizations commands.

The inspection report is divided into three sections as described below.

4-6.1 Section One – Purpose.

This section states who, when and where the inspection was performed. It states the purpose of the inspection, as well as the use of zinc anodes. The section should include the inspection rated condition and condition readiness criteria of the mooring.

4-6.2 Section Two – Inspection.

This section provides background information on the location of the mooring systems that were inspected, their mooring configuration, the type of diving requirements used to perform the inspection, the type of survey used to perform the inspection and representative photographs of the mooring system buoys or components. To aid in inspection planning for future inspections at the location, a table should be included that lists all moorings at the location, their riser and ground leg chain sizes, the buoy type and diameter and, if appropriate, the quantity of zincs replaced during the inspection. A Points of Contact (POC) table is included at the end of Section 2, providing a listing of the points of contact for the inspection. Theses POC's are usually the Inspector, Mooring Manager, the custodian, the diving superintendent, etc.

4-6.3 Section Three – Results.

This section provides the inspection results, discussion of inspection findings, results of engineering analysis and recommendations for mooring sustainment actions, repairs, upgrades, etc.

4-6.4 References.

A separate section, after Section 3, Results, and before any Appendices. References used to document the inspection report are included here. These references will always include the design and installation reports but can also include from this guideline, mooring drawings, software analysis of the mooring, previous inspection reports, etc.

4-6.5 Documentation Report Appendices.

The following appendices are included in the inspection report document.

- **Appendix A -** Inspection Data: Provides the completed mooring inspection forms for all moorings inspected.
- **Appendix B -** Survey Results: Provides a description of the survey equipment used during the inspection, benchmarks used and surveyed location of buoys and/or anchors computed during the inspection. If using a DGPS (Differential Global Positioning System), what was used to

provide what was used to serve as the base station or what commercial service was used. The coordinates used to record results are provided in Easting and Northings as needed by the local activity or custodian. If different, results should also be provided in the same datum used for prior inspections. Results should also be provided in geodetic latitudes and longitudes, World Geodetic System 1984 (WGS84). This Appendix may also include the actual survey data and tables listing comparison of surveyed locations between the inspection and prior inspections and/or installations.

- **Appendix C -** Mooring Usage Charts: Provide a copy of the current mooring usage chart for all inspected moorings. These charts are revised in accordance with results obtained during the inspection. Actions such as downgrading the mooring, new design requirements, rated conditions below C1 would require an updated mooring usage chart be provided to the custodian.
- **Appendix D -** Mooring Property Records: Provide a copy of the current mooring property record to include the most recent mooring configuration drawings for all inspected moorings. These records are revised in accordance with results obtained during the inspection. As these records also tell the custodian when the next planned fleet mooring action is to be performed (i.e. sustainment, repair, upgrade, removal, etc.) as the next scheduled inspection, they are updated as part of the documentation of an underwater inspection.
- **Appendix E -** Engineering Analysis: This section provides support documentation of engineering analysis performed as part of the inspection report. These files may consist of wind and current force calculations, chain wear assessment, analysis input and output files, etc.

Since the mooring inspection report is standardized, completion of sections one and two are very similar in format and content to prior inspection reports for that site. The Inspector will spend the majority of his/her time completing section three as well as Appendices A. B and E (if necessary).

A mooring inspection report template is provided in APPENDIX F.

CHAPTER 5 MOORING MAINTENANCE AND REPAIR

Safety Warning:

Ensure all personnel have, maintain, and wear PPE (steel toed shoes, personal floatation vest, hard hat and other PPE for specific tasks i.e. leather gloves, safety glasses, etc.).

Daily safety briefs should emphasize everyone's responsibility for applying risk management.

5-1 MOORING STUD LINK ANODE REPLACEMENT.

Anode replacement has been covered previously, see Section 3-2.13, and is usually done as part of a mooring inspection. The method to replace these anodes is repeated here.

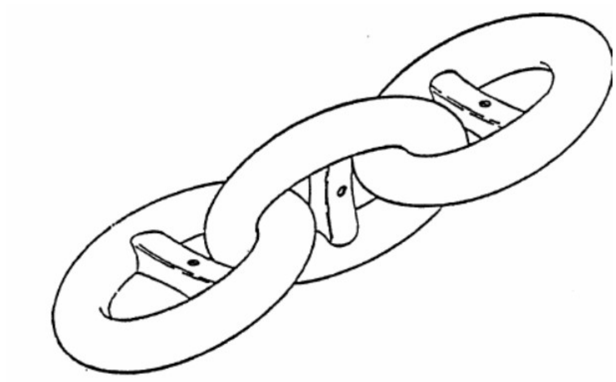
Replacement of zinc anodes is generally performed using the following procedures:

- Using an adjustable wrench or a 9/16-inch socket wrench, remove the existing anode screw and anode body from the chain link. For chain links that do not show an existing zinc anode, some cleaning of the chain link at the stud may be required to find the remaining anode. If all that is found is a screw inside a sleeve, that indicates that the anode material has been completely consumed.
- Using a small brush, clean out the anode mounting hole of debris.
- Attach a new anode to the stud of the chain link using a new screw.
- Tighten the anode to the chain link by applying a torque approximately 20 to 30 foot-pounds (27.1 to 40.7 N-m).

As the bolts are only 3/8-inch (9.5 mm) in diameter, applying too much torque could shear the screw. If the zinc feel's tight when grabbed by the diver's hand, it has sufficient torque to provide the necessary metallic path for the cathodic protection to properly perform.

Mounting holes for anodes are on the same side of every other chain link in a shot as shown in Figure 5-1.

Figure 5-1 Location of Anode Mounting Holes on FM3 Chain Links



Periodically, the diver will find chain links where the anode bolts were sheared at the stud during installation, preventing anodes to be attached to the chain link. The quantity of chain links unable to attach a zinc anode to should be recorded in the comment section of the mooring's inspection data sheet.

There are several methods that have been used on site to perform anode change out operations. Most methods involve the initial removal of the existing anodes, the initial loose attachment of new anodes followed by the tightening up of the new anodes. A supply of zincs is usually placed in a canvas bag positioned near the divers by topside support personnel. These tasks are usually divided among a dive buddy team based on diving conditions at the site, the quantity of zincs to be replaced and the direction of the dive supervisor. Diving operations shall be performed in accordance with US Navy Diving Manual (DoD dive units) or EM35-1-1, chapter 30 (non DoD dive units).

5-2 MOORING IN-SERVICE MAINTENANCE AND REPAIR.

5-2.1 Scope.

In-service maintenance and repair will be limited to the following:

- Minor underwater repairs.
- Minor buoy and riser assembly repairs.
- Replacement of damaged buoys and/or riser assemblies.

It should be noted that sufficient lift capability will be needed for replacement of buoys and/or riser assemblies and, in many instances, for repairs.

All mooring hardware must be tied down to prevent unplanned movements on the deck during transiting or from vessel motions during operations.

5-2.2 Equipment.

The following equipment must be readily available for use as needed:

- Crane barge, floating crane or vessel with lifting capacity, stability, quantity and size hooks, boom length and reach and if at all possible, means of self-mooring.
- A chain capture device (CCD) to securely stop off the chain to permit placement of the buoy onto the deck without personnel going underneath the load or in the fall zone.
- Tugboat, mule, or other vessel (for maneuvering and positioning the crane platform).
- Plenty of spare mooring connector hardware.
- High-pressure water pump (100 psi) and hose (for cleaning).
- Oxygen/acetylene kit and welder for chain cutting and welding operations.

5-2.3 Procedures.

Safety Warning:

At no time shall personnel be directly under a suspended load when the load is out of the water. Personnel on the barge deck shall be kept clear of the fall zone of the buoy and the riser chain to the maximum extent possible. The fall zone includes the area where a suspended load may fall. Personnel should be aware that the fall zone is moving as the buoy is lifted over the deck. Only qualified personnel, in accordance with EM385-1-1, under specific instruction from the designated Marine Construction Superintendent, may enter the fall zone to handle a load.

The buoy should be lifted only as high as minimally required.

Operation planning must include the use of a chain capture method that minimizes the necessity for personnel to work under suspended load.

Use a Load Indicating Device (LID) or crane equipped LID or Load Moment Indicator to determine the load for all installation/retrieval lifting operations.

Every attempt should be made to plan operations that keep DIVERS from working under the load. If no alternatives can be found, every effort should be done to minimize the diver’s time spent under the load.

5-2.3.1 Buoy Replacement (Riser-Type Mooring System).

A buoy in a riser-type mooring system can be replaced without removing the mooring. Proceed with the replacement as follows:

5-2.3.1.1 Lifting the Buoy out of the Water.

While planning the lift, make sure the type of buoy is known (foam or steel, peg-top or drum, tension bar or hawse pipe). If steel, make sure that the inspection showed no evidence of buoy flooding (visible holes, listing, etc.). Conduct pre-lift inspections of all connections on buoys prior to connection. If the buoy is flooded, it can still be lifted, but the weight of the entrapped water must be taken into account. If a tension bar buoy, make sure that there is no evidence of damage/excessive wear to the tension bar. If there is damage, it would be best to lift the buoy from the riser just below the buoy. If a steel hawse pipe buoy, then it is extremely difficult to ascertain the strength of the capture plate assembly between the riser and the buoy. Therefore, lift the buoy from the riser rather than from the top jewelry. Do not use the side pad eyes for lifting unless specific "as built" drawings of the buoy are available that a Professional Engineer can use to determine the padeye's working capacity for the planned use (i.e. lifting, lashing, maneuvering of buoy in water, small boat tie-downs, etc.). The crane should have two hooks, a main and an auxiliary of sufficient lift capacity at the working area. Use the main hook to lift from the riser and the auxiliary hook to lift and control the buoy in a 2-point pick. Attaching to the riser may require either divers to attach rigging or a heavy and long wire rope assembly to secure the mooring riser in either a choker hitch or in a basket hitch. Alternatively, remove the capture plate and lower the mooring riser to the bottom for future recovery. Recover the buoy by itself by lifting from suitable padeyes or from a chain bridle or other lifting device that is passed through the hawse pipe. The lift plan for recovery of steel hawse pipe buoys should be reviewed by a Professional Engineer. The lift plan must meet requirements of EM 385-1-1 for critical lifts as all in-water mooring lift operations are critical lifts.

On the newer foam hawse pipe buoys, the hawse pipe extends out of the urethane shell. The capture plate and its connecting bolts to the hawse pipe flange are exposed, but it is still difficult to determine the condition of the bolts. On these foam hawse pipe buoys, the existing capture plate and bolts can be replaced with new bolts and a capture plate specifically used for lift operations only.

Make sure you are familiar with crane safety and how it applies in this application. Review Paragraph 5-2.4 below on Crane Safety. Prepare and submit critical lift plans in accordance with EM 385-1-1 for acceptance by the cognizant authority. Ensure that operations are conducted within allowable wind and/or sea state conditions. It is preferable to conduct these types of operations during periods of minimal winds (moderate breeze, 11 knots or less), low tide and slack current conditions and from an anchored barge or a barge with winch operated spuds.

As floating crane or material barges generally have a freeboard between 5 to 8 feet, review the mooring drawings and water levels at the site to ensure that the mooring buoy will be able to be lifted onto the deck of the barge.

The following are generic steps for replacement of a mooring buoy:

- Bring the vessel alongside the buoy such that the crane can reach the buoy. If the vessel has its own anchors, anchor the vessel alongside the buoy. If the vessel is a spud barge, drop the spuds to the bottom to maintain position. Otherwise use the vessels drives or supporting tugboats to maintain position.
- Tie a soft line from the vessel to the buoy.
- Conduct a pre-lift briefing, if not already done so, with all personnel to include signalmen, riggers, crane operator, marine construction superintendent, safety personnel, deck winch operators and representatives from supporting tugboats.
- Rig the buoy in accordance with the accepted critical lift plan.
- Lower the crane hook(s) and attach the rigging to the crane hook(s).
- Begin taking in on the crane until the crane begins to see a load and the wire becomes taut.
- Untie the soft line from the vessel to the buoy.
- At this point, the vessel is effectively moored. The further up and out of the water, the tighter the mooring and the less movement will be seen. However, care must be taken not to overload the anchors, so continue to monitor the vessel location and use the vessels propulsion system to maintain position.
- Continue to lift the buoy until the bottom of the buoy is between 5 and 10 feet (1.5 and 3.1 m) over the chain capture device on the deck of the barge.
- Position the mooring riser into the chain capture device and secure the mooring riser into the chain capture device. One should keep at least 5 feet (1.5 m) of mooring riser chain above the chain capture device’s locking mechanism.
- Lower the buoy onto the deck (see Figure 5-2). Add blocking, bracing or tiedowns to prevent buoy rolling or movement during operations.

Figure 5-2 Mooring Riser Secured into a CCD

- Attach a secondary connection to the mooring riser, if not integral to the chain capture device. The secondary connection should be designed to support the loads as configured.
- Disconnect the mooring buoy from the riser. This can be done by either disconnecting the connecting hardware (usually either a riser swivel shackle or an anchor bolt shackle and anchor joining link) or one can cut the mooring riser (using an oxygen/acetylene torch) 2 to 3 full links above where it is secured in the chain capture device. Then use a spare chain joining link to reconnect the new buoy to the riser.

Safety Warning:

Adhere to EM 385-1-1 and OSHA 1910.253 for safe use of oxygen/acetylene torch.

- Disassemble the connections to the bottom of the buoy from the riser.
  - If the bottom connection is a swivel shackle, melt the lead plugs on the upper bale of the swivel shackle to remove the tapered pins. Place dunnage underneath the swivel shackle to prevent it from dropping onto the deck and potentially onto a worker’s foot. Using a heavy sledge hammer, remove the top swivel pin until it clears the buoy padeye. Ensure all appropriate personal protective equipment (PPE) is being used (i.e. gloves and eye protection).
- If the riser connection to the buoy is an anchor shackle-anchor joining link combination, remove cotter pins and/or safety bolts and if present, grind the weld off between the nut and pin. Place dunnage from dropping onto the deck and potentially onto a worker’s foot underneath the shackle. Take off the shackle nut and pin to disconnect it from the buoy. Melt the lead plug and using a pin punch and a sledge, knock out the tapered that holds the AJL together. ensure that the tapered pin is not knocked overboard.

Disassemble the AJL, making sure to save all the parts. Ensure all appropriate personal protective equipment (PPE) is being used (i.e. steel toes shoes, life vest, hard hat, gloves and eye protection).

- If the connecting hardware cannot be disassembled, you can cut it using a torch.
- Rig and swing the removed buoy to its storage location on the deck. It is recommended that the buoy be lifted using a 2-point pick. For hawse pipe buoys, attach rigging to the chain pigtail sticking out of the hawse pipe at both ends. For tension bar buoys, one can use the top buoy shackle as one connection point and the empty bottom buoy padeye as the other connection point. Using a 2-point lift on a tension bar pegtop shaped buoy will make it easier to place the buoy into a buoy cradle, if present or on dunnage if no buoy cradle is available. Providing that the bottom connecting hardware is in satisfactory condition, one could also attach rigging to the bottom buoy connection hardware, move the buoy to its storage location and disconnect the hardware at that location.
    - Note that as the buoy is already on its side, another option would be to flip the buoy upside down and store the buoy on its top. If doing so, one must remove the top jewelry from the top of the buoy. Bear in mind that enough dunnage is needed under the buoy to keep the top tension bar padeye or top deck capture plate assembly off the deck.
    - For either option, personnel should be clear of the moving fall zone and the buoy should be lifted only as high as minimally required.
- Disconnect the crane from the old buoy.

5-2.3.1.2 Installing the New Buoy.

The following are generic steps for installation of the replacement mooring buoy:

- Pre-rig the new buoy's bottom connection using either the removed connecting hardware or new connecting hardware.
    - Confirm that the AJL is fully assembled and lead plug is properly in place. For the buoy shackle, confirm that all the safety features are used, the cotter pin is in and spread and that the nut is tack welded to the shackle.
    - If using a riser swivel shackle, confirm that the swivel shackle is fully assembled and all 4 lead plugs are properly in place.
    - Confirm and note the manufacturing data for all components installed onto the new buoy to include the new buoy as well as the chain joining link if joining a short piece of chain to the mooring riser.
- Rig the original or new top jewelry on to the buoy. Confirm that all safety features are used on the attached top jewelry, such as cotter pins and/or safety bolts on shackles and buoy release hooks.

- If a section of the mooring riser was cut to free the old buoy, and if this cut section of chain is still in good condition, attach it to the new buoy's connecting hardware.
- Connect the crane to the new buoy using a 2-point pick to place the buoy sideways near the mooring riser. Lift the new buoy and swing it over where the riser chain is tied to the vessel. Personnel should be clear of the moving fall zone and the buoy should be lifted only as high as minimally required.
- Lower the buoy to the deck with the bottom connecting hardware of length of chain close to the bitter end of the riser. Place dunnage along both sides of the buoy to keep the buoy from rolling.
- Using a CJL, attach to riser to the chain under the buoy. Confirm that the lead plug is properly in place.
- Rig the connected buoy in accordance with the accepted critical lift plan. Disconnect the secondary connection to the mooring riser.
- Lift the buoy and swing outboard until the riser is over the chain capture device. Continue to lift until the load of the riser chain is on the crane. Once the load is off the chain capture device, release the mooring riser from the chain capture device.
- Lower the buoy into the water. When the sling is slack, tie the buoy to the ship using a soft line and then rigging from the mooring system. Untie the soft line, freeing the buoy.
- Move the vessel away from the buoy.
- Using high-pressure hose, wash the marine growth from the old buoy if permitted by local base policy. Otherwise, using flat shovels or scrapers, remove marine growth and place into plastic bags for disposal in accordance with local base policy.

An operational risk management (ORM) approach should be used to develop specific buoy replacement procedures based on local environmental conditions, project equipment and vessels and experience of the deck force.

Safety Warning:

If lifting a hawse pipe buoy, treat the lift as if the capture plate assembly is damaged and lift from below, while simultaneously lifting the buoy. On the newer ATFP and FMP foam hawse pipe buoys, the bolts that make this connection are exposed, but it is still difficult to determine the condition of the bolts. On these foam hawse pipe buoys, the existing capture plate and bolts can be replaced with new bolts and a capture plate specifically used for lift operations only.

Safety Warning:

Additional care is needed to make sure the additional loads on the crane (from lifting the ground ring out of the water) are taken into account. In addition, the stability issues based on these extra loads must also be accounted for.

Safety Warning:

If the tension bar is damaged, it is best to lift the buoy from below to take most of the weight off of the buoy/tension bar. A secondary crane hook should be used to simultaneously lift the buoy, keeping the buoy weight off the lift.

Section 5-2.3.2 through 5-2.3.6 provides an overview of some of the mooring sustainment operations. Actual procedures used are dependent on local environmental conditions, the mooring design, local environmental permit requirements, project equipment and vessels and experience of the deck force. These conditions will require the project team to develop a detailed execution plan specific to the mooring system to be repaired.

5-2.3.2 Riser Replacement.

Make sure you are familiar with crane safety and how it applies in this application. Review Paragraph 5-2.4 below on Crane Safety. Prepare and submit critical lift plans in accordance with EM 385-1-1 for acceptance by the cognizant authority. Ensure that operations are conducted well within allowable wind and/or sea state conditions. It is preferable to conduct these types of operations during periods of minimal winds (moderate breeze, 11 knots or less), low tide and slack current conditions and from an anchored barge or a barge with winch operated spuds.

Site conditions (water depth, currents, tides, predominant winds), mooring riser age and/or condition (C3 or C4), amount of chain slack (can the portion to be replaced be brought onto the deck of the work barge?) mooring configuration (riser-leg or riser-type), presence of ground legs (must the ground ring be brought on deck?, is there sufficient slack in the ground legs or must one or more be removed?), previous installation documentation will require the repair team to develop specific plans and procedures for the mooring ground leg repair operations.

The buoy removal from the mooring riser and subsequent attachment to the repaired mooring riser can be performed as described in Paragraph 5-2.3.1.2. Whether the riser is attached to multiple ground legs via a ground ring (Riser-type) or is a single riser that is attached to the anchor (riser-leg) will dictate the specific installation procedures.

For a riser-leg mooring system, the primary concern would be if the portion of the riser needing replacement can reach the deck with enough slack for the deck force to secure the riser into a CCD and perform the repairs. The local tides should be consulted and the repair procedures developed to perform the repairs at a decreasing tide level and be completed before the tide levels start to significantly increase (particularly at locations that have a large diurnal tide range). The repair team should monitor the tides to ensure that the secured mooring riser doesn't overload its deck attachments.

For a riser-type mooring system, the presence and condition of multiple ground legs will dictate the installation procedures. If the ground legs do not have sufficient slack for the portion of the mooring riser to be repaired to deck with enough slack for the deck force to secure the riser into a CCD and perform the repairs, then one or multiple ground legs may have to be removed. Additionally, any attached ground legs will need to be secured onto additional deck attachment points. Once the mooring riser is repaired, some additional chain may need to be added to the last detached ground leg to get all of the mooring system reconnected before lowering the system overboard to a point where the mooring buoy can be reattached.

An operational risk management (ORM) approach should be used to develop specific riser replacement or repair procedures based on local environmental conditions, project equipment and vessels and experience of the deck force.

5-2.3.3 Ground Leg Section Replacement

Make sure you are familiar with crane safety and how it applies in this application. Review Paragraph 5-2.4 below on Crane Safety. Prepare and submit critical lift plans in accordance with EM385-1-1 for acceptance by the cognizant authority. Ensure that operations are conducted well within allowable wind and/or sea state conditions. It is preferable to conduct these types of operations during periods of minimal winds (moderate breeze, 11 knots or less), low tide and slack current conditions and from an anchored barge or a barge with winch operated spuds.

Replacement of sections of the ground leg is usually performed on the portion of the ground leg that is connected to the ground ring.

Site conditions (water depth, currents, tides, predominant winds), mooring age and/or condition (C3 or C4), amount of chain slack (or lack thereof), mooring configuration (riser-leg or riser-type), previous installation documentation (how were the ground legs originally installed? Do they have sufficient slack? Estimated catenary forces of the ground legs once the end is recovered on deck), will require the repair team to develop specific plans and procedures for the mooring ground leg repair operations.

If only a few links need to be replaced, and there is sufficient slack in the ground legs, then each ground leg can be cut from the ground ring and the short section replaced in a similar manner as replacing a riser segment.

It is preferable to replace long sections of a ground leg using a double drum winch with two wires recovering the ground leg over a roller (see Figure 5-3) in a “hand-over-hand” procedure with the anchoring system, or tugboats, pulling the crane barge in the direction of the ground leg. The other ground legs can remain attached to the ground ring with a recovery wire attached to the ground ring or attached riser segment and to a pick-up buoy. Once the worn section of the ground leg is recovered, multiple stoppers are secured to the ground leg on the portion of the ground leg near the barge edge that will remain. One can then replace the worn portion of the ground leg in a similar manner as replacing a riser segment as described in Paragraph 5-2.3.2.

Figure 5-3 Recovery of a Ground Leg over a Roller

The repaired ground leg is placed back into the water using the double drum winch in a similar fashion, but in reverse, with the anchoring system, or tugboats, pulling the crane barge back toward the ground ring pick-up buoy.

The ground ring is recovered and the replaced ground leg reattached to the ground ring. Note that it may be required to detach the next ground leg to be repaired first.

This process is followed until all ground legs are repaired as required. The last ground leg may need to be lengthened in order to be attached to the ground ring.

An operational risk management (ORM) approach should be used to develop specific ground leg replacement or repair procedures based on local environmental conditions, project equipment and vessels and experience of the deck force.

5-2.3.4 Buoy Replacement (Non-Riser-Type Buoy).

A non-riser-type buoy will be more difficult to retrieve than a riser-type. If the mooring has been properly installed, there will be a catenary section of chain suspended in the water between the buoy and the anchor. If the catenary angle is large (as in a taut, properly installed mooring), then it may not be possible to stopper off all four anchor chain leg subassemblies on the barge deck simultaneously. It should also be noted that, in this type of installation, the buoy is kept in place by balanced opposing forces created by the catenaries of the anchor chain leg subassemblies. When one of the leg subassemblies is cut, the buoy will be pulled in the direction of the opposing leg. This pull will result in a potentially dangerous side loading (horizontal force) on the crane boom, especially if the buoy is being held aloft when the chain is cut. Connecting the replacement buoy to the anchor chain subassemblies is also difficult under these conditions. Therefore, in the case of a taut mooring, it is recommended that the non-riser buoy system be completely recovered prior to replacing the buoy, and that the mooring be reinstalled. This may involve the use of divers and cutting the chain at the seafloor. However, in many non-riser installations, significant slack exists in the anchor chain leg subassemblies directly below the buoy. In such cases, it may be possible to lift the buoy and simultaneously stopper off the legs on the barge deck. The new buoy can then be connected to the anchor chains and replaced in the water. There are actually very few of these buoys still in service with DoD, therefore procedures will need to be developed that are unique to that site.

5-2.3.5 Steel Buoy Minor Repairs.

In-service minor repairs to a steel buoy, such as replacing a fender, repairing an upper hull puncture, patching fiberglass or polyurethane, replacing anodes, replacement of the top hardware or spot painting the buoy, can be accomplished without taking the buoy ashore. In most cases, it is better to lift the buoy on to the deck rather than attempt the repair with the buoy still in the water.

Safety Warning:

Never cut or weld to the surface on an enclosed void (such as a steel buoy) until the interior has been properly ventilated and gas free. Potentially explosive gases can accumulate within the buoy.

Safety Warning:

No person should enter the buoy while the buoy is still in the water. A person should only enter the buoy when there is no possibility of the buoy sinking, i.e. either on the deck of the barge or ashore.

Entry of personnel into a buoy must comply with EM 385-1-1 and cognizant base requirements for confined space entry.

Safety Warning:

On a steel buoy, the buoy manhole cover must not be removed while the buoy is still in the water.

If a wood fender has been damaged and requires replacement, have a new fender cut to shape and holes drilled as required. While this should work, a drill and properly sized bit should be brought out to the buoy. Simply remove the bolts holding the fender in place and remove the old fender. Replace it with the new fender.

If the fender attachments have been damaged, it will be necessary to scarf off the old attachment pieces and weld on new ones. This can be done on site but must be accomplished on the deck of the barge. Never cut or weld to a surface on an enclosed void as potentially explosive gases can accumulate within the buoy. Open the manhole cover and let the buoy ventilate before any cutting or welding. A fan or blower can speed up the ventilation process. Once the interior has been properly ventilated and assured that it is gas free by a certified marine chemist, cutting and welding can occur.

If it is necessary to enter a buoy, this should be done only when the buoy is ashore or aboard a barge where there is no possibility of the buoy’s sinking. Special care must be taken to reseal the manhole and assure watertight integrity.

During the inspection of a mooring buoy, its associated top and bottom hardware should be closely inspected to determine whether any components need to be reconditioned or replaced. When reconditioning/replacement is required, the following should be observed:

- Welding chain appendages or cutting out retaining pins or rivets with a torch should never be done because heating will introduce internal stresses and reduce the strength of heat-treated steel components.
- Ensure that shackles, joining links, and other such fittings with removable parts are treated with an appropriate grease preservative and refitted. Care should be taken not to interchange matched parts of joining links. This can be avoided by tagging each part of the joining link with a unique identification number or by matching the stamped numbers on the parts. Locking pins of joining links and shackles should never be welded in place due to the probable resultant loss of tensile strength of the component.

5-2.3.6 Steel Buoy Coatings.

Because protective coatings are frequently damaged by impact or abrasion, it may be necessary to make in-service repairs to coatings of mooring buoys. In order to repair these coatings, it is necessary to first clean the exposed steel and the area surrounding the steel of rust, salt, and loose material. This can be accomplished by wire brushing the steel (preferably power wire brushing) or by scrubbing with a bristle brush and then drying the area with an air hose connected to an oil free compressor (when required). The intact coating surrounding the damaged areas should be abraded to ensure proper bond of the repair material. There are several proprietary putty-like coatings available called splash-zone compounds, that can be spread over the cleaned area, wet or dry. MIL P-28579(YD) describes such a curing epoxy-polyamide formulation. There are also available a number of proprietary brush on coatings that can be applied to damp surfaces and will cure either above or under the water. Either type of coating should completely cover the steel and extend at least 1/2 inch (13 mm) over the cleaned coating surrounding the steel.

General coating operations, materials and safety precautions are described in NAVFAC MO-110, Paints and Coatings. The recommended coating system for steel mooring buoys is the Navy epoxy-polyamide system for interior and exterior ship surfaces, MIL-DTL-24441D(SH). Procedures for its use are described in Naval Ships Technical Manual, NAVSEA S9086-VD-STM-010 and S9086-VD-STM-020. For optimal results, the coating should be applied to a clean dry surface.

Fiberglass patching should be accomplished in accordance with NAVSEA 0900-LP-006-0010. Fiberglass coating materials should be prepared and applied by personnel who have demonstrated proficiency in the application of the materials.

5-2.3.7 Foam Buoys.

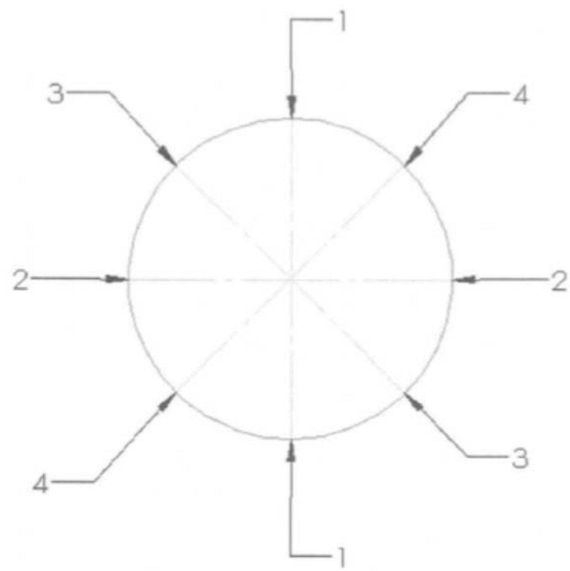
Minor damage to foam-filled polyurethane buoys can be repaired with commercially available patching kits containing the materials and procedures necessary to affect the repairs. Field repairs to the buoy hull should be limited to small rips, tears, punctures or gouges in the buoy skin and underlying foam.

The exposed tension bar and padeye on the tension bar should be cleaned to SSPC-SP3, Power Tool Cleaning and meet acceptable standard as listed in SSPC VIS-3 to permit proper inspections. The exposed tension bar and padeye should be coated with a phenalkamine epoxy meeting NAVSEA MIL-PRF-24647 to provide a dry film thickness of 8 to 12 mils. A topcoat of an aliphatic acrylic polyurethane finish having a dry film thickness of 2-4 mils should then be applied.

Chipped or missing paint on the padeye can be touched up with an epoxy-polyamide coating applied in accordance with MIL-C-22751D.

The bushing in the padeye should be inspected and replaced if the bushing has lost 50% or more of its original thickness (1/4-inch) or is severely corroded. To inspect the bushing, clean off rust and other debris using a steel wire brush. Using inside calipers, measure the inside diameter of the tension bar padeye with the bushing (Figure 5-4). Determine the remaining minimum thickness of the bushing by reviewing the buoy drawings to determine the original inside diameter of the bushing, padeye and bushing thickness.

Figure 5-4 Bushing inspection Points



If the bushing needs to be replaced, a new bushing of same size and material conforming to Abrasion-Resistant Bushing steel, ASTM A519, Grade 4140 should be used. Replacement bushings should be fabricated ahead of time to have onsite during foam buoy field refurbishment operations. Remove the existing bushing using a small right-angle grinder having a thin cut off wheel that can pass through the bushing, or a reciprocating saw with a 6 inches long blade. Care must be taken that you don’t cut into the padeye itself. The appropriate PPE should be worn (specifically gloves and safety glasses).

Installation of the replacement bushing requires an interference fit of 0.001 to 0.004 inch (0.025 to 0.102 mm) radially. Clean and debur the inside of the padeyes to remove any sharp edges for the bushing to hang up on. Sand the edges and inside diameter of the padeye smooth and clean with rags and a degreaser.

Apply an epoxy adhesive to the inside diameter of the padeye just immediately before the bushing is installed.

The bushing should be cooled with liquid nitrogen to cause it to shrink in size and allow for it to be installed into the padeye. The bushing should be handled with pliers when placing into the liquid nitrogen and into the tension bar padeye. In addition to standard PPE for barge operations (steel toed, shoes, floatation vest, hard hat) leather gloves and safety glasses should be worn.

If the padeye was found to be enlarged in one area, it may need to be rounded out and an evaluation be made if the tension bar padeye is still strong enough to meet its design requirements for the mooring. Unless spare bushings having a larger outer diameter are available, a standard sized bushing may have to be used with a high strength epoxy to fill the gap. The mooring system may have to be downgraded until the buoy is replaced.

If there is a chance for bushing replacements to be performed during field repairs, it may be more cost efficient to replace the foam buoy with a spare foam buoy and complete foam buoy refurbishment ashore.

Replacement of the reflective tape involves removal of the old tape using a wide scraper and removing remaining adhesives from the buoy shell using warm soapy water, isopropyl alcohol or a biodegradable cleanser. Apply the replacement reflective tape tightly around the buoy shell using a squeegee insuring that air bubbles are removed. Attach the top band 6 inches below the buoy deckline and the next band 6 inches below the top band so that both tape bands are in the top 2 feet from the top deck of the buoy (mooring buoys should maintain an average minimum freeboard of 2 feet below its deckline). Note that for the standard small and medium foam buoys applying the reflective tape just above and just below its single urethane fender will keep both tapes within the top two feet.

As it is much easier to be replaced when the buoy is on deck, replacement of reflective tape should always be part of mooring repair operations that involve recovery of the buoy. However, though it is more difficult, the reflective tape can be replaced with the buoy in the water from a small boat.

Reflective tape replacement should be planned to be performed as part of the three-year underwater inspection.

Major repairs on foam buoys should be undertaken only with the advice and assistance of the buoy manufacturer.

should be undertaken only with the advice and assistance of the buoy manufacturer.

5-2.4 Crane Safety.

See APPENDIX B for a discussion of crane safety.

5-3 MOORING INSTALLATION AND REMOVAL OPERATIONS OVERVIEW

5-3.1 Scope

Installation and removal operations overview will be limited to the following:

- Installation of a drag embedment riser-type or riser-leg mooring system.
- Installation of an embedment anchor riser-leg mooring system.
- Removal of a drag embedment riser-type or riser-leg mooring system.
- Mooring anchor pull test.

This section provides an overview of some of the mooring installation operations. Actual procedures used are dependent on local environmental conditions, the mooring design, local environmental permit requirements, project equipment and vessels and experience of the deck force. These conditions will require the project team to develop a detailed execution plan specific to the mooring system to be installed, modified, repaired or removed.

All mooring hardware must be tied down to prevent unplanned movements on the deck during transiting or from vessel motions during operations.

5-3.2 Equipment

The following equipment must be readily available for use as needed:

- Crane barge, floating crane or vessel with sufficient lifting capacity, stability, quantity and size hooks, boom length and reach and if at all possible, means of self-mooring.
- A chain capture device (CCD) to securely stop off the chain to permit placement of the buoy onto the deck without personnel going underneath the load or in the fall zone.
- Tugboat, mule, or other vessel (for maneuvering and positioning the crane platform).
- Spare mooring connecting hardware.
- High-pressure seawater (100 psi) pump and hose (for cleaning) for removal operations.
- Oxygen/acetylene kit and welder for chain cutting and welding operations.

5-3.3 Procedures Overview

Safety Warning:
Every attempt should be made to plan operations that keep personnel from working under the load. If no alternatives can be found, every effort should be done to minimize the time spent under the load.

5-3.3.1 Drag Embedment Riser-Type or Riser-Leg Installation

Safety Note:
While preparing the anchors, positioning on deck for deployment and deploying the anchor, personnel should not go under the flukes or shank of the anchor.

Make sure you are familiar with crane safety and how it applies in this application. Review APPENDIX B on Crane Safety. Prepare and submit critical lift plans in accordance with EM385-1-1 for acceptance by the cognizant authority. Ensure that operations are conducted well within allowable wind and/or sea state conditions. It is preferable to conduct these types of operations during periods of minimal winds (moderate breeze, 11 knots or less), low tide and slack current conditions and from an anchored barge or a barge with winch operated spuds.

Site conditions, such as water depth, currents, tides, predominant winds, soil conditions (type soil, bottom slope), environmental constraints and restrictions (presence of corals, mammal watches, construction window, turbidity constraints, eelgrass, etc) as well as available installation vessels (type and capacity of floating crane barge, tugboats and material barges) and the mooring system design (number of legs, type of drag embedment anchors, length of ground legs, allowable ground leg slack, chain sizes, etc) will require the installation team to develop specific plans and procedures for the mooring installation operations.

For a drag embedment mooring system installation, unique concerns would be the (1) Anchor's fluke angle; (2) Orientation of the anchor as placed on the bottom; and (3) Its final location after proof testing.

The soil conditions will dictate the desired angle between the anchor flukes and the anchor shank (fluke angle). Most drag embedment anchors typically used, such as the common U.S. Navy stockess anchor, STATO and NAVMOOR anchors have a desired fluke angle for mud or sand/stiff clay or hard bottom conditions. Though the stockless anchor with flukes fully open is at the fluke angle for mud condition, it is still recommended to fix the flukes at the fully open position to ensure that it will bury into the soil during proof testing. Not fixing the flukes to its desired fluke angle may lead to excessive drag distances to meet the proof load or failure of the anchor to meet the proof load. The above drag embedment anchors should be equipped with stabilizers to reduce the risk of the anchor rolling during proof testing. Typical drag embedment anchor features are shown in Figure 5-5. Fluke angles for sand or mud for these typical drag anchors are shown in Figure 5-6.

Figure 5-5 Features of a drag anchor

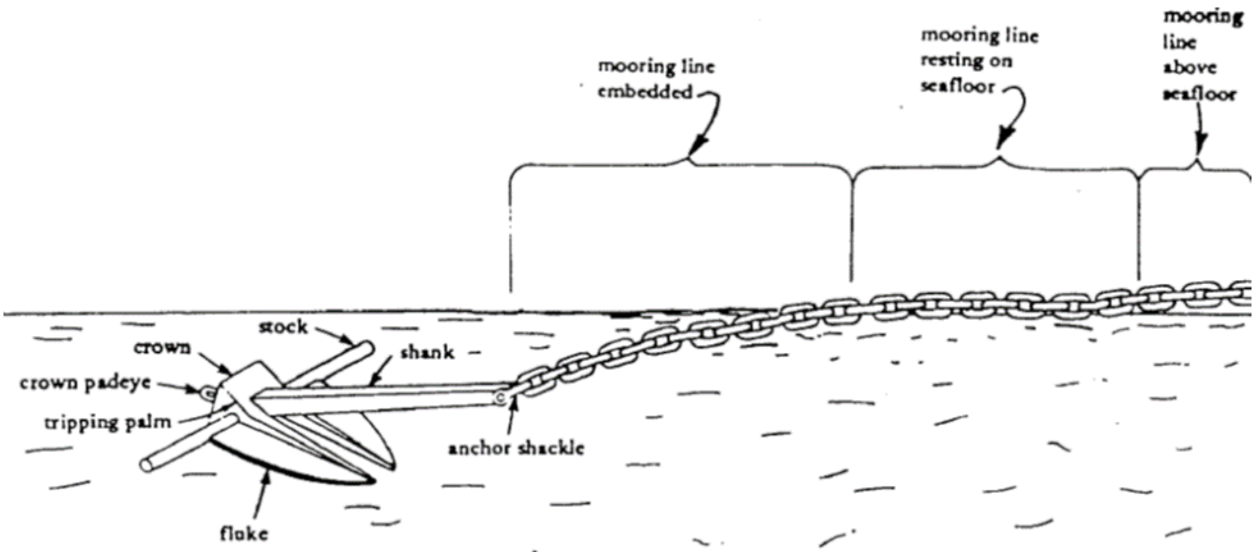


Figure 5-6 Fluke Angle Recommendations

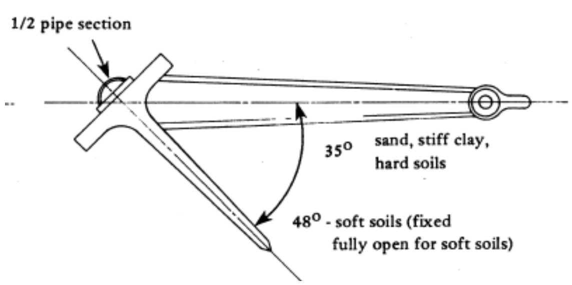
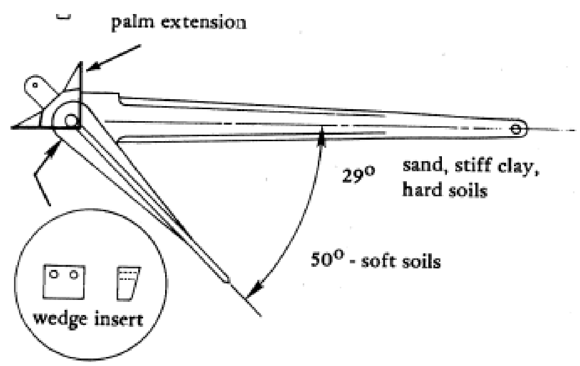
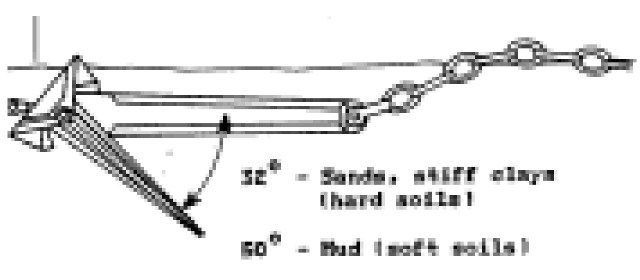


Navy Stockless Anchor



STATO Anchor



NAVMOOR Anchor

High capacity drag embedment anchors such as the NAVMOOR come with a sand wedge that can be welded onto the shank if soils are not soft/mud conditions (see

Figure 2-19). Otherwise, steel plate or bar can be used to lock the flukes in the desired angle (see Figure 2-18 for a stockless anchor).

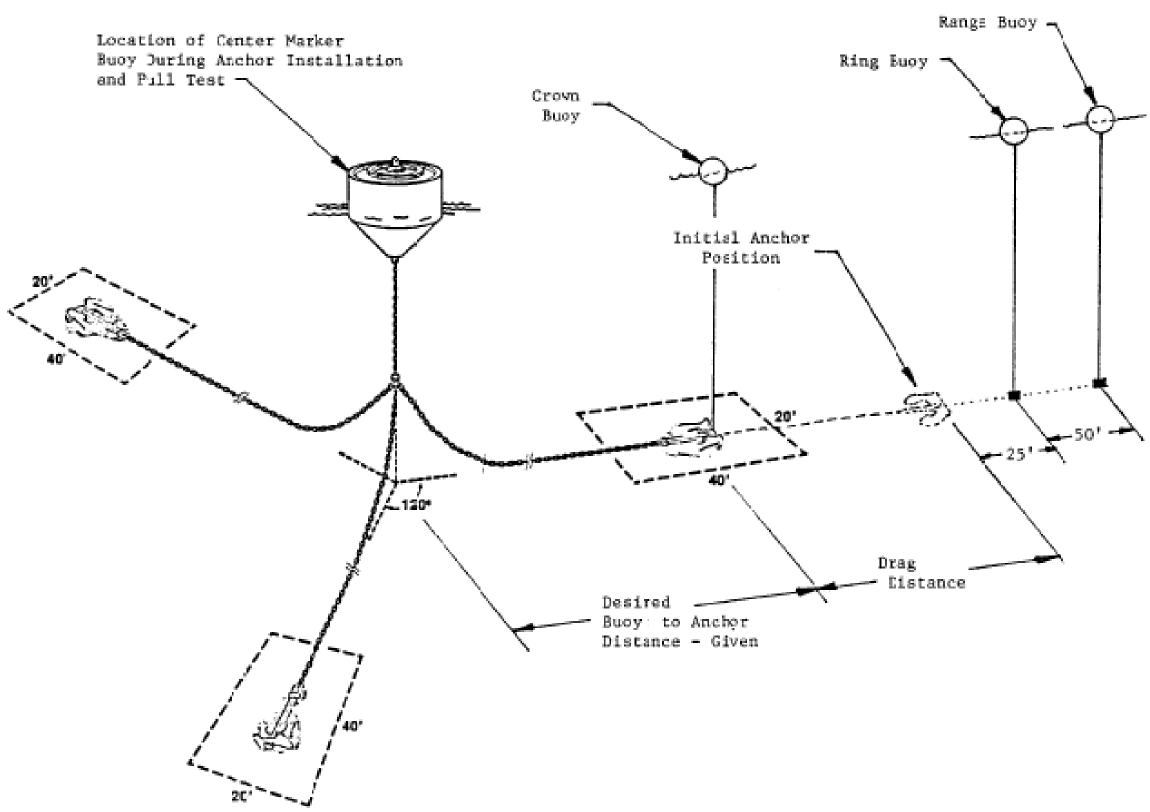
Once the flukes have been fixed, the anchor needs to be placed on the bottom with the flukes angled down toward the bottom and not toward the surface. As most locations, water depth is less than 50 FSW (MLLW) and floating crane barges with sufficient boom height will allow for a stockless anchor to be rigged and lowered in a horizontal configuration (Figure 5-7, NAVMOOR and Figure 5-8). Care must be taken to ensure that the attached ground leg chain does not impose any significant lateral tension on the anchor during deployment and initial touchdown. Lowering the anchor in a vertical orientation with its crown onto the seafloor risks the anchor's flukes not digging into the seafloor and the anchor sliding along the seafloor; particularly for the stockless anchor in soft sediments.

Figure 5-7 NAVMOOR Anchor Deployment

Figure 5-8 Stockless Anchor Deployment

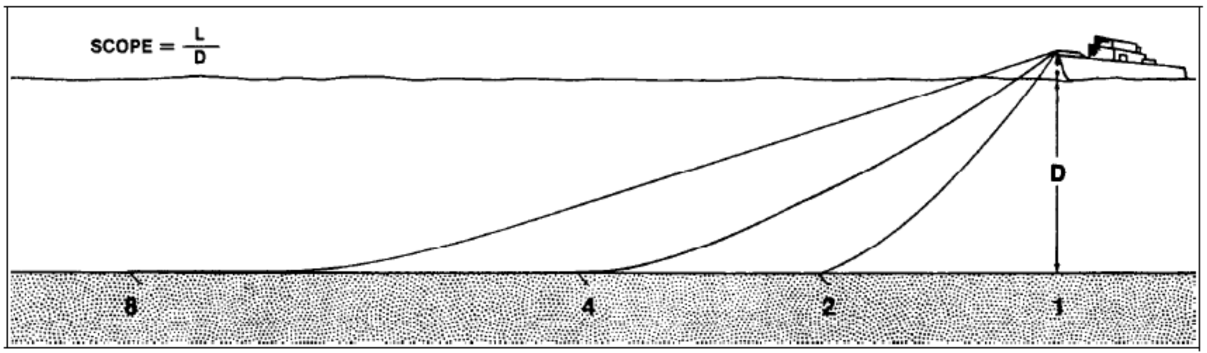
Several technical references are available to estimate drag distances for various types of drag embedment anchors. Drag distance is dependent on (1) soil conditions; (2) depth of the soil as there must be sufficient depth of soil for the anchor to develop its resistance; (3) fluke length; and (4) anchor line scope. For typical drag embedment anchors such as stockless, STATO or NAVMOOR, in addition to UFC 4-159-03, technical references such as ex-Naval Civil Engineering Laboratory (NCEL) tech data sheet 83-09 (Stockless and STATO anchor) and 87-05 (NAVMOOR) provide guidance on estimating drag anchor distances. Additionally, APPENDIX H provides drag distance tables taken from NAVFAC MANUAL MO-124. During installation operations, a marker buoy is placed both at the mooring center (where the buoy would ideally be) and at the location to initially place the anchor as well as a range marker to aid the installation team as shown in Figure 5-9. A crown buoy is also attached to the anchor.

Figure 5-9 Anchor Placement Allowable Area



As drag anchor capacity is based on a near horizontal orientation of the attached ground leg (6^{O} or less), it is important to proof test the anchor along the design direction of the ground leg and at an anchor line scope of 10:1 (10 feet of anchor line per foot of water depth) as shown in Figure 5-10. If the anchor ends up further away from its design distance to the mooring center (buoy), additional chain can be added to the ground leg (a reason to have spare chain and connecting hardware on site). However, if the anchor ends up closer to the mooring center, the ground leg may not have sufficient scope for the anchor to meet its design load at the desired factor of safety. Though this can be modified by the addition of sinkers along the ground leg, spare sinkers are usually not available and the anchor may have to be recovered and reinstalled at a location further away from the initial drop point and slightly off to one side to avoid the anchor dragging into the disturbed soil from the first proof test. APPENDIX I provides an extract from MO-124 of general installation procedures for a drag embedment riser-type mooring system.

Figure 5-10 Drag Embedment Anchor Proof Test Orientation



Scope is the ratio of length of rode (L) to depth of water (D), plus allowance for heigth of bow above water. At (1) length of rode equals the depth. At (2) rode length is twice the depth, at (4) four times the depth. Note how the angle between rode and bottom decreases. At (B) the scope is 8:1 and the short length of chain at the anchor lies flat on the bottom.

For all drag embedment anchor installation operations, all plans and procedures should ensure the following:

- Only qualified welders and riggers are used.
- Connecting links are secured with lead.
- Underwater shackles are secured.
- Ground legs or riser-legs are installed without twists and along its design path on the seafloor within 5 degrees.
- Data on all installed mooring components, such as manufacturer, specification, size, year of manufacturer and serial number are recorded from the anchor to the buoy.
- Critical lift plans are developed, reviewed and accepted by the cognizant authority.
- A roller or curved surface should be placed over the edge of the barge for ground leg deployment.
- A CCD is used.
- Hard points where rigging is to be positioned are protected with softeners.
- Rigging is designed and certified and with sufficient capacity, as placed, to withstand planned tensions with a recommended reserve of 25%. Rigging shall meet requirements of EM 385-1-1, as well as NAVFAC P-307 or the applicable agency document.

An operational risk management (ORM) approach should be used to develop specific riser-type or riser-leg drag embedment anchor mooring system installation procedures based on local environmental conditions, project equipment and vessels and experience of the deck force. APPENDIX J provides an extract from MO-124 of general procedures for drag embedment anchor pull testing.

5-3.3.2 Drag Embedment Anchor Riser-Type or Riser Leg Removal

Make sure you are familiar with crane safety and how it applies in this application. Review APPENDIX B on Crane Safety. Prepare and submit critical lift plans in accordance with EM385-1-1 for acceptance by the cognizant authority. Ensure that operations are conducted well within allowable wind and/or sea state conditions. It is preferable to conduct these types of operations during periods of minimal winds (moderate breeze, 11 knots or less), low tide and slack current conditions and from an anchored barge or a barge with winch operated spuds.

Site conditions, such as water depth, currents, tides, predominant winds, soil conditions (type soil, bottom slope), environmental constraints and restrictions (presence of corals, mammal watches, construction window, turbidity constraints, eelgrass, etc) as well as available installation vessels (type and capacity of floating crane barge, tugboats and material barges) and the mooring system design (number of legs, type of drag embedment anchors, length of ground legs, ground leg slack, chain sizes, etc) will require the installation team to develop specific plans and procedures for the mooring removal operations.

For a drag embedment mooring system removal, unique concerns would be (1) Removal of the initial ground leg; and (2) Break out of the buried drag embedment anchor.

For some riser-type mooring systems where there is insufficient slack, one or more ground legs may have to be disconnected from the common ring by divers cutting a chain link on the ground leg near the common ground ring using underwater cutting techniques. Underwater cutting (Figure 5-11) is performed using surface supply diving techniques and specific dive and crane operating procedures and diver safety requirements in accordance with the US Navy Diving Manual or EM 385-1-1 will need to be adhered to.

Once the first ground leg is cut off, it can be recovered by the installation team. The remaining 2 ground legs can be brought on deck and 1 ground leg cut off topside and then recovered as well.

The amount of force needed to free the drag anchor will depend on (1) Size and type of drag embedment anchor; (2) type of soils; (3) embedment depth; (4) time the anchor has been installed; and (5) whether the anchor was proof tested during installation or has been loaded to its design load during operational use.

As drag embedment anchors are designed to withstand horizontal forces by soil resistance on the face of the flukes that face the ground leg, recovery of the anchor is best accomplished by either (1) Applying a vertical force once the crane barge is directly over the anchor; (2) pulling the anchor in the opposite direction to how it is installed; or (3) A combination of both.

Figure 5-11 Navy Diver Cutting Connecting Shackle

Drag anchors embedded in sands can achieve their holding capacity with minimal burial (1 to 2 fluke lengths) while drag anchors embedded in soft sediments bury deeper to achieve their holding capacity (2.5 to 4.5 fluke lengths). Breakout of a drag anchor will be more sudden in sand and more gradual in soft sediments.

The ground leg should be attached to the primary hook of the floating crane barge with strong rigging that has a working load equal to the maximum load that the crane can apply based on its load chart. Breakout of 9-ton NAVMOOR anchors proof tested in soft sediments in New York City harbor for one week were on the order of 60 to 70 tons during recovery operations.

When applying a vertical load over the embedded anchor, the load should be applied in a slow manner and gradually building up to the allowable load that can be applied by the crane and or attached rigging and ground leg hardware. The load should be carefully monitored by a calibrated load cell rigged in line between the ground leg and the crane hook. It may be best to slowly reduce the load to no less than the weight of the anchor and suspended ground leg and then repeat the load every 10 minutes.

Breakout of the anchor will be seen by a reduction in load tension along with the raising of ground leg chain out of the water. Once this is noticed, the load can be held and then reduced as needed as the anchor comes out of the seabed (Figure 5-12). This technique is more suitable for soft sediment conditions than sand conditions.

Figure 5-12 NAVMOOR Anchor Recovery

For sand conditions as well as soft sediments, one can secure the end of the ground leg chain to a suitable deck attachment point on a tugboat or the crane barge and then transit the tugboat or barge in the opposite direction of how the anchor was initially set. This technique may need to be repeated to free the anchor.

Other techniques such as jetting or securing the ground leg to a deck fitting overnight to allow for an incoming tide to break the anchor free may need to be considered. Jetting will require divers and additional equipment and may not be practical due to time (cost) constraints. Calculations will be needed to ensure that any deck connection used to secure the ground leg will not break off when using the tide to free the anchor. For most applications, gradual vertical lifts on the anchor from a floating crane barge and/or with pulling the anchor it its opposite set direction will be suffice in recovery of the anchor.

APPENDIX I provides an extract from MO-124 of general installation procedures for a drag embedment riser-type mooring system.

For all drag embedment anchor removal operations, all plans and procedures should ensure the following:

- Only qualified welders and riggers are used.
- Critical lift plans are developed, reviewed and accepted by the cognizant authority. Break out of the anchor would be a critical lift.
- A roller or curved surface should be placed over the edge of the barge for ground leg deployment.
- A CCD is used.

- Hard points where rigging is to be positioned are protected with softeners.
- Rigging is designed and certified and with sufficient capacity, as placed, to withstand planned tensions with a recommended reserve of 25%. Rigging shall meet requirements of EM 385-1-1, as well as NAVFAC P-307 or the applicable agency document.

An operational risk management (ORM) approach should be used to develop specific riser-type or riser-leg drag embedment anchor mooring system removal procedures based on local environmental conditions, project equipment and vessels and experience of the deck force.

APPENDIX K provides an extract from MO-124 of general removal procedures for a drag embedment riser-type mooring system.

5-3.4 Embedment Anchor Installation

Make sure you are familiar with crane safety and how it applies in this application. Review APPENDIX B on Crane Safety. Prepare and submit critical lift plans in accordance with EM385-1-1 for acceptance by the cognizant authority. Ensure that operations are conducted well within allowable wind and/or sea state conditions. It is preferable to conduct these types of operations during periods of minimal winds (moderate breeze, 11 knots or less), low tide and slack current conditions and from an anchored barge or a barge with winch operated spuds.

Site conditions, such as water depth, currents, tides, predominant winds, soil conditions (type soil, bottom slope), environmental constraints and restrictions (presence of corals, mammal watches, construction window, turbidity constraints, eelgrass, etc), available installation equipment (follower and hammers), installation vessels (type and capacity of floating crane barge, tugboats and material barges) and the mooring system design (plate anchor size, required embedment depth, required pull test type and load, chain sizes, etc) will require the installation team to develop specific plans and procedures for the mooring installation operations.

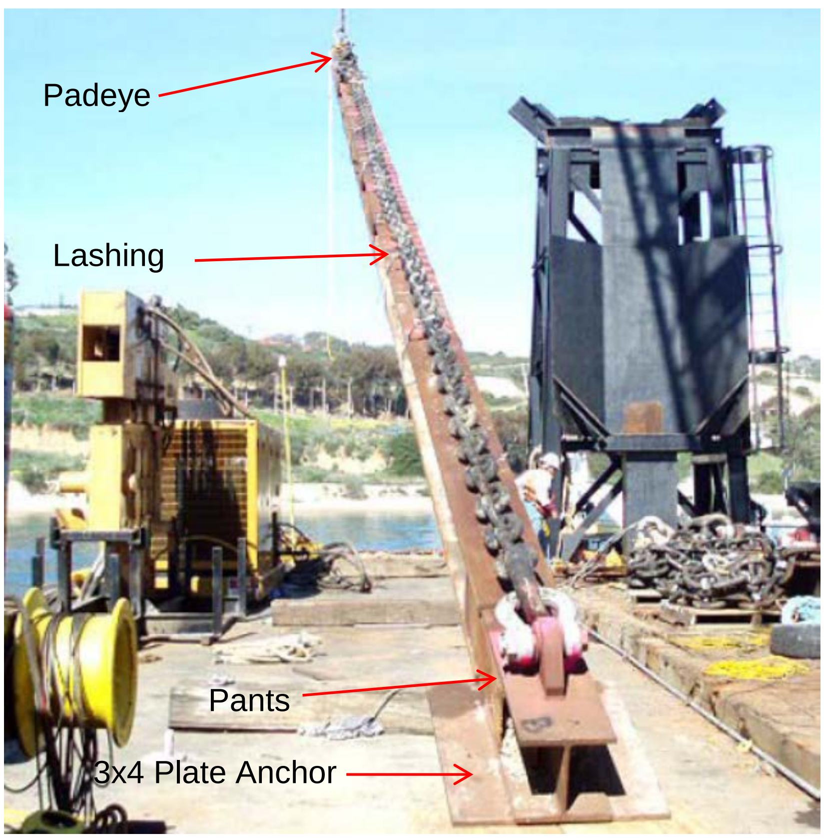
For an embedment mooring system installation, unique concerns would be the (1) Plate (or pipe) anchor follower system rigging and handling; and (2) Driving hammers.

A follower is a beam that is used to embed the plate anchor into the seabed to its required tip depth. It is usually a W14x283 beam but can also a combination of pipe with a W14x283 stinger. The length of the stinger is based on the required embedment depth for the anchor as well as its structural resistance to bending. The anchor end of the follower has an extension, commonly referred to as the “pants” that slides over the plate anchor beam to capture the plate anchor. Lifting as well as chain padeyes are found on the hammer end of the follower. The padeyes are spaced below the top of the follower to allow for placement of the driving hammers. The length of the follower is determined by the required plate (or pipe) anchor embedment depth, water depth, tides and barge freeboard.

Unlike conventional pile driving for piers and wharves where refusal criteria will govern the capacity of the pile for bearing, multiple variables in the plate anchor capacity equation are related to the embedment depth below the seafloor for the plate anchor. At locations with little or no knowledge of the soils, a soil boring may need to be obtained and a wave equation analysis (WEAP) may need to be performed to determine the required hammers to drive the anchor to its design tip depth.

The initial shot of mooring chain is stretched tight along the top of the follower and secured to a suitable turnbuckle. The total length of chain should be kept to 1 shot, but it must be long enough for deck personnel to secure to a barge deck fitting once the anchor has been driven to its tip elevation. Wire rope lashing is spaced out at an interval between 5 to 10 feet to tightly secure the chain to the follower. A rigged follower is shown in Figure 5-13. Rigged follower means that the anchor and mooring chain are secured on the follower.

Figure 5-13 Rigged Follower



The follower design should be performed by a Professional Engineer to ensure that it is structurally strong enough for driving and well as lifting operations to include both chain and lifting padeyes.

Lift plans should be detailed for handling of the follower at all stages to include positioning an empty follower onto the barge, lifting the rigged follower to be placed into its template (Figure 5-14) and lowering the empty follower onto the barge after extraction of the follower.

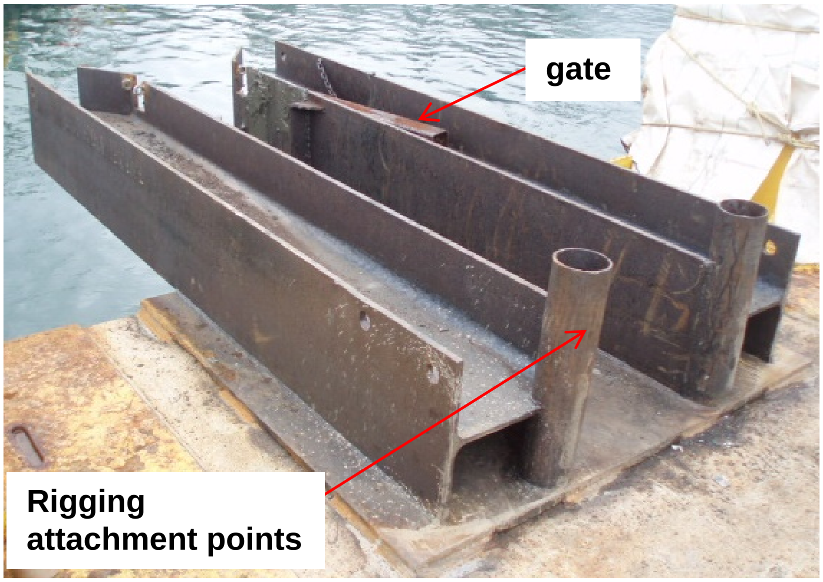
General steps for follower rigging and handling include:

- Positioning of the follower on dunnage on the crane barge or material barge.
- Positioning of the plate anchor into the follower pants
- Laying out the initial shot of chain along the top of the follower.
- Securing the rigged mooring leg tightly on the follower.
- Attaching lift rigging as well as safety rigging.
- Inspecting the follower and completing the follower checklist.
- Lifting the follower to a vertical position near the template in accordance with the accepted lift plan. Softeners such as welded slotted pipe should be used at locations along the follower where lifting rigging will come into contact.
- Positioning the follower into the template and lowering the follower until its weight is supported by the seabed. The follower is plumbed and template gate (lateral piece of steel used to help alignment of the follower and prevent it from coming out of the template if the rigged follower self-penetration is minimal) is closed.

Another piece of equipment needed for follower operations is either a manlift or a man basket. These are needed for personnel to disconnect lift rigging from the follower to free the crane hooks for lifting of the hammers. They will also be used at the end to reattach lifting rigging to remove the follower from the template. Both pieces of equipment have specific safety requirements for both personnel and equipment operation that are found in EM 385-1-1. Deck personnel will be needed to be trained in the use of fall protection.

The follower is usually positioned with the chain facing the barge for ease of operations by deck personnel. For hard clay or sand soil conditions, it is not important for the plate anchor padeye to be aligned along the design path of the mooring leg as the chain will be vertical at the anchor. This can be calculated using the program Chain-Soil Analysis Program (CSAP) and the anchor depth adjusted during the design period to ensure the chain is vertical. However, for soft sediment conditions, it is important for the padeye to be aligned with the design path of the mooring leg as the chain will not be vertical at the padeye.

Figure 5-14 Follower Template



Once the follower is positioned in the template, its weight supported by the seabed and lifting rigging detached, it is ready to be driven using conventional pile driving techniques.

Most embedment anchor installation operations have both a vibratory and an impact hammer. The vibratory hammer is generally used to extract the follower from the embedded anchor and the impact hammer is used to drive the embedment anchor to its design tip depth. For sand and mud conditions, the vibratory hammer can be used to drive the anchor partway or to its design tip depth.

Driving the rigged follower is similar to conventional pile driving operations to include operating the hammers and completing a driving record. The follower is also marked at 1-foot increments with the forward edge of the plate (top of pipe) anchor being the "zero" mark.

Unlike conventional pile driving operations, a chain is attached to the beam being driven. This chain usually has chain link zinc anodes attached on all chain links or on an upper portion. As the screws for the zinc anodes are only 3/8-inch and designed to secure the zinc anode at a 20 to 30 foot-pound torque, personnel need to be aware of zinc anodes falling off during driving operations, particularly when the vibratory hammer is being used. Several wraps of electrical tape will reduce the potential for zinc anodes from falling, but it is still a safety concern so deck personnel need to stay clear.

The design of the padeye as well as the addition of the mooring chain will increase the driving resistance of the rigged follower. Additionally, the anchor center of gravity will not be aligned with the follower and attached chain. This will create a bending moment to be generated each time the rigged follower is hit with the hammer. At locations with hard soils with multiple anchors to be embedded, spare follower sections/stingers will need to be available to perform repairs to the lower section of the follower. Bending usually occurs near the joint between stinger and pipe (Figure 5-15) or at the point along a W14x283 where lateral stiffener plates end or the upper embedment of the follower into a hard soil layer.

Figure 5-15 Bent Follower Stinger

Once the follower is extracted, a suitable sea water pump will be needed to remove the plug of soil that normally forms within the flanges of the follower at cohesive soil conditions. As the extracted follower will form a vertical plug below the seabed, sometimes steel plate is welded between the flanges to stiffen the follower at the bottom end. However, this adds additional cost and weight to the follower.

For all embedment anchor installation operations, all plans and procedures should ensure the following:

- Only qualified welders and riggers are used.
- Connecting links are secured with lead.
- Underwater shackles are secured.
- Data on all installed mooring components, such as manufacturer, specification, size, year of manufacturer and serial number are recorded from the anchor to the buoy.
- A rigged follower lift plan is developed by a Professional Engineer, reviewed and accepted by the cognizant authority.
- Critical lift plans are developed, reviewed and accepted by the cognizant authority.
- The follower design, to include associated attachment padeyes is performed by a Professional Engineer.

- A follower checklist is developed and completed prior to lift operations to verify the anchor and mooring chain is properly configured, oriented, positioned, secured along the follower, component data is recorded and lift rigging is correctly positioned according to the accepted lift plan.
- A driving record is completed to include information on the type hammer, fuel setting, recording of blow counts per foot of driving, water depth, tide, average blow count per minute, start and end times, type of follower and helmet/cushions used, final anchor tip depth to include adjustment to required datum (i.e. MLLW, etc.) and final anchor horizontal anchor location in required datum (i.e. Northings and Eastings to state plane or UTM coordinates, etc.).
- A CCD and a follower template are used.
- Hard points where rigging is to be positioned on the follower are protected with softeners.
- Rigging is designed and certified and with sufficient capacity. Rigging shall meet requirements of EM 385-1-1, as well as NAVFAC P-307 or the applicable agency document.

An operational risk management (ORM) approach should be used to develop specific embedment anchor mooring system installation procedures based on local environmental conditions, project equipment and vessels and experience of the deck force.

5-3.5 Mooring Anchor Pull Tests

Make sure you are familiar with crane safety and how it applies in this application. Review APPENDIX B on Crane Safety. Prepare and submit critical lift plans in accordance with EM385-1-1 for acceptance by the cognizant authority. Ensure that operations are conducted well within allowable wind and/or sea state conditions. It is preferable to conduct these types of operations during periods of minimal winds (moderate breeze, 11 knots or less), low tide and slack current conditions and from an anchored barge or a barge with winch operated spuds.

Site conditions, such as water depth, currents, tides, predominant winds, soil conditions (type soil, bottom slope), installation equipment (winches and multi-part blocks), available installation vessels (type and capacity of floating crane barge, tugboats and material barges), type of anchor (drag embedment or embedment anchor) and type of pull test (vertical or horizontal) will require the installation team to develop specific plans and procedures for the mooring pull test operations.

Unlike mooring hardware, mooring anchor pull tests are used to proof the installed anchor to only its design load. Plate anchors and high capacity drag embedment anchors have a design load factor of safety of 2 to its ultimate holding capacity. Drag embedment anchors such as the stockless anchor have a design load factor of safety of 1.5 to its ultimate holding capacity.

Generally, two types of mooring pull tests are performed. Horizontal pull tests are always performed on drag embedment anchors. APPENDIX J provides an extract from MO-124 for guidance on drag embedment anchor pull tests.

Vertical pull tests are usually performed on embedment anchors, but soil and design requirements at the specific site may require a horizontal pull test. Horizontal pull tests are usually performed by pulling one newly installed embedment anchor against another newly installed embedment anchor to increase installation efficiency.

All mooring pull tests should include the use of a calibrated remote load cell placed in line and at a location where frictional effects from the pull test configuration can be eliminated. For vertical pull tests, the load cell is positioned inline between the ground leg chain and the crane hook, as shown in Figure 5-16.

Figure 5-16 Vertical Pull Test Load Cell Positioning

Horizontal pull tests involving two embedment anchors have one end referred to as the “running” end and its opposite end referred to as the “static” end. The static end is where the mooring chain on one embedment anchor is secured to a suitable deck attachment point. The load cell is positioned just outside of the edge of the barge in line with the static leg. This provides a readout of the pull test tension on the embedment anchors eliminating the contributions of friction between the chain and the deck of the barge. Figure 5-17 shows the load cell placement on a static leg.

For horizontal pull tests involving only one anchor, the load cell should still be positioned in line with the mooring leg and at a location where frictional contributions can be eliminated from the load cell readout.

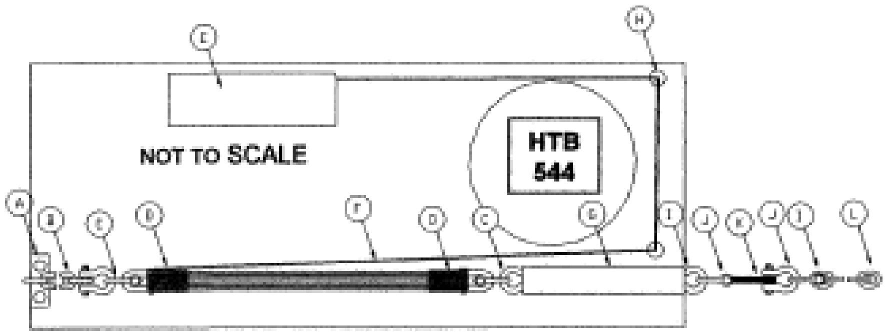
Figure 5-17 Horizontal Pull Test Load Cell Positioning

Embedment anchors installed in mud or soft sediments may have a wire rope between the anchor and the mooring chain to aid in the leg cutting through the soil and to minimize the keying (or net upward movement) distance to obtained the required test load.

The running end is usually configured with a multi-block system with wire rope reeved through the blocks. The reeving of the blocks will impose additional tensions on the individual wire rope parts as well as the friction between the running leg being pulled onto the barge (a roller or softener should be used where the running leg is to be pulled onto the barge). Though the load cell is positioned to avoid frictional contributions, pull test wire rope and other rigging must be sufficiently sized to account for all frictional contributions. Several sources are available to aid the design engineer in computing the additional frictional tensions.

For most horizontal pull tests, the barge should end up in vicinity of the middle between embedded anchors. This will mean adding additional chain to both the static and the running end, with more chain added to the running end. At the beginning of the pull test, the barge is positioned closer to the static anchor so at the completion of the pull test it ends in vicinity of the center between the anchors. It is still preferable to work in half to full shots of chain to minimize the amount of connecting links used. A general pull test schematic is shown in Figure 5-18.

Figure 5-18 Horizontal Pull Test Configuration



A	BOLSTER
B	RUNNING CHAIN LEG
C	DOUBLE 3-INCH G-2140 CROSBY SHACKLES
D	140 TON MCKISSICK 6-SHEAVE BLOCKS
E	AMERICAN WINCH
F	1.25-INCH 6X19 IWRC EIPS WIRE ROPE 13-PART
G	8 FT W14X283 LBS I-BEAM PADEYE
H	DECK SHEAVE
I	SINGLE 3-INCH G-2140 CROSBY SHACKLE
J	125 TON G-2160 CROSBY SHACKLE
K	EILON RON2000 125 TON LOAD CELL
L	STATIC CHAIN LEG

Both vertical and horizontal pull tests should be executed in a slow controlled manner by applying the load in increments of 5 to 10 tons until the pull test load is achieved. At each increment and wait of one minute should be done to allow for deck personnel to record the applied load, time, number of chain links recovered (from a reference point) and to visually check the rigging.

Upon completion of the pull test, the final embedment depth of the plate anchor padeye should be recorded. The actual orientation of the anchor plate is not known due to (1) A Factor of Safety of 2 is used for embedment anchors; and (2) Conservative estimates of soil strength during anchor design. The padeye location can be determined from the driving record, anchor drawing and results from the pull tests. It should be at or below the design depth for the anchor; however, embedment anchors that pass the pull test are generally not recovered unless post-test calculations or other geometry considerations indicate otherwise. This consideration would most likely be at a location with soft sediment or mud conditions.

For all mooring anchor pull test operations, all plans and procedures should ensure the following:

- Only qualified welders and riggers are used.
- Connecting links are secured with lead.

- A pull test plan is developed by a Professional Engineer, reviewed and accepted by the cognizant authority.
- Load cells have current calibration and positioned inline to the line of pull with the least amount of frictional or other effects. For horizontal pull tests, the load cell is positioned just outboard of the barge between the fixed deck attachment and the standing leg.
- A pull test rigging checklist is developed and completed prior to pull test operations to verify the pull test is properly configured and pull test rigging is correctly positioned according to the accepted pull test plan.
- A pull test record is completed to include information on the type load cell, depth of anchor padeye below the seabed at the start and end of the pull test, water depth, tide, link count at the start and end of the test above a reference point, links pulled in during pull test increments and final padeye depth below the seabed to include required datum (ie MLLW, etc).
- A CCD is used to secure the chain before and after a vertical pull test and after completion of horizontal pull tests.
- Rigging is designed and certified and with sufficient capacity, as placed, to withstand planned tensions to include additional tensions from frictional forces at the running end as well as within multi-part blocks. Rigging shall meet requirements of EM 385-1-1, as well as NAVFAC P-307 or the applicable agency document.

An operational risk management (ORM) approach should be used to develop specific mooring pull test procedures based on local environmental conditions, project equipment and vessels and experience of the deck force.

5-4 ASHORE INSPECTION AND REFURBISHMENT OF BUOYS.

5-4.1 Scope.

Ashore inspection and refurbishment of buoys will include visual inspections, repairs, tests, and replacement of damaged components. There are two types of buoy inspections: preliminary and detailed. The purpose of a preliminary inspection is to determine whether the buoy is in a condition for a further, more detailed inspection and subsequent refurbishment or whether it should be disposed of at this stage. If the results of the preliminary inspection indicate that refurbishment will be cost-effective, then a detailed inspection will be conducted. The buoy must be cleaned, completely inspected, and tested for airtight integrity to determine all repair requirements. The buoy can also be sandblasted to near white metal and, if required, a liquid dye penetrant or magnetic particle test conducted.

5-4.2 Preparation for Ashore Inspections.

Prepare the buoy(s) for ashore inspection as follows:

- Clean off buoy with high-pressure water during recovery.
- When brought ashore, place the buoy on chocks (railroad ties, cinder blocks, etc.) to keep the tension bar clear of the ground. For ease of working, the peg-top type buoy should be placed inverted on chocks.
- Remove the top and bottom jewelry, fenders, chafing strips, and manhole covers. Mark manhole cover positions before removal for later replacement in the same location.
- Remove shackles and joining links from the buoy, as necessary. After removal, shackles and joining links should be reassembled as complete units, including pins. Shackle pins and tapered locking pins should be used only in their original parent component.

5-4.3 Inspection Procedures.

Bear in mind that most of these inspection procedures are geared toward steel buoys. Inspections of foam buoys can be accomplished on the deck, since the fendering and chafing rails are integrally cast as part of the buoy. If the inspection reveals that damage to the buoy has occurred, it is often easier to repair the damage ashore and replace the buoy with another one.

5-4.3.1 Preliminary Inspection.

Before beginning the preliminary inspection, a 1-foot-square (0.09 m^2) section of the top and bottom and four 1-foot-square (0.09 m^2) sections (two above and two below the water line) of the side hull plates should be cleaned to bare metal. Visually inspect these four sections for pitting. In addition, perform a visual inspection as follows:

- Inspect the fenders and chafing strip fastenings for corrosion and wear.
- Check hull and deck plates for corrosion, cracks, pitting, and watertight integrity.
- Inspect the upper and lower ends of the tension bar (if the buoy is so constructed) for wear, cracks, rust, or pitting.
- If the buoy is a non-riser (telephone) type, check the padeyes for wear or cracks.
- Check the overall condition of the paint, fiberglass, or polyurethane coating.
- Ensure that the buoy is gas free by ventilating and certification by a marine chemist.
- Check the interior of the buoy for rust or corrosion.

Note:

If the buoy is a steel hawse pipe type, remove the buoy from service without doing any additional work by turning it in to the base steel recycling or local DLA Disposition Services.

Based on the results of this inspection (i.e., internal structural weaknesses, hull plate cracks, severe pitting or rusting, broken tension bar, excessive corrosion, etc.), a decision will be made whether to prepare the buoy for a detailed inspection or to dispose of it.

5-4.3.2 Detailed Inspection.

Detail Inspection is performed as follows:

Ultrasonic Inspection:

- Sandblast the buoy to near white metal in accordance with SSPC-SP-10/NACE 2.
- Inspect the buoy for damage, cracks, etc.
- Conduct an ultrasonic thickness test at four points on the buoy top, four points on the bottom, and eight points around the circumference of the hull. Four of the foregoing eight points will be below the waterline and four above the waterline.
- Using a pitting gauge, measure the depths of any pits observed on the hull of the buoy.

Pitting Inspection:

A visual inspection of the buoy hull plates will be made for pitting. The extent of pitting will determine the remaining life of the plates. ASTM G46-94, "Standard Guide for Examination and Evaluation of Pitting Corrosion" will be the standard reference used to evaluate the damage and to formulate a quantitative expression that will indicate its significance. To obtain a quantitative expression, ASTM G46-94 recommends that the deepest pit be measured, and that metal penetration be expressed in terms of the maximum pit depth or the average of the 10 deepest pits. Metal penetration can also be expressed in terms of a pitting factor. This is a ratio of the deepest metal penetration to the average metal penetration as shown in the following relationship:

$$Pitting\ Factor = \frac{Deepest\ Metal\ Penetration}{Average\ Metal\ Penetration}$$

A pitting factor of "one" represents uniform corrosion. The larger the number, the greater the depth of penetration. Pits will be rated in terms of density, size, and depth.

Welds:

Carefully check all welds, both internal and external, for cracks or corrosion. If any cracks, fissures, or other flaws are found or are suspected, then a liquid dye penetrant or magnetic particle test should be performed to determine the extent of the defects.

Buoy Air-Pressure Test:

Each buoy compartment will be tested for tightness at the joints by the application of air pressure. Unless the buoy is under cover, at least 2 hours of clear weather will be required for the test. The gauge used for the test must have a current calibration certification. Proceed as follows:

- Install a test plug fitted with a gauge in the top of each buoy compartment.
- Pressurize the compartment to 2 pounds per square inch (14 kPa). Allow 30 minutes to pass after pressure stabilization.
- Brush all joints and seams with a commercial leak testing solution. A 2% solution of potassium bichromate may be added to the leak testing solution to inhibit rust.
- Leaks detected will be repaired and the buoy retested.
- When all tests and repairs are finished, completely remove the leak testing solution before applying surface primers.

5-4.4 Buoy Repairs and Modifications.

5-4.4.1 General.

Steel Buoy repairs and modification will include manhole cover replacement, test plug and aperture maintenance, fender and chafing strip repairs, welding requirements and air pressure testing.

5-4.4.2 Procedures.

Steel buoy repair and modifications will be accomplished as follows:

5-4.4.2.1 Manhole Cover Replacement.

Manhole cover replacement will be accomplished as follows:

- Clean and lubricate the studs and use chaser nuts where required.
- Make match marks on the cover and the buoy body to ensure that the manhole cover goes in the proper location and in the correct orientation.
- Remove the manhole cover.

- Replace old gasket with a new 1/8-inch (3.2 mm) silicone rubber gasket held in place with RTV silicone gasket adhesive sealant (MIL-A-46106). Apply sealant only to bottom surface of gasket.
- Lift manhole cover by the extension lip and position it over studs.
- Lower manhole cover on studs.
- Secure cover bolts. Tighten in at least three steps using an opposite bolt tightening sequence. Apply final 45 foot-pounds (61 N-m) of torque.

Note:

Each manhole cover will be replaced on the opening from which it was originally removed. Match marks shall be made on cover and deck plate prior to removal to facilitate its replacement in the correct location and position.

Exercise care in lowering the cover on the studs so that stud threads and gasket are not damaged.

5-4.4.2.2 Test Plugs and Hull Apertures.

Clean and check test plug threads before placement of the plugs in the hull apertures. Teflon sealant tape should be applied to the threads to ensure a watertight seal.

5-4.4.2.3 Fenders and Chafing Strips.

Overhauled steel buoys will be provided rubber fenders and chafing strips. In most cases, this will require removal of the wooden fenders and their channeling, and the wooden chafing strips and connecting brackets. Channeling and brackets will be replaced by stainless steel stud bolts, 3/4-inch in diameter by 2 1/2 inches long (10 threads per inch). The bolts will be positioned and welded to conform to predrilled holes in the rubber fenders and chafing strips. If the rubber fenders and chafing strips are not predrilled, they will be drilled to conform to the positions of the stud bolts. Spacing of the bolts shall not exceed 16 inches (406 mm) on center.

5-4.4.2.4 Welding.

All welding will be accomplished by trained and qualified personnel following accepted procedures and standards contained in the latest edition of AWS D1.1, *Structural Welding Code - Steel*.

Safety Warnings:

Never cut or weld to the surface on an enclosed void (such as a steel buoy) until the interior has been properly ventilated and gas free. Potentially explosive gases can accumulate within the buoy.

Use qualified welding procedures and follow safe welding procedures per EM 385-1-1 and wear required PPE for welding operations

5-4.4.2.5 Buoy Air Pressure Test.

Each buoy compartment will be tested for tightness at the joints by the application of air pressure. Unless the buoy is under cover, at least 2 hours of clear weather will be required for the test. The gauge used for the test must have a current calibration certification. Proceed as follows:

- Install the test plug fitted with a gauge in the top of each buoy compartment.
- Pressurize each compartment with 2 pounds per square-inch (14 kPa) of air pressure for a minimum of 30 minutes after stabilization of the pressure.
- Brush all joints and seams with a solution of commercial leak testing fluid. Two percent potassium bichromate may be added to the solution to inhibit the formation of rust.
- Leaks detected will be repaired and the buoy retested.
- When all tests and repairs are completed, completely remove the leak testing solution before applying surface primers.

5-4.5 Protective Coatings.

5-4.5.1 Preparation for Application.

Preparation of buoys for application of protective coatings will include the following:

- Remove fenders, chain links, steel plates etc. from the buoy.
- When possible, open the buoy manhole and check the interior of the buoy for rust and water damage.
- Examine the hull areas that may need repair or replacement.
- Pits found that are 3/16 inch (4.8 mm) deep or more will be filled with clad welding or epoxy repair compounds conforming with MIL-C-24176.
- Buoys which are fiberglassed should have a steel reinforcing ring welded around the outside edge of the manhole opening if one is not already

present. The purpose of the ring is to provide a clean, secure surface on which to seat the manhole cover gasket as well as to reinforce the buoy deck. The ring should be of 1/2-inch (13 mm) steel plate and should extend a minimum of two inches outward from the edge of the manhole opening. If a ring is not used, then the manhole opening must be welded closed using flush steel plates which are reinforced on the underside by steel backup strips. If this is the case, the buoy will have to be cut open for subsequent inspections.

- Sandblast exterior surfaces of the metal hull in accordance with the latest edition of the *Steel Structures Painting Manual, Vol. II, Systems and Specifications*, Specification SSPC-SP-10. All sharp and irregular edges will be ground smooth. Be aware of potential for presence of Chromium VI during removal of existing coatings on older type steel buoys.

Note:

Do not apply paints or fiberglass coatings to the top surface of the reinforcing ring.

No sandblasted surface will remain uncoated for more than 4 hours.

Be aware of the presence of hazardous components such as lead or chromium VI that may be present on remaining coatings on old steel buoy coatings.

5-4.5.2 Foam Filled Elastomer Covered Buoys.

In the event of small rips, tears, punctures, or gouges in the skin and underlying foam, a repair kit containing the components and procedures required to accomplish minor repairs can be obtained from commercial vendors. If the buoy should be severely damaged and major repairs are required, the manufacturer of the buoy should be contacted for advice and/or assistance.

5-4.5.3 Fiberglass Polyester Resin (FPR) Coating Repair.

Fiberglass patches will be applied as follows:

- Sandblast the area around the repair to ensure a clean surface.

Note:

The term sandblasting here is used as a general term. Sand is not the recommended media for blasting fiberglass, softer media is recommended such as walnut shell grit, plastic grit or even dry ice.

No sandblasted surface will remain uncoated for more than 4 hours.

- Immediately after sandblasting the areas to be repaired, apply one coat of pretreatment primer (MIL-P-15328, Formula 117), 0.3 to 0.5 mil (7.6 to 12.7 μm) thickness. The thickness of the primer shall not exceed 0.5 mil (12.7 μm). Film thickness will be checked with a microtest thickness gauge or a comparable instrument.
- After the pretreatment primer has dried, apply one coat of clear polyester resin (MIL-R-21607) to the surfaces that are to receive the FPR coating patches.
- Commence with the first FPR lamination, which consists of the polyester resin and chopped fiberglass mat (MIL-M-43248). Apply the mat to the pre-coated surface and roll/squeeze to remove all lumps and air bubbles. Lay on additional polyester resin until the mat is thoroughly wet. Roll/squeeze until smooth, adding additional resin as necessary.
- Immediately after the first lamination is ready, apply three additional laminations, as follows, to give a maximum dry film thickness of 3/16 inch (4.8 mm). One lamination of fiberglass woven roving (MIL-C-19663) will be applied in a manner similar to the initial lamination. Apply one lamination of fiberglass mat. Apply one lamination of fiberglass woven roving. Note: Adjacent portions of mat or woven roving in all laminates shall overlap a minimum of 6 inches (152 mm).
- Apply additional polyester resin coatings for each successive lamination before and after the individual lamination reinforcement. The reinforcement will be rolled and squeegeed as in the initial lamination, and the polyester resin will be added and distributed, as needed, before starting the next lamination.
- Apply a generous, smooth-finished topcoat of the polyester resin mixture on the final lamination. The topcoat will be pigmented with 4 ounces (0.113 kg) of white color pigment per gallon of resin.
- NOTE: Personnel applying the FPR may, in lieu of the laminations of fiberglass mat, use a chopped fiberglass-polyester lamination sprayed on the surface being refinished at the rate of 2 ounces per square foot (0.61 kg/m2).
- If breaks occur on the surface such as around the tension bar, padeyes, and bolts and studs, the FPR coating will be edge-finished carefully using polyester resin.

5-4.5.4 Paint Coatings.

General coating operations, materials, and safety precautions are described in UFC-3-190-06, *Protective Coatings and Paints*. The recommended coating system for mooring buoys is the Navy epoxy-polyamide system for interior and exterior ship surfaces (MIL-P-24441 Type III). Procedures for its use are thoroughly described in the Naval Ships Technical Manual (NAVSEA S9086-VD-STM-010). For optimum results, this coating should be applied to dry steel cleaned to a near white metal surface, SSPC-SP-10/NACE 2. As a minimum, surfaces should be cleaned to commercial blast, SSPC-SP-6/NACE 3.

- The above coating should be applied in three coats, each at about 4-mil (101.6 μm) film thickness, to give an approximate 3-mil (76.2 μm) dry film thickness per coat and a minimum 8-mil (203.2 μm) total dry film thickness. There should be 16 hours of curing time between coats. The first coat should be the green primer (Formula 150); the second, haze gray (Formula 151); and the third, white (Formula 152).
- The two components of all MI L-P-24441 coatings should be mixed in equal volume by first thoroughly stirring each component separately and then stirring them together. After mixing, there should be a waiting period of about 2 hours at 50 to 60 °F (10 to 15.6 °C); 1 to 1 1/2 hours at 60 to 70 °F (15.6 to 21.1 °C); and 1/2 to 1 hour above 70 °F (21.1 °C) before applying the coating to ensure complete curing later. The mixed paints do not require thinning, but the low temperature application properties can be improved by adding 10%, by volume, of a mixture of equal parts of n-butyl alcohol and AMSCO Super High Flash Naphtha, or an equivalent mixture.

Usual paint spray equipment, either conventional or airless, can be used. The pot life of the mixed coating is about 6 hours at 73 °F (22.8 °C). If more than 7 days elapse between epoxy coats, the surface should be cleaned with water and detergent, rinsed with fresh water, dried, and then a tack coat (1 to 2 mils (25.4 to 50.8 μm) wet film thickness) of the last coat applied before application of the next full coat.

The above coating system, when properly applied, will provide at least 3 to 5 years of protection, depending upon the severity of the environment. Experience has shown that an antifouling paint is usually unnecessary because fouling will not damage the coating, add a significant amount of weight to the buoy, or otherwise adversely affect the mooring. In addition, the effective life of antifouling paint is usually much shorter than the time between buoy overhauls, so that significant fouling will still occur before the next overhaul. Should an antifouling paint be desired for the underwater portion of the buoy, MIL-P-15931, Formula 121/63, applied in two coats, is recommended. The antifouling paint, which is red, must be applied while the topcoat of epoxy (MIL-P-24441, Formula 152) is still tacky (within 4 to 6 hours after its application). If the epoxy has hardened, a tack coat of MIL-P-24441 (1 to 2 mils (25.4 to 50.8 μm) wet film thickness) must be applied and allowed to cure for 4 hours before the first coat of antifouling paint is applied.

Safety Note:

Painters shall use the appropriate PPE.

MSDS for all components shall be readily available on site.

All painting shall comply with USACE EM 385-1-1.

The emphasis is on the replacement of steel buoy with foam buoys. Over the 20 year life of a buoy, the steel buoy will normally require 4 overhauls while the foam buoy will require minimum maintenance, bringing a huge cost savings over that 20 year life span to the operator.

5-4.5.5 Quality of Work.

All of the workmanship on the coating systems shall be in accordance with the Naval Ships Technical Manual, NAVSEA S9086-VD-STM-010. The work shall be performed by or under the immediate and direct supervision of skilled personnel who have demonstrated a continuing proficiency in the application of multilayered coatings on extensively contoured areas similar and comparable to the exterior of mooring buoys. Quality of workmanship shall meet the highest standards as set forth in the specifications and manuals noted herein.

5-4.5.6 Coating Documentation Report.

After a buoy is coated, a documentation report, traceable to the buoy, should be prepared that shows the coatings used, the date the coatings were applied, the surface preparation performed to include surface profile measurements, wet and dry film measurements, measurement of ambient conditions during coating operations, QC procedures used, etc. The report shall be placed as part of the mooring documentation and provided to the mooring custodian. Sufficient inspection should be performed to ensure that the surface was properly prepared, the coating properly prepared and applied and the required dry film thickness and coverage obtained.

5-5 ASHORE INSPECTION AND REFURBISHMENT OF CHAIN AND ACCESSORIES.

5-5.1 Scope.

Chain and fittings are inspected to determine their suitability for continued use in the mooring system. The inspection process is two-phased, PRELIMINARY and DETAILED.

The preliminary inspection is conducted to determine if the chain or fitting is adequate for continued use, if it can be made serviceable by repair or refurbishment, or if it should be disposed of.

The results of the preliminary inspection are analyzed to determine the need for further inspection. If the results of the preliminary inspection indicate that the chain or fitting can be made serviceable by repair or refurbishment, a detailed inspection is conducted to develop a specification for the repair or refurbishment. If the preliminary inspection results indicate that the chain is adequate for continued use, then a detailed inspection should also be conducted to ensure that no faults in the chain have been missed prior to returning to service.

In planning an inspection of mooring chain and fittings, the inspection activity should consult the cognizant authority for guidance as to the extent of the inspection required. Some of the material in the mooring may be planned for reuse if found acceptable and some may be scheduled for disposal without further action.

5-5.2 Preliminary Inspection.

All fittings should be disassembled, removed from the chain, and reassembled as complete units until ready to be inspected. When joining links are disassembled, care should be taken that the parts of one joining link are not interchanged with the parts from another joining link. Chain should be arranged in shots or partial shots so that each link is accessible for inspection. Known or suspected high wear areas should be thoroughly cleaned with a scaling tool and wire brush or lightly sandblasted to SSPC SP-2 or SP-3 criteria.

The preliminary inspection should begin with a visual inspection of each fitting and each chain link. Visually inspect each link of chain for abnormal wear, cracks, deformation, or missing studs. Mark all links with obvious problems and all areas to be measured.

After the visual inspection is complete, measurements should be taken in known or suspected high wear areas and in any suspect areas noted during the visual inspection. Take single or double-link measurements on the first two to four links of chain at the end of each shot or partial shot and at any location in the chain where high wear is indicated by shiny metal or visible loss of wire diameter. Remember that the chain must be under tension to take accurate double-link measurements.

Disassemble each fitting and visually inspect each component of the fitting for indications of wear, deformation, or cracks. Pay particular attention to pins and pin locking holes. Check pins for loose fit before disassembling. Measure the wire diameter of joining links, shackles, and ground rings at known or suspected high wear areas. Reassemble all fittings as complete units on completion of the inspection. Apply a liberal coating of grease to all internal surfaces of joining links (mating surfaces, pins and pin locking holes) prior to reassembly. Grease should be in accordance with MIL-PRF-10924.

Based on the results of the preliminary inspection, tentatively classify the chain and fittings as good, fair, or poor in accordance with Table 5-1. Chain and fittings tentatively classified as good or fair should be retained for detailed inspection; chain and fittings tentatively classified as poor should be disposed of through normal disposal procedures.

Table 5-1 Classification of Mooring Component Condition

Condition	Amount of Deterioration
Good	90% or greater of original wire diameter
Fair	80 – 90% of original wire diameter
Poor	80% or less of original wire diameter

5-5.3 Detailed Inspection.

All chain and fittings that have been tentatively classified as good or fair as a result of the preliminary inspection should receive a detailed inspection to determine the action required to return the components to serviceable status. No further inspection should be conducted on chain or fittings that do not pass the visual inspection for any reason other than a slight deterioration of wire diameter. Before beginning the detailed inspection, all chain and fittings to be inspected should be sandblasted in accordance with the latest edition of the Steel Structures Painting Manual, Vol. II, Systems and Specifications, Specification SSPC-SP-6/NACE-3.

Single-link measurements should be taken on each link of the chain. Visually inspect each link for cracks, deformation, missing studs, or any other abnormalities. If a crack is suspected but not readily obvious to the naked eye, conduct an MT in the suspected area.

The wire diameter of each fitting should be taken in normal wear areas and in any areas designated as suspect as a result of the preliminary inspection. Check for worn pins, worn pin locking holes, cracks, or deformation. If cracks are suspected, conduct an MT to verify. Disassemble each joining link and shackle and inspect all components. Reassemble as complete units. Apply a liberal coating of grease to all internal surfaces of joining links in accordance with MIL-PRF-10924 prior to reassembly.

Classify the chain and fittings in accordance with Table 5-1. Material classified as good or fair may be coated and returned to inventory. It should be tracked separately, by classification, from new material. Material classified as poor, should be disposed of through normal disposal procedures.

The results of all inspections, including a record of all measurements taken, should be included in the pertinent material history file or mooring maintenance file and a copy forwarded the mooring manager.

5-5.4 Protective Coatings.

Chain and fittings classified as good or fair should be should be abrasive blasted to Steel Structures Painting Manual, Vol. II, Systems and Specifications, Specification SSPC-SP-6 or NACE-3. Spray, dip, or brush the abrasive blasted chain/fittings with an approved rust preventative (MIL-PRF-16173 Grade 1). Place the chain on a clean surface to dry. Once dry, put the chain back into inventory noting the condition of this chain.

- If the chain/fittings have not been sitting around too long after the blasting for the detailed inspection and no visible rust, dirt, etc. is apparent, then a reblasting is not required.
- For accessories with pins or bolts, ensure that the applied coating is not too thick. Otherwise, it will be difficult to remove or assemble the shackle pins or bolts.
- Coating operations should be avoided on cold/damp days.

5-6 ASHORE INSPECTION AND REFURBISHMENT OF ANCHORS.

5-6.1 Scope.

The primary purpose of inspecting an anchor is to determine its general physical condition and its suitability for reuse. The inspection of an anchor should only be conducted when the anchor is either temporarily aboard a barge or in a storage area ashore. There are two types of anchor inspections: preliminary, which can be conducted either aboard a barge or ashore, and detailed, which is normally conducted ashore. These inspections should be accomplished as soon as possible after the anchor is removed from the water.

5-6.2 Preliminary Inspection.

The anchor should be cleaned with a high-pressure water wash-down before beginning the preliminary inspection. When cleaned, the anchor should be laid on the deck or on the ground within reach of a crane so that it can be lifted and turned to gain access to all surface areas.

Every surface for the anchor and anchor shackle should be visually inspected for the presence of cracks, casting irregularities, abnormal wear, or any other obvious damage or defect. Caliper measurements should be taken to determine the wire diameter of the anchor shackle at the bow and at the wear area at the lugs of the shackle. Ensure that the shackle is free to move, not frozen in position.

Visually check the anchor for casting irregularities, cracks or obvious mechanical damage. If the anchor is of welded construction (STATO or NAVMOOR), or if the anchor has stabilizers welded to it, all weldments should be closely scrutinized for cracks, fissures, pitting corrosion, or other defects. Special attention should be paid to the very end of the shank, the fit of the shackle in the shank, and the base of the flukes.

A hammer test will determine whether there are major invisible cracks or other abnormalities in the anchor. The test is conducted by suspending the anchor from a crane hook and striking each fluke with a large (> 5 pounds or 2.2 kilograms) hammer. If a ringing tone results the anchor is sound. If a dull thud results, there are serious cracks or other irregularities in the anchor.

The results of the above preliminary inspection measurements, observations, and tests should be documented. If the inspected anchor is determined to be in satisfactory condition as a result of this inspection, no further effort will be expended, and the anchor will be made ready for further use or placed in a designated storage area. Anchors returned to service or placed in inventory in a ready status should be coated with a black-gloss solvent-type paint (MIL-P-2430).

5-6.3 Detailed Inspection.

A detailed inspection will only be conducted if, as a result of the preliminary inspection, abnormalities are suspected or if the condition of the anchor is questionable. The detailed inspection will include the following:

- Clean the anchor by abrasive blast clean to SSPC-SP-10/NACE-2 near white blast cleaning.
- Visually inspect the anchor for cracks or casting irregularities. Pay particular attention to the anchor flukes and welds.
- Perform a liquid dye penetrant or magnetic particle test on any suspected cracks or abnormalities in accordance with NAVSEA Technical Publication T9074-AS-GIB-010/271 Requirements for Non-Destructive Testing Methods.
- If the results of this testing indicate that cracks or other abnormalities do exist, a decision will have to be made to determine if these abnormalities can be corrected by grinding and welding or if they are too numerous or too deep for economical refurbishment of the anchor. If repairs can be made, then as soon as they are accomplished, the anchor should be protectively coated with a black-gloss solvent type paint (MIL-P-24380). If it is determined that refurbishment of the anchor is not economically feasible, then the anchor may be retained in storage for future use as a sinker/clump or disposed of. All findings/results of the detailed inspection shall be fully documented and filed.

CHAPTER 6 STORAGE OF MOORING MATERIALS

6-1 GENERAL REQUIREMENTS.

Mooring components are usually stored in open areas near a coastline, thus exposing them to weather and a marine environment. To prevent deterioration while in storage, some preventive maintenance will be required in addition to the routine material handling and inventory control tasks normally performed by a storage facility. The job of handling, maintaining, and controlling stored components will be made much easier if some basic guidelines, as noted below, are followed.

- The storage area should be large enough to permit efficient movement of forklifts, cranes, and other large mobile equipment.
- Arrangement of components should allow easy access for inspections, inventory checks, and selection.
- To reduce corrosion, all components except cathodic protection materials should be coated with paint, approved rust preventatives, or other suitable preservatives as detailed in CHAPTER 5.
- All components should be tagged or labeled to ensure proper identification and accurate inventory reporting.
- Chain accessories such as joining links, swivels, ground rings, and shackles should be crated or banded together on pallets to permit easy handling.

6-2 STORAGE AREA REQUIREMENTS.

Shore activities requiring spare mooring materials will require a suitable storage area. The following should be observed:

- The mooring materials should normally be stored in a secure area designated by activity personnel responsible for space allocation.
- The storage area should be on solid ground or on improved surfaces, and graded for drainage.
- The area should be large enough, as well as configured, to allow easy access of equipment and personnel involved in chain handling and other maintenance operations.
- The area should be close to maintenance areas, transportation equipment, and the waterfront to reduce both maintenance and transportation costs.

6-3 STORAGE PROCEDURES.

6-3.1 Buoys.

Store buoys as follows:

Place all drum type buoys on chocks or dunnage, with all metal parts clear of the ground, and tilted (using additional chocks or dunnage under one side) to facilitate water runoff.

Store peg-top buoys in a horizontal position (see Figure 6-1).

Figure 6-1 Proper Storage of a Foam Peg Top Buoy

Foam buoys should be stored on specially designed wood buoy cradles to avoid a permanent flat spot.

Buoys should be periodically inspected to aid in the detection and prevention of localized corrosion areas. If corrosion is found, corrective action should be implemented. Corrosion commonly develops in the web of channel irons securing wooden fenders, in the hull behind rubber fendering, and on the nuts/studs used to secure manhole covers, fenders, and chafing strips. Ground or chock contact points are also susceptible to higher corrosion rates. Any area on the top of the buoy that could collect water is susceptible to accelerated corrosion. In addition, the steel cradle for foam buoys should be inspected for corrosion.

6-3.2 Chain and Chain Accessories.

Chain is normally stored ranged out in tiers, a single shot of chain placed on a pallet, loaded in shipping crates, or in bundles. The ground where the chain is stored should be clear of all debris and growth, and well drained.

Mooring chain and accessories of different specifications and grades should always be stored separately, to prevent mooring components of a lesser grade being mixed into a mooring system that requires a higher grade of chain or accessories.

6-3.2.1 Tiered Chain.

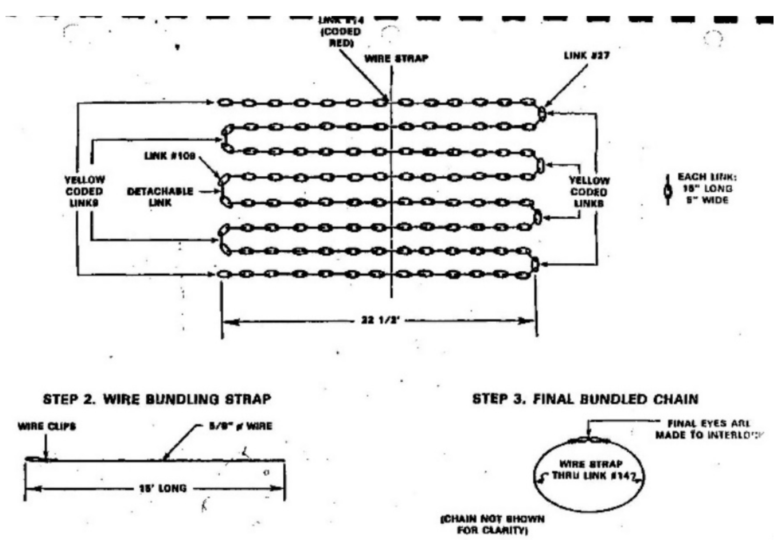
Store chain in tiers as follows:

- Lay chains down stretched out taut and free of turns.
- Pile tiers in multiple layers to reduce storage space.
- Each tier should contain chain of similar construction, size, and condition for ease of access and accurate inventory control.
- The ends of each length of chain should have an identification tag attached to it which contains the chain size (in inches), type (cast/forged/etc.), length (in feet), and manufacturer.

6-3.2.2 Palletized Chain.

Chain may also be stored and handled on pallets. Normally, chain is palletized in single shot lengths to reduce handling weights and to simplify inventory. Chain pallets normally consist of wooden or steel pallets onto which the chain is piled or bundled (see Figure 6-2).

Figure 6-2 Chain Bundling Method



It is recommended that the lashing not be used to lift the pallet/chain bundle unless it meets the local base policy for lift operations. One can pass the lifting sling through the captured links that can be used for lift operations or the pallet with the chain can be lifted with a forklift.

6-3.2.3 Crated Chain.

Reusable wooden crates can be used for the shipment and storage of chain and will normally contain a single shot of chain. The crates can be stacked to reduce deck space requirements if not loaded beyond the design capacities stamped on the crates (see Figure 6-3).

Figure 6-3 Stacked Crates of Chain

6-3.3 Mooring Accessories.

Store mooring accessories by type, by size and by specification/grade in either a crate, box or on a pallet. Connecting links, anchor bolt shackles and riser swivel shackles should be greased and loosely assembled, but they should never be stored disassembled and the parts stored separately. Plate shackles may be stored disassembled.

6-3.4 Anchors.

Place anchors on dunnage and in a vertical position. Store according to type and size for ease of inventory control. U.S. Navy anchors have identification marks cast, stamped, or cut on the anchor crown. When stored vertically, this information should be transferred to a suitable tag or stenciled to the anchor's shank.

6-3.5 Cathodic Protection Materials.

Larger anodes stored outside should be sealed in plastic liners and boxed to preclude premature galvanic action. Do not store anodes in the open or near other dissimilar metals, which could result in corrosion of the anodes. Chain stud anodes should be stored in HDPE 57-gallon plastic drums with removable lids. Only one size of anode shall be packed in each drum. Store screws in sealed plastic bags to prevent corrosion.

Cathodic protection material should be kept clean and should not be painted or coated with oil or grease during either storage or use.

6-3.6 Marking and Identification.

Marking and identification of components should be accomplished as described.

6-3.6.1 General.

Proper marking and identification of all mooring components will assist in conducting inventories, will help prevent use of improper or substandard materials, and will speed assembly and installation times when required components must be drawn from inventory.

6-3.6.2 Color Coding.

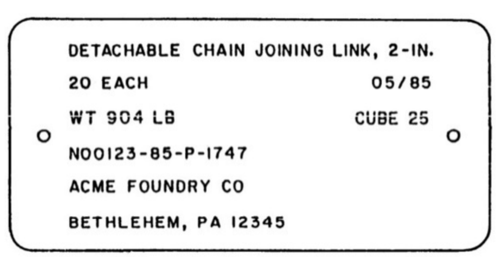
It is good practice to color code chain to identify its condition. Recommended colors to be applied to the last link on each end of a chain length are:

- White - for chain in new or good condition.
- Yellow - for chain in fair condition.
- Red - for chain in poor condition and ready for disposal.

6-3.6.3 Identification.

Identification of chain and accessories shall be on tags of 0.031-inch (0.787 mm) thick aluminum alloy 1100 or 3003, attached using 0.031-inch (0.787 mm) diameter 300 series corrosion resisting stainless steel wire through 0.125-inch (3.175 mm) diameter holes at each end of the tag. Characters shall be metal stamped using 0.25-inch (6.35 mm) high characters. Tag size and information content shall be as shown in Figure 6-4. On chain shots, tags shall be attached to the last link on each end of the shot. Tags will be attached snugly to each accessory in a location away from the grip area of the component and shall be bent to conform to the contour of the component to minimize risk of snagging or damaging the tag.

Figure 6-4 Example Shipping Tag

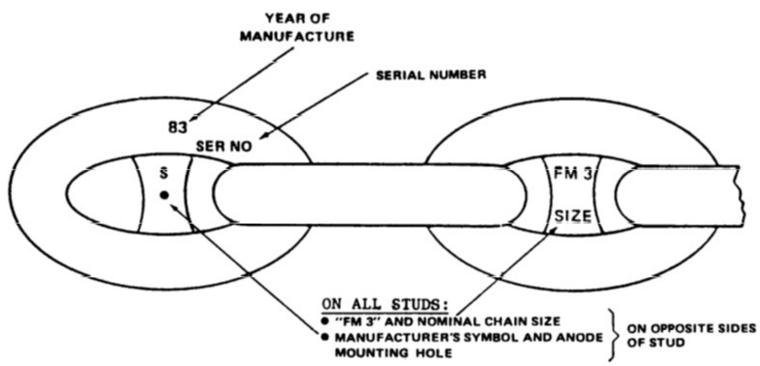


6-3.6.4 Fleet Mooring Inventory Chain and Accessories.

Chain and accessories procured under contract for the Fleet Mooring Inventory are marked and identified as followed:

- The size and the name of the manufacturer are stamped or forged on each chain link or accessory during manufacture.
- New FM3 chain will also have a unique serial number on each accessory, on the end links of each shot, and on the 3rd link from each end of chain (see Figure 6-5). The serial number will be used together with documentation furnished by the manufacturer (heat number, chemical composition, etc.) to monitor the performance of different heats of chain.
- Crates used to ship new chain and accessories from the manufacturer will be marked to show: contents, weight, contract and shipping data, and stacking limitations.

Figure 6-5 Chain Markings



6-3.6.5 Buoys.

New buoys should have an identification plate (Figure 6-6) showing the following:

- Serial number,
- Manufacturer,
- Date of manufacture,
- Diameter,
- Height,
- Weight in air,
- Maximum tension bar load, and
- NAVFAC drawing number.
- This plate should be protected during sandblasting and should not be painted or coated.

Steel buoys in service may not have an identification plate. If they are to remain in service an identification plate with the above information, based on available information, should be attached to the top of the buoy near, but not onto the tension bar (to avoid welding onto the load carrying component of the buoy). A serial number should be generated for maintenance and operations tracking purposes.

Figure 6-6 Buoy ID Plate

6-3.6.6 Anchors.

Identification information for anchors is cast on the crown, on the flukes, or on the side of the shank. Minimum information provided is as follows:

- Manufacturer
- Weight
- Serial number

6-3.7 Pre-Issue Inspection.

Items that are issued from inventory should be inspected prior to shipping or movement from the storage facility. A bill of material should be reviewed to ascertain the components required and a check of all material sizes accomplished. To ensure all mooring components fit when shipped to the field, a physical fit check should be accomplished prior to shipment. The many configurations and designs of mooring hardware increase the likelihood of a misfit if a physical fit check is not accomplished.

APPENDIX A BEST PRACTICES

A-1 NOTES AND SAFETY WARNINGS.

This section will highlight by repetition all the boxed warnings and safety notices throughout this document.

All efforts should be made to replace steel buoys with foam buoys since steel buoys are much more difficult to inspect and maintain. Steel tension bar buoys can still be used, but hawse pipe buoys shall be taken out of service, disassembled and disposed of in accordance with local steel recycling programs.

All personnel at or near a mooring component being secured by lead shall wear PPE commensurate with EM 385-1-1 (such as safety glasses, foot protection, floatation vest) and other required PPE for mooring operations.

Follow safe welding procedures per EM 385-1-1 and wear required PPE for welding operations.

Wear appropriate gloves when handling wire rope.

Ensure all personnel have, maintain, and wear PPE (steel toed shoes, personal floatation vest, hard hat and other PPE for specific tasks i.e. leather gloves, safety glasses, etc.).

Daily safety briefs should emphasize everyone’s responsibility for applying risk management.

Failure to properly clean the inspection area of the chain links may provide erroneous measurements leading the inspector, custodian, and users of the mooring system to an improper conclusion on the mooring condition that could result in an unsafe mooring condition for a moored vessel.

Divers should be aware of the potential movement of the chain, especially when working on the ground legs.

All efforts shall be made to replace steel buoys with foam buoys since steel buoys are much more difficult to inspect and maintain. Steel tension bar buoys can still be used, but hawse pipe buoys should be taken out of service.

Divers should use extreme caution when working directly below a live/moving buoy.

Divers should inspect the connections of suspended sinkers with caution as motions imposed on the mooring system from surface weather conditions or attached vessels can cause the suspended sinker to move within the water column.

While inspecting the anchors, divers should not go under the flukes or shank of the anchor.

Regardless of using the design anode size or oversized anodes, the mounting hole must be free of debris and the anode tightened to the recommended torque for the anodes to work properly.

Ensure all personnel have, maintain, and wear PPE (steel toed shoes, personal floatation vest, hard hat and other PPE for specific tasks i.e. leather gloves, safety glasses, etc.).

Daily safety briefs should emphasize everyone's responsibility for applying risk management.

At no time shall personnel be directly under a suspended load when the load is out of the water. Personnel on the barge deck shall be kept clear of the fall zone of the buoy and the riser chain to the maximum extent possible. The fall zone includes the area where a suspended load may fall. Personnel should be aware that the fall zone is moving as the buoy is lifted over the deck. Only qualified personnel, in accordance with EM385-1-1, under specific instruction from the designated Marine Construction Superintendent, may enter the fall zone to handle a load.

The buoy should be lifted only as high as minimally required.

Operation planning must include the use of a chain capture method that minimizes the necessity for personnel to work under suspended load.

Use a Load Indicating Device (LID) or crane equipped LID or Load Moment Indicator to determine the load for all installation/retrieval lifting operations.

Every attempt should be made to plan operations that keep DIVERS from working under the load. If no alternatives can be found, every effort should be done to minimize the diver's time spent under the load.

Adhere to EM 385-1-1 and OSHA 1910.253 for safe use of oxygen/acetylene torch.

If lifting a hawse pipe buoy, treat the lift as if the capture plate assembly is damaged and lift from below, while simultaneously lifting the buoy. On the newer ATFP and FMP foam hawse pipe buoys, the bolts that make this connection are exposed, but it is still difficult to determine the condition of the bolts. On these foam hawse pipe buoys, the existing capture plate and bolts can be replaced with new bolts and a capture plate specifically used for lift operations only.

Additional care is needed to make sure the additional loads on the crane (from lifting the ground ring out of the water) are taken into account. In addition, the stability issues based on these extra loads must also be accounted for.

If the tension bar is damaged, it is best to lift the buoy from below to take most of the weight off of the buoy/tension bar. A secondary crane hook should be used to simultaneously lift the buoy, keeping the buoy weight off the lift.

Never cut or weld to the surface on an enclosed void (such as a steel buoy) until the interior has been properly ventilated and gas free. Potentially explosive gases can accumulate within the buoy.

No person should enter the buoy while the buoy is still in the water. A person should only enter the buoy when there is no possibility of the buoy sinking, i.e. either on the deck of the barge or ashore.

Entry of personnel into a buoy must comply with EM 385-1-1 and cognizant base requirements for confined space entry.

On a steel buoy, the buoy manhole cover must not be removed while the buoy is still in the water.

Every attempt should be made to plan operations that keep personnel from working under the load. If no alternatives can be found, every effort should be done to minimize the time spent under the load.

While preparing the anchors, positioning on deck for deployment and deploying the anchor, personnel should not go under the flukes or shank of the anchor.

If the buoy is a steel hawse pipe type, remove the buoy from service without doing any additional work by turning it in to the base steel recycling or local DLA Disposition Services.

Each manhole cover will be replaced on the opening from which it was originally removed. Match marks shall be made on cover and deck plate prior to removal to facilitate its replacement in the correct location and position.

Exercise care in lowering the cover on the studs so that stud threads and gasket are not damaged.

Never cut or weld to the surface on an enclosed void (such as a steel buoy) until the interior has been properly ventilated and gas free. Potentially explosive gases can accumulate within the buoy.

Use qualified welding procedures and follow safe welding procedures per EM 385 1 1 and wear required PPE for welding operations

Do not apply paints or fiberglass coatings to the top surface of the reinforcing ring.

No sandblasted surface will remain uncoated for more than 4 hours.

Be aware of the presence of hazardous components such as lead or chromium VI that may be present on remaining coatings on old steel buoy coatings.

The term sandblasting here is used as a general term. Sand is not the recommended media for blasting fiberglass, softer media is recommended such as walnut shell grit, plastic grit or even dry ice.

No sandblasted surface will remain uncoated for more than 4 hours.

Painters shall use the appropriate PPE.

MSDS for all components shall be readily available on site.

All painting shall comply with USACE EM 385-1-1.

Wind and current conditions will usually dictate which subassembly is laid first.

Divers may be used to inspect connections and to check the orientation and tautness of the anchor chains. They may also be used to jet the anchors into the bottom if included as part of the design specification.

Ensure that the anchor is not recovered and reset in the furrow or disturbed bottom area caused by the initial pull test.

In the case of a taut mooring, one anchor chain subassembly may have to be separated from the ground ring by cutting the first A-link below the ground ring with a torch.

If the joining link cannot be removed, cut the first A-link with a torch.

A-2 SAFETY.

Safety is critical for all work on and around moorings, including inspection work and repair work.

Daily safety briefs should emphasize everyone's responsibility for applying risk management. Pay attention to what could go wrong and how it could go wrong.

Ensure all personnel have, maintain, and wear PPE (steel toed shoes, personal floatation vest, hard hat and other PPE for specific tasks i.e. leather gloves, safety glasses, etc.).

APPENDIX B CRANE SAFETY

B-1 CRANE SAFETY.

The definitive reference on crane safety is NAVFAC P-307, Management of Weight Handling Equipment (for Navy shore activities) and EM 385-1-1 (U.S. Army Corps of Engineers and NAVFAC Contractors). This section is not meant as a replacement for this standard but as a guide to help the users of this manual understand the basics as they apply to mooring work. Note that chapter 11 of NAVFAC P-307 lists requirements for NAVFAC Contractors performing weight handling operations at a Navy facility.

In general, you will be dealing with one of two types of cranes, either floating cranes which are built into a ship or barge or mobile cranes that are temporarily mounted on the deck of a barge or ship. There are many advantages to using a floating crane. The load curves include the listing of the vessel and other naval architectural considerations and you don’t have to worry about tying the crane down. On the other hand, mobile cranes are more readily available. You just have more planning efforts prior to the project.

B-2 CRANE SAFETY GUIDELINES.

The following documents serve as the basis for crane safety, as applicable.

a) SECNAVINST 11260.2, Navy Weight Handling Program for Shore Activities.
b) NAVFAC P-307, Weight Handling Program Management
c) OPNAVINST5100.23, Navy Occupational Safety and Health Program Manual
d) NAVSEA 0989-030-7000, Lifting Standard (If Applicable)
e) USACE 385-1-1, Safety and Health Requirements Manual
f) 29 CFR 1926 Subpart CC, Safety and Health Regulations for Construction, Cranes & Derricks in Construction
g) ASME B30.5 Mobile Cranes
h) ASME ASME B30.22 Articulating Boom Cranes,
i) ASME B30.9 Slings
j) ASME B30.26 Rigging Hardware

B-3 PLANNING.

As you begin planning the inspection/repair, you begin working toward a selection of a crane. If the work is being done by contract, you need to check the crane’s documentation, including the certificate of compliance (required by both NAVFAC P-307 and ACOE EM 385-1-1), as well as additional required documentation as described in section 11 of NAVFAC P-307 and Chapter 16 of EM385-1-1. The documentation needs to be supplied to the contracting officer. If the crane being considered is run by the military, as opposed to a commercial entity, the military organization will be maintaining the crane’s documentation. Documentation needs to be current. Most contractor cranes will have to submit an annual and a quadrennial certification for the floating crane.

In addition, crane operator certifications, to include medical examiner's certification, and rigger and signal person's qualifications should also be provided and be current.

If a mobile crane is to be mounted on a barge or vessel, this and additional information needs to be provided.

- A naval architectural stability analysis of the barge or vessel while conducting the planned lifts as well as lifts at the rated loads and reaches. Reduced load charts are usually required to ensure that the list/trim is taken into account for the additional loading it will impose on the crane and that the barge/vessel does not exceed its maximum list or trim. This revised load chart must be present in the cab of the crane during operations.
- An analysis of the barge/vessel's deck should be conducted. This analysis shall include loading on the deck of the outriggers and of the tie-downs. The outriggers shall rest on wooden blocking. The tie downs should be calculated to resist any lateral loads the crane may sustain. Except for crawler cranes without outriggers, the cranes shall be used with the outriggers.

A lift plan should be developed detailing all the lifts, reaches and loads expected to be seen. In addition, required critical lift plans need to be developed, detailing the lift plan with the maximum load and reach, and submitted to the cognizant authority for their approval. Requirements for critical lift plans are in both EM 385-1-1 and NAVFAC P-307.

B-4 MOBILIZATION.

The first thing that may need to be done in preparing the vessel is to obtain a "Gas Free" Certificate from a marine chemist. This will permit you to weld padeyes or other hold down devices to the vessel as well as to cut things off the vessel if needed. These padeyes will be needed to secure a mobile crane and possibly to tie down the mooring hardware. However, before any welding, cutting, grinding, etc. can be done on the vessel, a "Hot-Work" Certificate may also need to be obtained.

Once the welding is complete and inspected by qualified personnel, the crane will be brought on board, set up and tied down in accordance with the approved barge stability analysis and engineering drawings for the positioning of the mobile crane. Remember that the crane must be on its outriggers and the outriggers on wooden blocks. Before the crane can be operated on board the vessel, it must be inspected by the Navy Crane Center. This inspection involves two items. The first is an inspection to ensure that the crane is properly tied down and that it is ready to operate. The second is a test lift of the critical lift. The crane will pick up a weight equal to the maximum weight as described in the critical lift plan and hold it out at its expected reach. The inspection will not just test the crane but ensure that the list and trim caused by that lift are within allowable limits.

Once these tests have been conducted, the crane can be used on the vessel to support all operations.

B-5 OPERATIONS.

While many of the safety concerns with operating a crane on a vessel are the same as when operating a crane ashore, there are several additional concerns that need to be considered during at sea operations.

While weather is always a concern, wind and waves become much larger additional factors at sea. Waves and seas cause rolling, pitching and swaying motions of the vessel, which, in turn, cause swinging of the lifted load. Wind, especially gusty winds, also cause swinging of the loads. The use of tag lines to help control this swinging motion is useful but only to a point. If the weather becomes too severe, it will be necessary to halt operations. In absence of guidance from the crane manufacturer, a maximum wind speed of 15 knots (7.717 meters/second, 17.262 mph, 25.317 fps) shall be used.

Cranes are not designed to take side loading. While this is true, for either ashore or at sea operations, it is more likely to be attempted at sea, especially during mooring repairs. The desire might well be to keep the load (buoy) close to the deck, dragging the chain out of the water. While this does help to eliminate the distance that the load can fall if something fails, it places a large side load on the crane, very potentially damaging the crane and making it unusable. A better practice is to lift the buoy, secure the mooring riser in a CCD and remove the buoy. Then lift the rest of the mooring riser as needed, secure it into a CCD and lower the riser to the deck. Personnel on the barge deck shall keep clear of the fall zone of the buoy and the riser chain unless qualified and directed to complete a specific task under the direction of the Marine Construction Supervisor.

Use extreme care in lifting of any hawsepipe buoy or any tension bar buoy where the conditions of the tension bar is questionable. The actual lift point should be below the buoy on the riser chain. An auxiliary crane hook can be used to support the weight of the buoy while the main crane hook lifts the riser chain. Ensure the rigging methods are appropriate to support both the hawse pipe buoy and riser chain to ensure that both the buoy and riser chain are adequately supported during the lift.

B-6 DEMOBILIZATION.

While there is little beyond standard safety concerns during demobilization, before any cutting, welding or grinding is done on the vessel, a Gas-Free Certificate and a Hot-Work Permit need to be obtained.

APPENDIX E SAMPLE PRELIMINARY INSPECTION EMAIL

The following is a sample of a preliminary inspection email:

NAVFAC Engineering and Expeditionary Warfare Center (EXWC) East Coast Detachment conducted an underwater inspection of Fleet Mooring 7 located in vicinity of pier 1 at Naval Weapon Station (NWS) EARLE on 21 July 2010. The inspection was conducted by an engineer from EXWC and divers from underwater construction team one. The following is a preliminary report of the inspection results:

A. Fleet Mooring 7 was found to be in C3, fair condition, due to measurements on the riser chain between 80% and 90% of its original wire-diameter.

B. Measurements on the top jewelry pear links were found to be between 80% and 90% of its original wire diameter.

Mooring will be scheduled for repair in FY11 by the Fleet Mooring Program.

OVERALL INSPECTION ASSESSMENT

Current Class

List the corresponding Class of the mooring based on the results of the inspection.
The following table lists the standard fleet mooring classes

CLASS	***CAPACITY (1000 lbf)***	***CLASS***	***CAPACITY 1000 lbf)***
AA	300	C	100
BB	250	D	75
CC	200	E	50
DD	175	F	25
A	150	G	5
B	125	SPEC	OTHER

If the mooring's rated capacity does not match the standard class, then it is "SPEC" and its rated capacity is as stated in its design report.

Rated Capacity

List the corresponding rating of the mooring based on the results of the inspection.
Note that units are already defined in "Rated Capacity" cell. Ensure rated capacity matches design class (unless "SPEC").

Mooring Rated Condition (ICAP)

The following table lists mooring condition rating values based on the results of the inspection.

VALUE	***CONDITION***
90	All >90%; minimal corrosion present
80	All >90%; moderate corrosion present or partial damage to fenders or chafe rails or reflective tape in need of replacement
75	All >90%; heavy corrosion present or fenders or chafe rails completely missing or top jewelry not secure
70	All >90%; buoy refurbishment required or replacement of attached buoy connection hardware required.
60	Topside <90%; minimal -moderate corrosion present
55	Topside <90%; moderate-heavy corrosion present
50	Below water connection assembly not secure
40	Underwater <90%; minimal -moderate corrosion present
30	Underwater <90%; moderate-heavy corrosion present
20	<80%; minimal corrosion present or legs dragged off location
10	<80%; moderate corrosion present
0	<80%; heavy corrosion present or a ground leg detached

<table>
<tr><td>Mooring Condition Readiness</td><td>The following table lists the mooring condition readiness based on the results of the inspection.
<table><tr><th>RATING</th><th>MOORING CONDITION</th></tr><tr><td>C1 (Good)</td><td>Mooring is in Good condition and considered satisfactory for continued use.</td></tr><tr><td>C2 (Fair)</td><td>Topside measurements between 80% and 90% recorded. Mooring can be repaired without underwater work. Mooring may be unable to be used at its full design capacity. Restrictions could impair operations. Vessels may have to find alternate facilities to moor. An engineering assessment is required. Restrictions could impair operations. Failure of mooring is possible.</td></tr><tr><td>C3 (Fair)</td><td>Below waterline measurements between 80% and 90% recorded. Mooring will require underwater work for repairs. Mooring may be unable to be used at its full design capacity. An engineering assessment is required. Restrictions could impair operations. Failure of mooring is probable.</td></tr><tr><td>C4 (Poor)</td><td>Measurements found <80%. Mooring is restricted from use until repairs are completed. Failure of mooring is imminent.</td></tr></table></td></tr>
<tr><td>Required Repairs</td><td>List the mooring component(s) requiring repair or replacement to restore the mooring to C1 condition. If none, state “None”</td></tr>
<tr><td colspan="2">INSPECTION SURVEY RESULTS</td></tr>
<tr><td colspan="2">The coordinate results shown in this section should match what is provided in the survey appendix of the inspection report.</td></tr>
<tr><td>Datum
Geodetic</td><td>Provide coordinates in WGS84 geodetic latitude and longitude or geodetic datums used on nautical charts at the mooring location.</td></tr>
<tr><td>Latitude/Longitude</td><td>Provide as WGS84 in degrees-minutes-seconds to at least 2 decimal places. Include N or S for latitudes, E or W for longitudes.</td></tr>
<tr><td>Datum
Projected</td><td>Provide projected datum (ie NAD83, NAD27), state plane to include Zone identifier and units used. If using UTM WGS84, provide Zone identifier and use meters for units.</td></tr>
<tr><td>Northings/Eastings</td><td>Provide to at least 2 decimal places.</td></tr>
<tr><td colspan="2">INSPECTION CATHODIC PROTECTION RESULTS</td></tr>
<tr><td>% Anodes Depleted (0-99)</td><td>Provide an overall assessment of the percentage of anodes depleted. Anodes that crumble or disintegrate when tapped are considered to be depleted.
Note % defines the amount of the zinc that has been depleted.</td></tr>
<tr><td>Anode Size</td><td>List size anodes, by size, used for replacement.</td></tr>
<tr><td>Anode quantity</td><td>List qty, by size, anodes replaced.</td></tr>
<tr><td colspan="2">BUOY TOPSIDE INSPECTION ASSESSMENTS</td></tr>
<tr><td colspan="2">This section is used to describe the type of mooring buoy and to assess its’ overall condition.</td></tr>
<tr><td>Connection</td><td>List type of buoy connection; tension bar padeye or hawse-chain.</td></tr>
<tr><td>Padeye Bushing</td><td>Condition of wear bushing on upper padeye.</td></tr>
<tr><td>Hull</td><td>List type of hull form; peg-top, spherical or drum.</td></tr>
</table>

Hawse pipe bolts or screws	If applicable, list type and quantity of bolts or screws; list whether exposed or recessed.
Coating	List coating type; urethane (foam buoys), fiberglass, painted, none.
Fender/Rubrail	List type (urethane, rubber, wood, etc) and quantity.
Reflective Tape	List type (tape) and quantity.
Chafe/Rub Rails	List type (steel pipe, urethane, D-rubber, etc) and quantity.
Damage	Describe as major, moderate, minimal or none. For condition of buoy hull, hawse-chain connection buoy capture plate assembly (to include connecting hardware), fenders, chafe rails, reflective tape.
Wear	Describe as major, moderate, minimal or none. For assessment of tension bar padeyes and tension bar padeye bushings and hawse-chain buoy capture plate assembly (to include connecting hardware).
Discoloration	Describe as heavy, moderate, minor or none. Discoloration of non-metal components due to rust bleeding from metal components on buoy hull, etc. UV degradation or fading of reflective tape.
Corrosion	Describe as major, moderate, minimal or none. Corrosion of external steel buoy connections or other components to include haws pipe assembly connecting hardware.
Overall condition	Describe overall buoy condition as Good, Fair or Poor.
BUOY TOP JEWELRY INSPECTION MEASUREMENTS	
This section documents go no/go and caliper measurements of components inspected on top of the mooring buoy.	
Buoy Shackle	
Bale	Define bale dimension from catalog for new shackle. Take caliper measurements on the bale of the shackle *at the wear point and in the wear direction.* Ensure all rust debris is cleaned off prior to taking caliper measurement. List actual percentage based on “caliper measurement/minimum catalog value).
Pin	Define pin dimension from catalog for new shackle. Take caliper measurements on the pin adjacent to the buoy padeye *near the wear point*. Ensure all rust debris is cleaned off prior to taking caliper measurement. List actual percentage based on “caliper measurement/minimum catalog value).
Pear Link	
Bend	Define pear link bar diameter minimum and maximum dimensions from catalog values. Take caliper measurements on the bend of the pear link at the *wear point and in the wear direction*. Can report the smallest measurement of the 2 pear link bales. Ensure all rust/debris is cleaned off prior to taking caliper measurement. List actual percentage based on “caliper measurement/minimum PD value).
Chain Link or Joining Link	
Link Bar	Define bar dimension from catalog for new link.

	Take caliper measurements on the bar of the link *at the wear point and in the wear direction near contact points.* Ensure all rust debris is cleaned off prior to taking caliper measurement. List actual percentage based on "caliper measurement/minimum catalog value). If connecting link is an anchor joining link, take caliper measurements of bar diameters at both the larger and smaller ends and report both findings.
INSPECTION MEASUREMENT RESULTS	
This section documents go no/go and caliper measurements of components inspected on the mooring system below the buoy. **Record go no/go measurement results or caliper measurements in bold red font and highlight go no/go measurement results or caliper measurements found to be <90% in yellow.**	
Item	State mooring component inspected (riser, ground leg 1, ground leg 2, swivel shackle, ground ring, etc). Riser Set - a set of 3 consecutive go no-go measurements taken on the riser. Riser Link - one go no-go measurement taken on a riser link. Ground Leg 1 set - a set of 3 consecutive go no-go measurements taken on ground leg 1. Ground Leg 1 link - go no-go measurement taken on a link on ground leg 1.
Criteria	Criteria is "all 3>90" for measurement sets or ">90" for individual link measurements. Inspection points for riser and ground legs are taken as measurement sets. For accessory components, criteria is the minimum to maximum catalog value for the dimensions to be measured on the accessory component.
Inspection Point	Location of the measurements along the mooring riser, ground leg or on the accessory component. This cell entry is based on the entered data for Unit of Measure and Reference Point.
Unit of Measure	State units of measurements (inches, feet, meters, etc) or Links for the inspection points.
Reference Point	State the reference point for the inspection point for the inspected component. For risers, the reference point is usually the waterline. For ground legs, this can be the ground ring if the unit of measure is the links. For accessory components, repeat the name of the item being inspected.
Size/(in)	List the nominal size of the mooring chain or accessory component being inspected. *Note that this cell is not to record your measurement finding.*
Condition (%)/(in)	Reported as "All 3>90, All 3 >80 or All 3<80. If measurements within a set are not the same, provide the breakdown (ie; 2>90;1>80, etc). For connecting or accessory components, record the actual calipered measurement taken (in inches).
INSPECTION COMMENT RESULTS	
Below are some of the most common inspection comment blocks. Others can be added/removed by the document writer as needed to document inspection results of the mooring system. These sections are used to provide additional information on the inspection findings.	
General	State buoy's Mooring Condition Readiness and operational use or restrictions. State if and type of vessel moored to the buoy during the inspection. If Mooring Condition Readiness is C2 or worse, list required repairs to restore mooring to its original design rating and a C1 condition. Example: *Mooring X is in C1 (Good) condition and satisfactory for continued use as a Class Y mooring. No vessel attached to the buoy during inspection.*

Buoy	State the type of mooring buoy (type, shape, connection, diameter) and identification plate data (Manufacturer, serial number, contract number, month/year of manufacture). State condition of fenders, chafing or rub rails, reflective tape and any other buoy hull accessories. State condition of the buoy hull. State condition of padeye bushings. State condition of and if buoy zinc anodes were replaced. State hull condition. Assess buoy heel. Assess buoy draft.
Top Jewelry	List top jewelry components attached to the mooring buoy. State condition of all top jewelry components to include levels of corrosion and assessment of caliper measurements to its listed minimum catalog value. State size, manufacturer, year and serial numbers of top jewelry components.
Riser Assembly (includes, attachment hardware to the buoy and ground ring, ground ring, riser or ground ring sinker and ground leg connecting hardware on the ground ring)	State the condition of the riser. State type of measurements, type go/no gauges, quantity of measurements and locations the riser was measured. State the results of the go/no go measurements. If measurements are found to be <90%, list the location and amount of the riser (number of links) that needs to be repaired. Example: "*The riser is in good condition.* Consecutive *measurement sets were taken at four locations along the riser using double link go, no-go gauges. All measurements were found to be >90% of original wire diameter*". State the results of the inspection of the riser swivel shackle to include swivel shackle gap measurement, presence and quantity of lead plugs. State assessment of swivel shackle pin caliper measurements to its listed minimum catalog value. All four lead plugs in the swivel shackle were intact. If found, list water depth of chain joining links, presence of lead plug and joining link assembly assessment. If available for inspection, state assessment of ground ring bar caliper and inside diameter measurements to its listed minimum catalog value. State water depth of ground ring. If available for inspection, state quantity of anchor joining links connected to the ground ring, presence of lead plugs and joining link assembly assessment. If found, state presence, water depth and condition of sinkers found on riser or attached to the ground ring.
Ground Legs	State if all or quantity of ground legs buried and unable to be inspected. State the condition of all ground legs. State type of measurements, type go/no gauges, quantity of measurements and locations the ground legs was measured. State point of burial for ground legs inspected. Example: "Consecutive m*easurement sets were taken every 30 feet along all ground legs using double link go, no-go until the ground leg became buried and unable to be inspected. All measurements were found to be >90% of original wire diameter*". List ground leg headings from ground ring toward anchor. If found, list link count or chain length from the ground ring of chain joining links, presence of lead plug and joining link assembly assessment. *Note-a separate comment block may be used for each ground leg.*
Anchors	State if the anchors are buried and unable to be inspected. For drag embedment or deadweight anchors that are found and inspected, state if stabilizers are present, if the anchor is rightside up or upside down, if aligned with the ground leg heading, if the anchor is partially buried or completely exposed and the condition of connecting links and swivel shackles that attaches the anchor to the ground leg.

Anodes	State size of replacement anodes and quantity of new anodes installed on mooring riser, ground legs and lower buoy tension bar padeye. List any installation problems in attaching new anodes (i.e. sheared bolts, missing studs, etc).
Marine Growth	Describe marine growth type (soft, hard, shells) thickness and location along the riser (top, middle, bottom) and bottom of buoy.
Survey	If the buoy was surveyed, list the equipment used to perform the survey. If a GPS was used, list the accuracy of the GPS to include quantity of satellites, and level of precision (ie PDOP or HDOP). State the system and datum used to include units (i.e. US Feet or meters). State software used for coordinate conversions. Other than the dive or survey boat, state if a vessel was moored to the buoy during the survey.
Bottom	Describe the type of seafloor conditions found at the mooring site.
Photo	Provide a identification photo of the buoy that shows the entire buoy. The buoy should fill up the majority of the photo, and if present, include the stenciled buoy name.

WITHIN A REPORT, BE CONSISTENT IN COMMENT FORMAT THROUGHOUT ALL INSPECTION SHEETS.

APPENDIX G FM3 MOORING COMPONENT DATA

This Appendix provides data on FM3 components. Data on commercial components can be obtained from the manufacturer or distributer.

APPENDIX I GENERAL INSTALLATION PROCEDURES FOR A DRAG EMBEDMENT ANCHOR/RISER TYPE MOORING SYSTEM

The following is an excerpt from MO-124 providing general installation instructions for a drag embedment riser type mooring system.

I-1 GENERAL.

General installation procedures for the typical three-legged riser mooring system are presented below. The procedures are preceded by a description of the main parts of the mooring system which should be assembled before offshore operations begin.

I-1.1 Riser-Type Mooring System.

Installation of this mooring system shall generally follow the procedure set forth below.

I-1.1.1 Preinstallation Assembly.

A three-legged riser-type mooring system is normally assembled in three parts (see Figure I-1):

- Part I. This part is the first anchor chain subassembly with a sinker and anchor.
- Part II. This part includes the buoy, the riser chain subassembly from the buoy to the ground ring, and the second anchor chain subassembly with a sinker and anchor.
- Part III. This part is the third anchor chain subassembly with a sinker and anchor.

I-1.1.2 Installation Procedures.

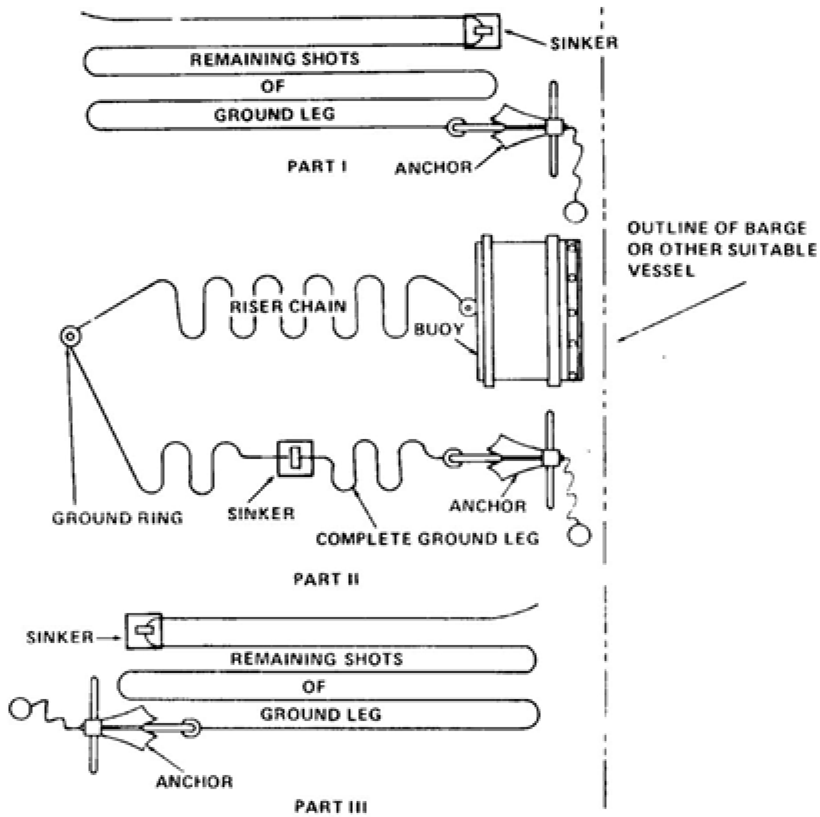
The marker buoys will be placed in their desired locations. The center marker buoy will be placed in the desired position of the mooring buoy. The ring marker buoys will be installed 25 feet past the point that the anchors will be lowered to the bottom and released. Predicted drag distance of the anchor is needed to determine this point. Table J-1 through Table J-8 provides predicted drag distances. The desired final location of the anchors should be indicated on the design drawing. provided by the mooring designer. After pulling the anchor to set it and test its capacity, (see 2.2.2.3) the final position of the anchor must be within a 40 foot by 20-foot box with the desired location at the center of the box (see Figure I-4). The range marker buoys should be installed about 50 feet beyond the ring marker buoys on the extension of the lines from the center marker buoy to the ring marker buoys.

Before beginning installation of the system, the free end of the first anchor chain subassembly of Part I should be attached to a pickup buoy for easy recovery during the placement operation.

Note:

Wind and current conditions will usually dictate which subassembly is laid first.

Figure I-1 Typical Riser-Type Mooring Material Pre-Installation Layout

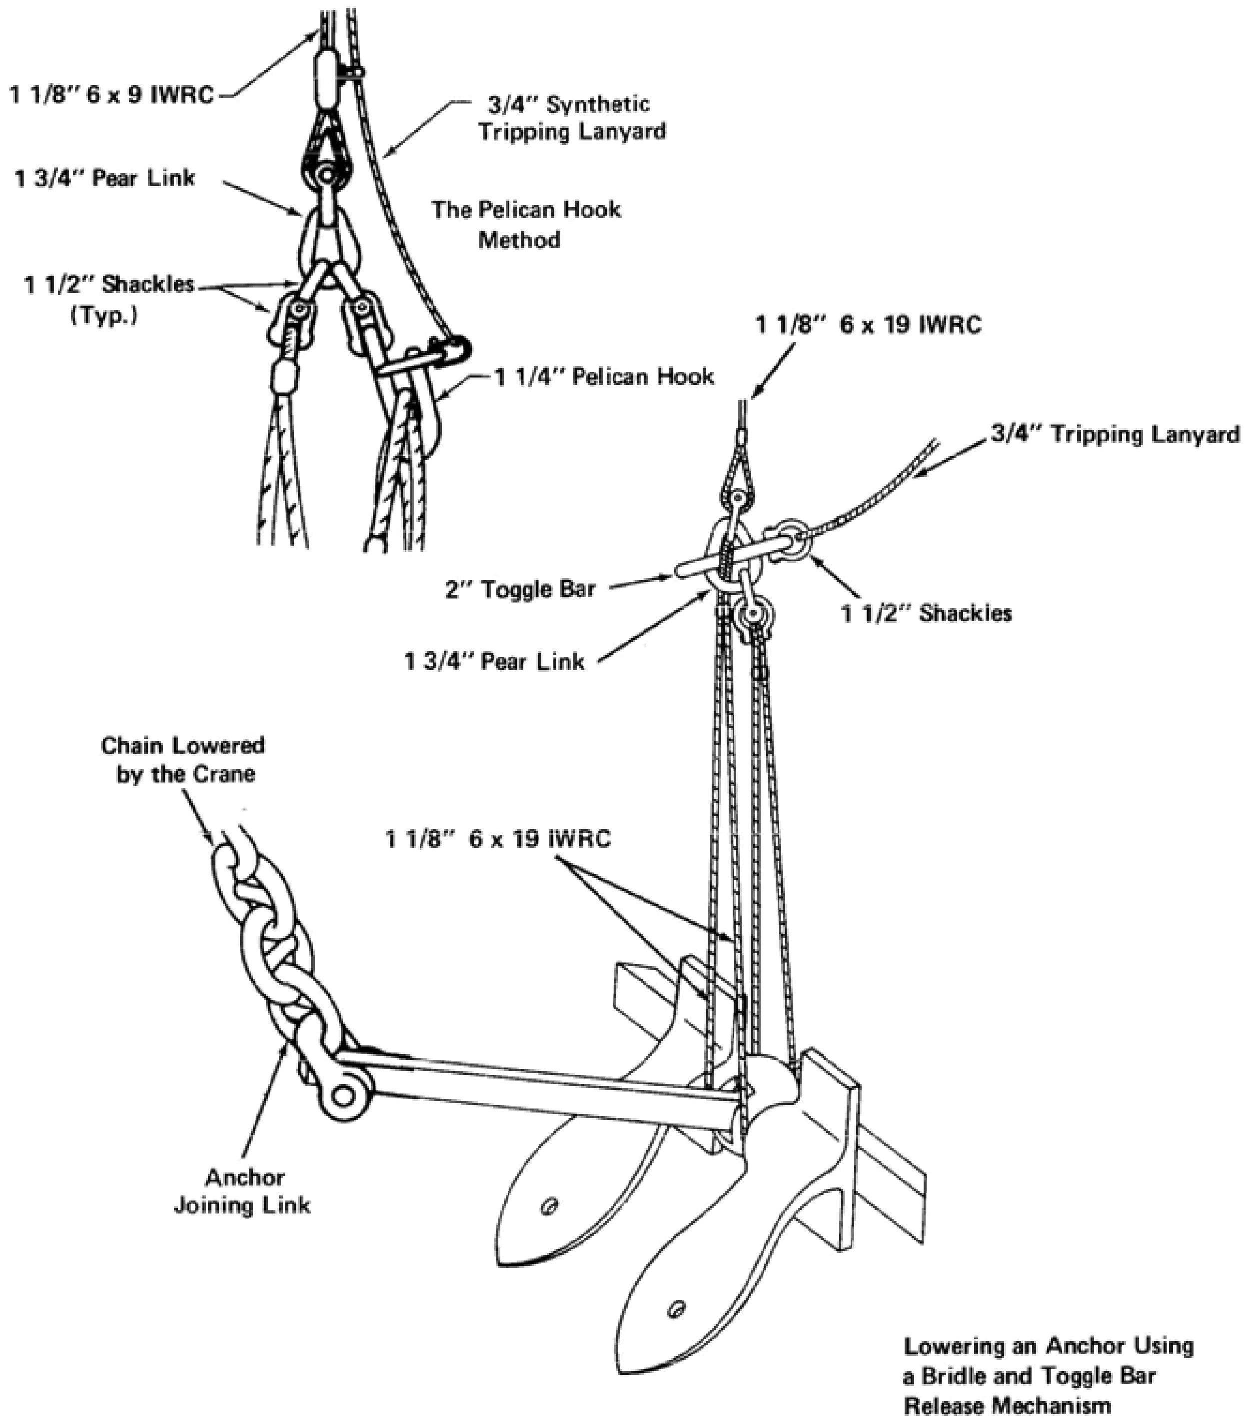


These general installation procedures should then be followed:

- Position the crane barge near one of the ring marker buoys (the one within 25 feet of the desired position for the anchor of the first anchor chain subassembly of Part I). During some installations, it may be necessary to weld the anchor flukes to a predetermined angle.
- The first anchor is slung by a bridle in a horizontal position and has attached to it a crown marker buoy and one anchor leg subassembly. The anchor is fitted with a pelican hook or a toggle bar quick release system as shown in Figure I-2. The crane lowers the anchor and chain simultaneously over the side. When installing moorings equipped with chain stud anodes, care must be exercised that the chain does not drag over sharp edges which can result in some of the anodes being stripped off.

- Upon reaching the bottom, release the anchor and recover the bridle. Move the barge toward the center marker buoy while slowly lowering the chain with a flat catenary.

Figure I-2 Lifting Bridle and Release Mechanism



- Upon approaching the center marker buoy, pull the subassembly taut so that the anchor is properly set. Then, lower the bitter end of the chain (with a pickup buoy attached to it) to the bottom.
- The crane barge now proceeds to the second marker buoy and lowers the anchor (of Part II) 25 feet from the marker toward the center marker buoy. The anchor is fitted with a quick release mechanism and has a crown buoy attached to it.
- Upon reaching the bottom, release the anchor and recover the bridle. Move the barge toward the center marker buoy while slowly lowering the chain with a flat catenary. Upon approaching the center marker buoy, pull the subassembly taut so that the anchor is properly set. Then, using the pickup buoy, retrieve the end of the first anchor chain subassembly and attach it to the ground ring. Attach the bitter end of the third anchor chain subassembly (Part Ill) to the ground ring also. Then lower the ground ring, riser, and buoy into the water alongside the center marker buoy.
- The crane barge will slowly lower the third anchor chain subassembly while proceeding toward the third ring marker. This ring marker and its range marker should be used to ensure that the chain is being installed in a straight line.
- When approaching the ring marker buoy, pull the anchor until the chain leg is taut and then lower the anchor (in a bridle with the flukes pointed downward) to the bottom and release it using the quick release mechanism (see Figure 2-7).
- Conduct a final inspection of the mooring. Site the three crown marker buoys from ashore. The positions of these three markers will be the positions of the anchors. If available, have divers make an underwater inspection of the mooring installation.
- Remove all marker buoys with their cables and anchors.

I-1.1.3 Pull Testing of Anchors.

Fleet moorings will be pull tested to the holding capacity of the mooring class listed in APPENDIX J.

I-1.1.4 Installation Barge.

Whenever possible, the YD or similar barge type craft to be used for mooring installation should be equipped with two stern winches to be used for pulling on kedge anchors. The installation barge should have the capability to anchor itself.

Note:

Divers may be used to inspect connections and to check the orientation and tautness of the anchor chains. They may also be used to jet the anchors into the bottom if included as part of the design specification.

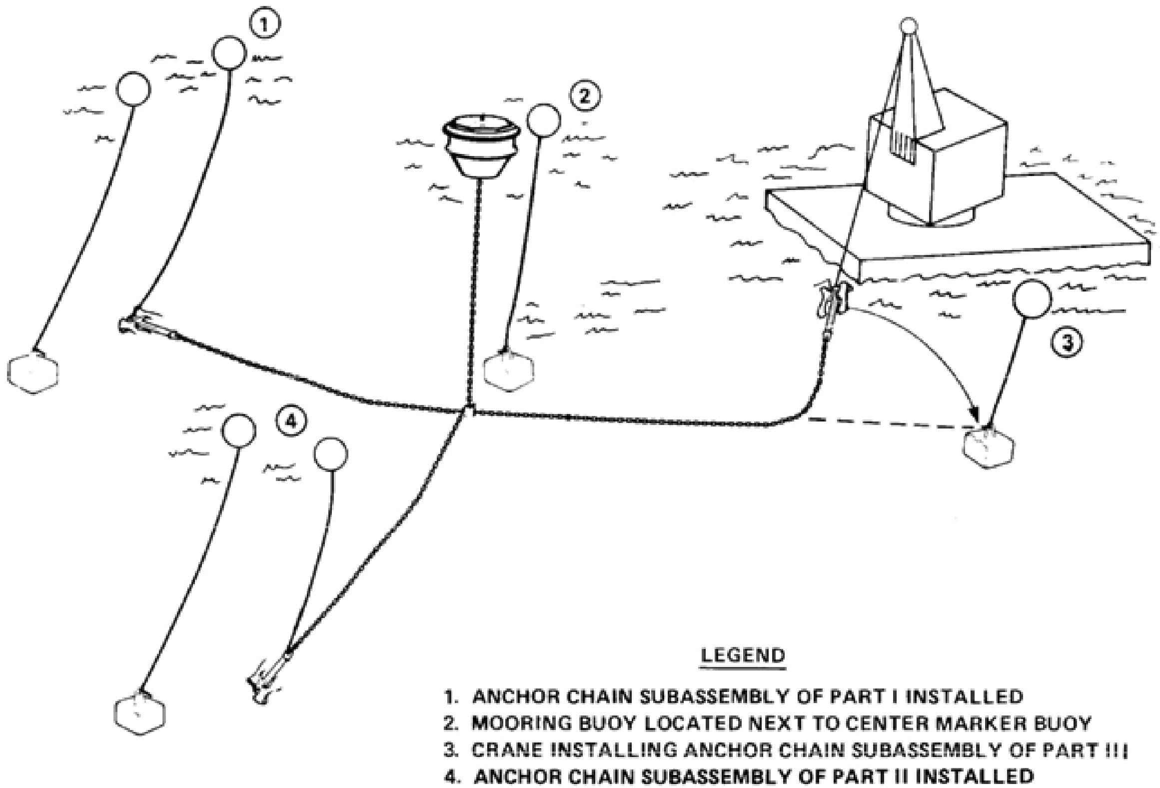

Figure I-4 Allowable Anchor Areas

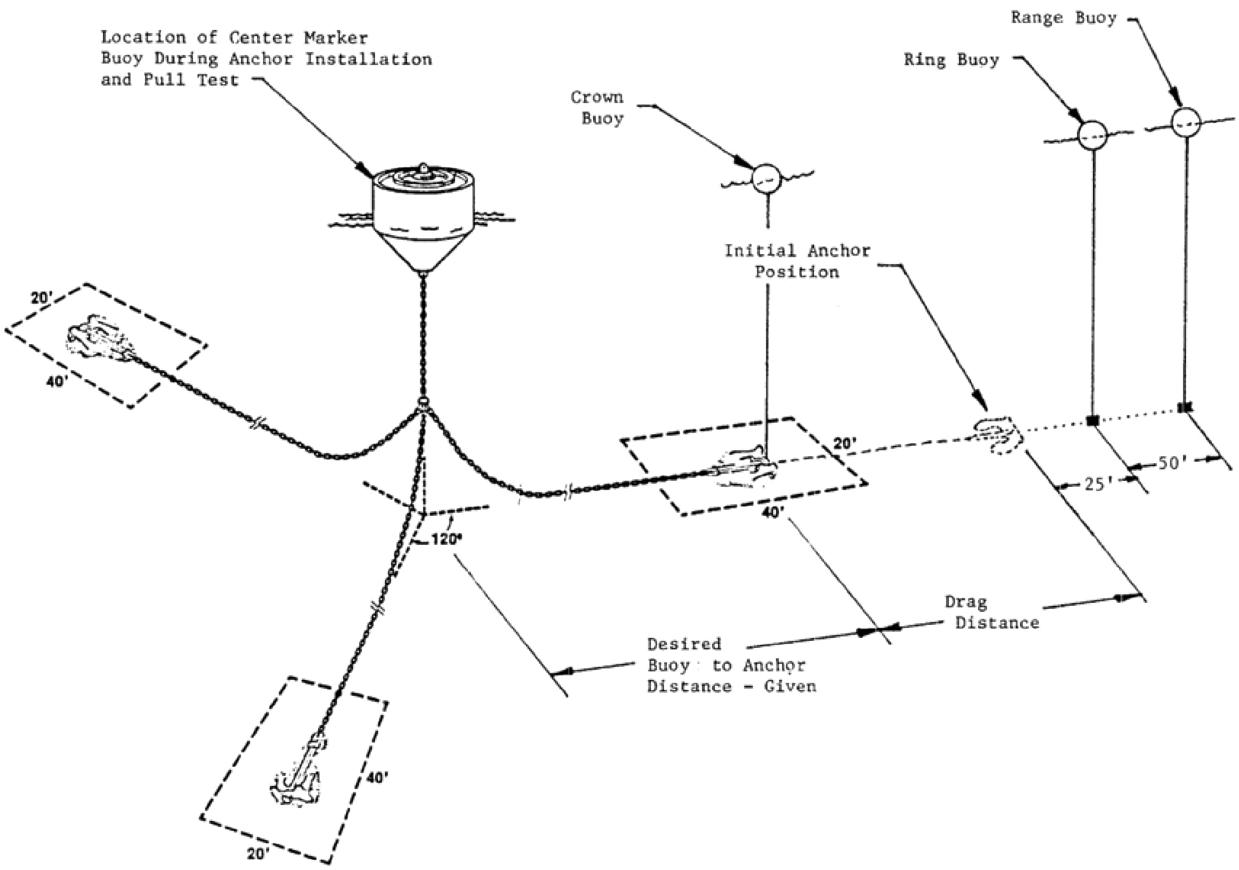


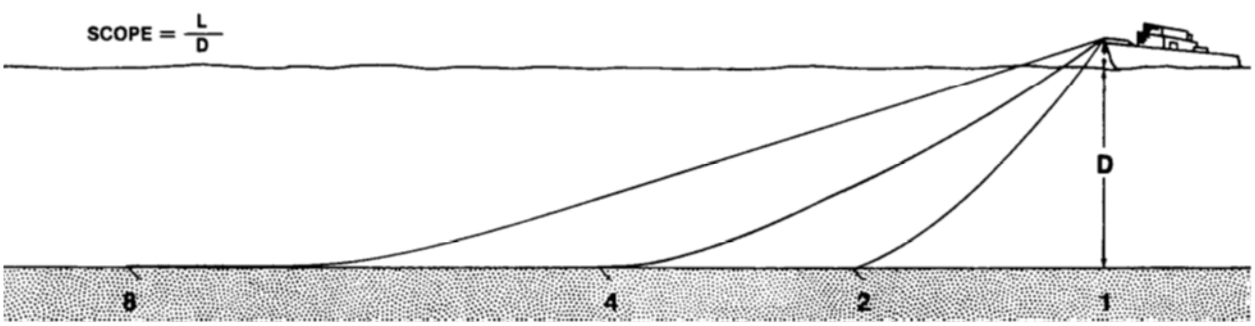
APPENDIX J DRAG EMBEDMENT ANCHOR PULL TESTING GUIDANCE

The following is an excerpt from MO-124 providing general installation instructions for a drag embedment anchor pull testing.

J-1 SETTING DRAG ANCHORS.

Proof setting of each anchor leg should be accomplished using harbor tugs, Fleet tugs or by pulling diametrically opposite anchor legs against each other. When setting the anchor, it is desirable to have a 10 to 1 scope (see Figure J-1 for definition) in the mooring line. This may be accomplished by adding chain or a work wire. The anchor drag distance to achieve the specified load level must be known to enable proper anchor placement prior to proof loading. Setting shall be accomplished by pulling to the design load of the mooring.

Figure J-1 Mooring Leg Scope



Scope is the ratio of length of rode (L) to depth of water (D), plus allowance for height of bow above water. At (1) length of rode equals the depth. At (2) rode length is twice the depth, at (4) four times the depth. Note how the angle between rode and bottom decreases. At (B) the scope is 8:1 and the short length of chain at the anchor lies flat on the bottom

J-2 DRAG DISTANCE.

- Single Anchors. The predicted anchor drag distance for single anchors can be obtained from Table J-1 through Table J-4.
- Tandem Anchor Systems. The predicted anchor drag distance for tandem anchor systems can be obtained from Table J-5 through Table J-8.

J-3 LOAD MEASUREMENT.

While setting the anchor, it is desirable to monitor the loads. A currently calibrated dynamometer should be placed in line to measure the load.

J-4 FINAL ANCHOR POSITION.

It is expected that the desired holding capacity can be achieved during setting and that the anchor will be within the 40-foot-long by 20-foot-wide allowable anchor area (see

Figure I-4). If after setting, the desired load is not obtained, or if the anchor drags outside the tolerance box, then the anchor must be repositioned and the pull test repeated.

J-5 PULL TESTING.

After the anchor is set, the pull test should be conducted. It is important that a length of chain equal to the total length of riser and ground leg be used for the test. Use of shorter chain lengths will create an uplift force on the anchor.

J-6 LOADING PROCEDURE.

Each anchor leg should be pull tested independently. The vessel performing the pull should gradually build up to the proof test load. Increase the load in 10,000 pound increments up to the required proof test load. After each 10,000-pound increase allow the dynamometer reading to stabilize. Once the required pull test load is reached, allow the dynamometer reading to stabilize, then hold the pull test load for 3 minutes.

J-6.1 Anchor Leg Adequate.

If the desired load is obtained and the anchor is positioned within the tolerance box, the anchor leg is adequate.

J-6.2 Anchor Leg Inadequate.

If either the pull test load is not achieved or the anchor is out of position, the anchor must be repositioned and the pull test repeated.

J-6.3 Pull Test Not Achieved.

If the pull test load cannot be achieved, the anchor system design may not be correct. Several options exist for increasing the anchors capacity:

- Changing the anchor fluke angle. Usually the fluke is fixed fully open for muds and partially open (approximately 35°) for sands.
- Soaking. When deploying anchors in silt or clay (muds) it is desirable to allow the anchors to soak. “Soaking” of an anchor is the practice of allowing a newly embedded anchor to rest for a period of time, typically 24 hours, before applying the required proof load.
- Jetting. If a drag anchor does not bury to a sufficient depth to develop the required capacity, it may be possible to use divers to jet the anchor to the required depth. The anchor should be jetted to a depth equal to or greater than the length of the anchor fluke.

J-6.4 Anchor Out of Position.

If the anchor is not within the tolerance box, reposition the anchor accordingly, reset and repeat the pull test

Note:

Ensure that the anchor is not recovered and reset in the furrow or disturbed bottom area caused by the initial pull test.

APPENDIX K GENERAL REMOVAL PROCEDURES FOR A DRAG EMBEDMENT RISER TYPE MOORING SYSTEM

The following is an excerpt from MO-124 providing general installation instructions for a drag embedment riser type mooring system.

K-1 GENERAL

General removal procedures for the typical three-legged riser mooring system are presented below. The procedures are preceded by a description of the main parts of the mooring system which should be assembled before offshore operations begin.

K-1.1 RISER-TYPE MOORING SYSTEM.

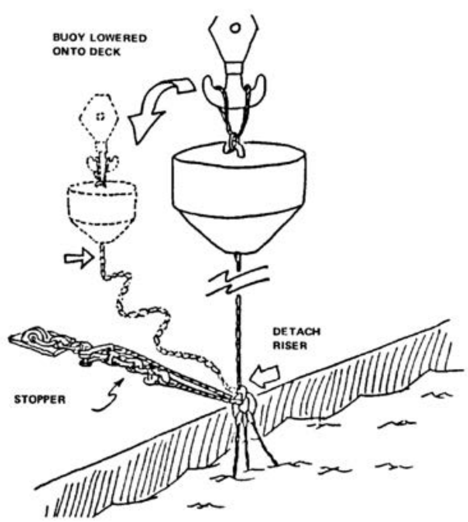
These systems are recovered by removing one anchor chain subassembly at a time. Proceed as follows:

- Sling the buoy from the top jewelry.
- Lift the buoy and riser until the ground ring is level with the deck of the crane barge.

Note:
In the case of a taut mooring, one anchor chain subassembly may have to be separated from the ground ring by cutting the first A-link below the ground ring with a torch.

- Stopper off the ground ring (see Figure K-1).

Figure K-1 Ground Ring Stoppered Off on Deck



- Lower the buoy down to the deck on its side. Disconnect the riser, and either block the buoy on its side or place it on blocks to avoid damaging the tension bar.

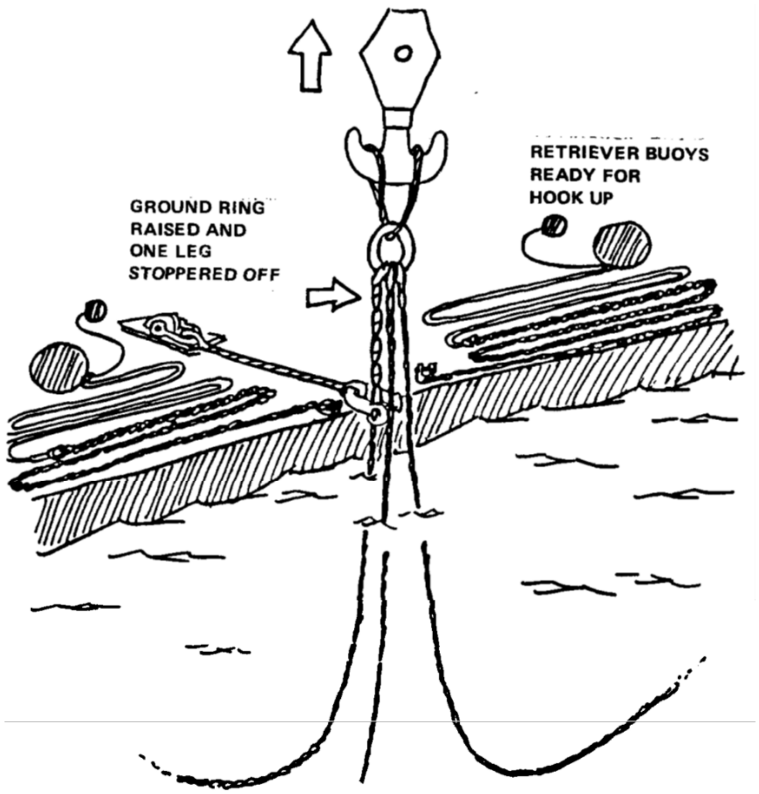
- Disconnect the riser from the ground ring and buoy.

Note:

If the joining link cannot be removed, cut the first A-link with a torch.

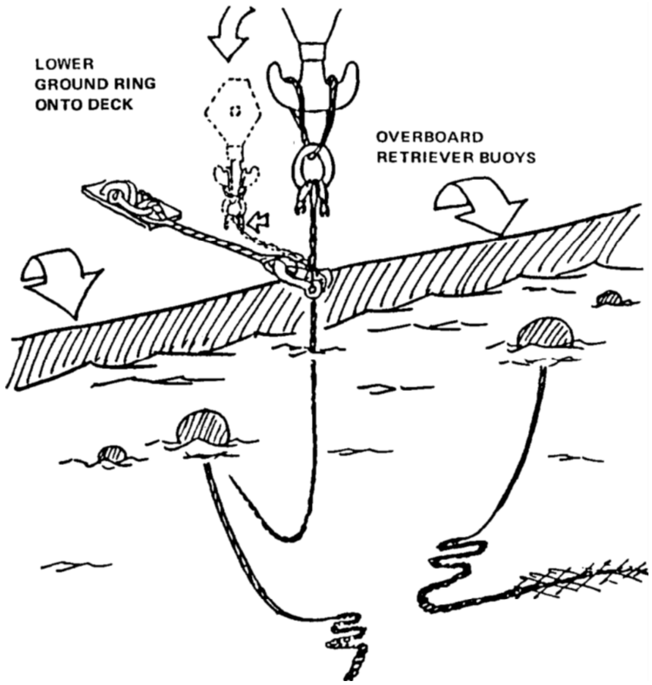
- Sling the ground ring and lift it until the anchor chain subassemblies accessible.
- Stopper off one subassembly (see Figure K-2).

Figure K-2 One Leg Stoppered Off



- Attach a retrieval buoy to each of the other two subassemblies. The third subassembly and the ground ring will be considered together. Fake the retriever buoy lines on deck to allow easy running.
- Cut one subassembly free from the ground ring one link below the chain joining link. Allow the chain to drop and retriever buoy to run free and over the side.
- Repeat with the other leg that has a retriever buoy attached. Lower the ground ring on deck (see Figure K-3). Disassemble the chain joining link, if possible, and disconnect the ground ring from the subassembly.

Figure K-3 Two Anchor Chain Subassemblies Overboarded



- Sling the chain to the main hoist, raise and remove the stopper.
- Continue raising until the next chain joining link is above deck. Stopper the chain, 3 links below the chain joining link, and lower the chain joining link to the deck for disassembly,
- When severed, move this shot of chain aside.
- Sling the chain and continue lifting and detaching chain shots as before.
- When all of the chain has been recovered, bring the anchor aboard.
- Pick up a retriever buoy and, using the same procedures, recover a second subassembly and anchor. Then recover the third.

Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	1 Sept 2012	Removed 5-5.2 “Emergency Power”; modified 4—1 and 5-1; editorial changes throughout, including updating references.

This UFC supersedes MIL-HDBK-1025/6, DATED May 1988.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Center for Engineering and the Environment (AFCEE) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

CHAPTER 1

INTRODUCTION

1-1 **SCOPE**. This UFC contains general criteria for the design of piling, deck, and substructure framing and bracing, and hardware and fittings for waterfront construction. Unless indicated otherwise, these criteria also apply to the design of offshore structures. This document, and all references contained herein, provides guidance primarily to DOD and U.S. Coast Guard activities. They may also be useful, however, to commercial firms that are engaged in the design and construction of waterfront facilities.

1-2 **CANCELLATION**. This UFC cancels and supersedes MIL-HDBK-1025/6, *General Criteria for Waterfront Construction*, (May 1988).

This page intentionally left blank.

CHAPTER 2

PILING

2-1 GENERAL REQUIREMENTS

2-1.1 Capacity

2-1.1.1 **Capacity as a Structural Member**. For pile sections embedded in the ground refer to \1\ UFC 3-220-01N, *Geotechnical Engineering Procedures for Foundation Design of Buildings and Structures* and UFC 3-220-10N, *Soil Mechanics*. /1/ For sections freestanding in water, treat piles as structural columns with accommodation made for their un-braced length. Where, due to long-term creep effects, the use of the coefficient of sub-grade reaction would be inappropriate or if one is unavailable, the following assumptions may be made:

2-1.1.1.1 In soft, cohesive soils, the point of fixity may be assumed to occur at a depth of 3.05 m (10 ft.) below the mudline for piles having modulus of elasticity - moment of inertia products (EI) of 2.925 x 10^9 kg-cm^2 (10 x 10^9 lb-in^2) or less. The point of fixity may be assumed to occur at a depth of 3.66 m (12 ft) below the mudline for piles having an EI greater than 2.925 x 10^9 kg-cm^2 (10 x 10^9 lb-in^2.) (E equals Modulus of Elasticity of Pile in pounds per in^2 and I equals moment of inertia of pile in in^4.)

2-1.1.1.2 In loose, granular soils and in medium cohesive soils, the point of fixity may be assumed to occur at a depth of 2.44 m (8 ft) below the mudline for piles having an EI of 2.925 x 10^9 kg-cm^2 (10 x 10^9 lb-in^2) or less, and at a depth of 3.05 m (10 ft) below the mudline for piles having an EI greater than 2.925 x 10^9 kg-cm^2 (10 x 10^9lb-in^2.)

2-1.1.1.3 For other cases, assume a point of fixity at a depth of 1.5 m (5 ft) below the mudline. The effective length factor K shall be taken as:

- 0.80 - when the deck structure is light, the piles have minimum embedment into the pile cap and there is no special provision for moment transfer into the deck structure.

- 0.73 - when the deck structure is light and provision is made for moment transfer by embedment or other device into the deck structure.

- 0.65 - when the deck structure is heavy and a positive means for moment transfer is provided.

NOTE: These provisions do not apply if pile embedment is less than 3.05 m (10 ft) into firm material or 6.10 m (20 ft) into soft or loose material. If lesser penetration is achieved, assume that the pile tips are hinged. Also, the indicated effective length factors (K) apply only if batter piles (minimum batter of one horizontal to three vertical) or some other means are provided to resist lateral loads, i.e., the plumb piles are not intended to resist lateral loads. If no such means are provided, side-sway can occur, and correspondingly increased K factors shall apply (usually taken as 2.0).

Design piles for a minimum eccentricity of 0.10 times the equivalent diameter of the pile. The moment resulting from this minimum eccentricity is not additive to the moments indicated by analyses of the actual applied loads.

2-1.1.2 **Capacity of the Ground to Support the Pile**. Refer to provisions of \1\ UFC 3-220-01N, *Geotechnical Engineering Procedures for Foundation Design of Buildings and Structures* and UFC 3-220-10N *Soil Mechanics* /1/, pertaining to friction, end bearing resistance, and settlements of single piles and pile groups.

2-1.1.3 **Lateral Load Capacity**. For pile groups within which individual piles are spaced between three and six diameters center-to-center, assume that the soil reacts laterally on an equivalent pile having a diameter equal to three times the actual diameter. For closer spacing, reduce the assumed equivalent diameter proportionally to the spacing.

NOTE: A number of design curves have already been published to illustrate this arching effect within a "retained" soil mass.

2-1.1.4 **Capacity of Existing Piles**. Refer to Chapter 6 for information pertaining to the capacity of existing piles.

2-1.2 **Details Applicable to All Pile Types**

2-1.2.1 **Minimum Penetration**. Conform minimum penetration of piles to the following:

- Penetrate sufficiently into an acceptable bearing stratum to distribute the axial pile load within the supporting capacity of the soil (refer to \1\ UFC 3-220-01N, *Geotechnical Engineering Procedures for Foundation Design of Buildings and Structures* and UFC 3-220-10N, *Soil Mechanics*. /1/).

- Penetrate sufficiently below any probable future dredge depth to distribute the pile load within the supporting capacity of the soil, discounting the resistance of soil that may be removed by future dredging. Depth should account for possible scour problems. All piles should be designed for a minimum of 1.5 m (5 ft) of potential scour or future dredging.

- Minimum values. If pile penetration is less than 3.05 m (10 ft) into firm material or less than 6.10 m (20 ft) into soft or loose material, assume the pile tip to be "pinned" and incorporate special provisions such as driving hardened tips into the refusing stratum, drilled sockets, or drilled dowels to secure the tips of the piles against lateral displacements due to eccentricities and intentional lateral forces. Develop a minimum lateral resistance of at least 5 percent of the pile's design axial load. Increase the effective length factors as described above.

2-1.2.2 **Tolerances on Installation**. For piles fully, or near fully, embedded in the ground, the provisions of Unified Facilities Guide Specifications apply. The following provisions relate to piling installed for elevated platforms where the piles project several feet above the mudline:

- A slope within 4 percent of plumb or the specified batter, as a reasonable compromise between the design requirements and the practicality of installation.

- In locating the pile head, there is no limit, provided the structure can tolerate the revised pile spacing. However, consider residual stresses in the piles due to forcing the pile into the pile cap in evaluating the capacity of the pile. Do not apply an increase (or additional increase) in allowable stress to stress-combinations that include these residual stresses.

NOTE: For effective un-braced length, divided by radius of gyration (Kl/r) between about 40 and 100, these effects can be substantial. But for fully embedded piles, Kl/r commonly is less than 40 and locked-in stresses can be neglected. Exercise caution when using driving frames because they prevent lateral movements of the head of the pile and mask the existence of locked-in stresses. Provide ample edge distances so that the piles will fit into the cap without excessive force or restraint. Allow for tolerance in the location of the pile head of at least 1.5 percent of the exposed height up to a maximum of 152 mm (6 inches).

2-1.2.3 **Minimum Spacing**. The minimum spacing requirements of piles are as follows:

- Provide for adequate distribution of the load on a pile group to the supporting soil. Recommend 1 m (36 inch) spacing.

- No minimum values are specified other than practical limitations to avoid piles interfering with or intersecting each other. One technique is to use a center-to-center spacing equal to 5 percent of the pile length for parallel piles.

2-1.2.4 **Pile Caps in Contact With the Ground**. Design piles to carry the entire superimposed load with no allowance made for the supporting contribution of the material between the piles.

2-1.2.5 **Connection of Piles to Caps**. The following requirements pertain to the connection of piles to pile caps:

2-1.2.5.1 **Timber Piles with Timber Caps**

- No Tension in piles - Secure pile tops to caps with spiral-drive drift pins or steel straps.

- Tension in piles - Secure pile top to clamp-type cap with thru-bolts with spike grids.

2-1.2.5.2 **Timber Piles with Concrete Caps**

- No Tension in Piles - Embed pile top 102 mm (4 inches) into cap and secure with single #5 dowel driven into pile butt.

- Tension in Piles - Secure pile tops with through-bolted dowel anchorage

2-1.2.5.3 **Concrete Piles with Concrete Caps**

- No Tension in Piles - Embed pile top 102 mm (4 inches) into pile cap and secure with deformed dowels or exposed pre-stressing strands as required to develop a tensile load equivalent to one-half the pile's rated compressive bearing capacity.

- Tension in Piles - Embed pile top 102 mm (4 inches) into pile cap and secure with deformed dowels or exposed pre-stressing strand as required to develop the tensile structural capacity of the pile cross-section.

2-1.2.5.4 **Steel Piles with Concrete Caps**

- No Tension in Piles - Embed pile top 102 mm (4 inches) (min.) into pile cap and secure with deformed dowels welded to the pile (within the jacketed length) capable of developing a tensile load equivalent to one-half the pile's rated compressive bearing capacity.

- Tension in Piles - Embed pile top 102 mm (4 inches) (min.) into pile cap and secure with deformed dowels welded to the pile (within the jacketed length) capable of developing a tensile load equivalent to the pile's rated compressive bearing capacity.

2-1.2.6 **Batter Piles**. Make connections to adjacent piles or to the pile cap capable of developing a tensile load equivalent to the smaller of the pile's compressive bearing capacity or the tensile structural capacity of the pile cross-section.

2-1.2.7 **Splicing**. The necessity for pile splicing should be avoided through selection of pile type and cross-section. However, where unavoidable, construct splices to provide and maintain true alignment and position of the component parts of the pile during installation. Construct splices capable of developing all germane structural capacities of the spliced pile cross-sections regardless of the expected design loads of the pile.

2-1.2.8 **Mixed Types or Capacities of Piling and Multiple Types of Installation Equipment or Methods**. Mixed types or capacities of piling and different types of installation equipment or methods are permitted, provided that the effects on the superstructure of differential elastic shortening and settlement are considered.

2-1.2.9 **Slope of Batter Piles**. Unless special provisions are made for the difficulties of installation and the effects of diminished driving energy on the capacity, keep the maximum slope of the batter piles to 5 horizontal to 12 vertical maximum batter or 4 horizontal to 12 vertical preferred or steeper.

2-2 REQUIREMENTS FOR SPECIFIC TYPE OF PILES

2-2.1 **Untreated Timber Piles.** Refer to \1\ UFGS 31 62 19.13, *Wood Marine Piles* /1/.

2-2.1.1 **Marine / Brackish Water Environment**. In general, do not use untreated timber piles without total encasement in a marine or brackish water environment. The one notable exception is their use as fender piles in volatile berthing areas where pile longevity is dictated by impact damage rather than by biological attack. Otherwise, encapsulate untreated piles exposed to air and water in one of the many flexible barrier products now available. It is becoming increasingly common to install untreated piles with these “wraps” as new construction, adding rub strips as appropriate for fender piles. Untreated piles are also required in some locations, i.e. San Diego, due to local environmental concerns over using salt treated timber in the marine environment.

2-2.1.2 **Fresh Water Environment**. Untreated, un-encased timber piles may be used in fresh water applications as long as they are not exposed to air. They must be cut off below the permanent ground water level or below MLW. As in the marine environment, it is becoming more common to install untreated piles with flexible “wraps” to protect the air-exposed portions as new construction.

2-2.1.3 **Geometry**. Where they are applicable, use untreated timber piles that conform to ASTM D25, *Specification for Round Timber Piles*. The greatest economy can be achieved by selecting the geometric property of butt diameter with respect to length in accordance with \1\ ANSI O5.1 /1/, Class 3 poles, those most commonly used by utility companies.

2-2.1.4 **Seasoning**. Seasoning for untreated timber piles is not required.

2-2.1.5 **Protection for Tops of Piling**. Protection for the tops of untreated, un-encapsulated timber piling is not required.

2-2.1.6 **Species**. Any species of wood may be used that will provide the necessary structural capacity and that will withstand the driving stresses.

2-2.1.7 **Peeling**. Peeling of untreated timber piles is not required.

2-2.2 **Treated Timber Piles**. Refer to \1\ UFGS 31 62 19.13, *Wood Marine Piles* /1/.

2-2.2.1 **Piles**. Use piles that conform to ASTM D25, *Specification for Round Timber Piles*. The greatest economy can be achieved by selecting the geometric property of butt diameter with respect to length in accordance with \1\ ANSI O5.1/1/ , Class 3 poles, those most commonly used by utility companies and most likely to be stocked at mills.

2-2.2.2 **Preservative Treatment**. Use treated marine piling that bear the appropriate American Wood Preservers Association (AWPA) Quality Mark as follows: MP-1 (dual treatment) for use in areas of extreme borer hazard and in marine waters where Limnoria and Pholadidea attack may be expected, or where oil slicks may contribute to borer attack, and MP-2 for other conditions where pholad attack is not expected. MP-4 treatment (water-borne preservatives) may be considered. For specific requirements at particular locations, \1\ consult NAVFAC Engineering Command, Pacific (NAVFAC PAC), Atlantic (NAVFAC LANT), Northern Division (NAVFAC ML), Southern Division (NAVFAC SE), NAVFAC WEST, /1/ and PWC Yokuska Applied Biology Offices. Refer to the paragraph entitled “Timber” for properties of treated wood.

2-2.2.3 **Seasoning**. Seasoning of treated timber piles is required prior to treatment.

2-2.2.4 **Species**. The preferred species are Southern pine and Douglas fir. Use of other species is subject to NAVFAC approval. \1\ AWPA Standard U1 /1/ requires that the species be either Southern pine or Douglas fir. It is not normally necessary to differentiate between these two species, as selection will be a function of geographic availability. In areas where treatable soft woods are scarce or unavailable in the length required, concrete piling often represents a more economical alternative than transported timber piles.

2-2.2.5 **Protection for Pile Tops**. Treat cut ends by puddling creosote. Puddling is accomplished by using a sheet metal band to form a reservoir on top of the pile. The reservoir is filled with creosote oil and left to stand for 8 to 12 hours. Alternative protection methods include coating pile tops with pitch (with or without sheet metal or plastic covers).

NOTE: Use of sheet metal covers as end protection for fender piles is discouraged because they are easily torn by impact and become a personnel hazard. However, sheet metal covers for bearing piles under pile caps provide good protection. In general, fit structural piling with waterproof caps.

2-2.3 **Precast (Including Prestressed) Concrete Piles.** These piles are covered in both \1\ UFGS 35 59 13.13, *Prestressed Concrete Fender Piling* and UFGS 31 62 13.20, *Precast/Prestressed Concrete Piles* /1/. Reference is also made to UFGS \1\ 03 31 29 /1/, *Marine Concrete*.

2-2.3.1 **Minimum Dimensions**. The minimum dimensions are 304.8 mm (12 in) for piles of uniform section and 203.2 mm (8 in) for tapered piles.

2-2.3.2 **Cover**. The minimum clear cover for reinforcement for permanent installations in salt water is 76.2 mm (3 in). For temporary installations and in fresh water, cover requirements may be relaxed to conform to the requirements of \1\ UFC 1-200-01, *General Building Requirements* /1/, for normal exposure conditions.

2-2.3.3 **Minimum Reinforcement**. Excluding pre-stressed piles, the minimum longitudinal reinforcement shall be 1.5 percent of the total cross section.

2-2.3.4 **Ties**. Provide spirals or ties for longitudinal reinforcement. Proportion spirals and ties in accordance with \1\ ACI 318/318R, *Building Code Requirements for Structural Concrete and Commentary* for structural columns except provide additional ties or spirals at ends as indicated in PCI STD-112, *Standard Prestressed Concrete Piles Square, Octagonal and Cylinder.* /1/

2-2.3.5 **Impact**. Forces induced by handling and driving shall be imposed magnified by a load factor of 1.25 (allowable overstress of 33 percent).

2-2.3.6 **Jetting**. Where jetting is contemplated, the jet pipe may be cast into the pile.

2-2.3.7 **Concrete Strength**. The minimum compressive concrete strength required is 34.47 MPa (5,000 psi) for pre-stressed concrete, and 27.58 MPa (4,000 psi) for non-pre-stressed concrete.

2-2.3.8 **Standard Details**. For information on standard details, refer to PCI STD-112.

2-2.3.9 **Minimum Residual Prestress**. The minimum residual pre-stress is 4.83 MPa (700 psi).

2-2.3.10 **Minimum Wall Thickness (Cylindrical Piles or square Piles With Voids)**. Provide a minimum of 3.81 mm (1-1/2 in) clear cover on inside (void) face. In no case may wall thickness be less than 102 mm (4 in).

2-2.3.11 **Venting**. If a void is provided which extends through to the lower end of the pile, vent the pile head to prevent the buildup of internal pressure during driving.

2-2.3.12 **Tolerances**. Locate voids, when used, within 9.5 mm (3/8 in) of the position shown on the plans. The maximum departure of the pile axis from a straight line, measured while the pile is not subject to bending forces, should not exceed 3.17 mm (1/8 in) in any 3.05 m (10 ft) length or 9.5 mm (3/8 in) in any 12.2 m (40 ft) length. Overall sweep should not exceed 0.1 percent of the pile length.

2-2.4 **Cast-in-Place Concrete Piles.** These piles are covered in \1\ UFGS 31 62 13.13, *Cast-In-Place Concrete Piles*. Reference is also made to UFGS 03 31 29, *Marine Concrete*. /1/

2-2.4.1 **General**. Cast-in-place concrete piles are not recommended for applications characterized by severe marine exposures and / or long un-braced lengths.

2-2.4.2 **Casings**. Use casings that meet the following criteria:

- Adequate strength to withstand driving stresses and to resist distortions imposed by the driving of adjacent piles.

- Except for portions of piles embedded more than 1.52 m (5 ft) below the mud line, casings are to remain in place to reinforce and / or protect the concrete core. Regardless of any coatings or other means of corrosion protection provided, do not consider casing metal thicknesses of 3.2 mm (1/8 in) or less as contributing to the structural capacity of the pile. Extend casings intended to provide flexural reinforcement to the point of fixity (defined in the paragraph entitled "Capacity as a Structural Member") and apportion the casings so that the metal thickness remaining at the end of the design service life equals or exceeds that required by analysis. Provisions for corrosion protection are discussed further in the paragraph entitled "On Hard Bottom (Rock or Hardpan)".

2-2.4.3 **Minimum Tip Diameter**. Use minimum tip diameter of cast-in-place concrete piles of 203 mm (8 in).

2-2.4.4 **Reinforcement**. Detail sections of piling requiring internal reinforcing in the same manner as pre-cast concrete piles. Cover requirements for reinforcing are the same as for pre-cast piles with spacers provided for longitudinal reinforcement to ensure that cover requirements are maintained.

2-2.4.5 **Concrete Strength**. The minimum concrete compressive strength to be used in the marine environment is 27.58 MPa (4,000 psi) and 24.13 MPa (3,500 psi) in freshwater applications.

2-2.5 **Steel H-Piles.** These piles are covered in UFGS \1\ 31 62 16.16 /1/, *Steel H-Piles.*

2-2.5.1 **Minimum Thickness of Metal**. Determine the thickness of metal from consideration of loss of section as established in \1\ UFC 1-200-01, *General Building Requirements* /1/ unless corrosion protection is provided as described in the paragraph entitled "Corrosion Protection". In any case, the minimum thickness should not be less than 10.55 mm (0.40 in). Splice plates should not be less than 9.5 mm (3/8 in) thick.

2-2.5.2 **Corrosion Protection**. When the required initial minimum thickness of unprotected metal would be excessive, provide alternative corrosion protection in the form of concrete encapsulation, bituminous or plastic (epoxy) coatings, flexible membrane / tape wrappings, or cathodic protection. For cathodic protection refer to \1\ UFC 3-570-02N, *Electrical Engineering Cathodic Protection* , UFGS 26 42 13.00 20, *Cathodic Protection by Galvanic Anodes*, and UFGS 26 42 19.00 20, *Cathodic Protection by Impressed Current*. /1/ Bituminous or plastic coatings are not considered effective below the mudline and require special care to avoid damage during driving. In tropical environments, and other locations where corrosion is particularly severe, encase steel pilings in concrete jackets to at least 0.61 m (3 ft) below MLLW and provide cathodic protection for the submerged and buried sections of steel.

2-2.5.3 **Cap Plates**. Bearing cap plates are not normally required for steel compression piles embedded in concrete pile caps. Where pile flexure or tension is intended, tie the tops of steel piles into the cap with reinforcing bars or structural sections welded to the pile and lap-spliced to the cap reinforcing.

2-2.5.4 **Hardware and Fittings**. Refer to Chapter 4 for guidance on specifications for hardware and fittings for H-piling.

2-2.5.5 **Limitation on Use**. The tips of all steel H-piles having a web thickness of less than 12.69 mm (1/2 in), and driven to end-bearing on sound rock by an impact hammer, must be reinforced with a driving tip (shoe). Both penetration resistance and equipment operation must be closely monitored so as to terminate pile driving immediately upon reaching refusal on the rock surface.

2-2.6 **Drilled Caissons and Auger-Placed Grout Piles**. These piles are covered in both \1\ UFGS 31 63 26, *Drilled Caissons* and UFGS 31 63 16, *Auger Cast Grout Piles.* /1/

2-2.6.1 **Applicability**. Usage of drilled caissons and / or auger-placed grout piles is normally reserved for conditions where the driven piles would bear on rock or other hard bottom, at shallow depth, without sufficient penetration for lateral support or uplift resistance.

2-2.6.2 **On Hard Bottom (Rock or Hardpan)**. Use a constant diameter shaft without the bell. Level sloping surfaces to receive the shaft. Anchorage in the form of grouted dowels or excavated keys should be considered.

2-2.6.3 **On Other Bottom Surfaces**. Consider shaft and bell construction if loads are heavy enough to warrant use of the bell. Unless supported on piling, embed the bell 0.61 to 1.22 m (2 to 4 ft) into firm material.

2-2.6.4 **Minimum Reinforcement**. Determine reinforcement by design requirements, not by a minimum reinforcement ratio.

2-2.6.5 **Embedment of Piling into the Bell**. Embed piling into the bell as required for transfer of load. Where tremie placement is employed, use 69 kPa (10 psi) bond resistance between pile and concrete, plus compression resistance of top of pile bearing in bell.

2-2.6.6 **Protection for Reinforcement**. The requirement for protection for reinforcement is the same as for concrete piling.

2-2.6.7 **Thickness of Metal Shell and Corrosion Protection**. The requirements for thickness of metal shell, and corrosion protection, are the same as for steel cased cast-in-place concrete piles.

2-2.6.8 **Installation**. Tremie placement of concrete fill is permitted. Provide for final cleanout of the bell or base of the cylinder immediately before concreting.

2-2.7 **Steel Pipe Piles**. Use pipe piles that conform to the applicable requirements for both steel H-piles and cast-in-place concrete piles (refer to the paragraphs entitled "Steel H-Piles and Drilled Caissons" and "Auger-Placed Grout Piles" \1\ /1/.) 2-2.7.1 **Material**. Use material conforming to ASTM A252, \1\ *Welded and Seamless Steel Pipe Piles* /1/, unless otherwise approved.

2-2.7.2 **Open-End Piles**. Reseat pipes installed with an open tip to full bearing after being cleaned out. If the pipe exhibits 50.8 (2 in) or more of additional penetration during re-seating, cyclically re-clean and re-drive until penetration on subsequent re-driving is less than 50.8 mm (2 in). If leakage of water into the pile is minor, pump the pile out and place one cubic yard of grout as an initial seal before the balance of concrete or sand fill is installed. If water leakage renders dry grout placement impractical, fill the pipe pile to its top with clean water and tremie the grout plug. Deposit the grout seal by means of a grout pipe to an elevation of at least 0.91 m (3 ft) above the bottom of the pile. After a sufficient time has elapsed to allow the grout to set, pump the pile dry and fill remaining space with concrete or clean dry sand.

2-2.7.3 **End Closure**. For friction piles, tip closures should not project more than 12.7 mm (1/2 in) beyond the pipe wall.

2-2.8 **Composite Piles**. These piles are seeing increase application throughout the Navy. \1\ NAVFAC LANT /1/ has prepared a regional guide specification, \1\ UFGS 35 59 13.14 20, *Polymeric Fender Piles* /1/ which covers their use.

2-2.9 **Sheet Piling--Steel**. This is covered in \1\ UFGS 31 41 16, *Metal Sheet Piling* /1/. The requirements for steel sheet piling are the same as previously established for steel H-piling (refer to the paragraph entitled "Steel H-Piles"), except as modified in the paragraphs below.

2-2.9.1 **Splices**. Use full-penetration butt welds for splices.

2-2.9.2 **Connection to Caps**. Embed steel sheet piles 52.3 mm (6 in) minimum into concrete caps. The use of structural sections for mechanical anchorage of sheet piling into the cap is neither required nor advised. However, provide stirrups (open to the side) through the handling hole near the top of each sheet as a positive connection between the steel sheet piles and the cap's longitudinal reinforcing. For steel channel caps, tack-weld each sheet to the cap member.

2-2.9.3 **Sleeves and Openings**. Detail all sleeves and openings for utilities and drains passing through the sheets to prevent loss of fill.

2-2.9.4 **Minimum Thickness of Metal**. For exposed faces of cofferdams, use a minimum sheet pile thickness of 12.7 mm (1/2 in). Elsewhere, use a minimum thickness consistent with the applied loading environment over the design service life of the structure. In no case should the minimum thickness be less than 3/8 in. (38 mm).

2-2.10 **Sheet Piling - Concrete**. Use piling that conforms to the requirements stated above for pre-cast, pre-stressed concrete piles (refer to the paragraph entitled "Precast (Including Prestressed) Concrete Piles**"**) except as modified in the paragraphs below.

2-2.10.1 **Joints**. Flush and grout joints tight to the mudline. Use of plastic sleeves is recommended.

2-2.10.2 **End of Sheets**. Use sheets cast with a drift-sharpened point. Embed tops of sheets 152.4 mm (6 in) into a continuous concrete cap.

2-2.10.3 **Sleeves and Openings**. The treatment of sleeves and openings in concrete sheet piling is similar to the procedure followed with steel sheet piling (refer to the paragraph entitled "Sheet Piling--Steel ").

2-2.11 **Sheet Piling - Timber**. Use timber sheet piling conforming to the requirements in the paragraphs entitled "Untreated Timber Piles**"** and "Treated Timber Piles**"** for treated and untreated timber piles except as modified in the paragraphs below.

2-2.11.1 **Applicability**. Timber, for the most part, no longer represents an economically competitive alternative for the construction of bulkheads. Within the range of structural applicability, aluminum and the burgeoning industry of plastic products represent lower life cycle costs than timber in all but the most benign marine environments. Therefore, the selection of timber will most probably be made based on specific aesthetic parameters.

2-2.11.2 **Treatment**. \1\ Use timber sheet piling in accordance with AWPA Standard U1 /1/. The types of treatment are as described for treated timber piles.

2-2.11.3 **Joints**. Use tongue and groove or splined joints (or Wakefield Type sheeting may be used). Install sheet piling tight to the mudline.

2-2.11.4 **Drift Sharpening**. Use drift sharpened timber sheet piling.

2-2.11.5 **Tops of Sheets**. Bolt tops of sheets to a continuous timber cap, with a width equal to or greater than the thickness of the sheet piling. Where a concrete cap is used, embed the sheets 152.4 mm (6 in).

2-2.11.6 **Sleeves and Openings**. Detail sleeves and openings through timber bulkheads to preclude the loss of fill material.

CHAPTER 3

DECK AND SUBSTRUCTURE FRAMING AND BRACING

3-1 **SUBSTRUCTURE**. The substructure includes pile caps, under-deck bracing, and other structural members (other than stringers) at and below the level of the pile caps.

3-1.1 **Pile Caps - All Types**. The effects of differential axial deformation among piles must be investigated where:

- heavy concentrated loads occur,
- piles are long,
- there is an appreciable variation in pile lengths
- pile types or installation methods vary.

Differential deformations will not appreciably affect ultimate strength if the cap can deform elastically without buckling or fracture.

3-1.2 **Timber**

3-1.2.1 **Hardware and Fittings**. For requirements pertaining to hardware and fittings, refer to Chapter 4.

3-1.2.2 **Species and Preservative Treatment**. Except for temporary structures, give substructure timbers a preservative treatment. Use a species that will accept deep treatment such as Southern pine or Douglas fir. Do not use untreated timber for permanent structures. Resistance to borers and decay of any untreated lumber - even of species presumed to be of superior resistance - is still inadequate for long-term use. Encase species that do not accept preservative treatment.

3-1.2.3 **Seasoning**. Use only seasoned timber for framing.

3-1.2.4 **Minimum Dimension**. The minimum nominal timber size should be 76 mm (3 in). National Fire Protection Association requires the following minimum dimensions: cross bracing – 102 mm (4 in); pile caps – 203 mm (8 in); stringers – 152 mm (6 in); and decking – 102 mm (4 in) with stringers, 76 mm (3 in) without stringers.

3-1.2.5 **Retention and Penetration of Preservative**. For guidance on the use of preservatives, conform to requirements of \1\ AWPA Standard U1 /1/.

3-1.3 **Concrete**. Refer to UFGS \1\ 03 31 29 /1/, *Marine Concrete.*

3-1.3.1 **Cover**. Use a cover that conforms to the requirements of the paragraph entitled “Cover”.

3-1.3.2 **Chamfer**. The minimum chamfer for all exposed outside corners should be 25.4 mm (1 in).

3-1.4 **Steel**. Use components comprising steel substructures that conform to the requirements for steel H piles (refer to the paragraph entitled “Steel H-Piles”).

3-2 **DECK**. The "deck" includes treads, planks, slabs, stringers, and other elements supported by the pile caps.

3-2.1 **Timber**. Use timber in the deck structure conforming to the requirements for substructure framing and bracing except as modified below.

3-2.1.1 **Treatment**. Give deck framing and bracing a preservative treatment. For the deck itself, do not use creosote on walking surfaces or surfaces normally touched by people (handrails, for example).

3-2.1.2 **Hardware and Fittings**. Refer to Chapter 4 for information on hardware and fittings.

3-2.1.3 **Decking**. Conform decking to the following materials and dimensions:

- Oak, maple, birch, black gum, or other species resistant to wear, may be used untreated for treads or traction cleats.
- Use decking not more than 300 mm (12 in) nor less than 100 mm (4 in) wide (nominal sizes).
- Use decking not less than 76 mm (3 in) thick (nominal size); 102 mm (4 in) when laid on timber stringers. Topping is 51 mm (2 in) sheathing, concrete, or asphalt.
- Provide a 10 mm (3/8 in) gap (minimum) between adjacent deck timbers.

3-2.2 **Concrete**

3-2.2.1 **General**. Conform to requirements for substructure framing and bracing.

3-2.2.2 **Deck Finish**. Broom-finish the deck to provide a skid-resistant surface.

3-2.3 **Steel**. When steel is used for stringers, use steel conforming to the requirements for steel H piles (refer to the paragraph entitled “Steel H-Piles”).

CHAPTER 4

HARDWARE AND FITTINGS (PERMANENT INSTALLATION)

4-1 **SALTWATER—IN OR BELOW SPLASH ZONE.** \1\ For information on mooring fittings, refer to UFC 4-159-03, *Design: Moorings*. /1/

4-1.1 **Minimum Diameter of Bolts**. Use bolt with minimum diameter of 25 mm (1 in).

4-1.2 **Minimum Thickness of Metal in Straps and Fittings**. Use metal with minimum thickness of 12.7 mm (1/2 in).

4-1.3 **Coatings**. Typically, mooring fittings are cast and painted.

4-1.4 **Washers**. Provide ogee washers for all bolts used in timber construction. Provide bolts used in concrete or steel structures with plate or standard circular washers with no more than two at any location. Fit inclined bolts or bolted surfaces with beveled washers.

4-1.5 **Size of Bolt Holes**. Drill all bolt holes in timber (other than holes for drift bolts) with a bit having a diameter 1.6 mm (1/16 in) larger than the diameter of the bolt shank. Align bolt-holes to allow insertion by tapping with a mallet. Do not drive or force-fit bolts. Drill holes for drift bolts 3.17 mm (1/8 in) less in diameter than the bolt diameter. Keep all drill bits sharp and control feed rate to produce shavings, rather than chips.

4-1.6 **Locking of Bolts**. Tack-weld nuts or damage the bolt threads outboard of the nut to lock all bolted connections.

4-2 **SALTWATER--ABOVE SPLASH ZONE**. Use same requirements as for installations in or below splash zone except as modified below:

- Minimum bolt diameter may be reduced to 19 mm (3/4 in).
- 10 mm (3/8 in) minimum thickness metal in straps and fittings.
- 6 mm (1/4 in) minimum thickness plate washers.

4-3 **FRESHWATER**. Requirements are the same for installation in saltwater, in or below splash zone, except as modified below:

- 15.87 mm (5/8 in) minimum diameter bolts.
- 6 mm (1/4 in) minimum thickness metal in straps, fittings, and plate washers.

4-4 **SPECIAL APPLICATIONS**

4-4.1 **Stainless Steel Fittings**. Stainless steel fittings may be used for special applications, if warranted, but should be used judiciously because many stainless steels do not perform well in saltwater. They often experience severe pitting and crevice corrosion more than regular carbon steel.

4-4.2 **Through Bolts**. Use through bolts to the fullest extent possible.

CHAPTER 5

SPECIAL CONSIDERATIONS

5-1 **SERVICE LIFE**. Unless specifically intended for a limited service life, or unless otherwise stipulated in job-specific criteria, design structures for a service life of 25 years. Where a service life of 1 year or less is intended, design may be predicated on an overall load factor of 1.15 for dead plus live load combined with any other single load; or 1.10 when combined with two or more other loads. Load factors for designs are intended for limited service life.

- Estimating Service Life. Assume structures detailed in accordance with this handbook meet the service life requirement in the paragraph entitled “Service Life”.

- Accessibility. Since waterfront structures frequently serve longer than 25 years, detail so that all components with an anticipated service life of less than 50 years can be inspected and repaired or replaced.

5-2 **CORROSION OF STEEL**. The principal factors affecting rate of corrosion loss are:

- Geographical location,
- Localized zones relative to tidal planes,
- Exposure to salt spray,
- Sand, earth, or other cover,
- Protective coating(s),
- Abrasive conditions (surf zone versus deep water),
- Stray electric currents, and
- Soil type.

5-2.1 **Service Life of Coating Systems**. Refer to Table 5-1 for approximate expected periods of protection afforded by various coating systems.

5-2.2 **Tropical Climates**. Encase steel H-piling in concrete in and above the tidal range and to a minimum depth of 1.5 m (5 ft) below MLW. Cap steel sheet piling with concrete rather than with a steel channel or timber.

Table 5-1 Period of Protection for Steel to be Expected from Various Coating Systems of Common Use[a]

COAT DESCRIPTION[b]	PERIOD OF PROTECTION[c]
Coal tar epoxy (15 to 20 mils thickness)	10 - 20 years
Galvanizing (7 to 9 mils thickness)	10 - 15 years
Metallized Aluminum	15 - 20 years
Concrete Encasement	25 years

Notes: (a) Marine exposure
(b) Coatings applied properly
(c) Periods of good to excellent protection, i.e. negligible loss of metal

5-2.3 **Use of Weathering Steels**. Use “weathering” steels conforming to the following requirements:

- The following steels require coating in the splash zone and other areas not boldly exposed to sun, wind, and rain: \1\ Alloy steels conforming to ASTM A242/A242M, *High-Strength, Low-Alloy Structural Steel*; A588/A588M, *High-Strength, Low-Alloy Structural Steel with 50 ksi (345 MPa) Minimum Yield Point with Atmospheric Corrosion Resistance*; or A690/A690M, *High-Strength Low-Alloy Nickel, Copper, Phosphorus Steel H-Piles and Sheet Piling with Atmospheric Corrosion Resistance for Use in Marine Environments*; and copper bearing steels conforming to ASTM A709/A709M, *Structural Steel for Bridges*. /1/

There are no consistent data on the rate of corrosion loss for steel surfaces in contact with various soils, so that consideration should be given to coating these surfaces in the same manner and degree as for \1\ ASTM A36/A36M, *Carbon Structural Steel*. /1/

- If an alloy conforming to \1\ ASTM A690/A690M is used, use hardware conforming to ASTM A588/A588M. /1/

5-3 **CATHODIC PROTECTION**. Consider cathodic protection for all buried or submerged steel structures or utilities in accordance with \1\ UFC 3-570-02N, *Electrical Engineering Cathodic Protection* /1/.

5-3.1 **Cathodic Protection Systems.** Consider a Cathodic Protection System (CPS) in conjunction with other protective measures such as material thickness incrementation, protective coatings and encasement for the following waterfront metallic structural systems:

- Steel sheet piling bulkheads
- Steel Bearing piles for piers
- Steel fender piles for piers
- Mooring components

In marine environments, CPS are most effective and can greatly extend the life of the submerged zones of steel waterfront structures. The splash and atmospheric zones will require reapplication of coatings and encasements for maximum system service life. Partial concrete encasement of steel piles creates a zone of high potential at the concrete encasement-to-bare steel pile interface where submerged. Provide CPS in these circumstances in addition to the partial encasement.

5-3.2 **Economic Feasibility.** Evaluate providing CPS for the following buried or submerges systems:

- Existing steel waterfront structures
- Reinforcing steel in concrete

Base implementation of CPS on life-cycle economics. Requirements for CPS will be determined by the corrosion engineer.

5-3.3 **Rehabilitation.** When rehabilitating existing steel pile bulkheads by driving new sheets outboard of the existing, include the following requirements for the CPS:

- Electrically isolate new piling from old piling
- Electrically isolate tie rods from existing sheet piling by cutting a hole in the old piling and providing a dielectiric sleeve through the pile.
- Coat tie rods and new piling on all sides.
- Consider CPS as part of the total corrosion protection system. Use conventional soil side anodes to protect the seaside and landside of the pile and to protect the tie rods if field tests indicate this to be feasible. Otherwise, consider using a deep anode bed system. Waterside anodes are appropriate only in areas not subject to maintenance dredging, water turbulence from ship/boat traffic, normal or storm generated heavy wave action, or constant movement of the sea bottom. Conduct a site survey to

determine the appropriate anode configuration and cathodic protection system requirements.

5-3.4 **Efficacy**. In general, the rate of corrosion loss below MLW is two-thirds to one-half the rate just below, at, and above MLW. Since cathodic protection is effective only below MLLW, it follows that cathodic protection should be accompanied by use of a concrete fascia or encasement to and below MLLW. Therefore, the obvious cost comparison is between such a composite system and complete concrete encapsulation.

5-3.5 **Maintenance Cost**. Consider the cost of electricity, replacement of anodes, and general repair of damage to wires and hangers in the economic analysis.

5-3.6 **Reliability of Maintenance Effort**. A cathodic protection system rendered fully or partially inoperative due to a lack of maintenance and repair is all too common. Implement regularly scheduled maintenance inspections to minimize risk of failure of the cathodic protection system.

5-4 EXPANSION, CONTRACTION, AND CONTROL JOINTS

5-4.1 **Open-Pile Platforms**. For open-pile pier and wharf platforms, refer to \1\ UFC 4-152-01, *Design: Piers and Wharves* /1/.

5-4.2 **Bulkheads**. In normal practice, no expansion or contraction joints are provided in the sheeting regardless of type. Assuming that a concrete cap will effectively grip the sheeting, there is no rational reason to joint the cap either as it is not free to strain axially anywhere along its length. Similarly, no special joints are required for timber or steel caps or for any anchor wall.

5-4.3 **Concrete Quaywalls**. Provide joints every 90 to 120 m (300 to 400 ft). Such formed joints need not be carried more than 1.52 m (5 ft) below MLLW.

5-5 MISCELLANEOUS REQUIREMENTS

5-5.1 **Protective Lighting**. \1\ Refer to UFC 4-025-01, *Waterfront Security Design,* currently in final draft and near final publication. /1/

\1\ /1/

5-5.2 **NAVAIDS**. Provide navigational aids at ends of piers, wharves, or quays. The cost of prominent, well-lighted markers is negligible in comparison to that of a collision. Refer to \1\ UFC 4-150-06, *Military Harbors and Coastal Facilities* /1/, for specific requirements.

5-6 **TIMBER**. The use of timber in the marine environment should be based on life-cycle economics. If timber is placed in the marine environment, it should be pressure treated according to American Wood Preservers Association Standards unless state and local regulations restrict its installation, cutting, use, or disposal. Conversely, the timber may be wrapped by plastic according to \1\ UFGS 31 62 21, *Piling: Composite, Wood and Cast In-Place Concrete* /1/. Field divisions and Activities should conduct site-specific risk assessments for each area containing a significant quantity of timber to determine the impact on the local marine environment. The risk assessment method may employ the software developed by the Western Wood Preservers Institute or other similar systems. The assessment may also include a leachability analysis if required by the locale. Most Field Divisions and Field Activities have applied biologists on staff to assist in the planning and design process.

For treated Douglas fir and Southern pine, see Table 5-2 for examples of structural characteristics as functions of preservative type.

5-7 FIRE PROTECTION REQUIREMENTS

5-7.1 **General**. Apply the provisions of the National Fire Protection Association (NFPA) Standard NFPA 307, *Standard for the Construction and Fire Protection of Marine Terminals, Piers, and Wharves*, and of \1\ UFC 3-600-01, *Fire Protection Engineering for Facilities* /1/.

5-8 **ANTI-TERRORISM / FORCE PROTECTION.** Refer to UFC 4-025-01, *Waterfront Security Design*, currently in final draft and near final publication /1/.

\1\ /1/

Table 5-2 Properties of Treated Woods

Type of Treatment	Average Properties

CHAPTER 6

STRENGTH EVALUATION OF EXISTING WATERFRONT STRUCTURES

6-1 **EVALUATING STRENGTH OF EXISTING MATERIALS.** Recent work by Naval Facilities Engineering Service Center (NFESC) has accomplished much in evaluating the strength of existing materials. NFESC has conducted impact load tests, followed by finite element analysis to evaluate the strength of a number of waterfront locations. This was followed by development of innovative repair techniques such as installation of a laminate composite overlay on the underside of existing Navy piers. \1\ A series of reports have been published on this topic that can be obtained from NFESC: https://portal.navfac.navy.mil/portal/page/portal/navfac/navfac_ww_pp/navfac_NFESC_pp . /1/ For strength evaluation of mooring hardware, reference UFC 4-150-08 *Inspection of Mooring Hardware.*

6-1.1 **General**. Apply the provisions of \1\ UFC 3-301-01, *Structural Engineering* /1/ relating to the use of used and / or unidentified materials.

6-1.2 **Number of Tests Required to Establish Strengths of Undocumented Materials**. Where no documentation exists pertaining to the strength of an existing material, the strength must be established by tests of the material. Use the value that sampling and testing indicates to have a 95 percent probability of being exceeded, as the strength of material to be assumed for strength evaluation of the structure. Use no fewer than four samples of a given material for testing.

6-1.3 **Tests and Test Specimens**

6-1.3.1 **Steel Members**. For steel members, take test specimens from locations and as described in \1\ ASTM A6/A6M, *Standard Specifications for General Requirements for Rolled Structural Steel Bars, Plates, Shapes and Sheet Piling.* /1/

6-1.3.2 **Concrete Members**. For concrete members, use drilled cores and sawed beams as described in \1\ ASTM C42/C42M, *Obtaining and Testing Drilled Cores and Sawed Beams of Concrete.*/1/

6-1.3.3 **Wood Members**. For wood members, stress-grade visually as described in \1\ ASTM D245, *Standard Practice for Establishing Structural Grades and Related Allowable Properties for Visually Graded Lumber*. /1/

6-2 **COMPUTING STRENGTH OF THE STRUCTURE**. Base analyses on measured in-place dimensions and existing conditions. A badly deteriorated or obviously overloaded structure often continues to support the applied loads with no discernible indications of distress. It is important to consider the factors contributing to this phenomenon when evaluating the strength of an existing structure. The more important of these factors are presented in the following paragraphs.

6-2.1 **Simplifying Design Assumptions**. Structural design commonly employs simplifying assumptions intended to make the design effort more manageable. These assumptions are invariably conservative and often result in substantial excess strength, for example, in presenting the distribution of concentrated loads to a slab, and in the structural design of variable sections.

6-2.1.1 **Distribution of Concentrated Loads to a Slab**. Conventional procedures, such as those described in the references of \1\ UFC 1-200-01, *General Building Requirements* /1/ and the American Association of State Highways and Transportation Officials (AASHTO), underestimate distribution of concentrated loads applied to a slab. Previous discussion in the paragraph entitled "Evaluating Strength of Existing Materials**"** relates here.

6-2.2 **Locations of Weakened Sections**. Members are proportioned for maximum stress conditions. The section required at points of maximum stress frequently is carried for the full length of the member to minimize the costs of fabrication or of form work, or for aesthetic reasons. If the deterioration of a member is localized and does not occur at a point of maximum stress, the "strength" of the overall member may not be impaired by exhibited deterioration.

6-2.3 **Changed Design Methodology**. If a structure was originally designed based on an elastic analysis, re-analysis based on ultimate strength, plastic redistribution of moments, or moment distribution based on the concept of yield line theory will frequently yield a greater analytical capacity.

6-2.4 **Design Live Loads**. Design live loads are seldom realized in practice. Therefore, original design loadings should be assessed and compared to actual load requirements for continuing validity.

6-2.5 **Excess Section**. Designs often contain excess strength by way of provision of sacrificial metal, rounding member sizes to the next heavier section, or to a lighter but stronger section, or for satisfaction of requirements for minimum thickness of metal or limiting deflection. Piling, in particular, is often sized beyond its structural requirement to resist driving stresses or for load transfer to the soil.

6-2.6 **Change of Structural Action**. The structural response to an applied load may differ from that assumed during design. Ordinary beams and slabs are a common case in point. These are proportioned on the basis of pure flexural behavior. However, except for large ratios of span to depth, pure flexural action is not realized, and the member resists the load, at least partly, by catenary action or arching. Composite actions between separate different structural elements may develop over time, which had not yet developed during original construction. Yield points may develop, changing the moment diagram and reactions, thus increasing some and decreasing others, with the changes often being non-critical.

6-2.7 **Change in Loading**. In some cases, the design load represents a temporary or construction condition, and the service loads are of lesser severity. For example, if a retaining wall is well drained, maximum lateral pressure will occur during and shortly after back-filling, dissipating somewhat with time. Another example is that of a hydraulic fill. The lateral pressure decreases as the fill drains. Borings will help in evaluating actual, in-place soil properties at the time that evaluation is made.

6-3 EVALUATING CONCRETE STRENGTH USING LOAD TESTS

6-3.1 **Method**. Apply the provisions of \1\ ACI 318/318R /1/, supplemented as described in the following paragraphs.

6-3.2 **Test Load**. Use test load magnitudes of 1.4D + 1.7L where live load is the reduced load (for tributary area). This increased loading intensity will require careful observation and control to preclude precipitating collapse. For this purpose, load in six increments, rather than four, and where feasible, use water-loading for safe provision of emergency drainage and load removal.

6-3.3 **Lateral Loads**. Simulate lateral loads expected to occur simultaneously with vertical loads in the test.

6-3.4 **Loaded Area**. Make the loaded area large enough to ensure that additional strength due to continuity and three-dimensional action within the structure is properly reflected in the test.

6-4 SPECIAL PROVISIONS REGARDING CAPACITY OF EXISTING PILES

6-4.1 **Structural Capacity**. Check existing piles checked for effects of deterioration. A reconnaissance survey should be made to identify areas of "worst conditions." Measurement of overall residual strength in 1 percent to 2 percent (but not less than 4) of the piles will be considered an adequate statistical sample on which to base judgment of capacity. Use the "worst" piles of the group as identified in the reconnaissance survey.

Give consideration to probable, future progression of loss of strength. Usually, the mudline under a platform has accreted well above the normal, stable slope line drawn from the existing dredge level alongside the platform. Discount this material in estimating the un-braced pile length (L). Should future dredging to greater depth be contemplated, consider the increased un-braced pile length that would result.

6-4.2 **Capacity of the Soil to Support the Pile**. Unless the embedded length of a pile has been reduced by scour or dredging, assume no reduction in bearing capacity from that initially achieved during driving. Where installed capacity is not known, consider the use of load tests to establish capacity.

6-4.3 **Sheet Piling**. Take the capacity of sheet piling to support vertical loads one-half the value indicated by conventional formulae relating capacity to driving resistance.

6-4.4 **Interpretation of Load Tests**. For interpretation of load tests refer to \\1\ UFC 3-220-01N, *Geotechnical Engineering Procedures for Foundation Design of Buildings and Structures* and UFC 3-220-10N, *Soil Mechanics*. /1/

CHAPTER 7

DETERIORATION OF WATERFRONT STRUCTURES

7-1 **GENERAL.** Considerable treatment of this topic may be found in UFC 4-150-07 *Maintenance of Waterfront Facilities* and UFC 4-150-08 *Inspection of Mooring Hardware.*

This UFC supersedes UFC 4-152-01, dated 28 July 2005 with Change 1, dated 1 September 2012.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

AUTHORIZED BY:

GEORGE O. LEA, P.E. Chief, Military Engineering Branch U.S. Army Corps of Engineers	JOSEPH E. GOTT, P.E. Chief Engineer Naval Facilities Engineering Command
EDWIN H. OSHIBA, SES, DAF Deputy Director of Civil Engineers DCS/Logistics, Engineering & Force Protection	MICHAEL McANDREW Director, Facilities Investment and Management Office of the Deputy Under Secretary of Defense (Installations and Environment)

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 4-152-01, *DESIGN: PIERS AND WHARVES*

Superseding: UFC 4-152-01, *DESIGN: PIERS AND WHARVES*, dated 28 July 2005 with Change 1, dated 1 September 2012.

Description of Change: UFC 4-152-01*, DESIGN: PIERS AND WHARVES* represents another step in the joint services effort to bring uniformity to the planning, design and construction of piers and wharves. This UFC contains extensive modifications in the following areas:

- Loads and seismic considerations
- Fender Systems
- Camels
- UFC general updates and revisions

Reasons for Change: The existing guidance was inadequate for the following reasons:

- Incorporation of changes described above
- Update to referenced documents

Impact: The following direct benefits will result from the update of 4-152-01, *DESIGN: PIERS AND WHARVES*:

- Although primarily a U.S. Navy document, a single, comprehensive, up to date criteria document exists to cover design of piers and wharves.
- Eliminates misinterpretation and ambiguities that could lead to design and construction conflicts.
- Facilitates updates and revisions and promotes agreement and uniformity of design and construction between the Services.

Service Exceptions: None.

CHAPTER 1 INTRODUCTION

\1\

1-1 PURPOSE AND SCOPE.

This UFC contains descriptions and design criteria for pier and wharf construction, including subsidiary, contiguous, and auxiliary structures. Loading details, regulations, furnishings, appurtenances, and other information are discussed when applicable. This UFC provides minimum facility planning and design criteria for efficient homeporting facilities of DoD vessels. Existing ports, facilities, and berths may not meet all criteria and may therefore, perform less efficiently, but do not necessarily require upgrade. This UFC focuses on the entire homeport operation. For example, ships will visit fueling and ammunition piers for short periods, but generally berth at general purpose berthing piers.

[C] 1-1 Triggers requiring an entire upgrade or replacement are under consideration for future revisions to this document.

1-2 APPLICABILITY.

This UFC applies to the design and construction of new, renovated, and repaired waterfront facility projects for the Department of Defense (DoD). It is applicable to all methods of project delivery and levels of construction. However, existing structures may not be able to meet some of the requirements in this UFC, but do not necessarily need to be upgraded. Incorporate requirements as best as possible and operationally for existing structures. Requirements in this UFC may support the need to replace an inadequate facility.

1-3 GENERAL FUNCTION.

An important consideration that often comes up has to do with differentiation between homeports and ports of call. A homeport for a specific ship has been identified as such by Commander Fleet Forces Command and is listed in the Naval Vessel Register (http://www.nvr.navy.mil). The homeport is where the ship is assigned and offers all requisite services required by the ship to include the full complement of hotel services. In contrast, a port of call would be any port where a ship stops along the way other than its homeport, e.g.: a fueling pier, an ammunition pier, a supply pier, or a repair pier. The only real requirements for a port of call would be that it has sufficient dredge depth and that it provides secure mooring. A ship does not go cold iron in port of call and uses its organic systems. However, local determinations and justifications can warrant adding specific features at ports of call. Many of the new classes of ships have concepts of operations and special mission requirements that have resulted in making accommodations at ports in forward operating areas that ordinarily would not be required, i.e. hotel services. These are handled on a case-by-case basis and driven by operational requirements. Generally, piers and wharves provide:

- Berths with sufficient dredge depths for vessels.

- Secure mooring for vessels berths.
- Transfer points for cargo and/or passengers between water carriers and land transport.
- Facilities for repair; and specialized functions.

1-4 CATEGORIES.

Piers and wharves are categorized into four (4) primary facility types and sub-types as follows:

1-4.1 Type I – Fueling, Ammunition, and Supply.

1-4.1.1 Fueling.

These are dedicated piers and wharves equipped with facilities for off-loading fuel from ship to storage and for fueling ships from storage. For additional design criteria, see UFC 4-150-02, *Dockside Utilities for Ship Service.*

1-4.1.2 Ammunition.

These are dedicated piers and wharves used for discharging ammunition for storage and for loading ammunition on outgoing ships. Explosives and ammunition quantity/distance standards are discussed in NAVSEA OP 5, Volume 1, *Ammunition and Explosives Safety Ashore*.

1-4.1.3 Supply.

Supply piers and wharves are used primarily for the transfer of cargo between ships and shore facilities. Provide standard gage railroad tracks when supplies will be brought in by rail.

1-4.2 Type II – General Purpose.

1-4.2.1 Berthing.

General purpose berthing piers and wharves are used primarily for mooring ships. Furthermore, berthing facilities may be active, as when ships are berthed for relatively short times and are ready to put to sea on short notice, and inactive, as when they are berthed for long periods in a reserve status. Depending upon intended pier usage, i.e. active berthing, maintenance/repair, inactive berthing, consider appropriate mooring service type as it relates to design/capacity of mooring fixtures. Activities that typically take place on berthing piers and wharves are personnel transfer, maintenance, crew training, cargo transfer, and waste handling. Under some circumstances, fueling and weapons system testing may also be carried out in these facilities.

1-4.2.2 Type IIA – Hybrid General Purpose/Repair.

A Type IIA 'Hybrid' General Purpose/Repair pier or berth is a Type II General Purpose pier/berth with enhanced features, similar to a Type III Repair pier typically found at a shipyard. It can support more advanced ship maintenance and repairs at a non-shipyard installation, but is not fully Type III compliant. It may be:

- A dedicated Type III repair pier/berth at a DoD general berthing installation that may or may not be situated in an enclave.
- A Type II pier or berth that does not meet the full requirements of a Type III repair pier/berth, but has limited capabilities to perform ship maintenance and repair.
- Or a Type II pier with dedicated berths that meet requirements of a Type III repair pier.

[C] There is not a definitive definition of a Type IIA 'Hybrid' repair/berth. Each requirement, location, function, and situation must be evaluated and balanced with operations and risks considered to determine what level of ship maintenance and repair can be provided at a non-shipyard Type III facility. The cognizant ship operating command and shore installation will have to determine who is responsible and fund the ship requirements.

A Type IIA pier/berth must meet the Type II requirements of this UFC, UFC 4-150-02, NAVSEA 8010, other UFCs, and include, but not limited to, the following:

- Heavy Weather Moorings (HWM).
- Permeant or temporary utility services, including a dedicated shore-supplied saltwater or nonpotable water supply for ship firefighting.
- Dedicated fire lane(s).
- Suitable capacity for crane operations.

Risks to be evaluated by installations and maintenance and repair activities (i.e. NAVSEA, CNIC, NAVFAC, DoD, and non-DoD commands) include:

- Limited availability of utilities.
- Limited deck space and laydown areas.
- Limited access.
- Limited crane operations.
- Limited dredge depth, slip width, clearance.

See other portions of this UFC, UFC 4-150-02, UFC 4-159-03, other applicable waterfront and facilities UFCs, and NAVSEA documents.

Each installation and project must consider, evaluate, and accept the risks of designating a Type IIA or Type III repair pier/berth at a DoD installation. This includes private shipyards.

1-4.2.3 Non-DoD Berthing.

Non-DoD agencies may be a tenant command at DoD installations. They may utilize DoD waterfront and supporting facilities on a DoD installation or fund and build their own facilities. They must have a MOA on record showing the agreement between the agencies. It must include the responsible Government Agency, financial commitment, criteria commitment, operations and maintenance plan, and plan to turn over a facility to the DoD if the non-DoD agency leaves the DoD installation.

1-4.3 Type III – Repair.

An important consideration for repair piers is the need to provide heavy weather mooring capability. This includes properly sized and spaced storm bollards and a compliment of heavy weather mooring lines. This consideration is predicated upon the fact that ships under repair may not be able to get underway during a heavy weather event.

See Type IIA definition for considerations regarding a ‘Hybrid’ Type II General Purpose pier and a fully capable Type III Repair pier.

1-4.3.1 Repair.

Repair piers and wharves are constructed and equipped to permit overhaul of ships and portions of a hull above the waterline. These structures are generally equipped with portal cranes or designed to accommodate heavy mobile cranes.

1-4.3.2 Floating Dry Docks.

Piers and wharves for floating dry docks are constructed and equipped to permit overhaul of ships above and below the waterline. Some floating dry docks have portal cranes on tracks on the wingwalls and some floating dry docks use cranes from the pier side. Provide adequate dredge depth at these facilities to accommodate the floating dry dock when submerged. Floating dry docks are normally moored using two or more vertical spuds that maintain the horizontal position of the dock throughout its full range of vertical movement from fully submerged to fully dewatered. Design the pier/wharf structure to accommodate mooring spud placement and loading. The pier or wharf layout should also consider personnel, material, and vehicle access to the dry dock pontoon deck when the dry dock is in the raised (dewatered) position. In the design of a pier or wharf structure, consider variations of the floating dry dock in the unballasted, ballasted, and partially ballasted positions.

1-4.4 Type IV – Specialized.

1-4.4.1 Magnetic Treatment and Electromagnetic Roll Piers.

These are piers that moor ships over an array of underwater instruments and large-area cable solenoids used specifically for removing and/or modifying the magnetic signature characteristics of surface vessels and submarines, as well as calibrating the on-board degaussing systems of mine countermeasure vessels. Magnetic treatment facility designs vary using slips, T-piers, or single piers depending upon location and requirement. Magnetic treatment piers designed to accommodate surface vessels are typically configured as T-shapes; whereas, submarines and mine countermeasure vessels are typically treated at drive-in piers built in parallel configurations.

1-4.4.2 Training, Small Craft, and Specialized Vessels.

These piers and wharves are typically light structures designed for specific but limited functions. Specific requirements are usually provided by the activity. Additional guidance can be found in UFC 4-152-07, *Small Craft Berthing Facilities*.

1-5 FLEXIBILITY OF BERTHS.

Typically, piers and wharves are designed to provide space, utility service, and other supporting facilities for specific incoming or homeported ships. However, berthing plans and classes of ships berthed change with time. While it is not economically feasible to develop a single facility to accommodate and service all known ship classes, design the facility with a certain amount of built-in flexibility to allow for anticipated future changes in the functional requirements. This is especially true for berthing piers and wharves that will be used to accommodate different classes of ships as well as support a variety of new operations.

1-6 APPURTENANCES AND FEATURES.

The following is a range of appurtenances and features that may be required for piers and wharves.

- Mooring devices to safely secure the ship.
- Fender systems, camels and separators.
- Hotel and ship service utilities.
- Communications.
- Cranes and crane trackage.
- Access facilities for railroad cars and trucks.
- Waste handling facilities.
- Cargo handling equipment.
- Covered and open storage spaces for cargo.

- Support building, tool shed, office space, and control rooms.
- Lighting poles and equipment.
- Lightning protection.
- Security systems.
- Firefighting equipment.
- Emergency medical facilities.
- Access structures and facilities.
- Fueling facilities.
- Safety ladders.
- Life-safety rings.

1-7 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-8 GLOSSARY.

APPENDIX B contains acronyms, abbreviations, and terms.

1-9 REFERENCES.

APPENDIX A contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.
/1/

CHAPTER 2 FACILITY PLANNING

2-1 LOCATION AND ORIENTATION.

2-1.1 General.

The location and alignment of piers and wharves in a harbor should consider factors such as:

- Maneuverability.
- Required quayage.
- Harbor line restrictions.
- Geotechnical conditions.
- Isolation requirements.
- Prevailing wind and current directions.
- Wave climate.
- Sea level change.
- Clearance between moored or passing vessels.
- Project depth.
- Shoaling patterns.
- Environmental permit restrictions.
- Port regulations.
- Landside access/proximity.
- Shoreside elements required as part of a pier/wharf project.
- Proximity to commercial and military airfields (potential restriction to crane operations).

For further discussion and criteria, see UFC 4-150-06, *Military Harbors and Coastal Facilities*.

2-1.2 Orientation for Environmental Conditions.

To the extent practical, orient piers and wharves so that a moored ship is headed into the direction of the prevailing winds and currents. Thus, the forces induced on mooring lines by these conditions would be kept to a minimum. If such an arrangement is not feasible, consider an orientation in which the wind or current holds the ship off the facility, although do not overlook the difficulty in mooring a ship under such conditions. In locations where criteria for both wind and current cannot be met, orient the berth parallel to the direction of the more severe condition. At locations exposed to waves and swell, locate the facility so that a moored ship is headed into the wave or swell front. If planning criteria dictate that a pier or wharf be oriented so that a moored ship is positioned broadside to the prevailing winds, currents, or waves, consider breast-off buoys to keep the ship off the facility and diminish the possibility of damage to the structure and ship. At oil storage terminals located in areas where meteorological and hydrological conditions are severe, consider using a single point mooring which allows a moored tanker to swing freely when acted upon by winds, waves, and currents from varying directions. See UFC 4-159-03, *Moorings*.

2-1.2.1 Pier Orientation.

A pier is oriented either perpendicular to or at an angle with the shore. There are generally ships on both sides, although there are instances where only one side has a ship because of site conditions or because there is no need for additional berthing. Piers may be more desirable than wharves when there is limited space available because both sides of a pier may be used for mooring ships. When both sides of a moored ship need to be accessed, two parallel piers with a slip in between may be preferred. Magnetic Treatment and Electromagnetic Roll piers usually require a magnetic north/south orientation, irrespective of other considerations.

2-1.2.2 Wharf Orientation.

A wharf is a structure oriented approximately parallel to the shore. Ships can only be moored at the offshore face of a wharf. When water depths close to shore are not adequate to accommodate deep draft ships, the wharf, consisting of a platform on piles, is located offshore in deep water and is connected to shore at one or more points by pile-supported trestles, usually at right angles to the wharf. If the trestle is located at the center of the wharf, the structure is referred to as a T-type wharf; if the trestle is located at an end, the facility is known as an L-type wharf; if trestles are located at both ends, the wharf is called a U-type wharf. Ships may be berthed on both sides of a T- or L-wharf. When the offshore wharf is used for transfer of bulk liquid cargo from the unloading platform to shore via submarine pipelines, the structure is referred to as an island wharf. A trestle from the offshore wharf to shore is not provided and both sides of the island wharf may be used for mooring ships. Launches are used for wharf access. Where a U-shaped berth is formed by a cut into land by two approximately parallel wharves, this may be referred to as a slip. For examples of pier and wharf types, see Figures 2-1 and 2-2. For general cargo, supply, and container terminals, a wharf structure, connected to upland shore area for its full length, is preferred because such an arrangement is more adaptable to loop rail and highway connections and the distance from wharf apron to transit sheds and open storage areas is shorter.

2-1.3 Vessel Ingress and Egress.

On occasion, a moored vessel is required to make a hasty departure from its berth and head out to sea. Accordingly, when planning a pier or wharf, consider providing adequate turning area so that a ship can be turned before it is docked, and moored with a heading that will permit a convenient and rapid departure.

Figure 2-1 Pier and Wharf Types

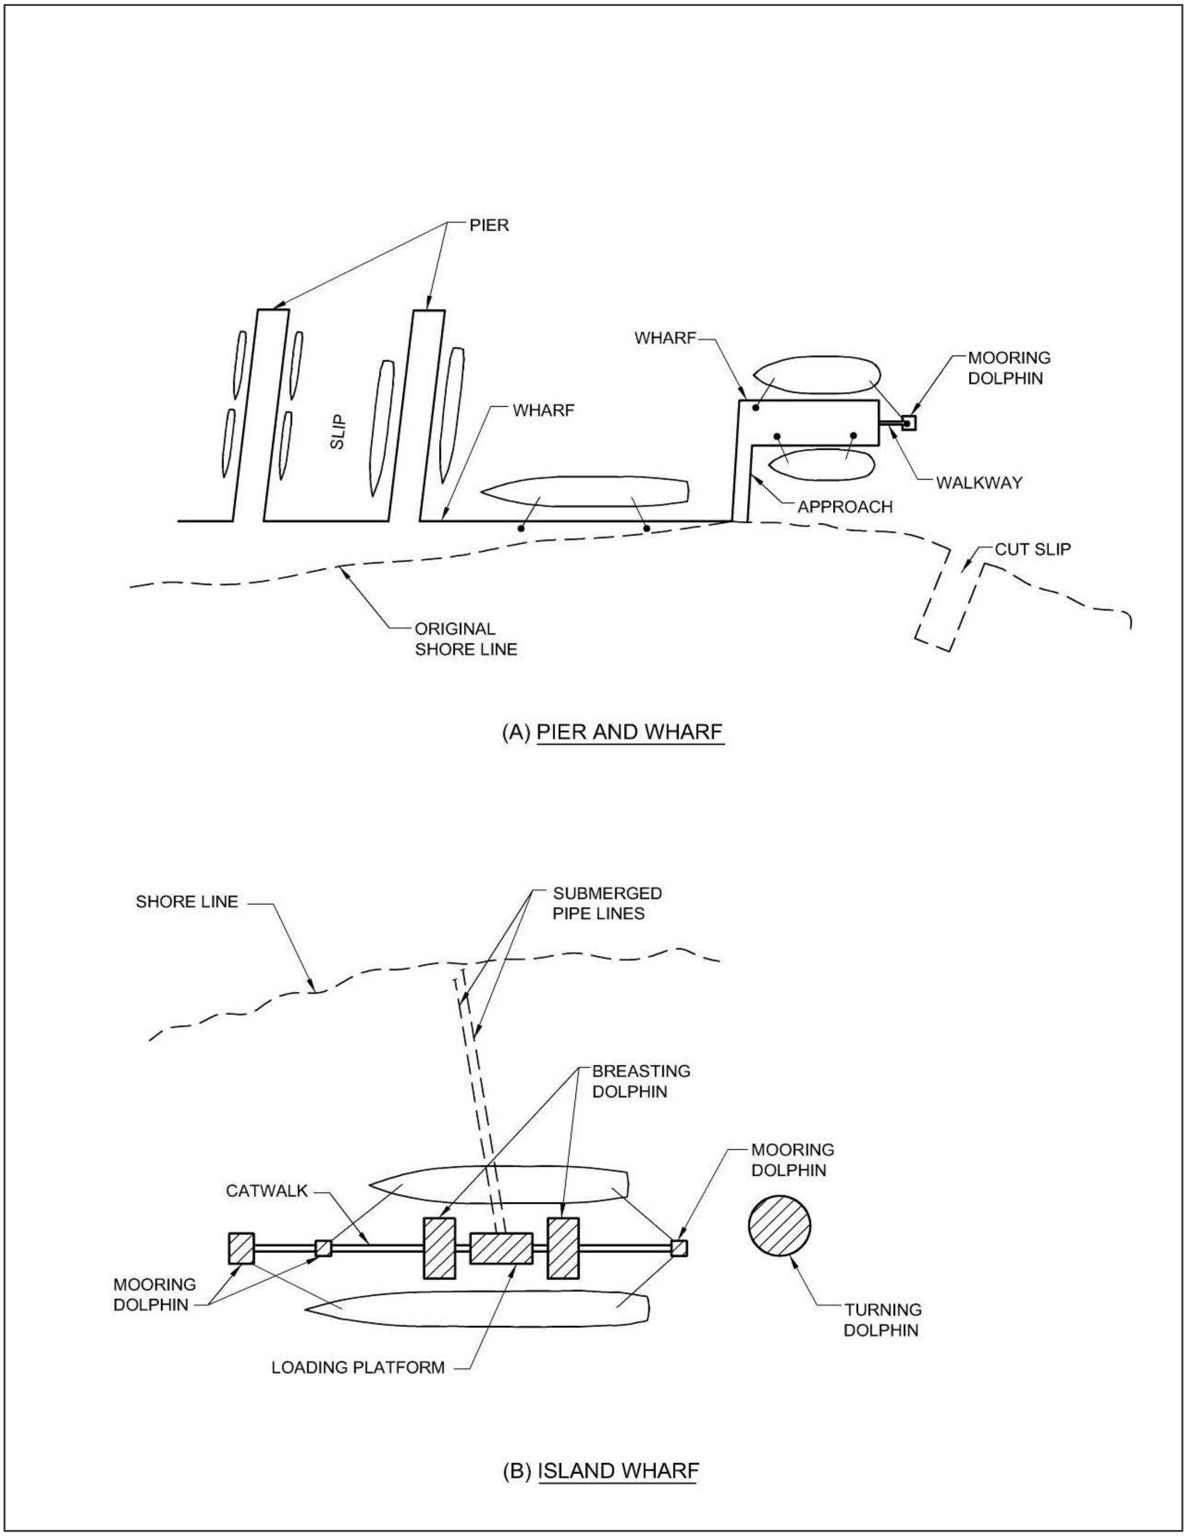

Figure 2-2 Wharf Types

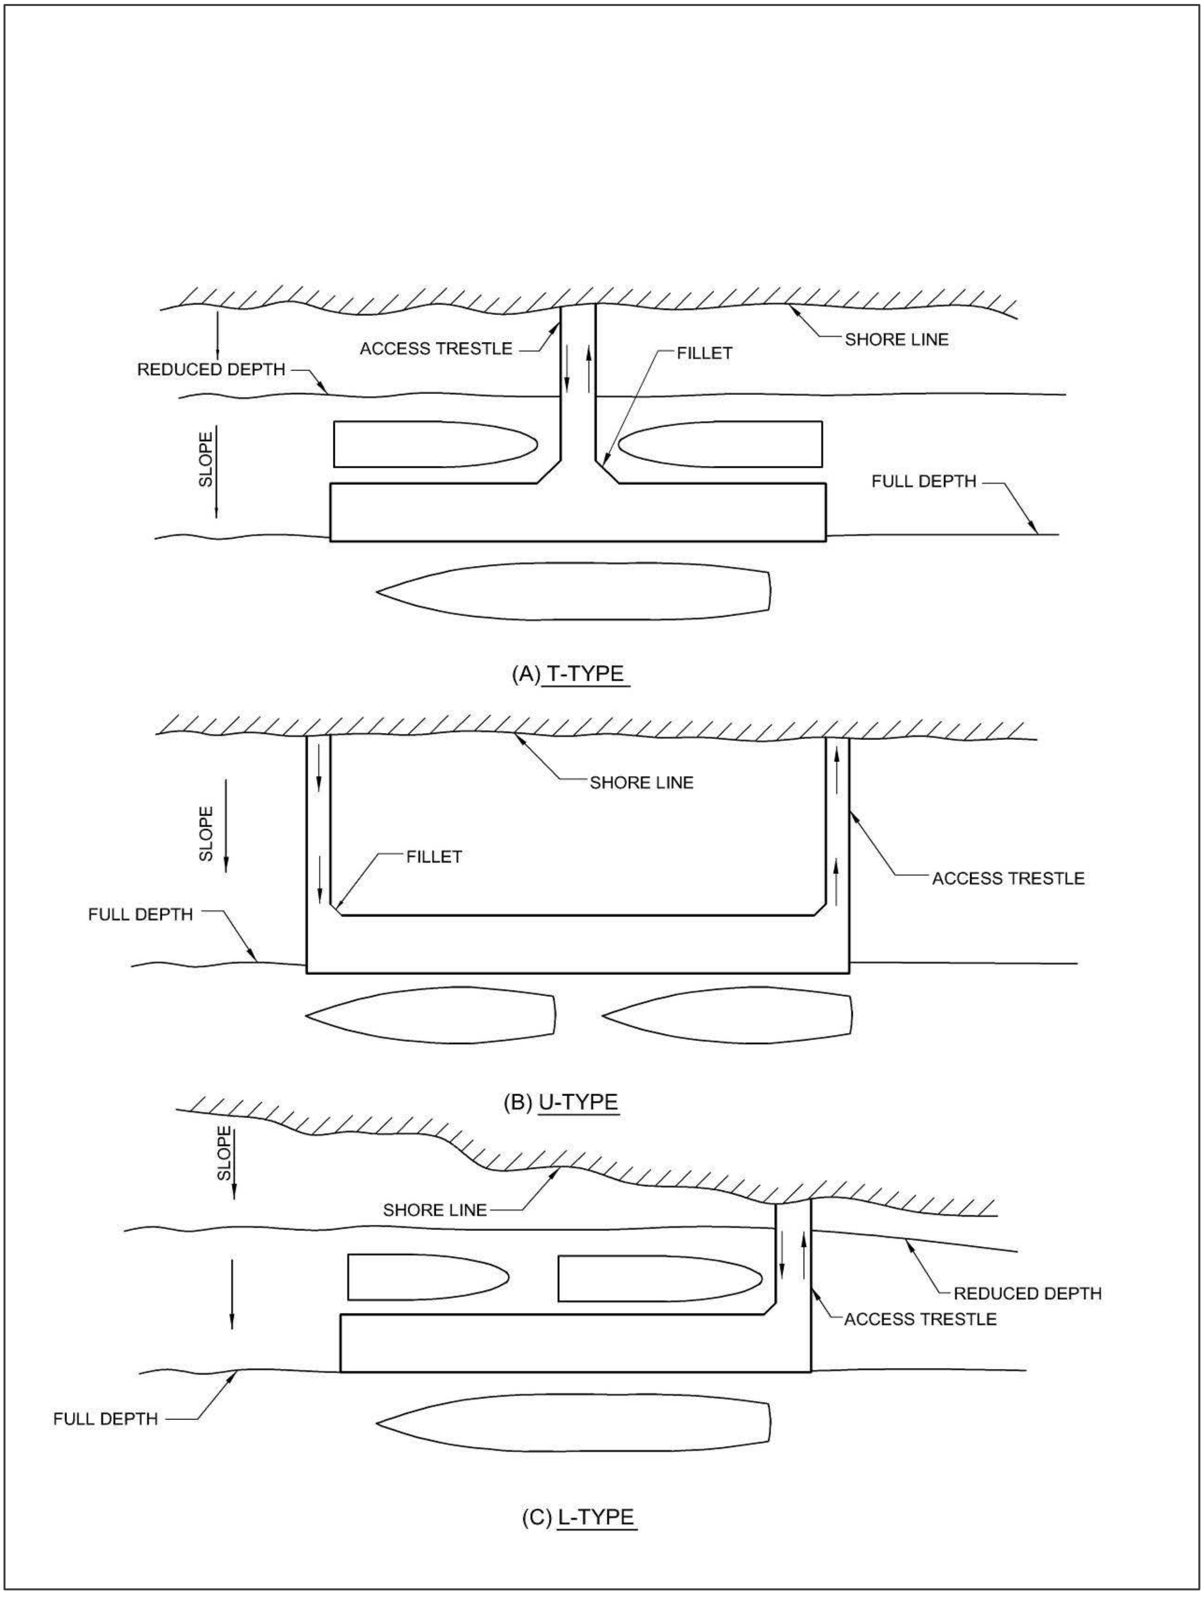

2-1.3.1 Disaster Control and Emergency Plans.

In an emergency, tugs may not be available. Therefore, the slip, berth, basin, and channels should allow the ship to get underway without assistance. See OPNAVINST 3040.5D, *Procedures and Operations Reporting Requirements for Nuclear Reactor and Radiological Accidents*. There will be cases where a ship will not be able to leave prior to heavy weather (such as during a Phased Maintenance Activity (PMA) or Planned Incremental Availability (PIA) for CVN). General-purpose berths are designed for Mooring Service Type IIB. Repair berths are designed for Mooring Service Type III. See the heavy weather mooring criteria contained in UFC 4-159-03, *Design: Moorings.*

Design facility systems for continuous operation in the event of a power outage, in other words, pier/wharf remains operational with exception of having shore power and lighting.

2-1.3.2 Harbor Elements.

Information on channel approaches (outer channels), entrances (inner channels), and turning basins to include recommended widths and depths is contained in UFC 4-150-06, *Military Harbors and Coastal Facilities.*

2-1.4 Water Depth.

Consider a wharf structure at locations where the required depth of water is available close to shore and the harbor bottom slopes steeply out to deeper water. At locations where water depths are shallow and extensive dredging would be required to provide the required depth of water close to shore, consider locating the facility offshore, in deeper water, by utilizing a T-, L-, or U-type wharf.

2-1.5 Dolphins.

These are small independent platforms or groups of piles used by themselves or in conjunction with a pier or wharf for specialized purposes. A mooring dolphin is sometimes used at the offshore end of a pier or both ends of a wharf to tie up the bow or stern lines of a ship at a more favorable angle. Mooring dolphins are usually accessed by a catwalk, as illustrated in Figure 2-1, and are provided with a bollard or capstan. Breasting dolphins are sometimes used for roll-on/roll-off facilities and at fueling terminals where a full-length pier or wharf is not required. They may also be used as part of the fender system. A turning dolphin is an isolated structure used solely for guiding the ships into a berth or away from known obstructions. Occasionally, a mooring dolphin may also be designed to function as a turning dolphin. Approach dolphins are used where the end of a pier or ends of a slip require protection from incoming ships. Breasting, berthing and turning dolphins are normally designed as semi- flexible structures with full utilization of their energy absorption capacity within elastic range, while mooring dolphins are normally designed as rigid systems.

2-2 COORDINATION OF REPAIR.

2-2.1 General.

Ships will undergo a Phase Maintenance Program based on the Class Maintenance Plan (CMP). These maintenance activities will generally be conducted at a repair berth. Ships in dry dock and in inactive status require specialized criteria that NAVFAC will provide as requested. Coordinate capability of local ship repair facilities and salvage operations with NAVSEA SUPSHIP. The following facilities should be available within a reasonable distance from the support facility homeport.

a. A Ship Maintenance Facility (SMF) housing the machine tools, industrial processes and work functions necessary to perform non-radiological depot level maintenance on ship propulsion plants.

b. A Maintenance Support Facility (MSF) housing both administrative and technical staff offices supporting ship propulsion plant maintenance, as well as central area for receiving, inspecting, shipping, and storing hazardous/mixed waste materials and maintenance materials, and controlled radiological tank storage.

c. A Controlled Industrial Facility (CIF) or Radiological Work Facility used for the inspection, modification, and repair of radiological controlled equipment and components associated with Naval nuclear propulsion plants. It also provides facilities and equipment for the treatment, reclamation, and packaging for disposal of radiologically controlled liquids and solids. It includes non-radiologically controlled spaces for administration and other support functions.

d. Dry dock facilities for various classes of ships. Refer to UFC 4-213-12, *Dry Docking Facilities Characteristics* for listing and details on active U.S. Navy graving dry docks. Consult with NAVSEA and the ship's Maintenance Program Master Plan and Class Master Plan (CMP) for specific requirements. Few floating dry docks remain active as service craft in the U.S. Navy inventory. Special moorings may be required for floating dry docks and special consideration for dredging (and shoaling) to allow for lowering of the dock is required.

e. Phased Maintenance Activities (PMA). PMA is a short, labor-intensive availability for ships in a Phased Maintenance Program for the accomplishment of maintenance and modernization. At some Naval stations, PMA is performed at general purpose berthing piers. PMA is discussed in detail in a subsequent section.

2-2.1.1 Aircraft Carriers.

Every 18 months an aircraft carrier will undergo a 6-month "Planned Incremental Availability (PIA)" at the repair berth. For CVN's, also coordinate with NAVSEA PMS 312 and NAVSEA 08, COMNAVAIRLANT N4, or COMNAVAIRPAC N4. Dry dock facilities for CVNs exist only at Puget Sound Naval Shipyard (PSNS), Norfolk Naval

Shipyard (NNSY), and Newport News Shipbuilding. NAVSEA 08 defines emergency dry dock facilities for CVNs. CVNs will be located at these facilities when this service is required.

2-3 OVERALL DIMENSIONS AND CLEARANCES.

2-3.1 General.

The overall dimensions and clearances required for piers and wharves are dependent on characteristics of the ships to be berthed and the support services provided. Comprehensive information on all U.S. Navy ships is found in the following locations or by contacting NAVFAC Atlantic - Engineering Criteria & Programs:

- Naval Vessel Register (NVR) (http://www.nvr.navy.mil/nvrships/index.htm). Note also that NVR provides a good reference regarding hull classification symbols, e.g. CVN = Multi-purpose aircraft carrier (nuclear propulsion)
- Military Sealift Command (MSC) (http://www.msc.navy.mil/inventory)

\1 Other Navy ship information can be found in a ship's Facility Planning Criteria (FPC). Contact other Services and Agencies for ship specific information on their ships.

2-3.1.1 Ship Characteristics.

Ship characteristics are provided in Tables 2-1 and 2-2. Data in tables is for various ship classes and is not all inclusive. There are many variants, blocks, and flights within a ship class. Designer is responsible for verifying information is correct and accurate for the ship(s) that will be berthed. **/1/**

[d] http://www.nvr.navy.mil/nvrships/S_TYPE.HTM
[e] Ships Characteristics Database (SCDB) **\1** Database is no longer available ***/1/***
[f] NAVSEA ltr ser 392T236/117 dtd 8 May 15
[g] 1/3 Cargo Stores
LOA = Length overall, feet
LWL = Length at waterline, feet
LBP = Length between perpendiculars, feet; also = L
D = Static draft of vessel, feet
M = Displacement of vessel, long tons
B = Beam at waterline, feet (Note: Not maximum beam)
A_y = Longitudinal projected area of ship, square feet
A_x = Transverse projected area of ship, square feet
h_h = Average height of hull above waterline, feet
h_s = Average height of superstructure, feet. Use the lightly loaded height of 180 feet (54.9 m) above the waterline. This includes combined superstructure and all communications / antenna array supported by the superstructure. Governing vessel is the LPD 17. Use the lightly loaded height of 215 feet (65.5 m). above the waterline for CVN's.

2-3.1.2 Supporting Items.

a. Provide fender/camel systems for the following arrangements:

- Multiple/nested berths for CG, DDG, LCS (surface combatants). Note that LCS 1 may be nested and LCS 2 may not be nested.
- Single berths for LHD, LHA, multiple berths for LPD, LSD (amphibious assault).
- Single berths for T-AKE, T-AO, T-AOE, (auxiliary).
- Single berths for CVNs. CR-NAVFAC-EXWC-CIOFP-1316, Oct. 2013, *USS Gerald R. Ford (CVN 78) Operational In-Port Analysis including Berthing, Mooring and Officers Brow Placement* has determined that extended CVN camels are required at double deck piers for both CVN 68 and CVN 78 class vessels.
- Multiple/nested berths for SSN, SSBN, SSGN.
- Multiple/nested berths for MCM, PC.

b. Aircraft require extensive support. Those requirements are not addressed herein.

c. A minimum of 5 acres (20,234 m^2) of laydown area in addition to pier/wharf space is desirable. The laydown area should be within 1/2 mile (0.8 km) of the pier or wharf.

d. Brows and Platforms are usually placed at ship's designated entry/egress points to the main deck. For CVN, two 45-foot (14 m) brows are usually placed on the ship's #2 elevator and one 60-foot (18 m) brow placed between elevators #2 and #3 to the main deck. Brow design length will be based on camel design and resulting standoff distance. CR-NAVFAC-EXWC-CIOFP-1316, Oct. 2013, *USS Gerald R. Ford (CVN 78) Operational In-Port Analysis including Berthing, Mooring and Officers Brow Placement* provides specific guidance concerning officer's brow placement for CVN 78 class vessel. To further define the unique brow requirements for CVN 78 a comprehensive 3D lift plan has been developed to model the lifting sequence for both installing and removing the brow. Similarly a 70- by 5-foot (21 by 1.5 m) counterweighted aluminum truss brow has been developed. For additional information, contact NAVFAC Atlantic - Engineering Criteria & Programs.

e. For criteria related to access to piers or wharves refer to: UFC 1-200-01, *DoD Building Code (General Building Requirements)*; *ABA Standards*; and Department of Defense Deputy Secretary of Defense Memorandum Subject: *Access for People with Disabilities*, October 31, 2008.

f. Sideport loading ramp access is of primary concern to LHA 1, LHD 1, and LPD 17. For double deck piers special ramps are required to access sideport loading ramp. Refer to *Amphibious Warfare Ship to Pier Interface Study* which provides details on the access problem as well as recommended special ramps.

g. Generally, design CVN berths to accommodate a variety of other classes of ships as well.

h. Design general warehouse space to be accessible to large trucks and handling equipment.

i. Do not permit pier interferences such as utilities and deck appurtenances in the zone of elevators for CVN (#1, #2, and #3), LHA, or LHD. At times these ships may have to move off of their normal berth bridge mark, i.e. move CVN offshore for ordnance load or move LHA/LHD toward bulkhead for stern gate ramp placement. Objective is to keep edge of pier free of obstructions.

j. Provide parking for ship's government and privately owned vehicles in proximity to entrance to the pier or wharf.

k. Provide sufficient security for ships on the pier. Consider minimally manned ships.

l. Provide safety equipment.

m. In the event that a building is required on a pier or wharf, give consideration to both wind and seismic loading in compliance with current, applicable codes and standards. Consider seismic mass of both structure and pier or wharf as well as interaction between structure and pier or wharf. For the building reference UFC 3-301-01, *Structural Engineering*. **/1/**

2-3.2 Pier and Wharf Length.

2-3.2.1 Single Berth.

The length of pier or wharf should equal the overall length of the largest ship to be accommodated, plus an allowance of 50 feet (15.2 m) at each end of the ship. For aircraft carriers (CVN), increase the allowance at each end of the vessel to 100 feet (30.5 m). Refer to Figure 2-3. Single berths are commonly used by LHA, LHD (amphibious assault ships), T-AKE, T-AO, T-AOE, (auxiliary), and CVNs. **\1** Other ships may berth in a single berth configuration or in multiple berth configuration with the same or a mixture of ship classes depending on pier/wharf and available berthing space. **/1/**

2-3.2.2 Multiple Berths.

The length of a pier or wharf should equal the total overall length of the largest ships simultaneously accommodated, plus clear distance allowances of 100 feet (30.5 m) between ships and 50 feet (15.2 m) beyond outermost moored ships. Refer to Figure 2-3. Multiple berths are commonly used by CG, DDG, LCS (surface combatants), SSN, SSBN, SSGN (submarines), MCM (mine warfare), and PC (patrol). **\1** See paragraph 2-3.2.4 for further requirements for submarines. **/1/**

2-3.2.3 Container and RO/RO Berths.

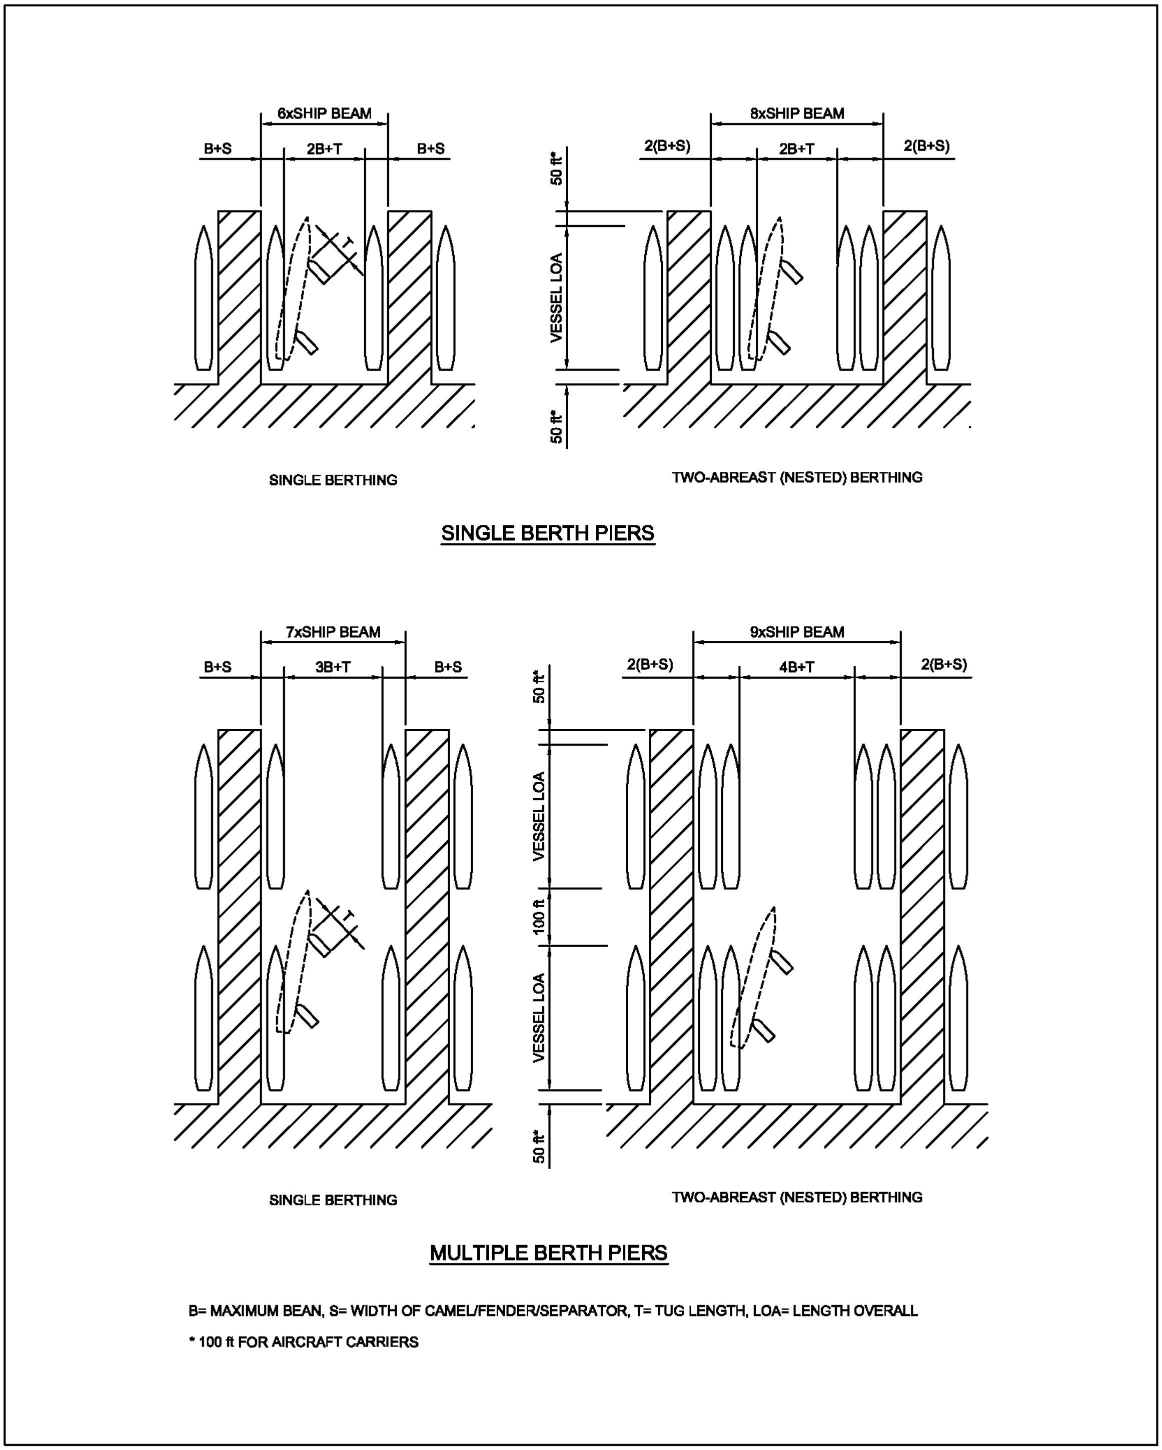
The length of berths used for container or RO/RO berths should account for the requirements of the container cranes or special ramps. Where shipboard ramps are used, provide adequate berth length to allow for efficient vehicle maneuvering.

2-3.2.4 Submarine Berths.

For most classes of submarines, a 50-foot (15.2 m) end distance to a quaywall or bulkhead is adequate. The nose-to-tail spacing for multiple berthing should also be a minimum of 50 feet (15.2 m). **\1** However, the nose-to-tail spacing and end distance at the stern of some submarines may require 100 feet (30.5 m) of clearance. Larger submarines such as the Ohio class (Trident, SSBN/SSGN) require 150 feet (45.7 m) or more nose-to-tail spacing and clearance to bulkhead or quay wall. **/1/** Where explosive safety distance considerations require the use of fragmentation barriers, or specific separation distances, provide spacing adjusted per the requirements of NAVSEA OP-5, *Ammunition And Explosives Safety Ashore*.

\1\

Figure 2-3 Length and Width of Slip



Note: Ship beam (B) is the extreme/maximum beam of the ship and not the beam at waterline.

/1/

2-3.2.5 CVN Berths.

CVNs are typically moored “starboard-side-to” to allow access to the ship’s elevators for loading/unloading.

2-3.3 Pier and Wharf Width.

\1 Pier width as used in this UFC refers to the edge to edge width of the structure, exclusive of fender systems. Refer to Figure 2-4. This definition also holds for U-, L-, and T-type wharves. However, with reference to wharves, the width is the dimension to a building, roadway, or other identifiable obstruction. Refer to Table 2-3 for minimum widths established for each functional type and ship. The dimensions in Table 2-3 are minimums for any pier or wharf constructed on a DoD installation and apply to all DoD and non-DoD tenant Commands. The pier and wharf widths must be followed unless a specific Memorandum of Agreement (MAO) is established and pier or wharf is completely funded and maintained by occupying tenant and facility will never be turned over to the DoD. Review with specific functional and operational requirements and physical constraints of the individual installation in mind before a final selection on width is made. /1/ Functional requirements include space for: cargo loading operations, line handling, ship maintenance, maintenance of utilities and layout of cables and hoses, solid waste collection, brows and platforms, crane operation, and other operations. For crane operation, consider crane outriggers, tail swing of crane counterweights, and overhang of vessels. For CVNs, coordinate the tail swing of gantry cranes with the overhang of the flight deck and elevators considering available camels and potential list of the ship. Also, these dimensions should not be less than the widths determined by geotechnical and structural considerations. Factors to be considered in the determination of pier and wharf width are discussed below.

Table 2-3 Minimum Pier and Wharf Widths

Function Classification/Type	Ship Type	Typical Pier Width (feet)		Typical Wharf Apron Width (feet)	Railroad Track (Standard Gage)	Rail Mounted Cranes
		Single Deck Pier	Double Deck Pier			
Ammunition	Ammunition	100	-	100	-	-
General Purpose Berthing	Auxiliary	115	93	65	-	-
	Surface Warfare	115	93	65	-	-
	CVN	150	93	90	-	-
	Submarine [a]	65	-	65	-	-
	Submarine [b]	85	-	65	-	-
Repair (Type III)	Surface Warfare	125	-	75	4 tracks; 2 each side	(2) 40-ft gage; 1 each side
	CVN	150	-	100	-	-
	Submarine	100	-	100	-	-
Type IIA	* must meet minimum requirements for a Type III	*	*	*	-	-
Fueling	Auxiliary	50	40/50 [c]		-	-
Supply (General)	Auxiliary	125	-	100	2 tracks	-
Supply (Container)	Auxiliary	125	-	100	Up to 3 tracks	(1) 100-ft gage

Note:

[a] Pier width is shown for a pier with only in-shore berths
[b] Pier width is shown for a pier with in-shore and off-shore berths (multiple berths along its length)
[c] Operational deck = 40 feet (12 m); utility deck = 50 feet (15 m)

/1/

2-3.3.1 Utilities.

One of the primary functions of a pier or wharf is to provide connections for utilities from ship to shore. Fixed utility terminals are usually provided close to the edge of the pier or wharf along the bullrail. Flexible hoses and cables are then connected to these terminals and to the ship. Depending upon the type of utility hoods, the terminals, hoses, and cables may require 10 to 15 feet (3 to 4.6 m) of space along the edge. Consider the types of utility hoods that require additional edge space for cable and hose laydown.

\1 For single deck piers, locating substations off of the pier deck is preferable. However, on some single deck piers, substations need to be mounted on the deck due to various constraints. This will take up approximately 25 feet (7.6 m) of pier width and may require a pier to be wider. If substations are mounted on the deck, locate them in areas that will minimize impacts on useable deck space and operations. Balance physical constraints with acceptable operational and local practices where necessary. **/1/** Double deck piers are used to clear the operations deck of obstructions or where the width of the berth area is constrained by adjacent facilities or other limitations. This configuration allows the utility enclosures and the associated hoses, cables and maintenance activities to be segregated from the operational areas and allow crane operations closer to the edge of the pier or wharf.

2-3.3.2 Berths on One Side.

For general purpose berthing of surface ships at wharves or piers with berths only on one side, the typical width is 65 feet (19.8 m) comprised of: 15 feet (4.6 m) bollards and utilities, 30 feet (9.1 m) mobile crane ops, and 20 feet (6.1 m) fire lane. For CVNs with berth on one side, the typical width is 90 feet (27.4 m) comprised of: 20 feet (6.1 m) bollards and utilities, 30 feet (9.1 m) mobile crane ops, 20 feet (6.1 m) fire lane, and 20 feet (6.1 m) for loading area.

2-3.3.3 Berths on Both Sides.

For general purpose berthing of surface ships at a single deck pier with berths on both sides, the typical width is 115 feet (35 m) comprised of: 30 feet (9.1 m) bollards and utilities, 65 feet (19.8 m) mobile crane ops/loading area, and 20 feet (6.1 m) fire lane. A typical single deck pier is shown in Figure 2-5. For a single deck pier with CVNs (or combination CVN/AOE) berthed on both sides, the typical width is 150 feet (45.7 m) comprised of: 40 feet (12.2 m) bollards and utilities, 65 feet (19.8 m) mobile crane operations, 25 feet (7.6 m) loading area, and 20 feet (6.1 m) fire lane. This 150 feet (45.7 m) recommended width is based largely upon operational experience of existing facilities.

2-3.3.4 Double Deck Pier with Berths on Both Sides.

\1 For double deck piers, typical width of top deck is 93 feet (28.3 m) comprised of: 8 feet bollards (2.4 m), 65 feet (19.8 m) mobile crane ops/loading area, and 20 feet (6.1 m) fire lane. A double deck pier provides: clear unobstructed pier to ship interface, isolation of operations deck services from lower deck utilities services (i.e. substation located on lower deck), reduced offset requirements for mobile crane operation (thereby reducing the requirement for floating cranes), higher main deck, improving mooring line angles and lessening need for brow platforms. A typical double deck pier is shown in Figure 2-6. **/1/**

2-3.3.5 Mobile Crane Operation.

With the exception of magnetic treatment/electromagnetic roll and fueling piers where a lighter duty mobile crane and/or forklift truck is sufficient, piers and wharves are subject to frequent usage by mobile cranes, forklifts, and straddle carriers. Typically, the cranes will be used to lift light loads (5 to 10 tons) (44 kN to 89 kN) but at a longer reach. This requires a high-capacity crane. If the crane operations are not allowable because of utility trenches and trenches with light-duty covers, such areas should be clearly marked with striping or separated by a raised curb to prevent accidental usage. Typically, mobile crane operators want to get as close as possible to the edge of the pier or wharf to reduce the reach. However, the edges of piers and wharves are also the best places for locating utility trenches and utility trenches. This conflict can be resolved by either designing all utility covers to the high concentrated load from the mobile crane or by allowing crane operations in discrete and dedicated spaces along the edges. Weight-handling equipment requires maneuvering and turnaround space on the deck for effective operation. If possible the deck space should be planned to allow mobile cranes to be backed up perpendicular to the bullrail. This permits the maximum load/reach combination. Make allowance for tail-swing of crane counter-weight. Refer to Navy Crane Center Instruction 11450.2, *Design of Navy Shore Weight Handling Equipment*. The Navy Crane Center may also be consulted for operating requirements.

Figure 2-5 Single Deck Pier

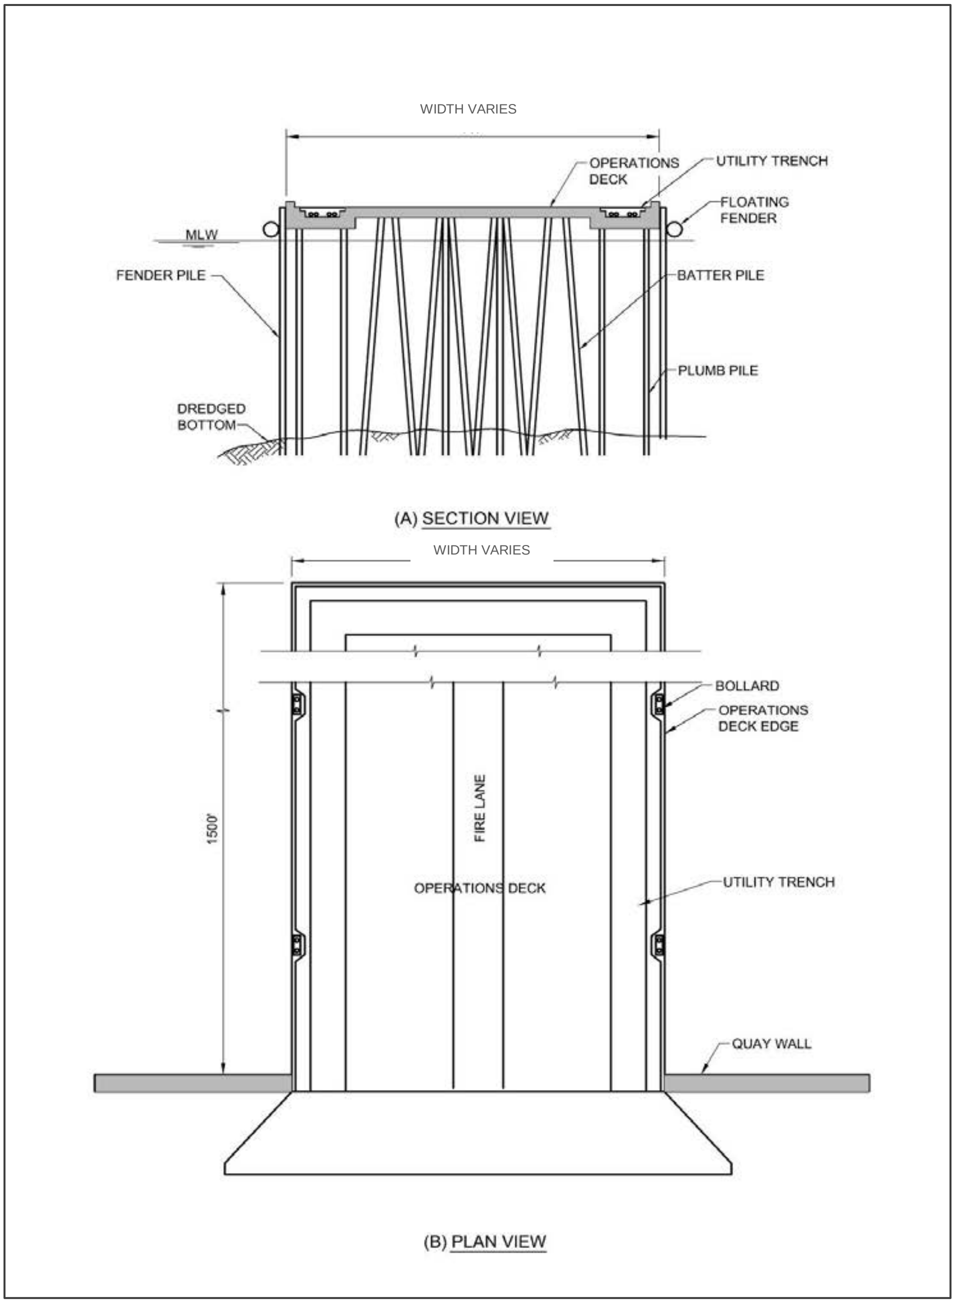

Figure 2-6 Double Deck Pier

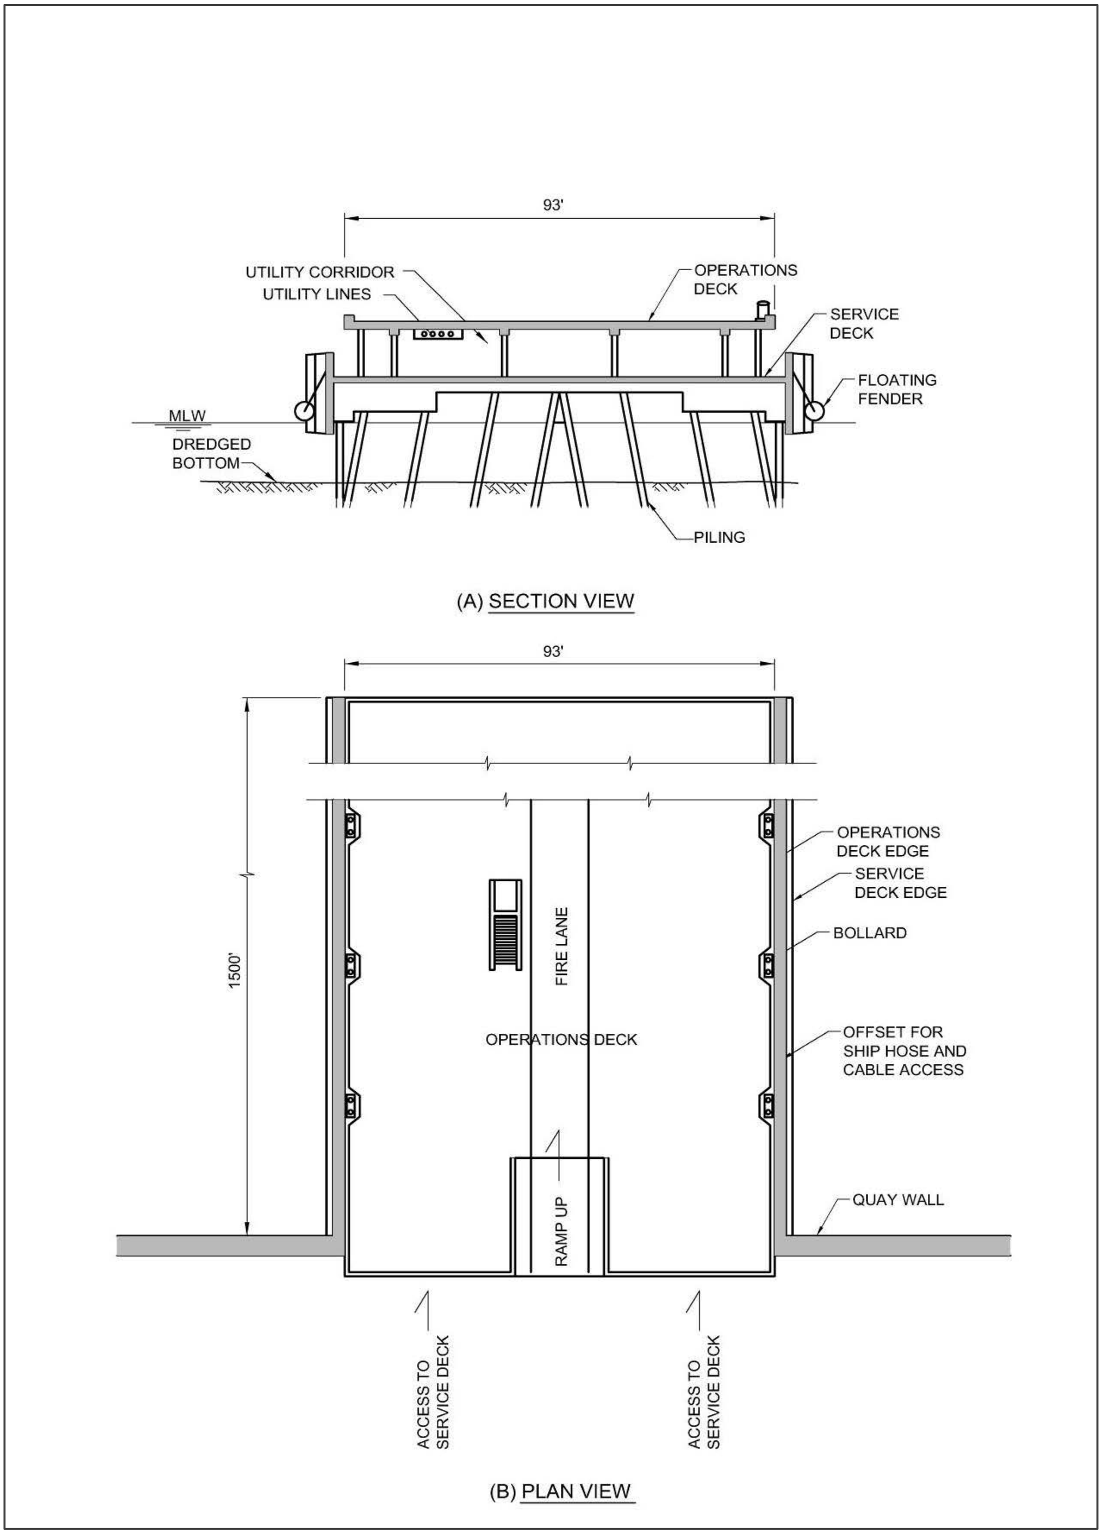

2-3.3.6 Railroad and Crane Trackage.

The number of railroad and crane tracks required and type of weight-handling equipment furnished on piers and wharves are dependent on the type of function, ships to be accommodated, amount of cargo to be handled, and rate of cargo transfer. Specific service requirements of the individual installation should be evaluated in conjunction with the following considerations:

Rail mounted cranes are often needed for loadout in repair facilities. Width requirements depend on equipment selected. The use of wide gage crane service at repair, ammunition and supply piers, and wharves should be considered. Provide rail gage of 40 feet (12.2 m) (portal crane gage at PSNS and IMF Bremerton Site is 20 feet (6.1 m)) for new cranes, except at container terminals or where it is necessary to conform to gages of existing tracks. When cranes are furnished, the distance from the waterside crane rail to the edge of the pier or wharf should be adequate to provide clearance for bollards, cleats, capstans, pits housing outlets for ship services, crane power conductors, and other equipment. Some electric powered gantry cranes may require either open or covered (panzer-belts) cable trenches in the pier or wharf deck for the power conductors. Where locomotive cranes are used on piers and wharves, the distances between tracks and curbs should be increased to accommodate the tail swings of the crane. For discussion of crane power conductors, see Navy Crane Center Instruction 11450.2, *Design of Navy Shore Weight Handling Equipment*. For trackage requirements, UFC 4-860-03, *Railroad Track Maintenance and Safety Standards*.

In general, do not consider railroad trackage for use on berthing piers and wharves (active or inactive). In cases where stations receive most of their cargo by rail, consider one or more tracks for use on active berthing piers. When there are existing railroad networks at the station, tracks should be considered for installation on repair, ammunition and supply piers and wharves. When trackage is required along aprons of piers and wharves, at least two tracks should be provided so that one track may be used as a running track when the other track is occupied. Track gage should conform to gage of existing trackage on adjacent piers and wharves to avoid creation of "captive" cranes. Except where local conditions require otherwise, standard gage should be used for trackage. Width of piers and wharves should be adequate to allow passing of trains and forklift trucks (or other material-handling equipment). Make allowances for stored cargo and other obstructions.

Where sponsons or flight decks of CVNs or other ship types with large deck overhangs are anticipated to be berthed, locate the crane rail so that all parts of the crane will clear the deck overhang.

Railroad and crane trackage should not be considered for use on piers and wharves used primarily for fueling (petroleum) operations. When railroad and crane trackage is required on piers and wharves, the spacings shown on Figure 2-4 may be used as a guide.

2-3.3.7 Trucks and Other Vehicles.

A variety of service trucks and vehicles can be expected to use piers and wharves for moving personnel, cargo, containers, and supplies to and from the ships. Provide adequate width allowing for operation and maneuvering of such vehicles. Turnaround areas should be provided.

2-3.3.8 Sheds and Buildings.

Storage sheds and buildings of any kind should be kept off piers and wharves unless their location can be justified by operational or security considerations. Transit sheds may be considered on piers and wharves where a suitable upland area is not available. When used on a pier, the transit shed should be located along the centerline with clear aprons on both sides consistent with the requirements set forth herein but not less than 20 feet (6.1 m) or more wide. On wharves, transit sheds and support buildings should be located on the land side edge with a clear apron toward the waterside. In general, support buildings on piers and wharves should be kept as small as feasible and located away from high-activity areas for least interference.

2-3.3.9 Movable Containers and Trailers.

During active berthing of ships, various containers of different sizes are temporarily or permanently located on pier deck to support the operations. These include shipyard toolboxes, garbage dumpsters, training trailers, and supply trucks. Adequate deck space should be available for locating and accessing these containers and trailers.

2-3.3.10 Fire Lane.

Retain and mark, with a painted yellow line, a 15-foot-wide (4.6 m) unobstructed fire lane. Provide a marked (with dashed, painted yellow lines) 2.5-foot wide (0.8 m) "dual use" buffer on both sides of the 15-foot-wide (4.6 m) unobstructed fire lane. Examples are shown in Figure 2-X. Local enforcement would keep this area clear enabling a total available fire lane width of 20 feet (6.1 m). However, encroachment into the "dual use" buffer by cranes is acceptable. Any other encroachment into the "dual use" buffer will be handled on a case-by-case basis. For wharves, provide a 20-foot-wide (6.1 m) unobstructed fire lane immediately adjacent to the operating area. These requirements need not be applied to small craft or yard craft piers.

\1 Retain and mark temporary traffic lanes including vehicular and pedestrian movements that may encroach upon the unobstructed fire lane. Parking, storage, and staging is not allowed within a fire lane. Mark fire lane with:

FIRE LANE **DO NOT BLOCK**

This includes bright yellow letters 12 inches (0.3 m) tall and 4 inch (102 mm) font spaced at 50 ft intervals.

On existing piers and wharves, mark fire lanes as close as possible to these requirements. It is understood that existing structures cannot meet these requirements due to construction and layout.

In some cases a crane may need to encroach or set up within a fire lane. In such cases, local crane operations must notify the local fire department and develop a safety plan include setting up a marked temporary fire lane.

> [C] The following background is necessary to understand the reasoning for the current fire lane width specified for piers. Previous criteria called for a 12 ft (3.7 m) fire lane which was later increased to 15 ft (4.6 m), allowing for one-way traffic and some adjacent working area.
>
> Later, an NFPA requirement calling for 20 ft (6.1 m) fire lanes was identified. Though it does not specifically apply to DoD piers, it was decided that it was a best practice and would be incorporated as a requirement with some stipulations. The current philosophy is supported by the fact that there are a number of considerations that go into development of pier width and pier area. Provide width and area for the following functions in addition to fire protection: berthing, maintenance, crew training, cargo transfer, light repair work, waste handling, fueling/ordnance handling (under some circumstances) and utilities that provide hotel services. Increasing pier width, by another 5 feet (1.5 m), over the length of the pier would cause a significant increase in construction cost and require additional real estate where multiple piers are arranged. Recognizing the fact that area is allotted for crane location along the length of the pier, this area will not be occupied a majority of the time, therefore, it is anticipated that additional area besides the 15 ft (4.6 m) fire lane and 2.5 ft (0.8 m) wide "dual use" buffer will be available along the pier for additional staging in the event of an emergency.

/1/

2-3.3.11 Fuel-Handling Equipment.

At specified berths, stationary fuel-handling equipment consisting of self-adjusting loading arms is often furnished to offload fuel products from tankers to onshore storage facilities. Pier or wharf width requirements depend on equipment selected and facilities furnished.

2-3.3.12 Phased Maintenance Activities (PMA).

The four levels of PMA and their estimated space requirements are as follows and as detailed in Table 2-4. For additional information, see NCEL TM-5, *Advanced Pier Concepts, Users Data Package* and OPNAVINST 4700.7L, *Maintenance Policy for U.S. Navy Ships*.

a. Intermediate Maintenance Availability (IMA). IMA consists of removal and repair of shipboard equipment performed by Regional Maintenance Center (RMC) personnel or tender forces, with a duration of approximately 30 days.

Gross deck requirements range from 2000 to 3000 square feet (185.5 to 287.8 m^2) with work area dimensions varying from 30 by 65 feet (9.1 by 19.8 m) to 30 by 100 feet (9.1 by 30.5 m).

b. Planned Restricted Availability (PRA). PRA consists of limited repairs of shipboard equipment and systems by contract forces under Supervisor of Shipbuilding and Repairs (SUPSHIP) control, with a duration of 30 to 60 days. Gross deck area requirements are about 10,800 square feet (1003.4 m^2) or 35 by 310 feet (10.7 by 94.5 m).

c. Selected Restricted Availability (SRA). SRA consists of expanded repairs and/or minor ship alterations to shipboard equipment and systems by SUPSHIP contract forces, with a duration of approximately 60 days. Gross deck area requirements are about 18,000 square feet (1672.3 m^2) or 35 by 515 feet (10.7 by 157 m).

d. Regular Overhaul (ROH). ROH consists of major repairs and ship alterations to shipboard equipment and systems by SUPSHIP contract forces, with a duration of six to eight months. Gross deck area requirements are about 24,000 square feet (2229.7 m^2) or 35 by 690 feet (10.7 by 210.3 m). In addition, there would be a requirement for turnaround areas on deck and warehousing off the pier or wharf.

Table 2-4 Estimated Space Requirements for PMA

Activity	PRA (ft^2)	SRA (ft^2)	ROH (ft^2)
Command Area [a]			
Mobile Administration Building	-	2,800	5,600
Parking Area	250	250	500
Bicycle Racks	70	140	200
Subtotal	320	3,120	6,300
Operating Area			
Demineralizer	-	1,500	1,500
Bilge Water/Stripping Tank	-	400	400
Dumpsters	1,150	1,440	1,730
Portable Solid-State Generators	-	240	240
Air Compressors	290	290	290
Welding	1,500	1,500	1,500
Flammable Storage	150	600	600
Transportation Laydown	600	900	1,500
Crane Work	3,850	3,850	5,250
Offload Area (oils, fuels, etc.)	3,000	3,600	4,500
Potable Heads	-	70	70
Additional Brow	-	400	400
Subtotal	10,540	14,790	17,980
Total	**10,860**	**17,980**	**24,280**

[a] For piers with ordnance handling berths, do not provide command area

2-3.4 Slip.

2-3.4.1 General Considerations.

The clear distance between piers, or slip width, should be adequate to permit the safe docking and undocking of the maximum size ships that are to be accommodated in the slip. The size of a slip should also permit the safe maneuvering and working of tugboats, barges, lighters, and floating cranes. At multiple berth piers, where ships are docked either one per berth, two abreast per berth, or more, sufficient clearance should be available to permit the docking and undocking of ships at the inboard berth without interfering with ships at the outboard berth. Because the size of a slip is affected by docking and undocking maneuvers, consideration should be given to the advice of local pilots who are familiar with the ships to be handled and with prevailing environmental conditions such as winds, waves, swells, and currents. Slip width is also influenced by

the size and location of camels/separators used between ship and structure and between ships. The width should be reviewed with specific functional requirements of the individual installation before a final determination is made.

2-3.4.2 Minimum Slip Length.

Slip length basically follows the same criteria provided previously under section 2-3.2.

2-3.4.3 Minimum Width of Slip for Active Berthing.

2-3.4.3.1 Minimum Slip Width.

Minimum slip width should be the greater of the two dimensions shown on Figure 2-3. Additionally, the width should not be less than 300 feet (91.4 m). Slip widths discussed in this section are applicable only if ships are turned outside the slip area. Refer to Tables 2-1 and 2-2 for the beam of typical ship types (Note: Beam (B) shown tables is the beam at waterline and not the extreme beam. Use the widest beam (extreme/maximum beam) to determine horizontal clearances and slip width both for single berth and nested configurations.

Location of homeport berthing facilities should allow nesting of DDG, CG, SSN, LCS 1, MCM, and PC class ships. Minimum slip width for surface combatant in a multiple berth, nested configuration is 600 feet (183 m). Minimum slip width for single amphibious warfare and combat logistic ship berths is 600 feet (183 m). Other typical berthing arrangements can be found in paragraph 2-3.1.2.

2-3.4.3.2 CVN Slips.

For CVN’s, minimum width is 600 feet (183 m) with no other ships, 800 feet (244 m) with CVN on opposite berth. Add 100 feet (30.5 m) to width if other ships are berthed at the bow or stern of the CVN. Use the widest beam to determine horizontal clearances and slip width both for single berth and nested configurations. Note that the waterline beam for CVN 68-77 is 134 feet (40.8 m) and the width of the flight deck structure (with antenna platforms, walkways, and portable flight deck sections removed) is 252 feet (76.8 m). Without removing these appurtenances, CVN 68 is 260 feet (79.2 m), CVN 76 is 280 feet (85.3 m), and CVN 78 is 256 feet (78 m) wide.

2-3.4.3.3 Submarines Slips.

At submarine slips, width requirements must consider fender system, camels, and separators, barges, and other items that will encroach (takeup, occupy, etc.) slip width or width should be increased two beam widths [need Port Ops and SUBFOR input to reduce four beam requirement to 2B or delete; appears to be a holdover from DM 25.1 when just XxB was used and before B+S was added] to account for camels and separators, to provide for ships' vulnerability if their safety is involved, to provide for special maneuvering requirements of other ships during berthing or passing, and to provide for special environmental conditions such as currents, waves, and winds. Use extreme beam of submarine including the width of the planes and any added appurtenances when determining slip width. Beam widths can very between vessels in the same class, so verify beam width of ships to be berthed and use the widest.

2-3.4.3.4 Slip Width for Nested Ships.

When more than two abreast berthing (nesting) is employed, the width of slip should be increased by one ship beam for each additional ship added in order to maintain adequate clearances between moored ships during berthing and unberthing maneuvers. Thus, for three-abreast berthing on both sides of a slip, the slip width for single-berth piers would be equal to 10 times ship beam and the slip width for multiple-berth piers would be equal to 11 times ship beam. Slip width may also be increased by accounting for appropriate ship beam plus separator (B + S).

2-3.4.3.5 Berthing on One Side of Slip.

The requirements discussed above apply where ships are berthed on both sides of a slip. Where ships are berthed on only one side of a slip, the width may be reduced by one ship beam plus separator (B + S). See Figure 2-3.

2-3.4.4 Minimum Width of Slip for Inactive Berthing.

At slips containing inactive berths where ships are stored for long periods of time on inactive status in nests of two, three, or more, clear distances between moored ships and slip width may be reduced by one or two ship beams to reflect the reduction in the frequency of berthing maneuvers and the decrease in activities of small boats and floating equipment.

2-3.4.5 Water Depth in Slips.

Information on required water depth in slips and at berths is contained in UFC 4-150-06, *Military Harbors and Coastal Facilities*.

2-3.5 Pier and Wharf Deck Elevation.

Set deck elevation as high as possible for surface ship berthing and as low as possible for submarine berthing, based on the following considerations. When determining proper deck elevation, give due consideration to different vessels that will occupy berths. Interferences often occur with appurtenances that rise above actual deck elevation, e.g. cleats, bollards, utilities, igloos, turtlebacks, etc.

2-3.5.1 Overtopping.

To avoid overflow, deck elevations should be set at a distance above mean higher high water (MHHW) level equal to two thirds of the maximum wave height, if any, plus a freeboard of at least 3 feet (1 m). Bottom elevation of deck slab should be kept at least 1-foot (0.3 m) above extreme high water (EHW) level. Where deck elevation selected would result in pile caps or beams being submerged partially or fully, consideration should be given to protecting the reinforcing from corroding. Also, when establishing deck elevation, consider utility trenches as they must be kept dry in all circumstances. In establishing the deck elevation, consideration may be given to the combined effects of sea level change, extreme water levels, and wave effects. Also, the intended service life of the structure should be taken into consideration as it relates to sea level rise and setting deck elevation. In locations where portal crane trackage is required, consider tie in with landside and limitations on grade change between pier/wharf and landside.

2-3.5.2 Ship Freeboard.

Consider the varying conditions of ship freeboard in relation to the use of brows and the operation of loading equipment such as conveyors, cranes, loading arms, and other material handling-equipment. Consider maintaining appropriate mooring line angles. Fully loaded ships at mean lower low water (MLLW) level and lightly loaded ships at MHHW level should be considered for evaluating the operation of such equipment.

2-3.5.3 Utilities.

Deck elevations should be set high enough above MHHW levels to allow for adequate gradients in drainage piping as well as to prevent flooding of utilities/trenches that are located below the pier deck.

2-3.5.4 Deck Elevation for CVN Berths.

Ensure that deck elevation does not conflict with CVN elevators. When lowered, the lowest projection of the elevator is 9 feet (2.7 m) above the design water line for a CVN. Use properly designed camels and pier fendering to provide sufficient standoff to prevent interference with appurtenances located on edge of pier deck such as mooring fittings, utility connections, igloos, etc.

2-3.5.5 Adjacent Land.

If possible, set deck elevation as close as possible to grade of the adjacent land for smooth access of mobile cranes, service vehicles, personnel vehicles, and railroad. Ramps may be used to access the deck set higher or lower than adjacent land. A maximum gradient of 15 percent may be used for such ramps when railroad access is not provided. Consideration should be made to reduce grade to 6 to 8 percent, comparable to state DOT requirements, in cold regions where snow or ice can be a problem. Ramps for pedestrian access should have a gradient less than 12 horizontal to 1 vertical, with 5 feet (1.5 m) minimum landings for every 30 inches (0.76 m) of rise to conform to American with Disabilities Act (ADA) of 1990. Vertical curves should be large enough so that long wheelbase or long overhang vehicles do not or drag. Where track mounted cranes are specified, all the deck areas serviced by the crane should be kept at the same elevation.

2-4 UTILITIES.

2-4.1 General.

For design criteria of utilities on piers and wharves, refer to UFC 4-150-02, *Dockside Utilities for Ship Service*. Usually, utility connection points (hoods, vaults, or mounds) are located and spaced along the pier or wharf edge to be as close as possible to the ships' utility terminals in the assumed berthing position. The connection points should be planned and located to accommodate reasonable future changes in berthing plan or in the type of ships served. Typical hotel services are: potable water, non-potable/saltwater, collection, holding, and transfer (CHT), oily waste/waste oil (OWWO), compressed air, steam, telecommunications, and shore power. All utility lines should be kept where they can be conveniently accessed from above deck. Typical utility configurations on piers and wharves are described below.

2-4.1.1 Utility Trenches.

These are basically protected trenches running along the waterside edge of a pier or wharf accessed by removable covers from the top. Refer to Figure 2-5. On a pier, the lines can go along one edge all the way to the end and be "looped" to the other edge back to land. On a wharf, the lines can be supplied and returned through smaller lateral "trenches." Where the number and size of lines is large enough, a utility tunnel or gallery can be utilized with access from the top or side. Where a fuel line is provided, it should be kept in a separate trench for containment of leaks.

2-4.1.2 Double Deck Pier.

As shown in Figure 2-6, utility lines are isolated on the lower deck and can be easily accessed. The upper deck is thus clear of all utility lines and terminations and is free for operations. There are situations on double deck piers (due to physical space and structural limitations) where some utilities are hung from underneath the lower deck (i.e. OWWO, CHT, and electrical).

2-4.1.3 Ballasted Deck.

This concept consists of a sloping deck filled with 1.5 to 3 feet (0.8 to 0.9 m) of crushed rock ballast, which provides a convenient medium to bury the utility lines and crane or rail trackage. The ballast is topped with concrete or asphalt paving, which will provide a firm working surface for operations. The paving and ballast can be removed to access the utility lines. Concrete pavers have been used successfully for paving ballasted decks and provide improved access to utilities buried in the wharf ballast. Future changes in utilities and trackage can similarly be accommodated. Also, the ballast helps to distribute concentrated load to the deck slab, thus allowing heavier crane outrigger loads. Ballast on the deck not only helps to distribute concentrated load to the deck slab, but also reduces or eliminates impact.

2-4.1.4 Precast Utility.

Precast tabletop slab sections discussed in section: Tabletop Pile Caps can be used for the utility trenches. This concept consists of a reinforced concrete or prestressed concrete platform that is integrated into the deck diaphragm. It is a durable structural element that is ideal for designs that orient pile cap beams in the longitudinal direction by creating a path for utility lines that do not interfere with key structural components along the length of the pier. Cantilevered ends and supplemental prestress should be used so that the concrete faces exposed to seawater remain uncracked under handling loads during erection and under service loads. Tie beams may be required to transfer berthing and mooring loads to the table top sections. A key element to the performance of the precast tabletop sections for utilidors is to ensure that they are watertight. Further details for tabletop slab sections can be found in TR-NAVFAC-EXWC-CI-1413, *The Use of Prestressed Concrete for Corrosion Prevention in US Navy Piers.*

2-5 LIGHTING.

Pier lighting is needed for security, safety, and operations. Provide safety and operations pier lighting in accordance with UFC 3-530-01, *Interior and Exterior Lighting Systems and Controls* and as follows:

2-5.1 Topside Lighting.

Refer to UFC 3-530-01, *Interior and Exterior Lighting Systems and Controls*. Instances of failures of high mast lighting light ring assembly failures have been reported. Additional information is contained in Appendix C. It is imperative that a registered structural engineer review all contract documents (plans and specifications) and construction contract submittals specifically related to high mast light ring assemblies. This is to ensure that design of light ring assembly provides for safe lowering, raising, and locking/securing into position.

2-5.2 Lower Deck Lighting.

Refer to UFC 3-530-01, *Interior and Exterior Lighting Systems and Controls*.

2-5.3 Underdeck Lighting.

Refer to UFC 3-530-01, *Interior and Exterior Lighting Systems and Controls*.

2-6 SECURITY.

For waterfront security and anti-terrorism/force protection criteria, refer to UFC 4-025-01, *Security Engineering: Waterfront Security*.

2-7 LANDSIDE APPROACHES.

2-7.1 Function.

Approaches are required to provide access from shore to piers and wharves located offshore. Usually, the approach is oriented at right angles to the shoreline. Except in special situations, provide approaches consisting of open-type trestle structures that minimize impediments to water flow and disturbances to the characteristics and ecology of the shoreline. Consider the volume of traffic flow, circulation of traffic, existing roads on shore side, fire lane requirements, and interruption of service due to accidental collision damage when planning and designing the landside approach. As approaches are also used to route utilities to the pier or wharf, the width of approaches will be further influenced by the space requirements of the utility lines being carried. Vehicle and pedestrian approach can usually be combined on the same structure. Consider a separate pedestrian approach when a large number of personnel are anticipated to access the facility.

2-7.2 Roadway Width.

a. Provide an approach roadway with a minimum width of 10 feet (3.1 m) curb to curb for one-lane vehicular traffic for infrequently accessed facilities (such as magnetic treatment / electromagnetic roll piers).

b. Provide an approach with a minimum width of 15 feet (4.6 m) curb-to-curb for clear access of emergency vehicles for fueling piers and wharves.

c. For all other functional types, provide a two-way 24-foot wide (7.3 m) curb-to-curb roadway. If two separate one-way approaches are provided, provide a minimum width of 12 feet (3.7 m) curb-to-curb. Notwithstanding, provide approaches with a width adequate to permit fast movement of all vehicles anticipated for use on the facility, including emergency vehicles and mobile cranes.

2-7.3 Walkway Width.

Provide a minimum clear width of 3 feet (1 m) for separate walkway structures. Where the walkway is attached to a vehicle traffic lane, provide a minimum width of 2.5 feet (0.8 m) clear, from curb to safety railing.

2-7.4 Roadway Deck Elevation.

The requirements for pier and wharf deck elevation are also applicable to the approaches. Where the adjacent land is higher or lower than pier or wharf, the approach can be sloped up or down to serve as a transition ramp. For approaches longer than 100 feet (30.5 m) limit the slope to 6 percent. For shorter approaches, limit the slope to 8 percent.

2-7.5 Number of Approaches.

2-7.5.1 One Approach.

For fueling and magnetic treatment/electromagnetic roll facilities, provide at least one single-lane approach structure, unless the facility is built as an island wharf or pier with access by watercraft.

2-7.5.2 Two Approaches.

a. Where volumes of vehicular movements are large, provide at least two approaches to ensure continuous uninterrupted traffic flows from pier or wharf to shore. At multiple-berth facilities, consider approach structures at least every 500 feet (152 m).

b. Where the width of the pier or wharf is not sufficient to permit turning of vehicles, provide two approaches. Thus, vehicular traffic may enter and leave the facility without having to turn around. Since it is easier for a truck to negotiate a left turn, design traffic patterns to favor left turns.

2-7.5.3 Railroad Access.

Where rail access is planned for either crane or railroad, a separate approach is not necessary. However, consider a separate walkway. Consider approach slope limit for crane or railroad.

2-7.6 Turning Room.

At the intersection of approach and piers and wharves, provide fillets or additional deck area at corners to allow for ease in executing turns. Where a one-lane approach roadway is provided as the only access, provide the pier or wharf with sufficient turnaround space on the facility so that outgoing vehicles do not have to back out along the approach.

2-7.7 Barriers.

On all approaches, provide safety barriers adequate for the type of traffic using the facility (pedestrian, vehicular, and/or rail). However, safety barriers should not be provided in areas where mission operations, such as ship or small craft berthing, are performed. Rail only approaches do not normally require safety barriers. Provide traffic barriers between pedestrian and traffic lanes. Conformance with AASHTO *Guide Specifications for Bridge Railings* and AASHTO *Bridge Guide and Manual Interim Specifications* is required for traffic and pedestrian barrier design.

2-8 STRUCTURAL TYPES.

2-8.1 General.

The three major structural types for piers and wharves are open, solid, and floating. Open type piers and wharves are pile supported platform structures that allow water to flow underneath. Figure 2-7 illustrates the open type. Another type of an open type pier is a jack-up barge. Solid type uses a retaining structure such as anchored sheet pile walls or quaywalls, behind which a fill is placed to form the working surface. Solid type will prevent stream flow underneath. Figure 2-7 illustrates the solid structural type. Floating type is a pontoon structure that is anchored to the seabed through spud piles or mooring lines and connected to the shore by bridges or ramps. A floating double deck pier is shown in Figure 2-8. For additional information, contact NAVFAC Atlantic - Engineering Criteria & Programs.

Figure 2-7 Open and Solid Type Piers/Wharves

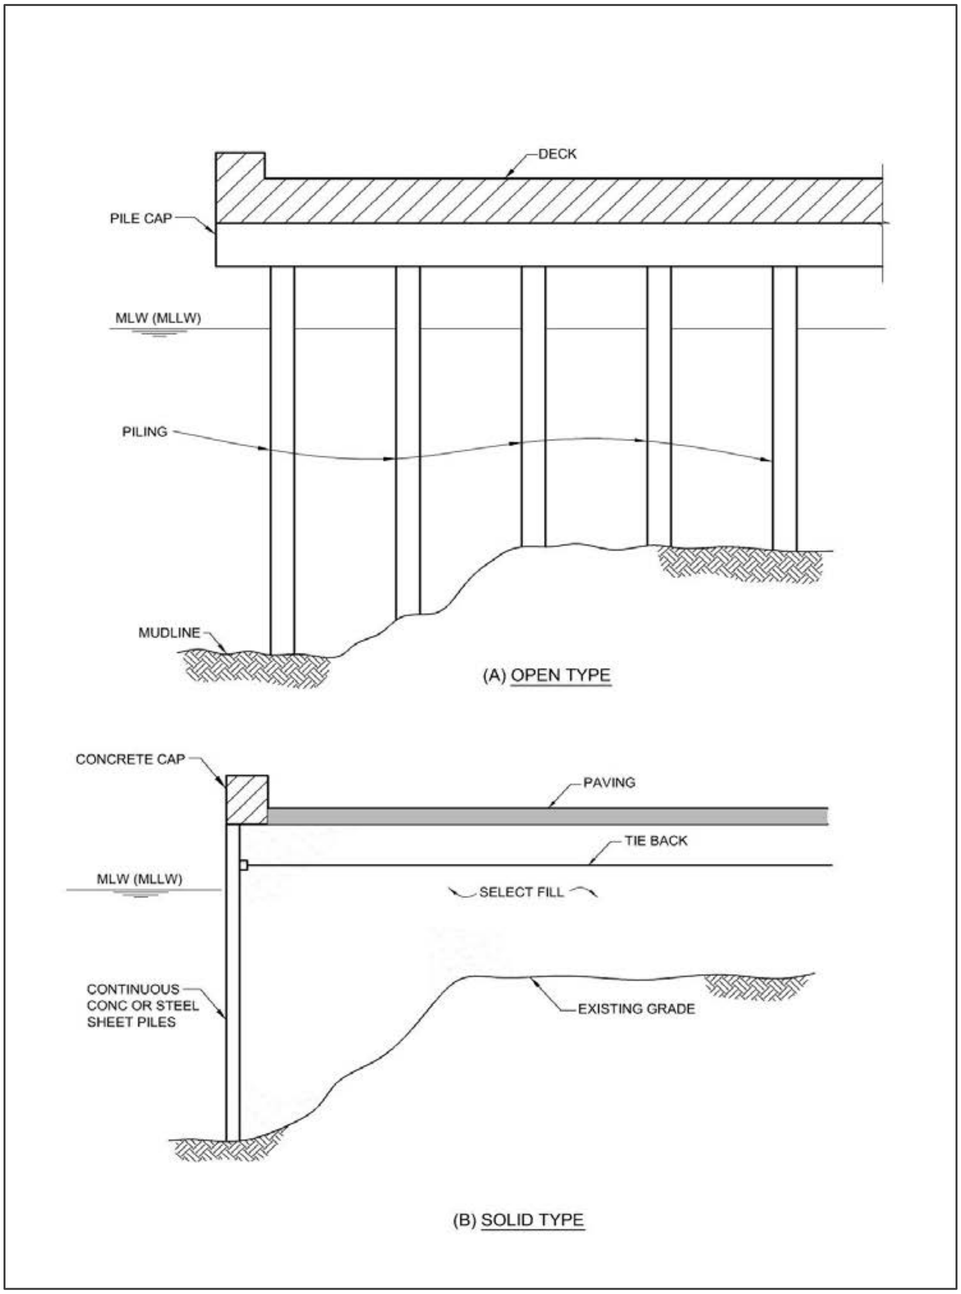

Figure 2-8 Floating Double Deck Pier

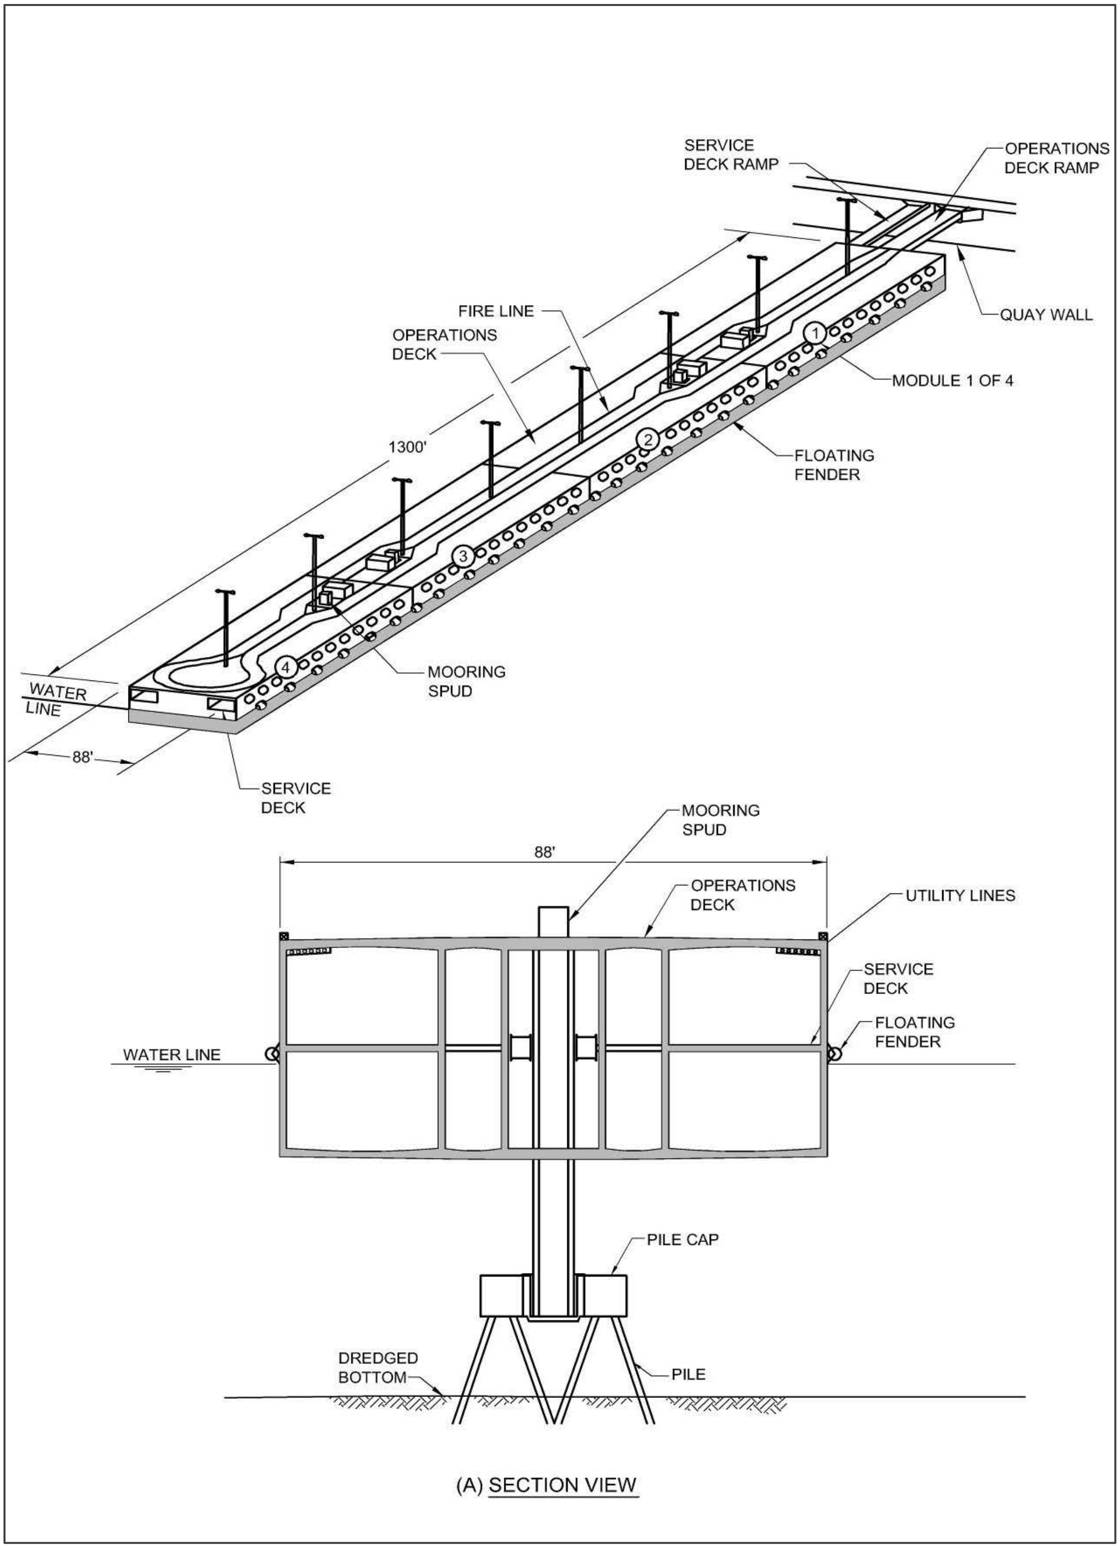


2-8.2 Selection of Type.

Numerous factors influence the selection of one structural type over the other. Evaluate each of these factors against the construction and operating costs of the facility before a final decision is made on the structural type. Place greater emphasis on selecting the type that will withstand: unexpected berthing/mooring forces, adverse meteorological and hydrological conditions, and the corrosive effects of a harsh marine environment such that it will require little or no maintenance. The geotechnical characteristics of a given site, and economic analysis of alternate structural types will often dictate structural requirements. For instance, in areas with poor near surface soils but with good end bearing for piles, an open pile supported structure with a shallow bulkhead (or no bulkhead) will be most economical. Conversely, in areas with good near surface soils and poor pile bearing, a solid bulkhead may be more economical. Consider environmental impacts when selecting type.

2-8.2.1 Shoreline Preservation.

The structural type is seriously influenced by aquatic and plant life existing along the shore of the planned facility. In environmentally sensitive areas such as river estuaries, the solid-type wharf, which would disturb or destroy a considerable length of shoreline, should not be considered. Select the open structural type, which would have the least impact on the shoreline.

2-8.2.2 Bulkhead Line.

When the facility extends beyond an established bulkhead line (the limit beyond which continuous solid-type construction is not permitted) use open type construction.

2-8.2.3 Tidal or Stream Prisms.

Where it is required to minimize restrictions of a tidal or stream prism (the total amount of water flowing into a harbor or stream and out again during a tidal cycle) use open type construction.

2-8.2.4 Littoral Drift.

Along shores where littoral currents transporting sand, gravel, and silt are present, use open type construction to mitigate shoreline erosion and accretion.

2-8.2.5 Ice.

In general, open type structures are vulnerable and should be carefully investigated at sites where heavy accumulations of sheet or drift ice occur. Also, when ice thaws, large blocks of ice may slide down the piling, impacting adjacent batter or plumb piles. Thus, the solid type may be preferable at such sites. To mitigate the effects of large blocks of ice sliding up and down the plumb and battered piles within the tide fluctuation zone, consider protecting piles from abrasion utilizing pile jackets within the tide fluctuation zone + 2 feet (0.6 m) beyond the tidal fluctuation. Consider bulkhead protection from the ice abrasion utilizing cementitious epoxy coating for the exposed surface of the sheet pile bulkhead.

2-8.2.6 Earthquake.

Consider the potential for liquefaction in areas of high seismic activity. Often, mitigation measures, such as soil improvements have been used. Recent wharf projects in Guam are good examples. P-204 Wharf Improvements Uniform and Tango used stone columns to mitigate liquefaction of soils behind a new bulkhead. P-518 X-Ray Wharf Improvements used deep soil cement mixing to mitigate liquefaction and create a soil-cement structure which would significantly reduce loads on the new bulkhead structure. When considering liquefaction, a number of good references are available, namely:

a. TR-2077-SHR, *Seismic Design Criteria for Soil Liquefaction (1997)*

b. NCEER-97-0022, *Proceedings of the NCEER Workshop on Evaluation of Liquefaction Resistance of Soils*

c. NCHRP Report 611, *Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankments (2008)*

d. ASCE 7-10, *Minimum Design Loads for Buildings and Other Structures*

e. ASCE/COPRI 61-14, *Seismic Design of Piers and Wharves*

In areas of high seismic activity, carefully consider construction utilizing sheet pile bulkheads or walls because of the high lateral earth pressures that can develop on the sheet piling. When a pile-supported platform (with curtain wall) is used for a wharf structure in conjunction with hydraulic fill, which is susceptible to liquefaction, consider a rock dike to resist the lateral forces that may be caused by liquefaction of the fill. The use of an engineered soil filter fabric between the rock dike and granular fill should also be considered. In areas of extremely high seismic risk, and where tsunamis and seiches are anticipated, seriously consider the floating type as it is less likely to be affected by or will suffer only minor damage from the seismic activity. The floating double deck pier has been developed as a viable option in areas of high seismicity. This is due to the fact that the pier structure is basically isolated from the seismic event at the interface of the pier structure and the founding shaft. Rubber arch fenders in the pier's moonpool accomplish the desired seismic isolation.

2-8.2.7 Water Depths.

Consider open type construction in all depths of water when accommodating naval vessels, cargo vessels, and tankers. Depth limits for solid-type construction, utilizing sheet pile bulkheads, are imposed by the magnitude of the applied surcharge, subsurface conditions, and freeboard of the bulkhead above the low waterline. Generally, anchored sheet pile bulkheads may be considered in water depths up to 30 to 35 feet (9.1 to 10.7 m) where favorable soil conditions exist. When greater water depths are required at solid type bulkhead structures, consider the use of relieving platforms, bulkheads consisting of reinforced high-strength steel sheet piles, or cellular construction.

2-8.2.8 Subsurface Conditions.

Generally, subsurface conditions do not limit the use of open type construction. For almost all subsurface conditions, with the possible exception of rock close to the harbor bottom surface, suitable piles or caissons can be designed. Where rock is close to the surface and pile seating may be difficult and costly, consider cellular construction. When open type construction is required in an area where rock is close to the surface, piles should be socketed and anchored into the rock. Consider sheet piling, used for bulkheads or retaining walls in conjunction with platform wharf structures or combination piers, only when subsurface conditions indicate that suitable anchorage and restraint for the toe of the sheet piling can be achieved and where select material is available for backfill.

2-8.2.9 Fill Loss.

When precast concrete and steel sheet pile bulkheads are used in pier and wharf construction, take special care to prevent fill leaching through the interlocks, causing subsidence of retained fill. Install a filter blanket or other method that could prevent or control fill leaching to reduce subsidence and consequent paving maintenance.

2-8.2.10 Construction Time.

Where an existing pier or wharf has to be replaced in active naval stations, the floating type has the advantage of minimizing the "downtime." Conventional construction may take too long where the loss of berths cannot be tolerated. The floating type in such situations may turn out to be the most expedient.

2-8.2.11 Ship Contact.

In certain situations, where tugboats or camels are not available, sheet pile bulkheads located along the offshore face of pier and wharf structures may be less desirable than open type construction because of the greater danger for contact between the sheet piling and the bulbous bow or sonar dome of a ship during berthing and unberthing maneuvers.

2-8.2.12 Track Mounted Crane.

Where a track-mounted crane is required for the pier or wharf, the solid type may not be suitable. The susceptibility of the solid filled type to settlement and movement will make it very difficult to maintain the close tolerance required for rail gage, elevation, and alignment. The surcharge loading on the sheet pile will also be considerable. For such cases, use an independent pile supported track.

2-8.3 Construction.

Several aspects of construction that are unique to each structural type should be considered.

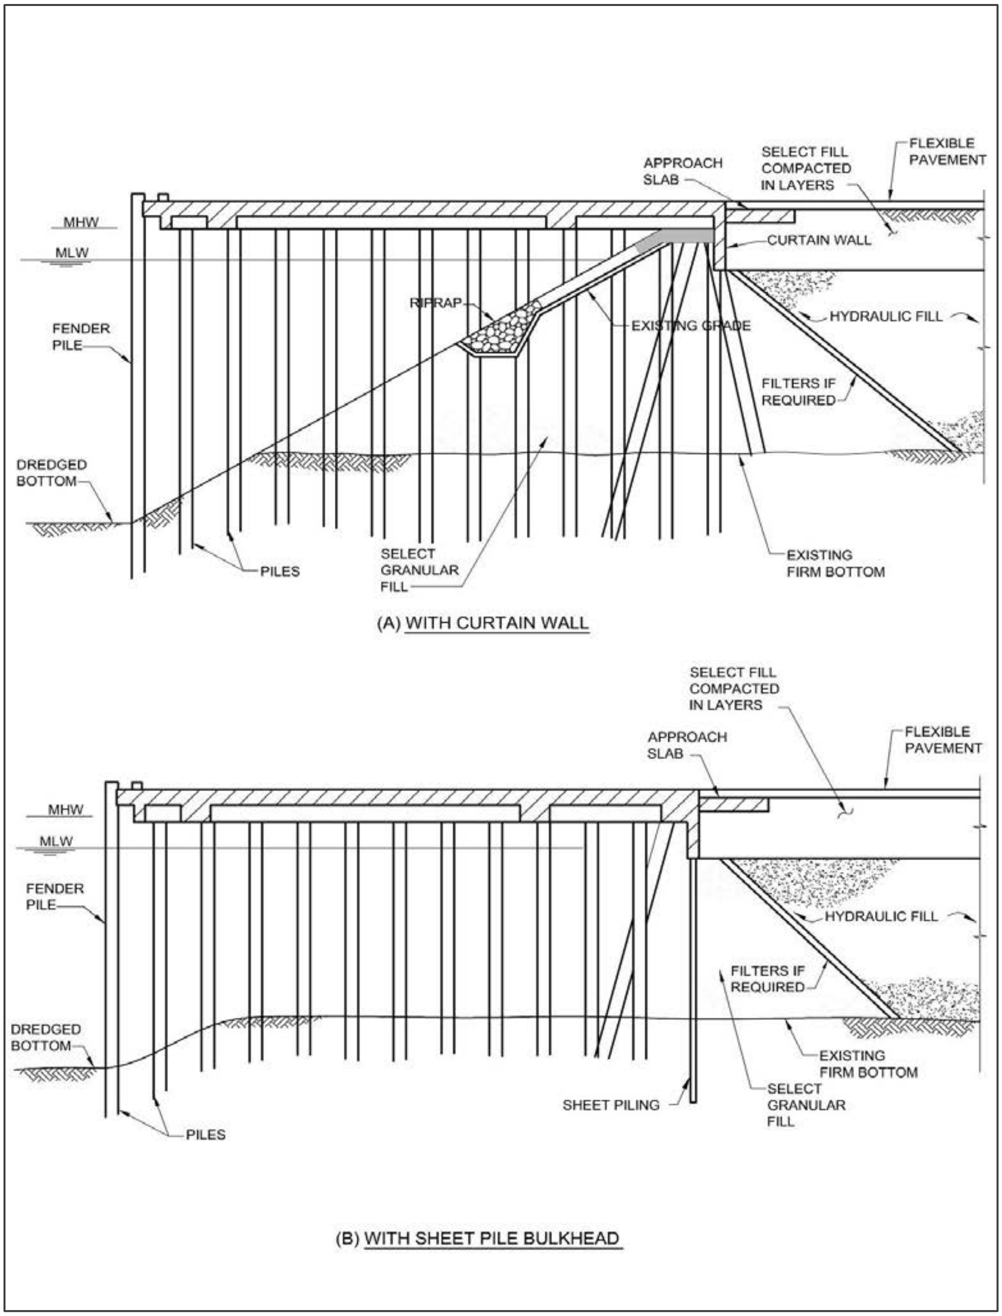
2-8.3.1 Open.

For open type wharves and landside ends of open piers, the following schemes should be considered for retaining upland fill:

a. Platform on Piles and a Curtain Wall at the Inshore Face. See Figure 2-9. The underwater slope should be as steep as possible, as limited by both constructional and geotechnical parameters, thus making the pile-supported platform narrow and more economical. In seismically active areas, where hydraulic fill susceptible to liquefaction is used for upland fill, a rock dike may be used instead of the granular fill dike to resist the lateral forces caused by liquefaction of the fill. The use of a filter fabric also should be considered at the hydraulic fill interface.

b. Platform on Piles and a Sheet Pile Bulkhead at the Inshore Face. See Figure 2-9. The sheet pile bulkhead permits a narrower platform. The cost tradeoff between platform width and bulkhead height should be investigated as the bulkhead may be found to cost as much or more than the pile supported platform width saved.

Figure 2-9 Open Type Wharf Concepts



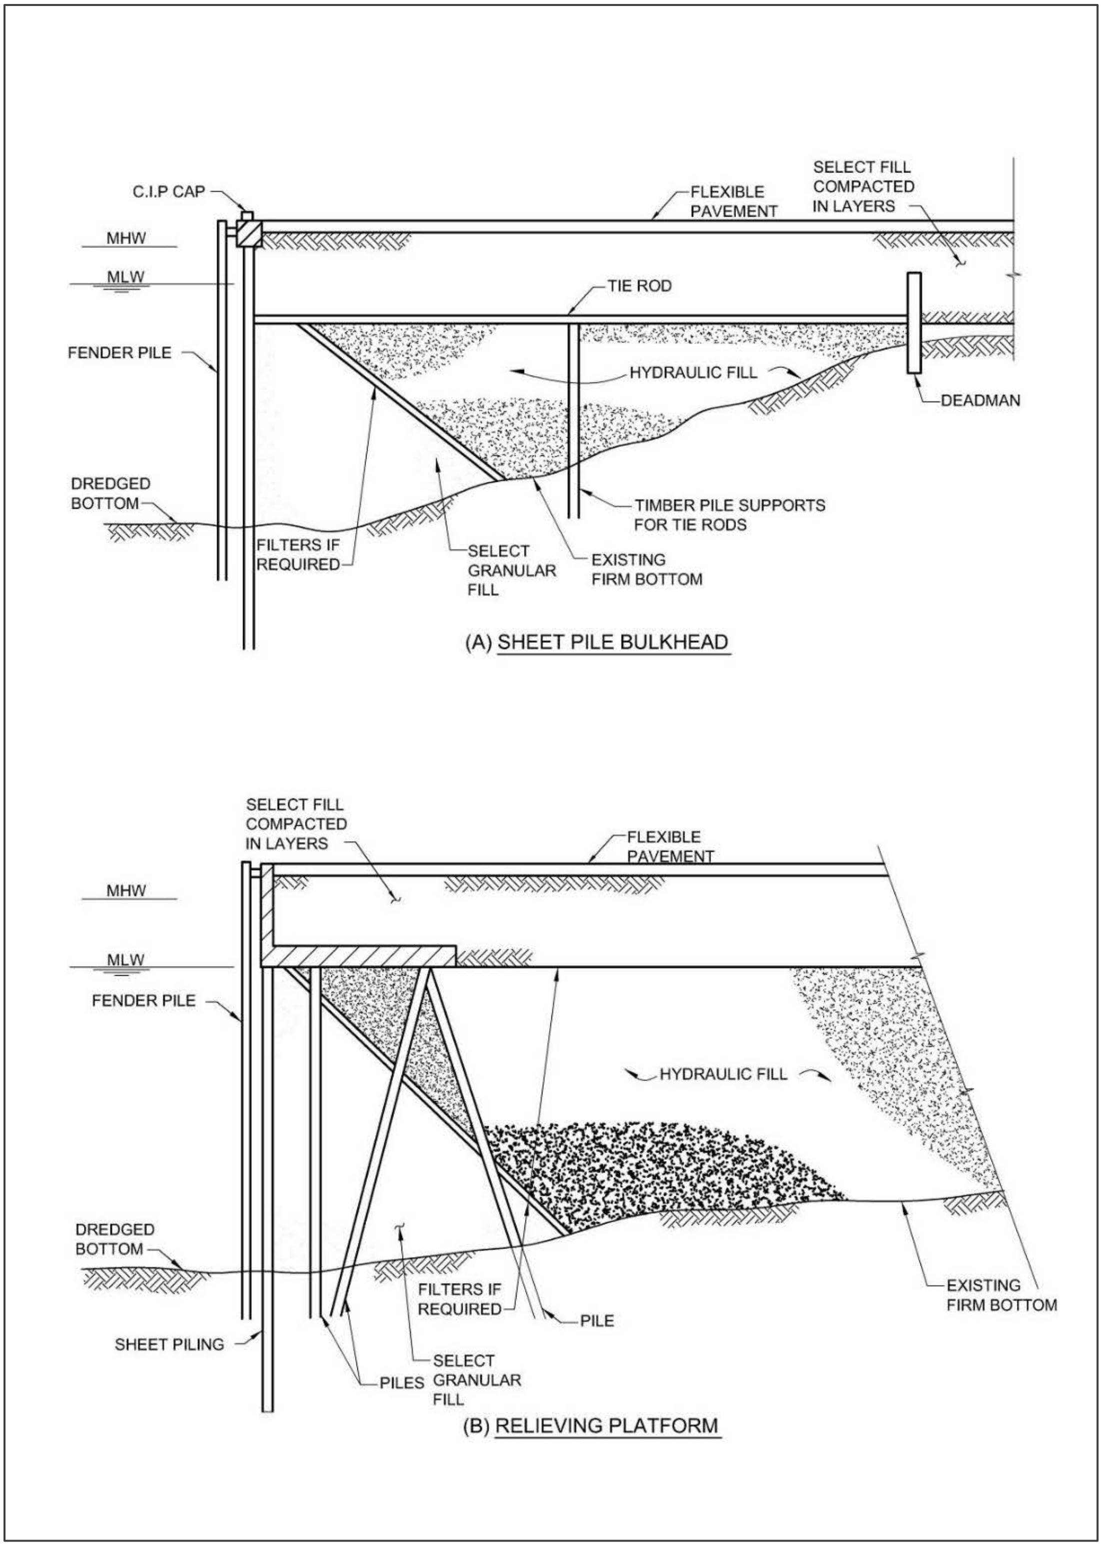
2-8.3.2 Solid.

Retaining structures may be constructed by the following means:

a. Sheet Pile Bulkhead. See Figure 2-10. The bulkhead consists of a flexible wall formed of steel or concrete sheet piling with interlocking tongue and groove joints and a cap of steel or concrete construction. The bulkhead is restrained from outward movement by placing an anchorage system above the low water level. Many types of anchorage systems can be used. The most common types in use in the United States consist of anchor rods and deadman anchors. The latter could be made of concrete blocks, steel sheet piling, or A-frames of steel, concrete, or timber piles. In countries outside the United States, an anchorage system consisting of piles, attached near the top of the sheet pile bulkhead and extending at batters up to 1 on 1 to embedment in firm material, is often used. Rock or earth anchors consisting of high-strength steel rods or steel prestressing cables are sometimes preferred in place of the anchor batter piles. Provide granular free-draining material adjacent to sheet pile bulkheads, extending from dredged bottom to underside of pavement on grade. Grade this material to act somewhat as a filter to limit subsequent loss of fines through the sheet pile interlocks. Placement of free-draining material should be in stages, commencing at the intersection of sheet piling and dredged bottom and progressing inshore. Eliminate mud and organic silt pockets. In general, do not consider hydraulic fill for backfill unless provision is made for the effects of fill settlement, potential liquefaction of fill in seismic zones, and high pressure exerted on sheet piling. Consider vibro-compaction for consolidation of hydraulic fill. In areas with tidal ranges greater than 4 feet (1.2 m), provide 2 inch (51 mm) diameter weep holes for the sheet piles above the mean low water level. If a waterline is located behind the bulkhead, provide weep holes. When weep holes are used, provide graded filters to prevent loss of finer backfill material. Provide openings in pavement or deck for replenishment of material in order to compensate for loss and settlement of fill. In general, flexible pavement using asphaltic concrete is preferred over rigid pavement with Portland cement concrete, as it is more economical to maintain and better able to accommodate underlying settlement.

b. Sheet Pile Bulkhead and Relieving Platform. The relieving platform is used in conjunction with a sheet pile bulkhead to reduce the lateral load on the sheet piling created by heavy surcharges and earth pressures. See Figure 2-10. Lateral restraint is provided by the batter piles supporting the relieving platform. A variation of this type of construction is to use only vertical piles for the relieving platform and to furnish an independent anchorage system consisting of tie rods and deadman, similar to the types specified for sheet pile bulkheads.

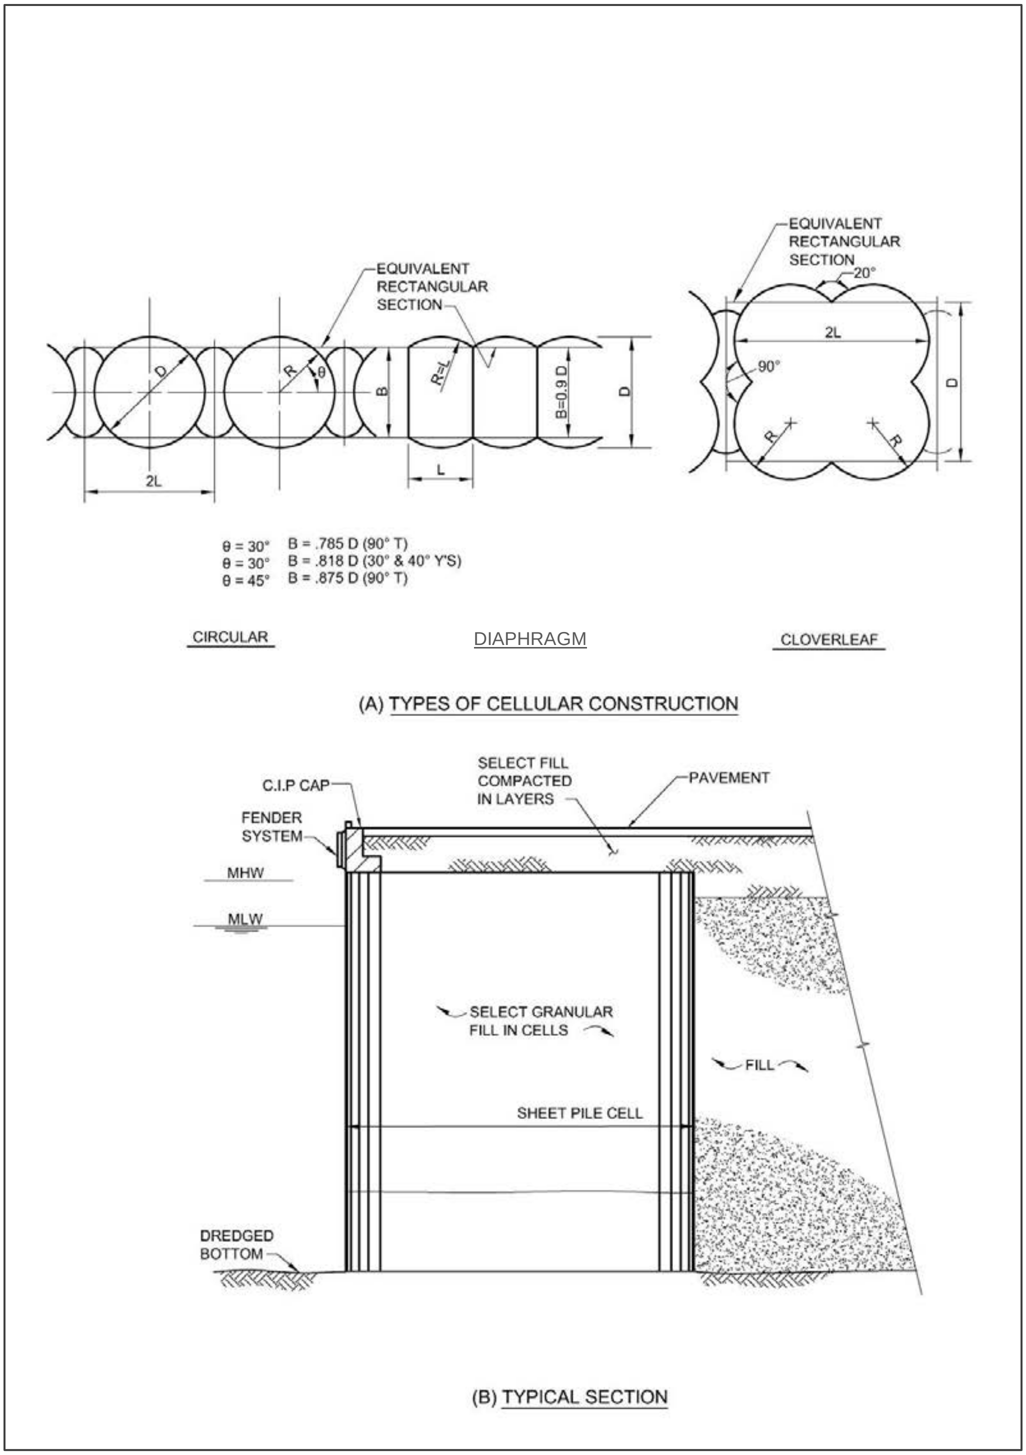
Figure 2-10 Closed Type Wharf Concepts



c. Cellular Construction Consisting of Sheet Pile Cells. For design procedures and selection of type, see UFC 3-220-01, *Geotechnical Engineering* and USACE EM 1110-2-2503, *Engineering and Design: Design of Sheetpile Cellular Structures, Cofferdams, and Retaining Structures.* Cellular structures are gravity retaining structures formed from the interconnection of straight steel sheet piles into cells. Strength of cellular structures derives from resistance to shear caused by friction and tension in the sheet pile interlocks and also from the internal shearing resistance of the fill within the cells. Accordingly, clean granular fill materials such as sand and gravel are usually used to fill the cells. Exercise extreme care in the construction of cellular structures because excessive driving onto boulders or uneven bedrock may cause ruptured interlocks, which can later unzip under hoop tension (from filling) and cause failures of the cell. Similarly, carefully control all aspects of fill placement, as cofferdams can unzip and cause sudden (little to no warning) failures of the cell. Compensate for movement and expansion of cells during construction of the cells and carefully control fill placement to satisfactorily maintain alignment of the face of the wharf. A concrete facing may be employed to protect the steel within the tidal zone. Cellular structures are classified according to the configuration and arrangement of the cells. The basic types are discussed below and are shown on Figure 2-11.

- Circular. This type consists of individual large-diameter circles connected together by arcs of smaller diameter. Each cell may be completely filled before construction of the next cell is started. Construction of this type is easier than the diaphragm type because each cell is stable when filled and thus may be used as a platform for construction of adjacent cells. Because the individual cells are self-supporting units, accidental loss of one cell will not necessarily endanger adjoining cells. Compared to a diaphragm type cellular structure of equal design, fewer piles per linear foot of structure are required. The diameter of circular cells is limited by the maximum allowable stresses in the sheet pile interlocks and, when stresses are exceeded, cloverleaf cells are used.
- Diaphragm. This type consists of two series of circular arcs connected together by diaphragms perpendicular to the axis of the cellular structure. The width of cells may be widened by increasing the length of the diaphragms without raising interlock stress, which is a function of the radius of the arc portion of the cell. Fill cells in stages so that the heights of fill in adjoining cells are maintained at equal levels to avoid distortion of the diaphragm walls. Diaphragm type cells present a flatter faced wall than circular cells and are considered more desirable for marine structures.

Figure 2-11 Solid Type, Cellular Construction



- Cloverleaf. This type is a modification of the circular cell type and is generally used in deep water where the diameter required for stability would result in excessively high interlock stress if diaphragms were not added.
- Modified Open Cell. This type relies on steel sheet walls as a form of tieback to the fill.

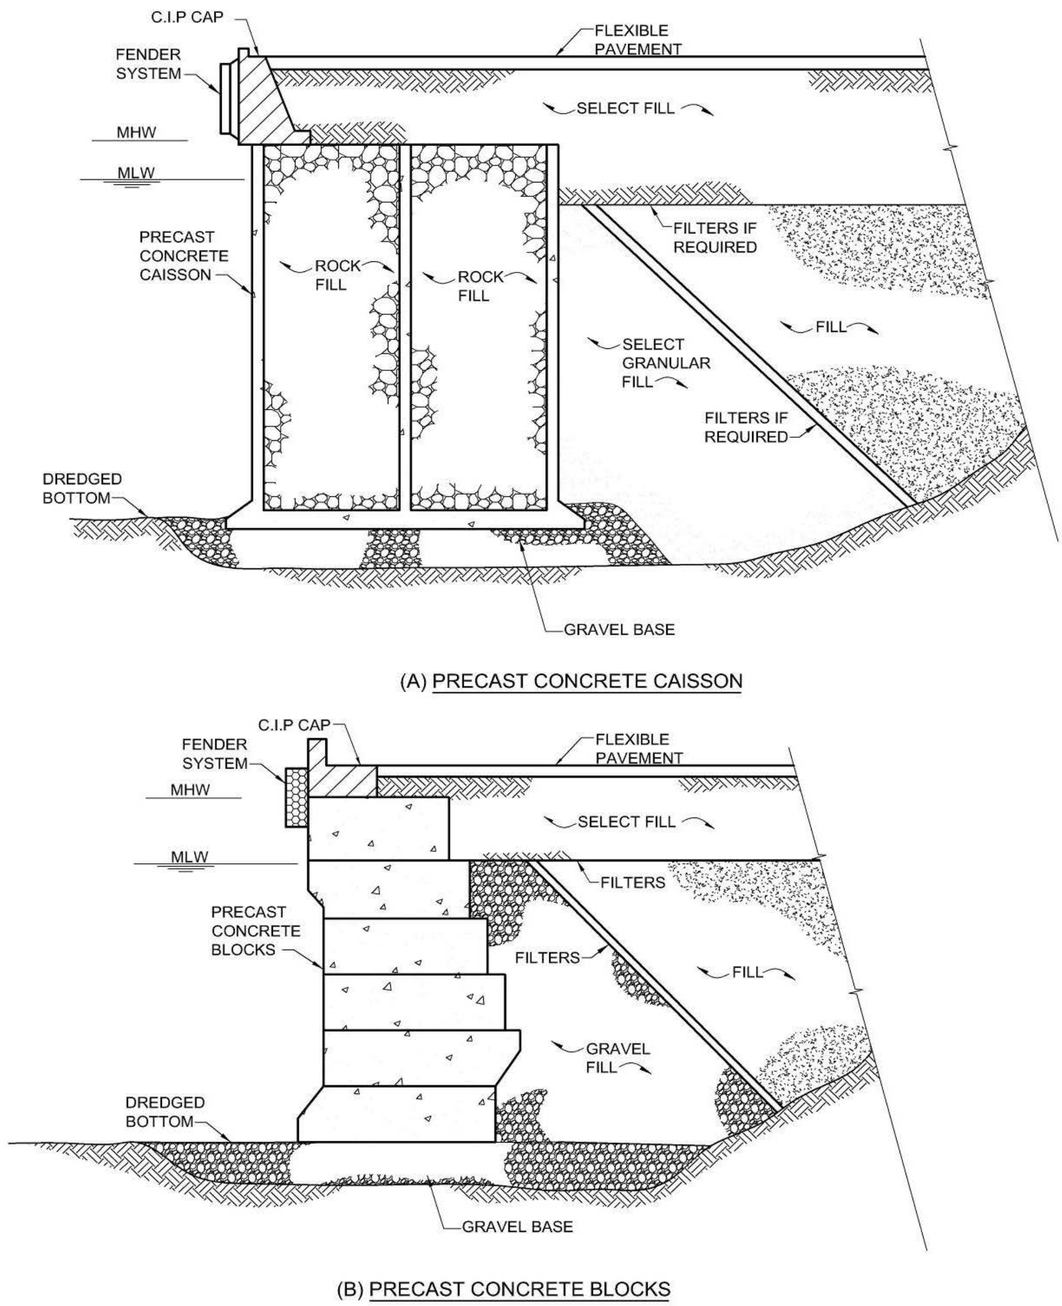
d. Reinforced Concrete Caisson. See Figure 2-12. In this type of construction, concrete caissons are cast in the dry, launched, and floated to the construction site where they are sunk on a prepared foundation. The caisson is filled with gravel or rock and a cast-in-place retaining wall is placed from the top of the caisson to the finished grade. This type of construction is prevalent in countries outside the United States. Reinforced concrete caissons come in two variations: closed and open end caissons (caissons without the bottom slab). Closed end caissons are normally floated and then sunk in place. Open bottom caissons are barge delivered, but are easier to install and have better rotational stability due to mobilization of the infill soil shear action (see cellular cofferdams). Closed end caissons require sub base leveling and sub base stabilization for prevention of the caisson roll off, particularly in areas with extreme wave climate. Sometimes, caissons are fabricated as the ring modules, barge delivered and preassembled at the site prior to installation.

e. Precast Concrete Blocks. See Figure 2-12. This form of solid wharf is a gravity type wall made up of large precast concrete blocks resting on a prepared bed on the harbor bottom. A select fill of granular material is usually placed in the back of the wall to reduce lateral earth pressures. This type of construction is popular outside the United States.

2-8.3.3 Floating.

Construction of the floating type usually requires a flood basin, graving dock, or dry dock. The units are essentially constructed in the dry and floated out and transported (on their own or on barges) to the site. Availability of such a facility and transportation of the floating units through open ocean waters and restricted inland waters for deployment at the site are serious considerations. In this respect, the floating type has a significant advantage over others in that the bulk of construction activity can be shifted to other parts of the country where labor, economic, and environmental conditions are more favorable. Other concepts of construction such as barge-mounted construction and floating-form construction are described in NCEL UG-0007, *Advance Pier Concepts, User's Guide*.

Figure 2-12 Solid Type, Caisson and Concrete Block Construction



2-8.3.4 Jack-up Barge.

This type consists of a structural steel seaworthy barge provided with openings for steel caissons, which are lowered to the harbor bottom when the barge has been floated into final position. The barge may be completely outfitted during construction with ship fenders, deck fittings, and utilities including power, lighting, communications, water supply, sanitary facilities, etc., so that once it is jacked into position and utility tie-ins are made, it is ready to receive ships. Circular pneumatic gripping jacks, mounted on the deck above the caisson openings, permit the barge to be elevated in steps. The barge is loaded with steel caissons, a crane for pile erection, and other tools and materials required for the fieldwork, and is towed to the site. At the site, the barge is moved into approximate position and the caissons are dropped through the jacks and hull by the crane. The caissons, suspended above the harbor bottom and supported by engaging the jacks, are then released and seated into the harbor bottom by dead weight. The barge-like deck is jacked to the required elevation and locked. Each caisson is then released from its jack and driven to refusal or required penetration. When all caissons are driven, the hull of the barge is welded to the caisson, the jacks are removed, and the caissons are cut off flush with the deck and capped with steel plates. In some situations, the caissons are filled with sand to avoid buoyancy problems. Jack-up barge type structures are also constructed using hydraulic jacks and open-trussed towers instead of pneumatic jacks and circular caissons.

2-9 HYDRAULIC FILL.

The soil drawn up by the suction head of a dredge, pumped with water through a pipe, and deposited in an area being filled or reclaimed is referred to as "hydraulic fill." At port and terminal facilities, where land is not available onshore and where dredging is required to provide adequate water depths for vessels at berths and approach channels, hydraulic fill is commonly used for land reclamation because of its availability and low cost. Hydraulic fill may be of good quality, consisting of granular materials, or may consist of plastic organic silt, which is considered poor quality. When hydraulic fill is used, investigate the stability of the structure retaining the fill, taking into consideration the effects of adjacent surcharge loadings in addition to the loadings from the fill. The placement of a select granular fill adjacent to the retaining structure may be required if the hydraulic fill is of poor quality. Hydraulic fill is in a loose condition when placed. To avoid fill settlements due to loadings from other structures, stacked cargoes, and mobile equipment, stabilization of the fill may be required. In areas of seismic activity, investigate the liquefaction of hydraulic fills. Stability with regard to both settlements and liquefaction may be enhanced by methods such as deep densification or by use of sand drains. Material other than hydraulic fill should be used when the cost of material obtained from onshore borrow areas is cheaper than the cost of material obtained from offshore borrow areas or where good quality fill material is required and is not available offshore.

CHAPTER 3 LOAD REQUIREMENTS

3-1 GENERAL.

Where loading conditions exist that are not specifically identified in this UFC, rely on accepted industry standards. Where applicable, reference is made to UFC 3-301-01, *Structural Engineering*. However, in no case will other standards supersede the requirements provided by this UFC.

3-2 DEAD LOADS.

3-2.1 General.

The dead load consists of the weight of the entire structure, including all the permanent attachments such as mooring hardware, light poles, utility booms, vaults, sheds, and service utility lines. A realistic assessment of all present and future attachments should be made and included. For floating piers and wharves, overestimating of dead loads would overstate draft and could have a significant effect on cost.

3-2.2 Unit Weights.

Use actual and available construction material weights for design. See Table 3-1 for unit weights that should be used for construction materials (unless lesser unit weights can be demonstrated by local experience). Pertinent information may also be found in ASCE 7, *Minimum Design Loads for Buildings and Other Structures.*

Table 3-1 Unit Weights

Material	Unit Weight (pcf)
Steel or cast steel	490
Cast iron	450
Aluminum alloys	175
Timber (untreated)	40 to 50
Timber (treated)	45 to 60
Concrete, reinforced (normal weight)	145 to 160
Concrete, reinforced (lightweight)	90 to 120
Compacted sand, earth, gravel, or ballast	150
Asphalt paving	135 to 150

3-3 VERTICAL LIVE LOADS.

3-3.1 General.

Although a number of loading conditions will be presented in subsequent sections, the advent and subsequent heavy usage of mobile cranes on piers will generally produce the controlling loading condition. For example, on a general purpose berthing pier, a design drawing will typically present different design live loads including uniform, vehicular (i.e. HS 20-44), forklift, and maximum outrigger float load. The outrigger load from the mobile crane invariably controls with the other loads more or less provided for informational purposes. Further, it is incumbent upon the designer to identify and document all of the particular loadings associated with his design that may not be included in the discussions in this section.

3-3.2 Uniform Loading.

See Table 3-2 for recommended uniform loadings for piers and wharves. Impact is not applied when designing for uniform loads.

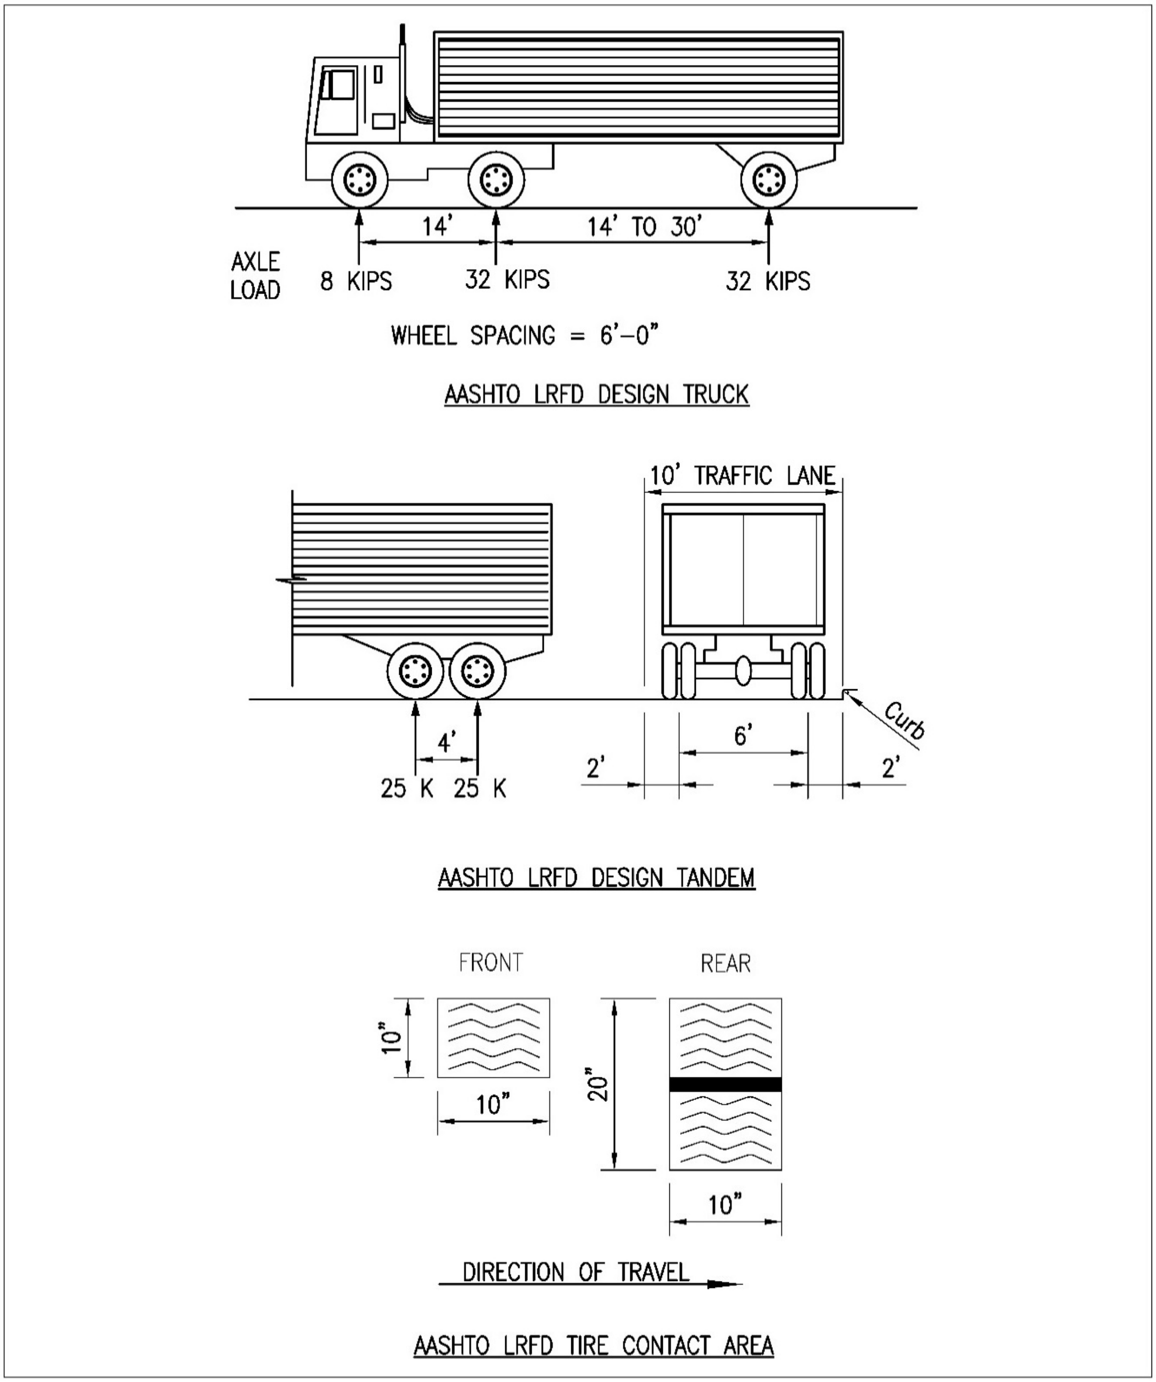
Table 3-2 Vertical Live Loads for Pier and Wharf Decks

Classification	Uniform Loading (psf)	Mobile Crane (tons)	Rail-Mounted Crane (tons)	Other Handling Equipment (tons)
Ammunition	600	90	--	20-lift truck
Berthing (carriers)	800	140	--	20-lift truck
Berthing (all others)	600	90	--	20-lift truck
Berthing (submarines)	600	90	--	20-lift truck
Repair	600	140	60/151 Portal	20-lift truck
Fueling	300	50	--	10-lift truck
Supply (general cargo)	750	140	--	20-lift truck
Supply (containers)	1,000	140	40/50 (long tons) Container	20-lift truck 33-straddle carrier

3-3.3 Truck Loading.

Calculate truck wheel loads in accordance with the AASHTO *Standard Specifications for Highway Bridges* except as modified below. Figure 3-1 is provided to show both AASHTO LRFD Design Truck and Design Tandem. In the design of slabs, beams, and pile caps, apply an impact factor of 15 percent. Structural elements below the pile caps need not be designed for impact. When truck loading is transferred through 1.5 feet (0.46 m) or more of crushed rock ballast and paving, and for filled construction, the impact forces need not be considered for design. Also, check with local activity for use of an overload vehicle such as weapons cradles, missile hauling vehicles, etc. which may have significantly higher wheel loads.

Figure 3-1 AASHTO LRFD Design Truck and Design Tandem



3-3.4 Rail-Mounted Crane Loading.

3-3.4.1 Portal Cranes.

For design of new piers and wharves, obtain specific crane wheel loads for the actual crane to be used. If the crane resources are not known at the time of design, consult the Navy Crane Center for design loading and crane procurement. When choosing design wheel loads, provide flexibility, considering different makes of cranes and ultimate crane replacement as well as future use of the pier or wharf. Piers and wharves have greater longevity than rail-mounted cranes. To this end, a wheel load of 110,000 pounds (489 kN) minimum on 4-foot (1.2 m) centers allows for a practical range of options. See Table 3-2 for typical rated capacities of cranes for a variety of pier and wharf deck uses.

Figure 3-2 lists a sampling of wheel loads for 60 ton (534 kN) and 151 ton (1343 kN) capacity portal cranes recently procured by the Navy. These cranes were procured around capacities of existing piers and wharves and have wheel loads that are somewhat restrictive for new design. The values provided are typical for existing equipment used by the Navy and are useful for design feasibility studies on existing structures. The rail gage should be approximately 30 feet (9.1 m) minimum for a 60 ton (534 kN) capacity portal crane, and up to 40 feet (12.2 m) for a portal crane of 100 tons (890 kN) capacity or greater. For handling of fuel containers at repair piers, portal cranes with up to 151-ton (1343 kN) capacity are required.

3-3.4.2 Container Cranes.

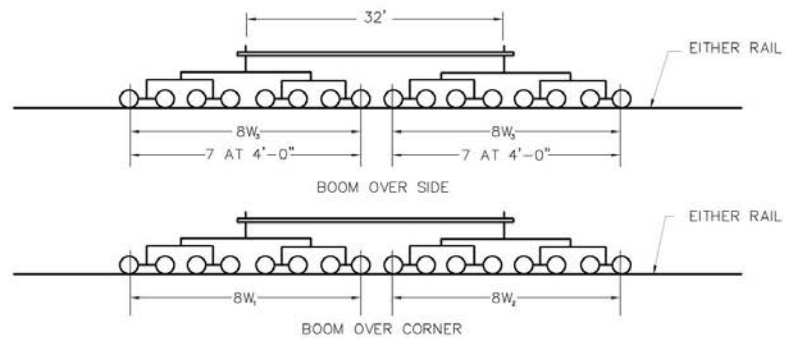
See Figure 3-3 for crane configuration and wheel loads of container cranes and Table 3-2 for the rated capacities of container cranes applicable to piers and wharves. The configuration and wheel loads are derived from several manufacturers and should be used only as a guide. A recent trend in the shipment of containerized cargo is to use larger ships, and this is the driving force in the design of container cranes. The size of the ship to be serviced will dictate the capacity, configuration, operational characteristics, and gage of the crane. The evolution in container crane design has been to increase the gage to 100 feet (30.5 m) and outreach on the boom to 150 feet (45.7 m) and larger while maintaining the lift capacity between 40 and 50 long tons (399 and 498 kN). Hence, specific information on the size of the ship to be serviced and details from the crane manufacturer needs to be obtained for final crane design.

3-3.4.3 Wheel Load Uncertainty.

Portal and container cranes are usually procured separately from the construction funds. The maximum allowable wheel loads are normally specified on the crane procurement documents. The number and spacing of wheels are critical to the structural capacity of an existing facility and structural design of a new facility. Having established the required capacity and configuration of a crane, the designer of a pier or wharf should consult with the Navy Crane Center and obtain wheel loads for which the supporting structure should be designed. In the absence of hard information, the 110,000 pound (489 kN) wheel load presented in the previous paragraph on portal cranes may be used. However, the container crane wheel loads presented in Figure 3-3 are only provided as a guide. Determine the design characteristics noted in the previous paragraph on container cranes in order to determine realistic wheel loads.

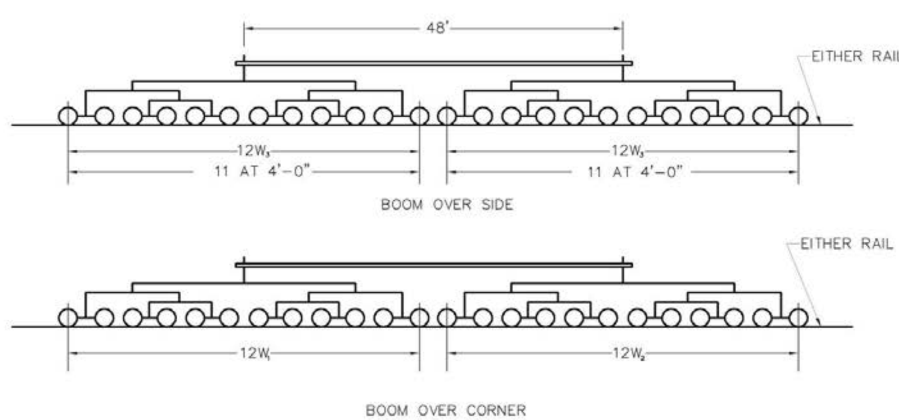
Figure 3-2 Wheel Loads for Portal Cranes

60 Ton Portal Crane



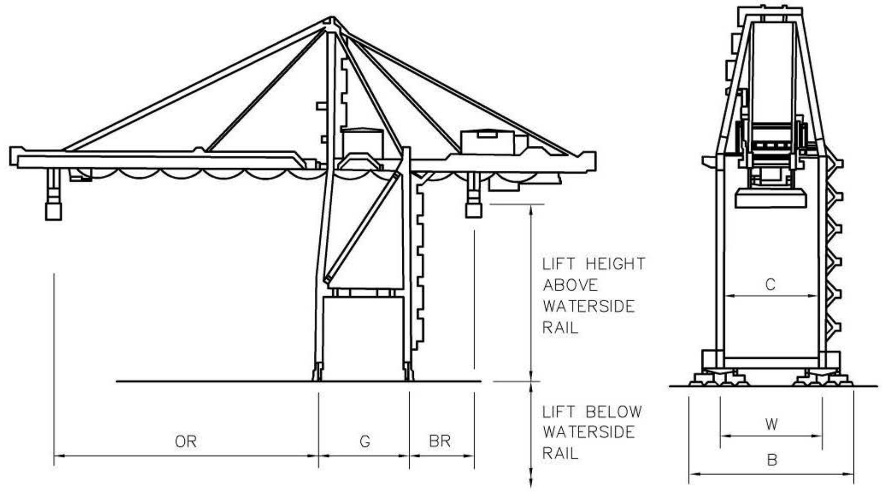
Main Hook Capacity	Rail Gage (ft)	Boom Over Corner		Boom Over Side
		W_1 (lbs)	W_2 (lbs)	W_3 (lbs)
120,000 lbs. at 90ft.	18	83,000	52,000	72,000
90,000 lbs. at 110 ft.	20	80,000	48,000	70,000
* 40 ft gage cranes have a jib extension and increased boom hinge height. "Boom over side" position is parallel to the rails for the 40 ft gage.	30	73,000	41,000	62,000
	40*	71,000	49,000	64,000

151 Ton Portal Crane



Main Hook Capacity	Rail Gage (ft)	Boom Over Corner		Boom Over Side
		W_1 (lbs)	W_2 (lbs)	W_3 (lbs)
302,000 lbs. at 65ft. 200,000 lbs. at 90 ft. 146,000 lbs. at 110 ft. 123,000 lbs. at 120 ft.	18	81,000	65,000	76,000
	40	70,000	58,000	65,000

Figure 3-3 Configuration and Wheel Loads for Container Cranes



ITEM			CRANE CAPACITY	
			40' LONG TONS	50' LONG TONS
GAUGE – G			50' TO 100'	100'
OUTREACH – OR			115' TO 155'	125' TO 172'
BACK REACH–BR			30' TO 60'	30' TO 60'
WHEEL BASE – W			45' TO 55'	45' TO 55'
CONTAINER CLEARANCE – C			55' TO 60'	55' TO 60'
BUMPER TO BUMPER – B			79' TO 90'	85' TO 90'
WHEEL SPACING (8 WHEELS/LEG)			4' TO 5'	4.5' TO 5'
LIFT HEIGHT ABOVE WATERSIDE RAIL LIFT HEIGHT BELOW WATERSIDE RAIL			90' TO 110' 55'	89' TO 110' 65'
MAXIMUM WHEEL LOAD IN KIPS (UNFACTORED WITH 10 PSF WIND)	OPERATING	WATERSIDE RAIL	87^k TO 120^k	110^k TO 170^k
		LANDSIDE RAIL	75^k TO 112^k	95^k TO 125^k
	STOWED	WATERSIDE RAIL	56^k TO 135^k	90^k TO 150^k
		LANDSIDE RAIL	60^k TO 150^k	100^k TO 165^k

3-3.4.4 Impact.

Apply an impact factor of 25 percent to the maximum listed wheel loads for the design of deck slab, crane girders, and pile caps. The impact factor is not applicable to the design of piles and other substructure elements.

3-3.5 Mobile Crane Loadings.

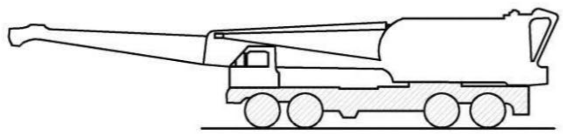
The deck design for open and floating structural types of piers and wharves is usually controlled by mobile crane loading. However, the operational constraints imposed by under specifying mobile crane loadings are severe. Consequently, take care to specify realistic loading. Refer to Table 3-2 for designated mobile cranes applicable to each functional type of pier and wharf. As a minimum design the pier or wharf for the designated mobile crane, however, check with the local activity to confirm whether a crane larger than that designated could be used at the facility, as the additional structural design cost for larger mobile cranes may be minimal at the preliminary design stage. Larger cranes may be used at a facility provided the demands are less than that of the design cranes listed in Figure 3-4, and Table 3-3. To assist the facility determine suitability of larger cranes provide the following on the design drawings structural notes:

- The maximum single outrigger load, ground bearing pressure.
- The maximum double outrigger load, ground bearing pressure, outrigger spacing.
- The maximum single axle load, tire pressure, footprint.
- The maximum multiple axle load, tire pressure, footprint, axle spacing, maximum number of axles.

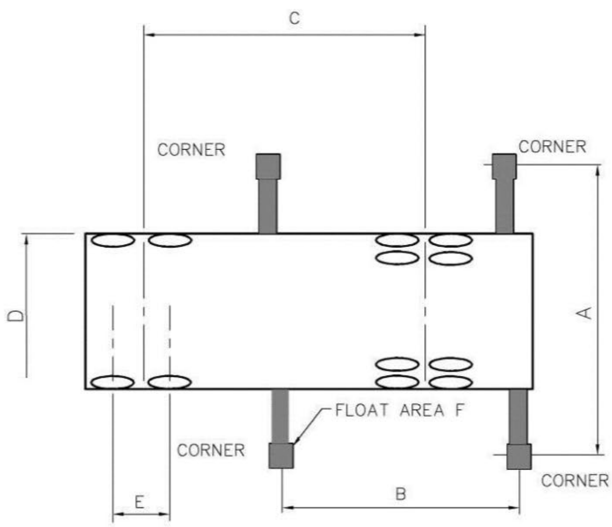
3-3.5.1 Wheel Loads.

See Figure 3-4 for wheel loads for 50-, 70-, 90-, 115-, and 140-ton capacity mobile cranes. The information in Figure 3-4 is for typical truck cranes, although rough-terrain type mobile cranes are also used on piers and wharves. Tire contact area should be as defined by AASHTO LRFD. As a rule of thumb, ground pressures for "on rubber" lifts are about 10 percent higher than tire inflation pressure. Crane manufacturers recommend that the majority of lifts be made on outriggers. In addition, capacities for "on rubber" lifts are substantially less than for "on outrigger" lifts. Hence, loads for "on rubber" lifts are not listed. Design all piers and wharves and their approaches for the wheel loads from the designated truck crane.

Figure 3-4 Wheel Loads and Dimensions for Truck Cranes



CRANE TRAVELING – BOOM OVER FRONT



CRANE TRAVELING – WHEEL LOADS WITH BOOM OVER FRONT				CRANE DIMENSIONS					
CRANE CAPACITY	TOTAL WEIGHT (lbs)	FRONT AXLE LOAD (lbs)	REAR AXLE LOAD (lbs)	A (ft)	B (ft)	C (ft)	D (ft)	E (ft)	F (in^2)

3-3.5.2 Outrigger Float Loads.

Table 3-3 lists outrigger float loads for different capacity cranes. The maximum single float load from a boom over corner position and maximum concurrent pair of float loads from a boom over side and back positions are listed. Typically, the float loads are at the maximum when lifting the rated load at a short radius (20 feet (6.1 m) and less) and should be used for design. However, for existing piers and wharves, the other listed loads may be used to analyze deck capacity. Typical outrigger float spacing is shown in Figure 3-4. Apply outrigger float loads to a 1.5 foot by 1.5 foot (0.46 m by 0.46 m) area unless actual float size is known, in which case use the actual float size for analysis.

3-3.5.3 Impact.

Apply an impact factor of 15 percent for all wheel loads when designing slab, beams, and pile caps. The impact factor need not be applied when designing for maximum outrigger float loads, piles and other substructure elements, filled structures, and where wheel loads are distributed through paving and ballast (1.5 foot (0.46 m) or more).

3-3.6 Forklift and Straddle Carrier Loadings.

3-3.6.1 Forklifts.

See Figure 3-5 for wheel loads from forklifts. Determine contact areas for wheel loads in accordance with AASHTO. For hard rubber wheels or other wheels not inflated, assume the wheel contact area to be a point load.

3-3.6.2 Straddle Carriers.

See Figure 3-6 for wheel loads for a straddle carrier. The straddle carrier shown is capable of lifting a loaded 20-foot (6.1 m) container or a loaded 40-foot (12.2 m) container.

3-3.6.3 Impact.

Apply an impact factor of 15 percent to the maximum wheel loads in the design of slabs, beams and pile caps. The impact factor need not be applied when designing piles and other substructure elements, when designing filled structures, and where wheel loads are distributed through paving and ballast (1.5 feet (0.46 m) or more).

3-3.7 Loading on Railroad Tracks.

For freight car wheel loads, use a live load of 8000 pounds per foot (117 kN/m) of track corresponding to Cooper E-80 designation of the American Railway Engineering Association (AREA) *Manual for Railway Engineering*. In the design of slabs, girders, and pile caps, apply an impact factor of 20 percent. Impact is not applicable for the design of piles and filled structures, or where loads are distributed through paving and ballast (1.5 feet (0.46 m) or more).

3-3.8 Buoyancy.

Typically, piers and wharf decks are not kept low enough to be subjected to buoyant forces. However, portions of the structure, such as utility trenches and vaults, may be low enough to be subject to buoyancy forces, which are essentially uplift forces applied at the rate of 64 psf (3064 kPa), for normal seawater at sea level, of plan area for every foot of submergence below water level.

3-3.9 Wave Loading.

For piers and wharves exposed to waves which may produce significant lateral or hydrostatic forces, determine wave loading in accordance with the procedures defined in UFC 4-150-06, *Military Harbors and Coastal Facilities.* Consider also that wave loading, may be vertical, resulting in uplift on the structure.

MINIMUM (40ft. CONTAINER)	(L)	25'–4"

3-3.10 Application of Loadings.

3-3.10.1 Concentrated Loads.

Wheel loads and outrigger float loads from designated pneumatic-tired equipment, such as trucks, truck cranes, forklifts, and straddle carriers may be oriented in any direction and the orientation causing the maximum forces on the structural members should be considered for design. Significant loads from fuel containers (exceeding 300 kips (1334.5 kN)) at repair piers may be encountered. Design manhole covers and frames for pneumatic-tired equipment only. Design trench covers, utility trench covers, and access hatch covers to handle the concentrated loads, where they are accessible to mobile equipment. However, designated areas on the pier deck may be exempted from wheel loads or outrigger float loads, or designed for lesser loads, when curbs, railings, and other physical barriers are provided to isolate those areas from vehicle access. Concentrated wheel loads from these vehicles are applied through small "footprints" to the deck structure. The distribution of these loads and computation of maximum moments and shears may be in accordance with the AASHTO *Standard Specification for Highway Bridges*. However, this method is conservative and more reasonable results may be obtained using NCEL R-935, *Lateral Load Distribution on One-Way Flat Slab*; *Influence Surfaces for Elastic Plates,* for different edge conditions, or finite element analysis. Maximum mobile crane concentrated loads should not be combined with maximum wind, seismic, mooring or berthing loads.

3-3.10.2 Simultaneous Loads.

Apply uniform and concentrated live loads in a logical manner. Do not apply designated uniform live loadings and concentrated live loading from pneumatic-tired equipment simultaneously in the same area. However, apply uniform live load between crane tracks (for 80 percent of gage). When railroad tracks are present between crane tracks, apply track loads simultaneously. However, the maximum loads from each track need not be assumed. Unique operations may warrant a more conservative approach, i.e., during a “trans-shipment operation” (handling of fuel containers), there could be a portal crane straddling a railroad car loaded with a container, with another container sitting on the pier deck in the immediate vicinity.

3-3.10.3 Skip Loading.

For determining the shear and bending moments in continuous members, apply the designated uniform loadings only on those spans that produce the maximum effect.

3-3.10.4 Critical Loadings.

Concentrated loads from trucks, mobile cranes, forklifts, and straddle carriers, including mobile crane float loads, are generally critical for the design of short spans such as deck slabs and trench covers. Uniform loading, mobile crane float loading, rail-mounted crane loading, and railroad loading are generally critical for the design of beams, pile caps, and supporting piles.

3-4 HORIZONTAL LOADS.

3-4.1 Berthing Energy.

Procedures for calculation of berthing energy are found in the subsequent section: BERTHING ENERGY DETERMINATION of this UFC.

3-4.2 Mooring Loads.

Forces acting on a moored ship are produced by winds, currents, and waves. The determination of mooring loads involves an evaluation of many variables including: direction and magnitude of winds, currents, and waves; exposure of the berth; orientation of the vessel; number and spacing of mooring points; layout and type of mooring lines; tides; and the loaded condition of the vessel (light, one-third stores, fully loaded). In sheltered waters where piers and wharves are usually constructed, wave forces are not significant and may be ignored. Type III and Type IV mooring design requires 30-second gust, 50 and 100 year return period wind speed respectfully. The wind speed provided in UFC 3-301-01, *Structural Engineering* is a 3-second gust with a return period from 300 to 1,700+ years, depending upon the importance of the structure. Therefore, in order to attain the appropriate wind speed for mooring design of Type III and IV structures, a procedure is required for converting: the 3-second gust to a 30-second gust (referenced at a 33 feet (10.1 m) height above mean sea level), and for determining 50 year and 100 year Exposure D design winds. This is illustrated below for converting to a 50 year return period wind (associated with Mooring Service Type III):

Step 1: Convert 1700 year return period wind speed to 50 year return period wind speed.

V_{1700} = 124 mph (Naval Station Norfolk: Cat III-V; 1700 year return wind)

$V_{50\text{-}3sec} = V_{1700} / (0.36 + 0.1*LN(12*1700))$ = 92 mph (Peterka & Schahid 1998)

Step 2: Convert 3 second wind gust to a 30-second wind.

$V_{50\text{-}30sec} = V_{50\text{-}3sec} / 1.175$ = 78 mph (UFC 4-159-03 Fig 3-5, Hurricane Region)

Step 3: Convert wind from Exposure C value to Exposure D.

$V_{III} = V_{50\text{-}30} * \text{sqrt}(1.18)$ = 85 mph (74 knots) – Type III Mooring Design Wind

Procedures for calculation of mooring loads are found in UFC 4-159-03, *Design: Moorings*. Local anchorage design of the mooring foundation shall exceed the working capacity of the fitting times the Mooring load factor for LRFD design. Global design of the pier or wharf is based on the demands from the mooring analysis (e.g. not all of the storm bollards will be engaged at one time).

3-4.3 Wind Loads on Structures.

Use UFC 3-301-01, *Structural Engineering* to provide minimum wind load on structures. Keep in mind that UFC 3-301-01 is based wind is a 3-second gust with a return period of 300 years or greater, thus wind on structure typically will not be combined with berthing, or mooring loads (e.g. vacant condition).

3-4.4 Loads on Piles.

In addition to the axial loads, bending moments, and shears caused by lateral loads at deck level due to berthing, mooring and seismic forces, piles are also subjected to other types of lateral loads acting along the length of the pile. Keep in mind that, in areas having large tidal ranges, lateral loads are applied much lower than the deck elevation creating significant shear and flexural stresses in the piles.

3-4.4.1 Current and Waves.

These loads are applied at and near the water level and may be significant where large size piles are used in high-current waters. An estimate of current and wave forces can be made using the UFC 4-150-06, *Military Harbors and Coastal Facilities.*

3-4.4.2 Sloping Fill Loads.

These loads are transmitted along the shaft of the piles by the lateral movement of the soil surrounding the piles beneath the structure, such as may occur along a sloping shoreline at marginal wharves, as shown in Figure 2-9. The maximum moments in the piles for this category of loading are determined by structural analysis and the methods outlined in UFC 3-220-01, *Geotechnical Engineering,* after the conditions of pile support in the pile cap and the soil have been established and the effective length of pile has been determined.

Piles of relieving platform types of solid wharves, shown on Figure 2-10, may be subjected to lateral earth loads if the stability of the slope beneath the platform is minimal and soil creep occurs. In such cases, stabilizing measures should be introduced, prior to installation of piles, to prevent movement of the soil along the slope. Among the stabilizing measures that may be used are surcharging (preloading), installation of sand drains or soil compaction piles, or replacement of unstable materials. If the piles supporting the structure are used to increase slope stability, or if time-dependent stabilizing measures are introduced after the piles are in place, calculate the resistance to soil movement provided by the piles and the piles checked for the bending moments induced by the calculated lateral earth loads, in addition to the increased loading caused by the downdrag of the settling soil.

The pile resistance to soil movement may be obtained from a stability analysis by determining the additional resistance, provided by the piles, which will provide a factor of safety that corresponds to zero soil movement. The minimum factor of safety required for this type of analysis varies and should be selected after evaluating the soil conditions, which exist at the site. The embedment length of piles needed for developing the required lateral resistance may be determined in accordance with the criteria given in UFC 3-220-01*, Geotechnical Engineering*.

3-4.4.3 Pile Driving Loads.

Piles are subjected to high compressive and tensile stresses during driving and should be proportioned to resist these in addition to the service loads. Where prolonged driving in alternately soft and hard layers of soil or driving through stiff "quaky" clays is anticipated, very high tensile stresses are set up and will require a higher level of effective prestress (1000 psi (6895 kPa) or more) in prestressed concrete piles. Give attention to controlling driving stresses by specifying frequent cushion replacement, and by requiring use of hammers capable of adjusting driving energy.

3-4.5 Loads on Utilities.

Utilities should be located above pier deck. It is important to keep utilities high above the water level and preferably protected in trenches. In some cases utilities are located under the pier deck and are therefore, more susceptible to damage from wind, wave, current, and impact from debris. Regardless of utility location, consider environmental loads, e.g. wind, wave, current. In evaluating these loads, consideration must also be given to the appropriate water level. An estimate of current and wave forces can be made using the UFC 4-150-06*, Military Harbors and Coastal Facilities.*

3-4.6 Earthquake Loads.

Use the procedures and methods contained in ASCE/COPRI 61-14 *Seismic Design of Piers and Wharves,* hereafter known as ASCE 61, for seismic design of Piers and Wharves unless otherwise directed herein. Note that the ASCE 61 committee made a conscious decision to reference ASCE 7-05 throughout and not to include ASCE 7-10, mainly because ASCE 7-10 was published after the ASCE/COPRI 61-14 had been prepared. The ASCE 61 committee will reconsider referencing the most recent version of ASCE 7 in future versions.

3-4.6.1 Design Approach:

Use the design approach from Section 3.4 of ASCE 61 as modified below unless approval for an alternative approach is obtained from the approving authority.

a. Define the Design Classification in accordance with Table 3-4.
b. Determine which performance levels along with associated hazard levels need to be satisfied per ASCE 61 Table 2-1.
c. Determine the design method per 3-4.6.3.
d. Base definition of ground motion for Design Earthquake (DE) on the procedures in ASCE 7-10, see 3-4.6.4.
e. Determine soil/structure modeling parameters (p-y and t-z springs) per ASCE 61 Sections 4.8 and 4.10.

f. Determination of other special geotechnical considerations or loads in ASCE 61 Chapter 4.

g. Development of the structural model, including general modeling considerations of ASCE 61 Section 3.7.

h. Calculations of structural demands per ASCE 61.

i. Calculation of structural capacity per ASCE 61.

j. Development of connection details per ASCE 61 Chapter 7.

k. Design of ancillary components per ASCE 61 Chapter 8.

3-4.6.2 Design Classification.

Table 3-4 Seismic Design Classifications

Classification	Pier/Wharf
High [a]	Ammunition Fueling Supply Explosive Handling General Purpose Berthing Repair Magnetic Silencing Access Trestle Deep Water Bulkhead
Moderate [b]	
Low	Inactive Berthing Cargo Staging Area Shallow Water Bulkhead Seawalls and Riprap Fleet Landing Small Craft Berthing Small Craft Boat Ramp

[a] Only consider Operating Level Earthquake when S_{DS} exceeds 0.33
[b] Site/project specific considerations may dictate moderate versus high or low classification

3-4.6.3 Determine Seismic Analysis Procedure:

a. Non-linear time history analysis should be considered for high value national assets such as Explosive Handling Wharves when warranted.

b. Displacement-based design is permitted for all design classifications.

c. Force-based design is permitted for “low” design classifications per Table 3-4.

d. Force-based design is permitted for all design classifications when S_{DS} < 0.33

e. Force-based design is permitted for all design classifications where it can be demonstrated that the capacity of all primary structural members exceeds the elastic earthquake demand when using a value of R = 1.0.

f. Force-based design is permitted for the design of equipment, piping supports, and minor structures.

g. Allowable stress design (ASD) is permitted for geotechnical design of shallow and deep foundations when the soils report does not contain LRFD soils values.

3-4.6.4 Design Spectra.

In the absence of a site specific ground motion study reference tables from UFC 3-301-01, *Structural Engineering* for Design Earthquake (DE), 10/50 and 20/50 spectral acceleration values. For structures with a High Performance Level and S_{DS} >0.33, use the following equation to determine the spectral acceleration values associated with ground motion with a probability of exceedance of 50% in 50 years (72 year return period):

The spectral acceleration values for earthquakes with a 2 and 10% probability of exceedance in a 50-year period are typically well defined. To obtain seismic spectral accelerations for other recurrence intervals use the following formula based upon the procedure presented in Section 1.6.1.3 of FEMA 356, *Prestandard and Commentary for the Seismic Rehabilitation of Buildings*.

$$S_i = S_{i(10/50)} (C_i)$$

where:

S_i = Spectral acceleration parameter ("*i*" = "*s*" for short-period, or "*i*" = "1" for 1-second period)

$S_{i(10/50)}$ = Spectral acceleration parameter ("*i*" = "*s*" for short-period, or "*i*" = "1" for 1-second period) at a 10 % probability of exceedance in 50 years

C_i = Modifier provided in Tables 3-5 and 3-6 below ("*i*" = "*s*" for short-period, or "*i*" = "1" for 1 second period).

Table 3-5 Values of C_S, Modifier for Short-Period Spectral Acceleration

Design Earthquake Probability of Exceedance in 50 Years

Region	10%	15%	20%	50%	65%	75%
California	1.0	0.83	0.72	0.44	0.36	0.32
Pacific Northwest	1.0	0.79	0.67	0.36	0.29	0.25
Eastern US	1.0	0.72	0.56	0.23	0.17	0.14
Other locations	1.0	0.79	0.67	0.36	0.29	0.25

Notes:

1. The modifier C_s includes a statistical adjustment factor, "P_R ", and a location adjustment factor, "n", as defined in section 1.6.1.3 in FEMA 356, *Prestandard and Commentary for the Seismic Rehabilitation of Buildings*, Nov. 2000. The value of "n" is taken as 0.54 for locations outside of the continental US.

2. This table is valid at locations where the Mapped MCE spectral acceleration for short-periods, S_S, is less than 1.5*g*.

Table 3-6 Values of C_1, Modifier for 1-Second Period Spectral Acceleration

Design Earthquake Probability of Exceedance in 50 Years

Region	10%	15%	20%	50%	65%	75%
California	1.0	0.83	0.72	0.44	0.36	0.32
Pacific Northwest	1.0	0.77	0.64	0.33	0.26	0.22
Eastern US	1.0	0.71	0.55	0.22	0.16	0.13
Other locations	1.0	0.77	0.64	0.33	0.26	0.22

Notes:

1. The modifier C_1 includes a statistical adjustment factor, "P_R ", and a location adjustment factor, "n", as defined in section 1.6.1.3 in FEMA 356, *Prestandard and Commentary for the Seismic Rehabilitation of Buildings*, Nov. 2000. The value of "n" is taken as 0.59 for locations outside of the continental US.
2. This table is valid at locations where the Mapped MCE spectral acceleration for short-periods, S_S, is less than 1.5g.

3-4.6.5 Dynamic Fill Loads.

In general, piles subjected to seismic forces behave as flexible members and their behavior is controlled primarily by the surrounding soil. Both vertical and batter piles move together with the surrounding soil during an earthquake. Provided that shear failure or liquefaction of the surrounding soil does not occur during ground shaking, the pile-supported structure will move a limited amount and remain stable after an earthquake. The magnitude of the horizontal movement depends on the earthquake magnitude and duration, design details of the platform, flexibility of the piles, and the subgrade modulus of the foundation soil. If the soil surrounding the piles is susceptible to liquefaction or if slope failure occurs, the piles will move excessively, resulting in serious damage to the piles and the structure. For these conditions, remove and replace unstable materials. When the piles penetrate a deep soft layer first and then a stiff layer of soil, the soils displace cyclically back and forth during an earthquake. During the cyclic ground shaking, the piles will move with the ground and return essentially to their original position if the soil does not fail during these cyclic displacements. Accordingly, if piles are to continue to safely support loads after an earthquake, it will be necessary for the piles to have the capability to withstand the induced curvature without failure.

3-4.6.6 Embankments and Fills.

For determining the stability of embankments and fills at solid wharves, when subjected to earthquake forces, refer to UFC 3-220-01, *Geotechnical Engineering*, NCEL TR-939, *The Seismic Design of Waterfront Retaining Structures* and NCHRP Report 611, *Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankments*.

3-4.6.7 Floating Structures.

Usually, floating structures are not directly affected by seismic events. However, waves created by offshore seismic activity such as a seiche or tsunami will affect floating structures. Also, the mooring system employed (spud piles and chain) will be subjected to the ground motions and should be investigated.

3-4.6.8 Earthquake Induced Hydrodynamic Loads.

Refer to STANDARD 61 Section 3.7.3 "*for 24 in. and smaller piles hydrodynamic mass may be ignored*." For larger piles include the hydrodynamic water mass inside and outside of the pile/structure in accordance with STANDARD 61 Section 3.7.3.

3-4.6.9 Crane Wharf Interaction.

Refer to STANDARD 61 Sections 3.7.3 and 8.5.2. "The mass of container cranes shall be determined in accordance with Section 8.5.2 and distributed over the length of the pier or wharf."

3-4.6.10 Dry Docks.

Refer to MIL-STD 1625D (SH) *Safety Certification Program for Dry docking Facilities and Shipbuilding Ways for U.S. Navy Ships* as it relates to seismic requirements for dry docks. Reference requires that a new seismic analysis be performed for dry docks and specifies design earthquake levels and performance criteria. Method(s) of performing analysis is currently under development by NAVFAC EXWC.

3-4.7 Earth and Water Pressures on Retaining Structures.

Consider the effects of tidal lag, overdredging, the potential for dredge depth increases to accommodate deeper draft vessels, and sloughing of fill.

3-4.7.1 Static Case.

Static earth pressures, acting on retaining structures, are determined in accordance with the criteria detailed in UFC 3-220-01*, Geotechnical Engineering.*

3-4.7.2 Dynamic Case.

Seismic forces may cause increased lateral earth pressures on earth retaining wharf structures accompanied by lateral movements of the structure. The degree of ground shaking that retaining structures will be able to withstand will depend, to a considerable extent, on the margin of safety provided for static loading conditions. In general, wharf retaining structures, designed conservatively for static loading conditions, may have a greater ability to withstand seismic forces than those designed, more economically, by less conservative procedures. Methods for determining lateral earth pressures due to seismic forces are discussed in UFC 3-220-01, *Geotechnical Engineering*, NCEL TR-939, *The Seismic Design of Waterfront Retaining Structures* and NCHRP Report 611, *Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankments*.

3-4.7.3 Water Pressure.

Consider pressures due to water level differentials, resulting from tidal fluctuations (tidal lag) and/or groundwater accumulations, in the design of sheet pile bulkheads, cells, and curtain walls, and in stability investigations for embankments and fills. Consider additional loading due to hydrodynamic pressure for retaining structures as addressed in UFC 3-220-01*, Geotechnical Engineering*.

3-4.8 Thermal Loads.

3-4.8.1 Temperature Differential.

The effect of thermal forces that build up in the structure due to fluctuations in temperature will vary from those measured at the time of construction. For piers and wharves, the large body of adjacent water has a substantial moderating effect on the structure. Consequently, the structure may not attain an overall temperature 10 to 20 °F (5.6 to 11.1 °C) higher or lower than the water temperature. The effect will be even less for ballasted deck construction (5 to 10 °F (2.8 to 5.6 °C) higher or lower than water temperature). However, unballasted decks may see a large temperature differential through depth. Consult with AASHTO for recommended thermal gradients over water. Solid-type piers and wharves and floating structures are not likely to be affected by temperature variations.

3-4.8.2 Pile-Supported Structures.

Typically, decks of pile-supported structures will be subjected to temperature differential. However, since the axial stiffness of the deck elements will be much higher than the flexural stiffness of piles, the deck will expand or contract without any restraint from piles (for narrow marginal wharves, the short inboard piles may offer some restraint, and hence need to be analyzed) and will subject the piles to bending moments and shear forces. Locate batter piles so as not to restrain thermal motion (usually in the middle portion of a long structure).

3-4.9 Ice Forces.

In addition to the weight of accumulated ice on the structure, consider the forces exerted by floating ice. The principal modes of action of floating ice are shown in Figure 3-7 and discussed below.

Figure 3-7 Principal Modes of Ice Action

NO.	DESCRIPTION	TYPICAL ENVIRONMENT	ILLUSTRATION
1	IMPACT OF MOVING SHEETS AND FLOES.	RIVERS AT BREAK-UP. COASTAL WATERS WITH APPRECIABLE CURRENTS	2	STATIC PRESSURE FROM EXPANDING OR CONTRACTING SHEETS.	LAKES, SHELTERED COASTAL WATERS. TEMPERATURE CHANGES AND JACKING BY REFREEZING OF CRACKS.	3	SLOW PRESSURE FROM ICE PACK OR JAM.	EXPOSED COASTAL WATERS, RIVERS.	4	VERTICAL MOVEMENT	TIDAL LOCATIONS WITH HEAVY ICE BUILD-UP.	
3-4.9.2 Dynamic Impact.

Follow the criteria in the AASHTO standard to the extent feasible. For lightly loaded structures and for open pile platforms, these criteria may result in structures of unreasonable proportions. In such cases, consider reducing the AASHTO criteria in accordance with CSA-S6 *Canadian Highway Bridge Design Code*. See AASHTO *Dynamic Ice Forces on Piers and Piles*. The values of effective pressure are:

- AASHTO .... 400 psi (2,758 kPa)
- CSA-S6 .... 100 to 400 psi (689 to 2,758 kPa) (highway bridges)
- CSA-S6 .... 200 to 250 psi (1379 to 1,724 kPa) (wharf piles)

3-4.9.3 Static Pressure.

Freshwater ice will exert less pressure on a structure than seawater ice of the same thickness. For freshwater ice, assume pressures of 15 to 30 psi (103 to 207 kPa). For sea ice, pressures of 40 psi (276 kPa) to as much as 150 psi (1,034 kPa) may be assumed. These are maximum values and relate to crushing of the ice. If the ice sheet can ride up on the nearby shore, the pressure exerted will be less than if the ice sheet is confined within vertical boundaries.

3-4.9.4 Slow Pressure.

Broken ice flows will exert less pressure than a solid ice sheet. In general, the pressures developed in this mode of action will be less than those experienced under the static pressure mode of action. Reliable values of pressure are not presently available.

3-4.9.5 Vertical Movement.

Assume that the structure will lift or depress a circular sheet of ice. Calculate the radius of the affected ice sheet on the basis of the flexural strength of ice as 80 to 200 psi (552 to 1,379 kPa). Check the shear on the basis of the strength (and adhesion) as 80 to 150 psi (552 to 1,034 kPa). Consider the formation of bustle (added thickness) of ice around the structure. See AASHTO *Ice Pressure on Engineering Structures*.

3-4.10 Shrinkage.

Open pier and wharf decks, which are usually constructed from concrete components, are subject to forces resulting from shrinkage of concrete from the curing process. Shrinkage loads are similar to temperature loads in the sense that both are internal loads. For long continuous open piers and wharves and their approaches, shrinkage load is significant and should be considered. However, for pile-supported pier and wharf structures, with cast-in-place concrete pile caps and decks, the effect is not as critical as it may seem at first because, over the long time period in which the shrinkage takes place, the soil surrounding the piles will slowly "give" and relieve the forces on the piles caused by the shrinking deck. The PCI Design Handbook (section 7.3.1.1) and ACI 209.2R 08, *Guide for Modeling and Calculating Shrinkage and Creep in Hardened Concrete* are recommended for design.

3-4.11 Creep.

This is also a material-specific internal load similar to shrinkage and temperature and is critical only to prestressed concrete construction. The creep effect is also referred to as rib shortening and should be evaluated using the *PCI Design Handbook.*

3-5 LOAD COMBINATIONS.

3-5.1 General.

Proportion piers and wharves to safely resist the load combinations represented by Tables 3-7 and 3-8. Analyze each component of the structure and foundation elements for all the applicable combinations.

3-5.2 Load Symbols.

The following load symbols are applicable for Table 3-7 and Table 3-8:

D = Dead load

L_u = Live load (uniform)

L_c = Live load (concentrated)

I = Impact load (for L_c only)

B = Buoyancy load

H = Loads due to lateral earth, ground water, or pressure of bulk material

Be = Berthing, for Accidental Berthing see section: Accidental Berthing

C = Current load on structure

EQ = Earthquake load

k = 50% of Peak Ground Acceleration (PGA)

k' = 0.7k = (0.7)(0.5)PGA = (0.35)PGA

W = Wind or wave load on structure

M = Mooring/Breasting load

R = Creep/rib shortening

S = Shrinkage

T = Temperature load

Ice = Ice load (includes snow load)

3-5.3 Load and Resistance Factor Design (LRFD).

Load combinations are presented in Table 3-7. For load cases not listed consult IBC Section 1605.2.

3-5.4 Service Load Design/Allowable Stress Design (ASD).

Load combinations are presented in Table 3-8. For load cases not listed consult IBC Section 1605.3.

Table 3-7 Load Combinations - Load and Resistance Factor Design (LRFD)

Load	U0	U1	U2	U3	U4	U5	U6	U7	U8	U9

CHAPTER 4 STRUCTURAL DESIGN

4-1 CONSTRUCTION MATERIALS.

4-1.1 Timber.

For the major functional types of piers and wharves such as ammunition, berthing, repair, and supply facilities subject to high concentrated wheel loads, timber construction should not be considered. Timber may be more effective and optimal for fender systems, dolphins, walkways, utility trays, and deck-supported small buildings. For light-duty piers and wharves, such as fueling, temporary, and Magnetic Treatment and Electromagnetic Roll piers, timber framing for deck and piling may be considered. Consult with the local activity and Facilities Engineering Command (FEC) for local requirements and restrictions on the use of treated timber. Obtaining permits for treated timbers, especially creosoted fender pile, is becoming very difficult in various areas of the country.

4-1.1.1 Preservative Treatment.

All timber members, with the exception of some fender piling, exposed to the marine environment and immersed in salt water or fresh water should be pressure treated. Per AWPA UC5C, treatment with CCA or ACZA in accordance with Best Management Practices is acceptable. Treat with waterborne (salts) chemical preservatives to protect against deleterious effects of decay, insects, and marine borers. In warmer waters, where severe marine borer activity can be anticipated, treat with salt. Consult the staff entomologist at the cognizant FEC for specific information on marine organisms present and the treatment required.

If possible, make pressure treatment after all holes and cuts are made. When holes and cuts are made in the field, treat timber members with preservative to prevent decay from starting in the holes or cuts. Consult a staff entomologist for the proper preservative. Field treatments are difficult in the tidal zone and are typically not very effective against marine borers. Therefore, whenever possible, design and detailing should avoid the necessity for making cuts or holes on underwater timber members. For example, avoid bracing or connections below mean high water. All connection hardware should be suitable for the saltwater exposure. For above water construction, waterborne salt treatment is preferable to creosote treatment due to the staining effect that creosote treatment produces.

4-1.1.2 Timber Species.

Douglas fir and southern pine are the most popular species for waterfront construction. Southern pine piles are limited to 65 feet (19.8 m) in length, whereas Douglas fir piles and poles can be used in up to 100-foot (30.5 m) lengths. Large beams and timber sizes needed for chocks and wales are generally available only in Douglas fir and southern pine. Treat chocks and wales with waterborne salts and not oilborne preservatives such as creosote. Evaluate the cost and availability of timber piles and other members for the project.

4-1.2 Steel.

When protected against corrosion by the use of coal tar epoxy or other marine coatings and cathodic protection systems, steel construction may be considered for all types of marine structures. Active cathodic systems are difficult to design, construct, and maintain properly, therefore, passive systems are preferred. UFC 3-570-01, *Cathodic Protection* provides criteria regarding cathodic protection system design. Additional steel thickness may be provided as a sacrificial corrosion allowance. Steel is particularly adaptable for use: in template and jack-up barge construction at advance base facilities; as piles for structures located in deep water where high lateral forces exist; as fender piles and fender panels; as piles for structures located in areas of high seismic activity; and where difficult driving is anticipated. When the utilization of other construction materials is considered feasible, the use of steel construction may be restricted due to cost and maintenance considerations.

Coating of structures and materials in the harsh marine environment is of the utmost importance, particularly in the area known as the splash zone. The “Splash Zone” is defined as the area between the year’s lowest tidal mark and up to ten feet above the year’s highest tidal mark. An earlier generation coating was developed formulated from polysulfide modified novolac epoxy. This was renamed Zero VOC, Coal Tar Free Splash Zone Coating (SZC). SZC is expected to provide at least “twice” the performance compared to the currently specified coating systems. ESTCP Project WP-200528 Zero VOC, Coal Tar Free Splash Zone Coating (SZC), Final Report provided a full scale validation of the SZC for use as an in-service waterfront maintenance system and enables the transition of this coal tar free coating directly into the hands of DOD end users who require waterfront metal (e.g., sea walls, sheet pile) maintenance painting. Further, this project addressed performance and environmental requirements for sustainment and reduction of VOC and HAP emissions due to the SZC being free of toxic metals, hazardous air pollutant free, contains no coal tar pitch, and has zero VOC’s.

4-1.3 Concrete.

For piers and wharves, concrete is generally the best material for construction. Properly designed and constructed facilities are highly durable in the marine environment. New advances in concrete technology have improved concrete durability. Concrete enhanced with fly ash and corrosion inhibitors has demonstrated superior performance and should be used whenever possible. UFGS 03 31 29, *Marine Concrete* contains the latest developments in marine concrete. Caution should be exercised when using silica fume considering the guidance and precautions contained in the UFGS. Concrete is also ideal for deck construction in open-type piers and wharves and, when properly designed, is more economical for floating structures. Proprietary stainless steel reinforcement bars, wires, and strands have been developed for use in concrete construction where nonmagnetic properties are desired as in Magnetic Treatment and

Electromagnetic Roll piers. In contrast to new concrete, repair concrete requires different considerations in terms of design, materials, construction and quality control. In this regard, TR-NAVFAC-EXWC-CI-1304 *Enhanced Guidelines for Marine Concrete Repair,* has been prepared documenting some of the key considerations for marine concrete repair and pointing to the need of a dedicated UFGS. Three primary advancements to be contained in the specification include: enhance quality control/quality assurance, use of embedded galvanic anodes, and use of form and pressure pump repair methods. Consider protection of the concrete reinforcement from corroding to all construction located in a spray zone, not only to partially submerged construction, but to concrete in a dry-wet zone. Consider achieving concrete densification using a fly ash as substitute in a concrete matrix and / or utilization of the cementitious epoxy coating for protection of the concrete and structural steel in the dry-wet zone.

4-1.3.1 Precast Concrete Piles.

Precast concrete piles should preferably be prestressed to resist the tensile forces frequently encountered during driving. Corrosion of reinforcement in prestressed concrete piles can be controlled by proper mix design and, in extreme cases, by epoxy coating the reinforcement. However, exercise sufficient control during driving of concrete piles to minimize cracking. Where difficult driving into very compact sands, gravels, or rock is anticipated, the tip of the piles may be equipped with a WF-shape or H-pile "stinger" to achieve needed penetration. Exercise caution when selecting the material for an internal jet pipe in solid precast piles. There have been issues on some projects during pile driving when plastic/PVC is used for the internal jet pipe. Issues arise when concrete piles are driven and jetted at the same time in clayey soils. The clays can clog the jet pipe resulting in water hammer. The plastic/PVC jet pipes tend to crack under these conditions resulting in cracks forming in the concrete pile.

Very large hollow cylindrical piles (48-inch (1.2 m) diameter and larger) have also been successfully employed for waterfront construction on the East coast. However, longitudinal cracking was encountered with these same types of piles during construction of Pier D at Bremerton, Washington. Recently, proprietary carbon fiber pre-stressing and post tension strands have come into the market. These strands could have future applications such as for Magnetic Treatment and Electromagnetic Roll piers.

4-1.4 Composites.

Composites made of concrete and steel, concrete and fiberglass, plastic and fiberglass, and plastic and steel have been successfully employed in piers and wharves. Composites offer many advantages over conventional materials but often have limitations that need to be considered. Some advantages may include improved corrosion resistance, lightweight, and ease of construction. Some of the disadvantages may include low strength, UV light deterioration, long-term durability and high cost.

4-1.4.1 Concrete and Steel.

Concrete-filled pipe piles, steel H-piles with a concrete casing, and steel beams with concrete decks are the more common composite types. The concrete casing or jacket for the steel H-piles may be required only in the splash or tidal zone. However, due to instances of severe deterioration of the pile just below the jacket, extend the jacket to Extreme Low Water (ELW) or to below mudline. Concrete may also be added to steel pipe piles for deadweight purposes to resist uplift forces or to increase the stiffness of the pile.

4-1.4.2 Concrete and Fiberglass.

Concrete-filled fiberglass piles have been used in facilities where high axial capacities are not required. The lightweight fiberglass piles are easily installed and do not require high capacity handling equipment.

4-1.4.3 Plastic and Fiberglass.

Fiberglass reinforced plastic piles and beams have been successfully used in pier and wharf construction primarily as fender piles, wales and chocks.

4-1.4.4 Plastic and Steel.

Recycled plastic piles with steel cage reinforcement have also been used in pier and wharf construction.

4-1.5 Aluminum.

For deck-supported structures and for support of piping and conduits, aluminum members are useful. However, do not use unprotected aluminum underwater or in the splash zone. To prevent corrosion, aluminum should be electrically isolated from adjacent materials by nonconductive gaskets, washers, or bolt sleeves. Aluminum construction may be used in the superstructure of Magnetic Treatment and Electromagnetic Roll piers, due to the nonmagnetic characteristics of the material.

4-1.6 Plastics.

Fiberglass-reinforced plastics (FRP), ultra-high molecular weight (UHMW) plastics, and high-density polyethylene (HDPE) are being increasingly used in waterfront construction. FRP grating and shapes are highly durable in the marine environment when shielded from ultraviolet rays. UHMW plastics are useful in fender systems design as rub strips where a high abrasion resistance and low coefficient of friction are required. UHMW plastics are available in various grades. The use of corrosion-resistant FRP components including reinforcing bars, prestressing tendons, structural shapes, and unidirectional or woven fabrics, are being developed and have been successfully used in the repair of piers and wharves. Consider using these materials when the situation warrants, but give special attention to the design of connections.

Carefully evaluate the use of FRP components as structural elements for new construction.

4-2 ALLOWABLE STRESSES.

4-2.1 General.

Allowable stresses for materials used in pier and wharf construction generally conform to industry standard codes for the type of material and the purposed application unless modified herein. Allowable stresses for fender system design are discussed in section: FENDER SYSTEMS.

4-2.2 Timber.

Design timber structural elements in accordance with UFC 1-200-01, *DoD Building Code (General Building Requirements)*. Allowable stresses are generally not affected by preservative treatment. However, modulus of rupture and modulus of elasticity are considerably reduced by preservative treatment. When preservative treatment for fire retardation is used, consult the National Design Specification (NDS) for reductions in allowable stresses.

4-2.3 Steel.

Design steel structural elements in accordance with UFC 1-200-01, *DoD Building Code (General Building Requirements)*.

4-2.4 Castings.

Design cast steel and cast iron mooring fittings with the following minimum factors of safety (FS), Minimum FS towards yield = 2.0, Minimum FS towards fracture = 3.0.

4-2.5 Concrete.

Design concrete structural elements in accordance with UFC 1-200-01, *DoD Building Code (General Building Requirements)*. For prestressed concrete members, “zero” tension design is preferred. When combining precast and cast-in-place concrete in composite deck systems required prestress level to prevent tensile stresses is likely to be governed by differential creep and shrinkage strains, which are sensitive to humidity, temperature, curing conditions, and age of precast at integration. All reinforced concrete deck members should meet the crack control requirements for severe exposure.

4-2.6 Other Materials.

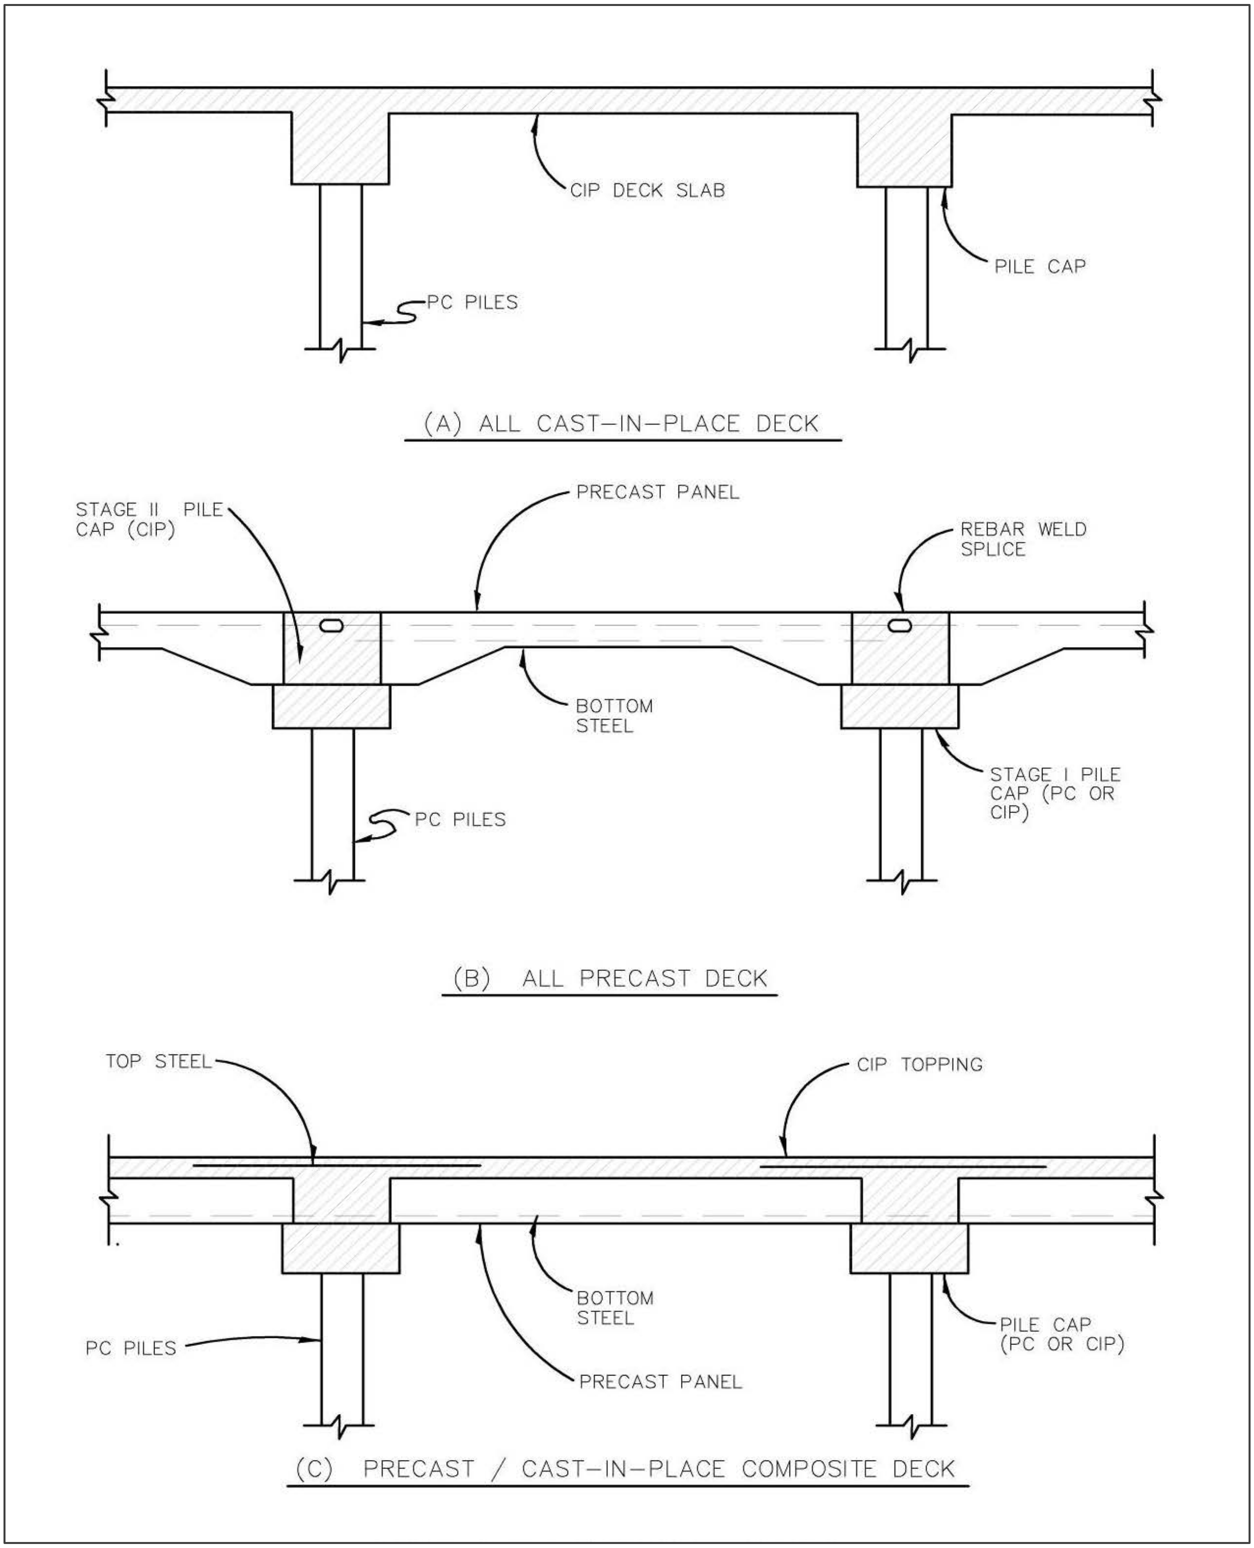
FRP, UHMW, and other new materials should be governed by the accepted industry standards for structural design and detailing.

4-3 DECK STRUCTURE DESIGN.

4-3.1 Deck Framing.

Concrete is generally considered the best material for deck framing and should be used for most pier and wharf decks. Although timber, steel, steel/concrete composite, and timber/concrete composite decks have been used in the past, they are neither cost-effective nor suitable for the high concentrated load capacities currently demanded of decks. From durability, maintenance, and life-cycle-cost viewpoints, a concrete deck is superior and is highly recommended. The deck framing should be slabs supported on pile caps, using an all cast-in-place, all precast, or composite construction, as shown in Figure 4-1. For the concentrated loads which typically control the deck design, a solid slab with its high punching shear resistance is recommended. Framing systems using thin slabs, as in cast-in-place slab/beam/girder systems, should not be used because of the tendency to spall along beam/girder corners and edges. Map cracking in the cast-in-place topping at the precast panel joints is sometimes seen. In precast/cast-in-place concrete composite structures design, consider differential creep and shrinkage when specifying post-tensioning stress level. Studies have demonstrated that prestress losses and redistribution of prestress forces can be significant in this construction type, minimizing the effectiveness of the intended crack mitigation measures. For distribution of horizontal loads, pier and wharf decks should be continuous, with as few expansion joints as possible. Where expansion joints are needed, the deck on each side of the joint should be supported on a separate pile cap or girder. Other options are flat plate requiring no pile cap.

Figure 4-1 Concrete Deck Construction



4-3.2 Pile Caps.

Orienting pile caps transverse to the length of the structure provides improved lateral stiffness for berthing and mooring forces. When this orientation is used, longitudinal pile caps are not needed unless crane trackage support or longitudinal seismic resistance is to be provided. For marginal wharves where lateral loads from mooring and berthing loads are transferred to the land, a longitudinal orientation of the pile cap may be considered if feasible for construction. Moments and shears on pile caps from live loads should take into account the elastic shortening of the piles and the effect of soil deformation at and near pile tips.

4-3.2.1 Pile Cap Orientation.

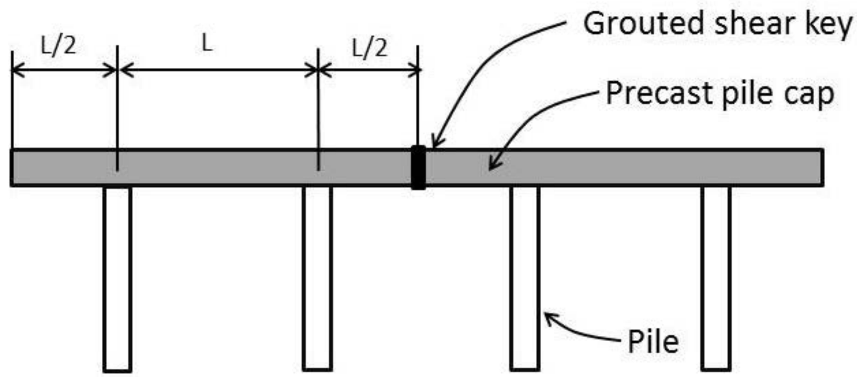
Traditionally, it was assumed to be more cost-effective to orient pile caps (and hence pile bents) transverse to the length of the structure. However, orientation of the pile caps longitudinal to the length of the pile provides uninterrupted paths for utilities that run in this direction, which may result in cost-savings over piers with pile caps in the transverse direction by minimizing conflicts between cap beams and utilities. Use of pile caps oriented in the longitudinal direction will require tie beams designed to transfer lateral loads from mooring and berthing loads to the foundation. Additional stiffness can be added to piers with pile caps in the longitudinal direction with the use of tabletop sections. An example of a cost-effective pier with pile caps oriented in the longitudinal direction and tabletop pile caps can be found in NAVFAC-EXWC-CI-TR-1413, *The Use of Prestressed Concrete for Corrosion Prevention in US Navy Piers.*

For computation of forces from high concentrated loads, the cap behaves as a beam on elastic foundation, and distributes the concentrated load to a number of piles adjacent to the load.

4-3.2.2 Precast/Prestressed Pile Cap.

A durable concept for precast/prestressed pile caps is a single span beam supported on two piles, which is balanced by two cantilevered ends that extend to the mid-span of the adjacent bays as shown in Figure 4-2. Prior to integration with the deck elements, it can be shown with a moment-diagram that the soffit of the cap beam will remain in compression under uniform load. This prestress from gravity will enhance durability by minimizing cracking of the concrete in the splash zone of the pier as illustrated in Figure 4-3. Additional prestress can be a specified for the cap beam during fabrication to maintain compression in the concrete under crane loads during installation and for service level loads after integration with the deck elements. Details for this design can be found in NAVFAC-EXWC-CI-TR-1413, *The Use of Prestressed Concrete for Corrosion Prevention in US Navy Piers.* A recommended detail for the joint between adjacent pile cap beams in shown in Figure 4-2.

Figure 4-2 Cantilevered Precast Pile Cap



4-3.3 Tabletop Pile Caps.

Precast construction is an effective method to enhance durability of waterfront structures while reducing cost; however, one of the challenges of precast construction is integrating individual pieces into a continuous structure. A solution for precast concrete construction is to use tabletop pile caps, which are two-way elements capable of transferring resisted loads to four support piles. Proper implementation will form a self-contained stable platform that when integrated into the deck diaphragm forms a complete lateral load resisting system. Tabletop configuration may vary based on pier requirements, but three potential tabletop variations are the slab, double cap, and utilidor, which are shown in Figure 4-4 along with a single span pile cap beam. Implementation of tabletop pile caps into a pier design is demonstrated in NAVFAC-EXWC-CI-TR-1413, *The Use of Prestressed Concrete for Corrosion Prevention in US Navy Piers.*

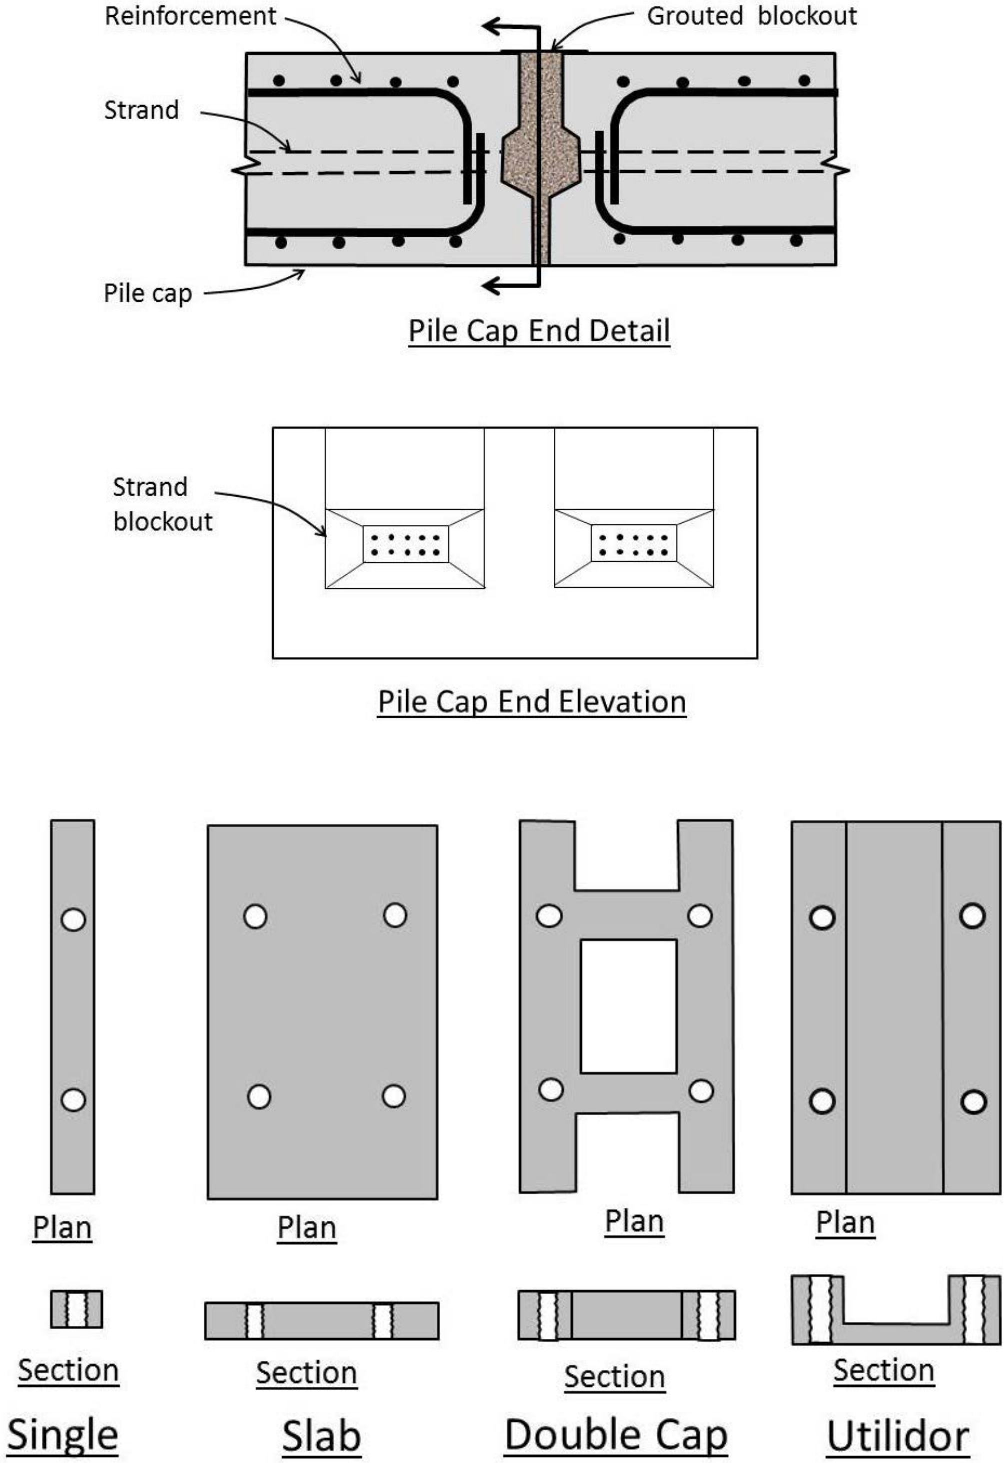
Precast Pile Cap Showing End Configurations

Figure 4-4 Tabletop Pile Cap Variations



4-4 SUBSTRUCTURE DESIGN.

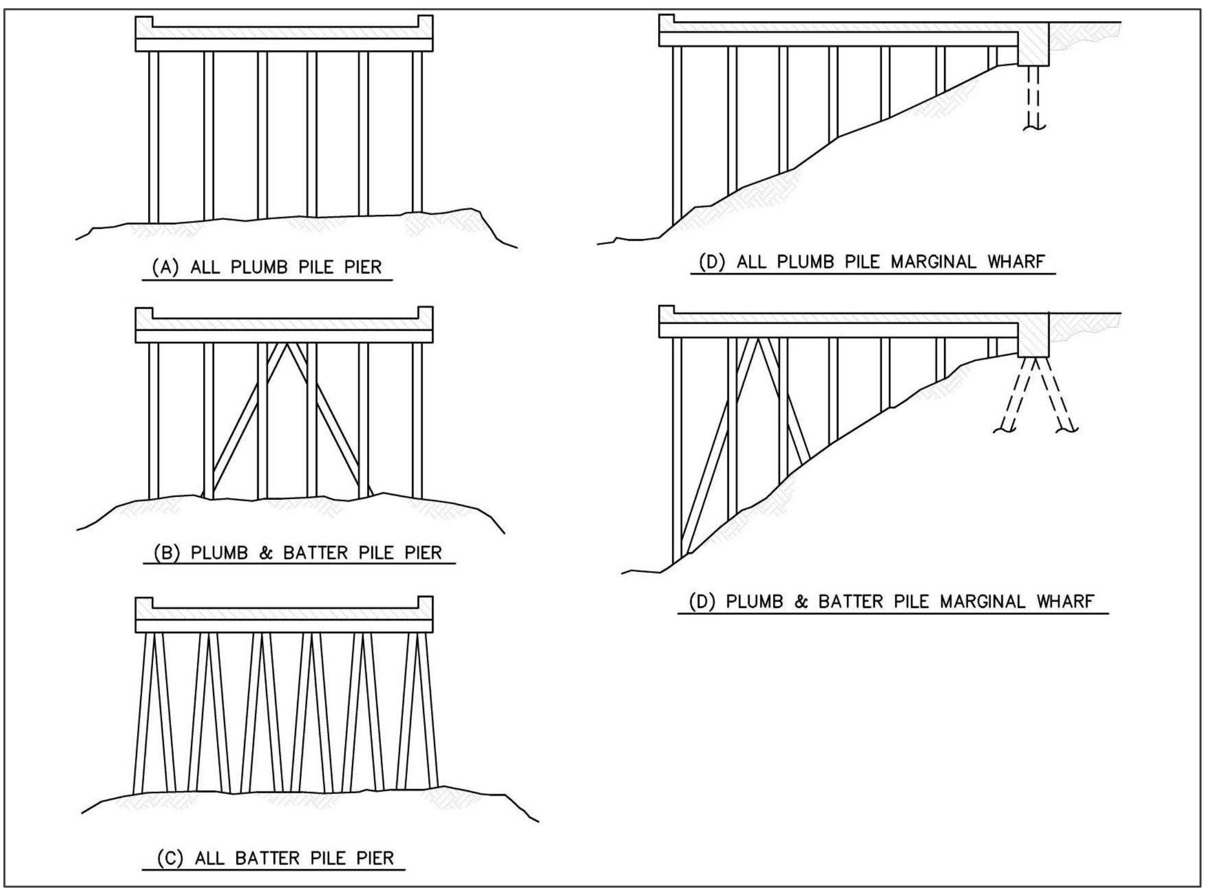
4-4.1 Geotechnical.

General geotechnical guidance and minimum technical requirements for DoD facilities is contained in UFC 3-220-01, *Geotechnical Engineering*. However, given the somewhat unique aspects of marine geotechnical engineering, traditional geotechnical engineering practices need to be supplemented. In this regard, an appropriate reference is *Handbook of Marine Geotechnical Engineering.* This document addresses a variety of structures ranging from piles, moorings, and anchors and the seafloor response whether in shallow or deep water.

4-4.2 Pile Bent Framing.

A pile-supported framing system is the most popular form for substructure design for open piers and wharves. Several framing concepts for open piers and wharves and marginal wharves are illustrated in Figure 4-5. Many variations and combinations of the illustrated concepts are possible.

Figure 4-5 Substructure Framing Concepts



4-4.2.2 All Plumb Pile System.

The lateral loads are resisted by "frame action," whereby the piles and the cap form a moment frame and resist the lateral load primarily by the flexural stiffness of the piles. However, for narrow structures, lateral deflection may be high for even small lateral loads. Also, sidesway is not prevented, which increases the effective length of the pile as a column. If piles vary in unsupported length, the shorter piles will attract a large portion of the lateral load. Because the piles are more efficient for axial loads and less so for bending moments, this framing usually is restricted to shallow waters and light lateral loads. However, for wide structures with a large number of piles, the total stiffness of the system may justify a reduced effective length. A more in-depth stability analysis is needed to validate a reduced effective length. Large diameter steel pipe and precast/prestressed concrete cylinder piles can provide improved lateral stiffness and are attractive for use in areas of high seismic activity.

4-4.2.3 Plumb/Batter Pile Systems.

In this type of framing, all the vertical loads are primarily handled by the plumb piles, and lateral loads are resisted primarily by the batter piles. The behavior of the system is one of "truss action." This system is more cost-effective as the lateral loads are resisted primarily by the axial stiffness of the batter piles. However, very high forces are transmitted to the caps, which will have to be designed and detailed to resist these forces. In areas of high seismic activity, the increased stiffness of the system reduces the period and leads to higher earthquake loads.

4-4.2.4 All Batter Pile System.

This system is a compromise between the two above, and is cost-effective in some circumstances. With this system, the batter slope may be near vertical. Natural periods can be as high as several seconds, making the approach attractive for seismic areas.

4-4.2.5 Batter Pile System with Seismic Isolation.

This system incorporates calibrated isolators or seismic fuses between the wharf deck and batter piles. The system allows for high displacements of the wharf deck once a threshold lateral load causes the isolator slip. Design guidance can be found in ASCE/COPRI 61-14, *Seismic Design of Piers and Wharves* and ASCE 7-10, *Minimum Design Loads for Buildings and Other Structures*. Consider the magnitude of lateral berthing and mooring forces such that they do not exceed the threshold lateral force of the isolator. In this case a separate fendering structure may be required.

4-5 MOORING HARDWARE.

4-5.1 General.

Ships are usually moored to bollards, bitts, and cleats. Occasionally, ships may be tied to a quick-release hook. The position of a ship on a berth is usually controlled by utility hookup and brow location requirements. The crew in charge of tying up the ship will usually tie the lines to whatever mooring hardware is convenient to give the required horizontal angle. This often results in lines tied to a lower capacity cleat while a high-capacity bollard may only be a few feet away. Hence, consider using only one type of high-capacity mooring hardware throughout the facility. When possible, size this mooring hardware for the maximum size vessel that could possibly use the facility. Space hardware to maximize the berth flexibility for use by ships other than the specific vessel the berth was designed to accommodate. In addition, mooring hardware requirements will depend on the mooring service type assigned to the berth as defined in UFC 4-159-03, *Design: Moorings*. For mooring service types III and IV, consider providing additional heavy weather mooring hardware set away from the face of the pier or wharf. Balance the desire to provide the higher capacity hardware with the additional cost of the higher strength hardware and supporting structure. The geometry of the hardware should preclude mooring lines from slipping off, as the mooring angle is often very steep.

4-5.2 Hardware Types.

Additional information (such as tabular data and figures) on mooring hardware is contained in UFC 4-159-03, *Design: Moorings*; UFC 4-150-08, *Inspection of Mooring Hardware;* and TR-6014-OCN**,** *Mooring Design Physical and Empirical Data*. The following are the most commonly used types of mooring hardware:

4-5.2.1 Bollards.

A bollard is a short single-column cast-steel fitting that extends up from a baseplate that is secured to a strong point of a shore structure or berthing facility. Bollards are used in checking the motion of a ship being moored, by tightening and loosening mooring lines that are fastened to them. Bollards are also used for securing a ship that has been placed in its final moored position. Do not use bollards without ears in facilities where a high vertical angle of the mooring line is anticipated, to prevent lines from slipping off.

4-5.2.2 Bitts.

Bitts are short, double-column, cast-steel fittings fastened to the deck of berthing facilities. Bitts are also found on navy vessels. They are used to secure a vessel. The double-columns allow for convenient and rapid tying and releasing of mooring lines, as well as for guiding a line through to other hardware.

4-5.2.3 Cleats.

Currently, available cleats are low-capacity, cast steel deck fittings having two projecting arms that are intended to be used for securing mooring lines of small craft. They are provided at most naval facilities. Given a choice, line-handling crews will use cleats in preference to bollards or bitts, even for large ships, as the possibility of line slippage is remote. However, cleats can easily be overloaded when they are used in lieu of major fittings such as bollards. Because of the low holding capacity of cleats, they should not be used in combination with higher capacity deck fittings.

4-5.2.4 Chocks.

Chocks are either stationary or roller-equipped cast deck fittings on ships that are used to train the direction of a mooring line. Chocks are available either open at the top, permanently closed, or closed by a hinged closing piece.

4-5.2.5 Capstans.

Ships outfitted with winch-mounted wire rope mooring lines require greater pulling power than can be provided by one or two deck hands to draw out the ship's lines. The assignment is handled by capstans mounted along the face of the wharf. The capstans are small electric winches with a drum rotating about a vertical axis. The capstan is used by a deck hand that receives a messenger line at the end of which is fastened the sling of the wire rope hawser. The capstan, receiving several wraps of the messenger line, provides the pulling power needed to draw out the wire rope hawser. The messenger line is then returned to the ship. Capstans are also used as primary guidance (breasting and in-haul) to berth ships in dry docks and slip-type berths (Trident facilities). For these uses, the capstans are of larger capacity and are typically two-speed.

4-5.2.6 Quick-Release Hooks.

The quick-release hook, generally mounted on a swivel base, is a deck fitting used to receive mooring lines. When a ship is required to make a hasty departure from its berth, a tug on the hook's release mechanism unfastens the mooring line. The mechanism can also be tripped from the ship when a tag line is provided. Thus, a ship can make a sudden departure without the assistance of shore personnel. Quick-release mooring hooks with integral power capstans are necessary for securing the steel mooring lines on petroleum tankers at fuel piers, while bollards are needed for the supplementary lines other than steel.

4-5.3 Strength.

The required strength of mooring hardware and its fastenings is determined through mooring analysis. Mooring hardware can and does receive more than one line and as many as three are not unusual. Design anchorage of mooring hardware based on the rated capacity e.g. for the anchorage of a Special Mooring Bollard “A” the working (service level) capacity is either a 660 kip (2,936 kN) horizontal line pull, or a 430 kip (1,913 kN) line pull at an angle of 45 degrees from the horizontal. Line loads are applied just below the horn elevation, and typically from 0 to 180 degrees in plan away from the pier or wharf. For strength level design use the mooring load factor listed in Table 3-7. Capacity design is used for anchorage and local foundation structural design only. Global structural design shall be based on mooring analysis. The sizes of mooring lines are limited to those that can be conveniently handled by deck hands. Thus, wire rope lines generally do not exceed 1-3/4 inch (45 mm) diameter.

4-5.4 Placement.

If a berthing facility were always to receive the same class of ship, each of which had identical arrangements for putting out mooring lines, a specific pattern for mooring hardware spacing, based on the ship's fittings, would be satisfactory. However, most naval berthing facilities require a high degree of flexibility in order to be able to receive several types and sizes of ships. Therefore, a universal pattern for mooring hardware spacing is preferred. Mooring hardware spaced at 60 feet (18.3 m) on centers along the berthing face of a structure will, in most instances, provide the number of fittings required to secure the ships during the periods of time that wind velocities and conditions of sea do not exceed the design criteria established for Mooring Service Types I and II. Mooring Service Types III and IV will likely require additional high capacity storm bollards which are normally set back as far as is practical from the face of the berth to provide a shallow line angle.

a. A berthing facility that will accommodate ships having large wind areas, such as aircraft carriers, should be outfitted with 12 to 100 ton (107 to 890 kN) bollards at 100-feet (30.5 m) centers and 4 to 200 ton (36 to 1779 kN) storm bollards at each end. Locate the storm bollards, which would be used to secure breasting lines, inshore from the face of the wharf, thus reducing vertical angles and permitting the use of longer (safer) mooring lines.

b. At submarine berths where mooring lines go down to the submarine, locate the mooring hardware as close as possible to the waterside edge of the bullrail to minimize chafing of the lines. Where this is not feasible, cast a continuous smooth member, such as a bent plate, in the concrete bullrail.

4-6 MOORING DOLPHINS/PLATFORMS.

4-6.1 Design.

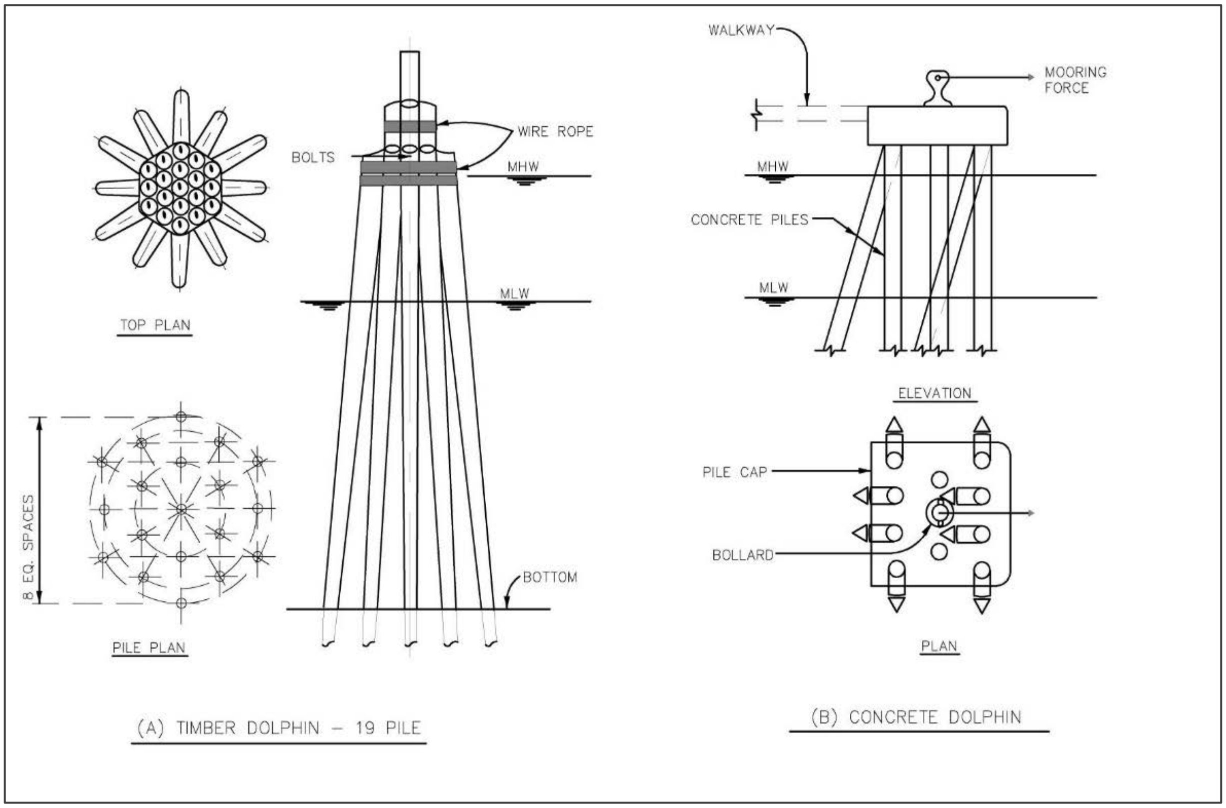
The primary load for a mooring dolphin comes from the tension in the mooring line. It is typically constructed as an open pile supported structure. Where filled (solid) construction is permitted, a single sheet pile cell may be used. When a platform is provided for the dolphin, it should be large enough to allow a 3-foot-wide (1 m) walking space all around the mooring hardware.

4-6.2 Construction.

Timber mooring dolphins can be constructed from 7, 19, or 37 wood piles with a king pile in the center and other piles arranged in a circular pattern around the king pile. A 19-pile dolphin is illustrated in Figure 4-6 (A). Limit the use of timber dolphins to facilities not requiring high capacity mooring points. Timber dolphins may be required for magnetic sensitive facilities. In areas with ready access to timber piles, timber dolphins may be popular for small craft, tugs, patrol craft and barges. For higher loads, a concrete dolphin is preferred, which is illustrated in Figure 4-6 (B). Because both timber and concrete dolphins can be expected to move significantly (1 to 6 inch (25 to

152 mm)) from the lateral load, design and detail the access walkway to allow for this movement.

Figure 4-6 Mooring Dolphins



4-7 MISCELLANEOUS CONSIDERATIONS.

4-7.1 Expansion Joints.

Because expansion joints require frequent maintenance for proper functioning, piers and wharves should use as few joints as possible. The size and number will depend on the temperature range and structural system employed. Provide expansion joints at the junction of an approach with the main structure and such other places where there is a major structural discontinuity. Provide additional expansion joints where necessary to limit buildup of thermal loads. (See also previous section: Thermal Loads) Continue the joint through railroad tracks and crane rail tracks. Recommended details are shown in Figures 4-7 and 4-8. Likewise, detail utilities crossing expansion joints to accommodate the expected longitudinal and lateral movements.

4-7.2 Drainage.

Pier and wharf decks should be sloped in transverse and longitudinal direction to deck drains or scuppers to provide for drainage of storm water. Where permitted, the storm water can be drained off to the water below; however, if fuel, oils, and chemicals are to be handled on the facility, the storm water should be collected and piped off for treatment. A complete review of local jurisdictional requirements for storm water management and treatment required for each facility may vary significantly between locations. It is customary to use subsurface drains in ballasted decks to handle any small amounts of water that may seep through the paving. This water is normally not collected.

4-7.3 Bullrail.

On all waterside edges of piers and wharves, provide a curb or bullrail 10 to 12 inch (254 to 305 mm) high by 12 to 24 inch (305 to 610 mm) wide. Some mooring hardware may be accommodated within the 24-inch (610 mm) width, thus permitting a clear inside face for easy snow removal and line handling. As shown in Figure 4-9, it is also generally possible to house utility vaults within the width of the bullrail. The bullrail should be sufficiently reinforced and anchored to the deck structure. When a continuous bullrail is available, it may be reinforced to serve as chord member for a structural diaphragm.

4-7.4 Utility Trench.

Because the utility services are mostly needed along the pier or wharf edge, the main utility trenches on single deck piers should be kept close to the bullrail. The trench may be underhung or kept above, as shown in Figure 4-10. The trench covers should be removable and made of concrete, steel, or composite construction. Fiberglass reinforced plastic (FRP) trench covers have been used on piers and offer the advantages of light weight and durability in a corrosive marine environment. When using FRP trench covers, give consideration to the proximity of heated steam lines.

Although the trench covers need not be watertight, use a good seal at joints to prevent accidental seepage of spilled liquids. Frequently spaced drains should be placed along the trench to prevent flooding. Provide adequate width and depth to allow access for maintenance of utilities.

Figure 4-7 Railroad Track Support

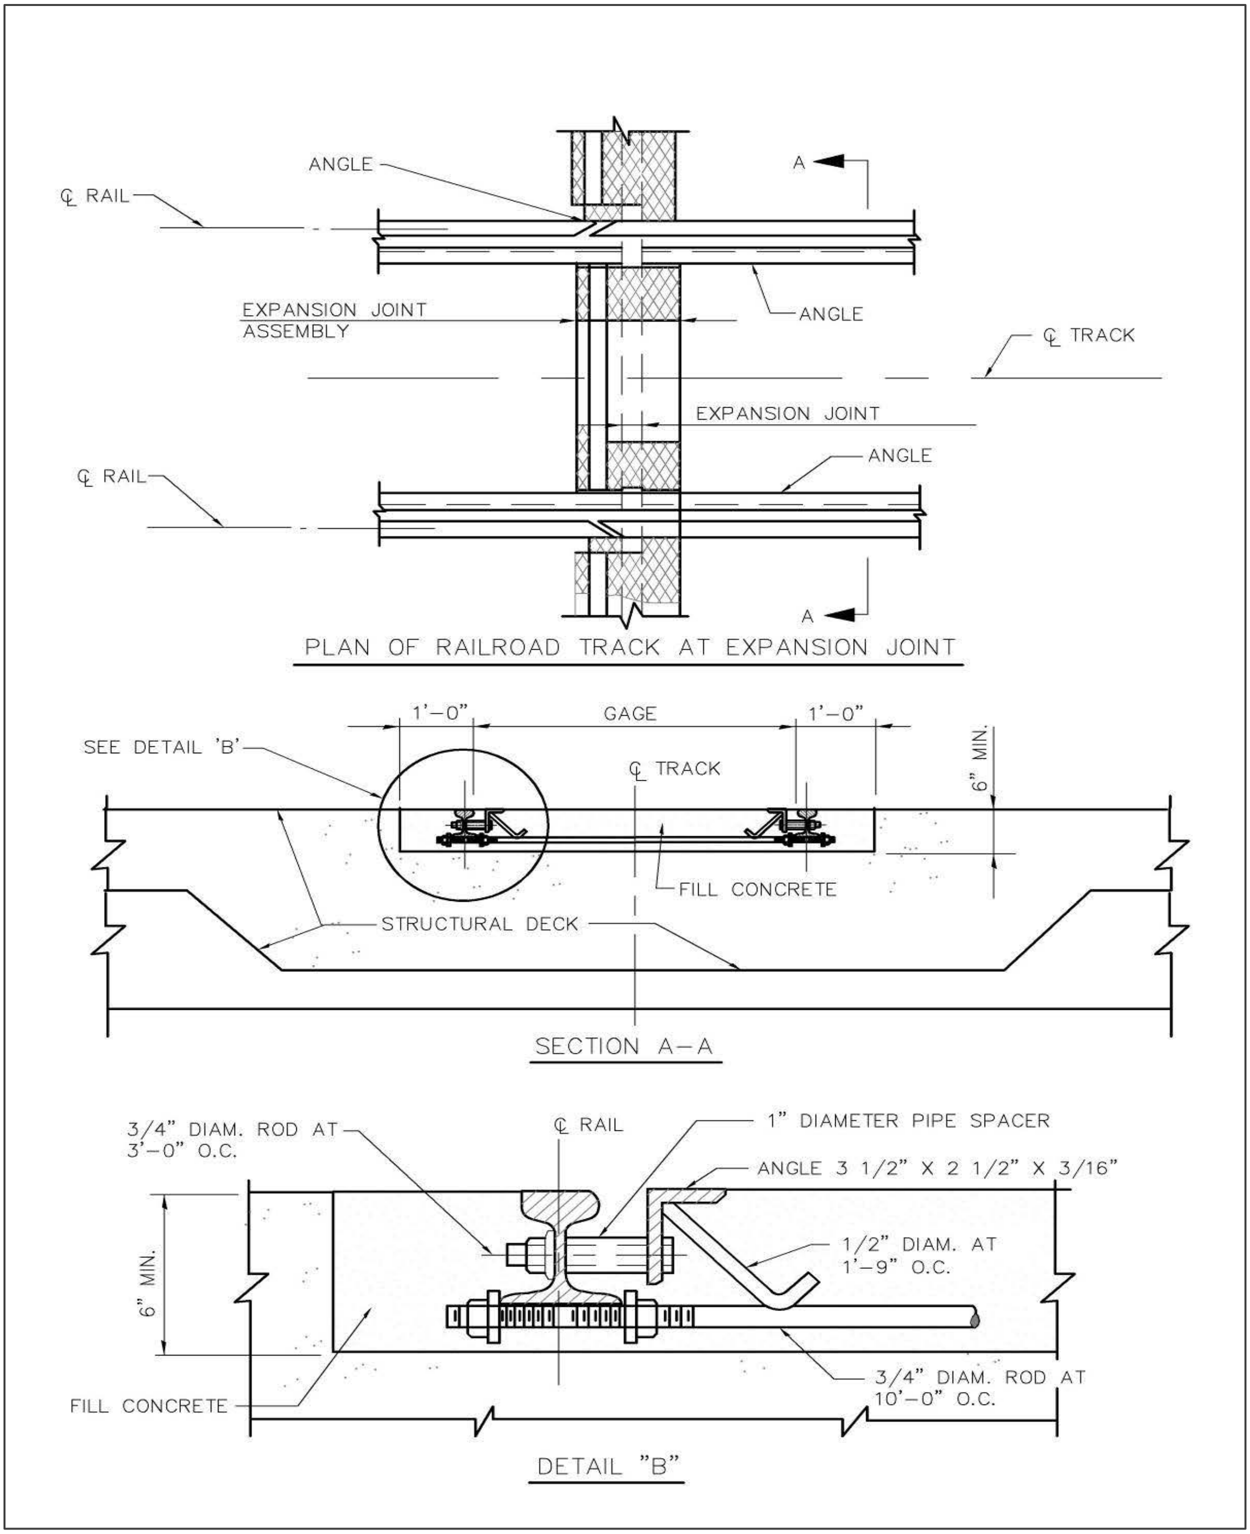


Figure 4-8 Crane Rail Support

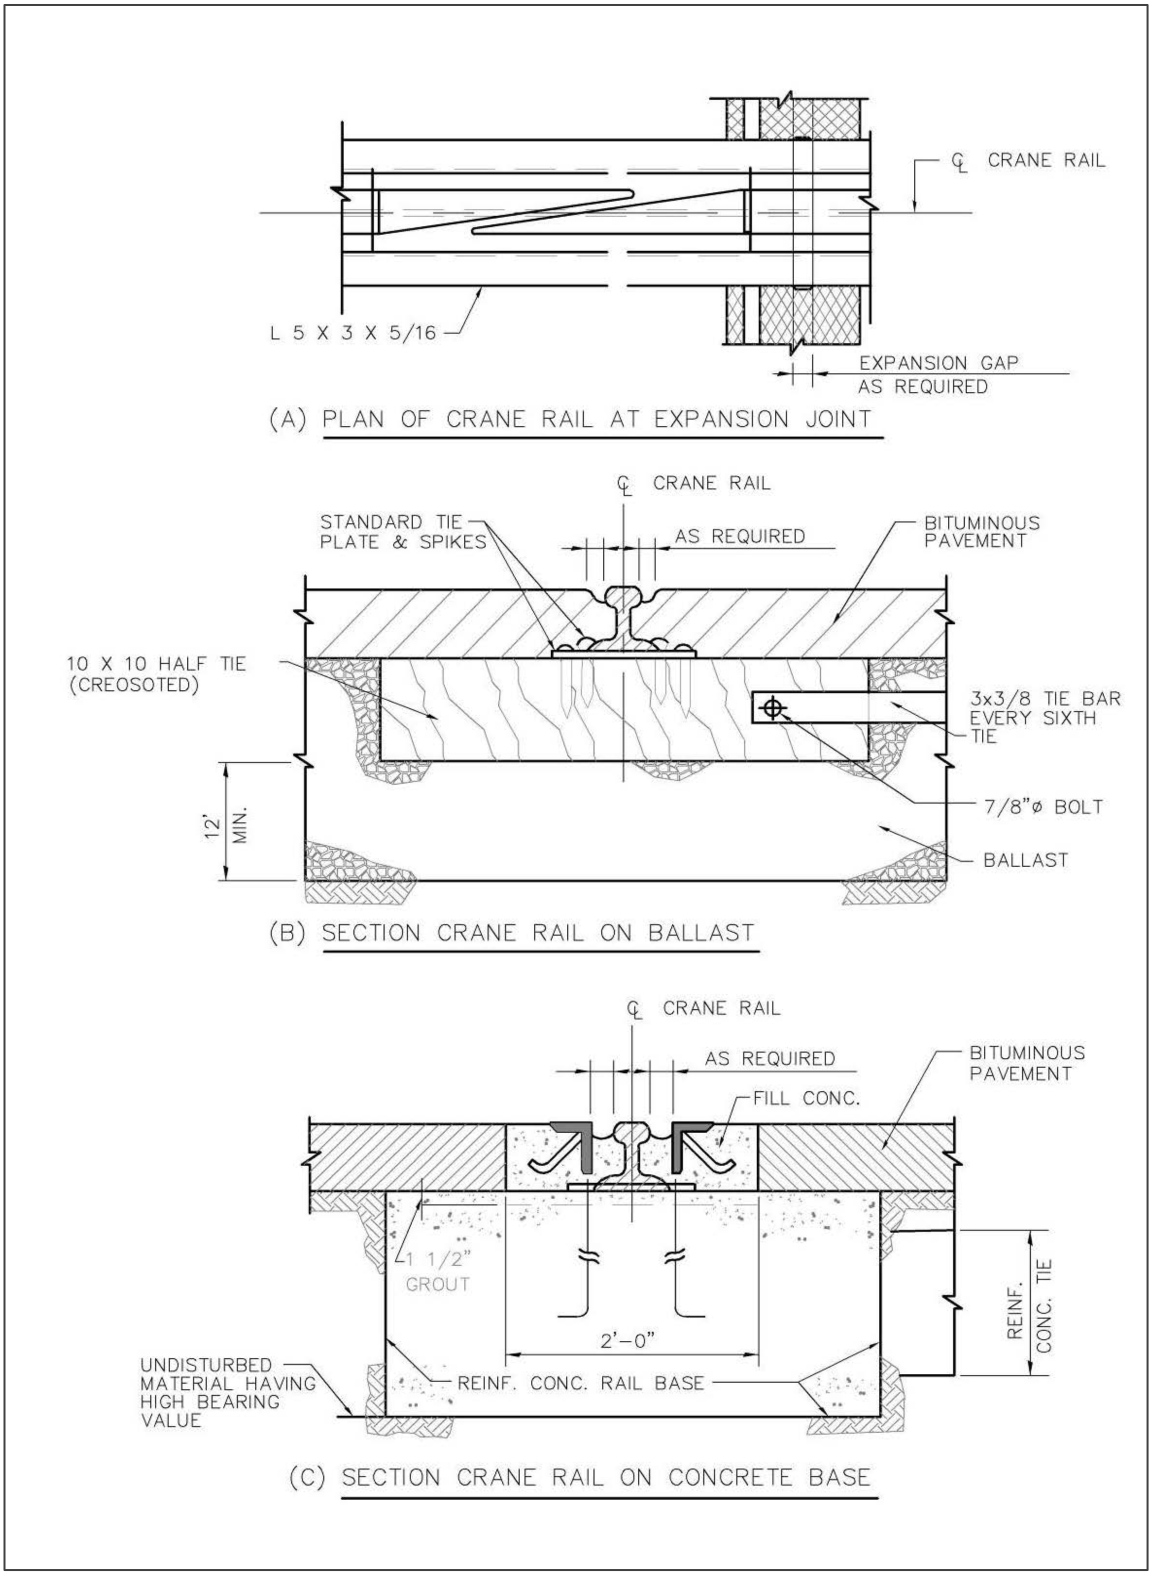

Figure 4-9 Bullrail Details

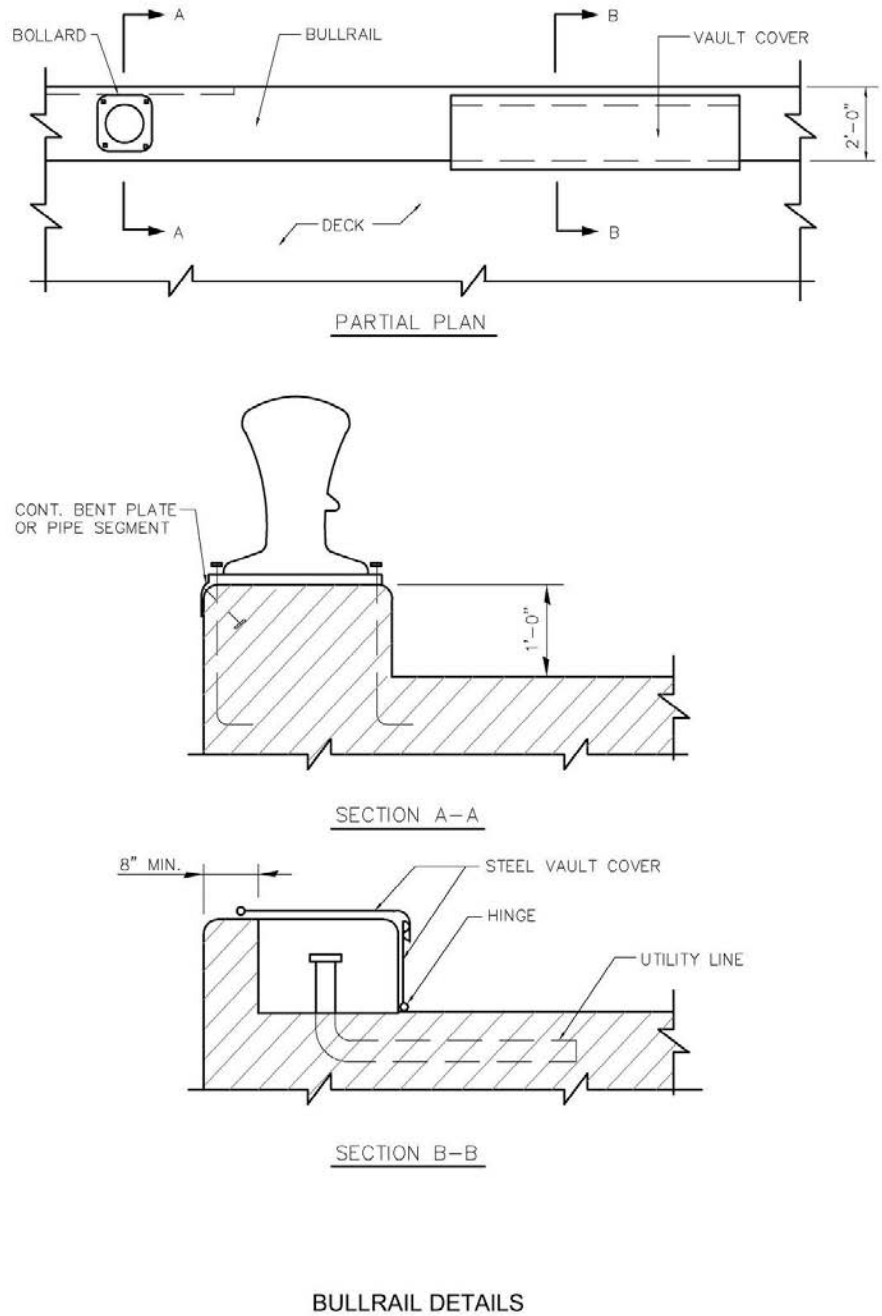

Figure 4-10 Utility Trench Concept

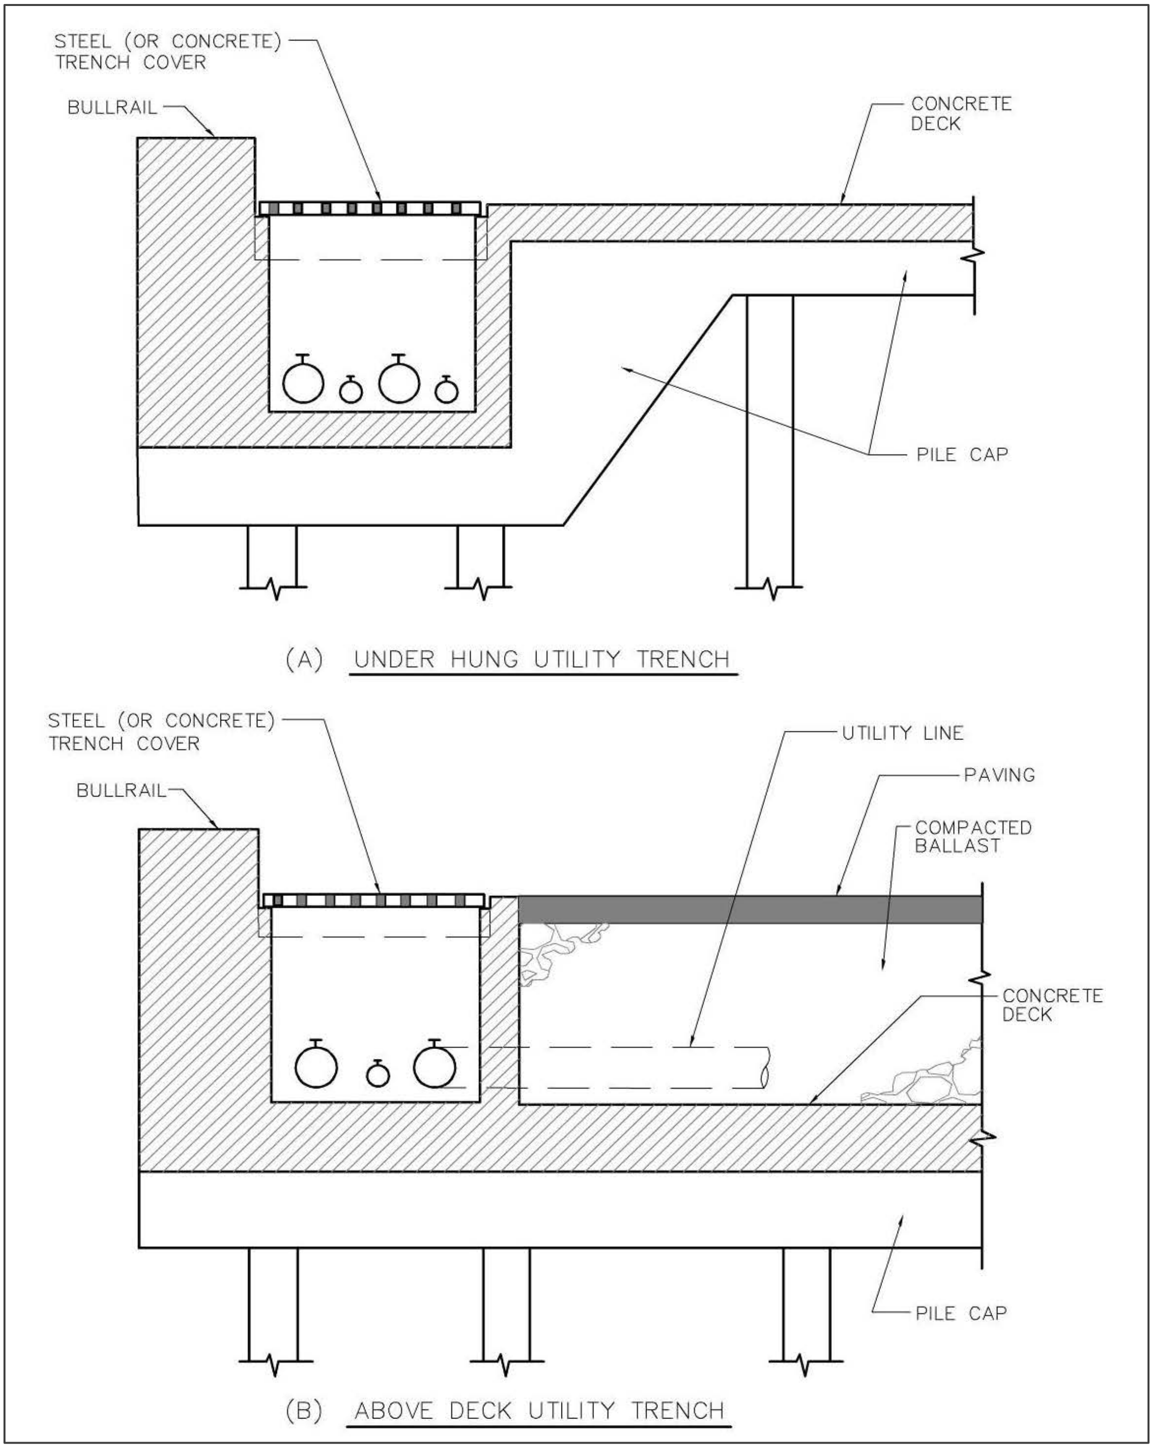

4-7.5 Utility Hoods.

Protect connection points or "utility risers" projecting above deck or bullrail from snagging of mooring lines by pipe rails or concrete hoods, as shown in Figure 4-11. Alternatively, when the bullrail is wide enough, employ hinged utility covers like the one shown in Figure 4-9. For convenience of the users, the risers should not face away from the ship, and should be adequately sized for ease of operation.

4-7.6 Wearing Course.

Generally, a wearing course is not needed for concrete deck structure. However, for precast concrete decks, an asphalt concrete or cement concrete wearing surface may be utilized to provide a slope for drainage. For ballasted decks and for solid (filled) type construction, a wearing course is necessary. For these applications, asphaltic concrete is preferred over cement concrete as the former is easier to repair and maintain and better tolerates substrate movement.

CHAPTER 5 FENDER SYSTEMS

5-1 GENERAL CONSIDERATIONS.

5-1.1 Description.

The fender system is the interface between the ship and the shore facility. During the berthing of a ship, the fender system is meant to act as a buffer in absorbing or dissipating the impact energy of the ship without causing permanent damage to the ship or the shore facility. Where ships are to be berthed against relatively inflexible solid piers and wharves, protection of the ship is a critical function. When ships are to be berthed against pile-supported piers, wharves, and dolphins (which are relatively flexible), protection of the structure may be the more serious concern. Once the ship is successfully berthed and moored to the shore facility, the fender system continues to provide the interface between ship and shore and transmits the environmental loads (wind, waves, and current) on the ship to the structure. For submarine and other low-profile ship berthing, the fender system also provides a physical barrier to prevent the vessel from going underneath the pier.

5-1.2 Berthing Practice.

The selection and design of a fender system is highly dependent on the berthing practice employed at the particular facility. Typically, two or more tugboats assist large ships into the berth. In some locations, smaller ships may be allowed to come in on their own power. When assisted by tugs, the ship would arrive off the berth and parallel to it. The ship then stops dead in the water and the tugs push and pull the ship transversely toward the berth in an attempt to make contact with as much of the fender system as possible. When unassisted by tugs, the smaller ship will be eased into its berth at some slight angle, referred to as the angle of approach. In both cases, the initial contact is limited to a relatively small portion of the fender system. Assumptions will have to be made regarding the approach angle and contact length.

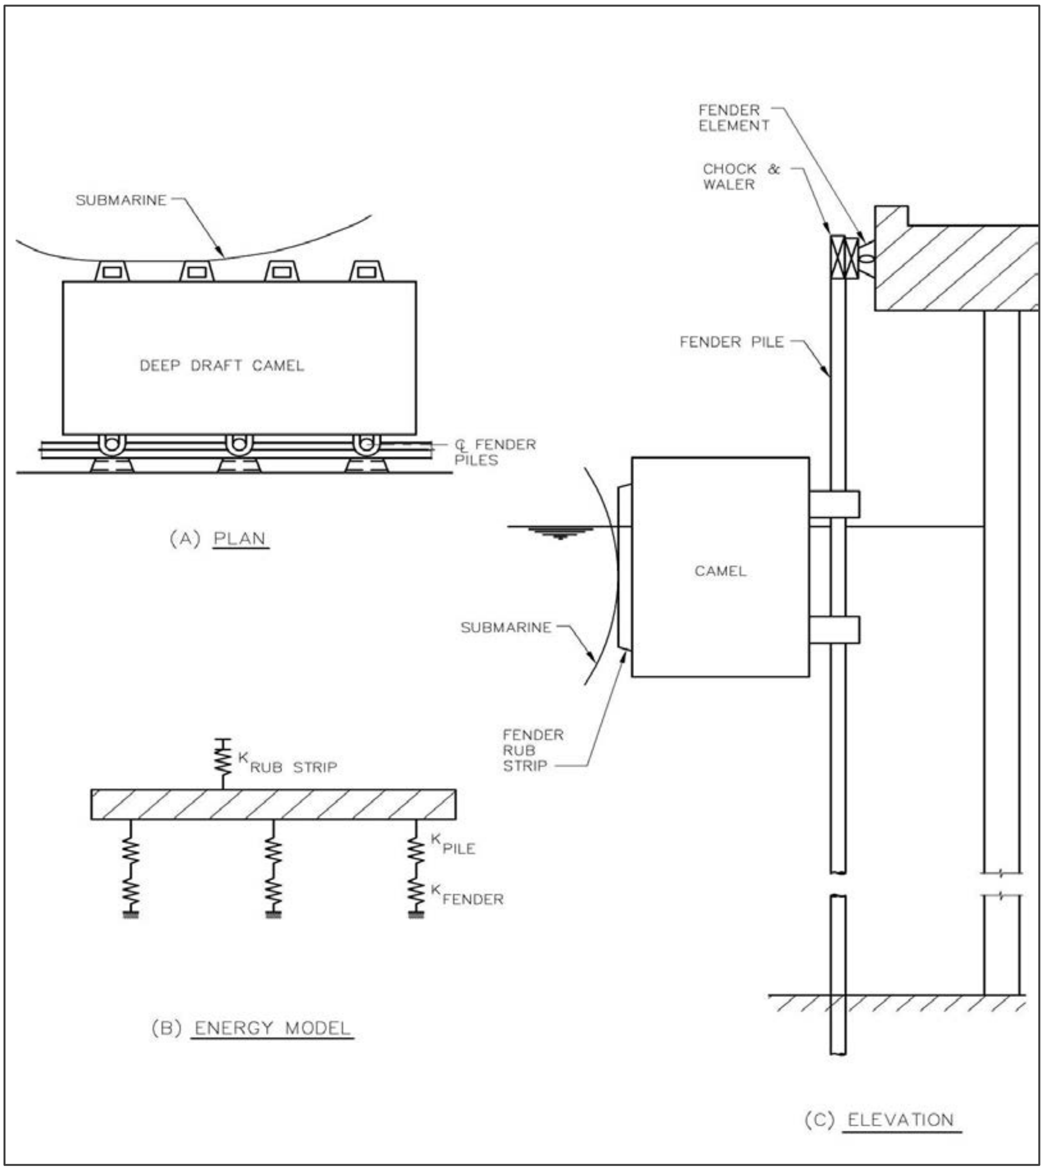
5-1.3 Camels and Separators.

Camels are located between ships and piers or wharves. Separators are located between nested ships. This practice is the most significant difference between commercial ship berthing and naval ship berthing. Berthing against camels concentrates the impact energy to a small length of the fender system as well as applies the energy at some distance below the deck. This is a critical aspect in all fender system design for Navy ships. A fender system designed for commercial ships will, in general, not be satisfactory for Naval applications. The practice of using camels has resulted in a general trend for a minimum of hull protrusions near the waterline. Fender systems with higher fender contact area are more susceptible to damage from longitudinal movement of the vessel due to snags.

5-1.4 Systems Approach.

The impact energy of the berthing ship is absorbed in a complex system of interconnected elements. For the system shown in Figure 5-1, the load passes from the ship's hull to the camel, which is backed by a series of fender piles. The fender piles, in turn, are supported by rubber fender units at the deck level. In this case, the ship's energy is absorbed by the ship's hull, rubbing strips, camel, fender piles, and rubber fenders at deck level. The system can be modeled as shown in Figure 5-1. The energy absorbed and the force developed, by each element can only be solved by an iterative process.

Figure 5-1 Energy Model of a Fender System



5-1.5 Functional Requirements.

5-1.5.1 Energy Absorption.

Design all fender systems for absorption of the ship's berthing energy in all the structural types of piers and wharves.

5-1.5.2 Normal Berthing.

The fender system should be able to absorb the energy from normal berthing operations within the working stress or acceptable deformation range as defined in this section. Most manufacturers indicate a load deflection curve tolerance of plus or minus 10%. If this is determined to be the case, the design normal berthing reaction on the structure should be increased by 10% and the normal energy absorption for design should be decreased by 10%. Variations in the speed of testing of fenders may affect the resulting load-deflection curves. Where the test loads are applied rapidly, i.e., at a speed comparable to the actual ship berthing, the load-deflection will indicate higher reaction and energy than if the test load is applied slowly. Therefore, take care when comparing test results from different manufacturers, and make appropriate adjustments in the factors of safety used in design. Differences on the order of 30% can be expected.

5-1.5.3 Accidental Berthing.

Because the fender system is less expensive than the ship or the berthing structure, some damage to it may be permissible and acceptable. So, in the event of an accidental situation, it is the fender system that should be "sacrificed." Loss of the berth has a much more serious consequence than loss of part or all of the fender system in terms of the cost and time required to restore the facility. The cost and time to repair a damaged ship is of much greater concern than the berth and the fender system. The accidental condition may be caused by increased approach angle or approach velocity or a unique situation that cannot be anticipated. In the absence of any other accident scenario, increase the berthing energy as calculated in this chapter by at least 50% and the fender system should be capable of providing this "reserve" capacity at or near failure of the system materials (including soils).

5-1.5.4 Moored Condition.

All fender systems selected should be capable of safely transferring the environmental loads on the ship to the mooring structure.

5-1.5.5 Hull Damage.

Design all fender systems to prevent permanent deformation of the ship's hull. It is much more expensive to repair a ship's hull than rehabilitate a damaged fender system. The composition of a typical Navy hull is steel plating welded to longitudinal (horizontal) stiffeners. Generally, the stiffeners are of sufficient strength to preclude failure from fender loading. However, the hull plating may yield when subjected to a uniformly distributed overload on the panel. Fender systems with rigid face elements or in combination with rigid camels tend to concentrate the reaction forces on the ships frames versus the hull plating due to the relative stiffness of the frames.

5-2 BERTHING ENERGY DETERMINATION.

5-2.1 Methods.

The following methods can be used in the determination of berthing energy of the ship.

5-2.1.1 Kinetic Method.

The kinetic energy method has been the widely accepted method for piers and wharves of Naval facilities. When the displacement tonnage of the ship is known, the energy equation can be written as:

$$E_{ship} = {}^{1}/_{2}\, W * v^2 \;/\; g$$ **(Equation 5-1)**

where:

- E_{ship} = Berthing energy of ship (foot-lbs)
- W = Weight of the ship in pounds (displacement tonnage, long tons x 2,240)
- g = Acceleration due to gravity (32.2 feet/second^2)
- v = Berthing velocity normal to the berth (feet/second)

However, there are several factors that modify the actual energy to be absorbed by the fender system. The expression can be written as:

$$E_{fender} = C_b * C_m * E_{ship}$$ **(Equation 5-2)**

where:

- E_{fender} = Energy to be absorbed by the fender system
- C_b = Berthing coefficient = $C_e * C_g * C_d * C_c$. Sometimes eccentricity (C_e), geometric (C_g), deformation (C_d), and configuration (C_c) coefficients are combined into a single value called berthing coefficient.
- C_m = Effective mass or virtual mass coefficient

Each of these coefficients is discussed separately below.

a. Eccentricity Coefficient (C_e). During the berthing maneuver, when the ship is not exactly parallel to the berthing line, not all the kinetic energy of the ship will be transmitted to the fenders. Due to the reaction from the fender, the ship will start to rotate around the contact point, thus dissipating part of its energy. Treating the ship as a rigid rod of negligible width in the analysis of the energy of impact on the fenders leads to the simple formula:

$$C_e = k^2 / (a^2 + k^2)$$

where:

- k = Radius of longitudinal gyration of the ship, feet.
- k = $(0.19C_{BL} + 0.11) * L$ (*Guidelines for the Design of Fender Systems*, PIANC, 2002)
- a = Distance between the ship's center of gravity and the point of contact on the ship's side, projected onto the ship's longitudinal axis, feet.
- C_{BL} = Block coefficient

$$C_{BL} = M / (L * B * D * \rho)$$

where:

- M = Displacement of vessel, long tons
- L = vessel length, feet
- B = Beam of vessel, feet
- D = Draft of vessel, feet
- ρ = Density of water (64 lb/ft^3)

Values of C_e typically are between 0.4 and 0.7. The values for C_e may be selected from Figure 5-2.

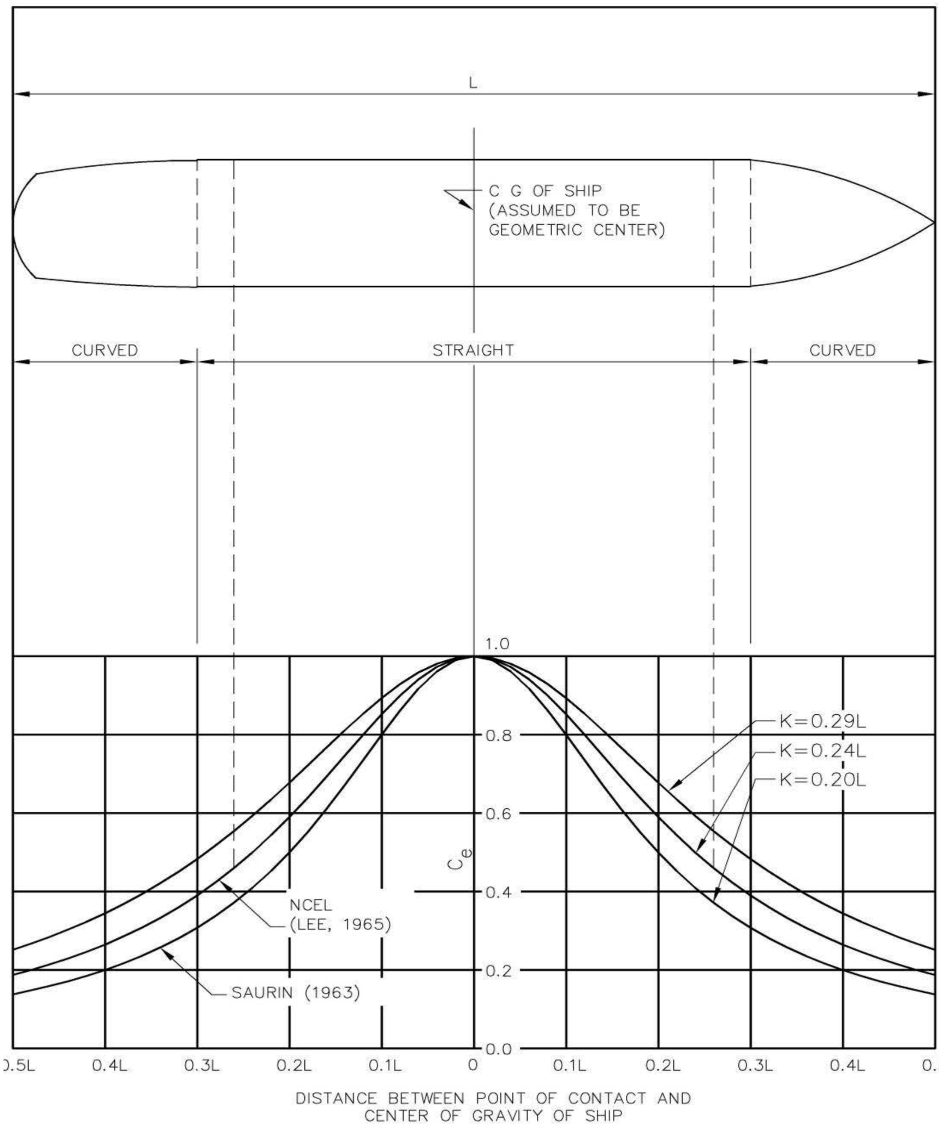
b. Geometric Coefficient (C_g). The geometric coefficient, C_g, depends upon the geometric configuration of the ship at the point of impact. It varies from 0.85 for an increasing convex curvature to 1.25 for concave curvature. Generally, 0.95 is intended for the impact point at or beyond the quarter points of the ship, and 1.0 for broadside berthing in which contact is made along the straight side.

c. Deformation Coefficient (C_d). This accounts for the energy reduction effects due to local deformation of the ship's hull and deflection of the whole ship along its longitudinal axis. The energy absorbed by the ship depends on the relative stiffness of the ship and the obstruction. The deformation coefficient varies from 0.9 for a non-resilient fender to nearly 1.0 for a flexible fender. For larger ships on energy-absorbing fender systems, little or no deformation of the ship takes place; therefore, a coefficient of 1.0 is recommended.

d. Configuration Coefficient (C_c). This factor has been introduced to take into account the difference between an open pier or wharf and a solid pier or wharf. In the first case, the movements of the water surrounding the berthing ship are not (or hardly) affected by the berth. In the second case, the water between the berthing ship and the structure is squeezed, which introduces a cushion effect that represents an extra force on the ship away from the berth and reduces the energy to be absorbed by the fender system. Therefore, a reduction factor has to take care of this effect. Experience has indicated that for a solid quaywall about one quarter of the energy of the berthing ship is absorbed by the water cushion; therefore, the following values for C_c appear to be justified:

- For open berth and corners of solid piers, C_c = 1.0.
- For solid piers with parallel approach, C_c = 0.8.
- For berths with different conditions, C_c might be chosen somewhere between these values.

Figure 5-2 Eccentricity Coefficient, C_e



e. Effective Mass or Virtual Mass Coefficient (C_m). When a ship approaches a dock, the berthing impact is induced not only by the mass of the moving ship, but also by the water mass moving along with the ship. The latter is generally called the "hydrodynamic" or "added" mass. In determining the kinetic energy of a berthing ship, the effective or virtual mass (a sum of ship mass and hydrodynamic mass) should be used. The hydrodynamic mass does not necessarily vary with the mass of the ship, but is closely related to the projected area of the ship at right angles to the direction of motion. Other factors, such as the form of ship, water depth, berthing velocity, and acceleration and deceleration of the ship, will have some effect on the hydrodynamic mass. Procedures for determining added mass are contained in TR-6064-OCN, *Berthing Guidelines for Submarines* and TR-6074-OCN, *Added Mass for Berthing U.S. Navy Vessels*.

The equations for added mass are as follows:

For submarines:

$$C_m = 2.36 + 1.74 * (T/d)^{3.5}$$

where:

T = vessel draft at mid-ships, feet

d = water depth at berth, feet

For all other surface vessels:

$$C_m = C_{M0} + (C_{m1} - C_{M0}) * (T/d)^{3.5}$$

where:

C_{M0} = added mass coefficient for $T/d = 0$ deepwater limit

C_{m1} = added mass coefficient for $T/d = 1$ shallow water limit

T = vessel draft, feet

d = water depth, feet

C_{M0} = $1.3 + 1.5 * (T/B)$

B = vessel beam, feet

C_{m1} = $F * [12.4(T/B)^{0.3} – 50 (T/L)]$

F = $1.5 * C_b$ for $C_b < 0.6$

F = 0.9 for $C_b > 0.6$

(C_b = berthing coefficient as defined previously)

f. Berthing or Approach Velocity (v). It should be noted that the kinetic energy of the berthing ship is a function of the square of the normal component of its approach velocity. Thus, the kinetic energy, as well as the resultant force on the berthing structure, is sensitive to changes in approach velocity. By doubling the design value of the approach velocity, the ship's kinetic energy is quadrupled. Design values used for the approach velocity normal to the berth may vary from 0.25 to 1.50 ft/s (0.08 to 0.46 m/s), depending on the size of the ship being docked and the tug assistance that is employed. Larger vessels with adequate tugboat assistance can generally berth gently and the lower design velocity may be used. Smaller vessels that self-dock may approach the wharf at considerably higher speeds and, accordingly, the higher design velocity should be used. The berthing velocity is also affected by the difficulty of the approach, maneuvering space for tugs (slip width), and location of the pier or wharf facility. Anticipate higher approach velocities when the berth is located in exposed waters where environmental loads cause difficulty in controlling the ship. Also, currents in tidal estuaries in protected waters can be of major concern. Approach velocity normal to the berth may be taken from Figures 5-3 and 5-4. Determining whether a facility is "exposed," "moderate," or "sheltered" depends on the environmental conditions at the site and is a matter for professional judgment by the designer. Most naval facilities in the United States are situated in protected waters and can be taken as "sheltered." Where high currents (0.3 ft/s (0.09 m/s) or more) or strong winds (40 knots (20.6 m/s) or more) occur frequently, a "moderate" condition should be assumed. The "exposed" condition may be used when unusually severe currents and winds are present. However, local experience with ship berthing should control the selection.

Figure 5-3 Berthing Velocity for Small Ships (up to 20,000 tons)

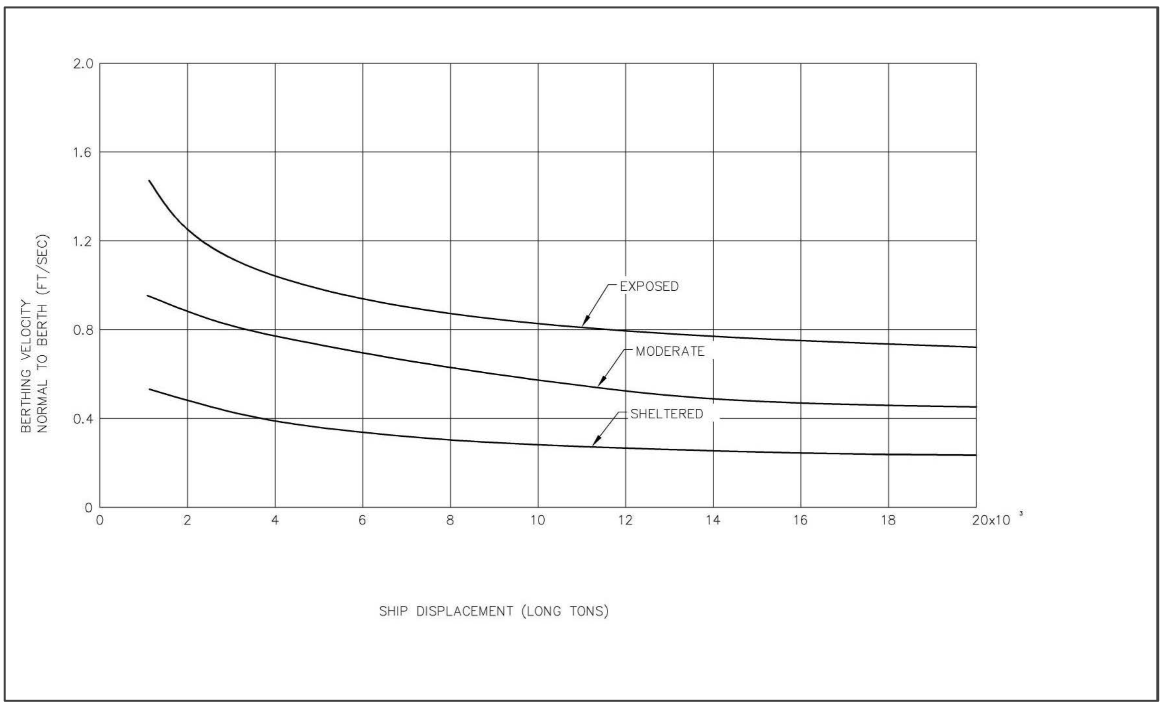


Figure 5-4 Berthing Velocity for Large Ship

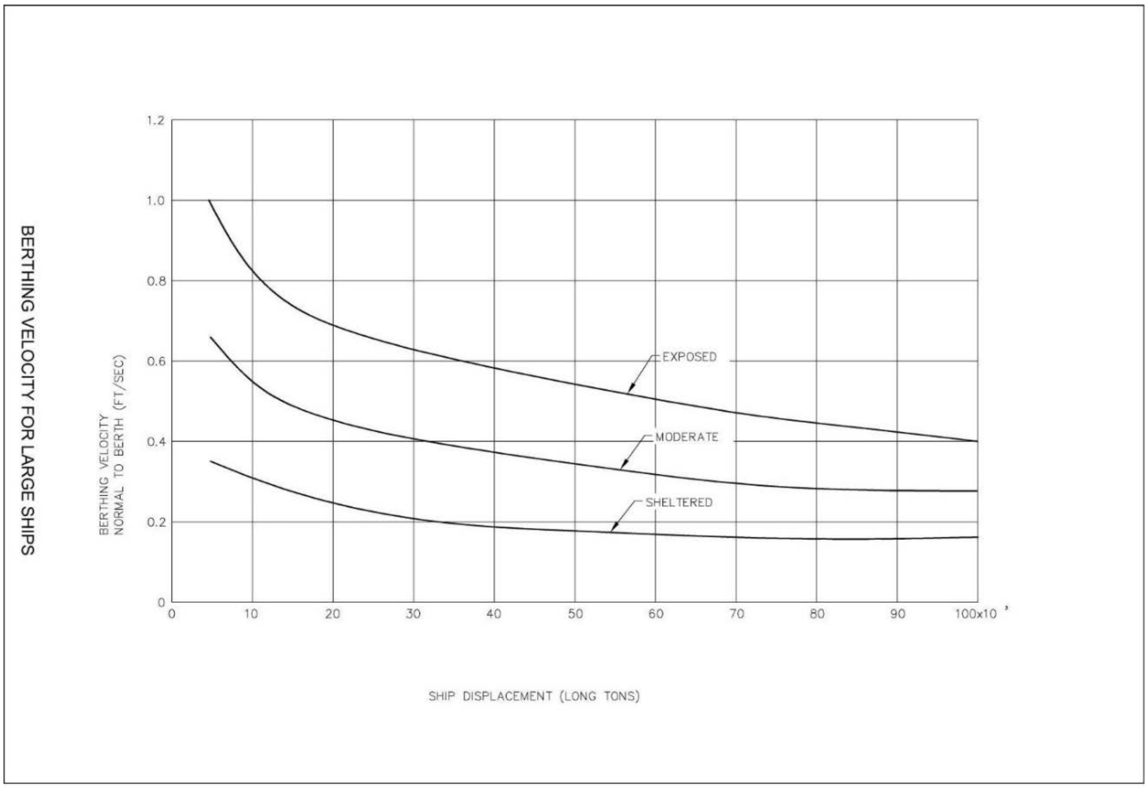

5-2.1.2 Berthing Models.

a. Statistical Method. This method is based on actual measurements of the energy of the impact at existing berths. This method is closely related to the conditions of the site where the measurements were taken and is dependent on the fender layout and construction, e.g., distance between piles, and the loading condition of the ship.

b. Scale Model. This method, which makes use of a small-scale model test of the berth to be designed in a well-equipped hydraulic laboratory or ship model basin, suffers from the scale and viscosity effects and requires experienced interpretation.

c. AQWA. NAVFAC EXWC typically uses the COTS AQWA software package to perform a dynamic analysis of berthing through six degrees of freedom in the time domain.

d. Analytical Model. NAVFAC EXWC has developed an analytical model that can accurately predict ship berthing impact forces. The model employs a computational fluid mechanics approach, coupling a Reynolds-Averaged Navier-Stokes (RANS) numerical method with a six-degree-of-freedom motion program for time-domain simulation of ship and fender reactions. The model has been verified with data from small-scale and full-scale tests. Results from the new model for two ship classes yield added mass coefficients close to those calculated by the PIANC formula as long as the depth-to-draft ratio exceeds 1.2. When the underhull clearance becomes small, i.e. for depth-to-draft ratios less than 1.2, predicted added mass coefficients can exceed the PIANC values. Added mass values of 5.0 or higher are predicted for ships berthing against open piers (pile supported) equipped with soft fenders, such as pneumatic or foam-filled cushions. Consider using higher values for the added mass coefficient under these conditions.

5-3 TYPES OF FENDER SYSTEMS.

5-3.1 General.

Fender systems absorb or dissipate the kinetic energy of the berthing ship by converting it into potential energy in the fender materials. This could be in the form of deflection of a fender pile, compression of a column of rubber, deformation of a foam-filled cylinder, torsion of a steel shaft, or pressuring of a pneumatic fender.

5-3.2 Fender Piles.

This is the most commonly used system in existing piers and wharves. This system is stiff and lacks the capacity for large deflection resulting in high reaction loads and frequent breakage of piling and hull damage. This system employs a series of closely spaced fender piles (5- to 10-foot spacing) (1.5 to 3 m) connected together by chocks and wales. A rubber fender unit is mounted between the wale and the berthing structure. A series of diagonal chains from the structure to the waler completes the system. Provide tight-fitting joints between chocks, wales, and pile head, with proper tension splices that provide compression and tension continuity along the face of berth. Ships may be berthed either directly against fender piles or by using additional fenders or camels between the ship and the fender piles. When camels are used, size the fender piling to resist the resulting bending and shear. In the working stress range, there is an approximate linear relationship between reaction force and deflection. When used with floating camels, which tend to cock between the ship and the piles, the ship's energy may become concentrated on just one or two piles. Hence, unless the floating camel is tightly secured to the piles (guided by piles), the system will not work well and frequent damage will occur. The pile-rubber fender unit is not recommended for solid and other types of piers and wharves where full deflection of the piles within the working range will be inhibited. When this system is employed throughout the length of berth, the rubber fender units should be sized for direct berthing of ships (without the use of camels).

5-3.2.1 Timber Fender Piles.

Timber fender piles have historically been the system of choice. Although timber fender piles are still in use, environmental concerns coupled with advances in other fender pile material, have led to a trend in replacement of this type of system. Further, in certain locations, timber fender piles may be susceptible to damage by marine borers.

5-3.2.2 Steel Fender Piles.

Steel HP sections, wide flange sections and pipes have been used for fender elements. These pile sections are typically coated and incorporate a cathodic protection system, a durable rubbing surface is required for fender systems, either UHMW-PE rubbing strips, or HDPE sleeves may be used to protect HP or pipe pile (PP) sections respectively. The typical steel system is comprised of steel HP or PP sections driven vertically and connected to a steel wale. The wale is attached to the supporting structure by a system of rubber fenders and chains.

5-3.2.3 Concrete Fender Piles.

Concrete fender piles are the most prevalent system in use. Square prestressed concrete fender piles have been tested and proven to have high-energy absorption fendering capabilities and greater strain energy at collapse than either timber or steel fender piling. They are typically 18 to 24 inches square (457 to 610 mm) prestressed concrete and have served well as primary fender piles for berthing and mooring. The fender piles are usually connected to a chock and wale system at the deck level and supported by rubber fender units at the bullrail. In the working stress range, there is a linear relationship between reaction force and deflection. Figure 5-5 shows a prestressed concrete fender pile installation. Additional guidance and design aids for concrete fender piles is contained in NCEL TM 53-89-03, *Prestressed Concrete Fender Piling User Data Package* and NCEL CR 89.005, *Prestressed Concrete Fender Piles: Fender System Designs*. In reviewing these documents the following is noted:

- Energy absorbing fender piles. The primary purpose of these piles is to absorb the berthing energy of a vessel and transfer the berthing reaction to the pier or wharf and harbor bottom. These piles were designed to be used with camels, but may be used without camels. Typically these piles are 18 inches (457 mm) square.
- Reaction fender piles. The primary function of these piles is to serve as a backing for foam filled or other marine fender units and to transfer the berthing reactions into the pier or wharf and harbor bottom. The foam filled fender is assumed to absorb all the energy required from vessel berthing. Energy absorption by the concrete piles adds to the system overload capacity. The reaction associated with the berthing energy is transmitted through the foam filled fender either directly into a row of closely spaced concrete reaction piles, or into a rigid bearing panel connected to concrete reaction piles at a greater spacing. The rigid bearing panel acts to distribute the reaction to the piles. Typically these piles are 24 inches (610 mm) square.

Figure 5-5 Foam-filled Fender System

Foam-filled fender, concrete fender piles, steel frame and polyethylene rub strips.
(Marine Fender Systems, by T.E. Spencer, ASCE PORTS 2004).

A test program conducted for concrete fender piles is documented in NCEL R-927, *Laterally Loaded Partially Prestressed Concrete Piles*. Key findings were:

- Partial prestressing to 600 psi (4137 kPa) (was sufficient to close flexural cracks.
- 18-inch (457 mm) square pile with twenty (20) 1/2 inch (13 mm) diameter prestress strands in a rectangular configuration confined by No. 3 ties with a 3-inch (76 mm) pitch performed best.
- 65-foot (19.8 m) lengths can be expected to perform well under cyclic load with an ultimate energy capacity of 30 ft-kips (41 kN-m) and a post ultimate capacity of more than 60 ft-kips (81 kN-m).

5-3.2.4 Composite Fender Piles.

There are two primary types of composite fender piles. One type of composite pile is made of fiber reinforced plastic (FRP) in the form of a tube that can be filled with concrete for greater strength and stiffness. Figure 5-6 shows an FRP fender pile system. Because of a higher susceptibility to abrasion and impact damage, the thermoset FRP tube type pile should have rubberized abrasion strips installed at potential contact points with berthed vessels.

The second type of composite pile is made of thermoplastics (such as high-density polyethylene, HDPE) and reinforced with either steel or FRP strands. Figure 5-7 shows a plastic fender pile system. The reinforced thermoplastic type pile generally exhibit larger load-deflection properties compared to conventional wood, steel or concrete piles.

To ensure uniform loading and avoid premature failure of fender system components, these type piles should not be used in parallel or mixed with conventional type piles in the same system. Relevant work to date on composite fender piles includes TM-2158-SHR, *Study of Recycled Plastic Fender Piles*. Follow on work to this is contained in SP-2005-SHR, *Limited Flexural Tests of Plastic Composite Pile Configurations*, which includes flexural load tests to failure and cyclic tests to determine the stiffness (EI), load/deflection, linearity, hysteresis, energy absorption, degradation, and failure mode. Tests showed that composite piles absorb more energy than timber piles, but are not as stiff. This could pose a problem if the composite fender pile deflects too much. To date, composite piles have been used primarily for corner protection, as secondary fender piles, and as primary fender piles for small craft facilities.

5-3.3 Fenders.

5-3.3.1 General.

The Navy has developed UFGS 35 59 13.16, *Marine Fenders* as the governing specification for selection of marine fenders.

5-3.3.2 Directly Mounted Fender Units.

In this system, individual fender units like the end-loaded, rubber shear, or buckling type, are attached directly to the pier or wharf face. For narrow tidal range in solid piers and wharves, and for narrow vessel size range, this system may be cost-effective for direct berthing of surface ships. Although this system is very popular in commercial piers and wharves throughout the world, it may not be suitable for some DoD facilities. This system is subject to damage from snagging on ship protrusions at levels of 8 to 10 feet (2.4 to 3 m) above the water line and from vertical loads resulting from snags on rails and protrusions during falling tides or from lateral loads due to snags on protrusion during longitudinal movement of the ship.

a. End-Loaded Rubber Fenders. These work by elastic compression of hollow rubber cylinder elements with small length-to-diameter ratios. As shown in Figure 5-8(A), steel fender panels with special rubbing material facing are usually required to minimize wear. The reaction force is an exponential function of the deflection. These fenders are usually attached directly to the pier or wharf structure in the form of a "cell fender."

b. Side-Loaded Rubber Fenders. These are hollow rubber units available in trapezoidal, circular, square, or D-shapes that, when loaded at their side, deform by trying to flatten out. See Figure 5-8(B). The potential energy is stored by a combination of compression and bending of the rubber elements. The reaction force is an exponential function of the deflection and the performance curve is quite similar for all the shapes. Fenders having a curved rather than flat external surface increase in stiffness more gradually as the area of contact increases during deformation. All these fenders experience a sharp and rapid increase in stiffness when the amount of deflection completely collapses the open bore, regardless of their external contour.

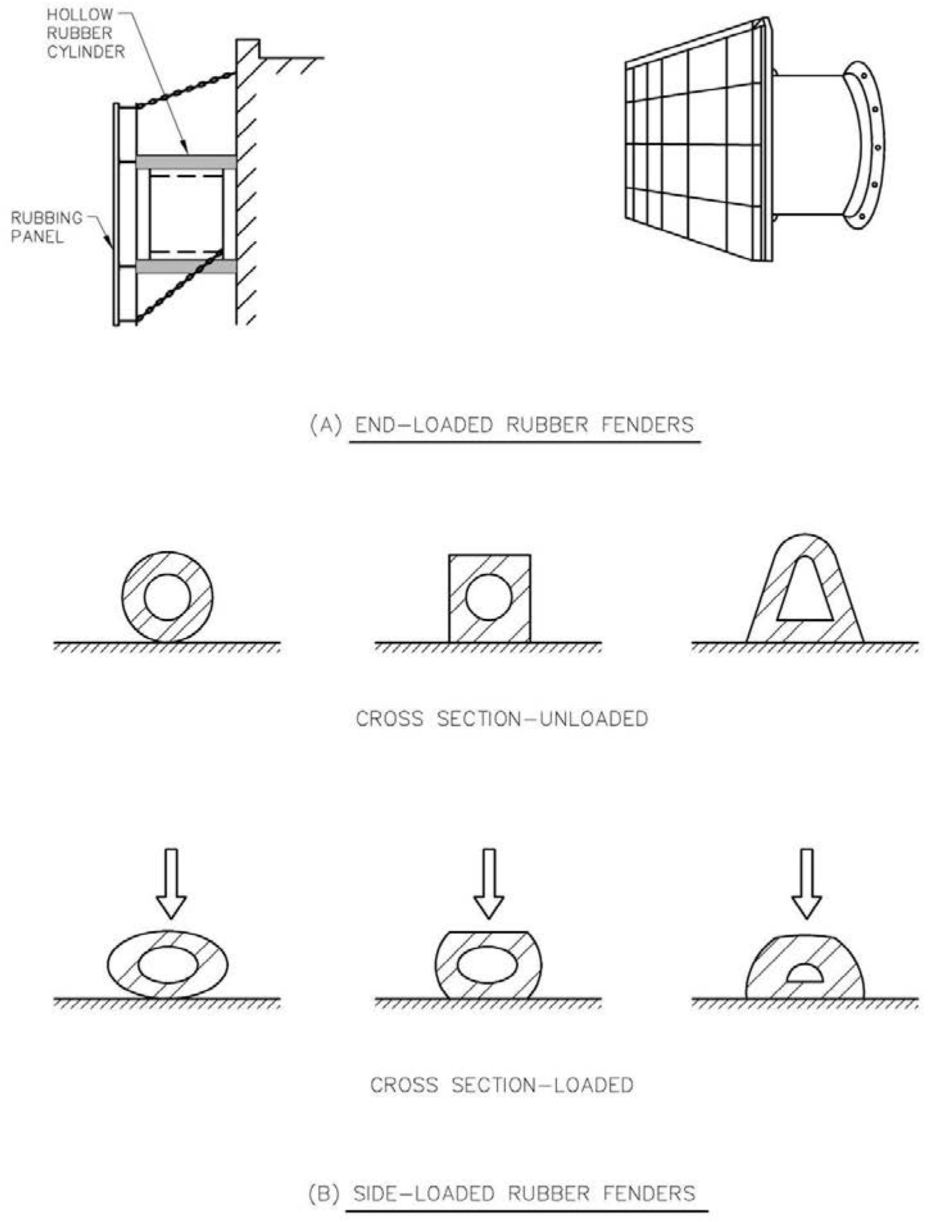
   Side-loaded rubber fenders will not absorb large amounts of energy and generally are not used alone. They are usually provided at the top of fender piles between the wale and berthing structure. A series of diagonal chains from the structure to the wale completes the system. When used with tight fitting joints between chocks, wales, and pile head, and when proper tension splices that provide compression and tension continuity along the face of the berth are used, the system has worked very well in both naval and commercial facilities. Ships may be berthed either directly or a floating camel may be used. When camels are used, size the fender piling to resist the resulting bending.

   Prestressed concrete, steel, and timber have been used successfully with side-loaded rubber fenders. This type of system provides good berthing flexibility. Ships of different sizes, tug boats, submarines, and barges can be accommodated without any modification.

c. Rubber Shear Fenders. The potential energy in these units is stored as elastic shear deformation of the rubber. Usually, a solid rubber block is vulcanized between two metal plates and the force is transferred through a fender frame or panel, as shown in Figure 5-9. These fenders are highly sensitive to proper manufacturing and installation as they depend on the bond between steel plates and the rubber. The force-deflection relationship is essentially linear.

d. Buckling Fenders. These fenders operate on the buckling column principle, in which a molded column of rubber is loaded axially until it buckles laterally. The end-loaded cylinder fenders described earlier are actually a buckling fender in principle. Most buckling fenders are not well suited for direct contact with a moving ship and hence are used with an abrasion or protector panel, as shown in Figure 5-10. The reaction force is linear up to a level when the pure compression behavior changes to the buckling mode. Hence, initially a relatively high reaction is built up with a small deflection, which then stays constant through the rest of the deflection range. Because buckling fenders are intended to buckle in a predetermined direction, any lateral deflection can significantly reduce their effectiveness. When lateral loads in either direction (parallel to length of berth or up/down) are anticipated, a cell-type fender is preferred. These fenders are becoming increasingly popular for berthing very large ships as they can absorb very high energy with a constant reaction force.

Figure 5-8 Side-loaded and End-loaded Rubber Fenders



SIDE-LOADED AND END-LOADED RUBBER FENDERS

Figure 5-9 Shear Fender

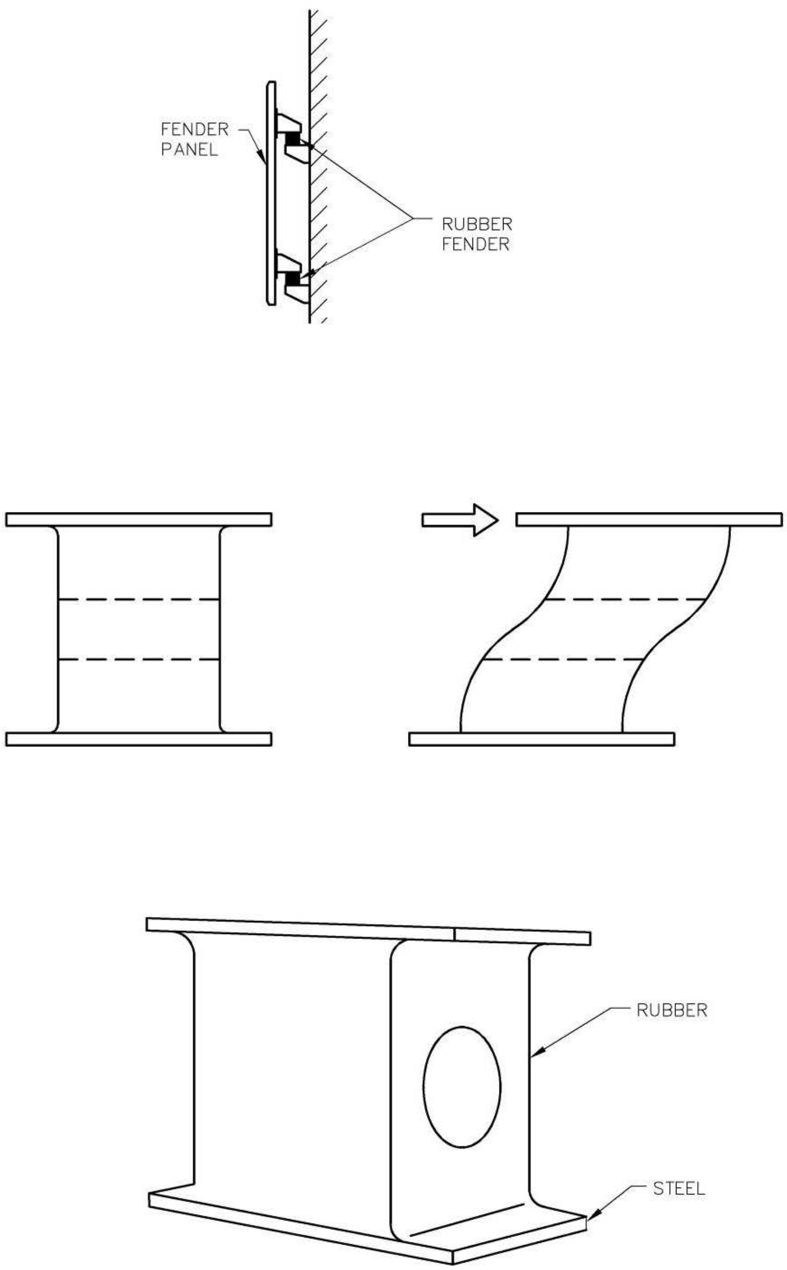


Figure 5-10 Buckling Fender with Contact Panel

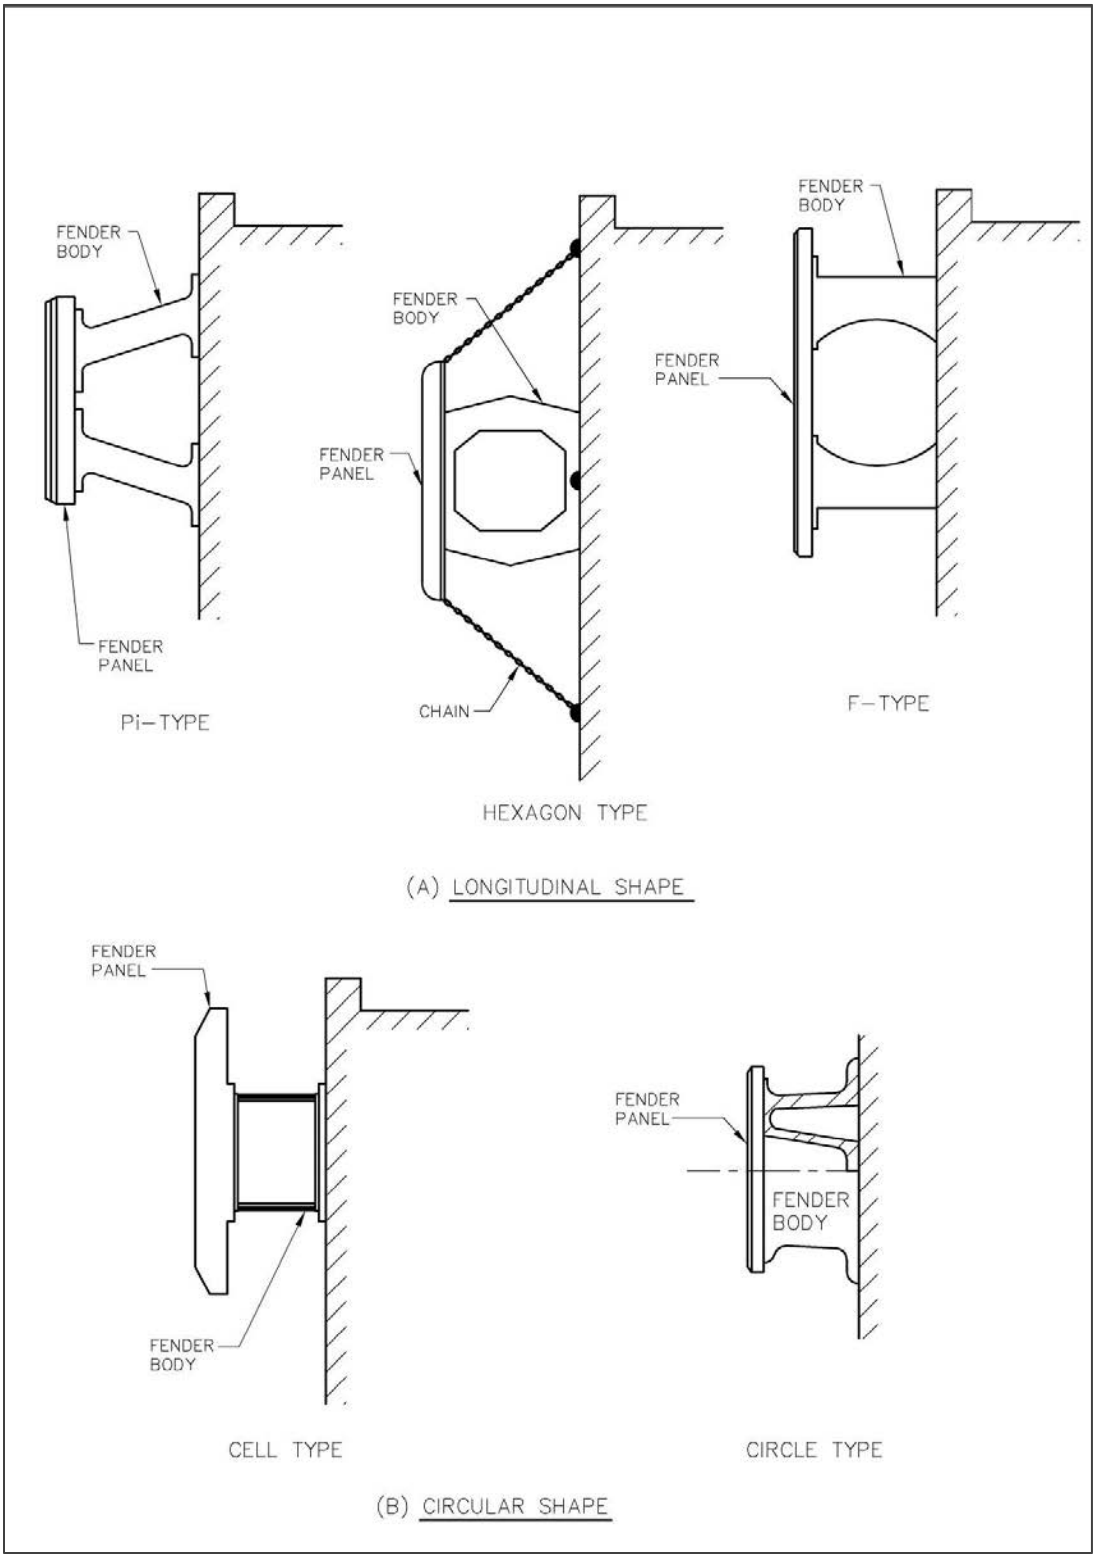

5-3.3.3 Floating Fender Units.

This system consists of pneumatic or foam-filled fender units and a backing system. As the fender units can be positioned to float with the tide, most surface ship types can be handled. Design the backing system to work with the fender unit for the full tidal range. Because the floating units are usually rather large, they provide a good standoff. The berthing structure may be designed with the backing system at different points along the length of berth and the fender units moved around as berthing plans change. When clustered piles or sheet piles are used for the backing system, additional energy can be absorbed by the piles and their support systems at the deck level.

a. Pneumatic / Hydro-Pneumatic Fenders. The potential energy in these fenders is stored by the elastic compression of a confined volume of air. By varying the internal pressure of air, the energy-absorption characteristic can be changed. To prevent the air pressure from increasing to a "blowout" level, pneumatic fenders are provided with a relief valve or deflection limiter within the body of the unit. The shell construction for these fenders is similar to an automobile tire with several laminations to provide the high tensile strength required. The surface pressure of these fenders is uniform, resulting in uniform hull pressure. Reaction force is an exponential function of deflection. The basic types of pneumatic fenders in common use are discussed below:

- Air Block and Air Cushion. The shells for these are chemically bonded and mechanically coupled to a rigid mounting plate that can be attached to a solid face of the berthing structure. See Figures 5-11(C) and 5-11(D).
- Floating. The floating type is usually cylindrical in shape with hemispherical ends and is attached to the structure by chains. It floats on the water and rises and falls with the tide. The unit requires a backing system to distribute the load. As shown in Figures 5-11(A) and 5-11(E), large floating pneumatic types are sometimes covered with a net of used automobile tires and cylindrical rubber sleeves to protect the fender from puncture and abrasion. The tire net and chains also form the means for rigging and attaching the fender to the pier.
- Tire. This type consists of a large-diameter tire mounted on an axle and backed by rollers. The unit can be mounted with its axis of rotation vertical or horizontal. This type is particularly suited for pronounced corners of the structure where ships may have approach difficulties. See Figure 5-11(B).
- Hydro-Pneumatic. This type of fender has been developed for use with submarines and consists of a vertically mounted cylindrical pneumatic fender partially filled with water and backed by a closely spaced group of fender piles. A ballast weight is added to adjust the degree of submergence of the fender to coordinate the vertical center of the fender with the horizontal center of the submarine hull; see Figure 5-12. The fender unit floats with the tide and therefore stays in the same relative position with the vessel.

Figure 5-11 Pneumatic Fenders

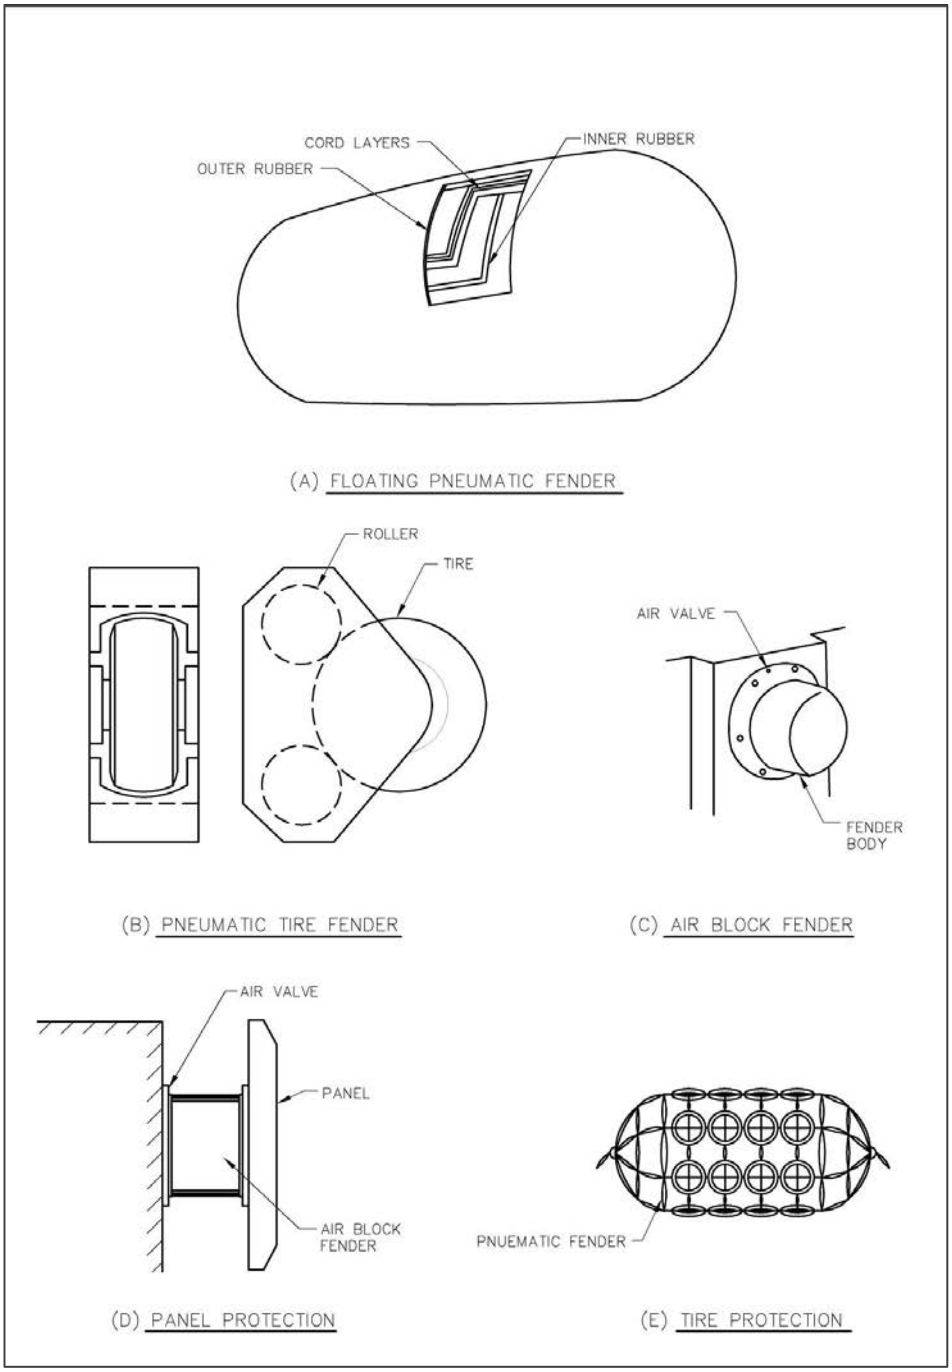

Figure 5-12 Hydro-pneumatic Fender

Hydro-pneumatic fender and counter weight being installed.
(*Marine Fender Systems*).

b. Foam-Filled Fenders. These are constructed of resilient, closed-cell foam surrounded by an elastomeric skin. Provide additional protection against abrasion by thicker elastomeric coatings or an external tire net, similar to the floating pneumatic type. The fender requires a backing system to distribute the load. Netless fenders cost more due to the need for thicker skins and coatings. However, the greater hull marking of the tire net and occasional maintenance need suggest that netless fenders may be preferred. The unit can either be utilized as a floating fender, moving up and down with the tide and held in place with chains or can be suspended from the pier/backing system. The cellular structure of the foam filling reacts like hundreds of millions of individual pneumatic fenders in deforming and absorbing the energy. The foam contains the air within its cellular structure and tends to compress upon itself rather than bulge peripherally. The foam-filled fenders have a high-energy absorption with comparatively small reaction force. Surface pressure of the fender is not quite uniform when it is compressed, so the hull pressure over the contact area is not quite uniform. Where rough concrete surfaces of the backing surface or prestressed concrete piles is a concern, use UHMW pads or strips to protect the skin of the foam filled fender. See Figure 5-5 for a typical foam-filled fender installation.

5-3.3.4 Combination System.

Any of the above-mentioned fender systems may be combined in the same berth. A berth may have either the floating fender units or directly mounted fenders at discrete points, with the in-between spaces filled up by the pile-rubber system designed to work with camels. Floating fenders and directly mounted fenders may be used alternately along solid or open types of piers and wharves.

5-3.3.5 Monopile System.

This fendering system is based on the use of a floating ring-shaped resilient fender unit that rides up and down on a large steel pile driven to the seabed. Special low-friction bearing pads are usually installed on the inner surface of the hull of the ring fender so that the fender unit can rotate and slide freely on the pile. This unique ability makes the monopile system very suitable for corner protection of piers and wharves and entrances to a narrow slip. The units can also work well as breasting and turning dolphins. Energy is absorbed both by the steel monopile in flexure and by the ring-shaped fender unit. This system is illustrated in Figure 5-13.

5-4 SELECTION AND DESIGN OF FENDER SYSTEMS.

5-4.1 General.

The major factors influencing the selection of the best fender system for a particular situation include the following:

5-4.1.1 Energy-Absorption Requirements.

Provide the fender system with sufficient energy-absorption capacity to absorb the kinetic energy of the berthing vessel.

5-4.1.2 Reaction Force.

This is the force that is exerted on the berthing structure during impact. The reaction force has a significant effect on the design of the berthing structure.

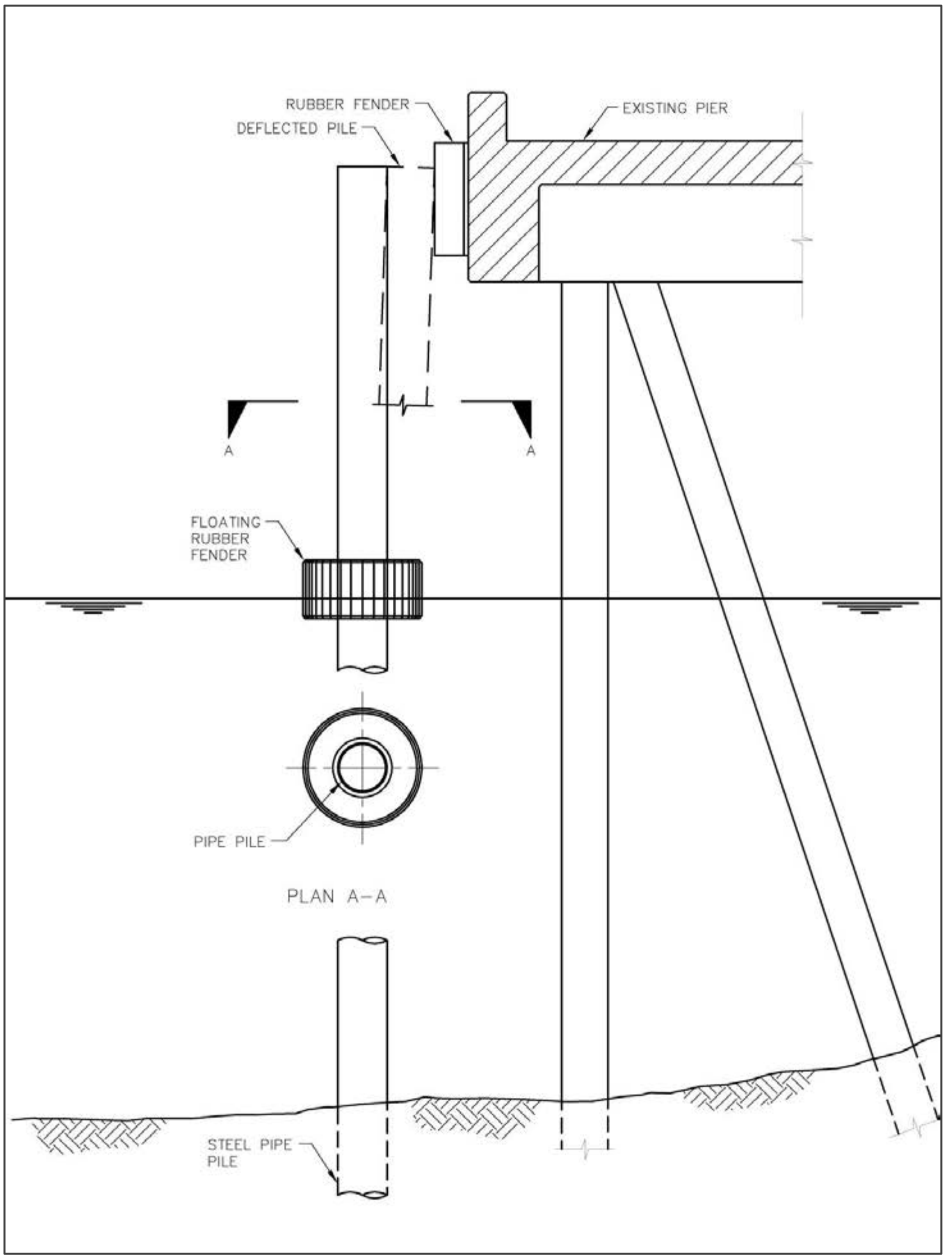
5-4.1.3 Hull Pressure.

This is the pressure exerted on the ship's hull by the fender unit and is derived by dividing the reaction force by the fender area in contact with the ship. Limit hull pressure to levels that will not cause permanent damage to the berthing ship.

5-4.1.4 Deflection.

This is the distance, perpendicular to the line of the berth that the face of the fender system moves in absorbing the ship's kinetic energy. The magnitude of the allowable deflection will be controlled by other protrusions from the berthing face and the ship.

Figure 5-13 Monopile Fender System



5-4.1.5 Reaction/Deflection Relationship.

The nature of the reaction deflection relationship determines the relative stiffness of the fender system.

5-4.1.6 Long-Term Contact.

This includes the changes in environmental conditions (i.e., wind, current, waves, and tide) during loading and unloading at the berth. The fender system should not "roll up," tear, abrade, or be susceptible to other forms of damage when subject to long-term contact.

5-4.1.7 Coefficient of Friction between the Face of the Fender System and the Ship's Hull.

This determines the resultant shear force when the ship is berthing with longitudinal and/or rolling motion and may have a significant detrimental effect on the energy-absorption performance of the fender system. The magnitude of the shear force also may have a significant effect on the cost of the berthing structure.

5-4.1.8 Degree of Exposures.

Where the berth is exposed to severe wind, current, and/or wave action, the fender selection may be governed by the design mooring conditions rather than berthing conditions.

5-4.1.9 Life-Cycle Costs.

Evaluate capital costs for both the fender system and the structure; also evaluate costs for operation, maintenance, and repair.

5-4.1.10 Berthing Practice.

The capability of the crews responsible for berthing the ship will have an effect on the energy-absorption requirement of the fender system. The berthing velocity and angle of approach are affected by the local berthing practice.

5-4.1.11 Maintenance.

Where maintenance is expected to be infrequent, a simple, possibly less efficient, fender system may be preferable to a system requiring a higher degree of maintenance.

5-4.1.12 Local Experience.

Consider fender types already used locally because their performance under actual conditions is known. Also, there may be an advantage in having interchangeability of spares, particularly if the number of new fenders required is small.

5-4.1.13 Frequency of Berthing Operations.

A high frequency of berthings normally justifies greater capital expenditures for the fender system.

5-4.1.14 Range of Ship Sizes Expected to Use the Berth.

While the energy-absorption capacity of the fender system may be selected for the largest ship expected to use the berth, ensure that the fender system is suitable for the full range of ships that the berth will accommodate. The effect of hull pressure and fender stiffness on the smaller vessels may have a significant influence on the selection and arrangement of the fenders.

5-4.1.15 Shape of Ship's Hull in Contact with the Fender System.

Where vessels with unusual hull configurations or protrusions are expected to use the berth or where the berth accommodates barges, pay special attention to the selection and arrangement of the fender system.

5-4.1.16 Range of Water Level to be Accommodated.

Consider the full range of water levels that may occur at the berth. Consider both the largest and smallest vessels, in both the loaded and light conditions, at high and low water levels. Where extreme water level variations occur, consider using floating fender systems.

5-4.1.17 Camels.

The size, type, and number of camels used in berthing operations will seriously influence selection of the fender system.

5-4.2 Fender System Behavior.

The fender systems having the most promise for new installations can be classified into three groups in terms of their behavior:

5-4.2.1 Flexible Pile Types.

The flexible pile types, or various fender piles discussed earlier, have basically a linear force-deflection relationship. Cantilevered piles or “monopile" systems likewise have a basically linear force-deflection relationship.

5-4.2.2 Buckling Column Types.

The buckling column types behave linearly up to a point where the rubber starts to buckle and behave nonlinearly from there on. Because the buckling type fender systems have the highest energy-absorption capacity for a given deflection and reaction, they are in very wide use in commercial piers and wharves. Due to the nature of the reaction/deflection/energy-absorption relationship of these types of fenders, a very high reaction (close to maximum) occurs during virtually every berthing operation. Design the berthing structure with this fact in mind. This fact also causes the fender to be relatively rigid when smaller ships use a berth designed for larger ones.

Many buckling-type fenders cause rather high contact pressures against the ship's hull and consequently require a panel to distribute and thus reduce the pressure. Size and locate the panel to ensure proper contact with both the largest and smallest vessels to use the berth. Another characteristic of these fenders to consider is their lowered performance when impacted by a vessel approaching at an angle to the berth or with a velocity component in the longitudinal direction. The reduction in energy-absorption capacity may be as much as 20 percent when the approach angle is 5 to 10 degrees, with additional reduction when combined with shear strain.

5-4.2.3 Pneumatic, Foam-Filled and Side-Loaded Rubber Fenders.

The pneumatic, foam-filled, and side-loaded rubber fenders exhibit very similar behavior with the reaction force building up more than proportional to increasing deflection. The floating pneumatic and foam-filled fenders have a similar appearance and similar reaction/deflection relationship. Compared to the buckling types, these fenders require greater deflection for a given reaction and energy-absorption capacity. Further, the pneumatic and foam-filled fenders present a relatively larger surface to the ship's hull and consequently have lower hull contact pressures. This eliminates the need for a panel between the ship and the fender. With the pneumatic and foam-filled types of fenders, the maximum reactions will normally occur only a very few times during the life of the facility, permitting the use of higher stress levels in the supporting structure. However, they require a rather large, solid face on the supporting structure, which may increase its costs. The main difference between pneumatic and foam-filled fenders is that the first will lose its strength completely when punctured by ship protrusions and that the latter may lose a significant part of its energy-absorption capacity under repeated heavy loadings.

5-4.3 Evaluation of Fender Systems.

5-4.3.1 Equal Energy and Reaction.

Figure 5-14 (A) illustrates the reaction-deflection characteristics of the three types of fender systems. The area under each of the reaction/deflection curves represents the energy absorbed by that type of fender. Each of the curves in the figure represents fender systems with equal rated reactions and equal energy-absorption capability. It is evident from the figure that, while the fenders of the various types illustrated provide equal energy absorption at equal rated reactions, the energy-absorption capacity is achieved through different deflections, with the buckling type deflecting the least.

5-4.3.2 Equal Reaction and Deflection.

A comparison of the various types of fenders may alternatively be considered on the basis of equal rated reaction and equal deflection, as illustrated in Figure 5-14 (B). This situation often occurs when new fender units are installed in conjunction with, and compatible with, an existing fender system. It may also occur when a replacement fender system is installed in an existing facility with cargo transfer equipment of limited reach. It is evident from the figure that the buckling type fenders have considerably more energy-absorption capacity for the same reaction and deflection than the other types.

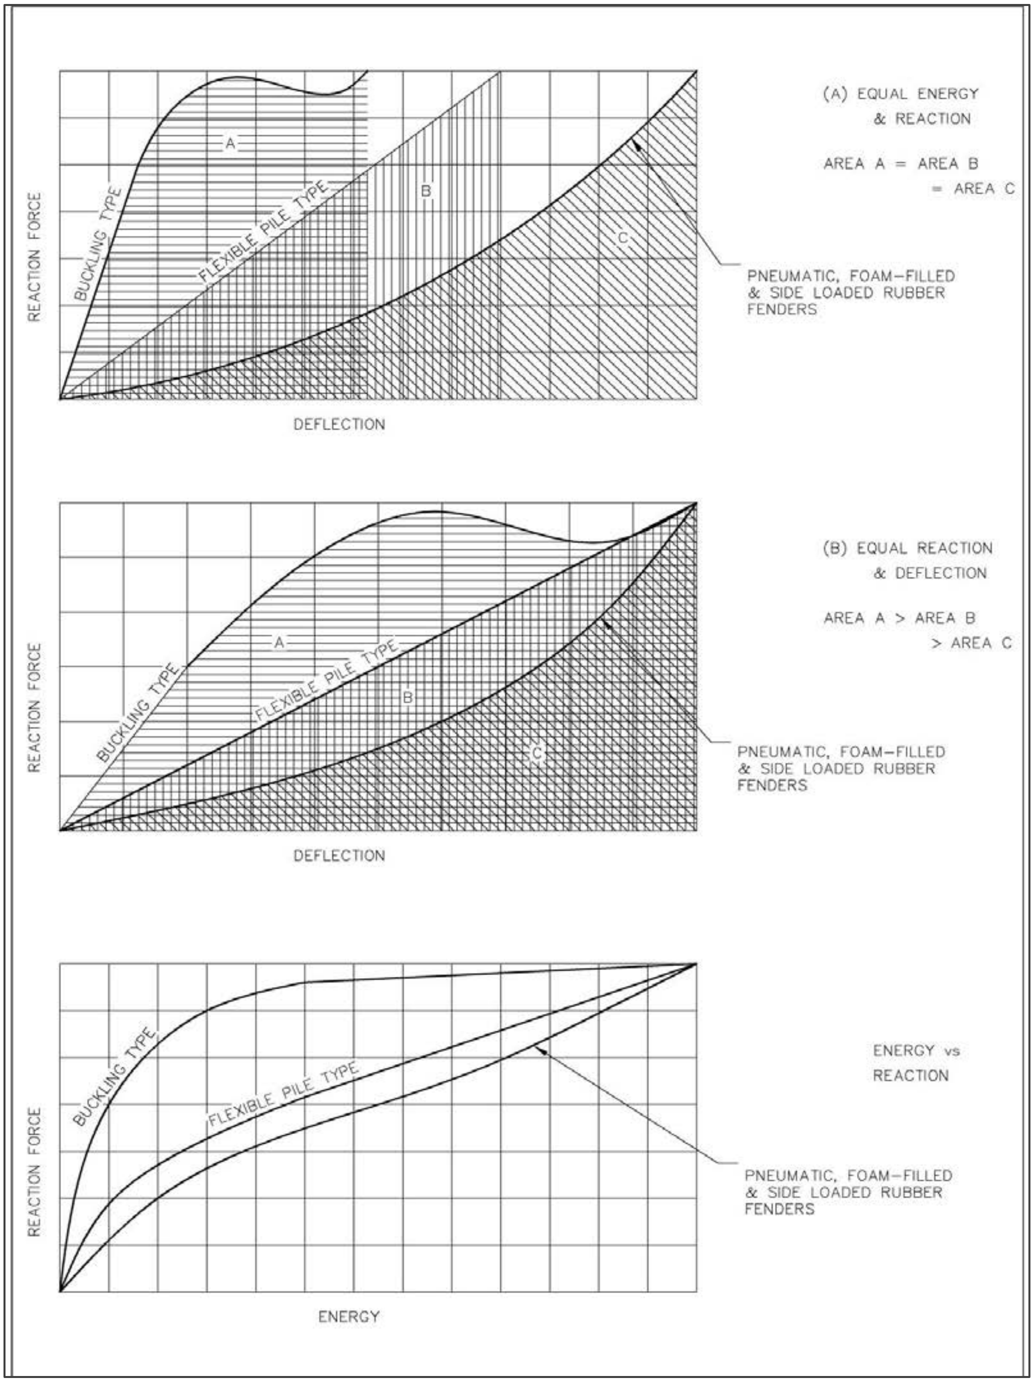
5-4.3.3 Reaction versus Energy Absorbed.

Comparing the various types of fender systems from the point of view of the reaction force that is developed for a given energy-absorption capacity, as illustrated in Figure 5-14 (C), it is evident that the pneumatic, foam-filled, and side-loaded rubber type fender units are the "softest." They have greater energy-absorption capacity at reaction levels less than their maximum rated reaction. This characteristic makes these fenders particularly attractive at berths that expected to accommodate a wide range of vessel sizes because the fenders will deflect significantly even when subjected to relatively small berthing impacts.

5-4.3.4 Accidental Overloads.

Also to be considered in the selection of a fender system is the consequences of an accidental overload of the system. The buckling and side-loaded rubber fenders "bottom out" if compressed beyond their maximum rated deflection, with resultant high reaction forces and the potential for severe damage to the berthing vessel and the support structure. The reaction of flexible pile fender systems will continue to increase at a uniform rate when overloaded until the yield stress of the pile material is reached, at which point continued deflection will occur as the material yields with no appreciable increase in reaction. Foam-filled fenders, when compressed beyond their maximum rated deflection, will exhibit a steadily increasing reaction and will incur permanent deformation and consequent loss of future energy-absorption capacity. The pneumatic fenders are normally fitted with relief valves so that when overloaded they continue to absorb energy with no increase in reaction beyond that which corresponds to the relief valve setting and no permanent damage to the fender unit.

Figure 5-14 Evaluation of Fender System Types



5-4.4 Fender System Design.

5-4.4.1 Ship Contact.

While the ideal berthing process would attempt to engage as many fender units as possible, in reality, at the time of impact, the ship will be at a slight angle to the berth and contact will be made over a small length. Design discrete fender units such as the buckling column type or the floating type, for one unit to absorb the full energy with a minimum of two units installed per berth. For the continuous system using flexible piles and fenders, the length of contact will be a function of the ship's hull radius at the level where contact is made, the flexibility and spacing of fender units, and the stiffness of the chock and wale assembly in the horizontal plane. The problem is analogous to a beam on an elastic foundation. In the absence of more rigorous analysis, the following assumptions for contact length may be made:

- 20 feet (6.1 m) for cruisers, destroyers, and frigates.
- 40 feet (12.2 m) for amphibious warfare ships, and auxiliary ships.

When berthing is made with camels, assume only one camel to be in contact at the time of impact, with a minimum of two camels installed per berth. Where the camels are guided by fender piles, assume all the piles to be effective in sharing the energy. When free-floating camels are used, not all the piles backing the separator will be effective. Local experience should dictate and a more conservative assumption should be made.

5-4.4.2 Allowable Hull Pressure.

When the ship's energy is resisted through foam-filled or pneumatic fenders, the resulting force is concentrated in a small area of the ship's hull. In such cases, the allowable pressure on the ship's hull becomes a critical design issue. Most surface combatants have a thin hull plating with a low allowable hull pressure. For more specific information on the ships being berthed, consult NAVSEA. See TR-6015-OCN, *Foam Filled Fender Design to Prevent Hull Damage*, and note that values in Table 7 are based on yielding of the hull plating and include a 1.5 safety factor. Consequently, when checking for an accidental condition, the allowable value for hull pressure may be increased by up to 50 percent.

5-4.4.3 Allowable Stresses.

Because ship berthing is a short-term impact type of loading, the following increases over previously published values are permitted.

a. Timber. For operating condition, the allowable stress in flexure (tension and compression) may be taken as 0.67 times modulus of rupture or the published allowable values increased by a factor of 2.0, whichever is less. For the accidental condition, the stress-strain curve may be assumed to be linear up to 0.9 times modulus of rupture, which should be taken as the limit.

b. Steel. For operating condition, the allowable stress in flexure (tension and compression) may be taken as 0.8 times yield stress. For the accidental condition, full yield stress may be used. However, the sections used should satisfy compactness requirements or the allowable stress reduced proportionately. Members should be sufficiently braced for development of the yield strength.

c. Concrete. Design reinforced and prestressed concrete members not intended for energy absorption with a load factor of 1.7 over forces developed due to operating condition; they will be satisfactory for the accidental condition. Do not allow further prestressed members to develop tensile stresses in excess of 12 f'_c (f'_c = 28-day compressive strength) in the precompressed zone. Prestressed concrete members specifically designed for energy absorption will have a maximum allowable working energy (E_{wc}) equal to 0.67 times the applied load (P) times the deflection at the point of the applied load. Satisfy the following three criteria to determine the maximum allowable working energy (E_{wc}) in the pile section for a given length:

- Maximum concrete compressive strain equal to or less than 0.0021 inch/inch (0.0021 mm/mm).
- Maximum stress in the prestressing steel at working energy equal to or less than 210,000 psi (1 447 899 kPa).
- The working energy (E_{wc}) no more than 2/3 of the nominal pile energy (E_{nc}). This provides a minimum factor of safety of 1.5 in case of overload of the pile.

5-4.4.4 Coefficient of Friction.

As the ship is berthed against the fender system, there will be force components developed in the longitudinal and vertical directions also. As the coefficient of friction between rubber and steel is very high, special fender front panels have been developed with reduced friction coefficient. Ultra high molecular weight (UHMW) plastic rubbing strips have been successfully used in front of timber piles. The following friction coefficients may be used in the design of fender systems.

- Timber to steel…………… 0.4 to 0.6
- Urethane to steel………… 0.4 to 0.6
- Steel to steel…………….... 0.25
- Rubber to steel…………... 0.6 to 0.7
- UHMW to steel…………… 0.1 to 0.2

5-4.4.5 Temperature Effects.

Fender piles, backing members, etc., are not affected by temperature fluctuations and can be expected to perform normally. However, in colder temperatures, rubber fender units become stiffer and their performance will be affected significantly. Hence, evaluate the energy-absorbing capability of the rubber unit and the fender system as a whole based on the lowest operating temperature expected. Carefully design and detail UHMW rubbing strips which have a significantly higher rate of expansion than steel or concrete to operate effectively.

5-4.5 Corner Protection.

Provide all corners of piers and wharves and entrances to slips with fender piles, rubbing strips, and rubber fenders for accidental contact with ships or routine contact with tugs. Use any of the different types of fender piles mentioned. See Figure 5-15 for typical details.

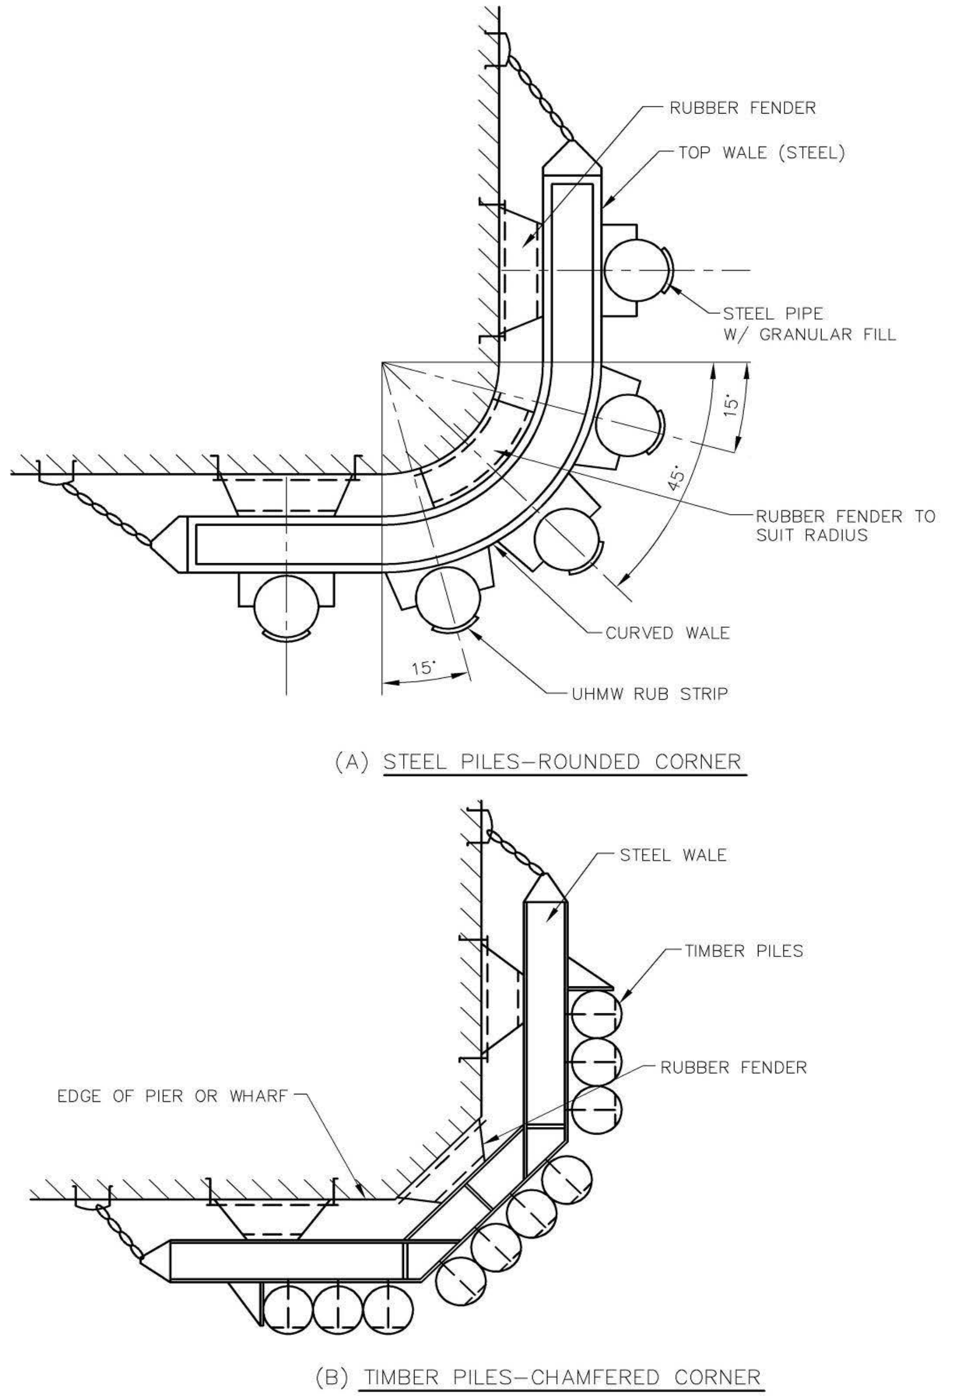
5-4.6 Support Chains.

Chains are commonly used in fender systems when a tension member is needed. Chains are used in continuous fender systems and large buckling and cell type units to resist the sudden energy released. For pneumatic and foam-filled resilient fender units, the chain is used to suspend the units. Chain smaller than 3/8 inch (9.5 mm) is not recommended. For better corrosion resistance, zinc coating is preferred. A common weldless high-test chain is usually more cost-effective than the stud link variety.

5-4.7 Chocks and Wales.

For selection and design of chocks and wales refer to SP-2045-SHR, *Proposed Design Criteria for Chocks and Wales.*

Figure 5-15 Corner Protection



This Page Intentionally Left Blank

CHAPTER 6 CAMELS AND SEPARATORS

6-1 FUNCTION AND APPLICATION.

Camels are structures used between the ship and the pier/wharf. Camels are a NAVFAC design responsibility. Separators are structures used between adjacent multiple berthed (nested) ships to provide a "standoff" or separation. Separators are a NAVSEA design responsibility. As mentioned in the previous section, design of fender piles or other backing system is required to provide the structural interface between the camel and the pier/wharf structure. Camels and separators are used at piers and wharves for the following reasons.

6-1.1 Hull Maintenance.

During active berthing, the ship's crew typically performs cleaning, painting, light hull repairs, and other routine maintenance activities on the ship. These activities are best performed when the ship is kept off the structure at discrete points.

6-1.2 Overhangs and projections.

Aircraft carriers that have large overhangs at the flight deck level, and several other ship types having bulges and projections at the side, require camels to prevent damage to the ship at these projections. Other protrusions include air masker bands, soft sonar domes, and stabilizer fins.

6-1.3 Special Hull Treatments.

Some ships are equipped with special hull treatments that can get damaged through constant rubbing against the structure. Camels and separators with rub strips can minimize the contact area and control the damage.

6-1.4 Submarine Berthing.

Navy submarines are typically berthed using camels. The submarines may be moored to the camels or moored directly to the berthing structure. Submarines require the camels to prevent damage to diving planes, screws, fairings, and the special hull treatments. Specifically, camels should not interfere with the Wide Aperture Array (WAA) found on some submarines. Further, special attention may be required for submarines equipped with the Conformal Acoustic Velocity Sonar (CAVES). These systems may require the camels to be located in specific locations. Develop berth specific camel mooring plans and coordinate with SUBFOR.

6-1.5 Multiple Berthing (Nesting).

Separators are required between ships that have to be berthed abreast for ship-to-ship transfer operations or for lack of berthing space at a naval station.

6-1.6 Fender Protection.

When the existing fender system can suffer damage due to motions of moored ships, a camel can be useful in reducing the damage as long as it is properly placed and the ship is properly moored.

6-2 CAMELS.

Experience has shown that camels left unattended in the vacant (no vessel present) condition at a berth can be subjected to damage from action by wind and waves, depending upon the degree to which the berth is sheltered. For this reason, a site specific study should be prepared for each berth where camels are to be utilized. The study should look at: environmental conditions, i.e. wind/wave climatology and vessels expected to utilize the berth. Procedures should be developed detailing how the camels will be moored and secured in place to include measures to buffer the camel face contacting the berth in order to prevent damage to the camel.

6-2.1 Log Camels.

These are large-diameter logs (24- to 36-inch (610 to 914 mm) diameter, 40 to 50 feet (12.2 to 15.2 m) long) held in the desired position from the deck by nylon ropes or chains. They are usually allowed to float with the tide. The longer length is preferred as they can distribute the load to a greater number of piles. Multiple log camels are made from several smaller diameter logs held together by wire rope at ends and at center. They are not as efficient as the single log camels. Plastic coated steel pipes have also been used successfully as camels. The pipe core is generally filled with foam to ensure positive flotation. Log camels fabricated from recycled plastics and composite materials are available. Sometimes a series of used tires may be fitted through the log to provide some energy absorption. Log camels do not provide much of a separation. When a wider separation is needed, other types of camels are more appropriate. Consider marine growth as it relates to log camel buoyancy.

6-2.2 Timber Camels.

These consist of several large timbers connected together by struts and cross braces to form a large crib. Additional flotation units may be inserted between the timbers for a higher freeboard. Wear causes bolt heads to become exposed and thus cause damage to hulls.

6-2.3 Steel Pontoon Camels.

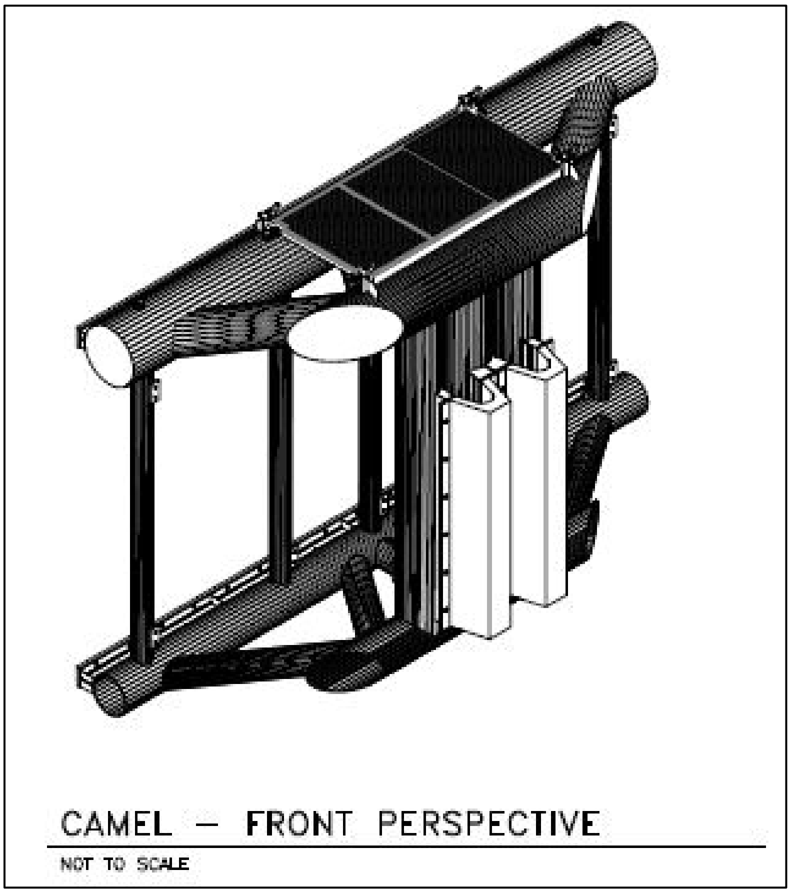
These are made of cubical or cylindrical steel pontoons connected by structural framing. The pontoons should preferably be filled with foam to reduce the risk of losing flotation by accidental puncturing of the units.

6-2.4 Deep-Draft Camels.

For submarine berthing where a good portion of the body is below the waterline, all the above camels are inadequate, as the camel will ride up on the submarine during berthing. Hence, deep-draft camels have been developed. They have limited energy absorption and a narrow working platform. These camels work well when mooring against a tender ship and for multiple berthing. When used against an open pier or wharf, these camels will require solid backing elements (below waterline) from the fender system. A typical deep-draft camel is shown in Figure 6-1.

Figure 6-1 Deep Draft Camel (NAVFAC drawing 100400035)

(Drawing By: B. Deneke)



6-2.5 Hydro-Pneumatic Fenders.

Although discussed previously under the section: Floating Fender Units, this type of fender has been used as a camel for submarines at a number of locations. One of the principle reasons for preparing the report, TR-6064-OCN, *Berthing Guidelines for Submarines,* was to investigate hydro-pneumatic fenders in terms of providing adequate clearance for the submarine's stern planes. Based upon the findings in this report, 14.8

feet (4.5 m) diameter hydro-pneumatic fenders are recommended in lieu of 10.8 feet (3.3 m) diameter hydro-pneumatic fenders.

6-2.6 Composite Camels.

NAVFAC EXWC developed a composite camel for use in berthing submarines. The camels are manufactured from composite materials intended to provide an extended service life over steel construction. The camels were developed and funded under a NAVFAC RDT&E effort and have been successfully used at SUBASE New London since mid-2000. Subsequently, a NAVFAC standard design has been developed and can be obtained at: http://www.wbdg.org/ffc/navy-navfac/cad. Universal composite submarine camels are shown in Figure 6-2.

Figure 6-2 Universal Composite Submarine Camel

6-2.7 Loads.

The camel loads are computed from berthing and mooring analysis of the ship, camel, fender, and structure system resisting the lateral loads. All the ship's berthing reaction loads as well as current and wind loads are transmitted through the camels to the pier or wharf structure. Assume all horizontal loads to be acting uniformly along the length. Design deck elements of large camels for 50 psf (2.4 kPa) vertical live load. Check the camel assembly for fabricated camels for lifting stresses. Where the pick-up points and rigging configurations are critical to control lifting stresses in the camels, provide clearly marked pick-up points or pad-eyes. For complex lifting requirements, provide lifting diagrams on the design drawings.

6-3 GEOMETRY.

The shape and size of fabricated camels are governed by the ship's geometry at waterline.

6-3.1 Length and Width.

Provide adequate length of camels in order to keep the contact pressure between camel and hull and between camel and pier fenders within allowable limits. This is particularly important where compressible fender faces are used that transfer reaction pressure directly to the hull plate versus the frames of the vessel. The length should not be less than the distance between three frames of the ship, three fenders or fender piles on the pier, or 30 feet (9.1 m), whichever is greatest. Minimum camel width is determined by the ship's required standoff; ships roll characteristics and freeboard, the presence of any overhanging projections on a ship and vertical obstructions on the dock such as gantry cranes or light poles.

6-3.2 Depth.

Provide adequate depth for submarine camels and separators to maintain contact with ship and pier/wharf in the full tidal range.

6-4 STABILITY.

There is usually some eccentricity between the horizontal load applied on the ship-side and the horizontal reaction provided on the dock-side. This is due to tilting of the camels (from imperfect flotation, buoyancy tank taking on water, etc.) and tendency of the camel to ride up and down with the vessel due to tidal fluctuations. The camel should have sufficient width, depth, and weight to provide roll stability for counteracting the effect of the load eccentricity and should have means of adjusting for variations in tilt and trim.

6-5 LOCATION.

For fine-lined ships, camels should generally be placed within quarter points of the ship to give strength and to bear on a reasonably straight portion of the hull. For straight-sided ships, camels may be located beyond the quarter points. Provide at least two camels for each class of ship. Camels should not be placed so as to bear directly against structural piles.

6-6 MISCELLANEOUS CONSIDERATIONS.

6-6.1 Protection.

Consider outfitting steel camels with a suitable protective coating or a cathodic protection system, depending on relative costs.

6-6.2 Buoyancy Tanks.

Buoyancy tanks should be compartmented or foam filled. Provide drainage plugs used for pressure testing the buoyancy tanks. Where pontoon camels are assembled in a single line, they should be ballasted for stability through plugged openings provided for this purpose. Consider the buoyancy of framing members and the weight of paint, if any, in the buoyancy and stability computations. Where buoyancy tanks are not foam filled to allow filling with ballast water or weights to adjust trim and freeboard of the camel, provide easily accessible fill/pump out and vent connections. These connections can be used to pump out excess water that leaks into the tanks.

6-6.3 Abrasion.

Camel fenders rubbing against a hull remove its paint. Exposed surfaces are subject to corrosive action, especially at the waterline. For these reasons, it is desirable to have camel fenders rub against hulls above the waterline where the hull can be repainted if necessary.

6-6.4 Service Life.

Service life is an important consideration related to camel selection operation and maintenance. Frequency of inspection, maintenance and overhaul should be determined for the type of camel system used. Life cycle economics should be considered in lieu of just first cost.

6-7 STANDARD CAMEL DESIGNS.

6-7.1 Submarine Camels.

Drawings and information on the camels described below may be obtained from the NAVFAC Atlantic - Engineering Criteria & Programs office.

6-7.1.1 Tapered Submarine Mooring Camel.

(NAVFAC Dwg 1404664-1404666). This tapered camel is framed from steel pipe with timber members on the front of the camel to support the rubber fender elements. This camel is intended for use with the SSN 688 class submarine.

6-7.1.2 Non-Tapered Submarine Mooring Camel.

(NAVFAC Dwg 1404943-1404947). This is a non-tapered version of the camel described above.

6-7.1.3 Attack Submarine Camel.

(NAVFAC Dwg 1404667-1404670). This camel is intended to replace the tapered camel described above. This camel is trapezoidal in shape and is framed from steel pipe. This camel is intended for use with both the SSN 688 and SSN 21 class submarines.

6-7.1.4 Revised Attack Submarine Camel.

(NAVFAC Dwg 10400031-10400034). This camel reflects recent revisions made to the attack submarine camel described above.

6-7.1.5 Trident Submarine Camels.

Specifically designed camels using guide piles along the specific wharves are used for trident submarine homeports at both Kings Bay, Georgia and Bangor, Washington.

6-7.1.6 Composite Camels.

Universal composite submarine camels have been designed and placed in use at numerous submarine bases. These camels were designed to be used with any class of submarine in the U.S. Navy. As a NAVFAC standard design, both drawings and specifications are readily available for use in procurements. Design criteria is provided on the drawings. NAVFAC drawings 14019607-14019615 are available at: http://www.wbdg.org/ffc/navy-navfac/cad. The Universal Composite Submarine Camel was designed with the flexibility to not interfere with the Wide Aperture Array (WAA) and can therefore be located along the length of the submarine with maximum flexibility. However, special attention may be required for submarines equipped with the Conformal Acoustic Velocity Sonar (CAVES). This system may require the camels to be located in specific locations. Develop berth specific camel mooring plans and coordinate with SUBFOR.

6-7.2 Aircraft Carrier Camels.

6-7.2.1 Steel Pontoon CVN Camels.

Aircraft carrier camels designed specifically for CVN 68 class aircraft carriers were available through an indefinite quantity contract (N00189-00-D-0254) which expired in September 2005. Camel design is proprietary. On 2 September 2004 an exercise was conducted in berthing CVN 65 alongside Pier 6 South at Naval Station Norfolk. This was to learn more about CVN berthing at a double deck pier. One significant finding was the need to increase the standoff of the aircraft camel by approximately 5 feet (1.5 m) to give additional standoff. Figure 6-3 shows a CVN camel in plain view (prior to the additional 5-foot (1.5-m) standoff).

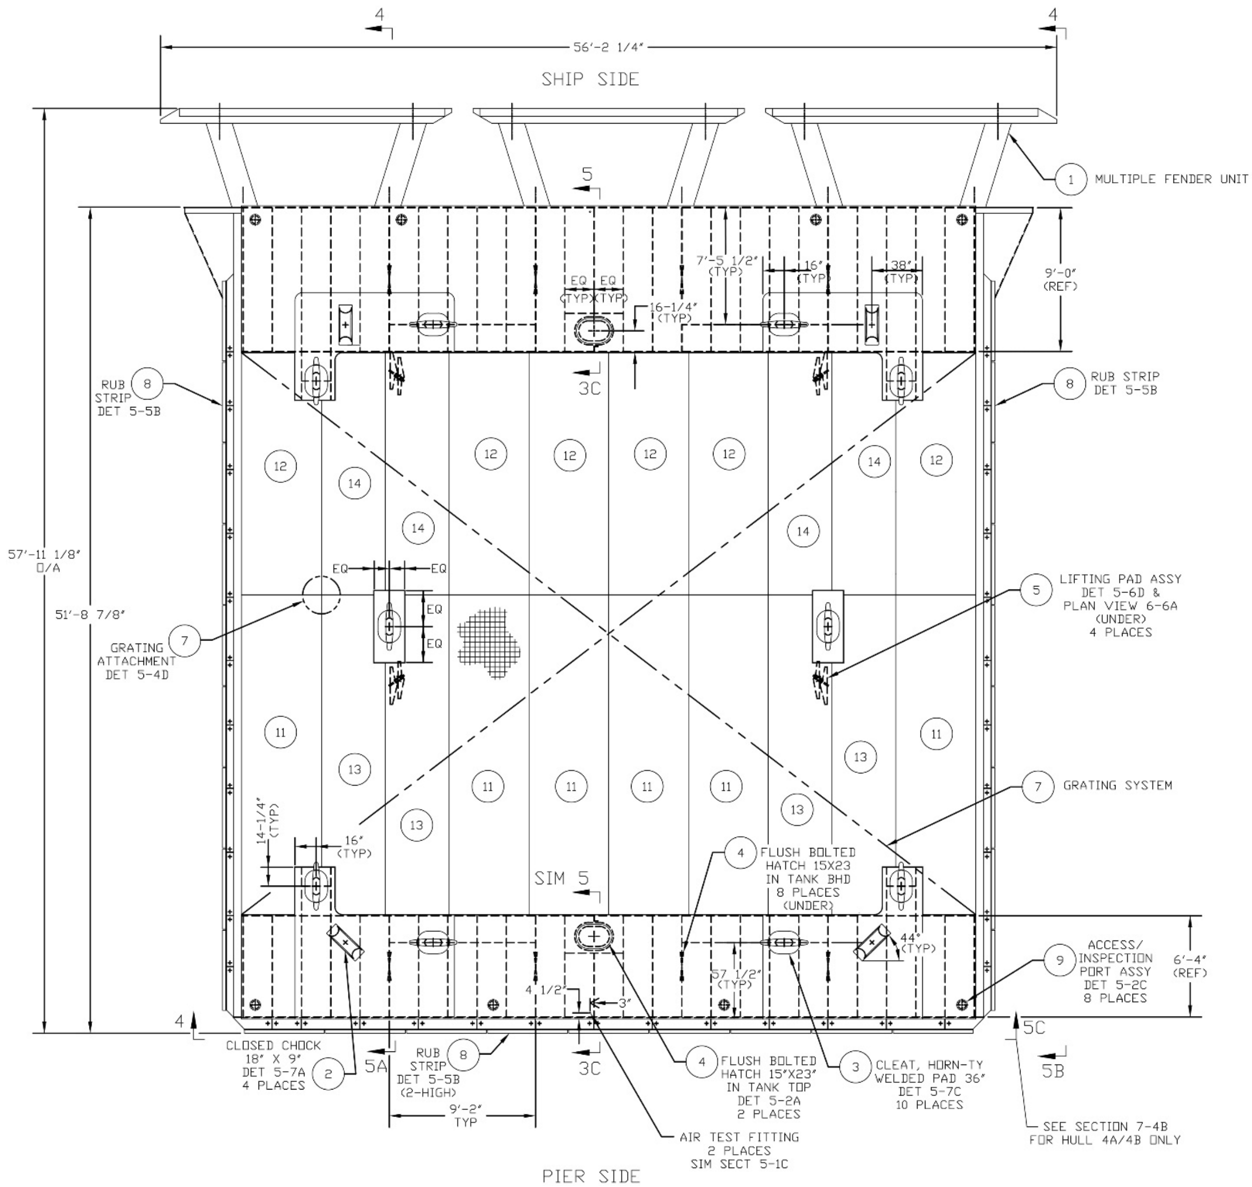
The following pertinent information is provided for the CVN camels:

- Construction – steel floating frame pontoon.
- Loads – 1500 kip (6672 kN) lateral and 500 kip (2224 kN) longitudinal reaction force transmitted to the camel fender system along the length of the camel. Values were based on maximum wind and current forces associated

with heavy weather conditions (95 mph (42.5 m/s) wind, 1 knot (0.51 m/s) current) and breasting reaction associated with CVN berthing assuming a maximum approach velocity of 0.5 feet/second (0.15 m/s).

- Suitable for placement along the flat side of the hull approximately between frames 110 and 190 with an allowable hull pressure of 30 psi (207 kPa).
- Working surface designed for 100 psf (4.8 kPa).
- Size: 56 feet-2 1/4 inch (17.1 m) wide with standoff of 57 feet-11 1/8 inch (17.7 m) (undeflected fender).
- Weight: 95.4 long tons (951 kN).
- Light draft: 3.66 feet (1.12 m); Live load draft: 4.34 feet (1.32 m).
- Light freeboard: 3.3 feet (1 m); Live load freeboard: 2.4 feet (0.73 m).

Figure 6-3 Aircraft Carrier Camel



6-7.2.2 Universal Composite CVN Camel.

Under a design-build procurement, NAVFAC has developed a universal composite CVN camel. Universal composite CVN camel rendering is shown in Figure 6-4.

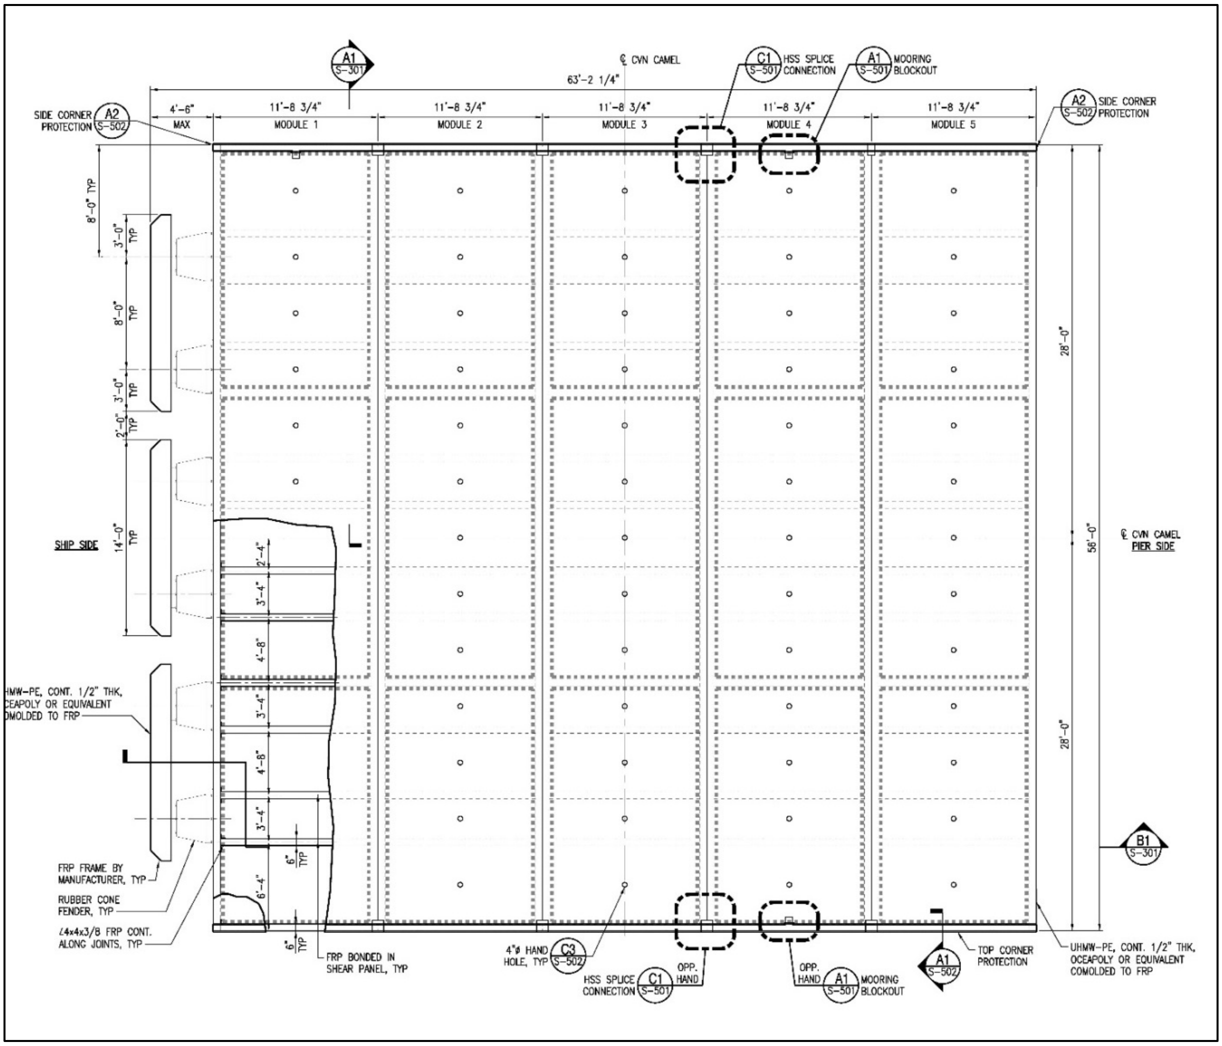
Universal composite CVN camel was developed based upon the following criteria:

- Construction – FRP.
- Loads – 1,500 kip (6,672 kN) lateral and 300 kip (1334 kN) longitudinal reaction force transmitted to the camel fender system along the length of the camel. Values were based on maximum wind and current forces associated with heavy weather conditions (95 mph (42.5 m/s) wind, 30 second gust, 1 knot (0.51 m/s) current) and breasting reaction associated with CVN berthing assuming a maximum approach velocity of 0.3 feet/second (0.09 m/s).
- Suitable for placement along the flat side of the hull approximately between frames 110 and 190 with an allowable hull pressure of 30 psi (207 kPa).
- Uniform live load on overall camel structure ~ 20 psf (1 kPa).
- Uniform live load on individual module top panel ~ 60 psf (3.9 kPa).
- Maximum vertical live load on top panel ~ 20 kips (89 kN) on 6 inch by 6 inch (152 mm by 152 mm) base plate.
- Size: 56 feet (17.1 m) wide with standoff of 63 feet-5 inch (19.3 m) (undeflected fender).
- Weight: 369.1 kips (1642 kN).
- Camel Height: 7 feet-8 inches (2.3 m).

6-8 SEPARATORS.

As mentioned previously, separators are a NAVSEA responsibility. Design for a universal submarine-to-submarine type separator is found on NAVSEA Dwg 6983485. A useful reference from NAVSEA is NSTM 018, Chapter 611, *Fenders and Separator*s.

Figure 6-4 Universal Composite CVN Camel



This Page Intentionally Left Blank

CHAPTER 7 ACCESS

7-1 GENERAL.

Several access structures are used in piers and wharves for moving personnel and cargo, and accommodating selected utility lines. They have unique design requirements. Some are of standard design while others are designed and constructed specifically to go with the facility. The access facilities covered by this manual are landing float, brow or gangway, brow platform, walkway or catwalk, and ramp. Utility booms are discussed in UFC 4-150-02, *Dockside Utilities for Ship Service*. Where there is a potential need for access by a physically handicapped person, meet the applicable requirements of the *Americans with Disabilities Act Accessibility Guidelines* and the *Uniform Federal Accessibility Standards*, and when they differ, the one with the greatest accessibility requirement will govern.

7-2 SAFETY.

Safety on piers and in pier design is an important consideration. Consider operational uses and where possible provide safety precautions, protections and warnings to minimize the potential hazards. Double deck piers require additional safety considerations. Potential uses and needs for pier deck space are unlimited and should be evaluated based on the local requirements. It is essential that safety and operators be involved in the pier design, so potential uses can be identified, categorized and policy determined. In particular high-voltage electrical, fall hazards, trip hazards, and access to industrial or mechanical areas are issues that require additional consideration. In light of this, a study was conducted entitled, *Lower Deck Pier Safety Study*. Numerous activities were examined in detail and a matrix developed specifying essential use activities as well as prohibited activities. Although this study was somewhat site specific for Naval Station Norfolk, it should be consulted for details on safety solutions and recommendations. For example, the study provides useful information such as details on all signage required and detailed plan views of both upper and lower decks for the double deck piers at Naval Station Norfolk which show:

- Utility locations
- Activity areas
- Striping
- Transit paths
- Vehicle turn locations
- Curb, fencing, guardrail, handrail, lighting, life ring, fall protection and signage locations

7-2.1 Fall Protection.

In contrast to previous versions of this document, fall protection is now a requirement for mitigating fall hazards on U.S. Navy piers and wharves. Comply with Department of the

Navy Fall Protection Guide, Section 9.13 Work Over Water. This reference provides the relevant information on standards, regulations, criteria, and requirements for fall protections. In particular, fall protection systems, criteria, and design requirements are provided.

7-3 LANDING FLOAT.

When piers and wharves need to be accessed from the waterside by small craft such as patrol boats (which cannot berth directly), a landing float and a brow are required.

7-3.1 Materials.

Flotation units may consist of foams of polystyrene and polyurethane, fiberglass-reinforced polyester resin shells with or without foam cores, metal pontoons, metal pipes, metal drums, and hollow concrete sections. Timber logs, the earliest form of flotation unit and the cheapest, have a tendency to become waterlogged and their use is not recommended. Decks of floats are variously made out of wood planks, plywood, plywood and fiberglass-resin coatings, concrete, and nonskid metal surfaces. Framework for floats is generally of preservative-treated timber, although steel and aluminum are often used. All ferrous metal hardware should be galvanized or otherwise protected from corrosion.

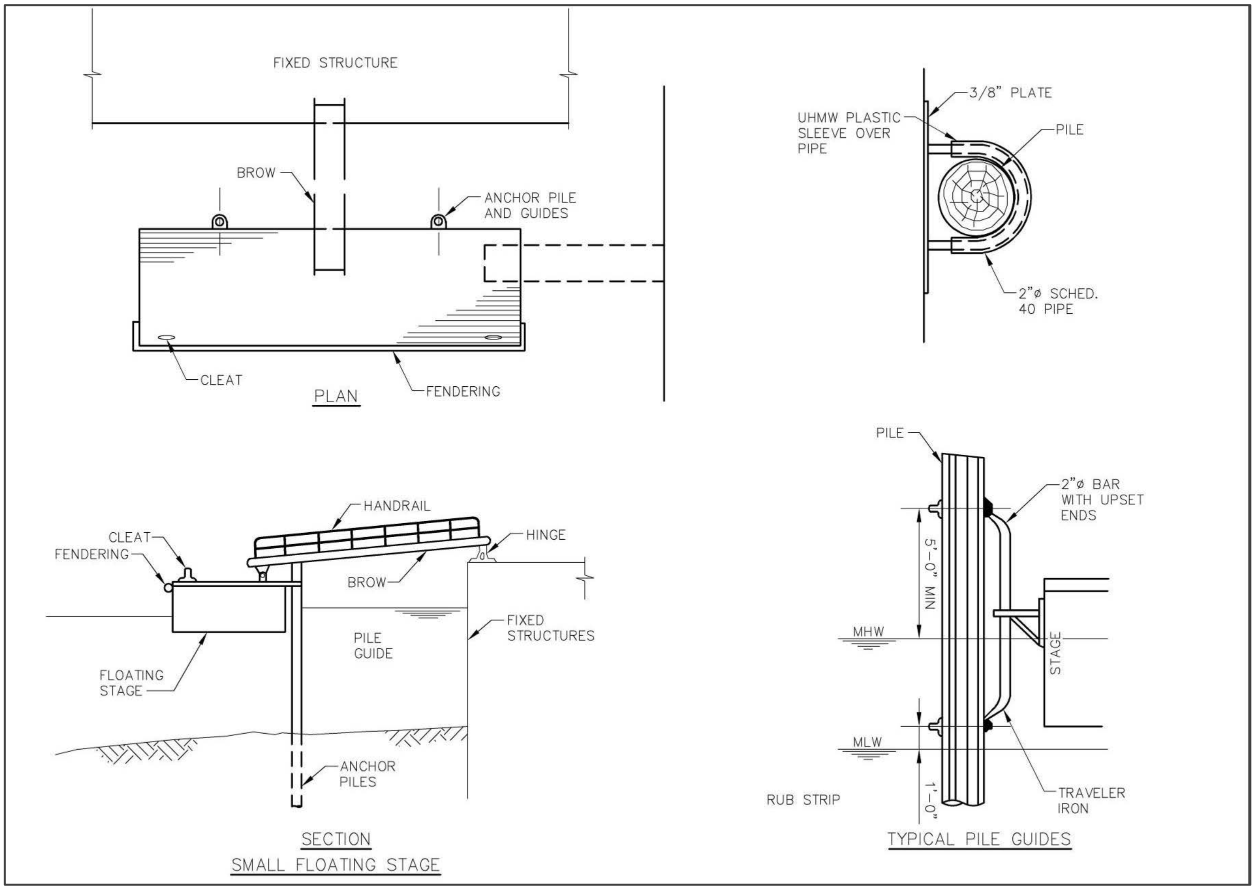
7-3.2 Mooring Systems.

Anchor floats to prevent movement by wind, current, waves and impact from the ships. Anchorage may consist of individual vertical (guide) piles, frames of batter and vertical piles, and cables or chains. When piles are used to anchor small floats, guides are furnished to secure the float to the anchor pile. Commonly used guides are rigidly braced metal hoops of pipes, rollers, or traveler irons. Chains and flat bar guides should not be used as they cause the float to hang up on the piles. See Figure 7-1 for details. This system works well for shallow waters with a large tidal range. In deeper water, the pile head may have to be supported by the structure or pile driven deeper. Anchorage may also be obtained from a cable or chain system attached to the ocean bottom or to the fixed pier or wharf structure.

7-3.3 Live Loads.

Design stages for landing personnel only for a uniform live load of 50 psf (2.4 kPa) or a concentrated live load of 500 pounds (2.2 kN) placed at any point on the deck surface. The float should not tilt more than 6 degrees from the horizontal when applying the concentrated live load of 500 pounds (2.2 kN).

Figure 7-1 Small Floating Stage



7-3.4 Freeboard.

Floating stages for small craft usually ride with the deck from 15 to 20 inches (381 to 508 mm) above the water surface under dead load. Live loads usually lower the float about 8 to 10 inches (203 to 254 mm).

7-3.5 Fendering.

Provide fenders on all floating stages. For small craft berthing, fenders may consist of soft, flexible rubbing strips (rubber tires, sections of hose).

7-3.6 Fittings.

Provide a minimum of three cleats (5,000-pound (22 kN) capacity) for securing small craft.

7-3.7 Finish.

Provide the deck with a nonskid surface. Where wheels or rollers from a brow will be resting on the float, provide guide channels or a skid plate to prevent damage to the float.

7-3.8 Concrete Float Elements.

Concrete encased plastic foam elements designed for use in concrete floating docks for marinas can be connected together in various configurations to be used as work floats. The mass added by the concrete encasement creates a very durable float that is less affected by waves and live loads than more lightweight systems.

7-4 BROW OR GANGWAY.

Brows are used for access to landing floats from the pier or wharf structure, however they are more frequently used to provide personnel access from a pier or wharf to a berthed ship.

7-4.1 Length.

Brows should be of sufficient length so that the slope will not exceed 1.5 horizontal to 1.0 vertical at the worst condition.

7-4.2 Widths.

Widths should be 36 inch (0.9 m) minimum (clear) passage for one-way traffic and 48 inch (1.2 m) minimum (clear) passage for two-way traffic. Provide a 60 inch (1.5 m) minimum (clear) passage for two-way traffic when personnel carry small loads.

7-4.3 Construction.

Use fiberglass, aluminum, steel, timber, or a combination of these materials. Aluminum and fiberglass are generally preferred for the low weight to strength ratio and corrosion protection.

7-4.4 Live Load.

Design the brow structure for a uniform live load of 75 psf (3.6 kPa) and a concentrated live load of 200 pounds (0.9 kN) applied anywhere. A reduction in the live load to 50 psf (2.4 kPa) may be permissible where the brow is to be used in conjunction with a landing float. For calculation of reaction to the landing float, the live load can further be reduced to 25 psf (1.2 kPa).

7-4.5 Handrails.

Design handrails to resist 50 plf (0.73 kN/m), applied in any direction at the top. Design handrails to resist a single concentrated load of 200 pounds (0.9 kN), applied at any direction at any point along the top. It is assumed that the uniform load and the concentrated load do not act concurrently. The handrail may be designed to serve as the top chord of a truss when sufficiently braced.

7-4.6 Safety.

Provide safety devices to keep the brow from rolling off the platform deck and to prevent movement of the platform while in use. Clip safety chains into position for personnel safety. Large tidal variations are a problem because these may cause the brow to roll off the platform. A similar situation exists when high winds, currents, and extreme tides pull a ship away from the pier. Numerous accidents have been associated with brows being supported by pallets either on the ship end or pier end of the brow. Brows are not to be used in conjunction with pallets. If a platform is necessary, properly engineer, design, and build under the technical cognizance of NAVFAC. NAVFAC EXWC had designed a safety gangway ramp as step to alleviate this issue. For additional information, contact NAVFAC Atlantic - Engineering Criteria & Programs.

7-5 BROW PLATFORMS.

Brow platforms are used when a brow from ship deck to pier deck is not practical, or presents an obstruction. Examples are portal crane trackage along repair berths, large tidal variations, and great height from deck to pier. Aircraft carriers (CVNs) usually use one brow forward and two aft. These brows require platforms 20 feet (6.1 m) or higher. This platform is basically a truncated tower, with typical measurements of 12 by12 feet (3.7 by 3.7 m) at the base, while the top deck is 5 feet (1.5 m) wide and 10 feet (3 m) long. If small stair platforms are built alternately opposite hand, the requirement for a large platform can be met by lashing two of the smaller ones together. Sometimes the ship end of the brow can be connected to a rotatable platform which is permanently fixed to the ship by means of pins that lock the brow pivot hooks to the circular rotating portion of the rotatable platform. Construction materials and live load requirements are the same as for brows.

7-6 BROW AND PLATFORM DESIGNS.

Standard designs for brows and platforms are found in NAVFAC Dwg SD1405000-1405041 at: http://www.wbdg.org/ffc/navy-navfac/cad.

7-7 WALKWAY OR CATWALK.

These are permanent personnel access bridges installed between shore and different elements of piers and wharves. One example is a walkway between the pier or wharf structure and a mooring dolphin located some distance away as shown in Figure 2-1.

7-7.1 Width.

For walkways between shore and a U-shaped wharf, a 4-foot (1.2 m) width is recommended. For infrequently used walkways, the minimum width should be 3 feet (0.9 m).

7-7.2 Live Load.

Design all walkway structures for 100 psf (4.8 kPa) live load.

7-7.3 Construction.

Walkway decking should be slip-resistant aluminum or fiberglass grating. Framing may be wood, aluminum, or fiberglass members. In view of the light loads encountered, piles supporting deck stringers can be of treated timber. Where loads and installation difficulty make timber piles inadequate, concrete and steel piles may be used.

7-7.4 Handrails.

Provide handrails on either side of the walkway. Consider handrails for use along edges of approach trestles and along non-berthing extents of docks or wharves.

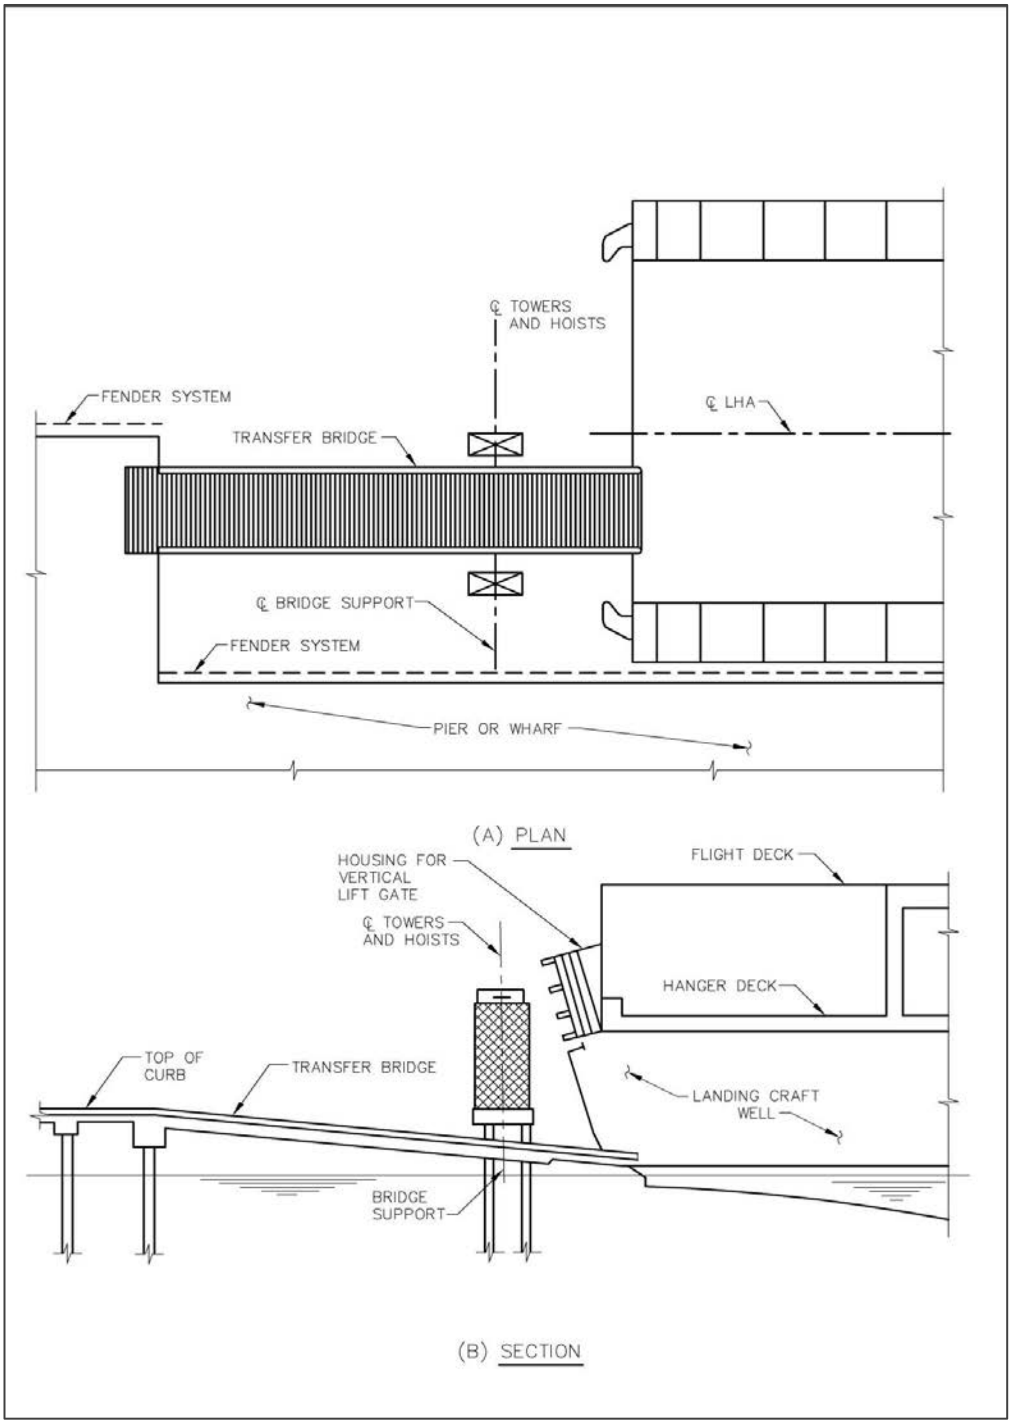
7-8 RAMPS.

Transfer bridges or ramps are sometimes required for moving vehicles or heavy cargo from ships, similar to a roll-on/roll-off (RO/RO) operation. MSC RO/RO ships do not require any special features on existing piers. Sideport ramps are stowed and handled by the ship. Sternport ramps are hinged to the vessel and extend to dockside or floating equipment (lighters, causeways, stages). These ships also have conventional cargo gear.

The LHA-class of amphibious assault ships has vertical lift stern gates, possess RO/RO capability. Installations accommodating vessels of this type should consider the use of a ramp or transfer bridge, as shown on Figure 7-2, to minimize the time required for movement of vehicular equipment and for loading of supplies. Design and construction of ramps should be similar to highway bridges. One key issue regarding ramps is clearance from pier/wharf edge obstructions, i.e. utility risers, cleats, bollards, etc. When designing piers and wharves, consider the specific location for ramp landing as well as structural deck strength.

As discussed previously, sideport loading ramp access for LHA, LHD, and LPD 17 class ships is an important consideration, particularly on double deck piers.

Figure 7-2 Transfer Bridge for LHAs



7-9 SAFETY LADDERS AND LIFE RINGS.

7-9.1 Safety Ladders.

Provide safety ladders from pier or wharf deck to water at a maximum spacing of 400 feet (122 m) or as noted below with regard to life rings. Such ladders should be at least 1 foot-4 inches (0.41 m) wide and should reach the lowest water elevation anticipated. Safety cages are not required. Safety ladders may have grab bars to protect from mooring lines and hinges to protect the ladder from small boat damage in lieu of rail extensions. It is recommended to provide guard timbers/fenders on either side of the ladder, or to protect within the fender system. Locate the ladders on either side for a pier wider than 50 feet (15.2 m). For piers less than 50 feet (15.2 m) wide, insure that an individual could swim under the pier to reach the ladder on the opposite side or provide ladders on both sides. Locate ladders on the waterside for a wharf at places convenient to anyone who might accidentally fall into the water. Figure 7-3 illustrates a safety ladder for a pier or wharf, while Figure 7-4 illustrates a safety ladder with a 3-foot (0.9 m) extension along an unprotected bulkhead, rope guards may be required to protect the ladder extension.

Safety/emergency egress ladders are different than access ladders. Safety regulations may vary from location to location. Coordinate with local safety office on specific ladder requirements, marking, and use.

7-9.2 Life Rings.

29 CFR 1917.26, *First Aid and Lifesaving Facilities* requires that a U.S. Coast Guard approved 30-inch (0.76 m) life ring, with at least 90 feet (27 m) of line attached, shall be available at readily accessible points at each waterside work area where the employees' work exposes them to the hazard of drowning. Provide a readily available portable or permanent emergency egress ladder giving access to the water within 200 feet (61 m) of work areas. Co-locate life rings with permanent ladders.

APPENDIX B GLOSSARY

B-1 DEFINITIONS.

Breasting Dolphin – A freestanding independent structure that a vessel will bear against when current, wind or berthing motion moves the ship into the pier or wharf. Breasting Dolphins are typically equipped with energy absorbing fender systems and are pile supported or solid fill structures.

Bulbous Bow – A protruding bulb at the bow (or front) of a ship just below the waterline.

Bullrail – A wide low curb along the outboard edge of the pier or wharf. The bullrail may be cast-in-place concrete, steel or timber. Bullrails may be fixed or removable. Mooring hardware is often mounted on top of the bullrail.

Camel – A floating structure used to separate a moored vessel from the pier or wharf. Camels are used with ships that have hull configurations that do not match well with typical pier or wharf fender systems, such as, submarines or where vessels require an offset from the pier or wharf due to deck or superstructure overhangs such as an aircraft carrier.

Catwalk – A narrow walkway, especially one high above the surrounding area, used to provide access or allow workers to stand or move.

Cold Iron – Used to describe the condition of a ship when all shipboard boilers, engines, and generators are inoperative during repairs or due to intentional shutdown and can furnish none of the ship’s required services.

Degaussing – The degaussing system is installed aboard ship to reduce the ship's effect on the Earth's magnetic field. In order to accomplish this, the change in the Earth's field about the ship's hull is "canceled" by controlling the electric current flowing through degaussing coils wound in specific locations within the hull. This, in turn, reduces the possibility of detection by these magnetic sensitive ordnance or devices.

Dolphins – A free standing pile supported or solid filled structure used for mooring and berthing vessels, protection of the end of piers or wharves, turning ships, or protection of bridge substructure.

Dry docks – A specialized facility used for the repair of ships where the vessel is removed from the water or placed within a lock and the water is removed leaving the ship in the dry to facilitate repairs.

Fenders – Energy absorbing devices used on the face of a pier, wharf or dolphin to protect the ship and shore facility from damage due to contact between the two during berthing and mooring.

Hawser – A thick cable or rope used in mooring or towing a ship.

Homeport – Port for a specific ship that has been identified as such by Commander Fleet Forces Command and is listed in the Naval Register. The homeport is where the ship is assigned and offers all requisite services required by the ship to include the full complement of hotel services.

Hotel Services – Dockside utilities provided for a ship at a berth (also called ships services, utility services, and cold iron services).

Lighterage – Small craft designed to transport cargo or personnel from ship to shore. Lighterage includes amphibians, landing craft, discharge lighters, causeways, and barges. Based on the idea of using use hollow, sheet steel boxes as pontoons and pontoon-assembled structures.

Magnetic Treatment Facility – Due to magnetic fields that are constantly being encountered during normal ship operations, ships and submarines build up a magnetic signature. The earth's natural magnetic fields between the North and South poles are being crossed routinely while the vessels are underway. The traversing of these natural fields, and vessels lying dormant for extended periods of time during scheduled maintenance, result in changes to a vessel's magnetic signature. Correcting those changes requires a thorough treatment process to minimize the level of permanent magnetism. This occurs at Navy Magnetic Treatment Facilities, also known as deperming stations.

Monopile Dolphin – A single pile dolphin usually consisting of a large diameter concrete or steel pipe pile filled with concrete. Monopile dolphins can be used as mooring or breasting dolphins. When used as a breasting dolphin, the monopile dolphin is faced with fendering elements.

Mooring Dolphin – A freestanding pile supported or solid filled structure used for mooring vessels. Mooring dolphins are usually placed at the bow or stern of a moored ship to provide mooring points to attach breasting lines, bow lines and stern lines.

Nesting – Placing vessels alongside one another in a parallel configuration in which they are moored to one another.

Pier – A pier is a structure that projects out from the shore into the water. A pier is oriented either perpendicular to or at an angle with the shore. It may be used on both sides, although there are instances where only one side is used because of site conditions or because there is no need for additional berthing.

Port of Call – Any port where a ship stops along the way other than its homeport, or a stop at a fueling pier, an ammunition pier, a supply pier, or a repair pier. The only real requirements for a port of call would be that it has sufficient dredge depth and that it provides secure mooring. Ship does not go cold iron in port of call and uses its organic systems. However, local determinations and justifications can warrant adding specific features at ports of call. Many of the new classes of ships have concepts of operations and special mission requirements that have resulted in making accommodations at ports in forward operating areas that ordinarily would not be required, i.e. hotel services. These are handled on a case by case basis and driven by operational requirements.

Roll on/Roll off – Also known as RORO. Provision on pier or wharf for vessels designed to carry wheeled cargo, such as cars, trucks, semi-trailer trucks, trailers, and railroad cars, that are driven on and off the ship on their own wheels or using a platform vehicle, such as a self-propelled modular transporter.

Scupper – An opening for the purpose of draining water.

Slip – The space between two approximately parallel piers or the space formed by a cut into the land that provides two approximately parallel mooring faces.

Sonar Dome – Located on the hulls of submarines and surface ships. Their purpose is to house electronic equipment used for detection, navigation, and ranging.

Sponson – A projection extending from the side of a vessel.

Weep Hole – A small opening in a wall which allows water to drain.

Wharf – A wharf is a structure oriented approximately parallel to the shore. Ships can only be moored at the offshore face of a marginal wharf. When water depths close to shore are not adequate to accommodate deep draft ships, the wharf, consisting of a platform on piles, is located offshore in deep water and is connected to shore along its length or at one or more points by pile-supported trestles, usually at right angles to the wharf.

APPENDIX C HIGH MAST LIGHTING

Please Post

NAVFAC
Naval Facilities Engineering Command

Safety Alert

Pier high mast lighting structural failure

DESCRIPTION/BACKGROUND:
High mast lighting systems are used for lighting on piers and other structures. Design includes a ring assembly at the "mast" or pole top to support fixtures facilitating lowering of the ring by an internal cable pulley/motor system to access/replace lights or bulbs.

CONCERN: Mast lighting systems at Naval Station Norfolk have experienced an apparent defect where the latching mechanism fractures at the top of the mast light assembly prematurely. These fractured latching arms can then fray associated support cables which support the light ring. Once the support cables fray to a critical point, the entire light ring assembly can fall catastrophically - which has occurred. A subsequent investigation at Naval Station Norfolk pier high mast lighting has revealed additional lights of various designs similarly affected by latching mechanism fracture and cable fray. Many of the latching mechanisms inspected were reported to have a clearly improved design however, and did not exhibit signs of wear or failure.

INDIRECT CAUSE: The cable was incorrectly tightened causing retraction of the cable.

LESSONS LEARNED/RECOMMENDATION: Inspect high mast light systems for latching mechanism fracture/cracking. Visually inspect support cables for signs of wear and fray. While not involved in the failure, it is also recommended that the inspection include (1) a visual examination of the internal master cable for signs of wear as it retracts/coils and (2) a visual examination of the high mast pole splice for any signs of cracking, particularly for systems that have been in operation for a number of years. Any latching mechanism or cable failures noted during inspection should result in the light ring being lowered to ground until repairs can be made (or if pole splice cracking is observed the pole taken down). In some case it may be acceptable to provide temporary safety strapping between the light ring and mast pole with engineering consultation to facilitate continued light use until permanent repairs can be made.

<u>RETROFIT</u>: Where failures are discovered, repairs/retrofit of internal motor/cable assembly and top latching assembly can be performed. Contractor repairs are underway at Naval Station Norfolk. A manufacturer source experienced with retrofitting high mast lights is (www.eaglehighmast.com).

SAFETY ABSTRACT – HIGH MAST PIER LIGHTS

DESCRIPTION OF THE HAZARD:

- A high mast light support cable parted causing the light assembly to be partially suspended at the top of the pole which did not allow for the light to be lowered for maintenance. The plan was to use an aerial work platform and crane to lower the light for maintenance and inspection. The area immediately around the light structure was secured with caution tape and traffic cones. Before coordinated efforts could be made, the supporting mechanisms failed causing the lighting assembly to fall to the pier surface. There were no injuries or damage to property other than the light assembly.

SYSTEM INVOLVED:

- High mast lighting systems are used by the Navy to illuminate piers and other structures. They utilize a light ring assembly supported by a system of wire cables. This light ring is designed to be lowered to the ground mechanically via an internal pulley system so that maintenance can be performed from the ground level.

EVENT:

- The High Mast Light ring assembly fell at a NAVSTA Norfolk double deck pier causing catastrophic damage to the light ring assembly.

SAFETY CONCERN:

- Potential Life Safety Concern related to High Mast Lighting systems on Navy piers and elsewhere.
- Multiple designs at Naval Station Norfolk have been discovered to have a design defect where the latching mechanism fractures at the top of the mast light. These fractures can then cause fraying of the support cables which support the light ring. When the cables fray to a critical point, the light ring can fall catastrophically. Subsequent investigation has revealed additional lights of various designs similarly affected by latching mechanism fracture and cable fraying.

DIRECT CAUSE:

- Stress and fatigue caused the failure of the supporting cables and locking devices which caused the light assembly to fall.

INDIRECT CAUSE:

- Movement of the lighting assembly due to environmental conditions caused chaffing and wearing of the supporting system.

RECOMMENDATION:

- PWDs throughout NAVFAC inspect High Mast Lighting systems for fractures/cracking. Visually inspect support cables for signs of wear. The internal master cable should be inspected. Recommend that the high mast pole splice point be examined for signs of cracking, particularly for systems that have been in operation for several years. Any latching mechanism or cable failures noted should result in the light ring being lowered until repairs effected.

This UFC supersedes \1\ UFC 4-152-07N, Design: Small Craft Berthing Facilities, dated June 2005 and /1/ Military Handbook 1025/5, Chapter 2, dated 30 September 1998.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Center for Engineering and the Environment (AFCEE) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request (CCR). The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 4-152-07
Superseding: UFC 4-152-07, dated 8 June 2005

Description of Changes:

- Prepared document in proper UFC format
- Expanded/updated references
- Significantly expanded treatment/discussion of types/classes of small boats and craft
- Deleted section on guest docks
- Expanded discussion on aids to navigation
- Abbreviated discussion on fixed versus floating berthing systems
- Added section on covered versus uncovered berths
- Added section on dead loads
- Considerably reduced discussion on floating pier berthing systems
- Added section on floating dock freeboard and stability
- Expanded discussion on environmental (lateral) loading
- Added section on berthing loads
- Deleted section on design criteria for other sheltered basin structures, i.e. slope stabilization/protection, bulkheads as this can be readily obtained from other references
- Deleted section on design criteria for entrance channel and protective structures as this can be readily obtained from other references as well as being briefly addressed in Section 4-3 of new UFC.
- Expanded discussion on hotel services (utilities)
- Revised section on boat launch hoists and lifts and added new methods currently in use
- Expanded section on launching ramps
- Deleted section on administration building
- Expanded section on dry storage facilities
- Expanded section on boat repair/maintenance
- Deleted section on hardware supply store
- Deleted section on transient housing facilities
- Deleted section on layout of utilities
- Deleted section on perimeter fencing
- Deleted section on signs
- Deleted section on environmental factors and protection
- Deleted section on summary of common design problems
- Overall, made document shorter and more concise, relying on other applicable standards where applicable

Reasons for Changes:

- Previous UFC 4-152-07, dated 8 June 2005 was merely a UFC cover sheet applied to MIL-HDBK 1025/5 dated 30 September 1988. Therefore, this new UFC 4-152-07 provides current criteria to replace a document over 20 years old.

Impact: There are negligible cost impacts. However, the following benefits should be realized.

- Over the last several years, NAVFAC LANT has been either directly or indirectly involved with numerous small craft basin projects in various stages of development. Current criteria for small craft berthing was not available. This new UFC will provide the criteria which was been found to be lacking.

Non-Unification Issues: None

CHAPTER 1

INTRODUCTION

1-1 PURPOSE AND SCOPE

This UFC provides general criteria for the design of small craft berthing facilities.

1-2 APPLICABILITY

This UFC applies to all DOD small craft berthing facilities.

1-3 GENERAL BUILDING REQUIREMENTS

All DoD facilities must comply with UFC 1-200-01, *General Building Requirements*. If any conflict occurs between this UFC and UFC 1-200-01, the requirements of UFC 1-200-01 take precedence.

1-4 SAFETY

All DoD facilities must comply with DODINST 6055.1 and applicable Occupational Safety and Health Administration (OSHA) safety and health standards. NOTE: All NAVY projects, must comply with OPNAVINST 5100.23 (series), *Navy Safety and Occupational Health Program Manual*. The most recent publication in this series can be accessed at the NAVFAC Safety web site: www.navfac.navy.mil/safety/pub.htm. If any conflict occurs between this UFC and OPNAVINST 5100.23, the requirements of OPNAVINST 5100.23 take precedence.

1-5 FIRE PROTECTION

All DoD facilities must comply with UFC 3-600-01, *Fire Protection Engineering for Facilities*. If any conflict occurs between this UFC and UFC 3-600-01, the requirements of UFC 3-600-01 take precedence.

1-6 ANTITERRORISM AND PHYSICAL SECURITY

Installations must focus on threats at the first line of defense – the installation perimeter. Antiterrorism and physical security at the waterfront is extremely important for the protection of waterfront assets and to Installation's security. At a minimum, small craft berthing require landside security, pier access control, and identification of restricted area waterways. Coordinate antiterrorism and physical security requirements with Service and Combatant Commander policies and regulations.

Project documents must provide only the minimum amount of information necessary for the installation of all elements required for force protection and must not contain information on force protection methods, philosophy, or information on design threats, as this information is considered sensitive and for official use only. For further guidance, contact the government reviewer.

1-7 REFERENCES

A complete list of references is contained in Appendix A

CHAPTER 2

APPLICABLE CLASSES AND CHARACTERISTICS OF SMALL CRAFT

Small craft berthing facilities will be designed, constructed and operated according to the type of small craft (boats) to be accommodated and the specific needs of those boats. The primary subject of this manual is the berthing of small craft that are owned and operated by the Armed Forces of the United States (U.S). Accordingly, the first portion of this chapter discusses the characteristics of these vessels currently in use. Following is a general overview of the types of vessels accommodated at a typical boating marina, which reflects the recreational segment of small craft operated and berthed in the U.S.

2-1 MILITARY SMALL BOATS AND CRAFT

A summary of the largest branches of the armed forces and the approximate number of small craft they own and operate is presented in Figure 2-1. The distinction between a ship, boat or small craft is subjective and varies between the branches: some distinctions are by use (warship and service craft by the Navy) and others are by length (small boat is defined as less than 65 feet by the Coast Guard). For this document, small craft are those vessels less than 150 ft in length.

Figure 2-1—Summary of U.S. Military Small Boats and Craft in Use

Branch of Military Armed Forces	Branch Abbreviation	Number of Vessels
Navy	USN	4,760
Coast Guard	USCG	1,445
Marine Corps	USMC	538
Army	USA	334
Military Sealift Command	MSC	57
Air Force	USAF	36
TOTAL =		7,170

The types of small craft owned and operated by the armed forces vary according to the mission of each branch. The following section provides an overview of the classes and general characteristics of these small craft. Figure 2-2 summarizes the primary vessel characteristics including length, displacement, and mission for each vessel classification.

Figure 2-2 U.S. Military Small Craft Characteristics

Vessel Classification	Ship Class	Number Active	Class Length (ft)	Displacement fully loaded (tons)	Mission
USN					
Small Boats and Service Craft	YTB 760	68	109	356	Provide a variety of services. Includes: patrol training craft (YP), tug boats (YTB), torpedo trials craft (YTT), landing craft, barges, transport boats, personnel boats, harbor patrol boats, work boats, utility boats, floating drydocks, and rigid inflatable boats
	YTB 756	3	109	409	
	YTB 752	1	101	375	
	YTT 9	3	187	1,200	
	YP 654	1	--	--	
	YP 676	27	--	--	
	Various others	4,089	12-192		
USCG					
Small Boats and Craft	Various	1,217	22-58	2-32	Used in harbors (drug interdiction, port security, cable repair, harbors and inland waters, navigation aids, illegal dumping, search and rescue, etc.), in rough surf for rescue, for inland river and lake patrol, as transports, and for firefighting
USMC					
RRC	Rigid Raiding Craft	120	18	--	Perform offensive amphibious operations
CRRC	Zodiak (replacing RRCs)	418	15	2	
USA					
Floating Utility	BC	37	120	760	Perform port terminal operations
	BD	10	140	1630	
	BG	8	120	763	
	BK	7	45	33	
	CHI	1	25	--	
	FB	2	75	64	
	HF	1	65	--	
	J-Boat	4	46	12	
	LT-128	6	128	1,057	
	LT-100	16	107	390	
	PB	10	25	--	
	Q-Boat	1	65	37	
	SLWT	4	--	--	
	ST-65	11	71	122	
	ST-45	2	45	29	
	T-Boat	1	65	--	
	Workboats	47	--	--	
Patrol Ships	ABT	7	190-194	1500-1,900	Perform drug interdiction in the Caribbean Sea

2-1.1 **U.S. Navy.** The Navy distinguishes between ships, crafts, and boats (SECNAVINST 5030.1L, 22 Jan 93; OPNAVINST 4780.6E, 24 Jan 06). Vessels applicable to this document would be craft and boats. Characteristics and additional information for service craft can be obtained from both the Craft & Boat Support System (CBSS) http://www.boats.dt.navy.mil/ and the Naval Vessel Register (NVR) http://www.nvr.navy.mil/. Characteristics and additional information for boats can also be obtained from the Craft & Boat Support System (CBSS) http://www.boats.dt.navy.mil/ and S9086-TX-STM-010/CH-583R3, NAVAL SHIP'S TECHNICAL MANUAL CHAPTER 583 BOATS AND SMALL CRAFT.

The Navy owns and operates approximately 4,760 small boats and service craft. The Navy classifies these boats according to the type of service they perform. Types include harbor security and escort boats (HSB or sometimes PB), transport boats, work boats (WB), and utility boats (UB).

In 2006 the Navy established the Navy Expeditionary Combat Command (NECC). NECC has become one of the Navy's largest employers of boats as it conducts Explosive Ordnance Disposal, Maritime Expeditionary Security, and Riverine type missions. Types include riverine patrol boats (RPB), riverine assault boats (RAB) and riverine command boats (RCB).

Many of the service craft are non-self-propelled "lighters," or barges (YC, YFN, YON, and YRBM), used for berthing, office, messing, or repair functions or to carry fuel or equipment. Other boats and service craft include: tugboats of various sizes (YTB, YTM, and YTL), training patrol craft (YP), landing craft (LCU, LCM, CM, and PL), torpedo retrievers (TWR, TRB, and TR), floating drydocks (AFDB, AFDL, AFDM, ARD, and ARDM), and rigid inflatable boats (designated RB or RIB). Boats are often out of the water when not in use to increase the vessels' longevity, for storage or for transiting to operational areas.

Figures 2-3 to 2-5 shows the dimensional characteristics of Navy Boats and Service Craft as a function of their length, as well as a comparison to guidelines for recreational vessels.

Figure 2-3 Vessel Beam vs. Length

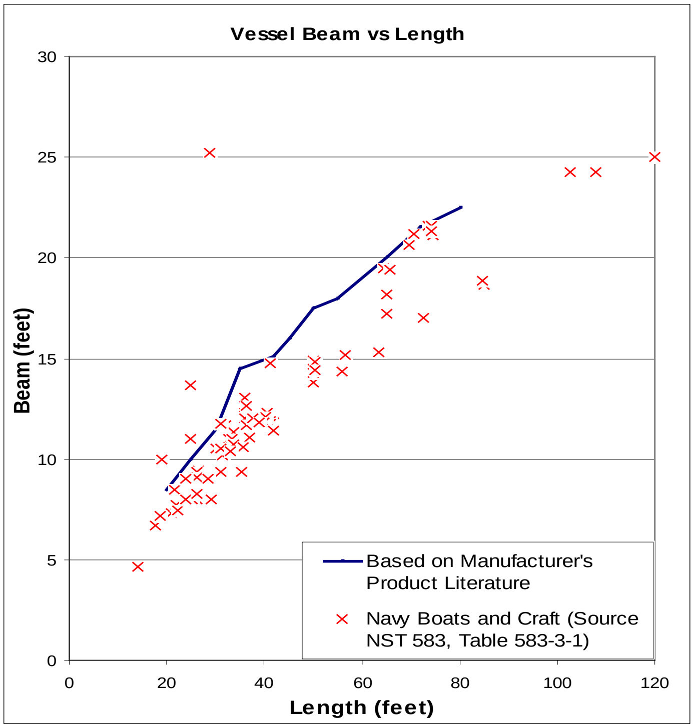

Figure 2-4 Vessel Height vs. Length

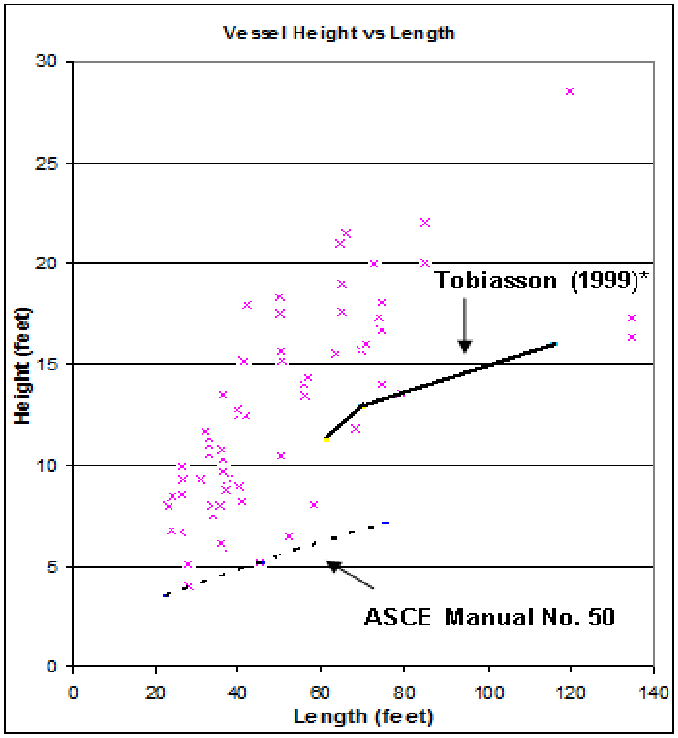

Figure 2-5 Vessel Draft vs. Length

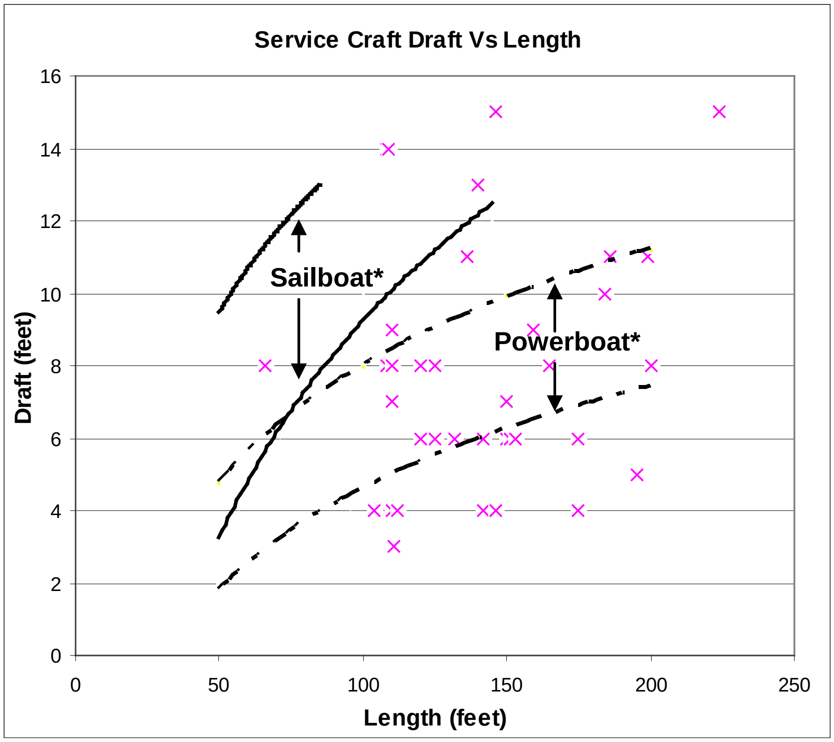


2-1.2 **U.S. Coast Guard.** Small boats and craft are used for various harbor duties, search and rescue, rough surf rescues, inland river and lake patrols, transporting equipment, and firefighting. Some of these vessels can be transported by trailer and used on inland waterways.

2-1.3 **U.S. Army.** The Army's fleet is divided into three sections: the Transportation Corps, the Intelligence and Security (I&S) Command, and the Corps of Engineers (COE). The I&S command operates patrol vessels in the Caribbean sea. The Army Transportation Corps operates lighterage and floating utility vessels. Lighterage are craft used to transport equipment, cargo, and personnel between ships, from ship to-shore, and for operational mission support, and include logistics support vessels, landing craft, and modular powered causeway ferries. Floating utility craft are used to perform port terminal operations and include ocean and harbor tugs, floating cranes, barges, and floating causeways.

The COE operates survey and construction craft, tugs, barges, and other utility craft; these craft are not included in the tables presented herein.

2-1.4 **U.S. Marine Corps.** The Marine Corps operates a large number of watercraft and amphibious craft used during special operations. The watercraft consists of inflatable combat rubber raiding craft (CRRC) and fiberglass rigid raiding craft (RRC). The CRRCs are used for in-port, river, lake, and coastal operations. The RRCs are normally deployed aboard Navy transport dock ships (i.e., LPDs) for transport to the combat area. The CRRCs and RRCs operate exclusively in coastal waters.

2-2 **RECREATIONAL BOATS.** The two primary types of recreational vessels are power boats and sail boats. Power boats can be further classified by the type of use: sport fishing, racing, waterskiing, cruising, etc. In recent years, recreational boats have been outfitted with more electronics and amenities such as refrigeration, complete living facilities and as a result have increased in length and beam. Slip dimensions in marinas have increased to accommodate these larger vessels. Some military boats are of a similar hull design and may be made by the same manufacturer as recreational power boats. Accordingly, manufacturer’s data may be applicable for the design of small craft berthing facilities for military vessels.

Other than for Morale/Recreational Facilities provided by the military, recreational marina berthing guidelines should be carefully considered for applicability when designing for military craft.

CHAPTER 3

SMALL CRAFT HARBOR PLANNING CRITERIA

3-1 BASIN SITING CONSIDERATIONS

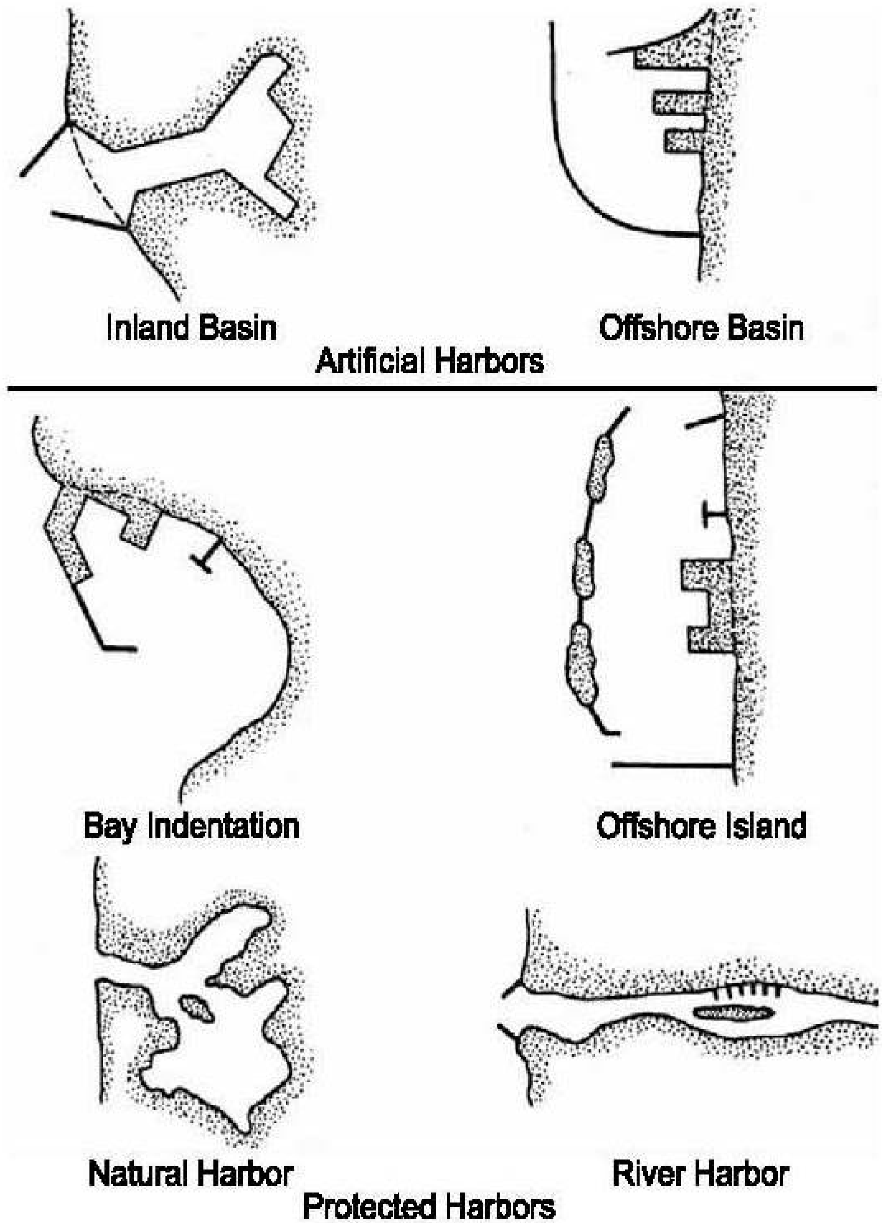
3-1.1 **Siting Considerations.** Small craft berthing facilities should be located in a sheltered harbor. The following key considerations apply for planning the location of the facility:

1. Protection from Winds, Waves and Currents
2. Sufficient Land and Water Area
3. Proximity to Operating Area
4. Adequate Water Depths
5. Limited Exposure to Sedimentation and Shoaling
6. Few Potential Environmental Concerns

Additional considerations include waterside access to the area where the small craft fulfill their mission, and convenient landside access for boat crews and support personnel. The most desirable sites are those that require the least amount of excavation, dredging, filling, breakwater construction, disturbance of sensitive habitat and environmental remediation. Since new sites meeting all criteria are rarely found, feasibility studies of alternative sites to compare the pros and cons of each are often required to identify the most attractive site based on an evaluation of combined engineering, environmental and economic considerations.

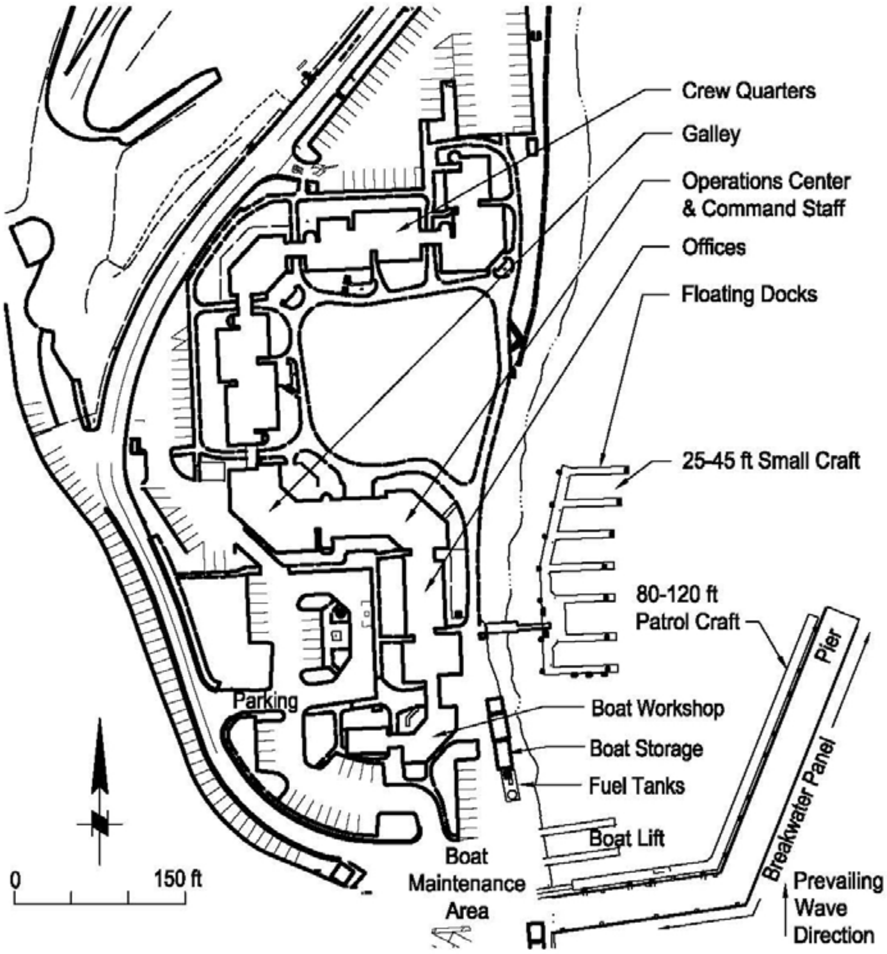
3-1.1.1 **Wave Protection.** The wave protection for the small craft facility is a function of land mass that surrounds the harbor basin to provide a barrier to the incoming waves. Figure 3-1 shows various configurations of landmass and classifications which make up these types of harbors. The source of waves that must be considered are both wind generated waves and vessel generated waves (or wakes). Wind generated waves can be locally generated short period waves (or chop) and longer period waves that are generated far offshore. Protection from waves is more difficult to provide and is a greater concern for small harbors on the coast that are exposed to long fetches than for harbors on inland waterways. When suitable protection is not provided by surrounding land mass, then some means of constructed wave protection must be considered.

Figure 3-1 Small Craft Harbor Site Classifications



3-1.1.2 **Water Area.** The harbor must be of sufficient area to accommodate the berthing facilities, described further in Chapter 5, as well as to provide space for safe maneuvering. There are existing guidelines for the number of boats that can be accommodated per acre of water area for recreational marinas (*ASCE Manual of Practice 50*). Recreational marinas berth relatively large numbers of small craft which leads to large boat/area ratios. In contrast, most military small craft harbors accommodate a much smaller number of craft and the harbor still needs to provide channels and turning areas resulting in smaller boat area ratios than a recreational marina. Figure 3-2 represents a typical layout of a small craft harbor at a DOD installation with associated shore support facilities.

Figure 3-2 Example Military Small Craft Harbor and Shore Facility

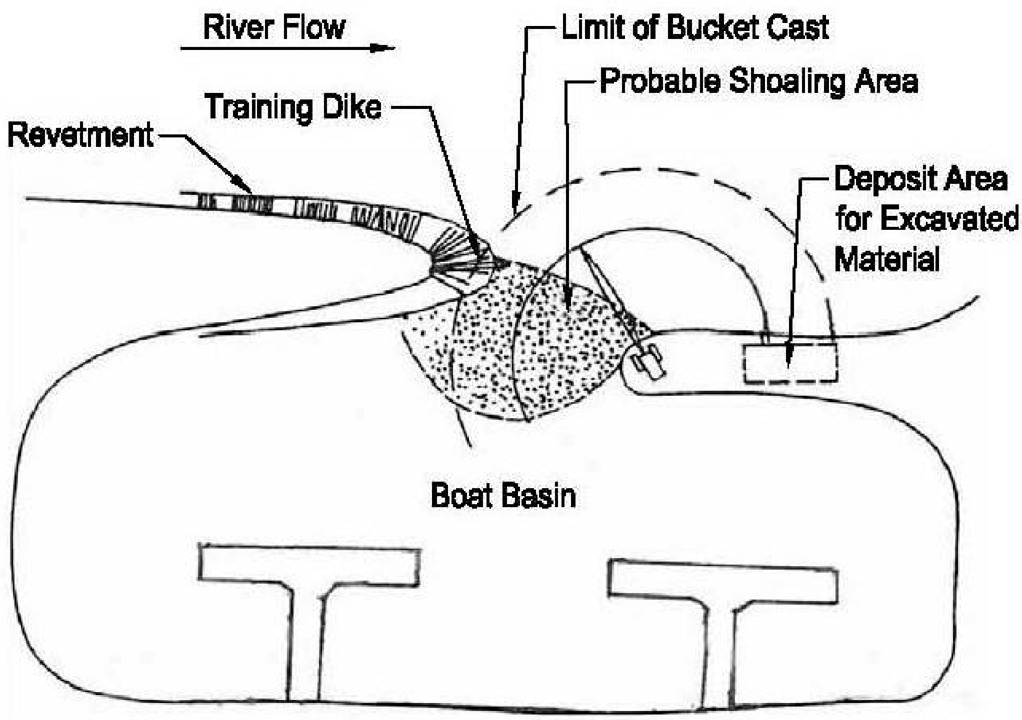


3-1.1.3 **Minimum Depths.** In sheltered harbors, the minimum water depth should extend at least 2 ft (.61 m) for a soft harbor bottom, and 3 ft (.91 m) for a hard bottom below the keel of the deepest draft boat at the design low water level. In tidal waters, the design low water level is typically taken as the Mean Lower Low Water (MLLW) tidal datum. In harbors where wave action causes vessel motion and sedimentation reduces water depths over time, additional under keel clearance should be provided.

3-1.1.4 **Location.** The facility should be located as close as practical to the area where the small craft are intended to operate, depending upon the mission of the craft. For security response or search and rescue missions, time from when the vessel leaves the dock to when it arrives on scene can be critical. For vessels that perform longer term patrols of several days, distance from the facility will be less critical. Where the distance from the facility to the area of operation is great, boats can be trailered from the facility to a boat launching facility close to the area of operation.

3-1.1.5 **Dredging.** Most small craft harbors require dredging to maintain water depths at the facility. Harbors located on the coast often have sediment deposited near the entrance (see Figure 3-3) from alongshore sediment transport (or littoral drift); similarly, harbors on a river often have sediment deposited near the entrance due to sediment transport processes in the river. In addition, suspended sediment can reach far into the harbor as water exchange occurs due to tidal action or river stage fluctuations, and contribute to sediment accumulation within the basin. The extent of this sedimentation can be estimated for a site with the aid of hydraulic models, and the sedimentation rate that will be experienced once a harbor is constructed evaluated for various configurations. Maintenance dredging can be a significant recurring cost due to the environmental concerns that often require disposal of dredged material in distant upland or offshore locations. When considering the minimum required water depth, include over depth to allow for sediment accumulation between maintenance dredging and for a dredging tolerance.

Figure 3-3 Maintenance of Entrance to Off-River Basin with Land-Based Equipment



3-1.2 **Recreational Marina Differences.** There are a number of design guidelines for recreational marinas such as *ASCE Manual of Practice 50*. However, there are important considerations in the layout of a recreational marina that would not apply directly to the design of a military harbor, some of these considerations are:

1. Economic Feasibility

2. Number and Dimensions of Vessels
3. Seasonal and Daily Boat Usage Patterns
4. Walking Distance to Car

Since most recreational marinas are financed by the fees that the boat owners pay to berth their boats in the harbor, cost efficiencies must be realized to make the fees that boaters pay competitive in the market with other marinas. Therefore, one of the primary objectives of the marina design is to accommodate the maximum number of vessels within the minimum water area.

Boat use by the recreational boater is mostly on an occasional basis that tends to occur at regular times: during daylight hours on weekends and holidays in season. In contrast, military small craft will be utilized by personnel who likely live or regularly work at the small craft facility. The military craft will be utilized according to the mission assigned which will likely be at any time and in any weather. Accordingly, layout of the berthing facility must be done to accommodate the unique function of a military facility.

3-2 BERTHING FACILITY LAYOUT

3-2.1 **Berth Location and Orientation.** Within the harbor, vessels that are more difficult to maneuver, usually the larger craft, should be berthed closer to the entrance to the facility. The boat slips should be oriented such that the boats are heading into the prevailing wind when entering the berth (“upwind slip”). When the slip is oriented at 90 degrees to the wind direction (“cross wind slip”), berthing is more difficult.

3-2.2 **Launch Ramps.** Where trailered craft are used, a launch ramp is a convenient method to launch and retrieve the boat. Further, a launch ramp allows water access at a location for a large number of trailerable boats. If a launch ramp is located at a facility where vessels are also berthed, then the launch ramp should be located with sufficient separation from the berths to avoid vessel traffic conflicts. Adequate area must be provided at the top of the launch ramp to allow maneuvering room for the trailer and tow vehicle to align with the ramp. Most guidelines for recreational launch ramp facilities reflect the need to accommodate high volume usage by the public at peak times. As a result, the parking and maneuvering areas for vehicle traffic on the shore, and courtesy docks for boats waiting to be boarded or to be retrieved from the water, may be scaled back at a military facility. Launch ramp layout and design are discussed in greater detail in Chapter 11.

3-2.3 **Marine Fueling.** Where marine fueling facilities are provided, the fuel tanks should be located on shore and the delivery piping and dispensing equipment should be located on a dedicated pier or dock close to the harbor entrance. The dispenser should be located to minimize the length of fuel piping supported on the pier or dock. The fuel tanks should be located to facilitate fuel delivery truck access.

3-2.4 **Dry Boat Storage, Boat Hoists and Lifts.** When necessary to retrieve small craft from the water to address concerns such as reducing saltwater corrosion or marine fouling on the craft, or avoiding ice on the water body, or to perform maintenance and repair on the vessels, a boat hoist or lift should be provided. The main types of retrieval mechanisms are:

1. Straddle Carrier
2. Fork Lift
3. Hoist-jib Crane
4. Floating Lift

The straddle carrier is the most versatile for the larger vessels (over about 33 ft. (10 m) in length). It requires a set of fixed piers over the water upon which a rubber tired straddle carrier with slings drives to retrieve the craft from the water. Once the carrier has lifted the craft in the slings, it can drive and move the craft overland within a fairly level area with suitable surface and then place the craft within a cradle or stands for storage or for work to be performed.

The fork lift is used primarily for placing and retrieving vessels within a dry storage rack system. It will not accommodate as wide a range of vessels as the straddle carrier and requires greater maneuvering area. Fork lifts with “negative” lift are available to enable launching and retrieving small craft, typically over a bulkhead.

A hoist-jib crane is often the simplest and least costly method of launching and retrieving small craft. It is a fixed crane located on a pier or adjacent to a bulkhead over which it lifts the craft from the water. The boats may have lift points built into the hull for slings that attach to the crane hook, though under hull slings can be used when lift points are not provided. Once the craft is lifted, the crane boom revolves in a horizontal plane and lowers the boat onto an awaiting trailer on the shore which is usually towed to a storage area. This method can be adapted for larger craft by using a mobile crane with a spreader and slings sized for the vessel.

Floating lifts and drive-on dry docking are becoming more common to store boats out of the water, but in a slip. Both systems employ pontoons that submerge to permit a boat to enter or leave the slip. The pontoons are equipped with a cradle to retain the boat as the pontoon is filled with air, its buoyancy increased, and the vessel lifted to its dry storage position.

These methods of retrieval are discussed in greater detail in Chapter 10.

3-2.5 **Boat Repair and Maintenance.** Boat repair and maintenance yards should be located close to the area where craft are retrieved from the water. An enclosed work area or high bay building with an overhead crane is desirable if full service to the craft is to be performed at the facility. This facility is usually located as close to the docks as possible at a military facility. Repair and maintenance facilities are discussed in greater detail in Chapter 9.

3-2.6 **Harbor Administration / Command Center.** At most military facilities, there is a shore side component that coordinates the waterfront operations—often a dispatch or command center. This is typically located to provide visual contact with the berthing area and ready boat crew access to the command center once their mission is completed for any follow up briefings or reports.

3-2.7 **Vehicular Parking.** Vehicle parking for the boat crew should be conveniently located no more than 500 ft (152.4m) from the furthermost berth on the pier or dock. If the craft are to be launched from the land at the facility, parking must include spaces for a tow vehicle with boat trailer.

This page intentionally left blank.

CHAPTER 4

BERTHING SYSTEM SITING CONSIDERATIONS

4-1 ENVIRONMENTAL

4-1.1 Weather

4-1.1.1 **Precipitation.** Frequency of occurrence and intensity of precipitation should be taken into consideration when siting a facility. They should be evaluated to determine the need for protective structures, such as dock covers, for maintenance activities and may also affect the determination of structure loads. Data on the frequency and intensity of precipitation is readily available from several sources, National Oceanic and Atmospheric Administration's (NOAA) National Climatic Data Center (NCDC) and United States Geodetic Survey (USGS).

4-1.1.2 **Wind.** Wind is a major factor affecting the design of small craft harbors as it generates waves and loading (pressure) on the berthed craft and structures. The frequency of occurrence of wind direction and speed should be determined. This information is available from the NCDC for most areas around the U.S. If information is not available, data collection should be carried out to determine the wind conditions.

Ideally, berths are oriented upwind to the prevailing wind direction so that vessels enter berths into the wind. If this configuration is impractical then the following configurations may be used in order of priority: downwind and crosswind. The direction of prevailing winds is also to be used to define entrance channel orientation. To the extent possible, vessels should enter the basin upwind. Orienting the entrance with a cross wind condition complicates entrance navigation, and should be avoided to the extent possible.

\1\ Perform a wind wave analysis study to determine design criteria requirements for small craft harbors. /1/

4-1.1.3 **Fog.** Determine the frequency of occurrence of fog and to the extent possible avoid areas of dense fog. Entrance and interior channels in facilities should be as straight as possible so boaters can more easily follow channel-marking devices.

4-1.1.4 **Ice.** Determine the frequency of occurrence of ice formation in the basin and to the extent possible avoid areas where the basin would become ice locked. If the occurrence of ice in the basin is unavoidable, consider boat removal to dry storage during the winter months. If ice formation in the basin is not heavy, the use of bubblers or current inducers can help to keep the berthing area free of ice. Deflecting booms should be used to protect the berthing area from ice flows when there is no breakwater or other structure to provide protection from drifting ice. A more complete discussion of ice and cold weather impact on small craft berthing facilities is given in *ASCE Manual of*

Practice 50.

4-1.2 **Water Level Fluctuations**

4-1.2.1 **Astronomical Tides.** Astronomical tides can affect access during low tides, and create strong currents in and around berthing areas. Tidal predictions for most areas are published. *Coastal Engineering Manual II-5-3* provides a comprehensive discussion of astronomical tides and the appropriate tidal datum for waterfront facility design, usually Mean Lower Low Water (MLLW).

4-1.2.2 **Storm Surge.** Storm surge should be incorporated in the determination of the extreme water level fluctuation and can be significant for sites located on large inland lakes and coastal areas with broad, shallow continental margins. *Coastal Engineering Manual II-5*-5 provides a comprehensive discussion of storm surge and the calculation methodology.

4-1.2.3 **Wave Action.** The berthing facility should be sheltered from waves. Consider the prevailing and storm wave directions and select a site with natural sheltering, if possible. For sites exposed to active shipping channels, consider ship wake as well. If natural shelter is not available, limit wave height by means of structures, such as breakwaters or wave attenuators. The berthing area should meet the wave climate criteria shown in Figure 4-1 adapted from *Design Wave Climate in Small Craft Harbors* to provide generally acceptable levels of dock system performance, vessel wear and tear, and comfort for crew that remain on board (or perform vessel maintenance) while at the berth. The criteria requires a smaller wave height for the more frequent events in the 3rd column of table 4-1, and allows a larger wave for infrequent events in the 2nd column (50 yr exceedence—a wave that occurs only once every 50 years on average). Further, the criteria provides subjective latitude by reducing the height of the allowable waves by 25% (multiple by 0.75) to provide an “excellent” climate, or increasing the wave height by 25% to provide a “moderate” climate.

Figure 4-1: Criteria for a “good” wave climate in small craft harbors

Direction and peak period of significant wave	Significant wave height (H_s) Exceedance	
	50 yrs.	1 yr.
Head seas less than 2 sec	Conditions not likely to occur during this event	Less than 1 ft wave
Head seas greater than 2 sec	Less than 2 ft wave	Less than 1 ft wave
Beam seas less than 2sec	Conditions not likely to occur during this event	Less than 0.5 ft wave
Beam seas greater than 2 sec	Less than 0.8 ft wave	Less than 0.5 ft wave

Note: Criteria for an “excellent” wave climate multiply wave height by 0.75, and for moderate wave climate multiply wave height by 1.25.

Wave climate information should be obtained for the berthing area. Determination of wave conditions will depend on the local bathymetry and exposure to the sources of waves noted above. Facilities should be located to provide protection for vessels entering and exiting the facility and avoid beam seas where possible. Wave transformation due to shoaling, refraction and diffraction within the harbor, and the determination of the potential for wave breaking must be considered as well. For further information on wave mechanics see the *Coastal Engineering Manual II*.

4-1.2.4 **Seiche.** Seiche is a phenomenon in harbors typically associated with long period, low amplitude incident waves, in which the basin geometry and incident wave combine to produce a resonant condition with basin wave heights and oscillatory velocities that are significantly greater than those of the incident wave. *Coastal Engineering Manual II-5-6* provides a comprehensive discussion of seiche, calculation methodology, and long waves.

4-1.2.5 **Tsunamis.** Tsunamis are very long period waves generated by an impulsive disturbance that can cause large water level fluctuations and high velocity currents though the source the disturbance may be thousands of miles away. Reports on the probability of occurrence for the tsunamis for many coastal locations have been prepared by the U.S. Army Corps of Engineers (USACE).

4-1.2.6 **River Stage.** For facilities located on rivers, river stage data is required for the determination of water level fluctuations. Flood stage recurrence intervals should be obtained from the stage data but extreme low river stages should be considered as well because of the impact on minimum water depths. *Coastal Engineering Manual II-5-5* and *II-8-6.f* discuss the importance of river stage and the calculation methodology used to determine the extreme water levels.

4-1.3 **Sediment Movement and Shoaling**

4-1.3.1 **Sediment Transport Processes.** Sediment transport and related deposition and erosion occur on open coasts, in tidal inlets, estuaries, harbors, and rivers, and play an important role in siting a facility. An understanding of sediment transport process at the site is necessary to determine potential for shoreline erosion, sediment deposition and to address needs for dredging over the lifetime of the facility. *Coastal Engineering Manual III-2*, *III-3* and *IV* provide a comprehensive discussion of sediment transport processes, methods for analysis and sources of coastal data.

4-1.3.2 **Effects of Structures on Sediment Transport.** Structures that interfere with the path of sediment transport typically cause deposition and erosion of sediment around the structure. Potential impacts of a structure can be evaluated through modeling or analysis of historical data. Bypassing trapped sediment, or other forms of sediment renourishment are often needed to maintain the natural sediment supply and avoid adverse impacts.

4-1.3.3 **Sedimentation Within Basins.** Protected basins typically experience sedimentation, which should be determined to estimate maintenance dredging requirements in order to avoid access problems related to reduced water depths in the basin. Regular maintenance dredging of the basin or channel is usually required. Sedimentation within existing basins can be determined from analysis of historical dredging records and/or hydrographic data.

4-1.4 **Regulatory Requirements.** Regulatory requirements relate to navigational, environmental and safety issues. The United States Army Corps of Engineers (USACE) and the United States Environmental Protection Agency (EPA) regulate construction activities and dredging in the navigable waters of the United States and its territories and possessions. Facilities within the coastal zone will often require a state water quality certificate and/or a consistency determination for federal projects in order to comply with the state's Coastal Zone Management Act (CZMA) Plan. *ASCE Manual of Practice 50* and *UFC 4-150-06* provide a comprehensive discussion of regulatory requirements in the United States.

4-1.5 Geotechnical Factors

4-1.5.1 **Geotechnical Investigations.** Geotechnical investigations determine the soil characteristics both physical and chemical, at the site. These investigations should include soil borings and soil testing to determine the engineering properties of the soil necessary for the proposed use and constructability of the project. *Coastal Engineering Manual V-2-14* and *ASCE Manual of Practice 50* provide a comprehensive discussion of geotechnical investigations.

4-1.6 **Dredging Projects.** Dredging is often necessary for the construction and maintenance of navigation channels and berthing areas to obtain sufficient water depth. Dredge material must be tested for contaminants to identify proper material handling and disposal methods. *ASCE Manual of Practice 50* provides further information on dredging.

4-2 HARBOR ENTRANCE CHANNEL

4-2.1 **Channel Alignment.** Alignment of the harbor entrance channel, outside of the protective breakwater, should consider the initial construction, long-term maintenance, and safe navigation and utilize natural conditions to the extent possible to minimize shoaling and wave penetration into the harbor. Channels are often aligned to provide the shortest path from the harbor to open water or to utilize an existing natural channel. Other considerations include aligning the channel to account for prevailing winds, waves, and currents.

Appropriate channel alignment allows vessels to transit channels upwind or downwind under the prevailing wind direction, and should not expose vessels to beam seas while in the channel. Channel alignment should also consider prevailing currents. The channel alignment may utilize existing currents to help minimize channel shoaling, but must avoid creating hazardous conditions for small craft. Channel stabilizing structures that constrict the channel area may induce higher current conditions for vessels in the channel. High current speeds can be reduced through channel enlargement.

Longshore sediment transport patterns should be considered in determining channel location because of potential impact on maintenance dredging and the shoreline adjacent to channel. If channel stabilizing structures are used, erosion of the downcoast shoreline may result. Sand bypassing around the channel to nourish the eroding shoreline should be planned using the material dredged from the channel, or from a sand trap provided on the up coast side of the channel.

4-2.2 **Channel Width.** Channel width is defined as the clear width at the design depth, and does not include the channel side slope. Channel width is dependent on the expected vessel types and volume of traffic. Minimum channel widths for 2-way traffic should be the greater of:

- 100 ft (30 m);
- 5B, where B= Beam of the largest vessel expected to use the channel;

Additional width may be warranted to provide allowances for:

- Wind, wave and current exposure that affect vessel maneuverability
- Traffic volume

Widening of the channel may be necessary at channel bends or if immediate turns exist inside the entrance channel. In order to improve the wave climate within the harbor, the channel at the breakwater opening may be narrowed to the greater of 75 ft (23 m) or 3B, where B is as defined above. This criteria includes the restriction to one-way traffic at the opening.

\1\
4-2.3 **Channel Depth and Berthing Basin.** The required channel depth at design low water should be determined by combining the following factors: /1/

- Maximum draft of vessels
- Allowance for under keel clearance
- Wave height (as it relates to vessel motions) outside the breakwater

The maximum draft of vessels should be determined for the type of craft to be berthed regularly at the facility. Where this information is unavailable, see Chapter 2 for typical vessel dimensions.

The "squat" of a vessel is the "drawdown" of the vessel when underway in shallow water when compared to the vessel draft at rest. This is generally a concern for larger vessels but not for small craft.

The minimum allowance for under keel clearance should be 2 ft (0.61m) for soft bottoms and 3 ft (0.91m) for hard bottoms. The overdepth applied for the wave motions outside of the breakwater is a minimum of one-half the significant wave height in the channel. These values should be applied to the design low water elevation.

Additionally, where the area outside of the breakwater is exposed to open sea conditions, the channel should be deep enough for the largest vessels to enter at extreme low tide. If the area outside is sheltered from the open sea, then the channel should be deep enough for the largest vessels to enter at the design low tides, excluding the largest vessels from entering at extreme low tide.

Additional overdepth may be provided in areas where a high rate of sedimentation is experienced to permit shoaling and reduce the frequency of maintenance dredging.

\1\ Either obtain or perform a bathymetric survey to determine design criteria requirements and suitability of site as a small craft harbor or marina. /1/

4-3 PROTECTIVE STRUCTURES

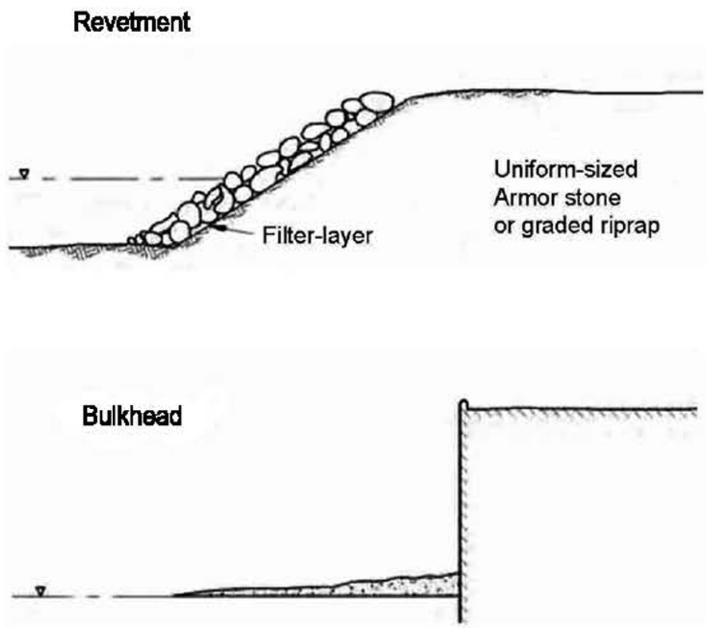
4-3.1 **Jetties.** Jetties stabilize tidal inlets by confining river and tidal currents, and help provide protection for the entrance channel from waves and shoaling. *Coastal Engineering Manual VI-2* provides a comprehensive discussion of Jetties and their application.

4-3.2 **Breakwaters.** Breakwaters provide protection from wave action. *Coastal Engineering Manual VI-2* and *Planning* and *ASCE Manual of Practice 50* provide a comprehensive discussion of breakwaters, their application and design.

4-3.3 **River Current Diverters.** River current diverters provide protection from river currents at an entrance channel and can aid in reducing entrance channel shoaling.

4-3.4 **Bank Protection.** Bank protection stabilizes the berthing basin bank from erosion. *Coastal Engineering Manual VI-2* provides a comprehensive discussion on bank protection systems. Figure 4-2 shows typical structures used for bank or shore protection.

Figure 4-2 Typical Bank Protection Structures



4-3.5 **Wave Attenuators.** Wave attenuators typically consist of floating breakwaters or fixed wave screens and may be used to help protect areas from short period waves (wind waves with a limited fetch, or ship wake). *Coastal Engineering Manual VI-7-5* and *ASCE Manual of Practice 50* provide a comprehensive discussion of wave attenuators and their application. \1\ There have been numerous recent problems associated with wave attenuators and floating structures. It is imperative that a competent coastal engineer perform a wind wave analysis study to properly ascertain design criteria for such floating structures. /1/

4-4 AIDS TO NAVIGATION

4-4.1 **Purpose.** The U.S. Coast Guard operates and administers the United States Aids to Navigation System. The principal purpose of the Aids to Navigation System is to mark channels and other areas of "safe water." In addition, aids to navigation are used to mark hazards to navigation, wrecks and obstructions. To accomplish this, the Coast Guard establishes, operates, and maintains the system in the Federal Channel and major areas of maritime activity in the U.S. In areas of less activity that serve less mariners, private aids are operated and maintained by private parties upon approval from the Coast Guard. The system utilizes audio, visual, radar, or radio methods to mark safe water for navigation. The U.S. marking system is a predominantly lateral system.

4-4.2 Types of Marks

4-4.2.1 **Lateral.** Lateral marks define the port and starboard sides of a route to be followed, usually the sides of channels. Port marks are green in color and indicate the left side of channels when proceeding in the conventional direction of buoyage (returning from seaward). Marks may consist of beacons, buoys or lights. Beacons have green square daymarks, while buoys are green can or pillar buoys. Green lights of various rhythms are used on port hand marks. Starboard marks are red in color and indicate the right side of channels and consist of the same types of marks as port marks

4-4.2.2 **Isolated Danger.** These marks are erected on, moored over, or placed immediately adjacent to an isolated danger that may be passed on all sides by system users. They are black with one or more broad horizontal red bands and will be equipped with a topmark of two black spheres, one above the other. If lighted, they display a white group flashing two light with a period of five seconds.

4-4.2.3 **Safe Water Marks.** Safe water marks indicate that there is navigable water all around the mark. Safe water marks have red and white vertical stripes.

4-4.2.4 **Special.** Special marks are not primarily intended to assist safe navigation, but to indicate special areas or features referred to in charts or other nautical publications. They may be used, for example, to mark anchorages, cable or pipeline areas, traffic separation schemes, military exercise zones, ocean data acquisition systems, etc. Special marks are colored solid yellow, and show yellow lights with a slow-flashing rhythm preferred.

4-4.2.5 **Information and Regulatory.** Information and Regulatory Marks are used to alert the mariner to various warnings or regulatory matters. These marks have orange geometric shapes against a white background.

A complete description of the aids to navigation system is described in Commandant Instruction M16500.7

CHAPTER 5

BERTHING SYSTEM LAYOUT

5-1 BERTHING SYSTEM ARRANGEMENTS

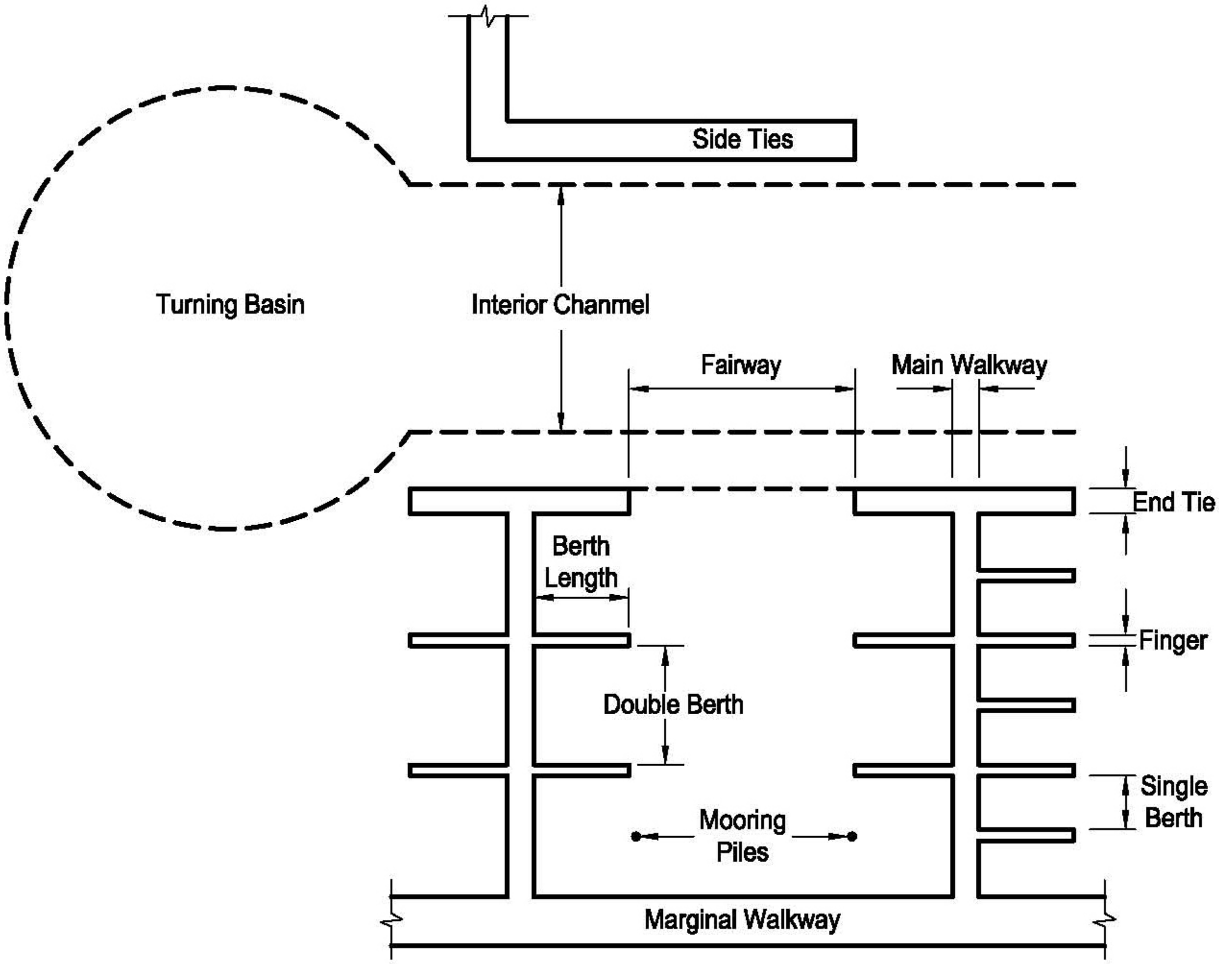
When determining the berthing arrangement, berth orientation should take into consideration the local wind and current conditions to facilitate safe berthing and vessel movements. Common berth arrangements are:

- A series of main walks extending perpendicular from the marginal wharf or dock, with finger piers or floats extending at right angles from the main walks on either side
- Larger vessels should be berthed closer to the entrance channel
- Smaller vessels should be berthed closer to the shore
- Launch and haul out facilities should be located away from other marina activities in quiet water
- Fuel service should be located near the entrance channel to facilitate access for larger vessels and separated from the berthing area.
- Seaward orientation to allow quick response

5-2 BERTHING SYSTEM DIMENSIONAL REQUIREMENTS

Figure 5-1 shows typical features and terms of a berthing system for small craft.

Figure 5-1 Typical Berthing Arrangement



5-2.1 **Interior Channels.** Interior channels connect the entrance channels with the berth fairways.

The minimum clear width of interior channels should be the greater of:

- 1.5 L , where L is the overall length of the longest boat using the channel or
- 75 ft. (23 m)

The preferred width of interior channels should be the greater of:

- 1.75 L, or
- 100 ft. (30 m)

Interior channel depths should be determined using the same considerations as entrance channels. The overdepth allowances for wave height and sedimentation should be included based on the wave and sedimentation patterns within the facility.

Since the minimum interior channel widths in the typical small craft harbor are based on vessel length, turning the vessel within, or at the end of the channel is accommodated without the need for an enlarged turning basin. However, if a situation arises in which a substandard channel width exists, a turning basin should be provided at an appropriate point in the channel; the basin should provide a clear turning circle whose minimum diameter is 1.5 L, where L is as defined above. Where channel currents or winds make turning difficult, this minimum should be increased to 2.0 L.

5-2.2 **Fairways.** Fairways provide vessel access from interior channels to individual berths.

The minimum clear width of fairways should be:

- 1.5 L_b (finger slips) \1\ for power boats and 1.75 L_b for sailboats /1/, where L_b is the length of the longest berth perpendicular to the fairway where vessel are not allowed to overhang the berth.

- 1.5 L_b (with side/end-ties) \1\ for power boats and 1.75 L_b for sailboats /1/, where L_b is the length of the longest berth parallel to the fairway where the fairway width does not include the side-tie berth width. A side/end tie is a berth at the end of the main walkway adjacent to the interior channel (See Figure 5-1).

The preferred clear width of fairways should be:

- 1.75 L, where L is the overall length of the longest boat using the fairway.

Fairway depths should be determined using the same considerations as interior channels.

5-2.3 **Berths.** Berth widths should be based on the particulars of the vessels to be berthed. When this information is not available, see Chapter 2 for typical vessel dimensions. The minimum width of a berth should be:

- Double berth: 2 x Beam of the wider vessels served + clearance for environmental conditions, boater experience, and fendering system

- Single Berth: Beam of the widest vessel served + clearance for environmental conditions, user experience, and fendering system

Typical clearances range from 3 ft (.9 m) to 7 ft (2.1 m), being greater for double berths, for longer berths, and where winds and currents make berthing difficult.

Berth depths should be the same as the fairway depth.

5-2.4 **Walkways.** The minimum clear width of main walkways should be 6 ft. (1.8 m). Depending on the need for dock carts passing each other and emergency access and egress, additional width may be necessary. Main walkways on floating docks should also be increased in width if they are not balanced by fingers on both sides. The width defined above is clear width between obstructions on the pier or dock such as cleats, piles, etc. The minimum clear width of marginal walkways is 8 ft. (2.4 m) to allow for increased pedestrian traffic resulting from the connection to main more than one walkway.

Walkway lengths should be limited to 700 feet for main walkways and 1000 ft for marginal walkways in consideration of:

- Walking distance between berths, parking, and restrooms
- Utility size increases due to distance
- Hauling distance for equipment, supplies and gear

5-2.5 **Fingers.** Finger width should support safe pedestrian use. The minimum clear width of the finger should be the greater of:

- 0.1 L, where L is the length of the slip served by the finger or

- 3 ft

The preferred minimum width to enhance stability of the finger is 5 ft.

Finger length should be sufficient to facilitate the loading and unloading of the vessel, and should not be less than 0.8 times the nominal length of the slip. Typically finger lengths are equal to the slip length and to the length of the boat allowed to occupy the berth. Under certain conditions overlength vessels may be permitted to “overhang” the slip into the fairway, but this practice encroaches on the required clear width of the fairway, and places a greater load on the pier or dock.

CHAPTER 6

BERTHING STRUCTURES

6-1 FIXED VS. FLOATING BERTHING SYSTEMS

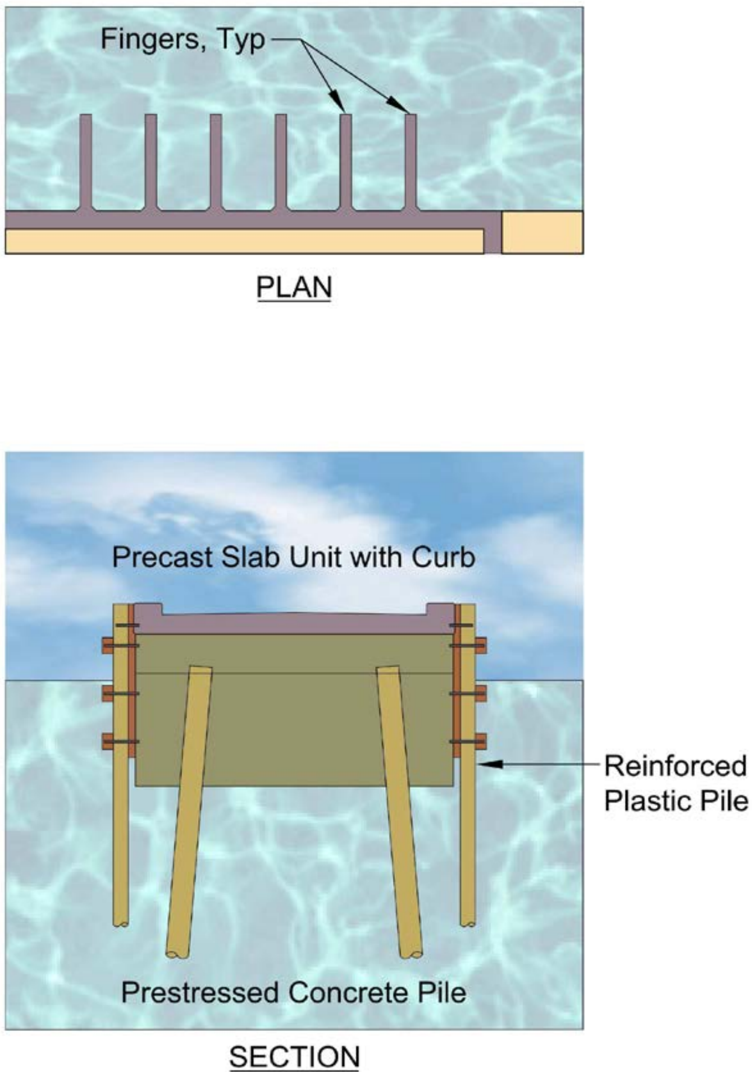
6-1.1 **Selecting a Fixed or Floating Berthing System.** The selection of a fixed or floating Berthing System is primarily determined by the water level fluctuation at the site. The basis for the selection is the requirement that the fixed pier or float deck elevation match as closely as practical the deck freeboard of vessels that use the pier or float, both to facilitate boarding and to reduce the need for mooring line adjustment.

A secondary consideration is wave height at exposed berths; where waves greater than 2 feet can occur and problems due to floating dock motions would over-ride the benefits provided by the floating dock, a fixed system is preferred.

At sites where a fixed pier exists and the water level fluctuation and wave height criteria for a floating system are met, a floating dock with a variable slope gangway to transition from the pier to the float should be provided.

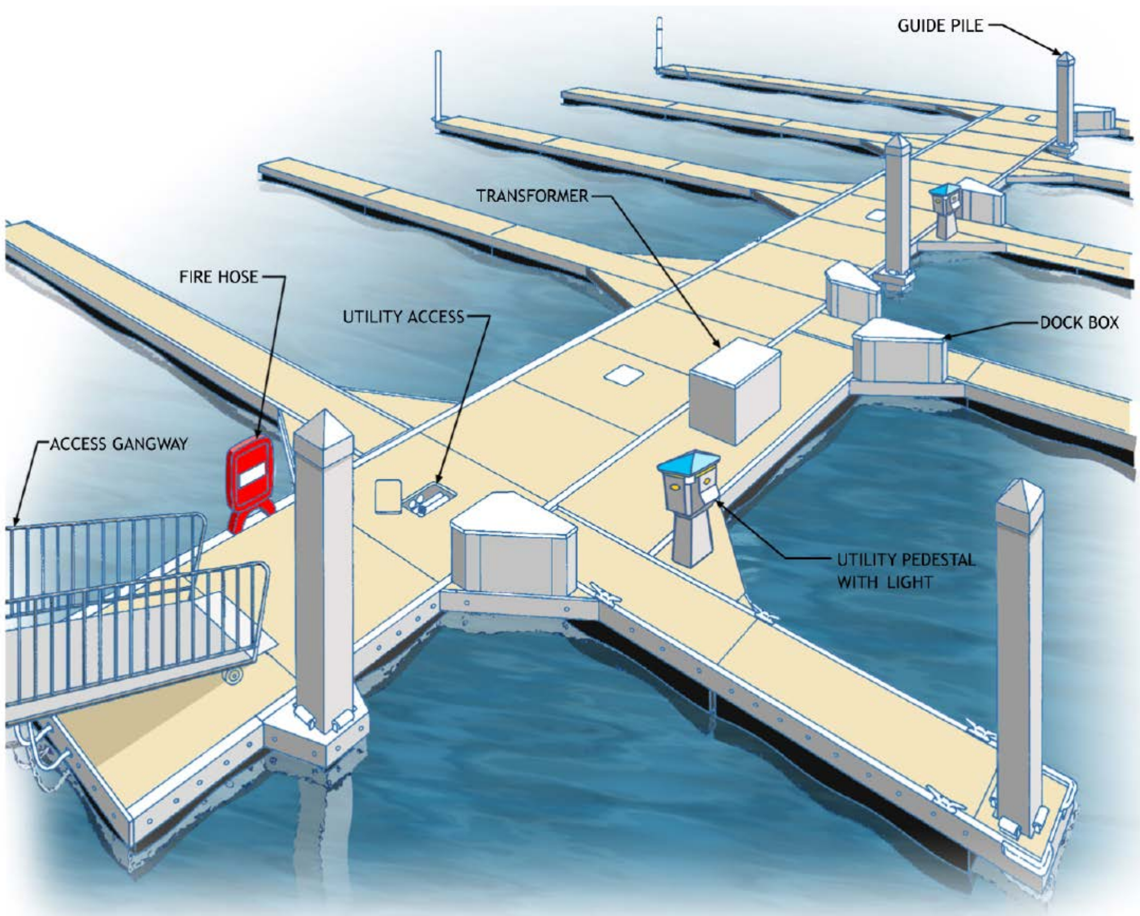
6-1.1.1 **Fixed systems.** Fixed systems are generally selected where the tidal range for coastal sites or the seasonal water level range for inland rivers or lakes is less than 3 feet (0.91m). Figure 6-1 shows a typical fixed pier system.

Figure 6-1 Typical Fixed Finger Pier



6-1.1.2 **Floating systems.** Floating systems are generally preferred where the tidal range or seasonal water level range is 3 feet (0.91m) or more. Figure 6-2 shows a typical floating pier system.

Figure 6-2 Typical Floating Finger Pier System



6-2 COVERED VS. UNCOVERED BERTHS

6-2.1 **Selecting Covered or Uncovered Berths.** Berthing systems are generally uncovered unless adverse weather, in particular precipitation, can be shown to interfere with boat operations, including boarding or essential dockside maintenance. Generally, covers to protect military vessels from exposure to the elements and retard weathering (though common in recreational marinas) are not provided.

Covers for fixed berthing systems are supported on the fixed piers. Covers for floating berthing systems may be supported on the floating dock where wave conditions permit or on fixed pile supports. Berth covers contribute significant additional dead and live loads on the fixed pier or floating dock. Besides the additional dead weight, winds can produce substantial lateral and uplift forces on the dock structure.

Fixed piers or floating docks should not be retrofitted with covers unless the structure (including flotation) was designed for the additional loads produced by the covers, or the berthing structure itself is retrofitted to withstand the additional loads.

6-3 BERTHING SYSTEM LOADING CRITERIA

6-3.1 **Dead Loads.** The dead load should include the self weight of the structure and all permanent attachments such as cleats, fenders, dock boxes, utility pedestals with associated electrical and water lines, fire suppression standpipes and fire lines, light stanchions, power centers, and where fitted, storage lockers, fuel dispensers and fuel lines, sewage pumpout units and sewage lines, etc. The water, fire, fuel and sewage lines should be considered full of liquid. If the berths will be covered, include the superimposed dead load of the cover structure.

The deadload for floating docks should also include the weight of pile guides or anchoring hardware, the superimposed dead load of the gangway reaction on the dock, and an allowance for weight gain due to water absorption in the dock flotation.

6-3.2 **Vertical Live Loads.** The vertical live load may be uniformly distributed or a concentrated point load; both cases should be checked to identify the governing case for design (See Figure 6-3). The restricted access pedestrian application may be used when dock access is controlled and the number of persons on the pier or dock at any one time can be limited to typical recreational marina densities. When it is possible for a large number of persons to congregate on the pier or dock, the unrestricted access pedestrian application should be used. In the case of floating docks, this will impose substantial additional demand on the dock to satisfy freeboard and stability criteria.

Figure 6-3 Vertical Live Loads on Berthing Systems

APPLICATION	UNIFORMLY DISTRIBUTED LOAD	CONCENTRATED POINT LOAD
Fixed Pier – Pedestrian		
▪ Restricted Access	40 psf (8 kPa)	400 lbs at any point on the pier per
▪ Unrestricted Access	100 psf (20 kPa)	
Vehicular	Per UFC 4-152-01	UFC 4-152-01
Floating Dock – Pedestrian		400 lbs at any point on the dock at least 1 ft from the dock edge
▪ Restricted Access	25 psf. (5 kPa)	
▪ Unrestricted Access	100 psf (20 kPa)	

6-3.3 **Floating Dock Freeboard and Stability.**

6-3.3.1 **Freeboard.** Floating docks under dead load only should have a minimum freeboard to the deck of 16 inches (40 cm) and a maximum of 24 (60 cm) inches. For a safe and visually pleasing dock system, the deck cross slope on walkways or fingers should not exceed 2% and the freeboard overall should not depart from the average by more than 1 inch (2.5 cm).

Under full live load plus dead load, floating docks should have a minimum freeboard of 10 in (25 cm).

In the event that a uniform live load of 100 psf (20 kPa) is required, additional dead load freeboard of at least 15 in (38 cm) would be needed to meet the fully loaded minimum freeboard of 10 in (25 cm). As a result, the dock may ride too high under dead load only to satisfy functional requirements. If this occurs, consideration may be given to reducing the fully loaded minimum freeboard if the fully loaded condition is a rare occurrence, provided that the stability requirements can still be satisfied.

The dock freeboard and stiffness requirements (to limit deck slopes) may control the structural and flotation design rather than the minimum live loads, and should be checked.

6-3.3.2 **Stability.** The dock should have a minimum freeboard of 2 in (5.1 cm) to the top of the buoyancy pontoon to provide reserve buoyancy under full live load plus dead load. If the buoyancy pontoons provide full flotation to the top of the deck, the minimum dock freeboard noted above is sufficient to satisfy this requirement. If the width of the pontoon varies (pipe pontoons for instance) with submergence, then the minimum freeboard of the pontoon should be increased to provide reserve buoyancy equivalent to the 2 inch (5.1 cm) requirement.

The dock must also be able to withstand overturning forces and return to a normal freeboard and level condition upon removal of any unbalanced forces. Floating dock systems that consist of interconnected walkway and finger docks will generally satisfy this requirement. However, long and narrow dock modules may not, in which case a metacentric method calculation of stability should be performed. A floating dock is stable if under all conditions of loading, the metacenter is located a safe distance above the center of gravity of the structure.

6-3.4 **Environmental Loads.** The principal environmental loads to consider (not all may apply at a particular site):

- Wind, on berthed vessels as well as the pier or dock structure
- Snow and ice due to accumulation on or against the structure
- Floods, surges and tsunamis that produce both extreme water levels and currents
- Floating debris due to impact or accumulation against the structure

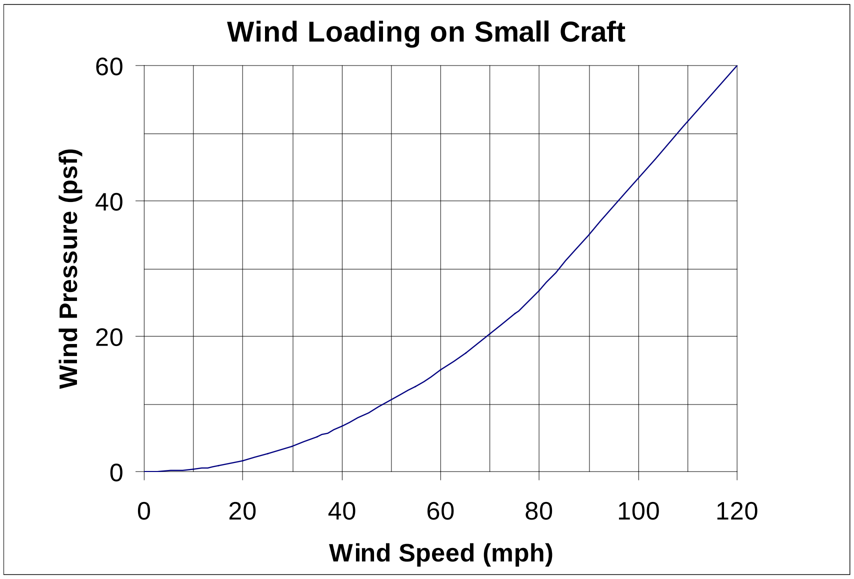
- Waves due to locally generated wind waves and boat wake, or swell arriving from offshore storms
- Currents due to tidal and/or river flows
- Seismic, generally of concern on fixed piers only

6-3.4.1. **Wind Load.** Wind load is based on a wind velocity pressure for steady conditions (neglecting gusts) acting on the above water profile of the berthed vessels and dock system

6-3.4.1.1 For wind velocities at various geographical locations consult \1\ UFC 3-301-01 /1/*.*

6-3.4.1.2 Convert the design wind velocity (in miles per hour) to velocity pressure using Figure 6-4 or other rational method.

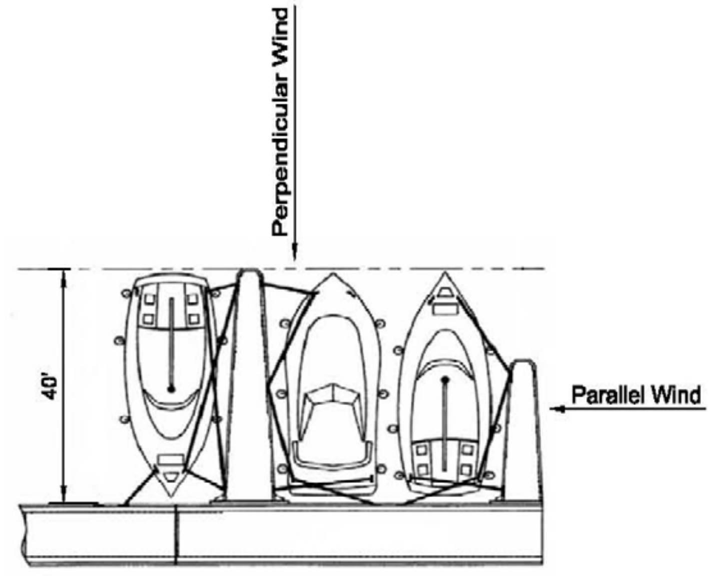
Figure 6-4 Wind Load on Small Craft



6-3.4.1.3 Determine the average profile height for the berthed vessels, generally taken as 15% of the berth length, but other rational method based on the berthed vessel dimensions may be used.

6-3.4.1.4 Compute the wind load, checking both parallel and perpendicular directions to the main axis of the pier or dock. Figure 6-5 shows a sample calculation for total wind load. Assume 100% berth occupancy. For vessels berthed in close proximity to each other, say on either side of a walkway or finger dock, the total force on the structure for each direction should be based on the full wind load applied to the windward (unshielded) vessels, and 20% of the full wind load applied to all leeward (shielded) vessels.

Figure 6-5 Sample Calculation for Windloading on a Floating Pier System



Design Wind Load: 15 PSF

Perpendicular Wind		
40' Boats:	3 Each x 19' Beam x 6.0' Height x 15 PSF	= 5,130 Lbs
Fingers:	2 Each x 4' Beam x 1.5' Height x 15 PSF	= 180 Lbs
	TOTAL PERPENDICULAR LOAD:	= 5,130 Lbs
Parallel Wind		
40' Boats Unshielded:	1 Each x 40' x 6.0' Height x 15 PSF	= 3,600 Lbs
40' Boats Shielded:	2 Each x 40' x 6.0' Height x 3 PSF	= 1,440 Lbs
Headwalk:	1 Each x 6' x 1.5' Height x 15 PSF	= 135 Lbs
	TOTAL PARALLEL LOAD	= 5,175 Lbs

In the case where one of the berthed vessels is larger than the rest, the unscreened part of its profile area should be taken into account. Further, when the above water area of the structure is unshielded, the force on the profile area exposed to the wind should be included in the total.

Individual fingers, however, should be designed to accommodate the full wind load on the berthed craft since the presence of a shielding boat cannot be assured.

6-3.4.2 **Snow and Ice.** Snow and ice loads appropriate to the site as spelled out in local building codes should be considered. Vertical snow and ice loads, resulting from precipitation or wind driven spray, can destabilize a floating dock. Non-moving ice formed on the water surface, or ice drifting against a pier or dock can exert tremendous forces and damage the structure unless counter measures are taken to limit ice formation or accumulation. Ice problems and solutions are discussed in the *ASCE Manual of Practice 50.*

6-3.4.3 **Currents.** Currents in rivers and tidal areas can produce high loads on piers and docks and the berthed vessels through their underwater profile areas. This condition is at its worst when vessels are berthed perpendicular to the current direction, and least when the vessels are aligned with the current direction. Generally, when the current exceeds 3 ft/sec (1 m/s), it could be a significant factor in design, and a rational method should be used to determine the current forces that include consideration of:

- Peak velocities (speed and direction)
- Drag coefficients to determine velocity pressure
- Underwater profile area

Even moderate current velocities passing under floating docks can produce a downward suction on the leading edge of the dock and cause the edge to submerge unless counter measures are taken to reduce the suction force.

6-3.4.4 **Hurricanes (Typhoons), Flood Flows and Tsunamis.** Hurricanes, flood flows and tsunamis are similar in that each can produce dramatic water level rises and destructive waves and currents. If the pier or dock cannot reasonably be designed to withstand such extreme conditions, the berthing system must be relocated to a more protected site, or the consequences of catastrophic failure accepted.

6-3.4.5 **Floating Debris.** Debris mats can form against piers or docks on river or reservoir sites and exert significant loads. The structure should be designed for the drag load produced by a debris mat at least 3 ft. thick (or twice the draft of the flotation for floating docks), or the load controlled by installing a fixed or floating debris boom to deflect the debris around the structure.

6-3.4.6 **Seismic.** Seismic loads appropriate to the site as spelled out in local building codes should be considered in the design of fixed piers. Generally, seismic loads are not significant in the design of floating docks, though seismic events may trigger marina basin oscillations, and the resulting current loads and water level fluctuations can be significant, and should be considered.

6-3.4.7 **Waves and Boat Wake.** Wave heights should be limited by locating the berthing system in a sheltered area. If necessary, additional wave protection may be provided by means of a fixed or floating wave attenuator incorporated in the berthing system design. Areas sheltered from wind waves may still be subject to boat wake, since even “no wake” zones may not succeed in preventing passing vessels from generating large wakes.

6-3.4.7.1. When describing the wave climate, the terms significant wave height (H_s) and maximum wave height (H_1) are generally used. Structural designers often use the maximum wave height to size members and connections, while the significant waveheight is used to estimate floating dock motions and cyclic loads for fatigue analyses.

6-3.4.7.2. Generally, when the design wave height exceeds 1 foot, it could be a significant factor in design and a rational method should be used to determine the wave forces that include consideration of:

- Vertical wave load on a floating dock resulting from hogging (and sagging) of the dock.

- Horizontal and vertical wave forces on the submerged portion of a fixed pier (piling and bracing), or on a floating dock pontoon.

6-3.4.7.3 Wave forces are dependent upon the direction of wave approach to the structure. In particular for floating docks, the vertical loads are greatest when the wave approach is parallel to the long axis of the dock, and the horizontal loads are greatest when the wave approach is perpendicular to the long axis. If the direction of wave approach is limited, then the wave loads may also be limited by appropriate orientation of the floating dock.

For larger vessels dynamic mooring forces under the action of waves can be significant and should be considered if the vessel is to remain at its berth during extreme wave conditions.

6-3.4.8 **Anchorage.** Anchorage forces for floating docks are dependent on the type of anchorage, which can take many forms:

- Piles

- Spuds

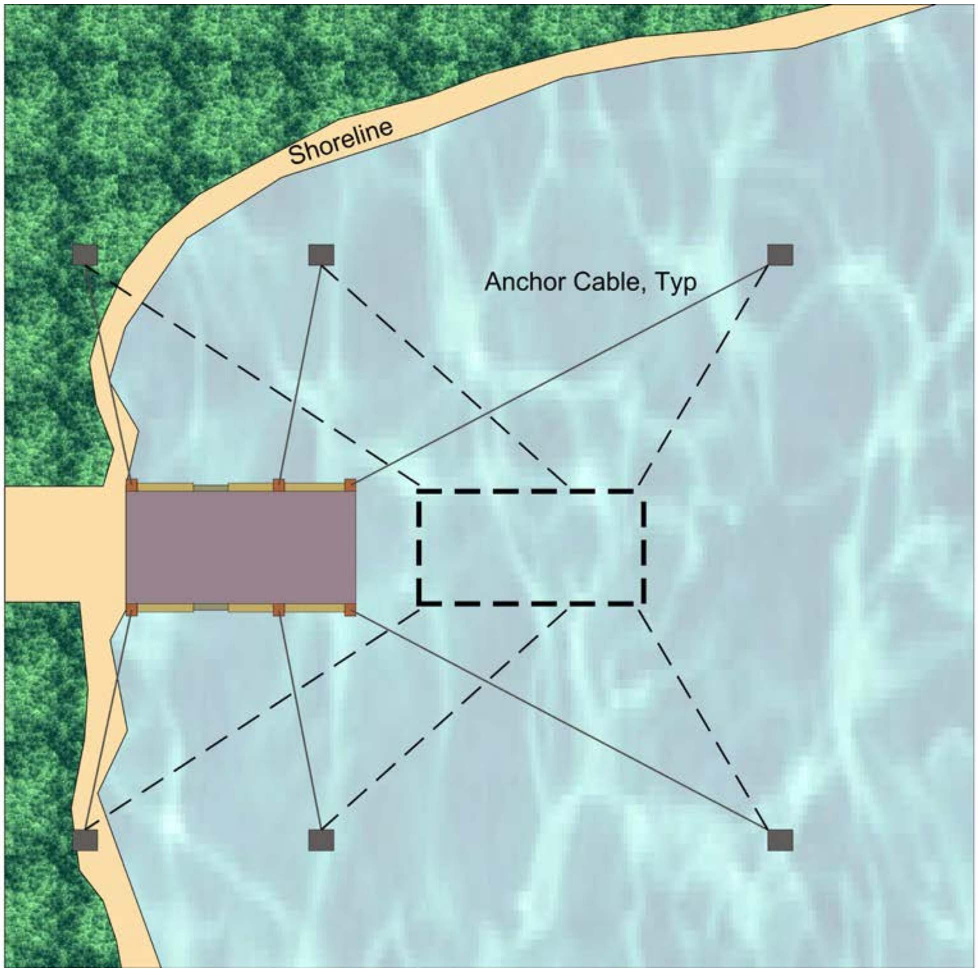
- Cable/Winch/Anchor

- Chain/ Anchor

- Strut-to-Shore

Cable anchor systems are often utilized when water depths are large, or water level fluctuations are large and bottom slope is shallow, requiring the docks to move horizontally to remain floating. Figure 6-6 shows a cable anchorage system that allows horizontal movement.

Figure 6-6 Cable Anchorage System



Specific site conditions should determine the most appropriate option, the principal site considerations being water depth, water level fluctuation, exposure to waves and condition of the submarine bed. An additional consideration is the permanence of the floating dock, as some situations require a system that can be relocated, with an anchorage that can be easily removed and reused.

Anchor loads for floating docks are generally determined by the horizontal live loads, which are additive in many cases. Specific site conditions will vary, but generally wind, wave and current loads are combined to get total loads when they can all arrive simultaneously. The type, number, location and size of the anchorage component are critical aspects of floating dock design. Inadequate anchorage is probably the most frequent cause of failure in floating dock systems. A discussion of anchorage design is presented in *ASCE Manual of Practice 50.*

6-3.5 **Berthing Loads**

6-3.5.1 **Berthing.** Berthing loads due to vessel impact on a pier or dock result from the kinetic energy of the vessel, which is a function of the design vessel's docking (laden) weight and approach velocity generally taken normal to the dock face. For small craft, no allowance is made for the bumpers typically provided on the dock face. However, deflection of the dock system anchorage for floating docks is generally considered to reduce the impact force.

6-3.5.1.1 The docking weight in lbs (w) of recreational craft may be estimated by $W=12L^2$, where L is the vessel length in feet. For military craft, the weight can be considerably greater, and vessel particulars should be obtained.

6-3.5.1.2 The approach velocity (v) generally varies with the vessel size, but the minimum should be:

- v=0.6 ft/sec for L > 60 ft. (0.2 m/s for L > 18 m)
- v=1.0 ft/sec for L < 60 ft. (0.3 m/s for L < 18 m)

The larger value should also be used regardless of length where adverse wind and current conditions create difficulty for pilots maneuvering into the berth.

6-4 BERTHING SYSTEM TYPICAL CONSTRUCTION

6-4.1 **Fixed Piers.** Fixed Piers may be constructed of many types of materials:

- Steel
- Concrete
- Aluminum

\1\
- Timber

/1/
- Combinations of the Above

The basic pier structure consists of piling with caps spanning pairs of piles, and a deck structure spanning between caps. In addition to the basic structure, bumpers, mooring hardware and utility systems (generally power, potable water, fire suppression and communications) are provided. Further, piers may include wastewater reception (pumpout), fuel dispensing and lockers for gear storage. Important safety features include a slip-resistant walking surface, lighting for night operations, guard rails where they do not interfere with vessel berthing requirements, boarding ladders if the deck freeboard exceeds 3 ft (0.9 m) at design low water, and flotation devices for emergency use.

6-4.1.1 Finished Deck Elevation should be a minimum 1 ft (0.3) above design high water, or a height sufficient to prevent deck structure submergence at design high water, including allowance for wave crests, whichever is greater.

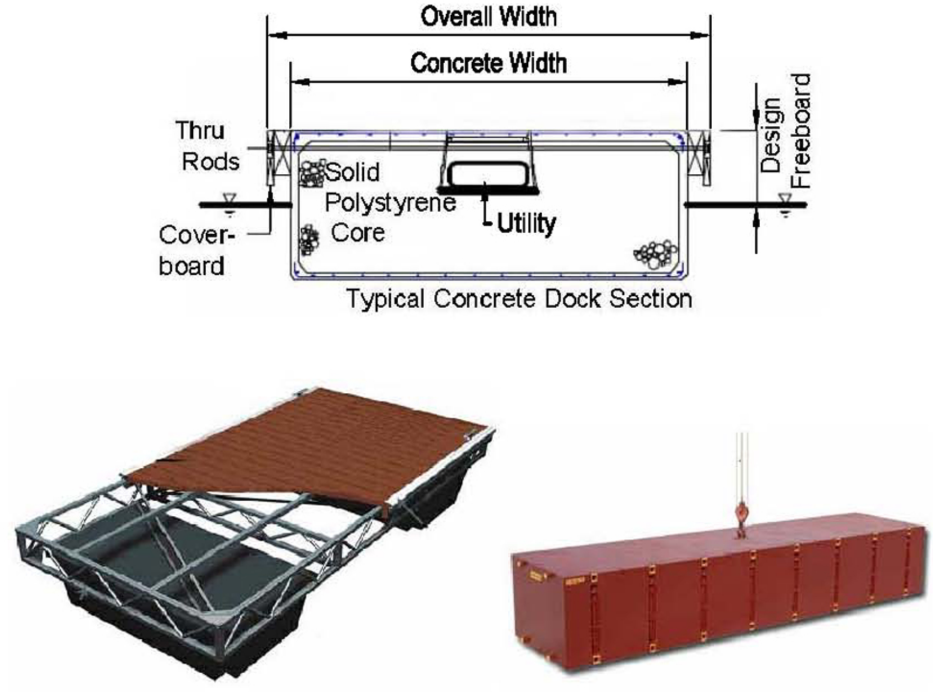
6-4.1.2 Provide bow and stern mooring points appropriately located and sized for the berth length.

6-4.1.3 Provide a bumper system able to accommodate vessels with a low rub rail without 'hanging up' on any structural components of the pier, for the full range of design water levels, and to accommodate vessels with a high gunwale.

6-4.1.4 For other design requirements, refer to UFC 4-152-01.

6-4.2 **Anchoring Floating Docks.** Floating Docks may be constructed of many types of materials, similar to fixed docks. In addition, plastic and fiberglass materials are finding increased use in floating dock construction. Modular factory fabricated floating dock systems are now in common use. Figure 6-7 shows some typical fabricated floating dock systems. Consideration should be given to using an appropriate commercial product, preferably one with a proven track record over many years of experience. The basic dock structure consists of the flotation pontoon, the structural frame, the deck, and the anchorage. In some proprietary systems the flotation, frame and deck are unitized so that system assembly consists essentially of bolting the modular pontoon units together. The basic dock structure should be finished with all of the appurtenances noted previously for fixed piers.

Figure 6-7 Various Types of Floating Docks



Truss
Steel frame pontoon with decking

Steel

6-4.2.1 **Flotation Pontoons.** Flotation pontoons should consist of a foam core completely encapsulated in a protective shell to prevent contact with water or other deleterious elements. The foam generally consists of expanded polystyrene (EPS) closed cell blocks, but other types of foam may be used. Although the foam should be protected by the shell from water contact; certain materials may lose their water-tightness over time. However, a quality foam core will prevent significant loss of buoyancy. This should be acceptable if the maximum water absorption of the EPS core is limited to less than 3% as determined by \1\ ASTM C272/C272M /1/, Method C, the amount of reground material is limited to less than 10%, and the form core is preformed to the interior configuration of the pontoon as a solid block.

6-4.2.2 **Deck Surface.** Deck surface should withstand prolonged exposure to the elements (sunlight, wetting/drying, freezing/thawing etc., unless the berth is covered), severe abrasion by scuffing and dropped objects, and fatigue due to dock motions and flexing. Further, the surface should be non-skid, and resistant to staining by spills and dirt.

6-4.2.3 **Floating Docks.** Floating docks should be anchored against lateral forces.

6-4.2.3.1 **Cantilever Anchor Piles.** Cantilever anchor piles are simple and the most commonly used anchorage. Generally they are preferred when the water depth at the design high water level is less than 30 ft (9 m). The pile should be high enough so that the dock will not float off the top, so allowance must be made for the dock freeboard and motions due to waves and surge in addition to the extreme high water level. Where piles are used, pile guides should be incorporated in the dock structure. Guides generally consist of collars faced with Ultra High Molecular Weight (UHMW) polyethylene rub blocks, which wear and are replaced periodically. In well protected basins, pile guide rollers may be used in lieu of the rub blocks. The anchor piles are generally prestressed concrete or steel pipe; timber marine piles are rarely specified due to concerns over preservative chemicals used to treat softwood piles, or tropical rain forest protection for the naturally resistant species. In situations where dock loads and water depths exceed the capability of simple cantilever anchor piles, multi-pile dolphins may be considered, with the braced vertical pile serving as the guide pile.

6-4.2.3.2 **Anchor Lines.** Anchor lines are generally used where the dock system is constructed in deep water, or where large water level fluctuations occur. For situations where the extreme wave exposure favors a more compliant anchorage to reduce peak loads, anchor lines are often used as well. The anchor lines consist of wire rope, steel cables or chains. Where the floating dock system requires movement through considerable horizontal distance with water level changes, or where large loads are involved, winch systems are used to adjust line tension and control dock position. In most cases the winches are located on the floating dock and the dead load of the winch and anchor line pull must be factored into the design of the dock floatation. A cable guide should extend a sufficient depth below the winch so that the cable leading away from the dock to the anchors will not interfere with the deepest part of the vessels likely to use the dock. Design of cable anchor systems involves complex non-linear analyses to determine cable behavior and the resultant loads on the ground anchors, particularly as the number of cables increase. Design requirements for mooring systems are described in UFC 4-159-03.

6-5 MOORING FITTINGS AND BUMPERS

6-5.1 **Cleats.** Vessel to pier or dock tie up generally utilizes cleats attached to the structure. Since cleat manufacturers do not specify guaranteed minimum holding strengths, the sizing of cleats and their attachment is largely driven by experience.

6-5.1.1 **Number and Location.** Provide a minimum of 3 equally spaced cleats per berth for vessels over 20 ft (6 m) in length and less than 60 ft (18 m); larger vessels will require additional cleats. Single berths (with a finger dock on each side) should have the minimum number of cleats on each side of the berth; double berths (with a finger dock on only one side of the vessel) should have an additional cleat for each berth on the main walk near the center of the slip. The cleats should be located along the edge of the pier or dock to minimize tripping hazard.

6-5.1.2 **Size.** Piers or docks required to hold vessels under extreme wind and wave conditions should receive a rational analyses of peak mooring loads, and an attempt made to obtain data from manufacturers on maximum cleat capacities in order to size the cleats. Generally, however, the following sizes have proven adequate for most situations:

Berth Length L – ft. (m)	Cleat Size – in. (cm)
L< 40 (12)	10 (25)
40 ≤ L < 60 (18)	15 (38)
60 ≤ L < 80 (24)	18 (46)
L ≥ 80	24 (61)

6-5.1.3 **Attachment.** Attach cleats with a minimum of two through bolts into the structural frame of the pier or dock. Plate washers should be used to distribute cleat pull out forces without crushing the structural support. Bolt heads should be recessed into the cleat so lines do not chafe on them; the recess should be filled to prevent water ponding and corrosion.

6-5.2 **Bumpers.** Vessels and piers or docks need protection from each other because of impact and chafing. Hardware used to fasten the various types of bumpers to the pier or dock structural frame should have all exposed heads on the berth face recessed to prevent hull damage. The solutions described below are considered part of the pier or dock, and would be in addition to the portable fenders typically deployed on the vessel itself.

6-5.2.1 **Horizontal Rub Rails.** Generally a continuous recycled plastic lumber, rub rail running the full length of the berth is attached wherever a vessel can contact the pier or dock. Additional protection may be provided by means of a continuous vinyl bumper strip attached to the top edge of the rub rail, largely to reduce marring of the vessel hull, but also to provide some cushioning.

6-5.2.2 **Vertical Rub Strakes.** Generally rub strakes extend below the deck to contact the lowest vessel rub rail at design low water, and prevent the rail from 'hanging up' on the horizontal member at the face of the dock or pier. The top of the rub strakes should extend above the deck far enough to contact the highest vessel rub rail at design high water for the same purpose. Rub strakes are generally fitted to fixed piers as the freeboard variations tend to be greater and the hull rub rail problem arises more often than with floating docks, whose freeboard remains relatively constant. If the berthed vessels are not fitted with rub rails, rub strakes should be avoided on floating docks in particular.

6-5.2.2.1 Rub strakes should be placed at 1/3 points on the berths, starting at the outer end and omitting the strake on the inner end: Do not omit strakes for continuous side tie berthing. Generally, recessed horizontal rub rails are still used between the strakes.

6-5.2.2.2 Rub strakes should be attached to the structural frame of the pier or dock.

Generally, the vessel (due to hull curvature) will lay up against only 2 strakes, and vessel loads are applied to the structure at the level of the vessel rub rail rather than the dock frame, creating a torsional load on the frame.

6-5.2.2.3 Vertical rub strakes may also be fitted with vinyl bumper strips attached on the berth face, similar to the horizontal rub rail.

6-6 ACCESS PIERS AND GANGWAYS

6-6.1 **Accessing Fixed Piers.** Access to a fixed pier berthing system is relatively straight forward, and may be provided by an extension of the berthing system main walkway. For situations where the elevation of the point of access on the shoreline bulkhead or landing is greater than the deck elevation on the fixed pier, a ramp should be provided that conforms to code requirements.

6-6.2 **Accessing Floating Docks.** Access to a floating dock system typically requires a hinged gangway with a variable slope ramp to span between the fixed access point on shore and the floating dock. Design Criteria for the variable slope gangway ramp are discussed in *DBW Layout and Design Guidelines*.

6-6.2.1 **Gangway Ramp Upper Support.** The upper end of the gangway ramp should be supported on the shoreline bulkhead, or on a fixed pier to provide access to a floating dock system that is located a considerable distance from shore. The support should be in the form of a “hinge” that accommodates the vertical swing of the gangway in response to changing water level as well as the horizontal sway in response to floating dock drift.

6-6.2.2 **Gangway Ramp Lower Support.** The lower end of the gangway ramp should be supported on the floating dock, which must be provided with additional flotation to offset the superimposed dead load of the ramp plus 50% of the live load reaction and maintain the required dock dead load freeboard. The remaining 50% of the live load reaction is distributed to the dock system flotation by the dock structure on demand. Experience has shown that providing sufficient flotation for 100% of the live load results in excessive dead load freeboard. The ramp support on the dock consists of HDPE skidplates or rollers to carry the loads and reduce wear on the deck as the ramp adjusts to changing water levels.

6-6.2.3 **Gangway Ramp Structure.** The gangway ramp construction may be of steel or aluminum, with aluminum being the most common because of weight savings. Standardized factory designed aluminum ramps are now in common use to cover a wide range of load requirements, widths and lengths.

6-6.2.3.1 The ramp should have a minimum of 3 ft (0.9 m) clear width.

6-6.2.3.2 The maximum slope at design low water should be 3 (horizontal) to 1 (vertical). The length of the ramp should be the minimum to achieve the slope requirement at design low water. Generally gangway lengths greater than 80 ft are not used; either steeper slopes (2.5 to 1 absolute maximum) or special stair-ramp structures that convert to stair steps at steeper slopes may be used instead.

6-6.2.3.3 The vertical live load on the ramp should be a minimum of 50 psf (10 kPa) if dock access is restricted; use 100 psf (20 kPa) if dock access is unrestricted or public assembly use is permitted.

6-6.2.3.4 The ramps should have guardrails and handrails on both sides in conformance with occupational safety requirements, and an aggressively non-slip walking surface when dry or wet. Raised treads placed transversely are sometimes used for this purpose, but are a potential tripping hazard and are not the preferred solution.

6-6.2.3.5 Generally ramps also support utility feeders for the dock systems, and the added dead load of the utility lines must be considered.

This page intentionally left blank.

CHAPTER 7

HOTEL SERVICES (UTILITIES)

7-1 POTABLE WATER

Potable water service is typically provided to individual berths by means of a ¾” hose bibb mounted next to the berth. The hose bibb is supplied by a line on the main walkway. Water demand is estimated to be about 25 gallons (95 L) per berth per day. When potable water is supplied from the public mains system it should be in accordance with the requirements of the local water authority. Piping should be non-corrodible and ultraviolet-stabilized. Flexible hose shall be used when making dock-to-shore connections to allow movements. Rigid lines may be used on piers and docks with the consideration of the expansion and contraction of the material, special consideration of line flexibility should be taken on floating dock systems.

7-2 SEWAGE AND OILY WASTEWATER

7-2.1 **Holding Tanks.** Pumpout facilities should be provided for the emptying of sewage holding tanks to meet the requirements of the local wastewater authority for proper disposal of sewage. Typical small craft sewage pumpout facilities consist of a central pump station with a flex hose that can vacuum out the vessel’s holding tank contents by means of a flex hose connection between the pumpout hydrant on the dock and the holding tank fitting on the vessel. Pumpout hydrants may be located at intervals throughout the marina so boats can be serviced at their berths, or located on a “public” dock for vessels to pull-up for service. Pumpout facilities are typically rated about 40 gals/min (150 L/min). The pumpout facility should include a water hose bibb to permit flushing of the holding tank; the hose bibb should be marked “non-potable water”. If the pumpout station is located near a fueling station, allow space sufficient between the two facilities so that vessels may utilize either facility without interfering with the operation of the other.

7-2.2 **Pump Station.** The pumpout station is connected to a landside sewer system via force main with a sewage pump.

The sewage pump is typically rated at about 40 gals/min (3.79 liter/min) and is a peristaltic or diaphragm type of pump, to reduce clogging from solids being pumped.

7-2.3 **Bilges.** Bilge water if contaminated with oil should be collected and disposed to the oily Waste system. Some marinas now offer bilge water pumpout facilities separate from the sewage pumpout to receive and treat oily wastes.

7-3 ELECTRICAL

Electrical service is provided to individual berths for vessel usage by means of weatherproof receptacles, mounted \1\ in a pedestal /1/ (as with potable water) or with lighting in pedestals. Electrical service is commonly provided at 120/240 vac single phase or 208 vac 3 phase, at currents of 20-100 amps, typically. *ASCE Manual of Practice 50* provides a detailed discussion of small craft berthing facility electrical systems.

7-4 COMMUNICATION

Communication systems include an intercommunication system, such as a public address or paging system with speakers located within easy hearing distance of every berth. Telephone service, though not commonly provided at Naval facilities, may be provided at each slip if desired, often located with lighting and electrical service in one pedestal. Fiber optic and high speed internet service can be included as well. Typically, the service provided installs the required equipment in raceways and cabinets provided for that purpose. *ASCE Manual of Practice 50* provides a detailed discussion of small craft berthing facility telephone service.

7-5 FUEL

Marine fueling stations are often provided in small craft berthing facilities and shall comply with the requirements of NFPA 30A, “Code for Motor Fuel Dispensing Facilities and Repair Garages", unless it is anticipated that some berthing facilities will not be constructed on government property. If berthing facilities will be constructed on private property, then comply with the requirements of the authority having jurisdiction. Determine the fueling requirements (types of fueling, fill rate and quantity) for the classes of vessels to be berthed. Fueling systems should be separated from the berths and landside facilities by required fire separation distances in accordance with UFC 3-600-01. The fueling station is typically located near the harbor entrance in an area that is protected from waves and is often near the sewage pumpout station. The adjacent land area must be suitable for fuel storage tanks and accessible for fuel delivery vehicles and fire fighting equipment. Provide spill containment equipment as required by the local environmental authority.

7-6 LIGHTING

Waterfront areas consist of a defined perimeter (landside and waterside), restricted area, entry control facilities at the entrance into the waterfront area, access control points located at each pier, and pedestrian access control points along the perimeter. In waterfront areas, utilize high mast lighting to reduce the number of poles minimizing obstructions to waterfront operations and maintaining clear paths for equipment and vehicles. Provide full cutoff or fully shielded fixtures mounted in the horizontal plane to limit direct and reflected glare. Lamps should be metal halide (MH) to improve color rendering and nighttime visibility. Refer to UFC 4-152-01 for Pier and Wharf operational lighting requirements and UFC 3-530-01 for lighting design. Note, in some regions, white light sources may interfere with the marine environment. Coordinate marine issues with the local environmental authority.

\1\ For recreational marinas pedestals are provided with lights integral to the units at each slip. If additional lighting is required, low profile bollards or lighting designed more to a pedestrian scale, no taller than 12 ft (4 m) with down lighting is recommended. /1/

7-7 FIRE FIGHTING

Fire protection should be provided through appropriate design and placement of firefighting equipment on the piers and docks in accordance with NFPA 303, "*Fire Protection Standard for Marinas and Boatyards"* and UFC 3-600-01. If any conflict occurs between this UFC, the NFPA 303 and UFC 3-600-01, the requirements of UFC 3-600-01 take precedence.

All firefighting equipment shall comply with the requirements of NFPA 303 and UFC 3-600-01. Firefighting equipment includes, but is not be limited to:

- Portable chemical extinguishers placed at 200 ft (60 m) intervals along each main walkway housed in cabinets painted red. \1\ For recreational marinas, place at 75 ft (23 m). /1/
- Fire-alarm boxes placed at convenient locations on or near piers.
- Fire hydrants or stand pipes located along the shoreline near where the dock/berthing slip meets the shoreline. \1\ For recreational marinas, provide a Class I dry stand pipe system and all related items on the pier. /1/

Firefighting equipment should be maintained and inspected in accordance with \1\ UFC 3-601-02 /1/.

7-8 LOCKER BOXES

Locker boxes provide a place for gear storage on the pier or dock, convenient to the berth. They are typically made of sheet metal, or fiberglass. Locker boxes are typically located in the knee brace of floating dock systems or other similar out-of-the-traveled-way place.

\1\

7-9 ALL-PURPOSE PEDESTAL

All-purpose pedestals may be provided for recreational marine use. The unit housing shall have a white heavy resin housing with a two-part polyurethane coating which is UV resistant. The unit shall have the following features:

- Lockable weatherproof doors
- Bus Bar Rating
- Photocell controlled 13 watt lighting with amber lens
- Dual or single hose bibs and stainless steel handles
- Electrical

- Slips up to 28 feet long – one 20 Amp, 125 VAC outlet and one 30 Amp, 125 VAC twist-lock outlet
- Slips greater than 28 feet long – one 20 Amp, 125 VAC outlet, one 30 Amp, 125 VAC twist-lock outlet, and one 50 Amp, 250 VAC twist-lock outlet

/1/

CHAPTER 8

DRY STORAGE FACILITIES

8-1 DESCRIPTION

Dry storage of small craft is the practice of removing the craft from the water until it is placed in service. Dry storage of boats is performed using two common methods: trailer storage in a yard (yard storage) and rack storage (drystack).

8-2 YARD STORAGE

The most common method of dry storage is storage on trailers within a yard area. In this method, boats are kept on trailers that allow them to be transported on the road (Figure 8-1 shows typical yard storage).

Figure 8-1, Yard Dry Storage

Once the boat is loaded onto the trailer, the trailer is kept in a designated spot within the yard—which is usually paved and enclosed with a locked security fence. The boat gains access to the water either by a ramp, or crane. For the ramp, the boat and trailer are towed, by a vehicle, down the ramp into the water until the trailer is submerged and the boat floats freely, whereupon, the trailer is usually returned to the dry storage yard until the boat is to be retrieved from the water, when the process is reversed. Utilizing a crane, the boat and trailer are towed to the crane location, which is usually close by on a pier or bulkhead adjacent to the water. (Figure 8-2 shows a typical crane). The boat is fitted with a wire rope sling that attaches to fittings on the boat and then to a single pick up point that the crane hook lifts the boat from the trailer. Once the boat is lifted free of the trailer, the crane swivels about a vertical axis to place the boat out above the water, and then it lowers the boat into the water. Again, the trailer is returned to the dry storage yard until the boat returns and the process is reversed.

Figure 8-2, Small Craft Crane Access (Jib-boom)

8-2.1 **Characteristics.** The general characteristics of yard dry storage are summarized as follows:

- Vessel stored on trailer
- Launched from ramp or crane
- Vessels < 35 ft (10.67 m) in length
- Vessel density: 50-80 vessels/acre

8-2.2 **Advantages.** The primary advantages of yard storage are:

- Less costly
- Low height
- Can be performed by boat operator
- Provides destructive weather (hurricanes, deep freeze) haven

8-2.3 **Disadvantages.** The disadvantages of yard storage are:

- Requires greater land area
- Requires time to launch/retrieve vessel

8-3 DRY STACK STORAGE

Figure 8-3, Drystack (rack) Storage

8-3.1 **Characteristics.** The general characteristics of dry stack (rack) storage are summarized as follows:

Vessel Weight:	< 6 tons
Vessel Length	< 35 ft
Rack levels	4-5 Max.
Vessel Density	392 vessels/acre

8-3.2 **Advantages.** The primary advantages of rack storage are:

- Reduced land area required to store a given number of small craft
- Craft are kept dry when not in use, reducing deterioration
- Increased security

8-3.3 **Disadvantages.** The disadvantages of stack storage are:

- Requires trained operator to retrieve and launch the vessel
- Requires landside facility
- Vessel is not immediately ready in the water
- High structure can be objectionable in view corridors
- Heavy structure loads require suitable foundation conditions

8-3.4 **Covered Storage.** The storage rack can be located inside a building, usually a metal building, to provide protection from the weather. The building will usually require sprinklers for fire protection in accordance with NFPA 303. Because these storage facilities are often higher than 35 ft (10.67m), they can be objectionable from a visual perspective along the waterfront.

8-4 APPLICABILITY

Dry storage provides increased security and increased service life of the vessels, as well as reduced maintenance, due to storage out of the water and out of the weather, if covered storage is used. However, yard storage is most probably the preferred method for military facilities.

As discussed above, the primary reason for constructing a stack storage system is to fit as many small craft as possible into a small area—typically done in areas of high real estate values in dense urban settings. This would rarely be the case at most military facilities due to the small number of small craft that need to be accommodated. Further, the advance notice required to launch vessels, may not lend itself to the operational needs of the small craft. For these reason, dry stack storage is generally suited for recreational vessels in urban areas or areas of inclement weather. Several publications provide additional guidance for dry stack storage *ASCE Manual of Practice 50*.

CHAPTER 9

BOAT REPAIR/MAINTENANCE

9-1 GENERAL

Repair and maintenance are required by all small craft during their service life. The location of the facility for repair and maintenance is often determined by the mission of the craft, and the availability of a standby craft to replace the ready boat while it undergoes repair/maintenance. The repair/maintenance facility can be located either at the same facility (onsite), or at a ship yard or another facility (offsite).

9-1.1 **Onsite.** Typically, at least minor maintenance and repair to deck equipment will be performed onsite, usually at the craft moorings, including replacement of broken fittings and tasks that can be performed with hand tools. More involved work can be performed onsite if the facility has a haul out and shoreside repair facilities to perform the work.

9-1.2 **Offsite.** Where onsite facilities do not exist, or do not have the capability to perform the required work, the maintenance and repair work will have to be performed offsite. Offsite facilities can either be boat yards that specialize in small craft repair including hull repair and coatings, or may be facilities that perform general work such as a machine shop or engine repair shop. In regions with large port and marine activities, boat/ship yards are generally available to work on small craft.

9-2 MAINTENANCE SCOPE

9-2.1 **Hull.** Repair and maintenance of the hull requires that either the vessel be hauled out of the water or the work be performed by a diver.

9-2.2 **Deck.** Most minor replacement of deck fittings and equipment (cleats, rails, antenna, etc) can be performed at the slip. For more extensive work, the vessel will usually be removed from the water and placed on land on stands or taken to a dry dock where overhead cranes can lift heavier equipment and where there is access to welding and other power equipment.

9-2.3 **Engine.** Similar to deck work, minor engine work can be performed on the vessel. There is an increased use of outboard engines on small craft under approximately 35 feet (10.67m) in length. This allows quick replacement of the engine if a spare is on hand, for more involved maintenance or repair of the affected engine either on site or at a specialized repair shop.

9-4 MAINTENANCE PROGRAM

All vessels require routine maintenance in order to reduce emergency break downs and required repair. This is particularly true for vessels moored in saltwater where the vessel and its equipment are subject to corrosion when not in use. Maintenance of the vessel is often performed by the boat crew to some extent and greater maintenance tasks are performed by specialized personnel, either on staff at the facility or provided by outside contract services.

9-4.1 **In-House Workforce.** For facilities with larger staff and vessels that perform continuous operations it is preferable to have skilled workers on staff dedicated to performing the maintenance and repair of the small craft equipment (deck, hull and engines). This allows the most control and flexibility to perform the work according to the schedule of the operational needs of the small craft. A scheduled maintenance program should be established in accordance with those established by the manufacturer of the engine, hull and various other equipment (radio, radar, etc.) on the vessel. Having the permanent staff to perform this work will usually increase operating costs which can be compared to costs paid for such work that is contracted out, if such records are available, to see if such staff is cost effective.

9-4.2 **Contract Services.** In larger cities, or where there is a large boating community, there may be skilled maintenance and repair facilities close by that can perform work fairly readily. For scheduled maintenance, skilled personnel often from the manufacturer's staff or trained by the manufacturer can be scheduled in advance to perform the work onsite. For facilities with fewer small craft or multiple standby craft, this may reduce costs or allow a smaller workforce without the requisite skills to perform the maintenance and repair of the vessels.

9-5 FACILITIES

9-5.1 **On Dock.** For minor repair and maintenance, much of the routine maintenance can be performed with the vessel berthed at the dock.

9-5.2 **Covered Mooring.** Where extensive maintenance must be performed on the berthed vessel at the dock by onsite personnel, the cost of a covered mooring may be warranted. In areas of inclement weather (rain, snow, wind) this allows greater time in which the staff can perform this work.

9-5.3 **Haul Out.** If a haul out facility (see Chapter 10) is provided at the facility, the small craft can be transferred to the shore where more extensive maintenance and repair can be performed. Generally, this includes work on the hull or work that requires use of a crane, welding or other powered tools to perform the necessary repairs or maintenance. A straddle type carrier provides the greatest flexibility and speed for retrieving vessels (see Figure 9-1) and is commonly used.

Figure 9-1, Vessel Haul out Facility for Straddle Carrier

9-5.4 **Yard Maintenance.** The vessel can be placed on a trailer or stands in the yard to allow access to the hull for needed repairs. This can be in the outdoors for work that does not require containment. Environmental considerations often require that, depending on the work being performed, that the vessel be fully contained for the work, such as if sand blasting or painting is being performed.

9-5.5 **Enclosed Shop.** An enclosed work shop building provides a facility in which all necessary repairs and maintenance could be performed. Such a building should be furnished with ventilation and filtration to allow painting and sandblasting to be performed, an overhead crane rail for lifting of the engine or similar heavy equipment, and a full supply of power tools including welding capabilities. The building should often be sized to allow a straddle carrier entry to place the vessel on stands or a cradle within the shop. Figure 9-2 shows a typical enclosed shop building.

Figure 9-2, Enclosed Shop Building, with Straddle Carrier

CHAPTER 10

BOAT LAUNCH HOISTS AND LIFTS

10 -1 GENERAL

The ability to remove small craft from the water is essential for any type of major repair or maintenance at a small craft facility. Further, the ability to launch small craft greatly increases the capacity of the facility and the flexibility to operate a greater number of small craft than accommodated at limited spaces on the floating docks or fixed piers. Because of these reasons, most dedicated small craft harbors have some provision to launch small craft. Various systems have been developed over time and the number of such types of systems has varied as technologies and vessel types change.

10-2 FIXED SYSTEMS

Fixed systems typically utilize a lift that is in a set position to retrieve the vessel from the water. Once the vessel is removed from the water, it is transferred to a trailer to be transported and kept at the storage location, or repair facility. Alternatively, if the vessel is the only vessel at the facility, or it is a dedicated system, the vessel will remain on the lift until it is to be placed in service again.

10-2.1 **Jib Boom.** This is the most common type of retrieval system and is comprised of a crane mast that rotates about a vertical axis. The hoist is mounted on a trolley on a fixed arm (jib boom) that is swung over the boat in the water. The boat is fit with a wire rope sling that attaches to fittings on the boat. A crane hook then attaches to a pickup point on the wire rope sling to lift the boat out of the water. Once the boat is lifted above the top of the seawall, the crane rotates about its axis to place the boat onto a waiting trailer. Once the boat is loaded onto the trailer, the trailer is kept in a dry storage yard until the boat is to be placed in service, when the process is reversed.

10-2.2 **Marine Railway.** A marine railway is a set of fixed rails that ramp down from the shore into the water. The rails are typically supported on piles within the water. A cradle with wheels is hauled by a cable and winch system mounted on the railway and runs into the water, sufficiently deep, such that the vessel can float over the cradle. The vessel is lashed to the risers on the cradle and the cradle is winched up the railway to haul the vessel out of the water. Once on shore, the wheeled cradle can be transferred to a rail siding; multiple work bays can be supported by a single inclined railway. This system is best suited to larger vessels and it requires a significant amount of land area. As such, it is not considered practical for most small craft facilities.

10-2.3 **Elevator Lift.** This method consists of a platform that is raised and lowered into the water by a number of synchronized winches mounted on dolphins along the sides of the platform. A cradle with wheels – similar to the marine railway described previously – is located on the platform when it is lowered into the water sufficiently deep such that the vessel can float over the cradle and platform to then be raised out of the water. The platform is fitted with rails that continue to the shore upon which the cradle and vessel are transported once it is out of the water. This system has been developed by the Syncrolift Corp and is best suited to larger vessels.

For small craft, a similar system is used that utilizes a fork lift mounted to a fixed vertical mast that operates similar to a mobile forklift with “negative” lift and is becoming more common. The forklift rotates about the mast to place the forks in the water, or over land where a mobile forklift can access the vessel. This system is more effective for stacked storage in that a conventional forklift can also store and retrieve the vessels.

10-3 MOVEABLE SYSTEMS

10-3.1 **Straddle Carrier.** This is probably the most versatile and cost effective system for small craft retrieval. The system is comprised of a self propelled carrier frame that drives over the water on a set of two fixed piers. The carrier frame supports a set of slings that is lowered into the water between the piers to a depth sufficient to allow the vessel to position itself over the slings. Then the slings are lifted out of the water by lifting mechanisms within the carrier frame. Once out of the water, the carrier drives off the piers and can maneuver to any location with its wheels that can be steered.

10-3.2 **Crane Lift.** This type of haulout can utilized a dedicated fixed crane or a rubber tire boom crane, or similar mobile crane. The crane supports a lifting frame fit with slings that is lowered into the water similar to the straddle carrier described previously. Once the vessel is lifted from the water, the crane swivels to place the boat on an awaiting trailer, or for a limited number of vessels, could place them onto stands within the arc swing of the crane.

10-3.3 **Forklift.** This method utilizes a forklift with “negative” lift. The forklift is positioned at a vertical bulkhead (marginal wharf) where it lowers the forks below the keel depth of the awaiting vessel. The vessel is placed over the forks and the forklift lifts the vessel out of the water. This method is rapid and has the advantage of being able to move the vessel to a storage location on land and to raise the vessel onto a storage rack.

10-3.4 **Trailer.** Various trailer methods are used to retrieve and launch vessels into the water. Trailers are utilized with jib booms, crane lifts or launch ramps, discussed in the following section. This is the most common method of moving vessels.

10-3.5 **Floating Lift.** Floating boat lifts use buoyancy chambers to raise small craft out of the water much like a floating dry dock. The typical floating lift is permanently installed in a single berth and is configured for the vessel that uses that berth. The boat is stored out of (but over) the water with minimal additional load on the dock system. This type of system is used increasingly by the Navy, with capacities up to 13,000 lb (5.897 metric tons).

10-3.6 **Drive On Dock.** The drive on dock is a shallow freeboard platform that floats a few inches above the water surface. Vessels approach the platform from the water and “drive up” onto the platform at low speed. The platform is constructed of multiple plastic blocks that are pinned together to form a flexible platform that yields to the hull when it drives up, sufficient to avoid damage to the hull. The “Jetdock” System (Moose Boats, Inc.) is a drive on dock system currently in use.

This page intentionally left blank.

CHAPTER 11

LAUNCHING RAMPS

11-1 GENERAL REQUIREMENTS – WATER AREA

11-1.1 **Fairway.** The Basin or other waterway into which a launching ramp extends should meet the following requirements:

11-1.1.1 Minimum water depth 4 ft (1.2 m) at design low water.

11-1.1.2 Minimum bottom width greater than the combined width of the launch ramp and boarding floats.

11-1.1.3 Minimum length of 50 ft beyond the toe of the ramp, and absolutely clear of obstructions and/or navigation hazards.

11-1.1.4 Mark with navigational aids in accordance with the Waterway Marker System rules per USCG (COMDTINST 16500 series) which identify the proper color and locations of channel markers.

11-1.2 **Launch Ramp.** The launch ramp should meet the following requirements:

11-1.2.1 **Ramp Slope.** Slope between 12% and 15%. Few trailered boats can be launched with slopes flatter than 12% without submerging the wheel hubs of the tow vehicle, which is to be avoided. The slope should be uniform over the entire length of the ramp.

11-1.2.2 **Ramp Toe.** The ramp should extend down to an elevation a minimum of 3 ft (0.9 m) below design low water. The toe of the ramp should be provided with a wheel stop to prevent trailers from backing off the end of the ramp.

11-1.2.3 **Ramp Head.** The ramp should extend up to an elevation 1 ft (0.3 m) minimum above design high water. In addition, the head of the ramp should be provided with a 20 ft (6.1 m) long vertical curve to provide a smooth transition between the steeper ramp slope and the flat slope of the apron/turnaround area.

11-1.2.4 **Ramp Finish.** Ramp surface should be constructed of reinforced concrete, either cast-in-place or pre-cast panels, or a combination of both, and provided with a V-groove surface finish to maximize traction. Typical launch ramp finish details are described in *Layout and Design Guidelines for Marina Berthing Facilities (DBW)*.

11-1.2.5 **Ramp Width.** Standard launching ramp lane width is 15 ft (4.5 m) when 2 or more lanes are provided. When a single lane is provided, the width should be 20 ft. (6.1 m). The number of lanes will be determined by the demand and the site specific conditions. One launching lane should handle up to 25 launch/retrievals (round trips) per day. The total width of the ramp structure is obtained by adding the width of the required number of lanes and boarding floats.

11-1.3 **Boarding Floats and Platforms.** The launch ramp should be fitted with a boarding float (or platform) along the side of the lane (minimum one per lane) meeting the following requirements:

11-1.3.1 **Float Width.** Minimum clear float width is 6 ft. (1.8 m). In cases where guide piles are located inside the boarding float frame on one side, provide a minimum clear distance of 4 ft to the opposite side of the float. Where the guide piles are located in the center of the float, provide a minimum clear distance of 3 ft. (0.9 m) to each side of the float.

11-1.3.2 **Float Length.** Provide a minimum of 50 ft. (15.2 m) in the water (measured from the water line at design low water). Articulated boarding floats are often used to accommodate changes in water level, however, the portion of the boarding float that remains permanently in the water should not be articulated, but be continuous, to enhance stability.

11-1.3.3 **Float Live Load.** Where access is restricted, floats should be designed for a minimum uniform live load of 20 psf 4.1 (kPa); where access is not restricted, the minimum uniform live load should be 40 psf 8.2 (kPa). The floats should also be designed for a live point load of 650 lbs. applied at any point on the float deck not less than 12 in. (0.3 m) from the edge of the float.

11-1.3.4 **Float Freeboard.** Freeboard under dead load only should be between 14 in. (35 cm) and 20 in. (51 cm); the float deck should be level within the following tolerances:

Difference in Freeboard Transverse Direction – 1 in. (2.5 cm) maximum

11-1.3.5 **Other Requirements.** See the discussion for floating docks in Section 6 for other requirements pertaining to floating dock design and construction.

11-1.3.6 **Non-Floating Boarding Platforms.** Non floating boarding platforms generally consist of movable wedge shaped scaffolds that rest on the launching ramp and remain in-place by self weight. Typically constructed of steel, with retractable wheels and fitted with hitches, they may be towed to position on the ramp in response to changing water levels. These are used at sites where water levels do not change rapidly, or where winter conditions dictate removal of the boarding platform to reduce risk of ice damage. Other types of boarding systems are described in the *Layout, Design and Construction Handbook for Small Craft Berthing Facilities*.

11-1.4 **Shoreside Support Facilities.**

11-1.4.1 **Trailer Maneuvering.** Provide sufficient area at the head of the ramp for trailer maneuvering; typically an area 50 ft x 50 ft (15.2 m x 15.2 m) will be sufficient.

11-1.4.2 **Trailer Parking.** Provide sufficient parking to meet the expected demand for car-trailer spaces; pull through parking spaces should be utilized where practical. See Figure 11-1 for layout of car-trailer parking space and maximum driveway dimensions.

Figure 11-1 Car/Trailer Parking Layout

B.

11-1.4.3 **Boat Washdown.** Provide a fresh water boat/engine washdown area for launching facilities in salt water areas. Capture runoff from the washdown area in a separator and direct to wastewater collection system. Locate washdown area away from the head of the ramp to minimize interference with launching and retrieval operations.

11-1.4.4 **Power Lines.** Overhead power lines should not be permitted to cross the launch ramp or its maneuvering or parking area unless minimum overhead clearances prescribed by the authority having jurisdiction are met.

11-1.4.5 **Lighting.** High level lighting for the launching and retrieval area may be required to support night time operations. Avoid glare that can interfere with navigation.

This UFC supersedes UFC 4-159-03 with Change 2, dated 23 June 2016.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFCA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFCA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 4-159-03, *Moorings*

Superseding: UFC 4-159-03, *Design: Moorings*, 3 October 2005, with Change 2, dated 23 June 2016

Description: Provide guidance for the analysis and design mooring and berthing systems of ships and watercraft at waterfront facilities.

Reasons for Document:

- To supplement existing Government and commercial standards for design and construction of mooring facilities. Revisions made to update references and verify document refers to most current standards and references.

Impact:

- There are no cost impacts.

Unification Issues:

- There are no unification issues.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides design policy and procedures for design of moorings for U.S. Department of Defense (DoD) and other federal agency vessels. The purpose is to ensure quality, consistency, and safety of DoD vessels, mooring hardware, and mooring facilities throughout the world.

1-2 APPLICABILITY.

This UFC applies to the planning, design, construction, sustainment, restoration, and modernization of DoD owned mooring facilities. It is applicable to all methods of project delivery and levels of construction as defined below.

1-3 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFC and government criteria referenced herein.

1-4 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed and maintained in accordance with UFC 4-010-06, *Cybersecurity of Facility-Related Control Systems*, and as required by individual Service Implementation Policy.

1-5 GLOSSARY.

APPENDIX B contains acronyms, abbreviations, and definition of terms.

1-6 REFERENCES.

APPENDIX C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

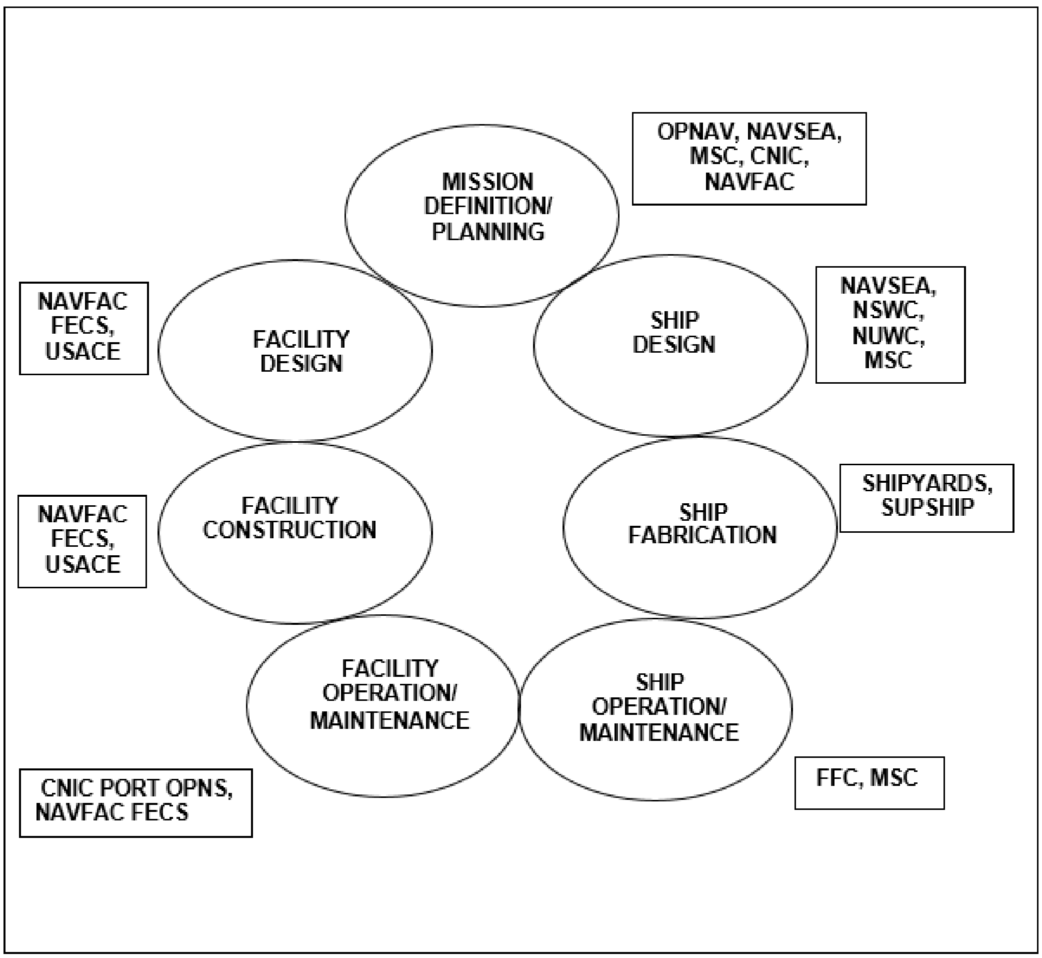
1-7 ORGANIZATIONAL ROLES AND RESPONSIBILITIES.

Over the design life of a mooring facility, many organizations are involved with the various aspects of a facility. Personnel involved range from policy makers, who set the initial mission requirements for vessels and facilities, to deck personnel securing lines. Figure 1-1 illustrates the DoD organizations that must understand the various aspects of moorings. In addition, all these groups must maintain open communications to ensure safe and effective moorings.

Safe use of moorings is of particular importance for the end users (the ship's personnel and facility operators). They must understand the safe limits of a mooring to properly respond to significant events, such as a sudden storm, and to be able to meet mission requirements.

It is equally important for all organizations and personnel shown in Figure 1-1 to understand moorings. For example, if the customer setting the overall mission requirement states, "We need a ship class and associated facilities to meet mission X, and specification Y will be used to obtain these assets" and there is a mismatch between X and Y, the ship and facility operators can be faced with a lifetime of problems, mishaps, and/or serious accidents.

Figure 1-1 DoD Organizations Involved with Ship Moorings



CHAPTER 2 MOORING SYSTEMS

2-1 INTRODUCTION.

The DoD uses several types of mooring systems to moor ships. These systems can be summarized into two broad categories of moorings:

- Fixed Moorings - Fixed moorings are defined as systems that include tension and compression members. Typical fixed mooring systems include moorings at piers and wharves.
- Fleet Moorings - Fleet moorings are defined as systems that include primarily tension members. Mooring loads are transferred into the earth via anchors. Examples of fleet moorings include fleet mooring buoys and ship's anchor systems.

The more common types of moorings are discussed in this chapter.

2-1.1 Purpose of Mooring.

The purpose of a mooring is to safely hold a ship in a certain position to accomplish a specific mission. A key need is to safely hold the vessel to protect the ship, life, the public interest, and to preserve the capabilities of the vessel and surrounding facilities. Ship moorings are provided for:

- Loading/Unloading - Loading and unloading items such as stores, cargo, fuel, personnel, ammunition, etc.
- Ship Storage - Storing the ship in a mooring reduces fuel consumption and personnel costs. Ships in an inactive or reserve status are stored at moorings.
- Maintenance/Repairs - Making a variety of repairs or conducting maintenance on the ship is often performed with a ship moored.
- Mission - Moorings are used to support special mission requirements, such as surveillance, tracking, training, etc.

Most DoD moorings are provided in harbors to reduce exposure to waves, reduce ship motions, and reduce dynamic mooring loads. Mooring in harbors also allows improved access to various services and other forms of transportation.

2-2 TYPES OF MOORING SYSTEMS.

Examples of typical moorings systems are given in this chapter.

2-2.1 Fixed Mooring Systems.

Examples of typical fixed moorings are given in Table 2-1 and illustrated in Figure 2-1 through Figure 2-5.

Table 2-1 Examples of Fixed Moorings

(a) Single Vessel Secured at Multiple Points

Mooring Type	Figure Number	Description
Pier/Wharf	Figure 2-1 Figure 2-2	Multiple tension lines are used to secure a vessel next to a pier/wharf. Compliant fenders, fender piles and/or camels keep the vessel offset from the structure. A T-pier may be used to keep the ship parallel to the current, where the current speed is high.
Spud Mooring	Figure 2-3	Multiple vertical structural steel beams are used to secure the vessel, such as a floating dry dock. This type of mooring is especially effective for construction barges temporarily working in shallow water. Spud moorings can be especially susceptible to dynamic processes, such as harbor seiches and earthquakes.

(b) Multiple Vessel Moorings

Mooring Type	Figure Number	Description
Opposite Sides of a Pier	Figure 2-4	Vessels can be placed adjacent to one another on opposite sides of a pier to provide some blockage of the environmental forces/moments on the downstream vessel.
Multiple Vessels Next to One Another	Figure 2-5	Vessels can be placed adjacent to one another to provide significant blockage of the environmental forces/ moments on the downstream vessel(s).

Figure 2-1 Single Ship, Offset From a Pier with Camels

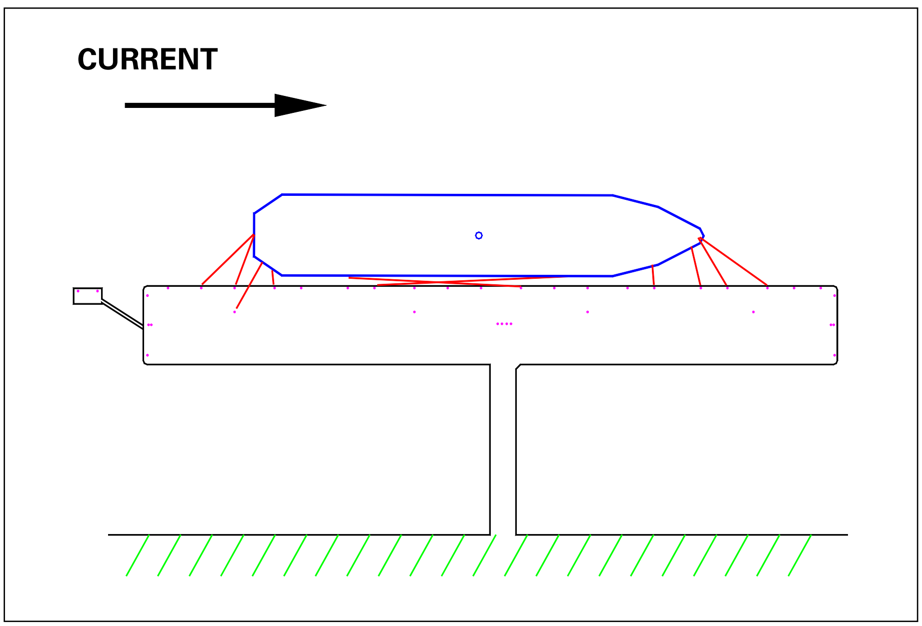

Figure 2-3 Floating Dry Dock Spud Moored

(spuds are secured to a pier, which is not shown, and the floating dry dock rides up and down on the spuds; profile view is shown)

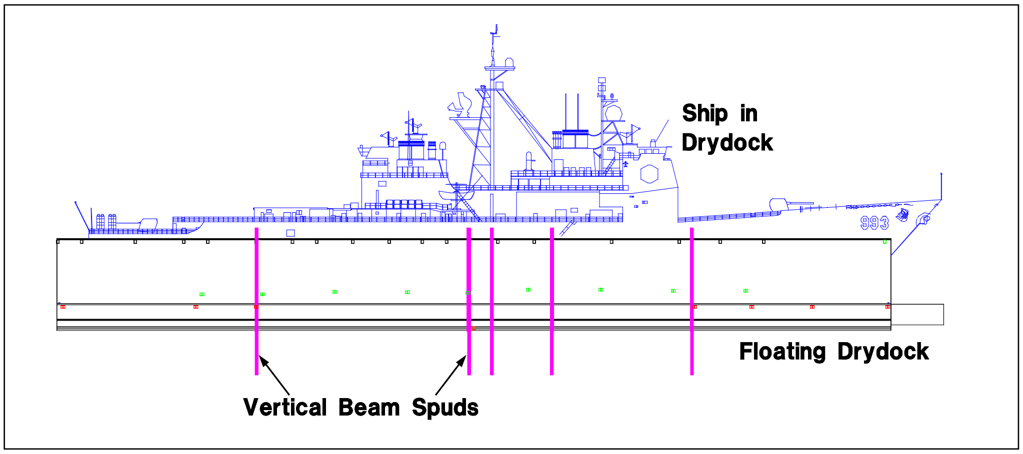

Figure 2-4 Ships on Both Sides of a Pier (plan view)

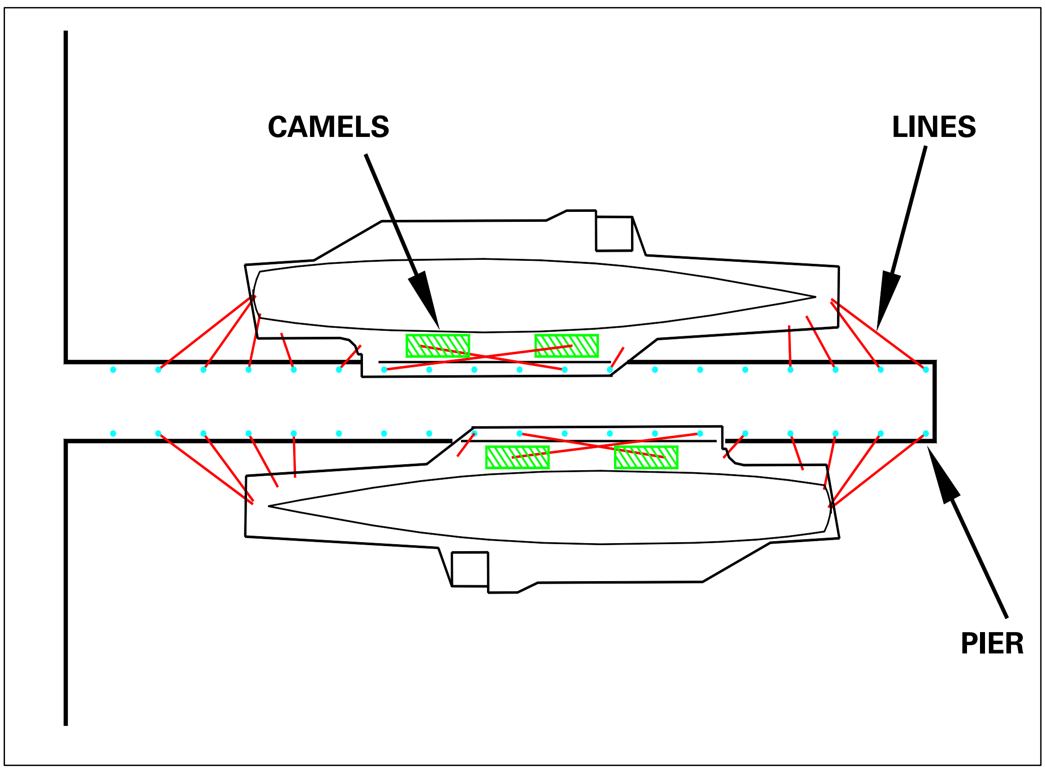

Figure 2-5 Two Ships on One Side of a Pier (plan view)

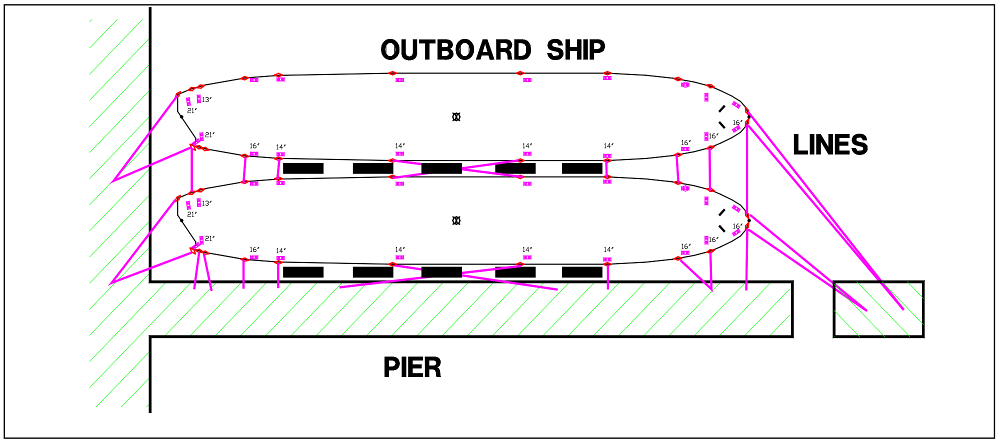

2-2.2 Fleet Mooring Systems.

Examples of typical fleet moorings are given in Table 2-2 and illustrated in Figure 2-6 through Figure 2-13.

Table 2-2 Examples of Fleet Moorings

(a) Vessel Secured at a Single Point

Mooring Type	Figure Number	Description
At Anchor	Figure 2-6	Typical configuration includes the ship deploying a single drag anchor off the bow. This is usually a temporary mooring used as a last resort in benign conditions. A large amount of harbor room is required for the ship swing watch circle. If the wind changes direction dramatically then the anchor will have to reset. Dynamic fishtailing, even under steady winds and currents, may be a problem. Putting out a second anchor in what is known as a Hammerlock mooring may be required in storm anchoring.
Single Mooring Buoy	Figure 2-7 Figure 2-8	A single point mooring (SPM) buoy is secured to the seafloor typically with 1 to 12 ground legs and either drag or plate anchors. The ship moors to the buoy using an anchor chain or hawser. The vessel weathervanes under the action of forcing, which helps to reduce the mooring load. This type of mooring requires much less room than a ship at anchor because the pivot point is much closer to the vessel. A vessel at a mooring buoy is much less prone to fishtailing than a ship at anchor. Many of the mooring buoys at U.S. Navy facilities around the world are provided under the U.S. Navy's Fleet Mooring Program.

(b) Vessel Secured at Two Points

Mooring Type	Figure Number	Description
Bow-Stern Mooring	Figure 2-9	A vessel is moored with one buoy to the bow and another to the stern. This system has a much smaller watch circle than a vessel at a single mooring buoy. Also, two moorings share the load. However, the mooring tension can be much higher if the winds, currents, or waves have a large broadside component to the ship.

(c) Vessel Secured at Multiple Points

Mooring Type	Figure Number	Description
Med-Mooring	Figure 2-10	The vessel bow is secured to two mooring buoys and the stern is moored to the end of a pier or wharf. This type of mooring is commonly used for tenders or in cases where available harbor space is limited. Commonly used in the Mediterranean Sea. Hence, the term “Med” Mooring.
Spread Mooring	Figure 2-11	Multiple mooring legs are used to secure a vessel. This arrangement of moorings is especially useful for securing permanently or semi-permanently moored vessels, such as floating dry docks and inactive ships. The ship(s) are usually oriented parallel to the current.

(d) Multiple Vessel Moorings

Mooring Type	Figure Number	Description
Nest	Figure 2-12 Figure 2-13	Multiple tension members are used to secure several vessels together. Separators are used to keep the vessels from contacting one another. Nests of vessels are commonly put into spread moorings. Nested vessels may be of similar size (as for inactive ships) or much different size (as a submarine alongside a tender). Advantages of nesting are: a nest takes up relatively little harbor space and forces/moments on a nest may be less than if the ships were moored individually.

CHAPTER 3 BASIC DESIGN PROCEDURE

3-1 DESIGN APPROACH.

Use specified parameters and engineering principles throughout the design process. Types of parameters associated with mooring projects are summarized in Table 3-1. The basic approach to performing mooring design with the facility and ship known is given in Table 3-2.

Table 3-1 Parameters in a Mooring Project

Parameter	Examples
1. Operational Parameters	Required ship position, amount of motion allowed
2. Ship Configuration	Basic ship parameters, such as length, beam, draft, displacement, wind areas, mooring fitting locations, wind/current force, mooring fitting safe working loads, allowable hull pressure, and moment coefficients
3. Facility Configuration	Facility location, water depth, dimensions, locations/type/safe working load of mooring fittings/fenders, facility condition, facility overall capacity
4. Environmental Parameters	Wind speed, current speed and direction, water levels, wave conditions and possibility of ice
5. Mooring Configuration	Number/size/type/location of tension members, fenders, camels, etc.
6. Material Properties	Stretch/strain characteristics and breaking strengths of the mooring tension and compression members

Table 3-2 Basic Mooring Design Approach with Known Facility for a Specific Site and a Specific Ship

Step	Examples
1. Define customer(s) requirements	Define the ship(s) to be moored, the type of service required, the maximum allowable ship motions, and situations under which the ship will leave.
2. Determine planning requirements	Define the impact/interaction with other facilities and operations, evaluate explosive arcs and other restricted areas, determine permit requirements, establish how the mooring is to be used, review the budget and schedule.
3. Prepare Environmental Impact Assessments	Prepare any required studies and paperwork.
4. Define site and environmental parameters	See Table 3-1
5. Determine Ship characteristics	See Table 3-1
6. Determine Ship forces/moments	Determine the forces, moments, and other key behaviors of the ship(s).
7. Evaluate mooring alternatives	Evaluate the alternatives in terms of safety, risk, cost, constructability, availability of hardware, impact on the site, watch circle, compatibility, maintenance, inspectability, and other important aspects.
8. Develop Design Calculations	Perform static and/or dynamic analyses (if required) for mooring performance, anchor design, fender design, etc.
9. Issue Notifications	Prepare Notice to Mariners for the case of in-water construction work and notify charting authorities concerning updating charts for the area.

Table 3-2 Basic Mooring Design Approach with Known Facility for a Specific Site and a Specific Ship (*Continued*)

Step	Examples
1. Plans/Specs	Prepare plans, specifications, and cost estimates.
2. Permits [a]	Prepare any required environmental studies and obtain required permits.
3. Installation planning [a]	Prepare instructions for installation, including safety and environmental protection plans.
4. Installation monitoring [a]	Perform engineering monitoring of the installation process.
5. Testing [a]	Perform pull tests of all anchors in mooring facilities to ensure that they hold the required load.
6. Documentation	Document the design and as-built conditions with drawings and reports.
7. Instructions	Provide diagrams and instructions to show the customer how to use and inspect the mooring.
8. Inspection	Perform periodic inspection/testing of the mooring to assure it continues to meet the customer(s) requirements.
9. Maintenance	Perform maintenance as required and document on as-built drawings.

Note:
[a] May not be required for existing berthing facilities

3-2 GENERAL DESIGN CRITERIA.

General design criteria shown in Table 3-3 should be addressed during the design process to help ensure projects meet customers' needs.

Table 3-3 Design Criteria

Criteria	Examples
1. Vessel operating conditions	Under what conditions will the vessel(s) exit? What are the operating mission requirements for the ship? What is the maximum allowable hull pressure?
2. Allowable motions	How much ship motion in the six degrees of freedom will be allowable for the moored ship? This is related to brow positions and use, utilities, ship loading and unloading operations, and other requirements. Many ships have high buoyancy forces, so moorings should be designed to allow for vertical ship motions due to water level changes.
3. User skills	Is the user trained and experienced in using the proposed system? What is the risk that the mooring would be improperly used? Can a design be formulated for easy and reliable use?
4. Flexibility	How adaptable is the design? Can it provide for new mission requirements not yet envisioned? Can it be used with existing facilities/ships?
5. Constructability	Does the design specify readily available commercial products and is it able to be installed and/or constructed using standard techniques, tolerances, etc.?
6. Cost	Are initial and life cycle costs life cycle costs controlled so that the design represents the best value that meets the technical requirements?
7. Inspection	Can the mooring system be readily inspected to ensure continued good working condition?
8. Maintenance	Can the system be maintained in a cost-effective manner?
9. Special requirements	What special requirements does the customer have? Are there any portions of the ship that cannot come in contact with mooring elements (e.g., submarine hulls)?

3-2.1 Mooring Service Types (MST).

Four Mooring Service Types (MST) are defined to help identify minimum design requirements associated with DoD ships and piers, and determine operational limitations. Facility and ship mooring hardware should accommodate the service types shown in Table 3-4.

Table 3-4 Mooring Service Types

Mooring Service Type (MST)	Description
TYPE I Mild Weather Mooring	This category covers moorings for mild weather (sustained winds of less than 35 knots (18 m/s); below gale force) and currents less than 1 knot (0.5 m/s). Mooring situations include ammunition facilities, fueling facilities, deperming facilities, and ports of call. Use of these moorings is normally selected in concert with forecasted weather.
TYPE II Standard/Storm Mooring	This category covers moorings that are used through storm conditions. Moorings include standard, storm and nested configurations. Vessel will normally leave prior to an approaching hurricane, typhoon, surge or other extreme event. Naval ships intend to go to sea if 50 knot (26 m/s) winds are expected, but storms may come up quickly, so higher design winds are recommended.
TYPE IIA Standard Mooring	MST IIA covers mooring in winds of 50 knots (26 m/s) or less in broadside currents of 1-1/2 knots (0.8 m/s) or less. The practice is to provide for full pier operation for MST IIA.
TYPE IIB Storm Mooring	MST IIB covers mooring in winds of 64 knots (33 m/s) or less in broadside currents of 2 knots (1 m/s) or less. This is the intended Navy ship mooring design requirement. It is encouraged for general homeporting because sudden storms can produce high winds on short notice. Pier operations may be impacted for MST IIB if lines must be run across a pier.
TYPE III Heavy Weather Mooring	This category covers moorings of vessels that cannot or may not get underway prior to an approaching hurricane, typhoon, surge or other extreme event. Moorings include fitting-out, repair, dry dock, and overhaul berthing facilities.
TYPE IV Permanent Mooring	This category covers moorings that are used to permanently moor a vessel that will not leave in case of a hurricane, typhoon, surge or other extreme event. Moorings include inactive ships, floating dry docks, ship museums, training berthing facilities, etc.

3-2.2 Facility Design Criteria for Mooring Service Types.

Mooring facilities are designed conforming to the site specific environmental criteria given in Table 3-5. Table 3-5 gives design criteria in terms of environmental design return intervals, R, and in terms of probability of exceedance, P, for 1 year of service life, N=1. The ship usually has the responsibility for providing mooring lines for MSTs I and II, while the facility usually provides mooring lines for MSTs III and IV.

Table 3-5 Facility Design Criteria for Mooring Service Types

Mooring Service Type (MST)	Wind [a]	Current [b]	Water Level	Waves
TYPE I	Less than 35 knots (18 m/s) [c]	1 knot (0.5 m/s) or less	mean lower low to mean higher high	N/A
TYPE IIA	V_w=50 knots (26 m/s) max.	1.5 knot (0.8 m/s) max.	extreme low to mean higher high	P=1 or R=1 yr
TYPE IIB	V_w=64 knots (33 m/s) max.	2.0 knot (1.0 m/s) max.	extreme low to mean higher high	P=1 or R=1 yr
TYPE III [d, e]	P=0.02 or R=50 yr	P=0.02 or R=50 yr	extreme low to extreme high	P=0.02 or R=50 yr
TYPE IV [d, e]	P=0.01 or R=100 yr	P=0.01 or R=100 yr	extreme water levels	P=0.01 or R=100 yr

Note:

a Use exposure D (UFC 1-200-01, *DoD Building Code*; flat, unobstructed area exposed to wind flowing over open water for a distance of at least 1 mile (1.61 km) for determining design wind speeds.) Min. = minimum return interval or probability of exceedance used for design; max. = maximum wind speed used for design.

b Specific site conditions might dictate consideration of a higher current speed. Local current data and information from site personnel should be used to determine appropriate current speed. To define the design water depth for ship current force calculations, use T/d=0.9 for flat-keeled ships. For ships with non-flat hulls (sonar domes or other projections), determine the water depth by adding 2 ft (0.61 m) to the maximum navigation draft of the ship (may vary depending on sonar dome size), and take the ship draft as the mean depth of the keel.

c This is considered an absolute minimum for design, 35 knots (18 m/s) minimum. Specific site conditions might dictate consideration of a higher wind speed. Local wind climatology should be examined to determine appropriate windspeed.

d Refer to UFC 4-152-01, *Piers and Wharves*, Mooring Loads for method to calculate wind speed for recurrence intervals associated with Type III and Type IV mooring service types.

e Refer to NAVFAC EXWC report SSR-NAVFAC ESC-06-2012 *Environmental Conditions Report* for design criteria associated with Type III and Type IV moorings.

3-2.3 Ship Hardware Design Criteria for Mooring Service Types.

Ship mooring hardware needs to be designed to accommodate various modes of ship operation. During Type II operation, a ship may be moored in relatively high broadside current and get caught by a sudden storm, such as a thunderstorm. Type III mooring during repair may provide the greatest potential of risk, because the ship is moored for a significant time and cannot get underway. There are several U.S. shipyards where DoD ships can undergo major repairs. Ship mooring hardware environmental design criteria are given in Table 3-6. For Type IV mooring, special provisions can be made for long-term storage such as extra pad eyes and other modifications to the ship hull.

Table 3-6 Ship Mooring Hardware Design Criteria

(a) Ship Anchor Systems [a]

Vessel Type	Minimum Water Depth ft (m)	Minimum Wind Speed knot (m/s)	Minimum Current Speed knot (m/s)
Ships	240 (73)	70 (36)	4 (2.1)
Submarines	120 (36.6)	70 (36)	4 (2.1)

(b) Ship Mooring Systems [b]

Mooring Service Type (MST)	Minimum Wind Speed knot (m/s)	Minimum Current Speed knot (m/s)
Type I	35 (18)	1 (0.51)
Type II [c]	64 (33)	2 (1.03)
Type III	95 (48.9)	2 (1.03

Note:

[a] Quasi-static design assuming wind and current are co-linear for ship and submarine anchor systems (after NAVSEASYSCOM DDS-581).

[b] Specific site conditions might dictate consideration of a higher current speed. Local current data and information from site personnel should be used to determine appropriate current speed. To define the design water depth for ship current force calculations, use T/d=0.9 for flat-keeled ships. For ships with non-flat hulls (sonar domes or other projections), determine the water depth by adding 2 ft to the maximum navigation draft of the ship (may vary depending on sonar dome size), and take the ship draft as the mean depth of the keel.

[c] Ships need to carry lines suitable for MST IIB.

3-2.4 Strength.

Moorings should be designed and constructed to safely resist the nominal loads in load combinations defined herein without exceeding the appropriate allowable stresses for the mooring components. Normal wear of materials and inspection methods and frequency need to be considered. Due to the probability of simultaneous maximum occurrences of variable loads, no reduction factors should be used.

Throughout this document there are references to Working Capacity, Ultimate Capacity/Strength, Breaking Strength, and other strength, load, and capacities. See APPENDIX B for definition of terms.

3-2.5 Serviceability.

Moorings should be designed to have adequate stiffness to limit deflections, vibration, or any other deformations that adversely affect the intended use and performance of the mooring. At the same time moorings need to be flexible enough to provide for load sharing, reduce peak dynamic loads and allow for events, such as tidal changes.

3-2.6 Design Methods.

All moorings should be designed by skilled and knowledgeable professional personnel. Methods must be used that assure that ships are safely moored. Below are some guidelines.

MST I and II moorings can often be designed using quasi-static tools with three degrees of freedom (surge, sway and yaw). Examples of tools include OPTIMOOR, ANSYS AQWA, etc. Specialized tools need to be considered for cases of high currents, high tidal ranges, passing ship effects, ship waves, multiple/nested ships, situations that are likely to be dynamic and other specialized cases. It is valuable to ships' and port operations personnel to provide generalized mooring designs for MSTs I and II.

MSTs III and IV must be designed on a case-by-case basis using dynamic methods because of the extremely high loading that occurs during extreme storms. It is recommended that NAVFAC EXWC be contacted concerning the design of these types of moorings.

3-2.7 General Mooring Integrity.

For multiple-member moorings, such as for a ship secured to a pier by a number of lines, the mooring system relies on load sharing among several members. If one member is lost, the ship should remain moored. Therefore, design multiple-member moorings to ensure that remaining members maintain a factor of safety at least 75% of the intact mooring factors of safety shown in Table 3-7 with any one member missing.

3-2.8 Quasi-Static Safety Factors.

Table 3-7 gives recommended minimum factors of safety for "quasi-static" design based on material reliability.

Table 3-7 Minimum Quasi-Static Factors of Safety

Component	Minimum Factor of Safety	Notes
Stockless and balanced fluke anchors	1.5	For ultimate anchoring system holding capacity; use 1.0 for ship's anchoring [a]
High efficiency drag anchors	2.0	For ultimate anchoring system holding capacity use 1.0 for ship's anchoring [a]
Fixed anchors (piles and plates)	3.0	For ultimate anchoring system holding capacity [a]
Deadweight anchors	-	Use carefully (see NCEL *Handbook for Marine Geotechnical Engineering*, 1985, Section 4.6)
Chain	3.0 4.0	For relatively straight lengths. For chain around bends. These factors of safety are for the new chain break strength.
Wire rope	3.0	For the new wire rope break strength.
Synthetic line [b]	3.0	For new line break strength.
Ship bitts	See note [c]	Use American Institute of Steel Construction (AISC) code.
Pier bollards	See note [c]	See note [c]

Note:

[a] It is recommended that anchors be pull tested.

[b] Reduce effective strength of wet nylon line by 15%.

[c] Reference UFC 4-152-01, *Piers and Wharves* section on Mooring Loads

3-2.9 Allowable Ship Motions.

Table 3-8 gives recommended operational ship motion criteria for moored vessels.

Table 3-8 (a) gives maximum wave conditions for manned and moored small craft (Permanent International Association of Navigation Congresses (PIANC), *Criteria for Movements of Moored Ships in Harbors; A Practical Guide*, 1995). These criteria are based on comfort of personnel on board a small boat and are given as a function of boat length and locally generated.

Table 3-8 (b) gives recommended motion criteria for safe working conditions for various types of vessels (PIANC, 1995).

Table 3-8 (c) gives recommended velocity criteria and Table 3-8 (d) and (e) give special criteria.

Table 3-8 Recommended Practical Motion Criteria for Moored Vessels

(a) Safe Wave Height Limits for Moored Manned Small Craft

(PIANC, 1995)

		Beam/Quartering Seas			Head Seas	
Vessel Length	Wave Period	Maximum Sine Wave Height, H_s		Wave Period	Maximum Sine Wave Height, H_s	
ft (m)	sec	ft	(m)	sec	ft	(m)
13.1 to 32.8 (4 to 10)	<2.0	0.66	0.20	<2.5	0.66	0.20
"	2.0-4.0	0.33	0.10	2.5-4.0	0.49	0.15
"	>4.0	0.49	0.15	>4.0	0.66	0.20
32.8 to 52.5 (10 to 16)	<3.0	0.82	0.25	<3.5	0.82	0.30
"	3.0-5.0	0.49	0.15	3.5-5.5	0.66	0.20
"	>5.0	0.66	0.20	>5.5	0.98	0.30
65.6 (20)	<4.0	0.98	0.30	<4.5	0.98	0.30
"	4.0-6.0	0.49	0.15	4.5-7.0	0.82	0.25
"	>6.0	0.82	0.25	>7.0	0.98	0.30

Table 3-8 (*Continued*)

(b) Recommended Motion Criteria for Safe Working Conditions [a]

(PIANC, 1995)

Vessel Type	Cargo Handling Equipment	Surge (m)	Sway (m)	Heave (m)	Yaw (º)	Pitch (º)	Roll (º)
Fishing vessels 10-3,000 GRT [b]	Elevator crane Lift-on/off Suction pump	0.15 1.0 2.0	0.15 1.0 1.0	- 0.4 -	- 3 -	- 3 -	- 3 -
Freighters & coasters <10,000 DWT [c]	Ship's gear Quarry cranes	1.0 1.0	1.2 1.2	0.6 0.8	1 2	1 1	2 3
Ferries, Roll-On/ Roll-Off (RO/RO)	Side ramp [d] Dew/storm ramp Linkspan Rail ramp	0.6 0.8 0.4 0.1	0.6 0.6 0.6 0.1	0.6 0.8 0.8 0.4	1 1 3 -	1 1 2 1	2 4 4 1
General cargo 5,000-10,000 DWT	-	2.0	1.5	1.0	3	2	5
Container vessels	100% efficient 50% efficient	1.0 2.0	0.6 1.2	0.8 1.2	1 1.5	1 2	3 6
Bulk carriers 30,000-150,000 DWT	Cranes Elevator/ bucket-wheel Conveyor belt	2.0 1.0 5.0	1.0 0.5 2.5	1.0 1.0 -	2 2 3	2 2 -	6 2 -
Oil tankers	Loading arms	3.0 [e]	3.0	-	-	-	-
Gas tankers	Loading arms	2.0	2.0	-	2	2	2

Note:

[a] Motions refer to peak-to-peak values (except for sway, which is zero-to-peak)

[b] GRT = Gross Registered Tons expressed as internal volume of ship in units of 100 ft^3 (2.83 m^3)

[c] DWT = Dead Weight Tons, which is the total weight of the vessel and cargo expressed in long tons, 2,240 lb (1,016 kg), or metric tons (1,000 kg)

[d] Ramps equipped with rollers.

[e] For exposed locations, loading arms usually allow for 5.0-meter motion.

Table 3-8 (*Continued*)

(c) Recommended Velocity Criteria for Safe Mooring Conditions for Fishing Vessels, Coasters, Freighters, Ferries and Ro/Ro Vessels

(PIANC, 1995)

Ship Size (DWT)	Surge (m/s)	Sway (m/s)	Heave (m/s)	Yaw (°/s)	Pitch (°/s)	Roll (°/s)
1,000	0.6	0.6	-	2.0	-	2.0
2,000	0.4	0.4	-	1.5	-	1.5
8,000	0.3	0.3	-	1.0	-	1.0

(d) Special Criteria for Walkways and Rail Ramps

(PIANC, 1995)

Parameter	Maximum Value
Vertical velocity	0.2 m/s
Vertical acceleration	0.5 m/s^2

(e.) Special Criteria

Condition	Maximum Amplitude Values ft (m)	Notes
Heave	-	Ships will move vertically with any long period water level change (tide, storm surge, flood, etc.). The resulting buoyancy forces may be high, so the mooring must be designed to provide for these motions due to long period water level changes.
Loading/unloading preposition ships	2 (0.6)	Maximum ramp motion during loading/unloading moving wheeled vehicles.
Weapons loading/unloading	2 (0.6)	Maximum motion between the crane and the object being loaded/unloaded.

3-3 DESIGN METHODS.

3-3.1 Quasi-Static Design.

Practical experience has shown that in many situations such as for MSTs I and II, static analysis tools, such as, OPTIMOOR and ANSYS AQWA, etc. can be used to reliably determine mooring designs in harbors. Winds are a key forcing factor in mooring harbors. Winds can be highly dynamic in heavy weather conditions. However, practical experience has shown that for typical DoD ships, a wind speed with a duration of 30 seconds can be used, together with static tools, to develop safe mooring designs. The use of the 30-second duration wind speed with static tools and the approach shown in Table 3-9 is called “quasi-static” design.

Table 3-9 Quasi-Static Design Notes

Criteria	Notes
Wind speed	Determine for the selected return interval, R. For typical ships use the wind that has a duration of 30 seconds at an elevation of 32.8 ft (10 m).
Wind direction	Assume the wind can come from any direction except in cases where wind data show extreme winds occur in a window of directions.
Current speed	Use conditions for the site (speed and direction).
Water levels	Use the range for the site.
Waves	Neglected. If waves are believed to be important, then dynamic analyses are recommended.
Factors of safety	Perform the design using quasi-static forces and moments (see CHAPTER 4), minimum factors of safety in Table 3-7, and design to assure that all criteria are met.

A review of the methodology and available software for the analysis of ship moorings is provided in the Memorandum, *Simplified Mooring Calculation Methodology and Software*.

3-3.2 Dynamic Mooring Analysis.

Conditions during MSTs III and IV and during extreme events can be highly dynamic. Unfortunately, the dynamic behavior of a moored ship in shallow water can be highly complex, so dynamics cannot be fully documented in this UFC. An introduction to dynamics is provided in CHAPTER 8, Table 3-10 contains example conditions when mooring dynamics may be important or when special considerations must be made.

Table 3-10 Conditions Requiring Special Analysis

Factor	Special Analysis Required
Wind	> 39 knots (20 m/s) for small craft > 65 knots (34 m/s) for larger vessels
Wind waves	> 1.5 ft (0.46 m) for small craft > 4 ft (1.22 m) for larger vessels
Wind gust fronts	Yes for SPMs
Current	> 3 knots (20.1 m/s)
Ship waves and passing ship effects	Yes for special cases (see Kizakkevariath, 1989; Occasion, 1996; Weggel and Sorensen, 1984 & 1986)
Long waves (seiches and tidal waves or tsunamis)	Yes
Berthing and using mooring as a brake or to check the motion of the ship being berthed	Yes (see UFC 4-152-01, *Piers and Wharves*)
Parting tension member	Yes. may be static or dynamic
Ship impact or other sudden force on the ship	Yes (if directed)
Earthquakes	Yes, if in a spud moor or stiff system
Explosion, landslide, impact	Yes (if directed)
Tornado (reference NUREG 1974)	Yes
Flood, sudden water level rise	Yes (if directed)
Ice forcing	Yes (if a factor)
Ship/mooring system dynamically unstable (e.g., SPM)	Yes (dynamic behavior of ships at SPMs can be especially complex)
Forcing period near a natural period of the mooring system	Yes; if the forcing period is from 80% to 120% of a system natural period

3-4 RISK.

Risk is a concept that is often used to design facilities, because the probability of occurrence of extreme events (currents, waves, tides, storm surge, earthquakes, etc.) is strongly site dependent. Risk is used to ensure that systems are reliable, practical, and economical.

A common way to describe risk is the concept of 'return interval', which is the mean length of time between events. For example, if the wind speed with a return interval of R = 100 years is given for a site, this wind speed would be expected to occur, on the average, once every 100 years. However, since wind speeds are probabilistic, the specified 100-year wind speed might not occur at all in any 100-year period. Or, in any 100-year period the wind speed may be equal to or exceed the specified wind speed multiple times.

The probability or risk that an event will be equaled or exceeded one or more times during any given interval is determined from:

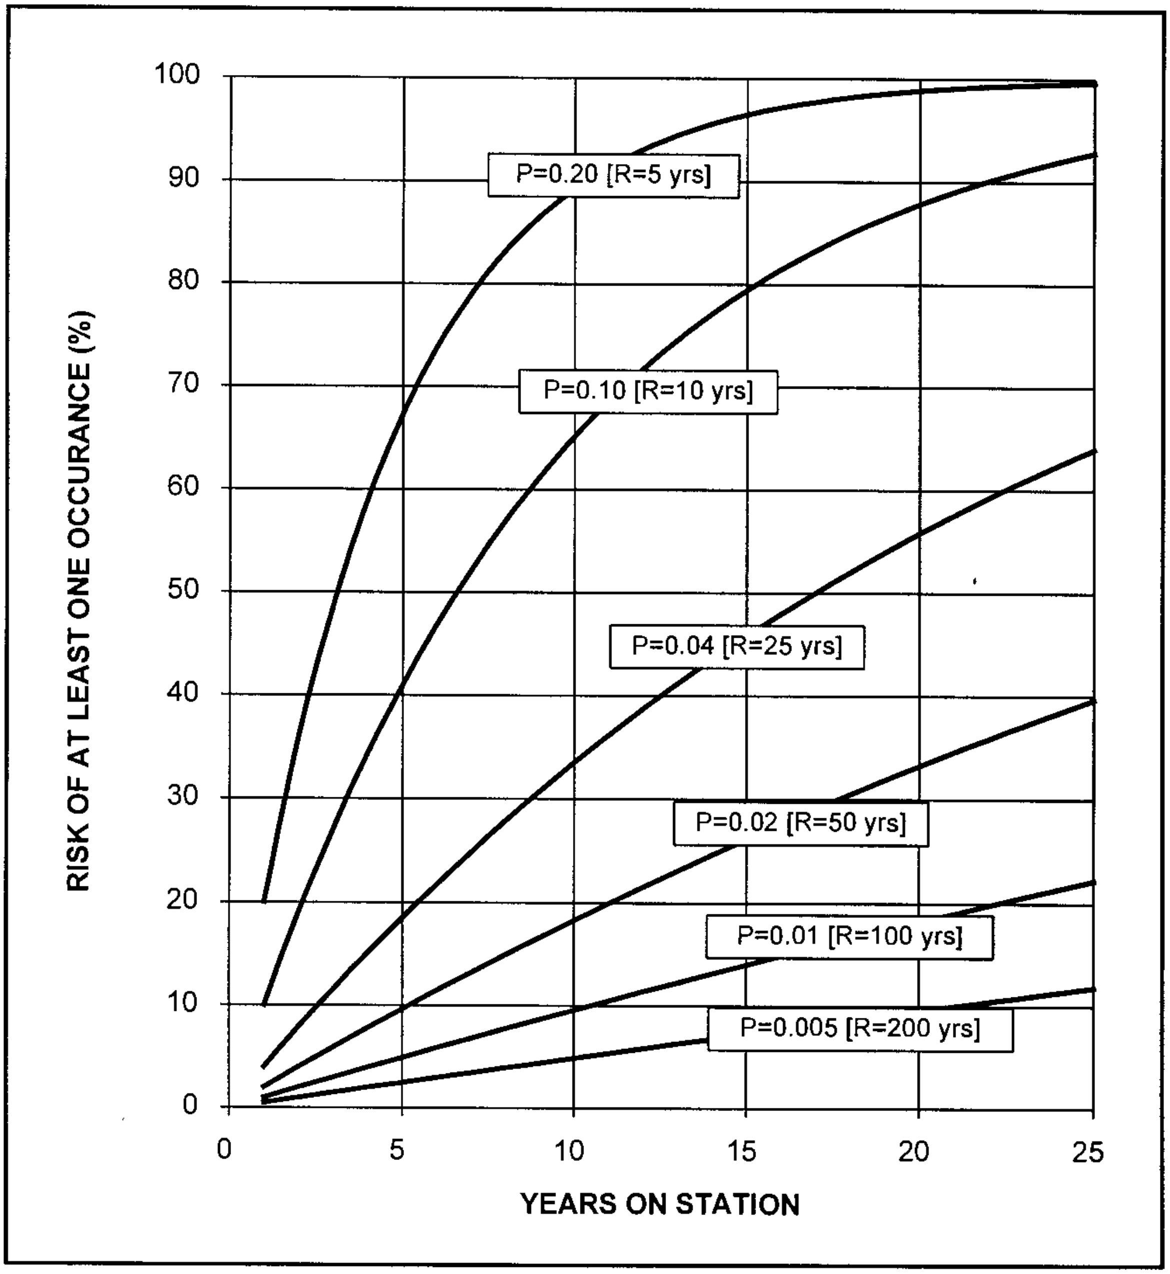
Equation 3-1

$$P = 100\% * \left(1 - \left(1 - \frac{1}{R}\right)^{N}\right)$$

where,
P = probability, in percent, of an event being equaled or exceeded one or more times in a specified interval
R = return interval (years)
N = service life (years)

Figure 3-1 shows risk versus years on station for various selected values of return interval. For example, take a ship that is on station at a site for 20 years (N = 20). There is a P = 18.2% probability that an event with a return interval of R = 100 years or greater will occur one or more times at a site in a 20-year interval.

Figure 3-1 Risk Diagram



3-5 COORDINATE SYSTEMS.

The various coordinate systems used for ships and mooring design are described below.

3-5.1 Ship Design/Construction Coordinates.

A forward perpendicular point (FP), aft perpendicular point (AP), and regular spaced frames along the longitudinal axes of the ship are used to define stations. The bottom of the ship keel is usually used as the reference point or "baseline" for vertical distances. Figure 3-2 illustrates ship design coordinates.

3-5.2 Ship Hydrostatics/Hydrodynamics Coordinates.

The forward perpendicular is taken as Station 0, the aft perpendicular is taken as Station 20, and various cross-sections of the ship hull (perpendicular to the longitudinal axis of the ship) are used to describe the shape of the ship hull. Figure 3-2 illustrates ship hydrostatic conventions.

3-5.3 Local Mooring Coordinate System.

Environmental forces on ships are a function of angle relative to the vessel's longitudinal centerline. A ship tends to move about its center of gravity. Therefore, the local "right-hand-rule" coordinate system, shown in Figure 3-3, is used in this UFC. The midship's point is shown as a convenient reference point in Figure 3-3 and Figure 3-4.

3-5.4 Global Coordinate System.

Plane state grids or other systems are often used to describe X and Y coordinates. The vertical datum is most often taken as relative to some water level, such as mean lower low water (MLLW).

3-5.5 Ship Conditions.

Loading conditions are defined in NAVSEA NSTM 096. There are three common conditions or displacements that a ship has at various stages including:

- <u>Light Condition</u> – This is the ship condition after first launching.
- <u>One-Third Stores Condition</u> – This is the typical ship condition during ship repair, as indicated in SUPSHIP docking/undocking records.
- <u>Fully Loaded Condition</u> – This is the ship condition during operations.

Figure 3-2 Ship Design and Hydrostatic Coordinates

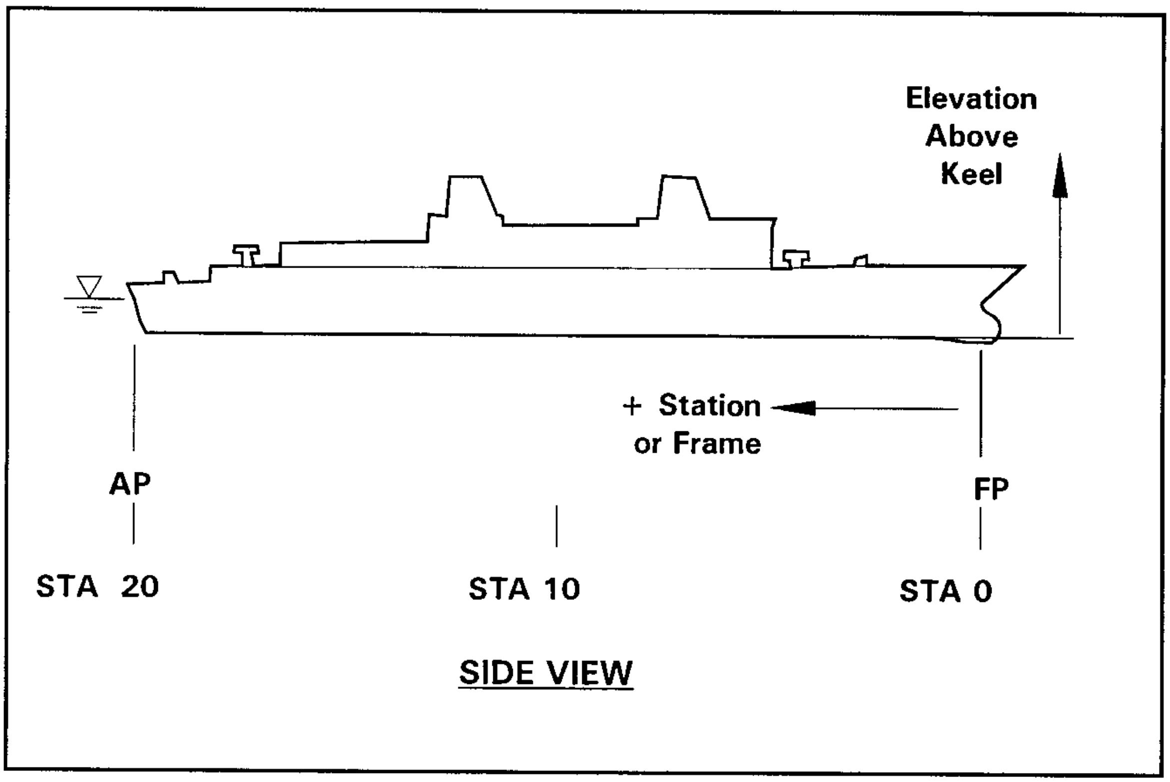


Figure 3-3 Local Mooring Coordinate System for a Ship

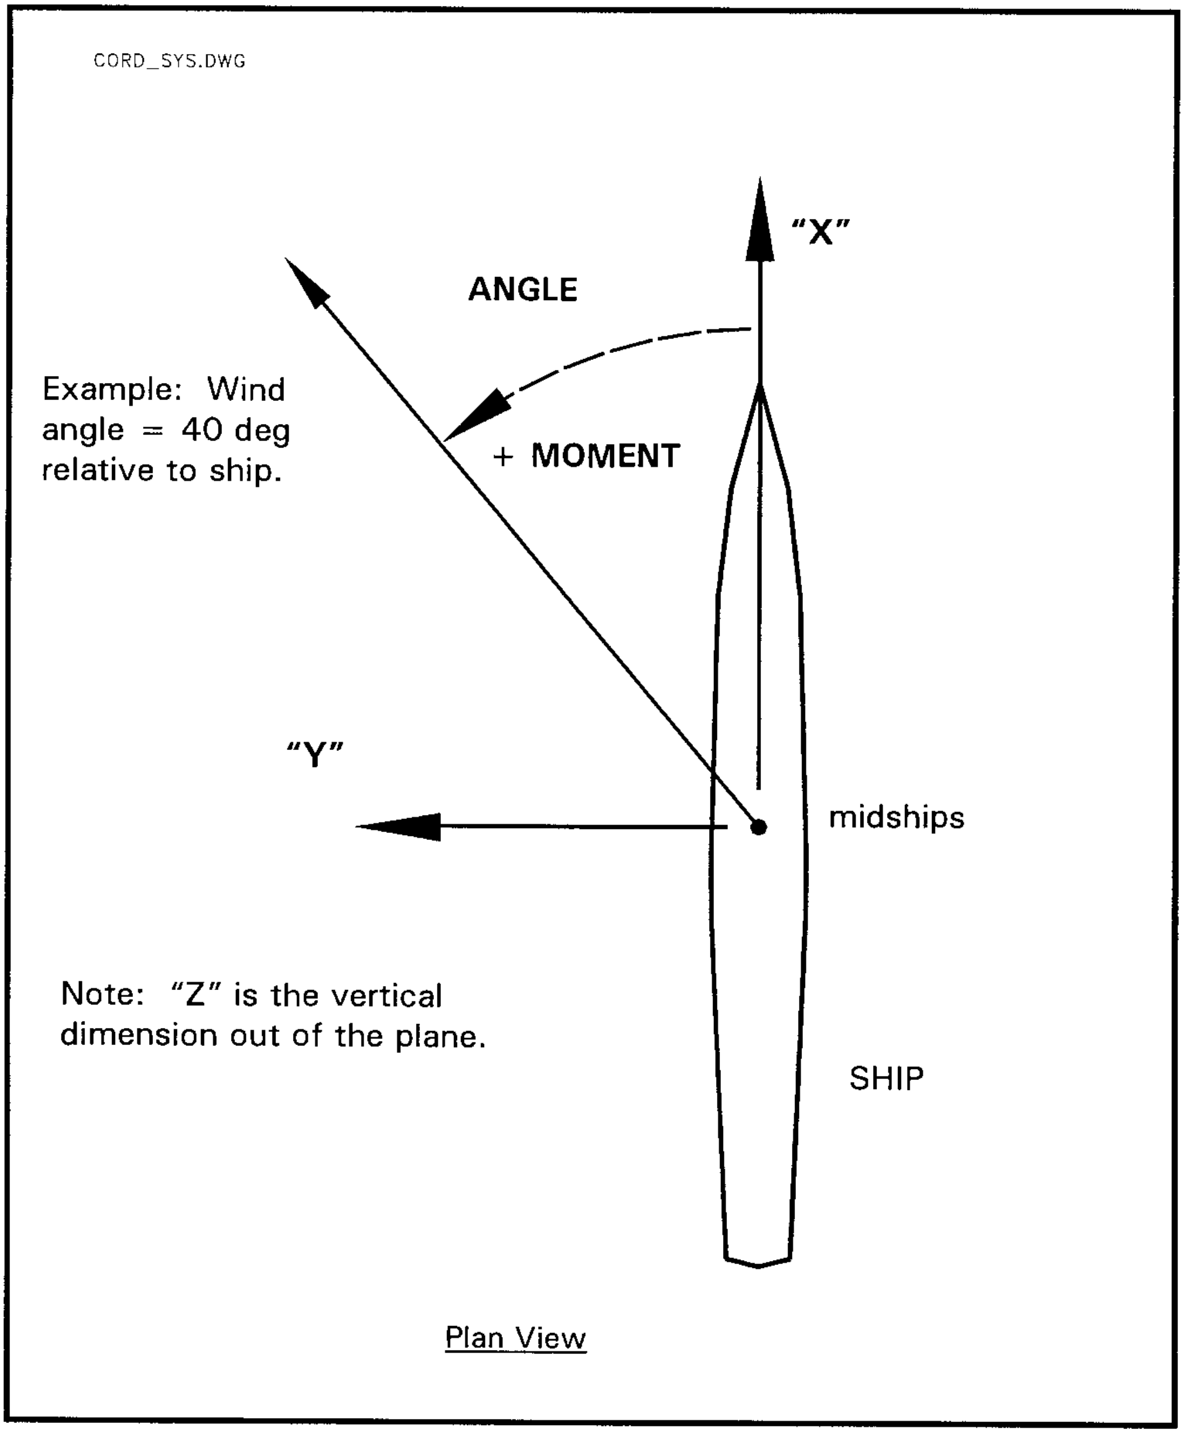

Figure 3-4 Local Mooring Coordinate System for a Ship

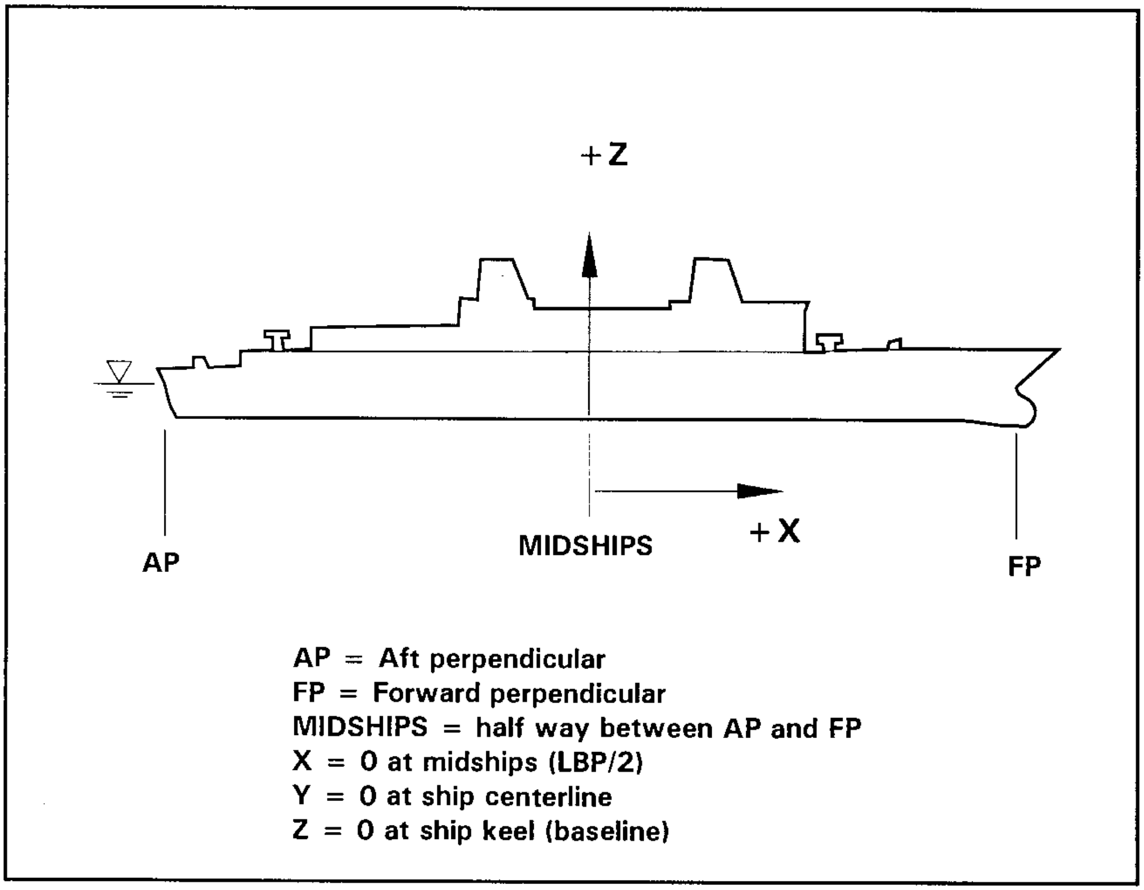

3-6 VESSEL DESIGN CONSIDERATIONS.

Some important vessel mooring design considerations are summarized in Table 3-11.

Table 3-11 Design Considerations - Ship

Parameter	Notes
Ship fittings	The type, safe working load, location, and number of mooring fittings on the ship are critical in designing moorings.
Ship hardware	The type, safe working load, location, and number of other mooring hardware (chain, anchors, winches, etc.) on the ship are critical.
Buoyancy	The ship's buoyancy supports the ship up in the heave, pitch, and roll directions. Therefore, it is usually undesirable to have much mooring capacity in these directions. A large ship, for example, may have over a million pounds of buoyancy for a foot of water level rise. If an unusually large water level rise occurs for a mooring with a large component of the mooring force in the vertical direction, this could result in mooring failure.
Hull pressures	Ships are designed so that only a certain allowable pressure can be safely resisted. Allowable hull pressures and fender design are discussed in NFESC TR-6015-OCN, *Foam-Filled Fender Design to Prevent Hull Damage*.
Personnel access	Personnel access must be provided.
Cargo Loading	Ramps/sideport locations
Hotel services	Provision must be made for utilities and other hotel services.
Ship condition	Ships are typically in the "Light", "One-Third Stores" or "Fully-Loaded" condition or displacement.

3-7 FACILITY DESIGN CONSIDERATIONS.

Some important facility mooring design considerations are summarized in Table 3-12.

Table 3-12 Design Considerations - Facility

Parameter	Notes
Access	Adequate ship access in terms of channels, turning basins, bridge clearance, etc. needs to be provided. Tugs and pilots must be available.
Mooring fittings	The number, type, location and capacity of mooring fittings or attachment points have to meet the needs of all vessels using the facility.
Fenders	The number, type, location, and properties of marine fenders must be specified to protect the ship(s) and facility.
Water depth	The water depth at the mooring site must be adequate to meet the customer's needs. Refer to UFC 4-150-06 for required underkeel clearances for military ships.
Shoaling	Many harbor sites experience shoaling. The shoaling and possible need for dredging needs to be considered.
Permits	Permits (Federal, state, environmental, historical, etc.) are often required for facilities and they need to be considered.

3-8 ENVIRONMENTAL FORCING DESIGN CONSIDERATIONS.

Environmental forces acting on a moored ship(s) can be complex. Winds, currents, water levels, and waves are especially important for many designs.

3-8.1 Winds.

A change in pressure from one point on the earth to another causes the wind to blow. Turbulence is carried along with the overall wind flow to produce wind gusts. If the mean wind speed and direction do not change very rapidly with time, the winds are referred to as "stationary."

Practical experience has shown that wind gusts with a duration of approximately 30 seconds or longer have a significant influence on typical moored ships with displacements of about 1000 tons or larger. Vessels with shorter natural periods can respond to shorter duration gusts. For the purposes of this UFC, a 30-second wind duration at a 33-foot (10-meter) elevation is recommended for the design for "stationary" winds. The relationship of the maximum wind speed averaged over t(s) to hourly mean wind speed is shown in Figure 3-5.

If wind speed and/or direction changes rapidly, such as in a wind gust front, hurricane or tornado, then winds are “non-stationary”. Figure 3-6, for example, shows a recording from typhoon Omar in 1992 at Guam. The eye of this storm went over the recording site. The upper portion of this figure shows the wind speed and the lower portion of the figure is the wind direction. Time on the chart recorder proceeds from right to left. This hurricane had rapid changes in wind speed and direction. As the eye passes there is also a large-scale change in wind speed and direction.

Figure 3-5 Ratio of Wind Speeds for Various Gusts

(after ASCE 7-16)

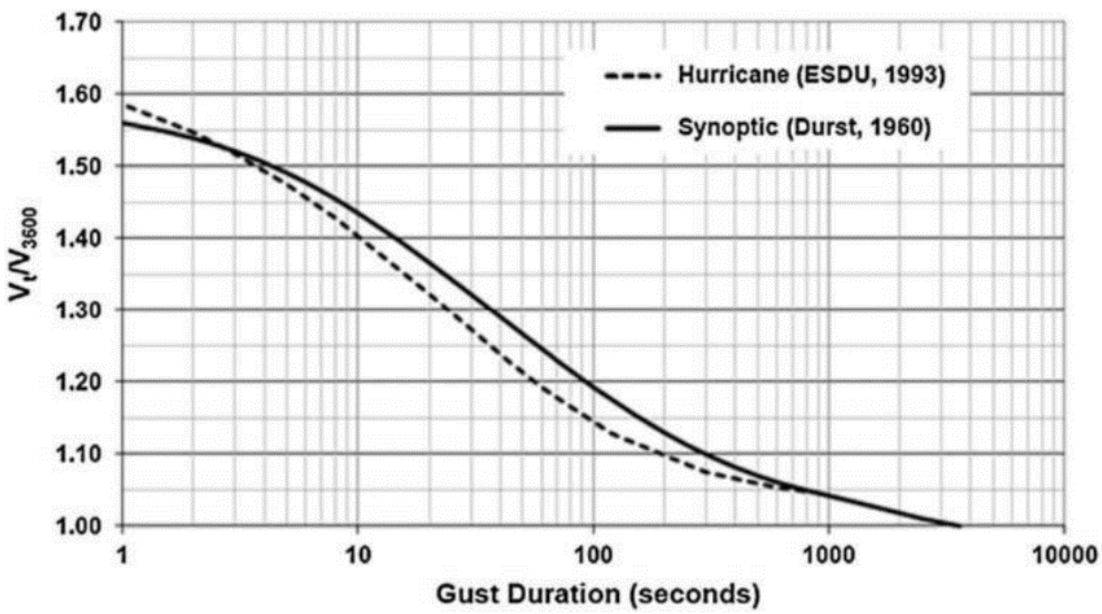

Figure 3-6 Typhoon Omar Wind Chart Recording

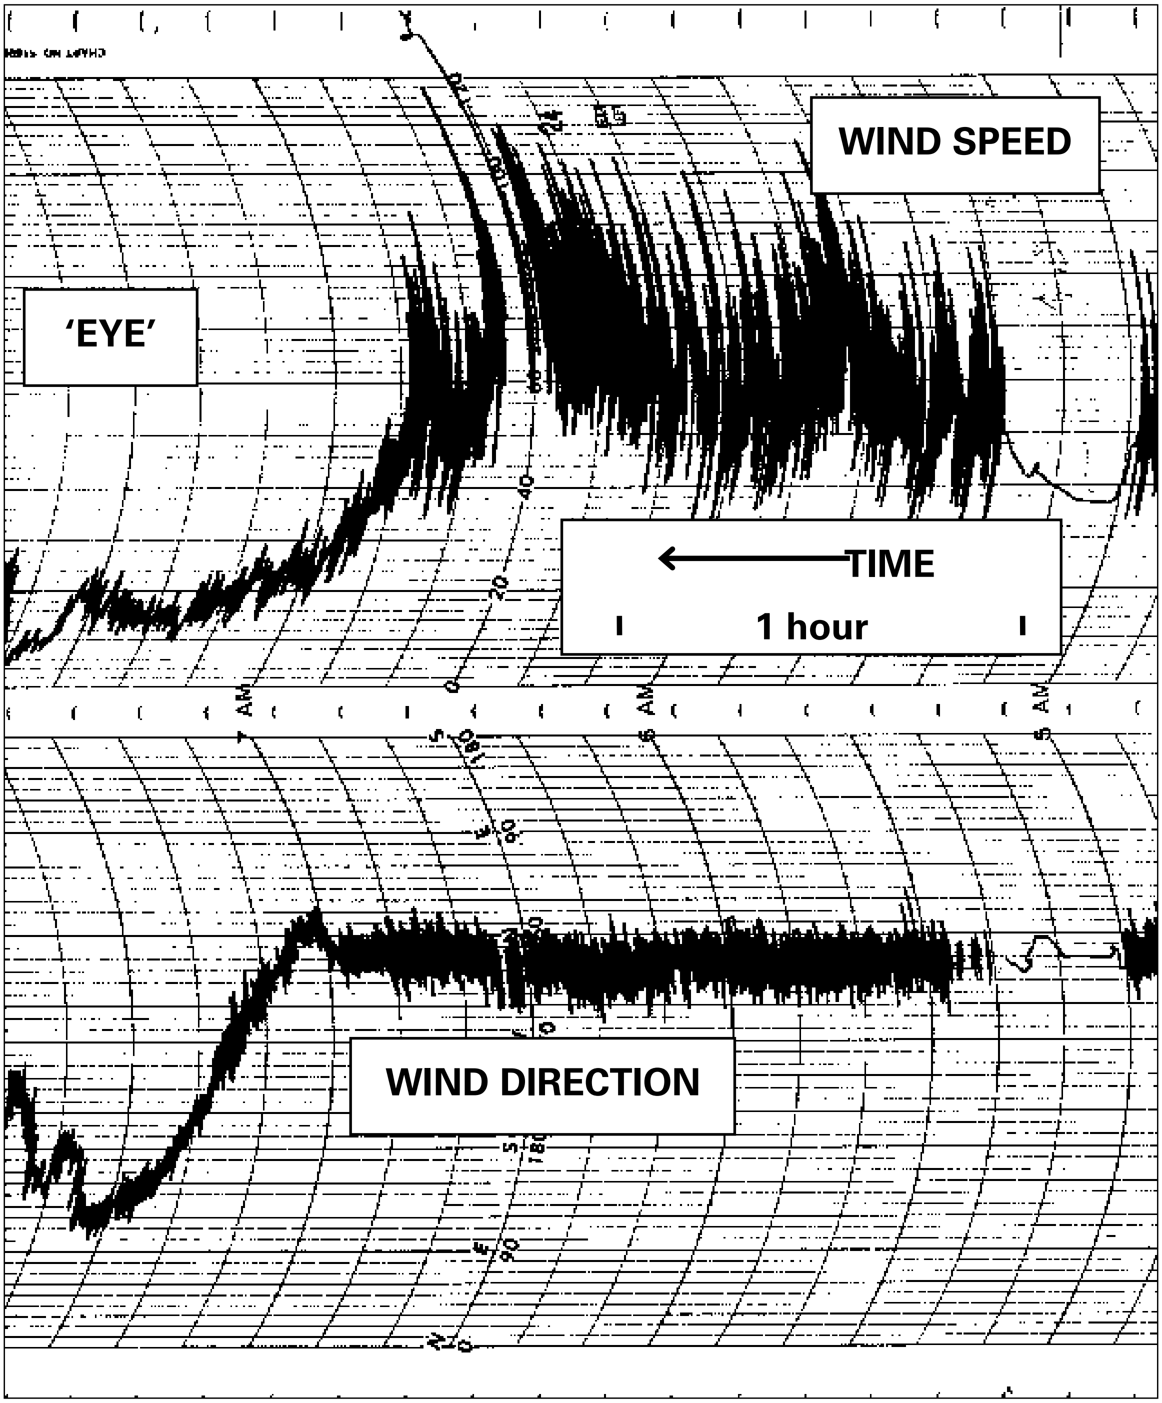

3-8.2 Wind Gust Fronts.

A particularly dangerous wind condition that has caused a number of mooring accidents is the wind gust front *(Mooring Dynamics Due to Wind Gust Fronts*, Seelig and Headland, 1998 and CHESNAVFACENGCOM, FPO-1-87(1), *Failure Analysis of Hawsers on BOBO Class MSC Ships at Tinian on 7 December 1986*). This is a sudden change in wind speed that is usually associated with a change in wind direction (*Wind Effects on Structures*, Simiu and Scanlan, 1996). The key problems with this phenomena are: (1) high mooring dynamic loads can be produced in a wind gust front, (2) there is often little warning, (3) little is known about wind gust fronts, and (4) no design criteria for these events have been established.

A study of Guam Agana Naval Air Station (NAS) wind records was performed to obtain some statistics of wind gust fronts (National Climatic Data Center (NCDC), Letter Report E/CC31:MJC, 1987). The 4.5 years of records analyzed from 1982 through 1986 showed approximately 500 cases of sudden wind speed change, which were associated with a shift in wind direction. These wind shifts predominately occurred in 1 minute or less and never took longer than 2 minutes to reach maximum wind speed. Figure 3-7 shows sudden changes in wind speed and direction that occurred over a 2-1/2 day period in October 1982. These wind gust fronts seemed to be associated with a nearby typhoon.

Table 3-13 gives the joint distribution of wind shifts in terms of the amount the increase in wind speed and the wind direction change. Approximately 60% of the wind gust fronts from 1982 through 1986 had wind direction changes in the 30-degree range, as shown in Figure 3-8.

Based on the Guam observations, the initial wind speed in a wind gust front ranges from 0% to 75% of the maximum wind speed, as shown in Figure 3-9. On the average, the initial wind speed was 48% of the maximum in the 4.5-year sample from Guam (NCDC, 1987).

Simiu and Scanlan (1996) report wind gust front increases in wind speed ranging from 3 m/s to 30 m/s (i.e., 6 to 60 knots). Figure 3-10 shows the distribution of gust front winds from the 4.5-year sample from 1982 through 1986 on Guam. This figure shows the probability of exceedance on the x-axis in a logarithmic format. The square of the wind gust front speed maximums was plotted on the y-axis, since wind force is proportional to wind speed squared. Figure 3-10 provides a sample of the maximum wind gust front distribution for a relatively short period at one site. Those wind gust fronts that occurred when a typhoon was nearby are identified with an “H.” It can be seen that the majority of the higher gust front maximums were associated with typhoons. Also, the typhoon gust front wind speed maxima seem to follow a different distribution that the gust front maxima associated with rain and thunderstorms (see Figure 3-10).

Effects of winds and wind gusts are shown in the examples in CHAPTER 8 of this UFC.

Figure 3-7 Sample Wind Gust Fronts on Guam, 2-4 October 1982

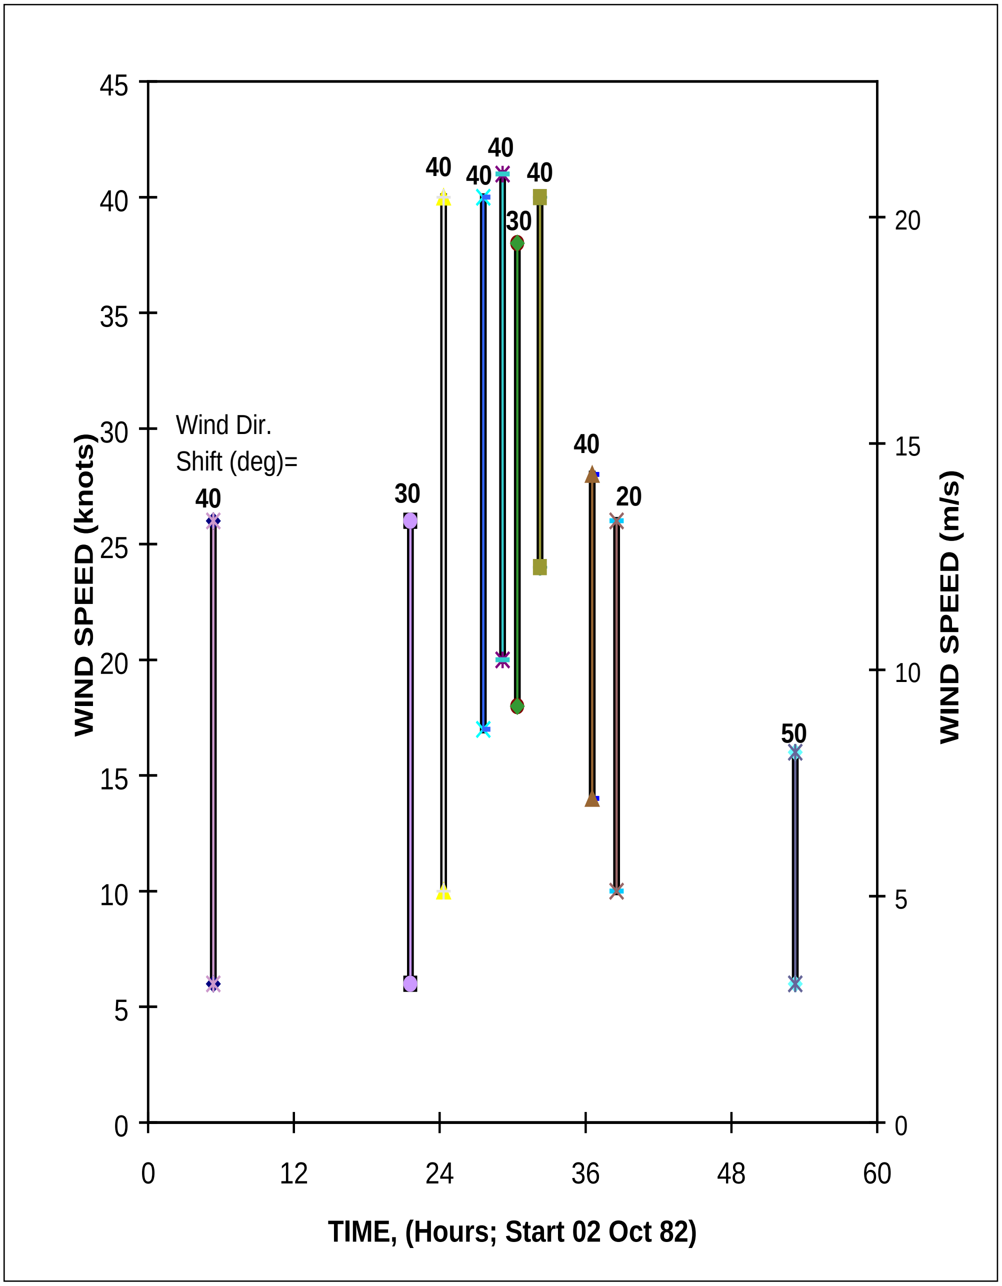

Table 3-13 Sample Distribution of Wind Gust Fronts on Guam (NAS Agana) 1982-1986

Wind Speed Change		Number Of Observations							
knot (m/s)		Wind Direction Change							
min.	max.	20°	30°	40°	50°	60°	70°	80°	90°

(d) World Meteorological Organization Sea State Scale [a]

	Sea State	**Sign. Wave Height**	**Sustained Wind Speed**	**Modal Wave Period Range**
		ft (m)	**knot (m/s)**	**seconds**
0	Calm/Glassy	-	-	-
1	Rippled	0-0.3 (0-0.1)	0-6 (0-3)	-
2	Smooth	0.3-1.6 (0.1-0.5)	7-10 (3.6-5.1)	3-15
3	Slight	1.6-4.1 (0.5-1.2)	11-16 (5.7-8.2)	3-15.5
4	Moderate	4.1-8.2 (1.2-2.5)	17-21 (8.7-10.8)	6-16
5	Rough	8.2-13.1 (2.5-4.0)	22-27 (11.3-13.9)	7-16.5
6	Very Rough	13.1-19.7 (4.0-6.0)	28-47 (14.4-24.2)	9-17
7	High	19.7-29.5 (6.0-9.0)	48-55 (24.7-28.3)	10-18
8	Very High	29.5-45.5 (9.0-13.9)	56-63 (28.8-32.4)	13-19
9	Phenomenal	>45.5 (13.9)	>63 (32.4)	18-24

Note:

[a] Sea States are representative of fully developed open ocean conditions and are not to be used for harbors or sheltered waterways.

3-8.4 Currents.

The magnitude and direction of currents in harbors and nearshore areas are in most cases a function of location and time. Astronomical tides, river discharges, wind-driven currents, and other factors can influence currents. For example, wind-driven currents are surface currents that result from the stress exerted by the wind on the sea surface. Wind-driven currents generally attain a mean velocity of approximately 3% to 5% of the mean wind speed at 33 ft (10 m) above the sea surface. The magnitude of this current decreases with depth.

Currents are site specific, so it is recommended that currents be measured at the design site and combined with other information available to define the design current conditions.

3-8.5 Water Levels.

At most sites some standard datum, such as mean low water (MLW) or mean lower low water (MLLW), is established by formal methods. Water levels are then referenced to this datum. The water level in most harbors is then a function of time. Factors influencing water levels include astronomical tides, storm surges, river discharges, winds, seiches, and other factors.

The design range in water levels at the site must be considered in the design process.

3-8.6 Waves.

Most DoD moorings are wisely located in harbors to help minimize wave effects. However, waves can be important to mooring designs in some cases. The two primary wave categories of interest are:

- <u>Wind waves</u> – Wind waves can be locally generated or can be wind waves or swell entering the harbor entrance(s). Small vessels are especially susceptible to wind waves.
- <u>Long waves</u> – These can be due to surf beat, harbor seiching, or other effects.

Ship waves may be important in some cases. The response of a moored vessel to wave forcing includes:

- A steady mean force, and
- First order response, where the vessel responds to each wave, and
- Second order response, where some natural long period mode of ship/mooring motion, which usually has little damping, is forced by the group or other nature of the waves.

If any of these effects are important to a given mooring design, then a six degree of freedom dynamic analysis of the system generally needs to be considered in design. Guidance on safe wave limits for moored manned small craft is given in Table 3-8 (a).

3-8.7 Water Depths.

The bathymetry of a site may be complex, depending on the geology and history of dredging. Water depth may also be a function of time, if there is shoaling or scouring. Water depths are site specific, so hydrographic surveys of the project site are recommended.

3-8.8 Environmental Design Information.

Some sources of environmental design information of interest to mooring designers are summarized in Table 3-15.

3-9 OPERATIONAL CONSIDERATIONS.

Some important operational design considerations are summarized in Table 3-16.

Table 3-16 Mooring Operational Design Considerations

Parameter	Notes
Personnel experience/ training	What is the skill of the people using the mooring?
Failure	What are the consequences of failure? Are there any design features that can be incorporated that can reduce the impact?
Ease of use	How easy is the mooring to use and are there factors that can make it easier to use?
Safety	Can features be incorporated to make the mooring safer for the ship and personnel?
Extreme events	Extreme events can occur unexpectedly. Can features be incorporated to accommodate them?
Future use	Future customer requirements may vary from present needs. Are there things that can be done to make a mooring facility more universal?

3-10 INSPECTION.

Mooring systems and components should be inspected periodically to ensure they are in good working order and are safe. Table 3-17 gives inspection guidelines.

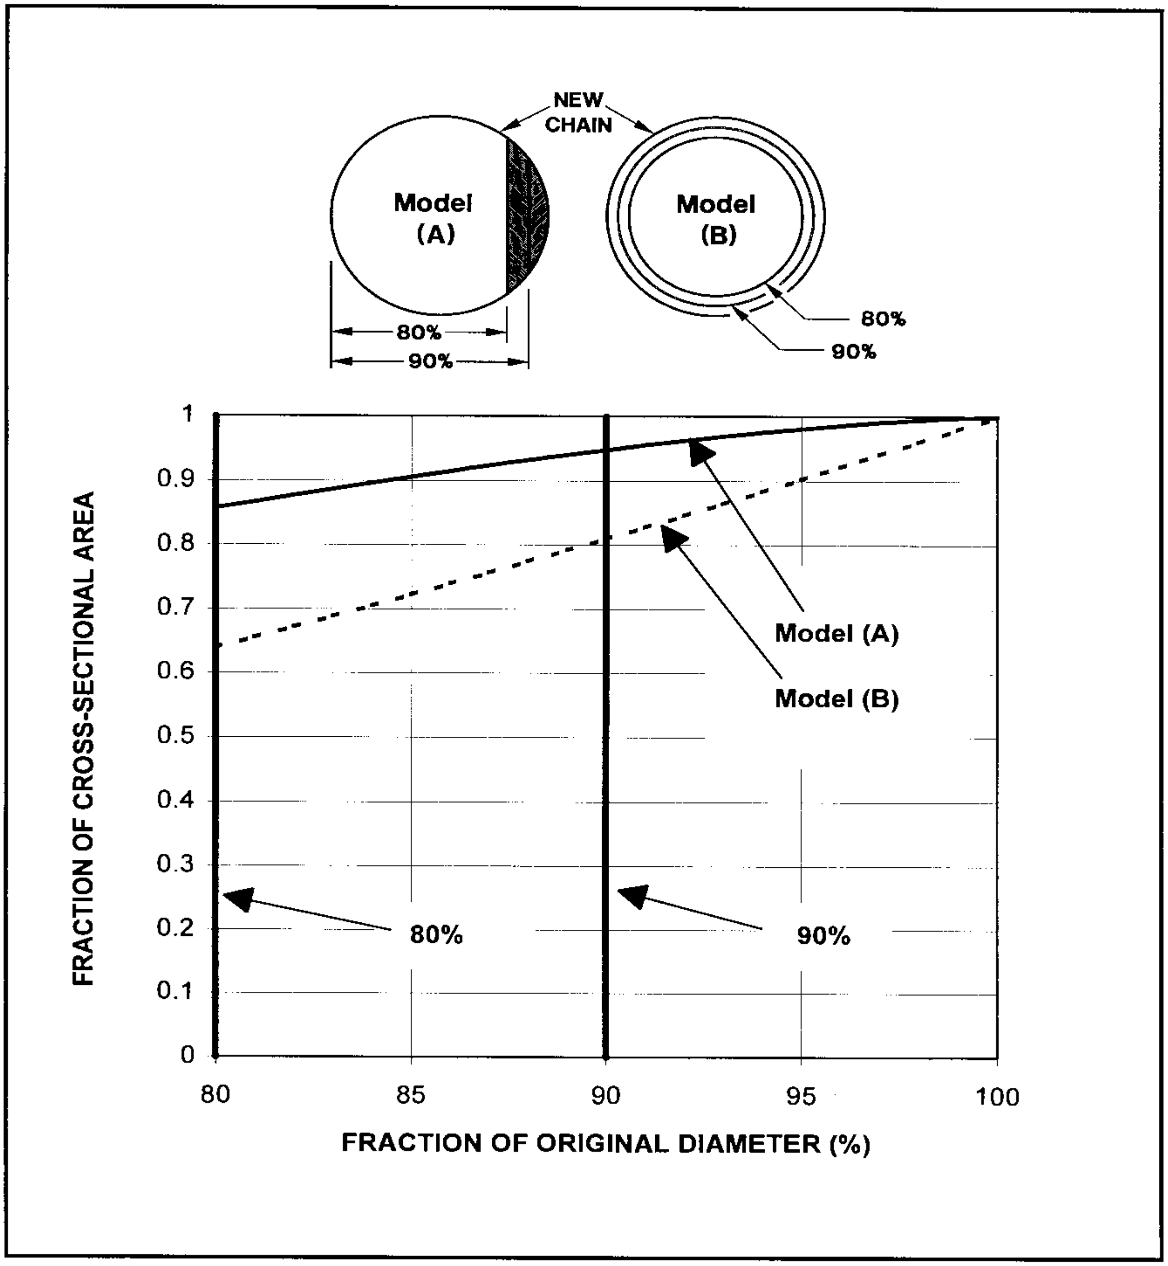
Table 3-17 Inspection Guidelines

Mooring System or Component	Maximum Inspection Interval	Notes
Piers and wharves	1 year 3 years 6 years	Surface inspection Complete inspection - wood structures Complete inspection - concrete and steel structures See UFC 4-150-07, *Waterfront Facilities: Maintenance and Operation* and NAVFAC MO-104.2, *Specialized Underwater Waterfront Facilities Inspections*; If the safe working load/condition of mooring fittings on a pier/wharf is unknown, then pull tests are recommended to proof the fittings.
Fleet Moorings	3 years	See CHESNAVFACENGCOM, FPO-1-84(6), *Fleet Mooring Underwater Inspection Guidelines*. Also inspect and replace anodes, if required. More frequent inspection may be required for moorings at exposed sites or for critical facilities.
Synthetic line	6 months	Per manufacturer's recommendations
Ship's chain	36 months 24 months 18 months	0-3 years of service 4-10 years of service >10 years of service (American Petroleum Institute (API) RP 2T, *Recommended Practice for Planning, Designing, and Constructing Tension Leg Platforms*)
Wire rope	18 months 12 months 9 months	0-2 years of service 3-5 years of service >5 years of service (API RP 2T)

3-11 MAINTENANCE.

If excessive wear or damage occurs to a mooring system, then it must be maintained. Fleet mooring chain, for example, is allowed to wear to a diameter of 90% of the original steel bar diameter. As measured diameters approach 90%, then maintenance is scheduled. Moorings with 80% to 90% of the original chain diameter are restricted to limited use. If a chain diameter reaches a bar diameter of 80% of the original diameter, then the mooring is condemned. Figure 3-11 illustrates some idealized models of chain wear.

Figure 3-11 Idealized Models of Chain Wear



3-12 GENERAL MOORING GUIDELINES.

Experience and practical considerations show that the recommendations given in Table 3-18 will help ensure safe mooring. These ideas apply to both ship mooring hardware and mooring facilities.

Table 3-18 Design Recommendations

Idea	Notes
Allow ship to move with rising and falling water levels	The weight and buoyancy forces of ships can be very high, so it is most practical to design moorings to allow ships to move in the vertical direction with changing water levels. The design range of water levels for a specific site should be determined in the design process.
Design mooring system so any failure will have minimal impact	A system is only as strong as its weakest segment; a system with components of similar strength can be the most economical. The mooring system should be designed such that the mooring lines fail before the ship or shore fitting.
Ensure load sharing	In some moorings, such as at a pier, many lines are involved. Ensuring that members will share the load results in the most economical system.
Bridle design	In cases where a ship is moored to a single point mooring buoy with a bridle, ensure that each leg of the bridle can withstand the full mooring load, because one member may take the full load as the vessel swings.
Provide shock absorbing in mooring systems	Wind gusts, waves, passing ships, etc., will produce transient forces on a moored ship. Allowing some motion of the ship will reduce the dynamic loads. ‘Shock absorbers’ including marine fenders, timber piles, synthetic lines with stretch, chain catenaries, sinkers, and similar systems are recommended to allow a moored ship to move in a controlled manner.
Limit the vertical angles of lines from ship to pier	Designing ships and piers to keep small vertical line angles has the advantages of improving line efficiency and reducing the possibility of lines pulling off pier fittings.
Select drag anchors to have a lower ultimate holding capacity than the breaking strength of chain and fittings	Design mooring systems that use drag anchors so that the anchor will drag before the chain breaks.
Limit the loading on drag anchors to horizontal tension	Drag anchors work on the principle of ‘plowing’ into the soils. Keeping the mooring catenary angle small at the seafloor will aid in anchor holding. Have at least one shot of chain on the seafloor to help ensure the anchor will hold.
Pull test anchors whenever possible to the full design load	Pull testing anchors is recommended to ensure that all facilities with anchors provide the required holding capacity.

This Page Intentionally Left Blank

CHAPTER 4 STATIC ENVIRONMENTAL FORCES AND MOMENTS ON VESSELS

4-1 SCOPE.

In this chapter design methods are presented for calculating static forces and moments on single and multiple moored vessels. Examples show calculation methods.

4-2 ENGINEERING PROPERTIES OF WATER AND AIR.

The effects of water and air at the surface of the earth are of primary interest in this chapter. The engineering properties of both are given in Table 4-1.

Table 4-1 Engineering Properties of Air and Water

(a.) Standard Salt Water at Sea Level at 15 °C (59 °F)

Property	English Units	SI Units
Mass density, ρ_w	1.9905 slug/ft^3	1026 kg/m^3
Weight density, γ_w	64.043 lbf/ft^3	10.06 kN/m^3
Volume per long ton (LT)	34.977 ft^3/LT	0.9904 m^3/LT
Kinematic viscosity, ν	1.2817 x10^{-5} ft^2/s	1.191 x10^{-6} m^2/s

(b.) Standard Fresh Water at Sea Level at 15 °C (59 °F)

Property	English Units	SI Units
Mass density, ρ_w	1.9384 slug/ft^3	999.0 kg/m^3
Weight density, γ_w	62.366 lbf/ft^3	9,797 N/m^3
Volume per long ton (LT)	35.917 ft^3/LT	1.0171 m^3/LT
Volume per metric ton (ton or 1,000 kg or 1 Mg)	35.3497 ft^3/ton	1.001 m^3/ton
Kinematic viscosity, ν	1.2817 x10^{-5} ft^2/s	1.141x10^{-6} m^2/s

(c.) Air at Sea Level at 20 °C (68 °F) [a]

Property	English Units	SI Units
Mass density, ρ_a	0.00237 slug/ft^3	1.221 kg/m^3
Weight density, γ_a	0.07625 lbf/ft^3	11.978 N/m^3
Kinematic viscosity, ν	1.615 x10^{-4} ft^2/s	1.50 x10^{-5} m^2/s

Note:

[a] Humidity and heavy rain has relatively little effect on the engineering properties of air (personal communication with the National Weather Service, 1996)

4-3 PRINCIPAL COORDINATE DIRECTIONS.

There are three primary axes for a ship:

X – Direction parallel with ship's longitudinal axis
Y – Direction perpendicular to a vertical plane through ship's longitudinal axis
Z – Direction perpendicular to a plane formed by "X" and "Y" axes

There are six principal coordinate directions for a ship:

Surge – Linear in "X"-direction
Sway – Linear in "Y"-direction
Heave – Linear in "Z"-direction
Roll – Angular about "X"-axis
Pitch – Angular about "Y"-axis
Yaw – Angular about "Z"-axis

Of primary interest are: (1) forces in the surge and sway directions in the "X-Y" plane, and (2) moment in the yaw direction about the "Z"-axis. Ship motions occur about the center of gravity of the ship.

4-4 STATIC WIND FORCES/MOMENTS.

Static wind forces and moments on stationary moored vessels are computed in this chapter. Figure 4-1 shows the definition of some of the terms used in this chapter. Figure 4-2 shows the local coordinate system.

4-4.1 Static Transverse Wind Force.

The static transverse wind force is defined as that component of force perpendicular to the vessel centerline. In the local ship coordinate system, this is the force in the "Y" or sway direction. Transverse wind force is determined from the equation:

Equation 4-1

$$F_{yw} = 0.5\,\rho_a\,V_w^2\,A_y\,C_{yw}\,f_{yw}\,(\theta_w)$$

where,
F_{yw} = transverse wind force (N)
ρ_a = mass density of air (from Table 4-1)
V_w = wind speed (m/s)
A_y = longitudinal projected area of the ship (m^2)
C_{yw} = transverse wind force drag coefficient
$f_{yw}(\theta_w)$ = shape function for transverse force
θ_w = wind angle (degrees)

The transverse wind force drag coefficient depends upon the hull and superstructure of the vessel and is calculated using the following equation, adapted from Naval Civil Engineering Laboratory (NCEL), TN-1628, *Wind-Induced Steady Loads on Ships.*

Equation 4-2

$$C_{yw} = C\left[\left(0.5\frac{(h_s + h_h)}{h_r}\right)^{\frac{2}{7}} A_s + \left(0.5\frac{h_h}{h_r}\right)^{\frac{2}{7}} A_h\right]/A_y$$

where,
C = empirical coefficient, see Table 4-2
h_r = reference height, 10 m (33 ft)
h_h = A_H/L_{wL} ;average height of the hull, m
A_H = longitudinal wind area of hull, m^2
L_w = ship length at waterline, m
h_s = height of superstructure above waterline, m
A_s = longitudinal wind area of superstructure, m^2

A recommended value for the empirical coefficient is C = 0.92 ± 0.1 based on scale model wind tunnel tests (NCEL, TN-1628). Table 4-2 gives typical values of C for ships and Figure 4-4 illustrates some ship types.

Table 4-2 Sample Wind Coefficients for Ships

Ship	C	Notes
Hull Dominated	0.82	aircraft carriers, submarines, drydocks, LHA/LHD
Typical	0.92	ships with moderate superstructure
Extensive Superstructure	1.02	destroyers, cruisers

Note: Wind coefficients are based on older ship profiles. Validation of current profiles is necessary. Professional judgement must be used regarding the appropriate coefficient to use for ship profile.

The shape function for the transverse wind force (NCEL, TN-1628) is given by:

Equation 4-3

$$f_{yw}(\theta_w) = +\frac{(\sin(\theta_w) - 0.05\ \sin(\theta_w))}{0.95}$$

Equation 4-3 is positive for wind angles $0° < \theta_w < 180°$ and negative for wind angles $180° < \theta_w < 360°$. Figure 4-5 shows the shape and typical values for Equation 4-3.

These two components were derived by integrating wind over the hull and superstructure areas to obtain effective wind speeds (NCEL, TN-1628). The following example illustrates calculations of the transverse wind force drag coefficient. The coefficients shown in Table 4-2 are based on the following ship hull profiles.

Figure 4-1 Definition of Terms

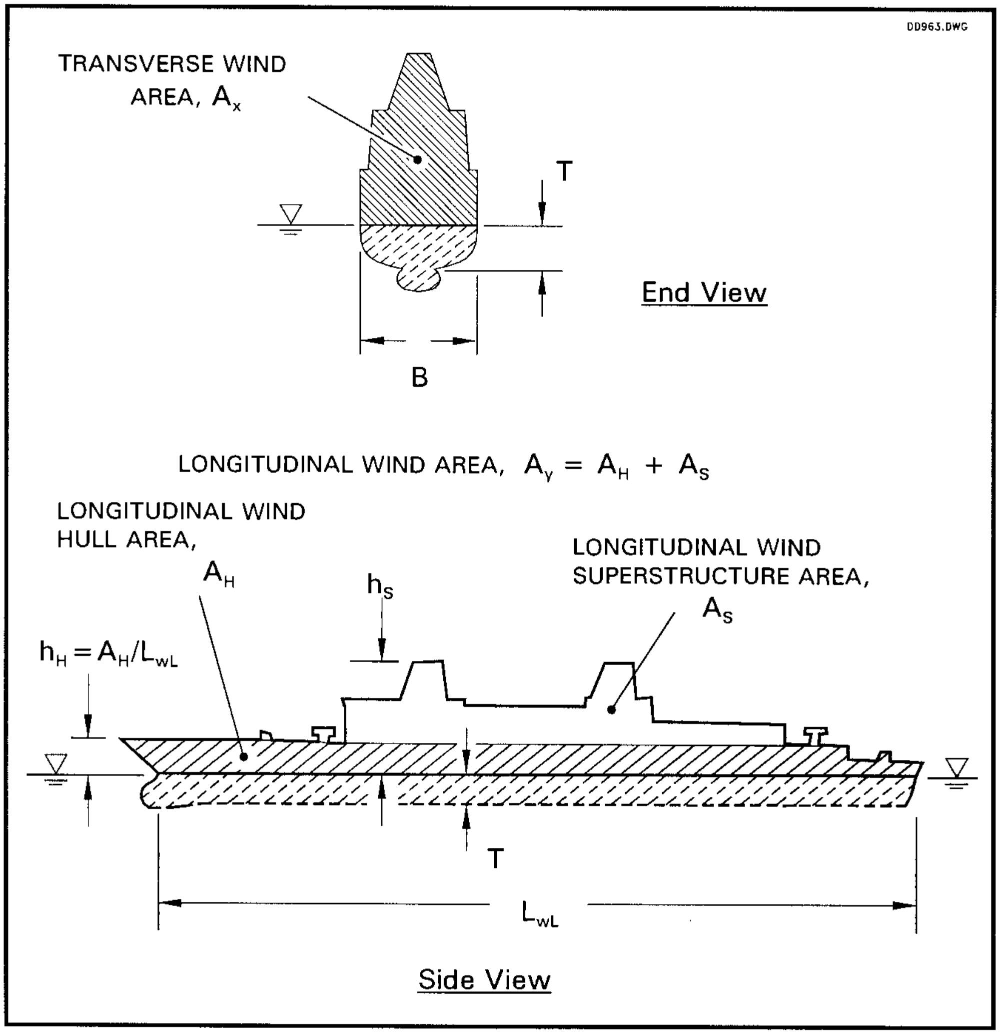


Figure 4-2 Local Coordinate System for a Ship

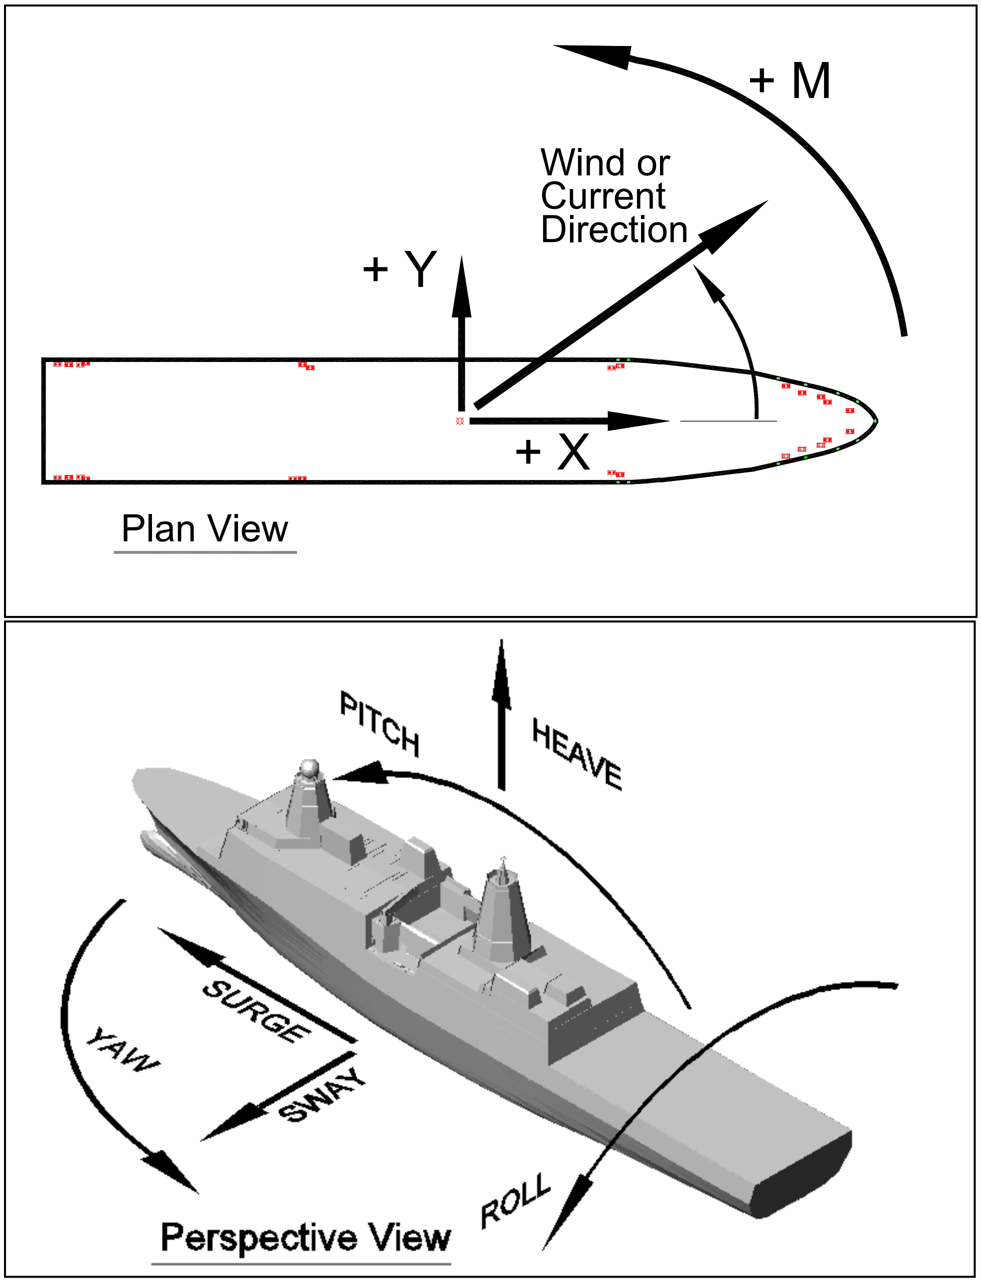

Figure 4-3 Sample Ship Profiles

Hull Dominated

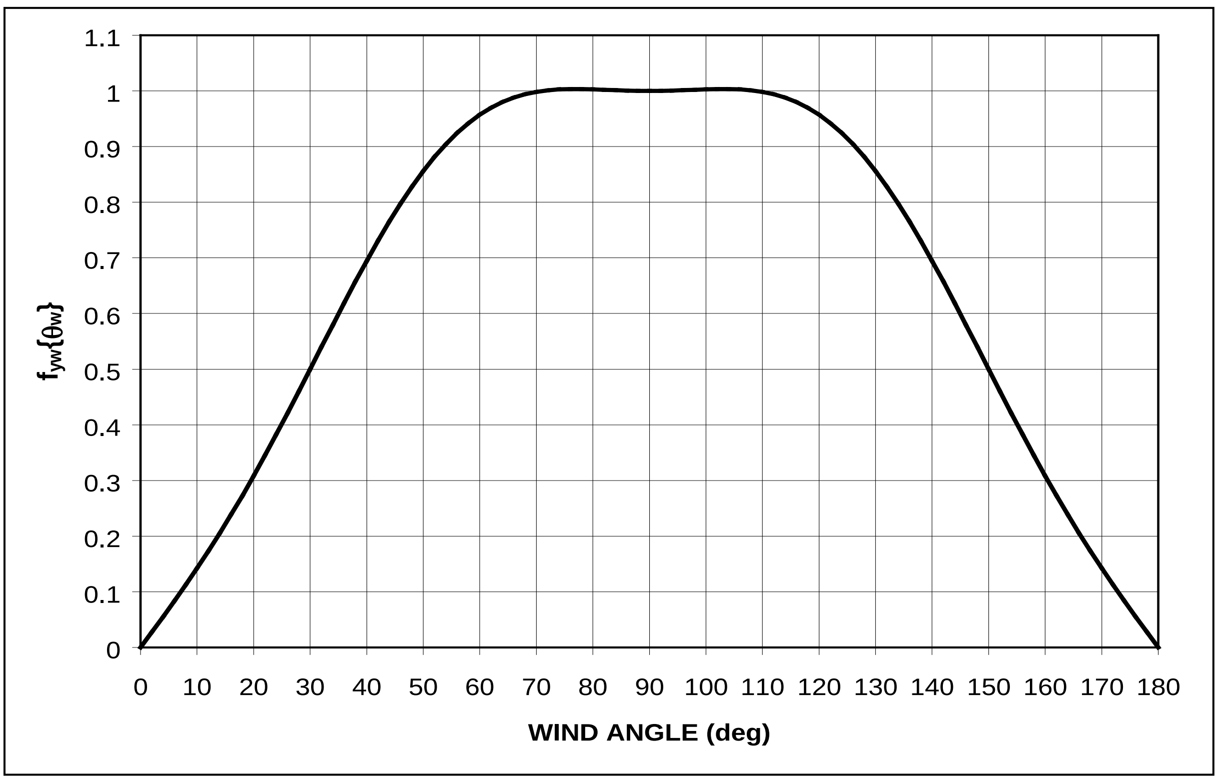
45	0.782	-	-



EXAMPLE: Find the transverse wind force drag coefficient on the destroyer shown in Figure 4-5.

SOLUTION: For this example, the transverse wind force drag coefficient from Equation 4-2 is:

$$C_{yw} = C\,\frac{\left[\left(\frac{0.5\,(23.9\,m + 6.43\,m)}{10\,m}\right)^{\frac{2}{7}}\,1203\,m^2 + \left(\frac{0.5\,(6.43\,m)}{10\,m}\right)^{\frac{2}{7}}\,1036.1m^2\right]}{2239\,m^2}$$

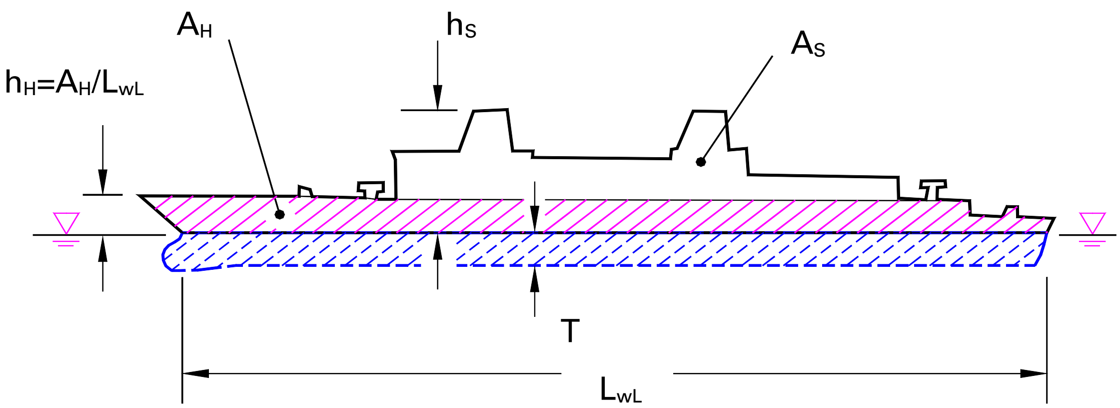
$$C_{yW} = 0.940\,C.$$

Destroyers have extensive superstructure, so a recommended value of C = 1.02 is used to give a transverse wind force drag coefficient of C_{yw} = 0.940 x 1.02 = 0.958.

For cases where an impermeable structure, such as a wharf, is immediately next to the moored ship, the exposed longitudinal wind area and resulting transverse wind force can be reduced. Figure 4-6 shows an example of a ship next to a wharf. For Case (A), wind from the water, there is no blockage in the transverse wind force and elevations of the hull and superstructure are measured from the water surface. For Case (B), wind from land, the longitudinal wind area of the hull can be reduced by the blocked amount and elevations of hull and superstructure can be measured from the wharf elevation.

Cases of multiple ships are covered in Section 4-6, *Wind and Current Forces and Moments on Multiple Ships*.

Figure 4-5 Example Destroyer for Transverse Wind Coefficient Calculator



Parameter	Value	
	(English Units)	(SI Units)
L_{wL}	529 ft	161.2 m
A_Y	24,100 ft^2	2,239 m^2
A_H	11,152 ft^2	1,036 m^2
A_S	12,948 ft^2	1,203 m^2
$h_H = A_H/L_{wL}$	21.1 ft	6.43 m
h_S	78.4 ft	23.9 m

END VIEW

4-4.2 Static Longitudinal Wind Force.

The static longitudinal wind force on a vessel is defined as that component of wind force parallel to the centerline of the vessel. This is the force in the “X” or surge direction in Figure 4-2. Figure 4-1 shows the definition of winds areas.

The longitudinal force is determined from NCEL, TN-1628 using the equation:

Equation 4-4

$$F_{xw} = 0.5\, \rho_a\, V_w^2 A_x\, C_{xw}\, f_{xw}\, (\theta_w)$$

where,
F_{xw} = longitudinal wind force (N)
A_x = transverse projected area of the ship (m^2)
C_{xw} = longitudinal wind force drag coefficient
$f_{xw}(\theta_w)$ = shape function for longitudinal force

The longitudinal wind force drag coefficient, C_{xw}, depends on specific characteristics of the vessel. Additionally, the wind force drag coefficient varies depending on bow (C_{xwB}) or stern (C_{xwS}) wind loading. Types of vessels are given in three classes: hull dominated, normal, and excessive superstructure. Recommended values of longitudinal wind force drag coefficients are given in Table 4-3.

Table 4-3 Recommended Ship Longitudinal Wind Force Drag Coefficients

Vessel Type	C_{xwB}	C_{xwS}
Hull Dominated (aircraft carriers, submarines, passenger liners)	0.40	0.40
Normal [a]	0.70	0.60
Center-Island Tankers [a]	0.80	0.60
Significant Superstructure (destroyers, cruisers)	0.70	0.80

Note:
[a] An adjustment of up to +0.10 to C_{xwB} and C_{xwS} should be made to account for significant cargo or cluttered decks.

The longitudinal shape function also varies over bow and stern wind loading regions. As the wind direction varies from headwind to tailwind, there is an angle at which the force changes sine. This is defined as θ_x and is dependent on the location of the superstructure relative to midships. Recommended values of this angle are given in Table 4-4.

Table 4-4 Recommended Values of θ_x

Location of Superstructure	θ_x (deg)
Just forward of midships	100
On midships	90
Aft of midships (tankers)	80
Warships	70
Hull dominated	60

Shape functions are given for general vessel categories below:

CASE I: SINGLE DISTINCT SUPERSTRUCTURE:

The shape function for longitudinal wind load for ships with single, distinct superstructures and hull-dominated ships is given below (examples include aircraft carriers, submarines, tankers, and cargo vessels):

Equation 4-5

$$f_{xw}(\theta_W) = \cos(\phi)$$

$$\phi^- = \left(\frac{90^0}{\theta_x}\right)\theta_w \ \ for\ \theta_w < \theta_x$$

$$\phi^+ = \left(\frac{90^0}{180^0 - \theta_x}\right)(\theta_w - \theta_x) + 90^0 \ for\ \theta_w > \theta_x$$

θ_x = incident wind angle that produces no net longitudinal force (Table 4-4)

Values of $f_{xw}(\theta_w)$ are symmetrical about the longitudinal axis of the vessel. So when $\theta_w > 80^o$, use $360^o - \theta_w$ as θ_w in determining the shape function.

CASE II: DISTRIBUTED SUPERSTRUCTURE:

Equation 4-6

$$f_{xw}(\theta_w) = \frac{\left(\sin(\gamma) - \frac{\sin(5\gamma)}{10}\right)}{0.9}$$

$$\gamma^- = \left(\frac{90^0}{\theta_x}\right)\theta_w + 90^0 \;\; for\ \theta_w < \theta_x$$

$$\gamma^+ = \left(\frac{90^0}{180^0 - \theta_x}\right)(\theta_w) + \left(180^0 - \left(\frac{90^0\ \theta_x}{180^0 - \theta_x}\right)\right) \;\; for\ \theta_w > \theta_x$$

Values of $f_{xw}(\theta_w)$ are symmetrical about the longitudinal axis of the vessel. So when $\theta_w > 180^o$, use $\theta_w > 360^o$ as θ_w in determining the shape function. The maximum longitudinal wind force for these vessels occurs for wind directions slightly off the ship's longitudinal axis.

EXAMPLE: Find the longitudinal wind drag coefficient for a wind angle of 40° for the destroyer shown in Figure 4-5.

SOLUTION: For this destroyer, the following values are selected:

$\theta_x = 70^o$ from Table 4-4
$C_{xwB} = 0.70$ from Table 4-3
$C_{xwS} = 0.80$ from Table 4-3

This ship has a distributed superstructure and the wind angle is less than the crossing value, so Equation 4-6 is used to determine the shape function:

$$\gamma^- = \left(\frac{90^0}{70^0}\right)40^0 + 90^0 = 141.4^0$$

$$f_{xw}(\theta_w) = \frac{\left(\sin(141.4^0) - \frac{\sin(5 * 141.4^0\ )}{10}\right)}{0.9} = 0.72$$

At the wind angle of 40°, the wind has a longitudinal component on the stern. Therefore, the wind longitudinal drag coefficient for this example is:

$$C_{xw}\ f_{xw}\ (\theta_w) = 0.8 * 0.72 = 0.57$$

4-4.3 Static Wind Yaw Moment.

The static wind yaw moment is defined as the product of the associated transverse wind force and its distance from the vessel's center of gravity. In the local ship coordinate system, this is the moment about the "Z" axis. Wind yaw moment is determined from the equation:

Equation 4-7

$$M_{xyw} = 0.5\, \rho_a\, V_w^2\, A_y\, L\, C_{xyw}\,(\theta_w)$$

where,
A_y = longitudinal projected area of the ship (m^2)
L = length of ship (m)
C_{xyw} (θ_w) = normalized yaw moment coefficient
θ_w = wind angle (degrees)

The normalized yaw moment coefficient depends upon the vessel type. Equation 4-8 gives equations for computing the value of the yaw moment coefficient and Table 4-5 gives empirical parameter values for selected vessel types. The normalized yaw moment variables are found from:

Equation 4-8

$$C_{xyw}\,(\theta_w) = -a1 * \sin\left(\frac{\theta_w * 180°}{\theta_z}\right) \quad for\ 0 < \theta_w < \theta_z$$

$$C_{xyw}\,(\theta_w) = a2 * \sin[(\theta_w - \theta_z) * \lambda] \ for\ \theta_z \leq \theta_w < 180°$$

where,
C_{xyw} (θ_w) = normalized wind yaw moment coefficient
a1 = negative peak value (from Table 4-5)
a2 = positive peak value (from Table 4-5)
θ_w = wind angle (degrees)
θ_z = zero moment angle (degrees) (from Table 4-5)
λ = (180°) / (180° - θ_z)

Table 4-5 Normalized Wind Yaw Moment Variables

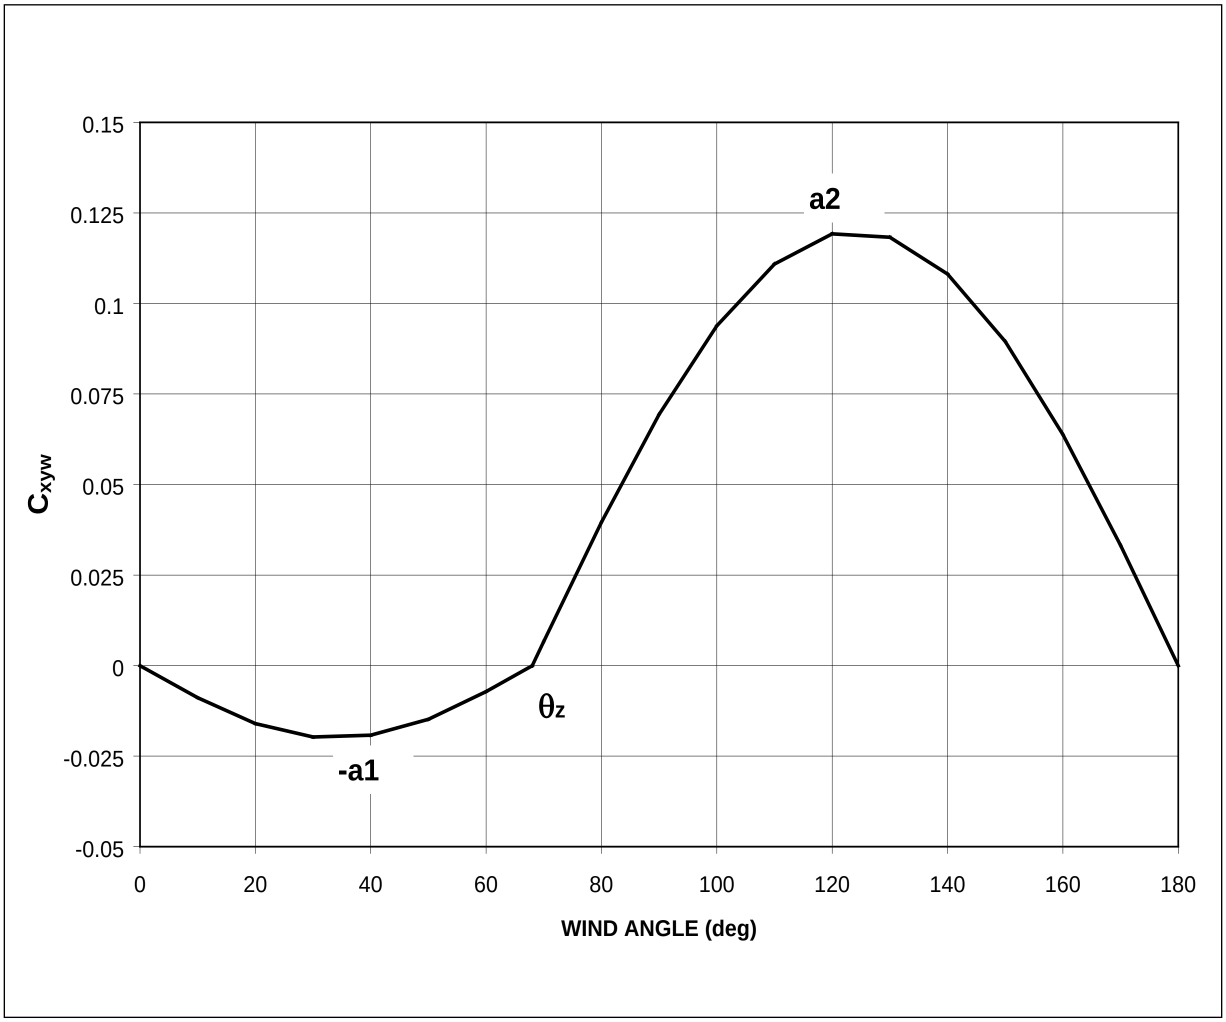
Ship Type	Zero Moment Angle (θ_z)	Negative Peak (a1)	Positive Peak (a2)	Notes
Liner	80°	0.075	0.14	
Carrier	90°	0.068	0.072	
Tanker	95°	0.077	0.07	Center island w/ cluttered deck
Tanker	100°	0.085	0.04	Center island w/ trim deck
Cruiser [a]	90°	0.064	0.05	outdated
Destroyer	68°	0.02	0.12	
Others:	130°	0.13	0.025	stern superstructure
	102°	0.096	0.029	aft midships superstructure
	90°	0.1	0.1	midships superstructure
	75°	0.03	0.05	forward midships superstructure
	105°	0.18	0.12	bow superstructure

Note:

[a] Modern Cruisers (CG) should be analyzed using the normalized wind yaw moment variables for the Destroyer (DDG) ship type.

A plot of the yaw normalized moment coefficient for the example shown in Figure 4-6 is given as Figure 4-7.

Figure 4-7 Example Normalized Yaw Wind Moment Coefficient



4-5 STATIC CURRENT FORCES/MOMENTS.

Methods to determine static current forces and moments on stationary moored vessels in the surge and sway directions and yaw moment are presented in this section. These planar directions are of primary importance in many mooring designs. Preferably, obtain current velocity from direct measurement at the specific site or from reliable local data. In the absence of this, refer to TR-NAVFAC-EXWC-CI-1901, *Revised Environmental Conditions for Mooring Service Types III and IV* to obtain current velocities at various installations.

4-5.1 Static Transverse Current Force.

The transverse current force is defined as that component of force perpendicular to the vessel centerline. If a ship has a large underkeel clearance, then water can freely flow under the keel, as shown in Figure 4-9 (a). If the underkeel clearance is small, as shown in Figure 4-9 (b), then the ship more effectively blocks current flow, and the transverse current force on the ship increases. These effects are considered and the transverse current force is determined from the equation:

Equation 4-9

$$F_{yc} = 0.5\, \rho_w\, V_c^2\, L_{wL}\, T\, C_{yc} \sin\theta_c$$

where,
ρ_w = *mass density of water (from Table 4-1)*
V_c = *current velocity (m/s)*
L_{wL} = *vessel waterline length (m)*
T = *average vessel draft (m)*
C_{yc} = *transverse current force drag coefficient*
θ_c = *current angle (degrees)*

The transverse current force drag coefficient as formulated in *Broadside Current Forces on Moored Ships*, Seelig et al. (1992) is shown in Figure 4-11. This drag coefficient can be determined from:

Figure 4-8 Examples of Ratios of Ship Draft (T) to Water Depth (d)

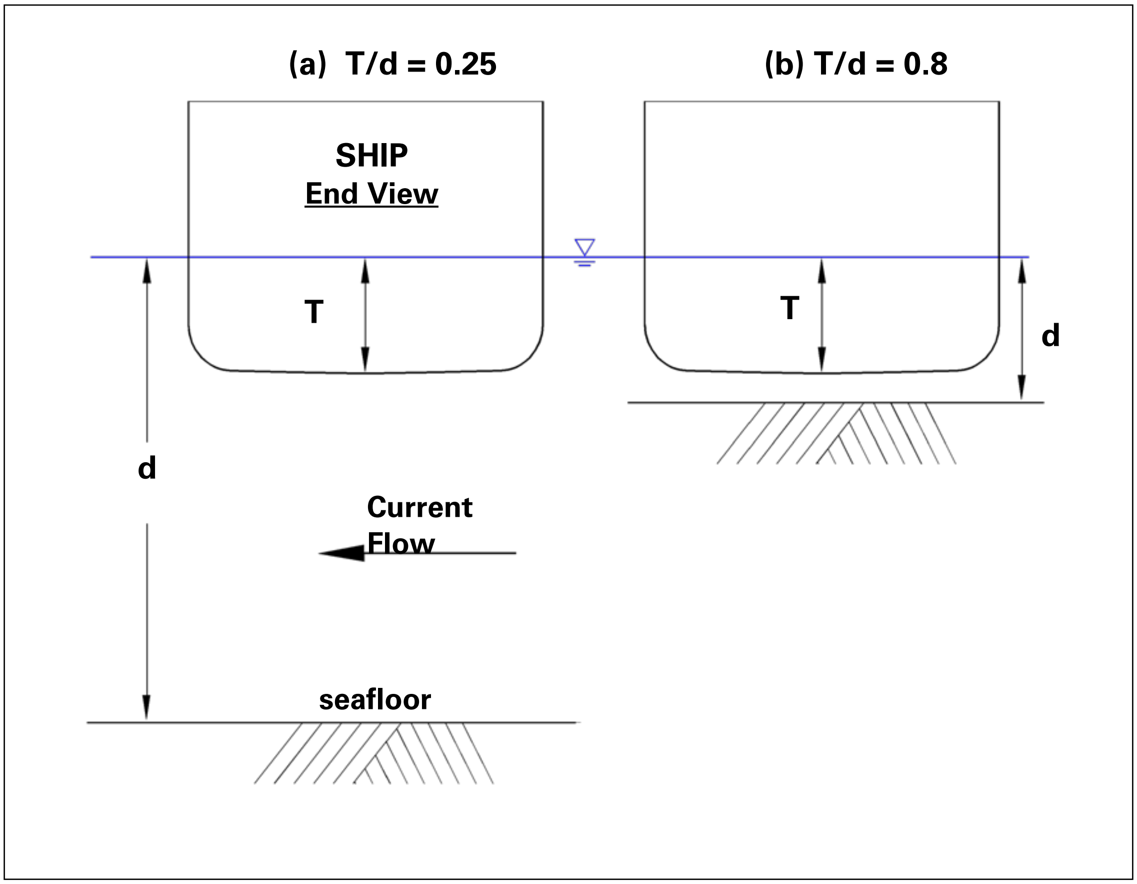


Figure 4-9 Broadside Current Drag Coefficient

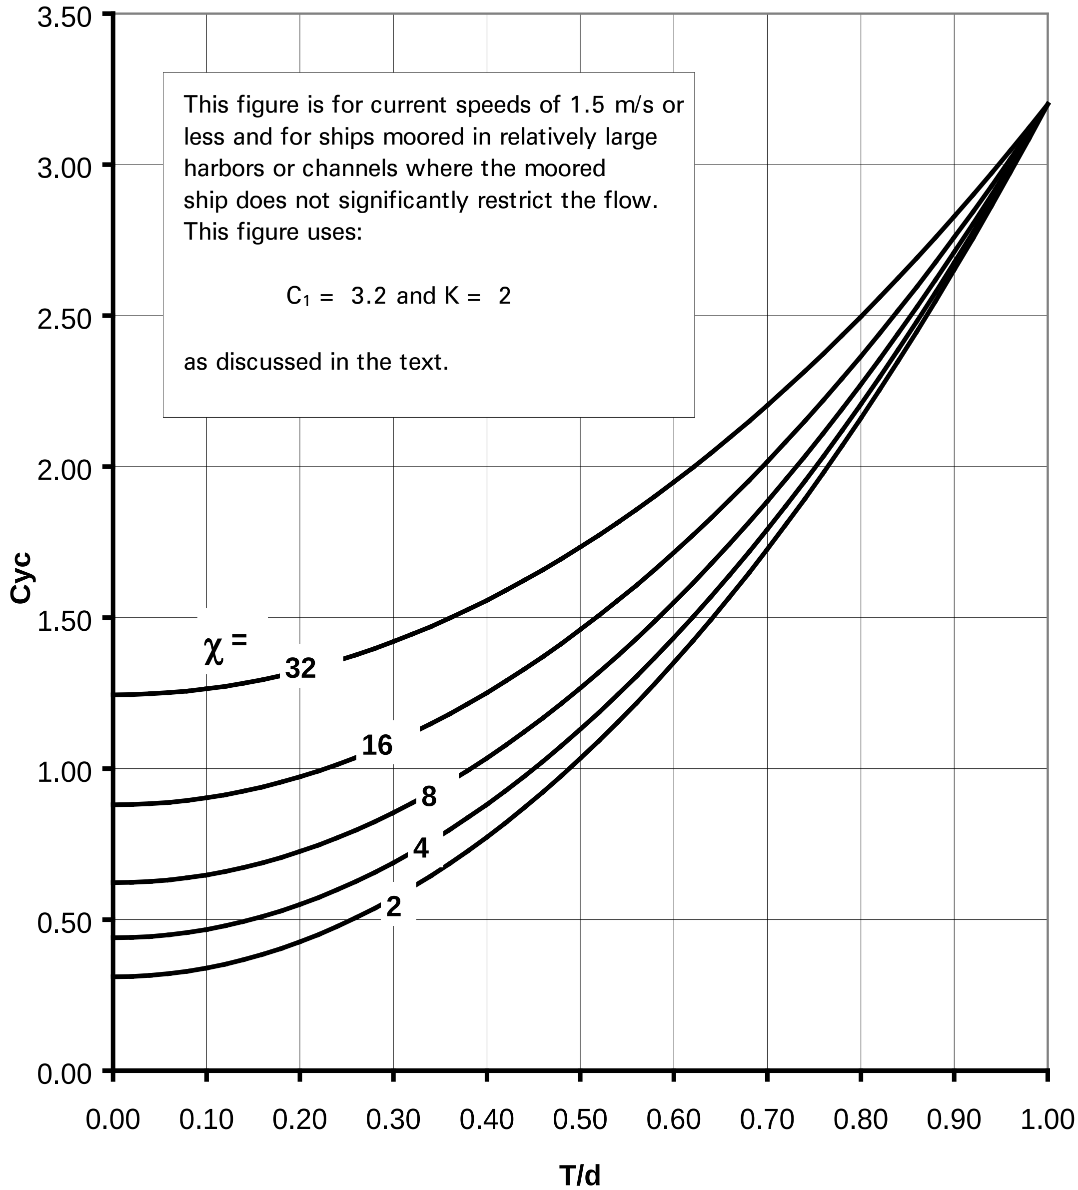


Equation 4-10

$$C_{yc} = C_0 + (C_1 - C_0)\left(\frac{T}{d}\right)^K$$

C_0 = deepwater current force drag coefficient for T/d ≈ 0.0; this deepwater drag coefficient is estimated from:

Equation 4-11

$$C_0 = 0.22 * \sqrt{\chi}$$

χ is a dimensionless ship parameter calculated as:

Equation 4-12

$$\chi = L_{wL}^2 * \frac{A_m}{(B * V)}$$

where,
L_{wL} = is the vessel length at waterline (m)
A_m = is the immersed cross-sectional area of the ship at midsection (m^2)
B = is the beam (maximum ship width at the waterline) (m)
V = is the submerged volume of the ship, (m^3)
(which can be found by taking the displacement of the vessel divided by the unit weight of water, given in Table 4-1)
C_1 = shallow water current force drag coefficient
where T/d = 1.0; for currents of 4.9 ft/s (2.9 knots or 1.5 m/s) or less; C_1 = 3.2 is recommended
T = average vessel draft (m)
d = water depth (m)
K = dimensionless exponent; laboratory data from ship models shows:
K = 2 Wide range of ship and barge tests; most all of the physical model data available can be fit with this coefficient, including submarines
K = 3 from a small number of tests on a fixed cargo ship and for a small number of tests on an old aircraft carrier, CVE 55
K = 5 from a small number of tests on an old submarine hull, SS 212

The immersed cross-sectional area of the ship at midships, A_m, can be determined from:

Equation 4-13

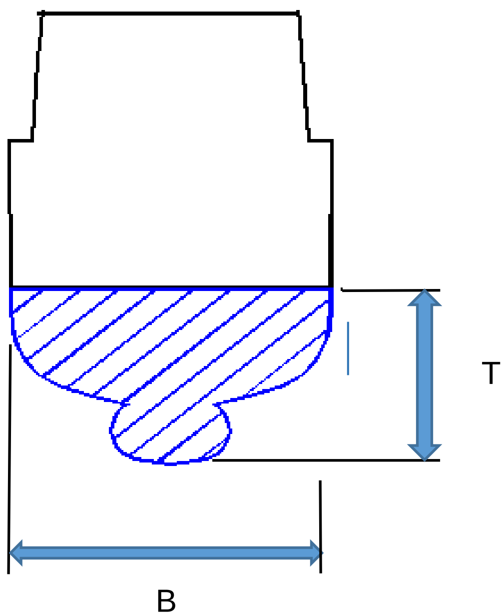
$$A_m = C_m * B * T$$

Midship coefficient, C_m is computed as follows:

Equation 4-14

C_m = Transverse area of vessel below waterline / (T*B), see Figure 4-10.

Figure 4-10 Midship Coefficient Diagram



The above methods for determining the transverse current force are recommended for normal design conditions with moderate current speeds of 4.9 ft/s (2.9 knots or 1.5 m/s) or less and in relatively wide channels and harbors (see Seelig et al., 1992).

If the vessel is moored broadside in currents greater than 4.9 ft/s (2.9 knots or 1.5 m/s), then scale model laboratory data show that there can be significant vessel heel/roll, which effectively increases the drag force on the vessel. In some model tests in shallow water and at high current speeds this effect was so pronounced that the model ship capsized. Mooring a vessel broadside in a high current should be avoided, if possible.

Scale physical model tests show that a vessel moored broadside in a restricted channel has increased current forces. This is because the vessel decreases the effective flow area of a restricted channel, which causes the current speed and current force to increase.

For specialized cases where:

- vessels are moored in current of 5 ft/s (3 knots or 1.5 m/s) or more, and/or
- for vessels moored in restricted channels then the designer should contact NAVFAC EXWC.

Full-scale measurements with a floating dry dock show the transverse current force equations should also be used to compute the longitudinal drag forces for vessels with a high block coefficient.

EXAMPLE: Find the current force on an FFG 7 vessel produced by a current of θ_c = 90 degrees to the ship centerline with a speed of 4.9 ft/s (2.9 knots or 1.5 m/s) in salt water for a given ship draft. At the mooring location, the harbor has a cross-sectional area much larger than the submerged ship longitudinal area, $L_{wL} * T$.

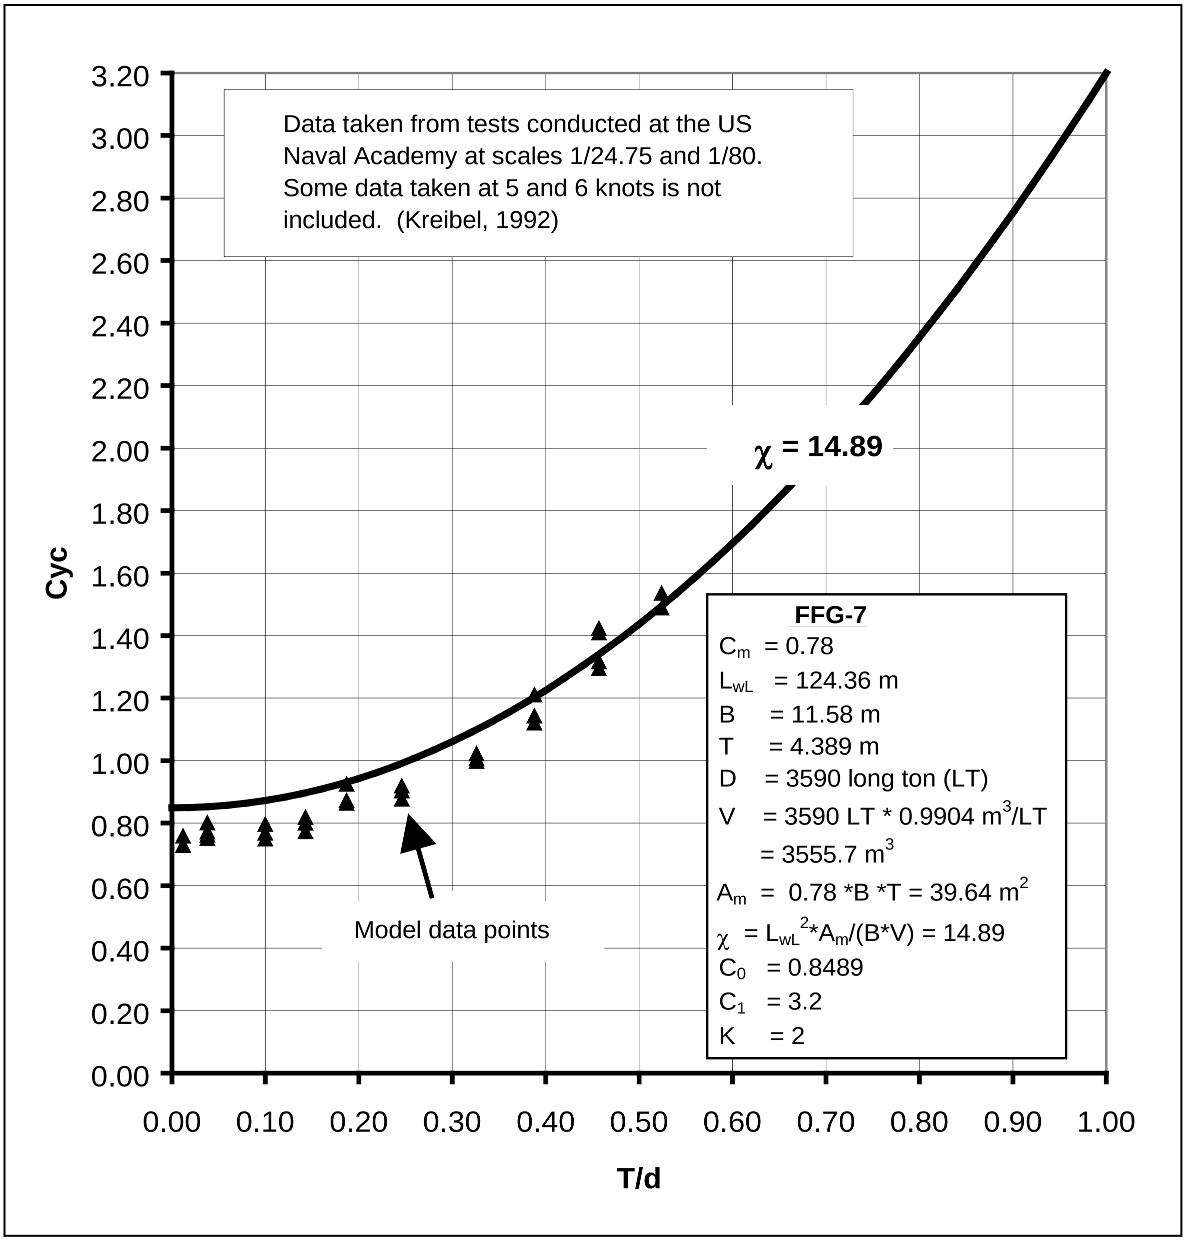
SOLUTION: Dimensions and characteristics of this vessel are summarized in the lower right portion of Figure 4-11. Transverse current drag coefficients predicted using Equation 4-10 are shown on this figure as a solid bold line. Physical scale model data (U.S. Naval Academy (USNA), EW-9-90, *Evaluation of Viscous Damping Models for Single Point Mooring Simulation)* are shown as symbols in the drawing, showing that Equation 4-10 provides a reasonable estimate of drag coefficients. Predicted current forces for this example are given in Table 4-6.

Table 4-6 Predicted Transverse Current Forces on FFG 7 for a Current Speed of 1.5 m/s (2.9 knots)

T/d	d ft (m)	F_{yc} kips (kN)
0.096	150 (45.7)	123 (547)
0.288	50 (15.2)	148 (658)
0.576	25 (7.6)	231 (1,028)
0.72	20 (6.1)	293 (1,303)
0.96	15 (4.6)	427 (1,899)

This example shows that in shallow water the transverse current force can be three times or larger than in deep water for an FFG 7.

Figure 4-11 Example of Transverse Current Drag Coefficients



4-5.2 Static Longitudinal Current Force for Ships.

The longitudinal current force is defined as that component of force parallel to the centerline of the vessel. This force is determined for streamlined ship-shaped vessels from the following equation (Naval Civil Engineering Laboratory (NCEL), TN-1634, *STATMOOR – A Single-Point Mooring Static Analysis Program)*:

Equation 4-15

$$F_{xc} = F_{xForm} + F_{xFriction} + F_{xProp}$$

where,
F_{xForm} = *longitudinal current load due to form drag (N)*
$F_{xFriction}$ = *longitudinal current load due to skin friction (N)*
F_{xProp} = *longitudinal current load due to propeller drag (N)*

Equation 4-16

$$F_{xFORM} = 0.5\, \rho_w\, V_C^2\, B\, T\, C_{xcb} \cos(\theta_c)$$

where,
ρ_w = *mass density of water, from Table 4-1*
V_c = *current speed (m/s)*
B = maximum vessel width at the waterline (m)
T = average vessel draft (m)
C_{xcb} = *longitudinal current form drag coefficient = 0.1*
θ_c = *current angle (degrees)*

Equation 4-17

$$F_{xFriction} = 0.5\, \rho_w\, V_C^2\, S\, C_{xca} \cos(\theta_c)$$

where,
S = wetted surface area (m^2); estimated

Equation 4-18

$$S = 1.7\, T\, L_{wL} + \left(\frac{D}{T\, \gamma_w}\right)$$

where,
T = average vessel draft (m)
L_{Wl} = *waterline length of vessel (m)*
D = ship displacement (N)
γ_w = *weight density of water, from Table 4-1*
C_{xca} = *longitudinal skin friction coefficient, estimated using:*

Equation 4-19

$$C_{xca} = \frac{0.075}{\left((\log_{10} R_N\,) - 2\right)^2}$$

Equation 4-20

$$R_N = \left| \frac{V_c \, L_{wL} \cos(\theta_c)}{\nu} \right|$$

where,
R_N = Reynolds Number
ν = kinematic viscosity of water, from Table 4-1

Equation 4-21

$$F_{xProp} = 0.5 \, \rho_w \, V_C^2 \, A_p \, C_{Prop} \cos(\theta_c)$$

where,
ρ_w = mass density of water, from Table 4-1
A_p = propeller expanded blade area (m^2)
C_{Prop} = propeller drag coefficient = 1.0

Equation 4-22

$$A_p = \frac{A_{Tpp}}{0.838}$$

A_{Tpp} = total projected propeller area (m^2) for an assumed propeller pitch ratio of p / d = 1.0

Equation 4-23

$$A_{Tpp} = \frac{L_{wL} \, B}{A_R}$$

A_R is a dimensionless area ratio for propellers. Typical values of this parameter for major vessel groups are given in Table 4-6. For vessels using water jets or other propulsors that are built into the hull, use A_R = 99999, or eliminate the longitudinal current load due to propeller drag F_{xPROP} from Equation 4-15.

Table 4-7 A_R for Major Vessel Groups

Ship	Area Ratio, A_R
Destroyer	100
Cruiser	160
Carrier	125
Cargo	240
Tanker	270
Submarine	125

In these and all other engineering calculations discussed in this UFC, the user must be careful to keep units consistent.

EXAMPLE: Find the longitudinal current force with a bow-on current of θ_c=180 degrees with a current speed of 3 knots (1.544 m/s) on a destroyer in salt water with the characteristics shown in Table 4-8.

SOLUTION: Figure 4-11 shows the predicted current forces. These forces are negative, since the bow-on current is in a negative "X" direction. For this destroyer, the force on the propeller is approximately two-thirds of the total longitudinal current force. For commercial ships, with relatively smaller propellers, form and friction drag produce a larger percentage of the current force.

Table 4-8 Example Destroyer

Parameter	English Units	SI Units
L_{wL}	529 ft	161.2 m
T	21 ft	6.4 m
B	55 ft	16.76 m
D, ship displacement	7810 long tons	7.93E6 kg
$C_{m;}$ estimated	0.83	0.83
S; est. from Equation 4-18	31,897 ft^2	2,963 m^2
A_R; from Table 4-8	100	100
R_N; from Equation 4-20	2.09×10^8	2.09×10^8
C_{xca}; est. from Equation 4-19	0.00188	0.00188
Ap; est. from Equation 4-22	347.2 ft^2	32.256 m^2

Table 4-9 Example Longitudinal Current Forces on a Destroyer

Force	English Units (kip)	SI Units (kN)	Percent of Total Force
F_{xForm}; Equation 4-16	-2.95	-13.1	22%
$F_{xFriction}$; Equation 4-17	-1.53	-6.8	12%
F_{xProp}; Equation 4-21	-8.87	-39.4	66%
Total F_{xc} =	-13.4	-59.4	100%

4-5.3 Static Longitudinal Current Force for Blunt Vessels.

The methods in Section 4-5.2, *Static Longitudinal Current Force for Ships* are inappropriate for very blunt-bow vessels, such as floating dry docks. For blunt-bow vessels use the methods and equations in the paragraph entitled "Static Transverse Current Force" for the longitudinal current force on the hull. In this case use the appropriate parameters as input.

For example, take the case of a floating dry dock 180 ft (55 m) wide with a draft of 67 ft (20.4 m) moored in a water depth of 70 ft (21.3 m). A current of 1.2 knots (2.33 m/s) is predicted (using methods in the paragraph entitled "Static Transverse Current Force") to produce a longitudinal current force of 144.9 kips (72.45 Tons) on this floating dry dock. Full-scale measurements were made on the actual dry dock for this case and the measured longitudinal force was 143 kips (71.5 Tons), approximately 1% lower than predicted.

4-5.4 Static Current Yaw Moment.

The current yaw moment is defined as that component of moment acting about the vessel's vertical "Z"-axis. This moment is determined from the equation:

Equation 4-24

$$M_{xyc} \qquad = F_{yc} \left(\frac{e_c}{L_{wL}}\right) L_{wL}$$

where,
F_{yc} = transverse current force (N)
e_c/L_{wL} = ratio of eccentricity to vessel waterline length
e_c = eccentricity of F_{yc} (m)
L_{wL} = vessel waterline length (m)

The eccentricity ratio e_c/L_{wL} is calculated by choosing the slope and y-intercept variables from Table 4-10 which are a function of the vessel hull. The eccentricity ratio is a dimensionless moment arm that is dependent upon the current angle to the vessel, as shown in Equation 4-25 and Equation 4-26:

Equation 4-25

$$\frac{e_c}{L_{wL}} = a + b * \theta_c \ \ for\ \theta_c = 0^0\ to\ 180^0$$

Equation 4-26

$$\frac{e_c}{L_{wL}} = a + (b * (360^0 - \theta_c)\,)\ for\ \theta_c = 180^0\ to\ 360^0$$

where,
a = y-intercept (refer to Table 4-10) (dimensionless)
b = slope per degree (refer to Table 4-10)
θ_c = current angle (degrees)

The above methods for determining the eccentricity ratio are recommended for normal design conditions with moderate current speeds of less than 1.5 m/s (3 knots or 5 ft/s). Values provided in Table 4-10 are based upon least squares fit of scale model data taken for the case of ships with level keels. Data are not adequately available for evaluating the effect of trim on the current moment.

Table 4-10 Current Moment Eccentricity Ratio Variables

Ship	a, Y-Intercept	b, Slope per Degree	Notes
SERIES 60	-0.291	0.00353	Full hull form typical of cargo ships
FFG	-0.201	0.00221	“Rounded” hull typical of surface warships
CVE 55	-0.168	0.00189	Old attack aircraft carrier
SS 212	-0.244	0.00255	Old submarine

4-6 WIND AND CURRENT FORCES AND MOMENTS ON MULTIPLE SHIPS.

If ships are moored in close proximity to one another then the nearby ship(s) can influence the forces/moments on a given ship. The best information available on the effects of nearby ships is results from physical model tests, because the physical processes involved are highly complex. NFESC Report TR-6003-OCN provides scale model test results of wind and current forces and moments for multiple identical ships. From two to six identical ships were tested and the test results were compared with test results from a single ship. Data are provided for aircraft carriers, destroyers, cargo ships, and submarines.

Cases included in NFESC Report TR-6003-OCN include: individual ships, ships in nests and ships moored on either side of piers. Results are provided for the effects of winds and currents in both tabular and graphical form.

This Page Intentionally Left Blank

CHAPTER 5 DESIGN PROCEDURES ANCHOR SYSTEM

5-1 GENERAL ANCHOR DESIGN PROCEDURE.

Anchor systems ultimately hold the mooring loads in fleet mooring systems. Anchors are used on both ships and in mooring facilities, so selection and design of anchors are included in this section.

The type and size of anchor specified depends upon certain parameters, such as those shown in Table 5-1.

The most commonly used anchors in DoD moorings are drag-embedment anchors and driven-plate anchors, so they will be discussed here. Other types of specialized anchors (shallow foundations, pile anchors, propellant-embedment anchors, rock bolts, etc.) are discussed in the NCEL *Handbook for Marine Geotechnical Engineering*.

Figure 5-1 and Figure 5-2 illustrate typical drag-embedment anchors. Figure 5-3 illustrates a driven-plate anchor. Some characteristics of these two categories of anchors are given in Table 5-2.

Table 5-1 Anchor Specification Considerations

Parameter	Description
Holding capacity	The size/type of anchor will depend on the amount of anchor holding required.
Soils	Engineering properties and sediment layer thickness influence anchor design.
Use	If anchors will be relocated, then drag anchors are most commonly used.
Weight	The amount of weight that can be handled or carried may control anchor specification.
Equipment	The size and characteristics of installation equipment are important in anchor specification.
Directionality	Drag anchors may provide little uplift capacity and primarily hold in one direction; driven plate anchors provide high omni directional capacity.
Performance	Whether anchor will be allowed to drag or not, as well as the amount of room available for anchors systems, will influence anchor specification.

Figure 5-1 Example of a Drag-Embedment Anchor (Stabilized Stockless Anchor)

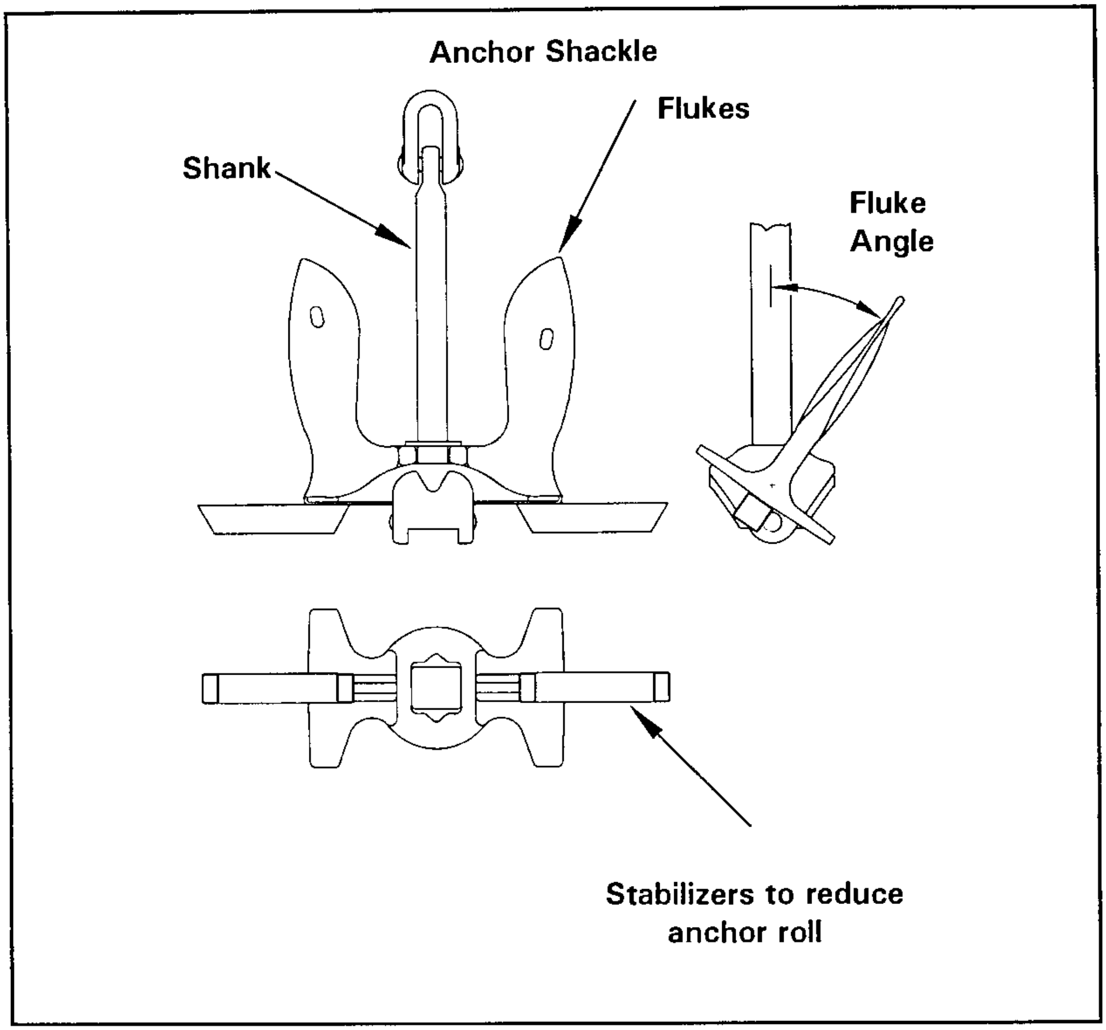


Figure 5-2 Example of a Drag-Embedment Anchor (NAVMOOR Anchor)

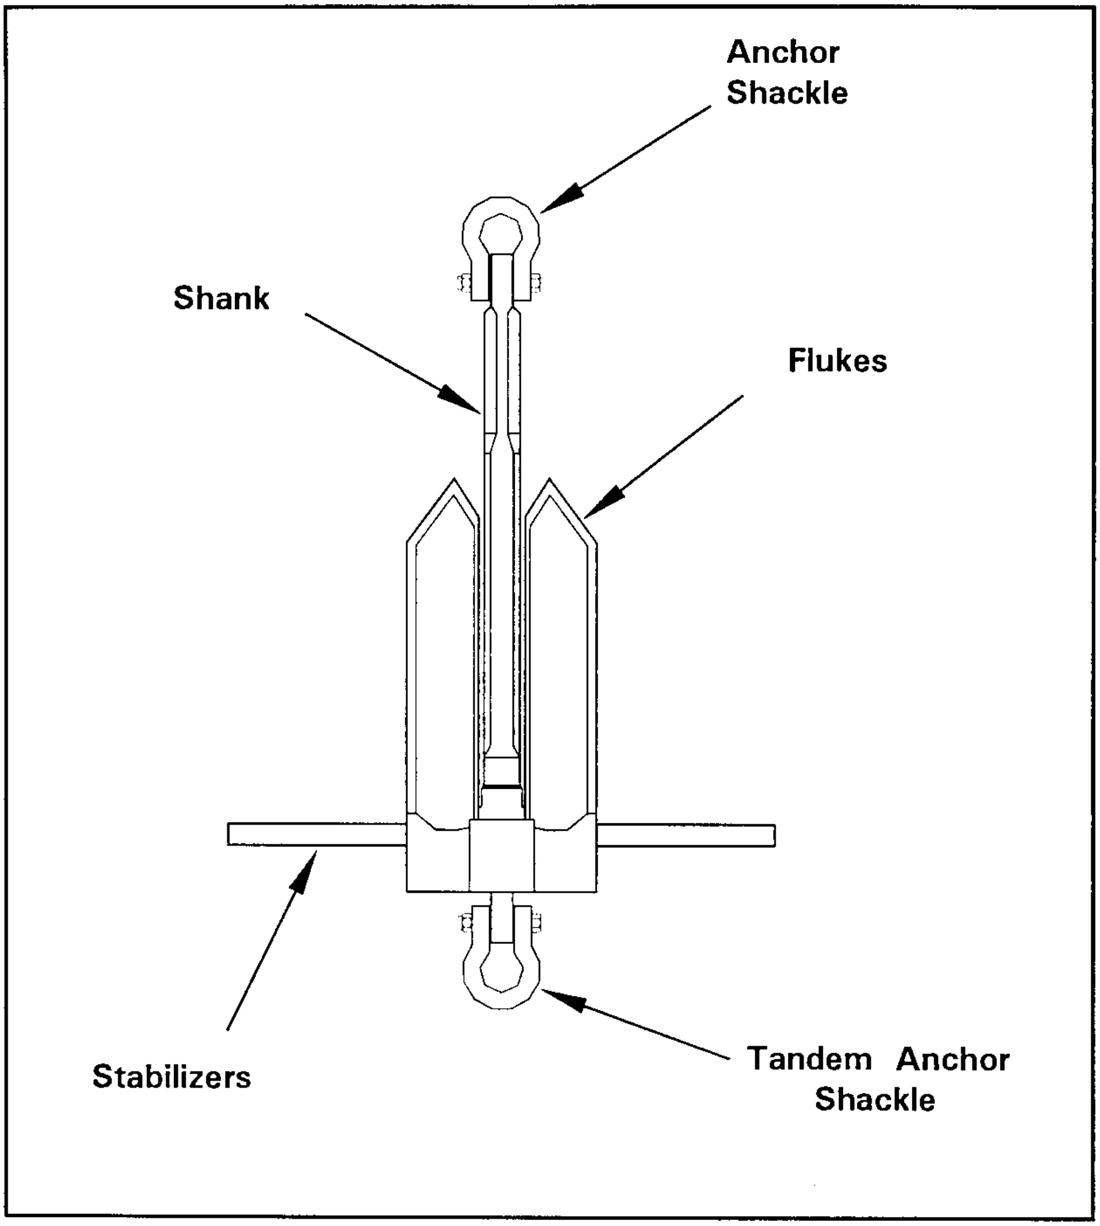

Figure 5-3 Driven-Plate Anchor

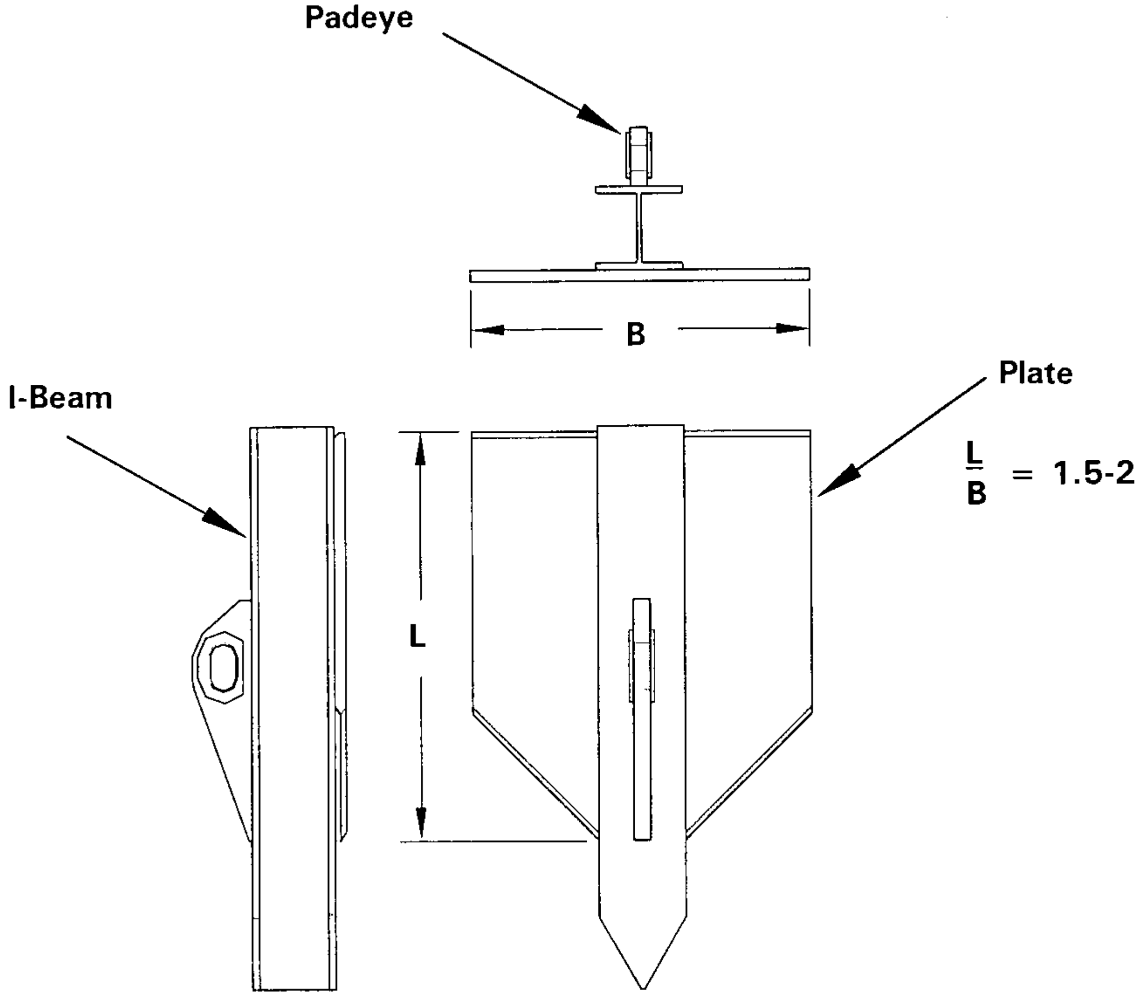

Keying flaps (not shown) can be added to the back of the anchor, opposite the padeye, to decrease the keying distance in cohesive soils (mud).

Table 5-2 Anchor Characteristics

(a) Drag-Embedment Anchors

Characteristics	Notes
Many basic designs and sizes are available from manufacturers.	NAVMOOR-10 & -15 and stockless of 20 to 30 kips (89 to 133.5 kN) are stocked by NAVFAC EXWC.
Works primarily in one horizontal direction.	Enough scope of chain and/or wire rope needs to be provided to minimize uplift forces, which can pull the anchor out. If a load is applied to a drag anchor at a horizontal axis off the centerline of the anchor, then the anchor may drag and reset.
Flukes should be set for the soil type.	Anchor performance depends on the soil type. Fixing the maximum angle of the fluke will help ensure optimum performance. For mooring installations, the flukes should be fixed open and stabilizers added for stockless anchors to help prevent overturning.
Adequate sediment required.	Sand layer thickness needs to be approximately one fluke length and mud needs to be 3 to 5 fluke lengths thick.
May not work in all seafloor types.	May be unreliable in very hard clay, gravel, coral, or rock seafloors; and in highly layered seafloors.
May not work well for sloping seafloors.	If the seafloor has a slope of more than several degrees, then the anchor may not hold reliably in the down-slope direction.
Anchor can drag.	If the anchor is overloaded at a slow enough rate, then the anchor can drag, which reduces the peak load. Anchor dragging can be a problem if the room for mooring is restricted. If adequate room is available, then anchor drag can help prevent failure of other mooring components.
Anchors can be reused.	Drag-embedment anchors can be recovered and reused.
Proof loading recommended.	Pulling the anchor at the design load in the design direction will help set the anchor and assure that the soil/anchor interaction provides adequate holding.

(b) Driven-Plate Anchors

Characteristics	Notes
Size and design of anchor are selected to provide adequate holding, to allow driving, and to provide adequate structural capacity.	These anchors have been used in a variety of soils from soft mud to hard coral. A driving analysis is recommended for hard soil, because the anchor must be able to be driven in order to work.
Multi-directional.	Can be used on short scope, since the anchor resists uplift forces. One plate anchor may be used to replace several drag anchor legs, since the anchors are multi-directional.
Anchors designed for the soil type.	Anchors designed for the soil engineering characteristics at the site.
Adequate sediment required.	A minimum of several fluke lengths of sediment is required to provide for keying and allow the anchor to hold (NFESC TR-2039-OCN, *Design Guide for Pile-Driven Plate Anchors*).
Anchor is fixed.	The anchor will not drag, so this type of anchor is well suited to locations with limited mooring area available. The anchors cannot be recovered or inspected.
Proof loading recommended.	Pulling the anchor at the design load in the design direction will help key the anchor and assure that the soil/anchor interaction provides adequate holding.
Installation equipment.	Mobilization can be expensive, so installing a number of anchors at a time reduces the unit installation cost.

5-2 DRAG-EMBEDMENT ANCHOR SPECIFICATION.

Drag-embedment anchors are carried on ships and used in many fleet-mooring facilities. Key considerations in selecting an anchor are: soil type, anchoring holding capacity, anchor weight, anchor stowage, cost, availability, and installation assets. In SI units the anchor mass is used to characterize anchor size, while in U.S. customary units the anchor weight as a force is used.

Drag-embedment anchor holding capacities have been measured in full-scale tests, modeled in the laboratory, and derived from soil analyses. Empirical anchor holding curves were developed from this information (Naval Civil Engineering Laboratory (NCEL), TDS 83-08R, *Drag Embedment Anchors for Navy Moorings*). Predicted static ultimate anchor holding is given by:

Equation 5-1

$$H_M = H_R \left(\frac{W_A}{W_R}\right)^b$$

where,
H_M = ultimate anchor system static holding capacity (kips or kN)
H_R = reference static holding capacity
W_A = weight of the anchor in air (for SI units use anchor weight in kilograms; U.S. units use anchor weight in pounds force)
W_R = reference anchor weight in air (for SI units use 4,536 kg; U.S. units use 10,000 lbf)
b = exponent

Values of H_R and b depend on the anchor and soil types. Values of these parameters are given in U.S. customary units in Table 5-3 and for SI units in Table 5-4.

Figure 5-4 and Figure 5-5 give holding capacities of selected anchors for mud and sand seafloors.

Table 5-3 Drag Anchor Holding Parameters U.S. Customary

Figure 5-4 Anchor System Holding Capacity in Cohesive Soil (Mud)

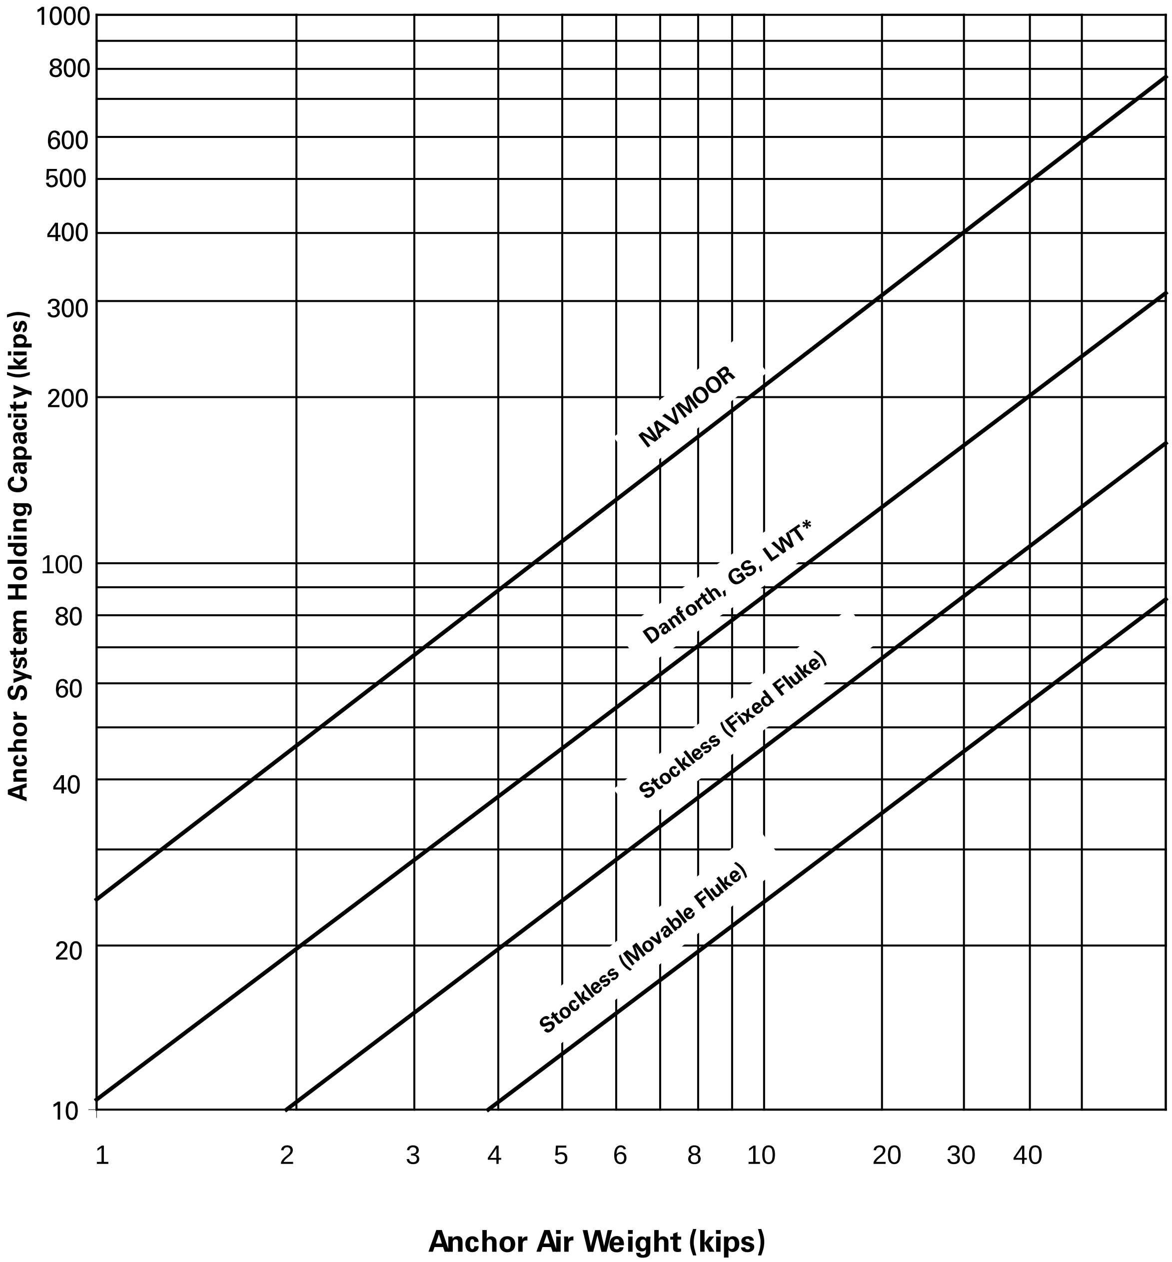

Figure 5-5 Anchor System Holding Capacity in Cohesionless Soil (Sand)

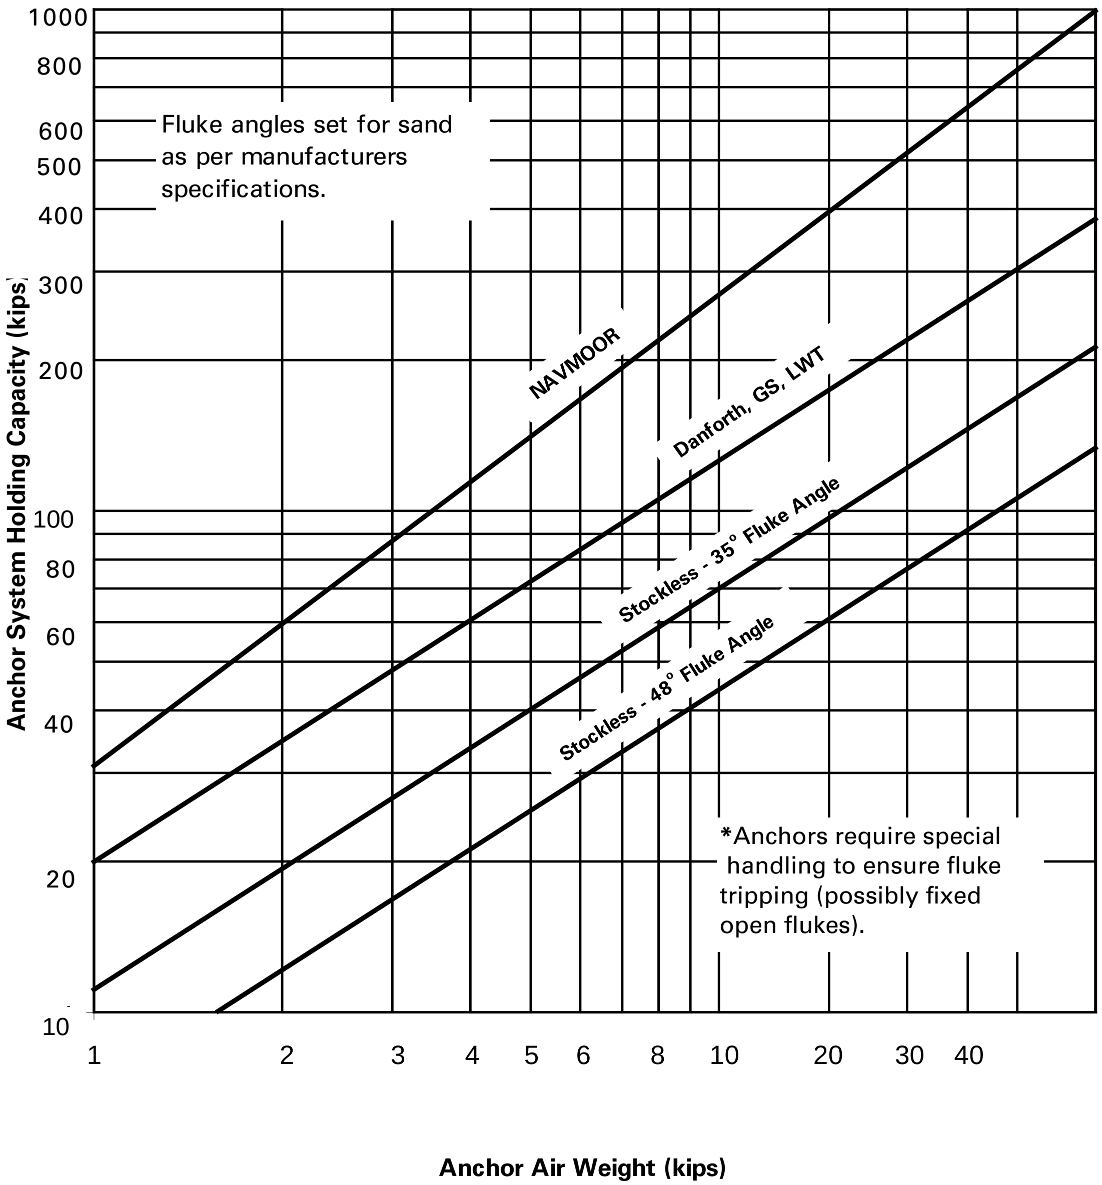


5-3 DRIVEN-PLATE ANCHOR DESIGN.

NAVFAC EXWC has found that various types of plate anchors are an efficient and cost effective method of providing permanent moorings. Detailed design procedures for these anchors are given in NFESC TR-2039-OCN, *Design Guide for Pile-Driven Plate Anchors*. Additional information is given in NCEL *Handbook for Marine Geotechnical Engineering*. An overview of plate anchor design is given here.

A driven-plate anchor consists of the components shown in Figure 5-3 and discussed in Table 5-5.

Table 5-5 Driven-Plate Anchor Components

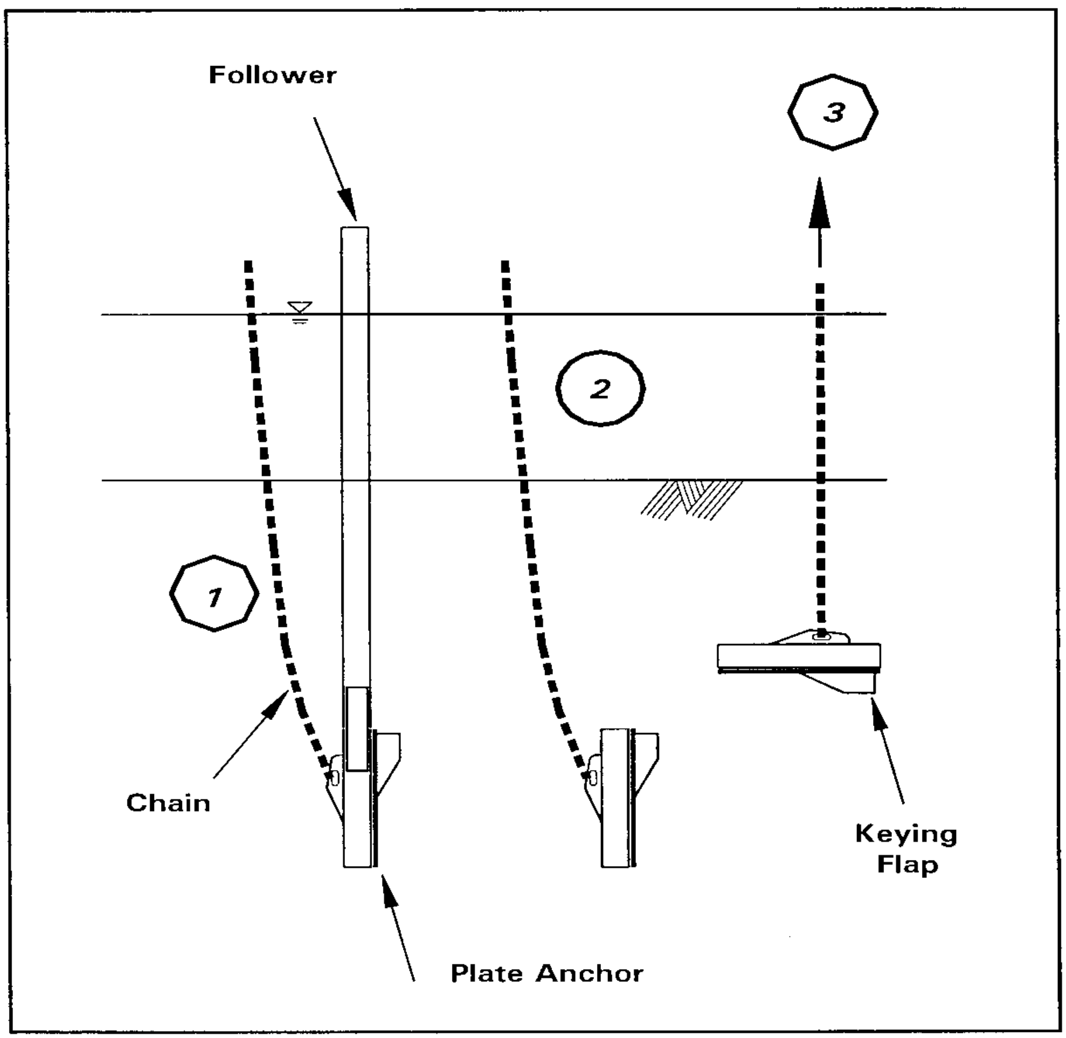
Component	Notes
Plate	Size the area and thickness of the plate to hold the required working load in the given soils. A plate length-to-width ratio of L/B = 1.5 to 2 is shown by practical experience to give optimum performance.
I-Beam	Size the beam to provide: a driving member; stiffness and strength to the anchor; and to separate the pad eye from the plate to provide a moment that helps the anchor key during proof testing.
Padeye	Size this structure as the point where the chain or wire rope is shackled onto the anchor prior to driving.
Follower	Length and size specified so assembly can safely be picked up, driven, and removed.
Hammer	Sized to drive the anchor safely. In most cases it is preferable to use an impact hammer. A vibratory hammer may be used in cohesionless soils or very soft mud. A vibratory hammer may also be useful during follower extraction.
Template	A structure is added to the side of the driving platform to keep the follower in position during setup and driving.

Installation of a plate anchor is illustrated in Figure 5-6. Installation consists of three key steps, as outlined in Table 5-6.

Table 5-6 Major Steps in Driven-Plate Anchor Installation

Step	Description
1.	Moor installation platform, place anchor in follower, shackle anchor to chain, place the follower/anchor assembly at the specified anchor location and drive the anchor to the required depth in the sediment (record driving blow count).
2.	Remove follower with a crane and/or extractor.
3.	Proof load the anchor. This keys the anchor, proves that the anchor holds the design load, and removes slack from the chain.

Figure 5-6 Major Steps of Driven-Plate Anchor Installation



Examples of plate anchors that have been used at various sites are summarized in Table 5-7.

Table 5-7 Typical Driven-Plate Anchors

Size/Location	Seafloor Type	Driving Distance Into Competent Sediment	Proof Load
0.91 m x 1.22 m (3 ft x 4 ft) Philadelphia, PA	Hard Clay	9 m (30 ft)	670 kN (150 kips) Vertical
0.61 m x 1.22 m (2 ft x 4 ft) San Diego, CA	Sand (Medium)	8 m (27 ft)	890 kN (200 kips) Vertical
m x 1.83 m (5 ft x 6 ft) Guam	Coral Limestone	12 m (40 ft)	1000 kN (225 kips) Vertical
m x 3.35 m (6 ft x 11 ft) Pearl Harbor, HI	Mud	21 m (70 ft)	890 kN (200 kips) Horizontal

The recommended minimum plate anchor spacing is five times the anchor width for mud or clay and 10 times the anchor width for sand.

CHAPTER 6 FACILITY MOORING EQUIPMENT GUIDELINES

6-1 INTRODUCTION.

Equipment most often used in mooring facilities is discussed in this section.

6-2 KEY MOORING COMPONENTS.

A mooring is a structure that holds a ship in a position using tension and compression members. The resulting mooring loads are transferred to the earth via anchors or some other members, such as pier piles or a wharf structure.

6-2.1 Tension Members.

The most commonly used tension members in moorings are:

- Chain
- Synthetic line
- Wire rope
- Tension bar buoys

6-2.2 Compression Members.

The most commonly used compression members in moorings are:

- Marine fenders
- Fender Piles
- Camels
- Mooring dolphins
- Piers
- Wharves

6-3 ANCHORS.

Anchors are structures used to transmit mooring loads to the earth. Anchors operate on the basis of soil structure interaction, so their behavior can be complex. Fortunately, the U.S. Navy has extensive experience with full-scale testing of a number of different anchor types in a wide variety of soils and conditions (NCEL *Handbook for Marine Geotechnical Engineering*). This experience provides a strong basis for design. However, due to the complex nature of structure/soil interaction, it is strongly recommended that anchors always be pull tested to their design load during installation. Design and illustration of some of the common anchor types routinely used are discussed in CHAPTER 5 of this UFC, and in NCEL *Handbook for Marine Geotechnical Engineering.*

A brief summary of some anchor experience is given in Table 6-1.

Table 6-1 Practical Experience with Anchors

Anchor Type	Description
Low Efficiency Drag Embedment Anchors (i.e., Stockless)	Reliable if stabilizers are added (see Figure 5-1). Not very efficient, but reliable through 'brute force'. Extensive experience. A large number available in the U.S. Navy Fleet Mooring inventory. Efficiency increased by fixing the flukes for the type of soil at the site. Should be set and proof tested during installation. Can be used in tandem in various configurations (NCEL TDS 83-05, *Multiple STOCKLESS Anchors for Navy Fleet Moorings*). Vertical angle of tension member should be approximately zero at the seafloor.
High Efficiency Drag Embedment Anchors (i.e., NAVMOOR)	Very efficient, highly reliable and especially designed so it can easily be used in tandem (NCEL TN-1774, *Single and Tandem Anchor Performance of the New Navy Mooring Anchor*). Excellent in a wide variety of soil conditions. These are available in the U.S. Navy Fleet Mooring inventory. Should be set and proof tested during installation. Vertical angle of tension member should be approximately zero at the seafloor in most cases.
Driven-Plate Anchors	Extremely efficient, can be designed to hold extremely high loads and will work in a wide variety of soils from mud to limestone (NFESC TR-2039, *Design Guide for Pile-Driven Plate Anchors*). Can take loads at any angle, so short scope moorings can be used. Extensive experience. Requires a follower and driving equipment. Most cost effective if a number are to be installed at one site at one time. Should be keyed and proof tested during installation.
Deadweight Anchors	Very low efficiency. Full-scale tests (NCEL, *Fleet Mooring Test Program – Pearl Harbor*) show anchor-holding capacity dramatically decreases after anchor starts dragging, just when the anchor capacity required may be most needed. As a result, use of this type of anchor can be dangerous. Deadweight anchors should be used with caution. NFESC TR-6037-OCN provides an Improved Pearl Harbor Anchor design.
Other anchor types	NCEL *Handbook for Marine Geotechnical Engineering* gives extensive technical and practical information on a wide variety of anchors and soil/structure interaction.

A summary sheet describing the stockless anchors in the U.S. Navy Fleet Mooring inventory is given in Table 6-2. NAVMOOR anchors in inventory are described in Table 6-3.

Table 6-2 Stockless Anchors in the U.S. Navy Fleet Mooring Inventory

6-4 CHAIN AND FITTINGS.

Chain is often used in fleet moorings because chain:

- Is easy to terminate.
- Can easily be lengthened or shortened.
- Is durable.
- Is easy to inspect.
- Is easy to provide cathodic protection.
- Has extensive experience.
- Is available.
- Is cost effective.
- Provides catenary effects.

DoD commonly uses stud link chain, with each chain link formed by bending and butt-welding a single bar of steel. Chain used in fleet moorings is Grade 3 stud link chain specifically designed for long-term in-water use (Naval Facilities Engineering Service Center (NFESC), FPO-1-89(PD1), *Purchase Description for Fleet Mooring Chain and Accessories*). This chain is designated as FM3. Properties of FM3 carried in stock are shown in Table 6-4 and in UFC 4-150-09, *Permanent Anchored Moorings, Operations and Maintenance*. Anodes for use on each link of FM3 chain, designed for diver replacement, are described in Table 6-4. Oversized anodes may be used to extend the anode life and increase the time interval required for anode replacement.

Older ships may use Die-Lock chain (not shown), which was made by pressing together male and female parts to form each link. Die-Lock is not recommended for long-term in-water use, because water may seep in between the male and female parts. The resulting corrosion is difficult to inspect.

Chain routinely comes in 90-foot (27.4-meter) lengths called ‘shots’. A number of other accessories are used with chain, as shown in Figure 6-1. For example, shots of chain are connected together with chain joining links. Anchor joining links are used to connect chain to anchors. Ground rings provide an attachment point for multiple chains. Buoy swivels are used to connect chain to buoys. Refer to NFESC TR-6014-OCN, *Mooring Design Physical and Empirical Data* and NFESC FPO-1-89(PD1) for additional information on chain and fittings.

Table 6-4 FM3 Mooring Chain Characteristics

Nominal Size (inch)	1.75	2	2.25	2.5	2.75	3.5	4

Weight per Full Drum (approx. lb)	976	979	917	993	869	602	550

Notes:

1. all screws are .375-16unc-2a, grade 5, hex cap
2. 4.00 inch anodes fit all chain sizes
3. all screw heads are 9/16 inch

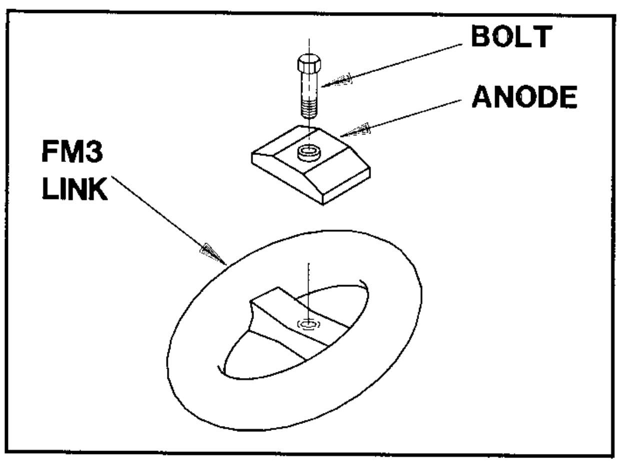

Figure 6-1 Chain Fittings

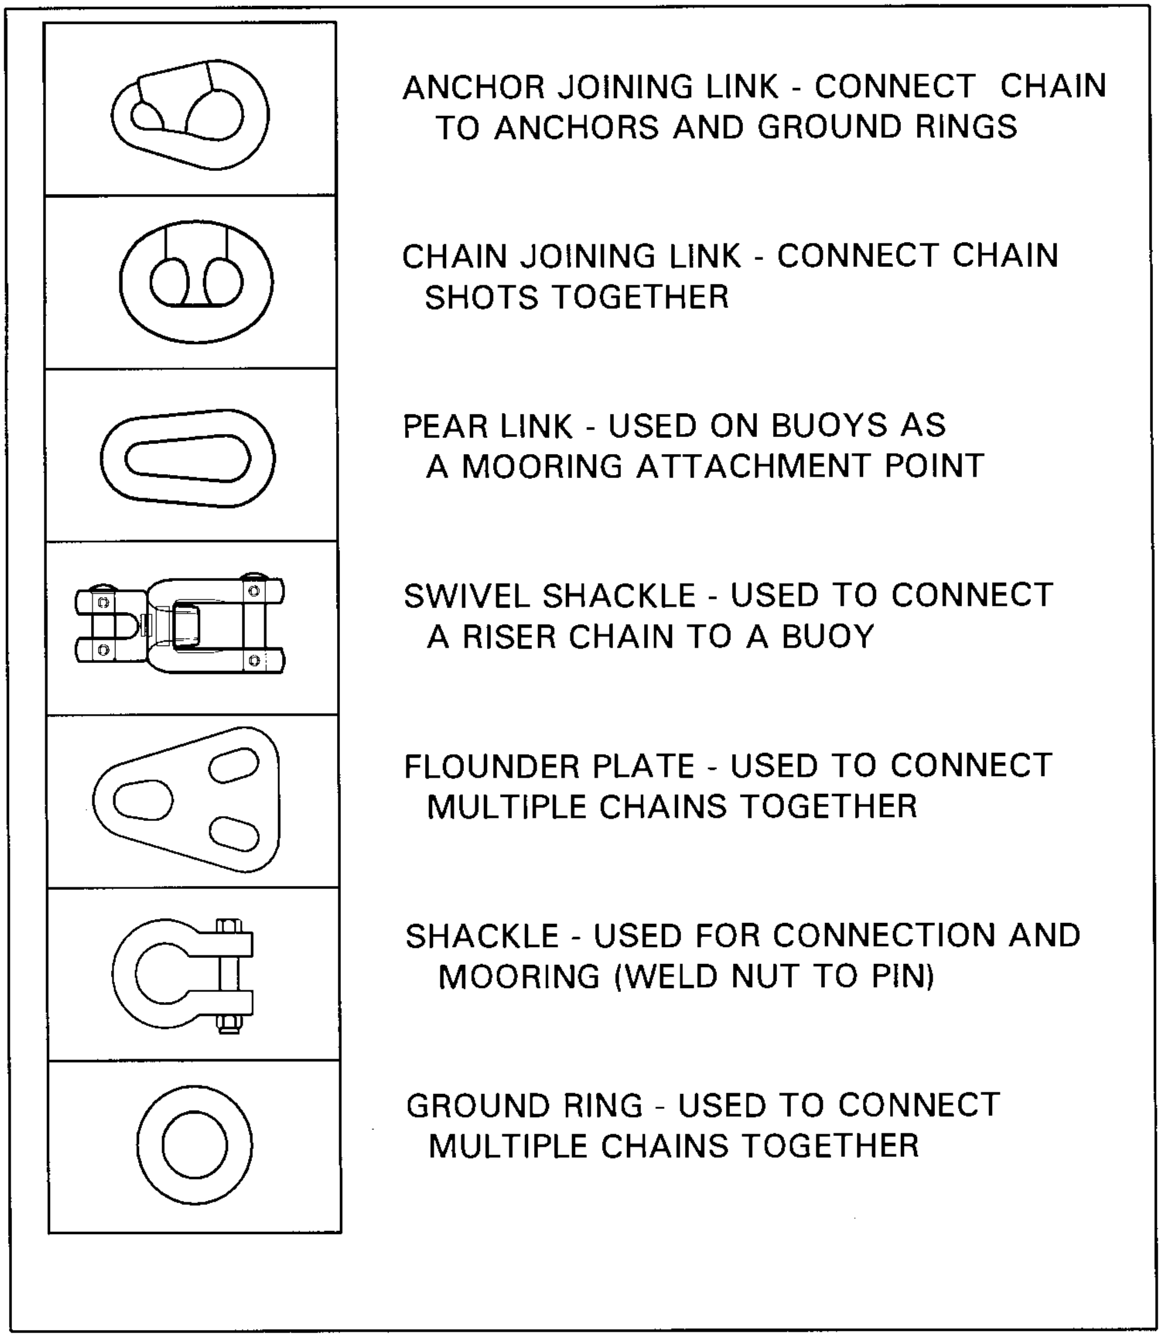

6-5 BUOYS.

There are two buoys commonly used on U.S. Navy Fleet moorings: an 8-foot (2.44 m) diameter buoy and a 12-foot (3.66 m) diameter buoy. These buoys have a polyurethane shell, are filled with foam, and have a tension bar to transmit mooring loads to the chain. Properties of these buoys are given in Table 6-6. Some of the key features of these buoys are that they require little maintenance and they are self-fendering. A variety of older steel buoys in use are being phased out, due to their relatively high maintenance cost. Some of the factors to consider in selecting the type of mooring buoy to use are: availability, size, cost, durability, maintenance, inspection, disposal and similar factors.

6-6 SINKERS.

Sinkers are placed on fleet moorings to tune the static and dynamic behavior of a mooring. Sinkers are usually made of concrete or low cost metal. Key sinker parameters that can be specified in design include:

- Mass
- Weight
- Location
- Number
- Size
- Design

Special care needs to be taken in the design and inspection of lifting eyes and attachment points on sinkers to ensure that they are safe.

6-7 MOORING LINES.

The most common tension member lines used are synthetic fiber ropes and wire rope. Synthetic lines have the advantage of easy handling and some types have stretch, which can be used to fine tune static and dynamic mooring behavior and aid in load sharing between tension members. Wire rope has the advantage of durability.

6-7.1 Synthetic Fiber Ropes.

Mooring lines are formed by weaving a number of strands together to form a composite tension member. Lines are made of different types of fiber and various constructions. Stretch/strain properties of selected lines are shown in Table 6-7 and Figure 6-2. Engineering characteristics of some double braided nylon and polyester lines are given in Table 6-8 and Table 6-9. Additional information is provided in NFESC TR-6014-OCN, *Mooring Design Physical and Empirical Data*. The size and type of synthetic line specified in a given design will depend upon parameters such as those shown in Table 6-10. A discussion of the use of various mooring line types is given in APPENDIX A.

Table 6-6 Foam-Filled Polyurethane Coated Buoys

Parameters	8-Foot Buoy	12-Foot Buoy
Weight in Air	4,500 lb (2041 kg)	10,400 lb (4,717 kg)
Net Buoyancy	15,000 lb (6804 kg)	39,000 lb (17,690 kg)
Working Buoyancy (24" FB)	6,150 lb (2790 kg)	20,320 lb (9,217 kg)
Proof Load on Bar (0.6 f_y)	300 kips (1334 kN)	600 kips (2,669 kN)
Working Load of Bar (0.3 f_y)	150 kips (667 kN)	300 kips (1,334 kN)
Diameter Overall (w/fenders)	8 ft 6 in (2.6 m)	12 ft (3.66 m)
Diameter of Hull	8 ft (2.44 m)	11 ft 6 in (3.5 m)
Length of Hull Overall	7 ft 9 in (2.36 m)	8 ft 9 in (2.7 m)
Length of Tension Bar	11 ft 4 in (3.45 m)	13 ft 1 in (3.97 m)
Height of Cylindrical Portion	4 ft 4 in (1.22 m)	5 ft 7 in (1.7 m)
Height of Conical Portion	3 ft 5 in (1.05 m)	3 ft 2 in (0.95 m)
Bar Thickness (top/bottom)	4.5/3.0 in (114/76 mm)	5.0/3.5 in (127/89 mm)
Top Padeye ID (top/bottom)	3.5/3.0 in (89/76 mm)	4.5/5.0 in (114/127 mm)
Shackle on Top	3.0 in (76 mm)	4.0 in (102 mm)
Maximum Chain Size	2.75 in (0.07 m)	4.0 in (102 mm)
Min. Recommended Riser Wt	1,068 lb (485 kg)	7,500 lb (3,401 kg)
Riser Wt for 24" freeboard	8,850 lb (4,014 kg)	18,680 lb (8,473 kg)
Max. Recommended Riser Wt	7,500 lb (3,401 kg)	21,264 lb (9,645 kg)
Moment to Heel 1 deg:		
Min Riser Wt	108 ft-lb (14.9 kg-m)	1,183 ft-lb (163.5 kg-m)
Max Riser Wt	648 ft-lb (89.6 kg-m)	2,910 ft-lb (402.3 kg-m)

6-7.2 Wire Ropes.

Wire rope is composed of three parts: wires, strands, and a core. The basic unit is the wire. A predetermined number of wires of the proper size are fabricated in a uniform geometric arrangement of definite pitch or lay to form a strand of the required diameter. The required number of strands are then laid together symmetrically around a core to form the rope. Refer to NAVSEA NSTM 613, USACE EM 1110-2-3200, and *Wire Rope User's Manual* and for additional information. Some factors to consider when specifying wire rope are listed in Table 6-10.

6-8 FENDERS.

Fendering is used between ships and compression structures, such as piers and wharves, in fixed moorings. Fenders act to distribute forces on ship hull(s) and minimize the potential for damage. Fendering is also used between nested ships. A wide variety of types of fenders are used including:

- Wooden piles
- Cylindrical marine fenders
- Hard rubber fenders
- Mooring dolphins
- Specially designed structures
- Composite fender piles
- Plastic fender piles
- Pre-stressed concrete fender piles

Camels are wider compression structures used, for example, to offset a ship from a pier or wharf.

The pressure exerted on ship hulls is a key factor to consider when specifying fenders. Allowable hull pressures on ships are discussed in NFESC TR-6015-OCN, *Foam-Filled Fender Design to Prevent Hull Damage*.

Refer to UFC 4-152-01, NAVSEA NSTM 611, and manufactures data for detailed information on fenders.

6-9 PIER FITTINGS.

Standard pier and wharf mooring fittings, as shown in Figure 6-3, include:

- Bollards
- Bitts
- Cleats

Cleats are not recommended for ships, unless absolutely necessary, because they are low capacity.

Some of the fittings commonly used on U.S. Navy piers are summarized in Table 6-11. Guidance for placing pier fittings in pier/wharf design is given in UFC 4-152-01, *Piers and Wharves*. Guidance for inspecting pier fittings is given in UFC 4-150-08, *Inspection of Mooring Hardware*.

Figure 6-3 Pier and Wharf Mooring Fittings Shown in Profile and Plan Views

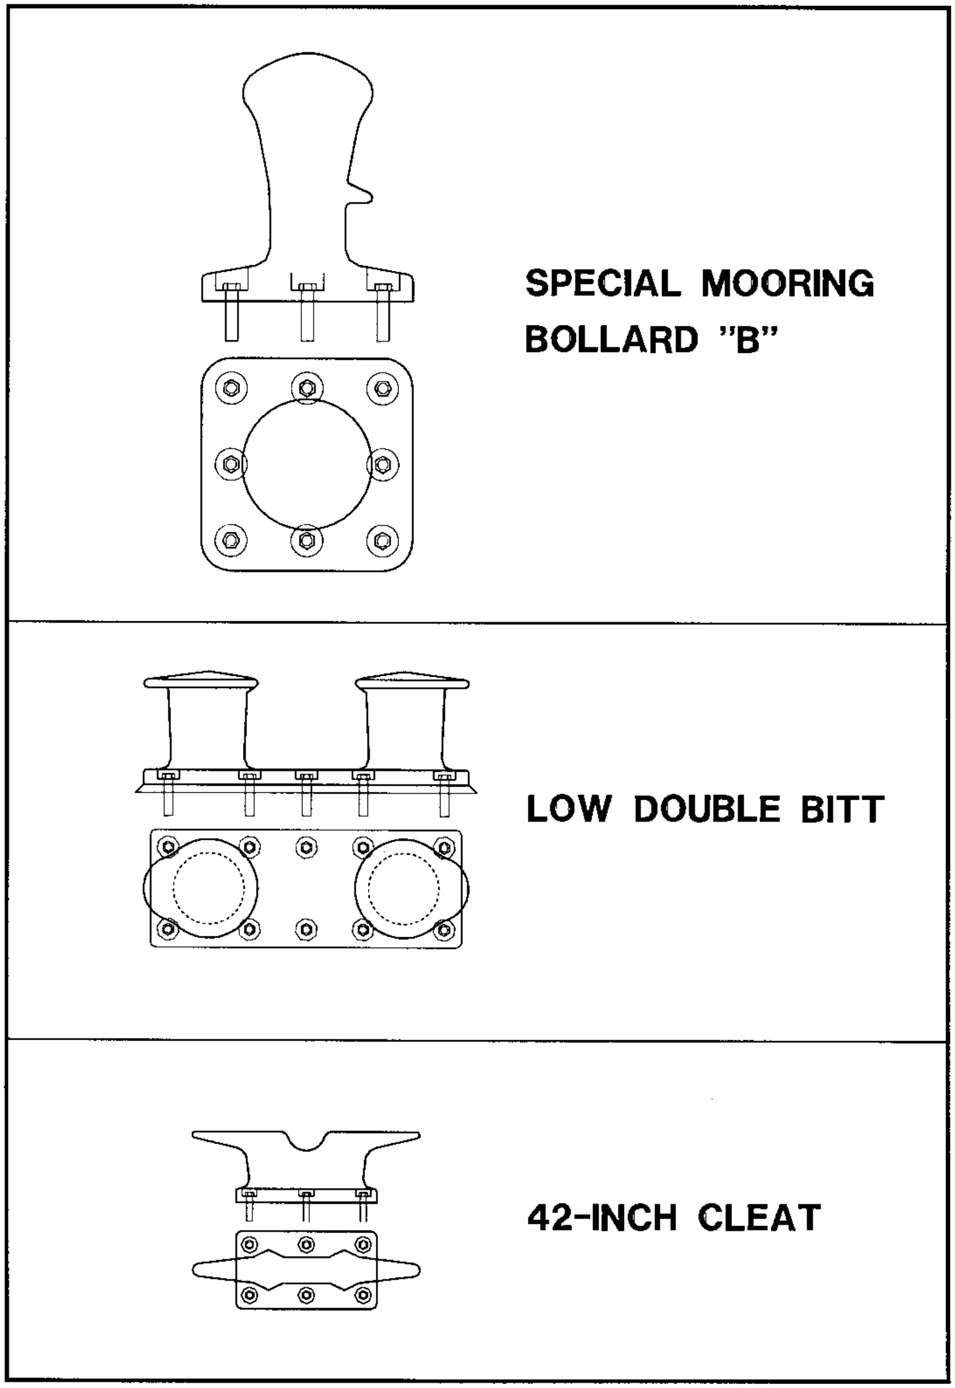

Table 6-11 Commonly Used U.S. Navy Pier Mooring Fittings

Description	Size		Bolts		Working Capacity		
	Height	Base	#	Dia.	Horz.	@ 45°	Nominal
	inch	inch		inch	kips		
Special Mooring Bollard "A"	48	48 x 48	12	2.75	660	430	450
Special Mooring Bollard "B"	44.5	39 x 39	8	2.25	270	216	200
Large Bollard with Horn	44.5	39 x 39	4	1.75	104	66	70
Large Double Bitt with Lip	26	73.5 x 28	10	1.75			75 [a]
Low Double Bitt with Lip	18	57.5 x 21.5	10	1.625			60 [a]
42 Inch Cleat	13	26 x 14.25	6	1.125			40
30 Inch Cleat	13	16 x 16	4	1.125			20

Note:
[a] Working capacity per barrel; NAVFAC Drawing No. 1404464

It is recommended that all mooring fittings be clearly marked with their safe working capacities on a plate bolted or welded to the base of the mooring device. Additional information concerning the sizes and working capacities of pier and wharf mooring fittings is found in NFESC TR-6014-OCN, *Mooring Design Physical and Empirical Data* and in UFC 4-152-01, *Piers and Wharves*. Also, NAVFAC EXWC assesses the condition of all mooring fittings during its routine pier/wharf inspections U.S. Navy waterfront facilities as part of their comprehensive Waterfront Inspection Program.

NAVFAC EXWC also has the capability to perform pull tests to proof the fittings if needed.

6-10 CATENARY BEHAVIOR.

It is not desirable or practical to moor a ship rigidly. For example, a ship can have a large amount of buoyancy, so it usually must be allowed to move with changing water levels. Another problem with holding a ship too rigidly is that some of the natural periods of the ship/mooring system can become short, which may cause dynamic problems.

A ship can be considered a mass and the mooring system as springs. During mooring design, the behavior of the mooring 'springs' can be controlled to fine tune the ship/mooring system behavior to achieve a specified performance. This can be controlled by the weight of chain or other tension member, scope of chain, placement of sinkers, amount the anchor penetrates the soil, and other parameters. The static behavior of catenaries can be modeled using the computer program CSAP2 (NFESC CR-6108-OCN, *Anchor Mooring Line Computer Program Final Report, User's Manual* *for Program CSAP2*). This program includes the effects of chain and wire rope interaction with soils, as well as the behavior of the catenary in the water column and above the water surface.

As an example, take the catenary shown in Figure 6-4. This mooring leg consists of four sections. The segment next to the anchor, Segment 1, consists of wire rope, followed by three segments of chain. Sinkers with the shown in-water weight are located at the ends of Segments 2 and 3. In this example, a plate anchor is driven 55 ft (16.8 m) into mud below the seafloor. The chain attachment point to the ship is 64 ft (19.5 m) above the seafloor. The mooring leg is loaded to its design horizontal load of H = 195 kips (867 kN) to key and proof load the anchor soon after the anchor is installed. The keying and proofing correspond to a tension in the top of the chain of approximately 210 kips (934 kN). Figure 6-5 shows the shape of the chain catenary predicted by CSAP2 for the design load.

The computed load/deflection curve for the design water level for this mooring leg, after proofing, is shown in Figure 6-5. The shape of this and the other mooring legs in this mooring, which are not shown, will strongly influence the static and dynamic behavior of the ship/mooring system during forcing.

Figure 6-4 Sample Catenary

Segment	Type	Dia. (inch)	Weight (lb/ft)	Length (ft)	Sinker (kips)
1	W	3.00	13.15	30	0
2	C	2.75	62.25	156	13.35
3	C	2.75	62.25	15	17.8
4	C	2.75	62.25	113	0

6-11 SOURCES OF INFORMATION.

Detailed NAVFAC information, including drawings, specifications, and manuals, is available in the Whole Building Design Guide (https://www.wbdg.org/). Further information can be obtained from the NAVFAC Engineering Criteria and Programs Office and the NAVFAC EXWC Moorings Center of Expertise. A list of sources for information on facility mooring equipment is provided in Table 6-12.

Table 6-12 Sources of Information for Facility Mooring Equipment

Item	Source

NAVMOOR anchors	NFESC purchase description of Nov. 1985 and drawing package of July 1990.
Stud link chain anodes	NFESC purchase description of June 1990.

CHAPTER 7 VESSEL MOORING EQUIPMENT GUIDELINES

7-1 INTRODUCTION.

A vessel must be provided with adequate mooring equipment to meet its operational and design requirements. This equipment enables the ship to anchor in a typical soil under design environmental conditions. In addition, the ship can moor to various piers, wharfs, fleet moorings, and other facilities. Equipment on board the ship must be designed for MSTs I, II, and III, as discussed in Section 3-1 entitled, *Design Approach*. Additional mooring hardware, such as specialized padeyes, mooring chains, wire ropes, and lines, can be added for MST IV situations.

7-2 TYPES OF MOORING EQUIPMENT.

Basic shipboard mooring equipment is summarized in Table 7-1. Additional information is provided in NAVSEA NSTM Chapters 581, 582, 611 and 613; from Naval Sea Systems Command drawings and publications; Cordage Institute, *Modeling the Long-Term Fatigue Performance of Fibre Ropes*, Hearle et al. (1993); Oil Companies International Marine Forum (OCIMF), *Mooring Equipment Guidelines* (2018); OCIMF *Recommendations for Equipment Employed in the Bow Mooring of Conventional Tankers at Single Point Moorings* (2007); OCIMF *Single Point Mooring Maintenance and Operations Guide* (2015); and *Fatigue of SPM Mooring Hawsers*, Parsey (1982), *Handbook of Fibre Rope Technology*, McKenna et al. (2006) and Tension Technology International Publications, https://www.tensiontech.com/papers.

7-3 EQUIPMENT SPECIFICATION.

Whenever possible, standard equipment is used on board ships as mooring equipment. The specification, size, number, and location of the equipment is selected to safely moor the ship. Some of the many factors that need to be considered in equipment specification are weight, space required, interaction with other systems, power requirements, reliability, maintenance, inspection, strength of supporting structures and cost.

7-4 FIXED BITTS.

Bitts provide a termination for tension members. Fixed bitts, Figure 7-1, are typically placed in pairs within a short distance forward or aft of a chock location. They are often placed symmetrically on both the port and starboard sides, so that the ship can moor to port or starboard. Capacities of the bitts are based on their nominal diameter. Table 7-1 provides fixed bitt sizes with their associated capacities. The basic philosophy for bitts use is that mooring lines should part well below the structural yield of the double bits in MSTs I and II to minimize the chance that ship’s mooring fittings need to be repaired. In MST III ‘Heavy Weather Mooring’ is designed to keep the ship moored as safely as possible, so the working capacities of the mooring lines can approximately equal the working capacities of the ship’s double bitts.

7-5 RECESSED SHELL BITTS.

Recessed shell bitts, Figure 7-2, are inset into ships' hulls well above the waterline. These bitts are used to moor lighterage or harbor craft alongside. They also assist in mooring at facilities. The standard NAVSEA shell bitt has a total working capacity of 92 kips (409 kN) with two lines of 46 kips (205 kN) maximum tension each.

7-6 EXTERIOR SHELL BITTS.

Aircraft carriers have exterior shell bitts, NAVSEA Drawing No. 600-6601101, that are statically proof loaded to 184 kips (818 kN). This proof load is applied 11 inches (280 mm) above the base. This testing is described in the Newport News Shipbuilding testing report for USS HARRY S TRUMAN *Bitts, Chocks and Mooring Rings.*

7-7 CHOCKS.

There are many types of chocks, such as closed chocks, Panama chocks, roller chocks, and mooring rings. Closed chocks are often installed on military vessels and characteristics of these fittings are shown in Table 7-3.

7-8 ALLOWABLE HULL PRESSURES.

As a ship berths or when it is moored, forces may be exerted on the hull by structures such as fenders, camels, and dolphins, on the ship hull. NFESC TR-6015-OCN, *Foam-Filled Fender Design to Prevent Hull Damage* provides a rational design criteria to prevent yielding of vessel hull plating. Additional information on a vessel's allowable hull pressures is available from the naval architect or ship builder.

7-9 SOURCES OF INFORMATION FOR SHIPS' MOORING EQUIPMENT.

Additional information is available from the Naval Sea Systems Command (NAVSEA 03P), NSWCCD-SSES, Military Sealift Command (MSC), and the U.S. Coast Guard (USCG). Table 7-4 provides a list of selected referenced materials.

Table 7-1 Types of Ship Based Mooring Equipment [a]

Equipment	Description
Drag embedment anchors	One or more anchors required. See CHAPTER 5 for anchor information.
Anchor chain	Stud link grade 3 chain (see the paragraph entitled “Chain and Fittings”) is used.
Anchor windlass/wildcat and associated equipment	Equipment for deploying and recovering the anchor(s), including the windlass(s), hawse pipe(s), chain stoppers, chain locker, and other equipment.
Mooring Attachment Points	Bitts and cleats for securing mooring lines.
Chocks, mooring rings and fairleads	Fittings through which mooring lines are passed.
Padeyes	Padeyes are provided for specialized mooring requirements and towing.
Mooring lines	Synthetic lines for mooring at piers, wharfs, and other structures. See the paragraph entitled, “Mooring Lines” for information.
Wire ropes	Wire rope is sometimes used for mooring tension members.
Fenders	Marine fenders, as discussed in the paragraph entitled, “Fenders”, are sometimes carried on board.
Winches and Capstans	Winches of various types can support mooring operations. Some ships use constant tension winches with wire rope automatically paid out/pulled in to adjust to water level changes and varying environmental conditions. Fixed-length synthetic spring lines are used in pier/wharf moorings that employ constant tension winches to keep the ship from ‘walking’ down the pier. A capstan is a form of winch mounted on a vertical axis used to aid in line handling.
Other	Various specialized equipment is carried to meet needs (such as submarines).

Note:

[a] See NAVSEASYSCOM Naval Ships’ Technical Manual for additional information and in the paragraph entitled, “Design Approach” for design criteria.

CHAPTER 8 EXAMPLE PROBLEMS

8-1 INTRODUCTION.

The design of mooring systems is illustrated through the use of several examples in this section. The emphasis of this UFC is on statics, so static results are shown. However, the marine environment can be dynamic, so dynamic effects are illustrated in the examples.

8-2 SINGLE POINT MOORING - BASIC APPROACH.

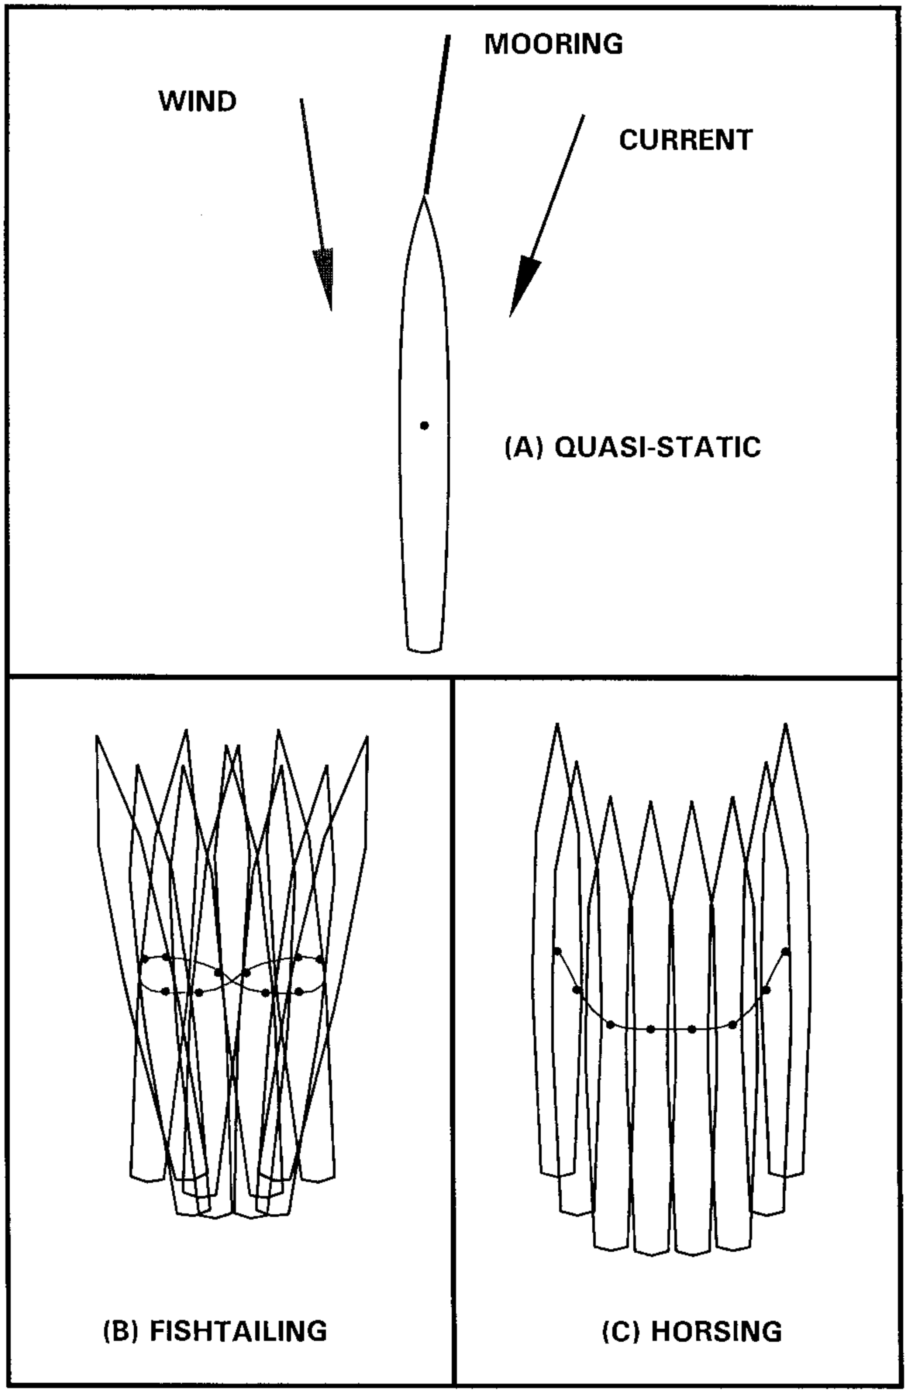
Design of single point fleet moorings (SPMs) is illustrated here.

Assuming the wind is coming from a specified direction and has stationary statistical properties. The current speed and direction are constant. In this case there are three common types of ship behavior, shown in Figure 8-1, that a vessel at a single point mooring can have:

- Quasi-static: In this case the ship remains in approximately a fixed position with the forces and moments acting on the ship in balance. For quasi-static behavior, the tension in the attachment from the ship to mooring will remain approximately constant. Quasi-static analyses can be used for design in this case.
- Fishtailing: In this case the ship undergoes significant surge, sway, and yaw with the ship center of gravity following a butterfly-shaped pattern. The mooring can experience high dynamic loads, even though the wind and current are constant.
- Horsing: In this case the ship undergoes significant surge and sway with the ship center of gravity following a U-shaped pattern. The mooring can experience high dynamic loads.

These cases show that the type of behavior of a given ship at a given single point mooring in a given environment can be very complex (Wichers, 1988), even though the wind and current are steady. It is recommended that a dynamic stability analysis first be conducted (Wichers, 1988) at the early stages of single point mooring design. Then the type of analysis required can be determined. The results from this analysis will suggest what type of method should be used to design a single point mooring. These methods are complex and beyond the scope of this UFC. Behavior of single point moorings is illustrated by example.

Figure 8-1 Some Types of Behavior of Ships at Single Point Moorings



8-2.1 Background for Example.

In this example two moorings were designed and installed. The original designs were based on quasi-static methods. Ships moored to these buoys broke their mooring hawsers when a wind gust front struck the ships. In this example, the design and hawser failures are reviewed. The effects of wind dynamics on a single point mooring are illustrated.

8-2.2 Ship.

A single 2nd LT JOHN P. BOBO (T-AK 3008) class ship was moored at each of two fleet mooring buoys. Table 8-1 gives basic characteristics of the ship.

Table 8-1 2nd LT JOHN P BOBO Parameters (Fully Loaded)

Parameter	Design Basis (English Units)	Design Basis (SI Units)
Length Overall	633.76 ft	193.2 m
Length at Waterline	614.58 ft	187.3 m
Length Between Perpendiculars	614.58 ft	187.3 m
Beam at Waterline	32.15 ft	9.80 m
Draft	32 ft	9.75 m
Displacement	46,111 LT	4.69 x10^7 kg
Line Size (2 nylon hawsers)	12 in.	300 mm

8-2.3 Forces/Moments.

In this case the design wind speed is 45 knots (23 m/s). Currents, waves, and tidal effects are neglected for these ‘fair weather’ moorings. The bow-on ship wind drag coefficient is taken as the value given for normal ships of 0.7, plus 0.1 is added for a clutter deck to give a drag coefficient of 0.8. Methods in Section 4 are used to compute the forces and moments on the ship. The computed bow-on wind force is 68.6 kips (300 kN) for 45 knot (23 m/s) winds, as shown in Figure 8-2.

8-2.4 Quasi-Static Design.

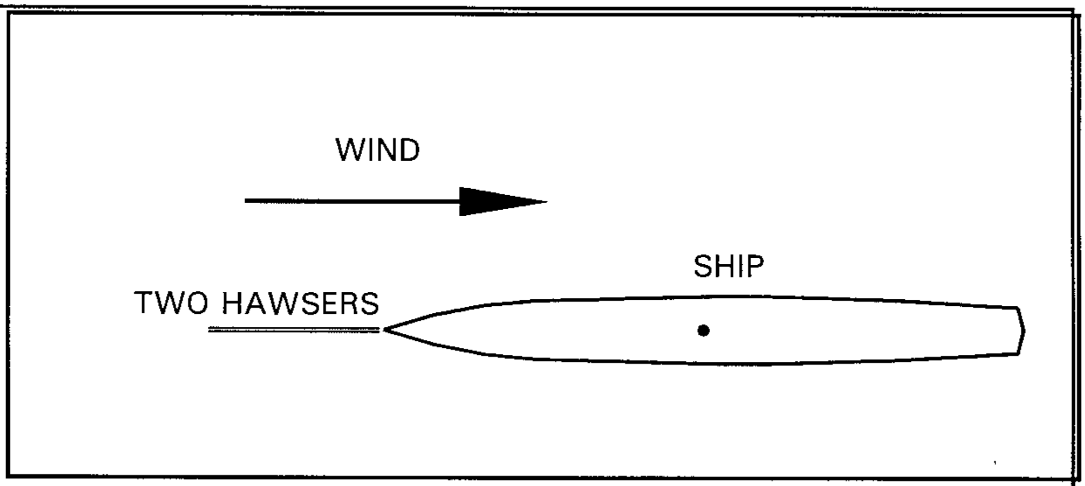
Quasi-static design procedures place the ship parallel to the wind for this example, because in this position the forces and moments on the ship are balanced out. Two mooring hawsers were specified for this design. Extra factor of safety was specified for the two 12 inch nylon mooring hawsers, which had a new wet breaking strength of 406 kips (180 kN), to account for poor load sharing between the two hawsers.

8-2.5 Mooring Hawser Break.

The ships were moored and faced into 15 knot (7.71 m/s) winds. The weather was unsettled, due to two nearby typhoons, so the ships had their engines in idle. A wind gust front struck very quickly with a wind speed increase from 15 to 50 knots (23 to 25.7 m/s). As the wind speed increased, the wind direction changed 90 degrees, so the higher wind speed hit the ships broadside. The predicted peak dynamic tension on the mooring hawsers was 1,140 kips (507 kN), (Seelig and Headland, 1998). Figure 8-3 is a simulation predicting the dynamic behavior of the moored ship and hawser tension. In this case, the mooring hawsers broke and the predicted factor of safety dropped to less than 1. In this event, the peak dynamic tension on the mooring hawser is predicted to be 13.5 times the bow-on wind force for 50 knot (25.7 m/s) winds.

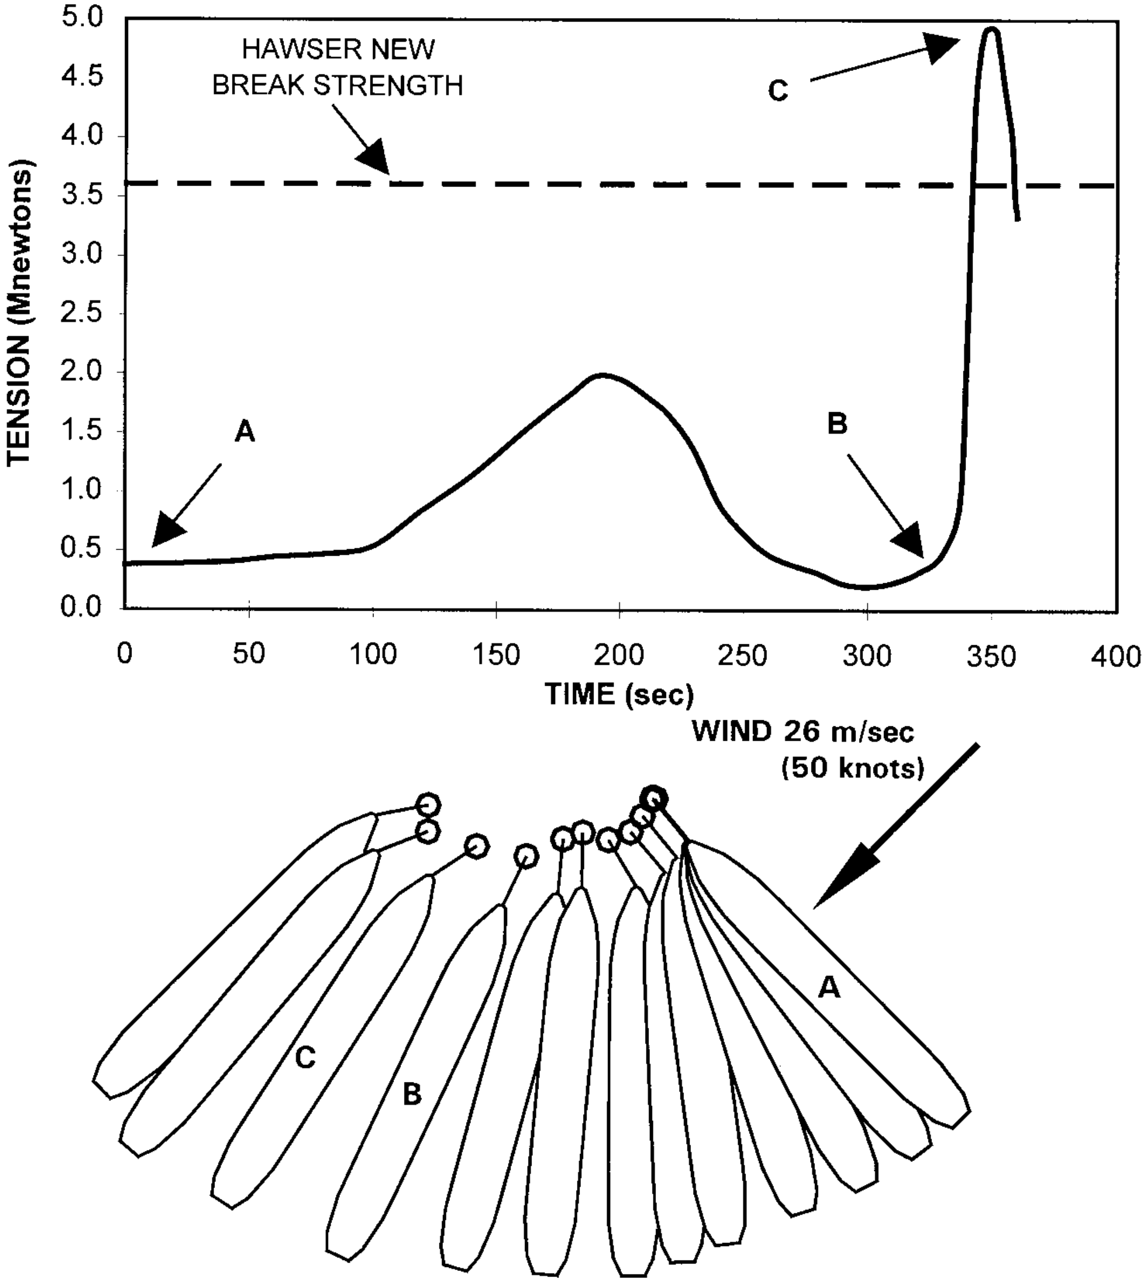
This example shows that single point moorings can be susceptible to dynamics effects, such as those caused by wind gust fronts or other effects.

Figure 8-2 Example Single Point Mooring



CONDITION	*BOW-ON SHIP WIND LOAD*	*F.S. FOR 1 HAWSER*	*F.S. FOR 2 HAWSERS*
45-KNOT WIND	68.5 KIPS	5.9	11.9
50-KNOT WIND	84.5 KIPS	4.8	9.6

Figure 8-3 Example Mooring Failure Due to a Wind Gust Front



Predicted ship positions at 30 second intervals.

8-3 FIXED MOORING - BASIC APPROACH.

Development of a design concept for a fixed mooring, a mooring that includes both tension and compression members, is illustrated here.

8-3.1 Background for Example.

Several new aircraft carrier berthing wharf facilities are being programmed. Users expressed concerns regarding the possibility of excessive ship movement. Wind is the major environmental parameter of concern. Assume the proposed sites have small tidal ranges and tidal currents.

8-3.2 Goal.

Develop a concept to moor USS NIMITZ (CVN 68) class ships at newly constructed wharves. Assume the Mooring Service Type is II and the design wind speed is 75 mph (33.5 m/s).

8-3.3 Ship.

Fully loaded USS NIMITZ (CVN 68) class ships are used in this example. Table 8-2 gives some ship parameters. Refer to UFC 4-152-01, *Piers and Wharves* for additional ship data.

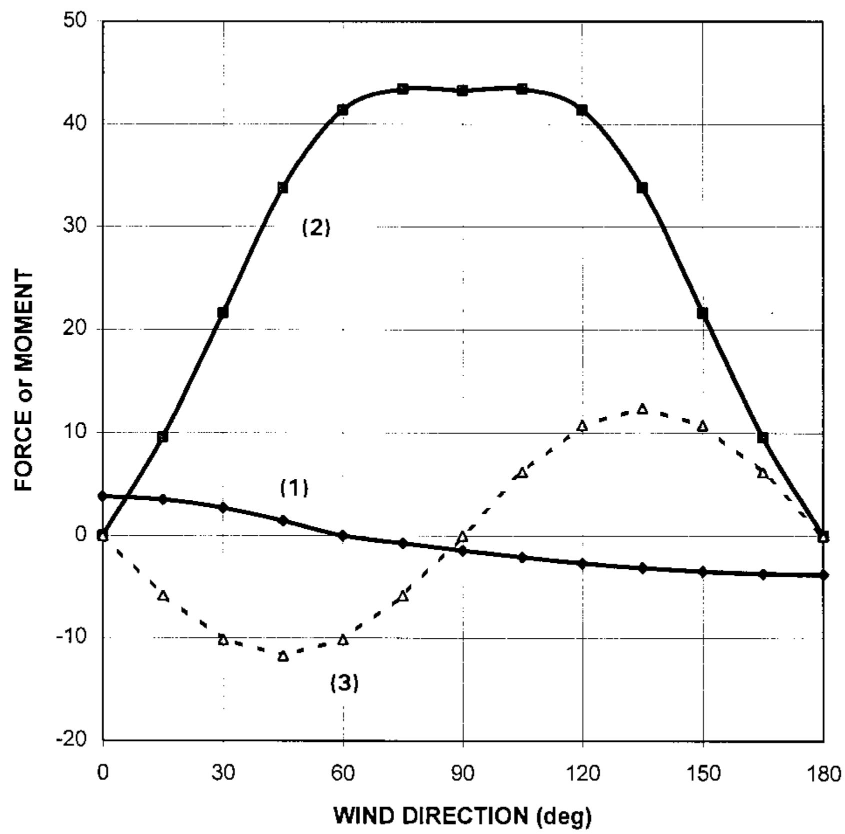
Table 8-2 CVN 68 Criteria (Fully Loaded)

Parameter	Design Basis (English Units)	Design Basis (SI Units)
Length Overall	1,092 ft	332.8 m
Length at Waterline	1,040 ft	317.0 m
Beam at Waterline	134 ft	40.8 m
Draft	37.91 ft	11.55 m
Displacement	91,700 LT	93,171,502 kg
Bitt Size	12 inch	305 mm
Line Size (nylon)	8 and 9 inch	203 and 229 mm

8-3.4 Forces/Moments.

Methods in CHAPTER 4 are used to compute the forces and moments on the ship. These values are summarized in Figure 8-4.

Figure 8-4 Wind Forces and Moments on a Single Loaded CVN 68 for a 75 mph Wind



PARAMETER	*CURVE*	*GRAPH UNITS*	*MAX. VALUE*
F_{xw}	(1)	E5 N	84.6 kips
F_{yw}	(2)	E5 N	975.5 kips
M_{xyw}	(3)	E7 N-m	91421 kip-ft

8-3.5 Definitions.

In this example we define a global coordinate system with “X” parallel to the wharf, as shown in Figure 8-5. Then “Y” is a distance perpendicular to the wharf in a seaward direction and “Z” is a vertical distance. Let “Pt 2” be the ship chock coordinate and “Pt 1” be the pier fitting. A spring line is defined as a line whose angle in the horizontal plane is less than 45 degrees and a breasting line whose angle in the horizontal plane is greater than or equal to 45 degrees, as shown in Figure 8-5.

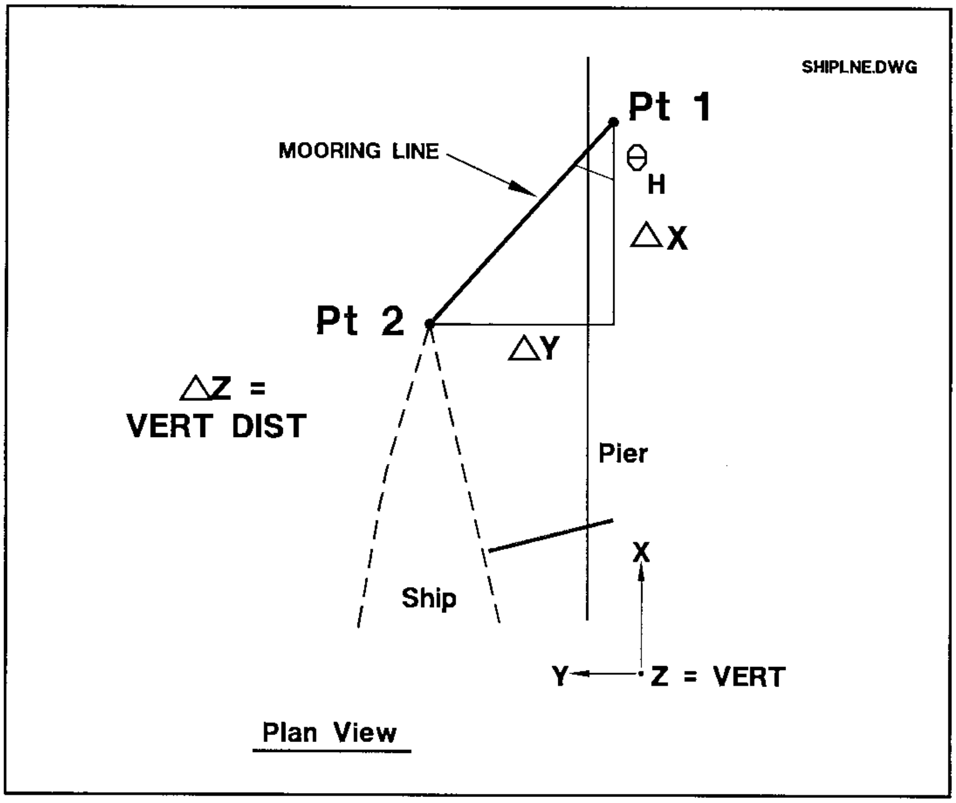
8-3.6 Preliminary Analysis.

The first step for fixed mooring design is to analyze the mooring requirements for the optimum ideal mooring shown in Figure 8-6. Analyzing the optimum ideal arrangement is recommended because: (1) calculations can be performed by hand and; (2) this simple arrangement can be used as a standard to evaluate other fixed mooring configurations (NFESC TR-6005-OCN, *EMOOR - A Planning/Preliminary Design Tool for Evaluating Ship Mooring at Piers and Wharves.)*

The optimum ideal mooring shown in Figure 8-6 consists of two spring lines, Lines 1 and 4, which are assumed to resist longitudinal forces. There are two breast lines, Lines 2 and 3, which are assumed to resist lateral forces and moments for winds with directions from 0° to 180°. Fenders are not shown. All lines are assumed to be parallel to the water surface in the ideal mooring.

A free body diagram is made of the optimum ideal mooring for a loaded CVN 68 in 75 mph (33.5 m/s) winds. It is found that the sum of the working mooring capacity required for Lines 1 and 4 is 174 kips (774 kN) and the sum of the working mooring capacity required for Lines 2 and 3 is 1,069 kips (4,760 kN), as shown in Figure 8-7. No working line capacity is required in the ‘Z’ direction, because the ship’s buoyancy supports the ship. The sum of all the mooring line working capacities for the optimum ideal mooring is 1,243 kips (5,529 kN).

Figure 8-5 Definitions



DEFINITIONS:

$$\Theta_H = \tan^{-1} \left| \frac{\Delta Y}{\Delta X} \right|$$

$$\Theta_V = \tan^{-1} \left| \frac{\Delta Z}{\Delta Y} \right|$$

IF $|\Theta_H| < 45$ deg → SPRING LINE

IF $|\Theta_H| \geq 45$ deg → BREASTING LINE

Figure 8-6 Optimum Ideal Mooring

(Lines are parallel to the water surface and breasting lines are spaced one-half ship's length from midships)

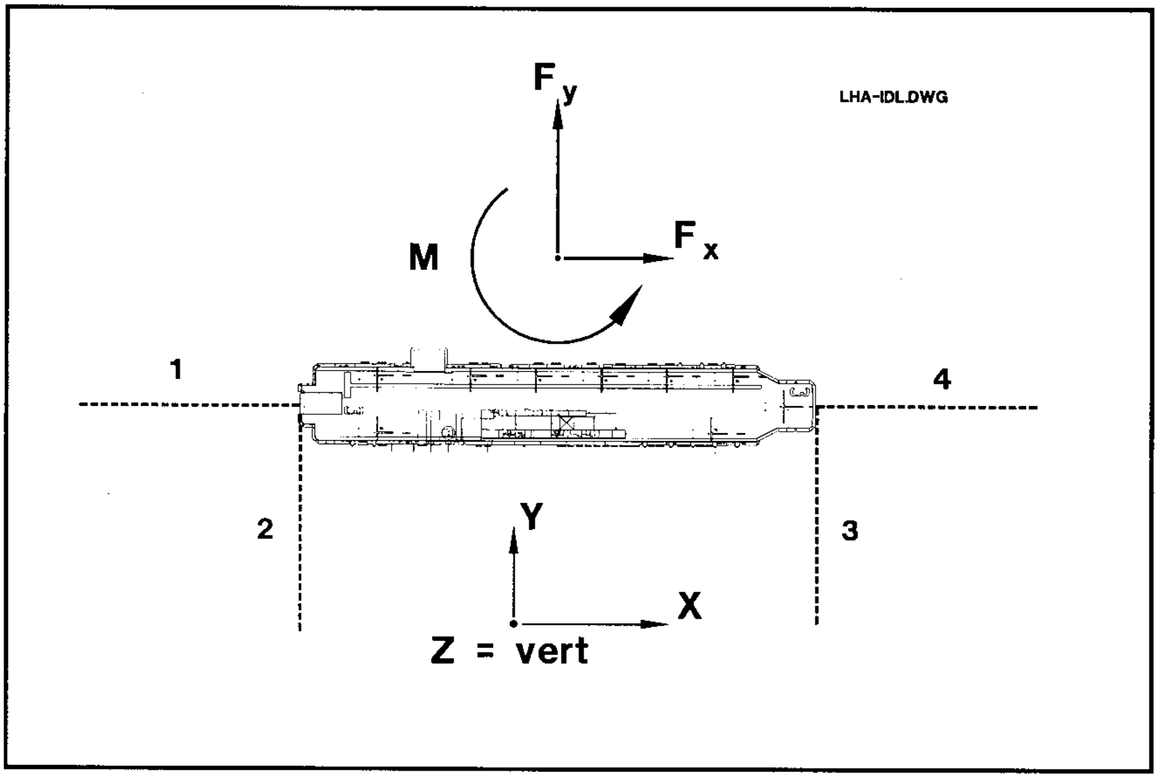


Figure 8-7 Required Mooring Capacity Using the Optimum Ideal Mooring

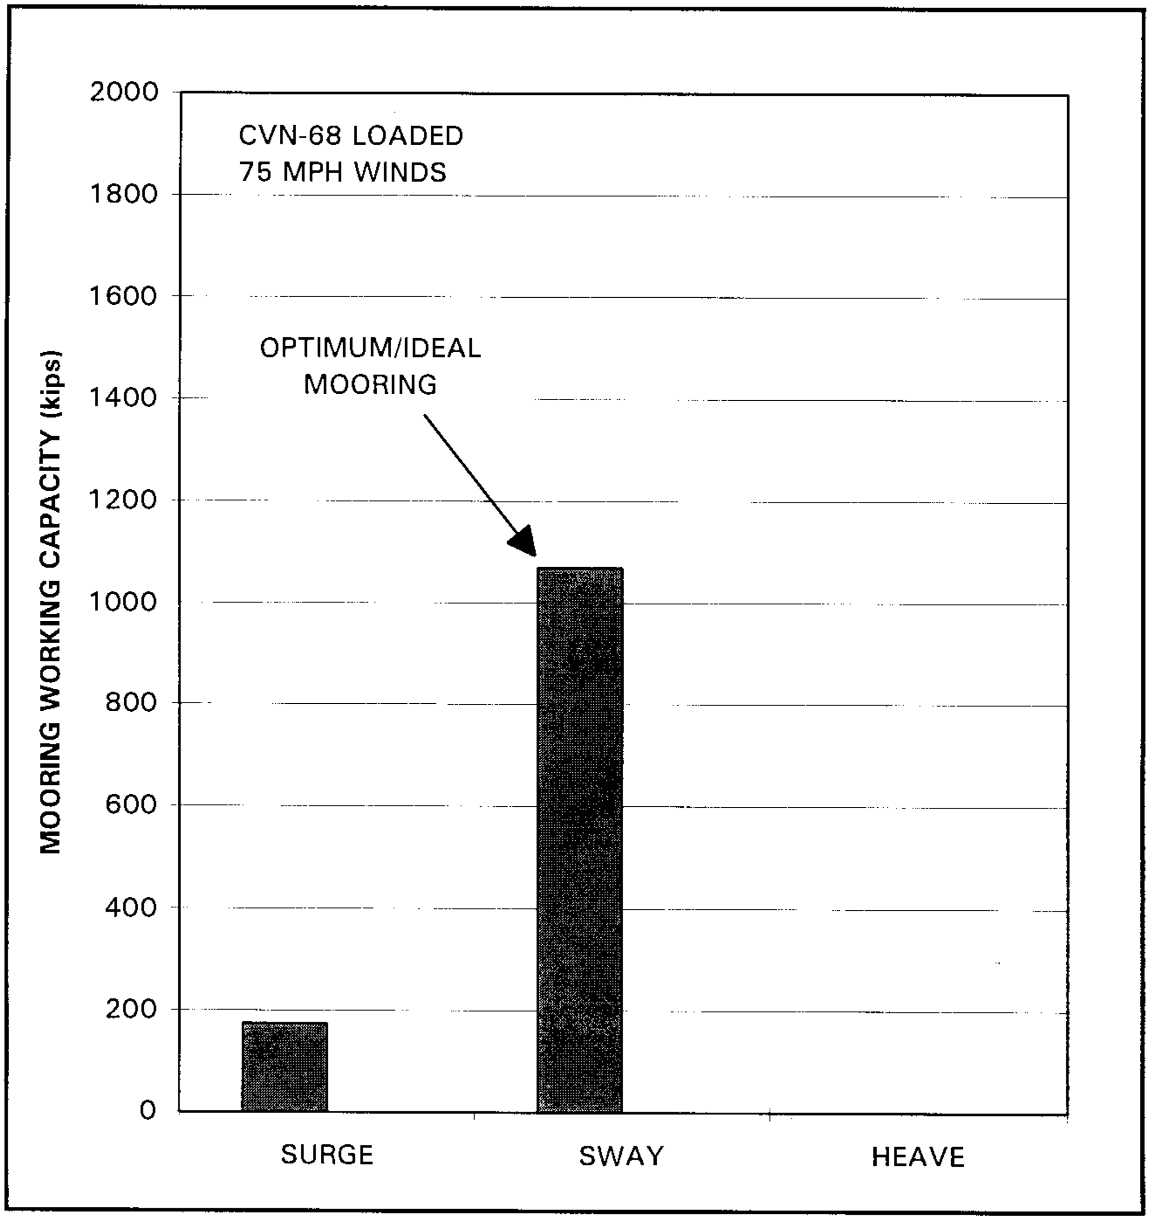

8-3.7 Wharf Mooring Concept.

Camels and fenders are located between the wharf and ship to offset the ship in this design. Also, the wharf breasting line bollards are set back from the face of the wharf, so that the vertical angles of the breasting lines are approximately 10 degrees. Figure 8-8, from a study of a number of ship moorings at piers and wharves (NFESC TR-6005-OCN) is used to estimate that a mooring system using synthetic lines will have an efficiency of approximately 0.67 for the case of breasting lines with a 10-degree vertical angle. The estimated total required working mooring line capacity is the working line capacity of the optimum ideal mooring divided by the efficiency. In this case, the estimated working line capacity required is 1,243 kips/0.67 or approximately 1,855 kips (8,250 kN).

For extra safety, the selected concept 'Model 2' is given 11 mooring lines of three parts each of aramid mooring line, as shown in Figure 8-9. A single part of line is taken as having a break strength of 215 kips (920 kN). These lines have a combined working strength of 11 lines x 3 parts x 215 kips / 3 = 2,365 kips (10,520 kN) with a factor of safety of 3. These lines are selected to provide extra safety. A component analysis, Figure 8-10, suggests that this mooring concept has adequate mooring line capacity in the surge and sway directions.

Quasi-static analyses are performed by computer using a fixed mooring software program (ANSYS, *ANSYS-AQWA Reference Manual*). Analyses are performed for various wind directions around the wind rose. Results show that the mooring line factors of safety are larger than the required minimum of 3 (i.e. line tensions divided by the new line break strength is less than 0.33), as shown in Figure 8-11. In this concept the spring lines are especially safe with a factor of safety of about 10. These analyses show ship motions of approximately 1 foot (0.3 m) under the action of the 75 mph (33.5 m/s) design winds.

Further quasi-static analyses show this concept is safe in up to 87-mph (38.9-m/s) winds with a factor of safety of 3 or more on all the mooring lines. The computed mooring efficiency for 'Model 2' at this limiting safe wind speed is 0.705, which is slightly higher than the estimated value of 0.67, as shown in Figure 8-5.

These preliminary calculations show that this fixed mooring concept could safely secure the ship. Figure 8-12 illustrates the mooring concept in perspective view. Further information on this example is provided in NFESC TR-6004-OCN, *Wind Effects on Moored Aircraft Carriers.*

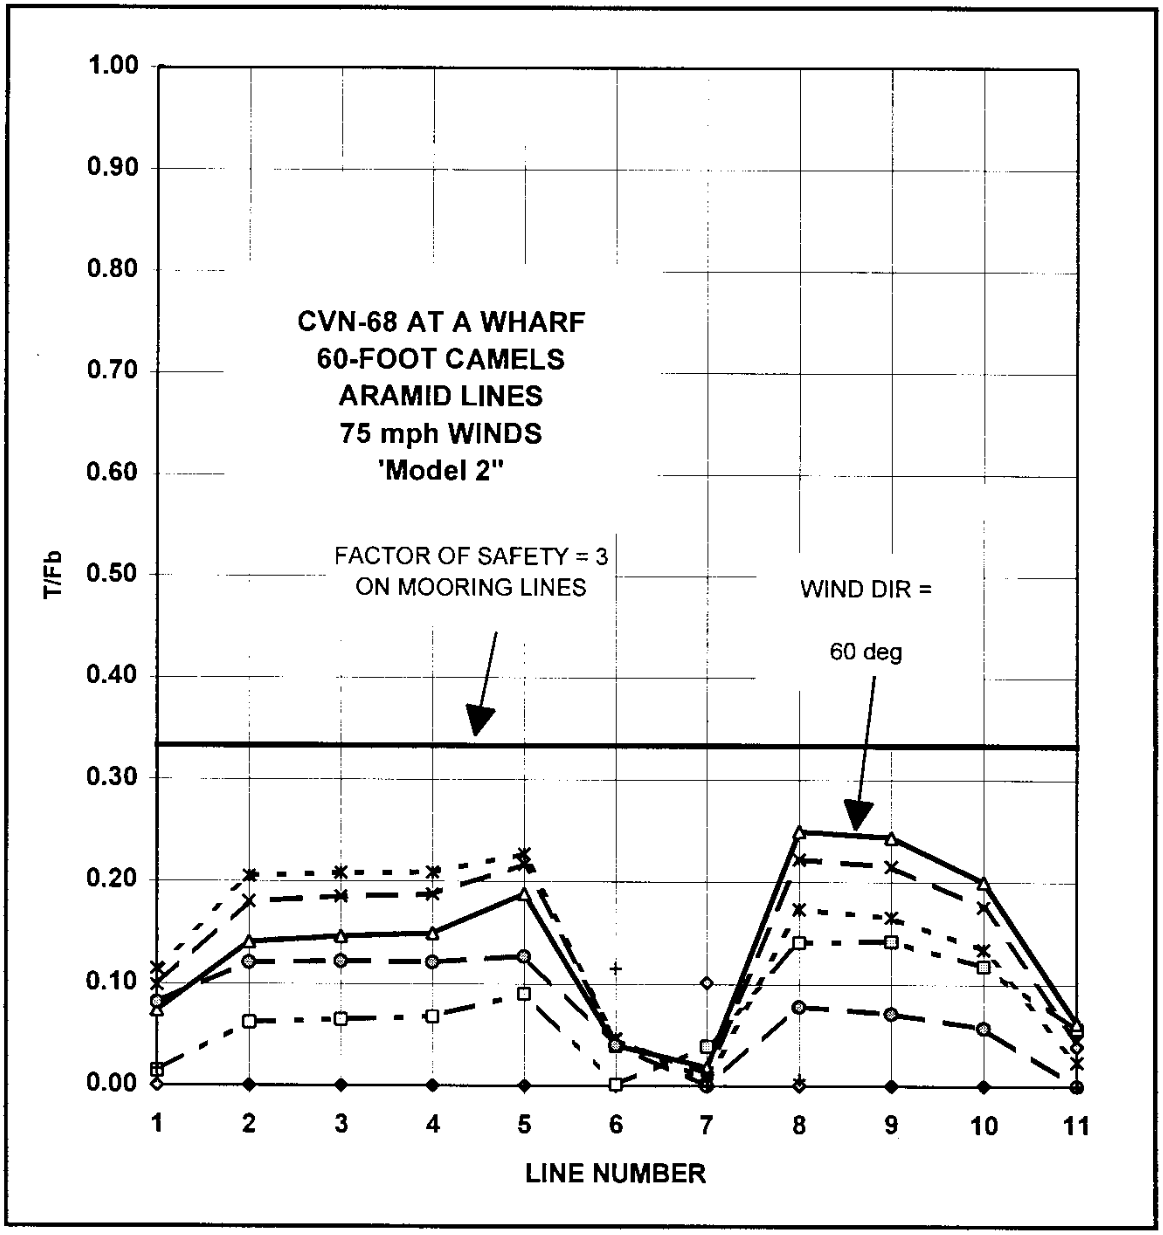

Figure 8-12 Aircraft Carrier Mooring Concept (perspective view)

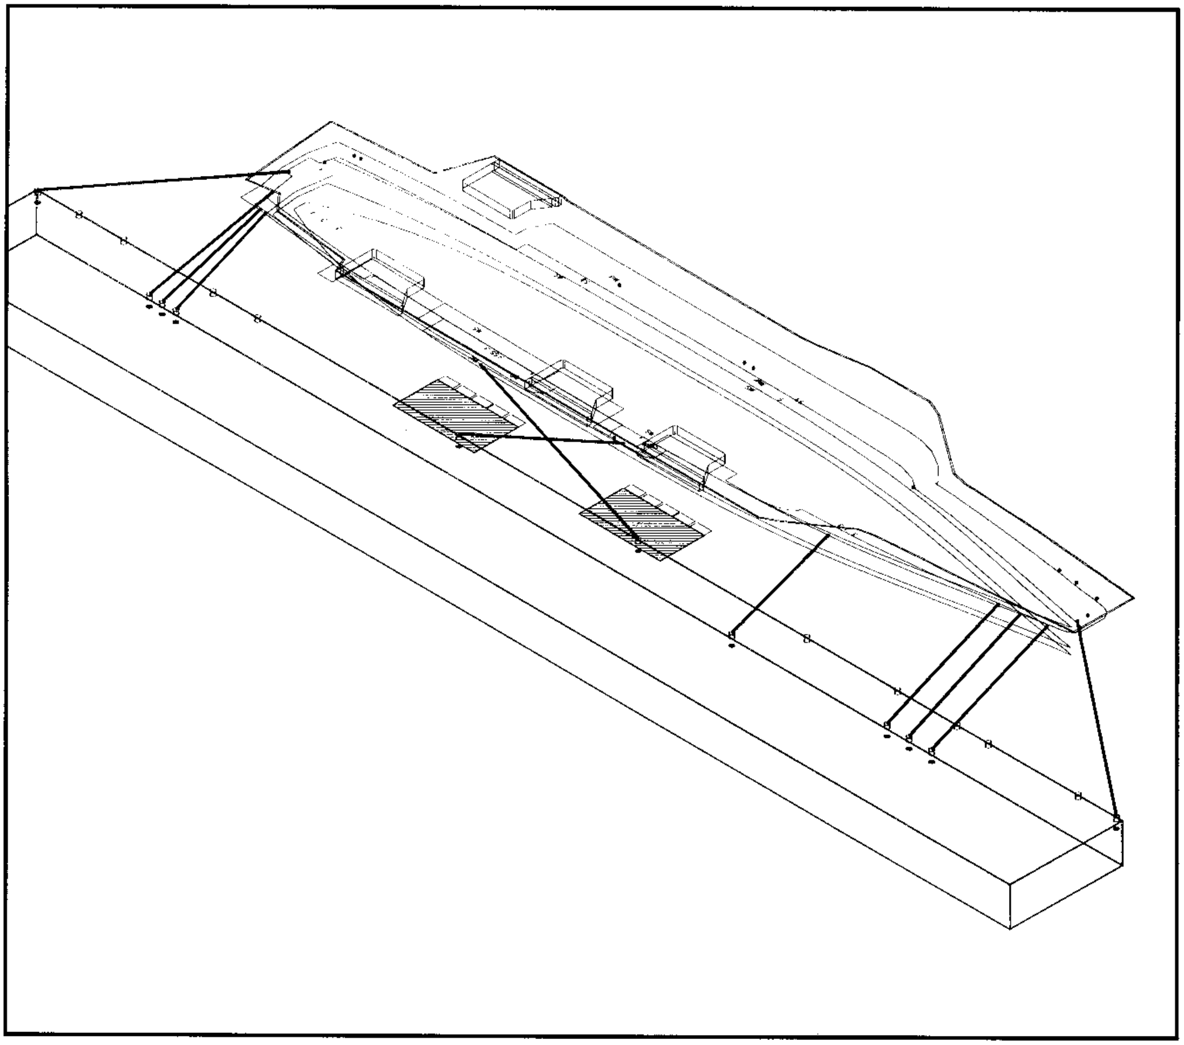


8-4 SPREAD MOORING - BASIC APPROACH.

Design of a spread mooring for a nest of ships is illustrated in this section.

8-4.1 Background for Example.

SPRUANCE class (DD 963) destroyers are scheduled for inactivation and a mooring is required to secure four of these vessels (NFESC SSR-6119-OCN, *D-8 Mooring Upgrade Design Report*). These ships are inactive and cannot go out to sea, so the mooring must safely secure the vessels in a hurricane using Mooring Service Type IV design criteria. At this location, wind is the predominant environmental factor of concern. At this site the tidal range and tidal current are small. Soil conditions at the site consist of an upper soft silty layer between 50 to 80 ft (15 to 24 m) in depth over a stiff clay underneath. Water depth at the site ranges between 31 to 35 ft (9.4 to 10.7 m) MLLW.

8-4.2 Goal.

Develop a concept to moor four DD 963 class destroyers in a spread mooring. Use MST IV criteria and a design wind speed of 78.3 mph (68 knots or 35 m/s).

8-4.3 Ship.

The ships are assumed to be at one-third stores/cargo/ballast condition, since DD 963 vessels are unstable in the light condition. Table 8-3 gives some ship parameters.

Table 8-3 DD 963 Criteria (1/3 Stores)

Parameter	Design Basis (English Units)	Design Basis (SI Units)
Length Overall Length at Waterline	564 ft 529 ft	171.9 m 161.2 m
Beam at Waterline	55 ft	16.8 m
Average Draft Draft at Sonar Dome	21.2 ft 29 ft	6.5 m 8.8 m
Displacement	8,928 LT	9.07×10^6 kg
Chock Height from Baseline	35 ft 52 ft	10.7 m stern 15.9 m bow

8-4.4 Forces/Moments.

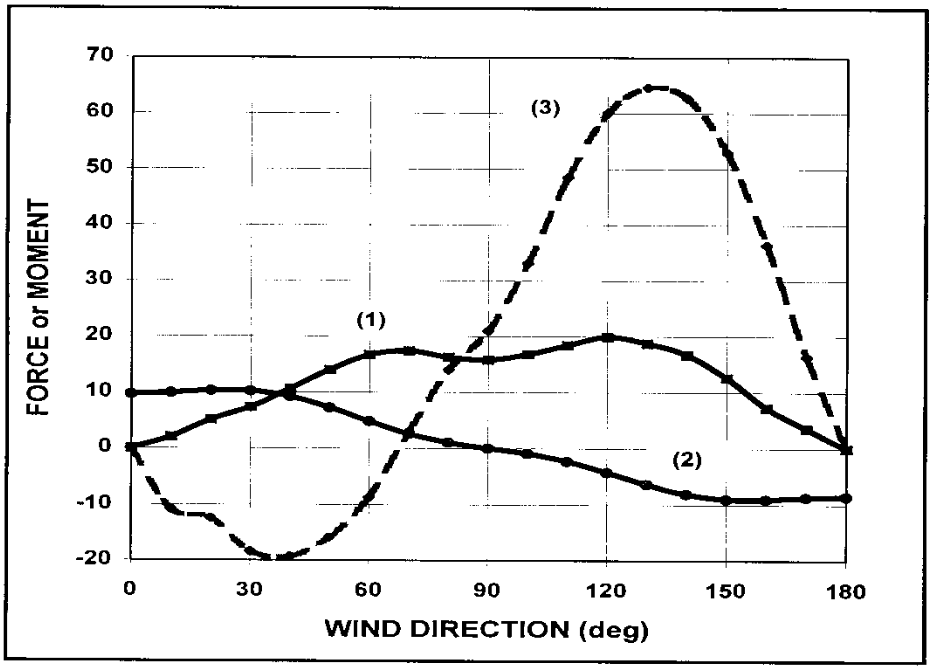
Methods in CHAPTER 4, as well as data in NFESC Report TR-6003-OCN, are used to compute the forces and moments on the ships. These values are summarized in Figure 8-13. Wind angles are based on the local coordinate system for a ship shown inFigure 4-2.

Wind tunnel model tests show that there is significant sheltering in the transverse direction of downwind ships in this nest of identical ships, as shown in NFESC Report TR-6003-OCN. However, there is little wind sheltering in the longitudinal direction. Table 8-4 summarizes the environmental force calculations used for this example.

Table 8-4   Environmental Forces

Condition	Parameter	Load (English Units)	Load (SI Units)
Single DD 963	Transverse Wind	374 kips	1,663.8 kN
	Longitudinal Wind	57.82 kips	257 kN
	Wind-Yaw Moment	26,531 ft-kips	35,972 kN-m
	Transverse Current	23.4 kips	104.2 kN
	Longitudinal Current	0.56 kips	2.5 kN
	Current Yaw Moment	863.1 ft-kips	1,216 kN-m
4 ea DD 963	Transverse Wind	447.4 kips	1,989.9 kN
	Longitudinal Wind	231.3 kips	1,028.7 kN
	Wind-Yaw Moment	47,643 ft-kips	64,595 kN-m
	Transverse Current	42.8 kips	190.6 kN
	Longitudinal Current	2.2 kips	9.8 kN
	Current Yaw Moment	2,372.7 ft-kips	3,342 kN-m

Figure 8-13 Wind Forces and Moments on a Nest of Four DD 963 Class Vessels for a Wind Speed of 78 mph



8-4.5 Anchor Locations.

Driven-plate anchors are selected as a cost-effective method to safely moor the nest of ships. The soils at the site are soft harbor mud of depths between 50 to 80 ft (15 to 24 m), so a chain catenary will form below the seafloor (in the mud) as well as in the water column, as illustrated in Figure 6-4 (Section 6-10). A horizontal distance of 100 ft (30 m) between the anchor location and the chain daylight location (point where the anchor leg chain exits the seafloor) is estimated based on Chain Soil Analysis Program (CSAP) modeling of the chain catenary in the soil and in the water column.

To ensure the mooring legs are efficient in resisting the imposed environmental horizontal forces, a target horizontal distance of 170 ft (52 m) is chosen between the predicted daylight location (where the chain exits the soil) and the attachment point on the ship for each of the mooring legs. Therefore, anchor locations are established at a horizontal distance of 270 ft (82 m) away from the vessel.

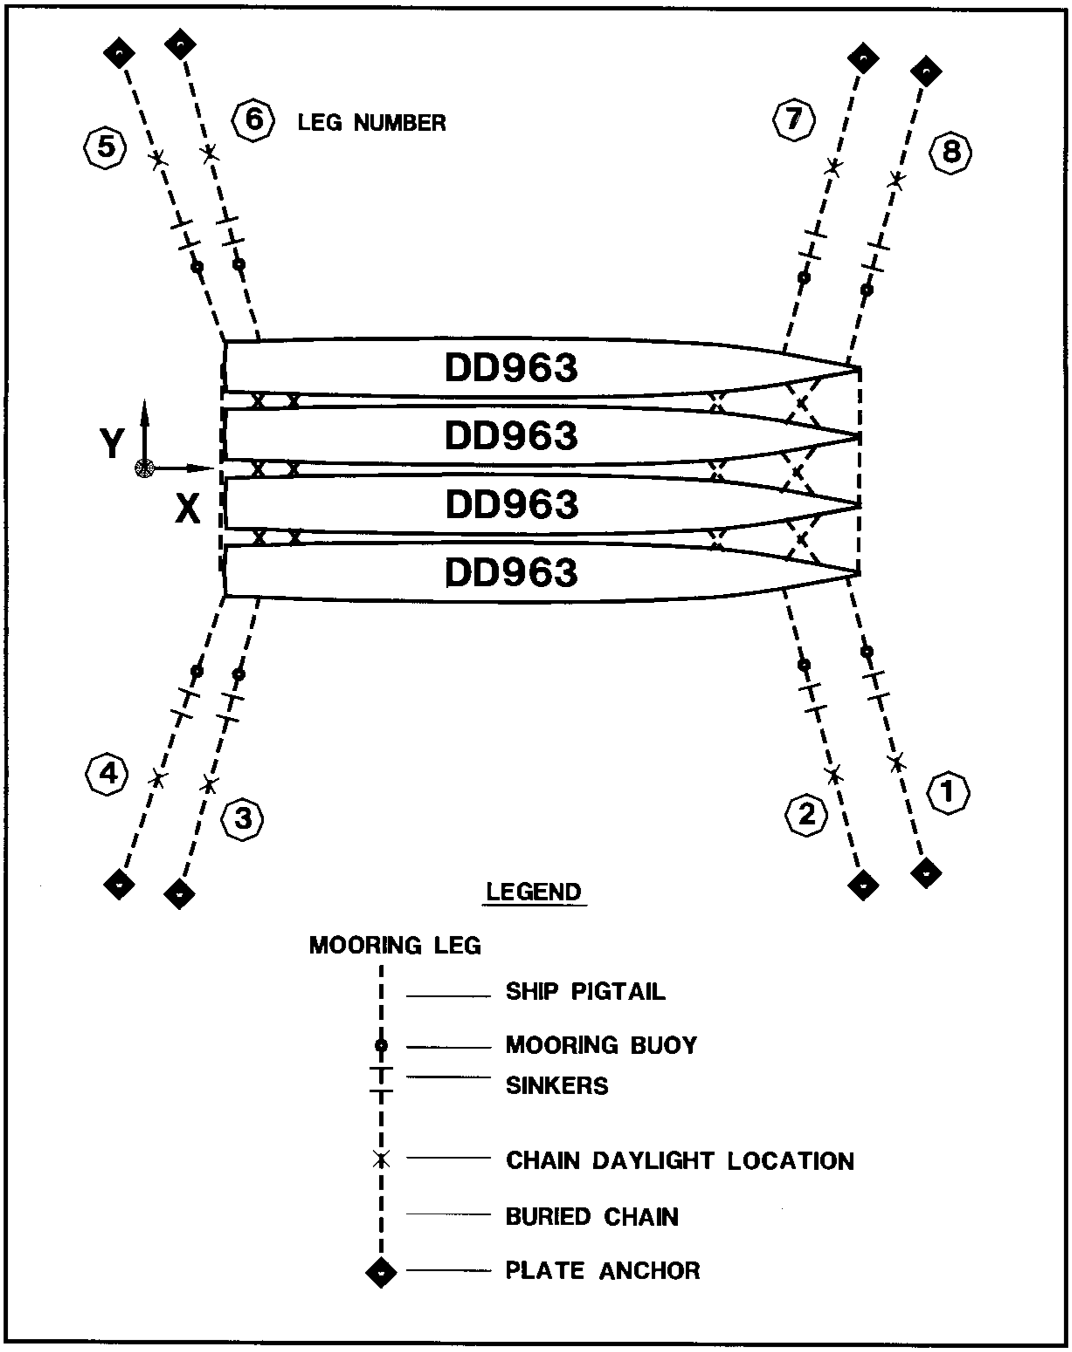
8-4.6 Definitions.

In this example, a local ship and a global coordinate system are defined. The local ship coordinate system is used to determine environmental loads at the various wind and current attack angles, as shown in Figure 4-2, with the origin of the “Z” direction at the vessel keel. A global coordinate system for the entire spread mooring design is selected with the point (0, 0, 0) defined to be at a specific location. For this example, the origin is selected to be in the middle of the vessel nest and 164 ft (50 m) aft of the stern of the vessels. The origin for the “Z” direction in the global coordinate system is at the waterline. This global coordinate system is used by the various analysis programs to define the “chain daylight” locations and the location of the vessel center of gravity within the spread mooring footprint.

8-4.7 Number of Mooring Legs.

It is estimated that eight 2.75 inch (70 mm) chain mooring legs are required, based on the safe working load of the chain (289 kips or 129 kN) and the applied environmental forces and moments on the nest of ships. Four legs are situated on both sides of the nest and each mooring leg is angled to be effective in resisting the longitudinal wind forces, as well as lateral wind forces and moments, from winds approaching at angles other than broadside. Legs are also placed toward the ends of the nest to be effective in resisting the yaw moment. To help control ship motions, two 20 kip (89 kN) sinkers are placed on each mooring leg approximately midway between the vessel attachment point and the predicted chain daylight location. A schematic of the planned spread mooring arrangement is shown in Figure 8-14.

Figure 8-14 Spread Mooring Arrangement for a Nest of Four Destroyers



8-4.8 Static Analysis.

A quasi-static analysis is performed on the mooring system using a mooring analysis program (ANSYS, *ANSYS-AQWA Reference Manual;* other approved mooring analysis programs could have been used). Each mooring leg is initially pretensioned to a tension of 10 kips (4.4 kN). Quasi-static analysis is performed for various combinations of wind and current directions. Quasi-static results for various wind directions in conjunction with a 60-degree flood tidal current of 0.6 knots (0.31 m/s) are shown in Table 8-5.

Table 8-5 Quasi-Static Leg Tensions for Spread Mooring at Various Wind Directions with a Flood Tidal Current

Wind Direction							
Leg	**0°**	**30°**	**60°**	**90°**	**120°**	**150°**	**180°**
kips							
1	11.8	48.33	100.49	136.91	212.45	194.69	121.62
2	-	14.05	78.23	109.26	172.88	208.4	128.37
3	155.79	211.55	189.74	132.19	125.89	77.33	21.02
4	150.17	181.65	137.36	87	57.33	10.25	-
5	139.83	110.16	19	-	-	-	-
6	126.57	102.06	14.55	-	-	-	-
7	-	-	-	-	-	49.68	100.94
8	-	-	-	-	-	69.47	126.79
kN							
1	52.49	214.99	447.01	609.02	945.05	866.04	541.00
2	-	62.50	347.99	486.02	769.03	927.03	571.03
3	693.00	941.04	844.02	588.02	560.00	343.99	93.50
4	668.00	808.04	611.02	387.00	255.02	45.60	-
5	622.01	490.03	84.52	-	-	-	-
6	563.02	454.00	64.72	-	-	-	-
7	-	-	-	-	-	220.99	449.01
8	-	-	-	-	-	309.02	564.00

- Indicates that the leg does not get loaded

A maximum load of 212 kips (943 kN) occurs on Leg 1 at a wind direction of 120 degrees. This provides a quasi-static factor of safety of approximately 4 to the breaking strength of 2.75 inch (70 mm) FM3 chain.

8-4.9 Dynamic Analysis.

A dynamic analysis is performed on the mooring system to evaluate peak mooring loads and vessel motions using a mooring analysis program (ANSYS, *ANSYS-AQWA Reference Manual*). The initial location of the vessel nest is based on the equilibrium location of the vessel nest determined in the quasi-static analysis. An Ochi-Shin wind spectrum is used to simulate the design storm *(Wind Turbulent Spectra for Design Consideration of Offshore Structures*, Ochi-Shin, 1988). This simulation is performed for a 60-minute duration at the peak of the design storm.

Figure 8-14 shows that the four vessels in the nest are close together and Figure 8-15 shows that the ships have a large ratio of ship draft to water depth. In this case it is estimated that the ships will capture the water between them as the ships move. Therefore, the nest of moored ships was modeled as a rectangular box having a single mass with the dimensions of 529 ft (161.2 m) (length of each ship at the waterline), 235 ft (71.62 m) wide (four ship beams + 5 ft spacing between ships), and 21.32 ft (6.5 m) deep (average vessel draft). Added mass for sway and surge was computed as if the nest was cylindrical in shape with a diameter equal to the average draft. Damping as a function of frequency was estimated from a diffraction analysis (ANSYS, *ANSYS-AQWA Reference Manual*).

Dynamic analyses were performed for various combinations of wind and current directions using a wind speed time history that simulated the design storm. Results showing the instantaneous peak tensions for various wind directions in conjunction with a flood tidal current of 0.6 knots (0.31 m/s) are shown on Table 8-6.

Figure 8-15 End View of DD 963 Mooring Nest

2	12.38	39.25	96.74	122.58	239.91	259.00	161.98
3	270.33	365.31	223.90	184.07	307.98	145.62	47.35
4	306.23	371.31	146.98	108.09	109.43	54.08	-
5	288.69	304.92	49.26	-	-	-	-
6	210.88	202.74	48.79	-	-	-	-
7	-	-	-	-	12.37	84.28	115.61
8	-	-	-	-	38.34	109.13	187.61
kN							
1	167.05	288.9	634.03	828.68	2246.2	1848.5	731.73
2	55.089	174.58	430.31	545.27	1067.2	1152.1	720.54
3	1202.5	1625	995.98	818.81	1370	647.78	210.62
4	1362.2	1651.7	653.82	480.82	486.77	240.56	-
5	1284.2	1356.4	219.12	-	-	-	-
6	938.06	901.87	217.04	-	-	-	-
7	-	-	-	-	55.019	374.91	514.26
8	-	-	-	-	170.54	485.43	834.54

Modeling shows that the instantaneous peak chain tension of 505 kips (2246 kN) is predicted on Leg 1 as the moored vessel nest responds to wind gusts. This provides a peak instantaneous factor of safety of 1.5 on the breaking strength of the selected chain size. For this example, the peak dynamic chain tension during the 1 hour at the peak of the design storm is 2.4 times the quasi-static tension in the mooring leg with the highest tension, Leg 1.

Nest motions for surge, sway, and yaw are provided in Table 8-7. This table shows that the maximum surge of the vessel nest is approximately 24.3 ft (7.4 m) from its equilibrium condition at no loading. Maximum sway and yaw of the vessel nest is 10.5 ft (3.2 m) and 1.59 degrees clockwise, respectively. During a dynamic analysis simulation, nest motions oscillated up to 17.7 ft (5.4 m) in surge (for a wind direction coming from the stern), 6.2 ft (1.9 m) in sway (for a wind direction 30 degrees aft of broadside), and 2.1 degrees in yaw (for a wind direction 30 degrees off the stern).

8-4.10 Anchor Design.

Using the quasi-static design mooring leg tension, anchor capacity and loads on the embedded plate anchor are calculated using procedures outlined in NFESC TR-2039-OCN, *Design Guide for Pile-Driven Plate Anchors* and NFESC CR-6108-OCN, *Anchor Mooring Line Computer Program Final Report, User's Manual for Program CSAP2*. Due to the lower shear strengths of the soft silty upper layers at the site, a 6-foot by 11-foot

(1.83 m by 3.35 m) mud plate anchor is specified (this anchor is summarized in the lower line of Table 8-7). A design keyed depth of 55 ft (16.76 m) is selected for the plate anchor. This will provide an estimated static holding capacity of 430 kips (1,913 kN).

CSAP is used to predict the mooring leg tension at the anchor. Input requirements of CSAP include: (1) mooring leg configuration between the anchor and the buoy or chock; (2) water depth or height of chock above the seafloor; (3) soil profiles and strength parameters; (4) location and size of sinkers; (5) horizontal tension component of the mooring leg at the buoy or chock; (6) horizontal distance or total length of the mooring leg between anchor and buoy or chock; and (7) anchor depth.

Output provided by CSAP includes: (1) chain catenary profile from the anchor to the buoy or chock attachment point; (2) angle of the mooring leg from the horizontal at the anchor, the seafloor, and the buoy or chock; (3) tension of the mooring leg at the anchor, seafloor, and at the buoy or chock; (4) predicted daylight location for the mooring leg; and (5) length of mooring leg required or horizontal distance between anchor and buoy or chock.

Min	0.52	0.83	0.93	1.35	1.27	1.43	1.11
Diff	0.32	0.66	1.72	1.78	1.93	1.07	0.34
Yaw (degrees)							
Origin	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Start	0.76	1.09	1.43	0.64	-0.08	-0.74	-0.89
Max	0.76	1.18	1.59	0.80	-1.22	-1.49	-1.12
Min	0.38	0.27	0.43	-0.25	0.76	0.54	-0.83
Diff	0.38	0.91	1.16	1.05	1.96	2.03	0.29

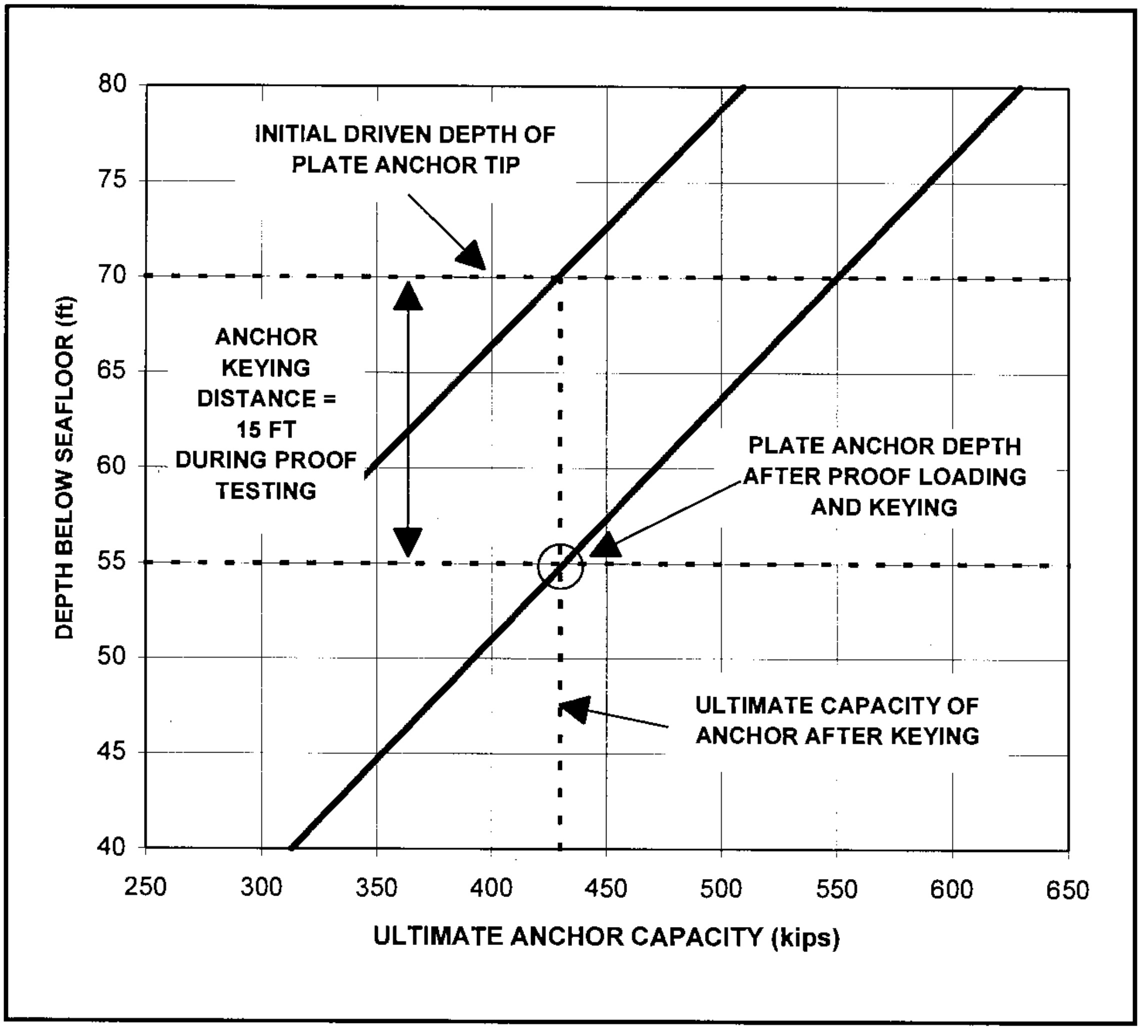
For this example, a keyed anchor depth of 55 ft (16.76 m) was selected. Input data included: (1) configuration of the mooring leg (30 ft (9.14 m) of 3 inch (76.2mm) wire attached to 2+ shots of 2.75 inch (70 mm) chain); (2) height of seafloor to vessel chock (46 ft (14 m) stern and 64 ft (19.5 m) bow); (3) soil profile and strength for the site (shear strength increases linearly at 10 pounds per ft^2 per foot of depth); (4) information on the sinkers (2 each 20-kip (89 kN) sinkers placed a horizontal distance of 170 ft (51.8 m) away from the anchor; (5) horizontal tension component of the mooring leg from the quasi-static results (195 kips); (6) horizontal distance between anchor and chock (280 ft (85 m)) from the quasi-static results; and (7) depth of anchor (55 ft (16.8 m)).

CSAP results for this design leg at this anchor depth indicate that the predicted daylight location of the mooring leg is approximately 99 ft (30 m) from the anchor location and the leg tension at the anchor is 166 kips (738.4 kN). A profile of this leg is shown in Figure 6-5. The interaction between the chain and the soil accounts for a 25% reduction in tension on the mooring leg at the anchor. This gives a predicted quasi-static anchor holding factor of safety of 2.6.

Based on the CSAP results, 6-foot by 11-foot plate anchors are specified. Based on predicted keying distances required for this anchor, as outlined in NFESC TR-2039-OCN, *Design Guide for Pile-Driven Plate Anchors*, the anchors should be installed to a tip depth of 70 ft (21 m) below the mudline to ensure that the anchor is keyed at a minimum depth of 55 ft (16.8 m). Figure 8-16 provides a comparison between tip depth, keyed depth and ultimate capacity for this size anchor.

Further information concerning this design is provided in NFESC SSR-6119-OCN.

Figure 8-16 Plate Anchor Holding Capacity (6-foot x 11-foot anchor with keying flaps in soft mud)



8-5 MOORING LPD 17, LHD 1 AND LHA 1.

As funding and time permit we are preparing general guidelines and recommendations for mooring and/or anchoring various classes of U.S. Navy ships. Work to date includes:

Reference	Title
NFESC TM-6010-OCN	*Some LHA(R) Mooring Concepts*
NFESC TR-6020-OCN	*Mooring USS WASP (LHD 1) Class Ships*
NFESC TR-6028-OCN	*Mooring USS TARAWA (LHA 1) Class Ships*
NFESC TR-6045-OCN	*LPD 17 USS SAN ANTONIO Class Berthing, Mooring and Anchoring*

Detailed information on mooring these three classes of ships is provided in the reports listed above.

8-5.1 MOORING LHD 1, Fully Loaded.

Examples of mooring LHD 1 (Figure 8-17 and Table 8-8) are illustrated in this section.

Figure 8-18 is a summary of the estimated safe mooring limits for LHD 1 based on the NFESC TR-6020-OCN for the ship moored with 32 parts of ship's lines. Figure 8-19 is a summary of the estimated safe mooring limits for LHD 1 based on the NFESC TR-6020-OCN for the ship moored with 28 parts of ship's lines.

8-5.2 Mooring LPD 17.

Examples of mooring LPD 17 (Figure 8-20 and Table 8-9) are illustrated in this section.

Figure 8-21 is a summary of the estimated safe mooring limits for LPD 17 based on the EMOOR planning tool for the ship moored with 28 parts of ship's lines. Figure 8-21 (upper) is for a water depth of 45 ft (13.72 m) (i.e. T/d = 0.5) and Figure 8-21 (lower) is for a water depth of 25.2 ft (7.7 m) (i.e. T/d = 0.9). The diagonal lines on the graph correspond to various broadside current speeds, *Vc*. The dashed horizontal lines are for the cases of 50 knot (25.7 m/s) and 64 knot (32.92 m/s) winds. The X-axis on each diagram is the mean vertical angle of the breasting lines. The Y-axis is the estimated maximum safe wind speed.

For example, take the case of the ship moored at a berth with a water depth of 25 ft (7.62 m) and a broadside current of 1.5 knots (0.77 m/s). For a mean vertical breasting line angle of 30 degrees, the maximum estimated safe wind speed from Figure 8-21 (lower) is 53 knots (27.3 m/s)

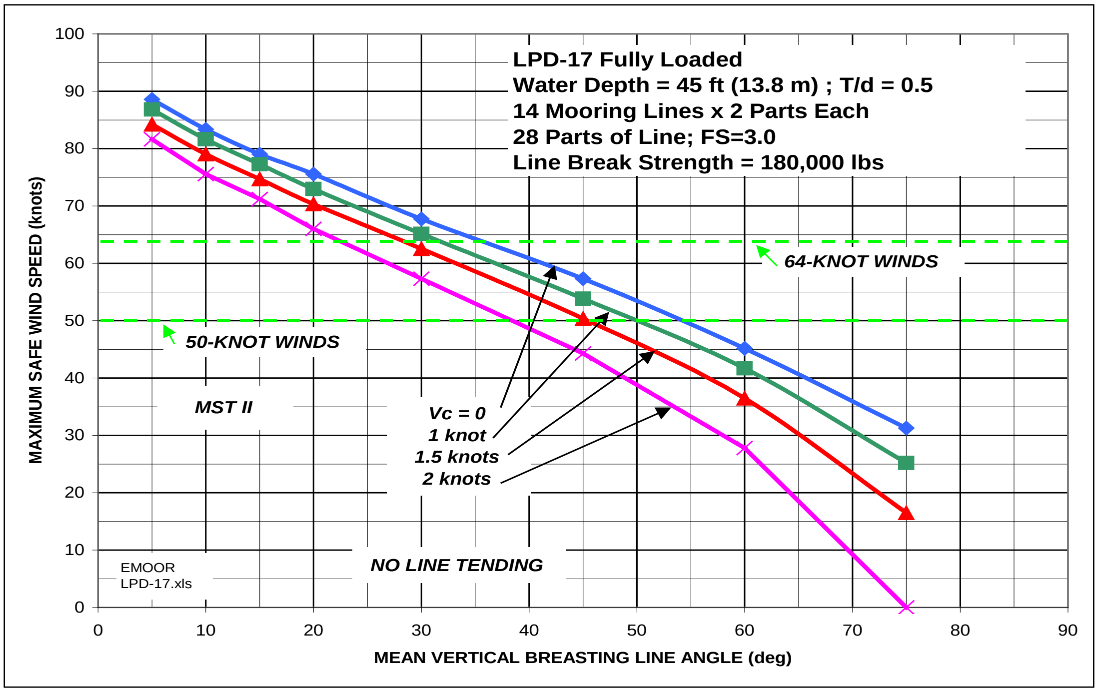
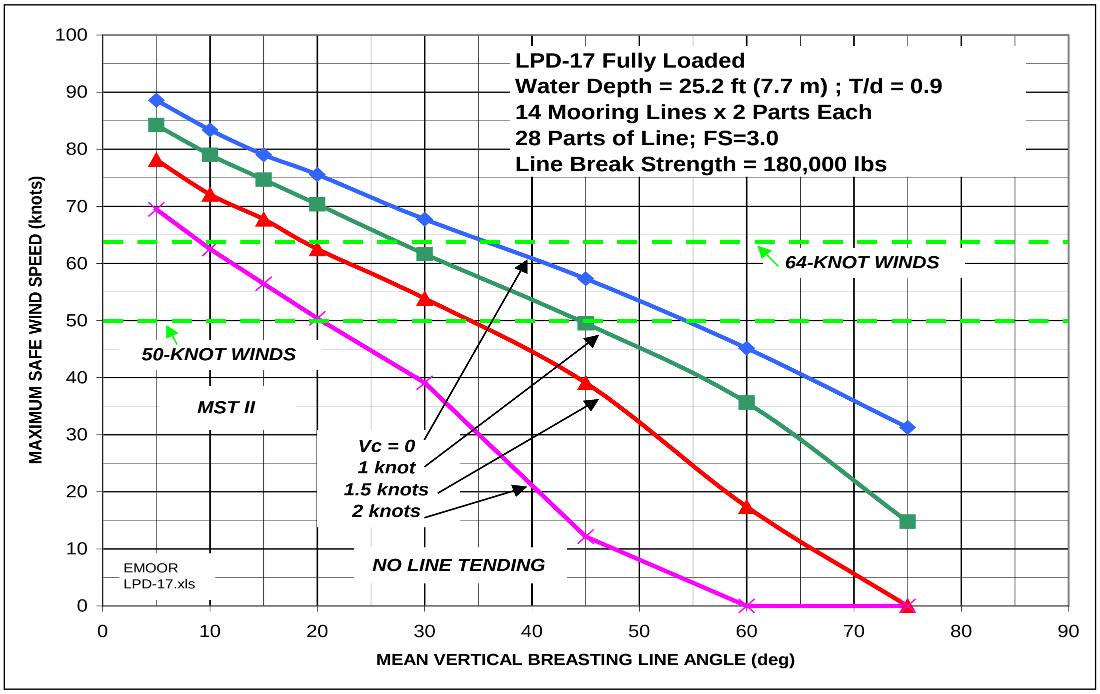
Figure 8-21 Approximate Safe Mooring Limits for LPD 17 with 28 Parts of Mooring Line





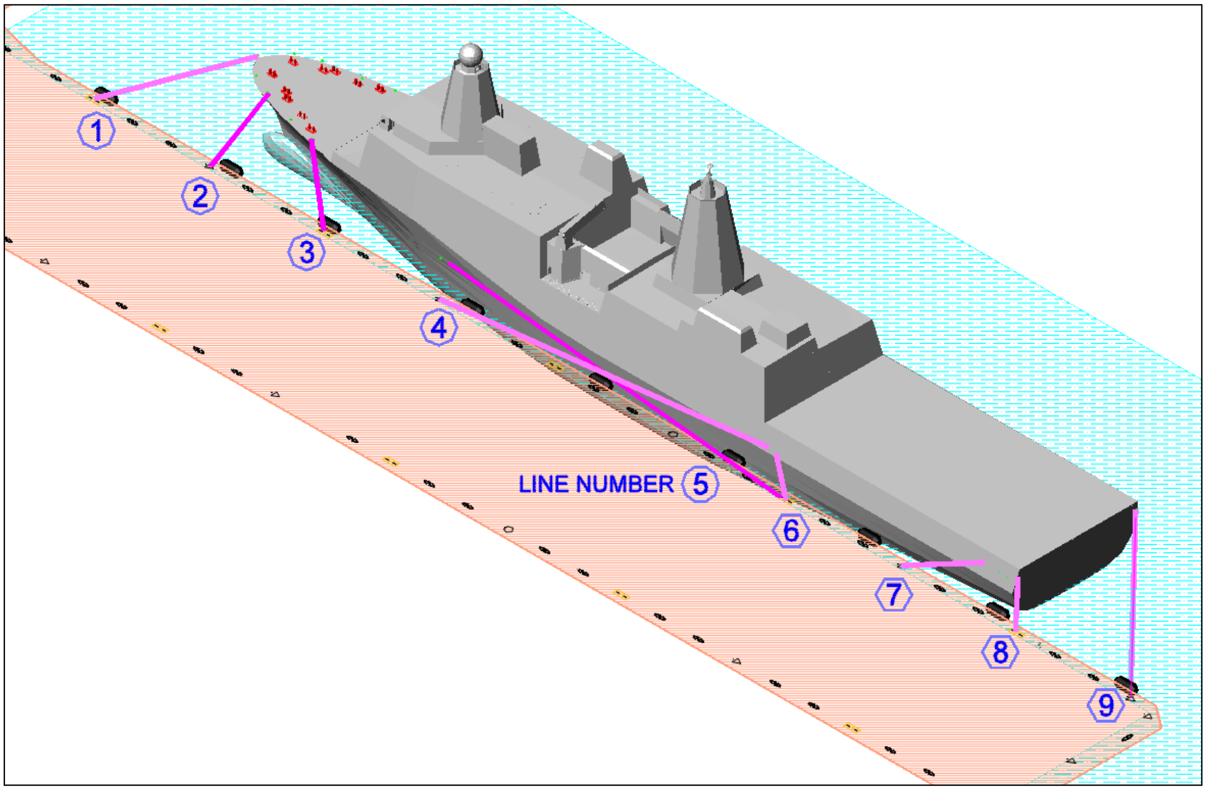
Six degree of freedom quasi-static analyses using the program ANSYS AQWA are performed on various LPD 17 mooring configurations to determine safe mooring limits as follows:

Figure 8-22 shows a sample Standard Mooring (MST IIA) for the ship broadside to a current pushing the ship off the pier. In this example the water depth is 45.3 ft (13.8 m) for a ship draft to water depth ratio of T/d = 0.5. The maximum safe wind speed for various current speeds is illustrated with a factor of safety of 3.0 or higher on all mooring lines.

Figure 8-23 shows a sample Storm Mooring (MST IIB) for the ship broadside to a current pushing the ship off the pier. For the case of a major approaching storm the lines are run across the pier to the bollards on the opposite side to significantly improve mooring efficiency. In this example the water depth is 30.2 ft (9.2 m) for a ship draft to water depth ratio of T/d = 0.75. The maximum safe wind speed for various current speeds is illustrated with a factor of safety of 3.0 or higher on all mooring lines.

Figure 8-24 shows a sample Heavy Weather Mooring (MST III) for the ship broadside to a current pushing the ship off the pier. For the case of a major approaching storm or hurricane the lines are run across the pier to the bollards on the opposite side to significantly improve mooring efficiency. Ship's lines are not adequate for heavy weather mooring. Therefore, double braided polyester lines are used because they have excellent fatigue resistance and some stretch to help improve load sharing. In this example the water depth is 40 ft (12.19 m) for a ship draft to water depth ratio of T/d = 0.57. The maximum safe wind speed for various current speeds is illustrated with a factor of safety of 2.5 or higher on all mooring lines. These dynamic analyses were performed with the six degree of freedom ANSYS AQWA. Figure 8-25 illustrates LPD 17 mooring at a double-deck pier.

Figure 8-22 Sample LPD-17 Standard Mooring (MST IIA)



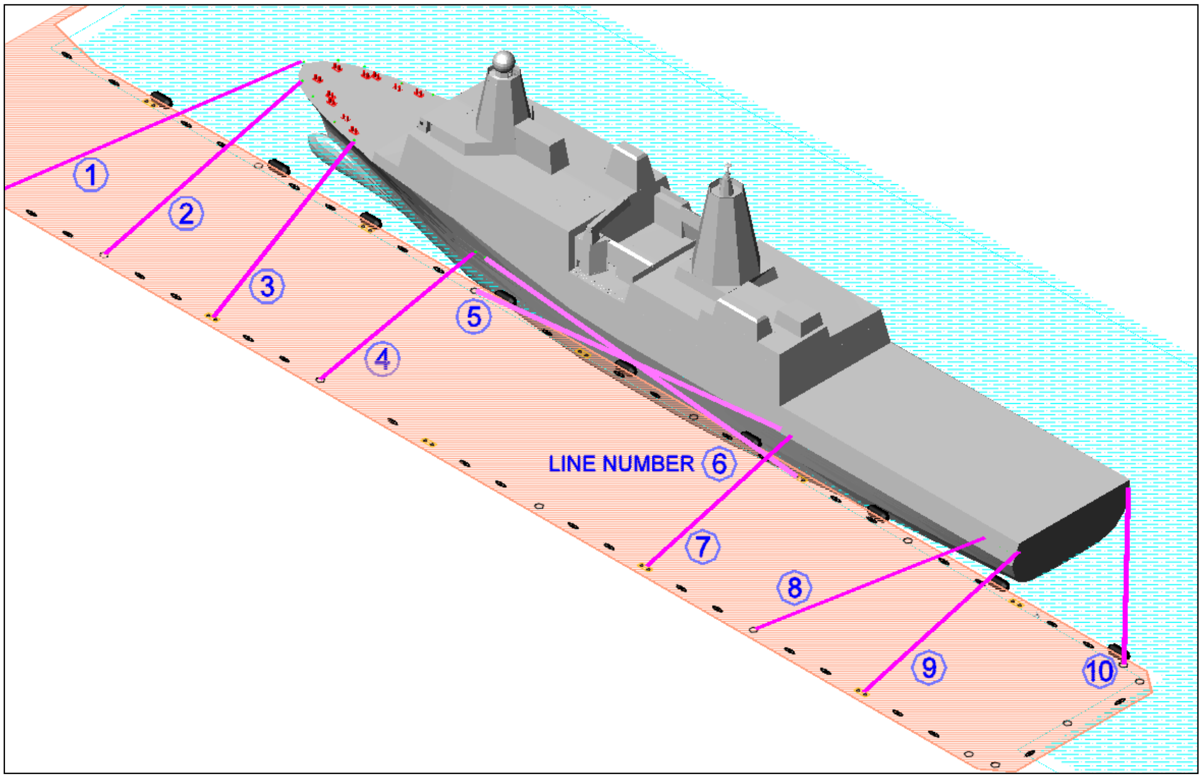
Ship's Mooring Lines
9 Lines of 2 Parts Each = 18 parts of line
1-Foot Slack Added to Lines 2, 7 & 8
Factor of Safety = 3.0 [a]
Water Depth = 45.3 ft (23.3 m/s) (T/d = 0.5)
Maximum Safe Wind Speed for:

Broadside

Current Speed	Maximum Safe Wind Speed
0 knot	55 knot (28.29 m/s)
1 knot (0.51 m/s)	48 knot (24.69 m/s)
1.5 knot (0.77 m/s)	44 knot (22.64 m/s)
2 knot (1.03 m/s)	37 knot (19.03 m/s)

Note:
[a] Factor of safety on new lines with all lines intact. With the most heavily loaded line broken, the factors of safety will likely be reduced.

Figure 8-23 Sample LPD 17 Storm Mooring (MST IIB)

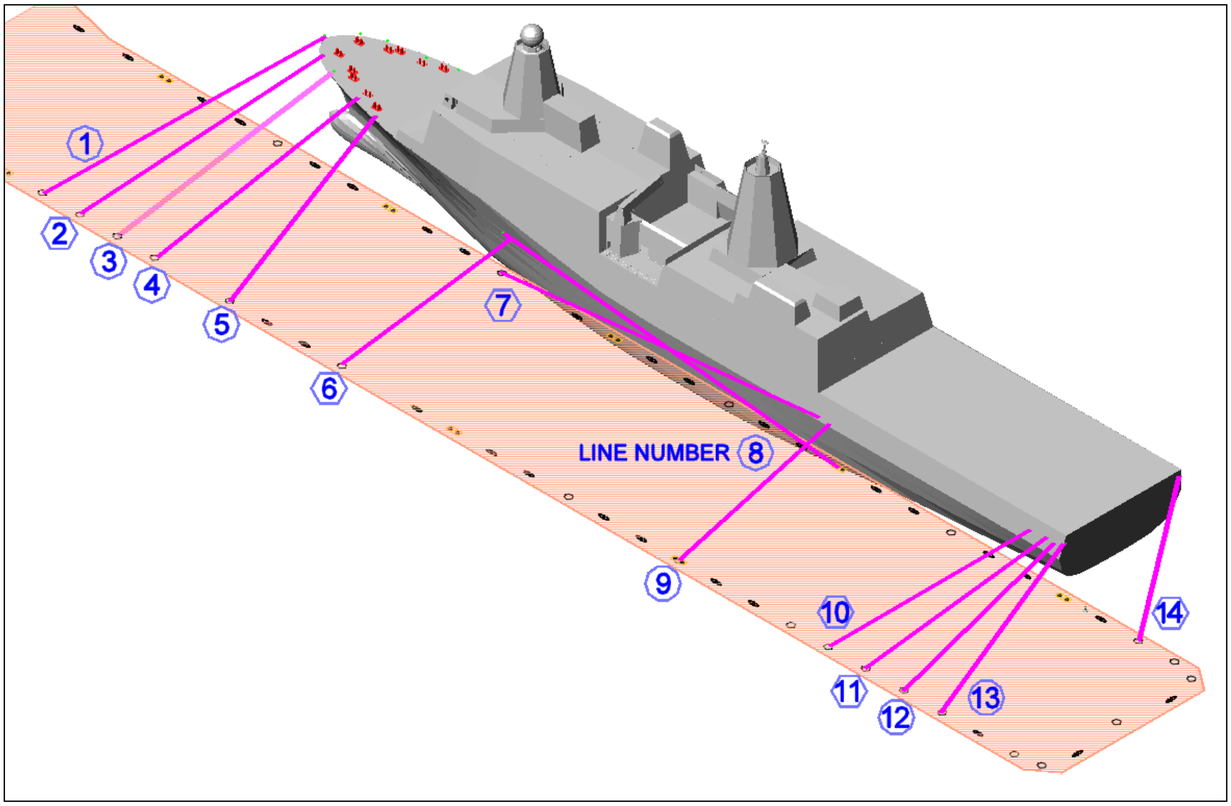


Ship's Mooring Lines
10 Lines of 3 Parts Each = 30 parts of line
Factor of Safety = 3.0 (see note on Figure 8-21)
Water Depth = 30.2 ft (9.2m) (T/d = 0.75)
Maximum Safe Wind Speed for:

Broadside

Current Speed	Maximum Safe Wind Speed
0 knot	85 knot (43.73 m/s)
1 knot (0.51 m/s)	81 knot (41.67 m/s)
1.5 knot (0.77 m/s)	76 knot (39.1 m/s)
2 knot (1.03 m/s)	68 knot (35 m/s)

Figure 8-24 Sample LPD 17 Heavy Weather Mooring (MST III)



Double Braided Polyester Lines Fb=180 kips
14 Lines of 3 Parts Each = 42 parts of line
Factor of Safety = 2.5 (see note on Figure 8-21)
Water Depth = 40 ft (T/d = 0.57)
Maximum Safe Wind Speed for:

Broadside

Current Speed	Maximum Safe Wind Speed
0 knot	118 knot (60.7 m/s)
1 knot (0.51 m/s)	117 knot (60.19 m/s)
1.5 knot (0.77 m/s)	115 knot (59.16 m/s)
2 knot (1.03 m/s)	113 knot (58.13 m/s)

CHAPTER 9 PASSING SHIP EFFECTS ON MOORED SHIPS

9-1 INTRODUCTION.

A ship moving through the water generates several types of waves that may have an effect on moored ships, structures, shoreline erosion, etc. One type of wave generated is a long-period pressure wave that may be very small. However, this long wave (together with Bernoulli effects) may have a major influence on moored ships.

9-2 PASSING SHIP EFFECTS ON MOORED SHIPS.

A ship navigating in a harbor or channel can produce major forces/moments on a nearby moored ship. The moored ship is forced through a combination of wave, long-wave and Bernoulli effects (NFESC TR-6027-OCN). NSTB Marine Accident Report, PB91-916404, NSTB/MAR-91/04, for example, discusses a case where a nearby passing ship caused a moored tanker to break its mooring and fuel lines. The resulting fire caused loss of life, in addition to total loss of the pier and tanker.

The forces and moments acting on the moored ship depend upon a great number of parameters including, relative size of the two ships, water depth, as well as passing ship speed and separation from the moored ship. Figure 9-1 shows an example passing ship case for parallel ships. This figure shows that the forces and moments acting on the moored ship are highly time-dependant. Therefore, dynamic programsare used to determine the response of the moored ship to the passing ship.

Parallel passing ships are discussed in detail in NAVFAC EXWC TR-6056-OCN, and perpendicular passing ships are discussed in detail in NAVFAC EXWC TR-6069-OCN. An associated spreadsheet PASS-MOOR.xls is available that aids in predicting passing ship forces and moments. Figure 9-2 illustrates example predictions. These examples show that peak forces and moments applied to the moored ship in various degrees of freedom occur at different times and highly dynamic. NAVFAC EXWC has capability of providing this type of analysis on a reimbursable funding document for any U.S. government or military agency.

Figure 9-1 Sample Passing Ship Situation

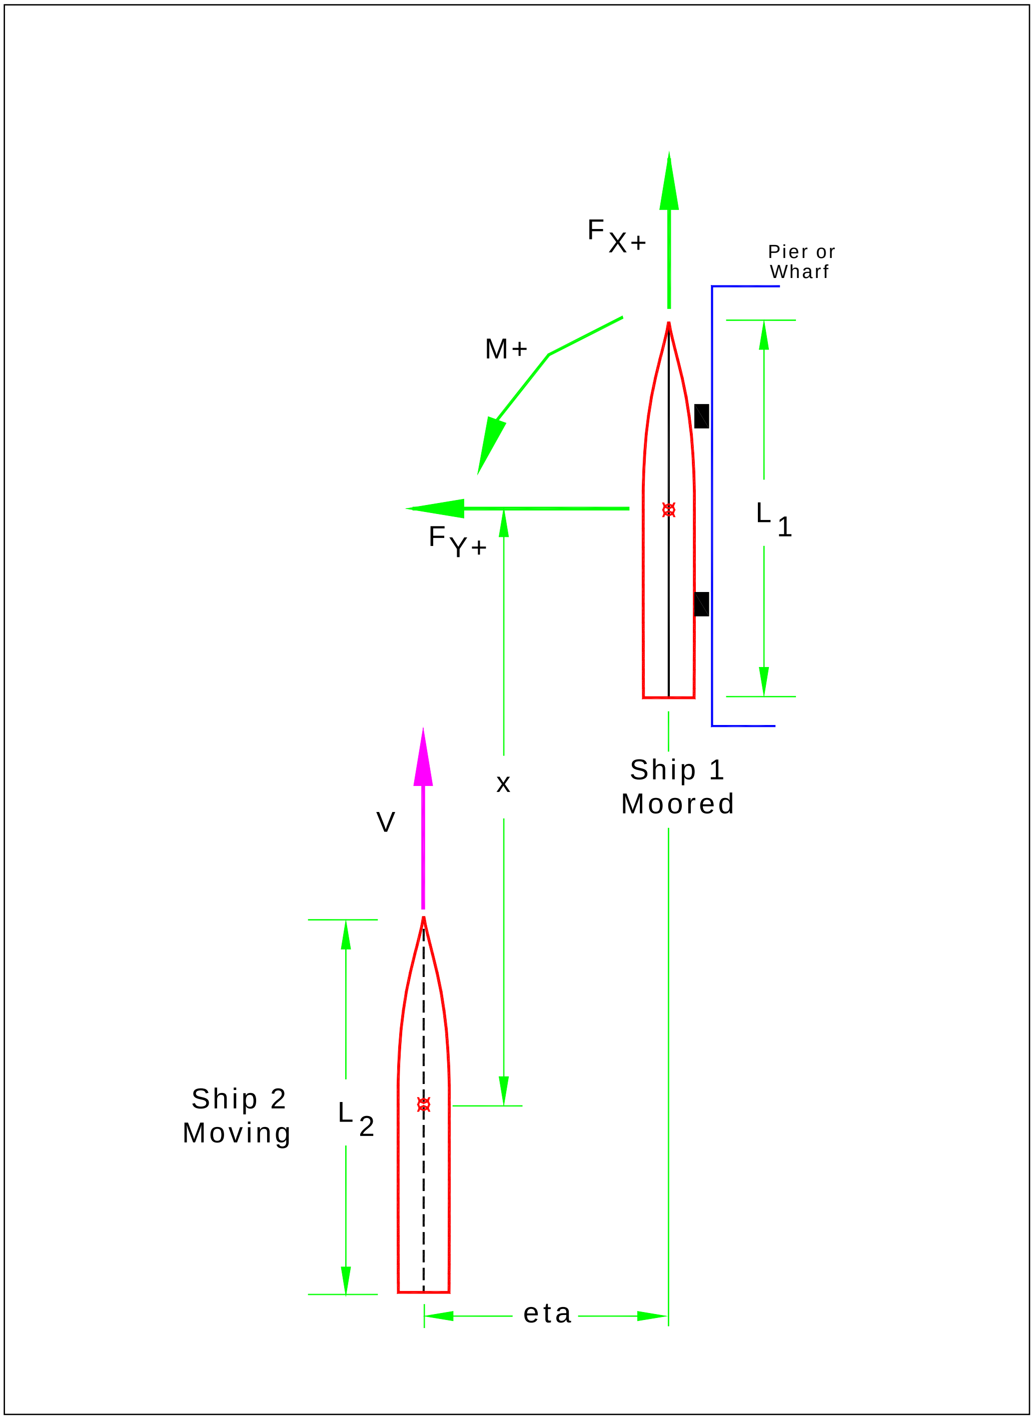

Figure 9-2 Example of Passing Ship Predictions

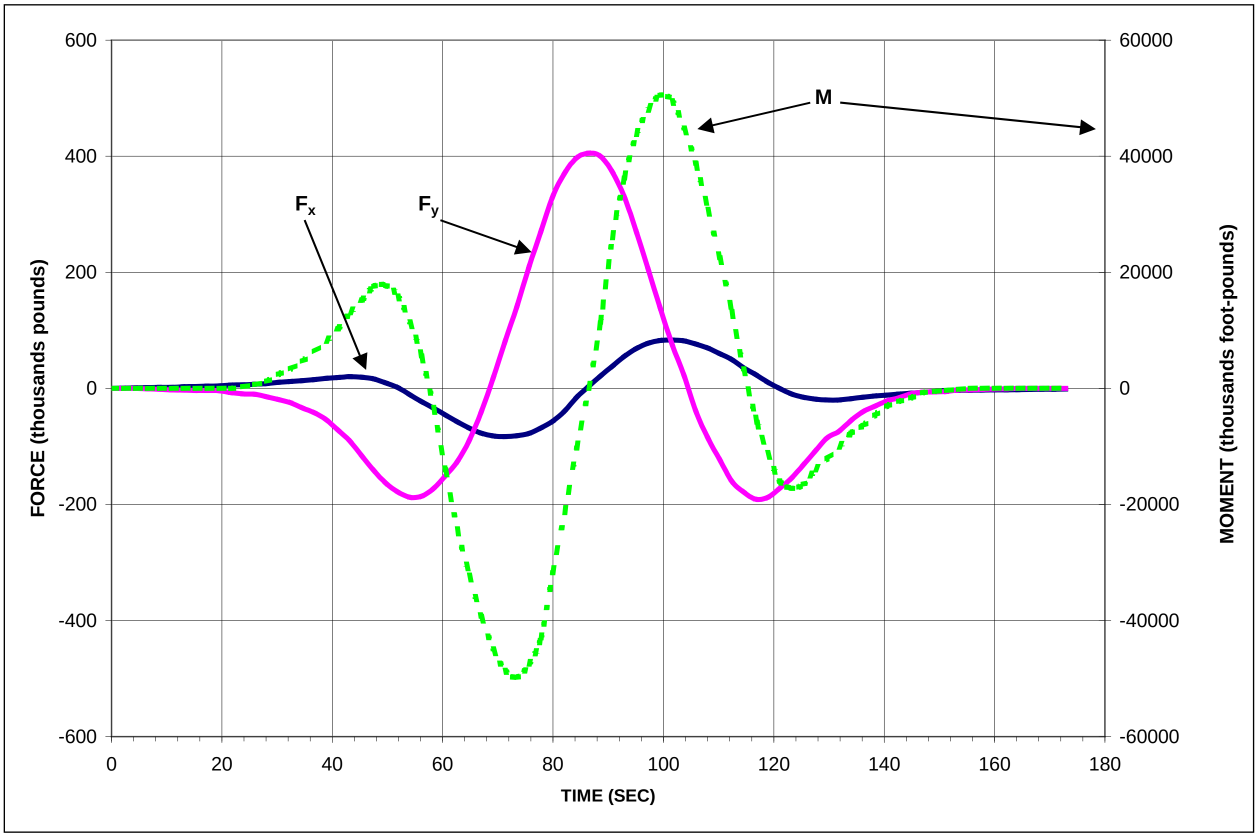

This Page Intentionally Left Blank

CHAPTER 10 SHIP WAVES

10-1 INTRODUCTION.

A ship moving through the water generates several types of waves that may have an effect on moored ships, structures, shoreline erosion, etc.

10-2 SHIP WAVES.

Two of the most noticeable waves generated by moving ships are the diverging (or bow wave) and transverse wave (Figure 10-1). These waves intersect to form a cusp locus line and then the size of the highest generated wave tends to decrease as the distance from the sailing line increases. Characteristics of the ship-generated waves is a complex function of ship shape, water depth, ship speed, etc. NFESC TR-6022-OCN summarizes measurements and recent findings on ship waves for ship hull-forms, such as those illustrated in Figure 10-2.

A spreadsheet SHIP-WAVE.xls is available for making ship wave predictions. This spreadsheet takes the measurements from a wide range of physical ship wave measurements and uses one type of Froude scaling to predict maximum wave height one wavelength away from the ship sailing line for a ship of interest.

Figure 10-3, for example, shows the minimum ship speed required to generate a given maximum wave height one wavelength away from the ship sailing line. The X-axis of this figure is water depth. The Y-axis of this figure is ship speed. Contours are for selected maximum wave heights. For deep water (the right side of this figure), the wave height generally increases as the ship speed increases for the range of conditions shown. In shallow water the wave height contours are much closer together at higher speeds. This shows that in shallow water a small increase in ship speed produces a dramatic increase in wave height.

The spreadsheet SHIP-WAVE.xls and report TR-6022-OCN provides additional information on waves generated by surface ships.

CHAPTER 11 HEAVY WEATHER MOORING GUIDELINES

11-1 INTRODUCTION.

The purpose of this guidance is to advise facility engineers, planners, and maintenance personnel of minimum facility planning and design criteria necessary to ensure safe mooring of naval vessels during MST III (Heavy Weather). Use this UFC to validate existing sites for heavy weather use and to design new or modified facilities and moorings for heavy weather. Existing facilities and moorings should not be used for heavy weather if they do not meet all criteria noted herein unless provisions are made according to COMNAVSEASYSCOM msg R 130351Z Jul 95 YZB. Since no Building Code or non-government standard exists for MST III design, this UFC provides the relevant safety requirements and criteria for facility aspects of ship mooring.

11-2 DISCUSSION.

This criterion is a compilation of lessons learned from heavy weather mooring studies for COMNAVSURFLANT by COMNAVFACENGCOM, NAVFAC EXWC, and COMNAVSEASYSCOM. This criterion has been extensively coordinated with COMNAVSEASYSCOM and internally within NAVFACENGCOM, COMNAVSURFLANT, CINCLANTFLT N37, N46, and CINCPACFLT N37, N46. It includes state of the art technology in vital facility areas such as mooring and risk assessment. Congressional support for all new construction is dependent on specific planning and design criteria applied consistently throughout the Navy - hence, the need to formalize this criteria. Upgrades to existing facilities likewise require documentation of new “code” requirements. A great deal of work has been performed to ensure that ships are safely moored in Heavy Weather conditions. For example, below is a list of some of the NAVFAC EXWC reports on heavy weather mooring.

NFESC Report	Title

11-3 HEAVY WEATHER MOORING GUIDELINES.

Ships under repair in graving docks may be relatively safe, since the ships are relatively protected from the potentially high wind forces and are out of current and waves effects. However, ships at piers and wharves may be subjected to high winds, wind gusts, wind gust fronts, currents, waves, storm surges, etc. It is common practice for U.S. Navy ships to exit port prior to arrival of hurricanes and other forecasted extreme weather conditions. This practice is normally executed when destructive winds (sustained wind speed above 50 knots) are expected in the local area. However, ships in availability (i.e. under repair) may not be able to go to sea. Therefore, these ships must be moored safely during heavy weather or be moved to nearby safe facilities before storm arrival. COMNAVSEASYSCOM msg R 130351Z Jul 95 YZB provides operational recommendations to mitigate many effects of heavy weather. The effectiveness of these mitigation measures is difficult to quantify. Therefore, facilities are often relied upon to resist the loads. In each homeporting region, only a portion of all berthing facilities must be capable of heavy weather mooring, since only a portion of the ships cannot go to sea. Ships carry enough lines to moor in MST II as defined below, but not for Type III. Also, facilities are generally designed for Type II and not Type III.

This section provides some general guidelines on heavy weather mooring. For additional information, see the publications listed above. For safe heavy weather mooring:

Ensure that the facility, mooring fittings and fenders are adequate (see UFC 4-150-07, *Waterfront Facilities: Maintenance and Operation*, UFC 4-150-08, *Inspection of Mooring Hardware*, UFC 4-151-10, *General Criteria for Waterfront Construction*, UFC 4-152-01, *Piers and Wharves, etc*.).

Identify alternative piers or wharves that the ship could be towed to that may be safer and work out ahead of time all the logistics necessary to ensure that the needed berth would be available and that the ship could arrive and be safely moored in adequate time.

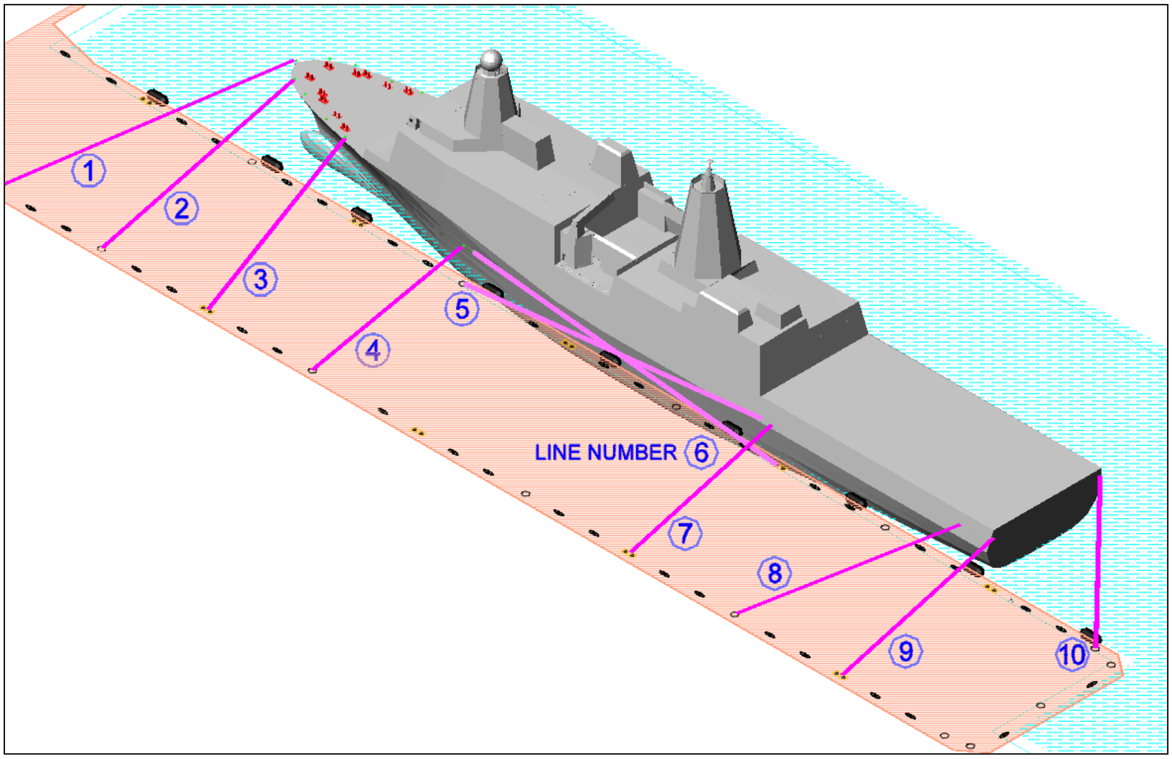
The facility needs to provide heavy weather mooring lines, since ship's lines are generally inadequate. Double braided polyester lines are recommended for heavy weather mooring, because the lines have excellent fatigue resistance. These lines also have some stretch which aids in load sharing between lines and helps accommodate water level changes.

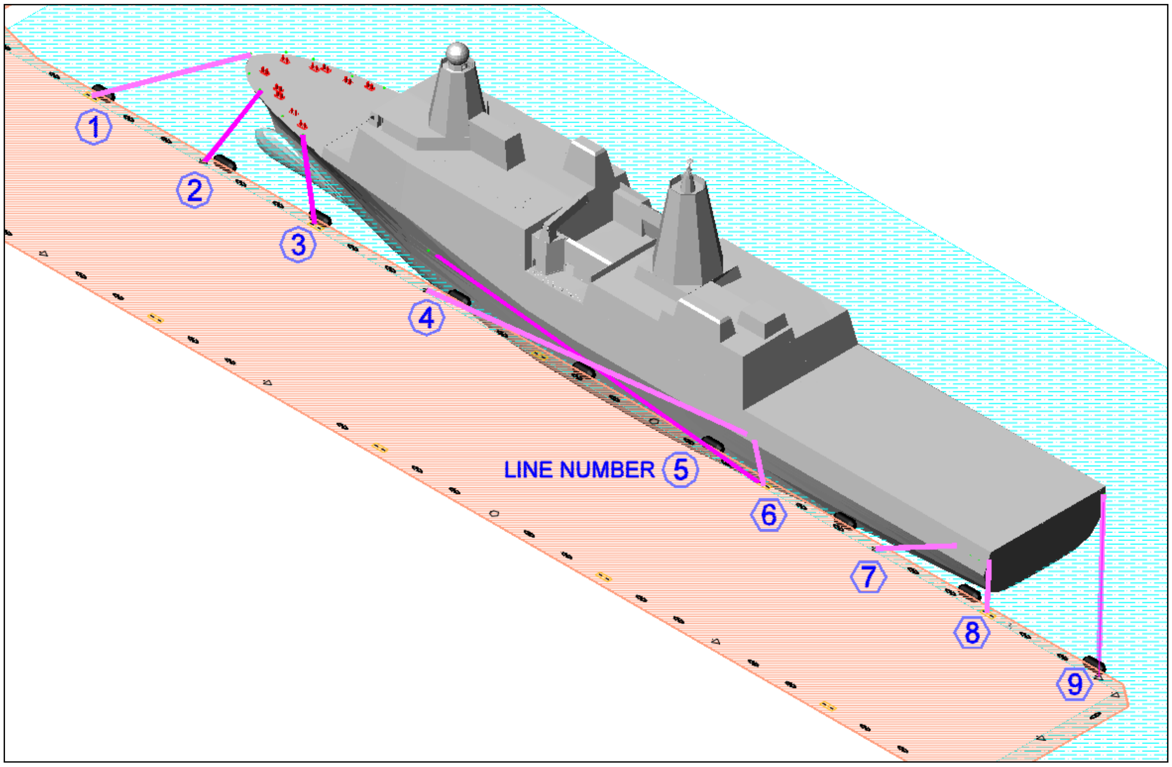
It is standard practice to first put the ship in a Standard or Storm Mooring (i.e. MST IIA or IIB) when a ship comes to a facility for repair (Figure 11-1 upper). These types of moorings are used since the mooring lines can be secured to mooring fittings near the ship, so the mooring lines have minimum interference with repair work.

It is then standard practice to put the ship in a heavy weather mooring (i.e. MST III) if storms, hurricanes or other threatening conditions are expected (Figure 11-1 lower). In heavy weather mooring, for example, mooring lines may be run across the pier to improve mooring efficiency and increase the number of mooring lines that are used.

Detailed structural analyses show that ship's double bitts have the maximum safe working capacity when equal load is applied to each of the two barrels of the bitts. It is recommended that methods be used to provide for equal loading to the barrels in heavy weather mooring.

Figure 11-1 Example of a Heavy Weather LPD 17 Mooring (Upper) and Standard Mooring (Lower)





In the case of using one line in two parts:

- Place eye of mooring line around inner bitt on ship (Figure 11-2 top)
- Place round turnabout pier bollard (Figure 11-2 bottom)
- Place round turnabout inner bitt on ship (Figure 11-2 top)
- Figure 8-1 at least 3 times to engage both barrels on ship's bitt (Figure 11-2 top)
- Bitter end of mooring line remains on ship for line tending
- In the case of using one line in three parts (doubling up).
- The eye is placed over the bollard first (Figure 11-3)
- The line is then run back to the ship and around the bitt
- The line is run directly back to and around the bollard
- The line is run back to the bitt
- The free end is figure-eighted at least 4 times before being tied off and bird nested atop the bitt

Anytime multiple parts of mooring line are used, check the capacity of the ships bitts and piers bollard with respect to being able to handle the Safe Working Load (SWL) of each part of the mooring line.

Detailed heavy weather mooring designs need to be prepared for each ship at each berth. These designs need to consider the site-specific design criteria and special circumstances. As a general rule-of-thumb:

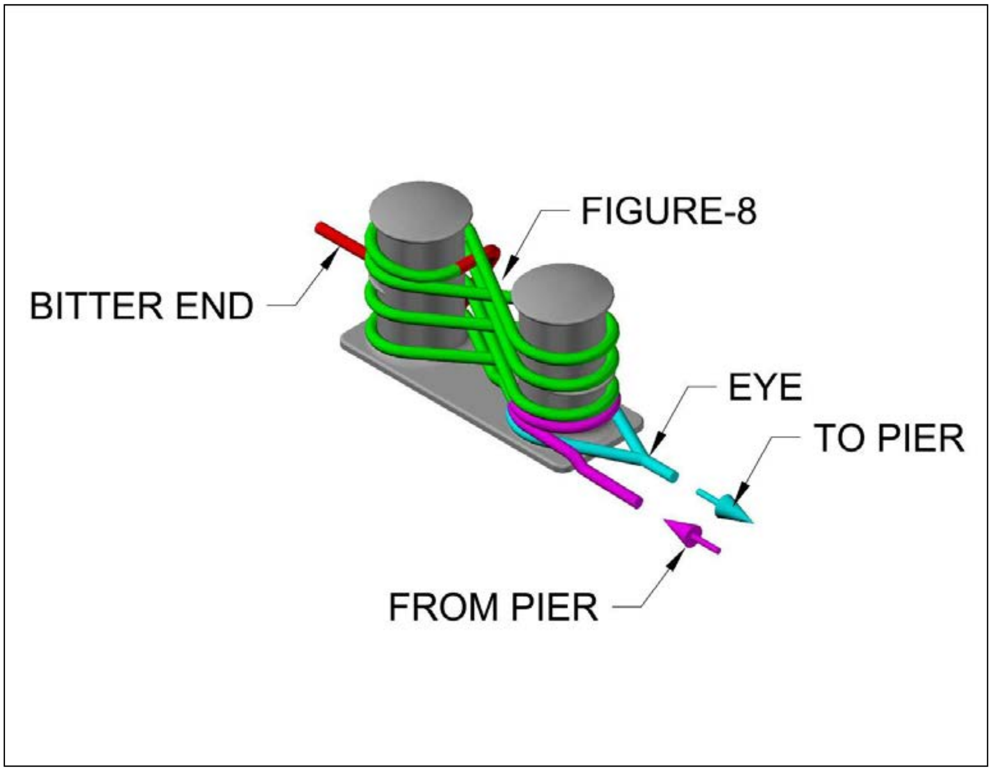
Provide adequate numbers of breasting lines to safely secure the ship. Place the lines towards the bow and towards the stern so they resist both lateral loads and moments.

Breasting lines should be approximately perpendicular to the ship's centerline (to resist loads and moments), be of similar length (to help improve load sharing) and should all have low vertical angles (to improve mooring efficiency and help account for water level changes).

Provide adequate numbers of spring lines, which are approximately parallel to the ship's centerline. Equal numbers of spring lines should be run towards the bow and stern. These lines should have rather low vertical angles to account for water level changes.

It is recommended that preliminary designs be developed with quasi-static designs and factors of safety of 2.5 or higher on all components. Dynamic methods can then be used to refine and verify the designs. The various references cited in this section provide examples of heavy weather mooring designs. CHAPTER 8 of this UFC also provides heavy weather mooring examples.

Figure 11-2 Securing Two Parts of Heavy Weather Mooring Line



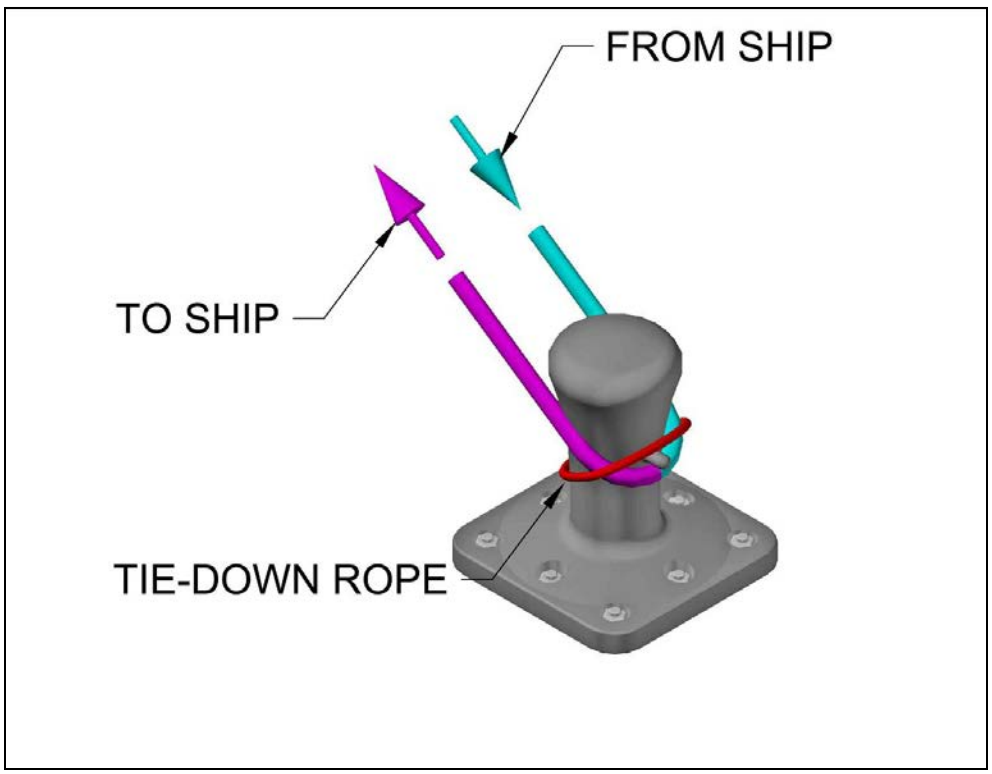


Figure 11-3 Securing Three Parts of Heavy Weather Mooring Line

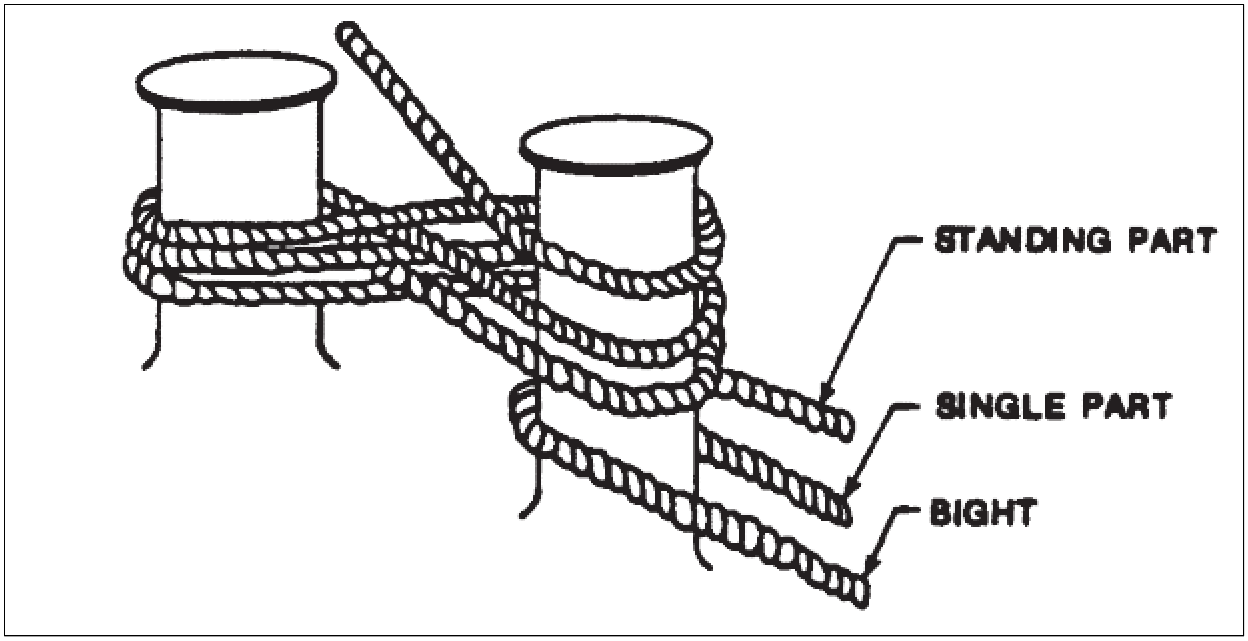

11-4 ACTION.

11-4.1 Planning.

NAVFAC Field Components and Activities should assist Claimants, Regional Commanders, and Shipyards to determine the number, location, and critical ship class requirement for moorings used locally during MST III. Mooring Service Type should be identified during the planning phase of waterfront structures. Recommendations are provided in TR-6012-OCN Rev B U.S. *Navy Heavy Weather Mooring Safety Requirements*.

11-4.2 Analysis and Design.

Engineers at NAVFAC Field Components should work with NAVFAC EXWC moorings engineers to analyze moorings according to climatological criteria stated in TR-6012-OCN Rev B *U.S. Navy Heavy Weather Mooring Safety Requirement*s. Commercial enterprises providing mooring for U.S. Navy ships should likewise conform to the criteria contained herein. Lines should provide a factor of safety against breaking of 2.5. Design pier and wharf fittings for a working load equal to the break strength of the largest lines expected to use the fitting. Moorings used for Type III service are subjected to significant dynamic wind loads and should be analyzed accordingly. NAVFAC EXWC has capability of providing this type of analysis on a reimbursable funding document for any U.S. government or military agency.

Stiff lines (such as aramid) respond differently to dynamic loads than elastic lines (such as nylon) and should be properly modeled in the analysis. Engineers should also verify the capacity of ship fittings for Type III Moorings. Dynamic analyses may indicate that in order to moor large ships in heavy weather, a ship alteration (SHIPALT) is required as well as facility upgrades. A SHIPALT, if required, is coordinated by NAVSEA.

11-4.3 Maintenance.

Maintenance personnel should inspect moorings to ensure acceptable performance during heavy weather. UFC 4-150-07, *Maintenance and Operation of Waterfront Facilities* and UFC 4-150-08, *Inspection of Mooring Hardware*, provide inspection guidance.

11-4.4 Operations.

Activities should provide additional mooring lines to supplement ship mooring lines for use during MST III.

11-5 ENVIRONMENTAL DESIGN CRITERIA FOR SELECTED SITES.

A risk-based approach is used in heavy weather mooring design to help ensure that ships are safe no matter where they are moored. Site-specific design criteria (i.e. winds, water levels, waves, etc.) associated each berth are used to help ensure that all ships are safely moored. See Section 3-2 for General Design Criteria.

APPENDIX A NOTES ON VARIOUS TYPES OF MOORING LINES

A-1 PURPOSE.

The purpose of this appendix is to describe the use and implications of various mooring line types. Each mooring line in a mooring configuration should be the same line type, size, and break strength. This does not preclude the use of mooring pennants / pig tails, which are an acceptable method of incorporating elasticity into a mooring arrangement.

A-2 MOORING LINE TYPES.

A-2.1 Nylon.

Nylon synthetic lines of various constructions have been used by U.S. Navy vessels. Some of the key features of nylon lines include:

- Nylon has relatively large amounts of elasticity (stretch) for a given applied tension (i.e. the stiffness of these lines are relatively low).
- Moorings using nylon tend to have good load sharing between lines due to the high elasticity.
- Nylon mooring lines require relatively little tending due to the high amount of stretch.
- Nylon loses approximately 15% of its strength when wet.
- Nylon has poor fatigue resistance, so the lines lose strength as the lines undergo cyclic loading.
- Nylon lines are bulky, thus considerable manpower is required to deploy.
- Nylon lines have a large snap-back when they fail under load, which has resulted in serious injury and death.

A-2.2 Polyester.

Polyester Lines:

- Polyester lines have a moderate amount of elasticity (stretch) for a given tension, which enables relatively good load sharing between lines for a well-designed mooring.
- Polyester lines require relatively little tending due to the moderate amount of elasticity.
- Polyester lines retain their strength when wet.
- Polyester lines have excellent fatigue resistance, so are well suited to dynamic situations.

- Polyester lines are not as bulky as nylon lines, thus less manpower is required to deploy.
- Polyester lines snap-back when they fail under load, so care must be taken when using them.
- Polyester lines are very well suited for use as heavy weather mooring lines (MST III), due to their combination of characteristics.

A-2.3 High Modulus Synthetic Fiber (HMSF) Lines.

Aramid, Liquid Crystal Polymer (LCP), and High Modulus Polyethylene (HMPE) (and other High-Modulus Synthetic Fibers):

- Have very little elasticity (stretch) for a given tension, so these lines are very stiff.
- It may be difficult to get good load sharing between HMSF lines, because the mooring lines are so stiff.
- HMSF lines are lighter per foot and have a smaller diameter compared to similar strength nylon or polyester, making them easier to handle and store.
- Chafe protection is important as HMSF lines are particularly vulnerable to chafe.
- HMSF lines require considerable tending, especially at berths with high tidal ranges.
- HMSF lines retain their strength when wet.
- HMSF lines are not be well suited for dynamic conditions. The mooring lines are relatively stiff, which reduces the natural periods of a ship-mooring system, which may result in higher peak dynamic tensions in the mooring lines. ‘Snap loads’ may also occur.
- HMSF line mooring may require a good deal of line tending. A standard ship mooring with HMSF lines may not be compatible with high rate of tidal change, so the lines may need to be tended. IF the lines are not tended then mooring lines may break, mooring fittings may fail and/or the ship could list toward the pier/wharf as the tide rises.
- HMSF lines store relatively little energy, so do not snap back as violently as other lines when they break. Lines can be fitted with tattletales to indicate that the lines may be overloaded.
- Due to their unique properties, HMSF lines are carried on ships for mild weather, standard and storm moorings (MST IIA and IIB).
- Due to their low elasticity, limited load sharing ability, and susceptibility to shock loads in dynamic environments, HMSF lines are generally not recommended for Heavy Weather Mooring.

APPENDIX B GLOSSARY

B-1 ACRONYMS.

ABS	American Bureau of Shipping
AISC	American Institute of Steel Construction
AP	Aft Perpendicular Point
ASCE	American Society of Civil Engineers
API	American Petroleum Institute

m^2/s	square meter per second
m^3/LT	cubic meter per long ton
m^3/ton	cubic meter per ton
mm	millimeter
mph	miles per hour
N	newton
N-m	newton-meter

N/m^3	Newton per cubic meter
P	port (left side of vessel when facing forward)
P	probability of exceedance
psi	pound per square inch
R	return interval
S	starboard (right side of vessel when facing forward)
sec	second
$slug/ft^3$	slug per cubic foot
ST	short ton (2,000 lb)
t	tonne = metric ton = 1000 kg
V	velocity
V_w	velocity of water
Wt	weight
yr	year

B-3 DEFINITION OF TERMS.

Breaking Strength: maximum force developed in an item prior to failure, similar to ultimate capacity.

Minimum Breaking Strength (MBS): often stated as Minimum Breaking Load (MBL) for mooring lines and chain, is the minimum load or capacity an item must be able to support without failure.

Nominal Load: unfactored service load exerted on an item.

Working Capacity, Working Strength: often stated as **Safe Working Load (SWL)** - is the maximum load an item is rated to resist. It contains a factor of safety (FS) applied to the breaking strength and is used during mooring design to ensure that the predicted loads are below breaking strength.

Working Load Limit (WLL): maximum load an item can support, factored or rated capacity.

Ultimate Capacity: maximum load an item can support without failure.
