Record of Changes (changes are indicated by **1**\ ... /**1**/)

Change No.	**Date**	**Location**
1	08/19/2020	Corrected metric conversions, references and terminology. Updated: multiple paragraphs to incorporate criteria change requests and to provide clarification. Updated Fig 3-1 and 3-2. Deleted paragraph A-8
2	07/30/2022	Updated Forward, deleted Summary Sheet, added paragraph 1-3, revised paragraphs: 3-3.6, 3-11.2, 3-19, 4-3.1, 4-3.2, 4-4, B-1. Updated definition of expeditionary structures.
3	05/24/2024	Corrected the progressive collapse criteria conflict between this UFC and UFC 4-023-03; updated threshold for temporary and relocatable buildings to be consistent with DoDI 4165.56; and incorporated all current CCRs from the field.

This UFC supersedes UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings*, dated 9 February 2012.

This Page Intentionally Left Blank

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States ***/2/* its territories, and possessions** /2/ is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), **\2** Naval Facilities Engineering Systems Command (NAVFAC) ***/2/***, and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. **\2** Technical content of UFC is the responsibility of the cognizant DoD working group. Defense agencies should contact the preparing service for document interpretation and improvements.***/2/*** Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code* **\1\/1/**, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

One of the findings in the 1996 Downing Commission report on the Khobar Towers bombing in Dhahran, Saudi Arabia was that there were no standards for force protection in fixed DoD facilities. In partial response to that finding, the initial version of this document was published as an interim standard in December 1999. It applied to Military Construction (MILCON) funded new construction and major renovations of DoD buildings beginning with the Fiscal Year 2002 program. It was transmitted by a memorandum dated 20 September 2002 from the Undersecretary of Defense for Acquisition, Technology and Logistics (USD (AT&L)) and was referenced as a requirement by DoD Instruction 2000.16.

1-2 PURPOSE AND SCOPE.

The purpose of this standard is to establish minimum engineering standards that incorporate antiterrorism (AT) based mitigating measures where no identified threat or level of protection has been determined in accordance with UFC 4-020-01. **\2**

1-3 REISSUES AND CANCELS.

This UFC reissues and cancels UFC 4-010-01, Change 1, dated August 2020. **/2/**

1-4 INTENT.

The intent of these standards is to reduce collateral damage and the scope and severity of mass casualties in the event of a terrorist attack. These standards provide cost effective, implementable, and enforceable construction standards to protect personnel against terrorist attacks. While complete protection against all potential threats for every inhabited building is cost prohibitive, the intent of these standards can be achieved through prudent master planning, real estate acquisition, and design and construction practices.

1-5 IMPLEMENTATION.

Implement in accordance with the Implementation, Administration, and Enforcement paragraph in UFC 1-200-01. These standards apply to projects funded under host-nation agreements after the implementation date of these standards or as soon as negotiations with the foreign governments can be completed.

Due to major changes between these standards and previous editions, projects currently under design and beyond 35% completion may consider complying with these standards where possible.

1-6 APPLICABILITY.

These standards apply to all DoD Components, to all DoD inhabited buildings and high occupancy family housing, to all inhabited tenant buildings on DoD installations, and to all DoD expeditionary structures.

1-6.1 New Construction.

Implementation of these standards is mandatory for all new construction regardless of funding source.

1-6.2 Existing Buildings.

Implementation of these standards is mandatory to existing buildings when triggered as specified below, regardless of funding source.

1-6.2.1 Major Investments.

Implementation of these standards to bring entire inhabited buildings into compliance is mandatory for all DoD building renovations, modifications, repairs, revitalizations, and restorations where project costs exceed 50% of the replacement cost of the existing building in accordance with UFC 3-701-01 except as otherwise stated in these standards. The **\1** project costs used to compare against the 50% threshold are exclusive of the additional **/1/** costs identified to meet these standards.

Where **\1** project **/1/** costs do not exceed the 50% threshold, compliance with these standards is recommended, but not required.

1-6.2.2 Change of Occupancy Level.

Implementation of these standards is mandatory when any building or portion of a building is converted from low occupancy to inhabited occupancy. Examples would include a warehouse (low occupancy) being converted to administrative (inhabited) use.

1-6.2.3 Window, Skylight, Glazing, and Door Replacement Projects.

Because of the significance of glazing hazards in a blast environment, implementation of all provisions of Standard 10 is mandatory for existing inhabited buildings any time a window, skylight, or glazing is being replaced. This also applies to installation of supplemental windows behind existing windows (inside face) and to installation of windows in new openings.

Because of the significance of door hazards in a blast environment, implementation of all provisions of Standard 12 is mandatory for existing inhabited buildings any time doors are being replaced.

1-6.2.4 Heating, Ventilating, and Air Conditioning (HVAC) Systems and Associated Controls.

Whenever HVAC systems featuring outside air intakes or control systems associated with HVAC systems including outside air intakes are being replaced or modified, apply provisions of Standards **\1** 16 and 18. **/1/** Modifications include, but are not limited to modifications such as complete air handling unit replacement, outside air control damper replacement, major ductwork reconfiguration, control system replacement, and control system reprogramming. Modifications do not include replacement of or repair of components such as coils and fans and do not include control system software updates or reprogramming in support of additional equipment added to an existing control system.

1-6.3 Building Additions.

Inhabited additions to existing buildings must comply with the minimum standards for new buildings. If the addition is 50% or more of the gross area of the existing building, the existing building will comply with the minimum standards for existing buildings in Chapter 3. Cost of building additions will not be included in calculating the 50% trigger for major investments.

Throughout these standards references to new construction will be considered to be inclusive of additions to existing buildings.

1-6.4 Leased Buildings.

\1 In accordance with DoD Instruction 2000.12, all leased facility space or space in buildings owned or operated by the U.S. General Services Administration (GSA) not located on DoD property must comply with the security standards established by the Interagency Security Committee (ISC) in The Risk Management Process for Federal Facilities: An Interagency Security Committee Standard. The ISC standard must additionally be applied to leased space not on DoD property in foreign countries. Facility space leased prior to 7 December 2012 must comply with the ISC standards to the extent practicable in accordance with existing lease agreements. **/1/**

1-6.5 Privatized Buildings.

Privatized inhabited buildings and high occupancy family housing that meet the applicability provisions above, will comply with these standards.

1-6.6 DoD Purchases of Existing Buildings.

Existing inhabited buildings purchased for use by DoD will comply with the minimum standards for existing buildings. Those buildings will meet the requirements before they can be occupied by DoD personnel.

1-6.7 Non-DoD Tenant Buildings on DoD Installations.

Tenant buildings on DoD installations other than those that meet one of the exemptions below are required to comply with these standards because it is assumed that the tenant buildings are likely to be turned over to DoD sometime during their design life and that they will then be occupied by DoD personnel. For the purposes of these standards, occupancy levels for non-DoD tenant-built building will be calculated assuming that building occupants are DoD personnel.

1-6.8 National Guard Buildings.

National Guard buildings that use Federal funding for new construction, renovations, modifications, repairs, or restorations that meet the applicability provisions above, will comply with these standards.

1-6.9 Expeditionary Structures.

Implementation of these minimum standards is mandatory for all expeditionary structures that meet the occupancy criteria for inhabited buildings. See Chapter 4 for structure types that meet the expeditionary structures criteria. Many expeditionary structures are in forward operating locations where there is a conventional and/or terrorist threat more severe than those addressed in these standards. In those situations, more detailed planning and additional measures are needed for providing protection. Refer to the GTA 90-01-011 **\1\/1/**.

1-6.9.1 New Structures.

These standards apply to all new expeditionary structures effective as of the implementation date of these standards.

1-6.9.2 Existing Structures.

These standards will apply to all existing expeditionary structures as they undergo major modifications or renovations as of the implementation date of these standards.

\3

1-6.10 Transitional, Temporary, and Relocatable Structures and Spaces in a Non-Expeditionary Environment.

Buildings, structures, and spaces that are required to maintain operations for limited durations during construction, for other temporary mission requirements, or for administering construction contracts, are required to comply with standards 1 through 5 only of this UFC. They are exempt from the remaining standards 7 through 21. Transitional, temporary, and relocatable structure provisions of this section are limited to those facilities intended for limited use not to exceed seven years. Those facilities initially planned for longer than seven years must comply with all of the provision of this UFC.

Lightweight buildings or trailers are frequently provided for these structures. These types of structures are commonly not commercially available with construction such as laminated glass windows that will meet these standards. Enforcing the standards on these structures would be of questionable economic feasibility for the short duration for which they are anticipated to be used.

1-6.10.1 Transitional Building Structures and Spaces.

Buildings and structures, including buildings and structures leased to provide transitional spaces during the life of the construction or renovation contract for which the transitional buildings and structures are being provided, must comply with standards 1 through 5 of this UFC.

1-6.10.2 Temporary and Relocatable Buildings.

Temporary and relocatable buildings in non-expeditionary environments, regardless of the procurement or funding source, must comply with standards 1 through 5 of this UFC.

1-6.10.3 Converting Transitional, Temporary, and Relocatable Structures to Real Property.

As prescribed by DODI 4165.56, *Relocatable Facilities*, existing temporary or relocatable buildings must be upgraded to comply with antiterrorism (AT) standards for existing buildings before they may be converted to permanent real property. Conversion to real property requires evaluation in accordance with UFC 4-020-01, *DoD Security Engineering Facilities Planning Manual*, to validate design basis threats and level of protection requirements. ***/3/***

1-7 EXCEPTIONS.

The following buildings are exempt from all provisions of these standards. Compliance with these standards for those buildings is recommended where possible. In addition, there are some exemptions to individual standards that are included in the text of those standards in CHAPTER 3.

1-7.1 Low Occupancy Buildings.

Buildings whose occupancies do not meet the occupancy levels of inhabited buildings.

1-7.2 Low Occupancy Family Housing.

Family housing with 12 units or fewer per building.

The exemption of family housing with 12 units or fewer in a single building acknowledges that the density of such units is generally low, reducing the likelihood of mass casualties. It also acknowledges the fact that low-density housing has rarely been directly targeted by terrorists.

1-7.3 Fisher Houses.

Fisher houses with 24 units or fewer

1-7.4 Town Centers.

Town Center buildings that include retail, health, or community services space on the first floor and not more than 12 units of family housing above that space

This exception does not apply where the buildings contain any occupancy other than retail, health, community services, and family housing or where the retail space is more than half of the total area of the family housing.

1-7.5 Enhanced Use Leases.

Facilities associated with enhanced use leases on DoD installations, unless a facility warrants additional force protection due to its specific purpose and/or location per title 10 U.S.C. section 2667(b)(8). Application of these standards must be justified on a case-by-case basis.

1-7.6 Military Protective Construction.

Facilities designed to the North Atlantic Treaty Organization (NATO) (or equivalent) standards for collaterally protected, semi-hardened, protected, and hardened facilities are exempt from all provisions of these standards. (Refer to Supreme Headquarters Allied Power Europe (SHAPE) document 6160/SHLOFA-059-82.)

These facilities are exempted because the military conventional and nuclear weapons threats to which they are designed are much more stringent than those included in these standards due to their purpose of protecting critical military functions. Facilities designed to protective construction standards will provide higher levels of protection for facility occupants than those required by these standards.

1-7.7 Parking Structures.

Parking structures are exempt from these standards except where there are areas built into the structures that meet the definition of inhabited buildings. People accessing their vehicles do not need to be included in any calculation of population or population density.

1-8 OCCUPANCY CALCULATION.

The starting point for applying the Standards is based on buildings or portions of buildings being routinely occupied by 11 or more DoD personnel and with a population density of greater than one person per 430 gross square feet (40 gross square meters). The determination of occupancy is usually straightforward but in some cases there are questions on how to calculate occupancies. The following are examples of how to determine occupancy.

1-8.1 Gas Stations and Car Care Centers.

Where DoD or non-DoD visitors to Gas Stations and Car Care Centers routinely increase the occupancy of those buildings to levels meeting the definition of inhabited buildings, those buildings will comply with these standards.

1-8.2 Visitor Centers and Museums.

Where DoD or non-DoD visitors to visitor centers, museums, and similar buildings on DoD property routinely increase the occupancy of those buildings to levels meeting the definition of inhabited buildings, those buildings will comply with these standards.

1-8.3 Visitor Control Centers at Entry Control Facilities / Access Control Points.

Where DoD personnel and the average daily peak occupancy of visitors routinely increase the occupancy of those buildings to levels meeting the definition of inhabited buildings, those buildings will comply with these standards. See UFC 4-022-01 for average daily occupancy calculation.

1-9 REGULATORY AUTHORITIES.

The following regulatory authorities may establish antiterrorism related requirements in addition to the Standards in this UFC.

1-9.1 DoD and Heads of DoD Components.

DoD and heads of DoD Components may establish additional guidance or standards for facilities under their authority or to account for any component related special circumstances.

1-9.2 Geographic Combatant Commanders.

Geographic Combatant Commanders (GCC) may establish additional guidance or standards within their areas of operations. Such guidance is typically included in Antiterrorism Operations Orders (OPORD).

1-9.3 Installation Specific Requirements.

As required by DoD Instruction O-2000.16 and service directives, each installation must have an Antiterrorism Plan. The plan provides procedures and recommendations for reducing risk and vulnerability of DoD personnel, their family members, facilities, and assets from acts of terrorism. Installation Antiterrorism Plans may define a Design Basis Threat for the installation; however, UFC 4-020-01 must be used to establish the Design Basis Threat and level of protection for individual projects.

1-10 EXPLOSIVE SAFETY STANDARDS.

These antiterrorism standards establish criteria to minimize mass casualties and progressive collapse of buildings from terrorist attacks. DoD 6055.09-M, DoD Ammunition and Explosives Safety Standards as implemented by Service component explosive safety standards, establish acceptable levels of protection for accidental explosions of DoD-titled munitions. The explosive safety and antiterrorism standards address hazards associated with unique events; therefore, they specify different levels of protection. Compliance with both standards is required where applicable. Where conflicts arise, the more stringent criteria will govern.

1-11 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code* **\1\/1/**. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

It is assumed that the provisions of these standards will be coordinated with all other applicable DoD building and design criteria and policies. Nothing in these standards should be interpreted to supersede the provisions of any other applicable building or design criteria. Where other criteria mandate more stringent requirements, the most stringent is applicable.

1-12 PROJECT PLANNING AND DESIGN CRITERIA.

The standards contained within this document do not establish the Design Basis Threat or Level of Protection for DoD buildings. Use UFC 4-020-01 to establish the Design Basis Threat and Level of Protection for individual projects.

1-13 HISTORIC PRESERVATION COMPLIANCE.

1-13.1 Security and Stewardship.

The Department of Defense remains the lead federal agency in balancing security threats with the protection of historic properties. The Department of Defense abides by federal legislation on protecting cultural resources and issues its own complementary policies for stewardship.

1-13.2 Compliance with Laws.

Implementation of these standards will not supersede DoD’s obligation to comply with federal laws regarding cultural resources to include the National Historic Preservation Act (NHPA) and the Archaeological Resources Protection Act (ARPA). Installation personnel must determine possible adverse effects to historic structures and/or archaeological resources during project development and consult accordingly.

Personnel at installations outside the United States should coordinate with the applicable host nation regarding possible adverse effects to cultural resources.

1-13.3 Compliance with DoD Standards.

Conversely, historic preservation compliance does not negate the requirement to implement other Department of Defense policy. Federal agencies are always the decision-maker in the Section 106 process of the National Historic Preservation Act. An agency should seek to avoid prolonged consultations that conflict with the imminent need to implement security requirements. Preservation considerations and antiterrorism standards are not mutually exclusive, and any compliance conflicts should be quickly and effectively resolved in consultation with appropriate stakeholders.

1-14 GLOSSARY.

APPENDIX D contains acronyms, abbreviations, and definitions of terms.

1-15 REFERENCES.

APPENDIX E contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

1-16 PLANNING AND INTEGRATION.

When the best procedures, proper training, and appropriate equipment fail to deter terrorist attacks, adherence to these standards goes toward mitigating the possibility of mass casualties from terrorist attacks against DoD personnel in the buildings in which they work and live. Although predicting the specific threat is not possible, proper planning and integration of those plans provide a solid foundation for preventing, and if necessary, reacting, when terrorist incidents or other emergencies unfold.

1-16.1 Threat-Specific Requirements.

Determining the Design Basis Threat is an installation function requiring programmers, antiterrorism officers, and members of the threat working group. Determining the facility specific Design Basis Threat is the first step in planning antiterrorism requirements. However, without a defined level of protection, only the minimum standards apply. The Design Basis Threat and level of protection are unique for each individual facility and are based on the threat likelihoods and the values of the assets in the building. Use UFC 4-020-01 to determine the Design Basis Threat and level of protection for individual projects. The process outlined in UFC 4-020-01 will determine if the minimum AT standards are adequate or if additional protective measures are required.

1-16.2 Effective Planning.

An effective planning process facilitates the necessary decision making, clarifies roles and responsibilities, and ensures support actions generally go as planned. A team consisting of the chain of command and key personnel from all appropriate functional areas who have an interest in the building and its operation executes this planning process. The team should include, as a minimum, antiterrorism/force protection, intelligence, security, and facility engineering personnel. This team is responsible for identifying requirements for the project, facilitating the development of supporting operational procedures, obtaining adequate resources, and properly supporting all other efforts needed to prudently enhance protection of the occupants of every inhabited DoD building. For further information on planning and integration, refer to UFC 4-020-01.

1-16.3 Critical Facilities.

\1 Buildings that must remain operational to maintain mission capability may warrant a level of protection higher than provided by these standards. When required, ensure the security design criteria is developed using UFC 4-020-01. **/1/**

1-17 MASTER PLANS.

Installation master plans must include roadmaps **\1** to accommodate present and future antiterrorism needs **/1/** for new and existing facilities. Master plans should consider threats and levels of protection for facilities. For site planning this may include standoff from parking, base perimeters, and entry control facilities / access control points, but it can also include utilities, vantage points, and the location of high value assets.

1-18 SECURITY ENGINEERING UFC SERIES.

This UFC is one of a series of security engineering unified facilities criteria documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include the following:

1-18.1 DoD Minimum Antiterrorism Standards for Buildings.

This UFC establishes standards that provide minimum protection against terrorist attacks for the occupants of all DoD inhabited buildings. This UFC is intended to be used by security and antiterrorism personnel and design teams to identify the minimum requirements that must be incorporated into the design of all new construction and major renovations of inhabited DoD buildings and inhabited tenant buildings on DoD installations. They also include recommendations that should be, but are not required to be incorporated into all such buildings.

1-18.2 Security Engineering Facilities Planning Manual.

UFC 4-020-01 presents processes for developing the design criteria necessary to incorporate security and antiterrorism into DoD facilities and for identifying the cost implications of applying those design criteria. Those design criteria may be limited to the requirements of the minimum standards, or they may include protection of assets other than those addressed in the minimum standards (people), aggressor tactics that are not addressed in the minimum standards, or levels of protection beyond those required by the minimum standards. The cost implications for security and antiterrorism are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they represent only representative construction that will meet the requirements of the design criteria. The manual also addresses the tradeoffs between cost and risk. The Security Engineering Facilities Planning Manual is intended to be used by planners as well as security and antiterrorism personnel with support from planning team members.

1-18.3 Security Engineering Facilities Design Manual.

UFC 4-020-02FA provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established using UFC 4-020-01. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them all work as a system. The information in UFC 4-020-02FA is in sufficient detail to support concept level project development, and as such can provide a good basis for a more detailed design. The primary audience for the Security Engineering Design Manual is the design team, but it can also be used by security and antiterrorism personnel.

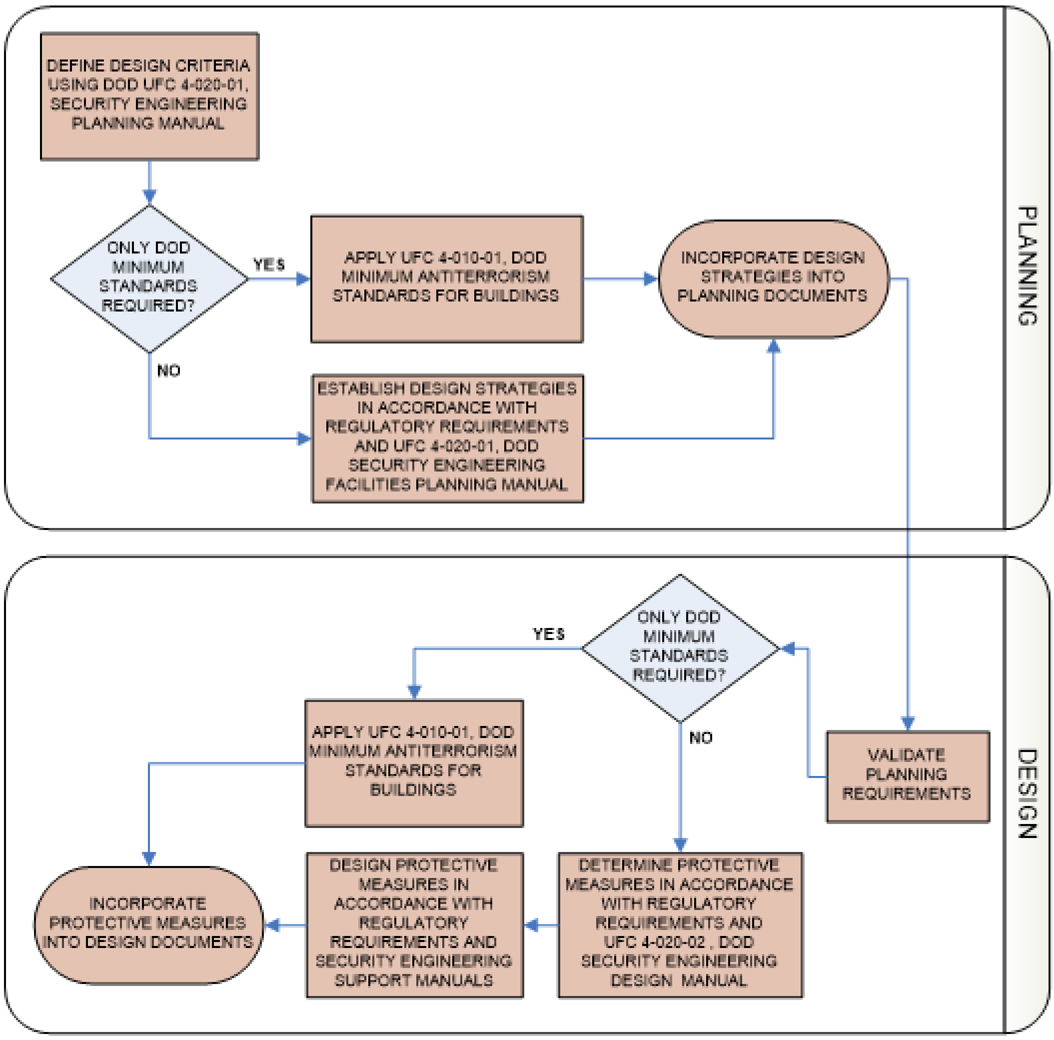
1-18.4 Security Engineering Support Manuals.

In addition to the standards, planning, and design UFCs mentioned above, there is a series of additional UFCs that provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02. These support manuals provide specialized, discipline specific design guidance. Some address specific tactics such as direct fire weapons, forced entry, or airborne contamination. Others address limited aspects of design such as resistance to progressive collapse or design of portions of buildings such as mail rooms. Still others address details of designs for specific protective measures such as vehicle barriers or fences. The Security Engineering Support Manuals are intended to be used by the design team during the development of final design packages.

1-18.5 Security Engineering UFC Application.

The application of the security engineering series of UFCs is illustrated in Figure 1-1. UFC 4-020-01 is intended to be the starting point for any project that is likely to have security or antiterrorism requirements. By beginning with UFC 4-020-01, the design criteria will be developed that establishes which of the other UFCs in the series will need to be applied. The design criteria may indicate that only the minimum standards need to be incorporated, or it may include additional requirements, resulting in the need for application of additional UFCs. Applying this series of UFCs in the manner illustrated in Figure 1-1 will result in the most efficient use of resources for protecting assets against security and antiterrorism related threats.

Figure 1-1 Security Engineering UFC Applicability



1-19 STANDARDS AND RECOMMENDATIONS.

Mandatory DoD minimum antiterrorism standards for new and existing inhabited buildings are contained in Chapter 3. Mandatory DoD minimum antiterrorism standards for expeditionary structures are contained in Chapter 4. Where specific Design Basis Threat and level of protection are identified, additional guidance is included in APPENDIX B.

Additional recommended measures for new and existing inhabited buildings are included in APPENDIX A. The standards and recommendations in this document include a combination of performance and prescriptive requirements. In many cases where there are minimum prescriptive requirements, those requirements are based on performance standards and there are generally provisions to allow those performances to be provided through alternate means where those means will provide the required levels of protection.

CHAPTER 2 PHILOSOPHY, DESIGN STRATEGIES, AND ASSUMPTIONS

2-1 GENERAL.

The purpose of this chapter is to clarify the philosophies on which these standards are based, the design strategies that are their foundation, and the assumptions inherent in their provisions. The further purpose of this chapter is to provide background and rationale for the requirements in Chapter 1 and Chapter 3; therefore, nothing in this chapter should be construed to establish a requirement. Effective implementation of these standards depends on a reasonable understanding of the rationale for them. With this understanding, engineers and security and antiterrorism personnel can maximize the efficiency of their solutions for complying with these standards while considering site-specific threat and mission related issues and constraints that might dictate measures beyond these minimums.

2-2 PHILOSOPHY.

The overarching philosophy upon which this document is based is that comprehensive protection for every inhabited facility against the range of possible threats is cost prohibitive, but that appropriate protective measures can be provided for all DoD personnel at a reasonable cost. Those protective measures are engineering solutions intended to lessen the risk of mass casualties and collateral damage resulting from terrorist attacks. Implementation of these standards will provide some protection against a wide range of threats and will reduce injuries and fatalities. The costs associated with these standards are assumed to be less than the physical and intangible costs associated with incurring mass casualties.

Furthermore, all DoD decision makers must commit to making smarter investments with the scarce resources available and stop investing money in inadequate buildings that DoD personnel will have to occupy for decades, regardless of the threat environment. There are two key elements of this philosophy that influence the implementation of these standards.

2-2.1 Time.

Protective measures must be in place prior to the initiation of a terrorist attack. Incorporating those measures into DoD buildings and inhabited tenant buildings on DoD installations is least expensive at the time those buildings are being constructed, are undergoing major renovation, repair, restoration, or modernization, or when existing buildings are being purchased. Because of that investment strategy, it is recognized that it may take significant time before all DoD buildings and inhabited tenant buildings on DoD installations comply with these standards.

2-2.2 Design Practices.

The philosophy of these standards is to build a baseline level of resistance to terrorist attack into all DoD inhabited buildings. That philosophy affects the general practice of designing inhabited buildings. While these standards are not based on an identified threat or level of protection, they are engineering solutions intended to provide the easiest and most economical methods to minimize injuries and fatalities in the event of a terrorist attack. The primary methods to achieve this outcome are to construct superstructures to avoid progressive collapse, minimize hazardous flying debris, provide effective building layout, limit airborne contamination, and provide building mass notification. These and related design issues are intended to be incorporated into standard design practice.

2-3 DESIGN STRATEGIES.

There are several major design strategies that are applied throughout these standards. They do not account for all of the measures considered in these standards, but they are the most effective and economical in protecting DoD personnel from terrorist attacks. These strategies are summarized below.

2-3.1 Prevent Building Collapse.

Provisions for preventing building collapse are essential to minimizing mass casualties of building occupants. Those provisions apply regardless of standoff distance or the ability of buildings to resist blast effects since structural systems that provide greater continuity and redundancy among structural components will help limit collapse for any extreme loading events.

2-3.2 Minimize Hazardous Flying Debris.

In past explosive events where there was no building collapse, a high number of injuries resulted from flying glass fragments and debris from walls, ceilings, and fixtures (non-structural features). Flying debris can be minimized through building design and avoidance of certain building materials and construction techniques. The glass used in most windows breaks at very low blast pressures, resulting in hazardous, dagger-like fragments. Minimizing those hazards through reduction in window numbers and sizes and through enhanced glazing construction has a major effect on limiting mass casualties. Hazardous fragments may also include secondary debris from such sources as barriers and site furnishings.

2-3.3 Provide Effective Building Layout.

Effective design of building layout and orientation can significantly reduce opportunities for terrorists to target building occupants or injure large numbers of people.

2-3.4 Limit Airborne Contamination.

Effective design of heating, ventilation, and air conditioning (HVAC) systems can significantly reduce the potential for chemical, biological, and radiological agents being distributed throughout buildings.

2-3.5 Provide Building Mass Notification.

Providing a timely means to notify building occupants of threats and what should be done in response to those threats reduces the risk of mass casualties. Effective designs will include means for both local and remote origination of information.

2-4 ASSUMPTIONS.

This section includes assumptions that form the foundation of these standards and assumptions and philosophies behind some of the provisions of these standards.

2-4.1 Baseline Antiterrorism Protective Measures.

The location, severity, and nature of terrorist threats are unpredictable. It would be cost prohibitive to provide protection against the worst-case scenario in every building. These standards provide a reasonable baseline of antiterrorism protective measures for inhabited DoD buildings and inhabited tenant buildings on DoD installations. Designing to these standards will provide general collateral protection and will establish a foundation upon which to build additional measures **\1\/1/** in the future.

The terrorist threats addressed in these standards are further assumed to be directed against DoD personnel. Threats to other assets and critical infrastructure and specific threats to facilities are beyond the scope of these standards, but they are addressed in UFC 4-020-01. The following are the terrorist tactics upon which these standards are based:

2-4.1.1 External Explosive Threats.

These minimum standards are not based on a specific Design Basis Threat identified against the facility being designed. These minimum standards provide collateral damage protection for explosive threats directed against other nearby facilities.

2-4.1.2 Mail Bombs.

Explosives in packages delivered through the mail can cause significant localized damage, injuries, and fatalities if they detonate inside a building. No assumption as to the size of such explosives is made in these standards. Provisions for mail bombs are limited to specifying locations of mail rooms so that they can be more efficiently hardened if a specific threat of a mail bomb is identified in the future.

2-4.1.3 Chemical, Biological, and Radiological Weapons.

For the purposes of these standards, these weapons are assumed to be improvised weapons containing airborne agents employed by terrorists. These standards do not assume comprehensive protection against this threat. They provide means to reduce the potential for widespread dissemination of such agents throughout buildings in the event of an attack either outside buildings or in mail rooms.

2-4.2 Policies and Procedures.

It is assumed that policies and procedures will be developed to support these standards and other related issues and that those policies and procedures will be incorporated into antiterrorism plans, training, and exercises. It is assumed for the purposes of these standards that policies and procedures will be developed by physical security personnel at individual installations or buildings based on their local capabilities and situations.

2-4.3 Training.

It is assumed that key security and facility personnel will receive training in security engineering, antiterrorism, physical security, and related areas. It is further assumed that all DoD personnel have been trained in basic antiterrorism awareness in accordance with DoD Instruction O-2000.16, that they are able to recognize potential threats, and that they know the proper courses of action should they detect a potential threat.

CHAPTER 3 STANDARDS

3-1 INTRODUCTION.

The purpose of this chapter is to establish standards to provide appropriate protective measures for the protection of DoD personnel at a reasonable cost. These standards represent engineering solutions intended to lessen the risk of mass casualties and collateral damage resulting from terrorist attacks. Implementation of these standards will provide some protection against a wide range of threats and should reduce injuries and fatalities.

The standards in this chapter provide the minimum protective measures for DoD inhabited buildings. Engineers, security and antiterrorism personnel must consider site-specific threats, mission related issues and constraints that might dictate measures beyond these minimums. Use UFC 4-020-01 to establish project requirements and determine if these minimum standards are adequate or if additional mitigation measures are required. The engineering risk analysis conducted as part of UFC 4-020-01 should be consistent with the terrorism risk analysis conducted by the installation security/AT staff.

3-2 STANDARD 1. STANDOFF DISTANCE.

The previous version of Standard 1 established standoff distances to parking, roadways, and controlled perimeters that were based on building construction and occupancy. In this revision of Standard 1, standoff distances only apply to distances to installation perimeters for new construction and additions to existing buildings that are required to comply with these standards.

Exception: Existing buildings within an installation perimeter are exempt from this standard.

3-2.1 Minimum Standoff.

The minimum standoff distance for new construction and additions to existing buildings to the installation perimeter is 20 ft. (6 m) **\1** when there is 30 ft. (9m) of clear zone or greater outside the perimeter. Provide a minimum aggregate standoff of 50 feet (15 m) inclusive of the clear zones outside and inside the installation perimeter. For example, if an installation has an established inner clear zone of 20 ft. (6 m) but the outer clear zone is 20 ft. (6 m) wide, the standoff distance to the installation perimeter must be 30 ft. (9 m) wide. Where there is no clear zone outside the perimeter, the minimum standoff distance is 50 ft. (15 m).

For buildings that are outside an installation perimeter, use UFC 4-020-01 to establish project requirements. Where UFC 4-020-01 determines project specific Design Basis Threat and Level of Protection, design the project for the resulting standoff distance in accordance with APPENDIX B. **/1/**

3-2.1.1 Clear Zone.

\1 This standard does not establish the requirement for clear zones. Clear zones are defined by DoD and Service policy. Clear zones are established around the perimeters to provide unobstructed views to enhance detection and assessment. Typically, clear zones are free of all obstacles, topographical features, and vegetation exceeding 8 in. (200 mm) in height that could impede observation or provide cover and concealment of an aggressor. Some installations and high security areas may have higher clear zone requirements into which buildings or structures cannot encroach. Consult with local antiterrorism and security personnel to determine clear zone requirements. See Figure 3-1 and Figure 3-2. **/1/** **\1**

Figure 3-1 Installation Perimeter with Outer Clear Zone

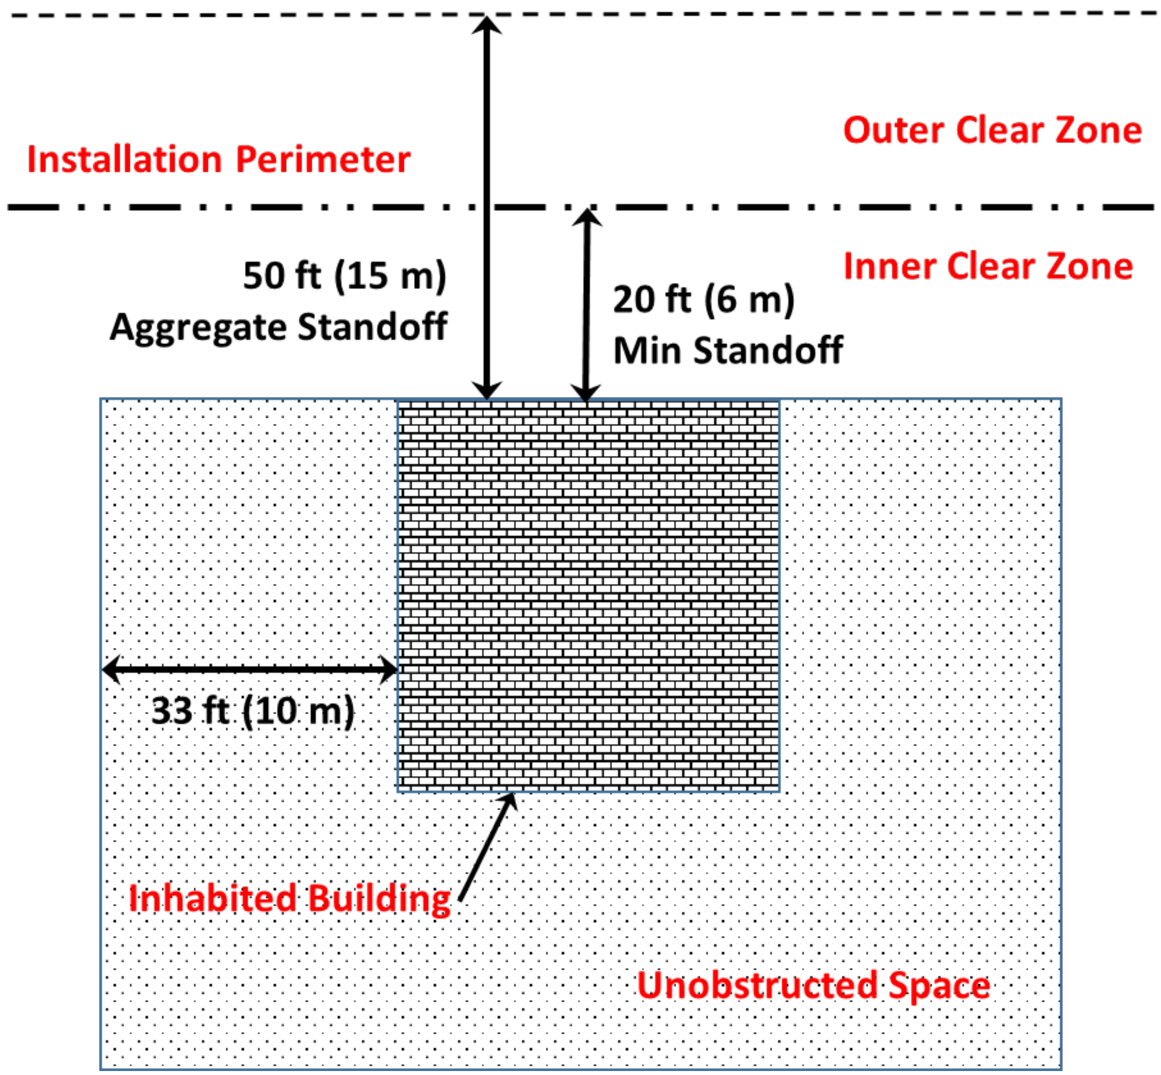


Figure 3-2 Installation Perimeter without Outer Clear Zone

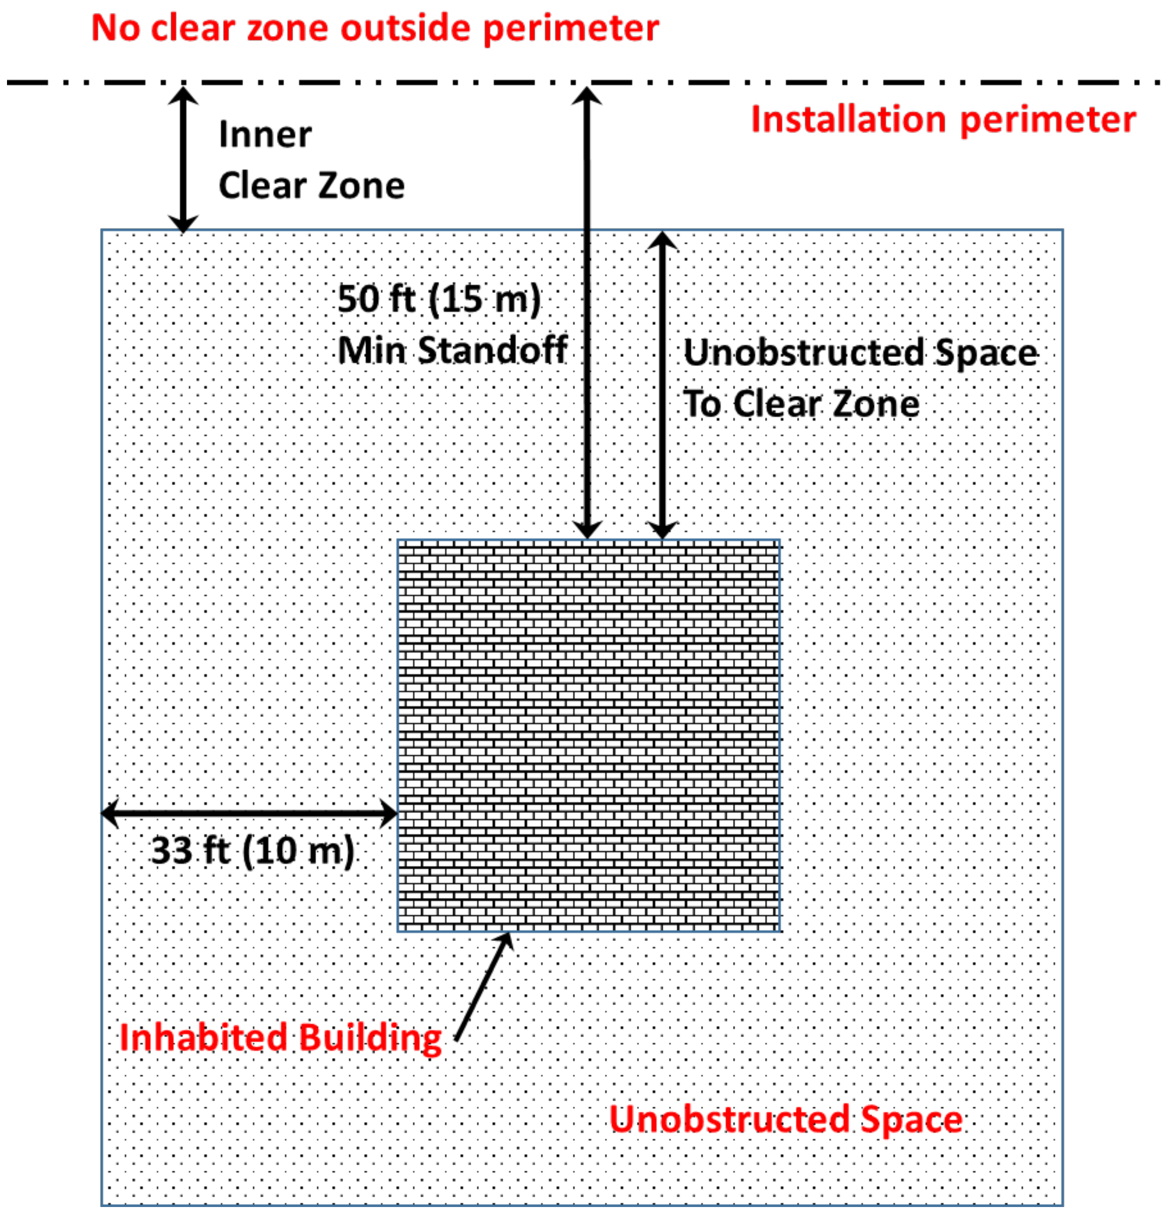

/1/

3-3 STANDARD 2. UNOBSTRUCTED SPACE.

Where buildings are required to meet these standards, the unobstructed space must extend out from the building **\1** to the edge of the inner clear zone, or 33 ft. (10 m), whichever is less **/1/**.

It is assumed that aggressors will not attempt to place explosive devices in areas near buildings where those explosive devices could be visually detected by building occupants. Ensure there are unobstructed spaces in which there are no obstructions or building features that might allow for concealment from observation of explosive devices with dimensions of no less than a 6 in. (150 mm) cube around buildings and underneath building overhangs or breezeways. This does not preclude the placement of site furnishings or plantings around buildings. It only requires conditions such that any explosive devices placed in the unobstructed spaces would be observable by building occupants or passers by either from within the buildings or as they walk into or around it. For trees or shrubs ensure that no foliage extends lower than 3 ft. (1 m) above the grounds to improve observation of objects underneath them.

Exceptions:

- Stand-alone franchised fast food operations, commercial, bank, and pharmacy facilities.
- Stand Alone Shoppettes, Mini Marts, and Commissaries with areas of less than 15,000 square feet (1394 square meters).

3-3.1 Concealment.

The requirements for the unobstructed space are based on eliminating opportunities to conceal objects indicated above. The key to determining what may be located in unobstructed spaces is whether or not a person could see the objects. Obstructions such as mechanical equipment, electrical equipment, trash containers, or landscaping features may be permissible if the devices could be seen from at least one direction. Concealment establishes the basis for the requirement for above ground objects or obstructions. When applicable, evaluate indentations in landscapes such as ditches with respect to concealment.

Evaluate the capacity to conceal objects underneath and inside equipment. If there are voids into which explosives could be inserted or space underneath equipment large enough to conceal objects, that equipment will need to be secured if it is within the unobstructed space. The test should be whether or not something could be concealed behind the equipment or trash container. If walls or other screening devices are two sided it is assumed that people could see something out of place by observation from at least one direction.

3-3.2 Trash Containers.

Trash containers are not allowed within the unobstructed space unless the containers are secured to preclude concealment of explosives as described above or if they are enclosed in accordance with 3-3.6.

3-3.3 Electrical and Mechanical Equipment.

Electrical and mechanical equipment may be located within unobstructed spaces if they do not provide opportunities for concealment of explosives as described above or if they are enclosed in accordance with 3-3.6.

3-3.4 Fuel Tanks.

Fuel tanks may be located within unobstructed spaces if they do not provide opportunities for concealment of explosives as described above or if they are enclosed in accordance with 3-3.6. Distances between buildings and fuel tanks are based on flammability (not explosive equivalence); therefore, they should be determined using NFPA 30.

3-3.5 Walls and Screens.

If walls or other screening devices with more than two sides are placed around trash containers, fuel tanks or electrical or mechanical equipment within the unobstructed space, provide enclosure in accordance with 3-3.6.

3-3.6 Enclosures.

When trash containers, fuel tanks or electrical or mechanical equipment within the unobstructed space provide the opportunity for concealment, they must be enclosed. Enclosures must have four sides and a top. Openings in screening materials and gaps between the ground and screens or walls making up an enclosure **\2** must be less than 6 in (150 mm). ***/2/*** Secure any surfaces of the enclosures that can be opened so that unauthorized personnel cannot gain access. Where opaque top enclosures are provided, they will have a pitch of at least 1 vertical to 2 horizontal to increase visibility of objects thrown onto them and to increase the likelihood that the objects will slide off. Alternatively, if the vertical surfaces of the enclosures are transparent and at least 7 ft. (2.1 m) high, a top enclosure is not required.

3-3.7 Parking Within Unobstructed Spaces.

Parking is allowed within the unobstructed space. Parking may be temporarily eliminated within the unobstructed space at a higher Force Protection Condition (FPCON).

3-3.8 Adjacent Existing Buildings.

Where projects for new and existing buildings designed in accordance with these standards are located within 33 ft. (10 m) of existing inhabited buildings that are not required to meet these standards, ensure that the unobstructed spaces for buildings that must comply with the standards are maintained between those buildings and other existing buildings. If there are opportunities for concealment in the spaces around the other existing buildings those spaces should be modified to ensure fully compliant unobstructed spaces around the buildings that must comply.

3-4 STANDARD 3. DRIVE-UP/DROP-OFF AREAS.

This standard has been removed and no longer applies.

3-5 STANDARD 4. ACCESS ROADS.

This standard has been removed and no longer applies.

3-6 STANDARD 5. PARKING BENEATH BUILDINGS OR ON ROOFTOPS.

Avoid parking beneath buildings or on rooftops of buildings required to comply with these standards. Where very limited real estate makes such parking unavoidable, the following measures must be incorporated **\1\/1/**.

Ensure that access control measures are implemented to prohibit unauthorized **\1\/1/** vehicles from entering underground or rooftop parking areas. Because situations vary from location to location, the development of one standardized “one-size-fits-all” access control package (measures, procedures, and equipment) is not possible and is beyond the scope of these standards. Access control is the responsibility of installation security personnel.

3-7 STANDARD 6. PROGRESSIVE COLLAPSE RESISTANCE.

\3 This standard has been removed from this UFC. The requirement for progressive collapse is incorporated into UFC 4-023-03, *Design of Buildings to Resist Progressive Collapse*. **/3/**

3-8 STANDARD 7. STRUCTURAL ISOLATION.

Structural isolation minimizes the possibility that collapse of one part of a building will affect the stability of the remainder of the building.

3-8.1 Building Additions.

Design building additions that are required to comply with these standards to be structurally independent from the adjacent existing buildings. Alternatively, verify through analysis that collapse of either the addition or the existing building will not result in collapse of the remainder of the building. **\3** Structural isolation is not necessary if the existing building was designed in accordance with UFC 4-023-03. **/3/**

3-8.2 Portions of Buildings.

Design low occupancy portions of inhabited buildings required to comply with these standards to ensure their superstructures are structurally independent from the inhabited portions of the buildings. Alternatively, verify through analysis that collapse of low occupancy portions of buildings will not result in collapse of any portion of buildings covered by these standards. This standard is not mandatory for existing structures, but it should be implemented where possible.

3-9 STANDARD 8. BUILDING OVERHANGS AND BREEZEWAYS.

For new construction required to comply with these standards, avoid building overhangs and breezeways with inhabited spaces above them where people could gain access to the areas underneath the overhangs. Where such overhangs or breezeways must be used, incorporate the following measures

3-9.1 Building Elements.

Ensure the areas underneath the overhangs or breezeways comply with the provisions of the unobstructed space requirements of Standard 2. The areas underneath the overhangs or breezeways can be considered to be extensions of the surrounding unobstructed spaces.

3-10 STANDARD 9. EXTERIOR MASONRY WALLS.

Unreinforced masonry walls are prohibited for the exterior walls of new construction required to comply with these standards. Exterior masonry walls must have vertical and horizontal reinforcement distributed throughout the wall section. The vertical reinforcement ratio must be at least 0.05%, spaced no more than 4 ft. (1200 mm) on center with reinforcement within 1.3 ft. (410 mm) of the ends of walls. The horizontal reinforcement ratio must be at least 0.025%, consisting of either joint reinforcement spaced no more than 1.3 ft. (410 mm) on center, or bond beam reinforcement spaced no more than 4 ft. (1200 mm) on center, with reinforcement within 1.3 ft. (410 mm) of the top and bottom of the wall. For conventional **\1** concrete masonry **/1/** cavity wall construction reinforcement only needs to be in the inner wythe unless other reinforcement is required by other criteria.

\1 Exterior unreinforced clay, concrete or stone masonry veneers used in conjunction with wood or metal studs that meet the analysis assumptions of Table C-5 may be considered to meet the provisions of this standard **/1/**. European masonry walls that are within the range of parameters in Table C-5 and PDC Technical Report 10-01 may be considered to meet the requirements of this standard.

3-11 STANDARD 10. GLAZING.

Glazing that is in compliance with this standard is not required to be designed or constructed for blast resistance. It is only intended to minimize hazardous glazing fragments.

Apply the following prescriptive provisions for exterior glazing for new construction or existing buildings that are required to comply with these standards.

3-11.1 Glazing.

For glazing in exterior building elements such as storefronts, doors, windows, curtain walls, clerestories, and skylights provide no less than 1/4 in. (6 mm) nominal polycarbonate or laminated glass. The 1/4 in. (6 mm) laminated glass consists of two nominal 1/8 in. (3 mm) glass panes bonded together with a minimum of a 0.030 in. (0.75 mm) interlayer of a material **\1** that has typically been used in blast resistant window applications. For insulated glass units (IGU), use the polycarbonate or laminated glass for the innermost pane as a minimum.

For polycarbonate, provide a glazing frame bite of no less than 1.5 times the polycarbonate thickness. For laminated glass, the laminated pane shall be adhered to its supporting frame using structural silicone sealant or adhesive glazing tape. The structural silicone sealant bite shall be equal to the larger of 3/8-in. (10-mm) or the thickness of the laminated glass to which it adheres. The minimum thickness of the structural silicone bead shall be 3/16-in. (5-mm). The glazing tape bite shall be equal to two times the thickness of the laminated glass to which it adheres. The structural silicone bead or glazing tape shall be applied to both sides of single pane laminated glass but need only be applied to the inboard (protected) side of an IGU. **/1/**

Monolithic glass or monolithic acrylic used as a single pane or as the inner pane of a multi-pane system is not allowed for the purposes of complying with this standard. Spandrel glass when backed by a structural wall or spandrel beam, translucent fiberglass panels, other lightweight translucent plastics, and glass unit masonry are not required to comply with this standard. Spandrel glass that is open to occupied space must **\1** comply **/1/** with this standard.

3-11.2 Exterior Stairwells, Vestibules, and Covered or Enclosed Walkways.

Glazing in stairwells, vestibules, and covered or enclosed walkways that are exterior to buildings **\2\ /2/** must meet the provisions of this standard. In addition, any windows, inner doors, sidelights, and transoms that are interior to the exterior stairwells, vestibules, or covered or enclosed walkways must meet the requirements of this standard.

3-11.3 Replacement with Wall or Roof Systems.

When windows or skylights are being replaced by filling in the openings with wall or roof material fill in the openings with the same or similar construction as the adjacent wall or roof construction. Alternatively install lightweight translucent fiberglass or plastic panels in the openings.

3-11.4 Alternative Window Treatments.

Window retrofits incorporating alternative window treatments such as fragment retention films and blast curtains are not acceptable alternatives for new buildings or existing buildings that are required to comply with these standards.

The primary reason for that is the fact that such solutions commonly have much shorter design lives than laminated glazing, which requires their replacement multiple times as compared to laminated glazing. Laminated glazing, while more expensive initially, is less expensive over its life cycle. In the case of blast curtains, there needs to be operational procedures to ensure that they remain closed at all times for them to be effective. Fragment retention films and blast curtains are good interim solutions where compliance with these standards is not required.

3-12 STANDARD 11. BUILDING ENTRANCE LAYOUT.

The areas outside of installation perimeters are commonly not under the direct control of installations. Where the main entrances to buildings face installation perimeters, people entering and exiting the buildings are vulnerable to being fired upon from vantage points outside those perimeters. Obscuration or screening that minimizes targeting opportunities and mass notification are assumed to be the primary means of protecting DoD personnel from direct fire weapons. Hardening to resist direct fire effects represents a higher level of protection than required by these standards. To mitigate those vulnerabilities, apply the following measures for buildings required to comply with these standards:

3-12.1 New Construction.

For new construction, ensure that the main entrance to the building does not face uncontrolled vantage points with direct lines of sight or provide means to block the lines of sight using mitigation such as walls, privacy fencing, or vegetation.

3-12.2 Existing Buildings.

For existing buildings where the main entrance faces uncontrolled vantage points, either use a different entrance as the main entrance or screen that entrance to limit the ability of potential aggressors to target people entering and leaving the building using mitigation such as walls, privacy fencing, or vegetation.

3-13 STANDARD 12. EXTERIOR DOORS.

For all new and existing buildings covered by these standards, ensure that all exterior doors into inhabited areas open outwards. By doing so, the doors will seat into the door frames in response to an explosive blast, increasing the likelihood that the doors will not enter the buildings as hazardous debris. Alternatively, position doors such that they will not be propelled into inhabited spaces or provide other means to ensure they do not become hazards to building occupants.

3-13.1 Glazed Doors.

Glazing in and around doors must comply with Standard 10.

3-13.2 Sliding Glass doors and Revolving Doors.

Sliding glass doors and revolving doors do not have to open outwards.

3-13.3 Overhead Doors.

Because of the nature of overhead door failures due to blast loads there are no antiterrorism requirements for overhead doors.

3-14 STANDARD 13. MAIL ROOMS AND LOADING DOCKS.

The following measures address the location of rooms to which mail or supplies are delivered or in which mail or supplies are handled in new buildings required to comply with these standards. This standard is not required for existing buildings, but it is recommended to be applied when possible. These standards need not be applied to mail rooms or loading docks to which mail or supplies that were initially delivered to a central mail or supplies handling facility. These standards should be applied to such mail rooms or loading docks where possible to account for potential changes in mail or supplies handling procedures over the life of the building. The measures in this standard involve limiting collateral damage and injuries and facilitating future upgrades to enhance protection should it become necessary. This standard does not require the hardening of mail rooms or loading docks because the mail and supplies bomb threats are beyond the scope of these standards.

3-14.1 Location.

Where new construction is required to comply with these standards, locate the mail rooms or loading docks on the perimeter of the building. By locating the mail rooms or loading docks on the building perimeters there are opportunities to modify them in the future if a mail or supplies bomb threat is identified. Where mail rooms or loading docks are located in the interiors of buildings, few retrofit options are available for mitigating the mail and supplies bomb threats. Having mail rooms and loading docks on the building perimeter avoids situations where contaminated packages would be transported through the buildings.

3-14.1.1 Proximity.

Locate mail rooms and loading docks as far from heavily populated areas of buildings and from critical infrastructure as possible. This measure will minimize injuries and damage if a mail or supplies bombs detonate in mail rooms or loading docks. Further, it will reduce the potential for wider dissemination of hazardous debris. This applies where mail rooms or loading docks are not specifically designed to resist those threats.

3-15 STANDARD 14. ROOF ACCESS.

For buildings required to comply with these standards, control access to roofs to minimize the possibility of aggressors placing explosives or chemical, biological, or radiological agents there or otherwise threatening building occupants or critical infrastructure.

3-15.1 New Construction.

For new construction eliminate all external roof access by providing access from internal stairways or ladders, such as in mechanical rooms.

3-15.2 Existing Buildings.

For existing buildings, eliminate external access where possible or secure external ladders or stairways with locked cages or similar mechanisms.

3-16 STANDARD 15. OVERHEAD MOUNTED ARCHITECTURAL FEATURES.

For new construction and existing buildings required to comply with these standards, ensure that overhead mounted features weighing 31 pounds (14 kilograms) or more (excluding distributed systems such as suspended ceilings that collectively exceed that weight) are mounted using either rigid or flexible systems to minimize the likelihood that they will fall and injure building occupants. Mount all such systems so that they resist forces of 0.5 times the component weight in any horizontal direction and 1.5 times the component weight in the downward direction. This standard does not preclude the need to design architectural feature mountings for forces required by other criteria such as seismic standards.

3-17 STANDARD 16. AIR INTAKES.

Ground level air intakes to heating, ventilating, and air conditioning (HVAC) systems at that are designed to move air throughout a building provide an opportunity for aggressors to easily place contaminants where they could be drawn into buildings. The following measures will be applied to minimize those opportunities.

Exception: Air intakes within enclosures that meet the requirements of paragraph 3-3.6 and are a minimum of 10 ft. (3 m) horizontally from the enclosure perimeter.

3-17.1 New Construction.

For new construction required to comply with these standards locate all air intakes at least 10 ft. (3 m) above the ground.

3-17.2 Existing Buildings.

For existing buildings required to comply with these standards locate all air intakes at least 10 ft. (3 m) above the ground or provide means such as exterior chimneys to extend the elevations of air intakes to at least 10 ft. (3 m).

3-18 STANDARD 17. MAIL ROOM AND LOADING DOCK VENTILATION.

For new construction required to comply with these standards, provide separate, dedicated HVAC systems for mail rooms and loading docks whose purpose is to receive initial delivery of mail or supplies. This is to ensure airborne chemical, biological, and radiological agents introduced into mail rooms and loading docks do not migrate into other areas of buildings in which the mail rooms and loading docks are located,

3-18.1 Other Heating and Cooling Systems.

Building heating and cooling systems such as steam, hot water, chilled water, and refrigerant may serve mail rooms as long as the airflow systems for the mail rooms and loading docks and other areas of the buildings in which they are located remain separate.

3-18.2 Dedicated Exhaust Systems.

Provide dedicated exhaust systems within mail rooms and loading docks to maintain slight negative air pressures (minimum of 0.05 in. of water [12.5 Pa]) with respect to the remainder of the buildings in which the mail rooms and loading docks are located so that the flow of air is into and contained in the mail rooms and loading docks. Though the airflow into the mail rooms and loading docks will not eliminate the potential spread of contamination by personnel leaving the mail room or the loading dock, it will limit the migration of airborne contaminants through openings and open doorways.

3-18.3 Outside Intakes, Relief, and Exhausts.

Provide mail room and loading dock ventilation system outside air intakes, relief air, and exhausts with low leakage isolation dampers that can be automatically closed to isolate the mail rooms and loading docks. The low leakage dampers will have maximum leakage rates of 3 cfm/square foot (15 liters/second/square meter) with a differential pressure of one inch of water gage (250 Pa) across the damper.

3-18.4 Isolation Controls.

Provide separate switches or methods of control to isolate mail rooms **\1** and loading docks in the event of a suspected or actual chemical, biological, or radiological release in the mail room or loading dock **/1/**.

3-18.5 Walls and Sealing Joints and Doors.

Mail room and loading dock walls will extend from true floor to true ceiling and all joints will be sealed. Doors between mail rooms and loading docks and inhabited areas of buildings will have gaskets or weather stripping to minimize leakage around the doors.

3-19 STANDARD 18. EMERGENCY AIR DISTRIBUTION SHUTOFF.

\1 Provide an emergency shutoff switch in the HVAC control systems of new construction and existing buildings required to comply with these standards. The switch will initiate a response in HVAC systems and low leakage dampers leading to the outside regardless of hand/off/auto position within 30 seconds of switch activation subject to the guidance below.

- Switch activation may, but is not required to shut down HVAC systems that do not draw air from the outside **\2\ /2/**. **\3** One example is a stand-alone bathroom exhaust fan. **/3/**
- Switch activation will not shut down HVAC systems but will close dampers leading to the outside for systems whose continued operation assists in preventing the spread of airborne contaminants and that do not serve mail rooms. An example would be a collective protection system.

Provide a minimum of one shutoff switch per floor. Locate the shutoff switch (or switches) to be easily accessible by building occupants by locating them adjacent to such locations as fire alarm pull stations, interior stairwell entrance doors such that the travel distance to the nearest shutoff switch on the same floor will not exceed 200 ft. (61 m). **/1/**

Ensure that the shutoff switches are well labeled, and of a different color than fire alarm pull stations.

3-19.1 Outside Air Intakes, Relief Air, and Exhausts.

Provide outside air intakes, relief air, and exhaust openings with low leakage dampers that are automatically closed when the emergency air distribution shutoff switch is activated. The low leakage dampers will have maximum leakage rates of 3 cfm/square foot (15 liters/second/square meter) with a differential pressure of one inch of water gage (250 Pa) across the damper. Low leakage dampers will be located at the building envelope or as close as possible to the building envelope. If shutting down an exhaust system will violate building or fire codes or create an unsafe condition, then the exhaust system may continue to operate. For example, the installation of dampers in kitchen exhaust ductwork, where the dampers can become laden with grease, may be a violation of fire codes. In addition, kitchen hood exhaust fans may have to continue to operate to avoid potential fire hazards.

3-19.2 Critical Areas.

Switch activation will not shut down HVAC systems, but will close dampers leading to the outside for systems that serve critical areas where cooling, heating, and / or airflow requirements must be maintained to prevent mission failure, or loss of data, or unsafe conditions such as computer rooms.

Switch activation will not shut down HVAC systems and will not close dampers leading to the outside for critical systems whose continued operation is required by code or other safety protocols such as bio containment laboratories, radio isotope spaces, or other hazardous material or explosive hazard spaces.

3-19.3 Unoccupied Areas.

Switch activation may, but is not required to shutdown HVAC systems and may, but is not required to close dampers leading to the outside for systems that serve one or more normally unoccupied spaces whose access is directly to the outside such as electrical, mechanical, and fire pump rooms.

\3

3-19.4 Fan Coil Unit Heaters and Air Conditioners Through Exterior Surfaces.

For all new buildings required to comply with these standards, fan coil unit heaters and air conditioners that draw air through exterior surfaces must have a system that shuts them off in an emergency. Fan coil unit heaters and air conditioners do not require low leakage dampers. **/3/**

For existing inhabited buildings required to comply with these standards, emergency shutoffs for fan coil unit heaters and air conditioners are recommended.

\3

3-19.5 Laundry Dryers.

For all new buildings required to comply with these standards, automatic shutoff of power to all dryers upon activation of the building emergency shutoff switch is required. Dryer exhaust ducts do not require low leakage dampers.

For existing inhabited buildings required to comply with these standards, automatic shutoff of power to all dryers upon activation of the building emergency shutoff switch is recommended. **/3/**

3-20 STANDARD 19. EQUIPMENT BRACING.

For new construction and existing buildings required to comply with these standards mount all overhead utilities and other fixtures weighing 31 pounds (14 kilograms) or more (excluding distributed systems such as piping networks that collectively exceed that weight) using either rigid or flexible systems to minimize the likelihood that they will fall and injure building occupants. Design all equipment mountings to resist forces of 0.5 times the equipment weight in any horizontal direction and 1.5 times the equipment weight in the downward direction. This standard does not preclude the need to design equipment mountings for forces required by other criteria such as seismic standards.

3-21 STANDARD 20. UNDER BUILDING ACCESS.

To limit opportunities for aggressors placing explosives underneath buildings, ensure that access to crawl spaces, utility tunnels, and other means of under building access is controlled in all buildings required to comply with these standards.

3-22 STANDARD 21. MASS NOTIFICATION.

All buildings required to comply with these standards must have a timely means to notify occupants of threats and instruct them what to do in response to those threats.
\3 Buildings must provide real-time information to building occupants or personnel in

the immediate vicinity of the building during emergency situations. The information relayed must be specific enough to determine the appropriate response actions. Design building mass notification systems in accordance with UFC 4-021-01. **/3/**

CHAPTER 4 STANDARDS FOR EXPEDITIONARY STRUCTURES

4-1 GENERAL.

Implementation of these minimum standards is mandatory for all expeditionary structures that meet the occupancy criteria for inhabited buildings. Many expeditionary structures are in forward operating locations where there is a conventional and/or terrorist threat more severe than those addressed in these standards. In those situations, more detailed planning and additional measures are needed for providing protection. Refer to GTA 90-01-011.

- New buildings built in expeditionary environments or existing buildings used by DoD in those environments will comply with all of the standards in Chapter 3.
- New expeditionary structures built in expeditionary environments will comply with the provisions of this chapter.

4-2 SITE PLANNING STANDARDS.

All the standards that are unique to expeditionary structures pertain to site planning. Integrate operational, logistic, and security requirements into the overall configuration of structures, equipment, landscaping, parking, roads, and other features during planning for expeditionary construction. The most cost-effective solution for mitigating explosive effects on expeditionary structures is to keep explosives as far away from them as possible. This is especially critical for these types of structures because hardening may not be possible or may be prohibitively expensive. Dispersed layouts reduce risks from a variety of threats by taking full advantage of terrain and site conditions; therefore, nothing in these standards is intended to discourage dispersal. Costs and requirements for expeditionary structure hardening are addressed in UFC 4-020-01.

4-2.1 Standard 1. Standoff Distances.

The previous version of Standard 1 established standoff distances to parking, roadways, and controlled perimeters that were based on building construction and occupancy. In this revision of Standard 1 standoff distances only apply to distances to installation perimeters for new construction and additions to existing buildings required to comply with these standards.

Exception: Existing buildings are exempt from this standard.

4-2.2 Minimum Standoff.

\1 The minimum standoff distance for new construction and additions to existing buildings to the installation perimeter is 20 ft. (6 m) **\1** when there is 30 ft. (9m) of clear zone or greater outside the perimeter. Provide a minimum aggregate standoff of 50 feet (15 m) inclusive of the clear zones outside and inside the installation perimeter. For example, if an installation has an established inner clear zone of 20 ft. (6 m) but the outer clear zone is 20 ft. (6 m) wide, the standoff distance to the installation perimeter must be 30 ft. (9 m) wide. **/1/** Where there is no clear zone outside the perimeter, the minimum standoff distance is 50 ft. (15 m).

For buildings that are outside an installation perimeter, use UFC 4-020-01 to establish project requirements. Where UFC 4-020-01 determines project specific Design Basis Threat and Level of Protection, design the project for the resulting standoff distance in accordance with Appendix B, Best Practices. **/1/**

4-2.2.1 Clear Zone.

\1 This standard does not establish the requirement for clear zones. Clear zones are defined by DoD and Service policy. Clear zones are established around the perimeters to provide unobstructed views to enhance detection and assessment. Typically, clear zones are free of all obstacles, topographical features, and vegetation exceeding 8 in. (200 mm) in height that could impede observation or provide cover and concealment of an aggressor. Some forward operating locations and high security areas may have higher clear zone requirements. Consult with local antiterrorism and security personnel to determine clear zone requirements. **/1/** See Figure 3-1 and Figure 3-2.

4-2.3 Standard 2. Structure Separation.

Structure separation requirements are established to minimize the possibility that an attack on one structure causes injuries or fatalities in adjacent structures. The separation distance is predicated on the potential use of indirect fire weapons. Structure separation also limits the ability of fire to spread from structure to structure, which is especially important in many of the types of construction used in expeditionary environments. Provide separation between structures in accordance with Figure 4-1.

4-2.4 Standard 3. Unobstructed Space.

Keep areas within 33 ft. (10 m) of all expeditionary structures free of items other than those that are part of the utilities and other supporting infrastructure. Do not allow roadways and trash containers within unobstructed spaces. Allowing parking within unobstructed spaces will be determined by security personnel.

4-3 ADDITIONAL STANDARDS.

In addition to the specific standards detailed in this chapter, apply the standards from Chapter 3 to expeditionary structures as follows:

4-3.1 Container Structures, \2\ Modular Structures, /2/ and Pre-engineered Buildings.

For these structures, all standards in Chapter 3 apply.

4-3.2 Fabric Covered, Trailers, \2\ /2/ and other Expeditionary Structures.

Apply the following standards from Chapter 3 to these structures:

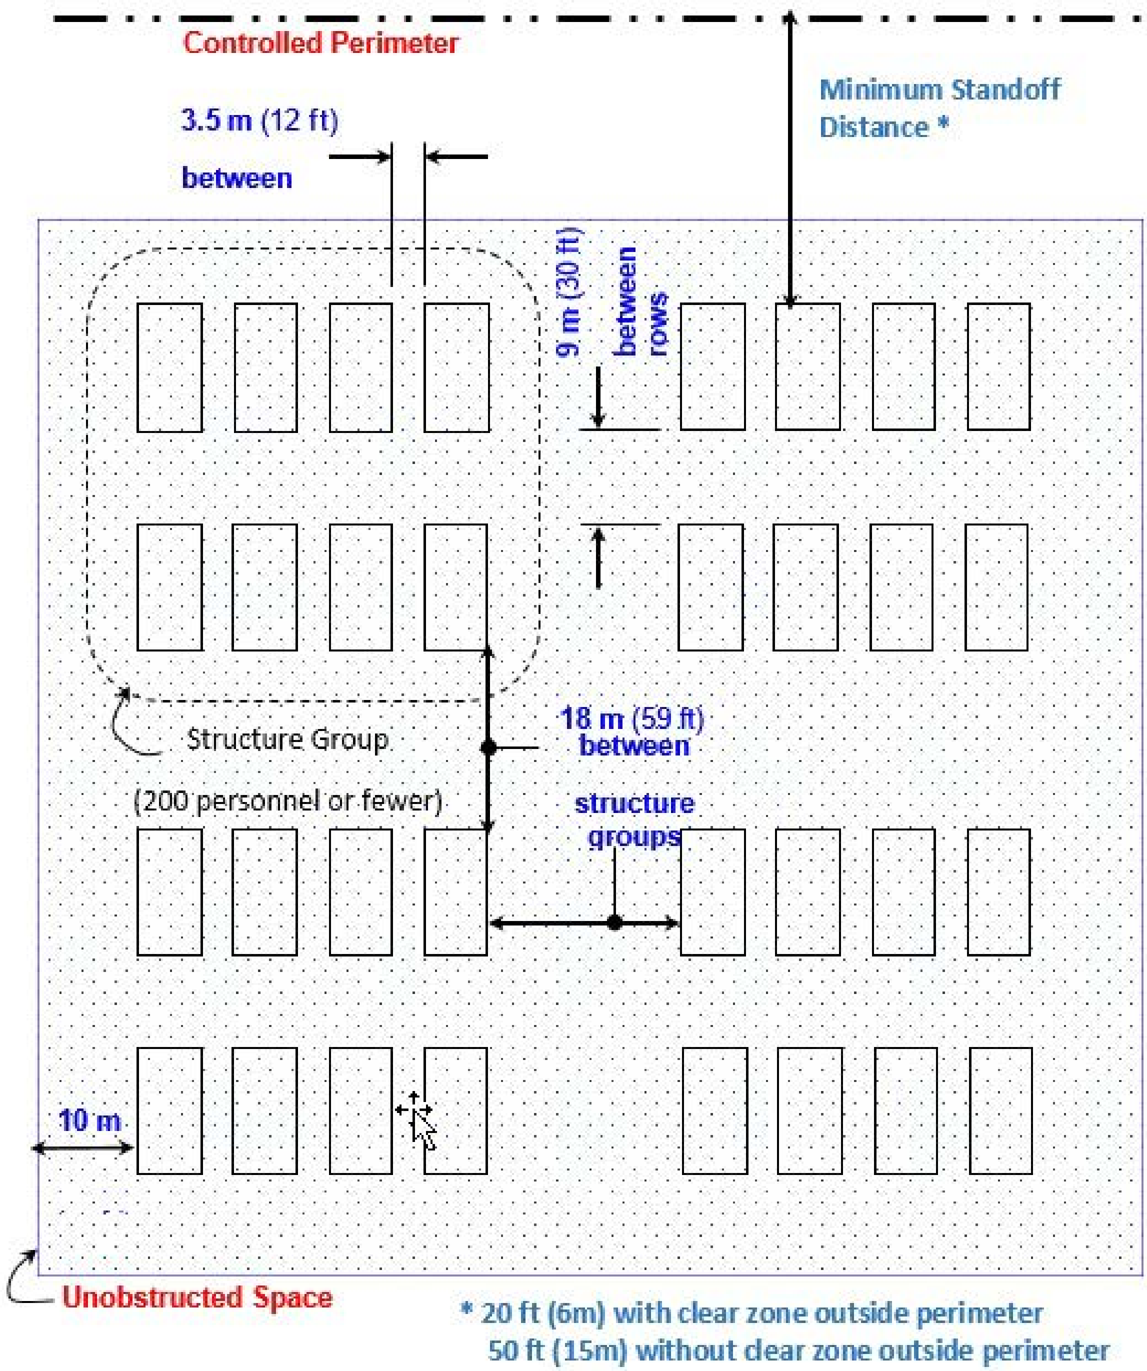
- Standard 10. Glazing
- Standard 11. Building Entrance Layout
- Standard 12. Exterior Doors
- Standard 15. Overhead Mounted Architectural Features
- Standard 19. Equipment Bracing
- Standard 21 Mass Notification

4-4 ANTITERRORISM RECOMMENDATIONS.

\2 Apply the following recommendations from Appendix A:

- Recommendation 1. Vehicle Access Points
- Recommendation 2. High-Speed Vehicle Approaches
- Recommendation 3. Drive-up/Drop-off Areas
- Recommendation 4. Building Location
- Recommendation 5. Railroad Location
- Recommendation 10. Asset Location
- Recommendation 11. Room Layout ***/2/***

Figure 4-1 Standoff and Separation Distances for Expeditionary Construction



APPENDIX A RECOMMENDED ANTITERRORISM MEASURES FOR NEW AND EXISTING BUILDINGS

A-1 INTRODUCTION.

The following additional measures, if implemented, will significantly enhance building occupants' safety and security with little increase in cost and should be considered for all new and existing buildings required to comply with these standards.

A-2 RECOMMENDATION 1. VEHICLE ACCESS POINTS.

The number of access points should be kept to the minimum necessary for security and operational purposes. This will limit the number of points at which access has to be controlled at increased Force Protection Conditions or if the threat increases in the future.

A-3 RECOMMENDATION 2. HIGH-SPEED VEHICLE APPROACHES.

The energy of a moving vehicle increases with the square of its velocity; therefore, minimizing a vehicle's speed enables the vehicle barriers used to be lighter and less expensive. To facilitate vehicle speed reduction, avoid unobstructed vehicle approaches that create direct paths to buildings.

A-4 RECOMMENDATION 3. DRIVE-UP/DROP-OFF AREAS.

Drive-up and drop-off areas should be located away from large glazed areas of buildings to minimize the potential for hazardous flying glass fragments in the event of an explosion. Consider locating the lanes at outside corners of buildings or otherwise away from main entrances or minimizing glazing in the proximity of drive-up and drop-off areas. Building geometries such as reentrant corners in the vicinity of drive-up and drop-off areas should be laid out to minimize the possibility that explosive blast forces could be increased due to being trapped or otherwise concentrated.

A-5 RECOMMENDATION 4. BUILDING LOCATION.

Activities with large visitor populations provide opportunities for potential aggressors to get near buildings with minimal controls and limit opportunities for early detection of aggressor activity. To limit opportunities for aggressors, separation distances should be maximized between buildings required to comply with these standards and areas with large visitor populations.

A-6 RECOMMENDATION 5. RAILROAD LOCATION.

For new construction avoid sites for buildings that are close to railroads. For existing buildings, procedures should be in place to prohibit trains from stopping in the vicinity of those buildings.

A-7 RECOMMENDATION 6. ACCESS CONTROL FOR FAMILY HOUSING.

For new family housing areas, allocate space at the perimeter of the housing area for an entry control facility/access control point designed in accordance with UFC 4-022-01 may be established if the need arises.

A-8 \1\/1/RECOMMENDATION 8. BUILDING SEPARATION.

For all new construction, buildings should be separated from adjacent buildings by at least 33 feet (10 meters).

This recommendation applies to new buildings and is established to minimize the possibility that an attack on one building causes injuries or fatalities in adjacent buildings.

A-9 RECOMMENDATION 9. VISITOR CONTROL.

Controlling visitor access maximizes the possibility of detecting potential threatening activities. Locations in buildings where visitor access is controlled should be kept away from sensitive or critical areas, areas where high-risk or mission-critical personnel are located, or other areas with large population densities of DoD personnel.

A-10 RECOMMENDATION 10. ASSET LOCATION.

To minimize exposure to direct blast effects and potential impacts from hazardous glass fragments and other potential debris, critical assets and mission-critical or high-risk personnel should be located away from the building exterior.

A-11 RECOMMENDATION 11. ROOM LAYOUT.

In rooms adjacent to the exterior of the building, personnel and critical equipment should be positioned to minimize exposure to direct blast effects and potential impacts from hazardous glass fragments and other potential debris.

A-12 RECOMMENDATION 12. EXTERNAL HALLWAYS.

Because doors can become hazardous debris during explosive blast events and designing them to resist blast effects is expensive, avoid building configurations that have large numbers of exterior doors leading into inhabited areas in buildings required to comply with these standards. A common example is a barracks/dormitory with exterior doors into each room or suite. Internal hallways with interior entrances to rooms or suites are preferable.

APPENDIX B BEST PRACTICES

B-1 INTRODUCTION.

\2 The contents in this appendix are not required to meet the minimum standards. This appendix presents a best practices strategy for site planning and designing facilities to protect against stationary vehicle bombs and hand delivered devices where a Design Basis Threat and Level of Protection are identified. **/2/**

The contents in this appendix are taken from the previous publication of this UFC to retain until publication of UFC 4-020-02. **\1** Use the information contained within based on Service, Agency, or Geographic Combatant Command guidance or when UFC 4-020-01 establishes a project specific Design Basis Threat and Level of Protection. **/1/**

B-2 SITE PLANNING FOR STATIONARY VEHICLE BOMBS AND HAND DELIVERED DEVICES.

Protective measures associated with site planning are established to address vehicle borne and hand placed explosive threats. The most cost-effective solution for mitigating explosive effects on buildings is to keep explosives as far as possible from them. Standoff distance should be coupled with appropriate building hardening to provide the necessary level of protection to DoD personnel as described in Table B-1.

Where conventional construction standoff distances cannot be achieved because land is unavailable, these best practices allow for building hardening to mitigate the blast effects. Planning level costs and requirements for building hardening are addressed in UFC 4-020-01. None of these best practices address physical barriers that are capable of stopping moving vehicles to prevent vehicles from accessing areas within the standoff distances established below. Measures using landscaping features, curbing, or pavement marking should meet the best practices for establishing standoff below. Those features address what is called the Stationary Vehicle Bomb Tactic in which the aggressor is assumed not to attempt to enter into areas where he or she would be noticed. Considerations for the Moving Vehicle Bomb Tactic where in the aggressor may be suicidal would include barriers that are capable of stopping the kinetic energy of the threat vehicle. For further discussion on both tactics, refer to UFC 4-020-01.

B-2.1 Standoff Distances.

Provide standoff distances between buildings and controlled perimeters, parking areas, roadways, and trash containers. The standoff distances are presented in Appendix C and illustrated in Figure B-1 and Figure B-2 for new buildings and Figure B-3 and Figure B-4 for existing buildings. For planning purposes, standoff distance is measured to the closest point on the building exterior. Vehicle barriers are not required to maintain these standoff distances unless threat analysis justifies them. **\1** Controlled perimeters can be utilized to limit the explosive weight that can get close to a building as illustrated in Figure B-1. **/1/**

B-2.1.1 Standoff Analysis.

Where the standoff distances in the “Conventional Construction Standoff Distance” (CCSD) columns of Table C-1 through Table C-4 can be met, conventional construction for the applicable building walls may be used for the buildings without a specific analysis of blast effects. Roofs do not need to be analyzed where the standoff distances for roofs in Table C-1 through Table C-4 are met and where they are within the ranges of one of the roof construction types in Table C-5. Types of construction not shown in Table C-5 may be permissible subject to validation by the designer of record. While the APPENDIX C tables address windows, the standoff distances shown should only be used for planning purposes as indicators of standoff distances at which conventionally constructed windows can be used. Standoff Distances for expeditionary structures are found in Table C-6.

Where conventional construction standoff distances are not available, lesser standoff distances may be validated through analysis that verifies the applicable level of protection is met, but none may be closer than the minimum standoff distance distances described in paragraph B-2.1.3 except as allowed for existing buildings. Allowable building damage and door and window hazards for the various levels of protection are described in Table B-1. Note that regardless of standoff distance, where buildings are three stories or more, the progressive collapse provisions of Standard 6 should be applied.

Figure B-1 Standoff Distances – With Controlled Perimeter

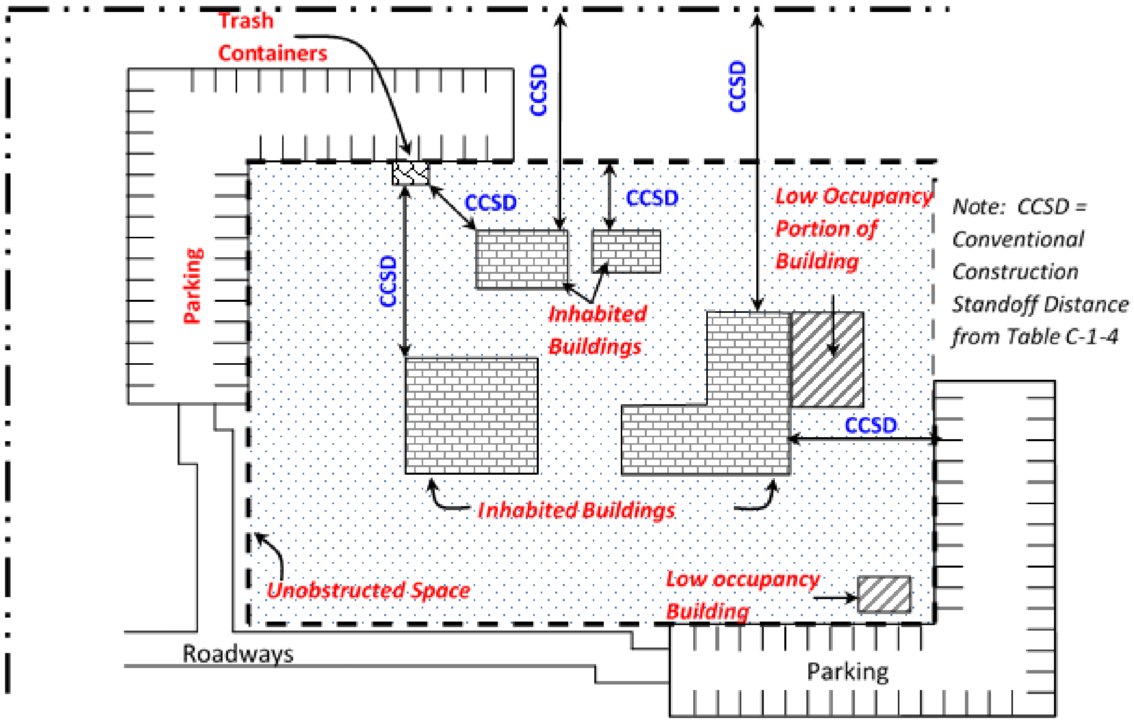


Figure B-2 Standoff Distances – No Controlled Perimeter

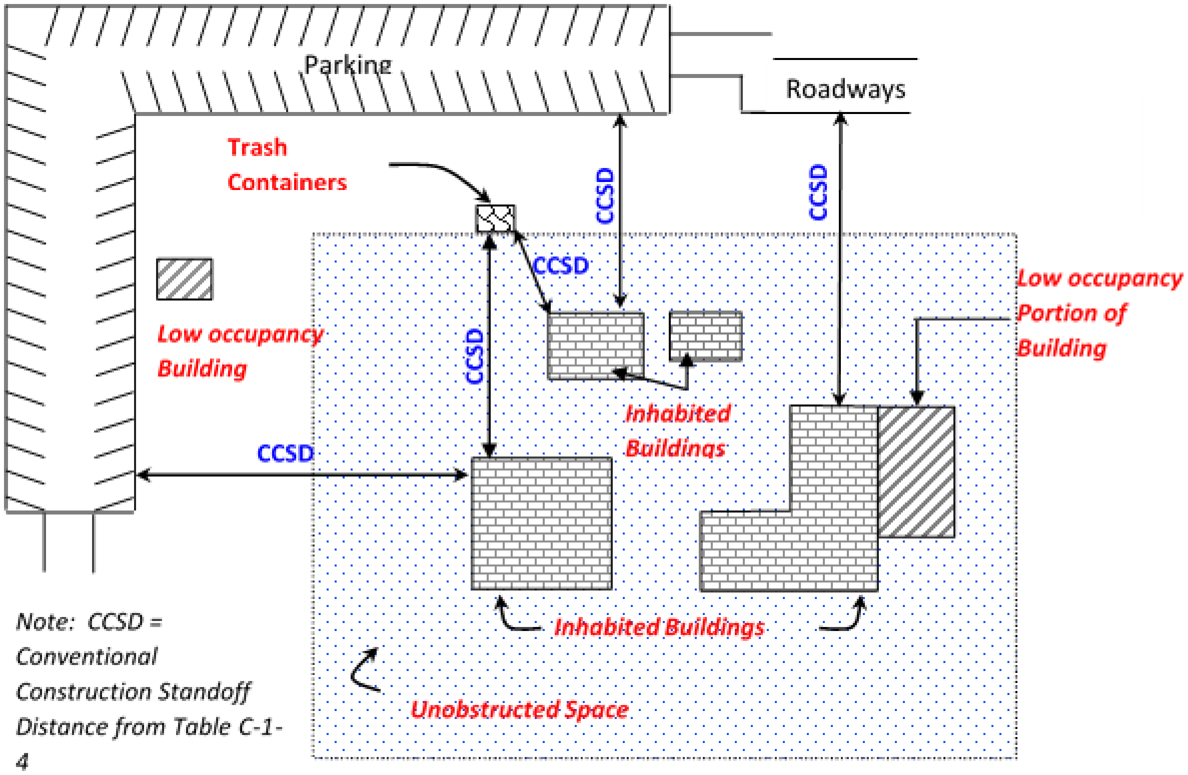

Figure B-3 Parking and Roadway Control for Existing Buildings – Controlled Perimeter

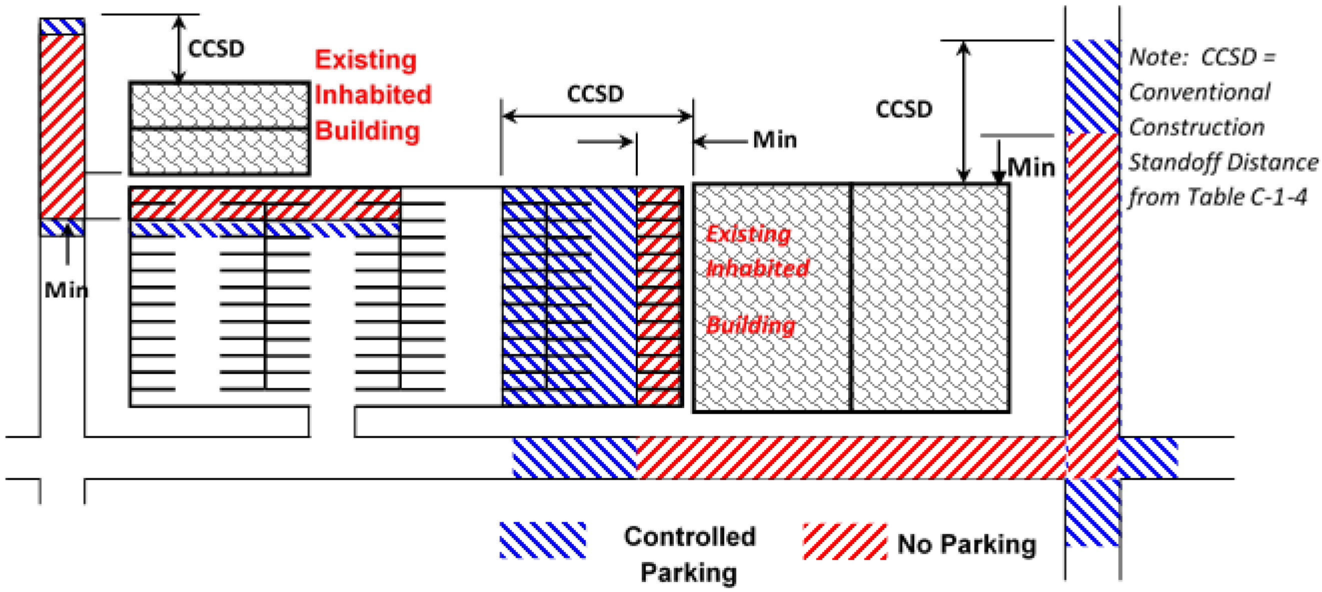

Figure B-4 Parking and Roadway Control for Existing Buildings – No Controlled Perimeter

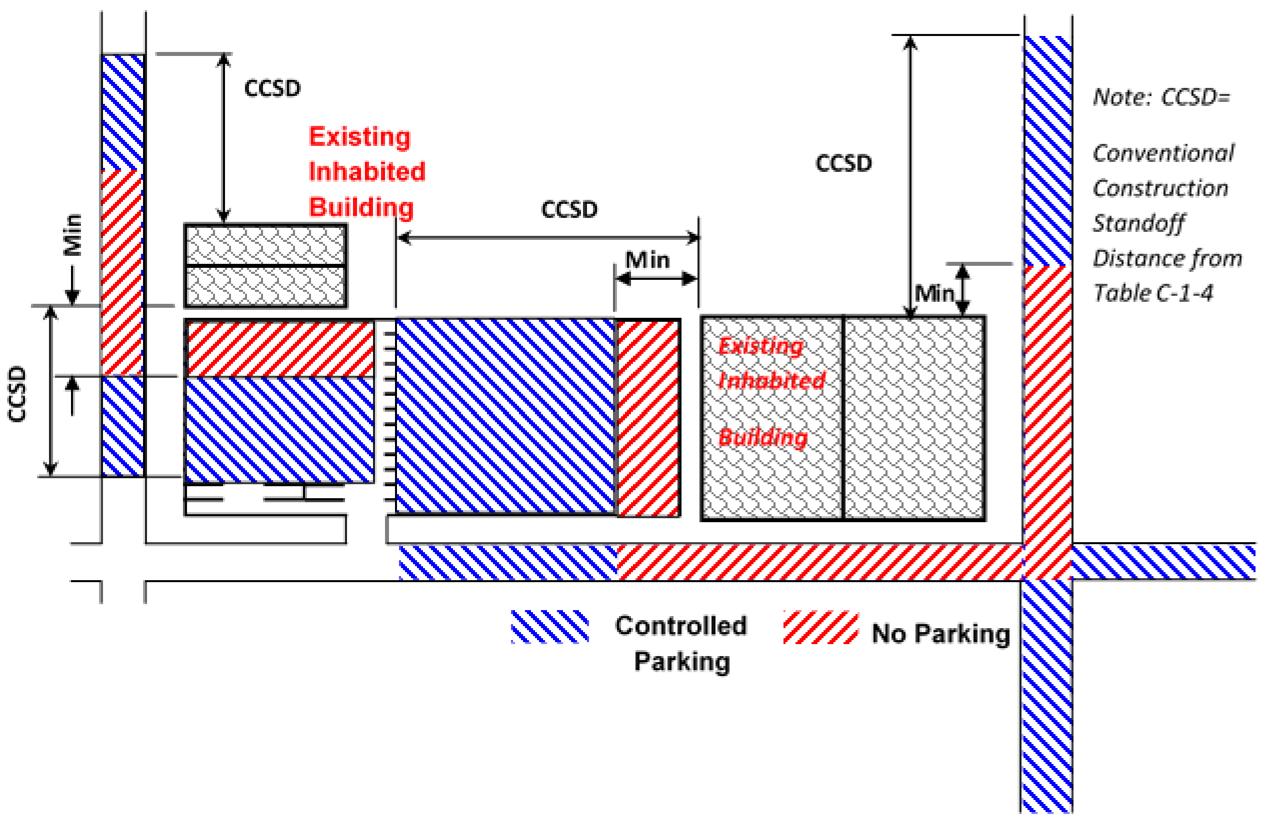

B-2.1.2 Conventional Construction Standoff Distance.

Standoff distances for buildings vary based on the specific construction of the walls, on whether they are load bearing or non-load bearing, by level of protection, and by explosive weight. The specific construction types upon which the standoff distances are based are indicated in Table C-1 through Table C-4 and detailed descriptions of their design parameters are tabulated in Table C-5. The separate conventional construction standoff distances columns in Table C-1 through Table C-4 for load bearing and non-load bearing wall construction reflect the fact that the damage allowed to load bearing construction is less than that allowed to non-load bearing construction for the same level of protection as explained in PDC Technical Report 06-08. Specific standoff distances are tabulated for different construction types. Note that the conventional construction standoff distance columns in Table C-1 through Table C-4 are primarily related to walls because the walls in that table always controlled the conventional construction standoff distance over any of the roofs indicated in Table C-5. Walls and roofs of construction other than those included in Table C-5 should be designed to provide the applicable response described in Table B-1 and detailed in PDC Technical Report 06-08. Standoff distances for windows in Table C-1 through Table C-4 are for conventional windows. When standoff distances are closer than those standoff distances windows will commonly be much heavier and more expensive than conventional windows.

Conventional construction standoff distances do not apply to doors; refer to B-3.2. Planners and designers will have to analyze tradeoffs between wall standoff and window and door construction. Standoff distances for expeditionary structures are based on structure types as indicated in Table C-6.

B-2.1.3 Minimum Standoff Distance.

Minimum standoff distance is the smallest permissible standoff distance allowed for buildings regardless of any analysis results or hardening of buildings that would allow for closer standoff distances, except as established below for existing buildings. Note that achieving the minimum standoff distance generally requires a significant degree of building component hardening; therefore, where only the minimum standoff distance is provided there should be analysis results that show it can be achieved while still providing the applicable level of protection. Minimum standoff distance R_M is determined as a scaled range of 3 by the following equations:

$$\text{For Feet: } R_M = 3\sqrt[3]{W}$$

$$\text{For Meters: } R_M = 1.19\sqrt[3]{W}$$

Where:

W is the threat explosive weight in pounds for feet or kilograms for meters.
R_M is the minimum standoff distance in feet or meters.

Table B-1 Levels of Protection – New and Existing Buildings

Level of Protection	Potential Building Damage/Performance [2]	Potential Door and Glazing Hazards[3,4]	Potential Injury
Below AT standards[1]	Severe damage. Progressive collapse likely. Space in and around damaged area will be unusable.	* Windows will fail catastrophically and result in lethal hazards. *(High hazard rating)* * Doors will be thrown into rooms. *(Category V)*	Majority of personnel in collapse region suffer fatalities. Potential fatalities in areas outside of collapsed area likely.
Very Low	Heavy damage - Onset of structural collapse, but progressive collapse is unlikely. Space in and around damaged area will be unusable.	* Glazing will fracture, come out of the frame, and is likely to be propelled into the building, with potential to cause serious injuries. *(Low hazard rating)* * Doors will become dislodged from the structure but will not create a flying debris hazard. *(Category IV)*	Majority of personnel in damaged area suffer serious injuries with a potential for fatalities. Personnel in areas outside damaged area will experience minor to moderate injuries.
Low	Moderate damage – Building damage will not be economically repairable. Progressive collapse will not occur. Space in and around damaged area will be unusable.	* Glazing will fracture, potentially come out of the frame, but at reduced velocity, does not present a significant injury hazard. *(Very low hazard rating)* * Doors will experience non-catastrophic failure, but will have permanent deformation and may be inoperable. *(Category III)*	Majority of personnel in damaged area suffer minor to moderate injuries with the potential for a few serious injuries, but fatalities are unlikely. Personnel in areas outside damaged areas will potentially experience minor to moderate injuries.
Medium	Minor damage – Building damage will be economically repairable. Space in and around damaged area can be used and will be fully functional after cleanup and repairs.	* Glazing will fracture, remain in the frame and results in a minimal hazard consisting of glass dust and slivers. *(Minimal hazard and No Hazard ratings)* * Doors will be openable but will have permanent deformation. *(Category II)*	Personnel in damaged area potentially suffer minor to moderate injuries, but fatalities are unlikely. Personnel in areas outside damaged areas will potentially experience superficial injuries.
High	Minimal damage. No permanent deformations. The facility will be immediately operable.	* Innermost surface of glazing will not break. (No Break hazard rating) * Doors will be substantially unchanged and fully operable. *(Category I)*	Only superficial injuries are likely.

1. This is not a level of protection and should never be a design goal. It only defines a realm of more severe structural response and may provide useful information in some cases.
2. For damage / performance descriptions for primary, secondary, and non-structural members, refer to PDC Technical Report 06-08.
3. Glazing hazard ratings are from ASTM F 2912.
4. Door damage level categories are from ASTM F 2247 and F 2927.

For new buildings, standoff distances of less than a scaled range of 3 should not be allowed. For existing buildings, the minimum standoff distances should be provided except where doing so is not possible. In those cases, lesser standoff distances may be allowed where the applicable level of protection can be shown to be achieved through analysis or can be achieved through building hardening or other mitigating construction or retrofit as described in these standards

B-2.1.4 Distances Between Conventional and Minimum Standoff Distances

Where the conventional construction standoff distances are not available, an engineer experienced in blast-resistant design should analyze the building and apply building hardening as necessary to mitigate the effects of the applicable explosives at the achievable standoff distance to the appropriate level of protection. The appropriate levels of protection are described in Table B-1 and in UFC 4-020-01. Detailed design parameters for meeting the levels of protection are in PDC Technical Report 06-08. Buildings should be designed for fully reflected blast pressures except where it can be proven that a wall could never be exposed to reflected pressures.

B-2.1.5 Parking and Roadways Standoff Distances.

Measure the standoff distance from the closest edge of parking areas, driving lanes within parking areas, and roadways to the closest point on the building exterior or inhabited portion of the building or to specific building components. In addition, the following apply:

B-2.1.5.1 New Buildings.

The minimum standoff distance for all new buildings regardless of hardening or analysis is that associated with a scaled range of 3 for both parking areas and roadways, whether parking is allowed on the roadways or not.

B-2.1.5.2 Existing Buildings.

Where possible, move parking and roadways away from existing buildings in accordance with the standoff distances in Table C-1 through Table C-4 for the threat explosive weight and the applicable level of protection. It is recognized that moving existing parking areas and roadways or applying structural retrofits may be impractical in some cases; therefore, the following operational options are provided for existing buildings.

B-2.1.5.2. Controlled Parking Areas.

Controlled parking associated with existing buildings may be allowed to be as close as the minimum standoff distance without hardening or analysis if access control (see definition in glossary) to the parking area is established at the applicable conventional construction standoff distance for parking. In cases where the applicable level of protection can be provided (based on hardening or analysis) with a standoff distance between the conventional construction standoff distance and the minimum standoff distance, uncontrolled parking may be allowed at the standoff distance at which the level of protection can be achieved subject to the requirements below, but not closer than the minimum standoff distance.

To mitigate the introduction of hand delivered explosives into the controlled parking areas in violation of the unobstructed space standard (Standard 2), controlled parking areas should have some means to control pedestrian access as well as vehicular access, such as fencing or walls.

B-2.1.5.2. Driving Lanes within Parking Areas.

Where limited space necessitates, driving lanes within parking areas may be closer to existing buildings than parking spaces located at the applicable standoff distances, but vehicles should not be left unattended in those driving lanes. Standoff distance in these cases should be to the nearest parking space. This should not be allowed for new buildings.

B-2.1.5.2. Alternate Situations.

Parking may be closer to existing buildings than the minimum standoff distance where it is impractical to achieve that distance and where it can be shown through analysis that the applicable level of protection can be provided at the lesser standoff distance or if it can be provided through building hardening or other mitigating measures or retrofits designed for those standoff distances. Allowing any parking closer than the distances established in the paragraphs above should be avoided wherever possible.

B-2.1.5.3 Parking on Existing Roadways.

Parking along roadways is subject to similar standoff considerations as to other parking. Where there are existing roads adjacent to existing inhabited buildings, ensure there is no parking on those roadways closer than the conventional construction standoff distance unless the applicable level of protection can be provided (based on hardening or analysis) with a standoff distance between the conventional construction standoff distance and the minimum standoff distance. Parking along those roadways should not be closer than the minimum standoff distance under any circumstance. (Refer to Figure B-3 and Figure B-4). Where parking along existing roadways adjacent to existing buildings can be controlled, parking may be allowed to be as close as the minimum standoff distance without hardening or analysis.

B-2.1.5.4 Parking for Existing High Occupancy Family Housing.

For existing high occupancy family housing within a controlled perimeter or where there is access control to the parking area, parking within the required standoff distances may be allowed where designated parking spaces are assigned for specific residents or residences. Do not label assigned parking spaces with names or ranks of the residents. Where the existing standoff distances are less than the required standoff distances do not encroach upon those existing standoff distances with any additional parking. Avoid parking closer than the minimum standoff distance.

B-2.1.5.5 Adjacent Underground Parking.

Where underground parking is provided adjacent to (not underneath) buildings, parking may be allowed as close to the buildings as the construction of the building superstructure will allow based on the applicable level of protection and explosive weight. Analysis should show that the soil-structure interaction and any venting into the building will not cause progressive collapse of the building or damage to inhabited areas of the building beyond the applicable level of protection. Also, ensure there is no venting into inhabited areas of buildings that could result in occupant injuries.

B-2.1.5.6 Government Vehicle Parking.

Limitations on parking near buildings apply to all vehicles, including official and tactical vehicles, except for mobile ground tactical platforms, emergency vehicles, and operations support vehicles that are never driven out of restricted access areas, as established in these best practices. Government vehicles other than those vehicles are included in the parking limitations in these best practices because it is assumed that when they are out of restricted access areas they may be out of the immediate control of their operators, which could make them susceptible to having explosives placed on or inside of them.

B-2.1.5.7 Parking of Emergency, Command, and Operations Support Vehicles.

Emergency and command vehicles, as well as operations support vehicles may be parked closer to buildings than allowed in Table C-1 through Table C-4 without hardening or analysis if access to the vehicles is continuously controlled or as long as they are never removed from a restricted access area. Command and operations support vehicles should not be parked closer than the applicable minimum standoff distance. In addition, where standard operation of buildings includes parking emergency vehicles inside them, such as in fire stations, those emergency vehicles may be parked inside the buildings.

Emergency vehicles and command vehicles are exempted from parking restrictions because they are assumed to be under strict control while they are both in and away from their usual parking spaces. Operational support vehicles are exempted because they are assumed to always operate within restricted access areas such as airfields.

B-2.1.5.8 Parking of Vehicles Undergoing Maintenance.

Vehicles undergoing maintenance may be parked inside maintenance buildings close to inhabited areas of those buildings while they are undergoing repair without providing any hardening or analysis of the buildings. Vehicles stored outside awaiting maintenance are subject to the parking limitations in these best practices.

B-2.1.5.9 Parking of Mobile Ground Tactical Platforms.

Where operational requirements require parking mobile ground tactical platforms containing non-removable sensitive compartmented information systems adjacent to buildings, ensure those parking areas are surrounded by a 7 foot (2 meter) chain link security fence topped by a single outrigger with three-strands of barbed wire and that access to those parking areas is controlled so that the vehicles cannot be accessed without being detected.

Mobile ground tactical platforms are exempted because they are provided strict security and access control due the sensitive nature of their missions and because they must be parked adjacent to buildings to support their connectivity for electronic system updates.

B-2.1.5.10 Parking for Handicapped Personnel.

Parking for handicapped personnel should not be located closer than the standoff distances necessary to meet the applicable levels of protection. Handicapped parking is only required to be the closest parking available. There is no set distance associated with it.

B-2.1.5.11 Parking and Roadway Projects.

Where practical, all roadway and parking area projects not associated with a building renovation, modification, repair, or restoration should comply with the applicable conventional construction standoff distances from existing inhabited buildings. Where parking areas that are within the applicable standoff distances from such existing buildings are being constructed, expanded, or relocated, those parking areas should not encroach on the existing standoff distances of any existing inhabited building unless it can be shown that the building can provide the appropriate level of protection that would apply if the building were required to meet a standoff distance. Parking and roadway projects should not be located closer than the applicable minimum standoff distances.

If roadway projects include road widening or encroachment on existing standoff distances is otherwise unavoidable, ensure there are operational procedures in place to prohibit parking on the roadways within those standoff distances as described in paragraph B-2.1.5.2. Driving lanes within parking areas may be allowed to be closer to existing buildings than the closest parking spaces where limited space necessitates, but vehicles may not be left unattended in those driving lanes.

B-2.1.5.12 Standoff to Entry Control Facilities/Access Control Points.

For stationary vehicle bomb threats standoff distances from buildings to Entry Control Facilities/Access Control Points should be measured from the identification check area to the closest point on the building exterior or inhabited portion of the building or to specific building components. For moving vehicle bomb threats standoff distances should be measured to the nearest final denial active vehicle barrier.

B-2.1.5.13 Location of Trash Containers.

Provide standoff distances from the nearest points of trash containers or trash container enclosures to the closest points on building exteriors, inhabited portions of buildings, or to specific building components in accordance with the conventional construction standoff distance for the threat hand carried explosive. Where the applicable conventional construction standoff distance is not available, analyze the building and apply building hardening as necessary to mitigate the effects of the applicable explosives for trash containers at the achievable standoff distance to the appropriate level of protection.

Alternatively, harden trash enclosures to mitigate the direct blast effects and secondary fragment effects of the explosive on the building if the applicable level of protection can be proven by analysis or testing. As an additional alternative, if trash containers or enclosures are secured to preclude introduction of objects 6-in. (150 mm) or greater in height or width into them by unauthorized personnel, they may be located closer to the building as long as they do not violate the unobstructed space provisions of paragraph B-2.2. Openings in screening materials and gaps between the ground and screens or walls making up an enclosure should not be greater than 6 in. (150 mm).

B-2.1.5.14 Adjacent Existing Buildings.

Where projects for new and existing buildings include locating parking, roadways, or trash containers near existing inhabited buildings, the standoff distances from parking, roadways, and trash containers to those buildings should comply with the applicable standoff distances in Table C-1 through Table C-4.

Where those standoff distances are not available, do not allow parking and roadways to encroach on existing standoff distances to parking and roadways associated with those existing buildings unless it can be shown that the building can provide the appropriate level of protection that would apply if the building were required to comply with the minimum standards in this UFC. The encroachment provision above applies only to parking and roadways. Do not allow trash containers associated with new or existing buildings to be located closer to existing inhabited buildings than the applicable standoff distances in Table C-1 through Table C-4.

B-2.1.5.15 Parking Structures.

Standoff distances between parking structures and inhabited buildings should be measured to actual parking spaces within the parking structures, including spaces on all floors of the parking structures.

B-2.2 Unobstructed Space.

Standard 2 covers unobstructed space requirements to meet the minimum standards, however, fully mitigating the effects of a hand placed explosive requires determining a standoff distance based on the building construction, threat explosive weight, and applicable level of protection. To achieve that mitigation, do the following in addition to what is required by Standard 2. The unobstructed space should extend out to the applicable conventional construction standoff distance to walls for parking and roadways in accordance with Table C-1 through Table C-4, but not less than the minimum standoff distance. If the standoff distance required to provide the applicable performance of windows or doors is greater than the conventional construction standoff distance, the unobstructed space should extend to the applicable window or door distance. Unobstructed space for expeditionary structures should be determined using Table C-6.

Alternatively, for distances between the conventional construction standoff distance and the minimum standoff distance, standoff distances may be validated through analysis. That analysis verifies the applicable level of protection is met based on mitigating the effects of the threat hand carried explosive at the distance between the location of the explosive and the area of the building being protected. For existing buildings where the standoff distances for parking and roadways have been established at less than the minimum standoff distance, the unobstructed space may be reduced to be equivalent to those distances.

B-2.2.1 Controlled Parking.

Where controlled parking associated with existing buildings is allowed, the unobstructed space should be considered to extend to the limits of those parking areas where access is controlled. To mitigate the introduction of hand delivered explosives into the controlled parking areas, those areas should have some means to control pedestrian access as well as vehicular access, such as fencing or walls. Security fences or walls should be a minimum of 7 ft. (2 m) high. Specific fence, wall, and access control requirements should be coordinated with physical security and antiterrorism personnel.

B-2.2.2 Parking Within Unobstructed Spaces.

When an explosive threat has been identified, parking should not be allowed within unobstructed spaces except for parking of emergency, command, and operations support vehicles and mobile ground tactical platforms.

B-2.2.3 Adjacent Uncontrolled Public Space.

Where there is a defined explosive threat and there are spaces with uncontrolled public access below, above or beside building areas that are occupied by DoD, it should be considered that the threat explosives may be located in those spaces and the spaces occupied by DoD should be designed **\1** for blast resistance **/1/** to ensure that they meet the applicable level of protection.

B-2.3 Drive-Up/Drop-Off Areas.

Some facilities require access to areas within the required standoff distances for dropping off or picking up people or loading or unloading packages and other objects. Examples that may require drive-ups or drop-offs include, but are not limited to, medical facilities, exchanges and commissaries, schools, and child care centers. In these cases, standoff distances should be measured to the nearest legal parking spaces, not the drive-ups or drop-offs. No building hardening should be required to compensate for the closer standoff distances associated with the drive-ups or drop-offs. This also applies to drive-through lanes such as those at stand-alone franchised food operations.

B-2.3.1 Marking.

Where operational or safety considerations require drive-up or drop-off areas or drive-through lanes near, ensure those areas or lanes are clearly defined and marked in accordance with the Manual on Uniform Traffic Control Devices and that their intended use is clear to prevent parking of vehicles in those areas.

B-2.3.2 Unattended Vehicles.

Do not allow unattended vehicles in drive-up or drop-off areas or drive-through lanes. Prohibit unattended vehicles within conventional construction standoff distances in accordance with Table C-1 through Table C-4 or ensure through analysis that buildings can provide the appropriate level of protection at lesser standoff distances. Unattended vehicles should never be allowed closer than the minimum standoff distance.

B-2.3.3 Location.

Do not allow drive-through lanes or drive-up/drop-off areas to be located under any inhabited portion of any new building. For existing buildings that have drive-through lanes or drive-up areas, either eliminate them or design the buildings to provide the applicable level of protection for the applicable explosive weight located underneath the portion of the building accessed by the drive-through or drop-off.

B-2.4 Access Roads.

Where access roads are necessary for the operation of buildings (including those required for emergency access and/or security operations), ensure that access control measures are implemented to prohibit unauthorized vehicles from using access roads within the applicable standoff distances. Because situations at various buildings and installations are different, the development of specific access control measures and procedures is beyond the scope of these standards. That is left to local physical security personnel.

B-2.5 Parking Beneath Buildings or on Rooftops.

Standard 5 in Chapter 3 establishes the minimum measures required for addressing this situation. To mitigate the effects of an explosive event underneath or on top of a building, ensure that there is no general collapse of more than one single bay of floor beneath or floors/roof above inhabited areas and that all other adjacent supporting structural elements will not fail from the detonation in the parking area of the threat explosive. Unless it can be shown that a greater standoff distance can be justified, evaluate structural elements in parking areas at a standoff distance of 4 ft. (1.2 m) horizontally or 30 in. (76 cm) above the elements. Failure should be evaluated based on the applicable level of protection in accordance with PDC Technical Report 06-08. Also, ensure there is no venting into inhabited areas of buildings that could result in occupant injuries. In addition, see Standard 6 of the minimum standards for progressive collapse avoidance requirements.

B-3 ARCHITECTURAL AND STRUCTURAL DESIGN.

CHAPTER 3 establishes minimum requirements for glazing and doors. Those requirements do not address mitigation of blast effects on structures. Where an explosive threat has been identified to a facility, the following apply.

B-3.1 Windows and Skylights.

To minimize hazards from flying debris from windows and skylights, apply the following provisions for glazing, framing, connections, and supporting structural elements for all new and existing buildings for which there is an identified explosive threat. These provisions apply to window systems at all standoff distances, even those that meet or exceed the wall conventional construction standoff distances. The specific requirements below will result in window and skylight systems that provide for effective hazard mitigation. These provisions allow for design by dynamic analysis, testing, or the ASTM F 2248 design approach as described in the paragraphs below. Use strength design with load factors of 1.0 and strength reduction factors of 1.0 for all methods of analysis referenced herein for flexure and use typical strength reduction factors for other modes of failure. Windows will be inclusive of storefronts, clerestories, and similar glazed construction. For glazed doors refer to paragraph B-3.2.2.

Monolithic glass or monolithic acrylic used as a single pane or as the inner pane of a multi-pane system is not allowed as glazing when there is an identified explosive threat. Spandrel glass when backed by a structural wall or spandrel beam, translucent fiberglass panels, other lightweight translucent plastics, and glass unit masonry should meet the performance requirements of Table B-1. That performance needs to be proven through testing or analysis. Engineered glass block window systems and spandrel glass that is open to occupied space should be designed in accordance with the following guidance.

B-3.1.1 Dynamic Analysis.

Any of the glazing, framing members, connections, and supporting structural elements may be designed using dynamic analysis to prove the window or skylight systems will provide performance equivalent to or better than the hazard rating associated with the applicable level of protection established in the project requirements and described in Table B-1. Dynamic analysis guidance is presented in PDC TR 10-02. The design loadings for dynamic analyses should be the appropriate pressures and impulses from the applicable explosive weights at the actual standoff distances at which the windows are sited. The design loading should be applied over the areas tributary to the element being analyzed. The allowable response limits of structural elements for all of the levels of protection are provided in PDC-TR 06-08. Response limits for steel and aluminum window frame members are provided in PDC-TR-10-02. Window frames constructed from materials other than aluminum or steel should be tested in accordance with paragraph B-3.1.2 or proven by analysis to demonstrate performance equivalent to or better than the hazard rating associated with the applicable level of protection as indicated in Table B-1.

B-3.1.2 Testing.

Window and skylight systems may be dynamically tested to demonstrate performance equivalent to or better than the hazard rating associated with the applicable level of protection as indicated in Table B-1. Testing should include the entire window or skylight system, including connections, and should be in accordance with ASTM F 1642 with hazard ratings in accordance with ASTM F 2912.

The structural supporting material used in the test for fastener attachment should be representative of the fielded application. Any deviations in field application of the connections or the connected elements from the test should be demonstrated by calculation to provide the applicable level of protection for the specific application. The design loading for a dynamic test should be the appropriate pressure and impulse from the applicable explosive weight at the actual standoff distance at which the window is sited.

B-3.1.3 ASTM F 2248 Design Approach for Laminated Glass Glazing Systems.

Windows and skylights fabricated using laminated glass may be designed using ASTM F 2248 and ASTM E 1300 in accordance with the requirements below. The application of ASTM F 2248 and ASTM E 1300 results in a medium level of protection as reflected in Table B-1.

B-3.1.3.1 Glazing.

Provide laminated glass with a minimum interlayer thickness of 0.030 in. (0.75mm) and a load resistance determined from ASTM E 1300 greater than or equal to the 3-second duration equivalent design load determined from ASTM F 2248.

Note that ASTM F 2248 can be used for a limited range of charge weights and standoffs, including those covered by this standard. For charge weights and standoffs outside of the range of ASTM F 2248, for conditions outside the range of ASTM E 1300, and for glazing alternatives to laminated glass that provide equivalent levels of protection, refer to PDC Technical Report 10-02.

B-3.1.3.2 Frames.

Provide window and skylight frames, mullions and sashes of aluminum or steel designed in accordance with ASTM F 2248. Window frames constructed from materials other than aluminum or steel should be tested in accordance with paragraph B-3.1.2 or proven by analysis to demonstrate performance equivalent to or better than the hazard rating associated with the applicable level of protection as indicated in Table B-1.

In the case of a punched or ribbon window, the supported edge length should be taken as equal to the longest span of a single pane of glass, regardless of any intermediate support connections. For storefront and curtain wall systems, primary mullions that span between points of structural support should be considered supporting frame members and may be designed dynamically in accordance with paragraph B-3.1.1 or statically. If designed by the static method the moment and shear capacities of framing members should be designed to resist two (2) times the load resistance of the glazing applied to the framing members only from the tributary area of the window, and deflection should be limited to 1/60 of the members' span lengths between points of structural support. Intermediate mullions should be checked for deflection with the supported edge length taken as equal to the longest span of a single glass panel and the deflection should be calculated based on simple support conditions for that length.

B-3.1.3.3 Glazing Frame Bite.

Glazing frame bite requirements for structurally or non-structurally glazed windows or skylights should be in accordance with ASTM F 2248. Apply structural silicone bead or glazing tape to both sides of the glass panel for single pane glazing but only to the inboard side for insulating glass units.

B-3.1.3.4 Connection Design.

Connections of window and skylight frames to surrounding walls or roofs, of hardware and associated connections, of glazing stop connections, and of other elements in shear should be designed for the connection design load determined in accordance with ASTM F 2248 and should account for the geometry of the particular frame and the connection configuration being used when calculating bending, shear, bearing, and pull out loads for the connections.

B-3.1.4 Design of Supporting Structural Elements.

Supporting structural elements (i.e., those structural elements that frame the rough opening) for window and skylight systems of any glazing material can be designed statically to account for the increase in tributary areas to the adjacent supporting elements due to windows or skylights. Building elements that have only glazing framed into them, such as curtain walls and storefronts, should be designed as frame members in accordance with paragraph B-3.1.3.2. For window and skylight systems in buildings situated at less than the wall conventional construction standoff distance, the surrounding wall and roof elements should be designed dynamically in accordance with paragraph B-3.1.1.

B-3.1.4.1 Static Design of Wall and Roof Elements.

For window and skylight systems in buildings situated at or beyond the wall conventional construction standoff distance for the wall material to which it is attached, the surrounding wall and roof elements and their connections to the rest of the structure should be designed as described below. The supporting structural elements adjacent to windows or skylights should be designed to account for their increased tributary areas. These areas represent the tributary areas of windows or skylights, and the walls or roof area above and below them, whose loads should be laterally supported by those elements. Those increases in tributary areas should be accounted for by applying a tributary area increase factor (C) to the moment and shear capacities of the wall or roof elements. The tributary area increase factor is the ratio of the tributary area that accounts for the windows or skylights and the walls or roofs above and below them to the tributary area upon which typical conventional wall sections or elements are designed. See PDC Technical Report 10-02 for an illustration. The tributary area increase factor is shown in Equation 1 and should not be taken as less than 1.

$$C = \frac{a_{trib}}{a_{wall}} \geq 1$$ Equation 1

a wall = tributary area for typical conventional wall section or element

a trib = combined tributary area for supported window or skylight and wall or roof section or element

Design the supporting structural elements to have moment and shear capacities equal to or greater than the calculated conventional wall capacities multiplied by the applicable tributary area increase factor as shown in Equation 2 and Equation 3. Connection loads for the supporting structural element should be determined based on the increase in member shear capacity.

$$M_{SSE} \geq C \cdot M_{CW}$$ Equation 2

$$V_{SSE} \geq C \cdot V_{CW}$$ Equation 3

MSSE and VSSE are moment and shear capacities of supporting structural element.

MCW and VCW are moment and shear capacities of conventional wall section.

B-3.1.4.2 Reactions for Static Design.

The reactions from the supporting structural element analysis normally do not have to be carried through the horizontal and lateral bracing systems of buildings to the foundations. The main concern is that these loads are transferred into horizontal floor and roof systems without failing those connections or the attached elements, as the building mass dissipates those loads before they are transferred to the foundation. It is left to the structural engineer to assess the adequacy of these connections, the attaching elements, and the need for further analysis.

B-3.1.5 Skylights.

Because glazing fragment hazards are increased when glazing falls from the elevations of skylights, skylight glazing should be designed as a minimum to break, but remain in the frame, which is equivalent to the minimal hazard rating in ASTM F 2912 (medium level of protection in Table B-1). Use the appropriate blast load for the applicable angle of incidence to design or test the skylight.

B-3.1.6 Window and Skylight Replacement Projects.

Whenever windows and skylights are being replaced in existing buildings that have an identified explosive threat, design glazing, frames, connections, and supporting structural elements to meet all of the requirements of **\1** B-3.1 **/1/**. Base the window designs on either the standoff distances to existing parking and roadways or to the planned locations for future parking and roadways in accordance with the installation or facility master plan. These provisions also apply to new windows installed in new wall openings.

Provide no less than 1/4 in. (6 mm) nominal polycarbonate or laminated glass for exterior windows or skylights. The 1/4 in. (6 mm) laminated glass consists of two nominal 1/8 in. (3 mm) glass panes bonded together with a minimum of a 0.030 in. (0.75 mm) interlayer of a material designed and tested for bomb blast resistance. For insulating glass units (IGU), use the polycarbonate or laminated glass for the innermost pane as a minimum. For laminated glass provide a glazing frame bite in accordance with ASTM F 2248. For polycarbonate provide a glazing frame bite of no less than 1.5 times the polycarbonate thickness.

B-3.1.7 Replacement with Wall or Roof Systems.

When windows or skylights are being replaced by filling in the openings with wall or roof material the openings should be filled with the same or similar construction as the adjacent wall or roof construction. Lightweight translucent fiberglass or plastic panels or other construction dissimilar to the existing adjacent construction may also be used. Regardless of the infill construction used, it must **\1** be designed and constructed for blast resistance to **/1/** provide the applicable level of protection.

B-3.1.8 Alternative Window Treatments.

For existing buildings in which windows are not being replaced, window retrofits incorporating alternative window treatments are viable and economical solutions to mitigating the effects of explosive attacks but will be evaluated prior to installation so that reduction in glass hazards **\1** for the applicable level or protection **/1/** may be validated.

B-3.1.9 Exterior Stairwells and Covered or Enclosed Walkways.

\1 Because the glazing in stairwells and covered or enclosed walkways must comply with Standard 10 in Chapter 3 **/1/** building components behind the exterior stairwell glazing should be capable of mitigating any hazards resulting from the stairwell or enclosed walkway glazing failure in response to a blast event in accordance with the applicable levels of protection described in Table B-1. To provide that debris resistance, any windows, inner doors, sidelights, and transoms that are interior to the exterior stairwells or enclosed walkways should meet the windborne debris resistance requirements of ASTM E 1996 (missiles A and D in Table 2) All building components behind stairwells and covered or enclosed walkways should also be designed for blast resistance as if the stairwells or walkways were not present.

B-3.2 Exterior Doors.

For new and existing buildings for which there is an identified explosive threat provide exterior doors into inhabited areas in accordance with the provisions below

B-3.2.1 Unglazed Doors

Provide unglazed doors that are tested to achieve the applicable damage level category in Table B-1 in accordance with ASTM F 2247, with ASTM F 2927, or that meet the provisions of the “Alternative Designs” paragraph below.

- The fasteners and anchorage methods used to attach the tested door assembly should be representative of the actual door installation. Any deviations in actual installation of the connections or the connected elements from those tested should be demonstrated by calculation to provide the applicable level of protection for the specific application.
- The design air blast loading for the test should be the appropriate pressure and impulse from the applicable explosive weight at the actual standoff distance at which the door is sited.

B-3.2.2 Glazed Doors.

Provide glazed doors that are tested to achieve the applicable door damage level category and glazing hazard rating in Table B-1 in accordance with ASTM F 2927 that meet the provisions of the “Alternative Designs” paragraph below. Unless included as part of the tested assembly, glazed sidelights and transoms around doors should meet the window design requirements above.

- The fasteners and anchorage methods used to attach the tested door assembly should be representative of the actual door installation. Any deviations in actual installation of the connections or the connected elements from those tested should be demonstrated by calculation to provide the applicable level of protection for the specific application.

- The design air blast loading for the test should be the appropriate pressure and impulse from the applicable explosive weight at the actual standoff distance between the location of the doors and potential locations for explosives.

B-3.2.3 Alternative Designs.

As an alternative to the above testing provisions for glazed and unglazed doors, position doors such that they will not be propelled into inhabited areas if they fail in response to a blast or provide other means to ensure they are intercepted by a surface with sufficient strength to keep the doors from translating into inhabited areas if they fail or otherwise ensure they do not become hazards to building occupants. The glazing in glazed doors should still meet the glazing and frame bite provisions of Standard 10 if this alternative is exercised to reduce the glazing hazard. The framing, connection, and supporting structure provisions above do not have to be applied for this alternative. Where it is not possible to design surfaces to safely intercept doors, the doors should be designed to remain in the door frames.

B-3.2.4 Vestibules or Foyers.

In vestibules, foyers, or similar entry configurations into inhabited areas where there are inner and outer doors the vestibules, foyers, or similar entries the inner doors should meet the provisions of this appendix and any other glazing associated with inner door entries such as sidelights and transoms should meet the requirements above. The inner doors and glazing should be capable of mitigating any hazards resulting from the enclosed vestibule or foyer outer doors and glazing failure in response to the design blast event. This is to account for the fact that at the levels of protection associated with these best practices the outer doors and glazing may fail, which would subject the inner doors and glazing to significant blast loads. To provide that debris resistance, the inner doors, sidelights, and transoms should meet the windborne debris resistance requirements of ASTM E 1996 (missiles A and D in Table 2).

Alternatively, exterior doors and glazed surfaces of the exteriors of vestibules or foyers can be designed to a minimum of a medium level of protection. Designing to that level will ensure that blast effects do not breach outer layers of vestibules or foyers, protecting inner doors and associated glazing from blast effects. Those inner doors and glazed surfaces could then be designed of conventional construction.

B-3.2.5 Overhead Doors.

Because it is impractical to design conventional overhead doors to meet the required performance in Table B-1, ensure overhead doors do not open into inhabited spaces or ensure that if they fail that they are intercepted by walls or tether systems that are designed with sufficient strength to keep the overhead doors from translating into areas that meet the definition of inhabited spaces.

APPENDIX C REPRESENTATIVE STANDOFF DISTANCES FOR CONVENTIONAL CONSTRUCTION AND EXPEDITIONARY STRUCTURES

C-1 INTRODUCTION.

The purpose of this appendix is to provide representative standoff distances for a number of conventionally constructed walls, roofs, and windows that fall within the parameters of Table C-5. The materials that were selected are for systems that are commonly used in DoD construction. These standoff distances should only be used for project planning and not used as a basis for final design. Even if the final structural elements fall within the parameters of Table C-5 they should be validated during design. The contents in this appendix will be included in UFC 4-020-02 when published. The information contained within may be used when a specific threat has been identified for the location or project based on UFC 4-020-01 or Service, Agency, or Geographic Combatant Command guidance.

C-2 USING THIS APPENDIX.

Each of Table C-1 through Table C-4 corresponds to specific levels of protection from very low to high. Within those columns there are standoff distances for each of the construction types in the leftmost column. Instructions for walls, roofs, and windows follow.

C-3 WALLS.

For each wall type there are two entries for each threat severity level. There is one for load bearing walls (LB) and one for non-load bearing (NLB). Either select a wall material based on available standoff distance or select a standoff distance based on a desired wall material. Note that where wall types include multiple cladding systems such as brick half way up the wall and EIFS above that, use the greater of the two applicable standoff distances for the two wall materials. Note that the walls in Table C-5 have specific ranges of spans and material properties. Table C-1 through Table C-4 are only valid within those ranges of properties. Users must not extrapolate outside of the tables.

C-4 ROOFS.

Roofs seldom control the designs of buildings with respect to blast resistance, but standoff distances for common concrete and metal roofs are tabulated for reference. Other roof types will have to be analyzed separately.

C-5 WINDOWS.

The standoff distances for windows are for conventional laminated glass windows with glazing consistent with the minimum glazing in Paragraph B-3.1.3.1. These windows can be considered conventional windows. Any standoff distances less than those in Table C-1 through Table C-4 for windows will require heavier and more costly blast resistant window systems.

C-6 EXPEDITIONARY STRUCTURES.

Standoff distances to expeditionary structures are based on structure types as indicated in Table C-6. Standoffs are based on blast testing of actual structures of the types indicated. Note that there are some entries that have NDA instead of distances. Those entries reflect instances where there was no data available to make a determination of standoff distance. **\1** For container structures, use standoff distances for pre-engineered buildings in Tables C-1 through C-4. **/1/** Note that there are no entries for windows. If there are windows in expeditionary structures, use the window entries from Tables C-1 through C-4. For more information on standoff distances for expeditionary structures refer to **\1** GTA 90-01-011 **/1/**.

Table C-1 Representative Standoff Distances for Very Low Level of Protection [7]

Construction [1]	Explosive Weight (TNT)											
	55 lbs (25 kg)		220 lbs (100 kg)		550 lbs (250 kg)		1,100 lbs (500 kg)		4,400 lbs (2,000 kg)		19,800 lbs (9,000 kg)	
	LB [2]	NLB [3]	LB [2]	NLB [3]	LB [2]	NLB [3]	LB [2]	NLB [3]	LB [2]	NLB [3]	LB [2]	NLB [3]
Metal Stud with Lightweight Sheathing [4]	150 ft (46 m)	67 ft (20 m)	376 ft (115 m)	162 ft (49 m)	661 ft (201 m)	290 ft (88 m)	971 ft (296 m)	445 ft (136 m)	1642 ft (500 m)	988 ft (301 m)	2656 ft (809 m)	2417 ft (737 m)
Metal Stud with Brick Veneer [4]	74 ft (22 m)	31 ft (9 m)	186 ft (57 m)	84 ft (26 m)	341 ft (104 m)	152 ft (46 m)	538 ft (164 m)	235 ft (72 m)	1303 ft (397 m)	571 ft (174 m)	2545 ft (776 m)	1416 ft (431 m)
Wood Stud with Lightweight Sheathing [4]	85 ft (26 m)	55 ft (17 m)	211 ft (64 m)	139 ft (42 m)	386 ft (118 m)	253 ft (77 m)	601 ft (183 m)	395 ft (120 m)	1441 ft (439 m)	958 ft (292 m)	2645 ft (806 m)	2304 ft (702 m)
Wood Stud with Brick Veneer [4]	36 ft (11 m)	17 ft (5 m)	103 ft (31 m)	64 ft (20 m)	193 ft (59 m)	127 ft (39 m)	303 ft (92 m)	203 ft (62 m)	761 ft (232 m)	498 ft (152 m)	2010 ft (613 m)	1307 ft (398 m)
Pre-engineered Building (Girt and Metal Panel) [4]	104 ft (32 m)	39 ft (12 m)	336 ft (102 m)	108 ft (33 m)	684 ft (209 m)	213 ft (65 m)	1132 ft (345 m)	345 ft (105 m)	1668 ft (508 m)	851 ft (259 m)	2780 ft (847 m)	2418 ft (737 m)
Unreinforced Concrete Masonry [4]	80 ft (24 m)	15 ft (4 m)	262 ft (80 m)	34 ft (10 m)	535 ft (163 m)	71 ft (22 m)	906 ft (276 m)	162 ft (49 m)	1893 ft (577 m)	538 ft (164 m)	2780 ft (847 m)	1651 ft (503 m)
Unreinforced European Clay Masonry [4]	38 ft (11 m)	15 ft (5 m)	163 ft (50 m)	29 ft (9 m)	398 ft (121 m)	51 ft (16 m)	748 ft (228 m)	84 ft (26 m)	1614 ft (492 m)	302 ft (92 m)	N/A	1304 ft (398 m)
Reinforced Masonry [4]	28 ft (9 m)	13 ft (4 m)	85 ft (26 m)	20 ft (6 m)	166 ft (51 m)	38 ft (12 m)	273 ft (83 m)	78 ft (24 m)	736 ft (224 m)	221 ft (67 m)	2212 ft (674 m)	644 ft (196 m)
Reinforced Concrete [4]	22 ft (7 m)	13 ft (4 m)	104 ft (32 m)	23 ft (7 m)	234 ft (71 m)	42 ft (13 m)	424 ft (129 m)	90 ft (27 m)	1255 ft (383 m)	341 ft (104 m)	2504 ft (763 m)	1231 ft (375 m)
Concrete roofs and Metal Roofs with concrete topping [5]	13 ft (4 m)		18 ft (5 m)		25 ft (8 m)		(47 ft (14 m)		155 ft (47 m)		560 ft (171 m)	
Windows [6]	40 ft (12 m)		93 ft (28 m)		155 ft (47 m)		230 ft (70 m)		504 ft (154 m)		1070 ft (326 m)	
Minimum Standoff Distance [8]	13 ft (4 m)		20 ft (6 m)		26 ft (8 m)		33 ft (10 m)		50 ft (15 m)		82 ft (25 m)	

1. Refer to **\1** Table C-5 **/1/** for details on the analysis assumptions and material properties for these wall and roof types.
2. Load bearing construction.
3. Non-load bearing construction.
4. Where wall types include multiple cladding systems, such as brick half way up the wall and EIFS above that, use the greater of the two applicable standoff distances. For additional information on Steel Studs see PDC TR 15-01, Minimum Standoff Distances for Non-Load Bearing Steel Stud In-Fill Walls.
5. Roof construction seldom controls standoff distances. Standoffs of at least those in this row will commonly be adequate for those roof types. Other roof types will have to be analyzed separately
6. At distances closer than these standoff distances windows will commonly be much heavier and more expensive than conventional windows.
7. Note that these standoff distances are for planning purposes only. All building components should be designed for blast loading and conventional loading.
8. See Paragraph B-2.1.3.

Table C-2 Representative Standoff Distances for Low Level of Protection [7]

Construction [1]	Explosive Weight (TNT)											
	55 lbs (25 kg)		220 lbs (100 kg)		550 lbs (250 kg)		1,100 lbs (500 kg)		4,400 lbs (2,000 kg)		19,800 lbs (9,000 kg)

Table C-5 Conventional Construction Parameters

Wall or Roof Type[1]	Analysis Assumptions[2, 10]						
	Sections	Span	Spacing	Support Condition	Supported Weight[5]	Reinforcement Ratio	Min. Static Material Strength
Wood Studs – Brick Veneer	2x4 & 2x6 in (50x100 & 50x150 mm)	8 – 10 ft (2.4 - 3 m)	16 - 24 in (400 – 600 mm)	S-S	44 psf (215 kg/m^2)	N/A	875 psi (6 MPa)
Wood Studs – EIFS	2x4 & 2x6 in (50x100 & 50x150 mm)	8 – 10 ft (2.4 – 3 m)	16 -24 in (400 -600 mm)	S-S	10 psf (49 kg/m^2)	N/A	875 psi (6 MPa)
Steel Studs – Brick Veneer[3]	600S162-43 600S162-54 600S162-68	8 – 12 ft (2.4 – 3.7 m)	16 - 24 in (400 – 600 mm)	S-S	44 psf (215 kg/m^2)	N/A	50,000 psi (345 MPa)
Steel Studs – EIFS[3]	600S162-43 600S162-54 600S162-68	8 – 12 ft (2.4 – 3.7 m)	16 - 24 in (400 – 600 mm)	S-S	10 psf (49 kg/m^2)	N/A	50,000 psi (345 MPa)
Metal Panels[6] (in wall or roof construction)	1.5 – 3 in (38 - 76 mm) 22, 20, & 18 ga	4 – 8 ft (1.2 - 2.4 m)	N/A	S-S	10 psf (49 kg/m^2)	N/A	33,000 psi (228 MPa)
Girts[6] (in wall or roof construction)	8Z3 &10Z3 16, 14, & 12 ga	20 – 25 ft (6 – 7.6 m)	6 – 8 ft (1.8 – 2.4 m)	S-S	5 psf (24 kg/m^2)	N/A	50,000 psi (345 MPa)
Reinforced Concrete[7]	≥ 6 in (≥ 150 mm)	12 – 20 ft (3.7- 6 m)	N/A	S-S, One way flexure	10 psf (49 kg/m^2)	≥ 0.0015	3,000 psi (21 MPa)
Unreinforced Concrete Masonry [4, 8]	6 – 12 in (150 – 300 mm)	8 – 12 ft (2.4 – 3.7 m)	N/A	S-S, One way flexure	10 psf (49 kg/m^2)	0	1,500 psi (10 MPa)
Reinforced Concrete Masonry [7, 8]	8 – 12 in (200 - 300 mm)	10 – 14 ft (3 – 4.3 m)	N/A	S-S, One way flexure	10 psf (49 kg/m^2)	0.0005 - 0.0030	1,500 psi (10 MPa)

Wall or Roof Type[1]	**Analysis Assumptions**[2, 10]						
	Sections	**Span**	**Spacing**	**Support Condition**	**Supported Weight**[5]	**Reinforcement Ratio**	**Min. Static Material Strength**
European Clay Block Masonry[4, 9]	6 – 8 in (150 – 200 mm)	10 – 12 ft (3 – 3.7 m)	N/A	S-S, Brittle Flexure	10 psf (49 kg/m^2)	0	1,800 psi (12 MPa)
Concrete Roofs[7]	4 – 12 in (100 - 300 mm)	6 ft (1.8 m)	N/A	F-S	15 psf (73 kg/m^2)	0.0015 - 0.005	3,000 psi (21 MPa)
Metal Roofs	K and LH joists with Metal Deck and/or 3.5 - 5.5 in (90 - 140 mm) Concrete Topping	30 ft (9.1m)	4 – 8 ft (1.2 – 2.4 m)	S-S	15 – 90 psf (73 – 439 kg/m^2)	N/A	50,000 psi (345 MPa)

1. Other types of construction other than that shown in this table may be permissible subject to validation by the designer of record.
2. See PDC Technical Report 10-01 for details on the analysis assumptions and material properties.
3. Steel studs are assumed to be connected top and bottom for load bearing walls. For non-load bearing walls steel studs are assumed to have a slip-track connection at the top. For additional information on Steel Studs see PDC TR 15-01, Minimum Standoff Distances for Non-Load Bearing Steel Stud In-Fill Walls.
4. Unreinforced masonry must have adequate lateral support at the top and bottom.
5. Weight supported by the wall that moves through the same deflection as the wall, not including self-weight of the component.
6. For walls or roofs built using metal panels and girts; use the greater of the standoffs for the metal panel and the girt.
7. Reinforcing steel is 60,000 psi (414 MPa) tensile strength.
8. Concrete Masonry Units (excluding European block) are medium weight (120 pcf / 1922 kg/m^3)
9. European clay block masonry complies with DIN: 105 Teil 1 + 2/HLz B
10. Shear will need to be checked when using higher than minimum material strengths.

S-S = Simple - Simple Supports F-S = Fixed - Simple Supports

Table C-6 Standoff Distances for Expeditionary Structures

Explosive Weight	LOP	Expeditionary Structure Type			
		TEMPER and GP Tents	Small Shelter System	SEA Hut	Retrofitted SEA Hut
55 lbs (25 kg)	VL	33 ft (10 m)	33 ft (10 m)	75 ft (23 m)	NDA*
	L	46 ft (14 m)	46 ft (14 m)	105 ft (32 m)	45 ft (14m)

D-2 DEFINITIONS OF TERMS.

Access control. For the purposes of these standards, any combination of barriers, gates, electronic security equipment, and/or guards that can limit entry or parking of unauthorized personnel or vehicles.

Access road. Any roadway such as a maintenance, delivery, service, emergency, or other special limited use road that is necessary for the operation of a building or structure.

Analysis. For the purposes of evaluating compliance with standoff distance and supporting structure requirements of these standards, evaluation of structural components using commonly accepted analysis methodologies such as single degree of freedom or finite element analysis.

Breezeway. A covered passage that passes between two buildings or portions of buildings or covered areas underneath or attached to buildings.

Building. A structure, usually enclosed by walls and a roof, constructed to provide support or shelter for an intended occupancy. Note that other structures, such as canopies or gazebos, are not considered buildings for the purposes of these standards.

Building hardening. Enhanced conventional construction that mitigates threat hazards where standoff distance is limited. Building hardening may also be considered to include the prohibition of certain building materials and construction techniques.

Building occupancy. For the purposes of these standards, the planned occupancy of a building or the allowable occupancy calculated in accordance with life safety codes where the occupancy is not known.

Building overhangs. Any structural configuration in which the outer walls or columns of the ground floor are set back from the outer walls or column lines of floors above.

Building separation. The distance between closest points on the exterior walls of adjacent buildings or structures.

Clear Zone. Areas commonly associated with perimeters that are free of all obstacles, topographical features, and vegetation exceeding 8 in. **\1** (200 mm) **/1/** in height that could impede observation or provide cover and concealment of an aggressor.

Collateral damage. Injury to personnel or damage to buildings that are not the primary targets of attacks.

Command vehicles. Government owned or leased vehicles operated by installation or senior mission commanders, exclusive of privately owned vehicles

Commercial facilities. Facilities that are not DoD owned or operated and that support commercial activities other than food service and retail activities such as banks.

Container structures. Structures built using shipping containers that are designed to withstand structural loadings associated with shipping, including Container Express (CONEX) and International Organization for Standardization (ISO) containers. Testing has shown that these structures behave similarly to buildings for the purposes of these standards.

Controlled parking. For the purposes of these standards, parking that is limited to authorized vehicles that is enforced through physical security measures such as card operated gates, identification or vehicle checks by personnel or similar measures that are acceptable to physical security personnel.

Controlled perimeter. For the purposes of these standards, a physical boundary at which vehicle access is controlled with sufficient means to channel vehicles to the access control points. At a minimum, access control at a controlled perimeter requires the demonstrated capability to search for and detect explosives. Where the controlled perimeter includes a shoreline and there is no defined perimeter beyond the shoreline, the boundary for measuring standoff distances will be at the mean high water mark or the elevation associated with top of bank (associated with a flood recurrence interval of 1.2 years).

Conventional construction. Building construction that is not specifically designed to resist weapons or explosives effects. Conventional construction is designed only to resist common loadings and environmental effects such as wind, seismic, and snow loads. Note that for the purposes of these standards, conventional construction may still require special windows, structural reinforcement around windows, and progressive collapse resistant construction.

Conventional construction standoff distance. The standoff distances at which conventional construction may be used for building components other than doors and windows without a specific analysis of blast effects, except as otherwise required in these standards.

Change of occupancy. Change of occupancy level as defined in these standards. It does not relate to conversions of facility category code. Examples include occupancy changing from low occupancy to inhabited.

Design basis threat. The threat (aggressors, tactics, and associated weapons, tools or explosives) against which assets within a building must be protected and upon which the security engineering design of the building is based.

DoD building. Any building or portion of a building (permanent, temporary, or expeditionary) owned, leased, privatized, or otherwise occupied, managed, or controlled by or for DoD. DoD buildings other than leased buildings are categorized within these standards as low occupancy, inhabited, and high occupancy family housing.

DoD components. The Office of the Secretary of Defense (OSD); the Military Departments (including their National Guard and Reserve Components); the Chairman, Joint Chiefs of Staff and Joint Staff; the Combatant Commands; the Office of the Inspector General of the Department of Defense; the Defense Agencies; the DoD Field Activities; and all other organizational entities within DoD.

DoD Installation. A base, camp, post, yard, center, homeport facility for any ship, or other activity under the jurisdiction of the Department of Defense

DoD personnel. Any U.S. military, DoD civilian or family member thereof, host-nation employees working for DoD, or contractors occupying DoD buildings. For the purposes of these standards, non-DoD visitors to DoD owned or controlled visitor centers, visitor control centers, museums, and similar facilities will be included in DoD personnel populations of those facilities. Visitor counts will be based on routine visitor levels.

Door. A building component for opening or closing an opening in a wall that allows normal access and passage.

Emergency vehicles. Vehicles such as fire trucks and ambulances and other vehicles that are critical to emergency response and for which close proximity to inhabited buildings or containment therein is essential.

Enhanced use lease. Out leases of non-excess DoD land or facilities to a public or private entities for development under the authority of 10 US Code Section 2667.

Equivalent level of protection. Performance of building components that results in building damage or door and glazing hazards similar to that required for the required level of protection as described in Table B-1 or as specified in PDC Technical Report 06-08.

Expeditionary structures. **\2** Non-permanent DoD facilities that are erected in support of military operations in accordance with UFC 1-201-01. **/2/** This group of structures typically includes but is not limited to tents, Small and Medium Shelter Systems, Expandable Shelter Containers (ESC), ISO and CONEX containers, General Purpose (GP) Medium tents and GP Large tents, trailers, and modular and light wood framed structures.

Fabric covered structures. A construction type that can be identified by wood or metal (usually aluminum) posts or load-bearing frames with some type of fabric (such as canvas) stretched or pulled over the posts or frames. Examples of the types of structures that should be considered under this classification of structures include Frame-Supported Tensioned Fabric Structures (FSTFS); Tent, Extendable, Modular, Personnel (TEMPER Tents); and Small and Medium Shelter Systems (SSS and MSS); General Purpose (GP) Medium tents and GP Large tents; and air supported fabric structures. Testing has shown that for these fabric structures, the posts and frames are what cause hazards.

Family housing. DoD buildings used as quarters for DoD personnel and their dependents. For the purposes of these standards, family housing will be considered to include Morale, Welfare, and Recreation housing (cottages) and temporary family lodging of similar occupancies.

Fan Coil Unit (FCU). A device consisting of a heating and / or cooling heat exchanger (coil) and a fan.

Final denial active vehicle barrier. Vehicle barriers that can be raised and lowered or otherwise moved to block traffic lanes to stop the motion of threat vehicles. In Entry Control Facilities / Access Control Points they are located at the end of the response zone (see UFC 4-022-01).

Fisher Houses. Houses constructed by the Fisher House Foundation at military medical centers for lodging families of military personnel while the military personnel are hospitalized.

Force Protection Condition (FPCON). A DoD-approved system that standardizes the Departments' identification and recommended preventive actions and responses to terrorist threats against U.S. personnel and facilities. This system is the principle means for a commander to apply an operational decision on how to protect against terrorism and facilitates inter-Service coordination and support for antiterrorism activities.

Glazing. The part of a window, skylight, or door assembly that is transparent or translucent and transmits light, but not air.

High occupancy family housing. Family housing with 13 or more units per building.

Identification check point. The location in an Entry Control Facility / Access Control Point at which driver identification is checked to control access into controlled perimeters

Inhabited building. Buildings or portions of buildings routinely occupied by 11 or more DoD personnel and with a population density of greater than one person per 430 gross square feet (40 gross square meters). This density generally excludes industrial, maintenance, and storage facilities, except for more densely populated portions of those buildings such as administrative areas. The inhabited building designation also applies to expeditionary structures with similar population densities. In a building that meets the criterion of having 11 or more personnel with low occupancy portions that do not have sufficient population densities to qualify as inhabited buildings, those portions that have sufficient population densities will be considered inhabited buildings while the remainder of the building may be considered low occupancy, subject to provisions of these standards. An example would be a hangar, warehouse, or maintenance facility with an administrative area within it. The administrative area would be treated as an inhabited building while the remainder of the facility could be treated as low occupancy. External stairwells and covered or enclosed walkways are not part of the inhabited space of a building. (Note: This definition differs significantly from the definition for inhabited building used by DoD 6055.09-M and is not to be construed as authorization to deviate from criteria of DoD 6055.09-M.)

Installation: For the purposes of these standards, the installation is an area or locality subject to the custody, jurisdiction, or administration of the Secretary of a Military Department or the Secretary of Defense, in the case of an activity in a foreign country, under the operational control of the Secretary of a Military Department or the Secretary of Defense. This term includes but not limited to, military reservations, bases, posts, camps, stations, or arsenals.

Installation Perimeter: For the purposes of these standards, the installation perimeter is defined as any demarcation identifying the limit of DoD property and directly or indirectly indicating that unauthorized access is prohibited. The landside perimeter may be established with fences, walls, signage, natural barriers or other means. The waterside perimeter will be at the mean high water mark or the elevation associated with top of bank (associated with a flood) recurrence interval of 1.2 years) or be established with channel markers, buoys, float lines, signage, or boat barriers.

Laminated glass. Multiple sheets of glass bonded together by a bonding interlayer.

Level of protection. The degree to which an asset (person, equipment, object, etc.) is protected against injury or damage from an attack.

Low occupancy building. Any building or portion of a building routinely occupied by fewer than 11 DoD personnel or with a population density of less than one person per 430 gross square feet (40 gross square meters).

Low occupancy family housing. Family housing with 12 or fewer units per building.

Mail room. A facility operated by or for the Department of Defense for the receipt and delivery of mail for military units or other authorized organizations and agencies by entities outside the DoD. This does not include mail rooms that receive mail distribution that was initially received at a central DoD mail handling facility.

Mass notification. Capability to provide real-time information to all building occupants or personnel in the immediate vicinity of a building during emergency situations.

Military protective construction. Military facilities designed to resist military conventional and nuclear weapons to the NATO (or equivalent) standards of hardened, protected, semi-hardened, collaterally protected, or splinter protected.

Minimum standoff distance. The smallest permissible standoff distance regardless of any analysis results or hardening of the building.

Mobile ground tactical platforms. Vehicle mounted tactical ground station for posting, processing, and distributing real-time intelligence, surveillance, and reconnaissance information.

Operations support vehicles. Vehicles such as airfield support equipment or material handling equipment whose purpose is direct support to operations, and which are operated only within a restricted access area.

Parking areas. Designated areas where vehicles may be left unattended, including parking lots, designated parking areas along roadways, and roadways within or accessing parking areas.

Progressive collapse. The spread of an initial local failure from building element to building element, eventually resulting in the collapse of an entire structure or a disproportionately large part of it.

Punched window. A window installed as a punched opening surrounded by cladding, as opposed to being arranged in vertical or horizontal strips.

Relocatable building. \3 A facility that is specially designed and constructed to be readily erected, disassembled, transported, stored, and re-used. Examples of relocatable facilities include, but are not limited to, trailers, CONEX boxes, sheds on skids, tension fabric structures, and air-supported domes. A relocatable facility is not constructed as a part of any other military vehicle, DoD tactical equipment (vehicle mounted or wheeled and towable), or equipment that is already accounted for in a designated accountable property system of record. **/3/**

Replacement Cost. The cost to design and construct a facility to current standards and building codes to replace an existing facility at the same location calculated in accordance with UFC 3-701-01.

Ribbon window. Windows installed in vertical or horizontal strips with no building wall elements between them but surrounded by cladding around the overall opening perimeter.

Roadways. Any surface intended for routine motorized vehicle traffic, including driving lanes of parking areas.

Routinely occupied. For the purposes of these standards, an established or predictable pattern of activity within a building that terrorists could recognize and exploit.

Scaled Range. A relationship based on cube-root scaling that allows comparisons to be made among blast wave properties created by detonations of different explosive quantities.

Security engineering. The process of identifying practical, risk managed short and long-term solutions to reduce and/or mitigate dynamic manmade hazards by integrating multiple factors, including construction, equipment, manpower, and procedures.

Skylight. Sloped or horizontal application of a fenestration product that allows for natural day lighting and that may be either fixed (non-operable) or venting (operable).

Spandrel Glass. Glass used in non-vision areas of building exteriors

Specific threat. Known or postulated aggressor activity focused on targeting a particular asset.

Standoff distance. A distance maintained between a building or portion thereof and the potential location for an explosive detonation.

Structural glazed window systems. Window systems in which glazing is bonded to both sides of the window frame using an adhesive such as a high-strength, high-performance structural silicone.

Superstructure. The supporting elements of a building above the foundation.

Supporting structural elements. Structural elements that support windows and that are not in direct contact with the glass, such as walls.

Temporary buildings. **\3** For the purposes of these standards, those buildings, other than expeditionary structures, that are real property facilities and are designed and constructed with a life expectancy of seven years or less. **/3/**

Testing. For the purposes of these standards, experiments performed in accordance with standardized procedures that prove that building components meet the performance required to meet a specific level of protection.

Town Centers. Mixed use small scale retail, health, or community services and family housing facilities in the same buildings.

TNT equivalent weight. The weight of TNT (trinitrotoluene) that has an equivalent energetic output to that of a different weight of another explosive compound.

Transitional structures and spaces. Structures or spaces within buildings that are used to temporarily relocate DoD occupants of buildings while those buildings or other buildings to which they will relocate undergo renovations, modifications, repairs, or restorations or are being constructed. (Also known as swing space.)

Uncontrolled Public Access. Spaces within and beneath buildings where there is insufficient positive access control to preclude unauthorized access. For the purposes of these standards, positive access control will be considered to include (but not be limited to) electronic access control on all exterior doors or providing personnel to control visitors.

Unobstructed space. Space around inhabited buildings in which there are no opportunities for concealment from observation of explosive devices of no less than a 6 in. (150 mm) cube.

Window or Skylight Replacement. The removal of an existing window or skylight assembly and replacement with a new window assembly. For the purposes of this definition a "window assembly" is considered to be the entire system of glazing, framing and anchorage components that fill in and fit within the opening in the wall or roof structure.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

This Page Intentionally Left Blank

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC is intended to provide unified criteria to make the planning, design and construction communities aware of the published regulatory requirements to ensure timely, consistent, and appropriate implementation.

1-2 REISSUES AND CANCELS.

This UFC reissues and cancels UFC 4-010-05, Change 1, 1 October 2013.

1-3 APPLICABILITY.

This document applies to all construction, renovation, and repair projects for DoD Sensitive Compartmented Information Facility (SCIF) or Special Access Program Facility (SAPF). This UFC applies to each phase of a project, from planning through construction.

1-3.1 SCIF.

SCIF is an accredited area(s), room(s) or building(s) where Sensitive Compartmented Information (SCI) is stored, used, processed or discussed. SCIF is only required for SCI and not required for Confidential, Secret or Top Secret information.

1-3.2 SAPF.

A specific physical space that has been formally accredited in writing by the responsible program security officer (PSO) that satisfies the criteria for generating, safeguarding, handling, discussing, and storing classified or unclassified program information, hardware, and materials.

1-4 GLOSSARY.

APPENDIX B contains acronyms, abbreviations, and terms.

1-5 REFERENCES.

APPENDIX C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of referenced publications applies.

1-6 POLICY.

There are multiple policy documents that establish the baseline requirements for planning, design, construction and accreditation of DoD facilities.

1-6.1 Office of the Director of National Intelligence.

Intelligence Community Directive (ICD) 705 was issued by the Director of National Intelligence (DNI) on May 26, 2010. Intelligence Community Standard (ICS) 705-1, ICS 705-02, and the Intelligence Community (IC) Tech Spec-for ICD/ICS 705 provides the physical and technical security standards for SCIFs, including existing, new construction, and renovations. Refer to ICS 705-1, ICS 705-02, and IC Tech Spec-for ICD/ICS 705 for additional information.

1-6.2 Department of Defense.

- DoDM 5105.21 (Volumes 1-3) are the primary documents associated with SCIFs for the DoD. The manuals are composed of several volumes, each having its own purpose. DoDM 5105.21 volume 2 concerns the physical security of a SCIF and it requires the implementation of Director of National Intelligence (DNI) policies for the protection of SCI and additional requirements.
- DoDM 5205.07 (Volumes 1-4) are the primary documents associated with SAPFs for the DoD. The manual is composed of several volumes, each having its own purpose. DoDM 5205.07 Vol 3 concerns the physical security of a SAPF and it establishes the construction of a SAPF will conform to the equivalent SCIF requirements, as defined in IC Tech Spec-for ICD/ICS 705.
- DoDM 5200.01 volumes 1-3 are the primary document associated with the protection of classified information for the DoD. The manual is composed of several volumes, each having its own purpose. DoDM 5200.01 volume 3 concerns the physical security of a classified information.
- DoDI 5200.48 is the primary document associated with the protection of Controlled Unclassified Information (CUI).

1-7 REGULATORY AUTHORITY.

1-7.1 DoD SCIF Authorities.

The DoDM 5105.21 manuals define the regulatory authorities for DoD SCIF.

1-7.2 Non-DoD SCIF Authorities.

In some cases, the DoD may build a SCIF for Non-DoD agencies. These projects will have an IC designated AO sponsor for each construction or renovation project for the Non-DoD agency.

1-7.3 DoD SAPF Authorities.

The DoDM 5205.07 manuals define the regulatory authorities for DoD SAPF. The special access program facility accrediting official (SAO) is defined as the AO for SAPF.

1-8 IMPLEMENTATION.

Note that this UFC was based on IC Tech Spec-for ICD/ICS 705 Version 1.5.1. When the National Counterintelligence and Security Center adopts a newer version, it will have precedence over the requirements contained in this UFC.

1-8.1 Department of Navy.

Refer to NAVFAC INST 4700.1 for additional policy for Department of Navy projects that include a SCIF. The NAVFAC instruction details various steps accomplished in the planning, design and construction phase of a SCIF including roles and responsibilities.

1-8.2 Department of the Army.

Department of the Army projects that include a SCIF, refer to *SCIF Security, Planning, Design, and Construction Tasks* downloadable at: https://www.wbdg.org/army/resource-library/scif-tasks. The task list details various steps accomplished in the planning, design, and construction of a SCIF, including the roles and responsibilities, Per USACE Engineering Regulation 1110-1-8158 Engineering and Design Centers of Expertise Program, for projects containing SCIFs completed by USACE, inclusion of representative(s) from the USACE Protective Design Center as part of the project delivery team is mandatory. For projects executed by any other services, inclusion of the USACE Protective Design Center is optional. Contact information can be found at: https://www.nwo.usace.army.mil/pdc/home/

1-8.3 Department of the Air Force.

Department of the Air Force projects that include a SCIF, the Construction Agency acting on behalf of the AF must utilize their respective task list for the planning, design, construction of SCIFs including the roles and responsibilities. In the rare case where the AF is acting as the DoD Construction Agent, either the NAVFAC or the USACE task list may be used.

1-9 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-10 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-10.1 Mission Critical Facility-Related Control Systems.

Determine facility-related control system categorization in coordination with supported command and mission owner. Incorporate cybersecurity into the mission critical facility-related control systems with a minimum Confidentiality/Integrity/Availability Categorization of Moderate/Moderate/Moderate as indicated in IC Standard 706-02.

1-11 FACILITY CLASSIFICATION.

SCIF and SAPF are classified based on operational requirements. There are various classifications.

1-11.1 Secure Working Area (SWA) or SAP Working Area (SAPWA).

Area where SCI or SAP is handled, discussed, and/or processed but not stored.

1-11.2 Temporary Secure Working Area (TSWA) or Temporary SAP Working Area (TSAPWA).

An accredited area used for the handling, discussing or processing of SCI or SAP information, when use is limited to less than 40 hours per month.

1-11.3 Temporary SCIF (T-SCIF) or Temporary SAPF (T-SAPF).

Established for a limited time to meet tactical, emergency, or immediate operational requirements.

1-11.4 Closed Storage.

An accredited facility where SCI or SAP material is required to be stored in GSA-approved storage containers when not in use. This includes all classified materials, equipment and information.

1-11.5 Open Storage.

An accredited facility in which SCI or SAP information may be openly stored or processed without using a GSA-approved storage container.

1-11.6 Continuous Operation.

An accredited facility staffed and operated 24/7.

1-12 SECURITY IN DEPTH.

Security in Depth (SID) is desired for all SCIF or SAPF and required for locations outside the United States, its possessions or territories. SID is a multilayered approach, which effectively employs human and other physical security measures throughout the installation or facility to create a layered defense against potential threats. The intent of SID is to increase the possibility of detection of potential aggressors prior to compromising the SCI or SAP materials. Per IC Tech Spec for ICD/ICS 705, the primary means to achieve SID include one of the following:

- Located on a Military installation, embassy compound, U.S. Government (USG) compound, or contractor compound with a dedicated response force of U.S. persons.
- Located within a controlled building with separate building access controls, alarms, elevator controls, stairwell controls required to gain access to the buildings or elevators.
- Controlled office areas adjacent to or surrounding the secure area that are protected by an Intrusion Detection System (IDS).
- Located within a fenced compound with access controlled vehicle gate and/or pedestrian gate.

1-13 SECURITY REQUIREMENTS.

ICS 705-1 and IC Tech Spec-for ICD/ICS 705 provide the security standards. Per IC Tech Spec-for ICD/ICS 705, exceeding or not meeting a standard, even when based upon risk, requires an approved waiver.

Waivers are processed and approved in accordance with DoDM 5105.21 Vol 2 for SCIF and DoDM 5205.07 Vol 3 for SAPF.

1-14 SITE SECURITY MANAGER (SSM).

The SSM is responsible for the security aspects of project planning, design and construction. The SSM is also responsible to ensure compliance of all regulatory requirements for the accreditation of the facility. Planners, Project Managers, Design Managers, Designers, and Construction Managers must work closely with the supported command and their designated SSM to determine the requirements for each project and ensure the implementation of the policy based requirements.

Projects with a SCIF and a SAPF may have two different SSMs reporting to two different AOs.

1-15 CONSTRUCTION SECURITY PLAN (CSP).

The CSP documents the security requirements from planning through construction for each project. Per IC Tech Spec-for ICD/ICS 705, a CSP is developed by the SSM and approved by the AO for each project.

Per IC Tech Spec – for ICD/ICS 705, do not award a construction contract without an approved CSP. See DoDM 5105.21 Vol 2 for SCIF and DoDM 5205.07 Vol 3 for SAPF for additional information and for Navy and Marine Corps projects, refer to NAVFAC INST 4700.01.

1-16 INFORMATION SECURITY.

Per ICS 705-1, construction plans and related documents are to be handled and protected in accordance with the CSP. Construction plans and related documents may be publicly releasable, CUI, or if Classification Guide dictates, plans and related documents may require classification. Refer to DoDM 5200.01 Vol 3 for the handling of classified information and DoDI 5200.48 for the handling of Controlled Unclassified Information (CUI).

1-16.1 SCIF Location and Identity.

DoDM 5105.21 Vol 2 states the facility's location (complete address) and identity of a SCIF must be protected at a minimum of CUI. Drawings or diagrams identified as a SCIF may not be posted on an UNCLASSIFIED website, transmitted over the Internet without some type of encryption or included on public releasable documents. Therefore, do not identify SCIF locations on planning or construction documents. With SSM's approval, areas may be identified as “Restricted Area”. “Controlled Space”, “Secure Area”, “Controlled Area” or some other non-identifiable name.

1-16.2 SAPF Location and Identity.

Similar to SCIF, coordinate with the SSM on how to identify SAPF locations on planning or construction documents. With the SSM's approval, areas may be identified as “Restricted Area”, “Controlled Space”, “Secure Area”, “Controlled Area” or some other non-identifiable name.

1-16.3 TEMPEST Vulnerabilities and Recommended Countermeasures.

TEMPEST vulnerabilities and recommended countermeasures are classified at a minimum of CONFIDENTIAL when associated with a physical location. A TEMPEST vulnerability or countermeasure associated with a SCIF ID number or in a manner that cannot be connected to the physical location is UNCLASSIFIED[1].

1-16.4 Security Environment Threat List (SETL) Information.

The SETL and its contents including a country's threat category is classified Secret.

1-17 DESIGN SECURITY.

Per IC Tech Spec – for ICD/ICS 705, design must be performed by U.S. companies using U.S. citizens or U.S. persons. AO must ensure mitigations are implemented when using non-U.S. citizens and these mitigations are documented in the CSP.

1-18 CONSTRUCTION SECURITY.

Depending on the location of the facility, the AO may impose procedures for the procurement, shipping, selection, and secure storage of construction materials. In

[1] DoDM 5105.21 Vol 2

addition, there may be site security and access control that may include vehicle and personnel inspections. The CSP documents the security requirements for each project. For reference, DoDM 5105.21-Volume 2 and DoD M5205.07 Volume 3 provide additional information on security requirements for DoD SCIF and SAPF construction projects.

1-18.1 Within the United States.

For facilities located within the U.S., its possessions or territories, general construction of the SCIF or SAPF must be performed by U.S. companies using U.S. citizens or U.S. persons. The AO must ensure mitigations are implemented when using non-U.S. citizens. These mitigations must be documented in the CSP.

Per IC Tech Spec – for ICD/ICS 705, Intrusion Detection System (IDS) installation and testing must be performed by U.S. companies using U.S. citizens. However, 5200.01, Volume 3 requires that the alarm installation and maintenance for IDS that protect classified information be accomplished by U.S. citizens who have been subjected to a trustworthiness determination.

1-18.2 Outside the United States.

For facilities located outside the U.S., its possessions or territories, general construction of the SCIF or SAPF must be performed using U.S. companies using U.S. citizens.

- On military facilities, the AO may authorize foreign national citizens or companies to perform general construction. In this situation, the SSM must prescribe, with AO approval, mitigating strategies. These mitigations must be documented in the CSP.
- U.S. Top Secret-cleared personnel must perform finish work in Category I and II countries. U.S. Secret-cleared personnel must perform finish work in Category III countries. Finish work includes activities such as closing up wall structures; installing, floating, taping and sealing wallboards; installing trim, chair rail, molding, flooring; acoustical ceiling tile, light fixtures, device plates, diffusers, registers, grilles, and painting.
- IDS installation and testing must be performed by personnel who are U.S. Top Secret-cleared or U.S. Secret-cleared and escorted by SCIF or SAPF personnel.

1-19 ACCREDITATION.

Accreditation is a formal process to ensure that a facility has been designed, constructed, inspected, and certified to operate in accordance with the provisions of ICD 705. Refer to DoDM 5105.21, Vol 2 and DoDM 5205.07 Vol 3 for the DoD policy on accreditation.

1-19.1 Accreditation Process.

Inspections and evaluations are typically performed by the SSM, or designee, prior to initial accreditation. The accreditation process includes, site inspections and a review of documents relating to design, construction, and testing. The SSM is responsible for assembling and submitting documents for AO approval. The forms for these documents are included in the IC Tech Spec – for ICD/ICS 705. These documents include, but are not limited to the following:

- Construction Security Plan
- Fixed Facility Checklist
- TEMPEST Addendum
- Pre-Construction Checklist

Planners, Designers of Record, Project Managers, and Construction Mangers must provide the SSM the project information needed to develop these documents to support the accreditation process. Information may include, site plans, floorplans, IDS plans, and information related to construction methods and materials.

1-19.2 Fixed Facility Checklist (FFC).

The FFC is a standardized form that documents the physical, technical, and procedural security information to obtain accreditation. This document may be CUI or Classified depending on contents.

1-19.3 TEMPEST Addendum.

The requesting command's Special Security Officer (SSO) or SSM will use the TEMPEST addendum to the FFC, sometimes referred to as the TEMPEST Checklist to request the TEMPEST Countermeasures Review (TCR) by the Certified Technical TEMPEST Authority (CTTA). For an initial TCR, the addendum will be submitted to AO during the planning phase[2]. While some specific information may not be known prior to construction, as much information as possible must be provided in order to minimize costly changes.

The CTTA will provide the TCR based on the TEMPEST addendum and recommend countermeasures to the AO as part of the accreditation process.

1-19.4 Pre-Construction Checklist.

The Pre-Checklist provides the AO with project information, points of contact and information required to assist in the determination of the security requirements for the project and final accreditation.

1-20 HISTORIC PRESERVATION COMPLIANCE.

[2] DoDM 5105.21 Vol 2

1-20.1 Security and Stewardship.

The Department of Defense remains the lead federal agency in balancing security threats with the protection of historic properties. The Department of Defense abides by federal legislation on protecting cultural resources, and issues its own complementary policies for stewardship.

1-20.2 Compliance with Laws.

Implementation of ICD 705 will not supersede DoD's obligation to comply with federal laws regarding cultural resources to include the National Historic Preservation Act (NHPA) and the Archaeological Resources Protection Act (ARPA). Installation personnel must determine possible adverse effects to historic structures and/or archaeological resources during project development and consult accordingly. Personnel at installations outside the United States should coordinate with the applicable host nation regarding possible adverse effects to cultural resources.

1-20.3 Compliance with DoD Standards.

Conversely, historic preservation compliance does not negate the requirement to implement other Department of Defense policy. Federal agencies are always the decision-maker in the Section 106 process of the National Historic Preservation Act. An agency should seek to avoid prolonged consultations that conflict with the imminent need to implement security requirements. Preservation considerations and security standards are not mutually exclusive, and any compliance conflicts should be quickly and effectively resolved in consultation with appropriate stakeholders.

1-21 SECURITY ENGINEERING UFC SERIES.

This UFC is one of a series of security engineering unified facilities criteria documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include the following:

1-21.1 DoD Minimum Antiterrorism Standards for Buildings.

UFC 4-010-01 establishes standards that provide minimum protection against terrorist attacks for the occupants of all DoD inhabited buildings. This UFC is intended to be used by security and antiterrorism personnel and design teams to identify the minimum requirements that must be incorporated into the design of all new construction and major renovations of inhabited DoD buildings and inhabited tenant buildings on DoD installations. They also include recommendations that should be, but are not required to be incorporated into all such buildings.

1-21.2 Security Engineering Facilities Planning Manual.

UFC 4-020-01 presents processes for developing the design criteria necessary to incorporate security and antiterrorism into DoD facilities and for identifying the cost implications of applying those design criteria. Those design criteria may be limited to the requirements of the minimum standards, or they may include protection of assets other than those addressed in the minimum standards (people), aggressor tactics that are not addressed in the minimum standards, or levels of protection beyond those required by the minimum standards. The cost implications for security and antiterrorism are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they represent only representative construction that will meet the requirements of the design criteria. The manual also addresses the tradeoffs between cost and risk. The Security Engineering Facilities Planning Manual is intended to be used by planners as well as security and antiterrorism personnel with support from planning team members.

1-21.3 Security Engineering Facilities Design Manual.

UFC 4-020-02FA provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established using UFC 4-020-01. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them all work as a system. The information in UFC 4-020-02FA is in sufficient detail to support concept level project development, and as such can provide a good basis for a more detailed design. The primary audience for the Security Engineering Design Manual is the design team, but it can also be used by security and antiterrorism personnel.

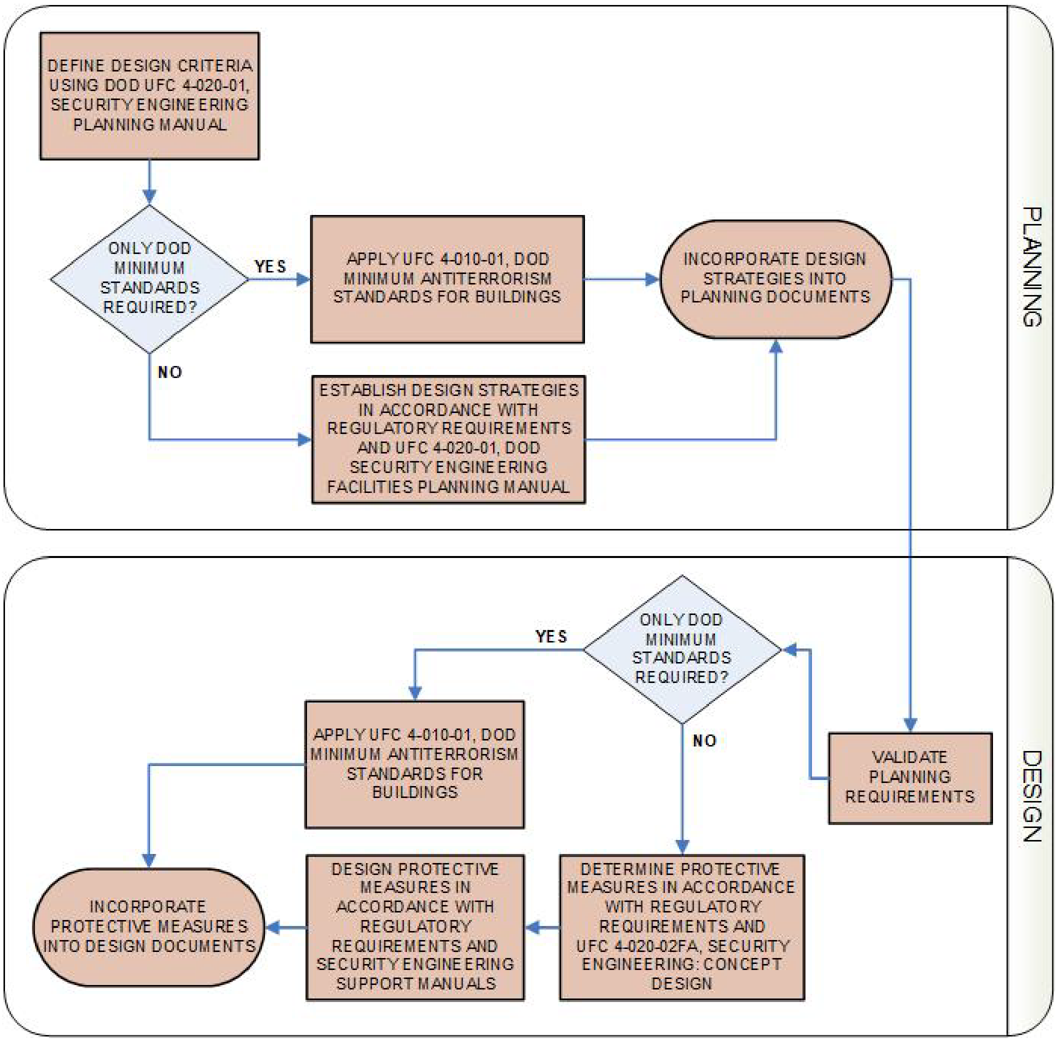
1-21.4 Security Engineering Support Manuals.

In addition to the standards, planning, and design UFCs mentioned above, there is a series of additional UFCs that provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02FA. These support manuals provide specialized, discipline specific design guidance. Some address specific tactics such as direct fire weapons, forced entry, or airborne contamination. Others address limited aspects of design such as resistance to progressive collapse or design of portions of buildings such as mail rooms. Still others address details of designs for specific protective measures such as vehicle barriers or fences. The Security Engineering Support Manuals are intended to be used by the design team during the development of final design packages.

1-21.5 Security Engineering UFC Application.

The application of the security engineering series of UFCs is illustrated in Figure 1-1. UFC 4-020-01 is intended to be the starting point for any project that is likely to have security or antiterrorism requirements. By beginning with UFC 4-020-01, the design criteria will be developed that establishes which of the other UFCs in the series will need to be applied. The design criteria may indicate that only the minimum standards need to be incorporated, or it may include additional requirements, resulting in the need for application of additional UFCs. Applying this series of UFCs in the manner illustrated in Figure 1-1 will result in the most efficient use of resources for protecting assets against security and antiterrorism related threats.

Figure 1-1 Security Engineering UFC Applicability



This Page Intentionally Left Blank

CHAPTER 2 PLANNING

2-1 ESTABLISH PLANNING REQUIREMENTS.

This chapter is intended to make planners aware of requirements that may affect the facility scope and budget. It is not intended to document the standard planning processes related to project development.

2-2 CONCEPT APPROVAL.

SCIFs and SAPFs are established when there are clear operational requirements that are critical to the supported command's mission. All projects begin with an AO's sponsorship. This sponsorship is formalized for SCIF and some SAPFs with the Concept Approval.

2-2.1 SCIF Concept Approval.

Per DoDM 5105.21 Vol 2, to establish a SCIF, the supported command must have Concept Approval. The Concept Approval is the first critical element in the establishment of a SCIF. For approval, the commander must submit a request for SCI to the Service Cognizant Security Authority (CSA), their designee, or DoD Component senior intelligence official (SIO). This is referred to as the request for Concept Approval. Concept Approval certifies that a clear operational requirement exists for the SCIF and there is no existing SCIFs to support the requirement. Proof of sponsorship in the form of a SCIF number or written documentation of Concept Approval from the supported command is required to establish a SCIF.

2-2.2 SAPF Concept Approval.

DoDM 5205.07 Vol 3 does not require Concept Approval for SAPF. Sponsorship for most SAPFs is formalized at the program level.

2-2.2.1 Navy SAPF Concept Approval.

Per DONSAPCO/0779-22 Memo, Director, Department of the Navy Special Program Central Office requires Concept Approval for the establishment of a SAPF. The organization with the requirement for the SAPF submits a concept request endorsed by the leadership of the organization via the Program Security Officer (PSO) and the Government Program Manager (GPM). The concept request must clearly define the operational requirement and identify why existing SAPFs do not meet the need. In addition, the organization is required to identify a Site Security Manager (SSM) for the project.

2-3 MINIMUM AND ENHANCED SECURITY.

ICS 705-1 and IC Tech Spec-for ICD/ICS 705 provide the minimum security standards. The security requirements are based on classification, location, and risk assessment of the facility. APPENDIX A provides an overview of the minimum construction requirements. To implement security enhancements above the minimum, the AO will evaluate the threat, SID and balance the security enhancements with cost at acceptable risk.

2-4 PLANNING TEAM.

Establish an interdisciplinary planning team with local considerations. The interdisciplinary planning team must work together to determine classification of the space and establish the minimum/enhanced security requirements. The planning team may consider user constraints such as operations, manpower requirements or limitations, and sustainment costs when determining the requirements for the overall security solution. The planning team should include the following:

- Planning
- Supported Command
- SSM(s)
- Communications
- Security
- Engineering
- Cultural resources (if historical building)

Some teams may require more than one SSM if the facility includes a SCIF and SAPF.

2-5 PLANNING DOCUMENTATION.

The classification, operation, security requirements, TEMPEST countermeasures, and resulting facility related requirements must be scoped, documented, and budgeted during the planning process. Concept Approval, Preliminary CSP, FFC and TEMPEST Addendum are prepared by the SSM and submitted during the planning phase. These documents define the baseline requirements for the project. For Navy and Marine Corps projects, refer to NAVFAC INST 4700.01 for additional information.

2-6 CONSOLIDATION OF SPACES.

When a facility has more than one SCIF or SAPF, serious consideration must be given to consolidating the multiple spaces into one with Compartmented Areas within. Any consolidation of spaces will reduce initial infrastructure and electronic security systems, associated accreditation requirements, and sustainment. Coordinate consolidation with the supported command to ensure the configuration meets command’s operational (compartmented) requirements.

2-7 VISITOR CONTROL.

Some larger facilities may require additional space at the entrance for processing and visitor control. Program adequate space for processing un-indoctrinated personnel and visitors, issuing badges and space for personnel awaiting escorts.

2-8 PRIMARY ENTRANCE VESTIBULE.

Program space for a vestibule at the primary entrance. Vestibules enhance the security of the space by precluding visual observation into the space and enhancing acoustic protection.

2-9 TELECOMMUNICATION SPACES.

Per UFC 3-580-01, the minimum size for a Telecommunications Room (TR) is 10 feet x 8 feet (3m x 2.4m). This and the normal net to gross calculation may be inadequate if the TR contains equipment racks for multiple networks such as Secret Internet Protocol Router Network (SIPRNet), Joint Worldwide Intelligence Communications System (JWICS), Non-classified Internet Protocol Router Network (NIPRNet) and voice services. Depending on the number of workstations served, this could generate a larger space requirement when considering RED/BLACK separation requirements.

UFC 3-580-01 allows the use of Equipment Room in lieu of a TR for buildings that house substantial Information Technology (IT) electronics. A telecommunication space that contains equipment for multiple classified networks such as SIPRNet, JWICS and NIPRNet all requiring RED/BLACK separation is considered as substantial Information Technology (IT) electronics which would allow for the use of the larger Equipment Rooms.

2-9.1 Temperature and Humidity Control.

Substantial Information Technology (IT) equipment generate a significant amount of heat. In these environments, the heat densities can be up to five times higher than in a typical office load. Traditional HVAC systems cannot remove enough heat to protect this equipment. Instead, these areas require dedicated computer room air conditioner (CRAC) units with higher cooling capabilities. The smallest high-powered CRACs require a minimum 10 ft. x 3 ft. (3m×1m) footprint for equipment and clearances. This area must be included in the equipment room area calculation.

2-10 RESILIENCY.

Some critical operations or communication systems may require redundant utilities, standby power, and redundant systems to ensure continuous operation in the event of utility or equipment failure. Coordinate system and the associated resiliency requirements with the mission commander.

2-10.1 Redundant Utilities.

Critical operations or communication systems may require redundant utilities such as telecommunication system connectivity and utility power services. To be redundant, they must be two separate utilities that are not routed together.

2-10.2 Standby Power Systems (SPS).

Critical operations or Command, Control, Computers, Communications, Cyber, Intelligence, Surveillance and Reconnaissance (C5ISR) systems may require an SPS designed to ensure continuity of electrical power to essential and uninterruptible loads upon loss of normal power sources.

2-10.2.1 Engine-Driven Generator.

When a SPS is required, provide a standby engine-driven generator sized for essential and uninterruptible loads to ensure continued operation upon loss of utility power.

2-10.2.2 Uninterruptible Power System (UPS).

When a SPS is required, provide UPS for the uninterruptible loads to filter commercial power and to support the uninterruptible loads during transitions to and from the standby generator.

2-10.3 Redundancy.

Some critical operations may require a minimum of N+1 redundancy to ensure system availability in the event of component failure. In this configuration, components (N) have at least one independent backup component (+1). An example would be chillers, CRACs, or generators.

2-11 HISTORIC PRESERVATION.

Preservation of Cultural Resources must be considered when converting a historical building into a secure facility or locating a secure space or room within a historic building. For instance, every effort should be made to minimize or eliminate windows, especially on the ground floor. Windows less than 18 feet above the ground or from the nearest platform affording access to the window (measured from the bottom of the window) and doors must be protected against forced entry and meet the standard for the perimeter, which may include acoustic and TEMPEST mitigation. State Historic Preservation Officers (SHPO) may consider window and door modifications to have an adverse effect but allow the modification if the impact is minimized and the effect mitigated. Planners need to explore options and consult with the State Historic Preservation Office (SHPO) to determine options that meet security requirements and are compatible with the Secretary of the Interior's Standards for Rehabilitation.

2-12 CONSTRUCTION SECURITY.

For locations outside the United States, its possessions or territories, the AO may impose procedures for the procurement, shipping, and storing of construction materials at the site. In addition, the AO may require access control to the construction materials and the construction area. These requirements and others are documented in the CSP. Since these additional security measures may have significant cost impacts on a project, they must be determined during project development and documented in the CSP, project planning documents, and the costs must be included in the project budget.

2-13 PROJECT DOCUMENTATION.

Work with the Supported Command, and the SSM to determine and document the classification, operation, and resulting facility requirements for the project. Projects in higher threat areas (outside the United States, its possessions or territories) may have additional security requirements. Determine and document the following during project development:

- Is the SCIF or SAPF the entire facility or an area within the facility?
- Will there be more than one SCIF or SAPF in the facility, if so how many?
  - If more than one, can they be consolidated?
- What is the classification of each space?
- Will the perimeter wall be standard, enhanced, or vault construction?
- What is the required Sound Transmission Class (STC) rating for the perimeter?
- Will there be Compartmented Areas? If so, how many?
  - Is there a STC requirement for the compartmented areas?
- Are there any Electronic Security System (ESS) requirements above that required by IC Tech Spec-for ICD/ICS 705?
- In addition to non-classified Internet Protocol Router Network (NIPRNet) and voice services, what networks such as Secret Internet Protocol Router Network (SIPRNet) or Joint Worldwide Intelligence Communications System (JWICS) that will be processing National Security Information (NSI) be required?
  - Multiple networks will require equipment rooms in lieu of standard telecommunication rooms.
  - Has area been allotted for multiple equipment racks with future expansion, RED/BLACK separation, and CRAC units within the telecommunication spaces?
    - The smallest high-powered CRACs require a minimum 10 ft. x 3 ft. (3m×1m) footprint for equipment and clearances.
- Will operations require redundant utilities such as utility power or telecommunications system connectivity?
- Will operations require standby generator and UPS for continuity of operations?
- Will operations require some level of resiliency such as N+1 chillers, CRACs or standby generators?

- Has the supported command provided the CTTA with a completed TEMPEST Addendum for the TCR?
    - If so, what will be the required TEMPEST countermeasures? RED/BLACK separation, shielding, or filters?
- Are there special procurement, shipping, and storage of construction materials required at the site? If so, what will be required?
- Are there access control requirements for the construction site?
- Are there access control and storage requirements for the construction materials?
- Will U.S. companies using U.S. citizens or U.S. persons be required for construction?
- For projects outside the United States, its possessions or territories:
    - Will U.S. Secret or U.S. Top Secret cleared personnel be required to perform finish work?
    - Will installation and testing of the ESS be performed by U.S. TOP SECRET-cleared personnel or escorted U.S. SECRET-cleared personnel?
- Will any mitigations or countermeasures above the minimum be required?
    - If so, is there an approved waiver?
- Some of these requirements are documented in the CSP. Therefore, it is very important to obtain the preliminary CSP during project development to ensure appropriate security requirements are documented and included in the project scope and budget.

CHAPTER 3 DESIGN

3-1 VALIDATE PLANNING REQUIREMENTS.

Work with the Supported Command and the SSM to validate the requirements established in the planning phase. Operation, classification, and threat classification may have changed since the project was planned. Validate and document the classification, operation, and resulting facility requirements documented in the CSP. Include requirements in the Design Build RFP, design documents, and construction contracts.

3-2 MINIMUM AND ENHANCED SECURITY.

ICS 705-1 and IC Tech Spec-for ICD/ICS 705 provide the minimum and enhanced security standards. APPENDIX A provides an overview of the minimum construction requirements. Per IC Tech Spec-for ICD/ICS 705, exceeding a standard, even when based upon risk, requires a waiver. Planners may have to provide the cost associated with exceeding a standard to include in the evaluation process.

Waivers are processed and approved in accordance with DoDM 5105.21 Vol 2 for SCIF and DoDM 5205.07 Vol 3 for SAPF.

3-3 GENERAL DESIGN STRATEGY.

The general design strategy for any tactic is the basic approach to developing a protective system to mitigate the effects of that tactic. It governs the general application of construction, building support systems, equipment, manpower, and procedures.

The design will vary depending on type, location, SID, risk assessment, and National Security Information (NSI) processing, storage and discussion requirements. Designers must take a six-sided approach when designing a secure space. Design the floor, ceiling, walls and any penetrations to meet the performance requirements for the perimeter.

3-3.1 Consolidation of Spaces.

When a facility has more than one SCIF or SAPF, serious consideration must be given to consolidate the multiple spaces into one. Any consolidation of spaces will reduce initial infrastructure, electronic security systems, associated accreditation requirements, and sustainment costs. Coordinate consolidation with the supported command to ensure the configuration meets command's operational and compartmented requirements.

3-3.2 Perimeter.

The perimeter includes perimeter walls, ceiling, floor, and all penetrations in the perimeter such as windows, doors, ducts and utilities. At a minimum, the perimeter provides:

- Resistance to forced entry
- Resistance to covert entry
- Visual evidence of surreptitious penetration
- Resistance to visual observation
- Sound Attenuation for acoustic eavesdropping
- Countermeasures for Electronic Emanations -TEMPEST (when required)

This includes above the false ceilings and below raised floors.

3-3.3 Building Layout.

To optimize the building layout for security and function, the designer must understand the various secure spaces in the facility, the security clearances of the occupants, visitor access, escort requirements, and the separations or adjacencies required. This takes an integrated design approach that balances the occupant's operational requirements, space requirements, visitor control, security-in-depth and the concept of zoning.

3-3.3.1 Zoning.

Zoning is the concept of grouping functional areas by security or access levels to enhance security. If configured correctly, having multiple zones within a facility can enhance the security of the higher security zones. This is accomplished by requiring personnel to transition through increasingly secure access control layers (zones) prior to accessing the highest security zone. Zones may include public access, controlled access, and restricted access, which can be related to public/visitor areas, service areas, controlled access areas, secret open storage, top secret open storage, SCIF or SAPF. See Figure 3-1 for access layers and Figure 3-2 for a bubble diagram example.

Figure 3-1 Access Layers

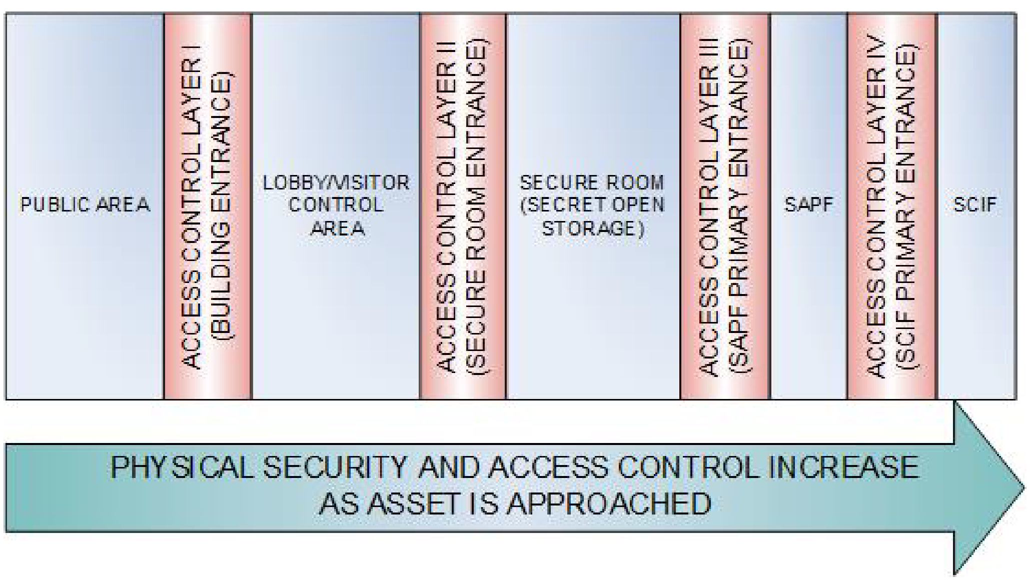


Figure 3-2 Security Zones

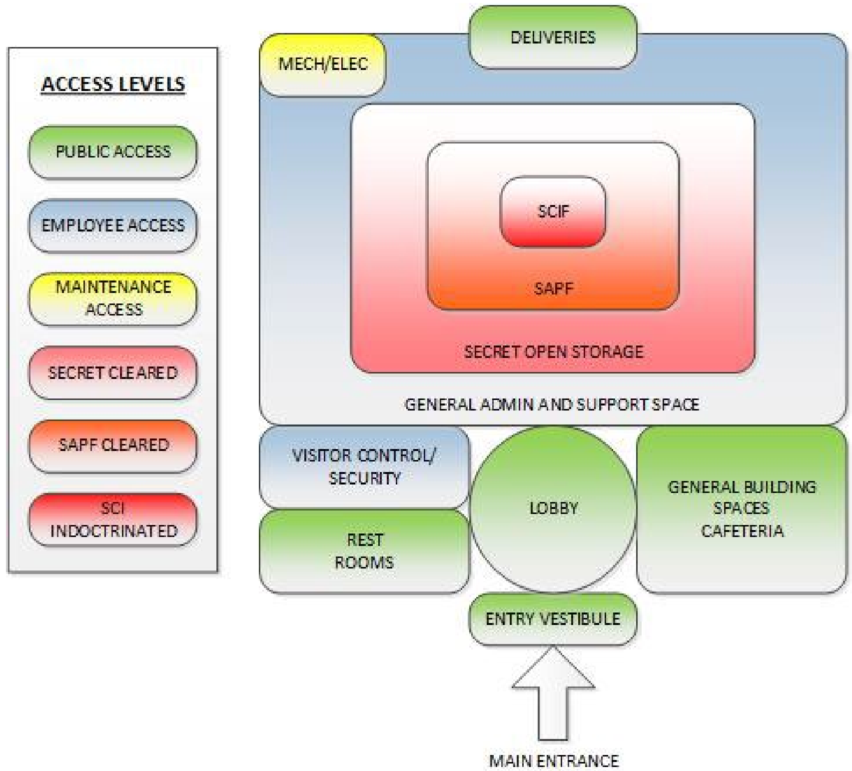

3-3.3.2 Layout Criteria.

In developing the building layout:

- Maximize the vertical and horizontal separation between the lowest and highest security areas.
- Maximize grouping of secure areas to enhance floor/ceiling security and to minimize locations of secure elements.
- In large facilities, the highest security area should be located in the building center, upper floor or basement.
- When a facility has multiple security levels, access to the highest security area should be through the area with the next lower security level. An example would be access to the SCIF through a SAPF or secret open storage area.
- Are foreign nationals allowed in the facility to work or participate in training given at the facility? If so, building layout should consolidate high security areas and provide the appropriate separation to minimize the technical threat and escort requirements.
- Utilities and general building support spaces should remain outside of the secure areas.

- Locate telecommunication spaces that contain the encryption equipment within or adjacent (shared wall) to the secure area to enhance security and minimize or eliminate Protected Distribution System (PDS) requirements.
- Entry into a lower security area cannot be through a higher security area. This would require escorts.
- Egress paths from the lower security areas must not pass through a higher security area.
  - Egress stairs intended for use as communicating stairs between secure areas must have appropriate access control at each floor level without compromising safe egress to grade from all floor levels.
  - Vertical circulation elements that are entirely within the secure area may not require additional controls at each landing.

3-3.3.3 Adjacent Space.

To increase SID, locate other areas that require access control adjacent to or surrounding the SCIF or SAPF.

3-3.3.4 Visitor Control.

Some larger facilities may require additional space at the entrance for processing and visitor control. For these facilities, provide adequate space for processing un-indoctrinated personnel and visitors, issuing badges and space for personnel awaiting escorts.

3-4 SPECIFIC DESIGN STRATEGY.

The specific design strategy for any tactic governs how the general design strategy varies for different levels of protection or threat severity. They may vary by the sophistication of the protective measures and the degree of protection provided. The specific design strategies reflect the degree to which assets will be left vulnerable after the protective system has been employed.

3-4.1 Perimeter Construction.

The secure area perimeters and the penetrations in those perimeters are the primary focus of the design and construction. IC Tech Spec-for ICD/ICS 705 provides the minimum and enhanced construction requirements for the perimeter with regard to forced entry, covert entry, visual evidence of surreptitious penetration, and sound attenuation. In addition, radio frequency (RF) shielding and other TEMPEST mitigation must be provided as documented in the TCR. Refer to Best Practices Guidelines for Architectural Radio Frequency Shielding for standard construction for RF shielding.

IC Tech Spec-for ICD/ICS 705 includes suggested construction details for acoustic wall construction and duct penetrations. Designers must ensure that details used from IC

Tech Spec-for ICD/ICS 705 comply with UFC 1-200-01. For example, IC Tech Spec-for ICD/ICS 705 has a suggested wall detail for Wall C - enhanced construction utilizing plywood. However, plywood used for construction of interior partitions must be Fire Retardant Treated (FRT) in buildings required to be of noncombustible construction.

3-4.1.1 Inspectable Perimeter.

Secure space perimeters, including the perimeter above the ceiling or below raised floors may need to be inspected for surreptitious penetration once a space becomes operational. The design should facilitate future inspections by minimizing the above ceiling obstructions on the controlled and uncontrolled side of the secure perimeter. Where hard ceilings are located adjacent to the perimeter, coordinate inspection methods with the SSM and SSO to ensure the capability of above ceiling or below raised floors inspections.

3-4.2 Compartmented Area.

A Compartmented Area may be an area, room, or a set of rooms within the accredited space that provides controlled separation between control systems, compartments, sub-compartments, or Controlled Access Programs. There are three types of compartmented areas. Type I is an area where discussion is not authorized so there is no sound rated construction required. Type II & III are a room, or set of rooms are constructed the same and require acoustic protection.

The design and layout of Type II & III Compartmented Areas is a critical element of the layout of the facility when acoustic protection is required for individual rooms within the space. Compartmented Areas, their type, and adjacencies must be identified early in the design process.

- Acoustic Z-Ducts can increase the above ceiling space requirement
- Sound baffles can significantly affect the HVAC system design due to the increase in backpressure.

3-4.3 Acoustic Protection.

The perimeter of the space must provide acoustic protection. The acoustic protection is intended to protect conversations from being inadvertently overheard outside the secure space, not to protect against deliberate interception of audio.[3]

3-4.3.1 Sound Transmission Class (STC).

The ability of an assembly to retain sound within the perimeter is rated using a descriptive value, the Sound Transmission Class (STC). Architectural Graphics Standards (AGS) established Sound Groups 1 through 4, of which Groups 3 and 4 are

[3] IC Tech Spec – for ICD/ICS 705

considered adequate for specific acoustical security requirements for construction. Per AGS:

- Sound Group 3 – (STC of 45) or better. Loud speech can be faintly heard but not understood. Normal speech is unintelligible.
- Sound Group 4 – (STC of 50) or better. Very loud sounds, such as loud singing, brass musical instruments or a radio at full volume, can be heard only faintly or not at all.

IC Tech Spec – for ICD/ICS 705 provides definitions for Sound Group 3 and 4 based on the above descriptions from AGS.

3-4.3.2 Sound Attenuation Descriptions.

The amount of sound energy reduction may vary according to individual facility requirements. However, Sound Group ratings will be used to describe the effectiveness of acoustical security measures afforded by various wall materials and other building components.

- A minimum of Sound Group 3 (STC 45 or better) for the perimeter unless additional protection is required for amplified sound[3]. This applies to the entire perimeter of the space to include walls, ceilings and floors and perimeter penetrations such as conduit, pipe, ducts, doors, and windows.
- Conference rooms or other areas where amplified audio is used such as video teleconference (VTC) equipment, audio visual systems, and speakerphones must meet Sound Group 4 (STC 50 or better)[3].

3-4.3.3 Minimum Perimeter STC Rating.

The SSM develops the CSP and recommends the STC rating for the perimeter with approval by the AO. The STC ratings for the perimeter should be either STC 45 or STC 50. When factory tested in accordance with ASTM E90, provide assemblies that are no less than STC 50 when STC 45 perimeter is required and no less than STC 55 when STC 50 perimeter is required. This will ensure the assemblies meet the minimum STC requirement when installed correctly. Most factory tests are conducted on assemblies with framing members spaced at 24” (607 mm) on center (o.c.). The spacing of the framing member may be reduced to 16” (406 mm) o.c. without compromising the STC rating[4].

3-4.3.4 Sound Masking.

When normal construction and baffling measures have been determined to be inadequate to meet the sound attenuation requirement, utilize sound masking. See IC Tech Spec for more information on the use of sound masking systems and devices.

[4] GA-600

3-4.4 Perimeter Walls.

SSM, with AO approval, will determine if the perimeter walls are Standard (Wall A), Enhanced (Wall B or C) or vault construction. Walls must go from floor slab (true floor) to underside of floor or roof deck (true ceiling). Perimeter walls, floor and ceiling must be permanently and solidly constructed and attached to each other. Seal partition continuously with acoustical sealant (both sides) and finished to match wall wherever it abuts another element such as the floor, ceiling, wall, or column.

Exception: When an existing wall is constructed with substantial material such as brick, concrete, masonry, the existing wall may be utilized to satisfy the specification[5].

3-4.4.1 Perimeter Wall Variations.

The IC Tech Spec-for ICD/ICS 705 included suggested wall drawings for Standard (Wall A), Enhanced (Wall B or C) and construction criteria for STC 45 and 50 walls. These are suggested and allow variations in wall construction techniques to meet the security standards.

There are criteria beyond the scope of the IC Tech Spec-for ICD/ICS 705 that require walls that may exceed the IC Tech Spec-for ICD/ICS 705. For example, the size of stud and gauge of the metal stud will vary depending on if this is a load bearing, non-load bearing or exterior wall. In some cases, walls may have to span heights greater than normal. For these cases, the stud size or gauge may be increased to reduce wall deflection. For exterior walls, the stud thickness is typically a minimum of 6” (152mm) depending on the thermal insulation requirements of the building envelope. These designs will exceed the IC Tech Spec-for ICD/ICS 705 required STC rating but should not require a waiver since the design exceeds the standard based on other criteria.

3-4.4.2 Gypsum Board.

IC Tech Spec-for ICD/ICS 705 indicates Standard STC 45 wall has three layers of 5/8 inch (15.9 mm) gypsum wallboard (GWB). One layer on the uncontrolled side (outside) of the protected area and two layers on the controlled side (interior) of the protected area to meet STC 45, see Figure 3-3. The STC 50 wall in IC Tech Spec-for ICD/ICS 705 indicates four layers. Two layers on the outside and two layers on the inside, see Figure 3-4.

- Stagger joints on the opposite sides of a partition so they are not on the same stud.
- Install the GWB so that the joints of the face layer are offset from the joints of the base layer.
- Joints in the face layer that are parallel to the framing members must fall over the framing members and offset from the base layer.

[5] IC Tech Spec – for ICD/ICS 705

Exception: When using adhesive between the layers, joints in the face layer do not have to occur over the framing member

3-4.4.3 Factory-Laminated GWB.

To enhance the sound attenuation of the assembly, one layer of factory laminated GWB meeting ASTM C1766 may be used. GWB meeting ASTM C1766 is designed for sound control systems and is composed of two layers of gypsum panels factory-laminated into a composite panel.

Figure 3-3 STC 45 Assembly

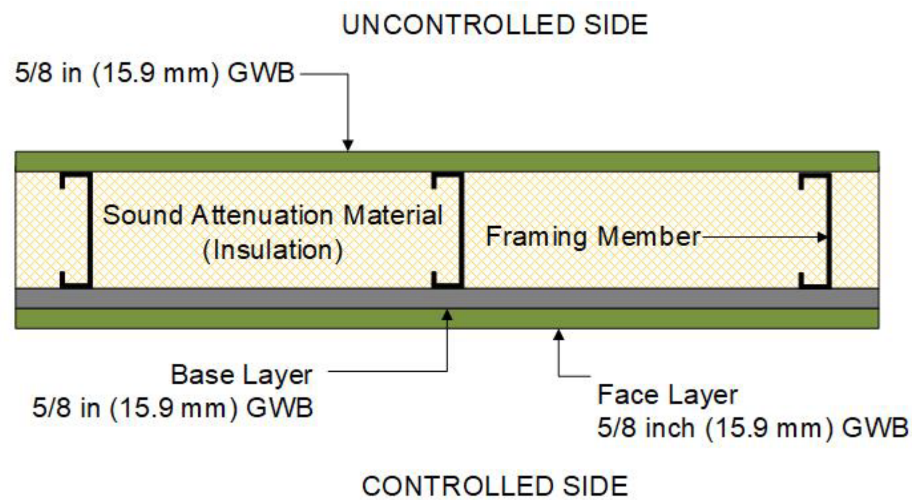

Figure 3-4 STC 50 Assembly

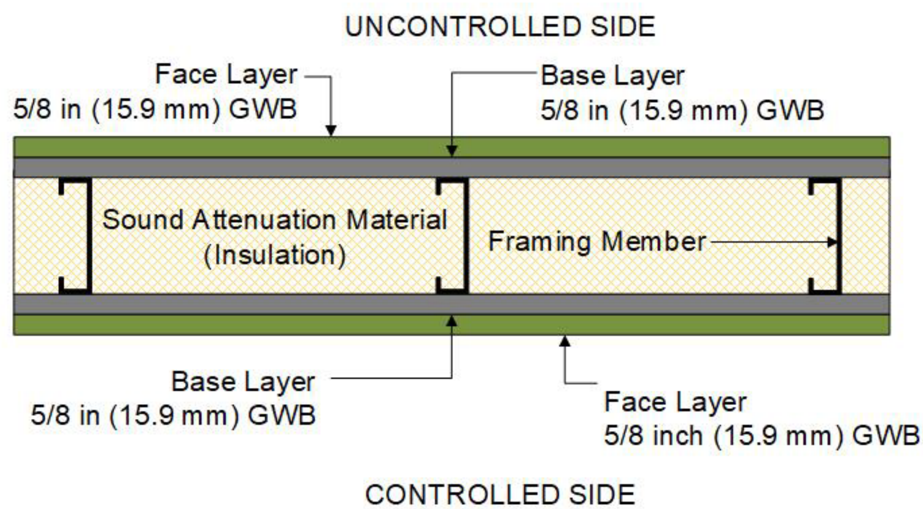


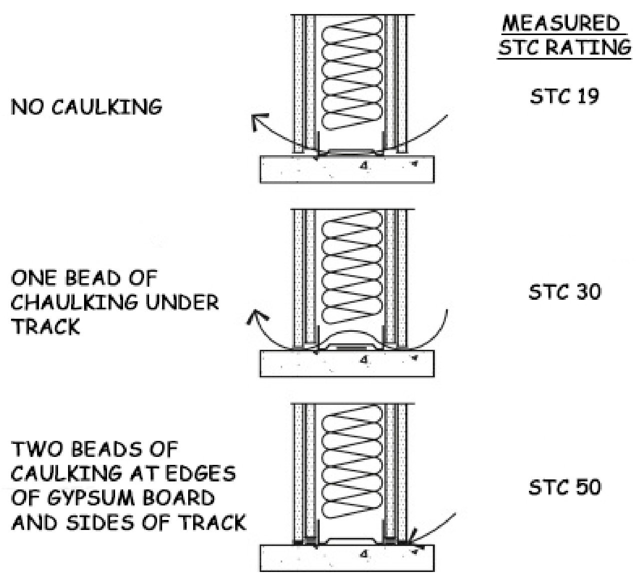
3-4.4.4 Insulation.

Use fibrous insulation to improve the sound isolating performance of the system. Over-packing the cavity may decrease the performance. In addition, the use of spray foam or other hardening insulations may decrease the sound performance.

3-4.4.5 Sealing Gaps.

Gypsum board panels are lifted into place during construction using a spacer under their bottom edge, so there is a 1/8 inch to 1/4 inch (3 mm to 6 mm) gap at the bottom. Sealing openings in partitions is critical to acoustical performance. Seal gaps on both sides with a non-hardening caulk so the acoustical rating of the wall is maintained. Figure 3-5 shows how sealing the gaps effect the STC ratings of the connection.

Figure 3-5 Sealing Tracks



3-4.4.6 Wall Finish.

Walls must be uniformly finished and painted from floor slab (true floor) to underside of floor or roof deck (true ceiling). See Figure 3-6.

3-4.4.7 Utilities on Perimeter Wall.

Utilities such as power, telecommunications, signal, and plumbing on the perimeter or compartmented wall treated for acoustic or RF must be surface mounted or construct a furred out wall for routing of utilities. This include recessed outlet boxes, recessed panels for power, telecommunications, ESS, fire alarm and other systems. Do not mount utilities in a manner that will affect the acoustic or RF shielding performance.

If a furred out wall is used, provide a minimum 3/8 inch (10 mm) gypsum board. The gypsum board only needs to go above the false ceiling. Figure 3-7 shows an example of a furred out wall prior to the installation of the 3/8 inch (10 mm) gypsum board.

Figure 3-6 Wall Finish

<table>
<tr><td></td><td><u>UNACCEPTABLE</u>
• Wall not uniformly finished and painted.
• Wall assembly does not meet acoustic rating
  - Wall not continuous and sealed where wall abuts floor pan.
• Wall penetrations not sealed.</td></tr>
<tr><td></td><td><u>UNACCEPTABLE</u>
• Not uniformly finished and painted.
• Gap between finished and unfinished GWB
• Gap between unfinished GWB and duct penetration
• Not finished and painted and the penetrations are not sealed and finished.</td></tr>
<tr><td></td><td><u>ACCEPTABLE</u>
• Wall is true floor to true ceiling
• Wall is sealed where wall abuts floor pan.
• Wall is uniformly finished and painted from true floor to true ceiling
• Wall penetrations are sealed.</td></tr>
</table>

Figure 3-7 Furred Out Wall for Utilities

3-4.4.8 Recessed Fire Extinguisher Cabinets.

Recessed fire extinguisher cabinets are prohibited on perimeter or sound rated compartmented area walls.

3-4.5 Ceilings and Floors.

Ceilings and floors must meet the same requirements as walls with regard to forced entry, covert entry, visual evidence of surreptitious penetration, and sound attenuation. In addition, ceilings, floors and all penetrations must meet TEMPEST requirements when recommended by the TCR

3-4.6 Perimeter Doors.

Perimeter doors and frame assembles must meet acoustic requirements unless declared a non-discussion area and protected by IDS. Provide dead bolts for perimeter doors with day access controls for occupants. In addition, perimeter doors must meet TEMPEST requirements when recommended by the TCR. All perimeter doors must be solid with no lites or sidelites.

3-4.6.1 Acoustic Rated Doors.

Use UFGS 08 34 73 to specify acoustical rated door assemblies to include door, seals, hinges, door closer, frame and threshold. Provide door assemblies that are factory tested in accordance with ASTM E90 to no less than STC 50 when a STC 45 perimeter is required and no less than STC 55 when STC 50 perimeter is required. This will help ensure the door assemblies meet the minimum STC requirement when installed correctly.

Acoustical rated door assemblies are much heavier than typical doors and require heavy-duty hardware and structurally adequate support. For acoustics, utilize structural C or U channel in lieu of tubing. Coordinate design of structural support with a Structural Engineer and install in door assembly in accordance with UFGS 08 34 73 and manufacturer's instructions.

3-4.6.2 Wood doors.

When used, wood doors must meet following minimum specifications:

- 1 ¾ inch (45 mm) thick solid wood core (wood stave, structural composite lumber).
- Lock area predrilled.

3-4.6.3 Steel Doors.

At a minimum, steel doors must meet following specifications:

- 1 ¾ inch (45 mm) thick face steel equal to 18 gauge.
- Lock area predrilled and reinforced to 10 gauge.

3-4.6.4 Door Closers.

Equip perimeter doors with a heavy-duty automatic non-hold door-closer installed internal to the perimeter the installation area reinforced to a minimum of 12 gauge for a steel door and at the top rail for a wood door.

3-4.6.5 Electric Locks.

Electric door strikes or electrified mortise locks installed with an access control system (ACS) must have a positive engagement, fail secure, and approved under UL 1034 for burglar resistance.

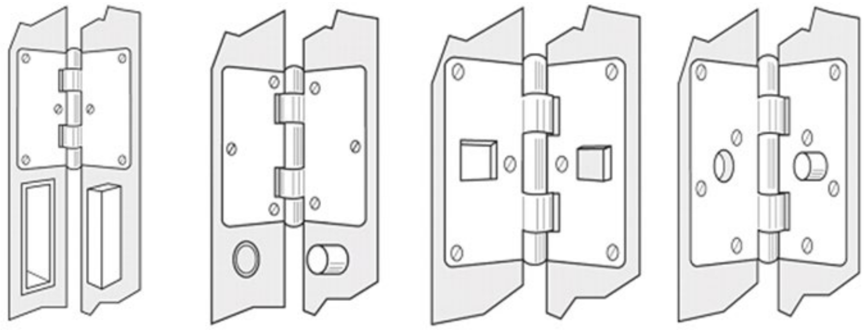
3-4.6.6 Hinges.

Hinges must be reinforced to a minimum of 7 gauge, and be cam-lift for acoustical door assemblies.

3-4.6.6.1 Hinge Pins.

Hinge pins on perimeter doors must be tamper resistant unless mounted on the protected side of the door. Tamper resistant hinges must have non-removable pins, security pins, set screws, welded, or equipped with a safety stud. See Figure 3-8.

Figure 3-8 Tamper Resistant Hinges



3-4.6.7 Primary Entrance.

Unless approved by the AO, provide one primary entrance where visitor control is conducted. Primary entrance must be:

- Equipped with an approved automated access control device.
- Equipped with a GSA-approved pedestrian door deadbolt meeting Federal Specification FF-L-2890.
- Equipped with combination lock meeting Federal Specification FF-L-2740.
- Equipped with a key override in the event of a malfunction or loss of power to the ACS.

3-4.6.8 Secondary Entrance.

In addition to the primary entrance, a secondary entrance may be allowed with AO approval. As with the primary entrance, the secondary entrance should incorporate a vestibule to preclude visual observation and enhance the acoustic protection. Secondary entrance must be:

- Equipped with an approved automated access control device.
- Equipped with a GSA-approved pedestrian door deadbolt meeting Federal Specification FF-L-2890. Additional standalone and flush mounted deadbolts are prohibited.

3-4.6.9 Primary and Secondary Entrance Vestibule.

When practical, the primary and secondary entrance should incorporate a vestibule to preclude visual observation and enhance acoustic protection. Primary entrance vestibule may have to accommodate space for visitor check-in and badging. In most applications, the interior door of the vestibule will be sound rated and the secure perimeter. To improve acoustic protection, provide acoustic treatments in vestibules to help absorb and diffuse sound.

3-4.6.10 Emergency Exit Doors.

Emergency exit doors must meet perimeter door requirements and:

- Have no exterior hardware; see Figure 3-9.
- Equipped with a GSA-approved pedestrian door deadbolt meeting Federal Specification FF-L-2890. Additional standalone flush-mounted deadbolts are prohibited.
- Alarmed 24/7 and equipped with a local annunciation.
- Delayed-egress is recommended with NFPA 101 compliance.

Figure 3-9 Emergency Exit Doors

3-4.6.11 Vault Doors.

General Services Administration (GSA)-approved Class 5 vault door equipped to meet Architectural Barriers Act (ABA) Standards. General Services Administration (GSA) has authorized the use of federal specification AA-D-600D for vault doors.

3-4.6.12 Roll-up Doors.

Roll-up doors can only be located in an area of non- discussion due to the inability to treat for acoustics. Roll-up doors must be 18 gauge or greater and secured with dead bolts on each side of the door.

3-4.6.13 Double Doors.

Double doors should not be used on the perimeter. If double doors are used:

- Secure one side with deadbolts at the top and bottom.
- Provide an astragal strip attached to either door to prevent observation into the space through the opening between the doors.
- Provide an independent high security switch (HSS) level 2 on each door.

3-4.7 Personal Electronic Device (PED) Cabinets.

Provide lockable metal cabinets outside the primary entrance for the storage of PEDs, see Figure 3-10. PED cabinets cannot be located within 10 ft. (3 m)[6] of equipment processing unencrypted NSI. Recessed PED cabinets are prohibited on perimeter walls.

Figure 3-10 PED Cabinets

3-4.8 Windows.

Every effort should be made to minimize windows, especially on the ground floor. When used, windows must be non-opening, be provide visual and acoustic protection and include TEMPEST requirements when recommended by the TCR.

3-4.8.1 Windows less than 18 feet (5.5 meters).

Windows less than 18 feet (5.5 meters) (measured from the bottom of the window) above the ground or from the nearest platform; such as lower roof, canopy or mechanical equipment, which affords access to the window must:

- Meet the standards of the perimeter
- Monitored by IDS

Large glazing panels may require noise generator transducers to achieve acoustic protection.

3-4.9 Daylighting.

Secure facilities are not exempt from the high performance building requirements of UFC 1-200-02. Promote access to daylight in breakrooms and other common spaces.

---

[6] DoDM 5105.21-V2 and CNSSAM TEMPEST/1-13

When provided, daylighting design must be coordinated with the SSM. Design daylighting fenestration to be non-opening, provide visual and acoustic protection and include TEMPEST countermeasures when recommended by the TCR.

3-4.9.1 Daylighting Penetrations less than 18 feet (5.5 meters).

Daylighting penetrations that are less than 18 feet (5.5 meters) (measured from the bottom of the fenestration) above the ground or from the nearest platform; such as lower roof, canopy or mechanical equipment, which affords access to the fenestration or accessible from the roof must:

- Meet the standards of the perimeter
- Monitored by IDS

3-4.10 Visual Protection of Windows and Daylighting Fenestration.

Provide visual protection by methods such as full surface acid etching, sand blasting, or an obscure polyvinyl butyral interlayer. Method must obscure vision into the protected area while providing light transmission. Specify a maximum of 75% diffuse transmittance and a minimum haze of 90% when tested in accordance with ASTM D1003.

For existing windows, blinds, drapes or other coverings may be used with SSM/SSO approval.

3-4.11 Perimeter Penetrations.

Keep penetrations of the perimeter to a minimum. Ducts, conduits, pipes, or anything that penetrates the perimeter presents a vulnerability that must be addressed. All penetration must meet the acoustic requirements of the perimeter. In addition, perimeter penetrations may require TEMPEST countermeasures when recommended by TEMPEST Countermeasure Review.

Ducts, conduits or pipes servicing other areas cannot penetrate the perimeter unless mitigated with AO approval.

3-4.11.1 Utility Penetrations.

Utilities (power and signal) should enter at a single point. Seal all utility penetrations to mitigate acoustic emanations and covert entry. Spare conduits are allowed for future expansion provided the expansion conduit is filled with acoustic fill and capped or a Fire Stop System may be required for fire rated assemblies.

3-4.11.2 Metallic Penetrations.

All metallic penetrations through the perimeter are considered carriers of compromising emanations (CE) and pose TEMPEST hazards that must be addressed. Unless directed otherwise by the TEMPEST Countermeasure Review:

- Metal conduit or pipe: provide a nonconductive union inside the perimeter adjacent to the penetration, or ground the conduit within 6 inch (150 mm) of the perimeter penetration using a no. 4 wire (0.2043-diameter copper wire) to the building grounding system.
- Metallic sprinkler (fire suppression) pipe: ground the pipe within 6 inch (150 mm) of the perimeter penetration using a no. 4 wire (0.2043-diameter copper wire) to the building grounding system.
- Mechanical system refrigerant lines: ground the line within 6 inch (150 mm) of the perimeter penetration using a no. 4 wire (0.2043-diameter copper wire) to the building grounding system. Maintain integrity of refrigerant line insulation.
- HVAC ducts: provide a nonconductive break (flex connection) using material appropriate for the climate, for a 2- to 6-inch (50 to 150 mm) section of the duct inside the perimeter adjacent to the penetration, see Figure 3-11. When a waveguide is recommended by TEMPEST Countermeasure Review, provide between the perimeter and the nonconductive break.

In addition, the TEMPEST Countermeasure Review may require additional countermeasures.

Figure 3-11 Duct Penetrations

3-4.11.3 Penetration Seals.

Seal both sides of perimeter penetrations with an acoustical foam or sealant finished to match adjacent wall, floor, or ceiling see Figure 3-12. Fire Stop System may be required for fire rated assemblies. In addition, penetration seals must meet TEMPEST requirements when recommended by the TEMPEST Countermeasure Review.

Figure 3-12 Sealing Penetrations

3-4.12 Vents and Ducts.

Protect all vents or duct openings exceeding 96 square inches (619 cm2) that penetrate the perimeter with permanently affixed bars, grills, diamond mesh, welded wire fabric, metal sound baffles or waveguides. If one dimension of the penetration measures less than 6 inch (150 mm), protection is not required. One of the following can be used to secure openings 6-inches (150 mm) or more in any dimension.

- A minimum of ½ inch (13 mm) diameter steel bars welded vertically and horizontally 6 inch (150 mm) on center. A deviation of ½ inch (13 mm) in vertical and/or horizontal spacing is permissible, see Figure 3-13.
- ¾ inch (20 mm) #9 (10 gauge) case hardened expanded metal grills.
- Carbon steel standard expanded metal diamond mesh, 1-1/2” (38 mm) #10 (13 gauge). With a maximum design size of 1-3/8” by 3” (35 mm x 76 mm), strand size thickness of 0.093” (2.36 mm), with at least 80% open design).
- Welded wire fabric (WWF) 4x4-W2.9xW2.9 (6 gauge) smooth steel wire welded vertically and horizontally four inches on center.
- Metal sound baffles or waveguide permanently installed and set no farther apart than 6 inch (150 mm) in one dimension.

Coordinate material selection with Mechanical Engineer to ensure proper airflow and fan sizing.

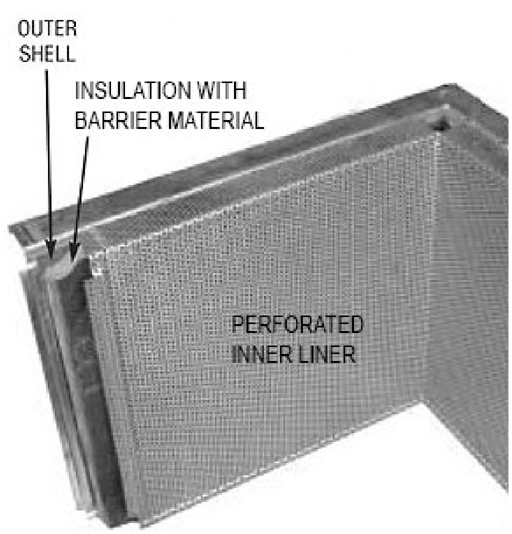
Figure 3-13 Bars on Penetration

3-4.13 Acoustic Protection for Ducts.

To ensure acoustic performance of the perimeter is not compromised, provide sound baffles (duct silencers) or (Z) Duct Penetrations. IC Tech Spec – for ICD/ICS 705 provides an example of a (Z) Duct Penetration. Coordinate selection with the mechanical engineer. Backpressures created by the baffles may significantly impact the HVAC system design.

Be aware, (Z) Duct Penetration in IC Tech Spec – for ICD/ICS 705 indicates acoustically lined duct. Per UFC 3-410-01, acoustical duct liner is not allowed. In lieu of acoustical duct liner, provide double wall acoustic duct, see Figure 3-14. For contamination protection, include a barrier material between the perforated liner and the insulation designed to prevent air quality issues caused by bacteria and other contaminates that can embed in the insulation.

Figure 3-14 Double Wall Acoustic Duct

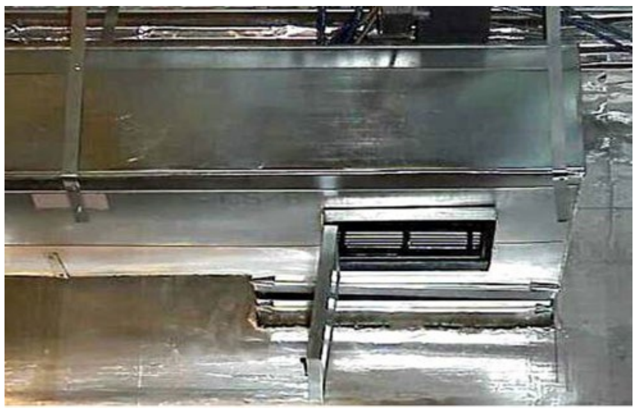


3-4.14 Access Port.

For vents or ducts that require bars or grill, provide an accessible access panel in the bottom within the perimeter to allow visual inspection of the bars, grill, or waveguide, see Figure 3-15.

If the area outside the perimeter is controlled (SECRET or equivalent proprietary space), the inspection port may be installed outside the perimeter, and be secured with an AO approved high-security lock such as a GSA combination padlock meeting Federal Specification FF-P-110.

Figure 3-15 Access Port



3-4.15 Flashing or Rotating Light.

Per DoDM 5105.21 Vol 2 and DoDM 5205.07 Vol 2, personnel must be informed when non-indoctrinated personnel have entered and departed the space. Per IC Tech Spec, Lights, signs, or other alerting mechanisms or procedures must be used to alert occupants of the presence of uncleared personnel. This may be accomplished either verbally or through visual notification methods. A flashing or rotating light is an approved method to indicate the presence of non-indoctrinated personnel in the area. This can be hand held or installed.

Coordinate use of flashing or rotating notification lights with mission requirements. There may be light-sensitive or simulation equipment that preclude use of such light during ongoing operations. When installed, place lights to ensure visual observation by the occupants of the space. At a minimum, provide controls within the perimeter at each entrance into the space or compartmented area.

3-4.16 Duress Alarm.

When a duress alarm is required, duress alarm must initiate an alarm condition at the central monitoring station and no audible or visual signal in the protected area.

3-4.17 Electronic Security System (ESS).

An ESS is comprised of three primary subsystems; intrusion detection system (IDS), access control system (ACS), and video system along with a supporting data transmission network and electrical power system.

ESS systems must meet the requirements of ICS 705-1 and IC Tech Spec-for ICD/ICS 705 and be designed in accordance with UFC 4-021-02. UFC 4-021-02 provides notional layouts for typical ESS systems.

3-4.17.1 Access Control System (ACS).

At a minimum, provide card reader with keypad at the primary entrance and when provided, the secondary entrance. Unless otherwise directed, the default ACS identifier credential is the Common Access Card (CAC)[7].

- Locate equipment containing access-control software programs within the perimeter or a SECRET controlled area.
- Protect system data that is carried on transmission lines (e.g., access authorizations, personal identification, or verification data) to and from equipment located outside the perimeter using FIPS AES certified encrypted lines. If this communication technology is not feasible, provide transmission lines as approved by the AO.
- Provide electric locks with positive engagement, fail secure, and approved under UL 1034 for burglar resistance.

3-4.17.2 Video System.

Cameras are not allowed within the perimeter or enable observation within the perimeter. A camera may be provided on the exterior to supplement the monitoring of a primary entrance for remote control of the door from within the space. A Video Intercom System may provide this capability. The system must provide a clear view of the primary entrance that is monitored and operated by indoctrinated personnel.

3-4.17.3 Intrusion Detection System (IDS).

Protect the space with IDS when not occupied. Protect all Interior areas through which reasonable access to the asset could be gained with IDS.

- The IDS must be independent of systems safeguarding other facilities and compatible with Installation’s central monitoring system.
- Provide point sensors on perimeter doors and man-passable openings such as roof hatches.
- Provide motion sensors within the perimeter to protect perimeter windows, doors, daylight fenestrations, and man-passable openings.

[7] Per DoD 5200.08-R

- Strategically place motion sensors within the space to detect movement where assets are stored or where assets are stored or in pathways leading to the asset. One hundred percent coverage is not required.
- Motion sensors are not normally required above false ceilings or below false floors; however, these detectors may be required by the AO for critical and high threat facilities outside the U.S.
- Monitor emergency exit doors 24 hours a day. Provide local annunciation to alert occupants when the door opened with identification of the appropriate door when there is an alarm indication.

3-4.17.3.1 Intrusion Detection Installation and Components.

Per IC Tech Spec – for ICD/ICS 705, IDS installation, related components, and monitoring stations must comply with Underwriters Laboratories (UL) 2050 Extent 3 standards. Systems developed and used exclusively by the U.S. Government do not require UL certification but must comply with UL 2050 Extent 3 standards for installation. UL 2050 materials are restricted and only distributed to those demonstrating relevant national industrial security involvement. However, UL 2050 implements UL 681, Installation and Classification of Burglar and Holdup Alarm Systems for alarm system installation. See UFC 4-021-02 for additional information and a notional ESS layout.

3-4.17.3.2 Motion Detection Sensors.

UL 639 Listed. Dual-technology sensors may be used when authorized and when each technology transmits alarm conditions independent of the other technology (“or” configuration).

3-4.17.3.3 Point Sensors.

UL 634 HSS level 2. Level 2 rated switches only include Balanced Magnetic Switches that pass additional performance testing.

3-4.17.3.4 Sensor Cabling.

Cabling between sensors and the PCU must be dedicated to the system, contained within the perimeter, and comply with Committee for National Security Systems (CNSS) standards. If the wiring cannot be contained within the perimeter, meet the requirements for External Transmission Line Security.

3-4.17.3.5 Premise Control Unit (PCU).

Locate PCU within the Perimeter. Configure system to only allow cleared personnel located within the secure/protected area to initiate changes in access modes or alarm conditions.

PCUs certified under UL 1610 must meet FIPS 197 or FIPS 140-2 encryption certification and methods. For PCUs certified under UL1076, only FIPS 140-2 is the acceptable encryption certification and method.

3-4.17.3.6 External Transmission Line Security.

IDS transmission lines to the central monitoring station, must meet National Institute of Standards and Technology, Federal Information Processing Standards (FIPS) certified encrypted lines.

All lines employing line supervision require certification of the algorithm by the National Institute of Standards and Technology (NIST) (a NIST certificate). An alternate form of line supervision may be approved on a case-by-case basis.

3-4.17.3.7 Standby Power.

Provide twenty-four hours of uninterruptible standby power. This may be provided by batteries, uninterruptible power supply (UPS), or engine-generators, or any combination. Standby power for IDS should not generate the requirement for a UPS or engine-generator. When an engine-generator is available for standby power, provide batteries for IDS that provide a minimum of four hours of standby power to allow uninterrupted power during transitions to and from standby generator power.

In the event of primary power failure, the IDS must:

- Automatically transfer to the backup power source without causing alarm activation.
- Initiate an audible or visual indicator at the PCU to provide an indication of the primary or backup power source in use.
- Initiate an audible or visual indicator at the monitoring station indicating a failure in a power source or a change in power source.

3-4.17.3.8 IDS Approval.

The AO must approve IDS proposals and plans prior to installation as part of the pre-construction approval process.

3-4.18 Telecommunications Space.

Per UFC 3-580-01, the minimum size for Telecommunications Room (TR) is 10 feet x 8 feet (3m x 2.4m). This will be inadequate if the telecommunications space contains equipment racks for multiple networks such as Secret Internet Protocol Router Network (SIPRNet), Joint Worldwide Intelligence Communications System (JWICS), Non-classified Internet Protocol Router Network (NIPRNet), voice services, and other equipment or services. Depending on the number of workstations served, this could generate a larger space requirement when considering the equipment racks and RED/BLACK separation requirements.

UFC 3-580-01 allows the use of an Equipment Room in lieu of a TR for buildings that house substantial Information Technology (IT) electronics. A telecommunication space that contains equipment for multiple networks such as SIPRNet, JWICS and NIPRNet all requiring RED/BLACK separation is considered as substantial Information Technology (IT) electronics which would allow for the use of a larger Equipment Room.

3-4.18.1 Telecommunications Expansion.

Design the telecommunication spaces to accommodate future equipment expansion. At a minimum, UFC 3-580-01 requires one spare rack for every four utilized racks with the minimum of one spare rack. Future operational capability for these types of facilities may require additional expansion space. Coordinate future expansion capabilities with mission commander and the C5ISR equipment provider. Provide additional power, environmental support, and floor space for the future expansion.

3-4.18.2 Temperature and Humidity Control.

Substantial Information Technology (IT) equipment generate a significant amount of heat. In these environments, the heat densities can be up to five times higher than in a typical office load. Traditional HVAC systems cannot remove enough heat to protect IT equipment. Instead, these areas require systems with higher cooling capabilities such as a computer room air conditioner (CRAC). The smallest high-powered CRACs require a minimum 10 ft. x 3 ft. (3m×1m) footprint for equipment and clearances.

Design air-conditioning systems for year-round cooling with very high cooling intensity. The high sensitivity of electronic components in such facilities requires that temperature, humidity, air movement and air cleanliness must be kept consistent and within specific limits to prevent premature equipment failures and costly downtime.

3-4.19 Telecommunication Cabling System.

Cabling, patch panels, connector blocks, work area outlets, and cable connectors must be color coded[8] to distinguish their classification level. If color-coding is not possible, cabling must be clearly marked to indicate their classification level. Cabling must enter the protected area from a single location and must be identified and labeled with its purpose and destination at the point of entry. Backbone and horizontal cabling may differ depending on network classification, service provider, and TEMPEST requirements. Coordinate requirements with SSM and service provider. See TEMPEST Countermeasures.

3-4.20 Protected Distribution Systems (PDS).

Protect signal distribution systems containing unencrypted NSI that enters an area of lesser classification, unclassified area, or uncontrolled (public) area with a PDS in accordance with CNSSI No 7003.

---

[8] Per DoDM 5105.21 Vol 1

Avoid the use of PDS whenever possible due to inspection requirements. To avoid PDS, keep cabling transmitting unencrypted NSI within the protected perimeter.

3-4.21 RESILIENCE.

Some facilities must continue to operate effectively or recover rapidly to support the mission in the event of severe weather, earthquake, loss of utility, or equipment failure. Defining the appropriate International Building Code (IBC) Risk Category is critical in determining the earthquake, flood, snow and wind load requirements that will apply to the building. Some critical operations or C5ISR systems require redundant utilities, standby power systems, and redundant support systems to ensure continuous operation in the event of utility or equipment failure.

Coordinate resiliency requirements with the mission commander.

3-4.21.1 Redundant Utilities.

Critical operations or C5ISR systems may require redundant utilities such as telecommunication system connectivity or utility power service. To be redundant, the utilities providing connectivity or power to the facility must be two separate utilities that are not routed together.

3-4.21.2 Standby Power System (SPS).

Critical operations or C5ISR systems may require an SPS designed to ensure continuity of electrical power to essential and uninterruptible loads upon loss of normal power sources. Design SPS in accordance with NFPA 70 and NFPA 110. The SPS must have the capacity and rating to meet the maximum demand likely to be produced by the essential and uninterruptible loads and be consistent with the facilities emergency operations plan.

3-4.21.2.1 Engine-Driven Generator.

When a SPS is required, provide a standby engine-driven generator for essential and uninterruptible loads to ensure continued operation upon loss of utility power. Design the standby generator in accordance with UFC 3-540-01.

3-4.21.2.2 UPS Systems.

When a SPS is required, provide UPS for the uninterruptible loads to filter commercial power and to support the uninterruptible loads during transitions to and from the standby generator.

3-4.21.3 Redundant Support Systems.

Some critical operations may require support systems with a minimum of N+1 redundancy to ensure continuous operation in the event of component failure. In this configuration, components (N) have at least one independent backup component (+1). For a critical communication system, the N+1 redundancy would be applied to support systems such as the air-conditioning systems and SPS required to support continuous operation. For example, if the essential and uninterruptible loads required two 250 kW generators, N+1 would result in three 250 kW generators.

3-4.22 TEMPEST.

TEMPEST is a short name referring to investigation, study and control of compromising emanations from telecommunications and automated information systems equipment. In general, TEMPEST countermeasures apply when there is equipment that will be processing national security information (NSI). The intent is to minimize the likelihood that these emanations will be intercepted.

3-4.22.1 TEMPEST Countermeasures Review (TCR).

Each project requires a TEMPEST countermeasures review (TCR), performed or verified by the Certified TEMPEST Technical Authority (CTTA). The SSO or SSM will request a TCR by submitting a TEMPEST addendum to the FFC. For an initial TCR, the TEMPEST addendum will be submitted to AO during the preliminary design phase. While some specific information may not be known prior to construction, as much information as possible must be provided in order to minimize costly changes. Based on the results of the TCR, the CTTA will determine the most cost-effective countermeasures and will document these requirements in writing[9].

3-4.22.2 TEMPEST Countermeasures.

TEMPEST-suppressed equipment, radio frequency (RF) shielded enclosures, filters (power, signal, telephone, etc.), nonconductive conduit or duct sections, or other potentially expensive TEMPEST countermeasures must not be applied without AO approval. Normally, facilities located on military installations within the United States do not require additional countermeasures beyond implementing RED/BLACK separation guidance depending on threat and mission requirements. However, facilities that are located outside the U.S., off a military installation, in close proximity with a foreign entity; or facilities that share a common wall, floor, or ceiling with a non-government element may require additional measures beyond implementing RED/BLACK separation[9]. These additional measures are determined through the TCR process and approved by the AO.

3-4.22.3 RED/BLACK Telecommunication Systems.

All equipment, wirelines, components, and systems that process National Security Information (NSI) are considered RED. Equipment, wirelines, components, and systems that process encrypted NSI and non-NSI are considered BLACK. BLACK lines and other electrically conductive materials that egress the inspectable space are potential carriers of Compromising Emanations (CE) that can inadvertently couple to the RED lines. Various signal line isolation techniques such as separation and filtering are

[9] DoDM 5105.21 Vol 2 and DoDM 5205.07 Vol 3

used to protect the signal line, the distribution system or other fortuitous conductors from conducting compromising signals beyond secure areas.

Apply fundamental RED/BLACK mitigations in accordance with CNSSAM TEMPEST/01-13 to prevent the inadvertent transmission of classified data over telephone lines, power lines, signal lines, and electrical components, circuits, and communication media. The application of RED/BLACK separation establishes areas where equipment processing classified information (RED) are isolated from areas where equipment processing unclassified (BLACK) are located.

3-4.22.4 Radio Frequency (RF) Mitigation.

As documented in the TCR, protect the space from compromising emanations. When directed, provide RF mitigation for perimeter walls, ceilings, floors, doors, windows, skylights and penetrations with RF shielding, non-conductive breaks, and grounding. RF mitigations for penetrations may include waveguides.

When required, place foil layer on the secure side of the perimeter wall between the first and second layer of gypsum board. When required, place RF shielding material on floor and ceiling. Doors must be steel with RF gasket, and door frame must be electrically bonded continuously to RF shield. Entire window or skylight assembly must be RF shielded and widow or skylight frame and must be electrically bonded continuously to RF shield. Shielding must be electrically bonded continuously, with no gaps or discontinuities at any point, at interfaces between, walls, floors, ceilings, doors, windows, and skylights and penetrations. Power and low voltage systems may include power line and telecommunication line filters. Refer to *Best Practices Guidelines for Architectural Radio Frequency Shielding* for standard construction for RF shielding.

- Do not connect mounting apparatus to the RF shielding material in a manner that affects RF shielding performance.
- Consider providing furred out walls to protect RF shielding from future compromise.

3-4.22.5 RF Door ABA Compliance.

RF doors that utilize a knife-edge may not meet ABA Standards without modification due to accessibility requirements at the sill, see Figure 3-16. The use of temporary ramps will not meet ABA Standards.

3-4.22.6 Paging, Intercom, and Public Address Systems.

Systems should be totally contained within the perimeter. Refer to the TCR to determine TEMPEST countermeasures. Possible countermeasures may include:

- Separation of equipment and signal lines from RED telecommunication lines and processors.
- Provide a local buffer amplifier to prevent speakers or earphones from functioning as microphone. For most systems, this is a simple amplifier

within the perimeter that takes the incoming audio signal and amplifies/distributes the signal to the speakers within the perimeter.

- Provide electronic isolation for systems that require two-way communication. The system must alert occupants when the system is activated.
- Provide voice frequency, bandpass filters if they are not totally contained within the inspectable space. This protects against TEMPEST signals on the cables but does not protect against voice modulation of the speakers.
- Provide a subpanel within the perimeter with optical fiber backbone to the building system or convert the electrical signal to an optical signal before penetration of the perimeter. Provide optical fiber with no metallic shielding, cladding, or strength members.
- When required, provide electronic isolation components within the perimeter as near to the point of penetration as possible.

Figure 3-16 ABA Non-Compliant RF Door

3-4.22.7 Fire Alarm and Mass Notification System (MNS).

The introduction of electronic systems that have components outside the perimeter should be avoided. TEMPEST concerns may require electronic isolation. Speakers or other transducers, which are part of a system that is not wholly contained within the perimeter, may require mitigation. Refer to the TCR to determine TEMPEST countermeasures. Possible countermeasures may include:

- Separation of equipment and signal lines from RED telecommunication lines and processors.
- For eavesdropping (using the speakers as microphones), a simple buffer amplifier is the standard mitigation. For most systems, this is a simple amplifier within the perimeter that takes the incoming audio signal and amplifies/distributes the signal to the speakers within the space. However, equipment such as pre-amplifiers, amplifiers and products translating or converting live voice signals for use in mass notification systems must comply with the applicable requirements in UL 864, the Standard for Amplifiers for Fire-Protective Signaling Systems. Therefore, any amplifier used in a MNS must meet UL 864.
- Provide a MNS/Fire alarm subpanel within the perimeter with optical fiber backbone to the building system or convert the electrical signal to an optical signal before penetration of the perimeter. Provide optical fiber with no metallic shielding, cladding, or strength members.
- Provide electronic isolation for systems that require two-way communication. The system must alert the occupants when the system is activated.
- When required, provide electronic isolation components within the perimeter as near to the point of penetration as possible.

3-4.22.8 Power Systems.

The power requirements are divided into two groups -- power for the mission equipment (technical) and power for the supporting services (nontechnical). Supporting services include lighting, heating, ventilating, air conditioning, etc. Provide a separate service feeder dedicated to the sensitive equipment and control its distribution reducing the opportunity for unauthorized detection of compromising signals on those lines. Power line conduction occurs when data is transferred onto the power line by RED equipment, or radiated through free space and coupled onto the power lines. If a facility is processing NSI, power is sometimes divided into RED and BLACK power. RED power provides isolation for those non-TEMPEST approved equipment processing NSI. BLACK power is provided for equipment processing non-NSI because power isolation is not required. This separation prevents conducted emissions from RED equipment being coupled through BLACK equipment to BLACK lines that might egress the inspectable space. Refer to the TCR to determine TEMPEST countermeasures. Possible countermeasures may include:

- Separation of BLACK power lines from RED telecommunication lines and processors.
- Power line Filters. UPS within the perimeter may eliminate power line filters.

3-4.22.9 RF Communications Systems.

Facilities that require large RF communications systems (combat net radios, microwave systems, air to ground, or ship to shore) should be designed to place RF communications systems as far away from RED processors as possible.[10]

[10] DoDM 5105.21 Vol 2

CHAPTER 4 CONSTRUCTION

4-1 CONSTRUCTION AWARD.

Per IC Tech Spec – for ICD/ICS 705, prior to awarding a construction contract, a CSP for each project must be approved by the AO. The CSP documents the security requirements for the project. For Navy and Marine Corps projects, refer to NAVFAC INST 4700.01 for additional information.

4-2 CONSTRUCTION PLANS SECURITY.

Per ICS 705-1, protect and handle construction plans and related documents in accordance with the CSP. If classification guides dictate, plans and related documents may require classification. Under no circumstances should plans, diagrams, etc. that are identified for a SCIF or SAPF be sent or posted on unprotected information technology systems, networks or Internet venue without encryption.

4-3 CONSTRUCTION SITE SECURITY.

The SSM is the single point of contact regarding security and the individual responsible for the security aspects of the construction. The SSM will have 24-hour unrestricted access to the site to conduct periodic security inspections for the duration of the project. DoDM 5105.21 Vol 2 defines the minimum security requirements for the SCIF construction site. DoDM 5205.07 does not identify minimum security requirements for the SAPF construction site.

Refer to the CSP for the project specific security requirements.

4-4 ACCREDITATION PROCESS.

In support of the accreditation process and the updating of the FFC, and other required documentation, Project/Construction mangers will provide the SSM site plans, building floorplans, IDS plans, and information related to the perimeter's construction, penetrations, doors, locks, deadbolts, IDS, telecommunication systems, acoustical protection, low voltage systems, electrical power systems, and TEMPEST countermeasures. For SCIFs, refer to DoDM 5105.21 Vol 2, and for SAPFs, refer to DoDM 5205.07 Vol 3.

4-5 INSPECTIONS.

Coordinate preliminary walkthrough with the SSM prior to substantial completion of the space. SSM conducts periodic inspections of the area to validate and document elements for accreditation. Inspection elements may include:

- Perimeter construction
  - Wall goes from floor slab (true floor) to underside of floor or roof deck (true ceiling)
  - Wall uniformly finished and painted from true floor to true ceiling

- Top and bottom of walls are sealed (both sides) with acoustical foam or sealant
- Acoustic insulation is securely fastened
- Gypsum Wallboard installation
- Floor and Ceiling construction

- Perimeter Penetrations
  - Sealed (both sides) with acoustical foam or sealant
  - Finished to match wall
- Perimeter Doors
  - Door assemblies sealed with acoustical foam or sealant (both sides) and finished to match wall
  - Door hardware (locks, closers, sweeps and hinges)
  - ASTM E90 laboratory Test Report
  - ASTM E336 field Test Report
- HVAC Systems
  - Man-bar installation
  - Inspection Ports
  - Nonconductive break
  - Acoustic mitigation
    - Z-duct installation or sound baffle installation
- ESS installation
- TEMPEST Countermeasures (as applicable)
  - RED/BLACK LAN separation
  - Metallic penetrations at perimeter (non-conductive break or grounded at the interior perimeter
  - RF shielding including penetrations
  - Waveguides
  - Doors including RF gaskets
  - Power Line Filters
  - Signal Line Isolators and Filters

4-6 CONSTRUCTION DRAWINGS AND SUBMITTALS.

Prior to walk through; assemble required documents in support of the accreditation process. Requirements vary depending on project but in general assemble the following documents:

- Drawings:
  - Civil Site Plan
  - Architectural
    - Floor and Reflective Ceiling Plans
    - Perimeter wall sections (floor to ceiling)
    - Floor and Ceiling section
    - Door Schedule
    - Perimeter Door head, jamb, and threshold details
    - Window schedule and details
  - Fire Protection
    - Sprinkler piping grounding and penetration details
    - Low voltage cabling penetrations
    - Fire Alarm system
    - Mass Notification System
  - Mechanical
    - HVAC plans, sections and details of perimeter penetrations, ductwork details sheets
    - Plumbing floor plans, detail for perimeter penetrations
  - Electrical
    - Site plan
    - Lighting, Power, Telecommunications, Grounding, and ESS plans. Plans must indicate device and panel locations and when provided, include strobe lights and controls
    - One-line diagrams for Power, Telecommunications including RED/BLACK separation, and ESS
    - ESS door wiring details
    - Perimeter penetration details
- Submittals
  - Doors
  - Door Hardware (locks, closers, and hinges)
  - Acoustical rated assemblies
    - ASTM E90 Test Reports
  - Electronic Security Systems
  - TEMPEST Countermeasures (as applicable)

        - Non-metallic breaks
        - RF shielding
        - RF sealant
        - Waveguides
        - RF Shielded Doors including RF gaskets
        - RF Shielded Windows
        - Power Line Filters
        - Signal Line Isolators and Filters
    - RF Shielding Test Reports (as applicable)
- As-Built drawings

4-7 PHOTOGRAPHIC CONSTRUCTION SURVEILLANCE RECORD.

Photographic Construction Surveillance Record may be accomplished by the SSM or approved personnel to expedite the accreditation process. It is important to capture areas which will be covered up during construction. Pictures should capture:

- Wall construction
    - Stud walls
    - Acoustic insulation
    - Enhanced wall layer (when applicable)
    - Initial GWB layer installation
    - RF shielding installation
    - Wall penetrations
    - Wall finishes (true floor to true ceiling)
- Duct construction including inspection ports, Z-Ducts, Sound baffles and man-bars.

APPENDIX A MINIMUM CONSTRUCTION

A-1 MINIMUM CONSTRUCTION.

Table A-1 is provided as a synopsis of the construction and alarm requirements based on the IC Tech Spec-for ICD/ICS 705. Construction is determined on a project-by-project basis by the Commander or their designated SSM working with the AO.

Table A-1 Minimum Construction and Alarm

	CLASSIFICATION	TYPE OF CONSTRUCTION[1]	IDS[3]	ACS[4]	DURESS
INSIDE UNITED STATES, ITS POSSESSIONS OR TERRITORIES	Open Storage without SID[5]	Wall B - Enhanced Wall (Expanded Metal)[2] Wall C - Enhanced Wall (Plywood)[2]	YES	YES	NO
	Open Storage with SID[5]	Wall A - Standard Wall[2]	YES	YES	NO
	Closed Storage	Wall A - Standard Wall[2]	YES	YES	NO
	Continuous Operations	Wall A - Standard Wall[2]	YES	YES	NO
	Secure Working Area (SWA)	Wall A - Standard Wall[2]	YES	YES	NO
OUTSIDE UNITED STATES, ITS POSSESSIONS OR TERRITORIES	SETL Cat I[6]				
	Open Storage	Vault [2]	YES	YES	RECOMMENDED
	Closed Storage	Wall B - Enhanced Wall (Expanded Metal)[2] Wall C - Enhanced Wall (Plywood)[2]	YES	YES	NO
	Continuous Operation	Wall B - Enhanced Wall (expanded Metal)[2] Wall C - Enhanced Wall (Plywood)[2]	YES	YES	YES
	SETL Cat II & III[6]				
	Open Storage	Wall B - Enhanced Wall (expanded Metal)[2] Wall C - Enhanced Wall (Plywood)[2]	YES	YES	RECOMMENDED
	Closed Storage	Wall B - Enhanced Wall (Expanded Metal)[2] Wall C - Enhanced Wall (Plywood)[2]	YES	YES	NO
	Continuous Operation	Wall A - Standard Wall[2]	YES	YES	RECOMMENDED
	Secure Working Area (SWA)	Wall A - Standard Wall[2]	YES	YES	RECOMMENDED

Notes:

1. Table indicates the minimum construction from IC Tech Spec-for ICD/ICS 705.
2. Refer to IC Tech Spec-for ICD/ICS 705 for construction definitions and suggested details. Include Radio Frequency (shielding) protection, enhanced construction and sound attenuation as required.
3. IDS - Intrusion Detection System
4. ACS - Access Control System at Primary and secondary (if provided) entrance.
5. SID - Security in Depth
6. Security Environment Threat List (SETL). SETL Categories are classified.

B-2 DEFINITION OF TERMS.

Accrediting Official (AO): Person designated by the Cognizant Security Authority (CSA) that is responsible for all aspects of SCIF management and operations to include security policy implementation and oversight.

BLACK Equipment: A term applied to equipment that processes only unclassified and/or encrypted information. (CNSSAM TEMPEST/1-13)

BLACK LAN: A term applied to equipment, cables, or fiber that processes or carries only unclassified and/or encrypted information. (CNSSAM TEMPEST/1-13)

Certified TEMPEST Technical Authority (CTTA): U.S. Government employee who has met established certification requirements in accordance with NSTISSC-approved criteria and has been appointed by a U.S. Government department or agency.

Classification Guide: A documentary form of classification guidance issued by an Original Classification Authority (OCA) that identifies the elements of information regarding a specific subject that must be classified and establishes the level and duration of classification for each such element. (ODNI 80.16)

Cleared American Guard: A U.S. Secret cleared guard that performs access control functions to screen all non-cleared workers, vehicles, and equipment entering or exiting the site and conducts random inspections of site areas. (IC Tech Spec – for ICD/ICS 705)

Closed Storage: The storage of sensitive material in properly secured GSA approved security containers within an accredited space.

Cognizant Security Authority (CSA): The single Principal designated to serve as the responsible official for all aspects of security program management with respect to the protection of intelligence sources and methods.

Compartmented Area (CA): An area, room, or a set of rooms within the accredited space that provides controlled separation between control systems, compartments, sub-compartments, or Controlled Access Programs. (IC Tech Spec – for ICD/ICS 705)

DoD Construction Agent. The U.S. Army Corps of Engineers, the Naval Facilities Engineering Systems Command, or such other approved DoD activity assigned the design or construction execution responsibilities associated with the military construction program. (DoDD 4270.5)

Construction Security Plan (CSP): The plan developed by the SSM and approved by the AO, which outlines security protective measures that will be applied to each phase of the construction project. (IC Tech Spec – for ICD/ICS 705)

Construction Security Technician (CST): A U.S. Top Secret cleared person specially trained in surveillance and the construction trade to deter technical penetrations and thwart implanted technical collection devices. (IC Tech Spec – for ICD/ICS 705)

Continuous Operation: This condition exists when the secure space is staffed 24 hours every day.

Duress Alarm: A silent alarm signal generated by the manual activation of a device requiring a security force response.

Equipment Room (ER): An environmentally controlled, centralized space for telecommunications equipment that usually houses a main or intermediate cross-connect. (UFC 3-580-01)

Essential Loads: Loads that require standby power, but can be de-energized until they can be supplied from an engine generator system. Loads in this category usually include HVAC loads to vital facilities or other load types that can be de-energized for short periods without severe consequence. (UFC 3-540-01)

Fixed Facility Checklist (FFC): Checklist used by CSAs to determine whether construction requirements have been met.

Inspectable Space. The three-dimensional space surrounding equipment that processes classified or sensitive information within which TEMPEST exploitation is not considered practical or where legal authority to identify and remove a potential TEMPEST exploitation exists. Inspectable space may include parking areas around the facility which are owned or randomly inspected daily by the organization, public roads along which parking is not allowed, heavily wooded or other undeveloped areas with restricted vehicular access, and any areas where U.S. security personnel have unannounced 24-hour access. (DoD 5105.21-M Vol 2)

Open Storage: Storage of classified information within an approved facility where securing classified information in GSA approved storage containers while the facility is not occupied by authorized personnel is not required. (DoD 5105.21-M Vol 2)

Protected Distribution System (PDS): Wire line or fiber optic system that includes adequate safeguards and/or countermeasures (e.g., acoustic, electric, electromagnetic, and physical) to permit its use for the transmission of unencrypted information through an area of lesser classification or control. (CNSSAM TEMPEST/01-13)

RED Equipment: A term applied to equipment that processes unencrypted NSI that requires protection during electrical/electronic processing. (CNSSAM TEMPEST/1-13)

RED LAN: A term applied to equipment, cables, or fiber that processes or carries unencrypted National Security Information (NSI) that requires protection during electrical/electronic processing. (CNSSAM TEMPEST/1-13)

Secure Working Area (SWA): An accredited SCIF used for handling, discussing and/or processing of SCI, but where SCI will not be stored.

Security Environment Threat List (SETL): Classified list managed by the Office of Intelligence and Threat Analysis (ITA). The SETL reflects four categories of security threat, including political violence and crime for U.S. missions overseas.

Site Security Manager (SSM): Person designated for the construction project that is responsible for all aspects of security to include security policy implementation and oversight.

Sensitive Compartmented Information (SCI): Classified information concerning or derived from intelligence sources, methods, or analytical processes, which is required to be handled within formal access control systems established by the Director of National Intelligence.

Sensitive Compartmented Information Facility (SCIF): Accredited area, room, group of rooms, buildings, or installation where SCI may be stored, used, discussed, and/or processed.

Sound Transmission Class (STC): An integer rating of how well a building partition attenuates airborne sound.

Special Access Program Facility (SAPF): An accredited area, room, group of rooms, building, or installation where SAP materials may be stored, used, discussed, manufactured, or electronically processed. (DoDM 5205.07, Volume 3)

Special access program facility accrediting official (SAO): A properly trained SAP facility accrediting official designated by the CA SAPCO to physically inspect and review and approve or disapprove physical security preconstruction plans for a SAPF, T-SAPF, SAPCA, and SAPWA or SAPTSWA before accreditation. (DoDM 5205.07, Volume 3)

Special Security Officer (SSO): The SSO designated by the Senior Intelligence Official for any activity that is accredited for and authorized to receive, use, and store SCI. The activity SSO is responsible, IAW DoDM 5105.21, Volumes 1-3 and ICD 703 for the day-to-day security management, operations, implementation, use and dissemination of SCI within the activity. (DoDM 5200.01, Vol 1)

STC Rating: STC is a single number rating used to determine the sound barrier performance of walls, ceilings, floors, windows, and doors.

TEMPEST: A name referring to the investigation, study, and control of unintentional compromising emanations from telecommunications and automated information systems equipment. (CNSSI No. 4009)

TEMPEST Addendum: An addendum to the FFC that provides information to the CTTA to aid in the determination of what TEMPEST countermeasures, if any, need to be applied. (DoD 5105.21-M Vol 2)

TEMPEST Counter Measure Review (TCR): The review conducted or validated by the Certified TEMPEST Technical Authority to document the recommended TEMPEST countermeasures for the project.

Telecommunications Room (TR): An architectural space designed to contain telecommunications equipment, cable terminations, and cross connect cabling. (UFC 3-580-01)

Telecommunications System: Any system that transmits an analog or digital signal over a physical (cable or wire) or non-physical (wireless) connection. This includes systems such as information technology, control, cable television, electronic security, fire alarm, paging, intercom, public address, and mass notification.

Temporary Secure Working Areas (TSWAs): An accredited facility where handling, discussing, and/or processing of SCI is limited to less than 40-hours per month and the accreditation is limited to 12 months or less.

United States and its territories: The 50 states, the District of Columbia, Puerto Rico, Guam, American Samoa, the United States Virgin Islands, Wake Island, Johnston Atoll, Kingman Reef, Palmyra Atoll, Baker Island, Howland Island, Jarvis Island, Midway Islands, Navassa Island, and Northern Mariana Islands. (DoDM 5200.01, Volume 3)

Uninterruptible Load: Loads that require continuous power and cannot experience even momentary power disruptions. Loads in this category usually involve life safety or include hazardous or industrial process equipment, command, control, computer, data center, and communications systems. (UFC 3-540-01)

U.S. Person: An individual who has been lawfully admitted for permanent residence as defined in 8U.S.C. § 1101(a)(20) or who is a protected individual as defined by Title 8 U.S.C. §1324b (a)(3)). (IC Tech Spec – for ICD/ICS 705)

Vault: A room(s) used for the storing, handling, discussing, and/or processing of SCI and constructed to afford maximum protection against unauthorized entry. (IC Tech Spec – for ICD/ICS 705)

Waveguide: Devices installed at perimeter penetrations that are formed by metal tubing or ducting intended to attenuate wave energy.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

1-1.1 Control System Definition

Control systems are a combination of special purpose controlling devices (controllers), control components (e.g. electrical, mechanical or pneumatic sensors and actuators), and generally (but not always) network infrastructure (which may contain standard IT components) that act together upon underlying mechanical and/or electrical equipment to achieve an objective. A control system (CS) typically consists of sensors and actuators connected to networked digital controllers, includes a user interface, and is used to control and monitor equipment.

Some control systems are “monitor only” (they do not exercise control) but are still considered control systems.

1-1.2 Facility-Related Control Systems

There are many types of control systems ranging from building control systems to manufacturing control systems to weapon control systems, all with different names and terminology. Facility-Related Control Systems (FRCS) are a subset of control systems that are used to monitor and control equipment and systems related to DoD real property facilities (for example, building control systems, utility control systems, electronic security systems, and fire and life safety systems).

1-1.3 Risk Management Framework (RMF)

The Risk Management Framework (RMF) is the DoD process for applying cybersecurity to information technology (IT), including control systems. The RMF categorizes systems by the impact the system can have on organizational mission using HIGH, MODERATE, and LOW impact levels. The RMF is further described in CHAPTER 2 and APPENDIX A.

1-2 PURPOSE AND SCOPE.

This UFC describes requirements for incorporating cybersecurity in the design of all facility-related control systems which include a network. This UFC covers the cybersecurity aspects of control system design, and the requirements of this UFC must be coordinated with the control system design and the criteria relevant to the control system. This UFC only covers aspects specific to control system design. Many projects have IT-specific components (such as IP network design security) which are not covered by this UFC; in those cases, the controls designer will need to coordinate with other disciplines. This UFC defines a process for identification of cybersecurity requirements based on the Risk Management Framework suitable for control systems of any impact rating and provides specific guidance suitable for control systems assigned LOW or MODERATE impact level.

This UFC covers the incorporation of cybersecurity concepts and requirements in support of the Risk Management Framework. This UFC does not implement the RMF and does not address anything beyond the design of the system. Use of this UFC does not result in an ATO under the RMF process but will provide a system that is more capable of receiving an ATO than a system not designed in accordance with this UFC.

1-3 APPLICABILITY.

This UFC applies to all planning, design and construction, renovation, and repair of new and existing facilities (both permanent and non-permanent) and installations that result in DoD real property assets which include a control system with a network, regardless of funding source (and regardless of network type). Restated another way, this UFC applies to any project with any control system that includes architecture levels, as defined in this UFC, of 1 or higher. While this UFC can assist with the design of any system, portions of it are applicable only to the design of LOW and MODERATE impact systems and HIGH Impact system will typically require additional customized requirements to achieve appropriate levels of cybersecurity. Design of such systems should be coordinated with the points of contact provided in Paragraph 1-6.

In defining specific requirements for LOW or MODERATE systems, this UFC assumes the control system is being implemented on a DoD Installation or other DoD site, which allows inheritance of some cybersecurity controls. Systems not being implemented on a DoD Installation may require additional requirements not included in this UFC.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, DoD Building Code (General Building Requirements). UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 ORGANIZATION.

CHAPTER 2 provides an overview of the RMF as it applies to control systems, control system architecture and the cybersecurity approach to control systems. CHAPTER 3 defines a 5-step approach to incorporating cybersecurity into the design of control systems. CHAPTER 4 defines minimum design requirements for control systems to be implemented in addition to the specific requirements identified through the 5-step process described in CHAPTER 3. CHAPTER 5 defines the submittal requirements for documenting cybersecurity aspects of control system design.

APPENDIX A provides an overview of the Risk Management Framework as it pertains to control systems. APPENDIX B provides additional detail on the Platform Enclave concept. APPENDIX C describes the 5-Level architecture for control systems. APPENDIX D describes considerations in determination of control system impact ratings. APPENDIX E discusses considerations in the integration of critical building systems into a non-critical UMCS. APPENDIX F provides guidance for security control families, and individual security controls. APPENDIX G categorizes CCIs by impact and responsibility.

1-6 CYBERSECURITY POINTS OF CONTACT BY SERVICE.

Cybersecurity policies and approaches are evolving, and projects may have unique requirements. Assistance for control system cybersecurity design is available from the following Service organizations:

- Army, other than Civil Works: Control System Cybersecurity Mandatory Center of Expertise (CSC-MCX), Huntsville Engineering and Support Center (CSC-MCX@usace.army.mil)
- Army, Civil Works: HQUSACE Engineering and Construction Control System Community of Practice Leader (controlsystemcopleader@usace.army.mil).
- Navy (and Marine Corps): Naval Facilities Engineering Command, Command Information Office (CIO).
- Air Force (and Space Force): Air Force Civil Engineering Center (AFCEC) Operations Directorate, Tyndall Air Force Base. Support can be obtained via the reach-back center at AFCEC.RBC@us.af.mil. Note: All requests for support must be initiated by the Contracting Officer's Representative (COR) or, for government-designed projects, by the Project Lead.

1-7 GLOSSARY.

APPENDIX H contains acronyms, abbreviations, and definitions.

1-8 REFERENCES.

APPENDIX I contains a list of references used in this document. The publication date or revision of the code or standard is not always included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

This Page Intentionally Left Blank

CHAPTER 2 CONTROL SYSTEM CYBERSECURITY OVERVIEW

2-1 RISK MANAGEMENT FRAMEWORK OVERVIEW.

The risk assessment process, or Risk Management Framework (RMF), inventories the system components, identifies the System Owner (SO) and Authorizing Official (AO), and implements risk reduction measures. The Authorizing Official then evaluates the risk and either accepts the risk and issues an Authority to Operate (ATO) or denies the ATO. At this point, the system is allowed to operate and (if necessary) connect to DoD network infrastructure. Risk reduction measures include removal of network and wireless capabilities, documenting the system, and altering the system to limit capabilities.

APPENDIX A contains a more extensive summary of the RMF as it relates to this UFC. It is highly recommended that readers unfamiliar with the RMF review APPENDIX A before incorporating cybersecurity requirements into control system design.

2-1.1 Security Controls.

The RMF relies on the implementation of security controls, where a control is a specific action taken to secure a system. Note that this usage of the word ‘control’ is different from control engineering or control systems engineering, which is the engineering discipline that applies control theory to design systems with desired behaviors. To provide clarity of usage, this UFC will use the term “security control” to refer to cybersecurity controls.

2-1.2 RMF Goal.

For FRCS, the goal of the RMF is to reduce and mitigate vulnerabilities until the risk to the mission supported by the FRCS is deemed acceptable by the System Owner (SO) and Authorizing Official (AO). Under the RMF, risk reduction is not "all or nothing", rather the security solution must reduce risk while considering the constraints of resources and mission requirements. For application of the RMF to control systems, the determination of cybersecurity risk reduction must also account for any additional risks to system functionality due to application of the security controls. The final decision of whether a level of risk is acceptable is made by the assigned government AO.

2-1.3 RMF Roles of the Designer and Control System Installer.

2-1.3.1 RMF Role of the Designer

The designer has one primary role and one secondary role in the RMF process. Their primary role is to identify security controls which can be addressed by the design (during project planning and design) and implement those security controls in the design. As a secondary role, the designer provides input into the risk analysis process by advising on the impact, or lack thereof, of applying security controls to the control system and by advising on how the control system does or does not impact supported missions.

For an example of the need for designer input, consider the mechanical design of an HVAC system. These systems are designed to specific criteria - design day environmental conditions - and those criteria are a compromise between a system that is oversized for most of its operation, and a system that is sometimes under-sized. The criteria are well-established, and the tradeoffs are understood and accepted. Cybersecurity involves similar trade-offs but, unlike for HVAC design, the criteria are not well-established, and the AO must determine the balance point between an over-secure system (which will likely be more expensive, and harder to install, commission, and maintain) and a system that still has some residual risk. Evaluating this risk requires a detailed understanding of the control system functioning which the AO may not possess, necessitating input from the designer.

2-1.3.2 RMF Role of Control System Installer

The construction installer is – as with any other aspect of a construction project – responsible for meeting the specifications and requirements of the contract. They are not directly responsible for Cybersecurity. Given a proper design, meeting the specifications will provide for a proper implementation of Cybersecurity.

2-1.4 Platform Information Technology.

DoD Instructions 8500.01 and 8510.01 define the Risk Management Framework (RMF) for the DoD and establish a category for “special purpose” systems that are not traditional information technology or information systems, called Platform Information Technology (PIT) systems. These PIT systems, including control systems, use specifically tailored security controls sets and require the AO to have expertise in the system.

As further discussed in CHAPTER 3, the designer provides input into the determination of the control system impact rating by advising on the relationship between the control system and the mission supported and provides input on the security control selection by advising on the feasibility and potential impacts of applying a security control.

2-1.5 Inherited Security Controls.

An inherited security control is a security control that a system meets by virtue of someone else addressing it in such a way that it applies to the system. A control system will generally inherit security controls one of three ways: by existing within a physical security boundary, by being covered by policies and procedures already in place, or by connection to another system which addresses the security controls.

Since inheritance often requires the SO to coordinate with others, it’s critical to document all security controls the control system expects to inherit. During control system design, the designer must identify and document any security controls which are expected to be inherited.

2-1.5.1 Physical Security Inheritance Example.

DoD installations implement physical security to manage risk to an acceptable level. For a control system on a DoD Installation, a security control requiring that members of the public not be allowed unrestricted physical access to components of a control system will be met by virtue of the control system existing within that physical security boundary. Although military installations are on occasion opened to the public for events such as boot camp graduations, the access is not unrestricted, and the level of access has been accepted by installation security. Since control systems are innately tied to and co-located with the physical systems they control, in most cases a control system will be able to inherit physical security from the installation or separately secured facilities.

2-1.5.2 Policy and Procedures Inheritance Example.

The DoD has policies in place governing many aspects of cybersecurity. A control system can therefore inherit a security control such as “the organization defines the frequency to review and update the current security planning policy”.

2-1.5.3 Connection to another System Inheritance Example.

When a control system connects to another system, such as an Installation-wide network, inheritance may not be automatic but may require an agreement between the SOs of the systems. Such an agreement would cover acceptable behavior of the control system and explicitly define the security controls that will be inherited from the other system.

2-1.6 Applicability of RMF Security Controls to Design.

Security controls cover a wide range of requirements, many of which must be addressed by someone outside the control system design process. For example, a security control[1] that states “The organization protects the control system from unauthorized modification by members of the organization” is normally not addressed by the designer; but rather is addressed through policies and procedures put in place by the organization that owns and operates the control system.

2-1.6.1 Applicability of RMF Security Controls to Design of Critical Systems.

The determination of whether a security control should be applied at design can become particularly complex for more critical (higher impact) systems. While it may be sufficient for a LOW impact system to assume a particular security control is addressed by another entity, the designer of a HIGH impact system may need to explicitly address

[1] This is not an actual security control, but rather an illustrative example using a fictitious control.

a security control to ensure it is being implemented properly, to apply it at a higher standard, or to provide tools to the responsible parties to assist their implementation of the security control. For example, while a security control stating[2] "The organization protects the control system from unauthorized modification by members of the organization" might be addressed through policies and procedures for a LOW impact system, a higher impact system may require the designer to explicitly design in additional barriers to unauthorized modification, or to provide guidance to the organization concerning the importance of properly securing the control system against modification. In this case, however, it's vital to consider the impact these restrictions may have on the ability to make necessary authorized changes. For this reason, designers of systems with HIGH mission impact should likely seek the assistance of a dedicated cybersecurity engineer. MODERATE systems may also require specialized attention depending on the circumstances of the design.

2-1.6.2 Applicability to Control Systems as Compared to IT Systems

Another issue to be considered in the design of critical systems is the potential gap between the strict requirements of the (IT-centric) RMF and what is practical in control system design. Consider, for example, a fire alarm system and the level of support a fire alarm panel will have for Personal Identity Verification (PIV, such as the DoD CAC) compared to the RMF requirements at the MODERATE level. As a practical matter, it's likely impossible to install a fire alarm system that meets the PIV requirements of a MODERATE impact system.

In this case, insisting on RMF requirements "as written" is particularly problematic as it would prevent the procurement and installation of the system until the manufacturer develops a custom system and then obtains UL certification. In other cases, the designer could insist on the RMF-required functionality, driving the installing contractor to create custom solutions using specialized equipment, but this is rarely the best approach as it greatly increases the overall risk that the system will not function properly. The unique solutions required to meet these requirements will likely require controllers that are not designed for the purpose in which they are used, and the system will likely be installed by contractors with experience in securing systems but not in the specific functionality of the control system. Because of its non-standard nature the system is likely to be significantly more expensive and more difficult to install, test, operate and maintain, all of which reduce the overall reliability of the system.

2-1.6.3 Other Applicability Input

In addition to providing input on the impact the control system will have on the supported mission, designers may be required to provide input on the ability (or inability) of the control system to meet cybersecurity requirements. This assists the AO in defining and accepting requirements that address cybersecurity risks without introducing functional risks.

---

[2] This is not an actual security control, but rather an illustrative example using a fictitious control.

2-2 5-LEVEL CONTROL SYSTEM ARCHITECTURE.

Even though control systems are becoming more like standard IT systems, there remain major differences that must be recognized. The 5-Level control system architecture shown in Figure 2-1 is a framework for describing the system architecture of any control system. This architecture allows distinctions to be made between portions of the control system that look like standard IT, and portions that do not look like standard IT. This is important as many security controls can be applied in the normal fashion to the portion of the control system that looks like a standard IT system but cannot be applied without modification (or sometimes cannot be applied at all) to the portion that does not look like a standard IT system.

APPENDIX C provides a more in-depth description of the 5-Level control system architecture.

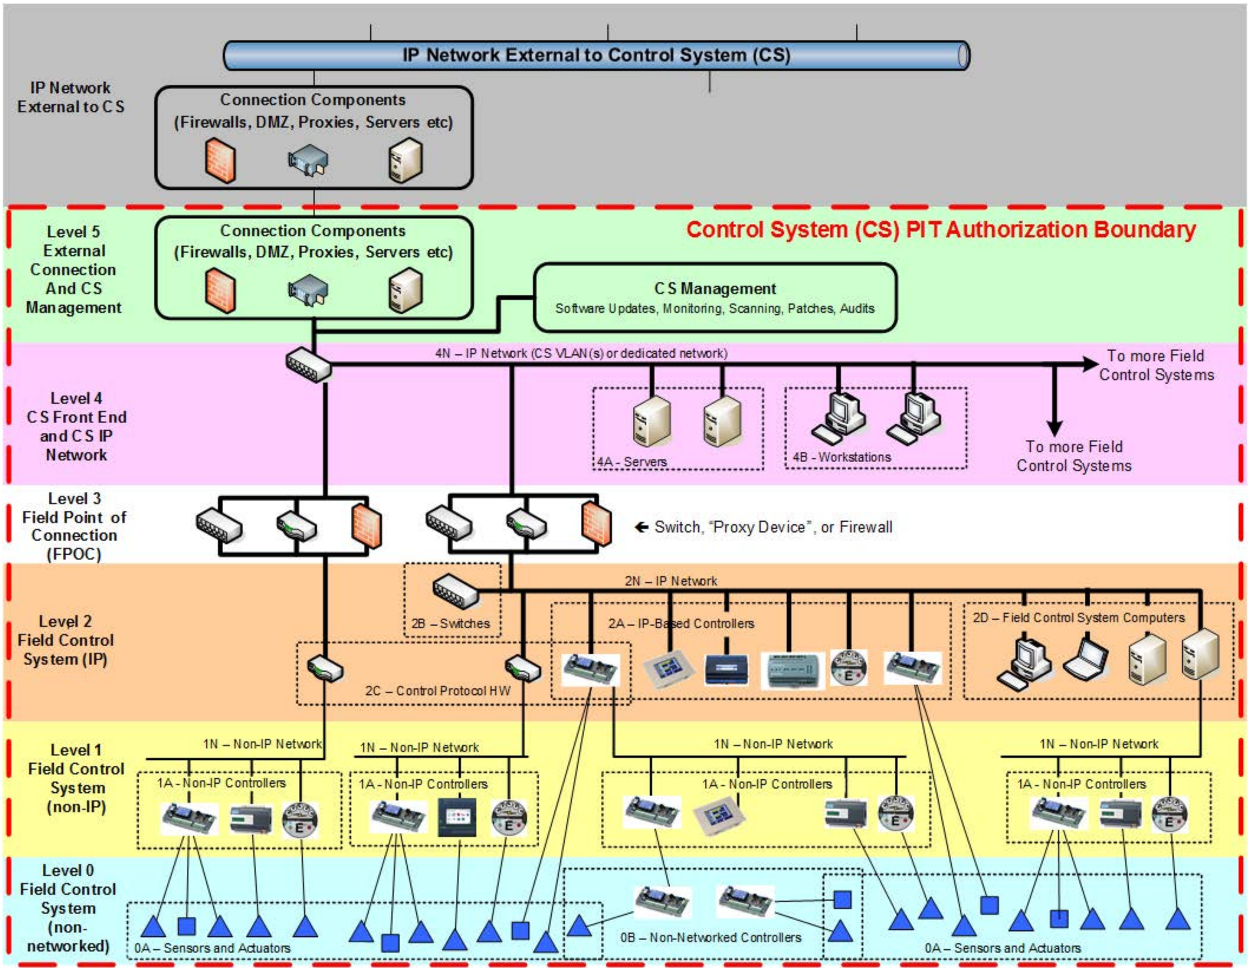
2-2.1 Architecture Is a General Architecture

This architecture is designed to highlight Cybersecurity aspects of the control system; it is not intended to be an exact depiction of a control system. A single control system may have multiple authorizations and the boundaries of these authorizations may not be easily depicted by the architecture itself. Other control systems with a single authorization might lack a system-wide network and – from an IT perspective – appear to be several distinct systems; these might not be easily depicted by a single architecture drawing. For example, an installation-wide fire protection system generally does not have a system-wide network; each building has a separate network, and the buildings are connected to a central monitoring station by radios and relay panels[3].

A single system may be described by the architecture in multiple ways – a multi-building control system with a dedicated IP network connecting the buildings may be described as a single FCS consisting only of levels 0-2 with the entire IP network residing at level 2, or it could be described as using levels 0-4 with multiple Level 2 networks connecting to a Level 4 IP network through multiple FPOCs. Depending on the system functionality as well as the cybersecurity approach, either or both may be valid, and which is the more appropriate depiction of the system depends on the details of the system itself and must be determined on a case-by-case basis. Both fit within and can be described by the 5-level architecture, and the intent of the architecture is to provide a common lexicon for defining systems and not to confine systems to a set definition.

[3] The use of relay panels breaks the system into a base-wide radio network and a collection of buildings, each with an ***independent*** network in it.

Figure 2-1 5-Level Control System Architecture



2-2.2 "Standard IT" Parts of the Control System.

The parts of the control system that most resemble a standard or traditional IT system are referred to as the "Standard IT" parts:

- The IP Network portion of Level 4 (Level 4N).
- The IP Network portion of Level 2 (Levels 2N and 2B).
- The field point of connection (FPOC) at Level 3.
- The computer hardware for both servers and workstations (Levels 2D, 4A, 4B)
- The computer OS and other standard packages (such as antivirus) for both servers and workstations (desktops and laptops) (Levels 2D, 4A, 4B). Note that this does not include control system software such as front-end packages or engineering tools, but it might include things like web servers and database engines used by the front end. While front end packages and engineering tools likely run on standard desktop operating systems and have many characteristics

in common with standard IT applications, they may have unique features and applying cybersecurity to them may require special expertise.

- External connections and control system management at Level 5.

The cybersecurity for the "standard IT" parts of the control system are largely addressed using standard cybersecurity practices and are generally outside the scope of control system design and are not addressed by this UFC. The designer should coordinate with IT experts for cybersecurity of those portions of the control system. The designer must address the IP Network at Level 2N, which is generally procured and installed by the control system contractor, and the control system specific software used by the front end, which is generally not adequately covered by standard IT approaches.

2-2.3 "Non-Standard IT" Parts of the Control System.

What makes cybersecurity for a control system challenging are the parts of the control system that do not generally resemble a standard IT system: Level 0, Level 1, Level 2A, Level 2C and the control system applications at Level 2D, Level 4A and Level 4B. These parts of the control system are referred to as the "non-standard IT" parts in order to differentiate them from the "standard IT" parts. Traditional cybersecurity tools and requirements such as vulnerability management alerts, bulletins, Secure Technical Implementation Guides (STIGs), Security Requirements Guides (SRGs), and DoD IT Policies are seldom applicable to these non-standard IT components, particularly to devices at Levels 0, 1 or 2. For example, a security control[4] requiring the screen to be locked when the user leaves the computer is not applicable to devices that do not have a screen or support user login. Different levels of the architecture have different issues related to the application of standard cybersecurity tools and requirements.

Cybersecurity for these portions of the control system must be addressed by the control system designer.

2-2.3.1 Computers at Level 2

If front end computers are on the same dedicated IP network as the control system (generally within the same building as the control system) they are considered to be at Level 2 rather than Level 4. This is a common scenario in legacy systems, and is sometimes found in new installations, particularly for systems that are not interfaced to a base-wide front end or where (typically to meet availability requirements) the front end servers (Level 4A) must be placed on that building's Level 2 network. However, when installing new computers as part of a project, the cybersecurity requirements are largely the same regardless of whether the computers are at Level 2 or Level 4.

2-2.3.2 Level 0 Components vs Systems

A common question that arises is: "How complex can a 'thing' be and still be considered a Level 0 device?" For example, consider a packaged backup power unit, with diesel engine, generator, and Automatic Transfer Switch (ATS). This unit has dozens of

[4] For reference – security control AC-11 deals with session lock requirements.

sensors and actuators, multiple controllers, and an internal network connecting them all together. Since it is a ***packaged unit*** and procured as a single component, if the unit ***does not*** have a network interface to the rest of the system it ***could*** be considered a single Level 0 device, even if procured independently of any other control system. Alternatively, the unit could be considered its own mini field control system.

Ultimately the decision on how best to address such units must be made in coordination with the SO and AO, but a general guideline is to consider packaged units with hardware interfaces to be Level 0 devices, and to consider built-up units connected with hardware interfaces to be separate FCS. Note that any device, no matter how "dumb," is not a Level 0 component if it is connected to a network (has a network interface as opposed to simple binary and analog connections), so even a simple networked temperature sensor is not a Level 0 device.

2-2.3.2.1 As a Level 0 Component

A Level 0 device with an internal network - particularly if procured independently of any other control system -, might need to go through the RMF process – as a FRCS consisting of a single Level 0 device with a greatly reduced set of cybersecurity requirements. Or the AO could greatly simplify the process and accept the risk up front for a Level 0 device (albeit an expensive and complex Level 0 device).

2-2.3.2.2 As a Mini Field Control System

The unit could be considered its own mini field control system, which requires the internal components of the packaged unit be defined as well as the hardware (non-networked) interface between the backup power unit and the building system. This adds a lot of effort and documentation for very little benefit, and is almost never the right choice. Note that this may also cause a separate ATO for the unit to be required, significantly increasing the burden even further.

2-2.3.3 Describing Systems Using the 5-Level Architecture.

As stated previously, the 5-level architecture provides a common lexicon for defining systems and is not intended to confine systems to a set definition. The basic architecture drawings presented in this UFC generally describe a single system with a single authorization, or with two authorizations where one of them is a Platform Enclave. Other control systems may require architecture drawings which depict systems using the 5-level architecture in various other ways. In some cases, the architecture may need to indicate additional authorization boundaries, and in others the architecture levels may be connected in ways not shown on the basic drawings in this UFC. For example:

- A base-wide fire reporting system where a system in a building is connected via radio to a base-wide central monitoring system at the main fire station. In this case, the building level system exists at Levels 0 – 2 and there is a Level 0 interface (relay panel) between it and a sitewide radio network. The radio network is (typically) a Level 1 (dedicated non-IP network) interface to a central front end and other Level 0 – 2 building level fire systems.

- A fire protection system where some subsystem (such as the releasing panel controlling a pre-action fire sprinkler system in a datacenter) has a higher cyber impact rating (say MODERATE) than the rest of the system (presumed to be LOW). In this case, the system may be authorized in two different ways:
    - A single authorization covering the entire building fire protection system. Because the releasing panel has a MODERATE impact, the entire system would need to meet MODERATE requirements.
    - Two separate authorizations: a) A small MODERATE authorization for the releasing panel, and b) A large LOW authorization for the remainder of the building. In this case, the two systems would need to have a cyber-secure separation between them; the easiest (but not only) way to achieve this this would be via an interposing relay panel.
- A MODERATE building control system needing integration into a base-wide LOW system. Again, there is a choice between either treating the base-wide system as a MODERATE system (a potentially very expensive solution) or having two authorizations – a MODERATE for the building and a LOW for the base-wide system. The tradeoff in this case is that the integration will need a high level of isolation and will likely be more expensive and provide much less functionality than the normal integration of a building into the base-wide system. This specific case is covered in more detail in APPENDIX E.

The key point here is that all FRCS can be described in terms of components at one or more of the 5 levels of this architecture.

2-2.4 Wireless Networks

Although not explicitly shown in the architecture, wireless networks may exist at Level 1, Level 2 or Level 4 of the architecture. Wireless networks require additional cybersecurity measures, and unless furnished by the project site must be carefully coordinated to ensure the use of wireless is approved and meets all the additional requirements.

2-2.5 Platform Enclave.

Many control systems are hosted within a network that is segmented from the general day-to-day business application (such as email, file servers) network either physically or virtually. This separate IT infrastructure environment dedicated to the delivery of common level services (for example, Active Directory Services, Assured Compliance Assessment Solution (ACAS) Services, Host Base Security System (HBSS) Services) to the FRCS is referred to as the Platform Enclave. In some cases, this Platform

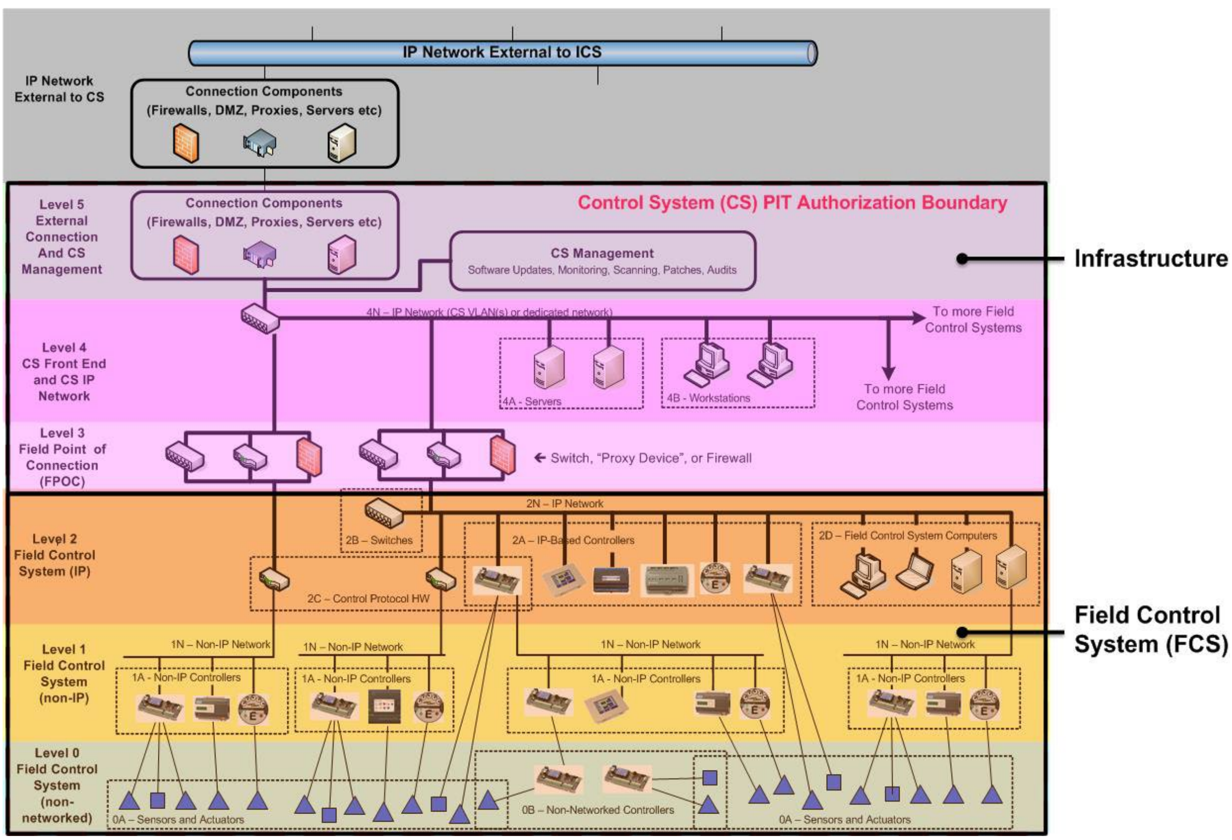
Enclave will have a separate authorization from the control systems within the enclave. The control systems will have their own authorization for their Operational Architecture which primarily covers the “non-standard IT” components of the system. In other cases, it is possible that a single authorization will be used for the entire system, both the enclave and the control system. Even in cases where a single authorization is used, however, it’s helpful to identify and categorize the “standard IT” portions of the control system. More information on the Platform Enclave approach is in APPENDIX B.

2-3 CONTROL SYSTEM PROCUREMENT OVERVIEW.

The DoD does not procure most installation-wide control systems as an entire 5-Level system as depicted in Figure 2-1. Typically, some Field Control Systems (FCS; architecture Levels 0 - 2 as shown in Figure 2-2) are procured along with a front end for those systems. Over time additional FCS are procured; these new FCS are integrated with the existing front end and added to the authorization (ATO) for the existing system to expand the installation-wide system. When designing an FCS that will be added to an existing system, there may be cybersecurity requirements that are specific to the authorization of the existing system which must be incorporated into the FCS design. Also note that the Level 3 FPOC and Level 4 IT infrastructure are usually provided by the site-wide IT support organization; they are not procured for (and are often not dedicated to) the control system. This UFC cannot address site-specific requirements; when designing systems which will be added to an existing system authorization coordinate with the project site to obtain relevant requirements from the existing system.

Some control systems are procured to operate independently, with no integration to a larger system and without further significant expansion. Depending on the circumstances and architecture, treat these systems either as complete systems, containing all 4 or 5 Levels, or as a FCS (Level 0-2) with its own user interface at Levels 1 or 2. See Table C-3 in APPENDIX C for more information on the Level 2D computers.

Figure 2-2 Control System Architecture



This Page Intentionally Left Blank

CHAPTER 3 APPLYING CYBERSECURITY IN DESIGN

3-1 OVERVIEW.

The design of cybersecurity for facility-related control systems is a five-step process. In some cases, a specific step may be performed by someone other than the designer but may still require input from the designer. Documentation of cybersecurity-related design decisions and input to others is described in CHAPTER 5.

In addition to requirements specific to Control Correlation Identifier (CCIs), design all control systems according to the minimum cybersecurity design requirements in CHAPTER 4 and cybersecurity requirements otherwise standard for the type of control system being designed.

3-1.1 Five Steps for Cybersecurity Design.

The five steps for cybersecurity design are:

Step 1: Identify the Confidentiality, Integrity, and Availability (C-I-A) impact levels (LOW, MODERATE, or HIGH) to use for the control system design.

Step 2A: Use the impact levels to select the proper list of controls from NIST SP 800-82.

Step 2B: Using the DoD master Control Correlation Identifier (CCI) list, create a list of relevant CCIs based on the controls selected in Step 2A.

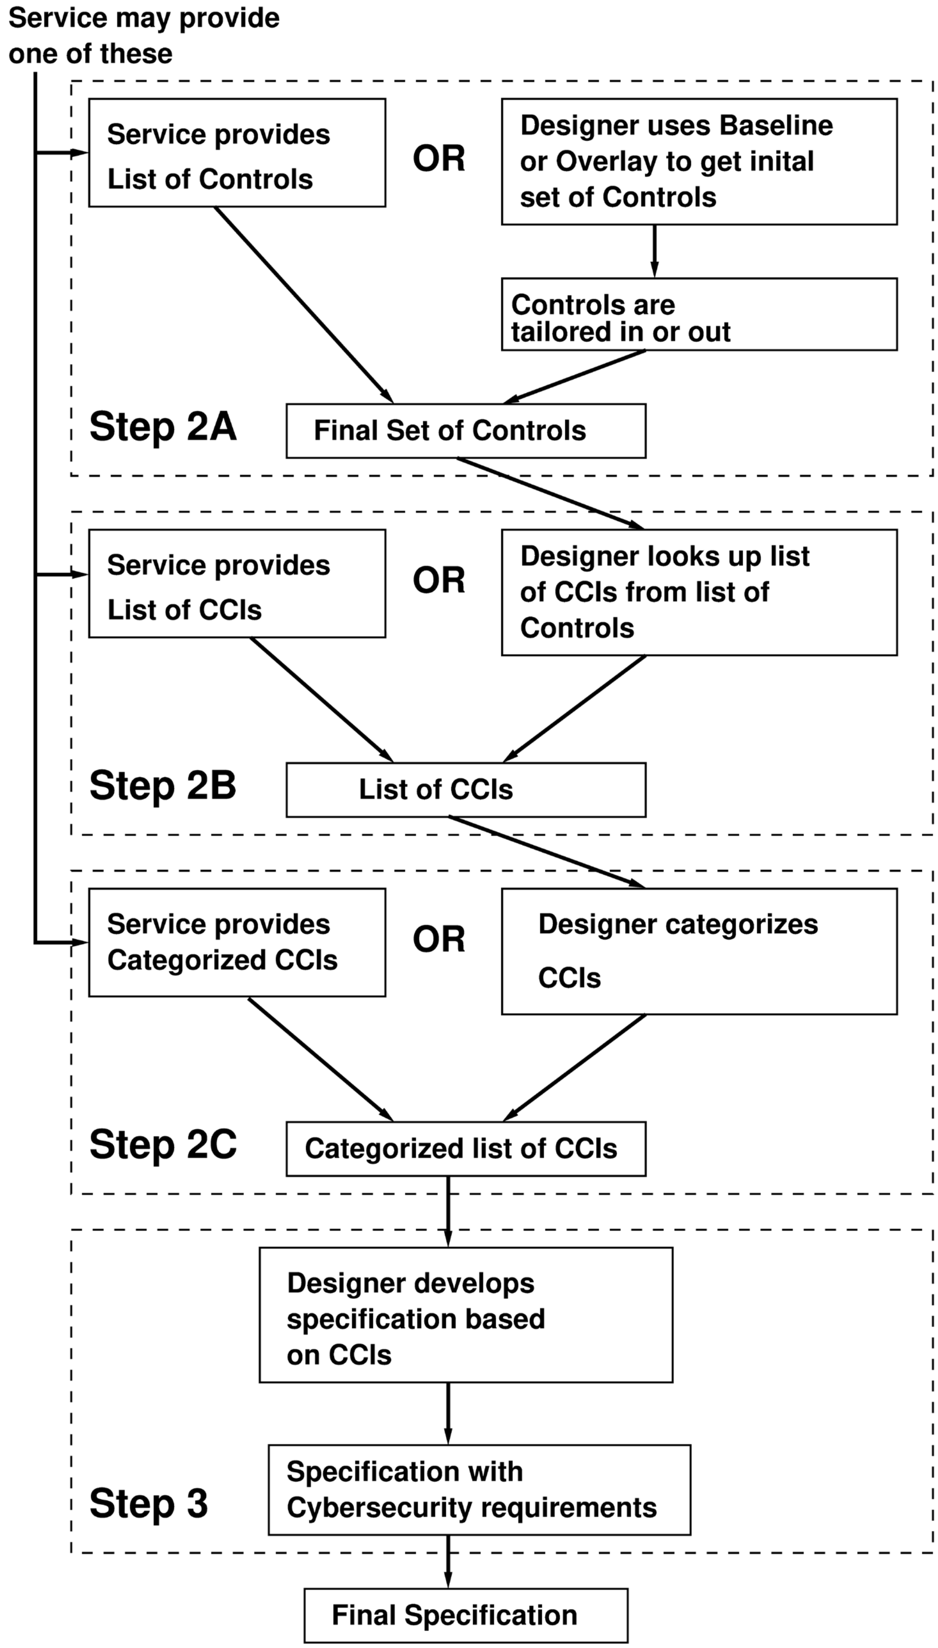
Step 2C: Categorize CCIs and identify CCIs that require input from the designer or are the designer's responsibility.

Step 3: Include cybersecurity requirements in the project specifications and provide input to others as required.

These steps are numbered in this way to align with the corresponding steps of the 7-step[5] RMF Process. For example, Steps 2A, 2B, and 2C all occur at Step 2 of the RMF process, "Select Security Controls". APPENDIX G contains tables covering Steps 2A, 2B and 2C for LOW and MODERATE systems, assuming the existence of a Platform Enclave. These tables, with additional information in a filterable format, are also available in Excel format on the RMF Knowledge Service (https://rmfks.osd.mil) and the use of that spreadsheet is highly recommended. This website is CAC-enabled; designers without a CAC must request assistance from the Service if tables and information were not provided. Figure 3-1 below provides an overview of steps 2A through 3, and APPENDIX F provides additional guidance on the implementation of specific controls.

[5] Formerly a six step process, the RMF has introduced a seventh step as "Step 0: Prepare"

Figure 3-1 Overview of Steps 2A through 3



3-1.1.1 Beginning Mid-Process

These five steps fully define the Cybersecurity portion of the design process when starting with a “blank page”. Strictly speaking, Step 1 should be completed by the AO or SO, and in some cases, the asset owner or Service may also have defined the list of cybersecurity controls (they have completed Step 2A), or the list of CCIs (they have completed step 2B), or even the specific CCIs to be addressed by the designer (they have completed step 2C). In these cases, (as shown in Figure 3-1 above) begin the design process at the appropriate step using the information provided.

3-1.2 Definition of “Organization”.

Security controls often refer to the “organization” in identifying responsibilities and risk, making proper determination of “organization” critical to proper evaluation of impact. For example, loss of heating, ventilating, and air-conditioning (HVAC) at the Houston franchise of a national hotel chain in August might be catastrophic to the local facility manager, but it is hardly a significant blow to the United States, or even to the hotel chain. Unless otherwise indicated, for the purposes of implementation of the RMF to control systems:

- For determining the impact level of a system, treat the “organization” as the relevant Service (Army, Navy, Air Force).
- For determining implementation requirements for specific controls, treat the “organization” as the Installation (garrison, post or base) or Region (for regional systems). Note that this doesn’t conflict with the above statement regarding the organization for determining impact, but rather indicates the portion of the Service that will have responsibility for implementation of the control.

3-1.3 Designer Coordination

- Meeting cybersecurity requirements may require substantial coordination between different design disciplines. Many systems will be unable to meet identification and authentication requirements for user interfaces and physical security is recommended as a compensating control. These requirements (such as “install controllers in locked enclosures”) will need to be coordinated with the physical security designer. Similarly, the use of insecure network protocols may require physical security to prevent unauthorized access to the network.

- In almost all cases, the control system is only as important as the controlled equipment. For example, an air handler controller is of no relevance if the air handler has failed for some simple mechanical reason. Some cyber requirements may suggest additional requirements on underlying equipment and coordination with those designers may be required.

- In many cases, good cybersecurity design is best accomplished via good control system design. In the case where the designer following this UFC is other than the controls designer, some requirements needed to address cybersecurity controls must be included in the control system specification by the control system designer and documented in the design submittals defined in this UFC.

- Requirements in the cybersecurity specification have potential to conflict with those in the control system design or may pose functional issues for the control system. Close coordination is required to ensure requirements are implementable.

3-2 STEP 1: DETERMINE CONTROL SYSTEM IMPACT RATING TO USE FOR DESIGN.

The first step of the design process is to determine an impact rating for the control system design. Ideally this impact rating will be the actual impact rating for the control system, but, in some cases, it will be an impact rating determined or assumed for the purposes of the design only.

3-2.1 Obtaining Actual Impact Ratings

The SO, with concurrence from the AO, determines the impact levels of the control system. The SO may seek assistance from the designer in defining the functionality of the control system, the information the control system contains, and the ***impact of failure of the control system***. While the SO and AO are uniquely qualified to determine the criticality of the mission in the facility, they will likely require assistance from the designer to determine the impact of the control system on the mission. For example, a critical mission of processing real-time DoD intelligence data may not depend at all on the lighting control system in the data center. For the DoD, impact levels are determined based on the mission of the relevant Service and in many cases can use the mission criticality rating of the facility (mission support, mission essential, mission critical) as a starting point to determining control system impact. It's also important to note that while a traditional information system generally prioritizes Confidentiality, then Integrity and lastly Availability, control systems usually prioritize Availability and Integrity over Confidentiality.

Note this discussion assumes that the SO and AO have been identified for the system. In many cases, this may be difficult – at this stage of the project the SO may not yet identified. In many cases the impact of the control system is driven by the impact of the control system on the mission supported by the control system (such as a data center supported by mechanical and electrical systems) so, while the local O&M staff may "own" the control system, the impact of the control system is driven by the underlying mission supported by the control system so that the "effective" SO is a facility tenant. Ultimately, while identification of an SO and AO is not the designer's responsibility, lack of identification can present a roadblock to successful project implementation.

3-2.2 When Impact Ratings Aren't Provided

If impact ratings aren't provided, request them from the Service. If the Service is unable to provide impact ratings, then request direction from the Service and follow one of the following three courses of action as directed:

1. Use one of the categorization methods discussed in APPENDIX D to categorize the system for purposes of design and document how the categorization was determined.
2. Design the system to a L-L-L impact rating.
3. Do not proceed with the design until C-I-A Impact ratings are provided.

Note that these options are presented in preference order, with course of action 1 being the preferred solution. When the Service provides direction on which course of action to follow, follow that course of action. Should the Service not provide direction, use the first course of action.

3-2.3 Considerations for Reduction of Control System Impact

Whether assisting the SO and AO in determining the control system impact rating, or determining a design impact rating, it's vital to remember that the impact rating of the control system may be less than (but not greater than) the impact rating of the mission served, and a MODERATE impact mission does not necessarily imply a MODERATE impact control system. Only when loss of the control system necessarily results in loss of mission is the control system impact the same as the mission's impact rating. Several options (suggested in a flowchart in APPENDIX D) are available to the designer to potentially reduce the impact rating of the control system, such as:

- Can manual controls be added to compensate for a compromised control system?

- Some critical facilities may be staffed 24/7. In this case, a local controls front end might be installed inside the facility and facility staff provided sufficient training to make basic adjustments to the system. Another option is to add local display panels (limited operator interfaces within the control system) in mechanical rooms, again with the intent of allowing onsite staff the ability to maintain system operation (perhaps in a degraded state, but sufficient to maintain basic mission capabilities).

- Can simple standalone backup systems be added to compensate for a failed (base-wide) control system? For example, for a data center, can a standalone air conditioning unit be added that would start based on a local thermostat and run independently of the base-wide system? Particularly in the case of a critical facility (which likely has redundant HVAC equipment), can the "normal" or "primary" unit be connected to the base-wide UMCS, while the "backup" or "secondary" unit operates in a standalone configuration with purely local controls? Again, note that control system operation in a degraded state may be acceptable, provided it continues to support the mission.

- Some buildings may overall be non-critical but have a small critical room or facility inside the larger building. Again, can a small standalone unit, such as a small backup generator unit be added specifically to support the critical room or facility?

Critical facilities often require redundant mechanical / electrical equipment, and in these cases, the question is: “Can the control system design take advantage of this equipment to reduce the dependency of the mission on the control system to the point that the impact rating of the control system is LOW?” By use of redundancy and following general principals of design simplicity, the effect of a compromised control system can be minimized. The additional hurdles required to secure a MODERATE impact system will often make reduction of control system impact rating a worthwhile approach.

3-3 STEP 2A: DETERMINATION OF SECURITY CONTROLS.

When the list of relevant controls is not provided by the Service, determine a starting list of controls based on the Confidentiality (C), Integrity (I) and Availability (A) impact ratings (or C-I-A ratings) provided by the Service (or using the design CIA rating if the actual rating was not provided) and the appropriate control system overlay or baseline. Using the resultant initial control set, review the security controls to recommend security controls that should be considered for tailoring out by the SO and AO.

3-3.1 Overlay versus Baseline

In the RMF process, a baseline is a complete set of security controls, and an overlay is a defined set of changes (additions or subtractions). So, in the example table (Table 3-1) below we have 2 baseline sets of controls, Base 1 and Base 2, along with a single overlay that is applied to both. The baselines define controls to apply (“Do control A”, “Do control B”, etc.) and the overlay can be applied to either Baseline, with the results shown in B1 + Overlay and B2 + Overlay.

Table 3-1 Overlay versus Baseline

Base 1	**Overlay**	**B1 + Overlay**		**Base 2**	**Overlay**	**B2 + Overlay**
Do A	Add A	Do A			Add A	Do A
Do B		Do B		Do B		Do B
Do C	Skip C				Skip C	
Do D		Do D		Do D		Do D
	Skip E			Do E	Skip E	
				Do F		Do F

While this is technically the definition of overlays and how they work, as a practical matter, overlays are rarely presented as a "bare" overlay, but as the result of an overlay applied to a specific baseline – effectively becoming a baseline. The initial set of security controls will come from a baseline or an overlay and the fact that one may be called a "baseline" and the other an "overlay" is of no practical significance to the designer.

3-3.2 Determining Initial Control Set Using an Overlay

3-3.2.1 High Water Mark Versus Individual C-I-A Values

The DoD implements RMF for control systems using CNSSI 1253, which identifies applicability of security controls using individual C-I-A values - so a L-L-M system may have different controls than a M-L-L system. Other processes (including those based on NIST SP 800-53 and NIST SP 800-82), and many overlays, employ a "high water mark" which assigns a single overall impact rating equal to the highest impact rating, so a L-L-M and M-L-L system are both essentially treated as M-M-M. CNSSI 1253 provides a table defining, for each control, whether that control affects C, I, or A, so it is possible to take a table prepared using a "high water mark" and back out a table appropriate to individual C-I-A values[6], but for control system design purposes this is often not worthwhile and the high water mark can generally be used as a "conservative" approach (since the high water mark will at least have all the controls as the individual impact approach)

3-3.2.2 Identifying An Appropriate Overlay

Based on the Service, project site and control system type there are several different overlays that may apply, including:

- NIST SP 800-82
- The Control System Overlay for Moderate Impact Systems published by the Risk Management Framework Technical Advisory Group (RMF TAG Overlay)
- (NAVY) The Navy Assess-Only Overlay
- (AIR FORCE) The Air Force Control System Overlay

When the Service does not provide a specific overlay, use NIST SP 800-82 or the RMF TAG Overlay (or a combination) to define the control set for design based on the C-I-A Impact Ratings:

- For a system with L-L-L Impact ratings: Use NIST SP 800-82.
- For a system with M-M-M Impact ratings: Use the RMF Tag Overlay

[6] Imagine a L-M-M system using a M-M-M table that includes a control that states "Sensor values must be protected against unauthorized disclosure". CNSSI 1253 indicates that this control is for C. Consult the corresponding L-L-L table and see if the control is required, if not, it may be removed from consideration.

- For a system with a mix of Impact Levels (such as L-M-M), use CNSSI 1253 to determine – for each control – which element of the CIA triad (the Confidentiality, Integrity or Availability) that control applies to. Then determine applicability of the control based on the assigned impact levels using the appropriate overlay:
  - For Low impact elements, use NIST 800-82
  - For Moderate impact elements, use the RMF TAG Overlay
  - For High impact elements, use both NIST 800-82 and the RMF TAG Overlay and include controls in the baseline if they are included by either overlay.

As described in the next paragraph, there are tables in the UFC that use these overlays with a high-water mark, and an Excel tool that can be used for systems with a mix of Impact Levels.

3-3.2.3 UFC Control Set and Control Set Tool

The control lists in APPENDIX G of this UFC have been generated as described above using the NIST 800-82 Revision 2 overlay for LOW impact systems and the RMF TAG Overlay for MODERATE Impact Systems. Both of these overlays are based on NIST 800-53 Revision 4. An Excel spreadsheet is posted to the document page for this UFC[7] which will generate control sets based on these two overlays for any combination of C, I and A impacts, where those overlays have been converted from the high-water mark employed by the overlay to the individual C-I-A value approach used by CNSSI 1253.

3-3.3 Recommend Security Controls to Tailor Out (or In).

Review the starting controls baseline obtained by applying the overlay(s) and provide recommendations for controls to be tailored out from (or added to) the security control set as part of the cybersecurity documentation required by CHAPTER 5.The standard security control baselines were developed for standard information systems and contain security controls that are inapplicable to control systems (or other Platform Information Technology), or are impractical to implement due to technical or resource constraints. The RMF process allows these baselines to be tailored for the project by the removal or addition of specific controls (with the constraint that the final set must be approved by the AO). While not likely to impact the final design (controls recommended to be tailored out won't apply to the system and will not result in design requirements), this step allows the AO to consider additional tailoring based on subject matter input from the designer.

Note this tailoring can either be applied at the security control level during Step 2A, at the CCI level during Step 2B, or at both Steps 2A and 2B of the design process.

[7] UFC Document Page is at https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-4-010-06

Tailoring at the security control level is often easier, but the CCI level offers a more precise level of control over which requirements to include.

3-3.4 Additional Resources and Information for Step 2A

Additional resources and information related to this step can be found as listed here. The use of these resources is optional, and the designer remains responsible for ensuring all design requirements are met whether or not these resources are used.

- There is a spreadsheet which automates the application of the NIST 800-82 and RMF Tag Overlays as described above located on the document page of this UFC at the Whole Building Design Guide Website (WBDG.org). This spreadsheet provides a list of controls and CCIs identifiers for given impact levels.
- There is a spreadsheet which provides a table of control information (control text, etc.) based on a list of control identifiers located on the document page of this UFC at the Whole Building Design Guide Website (WBDG.org).
- APPENDIX G of this UFC contains tables showing the control sets obtained from applying the NIST 800-82 and RMF Tag Overlay to LOW and MODERATE Impact systems.
- For LOW and MODERATE Impact systems, APPENDIX G lists recommended Controls to be tailored out.

3-4 STEP 2B: IDENTIFICATION OF CONTROL CORRELATION IDENTIFIERS.

Using the list of security controls provided by the Service or derived from Step 2A, generate the list of corresponding control correlation identifiers (CCIs). Note that generating CCIs from control lists is a purely mechanical process, a given control (perhaps SI-4) always maps to a specific list of CCIs. This list of CCIs provides the starting point for identifying cybersecurity requirements to be included in control system design. The complete CCI list (covering all controls) is available at the RMF Knowledge Service website via the “Export All Assessment Procedures to Spreadsheet" link at: https://rmfks.osd.mil/rmf/General/SecurityControls/Pages/ControlsExplorer.aspx. From the URL, select "All Control Families" from the "Choose Control Family" pull-down. After the page re-populates with the controls, click on “Export Implementation Guidance and Assessment Procedures” to download the CCIs into Excel. Note: This website is CAC-enabled; designers without a CAC must request the CCI list from the Service if it was not provided.

Additional resources are listed here. The use of these resources is optional, and the designer remains responsible for ensuring all design requirements are met whether or not these resources are used.

- There is a spreadsheet which provides a table of CCI information based on a list of CCIs located on the document page of this UFC at the Whole Building Design Guide Website (WBDG.org).

- APPENDIX G includes tables of all CCIs for LOW and MODERATE impact systems based on the initial control sets determined by the application of the NIST 800-82 and RMF TAG Overlays as described above.

3-5 STEP 2C: CATEGORIZATION OF CONTROL CORRELATION IDENTIFIERS BY RESPONSIBILITY.

3-5.1 Identifiers by Responsibility

Categorize each CCI provided by the Service or identified in Step 2B as ***one or more of*** the following categories:

- ***DoD-Defined:*** Either the DoD has provided a value for the "organization selected" values, or the DoD implementation guidance states that the CCI is already met by existing policy or regulation. These values are defined in the CCI list obtained from the RMF Knowledge Service. Note that definition or guidance provided may not be relevant for a control system – the organization definitions were determined from the perspective of a traditional information system, not for a control system.
- ***Designer:*** The designer has a role to address for this CCI. The designer must do one of the following:
    - provide design specifications to cover a requirement for the control system itself, or
    - provide input to others regarding the implementation of the CCI, or
    - provide input to others regarding lack of feasibility of the CCI (typically because the CCI was written with an IT system, rather than a control system, in mind).
- ***Non-Designer:*** The CCI is not the responsibility of the designer, and is the responsibility of someone else – typically the SO. This does not diminish the importance of these CCIs, but, as these CCIs are not the responsibility of the designer, they are beyond the scope of this UFC.
- ***Platform Enclave:*** The CCI contains a requirement which is expected to be implemented at the Platform Enclave and inherited by the control system or is mostly implemented at the Platform Enclave but also needed within the field control system (in which case the CCI is also in the "Designer" category). For example, passwords are implemented at the Platform Enclave, but are also necessary at the control system user interface itself, local display panels and some controllers (those which support passwords). While implementation of the Platform Enclave is not the designer's responsibility (a key point of the Platform Enclave is that it

is a standard approach that can be implemented across multiple control systems), it's important to document CCIs the control system expects to inherit from the Platform Enclave, should there be one.

In cases where there is a Platform Enclave, some non-designer CCIs should be addressed by the Enclave and these CCIs are identified as such. For projects or sites that do not have a Platform Enclave, all "Platform Enclave" CCIs (not also listed as "Designer") can be considered Non-Designer.

- ***Impractical:*** The CCI is impractical to fully implement in a control system but may be applied in a limited manner to at least some part of the control system. In most cases, these are CCIs that can be implemented at Level 4 of the architecture but would be prohibitively difficult to implement at Levels 0, 1, or 2. Note that these CCIs are generally also categorized as "Designer", and the designer must indicate what was done and what wasn't.

Many CCIs will be assigned multiple categories. For example, a security control related to passwords would be categorized in both "Platform Enclave" and "Designer" categories as it must be addressed at the Level 4 computers as well as at Level 1 and Level 2. If the DoD has selected a minimum password length for use with this control which cannot be met by all devices, it would also be categorized as "Impractical", and the designer must document how the security control was implemented for devices unable to meet the DoD selected value.

3-5.2 Additional Resources and Information For Step 2C

Additional resources and information related to this step can be found as listed here. The use of these resources is optional, and the designer remains responsible for ensuring all design requirements are met whether or not these resources are used.

- APPENDIX G includes tables with example categorization for LOW and MODERATE Impact Systems.
- There is a spreadsheet which provides a table of CCI information based on a list of CCIs located on the document page of this UFC at the Whole Building Design Guide Website (WBDG.org). This spreadsheet includes example categorization for LOW and MODERATE Impact systems

3-6 STEP 3: INCORPORATE CYBERSECURITY REQUIREMENTS.

In addition to requirements specific to CCIs, design all control systems according to the minimum cybersecurity design requirements in CHAPTER 4 and cybersecurity requirements otherwise standard for the type of control system being designed.

For each CCI identified as "designer" during Step 2C (see APPENDIX G for example tables resulting from Step 2C), address the CCI in one or more of the following three ways (summarized here, with details provided in following paragraphs):

- First, select or identify required changes to standard CCI requirements which affect CCI implementation, such as the value of a specific parameter. Note that approval or rejection of these values by the Service (the AO or their designated representative) will impact control system design.
- Based on requirements and CCIs (including potential changes identified above), incorporate cybersecurity requirements appropriate to the control system in a dedicated Cybersecurity specification for the system based on UFGS 25 05 11 "Cybersecurity for Facility-Related Control Systems". Some requirements may instead be covered in the project control system specifications.
- For the remaining "designer" CCIs (those that do not directly translate to a control system requirement), provide information about the design to others so they can implement a CCI. In particular, document CCIs that the system is expected to be inherited from another system or the Platform Enclave.

3-6.1 Addressing DoD Selected Values in CCIs.

Many CCIs have DoD standard values and are indicated in the Master CCI List as being automatically met or inherited based on the standard value. These CCIs have been derived from the general security controls in NIST SP 800-53, without regard to special consideration which might apply to a control system, such as the tailoring and supplemental guidance in NIST SP 800-82. Many of these CCIs cannot be applied to control systems using the approach identified by the DoD. In these cases, implement the CCI to the greatest extent practical, and document the incompatibilities.

3-6.2 Other "Organization Defined Values" in CCIs.

For CCIs which refer to "organization defined values" where the DoD has not defined a value and one has not been provided, request appropriate values from the Service. If the Service is unable to provide values, propose reasonable values and document the proposed value with rationale.

3-6.3 Requirement Definition and Implementation CCIs.

Often, one CCI defines a requirement, and a second requires the implementation of that requirement. A hypothetical example[8] is:

- CCI #1 says "organization defines which components collect audit records". The implementation guidance for this CCI says "this is automatically met because the DoD has defined the components as 'all components'".

[8] This example uses simplified fictitious CCIs for illustrative purposes. The AU family of security controls deals with audit logs.

- CCI #2 says “the information system collects audit records at the defined components”.

Together, these create an impossible requirement: if one accepts the definition in #1 (and that it’s “automatically met”), then the system fails to meet #2 because, for example, Level 0 sensors can’t collect audit records. In this case, both CCIs are “Designer” category; propose reasonable values for CCI #1, implement CCI #2 using these values and document the proposed values for CCI #1.

3-6.4 Additional Resources and Information for Step 3

Additional resources and information related to this step can be found as listed here. The use of these resources is optional, and the designer remains responsible for ensuring all design requirements are met whether or not these resources are used.

- APPENDIX G includes tables which indicate where specific CCIs are referenced in (an unedited/untailored) UFGS 25 05 11.
- There is a spreadsheet located on the document page of this UFC at the Whole Building Design Guide Website (WBDG.org) which provides a table of CCI information based on a list of CCIs. This spreadsheet includes UFGS references for LOW and MODERATE Impact systems.
- There is a spreadsheet which parses a SpecsIntact file to identify the location of CCI References (provided specific formatting rules are followed for the CCI references) on the document page of this UFC at the Whole Building Design Guide Website (WBDG.org).

This Page Intentionally Left Blank

CHAPTER 4 MINIMUM CYBERSECURITY DESIGN REQUIREMENTS

4-1 DESIGN TO MINIMIZE FAILURE.

4-1.1 Reduce Dependency on the Network.

Avoid dependence on the network for the execution of control strategies. For example, a backup generator should always start based on a local measurement of utility availability, and not require a network "START" command. When dependence on the network is unavoidable, isolate that portion of the network as much as possible so that non-local network outages do not affect the required portions of the network. When operator input is absolutely required for the functioning of a control strategy, consider a local interface (local display panel) or a dedicated front end (Level 2 front end) physically co-located with the equipment.

In some cases, it may be necessary to take additional steps to protect critical functions from modification over the network, for example a controller where critical parameters are exposed to network manipulation based on the controller design. In these cases, design barriers to manipulation into the control network architecture itself. See APPENDIX E for one possible approach.

4-1.2 Reduce Extraneous Functionality

Since additional capabilities often result in additional vulnerabilities, a key cybersecurity concept is “least functionality”, which means not adding capabilities which are not specifically needed. Design control systems to minimize additional functionality which may create vulnerabilities in the control system, including but not limited to:

- Consider mission requirements before implementing remote adjustment of system parameters which are not expected or required to change. For example, a critical air conditioner serving a data center, a critical command and control building, or a UPS room which needs to maintain space temperature at 65 degrees Fahrenheit, 24 hours a day, 365 days a year should not have a network configurable operating schedule or set point.
- Advanced or complex control strategies often require increased sensor inputs and a greater level of maintenance. Use care when requiring these strategies as the increased complexity results in increased probability of failure if the system is not properly maintained or if any specific parameter is compromised.

4-2 DESIGN TO MANAGE FAILURE.

4-2.1 Design for Graceful Failure.

4-2.1.1 Unitary Control Systems.

For control systems controlling a single process or piece of equipment, coordinate with the equipment designer to determine any additional redundancy and failure requirements, and design the control system to match the requirements for the underlying equipment. In all cases design these systems to fail "safe" as defined by the criteria for the controlled system. For example, in cold climates, outside air intake dampers must fail closed based on the requirements of the heating, ventilation, and air conditioning UFC. Similarly, zones that are dominated by interior loads should consider failing to full cooling.

4-2.1.2 Control Systems with Independent Subsystems.

Many control systems are described as a single system but are actually composed of many (hundreds, even thousands) of essentially independent systems. A common example of this would be an installation-wide UMCS, where the air handler (AHU) controllers in one building have no dependence on the AHU in another building, and often no dependence on AHUs in the same building.

For control systems with independent subsystems, design each subsystem as required in paragraph 4-2.1.1, Unitary Control Systems, and design the overall system such that loss of a single subsystem does not affect the operation of the rest of the system. Reduce information required to be shared between subsystems and minimize dependence on the network. For subsystems which must rely on other subsystems define default ("fall back") behavior should the other subsystem fail.

4-2.2 Degraded Operation.

After a system fails to a safe state, it may need continue or resume operation in a degraded capacity using some automated or manual method, recognizing there may be risk in this operation, but that the risk is manageable and outweighed by mission requirements.

Based on mission requirements, consider requiring means for manual operation including both monitoring instrumentation (thermometers, pressure gauges, meters), and manual control devices (such as "hand-off-auto" switches and actuators with manual actuation capability). Consider if a local controls front end might be installed inside the facility and facility staff might be provided sufficient training to make basic adjustments to the system. Another option to consider is the addition of local display panels (limited operator interfaces within the control system) in mechanical rooms, again with the intent of allowing on-site staff the ability to maintain system operation (perhaps in a degraded state, but sufficient to maintain basic mission capabilities).

4-2.3 Redundancy.

If the criticality of the mission requires redundancy in the design of the control system, then the system must be designed to provide that redundancy without external intervention, and especially without human intervention. Design control strategies such that spare units start automatically when running units shut down, or have all units run and share load. Care must be taken when load-sharing to ensure that operators are notified when one unit of a redundant set fails since the remaining units will automatically pick up the load with no disruption in the load. Do not rely on an operator to start any backup unit; the odds of the operator not being available, or taking an incorrect action are too great. Provide alarms to alert operators of failures.

Note that the control system is often more reliable than the underlying controlled equipment. For example, a backup electrical source powered by a diesel generator is most likely to fail due to a mechanical fault. If installing a redundant control system do not neglect to install redundant mechanical and electrical controlled equipment as well.

4-2.4 Redundancy with independent control systems.

Where backup systems are required to meet mechanical or electrical needs consider installing simple, standalone backup systems with a simple, but completely independent control system. For example, for a data center, perhaps a standalone computer room air conditioner (CRAC) unit could be added that would start based on a local thermostat and run independently of the base wide system. Particularly in the case of a critical facility (which likely has redundant HVAC equipment), consider if the primary unit could possibly be connected to the base wide UMCS while the secondary unit might operate in a standalone configuration with purely local controls

Another example might be a non-critical buildings containing a small critical room or facility inside the larger building. Consider if it is possible to add a small independent standalone unit, such as a small Direct Expansion (DX) unit or dedicated backup generator.

4-3 DO NOT IMPLEMENT STANDARD IT FUNCTIONS.

As a type of Platform IT, control systems are special purpose systems and must not be used as general computing resources. In particular:

- Do not share control system resources with other systems, particularly with any system that is not a control system. Some exceptions such as separate virtual servers running on common hardware or shared Ethernet media with separate VLANs, may be permitted, but the overlap between control systems and other systems must be minimized.
- Do not allow control systems to provide, or share resources with, other applications that provide standard IT services. For example, do not use control system components as Domain Name System (DNS) servers. (DNS servers may be implemented within the “Platform Enclave” at Level 5, but that is beyond the scope of the control system designer’s responsibility and not addressed by this UFC.)
- Do not allow control systems to be publicly accessible over the Internet (if this capability is required, it must be restricted access and carefully implemented by IT professionals).
- Ensure that user interfaces with the ability to manipulate the system are secured with some combination of authentication (passwords, etc.) and physical security (in controlled space or locked enclosures).

- Prohibit the use of mobile code, except mobile code may be allowed at Level 4. Note that control systems may use mobile code technologies, Java in particular, within the control system, but must not download code without direct user approval.
- Do not use control system computers as standard computers for general applications.
- Do not implement Voice over Internet Protocol (VoIP) within the control system.
- Do not implement collaborative computing devices, technologies or protocols within the control system.
- Unless specifically authorized by the Service and required by the project site, do not allow control system components to access non-military IP addresses. Do not allow control system components to access social media. (Note that access to non-military IP address space is generally not needed, and when needed will generally be a function of the front end, not the field control system.)
- Do not allow control systems to receive email (note that at Level 4 they may need a method of sending email for notifications).

4-4 DO NOT PROVIDE REMOTE ACCESS.

Do not provide remote (off site) access to the control system. If required, remote access to the Level 4 network should be provided by the Platform Enclave or the site IT organization. Coordinate remote access requirements with the project site IT organization and with the POCs listed in 0.

4-5 AVOID PROBLEMATIC NETWORKS

While wireless networks are of great value in IT systems, their value in FRCS is very limited and they should - for the most part – be avoided. Most FRCS are fixed, they do not move, and there is no requirement for a wireless network. While wireless may apparently have a lower first cost, the frequent necessity to provide power to the control system devices or controlled equipment itself means that wires will be installed to provide power and there are multiple technologies that allow both power and network over the same wires (such as Power over Ethernet (PoE) and Powerline Networking).

- Be careful when designing for or allowing the use of wireless networks. Coordinate all use of wireless with the project site and where it is allowed require FIPS 140-2 validated radios wherever possible. Where using wireless IP (such as Wi-Fi) coordinate closely with the site IT group to ensure that the network meets current IT security standards.

- Where radios cannot be avoided – for example, in fire protection systems where buildings use radios to communicate with a base fire department – provide hardware isolation panels (relays) to isolate the control system from the radio.

- While many control systems run over IP networks, others instead use protocols that were designed specifically for the control system – protocols that are inherently more limited and have fewer vulnerabilities. Before selecting IP as a network protocol, carefully consider the pros and cons and consider implementing the control system using a less vulnerable non-IP protocol.

4-6 PROTECT THE CONTROL SYSTEM WITH PHYSICAL SECURITY

Ensure that access to the control system – controllers and network – is at least as difficult to obtain as access to the controlled equipment (mechanical and electrical) itself. Controllers should be co-located with the controlled equipment. Consider the potential for an aggressor with access to one controller to affect equipment controlled by another controller. Protect the network media itself from physical access. Depending on the situation, this may involve keeping controllers in locked controlled spaces, providing separate locked enclosures for controllers, and installing network media in metallic conduit.

4-7 PROTECT PRIVILEGED USER INTERFACES

By analogy with privileged users in the IT world, a Privileged UI is a UI that has sufficient capabilities or functionality that it requires specific cybersecurity measured to be put in place to limit its unauthorized use. Typically, this requires one or more of the following:

- Use of physical security to block access to the interface. Note that this will not work with interfaces that can be accessed over the network.

- Use of strong access controls, including hard passwords and/or PIV (smart cards)

- Use of strong network encryption for interfaces with network access.

4-8 EMPLOY PRINCIPALS OF DESIGN SIMPLICITY

Often there exist performance requirements that will push a control system towards increased complexity, and operational requirements that will drive a system towards simplicity. The more complex a system is, the more difficult the maintenance and operation of that system tends to be. More complex systems often have more vulnerabilities as well. For control systems, typically (historically), this complexity is in terms of number of components or the complexity of the sequence of operation of the system.

RMF requirements are geared toward IT systems and drive control systems to resemble IT, introducing new complexities. Simple controllers typically found in many BCS, for example, cannot begin to meet the access control and auditing requirements that a computer so easily meets. Left unchecked, this will lead to incredibly complex and unique systems which meet cybersecurity requirements at the cost of control functionality, maintainability, or operational capability.

4-8.1 Example: Using PLCs for HVAC Control

For example, Programmable Logic Controllers (PLCs) will generally more readily meet cybersecurity requirements than the direct digital controllers used for HVAC control systems. However, because PLCs are not generally used for HVAC, using PLCs to control the HVAC systems introduces significant risks:

- The standard and well-tested HVAC control routines developed by the HVAC controls industry won't be available to the system, and custom PLC programming will be required.
- The controls installer of the PLC system is unlikely to know HVAC well, so is more likely to miss operational requirements or pitfalls – including basic system physics such as thermodynamics of air-to-water heat exchangers.
- The HVAC maintenance staff is unlikely to be familiar with PLCs, resulting in an increased training burden or a reliance on contracted maintenance.

4-8.2 Consideration of Overall System Risk

It's vital that the cybersecurity requirements for the control system be balanced with the complexity of the system and the risk involved with an overly complex system. There is a point for every system where the application of an additional cybersecurity requirement will result in an overall increase in risk. This is an especially important consideration for more critical (higher impact) systems where the control system must operate properly to support the mission.

4-9 CYBERSECURITY DURING CONSTRUCTION

Do not neglect the potential for an aggressor to introduce malware into the control system during the construction process. While the government does not own the system during construction, it is naive to assume that there are no bad actors targeting government systems during the construction process[9] and that any cyber exploits during construction will be uncovered during the commissioning process. Require basic "cyber hygiene" of contractor systems touching the control system.

4-10 ADDITIONAL REQUIREMENTS FOR MODERATE SYSTEMS

For MODERATE impact systems, also include the following requirements:

- Do not allow devices with user interfaces capable of being accessed remotely, or capable of accessing other devices unless one is specifically required for the system. Do not allow devices with full remote user interfaces to execute sequences of operation.

[9] Consider the case of listening devices designed into overseas embassies during construction by foreign adversaries.

- Do not allow networked sensors or actuators unless one is specifically required for the system. (A networked sensor or actuator is a sensor or actuator that has an integral network interface where the device does not execute a sequence of operation; the sole purpose of the network interface is to communicate the sensor/actuator data over the network.) Note that this requirement does not prohibit networked I/O where the network is required to support high reliability/redundant I/O – such as PROFIBUS or CHARMS networked I/O busses.

- Do not rely on the network for execution of a sequence; to the greatest extent possible homerun I/O via analog/binary signals to a single controller executing the sequence of operation.

This Page Intentionally Left Blank

CHAPTER 5 CYBERSECURITY DOCUMENTATION

This chapter describes cybersecurity documentation that is required as part of the control system design package. This documentation is in addition to the documentation required by the relevant control system design criteria.

5-1 OVERVIEW.

Cybersecurity documentation for control system design documents the security controls and CCIs applied to the control system along with assumptions made regarding CCI selection, implementation, and information required by others.

5-2 USE OF GUIDE SPECIFICATION.

The design specifications for control system cybersecurity developed in accordance with this UFC must derive from UFGS 25 05 11.

For projects designed by or for USACE, develop separate cybersecurity specifications for each system type and for each impact level. This prevents misinterpretation of specification requirements. Use fourth level numbering of the specification to differentiate the specification by system. Different fourth level numbering schemes are possible; the scheme that is clearest for the project should be used and should be used across the entire project. Two example schemes are using sequential numbering (such as Section 25 05 11.01: Low Impact HVAC, Section 25 05 11.02: Low Impact Lighting Controls, Section 25 05 11.03: Moderate Impact HVAC Controls, etc.) or using numbering that aligns with the division that the control specification is in (such as Section 25 01 11.23: HVAC, Section 25 05 11.26: Lighting). Note that the second scheme becomes unusable when multiple different systems have the same division number, or there are multiple systems of the same type but with different impact levels.

5-3 COORDINATION WITH OTHER DISCIPLINES

As discussed in CHAPTER 3, in order to develop a specification properly aligned with site choices, several design steps must be coordinated with other disciplines. To facilitate this coordination, an optional reference Cybersecurity Design Coordination Worksheet is posted on the Whole Building Design Guide document page for this UFC (https://www.wbdg.org/ffc/dod/unified-facilities-criteria-ufc/ufc-4-010-06).

5-3.1 Determination of Points of Contact

For this document, the primary points of contact are the System Owner (SO) and the Authorizing Official (AO) for the determination of the C-I-A Impact ratings. In addition there may be coordination with the controls designer, if this individual is separate from the cybersecurity designer, and possibly the SO and AO for the discussion of cybersecurity controls that are not feasible for the FRCS.

5-3.2 UFGS Coordination Issues

- For UFGS 25 05 11, there are many designer options that require input from the control's designer, SO, AO, and site personnel. Major consideration includes the following:

- Whether wireless will be allowed. If so, where? How will it be secured? How will it be tested?

- User Interfaces. Where will they be located? Which, if any, will be privileged? How will they be secured?

- User Interface behavior such as session termination and unsuccessful login handling

- Specific requirements for Fire Protection systems

- Submittal review. Specific details about documentation, level of inventory reporting, and other submittal requirements

- Specific hardware or software requirements: Ethernet switches, web and database servers, and device and equipment power.

- Auditing: front-ends, software, storage capacity, and information system monitoring

- User Authentication: PKI, passwords, and setting of passwords

- Cybersecurity testing and training: Field QC, PVT, level of training

5-4 REQUIREMENTS BY DESIGN PHASE.

Cybersecurity documentation requirements are indicated here by typical Design-Build or Design-Bid-Build design submittals. Some of these will require new design documents while others add requirements to design documents that are already required by other criteria or project requirements. The percentage design levels provided here are notional only to demonstrate the order and extent of information needed by each submittal. If the design is using a different submittal schedule, adjust accordingly. The documentation requirements here apply per system and impact level – if the project includes multiple systems or impact levels, a copy of the required documentation for each is required. Submittal templates are posted to the document page for this UFC.

The requirements here reference the five-step cybersecurity design process defined in CHAPTER 3.

5-4.1 Basis of Design (10-15%).

At the Basis of Design (10-15% design) submittal, or the equivalent submittal step for projects not incorporating a Basis of Design submittal, provide the following items:

- **System Description:** A brief functional description of the system
- **CIA Impact Level:** The C-I-A impact level for the control system and whether it was provided by the Service, or was determined using one of the courses of action described in CHAPTER 3 for when impact ratings aren't provided. If using the methods discussed in APPENDIX D provide a narrative documenting how the impact rating was determined.
- **Starting Security Control Set and Tailoring Recommendation:** A list of the security controls generated during Step 2A along with recommendations and justifications for further tailoring of the security control set
- **Network Connectivity Description:** A general description of expected network connectivity type, such as stand-alone, closed restricted network, dedicated transport, or shared transport.
- **System Connections:** Planned, expected, or required connections to other systems (if any).

5-4.2 Concept Design (30-35%).

At the Concept Design (30-35% design) submittal, or the equivalent submittal step for projects not incorporating a Concept Design submittal, provide a list of the CCIs resulting from the approved tailored security control list (Step 2B) or provided by the Service, and an initial classification for each CCI (Step 2C).

5-4.3 Interim Design (50-65%).

At the Interim Design (50-65% design) submittal, or the equivalent submittal step for projects not incorporating an Interim Design submittal, provide the following items:

- **CCI List:** The recommended format for this list is to use the format of the tables in APPENDIX G with the addition of a column to document the required information. In addition to any other required formats, provide the CCI list in a format compatible with Microsoft Excel. The list must include the following items.
    - The final classification (Designer, etc..) of each CCI (Step 2C).
    - For each CCI categorized as designer and addressed in the design, include:

    - ◊ Identification where and why the standard CCI requirements cannot be incorporated into the design (identified in Step 3), description of what requirements will be incorporated instead, and an explanation of the changes.
    - ◊ Documentation of how the CCI has been incorporated into the control system design (Step 3), including specification or drawing references. If there are specific changes from standard requirements, or multiple options available, document these changes or options..
  - For each CCI categorized as designer due to requiring information be provided (Step 3), provide the relevant information for use by others.
- **Redlined Specifications and Drawings:** Draft specifications based on UFGS 25 05 11 with appropriate tailoring for system type and impact rating and edited for project requirements, and any relevant drawings or other attachments when requirements have been incorporated into drawings or other attachments.
- **Riser Diagrams:** One-line/riser diagram showing concept architecture and major components.
- **System Connections:** A document either indicating no network connections to other systems will exist or describing the network connections to other systems. For system connections include a description of the other system, the nature and purpose of the connection, and all protocols used by the communication interface.

5-4.4 Final Design (Unreviewed 100%).

At the Final Design (Unreviewed 100% design) submittal, or the equivalent submittal step for projects not incorporating a Final Design submittal, provide all items from the Interim Design (50-65%) with updated Final Design information.

5-4.5 Issued for Construction (Reviewed 100%).

At the Issued for Construction (Reviewed 100% design) submittal, or the equivalent submittal step for projects not incorporating an Issued for Construction submittal, provide all items from the Final Design (Unreviewed 100%) with updated Issued for Construction information.

APPENDIX A RISK MANAGEMENT FRAMEWORK (RMF) OVERVIEW

A-1 RMF OVERVIEW

As defined by the National Institute of Standards and Technology (NIST), the RMF is "The process of managing risks to organizational operations (including mission, functions, image, reputation), organizational assets, individuals, other organizations, and the Nation, resulting from the operation of an information system, and includes: (i) the conduct of a risk assessment; (ii) the implementation of a risk mitigation strategy; and (iii) employment of techniques and procedures for the continuous monitoring of the security state of the information system.". The RMF details how Risk Management is applied to Department of Defense (DoD) information technology in accordance with DoDI 8510.01.

A-2 RMF PROCESS

As shown in Figure A-1, the RMF is a seven-step process:

0. Prepare: Carry out essential activities to help prepare all levels of the organization to manage its security and privacy risks using the RMF

1. Categorize the System: Categorization of the control system by Confidentiality, Integrity and Availability (C-I-A) Impact levels, taking into consideration both the importance of the mission and the importance of the control system to the mission. Determination of the C-I-A Impact levels will be made by the System Owner (SO) and is outside the scope of this UFC. The dashed box around Step 1 in the figure indicates that the designer needs information from this step when executing design in accordance with this UFC. When this information is not provided, the designer may need to determine a "design C-I-A" rating to use for the design.

2. Select Security Controls: Based on the C-I-A level, a set of controls and an overlay to be implemented will be selected from CNSSI No. 1253 and NIST SP 800-82. In many cases, these controls will be further tailored based on the requirements of the Control System prior to implementation. While this UFC includes guidance concerning applicability of specific controls, the process of selecting security controls is generally outside the domain of the designer. The solid box around Step 2 in the figure indicates that the designer must select controls for the design using the provided C-I-A value, and must provide information on the controls that are applicable (or not) to the control system.

3. Implement Security Controls: Implementation of many security controls will be outside the scope of designer responsibilities. This UFC focuses on security controls which the designer must somehow address in design, generally through the incorporation of requirements into the plans and drawings, and on security controls which others may ask the designer to

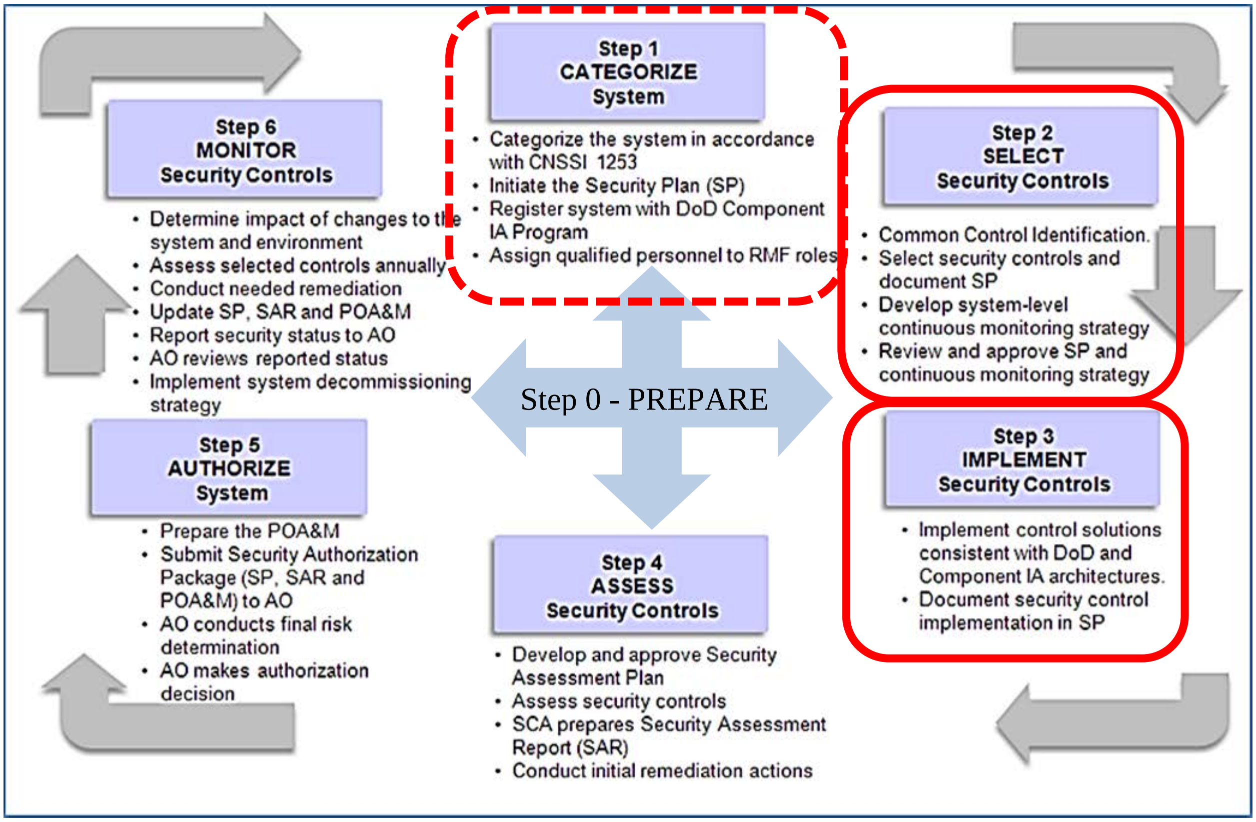
provide input on. The solid box around Step 3 in the figure indicates that the designer must develop specifications and designs that implement cybersecurity protections based on the controls identified in Step 2.

4. Assess Security Controls: After implementation, the effectiveness of the implementation is evaluated.

5. Authorize the System: Assuming a satisfactory evaluation, the Authorizing Official (AO) formally accepts the residual risk from the control system and authorizes operation of the system by issuing an authorization to operate.

6. Monitor Security Controls: The RMF enters a monitoring and evaluation phase, where the control system is monitored and periodically re-evaluated.

Figure A-1 NIST Risk Management Framework Steps



A-3 DEFINITION OF CONTROLS FROM NIST AND DODI 8510

A-3.1 Control Families

Since it is difficult to evaluate a performance requirement (“reduce risk below a specific level”), NIST provides a catalog of prescriptive requirements where meeting a particular requirement reduces the overall risk to the system. These requirements are broadly categorized into the following groupings (which are often referred to as "control families"):

- AC – Access Control
- AT – Awareness and Training
- AU – Audit and Accountability
- CA – Security Assessment and Authorization
- CM – Configuration Management
- CP – Contingency Planning
- IA – Identification and Authorization
- IR – Incident Response
- MA – Maintenance
- MP – Media Protection
- PE – Physical and Environmental Protection
- PL – Planning
- PM – Program Management
- PS – Personnel Security
- RA – Risk Assessment
- SA – System and Services Acquisition
- SC – System and Communications Protection
- SI – System and Information Integrity

A-3.2 Control Elements and Enhancements

Within each control family, there are numerous controls; most having multiple sub-elements. Many controls also have enhancements, additional actions that can be taken to enhance the effectiveness of the control. Individual controls are assigned a number within the control family, enhancements are sub-numbered, and elements of controls or enhancements are lettered. Enhancements and elements are written in parenthesis after the control number. An example of the AC-2 control from NIST SP 800-53 (Revision 4) is shown in Figure C-4.

Figure A-2 NIST SP 800-53 Control AC-2

AC-2 ACCOUNT MANAGEMENT

Control: The organization manages information system accounts, including:
Identifying account types (i.e., individual, group, system, application, guest/anonymous, and temporary);

a. Identifies and selects the following types of information system accounts to support organizational missions/business functions: [*Assignment: organization-defined information system account types*];
b. Assigns account managers for information system accounts;
c. Establishing conditions for group and role membership;
d. Specifies authorized users of the information system, group and role membership, and access authorizations (i.e., privileges) and other attributes (as required) for each account;
e. Requires approvals by [*Assignment: organization-defined personnel or roles*] for requests to create information system accounts;
f. Creates, enables, modifies, disables, and removes information system accounts in accordance with [*Assignment: organization-defined procedures or conditions*];
g. Monitors the use of information system accounts;
h. Notifying account managers:
   1. When accounts are no longer required;
   2. When users are terminated or transferred; and
   3. When individual information system usage or need-to-know changes;
i. Authorizes access to the information system based on:
   1. A valid access authorization;
   2. Intended system usage; and
   3. Other attributes as required by the organization or associated missions/business functions;
j. Reviews accounts for compliance with account management requirements [*Assignment: organization-defined frequency*]; and
k. Establishes a process for reissuing shared/group account credentials (if deployed) when individuals are removed from the group.

Supplemental Guidance: Information system account types include, for example, individual, shared…[10]
Related controls: AC-3, AC-4, AC-5, AC-6, AC-10, AC-17, AC-19, AC-20, AU-9, IA-2, IA-4, IA-5, IA-8, CM-5, CM-6, CM-11, MA-3, MA-4, PL-4, SC-13.

Control Enhancements:

(1) ACCOUNT MANAGEMENT | AUTOMATED SYSTEM ACCOUNT MANAGEMENT[10]
The organization employs automated mechanisms to support the management of information system accounts.

(2) ACCOUNT MANAGEMENT | REMOVAL OF TEMPORARY / EMERGENCY ACCOUNTS[10]
The information system automatically [*Selection: removes; disables*] terminates temporary and emergency accounts after [*Assignment: organization-defined time period for each type of account*].

(3) ACCOUNT MANAGEMENT | DISABLE INACTIVE ACCOUNTS
The information system automatically disables inactive accounts after [*Assignment: organization defined time period*].

(4) ACCOUNT MANAGEMENT | AUTOMATED AUDIT ACTIONS[10]
The information system automatically audits account creation, modification, enabling, disabling, and removal actions and notifies [*Assignment: organization-defined personnel or roles*].

(5) ACCOUNT MANAGEMENT | INACTIVITY LOGOUT[10]

[10] For sake of brevity, complete 'Supplemental Guidance' text is not shown for AC-2 ACCOUNT MANAGEMENT.

The organization requires that users log out when [Assignment: organization-defined time-period of expected inactivity or description of when to log out].

(6) ACCOUNT MANAGEMENT | DYNAMIC PRIVILEGE MANAGEMENT[10]
The information system implements the following dynamic privilege management capabilities: [*Assignment: organization-defined list of dynamic privilege management capabilities*].

(7) ACCOUNT MANAGEMENT | ROLE-BASED SCHEMES[10]
The organization:
(a) Establishes and administers privileged user accounts in accordance with a role-based access scheme that organizes allowed information system access and privileges into roles;
(b) Monitors privileged role assignments; and
(c) Takes [*Assignment: organization-defined actions*] when privileged role assignments are no longer appropriate.

(8) ACCOUNT MANAGEMENT | DYNAMIC ACCOUNT CREATION[10]
The information system creates [*Assignment: organization-defined information system accounts*] dynamically.

(9) [10]ACCOUNT MANAGEMENT | RESTRICTIONS ON USE OF SHARED / GROUP ACCOUNTS
The organization only permits the use of shared/group accounts that meet [*Assignment: organization-defined conditions for establishing shared/group accounts*].

(10) ACCOUNT MANAGEMENT | SHARED / GROUP ACCOUNT CREDENTIAL TERMINATION
The information system terminates shared/group account credentials when members leave the group.

(11) ACCOUNT MANAGEMENT | USAGE CONDITIONS[10]
The information system enforces [*Assignment: organization-defined circumstances and/or usage conditions*] for [*Assignment: organization-defined information system accounts*].

(12) ACCOUNT MANAGEMENT | ACCOUNT MONITORING / ATYPICAL USAGE[10]
The organization:
- **(a) Monitors information system accounts for [*Assignment: organization-defined atypical usage*]; and**
- **(b) Reports atypical usage of information system accounts to [*Assignment: organization-defined personnel or roles*].**

(13) ACCOUNT MANAGEMENT | DISABLE ACCOUNTS FOR HIGH-RISK INDIVIDUALS[10]
The organization disables accounts of users posing a significant risk within [*Assignment: organization-defined time period*] of discovery of the risk.

In this notation, AC-2 (5) is enhancement 5: “The organization requires that users log out when….”.

A-3.3 Control Correlation Identifiers

The DoD implementation of the NIST controls for control systems is DoDI 8500. The DoD took the additional step of breaking down each control and control element into specific actions; each action is identified by a unique Control Correlation Identifier (CCI). For example, the above control, AC-2, is broken down into 61 separate CCIs, with 11 distinct CCIs for AC-2 (4) alone.

While this leads to a very fine level of implementation (the control system could audit account creation, but not audit account modification), it also leads to many dependencies between CCIs. For example, two of the CCIs associated with security control AC-2(4) found on the RMF Knowledge Service (Security Control Explorer) are:

- CCI-000018: “The information system automatically audits account creation actions.”
- CCI-001683: “The information system notifies organization-defined personnel or roles for account creation actions.”

Note: The RMF Knowledge Service website is https://rmfks.osd.mil.

While these are written as independent CCIs, they are clearly closely related, and it is difficult to imagine a notification system that did not include an auditing capability.

A-4 REQUIREMENT DEFINITION VS IMPLEMENTATION

Broadly speaking, CCIs can be categorized into requirement definition and requirement implementation.

1. A CCI defines a requirement when the CCI is of the form “<someone> defines a <requirement>”. Examples of CCIs that define a requirement include those that state “The organization defines ….”

    a. “…a minimum level of detail for documentation”,

    b. “…a minimum frequency to review some criteria”,

    c. “…a list of events that raise a red flag for security”, or

    d. “…a policy or procedure for modifications to the control system”

2. A CCI implements a requirement when the CCI is of the form “<someone/something> meets a <requirement>”, where the requirement is typically defined in a related CCI. Examples of CCIs which implement a requirement defined in the previous example include CCIs that state “The organization ….”

    a. …obtains the required level of documentation”,

    b. …reviews a security plan annually”,

    c. …responds to breaches of physical security”, or

    d. …approves changes to the control system via a configuration management board”

A-4.1 CCIs Defining a Requirement

CCIs which define a requirement may be addressed by the designer but are often addressed by the organization or already defined DoD-wide. In some cases, the final statement of the requirement may be by the organization, but with input from the designer based on knowledge of the control system and the specific vulnerability to be addressed. For example, the designer needs to provide input on password complexity since not all control system components will support passwords, and those that do may support different complexities. In many cases, DoD-defined requirements are completely inappropriate for control systems and the designer must document deviations from the DoD definitions for these requirements in the design.

A-4.2 CCIs Requiring Implementing a Requirement

Implementation CCIs may further be classified by who/what does the implementation: the organization (or inherited from some other element), or the control system. "The organization conducts background checks" is an example of the former while "the control system logs users off after a period of inactivity" belongs to the latter. In some cases, this is not clear – a CCI that states "The organization enforces a minimum password length"[11] appears to create a requirement on the organization, but a moments consideration will make clear that this action must be implemented by the control system (since the control system either accepts or rejects a password entry), not the organization. CCIs that are implemented by the organization are not addressed by the designer and are outside the scope of this UFC. On the other hand, CCIs that are implemented by the control system must typically be addressed by the designer since implementing a CCI becomes a performance requirement in the specification of the control system.

A-5 PLATFORM INFORMATION TECHNOLOGY

The DoD implementation of the RMF defines Platform Information Technology (PIT) as "IT, both hardware and software, which is physically part of, dedicated to, or essential in real time to the mission performance of special purpose systems", and differentiates PIT systems from standard information systems. Most specifically, DoDI 8500.01 indicates that PIT Systems "require uniquely tailored security control sets and control validation procedures and require security control assessors and AOs with specialized qualifications"

The Cybersecurity of PIT systems, such as control systems, requires not only the use of customized control baselines, but also further tailoring of controls as appropriate for the specific control system.

[11] This is not the text of an actual CCI, but rather a simple fictitious example used for illustrative purposes.

This Page Intentionally Left Blank

APPENDIX B PLATFORM ENCLAVE

B-1 PLATFORM ENCLAVE CONCEPT OVERVIEW

The fact that a significant portion of the control system resembles a standard IT system which can be implemented for different control systems regardless of the details of the control system itself has led to the creation of the Platform Enclave concept. This concept groups the standard IT portions of the control system into an entity which can be handled separately from the rest of the control system. In some cases, this Platform Enclave will be separately authorized, and the overall control system will have two authorizations, while in other cases a single authorization will be used for the entire system. Even in cases where a single authorization is used, however, it's helpful to identify and categorize the standard IT portions of the control system.

B-2 PLATFORM ENCLAVE USING TWO AUTHORIZATIONS

A primary reason to define to a Platform Enclave is to enable the approach where a control system is implemented using ***two*** Risk Management Framework authorizations, one for the Platform Enclave and one for the non-Platform Enclave portions of the control system, sometimes referred to as the "non-standard IT" portions. While this may seem to lead to a duplication of effort, in practice this generally isn't the case:

- While many controls, such as policies and procedures, will need to be done at both the Platform Enclave and "non-standard IT" portions, these policies and procedures can often be inherited by both from another Authorization, or implemented the same way in both the Platform Enclave and the "non-standard IT".
- Some controls can be applied at the Platform Enclave and then inherited by the "non-standard IT". For example, controls related to remote access can be defined independently of the "non-standard IT" by the Platform Enclave, and then inherited by the "non-standard IT" if necessary.
- While some controls will need to be addressed by both the Platform Enclave and the "non-standard IT", they will need to be addressed differently, and often to a different extent, in each.

B-3 PLATFORM ENCLAVE BENEFITS

The primary benefit of the Platform Enclave approach is that it allows for separation of the "standard IT" and "non-standard IT" components of the control system and allows for a single authorization for the IT portion to cover multiple control system types. This approach is most beneficial when there is an existing network and cybersecurity infrastructure on which to establish the Platform Enclave, such as those that exist on most DoD installations. Ideally, the Platform Enclave will be a standard established and authorized by each Service for implementation at every installation, in contrast to the authorization for the "non-standard IT" portion of the control system (the "Operational Architecture"), where factors such as control system type, vendor and protocol are more likely to make each authorization unique and non-standard.

B-4 ARMY PLATFORM ENCLAVE APPROACH

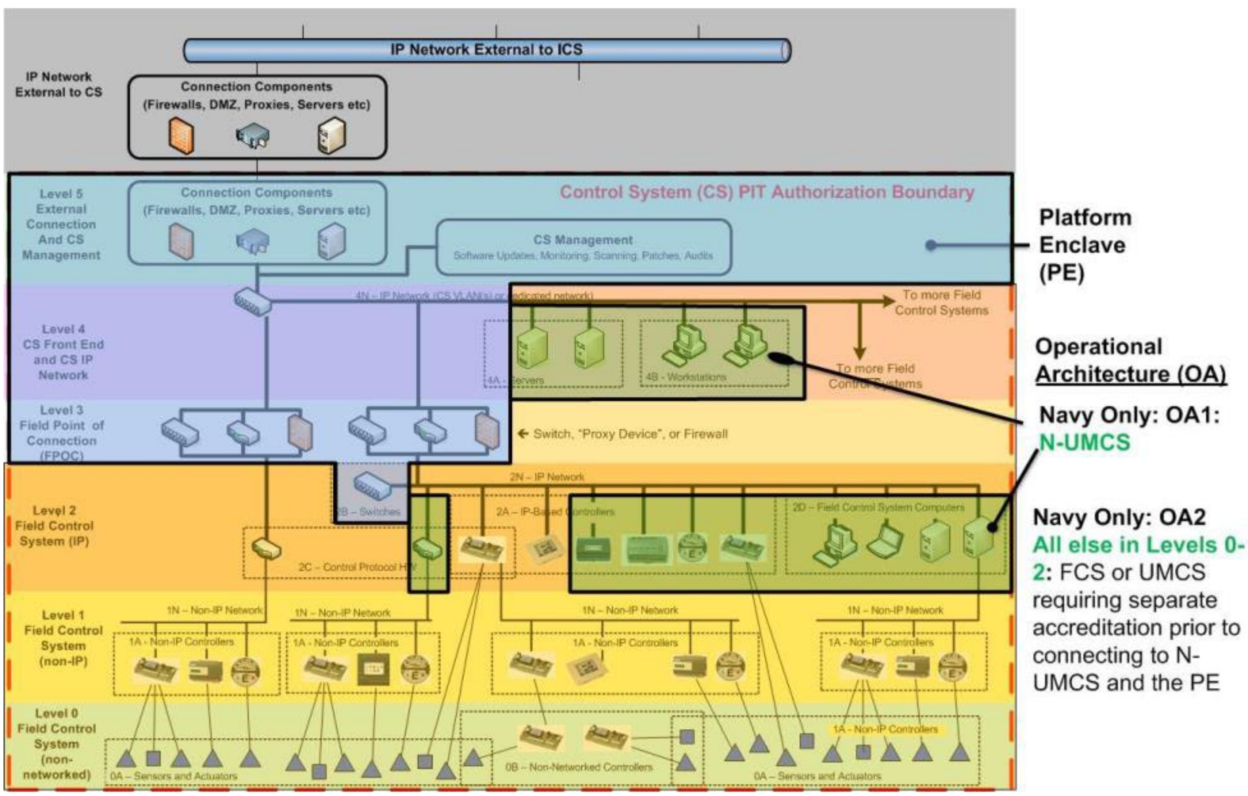
The Army has not formalized a Platform Enclave approach.

B-5 NAVY PLATFORM ENCLAVE APPROACH FOR BCS AND UCS

Figure B-1 shows which components of the 5-Level control system architecture are included in the Navy's Platform Enclave (PE) called the Control System Platform Enclave (CS-PE). The Navy's CS-PE is implemented at and has a presence today at Navy installations. The Navy is deploying an operational architecture (OA) called the Navy Utilities Monitoring and Control System (NUMCS), which is also shown in Figure B-1.

All Control Systems must connect to the Platform Enclave and must either be separately authorized or fall under the type accreditation of the CS-PE and NUMCS.

Figure B-1 Navy Platform Enclave and Operational Architecture



B-6 AIR FORCE PLATFORM ENCLAVE APPROACH

The Air Force currently does not have a formal Platform Enclave approach. The AF has deployed the Civil Engineering Community of Interest Network (COIN) at most locations. COIN has its own type accreditation and individual control systems for the most part have their own individual accreditations. CE control systems can use COIN for connectivity, but are not covered under the COIN authorization in a Platform Enclave approach at this time. As a prototype, the AF is deploying the Installation Resilience

Operations Center (IROC) network concept at selected locations, which will include selected control systems within the IROC type accreditation.

This Page Intentionally Left Blank

APPENDIX C 5-LEVEL CONTROL SYSTEM ARCHITECTURE

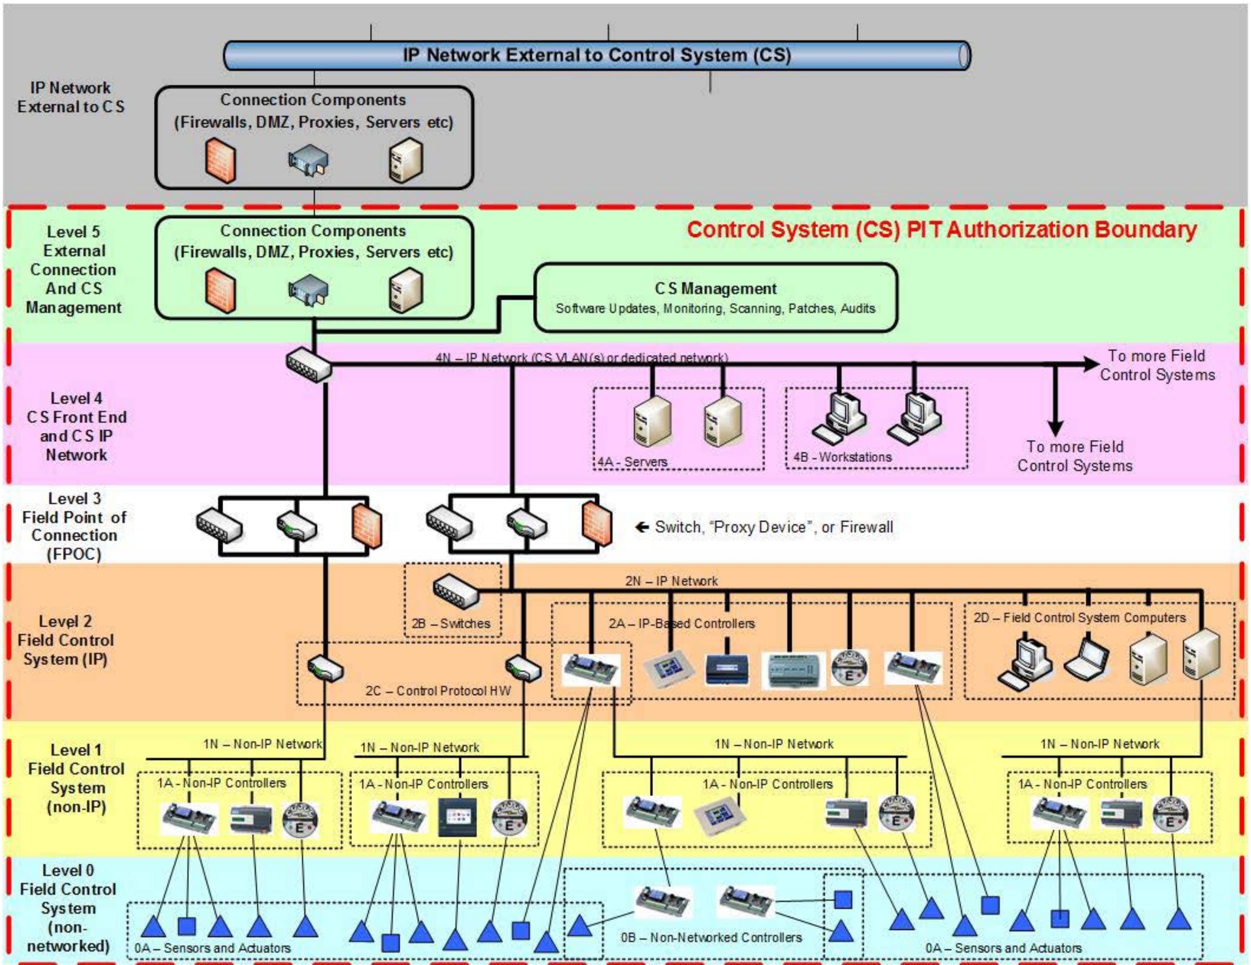
C-1 INTRODUCTION

As shown in Figure C-1, control systems are represented as a 5-Level architecture, where each level represents a collection of components that are logically grouped together by function, and which generally share a cybersecurity approach. This architecture is defined as a general architecture suitable for a wide range of control systems, thus there are some key considerations when using it to describe a specific control system:

- Not every implementation of a control system will make use of every level, or every type of component shown at a level.
- The same device may reside in different levels, depending on its configuration and its network interface. Some controllers even support different networks based on onboard switches, and thus the same device could reside in either Level 1 or Level 2 (but not both simultaneously – though a single system could have the same type of controller shown at both levels).
- In many cases, a device will fit multiple sub-levels within the same principal level, usually within Level 2. For example, a Level 2A controller may act as a Level 2C router to a Level 1 network beneath it.

This Appendix describes the 5-Level architecture for control systems and presents cybersecurity considerations for each level. Note that although there are more than five levels in the architecture shown in Figure C-1, it is commonly referred to as the “5-Level Control System Architecture”. This architecture applies to all control system types; while many of the example components or technologies included in this Appendix are based on building or utility control systems this is not meant to imply that this architecture is specific to these types of control systems.

Figure C-1 5-Level Control System Architecture



C-2 5-LEVEL ARCHITECTURE OVERVIEW

A brief description of each Level (from simple to complex devices) is:

Level 0. Non-networked devices which communicate using analog and binary signals. These include ("dumb") sensors and actuators as well as non-networked controllers (including their dedicated sensors and actuators). These communicate with Level 1 via hardware I/O (analog and binary signals).

Level 1. Networked controllers not on an IP network (such as BACnet MS/TP, RS-485 (DNP, Modbus), LonWorks TP/FT-10).

Level 2. Networked controllers on an IP network.

Level 3. The Field Point of Connection (FPOC), which is a connection between the field control system IP network at Level 2 and the Level 4 IP network.

Level 4. The site-wide IP network used for the control system, along with front end servers and workstations (desktops and laptops).

Level 5. Interfaces to “external” networks (IP networks other than the control system network). In many cases this level will not be a requirement of the project and will be provided by others. When it is part of the project it must be specified separately than the control system using IT specifications and standards.

Note that some levels contain sub-levels as indicated in Figure E-1.

C-3 LEVEL 0: SENSORS AND ACTUATORS

Level 0 consists of non-networked devices which communicate using analog and binary signals. These include (“dumb”) sensors and actuators, as well as non-networked controllers. These communicate with Level 1 or Level 2 via hardware I/O (analog and binary signals). Details for Level 0 are shown in Table C-1.

Table C-1 Level 0

LEVEL 0: Sensors and Actuators	
Definition	Level 0 devices lack a network and therefore cannot be attacked over a network. Level 0 devices, if they communicate at all, use only simple analog and binary signals, they do not use any form of digital protocol for communication. A sensor or actuator that uses a communications protocol (such as Zigbee, Bluetooth) is a Level 1 (non-IP) or Level 2 (IP) device.
Functional Description	The interface between the control system and the underlying controlled process / equipment where electrical signals in the control system get converted to/from physical values and actions in the underlying controlled system. Level 0A consists of Sensors and actuators Level 0B consists of non-networked controllers and their integral sensors and actuators. Level 0B devices may have some intelligence and may even have an internal network, but the device does not expose any internal network to other devices. These devices are typically packaged units with factory-installed integral controllers. Note that a “stand-alone” built-up unit with multiple field installed controllers which communicate over a network specific to that unit is NOT a Level 0 component, but rather a stand-alone field control system of its own.

<table>
<tr><th colspan="2">LEVEL 0: Sensors and Actuators</th></tr>
<tr><td>Implemented Via</td><td>Devices which:
Convert physical properties (temperature, pressure, etc.) to a binary or analog electrical signal
Take a binary or analog electrical signal and produce a physical action (open / close a valve or damper, etc.)
These electrical signals are purely binary or analog – there are no exposed digital signals or networks at this level. Also note that "smart" sensors or “smart” actuators which include a controller and network connection are considered to be Level1 or Level 2 devices.</td></tr>
<tr><td>Installed By</td><td>Controls contractor during installation or renovation of underlying mechanical or electrical system.</td></tr>
</table>

<table>
<tr><th colspan="2">LEVEL 0: Sensors and Actuators</th></tr>
<tr><td>Example Components</td><td>The vast majority of these devices are very simple (“dumb”) sensors or actuators, but more complex equipment may be at level 0 – as long as it lacks a network connection. Some examples are:
• A thermistor temperature sensor which simply provides a changing resistance as an indication of temperature is a Level 0A device.
• An electric actuator which takes a 4-20 mA signal and produces a proportional physical response is a Level 0A device.
• An occupancy sensor which uses BACnet to communicate occupancy values is a Level 1 (or Level 2) device, not a Level 0 device.
• A variable frequency drive controlling an air handler fan and using only binary and analog signals to communicate with the air handler controller is a Level 0B device.
• A flow sensor using HART over an analog wire is using a digital protocol (HART) and is a Level 1 device, not a Level 0 device.
• A packaged diesel generator operating in a stand-alone configuration – again with no network connection to other devices - is a Level 0B device, even if it has binary or analog connections to other devices.
• A relay panel acting as a Level 0 hardware interface between a building fire protection system and a sitewide radio network to a sitewide fire department.
The last three examples illustrate that the defining characteristic for Level 0 is not the complexity of the device, but rather whether the device communicates with other devices using a network.</td></tr>
</table>

LEVEL 0: Sensors and Actuators	
Security Control Considerations	In general, management and operational controls such as physical security and access control may still apply to this level. These devices are physically attached to the mechanical/electrical system and physical security is dictated and implemented based on the physical access to the equipment. Utility vaults, Mechanical, Electrical, Plumbing rooms, Pump Stations, etc. should be secure and only authorized personnel should have access. These devices, while they do not have network communication, can cause physical damage, for example a valve left in the “Open” position.

C-4 LEVEL 1: FIELD CONTROL SYSTEM (NON-IP)

Level 1 contains networked controllers not on an IP network (such as BACnet MS/TP, RS-485 (DNP, Modbus), LonWorks TP/FT-10). Details for Level 1 are shown in Table C-2.

Table C-2 Level 1

LEVEL 1: Field Control System (non-IP)	
Definition	That portion of the controls network which does not use the IP protocol. This includes both the controllers themselves (Level 1A) and the network (Level 1N).
Functional Description	(Level 1A) This is where the control logic resides and gets converted to or from binary and analog electrical signals, as well as the portion of the control system where: • Analog and binary electrical signals (from sensors) get converted to digital signals via analog-to-digital (A-D) converters. • Digital information is converted to analog and binary electrical signals (to actuators) via digital-to-analog (D-A) converters. • Digital information is transmitted and received over a network. • Digital information is processed according to a user-defined sequence to generate new digital information.

LEVEL 1: Field Control System (non-IP)	
	• Devices may incorporate integral Level 0 sensors and actuators, for example, many variable air volume (VAV) box controllers incorporate an electric actuator. Not all controllers will have hardware inputs. While there is exchange of data over the network, good design practice dictates that most of the data processing occurs using local (integral or via analog or binary signals) sensor data and local actuator outputs; the system is designed to minimize dependence on networked data. (Level 1N) The Level 1 network (media and hardware) does not use IP. It uses a variety of media at OSI Layers 1 and 2 (some standard, some not) and it uses Layer 3 protocols other than IP. Some examples are: • BACnet over MS/TP, or BACnet over ARCnet • LonTalk over TP/FT-10 or LonTalk over TP/XF-1250 • Modbus over RS-485 For this reason, it is generally very specific to the control application and cannot be used for "standard" IT protocols and applications.
Implemented Via	(Level 1A) Controllers, typically equipped with multiple analog and binary inputs and outputs and corresponding A-D and D-A converters. These devices are driven by cost to have the minimal functionality for the application and are very constrained in random access memory (RAM), processing power, and network input/output (I/O). In addition, these devices come in a vast variety of architectures, processors, vendors, and firmware. (Level 1N) The network media and hardware are similarly dedicated to that specific control protocol and are made by a variety of vendors.
Installed By	Controls contractor during installation or renovation of underlying mechanical or electrical system. Generally during new building construction or major renovation.
Example Components	VAV box controllers Networked (non-IP) electric meter Intelligent (networked) thermostat

LEVEL 1: Field Control System (non-IP)	
	LonWorks TP/XF-1250 (media) to TP/FT-10 (media) router. (This is not an IP router but routes the control system protocol at Open Systems Interconnection layer 3.)
Security Control Considerations	Since devices (controllers) in this tier tend to be simpler devices, often few security controls can be applied, particularly after the system has been designed and installed. Since they do not use IP, network attacks must be very protocol-specific. Some basic controls/measures that can be applied at this tier include: • Disabling (or at a minimum prohibiting) secondary network connections (connections other than to the Level 1 network) • The use of passwords on devices such as displays (to the capability supported by the device – many of which do not permit 14 character passwords, for example) • The application of physical security measures – which will be dictated and implemented by the underlying equipment

C-5 LEVEL 2: FIELD CONTROL SYSTEM (IP)

Level 2 consists of networked controllers on an IP network. Details for Level 2 are shown in Table C-3.

Table C-3 Level 2

LEVEL 2: Field Control System (IP)		
Definition		The portion of the control system which uses IP but is not shared with any other system. “Shared” in this context primarily refers to physical equipment and media. Note the Level 2 IP network is typically contained within a single building but may span multiple buildings in support of a control system for a single (linear) facility.
Functional Description	2A	This Level (along with Level 1) is where the control logic resides and where it gets converted to/and from electrical signals and can have the first IP connections. This is the portion of the control system where: • Analog and binary electrical signals (from sensors) get converted to digital signals via A-D converters

LEVEL 2: Field Control System (IP)		
		(although not all controllers will have hardware inputs). • Digital information is converted to analog and binary electrical signals (to actuators) via D-A converters (although not all controllers will have hardware outputs). • Digital information is transmitted and received over a network. • Digital information is processed according to a user-defined sequence to generate new digital information. • These devices may incorporate integral Level 0 sensors and actuators, for example, many Variable Air Volume (VAV) box controllers incorporate an electric actuator. Note this functional description is identical to that of Level 1. From a controls perspective, there is little difference between Level 1 and Level 2.
	2N/2B	The IP network (media and hardware) dedicated to the control network and carrying the control protocol (such as Distributed Network Protocol (DNP), IEC-61850, BACnet/IP or Lon/IP)). Generally, IP over Ethernet.
	2C	Control Protocol Routers and Gateways. Control Protocol Routers route the control protocol – that is, they selectively forward control protocol packets based on destination address. They are not IP routers. Control Protocol Gateways translate between Control Protocols.
	2D	Where the local control system has an elevated C-I-A requirement (due for example to a reliability requirement, an operator response time, or a need for local operators which cannot be met by the remote site-wide front end), the facility control system may contain a local operator interface similar to what is normally found at Level 4 but dedicated to this specific control system. In other cases, for either legacy or stand-alone systems (not necessarily isolated but stand alone in that they do not rely on another system such as a control system), the front-end operator interface may be physically local to that system. In this case, the operator interface is considered

LEVEL 2: Field Control System (IP)		
		to be part of Level 2 since it is dedicated to that building or facility and traffic between it and the Level 1 and Level 2 devices does not pass through the Level 3 FPOC.
Implemented Via	2A	Controllers, typically equipped with multiple analog inputs and outputs and corresponding A-D and D-A converters. These devices are driven by cost to have the minimal functionality for the application and are very constrained in RAM, processing power, and network I/O. In addition, these devices come in a vast variety of architectures, processors, vendors, and firmware. Aside from the fact that they use IP and are generally more powerful than Level 1A devices, they are otherwise identical to Level 1A devices. Many devices are available as either Level 1A or 2A devices, where the hardware is identical except for the transceiver; some can even be field configured for one or the other
	2N/2B	The Level 2N IP network is generally Ethernet, and the Level 2B network hardware is standard IT network hardware, though sometimes with reduced functionality. For example, there may not be any requirement for remotely managed switches. Similarly, there is seldom a need for an IP router, since field control systems generally reside within a single (private) IP subnet.
	2C	Controllers very similar in hardware characteristics to Level 2A devices except that these devices typically have multiple network interfaces.
	2D	Computers (as for Level 4) Computers for legacy systems Custom or modified computers with a touch screen interface
Installed By		Controls contractor during installation or renovation of underlying mechanical or electrical system. Generally during new building construction or major renovation
Example Components	2A	Air Handler Controller Chiller Controller

<table>
<tr><th colspan="3">LEVEL 2: Field Control System (IP)</th></tr>

LonWorks TP/FT-10 to LonWorks IP Router</td></tr>
<tr><td>2D</td><td>Control system at a central plant where the nature and criticality of the system requires a local operator interface.</td></tr>
<tr><td>Security Control Considerations</td><td>2A</td><td>Controllers residing on the dedicated IP network vary greatly from devices residing on a typical IP network.
• They use a single fixed protocol (or a small number of fixed protocols)
• They often do not support “log in” functionality
• There is often no “session” capability
• They usually do not include a user interface, and if they do it’s generally extremely limited.
• They have very limited hardware capabilities (RAM, CPU, storage, etc.)
• They generally do not use Windows, and seldom use Linux. They are generally some version of a real time operating system (RTOS).
Many of the controllers will have the same limitations as the controllers in Level 1, where most security controls cannot/or will not apply to them. Some controllers will have significantly more capability, however, and additional controls will be applicable. In either case, the controllers</td></tr>
</table>

LEVEL 2: Field Control System (IP)		
		should disable any network connections or services not required for operation of the control system.
	2N/2B	This network is dedicated to the control system and is generally installed by the control system contractor, not the IT organization. This doesn't reduce the need for securing this network, but does affect the way in which this network is secured, and the risks and vulnerabilities that need to be addressed Some key differentiators between the Level 2 network and a standard IP network are: • The network structure and connected devices remain more static throughout the life of the system. Generally components are not added and removed on a regular bases. • The protocol(s) used are fixed, and in many cases only a single protocol is used. The protocols also differ from "regular" IP networks in that they are control system protocols rather than standard IT protocols. This allows for the implementation of very simple (a few very broad rules) firewalls to limit traffic. • Bandwidth usage is lower. Because the network configuration is more static, the bandwidth usage is also more fixed. • The devices residing on the network have fewer capabilities, and generally don't support network security standards such as IEEE 802.1X. • The control system does not require the level of functionality that Approved Product List (APL) network infrastructure devices provide. The Navy, however, does require APL products for all IP Network Hardware.. • Standard IT devices typically do not meet the UL Listing requirements for fire and life safety systems, so specialized network hardware may be required to meet the control system needs.
	2C	These devices are not manufactured by traditional IT companies and do not run standard IT software. Their functionality is often included as part of a Level 2A device. They do not route IP.

LEVEL 2: Field Control System (IP)		
	2D	While functionally, Level 2D components act similarly to computers at Level 4, the fact that they are local to (and dedicated to) a specific control system means that from a security controls perspective, they are better addressed as Level 2 components. There are two main reasons for computers at Level 2D: • Legacy systems that cannot be patched. The computers at Level 2D may be running an older operating system and may not support some of the security controls. In this case, the controls which can be applied without negatively affecting the availability of the system should be applied, and mitigating controls and measures should be taken when otherwise needed. Systems containing these computers should not be connected to other systems (i.e., should be operated stand-alone) until they can be properly addressed, with the computers replaced or otherwise upgraded to Level 4 standards. • Where a new system requires a local front end that, for whatever reason, cannot be installed on the base-wide shared IP network (Level 4). This is typically due to a C-I-A requirement. When installing a new system with a Level 2 front end, it's important to note that the Level 2 front end should be subject to the same controls as a Level 4 front end. While implementation and inheritance of security controls at this level may differ from the Level 4 front end, computers at this Level should be subject to the same controls as a "normal" Level 4 front end of equivalent criticality.

C-6 LEVEL 3: FIELD POINT OF CONNECTION (FPOC)

Level 3 is the Field Point of Connection (FPOC), which is a connection between the field control system IP network at Level 2 and the Level 4 IP network. Details for Level 3 are shown in Table C-4.

Note that there may be devices which resemble an FPOC in the sense that they are a security device providing a managed interface between different networks but are not located between a dedicated IP network and a base-wide shared IP network. While these devices (discussed in Chapter 2, and under the Level 0 description above) act as a security barrier, the term FPOC is reserved for a security device between Level 2 and Level 4.

Table C-4 Level 3

LEVEL 3: Field Point of Connection (FPOC)	
Definition	The device which connects the dedicated Level 2 IP network with the Level 4 IP network.
Functional Description	For each field control system, the FPOC is the specific single demarcation point in the control system between that field control system and the front-end system. The FPOC is a standard IT device, usually an Ethernet Switch. The FPOC generally has security controls in that it restricts access (by user, protocol, or specific commands) between levels above and levels below. Note that a large system (consisting of hundreds of FCSes) will have hundreds of these FPOC devices, one at each connection of a field control system to the local network.
Implemented Via	Almost always an Ethernet switch or IP router
Installed By	Generally installed by installation network staff or by the control system contractor with oversight by the network staff.
Example Components	Standard IT managed Ethernet switch or IP router
Security Control Considerations	This device is critical from a security controls perspective as it is where the dedicated local field control network connects to the installation-wide IP network. Normally, securing this device protects the installation-wide network from the local field systems (which often have a difficult time meeting security controls). Occasionally, where there is a critical field control system, this device can protect the more critical field control system from the less-secure local system (i.e., where there are 99 non-critical systems and 1 critical one, isolate the 1 from the 99 rather than try and secure the 99). This device should, in effect, have a "deny all / permit by exception" policy applied. The FPOC should be set up with the most restrictive set of access control list (ACL) possible.

C-7 LEVEL 4: CONTROL SYSTEM FRONT END AND CONTROL SYSTEM IP NETWORK

Level 4 is the IP network used to connect multiple Level 2 networks, along with front end servers and workstations (desktops and laptops). Details for Level 4 are shown in Table C-5.

Table C-5 Level 4

LEVEL 4: Control System Front End and Control System IP Network	
Definition	Front End computers and the IP network which connects multiple Level 2 Field Control Networks and is (generally) not dedicated to a specific FCS. The IP network may be shared with other applications, a dedicated physical network, or a Virtual Local Area Network (VLAN) or a Virtual Private Network (VPN) riding on top of another network.
Functional Description	(Level 4A and 4B) The multi-facility operator interface for the system. This is typically a web-based client-server system with the servers (Level 4A) running vendor-specific software on standard server PCs and the clients (Level 4B) accessing the servers via standard web browser software. Some functions of the control system are: • Providing graphical screens for monitoring and control of the system • Allowing operators to schedule systems, set up historical trends, and respond to alarm conditions • Provide for and support global control and optimization strategies that are impractical to implement within the control systems • Perform real-time analytical analysis and take appropriate real-time actions through supervisory commands to devices at levels 1 or 2. This level usually also includes Engineering Tool Software which provides tools for creating and modifying the control system. The Level 4N network is the network that connects multiple facility networks into a common base-wide network. (Note that generally this network is referred to as base-wide as that’s the normal use case, but it could be entirely contained within a single building)

LEVEL 4: Control System Front End and Control System IP Network	
Implemented Via	Either a dedicated physical network, or a Virtual Local Area Network (VLAN) or a Virtual Private Network (VPN) riding on top of another network, or some combination of these options. Personal Computers, servers and network devices.
Installed By	The network (Level 4N) is typically government furnished. The computers (servers and workstations in Levels 4A and 4B) are often government furnished. The software application is typically provided, installed and configured by the controls vendor.
Example Components	Servers and racks, computers, Laptops, operator interfaces, and network devices. The control system racks, hardware and software will likely be located in an Energy Operations Center, Campus Wide Operations Center, Facility Operations Center, Facility and Energy Operations Center, Security Operations Center, or Regional Operations Center.
Security Control Considerations	Level 4 is where the CSs most closely resemble a “standard” information system, and most security controls can be applied at this layer. It’s critical to remember that control system is NOT a standard IS, however, and that controls must be applied in such a way as to not hamper the availability of the system. For example, some control systems require software updates from the manufacturer prior to the implementation of a Java patch, and controls relating to the application of patches must not be implemented in a manner that requires automatic or immediate patching without ensuring that this won’t cause the system to go offline. Unlike standard IT applications (such as virus software or office automation tools), control system applications are generally a niche product and while standard guidance may cover some aspects of securing these applications, it will likely be insufficient to fully secure them.

C-8 LEVEL 5: EXTERNAL CONNECTION AND CONTROL SYSTEM MANAGEMENT

Level 5 contains interfaces to “external” networks (IP networks other than the control system network). Details for Level 5 are shown in Table C-6.

Table C-6 Level 5

<table>
<tr><th colspan="2">LEVEL 5: External Connection and Control System Management</th></tr>
<tr><td>Definition</td><td>Additional hardware, software, and networking used to manage the control system, provide security functionality, user management, and external access. These are IT management and IT security functions, and don’t provide control system functionality.</td></tr>
<tr><td>Functional Description</td><td>In many architectures, this level provides the enclave boundary defense between the control system (at Level 4 and below) and IP networks external to the control system. (In other architectures, this boundary defense occurs in the external network). In many cases, there is a component within the control system which would reside in Level 5.

This level may be absent for a variety of reasons: there may not be an external connection, or the connection may be handled in the external network.

Additional functionality allowed through external connections may include:
• Sending alarm notification using outbound access to a SMTP email server.
• Upload of historical data and meter data to an enterprise server using outbound HTTP/HTTPS access for uploading.

In some cases, inbound HTTP/HTTPS may be allowed from web clients on the external network to the Level 4A server, but this is not required and is often prohibited for security reasons. The Navy prohibits this functionality.</td></tr>
<tr><td>Implemented Via</td><td>Firewalls
DMZ/Perimeter Networking
Proxy Servers
Domain Controller, etc.</td></tr>
<tr><td>Installed By</td><td>IT and communications staff and contractors.</td></tr>
<tr><td>Example Components</td><td>Wide Area Networks
Metropolitan Area Networks
Local Area Networks</td></tr>
</table>

	Campus Area Networks Virtual Private Networks Point of Presence Demarcation Point or Main Point of Presence
Security Control Considerations	Generally speaking, if the control system can function in a completely isolated configuration, it should, and external connection should be absent. This Level should implement a "deny all / permit exception" policy to protect the control system from the external network and the external network from the control system.

C-9 ARCHITECTURE FREQUENTLY ASKED QUESTIONS (FAQ)

- ***Can there be controllers at Level 4?*** No, all networked controllers must be at Level 2 or Level 1. Non-networked controllers may also exist at Level 0.
- ***Can one Field Control System have multiple Level 2 networks?*** Yes. One case is multiple Level 2 networks with no IP connection between. In this case there may still be a Level 1 or Level 0 connection between them.

  Another possibility is that instead of having a single Level 2 network, you may architect the system to have multiple Level 2 networks which are connected by a Level 4 network.
- ***Can one Level 2 network support multiple field control systems?*** Yes, but they would have to share a cybersecurity authorization.
- ***I have a control system supporting a linear facility that operates across a wide geographic area using a network that no other system used. Is that a Level 4 or Level 2 network?*** It could be either – it can be defined using the architecture as a single Level 2 network, or as multiple Level 2 networks connected by a Level 4 network. Which is more accurate will depend on the details of the specific installation. Factors affecting how this system is best described include authorization boundaries, procurement and operation responsibilities for the network, and preference of the Authorizing Official. In a broad sense, the more tightly the network is tied to the control system (maintained by the same people for example) the more it resembles Level 2.

APPENDIX D CONSIDERATIONS IN DETERMINATION OF CONTROL SYSTEM IMPACT RATINGS

D-1 BACKGROUND

This appendix discusses methods for determining the cybersecurity impact rating for a building control system. A system is categorized based on an evaluation of the impact associated with the loss of confidentiality (C), integrity (I), or availability (A) (generally written as CIA) in organizational operations, organizational assets, or individuals. The system impact is categorized as high, moderate, or low. This is sometimes referred to as either the CIA level, CIA value, impact level, or security category. Where this categorization is not provided by the system owner (SO) or authorizing official (AO), the procedures in this appendix may be used to determine interim categorization values to allow the design process to move forward. These values cannot be assumed to be the values that will be used for authorization.

Before defining the system categorization, it is important to understand what is meant by a loss of confidentiality, integrity, or availability, and what is meant by a high, moderate and low impact.

D-1.1 Types of Security Breach

The RMF considers three types of security breaches:

- Loss of Confidentiality. Information within the system is leaked to the outside.
- Loss of Integrity. Information in the system is subject to unauthorized modification.
- Loss of Availability. The system (or information in the system) is unavailable.

D-1.2 Impact Ratings

The RMF categorizes systems as LOW, MODERATE, or HIGH based on the potential impact of a security breach. The DoD definitions for LOW, MODERATE, and HIGH impact are given in FIPS-199 (Federal Information Processing Standards) as modified in CNSSI-1253. (CNSSI adds the phrase “exceeding mission expectations” to each definition):

D-1.2.1 LOW Impact Definition

The potential impact is LOW if the loss of confidentiality, integrity, or availability could be expected to have a limited adverse effect on organizational operations, organizational assets, or individuals.

AMPLIFICATION: A limited adverse effect means that, for example, the loss of confidentiality, integrity, or availability might (i) cause a degradation in mission capability to an extent and duration that the organization is able to perform its primary functions, but the effectiveness of the functions is noticeably reduced; (ii) result in minor damage to organizational assets; (iii) result in mi-nor financial loss; or (iv) result in minor harm to individuals [exceeding mission expectations].

D-1.2.2 MODERATE Impact Definition

The potential impact is MODERATE if the loss of confidentiality, integrity, or availability could be expected to have a serious adverse effect on organizational operations, organizational assets, or individuals.

AMPLIFICATION: A serious adverse effect means that, for example, the loss of confidentiality, integrity, or availability might (i) cause a significant degradation in mission capability to an extent and duration that the organization is able to perform its primary functions, but the effectiveness of the functions is significantly reduced; (ii) result in significant damage to organizational assets; (iii) result in significant financial loss; or (iv) result in significant harm to individuals that does not involve loss of life or serious life-threatening injuries [exceeding mission expectations].

D-1.2.3 HIGH Impact Definition

The potential impact is HIGH if the loss of confidentiality, integrity, or availability could be expected to have a severe or catastrophic adverse effect on organizational operations, organizational assets, or individuals.

AMPLIFICATION: A severe or catastrophic adverse effect means that, for example, the loss of confidentiality, integrity, or availability might (i) cause a severe degradation in or loss of mission capability to an extent and duration that the organization is not able to perform one or more of its primary functions; (ii) result in major damage to organizational assets; (iii) result in major financial loss; or (iv) result in severe or catastrophic harm to individuals involving loss of life or serious life-threatening injuries [exceeding mission expectations.]

D-2 SYSTEM CATEGORIZATION AND DETERMINATION OF IMPACT RATING

Step 1 of the RMF requires categorizing the system in accordance with Committee on National Security Systems Instruction (CNSSI) 1253. This instruction describes how the CIA impact level is determined by the type of information on the system and mission criticality of the system. Rationales for system categorization will be required and may be supported by four approaches (listed in order of preference):

1. Compare to Similar Systems. This is probably the most defensible and easiest approach; is the project similar to an existing project with established categorization values?
2. Methodical System Review. This is a “common sense” approach to determining impact ratings based on the mission and the relationship the control system has to the mission.

3. Office of the Assistant Secretary of Defense for Sustainment (Energy, Installations and Environment) FRCS Master List (https://www.acq.osd.mil/eie/IE/FEP_CSC.html).This list includes “starting point” CIA impact ratings by control system type for three mission criticalities. The values here have generally (and more specifically for Utility Monitoring and Control System (UMCS), BCS, and UCS) been determined through an application of the “common sense” methodical process defined here.
4. National Institute of Standards and Technology (NIST) Guidance. This is the “proper formal way” to determine impact ratings but is not easily applicable to control systems. In practice, the approach used is to determine CIA using another approach first and then to confirm/document that impact rating determination using the NIST guidance.

D-2.1 Compare to Similar to Systems

At many sites, the project will be similar to existing control systems in similar mission space. It may be possible to simply determine what categorization values were used in the other project and assume those same values in the current project. Note that “similar” in this context must include the following elements (in order from most to least important):

- The other project should have the same organizational AO. Since acceptance of risk is subjective, it is vital to have the same organization accepting the risk.
- The other project must have a control system supporting a mission with a similar impact of the mission itself. Note: this has nothing to do with the control system, it is the criticality of the mission itself. Even if the mechanical systems were identical, a project supporting a mission of “processing real-time battlefield intelligence” cannot be compared to a project supporting a mission of “providing recreational facilities to soldiers.”
- The other project must have a similar dependency between the control system and mission. The key question here is “if the control system fails, how much impact is there on the mission?”

If there is a similar project that can be referenced, then a reasonable assumption is that “similar projects will have similar C-I-A impact categorization values”.

D-2.2 Methodical System Review

In almost all cases, loss of confidentiality of the information in the control system is of little or no consequence (even when it is, it is generally much less important than integrity or availability) and the impact of the control system is primarily due to loss of integrity or availability. Loss of integrity or availability relates to how these losses may impact the mission supported by the specific facility-related control system (FRCS). Determination of impact for the control system is typically a two-step process:

- What is the impact of the mission? Will loss of the mission result in a LOW, MODERATE, or HIGH impact?
- How much will a loss of (integrity or availability of) HVAC controls impact the mission?

This process will provide a rational (“common sense”) starting point for determining criticality of an FRCS to use during design but is not official policy. Ultimately, system criticality is determined by the AO (in coordination with the SO and based on input from the designer of the control system).

D-2.2.1 Impact of the HVAC Control System

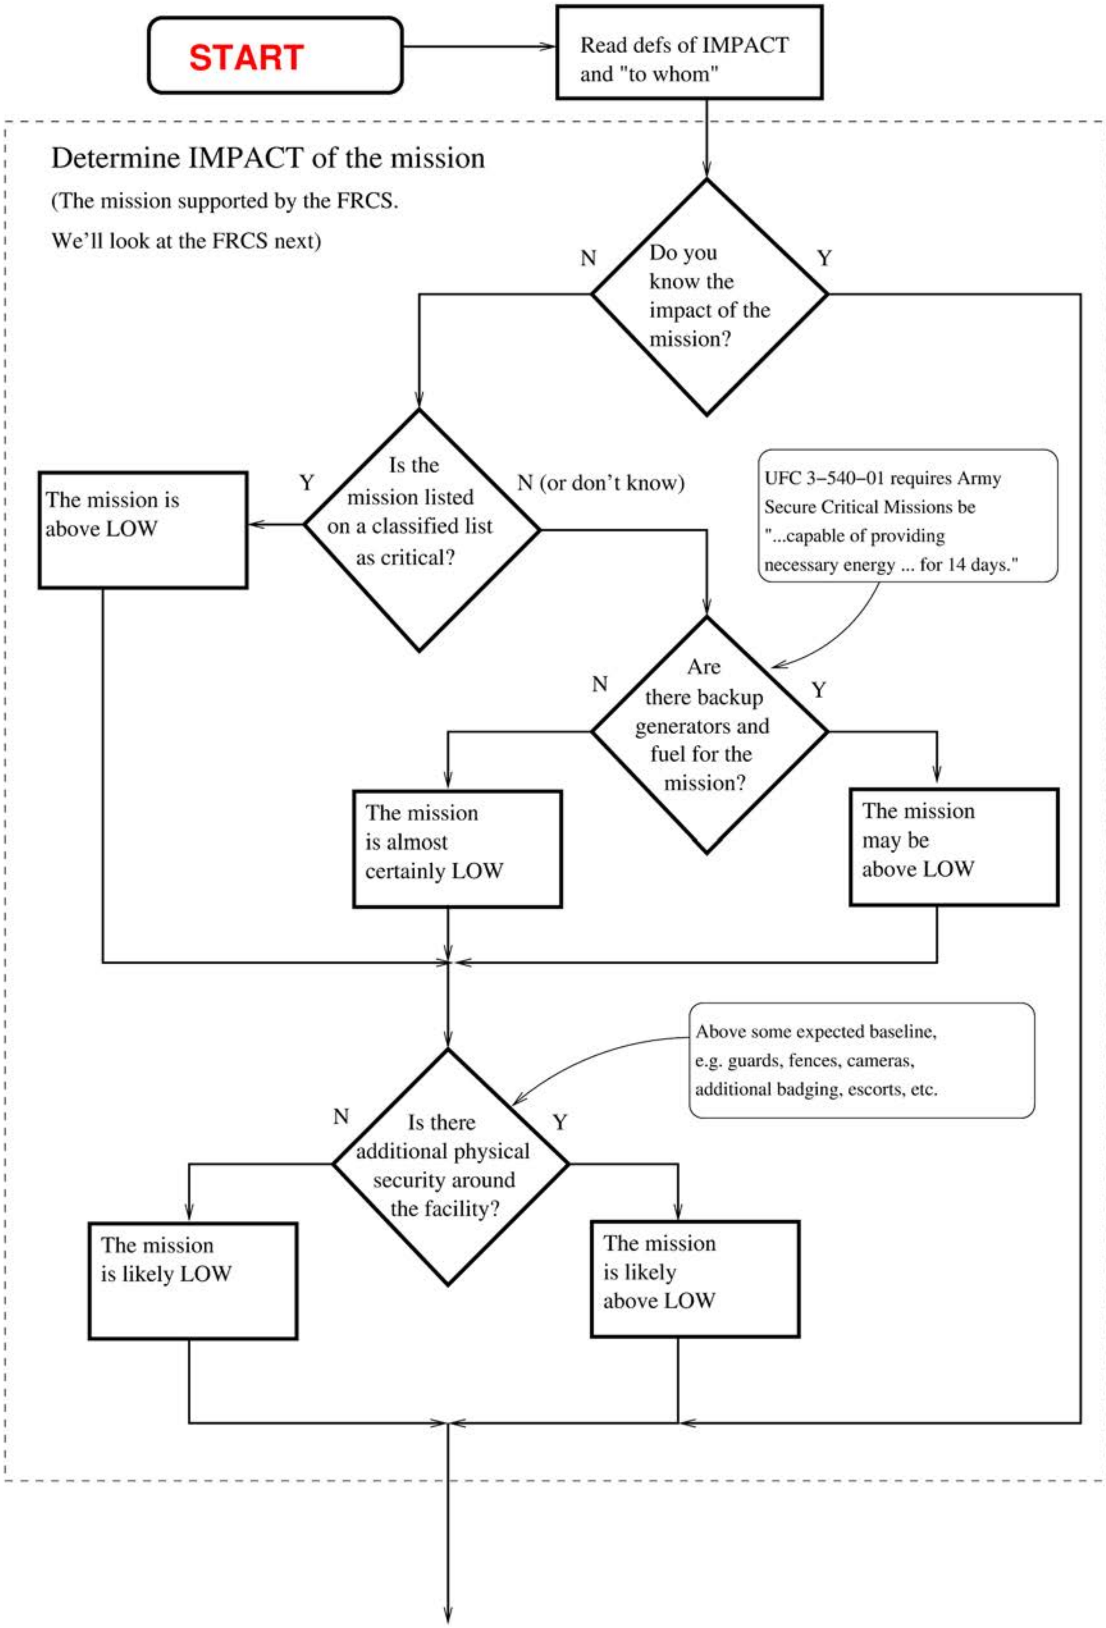
D-2.2.1.1 Mission Impact

Ideally, the AO, SO, or mission tenant will identify the mission impact, but this is often not feasible (mission tenants may not in fact know and frequently overstate their own importance). In cases where the mission impact is not known, or when the claimed mission impact seems exaggerated and confirmation is desired, the flow chart in Figure D-1, Figure D-2, and Figure D-3 may be helpful. The flowchart assumes that availability and integrity have the same impact rating and disregards confidentiality. (Although this is a single flowchart, it has been broken out across three figures to facilitate discussion of the flowchart).

The first part of the flowchart, Figure D-1, deals with the determination of the impact of the mission itself. This chart relies on three observations:

1. Critical mission facilities are often on a (classified) list of critical facilities.
2. Critical mission facilities generally have a requirement for local backup generators. UFC 3-540-01, Engine-Driven Generator Systems for Prime and Standby Power Applications requires that “For Army Secure Critical Missions, the Army will reduce the risk by being capable of providing necessary energy and water for 14 days.”
3. Critical mission facilities generally have a requirement for physical security above and beyond what is typical on the installation. Note that this is not definitive: child development centers typically have additional security but might not be considered mission critical. These security measures might include such things as additional fencing, cameras, security guards, additional badging, or requirements for escorts inside the facility. When electrical and mechanical infrastructure is outside the facility (for example, a diesel generator), there is typically a security fence surrounding the facility and the electrical and mechanical infrastructure.

**Figure D-1 - FRCS Impact Determination Flowchart Part 1
Determining Mission Impact**



D-2.2.1.2 Impact of Control System on Mission

Once the impact of the mission is known, the impact of the FRCS on the mission is evaluated. The flowchart continues in Figure D-2 and Figure D-3 and considers the relationship between the FRCS, the underlying equipment, and the mission itself:

- A key consideration is whether the mission depends on the equipment controlled by the FRCS. A computer server room is clearly dependent on continuous cooling for operation, while an outdoor training area is clearly not. Other related considerations are:
    - How long the mission can function before a loss of the controlled equipment will cause a mission failure. For example, a computer server room might fail completely if it loses cooling for 30 minutes, while an office environment (even one performing a critical function) might continue to function for hours before their mission was impacted and may be able to carry on indefinitely (with some reduced efficiency) without completely failing at their mission.
    - The extent that the controlled equipment relies on the FRCS for operation. For example, a lighting system controlled by an occupancy sensor that also has a manual ON/OFF switch relies very little on the occupancy sensor for meeting mission goals.

The next several considerations address the equipment controlled by the FRCS and the ability of site personnel to operate the underlying equipment after a control's failure.

- If the equipment controlled by the FRCS is critical, it likely requires the same level of backup power as the supported mission, which normally means local backup power generation.
- If the equipment controlled by the FRCS is critical, there will likely be redundant equipment to allow for failure (such as mechanical failure) of a piece of equipment (such as a broken belt or burned out bearing).
- If local controls are available that will allow staff (either installation operations and maintenance [O&M] staff or adequately trained mission staff) to restore operation of the equipment before the mission fails. Note that these manual controls might lead to reduced energy efficiency, but the key point is that the mission can continue with minimal disruption.
- The ability of O&M staff to repair or restore system operation before the mission fails due to the loss of the systems must be considered, as this ability to repair before failure is a mitigation that would lower the FRCS Impact level.
- The Integrity and Availability impact of the FRCS controls cannot exceed the supported mission impact. However, in cases where confidentiality is important, the Confidentiality impact rating of the FRCS impact may exceed the mission impact.

**Figure D-2 - FRCS Impact Determination Flowchart Part 2a
Determining FRCS Impact Based on Mission Impact**

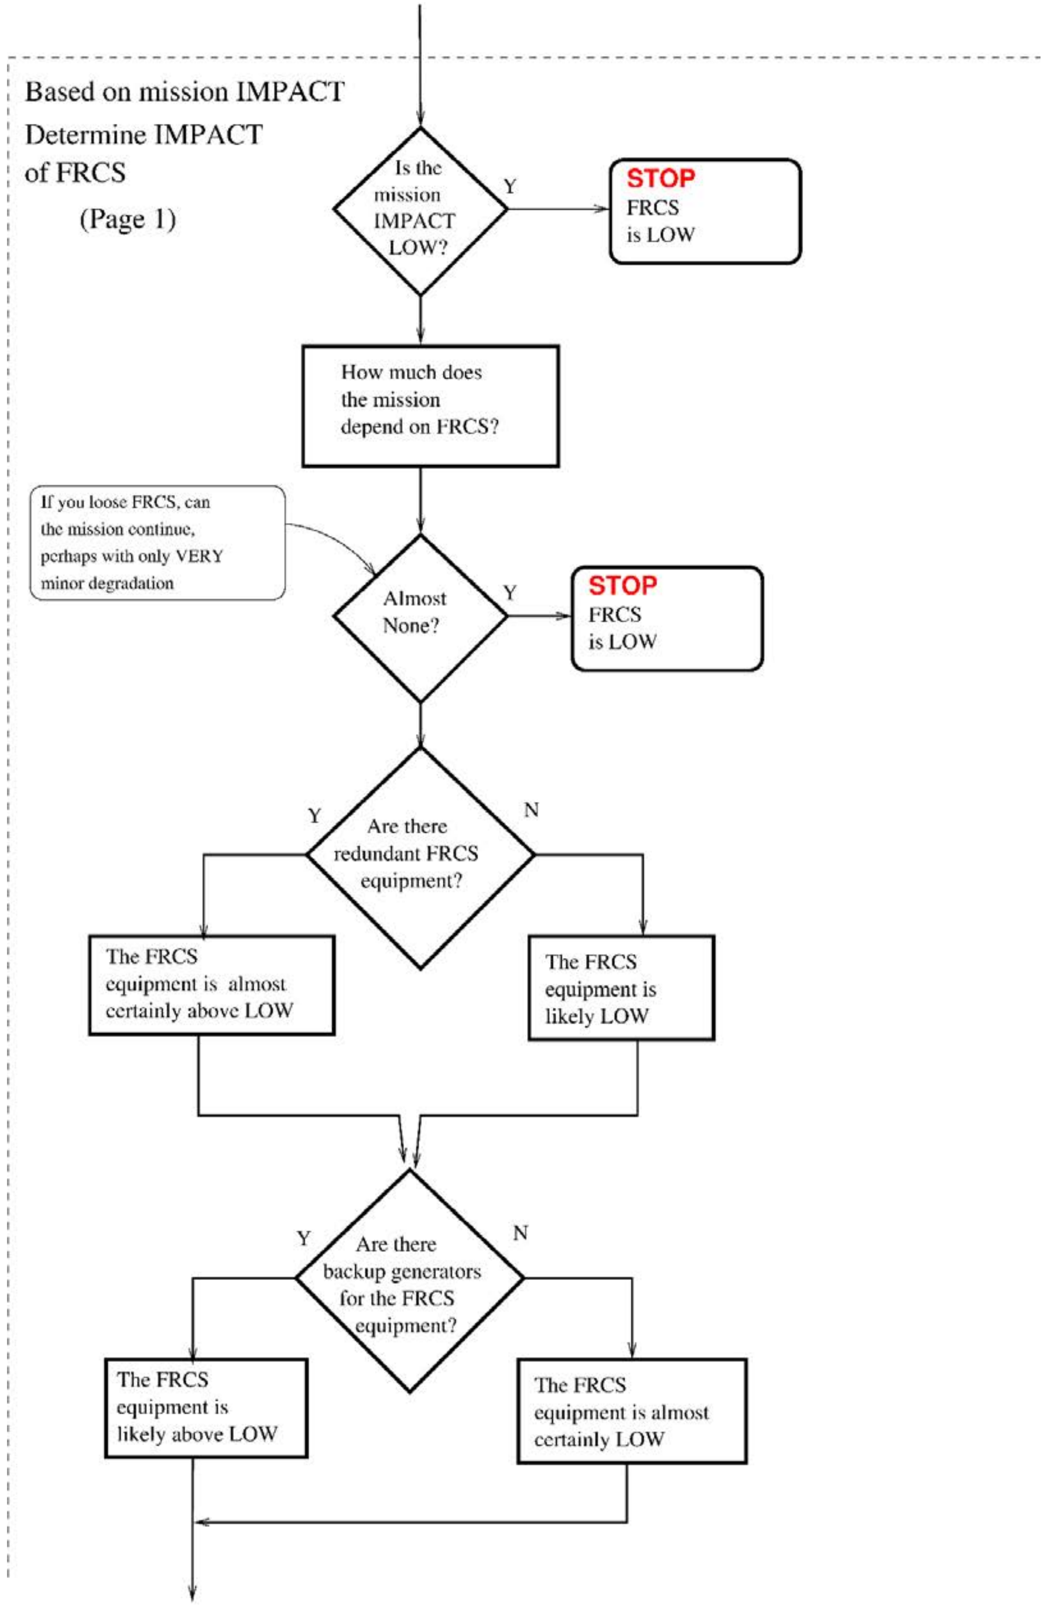


Figure D-3 - FRCS Impact Determination Flowchart Part 2b Determining FRCS Impact Based on Mission Impact.

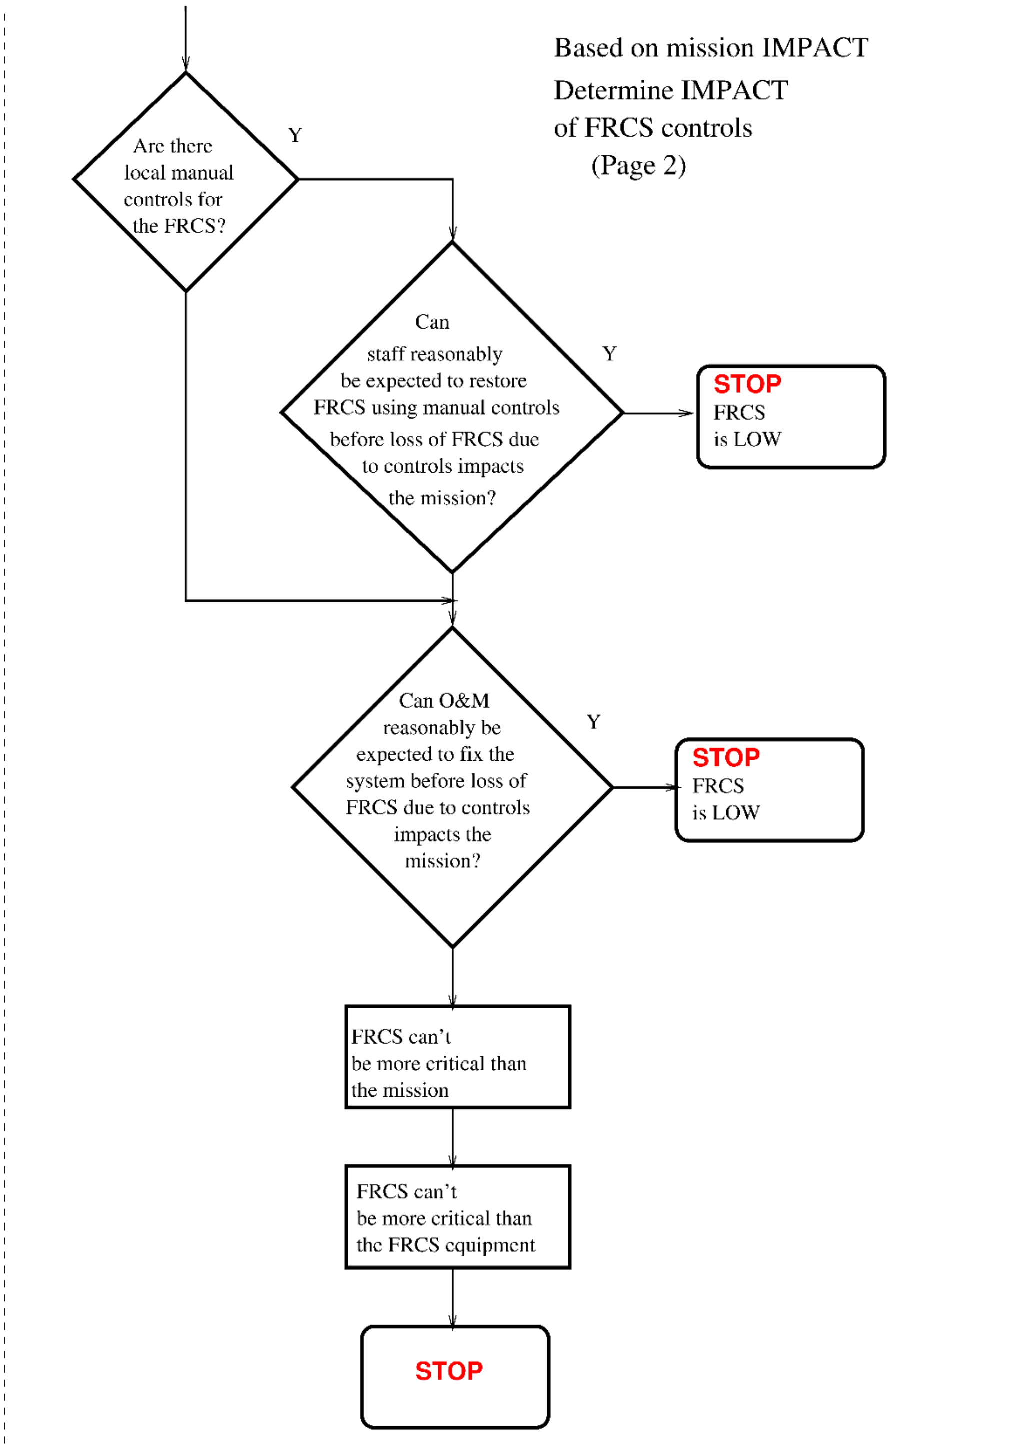


D-2.2.2 Addressing the critical control system and reducing system criticality

Several options for addressing a critical FRCS (and possibly reducing its criticality) are suggested by the above drawing and are described in CHAPTER 4, such as the addition of manual controls, the use of local front ends or local display panels, and redundant equipment with independent control systems.

If the standalone system approach is used, this might mean that the standalone system cannot be monitored by the primary systems. Multiple strategies are discussed in APPENDIX E to allow for a lower-impact system to monitor a higher-impact system.

D-2.3 System categorization based on Facility-Related Control Systems (FRCS) Master List

The Facility-Related Control Systems (FRCS) Master List available on the Office of the Assistant Secretary of Defense for Sustainment FRCS Cybersecurity Website (https://www.acq.osd.mil/eie/IE/FEP_CSC.html), provides preliminary impacts dependent on supported mission criticality.

D-2.3.1 Supported Facility Criticality

The Master List uses three categories of mission criticality into which the facility or mission the system supports will fall. The DoDI 5000.02 defines them as:

- Mission Support. Not designated as mission essential or critical
- Mission Essential. “is basic and necessary for the accomplishment of the organizational mission. (designated by the DoD Component head)”
- Mission Critical. “the loss of which would cause the stoppage of warfighter operations or direct mission support of warfighter operations. (designated by the DoD Component head)”

Assuming that the mission is heavily dependent on the FRCS, then the CIA values under the mission criticality for the facility or mission can be used as preliminary CIA values for the FRCS. Figure D-4 shows an excerpt of the Master List for UMCS.

**Figure D-4 – Example FRCS Master List Entry
UMCS Categorization Based on Mission Criticality**

FRCS Type and Description	Preliminary Baseline C-I-A								
	Mission Support			Mission Essential			Mission Critical		
System Name	C	I	A	C	I	A	C	I	A
Utility Monitoring and Control System (UMCS)	L	L	L	L	L	L	L	M	M

* C=confidentiality, I = integrity, A=availability** L=low, M=medium, H-high

Note that the CIA values for mission essential or mission critical facilities should be lower than shown on the "Master List" if the mission does not depend heavily on the FRCS.

Note also that the Baseline C-I-A values from the Master List are not policy, rather they are guidance in helping one determine categorization. The focus on determining categorization is in the following instructions on the National Institute of Standards and Technology (NIST) Special Publication (SP) 800-60 (NIST 2008). For example, one may have a physical access control system that does not rise to the suggested CIA impact categorization of MMH (for moderate confidentiality, moderate integrity, and high availability impact) as depicted in the "Master List." Follow the next section and provide a clear concise categorization rationalization.

D-2.4 NIST SP 800-60, Vol. II -Rev. 1, Information Types

NIST SP 800-60, Vol. II, Appendices to Guide for Mapping Types of Information and Information System to Security Categories (NIST 2008) is the authoritative document to help SOs determine the CIA values for the information processing types of their systems.

NIST SP 800-60, Table D-1, "Mission-Based Information Types and Delivery Mechanisms Mission Areas and Information Types" lists information type. (NIST 2008).

While many system types are not an ideal match to the systems listed in Table D-1, UMCSs (and HVAC, electrical, and lighting systems) will most likely fall into information systems described in Section D.7, "Energy." The information types in D.7 are

- Energy Supply
- Energy Conservation and Preparedness (common information type for an Army UMCS)
- Energy Resource Management
- Energy Production

NIST SP 800-60, Table D-2 (shown in Figure D-5) lists the anticipated CIA categorization for each of the above types. Note that UMCSs fall in the energy conservation and preparedness information type and have a baseline CIA level of low-low-low.

Figure D-5 – Example FRCS Master List Entry
UMCS Categorization Based on Mission Criticality

Information Type	Confidentiality	Integrity	Availability
Energy Supply	Low	Moderate	Moderate
Energy Conservation and Preparedness (includes UMCS)	Low	Low	Low
Energy Resource Management (does not include UMCS)	Moderate	Low	Low
Energy Production	Low	Low	Low

This is still not enough information for you to appropriately justify your CIA categorization. Go to NIST SP 800-60 section D.7 “Energy” and review the definitions of the four types of energy (as listed above) and determine what best fits the system. Select all information types that are applicable to your system. Make sure you look at the definitions of confidentiality, integrity, and availability and any special factors that could elevate the baseline CIA.

D-2.5 Summary and required categorization rationale

Where applicable, the best approach is likely “compare to similar systems.” If that is not an option, the best approach may be to use the “methodical system review” approach to determine impact level, then select (if there is a plausible fit) the system type from NIST SP 800-60 to defend the decision.

This Page Intentionally Left Blank

APPENDIX E CYBERSECURITY CONSIDERATIONS FOR INTEGRATING CRITICAL UTILITY OR BUILDING CONTROL SYSTEMS WITH NON-CRITICAL UMCS

NOTE: This appendix applies to Utility Control Systems (UCS) and Building Control Systems (BCS). For the purpose of this Appendix, the term Field Control Systems (FCS) is used to refer to both UCS and BCS, but not necessarily to other Field Control System (FCS) types.

E-1 INTRODUCTION

In those cases where a Building Control System (BCS) or Utility Control System (UCS) contains classified information, controls critical infrastructure, or otherwise supports critical missions or life safety, the FCS is a critical system. While some of the requirements for securing the FCS are covered in the list of CCIs to be applied to a MODERATE or HIGH system, there are issues specifically related to critical systems on a typical installation where the preponderance of systems is non-critical.

There are three main approaches to address the connection of a critical FCS to a UMCS:

1. **Secure the UMCS at the same Impact level as the FCS**. Conceptually, this is the most straightforward approach, but it requires the UMCS Front End to be addressed at the higher Impact level and requires special consideration all other connected FCS which are not at the higher impact level (and are therefore connecting to a higher impact system). A typical DoD installation will have many more non-critical FCS than critical FCS, so this approach will often prove to be impractical, particularly when connecting a lower impact FCS to a higher impact UMCS Front End is difficult. This approach is the preferred solution for the Navy, and the Navy has identified an approach to connect the lower impact systems without requiring them to be assessed at the higher impact level.

2. **Implement a stand-alone UMCS for the FCS.** In this case, the FCS is part of a dedicated local critical UMCS which is not connected to the UMCS serving the larger installation. This approach eliminates the risk of connection to a less critical system, but requires that the critical UMCS function independently, with its own dedicated UMCS operators. It also removes the ability to remotely monitor the critical system.

   In many cases this approach is logistically infeasible to sustain and must be carefully considered before implementing. Facility operation and maintenance staff must be willing and able to operate the stand-alone facility for this approach to work.

3. **Provide a secure connection between the critical FCS and a non-critical UMCS**. This approach connects the critical FCS to the installation-wide UMCS in a way that does not increase the impact level of the UMCS. While this connection requires a great deal of planning and

care, it can provide a more practical means of connecting the critical FCS than either implementing a stand-alone UMCS or raising the Impact level of the installation-wide UMCS.

This approach provides a security separation between the FCS and UMCS and is the preferred approach for the Army.

This Appendix presents design considerations specifically for connecting critical building control systems to a non-critical UMCS as described in approach 3. Considerations for the implementation of approach 1 or 2 are NOT addressed herein. While the considerations in this Appendix may be applicable to other control systems, particularly other building control systems or utility control systems, they are discussed here within the context of a Heating, Ventilation and Air Conditioning (HVAC) Building Control System.

E-2 LIMIT OUTSIDE FUNCTIONALITY

The key concept in connecting a critical FCS to a non-critical UMCS is limiting the ability of the UMCS to affect the FCS. The interactions between the FCS and UMCS should be specific and well-defined, and restricted to those required for system operation. In general, this will entail information from the FCS being sent to the UMCS for monitoring while greatly restricting or even eliminating information from the UMCS being sent to the FCS for control purposes. For example, a critical FCS may send status and alarm information to the non-critical UMCS but should not be receiving start/stop commands from the UMCS as this introduces vulnerabilities to the critical system. Operator changes to the critical FCS should always be carefully considered – by an operator in the zone, with ***full awareness of their actions and understanding of the impact of their actions***.

E-3 FCS-UMCS CONNECTION METHODS

Limiting ***possible*** actions is a very difficult requirement for networked controllers; in many cases the aggressor can connect their laptop to the UMCS network and download a new program to a device in the critical FCS. This is not to trivialize the significant barriers preventing this action, but by assumption, the UMCS is not sufficiently secured to protect the FCS, so it must be assumed that this action is possible and guard against it. This is similar to the additional physical security usually protecting a critical facility. Even though there are barriers limiting access to the installation in general, the assumption is that an aggressor can get access to the installation and critical facilities have additional physical security to further limit access.

There are three primary methods which can be employed to provide a secure connection between a critical FCS and a non-critical UMCS: a Hardware I/O interface, Hardware Gateway, and Network Firewall. Of these three, the recommended approach for critical FCS is the use of the Hardware I/O interface.

E-3.1 Hardware I/O Interface

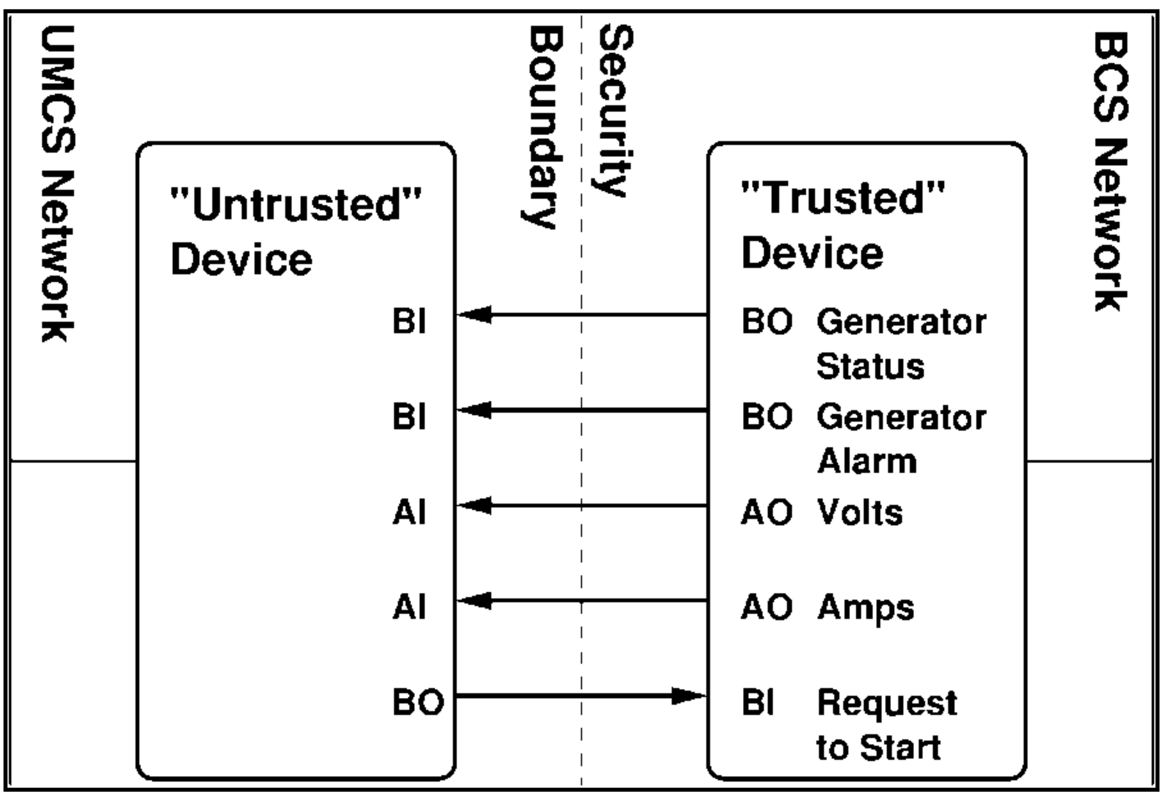
The most secure method to connect an FCS to a UMCS is to share data across the boundary using only analog and binary signals. Do ***not*** connect the FCS to the UMCS via a network. Using hardware I/O prevents an aggressor from “piggybacking” an unwanted command onto the interface as the information exchange is defined and restricted by the hardware connections. Even if an aggressor controls the untrusted device, the trusted device can only receive the commands that it has been designed and constructed to receive.

E-3.1.1 Hardware I/O Interface Overview

A Hardware I/O Interface consists of two controllers which share information between systems via binary or analog I/O, typically using dry contacts, 4-20mA signals or 0-10V signals.

Figure E-1 illustrates a Hardware I/O Interface where a generator serving a critical facility provides a few key monitoring points to a UMCS, and receives a control point, "Request to Start" from the UMCS. It’s important that this point is only a ***Request*** for the system to start, and that the actual decision of whether the generator will start or stop ***must*** be made by the critical FCS.

Figure E-1 Hardware I/O Interface Example



E-3.1.2 Hardware I/O Interface Implementation

Implementing a Hardware I/O Interface requires controllers on the FCS and UMCS with matching hardware points. An aggressor could apply excessive voltages to the I/O lines and physically damage the controller on the FCS side. To mitigate this vulnerability, either:

- Use a controller dedicated to the communication interface and performing no other functions on the FCS side so that damage to it doesn’t impact the control system.

  or

- Provide optical isolation of the analog and binary signals between the devices.

The controller on the UMCS side of the connection may be on a controller which performs other functions as the concern is exposing the more critical FCS to risk from the UMCS, and not the other direction. While the controller on the UMCS side is logically part of the UMCS (a "hardware I/O gateway"), procurement and installation may be simpler if it is furnished and installed by the FCS contractor.

E-3.1.3 Hardware I/O Interface Advantages and Disadvantages

This method is by far the most secure method of communication between the FCS and UMCS, as there is nothing an aggressor can do to the untrusted device that impairs the critical system. The potential disadvantage of this approach is the additional cost in the procurement and installation of two additional hardware I/O points each monitoring and/or control point. Depending on the amount and complexity of data being shared this may or may not be more costly than other approaches.

This approach is also conceptually the easiest to implement and requires no particular cybersecurity expertise skill, other than careful attention to limiting control points.

E-3.2 Hardware Gateway Interface

A Hardware Gateway is another means of connecting a critical FCS to a non-critical UMCS. While not as secure as a Hardware I/O Interface, it will be much more cost-effective if there is a large amount of data to exchange between the FCS and UMCS.

E-3.2.1 Hardware Gateway Overview

In this context, a gateway is a device with a connection to the UMCS network and a ***separate*** connection to the FCS network that does not pass network traffic between the two connections (i.e., it does not route packets between the two networks). Instead, information from one network is received by the gateway, processed by the gateway and then identical information is transmitted on the other network. While in theory the UMCS and FCS could both use the same protocol (like BACnet), in practice it may be difficult to find a gateway using the same protocol on “both sides” that is sufficiently secure, as typical designs would use the same connection for matching protocols.

E-3.2.2 Hardware Gateway Implementation

The key requirements for implementing a secure gateway are:

- The gateway must provide complete isolation / separation between the UMCS network and FCS network. This requires 2 separate network connections and may be difficult to meet if the FCS and UMCS protocols are the same.
- The gateway must not be able to be programmed, configured, or otherwise modified from the UMCS network. Since the gateway can likely be configured over the “primary” network, this requirement may be difficult to achieve if the UMCS and FCS protocols are the same. If both use the same protocol, the gateway is more likely to be configurable from both the UMCS and FCS. The configuration capability depends on the actual implementation of the gateway, so care must be taken to specify that the Gateway is not configurable from the UMCS network.
- The gateway must be configured to only expose those points absolutely necessary for the UMCS.

The gateway is part of the FCS and should be installed by the FCS contractor.

E-3.2.3 Hardware Gateway Advantages and Disadvantages

The main security concern with the gateway (assuming the above requirements are met) is security flaws in the gateway implementation. Just as a web server may have a flaw which allows an aggressor to take control of the server, a gateway may have an implementation flaw which would allow control of the gateway; once in control of the gateway, the aggressor could reconfigure the gateway to attack the FCS itself.

The gateway may provide a cost-effective alternative to the use of Hardware I/O points for systems with a requirement to share many points, and the cost of the gateway is not as dependent on the number of points as the Hardware I/O Interface.

E-3.3 Firewall Interface

The third option for securing a network connection between the UMCS and FCS is to allow a network connection but use a firewall to selectively block traffic between the two networks. The firewall requires a network connection and is therefore only applicable when the UMCS and FCS use the same protocol.

E-3.3.1 Firewall Interface Overview

Unlike a gateway where there is no network connection between the two networks and the gateway explicitly transmits information from one to the other, with the firewall the two networks are connected, and the firewall selectively limits the traffic allowed between the two. This inherently makes the firewall less secure than the gateway.

E-3.3.2 Firewall Interface Implementation

The key requirements for a secure firewall are:

- The firewall can only be programmed from within the critical facility. This is usually not a difficult requirement to meet because as security appliances, firewalls are designed with a "secure" side and an "insecure" side.
- Unlike traditional IT firewalls, the firewall must be able to filter traffic based on the detailed information in the packet. While a standard firewall can limit traffic based on IP address and TCP/UDP port and might block all traffic except that going to or from the UMCS server, the control system firewall must also be able to block all but specific commands. In addition to blocking all traffic except to/from the UMCS front end server, it might also block all traffic except for very specific messages – such as a BACnet ReadProperty requests for specific point values. This requires a firewall that understands the specific control protocol (BACnet in this case) and can selectively block traffic based on the specific message.

E-3.3.3 Firewall Interface Pros and Cons

The main implementation problem with a firewall is the lack of availability of a firewall that can decode control protocol packets and selectively filter based on the message. One advantage of the firewall over the gateway is that the firewall is designed for security and is less likely to have an implementation flaw than the gateway, which is typically not designed as a security device.

E-3.4 Data Diodes

Data diodes provide a physically-enforced, one-way data flow which can be used for the monitoring of control systems. This technology was until recently very expensive and geared more toward IT applications, but data diodes by multiple providers are coming down in price and some even have legacy RS-485 (screw terminal) connections to bring older equipment into a modern, connected architecture.

E-3.4.1 Methods of Isolation

Most data diodes provide isolation by (both of) the following two methods:

- Optical isolation. While inputs and outputs are via electrical signals, information is passed between the inputs and outputs via light (usually an LED and a photodetector). This isolation prevents electrical surges coming in from outside from causing damage to the inside network.

- Uni-directional transmission: Signals and information can only pass from inside to outside, there is no capability for information to come in from outside.

E-3.4.2 Data Diode Protocol Challenges

Uni-directional transmission can create problems for many protocols which use acknowledged transmissions. Consider the difference between regular email and email with acknowledgement or read receipt. In many cases, it's important to know that the information was received by the recipient, but that requires the ability to send a response message back to the sender; by definition the data diode blocks any sort of return message. For some protocols, this can be a showstopper; the protocol itself uses acknowledged transmissions. While all data diodes have hardware to copy the input to the output, data diodes supporting these protocols must "understand" these protocols and incorporate additional hardware to support them.

Consider a case where device A, an "inside" device, wants to send data to device B, an "outside" device, using an acknowledged send.

- Initially, device A sends the data to the data diode. The "inside" side of the data diode does two things:
    - Send the information across the optical isolator to the "outside" side of the diode
    - Uses additional hardware to generate an acknowledgement message to send back to device A.
- The "outside" side of the data diode then forwards the data on to device B and (if the message is received) gets an acknowledgement back from device B.

While this process can support protocols that use acknowledged transmissions, note that the overall message is not acknowledged – device A device received an acknowledgement from the data diode, but there's no knowledge of whether device B ever received the message. (While device B sends an acknowledgement back to the data diode, there's no capability to do anything based on the receipt, or lack thereof. The data diode cannot tell device A whether or not device B ever got the message.)

E-3.4.3 Data Diode Pros and Cons

Some pros and cons of data diodes are:

- If used with protocols that use acknowledged transmissions, the data diode must understand the protocol well enough to be able to reproduce the acknowledgements.
- There is no actual indication of end-to-end success of the transmission, and it may be desirable to send the information multiple times to ensure success.
- Unlike the simple hardware I/O interface, the data diode can easily move large amounts of data rapidly across the security boundary.
- Unlike the hardware I/O interface, the data diode cannot send any information in from outside. If there is a need to send in carefully

proscribed information (e.g., “Request Generator Start”), then the hardware I/O interface is likely the only viable solution.

E-4 OTHER CONSIDERATIONS

E-4.1 Local User Interfaces

Critical systems should be provided with additional local User Interfaces to allow maintenance personnel inside the secure area access to control data to allow for troubleshooting. Liberal use of local display panels is strongly recommended. For larger critical systems, it might be desirable to provide a more functional interface than normally obtainable via LDPs, such as an independent UMCS front end or a web interface appliance. For the largest or most critical systems, consideration should be given to installing a full-featured UMCS as specified in UFGS 25 10 10. This UMCS should be dedicated to the FCS (such as a Level 2D front end) and should reside fully within the physical security footprint of the critical systems.

E-4.2 Management of Risk

It must always be remembered that there is no perfect solution for cybersecurity for control systems. Cybersecurity experts often say, “there is no such thing as an air gap”. While it may be more accurate to say, “there are always ways to go around the air gap”, the intent remains – a determined aggressor will always find a way around, over, or through the protections put in place. The goal in the design of cybersecurity of control systems, and critical control systems in particular, is to do whatever is practical to make this as hard as possible.

APPENDIX F IMPLEMENTATION GUIDANCE FOR SECURITY CONTROLS

F-1 INTRODUCTION

This Appendix contains guidance on the implementation of security controls for control systems. The focus of this guidance is on LOW and MODERATE impact systems (L-L-L or M-M-M C-I-A Impact rating) which are being fielded on a DoD installation, particularly building control systems and utility monitoring and control systems. The CCI tables in APPENDIX G provide specific breakout of responsibilities by security control and CCI. The notes in this appendix supplement those CCI tables. Where these notes refer to the UFGS, it is UFGS 25 05 11, Cybersecurity for Facility-Related Control Systems.

F-2 GENERAL GUIDANCE

F-2.1 Control System versus Standard IT System Terminology

Security controls and CCIs were written for traditional IT systems, and many contain terminology and requirements that are confusing and conflicting when applied to a control system. For example, “incident” as used in the IR family of security controls includes all incidents – a broken fan belt is an “incident”, but “flaw” as used in security control SI-2 only covers security flaws, not operational flaws – an inaccurate sensor is not a “flaw”.

In most cases, the notes below will help make the application of the security control to a control system clear. In other cases NIST SP 800-53 should be consulted as it contains the best definition of the security controls as well as “Supplemental Guidance” that can assist in the interpretation and application of the CCI to a control system. NIST SP 800-82 (section 6.2 of revision 2) also has general information on the security control families, as well as guidance on the application of the security controls to Industrial Control Systems, which are a subset of control systems and have similar characteristics to facility-related control systems.

F-2.2 DoD-Defined Values

Many CCIs have DoD defined values of “all employees”, and many CCIs have DoD defined values of “all components” or similar where this level of detail is not appropriate for a LOW impact control system. It will be necessary to re-define (and document) values for CCIs when the DoD-defined values do not make sense for control systems.

F-2.3 Security Controls Which are “Automatically Met”

Some security controls may be “automatic” in the sense that they have already been implemented for another information system or control system. A security control that states “the organization does <something>…” may have already been met as a requirement for a different authorization for a different system.

F-2.4 Security Controls Applicability by Architecture Level

Many security controls may be difficult or impossible to apply below Level 3 for most control systems. Note, however, that some system, Electronic Security Systems (ESS) in particular, may be able to meet many of these security controls below Level 3. For example, an air handler controller (with a user interface) may have only a 4-character password, or no password support at all. A door lock on an ESS may have a CAC reader.

F-2.5 Impact Level Applicability

Only security controls for systems categorized with L-L-L (“LOW impact level”) and M-M-M (“MODERATE impact level”) are addressed by this Appendix and the CCI tables in APPENDIX G. The guidance provided for the baseline security controls is determined by the C-I-A impact level value for the control system:

- L-L-L Baseline Security Controls: Guidance is provided for a system categorized with a LOW impact value. These same security controls are also required for a system determined to have a MODERATE (or HIGH) impact level value, but additional security enhancements and implementation guidance may be required. When applying this guidance to MODERATE (or HIGH) impact systems, evaluate the guidance to determine if it applies or must be modified for the system.
- M-M-M Baseline Security Controls: Guidance is provided for a system categorized with a MODERATE impact value. These security controls aren’t used for LOW impact value systems. The guidance may not be the same for HIGH impact systems (using the same security controls).

The guidance in this Appendix and in the CCI tables in APPENDIX G is primarily targeted to LOW impact systems which are most capable of being addressed in a standard fashion. Care must be taken when extrapolating this guidance to systems with MODERATE or HIGH impact values.

F-3 GUIDANCE FOR INDIVIDUAL SECURITY CONTROLS

F-3.1 Access Control (AC) Control Family

Design guidance for the Access Control (AC) control family is shown in Table F-1

Table F-1 Access Control (AC) Control Family

Security Control ID	Security Control Name and Design Guidance
AC-2	**Account Management**: One significant issue is that many control system field devices cannot support accounts at the level of granularity required by the RMF. The UFGS defines three levels of support: NONE, MINIMAL, and FULL and then provides specific requirements for which devices must provide what level of support for accounts. Specify what account types provide which permissions in the control system (e.g. “view only”, “acknowledge alarms”, “change set-points”, etc.). Note that designer may need to explain these roles to the ISSM / ISSO so they can perform their DoD-defined duties under this control. Note that “accounts” (and particularly “temporary” or “emergency” accounts) likely exist at Level 4 and may or may not exist at Levels 1 or 2, depending on the control system type. (For example, many building control systems won’t have user accounts at these levels, but many utility control systems do). Designer may need to explain lack of “accounts” at Levels 1 and 2. Specifications should require that account activities be audited (logged), but auditing may be limited to software applications, and require notification be supported. Note that notification (e.g. email, rollup to another system) will generally require Platform Enclave or other Level 4 and Level 5 support for actual execution.
AC-3	**Access Enforcement:** AC-3 is met by requiring the contractor to configure any control system component which has a STIG or SRG in accordance with that STIG or SRG”. The UFGS has additional specific requirements for computers and web servers.
AC-4	**Information Flow Enforcement:** Information flow can be regulated by the IT organization at the FPOC. Level 2N devices exist that could be used at Level 2 to regulate flow (but they are not required in the UFGS). Similar Level 1N devices may exist. Include requirements in the specification that the installing contractor document necessary communications (to be used for “whitelisting”). If information flow enforcement at Level 2N is a requirement, include implementation requirements in the specification.

Security Control ID	Security Control Name and Design Guidance
AC-6	**Least Privilege:** Within the control system (as opposed to the Platform Enclave) least privilege should be met by specifications that limit functionality at the front end by user and roles (e.g., some users can only viewpoints, others can change values, etc.). Note the DoD definition of what requires explicit authorization includes (for a control system) everything – up to and including hardware. This may not be practical. Designer would need to ensure implementation via project specification requirements including physical security. Note also that AC-6 (2) requires that control system operators with access to privileged functions (via login to a privileged account) have a separate account when accessing non-privileged functions. This is probably not practical, or desirable for control system applications when considering the role that operators play (where it's impractical to expect an operator to log out and then back in to override a point, for example).
AC-7	**Unsuccessful Logon Attempts**: Note that a requirement for a HIGH availability at the front end may preclude locking out an account for failed login attempts. This control may be impractical below Level 3 and, even at Level 4, may only be implemented by login to the OS as a prerequisite for access to the control system. Designer needs to identify where this can be supported and include requirements in the specification where this is needed. The UFGS groups interfaces by level of account support, then provides different requirements for each group.
AC-8	**System Use Notification:** Login banners must be implemented at user login to government computers – e.g. at the Platform Enclave, Level 4 and Level 2 computers. User interfaces at Levels 0, 1 and 2 (e.g. Local Display Panels (LDP)) generally won't support a login banner. Require login banners where practical according to best industry practice and indicate where implementation is not practical. The UFGS allows for a permanently affixed label.
AC-11 and AC-12	**Session Lock and Session Termination:** The whole notion of a "session" generally only makes sense at a computer (i.e., Level 4) and for the computer these controls should be implemented by the operating system and inherited from the Platform Enclave. At Level 1 and Level 2, devices generally lack user interfaces. Designers should require that devices with user interfaces (e.g. LDPs) be password protected and automatically log out a user after a certain period of inactivity.

Security Control ID	Security Control Name and Design Guidance
AC-14	**Permitted Actions Without Identification or Authentication:** At Level 4, all actions should require authentication to the (Windows) Operating System. User interfaces at Level 1 or 2 should be password protected. Note that this security control is specifically about user actions, not "processes acting for a user". In most cases, this is met by virtue of the user having logged into a computer. Physical security may be required to deny access to devices and equipment and can be implemented at multiple levels through means such as lockable enclosures, tamper switches, room access control, people trap, and paper access logs. Some user interfaces may not sufficiently support authentication and necessary physical security should be considered. When considering physical security of such devices, it is generally not beneficial to secure an interface which is co-located with the controlled equipment without also securing the controlled equipment, as the equipment would remain vulnerable.
AC-17	**Remote Access:** Remote access should be covered by the Platform Enclave (see general notes for AC control family).
AC-18	**Wireless Access:** Wireless at Level 4 should be provided by the appropriate IT organization. Avoid wireless to the greatest extent possible at Levels 1 and 2. Wireless may be considered for retrofits where running wires would be prohibitive, but other technologies (such as powerline carrier) should be considered first. When permitting wireless, require extremely limited range such that signals are not available beyond the necessary ranges. In many cases Authentication and Encryption support will be marginal at Levels 1 and 2.
AC-19	**Access Control for Mobile Devices:** Mobile devices refer to tablets, phones, etc. These are addressed at the Platform Enclave. When permitted they may be used as workstations for browser-based clients or may be restricted to receiving alerts/notifications from the control system.
AC-20	**Use Of External Information Systems:** Connections from External systems, and portable storage, should all be handled at the Platform Enclave.
AC-21	**Collaboration And Information Sharing:** Control systems typically shouldn't share information. Any sharing is handled at the Platform Enclave.
AC-22	**Publicly Accessible Content:** Control systems should not be publicly accessible.

F-3.2 Audit and Accountability (AU) Control Family

Auditing (in the cybersecurity sense) can typically only be performed at Level 4, although some Level 1 or 2 devices may provide limited auditing capability. Designer needs to require auditing where possible and be prepared to justify not auditing where it is simply impractical. Designer may provide input into what can be audited, where it can be audited, and what types of information may be gathered. It might make sense for these controls to be inherited from the Platform Enclave.

Design guidance for controls in the Audit and Accountability (AU) control family is shown in Table F-2.

Table F-2 Audit and Accountability (AU) Control Family

Security Control ID	Security Control Name and Design Guidance
AU-2	**Audit Events:** No additional control-specific guidance. Use general control family guidance preceding this table for this control. The UFGS has extensive discussion of this, but not particularly definitive guidance.
AU-3	**Content Of Audit Records:** Note that this – particularly the “user” portion - may only be possible at Level 4
AU-4	**Audit Storage Capacity:** Long term audit storage will be at a computer at Level 4. Transfer from the control system to long term storage is likely a manual process, or perhaps scripted via by the computer operating system, but it is likely not an inherent feature of the control system. Designer needs to require that control system auditing can be accessed by operating system tools (e.g. control system supports or exports to standard file formats). The UFGS considers the possibility that there may be a separate computer specifically for audit storage and processing (review, analysis, reporting).
AU-5	**Response To Audit Processing Failures:** Notifications and specific actions may only be possible at Level 4.
AU-6	**Audit Review, Analysis, And Reporting:** No additional control-specific guidance. Use general control family guidance preceding this table for this control.
AU-7	**Audit Reduction and Report Generation:** Post-processing of audit logs can typically only be done by external tools at Level 4, but since the tools are specific to the control system audit log format, this will likely need to be met within the control system, not the Platform Enclave.

Security Control ID	Security Control Name and Design Guidance
AU-8	**Time Stamps:** Typically, the timing requirement inherent in the control system will be sufficient.
AU-9	**Protection Of Audit Information:** Can only be done at the Level 4 front end server or another computer. Audit logs must be stored (and protected) there.
AU-11	**Audit Record Retention:** No additional control-specific guidance. Use general control family guidance preceding this table for this control.
AU-12	**Audit Generation:** No additional control-specific guidance. Use general control family guidance preceding this table for this control. For UFGS content, see note on AU-2.

F-3.3 Security Assessment and Authorization (CA) Control Family

Design guidance for controls in the Security Assessment and Authorization (CA) control family is shown in Table F-3.

Table F-3 Security Assessment and Authorization (CA) Control Family

Security Control ID	Security Control Name and Design Guidance
CA-3	**System Interconnections:** Note this is about connections to other systems. These should be documented at the Platform Enclave. Specifications should define a specific protocol. The UFGS has an Interconnection Submittal.
CA-6	**Security Authorization:** The Authorizing Official is a senior-level executive or manager.
CA-9	**Internal System Connections:** The control system is a special purpose system. By design, only necessary connections should be allowed; typically this means use of a single specific protocol with limited capabilities. The specifications, points schedules, and network design document these controls. The UFGS has a submittal requirement if the standard controls submittals are insufficient.

F-3.4 Configuration Management (CM) Control Family

Design guidance for controls in the Configuration Management (CM) control family is shown in Table F-4.

Table F-4 Configuration Management (CM) Control Family

Security Control ID	Security Control Name and Design Guidance
CM-2	**Baseline Configuration:** This control is for a type accredited system. Typical control system contract submittals (drawings, software licenses, programmable controller "source code" etc.) should meet this CCI. Designer should assist in determining which devices are in areas of significant risk, and what additional configurations should be applied to those devices. Note that control systems (supporting fixed facilities) are not mobile.
CM-5	**Access Restrictions for Change:** Much of the control system may be in space outside the organization's control. May only apply at Level 4. See comments on PE Controls.
CM-6	**Configuration Settings:** For the designer, this is largely ensuring that other security design requirements are included in the control system requirements document and that these requirements are verified during control system commissioning. Designer should ensure specifications disable unnecessary ports, protocols, and services. Note that the assumption that the control system is "automatically" compliant because of existing STIGs etc. is completely false below Level 3 and designer may need to provide justification for the control system not meeting the standard checklists. As a control system is designed to have regularly configurable parameters, documentation and approval for all changes to controllers at Levels 1 and 2 is not practical. Significant architectural configuration changes should still be documented and approved. See UFGS comment on CA-9.
CM-7	**Least Functionality:** The control system has a specific purpose (not a general one), and its functions (and limitations) are specified by the control system architecture and protocols. Specifications should require disabling any ports/protocols/services not specifically needed by the control system. Required software should be covered by specification; all other software should be prohibited.

Security Control ID	Security Control Name and Design Guidance
CM-8	**Information System Component Inventory:** Initial configuration is specified by as-built documentation. In most cases automated tools for component inventory below Level 3 do not currently exist for many systems, although new tools may be available for systems in the future and should be implemented once available. See UFGS comment on CA-9.
CM-9 and CM-10	**Configuration Management Plan and Software Usage Restrictions:** Contract documents must require that the software licenses grant the Government the Rights in Technical Data to operate and maintain the systems and use the software as required.

F-3.5 Contingency Planning (CP) Control Family

Design guidance for controls in the Contingency Planning (CP) control family is shown in Table F-5.

Table F-5 Contingency Planning (CP) Control Control Family

Security Control ID	Security Control Name and Design Guidance
CP-2	**Contingency Plan:** Designer should assist in identifying critical control system assets supporting essential missions.
CP-6	**Alternate Storage Site:** For a control system, alternate storage only makes sense for backups and is at the Platform Enclave.
CP-7 and CP-8	**Alternate Processing Site and Telecommunications Services:** A PIT system can have an alternate front end (Level 4) and/or alternate connections from the front end to the lower levels, but you can’t separate the control system from the controlled equipment – whatever site-wide incident disables the AHU controller will also disable the AHU. These controls only apply at the Platform Enclave (Level 4), and, when determining whether to apply them, note that the front end (Level 4) will typically have lower availability requirements than the field controls (Levels 1 and 2). If the requirements are for a redundant control system at the field control system, then redundant controlled equipment and/or redundant tenant spaces should be considered as well.
CP-9	**Information System Backup:** Backups at Level 4 / Platform Enclave only

Security Control ID	Security Control Name and Design Guidance
CP-10	**Information System Recovery and Reconstitution:** Designer should require submittals containing data, documentation and software sufficient to restore the system to its final accepted as-built state. This must include custom programming and configuration for controllers or workstations. The UFGS has a specific submittal requirement.
CP-12	**Safe Mode:** The designer should determine, based on the criticality of the controlled equipment, what conditions to consider and which actions, if any, the control system should take when these conditions are true. This should all be specified in the control logic (e.g. sequence of operations), in particular by addressing normal/failed positions of output devices, and in the overall system design. Where high reliability is required, the analysis should consider the addition of redundant equipment to the design. See also SC-24 and SI-17, and CHAPTER 4.

F-3.6 Identification and Authorization (IA) Control Family

Note that authenticators might be either physical authenticators (CAC cards, tokens, etc.), non-physical ones (such as passwords), or biometrics. While Level 4 (Platform Enclave) may use any of these, most control systems will not support anything other than passwords at Level 2 and below – and even password support may only allow for "weak" passwords (much of IA-5 will not be supported except at Level 4). Therefore, DoD defined requirements may not be appropriate at Level 2 or below. Note that ESS is an exception, ESS will likely support CAC or biometrics - for example a door swipe. Designer should specify where possible to standard/best industry practice and be prepared to defend that decision when it does not meet DoD IT-centric standards.

Design guidance for controls in the Identification and Authorization (IA) control family is shown in Table F-6.

Table F-6 Identification and Authorization (IA) Control Control Family

Security Control ID	Security Control Name and Design Guidance
IA-2	**Identification And Authentication (Organizational Users):** Much of this can only be met at Level 4, and much of it depends on the computer operating system. Designer should provide specifications where possible and be prepared to justify non-implementation in the control system. Whenever possible, require that the control system (for access via a computer) support CAC (or similar) logins. Note that remote access is covered at the Platform Enclave. The UFGS defines these requirements by level of account support.
IA-3	**Device Identification and Authentication:** Much of this can only be met at Level 4, and much of it depends on the computer operating system. Typically, authentication between devices can be implemented between computers (Level 2 and 4) or between network hardware (Level 2, 3 or 4). Authentication may be supported between controllers, where not all controllers will support this capability and it will be more often supported at Level 4 than at Level 2. In general, device authentication between controllers will not be required, for LOW impact system. Even in MODERATE or HIGH, ensure that it can be met before requiring it. Exercise care before requiring non-standard control hardware and software in order to meet this requirement. Designer should provide specifications requiring authentication where possible and be prepared to justify non-implementation in the control system. The UFGS requires (in some cases) use of HTTPS. It also calls for use of 802.1x in some cases, but strongly cautions against it in most cases.
IA-5	**Authenticator Management:** The DoD-defined password complexity values may be impractical for control system components to meet. Specify password complexity at DoD-defined values where practical. The UFGS discusses this and provides some guidance. Require that default passwords be changed from defaults, and that passwords are submitted in a secure manner. For PKI systems, certificate paths should be provided by the Platform Enclave.
IA-6 and IA-7	**Authenticator Feedback and Cryptographic Module Authentication:** Almost certainly Platform Enclave only and not supported below that level. Designer may need to provide input/justification for this. The UFGS discusses the use of feedback and provides guidance in the unlikely case that Cryptographic Modules are required.

Security Control ID	Security Control Name and Design Guidance
IA-8	**Identification And Authentication (Non-Organizational Users):** As this deals with non-organizational users, this control generally doesn't apply to control systems other than some ESS. This may be addressed by the Platform Enclave (via computer login requirements).

F-3.7 Incident Response (IR) Control Family

Note that the definition of "incident" includes non-security related failures. A broken fan belt is an incident, as is a sticking valve, or an out-of-calibration sensor. The designer may need to provide input to the incident response plan to address any control system-specific actions. For example, the response to a successful attack on the front end might be to place equipment in Manual / Hand operation.

F-3.8 Maintenance (MA) Control Family

Design guidance for controls in the Maintenance (MA) control family is shown in Table F-7.

Table F-7 Maintenance (MA) Control Control Family

Security Control ID	Security Control Name and Design Guidance
MA-3	**Maintenance Tools:** Require that control system maintenance tools (software or hardware required to maintain the control system – most commonly engineering tool software) be provided. The UFGS requires this for MODERATE impact systems.
MA-4	**Nonlocal Maintenance:** This is met through operating system login for the use of the engineering tool maintenance software.

F-3.9 Media Protection (MP) Control Family

Media Protection is addressed only at the Platform Enclave.

Design guidance for controls in the Media Protection (MP) control family is shown in Table F-8.

Table F-8 Media Protection (MP) Control Family

Security Control ID	Security Control Name and Design Guidance
MP-5	**Media Transport:** CCI-001027 (MP-5 (4)) places a requirement on the control system, but only when the control system is outside a "controlled area" where "controlled area" is defined in CCI-001016 as areas approved for processing the information. By definition, an area must be approved for processing the information necessary for the control systems in that area. For transportation outside that area, the data would have to be encrypted by tools provided by the Platform Enclave.

F-3.10 Physical and Environmental Protection (PE) Control Family

Note that control systems are often distributed, with large portions of the system being in spaces outside the control of the organization. This impacts many of the PE controls, in particular PE-16 can only be met for spaces controlled by the organization. In general, these are met at the Platform Enclave, but implementation may be spotty below that. Designer should require locked rooms where possible. Level 4, 3, and 2N equipment should either be in locked rooms or locked enclosures. Level 2, Level 1 and Level 0 equipment will frequently be located in tenant spaces and outside the control of the organization. For some systems, it may be necessary to require lockable enclosures for some controllers at Level 2 and Level 1, but this must be weighed against the need for maintenance personnel to access the equipment. In general, there is little benefit in requiring lockable enclosures for controllers when the underlying equipment is readily accessible from the controller location.

Most of the control system is not in "normal" server spaces. For the normal server spaces, PE requirements will be met at the Platform Enclave. For the remainder of the control system, PE requirements (such as PE-14's temperature and humidity requirements) are either N/A or are covered by design specifications. Note that NIST guidance states that several PEs (PE-10, PE-12, PE-13, PE-14, and PE-15) only apply at major server rooms, not individual components. These are covered by the Platform Enclave and are N/A in the control system. Design guidance for controls in the Physical and Environmental Protection (PE) control family is shown in Table F-9.

Table F-9 Physical and Environmental Protection (PE) Control Family

Security Control ID	Security Control Name and Design Guidance
PE-4	**Access Control for Transmission Medium:** Designer should require physical security for network media and may need to coordinate with electrical designer for conduit requirements. Note that physical security may be required outside spaces controlled by the organization as well. See SC-8.
PE-5	**Access Control for Output Devices:** Note that “physical outputs” for a control system correspond to the location of the controlled equipment, which must also be secured so there are unlikely to be additional requirements for the control system components
PE-9	**Power Equipment and Cabling:** For systems requiring redundant power, designer should coordinate with electrical designer. Note that the weak link in reliability will often be the controlled equipment. For example, if a single backup generator is needed, a system with 2 generators - each with a single controller - will be more reliable than a single generator with redundant controllers. Note that, for a control system, redundant power to controllers is pointless without redundant power to the controlled system. In many cases, redundant controlled equipment (N+1 equipment design) may be required. The UFGS has an extensive designer note on this topic.
PE-11	**Emergency Power:** Within the control system, require an uninterruptible power supply (UPS), either in the control system specification or by coordination with electrical specification, when backup power is required. At the front end, this could either be met by the Platform Enclave, or by control system specification requirements also. For the majority of LOW impact systems, this control will not be implemented. See UFGS comment for PE-9.
PE-16	**Delivery And Removal:** No additional control-specific guidance. Use general control family guidance preceding this table for this control.
PE-17	**Alternate Work Site:** PE-17 can’t be applied except at Level 4 – there is no possible “alternate work site” for PIT. This is all at the Platform Enclave.

F-3.11 Planning (PL) Control Family

Design guidance for controls in the Planning (PL) control family is shown in Table F-10.

Table F-10 Planning (PL) Control Family

Security Control ID	Security Control Name and Design Guidance
PL-2	**System Security Plan:** While the designer is not directly responsible for the system security plan itself, the design must provide information to be used in this plan. For example, the system architecture drawing is part of the definition of the authorization boundary. The designer may also provide input for the security categorization since they have the specific knowledge of the underlying mechanical/electrical systems and can help assess the impact of those systems on control system tenants. The UFGS covers this with a Cybersecurity Riser Diagram submittal.
PL-4	**Rules Of Behavior:** As indicated in CHAPTER 4, social media should be completely inaccessible from the control system.
PL-7	**Security Concept of Operations:** Designer needs to provide input to a security concept of operations since the range of possible operations is defined by the underlying equipment, sequences of operation, selection of controllers, and front-end capabilities.
PL-8	**Information Security Architecture:** System architecture submittals are necessary inputs to the security architecture. Dependencies on external services should be minimal, if any.

F-3.12 Program Management (PM) Control Family

Generally, the designer does not get involved in project planning; therefore the PM controls are not a primary designer responsibility, but designer may need to provide input to support others.

Design guidance for controls in the Program Management (PM) control family is shown in Table F-11.

Table F-11 Program Management (PM) Control Family

Security Control ID	Security Control Name and Design Guidance
PM-3	**Information Security Resources:** See General Guidance for PM Control Family and SA-2.
PM-5	**Information System Inventory:** Initial inventory is provided by as-built bill of materials.
PM-11	**Mission/Business Process Definition:** Calls for "…an achievable set of protection needs are obtained" and may require designer input.

F-3.13 Personnel Security (PS) Control Family

None of the Personnel Security controls are the responsibility of the designer.

F-3.14 Risk Assessment (RA) Control Family

By and large, the implementation of the RA controls is outside the responsibility of the designer.

Design guidance for controls in the Risk Assessment (RA) control family is shown in Table F-12.

Table F-12 Risk Assessment (RA) Control Family

Security Control ID	Security Control Name and Design Guidance
RA-3	**Risk Assessment:** The designer is well versed in the control system and the underlying mechanical / electrical system and may therefore need to assist in identifying risks to the tenants served by the control system.
RA-5	**Vulnerability Scanning:** Scanning can be performed at Levels 3 and 4 and scanning of the control system at this level should be performed by the Platform Enclave. Scanning below this level – and particularly at Level 1 - is not supported by standard IT-centric tools but is supported by standard control system tools. Most control system software provides a tool which can probe the control system network and generate a map of the control system; this process corresponds to Vulnerability Scanning. Note that scanning tools should be within the Platform Enclave, scanning from outside the Platform Enclave just opens up a hole for an attacker. Designer may need to provide input to organizations attempting to meet RA-5. See SC-7, SI-3

F-3.15 System and Services Acquisition (SA) Control Family

The NIST description of “External information services” (SA-9) makes it clear that it’s an “external information system” not “external services (e.g. contractor) on this information system”

Design guidance for controls in the System and Services Acquisition (SA) control family is shown in Table F-13.

Table F-13 System and Services Acquisition (SA) Control Family

Security Control ID	Security Control Name and Design Guidance
SA-2	**Allocation Of Resources:** Designer may need to provide input to this process. See PM-3
SA-4	**Acquisition Process:** SA-4 is at least partially met by the designer incorporating security-specific requirements in the design, including acceptance testing. Requirements for FIPS PUB 201-2 may only apply at the Platform Enclave and designer may need to provide rationale for not meeting those requirements in the control system. Similarly, many of the requirements on the developer probably cannot be enforced on a COTS system. ESS systems may need to meet FIPS PUB 201-2 at Levels 1 and 2. The UFGS has extensive requirements for Cybersecurity during construction to prevent vulnerabilities from being exploited during construction to create exploits after acceptance.
SA-5	**Information System Documentation**: Designer should require submittals providing the documentation which is required by these CCIs. Note that some of the required documentation may not be obtainable, particularly for a COTS system. The UFGS has a submittal that covers this, but the requirements are limited by what is practical.
SA-9	**External Information System Services:** In general, control systems should not use external IS, so this control should not apply. Where it does, it should be addressed at the Platform Enclave.
SA-10 and SA-11	**Developer Configuration Management and Developer Security Testing and Evaluation:** SA-10, SA-11 are likely impossible for COTS systems. Designer needs to specify what can be specified (which will often require additional submittals) and explain what can't be specified. Note that the control assumes the developer has a role during implementation and/or operation – this is often not true.

F-3.16 System and Communications Protection (SC) Control Family

Design guidance for controls in the System and Services Acquisition (SA) control family is shown in Table F-14.

Table F-14 System and Communications Protection (SC) Control Family

Security Control ID	Security Control Name and Design Guidance
SC-2	**Application Partitioning:** This is met by separating out computer administration and by design specifications that require different user permissions within the control system (e.g. "view data" vs "modify data").
SC-4	**Information In Shared Resources:** Typically the control system will all be dedicated hardware and software, so there are no shared resources. This control might have some applicability at Level 4 if computer resources are shared.
SC-5	**Denial Of Service Protection:** Within the control system, denial of service attacks are mitigated by designing the system to not depend on the network or on computers. Otherwise, this is a Platform Enclave control. The UFGS has specific requirements for this (though they are sometimes caveated with "… whenever possible…"). The UFGS combines these requirements with SC-7 and SC-39 under "System and Communication Protection".
SC-7	**Boundary Protection:** Implementation at the external boundary should be the responsibility of the Platform Enclave. The Platform Enclave can perform monitoring/traffic control at Level 3, and perhaps key points near Level 4 assets. Aside from those locations, this control may be difficult to meet within the control system. Designer may need to provide justification for not monitoring or controlling traffic below Level 3. It may not be prudent for the control system to fail to a "secure" state after loss of a boundary protection device since this allows an attack vector to disable controlled equipment by taking out the boundary device. Control systems must continue to run independently when boundary devices are lost. See CP-12 comments and RA-5, SI-3, SC-24. The UFGS combines these requirements with SC-5.
SC-8	**Transmission Confidentiality and Integrity:** Note that NIST guidance suggests this only applies to information outside a secure physical boundary, and that, when this control cannot be met, alternate physical security safeguards such as a protected distribution system can be employed.
SC-10	**Network Disconnect:** Data within a control system is often communicated without setting up a "session". Most control systems will not use sessions other than for communications within Level 4.

Security Control ID	Security Control Name and Design Guidance
SC-12	**Cryptographic Key Establishment and Management:** Below Level 4, control systems support for cryptographic keys is extremely limited and it is impractical to implement many of these controls. The UFGS discusses use of HTTPS but suggests that other cryptography is seldom required.
SC-13	**Cryptographic Protection:** Note that NIST states this control does not require cryptography, it merely provides requirements for the implementation of cryptography where it is required. The vast majority of control systems should not have any information requiring the use of cryptography (and in the few cases where it is even possible, the designer should review whether it is really necessary for the control system to have this information). For UFGS comments, see SC-12.
SC-15	**Collaborative Computing Devices:** In general, control systems shouldn't use collaborative computing devices.
SC-18	**Mobile Code:** This control can and should be fully applied at Level 4. Below that, there's an important distinction between "mobile code" and "mobile code technologies": Java is a "mobile code technology" used by many control systems at Level 2 (and possibly other Levels), but Java should not be used as "mobile code" – which is code that is downloaded and executed without explicit user action. So, while mobile code technologies may be permissible below Level 4, mobile code should not be. Mobile code restrictions within the control system should be covered by design specifications. For example, common building control system products use Java, and serve web pages to clients. These pages do not constitute mobile code. Downloading a Java application, however, would be an example of mobile code.
SC-21 and SC-22	**Secure Name /Address Resolution Service (Recursive or Caching Resolver) and Architecture and Provisioning for Name / Address Resolution Service:** These controls apply only at the Platform Enclave.
SC-23	**Session Authenticity:** See comments on SC-10.
SC-24	**Fail In Known State:** What is key here is the status of controlled equipment after a control system failure. Designer should specify this where necessary. Note that the DoD requirement of a "secure state" may not be applicable and would be superseded by a "safe state", or by a "support the mission" state. Data preserved through a failure may be limited by the nature of the control system and designer should specify what is reasonable. See CP-12.

Security Control ID	Security Control Name and Design Guidance
SC-28	**Protection Of Information at Rest:** Note that many (if not most) control systems will not have any data requiring protection at rest since they will not have PII or classified data. Note, however, that Electronic Security Systems will often require protection of data at rest.
SC-39	**Process Isolation:** For control systems controlling multiple systems, a distributed control system meets this. See comment on SC-5.
SC-41	**Port And I/O Device Access:** See comments on CM-7. The UFGS has a Network Communication Report submittal which covers this, as well as requirements under "Least Functionality"

F-3.17 System and Information Integrity (SI) Control Family

Design guidance for controls in the System and Information Integrity (SI) control family is shown in Table F-.

Table F-15 System and Information Integrity (SI) Control Family

Security Control ID	Security Control Name and Design Guidance
SI-2	**Flaw Remediation:** SI-2 is about security updates and patches for software and firmware. While this can (and should) be applied at Level 3 and Level 4, this control may be largely "not applicable" or "impractical" below Level 3, due to both the relative infrequency of available updates and also the difficulty of patching controllers at Level 1 and 2. This is also largely irrelevant at Level 1 and 2, since it completely ignores flaws in the underlying equipment, which are likely to be much more common and much more significant. The UFGS requires security related software updates and patches.
SI-3	**Malicious Code Protection:** Should be implemented by the Platform Enclave at entry/exit points. Periodic scans within the control system may be difficult and the designer may need to justify their non-implementation. See RA-5, SC-7. The UFGS requires that computers meet the STIGS.

Security Control ID	Security Control Name and Design Guidance
SI-4	**Information System Monitoring:** Data collected can only be preserved at the Platform Enclave. Designer should provide input to monitoring objectives and methods based on the control system, the underlying mechanical/electrical system, and the impact on tenants. Note that this is not about operational monitoring of the control system (e.g. viewing graphics, receiving alarms), but about monitoring for security. The UFGS has a placeholder for this, but no default requirements.
SI-7	**Software, Firmware, And Information Integrity:** Integrity verification tools may only be possible at Level 4. Designer should provide input on what is reasonable based on the control system capabilities, and where this control is not feasible.
SI-10	**Information Input Validation:** This could cover network data, sensor input, or input from a user. Designer could require additional sanity checks on sensor input, or redundant sensors. User input validation would likely need to be addressed by policy. Network validation may not be possible except at Level 4.
SI-11	**Error Handling:** Designer should require alarm messages and other control system feedback to meet this. Note that the DoD definition of recipients is not applicable for a control system.
SI-16	**Memory Protection:** Memory Protection only makes sense at Level 4.
SI-17	**Fail-Safe Procedures:** See SC-24 and CP-12 comments, where failure is one of the conditions to consider.

APPENDIX G CONTROL CORRELATION IDENTIFIER (CCI) TABLES

G-1 INTRODUCTION

This appendix provides a number of tables which help classify the CCIs for a LOW or MODERATE system on a DoD installation where there is a separate authorization for the Platform Enclave and the minimum cybersecurity design requirements have been followed.

G-2 TABLE STRUCTURE AND CONTENT

Within each table, the following columns are defined. Note that not all tables use all columns:

- **CCI**: The CCI number.
- **NIST SP 800-53 Control Text Indicator**: NIST SP 800-53 breaks individual controls (i.e., single Control IDs) down into multiple elements and enhancements, where an enhancement is a more stringent requirement than the base control. The Control Text Indicator uniquely identifies each of these elements and enhancements. A letter indicates an element within a control, a number is an enhancement. For example, "AC-17 (4)(b)" is the second element of the fourth enhancement to AC-17.
- **CCI Definition**: The definition of the CCI.
- **Applies At or Above Impact**: This CCI should be applied if the control system impact is this or above.
- **Table Reference:** Indicated which other table(s) in this Appendix the CCI is found in.
- **Applicable to a Control System:** Is this CCI applicable to a control system?
- **Rational for non-inclusion:** Reason the CCI is not applicable to control systems
- **Rational for Removal from a LOW Baseline:** Reason the CCI should be removed from the baseline for a LOW impact control system.
- **Responsibility:** Indicates who has responsibility for implementing the control. One or more of:
    - ***DoD-Defined:*** Either the DoD has provided a value for the "organization selected" values, or the DoD implementation guidance states that the CCI is already met by existing policy or regulation. ***Note that definition or guidance provided may not be relevant for a control system – the organization definitions were determined from the perspective of a traditional information system, not for a control system.***
    - ***Designer:*** The designer has a role to address for this CCI. Either the designer needs to provide design specifications to cover a

requirement on the control system itself, or the designer must provide input to others regarding the implementation or lack of feasibility of the CCI (typically because the CCI was written with an IT system, not a control system, in mind).

- ***Non-Designer:*** The CCI is beyond the responsibility of the designer and is the responsibility of someone else – typically the System Owner (SO). This does not diminish the importance of these CCIs, but as these CCIs are not the responsibility of the designer they are beyond the scope of this UFC.
- ***Platform Enclave:*** The CCI contains a requirement which is assumed to be implemented at the Platform Enclave and inherited by the control system or is mostly implemented at the Platform Enclave but also needed within the field control system. Note that if there is no Platform Enclave, then CCIs listed in the "Platform Enclave" category are instead in the "Non-Designer" category.
- ***Impractical:*** The CCI is impractical to fully implement in a control system but may be applied in a limited manner to at least some part of the control system. Most often CCIs that can be applied to only part of the control system can be implemented at Level 4 of the architecture but would be prohibitively difficult to implement at Levels 1 or 2. Note that "prohibitively" is a judgment based on a typical LOW control system – for a MODERATE or HIGH system, it may be worthwhile to implement these controls at all possible levels even if this adds significant cost and complexity.

G-3 CCI TABLE NOTES

G-3.1 Controls Inherited from Platform Enclave

Note that not all controls that can be inherited from the Platform Enclave have ***necessarily*** been identified as such -- some controls labeled "Non-Designer" may in fact be implemented at the Platform Enclave and the control system inherits from that.

G-3.2 CCIs in Multiple Tables

Note that some CCIs will appear in multiple tables, typically "Designer and Platform Enclave" or "Platform Enclave and Other". For example, scanning (RA-5) should happen at the Platform Enclave level and not in the control system. But the designer may need to provide input to the selection of scanning tools appropriate for the control system. The purpose of these tables is to break down the responsibilities for each control such that a specific individual/role would not be required to look at all the tables to determine what needs to be done.

G-4 CCI TABLE DESCRIPTIONS

Multiple CCI tables are included in this Appendix, each including CCIs that meet certain characteristics as described. An electronic version of the CCI tables in Excel format is available at the RMF Knowledge Service website.

- **Table G-1 Summary of CCIs for LOW and MODERATE Impact Systems** summarizes all the CCIs that can be applied to a MODERATE or lower control system, based on NIST 800-82. This table also indicates which other tables each CCI can be found in.

- **Table G-2 CCIs Not Applicable to Control Systems (CS)** lists CCIs that (assuming the minimum cybersecurity requirements in CHAPTER 4 have been met) never apply to a control system and provides a rationale for not using them.

- **Table G-3 CCIs Removed from LOW Impact Control Systems Baseline** lists CCIs that NIST 800-82 includes in the LOW baseline, but do not apply to a LOW control system, and provides a rationale. Note that CCIs here are listed as LOW but aren't used at LOW.

- **Table G-4 Designer CCIs for LOW and MODERATE Impact Control Systems** lists CCIs that should be addressed in design for both LOW and MODERATE Impact Systems. In many cases, guidance on addressing specific security controls in design is provided in APPENDIX F.

- **Table G-5 Additional Designer CCIs for MODERATE Impact Control Systems** lists CCIs (in addition to those shown in **Table G-4**) that should be addressed in design of MODERATE Impact Systems. In many cases, guidance on addressing specific security controls in design is provided in APPENDIX F.

- Similar to Designer CCIs in **Table G-4** and **Table G-5**, **Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems** and **Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems** list CCIs in the "Platform Enclave" category. While implementation of the Platform Enclave is not the designer's responsibility (a key point of the Platform Enclave is that it is a standard approach that can be implemented across multiple control systems), those responsible for the Platform Enclave need to be aware of CCIs that the control system expects to inherit from the Platform Enclave

G-5 CCI TABLES

Table G-1 Summary of CCIs for LOW and MODERATE Impact Systems

CCI #	800-53 Control Text Indicator	Applies At Or Above Impact	Table Reference	Applicable to a Control System?
CCI-002107	AC-1(a)	LOW	None (Non-Designer)	TRUE
CCI-002108	AC-1(a)	LOW	None (Non-Designer)	TRUE
CCI-000001	AC-1(a)(1)	LOW	None (Non-Designer)	TRUE

Table G-1 Summary of CCIs for LOW and MODERATE Impact Systems				
CCI #	**800-53 Control Text Indicator**	**Applies At Or Above Impact**	**Table Reference**	**Applicable to a Control System?**
CCI-000002	AC-1(a)(1)	LOW	None (Non-Designer)	TRUE
CCI-000004	AC-1(a)(2)	LOW	None (Non-Designer)	TRUE
CCI-000005	AC-1(a)(2)	LOW	None (Non-Designer)	TRUE
CCI-001545	AC-1(b)(1)	LOW		TRUE
CCI-000003	AC-1(b)(1)	LOW	None (Non-Designer)	TRUE
CCI-001546	AC-1(b)(2)	LOW		TRUE
CCI-000006	AC-1(b)(2)	LOW	None (Non-Designer)	TRUE
CCI-002110	AC-2(a)	LOW	Table G-4 (Designer)	TRUE
CCI-002111	AC-2(a)	LOW	None (Non-Designer)	TRUE
CCI-002112	AC-2(b)	LOW	None (Non-Designer)	TRUE
CCI-000008	AC-2(c)	LOW	None (Non-Designer)	TRUE
CCI-002113	AC-2(c)	LOW	None (Non-Designer)	TRUE

Table G-2 CCIs Not Applicable to Control Systems (CS)			
CCI #	**800-53 Control Text Indicator**	**CCI Definition**	**Rationale for non- inclusion**
CCI-001384	AC-8(c)(1)	The information system, for publicly accessible systems, displays system use information organization-defined conditions before granting further access.	CS is not publically accessible
CCI-001385	AC-8(c)(2)	The information system, for publicly accessible systems, displays references, if any, to monitoring that are consistent with privacy accommodations for such systems that generally prohibit those activities.	CS is not publically accessible
CCI-001386	AC-8(c)(2)	The information system for publicly accessible systems displays references, if any, to recording that are consistent with privacy accommodations for such systems that generally prohibit those activities.	CS is not publically accessible
CCI-001387	AC-8(c)(2)	The information system for publicly accessible systems displays references, if any, to auditing that are consistent with privacy accommodations for such systems that generally prohibit those activities.	CS is not publically accessible
CCI-001388	AC-8(c)(3)	The information system, for publicly accessible systems, includes a description of the authorized uses of the system.	CS is not publically accessible
CCI-001473	AC-22(a)	The organization designates individuals authorized to post information onto a publicly accessible information system.	CS is not publically accessible
CCI-001474	AC-22(b)	The organization trains authorized individuals to ensure that publicly accessible information does not contain nonpublic information.	CS is not publically accessible
CCI-001475	AC-22(c)	The organization reviews the proposed content of information prior to posting onto the publicly accessible information system to ensure that nonpublic information is not included.	CS is not publically accessible
CCI-001476	AC-22(d)	The organization reviews the content on the publicly accessible information system for nonpublic information on an organization-defined frequency.	CS is not publically accessible
CCI-001477	AC-22(d)	The organization defines a frequency for reviewing the content on the publicly accessible information system for nonpublic information.	CS is not publically accessible
CCI-001478	AC-22(e)	The organization removes nonpublic information from the publicly accessible information system, if discovered.	CS is not publically accessible

Table G-2 CCIs Not Applicable to Control Systems (CS)			
CCI #	800-53 Control Text Indicator	CCI Definition	Rationale for non- inclusion
CCI-001739	CM-2(7)a	The organization issues organization-defined information systems, system components, or devices with organization-defined configurations to individuals traveling to locations the organization deems to be of significant risk.	CS aren't mobile.
CCI-001815	CM-2(7)b	The organization defines the security safeguards to be applied to devices when they return from areas of significant risk.	CS aren't mobile.
CCI-001816	CM-2(7)b	The organization applies organization-defined security safeguards to devices when individuals return from areas of significant risk.	CS aren't mobile.
CCI-000444	CP-2(a)(1)	The organization develops a contingency plan for the information system that identifies essential business functions.	CS are not business systems
CCI-000451	CP-2(a)(4)	The organization develops a contingency plan for the information system that addresses maintaining essential business functions despite an information system disruption.	CS are not business systems
CCI-000453	CP-2(a)(4)	The organization develops a contingency plan for the information system that addresses maintaining essential business functions despite an information system compromise.	CS are not business systems
CCI-000455	CP-2(a)(4)	The organization develops a contingency plan for the information system that addresses maintaining essential business functions despite an information system failure.	CS are not business systems
CCI-000474	CP-2(3)	The organization defines the time period for planning the resumption of essential business functions as a result of contingency plan activation.	CS are not business systems
CCI-000476	CP-2(3)	The organization plans for the resumption of essential business functions within the organization-defined time period of contingency plan activation.	CS are not business systems
CCI-002829	CP-2(8)	The organization identifies critical information system assets supporting essential business functions.	CS are not business systems
CCI-000514	CP-7(a)	The organization establishes an alternate processing site including necessary agreements to permit the transfer and resumption of organization-defined information system operations for essential business functions within organization-defined time period consistent with recovery time and recovery point objectives when the primary processing capabilities are unavailable.	CS are not business systems

Table G-2 CCIs Not Applicable to Control Systems (CS)			
CCI #	800-53 Control Text Indicator	CCI Definition	Rationale for non- inclusion
CCI-000523	CP-8	The organization defines the time period to permit the resumption of organization-defined information system operations for essential business functions when the primary telecommunications capabilities are unavailable at either the primary or alternate processing or storage sites.	CS are not business systems
CCI-000525	CP-8	The organization establishes alternate telecommunication services including necessary agreements to permit the resumption of organization-defined information system operations for essential business functions within organization-defined time period when the primary telecommunications capabilities are unavailable at either the primary or alternate processing or storage sites.	CS are not business systems
CCI-002841	CP-8	The organization defines the information system operations to be resumed for essential business functions within the organization-defined time period when the primary telecommunications capabilities are unavailable at either the primary or alternate processing or storage sites.	CS are not business systems
CCI-000963	PE-12	The organization employs and maintains automatic emergency lighting for the information system that activates in the event of a power outage or disruption and that covers emergency exits and evacuation routes within the facility.	CS does not need lighting, it functions perfectly well in the dark
CCI-002395	SC-7(b)	The information system implements subnetworks for publicly accessible system components that are physically and/or logically separated from internal organizational networks.	CS is not publically accessible
CCI-001173	SC-19(a)	The organization establishes usage restrictions for Voice over Internet Protocol (VoIP) technologies based on the potential to cause damage to the information system if used maliciously.	CS does not use VoIP
CCI-001174	SC-19(a)	The organization establishes implementation guidance for Voice over Internet Protocol (VoIP) technologies based on the potential to cause damage to the information system if used maliciously.	CS does not use VoIP
CCI-001175	SC-19(b)	The organization authorizes the use of VoIP within the information system.	CS does not use VoIP
CCI-001176	SC-19(b)	The organization monitors the use of VoIP within the information system.	CS does not use VoIP

Table G-2 CCIs Not Applicable to Control Systems (CS)			
CCI #	**800-53 Control Text Indicator**	**CCI Definition**	**Rationale for non- inclusion**
CCI-001177	SC-19(b)	The organization controls the use of VoIP within the information system.	CS does not use VoIP
CCI-001178	SC-20(a)	The information system provides additional data origin authentication artifacts along with the authoritative name resolution data the system returns in response to external name/address resolution queries.	CS does not act as external DNS server
CCI-002462	SC-20(a)	The information system provides additional integrity verification artifacts along with the authoritative name resolution data the system returns in response to external name/address resolution queries.	CS does not act as external DNS server
CCI-001179	SC-20(b)	The information system, when operating as part of a distributed, hierarchical namespace, provides the means to indicate the security status of child zones.	CS does not act as external DNS server
CCI-001663	SC-20(b)	The information system, when operating as part of a distributed, hierarchical namespace, provides the means to enable verification of a chain of trust among parent and child domains (if the child supports secure resolution services).	CS does not act as external DNS server
CCI-001182	SC-22	The information systems that collectively provide name/address resolution service for an organization are fault-tolerant.	CS does not act as external DNS server
CCI-001183	SC-22	The information systems that collectively provide name/address resolution service for an organization implement internal/external role separation.	CS does not act as external DNS server
CCI-002741	SI-8(a)	The organization employs spam protection mechanisms at information system entry points to detect and take action on unsolicited messages.	While control systems may have outbound email for alarm, event and audit reporting, control systems don't use inbound email.
CCI-002742	SI-8(a)	The organization employs spam protection mechanisms at information system exit points to detect and take action on unsolicited messages.	While control systems may have outbound email for alarm, event and audit reporting, control systems don't use inbound email.
CCI-001306	SI-8(b)	The organization updates spam protection mechanisms when new releases are available in accordance with organizational configuration management policy and procedures.	While control systems may have outbound email for alarm, event and audit reporting, control systems don't use inbound email.
CCI-001307	SI-8(1)	The organization centrally manages spam protection mechanisms.	While control systems may have outbound email for alarm, event and audit reporting, control systems don't use inbound email.

Table G-2 CCIs Not Applicable to Control Systems (CS)			
CCI #	**800-53 Control Text Indicator**	**CCI Definition**	**Rationale for non- inclusion**
CCI-001308	SI-8(2)	The information system automatically updates spam protection mechanisms .	While control systems may have outbound email for alarm, event and audit reporting, control systems don't use inbound email.

Table G-3 CCIs Removed from LOW Impact Control Systems Baseline			
CCI #	**800-53 Control Text Indicator**	**CCI Definition**	**Rationale for non-inclusion**
CCI-000443	CP-2(a)(1)	The organization develops a contingency plan for the information system that identifies essential missions.	A LOW CS doesn't have any "essential" mission
CCI-000450	CP-2(a)(4)	The organization develops a contingency plan for the information system that addresses maintaining essential missions despite an information system disruption.	A LOW CS doesn't have any "essential" mission
CCI-000452	CP-2(a)(4)	The organization develops a contingency plan for the information system that addresses maintaining essential missions despite an information system compromise.	A LOW CS doesn't have any "essential" mission
CCI-000454	CP-2(a)(4)	The organization develops a contingency plan for the information system that addresses maintaining essential missions despite an information system failure.	A LOW CS doesn't have any "essential" mission
CCI-002955	PE-11	The organization provides a short-term uninterruptible power supply to facilitate an orderly shutdown of the information system and/or transition of the information system to long-term alternate power in the event of a primary power source loss.	NIST 800-53 does not have this in a LOW baseline. NIST 800-82 included it with the rationale "ICS may support critical activities....". By definition, a CS supporting "critical activities" is not a LOW system.
CCI-000961	PE-11(1)	The organization provides a long-term alternate power supply for the information system that is capable of maintaining minimally required operational capability in the event of an extended loss of the primary power source.	NIST 800-53 does not have this in a LOW baseline. NIST 800-82 included it with the rationale "ICS may support critical activities....". By definition, a CS supporting "critical activities" is not a LOW system.
CCI-002449	SC-13	The organization defines the cryptographic uses, and type of cryptography required for each use, to be implemented by the information system.	A LOW CS doesn't have any classified information
CCI-002450	SC-13	The information system implements organization-defined cryptographic uses and type of cryptography required for each use in accordance with applicable federal laws, Executive Orders, directives, policies, regulations, and standards.	A LOW CS doesn't have any classified information
CCI-000216	PM-8	The organization develops and documents a critical infrastructure and key resource protection plan that addresses information security issues.	A LOW Control System doesn't deal with critical infrastructure.
CCI-001640	PM-8	The organization updates the critical infrastructure and key resources protection plan that addresses information security issues.	A LOW Control System doesn't deal with critical infrastructure.

Table G-4 Designer CCIs for LOW and MODERATE Impact Control Systems				
CCI #	**800-53 Control Text Indicator**	**CCI Definition**	**Responsibility**	**UFGS Reference**
CCI-002110	AC-2(a)	The organization defines the information system account types that support the organizational missions/business functions.	Designer	3.3.1 User Accounts
CCI-000213	AC-3	The information system enforces approved authorizations for logical access to information and system resources in accordance with applicable access control policies.	Designer	3.3.1 User Accounts
CCI-000043	AC-7(a)	The organization defines the maximum number of consecutive invalid logon attempts to the information system by a user during an organization-defined time period.	DoD-Defined Designer Impractical	3.3.2 Unsuccessful Logon Attempts
CCI-000044	AC-7(a)	The information system enforces the organization-defined limit of consecutive invalid logon attempts by a user during the organization-defined time period.	Designer	3.3.2 Unsuccessful Logon Attempts
CCI-001423	AC-7(a)	The organization defines the time period in which the organization-defined maximum number of consecutive invalid logon attempts occur.	DoD-Defined Designer Impractical	3.3.2 Unsuccessful Logon Attempts
CCI-002236	AC-7(b)	The organization defines the time period the information system will automatically lock the account or node when the maximum number of unsuccessful attempts is exceeded.	DoD-Defined Designer Impractical	3.3.2 Unsuccessful Logon Attempts
CCI-002237	AC-7(b)	The organization defines the delay algorithm to be employed by the information system to delay the next login prompt when the maximum number of unsuccessful attempts is exceeded.	DoD-Defined Designer Impractical	3.3.2 Unsuccessful Logon Attempts
CCI-002238	AC-7(b)	The information system automatically locks the account or node for either an organization-defined time period, until the locked account or node is released by an administrator, or delays the next login prompt according to the organization-defined delay algorithm when the maximum number of unsuccessful attempts is exceeded.	Designer Impractical	3.3.2 Unsuccessful Logon Attempts
CCI-002247	AC-8(a)	The organization defines the use notification message or banner the information system displays to users before granting access to the system.	DoD-Defined Enclave Designer Impractical	3.3.3 System Use Notification

Table G-4 Designer CCIs for LOW and MODERATE Impact Control Systems				
CCI #	**800-53 Control Text Indicator**	**CCI Definition**	**Responsibility**	**UFGS Reference**
CCI-000048	AC-8(a)	The information system displays an organization-defined system use notification message or banner before granting access to the system that provides privacy and security notices consistent with applicable federal laws, Executive Orders, directives, policies, regulations, standards, and guidance.	Enclave Designer Impractical	3.3.3 System Use Notification
CCI-002243	AC-8(a)(1)	The organization-defined information system use notification message or banner is to state that users are accessing a U.S. Government information system.	DoD-Defined Enclave Designer Impractical	3.3.3 System Use Notification
CCI-002244	AC-8(a)(2)	The organization-defined information system use notification message or banner is to state that information system usage may be monitored, recorded, and subject to audit.	DoD-Defined Enclave Designer Impractical	3.3.3 System Use Notification
CCI-002245	AC-8(a)(3)	The organization-defined information system use notification message or banner is to state that unauthorized use of the information system is prohibited and subject to criminal and civil penalties.	DoD-Defined Enclave Designer Impractical	3.3.3 System Use Notification
CCI-002246	AC-8(a)(4)	The organization-defined information system use notification message or banner is to state that use of the information system indicates consent to monitoring and recording.	DoD-Defined Enclave Designer Impractical	3.3.3 System Use Notification
CCI-000050	AC-8(b)	The information system retains the notification message or banner on the screen until users acknowledge the usage conditions and take explicit actions to log on to or further access.	Enclave Designer	3.3.3 System Use Notification
CCI-002248	AC-8(c)(1)	The organization defines the conditions of use which are to be displayed to users of the information system before granting further access.	DoD-Defined Enclave Designer Impractical	3.3.3 System Use Notification

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-002247	AC-8(a)	The organization defines the use notification message or banner the information system displays to users before granting access to the system.
CCI-000048	AC-8(a)	The information system displays an organization-defined system use notification message or banner before granting access to the system that provides privacy and security notices consistent with applicable federal laws, Executive Orders, directives, policies, regulations, standards, and guidance.
CCI-002243	AC-8(a)(1)	The organization-defined information system use notification message or banner is to state that users are accessing a U.S. Government information system.
CCI-002244	AC-8(a)(2)	The organization-defined information system use notification message or banner is to state that information system usage may be monitored, recorded, and subject to audit.
CCI-002245	AC-8(a)(3)	The organization-defined information system use notification message or banner is to state that unauthorized use of the information system is prohibited and subject to criminal and civil penalties.
CCI-002246	AC-8(a)(4)	The organization-defined information system use notification message or banner is to state that use of the information system indicates consent to monitoring and recording.
CCI-000050	AC-8(b)	The information system retains the notification message or banner on the screen until users acknowledge the usage conditions and take explicit actions to log on to or further access.
CCI-002248	AC-8(c)(1)	The organization defines the conditions of use which are to be displayed to users of the information system before granting further access.
CCI-000063	AC-17(a)	The organization defines allowed methods of remote access to the information system.
CCI-002310	AC-17(a)	The organization establishes and documents usage restrictions for each type of remote access allowed.
CCI-002311	AC-17(a)	The organization establishes and documents configuration/connection requirements for each type of remote access allowed.
CCI-002312	AC-17(a)	The organization establishes and documents implementation guidance for each type of remote access allowed.
CCI-000065	AC-17(b)	The organization authorizes remote access to the information system prior to allowing such connections
CCI-000082	AC-19(a)	The organization establishes usage restrictions for organization controlled mobile devices.
CCI-002325	AC-19(a)	The organization establishes configuration requirements for organization controlled mobile devices.
CCI-002326	AC-19(a)	The organization establishes connection requirements for organization controlled mobile devices.
CCI-000083	AC-19(a)	The organization establishes implementation guidance for organization controlled mobile devices.
CCI-000084	AC-19(b)	The organization authorizes connection of mobile devices to organizational information systems.

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-000093	AC-20(a)	The organization establishes terms and conditions, consistent with any trust relationships established with other organizations owning, operating, and/or maintaining external information systems, allowing authorized individuals to access the information system from the external information systems.
CCI-000098	AC-21(a)	The organization facilitates information sharing by enabling authorized users to determine whether access authorizations assigned to the sharing partner match the access restrictions on the information for organization-defined information circumstances where user discretion is required.
CCI-001470	AC-21(a)	The organization defines information sharing circumstances where user discretion is required.
CCI-001471	AC-21(b)	The organization employs organization-defined automated mechanisms or manual processes required to assist users in making information sharing/collaboration decisions.
CCI-001472	AC-21(b)	The organization defines the automated mechanisms or manual processes required to assist users in making information sharing/collaboration decisions.
CCI-000139	AU-5(a)	The information system alerts designated organization-defined personnel or roles in the event of an audit processing failure.
CCI-000140	AU-5(b)	The information system takes organization defined actions upon audit failure (e.g., shut down information system, overwrite oldest audit records, stop generating audit records).
CCI-001490	AU-5(b)	The organization defines actions to be taken by the information system upon audit failure (e.g., shut down information system, overwrite oldest audit records, stop generating audit records).
CCI-000162	AU-9	The information system protects audit information from unauthorized access.
CCI-000163	AU-9	The information system protects audit information from unauthorized modification.
CCI-000164	AU-9	The information system protects audit information from unauthorized deletion.
CCI-001493	AU-9	The information system protects audit tools from unauthorized access.
CCI-001494	AU-9	The information system protects audit tools from unauthorized modification.
CCI-001495	AU-9	The information system protects audit tools from unauthorized deletion.
CCI-000257	CA-3(a)	The organization authorizes connections from the information system to other information systems through the use of Interconnection Security Agreements.
CCI-000259	CA-3(b)	The organization documents, for each interconnection, the security requirements.
CCI-000260	CA-3(b)	The organization documents, for each interconnection, the nature of the information communicated.
CCI-000258	CA-3(b)	The organization documents, for each interconnection, the interface characteristics.
CCI-001732	CM-10(c)	The organization controls the use of peer-to-peer file sharing technology to ensure that this capability is not used for the unauthorized distribution, display, performance, or reproduction of copyrighted work.
CCI-001733	CM-10(c)	The organization documents the use of peer-to-peer file sharing technology to ensure that this capability is not used for the unauthorized distribution, display, performance, or reproduction of copyrighted work.

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-000535	CP-9(a)	The organization conducts backups of user-level information contained in the information system per organization-defined frequency that is consistent with recovery time and recovery point objectives.
CCI-000537	CP-9(b)	The organization conducts backups of system-level information contained in the information system per organization-defined frequency that is consistent with recovery time and recovery point objectives.
CCI-000539	CP-9(c)	The organization conducts backups of information system documentation including security-related documentation per organization-defined frequency that is consistent with recovery time and recovery point objectives.
CCI-000540	CP-9(d)	The organization protects the confidentiality, integrity, and availability of backup information at storage locations.
CCI-000550	CP-10	The organization provides for the recovery and reconstitution of the information system to a known state after a disruption.
CCI-000551	CP-10	The organization provides for the recovery and reconstitution of the information system to a known state after a compromise.
CCI-000552	CP-10	The organization provides for the recovery and reconstitution of the information system to a known state after a failure.
CCI-001933	IA-1(a)	The organization defines the personnel or roles to be recipients of the identification and authentication policy and the procedures to facilitate the implementation of the identification and authentication policy and associated identification and authentication controls.
CCI-001934	IA-1(a)	The organization documents procedures to facilitate the implementation of the identification and authentication policy and associated identification and authentication controls.
CCI-000756	IA-1(a)(1)	The organization develops and documents an identification and authentication policy that addresses purpose, scope, roles, responsibilities, management commitment, coordination among organizational entities, and compliance.
CCI-000757	IA-1(a)(1)	The organization disseminates to organization defined personnel or roles an identification and authentication policy that addresses purpose, scope, roles, responsibilities, management commitment, coordination among organizational entities, and compliance.
CCI-001932	IA-1(a)(1)	The organization documents an identification and authentication policy that addresses purpose, scope, roles, responsibilities, management commitment, coordination among organizational entities, and compliance.
CCI-000760	IA-1(a)(2)	The organization develops and documents procedures to facilitate the implementation of the identification and authentication policy and associated identification and authentication controls.
CCI-000761	IA-1(a)(2)	The organization disseminates to organization-defined personnel or roles procedures to facilitate the implementation of the identification and authentication policy and associated identification and authentication controls.
CCI-000758	IA-1(b)(1)	The organization reviews and updates identification and authentication policy in accordance with the organization defined frequency.
CCI-000759	IA-1(b)(1)	The organization defines a frequency for reviewing and updating the identification and authentication policy.

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-000762	IA-1(b)(2)	The organization reviews and updates identification and authentication procedures in accordance with the organization defined frequency.
CCI-000763	IA-1(b)(2)	The organization defines a frequency for reviewing and updating the identification and authentication procedures.
CCI-000764	IA-2	The information system uniquely identifies and authenticates organizational users (or processes acting on behalf of organizational users).
CCI-000765	IA-2(1)	The information system implements multifactor authentication for network access to privileged accounts.
CCI-001953	IA-2(12)	The information system accepts Personal Identity Verification (PIV) credentials.
CCI-001954	IA-2(12)	The information system electronically verifies Personal Identity Verification (PIV) credentials.
CCI-000777	IA-3	The organization defines a list of specific and/or types of devices for which identification and authentication is required before establishing a connection to the information system.
CCI-000778	IA-3	The information system uniquely identifies an organization defined list of specific and/or types of devices before establishing a local, remote, or network connection.
CCI-001958	IA-3	The information system authenticates an organization defined list of specific and/or types of devices before establishing a local, remote, or network connection.
CCI-001970	IA-4(a)	The organization defines the personnel or roles that authorize the assignment of individual, group, role, and device identifiers.
CCI-001971	IA-4(a)	The organization manages information system identifiers by receiving authorization from organization-defined personnel or roles to assign an individual, group, role or device identifier.
CCI-001972	IA-4(b)	The organization manages information system identifiers by selecting an identifier that identifies an individual, group, role, or device.
CCI-001973	IA-4(c)	The organization manages information system identifiers by assigning the identifier to the intended individual, group, role, or device.
CCI-001974	IA-4(d)	The organization defines the time period for which the reuse of identifiers is prohibited.
CCI-001975	IA-4(d)	The organization manages information system identifiers by preventing reuse of identifiers for an organization-defined time period.
CCI-000794	IA-4(e)	The organization defines a time period of inactivity after which the identifier is disabled.
CCI-000795	IA-4(e)	The organization manages information system identifiers by disabling the identifier after an organization defined time period of inactivity.
CCI-001990	IA-5(j)	The organization manages information system authenticators by changing authenticators for group/role accounts when membership to those accounts changes.
CCI-000192	IA-5(1)(a)	The information system enforces password complexity by the minimum number of upper case characters used.
CCI-000193	IA-5(1)(a)	The information system enforces password complexity by the minimum number of lower case characters used.

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-000194	IA-5(1)(a)	The information system enforces password complexity by the minimum number of numeric characters used.
CCI-000205	IA-5(1)(a)	The information system enforces minimum password length.
CCI-001619	IA-5(1)(a)	The information system enforces password complexity by the minimum number of special characters used.
CCI-000195	IA-5(1)(b)	The information system, for password-based authentication, when new passwords are created, enforces that at least an organization-defined number of characters are changed.
CCI-000196	IA-5(1)(c)	The information system, for password-based authentication, stores only cryptographically-protected passwords.
CCI-000197	IA-5(1)(c)	The information system, for password-based authentication, transmits only cryptographically-protected passwords.
CCI-000199	IA-5(1)(d)	The information system enforces maximum password lifetime restrictions.
CCI-001618	IA-5(1)(e)	The organization defines the number of generations for which password reuse is prohibited.
CCI-000200	IA-5(1)(e)	The information system prohibits password reuse for the organization defined number of generations.
CCI-002041	IA-5(1)(f)	The information system allows the use of a temporary password for system logons with an immediate change to a permanent password.
CCI-002002	IA-5(11)	The organization defines the token quality requirements to be employed by the information system mechanisms for token-based authentication.
CCI-002003	IA-5(11)	The information system, for token-based authentication, employs mechanisms that satisfy organization-defined token quality requirements.
CCI-000206	IA-6	The information system obscures feedback of authentication information during the authentication process to protect the information from possible exploitation/use by unauthorized individuals.
CCI-000803	IA-7	The information system implements mechanisms for authentication to a cryptographic module that meet the requirements of applicable federal laws, Executive Orders, directives, policies, regulations, standards, and guidance for such authentication.
CCI-000804	IA-8	The information system uniquely identifies and authenticates non-organizational users (or processes acting on behalf of non-organizational users).
CCI-002009	IA-8(1)	The information system accepts Personal Identity Verification (PIV) credentials from other federal agencies.
CCI-002010	IA-8(1)	The information system electronically verifies Personal Identity Verification (PIV) credentials from other federal agencies.
CCI-002011	IA-8(2)	The information system accepts FICAM-approved third-party credentials.
CCI-002013	IA-8(3)	The organization employs only FICAM-approved information system components in organization-defined information systems to accept third-party credentials.
CCI-002014	IA-8(4)	The information system conforms to FICAM-issued profiles.
CCI-002566	MP-1(a)(1)	The organization defines personnel or roles to whom a documented media protection policy and procedures will be disseminated.

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-000995	MP-1(a)(1)	The organization develops and documents a media protection policy that addresses purpose, scope, roles, responsibilities, management commitment, coordination among organizational entities, and compliance.
CCI-000996	MP-1(a)(1)	The organization disseminates to organization-defined personnel or roles a media protection policy.
CCI-000999	MP-1(a)(2)	The organization develops and documents procedures to facilitate the implementation of the media protection policy and associated media protection controls.
CCI-001000	MP-1(a)(2)	The organization disseminates to organization-defined personnel or roles procedures to facilitate the implementation of the media protection policy and associated media protection controls.
CCI-000998	MP-1(b)(1)	The organization defines a frequency for reviewing and updating the current media protection policy.
CCI-000997	MP-1(b)(1)	The organization reviews and updates the current media protection policy in accordance with organization-defined frequency.
CCI-001002	MP-1(b)(2)	The organization defines a frequency for reviewing and updating the current media protection procedures.
CCI-001001	MP-1(b)(2)	The organization reviews and updates the current media protection procedures in accordance with organization-defined frequency.
CCI-001003	MP-2	The organization restricts access to organization-defined types of digital and/or non-digital media to organization-defined personnel or roles.
CCI-001004	MP-2	The organization defines types of digital and/or non-digital media for which the organization restricts access.
CCI-001005	MP-2	The organization defines personnel or roles to restrict access to organization-defined types of digital and/or non-digital media.
CCI-001028	MP-6(a)	The organization sanitizes organization-defined information system media prior to disposal, release out of organizational control, or release for reuse using organization-defined sanitization techniques and procedures in accordance with applicable federal and organizational standards and policies.
CCI-002578	MP-6(a)	The organization defines information system media to sanitize prior to disposal, release out of organizational control, or release for reuse using organization-defined sanitization techniques and procedures in accordance with applicable federal and organizational standards and policies.
CCI-002579	MP-6(a)	The organization defines the sanitization techniques and procedures in accordance with applicable federal and organization standards and policies to be used to sanitize organization-defined information system media prior to disposal, release out of organizational control, or release for reuse.
CCI-002580	MP-6(b)	The organization employs sanitization mechanisms with the strength and integrity commensurate with the security category or classification of the information.
CCI-002581	MP-7	The organization defines the types of information system media to restrict or prohibit on organization-defined information systems or system components using organization-defined security safeguards.
CCI-002582	MP-7	The organization defines the information systems or system components to restrict or prohibit the use of organization-defined types of information system media using organization-defined security safeguards.

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-002583	MP-7	The organization defines the security safeguards to use for restricting or prohibiting the use of organization-defined types of information system media on organization-defined information systems or system components.
CCI-002584	MP-7	The organization restricts or prohibits the use of organization-defined types of information system media on organization-defined information systems or system components using organization-defined security safeguards.
CCI-000965	PE-13	The organization employs and maintains fire suppression and detection devices/systems for the information system that are supported by an independent energy source.
CCI-000971	PE-14(a)	The organization maintains temperature and humidity levels within the facility where the information system resides at organization-defined acceptable levels.
CCI-000972	PE-14(a)	The organization defines acceptable temperature and humidity levels to be maintained within the facility where the information system resides.
CCI-000973	PE-14(b)	The organization monitors temperature and humidity levels in accordance with organization-defined frequency.
CCI-000974	PE-14(b)	The organization defines a frequency for monitoring temperature and humidity levels.
CCI-000977	PE-15	The organization protects the information system from damage resulting from water leakage by providing master shutoff or isolation valves that are accessible.
CCI-000978	PE-15	The organization protects the information system from damage resulting from water leakage by providing master shutoff or isolation valves that are working properly.
CCI-000979	PE-15	Key personnel have knowledge of the master water shutoff or isolation valves.
CCI-000981	PE-16	The organization authorizes organization-defined types of information system components entering and exiting the facility.
CCI-000982	PE-16	The organization monitors organization-defined types of information system components entering and exiting the facility.
CCI-000983	PE-16	The organization controls organization-defined types of information system components entering and exiting the facility.
CCI-000984	PE-16	The organization maintains records of information system components entering and exiting the facility.
CCI-002974	PE-16	The organization defines types of information system components to authorize, monitor, and control entering and exiting the facility and to maintain records.
CCI-003051	PL-2(a)(2)	The organization's security plan for the information system explicitly defines the authorization boundary for the system.
CCI-001055	RA-5(a)	The organization defines a frequency for scanning for vulnerabilities in the information system and hosted applications.
CCI-001054	RA-5(a)	The organization scans for vulnerabilities in the information system and hosted applications on an organization-defined frequency.
CCI-001056	RA-5(a)	The organization scans for vulnerabilities in the information system and hosted applications when new vulnerabilities potentially affecting the system/applications are identified and reported.

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-001641	RA-5(a)	The organization defines the process for conducting random vulnerability scans on the information system and hosted applications.
CCI-001643	RA-5(a)	The organization scans for vulnerabilities in the information system and hosted applications in accordance with the organization-defined process for random scans.
CCI-001057	RA-5(b)	The organization employs vulnerability scanning tools and techniques that facilitate interoperability among tools and automate parts of the vulnerability management process by using standards for: enumerating platforms, software flaws, and improper configurations; formatting checklists and test procedures; and measuring vulnerability impact.
CCI-001058	RA-5(c)	The organization analyzes vulnerability scan reports and results from security control assessments.
CCI-001059	RA-5(d)	The organization remediates legitimate vulnerabilities in organization-defined response times in accordance with an organizational assessment risk.
CCI-003116	SA-4(10)	The organization employs only information technology products on the FIPS 201-approved products list for Personal Identity Verification (PIV) capability implemented within organizational information systems.
CCI-003137	SA-9(a)	The organization defines security controls that providers of external information system services employ in accordance with applicable federal laws, Executive Orders, directives, policies, regulations, standards, and guidance.
CCI-000669	SA-9(a)	The organization requires that providers of external information system services comply with organizational information security requirements.
CCI-000670	SA-9(a)	The organization requires that providers of external information system services employ organization-defined security controls in accordance with applicable federal laws, Executive Orders, directives, policies, regulations, standards, and guidance.
CCI-000671	SA-9(b)	The organization defines government oversight with regard to external information system services.
CCI-000672	SA-9(b)	The organization documents government oversight with regard to external information system services.
CCI-000673	SA-9(b)	The organization defines user roles and responsibilities with regard to external information system services.
CCI-000674	SA-9(b)	The organization documents user roles and responsibilities with regard to external information system services.
CCI-003138	SA-9(c)	The organization employs organization-defined processes, methods, and techniques to monitor security control compliance by external service providers on an ongoing basis.
CCI-003139	SA-9(c)	The organization defines processes, methods, and techniques to employ to monitor security control compliance by external service providers on an ongoing basis.
CCI-001093	SC-5	The organization defines the types of denial of service attacks (or provides references to sources of current denial of service attacks) that can be addressed by the information system.
CCI-002386	SC-5	The organization defines the security safeguards to be employed to protect the information system against, or limit the effects of, denial of service attacks.

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-002385	SC-5	The information system protects against or limits the effects of organization-defined types of denial of service attacks by employing organization-defined security safeguards.
CCI-001097	SC-7(a)	The information system monitors and controls communications at the external boundary of the system and at key internal boundaries within the system.
CCI-001098	SC-7(c)	The information system connects to external networks or information systems only through managed interfaces consisting of boundary protection devices arranged in accordance with an organizational security architecture.
CCI-002428	SC-12	The organization defines the requirements for cryptographic key generation to be employed within the information system.
CCI-002429	SC-12	The organization defines the requirements for cryptographic key distribution to be employed within the information system.
CCI-002430	SC-12	The organization defines the requirements for cryptographic key storage to be employed within the information system.
CCI-002431	SC-12	The organization defines the requirements for cryptographic key access to be employed within the information system.
CCI-002432	SC-12	The organization defines the requirements for cryptographic key destruction to be employed within the information system.
CCI-001150	SC-15(a)	The information system prohibits remote activation of collaborative computing devices excluding the organization-defined exceptions where remote activation is to be allowed.
CCI-001151	SC-15(a)	The organization defines exceptions to the prohibiting of collaborative computing devices where remote activation is to be allowed.
CCI-001152	SC-15(b)	The information system provides an explicit indication of use to users physically present at collaborative computing devices.
CCI-002465	SC-21	The information system requests data origin authentication verification on the name/address resolution responses the system receives from authoritative sources.
CCI-002466	SC-21	The information system requests data integrity verification on the name/address resolution responses the system receives from authoritative sources.
CCI-002467	SC-21	The information system performs data integrity verification on the name/address resolution responses the system receives from authoritative sources.
CCI-002468	SC-21	The information system performs data origin verification authentication on the name/address resolution responses the system receives from authoritative sources.
CCI-002544	SC-41	The organization defines the information systems or information system components on which organization-defined connection ports or input/output devices are to be physically disabled or removed.
CCI-002545	SC-41	The organization defines the connection ports or input/output devices that are to be physically disabled or removed from organization-defined information systems or information system components.
CCI-001228	SI-2(b)	The organization tests software updates related to flaw remediation for effectiveness before installation.

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-001229	SI-2(b)	The organization tests software updates related to flaw remediation for potential side effects before installation.
CCI-002602	SI-2(b)	The organization tests firmware updates related to flaw remediation for effectiveness before installation.
CCI-002603	SI-2(b)	The organization tests firmware updates related to flaw remediation for potential side effects before installation.
CCI-001227	SI-2(a)	The organization corrects information system flaws.
CCI-002619	SI-3(a)	The organization employs malicious code protection mechanisms at information system entry points to detect malicious code.
CCI-002621	SI-3(a)	The organization employs malicious code protection mechanisms at information system entry points to eradicate malicious code.
CCI-002620	SI-3(a)	The organization employs malicious code protection mechanisms at information system exit points to detect malicious code.
CCI-002622	SI-3(a)	The organization employs malicious code protection mechanisms at information system exit points to eradicate malicious code.
CCI-001241	SI-3(c)(1)	The organization configures malicious code protection mechanisms to perform periodic scans of the information system on an organization-defined frequency.
CCI-002624	SI-3(c)(1)	The organization configures malicious code protection mechanisms to perform real-time scans of files from external sources at network entry/exit points as the files are downloaded, opened, or executed in accordance with organizational security policy.
CCI-001242	SI-3(c)(1)	The organization configures malicious code protection mechanisms to perform real-time scans of files from external sources at endpoints as the files are downloaded, opened, or executed in accordance with organizational security policy.
CCI-001244	SI-3(c)(2)	The organization defines one or more actions to perform in response to malicious code detection, such as blocking malicious code, quarantining malicious code, or sending alert to administrator.
CCI-001243	SI-3(c)(2)	The organization configures malicious code protection mechanisms to perform organization-defined action(s) in response to malicious code detection.
CCI-001253	SI-4(a)(1)	The organization defines the objectives of monitoring for attacks and indicators of potential attacks on the information system.
CCI-002641	SI-4(a)(1)	The organization monitors the information system to detect attacks and indicators of potential attacks in accordance with organization-defined monitoring objectives.
CCI-002642	SI-4(a)(2)	The organization monitors the information system to detect unauthorized local connections.
CCI-002643	SI-4(a)(2)	The organization monitors the information system to detect unauthorized network connections.
CCI-002644	SI-4(a)(2)	The organization monitors the information system to detect unauthorized remote connections.
CCI-002645	SI-4(b)	The organization defines the techniques and methods to be used to identify unauthorized use of the information system.
CCI-002646	SI-4(b)	The organization identifies unauthorized use of the information system through organization-defined techniques and methods.

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-001256	SI-4(c)	The organization deploys monitoring devices at ad hoc locations within the system to track specific types of transactions of interest to the organization.
CCI-002647	SI-4(d)	The organization protects information obtained from intrusion-monitoring tools from unauthorized access.
CCI-002648	SI-4(d)	The organization protects information obtained from intrusion-monitoring tools from unauthorized modification.
CCI-002649	SI-4(d)	The organization protects information obtained from intrusion-monitoring tools from unauthorized deletion.
CCI-001257	SI-4(e)	The organization heightens the level of information system monitoring activity whenever there is an indication of increased risk to organizational operations and assets, individuals, other organizations, or the Nation based on law enforcement information, intelligence information, or other credible sources of information.
CCI-001258	SI-4(f)	The organization obtains legal opinion with regard to information system monitoring activities in accordance with applicable federal laws, Executive Orders, directives, policies, or regulations.
CCI-002650	SI-4(g)	The organization defines the information system monitoring information that is to be provided the organization-defined personnel or roles.
CCI-002651	SI-4(g)	The organization defines the personnel or roles that are to be provided organization-defined information system monitoring information.
CCI-002652	SI-4(g)	The organization defines the frequency at which the organization will provide the organization-defined information system monitoring information to organization-defined personnel or roles
CCI-002654	SI-4(g)	The organization provides organization-defined information system monitoring information to organization-defined personnel or roles as needed or per organization-defined frequency.
CCI-002692	SI-5(a)	The organization defines the external organizations from which it receives information system security alerts, advisories and directives.
CCI-001285	SI-5(a)	The organization receives information system security alerts, advisories, and directives from organization-defined external organizations on an ongoing basis.
CCI-001286	SI-5(b)	The organization generates internal security alerts, advisories, and directives as deemed necessary.
CCI-002693	SI-5(c)	The organization defines the elements within the organization to whom the organization will disseminate security alerts, advisories and directives.
CCI-001288	SI-5(c)	The organization defines the personnel or roles to whom the organization will disseminate security alerts, advisories and directives.
CCI-001287	SI-5(c)	The organization disseminates security alerts, advisories, and directives to organization-defined personnel or roles, organization-defined elements within the organization, and/or organization-defined external organizations.
CCI-001289	SI-5(d)	The organization implements security directives in accordance with established time frames, or notifies the issuing organization of the degree of noncompliance.
CCI-000080	PM-3(a)	The organization ensures that all capital planning and investment requests include the resources needed to implement the information security program and documents all exceptions to this requirement.

Table G-6 Platform Enclave CCIs for LOW and MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-000081	PM-3(b)	The organization employs a business case/Exhibit 300/Exhibit 53 to record the resources required.
CCI-000141	PM-3(c)	The organization ensures that information security resources are available for expenditure as planned.
CCI-002991	PM-4(a)(1)	The organization implements a process for ensuring that plans of action and milestones for the security program and associated organizational information systems are developed.
CCI-000142	PM-4(a)(1)	The organization implements a process for ensuring that plans of action and milestones for the security program and the associated organizational information systems are maintained.
CCI-000170	PM-4(a)(2)	The organization implements a process for ensuring that plans of action and milestones for the security program and associated organizational information systems document the remedial information security actions to adequately respond to risk to organizational operations and assets, individuals, other organizations, and the Nation.
CCI-002992	PM-4(a)(3)	The organization implements a process for ensuring that plans of action and milestones for the security program and associated organizational information systems are reported in accordance with OMB FISMA reporting requirements.
CCI-000236	PM-11(b)	The organization determines information protection needs arising from the defined mission/business processes and revises the processes as necessary, until an achievable set of protection needs are obtained.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-000015	AC-2(1)	The organization employs automated mechanisms to support the information system account management functions.
CCI-001361	AC-2(2)	The organization defines a time period after which temporary accounts are automatically terminated.
CCI-001365	AC-2(2)	The organization defines a time period after which emergency accounts are automatically terminated.
CCI-001682	AC-2(2)	The information system automatically removes or disables emergency accounts after an organization-defined time period for each type of account.
CCI-000016	AC-2(2)	The information system automatically removes or disables temporary accounts after an organization-defined time period for each type of account.
CCI-000017	AC-2(3)	The information system automatically disables inactive accounts after an organization-defined time period.
CCI-000018	AC-2(4)	The information system automatically audits account creation actions.
CCI-001403	AC-2(4)	The information system automatically audits account modification actions.
CCI-002130	AC-2(4)	The information system automatically audits account enabling actions.
CCI-001404	AC-2(4)	The information system automatically audits account disabling actions.
CCI-001405	AC-2(4)	The information system automatically audits account removal actions.
CCI-001683	AC-2(4)	The information system notifies organization-defined personnel or roles for account creation actions.
CCI-001684	AC-2(4)	The information system notifies organization-defined personnel or roles for account modification actions.
CCI-002132	AC-2(4)	The information system notifies organization-defined personnel or roles for account enabling actions.
CCI-001685	AC-2(4)	The information system notifies organization-defined personnel or roles for account disabling actions.
CCI-001686	AC-2(4)	The information system notifies organization-defined personnel or roles for account removal actions.
CCI-001368	AC-4	The information system enforces approved authorizations for controlling the flow of information within the system based on organization-defined information flow control policies.
CCI-001414	AC-4	The information system enforces approved authorizations for controlling the flow of information between interconnected systems based on organization-defined information flow control policies.
CCI-001548	AC-4	The organization defines the information flow control policies for controlling the flow of information within the system.
CCI-001549	AC-4	The organization defines the information flow control policies for controlling the flow of information between interconnected systems.
CCI-001550	AC-4	The organization defines approved authorizations for controlling the flow of information within the system.
CCI-001551	AC-4	The organization defines approved authorizations for controlling the flow of information between interconnected systems.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-002220	AC-5(c)	The organization defines information system access authorizations to support separation of duties.
CCI-000225	AC-6	The organization employs the concept of least privilege, allowing only authorized accesses for users (and processes acting on behalf of users) which are necessary to accomplish assigned tasks in accordance with organizational missions and business functions.
CCI-002231	AC-6(7)(b)	The organization reassigns or removes privileges, if necessary, to correctly reflect organizational mission/business needs.
CCI-000059	AC-11(a)	The organization defines the time period of inactivity after which the information system initiates a session lock.
CCI-000058	AC-11(a)	The information system provides the capability for users to directly initiate session lock mechanisms.
CCI-000056	AC-11(b)	The information system retains the session lock until the user reestablishes access using established identification and authentication procedures.
CCI-000060	AC-11(1)	The information system conceals, via the session lock, information previously visible on the display with a publicly viewable image.
CCI-002360	AC-12	The organization defines the conditions or trigger events requiring session disconnect to be employed by the information system when automatically terminating a user session.
CCI-002361	AC-12	The information system automatically terminates a user session after organization-defined conditions or trigger events requiring session disconnect.
CCI-000067	AC-17(1)	The information system monitors remote access methods.
CCI-002314	AC-17(1)	The information system controls remote access methods.
CCI-000068	AC-17(2)	The information system implements cryptographic mechanisms to protect the confidentiality of remote access sessions.
CCI-001453	AC-17(2)	The information system implements cryptographic mechanisms to protect the integrity of remote access sessions.
CCI-001561	AC-17(3)	The organization defines managed access control points for remote access to the information system.
CCI-002315	AC-17(3)	The organization defines the number of managed network access control points through which the information system routes all remote access.
CCI-000069	AC-17(3)	The information system routes all remote accesses through organization-defined number managed network access control points.
CCI-000070	AC-17(4)(a)	The organization authorizes the execution of privileged commands via remote access only for organization-defined needs.
CCI-002316	AC-17(4)(a)	The organization authorizes the access to security-relevant information via remote access only for organization-defined needs.
CCI-002317	AC-17(4)(a)	The organization defines the operational needs when the execution of privileged commands via remote access is to be authorized.
CCI-002318	AC-17(4)(a)	The organization defines the operational needs when access to security-relevant information via remote access is to be authorized.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	800-53 Control Text Indicator	CCI Definition
CCI-002319	AC-17(4)(b)	The organization documents in the security plan for the information system the rationale for authorization of the execution of privilege commands via remote access.
CCI-002320	AC-17(4)(b)	The organization documents in the security plan for the information system the rationale for authorization of access to security-relevant information via remote access.
CCI-002321	AC-17(9)	The organization defines the time period within which it disconnects or disables remote access to the information system.
CCI-002322	AC-17(9)	The organization provides the capability to expeditiously disconnect or disable remote access to the information system within the organization-defined time period.
CCI-002329	AC-19(5)	The organization defines the mobile devices that are to employ full-device or container encryption to protect the confidentiality and integrity of the information on device.
CCI-002330	AC-19(5)	The organization employs full-device encryption or container encryption to protect the confidentiality of information on organization-defined mobile devices.
CCI-002333	AC-20(1)(a)	The organization permits authorized individuals to use an external information system to access the information system only when the organization verifies the implementation of required security controls on the external system as specified in the organization’s information security policy and security plan.
CCI-002334	AC-20(1)(a)	The organization permits authorized individuals to use an external information system to process organization-controlled information only when the organization verifies the implementation of required security controls on the external system as specified in the organization’s information security policy and security plan.
CCI-002335	AC-20(1)(a)	The organization permits authorized individuals to use an external information system to store organization-controlled information only when the organization verifies the implementation of required security controls on the external system as specified in the organization’s information security policy and security plan.
CCI-002336	AC-20(1)(a)	The organization permits authorized individuals to use an external information system to transmit organization-controlled information only when the organization verifies the implementation of required security controls on the external system as specified in the organization’s information security policy and security plan.
CCI-002337	AC-20(1)(b)	The organization permits authorized individuals to use an external information system to access the information system or to process, store, or transmit organization-controlled information only when the organization retains approved information system connection or processing agreements with the organizational entity hosting the external information system.
CCI-000097	AC-20(2)	The organization restricts or prohibits the use of organization-controlled portable storage devices by authorized individuals on external information systems.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-001875	AU-7(a)	The information system provides an audit reduction capability that supports on-demand audit review and analysis.
CCI-001876	AU-7(a)	The information system provides an audit reduction capability that supports on-demand reporting requirements.
CCI-001877	AU-7(a)	The information system provides an audit reduction capability that supports after-the-fact investigations of security incidents.
CCI-001878	AU-7(a)	The information system provides a report generation capability that supports on-demand audit review and analysis.
CCI-001879	AU-7(a)	The information system provides a report generation capability that supports on-demand reporting requirements.
CCI-001880	AU-7(a)	The information system provides a report generation capability that supports after-the-fact investigations of security incidents.
CCI-001881	AU-7(b)	The information system provides an audit reduction capability that does not alter original content or time ordering of audit records.
CCI-001882	AU-7(b)	The information system provides a report generation capability that does not alter original content or time ordering of audit records.
CCI-000158	AU-7(1)	The information system provides the capability to process audit records for events of interest based on organization-defined audit fields within audit records.
CCI-002081	CA-3(5)	The organization defines the information systems that employ either allow-all, deny-by-exception or deny-all, permit by exception policy for allowing connection to external information systems.
CCI-002082	CA-3(5)	The organization selects either allow-all, deny-by exception or deny-all, permit by exception policy for allowing organization-defined information systems to connect to external information systems.
CCI-002080	CA-3(5)	The organization employs either an allow-all, deny-by exception or deny-all, permit by exception policy for allowing organization-defined information systems to connect to external information systems.
CCI-000338	CM-5	The organization defines physical access restrictions associated with changes to the information system.
CCI-000339	CM-5	The organization documents physical access restrictions associated with changes to the information system.
CCI-000340	CM-5	The organization approves physical access restrictions associated with changes to the information system.
CCI-000341	CM-5	The organization enforces physical access restrictions associated with changes to the information system.
CCI-000342	CM-5	The organization defines logical access restrictions associated with changes to the information system.
CCI-000343	CM-5	The organization documents logical access restrictions associated with changes to the information system.
CCI-000344	CM-5	The organization approves logical access restrictions associated with changes to the information system.
CCI-000345	CM-5	The organization enforces logical access restrictions associated with changes to the information system.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-000419	CM-8(5)	The organization verifies that all components within the authorization boundary of the information system are not duplicated in other information system inventories.
CCI-000505	CP-6(a)	The organization establishes an alternate storage site including necessary agreements to permit the storage and retrieval of information system backup information.
CCI-002836	CP-6(b)	The organization ensures that the alternate storage site provides information security safeguards equivalent to that of the primary site.
CCI-000507	CP-6(1)	The organization identifies an alternate storage site that is separated from the primary storage site to reduce susceptibility to the same threats.
CCI-000509	CP-6(3)	The organization identifies potential accessibility problems to the alternate storage site in the event of an area-wide disruption or disaster.
CCI-001604	CP-6(3)	The organization outlines explicit mitigation actions for organization identified accessibility problems to the alternate storage site in the event of an area-wide disruption or disaster.
CCI-000510	CP-7(a)	The organization defines the time period consistent with recovery time and recovery point objectives for essential missions/business functions to permit the transfer and resumption of organization-defined information system operations at an alternate processing site when the primary processing capabilities are unavailable.
CCI-000513	CP-7(a)	The organization establishes an alternate processing site including necessary agreements to permit the transfer and resumption of organization-defined information system operations for essential missions within organization-defined time period consistent with recovery time and recovery point objectives when the primary processing capabilities are unavailable.
CCI-002839	CP-7(a)	The organization defines information system operations that are permitted to transfer and resume at an alternate processing sites for essential missions/business functions when the primary processing capabilities are unavailable.
CCI-000515	CP-7(b)	The organization ensures that equipment and supplies required to transfer and resume operations are available at the alternate processing site or contracts are in place to support delivery to the site within the organization-defined time period for transfer/resumption.
CCI-000521	CP-7(c)	The organization ensures that the alternate processing site provides information security safeguards equivalent to that of the primary site.
CCI-000516	CP-7(1)	The organization identifies an alternate processing site that is separated from the primary processing site to reduce susceptibility to the same threats.
CCI-000517	CP-7(2)	The organization identifies potential accessibility problems to the alternate processing site in the event of an area-wide disruption or disaster.
CCI-001606	CP-7(2)	The organization outlines explicit mitigation actions for organization identified potential accessibility problems to the alternate processing site in the event of an area-wide disruption or disaster.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-000518	CP-7(3)	The organization develops alternate processing site agreements that contain priority-of-service provisions in accordance with the organizational availability requirements (including recovery time objectives).
CCI-000522	CP-8	The organization defines the time period to permit the resumption of organization-defined information system operations for essential missions when the primary telecommunications capabilities are unavailable at either the primary or alternate processing or storage sites.
CCI-000524	CP-8	The organization establishes alternate telecommunication services including necessary agreements to permit the resumption of organization-defined information system operations for essential missions within organization-defined time period when the primary telecommunications capabilities are unavailable at either the primary or alternate processing or storage sites.
CCI-002840	CP-8	The organization defines the information system operations to be resumed for essential missions within the organization-defined time period when the primary telecommunications capabilities are unavailable at either the primary or alternate processing or storage sites.
CCI-000526	CP-8(1)(a)	The organization develops primary telecommunications service agreements that contain priority-of-service provisions in accordance with the organizations availability requirements (including recovery time objectives).
CCI-000527	CP-8(1)(a)	The organization develops alternate telecommunications service agreements that contain priority-of-service provisions in accordance with the organizations availability requirements (including recovery time objectives).
CCI-000528	CP-8(1)(b)	The organization requests Telecommunications Service Priority for all telecommunications services used for national security emergency preparedness in the event that the primary telecommunications services are provided by a common carrier.
CCI-000529	CP-8(1)(b)	The organization requests Telecommunications Service Priority for all telecommunications services used for national security emergency preparedness in the event that the alternate telecommunications services are provided by a common carrier.
CCI-000530	CP-8(2)	The organization obtains alternate telecommunications services to reduce the likelihood of sharing a single point of failure with primary telecommunications services.
CCI-000541	CP-9(1)	The organization defines the frequency to test backup information to verify media reliability and information integrity.
CCI-000542	CP-9(1)	The organization tests backup information per organization-defined frequency to verify media reliability and information integrity.
CCI-000766	IA-2(2)	The information system implements multifactor authentication for network access to non-privileged accounts.
CCI-000767	IA-2(3)	The information system implements multifactor authentication for local access to privileged accounts.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-001947	IA-2(11)	The organization defines the strength of mechanism requirements for the device that is separate from the system gaining access and is to provide one factor of a multifactor authentication for remote access to privileged accounts.
CCI-001950	IA-2(11)	The organization defines the strength of mechanism requirements for the device that is separate from the system gaining access and is to provide one factor of a multifactor authentication for remote access to non-privileged accounts.
CCI-001948	IA-2(11)	The information system implements multifactor authentication for remote access to privileged accounts such that one of the factors is provided by a device separate from the system gaining access.
CCI-001952	IA-2(11)	The device used in the information system implementation of multifactor authentication for remote access to non-privileged accounts meets organization-defined strength of mechanism requirements.
CCI-001951	IA-2(11)	The information system implements multifactor authentication for remote access to non-privileged accounts such that one of the factors is provided by a device separate from the system gaining access.
CCI-001949	IA-2(11)	The device used in the information system implementation of multifactor authentication for remote access to privileged accounts meets organization-defined strength of mechanism requirements.
CCI-000185	IA-5(2)(a)	The information system, for PKI-based authentication validates certifications by constructing and verifying a certification path to an accepted trust anchor including checking certificate status information.
CCI-000186	IA-5(2)(b)	The information system, for PKI-based authentication enforces authorized access to the corresponding private key.
CCI-000187	IA-5(2)(c)	The information system, for PKI-based authentication, maps the authenticated identity to the account of the individual or group.
CCI-001991	IA-5(2)(d)	The information system, for PKI-based authentication, implements a local cache of revocation data to support path discovery and validation in case of inability to access revocation information via the network.
CCI-001992	IA-5(3)	The organization defines the personnel or roles responsible for authorizing the organization's registration authority accountable for the authenticator registration process.
CCI-001993	IA-5(3)	The organization defines the registration authority accountable for the authenticator registration process.
CCI-001994	IA-5(3)	The organization defines the types of and/or specific authenticators that are subject to the authenticator registration process.
CCI-001995	IA-5(3)	The organization requires that the registration process, to receive organization-defined types of and/or specific authenticators, be conducted in person, or by a trusted third-party, before organization-defined registration authority with authorization by organization-defined personnel or roles.
CCI-002890	MA-4(6)	The information system implements cryptographic mechanisms to protect the integrity of nonlocal maintenance and diagnostic communications.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-003123	MA-4(6)	The information system implements cryptographic mechanisms to protect the confidentiality of nonlocal maintenance and diagnostic communications.
CCI-002891	MA-4(7)	The information system implements remote disconnect verification at the termination of nonlocal maintenance and diagnostic sessions.
CCI-001010	MP-3(a)	The organization marks information system media indicating the distribution limitations, handling caveats, and applicable security markings (if any) of the information.
CCI-001011	MP-3(b)	The organization exempts organization-defined types of information system media from marking as long as the media remain within organization-defined controlled areas.
CCI-001012	MP-3(b)	The organization defines types of information system media to exempt from marking as long as the media remain within organization-defined controlled areas.
CCI-001013	MP-3(b)	The organization defines controlled areas where organization-defined types of information system media are exempt from being marked.
CCI-001014	MP-4(a)	The organization physically controls and securely stores organization-defined types of digital and/or non-digital media within organization-defined controlled areas.
CCI-001015	MP-4(a)	The organization defines types of digital and/or non-digital media to physically control and securely store within organization-defined controlled areas.
CCI-001016	MP-4(a)	The organization defines controlled areas where organization-defined types of digital and/or non-digital media are physically controlled and securely stored.
CCI-001018	MP-4(b)	The organization protects information system media until the media are destroyed or sanitized using approved equipment, techniques, and procedures.
CCI-001020	MP-5(a)	The organization protects and controls organization-defined types of information system media during transport outside of controlled areas using organization-defined security safeguards.
CCI-001021	MP-5(a)	The organization defines types of information system media protected and controlled during transport outside of controlled areas.
CCI-001022	MP-5(a)	The organization defines security safeguards to be used to protect and control organization-defined types of information system media during transport outside of controlled areas.
CCI-001023	MP-5(b)	The organization maintains accountability for information system media during transport outside of controlled areas.
CCI-001025	MP-5(c)	The organization documents activities associated with the transport of information system media.
CCI-001024	MP-5(d)	The organization restricts the activities associated with the transport of information system media to authorized personnel.
CCI-001027	MP-5(4)	The information system implements cryptographic mechanisms to protect the confidentiality and integrity of information stored on digital media during transport outside of controlled areas.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-002585	MP-7(1)	The organization prohibits the use of portable storage devices in organization information systems when such devices have no identifiable owner.
CCI-000956	PE-10(a)	The organization provides the capability of shutting off power to the information system or individual system components in emergency situations.
CCI-000957	PE-10(b)	The organization places emergency shutoff switches or devices in an organization-defined location by information system or system component to facilitate safe and easy access for personnel.
CCI-000958	PE-10(b)	The organization defines a location for emergency shutoff switches or devices by information system or system component.
CCI-000959	PE-10(c)	The organization protects emergency power shutoff capability from unauthorized activation.
CCI-002955	PE-11	The organization provides a short-term uninterruptible power supply to facilitate an orderly shutdown of the information system and/or transition of the information system to long-term alternate power in the event of a primary power source loss.
CCI-000961	PE-11(1)	The organization provides a long-term alternate power supply for the information system that is capable of maintaining minimally required operational capability in the event of an extended loss of the primary power source.
CCI-001062	RA-5(1)	The organization employs vulnerability scanning tools that include the capability to readily update the information system vulnerabilities to be scanned.
CCI-001063	RA-5(2)	The organization updates the information system vulnerabilities scanned on an organization-defined frequency, prior to a new scan and/or when new vulnerabilities are identified and reported.
CCI-001067	RA-5(5)	The information system implements privileged access authorization to organization-identified information system components for selected organization-defined vulnerability scanning activities.
CCI-001645	RA-5(5)	The organization identifies the information system components to which privileged access is authorized for selected organization-defined vulnerability scanning activities.
CCI-002906	RA-5(5)	The organization defines the vulnerability scanning activities in which the information system implements privileged access authorization to organization-identified information system components.
CCI-000634	SA-4(7)(a)	The organization limits the use of commercially provided information assurance (IA) and IA-enabled information technology products to those products that have been successfully evaluated against a National Information Assurance partnership (NIAP)-approved Protection Profile for a specific technology type, if such a profile exists.
CCI-000635	SA-4(7)(b)	The organization requires, if no NIAP-approved Protection Profile exists for a specific technology type but a commercially provided information technology product relies on cryptographic functionality to enforce its security policy, that the cryptographic module is FIPS-validated.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-003143	SA-9(2)	The organization requires providers of organization-defined external information system services to identify the functions, ports, protocols, and other services required for the use of such services.
CCI-003144	SA-9(2)	The organization defines the external information system services for which the providers are required to identify the functions, ports, protocols, and other services required for the use of such services.
CCI-001082	SC-2	The information system separates user functionality (including user interface services) from information system management functionality.
CCI-001090	SC-4	The information system prevents unauthorized and unintended information transfer via shared system resources.
CCI-001094	SC-5(1)	The information system restricts the ability of individuals to launch organization-defined denial of service attacks against other information systems.
CCI-001101	SC-7(3)	The organization limits the number of external network connections to the information system.
CCI-001102	SC-7(4)(a)	The organization implements a managed interface for each external telecommunication service.
CCI-001103	SC-7(4)(b)	The organization establishes a traffic flow policy for each managed interface for each external telecommunication service.
CCI-002396	SC-7(4)(c)	The organization protects the confidentiality and integrity of the information being transmitted across each interface for each external telecommunication service.
CCI-001105	SC-7(4)(d)	The organization documents each exception to the traffic flow policy with a supporting mission/business need and duration of that need for each external telecommunication service.
CCI-001108	SC-7(4)(e)	The organization removes traffic flow policy exceptions that are no longer supported by an explicit mission/business need for each external telecommunication service.
CCI-001106	SC-7(4)(e)	The organization reviews exceptions to the traffic flow policy on an organization-defined frequency for each external telecommunication service.
CCI-001109	SC-7(5)	The information system at managed interfaces denies network communications traffic by default and allows network communications traffic by exception (i.e., deny all, permit by exception).
CCI-002397	SC-7(7)	The information system, in conjunction with a remote device, prevents the device from simultaneously establishing non-remote connections with the system and communicating via some other connection to resources in external networks.
CCI-001113	SC-7(8)	The organization defines the internal communications traffic to be routed to external networks.
CCI-001114	SC-7(8)	The organization defines the external networks to which the organization-defined internal communications traffic should be routed.
CCI-001112	SC-7(8)	The information system routes organization-defined internal communications traffic to organization-defined external networks through authenticated proxy servers at managed interfaces.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	800-53 Control Text Indicator	CCI Definition
CCI-002398	SC-7(9)(a)	The information system detects outgoing communications traffic posing a threat to external information systems.
CCI-002399	SC-7(9)(a)	The information system denies outgoing communications traffic posing a threat to external information systems.
CCI-002403	SC-7(11)	The information system only allows incoming communications from organization-defined authorized sources routed to organization-defined authorized destinations.
CCI-002401	SC-7(11)	The organization defines the authorized sources from which the information system will allow incoming communications.
CCI-002402	SC-7(11)	The organization defines the authorized destinations for routing inbound communications.
CCI-002404	SC-7(12)	The organization defines the host-based boundary protection mechanisms that are to be implemented at organization-defined information system components.
CCI-002405	SC-7(12)	The organization defines the information system components at which organization-defined host-based boundary protection mechanisms will be implemented.
CCI-002406	SC-7(12)	The organization implements organization-defined host-based boundary protection mechanisms at organization-defined information system components.
CCI-001120	SC-7(13)	The organization defines key information security tools, mechanisms, and support components to be isolated.
CCI-001119	SC-7(13)	The organization isolates organization-defined information security tools, mechanisms, and support components from other internal information system components by implementing physically separate subnetworks with managed interfaces to other components of the system.
CCI-001121	SC-7(14)	The organization protects against unauthorized physical connections at organization-defined managed interfaces.
CCI-001122	SC-7(14)	The organization defines the managed interfaces where boundary protections against unauthorized physical connections are to be implemented.
CCI-002407	SC-7(14)	The organization defines the managed interfaces at which the organization protects against unauthorized physical connections.
CCI-001133	SC-10	The information system terminates the network connection associated with a communications session at the end of the session or after an organization-defined time period of inactivity.
CCI-002449	SC-13	The organization defines the cryptographic uses, and type of cryptography required for each use, to be implemented by the information system.
CCI-002450	SC-13	The information system implements organization-defined cryptographic uses and type of cryptography required for each use in accordance with applicable federal laws, Executive Orders, directives, policies, regulations, and standards.
CCI-001159	SC-17	The organization issues public key certificates under an organization-defined certificate policy or obtains public key certificates from an approved service provider.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-002456	SC-17	The organization defines the certificate policy employed to issue public key certificates.
CCI-001160	SC-18(a)	The organization defines acceptable and unacceptable mobile code and mobile code technologies.
CCI-001161	SC-18(b)	The organization establishes usage restrictions for acceptable mobile code and mobile code technologies.
CCI-001162	SC-18(b)	The organization establishes implementation guidance for acceptable mobile code and mobile code technologies.
CCI-001163	SC-18(c)	The organizations authorizes the use of mobile code within the information system.
CCI-001164	SC-18(c)	The organization monitors the use of mobile code within the information system.
CCI-001165	SC-18(c)	The organization controls the use of mobile code within the information system.
CCI-001166	SC-18(1)	The information system identifies organization-defined unacceptable mobile code.
CCI-001662	SC-18(1)	The information system takes organization-defined corrective action when organization-defined unacceptable mobile code is identified.
CCI-002457	SC-18(1)	The organization defines the corrective actions to be taken when organization-defined unacceptable mobile code is identified.
CCI-002458	SC-18(1)	The organization defines what constitutes unacceptable mobile code for its information systems.
CCI-001184	SC-23	The information system protects the authenticity of communications sessions.
CCI-001199	SC-28	The information system protects the confidentiality and/or integrity of organization-defined information at rest.
CCI-001234	SI-2(2)	The organization defines a frequency for employing automated mechanisms to determine the state of information system components with regard to flaw remediation.
CCI-001233	SI-2(2)	The organization employs automated mechanisms on an organization-defined frequency to determine the state of information system components with regard to flaw remediation.
CCI-001246	SI-3(1)	The organization centrally manages malicious code protection mechanisms.
CCI-001247	SI-3(2)	The information system automatically updates malicious code protection mechanisms.
CCI-002655	SI-4(1)	The organization connects individual intrusion detection tools into an information system-wide intrusion detection system.
CCI-002656	SI-4(1)	The organization configures individual intrusion detection tools into an information system-wide intrusion detection system.
CCI-001260	SI-4(2)	The organization employs automated tools to support near real-time analysis of events.
CCI-002659	SI-4(4)	The organization defines the frequency on which it will monitor inbound communications for unusual or unauthorized activities or conditions.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-002660	SI-4(4)	The organization defines the frequency on which it will monitor outbound communications for unusual or unauthorized activities or conditions.
CCI-002661	SI-4(4)	The information system monitors inbound communications traffic per organization-defined frequency for unusual or unauthorized activities or conditions.
CCI-002662	SI-4(4)	The information system monitors outbound communications traffic per organization-defined frequency for unusual or unauthorized activities or conditions.
CCI-001264	SI-4(5)	The organization defines indicators of compromise or potential compromise to the security of the information system which will result in information system alerts being provided to organization-defined personnel or roles.
CCI-002663	SI-4(5)	The organization defines the personnel or roles to receive information system alerts when organization-defined indicators of compromise or potential compromise occur.
CCI-002664	SI-4(5)	The information system alerts organization-defined personnel or roles when organization-defined compromise indicators reflect the occurrence of a compromise or a potential compromise.
CCI-001273	SI-4(11)	The organization analyzes outbound communications traffic at the external boundary of the information system to discover anomalies.
CCI-001671	SI-4(11)	The organization analyzes outbound communications traffic at selected organization-defined interior points within the system (e.g., subnetworks, subsystems) to discover anomalies.
CCI-001673	SI-4(14)	The organization employs a wireless intrusion detection system to identify rogue wireless devices and to detect attack attempts and potential compromises/breaches to the information system.
CCI-001282	SI-4(15)	The organization employs an intrusion detection system to monitor wireless communications traffic as the traffic passes from wireless to wireline networks.
CCI-002683	SI-4(22)	The information system detects network services that have not been authorized or approved by the organization-defined authorization or approval processes.
CCI-002684	SI-4(22)	The information system audits and/or alerts organization-defined personnel when unauthorized network services are detected.
CCI-002685	SI-4(23)	The organization defines the host-based monitoring mechanisms to be implemented at organization-defined information system components.
CCI-002687	SI-4(23)	The organization implements organization-defined host-based monitoring mechanisms at organization-defined information system components.
CCI-002703	SI-7	The organization defines the software, firmware, and information which will be subjected to integrity verification tools to detect unauthorized changes.
CCI-002704	SI-7	The organization employs integrity verification tools to detect unauthorized changes to organization-defined software, firmware, and information.
CCI-002705	SI-7(1)	The organization defines the software on which integrity checks will be performed.

Table G-7 Additional Platform Enclave CCIs for MODERATE Impact Control Systems		
CCI #	**800-53 Control Text Indicator**	**CCI Definition**
CCI-002706	SI-7(1)	The organization defines the firmware on which integrity checks will be performed.
CCI-002707	SI-7(1)	The organization defines the information on which integrity checks will be performed.
CCI-002710	SI-7(1)	The information system performs an integrity check of organization-defined software at startup, at organization-defined transitional states or security-relevant events, or on organization-defined frequency.
CCI-002711	SI-7(1)	The information system performs an integrity check of organization-defined firmware at startup, at organization-defined transitional states or security-relevant events, or on organization-defined frequency.
CCI-002712	SI-7(1)	The information system performs an integrity check of organization-defined information at startup, at organization-defined transitional states or security-relevant events, or on organization-defined frequency.
CCI-002708	SI-7(1)	The organization defines the transitional state or security-relevant events when the information system will perform integrity checks on software, firmware and information.
CCI-002719	SI-7(7)	The organization defines the unauthorized security-relevant changes to the information system that are to be incorporated into the organizational incident response capability.
CCI-002720	SI-7(7)	The organization incorporates the detection of unauthorized organization-defined security-relevant changes to the information system into the organizational incident response capability.
CCI-002823	SI-16	The organization defines the security safeguards to be implemented to protect the information system's memory from unauthorized code execution.
CCI-002824	SI-16	The information system implements organization-defined security safeguards to protect its memory from unauthorized code execution.

This Page Intentionally Left Blank

APPENDIX H GLOSSARY

H-1 ACRONYMS

H-1.1 General Acronyms

Acronym	**Term**
ACL	Access Control List
AO	Authorizing Official
BAS	Building Automation System
BCS	Building Control System
CCTV	Closed Circuit Television
CNSSI	Committee on National Security Systems Instruction
CCI	Control Correlation Identifier
COTS	Commercial Off The Shelf
CS	Control System
DoD	Department of Defense
ESS	Electronic Security System
FCN	Field Control Network
FCS	Field Control System
FIPS	Federal Information Processing Standards
FISMA	Federal Information Security Management Act
FPOC	Field Point of Connection
GFE	Government Furnished Equipment
ICS	Industrial Control System
IDS	Intrusion Detection System
ISSM	Information System Security Manager
ISSO	Information System Security Officer
IP	Internet Protocol
IT	Information Technology
MOA	Memorandum Of Agreement
MOU	Memorandum Of Understanding
NIST	National Institute of Standards and Technology
OS	Operating System

Acronym	**Term**
PIT	Platform Information Technology
PKI	Public Key Infrastructure
SO	System Owner
UCS	Utility Control System
UFC	Unified Facilities Criteria
UFGS	Unified Facilities Guide Specification
UMCS	Utility Monitoring and Control System
UPS	Uninterruptible Power Supply
USACE	U.S. Army Corps of Engineers

H-1.2 Security Control Family Acronyms

Acronym	**Term**
AC	Access Control
AT	Awareness and Training
AU	Audit and Accountability
CA	Security Assessment and Authorization
CM	Configuration Management
CP	Contingency Planning
IA	Identification and Authorization
IR	Incident Response
MA	Maintenance
MP	Media Protection
PE	Physical and Environmental Protection
PL	Planning
PM	Program Management
PS	Personnel Security
RA	Risk Assessment
SA	System and Services Acquisition
SC	System and Communications Protection
SI	System and Information Integrity

H-2 DEFINITION OF TERMS

Note that UFGS 25 05 11, “Cybersecurity for Facility-Related Control Systems” also has definitions that complement those provided here.

Term	Definition
Authorizing Official (CNSSI No. 4009)	A senior (federal) official or executive with the authority to formally assume responsibility for operating an information system at an acceptable level of risk to organizational operations (including mission, functions, image, or reputation), organizational assets, individuals, other organizations, and the Nation. Within the DoD, they are presumed to be SES or flag-level officers.
Building Automation System (BAS)	The system consisting of a UMCS Front End, connected Building Control Systems which control building electrical and mechanical systems, and user interfaces for building control supervision. The BAS is a subsystem of the Utility Monitoring and Control System. This term is being phased out in favor of UMCS.
Building Control System (BCS)	A system that controls building electrical and mechanical systems such as HVAC (including central plants), lighting, vertical transport systems, and irrigation systems. Building Control Systems generally do not have a full-featured user interface; they may have “local display panels” but typically rely on the UMCS front end for full user interface functionality. BCS is a subsystem of the Utility Monitoring and Control System and is a class of Field Control System.
Closed Circuit Television System (CCTV)	An ESS that allows video assessment of alarm conditions via remote monitoring and recording of video events. Video monitoring may also be incorporated into other systems which are not CCTV.
Control Correlation Identifier (CCI)	The Control Correlation Identifier (CCI) provides a standard identifier and description for each of the singular, actionable statements that comprise a security control.

Term	Definition
Control System (CS)	Control systems are a combination of special purpose controlling devices (controllers), control components (e.g. electrical, mechanical or pneumatic sensors and actuators), and generally (but not always) network infrastructure (which may contain standard IT components) that act together upon underlying mechanical and/or electrical equipment to achieve an objective. A control system (CS) typically consists of sensors and actuators connected to networked digital controllers, includes a user interface, and is used to control and monitor equipment. Some control systems are "monitor only" (they do not exercise control) but are still considered control systems.
Controller	An electronic device – usually having internal programming logic and digital and analog input/output capability – which performs control functions.
Distributed Control System	This term describes a system architecture (not system functionality) and appears in some reference material (such as a NIST publications) but is not used by this UFC. (It's included here due to use in some reference material.)
Electronic Security System (ESS)	The integrated electronic system that encompasses interior and exterior (physical) intrusion detection systems (IDS), CCTV systems for assessment of alarm conditions, access control systems, data transmission media, and alarm reporting systems for monitoring, control, and display.
Engineering Tool Software	Software that is used to perform device or network management for a control system, including network configuration, controller configuration and controller programming.
Facility-Related Control System	A control system which controls equipment and infrastructure that is part of a DoD building, structure, or linear structure.
Field Control System (FCS)	A Building Control System, Utility Control System, Electronic Security System, etc. within the Facility and "downstream" of the FPOC.
Field Control Network (FCN)	The network used by the Building Control System, Utility Control System, etc., within a facility "downstream" of the FPOC. This includes IP, Ethernet, RS-485, TP/FT-10 and other network infrastructure that support control system(s) in a given facility.

Term	Definition
Field Point of Connection (FPOC)	The FPOC is the point of connection between the Level 4 control system IP network and the Level 2 field control IP network. Note the Level 2 IP network here may consist entirely of a single patch cable from the FPOC to a Level 1-to-Level 2 device. The hardware which provides the connection at this location is an IT device such as a switch, IP router, or firewall.
[UMCS, ESS, etc.] Front End	The portion of the control system consisting primarily of IT equipment, such as computers and related equipment, intended to perform operational functions and run monitoring and control/engineering tool application software. The front end does not directly control physical systems; it interacts with them only through field control systems (FCS). The front end is a component of the [UMCS, ESS, etc.] infrastructure (see definition).
Impact	The effect on organizational operations, organizational assets, or individuals due to a loss of Confidentiality, Integrity, or Availability in the control system. Impact is categorized as one of three levels: • LOW: limited adverse effect • MODERATE: serious adverse effect • HIGH: severe or catastrophic adverse effect The impact level of a system is generally written in ALL CAPS for clarity. Further discussion of Impact level is in APPENDIX D
Incident (FIPS PUB 200)	An occurrence that actually or potentially jeopardizes the confidentiality, integrity, or availability of an information system or the information the system processes, stores, or transmits or that constitutes a violation or imminent threat of violation of security policies, security procedures, or acceptable use policies
Industrial Control System (ICS)	One type of control system. Most specifically a control system which controls an industrial (manufacturing) process. Sometimes also used to refer to other types of control systems, particularly utility control systems such as electrical, gas, or water distribution systems.

Term	**Definition**
Information System (CNSSI No. 4009)	A discrete set of information resources organized for the collection, processing, maintenance, use, sharing, dissemination, or disposition of information. Note: Information systems also include specialized systems such as industrial/process controls systems, telephone switching and private branch exchange (PBX) systems, and environmental control systems.
Information Technology (IT)	Any equipment or interconnected system or subsystem of equipment that is used in the automatic acquisition, storage, manipulation, management, movement, control, display, switching, interchange, transmission, or reception of data or information by the executive agency.
[UMCS, ESS, ...] Infrastructure	The portion of a control system (such as a UMCS or ESS) which includes all components that are not part of a field control system. These components include the FPOC, the Platform Enclave, and the front end (i.e., its architecture Levels 3, 4 and 5)
Intrusion Detection System (IDS) [Physical/ESS]	A system consisting of interior and exterior sensors, surveillance devices, and associated communication subsystems that collectively detect an intrusion of a specified site, facility, or perimeter and annunciate an alarm.
Intrusion Detection System (IDS) [Cyber]	A device or software application that monitors network or system activities for malicious activities or policy violations and produces reports to management.
Least Privilege (CNSSI No. 4009)	The principle that a security architecture should be designed so that each entity is granted the minimum system resources and authorizations that the entity needs to perform its function.
Mobile Code (NIST SP 800-53r4)	Software programs or parts of programs obtained from remote information systems, transmitted across a network, and executed on a local information system without explicit installation or execution by the recipient.
Mobile Code Technology (NIST SP 800-53r4)	Software technologies that provide the mechanisms for the production and use of mobile code (e.g., Java, JavaScript, ActiveX, VBScript). Note that use of Mobile Code Technology does not necessarily imply the use of Mobile Code.

Term	Definition
Network	A network is a group of two or more devices that can communicate using a network protocol. Network protocols must provide a method for addressing devices on the network; a communication method that does not provide an addressing scheme is not a networked form of communication. Devices that communicate using a method of communication that does not support device addressing are not using a network.
Non-Local Maintenance (NIST SP 800-53)	Maintenance activities conducted by individuals communicating through a network; either an external network (e.g., the Internet) or an internal network.
Operational Architecture (OA)	Those components of a control system that represent the purely operational components of the system such as controllers, Front End software, and other devices which support operational functions. When the “Platform Enclave” approach to authorizing a control system is used, the “non-standard IT” portions of the control system are authorized as the Operational Architecture and the overall system has two authorizations: Platform Enclave and Operational Architecture.
[UMCS, ESS, ...] Platform Enclave	Those components of the control system that are standard IT components and can be secured in a standard manner independent of the type of control system. These components serve only the control system and include the IP network, network management and security devices (e.g., switches, routers), software, computers and/or other devices which provide management and security of the network.
Platform IT (PIT)	IT, both hardware and software, which is physically part of, dedicated to, or essential in real time to the mission performance of special purpose systems.
Remote Access (NIST SP 800-53)	Remote access is access to organizational information systems by users (or processes acting on behalf of users) communicating through external networks (e.g., the Internet). See definition of “User Interface, Remote” for critical distinction in use of terminology

Term	**Definition**
Risk (NIST SP 800-53)	A measure of the extent to which an entity is threatened by a potential circumstance or event, and typically a function of: (i) the adverse impacts that would arise if the circumstance or event occurs; and (ii) the likelihood of occurrence. Information system-related security risks are those risks that arise from the loss of confidentiality, integrity, or availability of information or information systems and reflect the potential adverse impacts to organizational operations (including mission, functions, image, or reputation), organizational assets, individuals, other organizations, and the Nation.
Risk Management (NIST SP 800-53)	The process of managing risks to organizational operations (including mission, functions, image, reputation), organizational assets, individuals, other organizations, and the Nation, resulting from the operation of an information system, and includes: (i) the conduct of a risk assessment; (ii) the implementation of a risk mitigation strategy; and (iii) employment of techniques and procedures for the continuous monitoring of the security state of the information system.
Supervisory Control and Data Acquisition (SCADA)	This term has a variety of meanings depending on context and is therefore not used in this UFC.
System Owner (SO) (CNSSI No. 4009)	Person or organization having responsibility for the development, procurement, integration, modification, operation and maintenance, and/or final disposition of an information system.
User Interface	A User Interface is something that allows a person to interact with the control system. For purposes of cybersecurity, a User Interface does not include simple analog and/or binary inputs such as HOA switches, dials, etc. (“Manual Local Input” in UFGS 25 05 11) or simple Card Readers. Proper addressing of User Interfaces is critical for cybersecurity. Note that User Interfaces are defined in a more exhaustive and prescriptive manner in UFGS 25 05 11 to enable specification of user interface requirements.

Term	**Definition**
User Interface, Remote or Local	A Remote User Interface implements a Client/Server model where the physical hardware the user interacts with (Client) is physically distinct from the device being affected (Server). Most or all of the security and functionality characteristics of the user interface are defined by the Server, not the Client. A common example of a remote user interface is a web-based interface where the browser (client) is generally on different hardware than the web server (server). A Remote UI remains a Remote UI even if the user happens to be at a Client on the same hardware as the Server. What is important is that a) the Client may be on different hardware than the Server and b) the majority of the security and functional characteristics of the interface are defined at the Server. A Local User Interface is a user interface where the physical hardware the user interacts with (keyboard, buttons, display, etc.) is physically part of the device being affected. All of the relevant characteristics of the user interface are embodied within a single device. Note that this definition of "remote" is consistent with that generally used in the control industry but is not aligned with the NIST 800-53 definition of "Remote" or “Remote Access”, which refers to "outside the system". The term "Remote" here better aligns with the NIST 800-53 definition of "Network" (remote from within the system) Access.
User Interface, Limited or Full	A Limited User Interface is a user interface that - by design - can only alter information local to the user interface. Note that the determination of "alter" includes only direct interactions, it explicitly excludes interactions that might occur as secondary effects. For example, an interface changing the flow setpoint in a pump controller is a direct interaction, the subsequent change in flow (as well as any subsequent downstream changes in valve position) are not direct interactions. For example, a variable speed drive has a Limited Local User Interface which allows the user to change properties within the drive but does not allow affecting things outside the drive. A Full User Interface can alter information in devices outside the device with the user interface. For example, a typical Local Display Panel is a Full Local User Interface while a browser-based front end is a Full Remote User Interface.

Term	**Definition**
User Interface, Privileged	A Privileged UI is a UI that has sufficient capabilities or functionality that it requires specific cybersecurity measures to be put in place to limit its unauthorized use. Ultimately, whether a specific user interface is considered a Privileged User Interface must be determined by usage. In general however, user interfaces that do not offer significant capabilities above and beyond those available at that location via other means (e.g., a disconnect switch, breaker, hand-off-auto switch, or direct physical attack) are not privileged. Note that UFGS 25 05 11 contains additional information and requirements on identifying when a UI is a Privileged UI to enable specification of UI requirements.
Utility Control System (UCS)	A type of field control system used for control of utility systems such as electrical distribution and generation, sanitary sewer collection and treatment, water generation and pumping, etc. Building controls are excluded from a UCS, however it is possible to have a Utility Control System and a Building Control System in the same facility, and for those systems to share components such as the FPOC. A UCS is a subsystem of a Utility Monitoring and Control System (UMCS) and is a class of Field Control System (FCS).
Utility Monitoring and Control System (UMCS)	The system consisting of one or more building control systems and/or utility control systems and the associated UMCS Infrastructure. In other words, it is the complete utility monitoring system – from the front end to the controllers. At the highest level the UMCS is composed of a UMCS Platform Enclave and UMCS Front End (jointly referred to as UMCS Infrastructure) and connected Field Control System(s). There are many different names for a UMCS – Energy Monitoring and Control System being a common one – but regardless of the name systems that perform this function are a type of UMCS.
Vulnerability (NIST SP 800-53)	Weakness in an information system, system security procedures, internal controls, or implementation that could be exploited or triggered by a threat source.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD(AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Support Agency (AFCESA) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request (CCR). The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

Unified Facilities Criteria (UFC)
New Document Summary Sheet

Subject: UFC 4-020-01, DoD Security Engineering Facilities Planning Manual

Cancels: UFC 4-020-01 FA, Security Engineering Project Development

Document Description and Need:

- **Purpose:** This UFC supports the planning of DoD facilities that include requirements for security and antiterrorism. It will be used in conjunction with UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings*, to establish the security and antiterrorism design criteria that will be the basis for DoD facility designs. Those criteria include the assets to be protected, the threats to those assets, the levels to which those assets are to be protected against those threats, and any design constraints imposed by facility users. This document also provides a means for identifying the costs for providing the applicable levels of protection and a risk management process for evaluating those costs and the protection options.
- **Application and Use:** Commanders, security and antiterrorism personnel, planners, and other members of project planning teams will use this UFC to establish project specific design criteria for DoD facilities, estimate the costs for implementing those criteria, and evaluating both the design criteria and the options for implementing it. The design criteria and costs will be incorporated into project programming documents. This UFC also provides guidance for incorporation of security and antiterrorism principles into installation master planning.
- **Need:** This UFC is one in a series of security engineering Unified Facilities Criteria that address minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. This UFC provides the starting point for application of all of the manuals within the security engineering series. Without this UFC, there would be no standardized DoD-wide process for identifying and justifying design criteria for security and antiterrorism and no basis for applying the other manuals in the series.

Impact. The following direct benefits will result from publication of UFC 4-020-01:

- Creates a standardized approach for identifying and justifying security and antiterrorism design criteria for DoD facilities
- Creates standardized nomenclature and criteria for asset, threat, and level of protection definition.
- Creates a standardized procedure for identifying costs for DoD facilities with security and antiterrorism requirements to a planning level of detail.
- Creates a standardized process for evaluating design criteria and protection options based on cost and risk management.
- Provides guidance for incorporating security and antiterrorism principles into installation master planning.
- Does not have any adverse impacts on environmental, sustainability, or constructability policies or practices.

CHAPTER 3 DESIGN CRITERIA DEVELOPMENT

Paragraph	3-1	INTRODUCTION	3-1
	3-1.1	Design Criteria	3-2
	3-1.2	Other Standards	3-2
	3-1.3	Priority	3-2
	3-1.4	Risk Management	3-2
	3-2	USING THIS PROCEDURE	3-3
	3-3	STEP 1: CONVENE THE PLANNING TEAM	3-7
	3-4	STEP 2: IDENTIFY ASSETS	3-7
	3-4.1	Determine Facility Types	3-7
	3-4.2	Determine Default Assets	3-7
	3-5	STEP 3: DETERMINE ASSET VALUE	3-9
	3-5.1	Value Rating Factors	3-9
	3-5.2	Determine Asset Value Rating	3-21
	3-5.3	Eliminate Assets with “Very Low” Value Ratings	3-21
	3-6	STEP 4: IDENTIFY AGGRESSOR LIKELIHOODS	3-21
	3-6.1	Select Applicable Aggressors	3-21
	3-6.2	Assess Aggressor Likelihood Ratings	3-21
	3-6.3	Determine Likelihood Ratings	3-34
	3-6.4	Aggressors With “Very Low” Likelihood Ratings	3-34
	3-7	STEP 5: IDENTIFY TACTICS AND THREAT SEVERITY LEVELS	3-35
	3-7.1	Select Applicable Tactics Based on Assets	3-35
	3-7.2	Select Applicable Tactics Based on Aggressors	3-35
	3-7.3	Identify Threat Severity Levels	3-35
	3-8	STEP 6: CONSOLIDATE INTO INITIAL DESIGN BASIS THREAT	3-40
	3-8.1	Initial Design Basis Threat	3-40
	3-8.2	Modifying the Initial Design Basis Threat	3-40

3-9 STEP 7: DETERMINE INITIAL LEVEL OF PROTECTION 3-42
3-9.1 Initial Level of Protection 3-43
3-9.2 Example 3-43
3-9.3 Modifying the Initial Level of Protection 3-43
3-10 STEP 8: DETERMINE PLANNING RISK LEVELS 3-43
3-10.1 Determine Threat Effectiveness Ratings 3-43
3-10.2 Select Initial Protection Factors 3-45
3-10.3 Calculate Average Initial Protection Factors 3-47
3-10.4 Adjust Initial Protection Factors 3-47
3-10.5 Determine Risk Level 3-47
3-11 STEP 9: ASSESS ACCEPTIBILITY OF RISK LEVELS 3-48
3-11.1 Cost and Risk Evaluation 3-48
3-11.2 Cost and Risk Analysis 3-49
3-12 STEP 10: IDENTIFY USER CONSTRAINTS 3-51
3-12.1 Political Considerations 3-51
3-12.2 Financial Considerations 3-51
3-12.3 Regulations 3-51
3-12.4 Procedural or Operational Considerations 3-51
3-12.5 Facility and Site Constraints 3-52
3-12.6 Response Force 3-53
3-12.7 Response Time 3-53
3-12.8 Manpower Allocation 3-53
3-13 INFORMATION SENSITIVITY 3-54
3-13.1 Derivative Classification 3-54
3-13.2 Classification Guides 3-54
3-13.3 Original Classification 3-54

CHAPTER 1

INTRODUCTION

1-1 **BACKGROUND.** In December 1999 DoD published the *Interim Department of Defense Antiterrorism / Force Protection Construction Standards,* which was the first attempt by DoD to ensure that antiterrorism standards were incorporated into the planning, programming, and budgeting for the design and construction of military facilities. Those standards were replaced by UFC 4-010-01, the *DoD Minimum Antiterrorism Standards for Buildings*. The development of minimum standards for protecting DoD personnel against terrorist acts was required by Title 10 U.S. Code, Subtitle A, PART IV, CHAPTER 169, SUBCHAPTER III, §2859 and implemented by DoD Instruction 2000.16.

The minimum standards provide baseline minimum levels of protection with which all DoD inhabited buildings must comply as long as they meet specific "triggers". Those levels of protection can be achieved using conventional construction if certain minimum standoff distances are provided. There needed to be guidance for how to design buildings where the minimum standoff distances were not available. In addition, there needed to be guidance for providing higher levels of protection where users could justify them, for addressing threats other than terrorist threats, and for addressing protection of assets other than people.

Up until the development of the security engineering series of UFC, there was no DoD-wide standardized process for identifying and justifying design criteria beyond the minimum standards, which resulted in a wide range of solutions. Some of those solutions provided unjustifiably high levels of protection or protection to unrealistic threats. Some resulted in unreasonably low levels of protection. Design and planning guidance was spread among multiple service specific documents that were neither coordinated nor uniform. This UFC is intended to provide the uniformity and consistency in planning for security and antiterrorism that were not previously available.

1-2 **PURPOSE.** The purpose of this UFC is to support planning of projects that include requirements for security and antiterrorism. Those requirements come from the *DoD Minimum Antiterrorism Standards for Buildings*, combatant command standards, standards from other DoD components or commands, regulations, or installation or user requirements. Projects include new construction, existing construction or expeditionary and temporary construction. The intended users of this UFC are engineering planners responsible for project development and planning teams responsible for developing design criteria for projects. The ultimate purpose of this guidance is to develop appropriate, effective, unobtrusive, and economical protective designs to a level appropriate for project programming and to provide commanders with the information they need to allocate resources.

1-3 **SCOPE.** The scope of this UFC includes the following:

1-3.1 **Design Criteria Development.** This UFC includes a process for defining the design criteria for a protective system that protects important assets associated with a permanent facility or one in an expeditionary environment. The design criteria will consist of the assets to be protected, the threats to those assets, the degree to which those assets will be protected against the threat, and any constraints that might be imposed on a design. The design criteria may be limited to that defined in minimum standards or it may go beyond those requirements.

1-3.2 **Cost Increase Identification.** This UFC includes a process for identifying the increases in cost associated with protecting the identified assets to the applicable threat and to the appropriate level of protection over that of conventional construction.

1-3.3 **Cost Increase Justification.** The processes in this UFC provide a basis for justifying increased project costs related to security and antiterrorism in programming documents using relative risk to ensure the added costs are not deleted in the budgetary process.

1-4 **APPLICABILITY.** This UFC applies to all DoD components and to all DoD assets and facilities that are owned, leased, privatized, or otherwise occupied, managed, or controlled by or for DoD.

1-6 **THE PLANNING TEAM.** Establishing the design criteria for security and antiterrorism is not something that can be done effectively by any one person. It requires a team of people to ensure that the varied interests relating to a project are considered appropriately. The specific membership of a planning team will be based on local considerations, but in general, the following functions should be represented.

1-6.1 **Facility User.** The ultimate users of the planned facility identify the assets within the facility that will require protection and establish their relative value. The users also identify any special operational or logistical design constraints for the facility.

1-6.2 **Antiterrorism.** DoD Instruction 2000.16 requires every installation or base to have an antiterrorism officer. The role of the antiterrorism officer is to orchestrate the development of comprehensive antiterrorism plans and to coordinate the efforts of all organizations on the installations with respect to antiterrorism preparation and response. As such, the antiterrorism officer is a critical member of the planning team.

1-6.3 **Intelligence.** Representatives of this function are responsible for providing input for the identification of threats to identified assets including information on potential aggressors, their likely targets, and their likely tactics. Because the scope of security engineering potentially includes criminals, terrorists, subversives, and foreign intelligence agents, the intelligence role might not be represented by one person or organization. Criminal intelligence and terrorist intelligence may be in different organizations, for example. This varies by DoD component and location.

1-6.4 **Operations.** Representatives of this function may be considered to serve as installation level user representatives or representatives of the senior tactical commander on an installation. The installation antiterrorism office and the responsibility for antiterrorism commonly reside in operations.

1-6.5 **Security.** Representatives of the security and law enforcement function are responsible for detecting and defeating acts of aggression against assets. Therefore, these representatives supply information about the response capabilities of military police, contract or security guards, local police, or other applicable security forces. They may also provide information on general security requirements and on criminal threats.

1-6.6 **Logistics.** Representatives of this function are commonly responsible for maintenance of installed equipment in facilities. They provide input on equipment maintenance and on integrating with existing systems.

1-6.7 **Engineering.** Representatives of this function are responsible for facility planning, design, construction, maintenance, and repair. The Director of Public Works (DPW) or Base Civil Engineer (BCE) (or equivalent) organizations commonly include the master planner or project programmer. The programmer organizes and leads the planning team; consolidates all facility requirements, design criteria, and project cost information into the appropriate programming documents; and establishes the project cost estimate or budget.

1-6.8 **Resource Management.** The resource manager will be responsible for obtaining the funds necessary to implement whatever projects are formulated as part of this process. They are also familiar with what funds sources are available and with the requirements for programming those funds.

1-6.9 **Others.** Based on local considerations, there may be others who should be consulted for input into the design criteria. They might include Fire Marshals, communications people, environmental people, and historic preservation officers.

1-7 **INTEGRATING WITH OTHER REQUIREMENTS.** Security and antiterrorism requirements will never be the only requirements associated with a project. Even where a project is specifically for security and antiterrorism upgrades, there will still be other requirements that must be considered. There will be times where one criterion is more stringent than another, in which case the more stringent one must be applied. In some cases, criteria may conflict. In those cases, those conflicts must be resolved, which may require compromise or adjustment to one or the other criteria. The following are examples of common criteria that must be integrated with security and antiterrorism requirements.

1-7.1 **Security Regulations.** Many security regulations specify protective measures, policies, and operations related to security. This UFC is intended to complement those existing regulations, not to contradict or supersede them. Regulatory requirements must be accommodated and coordinated.

1-7.2 **Explosive Safety.** Antiterrorism standards establish criteria to minimize the potential for mass casualties and progressive collapse from a terrorist attack. In addition, based on application of this UFC, planning teams may identify higher levels of protection against explosives threats than are mandated by the minimum standards. DoD 6055.9-STD, *DoD Ammunition and Explosive Safety Standards* as implemented by Service component explosive safety standards, establish acceptable levels of protection for accidental explosions of DoD-titled munitions. The explosive safety and antiterrorism standards address hazards associated with unique events; therefore, they may specify different levels of protection. Compliance with both standards is required. Where conflicts arise, the more stringent criteria will govern.

1-7.3 **Other DoD Component Standards.** DoD components and Combatant Commanders are allowed to supplement the *DoD Minimum Antiterrorism Standards for Buildings,* but those supplemental requirements may not be less stringent. Examples of such supplemental requirements include USEUCOM Operations Order 08-01 and USCENTCOM Operations Order 05-01. Those operations orders establish additional construction standards for projects constructed in the European and Central Command areas of operations. In addition, DoD components may establish implementing instructions for applying the *DoD Minimum Antiterrorism Standards for Buildings,* which need to be taken into account in project planning.

1-7.4 **Historic Preservation.** Implementation of security and antiterrorism requirements cannot supersede the DoD obligation to comply with federal laws regarding cultural resources to include the National Historic Preservation Act and the Archaeological Resources Protection Act. The planning team needs to determine possible adverse effects upon an historic structure and/or archaeological resource in conjunction with establishing antiterrorism and security requirements to the greatest extent possible and to consult accordingly. Personnel at installations abroad should coordinate with the host nation regarding possible adverse effects to cultural resources. Conversely, historic preservation compliance does not negate the requirement to implement security and antiterrorism standards and requirements. Federal agencies are always the decision-maker in the Section 106 process of the National Historic Preservation Act. An agency should not allow for prolonged consultations that conflict with the eminent need to implement security and antiterrorism standards and requirements. Preservation issues need to be quickly and effectively resolved to avoid obstructing security and antiterrorism efforts.

1-7.5 **Sustainable Design.** Sustainable design seeks to reduce negative impacts on the environment and on the health and comfort of building occupants, thereby improving building performance. The basic objectives of sustainability are to reduce consumption of non-renewable resources, minimize waste, and create healthy, productive environments. Requirements for security and antiterrorism may pose challenges for sustainable design, but the two goals are not mutually exclusive. Two of the most significant areas of conflict are in providing plantings close to buildings for shading and water conservation and in maximizing natural lighting. Issues such as those require careful coordination among design disciplines and may require tradeoffs.

1-7.6 **Other Facility Requirements.** Project programmers and designers also must consider issues such as life safety and fire protection, functional issues, energy conservation, seismic criteria, barrier-free handicapped access, and aesthetics. Protective measures may enhance energy conservation or seismic survivability, but the objectives of life safety requirements or barrier-free access may conflict with the objectives of the protective system. The programmer and the planning team need to recognize conflicts and establish priorities in the programming phase to guide designers to appropriate and optimal solutions.

1-8 **SECURITY ENGINEERING UFC SERIES.** This UFC is one of a series of security engineering Unified Facilities Criteria documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include the following:

1-8.1 **DoD Minimum Antiterrorism Standards for Buildings.** UFC 4-010-01 and 4-010-02 establish standards that provide minimum levels of protection against terrorist attacks for the occupants of all DoD inhabited buildings. Those UFC are intended to be used by security and antiterrorism personnel and design teams to identify the minimum requirements that must be incorporated into the design of all new construction and major renovations of inhabited DoD buildings. They also include recommendations that should be, but are not required to be incorporated into all such buildings.

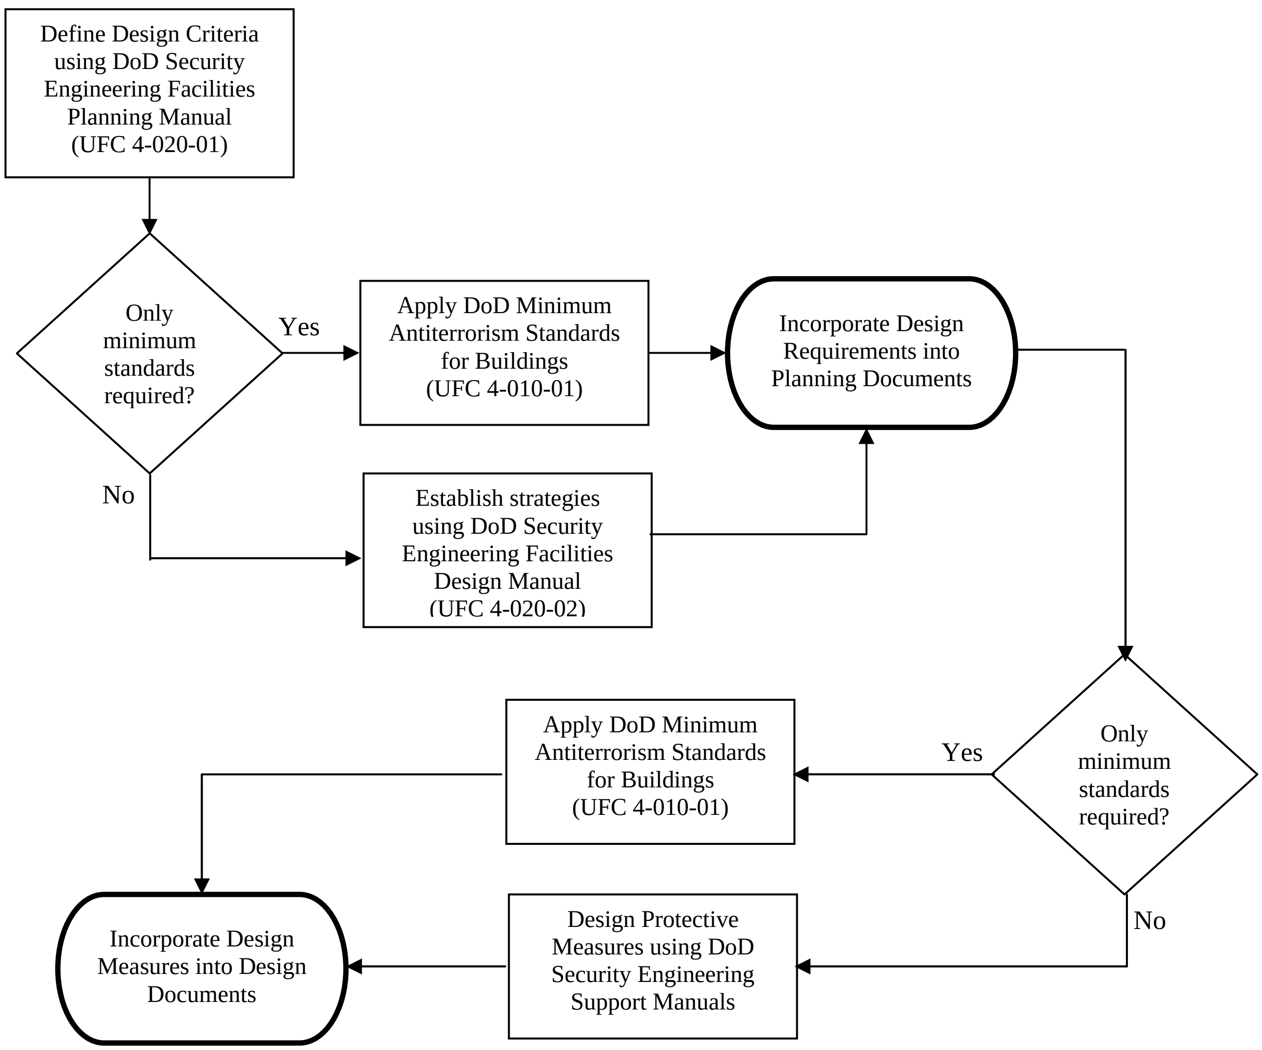
1-8.2 **Security Engineering Facilities Planning Manual.** This manual presents processes for developing the design criteria necessary to incorporate security and antiterrorism into DoD facilities and for identifying the cost implications of applying those design criteria. Those design criteria may be limited to the requirements of the minimum standards, or they may include protection of assets other than those addressed in the minimum standards (people), aggressor tactics that are not addressed in the minimum standards, or levels of protection beyond those required by the minimum standards. The cost implications for security and antiterrorism are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they represent only representative construction that will meet the requirements of the design criteria. The manual also addresses the tradeoffs between cost and risk. The Security Engineering Facilities Planning Manual is intended to be used by planners as well as security and antiterrorism personnel with support from planning team members.

1-8.3 **Security Engineering Facilities Design Manual.** UFC 4-020-02 provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established using UFC 4-020-01. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them all work as a system. The information in UFC 4-020-02 is in sufficient detail to support concept level project development, and as such can provide a good basis for a more detailed design. The manual also provides a process for assessing the impact of protective measures on risk. The primary audience for the Security Engineering Design Manual is the design team, but it can also be used by security and antiterrorism personnel.

1-8.4 **Security Engineering Support Manuals.** In addition to the standards, planning, and design UFCs mentioned above, there is a series of additional UFCs that provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02. These support manuals provide specialized, discipline specific design guidance. Some address specific tactics such as direct fire weapons, forced entry, or airborne contamination. Others address limited aspects of design such as resistance to progressive collapse or design of portions of buildings such as mail rooms. Still others address details of designs for specific protective measures such as vehicle barriers or fences. The Security Engineering Support Manuals are intended to be used by the design team during the development of final design packages.

1-9 Security Engineering UFC Application. The application of the security engineering series of UFCs is illustrated in Figure 1-1. This manual is intended to be the starting point for any project that is likely to have security or antiterrorism requirements. By beginning with this UFC, the design criteria will be developed that establishes which of the other UFCs in the series will need to be applied. The design criteria may indicate that only the minimum standards need to be incorporated, or it may include additional requirements, resulting in the need for application of additional UFCs. Even if only the minimum standards are required other UFCs may need to be applied if sufficient standoff distances are unavailable. Applying this series of UFCs in the manner illustrated in Figure 1-1 will result in the most efficient use of resources for protecting assets against security and antiterrorism related threats.

Figure 1-1. Security Engineering UFC Application



CHAPTER 2

AGGRESSOR THREATS AND TACTICS

2-1 **INTRODUCTION.** Historical patterns and trends in aggressor activity indicate general categories of aggressors and the common tactics that they can be predicted to use against DoD assets. These aggressor tactics and their associated tools, weapons, explosives, and agents are the basis for the threat to assets. Understanding the basis for the threat and the aggressors' objectives is essential to effective protective system design. This chapter describes aggressors, tactics, tools, weapons, explosives, and agents that are referred to throughout the security engineering series of UFC.

For the purposes of designing a protective system, the perpetrators of terrorist or criminal acts or acts of espionage are not important. To designers the important issue is how an aggressor attacks the asset and with what. Within this UFC aggressors will only be considered in determining the tactics that will be used against assets and the tools, weapons, explosives, and agents associated with those tactics. The aggressors will not be carried into the design criteria.

This is by no means a comprehensive treatment of threat. The purpose of this chapter is to provide a common basis for defining threat for the purposes of facility design. Planning teams may add additional threat parameters as they find it necessary.

2-2 **AGGRESSORS.** Aggressors are people who perform hostile acts against assets such as equipment, personnel, and operations. The aggressor objectives and aggressor categories considered in this UFC are described below.

2-2.1 **Aggressor Objectives.** There are four major aggressor objectives that describe aggressor behavior. An explanation of how these objectives apply to each aggressor category is presented in subsequent paragraphs. Aggressors may use the first three objectives to accomplish the fourth. The four aggressor objectives include:

- Inflicting injury or death on people
- Destroying or damaging facilities, property, equipment, or resources
- Stealing equipment, materiel, or information
- Creating adverse publicity

2-2.2 **Aggressor Categories.** The four broad categories of aggressors considered in this manual are criminals, protesters, terrorists, and subversives. Hostile acts performed by these aggressors range from crimes such as burglary to low-intensity conflict such as unconventional warfare. Each of these aggressor categories describes predictable aggressors that pose threats to DoD assets and who share common objectives and tactics. This manual does not address the commonly referenced aggressor category of disaffected persons, which includes disoriented persons and disgruntled employees. Those aggressors are not covered separately in this manual because they may exhibit similar characteristics to any of the four categories included or they generally do not present a predictable threat.

2-2.2.1 **Criminals.** Criminals are divided into one of three possible groups based on their degree of sophistication. These three groups are defined as unsophisticated criminals, sophisticated criminals, and organized criminal groups. The common objective for all three criminal groups is assumed to be theft of assets.

2-2.2.1.1 **Unsophisticated Criminals.** Unsophisticated criminals are unskilled in the use of tools and weapons and have no formal organization. Their targets are those that meet their immediate needs such as drugs, money, and pilferable items. Unsophisticated criminals are interested in opportune targets that present little or no risk. Breaking and entering or smash-and-grab techniques are common. Theft by insiders is also common.

2-2.2.1.2 **Sophisticated Criminals.** Sophisticated criminals are skilled in the use of certain tools and weapons and are efficient and organized. They plan their attacks and have sophisticated equipment and the technical capability to employ it. Sophisticated criminals are often assisted by insiders. They target high value assets, frequently steal in large quantities, yet target assets with relatively low risk in handling and disposal. Commonly targeted facilities include controlled substance (drug) storage, warehouses, post exchanges, and Class VI (liquor) stores.

2-2.2.1.3 **Organized Criminal Groups.** Organized criminal groups are highly sophisticated, are able to draw on specialists, and are able to obtain the equipment needed to achieve their goals efficiently. These groups form efficient, hierarchical organizations which can employ highly paid insiders. Examples include drug cartels, organized crime "families," the Yakuza, and MS-13. Targets of organized criminal groups may involve a high degree of risk in handling and disposal such as large quantities of money; equipment; and arms, ammunition, and explosives. In addition, some such organizations have exhibited the will to inflict death or injury to support their activities or intimidate law enforcement personnel.

2-2.2.2 **Protesters**. For the purposes of this manual, only violent protesters are considered to be a threat. Protesters include the two general groups of vandals/activists and extremist protesters. Both groups are politically or issue oriented and act out of frustration, discontent, or anger against the actions of other social or political groups. The primary objectives of both groups commonly include destruction and publicity.

2-2.2.2.1 **Vandals/Activists.** Vandals/activists are commonly unsophisticated and superficially destructive. They generally do not intend to injure people or cause extensive damage to their targets. Their actions may be covert or overt. Typically, they choose symbolic targets that pose little risk to them. For the purposes of risk analysis in this document, vandals/activists are grouped with criminals.

2-2.2.2.2 **Extremist Protest Groups.** Extremist protest groups are moderately sophisticated and are usually more destructive than vandals. Their actions are frequently overt and may involve the additional objective or consequence of injuring people. They attack symbolic targets, including authority figures such as high-ranking officials and police, weapon systems, and things they consider to be environmentally unsound. For the purposes of risk analysis in this document, extremist protest groups are grouped with terrorists.

2-2.2.3 **Terrorists.** Terrorists are ideologically, politically, or issue oriented. They commonly work in small, well-organized groups or cells. They are sophisticated, skilled with tools and weapons, and possess an efficient planning capability. Terrorist objectives usually include death, destruction, theft, and publicity. Three types of terrorist groups are identified in this manual based on their areas of operation and their sophistication. The three types are domestic terrorists, international terrorists, and state sponsored terrorists.

2-2.2.3.1 **Domestic Terrorists.** Domestic terrorists for the purposes of this UFC are terrorists indigenous to the United States, Puerto Rico, and the US territories who are not directed by foreign interests. Domestic terrorists in the United States have typically been political extremists operating in distinct areas of the country. They have primarily consisted of ethnic and white supremacy groups, many with ties to groups that originated during the 1960's and 1970's. Historically, most acts of terrorism in the United States by domestic terrorists have been less severe than those outside the United States, and operations have been somewhat limited. One noted exception to that trend was the bombing of the Alfred P. Murrah Building in Oklahoma City.

2-2.2.3.2 **International Terrorists.** International terrorists are either connected to a foreign power or their activities transcend national boundaries. International terrorists have typically been better organized and better equipped than their domestic counterparts. They have included political extremists and ethnically or religiously oriented groups. Their attacks have also been more severe and more frequent than those by domestic terrorists in the United States. Examples of foreign terrorist groups designated by the U.S. Department of State include the Revolutionary Group 17 November, the Aum Shinrikyo Group, Basque Fatherland and Liberty (ETA), Sendero Luminoso (Shining Path), and the al-Aqsa Martyrs Brigade.

2-2.2.3.3 **State Sponsored Terrorists.** State sponsored terrorist groups generally operate independently, but receive foreign government support, to include intelligence and even operational support. They have exhibited military capabilities and have used a broad range of military and improvised weapons. They have historically staged the most serious terrorist attacks, including suicidal attacks. They are predominantly ethnically or religiously oriented. Some of these groups have legitimate political wings in addition to their terrorist wings. Examples of state sponsored terrorist groups designated by the U.S. Department of State include al Qaida, the Palestinian Islamic Jihad, Hizballah, and the Revolutionary Armed Forces of Columbia (FARC).

2-2.2.4 **Subversives.** Subversives include aggressors from foreign governments or from groups trying to overthrow the government by force. They include saboteurs and foreign intelligence agents.

2-2.2.4.1 **Saboteurs.** Saboteurs include guerrillas and unconventional warfare forces. They are paramilitary or actual military personnel who are very sophisticated, highly skilled, and employ meticulous planning. They commonly act in small groups, have an unlimited arsenal of weapons, and are well-trained in the use of those weapons. The objectives of saboteurs usually include destruction of property and death and their targets include mission-critical personnel, equipment, and operations. The scope of this manual is limited to sabotage in a low intensity conflict; therefore, full-scale attacks by guerrillas or commandos during wartime are not addressed.

2-2.2.4.2 **Foreign Intelligence Agents.** Foreign intelligence agents are highly skilled and very sophisticated. They are generally foreign agents, but they frequently employ insiders for assistance. These agents commonly operate covertly to avoid detection before, during, or after an action. Their objective is usually assumed to be theft of sensitive information.

2-3 **AGGRESSOR TACTICS.** Aggressors have historically employed a wide range of offensive strategies reflecting their capabilities and objectives. This UFC and subsequent UFCs in the security engineering series categorize these offensive strategies into 13 tactics that are specific methods of achieving aggressor goals. Separating these tactics into categories allows facility planners to define threats in common terms that can be used by facility designers.

2-3.1 **Moving Vehicle Bomb Tactic.** In this tactic aggressors drive an explosives-laden car or truck into a facility and detonate the explosives. The aggressors' goals are to damage or destroy the facility and/or to kill people. This is a suicide attack.

2-3.2 **Stationary Vehicle Bomb Tactic.** In this tactic aggressors covertly park an explosives-laden car or truck near a facility. It is assumed that the aggressors park the vehicle in a legal location to avoid being noticed. The aggressors then detonate the explosives either by time delay or remote control. The aggressors' goals in this tactic are the same as for the moving vehicle bomb tactic with the additional goal of destroying assets within the blast area.

2-3.3 **Hand Delivered Device Tactic.** In this tactic aggressors attempt to enter a facility or get close to the exterior of a facility or to assets not located within a facility with either placed or thrown explosives or incendiary devices. This tactic also includes explosive or incendiary devices delivered through the mail or to supply and materiel handling points such as loading docks. The aggressors' goals are to damage the facility, to injure or kill its occupants, or to damage or destroy assets.

2-3.4 **Indirect Fire Weapons Tactic.** In this tactic aggressors fire military or improvised indirect fire weapons at a facility from a significant distance. Indirect fire weapons (commonly mortars or rockets) do not require a clear line of sight to the target. They can be fired over obstacles. The aggressors' goals are to damage the facility, to injure or kill its occupants, or to damage or destroy assets.

2-3.5 **Direct Fire Weapons Tactic.** In this tactic aggressors fire weapons that require direct lines of sight to targets. These attacks may be from a significant distance or may be close-up as in a drive-by shooting. Direct fire weapons include antitank weapons and various small arms, such as pistols, submachine guns, shotguns, and rifles. The aggressors' goals are to injure or kill facility occupants or to damage or destroy assets.

2-3.6 **Forced Entry Tactic.** In this tactic aggressors forcibly enter a facility using forced entry tools, explosives, and small arms. The aggressor uses the tools and explosives to create a man-passable opening or to operate an operable assembly in the facility's walls, doors, roof, windows, or utility openings. The aggressor may also use explosives or small arms to overpower guards as part of this tactic. The aggressors' goals are to steal or destroy assets, compromise information, injure or kill facility occupants, or disrupt operations.

2-3.7 **Covert Entry Tactic.** In this tactic aggressors attempt to enter a facility or portion of a facility to which they do not have authorized access by using false credentials, by stealth, and by surreptitious entry. Covert entry can either be by people not associated with a facility or insiders who try to access areas in which they are not authorized. The aggressors' goals are to steal assets, to compromise information, to disrupt operations, or to injure or kill building occupants.

2-3.8 **Visual Surveillance Tactic.** In this tactic aggressors employ ocular and photographic devices such as binoculars and cameras with telephoto lenses to monitor facility or installation operations or to see assets. The aggressors' goal is to compromise information. Aggressors may also use this tactic as a precursor to other tactics to determine information about an asset of interest or about security measures.

2-3.9 **Acoustic Eavesdropping Tactic.** In this tactic aggressors employ listening devices from outside a facility or restricted area of a facility to monitor voice communication or other audibly transmitted information. This tactic does not include the use of listening devices "planted" inside facilities. Those devices are in the realm of technical security and are beyond the scope of this manual. The aggressors' goal in this tactic is to compromise information.

2-3.10 **Electronic Emanations Eavesdropping Tactic.** In this tactic aggressors employ electronic emanation surveillance equipment from outside a facility or restricted area of a facility to intercept electronic emanations from computers, communications, and related equipment. This tactic is commonly treated in the context of TEMPEST protection, most of the details of which are classified. There are, however, unclassified facility design related issues that will be described in the security engineering series of UFCs. The aggressors' goal in this tactic is to compromise information.

2-3.11 **Airborne Contamination Tactic.** In this tactic aggressors contaminate the air supply of a facility by introducing chemical, biological, or radiological agents into it. These agents can be delivered to facilities either by external or internal release. External release can be from directed plumes spread from a standoff distance, from a point or line source, from general aerial release, or by directly inserting them into outside air intakes. Internal release can be through the mail, by supplies delivery, direct release within the building area, or insertion into the building ventilation system. The aggressors' goal is to kill or injure people.

2-3.12 **Waterborne Contamination Tactic.** In this tactic aggressors contaminate the water supply to a facility by introducing chemical, biological, or radiological agents into it. These agents can be introduced into the system at any location with varying effectiveness depending on the quantity of water and the contaminant involved. The aggressors' goal is to kill or injure people.

2-3.13 **Waterfront Attacks.** In this tactic aggressors attack people or other waterfront assets from the water either by swimming or on watercraft. Attacks on waterfront assets from the land are covered by other tactics. The aggressors' goal is to kill or injure people or to damage or destroy equipment or other assets.

2-3.14 **Tactics Not Addressed.** This UFC and the security engineering series of UFCs address the typical threats to fixed facilities for which designers can provide protective measures. Some common terrorist tactics are beyond the protection facility designers can provide. Kidnappings, hijackings, and assassinations that take place away from facilities or during travel between facilities are beyond the designers' control. Protection against those threats is provided through operational security and other means not associated with facility design. This UFC does not address such tactics or postulated tactics that have minimal historical or intelligence basis among the aggressors addressed in this UFC such as airborne bombings or airborne attacks using light or remote-controlled aircraft. While attacks like the aircraft attack on the World Trade Center have precedent, they are not addressed in this UFC because it is impractical to design conventional facilities to resist them. The use of nuclear devices is not addressed for the same reason.

2-4 **TOOLS, WEAPONS, EXPLOSIVES, AND AGENTS.** Aggressors use various tools, weapons, explosives, and agents to attain their objectives. The tools, weapons, explosives, and agents included in this UFC and discussed throughout the security engineering series of UFCs represent those used currently and historically or those that can be reasonably expected in the near future. Specific tools, weapons, explosives, and agents associated with each tactic are identified in chapter 3 of this UFC. General descriptions of these tools, weapons, explosives, and agents are provided below.

2-4.1 **Tools.** Tools used to breach protective construction components or barriers include forced entry tools, vehicles, and surveillance tools. Credentials used to gain access to an asset can also be considered tools.

2-4.1.1 **Forced Entry Tools.** These tools include hand, power, and thermal tools and explosives that can be carried by two people. In this manual, forced entry tools are divided into the following categories based on increasing levels of sophistication, skill required to use the tools, and risk of detection associated with use of the tools (referred to as observability).

2-4.1.1.1 **Limited Hand Tools.** Limited hand tools are those hand tools that have low observability. They include claw tools, carpenter's saws, hacksaws, Kelly tools, bolt cutters, pliers, spanner wrenches, tin snips, wrecking and pry bars, and wire cutters. These kinds of tools can be found in homes and small workshops and require little skill or sophistication to use.

2-4.1.1.2 **Unlimited Hand Tools.** These tools include the limited hand tools listed above plus high observable tools such as hammers, sledgehammers, cutting mauls, shovels, pry axes, pick head axes, and fire axes. These include tools that are not as commonly available such as those that are used by firefighters.

2-4.1.1.3 **Power Tools.** Power tools are categorized a limited or unlimited. Unlimited power tools include electric (with external power), gasoline, or air-powered circular saws, reciprocating saws; chain saws; saber saws; roto-hammers (rotating jackhammers) and drills. Limited power tools can be the same as unlimited (circular and reciprocating saws, etc.), but the power source is self-contained (batteries). Hydraulic bolt cutters and rescue tools are also included in the limited tool category.

2-4.1.1.4 **Thermal Tools.** Thermal tools include oxyacetylene, electric arc, or oxygen fed cutting torches, burn bars, and rocket torches. Burn bars are pipes containing steel rods and an oxygen supply tube. They emit a stream of extremely hot flame capable of burning through thick steel plate and concrete.

2-4.1.1.5 **Explosives.** Explosives used as forced entry tools include bulk or equivalent tamped explosive breaching charges and linear shape charges. Breaching charges are quantities of explosives placed directly against an object the aggressor intends to breach or destroy. Such charges can be backed up with a mass such as a steel plate or soil to direct their explosive effects. This practice is referred to as tamping the charge. Linear shape charges are explosives that are manufactured in strips and formed into shapes that direct the force of the explosives into a narrow area directly underneath the strip. They are used to cut man-passable openings through materials.

2-4.1.2 **Vehicles.** Used as tools, vehicles breach layers of defense or barriers and may carry explosives. The vehicles considered in this UFC include cargo trucks ranging from 7000 to 18000 kilograms (approximately 15,000 to 40,000 pounds) gross vehicle weight, small trucks up to 2500 kilograms (approximately 5,500 pounds) gross vehicle weight, and cars up to 1800 kilograms (approximately 4,000 pounds) gross vehicle weight.

2-4.1.3 **Watercraft.** Used as tools, watercraft can breach defined perimeters associated with waterfronts. Watercraft considered in this UFC include small powerboats, Combat Rubber Raiding Craft, Rigid Hulled Inflatable Boats, jet skis, swimmer delivery vehicles, and torpedoes.

2-4.1.4 **Surveillance Tools.** Surveillance tools enable aggressors to gather information from a distance. The various types of these tools are described below.

2-4.1.4.1 **Ocular Devices.** These enhance vision for visual surveillance. Ocular devices include binoculars, telescopes, cameras, and night vision devices.

2-4.1.4.2 **Listening Devices.** These include devices that amplify audible communication signals such as speech. They include directional microphones and laser operated listening devices. For the purposes of this UFC, they do not include electronic microphones (bugs) hidden in a facility. Those devices are covered in the area of technical security, which is beyond the scope of this UFC and generally beyond the scope of facility design.

2-4.1.4.3 **Electronic Emanations Eavesdropping Equipment.** This equipment includes devices that intercept and translate emanations from electronic equipment. This equipment is generally described in the context of the TEMPEST threat, most of the details of which are classified.

2-4.1.5 **False Credentials.** False credentials include any form of authorization or identification credential that can be falsified or counterfeited and used by unauthorized personnel or otherwise misused. These include, but are not limited to, keys, key cards, badges, and identification or authorization documents. False credentials are used in the covert entry tactic.

2-4.2 **Weapons.** Aggressors kill or injure people or damage or destroy facilities or assets using weapons that range from incendiary devices to mortars. Categories of weapons and their uses are described below.

2-4.2.1 **Incendiary Devices.** These devices include a wide range of devices that can be used to spread fire, most of which are improvised. A prime example of an improvised incendiary device (IID) is a Molotov cocktail, which is a bottle of flammable liquid with a rag in the top. After the rag is lit, the bottle is thrown, it breaks on the surface it hits, the flammable liquid catches fire, and the fire spreads over whatever it hits. Incendiary devices may be used to attack the exterior of a facility or to sabotage an asset.

2-4.2.2 **Direct Fire Weapons.** Direct fire weapons must be aimed directly at a target and the line of sight to the target must be clear to successfully hit it. There is a broad range of indirect fire weapons, but for the purposes of this UFC, they will be limited to small arms and anti-tank weapons.

2-4.2.2.1 **Small Arms.** Small arms include pistols, rifles, shotguns, and submachine guns that can be either military issue or civilian weapons. The weapons are described in this UFC in terms of ballistics standards developed for testing the resistance of building elements or assemblies to the weapons' effects. These standards generally indicate the weapon to be used in the test, the ammunition, the muzzle velocity, and the number of rounds to be fired. Aggressors use small arms to attack assets from a distance and may also use them to overpower guards. They are not used to shoot off locks or similarly breach construction components.

2-4.2.2.2 **Antitank Weapons.** Antitank weapons are fired from a distance and may be directed against facilities, vehicles, or other assets that could be targeted from a distance. The antitank weapons considered in this manual are shoulder-fired, rocket propelled grenade (RPG) launchers. Examples of weapons that have been used by terrorists include the Russian RPG-7, RPG 18, and RPG 22 and the U.S. M-72 Light Antitank Weapon (LAW). While there are more effective antitank weapons and missiles, only the class of such weapons stated above will be considered due to their wide availability and the history of their use. In addition, building conventional buildings to resist more effective weapons is impractical.

2-4.2.3 **Indirect Fire Weapons.** Indirect fire weapons are those that can be fired over obstacles to hit targets. They do not require a clear line of sight as direct fire weapons do, but they do require a clear line of flight. For the purposes of this UFC, indirect fire weapons will be considered to include mortars and small rockets. The small rockets considered here are improvised or military rockets with small explosive or incendiary charges on them, which are representative of historical terrorist attacks. The mortars considered in this UFC include both military and improvised mortars. Historically, the improvised versions of mortars have carried larger quantities of explosives than the military versions used by terrorists.

2-4.3 **Explosives.** Aggressors commonly use explosives to damage or destroy facilities or assets or to kill or injure people. Explosives used to force entry are described in the discussion on tools above. Explosives are particularly attractive to terrorists because bombs are inexpensive to build and provide a significant psychological and destructive impact. Explosives are measured according to their equivalence to a particular weight of TNT, which is referred to as TNT equivalence. The types of explosives covered in this UFC are described below.

2-4.3.1 **Improvised Explosive Devices (IED).** These are homemade bombs built of explosives such as plastic explosives or TNT. Plastic explosives are the explosive of choice for terrorists and extremist protesters because they are readily formable, stable, and difficult to detect.

2-4.3.2 **Hand Grenades.** These include common military issue antipersonnel and fragmentation hand grenades that consist of casings filled with explosives that may or may not include a fragmenting material.

2-4.3.3 **Vehicle Bombs.** These bombs contain large quantities of explosives delivered in various sizes of both land vehicles and watercraft. The explosives weight categories chosen for use in this manual are based on historical precedent and concealability and vary with vehicle size. One of the more common explosives used in these large bombs is ammonium nitrate fuel oil (ANFO), which can be made easily from fertilizer and fuel oil.

2-4.4 **Chemical, Biological, and Radiological Agents.** Chemical, biological, and radiological agents and industrial chemical and radiological agents can be categorized by physical state as liquids, solids (or particulates), and gases (or vapors). In addition, for the purposes of waterborne contaminants, they can be further categorized based on the duration of their stability in water and the ease with which they can be disinfected with chlorine or chloramine.

2-4.4.1 **Toxic Industrial Chemicals.** These are liquids and gases produced for commercial and industrial applications. They are generally of lower toxicity than the military nerve agents but are available throughout the world. An industrial task force identified a list of 98 of these chemicals as presenting particular threat because of their toxicity and availability. in the Final Report of Task Force 25, Hazard from Industrial Chemicals, Facilities may be vulnerable to an accidental or terrorist caused release of toxic industrial chemicals from nearby manufacturing or storage facilities. Industrial chemicals can also be released from accidents or sabotage involving trucks or train cars carrying toxic industrial chemicals traveling near the facility.

2-4.4.2 **Military Chemical Agents.** Military chemical agents are described in U.S. Army Field Manual 3-9, Navy Publication P-467, and Air Force Manual 355-7. They can be liquid, gas, or aerosol at standard conditions. Most of the toxic military agents are liquids, which evaporate at differing rates to produce vapor. Chemical agents produce casualties through inhalation or contact with the skin or eyes.

2-4.4.3 **Biological Agents.** Biological agents are small particles of biological material, generally in the size range of 1 to 5 microns if they are to be delivered effectively as aerosols. Toxins, which are agents of biological origin, may be in liquid or crystalline form. Many of these agents can be cultured in unsophisticated laboratories using commercially available equipment. For descriptions of biological agents, refer to Army Field Manual 3-6, Marine Corps Publication FMFM 7-11-H, or Air Force Manual 105-7.

2-4.4.4 **Radiological Agents.** Terrorists could possibly build and detonate a nuclear weapon, but the intentional spread of radioactive isotopes or radioactive waste is much more likely. A potential means to spread radioactive materials is by incorporating radiological materials into a bomb made with a conventional explosive and letting the explosion disperse the radiological material. That kind of device is commonly referred to as a “dirty bomb.” Radioactivity can persist for years. Radioactivity is unaffected by chemical reactions, so it cannot be neutralized. Radioactive waste is typically disposed of by dilution of concentration. Concentration and storage at a disposal site is necessary for high-level (very radioactive) waste. For descriptions of radiological agents, refer to Army Field Manual 3-6, Marine Corps Publication FMFM 7-11-H, or Air Force Manual 105-7.

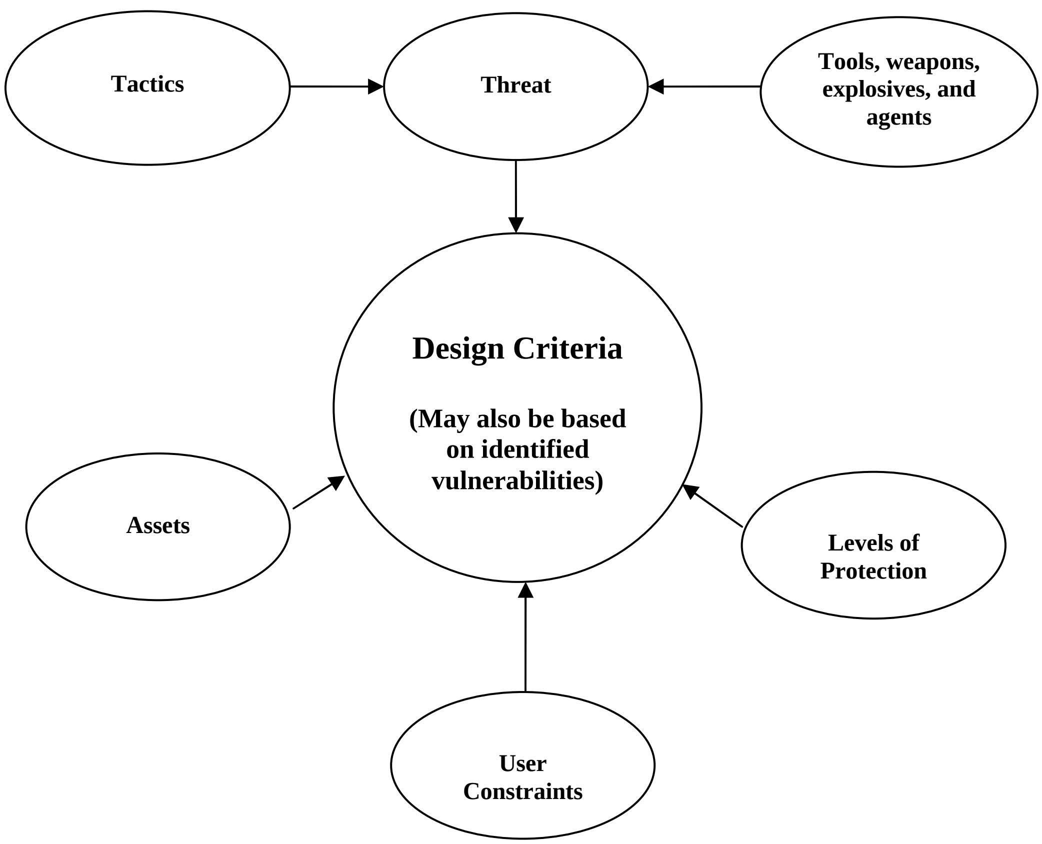
CHAPTER 3

DESIGN CRITERIA DEVELOPMENT

3-1 **INTRODUCTION.** This chapter presents a procedure for developing design criteria for a facility as illustrated in Figure 3-1 below. The procedure is designed to capture and apply the inputs of the diverse members of a Planning Team as described in Chapter 1. The procedure includes the development of preliminary design criteria based on consideration of the assets associated with a facility in terms of their value to their users and the likelihoods that different aggressors will target them. The preliminary design criteria are then evaluated using a preliminary risk analysis. The Planning Team may then adjust the preliminary design criteria to reflect the risk analysis or the cost necessary to implement the design criteria. The Planning Team may also adjust the criteria as necessary according to the professional judgments of the members of the team based on local and regional considerations. The resulting design criteria will be the basis for planning and preliminary design. It may be further adjusted during the design process based on the more detailed risk analysis process in UFC 4-020-02.

Figure 3-1. Design Criteria



3-1.1 **Design Criteria.** Design criteria are the basis for defining a protective system that mitigates vulnerabilities to assets. The criteria describe the assets associated with a facility, the threat to those assets, the level to which those assets are to be protected against the threat, and any constraints to the protective system design that may be imposed by the Planning Team. For existing facilities, vulnerabilities are additional factors in establishing the design criteria. Those vulnerabilities will be based on evaluating how existing conditions affect the protection of the identified assets against the identified threats to the applicable levels of protection. Figure 3-1 shows the components of the protective system criteria. Including security requirements with project criteria allows security to be addressed at the start of the project and to be integrated into the total design efficiently and cost-effectively. In the absence of any other standards, the process in this chapter should be used to establish facility design criteria for security and antiterrorism related issues.

3-1.2 **Other Standards.** This UFC is designed to provide guidance for determining if design criteria beyond those established in various minimum standards, such as the DoD Minimum Antiterrorism Standards for Buildings, are necessary or justifiable. In addition, where design criteria are established as part of minimum standards or Operations Orders issued by various Combatant Commanders, those threats should be considered to override threats established through the procedure in this manual where there is any conflict or where the Combatant Command standards are more stringent. In addition, any applicable regulations or other Service guidance needs to be incorporated into designs.

3-1.3 **Priority.** Security requirements comprise only one component of a project criteria package and receive different emphasis depending upon their priority in a project. For example, if a facility is intended to provide maximum protection for an asset, security may receive top priority. This may necessitate modifications to other previously established criteria. The Planning Team must consider how security fits into the total project design and give it appropriate emphasis.

3-1.4 **Risk Management.** Risk management can be defined for the purposes of security engineering as evaluating alternative countermeasures and design requirements and selecting among them based on their effectiveness in mitigating threats and on their costs. This involves consideration of political, social, economic, and engineering information in conjunction with risk-related information to develop, analyze, and compare acceptable options and to select the appropriate response to a potential threat. The selection process requires placing values on such issues as the acceptability of risk, the reduction in risk due to applied countermeasures, and the reasonableness of the costs of the countermeasures.

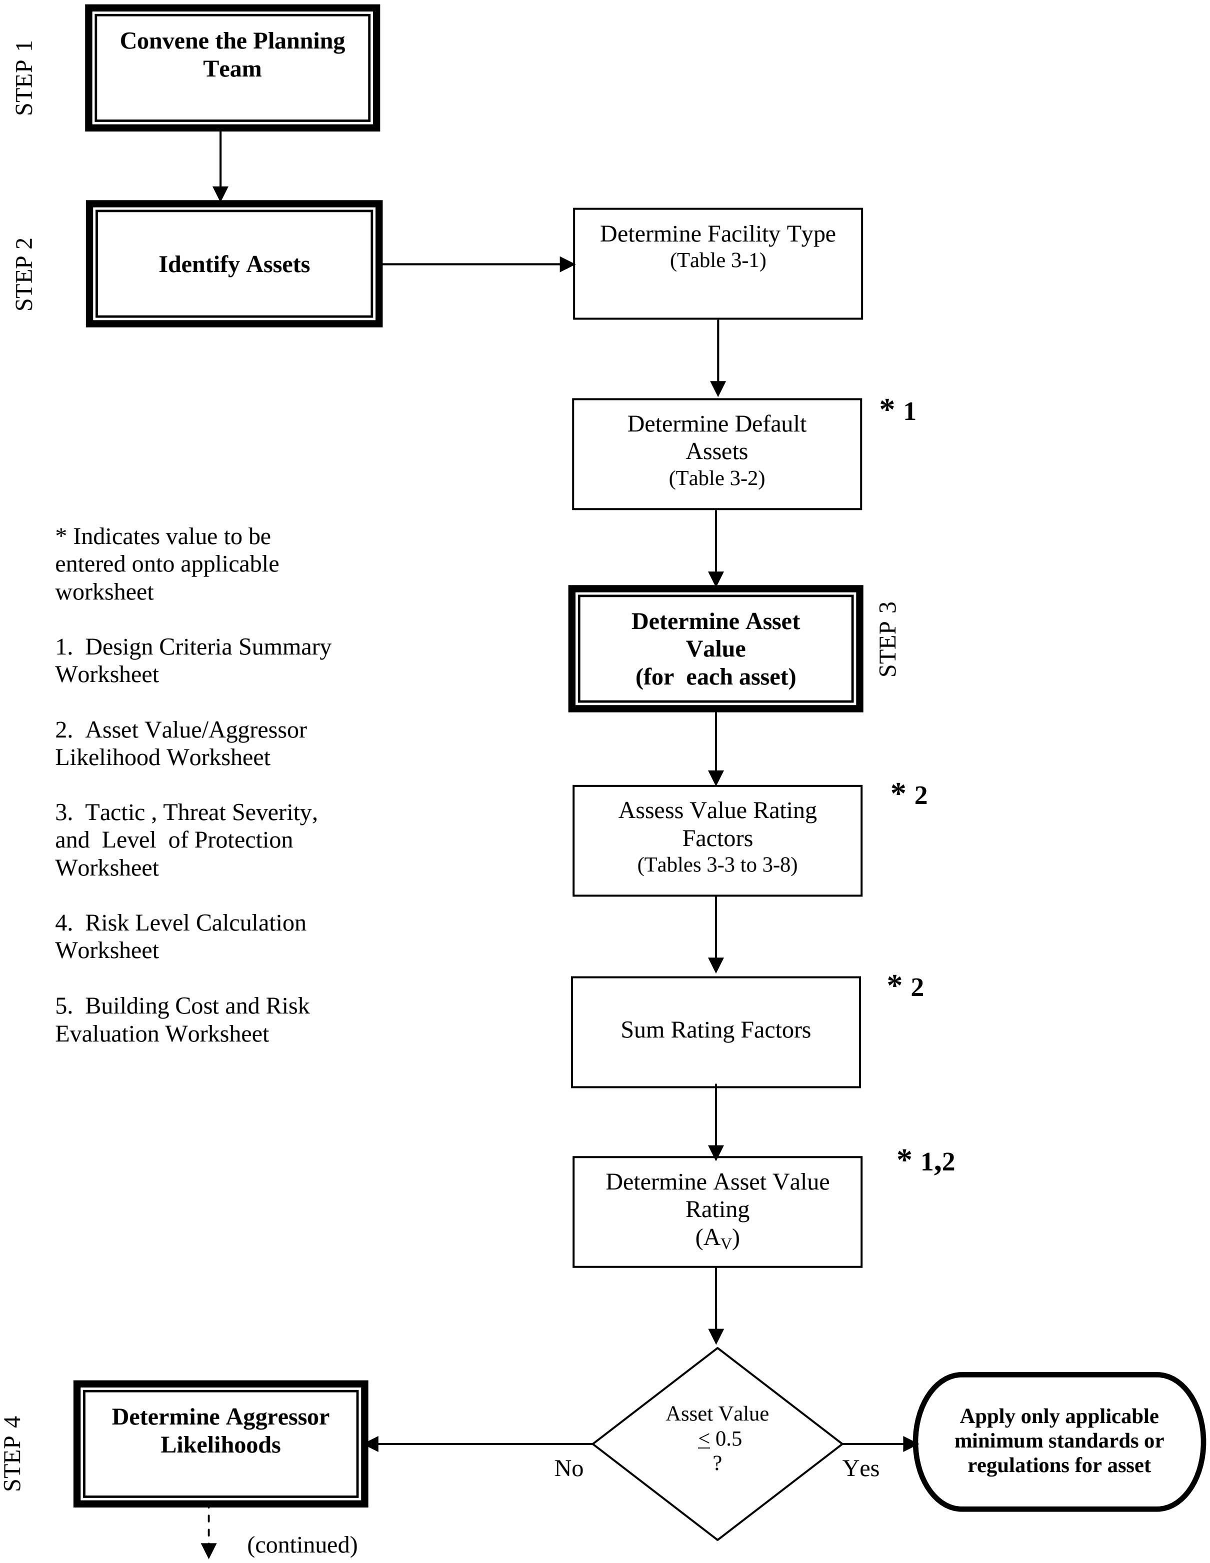
3-1.4.1 **Risk Analysis.** There are many ways to evaluate risk. Most are very rigorous and require a definitive database of frequency of events as well as detailed information on consequences and vulnerabilities. There is not yet a good enough database of terrorist, criminal, and other aggressors’ acts against DoD or Government assets to provide the basis for a realistic statistical distribution to predict such events. Aggressor acts against DoD and Government assets are so uncommon as to be statistically insignificant. That does not, however, mean we should be complacent because we know that such acts can occur at any time in any place. Evaluating risk, therefore, is necessary, but it requires a “relative” approach. The procedure in this chapter represents such an approach.

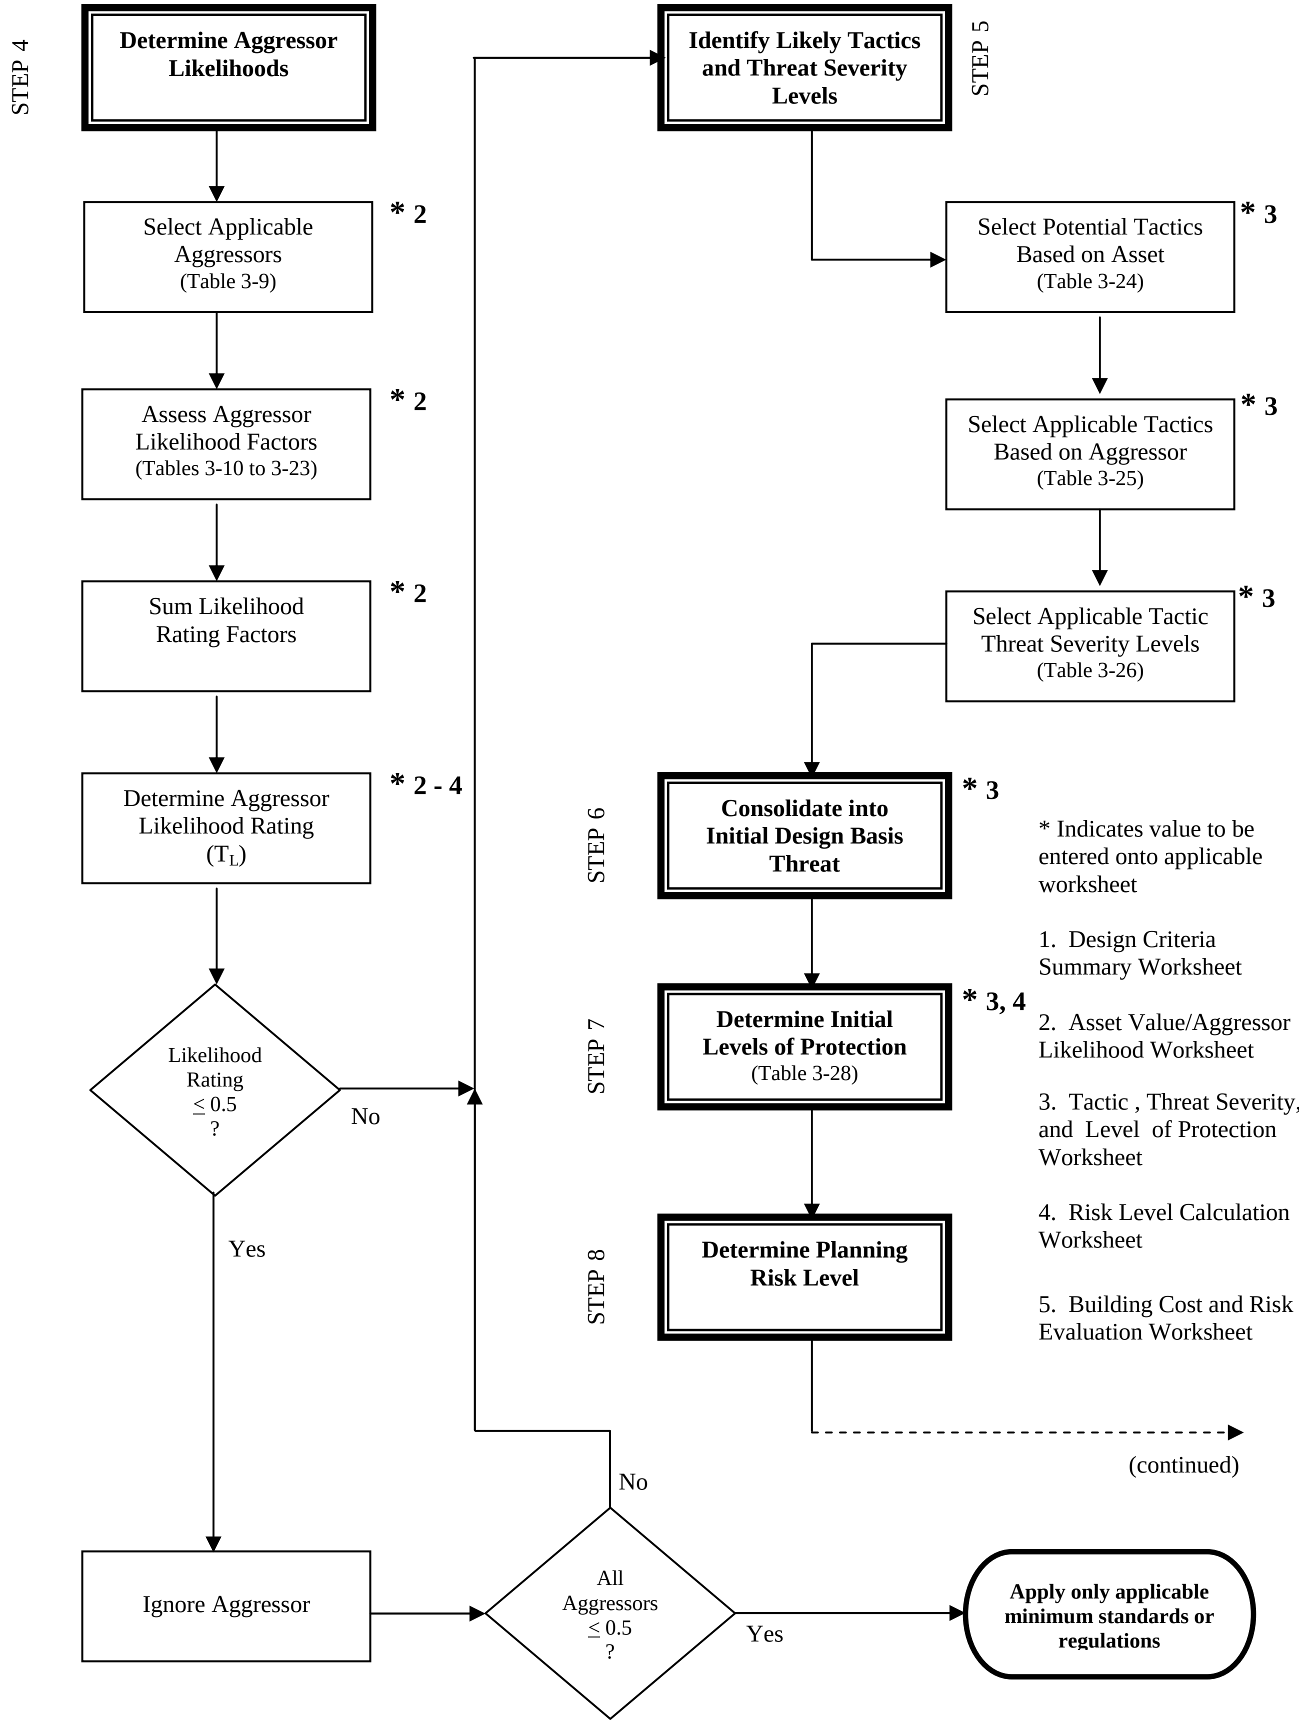
3-1.4.2 **Risk Analysis Procedure.** The procedure in this UFC evaluates risk based on likelihood of attack, the consequences of that attack, and the effectiveness of applied countermeasures in mitigating any attack. The latter is inversely related to vulnerability. Highly effective countermeasures commonly reflect lower vulnerability. The procedure is based on a subjective approach to determining design criteria and on a relative approach to evaluating vulnerabilities. The procedure also allows for quantification of risk acceptance by comparing the costs associated with changes in relative risk. The basic risk equation used in this procedure is the product of asset value, threat likelihood, and a measure of the effectiveness of protection. It will be described in detail later in the chapter. Risk analysis for the purposes of design criteria development and planning is predicated on simplifying assumptions regarding countermeasures. More detailed treatment of the contributions of individual countermeasures to risk is covered in UFC 4-020-02.

3-1.4.3 **Background.** In developing this procedure several other established procedures were considered. They included the procedure in the Joint Antiterrorism Guide, the procedure in Army Technical Manual 5-853-1/Air Force Manual AFMAN 32-1071, Volume 1 and Department of the Army Pamphlet 190-51, the CARVER process, the DSHARPP process, the MSHARPP process, and the Naval Facilities Engineering Service Center’s Risk Analysis Vulnerability Assessment (RAVA) process. In addition, processes in use by other agencies of the U.S. Government and private sector processes were evaluated. None of those processes were found to address all the needs of this UFC; therefore, the process in this document was developed. There were many elements of the other processes that were very useful, however. Those elements were incorporated into this process to the greatest extent possible. Detailed discussions on MSHARPP and CARVER can be found in DoD O-2000.12-H.

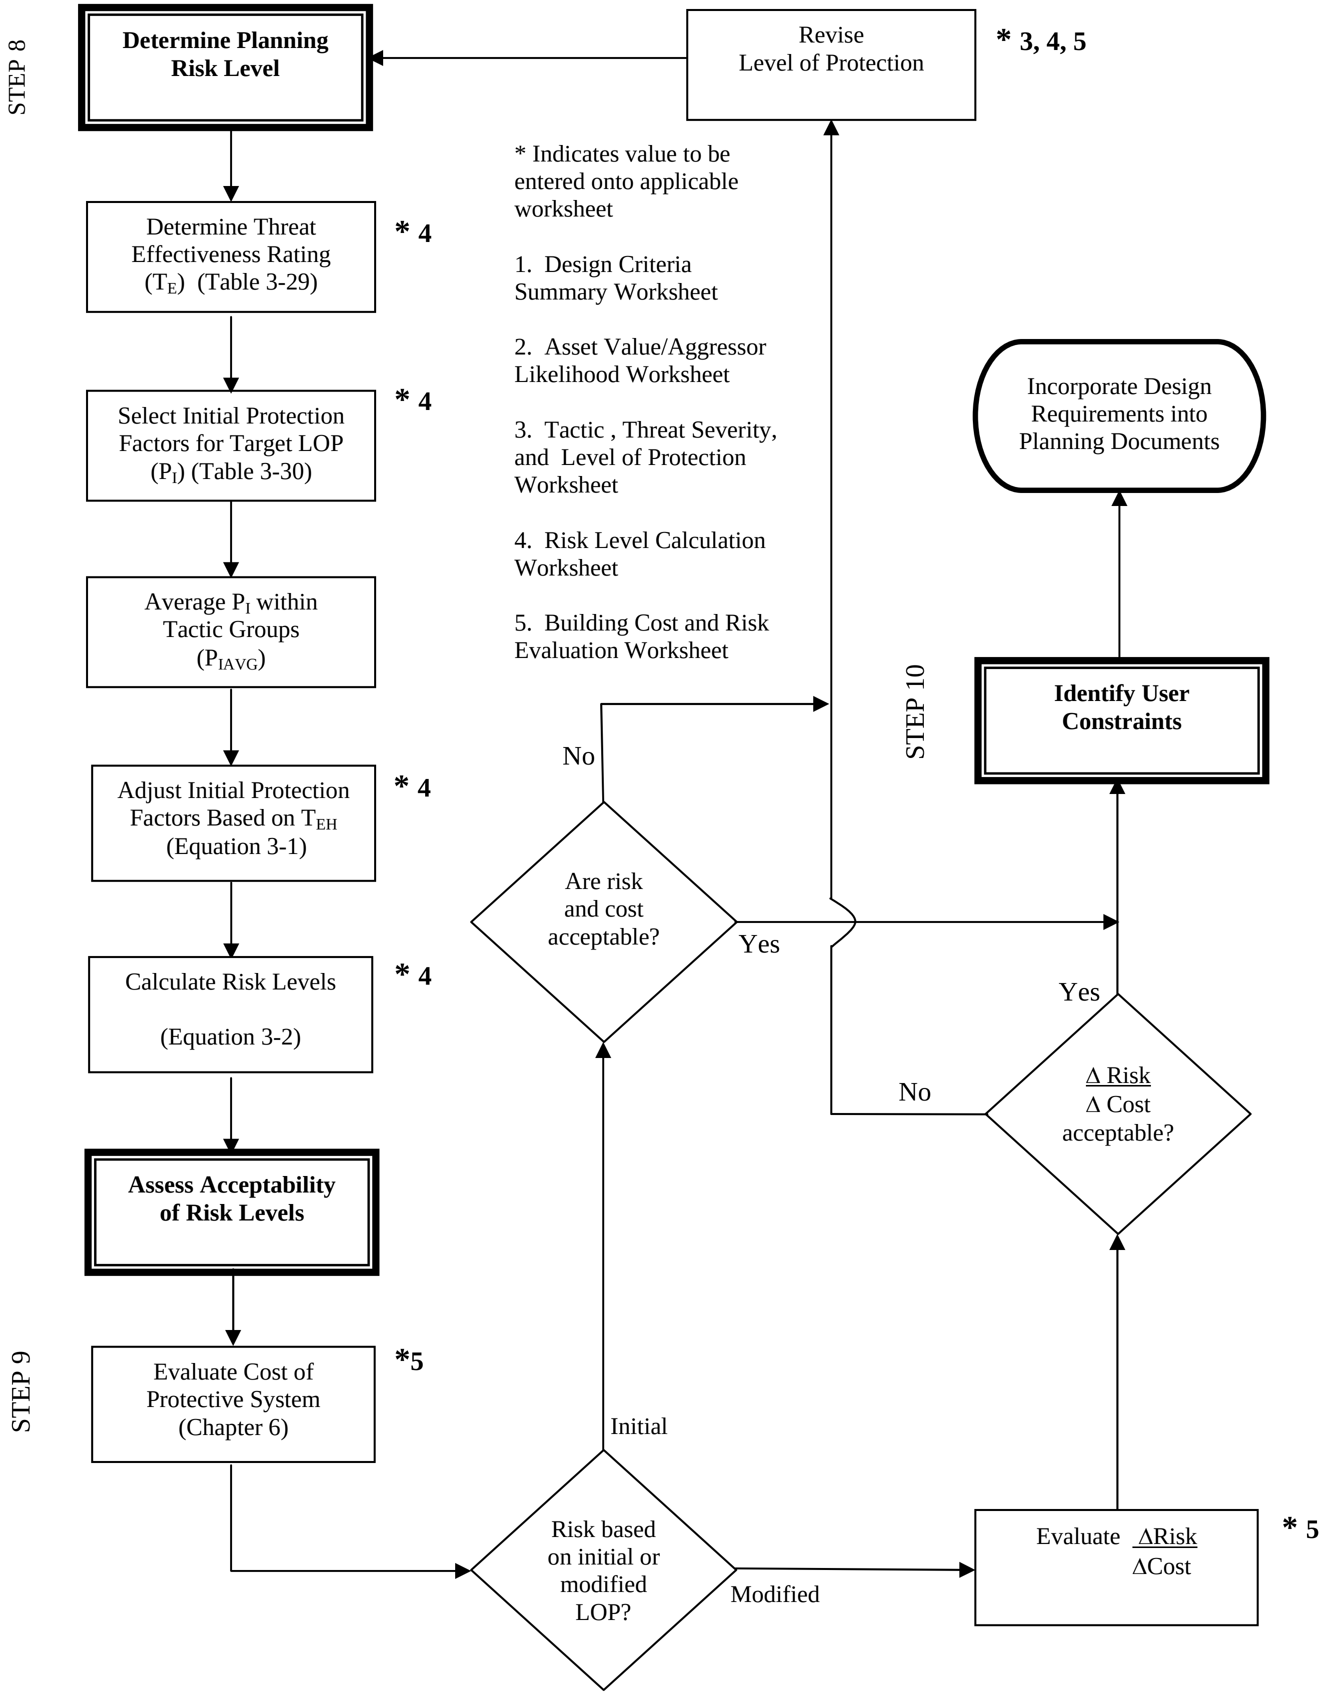
3-2 **USING THIS PROCEDURE.** The design criteria development procedure in this chapter comprises ten steps. The ten steps address the identification of the elements of design criteria and the adjustment of them through preliminary risk analysis. The procedure is summarized in the flow chart in Figure 3-2. The procedure uses worksheets to guide the Planning Team through the series of decisions necessary to identify the applicable assets, threats, and levels of protection. The decisions are based on a series of subjective questions that may lead the Planning Team to an objective answer in a manner that is reproducible among different Planning Teams and over time. The preliminary design criteria thereby developed may be adjusted through a common means of risk analysis. The ten steps in the design criteria development procedure are described separately below. In addition to the basic principles associated with each step, each of the applicable tables associated with that step is described and guidance is provided on their application.

Figure 3-2. The Design Criteria Development Procedure





STEP 4
Determine Aggressor Likelihoods
Select Applicable Aggressors (Table 3-9)
* 2
Assess Aggressor Likelihood Factors (Tables 3-10 to 3-23)
* 2
Sum Likelihood Rating Factors
* 2
Determine Aggressor Likelihood Rating (T_L)
* 2 - 4
Likelihood Rating ≤ 0.5 ?
No
Yes
Ignore Aggressor
All Aggressors ≤ 0.5 ?
No
Yes
Apply only applicable minimum standards or regulations
STEP 5
Identify Likely Tactics and Threat Severity Levels
Select Potential Tactics Based on Asset (Table 3-24)
* 3
Select Applicable Tactics Based on Aggressor (Table 3-25)
* 3
Select Applicable Tactic Threat Severity Levels (Table 3-26)
* 3
STEP 6
Consolidate into Initial Design Basis Threat
* 3
STEP 7
Determine Initial Levels of Protection (Table 3-28)
* 3, 4
STEP 8
Determine Planning Risk Level
(continued)
* Indicates value to be entered onto applicable worksheet
1. Design Criteria Summary Worksheet
2. Asset Value/Aggressor Likelihood Worksheet
3. Tactic , Threat Severity, and Level of Protection Worksheet
4. Risk Level Calculation Worksheet
5. Building Cost and Risk Evaluation Worksheet



STEP 8
Determine Planning Risk Level
Revise Level of Protection
* 3, 4, 5
Determine Threat Effectiveness Rating (T_E) (Table 3-29)
* 4
Select Initial Protection Factors for Target LOP (P_I) (Table 3-30)
* 4
Average P_I within Tactic Groups (P_{IAVG})
Adjust Initial Protection Factors Based on T_{EH} (Equation 3-1)
* 4
Calculate Risk Levels (Equation 3-2)
* 4
Assess Acceptability of Risk Levels
STEP 9
Evaluate Cost of Protective System (Chapter 6)
*5
* Indicates value to be entered onto applicable worksheet
1. Design Criteria Summary Worksheet
2. Asset Value/Aggressor Likelihood Worksheet
3. Tactic , Threat Severity, and Level of Protection Worksheet
4. Risk Level Calculation Worksheet
5. Building Cost and Risk Evaluation Worksheet
Incorporate Design Requirements into Planning Documents
STEP 10
Identify User Constraints
No
Are risk and cost acceptable?
Yes
Yes
No
Δ Risk
Δ Cost
acceptable?
Initial
Risk based on initial or modified LOP?
Modified
Evaluate ΔRisk
ΔCost
* 5

3-3 **STEP 1: CONVENE THE PLANNING TEAM.** The first step of the process of developing design criteria is to convene the Planning Team as described in Chapter 1. It is essential to the effectiveness of the design criteria development to have an interdisciplinary team involved in the process. All the members of that team have unique perspectives that need to be reflected in the effort. The team should be convened at the inception of project planning and should provide review and oversight at all stages of project development. It should also be consulted during the design process as described in UFC 4-020-02.

3-4 **STEP 2: IDENTIFY ASSETS.** The design criteria developed in this chapter relate primarily to assets associated with facilities as opposed to the facilities themselves. Protecting individual assets is generally more cost effective than protecting an entire facility. Buildings should only be considered assets if they are the likely direct target of aggression, as in vandalism or where the buildings have some special significance such as a highly symbolic or historic structure. Determining the assets to be protected is the first step in establishing any protective system. The following two steps are provided to facilitate a degree of consistency in identifying DoD assets.

3-4.1 **Determine Facility Types.** There are many types of facilities on military installations or used by the military off installations. For the purposes of easily identifying assets in a consistent manner, those facilities have been divided into 22 broad categories. Those categories are tabulated in Table 3-1, which also includes common examples of each of those facility types. Table 3-1 also includes the baseline building categories that are referred to in Chapter 4 and that are used in determining costs for the protective systems necessary to implement the design criteria developed using this process. Determine which of the facility types from the center column of Table 3-1 applies to the facility being analyzed.

3-4.2 **Determine Default Assets.** There are an almost unlimited number of different kinds of assets likely to be found in DoD facilities. Those assets may be grouped into categories to effectively deal with them. Table 3-2 includes a list of generic asset categories into which assets can be grouped. These categories include the assets that are commonly targeted by aggressors and which are frequently of significant value to their users. These categories also include assets that are required to be protected by regulation. They do not, however, include nuclear weapons or materials or chemical weapons because those assets have very strict regulations for their protection that are well established and generally more stringent than the countermeasures reflected in this manual.

The asset categories in Table 3-2 are assigned letters for ease of use. Those letters should not be interpreted to represent priorities. The assets that are likely to be present in various facility types are predictable, and can therefore be tabulated on a default basis. Table 3-2 provides a default list of asset types that may be expected to be found in the common facility types listed in Table 3-1.

Use Table 3-2 to identify default assets associated with the applicable facility type, and then adjust that list based on which of those assets are actually present in the facility. Also identify any other assets within a facility or associated with a project that are of value to the user based on their importance to the user's mission or on some other measure of value such as monetary worth. In addition, identify any additional assets that are to be protected based on policies, command directives, or regulations, and identify people who will be considered assets based on one or more of the above considerations. In the case of people, the Planning Team will have to determine whether they are mission critical people or the general population. The assets established in this step are the assets that the Planning Team should consider in the remainder of this procedure. Enter the identified assets and their applicable asset categories into the appropriate columns of the Design Criteria Summary Worksheet as illustrated in Figure 3-3.

Table 3-1. Common Facility Types

Baseline Building Category	Facility Type	Examples
Administrative and Community Support Buildings *	Headquarters and Operations Facilities and Other Administrative Facilities	Brigade, Battalion, Company Headquarters
		Airfield Operations Facility
		Aviation Unit Operations Facility
		Field Operations Facility
		Ship Operations Facility
		Emergency Operations Facility
		Fire / Police Station
		National Guard / Reserve Centers
		Cargo Handling Office
		Dispatch Building
		Courtroom
		General Administrative Facility
	Schools and Education Facilities	Education Center
		Dependent School
		Religious Education Center
	Community Facilities	Community Service Center
		Child Development Center
		Drug / Alcohol Abuse Center
		Red Cross Building
		Craft Centers
	Small Retail Facilities	Shoppette
		Golf Clubhouse
		Laundry
		Video Rental Store
Unaccompanied Personnel Housing *	Unaccompanied Personnel Housing	Enlisted Barracks / Dormitories
		Trainee Barracks / Dormitories
		Transient Unaccompanied Personnel Housing
		Unaccompanied Officers / Enlisted Personnel Housing
Family Housing	Family Housing	Family Housing Units
Dining Facilities *	Dining Facilities	Dining Facilities
		EM Club

(Table 3-1 continued)

Medical Facilities *	Medical Facilities	Hospital
		Medical Clinic
		Dental Clinic
		Pharmacy
		Veterinary Clinic
		Laboratory
Special Structures *	Religious Facilities	Chapel
	Recreation Facilities	Auditorium
		Gymnasium
		Bowling Alley
		Theater
	Commissaries and Exchanges	Commissary
		Exchange
	Alert Systems, Forces, and Facilities	Alert Systems, Forces, and Facilities
Maintenance Facilities (other than weapons)	Equipment Maintenance Facilities	Equipment Maintenance Facilities
	Aviation Maintenance Facilities	Aviation Maintenance Facilities
	Motor Pools	Motor Pools
	Aircraft Parking Areas - hangars	Aircraft Parking Areas
	Ship or Boat Berths	Ship or Boat Berths
	Arms, Ammunition, and Explosives Storage Facilities	Magazines
		Arms Rooms
		Weapons Maintenance Facilities
	Petroleum, Oils, and Lubricants Storage Facilities	Petroleum, Oils, and Lubricants Storage Facilities
	Research and Development Facilities	Research and Development Facilities
	Warehouses	Warehouses
	Utilities and Substations	Utilities and Substations
* Building types included in cost tables in Appendices A - C		

3-5 **STEP 3: DETERMINE ASSET VALUE.** Asset value refers to the value of an asset to its user. It is a reflection of the consequence of having the asset compromised by an aggressor. The asset value helps the Planning Team to determine the level of protection that is warranted for the asset.

3-5.1 **Value Rating Factors.** The value of an asset to its user is determined by evaluating up to five value rating factors, depending on the asset category. Those factors include mission criticality to the asset's user, impact on the national defense, replaceability, political sensitivity, and relative value. Not all factors are evaluated for general population, critical infrastructure, operations and activities, and sensitive information. Table 3-3 shows which factors are applicable to each asset category. The applicability of value rating factors is also indicated on the Asset Value/Aggressor Likelihood Worksheet. The factors are evaluated using tables in this chapter. These tables include statements that describe the value rating factors qualitatively. Select the statement from each table that most closely reflects the asset's value. Each statement has a numerical value associated with it that is used in determining the asset value rating. Where there is any question about the meaning of a specific statement in a table, consider all the statements in terms of "on a scale of 0 to 5." For each asset, enter the appropriate numerical value from each applicable value rating table in the spaces provided on the Asset Value/Aggressor Likelihood Worksheet. These will also

Table 3-3. Value Rating Factor Applicability

Asset Category	Value Rating Factor				
	Criticality to User / Population Type	Impact on National Defense	Replaceability	Political Sensitivity	Relative Value to User
General Population	✓			✓	✓
Critical Infrastructure and Operations and Activities	✓	✓	✓	✓	
Sensitive Information					✓
All Other Assets (including Mission Critical Personnel)	✓	✓	✓	✓	✓

3-5.1.1 **Criticality to User's Mission / Population Type.** This factor addresses the criticality of the asset in its support of its user's mission and, in the case of the general population, whether they are military, DoD civilians, or dependents and other civilians. Criticality of mission critical personnel and property is measured in terms of the impact the person's or asset's loss would have on the user's operations, output, production, or service. In the case of operations and activities, consider the impact of the activity's or operation's compromise. For the general population, because they are not mission critical, they are evaluated according to their status. The assumption therein is that the loss of military people is more readily accepted than the other types of personnel and the loss of DoD civilians is more accepted than dependents or other civilians. This factor is not evaluated for sensitive information. Evaluate this factor using Table 3-4.

Table 3-4. Criticality to User / Mission Impact/ Population Type

Asset Category	Population Type, Degradation Installation Mission, or Impact of Asset's Loss or Activity's Compromise on User's Mission	Value Rating Factor
General Population	Population is primarily military personnel	1
	Population is primarily DoD civilians and contractors	3
	Population is primarily dependents and other civilians	5
Critical Infrastructure	Loss would degrade or cause failure of specific functions, but have no effect on the installation-wide mission or missions of DoD facilities off installations	1
	Loss would cause failure of specific functions and minimally degrade the installation-wide mission or missions of DoD facilities off installations	2
	Loss would cause failure of specific functions and moderately degrade the installation-wide mission or missions of DoD facilities off installations	4
	Loss would cause installation-wide mission failure or failure of missions of DoD facilities off installations	5
All Other Assets (except for sensitive information) (including mission critical personnel, operations and activities, and critical industrial equipment)	Asset's loss or operation's /activity's compromise would have no significant effect on operations, output, production, or service	0
	Asset's loss or operation's /activity's compromise would result in halting operations within 1 month or would result in a 10% curtailment in output, production, or service	1
	Asset's loss or operation's /activity's compromise would result in halting operations within 2 weeks or would result in a 25% curtailment in output, production, or service	2
	Asset's loss or operation's /activity's compromise would result in halting operations within 1 week or would result in a 50% curtailment in output, production, or service	3
	Asset's loss or operation's /activity's compromise would result in halting operations within 1 day or would result in a 75% curtailment in output, production, or service	4
	Asset's loss or operation's /activity's compromise would immediately halt operations, output, production, or service. The user cannot function without it.	5

3-5.1.2 **Impact on the National Defense.** This factor addresses the criticality of the asset in its support of the defense of the United States and its interests. It accounts for the fact that some assets may be critical to their user's mission, but not to the broader national defense mission. An example of such an asset might be kitchen equipment in a community club. The equipment may be critical to the club's mission, but is unlikely to be critical to the war-fighting mission of the installation's tenant units. Considering this factor ensures that assets that are critical to military readiness receive a higher priority than those that are not. This factor is not evaluated for the general population or sensitive information. Evaluate this factor using Table 3-5.

Table 3-5. Impact on the National Defense

Impact of Asset’s Loss on the National Defense	Value Rating Factor
The loss, theft, destruction, or misuse of the asset or operation’s /activity’s compromise could have insignificant impact on the United States or a region.	0
The loss, theft, destruction, or misuse of the asset or operation’s /activity’s compromise could have significant mission impact on a regional level.	1
The loss, theft, destruction, or misuse of the asset or operation’s /activity’s compromise could compromise the defense infrastructure of the United States.	2
The loss, theft, destruction, or misuse of the asset or operation’s /activity’s compromise could impact the tactical capability of the United States.	3
The loss, theft, destruction, or misuse of the asset or operation’s /activity’s compromise could be expected to harm the operational capability of the United States.	4
The loss, theft, destruction, or misuse of the asset or operation’s /activity’s compromise could result in great harm to the strategic capability of the United States.	5

3-5.1.3 **Asset Replacement.** This factor addresses the ease with which assets can be replaced. There are separate entries for people and assets other than people. This factor is not evaluated for the general population or sensitive information. Evaluate this factor using Table 3-6.

3-5.1.3.1 **Mission Critical Personnel.** This table reflects the difficulty of finding replacements for personnel who are injured based on the skills and training necessary for replacement personnel. Note that this factor is only applied to people who are considered mission critical. It is not applied to the general population.

3-5.1.3.2 **Assets Other Than People.** This table is based on the amount of time required to replace assets or reestablish operations and activities that have been compromised, either in-kind or with substitutes that are acceptable to the user or the Planning Team. The replacement assets or operations or activities can also be either temporary or permanent depending on the Planning Team’s judgment. This factor accounts for the impact of delay in replacement of assets on the user's mission.

Table 3-6. Asset Replacement

Asset Category	Availability of Replacement Personnel or Time to Asset Replacement, Repair, or Substitution	Value Rating Factor
Mission critical personnel	Personnel would be immediately available to resume the functions of casualties	1
	Personnel would have to be transferred from other units on the installation to resume the function of the casualties	2
	Personnel would have to be transferred from other units at other installations to resume the function of the casualties	3
	Personnel would have to be trained over an extended period to resume the functions of the casualties	4
	Personnel of such a critical nature that “replacement” would not be realistic	5
All assets other than people and sensitive information (including operations and activities)	Asset can be replaced or operation / activity could be reestablished in less than 24 hours	0
	Asset can be replaced or operation / activity could be reestablished in 24 to 72 hours	1
	Asset can be replaced or operation / activity could be reestablished in 72 hours to 1 week	2
	Asset can be replaced or operation / activity could be reestablished in 1 week to 1 month	3
	Asset can be replaced or operation / activity could be reestablished in one to six months	4
	Asset will require more than a 6 months to replace or operation / activity will require more than 6 months to reestablish	5

3-5.1.4 **Political Sensitivity.** This factor accounts for the Planning Team’s perception of the political repercussions associated with the asset’s loss, destruction, or death or the operation’s or activity’s compromise. Considerations could include adverse publicity, erosion of confidence, and the perception of poor security. Note that political sensitivity is somewhat dependent on media attention; therefore, what asset is compromised and where may be significant factors. For example, a person being killed will be a much more politically sensitive issue than a computer being stolen. In addition, regarding people, killing a person in the Continental U.S. may be far more politically sensitive than killing somebody in a forward deployed location or a war zone. This factor is not evaluated for sensitive information. Evaluate this factor using Table 3-7.

Table 3-7. Perceived Political Sensitivity

User’s Perceived Political Sensitivity of Loss of Asset	Asset Value Rating
Negligible: Media attention would be unlikely	0
Minimal: Media attention would likely be limited to local media	1
Moderate: Media attention would likely extend to national media	3
High: Media attention would likely extend to international media.	5

3-5.1.5 **Relative Asset Value.** This factor provides a measure of the relative value of an asset based on measures of value appropriate for particular asset categories. The relative values of the different asset categories are measured in different ways. The most appropriate ways of measuring cost for various asset categories are reflected in Table 3-8. This factor is not evaluated for critical infrastructure or operations and activities. Evaluate this factor using Table 3-8.

3-5.1.5.1 **Personnel.** The relative value for personnel is based on the number of such personnel routinely inhabiting a facility. For mission critical personnel, this factor also considers the percentage of people required for mission execution that are routinely present in the facility. Assigning monetary costs to people is difficult, so value of personnel is based on numbers of people. That assumes that injuring or killing many people is inherently worse than injuring or killing only a few. There are separate entries for the general population and for mission critical personnel. Those for mission critical personnel are lower than those for the general population to reflect the increased importance to mission execution of those people. Where people are an asset and there are both mission critical personnel and general population in a building, either the higher value rating for the two categories of personnel can be applied for the entire facility or the facility can be broken onto mission critical personnel and general population areas. In the latter case, the different areas could have separate asset value ratings.

3-5.1.5.2 **Aircraft.** Relative values for aircraft are based on the types of aircraft commonly parked at an aviation facility (trainers; cargo, refueling, or utility aircraft; tactical or attack aircraft; and strategic aircraft.) They are also based on the size of the unit that operates the aircraft, either smaller or larger than squadron or company strength. This reflects the fact that a large number of aircraft is relatively more valuable than a small number.

3-5.1.5.3 **Ships, Boats, and Watercraft.** Relative value of watercraft is based on the categories of ships moored at a location, regardless of number. The relative values of those categories of ships reflect their relative importance. Ships moored near higher category vessels should be assigned the same value rating as the higher category ships.

3-5.1.5.4 **Vehicles.** Relative value for vehicles is based on similar assumptions to those for aircraft. The relative values of vehicles is based on whether they are or are not tactical vehicles or critical maintenance or support vehicles or whether they include carriage mounted or towed weapons systems. The breaks between numbers of vehicles are based on the number of vehicles in a company-sized element. The assumption is that these vehicles are in a motor pool , that the number of vehicles associated with a company-sized element constitutes a significant number, and that the loss of many vehicles is worse than the loss of a few.

3-5.1.5.5 **Petroleum, Oils, and Lubricants (POL).** The relative value of POL is based on the quantities of POL stored at the location in question. The quantities in the tables reflect the quantities handled by the various sizes of Army tactical units from battalion up to Theater Army. They are also representative of quantities handled by increasingly larger Air Force, Navy, and Marine Corps elements.

3-5.1.5.6 **Arms, Ammunition, and Explosives (AA&E).** The relative value of AA&E is based on its risk level as defined in DoD 5100.76-M. The categories of I through IV (highest to lowest risk, respectively) reflect the relative utility, attractiveness, and availability to criminal elements of the AA&E. As a general rule, only arms, missiles, rockets, explosive rounds, mines, and projectiles that have an unpacked unit weight of 100 pounds or less are categorized as sensitive for purposes of DoD 5100.76-M. In addition, any single container that contains a sufficient amount of spare parts that, when assembled, will perform the basic function of the end item will be categorized the same as the end item. Nuclear and chemical weapons are not to be addressed using this UFC. The requirements established in DoD instructions for protecting them are much more stringent than anything that would be established using the security engineering series of UFCs.

3-5.1.5.7 **Controlled Substances and Medically Sensitive Items.** Relative values for these assets are measured by their designation as sensitive items as established by the Drug Enforcement Agency and by the type of facility in which they are stored. Contact medical or pharmacy personnel to determine which of these designations apply. Quantity is accounted for in considering mission criticality. Substances that are protected under protocols for biosafety in microbiological laboratories are not within the scope of this UFC.

3-5.1.5.8 **Assets with Identifiable Monetary Value.** These are assets for which costs are readily definable. Their value, therefore, is based only on their value in U.S. dollars. In general, use this measure of relative value for assets that are not specifically covered by one of the asset types in this table. There are two entries for assets that are measured by their monetary value. One is to be used where only a single asset is being considered. The other is to be used where the assets are stored in quantities that are more appropriately measured as inventories.

3-5.1.5.9 **Controlled Cryptographic Items.** These are devices that process sensitive information. Their relative value is based on the level of sensitivity of the information they are accredited to process.

3-5.1.5.10 **Sensitive Information.** This is sensitive classified or unclassified information. Unlike other assets, the relative value of sensitive information is based only on this single factor. That is because many of the issues that are addressed in the criticality and replaceability factors are reflected in decisions on the classification of sensitive information.

Table 3-8. Relative Value to User

Asset Type		Measure of Relative Value	Relative Value	Value Rating Factor
People	Mission Critical Personnel	Number of people present in facility	Number of mission critical personnel in the facility is less than 5 or 10% of people needed for mission execution are routinely present in the facility	1
			Number of mission critical personnel in the facility is 6 to 10 or 25% of people needed for mission execution are routinely present in the facility	2
			Number of mission critical personnel in the facility is 11 to 49 or 50% of people needed for mission execution are routinely present in the facility	3
			Number of mission critical personnel in the facility is 50 to 100 or 75% of people needed for mission a execution re routinely present in the facility	4
			Number of mission critical personnel in the facility is greater than 100 or 90% of people needed for mission execution are routinely present in the facility	5
	General Population	Number of people present in facility	Number of people in the facility is less than 11	0
			Number of people in the facility is 11 to 49	1
			Number of people in the facility is 50 to 100	2
			Number of people in the facility is 101 to 500	3
			Number of people in the facility is 501 to 1000	4
			Number of people in the facility is greater than 1000	5
Aircraft		Organizational unit and aircraft type	Aircraft limited to trainers	1
			Aircraft include cargo, refueling, or utility type aircraft in units of less than company or squadron strength	2
			Aircraft include cargo, refueling, or utility type aircraft in units of greater than company or squadron strength	3
			Aircraft include tactical or attack type aircraft in units of less than company or squadron strength	3
			Aircraft include tactical or attack type aircraft in units of greater than company or squadron strength	4
			Aircraft include strategic aircraft	5
Watercraft		Number and type of watercraft	All other watercraft	1
			Patrol Coastal, MSC strategic sealift ships (reduced operational status)	2
			Surface combatants, other amphibious, auxiliary, MSC, strategic sealift ships, ammunition ships, and mine warfare	3
			Aircraft carriers or large deck amphibious (LHA,LHD, etc.) and other submarines	4
			SSBN and Sea Based X-Band Radar (SBX)	5

(Table 3-8 continued)

Vehicles	Number and type of vehicles	Fewer than 20 vehicles are parked in the vehicle parking area or motor pool. Vehicles do not include tactical vehicles, carriage mounted or towed weapons systems, or critical maintenance or support vehicles	1
		Fewer than 20 vehicles are parked in the vehicle parking area or motor pool. Vehicles include tactical vehicles and critical maintenance or support vehicles, but do not include carriage mounted or towed weapons systems	2
		Fewer than 20 vehicles are parked in the vehicle parking area or motor pool. Vehicles include carriage mounted or towed weapons systems	3
		20 or more vehicles are parked in the vehicle parking area or motor pool. Vehicles do not include tactical vehicles, carriage mounted or towed weapons systems, or critical maintenance or support vehicles	3
		20 or more vehicles are parked in the vehicle parking area or motor pool. Vehicles include tactical vehicles and critical maintenance or support vehicles, but do not include carriage mounted or towed weapons systems	4
		20 or more vehicles are parked in the vehicle parking area or motor pool. Vehicles include carriage mounted or towed weapons systems	5
Petroleum, Oils, and Lubricants	Quantity stored	Quantity of fuel stored is less than 190,000 liters (50,000 gallons)	1
		Quantity of fuel stored is greater than or equal to 190,000 liters (50,000 gallons) and less than 570,000 liters (150,000 gallons)	2
		Quantity of fuel stored is greater than or equal to 570,000 liters (150,000 gallons) and less than 1,900,000 liters (500,000 gallons)	3
		Quantity of fuel stored is greater than or equal to 1,900,000 liters (500,000 gallons) and less than 3, 800,000 liters (1,000,000 gallons)	4
		Quantity of fuel stored is greater than or equal to 3,800,000 liters (1,000,000 gallons)	5
Arms, Ammunition, and Explosives	Risk category (DoD 5200.76M)	Uncategorized	1
		Category IV	2
		Category III	3
		Category II	4
		Category I	5

(Table 3-8 continued)

Controlled Substances and Medically Sensitive Items	Sensitivity and storage location	Non-sensitive pharmaceuticals and other non-sensitive medical items	1
		Medically sensitive items in pharmacies, wards, clinics, or RDT&E facilities	2
		Medically sensitive items in bulk storage facilities	3
		Items identified as Note R in the Federal Supply Catalog, non-standard DEA Schedule II controlled substances , or standard drug items identified as Note Q in the Federal Supply Catalog , non-standard DEA Schedule III, IV, and V controlled substances in pharmacies, wards, clinics, or RDT&E facilities	4
		Items identified as Note R in the Federal Supply Catalog, non-standard DEA Schedule II controlled substances , or standard drug items identified as Note Q in the Federal Supply Catalog , non-standard DEA Schedule III, IV, and V in bulk storage facilities	5
Individual Assets with Monetary Value	Replacement cost	Asset value is less than $2500	0
		Asset value is greater than or equal to $2500 and less than $10,000	1
		Asset value is greater than or equal to $10,000 and less than $25,000	2
		Asset value is greater than or equal to $25,000 and less than $50,000	3
		Asset value is greater than or equal to $50,000 and less than $100,000	4
		Asset value is greater than $100,000	5
Inventories of Assets with Monetary Value	Replacement cost	Asset inventory value is less than $100,000	0
		Asset inventory value is greater than or equal to $100,000 and less than $250,000	1
		Asset inventory value is greater than or equal to $250,000 and less than $500,000	2
		Asset inventory value is greater than or equal to $500,000 and less than $1,000,000	3
		Asset inventory value is greater than or equal to $1,000,000 and less than $2,000,000	4
		Asset inventory value is greater than $2,000,000	5
Controlled Cryptographic Items (CCI)	Sensitivity of information processed	CCI processes unclassified and non-sensitive information	0
		CCI processes unclassified, but sensitive information (i.e. For Official Use Only)	1
		CCI processes Confidential information	2
		CCI processes Secret information	3
		CCI processes Top Secret information	4
		CCI processes Secure Compartmented information	5
Sensitive Information	Sensitivity or classification level	Unclassified sensitive (i.e. For Official Use Only)	5
		Confidential	7.5
		Secret	8.5
		Top Secret	9.5
		Secure Compartmented Information	10

3-5.2 **Determine Asset Value Rating.** Asset value ratings (except for sensitive information) are determined based on the sums of the applicable value rating factors and the percentages of the possible points those sums represent. Sum the applicable value rating factors for each asset and enter the sum in the appropriate box on the Asset Value/Aggressor Likelihood Worksheet. Then divide the sums by the applicable number of points possible for that asset category. Those total numbers of points will be 10 for sensitive information, 15 for general population, 20 for critical infrastructure and activities and operations, and 25 for all other assets. The resulting percentage is the asset value rating. Enter it in the appropriate boxes on the Asset Value/Aggressor Likelihood Worksheet as illustrated in Figure 3-4. Also enter it on the Design Criteria Summary Worksheet, the Tactic, Threat Severity, and Level of Protection Worksheet, and the Risk Level Calculation Worksheet.

3-5.3 **Eliminate Assets with "Very Low" Value Ratings.** Assets whose value ratings are less than or equal to 0.5 may be considered to be of minimal value and do not warrant further analysis. Eliminate those assets from further consideration. For those assets only countermeasures required by regulation or measures required by one or more of the minimum construction standards (either DoD or Combatant Command) should be applied. For other assets continue on to the next step of the procedure.

3-6 **STEP 4: IDENTIFY AGGRESSOR LIKELIHOODS.** The next step in the procedure after identifying the assets and their values is to look at those assets from the perspective of potential aggressors. This step includes identifying potential aggressors and determining the likelihoods that they will attempt to compromise the assets.

3-6.1 **Select Applicable Aggressors.** Table 3-9 indicates which of the 10 aggressor types defined in chapter 2 are likely to attempt to compromise assets in each of the 18 established asset categories. These aggressor selections represent default potential aggressors and were established based on assessment of the common goals and characteristics historically exhibited by those aggressor types. Further evaluation by the Planning Team relative to a specific asset's locality is required to make a final determination of the applicable aggressors. Indicate on the Asset Value/Aggressor Likelihood Worksheet the aggressor types applicable to an asset by placing "X's" or check marks in the spaces adjacent to them. Note that Table 3-9 also includes default aggressor goals, which are used later in the chapter.

3-6.2 **Assess Aggressor Likelihood Ratings.** The likelihood that a given aggressor will attempt to compromise an asset is evaluated using 14 likelihood rating factors for terrorists and 11 likelihood rating factors for all other aggressors. Each of those factors is described below. The factors measure likelihood by considering issues that reflect how likely an aggressor is to know that an asset exists, how common the asset is, where it is located, history of attacks on those assets, the state of law enforcement support, how it is stored, and the threat level. There are also asset specific considerations of the relative value of the asset to the aggressors. In evaluating the individual likelihood rating tables, select the entry from each applicable table that most closely applies to the aggressor and the asset. The rating factors are evaluated on scales of 0 to 5, 0 to10, 0 to 15, 0 to 20, or 0 to 30. In the higher range cases, the rating factors are rated higher to reflect increased importance of the issues reflected in

Figure 3-4. Sample Asset Value / Aggressor Likelihood Worksheet

ASSET VALUE/AGGRESSOR LIKELIHOOD WORKSHEET

		Foreign Intelligence Services																

1. Population Type applies to General Population only
2. Sum of Value Ratings ÷ 10 for Sensitive Information 15 for General Population; 20 for Critical Infrastructure and Operations and Activities; 25 for all other assets
3. G for mission related goal, P for publicity related goal, M for monetary related goal.
4. Factors that should be same for all aggressors for given asset
5. Applies to all aggressors other than terrorists
6. Applies to Terrorists only
7. Sum of Likelihood Ratings ÷ 180

those factors. The likelihood rating factors can be subdivided into three main areas: factors relating to the assets themselves (the first 7), factors relating to asset protection (law enforcement and perception of success), and factors relating to history, threat level, and characteristics of terrorist groups (all others). The sums of all the factors within each of those areas are 1/3 of the total (180). Where the differences in meaning between descriptions in the tables are difficult to determine, think of them in terms of "on a scale of 0 to 5" or whatever the applicable range may be. Record the numerical values for the applicable likelihood rating factors in the appropriate spaces on the Asset Value/Aggressor Likelihood Worksheet.

Table 3-9. Potential Aggressors and Default Goals

		Default Aggressor Types									
	Asset Categories	Unsophisticated Criminals	Sophisticated Criminals	Organized Criminal Groups	Vandals	Extremist Protest Groups	Domestic Terrorists	International Terrorists	State Sponsored Terrorists	Saboteurs	Foreign Intelligence Services
A	People			G	P	P	P	P	P	G

R	Activities and Operations			G		G	P	P	P	G	G
	1. May be mission, publicity, or monetary related goal (see Table 3-16) G = Mission related goal P = Publicity related goal M = Monetary related goal										

3-6.2.1 **Installation Location.** This factor reflects the assumption that installations that are outside the Continental United States are more likely targets of attack than those in the Continental United States and that the threat is higher near major population centers. Use Table 3-10 to evaluate this factor.

Table 3-10. Asset Location

Installation or facility Location	Likelihood Rating Factor
Located within the Continental United States away from major metropolitan areas	1
Located within the Continental United States near a major metropolitan area	2
Located outside the Continental United States away from major metropolitan areas	4
Located outside the Continental United States near a major metropolitan area	5

3-6.2.2 **Publicity Profile.** This factor addresses the level of publicity associated with an installation or facility. It accounts for the fact that some installations are very controversial and well known throughout a region while others are rather obscure. This factor is based on the assumption that installations or facilities that have a high publicity profile are more likely targets than those that are relatively unknown. Use Table 3-11 to evaluate this factor.

Table 3-11. Installation or Facility Publicity Profile

Level of Publicity Associated with Installation or Facility	Likelihood Rating Factor
Installation or facility is relatively unknown both locally and regionally.	1
Installation or facility is well known locally but is relatively unknown regionally.	2
Installation or facility is well known locally and regionally, but it relatively un known nationally.	3
Installation or facility is well known locally, regionally, and nationally, but is relatively unknown internationally	4
Installation or facility is well known locally, regionally, nationally and internationally	5

3.6.2.3 **Accessibility.** This factor addresses the assumption that assets are more vulnerable when the facilities in which or at which they are stored are readily accessible. This factor is evaluated using Table 3-12, which addresses whether or not the facility is on an “open” or access controlled installation and the proximity of the facility to the installation perimeter.

Table 3.12 Asset Accessibility

Asset Location and Access Controls	Likelihood Rating Factor
The facility in which or at which the asset is located is on a closed military installation or government compound to which access is controlled, the facility is in a separate access controlled compound interior of the installation, and there are no direct lines of sight to the facility from outside the installation	0
The facility in which or at which the asset is located is on a closed military installation or government compound to which access is controlled and the facility is in the interior of the installation	2
The facility in which or at which the asset is located is on a closed military installation or government compound to which access is controlled and the facility is within 100 meters of the installation perimeter	4
The facility in which or at which the asset is located is on an open military installation or government compound to which access is not controlled and the facility is in the interior of the installation	6
The facility in which or at which the asset is located is on an open military installation or government compound to which access is not controlled and the facility is within 100 meters of the installation perimeter	8
The facility in which or at which the asset is located is not on a military installation or government compound	10

3-6.2.4 **Asset Availability.** This factor assesses how common the asset is in the general area where it is located. The rating table addresses availability both on military installations or at other sites where military assets are housed and in their immediate vicinities. It reflects the assumption that the likelihood that an aggressor will attempt to compromise an asset in one particular location is less if it is widely available, assuming all locations are equally likely. Conversely, the likelihood increases if the location in question is the only place the asset can be found and it assumed the aggressor wants that specific asset. Use Table 3-13 to evaluate this factor.

Table 3-13. Asset Availability

Asset Availability	Likelihood Rating Factor
Similar assets are widely available both on and in the immediate vicinity off the installation or site	0
Similar assets have limited availability in the immediate vicinity off the installation, but are widely available on the installation or site	1
Similar assets are not available in the immediate vicinity off the installation, but are widely available on the installation or site	2
Similar assets have limited availability on the installation and are not available in the immediate vicinity off the installation or site	3
Similar assets are available at fewer than 3 other locations on the installation and are not available in the immediate vicinity off the installation or site	4
There are no similar assets on or off the installation except at this location or site	5

3-6.2.5 **Asset Dynamics.** This factor accounts for the assumption that an aggressor is less likely to attempt to attack an asset that is moved frequently or randomly because of the uncertainty of its location at any given time and the uncertainties in planning inherent in that condition. Use Table 3-14 to evaluate this factor.

Table 3-14. Asset Dynamics

Frequency of Asset Relocating or Moving	Likelihood Rating Factor
Asset is moved frequently on a random basis	1
Asset is moved frequently on a predictable basis	2
Asset is moved periodically on a random basis	3
Asset is moved periodically on a predictable basis	4
Asset is not moved.	5

3-6.2.6 **Recognizability.** This rating factor assesses how likely an aggressor is to know that an asset exists in the location where it is located. That likelihood should be evaluated based on assumptions about the sophistication of the aggressor and the amount of training or intelligence support the aggressor would need to be aware of the asset. Use Table 3-15 to evaluate this factor for all assets. Select the likelihood rating factor from the column that corresponds to the applicable aggressor. Different ratings factors apply to different aggressors to reflect their assumed intelligence capabilities.

Table 3-15. Recognizability

Recognizability	Likelihood Rating Factor		
	Unsophisticated Criminals Sophisticated Criminals Vandals	Organized Criminal Groups Extremist Protest Groups Domestic Terrorists	International Terrorists State Sponsored Terrorists Saboteurs Foreign Intelligence Services
The asset's existence can be recognized only by aggressors who are experts or who have expert intelligence support	3	6	9
The asset's existence can be recognized only by aggressors with a significant amount of training or intelligence support	6	9	12
The asset's existence can be recognized only by aggressors with a moderate amount of training or intelligence support	9	12	15
The asset's existence can be recognized only by aggressors with a minor amount of training or intelligence support	12	15	15
The asset's existence is obvious to the aggressor. It can be recognized by aggressors with little or no training or intelligence support	15	15	15

3-6.2.7 **Relative Value to Aggressor.** This factor assesses how likely aggressors are to attempt to target assets based on the value of those assets to those aggressors. Relative value is addressed differently for different aggressors and asset categories. Relative value is measured on the basis of an asset's value to the aggressors in achieving future or mission goals, the resultant publicity associated with destroying an asset, or the monetary value of an asset. Use Table 3-16 in evaluating this factor subject to the guidance below and the notes in the table. Enter the assumed goal of the aggressor into the appropriate space in the Asset Value/Aggressor Likelihood Worksheet for each aggressor using the abbreviations below. The aggressor goals will be used to select among options in Table 3-16. Default aggressor goals are tabulated in Table 3-9. They can be evaluated by the Planning Team for applicability.

- **G** where targeting the asset meets a specific mission related goal of an aggressor or where it can be used in future attacks
- **P** where the goal of targeting the asset would be to gain publicity
- **M** where the goal for targeting the asset would be related to its monetary value such as to sell it

3-6.2.7.1 **Value to Mission or Future Goals.** Use this portion of Table 3-16 to assess the value for assets where targeting them would satisfy a particular mission goal of the aggressor. This principally applies to saboteurs and foreign intelligence services because their primary interest in assets is likely to be associated with their mission to compromise them. This also applies to terrorists and extremist protest groups who might steal arms, ammunition, and explosives for the purposes of using them in a future attack. For organized criminal groups, use this portion of the table only where it is likely that they will target assets or officials for the purpose of deterring law enforcement officials from targeting them or for some similar purpose.

3-6.2.7.2 **Publicity Value.** Use this portion of Table 3-16 where the value of assets to users is likely to be based on the amount of publicity the aggressors could expect if they targeted the asset.

3-6.2.7.3 **Relative Value Based on Asset Cost.** Use these portions of Table 3-16 to assess value for assets for which a monetary cost can be identified and is the best measure of asset value to potential aggressors. The cost ranges in this table are the same as those previously used to assess asset value to the user, except for assets whose values to their users were not based on their costs (vehicles, POL, AA&E, and controlled cryptographic items.) For those assets, for the purposes of this table, estimate their monetary value. Use the upper portion where only one or a small number of assets are being considered and use the lower portion where asset inventories are more applicable in describing the asset quantities, as in assets stored in bulk. Note also that the points associated with cost ranges vary by aggressor. That reflects the assumption that sophisticated aggressors will not target low value assets and that unsophisticated criminals do not have the capability to effectively dispose of high value assets.

Table 3-16. Relative Value to Aggressors

Asset Category	Aggressor	Aggressor Goal[1]	Relative Value	Likelihood Rating Factor	
A B C D E F[2] O P Q R	Saboteurs and Foreign Intelligence Agents, or Organized Criminal Groups[3]	Target asset for value to mission or support to future goals	Compromising assets would have negligible utility to accomplishment of aggressor's mission or future goals.	0	
			Compromising assets would have minor utility to accomplishment of aggressor's mission or future goals.	3	
			Compromising assets would have moderate utility to accomplishment of aggressor's mission or future goals.	6	
			Compromising assets would have significant utility to accomplishment of aggressor's mission or future goals.	8	
			Compromising assets would have major utility to accomplishment of aggressor's mission or future goals.	12	
			Compromising assets would likely be critical to accomplishment of aggressor's mission or success of future goals.	15	
A B C D E F[2] O P R	Terrorist / Extremist Protest Group, Vandals	Target asset for Publicity value	Aggressor is likely to believe asset's compromise would result in insignificant publicity	0	
			Aggressor is likely to believe asset's compromise would result in publicity limited to local media	3	
			Aggressor is likely to believe asset's compromise would result in publicity that would likely extend to national media	9	
			Aggressor is likely to believe asset's compromise would result in publicity that would likely extend to international media	15	

Table 3-16 (continued)

Asset Category	Aggressors ⇨	Aggressor Goal[1]	Relative Value	Likelihood Rating Factors: Unsophisticated Criminals	Sophisticated criminals	Organized criminal groups	Others[5]
B C D E F[2] G H I J K L M N P	Individual assets[4]	Target asset for Monetary value	Asset value is less than $2500	9	3	0	3
			Asset value is greater than or equal to $2500 and less than $10,000	12	6	3	6
			Asset value is greater than or equal to $10,000 and less than $25,000	15	9	6	9
			Asset value is greater than or equal to $25,000 and less than $50,000	15	12	9	12
			Asset value is greater than or equal to $50,000 and less than $100,000	12	15	12	15
			Asset value is greater than $100,000	9	15	15	15
B E F[2] G H I J K L M N P	Asset inventories[4]	Target asset for Monetary value	Asset inventory value is less than $100,000	9	3	0	3
			Asset inventory value is greater than or equal to $100,000 and less than $250,000	12	6	3	6
			Asset inventory value is greater than or equal to $250,000 and less than $500,000	15	9	6	9
			Asset inventory value is greater than or equal to $500,000 and less than $1,000,000	15	12	9	12
			Asset inventory value is greater than or equal to $1,000,000 and less than $2,000,000	12	15	12	15
			Asset inventory value is greater than $2,000,000	9	15	15	15

Notes:

1. Select applicable measure of asset value to aggressors (defaults at Table 3-9).
2. For arms, ammunition, and explosives (AA&E) subject to action by terrorists or extremist protest groups, select the upper factor if the goal is to steal the AA&E for use in future attacks, select the second if the goal is to destroy it, and among the lower two if the goal is to steal and sell it.
3. Only use this factor for organized criminal groups where it is likely they would kill people to further their goals. See paragraph 3-6.2.7.1.
4. Select between factors based on whether analyzing individual assets or inventory of assets.
5. Use only where non-criminal aggressors are likely to steal assets to sell them.

3-6.2.8 **Law Enforcement Personnel Visibility.** This factor should be addressed in conjunction with installation law enforcement personnel. It addresses the visibility of law enforcement personnel or guards at an installation perimeter or in the vicinity of a facility and reflects the assumption that a strong law enforcement or guard presence can limit the likelihood that an aggressor will attempt to compromise assets there. It can be evaluated with respect to DoD or military police, contract or unit guards, and local or host nation law enforcement personnel as applicable. Use Table 3-17 in evaluating it. Enter the matrix on the left with the frequency of law enforcement or guard presence at the installation perimeter and enter it at the top with frequency of presence in the immediate vicinity of the facility housing the asset. Read the value rating factor at the intersection of the two frequencies. Note that the range of likelihood rating factors is higher for this factor because of its added significance to likelihood.

Table 3-17. Law Enforcement Personnel Visibility

		Frequency of Presence in Vicinity of Facility			
		Infrequent	Occasional	Frequent	Continuous
Frequency at Installation Perimeter	Occasional	30	24	18	12
	Scheduled	24	18	12	6
	Continuous	18	12	6	0

3-6.2.9 **Aggressors' Perception of Success.** This factor assesses aggressors' likely perception of the possibility that they will successfully compromise an asset and escape (where escape is a goal). It should be evaluated considering visible countermeasures that exist, are planned, or are otherwise likely to be present, in the context of how they would likely deter aggressors or otherwise affect their perception of their chances for success. At this point, countermeasures should only be considered in a very general sense. Specific countermeasures and their contribution to mitigation of vulnerabilities will be assessed in more detail in the design phase of this process using UFC 4-020-02. Use Table 3-18 to evaluate aggressor perceptions as described below. Note that more sophisticated aggressors are likely to be less easily deterred than less sophisticated ones. Where the differences in meaning between entries in the table are difficult to determine, think of them in terms of "on a scale of 6 to 30" with respect to the likely affect on aggressor perception.

3-6.2.9.1 **Exterior Assets.** This assesses deterrence due to visible countermeasures common to security of assets stored in exterior areas assuming the aggressor will try to gain access to the assets. Consider measures such as fences, lighting, intrusion detection systems (IDS), and closed circuit television (CCTV).

3-6.2.9.2 **Interior Assets.** This assesses the deterrence from visible security measures applied to assets stored inside structures assuming the aggressor will try to gain access to the assets. Consider the effect of building construction (walls, roofs, windows, and doors) and how it may provide resistance to forced entry. For example, reinforced concrete or masonry construction, heavy doors, and window barriers are commonly more resistant than lighter weight construction. Also consider perimeter security such as fences or walls, interior locations of assets, and measures such as IDS and CCTV.

3-6.2.9.3 **Interior Assets Subject to Destruction.** This is assessed for assets that are stored inside structures and are subject to being damaged or, in the case of people, killed. Consider how the building construction might be or might appear to be resistant to weapons and explosives effects. Again, reinforced concrete or masonry construction is generally more resistant than lightweight construction.

Table 3-18. Aggressors' Perception of Success

Aggressor's Likely Perception of Possibility of Success Based on Likely Presence of Visible Countermeasures	Likelihood Rating Factor
Based on the visible countermeasures that are likely to be present or are present at the facility where the asset is or will be located, aggressor would likely perceive a very low possibility of successfully compromising or destroying the asset and escaping.	6
Based on the visible countermeasures that are likely to be present or are present at the facility where the asset is or will be located, aggressor would likely perceive a low possibility of successfully compromising or destroying the asset and escaping.	12
Based on the visible countermeasures that are likely to be present or are present at the facility where the asset is or will be located, aggressor would likely perceive a moderate possibility of successfully compromising or destroying the asset and escaping.	18
Based on the visible countermeasures that are likely to be present or are present at the facility where the asset is or will be located, aggressor would likely perceive a high possibility of successfully compromising or destroying the asset and escaping.	24
Based on the visible countermeasures that are likely to be present or are present at the facility where the asset is or will be located, aggressor would likely perceive a very high possibility of successfully compromising or destroying the asset and escaping.	30

3-6.2.10 **Threat Level.** This factor addresses the general level of threat activity for a country, region, or locale. It will be evaluated differently for terrorists than for all other aggressors. In the case of terrorists, use the applicable DoD or Combatant Command terrorist threat level established for the locality or region. Those levels will be low, moderate, significant, or high as established in DoD O-2000.12-H. Established terrorist threat level methodologies commonly include considerations of the presence of a threat, operational capability, intentions, activity, and the operating environment. Those are the basis for the DoD and Combatant Command threat level determinations.

Terrorist threat levels can commonly be obtained from intelligence sources or from antiterrorism officers, who should be part of the Planning Team. Criminal, protester, foreign intelligence, and saboteur threat levels can be assigned similar descriptors to reflect the activity of those aggressors in an area. While the same considerations can be taken into account for threat levels for aggressors other than terrorists, the programs for doing so are far less formal than for terrorists. The information for those assessments may be established locally or by regional or national level entities. It should be available to local intelligence or law enforcement personnel, who should be part of the Planning Team.

Use Table 3-19 to assess likelihood ratings for this factor. Note that the range for aggressors other than terrorists is higher than for terrorists. The reason for that is that for terrorists the specific threat methodology factors of intention, operational capability, operational environment, and activity are addressed separately on a local basis, while they are all effectively incorporated into one factor for the other aggressors. By using different ranges for the factors, the overall weighting for the similar "groups" of factors is maintained at 1/3 of the total.

Table 3-19. Threat Level

Terrorist, Criminal, Vandal, Protestor, Foreign Intelligence, or Saboteur Threat Level	Likelihood Rating Factor	
	Terrorists	All Other Aggressors
Low	5	6
Moderate	10	14
Significant	15	22
High	20	30

3-6.2.11 **History / Intentions.** These are actually two closely related factors. History applies to all aggressors except for terrorists. It addresses the fact that previous attempts to compromise assets are potentially good indicators of future attempts to do so. It also reflects the fact that such attempts locally or regionally are better indicators than attempts elsewhere in the world and that more recent attempts are also potentially better indicators. Evaluate this factor in the contexts of each applicable aggressor's history.

Use intentions as a consideration in evaluating the local terrorist threat. Intentions reflect the stated and/or actual history of particular terrorist groups attacking U.S. Interests. For more information on intentions, refer to DoD 0-2000.12-H.

Use Table 3-20 to evaluate both history and intentions. The ranges of the factors for terrorists and for other aggressors are the same as for the threat level factor described above.

Table 3-20. History of Acts Against Like Assets / Terrorist Intention

Aggressor / Factor	History or Intention	Likelihood Rating Factor
Aggressor: All except terrorists Factor: History	There is no history of attacking or otherwise compromising assets of this type.	6
	There is little or no history of attacking or otherwise compromising assets of this type.	12
	There is history of attacking or otherwise compromising assets of this type, but not locally or regionally.	18
	There is local or regional history of attacking or otherwise compromising assets of this type in the past 10 years.	24
	There is a strong history of attacking or otherwise compromising assets of this type locally and regionally in the past 3 years.	30
Aggressor: Terrorists Factor: Intentions	No history of attacks	2
	Anti-U.S. ideology, but no direct attacks	4
	Anti-U.S. ideology, with a history of attacks outside region	6
	Recent attacks against U.S. interests regionally	8
	Recent attacks against U.S. interests locally	10

3-6.2.12 **Operational Capability.** This factor should be used to assess the local terrorist threat. It should not be applied for any other aggressors. Operational capability is the acquired, assessed, or demonstrated level of operational capability to conduct terrorist attacks. For more information on this factor, refer to DoD 0-2000.12-H. Use Table 3-21 to evaluate this factor.

Table 3-21. Terrorist Operational Capability

Capability to Conduct Terrorist Attack	Likelihood Rating Factor
Insignificantly capable	2
Minimally capable	4
Capable	6
Very capable	8
Extremely capable	10

3-6-2.13 **Operating Environment.** This factor considers how the overall environment, to include political and security considerations, influences a terrorist group's ability and motivation to conduct an attack. It should not be applied for any other aggressors. For more information on this factor, refer to DoD 0-2000.12-H. Use Table 3-22 to evaluate this factor.

Table 3-22. Terrorist Operating Environment

Environment for Terrorists Operating	Likelihood Rating Factor
Favors U.S. or host nation	2
Neutral	6
Favors terrorist	10

3-6.2.14 **Activity.** This factor considers the fact that a terrorist group's activity in a country may not always be related to operational planning or present a threat to U.S. / Host Nation interests. Many groups use countries as support bases and may not want to jeopardize their status by conducting terrorist acts there. For more information on this factor, refer to DoD 0-2000.12-H. Use Table 3-23 to evaluate this factor.

Table 3-23. Terrorist Activity

Terrorist Activities in the Applicable Country or Region	Likelihood Rating Factor
Present but inactive	2
Recruiting, fund-raising or non-directed activity	4
Suspected surveillance, threats, and suspicious incidents	6
Identified cell activity (operational or support)	8
Credible indications of targeting U.S. assets	10

3-6.3 **Determine Likelihood Ratings.** Likelihood ratings are determined based on the sums of the 11 or 14 applicable likelihood rating factors, depending on whether the applicable aggressor is a terrorist or any of the other aggressor categories. Sum the likelihood rating factors for each asset and enter their sums in the appropriate boxes on the Asset Value/Aggressor Likelihood Worksheet. Then divide the sums by the total number of points possible (180). The resulting percentages are the aggressor likelihood ratings. Enter them in the appropriate boxes on the Asset Value/Aggressor Likelihood Worksheet as well as on the Tactic, Threat Severity, and Level of Protection Worksheet and the Risk Level Calculation Worksheets.

3-6.4 **Aggressors with "Very Low" Likelihood Ratings.** Aggressors who have likelihood ratings of less than or equal to 0.5 need not be considered for further evaluation. Because of their very low assessed likelihood it is unlikely that they will be a threat to the assets under consideration and the risk of ignoring them should be acceptable. Any aggressors who have a likelihood rating of higher than 0.5 should be further evaluated in the next step. Enter the likelihood ratings for those aggressors on the Tactic, Threat Severity, and Level of Protection Worksheet in the applicable locations, using one worksheet for each asset. If all aggressors have received likelihood ratings of 0.5 or less, there will be no threat postulated for the asset and only minimum measures required by regulation and measures required by minimum construction standards (DoD or Combatant Command) should be applied.

3-7 **STEP 5. IDENTIFY TACTICS AND THREAT SEVERITY LEVELS.** The tactics aggressors are likely to use in attempting to compromise assets can be selected on a default basis considering the likely objectives of the aggressors toward the assets and the asset categories. The threat severity levels will indicate the initial tools, weapons, explosives, or agents that will be associated with those tactics for the purposes of the planning level risk analysis. These form the basis for a preliminary protective system for an asset that can be used to develop a planning level cost estimate. These threat severity levels may be adjusted based on the risk analysis results with the adjusted levels becoming part of the design criteria for the project. Selecting the likely tactics is a two-step process. The first step is to identify the tactics based only on the assets and the second is to consider the aggressors. Selecting the initial threat severity levels is a third step.

3-7.1 **Select Applicable Tactics Based on Assets.** Use Table 3-24 to determine which of the 13 tactics defined in Chapter 2 may apply against the identified assets based on the asset categories. These are default tactics based only on the asset category and do not include considerations of which aggressors are likely to carry out those tactics or if the specific goals of aggressors toward an asset would lead them to use that tactic against it. Those considerations will be addressed in the next step. Table 3-24 includes all the tactics that any aggressor might use against the asset.

3-7.2 **Select Applicable Tactics Based on Aggressors.** The previous step excluded aggressor considerations. In this step those considerations are taken into account. Use Table 3-25 to do the final selection of applicable tactics. That table reflects considerations relating to tactics specific aggressors may use based on their likely goals toward the asset. Select tactics for each applicable aggressor for which there are entries under a tactic. As an illustration of the additional filtering associated with this step, Table 3-25 indicates that hand delivered devices may be used against arms, ammunition, and explosives. In evaluating criminals with respect to that asset, Table 3-25 would not attribute that tactic to the criminals, who are limited to theft-oriented tactics. Enter "X's" or check marks in the appropriate locations for the applicable tactics on the Tactic, Threat Severity, and Level of Protection Worksheet as illustrated in Figure 3-5. These are the initial default tactics. If in the judgment of the Planning Team any of the default tactics do not apply, do not enter them on the worksheet. Similarly, if the Planning Team thinks tactics that were not included in the default tactics should be included, add them.

3-7.3 **Identify Threat Severity Levels.** A range of tools, weapons, explosives, or agents may apply to each tactic. A tactic's threat severity level defines which tools, weapons, explosives, or agents within that range apply for a given threat. Threat severity levels may be designated as very low, low, medium, high, or very high. Different tactics may have different numbers of possible threat severity levels. In some cases, a tactic only has one possible threat severity level. In those cases, the severity level is indicated by a "yes." In addition, some of those levels are not postulated to apply to all aggressors. The threat severity levels are selected based upon the likelihood ratings for the applicable aggressors. Selecting threat severity levels considering likelihood of aggression is based on the principles of risk acceptance. If the likelihood of aggression for an aggressor is low, the protective system can be designed for a threat severity level lower than the maximum threat severity level for that aggressor. That is based on the user assuming that the aggressors will expend less effort

Figure 3-5. Sample Tactic, Threat Severity, and Level of Protection Worksheet

Foreign Intelligence Services						L	H VH	H	H	H			

and fewer resources on assets that are less attractive to them. The Planning Team accepts the risk that this assumption is correct and that the aggressor does not attack at a higher threat severity level. If the Planning Team does not wish to accept the risk inherent in that assumption, they may choose to specify higher threat severity levels.

3-7.3.1 **Select Applicable Threat Severity Levels.** Table 3-25 indicates multiple threat severity levels for some aggressors for some tactics. Table 3-26 is used to determine which applies based on the aggressor likelihood ratings. To use Table 3-26, note how many possible threat severity levels apply for a specific aggressor in Table 3-25. Enter Table 3-26 on the left side with the number of possible threat severity levels (1, 2, 3, or 4,) and enter along the top of the table with the likelihood rating for the applicable aggressor. At the intersection of the two, read the number of the threat severity level that should be applied. Where only a "yes" is indicated in the table, there is only one threat severity level for that tactic, and any likelihood rating greater than 0.5 will mean that tactic and its single threat severity level apply. Enter the applicable threat severity level associated with the selection in the appropriate location on the Tactic, Threat Severity, and Level of Protection Worksheet as illustrated in Figure 3-5. Note that in Table 3-26 "minimum" is entered for likelihood ratings of less than or equal to 0.5. That indicates that minimum measures required by regulations or DoD or Combatant Command construction standards apply as described previously.

3-7.3.2 **Example.** As an example, assume the likelihood rating for international terrorists is 0.92. For the indirect weapons attack Table 3-25 indicates three possible choices for international terrorists, "low", "medium", and "high". Entering Table 3-26 with 3 choices and a likelihood rating of 0.92 indicates that the "3rd" choice should be used. Therefore, the applicable threat severity level for that aggressor is "high."

Table 3-26. Threat Severity Selection

Number of Threat Severity Level Choices *	Likelihood Rating				
	≤ 0.5	0.51 – 0.74	0.75 – 0.89	0.90 – 0.94	0.95 – 1
4	Minimum	1st	2nd	3rd	4th
3	Minimum	1st	2nd	3rd	3rd
2	Minimum	1st	1st	2nd	2nd
1	Minimum	1st	1st	1st	1st
* See Table 3-25					

3-8 **STEP 6: CONSOLIDATE INTO INITIAL DESIGN BASIS THREAT.** The initial design basis threat is the threat upon which the preliminary protective system will be based. It represents the worst-cases of the applicable threat severity levels for each applicable tactic for a given asset. The initial design basis threat may be changed during the design process based on detailed risk analysis as described in UFC 4-020-02. It will also be used to assess vulnerabilities in the case of existing facilities.

3-8.1 **Initial Design Basis Threat.** Determine the initial design basis threat by identifying the highest applicable threat severity level for each tactic across all aggressor types as entered on the Tactic Threat Severity, and Level of Protection Worksheet. Enter the initial design basis threat severity level for each tactic in the spaces provided at the bottom of the Tactic Threat Severity, and Level of Protection Worksheet. Refer to Table 3-27 to determine the design parameters (tools, weapons, explosives, and agents) associated with each of the threat severity levels for each tactic. In tactics with multiple threat severity levels, each threat severity level also includes the tools, weapons, explosives, and agents from lower threat severity levels. The threat severity levels will also be entered onto the Building Cost and Risk Evaluation Worksheet if that worksheet is used.

3-8.2 **Modifying the Initial Design Basis Threat.** The threat severity levels indicated are for generic aggressors in unspecified locations. If intelligence, experience, or the judgment of the Planning Team indicates that a different threat severity level applies based on known aggressor characteristics or site or asset specific considerations, those threat severity levels may be modified. In addition, if such considerations indicate that a specified tactic is inapplicable to threats against the asset under consideration, that tactic may be deleted from the threat. Also, if a Combatant Command standard indicates a specific threat, ensure that the initial design basis threat severity level is at least that which has design parameters equivalent to the threat associated with the Combatant Command threat. Ensure that the reasons for any change in the default threat severity levels are recorded for future reference.

Table 3-27 Threat Parameters

Aggressor Tactic	Design Basis Threat	Weapons	Tools Or Delivery Method
Moving and Stationary Vehicle Devices	Special Case [1]	9000 kg (19,800 lbs) TNT	18,000 kg / ~ 40,000 lbs truck
	Very High	2000 kg (4400 lbs) TNT, Fuel	7000 kg / ~ 15,000 lbs truck
	High	500 kg (100 lbs) TNT, Fuel	2500 kg / ~ 5500 lbs truck
	Medium	250 kg (550 lbs) TNT, Fuel	1800 kg / ~ 4000 lbs car
	Low	100 kg (220 lbs) TNT	1800 kg /~ 4000 lbs car
	Very Low	25 kg (55 lbs) TNT	1800 kg / ~ 4000 lbs car
Hand Delivered Devices	High	IID, IED (up to 25 kg/55 lbs TNT) &hand grenades (Mail bomb limited to 1 kg/2.2 lbs TNT)	None
	Medium	IID, IED (up to 1 kg/2.2 lbs TNT) & hand grenades	
	Low	IID	
Indirect Fire Weapons Attack	Very High	Improvised mortar (up to 20 kg/44 lbs TNT)	None
	High	122 mm rocket	
	Medium	82 mm mortar	
	Low	Incendiary devices	
Direct Fire Weapons Attack	Very High	Light antitank weapons, and UL 752 Level 10 (12.7 mm (0.50 caliber), 1 shot)	None
	High	UL 752 Level 9 (7.62mm NATO AP, 1 shot)	
	Medium	UL 752 Level 5 (7.62mm NATO ball)	
	Low	UL 752 Level 3 (.44 magnum)	
Forced Entry	Very High	Handguns and sub-machine guns (up to UL 752 Level 3 to overpower guards)	Bulk explosives (up to 25 kg / 55 lbs TNT), linear shaped charges (up to 10,500grains per foot), unlimited hand, power, thermal tools
	High		Unlimited hand, power, and thermal tools
	Medium	None	Unlimited hand tools - limited battery powered tools
	Low		Limited hand tools - low observables
Covert Entry	Very High	Handgun	Electronic Neutralization Equipment Drill & Specialized Tools Robotic Dialer Manipulation Enhancer
	High	Handgun	Mechanical & Electronic Lock Decoder Drill, simple tools & camouflage Specialized bypass tools
	Medium	None	Lock Picks Bypass techniques High Quality False Credentials Observation tools
	Low	None	Easily Duplicated False Credentials

(Table 3-27 continued)

Visual Surveillance	High	None	Ocular devices
Acoustic Eavesdropping	High		Sound amplification or laser "listening" devices
Electronic Emanations Eavesdropping	High		Electronic emanations interception equipment
Airborne Contamination	High	Internal and external release of all agents listed below	Limited hand tools +1 kg/2.2 lbs explosive (dirty bomb)
	Medium	Agents associated with Low plus external release of toxic military chemical agents	Limited hand tools
	Low	Agents associated with Very Low plus external release of biological and radiological particulates	
	Very Low	External and internal release of Toxic Industrial Chemicals or Toxic Industrial Materials (TIC and TIM)	
Waterborne Contamination	High	Liquid or particulate agent stable in water greater than 30 days and not easily mitigated by chlorine	Limited hand tools
	Medium	Liquid or particulate agent stable in water between 2 hours and 30 days and not easily mitigated by chlorine	
	Low	Liquid or particulate agent stable in water less than 2 hours or easily mitigated by chlorine	
Waterfront Attack Surface and/or Submerged Attack	High	500 kg (1100 lbs) TNT (surface or submerged) Anti-Tank Weapons UL 752 Level 10 (12.7 x 99 mm (0.50 caliber))	Powerboat Multiple small craft Swimmer delivery vehicle Torpedo
	Medium	250 kg (550 lbs) TNT (surface) 25 kg (55 lbs) TNT (submerged) UL 752 Level 10 (12.7 x 99 mm (0.50 caliber))	Combat Rubber Raiding Craft Rigid Hulled Inflatable Boat Torpedo Swimmer / diver
	Low	100 kg (220 lbs) TNT (surface) 25 kg (55 lbs) TNT (submerged) UL 752 Level - 5	Jet Ski Swimmer / diver
1. Note that the process in this UFC does not lead to the Special Case. Applicability is known by those to whom it applies.			

3-9 **STEP 7: DETERMINE INITIAL LEVEL OF PROTECTION.** Levels of protection reflect the degree to which an asset is protected against the threat based on its value to its user. A level of protection of “very high” corresponds to a low possibility that an asset will be compromised if attacked. For some tactics, level of protection refers to the amount of damage a facility or asset would be allowed to sustain in the event of an attack. A low amount of allowed damage equates to a high level of protection. For other tactics, level of protection refers to the probability that an aggressor will be defeated before the asset is compromised. A high probability of defeat equates to a high level of protection. There are one or more levels of protection (“very high”, ”high”, ”medium”, “low”, or “very low”) for each of the 12 tactics, as shown in Table 3-28. The levels of protection are described for each tactic in Chapter 4. Levels of protection apply to all threat severity levels for each tactic. The initial level of protection may be changed during the design process based on detailed risk analysis as described in UFC 4-020-02.

3-9.1 **Initial Level of Protection.** For each asset, determine the initial level of protection for each applicable tactic with a design basis threat entry. Use Table 3-28 and the asset's value rating listed to select appropriate levels of protection. Enter the initial levels of protection in the appropriate spaces on the Tactic, Threat Severity, and Level of Protection Worksheet. Also enter them into the appropriate spaces on the Risk Level Calculation Worksheet and the Building Cost and Risk Evaluation Worksheet.

3-9.2 **Example.** For example, for the indirect fire weapons tactic for an asset with a value rating of 0.81, select the medium level of protection. Enter the level of protection for each applicable tactic on the Tactic, Threat Severity, and Level of Protection Summary Worksheet in the appropriate cell associated with each applicable tactic as illustrated in Figure 3-3. Also enter the levels of protection on the Risk Level Calculation Worksheet as illustrated in Figure 3-6 and on the Building Cost and Risk Evaluation Worksheet as illustrated in Figure 3-7.

3-9.3 **Modifying the Initial Level of Protection.** The level of protection determined using Table 3-28 is a default level. If the Planning Team determines that the level of protection selected for a tactic is too high or too low, they may modify it. However, lowering the level of protection may result in the asset being protected less than its value warrants with a higher risk of asset compromise. Conversely, raising the level of protection may result in greater protection than the asset value warrants, resulting in a greater cost for the protective system. The best basis for considering changes in levels of protection is to evaluate them based on cost and risk levels. That process is described in the next step of this process. Ensure that the reasons for any change in the default levels of protection are recorded for future reference.

3-10 **STEP 8: DETERMINE PLANNING RISK LEVELS.** Risk levels are used as a basis for comparing alternatives among levels of protection or countermeasures. Risk levels are based on asset values, aggressor likelihoods, and protection factors that reflect levels of protection provided to the assets. The risk analysis process in this UFC is for developing design criteria. A more detailed treatment of risk that considers the contribution of specific countermeasures is in UFC 4-020-02. Follow the steps below to determine risk levels. Risk levels will be determined from groups of tactics as described below and indicated on the Risk Level Calculation Worksheet illustrated in Figure 3-6. Note that risk in this UFC is a relative risk level that is intended to be used as an aid in decision making. Specific risk levels should not be used as goals or targets.

3-10.1 **Determine Threat Effectiveness Ratings.** The capabilities of aggressors to find weaknesses in security measures and to exploit them have a significant impact on risk, and it varies widely for different aggressors. Some of the questions used in determining aggressor likelihood ratings included considerations that were specific to aggressor types, but those considerations did not reflect how effective countermeasures were likely to be against the aggressors. They dealt with the likelihood that those aggressors would target an asset. Applying an effectiveness factor to adjust protection effectiveness accounts for how the sophistication, motivation, and risk acceptance of the aggressors affects the risk levels for the assets those aggressors

Table 3-28. Applicable Levels of Protection

Tactic	Threat Severity Level	Asset Value ≤ 0.5	Asset Value 0.51 – 0.74	Asset Value 0.75 – 0.85	Asset Value 0.86 – 0.95	Asset Value 0.96 - 1
Moving Vehicle Bomb	All	Very Low[1]	Low[2]	Medium	High	
Stationary Vehicle Bomb		Very Low[1]	Low[2]	Medium	High	
Hand Delivered Devices		Very Low[1]	Low[2]	Medium	High	
Indirect Fire Weapons		Very Low[1]	Low	Medium	High	
Direct Fire Weapons	VH	Very Low[1]	Low	Medium[3]	High	
	L, M, H	Very Low[1]	Low		High	
Forced Entry	All	Very Low[1]	Low	Medium	High	Very High
Covert Entry			Low	Medium	High	Very High
Visual Surveillance			High			
Acoustic Eavesdropping			Low	Medium	High	Very High
Electronic Emanations Eavesdropping			High			
Airborne Contaminants		Very Low[1]	Low	Medium	High	
Waterborne Contaminants		Very Low[1]	Low	Medium	High	
Waterfront Attack		Very Low[1]	Low	Medium [3]	High	Very High

1. The very low level of protection includes only measures required by UFC 4-010-01 minimum standards or other applicable standards, operations orders, or regulations.
2. The low level of protection is the minimum for those tactics that are addressed in UFC 4-010-01 for primary gathering buildings. Note also that while the moving vehicle bomb tactic is not expressly addressed in UFC 4-010-01, if it applies it should also be given the same minimum level of protection as the stationary vehicle bomb tactic for primary gathering buildings.
3. The medium level of protection commonly does not apply to ballistics below 12.7 mm (.50 caliber), which are the weapons in the low through high threat severity levels. For those threat severity levels, apply the low level of protection for this range of asset value ratings.

might target. Establishing threat effectiveness ratings is a complex task that requires significant intelligence resources. To expedite this procedure, the threat effectiveness ratings have been established as defaults for specific aggressor types.

3-10.1.1 **Select Threat Effectiveness Ratings.** Use Table 3-29 to determine the appropriate threat effectiveness ratings for the applicable aggressors. Enter the effectiveness ratings in the appropriate spaces in the Risk Level Calculation Worksheet as illustrated in Figure 3-6. The threat effectiveness ratings will be used in the risk equation to adjust the previously determined protection factors to reflect that a protective system that is highly effective against an unsophisticated aggressor may not be as effective against a highly sophisticated one.

Table 3-29. Threat Effectiveness Ratings

Aggressor Type	Effectiveness Rating (T_E)
Unsophisticated criminals	1.0
Sophisticated criminals	0.98
Organized criminal groups	0.95
Vandals	1.0
Extremist protest groups	0.96
Domestic terrorists	0.95
International terrorists	0.93
State sponsored terrorists	0.90
Saboteurs	0.90
Foreign intelligence services	0.91

3-10.1.2 **Select Applicable Effectiveness Ratings for Aggressor Categories.** The threat effectiveness ratings will be used to adjust protection factors that are associated with each applicable tactic. For the purposes of the risk analysis the aggressors will be grouped into criminals, terrorists, saboteurs, and foreign intelligence services as indicated on the Risk Level Calculation Worksheet. Identify the threat effectiveness ratings associated with the aggressors with the highest likelihood rating for each of the applicable aggressor categories and enter them into the appropriate spaces on the Risk Level Calculation Worksheet. This entry is designated as T_{EH}.

3-10.2 **Select Initial Protection Factors.** Select the appropriate protection factor for each tactic based on the applicable level of protection using Table 3-30. These factors do not include any consideration of aggressor effectiveness. They only reflect the initial level of protection. These factors also do not reflect individual countermeasures. Instead, they are predicated on applying all of the countermeasures necessary to achieve a particular level of protection as tabulated in UFC 4-020-02. This assumption is appropriate for planning purposes. Consideration of individual countermeasures is left to the design process. Enter these factors in the appropriate spaces on the Risk Level Calculation Worksheet.

Table 3-30. Initial Protection Factors

Level of Protection	Protection Factor (P_I)
Very Low	0.1
Low	0.3
Medium	0.7
High	0.9
Very High	0.95

Figure 3-6. Sample Risk Level Calculation Worksheet

	Electronic Emanations Eavesdropping											
Contamination Tactics	Airborne Contamination											
	Waterborne Contamination											
Waterfront Attack												

1. From Tactic, Threat Severity, and LOP Worksheet.
2. Highest likelihood rating for each aggressor group.
3. Effectiveness rating for aggressor with highest likelihood.
4. From Table 3-30.
5. Average for P_I for all tactics within tactic group.
6. $P_E = T_{EH} \times P_{IAVG}$ for each aggressor & tactic group combination.
7. $R = A_V \times T_{LH} \times (1-P_E)$ for each aggressor & tactic group.

3-10.3 **Calculate Average Initial Protection Factors.** Risk levels are calculated for tactic groups instead of individual tactics to minimize the number of risk levels to be evaluated. An initial protection factor must, therefore, be determined for each tactic group. Use the average of the initial protection factors for each tactic group. Enter the average for each group into the applicable space on the Risk Level Calculation Worksheet. This entry is designated as P_{IAVG}.

3-10.4 **Adjust Initial Protection Factors.** Adjust the average initial protection factors to reflect threat effectiveness ratings. Determine effective protection factors for each applicable tactic. Enter the applicable threat effectiveness ratings (T_{EH}) for each of the applicable aggressor categories associated with the applicable average initial protection factors (P_{IAVG}) into Equation 3-1. The applicable aggressor categories for each tactic are those to whom those tactics apply as identified on the Tactic and Threat Severity Level Worksheet. For example, if the indirect fire weapons tactic was determined to be part of the initial design basis threat based on consideration of terrorists, use the applicable threat effectiveness rating for terrorists to determine the effective protection factor for that tactic using Equation 3-1. Where multiple aggressor categories are applicable to a given tactic, calculate a separate effective protection factor for each aggressor group. Enter the effective protection factors (P_E) in the appropriate spaces in the Risk Level Calculation Worksheet.

Equation 3-1. $$\mathbf{P_E = T_{EH} \times P_{IAVG}}$$

3-10.5 **Determine Risk Level.** Calculate risk levels for each asset and for each applicable tactic group and aggressor group as indicated on the Risk Level Calculation Worksheet. Risk levels are established by entering the likelihood and asset value ratings and the protection effectiveness factors into Equation 3-2. By subtracting P_E from 1, the risk equation reflects the fact that increases in protection effectiveness reduce risk. The 1- P_E term reflects "vulnerability".

Equation 3-2. $$\mathbf{R = A_V \times T_{LH} \times (1-P_E)}$$

3-10.5.1 **Asset Value Ratings.** Enter the asset value ratings (A_V) for each asset into the risk equation for each applicable tactic group.

3-10.5.2 **Likelihood Ratings.** Enter the highest likelihood ratings (T_{LH}) for each applicable aggressor group associated with each applicable tactic group as identified on the Tactic and Threat Severity Worksheet. Use the likelihood rating for the aggressor group that includes the aggressors who were used to establish the applicability and threat severity levels for that tactic group. For example, terrorists would commonly be the aggressors upon whom the applicability and threat severity levels for explosives tactics are based. Therefore, to determine the risk level for the explosives tactics, enter the highest likelihood rating for the terrorist aggressor group. Where there are multiple aggressor categories that were used to establish applicability and threat severities for a particular tactic group, calculate a separate risk level for each group.

3-10.5.3 **Protection Effectiveness factors.** Enter the protection effectiveness factor for each applicable tactic group and for each applicable aggressor group.

3-10.5.4 **Risk Level.** Enter the risk levels calculated using Equation 3-2 in the appropriate spaces on the Risk Level Calculation Worksheet.

3-11 **STEP 9: ASSESS ACCEPTABILITY OF RISK LEVELS.** There are no specific criteria for determining whether or not a given risk level is acceptable. In some cases the Planning Team may have a goal for a risk level, although that is not recommended. In other cases the costs for achieving a level of protection associated with a risk may be the basis for a risk being acceptable. Because the risk levels in this UFC are relative, their best use is as an aid in decision making. The risk level means relatively little in itself, but when the reduction in risk can be evaluated with respect to the cost of a protective system, that provides a rough means of evaluating benefit versus cost. The benefit is the reduction in risk. For example, if a large expenditure for countermeasures results in a very small reduction in risk, that may not be a good investment. On the other hand, when a small expenditure for countermeasures results in a large reduction in risk, that may be a good investment. Evaluating risk versus cost in that manner provides a basis for evaluating various alternatives.

3-11.1 **Cost and Risk Evaluation.** The Building Cost and Risk Evaluation Worksheet is provided to assist in evaluating changes in risk levels due to changes in threat severity levels or levels of protection. It has spaces for initial and revised conditions for threat severity levels, levels of protection or protection factors, risk levels, and cost increases. It also has spaces that support analysis of the differences between the initial and revised conditions. Those spaces include change in cost, change in risk, and the ratio of the two. Note that changes to threat severity levels will intuitively impact risk due to changes in the design basis threat, but those impacts are not captured in the risk calculation. Use one worksheet for each asset and for each option evaluated to ensure there is a “paper trail” for each option. Use the Risk Level Calculation Worksheet to evaluate the effects of changes in levels of protection or protection factors on risk levels.

3-11.1.1 **Risk Levels.** Enter risk levels for each tactic group on the Building Cost and Risk Evaluation Worksheet. In cases where there are multiple aggressors to whom tactics within a tactic group apply, use the risk level for the aggressor whose threat severity level is the basis for the design basis threat on the Tactic, Threat Severity, and Level of Protection Worksheet.

For example, in Figure 3-5, the forced and covert entry tactics apply to criminals, terrorists, and saboteurs, but the threat severity level for the terrorists is the basis for the design basis threat. In that case, the risk level for terrorists from the Risk Level Calculation Worksheet would be entered for the entry tactics on the Building Cost and Risk Evaluation Worksheet.

3-11.1.2 **Cost Increases.** To determine the costs of initial protective systems for planning purposes refer to Chapter 6 and Appendices A through C. Note that those costs are based on applying all the applicable countermeasures to achieve a particular level of protection. A more detailed treatment of cost and risk that considers the contribution of individual countermeasures is presented in UFC 4-020-02.

Enter the cost increases for each applicable tactic. In cases such as the hand delivered devices tactic, there are separate entries for different applications of that tactic (building exterior, mail rooms, loading docks, and entry areas). In those cases, enter cost increases for each applicable application.

Sum the costs for all applicable tactics and applications within each tactic group with the following exception. Because the construction to mitigate the effects of the vehicle bomb tactics and exterior application of the hand delivered devices tactic is similar, where more than one of those tactics applies, use the cost of the most expensive to represent all three rather than adding them together. All other tactics and applications should be additive. Note that the construction necessary to provide protection against some tactics is very similar to that for other tactics, which means that summing all the applicable costs as described above may be conservative due to potentially accounting for similar upgrades more than once. For example, walls to resist vehicle bombs may be adequate for resisting indirect fire weapons effects and windows to resist small arms may be effective for blast resistance. Accounting for such redundancy is very complex; therefore, it is beyond the scope of this UFC. It can be dealt with during design.

3-11.2 **Cost and Risk Analysis.** Use the analysis columns of the Building Cost and Risk Evaluation Worksheet to evaluate risk and cost changes. Enter the difference between the cost increases for the initial and revised conditions in the appropriate spaces on the Building Cost and Risk Evaluation Worksheet. Do the same for the changes in risk levels. Finally, enter the ratio of change in risk to change in cost. Note that the entries in the analysis columns are by tactic groups.

3-11.2.1 **Unacceptable Cost and Risk.** If the cost and risk are determined by the Planning Team to be unacceptable, for the purposes of planning, revise the level of protection, rerun the risk level calculation, and re-evaluate the acceptability of the risk. Alternatively, the team may modify threat severity levels for individual tactics and make similar adjustments.

3-11.2,2 **Acceptable Cost and Risk.** If the cost and risk are determined by the Planning Team to be acceptable, incorporate the design criteria developed using this procedure into the planning documents as requirements for the project design. Use the Design Criteria Summary Worksheet to record the design criteria, which will include the assets to be protected, the threats to those assets (tactics with associated threat severity levels), and the levels of protection to which those assets are to be protected, Recall that the design criteria also includes design constraints that might be imposed by the Planning Team, which is the subject of the next and final step of this process.

2. From Tactic, Threat Severity and LOP Worksheet
3. Level of Protection or Initial Protection Level
4. From Risk Level Calculation Worksheet
5. One risk level for each tactic group
6. Risk level for aggressor whose threat severity level controls DBT(from Tactic, Threat Severity , and LOP Wksht)
7. Indicate which aggressor controls
8. From Appendix A or B or from other cost estimate
9. Enter small, medium, or large room
10. Enter percentage of building perimeter protected
11. (Revised cost sum– initial cost sum) ÷ initial cost sum
12. (Revised risk level – initial risk level) ÷ initial risk level
13. Change in risk ÷ change in cost
14. Total building cost increase (w/o progressive collapse)

3-12 **STEP 10: IDENTIFY USER CONSTRAINTS**. User constraints include physical characteristics and qualities or operational considerations that restrict or dictate the design of a protective system. During design criteria development the Planning Team considers non-technical constraints relating to user requirements. As part of the design of the protective system the designers may identify more technical design constraints related to specific countermeasures. User constraints are specific to an asset, a facility, a site, an entire installation, or a city. Installation master planning requirements and facility design criteria unrelated to security often constrain protective system design. Consider the following categories of constraints to the extent that they apply to the individual project. List the user constraints and describe them in a narrative to be included with the design criteria documents.

3-12.1 **Political Considerations.** The relationship between the military and the public, including personnel on or off the installation, may influence design. Evaluate the following:

3-12.1.1 **Adjacent Landowners or Other Tenant Organizations.** Assess potential problems such as the impact of high-intensity security lighting or traffic restrictions. Identify any neighbors requiring special consideration.

3-12.1.2 **Appearance.** Consider public perception of the appearance of a proposed secure facility, site, or area. For example, public perception of a “fortress” may be either desirable or undesirable depending on the intent of the Planning Team. Such facilities may provide deterrence. They may also be perceived negatively.

3-12.1.3 **Public Access.** Identify restrictions on limiting public access to a facility, a site, or an area of an installation.

3-12.1.4 **Political Climate.** Consider how the local political situation influences facility design or land use decisions. Politically unpopular decisions may attract acts of aggression to completed facilities.

3-12.2 **Financial Considerations.** Identify funding limitations for security based on such criteria as policy, available funds, asset value, or the Planning Team's judgment of a reasonable limit for security costs. Describe limitations in terms of actual cost or percentage of facility cost. In defining an acceptable cost, consider all costs of replacing the asset and costs of operating without it.

3-12.3 **Regulations.** Ensure that all pertinent regulations are cited to ensure that the designers consider them. Also consider requirements imposed by the installation's physical security and antiterrorism plans.

3-12.4 **Procedural or Operational Considerations.** Installation or facility user requirements related to operations in either normal or heightened Force Protection Conditions (FPCON) may constrain design. If there are specific user constraints related to procedures and operations, ensure they are communicated to the designers so they do not make conflicting recommendations as part of their protective system design. A protective system must comprise an integration of construction, building support systems, equipment, manpower, and procedures. Examples of applicable procedures and operations include the following:

3-12.4.1 **Deliveries.** Identify specific existing or planned requirements for how deliveries or pickups are to be made. Consider mail, supplies, materiel, and trash. Include limitations on where deliveries or pickups may be made. Also consider service or construction vehicles.

3-12.4.2 **Restricted Areas.** Identify areas within facilities or within the installation that require restricted access and state the scope of the restriction. Consider also how existing access limitations may impact design or construction.

3-12.4.3 **Access Controls.** Identify who or what is to be controlled, to what degree, and where and when the controls apply. Include personnel identity and weapons checks, vehicle checks, and checks of packages for such items as explosives or classified information.

3-12.4.4 **Functional Requirements.** Determine how the user will operate the facility and identify constraints related to operation. Include functional relationships between organizations or components of organizations, work schedules, types of operations to be performed, and special requirements for facility layout or construction.

3-12.5 **Facility and Site Constraints.** Examine the installation's master plan, existing facilities, and any plans or sketches for the proposed project. Identify requirements related to site or facility layout or construction. Potential constraints include the following:

3-12.5.1 **Occupancy Requirements.** Identify any special space requirements, window ratios, and other occupancy-related design constraints.

3-12.5.2 **Barrier-Free Accessibility.** Public facilities and facilities which may shelter or be used by military dependents or civilians must conform to the guidelines found in the *Uniform Federal Accessibility Standards* which may constrain security-related design.

3-12.5.3 **Parking Lots and Roads.** Identify specific requirements for parking lots and roads that could impact security. Consider, for example, how close to the protected building vehicles must be allowed to approach or park (with and without entry control) for operational purposes.

3-12.5.4 **Fences and Lighting.** Identify specific requirements or restrictions for installation of fences or security lighting.

3-12.5.5 **Electronic Security Systems.** Identify specific requirements for electronic security systems including CCTV, electronic entry control equipment unrelated to the threats identified in this process.

3-12.5.6 **Architectural Theme.** Identify requirements or restrictions on the construction materials or architectural style to be used for the building. Some installations provide architectural guidelines that define appropriate styles and limit construction materials.

3-12.5.7 **Existing Facilities.** Determine whether layout, proximity, construction, or operations of existing facilities constrain new projects.

3-12.5.8 **Miscellaneous.** Determine design constraints imposed by landmark status of buildings or areas, floodplain restrictions, endangered wildlife or plant species, or any other design considerations that can be addressed at this stage of project development.

3-12.6 **Response Force.** Identify the response forces that would respond to an act of aggression. The design of a protective system assumes the response force is capable of neutralizing the threat. Consider the following with respect to whether or not such forces are available for integration into the protective system:

3-12.6.1 **Armed Force.** Department of Defense civilian police or security guards, military or security police, troops, and special reaction teams may respond to detected attacks.

3-12.6.2 **Explosive Ordnance Disposal (EOD) Team.** When acts of aggression involve explosives, an EOD team may attempt to dispose of the explosives before detonation.

3-12.6.3 **Fire Department.** The fire department responds to support the EOD team, responds after a successful attack to contain fire damage and rescue victims, and may constitute the first responders to a chemical, biological, or radiological attack.

3-12.7 **Response Time.** The time required for a force to detect and assess an act of aggression and to reach a facility in response to the act is the response time. Response time has direct design implications only in the forced entry tactic, for which it is important because it determines the length of time building elements must delay an aggressor to allow an adequate response. . For certain assets, regulations specify maximum response times.

3-12.8 **Manpower Allocation.** Identify available security personnel that can be integrated into the protective system or positions to be eliminated. Consider the personnel listed below.

- Command and control center personnel or IDS operators.
- Entry/access control guards.
- Fixed post guards.
- Roving guards.

3-13 **INFORMATION SENSITIVITY.** Information generated by the Planning Team as output from the planning procedure indicates the assets the user considers important and the threats against which the protective system is designed. This is sensitive information and will be treated as "For Official Use Only" as a minimum. This applies to completed forms and to other documentation that reflects the sensitive information on the forms. The information will be considered for classification at an appropriate level when either of the following criteria exists:

3-13.1 **Derivative Classification.** If classified information is used in generating the output of this procedure, the resulting information may need the derivative classification of the material from which it was derived.

3-13.2 **Classification Guides.** For some situations, there may be a classification guide that governs the classification of information relating to that situation. Where there are such guides, they may govern classification of elements if the design criteria.

3-13.3 **Original Classification.** Capabilities or design parameters must be protected for operational security reasons. Operational security is especially relevant for overseas projects constructed in high-threat areas and for mission-essential facilities. The installation commander or a designated representative with original classification authority should determine the appropriate classification level to protect the facility design information.

CHAPTER 4

DESIGN STRATEGIES – WEAPONS AND EXPLOSIVES TACTICS

4-1 **INTRODUCTION.** The approaches to mitigating the effects on assets from any of the tactics described in this UFC are referred to as design strategies. It is not intended for planners to apply these design strategies in a detailed manner, but planners should understand how the design strategies affect the designs of facilities. With that understanding, planners can explain the basis for the costs associated with protecting against a given tactic as reflected in the cost increase appendices in this UFC. This chapter, therefore, describes the design strategies as well as summarizes the likely impacts on construction that will result from the application of those strategies. There are two levels of design strategies associated with each tactic, the general design strategy and the specific design strategy. Both levels of design strategies will be described for each tactic.

4-1.1 **General Design Strategy.** The general design strategy for any tactic is the basic approach to developing a protective system to mitigate the effects of that tactic. It governs the general application of construction, building support systems, equipment, manpower, and procedures.

4-1.2 **Specific Design Strategy.** The specific design strategy for any tactic governs how the general design strategy varies for different levels of protection. The specific design strategies and their nature vary with each tactic. They may vary by the sophistication of the protective measures, the degree of protection provided, or the degree of damage a building will be allowed to sustain, among others. The specific design strategies reflect the degree to which assets will be left vulnerable after the protective system has been employed.

4-1.3 **Project Scope Implications.** Because this UFC is intended to support project planning, it does not include detailed discussions on protective measures. Planners must have a basic understanding of the implications on project scopes of application of the design strategies for various levels of protection and tactics, however. To support that understanding, brief summaries of the types of protective measures that can be expected are provided for each tactic. Those summaries are only intended to aid in understanding the basis for the cost increases in the cost appendices. More detailed discussions of protective measures are included in the *DoD Security Engineering Facilities Design Manual (UFC-4-020-02).* The protective measures are divided into the categories below. Not all categories apply to all tactics.

4-1.3.1 **Sitework Elements.** These include all protective measures that are associated with areas surrounding buildings beyond 1.5 m (5 ft) from the building, excluding measures that are included under equipment. Commonly these will include such measures as fences, barriers, and landscaping.

4-1.3.2 **Building Elements.** These include all protective measures directly associated with buildings such as walls, doors, windows, roofs, superstructure, and building layout.

4-1.3.3 **Building Support Systems.** For the purposes of this UFC, building support systems will include those systems that are necessary to make the building operate on a day-to-day basis. The heating, ventilating, and air conditioning (HVAC) system is the primary such system addressed in this UFC.

4-1.3.4 **Equipment.** For the purposes of this UFC, equipment will include protective measures such as intrusion detection systems, electronic entry control systems, closed circuit television systems, and other electronic systems that support functions such as access control and detection of aggressors or tools, weapons, explosives, and agents.

4-1.3.5 **Manpower and Procedures.** While these are not engineering or architectural issues, they may have impact on the overall engineering and architecture of projects. The availability of manpower and the procedures that are in place may also affect the form of the protective system and, therefore, its cost. Manpower includes the guards or operators needed to operate whatever systems are provided or to provide functions such as access control and the response forces that are needed to respond to an act of aggression.

4-1.3.6 **Expeditionary and Temporary Construction Considerations.** The general and specific design strategies that apply to permanent construction also apply to expeditionary and temporary construction, but the forms of the protective measures may be somewhat different. For each tactic, the expeditionary and temporary construction considerations will address those differences.

4-2 **VEHICLE BOMB TACTICS.** Both the general and specific design strategies for the moving and stationary vehicle bomb tactics are the same. Only the details of the application of the countermeasures change.

4-2.1 **General Design Strategy.** The general design strategy for these tactics comprises four elements, standoff distance, building hardening, barriers, and manpower and procedures.

4-2.1.1 **Standoff Distance.** The pressures resulting from explosive blasts can be very high, but they decrease rapidly with distance (proportional to the cube root of the distance.) That suggests that where land is available the least expensive way to provide protection against explosives is to maximize the standoff distance. The general design strategy, therefore, is to provide as much standoff distance between protected facilities and potential locations for vehicles, such as parking areas, roadways, and other locations that could be accessible by vehicles. The only difference in the application of this strategy for moving vehicle bombs versus stationary vehicle bombs with respect to standoff distance is that the locations to be considered for the stationary vehicle bomb can be limited to those where parking or other vehicle access is common.

The reason for that is the assumption that the aggressors who would employ the stationary vehicle bomb seek to be covert as described in chapter 2. In the case of the moving vehicle bomb, that assumption is invalid because the aggressors are assumed to be suicidal. Detection is assumed not to be a deterrent to them.

4-2.1.2 **Building Hardening.** Where the standoff distance from a vehicle bomb to a protected facility is sufficient, the facility can be of conventional construction, which means that it can be built without any hardening of building elements. One major exception to that is windows, which would have to be constructed to minimize fragmentation as reflected in the windows required by the *DoD Minimum Antiterrorism Standards for Buildings (UFC 4-010-01).* Where the sufficient standoff distances cannot be provided, building elements such as walls, doors, windows, roofs, and, potentially, building superstructures may have to be hardened to resist the explosive effects to the applicable level of protection. The cost tables in Appendices A and B account for building hardening where appropriate.

4-2.1.3 **Vehicle Barriers.** The general design strategy for both of these tactics includes the application of some form of vehicle barriers to establish and maintain the standoff distance between vehicles and facilities. Those barriers will commonly include passive perimeter barriers that define the standoff distance and active barriers that allow entry through the perimeter. For the stationary vehicle bomb tactic, both the passive perimeter and active barriers only need to define the perimeter and provide an obstacle whose breaching would draw attention. For the moving vehicle bomb tactic those barriers must actually stop the kinetic energy of the moving vehicle because the driver is assumed to be suicidal.

4-2.1.4 **Manpower and Procedures.** The general design strategy also depends on manpower and procedures. While those are not an engineering issue, because they are an integral part of the protective system necessary for mitigating these tactics, they must be incorporated in the design. That will require coordination with the operations or security people associated with each project, who ultimately will establish manpower requirements and define the procedures based on local considerations. The manpower and procedures support the general design strategy in controlling access closer to the facility than the standoff distance.

4-2.2 **Specific Design Strategies.** The specific design strategies for these tactics reflect differences in how protective measures are applied for different levels of protection. Those differences may manifest themselves in differing standoff distances or differences in the construction of building elements for different levels of protection. The general goals for manpower and procedures also vary with levels of protection. Barrier requirements commonly do not, however. The design goals associated with the various level of protection are reflected in Tables 4-1 and 4-2 for new and existing construction and expeditionary and temporary construction, respectively. Table 4-3 summarizes the manpower and procedures goals that are associated with each level of protection for new and existing buildings and for expeditionary and temporary construction.

Table 4-1 Levels of Protection – New and Existing Buildings

Level of Protection	Potential Building Damage / Performance [2]	Potential Door and Glazing Hazards[3]	Potential Injuries
Below Very Low [1]	Severe damage. Progressive collapse likely. Space in and around damaged area will be unusable.	Doors windows will fail catastrophically and result in lethal hazards. (High hazard rating)	Majority of personnel in collapse region suffer fatalities. Potential fatalities in areas outside of collapsed area likely.
Very Low	Heavy damage - Onset of structural collapse, but progressive collapse is unlikely. Space in and around damaged area will be unusable.	Glazing will fracture, come out of the frame, and is likely to be propelled into the building, with the potential to cause serious injuries. (Low hazard rating) Doors may be propelled into rooms, presenting serious hazards.	Majority of personnel in damaged area suffer serious injuries with a potential for fatalities. Personnel in areas outside damaged area will experience minor to moderate injuries.
Low	Moderate damage – Building damage will not be economically repairable. Progressive collapse will not occur. Space in and around damaged area will be unusable.	Glazing will fracture, potentially come out of the frame, but at a reduced velocity, does not present a significant injury hazard. (Very low hazard rating) Doors may fail, but they will rebound out of their frames, presenting minimal hazards.	Majority of personnel in damaged area suffer minor to moderate injuries with the potential for a few serious injuries, but fatalities are unlikely. Personnel in areas outside damaged areas will potentially experience a minor to moderate injuries.
Medium	Minor damage – Building damage will be economically repairable. Space in and around damaged area can be used and will be fully functional after cleanup and repairs.	Glazing will fracture, remain in the frame and results in a minimal hazard consisting of glass dust and slivers. (Minimal hazard rating) Doors will stay in frames, but will not be reusable.	Personnel in damaged area potentially suffer minor to moderate injuries, but fatalities are unlikely. Personnel in areas outside damaged areas will potentially experience superficial injuries.
High	Minimal damage. No permanent deformations. The facility will be immediately operable.	Glazing will not break. (No hazard rating) Doors will be reusable.	Only superficial injuries are likely.

Notes:
1. This is not a level of protection, and should never be a design goal. It only defines a realm of more severe structural response, and may provide useful information in some cases.
2. For damage / performance descriptions for primary, secondary, and non-structural members, refer to UFC 4-020-02.
3. Glazing hazard levels are from ASTM F 1642.

Table 4-2 Levels of Protection – Expeditionary and Temporary Structures

Level of Protection	Potential Structural Damage	Potential Injuries
Below Very Low	Severe damage. Frame collapse/massive destruction. Little left standing.	Majority of personnel in collapse region suffer fatalities. Potential fatalities in areas outside of collapsed area likely.
Very Low	Heavy damage. A majority of the structure will collapse and a majority of secondary structural members will collapse.	Majority of personnel in damaged area suffer serious injuries with a potential for fatalities. Personnel in areas outside damaged area will experience minor to moderate injuries.
Low	Moderate damage. Damage will be unrepairable Some sections of the structure may collapse or lose structural capacity.	Majority of personnel in damaged area suffer minor to moderate injuries with the potential for a few serious injuries, but fatalities are unlikely. Personnel in areas outside damaged areas will potentially experience a minor to moderate injuries.
Medium	Minor damage. Damage will be repairable. Minor to major deformations of both structural members and non-structural elements. Some secondary debris will be likely, but the structure remains intact with collapse unlikely.	Personnel in damaged area potentially suffer minor to moderate injuries, but fatalities are unlikely. Personnel in areas outside damaged areas will potentially experience superficial injuries.
High	Minimal damage. No permanent deformation of primary and secondary structural members or non-structural elements.	Only superficial injuries are likely.

Table 4-3. Manpower and Procedures Goals for Vehicle Bomb Tactics

Level of Protection	Manpower and Procedures Goals
Below Very Low	None
Very Low	Driver and vehicle authorization checked and visible areas of vehicles checked visually
Low	Driver and vehicle authorization and visual check of visible areas of all vehicles plus visual check of cargo areas or trunks for random number of vehicles
Medium	Driver and vehicle authorization and visual check of visible areas of all vehicles plus comprehensive search of random number of vehicles.
High	Driver and vehicle authorization plus comprehensive search of all vehicles.

4-2.3 **Project Scope Implications.**

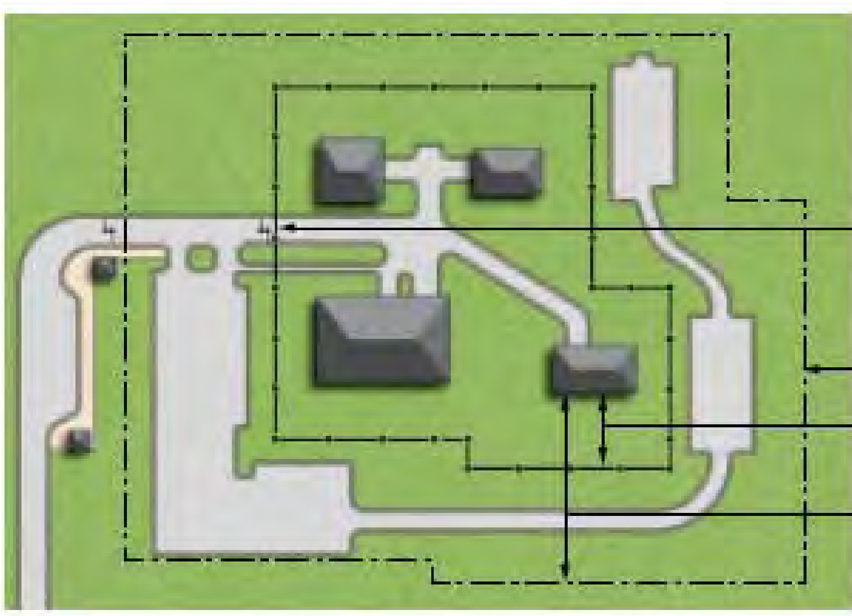
4-2.3.1 **Sitework Elements.** The impacts on project planning for sitework elements include standoff distance and barriers to establish and maintain that standoff distance.

4-2.3.1.1 **Standoff Distance.** The primary impact on project scope for sitework will be the establishment and maintenance of standoff distance. That standoff will have to be provided to any location that is accessible to vehicles. For the stationary vehicle bomb tactic those locations may be limited to those that have legitimate vehicle access such as parking areas and roadways. For the moving vehicle bomb tactic those locations will need to go beyond the areas that are legitimately accessible to vehicles and include those that are physically accessible.

The key to understanding the planning implications of the standoff distance is in knowing the type of vehicle and the explosive weight associated with the threat and determining where access of those vehicles will be controlled. Refer to Table 3-27 for the vehicles and explosive weights associated with the various threat severity levels. In addition, planners need to recognize that where a higher threat severity level applies, all those below it also apply. One approach, therefore, is to establish a standoff distance based on the largest applicable explosive weight based on the applicable threat severity level and require access procedures for entry past that perimeter to be applied to all vehicles at that standoff distance. In cases where the threat severity level is equal to or greater than "high" (where the threat vehicles are trucks), all vehicles would be required to be searched at that standoff distance. The operational implications of that requirement may be impractical in most locations.

Those operational challenges suggest another option for application at higher threat severity levels. That option capitalizes on the fact that trucks are assumed to carry more explosives than cars and recognizes that there are usually more cars than trucks that require access near facilities. The approach of this second option is to create a two tiered system of standoff distances where trucks are controlled at the standoff distance associated with the highest applicable threat severity level and a second tier of standoff distances is established within that outer perimeter at a distance associated with the largest explosive weight cars are assumed to carry, which is 100 kg (220 lbs). Note that where threats larger than 100 kg (220 lbs) apply, all threats smaller than them also apply. With the option of establishing two separate perimeters, trucks can be searched at the greater standoff distance and cars can be allowed to go up to the closer standoff distance before they have to be controlled and searched. This approach minimizes the operational challenges of searching all vehicles at the standoff distance associated with trucks. The perimeter associated with the higher explosive weight could be a controlled perimeter as described in UFC 4-010-01. It can be anywhere the installation operations and security personnel wanted to establish access control, including the installation perimeter. The option described above is illustrated in Figure 4-1. Note that in Figure 4-1, either of the perimeters can be anywhere as long as they provide the appropriate standoff distance for the building construction.

Figure 4-1. Standoff Zones



4-2.3.1.2 **Vehicle Barriers.** Vehicle barriers are part of the design strategy for both vehicle bomb tactics and for all levels of protection. Vehicle barriers will include both passive perimeter barriers and active vehicle barriers that are applied at entries through the passive perimeter barriers. Their application differs significantly for the moving and stationary vehicle bomb tactics, however. Note also that to be effective barriers need to span the entire perimeter and all entries though it. They do not need to all be the same, but they do need to meet the same requirements as described below.

Active and passive perimeter barriers for the stationary vehicle bomb tactic only need to present an obstacle that would draw attention to the drivers of vehicles as they breached them. Examples of passive perimeter barriers that would satisfy the design strategy are high curbs, shrubbery, and unreinforced fences as shown in Figure 4-2. Examples of satisfactory active barriers would be chains draped between poles and drop arm barriers such as those found commonly in commercial parking lots as shown in Figure 4-4.

Active and passive perimeter barriers for the moving vehicle bomb tactic need to be able to stop the full kinetic energy of the threat vehicle. The construction of those barriers will vary significantly based on the weight of the loaded threat vehicles and the speed they can attain. Passive perimeter barriers range from reinforced fences to heavily reinforced retaining walls such as those shown in Figure 4-3. There is a wide range of possible solutions that engineers and landscape architects can develop for passive perimeter barriers. Active barriers will commonly include retractable bollards, pop-up plate or drum barriers, and reinforced sliding gates such as those shown in Figure 4.5. They all need to have been tested to resist the threat vehicle.

Figure 4-2. Passive Perimeter Barriers for Stationary Vehicle Bombs

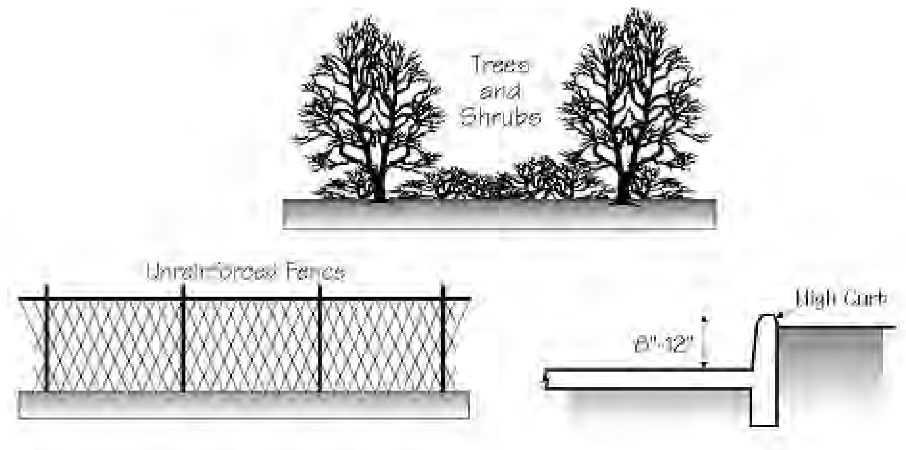


Figure 4-3. Passive Perimeter Barriers for Moving Vehicle Bombs

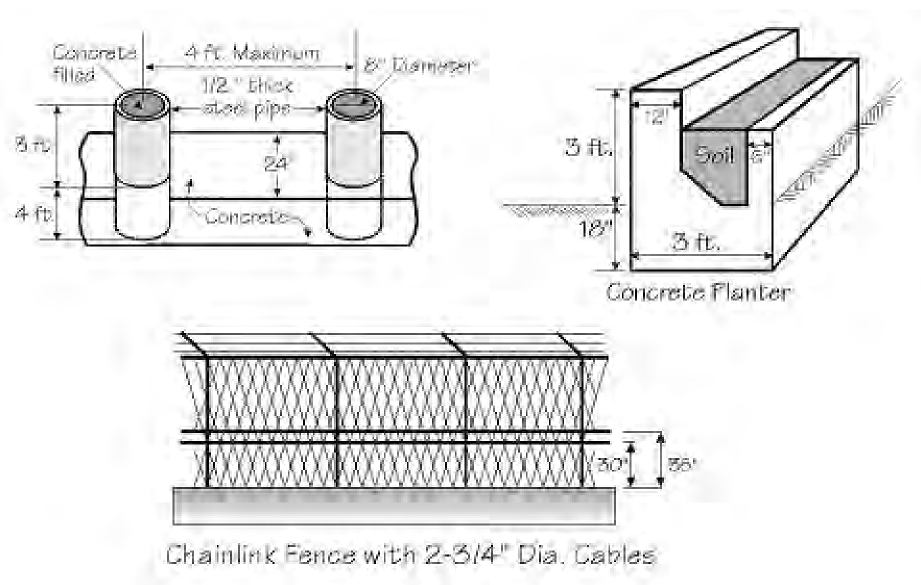

Figure 4-4. Active Vehicle Barriers for Stationary Vehicle Tactic

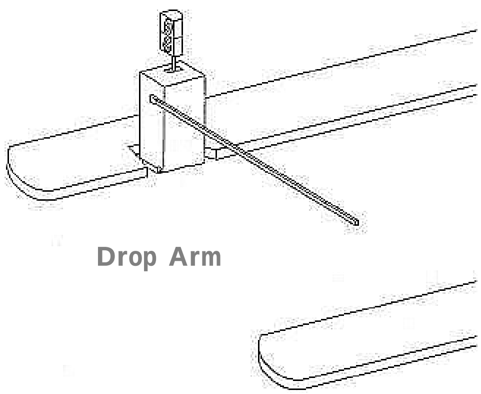

Figure 4-5. Active Vehicle Barriers for Moving Vehicle Tactic

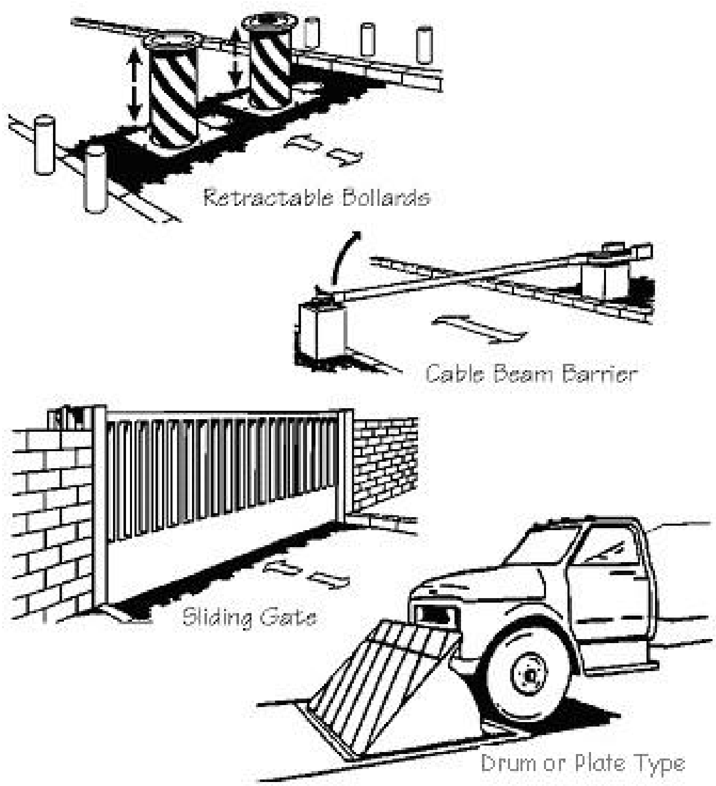
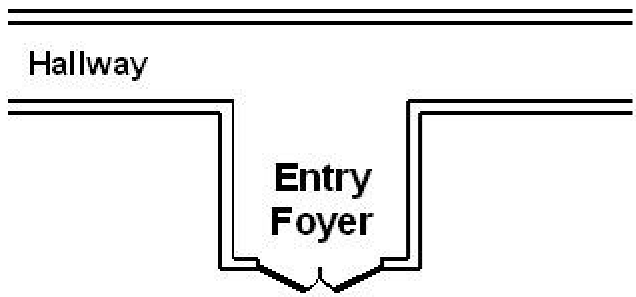


4-2.3.2 **Building Elements.**

4-2.3.2.1 **New Construction.** Where standoff distances for conventional construction can be met, the impact on building construction will be limited. If the building is less than 3 stories, the only building elements that will have requirements beyond conventional construction are the doors and windows. Windows will have to be made with laminated glass and heavier frames than are common in conventional construction as required by the *DoD Minimum Antiterrorism Standards for Buildings (UFC 4-010-01)*. Glazed doors will require laminated glass as well, and unglazed doors should be hollow steel to minimize fragmentation in the event of an explosion. They should also open outward, which may have some impact on elevated walkway widths. Finally, to minimize hazards from doors flying onto rooms, they should be backed up with walls that could intercept them as illustrated in Figure 4-6. For inhabited buildings that have three or more stories, the progressive collapse provisions of UFC 4-010-01 will have to be incorporated into the design.

Figure 4-6. Entry Foyer to Reduce Door Hazards



Where conventional construction standoff distances are not available, most of the major components of buildings are likely to be impacted. Walls and roofs may be thicker and heavier, windows may be heavier and constructed out of more expensive materials, and doors may be of heavy steel construction. In addition, building frames and other superstructure elements may also have to be heavier. The cost increases associated with those modifications to conventional construction are reflected in the cost appendices in this UFC.

4-2.3.2.2 **Existing Buildings.** Where conventional construction standoff distances can be met, the only impact on the existing construction is likely to be in windows and doors. The same considerations apply for windows and doors as described in the previous paragraph, but in the case of existing buildings, the existing windows and doors will probably have to be removed and replaced with the windows and doors described above. Where an existing building is not required to meet the requirements of the *DoD Minimum Antiterrorism Standards for Buildings (UFC 4-010-01)*, window retrofits using materials such as fragment retention film or drapes may be used. There may also be cases in which the walls around the windows and doors have to be strengthened to handle the loads associated with the new windows and doors resisting the explosives effects.

Where conventional construction standoff distances are not available, the buildings' walls and roofs may have to be retrofitted to resist the applicable blast loads. In the case of the walls, there are retrofits that can be applied to the inner faces of the existing walls. In the case of roofs, removing the existing roof and replacing it with a new roof is the most economical way to provide the required protection.

4-2.3.3 **Equipment.** Equipment such as electronic entry control devices like card readers may be incorporated into protective systems to reduce requirements for permanent manpower. Those systems may also be augmented with closed circuit television systems or such systems may be employed in support of access control with equipment such as intercoms instead of electronic entry control systems. In general, these kinds of equipment will be installed in support of access control at entry control points through perimeters.

4-2.3.4. **Manpower and Procedures.** As stated above in the context of the design strategy for these tactics, manpower and procedures are a critical element of protective systems for these tactics. Their impacts on project scope mostly relate to the potential for increased equipment requirements where there are inadequate manpower resources available. Procedures may also increase requirements because they may increase the time required to allow vehicles through entry control points, which may lead to needing either more lanes at the entry control points or additional entry points. Manpower considerations may also drive the need for shelters for guards and other such appurtenances that may add to sitework costs.

4-2.3.5 **Expeditionary and Temporary Construction Considerations.** Most of the protective measures that will be applied in the expeditionary environment are sitework measures. Because it is generally impractical to harden or retrofit expeditionary and temporary construction significantly, increased standoff distance is the primary approach to providing protection in that environment. That will commonly drive the need for larger sites. In addition, barrier construction will generally include more temporary or improvised barriers than would commonly be provided for permanent construction.

4-3 **HAND DELIVERED DEVICES.** Because this tactic includes delivery of explosives and incendiary devices either to the exterior of buildings or attempts to deliver them into buildings, the design strategies will be discussed in the context of the exteriors of facilities and building entry points, mail rooms, and supplies handling areas.

4-3.1 **General Design Strategy.** The general design strategy for this tactic, regardless of the location of the explosive or incendiary device, is to attempt to detect the device and to ensure that assets inside buildings are protected in accordance with the applicable level of protection in the event a device detonates. For devices assumed to be placed exterior to a building, that generally requires an unobstructed space within which placed explosives or incendiary devices can be visually detected and building elements that are designed to resist the explosive effects of a detonation outside the distance associated with that unobstructed space. For devices at entry and delivery points into buildings, the general design strategy includes providing for detection of the device at those points and designing those areas to minimize damage to assets inside the building from a detonation inside those entry or delivery points.

4-3.2 **Specific Design Strategies.** Specific design strategies generally follow the same goals for protection of assets as the vehicle bomb tactic, but with additional emphasis on detection.

4.3.2.1 **Sitework Elements.** Sitework elements are only an issue for this tactic in the context of explosives or incendiary devices being placed at the exteriors of buildings. The only variance among levels of protection is that the high level of protection requires perimeter barriers to control access to the unobstructed spaces around the buildings and to reduce vulnerabilities associated with thrown devices.

4-3.2.2 **Building Elements.** The design goals associated with the different levels of protection are summarized in Tables 4-2 and 4-3. For exterior explosions those design goals are focused on the exterior building elements. For explosions at entry points, mail rooms, and supplies handling areas, those goals are focused on the building elements directly associated with the entry point areas and with the building elements in the immediate vicinity of those areas elsewhere in the buildings.

4-3.2.3 **Detection.** Detection is a critical component of the design strategy for this tactic. How detection is applied is significantly different whether the explosive or incendiary device is at the exterior of a building or at an entry point, mail room, or supplies handling area.

4-3.2.3.1 **Exterior Attacks.** For exterior attack considerations, detection at the low and medium levels of protection is based on visual observation of the unobstructed space. The high level of protection adds the requirement for perimeter detection outside the unobstructed space using some form of exterior intrusion detection system or guards.

4-3.2.3.2 **Attacks at Entry and Delivery Points.** At entry and delivery points it is necessary to detect explosives or incendiary devices either being carried into buildings or delivered to them. Detection is provided using either operational procedures or electronic equipment, depending on the level of protection. For the low level of protection, detection is provided only through operational procedures. For the medium level of protection, X-ray equipment and metal detectors are applied. The high level of protection includes the addition of explosive detectors. These measures will be applied at mail rooms and supplies handling areas as applicable for delivered devices and at either building or site entry points for devices that are being carried into buildings.

4-3.3 **Project Scope Implications.**

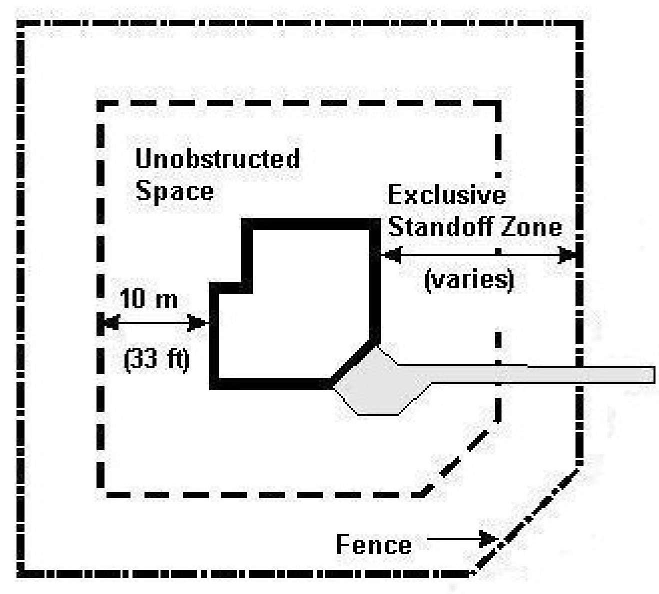
4-3.3.1 **Sitework Elements.** Sitework elements are only a consideration for explosive or incendiary devices being placed outside buildings or thrown at them. At the low and medium levels of protection, sitework considerations are limited to establishing unobstructed spaces as required in the *DoD Minimum Antiterrorism standards for Buildings (UFC 4-010-01.)* The extent of that unobstructed space can vary with threat severity level (explosive weight) and level of protection.

4-3.3.1.1 **Low and Medium Threat Severity Levels.** The 10 meter (33 feet) unobstructed space required by the minimum standards will generally be adequate for the low and medium threat severity levels at all levels of protection. The assumption in that is that explosives placed in that unobstructed space will be seen by passers by and that they are relatively small, so their detonation would result in minimal damage to people inside the buildings anyway.

4-3.3.1.2 **High Threat Severity Level.** For the high threat severity level at the low and medium levels of protection, the unobstructed space may need to be extended farther from the building. The reason for that goes back to the assumption that explosives placed in the unobstructed space will be visually detected; therefore, it is further assumed that the explosive will generally not be placed in that space. The unobstructed space may need to be extended because the standoff distance it provides will have to be based on the larger explosive associated with the high threat severity level. That standoff distance will be based on both available land and building construction. Where there is adequate standoff distance, conventional construction may be adequate to provide the required level of protection. Where there is insufficient standoff, building hardening may be necessary. The cost tables in Appendices A and B account for building hardening where appropriate.

4-3.3.1.3 **High Level of Protection.** For the high level of protection for all threat severity levels, there are additional sitework requirements to the unobstructed space. That level of protection requires establishment of an exclusive standoff zone to ensure aggressors cannot get close enough to the building to place an explosive. That exclusive standoff zone is located at whatever standoff distance is necessary to provide the required level of protection against the threat explosive based on the building construction. That standoff zone should be fenced to provide an effective barrier to access. In addition, to minimize vulnerabilities associated with thrown explosives, trees may be placed around that perimeter to assist in intercepting those thrown explosives. The unobstructed space, therefore, is not as significant a consideration, but the minimum unobstructed space should be retained in accordance with the *DoD Minimum Antiterrorism standards for Buildings (UFC 4-010-01.)* Figure 4-7 illustrates a site design that would meet the requirements for the high level of protection.

Figure 4-7. Site design example for high level of protection



4-3.3.2 **Building Elements.** Building elements have the most significant implications for project scope for this tactic. The implications are for the exterior of the building as well as at and in the vicinities of entry and delivery points. Variances among levels of protection are limited to how much damage will be allowed in response to an explosion as reflected in Tables 4-2 and 4-3.

4-3.3.2.1 **New Construction.**

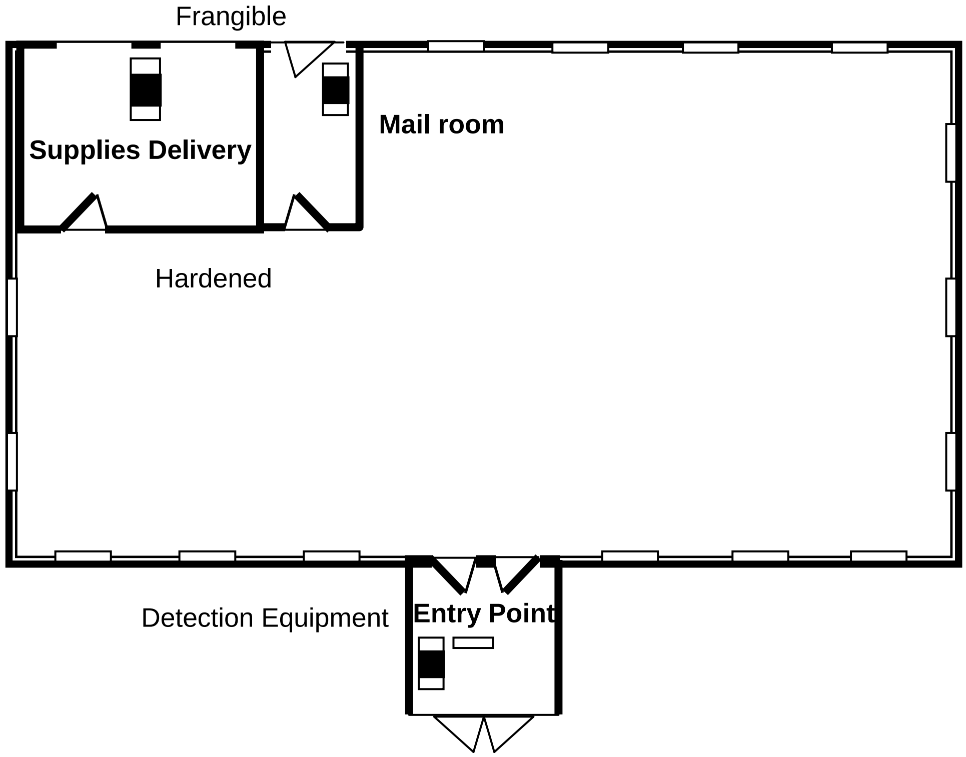
4-3.3.2.1.1 **Building Exterior.** The building exterior should be designed to provide the applicable level of protection to the bulk explosive at the edge of either the unobstructed space or the exclusive standoff zone. It should also be designed for smaller thrown explosives and incendiary devices well within those standoff distances.

For the low threat severity level, the only exterior requirements are that the building exterior be fire resistant, which is consistent with common building practice, and that windows be resistant to thrown objects. The DoD minimum window required by UFC 4-010-01 is generally adequate for that. For the medium threat severity level, the building exterior must further provide resistance to the small explosive and fragments associated with the explosives at that threat severity level. Because of the small size of the explosives, significant hardening is only considered at the high level of protection.

For the high threat severity level, where the unobstructed space or exclusive standoff zones are set at a standoff distance in accordance with Table 4-1, the only building elements for which there are any implications above those of conventional construction are doors and windows, which will have to meet the minimum standards in UFC 4-010-01. Where those conventional construction standoff distances cannot be provided, the implications for the exterior building elements will commonly be thicker and more heavily reinforced walls, blast resistant windows, heavier doors, and thicker and more heavily reinforced roofs. Those enhanced building elements will need to be applied over the entire building perimeter except in areas that are not inhabited.

4-3.3.2.1.2 **Entry and Delivery Points.** Because the general design strategy for this tactic assumes that no explosives or incendiary devices will be allowed into buildings, the entry and delivery points must be built such that there are opportunities to detect those devices and designed such that damage in the event of an explosion will be minimized outside the immediate vicinity of the entry or delivery points. One implication of implementing that assumption is that the entry and delivery points may have to be larger to accommodate detection equipment and search areas. The other implications are that the entry and delivery point areas will have hardened construction consisting of heavily reinforced interior walls and ceilings and blast resistant doors between those areas and the rest of the building. At least one exterior wall for the entry and delivery points will be designed to fail in response to an explosion so they can vent the explosive effects. The latter issue may result in additional requirements for the exterior of the building in the vicinities of the entry and delivery points as well. If possible, configurations of mail rooms and delivery areas should avoid doors directly into the buildings. Figure 4-8 illustrates these principles.

Figure 4-8. Entry and Delivery Points



4-3.3.2.2 **Existing Buildings.** Building retrofit considerations are similar to those for new construction, but they may involve modifying the existing construction. For the exterior of the building, there should be no issues other than the replacement of the windows as described above for the low threat severity level. Similarly, there should be minimal impacts for the medium threat severity level except for at the high level of protection.

For the high level of protection at the medium threat severity level and for all levels of protection at the high threat severity level, the building exterior may have to be retrofitted, including replacing windows and doors and adding wall retrofits to the interior of the buildings' exterior walls. Regarding roofs, in most cases the existing roofs will have to be removed and replaced with new ones.

For entry and delivery points, because of their limited size, the most economical solution is to remove the existing building components and replace them with construction similar to that for new construction.

4-3.3.3 **Equipment.** Equipment has minimal project implications for this tactic, except at the medium level of protection and higher. The equipment will generally include access control, metal detection, X-ray screening, or explosive detection equipment installed at the entry and delivery points. That equipment will commonly not be able to be provided as part of the Military Construction funding because it will not be installed equipment that is affixed to or built into the facility. Such equipment will commonly have to be funded through other appropriations in accordance with DoD component guidance. At the high level of protection, an additional equipment implication is the installation of perimeter intrusion detection systems at the exclusive standoff zone. That intrusion detection equipment may or may not be augmented with closed circuit television equipment for assessing intrusion alarms depending on user preference and operational considerations. The intrusion detection equipment also commonly will not be able to be funded as part of Military Construction.

4-3.3.4 **Manpower and Procedures.** Manpower and procedures implications on construction are limited, but they need to be incorporated into the overall project planning and operation. For the design strategy for this tactic to be effective, there need to be trained people capable of detecting explosives and incendiary devices available. For those devices placed outside of buildings, that detection may be provided through increased occupant awareness and procedures for what to do in the event that an explosive or incendiary device is observed outside the building. For detection of devices at entry and delivery points there need to be trained people dedicated to detecting those devices either through operational procedures or through the operation of detection equipment. In either case, there also need to be qualified people who will respond to detection of an explosive or incendiary device, such as an explosive ordnance disposal team.

4-3.3.5 **Expeditionary and Temporary Construction.** Generally, considerations such as hardening building elements are not realistic for expeditionary and temporary construction.

4-4 **INDIRECT FIRE WEAPONS.** Because this tactic involves weapons fired from a distance and over any practical obstacles that could be erected to block them, the design strategies for this tactic are all based on hardening of buildings to resist the effects of the weapons impacting on or near buildings.

4-4.1 **General Design Strategy.** The general design strategy for this tactic is to design a targeted building to protect assets inside it from the detonation of the threat weapon at locations that vary by level of protection. That design will generally require building hardening, which will vary with threat severity because the weapons range from simple incendiary devices to large improvised high explosive warheads.

4-4.2 **Specific Design Strategies.** Specific design strategies vary based on the distance from the impact of the threat weapon to the target building, the response of the building elements to the detonation of the weapon, and the fragment penetration through the building elements.

4-4.2.1 **Impact Distance.** Because the low level of protection commonly involves acceptance of significant risk, the impact distance for that level of protection is assumed to be a “near miss” at 5 meters (approximately 16 feet). Note that 5 meters is half of the recommended separation distance between buildings in the *DoD Minimum Antiterrorism Standards for Buildings (UFC 4-010-01)*, which suggests that in the case of adjacent buildings, the impact point will be midway between the buildings where that recommendation is followed. The impact distance for the medium level of protection is a near miss of 2 meters (approximately 6 feet). The impact distance for the high level of protection is based on a “near contact” condition equal to the warhead diameter of the weapon. Impact distance is only an issue for walls, doors, and windows. Because it is as likely that a round would land on a roof as it is to land nearby, the roofs are designed for direct impact.

4-4.2.2 **Building Element Response.** Building element responses will vary significantly with the kind of building element (wall, roof, window, door) and the materials used. In general, building element response will be evaluated based on the overall member response and on the degree of “breach.” The overall building element response is governed by Tables 4-2 and 4-3.

Breach refers to the degree to which the building materials are locally damaged and their resulting dispersal into the protected building. Breach is where the material fails and there is a hole through the wall, roof, or other element. The material from that element may disperse into the protected building, potentially injuring people or damaging other assets. Spalling is a phenomenon exhibited by many materials wherein the building element is not breached in response to an explosion effect or an impact, but a portion of the interior face of the element “pops off” and disperses into the building. Spall is commonly less dangerous than breaching. Spall and breach are governed by the criteria below:

- Low level of protection: Onset of breach (spall)
- Medium level of protection: Medium spall (no breach)
- High level of protection: Onset of spall

Application of building element response and spall or breach is covered in more detail in the *DoD Security Engineering Facilities Design Manual (UFC 4-020-02.)*

4-4.2.3 **Fragment Penetration.** Most indirect fire weapons involve what are referred to as primary fragments, which are pieces of the casing for the explosive that are propelled at high velocity in response to the detonation of the warhead. Those primary fragments result in a specific loading on building elements, and they also may penetrate them. The following summarizes the criteria for considering fragment penetration (where applicable):

- Low level of protection: Perforation by 10 fragments
- Medium level of protection: Perforation by 3 fragments
- High level of protection: Perforation by 1/2 fragment

4-4.3 **Project Scope Implications.**

4-4.3.1 **Sitework Elements.** Because indirect fire weapons fire over obstacles, there are no practical sitework elements that can be applied to mitigate this tactic. The only sitework issue would be building separation to minimize the possibility of causing damage to multiple facilities from one weapon.

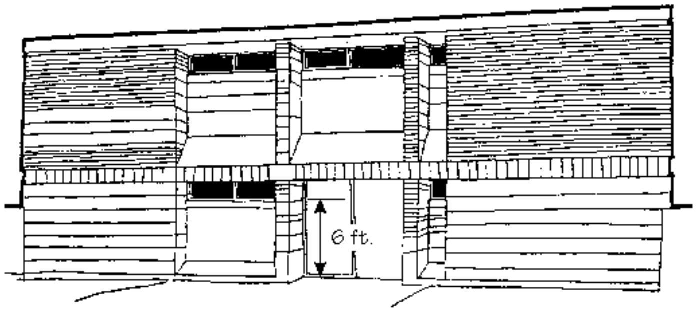
4-4.3.2. **Building Elements.** Effectively, all of the impacts on project scope will be in building elements, which will be affected by whatever hardening is applied to meet the applicable level of protection.

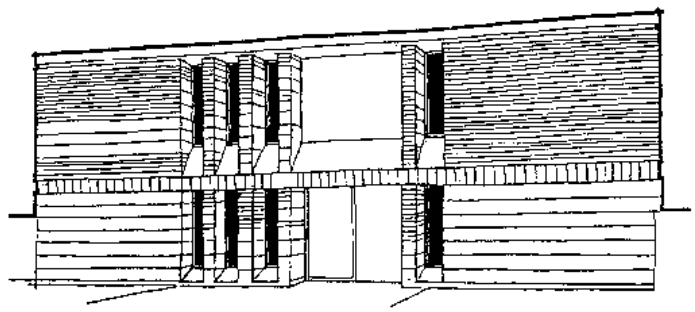
4-4.3.2.1 **New Construction.** For the low threat severity level (incendiary devices) the only implications to building element design are in flame resistance and the ability to keep the incoming warhead from penetrating the building and igniting inside. For the higher threat severity levels, however, the building elements will have to resist the effects of exploding warheads. Those effects will result in thicker walls, which will most commonly be constructed of reinforced masonry or concrete. They could also be built or retrofitted with steel plate, but that is generally more expensive.

4-4.3.2.1.1 **Windows.** Windows that are designed to resist the resulting explosive and fragment effects will generally need to be quite thick and would require the use of special materials such as polycarbonate. Because of that, the recommended solution is to use narrow, elevated windows that do not resist fragments, but only allow fragments to pass over the heads of building occupants. Where windows need to be able to be used for emergency egress, narrow, vertical windows can be used instead. In those cases, room layout would have to be adjusted to minimize exposure to occupants behind those windows. Those windows are illustrated in Figure 4-9. In either of the previous cases, the windows will still need to be designed to resist the blast load to the appropriate level of protection to minimize exposure of occupants to hazardous window fragments. Windows are not practical for the high level of protection.

4-4.3.2.1.2 **Doors.** Doors designed to resist the explosive and fragment effects would require the use of heavy steel plates. Such doors would be very heavy and expensive. For those reasons, the approach taken in this UFC is to build a foyer outside the building’s doors and allow the foyer to take the explosive and fragmentation effects of an exploding round, the foyers need to have walls constructed the same as the building’s walls. Doors into the foyers need to be offset from the doors into the building. The roofs of the foyers need to be designed the same as for the rest of the building to ensure incoming rounds do not penetrate them and explode within the foyer. Figure 4-10 shows foyers on the outside of a building.

Figure 4-9. Narrow Windows

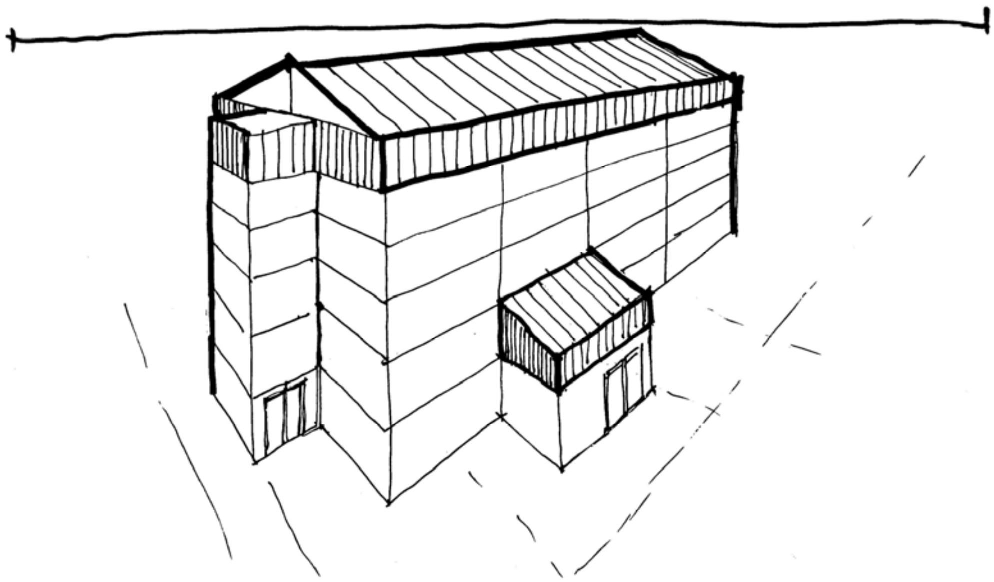




4-4.3.2.1.3 **Roofs.** Roofs designed to resist the direct impact of an incoming round will generally require thick heavily reinforced concrete. A more economical approach to the problem is to construct a sacrificial roof above the building's primary roof and to construct the primary roof to resist the effects of the round exploding at that standoff distance. That is the approach taken in developing the costs in Appendices A and B. The building's walls have to be extended to hold up the sacrificial roof and ensure rounds don't enter underneath it.

The sacrificial roof can be of conventional construction, although some lightweight roofs may need to be hardened slightly using such construction as rigid insulation and steel deck underneath to ensure incoming rounds detonate on the roof instead of beneath it. The insulation is used because some common mortar and rocket rounds have fuses that are inset from the nose of the round. Such rounds may not detonate on some solid conventionally constructed roofs, but they detonate as they pass through the rigid insulation because the insulation pushes into the recess in the nose cone. The hardened roof beneath the sacrificial roof will be reinforced concrete. For the purposes of developing costs in Appendices A and B, the standoff distances to the sacrificial roofs are at 2 meters (6 feet) and 4 meters (12 feet), representing half story and full story height, respectively. The space between the sacrificial roof and the hardened roof should not be occupied. Figure 4-10 shows sacrificial roofs on the building and on foyers.

Figure 4-10. Sacrificial Roof and Exterior Foyers



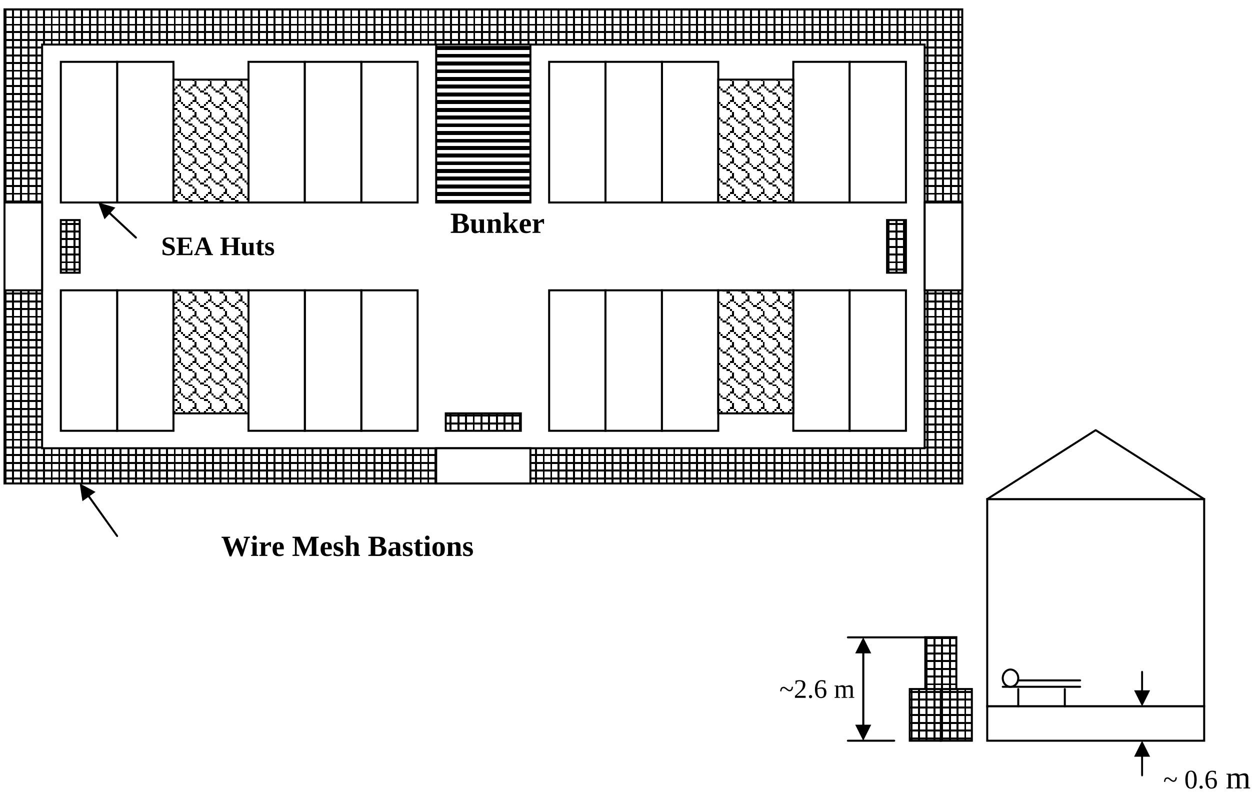
4-4.3.2.2 **Existing Buildings.** At the low threat severity level, which only requires fire resistant construction sufficient to keep the incendiary device from penetrating the building shell, retrofits should be minimal. At the higher threat severity levels, however, retrofitting existing buildings to resist the indirect fire weapons effects may be impractical in most cases. Walls require retrofits that resist the blast effects based on the explosive weight in the round, and they must provide sufficient thickness of concrete, masonry, or steel to resist the weapons' fragments. Such retrofits are only practical for the low and medium levels of protection for the medium and high threat severity levels. There are no practical retrofits for the very high threat severity level. Windows have to be replaced and the surrounding walls modified to create narrow window configurations such as those shown in Figure 4-9. In those cases, room layout has to be adjusted to minimize exposure to occupants behind those windows. Doors have to be replaced to provide door configurations similar to those described for new construction. Roofs would have to be removed and replaced with roofs similar to those described for new construction, including sacrificial roofs.

4-4.3.3 **Equipment.** The application of equipment to detect incoming indirect fire is impractical, so there are no equipment implications to project scope.

4-4.3.4 **Manpower and Procedures.** Because of the nature of the indirect fire weapon threat, there are no effective procedures that can be directly associated with an individual building to mitigate the attacks other than in response after an attack. At that point there should be emergency response procedures (fire and rescue) and building occupants should know to duck under whatever furniture they can.

4-4.3.5 **Expeditionary and Temporary Construction.** In general, hardening expeditionary and temporary construction to mitigate indirect fire weapons attack is impractical. The solutions, therefore, are commonly in dispersal of facilities so that one weapon does not damage multiple facilities and in construction of collective bunkers to which people can evacuate in anticipation of additional attacks. In addition, barriers such as wire mesh bastions or shielding walls can be erected to shield structures from fragments and to mitigate propagation of weapons effects to adjacent structures. These approaches are illustrated in Figure 4-11 below, which shows a cluster of SEA huts surrounded by wire mesh bastions.

Figure 4-11. Shielded SEA Hut Cluster



4-5 **DIRECT FIRE WEAPONS.** Because there are generally no opportunities to detect and prevent direct fire weapons attacks, the design strategies for this tactic are based on shielding and hardening.

4-5.1 **General Design Strategy.** The general design strategy involves identifying vantage points from which direct fire weapons can be launched and, depending on the level of protection, either blocking sightlines to assets and building occupants or hardening the building elements to resist the direct fire weapons effects.

4-5.2 **Specific Design Strategies.** Because this tactic includes both small arms and antitank weapons, and because the effects of those weapons vary significantly, the specific design strategies will not apply equally to all threat severity levels. Specifically, the medium level of protection only applies to the high threat severity level, which includes antitank weapons and high caliber small arms (12.7 mm or .50 caliber). For the threat severity levels that are limited to small arms of less than 12.7 mm (.50 caliber), apply the low level of protection design strategy for the medium level of protection.

4-5.2.1 **Low Level of Protection.** For all threat severity levels (involving both small arms and antitank weapons), the design strategy for this level of protection is to block sightlines to building occupants or assets. The assumption in that is that aggressors will not shoot at what they cannot see. Blocking sightlines may include applying both building and sitework elements.

4-5.2.2 **Medium Level of Protection.** The medium level of protection may apply to all threat severity levels, but is only practical in the case of large caliber small arms (like the 12.7 mm or .50 caliber) and antitank weapons. It includes the installation of predetonation screens that detonate antitank rounds at a specific distance from a target, and allow the effects of the antitank rounds to dissipate prior to impacting a building. The combination of that standoff distance and building element construction will prevent the small arms and antitank rounds from breaching the building envelope. An energy absorption screen can be installed in the case of large caliber small arms to reduce the energy of the small arms rounds before they impact the building.

4-5.2.3 **High Level of Protection.** For all threat severity levels (involving both small arms and antitank weapons), the design strategy for this level of protection is to harden building elements such that they resist the direct effects of the threat weapon.

4-5.3 **Project Scope Implications.**

4-5.3.1 **Sitework Elements.** Sitework elements only apply at the low and medium levels of protection. At the low level of protection, various landscaping elements or opaque barriers can be applied to block sightlines to occupied portions of buildings. The medium level of protection includes an energy absorption screen or a predetonation screen. The predetonation screen can be a solid fence or wall that will be sufficient to detonate an antitank round on impact. Commonly, that requires a surface of concrete, concrete masonry, steel, or at least 20-millimeter (approximately ¾ inch) thick wood. The predetonation screen should be placed to shield the occupied portions of buildings and will have to be between 3 and 12 meters (approximately 10 and 40 feet) away from the building depending on building construction. To serve as both a predetonation and energy absorption screen requires reinforced concrete or masonry because it requires much more mass to reduce the energy of a large caliber bullet than to predetonate an antitank round.

4-5.3.2 **Building Elements.** Implications to building elements are dependent on the level of protection.

4-5.3.2.1 **New Construction.**

4-5.3.2.1.1 **Low Level of Protection.** Because the design strategy for the low level of protection for all threat severity levels is concealment, there are limited implications to building elements. Since walls and roofs are generally opaque, there are no considerations for them. The only considerations, therefore, are for openings such as windows, skylights, and doors. The implications to windows and doors are either to configure them so that occupants and other assets are not visible through them or to provide treatments such as reflective coatings, shades, or drapes that make them difficult to see through. Skylights would have similar implications, but only if there were vantage points nearby from which those could be targeted.

4-5.3.2.1.2 **Medium and High Levels of Protection.** At the medium and high levels of protection the exterior building elements will have to resist the weapons effects for the threat weapons. For the small arms threats the implication to that is the use of bullet resisting construction. Generally, reinforced masonry or concrete walls will provide such resistance with 200-millimeter (8-inch) thick reinforced masonry or 150-millimeter (7-inch) reinforced concrete providing resistance up to the 7.62-millimeter rounds. For the higher caliber bullets and antitank rounds in the high threat severity level, the walls are likely to be thicker.

Doors and windows are commercially available to resist the small arms threats of 7.62 millimeters and smaller, but those assemblies will be thicker and heavier than conventional windows and doors. Windows and doors are also available that can stop higher caliber bullets, but they are not as commonly available. Windows and doors that would resist either predetonated antitank rounds or direct hits from those rounds are not practical. The implications for that are that those windows and doors will have to be shielded, configured to preclude lines of sight to occupants or assets, or eliminated.

Roofs and skylights are only an issue where there are sightlines to them from nearby vantage points. Where there are such sightlines, roofs and skylights will have to be treated similarly to walls and windows.

4-5.3.2.2 **Existing Buildings.** Retrofit considerations for the low level of protection are similar those for new construction. Windows and doors would need to have means to limit vision through them as described above. For the medium and high levels of protection, windows and doors will have to be replaced with bullet resistant window and door assemblies. Walls may have to have additional thickness of concrete or masonry added or steel plate added to the backs of the walls.

4-5.3.3 **Equipment.** Because of the fact that these attacks are commonly launched from a distance without warning, there is no practical opportunity to apply equipment to mitigate vulnerabilities to this tactic.

4-5.3.4 **Manpower and Procedures.** As with equipment, there are no practical applications of manpower and procedures in mitigating these attacks other than ensuring that people know to take cover immediately after detecting an incoming round and in some environments, firing back at the aggressors.

4-5.3.5 **Expeditionary and Temporary Construction.** It is generally not difficult to provide the low level of protection for expeditionary and temporary construction, but it is generally not practical to provide higher levels of protection through hardening of the structures themselves. The approach, therefore, is to provide shielding such as that illustrated in Figure 4-11.

4-6 **AIRBORNE CONTAMINATION TACTIC.** One of the critical assumptions inherent in the design strategies for this tactic is that airborne contaminants will be delivered into buildings from either outside the building or at entry or delivery points. Contaminants cannot be allowed to enter into buildings further than those points.

4-6.1 **General Design Strategy.** Based on the above assumption, the general design strategy for this tactic is to provide access control and screening to ensure that agents are not introduced into buildings and to design the building elements and building support systems to ensure that agents introduced from outside the buildings or at entry and delivery points are kept out of the buildings. This is commonly referred to as collective protection.

That generally means that building envelopes will be designed to minimize air infiltration and exfiltration and that at other than the very low level of protection the buildings will be pressurized to keep airborne agents out. That pressurization requires filtration to retain the purity of the makeup air necessary to retain overpressurization. In addition, ventilation systems for entry and delivery points will be isolated from the remainder of the buildings.

Note that the design strategy does not include detection of agents. Theoretically, automatic detectors can be used to initiate protective actions such as shutdown of ventilation systems, closing outside air intakes, or turning on filtration systems. Detection of radiological agents can be performed quickly with off-the-shelf equipment; however, current biological detection technology requires a minimum delay of approximately 15 minutes to detect the presence of biological agents, although there is high-end research and development equipment capable of detecting within a few minutes. Practical application of chemical detection is limited by shortcomings in response time, false alarms, broad-spectrum capability, maintenance requirements, cost, and the quantity of sensors needed for the various chemical agents at air intake locations. Therefore, the design strategy will be dependent on intelligence or operational detection of events rather than automated detection.

4-6.2 **Specific Design Strategies.** The specific design strategies associated with the levels of protection vary in the type of filtration provided, the air that is filtered, and the continuity of operation. The application of higher levels of protection includes the applications of all measures in lower levels of protection. Collective protection is also described by overpressurization class, which refers to the duration that the asset must be protected against the threat based on emergency operational procedures and the overpressurization that must be provided to resist particular wind speeds within the collective protection area.

4-6.2.1 **Very Low Level of Protection.** The strategy at this level of protection can be referred to as sheltering in place. It includes application of passive building element features to minimize air infiltration and the means to shut down the ventilation systems to limit dispersal of any agents that might infiltrate the building envelope.

4-6.2.2 **Low Level of Protection.** The strategy at this level of protection adds to that of the previous level of protection the application of high efficiency particulate air (HEPA) filters at air intakes. As a practical matter, however, the HEPA filters are generally installed in the central air-handling unit and they filter both the outside and recirculated air. A slight positive overpressurization of the building, referred to as Class II overpressure, should be added. The HEPA filtration should be run continuously and will remove biological and radiological agents.

4-6.2.3 **Medium Level of Protection.** The strategy at this level of protection also includes HEPA filtration and adds vapor adsorber systems with carbon filters to the outside air intakes to filter out chemical agents. It also provides either Class II or Class I overpressurization depending on operational considerations (see UFC 4-020-02). The filter system should be run continuously or in response to a threat or a heightened force protection condition.

4-6.2.4 **High Level of Protection.** The strategy at this level of protection includes HEPA filtration and vapor adsorber systems with carbon filters for both outside and recirculated air. It also includes Class II or Class I overpressurization, depending on operational considerations (see UFC 4-020-02). The filter system should be run continuously.

4-6.3 **Project Scope Implications.** The project scope implications for this tactic include building support systems, which were not included for the previous tactics.

4-6.3.1 **Sitework Elements.** Because the focus of this tactic is on keeping agents out of buildings, there are very limited sitework element implications. The only issues are in maintaining unobstructed space around buildings and avoiding locating buildings in depressions where air could stagnate.

4-6.3.2 **Building Elements.** The only implications to building element design are in designing building elements to minimize air infiltration and exfiltration. Modern energy efficiency design considerations go a long way toward achieving this design goal. In addition, windows should be inoperable and access to mechanical rooms and exterior ventilation system components should be secured. The considerations are the same for new construction and for existing buildings.

4-6.3.3 **Building Support Systems.** The most significant implications to project scope are in the heating, ventilating, and air conditioning (HVAC) systems. Fresh air intakes will need to be elevated to at least 3 meters (10 feet) as required by the *DoD Minimum Antiterrorism Standards for Buildings (UFC 4-010-01).* In addition, UFC 4-010-01 requires that the ventilation system be capable of being shut off from multiple locations throughout buildings in response to a threat. Other implications to the HVAC systems include isolating entry and delivery points from the remainder of the protected buildings and providing the filtration systems required to meet the applicable levels of protection. Those filtration systems as well as the overpressurization requirements may necessitate larger air handling units and will necessitate larger mechanical rooms. The considerations are the same for new construction and for existing buildings.

4-6.3.4 **Equipment.** Equipment is generally assumed for the purposes of this manual to be associated with detection and access control, both of which are applicable to the design strategies for this tactic. The equipment implications, therefore, are oriented to electronic entry control equipment and other equipment such as X-ray devices and metal detectors to support detection of contraband that might include chemical, biological, and radiological agents. This equipment would be located at entry and delivery points. At this time, equipment will not be considered to include chemical or biological agent detectors but may include radiological material detectors. The state of the art of chemical and biological agent detectors is not sufficiently advanced to incorporate such detectors into protective systems for buildings.

4-6.3.5 **Manpower and Procedures.** Manpower implications are limited to the people necessary to operate the equipment at the entry and delivery points. Procedures will have to be developed for such issues as how and when to shut down the HVAC systems in response to attacks and how to operate within the protected areas in terms of such things as opening and closing doors and entering and leaving buildings. In addition, there will be additional periodic maintenance requirements associated with the HVAC and filtration systems and with maintenance of other building elements to ensure minimal air infiltration and exfiltration.

4-6.3.6 **Expeditionary and Temporary Construction.** Generally the construction of expeditionary and temporary structures or the condition of buildings the DoD may occupy will limit opportunities for providing the kind of protection envisioned for this tactic directly into those projects. There are expedient shelters and transportable collective protection equipment that can be used, however. Those include self-contained shelters and liners that can be installed in tents or rooms, both of which include the necessary HVAC equipment to operate in a contaminated environment. Refer to UFC 4-024-01 for additional information on these systems.

4-7 **WATERBORNE CONTAMINATION TACTIC.** The assumption inherent in the design strategy for this tactic is that it takes large amounts of contaminants to contaminate a water supply. Of 38 likely chemical contaminants that could be entered into a small reservoir (on the order of 38,000 cubic meters or 10,000,000 gallons), 3 would require a tank car load, 19 would require a dump truck load, and 16 would require a station wagon load to create a dangerous concentration. To put that quantity of water into perspective, it represents the average daily consumption for a city of 100,000 people. In addition, most chemical and biological agents are removed by water treatment processes. Because of those facts, the focus of the design strategy for this tactic is on components of the treated potable water supply system. Another possible approach, which would require lesser amounts of contaminants, would be to introduce contaminants into the system by overpressurizing the system at water discharge points such as faucets and hydrants. That approach is also dealt with by protecting elements of the water distribution system and through physical security.

4-7.1 **General Design Strategy.** The general design strategy for this tactic is to protect treated potable water supply and distribution system components from the introduction of large quantities of contaminants at likely access points and from small quantities introduction into the system closer to or inside buildings through physical security. The general design strategy also includes providing alternate drinking water sources in the event that the water gets contaminated. It involves both contamination avoidance and treatment. The locations to which this design strategy is should be applied include the following:

- Water sources
- Treatment plants
- Treated water storage
- Water distribution system
- Building water distribution system (plumbing)

4-7.2 **Specific Design Strategies.** There are three levels of protection associated with this tactic. The specific design strategies associated with those levels of protection vary with the sophistication of the security of the water supply and distribution system components and the frequency of use of alternate drinking water sources. All three levels of protection include protecting against the equivalent of a low threat severity level forced entry attack to the applicable level of protection and the application of access controls.

4-7.2.1 **Low Level of Protection.** This level of protection provides access control to treated potable water supply and distribution system components based on operational and procedural measures only and protection against forced and covert entry using elements of the low level of protection for those tactics (described later in this chapter.) It does not include the application of intrusion detection systems. There are no additional treatment or alternate source requirements for this level of protection.

4-7.2.2 **Medium Level of Protection.** This level of protection provides access control to treated potable water supply and distribution components to the equivalent of the medium level of protection for the covert entry tactic and to the equivalent of the low level of protection for the forced entry tactic (both described later in this chapter.) It also includes backflow prevention devices to be installed on treated potable water distribution elements and for the provision of a standby point of use treatment system to be applied either for an individually targeted building or a cluster of buildings.

4-7.2.3 **High Level of Protection.** This level of protection provides access control to water supply and distribution components to the equivalent of the high level of protection for the covert entry tactic and to the equivalent of the medium level of protection for the forced entry tactic (both described later in this chapter.) It also includes backflow prevention devices as for the medium level of protection and adds the capability to detect contaminants at the targeted facility. Water treatment is handled through continuously operated point of use treatment systems, internal potable water production (as from a well) or from redundant water storage tanks.

4-7.3 **Project Scope Implications.** The project scope implications for this tactic are relatively limited with most resulting from consideration to forced or covert entry to water system components. This tactic also has protective systems for water distribution system elements and water storage that are not present for other tactics.

4-7.3.1 **Sitework Elements.** The project scope implications for sitework elements are limited to controlling access to the areas around water treatment plants. Because most such facilities are fenced for safety purposes, the additional project implications should be minimal. They would be limited to providing means to control access through gates. There should only be limited differences among the three levels of protection. Those differences will be in the sophistication of access control measures.

4-7.3.2 **Building Elements.**

4-7.3.2.1 **New Construction.** The implications to building elements are focused on access control and resistance to forced entry. The additional requirements will primarily be at buildings associated with water treatment and distribution or at locations in targeted buildings where the building water system could be accessed. The access control requirements may change building entry configurations and the forced entry resistance may change the construction of building components such as walls, doors, windows, and roofs.

4-7.3.2.2 **Existing Buildings.** For existing buildings, windows and doors may need to be replaced with forced entry resistant window and door assemblies or, in the case of windows, they may have forced entry resistant barriers added. Walls and roofs may have retrofits added to increase their forced entry resistance as described in the forced entry section below.

4-7.3.3 **Water Distribution System Elements.** Because there is a possibility of contaminants being introduced through discharge points such as faucets and hydrants through overpressurization, water distribution system components may be required to be fitted with backflow prevention devices. In addition, any other water distribution system components at which contaminants could be introduced will need to be secured against forced and covert entry. In most cases, the additional requirements will be limited to locks except as described in the paragraph on equipment below. The considerations are the same for new construction and for existing buildings.

4-7.3.4 **Water Treatment Elements.** The medium and high levels of protection potentially include the provision of point of use treatment systems. The implications to project scope include both providing and installing that equipment and making space for it.

4-7.3.5 **Water Storage.** Because the high level of protection may include drinking water storage, designers will have to determine appropriate water storage requirements. Those requirements will vary based on the climate and other factors. For example, water requirements will be higher in desert regions than in temperate regions. While estimation of water demand is beyond the scope of this UFC, an approximate quantity for planning purposes could be 8 liters per person per day (approximately 2 gallons per person per day). Those quantities could be provided based on the expected full time occupants of a building plus a percentage of that for the expected number of visitors per day. The percentage for visitors would vary based on how long visitors would be expected to stay. It might be larger for a building where visitors are likely to attend all day events as opposed to a building where visitors only stop briefly.

While overall water demand depends on other considerations such as toilet flushing, washing, industrial uses, and irrigation, for the purposes of addressing this threat, the focus should be limited to drinking water based on the assumption that most people could be evacuated from the building in response to a contamination event instead of staying there and operating. Where there is an operational need to provide water for washing, limited additional demand could increase storage quantities to 20 liters per person per day (approximately 5-1/4 gallons) or more.

The water storage requirements for the high level of protection are further complicated by the need for redundant storage. With that, one storage source can be used while the other is filled, allowing for testing immediately after filling and prior to use. The implications to project scope include both providing and installing the storage tanks with the appropriate contaminant sensors and making space for them.

4-7.3.6 **Equipment.** Project scope considerations for security equipment are limited to the medium and high levels of protection. Those levels of protection will add requirements for access control equipment and for intrusion detection equipment to detect aggressors as they attempt to access water distribution system elements and the water treatment site.

4-7.3.7 **Manpower and Procedures.**

4-7.3.7.1 **Manpower.** The implications for manpower are potentially to add guards at treatment plant entrances if they are not there already. Where the high level of protection applies, there may also be requirements for additional people to monitor intrusion detection systems if there are none monitoring such systems already or if the additional equipment associated with these requirements overwhelms existing personnel capabilities.

4-7.3.7.2 **Procedures.** Additional procedural measures will primarily be associated with access control to water distribution system elements. In addition, at times when building occupants are to be consuming water from the alternate sources provided, there will need to be procedures to inform building occupants of that requirement. There should also be procedures to shut off drinking fountains and other water sources that could be used for drinking water. Additional procedures may be necessary to replace consumed water and monitor its quality.

4-7.3.7 **Expeditionary and Temporary Construction.** Water distribution in expeditionary environments often does not involve the level of infrastructure that is present in fixed installations. Often drinking water requirements are met completely with bottled water. Where there is a distribution infrastructure, however, much of the guidance above may apply to water distribution in expeditionary environments, but it will have to be tailored to the specific situation. In general, the same strategies of securing water sources and distribution and potentially providing alternate drinking water sources apply.

4-8 **WATERFRONT ATTACK.** For the purposes of this UFC, waterfront attacks are considered to come from the water. Landside attacks are covered by the other tactics in this UFC. Because this tactic involves attacks from the water, the design strategies will be based on detection and delay of and response to intruding watercraft. Requirements relating to waterfront security will also be significantly affected by Force Protection Conditions.

4-8.1 **General Design Strategy.** The general design strategy for the waterfront attack is to lay out and maintain defense in depth through the application of barriers, electronic security systems, and operational procedures. The defense in depth involves the following "zones."

4-8.1.1 **Assessment Zone.** The Assessment Zone is an area well beyond the government's property line. Vessels approaching the waterfront can be detected and patrol craft can be vectored to intercept them.

4-8.1.2 **Warning Zone.** The Warning Zone is an area just outside the government's property line. It is delineated by floating signage, signs on pilings, or other lines of demarcation at the property line. Watercraft in the warning area are often paralleled by patrol craft.

4-8.1.3 **Threat Zone.** The Threat Zone is the waterside area between the government's property boundary and the floating barrier. The inner boundary of the Threat Zone is marked with floating barriers.

4-8.1.4 **Engagement Zone.** The Engagement Zone is the area between a line of floating barriers and an asset. Watercraft entering this area are engaged and stopped using active defense measures.

4-8.2 **Specific Design Strategies.** Specific design strategies for this tactic involve increasing application of countermeasures.

4-8.2.1 **Low Level of Protection.** At the low level of protection, there are no special requirements on waterways, but restricted areas will be established with buoys and signs.

4-8.2.2 **Medium Level of Protection.** At the medium level of protection, a security zone will be established around the asset. Where possible that should be coordinated with the Coast Guard or its equivalent. This level of protection will also include harbor patrol boats and may include water barriers able to stop most small boats.

4-8.2.3 **High Level of Protection.** The high level of protection will include both waterside electronic security systems and water barriers designed to stop most powerful small boats and provide at least 5 minutes of delay.

4-8.2.4 **Very High Level of Protection.** The very high level of protection will incorporate the same measures as the high level of protection, but the water barriers will be able to stop all but the most powerful small boats.

4-8.3 **Project Scope Implications.**

4-8.3.1 **Sitework Elements.** For this tactic, the sitework elements are water barriers as described above and exterior electronic security systems as described below.

4-8.3.2 **Building Elements.** Because the focus of this tactic is on waterside approaches, building elements are only issues to the extent that an explosive laden watercraft could get near a building or that the applicable direct fire weapons effects would impact the building construction. In those cases, refer to the sections on vehicle bombs and direct fire weapons.

4-8.2.3 **Equipment.** Equipment for this tactic includes waterside electronic security system equipment such as closed circuit television (CCTV), surface or swimmer detection, and underwater detection.

4-8.2.4 **Manpower and Procedures.** There are few facility related issues related to manpower and procedures, but there do need to be qualified people to respond to watercraft incursions, and their response time may affect the distances associated with the various zones associated with the defense in depth. There may also be facility issues relating to supporting the patrol personnel and their patrol craft.

4-8.3.5 **Expeditionary and Temporary Construction.** The same principles apply in the expeditionary environment, but the nature of the barriers and the boundary demarcation may be different in that it is likely to be of a temporary nature.

4-9 **FORCED ENTRY TACTIC.** In this tactic aggressors are assumed to force their way through building elements or barriers. Attempts to gain entry through stealth are covered under the covert entry tactic.

4-9.1 **General Design Strategy.** Based on the above assumption, the general design strategy for this tactic is to detect aggressors either prior to their reaching barriers or as they attempt to breach them and then to provide sufficient delay to forced entry in the construction of those barriers to allow responding forces to arrive and defeat the aggressors before they can compromise the asset. Inherent in this strategy, therefore, is that there is an intrusion detection system that provides an alarm to a monitoring station in response to intrusion and that there is a response force that can respond to an alarm and reach its location before aggressors are able to breach the barriers between that point and the assets being protected.

4-9.2 **Specific Design Strategies.** The specific design strategies associated with the different levels of protection vary by the amount of delay provided and the sophistication of the intrusion detection. Note that the levels of protection have specific delay times associated with them. Those delay times are generalized goals, but if the planning team is confident that response times are either more or less than those associated with the applicable levels of protection, the applicable delay times may have to be adjusted. All building elements in the protective envelope that provides the delay time must provide at least the minimum delay time associated with the applicable level of protection based on the assumption that aggressors will always be able to identify the weakest element in the envelope. That protective envelope may be all in one layer, such as the shell of a room or the exterior of a building, or it may encompass multiple layers such as the building exterior and multiple rooms arrayed in rings around the asset. The detection element of the protective system may also include closed circuit television to assess the validity of alarms.

4-9.2.1 **Low Level of Protection.** The specific design strategy associated with this level of protection incorporates an envelope of building elements (walls, doors, windows, roofs, etc.) surrounding an asset that provides a delay time to the specified threat tools of at least 1 minute. In addition, the protective system incorporates intrusion detection sensors at all operable openings. Entry though other building elements would be detected through operational procedures, such as roving patrols.

4-9.2.2 **Medium Level of Protection.** The specific design strategy associated with this level of protection incorporates an envelope of building elements (walls, doors, windows, roofs, etc.) surrounding an asset that provides a delay time to the specified threat tools of at least 5 minutes. It also incorporates a complete ring of detection covering all possible approaches through the protective envelope.

4-9.2.3 **High Level of Protection.** The specific design strategy associated with this level of protection incorporates an envelope of building elements (walls, doors, windows, roofs, etc.) surrounding an asset that provides a delay time to the specified threat tools of at least 15 minutes. It also incorporates a complete ring of detection covering all possible approaches to the asset. That ring must include two different sensor phenomenologies covering each approach.

4-9.2.4 **Very High Level of Protection.** The specific design strategy associated with this level of protection incorporates the same delay and detection elements as the high level of protection, but the delay time is at least 30 minutes.

4-9.3 **Project Scope Implications.**

4-9.3.1 **Sitework Elements.** There will commonly be few sitework considerations that have any significant cost implications. The most significant issue is establishing unobstructed spaces around buildings or other enclosures housing assets, which in the case of inhabited buildings is required by the minimum standards in UFC 4-010-01. In general, sitework elements such as fences and walls, which may be considered barriers to forced entry, provide minimal delay. Therefore, they are not commonly used as part of a forced entry resistant protective system when the asset is stored within a building.

4-9-3.2 **Building Elements.** Building elements are a critical part of the protective system for protecting against forced entry, and the implications on their construction may be significant depending on the level of protection and the tools associated with the threat.

4-9.3.2.1 **New Construction.** In general, the walls and roofs will have to be more substantial than common lightweight conventional construction. In addition, the doors will be stronger and will have more robust locksets and hardware than conventional doors and windows will either be heavier and tougher or they will have external barriers. There may also have to be barriers installed over other potential man-passable openings (greater than 620 square centimeters or 96 square inches) such as air vents and utility openings.

4-9.3.2.2 **Existing Buildings.** Similar to new construction, walls and roofs will have to be more substantial than conventional construction, but in the case of existing construction, obtaining that will require retrofits of additional building materials. Windows and doors will either be replaced with forced entry resistant window and door assemblies or, in the case of windows, they may be fitted with forced entry resistant window barriers.

4-9.3.3 **Equipment.** Equipment, in the context of the design strategy for this tactic, is predominantly intrusion detection equipment. Intrusion detection systems include sensors, alarm monitoring systems, and data transmission media to get the signals from the sensors to the alarm monitoring system. The scope of the sensor application depends on the level of protection, how much space is monitored, and the kinds of sensors used. The important goal to keep in mind is that detection must occur prior to any forced entry resistant barriers for the system to work effectively.

Some locations may already have central monitoring stations; in which case, there may be opportunities to add to an existing monitoring system. In others, new monitoring stations may have to be established. Such considerations, in addition to the distance from the protected building to the monitoring station, make it difficult to easily estimate the cost implications of an intrusion detection system.

In addition to the intrusion detection system, equipment may include closed circuit television cameras to assess the alarms. In those cases, there will have to be enough cameras to view every alarm point or zone. Another alternative is to respond to every alarm with a response force of some kind. The cameras may allow for avoidance of responses to false alarms and may provide additional information to response forces if the alarm is valid, such as how many aggressors there are and whether or not they're armed. Lastly, in many cases there may be electronic entry control systems within the scope of the project or existing in a building. That will be particularly true where the convert entry tactic applies. In those cases, the intrusion detection system may have coordinated or integrated with the entry control system. Access control does not need to be very sophisticated if only the forced entry tactic is a concern.

4-9.3.4 **Manpower and Procedures.** Manpower and procedures are critical elements of any protective system designed to protect against forced entry. The design of the protective system should optimally be coordinated with available manpower and local procedures, for both response and alarm monitoring. Where there are no such capabilities or where what exists is inadequate, the designers will have to work with the applicable law enforcement authorities to coordinate the system design and the procedures.

4-9.3.5 **Expeditionary and Temporary Considerations.** The nature of the expeditionary and temporary environment and the facilities commonly available does not commonly lend itself to sophisticated intrusion detection systems and forced entry resistant construction. There are forced entry resistant containers available, and valuable assets may be stored in other common containers, but hardening of buildings or structures is generally economically infeasible. Because of those considerations, protection against forced entry in the expeditionary and temporary environment is commonly manpower intensive, involving the use of guards. Those guards may be supplemented by intrusion detection systems such as perimeter systems or alarms on containers; however, successfully protecting assets is likely to depend on a rapid response.

4-10 **COVERT ENTRY TACTIC.** The underlying assumption for the covert entry tactic is that aggressors will not force entry because their goal is to employ stealth to access assets without anybody knowing they have done so. Those aggressors may be outsiders or they may be people who legitimately have access to facilities, such as employees. The latter are commonly referred to as insiders, and they provide additional challenges to designers. Covert entry and forced entry are often both included in threats to assets, in which case the designers need to coordinate the protective measures for both tactics.

4-10.1 **General Design Strategy.** Because the assumption inherent in protecting against this tactic is that aggressors will not attempt to force entry, the general design strategy is limited to providing construction that presents a barrier between potential aggressors and assets and then providing access control through those barriers. Where only outsiders are a concern, that approach can be applied to entire buildings or large areas of buildings. Where insiders are a concern, there may have to be compartmentalization within the building.

4-10.2 **Specific Design Strategies.** The levels of protection vary in the sophistication of the access control measures associated with them. All four level of protection involve using access control measures and construction that allows assets to be segregated from unauthorized personnel.

4-10.2.1 **Low Level of Protection.** The design strategy for the low level of protection is to prevent the use of easily duplicated identification badges as a method of covert entry.

4-10.2.2 **Medium Level of Protection.** The design strategy for the medium level of protection is to prevent the use of easily duplicated identification badges or stolen electronic access control badges as a method of covert entry. It also involves provision of protection for mechanical locking systems to prevent bypassing.

4-10.2.3 **High Level of Protection.** The design strategy for the high level of protection is to prevent the use of electronic access control cards duplicated using sophisticated electronic methods through the use of primary and secondary credential systems (i.e., card and personal identification number (PIN) or retina, signature, or voice recognition, etc.). It also involves initiating tailgating policies or installing prevention equipment and providing protection for mechanical locking systems to prevent bypassing.

4-10.2.4 **Very High Level of Protection.** The design strategy for the very high level of protection is the same as the high level of protection with the addition of providing equipment that will detect the presence of weapons or material that could be used to carry out terrorist or criminal acts.

4-10.3 **Project Scope Implications.** The project scope implications for this tactic are predominantly in access control, but there are considerations in the other common areas as well.

4-10.3.1 **Sitework Elements.** Sitework issues for the covert entry tactic where assets are stored in buildings are limited to minimizing opportunities around buildings for aggressors to hide. That goal is effectively solved for inhabited buildings by applying the unobstructed space requirements from UFC 4-010-01. The only other area where sitework considerations are an issue is where assets to which access must be controlled are stored in other than buildings. In those cases, the assets will need to be surrounded with a barrier such as a fence such that potential aggressors cannot access the assets without breaching the barriers. The assumption therein is that they will not breach barriers because it would subject them to potential detection.

4-10.3.2 **Building Elements.** The implications on project scope on building construction are limited. Because of the assumption that aggressors will not force entry through barriers, walls, floors, ceilings, and roofs surrounding asset need only be sufficiently constructed such that breaching them leaves evidence of the act. Therefore, common lightweight construction is adequate. Windows must either be capable of being locked or be inoperable. Doors must also be lockable with door hardware that cannot be defeated without leaving evidence of the act. The only other building oriented issue is in building layout. The architectural layout of buildings will have to support separating assets into areas to which access can be controlled. This may be complicated where insider considerations must be taken into account, in which case the building layout may need to support compartmentalization. The considerations are the same for new construction and for existing buildings.

4-10.3.3 **Equipment.** This is the area where the project scope will be most affected. The primary implications in this are access control equipment, the requirements for which are summarized below. Where the threat is limited to outsiders, equipment can be provided at the building exterior or at a particular area. Where insiders are a concern, there may be access control requirements at multiple points interior to the building to support compartmentalization.

4-10.3.3.1 **Low Level of Protection.** The low level of protection requires installation of single-door mechanical or electronic access control at primary entrances and locks or internal emergency exit devices on all other doors.

4-10.3.3.2 **Medium Level of Protection.** The medium level of protection requires installation of a centralized electronic access control system capable of restricting access times for registrants and immediately removing stolen card credentials from the system. Those systems would be applied at primary entrances to controlled areas, It also requires installation of an internal intrusion detection system to detect after-hours entry and entry through access-controlled doors, emergency exit doors, and windows at all times.

4-10.3.3.3 **High Level of Protection.** The high level of protection requires installation of electronic access control with biometric recognition or a personal identification number (PIN) as a secondary credential, in conjunction with tailgating prevention measures. Tailgating is where one person enters with another person without the second person's access authority being checked, such as an unauthorized person forcing an authorized person to help him or her get access. In addition, closed circuit television may be provided to assess entry authority. The high level of protection also includes the same intrusion detection requirements as the medium level of protection.

4-10.3.3.4 **Very High Level of Protection.** The very high level of protection has the same requirements as the high level of protection with the addition of positive tailgating prevention hardware, such as turnstiles or mantraps. Is also includes the application of CCTV to assess entry authority, installation of metal and explosive detectors to prevent introduction of weapons into secured areas, and the same intrusion detection requirements as the medium level of protection.

4-10.3.4 **Manpower and Procedures.** Manpower and procedures are a critical part of protection against covert entry. Designers must incorporate manpower and procedures into the system design, which involves coordination with building users and supporting law enforcement personnel. In some cases, assigning guards to control access may eliminate the need for an access control system. For the low and medium levels of protection guards checking identification that includes photographs of authorized personnel may be adequate. In the case of the medium level of protection, however, a badge exchange procedure would have to be implemented. That procedure involves two distinct badges for each authorized person. A person entering a controlled area must surrender his or her identification to a guard who trades it for a badge that is under the guard's control. That system requires aggressors to forge both identification under their control and badges under the control of guards.

Where guards are not used to directly control access, there are still manpower requirements in that there must be procedures to respond to unauthorized entry attempts. In addition, where screening equipment is used, there will have to be personnel to operate it and procedures developed on how to operate it.

In addition, the application of the two-person rule may prevent insiders from breaching security. In the two-person rule, one person can never be alone in the vicinity of a protected asset. That way two employees would have to be co-opted to allow compromising an asset. The two-person rule can be a strictly procedural measure or it can be enforced through application of access control equipment that requires two people to provide the required credentials before access is granted.

4-10.3.5 **Expeditionary and Temporary Construction.** There are commonly limited opportunities to provide complex access control systems in the expeditionary and temporary environment, so the approach tends to be manpower intensive. There are opportunities to store assets in safes or containers when they are not in use. In those cases the containers need to be able to be locked with locks that cannot be defeated without leaving evidence.

4-11 **VISUAL SURVEILLANCE TACTIC.** The design strategy for mitigating this tactic involves preventing unauthorized people from seeing assets that users do not want to be seen.

4-11.1 **General Design Strategy.** The general design strategy for this tactic is simply to prevent aggressors from seeing assets.

4-11.2 **Specific Design Strategy.** There is only one level of protection associated with this tactic, so the specific design strategy is the same as the general design strategy. Because there is only one level of protection, either protection is provided or it is not.

4-11.3 **Project Scope Implications.** Project scope implications are minimal. They involve blocking sightlines to assets from areas outside of the control of the facility occupants. Identifying potential vantage points from which aggressors might observe assets is a key to the design strategy for this tactic. Once those points are identified, measures can be implemented to block those sightlines.

4-11.3.1 **Sitework Elements.** Sightlines may be blocked using such measures as walls or fences with obscuration screening. Also, vegetation such as trees can be used to block sightlines. Note that where vegetation is used, it should be a variety that maintains its foliage year-round.

4-11.3.2 **Building Elements.** Employing building elements to block sightlines to assets is the most effective means of providing protection against this tactic. One approach is to lay out buildings such that no assets subject to observation from outside the building are in exterior rooms or that windows are laid out and assets are located such that the assets cannot be viewed through the windows. Where that opportunity does not exist, it will be necessary to avoid transparent building elements (windows, doors, and skylights) or provide means to obscure vision through them. Common means to obscure vision through windows are to install reflective or tinted window treatments such as reflective fragment retention film or to use figured or translucent glazing. Another solution is to use drapes or blinds, but they require operational discipline to ensure they are closed when sensitive assets are in view. Note that where reflective films or glazings are used, they will be ineffective at night, so drapes or blinds will still have to be incorporated into the project scope. The considerations are the same for new construction and for existing buildings.

4-11.3.3 **Equipment.** There are no equipment implications associated with this tactic.

4-11.3.4 **Manpower and Procedures.** The only issue with respect to procedures for this tactic is that there will need to be procedures in place to ensure that drapes or blinds are closed when they need to be or that sensitive assets are kept away from locations where unauthorized personnel can view them.

4-11.3.5 **Expeditionary and Temporary Construction.** There are no special considerations for expeditionary and temporary construction. The same principles apply as to fixed facilities but the options for providing obscuration may be more limited.

4-12 **ACOUSTIC EAVESDROPPING.** The design strategy for mitigating this tactic involves keeping aggressors from hearing audible information from outside of controlled areas. This UFC does not address the use of covert electronic listening devices placed within buildings. That is within the scope of technical security, which is dealt with by others and is outside the scope of facility design.

4-12.1 **General Design Strategy.** The general design strategy for this tactic is to design building exteriors or rooms within buildings that have construction that attenuates sound transmission so that secure conversations can be held in the building.

4-12.2 **Specific Design Strategies.** The design strategies associated with the various levels of protection all involve providing walls, doors, window, ceiling, floor, and roof construction that provides the required sound attenuation. The only difference between levels of protection is the level of sound attenuation provided. Sound attenuation is categorized by Sound Transmission Class (STC). The STC ratings for each level of protection and the level of sound attenuation they provide are summarized in Table 4-5.

4-12.3 **Project Scope Implications.** The scope of project changes is mostly limited to building construction, and then only in those areas where the building user needs to be able to have secure conversations.

4-12.3.1 **Sitework Elements.** The only implications to sitework design are in keeping aggressors from getting near enough to areas of buildings where secure conversations might be held. That requirement will generally be met by providing the unobstructed space required for inhabited buildings by UFC 4-010-01.

4-12.3.2 **Building Elements.**

4-12.3.2.1 **New Construction.** The scope of additional construction requirements is dependent on how much of the building needs to meet the required STC rating. Beyond that, in general, construction to meet the required STC ratings is within the scope of conventional construction. The higher STC ratings may require the use of masonry or concrete for walls and roofs for exterior construction, but they can commonly be provided through additional insulation and special construction details for interior construction. Doors and windows meeting other than the lowest STC rating in Table 4-4 will commonly have to be purchased as tested STC rated assemblies.

4-12.3.2.2 **Existing Buildings.** Considerations for existing buildings are similar to new construction, but retrofits to existing construction may require adding building materials to the existing walls, roofs, ceilings, and floors to achieve the applicable STC ratings. Doors and windows will have to be replaced with STC rated assemblies.

Table 4-4. STC Ratings for Levels of Protection

Level of Protection	STC Rating	Sound Attenuation
Low	30	Loud speech can be understood fairly well. Normal speech cannot be easily understood.
Medium	40	Loud speech can be heard, but is barely intelligible. Normal speech can be heard only faintly, if at all.
High	45	Loud speech can be heard only faintly, but cannot be understood. Normal speech is inaudible.
Very high	50	Very loud sounds on the order of brass musical instruments can be heard only faintly or not at all.

4-12.3.3 **Equipment.** There are generally no equipment requirements associated with this tactic.

4-12.3.4 **Manpower and Procedures.** There are limited requirements for manpower and procedures associated with this tactic, and there are none that have to be coordinated into designs. The extent of these measures is to ensure that no unauthorized personnel are allowed to get close enough to the perimeters of secure conference rooms to listen to the secure conversations.

4-13 **ELECTRONIC EMANATIONS EAVESDROPPING.** The design strategy for mitigating this tactic involves preventing sensitive electronic emanations from being intercepted by aggressors from outside of controlled areas. Much of the specific guidance associated with mitigating this tactic involves what is known as TEMPEST protection. The requirements for TEMPEST protection are established based on TEMPEST assessments, which are performed by the applicable elements of the intelligence community. Those assessments, the criteria on which they are based, and much of the criteria on which mitigation measures are based are classified. The scope of this UFC will be to reflect the implications to construction if certain measures are specified as a result of the TEMPEST assessment.

4-13.1 **General Design Strategy.** The general design strategy for this tactic will follow one or more of the following depending on the TEMPEST assessment.

- Follow applicable information system security policy, which means no specific TEMPEST measures are required.
- Provide controlled space outside the area where sensitive information is being processed. This reflects the fact that emanations attenuate with distance.
- Provide TEMPEST shielded equipment.
- Provide separation between electrical and electronic circuits, components, and equipment that process classified and unclassified information.
- Provide TEMPEST shielded enclosures.

4-13.2 **Specific Design Strategy.** There is only one level of protection associated with this tactic for the purposes of this UFC. That reflects the fact that no requirements established within the scope of this UFC will govern which of the design strategies above are applicable. The requirements will be established through the TEMPEST assessment.

4-13.3 **Project Scope Implications.** Only two of the design strategies above have significant project scope implications. Those are described below.

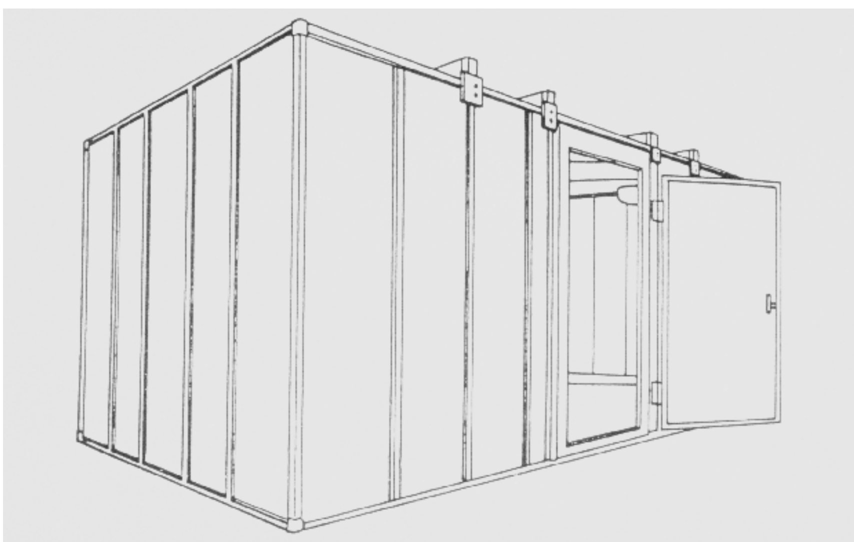
4-13.3.1 **Sitework Elements.** There are generally no significant project scope implications associated with this tactic. The only one that may have implications is the establishment of controlled space. The TEMPEST assessment may result in a requirement to establish a controlled area outside a protected building, which could require additional unobstructed space beyond that required for inhabited buildings by UFC 4-010-01. It could also require that the controlled space be fenced.

4-13.3.2 **Building Elements.** Requirements established as the result of TEMPEST assessments will have the most impact on building elements.

4-13.3.2.1 **New Construction.** To a minor extent the results of TEMPEST assessments could affect building layout by establishing a need to create controlled space around an area in which classified information is processed. Generally, however, the significant implications to building elements will be where a TEMPEST shielded enclosure is required. In those cases the entire building envelope of the area in which classified information is processed will need to be constructed using specialized TEMPEST shielding. That shielding is very expensive. In addition, special doors and windows are required and any penetrations of the envelope such as utility penetrations need to have emanations filters. Another option would be to provide a modular TEMPEST shielded enclosure such as the one shown in Figure 4-12 if the area requiring shielding is small enough. Cost information in the cost appendices does not include modular enclosures.

4-13.3.2.2 **Existing Buildings.** Considerations for existing buildings are similar to new construction, but retrofits to existing construction may require adding TEMPEST shielding to the existing walls, roofs, ceilings, and floors. Doors and windows will have to be replaced with TEMPEST shielded assemblies. Alternatively, as for new construction, where the areas requiring shielding are small enough, modular TEMPEST shielded enclosures can be provided.

Figure 4-12. Modular TEMPEST Enclosure



4-13.3.3 **Equipment.** Where TEMPEST shielded equipment is required as a result of the TEMPEST assessment, that equipment generally will be outside the scope of construction funding. It will commonly be installed by the users after construction is complete. The only area that has significant implications to equipment that falls within the scope of construction funding is in separation of between classified and unclassified circuits. That requirement may require additional conduit and conductor.

4-13.3.4 **Manpower and Procedures.** There may be many procedural requirements that need to be implemented as a result of the TEMPEST assessment, but they are beyond the scope of this UFC to describe and most will have limited implications to the scope of the project.

CHAPTER 5

MASTER PLANNING CONSIDERATIONS

5-1 **INTRODUCTION.** Master planning is also referred to as comprehensive planning, regional planning, land use planning, and facilities planning. For the purposes of this UFC it refers to a process by which an entity (government, base, installation etc) is concerned with documentation, planning and implementation of the long term goals, policies, and action strategies for a specific physical area. Its focus is usually long term (10-20 years) but may include near and mid-term strategies. The result is usually a "blueprint" for the physical development of a particular geographic area. Among DoD components, the master planning process is intended to provide a commander with a broad, long-term picture of facility needs and land use for an installation or base. In many ways the process is similar to the municipal planning process employed by cities in their attempts to anticipate growth and program improvements, which is appropriate because installations are effectively small cities. Each of the services has its own approach to "master planning" that is unique in terms of details, nomenclature and process, yet each attempts to provide the service with a long term policy guide for the physical development of installations. The Army and Marine Corps use the term Master Plan, and the Air Force refers to it as the General Plan. A number of land/facility planning processes are used by the Navy; however, the Regional Shore Infrastructure Planning process is the method that corresponds most closely with the recognizable master planning process.

Many security and antiterrorism objectives can be achieved through the master planning process. The least costly and often the most effective protection measures are those incorporated during this process. Implementing appropriate security and antiterrorism measures as part of master planning can preclude the need for piecemeal and costly security enhancements later on. That is particularly the case for issues relating to antiterrorism because of issues such as vehicular control and standoff distance.

It is also important to remember that the nature of the threat is ever changing. Some degree of security should be provided during master planning, with consideration given to increased or enhanced protection at times of increased threat. Security and antiterrorism objectives must be balanced with other planning objectives, such as the efficient use of land and resources, area development planning, and vehicular access and circulation, and they must take into account existing physical, programmatic, and fiscal constraints.

5-2 **SECURITY AND ANTITERRORISM PLANNING.** Security and antiterrorism planning is a parallel, but separate discipline that has its own DoD and service regulations and instructions. Security and antiterrorism requirements, responsibilities, and management controls are well defined by directives, instructions, regulations, and guides at all levels; however, those documents do not acknowledge their existence in broader based land and facility planning. Because of that, security and antiterrorism planning and land/facilities planning are generally accomplished independently using distinctly separate processes.

DoD protective design guides, standards, criteria, and vulnerability assessment programs stand as models, and are used by agencies and organizations throughout the world to implement needed security upgrades and to improve capabilities to mitigate vulnerabilities associated with terrorist attacks and criminal acts. While security and antiterrorism requirements are being addressed in Military Construction, minor construction, and other short-term projects, there is a general lack of security and antiterrorism guidance, coordination, and communication on long term planning issues such as land use, space management, and area development. Part of the problem might be attributed to the fact that security and antiterrorism tend to be more focused on the near term and directed at individual facility planning and design. Mitigation options to patch or fix vulnerabilities are typically short-term remedies or are incorporated into new construction or major renovations, modifications, repairs, and restorations of individual facilities.

There is abundant experience that demonstrates that the incorporation of improved security, protective, and response and recovery elements into new construction and at times of major rehabilitation of facilities are factors of two to ten times less expensive than upgrading security and protective systems in operating facilities. This cost differential can be even larger when life cycle costing is analyzed because quick reaction responses typically employ larger numbers of people. Well designed solutions, incorporating new and innovative uses of appropriate technology, Crime Protection Through Environmental Design (CPTED) concepts, and other architectural elements, can maximize security while minimizing operating costs.

5-3 **ISSUES IN MASTER PLANNING.** The master planning process provides a suitable framework for long-term security and antiterrorism planning and programming. Security and antiterrorism and land/facility planning converge at several component levels of master plan development, to include the following.

5-3.1 **Land Use Planning.** In most cases, integration of antiterrorism measures at the master planning level will increase the land area needed for individual facilities. Accordingly, future land use plans must take proposed antiterrorism measures into account when calculating land area requirements. Open circulation and common spaces on an installation, which are desirable from a conventional design perspective, may be undesirable from an antiterrorism perspective. Security considerations can be integrated into planning in such a way as to complement, rather than compete with other planning elements. For example, open space provides a number of mutual benefits. If the space is impassible for vehicles such as the case of a wetland or densely vegetated area, it provides not only environmental and aesthetic amenities, but helps to prevent vehicle intrusion as well. Permeable open space allows storm water to percolate into the ground, while enhancing surveillance and standoff distances and reducing the need for culverts, drainage pipes, and other site access or concealment opportunities. Plans must also consider high risk land uses with high concentrations of personnel, as well as off-base adjacent land use and zoning plans for potential development that may impact security of the installation. For example, planners must take into account adjacent land uses (internal and external) that could facilitate attacks or may be potential targets themselves, such as off-site roads, concealment areas for sniper attacks, or internal or external fuel storage or distribution points. Consider the following:

- When preparing land use plans, locate high-risk land uses in the interior of the installation. High-risk land uses contain high concentrations of personnel, such as administrative, community, and housing areas.

- Consolidate high-risk land uses to take advantage of opportunities for security efficiency such as minimized entry control points.

- Assess off-base adjacent land use and zoning plans for potential development that might impact security within the installation.

- When selecting a site for a facility, consider its location relative to the installation perimeter. Maximize the distance between the perimeter fence and developed areas, providing as much open space as possible inside the fence along the installation perimeter.

- When selecting a site for a facility, consider the facility design tradeoffs between the fact that elevated sites generally enhance surveillance of the surrounding area and the fact that adjacent high terrain or structures outside the base boundary may allow observation of on-base areas by outsiders.

- Recognize that dense vegetation in proximity to a facility can screen covert activity and should be avoided. Either avoid such areas or plan to remove some of the vegetation.

- Avoid low-lying topographic areas when siting facilities because airborne chemical, biological, and radiological agents, which are commonly heavier than air, can be trapped in those low-lying areas.

5-3.2 **Site Planning and Space Management.** Defensible space, access control, and standoff distance are key drivers in all aspects of development planning and site selection. The placement of buildings offers some challenges to security and antiterrorism and installation master planning. For example, clustering buildings or concentrating people, property, and operations in a single location increases opportunities for collateral impacts and single point vulnerabilities. On the other hand, grouping high-risk activities and concentrating personnel and critical functions in a cluster can provide opportunities for maximizing standoff distance and for creating defensible space. While the dispersal of buildings, people, and operations across an installation reduces the risk that an attack on any one location will impact others, such dispersal could have an isolating effect that reduces the effectiveness of existing security provisions, increases the complexity of emergency response, and creates less defensible space. Tradeoffs need to be carefully considered by planners; however, as illustrated in Figure 5-1, consolidating facilities that are functionally compatible and have similar threat levels reduces the perimeter area to be protected, limits access points, and results in defensible space that can be protected more efficiently. Other development or space management considerations include:

- Consider placement, orientation, and proximity of facilities with common functional uses (operations, administrative, support, logistics, housing etc) or similar threat levels to maximize opportunities for more efficient security.

- Avoid collocating high risk operations with low risk operations.

- Avoid locating facilities considered to be high risk in areas near uncontrolled public areas.

- Consider siting facilities to maximize opportunities for observation from nearby facilities as illustrated in Figure 5-2.

- Where possible, provide separation distances of at least 10 meters (33 feet) to minimize collateral damage in an explosive or indirect fire event.

- Consider locating safe havens or collective protection facilities with appropriate protection where large numbers of people could congregate in the event of an attack such as a chemical attack.

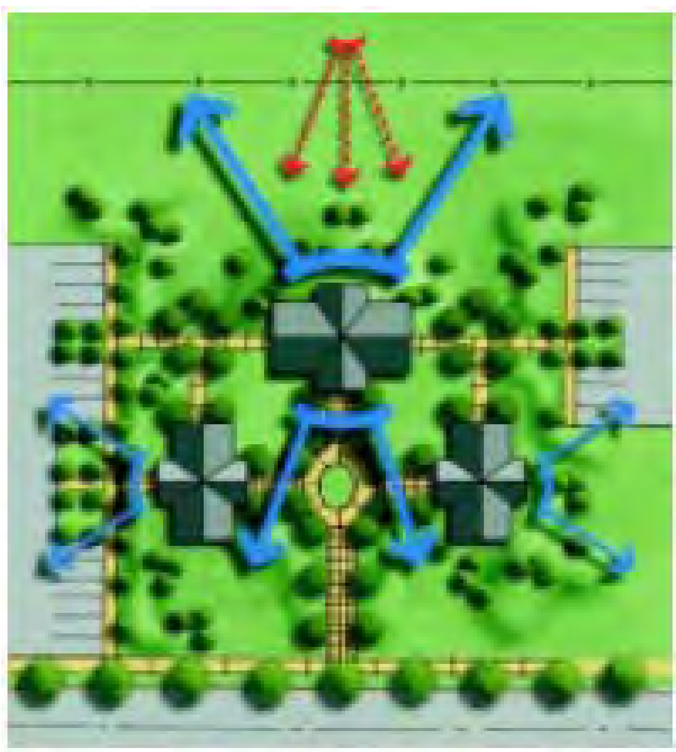
- Where possible, isolate loading docks and mail rooms to minimize the effects of explosives detonate within them on surrounding areas and other areas within the buildings. Where possible separate loading docks from other service areas and utility mains by at least 15 meters (approximately 50 feet.) Likewise, locate mail rooms on exterior walls of buildings away from main entrances or areas containing critical utility services.

5-3.3 **Vehicle Access and Circulation.** Vehicle bomb threats are among the most severe terrorist threats that might be expected on an installation. Most of the mitigating measures for such attacks are applied either at entry control points or at individual buildings. There are, however, some master planning oriented considerations that can reduce requirements for countermeasures to resist these attacks.

5-3.3.1 **Entry Control.** Controlling which vehicles gain access through controlled perimeters and controlling what those vehicles carry is a central factor in protecting against vehicle bombs. While design of entry control points is both beyond the scope of this UFC and not specifically a master planning issue, there are significant master planning considerations in establishing entry control points. The most significant such issue is establishing the appropriate number of entry control points. That number will be based on the number of vehicles that must enter the installation or interior controlled

Figure 5-1. Consolidated vs. Separated Facilities

Figure 5-2. Opportunities for Observation from Adjacent Facilities



perimeter and the number of personnel available to operate them. Also, because entry control point design to accommodate large trucks is more demanding than design to support personal and similar vehicles, master planners should consider establishing separate entry control points for trucks. The remaining significant master planning issue for entry control points is to ensure that the necessary space for them is figured into the master plan.

5-3.3.2. **Vehicle Circulation.** There are a number of goals relating to controlling potential threat vehicles that have master planning implications. The primary ones are keeping vehicles as far from buildings to which they might be a threat as possible, controlling their speed, and controlling their approaches. Keeping vehicles away from buildings can be addressed during site design for individual buildings, but it can also be addressed through measures such as road routings, road closures, and road restrictions, all of which have potential master planning issues. Vehicle speed can be addressed through such measures as creating curves in roads through road design, application of barriers, traffic calming devices, and traffic circles. Controlling approaches to buildings generally is done through road and parking lot configuration and closures. While parking lot entrance and layout is predominantly a facility planning issue, they can have an impact on master planning in that they may affect adjacent roads and traffic patterns. Figures 5-3 and 5-4 illustrate some of these principles of vehicle circulation through master planning. Consider the following:

- Where possible, designate centralized delivery points for commercial vehicles and limit the routes those vehicles use to access those points.

- Route roads away from buildings to which vehicle bomb threats may apply.

- Limit road access near buildings to which vehicle bomb threats may apply through road removal, road closures, and road restrictions. Figure 5-5 illustrates road closures to establish standoff distance to a building.

- Control vehicle speed by designing sharp curves into roadways through road design or placing barriers to create “serpentines,” employing traffic calming devices, or building traffic circles.

- Provide centralized parking to multiple buildings to the extent possible to maximize opportunities to provide standoff between parking and buildings.

- Eliminate straight-line approaches to buildings by rerouting or closing nearby roads and relocating parking lot entrances. See figure 5-6.

- Design parking lots to limit speed through parking layout and application of planted areas as shown in Figure 5-7.

CHAPTER 6

PROJECT COST DEVELOPMENT

6-1 **INTRODUCTION.** This UFC can be used to develop programming level cost estimates for new construction and major renovations (retrofit construction) where protection against the threats identified in this UFC is required. The costs are presented as increases (in percentages) over conventional new construction. By tabulating costs as percentage increases over common new construction, this UFC can avoid providing actual costs, which would be out of date shortly after publication. The general relationships among cost escalations of the various building components are such that the increased percentages approach is valid over time. The cost increases are currently tabulated for only the limited number of building types described below. The costs in this UFC include all labor, material, and markup costs.

6-2 **BUILDING TYPES.** The six building types addressed in the cost tables in this UFC are representative of the construction of a significant majority of the buildings built by DoD. They are selected based on their construction rather than their function. Table 3-1 lists examples of facility types that are represented by those six building types. The six building types are:

- Administrative buildings
- Medical facilities
- Dining facilities
- Barracks with internal entrances to rooms
- Barracks with external entrances to rooms
- Special structures (high bay, long span)

6-3 **BASELINE COSTS.** The baseline costs for the six building types were established by studying a significant number of buildings constructed similarly to buildings of the six types above, including buildings indicated in Table 3-1. Those baseline costs represent the common conventional construction cost for those buildings where there is an area cost factor of one. That means that construction in some areas of the United States or overseas will have to be adjusted according to the applicable area cost factors for those locations.

6-4 **NEW BUILDING CONSTRUCTION.** Use Appendix A to determine cost increases for new construction. Appendix A presents cost increases above the costs of the common conventional construction for the six building types in percentages above the baseline costs. Those increased percentages include the costs of walls, windows, doors, and roofs that are enhanced to mitigate the effects of the various threats to the applicable levels of protection. Refer to Appendix A for a description of the formulation of the cost tables for new construction. Those cost tables are for specific tactics, threat severity levels, and levels of protection. There is also guidance in Appendix A for estimating the additional costs for constructing to avoid progressive collapse.

6-5 **EXISTING BUILDING CONSTRUCTION.** Use Appendix B to determine costs for retrofits to existing construction. The costs in Appendix B are tabulated as increases over the costs of new construction. The reason for basing retrofit costs on increases over new construction costs is that the new construction costs are readily identifiable. The costs for the retrofit construction necessary to mitigate the effects of various threats to the applicable levels of protection were determined and tabulated as percentages above the cost for new construction. It is those percentages that are tabulated in Appendix B. Planning level costs, therefore, can be estimated by applying the percentages in Appendix B to costs in UFC 3-701-XX, *DoD Facilities Pricing Guide*. Refer to Appendix B for a description of the formulation of the cost tables for retrofit construction. Those cost tables are for specific tactics, threat severity levels, and levels of protection.

6-6 **SITEWORK COSTS.** The countermeasures required to mitigate the effects of some tactics require barriers at some locations on the site. Those barriers can be either passive perimeter barriers or active barriers, and they can also include screens. Tables A-52 and B-52 include cost multipliers for such barriers above the cost of baseline barriers for application for new and existing construction, respectively. Those baseline barriers are 8-foot chain-link fence and a 12 foot wide (1 traffic lane) motorized 8-foot chain link gate for passive perimeter and active barriers, respectively. The baseline barriers are very common, and their costs are easy to determine using various cost estimating guides. Representing the costs as multipliers above those of the baseline barriers avoids those costs being out of date shortly after the publishing of this UFC. Experience has shown that the costs of all of the barriers in Tables A-52 and B-52 escalate at approximately the same rate, so the cost multipliers should be adequate for planning purposes indefinitely.

6-7 **DETERMINING NEW CONSTRUCTION COST INCREASES.** Use the following steps to determine the cost increases for new construction for buildings that are built similarly to one of the six building types above as reflected in Table 3-1.

6-7.1 **Determine Representative Building Type.** Determine if one of the six baseline building types above is similar in construction to the building whose cost increase needs to be determined. Refer to Table 3-1 for common facility types that fall within the six baseline building types. Also refer to Table C-2 to determine if the baseline construction of the planned building is likely to be like that for the baseline construction in the cost model in Appendix A. If the baseline is not representative, the cost model in Appendix A may be inaccurate. For example, if the planned building is in a high seismicity or hurricane zone where buildings are commonly built with reinforced concrete walls, and the baseline construction in Table C-2 is brick veneer over metal studs, the cost model in Appendix A may be unreasonably conservative. In that case, it may be possible to use Appendices A and C together to interpolate a valid cost increase. The percentages of total building costs represented by the walls, doors, windows, and roofs are tabulated in Table C-2 to assist in those interpolations.

6-7.2 **Determine Facility Baseline Cost.** For the facility being considered, determine the common cost per unit area using UFC 3-701-05 or other master planning guidance. Initially use the cost for an area cost factor of one.

6-7.3 **Find Applicable Cost Tables.** Use Table A-1 to determine which of the cost tables apply to the facility being planned based on the applicable threats and levels of protection.

6-7.4 **Find the Cost Increase.** Find the applicable cost increase (a percentage) for each applicable tactic, threat severity level, and level of protection. Where multiple tactics apply, record all increases separately for later resolution, except that where the vehicle bomb tactics and the exterior application of the hand delivered device tactic apply, use only the highest cost increase of those three tactics.

6-7.5 **Resolve Construction Components.** Use Appendix C to determine the construction represented by the cost increases tabulated in Appendix A. In some cases, the construction indicted by one tactic will be adequate to provide protection against another. There are no convenient relationships between tactics to model that generically, so the construction components will have to be examined by the user to determine if there is likely to be any redundancy. For example, if the enhancements of building components for indirect fire weapons require heavier components than for hand delivered devices or for direct fire weapons, increases for all three tactics would not be required and the larger of the increases could be used. The percentages of total building costs represented by the walls, doors, windows, and roofs are tabulated in Table C-2 for use in resolving cost increase redundancies.

6-7.6 **Determine Facility Cost Increase.** Multiply the sum of the cost increases for the applicable tactics and multiply that by the facility's unit cost. That cost will be the cost increase for the building.

6-7.7 **Record the Cost Increase.** If the cost estimate is for the purposes of preparing a DD Form 1391, enter the cost increase under Primary Facility as a lump sum under the Antiterrorism/Force Protection line item. If the cost estimate is for another purpose, document the cost increase as is appropriate for that purpose.

6-8 **DETERMINING RETROFIT CONSTRUCTION COST INCREASES.** Use the following steps to determine the cost increases for modifications to existing construction for buildings that are built similarly to one of the six building types above as reflected in Table 3-1.

6-8.1 **Determine Representative Building Type.** Determine if one of the six baseline building types above is similar in construction to the building whose cost increase needs to be determined. Refer to Table 3-1 for common facility types that fall within the six baseline building types. Also refer to Table C-2 to determine if the existing construction of the building being modified is similar to that for the baseline construction in the cost model in Appendix B. If the existing construction is not similar, the cost model in Appendix B may be inaccurate. For example, if the existing building is built with heavy unreinforced masonry walls, and the baseline construction in Table C-2 is brick veneer over metal studs, the cost model in Appendix B may be unreasonably conservative. In that case, it may be possible to use Appendices B and C together to interpolate a valid cost increase. The percentages of total building costs represented by the walls, doors, windows, and roofs are tabulated in Table C-2 to assist in those interpolations.

6-8.2 **Determine Facility Baseline Cost.** For the facility being considered, determine the common cost per unit area for new construction using UFC 3-701-05 or other master planning guidance. Initially use the cost for an area cost factor of one.

6-8.3 **Find Applicable Cost Tables.** Use Table B-1 to determine which of the cost tables apply to the facility being planned based on the applicable threats and levels of protection.

6-8.4 **Find the Cost Increase.** Find the applicable cost increase (a percentage) for each applicable tactic, threat severity level, and level of protection. Where multiple tactics apply, record all increases separately for later resolution, , except that where the vehicle bomb tactics and the exterior application of the hand delivered device tactic apply, use only the highest cost increase of those three tactics..

6-8.5 **Resolve Construction Components.** Use Appendix C to determine the construction represented by the cost increases tabulated in Appendix B. In some cases, the construction indicted by one tactic will be adequate to provide protection against another. There are no convenient relationships between tactics to model that generically, so the construction components will have to be examined by the user to determine if there is likely to be any redundancy. For example, if the enhancements of building components for indirect fire weapons require heavier components than hand delivered devices or for direct fire weapons, increases for all three tactics would not be required and the larger of the increases could be used. The percentages of total building costs represented by the walls, doors, windows, and roofs are tabulated in Table C-2 for use in resolving cost increase redundancies.

6-8.6 **Determine Facility Cost Increase.** Multiply the sum of the cost increases for the applicable tactics and multiply that by the facility unit area cost for new construction. That cost will be the cost for the building modifications.

6-8.7 **Record the Cost Increase.** If the cost estimate is for the purposes of preparing a DD Form 1391, enter the cost increase under Primary Facility as a lump sum under the Antiterrorism/Force Protection line item. If the cost estimate is for another purpose, document the cost increase as is appropriate for that purpose.

6-9 **DETERMINING SITEWORK COSTS.** Where barriers are needed to mitigate the effects one or more tactics, follow the steps below to determine the costs of those barriers. Barrier costs are the same for new construction and for additions to existing facilities because it is assumed that such sitework elements will always be added to a project as opposed to modifying existing barrier construction.

6-9.1 **Identify Applicable Tactic and Threat Severity Level.** Determine whether the barriers needed are for the moving or stationary vehicle bomb tactic or if they are screening to mitigate direct fire weapons. In addition, if the moving vehicle tactic applies, identify the applicable threat severity level. The threat severity level will establish which vehicle must be stopped. For planning purposes, all vehicles are assumed to able to achieve a speed of 50 miles per hour. That assumption will result in a conservative cost estimate that may be adjusted during the design process through effective site design.

6-9.2 **Identify Costs of Baseline Barriers.** Identify the costs of the 8-foot high chain link fence or 12-foot wide, 8-foot high motorized chain link gate for passive or active barriers, respectively. Those costs can be found in cost estimating guides or local costs for those components may be well known. In the latter case, if the local costs are greater than costs for an area cost factor of one, ensure the area cost factor is not added again in the planning documents or adjust the baseline cost by the area cost factor.

6-9.3 **Find Applicable Barrier Multiplier.** Use Table A-52 or B-39 to determine the appropriate cost multipliers for passive perimeter barriers based on the applicable tactic and level of protection. Do the same for active barriers if they are to be used.

6-9.4 **Identify the Applicable Quantities.** Identify the applicable perimeter along which perimeter barriers are required and identify the number of traffic lanes for which active barriers will be needed.

6-9.5 **Determine Barrier Costs.** Multiply the appropriate cost multipliers by the costs of the applicable baseline barriers and multiply that product by the length of the perimeter or the number of traffic lanes that will require barriers, as applicable.

6-9.6 **Record Barrier Costs.** If the cost estimate is for the purposes of preparing a DD Form 1391, enter the barrier costs under Supporting Facilities as a lump sum under the Antiterrorism/Force Protection line item. If the cost estimate is for another purpose, document the cost increase as is appropriate for that purpose

6-10 **EXAMPLE PROBLEM.** The following is an example problem demonstrating how the cost tables are applied for a new construction project. The facility that is being programmed is an 8000 square foot Field Operations Facility whose baseline cost is $162 per square foot. The standoff distance from the building is 100 feet, resulting in a perimeter of 1160 feet, and there will need to be 2 one-lane entries through the perimeter. There is an unobstructed space around the facility of 10 meters. There is a loading dock (10 ft. x 22 ft.) and an entry lobby (15 ft. x 30 ft.) for the building, but no mail room. There is an 18 ft. x 24 ft. internal room that houses assets to which there is a forced entry threat. The design criteria include the following threats:

- Moving vehicle bomb threat at high threat severity level and medium level of protection

- Stationary vehicle bomb tactic at high threat severity level and medium level of protection.

- Hand delivered device tactic at high threat severity level and medium level of protection.

- Direct fire weapon tactic at high threat severity level and high level of protection.

- Forced entry tactic at high threat severity level and medium level of protection. The target asset for this tactic is limited to a single interior room.

6-10.1 **Building Cost Increase.**

6-10.1.1 **Determine Representative Building Type**. By referring to Table 3-1, the field operations facility can be seen to fall under the general category of an administrative building based on its construction.

6-10.1.2 **Determine Facility baseline Cost.** The baseline cost was given in the problem statement as $162 per square foot. Assume the baseline construction given in Appendix C is applicable to this building, so the tables in Appendix A can be used. Assume the baseline interior construction to cost $60 per square foot.

6-10.1.3 **Find Applicable Cost Tables.** The following are the applicable tables for the various tactics (Table A-1):

- For both the moving vehicle and stationary vehicle tactics, use Table A-15.

- For the hand delivered devices tactic, use Table A-3 for the exterior of the building, Table A-29 for the loading dock, and Table A-31 for the entry lobby.

- For the direct fire weapons tactic, use Table A-38.

- For the forced entry tactic, use Table A-48 (interior room).

6-10.1.4 **Find the Cost Increases.** The following are the applicable cost increases for the various tactics.

- For the moving and stationary vehicle tactics, the increase is 30.6% for the administrative facility Construction Type for 100 foot standoff (30.5 m).

- For the hand delivered devices tactic, assume the standoff distance to the building is the limit of the unobstructed space, 10 meters. In that case, the increased building cost will be 28.5%.

- For the hand delivered device at the loading dock, the cost increase to enhance the construction of the small loading dock is 1.5% of the cost of the whole building (medium LOP).

- For the hand delivered device in the entry lobby, the cost increase to enhance construction of the entry lobby is 1.7% of the cost of the whole building (medium LOP).

- For the direct fire weapons tactic, the cost is 37.7% (high LOP).

- For the forced entry tactic, the cost increase is 1.4%.

6-10.1.5 **Resolve Construction Components.** Looking at the construction component identifiers in the applicable tables in Appendix A and using the appropriate tables in Appendix C results in the enhanced construction indicated in Table 6-1. The vehicle bomb tactics and the external hand delivered devices tactic both will affect the exterior of the building. Note that the cost increase for the vehicle bombs is higher than that for the hand delivered device. In comparing the walls, those required for the hand delivered device are thicker than those for the vehicle bombs, but they are reinforced CMU instead of reinforced concrete and they have moderate instead of heavy reinforcement, so they will be less expensive. That can be verified by noting that in table C-3 the 200 mm heavily reinforced concrete wall is above the 300 mm moderately reinforced CMU wall. The construction in that table is arranged from most expensive at the top to least expensive at the bottom. Also note that the other components for the vehicle bomb tactics are heavier than those for the hand delivered device tactic, so the vehicle bomb tactic can be validated to control between those two tactics. Further comparison between the vehicle bomb tactics and the direct fire weapon tactic shows the direct fire weapon cost increase being higher, but in examining the building components, only the windows seem to be heavier for the direct fire weapon tactic. Because there is no easy way using these tables to determine the relative contribution of individual building components to the total cost increase, use the higher of the two cost increases (37.7%), which will ensure that all the necessary costs are covered. The other tactics do not need to be resolved because they relate to separate internal spaces.

6-10.1.6 **Determine Facility Cost Increase.** The following calculations show the total cost increase necessary to accommodate the requirements for mitigating the effects of all tactics (rounded to the nearest $1000):

- Building Exterior: 37.7% x ($162 per square foot X 8000 square feet) = $489,000

- Loading Dock: 1.5% x ($162 per square foot X 8000 square feet) = $19,000

- Entry Lobby: 1.7% x ($162 per square foot X 8000 square feet) = $22,000
- Secure Room: 1.4% x ($162 per square foot X 8000 square feet) = $18,000

Total: $548,000

6-10.1.7 **Record the Cost Increase.** The total cost increase for the building ($548,000) would be entered as a lump sum on a separate line item for Antiterrorism Measures under the Primary Facility if a DD Form 1391 was being prepared.

Table 6-1. Example Problem Building Components

Tactic	Wall	Window	Door	Roof/Ceiling
Vehicle Bombs (From Table C-3)	200 mm heavily reinforced concrete	1/4" + 4 x 5/32" glass + 3 x 0.045 in PVB	25 psi blast door	20K10 L=30', B=6'
Hand Delivered Devices (external) (From Table C-3)	300 mm moderately reinforced CMU	1/4" + 2 x 5/32" glass + 0.060 in PVB	Hollow metal with backer wall	20K10 L=30', B=6'
Hand Delivered Devices (Loading Dock) * (From Table C-7)	24-inch moderately reinforced concrete	None	-	27-inch heavily reinforced concrete
Hand Delivered Devices (Lobby)* (From Table C-7)	14-inch moderately reinforced concrete	None	-	14-inch heavily reinforced concrete
Direct Fire Weapons (From Table C-10)	8-inch fully grouted CMU	1-5/8 inch laminated glass with 1/4 inch polycarbonate	Industrial door with 11/16 inch armor plate	No special construction
Forced Entry * (From Table C-12)	8-inch grout filled CMU with #6 bars at 4 inches vertically and at 8 inches horizontally	None	12 gage hollow metal filled with lightweight fireproofing	7-inch re3inforced concrete with 6x6 welded wire mesh, 10 gage steel deck
* Note: Internal construction not affecting other components				

6-10.2 **Barrier Costs.** Only the vehicle bomb tactics have any barrier requirements in this example.

6-10.2.1 **Identify Applicable Tactic and Threat Severity Level.** Both the moving and stationary vehicle bomb tactics apply, but the threat severity level is only an issue for the moving vehicle bomb, for which the threat severity level is high.

6-10.2.2 **Identify Costs of Baseline Barriers.** The baseline barrier costs are for 8-foot chain link fence and motorized gates. Those costs can be found in common cost engineering guides. Assume for the purpose of this problem that the cost of the chain link fence is $15 per linear foot (lf) and the cost of the gates is $5000 per traffic lane.

6-10.2.3 **Find Applicable Barrier Multiplier.** From Table A-52, the cost multipliers for perimeter barriers and active barriers for the high threat severity level of the moving vehicle bomb tactic are 5.0 and 7.4, respectively. Note that the costs for the stationary vehicle bomb tactic are less, so the requirements to mitigate the effects of the moving vehicle bomb will control the barrier costs.

6-10.2.4 **Identify the Applicable Quantities.** The problem statement says that the site perimeter is 1160 feet and there need to be two one-lane entries, which would require active barriers.

6-10.2.5 **Determine Barrier Costs.** The following calculations show the total costs for barriers for this problem:

- Perimeter Barriers: 5.0 x $15 per lf x 1160 lf = $87,000
- Active Barriers: 7.4 x $5000 per lane * 2 lanes = <u>$74,000</u>

Total: $161,000

6-10.2.6 **Record Barrier Costs.** The total cost for barriers would be entered as a lump sum on a separate line item for Antiterrorism Measures under the Supporting Facilities if a DD Form 1391 was being prepared. Information as it would be entered onto the front page of a DD Form 1391 is illustrated in Table 6-2.

USEUCOM	United States European Command
USCENTCOM	United States Central Command

TERMS:

Area Cost Factor. A multiplier by which facility costs can be multiplied to account for increases in local construction costs based on labor, materials, and equipment costs for specific localities.

Access control. For the purposes of this document, any combination of barriers, gates, electronic security equipment, and/or guards that can deny entry to unauthorized personnel or vehicles.

Active vehicle barrier. A vehicle barrier that must be manually or automatically deployed in response to detection of a threat.

Aggressor. Any person seeking to compromise an asset. Aggressor categories include protesters, criminals, terrorists, and subversives.

Aggressor group. For the purposes of calculating risk, broad groupings of aggressors who exhibit similar threat characteristics.

Antitank weapons. For the purposes of this document, shoulder fired, direct fire weapons consisting of a rocket propelled projectile with a conical shaped charge warhead that are designed to perforate the armor of armored vehicles.

Antiterrorism. Defensive measures used to reduce the vulnerability of individuals and property to terrorist acts, to include limited response and containment by local military and civilian forces.

Assessment. Visual verification of the validity of an alarm from an electronic security system.

Assessment zone. In waterfront security, the area well beyond the government's property line.

Asset. A resource requiring protection.

Asset value rating. A measurement of the importance of an asset to its user.

Baseline cost. The common conventional construction cost of an element or a building.

Biological agents. Pathogens and toxins that can be used to contaminate air or water.

Breaching. Making a hole completely through a building surface through the use of tools or explosives.

Building elements. Components of buildings and countermeasures associated directly with building interiors and exterior surface features.

Building hardening. Enhanced conventional construction that mitigates threat hazards where standoff distance is limited. Building hardening may also be considered to include the prohibition of certain building materials and construction techniques.

Chemical Agents. Chemicals, including toxic industrial chemicals, toxic industrial materials, and military chemical agents that can be used to contaminate air or water.

Collective protection. Establishment of an area of a building where personnel can work or shelter during release of a chemical, biological, or radiological agent.

Combatant command. A unified or specified command with a broad continuing mission under a single commander established and so designated by the President, through the Secretary of Defense and with the advice and assistance of the Chairman of the Joint Chiefs of Staff. Combatant commands typically have geographic or functional responsibilities. See also specified command; unified command.

Controlled perimeter. A physical boundary at which vehicle access is controlled at the perimeter of an installation, an area within an installation, or another area with restricted access. A physical boundary will be considered as a sufficient means to channel vehicles to the access control points. At a minimum, access control at a controlled perimeter requires the demonstrated capability to search for and detect explosives. Where the controlled perimeter includes a shoreline and there is no defined perimeter beyond the shoreline, the boundary will be at the mean high water mark.

Critical Asset. Any facility, equipment, service or resource considered essential to DoD operations in peace, crisis, and war and warranting measures and precautions to ensure its continued efficient operation, protection from disruption, degradation, or destruction, and timely restoration. Critical assets may be DoD assets or other government or private assets, DoD O-2000.12-H. (e.g. industrial or infrastructure critical assets), domestic or foreign, whose disruption or loss would render DoD critical assets ineffective or otherwise seriously disrupt DoD operations. Critical assets include traditional “physical” facilities and equipment, non-physical assets (such as software systems), or “assets” that are distributed in nature (such as command and control networks, wide area networks or similar computer-based networks).

Critical Infrastructure. Infrastructure deemed essential to DoD operations or the functioning of a Critical Asset.

Design Basis Threat. The threat upon which a system of countermeasures protecting assets is based. The design basis threat includes the aggressor tactics and the associated weapons, explosives, tools, and agents.

Direct fire weapons. A weapon that is fired from a distance directly at a target and which requires an unobstructed line of sight from the weapon to the target.

Design criteria. For the purposes of this document, the basis for defining a protective system that mitigates vulnerabilities to assets. Design criteria include assets, threats, levels of protection, and design constraints.

Dirty bomb. A bomb that combines conventional explosives with radioactive materials in the form of powder or pellets that are dispersed by the explosion to contaminate a wide area. (Also known as a Radiological Dispersal Device.)

Energy absorption screen. A vertical or horizontal surface place at a standoff distance from a target that reduces the energy of a projectile to limit its effect on the target.

Engagement zone. In waterfront security, the area between a line of floating barriers and an asset.

Entry Control Point. A continuously or intermittently manned station at which entry through a perimeter is controlled.

Equipment. As part of a protective system, countermeasures such an electronic security system elements and other devices used by personnel for detection and assessment of threats or weapons, tools, explosives, or chemical, biological, or radiological agents.

Exclusive standoff zones. A controlled area surrounding a facility into which only service and delivery vehicles and other vehicles that must be allowed access within the perimeter are allowed. The perimeter of this area is defined by perimeter barriers and is set at a standoff distance sufficient to reduce the blast effects of vehicle bomb detonations on the protected facility.

Expeditionary construction. Construction that commonly built in forward areas and that is intended to be used for no more than 1 year after it is erected. Common structures typically include tents, Small and Medium Shelter Systems, Expandable Shelter Containers (ESC), ISO and CONEX containers, and General Purpose (GP) Medium tents and GP Large tents, etc.

Explosive safety. The practice of providing the maximum possible protection to personnel and property, both inside and outside the installation, from the damaging effects of potential accidents involving DoD ammunition and explosives.

Force Protection Conditions (FPCONs). A DoD-approved system that standardizes the Departments' identification and recommended preventive actions and responses to terrorist threats against U.S. personnel and facilities. This system is the principle means for a commander to apply an operational decision on how to protect against terrorism and facilitates inter-Service coordination and support for antiterrorism activities.

Fragment. For the purposes of developing protective systems, pieces of the materials surrounding an explosive that may be propelled at high velocity toward a building or other target as a result of an explosion of a bomb or a warhead.

General design strategy. The basic approach to developing a protective system to mitigate the effects of a given tactic. It governs the general application of construction, building support systems, equipment, manpower, and procedures.

Historic preservation. Protection afforded to districts, sites, buildings, structures, or objects listed on or eligible for inclusion on the National Register of Historic Places in accordance with the National Historic Preservation Act (Public Law 89-665 as amended; 16 USC 470 et seq)

Incendiary devices. Devices designed to spread fire.

Indirect fire weapons. Weapons that are designed to propel projectiles over obstacles, potentially over long distances, to effectively target assets where there are no clear lines of sight.

Inhabited facilities. Buildings or portions of buildings routinely occupied by 11 or more DoD personnel and with a population density of greater than one person per 40 gross square meters (430 gross square feet). This density generally excludes industrial, maintenance, and storage facilities, except for more densely populated portions of those buildings such as administrative areas. The inhabited building designation also applies to expeditionary and temporary structures with similar population densities. In a building that meets the criterion of having 11 or more personnel, with portions that do not have sufficient population densities to qualify as inhabited buildings, those portions that have sufficient population densities will be considered inhabited buildings while the remainder of the building may be considered uninhabited, subject to provisions of these standards. An example would be a hangar with an administrative area within it. The administrative area would be treated as an inhabited building while the remainder of the hangar could be treated as uninhabited. (Note: This definition differs significantly from the definition for inhabited building used by DoD 6055.9-STD and is not construed to be authorization to deviate from criteria of DoD 6055.9-STD.)

Level of protection. The degree to which an asset (e.g., a person, a piece of equipment, or an object, etc.) is protected against injury or damage from an attack.

Likelihood rating. A number between 0 and 1 that measures how likely an aggressor is to attempt to compromise a given asset.

Manpower. Countermeasures that relate to the use of guards or other personnel necessary to implement or operate elements of the protective system.

Military chemical agents. Liquid, gaseous, or aerosolized chemical agents designed for use in military weapons.

Minimum standoff distance. A standoff distance less than the Conventional Construction Standoff Distance at which the required level of protection can be shown to be achieved through analysis or can be achieved through building hardening or other mitigating construction or retrofit.

Overpressurization class. A measure of collective protection capability based on event duration and wind speed.

Passive Perimeter barriers. Vehicle barriers that are permanently deployed and do not require a response to be effective and fences, walls, screens, landforms, and lines of vegetation applied along an exterior perimeter used to obscure vision, hinder personnel access, or hinder or prevent vehicle access.

Penetration. Relating to bullets or fragments, entry into a material without passing all the way through.

Perforation. Relating to bullets and fragments, passing all the way through a material.

Planning team. A team of people with responsibilities relating to a project that is formed to develop design criteria and review material from all phases of the design process.

Predetonation screen. A fence, wall, or screen that causes an antitank round to detonate before it reaches its target. When placed at the proper distance for the facility construction, the screen will prevent penetration of the facility exterior by the antitank round.

Protective system. An integrated system of countermeasures designed to protect assets against threats to specific levels of protection. Protective systems include building elements, sitework elements, equipment, and manpower and procedures.

Protection Effectiveness factor. A number between 0 and 1 that reflects the effectiveness of countermeasures in mitigating the vulnerabilities associated with a given threat.

Procedures. Countermeasures that relate to actions taken by people, including guards and building occupants, to implement or operate elements of the protective system.

Risk. A means to quantify the combined issues of the value of an asset or the impact of its loss, the likelihood of the asset being attacked, and the effectiveness of the protection afforded the asset that can be used as a tool in making decisions about asset protection.

Risk analysis. The process of determining risk levels for assets.

Risk management. The process of evaluating how changes in countermeasures application affect risk levels and costs for the purpose of decision making.

Risk level. A number between 0 and 1 that reflects the product of asset value, aggressor likelihood, and protection effectiveness.

Shielding walls. Walls designed to intercept and resist fragment penetration and possibly to attenuate blast effects.

Sitework elements. Countermeasures that are applied beyond 1.5 meters (5 feet) from a building, excluding countermeasures categorized under equipment.

Sound Transmission Class. A numerical evaluation of an assembly’s effectiveness in isolating airborne sound transmission.

Spall. The condition in which pieces of a material are broken loose from the inner surface of a wall, roof, or similar element by tensile forces that are created when a compression shock wave travels through the body and reflects from the surface.

Specific design strategy. The approach to applying general design strategies based on the applicable levels of protection.

Standoff distance. A distance maintained between a building or portion thereof and the potential location for a weapon or explosive detonation.

Surreptitious entry. A method of entry, such as lock manipulation or radiological attack on a combination lock, which would not be detectable during normal use or during inspection by a qualified person.

Sustainable design. The design, construction, operation, and reuse/removal of the built environment (infrastructure and buildings) in an environmentally and energy efficient manner. (Synonymous with Sustainable Design is "Green Building.")

Tactics. The specific methods of achieving the aggressor's goals to injure personnel, destroy assets, or steal materiel or information.

Terrorist Threat Level. An intelligence threat assessment of the level of terrorist threat faced by U.S. personnel and interests. The assessment is based on a continuous intelligence analysis of a minimum of four elements: terrorist group operational capability, intentions, activity, and operational environment. There are four threat levels: LOW, MODERATE, SIGNIFICANT, and HIGH. Threat levels should not be confused with FPCONs. Threat level assessments are provided to senior leaders to assist them determine the appropriate local FPCON.

TEMPEST. An unclassified short name referring to investigations and studies of compromising emanations. It is sometimes used synonymously for the term "compromising emanations"; e.g., TEMPEST tests, TEMPEST inspections.

TEMPEST Shielding. Shielding (commonly metallic) that attenuates compromising emanations.

Temporary construction. Construction with an expected occupancy of 3 years or less. Common structures typically includes wood frame and rigid wall construction, and such things as Southeast Asia (SEA) Huts, hardback tents, ISO and CONEX containers, pre-engineered buildings, trailers, stress tensioned shelters, Expandable Shelter Containers (ESC), and Aircraft Hangars (ACH).

Threat Effectiveness rating. A number between 0 and 1 that reflects the capabilities of aggressors to find weaknesses in security measures and to exploit them considering their sophistication, motivation, and risk acceptance.

Threat zone. In waterfront security, the area between the government's property line and the line of floating barriers.

TNT equivalent weight. The weight of TNT (trinitrotoluene) that has an equivalent energetic output to that of a different weight of another explosive compound.

Toxic Industrial chemicals. Liquid, particulate, and gaseous chemicals used in commercial and industrial applications.

Toxic Industrial materials. Liquid, particulate, and gaseous materials used in commercial and industrial applications.

Unobstructed space. Space within 10 meters (33 feet) of an inhabited building that does not allow for concealment from observation of explosive devices 150 mm (6 inches) or greater in height.

Vulnerability. Any weakness in the design or operation of a protective system for an asset that can be exploited by an aggressor to disrupt, damage, destroy, injure, or otherwise compromise the asset.

Warning zone. In waterfront security, the area just outside the government's property line.

APPENDIX A

NEW CONSTRUCTION COST TABLES

A-1 **INTRODUCTION.** The purpose of the tables in this appendix is to provide planning level estimates of cost increases for new construction of buildings representative of those commonly built by the Department of Defense. The costs tabulated are increases (in percentage of baseline cost) over the common conventional construction for those building types or rooms within buildings of those types.

A-2 **NAVIGATING THE TABLES.** Table A-1 provides a guide to locating the cost tables for various threats. It is organized by tactic, threat severity level, and level of protection for all but the hand delivered devices and forced entry tactics. For the hand delivered devices tactic, the costs are tabulated by external attack, attacks on interior spaces for improvised incendiary devices, and attacks on mail rooms, loading docks, and entrance areas using different explosive weights.

A-3 **BUILDING COMPONENT COST FORMULATION.** The cost tables were formulated by arraying a number of components that would meet the requirements of mitigating the effects of particular tactics to the applicable threat severity levels and levels of protection. Those components were then sorted based on cost, and the least cost components were entered into a building cost model. That building cost model included the baseline costs of the building components that were found to be commonly used for those buildings and that were representative of the building components that are in military construction pricing guidance. The costs in these tables are for an area cost factor of one.

The additional costs for the enhanced construction components over the conventional component costs were determined as a percentage increase over conventional costs. The percentages of the building cost represented by each of the components were built into the model; therefore, the percentage increase in the total building costs represented by the enhanced building components could be determined. It is those cost increases that are tabulated.

Note that in the case of administrative buildings the cost increases are often very high. That is due to the fact that those buildings commonly have a high percentage of windows. Replacement windows to provide levels of protection against many of the threats covered by this UFC are very costly. Reducing window areas in those buildings may be an effective way to reduce costs; however, this appendix does not directly support determining those cost reductions.

A-4 **PROGRESSIVE COLLAPSE COSTS.** UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings,* requires that all inhabited buildings three stories or greater in height must be designed to resist progressive collapse. The following costs should be added to buildings of three of more stories in addition to any other costs arising out of this appendix. Because detailed guidance for application of those costs have not been developed, use the highest costs in the applicable ranges below:

- Framed structures
  - Very Low and Low Levels of Protection: 0.13 – 0.74%
  - Medium and High Levels of Protection: 0.32 – 2.74%
- Shear wall type construction
  - Masonry wall / reinforced concrete slab floor construction: 1.29% to 2.80%
  - Timber construction: 5.01% to 6.11%

A-5 **SITEWORK COST MULTIPLIERS.** Sitework costs are tabulated in Table A-57 as multiples of a baseline barrier. The baseline barrier is either an 8-foot chain link fence (7-foot fabric with outrigger) or an 8-foot high, 12-foot wide (one traffic lane) motorized chain link gate. The costs of those two barriers are easily located in commercial cost estimating guides or in military construction cost databases. The cost multipliers for other barriers were determined by comparing the costs of those barriers to the costs of the baseline barriers. The barriers in Table A-57 are identified by threat severity level for perimeter and active barriers. The barriers associated with those threat severity levels are identified in Appendix C. Boat barrier costs are not included because the costs vary widely and the design guidance is still being developed.

Table A-1. Guide to Cost Tables

	Interior [4]					
Sitework Costs		All	None	All	A-57	A-71

Notes:

1. No cost increases over conventional construction because interior construction commonly fire resistant and it is assumed there are no windows.
2. Apply applicable table based on level of protection
3. Do not use very high threat severity level for interior case because it includes explosives, which are considered unlikely due to collateral damage. Apply cost for High threat severity level.
4. Use the exterior tables where entire buildings or large portions of them are to be protected. In the latter case, use percentages of the costs shown in the table based on the percentage of building perimeter area that will be protected. Use interior tables where protection will be focused on interior rooms within buildings. Combinations of interior and exterior costs can also be used where applicable.

Administration Building	1.43					23.2				A
						23.9				B
Medical Clinic	0.23					4.4				A
		A	A	A	A	7.2	B	C	B	B
Barracks with Exterior Entrances	0.24					9.9				A
						10.4				B
Barracks with Interior Entrances	0.24					4.3				A
						4.8				B
Special Structures	0.37					7.5				A
						10.8				D

Note: Costs are for entire building exterior. For smaller portions of buildings use a straight percentage of protected perimeter ÷ total perimeter

1. For roofs to which there is no sightline, use top number in each pair of values for % cost increase. Where there is a sightline to a roof, use bottom number in each pair of values for % cost increase.
2. For roofs to which there is no sightline, the top roof designation in each pair indicates the roof construction on which the cost increase is based. The bottom roof designation in each pair indicates the roof construction on which the cost increase is based where there is a sightline to the roof.

1. Room size: 12 ft. x 12 ft. x 10 ft. high
2. Room size: 12 ft. x 24 ft. x 10 ft. high
3. Room size: 18 ft. x 24 ft. x 10 ft. high
4. Windows are not included because areas are interior spaces.

Table A-56. Building Cost Increases for Electronic Emanations Eavesdropping Tactic

Building Type		% Increase	Walls	Windows	Doors	Ceiling / Roof
Building Exterior Shielded	Dining Facility	27.3	TEMPEST shielding in walls	Specially manufactured TEMPEST windows	Specially manufactured TEMPEST doors	TEMPEST shielding in roof or ceiling
	Administrative Facility	53.1				
	Medical Clinic	34.1				
	Barracks with Exterior Entries	46.7				
	Barracks with Interior Entries	17.8				
	Special Structure	34.1				
Interior Room Shielded	1 story building • Small [1] • Medium [2] • Large [3]	 1.44 1.69 1.85		None		
	Multi-story building • Small [1] • Medium [2] • Large [3]	 1.35 1.55 1.69				

1. Room size: 12 ft. x 12 ft. x 10 ft. high
2. Room size: 12 ft. x 24 ft. x 10 ft. high
3. Room size: 18 ft. x 24 ft. x 10 ft. high

Table A-57. Sitework Cost Multipliers

Tactic	Barrier Type	Threat Severity Level	Cost Multiplier [1]	Construction
Moving Vehicle Bomb	Passive Perimeter	Minimum	1.2	B
		Low	1.3	C
		Medium	1.4	D
		High	5.0	E
		Very High	7.5	F
		Special Case	8.5	G
	Active	Minimum	1.0	I
		Low	5.6	J
		Medium	7.4	K
		High	7.4	L
		Very High	11.1	M
		Special Case	16.7	N
Stationary Vehicle Bomb	Passive Perimeter	All	1.0	A
	Active	All	1.0	H
Direct Fire Weapons	Screen	Very High [2]	2.3	O

1. Cost multipliers based on Standard 8-foot chain link fence (7-foot fabric with outrigger) for passive perimeter barriers and a motorized 8-foot high x 12 feet wide chain link gate for active barriers.
2. Predetonation screen only. Directly hardening building for ballistics element of this tactic is less expensive than employing energy absorption screen.

APPENDIX B

RETROFIT CONSTRUCTION COST TABLES

B-1 **INTRODUCTION.** The purpose of the tables in this appendix is to provide planning level estimates of cost increases for retrofit construction for buildings representative of those commonly built by the Department of Defense. The costs tabulated represent the costs to meet the design criteria as percentages of new construction costs for the common existing conventional construction for those building types or rooms within buildings of those types. Presenting retrofit costs as increases over new construction costs was done because new construction costs for common military construction can be easily identified.

B-2 **NAVIGATING THE TABLES.** Table B-1 provides a guide to locating the cost tables for various threats. It is organized by tactic, threat severity level, and level of protection for all but the hand delivered devices and forced entry tactics. For the hand delivered devices tactic, the costs are tabulated by external attack, attacks on interior spaces for improvised incendiary devices, and attacks on mail rooms, loading docks, and entrance areas using different explosive weights.

B-3 **BUILDING COMPONENT COST FORMULATION.** The cost tables were formulated by arraying a number of components that would meet the requirements of mitigating the effects of particular tactics to the applicable threat severity levels and levels of protection. Those components were then sorted based on cost, and the least cost components were entered into a building cost model. That building cost model included the new construction baseline costs of the building components that were found to be commonly used for those buildings and that were representative of the building components that are in military construction pricing guidance. The costs in these tables are for an area cost factor of one.

The additional costs for the enhanced construction components over the conventional component costs were determined as a percentage increase over new conventional construction costs. The percentages of the building cost represented by each of the components were built into the model; therefore, the percentage increase in the total building costs represented by the enhanced building components could be determined. It is those cost increases that are tabulated. Note that in some retrofit tables there are not multiple levels of protection for all building components. In those cases there is insufficient development in the retrofit technologies to support different performances for different levels of protection, so one solution applies to multiple levels of protection.

Note that in the case of administrative buildings the cost increases are often very high. That is due to the fact that those buildings commonly have a high percentage of windows. Replacement windows to provide levels of protection against many of the threats covered by this UFC are very costly. Reducing window areas in those buildings may be an effective way to reduce costs; however, this appendix does not directly support determining those cost reductions. In addition, note that Special

Structures are excluded from the cost increase tables for explosive related tactics (Tables B-2 – B-7). That is because for those structure types, existing construction is too variable to develop common cost models. For those structures, special cost studies will need to be performed.

B-4 **PROGRESSIVE COLLAPSE COSTS.** UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings,* requires that all inhabited buildings three stories or greater in height must be designed to resist progressive collapse. For existing buildings, that requirement applies when a building is undergoing renovations, modifications, repairs, and restorations whose costs exceed 50% of the replacement cost of the building. While Appendix A contains cost guidance for new construction, there are no such convenient relationships for existing construction, and those buildings must be evaluated for progressive collapse on a case by case basis; therefore, those costs are no included on this appendix.

B-4. **SITEWORK COST MULTIPLIERS.** Sitework costs are tabulated in Table B-39 as multiples of a baseline barrier. The baseline barrier is either an 8-foot chain link fence (7-foot fabric with outrigger) or an 8-foot high, 12-foot wide (one traffic lane) motorized chain link gate. The costs of those two barriers are easily located in commercial cost estimating guides or in military construction cost databases. The cost multipliers for other barriers were determined by comparing the costs of those barriers to the costs of the baseline barriers. The barriers in Table B-39 are identified by threat severity level for perimeter and active barriers. The barriers associated with those threat severity levels are identified in Appendix C. Boat barrier costs are not included because the costs vary widely and the design guidance is still being developed.

Table B-1. Guide to Retrofit Cost Tables

Tactic		Threat Severity Level	Explosive Weight or other Information	Level of Protection	Table	Page
Vehicle Bombs[1]		VL	25 kg (55 lbs)	All	B-2	B-5

Waterborne Contamination		All	Chem, Bio and Rad. Agents	All	B-38	B-45
Sitework Costs		All		All	B-39	B-45

1. Special structures not included. See paragraph B-3.
2. Very low level of protection is not tabulated because baseline construction for all six building types will provide the very low level of protection as close as 10 meters, and no standoff distances less than 10 meters were included in this manual due to requirements in UFC 4-010-01.
3. No cost increases over conventional construction because interior construction is commonly fire resistant already and it is assumed there are no windows.
4. There are no practical retrofits for the improvised mortar.
5. Very high threat severity level not tabulated because it includes explosives, which are considered unlikely for interior use due to collateral damage. Use cost for High threat severity level.
6. Use the exterior tables where entire buildings or large portions of them are to be protected. In the latter case, use percentages of the costs shown in the table based on the percentage of building perimeter area that will be protected. Use interior tables where protection will be focused on interior rooms within buildings. Combinations of interior and exterior costs can also be used where applicable.

Notes:

1. For walls, upper letter applies to retrofits for non-load bearing walls and lower letter applies to retrofits for load bearing walls.
2. For load bearing walls, a "-" entry means that no economical retrofit is available at that standoff distance
3. cc = conventional construction. No retrofits required.
4. Percentages of cost increases are over new construction costs for the applicable building types.

APPENDIX C

CONSOLIDATED CONSTRUCTION COMPONENT TABLES

C-1 **INTRODUCTION.** The purpose of this appendix is to identify the construction components that were the basis for the cost tables in Appendices A and B. The baseline construction for the six common building types is also identified in this appendix. Table C-1 provides a guide to the construction component tables organized by tactic for all tactics except the hand delivered device tactic. For that tactic, the entries are organized by explosive weight and whether the threat is applied to the exterior or the interior of buildings.

C-2 **BASELINE CONSTRUCTION.** Table C-2 contains the baseline construction for the six common building types identified in Chapters 3 and 6 and for which the cost tables are tabulated in Appendices A and B. The building elements in Table C-2 are common to the building types identified in the tables and are representative of the construction upon which the baseline costs in the *DoD Facilities Pricing Guide (UFC 4-701-05)* are based. They may not be representative of how such buildings are built in all parts of the country or the world, but they represent very common construction. If common construction in your area is significantly different from a cost standpoint than that in Table C-2, the cost tables in Appendices A and B may not work for you or you may have to do some interpolating or extrapolating. Table C-2 also includes the percentages of the entire building cost represented by the major building components that are affected by security and antiterrorism (walls, doors, windows, and roofs). Those percentages may also be used to evaluate costs where local construction practices are different than the baseline construction in Table C-2.

C-3 **ENHANCED BUILDING CONSTRUCTION.** The building construction identified in tables C-3 through C-17 in this appendix is representative of construction that will mitigate the effects of the various threats identified. They do not represent the only possible selections. They only represent selections that reflect a representative minimum cost for providing the required protection using common construction practice. Issues specific to each of the tables in this appendix follow. They include both new construction and retrofit construction. For retrofit construction, all retrofit costs include the costs of removing existing building materials and providing new finished surfaces where applicable.

C-3.1 **Blast Resistant Exterior Construction.** Blast resistant exterior construction is described separately for new construction and retrofits to existing construction.

C3.1.1 **New Construction.** Table C-3 contains the walls, windows, doors, and roofs that were used in establishing the cost factors in Appendix A for vehicle bombs and hand delivered devices of 25 kg (55 lbs) or more. Additional costs for other building components are not included because necessary modifications to them generally do not have a significant impact on cost.

C-3.1.1.1 **Walls.** The walls are either reinforced concrete masonry using US standard concrete blocks or reinforced concrete. Reinforcement is based on the following ratios:

- Reinforced concrete
  - Heavy reinforcement: 0.50%
  - Moderate reinforcement: 0.25%
  - Light reinforcement: 0.15% (generally minimum reinforcement)

- Reinforced masonry
  - Heavy reinforcement: 0.30%
  - Moderate reinforcement: 0.15%
  - Light reinforcement: 0.05% (generally minimum reinforcement)

C-3.1.1.2 **Windows.** Windows are either laminated annealed glass or polycarbonate. The minimum window glazing in the table is the window required by the *DoD Minimum Antiterrorism Standards for Buildings (UFC 4-010-01)***.**

C-3.1.1.3 **Doors.** Doors are either conventional hollow metal doors in steel frames or blast resistant doors designed to resist specific blast pressures (in pounds per square inch). The table also includes an option for providing backing walls constructed behind a conventional hollow metal door to intercept the door if it flies into the building in response to a blast or for providing conventional doors in foyers to serve a similar function.

C-3.1.1.4 **Roofs.** Roof construction includes both reinforced concrete flat slabs and steel deck on top of bar joists. The bar joists are built to US standards, so foreign made joists may not directly match.

C-3.1.2 **Retrofit Construction.** Table C-4 contains the walls, windows, doors, and roofs that were used in establishing the cost factors in Appendix B for vehicle bombs and hand delivered devices of 25 kg (55 lbs) or more. Additional costs for other building components are not included because necessary modifications to them generally do not have a significant impact on cost.

C-3.1.2.1 **Walls.** Wall retrofits are of two major types; those that may be used on masonry walls and those that can be used on lightweight construction. They also differ in that some may be used for load-bearing walls and others can only be used for non-load-bearing walls. The following retrofits are included:

C-3.1.2.1.1 **Steel Stud Retrofit.** This is a retrofit that can be applied to steel stud walls. It involves adding an additional steel stud wall in the interior of the building. That wall has back-to-back steel studs with special connections to steel channels. It also has light gage sheet steel on one side and polycarbonate reinforced gypsum wall board with sheet metal reinforcing strips on the other.

C-3.1.2.1.2 **Reinforced Concrete Backer Walls.** This retrofit can be applied behind masonry walls to minimize the debris from the masonry wall when it fails. They can be either bonded to the masonry or unbonded.

C-3.1.2.1.3. **High Capacity Wall Catcher System.** This retrofit uses foam block behind the existing wall and light gage sheet steel behind the foam blocks. The system is bolted to the floor and ceiling. It is designed to catch hazardous debris.

C-3.1.2.1.4 **Geotextile Fabric Retrofits.** This retrofit uses common geotextiles fastened to floors and ceilings behind existing masonry walls to minimize debris from the masonry wall when it fails.

C-3.1.2.2 **Windows.** Because retrofits applied in this UFC are assumed to be used as elements of major renovations, all window retrofits involve removing the existing windows and replacing them with new, blast resistant window assemblies.

C-3.1.2.3 **Doors.** Door retrofits in this UFC are limited to building foyers incorporating the existing doors to ensure that when they fail in response to a blast they will be caught by the foyer wall and not become hazardous flying debris.

C-3.1.2.4 **Roofs.** The most economical roof retrofits involve removing the old roofs and replacing them with the roofs specified for new construction.

C-3.2 **Construction Resistant to Hand Delivered Devices.** Table C-5 includes the walls, doors, windows, and roofs that are necessary to meet the requirements for small hand delivered devices delivered external to buildings. Tables C-6 and C-7 include construction to resist internal explosions in mail rooms, loading docks, and entry areas of multiple sizes.

C-3.2.1 **Walls.** Walls to resist externally delivered hand delivered devices of 1 kg (2.2 lbs) or less are either conventional construction of any sort, conventional masonry construction that is reinforced to the minimum requirements of the *DoD Minimum Antiterrorism Standards for Buildings (UFC 4-010-01),* or lightly reinforced concrete. Walls to resist internal explosions are reinforced concrete with reinforcement ratios as discussed above. They are tabulated according to the purpose of the interior space (mail rooms, loading dock, or entry area), the size of the space, the explosive weight, and the level of protection. Exterior retrofits are similar to those described for other blast resistant construction. Interior retrofits assume it is more economical to remove existing interior walls and replace them with the same construction that would be used for new construction.

C-3.2.2 **Windows.** Windows to resist externally delivered devices of 1 kg (2.2 lbs) or less either have the minimum laminated glass required by the *DoD Minimum Antiterrorism Standards for Buildings (UFC 4-010-01)* or polycarbonate glazing. The latter is sized to resist fragments. There are no windows provided for internal explosions except those on the exterior walls of those areas. The exterior windows are laminated glass intended to fail quickly to allow the blast pressures to vent out of the internal areas. As for other blast resistant construction, all window retrofits involve replacing the existing windows with appropriate new window assemblies.

C-3.2.3 **Doors.** Doors to resist externally delivered devices of 1 kg (2.2 lbs) or less are conventional hollow steel for all cases, except they are incorporated into entry foyers for higher levels of protection as described in Chapter 4. Doors for internal explosions are blast resistant doors, but their costs are not currently included in the tables in this appendix. Retrofitted doors similarly use foyers to back them up.

C-3.2.4 **Roofs.** Roofs to resist externally delivered devices of 1 kg (2.2 lbs) or less are either conventional construction or lightly reinforced concrete. Ceilings of rooms subject to internal explosions will be reinforced concrete reinforced according the reinforcement ratios described above. The basis for tabulating ceilings is the same as for walls. Retrofits to existing construction involve removing existing roofs and ceilings where necessary and replacing them with the same construction as is specified for new buildings.

C-3.3 **Construction to Resist Indirect Fire Weapons.** Construction to resist indirect fire weapons is in Table C-8 for new construction and Table C-9 for existing construction. In both cases construction must resist both the effects of blast pressures from the exploding rounds and the effects of the fragmentation of the warhead. It depends, therefore, significantly on mass. Considerations are similar for new construction and retrofits, but they will still be described separately here.

C-3.3.1 **New Construction.**

C-3.3.1.1 **Walls.** Walls must provide blast resistance similar to those described for blast resistant exterior construction, but they must also have sufficient mass to stop or significantly reduce the effects of the warhead fragments. For the lower threat severity level weapons and lower levels of protection, that can be done by slightly enhancing the baseline construction such as by spacing studs closer together for lightweight construction or lightly reinforcing masonry walls for the masonry construction. For all building types the exterior is assumed to have at least a clay brick face, which is sufficient to stop the fragments at those levels. At higher threat severity levels and levels of protection, walls become increasingly heavier reinforced concrete and reinforced concrete masonry.

C-3.3.1.2 **Windows.** While windows can be designed to resist the blast pressure effects of the exploding rounds, they cannot be economically designed to resist the fragment effects as well. Because of that, the approach in this UFC is to replace windows with window assemblies that are resistant to the blast pressure effects, and that are narrow so they minimize exposure to fragments instead of resisting them. Windows cannot be made economically to provide a high level of protection to any but the low threat severity level. In those cases, for the purposes of this UFC, the windows are eliminated and replaced by the same material as is used for the buildings’ walls.

C-3.3.1.3 **Doors.** Building doors to resist both blast and fragments is very expensive and the resulting doors would not be easy to operate. Because of that, all doors for this tactic are backed up by foyers to both catch the failing door and to intercept the fragments. The foyer walls and roofs are of the same construction as the rest of the building.

C-3.3.1.4 **Roofs.** Conventional roofs are sufficient to resist the indirect fire weapons effects for only the low threat severity level. For all other threat severity levels, roof construction is based on a sacrificial roof of conventional construction at either 2 meters (6 feet) or 4 meters (12 feet) above reinforced concrete slab construction of increasing thickness. The sacrificial roof in each case uses the roof construction in the baseline construction as tabulated in Table C-2. Where the baseline construction is standing seam metal roof, the sacrificial roof needs to be hardened slightly using rigid foam insulation and corrugated steel deck.

C-3.3.1.5 **Wall Extensions.** The sacrificial roofs are held up by extended walls to ensure that rounds do not detonate beneath the sacrificial roofs. The wall extensions are of construction similar to that used for the hardened construction, but they are not as heavily reinforced and they may not be as thick.

C-3.3.2 **Existing Construction.**

C-3.3.2.1 **Walls.** Designing wall retrofits to resist the blast pressure and fragmentation effects is only economical at the lower levels of protection and lower threat severity levels. In those cases, walls retrofits are mostly those that were described above for blast resistant exterior construction. They also include adding steel plate to stop the fragment, however. Retrofits to higher threat severity levels and levels of protection are not included at all due to their impracticality.

C-3.3.2.2 **Windows.** Window retrofits involve replacing existing windows with new window assemblies. As for new construction, they only resist the blast pressure effects from the exploding rounds, and not the fragmentation. For buildings with masonry or concrete exteriors, the retrofits include concrete in-fill to minimize the size of the window opening so narrow windows can be installed.

C-3.3.2.3 **Doors.** Doors for retrofits use the same foyers as those for new construction.

C-3.3.2.4 **Roofs.** Roofs for retrofits involve removing the existing roofs and installing new roofs like those for new construction.

C-3.3.2.5 **Wall Extensions.** The wall extensions that support the sacrificial roofs use similar construction to that used for the hardened wall construction, but the wall extensions are not as heavily reinforced, may not be as thick, or may not include the retrofit that is applied to the hardened walls. The wall extensions only need to keep rounds from penetrating and detonating under the sacrificial roof.

C-3.4 **Construction to Resist Direct Fire Weapons.** Construction to mitigate the effects of direct fire weapons is in Table C-10 (new construction) and C-11 (retrofit construction). In both cases, the construction either obscures sightlines to assets (low level of protection) or provides resistance to the effects of the weapons (other levels of protection).

C-3.4.1 **Walls.** Other than the conventional construction to provide obscuration, the walls required to resist the weapons effects are either masonry or reinforced concrete for new construction. For retrofit construction, the walls have steel plate of varying thicknesses added.

C-3.4.2 **Windows.** Windows will be reflective (using fragment retention film or factory applied coatings) for the low level of protection. For the higher levels of protection they are provided only for bullet resistance and include varying thicknesses of laminated glass. The same windows are used for new and retrofit construction, assuming that windows will be replaced during major renovations. There will not be windows at the higher levels of protection for antitank weapons.

C-3.4.3 **Doors.** Doors at the low level of protection will be opaque to obscure sightlines. For the high level of protection for the threat severity levels that are limited to small arms, the doors will be bullet resistant assemblies for new construction and they will be retrofitted with steel plate for retrofit construction. For the higher levels of protection for the larger caliber bullets and the anti-tank weapons, doors are impractical, so conventional doors will be installed in shielded entry foyers.

C-3.4.4 **Roofs.** Roofs in this table are conventional construction based on the assumption that there are no direct fire sightlines to roofs. If there are such sightlines, additional cost will need to be added to account for using reinforced concrete for new construction or adding steel for retrofit construction.

C-3.5 **Construction to Mitigate Airborne Contamination.** The building elements associated with construction to mitigate airborne contamination are limited to enhancements to heating, ventilating, and air conditioning systems. They include increases in system air handling capacity and the addition of filters. Those elements are shown in Table C-12

C-3.6 **Construction to Mitigate Waterborne Contaminants.** Enhancements for waterborne contaminants are limited to water treatment and distribution system elements that are reflected in Table C-13.

C-3.7 **Construction to Mitigate Waterfront Attacks.** The construction enhancements for this tactic are addressed under blast resistant exterior construction and construction to resist direct fire weapons as applicable.

C-3.8 **Forced Entry Resistant Construction.** Construction to resist forced entry is tabulated in Tables C-14 and C-15. The construction includes materials and assemblies that have been tested to provide forced entry resistance for specific time periods against a range of tools.

C-3.8.1 **Walls.** For new construction, walls are reinforced masonry or concrete with varying amounts of reinforcing steel or with the addition of expanded metal mesh. In the case of the varying reinforcement, the reinforcement is both vertical and horizontal and often consists of staggered meshes. For retrofitted walls, various combinations of steel and plywood are added to the existing walls.

C-3.8.2 **Windows.** Windows to resist forced entry, where possible, are laminated glass of varying thicknesses. The same windows are used for new and retrofit construction, assuming that windows will be replaced during major renovations.

C-3.8.3 **Doors.** Doors to resist forced entry have thick steel plate and may be filled with concrete or may include expanded metal meshes. Retrofit doors are similar, assuming doors can be replaced relatively easily during major retrofits.

C-3.8.4 **Roofs.** For new construction, roofs are reinforced concrete with varying levels of reinforcement and expanded metal as described for walls. For retrofit construction, similar additions are made to the roofs as are made to the walls.

C-3.9 **Covert Entry Construction.** There are no significant requirements for construction for mitigating covert entry. The requirements are limited to employing access control equipment and procedures with varying levels of sophistication. The specific equipment reflected in Table C-16 is described in detail in the *DoD Security Engineering Design Manual (UFC 4-011-02).*

C-3.10 **Construction for Mitigating Acoustics Eavesdropping.** Construction to mitigate acoustics eavesdropping is tabulated in Table C-17. It includes considerations for the four major building components as follows:

C-3.10.1 **Walls.** Generally, conventionally constructed interior walls provide adequate attenuation of sound transmission to meet the requirements of all levels of protection. Common interior construction may require the installation of additional layers of gypsum wall board and emplacing insulation in the voids between studs. Retrofit construction effectively is only a consideration for interior walls. It involves removing gypsum wall board from one side of the existing wall, emplacing insulation inside the wall, and replacing the gypsum wall board.

C-3.10.2 **Doors.** Doors to provide sound transmission attenuation can either be conventional solid core wood doors with gaskets around them, which only apply to the low level of protection, or specially manufactured door assemblies designed to provide the applicable STC rating. For retrofits, the existing doors will have to be replaced with the same doors as are used for new construction.

C-3.10.3 **Windows.** Windows used in this manual for attenuating sound transmission are laminated glass of varying thicknesses and configurations insulating glass with differing air space dimensions. For retrofit construction, the existing windows are removed and replaced with windows like those specified for new construction.

C-3.10.4 **Roofs.** Roofs are commonly adequate to attenuate sound transmission without modification. Ceilings are either varying thicknesses of reinforced concrete slab or combinations of gypsum wall board and insulation. One of the tabulated ceilings refers to channels on which the gypsum wall board is mounted. Those channels are light gage steel channels that are common to sound attenuating construction.

C-2.11 **Construction to Mitigate Electronic Emanations Eavesdropping.** Construction to attenuate electronic emanations is very specialized. It involves installing steel sheets in walls, roofs, and ceilings and providing specially manufactured TEMPEST rated doors and windows. For retrofit construction, the doors and windows must be replaced with doors and windows like those used for new construction. Walls, roofs, and ceilings can have the steel sheets added to them, but the interior finish may have to be removed and replaced. There is no table in this appendix for building components associated with this tactic because the costs are too complex and site specific.

C-3.6 **Sitework Element Construction.** Barriers in Table C-18 are perimeter barriers, active barriers, or screens to either provide predetonation of antitank rounds or to shield assets from those weapons. The passive perimeter barriers are either chain link fence or concrete filled pipe bollards. In the case of the chain link fence, it is reinforced with cable except for in the case of the stationary vehicle bomb tactic where the only requirement is to ensure there is an obstacle to easy passage through the perimeter. In that case, the basic chain link fence is adequate for cost estimating purposes. For the active barriers the chain link gate is for the stationary vehicle bomb tactic. The others are tested to resist moving vehicle penetration. Specific models of active barriers were included in the table. They were chosen because they were representative of what is available on the market, and the selections include products from multiple manufacturers. Most manufacturers can provide a model of barrier to meet each requirement, and procurement should be through guide specifications. In the case of the screens, both are free standing and constructed adequately to withstand wind loads. The wood slat fence has posts in concrete footings and the wall has a foundation that extends to frost depth (at least 1 meter for cost estimating purposes.)

Table C-8. Indirect Fire Weapons Resistant Building Construction (New Construction)		
Building Component	**Construction Description**	**Construction Type**
Walls	150 mm (6 in) steel stud wall at 300 mm (12 in.) o.c. with brick veneer	A
	200 mm (8 in) lightly reinforced CMU	B
	200 mm (8 in) moderately reinforced CMU	C
	100 mm (4 in) lightly reinforced concrete	D
	300 mm (12 in) lightly reinforced concrete	E
	600 mm (24 in) lightly reinforced concrete	F
	450 mm (18 in) heavily reinforced concrete	G
	1400 mm (56 in) moderately reinforced concrete	H
Wall Extensions	150 mm (6 in) steel stud wall at 300 mm (12 in.) o.c. with brick veneer	A
	200 mm (8 in) lightly reinforced CMU	B
	100 mm (4 in) lightly reinforced concrete	C
Windows	6 mm (1/4 in) + 2 x 3 mm (1/8 in) glass with 0.75 mm (0.030 in) PVB in narrow window	A
	6 mm (1/4 in) + 4 x 3 mm (1/8 in) glass with 3 x 1 mm (0.045 in) PVB in narrow window	B
	No window – use wall material as in fill	C
Doors	Doors in entry foyer using same construction as rest of building (walls, wall extensions, hardened roof, sacrificial roof)	A
Hardened Roofs	Standing seam metal roof + 50 mm (2 in) extruded polystyrene insulation + 50 mm (2 in) corrugated steel deck	1
	150 mm (6 in) moderately reinforced concrete (1.5 m / 5 ft span – 2 m / 6 ft high)	2
	225 mm (9 in) lightly reinforced concrete (1.5 m / 5 ft. span)	3
	225 mm (9 in) lightly reinforced concrete (3.8 m / 12.5 ft. span)	4
	225 mm (9 in) lightly reinforced concrete (6 m / 20 ft. span)	5
	225 mm (9 in) moderately reinforced concrete (1.5 m / 5 ft. span)	6
	225 mm (9 in) moderately reinforced concrete (3.8 m / 12.5 ft. span)	7
	225 mm (9 in) moderately reinforced concrete (6 m / 20 ft. span)	8

Table C-8 (continued)

Hardened Roofs (continued)	225 mm (9 in) heavily reinforced concrete (6 m / 20 ft. span)	9
	300 mm (12 in) moderately reinforced concrete (6 m / 20 ft. span)	10
	300 mm (12 in) heavily reinforced concrete (6 m / 20 ft. span)	11
Sacrificial Roofs	Conventional built up roofing at 2 m (6 ft)	1
	Conventional built up roofing at 4 m (12 ft)	2
	Standing seam metal roof + 50 mm (2 in) extruded polystyrene insulation + 50 mm (2 in) corrugated steel deck at 2 m (6 ft)	3
	Standing seam metal roof + 50 mm (2 in) extruded polystyrene insulation + 50 mm (2 in) corrugated steel deck at 4 m (12 ft)	4

Table C-9. Indirect Fire Weapons Resistant Building Construction (Existing Construction)

Building Component	Construction Description	Construction Type
Walls	Add steel studs between existing studs in existing steel stud wall (with brick veneer)	A
	100 mm (4 in) unbonded lightly reinforced concrete backing wall	B
	150 mm (6 in) unbonded lightly reinforced concrete backing wall	C
	150 mm (6 in) unbonded moderately reinforced concrete backing wall	D
	Steel stud wall retrofit	E
	Steel stud wall retrofit with 50 mm (2 in) steel plate	F
Wall Extensions	150 mm (6 in) steel stud wall at 300 mm (12 in.) o.c. with brick veneer	A
	200 mm (8 in) lightly reinforced CMU	B
Windows	1/4" (6 mm) + 2 x 1/8 in (3 mm) glass + 0.030 in (0.75 mm) PVB narrow window with wall in fill	A
Doors	Doors in entry foyer using same construction as rest of building (walls, wall extensions, hardened roof, sacrificial roof)	A
Hardened Roofs	Standing seam metal roof + 50 mm (2 in) extruded polystyrene insulation + 50 mm (2 in) corrugated steel deck	1
	150 mm (6 in) moderately reinforced concrete (1.5 m / 5 ft span - 2 m / 6 ft high)	2
	225 mm (9 in) lightly reinforced concrete (1.5 m / 5 ft. span)	3
	225 mm (9 in) lightly reinforced concrete (3.8 m / 12.5 ft. span)	4
	225 mm (9 in) lightly reinforced concrete (6 m / 20 ft. span)	5
	225 mm (9 in) moderately reinforced concrete (1.5 m / 5 ft. span)	6
	225 mm (9 in) moderately reinforced concrete (3.8 m / 12.5 ft. span)	7
	225 mm (9 in) moderately reinforced concrete (6 m / 20 ft. span)	8
	225 mm (9 in) heavily reinforced concrete (6 m / 20 ft. span)	9
	300 mm (12 in) moderately reinforced concrete (6 m / 20 ft. span)	10

Table C-9 (continued)

Hardened Roofs (continued)	300 mm (12 in) heavily reinforced concrete (6 m / 20 ft. span)	11
Sacrificial Roofs	Conventional built up roofing at 2 m (6 ft)	1
	Standing seam metal roof + 50 mm (2 in) extruded polystyrene insulation + 50 mm (2 in) corrugated steel deck at 2 m (6 ft)	2

Table C-10. Direct Fire Weapons Resistant Building Construction (New Construction)		
Building Component	**Construction Description**	**Construction Type**
Walls	No special construction (opaque)	A
	4-inch fully grouted concrete masonry unit or 4-inch clay brick	B
	6-inch fully grouted concrete masonry unit	C
	8-inch fully grouted concrete masonry unit	D
	24-inch thick reinforced concrete	E
Windows	4-mil reflective fragment retention film	A
	1/4 inch laminated glass in accordance with DoD minimum antiterrorism standards	B
	1/2 inch laminated tempered glass, 1/4 inch air gap and 3/4 inch glass clad polycarbonate (1/2 inch polycarbonate with 1/4 inch tempered glass on inside face)	C
	3/4 inch laminated tempered glass, 1/4 inch air gap and 1-3/16 inch glass clad polycarbonate (15/16 inch polycarbonate with 1/4 inch tempered glass on inside face)	D
	1-5/8 inch laminated annealed glass and 1/4 inch polycarbonate (1/4 inch polycarbonate with 1/4 inch tempered glass on inside face)	E
Doors	Standard hollow metal door	A
	Industrial door (3 foot by 7 foot) with interior 1/4 inch thick steel armor plate	B
	Industrial door (3 foot by 7 foot) with interior 7/16 inch thick steel armor plate	C
	Industrial door (3 foot by 7 foot) with interior 11/16 inch thick steel armor plate	D
	Doors shielded with 24-inch reinforced concrete walls	E
Roofs	No special roof construction (opaque)	A
	20K10 L=30’ (9.1 m);B=6’ (1.8 m) with metal deck and 4.5” (115 mm) concrete	B
	30K12 L=40’ (12.2 m);B=6’ (1.8 m) with metal deck and 4.5” (115 mm) concrete	C
	30K12 L=60’ (18.2 m);B=6’ (1.8 m) with metal deck and 4.5” (115 mm) concrete	D
	225 mm (9in) lightly reinforced concrete	E
	600 mm (24 in) lightly reinforced concrete	F

Table C-11. Direct Fire Weapons Resistant Building Construction (Retrofit Construction)		
Building Component	**Construction Description**	**Construction Type**
Walls	No special construction (opaque)	A
	5/16 mild steel plate	B
	9/16 mild steel plate	C
	13/16 mild steel plate	D
Windows	4-mil reflective fragment retention film	A
	1/2 inch laminated tempered glass, 1/4 inch air gap and 3/4 inch glass clad polycarbonate (1/2 inch polycarbonate with 1/4 inch tempered glass on inside face)	B
	3/4 inch laminated tempered glass, 1/4 inch air gap and 1-3/16 inch glass clad polycarbonate (15/16 inch polycarbonate with 1/4 inch tempered glass on inside face)	C
	1-5/8 inch laminated annealed glass and 1/4 inch polycarbonate (1/4 inch polycarbonate with 1/4 inch tempered glass on inside face)	D
Doors	Standard hollow metal door	A
	Industrial door (3 foot by 7 foot) with interior 1/4 inch thick steel armor plate	B
	Industrial door (3 foot by 7 foot) with interior 7/16 inch thick steel armor plate	C
	Industrial door (3 foot by 7 foot) with interior 11/16 inch thick steel armor plate	D
Roofs	No special roof construction (opaque)	A
	UL Level 3 ballistics rated fiberglass	B
	UL Level 5 ballistics rated fiberglass	C

Table C-12. HVAC Requirements for Airborne Contamination

Level of Protection	HEPA filtration	HEPA and carbon filtration for outside air	HEPA and carbon filtration for all supply air	Overpressurization
Low	X			
Medium		X		X
High			X	X
Note: Overpressurization based on 0.25 cfm /ft^2 plus exhaust				

Table C-13. Water Treatment Requirements for Waterborne Contamination

Level of Protection	Superchlorination	Micro-filtration	Carbon filtration	Chlorination	Reverse Osmosis
Low	X				
Medium		X	X	X	
High		X	X	X	X

Table C-14. Forced Entry Resistant Building Construction (New Construction)		
Building Component	**Construction Description**	**Construction Type**
Walls	4-inch, solid-core, filled and reinforced masonry construction with interior wall system	A
	8-inch, solid-core, filled concrete masonry with #3 bars at 8 inches on center each way	B
	8-inch, solid-core, filled concrete masonry with #5 bars at 8 inches on center each way	C
	8-inch, mortar-filled concrete block with #6 bars at 8 inches on center each way	D
	8-inch, reinforced concrete with # 4 bars at 6 inches on center each way	E
	12-inch, mortar-filled, concrete block with #6 bars at 8 inches on center each way	F
	8-inch, solid-core, filled concrete masonry with #6 bars at 4 inches on center vertically and 8 inches on center horizontally	G
	12-inch, reinforced concrete with # 5 bars at 6 inches on center each way	H
	12-inch, reinforced concrete with 2 layers of #5 bars at 6 inches on center each way	I
	12-inch, reinforced concrete with 2 layers of # 7 bars at 4 inches on center each way	J
	12-inch, reinforced concrete with 5/16 expanded metal 2½ inches on center (4 layers)	K
	12-inch, reinforced concrete with 5/16-inch, expanded, metal mesh at 2½ inches on center and a ¼-inch backing plate	L
	18-inch-thick reinforced concrete with 5/16-inch expanded metal at 2½ inches on center and a ¼-inch backing plate	M
Windows	11/16-inch, glass-clad with 3/8-inch polycarbonate core	A
	13/16-inch, glass-clad with ½-inch polycarbonate core	B
	15/16-inch, glass-clad with 3/4-inch polycarbonate core	C

Table C-14 (continued)

Doors	Standard 16-gage, hollow, metal door (3 feet by 7 feet) with hinge-side protection, anti-pry strip, and drill-resistant dead bolt lock	A
	12-gage, hollow, metal door (3 feet by 7 feet) with hinge-side protection, anti-pry strip, and drill-resistant dead bolt lock	B
	12-gage, hollow, metal door with hinge-side protection, anti-pry strip, drill-resistant dead bolt lock, and filled with lightweight fireproofing	C
	12-gage, hollow, metal door filled with lightweight concrete (3 feet by 7 feet) with hinge-side protection, anti-pry strip, and drill-resistant dead bolt lock	D
	12-gage, hollow, metal door (3 feet by 7 feet) with hinge-side protection, anti-pry strip, drill-resistant dead bolt lock, and multipoint (3) locking	E
	Swinging door (6 inches thick) with ½-inch plate inside and out, lightweight concrete fill, and an internal locking system	F
	Sliding door (6 inches thick) filled with lightweight concrete that has been reinforced with expanded metal mesh with a 3/4-inch steel front plate, 1/4–inch back plate, and an internal locking system	G
	Swinging door (10 inches thick) with ½-inch plate inside and out	H
	Swinging door (10 inches thick) with ½-inch plate inside and out, lightweight concrete fill, and an internal locking system	I
	Swinging door (10 inches thick) with ½-inch plate inside and out, lightweight concrete fill reinforced with expanded metal mesh, and an internal locking system	J
	Swinging door (10 inches thick) with ½-inch plate inside and out, lightweight concrete fill reinforced with expanded metal mesh, and an internal locking system with a welded C-steel grating vestibule around the door for standoff protection	K

Table C-14 (continued)

Roofs	Built-up roof with gravel and rigid insulation on steel decking	A
	Built-up roof with gravel and rigid insulation and 2.5-inch lightweight concrete on steel decking	B
	Built-up roof with gravel and rigid insulation and 4-inch lightweight concrete with #5 bars at 8 inches on center each way on steel decking	C
	6-inch, reinforced concrete with #4 bars at 8 inches on center each way on steel decking and with built-up roofing	D
	6-inch, reinforced concrete with # 4 bars at 6 inches on center each way on steel decking and with a built-up roofing system	E
	8-inch, reinforced concrete with #4 bars at 8 inches on center each way on steel decking and with built-up roofing	F
	4-inch, reinforced concrete with 6 by 6 welded wire mesh, 10-gage reinforcing on steel decking and a built-up roofing system	G
	6-inch, reinforced concrete with 6 by 6 welded wire mesh, 10-gage reinforcing on steel decking and a built-up roofing system	H
	10-inch, reinforced concrete with # 5 bars at 6 inches on center each way on steel decking and with a built-up roof	I
	10-inch, reinforced concrete with 2 layers of #5 bars at 6 inches on center each way on steel decking and with a built-up roofing system	J
	10-inch, reinforced concrete with 5/16 expanded metal 2½ inches on center on steel decking with a built-up roofing system	K
	12-inch, reinforced concrete with 2 layers of # 7 bars at 4 inches on center each way on steel decking and built-up roofing	L
	10-inch, reinforced concrete with 5/16-inch, expanded, metal mesh at 2½ inches on center with ¼-inch decking and a built up roofing system	M
	12-inch-thick, reinforced concrete with 5/16-inch expanded metal at 2½ inches on center, ¼-inch steel decking, and built-up roofing	N

Table C-15. Forced Entry Resistant Building Construction (Retrofit Construction)		
Building Component	**Construction Description**	**Construction Type**
Walls	Add ¾-inch plywood to the inside face	A
	Add #5 bars at 8 inches on center reinforcing or grating to the inside face between exterior and interior walls.	B
	Add 9-gage, expanded, metal mesh between existing exterior and interior wall systems	C
	Add 9-gage sheet metal between existing exterior and interior wall systems	D
	Add ¼-inch steel plate between existing exterior and interior wall systems	E
	Add 3-layer (10-gage steel/ ¾-inch plywood/10-gage steel), steel-plywood system between existing exterior and interior wall systems	F
	Add 5-layer (10-gage steel/ ¾-inch plywood/10-gage steel/ ¾-inch plywood/10-gage steel) steel-plywood system between existing interior and exterior wall systems.	G
	Add 7-layer (10-gage steel/ ¾-inch plywood/10-gage steel/ ¾-inch plywood/10-gage steel/ ¾-inch plywood/10-gage steel) steel-plywood system between existing interior and exterior wall systems	H
Windows	11/16-inch, glass-clad with 3/8-inch polycarbonate core	A
	13/16-inch, glass-clad with ½-inch polycarbonate core	B
	15/16-inch, glass-clad with ¾-inch polycarbonate core	C
Doors	Standard 16-gage, hollow, metal door (3 feet by 7 feet) with hinge-side protection, anti-pry strip, and drill-resistant dead bolt lock	A
	A vestibule outside entrance door, designed to resist explosive effects, must be provided to force two explosive attempts	B
	12-gage, hollow, metal door (3 feet by 7 feet) with hinge-side protection, anti-pry strip, and drill-resistant dead bolt lock	C

Table C-15 (continued)

Doors (continued)	12-gage, hollow, metal door (3 feet by 7 feet) with hinge-side protection, anti-pry strip, and drill-resistant dead bolt lock and filled with lightweight fireproofing	D
	Steel door with ¼-inch inner and outer face (3 feet x 7 feet) with hinge-side protection, anti-pry strip, drill-resistant dead bolt lock, and multipoint (3) locking	E
	Sliding door (6 inches thick) filled with lightweight concrete that has been reinforced with expanded metal mesh with a 3/4-inch steel front plate, 1/4–inch back plate, and an internal locking system	F
	Swinging door (6 inches thick) with ½-inch plate inside and out, lightweight concrete fill, and an internal locking system	G
	Swinging door (10 inches thick) with ½-inch plate inside and out	H
	Swinging door (10 inches thick) with ½-inch plate inside and out, lightweight concrete fill, and an internal locking system	I
	Swinging door (10 inches thick) with ½-inch plate inside and out, lightweight concrete fill reinforced with expanded metal mesh, and an internal locking system	J
Roofs	Built-up roof with gravel and rigid insulation on steel decking	A
	Add ¾-inch plywood and built-up roofing on top of existing metal seam construction	B
	Install #5 bar 8 inches on center square grid under existing roof construction.	C
	Add 9-gage, expanded, metal mesh on top of existing roof system, then resurface	D
	Add 9-gage, steel sheet on top of existing roofing system, then resurface	E
	Install ¼-inch steel plate on top of existing roofing system, and then resurface.	F
	Add 3-layer (10-gage steel/ 3/4-inch plywood/10-gage steel), steel-plywood system under the existing roof system	G
	Add 3-layer (10-gage steel/ 3/4-inch plywood/10-gage steel), steel-plywood system on top of existing roof system, then resurface	H

Table C-15 (continued)

Roofs (continued)	Add 5-layer (10-gage steel/ 3/4-inch plywood/10-gage steel/ 3/4-inch plywood/10-gage steel), steel-plywood system on top of existing roof, and then resurface.	I
	Add 7-layer (10-gage steel/ 3/4-inch plywood/10-gage steel/ 3/4-inch plywood/10-gage steel/ 3/4-inch plywood/10-gage steel) steel-plywood system on top of existing roof, and then resurface	J

Table C-16. Access Control Equipment for Covert Entry Tactic

Threat Severity Level	Equipment Set	Level of Protection	Equipment												
			Electric Strike Lock	Mag. Lock	Card Reader	PIN Reader	Shielded PIN Reader	Biometric Device	Portal Counter	Turnstile	Person-trap	IDS on Operable Openings	Motion Sensor in Information	CCTV	Metal Detector
Very High	P	Very High						X			X	X	X	X	X
	O	High					X			X		X	X	X	X
	N	Medium		X			X		X			X			
	M	Low		X			X		X						
High	L	Very High						X			X	X	X	X	X
	K	High					X			X		X	X	X	X
	J	Medium		X			X		X			X			
	I	Low		X			X		X						
Medium	H	Very High		X				X				X	X	X	
	G	High		X			X					X	X	X	
	F	Medium		X			X					X			
	E	Low		X			X								
Low	D	Very High		X	X	X		X				X	X	X	
	C	High		X	X							X	X	X	
	B	Medium		X		X						X			
	A	Low	X												

Note: No special construction is required for this tactic
NR = Not required

Table C-17. Construction for Acoustics Eavesdropping Tactic (New and Existing Construction)

Building Component	Construction Description	Construction Type
Walls	Conventional construction	A
	Steel studs with gypsum wallboard both sides and insulation in cavity	B
	Steel studs with 2 layers of gypsum wallboard on one side and one on the other with insulation in cavity	C
Windows	6 mm (1/4 inch) laminated glass	A
	Insulated glass window with 10 mm (3/8 inch) laminated glass inside, 6 mm (1/4 inch) laminated glass outside, 12 mm (1/2 inch) airspace	B
	Insulated glass window with 6 mm (1/4 inch) laminated glass inside, 6 mm (1/4 inch) laminated glass outside, 50 mm (2 inch) airspace	C
	Insulated glass window with 12 mm (1/2 inch) laminated glass inside, 5 mm (3/16 inch) laminated glass outside, 100 mm (4 inch) airspace	D
Doors	Conventional solid core wood or insulated steel door with gaskets	A
	Specially manufactured STC 40 rated door	B
	Specially manufactured STC 45 rated door	C
	Specially manufactured STC 50 rated door	D
Ceilings / Roofs	Conventional construction	A
	Wood joists with 2 layers of plywood subfloor gypsum wallboard underneath	B
	100 mm (4 inch) reinforced concrete	C
	Wood joists with 2 layers of plywood subfloor gypsum wallboard suspended on channels underneath	D
	150 mm (6 in) (6 inch) reinforced concrete	E
	Wood or steel joists with gypsum wall board and insulation in cavities	F
	Wood or steel joists with 2 layers of gypsum wallboard and insulation in cavities	G

Table C-18. Sitework Element Construction		
Barrier Category	**Barrier Construction**	**Construction Type**
Passive Perimeter	Standard 8-foot high, (7-foot fabric) 9 gage steel chain link fence with outrigger	A
	Standard chain link fence with a single ¾-inch cable anchored every 200 feet; allows 20- to 40-foot penetration into site	B
	Standard chain link fence with two ¾-inch cables anchored every 200 feet; allows 20- to 40-foot penetration into site	C
	Standard chain link fence with three ¾-inch cables anchored every 200 feet; allows 20- to 40-foot penetration into site	D
	8-inch diameter, concrete-filled bollards at 3 feet on center; penetration into site 0 to 3 feet	E
	8-inch diameter, concrete-filled bollards at 2 feet on center; penetration into site 0 to 3 feet	F
	8-inch diameter, concrete-filled bollards at 2 feet on center with 12-inch channel rail; penetration into site 3 to 20 feet	G
Active	Standard chain link gate	H
	Barriers similar to the ARMR Model 712 cable crash beam barrier or the Delta Scientific Model TT212 crash tested and shown to stop 40 K foot-pounds of kinetic energy	I
	Barriers similar to the Nasatka Model XI or the Delta Scientific Model TT203 crash tested and shown to stop 350 K foot-pounds of kinetic energy	J
	Barriers similar to the Nasatka Model VII or the Delta Scientific Model TT210 have been crash tested and shown to stop 450 K foot-pounds of kinetic energy	K
	Barriers similar to the Nasatka Model IIIb or the Delta Scientific Model TT207 crash tested and shown to stop 1.2 M foot-pounds of kinetic energy	L
	Barriers similar to the Nasatka Model V or Delta Scientific Model TT207 (S) have been crash tested and shown to stop 1.2 M foot-pounds of kinetic energy	M
	No commercial active barriers available that have been tested at this level of impact; however, basic construction of standard vehicles makes them vulnerable to barrier systems recommended for the very high threat severity level. Penetration of the disabled vehicle into the site could exceed requirements at this level	N
Screen	¾ -inch wood slat fence predetonation screen x 8 feet high	O
	2-foot thick reinforced concrete shielding wall x 8 feet high	P
Note: All active vehicle barriers may allow vehicle penetration of 3 to 20 feet.

APPENDIX D

EXPEDITIONARY CONSTRUCTION COSTS

D-1 **INTRODUCTION.** The purpose of the table in this appendix is to provide planning level estimates of costs to incorporate countermeasures for security and antiterrorism into expeditionary and temporary construction.

D-2 **FORMULATION.** While the tables in Appendices A and B tabulate cost increases over the cost of new construction, that approach is not realistic for expeditionary construction due to the fact that there is no DoD-wide data base of expeditionary construction the way there is for permanent new construction. Expeditionary construction is not done as commonly as permanent new construction and the nature of expeditionary construction is that its cost varies significantly depending on who is building it and where it is being built. Because of the wide variability of this construction, the costs are tabulated here as actual costs of labor, materials, and equipment. In addition, the number of man-hours necessary to do the construction is tabulated. These costs can be used on a relative basis by comparing them to known costs of labor, materials, and equipment in the location where cost is being estimated or by using area cost factors as tabulated in the *DoD Facilities Pricing Guide (UFC 4-701-05)* .

D-3 **USING THE TABLE.** To use Table D-1, determine the countermeasure that is needed to mitigate a threat and the quantity of that component that is required. The costs shown for materials, labor, and equipment are in dollars per man-hour of installation time. The installation time is shown in man-hours per unit of measure. To determine the total cost of installing a given countermeasure, sum the applicable material, labor, and equipment costs per unit of measure and multiply that sum by the quantity of units required. The costs tabulated are for an area cost factor of one. They will need to be adjusted to reflect differences in costs of construction in other areas using either the area cost factors in the *DoD Facilities Pricing Guide (UFC 4-701-05)* or known costs for materials, labor, and equipment in the area. The installation time requirements are in man-hours per unit. To calculate the amount of time required for installation in terms of man-hours, multiply the number of units required by the installation number.

The cost and installation time would be calculated as follows:

- Cost = Units x (Materials +Labor + Equipment)
- Installation Time = Units x Installation

D-4 **EXAMPLE.** A base camp needs to be surrounded by one mile (5280 feet) of triple standard concertina fence and a countermobility berm. There also need to be four entry lanes with motorized gates. The costs and installation times would be as follow:

- Triple Standard Concertina Fence:
  Cost = 5280 lf x ($9.00/lf + $0.95/lf + $0.00/lf) = $52,536
  Installation Time = 5280 lf x 0.03 mh/lf = 158.4 man-hours

- Freestanding Soil Berm (6 ft High):
  Cost = 5280 lf x ($0.00/lf + $11.00/lf + $17.60/lf) = $151,008
  Installation Time = 5280 lf x 0.3 mh/lf = 1584 man-hours

- Fence Gate (12 ft, One Lane):
  Cost = 4 lanes x ($530.00/lane + $630.00/lane + $310.00/lane) = $5,880
  Installation Time = 4 lanes x 20.4 mh/lane = 81.6 man-hours

- Mechanical Fence Gate Operator (12 ft, One Lane):
  Cost = 4 lanes x ($1,560.00/lane + $520.00/lane + $240.00/lane) = $9,280
  Installation Time = 4 lanes x 17 mh/lane = 68 man-hours

- Total Cost: $ 218,704

D-5 **RECORDING THE COST.** How costs are recorded for expeditionary construction is widely variable depending on the operation and the funds source. Follow guidance established for the applicable operation.

Table D-1. Expeditionary Costs

Expedient Passive Defense Measure	Unit	Installation (M.H/Unit)	Materials ($/Unit)	Labor ($/Unit)	Equipment ($/Unit)
Signage					
Warning Signs	Ea	0.20 mh	$26.00	$6.00	$5.00
Physical Barriers					
Traffic Barricades	Ea	0.10 mh	$87.00	$4.00	$0.00
Plastic Safety Fence	Lf	0.03 mh/lf	$1.44	$0.40	$0.00
Ornamental Steel Fence	Lf	0.16 mh/lf	$24.00	$5.00	$2.30

This UFC supersedes UFC 4-021-01, dated 18 December 2002.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD(AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Support Agency (AFCESA) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request (CCR). The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 4-021-01
Superseding: UFC 4-021-01, dated 18 December 2002

Description of Changes: This revision to UFC 4-021-01 incorporates new mass notification system (MNS) design requirements for the Air Force, Army, Marine Corps, and Navy. Design figures were changed accordingly. Criteria was added approving the use of combined MNS and fire alarm systems in some facilities. Chapters were added on wide area MNS, operational characteristics, and special considerations. Sample pre-recorded MNS messages were added in Appendix B. Progress towards incorporation of Internet capability into DOD mass notification is discussed in Appendix C.

Reasons for Changes:

- Incorporate lessons learned from field experience since the initial revision of this UFC in 2002.
- Achieve consistency with new national consensus standards for MNS.
- Incorporate Marine Corps MNS requirements into one consolidated manual.
- Comply with the new format for Security Engineering UFC series documents.

Impact: There are negligible cost impacts; however, these benefits should be realized:

- Simplify construction and avoid installation costs in many new and renovated facilities by permitting combined MNS and fire alarm systems.
- Simplify procurement of MNS equipment by requiring consistency with national consensus standards for MNS.
- Ensure future MNS will coordinate with the new national “public alert and warning system” required by Executive Order 13407 of 28 June 2006.

CHAPTER 1

INTRODUCTION

1-1 **BACKGROUND.** Mass notification provides real-time information and instructions to people in a building, area, site, or installation using intelligible voice communications along with visible signals, text, and graphics, and possibly including tactile or other communication methods. The purpose of mass notification is to protect life by indicating the existence of an emergency situation and instructing people of the necessary and appropriate response and action.

This Unified Facilities Criteria (UFC) was developed by collecting and refining criteria from Department of Defense (DOD) antiterrorism guidance, examining previous mass notification system (MNS) evaluation reports, and reviewing the capabilities of representative, commercially available MNS and products.

1-2 **PURPOSE.** This UFC provides technical criteria for systems that will:

- Implement mass notification in compliance with the DOD antiterrorism requirements as specified in UFC 4-010-01

- Implement national design standards and recommendations for mass notification systems as provided in National Fire Protection Association (NFPA) Standard 72 (including Annex E)

- Achieve coordination of DOD mass notification capabilities with national systems as required by Executive Order 13407

1-3 **SCOPE.** This UFC provides the design, operation, and maintenance requirements of MNS for DOD facilities. The requirement for a MNS is established by UFC 04-010-01. This document is intended to assist in the design of systems that meet the requirement established by UFC 04-010-01 and to give guidance to commanders, architects, engineers, and end users on design, operation, and maintenance of MNS.

1-3.1 **Applicability**. This UFC applies to new construction, major renovations, and leased buildings and must be used in accordance with the applicability requirements of UFC 4-010-01 or as directed by service guidance. See UFC 4-010-01 for more information on the applicability requirements.

1-3.2 **Service Exception.** Where one or more service's criteria vary from the other services' criteria, it is noted in the text with the SE (Service Exception) symbol.

1-3.3 **Compliance with Technical Criteria.** Do not deviate from the technical criteria of this UFC without prior approval from the component office of responsibility:

- U.S. Air Force: Air Force Civil Engineer Support Agency, \1\ Operations and

Programs Support Division /1/ (HQ AFCESA/CEO)

- U.S. Army: U.S. Army Corps of Engineers, Directorate of Civil Works, Engineering and Construction (HQ USACE/CECW-CE)
- U.S. Navy: Naval Facilities Engineering Command, Headquarters Chief Engineer's Office (NAVFACENGCOM HQ Code CHE)
- U.S. Marine Corps (HQMC), Code PS and Code LFF-1
- Defense Logistics Agency Director (HQ DLA-D) through Support Services (DLA-DES-SE)
- National Geospatial-Intelligence Agency (NGA), Security and Installations
- Other DOD components: the Office of the Deputy Under Secretary of Defense (Installations & Environment) (DUSD [I&E]) via the DOD Committee on Fire Protection Engineering

1-3.4 **Authority having Jurisdiction (AHJ).** The component office of responsibility listed in paragraph 1-3.3 is also referred to in this UFC as the AHJ.

1-3.5 **Waivers and Exemptions.** The AHJ may approve waivers and exemptions to the technical criteria of this UFC only. Waivers and exemptions shall comply with the requirements of MIL-STD-3007, *Department of Defense Standard Practice for Unified Facilities Criteria and Unified Facilities Guide Specifications*.

1-3.6 **Implementation.** Implementation of an effective MNS will require the coordinated efforts of engineering, communications, and security personnel. Fire protection engineering personnel are needed for the successful implementation of this UFC because they bring a special expertise in life safety evaluations, building evacuation systems, and the design of public notification systems. Coordination with communications personnel is required when the MNS is connected to the DOD installation's communications infrastructure. The designated first responders of the DOD installation are ultimately responsible for the protection of building occupants, and will be the primary users of an individual building MNS. Designated security or command personnel will be the primary users of a wide area MNS and should recommend installation projects, oversee access control, update central control system mapping and, as necessary, develop associated local recipient groups for targeted notification.

1-3.7 **Responsibilities.** DOD does not mandate which organizations are responsible for funding, operation, or maintenance of MNS installed in accordance with UFC 4-010-01; each DOD component must assign those responsibilities.

1-3.8 **Retroactivity.** Existing MNS installed in compliance with an earlier version of this UFC do not have to be modified to meet the requirements of the current edition of this UFC; however, any alteration or any installation of new equipment shall meet, as nearly as practicable, the requirements for new MNS.

1-4 **REFERENCES.** See Appendix A.

1-5 **QUALIFICATIONS OF SUPPLIERS AND CONTRACTORS**

1-5.1 **System Integrators and Contractors.** Use system integrators and contractors that are able to demonstrate a full knowledge and understanding of systems used for mass notification, and that have factory-trained personnel to perform system design, installation, testing, training, and maintenance.

1-5.2 **MNS Component Products and Manufacturers.** Only accept products from manufacturers that can meet the design criteria of this UFC and can demonstrate 5 years of experience in producing products similar to those required for mass notification. Utilize products of current manufacture with replacement parts and components available for a minimum of ten years.

1-5.3 **Performance and Acceptance Testing**

1-5.3.1 Upon completion of the installation, the contractor must complete performance testing of the MNS for compliance with this UFC. Verification of performance testing will be checked by local representatives of the AHJ. Performance results, including the required sound pressure levels and intelligibility values, shall be documented and submitted to the AHJ with notation of any deficiencies and corrective actions.

Note: The AHJ are those component offices of responsibility listed in paragraph 1-3.3 (see paragraph 1-3.4).

1-5.3.2 Upon successful completion of performance testing, the contractor must complete a witnessed acceptance test. Acceptance testing will be witnessed by local representatives of the AHJ. (See paragraph 1-3.4 for more information on the AHJ.)

1-5.4 **Installation Records.** The contractor must provide a complete set of record drawings and operations and maintenance manuals for the MNS. Record drawings and operations and maintenance manuals must provide information for troubleshooting, preventive maintenance, and corrective maintenance.

1-6 **SECURITY ENGINEERING UFC SERIES.** This UFC is one of a series of security engineering UFC documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include:

1-6.1 **DOD Minimum Antiterrorism Standards for Buildings.** UFC 4-010-01 and 4-010-02 establish standards that provide minimum levels of protection against terrorist attacks for the occupants of all inhabited DOD buildings. These UFC are intended to be used by security and antiterrorism personnel and design teams to identify the minimum requirements that must be incorporated into the design of all new construction and major renovations of inhabited DOD buildings. These UFC also include recommendations for designs that should be, but are not required to be, incorporated into all such buildings.

1-6.2 **Security Engineering Facilities Planning Manual.** UFC 4-020-01FA presents processes for developing the design criteria necessary to incorporate security and antiterrorism measures into DOD facilities and for identifying the cost implications of applying those design criteria. These design criteria may be limited to the requirements of the minimum standards, or they may include protection of assets other than those addressed in the minimum standards (people), aggressor tactics that are not addressed in the minimum standards, or levels of protection beyond those required by the minimum standards. The cost implications for security and antiterrorism are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they represent only representative construction that will meet the requirements of the design criteria. The manual also addresses the tradeoffs between cost and risk. UFC 4-020-01FA is intended to be used by planners as well as security and antiterrorism personnel with support from planning team members.

1-6.3 **Security Engineering Facilities Design Manual.** UFC 4-020-02FA provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established in UFC 4-020-01FA. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them work as a system. The information in UFC 4-020-02FA is in sufficient detail to support concept-level project development, and as such can provide a good basis for a more detailed design. The manual also provides a process for assessing the impact of protective measures on risk. The primary audience for UFC 4-020-02FA is the design team, but the UFC can also be used by security and antiterrorism personnel.

1-6.4 **Security Engineering Support Manuals.** In addition to the standards, planning, and design UFC discussed in paragraphs 1-6.1 through 1-6.3, a series of additional UFC documents is planned that will provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02FA. These support manuals will provide specialized, discipline-specific design guidance. Some will address specific tactics such as direct-fire weapons, forced entry, or airborne contamination. Others will address limited aspects of design such as resistance to progressive collapse or the design of portions of buildings such as mailrooms. Still others will address details of designs for specific protective measures such as vehicle barriers or fences. The security engineering support manuals are intended to be used by the design team during the development of final design packages.

CHAPTER 2

OVERVIEW OF SYSTEMS

2-1 **SCOPE.** This chapter includes important definitions and provides an overview of MNS.

2-2 **CAPABILITY.** Mass notification provides real-time information and instructions to people in a building, area, site, or DOD installation using intelligible voice communications along with visible signals, text, and graphics, and possibly including tactile or other communication methods. MNS are intended to protect life by indicating the existence of an emergency situation and instructing people of the necessary and appropriate response and action.

2-3 **LIFE SAFETY SYSTEMS.** MNS are designated as life safety systems in a manner similar to DOD-required fire protection systems.

2-4 **ACCESSIBILITY.** Compliance with \1\ Architectural Barriers Act Accessibility Guidelines (ABAAG) /1/ for MNS is required. Visual alarm notification appliances shall be provided inside of buildings for hearing impaired persons when new MNS are installed. Providing visual alarm notification appliances is required for DOD compliance with Executive Order 13347*.*

2-5 **PUBLIC ALERT AND WARNING SYSTEM.** Coordination of MNS with national alert and warning systems is required for DOD compliance with Executive Order 13407*.*

2-6 SYSTEM TYPES

Note: See Appendix C for a discussion of Internet-based alerting systems.

2-6.1 **Wide Area MNS.** Wide area MNS are installed to provide real-time information to outdoor areas of a DOD installation. These systems are normally provided with and operated from two or more central control stations. Communications between central control stations and individual building MNS is provided. Communications between the central control stations and regional or national command systems may also be provided. The requirements to install wide area MNS are specific to each DOD component. A general DOD requirement to install these systems on all DOD installations has not yet been established.

2-6.1.1 **Interconnection with Individual Building MNS.** The wide area MNS manufacturer shall provide a standard interface method (such as an audio line-level output and multiple relay contacts) or supply the necessary digital communication protocols to permit the DOD installation to select more than one manufacturer of individual building MNS. Depending on system architecture, the manufacturer may be required to provide a system Internet Protocol (IP) interface capable of allowing data transfer from an outside source to internal mass notification functions via a common data communications protocol.

2-6.1.2 **Army Installations.** Wide area MNS shall be installed on Army installations in accordance with Army Chief of Staff antiterrorism guidance.

2-6.1.3 **Air Force Installations.** A wide area MNS shall be a component of and connected to the Installation Notification and Warning System (INWS) as defined by Air Force instruction (AFI) 10-2501. The INWS typically includes a "giant voice" system for outdoor notification of personnel.

2-6.1.4 **Marine Corps Installations.** Wide area MNS shall be installed on Marine Corps installations in accordance with the most current edition of Marine Corps Order (MCO) 5530.14 and MCO 3302.1.

Note: Marine Corps designs use central control stations shared by both the wide area MNS and the individual building MNS.

2-6.1.5 **Navy Installations.** Wide area MNS shall be installed on Navy installations in accordance with Chief of Naval Operations (CNO) antiterrorism guidance.

2-6.2 **Individual Building MNS.** Individual building MNS are installed to provide real-time information to all building occupants or personnel in the immediate vicinity of a building, including exterior egress and gathering areas. These systems are designed to operate from one or more locations in the building, and operate with or without connection to a wide area MNS—but must be connected to with the wide area MNS if one is provided on the DOD installation. All DOD components are required to provide individual building mass notification capability.

SE Marine Corps individual building MNS are not required to provide the capability to initiate messages from any location within the individual building.

Note: Marine Corps designs use central control stations shared by both the wide area MNS and the individual building MNS.

2-6.2.1 **DOD Requirements.** The DOD must provide mass notification for new and existing buildings when required by UFC 4-010-01. Mass notification is required in all new inhabited buildings, including new primary gathering buildings and new billeting. Mass notification is required in existing primary gathering buildings and existing billeting when implementing a project exceeding the replacement cost threshold specified in UFC 4-010-01 or when prioritized by local command personnel. Mass notification is recommended in other existing inhabited buildings when implementing a project not exceeding the replacement cost threshold. Mass notification is required for leased buildings, building additions, and expeditionary and temporary structures.

Note: UFC 4-010-01 provides specific definitions of inhabited buildings, primary gathering buildings, and billeting for application of antiterrorism requirements.

CHAPTER 3

WIDE AREA MNS

3-1 **SCOPE.** Wide area MNS are intended to provide real-time information to outdoor areas of a DOD installation. Small facilities that are exempted by UFC 4-010-01 from providing individual building MNS could be covered by a wide area MNS. These facilities could include buildings such as single-family and duplex military family housing, individual lodging buildings housing 10 occupants or less, shopettes, automobile service stations, storage buildings with very low density of occupancy, and military family campgrounds. The requirements to install wide area MNS are specific to each DOD component. A general DOD requirement to install these systems on all DOD installations has not been established.

3-2 REQUIREMENTS FOR SYSTEM DESIGNERS

3-2.1 **Designer Qualifications.** The wide area MNS shall be designed under the supervision of a registered professional engineer with a minimum of 4 years' current work experience in fire protection, electrical, and communication-electronics engineering areas specific to wide area MNS. Alternately, the wide area MNS may be designed by an engineering technologist verified by the National Institute for Certification in Engineering Technologies (NICET) as certified at Level IV in low voltage electronic-communications systems or Level IV in fire alarm systems, plus this engineering technologist shall possess a minimum of 4 years' current work experience specific to wide area MNS communications-electronics. Alternately, the wide area MNS may be designed by an engineering technologist that possesses a minimum of 10 years' documented current work experience specific to wide area MNS communications-electronics. The speaker array supporting structure shall be designed by a registered professional structural engineer to resist all environmental loads, including site-specific wind and seismic forces. The individual's name, signature, and professional engineer number or NICET certification number (when applicable) shall be included on all final design documents.

3-2.2 **System Integrators and Contractors.** Use system integrators and contractors that can demonstrate a full knowledge and understanding of systems used for mass notification, and that have factory-trained personnel to perform system design, installation, testing, training, and maintenance.

Note: The MNS designer should have demonstrated expertise in audio system design, sound pressure and intelligibility measurement and evaluation, radio communications systems, audible and visual notification appliances, and central control station designs.

3-3 **SYSTEM SIGNALS.** Wide area MNS shall include an outdoor speaker and siren system providing voice signals, music, and alarm tones.

3-3.1 **Voice Signals.** Wide area MNS shall be capable of providing intelligible live and pre-recorded voice signals.

3-3.2 **Music.** Wide area MNS shall be capable of providing music such as the national anthem and other musical signals such as Attention to Colors, Reveille, and Taps.

3-3.3 **Tones.** Wide area MNS shall be provided with standard Federal Emergency Management Agency (FEMA) weather warning tones. Military-specific warning tones shall be provided as specified by the DOD installation, and should include tones for conventional attack warning, non-conventional attack warning, all clear, and a system test tone. Such tones should be similar to Civil Defense tones originally developed during World War II and the Cold War era.

3-4 **SUBSYSTEMS.** Wide area MNS includes several subsystems: central control stations; high power speaker arrays (HPSA); communication links; and ancillary equipment.

3-4.1 **Central Control Stations.** These stations operate and control the system.

3-4.2 **HPSA.** The speakers are used to provide the sound signals to the outdoor locations on the DOD installation.

3-4.3 **Communications Links.** Communications links are used for sending signals between the central control stations and the HPSA, and between the central control stations and regional or national command centers. A redundant (backup) means of communication shall be provided unless the primary means of communication is highly reliable, well protected, and constantly monitored by the central control station for operational status.

Note: See Appendix C for a discussion of requirements for Internet-based communication systems (under development).

3-4.4 **Ancillary Equipment.** This equipment includes items such as aircraft obstruction lights, anti-nesting spikes, and meters to meet local DOD installation requirements.

3-5 **CENTRAL CONTROL STATIONS.** The wide area MNS shall be provided with at least one primary and one redundant central control station.

3-5.1 **Locations.** The locations of the central control stations shall be coordinated with the first responders on each DOD installation. The primary central control station should be located at the installation control center (ICC), command post, emergency operations center (EOC), or similar location. The redundant central control center should be located at a physically separate location such as a security forces building, military police station, fire station, or director of emergency services office.

Marine Corps primary central control stations should be located at a security forces or military police dispatch center, and the redundant central control center should be located at the ICC, EOC, operations center, or similar location.

3-5.2 **On-Installation Control.** The central control stations shall control the operation of outdoor speakers on the DOD installation. Communications shall be provided between the central control stations and individual building MNS. The wide area MNS shall have the capability to communicate with other notification systems on the DOD installation such as the telephone alerting system, paging system, commander's channel on public access television stations, and highway advisory radio and sign control system (used for dynamic control of radio information and traffic signs for emergency information and traffic management).

Communication with other notification systems is not required for Marine Corps systems.

3-5.3 **Off-Installation Interfaces.** Communications between the central control stations and regional or national command systems shall be provided. This shall include the receipt, recording, and distributing of voice messages and alert signals received from the Commander in Chief through the national public alert and warning system.

3-5.4 **Central Control Station Requirements.** The central control unit shall consist of these components and features:

3-5.4.1 **Graphical User Interface (GUI).** This should be a computer interface with sufficient capability to operate the system with easy point and click operations.

3-5.4.2 **Backup Power.** Each central control station shall be equipped with batteries to supply power for a minimum of 4 hours of full-load operation when the central control station is provided with a permanently installed backup electrical power generator. This electrical power generator need not be dedicated solely to the central control station but may be intended to supply other important electrical loads in addition to the central control station. If not provided with a permanently installed backup electrical power generator, a portable backup electrical power generator may be used if procedures are established that ensure that the central control station is provided with electrical power within 4 hours.

3-5.4.3 **Inputs.** The central control station must provide capability for at least these features:

3-5.4.3.1 Total, zone, and single voice activations

3-5.4.3.2 Total, zone, and single tone activations

3-5.4.3.3 Total, zone, and single music activations

3-5.4.3.4 Total, zone, and single tests

3-5.4.3.5 Total, zone, and single signal cancellations

3-5.4.3.6 Automatic status reporting for each HPSA and for all activations and the status of the activations

3-5.4.3.7 Alarm summary report that provides a historical report for, at least, all changes of status, including all troubles, equipment failure, power system trouble (including normal and emergency power), unsolicited messages, tamper/supervision of the enclosure for the HPSA electronics, amplifier status, last activation and synchronization error, operator log on and log off, and configurable reports for time-based events such as “report all troubles from 1/01/04 to 6/30/04.”

3-5.4.3.8 Communications logs in tabular format

3-5.4.3.9 Screen displays of the customized DOD installation maps showing the general status of the speakers or remote equipment. This GUI shall provide for easy uploading of DOD installation-specific plan changes and for interactive operation.

Note: The DOD installation should specify the source of maps used by the GUI.

Note: Automatic recognition and display of new speakers, new remote equipment, and newly connected individual building MNS is available for some digital control systems. This feature, if provided, can significantly reduce system maintenance costs for the DOD installation.

3-5.4.3.10 Global Positioning System (GPS) coordinates of HPSA and facilities provided with an individual building MNS

3-5.4.3.11 Multiple levels of password protection, including levels for system operators, maintainers, supervisors, and military commanders, at a minimum

3-5.4.3.12 The ability to record and send digital messages to the HPSA via the primary (and redundant, if provided) communication link and to receive confirmation that the messages were received and stored at the HPSA. Alternately, the DOD installation may authorize use of fixed, pre-recorded emergency messages that are physically installed in each HPSA (typically by installing an erasable programmable read-only memory (EPROM) or flash memory device).

3-5.4.3.13 The capability to connect to and control message signs to direct vehicular traffic on roadways

SE Not required for Marine Corps systems

3-5.4.3.14 The capability to deliver at least two essentially concurrent voice messages: one for threatened areas or buildings and one for adjacent areas or buildings. This includes the capability for two pre-recorded voice messages, or one live and one pre-recorded voice message.

Marine Corps systems may deliver sequential voice messages (at least 2) instead of at least 2 concurrent voice messages.

3-5.4.3.15 The capability to target specific messages to any individual HPSA, zone of HPSAs, or to all areas on the DOD installation

3-5.4.3.16 Means for dynamic or "on-the-fly" configuration of zoning, with a minimum of 8 zones available

3-5.4.3.17 Secure method for easily creating or modifying recorded messages

3-5.4.3.18 The capability to store at least 60 minutes of pre-recorded messages

3-5.4.3.19 The capability to deliver text pager messages to pager stations

Not required for Marine Corps systems

3-5.4.3.20 The capability to deliver faxes

Not required for Marine Corps systems

3-5.4.3.21 The capability to connect to Reverse 911® systems and other telephone dialing/notification systems

Not required for Marine Corps systems

3-5.4.3.22 Microphone for live voice announcements

3-5.4.3.23 The capability to perform silent tests, including a test of the amplifiers, controllers, and sound drivers, and tests to verify that communications are operational

3-5.4.3.24 The capability to control individual speaker zones of those HPSAs designated by the DOD installation

Not required for Marine Corps systems

3-5.4.3.25 The capability to receive, record, and broadcast throughout the DOD installation all voice messages and alert signals received from the Commander-in-Chief through the national public alert and warning system. This will include the capability to immediately broadcast the messages and signals without a noticeable time delay, and the capability to delay the broadcast so not to interfere with operational requirements when so authorized by the DOD installation commander.

3-6 HPSA

3-6.1 **Arrangement in Zones.** HPSAs shall be arranged into zones so that each zone can be individually controlled by the control station.

3-6.2 **Directional Characteristics.** HPSAs shall be designed with directional characteristics that will minimize the distortion of voice signals by interface from other zones, and will minimize the transmission of voice, siren, or other sound signals into environmentally sensitive areas or off the DOD installation.

Note: HPSAs with omnidirectional (i.e., approximately spherical shape) sound transmission characteristics may be considered for specific areas of the installation but should be used only for isolated areas having minimal concern for mutual interference between HPSA zones, when local operation of the HPSA is not required by the DOD installation, when Occupational Safety and Health Administration (OSHA) noise exposure levels will not be exceeded beneath the HPSA, and when omnidirectional speakers can be shown to be the most cost effective design.

SE Marine Corps systems will primarily use omnidirectional, 360-degree coverage HPSAs and speaker towers to maximize the alerting coverage area; however, directional speaker towers may be used as needed to minimize off-base or host nation disturbances.

3-6.3 **Outdoor Areas.** HPSAs shall be designed to maintain the intelligibility of voice signals within the zone at a level no less than 0.7 on the Common Intelligibility Scale (CIS) or 0.5 on the Speech Transmission Index (STI) measure in outdoor areas during normal weather conditions. Intelligibility may be less than 0.7 CIS in areas of the zone if personnel can determine that a voice signal is being broadcast and they could walk less than 50 meters (m) (164 feet (ft)) to find a location in the zone with at least 0.7 CIS.

Note: Values of 0.65 through 0.74 will be rounded to 0.7.

Note: Physical limitations in outdoor sound propagation normally limit the maximum distance of personnel from the sound system speaker to the range of about 550 to 610 m (1800 to 2000 ft) for the receipt of an intelligible voice message. Increases in speaker output power may extend the sound wave propagation distance but often cause excessive distortion of the voice message and decrease intelligibility to unacceptably low levels.

Note: Commercially available test instrumentation should be used to measure intelligibility using the CIS as specified by International Electrotechnical Commission (IEC) 60849 and IEC 60268-16. Alternately, trained human speakers and listeners may be used to measure intelligibility using the STI as specified in American National

Standards Institute (ANSI) 3.2. The mean value of at least 3 readings is required to compute the intelligibility score at each test location when using the test instrumentation method.

Note: Normal weather conditions should be specified by the DOD installation as appropriate for its geographic location. Intelligibility meters with internal compensation should be used to adjust CIS measurements for other than normal weather conditions. Weather data for the DOD is maintained by the Air Force Combat Climatology Center and may be accessed for all DOD locations at https://www2.afccc.af.mil/. This site contains a database of engineering weather data that may be searched by installation or city name. Use of the average wind speed and direction data from the “Dry Bulb Temperature” section of the “Design Criteria Data” table is recommended.

3-6.4 **Special Outdoor Areas (Army and Air Force Projects).** HPSAs shall be designed to maintain the intelligibility of voice signals within the zone at a level no less than 0.8 CIS or 0.7 STI during normal weather conditions in special outdoor areas such as those with a high concentration of multi-story buildings in close proximity. Parade grounds, training fields, and similar outdoor areas should also be provided with this higher intelligibility. Many DOD installations contain one or more special outdoor areas. The boundaries of special outdoor areas shall be established by the DOD installation. Intelligibility may be less than 0.8 CIS in areas of the zone if personnel can determine that a voice signal is being broadcast and could walk less than 25 m (82 ft) to find a location in the zone with a CIS score of at least 0.8.

Note: Values of 0.75 through 0.84 will be rounded to 0.8.

Note: In special outdoor areas (such as in industrial areas with many multi-story buildings), the maximum distance of personnel from an outdoor speaker often has to be significantly reduced to retain acceptable intelligibility of the voice message. Speakers that provide directional capability should be used. These may be mounted on building exteriors if the speakers do not radiate unacceptable levels of sound into the building on which they are mounted.

Note: Physical limitations in outdoor sound propagation normally limit the maximum distance of personnel from the sound system speaker to the range of about 550 to 610 m (1800 to 2000 ft) for the receipt of an intelligible voice message. Increases in speaker output power may extend the sound wave propagation distance but often cause excessive distortion of the voice message and decrease intelligibility to unacceptably low levels.

Note: Commercially available test instrumentation should be used to measure intelligibility using the CIS as specified by IEC 60849 and IEC 60268-16. Alternately, trained human speakers and listeners may be used to measure intelligibility using the STI as specified in ANSI 3.2. The mean value of at least three readings is required to compute the intelligibility score at each test location when using the test instrumentation method.

Note: Normal weather conditions should be specified by the DOD installation as appropriate for its geographic location. Intelligibility meters with internal compensation should be used to adjust CIS measurements for other than normal weather conditions. Weather data for the DOD is maintained by the Air Force Combat Climatology Center and may be accessed for all DOD locations at https://www2.afccc.af.mil/. This site contains a database of engineering weather data that may be searched by installation or city name. Use of the average wind speed and direction data from the "Dry Bulb Temperature" section of the "Design Criteria Data" table is recommended.

3-6.5 **Occupational Noise Exposure.** It is necessary to control the occupational noise exposure to personnel from the HPSA to comply with Federal regulations (Title 29, Code of Federal Regulations, Parts 1910.95 and 1926.52). Sound levels at any location where personnel may be located, including directly underneath the HPSA, shall not exceed 120 decibels (adjusted) (dBA) when measured on the A-scale of a standard sound level meter at slow response. Do not exceed 85 dBA at the location of the individual HPSA equipment cabinet for those HPSAs designated by the DOD installation to be furnished with a local microphone.

Note: The 120-dBA maximum is based on the assumption that the wide area MNS will expose personnel on the ground to a sound level of 120 dBA for no more than a total of 7.5 minutes out of any 24-hour period. This noise exposure limit should accommodate most anticipated daily messages and the occasional antiterrorism exercise without exceeding OSHA limits. DOD installations that anticipate that personnel will receive a longer time of noise exposure at this sound level must establish a lower maximum value (e.g., 90 dBA will permit up to an 8-hour noise exposure, 100 dBA for 2 hours' exposure, 110 dBA for 30 minutes' exposure) or provide hearing protection.

3-6.6 **Noise Pollution.** At some DOD installations, it is necessary to control the amount of sound that propagates in undesirable directions, such as into civilian communities adjacent to the DOD installation boundaries or into wildlife areas with protected or endangered animal species. Additionally, in some areas it might be necessary to mount wide area MNS speakers on the side of a building while simultaneously preventing an unacceptable increase in that building's interior noise levels.

3-6.6.1 **Design Goals.** Use speakers designed to minimize back-plane emissions for HPSA zones where the speakers will be mounted directly to an occupiable building, or where noise pollution is a concern for off-installation populated areas or sensitive wildlife areas.

3-6.6.2 **Speakers Attached to Buildings.** Speakers attached to occupiable buildings shall be capable of using phase shifting and filtering to help eliminate unwanted "spillover" emissions and back-plane noise.

3-6.6.3 **Measuring Noise in Buildings.** Back-plane noise transmitted inside of occupiable buildings shall be no more than 15 dBA above ambient noise.

3-6.7 **HPSA inside of Buildings.** HPSA zones shall not be used to provide mass notification inside any structures when UFC 4-010-01 would require an individual building MNS if the structure were built new or renovated.

3-6.8 **HPSA Speaker Sites.** Each HPSA site for each zone shall include a field-mounted local control unit, microprocessor, amplifier, standby batteries, charger, power supply, radio, mounting brackets and loudspeaker assembly for pole or building mounting. Those HPSA sites designated by the DOD installation shall be capable of microphone input and shall be provided with a microphone designed to prevent feedback at that particular microphone location.

3-6.8.1 **Locations of Sites.** Locations of the HPSA sites shall be verified and recorded with GPS coordinates. These locations shall be established prior to the installation of speaker array supporting structures as part of a site survey conducted jointly by the installing contractor and the DOD installation.

3-6.8.2 **Equipment Cabinets.** All equipment for each HPSA speaker site shall be housed in modular, mountable cabinets suitable for the local environmental conditions, including space heaters and ventilation fans, as appropriate.

Note: Enclosures qualified to the requirements of National Electrical Manufacturers Association (NEMA) 3R (rain tight), NEMA 4 (wash-down areas), or NEMA 4X (harsh environments) should be used for all outdoor applications.

3-6.8.3 **Surge Suppression.** All external conductors (conductors passing outside of the HPSA equipment cabinet) shall be provided with surge suppression tested to Underwriters Laboratories, Inc. (UL) standards as specified by UFC 3-520-01.

3-6.9 **HPSA Performance.** The HPSA control units shall provide at least these components and features:

3-6.9.1 A digitally addressable controller

3-6.9.2 The ability to receive and store messages via the primary (and redundant, if required) communication link with a confirmation signal sent back to the primary and redundant central control stations. Alternately, the DOD installation may authorize use of fixed, pre-recorded emergency messages that are physically installed in each HPSA (typically by installing an EPROM or flash memory device).

3-6.9.3 A charger/ power supply that will accept alternating current (AC) input, backup electrical power generator input, battery input, or solar power cell input

3-6.9.4 The capability of storing at least 60 minutes of pre-recorded messages

3-6.9.5 The capability of providing a minimum of 7 standard tones. In addition, the systems shall have the capability to provide custom tones.

Marine Corps systems require a minimum of 6 standard tones.

3-6.9.6 The ability to accept and play an auxiliary input from a digital recording device such as a compact disk (CD) player or Moving Picture Experts Group (MPEG) Layer 3 player

3-6.9.7 An amplifier efficiency of not less than 90 percent. The amplifier shall have not more than 0.1 percent total harmonic distortion (THD). The amplifier frequency response shall be at least 200 hertz (Hz) to 10,000 Hz. There shall be no more than 2 percent THD at the speaker at 1000 Hz.

Note: Some outdoor warning systems use amplifiers that are rated for as little as 30 minutes of continuous operation. These amplifiers are often of low efficiency and may be damaged by heat buildup. Such amplifiers may be adequate for many non-emergency applications; however, higher efficiency amplifiers with improved cooling capabilities should be used to provide the capability needed for antiterrorism operations.

3-6.9.8 The capability for local control at those HPSAs designated by the DOD installation. Designated HPSAs shall be able to function independently of the central control station. Designated HPSAs shall be furnished complete with a local microphone and local controls. The local microphone shall be designed to prevent feedback at that particular microphone location.

Note: Local control capability should be designated for all HPSAs where an on-scene commander is expected to be located during emergencies. This capability should also be designated for areas used for troop formations, parade fields, parks and sports fields, areas opened to the public for air shows or fireworks displays, and any other areas where an individual HPSA could be used by the DOD installation in lieu of providing a temporary public address (PA) system.

3-6.9.9 A headphone output port to permit private listening of the system broadcast at each HPSA designated by the DOD installation for testing purposes

Not required for Marine Corps systems

3-6.9.10 An input port for connecting a laptop computer or digital device to make field changes. Alternately, the DOD installation may authorize use of fixed, pre-recorded emergency messages that are created elsewhere and physically installed in the HPSA (typically by installing an EPROM or flash memory device).

Not required for Marine Corps systems

3-6.9.11 A tamper switch that will signal the central control station that the HPSA enclosure door is open

3-6.10 **Temperature Rating.** Speakers shall be able to operate between temperatures of -40 degrees Celsius (C) (-40 degrees Fahrenheit (F)) to +60 degrees C (+140 degrees F). Enclosures shall protect the HPSA control unit from external temperatures ranging from -40 degrees C (-40 degrees F) to +60 degrees C (+140 degrees F). The DOD installation should specify an upper external temperature limit of +80 degrees C (+175 degrees F) in those geographic locations subject to extreme heat.

3-6.11 **Battery Backup Power.** Each HPSA site shall be equipped with backup batteries to supply power for a minimum of 72 hours of electrical supervision following the loss of normal charging power, followed by a total of 60 minutes of full load operation at the end of the supervisory period.

Note: The DOD installation should specify the temperature to be used to size the backup batteries for the HPSA. Weather data for the DOD is maintained by the Air Force Combat Climatology Center and may be accessed for all DOD locations at https://www2.afccc.af.mil/. This site contains a database of engineering weather data that may be searched by installation or city name. Use of the lowest mean minimum temperature from the "Annual Summary of Temperatures" graph is recommended. Alternately, use the minimum design temperature of the HPSA control unit enclosure if internal heating is provided within the enclosure.

3-6.12 **Connection to Portable Electrical Power Generator.** Each HPSA site so designated by the DOD installation shall be capable of direct connection to a commercially available portable electrical power generator or a military-approved mobile electrical power (MEP) generator.

3-6.13 **Elevated Supporting Structure**

3-6.13.1 **Required.** An elevated supporting structure (e.g., pole, tower) shall be provided at each HPSA site other than those attached directly to a building.

3-6.13.2 **Structural Loads, Wind and Seismic Design.** The supporting structure shall be designed for the structural loads listed in UFC 3-310-01, except that the design wind speed shall be not less than 100 miles per hour (mph) (161 kilometers per hour (km/h), 86.8 knots). The supporting structure shall be sized to accommodate the static and dynamic loads produced by the sound systems and all attachments.

3-6.13.3 **Mounting Height**. The HPSA shall be attached to the elevated supporting structure. The minimum mounting height of the speakers shall be based on the rated output of the speakers and shall prevent hearing damage to anyone directly below the speakers. Do not exceed noise exposure limits as specified in paragraph 3-6.5. The height shall not be less than 9 m (30 ft) or greater than 18 m (60 ft) above ground level.

Ensure that the location and height of HPSA supporting structures do not interfere with aircraft flight operations.

3-6.13.4 **Mounting of Cabinets.** HPSA equipment cabinets shall be mounted on the elevated supporting structure with the top of the enclosure no more than 3 m (10 ft) above ground level. The equipment cabinet and power boxes must be capable of being locked shut.

3-6.14 **HPSA attached to Buildings**

3-6.14.1 **Mounting Height.** The HPSA shall be mounted at a minimum mounting height that is based on the rated output of the HPSA and shall prevent hearing damage to anyone directly below the speakers. Do not exceed noise exposure limits as specified in paragraph 3-6.5.

3-6.14.2 **Structural Loads, Wind and Seismic Design.** The mounting of the HPSA shall be designed for the structural loads listed in UFC 3-310-01, except that the design wind speed shall be not less than 100 mph (161 km/h, 86.8 knots). The mounting shall be sized to accommodate the static and dynamic loads produced by the sound systems and all attachments.

3-6.14.3 **Sound into Building.** If attached to an occupiable building, the HPSA shall not permit unacceptable levels of sound into the building. (See paragraph 3-6.6.3.)

3-6.14.4 **Noise Exposure under HPSA.** Do not exceed the OSHA occupational noise exposure limits specified in paragraph 3-6.5.

3-7 **COMMUNICATIONS LINKS**

3-7.1 **Primary Communications Link.** Primary communications shall use radio frequency-type systems that comply with National Telecommunications and Information Administration (NTIA) requirements. The systems shall be designed to minimize the potential for interference, jamming, eavesdropping, and spoofing.

Note: See Appendix C for a discussion of requirements for Internet-based communication systems (under development).

3-7.1.1 **Licensed Radio Frequency Systems**. An approved DD Form 1494 for the system is required prior to operation. When available, use systems designed for secure digital communication standards such as the Association of Public-Safety Communications Officials (APCO) Standard 25.

Note: APCO 25 is an industry-wide effort to set the recommended voluntary standards of uniform digital two-way radio technology for public safety organizations.

Note: Receiving a new radio frequency assignment often takes a relatively long time. Be sure to request the frequency assignment early in the design process.

3-7.1.2 **Non-licensed Radio Frequency Systems.** When authorized by the DOD installation commander, the NTIA permits the use in the continental United States (CONUS) of non-licensed radio frequency-type devices that conform to Federal Communications Commission (FCC) rules and regulations (47 CFR 15); however, all transmitting devices on a military installation require an approved DD Form 1494 prior to installation. In locations outside of the continental United States (OCONUS), confirm that the devices conform to host-country regulations and obtain the approval from the DOD installation commander prior to using non-licensed radio frequency-type devices. In all cases, request permission from the spectrum manager for the local area. Provide GPS coordinates of installed transmitters when required by the spectrum manager.

Note: Non-licensed devices operate at very low power levels, have no vested or recognized right to any part of the radio frequency spectrum, and are not <u>required</u> to provide any immunity to interference. If a non-licensed system is selected, be sure the system compensates for these limitations by providing suitable radio signal modulation features (e.g., spread spectrum and frequency hopping) and that propagation distance parameters for the radio signals are not exceeded.

3-7.2 **Redundant Communications Link.** Redundant communication means (when required) should be established using several alternate wireless radio frequency paths to the radios. In some cases, the redundant communication means might be accomplished by using the DOD installation's communications backbone network (e.g., optical fiber cable). In this case, the central control units should accomplish this by being directly connected to the backbone network.

Note: All software and hardware to be installed on DOD Ethernet or Internet systems must first successfully complete an accreditation process. Accreditation often takes a relatively long time.

Note: See Appendix C for a discussion of requirements for Internet-based communication systems (under development).

3-7.3 **Off-the-Shelf Equipment.** Communications equipment furnished as part of the wide area MNS shall be commercial off-the-shelf (COTS). All programming codes or passwords required to access, update, modify, and maintain the communications equipment shall be provided to the DOD installation no later than the date of final system acceptance.

Note: Receiving authorization to operate any communications equipment often takes a relatively long time. Be sure to request approval early in the design process. At some DOD installations, a Certificate to Operate (CTO) or Certificate of Networthiness (CON) is required.

3-7.4 **Supervision.** Full system supervision shall be provided. Notification of system alarm, supervisory, and trouble signals shall be provided to the central control stations within a time period not to exceed 200 seconds.

3-7.5 **Diagnostics.** The communications systems shall provide self-test and diagnostics capabilities. Local diagnostics information shall be transmitted to the central control stations.

3-7.6 **Interfaces with Other Systems.** The communications systems shall be capable of interfacing with existing fire alarm systems, existing PA systems, and existing telephone dialing systems on the DOD installation. The communications systems shall be designed with an established protocol that is provided to the DOD installation to allow existing and future individual building MNS from other manufacturers to interface with the wide area MNS. The wide area MNS manufacturer shall provide a standard interface method (such as an audio line-level output and multiple relay contacts) or supply the necessary digital communication protocols to permit the DOD installation to select more than one manufacturer of individual building MNS.

SE Marine Corps systems will interface with the telephone dialer system that has been approved by the AHJ. (See paragraph 1-3.4 for more information on the AHJ).

CHAPTER 4

INDIVIDUAL BUILDING MNS FOR NEW CONSTRUCTION PROJECTS

4-1 **SCOPE.** Individual building MNS are intended to provide real-time information to personnel within and in the immediate vicinity of buildings on a DOD installation. These systems are required by UFC 4-010-01 for new construction and renovation of existing buildings. This chapter provides the design criteria for new construction projects. It discusses the requirements of the individual building MNS that is installed in new construction as part of a combined MNS/fire alarm system.

Note: In most cases, the simplest and most economical approach for new construction will be to install a combined system that performs both as an individual building MNS and as the building fire alarm/voice evacuation system.

4-2 **REQUIREMENTS FOR SYSTEM DESIGNERS.** The individual building MNS shall be designed under the supervision of a registered fire protection engineer, by a registered professional engineer having at least four years of current experience in the design of fire protection and detection systems, or by an engineering technologist qualified at NICET Level IV in fire alarm systems. The individual's name, signature, and professional engineer number or NICET certification number shall be included on all final design documents.

SE Navy systems shall be designed only by a registered fire protection engineer who has passed the fire protection engineering written examination administered by the National Council of Examiners for Engineering and Surveys (NCEES).

4-3 **SYSTEM OVERVIEW.** A combined system is required by the Navy and is highly recommended by the Army and Air Force. The combined system design may be used by the Marine Corps when specifically approved by the AHJ based on the class and size of the building requiring the MNS. Otherwise, Marine Corps projects will use the technical criteria of Chapter 5. If an Army or Air Force installation approves use of a separate MNS and separate building fire alarm system in a new construction project, use the technical criteria of Chapter 5.

SE A separate MNS may be installed in Navy projects for a building not provided with a fire alarm system. See Chapter 5.

Note: See paragraph 6-5 for MNS requirements for special occupancies such as medical facilities and facilities intended for occupancy by persons not capable of self-preservation.

4-3.1 **Subsystems.** An individual building MNS for new construction projects includes several subsystems: autonomous control unit (ACU); local operating consoles (LOC); notification appliance network; and interface with the wide area MNS on the DOD installation. System design and wiring is designed to meet NFPA 72 requirements for MNS and fire alarm systems.

4-3.2 **ACU**

4-3.2.1 **Functions.** The ACU is used to monitor and control the notification appliance network. At the ACU, personnel in the building can initiate delivery of pre-recorded voice messages, provide live voice messages and instructions, and initiate visual strobe and alphanumeric message notification appliances. Actions taken at the ACU take precedence over actions taken at any other location, including the LOC, or inputs from the wide area MNS on the DOD installation.

4-3.2.2 **Combined System.** For new construction, the ACU shall be integrated with the building fire alarm control panel (FACP) to form one combined system that performs both functions. The building PA system for smaller buildings may be integrated with the combined system so that all three functions—mass notification, fire alarm, and PA—are provided by one building system. In large buildings, however, combining the PA system will typically require the design of very complex speaker switching matrices and is not recommended. Combined systems shall meet the requirements of NFPA 72.

Note: A combined system may include an ACU and FACP supplied from different manufacturers or placed in separate equipment enclosures; however, the ACU and FACP must be integrated in their controls and performance to meet the requirements of NFPA 72 and this UFC.

Note: The Army and Air Force permit the MNS and fire alarm system to be installed as separate systems if mandated by the DOD installation. The Marine Corps normally requires the MNS and fire alarm system to be installed as separate systems unless specifically permitted by the AHJ. See Chapter 5 for technical criteria for this design approach.

4-3.3 **LOC.** A LOC is a unit designed to allow emergency response forces and building occupants to operate the individual building MNS, including initiating delivery of pre-recorded voice messages, providing live voice messages and instructions, initiating visual strobe and alphanumeric message notification appliances, overriding external voice announcements, and terminating mass notification functions. A LOC is usually contained in a small, wall-mounted enclosure. Not all functions that could be performed at the ACU are necessarily available at a LOC.

4-3.4 **Notification Appliance Network.** A notification appliance network consists of a set of audio speakers, strobes, and text signs (when required) that are located to alert occupants and provide intelligible voice and visual instructions.

4-3.4.1 **Audio Appliance Network.** Speakers are provided at all locations in the building and also around the building at entrances/exits and other outdoor areas (such as courtyards) commonly used by the building occupants. Important design considerations for the audio speakers include intelligibility and audio intensity.

Note: Outside notification more than 5 m (16 ft) from the building should be provided by the wide area MNS.

4-3.4.1.1 Intelligibility is defined in NFPA 72. Commercially available test instrumentation shall be used to verify intelligibility.

4-3.4.1.2 Effective voice communication within buildings occurs by using a system design of many speakers, each with low audio intensity.

4-3.4.2 **Visual Appliance Network.** Strobes are provided at all locations inside the building to meet the accessibility requirements of \1\ ABAAG /1/ for persons with hearing disabilities. Strobes are provided at the same locations in a building that would be required for a fire alarm system notification appliance. Combined MNS/FACP systems may use either one strobe (clear) or two strobes (clear for fire and amber for MNS) as specified by the AHJ.

4-3.4.2.1 Navy installations shall use one clear strobe and also shall provide text signs. Text signs are required over the door to each egress stairwell and over (or adjacent to) the substantial means of egress from the level of discharge. Exterior exit doors from a single room (e.g., mechanical or electrical rooms) do not require a text sign.

4-3.4.2.2 Army and Air Force installations shall use a clear strobe for fire and an amber strobe for MNS. Use of text signs is optional and at the discretion of the DOD installation. If provided, text signs shall be located over the door to each egress stairwell and over (or adjacent to) the substantial means of egress from the level of discharge. Exterior exit doors from a single room (e.g., mechanical or electrical rooms) do not require a text sign.

4-3.4.2.3 Marine Corps installations shall contact the AHJ for guidance on visual notification appliances.

4-3.5 **Interfaces with the Wide Area MNS**. If a wide area MNS is provided on the DOD installation, the individual building MNS communicates with the central control units of the wide area MNS to provide status information, receive commands, activate pre-recorded messages, and originate live voice messages. If no wide area MNS is provided on the DOD installation, at a minimum, the individual building MNS shall be able to receive an audio line-level input.

4-3.6 **Logical Block Diagrams.** Figures 4-1 and 4-2 show the logical block diagrams for acceptable configurations of the individual building MNS for new construction.

Note: These diagrams are intended to show only the functional relationships of the major components. They are not intended to serve as wiring diagrams. Many essential design features for an operational system, such as end-of-line resistors, are not shown.

Figure 4-1. Individual Building Mass Notification System: Combination Fire Alarm System and MNS (Navy)

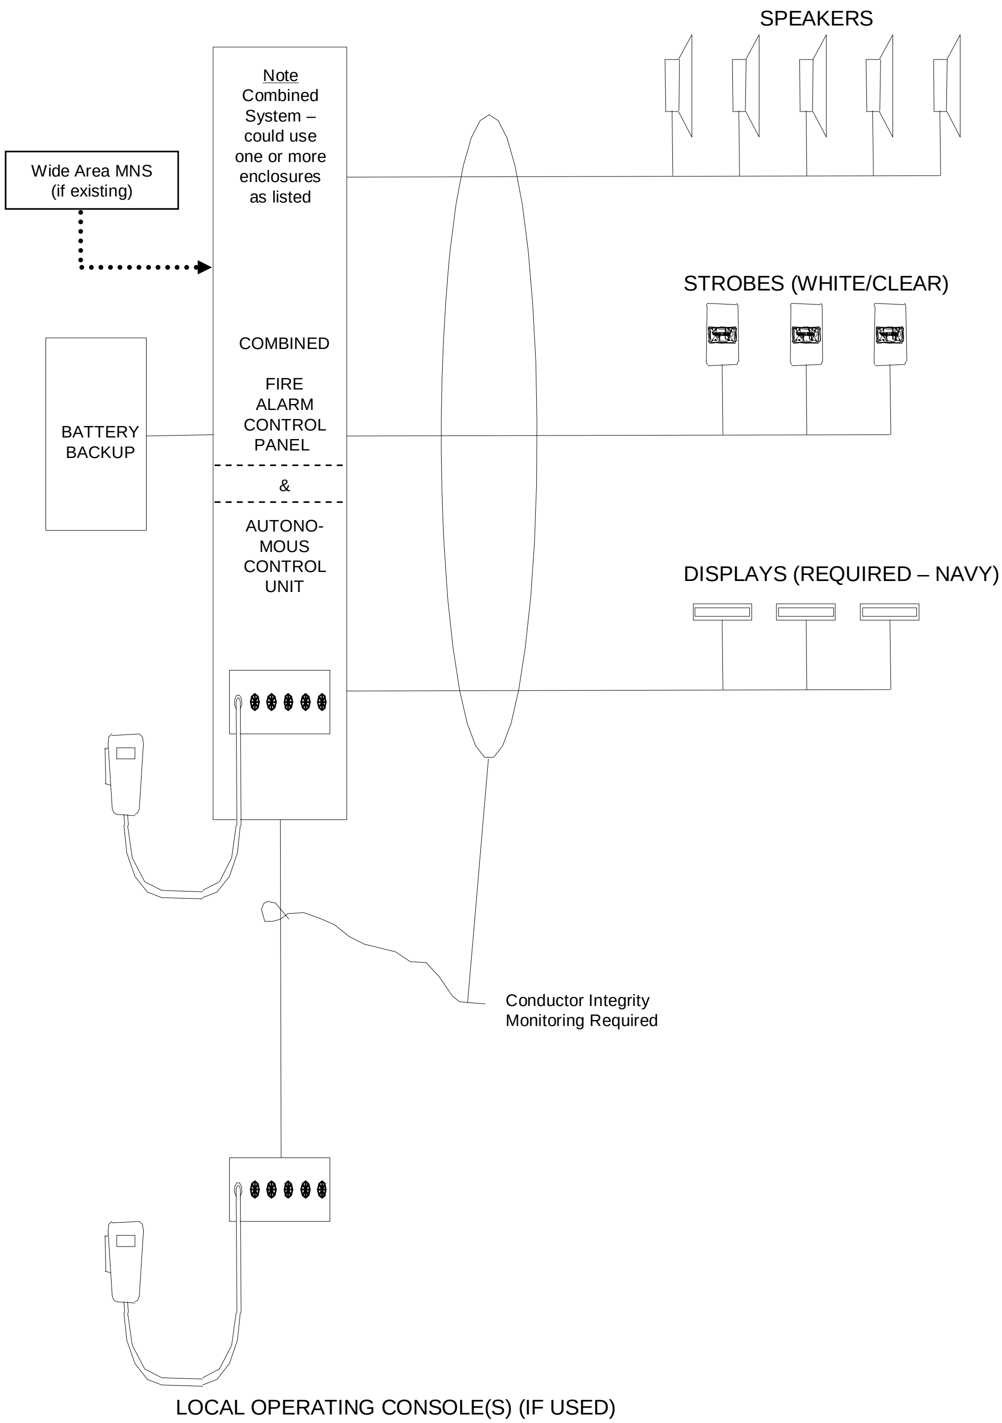

Figure 4-2. Individual Building Mass Notification System: Combination Fire Alarm System and MNS (Army and Air Force)

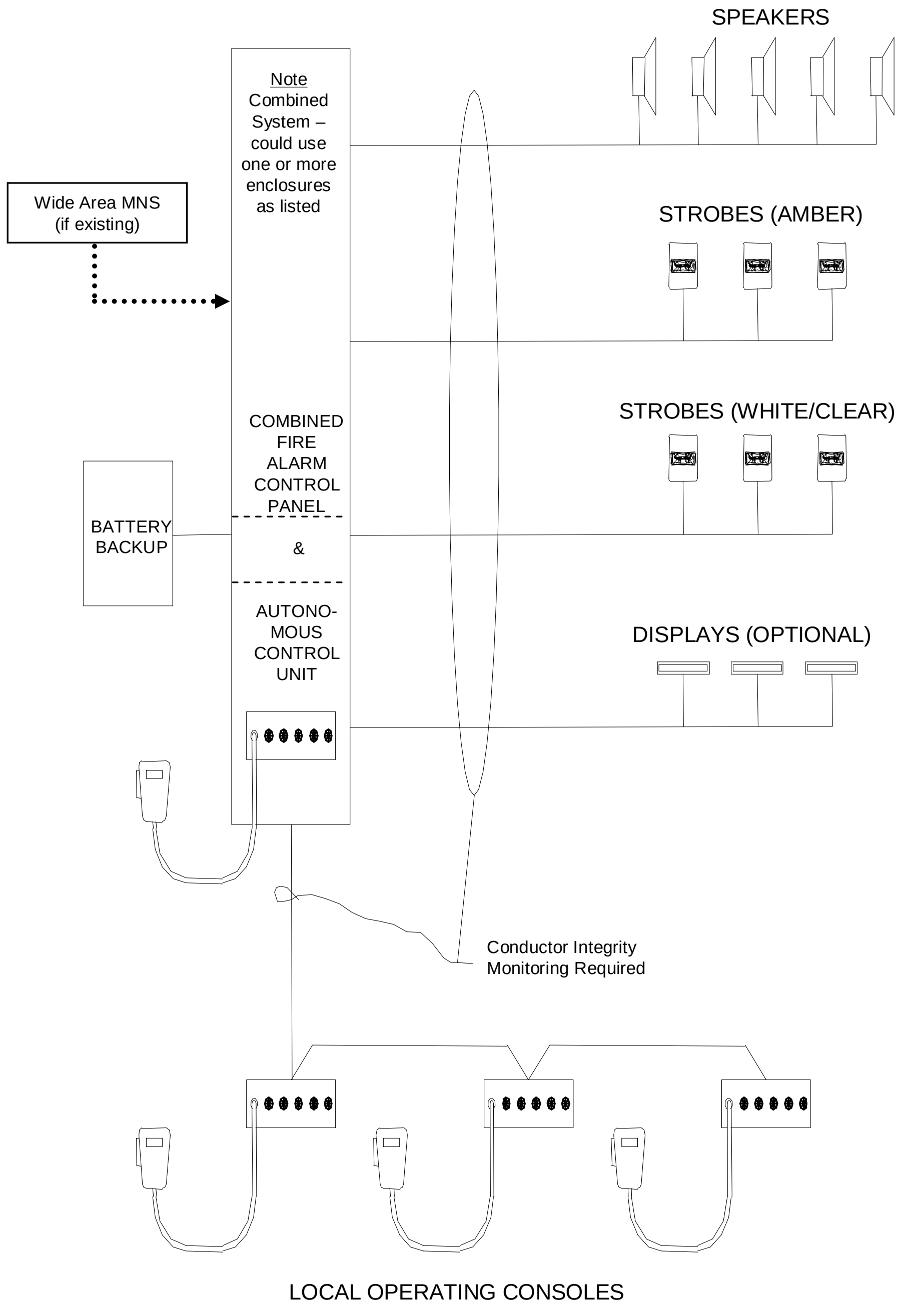

4-4 ACU

4-4.1 **Locations.** The ACU shall form a combined system with the FACP. These control panels may be co-located in the same enclosure or may be physically separated. If they are located in the same enclosure, install the enclosure at the location normally specified by the DOD component AHJ for a stand-alone FACP.

4-4.2 **Design Features.** The ACU shall:

- Be able to function independently upon failure of the wide area MNS (if provided on the DOD installation).
- Be a listed combination system with the fire alarm system as described in NFPA 72 and meeting UL Standard 864 and the specific requirements of this UFC. The listing evaluation shall be accomplished by UL, Factory Mutual Research Corporation (FM), or another nationally recognized testing laboratory (NRTL).

Note: Systems designed to UL 2017 instead of UL 864 may not be used for a combination system. Systems designed to UL 2017 are permitted for a MNS separate from the fire alarm system (see Chapter 5).

- Be able to activate strobes and text signs:
  - Navy: Energize clear strobe lights marked “ALERT” along with light-emitting diode (LED)-type text signs. Text signs are required over the door to each egress stairwell and over (or adjacent to) the substantial means of egress from the level of discharge. Exterior exit doors from a single room (e.g., mechanical or electrical rooms) do not require a text sign. Strobes shall meet all UL listing requirements for fire alarm system strobes except for the marking “ALERT.”
  - Marine Corps: Contact the AHJ for guidance on visual notification appliances.
  - Army and Air Force: Energize either one set of clear strobe lights marked “FIRE” for the fire alarm system or a separate set of amber strobe lights marked “ALERT” for the MNS as appropriate for the emergency. Energize LED-type text signs if required by the DOD installation.
- Make general paging or other non-emergency messages available without the activation of strobes. A separate microphone must be provided for this purpose.
- Have the ability to interrupt PA system announcements and to silence building background music while delivering voice messages.

- Be able to accept voice messages from the DOD installation telephone system

- Have conductor connections that comply with NFPA 72.

Note: Ethernet or IP connections for initiating and indicating circuits are not currently available that will meet NFPA 72 requirements and, therefore, may not be used. Additionally, all software and hardware to be installed on DOD Ethernet or Internet systems must first successfully complete an accreditation process. Accreditation often takes a relatively long time.

- Have conductor integrity monitoring for strobes, speaker wiring, power supplies, and connections to the LOC.

- Be able to switch between MNS and fire alarm notification functions without generating trouble alarms in either system.

- Have the capacity for multiple pre-recorded messages (at least eight, but more if required by the DOD installation). Pre-recorded messages shall be passed in the English language and, for OCONUS locations, also in the predominant language(s) used by the host nation. Pre-recorded messages, if used, should address at least these subjects:

    - Bomb threat or actual bomb within/around the building

    - Intruder/hostile person sighted within/around the building

    - Directions to occupants to take cover within the building

    - Evacuation of the building using exits other than the normal main entrance/exit (since the front entrance/exit is often a location targeted by terrorists)

    - Emergency weather conditions appropriate for the local area

    - “All Clear” message

    - A test message intended for verifying functionality of the system.

    The Marine Corps AHJ will determine the number and content of pre-recorded messages.

- \1\ Provide an alerting sound prior to playing pre-recorded messages. The alerting sound for fire alarm messages shall be different than that used for other pre-recorded messages. The fire alarm alerting sound for buildings other than child development centers shall be either the temporal three-tone or the slow whoop for fire alarm messages, unless otherwise approved by the approving authority (i.e., the AHJ for the Navy and Marine Corps; the DOD installation in conjunction with the contracting officer for the Army and Air Force). The fire alarm alerting sound for child development centers shall be a chime sound. /1/

- Be able to deliver messages quickly.
- Be able to automatically repeat pre-recorded messages until they are terminated.
- Have a microphone for delivering live voice messages.
- Have adequate discrete outputs to initiate text signs and initiate strobes.
- Interface to the LOC for initiating recorded messages and delivering live voice messages from locations in the building other than at the ACU.
- Establish priority for passing messages to prevent interference between the ACU, LOC, and the wide area MNS on the DOD installation.
- Allow the MNS to temporarily override fire alarm audible messages and visual signals, and to provide intelligible voice commands during simultaneous fire and terrorist events. All other features of the fire alarm system, including the transmission of signals to the fire department, shall function properly. MNS messages shall take priority and continue to override fire alarm audible messages until the MNS message is either manually or automatically ended. If not manually ended, the MNS message will automatically end after 10 minutes.
- Provide a supervisory signal if the MNS is used to override fire alarm audible messages and visible signals during simultaneous fire and terrorist events. The supervisory signal shall be annunciated at the FACP and any remote fire alarm annunciators and be transmitted to the fire department. The visual annunciation of the separate supervisory signal shall be distinctly labeled or otherwise clearly identified.

SE The Army requires that this supervisory signal be separate from other fire alarm system supervisory signals.

- Remote monitoring of trouble, supervisory, and alarm functions to a constantly occupied location meeting the requirements of NFPA 72
- Have a single switch or operating mechanism capable of shutting down all heating, ventilating, and air conditioning (HVAC) equipment in the facility in accordance with the requirements of UFC 4-010-01. If permitted by the DOD installation, this shutdown capability may be provided at a LOC or be deleted entirely if the capability is otherwise provided at a location readily accessible

to building occupants.

- Provide a complete set of self-diagnostics for the controller and appliance network.
- Have a local diagnostic information display.
- Provide a local system event log file.

4-4.3 **Off-the-Shelf Equipment.** ACU equipment furnished as part of the individual building MNS shall be COTS and shall be tested to the standards of UL or FM by a NRTL.

4-4.4 **Programming Codes.** All programming codes or passwords required to access, update, modify, and maintain the ACU shall be provided to the DOD installation no later than the date of final system acceptance.

4-4.5 **Power Supply Features.** The power supply shall:

- Be capable of accepting 120/240 VAC, 50/60 Hz.
- Be appropriate for a MNS/FACP system that meets at least the minimum NFPA 72 requirements for standby power capacity. In addition, secondary (standby) power should be provided as follows: immediately upon loss of normal AC power, the standby source of power shall provide a minimum of 60 minutes of mass notification at the maximum connected load.
- Disable use of any microphones intended solely for general paging or other non-emergency messages upon loss of normal AC power.
- Conform to applicable sections of NFPA 72.
- Use only COTS components.
- Provide surge protection in accordance with UFC 3-520-01.

4-5 LOC

4-5.1 **Locations.** Provide a LOC to allow emergency response forces and building occupants to access the MNS and originate messages in emergency situations from locations in the building other than from the ACU. Follow these requirements:

- Provide a separate LOC for use by the fire department near the building FACP (or fire command center) unless this is also the location of the ACU.
- Do not place a LOC inside a locked room or closet (with the possible exception of the LOC intended for use by the fire department near the FACP).

- Install a LOC at those facility entrances/exits that will be used when building access is limited because of elevated terrorism threat levels.

Note: This LOC is intended to enable immediate notification of building occupants when unauthorized building access is threatened or has occurred at this location.

- Army and Air Force: Provide a LOC so that occupants do not need to travel more than 61 m (200 ft) horizontally or to travel to other floors to access a LOC.

- Army and Air Force: Make a LOC available for use by visitors in those facilities open to unescorted visitors or to the public.

- Navy: Provide no more than one LOC (if necessary) in addition to the ACU. Locate the LOC as directed by the responsible fire protection engineer.

- Marine Corps: Provide no more than one LOC (if necessary) in addition to the ACU. Locate the LOC as directed by the AHJ.

4-5.2 **Design Features.** The LOC shall:

- Have a remote microphone station that emulates operation of the MNS from the ACU.

- Have an easy method (such as individual manual activation push buttons) of activating the MNS pre-recorded messages. Signage shall be provided to allow rapid recognition of the means of initiating the pre-recorded messages.

Activation of MNS pre-recorded messages is not required for Marine Corps LOC.

- Provide a single switch or operating mechanism capable of shutting down all HVAC equipment in the facility in accordance with the requirements of UFC 4-010-01. If permitted by the DOD installation, this shutdown capability may be provided at only one LOC when multiple LOCs are installed, or be deleted from all LOCs if the capability is otherwise provided at a location readily accessible to building occupants.

- Be protected in a small, wall-mounted enclosure.

- Have supplemental heating and ventilation for those enclosures located outdoors or in areas where the LOC will be exposed to temperatures or humidity outside of the manufacturer’s design limits.

- Be protected from tampering by use of a break-glass, thumb-lock, tamper wire, tamper alarm, or equivalent protection. This is not required in those facilities with limited access so that unauthorized use would not reasonably be expected to occur. Enclosures that can be opened only by a key shall not be used.

Marine Corps LOC may use key-operated locks when emergency response forces are provided with immediate access (e.g., master key, Knox-box®)

- Have signage on the outside of the enclosure similar to “Mass Notification” and “HVAC Emergency Shutdown” (if applicable).

4-6 NOTIFICATION APPLIANCE NETWORK

Note: Also see paragraph 6-5 for notification appliance requirements in special occupancies.

4-6.1 **Audible Appliance Network.** These are the requirements of the audible appliance network:

- Provide appliances capable of satisfying \1\ ABAAG. /1/
- Use speakers suitable for the intended climatic and environmental conditions.
- Use speakers suitable for installation in commercial/industrial applications with consideration of electrically hazardous (classified) locations.
- Provide speakers and installation methods compliant with Director of Central Intelligence Directive (DCID) 6/9 for areas classified as sensitive, compartmented information facilities (SCIF).
- Speakers shall meet the listing requirements of UL Standard 1480.
- System design shall comply with NFPA 72.
- Provide speakers at all locations inside a building where the building fire alarm must be audible.
- \1\Ensure speakers in the vicinity of the ACU and LOC will not create acoustical feedback or otherwise interfere with the ability to deliver live voice messages./1/
- Provide speakers mounted on the exterior of the building to provide notification of any areas commonly used by building occupants. These include courtyards, covered break areas, designated smoking areas, and sidewalks leading from the building’s exit doors to a public street or from parking areas for a distance up to 5 m (16 ft) from the building. Use speakers with directional characteristics that transmit minimal backplane noise when mounted on the sides of the building. Generally, the speakers should be

located near entrance/exit doors.

- Provide an effective voice communication within buildings using a design including many speakers, each with low audio intensity.

- Install speakers with field-adjustable tap settings to allow adjustment after installation to meet audibility and intelligibility requirements.

- Do not use speakers exceeding 15 watts (W) for indoor applications without prior approval of the AHJ.

- Wiring methods shall comply with NFPA 72. Class B wiring is permitted unless Class A wiring is required for fire alarms systems on the DOD installation.

4-6.1.1 **Speaker Design Recommendations**

- Speakers rated at 2 W or less and with multiple tap settings to adjust the output power can often provide acceptable sound quality in most occupied areas.

- Speakers rated at 8 W or less and with multiple tap settings can often provide acceptable sound quality for most large or very noisy areas.

- Speakers rated at 8 to 10 W for interior distribution should be used when the speakers are also intended to meet the better sound quality normally expected from PA systems. These speakers should be capable of a frequency response over the range at least 200 Hz to 10,000 Hz.

  Note: Such speakers are often adjusted to operate at a tap setting of 2 W or less, but are used because their sound quality is greatly superior to the small speakers typically used in fire alarm systems.

4-6.1.2 \1\ **Intelligibility** /1/ **Requirements**

- Verify intelligibility by measurement after installation.

- \1\ Ensure that a CIS value greater than the required minimum value is provided in each area where building occupants typically could be found. The minimum required value for Navy and Marine Corps is 0.7 CIS. The minimum required value for Army and Air Force is 0.8 CIS, although rounding is permitted such that a value of 0.75 may be rounded to 0.8. /1/

- Areas of the building provided with hard wall and ceiling surfaces (such as metal or concrete) that are found to cause excessive sound reflections may be permitted to have a CIS score less than \1\ the minimum required value /1/ if approved by the DOD installation, and if building occupants in these areas can determine that a voice signal is being broadcast and they must walk no more than 10 m (33 ft) to find a location with at least \1\ the minimum required CIS value within the same area. /1/

- Areas of the building where occupants are not expected to be normally present are permitted to have a CIS score less than \1\ the minimum required value /1/ if personnel can determine that a voice signal is being broadcast and they must walk no more than 15 m (50 ft) to a location with at least \1\ the minimum required CIS value within the same area. /1/

- Measurements should be taken near the head level applicable for most personnel in the space under normal conditions (e.g., standing, sitting, sleeping, as appropriate).

- \1\ The distance the occupant must walk to the location meeting the minimum required CIS value shall be measured on the floor or other walking surface as follows:

    - Along the centerline of the natural path of travel, starting from any point subject to occupancy with less than the minimum required CIS value.

    - Curving around any corners or obstructions, with a 300-mm (12 in.) clearance therefrom.

    - Terminating directly below the location where the minimum required CIS value has been obtained. /1/

- Commercially available test instrumentation shall be used to measure intelligibility as specified by IEC 60849 and IEC 60268-16. The mean value of at least three readings shall be used to compute the intelligibility score at each test location.

- \1\ Occasionally, large DOD buildings are designed to provide cavernous-type open areas to meet unique operational requirements. Such areas are typically designed with hard wall and ceiling surfaces (such as metal or concrete) without acoustical treatments, and this has been found to cause excessive sound reflections that prevent obtaining the normal, minimum required CIS value. In such facilities, the cavernous-type open area is permitted to have locations with a CIS value lower than the normal, minimum required CIS value when the following conditions are met:

    - The requirement for a deviation from the normal, minimum CIS criteria is identified in the design phase.

    - Justification for the deviation from the normal, minimum CIS criteria is provided to the approving authority (i.e., the AHJ for the Navy and Marine Corps; the DOD installation in conjunction with the contracting officer for the Army and Air Force). The justification shall address all factors relevant to the request for deviation from normal, minimum CIS criteria, including, but not limited to: the operational requirements that restrict the installation of acoustical wall and ceiling treatments; the potential use of special speaker technologies such as directional speakers or stacked speaker systems; and, the availability of physically larger or higher-fidelity speakers even though such speakers might not be listed for fire alarm use.

Note: Deviation from normal, minimum CIS criteria should not be requested for the design of normal, large, open areas that are typically found in permanent DOD buildings, such as dining halls, theaters, and gymnasiums. The potential for deviation from normal criteria is intended to address the rare exception to normal criteria that is sometimes needed for DOD buildings with unique operational requirements.

- o Building occupants located in the large, cavernous area can adequately understand the message content in the voice signal being broadcast. Whether the voice message is adequately understood shall be determined by the approving authority (i.e., the AHJ for the Navy and Marine Corps; the DOD installation in conjunction with the contracting officer for the Army and Air Force).

- o The CIS value is not less than 0.6 at any location within the large, cavernous area.

- o The building occupants in the large, cavernous area must walk no more than 30 m (98 ft) to find another location within the large, cavernous area having at least the normal, minimum required CIS value. /1/

Note: An STI score of 0.5 is considered equivalent to a CIS score of 0.7. \1\ An STI value of 0.7 is considered equivalent to a CIS value of 0.8. /1/

4-6.1.3 \1\ DELETED /1/

4-6.2 **Visual Appliance Network.** These are the requirements for the visual appliance network:

- Provide visual appliances capable of satisfying \1\ ABAAG. /1/
- Use visual appliances suitable for the intended climatic and environmental conditions.
- Use visual appliances suitable for installation in commercial/industrial applications with consideration of electrically hazardous (classified) locations.
- Strobes shall meet the listing requirements of UL Standards 1638 and 1971.

Text signs shall comply with UL Standard 48.

- Strobes are not required outside the building.
- Where more than two visible notification appliances are in any field of view, they shall flash in synchronization.
- Wiring methods shall comply with NFPA 72. Class B wiring is permitted unless required otherwise by the local AHJ.

4-6.2.1 **Navy-Specific Requirements**

- Provide clear strobes marked with the word “ALERT” for shared use by the building’s combination MNS/FACP.
- Provide LED text signs. Text signs are required over the door to each egress stairwell and over (or adjacent to) the substantial means of egress from the level of discharge. Exterior exit doors from a single room (e.g., mechanical or electrical rooms) do not require a text sign. (See Chapter 7 for operational requirements and information on message content.)

4-6.2.2 **Marine Corps-Specific Requirements**

- Contact the AHJ for guidance on visual notification appliances.

4-6.2.3 **Army- and Air Force-Specific Requirements**

- Provide amber-colored strobes marked with the word “ALERT” to alert the hearing impaired. Provide these strobes in addition to existing clear strobes provided for the building fire alarm system.
- Amber strobes activated in conjunction with the delivery of a pre-recorded voice message shall operate continuously until message termination. Amber strobes activated in conjunction with the delivery of a live voice message shall operate during the message and for not less than 15 seconds after the message ends.
- Clear/white strobes activated by the fire alarm system shall not operate during those periods when the amber strobes are in operation, but otherwise shall operate continuously until the fire alarm system is reset.

4-7 **INTERFACES WITH WIDE AREA MNS.** The individual building MNS shall be capable of being interoperable with an existing wide area MNS. If a wide area MNS is not presently provided on the DOD installation, the individual building MNS shall be designed to allow future interface with a wide area MNS procured from another manufacturer. The electrical requirements, computer codes, or other protocols that are needed to interface the systems shall be provided to the DOD installation.

Note: When a wide area MNS is provided on the DOD installation, the system manufacturer should provide a standard method (such as an audio line-level output and multiple relay contacts) or supply the necessary digital communication protocols to permit the DOD installation to select more than one manufacturer of individual building MNS. Depending on system architecture, the manufacturer may be required to provide a system IP interface capable of allowing data transfer from an outside source to internal mass notification functions via a common data communications protocol.

CHAPTER 5

INDIVIDUAL BUILDING MNS FOR RENOVATION PROJECTS

5-1 **SCOPE.** Individual building MNS are intended to provide real-time information to personnel within and in the immediate vicinity of buildings on a DOD installation. These systems are required by UFC 4-010-01 for new construction and renovation of existing building. This chapter provides the design criteria for renovation projects, including the installation of MNS in existing buildings. This chapter should be used for new Marine Corps projects unless combination systems (see Chapter 4) are specifically approved by the AHJ. This chapter should also be used when an Army or Air Force installation approves the use of a separate MNS and separate building fire alarm system in a new construction project.

Note: See paragraph 6-5 for MNS requirements for special occupancies such as medical facilities and facilities intended for occupancy by persons not capable of self-preservation.

5-2 **REQUIREMENTS FOR SYSTEM DESIGNERS.** The individual building MNS shall be designed under the supervision of a registered professional engineer with a minimum of 4 years of current work experience in fire protection, electrical, and communication-electronics engineering areas specific to individual building MNS. Alternately, the individual building MNS may be designed by an engineering technologist verified by NICET as certified at Level IV in low voltage electronic-communications systems or at Level IV in fire alarm systems, plus this engineering technologist shall possess a minimum of 4 years current work experience specific to individual building MNS communications-electronics. Alternately, the individual building MNS may be designed by an engineering technologist that possesses a minimum of 10 years of documented current work experience specific to individual building MNS communications-electronics. The individual's name, signature, and professional engineer number or NICET certification number (when applicable) shall be included on all final design documents.

5-3 USE OF NEW CONSTRUCTION CRITERIA

5-3.1 **FACP Replacement: No Existing MNS in Building.** When replacing a FACP in a building without an existing MNS, provide a combination mass notification and fire alarm system meeting the requirements for new construction projects (see Chapter 4).

5-3.2 FACP Replacement: Existing MNS in Building

5-3.2.1 When replacing a FACP in a building with an existing separate MNS, removal of both systems and installation of a combination system meeting new construction criteria is recommended but not required. Consider the age and condition of the MNS and the life-cycle costs of keeping the existing MNS when determining whether to install a new combined system or remain with separate systems.

5-3.3 MNS Installation Projects

5-3.3.1 When installing a MNS in a building with an existing separate FACP, removal of both systems and installation of a combination system meeting new construction criteria is recommended but not required. Consider the age and condition of the FACP and the life-cycle costs of keeping the existing FACP when determining whether to install a new combined system or remain with separate systems.

Separate systems are required for Marine Corps projects unless a combination system is specifically permitted by the AHJ.

5-4 SYSTEM OVERVIEW

5-4.1 **Subsystems.** An individual building MNS for renovation projects includes several subsystems: ACU; LOC; notification appliance network; interface with facility FACP; interface with facility PA system; and interface with the wide area MNS on the DOD installation. System design and wiring must meet NFPA 72 requirements for MNS and fire alarm systems.

Individual building MNS for Marine Corps projects shall serve as a subsystem of the wide area MNS.

5-4.2 **ACU.** The ACU is used to monitor and control the notification appliance network. At the ACU, personnel in the building can initiate delivery of pre-recorded voice messages, provide live voice messages and instructions, initiate visual strobe and alphanumeric message notification appliances, and temporarily silence fire alarm system visual and audible notification appliances.

Marine Corps MNS designs are not required to use an ACU.

5-4.3 **LOC.** A LOC is a unit designed to allow emergency response forces and building occupants to operate the individual building MNS, including initiating delivery of pre-recorded voice messages, providing live voice messages and instructions, initiating visual strobe and alphanumeric message notification appliances, temporarily silencing fire alarm system visual and audible notification appliances, overriding external voice announcements, and terminating mass notification functions. A LOC is usually contained in a small, wall-mounted enclosure. Not all functions that could be performed at the ACU are necessarily available at a LOC.

Marine Corps MNS designs are not required to use a LOC.

5-4.4 **Notification Appliance Network.** A notification appliance network consists of a set of audio speakers, strobes, and text signs (when required by the AHJ) located to alert occupants and provide intelligible voice and written instructions. When required, text signs are installed over the door to each egress stairwell and over (or adjacent to) the substantial means of egress from the level of discharge. Exterior exit doors from a single room (e.g., mechanical or electrical rooms) do not require a text sign.

Text signs are not authorized in Marine Corps MNS designs unless specifically permitted by the AHJ.

5-4.4.1 **Audio Appliance Network.** Speakers are provided at all locations in the building and are provided around the building at entrances/exits and other outdoor areas (such as courtyards) commonly used by the building occupants. Important design considerations for the audio speakers include intelligibility and audio intensity.

Note: Outside notification more than 5 m (16 ft) from the building should be provided by the wide area MNS.

5-4.4.1.1 Intelligibility is defined in NFPA 72. Commercially available test instrumentation shall be used to verify intelligibility.

5-4.4.1.2 Effective voice communication within buildings occurs by using a system design of many speakers, each with low audio intensity.

5-4.4.2 **Visual Appliance Network.** Strobes are provided at all locations inside the building to meet \1\ ABAAG /1/ for persons with hearing disabilities. Strobes are provided at the same locations in a building that would be required for a fire alarm \1\ visual /1/ notification appliance. Separate MNS and FACP systems may use either one strobe (clear) or two strobes (clear for fire and amber for MNS) as specified by the AHJ. Text signs may be required by the AHJ over the door to each egress stairwell and over (or adjacent to) the substantial means of egress from the level of discharge. Exterior exit doors from a single room (e.g., mechanical or electrical rooms) do not require a text sign.

5-4.4.2.1 Army and Air Force installations shall use existing clear/white strobes for fire and install amber strobes for MNS. New amber strobes will be marked with word "ALERT." Installation of text signs is optional and at the discretion of the DOD installation.

\1\ 5-4.4.2.2 Navy installations shall use clear/white strobes marked with the word "ALERT." Text signs shall be located over the door to each egress stairwell and over (or adjacent to) the substantial means of egress from the level of discharge. Exterior doors from a single room (e.g., mechanical or electrical rooms) do not require a text sign. /1/

\1\ 5-4.4.2.3 /1/ Marine Corps installations shall contact the AHJ for guidance on visual notification appliances.

5-4.5 **Interfaces with Facility FACP.** The MNS shall provide the capability (either internally as a design feature, or with an approved or listed external controller) to temporarily deactivate the facility's fire alarm system audible and visual notification appliances. This is intended to allow the MNS to provide intelligible voice commands inside an individual building during simultaneous fire and terrorist events. System features are provided to compensate for the increased risk from fire in these cases.

Marine Corps MNS designs may interface with the facility FACP. Contact the AHJ for guidance.

5-4.6 **Interfaces with Facility PA System.** The use of the speakers and other components in the existing PA system may be appropriate in smaller size buildings in which the installation of a new speaker system is not cost effective and the existing PA system is new or relatively new, in excellent condition, and of relatively simple design. If this implementation approach is taken, an ACU must be interfaced with the existing PA system. The existing PA system must be tested to demonstrate acceptable intelligibility of the voice messages, and additional speakers must be added as required. These features must be provided in or added to the PA system:

- Emergency messages must have priority over non-emergency messages.
- All individual or zone speaker volume controls must default to the emergency sound level when used for an MNS message.
- Provide a supervisory signal when the PA system has been placed in the “OFF” condition.
- When monitoring of circuit integrity is provided by the PA system, continue monitoring even if local speaker volume controls are placed in the “OFF” position.
- Provide the required visual notification appliance network (i.e., strobes and text signs).

Marine Corps MNS designs are not required to provide an interface with the facility PA system.

Note: The term “public address system” (or “PA system”) is used in this UFC to mean both PA and intercommunication systems.

5-4.7 **Interfaces with the Wide Area MNS**. If a wide area MNS is provided on the DOD installation, the individual building MNS communicates with the central control units of the wide area MNS to provide status information, receive commands, activate pre-recorded messages, and originate live voice messages. Depending on system architecture, the manufacturer may be required to provide a system IP interface capable of allowing data transfer from an outside source to internal mass notification functions via a common data communications protocol.

Marine Corps MNS designs shall interconnect the wide area MNS with the individual building MNS through the use of common control systems.

Note: When a wide area MNS is provided on the DOD installation, the system manufacturer should provide a standard method (such as an audio line-level output and multiple relay contacts) or supply the necessary digital communication protocols to permit the DOD installation to select more than one manufacturer of individual building MNS.

5-4.8 **Logical Block Diagrams.** Figures 5-1 through 5-7 show the logical block diagrams for acceptable configurations of the individual building MNS for renovation projects, including the installation of MNS in existing buildings.

Note: These diagrams are intended to show only the functional relationships of major components. The diagrams are not intended to serve as wiring diagrams. Many essential design features for an operational system, such as end-of-line resistors, are not shown.

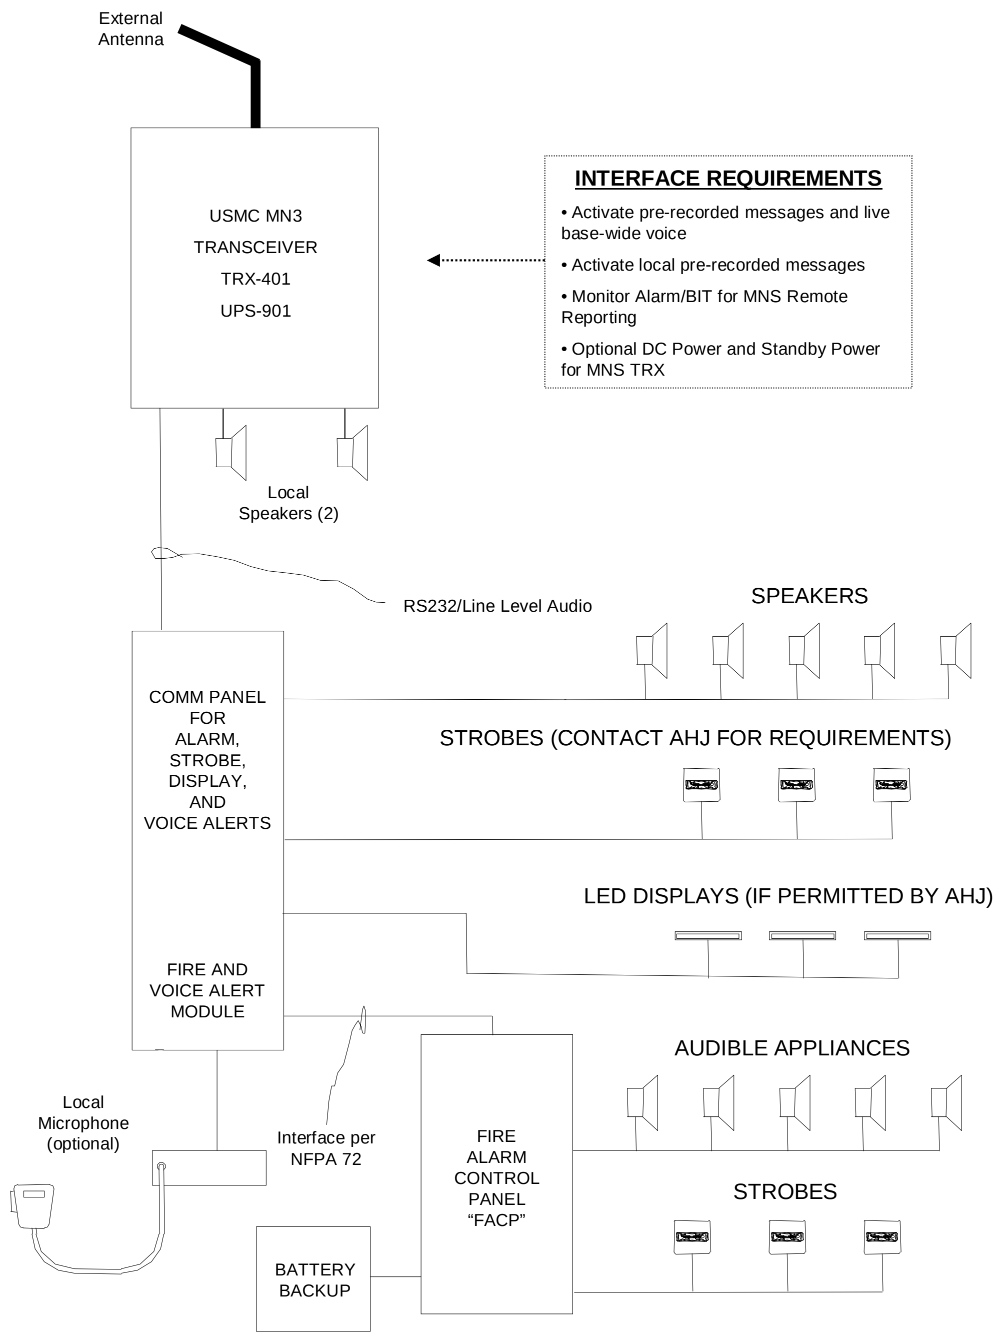

Figure 5-4. Individual Building Mass Notification System: Speakers Shared by Fire Alarm System and MNS (Navy)

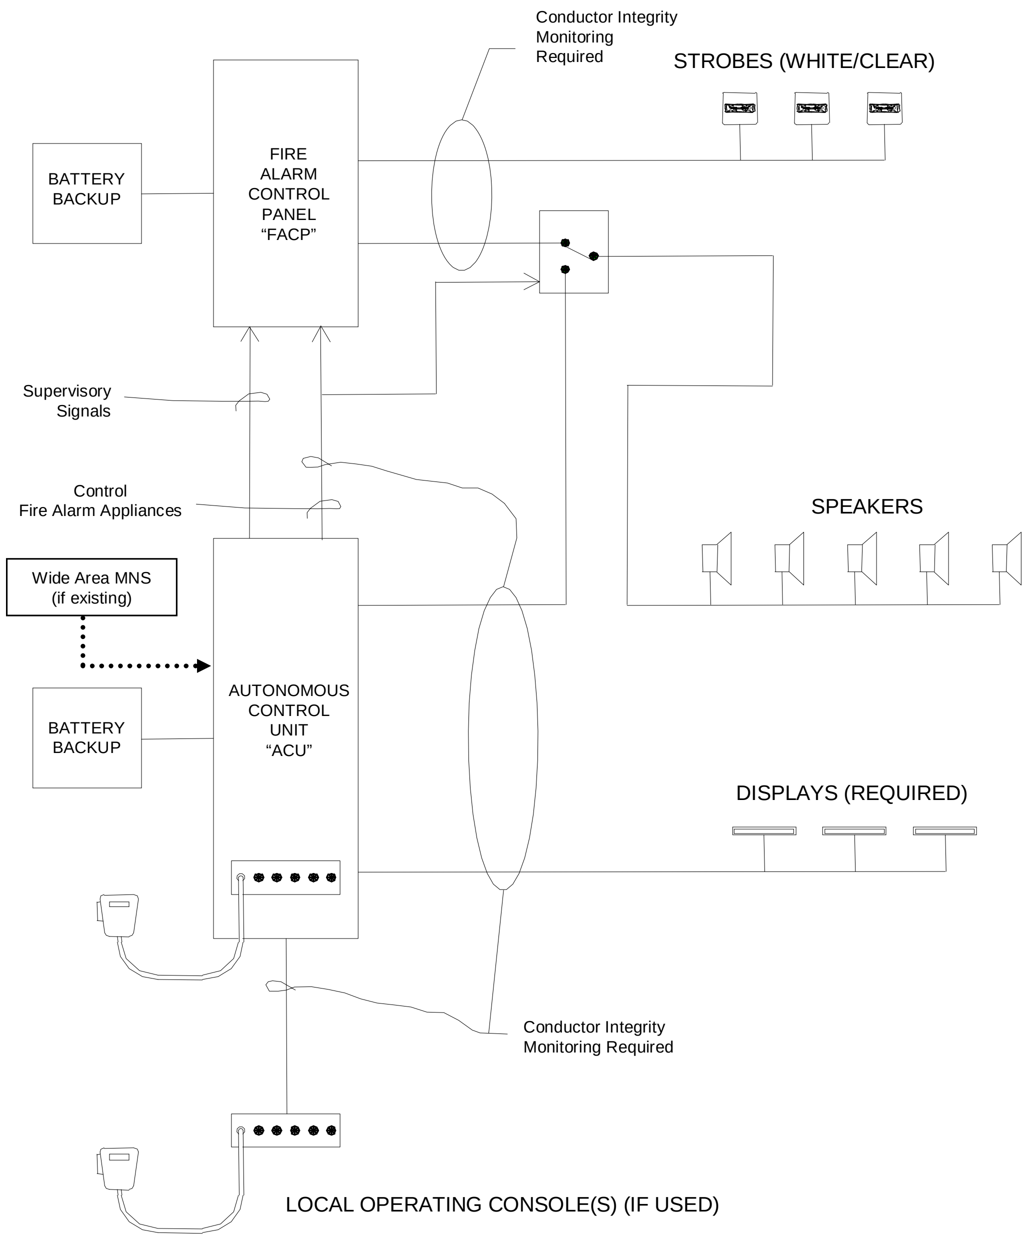

Figure 5-5. Individual Building Mass Notification System: Speakers Shared by Fire Alarm System and MNS (Army and Air Force)

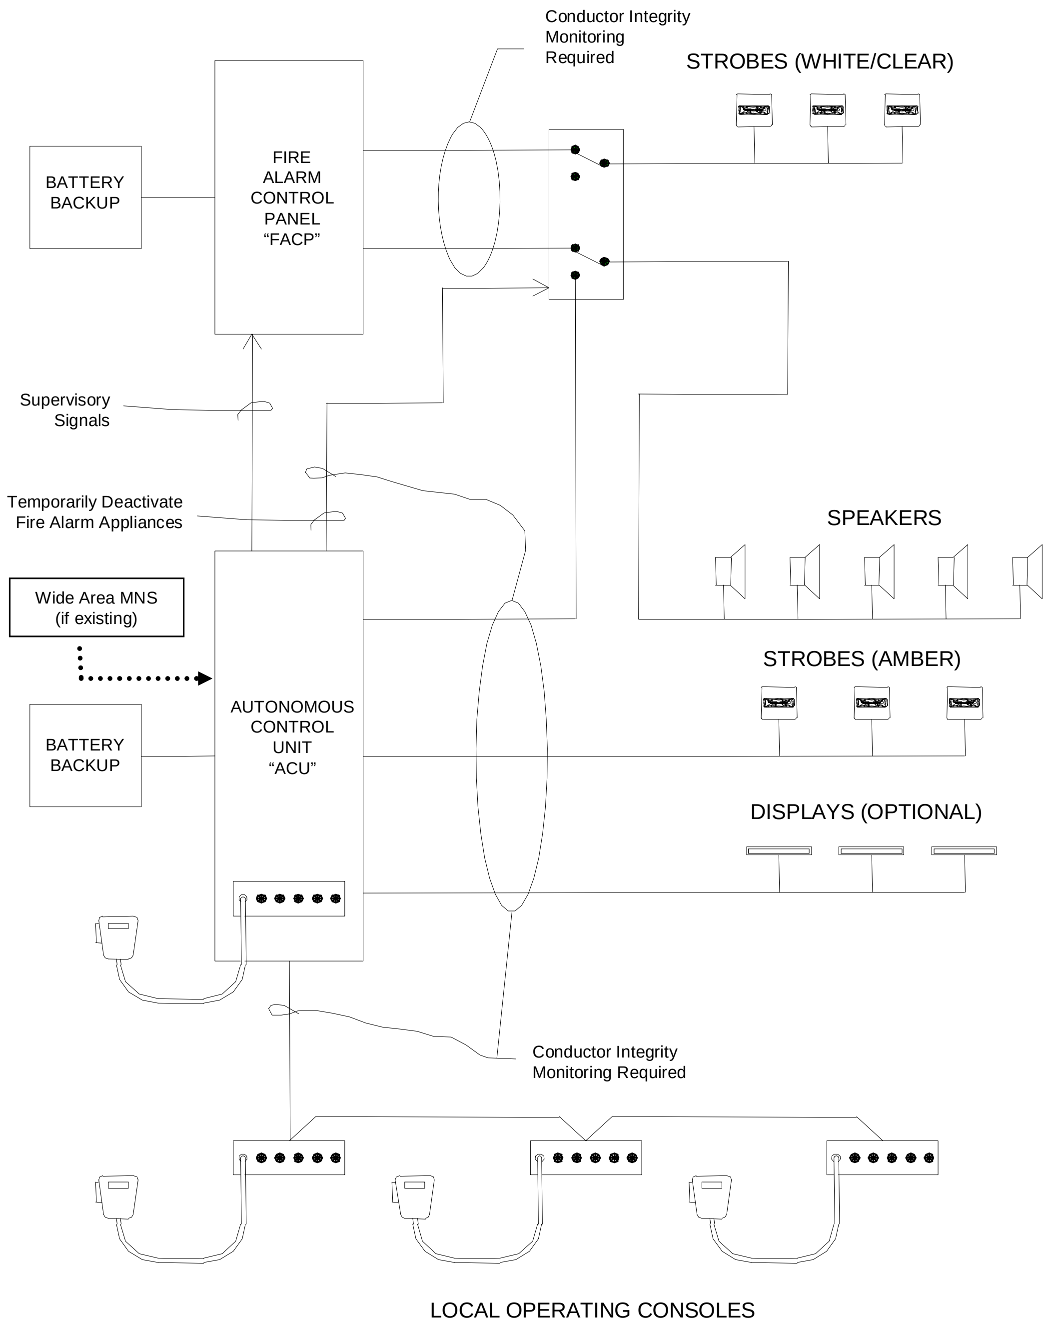

Figure 5-6. Use of Existing Public Address System: Navy

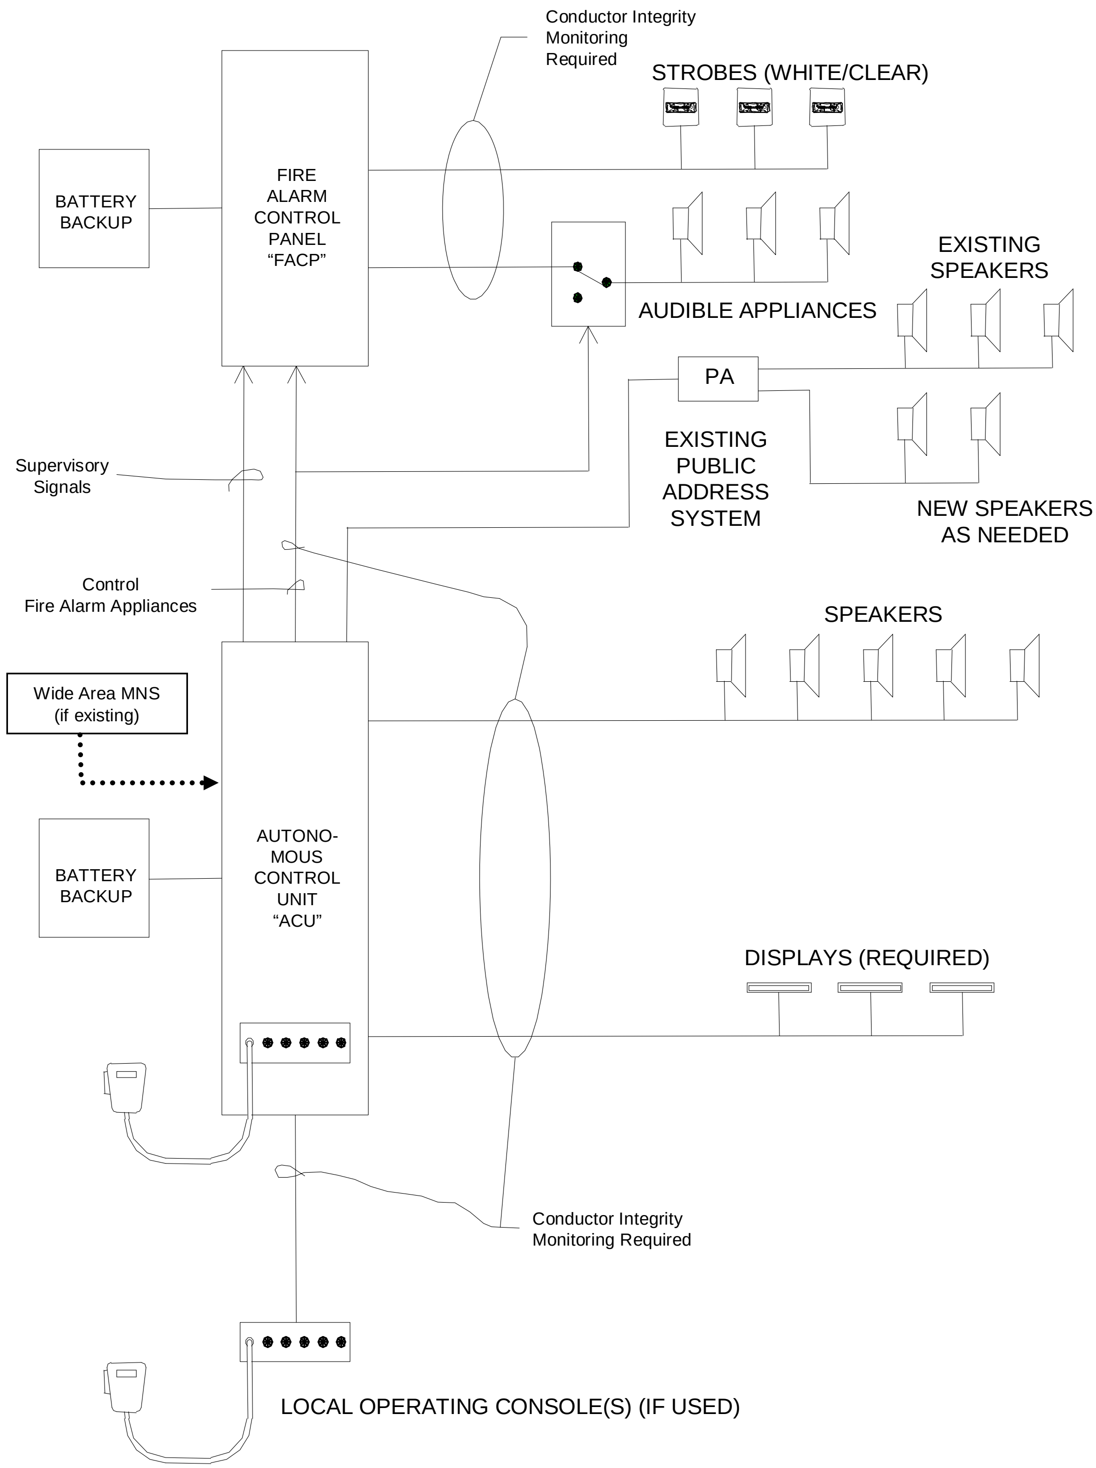

Figure 5-7. Use of Existing Public Address System: Army and Air Force

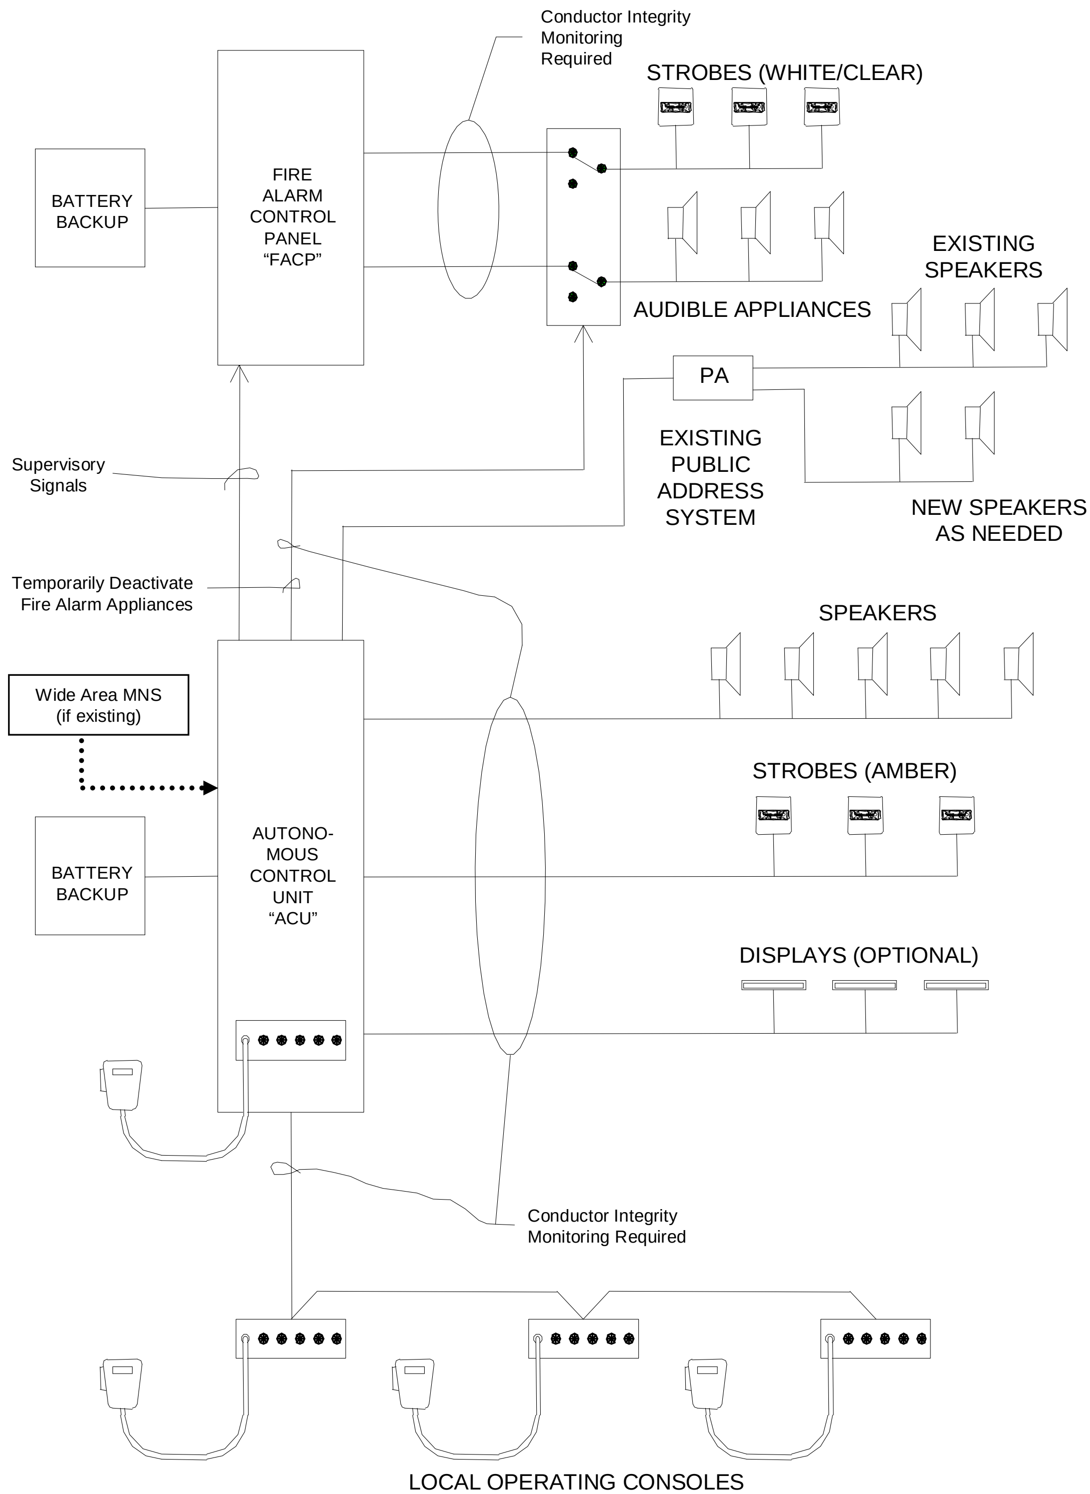

5-5 **ACU**

5-5.1 **Location.** Install the ACU at the location normally specified by the DOD component AHJ for a stand-alone FACP.

5-5.2 **Design Features.** The ACU shall:

- Be able to function independently upon failure of the wide area MNS (if provided on the DOD installation).

- Meet UL Standard 864 or UL Standard 2017, and meet the MNS requirements in NFPA 72 and the specific requirements of this UFC. The listing evaluation shall be accomplished by UL, FM, or another NRTL.

- Be able to activate strobes and text signs:

  - Navy: Energize LED-type text signs. Text signs are required over the door to each egress stairwell and over (or adjacent to) the substantial means of egress from the level of discharge. Exterior exit doors from a single room (e.g., mechanical or electrical rooms) do not require a text sign.

  - Marine Corps: Contact the AHJ for guidance on visual notification appliances.

  - Army and Air Force: Energize a set of amber strobe lights marked “ALERT” for the MNS. Simultaneously de-energize clear/white strobe lights used by the fire alarm system. Energize LED-type text signs if required by the DOD installation.

- Make general paging or other non-emergency messages available without the activation of strobes. A separate microphone must be provided for this purpose.

- Be able to interrupt PA system announcements and to silence building background music while delivering voice messages.

- Be able to accept voice messages from the DOD installation telephone system.

- Have conductor connections that comply with NFPA 72.

- **Note:** Ethernet or IP connections for initiating and indicating circuits are not currently available that will meet NFPA 72 requirements and, therefore, may not be used. Additionally, all software and hardware to be installed on DOD Ethernet or Internet systems must first successfully complete an accreditation process. Accreditation often takes a relatively long time.

- Have conductor integrity monitoring for strobes, speaker wiring, power supplies, and connections to LOC.

- Be able to switch between MNS and fire alarm notification functions without generating trouble alarms in either system.

- Have the capacity for multiple pre-recorded messages (at least eight, but more if required by the DOD installation). Pre-recorded messages shall be passed in the English language and, for OCONUS locations, also in the predominant language(s) used by the host nation. Pre-recorded messages, if used, should address at least these subjects:

  - Bomb threat or actual bomb within/around the building

  - Intruder/hostile person sighted within/around the building

  - Directions to occupants to take cover within the building

  - Evacuation of the building using exits other than the normal main entrance/exit (since the front entrance/exit is often a location targeted by terrorists)

  - Emergency weather conditions appropriate for the local area

  - “All Clear” message

  - A test message intended for verifying functionality of the system

  Marine Corps AHJ will determine the number and content of pre-recorded messages.

- \1\ Provide an alerting sound prior to playing pre-recorded messages. The alerting sound for fire alarm messages shall be different than that used for other pre-recorded messages. The fire alarm alerting sound for buildings other than child development centers shall be either the temporal three-tone or the slow whoop for fire alarm messages, unless otherwise approved by the approving authority (i.e., the AHJ for the Navy and Marine Corps; the DOD installation in conjunction with the contracting officer for the Army and Air Force). The fire alarm alerting sound for child development centers shall be a chime sound. /1/

- Be able to deliver messages quickly.

- Be able to automatically repeat pre-recorded messages until they are terminated.

- Have a microphone for delivering live voice messages.

- Provide adequate discrete outputs to initiate text signs and MNS strobes, and de-energize fire alarm strobes.

- Interface to the LOC for initiating recorded messages and delivering live voice messages from locations in the building other than at the ACU.

- Establish priority for passing messages to prevent interference between the ACU, LOC, and the wide area MNS on the DOD installation.

- Interface with the FACP to override fire alarm audible and visual notification appliances. The FACP shall provide supervised circuit integrity of interconnecting wiring between the MNS and FACP.

- Allow the MNS to temporarily override fire alarm audible messages and visual signals, and to provide intelligible voice commands during simultaneous fire and terrorist events. All other features of the fire alarm system, including the transmission of signals to the fire department, shall function properly. MNS messages shall take priority and continue to override fire alarm audible messages until the MNS message is either manually or automatically ended. If not manually ended, the MNS message will automatically end after 10 minutes.

- Provide a supervisory signal if the MNS is used to override fire alarm audible messages and visible signals during simultaneous fire and terrorist events. The supervisory signal shall be annunciated at the FACP and any remote fire alarm annunciators, and be transmitted to the fire department. The visual annunciation of the separate supervisory signal shall be distinctly labeled or otherwise clearly identified.

SE The Army requires that this supervisory signal be separate from other fire alarm system supervisory signals.

- Provide remote monitoring of trouble, supervisory, and alarm functions to a constantly occupied location. This may be the same location that receives fire alarm system signals or to the central control units of the wide area MNS on the DOD installation.

- Provide a single switch or operating mechanism capable of shutting down all HVAC equipment in the facility in accordance with the requirements of UFC 4-010-01. If permitted by the DOD installation, this shutdown capability may be provided at a LOC or be deleted entirely if the capability is otherwise provided at a location readily accessible to building occupants.

- Provide a complete set of self-diagnostics for the controller and appliance network.

- Have a local diagnostic information display.

- Have a local system event log file.

5-5.3 **Off-the-Shelf Equipment.** ACU equipment furnished as part of the individual building MNS shall be COTS and shall be tested to the standards of UL or FM by a NRTL.

5-5.4 **Programming Codes.** All programming codes or passwords required to access, update, modify, and maintain the ACU shall be provided to the DOD installation no later than the date of final system acceptance.

5-5.5 **Power Supply Features.** The power supply shall:

- Be capable of accepting 120/240 VAC, 50/60 Hz.

- Be appropriate for a MNS that meets at least the minimum NFPA 72 requirements for standby power capacity. In addition, secondary (standby) power should be provided as follows: immediately upon loss of normal AC power, the standby source of power shall provide a minimum of 60 minutes of mass notification at the maximum connected load.

- Disable use of any microphones intended solely for general paging or other non-emergency messages upon loss of normal AC power.

- Conform to applicable sections of NFPA 72.

- Use only COTS components.

- Provide surge protection in accordance with UFC 3-520-01.

5-6 **LOC**

5-6.1 **Locations.** Provide LOC to allow emergency response forces and building occupants to access the MNS and originate messages in emergency situations from locations in the building other than from the ACU. Follow these requirements:

- Provide a separate LOC for use by the fire department near the building FACP (or fire command center) unless this is also the location of the ACU.

- Do not place a LOC inside of locked rooms or closets (with the possible exception of the LOC intended for use by the fire department near the FACP).

- Install LOC at those facility entrances/exits that will be used when building access is limited because of elevated terrorism threat levels.

Note: This LOC is intended to enable immediate notification of building occupants when unauthorized building access is threatened or has occurred at this location.

- Army and Air Force: Provide a LOC so that occupants do not need to travel a distance in excess of 61 m (200 ft) horizontally or to travel to other floors to access a LOC.

- Army and Air Force: Make LOC available for use by visitors in those facilities open to unescorted visitors or to the public.

- Navy: Provide no more than one LOC (if necessary) in addition to the ACU. Locate the LOC as directed by the responsible fire protection engineer.

- Marine Corps: Provide no more than one LOC (if necessary) in addition to the ACU. Locate the LOC as directed by the AHJ.

5-6.2 **Design Features.** The LOC shall:

- Have a remote microphone station that emulates operation of the MNS from the ACU.

- Have an easy method (such as individual manual activation push buttons) of activating the MNS pre-recorded messages. Signage shall be provided to allow rapid recognition of the means of initiating the pre-recorded messages.

SE Activation of MNS pre-recorded messages is not required for Marine Corps LOC.

- Provide a single switch or operating mechanism capable of shutting down all HVAC equipment in the facility in accordance with the requirements of UFC 4-010-01. If permitted by the DOD installation, this shutdown capability may be provided at only one LOC when multiple LOCs are installed, or be deleted from all LOCs if the capability is otherwise provided at a location readily accessible to building occupants.

- Be protected in a small, wall-mounted enclosure.

- Have supplemental heating and ventilation for those enclosures located outdoors or in areas where the LOC will be exposed to temperatures or humidity outside of the manufacturer's design limits.

- Be protected from tampering by use of a break-glass, thumb-lock, tamper wire, tamper alarm, or equivalent protection. This is not required in those facilities with limited access so that unauthorized use would not reasonably be expected to occur. Enclosures that can be opened only by a key shall not be used.

SE Marine Corps LOC may use key-operated locks when emergency response forces are provided with immediate access (e.g., master key, Knox-box®)

- Have signage on the outside of the enclosure similar to “Mass Notification” and “HVAC Emergency Shutdown” (if applicable).

5-7 NOTIFICATION APPLIANCE NETWORK

Note: Also see paragraph 6-5 for notification appliance requirements in special occupancies.

5-7.1 **Audible Appliance Network.** These are the requirements for the audible appliance network:

- Provide appliances capable of satisfying \1\ ABAAG /1/.

- Use speakers suitable for the intended climatic and environmental conditions.

- Use speakers suitable for installation in commercial/industrial applications with consideration of electrically hazardous (classified) locations.

- Provide speakers and installation methods compliant with DCID 6/9 for areas classified as SCIF.

- Network design shall comply with NFPA 72.

- Speakers shall meet the listing requirements of UL Standard 1480.

- Provide speakers at all locations inside a building where the building fire alarm must be audible.

- \1\ Ensure speakers in the vicinity of the ACU and LOC will not create acoustical feedback or otherwise interfere with the ability to deliver live voice messages. /1/

- Provide speakers mounted on the exterior of the building to provide notification of any areas commonly used by building occupants. These include courtyards, covered break areas, designated smoking areas, and sidewalks leading from the building’s exit doors to a public street or from parking areas for a distance up to 5 m (16 ft) from the building. Use speakers with directional characteristics that transmit minimal backplane noise when mounted on the sides of the building. Generally, the speakers should be located near entrance/exit doors.

- Provide an effective voice communication within buildings using a design including many speakers, each with low audio intensity.

- Install speakers with field-adjustable tap settings to allow adjustment after installation to meet audibility and intelligibility requirements.

- Do not use speakers exceeding 15 W for indoor applications without prior approval of the AHJ.

5-7.1.1 **Speaker Design Recommendations**

- Speakers rated at 2 W or less and provided with multiple tap settings to adjust the output power can often provide acceptable sound quality in most occupied areas.

- Speakers rated at 8 W or less and provided with multiple tap settings can often provide acceptable sound quality for most large or very noisy areas.

- Speakers rated at 8 to 10 W for interior distribution should be used when the speakers are also intended to meet the better sound quality normally expected from PA systems. These speakers should be capable of a frequency response over the range of at least 200 to 10,000 Hz.

Note: Such speakers are often adjusted to operate at a tap setting of 2 W or less, but are used because their sound quality is greatly superior to the small speakers typically used in fire alarm systems.

- Wiring methods shall comply with NFPA 72. Class B wiring is permitted unless Class A wiring is required for fire alarms systems on the DOD installation.

5-7.1.2 \1\ **Intelligibility** /1/ **Requirements**

- Verify intelligibility by measurement after installation.

- \1\ Ensure that a CIS value greater than the required minimum value is provided in each area where building occupants typically could be found. The minimum required value for Navy and Marine Corps is 0.7 CIS. The minimum required value for Army and Air Force is 0.8 CIS, although rounding is permitted such that a value of 0.75 may be rounded to 0.8. /1/

- Areas of the building provided with hard wall and ceiling surfaces (such as metal or concrete) that are found to cause excessive sound reflections may be permitted to have a CIS score less than \1\ the minimum required value /1/ if approved by the DOD installation, and if building occupants in these areas can determine that a voice signal is being broadcast and they must walk no more than 10 m (33 ft) to find a location with at least \1\ the minimum required CIS value within the same area. /1/

- Areas of the building where occupants are not expected to be normally present are permitted to have a CIS score less than \1\ the minimum required value /1/ if personnel can determine that a voice signal is being broadcast and they must walk no more than 15 m (50 ft) to a location with at least \1\ the minimum required CIS value within the same area. /1/

- Measurements should be taken near the head level applicable for most personnel in the space under normal conditions (e.g., standing, sitting, sleeping, as appropriate).

- \1\ The distance the occupant must walk to the location meeting the minimum required CIS value shall be measured on the floor or other walking surface as follows:

    - Along the centerline of the natural path of travel, starting from any point subject to occupancy with less than the minimum required CIS value.

    - Curving around any corners or obstructions, with a 300-mm (12 in.) clearance therefrom.

    - Terminating directly below the location where the minimum required CIS value has been obtained. /1/

- Commercially available test instrumentation shall be used to measure intelligibility as specified by IEC 60849 and IEC 60268-16. The mean value of at least three readings shall be used to compute the intelligibility score at each test location.

- \1\ Occasionally, large DOD buildings are designed to provide cavernous-type open areas to meet unique operational requirements. Such areas are typically designed with hard wall and ceiling surfaces (such as metal or concrete) without acoustical treatments, and this has been found to cause excessive sound reflections that prevent obtaining the normal, minimum required CIS value. In such facilities, the cavernous-type open area is permitted to have locations with a CIS value lower than the normal, minimum required CIS value when the following conditions are met:

    - The requirement for a deviation from the normal, minimum CIS criteria is identified in the design phase.

    - Justification for the deviation from the normal, minimum CIS criteria is provided to the approving authority (i.e., the AHJ for the Navy and Marine Corps; the DOD installation in conjunction with the contracting officer for the Army and Air Force). The justification shall address all factors relevant to the request for deviation from normal, minimum CIS criteria, including, but not limited to: the operational requirements that restrict the installation of acoustical wall and ceiling treatments; the potential use of special speaker technologies such as directional speakers or stacked speaker systems; and the availability of physically larger or higher-fidelity speakers even though such speakers might not be listed for fire alarm use.

Note: Deviation from normal, minimum CIS criteria should not be requested for the design of normal, large, open areas that are typically found in permanent DOD buildings, such as dining halls, theaters, and gymnasiums. The potential for deviation from normal criteria is intended to address the rare exception to normal criteria that is sometimes needed for DOD buildings with unique operational requirements.

- o Building occupants located in the large, cavernous area can adequately understand the message content in the voice signal being broadcast. Whether the voice message is adequately understood shall be determined by the approving authority (i.e., the AHJ for the Navy and Marine Corps; the DOD installation in conjunction with the contracting officer for the Army and Air Force).
- o The CIS value is not less than 0.6 at any location within the large, cavernous area.
- o The building occupants in the large, cavernous area must walk no more than 30 m (98 ft) to find another location within the large, cavernous area having at least the normal, minimum required CIS value. /1/

Note: An STI score of 0.5 is considered equivalent to a CIS score of 0.7. \1\ An STI value of 0.7 is considered equivalent to a CIS value of 0.8. /1/

5-7.1.3 \1\ DELETED /1/

5-7.2 **Visual Appliance Network.** These are the requirements for the visual appliance network:

- Provide visual appliances capable of satisfying all \1\ ABAAG. /1/
- Use visual appliances suitable for the intended climatic and environmental conditions.
- Use visual appliances suitable for installation in commercial/industrial applications with consideration of electrically hazardous (classified) locations.
- Strobes shall meet the listing requirements of UL Standards 1638 and 1971. Text signs shall comply with UL Standard 48.
- Strobes are not required outside the building.
- Where more than two visible notification appliances are in any field of view, they shall flash in synchronization.
- Wiring methods shall comply with NFPA 72. Class B wiring is permitted unless required otherwise by the local AHJ.

5-7.2.1 **Navy-Specific Requirements**

- Provide clear strobes marked with the word "ALERT" for shared use by the facility's MNS and FACP.

- Provide LED text signs. Text signs are required over the door to each egress stairwell and over (or adjacent to) the substantial means of egress from the level of discharge. Exterior exit doors from a single room (e.g., mechanical or electrical rooms) do not require a text sign. (See Chapter 7 for operational requirements and information on message content.)

5-7.2.2 **Marine Corps-Specific Requirements**

- Contact the AHJ for guidance on visual notification appliances.

5-7.2.3 **Army- and Air Force-Specific Requirements**

- Provide amber-colored strobes marked with the word "ALERT" to alert the hearing impaired. Provide these strobes in addition to existing clear strobes provided for the building fire alarm system.

- Amber strobes activated in conjunction with the delivery of a pre-recorded voice message shall operate continuously until message termination. Amber strobes activated in conjunction with the delivery of a live voice message shall operate during the message and for not less than 15 seconds after the message ends.

- Clear/white strobes activated by the fire alarm system shall not operate during those periods when the amber strobes are in operation, but otherwise shall operate continuously until the fire alarm system is reset.

5-8 **INTERFACES WITH WIDE AREA MNS.** The individual building MNS shall be capable of interfacing with an existing wide area MNS. If a wide area MNS is not presently provided on the DOD installation, the individual building MNS shall be designed to allow future interface with a wide area MNS procured from another manufacturer. The electrical requirements, computer codes, or other protocols that are needed to interface the systems shall be provided to the DOD installation. At a minimum, the wide area MNS shall be able to provide and the individual building MNS shall be able to receive an audio line-level input. The individual building MNS shall not be activated or controlled by a giant voice system unless the giant voice system also meets the design and performance requirements of a wide area MNS.

CHAPTER 6

SPECIAL CONSIDERATIONS

6-1 **OVERVIEW.** DOD requirements for antiterrorism mandate the installation of individual building MNS during new construction and renovation projects. These systems are presently being installed on most DOD installations. Although not required by the DOD, use of a wide area MNS may be an important part of the antiterrorism strategy established by DOD installations.

6-2 **IMPLEMENTATION PLAN.** Each DOD installation should establish an implementation plan that establishes a comprehensive approach to MNS that is acceptable to security, communications, and fire protection engineering personnel. Elements of an implementation plan should include a needs assessment, requirements definition, alternatives evaluation, system selection, and implementation schedule. Some DOD installations may choose to first select and install a wide area MNS and subsequently install an individual building MNS that is compatible with the wide area MNS. This is not required by the DOD but will immediately increase the readiness of the DOD installation to respond to terrorist and other threats. Other DOD installations may choose to install individual building MNS in new construction and renovation projects, and also in their most significant and important facilities. This approach will spread the cost of installation over a longer time. The completed implementation plan will serve as a roadmap to address the specific needs and unique circumstances associated with each particular DOD installation.

6-3 **GIANT VOICE SYSTEM.** Some DOD installations are currently provided with a giant voice system for outdoor notification. Many of these systems were designed in the Cold War era and were intended to transmit tones signals, not voice signals. These systems may not adequately provide intelligible voice signals over much of the DOD installation. Closer spaced and less powerful speaker arrays are often required to achieve adequate intelligibility. Existing giant voice systems often have proved unsatisfactory in providing intelligible messages between multi-story buildings in high population density areas (such as industrial areas). Newer speaker technologies are available and should be considered for installation in these areas. Additionally, this UFC does not permit the use of giant voice systems inside of buildings because of the difficulty in achieving acceptable intelligibility of voice messages, the need to monitor circuit integrity, and the requirement to provide visual notification appliances for persons with hearing disabilities. This UFC does not permit an existing giant voice system to activate or control an individual building MNS unless the giant voice system fully complies with the requirements for a wide area MNS.

6-4 **TELEPHONE ALERTING SYSTEM.** A telephone alerting system may be useful in supplementing a wide area MNS and providing notification to building occupants where mass notification would not be required by UFC 4-010-01, such as in small facilities with only a few occupants and single-family and duplex military family housing. Telephone alerting system services are sometimes outsourced to reduce the operation and maintenance burden on the base; however, outsourcing increases reliance on systems not under direct control of the facility being serviced and could impact the reliability or vulnerability of the telephone system capability.

6-5 SPECIAL OCCUPANCIES

6-5.1 **No Self-Preservation Capability.** This UFC does not require the installation of mass notification capability for those persons who are unable to protect themselves and could not take action without the assistance of others. Examples include prisoners in correctional facilities that are physically prevented from taking action or patients in a hospital that require assistance from the medical staff to take action. Mass notification capability is still required for the staff of these facilities so they may know to take action to protect themselves and those in their care. The appropriate approach for these facilities is to emulate the design solution that would be applied in that building for the installation of a new fire alarm system.

Individual building MNS for Marine Corps projects shall serve as a subsystem of the wide area MNS as described in chapters 3 and 5.

6-5.2 **Not Occupied by Hearing Impaired Persons.** This UFC does not require the installation of visual notification signals in areas not subject to occupancy by persons who are hearing impaired, except that visual notification signals shall be provided in areas where hearing protection is worn due to high ambient noise levels.

Note: Visual notification signals must be provided even if the area is only accessed occasionally by personnel who are hearing impaired and granted unaccompanied access, such as maintenance or cleaning personnel, except for those areas listed in section 6-5.3.

6-5.3 **Housing and Lodging Facilities.** When MNS is required for personnel housing (such as barracks, dormitories, lodges, temporary or transient living facilities, and other sleeping quarters with 11 or more unaccompanied persons) or for military family housing (such as 13 or more family units in one building), audible and visible MNS appliances shall be provided.

6-5.3.1 Audible appliances, including in sleeping areas, shall provide a sound level of at least 15 dBA above the average ambient sound level and at least 5 dBA above the maximum sound level having a duration of at least 60 seconds, and they shall provide a CIS score equal to or greater than 0.7 (Navy and Marine Corps) or 0.8 (Army and Air Force). Sleeping areas shall also be provided with a minimum sound level of 75 dBA unless a CIS score equal to or greater than 0.7 (Navy and Marine Corps) or 0.8 (Army and Air Force) is provided.

6-5.3.2 Visual appliances are not required within private living and sleeping rooms except those that are specifically designated by the DOD installation for the accommodation of hearing-impaired individuals. Visual notification appliances shall be provided in other general usage areas such as common rooms, day rooms, meeting rooms, hallways, corridors, lobbies, and public restrooms.

CHAPTER 7

OPERATIONAL CHARACTERISTICS

7-1 **INTRODUCTION.** This chapter provides a description of the most significant operating characteristics of wide area MNS and individual building MNS.

7-2 WIDE AREA MNS

7-2.1 **Central Control Stations.** A primary and backup central control station are provided. At each central control station, a computer with a GUI is provided. With the GUI, the system operator can send live voice signals using a microphone and can send or activate pre-recorded voice signals, tones, and music signals. The signals can be sent to individual buildings, zones of buildings, individual outdoor speaker arrays, zones of outdoor speaker arrays, or to the entire DOD installation. Different signals can be sent to different locations. The central control station can receive voice signals by telephone or radio and patch those signals through to desired locations on the DOD installation. Music, such as Reveille and the national anthem, can be transmitted throughout the DOD installation. The central control station automatically or manually assigns priorities to all transmitted signals.

7-2.2 **Regional or National Command Centers.** When required by the DOD component, those signals transmitted on the DOD installation that meet a screening criteria for priority are automatically relayed to a regional or national command center, or to nearby DOD installations that have a need to know of the emergency.

7-2.3 **Public Alert and Warning System.** This national system is under development by the Department of Homeland Security as directed by Executive Order 13407. DOD systems are required by this same Executive Order to coordinate with the national system. The wide area MNS will be designed with the capability to receive, record, and distribute voice messages and alert signals received from the Commander-in-Chief through the national public alert and warning system. This will permit the central control station to immediately distribute the voice messages or alert signals, or to delay the distribution as necessary to meet operational requirements as approved by the DOD installation commander.

7-2.4 **HPSA.** Designated HPSAs are provided with a microphone to enable an on-scene commander, security forces, or others (such as a drill instructor) to use the HPSA for local announcements and instructions. In some cases, individual speakers or all speakers of these arrays may be locally selected and energized. The speakers for these arrays will be highly directional when designed to permit operation from a location directly below the speakers without feedback or harmful sound pressure levels.

7-2.5 **Supplemental Mass Notification Delivery Systems.** The wide area MNS can also interface with and control other notification systems such as telephone dialers, tone alert systems, computer network alerting systems, pagers, facsimile machines, and vehicular traffic directional control signs. Text notification via wireless devices and desktop computer notification are effective means for delivering mass notification messages to multiple recipient groups. Wireless text messaging is effective in reaching off-base personnel. This is especially useful for OCONUS locations. Desktop notification is particularly effective when more complex information must be conveyed, and can be a cost-effective interim solution prior to installing an individual building MNS.

Note: See Appendix C for a discussion of requirements for Internet-based communication systems (under development).

7-3 INDIVIDUAL BUILDING MNS

7-3.1 **Combined Systems.** In new construction, mass notification and fire alarm functions are combined into one system. PA may also be combined into this system. In renovation projects, combined systems are preferred, but separate systems may be permitted in some applications. The mass notification functions can temporarily disable the fire alarm notification appliances to allow intelligible voice announcements when needed in the case of simultaneous terrorist and fire events. This is necessary because arson and unauthorized fire system activation are methods of attack that have been used previously by terrorists.

SE Individual building MNS for Marine Corps projects shall serve as a subsystem of the wide area MNS as described in Chapters 3 and 5, and might not interface with the fire alarm system.

7-3.2 **LOC.** These consoles are provided to allow building occupants and emergency response forces to operate the system and provide live voice or pre-recorded messages to personnel in the building. They also enable the building occupants to completely shut down the heating, ventilating, and air conditioning system as needed to respond to a terrorist event or external natural disaster. Army and Air Force systems permit most building occupants to access the LOC, and use tamper-resistant features to minimize unauthorized use. The Navy limits access to the LOC to emergency response forces and a few of the building occupants, such as the building manager, security staff, or the commanding officer’s staff. The Marine Corps does not provide a LOC but does provide a remote microphone.

7-3.3 **ACU.** The ACU has the same capabilities to operate the system as a LOC, plus the ability to override or disable the mass notification capability. Access to the ACU is limited to emergency response personnel.

7-3.4 **Notification Appliances.** Speakers are used to provide intelligible voice signals for mass notification. Strobes are used to meet the accessibility requirements for those persons with hearing disabilities. The Army and Air Force use amber-colored strobes to alert those with hearing disabilities. The Navy uses one set of clear strobes for both fire and mass notification. These strobes are marked “ALERT” instead of “FIRE”. The Navy also uses text signs to assist persons with hearing disabilities. These signs read “EVACUATE” when the fire alarm system is in alarm. The signs read “ANNOUNCEMENT” when a mass notification message is being transmitted, and the text sign will continue for 10 seconds after the end of the announcement. Text signs are required over the door to each egress stairwell and over (or adjacent to) the substantial means of egress from the level of discharge. Exterior exit doors from a single room (e.g., mechanical or electrical rooms) do not require a text sign.

Note: The Marine Corps uses notification appliances as specified by the AHJ.

CHAPTER 8

MAINTENANCE

8-1 **INTRODUCTION.** This chapter was developed on the basis of recommendations from MNS manufacturers, as well as experience with similar computer-based systems. Maintenance requirements established for each MNS must consider the manufacturer's maintenance recommendations and the applicable DOD maintenance requirements. MNS shall be maintained so that they comply with the minimum operating parameters recommended by the manufacturer.

8-2 **MAINTENANCE RESPONSIBILITIES.** DOD components that have assigned maintenance responsibilities include:

8-2.1 **Air Force.** Air Force communications squadrons are responsible for maintaining giant voice systems in accordance with AFI 21-116 on Air Force installations. Civil engineering squadrons are usually responsible for maintaining individual building MNS on Air Force installations that are designed and installed in accordance with this UFC.

8-2.2 **Marine Corps.** Headquarters Marine Corps (HQMC) Technical Service Agency is responsible for maintaining the MNS across the Marine Corps.

8-3 QUALIFICATIONS OF MAINTENANCE PERSONNEL

8-3.1 **Inspection, Testing, and Maintenance Tasks.** Only personnel trained and qualified in maintaining and repairing MNS will perform inspection, testing, and maintenance tasks. Most types of MNS use technology commonly found in fire alarm systems, giant voice, or other outdoor voice and siren warning systems, and similar maintenance skills are needed. If specific manufacturer training is available, maintenance personnel must satisfactorily complete the training to be considered qualified. If specific manufacturer training is not available for a MNS, personnel shall be considered qualified if they have achieved a NICET Level III in fire alarm systems or in low-voltage electronic communication systems, or have achieved the UL certification level for fire alarm systems. Tasks must be performed according to the manufacturer's instructions. Certain jurisdictions may require varying levels of continuing education to maintain recognized qualifications. Overseas locations should contact their command fire protection engineering office for guidance on appropriate qualifications. Military personnel who have satisfactorily completed the required schools in their career field in fire detection and alarm system maintenance or communications electronics are considered qualified.

8-3.2 **Other Inspections.** This UFC lists inspection tasks that must be performed during regularly scheduled facility inspections. Fire prevention, safety, and maintenance personnel, as well as other individuals familiar with MNS operations, shall perform these inspection tasks.

8-3.3 **Maintenance Records.** Each DOD installation must maintain a permanent record of completed inspection, testing, and maintenance tasks in accordance with each agency's program for record keeping of recurring facility maintenance. Records may be hard copy or electronic. Where no DOD component-wide programs exist, records should be developed locally. Records must be maintained for every facility and must include, as a minimum, each task, the date scheduled, the date completed, and the name of the person completing the task.

8-4 **INDIVIDUAL BUILDING MNS.** See UFC 3-600-02, paragraph 2-2.2, "Fire Detection and Alarm Systems," for applicable guidance on inspecting, testing, and maintaining engineered protection features in DOD facilities.

8-5 **WIDE AREA MNS.** Tables 8-1 and 8-2 provide maintenance information for the central control unit and communications network for a wide area MNS.

Table 8-1. Central Control Unit Maintenance

Frequency	Component	Tasks
Weekly	Central control unit, diagnostic log files	• Review the event log file; verify that the correct events were logged. • Review the system diagnostic log file; correct deficiencies noted in the file.
	Central control unit, hard drive	• Delete unneeded log files. • Delete unneeded error files. • Verify that sufficient free disk space is available.
	System – Functional test	Send out an alert to a small set of pre-designated receiving devices and confirm receipt.
	System – Security	If remote control software is loaded onto the system, verify that it is disabled to prevent unauthorized system access.

Frequency	Component	Tasks
Monthly	System – Functional test	Send out an alert to a diverse set of pre-designated receiving devices and confirm receipt. Include at least one of each type of receiving device.
	Central control unit, reset	Power down the central control unit computer and restart it.
Quarterly	System – Software backups	Make a full system software backup. Rotate backups based on the accepted practice at the site.
	Central control unit, computer	• Verify proper operation of the computer. • Defragment the hard drive. • Verify unobstructed flow of cooling air. Clean filters. Remove dust buildup on cooling fans, cooling fins, and air intake vents.
	Central control unit, uninterruptible power supply (UPS)	• Verify that the system will operate in the absence of line power; discontinue line power to the system and verify functionality. • Test the UPS. See NFPA 70B.
Yearly	System – Software backups	Test the current software backup system by installing the system backup.
	Central control unit, operation	• Verify the content of pre-recorded messages. • Verify activation of the correct pre-recorded message based on a selected event. • Verify activation of the correct pre-recorded message based on a targeted area. • Verify that the central control unit security mechanism is functional.

Table 8-2. Communications Network Maintenance

Frequency	Component	Tasks
Weekly	Central control console	Verify that no diagnostic failures are indicated.
Monthly	HPSA/Wireless transceivers	Perform silent activation and/or health monitoring of all components.
	Total system functionality	• Perform a test system activation for a particular zone/building/area. • Verify that field components perform as expected.
Quarterly	Central control unit, UPS	• Verify that the system will operate in the absence of line power; discontinue line power to the system and verify functionality. • Test the UPS. See NFPA 70B.
Every 6 months	Field components	• Perform a visual inspection of all components. Verify that enclosure integrity is not compromised. • Perform a visual inspection of the antenna. Verify a solid connection and no corrosion. • Perform a visual inspection of the transceivers. Verify proper operation. • Generate a conductor integrity monitor alarm. Verify the alarm status on the central console. • Disconnect AC power. Verify the AC power failure alarm status on the central console. • Disconnect AC power. Verify the battery voltage under load.
Every 6 months	Wireless signals	Check forward/reflected radio power.

GLOSSARY

Acronyms and Abbreviations

\1\ **ABAAG**—Architectural Barriers Act Accessibility Guidelines /1/

AC—alternating current

ACU—Autonomous Control Unit

AFB—Air Force base

AFI—Air Force instruction

AHJ—authority having jurisdiction

ANSI—American National Standards Institute

APCO—Association of Public-Safety Communications Officials

C—Celsius

CAC—Common Access Card

CAP—common \1\ alert /1/ protocol

CD—compact disk

CIS—Common Intelligibility Scale

CNO—Chief of Naval Operations

CON—Certificate of Networthiness

CONOPS—concept of operations

CONUS—continental United States

COTS—commercial off-the-shelf

CSC-STD—DOD Computer Security Center Standard

CTO—Certificate to Operate

dBA—sound/noise power, adjusted, in decibels

DCID—Director of Central Intelligence Directive

DD—Department of Defense (as used on forms)

DIACAP—DOD Information Assurance Certification and Accreditation Process

DITSCAP—DOD Information Technology Security Certification and Accreditation Process

DOD—Department of Defense

EM—emergency management

EMWIN—Emergency Managers Weather Information Network

EOC—Emergency Operations Center

EPROM—erasable programmable read-only memory

F—Fahrenheit

FACP—fire alarm control panel

FCC—Federal Communications Commission

FEMA—Federal Emergency Management Agency

FM—Factory Mutual Research Corporation

FPCON—force protection condition

ft—feet

GPS—Global Positioning System

GUI—Graphical User Interface

HAZMAT—hazardous materials

HPSA—high power speaker array

HQ AFCESA/CEO—Air Force Civil Engineer Support Agency, \1\ Operations and Programs Support Division /1/

HQ DLA-D—Defense Logistics Agency Director

HQ DLA-DES-SE—Defense Logistics Agency, Support Services

HQ USACE/CECW-CE—U.S. Army Corps of Engineers, Directorate of Civil Works, Engineering and Construction

HQMC CODE PS—U.S. Marine Corps, Critical Infrastructure Assurance Branch

HVAC—heating, ventilation, air conditioning

Hz—hertz

ICC—Installation Control Center

IEC—International Electrotechnical Commission

INWS—Installation Notification and Warning System

IP—Internet Protocol

kHZ—kilohertz

km/h—kilometers per hour

LDAP—Lightweight Directory Access Protocol

LED—light-emitting diode

LOC—Local Operating Console

m—meter

MCO—Marine Corps Order

MEP—mobile electrical power

METOC—meteorology and oceanography

MIL-STD—military standard

MNS—mass notification system

MPEG—Moving Picture Experts Group

mph—miles per hour

NAVFACENGCOM HQ Code CHE—Naval Facilities Engineering Command, Headquarters Chief Engineer's Office

NCAS—Net-Centric Alerting System

NCEES—National Council of Examiners for Engineering and Surveys

NEMA—National Electrical Manufacturers Association

NFPA—National Fire Protection Association

NGA—National Geospatial-Intelligence Agency

NICET—National Institute for Certification in Engineering Technologies

NRTL—Nationally Recognized Testing Laboratory

NTIA—National Telecommunications and Information Administration

OCONUS—outside of the continental United States

OSHA—Occupational Safety and Health Administration

PA—public address

PC—personal computer

PDA—personal data assistant

ROC—regional operations center

SCIF—Sensitive, Compartmented Information Facilities

SE—Service Exception

STI—Speech Transmission Index

THD—total harmonic distortion

UFC—Unified Facilities Criteria

UL—Underwriters Laboratories, Inc.

UPS—uninterruptible power supply

VAC—volts of alternating current

VoIP—voice over IP

XML—Extensible Markup Language

Terms

Contractor—An entity that executes work in accordance with a contract.

Giant Voice—A nickname for the wide area outdoor siren and voice signaling system often found on military bases. An earlier name for this system was “Big Voice.”

Mass Notification System—A system that provides real-time information to all building occupants or personnel in the immediate vicinity of the building during emergency situations.

System Integrator—A contractor that designs, fabricates, installs, starts up, tests, and documents electrical and electronic systems using COTS components manufactured by others. Qualified manufacturers can act as system integrators.

APPENDIX B

SAMPLE PRE-RECORDED MNS MESSAGES

B-1 **OVERVIEW.** Pre-recorded messages are not required, but can prove beneficial in emergency situations. This appendix contains the sample text for pre-recorded MNS messages based on actual messages in use at several DOD installations. These sample messages are provided for information only to assist DOD installations in defining the content of their pre-recorded MNS messages. Each DOD installation should create MNS messages appropriate for its particular locale.

\1\ **Note:** DOD has implemented a requirement for a standardized alerting sound to be played prior to playing pre-recorded messages for new and replacement MNS. (Refer to paragraphs 4-4.2 and 5-5.2). The following messages were fielded prior to establishment of the requirement and some do not include the currently required alerting sound. /1/

B-2 **SAMPLE PRE-RECORDED MESSAGES**

B-2.1 **ARMY: FORT XXX.** All messages were recorded in a female voice.

B-2.1.1 **Red-Fire.** Five seconds of siren are played, followed by the message:

"Attention, attention. A fire emergency has been reported. Please leave the building using the nearest exit."

B-2.1.2 **Blue-Weather.** Five seconds of 100-kHz steady tone are played, followed by the message:

"The National Weather Service has issued a weather alert for this area; further information will be broadcast as it becomes available."

B-2.1.3 **Orange-Force Protection Antiterrorism Threat.** Five seconds of fast whoop sound are played, followed by the message:

"Attention. A force protection antiterrorism threat has been issued for this area. Effective immediately, we are operating, 'secure and lockdown procedures.' All personnel should remain calm and stay where you are. Please wait for further instructions."

B-2.1.4 **Green-All Clear.** Five seconds of chime sound are played, followed by the message:

"The emergency has now ended. Please resume normal operations. Thank you for your cooperation."

B-2.2 **AIR FORCE: XXY Air Force Base**

B-2.2.1 **MESSAGE #1.** A 1-kHz tone is sounded for 5 seconds, followed by the message:

"May I have your attention, please. This is the command post with a test of the ____ Air Force Base mass notification system. Repeat, this is only a test."

B-2.2.2 **MESSAGE #2.** Five seconds of wail are played, followed by the message:

"Attention, attention. ____ Air Force Base is in Force Protection Condition Charlie. All personnel immediately implement FPCON Charlie actions."

B-2.2.3 **MESSAGE #3.** Five seconds of wail are played, followed by the message:

"Attention, attention. ____ Air Force Base is in Force Protection Condition Delta. All personnel immediately implement FPCON Delta actions."

B-2.2.4 **MESSAGE #4.** No alerting tone is used. The message played is:

"May I have your attention, please. All clear. The emergency has ended."

B-2.2.5 **MESSAGE #5.** One round of code 3 horn is played, followed by the message:

"Your attention, please. ____ Air Force Base has issued a severe weather warning. Take required actions and tune into local radio or television for the latest update."

B-2.2.6 **MESSAGE #6.** One round of code 3 temporal is played, followed by the message:

"Attention. A fire emergency has been reported. Please evacuate the building."

B-2.3 **Air Force: XXZ Air Force Base.** Messages were pre-programmed for the MNS ACU and recorded in a male voice. All messages are repeated twice.

B-2.3.1 **Force Protection Condition Alert.** This message is labeled "FPCON ALERT." A siren is played for 5 seconds (sound clip from manufacturer), followed by the message:

"Attention, attention. The Force Protection Condition for ____ AFB has been elevated. All personnel are to immediately implement prescribed actions. Tune your television to the Commander's access channel or access the base intranet for further information."

B-2.3.2 **Peacetime Emergency Warning.** This message is labeled “Peacetime emergency.” A horn sound is played for 5 seconds (sound clip from the manufacturer), followed by the message:

“Your attention, please. An emergency has been reported on ____ AFB. Immediately take shelter inside a facility. Remain in place and await further instructions.”

B-2.3.3 **Severe Weather Warning.** This message is labeled “Severe Weather.” A horn sound is played for 5 seconds (sound clip from the manufacturer), followed by the message:

“Your attention, please. A severe weather warning has been issued for ____ AFB. Take appropriate action and tune in to the local radio or television stations for the latest updates.”

B-2.3.4 **Natural Disaster Warning.** This message is labeled “Natural Disaster.” A horn sound is played for 5 seconds (sound clip from the manufacturer), followed by the message:

“Your attention, please. A natural disaster has either occurred or is expected shortly that will impact ____ AFB. Take appropriate action and tune in to the local radio or television stations for the latest updates.”

B-2.4 **AIR FORCE: XYX Air Force Base.** Messages were recorded in a male voice. The language used was English.

B-2.4.1 Three 1-kilohertz (kHz) tones (one second each) are played, followed by the message:

“Attention, attention. Implement Force Protection Condition Delta. Refer to ____ AFB intranet for current Battle Staff Directive.”

B-2.4.2 Three 1-kHz tones (one second each) are played, followed by the message:

“Attention, attention. Disaster control group recall. Report to primary rally point.”

B-2.4.3 Three 1-kHz tones (one second each) are played, followed by the message:

“Attention, attention. All personnel shelter in place.”

B-2.4.4 Three 1-kHz tones (one second each) are played, followed by the message:

“Attention, attention. Battle-staff recall. Key personnel report to command post.”

B-2.4.5 Three 1-kHz tones (one second each) are played, followed by the message:

"Attention, attention. Implement Force Protection Condition Charlie. Refer to ____ AFB intranet for current Battle Staff Directive."

B-2.4.6 Three 1-kHz tones (one second each) are played, followed by the message:

"Attention, attention. Implement Force Protection Condition Bravo. Refer to ____ AFB intranet for current Battle Staff Directive."

B-2.4.7 Three 1-kHz tones (one second each) are played, followed by the message:

"Attention, attention. Implement Force Protection Condition Alpha. Refer to ____ AFB intranet for current Battle Staff Directive."

B-2.4.8 No alerting tone is used. Message played is:

"May I have your attention, please. The National Weather Service has issued a severe weather warning for our area."

B-2.5 **AIR FORCE: XYY Air Force Base.** Messages were pre-programmed for the MNS ACU and recorded in a male voice. All messages were repeated twice.

B-2.5.1 **Force Protection Condition Alert.** This message is labeled "FPCON." The button color used was red. A siren is played for 5 seconds (sound clip from manufacturer), followed by the message:

"Attention, attention. The Force Protection Condition for ____ AFB has been changed. All personnel are to immediately implement prescribed actions. Tune your television to the Commander's access channel or access the base intranet for further information."

B-2.5.2 **Bomb Threat Warning.** This message is labeled "BOMB." The button color used was red. A horn sound is played for 5 seconds (sound clip from the manufacturer), followed by the message;

"Attention, attention. A bomb threat alert has been issued for this building. All personnel are to evacuate immediately using the nearest exit. Further instructions will be issued outside the building by emergency response teams."

B-2.5.3 **Terrorist Threat Warning.** This message is labeled "TERRORIST." The button color used was red. A horn sound is played for 5 seconds (sound clip from the manufacturer), followed by the message:

"May I have your attention, please. A terrorist threat has been received. Effective immediately, we are operating 'secure and lockdown procedures.' All personnel should remain calm and stay where you are. Please await further instructions."

B-2.5.4 **All Clear.** This message is labeled "ALL CLEAR." The button color used was blue. A horn sound is played for 5 seconds (sound clip from manufacturer), followed by the message:

"The building emergency has now ended. Please resume your normal duties. Thank you for your cooperation."

APPENDIX C

NET-CENTRIC ALERTING SYSTEMS (NCAS)

C-1 **OVERVIEW.** This appendix provides information on on-going development of system requirements for alerting systems that will be based on IP technologies. This appendix is not mandatory but is provided to stimulate development of suitable requirements and standards for DOD installations. Consequently, user suggestions and feedback on this appendix are highly encouraged and requested. Methods to ensure reliability and robustness in off-normal or emergency conditions are of particular concern. The required amount of and method for isolating alerting functions from normal, non-alerting system functions needs development. The need for listing or approval by NRTLs is also an area of investigation.

C-2 SUGGESTED CAPABILITIES OF A NCAS

C-2.1 **Overview.** NCAS are enterprise-class systems for the management of and mass distribution of emergency notification messages within buildings, throughout installations, across entire geographical regions, or throughout a worldwide military command. Net-centric alerting may not be used in lieu of required audible alerting MNS but should be integrated with MNS whenever possible. Using NCAS, designated system operators would be able to rapidly and reliably inform appropriate personnel about anti-terrorism/force protection conditions (FPCON) (including chemical, biological, radiological, and nuclear threats), hazardous weather conditions, and many other critical events—possibly with near real-time response capability. NCAS leverages the IP network infrastructure to instantly reach those personnel who have access to nearly any IP-connected devices (such as pop-up alerts on personal computers (PC), text messages to personal data assistants (PDA) and cellular telephones, electronic mail to IP-capable cellular telephones, and recorded voice messages to voice-over-IP (VoIP) telephones and PCs). Additionally, NCAS could be used to activate, through a single interface, non-IP alerting systems such as giant voice outdoor warning systems and traditional dial-up telephone alerting systems.

NCAS would also enable the central management of the entire notification flow, including users' management, groups targeting, operators' permissions, access policies, pre-defined emergency scenarios, and response tracking and reporting. This capability would provide NCAS with the flexibility to comply with existing concept of operations (CONOPS) for emergency management (EM) and personnel notifications. NCAS could also monitor external sensors and third-party sources of emergency events, such as government-supplied weather information, and could be used to automatically initiate alerts based on pre-defined alerting scenarios.

C-2.2 **Installed Independently in each Facility or centrally in a 24/7 Regional Operations Center (ROC).** NCAS would be installed independently in each installation/facility (such as in the base network control center) or centrally in a 24/7 ROC that covers multiple geographically separated facilities and installations.

In a centrally managed NCAS configuration, personnel and facilities in the ROC's particular area of coverage could be alerted instantly by events either from any individual installation or centrally from the ROC. Using management tools, designated operators from each installation in the region could log in via a Web browser and have complete access to their own portion of the NCAS. The ROC would retain the ability to centrally monitor and manage all portions of the system.

C-2.3 **Network Security Compliance.** The NCAS would be installed behind the appropriate Internet system firewalls. It would be provided with net-centric architecture that fully supports DOD networking standards and security requirements. More specifically, the NCAS would use a Web-based user interface, support DOD standard network ports and protocols, and provide open interfaces to support interoperability such as Extensible Markup Language (XML)- and common \1\ alert /1/ protocol (CAP)-based emergency messages. The system would include provisions for secure communications, authentication, and encryption using DOD and industry-standard encryption technologies. The system would be DOD Information Technology Security Certification and Accreditation Process/DOD Information Assurance Certification and Accreditation Process (DITSCAP/DIACAP) approved/certified, comply with DOD Computer Security Center Standard (CSC-STD) 002-85, and have a proven support for DOD Common Access Card (CAC) authentication.

C-2.4 **General NCAS Functionality.** The NCAS would be a COTS software product and use industry standards. The NCAS would have server-based architecture, allowing central alert activation, control, and management; such server(s) would be connected to the local network and integrated with the local user directory (i.e., support for Lightweight Directory Access Protocol (LDAP) and Active Directory integration is required).

C-2.4.1 **Delivery Methods.** The NCAS would be capable of sending alert messages to end-users (recipients) via multiple delivery methods, including:

- Audio-visual network alerts to desktops and laptops via desktop pop-up
- Text alerts to mobile phones and pagers
- Text alerts to electronic mail (e-mail) clients
- Audio alerts to phones
- Audio alerts to existing outdoor PA/giant voice systems
- Network alerts to any other IP-connected devices via standard XML and CAP protocols

The system would be extendable to support additional delivery methods in the future as this technology develops.

C-2.4.2 **Targeted Recipients.** The NCAS would be capable of sending alert messages to target recipients according to:

- Hierarchical organizational structure (as would be imported from an LDAP or Active Directory)
- Organizational roles
- Specific distribution lists (e.g., hazardous materials (HAZMAT) response teams)
- Dynamic groups created through on-the-fly queries of the user directory
- Geographical locations (e.g., entire bases, zones within bases)
- IP addresses (required for targeting devices in specific physical locations)

C-2.4.3 **Tracking and Reporting Functions.** The NCAS would be able to centrally track, in real-time, all alerting activities for each individual recipient, including sending, receiving, and responding to alerts, and be able to generate reports based on tracked information.

C-2.4.4 **Signal and Message Library.** The NCAS would incorporate a pre-defined library of signals and messaging appropriate to:

- FPCONs
- Terrorism threats, watches, or warnings
- Evacuation routes
- Battle staff directives
- Personnel recall requirements
- Federal, DOD, or installation-specific warning and notification requirements

The NCAS would provide means for monitoring and integrating with external event sources, and activating alerts automatically based on identifying a match with pre-defined conditions.

C-2.4.5 **Web-based Management.** The NCAS would incorporate a Web-based management and alert activation application through which all operators and administrators could gain access to the system's capabilities based on the users' permissions and the defined access policy. Such a management application would incorporate management of the alert activation flow through all delivery methods, as well as end-user management, operators' permission and access, tracking and reporting, and all administrative aspects of the system.

C-2.5 **Interoperability.** The NCAS would be able to interface and interoperate with UFC 4-021-01-compliant mass notification capabilities, including wide area MNS, individual building MNS, giant voice outdoor warning systems, and telephony alerting systems. During emergencies, systems operators should not need to send notifications using multiple alerting systems. The NCAS would provide the capability to integrate user interfaces and consolidate access to multiple mass notification and alerting systems.

C-2.6 **Monitoring and Automating Emergency Alerts Flow.** The NCAS would be capable of monitoring emergency notifications from multiple data sources (National Weather Service, Emergency Managers Weather Information Network (EMWIN), meteorology and oceanography (METOC), and others) and automatically sending out notifications to designated facilities and personnel based on pre-defined rules.

C-2.7 **Back-up NCAS Systems.** The NCAS would support multiple server configurations to achieve a “hot standby” failover configuration (i.e., no down time in case of failure in a single server) as well as to support higher load scenarios (e.g., more users).

This UFC supersedes UFC 4-021-02, dated 1 October 2013

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, General Building Requirements, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
DOCUMENT SUMMARY SHEET

Document: UFC 4-021-02, *Electronic Security Systems Change 1*

Superseding: UFC 4-012-02, dated 01 October 2013.

Description: This UFC (Unified Facilities Criteria) document provides design requirements and guidance on how to design electronic security systems required by the current antiterrorism/force-protection and physical security environment. Electronic security systems consist of access control systems (card reader systems), closed-circuit television (CCTV) system, intrusion detection systems, data transmission media systems (a means to communicate information internally and externally to DoD sites), and provision of local or regional dispatch centers (also known as security command centers). Electronic security systems are one part of an overall physical security plan. This document provides guidance to commanders, architects and engineers on how to design electronic security systems for projects to include new construction, additions, renovations, expeditionary, or temporary construction.

Reasons for Document:

- The design of physical security measures is a specialized technical area that does not fall in the normal skill record and resume of commanders, architects, engineers, and project managers. This document provides guidance to those parties tasked with implementing existing and emerging physical protection system requirements for the protection of DoD assets.

Impact:

- Reduced project costs are achieved by a better understanding of baseline requirements in the specialized technical area of electronic security systems.

Unification Issues

There are no unification issues.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE.

The purpose of this UFC is to provide guidance for designing Electronic Security Systems (ESS) in support of the Department of Defense (DoD) physical security program requirements. An ESS is one of many physical security measures that must be considered when addressing the physical security posture of a facility. This UFC is intended to provide uniformity and consistency in the design of an ESS.

1-2 SCOPE.

This UFC provides design requirements and guidance for the design of ESS. It is not intended to create the requirement for an ESS, but rather to assist in designing systems that meet an established requirement and to give guidance to commanders, architects, and engineers on designing an ESS for new projects. Headquarters, Major Command, and installation physical security personnel should be consulted for DoD and Service directives outlining ESS requirements for asset protection. The ESS requirement may come from DoD policy, service policy, installation requirements, or user requirements. Projects may include new construction, additions, renovations, expeditionary, or temporary construction.

1-3 VULNERABILITY AND RISK ASSESSMENT.

In accordance with DOD O-2000.12H Antiterrorism handbook, a vulnerability and risk assessment must be conducted prior to beginning any security project. Upon identifying facility or asset vulnerabilities to threats, physical security measures such as ESS may be deployed to reduce vulnerabilities. In summary, this document assumes the pre-design phases, including the risk analysis, are complete prior to beginning design. For information on Security Engineering Planning and Design process, refer to UFC 4-020-01 and UFC 4-020-02 (described in the section “Security Engineering UFC Series” in this chapter). The engineering risk analysis conducted as part of UFC 4-020-01 should be consistent with the terrorism risk analysis conducted by the installation security/AT staff.

1-4 APPLICABILITY.

This UFC provides planning and design criteria for DoD components and participating organizations. This UFC applies to all construction, renovation, or repair projects that include an Electronic Security System.

1-5 GENERAL BUILDING REQUIREMENTS.

UFC 1-200-01, "General Building Requirements", provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, sustainability, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-6 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. The most recent edition of referenced publications applies, unless otherwise specified.

1-7 GLOSSARY.

Appendix B contains acronyms, abbreviations, and terms.

1-8 SECURITY ENGINEERING UFC SERIES.

This UFC is one of a series of security engineering unified facilities criteria documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed for a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include: the following:

1-8.1 DoD Minimum Antiterrorism Standards for Buildings.

UFC 4-010-01 and UFC 4-010-02 establish standards that provide minimum levels of protection against terrorist attacks for the occupants of all DoD inhabited buildings. These UFCs are intended to be used by security and antiterrorism personnel and design teams to identify the minimum requirements that must be incorporated into the design of all new construction and major renovations of inhabited DoD buildings. They also include recommendations that should be, but are not required to be incorporated into all such buildings.

1-8.2 DoD Security Engineering Facilities Planning Manual.

UFC 4-020-01 presents processes for developing the design criteria necessary to incorporate security and antiterrorism into DoD facilities and for identifying the cost implications of applying those design criteria. Those design criteria may be limited to the requirements of the minimum standards, or they may include protection of assets other than those addressed in the minimum standards (people), aggressor tactics that are not addressed in the minimum standards or levels of protection beyond those required by the minimum standards. The cost implications for security and antiterrorism are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they represent only representative construction that will meet the requirements of the design criteria. The manual also addresses the tradeoffs between cost and risk. The Security Engineering Facilities Planning Manual is intended to be used by planners as well as security and antiterrorism personnel with support from planning team members.

1-8.3 DoD Security Engineering Facilities Design Manual.

UFC 4-020-02 provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established using UFC 4-020-01. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them all work as a system. The information in UFC 4-020-02 is in sufficient detail to support concept level project development, and as such can provide a good basis for a more detailed design. The manual also provides a process for assessing the impact of protective measures on risk. The primary audience for the Security Engineering Design Manual is the design team, but it can also be used by security and antiterrorism personnel.

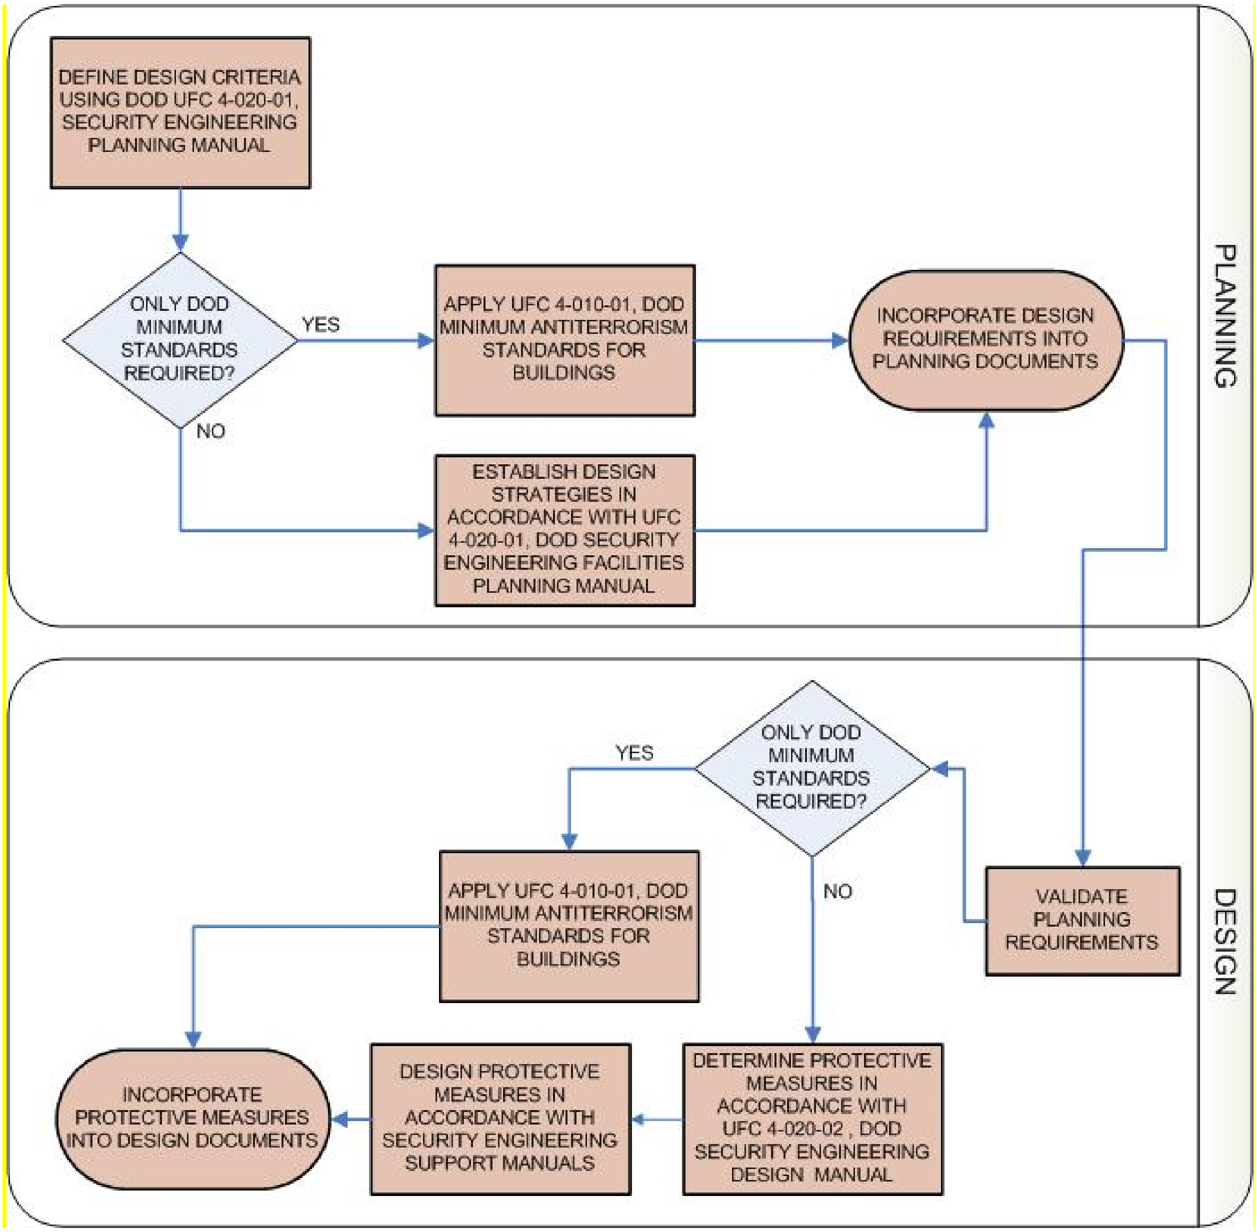
1-8.4 Security Engineering Support Manuals.

In addition to the standards, planning, and design UFCs mentioned above, there is a series of additional UFCs that provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02. These support manuals provide specialized, discipline specific design guidance. Some address specific tactics such as direct fire weapons, forced entry, or airborne contamination. Others address limited aspects of design such as resistance to progressive collapse or design of portions of buildings such as mail rooms. Still others address details of designs for specific protective measures such as vehicle barriers or fences. The Security Engineering Support Manuals are intended to be used by the design team during the development of final design packages.

1-8.5 Security Engineering UFC Application.

The application of the security engineering series of UFCs is illustrated in Figure 1-1. UFC 4-020-01 is intended to be the starting point for any project that is likely to have security or antiterrorism requirements. By beginning with UFC 4-020-01, the design criteria will be developed that establishes which of the other UFCs in the series will need to be applied. The design criteria may indicate that only the minimum standards need to be incorporated, or it may include additional requirements, resulting in the need for application of additional UFCs. Even if only the minimum standards are required other UFCs may need to be applied if sufficient standoff distances are unavailable. Applying this series of UFCs in the manner illustrated in Figure 1-1 will result in the most efficient use of resources for protecting assets against security and antiterrorism related threats.

Figure 1-1 Security Engineering UFC Application.



CHAPTER 2 ELECTRONIC SECURITY SYSTEM OVERVIEW

2-1 OVERVIEW.

ESS is the integrated electronic system that encompasses the ACS, interior and exterior IDS, CCTV systems for assessment of alarm conditions, the DTM, alarm reporting systems for monitor, control, and display, and the policies, procedures, and response times that ensure that all elements of the ESS work effectively. It is part of an overall physical protection system. As shown in Figure 2-1, the overall physical protection system consists of civil engineering features of fences, gates, entry points, clear zones, and standoff distances; architectural issues of construction materials, barriers, doors, windows, and door hardware; structural issues of blast resistant protection; mechanical issues of HVAC protection and redundancy, electrical engineering issues of power redundancy and lighting systems, ESS, and operational considerations such as policy, procedures, and response times. In summary, the ESS is one component of a bigger physical protection scheme. This chapter describes the ESS in general as a lead-in to subsequent detailed chapters on each of the ESS subsystems.

Service Exception, Marine Corps: Aboard Marine Corps Installations, Mass Notification Systems (MNS) are considered a component of the ESS. Design of Mass Notification Systems is not within the scope of this UFC. Refer to UFC 4-021-01 for Mass Notification System design guidance.

2-2 DETECT, DELAY, AND RESPOND.

For effective intrusion intervention, the ESS should operate on the Detect, Delay, and Respond principle that ensures the time between detection of an intrusion and response by security forces is less than the time it takes for damage or compromise of assets to occur. Refer to Figure 2-2. (Note: Some documents consider the additional specific steps of Annunciate, Classify, and Assess as part of the intrusion intervention process. These additional steps are part of the process, but for this document are intrinsically included as part of the Detect step.)

2-2.1 Detect, Delay and Respond Example.

Table 2-1 provides an example of the times related to each detect and delay option in Figure 2-2. The cumulative delay times shown in this example are estimated at slightly over eight and a half minutes. Assuming a security forces response time of eleven minutes, the sequence of events shown in Table 2-1 allows sufficient time for an adversary to compromise and/or damage the targeted asset. Conversely, assuming a security forces response time of five minutes, the sequence of events shown in Table 2-1 allows sufficient time to intervene on the intrusion efforts. Depending on the nature of the asset, there are some dictated response times. The ESS designer should work with the facility/base security officer to identify the response forces and reaction times. Security and planning personnel should refer to DoD, agency, and service directives to identify response requirements.

Detect, Delay, and Respond Factors Samples. The above example is provided to illustrate the general principles of Detect, Delay, and Respond. Table 2-2 provides additional samples of Detect, Delay, and Respond factors. For additional information on delay times, refer to the book, *The Design and Evaluation of Physical Protection Systems.*

Figure 2-1. ESS as a Part of a Physical Security System.

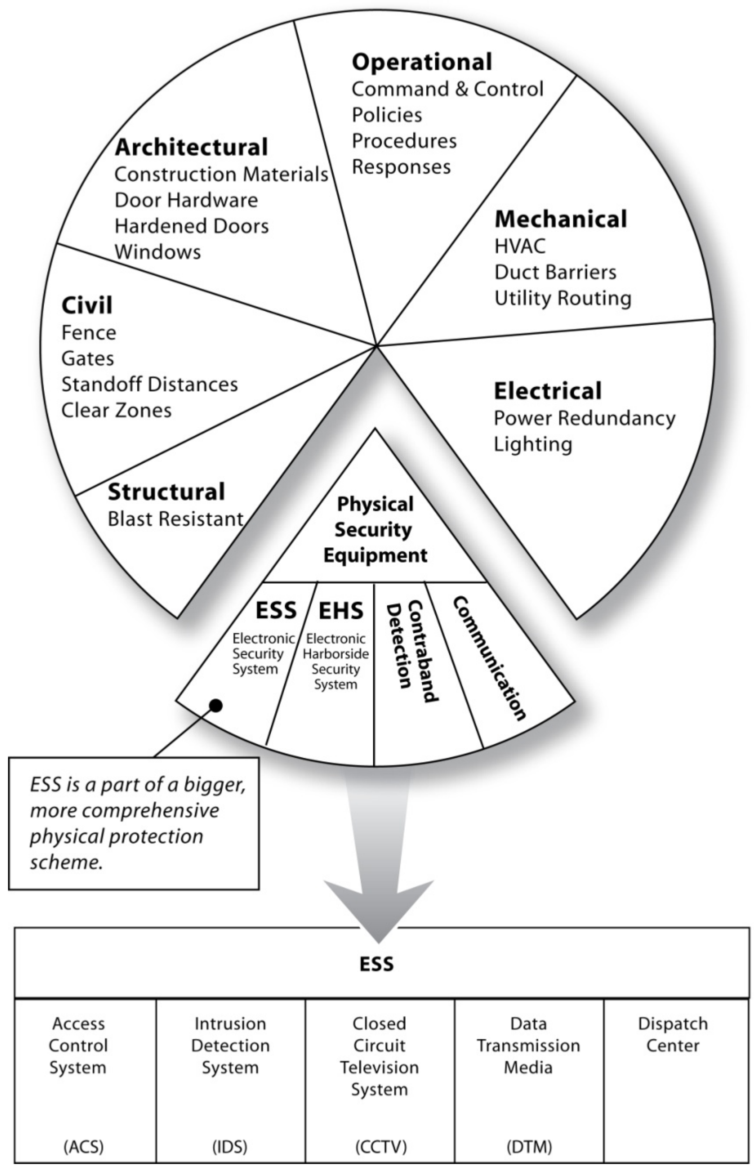


Figure 2-2. Example Detect and Delay Options.

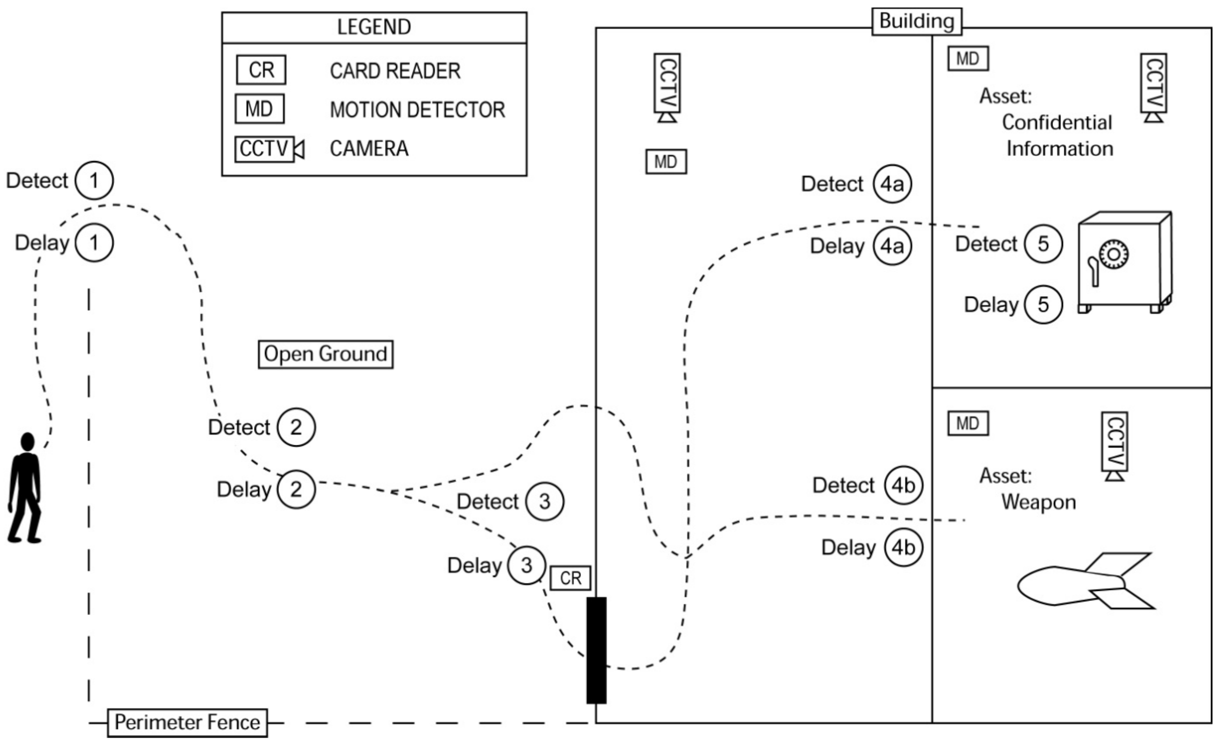

Table 2-1. Example Breach Events and Delay Time.

	Delay Options	Delay Time	Detection Options
1	Climb fence	8-10 sec.	Perimeter fence detection system
2	Cross open ground (for example 600 feet)	10 feet/sec.	Microwave sensors
3	Breach building door or window or wall	1-2 min.	Door contacts or glass breakage sensor
4	Breach interior hardened door	2-4 min.	Door contacts
5	Work time in breached space	3 min.	Motion sensor
TOTAL DELAY TIME		**8 min 39 sec nominal for this example**	

Table 2-2. Sample Detect, Delay, and Respond Measures.

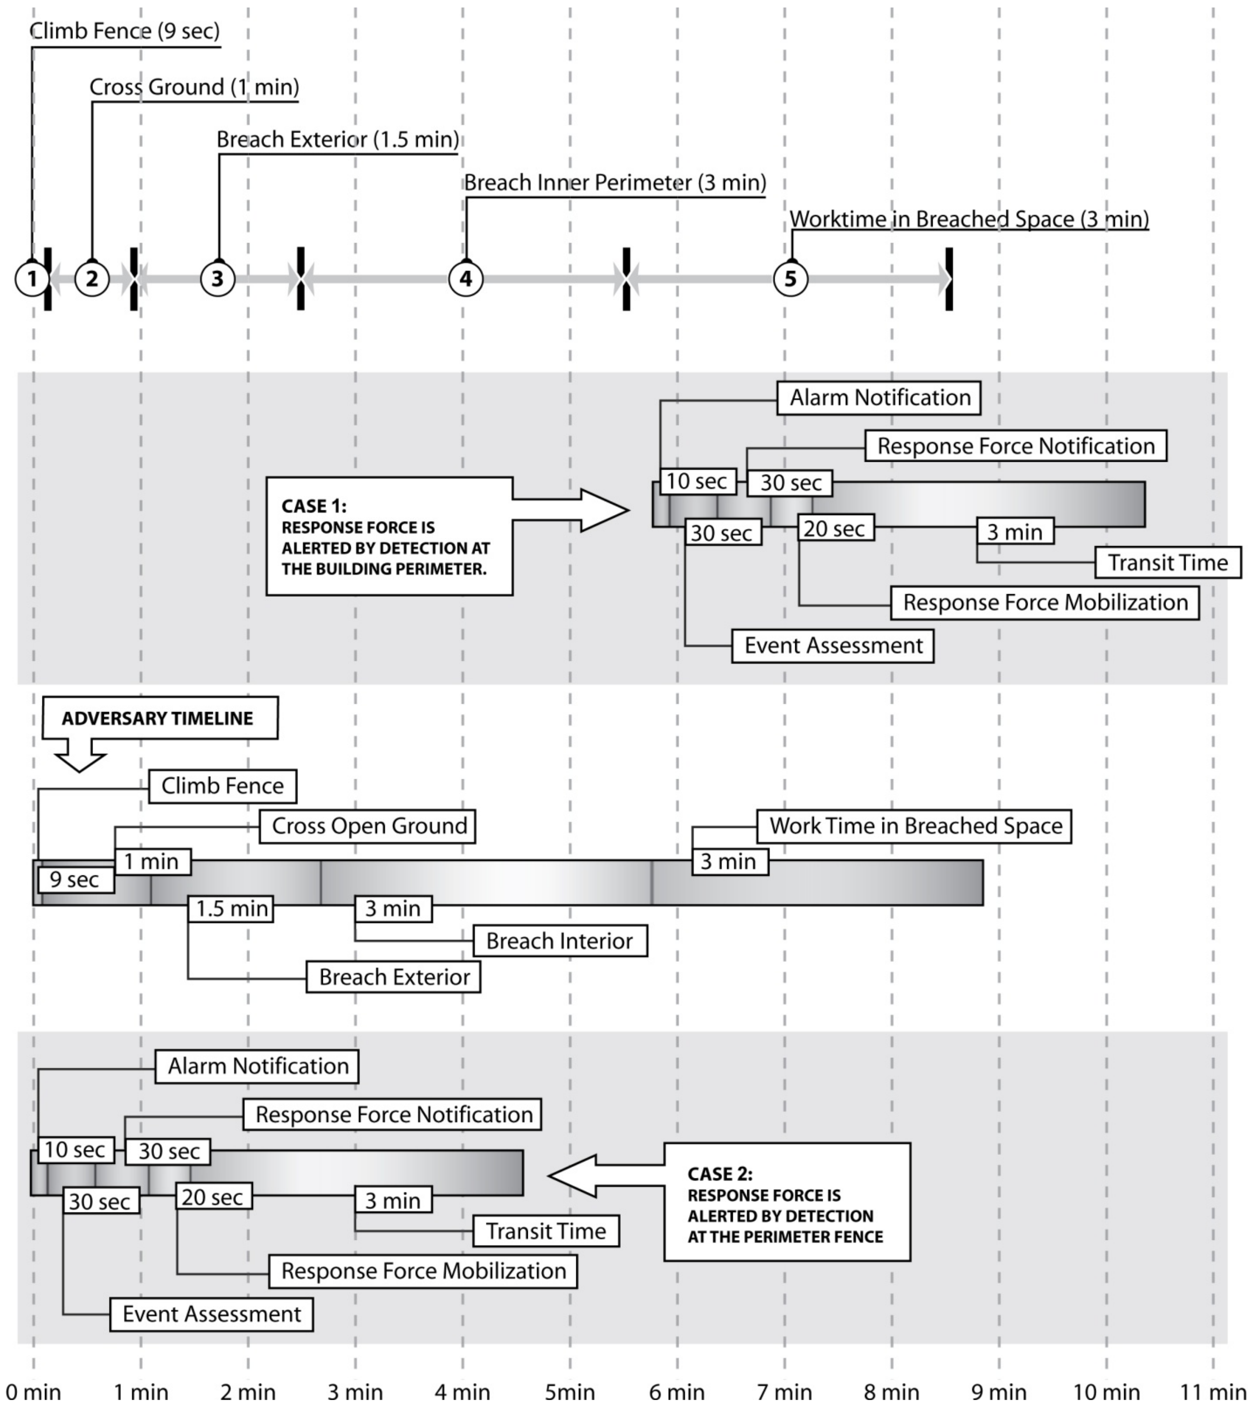
Detect Measures	Delay Measures	Respond Measures
Intrusion detection devices	Fences	Response force alerted
Alarm notification	Walls	Response force travel
Visual displays	Doors	Neutralization

2-2.2 Alerting a Response Force.

Figure 2-3 shows two cases of alerting a response force. In the first case, initial detection is not made until the interior wall of the critical asset has been breached. With initial detection nearly six minutes after the adversary climbs the perimeter fence, response forces do not arrive on the scene until after some compromise of the critical asset has been achieved. In the second case, initial detection is made at the fence line, thus allowing response forces to arrive and intervene before the asset is compromised.

The timeline in figure 2-3 illustrates two different security strategies - containment and denial. A containment strategy concedes that the adversary may gain physical access to the protected asset, but it ensures that the response force arrives soon thereafter, thus containing the degree to which the asset is compromised. However, the asset may be damaged or destroyed, depending on the objective and capabilities of the adversary. A denial strategy, on the other hand, ensures that the protected asset is in no way compromised by the adversary. Denial generally requires early detection, long delay, and rapid response to ensure that the adversary is unable to gain physical access to the protected asset.

Figure 2-3. Timeline Showing Two Cases of Breach and Detection.



2-3 ESTABLISH REQUIREMENTS.

2-3.1 Planning Process.

Establish the requirement for ESS early in the planning process. Establishing the requirement necessitates an interdisciplinary planning team to ensure all interests related to a project are considered appropriately and to determine how security fits into the total project design. The specific membership of the planning team will be based on local considerations, but, in general, the following functions should be represented: facility user, antiterrorism officer, operations officer, security, logistics, engineering, life safety, information assurance, and others as required. The interdisciplinary planning team will use the process in UFC 4-020-01 to identify the design criteria, which includes the assets to be protected, the threats to those assets (the Design Basis Threat), and the levels of protection to be provided for the assets against the identified threats. In addition to the above-listed criteria elements, the planning team may also identify user constraints such as appearance, operational considerations, manpower requirements or limitations, and sustaining costs. That design criteria will be the basis for establishing the requirements of the ESS and other elements of the overall security solution.

2-3.2 Existing Facilities.

For existing facilities, the design criteria are used to perform a vulnerability assessment, the results of which are used to establish the requirements for the ESS. For new facilities, the design criteria are used to establish the requirements directly. The levels of protection will be the most important criteria element in establishing the ESS requirements. The process outlined in UFC 4-020-01 establishes the planning requirements. It also provides a risk management process that can be used to evaluate the resulting requirement. Figure 2-4 depicts the life cycle of an ESS.

2-4 SYSTEM COMPLEXITY.

2-4.1 General.

ESS can range from simple to complex systems. While there may be some different views or definitions of what constitutes a simple or a complex system, this guide will use the criteria described in this section. The definitions used are an academic basis for presenting different system configurations and integration needs rather than standardized industry terminology, which does not exist for defining system complexity.

2-4.2 Simple System.

The simplest ESS consists of a single ESS subsystem. For example, an IDS at a low value asset is a simple system. Other examples are an IDS with door contact, motion sensors, break-glass sensors and other digital input type sensors that do not require integration with another ESS subsystem. Another example of a simple system would be a basic CCTV system of two cameras going to a Digital Video Recorder (DVR).

2-4.3 Intermediate System.

An intermediate system contains elements of at least two ESS subsystems requiring integration. One example would be an ESS system requiring both an ACS and an IDS. Virtually all ACS can accommodate digital input signals. Quite often it is possible to combine ACS and IDS when the IDS inputs are limited to simple digital input devices that do not require separate IDS controllers. Examples of these types of digital input IDS devices are door contacts, glass-break sensors, and motion sensors. A basic block diagram for this type of system reporting to a common Dispatch Center is shown in Figure 2-5.

Figure 2-4. Project Process.

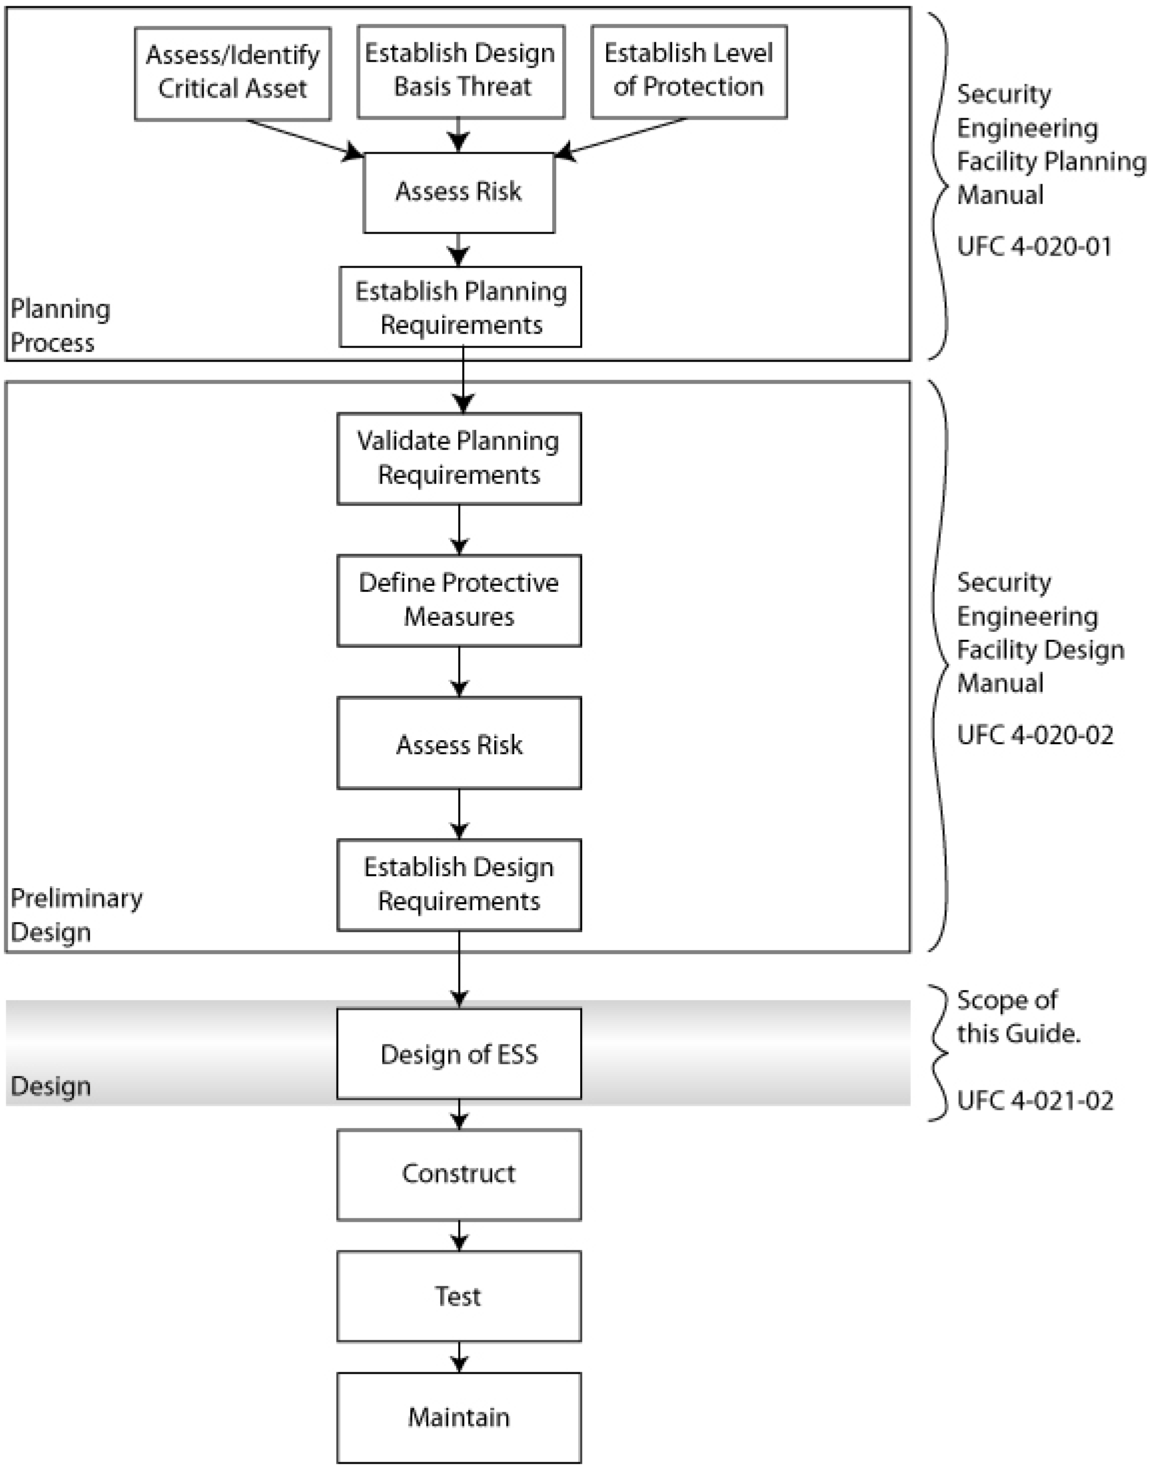


Figure 2-5. Intermediate System with Separate ACS and IDS.

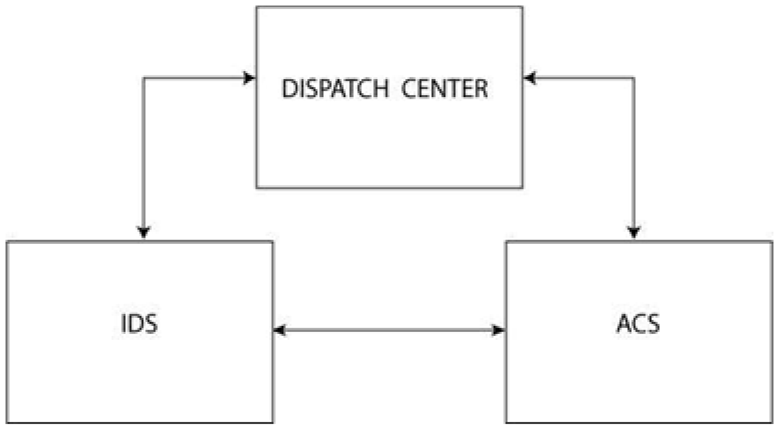
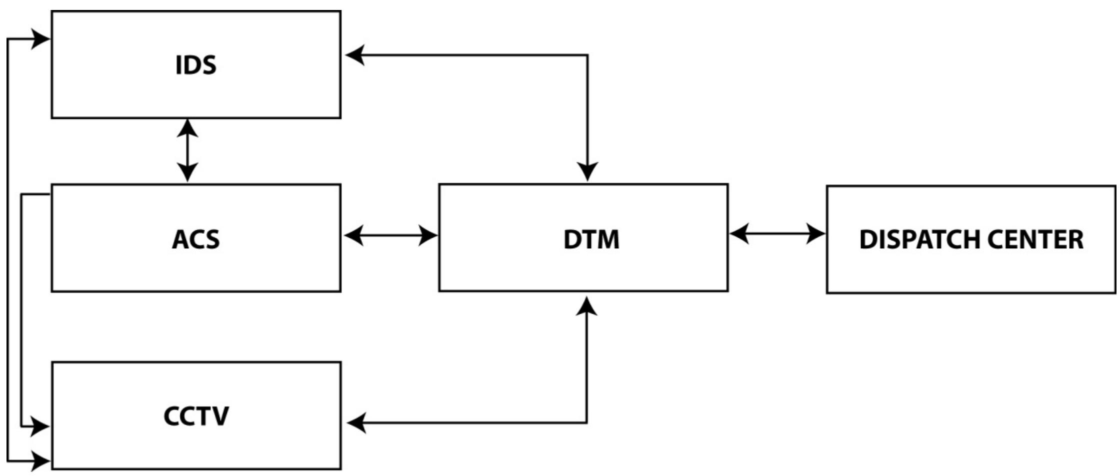


2-4.4 Complex System.

A complex system has a separate ACS and IDS system as well as a CCTV system communicating to a Dispatch Center through a DTM as shown in Figure 2-6.

Figure 2-6. Complex System With Separate ACS, IDS, and CCTV Subsystems.

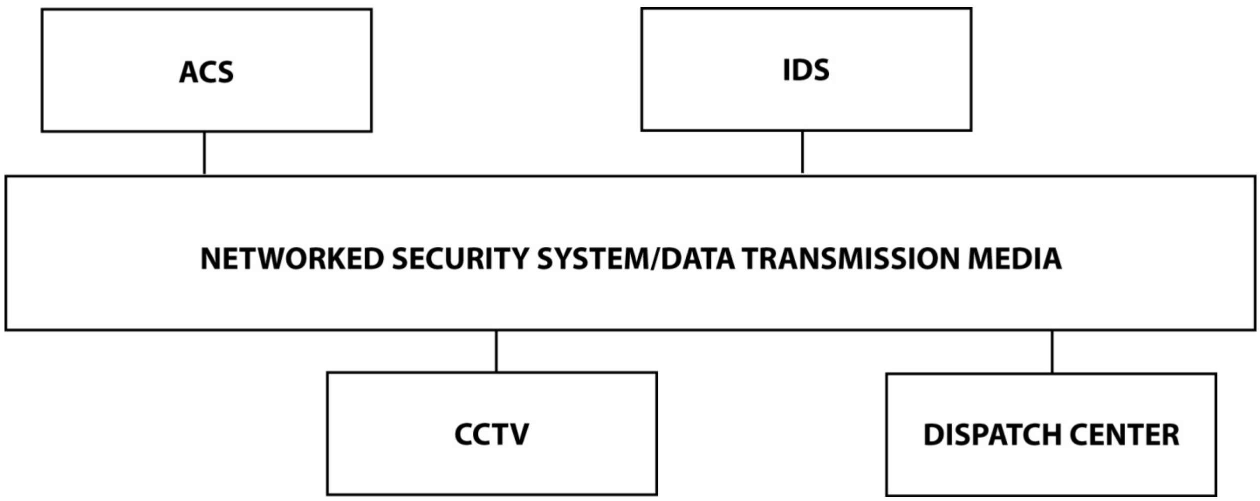


In Figure 2-6, the lines from the ACS/IDS to the CCTV system represent the integration required to automatically display a user-specified camera scene when triggered by a corresponding intrusion or access control alarm. The integration can vary from hardwired contacts to intelligent data communications. System interfaces and integration are described further in Chapter 8, “ESS Subsystem Integration.”

2-4.5 Networked System.

The networked security system, illustrated in Figure 2-7, operates on a single network with drivers to the different discrete components of the subsystems. Responding to the proliferation of networks supporting Ethernet and Internet protocols, the security industry now offers many network-ready components such as local processors for ACS and IDS, intrusion panels, cameras, biometric devices, intercom stations, video recorders, central station receivers, file servers, and workstations. Application software and device drivers are also widely available to allow integration and management of all subsystems across the network. Refer to Chapter 8, "ESS Subsystem Integration" for more information.

Figure 2-7. Networked System.



Networked security systems are typically a Proprietary Security Network. A Proprietary Security network is a completely self-contained dedicated local area network (LAN) with security system software installed and run on a host server (computer). Proprietary Security Networks are dedicated to the ESS with no outside (Internet, LAN, or WAN) connections. All networks must meet the applicable DoD and service component information assurance policies and procedures. For example, the DoD Information Assurance Certification and Accreditation Process (DIACAP) is described in DoDI 8510.01. A unique user ID and password is required for each individual granted access to the host computer. Public Key Infrastructure (PKI) certificates may be used in lieu of User ID and password for positive authentication. Positive authentication methods must be in accordance with published DoD policy and procedures. The system must monitor and log all network and ESS component access attempts and all changes to ESS applications using auditing and network intrusion detection software or similar enhancements. If connection to an outside LAN/WAN is a system requirement, the system would not be considered a Proprietary Security Network and the following additional requirements would apply:

- Encrypt all host server communications to the LAN/WAN using a NIST-approved algorithm with a minimum of 128-bit encryption.
- Protect the system from compromise with firewalls, or similar enhancements that are configured to only allow data transfers between ESS components and authorized monitoring components.

2-5 MONITORING METHODS.

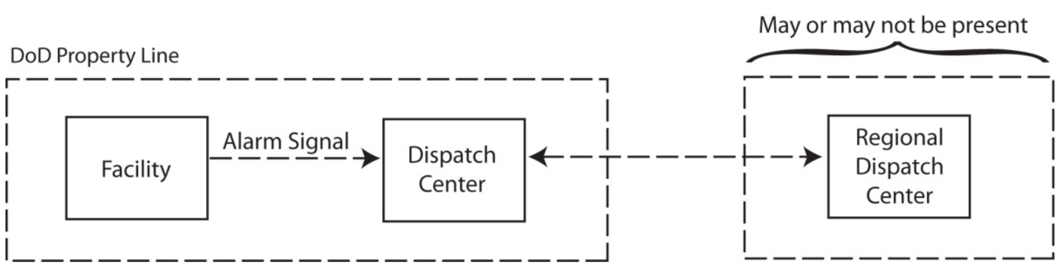
2-5.1 General.

The ESS designer must determine the alarm monitoring method early in the project planning process. This will ensure that issues related to alarm monitoring such as equipment compatibility, data transmission, space allocation, manpower, and standard operating procedures can be adequately addressed in the design phase. Four alarm monitoring methods are defined in DoD 0-2000.12-H - proprietary station, local alarm, central station, and police connection. These methods are described in the following paragraphs.

2-5.2 Proprietary Station.

A proprietary station is a method in which a property owner provides all facilities, equipment, and staffing necessary to monitor alarms. This is the preferred and most common method for a DoD installation where a Dispatch Center functions as a proprietary station and the installation security force responds to all ESS alarms. As a basic configuration, the Dispatch Center may be centrally located at an installation. Two possible configurations of a Proprietary Station Dispatch Center are shown in Figure 2-8: a Dispatch Center centrally located at a base or a detached Regional Dispatch Center (RDC).

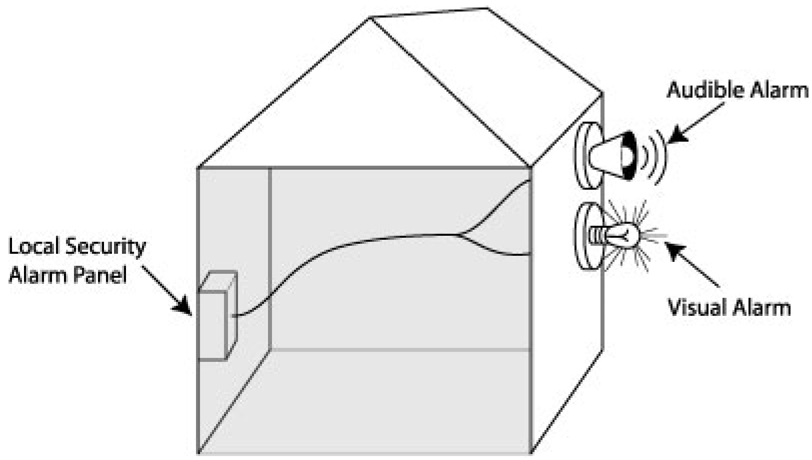
Figure 2-8. Proprietary Station Monitoring.



2-5.3 Local Alarm.

Local alarms actuate a visible and/or audible signal, usually located on the exterior of the facility. Refer to Figure 2-9. Alarm transmission lines do not leave the facility. Response is generated from security forces located in the immediate area. Without security forces in the area, response may only be generated upon report from a person(s) passing through the area or during security checks. Local alarms may offer some deterrence value, but they cannot be relied upon to initiate the Detect, Delay, Respond sequence. Because of this limitation, a local audible/visible alarm should not be used as the sole means of annunciation. In some cases, however, it may be beneficial to provide a local alarm in addition to annunciation at a qualified monitoring station.

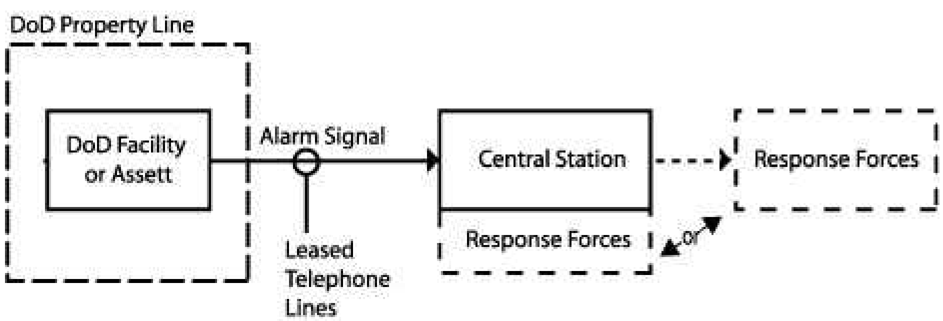
Figure 2-9. Local Alarm Monitoring.



2-5.4 Central Station.

Devices and circuits are automatically signaled to, recorded, maintained, and supervised from a central station owned and managed by a commercial firm with operators in attendance at all times. The Central Station personnel monitor the signals and provide the response force to any unauthorized entry into the protected area. Connection of alarm equipment to the central station is usually over leased telephone company lines for systems of significance. Other connection options are dial-up modems with cellular backup and the Internet. Refer to Figure 2-10.

Figure 2-10. Central Station Monitoring.



2-5.5 Police Connection.

Police connection systems are transmitted to and annunciated at a local police agency dispatch center that records alarm annunciation. Connection to the police is primarily over leased telephone lines. Police personnel respond to alarms. A formal agreement with the police department is required to ensure monitoring and response requirements. Often police departments impose a penalty after some quota of false alarms, thus the sensitivity is often turned down to minimize nuisance alarms and may result in missed indications. Police responders may be attending to other emergencies and unavailable to respond when needed. Police connection configurations may be used for highly valued assets not located on a DoD base or installation. Refer to Figure 2-11 for a diagram of a police station connection.

Figure 2-11. Police Connection Monitoring.

2-5.6 Summary.

Table 2-3 provides a summary of the pros and cons of each type of monitoring method.

Table 2-3 Pros and Cons of Monitoring Methods.

	Pros	Cons
Proprietary Station	Not reliant on outside sources. Can be equipped with CCTV monitoring capability for alarm assessment, video analytics, and general surveillance.	Requires 24/7 trained personnel; possibly increased staffing. Requires real estate space and fit-out hardware. Increased recurring labor cost of Dispatch Center operators.
Local Alarm	Easy to implement Cost effective Simple	No guaranteed response, relies on support forces being in audible/visual range
Central Station	Does not require any additional space or building Probably does not require any additional staffing	Requires an existing Central Station Some complexity in establishing connection May rely on non-DoD forces CCTV capability may be limited or non-existent
Police Connection	Direct communication with law enforcement/response forces without delay.	Requires a cooperating law enforcement station with space and equipment. Must consider separate archiving resource Probably does not have CCTV assessment capability. Ongoing fee may be required for monitoring Interface connection is required. Systems often operate with reduced sensitivity to minimize the number of nuisance alarms.

CHAPTER 3 ACCESS CONTROL SYSTEMS

3-1 OVERVIEW.

The primary function of an ACS is to ensure that only authorized personnel are permitted ingress to a controlled area. The ACS should log and archive all transactions and alert authorities of unauthorized entry attempts. ACS can be interfaced with the CCTV system to assist security personnel in the assessment of unauthorized entry attempts.

3-1.1 Elements.

An ACS can have many elements, including electric locks, card readers, biometric readers, door contacts, and request-to-exit devices, all monitored and controlled by a distributed processing system and one or more workstations. ACS workstations allow security personnel to enroll authorized users in the system, set user access permissions, monitor events and alarms, and run reports on past system activity. Figure 3-1 shows an example ACS configuration, and detailed descriptions of the various elements of an ACS are provided later in this chapter.

3-1.2 Methodology.

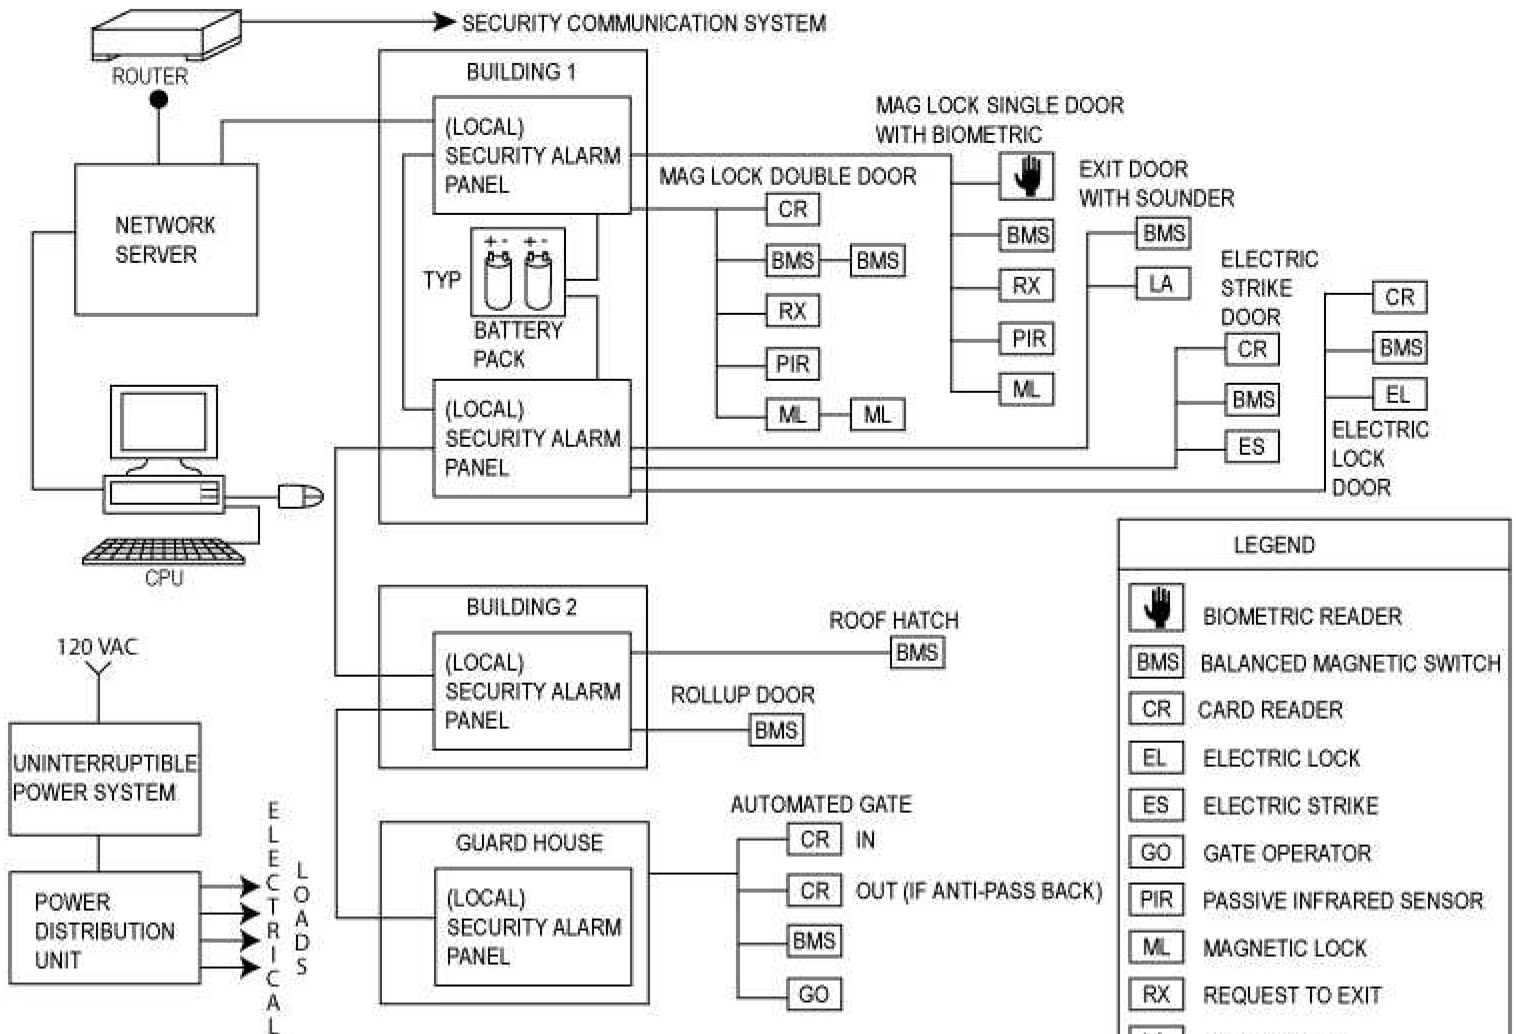
In general, an ACS compares an individual’s entry authorization identifier against a verified database. If an individual's identity is verified, the ACS sends output signals to allow that authorized individual entry through controlled portals such as gates or doors. The system has the capability of logging entry attempts (authorized and unauthorized) that are archived. (Event and tracking logs are discussed in more detail in Paragraph 3-3.4 Event Tracking/Event Logs.) Typically the ACS interfaces with the IDS for input of digital alarm signals at access portals controlled by the ACS. An example of this would be “door forced” alarms at a card reader controlled door. Similarly, the ACS interfaces with the CCTV system in that cameras could be placed at remote gates to verify identity of entrants before manually actuating the remote gate. Signals from the ACS are communicated to the Dispatch Center through the transmission lines of the DTM. Further information on the specifics of how the ACS interfaces with the rest of the ESS is provided in Chapter 8, “ESS Subsystem Integration.”

3-2 ACS ENTRY-AUTHORIZATION IDENTIFIERS.

ACS entry-authorization identifiers are grouped into three categories:

- Credential devices
- Coded devices
- Biometric devices

Figure 3-1. Example Access Control System (ACS).



These devices operate on three basic techniques:

- Something a person has, such as a Common Access Card (CAC) **\1\/1/**
- Something a person knows, such as a personal identification number (PIN)
- Something a person is or does, such as a biometric identifier

3-2.1 Credential Devices.

Credential devices allow a person possessing a recognized credential to enter a controlled area. A coded credential (such as a plastic card or key) contains a prerecorded, machine-readable code. When the card or key is read, an electric signal unlocks the door if the code stored on the credential matches the code stored in the system. A credential device only authenticates the credential; it assumes a user with a recognized credential is authorized to enter. Various technologies are used to store the code within a card or key. The most common types of cards are described in more detail in the section Card Types.

Advantages and disadvantages of using credential devices are shown in Figure 3-2.

Figure 3-2. Advantages and Disadvantages of Using Credential Devices.

Advantages

- Cards and card readers are reliable.

Disadvantages

- Cards can be lost or stolen.
- Some types of cards can easily be duplicated.

Each type of card and card reader has its own advantages and disadvantages. Refer to the subsections *Card Readers* and *Card Types* in the section *ACS Equipment* in this chapter for more on the advantages and disadvantages of each.

3-2.2 Coded Devices.

Coded devices such as keypads operate on the principle that a person has been issued a code or PIN to enter into the device that will verify the authenticity of the code entered. Any person entering a correct code is authorized to enter the controlled area.

Advantages and disadvantages of using coded devices are shown in Figure 3-3. For information about the different types of coded devices see the section Keypads and PIN Codes, later in this chapter.

Figure 3-3. Advantages and Disadvantages of Using Coded Devices.

Advantages

- Keypads are compact and easily understood.
- Different codes may be used to give access to different points and doors.
- Maintenance is easy.
- Keypads are not expensive. They are reliable and easily replaced or repaired. Little complex hardware is needed.
- No cards or tokens need be carried so there is nothing to lose.
- A duress code, known only to the user, can be input covertly if a legitimate person is forced to enter under duress.

Disadvantages

- Codes are easily passed on to other unintended or unwelcome visitors.
- The code can possibly be viewed by others and thus used for unapproved entry.
- Hands-free operation is not an option.
- The number of allowable unique codes can be limited. For example, a four-digit PIN only provides 10,000 different possible codes.

3-2.3 Biometric Devices.

Biometric devices rely on the comparison of a specific biological characteristic to a stored template. Fingerprint, facial patterning, hand geometry and iris scanning are the predominant biometric modalities used within DoD. Selected individual characteristics are stored in a device’s memory or on a card, from which stored reference data can be analyzed and compared with the presented template. A one-to-many (identification) or a one-to-one (verification) comparison of the presented template with the stored template can be made, and access granted if a match is found (depending on the authorized security level). The verification mode generally provides faster transaction times but does require a user to present a credential or enter a code to cue a specific stored template for the one-to-one comparison. Verification is the preferred mode of operation for ACS biometric applications in DoD.

3-2.3.1 Biological Measurements.

Because of the potential differences in biological measurements made over time, the comparison of the current biological measurement with the stored template is not likely to result in a perfect match. Therefore, the algorithm allows for a small percentage of variation. While the allowed variation is small, it does raise the possibility of the two types of errors associated with ACS. The first is false reject (commonly referred to as a Type I error) where the difference between the current biological measurement and the stored template is beyond the level of acceptable variation. The second is false accept (commonly referred to as a Type II error) where an individual's biological characteristic is sufficiently close to that of another individual that access is incorrectly granted. While biometrics can introduce both types of errors, the most likely impact will be on the overall false reject rate of an ACS. All ACS have some percentage of false positive (accept) alarm signals, and ESS system designers must understand the issues and work to minimize the number of false positive (accept) events. From a logistics perspective, missions cannot be accomplished if false reject rates are high and authorized personnel are regularly unable to enter their workspace or facility.

3-2.3.2 Advantages and Disadvantages.

Advantages and disadvantages of using biometric devices to grant or deny access are shown in Figure 3-4. For information about the different types of biometric technologies, see the subsection Biometric Readers in the section ACS Equipment in this chapter.

Figure 3-4. Advantages and Disadvantages of Using Biometric Devices.

Advantages

- They provide automated verification that the person attempting to gain access is authentic.
- Biometric credentials are extremely difficult to duplicate.

Disadvantages

- The cost is slightly higher.
- Longer verification time.
- Require special housings.
- Some devices are not well-suited to outdoor use.

3-2.4 Combining Entry Authorization Identifiers.

A site's security can be significantly enhanced by combining two or more entry authorization identifiers such as a biometric characteristic with a smart card **\1\/1/** with a PIN code. However, combining identifiers results in increased verification time and will decrease throughput rate. Throughput time must be considered when making decisions about whether or not to use multiple identifiers. Another consideration in combining two identifiers is that a system can be required to use one identifier during lower risk times (such as during normally staffed times) and two identifiers during higher risk periods (such as nights and weekends). The same philosophy can be applied for access control enhancement during times of heightened force protection threat levels.

3-2.5 Selecting Entry Authorization Identifiers.

The type of identifier (credential, code, biometric attribute or a combination thereof) that will be used needs to be selected early in the project. This selection will drive the specifications for card readers, keypads, and biometric devices, and it will influence the layout of access control equipment at doors and other portals. The ESS designer must solicit user input concerning previously-issued credentials, such as the CAC, that may be appropriate for the ACS.

3-3 OTHER ACS FEATURES.

Other features to consider implementing as part of an ACS include anti-passback, anti-tailgating, two-man rule, and event tracking. These are described in the following sections.

3-3.1 Anti-Passback.

Anti-passback is a functional characteristic employed within ACS. It is used to eliminate/mitigate the risk of someone giving their credential (passing it back) to another person after that credential is used to access a secure area. Anti-passback requires that a person present a credential to enter an area or facility, and then again use the credential to “badge out.” This makes it possible to know how long a person is in an area, and to know who is in the area at any given time. This requirement also has the advantage of instant personnel accountability during an emergency or hazardous event. In a rigid anti-passback configuration, a credential is used to enter an area and that same credential must be used to exit. If a credential holder fails to properly “badge-out”, entrance into the secured area can be denied. Anti-passback is a standard software feature for Commercial-Off-The-Shelf (COTS) access control systems, but enabling this feature requires that every portal be equipped with two credential readers, one on the entry side and the other on the exit side.

An alternative approach to “badging out,” which is not as rigid as the process described above, is use of a time delay on entrance readers. In this design, the credential (card or PIN) cannot be reused within a prescribed minimum time period. This time delay feature can be programmed and set for a time period such as a half-hour. During the half-hour time period, the same card or PIN cannot be used for a second entry. While affording some increased security, this process is not as rigid or secure as a ‘badge-out” process.

3-3.2 Anti-Tailgating.

While not commonly required, a project security requirement may be to deter tailgating. Tailgating is the act of a person following another authorized person closely in order to gain ingress through the same portal when the authorized person’s credential grants access. An example of a simple anti-tailgating requirement would be a pedestrian turnstile for access control. Since turnstiles are easily defeated, when significant, anti-tailgating measures are required, high-security vestibules or guard-controlled entrances can be a solution. Such application may slow down access.

3-3.3 Two-Man Rule.

The two-man rule is a strategy where two people must be in an area together, thus mitigating insider threats to certain critical areas. Two-man rule programming is optional with many identification systems. It prevents an individual cardholder from entering a selected empty security area unless accompanied by at least one other person. Once two card holders are logged into the area, other card holders can come and go individually as long as at least two people are in the area. Conversely, when exiting, the last two occupants of the security area must leave together using their cards. Most ACS software will enable the assignment of a specific second person that can be established (such as clearance escort requirement).

3-3.4 Event Tracking/Event Logs.

Event tracking/event logs are lists or logs of security events recorded by the access control system that indicate the actions performed and monitored by the system. Each event log entry contains the time, date, and any other information specific to the event. This feature allows security personnel to query the ACS database based on specific portals, persons, or time periods of interest.

3-4 ACS EQUIPMENT.

Once the type of identifier and other implementation strategies are determined, the ESS designer must identify the type of equipment necessary to implement all required system features. Various types of ACS equipment are available, as described in the following sections.

3-4.1 Badging Equipment.

When access credentials have an associated identification badge function, ancillary badging equipment is needed. Note that besides the CAC issued to all DoD personnel, supplemental badging may be required for certain restricted access facilities. The Activity must provide justification to support the requirement for any badging equipment. Badging equipment includes:

- Camera for capturing photographs
- Software for creating badge images
- Signature capture tablet
- Biometric template capture device (where applicable)
- Badge printer capable of printing a color ID template on the front and back of the badge. There are new technology printers that are capable of printing pseudo holograms on the clear protective laminate, which may be considered for higher security applications.
- Computer for retention and programming of the security credential database. This computer may be a stand-alone or client workstation that is connected to the ACS server database in client/server architecture.

If there is no existing badging location and equipment, the design must include the badging infrastructure described above as well as space allocation for equipment and storage requirements. If there is an existing system, an interface to an existing personnel database where the necessary information is stored and maintained will be required. If so, requirements for this database interface and security must be established.

3-4.2 ACS Central Computer.

The central computer is where the ACS application software and database reside and where all system activity is archived. For a small ACS, a single personal computer may be sufficient, but a large ACS may require one or more servers. A multi-server "cluster" configuration provides failover redundancy and ensures high-availability for the ACS application software and database. The central computer, together with all distributed local processors, can be thought of as the "brain" of the ACS.

3-4.3 ACS Workstation.

An ACS workstation allows personnel to view and interact with the ACS hardware and software. The central computer can function as a workstation for small systems, but a large system will likely require multiple client workstations connected to the ACS server(s) via network. The location of all ACS workstations must be identified early in the design process, recognizing that any computer with the appropriate network access and ACS software can function as a workstation.

3-4.4 ACS Local Processor.

Local processors collect inputs from card readers, keypads, biometric devices, door sensors, and request-to-exit devices, and provide output signals to electronic door locks, electric door strikes, turnstiles or gate operators. With its onboard microprocessor and memory, a local processor is able to process portal transactions even during periods when its connection to the central computer is down. This continuity is a major benefit of the distributed intelligence architecture employed by an ACS.

Local processors may employ multiple connection methods such as dial-up modem, serial (RS-232), multi-drop (RS-485), and network TCP/IP.

3-4.5 Card Readers.

The most common form of credential verification is a security card reader, and there are a number of different types. Insertion readers require that you insert the card into a slot that is just large enough to accommodate the card and then remove it. \1\/1/ Contactless readers require that you hold the card in front of the blank face of the reader.

3-4.5.1 Insertion Readers.

\1 Insertion readers, while functional, are generally considered less convenient for users when compared to 13.56 MHz contactless readers. This inconvenience factor, coupled with the mechanical wear associated with inserting cards favors the selection of contactless readers over insertion readers. **/1/**

3-4.5.2 Door Configuration.

Figure 3-5 displays a sample configuration for a single door equipped with a card reader and electric lock. Refer to the subsections on Doors and Door Locks in Chapter 9, General Requirements and Cross-Discipline Requirements for additional information on door hardware types and interface considerations.

3-4.6 Card Types.

Card readers use a number of different card types, the most common of which are described in the following subsections.

\1\/1/

3-4.6.1 Smart Cards.

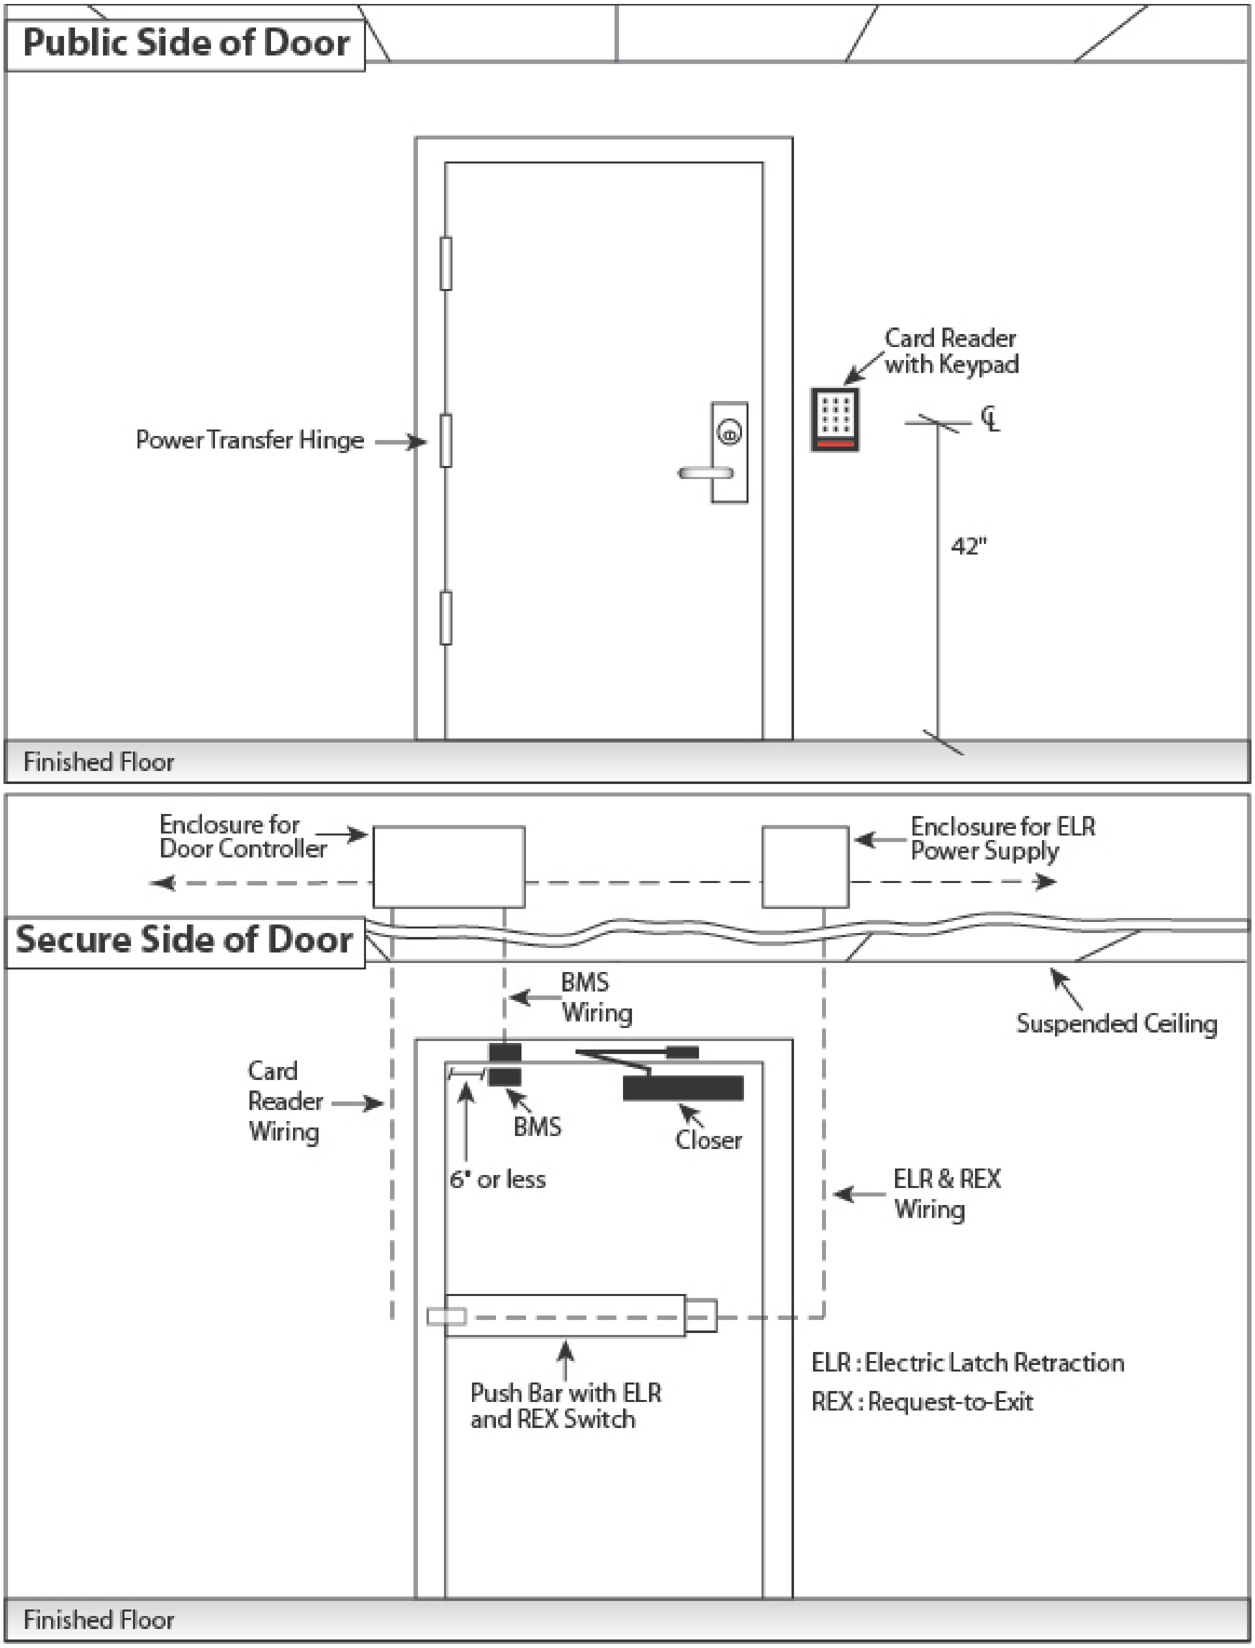
Smart cards are credential cards with a microchip embedded in them. The term “smart card” can define cards that simply carry data, but more commonly is used to describe cards with integral microprocessing and read/write data storage capability. Smart cards are available as a “Contact” type or as a “Contactless” (and wireless) type. An example of a “Contact” smart card is one which can interface to a computer through the embedded contact. The contactless, wireless smart card operates at 13.56 MHz, which is more than a hundred times faster than the data exchange rate of 125kHz proximity cards. There are also hybrid cards available, which have both types of smart card chips in one plastic body or have both contact and contactless interfaces to one microprocessor in the plastic body. Smart cards can store enormous amounts of data such as access transactions, licenses held by individuals, qualifications, safety training, security access levels, and biometric templates. One principal security advantage of smart cards is that cryptographic capabilities can be used to send card information to legitimate readers and encrypts that transmission such that the system remains immune from replay attacks. It is difficult to copy security credential information onto a forged card. For more information on the federal standard for electronic smart cards, refer to National Institute of Standards and Technology Federal Information Processing Standards (NIST FIPS) 201.

3-4.6.2 Common Access Card (CAC).

The CAC is a credential used by the DoD to allow access to DoD computers and physical locations worldwide. For each individual, one card works for all access to computers and physical locations. The CAC is a JAVA-based smart card. It can store a number of personal demographic data elements. It supports multiple bar codes **\1\/1/** for legacy applications, making the card extremely versatile.

Per DoD 5200.08-R, “the CAC must be the principal identity credential for supporting interoperable access to installations, facilities, buildings, and controlled spaces.” For physical access control, the contactless smart chip is the preferred feature of the CAC. However, a dual-technology smart card reader allows the contact interface to be used (via insertion) as a fallback should the contactless antenna in a card become damaged.

Figure 3-5. Sample Card Reader Door Configuration.



3-4.6.3 Operational Strategies.

Operational strategies for badge policy such as where the badge is worn, the type of photograph (if required), backgrounds for area authorization, rules of challenge, penalties for not wearing, and losing are important but are not within the scope of this design guide.

3-4.7 Keypads and PIN Codes.

Coded devices use a series of assigned numbers commonly referred to as a PIN. This series of numbers is entered into a keypad and is matched to the numbers stored in the ACS. By itself, this technology does not offer a high level of security since a PIN can be stolen by even casual observation. However, coded devices can be effective when used in combination with a credential or biometric technology. For an ACS that uses keypads as the sole entry authorization identifier, microprocessor-controlled keypads are preferred. Unlike a standard keypad, a microprocessor-controlled keypad alters the arrangement of numbers each time it is used, thereby making it more difficult for an onlooker to determine a PIN by observing which keys are pressed. Numbers are displayed on LEDs with a narrow viewing angle so that only the person directly in front of the keypad can clearly see the numbers.

3-4.8 Biometric Readers.

Biometric readers verify personal biological metrics (biometrics) of an individual. Biometric readers may be used in addition to credential devices or with a PIN code.

3-4.8.1 Biometric Devices.

Biometric devices are well suited for very high security areas, but may not be appropriate for portals where high throughput is a primary design objective. Designers have to evaluate the tradeoff between added security and decreased throughput.

There are several types of biometric characteristics that can be used. The most common are described in the following sections.

3-4.8.1.1 Fingerprint.

Fingerprint technology scans the loops, whorls, and other characteristics of a fingerprint and compares it with stored templates. When a match is found, access is granted (depending on the authorized security level). This technology is mature and well understood but performance can be degraded if cuts or sores appear on fingers or if grease or other medium contaminates the fingers and the scanning plates. Some systems create two templates for two different fingers, in the event that one finger is altered by injury or other means. Fingerprint technology is not convenient in environments where workers wear gloves. Early fingerprint readers were compromised by picking up a valid fingerprint from a reader with a manufactured “finger”. To combat this shortcoming of the technology, sensors were equipped with the ability to sense a pulse and temperature. Fingerprint technology is the first choice biometric method per FIPS 201.

3-4.8.1.2 Facial Image.

This technology measures the geometric properties of the subject's face relative to an archived image. Specifically, the centers of the subject's eyes must be located and placed at precise (within several pixels) locations. Facial imaging is the backup technology for biometric authentication per FIPS 201.

3-4.8.1.3 Hand Geometry.

This technology assesses the hand's geometry: height, width, and distance between knuckle joints and finger length. Advantages of hand geometry are that the systems are durable and easily understood. The speed of hand recognition tends to be more rapid than fingerprint recognition. Hand recognition is reasonably accurate since the shape of each hand is unique. A disadvantage is that they tend to give higher false accept rates than fingerprint recognition. As with fingerprint technology, hand geometry is not convenient in environments where workers wear gloves.

3-4.8.1.4 Handwriting.

Handwriting recognition analyzes the pressure and form of a signature. This technology is only used in an ACS without heavy traffic because the procedure of verification is slow. A PIN is typically entered into the system first so that the computer can more quickly find a template against which to identify the person seeking entry. Handwriting systems are not widely used.

3-4.8.1.5 Voice Recognition.

Voice recognition identifies the voice characteristics of a given phrase to that of one held in a template. Voice recognition is generally not performed as one function, and is typically part of a system where a valid PIN must be entered before the voice analyzer is activated. An advantage of voice recognition is that the technology is less expensive than other biometric technologies. Additionally, it can be operated hands-free. A disadvantage is that the voice synthesizer must be placed in an area where the voice is not disturbed by background sounds. Often a booth has to be installed to house the sensor in order to provide the system an acceptable quiet background. Voice recognition systems are not widely used.

3-4.8.1.6 Iris Patterns.

Iris recognition technology scans the surface of the eye and compares the iris pattern with stored iris templates. Iris scanning is the most accurate and secure biometric. After DNA, irises are the most individualized feature of the human body. Even identical twins have different irises, and each person's two irises differ from each other. The unique pattern of the human iris is fully formed by ten months of age and remains unchanged through a person's lifetime. A benefit of iris recognition is that it is not susceptible to theft, loss, or compromise, and irises are less susceptible to wear and injury than many other parts of the body. Iris scanners allow scanning to occur from up to sixteen inches away. A disadvantage of iris scanning is that some people are timid about having their eye scanned. Throughput time for this technology must be considered. Typical transaction time is two seconds. If a number of people need to be processed through an entrance in a short period of time, this can be problematic.

3-4.8.1.7 Retinal Scanning.

Retinal scanning is an older, comparable technology that reads the blood vessel pattern on the retina in the back of the eye, but it is not readily available in the marketplace. Whereas iris scanners can work up to sixteen inches from the reader, retinal scanners require individuals to look into a device that shines a harmless infrared light into the eye. Hesitance to look directly into such a reader has curtailed the acceptance of retinal scanners in most applications.

3-4.9 Request-to-Exit (REX) Devices.

Doors and other portals secured with an ACS must provide a means of authorized egress for personnel inside the controlled space. A REX device performs this function by initiating a temporary shunt of the door sensor alarm, thus allowing the ACS to distinguish between an authorized exit and an unauthorized (forced) entry. For some door configurations the REX device also releases the door locking/latching mechanism.

An ACS designer must work with the project architect to analyze each controlled door and portal to determine the appropriate REX device, taking into account security, life safety, Americans with Disabilities Act (ADA), aesthetics, ergonomics, and wiring. An overview of the four categories of REX devices is as follows:

3-4.9.1 Door Hardware.

Practically any type of door hardware can be equipped with an internal REX switch. This approach eliminates the need for an external REX device but requires that wiring be extended to the door either through an electrified hinge or exposed armored flex conduit.

3-4.9.2 Buttons.

A button labeled "PUSH TO EXIT" can be mounted on the door frame or an adjacent wall.

3-4.9.3 Motion Sensors.

A motion sensor can be mounted above the door to detect a person approaching from the secure side. This is generally considered to be the least secure REX device due to the potential for false activations.

3-4.9.4 Card Readers, Keypads, and Biometric Devices.

Using a card reader, keypad, or biometric device as a REX device offers the potential for "who's in and who's out" accountability. Refer to section 3-3 for further discussion of ACS features that require exit readers.

3-5 ACS DESIGN CONSIDERATIONS.

a. Specify a card reader with an integrated keypad for portals where the added security of credential plus code access is required.

b. All card readers must be UL 294 listed.

c. Contactless card readers must conform to ISO/IEC 14443 Parts 1 through 4 and NISTIR 6887, The Government Smart Card Interoperability specification (GS-IS).

d. For facilities requiring a higher degree of security, provide biometric capability in addition to the minimum.

e. Per FIPS 201, fingerprint reading is the biometric technology of choice. Facial imaging is listed as a secondary biometric credential.

f. Outside hand-geometry readers require special exterior housings. Check with manufacturer's specifications for external applications on other biometric readers.

g. A common cable type for card readers is a twisted, shielded cable (typically, six conductor). One pair is used for low voltage dc power, one pair is used for data transmission, and one pair is normally used for LED or signal illumination. Verify the cable requirements with the equipment manufacturer.

h. In general, the ESS designer must balance security requirements with life safety, fire-alarm interface, and normal operational convenience factors.

i. Work with the project architect to clearly define controlled access boundaries and portals early in the design process. Specify the entry and exit function of each door on a controlled access boundary, and identify any special portal equipment such as turnstiles and security booths. Ensure that the Life Safety Plan addresses any egress restrictions associated with the ACS.

j. Avoid using a life safety emergency exit as a high security entry portal.

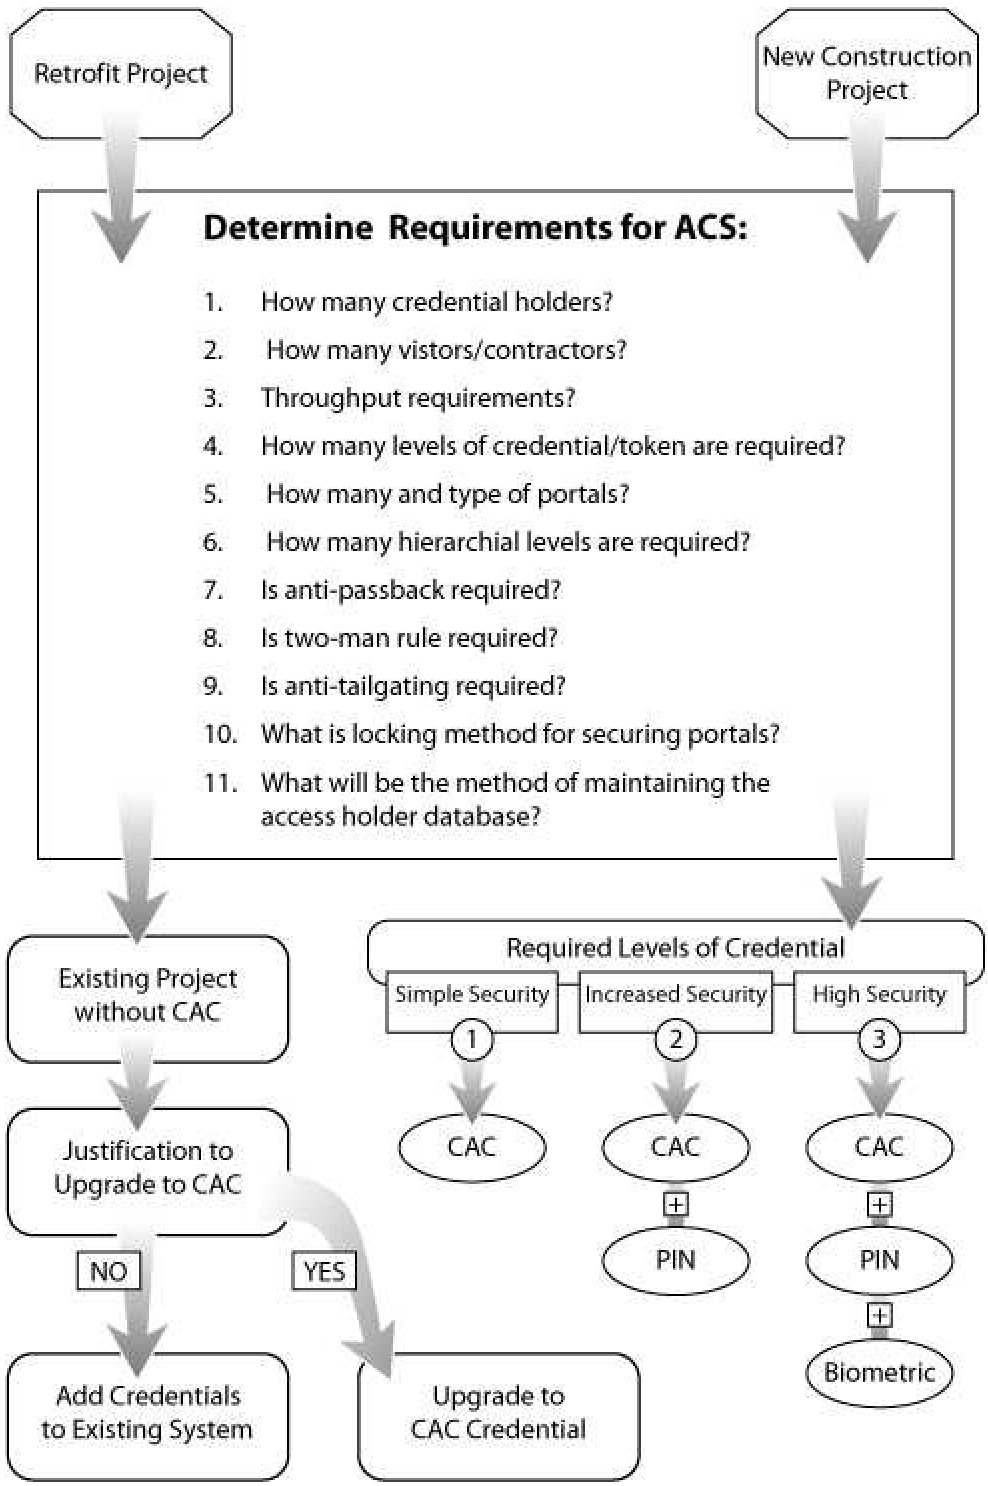
k. Limit entrances into the controlled area. SCIFs are limited to one primary entrance.

l. Coordinate with the Architect to ensure proper doors, door frames, and door hardware are provided. For example, when an electric door strike is specified, the door frame and hardware must be checked or specified such that they are compatible with the strike in terms of wiring and latching.

m. Consider throughput and traffic flow of normal operational traffic and emergency exiting requirements. Ensure that entry throughput at controlled portals will be adequate for the morning surge period.

n. Additional design guidance for ACS is provided in Figure 3-6.

Figure 3-6. ACS Design Process.



CHAPTER 4 CLOSED CIRCUIT TELEVISION SYSTEMS

4-1 OVERVIEW.

The CCTV system is another core subsystem of an overall ESS. It is the collection of cameras, recorders, switches, keyboards, and monitors that allow viewing and recording of security events. The CCTV system can be integrated with ACS and IDS and may be centrally monitored at the Dispatch Center or locally monitored by security personnel at an individual facility. Uses of CCTV systems for security services include several different functions as described below.

4-1.1 Alarm Assessment.

When alerted by an alarm notification, CCTV cameras allow security personnel to visually assess the situation and make a determination as to what type of response may or may not be required. An example would be an intrusion alarm at a remote facility. Visual assessment and other confirmation may indicate an unannounced maintenance crew at work. Symptoms of intrusion would lead to a response.

4-1.2 Access Control.

Cameras can be used by security personnel to visually identify persons and vehicles requesting entry prior to releasing a controlled portal (door, turnstile, gate, vehicle barrier, etc.).

4-1.3 Surveillance.

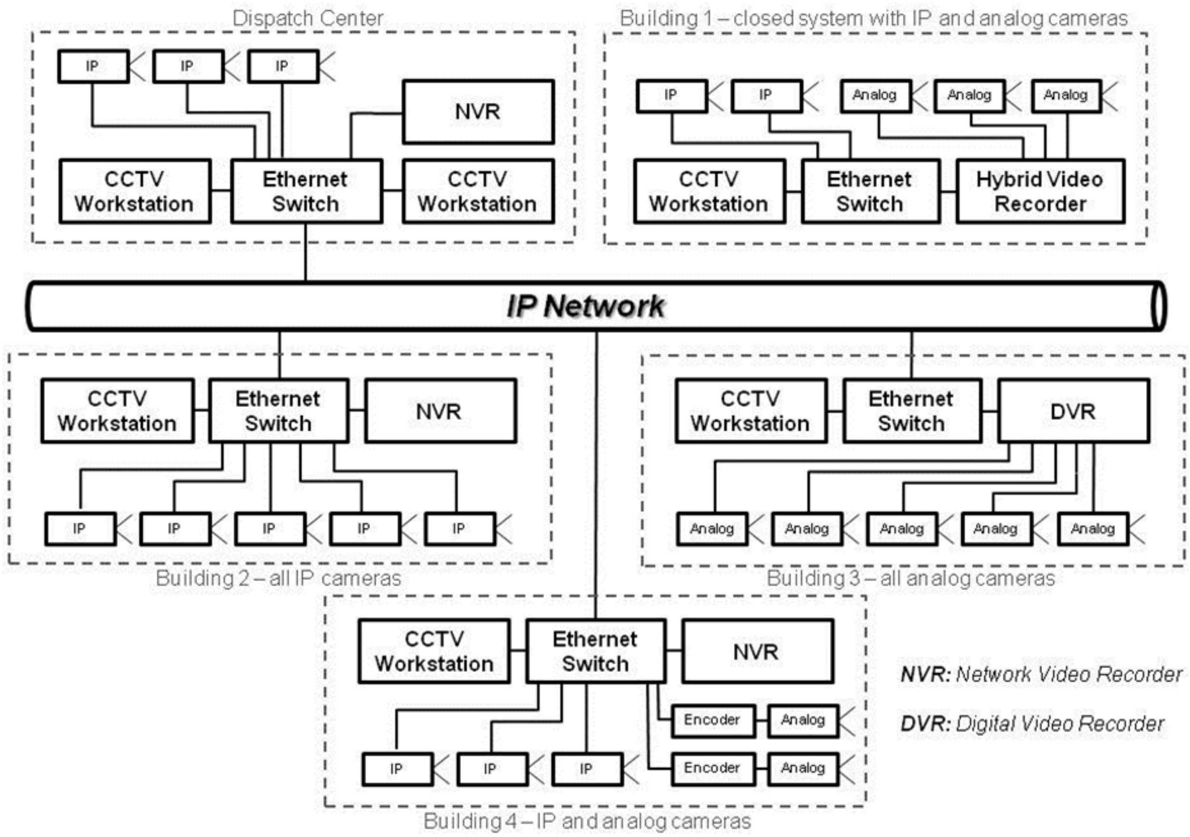
CCTV cameras can be used to give security personnel the capability to be made aware of or view visual events at multiple locations from a centralized remote viewing area. CCTV camera technology makes visual information available that would normally only be available through multiple (possibly roving) human resources. Video analytics can significantly enhance surveillance effectiveness by cuing scenes of interest and highlighting areas within scenes for priority viewing by an operator.

4-1.4 Evidentiary Archives.

Retrieval of archived images may be helpful in identification or prosecution of trespassers, vandals, or other intruders.

As shown in Figure 4-1, a large networked CCTV system may encompass several buildings and can include multiple workstations where live and recorded video can be viewed. Both analog and Internet Protocol (IP) cameras can be used to gather video images which are then stored in a digital format. Building 1 represents a closed system with no connection to an outside network, in which case all video recording, viewing and management is done within the building.

Figure 4-1. Example Block Diagram for a Networked CCTV System.



4-2 CAMERAS.

Selecting the appropriate cameras is critical to a CCTV design. The following paragraphs provide guidance regarding basic camera types and features.

4-2.1 Color Versus Black and White.

Color cameras offer more information such as color of a vehicle or subject's clothing. Some ultra-low light color cameras are able to automatically sense the ambient light conditions and switch from color to black and white in low light conditions. Cameras must have auto-white balance to adjust for the changing color temperature of daylight and artificial lighting needed for night-time viewing. Black and white cameras are more sensitive than color cameras under low-light conditions and are best used when IR illuminators are required. These cameras are further described in the Viewing in Low-Light Conditions Section of this chapter.

Color cameras require a higher illumination level than black and white cameras to be effective. Typically, a high-quality color camera will work well down to 1 foot-candle (fc) (10 lux) of scene illumination, whereas a black and white camera might only require 0.1

fc (1 lux). These lighting level requirements vary with the camera model and manufacturer, so be sure to specify the appropriate illumination level for the scene of interest.

4-2.2 Indoor Cameras.

Indoor camera installations reduce the complexity of the system, but care must be taken to correctly specify the lens, field-of-view and camera hardware. Indoor cameras need:

- Sturdy, secure mounting.
- Auto-iris for lighting control.
- Auto-white balance to ensure proper color correction to accommodate changes in color temperature of lighting if it is dimmed or lighting is changed due to a light outage.
- To be mounted in a position to prevent glare from overhead lighting.

4-2.3 Outdoor Cameras.

Outdoor camera installations cost more than indoor cameras due to the need to environmentally house, heat, and ventilate the outside camera. When mounting a camera outdoors, the lighting requirement changes depending on the time of day and the weather. Because of this, consider the following for outdoor cameras:

a. Shrubs, trees, and other vegetation in a camera’s line of sight may cause obstructed views. Designers need to be aware of this when determining where to place cameras. Also, video motion detection systems can register a false positive when plants in the field-of-view move in windy conditions.

b. Provide heaters in cold weather applications.

c. Always use auto-iris lenses with outdoor cameras. The iris automatically adjusts the amount of light reaching the camera and thereby optimizes its performance. The iris also protects the image sensor from getting damaged by strong sunlight. Always set the focus in low light with an auto-iris lens. If the adjustment is made in sunlight, it is very easy to focus, but at night the iris diameter increases and the image is not in focus anymore. Special dark focus filters called “neutral density” filters or ND filters help reduce lighting by one or more stops of exposure. These filters do not affect the color of the image.

d. Use caution when mounting a camera behind glass. If you mount a camera behind glass, such as in housing, make sure that the lens is close to the glass. If the lens is too far away from the glass, reflections from the camera and the background will appear in the image.

e. Always try to avoid direct sunlight in an image. Direct sunlight blinds the camera and may permanently bleach the small color filters on the sensor chip, causing stripes in the image.

f. When using a camera outdoors, avoid viewing too much sky. Due to the large contrast, the camera will adjust to achieve a good light level for the sky, and the landscape and objects that must be assessed might appear too dark. One way to avoid these problems is to mount the camera high above ground. Use a pole if needed. Given mounting choices, mount cameras facing away from rising or setting sun, realizing that this varies by season.

g. Always use sturdy mounting equipment to avoid vibrations caused by strong wind. This is especially important with a long focal length lens. These lenses amplify even the smallest movement of the mount. Building mounts are generally more stable than pole mounts. When in extremely windy conditions for a critical camera, consider using a gyro-stabilized mount lens to avoid vibration caused by wind. The gyro-stabilized lens has a cost premium and is not appropriate for general applications.

4-2.4 Fixed Position Cameras.

After being mounted, aimed, and focused by an installer, a fixed position camera provides a field of view that cannot be changed via remote control. When used for visually assessing intrusion or access control alarms, fixed cameras are good for review of pre-alarm conditions because there is a constant view of the scene in which the alarm was triggered. Pre-alarm allows the review of video information for the time period (typically ten to fifteen seconds) immediately before the alarm occurred. Pre-alarm video is often the most useful video content for determining the actual cause of the alarm. Because of their static field of view, fixed cameras are well suited for video motion detection, but are not able to track a target of interest after it leaves the camera scene. The installation and cost of fixed cameras is lower because there is no associated motor and control wiring.

4-2.5 Pan/Tilt/Zoom (PTZ) Cameras.

A PTZ camera contains a motorized mechanism for adjusting camera aim point and lens focal length, thus allowing an operator to dynamically change the field of view via remote control. This gives the operator a much better view of the overall area compared to a fixed camera. PTZ cameras are often used for both alarm assessment and video surveillance applications; however, they are not well-suited for pre-alarm assessment because they may not be focused on the alarm area at all times. Because of the drive motor, housing, and wiring for controls, PTZ cameras are typically three to four times more expensive than fixed cameras. Table 4-1 compares other salient parameters of fixed and PTZ cameras.

A PTZ camera can be controlled by an operator or it can be programmed to perform a guard tour during which it moves sequentially through a series of user-defined preset views. When not under operator or guard tour control, a PTZ can be set to return to a home position preset corresponding to the most important scene of interest. Preset views for alarm conditions can be programmed to override operator control, guard tour, and home position.

Table 4-1. Fixed versus PTZ Cameras.

	Applications	Cost	Pre-alarm Review	Video Motion Detection	Intruder Tracking Capability
Fixed	Alarm assessment for doors, gates and fence lines	Lower	Recommended	Recommended	None
PTZ	Surveillance for large open areas such as ports and airfields	Three times more expensive than a fixed camera	Poor application	Only for fixed, preset scenes	Good

4-2.6 Dome Cameras.

A dome camera is mounted in a hardened plastic lower-dome, which is commonly smoked-colored to conceal the camera. The use of smoke-colored domes provides covert lens positioning, while the use of clear domes provides for better low-light performance. Dome cameras are a good design solution for applications where the camera needs to be protected from the environment (such as dust) or it is desired to conceal the camera’s aim point. The variety of dome cameras is extensive, giving the designer a dome option for nearly any security application: fixed or PTZ, indoor or outdoor, full-size or mini-dome, analog or IP. A common application of dome cameras is in office buildings with suspended ceilings where aesthetics and ease of installation are important factors. PTZ dome cameras can move quickly from a home position to any preset, typically in less than two seconds.

4-2.7 IP and Analog Cameras.

A CCTV camera can be specified as either IP or analog, depending on the required video output format. As illustrated previously in Figure 4-1, an IP camera connects directly to an Ethernet switch from which the camera signal can be transmitted to any network node for viewing or recording. An analog camera typically connects to a digital video recorder from which live or recorded video can be transmitted to one or more CCTV workstations on the network. To ensure reliable video storage and viewing, IP cameras generally require a network with high bandwidth, high availability, and low latency.

4-3 ILLUMINATION.

4-3.1 Illuminance.

The CCTV designer must coordinate with the project's lighting engineer, landscape architect and interior designer to ensure that illuminance within scenes of interest is sufficient for cameras to render full video. Meeting this objective involves analyzing two parameters - faceplate illuminance and scene illuminance - which are illustrated in Figure 4-2 and related by the following equation:

$$\mathbf{C} = \mathbf{BR}\left(\frac{\mathbf{T}}{\mathbf{4N^2}}\right)$$

where

C = faceplate illuminance (units are foot-candles or lux)

B = scene illuminance (units are foot-candles or lux)

R = scene reflectivity factor (dimensionless number between 0 and 1)

T = lens transmittance efficiency (dimensionless number, typical value is 0.8)

N = lens f-number (ratio of lens focal length to aperture diameter)

To illustrate the use of this equation, consider the following example:

A specific outdoor fixed camera has been proposed for use at an aircraft parking area. Examining the manufacturer's data reveals that the camera requires 0.0007 foot-candle of illuminance at the faceplate to generate useable video. To achieve the desired field of view, a 5-mm lens with an f-number of 1.6 and transmittance efficiency of 0.8 is proposed. During a nighttime lighting survey it is determined that the scene of interest includes dark-colored rotary wing aircraft parked on asphalt concrete. The reflectivity factor for this scene is estimated to be 0.07. Noting that existing light fixtures are in place, light meter readings are taken at several locations within the scene and the average illuminance value is calculated to be 1.2 foot-candle. Using this average scene illuminance, faceplate illuminance is calculated as follows:

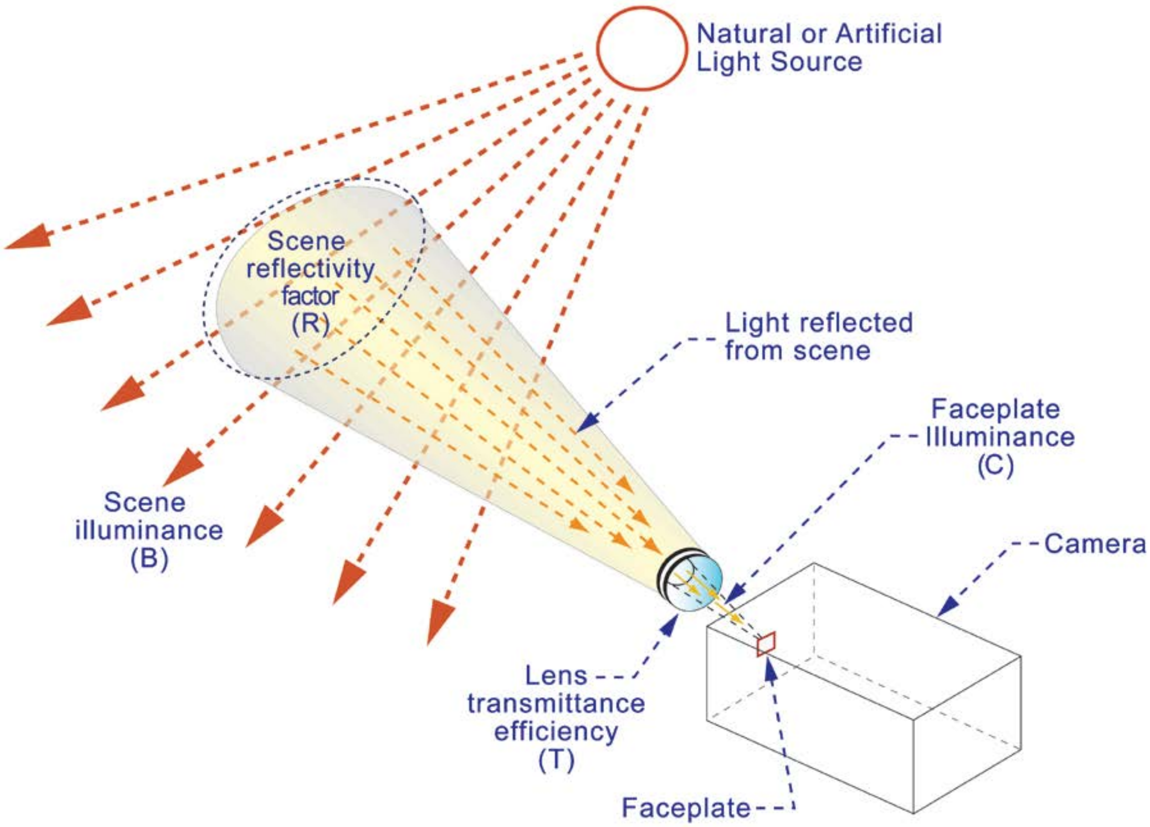
$$C = (1.2)(0.07)\left[\frac{0.8}{(4)(1.6)^2}\right] = 0.007\ footcandles$$

Comparing this calculated value with the manufacturer's specification (0.0007 foot-candle) indicates that existing nighttime illumination at the aircraft parking area is more than adequate to support full video capture by the proposed camera.

4-3.2 Uniformity.

Uniform illuminance within a camera scene yields the highest video quality. While not always achievable, the designer should strive for an average-to-minimum uniformity ratio of 4:1 within a scene of interest. Video quality degrades noticeably when the uniformity ratio exceeds 8:1. For additional guidance on uniformity and other CCTV illumination parameters, refer to UFC 3-530-01.

Figure 4-2. Scene Illuminance and Faceplate Illuminance.



Reflectivity factors for a range of surface conditions are presented in Table 4-2, and these values can be used to estimate reflectivity for actual scenes of interest.

Table 4-2. Reflectivity Factors for Various Surface Conditions.

Scene Description	Reflectivity Factor
Asphalt concrete	0.07
Grass and trees	0.2
Red brick	0.35
Portland cement concrete	0.4
White matte painted surface	0.6
Glass window or wall	0.7
Snow-covered surface	0.85

4-3.3 Glare Reduction.

Glare is very detrimental to CCTV camera performance as illustrated in Figure 4-3. Glare reduction can be achieved by specifying full cut-off luminaires and insuring that luminaires are not in a camera's field of view. In general, the source of illumination is best located above the level of the camera. The CCTV designer must coordinate with the lighting designer to ensure that these glare-reduction objectives are met.

Figure 4-3. Effect of Glare on CCTV Camera Image Quality.

4-3.4 Interior Lighting.

Interior lighting for CCTV presents special issues that need to be considered by the designer. For example, after-hours lighting may be significantly lower than normal operation lighting. Two solutions help minimize this impact.

a. The first technique is the use of cameras with automatic backlight compensation. Backlight compensation is a camera feature that enables the camera to automatically adjust picture brightness depending on lighting conditions, which compensates for bright backgrounds so foreground objects are not silhouetted. Frequently, CCTV cameras near windows are affected by backlighting, causing shadows and silhouettes, so the use of appropriate cameras with backlight compensation is effective.

b. The second technique is the use of cameras with automatic gain control, a feature that amplifies existing video to help a camera create an enhanced video signal at low light levels.

Both of these techniques enable cameras to function more effectively in interior low-light conditions and are useful for outdoor cameras as well. In some cases, the integration of CCTV cameras with night-lights and intrusion sensors can be very effective. The sequence of events might be as follows: an intruder activates an interior presence sensor which, in turn, activates instant-on lighting for CCTV camera assessment.

4-4 VIEWING IN LOW-LIGHT CONDITIONS.

In addition to increasing the illumination level of the surrounding area, several technology solutions are available to permit viewing under low-light conditions. These include black/white switching cameras, infrared illuminators, or thermal imagers. These technologies are often used where visible light either brings undesired attention to a critical facility, or surrounding property owners object to visible light adequate for good visual camera operation.

4-4.1 Black/White Switching.

Many cameras will automatically switch from color during daytime to black/white at night, which permits viewing under low light conditions. This can be an effective solution in situations where the existing illumination levels are too low during night conditions to permit color camera use, but color camera use is desired during daytime conditions. Numerous CCTV camera manufacturers offer auto-switching black/white cameras.

4-4.2 Infrared Illuminators.

The human eye cannot see infrared light. Most monochrome CCTV (black/white) cameras, however, can. Thus, invisible infrared light from either an LED or laser source can be used to illuminate a scene, which allows night surveillance without the need for additional artificial lighting. IR illumination patterns can be matched to camera field of view. A variety of patterns are available ranging from narrow- to wide-angle and short- to long-range coverage. LED IR illuminators are a good choice for short-range flood coverage and medium-range spot coverage. Approximate coverage ranges for a 26-watt LED illuminator are 65 feet (20 m) for a 120-degree flood pattern and 310 feet (95 m) for a 10-degree spot pattern. Laser IR illuminators should be considered when the desired coverage range exceeds the capabilities of LED illuminators. For example, a 60-watt laser IR illuminator can project a 10-degree pattern to a maximum effective distance of approximately 2300 feet (700 m). Infrared provides the following benefits over conventional lighting:

- Extended service life - up to 10 years.
- Lower running costs (but higher installation costs).
- Covert surveillance - no visible lighting to alert or annoy neighbors.

It is important to design illumination specifically for the CCTV camera being used. For example, infrared illuminators require black/white cameras and do not work on color cameras, unless the color camera has an automatic black-and-white switching feature. Cameras will not render color images when used under infrared illumination. The range that the camera will see in the dark depends on sensitivity and spectral response of the camera and lens combination. Many black and white cameras use infrared filters to intentionally filter out non-visible light. Therefore, black and white cameras which are designed to be used in conjunction with infrared lighting must not have an infrared filter. Dual mode cameras that can switch from color to monochrome operation in low light conditions must not have an infrared filter for the reason cited above.

4-4.3 Thermal Imagers.

Thermal imagers use a special technology that senses heat signatures rather than visual information. These cameras operate under complete darkness. Thermal imagers are best used in long-range detection and surveillance applications. Thermal imagers detect and display images based on infrared energy emitted from objects rather than visible light reflected off objects. The most common technology is Forward Looking Infrared (FLIR). Thermal cameras work on a temperature differential between the object and the background. In desert environments, the background is white and people are black. In cooler environments, the background is black and people are shown as white images. A key advantage of long-range thermal imagers is that they are less susceptible to environmental influences from rain and fog in comparison to visible light cameras. The disadvantage of thermal-imagers is the high cost and the inability to discern facial features and other fine details in the scene.

Typically thermal imagers are classified as medium or long wavelength as illustrated in Table 4-3. For security applications in which the object of interest is a man-size target within a few hundred meters of the camera, uncooled long-wavelength imagers are preferred because of their lower cost, both in terms of initial purchase and lifecycle maintenance. Cooled medium-wavelength imagers, though more costly, can resolve very small thermal gradients and, equipped with the appropriate lens, can capture images of man-size targets at ranges out to a few thousand meters.

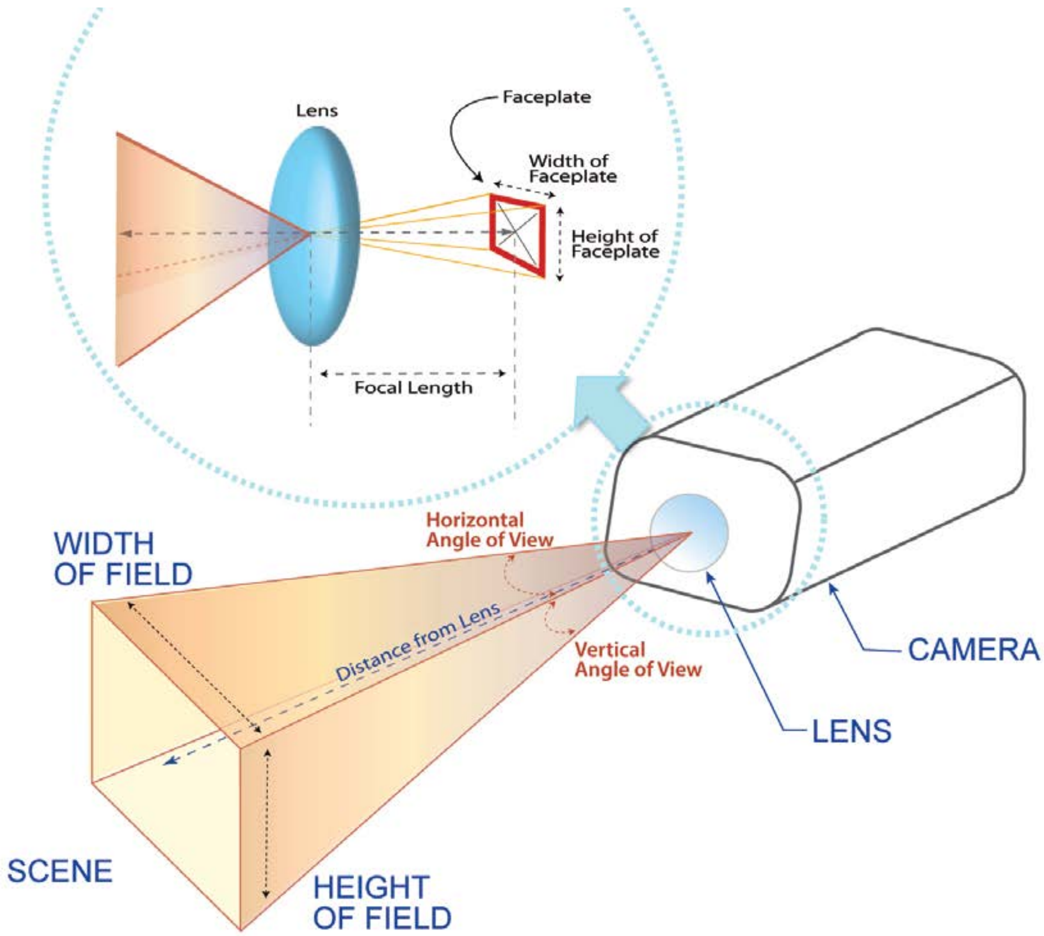
Table 4-3. Characteristics of Thermal Imagers.

Classification	Wavelength	Cooling	Cost	Recommended Service Period
Medium Wavelength	3- 5 microns	Cryogenically cooled	$50K - $150K	7,500 hours
Long Wavelength	7-14 microns	Uncooled	$5K - $50K	30,000 hours

4-5 ANGLE OF VIEW AND FIELD OF VIEW.

An important consideration when designing a CCTV system is determining the desired field of view for each camera. Field of view and angle of view are illustrated in Figure 4-4. Based on the desired field of view, the designer must specify the appropriate camera mounting location, aim point, format, and lens focal length to capture the required image.

Figure 4-4. Angle of View and Field of View.



Camera format refers to the nominal diagonal measure of the image sensor (also called the faceplate), and typical sizes are shown in Table 4-4. Given the faceplate dimensions and the lens focal length, the angle of view for any camera-lens combination can be calculated as follows:

$$\boldsymbol{\alpha} = 2\,\boldsymbol{tan}^{-1}\frac{\boldsymbol{l}}{2\mathrm{f}}$$

where

α = angle of view (horizontal or vertical)

l = length of image sensor (width or height, refer to Table 4-4)

f = focal length of lens

A relatively narrow angle of view would be provided by a 2/3-inch format camera equipped with 50-mm lens. In this example, the angles of view would be as follows:

$$\alpha_{horizontal} = 2tan^{-1}\left[\frac{8.8}{(2)(50)}\right] = 10.1°$$

$$\alpha_{vertical} = 2tan^{-1}\left[\frac{6.6}{(2)(50)}\right] = 7.6°$$

A relatively wide angle of view would be provided by a 1/3-inch format camera equipped with 5-mm lens. In this example, the angles of view would be as follows:

$$\alpha_{horizontal} = 2tan^{-1}\left[\frac{4.8}{(2)(5)}\right] = 51.3°$$

$$\alpha_{vertical} = 2tan^{-1}\left[\frac{3.6}{(2)(5)}\right] = 39.6°$$

The following simple ratios can be used to perform several types of field of view calculations:

$$\frac{l_{width}}{W} = \frac{l_{height}}{H} = \frac{f}{D}$$

where
l_{width} = width of image sensor
W = width of field
l_{height} = height of image sensor
H = height of field
f = focal length of lens
D = distance from lens
To show the application of these field-of-view ratios, consider this example. A ½-inch format camera will be mounted on a pole located 30 feet (10 m) from a pedestrian turnstile on the perimeter of an outdoor restricted area. If the desired vertical field of view is a full-height image of each person entering the restricted area, what lens focal length is needed? Assuming a 7-foot (2,134 mm) height of field at a distance of 30 feet (9,144 mm), lens focal length can be calculated as follows:

$$f = \frac{Dl_{height}}{H} = \frac{(9144)(4.8)}{2134} = 20.6\ mm$$

In this example, the designer could specify a varifocal lens to allow some fine tuning of the field of view during the installation process or later adjustment to meet a new field-of-view requirement. A 10-40 mm varifocal lens set at 20.6 mm would meet the stated objective of providing a full-height image of a person at the turnstile, but the same varifocal lens could be set to 40 mm to provide better facial detail or to 10 mm to cover an adjacent vehicle gate. Supporting calculations for these focal lengths are as follows:

$$H = \frac{Dl_{height}}{f} = \frac{(9144)(4.8)}{40} = 1,097\ mm = \text{ 3.6 feet (Better Facial Detail)}$$

$$W = \frac{Dl_{width}}{f} = \frac{(9144)(6.4)}{10} = 5,852\ mm = 19 \text{ feet (Cover Vehicle Gate)}$$

Table 4-4. Typical Faceplate Sizes.

Nominal Diagonal Measure	Actual Width	Actual Height
1/4 inch	3.2 mm	2.4 mm
1/3 inch	4.8 mm	3.6 mm
1/2 inch	6.4 mm	4.8 mm
2/3 inch	8.8 mm	6.6 mm
1 inch	12.8 mm	9.6 mm

4-6 CAMERA RESOLUTION.

Camera resolution refers to the “graininess” of images captured and transmitted by a camera and is expressed in terms of televisions lines (TVL) for analog cameras and picture elements (pixels) for IP cameras. Table 4-5 correlates qualitative resolution descriptions to equivalent camera specifications for both analog and IP cameras. For each scene of interest, the CCTV designer must determine the camera resolution required to achieve the desired discrimination level for objects in the scene. Visual target discrimination criteria developed by John Johnson in the 1950’s, commonly referred to as the Johnson criteria and summarized in Table 4-6, can be used to analyze the impact of camera resolution on object discrimination for any given angle of view. These criteria are based on a 50% probability of accurate discrimination by a person viewing the camera image. The following example applies the Johnson criteria to illustrate the difference in object discrimination performance between a high-resolution camera and a megapixel camera.

Table 4-5. Typical Camera Resolution Specifications.

	Equivalent Camera Resolution Specification	
Qualitative Description	Analog Camera	IP Camera
Very Low Resolution - Quarter VGA	N/A	320 X 240 pixels
Low Resolution - VHS	330 TVL	N/A
High Resolution - DVD	540 TVL	720 X 480 pixels
Megapixel Resolution	N/A	1280 X 1024 pixels (and higher)
HD 1080p Resolution	N/A	1920 x 1080 pixels

Table 4-6. Object Discrimination Levels Based on Johnson Criteria.

Discrimination Level	Meaning	Pixels required across minimum dimension	Example
Detection	An object of a specified size is present.	2	An object with minimum dimension of 60 inches in the vertical orientation is present in the scene.
Recognition	The class to which the object belongs can be determined.	8	The object is a vehicle, not people or animals.
Identification	The type of object within the class can be determined.	16	The vehicle is a sedan, not a truck, SUV or van.

A 2/3-inch format camera with a 25-mm lens will be used to visually assess outdoor perimeter intrusion alarms along a restricted area. The camera will be aimed parallel to the fence line to view objects in the clear zone. The objective is for the camera to provide recognition level discrimination for a person crawling through the clear zone. This level of discrimination will allow a human crawler to be distinguished from objects of similar size such as animals and wind-blown debris. The minimum dimension for a human crawler is 12 vertical inches (0.3 m), and applying the Johnson criteria suggests that this 12-inch (0.3 m) vertical profile must be “painted” by 8 vertical pixels on the image collected by the camera. Given the properties of the camera, lens, and object to be viewed, the following equation can be used to calculate the maximum range for “recognizing” the human crawler:

$$\boldsymbol{D = \frac{hfR_{vertical}}{p_{vertical}l_{height}}}$$

where

D = distance from lens to object

h = height of object

f = focal length of lens

$R_{vertical}$ = vertical resolution of the camera in pixels

$p_{vertical}$ = vertical pixels required on object

l_{height} = height of image sensor

Converting the height of the human crawler from 12 inches to 305 mm and solving this equation yields the following result for a high-resolution (720 X 480 pixels) camera:

$$\boldsymbol{D = \frac{(305)(25)(480)}{(8)(6.6)} = 69,318\ mm = 227\ feet}$$

A megapixel camera (1,280 X 1,024 pixels), by comparison, provides a maximum “recognition” range of:

$$\boldsymbol{D = \frac{(305)(25)(1,024)}{(8)(6.6)} = 147,879\ mm = 485\ feet}$$

In this illustration, even though the angles of view are the same for both cameras (20° horizontal & 15° vertical), the megapixel camera has two times the effective range of the high-resolution camera.

For objects having a minimum dimension equal to their width (such as a person walking), the following equation can be used in conjunction with the Johnson criteria to calculate maximum effective range:

$$\boldsymbol{D = \frac{wfR_{horizontal}}{p_{horizontal} l_{width}}}$$

where

D = distance from lens to object

w = width of object

f = focal length of lens

$R_{\text{horizontal}}$ = horizontal resolution of the camera in pixels

$p_{\text{horizontal}}$ = horizontal pixels required on object

l_{width} = width of image sensor

4-7 VIDEO FRAME RATE.

Video frame rate is an important CCTV design parameter that affects video transmission, storage, and display. A frame rate of 30 frames per second (fps) is generally considered to be “full motion video” based on the National Television Standards Committee (NTSC) analog video standard. However, the transmission and recording frame rates for digital video can be set for a range of values between 1 and 30 fps, and some IP cameras and network video recorders support frame rates up to 60 fps. For most security applications, including alarm assessment and evidentiary archives, frame rates between 4 and 10 fps are fully adequate. Higher frame rates are appropriate for surveillance applications in which a smooth video stream is beneficial to the operator, especially when using a PTZ camera. Frame rates of 24 fps and higher will be perceived as “smooth” when viewed by an operator for extended periods of time. In most digital video systems, transmission and recording frame rates can be programmed to automatically change in response to an external event such as an intrusion alarm or an internal video motion detection trigger.

4-8 DIGITAL VIDEO BANDWIDTH.

The CCTV designer must coordinate closely with the appropriate network designer or administrator to ensure that network bandwidth will support digital video transmission. Estimating bandwidth requirements using the equation below will aid in this coordination.

$$\boldsymbol{b = krz}$$

where

$\boldsymbol{b}$ = bandwidth required for a single video stream

$\boldsymbol{k}$ = network overhead factor, typical value is 1.4

$\boldsymbol{r}$ = video frame rate

$\boldsymbol{z}$ = average compressed file size of a single video frame

The average file size for a single frame is dictated by the video resolution and compression, and typical values are given in Table 4-7. The following example illustrates the use of this table and the equation above.

Four IP cameras will be installed in an administrative building as part of an access control upgrade. One fixed camera will be installed at the main entry door and the other three fixed cameras will be installed at doors designated for emergency exit only. Each camera has megapixel (1280 X1024) resolution and H.264 video compression. Video from the administrative building will be transmitted via network at 5 fps to a headquarters building for recording and viewing. How much network bandwidth is required to support these four cameras?

Assuming that the main entry camera will have high scene activity, a single video frame will have an average compressed file size of 72 kB. The other three cameras will each have low scene activity and a corresponding file size of 36 kB. Using these file size values from Table 4-7, along with the specified frame rate of 5 fps, the following bandwidth estimates can be made, with the results expressed in units of Megabits per second (Mbps):

ENTRY DOOR CAMERA: $\mathbf{b_{entry} = (1.4)(5)(72) = 504\ kBps = 4.03\ Mbps}$

EXIT DOOR CAMERA: $\mathbf{b_{exit} = (1.4)(5)(36) = 252\ kBps = 2.02\ Mbps}$

TOTAL FOR ALL CAMERAS: $\mathbf{b_{total} = b_{entry} + 3b_{exit} = 10.09\ Mbps}$

(Note: 1 Mbps = 125 kBps)

Based on this calculation, the four IP cameras will require approximately 10 Mbps of network bandwidth to transmit video from the administrative building to the headquarters building.

Table 4-7. Single-frame File Size for Various Resolution Values and Compression Schemes

Resolution (H x V pixels)	Average Compressed File Size (kB) for a Single Video Frame		
	H.264 - Low Scene Activity	H.264 - High Scene Activity	MJPEG - High Quality
320 X 240	4	8	20
720 X 480	12	24	60
1280 X 1024	36	72	180
1920 X 1080	50	100	250

4-9 DIGITAL VIDEO RECORDING.

The CCTV designer must plan for digitally recording video from all cameras, and several technology options are available. The following paragraphs provide a brief overview of four of the most common video recording methods followed by an explanation of how to estimate video storage requirements.

4-9.1 Memory Card.

Several camera models have a built-in memory card which allows video to be recorded at the edge of the CCTV system. This ensures uninterrupted recording even when the connection between the camera and the central system is lost, but storage capacity is very limited. An SD card, for example, has a capacity of 2 GB.

4-9.2 Digital Video Recorder (DVR).

A DVR digitizes analog camera inputs and stores the video on one or more internal hard drives. The number of camera inputs ranges from 4 to 32, depending on the model selected. Recording resolution up to 720 X 480 at 30 fps is available on many models. Access to live and recorded video from remote workstations is enabled by a network interface card in the DVR, but video will continue to be recorded even if network connectivity is lost. A DVR can provide several terabytes of video storage capacity.

4-9.3 Network Video Recorder (NVR).

An NVR records digital video from multiple IP cameras and video encoders to one or more internal hard drives. The capacity and sophistication varies greatly within this category of video recording technology. A low-end NVR can typically record up to 16 cameras at 30 fps, with recording resolution no greater than 720 X 480. A high-end NVR can accommodate 50 or more cameras, recording each camera at 24 fps with HD 1080p resolution. All NVRs have an internal network interface card to receive and distribute IP video streams, and high-end units have two or more Gigabit Ethernet ports. A CCTV designer must ensure that each network path connecting an IP camera with its associated recording node is adequate in terms of both availability and bandwidth. NVR storage capacity ranges from 1 TB at the low end of the category to greater than 10 TB for high-end units.

4-9.4 Hybrid Video Recorder (HVR).

Combining the functionality of a DVR and an NVR into a single unit, an HVR can digitize and record multiple analog camera inputs while simultaneously recording multiple IP video streams. Many HVRs provide up to HD 1080p recording resolution for IP cameras, and HVR video storage capacities generally range from 2 to 10 TB.

4-9.5 Required Storage Capacity.

Once all cameras have been specified for a project, the CCTV designer should use the following equation to estimate the required storage capacity for each video storage device:

$$\mathbf{s = trz}$$

where

s = required video storage capacity for a single camera

t = required video storage duration

r = video frame rate

z = average compressed file size of a single video frame

The following example illustrates the methodology and calculations needed to estimate required video storage capacity for a single storage device.

The CCTV system for an access control point will be upgraded. All existing components, with the exception of two analog PTZ cameras, will be removed and replaced with 5 new megapixel IP cameras, all fixed, and an NVR. Video encoders will be used to convert the analog camera signals to IP video streams which will be recorded to the NVR along with the 5 IP camera feeds. The security manager has stated that the fixed cameras will be recorded at 4 fps with a resolution of 1280 X 1024, and the PTZ cameras will be recorded at 10 fps with a resolution of 720 X 480. The security manager also stated that there is a 7-day video storage requirement for all access control point cameras. The IP cameras and the encoders for the PTZ cameras will all use MJPEG compression. How much video storage is required for the NVR?

Converting 7 days to 604,800 seconds, the storage required for a single fixed IP camera can be calculated as follows:

$$\mathbf{s_{fixed} = (604,800\ s)(4\ fps)(180\ kB) = 435,456,000\ kB \cong 415\ GB}$$

The storage required for a single PTZ camera can be calculated in a similar manner:

$$\mathbf{s_{ptz} = (604,800\ s)(10\ fps)(60\ kB) = 362,880,000\ kB \cong 346\ GB}$$

Taking into account the quantity of fixed and PTZ cameras, the total storage required for all cameras can be calculated as follows:

$$\mathbf{s_{total}} = (\mathbf{5})(\mathbf{415\ GB}) + (\mathbf{2})(\mathbf{346\ GB}) = \mathbf{2,767\ GB} \cong \mathbf{2.7\ TB}$$

(Note: 1 TB = 1024 GB = 1,073,740,000 kB)

4-10 CCTV WORKSTATION.

To allow viewing of live and recorded video, the designer must specify at least one workstation for each CCTV system, and multiple workstations may be required for a large distributed system. Because of the computational demands associated with processing and displaying digital video streams, a “gaming” computer is a good choice for a CCTV workstation. These computers generally have high-speed processors, large amounts of RAM, fast graphics cards with high-resolution output, and network interface cards supporting Gigabit Ethernet speed. For a single-operator workstation, a graphics card feeding one or two monitors will usually be sufficient for CCTV viewing and management. If three or four monitors are needed for a workstation, two dual output graphics cards or a single quad output graphics card must be specified for the workstation. The graphics card and monitor must provide display resolution equal to or greater than the highest resolution camera in the system. Any workstation that will be used to control PTZ cameras must be equipped with a joystick. Video management software that is compatible with all cameras, encoders, and recording devices must be installed on each workstation.

4-11 VIDEO ANALYTICS.

If surveillance is an important security objective for a CCTV system, the designer must consider including video analytics as part of the system specification. Video analytics software allows the user to input a specific set of rules for each scene of interest, which, if violated, generate visual cues on the monitor, thus drawing the operator’s attention to suspicious objects or behaviors. This capability to automatically prioritize scenes and highlight suspicious areas for the operator maximizes the effectiveness of surveillance activities. Video analytics can be especially beneficial when a single operator is required to perform surveillance with a large number of cameras. Video analytics algorithms can be embedded in IP cameras, encoders, and recording devices or they can run on dedicated file servers. Common rule violations programmed to alert the operator include crossing a virtual tripwire, loitering in a prohibited area, moving in the wrong direction, leaving an unattended object, and removing an object.

4-12 CCTV DESIGN PROCESS SUMMARY.

4-12.1 Define Security Objectives for the CCTV System.

Begin by evaluating specific project requirements in light of the four most common CCTV functions: 1) alarm assessment, 2) access control, 3) surveillance, and 4) evidentiary archives. Concisely state objectives with enough detail to facilitate camera selection and layout. Example objectives are as follows:

- Visually assess perimeter intrusion alarms for seven bistatic microwave sensor zones around the satellite communications facility.
- Visually identify the driver and vehicle prior to opening the gate at the test area.
- Perform surveillance of four exhibit areas in the museum and maintain a 30-day video archive for evidentiary purposes.

4-12.2 Develop a Camera Layout to Meet the Security Objectives.

Indicate camera locations on site plans and building floor plans, identifying each camera as fixed or PTZ. Specify the mounting configuration (wall, ceiling, pole, roof, etc.) for each camera, and select the appropriate camera and lens for the intended field of view.

4-12.3 Verify That Illumination Is Sufficient For Each Scene Of Interest.

Ensure that camera specifications for faceplate illumination are met and that uniformity ratios are within acceptable limits. Specify lighting upgrades as needed.

4-12.4 Specify Workstation Locations.

Indicate workstation locations on building floor plans, and describe the basic configuration of each workstation including quantity and size of monitors. Identify any special furniture or console requirements.

4-12.5 Specify Recording Locations and Capacity.

Indicate recording locations on building floor plans, and describe the type and quantity of recording devices required at each location. Calculate the required video storage capacity for each recording device.

4-12.6 Define Network Architecture.

Develop a block diagram to illustrate connectivity for all cameras, recorders, workstations, and networking devices. Specify cables required for equipment interconnection, and calculate bandwidth requirements for all network connections.

4-12.7 Define Power Requirements.

Determine the power requirements for each component. Specify all power circuits and the location of all power supplies.

4-12.8 Describe Software and Integration Requirements.

Specify features and functions required for camera control, video management, and analytics. State alarm assessment requirements for integration with intrusion detection and access control software.

CHAPTER 5 INTRUSION DETECTION SYSTEM

5-1 OVERVIEW.

The function of an IDS is to detect intruders. The detection of an intruder starts the “clock” on the Detect, Delay, Respond timeline addressed in Chapter Two, Electronic Security Systems Overview. The principal elements of an IDS include sensors, local processors, arm/disarm devices, workstations, and the central system along with the supporting data transmission infrastructure. These elements are shown in Figure 5-1. An IDS requires integration with a process and mechanisms for assessing and responding to intrusion alarms.

5-2 SYSTEM CONFIGURATION.

The designer must determine the appropriate IDS configuration early in the planning stage of a project. The four most important configuration issues that must be resolved are policy compliance, alarm monitoring location(s), zone definition, and IDS/ACS integration. These four issues are discussed in the following paragraphs.

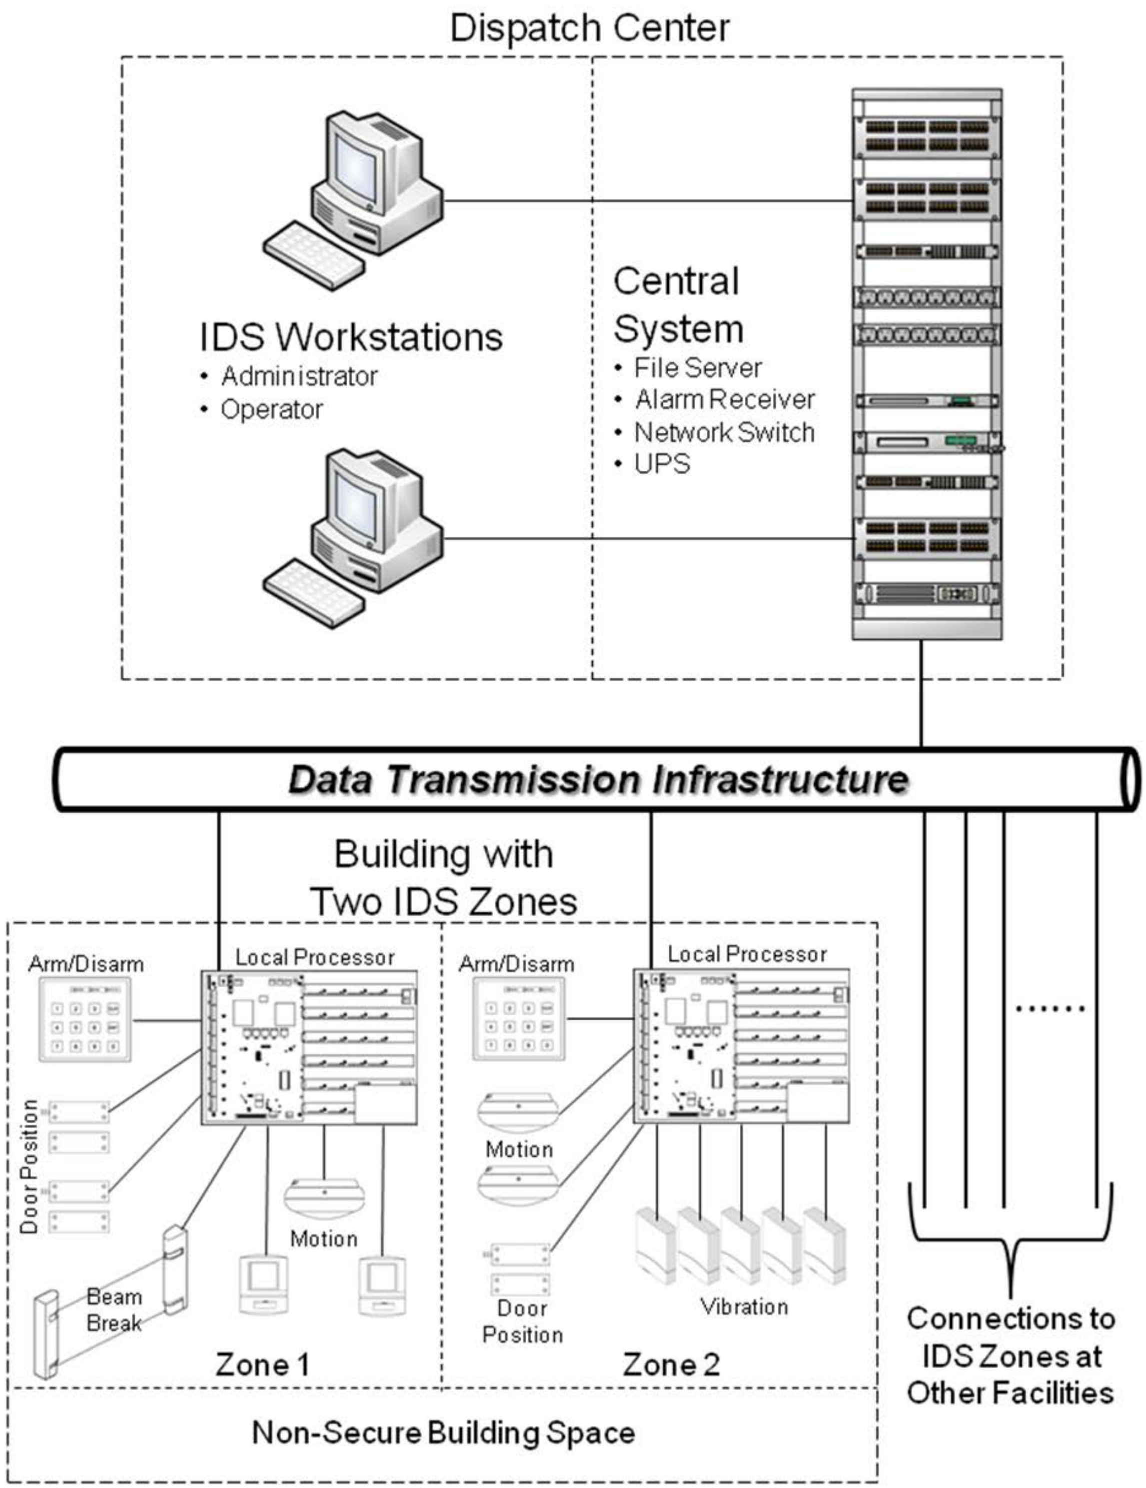
5-2.1 Policy Compliance.

Determining which assets require IDS coverage is an essential first step in the IDS design process. The designer must work closely with the facility owner/user to understand what assets are present and then determine whether or not IDS is required based on applicable security policy. The goal of this activity is to focus IDS coverage where it is required at a facility (arms room, SCIF, etc.) while avoiding frivolous investment to cover low-security areas (office suite, conference room, etc.) This activity is also beneficial in defining IDS zones as described in greater detail later in this section. Notional interior IDS configurations for a variety of assets are provided in Appendix C along with policy references for each. Examples of assets that generally require exterior perimeter IDS are special weapons (nuclear, chemical) storage facilities, high-value aircraft parking areas, and ballistic missile defense sites.

5-2.2 Alarm Monitoring Location(s).

Since most IDS requirements are focused on protecting unattended high-value assets, the designer must identify the best method for continuous alarm monitoring during periods when the secure area is not occupied. For IDS zones located in a facility that has a continuously-manned security desk, local monitoring may be the best option. Most buildings on military installations, however, do not have around-the-clock security staffing. This is especially true of smaller buildings that may have only one or two IDS zones such as an arms room or SECRET open storage area. The best option for these facilities is connecting the IDS zone(s) to a base-wide IDS with continuous alarm monitoring at the Dispatch Center. This configuration is illustrated in Figure 5-1. For some projects, it may be appropriate to provide the capability to monitor IDS alarms locally (at the security desk during duty hours, for example) and also at the Dispatch Center (primarily after duty hours).

Figure 5-1. Example Intrusion Detection System (IDS).



5-2.3 Zone Definition.

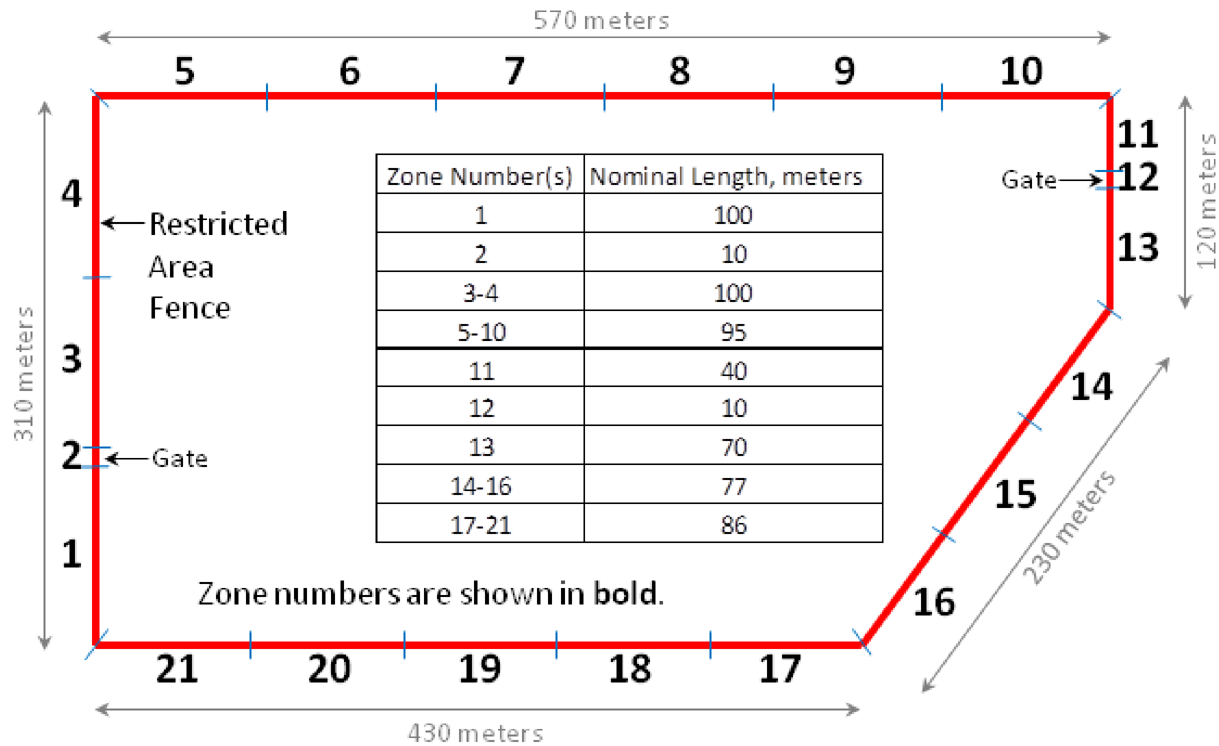
The designer must define zones for both interior and exterior IDS. In general terms, an interior IDS zone is a room or space within a building that can be armed and disarmed independently from all other zones. The simplest interior zone is a single room with a specialized function protected by a few sensors connected to a local processor. A good example of a simple interior zone is an arms room. A large zone may encompass several adjacent rooms (to include an entire floor, wing or office suite in some buildings) or a large open area, and it may have twenty or more sensors connected to the local processor. Regardless of the size or complexity of a given interior zone, the designer should specify that each sensor annunciate as a discrete, identifiable alarm point in the IDS. Examples of interior IDS zones are provided in Appendix C. An exterior IDS zone is a continuous section of perimeter for which alarms are annunciated independently from all other alarm zones.

Like its interior counterpart, an exterior IDS zone can also be independently armed and disarmed. The designer must determine the appropriate perimeter zone layout based on the shape of the perimeter, length of each side or fence segment, location of access roads and gates, and the range capability of the candidate sensor technology. As a general rule, shorter zones enhance alarm assessment and response, but longer zones are more economical. Best practice dictates that a standard zone length of approximately 330 feet (100 m) achieves a good balance between system cost and system effectiveness and is well within the range capabilities of most sensor technologies. Another advantage of a 330 feet 100 m) zone is that alarms can be visually assessed anywhere in the zone with a single fixed camera (assuming that the appropriate lens focal length and faceplate resolution are specified). An example of an exterior IDS zone layout is shown in Figure 5-2.

5-2.4 IDS/ACS Integration.

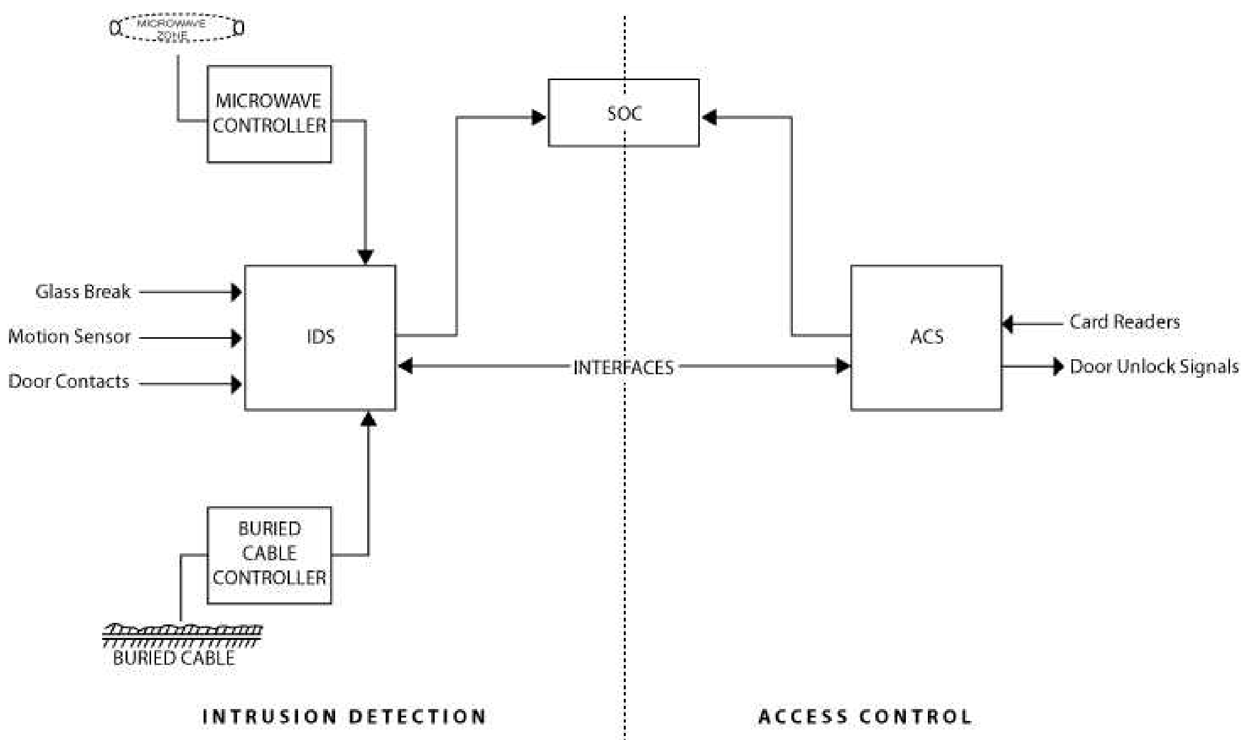
For each ESS project, the designer must determine whether IDS and ACS functions would be best provided through a single unified IDS/ACS or through two separate systems. Even if it is appropriate to field separate systems as shown in Figure 5-3, some degree of IDS/ACS integration is often desirable. In general, any output from one system can be incorporated as an input to another system through a simple relay-to-relay integration. As an example, door held open violations from an ACS can be annunciated as alarms in a separate IDS by wiring ACS outputs to IDS inputs at the local processor level. Additional information on IDS/ACS integration is provided in Chapter 8.

Figure 5-2. Example Exterior IDS Zone Layout.



Zone Number(s)	Nominal Length, meters
1	100
2	10
3-4	100
5-10	95
11	40
12	10
13	70
14-16	77
17-21	86

Figure 5-3. Separate ACS and IDS.



5-3 INTERIOR SENSORS.

This section covers both interior point sensors and interior volumetric sensors. For additional information on interior IDS sensors to include types, purposes, principles of operation, common causes of false alarms, and appropriate applications refer to DoD O-2000.12-H. Table 5-1 provides application notes for interior IDS sensors.

5-3.1 Interior Point Sensors.

5-3.1.1 Balanced Magnetic Switch(s) (BMS).

BMS use a magnetic field or mechanical contact to determine if an alarm signal is initiated (for example, if an access portal such as a door, window, or roof hatch has been opened). BMS differ from standard magnetic status switches in that BMS incorporate two aligned magnets with an associated reed switch. If an external magnet is applied to the switch area, it upsets the balanced magnetic field such that an alarm signal is received. Standard magnetic switches can be defeated by holding a magnet near the switch. Mechanical contacts can be defeated by holding the contact in the closed position with a piece of metal or taping them closed. Balanced magnetic switches are not susceptible to external magnetic fields and will generate an alarm if tampering occurs. Therefore, only specify balanced magnetic switches for access portal sensors. Figures 5-4, 5-5, and 5-6 show some typical applications of BMS.

Figure 5-4. Sample Door Configuration.

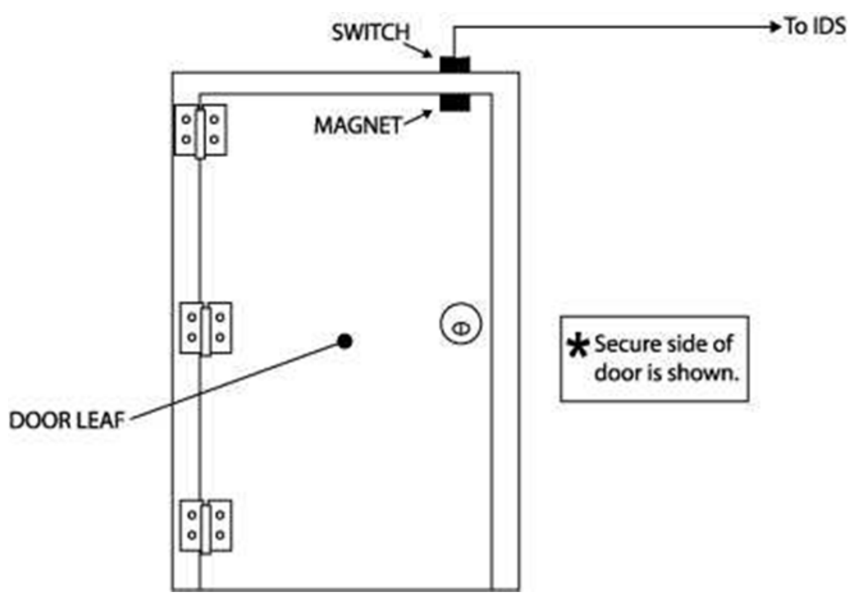


Figure 5-5. Sample Window Configuration.

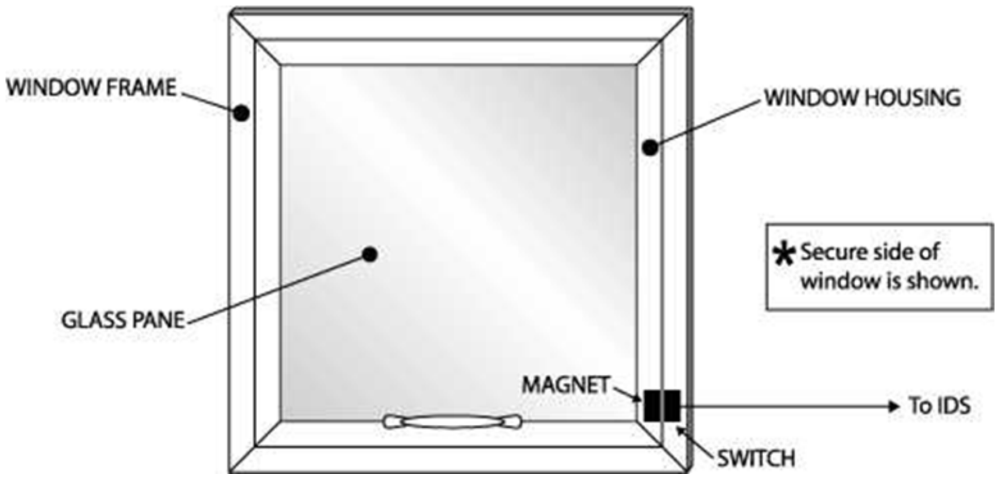

Figure 5-6. Sample Roof Hatch Configuration.

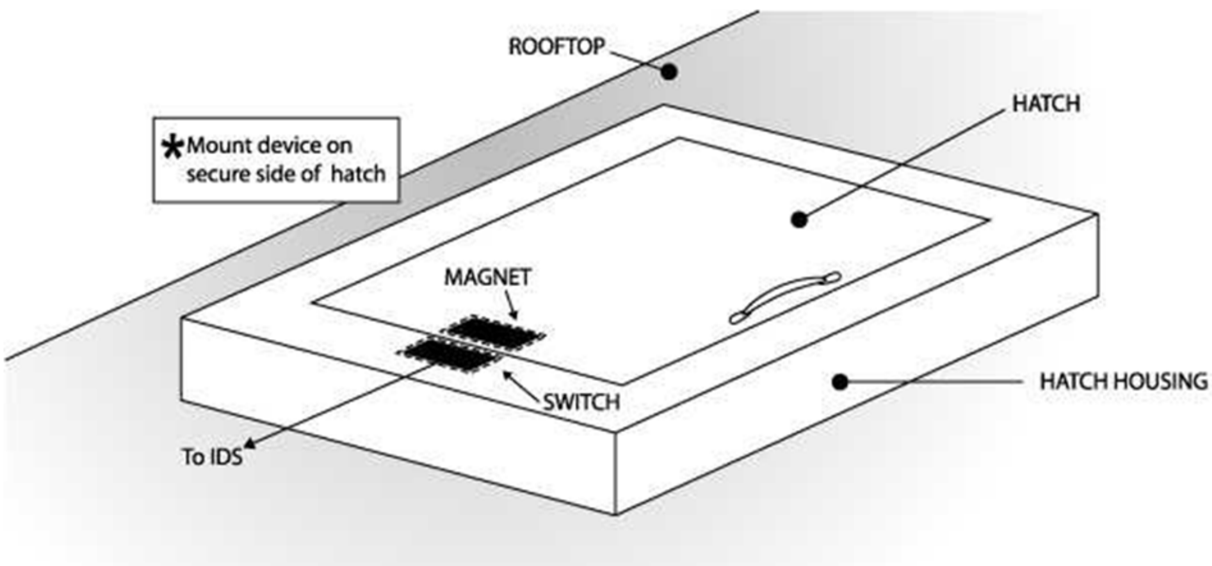


5-3.1.2 Glass Break.

Glass break sensors are a good intrusion detection device for buildings with a lot of glass (windows, doors with glass panes). Glass as an exterior protection barrier is easily defeated. Windows can be quickly and easily broken. Consider the case of installing a card reader on an administrative exterior door. The determined intruder will not let the door lock deter the intrusion effort, but can take the option of breaking nearby accessible windows. Glass break sensors can be used to cover multiple windows.

There are three basic types of glass-break sensors: acoustic sensors (listens for an acoustic sound wave that matches the frequency of broken glass), shock sensors (feels the shock wave when glass is broken), and dual technology sensors (senses acoustic and shock vibrations). Glass-break sensors must be used in conjunction with other methods (such as volumetric sensors) because they do not sense motion or intrusion from entering a door or hatch.

5-3.1.2.1 Glass Types.

There are a variety of glass types: plate, tempered, laminated, and wired. For inhabited facilities, UFC 4-010-01 requires laminated glass for windows. Most glass break sensors work with all glass types to include laminated glass.

5-3.1.3 Glass Break Sensor Guidance.

a. Do not use window mounted glass break sensors.

b. Glass break sensors should only be used in protected areas with windows on the ground floor or that are easily accessible.

c. Use volumetric sensors in conjunction with glass break sensors in protected areas.

d. Use dual-technology glass break sensors (acoustic and shock wave). There is not a significant price difference between a simple acoustic sensor and a combination sensors (acoustic and shock). For the nominal component price increase, which is a fraction of the total installed cost, the increased capability justifies the higher cost.

e. Check glass break sensor specifications to ensure they are rated for the type of glass used, typically laminated glass.

5-3.2 Interior Volumetric Sensors.

Volumetric sensors monitor an internal area to detect the presence of an intruder. There are several types of volumetric sensors including acoustic, infrared linear beam sensors, passive infrared (PIR), ultrasonic and dual-technology (microwave and PIR).

5-3.3 Acoustic Sensors.

Acoustic sensors use passive listening devices to monitor building spaces. An application is an administrative building that is normally only occupied in daylight working hours. Typically, the acoustic sensing system is tied into a password protected building entry control system, which is monitored by an off-site Central Station. When someone has logged into the building with a proper password, the acoustic sensors are disabled. When the building is secured and unoccupied, the acoustic sensors are activated. After hours intruders make noise which is picked up by the acoustic array and an alarm signal is generated.

Acoustic sensors act as a detection means for stay-behind covert intruders.

5-3.4 Passive Infrared (PIR) Sensors.

Passive Infrared (PIR) Sensors are one of the most common interior volumetric intrusion detection sensors. PIRs pickup heat signatures (infrared emissions) from intruders by comparing infrared receptions to typical background infrared levels. Typically, activation differentials are 3 degrees Fahrenheit. These devices work best in a stable environmentally-controlled space.

5-3.4.1 PIR Coverage.

Different lenses can be placed on the PIR to focus or spread-out the coverage of the detection window. In other words, standard supplied covers for lens can be made to provide a narrower or wider sensor coverage area.

5-3.4.2 PIR Sensor Guidance.

a. Use caution when specifying this sensor for areas that can be exposed to sudden changes in background environmental temperature.

b. Best use is in interior climate-controlled spaces.

c. PIRs can receive false alarms from other heat radiating objects such as heat-system registers, rodents, pets, or other warm objects (in one case a mop bucket with hot water in it).

d. PIRs can also be defeated by a trained, slow-moving intruder. (Very hard to achieve.)

e. PIRs are much more sensitive to travel crossing its sensing area as opposed to travel toward the sensor.

5-3.5 Ultrasonic Sensors.

Ultrasonic Sensors use active transmission of sound waves to pick up intruders much like a radar transmitter and receiver. To get an alarm signal, a signal must be transmitted, bounced off an intruder and receipt signal received. Ultrasonic sensors are rarely used.

5-3.6 Dual-Technology Sensors.

Dual-technology sensors use both microwave and PIR sensor circuitry within a single housing. An alarm condition is generated if either the microwave or PIR sensor detects an intruder. In some dual-technology sensors, alarm settings may be adjusted to require that both the microwave and the PIR unit detect an intruder presence before an alarm condition is generated. Since two independent means of detection are involved, false alarm rates are reduced when configured in the “AND” condition (both microwave and PIR sense an intruder). Dual-technology sensors can only be used in a SCIF, vault, or secure room if the technologies operate in an “OR” configuration (either the microwave or PIR sense an intruder). Therefore dual technology sensors are not recommended for this application.

Table 5-1. Application Notes – Interior IDS Sensors.

Application	Sensor Type	Notes
Doors	Balance magnetic switch (BMS).	Proper alignment and properly installed doors minimize false alarms. Used in conjunction with volumetric sensors.
Windows	BMS Break Glass Sensor Acoustic Shock Dual Technology	Use combination acoustic/shock wave sensor. Used in conjunction with volumetric sensors.
Roof Hatches	BMS	Proper alignment and proper installation minimize false alarms. Used in conjunction with volumetric sensors.
Room/Hallways	Volumetric Sensors: Passive Infrared Microwave Dual Tech (PIR & MW) Ultrasonic	Do not use dual-tech devices in SCIFs.
Walls	Vibration Sensors Fiber Optic Sensors.	Design to detect a compromise of a wall to a secure area.

5-4 EXTERIOR SENSORS.

This section covers exterior sensors for intrusion detection in the following categories: (1) open terrain sensors such as infrared and microwave sensors, (2) property/fence-line sensors such as electro-mechanical systems and fiber-optic sensing systems, and finally (3) other sensor technologies such as buried cable and wide area sensors.

5-4.1 Open Terrain.

Open terrain sensors include infrared, microwave systems, combination (dual technology), and vibration sensors. In general, open terrain sensors work best on flat, cleared areas. Heavily or irregular contoured areas are not conducive to open terrain sensing systems.

5-4.1.1 Infrared Sensors.

5-4.1.1.1 Passive.

Passive sensors can work well in exterior environments, but outside interference issues of reflected light or radiated light have to be considered.

5-4.1.1.2 Active.

Active infrared sensors transmit an infrared signal via a transmitter. The location for reception is at a receiver. Interruption of the normal IR signal indicates an intruder or object has blocked the path. The beam can be narrow in focus, but should be projected over a cleared path. Refer to Figure 5-7 for a conceptual diagram of how an active infrared IDS works.

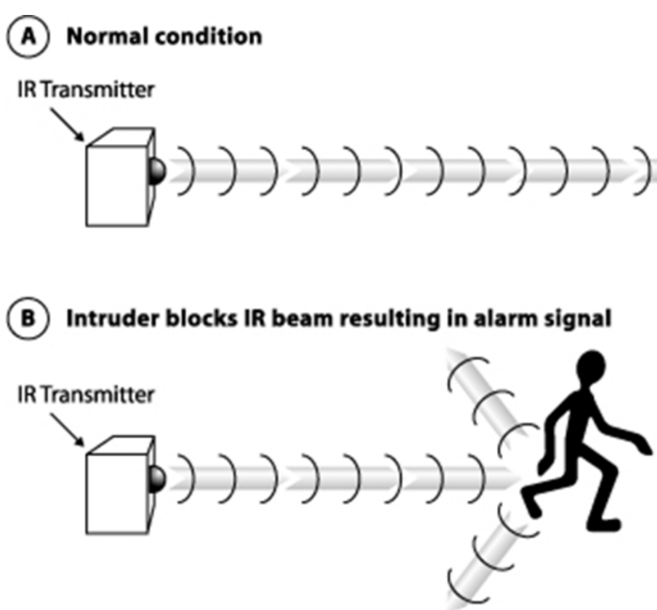
5-4.1.1.3 Infrared Sensors Guidance.

a. Check that the terrain is suitable for clear signal transmission.

b. Infrared arrays do not work well in areas with heavy snowfall because drifts or snow mounds cover sensors and or block transmission and reception paths.

c. Shield receiver from direct sunlight.

Figure 5-7. Active Infrared IDS.



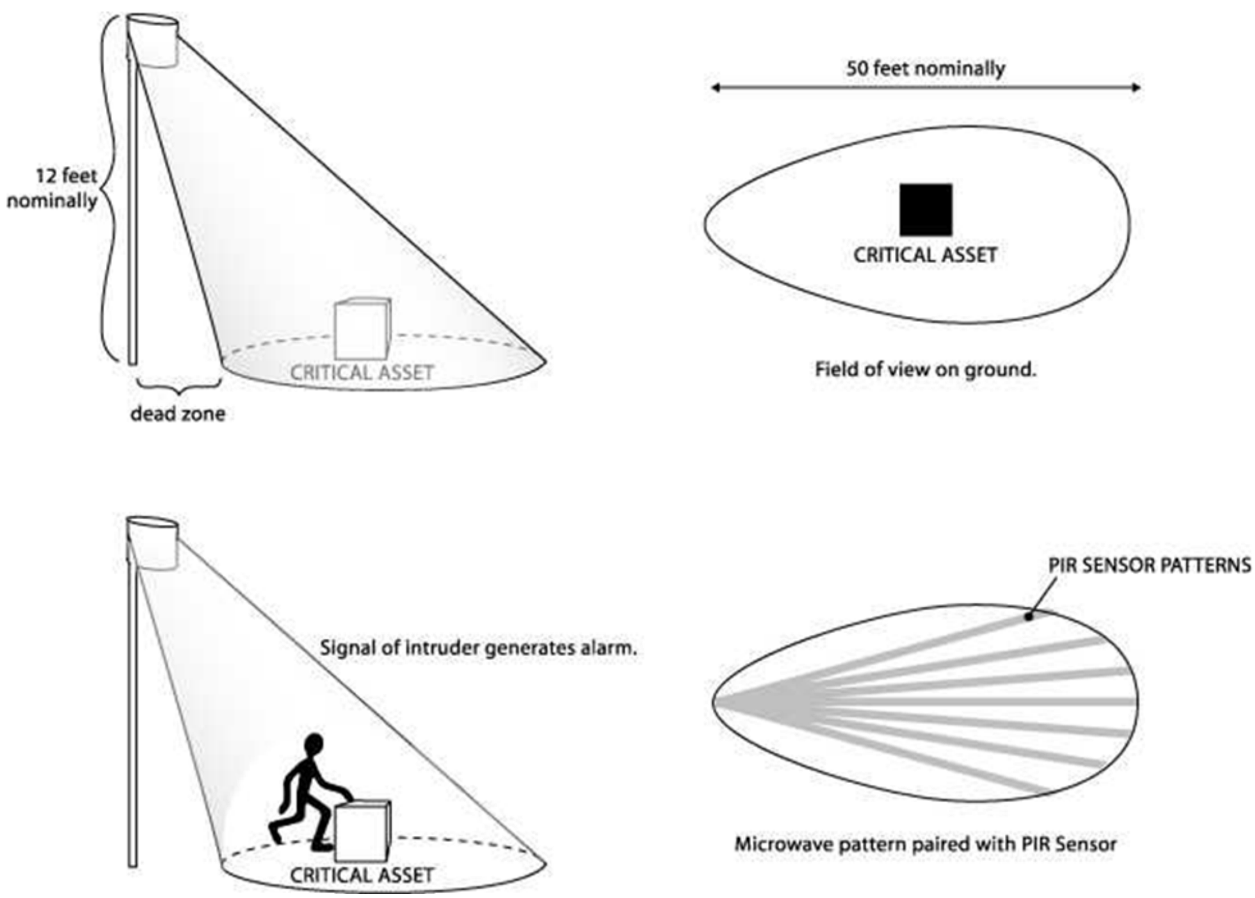
5-4.1.2 Microwave Sensors.

Microwave sensors come in two configurations: bistatic and monostatic. With both bistatic and monostatic sensors, the sensors operate by radiating a controlled pattern of microwave energy into the protected area. The transmitted microwave signal is received, and a base level "no intrusion" signal level is established. Motion by an intruder causes the received signal to be altered, setting off an alarm. Microwave signals pass through concrete and steel and must be applied with care if roadways or adjacent buildings are near the area of coverage. Otherwise nuisance alarms may occur due to reflected microwave patterns.

5-4.1.2.1 Monostatic.

Monostatic microwave sensors use a single sensing unit that incorporates both transmitting and receiving functions. Many monostatic microwave sensors feature a cut-off circuit, which allows the sensor to be tuned to only cover within a selected region. This helps to reduce nuisance alarms. Refer to Figure 5-8 for illustrations of a monostatic microwave sensor and associated footprints.

Figure 5-8. Monostatic Microwave Sensor and Associated Footprints.



5-4.1.2.2 Bistatic.

Bistatic microwave sensors are more commonly used than monostatic sensors for wide-area surveillance. Bistatic microwave sensors use a transmitter and receiver pair. Bistatic sensors work over longer distances than mono-static sensors. Typical distances for transmitter-receiver pairs are 10 - 600 feet (3 – 182 m) for X-band frequencies and

100 - 1500 feet (30 – 457 m) for K-band frequencies. The bistatic transmitter typically sends out a high frequency open-band radio frequency in a 3-8 degree pattern. (Common microwave frequencies are X-band 10 GHz or K-band 24 GHz.) Refer to Figure 5-9 and Figure 5-10 for illustrations of bistatic microwave sensor operation.

Figure 5-9. Bistatic Microwave Sensor Operation.

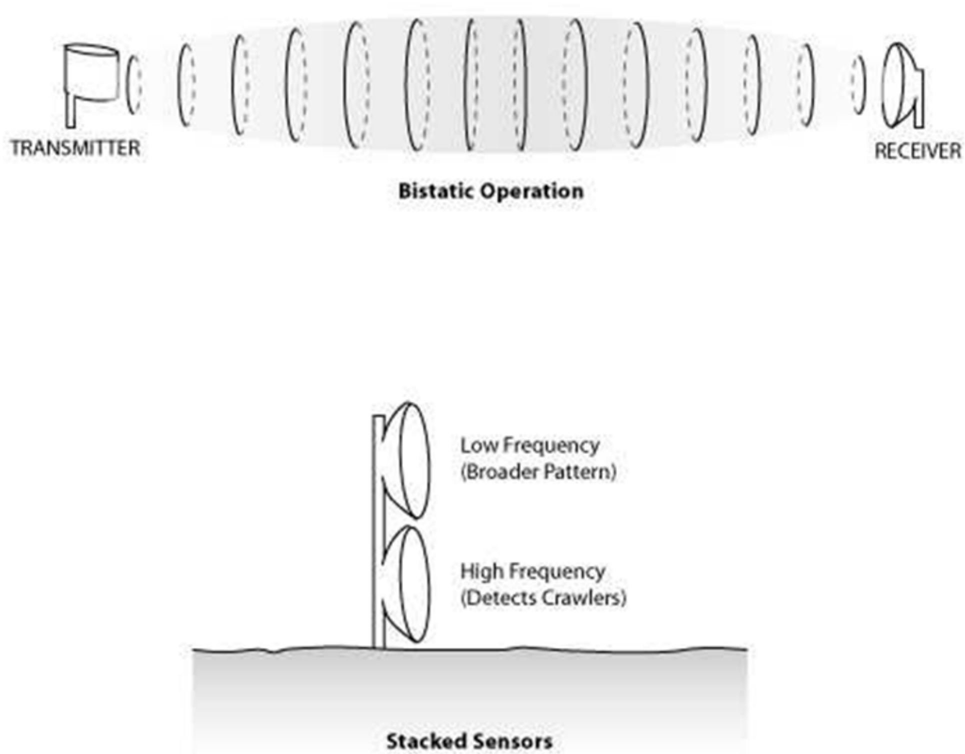


Figure 5-10. Typical Bistatic Microwave Layout and Guidance.

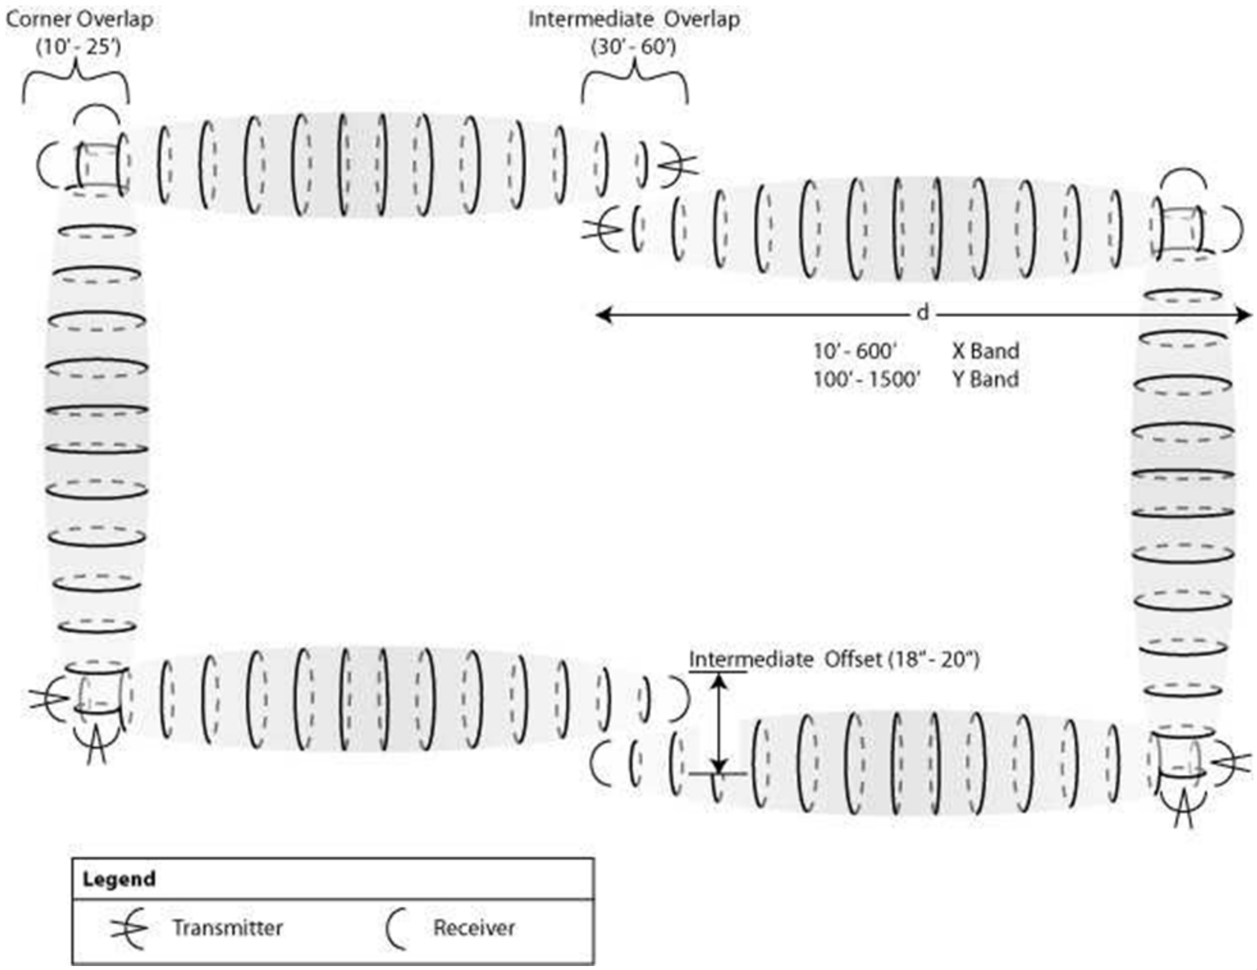


5-4.1.2.3 Microwave Design Guidance and Recommendations.

a. The detection zone should be free of bushes and obstructions.

b. The detection zone should be graded to within three inches to detect crawling intruders.

c. Grass should be kept cut to less than three inches. A gravel surface prepared for water drainage is better than a grass surface. Since a typical microwave pattern is 10 feet (3 m) by 10 feet (3 m), a 20 foot (6 m) wide gravel bed works well.

d. Avoid water puddles. The wave action of wind on water can cause nuisance alarms.

e. For high security applications, consider use of stacked sensors (one sensor on top of another), with the lower frequency (wider/broader pattern) on top and the higher frequency (more focused pattern) to detect crawling intruders on the bottom.

f. Do not place sensors too close to perimeter fences. Wind action on the fence fabric can cause false alarms.

5-4.1.3 Dual-Technology.

As discussed previously, dual-technology sensors use a combination of PIR and microwave technology. Techniques of “ANDing” or “ORing” the microwave signal and the PIR signal are reviewed in Paragraph 5-6 “AND/OR” CONFIGURATION OPTIONS.

5-4.1.4 Vibration Sensors.

Vibration sensors sense intrusion through vibrations caused by personnel or vehicular movement. These sensors are not well employed near railroad tracks, roadways, rock quarries, or runways. Many of these systems use wireless battery-powered sensors to send alarm signals to a notification station.

5-4.2 Property/Fence Line Detection.

Several types of fence-mounted perimeter IDS exist. With all fence-mounted systems it is critical that the fence construction be of high quality, with no loose fabric, flexing, or sagging material. The fence must have solid foundations for posts and gates. Otherwise nuisance alarms may occur. Five types of exterior fence-sensing systems will be discussed: (1) electro-mechanical systems, (2) taut-wire systems, (3) coaxial strain-sensitive cable, (4) Time Domain Reflectometry (TDR) systems, and (5) fiber-optic strain-sensitive cable systems.

5-4.2.1 Electro-Mechanical Systems.

According to the “Perimeter Security Sensor Technologies Handbook,” electro-mechanical fence-sensing systems use either mechanical inertia switches or mercury switches to detect a fence climbing or cutting incident. An electronic controller looks for momentary contact openings of the inertia or mercury switches. For more information on electro-mechanical fence-sensing systems refer to the “Perimeter Security Sensor Technologies Handbook.” Due to advances with other (better) technologies, electro-mechanical systems are not recommended for DoD use.

5-4.2.2 Taut Wire Systems.

Taut-wire fence-sensing systems use a series of parallel wires under tension with numerous micro-switches attached to it. The system is very sensitive, but requires frequent maintenance. For more information on taut-wire systems refer to The Design and Evaluation of Physical Protection Systems.

5-4.2.3 Coaxial Strain-Sensitive Cable Systems.

Coaxial strain-sensitive cable systems use a coaxial cable woven through the fabric of the fence. The coaxial cable transmits an electric field. As the cable moves due to strain on the fence fabric caused by climbing or cutting, changes in the electric field are detected within the cable, and an alarm condition occurs.

Coaxial strain-sensing systems are readily available and are highly tunable to adjust for field conditions due to weather and climate characteristics. Some coaxial cable systems are susceptible to electromagnetic interference and radio frequency interference.

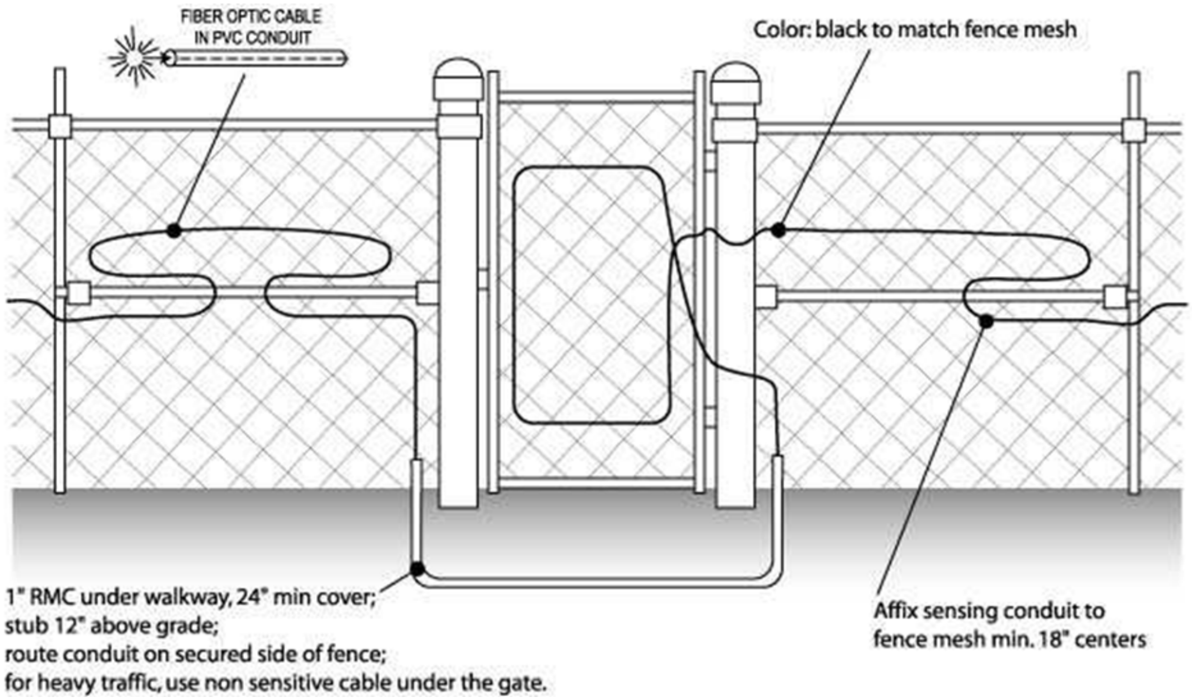
5-4.2.4 TDR Systems.

Time Domain Reflectometry systems send an induced radio-frequency (RF) signal down a cable attached to the fence fabric. Intruders climbing or flexing a fence create a signal path flaw that can be converted to an alarm signal. When the conductor cable is bent or flexed, a part of the signal returns to the origination point. This reflected signal can be converted to an intrusion point by computing the time it takes for the signal to travel to the intrusion point and return. The cable can be provided in armored cable, which requires more than a bolt cutter to sever the sensing cable. These systems require their own processor unit and can be configured in a closed loop, such that if the cable is cut, a detection can be detected by the other return path.

5-4.2.5 Fiber-Optic Strain-Sensitive Cable Systems.

Fiber-optic strain-sensitive cable systems are similar to the coaxial strain-sensitive cable systems. The fiber-optic system uses a fiber-optic cable, rather than a coaxial cable, woven through the fence fabric. Strain on the fence fabric causes micro-bending of the fiber cable, which is monitored by the control panel and generates an alarm condition. Figure 5-11 shows a typical fiber-optic fence detection illustration. Fiber-optic strain-sensing systems are relatively newer detection systems but have a strong following. The systems are readily available and are highly tunable to adjust for field conditions due to weather and climate characteristics. The systems are impervious to lightning, electromagnetic interference, radio frequency interference, or other electronic signals and can be used over long distances.

Figure 5-11. Typical Fiber Optic Fence Detection System.



5-4.2.6 Defeat Measures and False Positives.

Possible defeat measures include tunneling, jumping, or bridging across the fence system. Careful climbing at corner posts may not generate sufficient vibration to generate an alarm condition.

Possible false positives can occur from debris, animals, and plants.

5-4.3 Other Exterior Sensors.

5-4.3.1 Buried Cable.

Two common types: buried ported cable and buried fiber-optic cable. The two principle advantages of buried cable are that (a) it is covert, and (b) it follows the terrain. A limitation is buried cable systems do not work well with shrubbery or trees on it and require landscaping and maintenance. It is important that the cable be buried to a uniform depth. Changes in soil conductivity can affect the sensor readings.

5-4.3.2 Ported Cable.

Ported cable comes in two principal configurations, Single cable and paired cable. A single cable system uses one cable to create a sensing field approximately 6 feet (1.8 m) in diameter around the cable. Paired cable systems use two cables routed in parallel approximately five feet (1.5 m) apart. One cable transmits and the other receives a signal to create the sensing field.

5-4.3.3 Fiber Optic.

Fiber optic lines can be used to monitor pipelines or manholes.

5-4.3.4 Wide Area Sensors.

Wide area sensors such as radar can be employed on logical approach paths for large terrain or water territories/boundaries. Wide area sensors can assist response forces with early alerting or tracking of intruders. This technology approach has the advantage of being able to detect intruders beyond the defined perimeter. In other words, the system can detect intruders before they have crossed the protected area's perimeter.

5-4.4 Double Fence Concept.

When fence detection sensors are used, the best application is to use the double-fence concept. The typical configuration is outer clear zone, outer fence, isolation zone, inner fence, and inner clear zone, see Figure 5-12. Outer fence line defines the protected or restricted area boundary and is intended to keep animals, people, vehicles, and windblown debris out of the isolation zone to reduce nuisance alarms. No sensors should be placed on the outer fence of a double fence line system. Refer to MIL-HDBK-1013/10 (scheduled to be replaced by UFC 4-022-03, Security Engineering: Fences and Gates) for fence requirements.

Figure 5-12. Double Fence Example.

5-4.5 False Alarm Causes for Exterior Sensors.

Table 5-2 displays typical false alarm causes for exterior IDS sensors. Snowfall, removal of snow, winds, temperature change, and rain drainage are some factors to consider in exterior sensor selection. Refer to the "Perimeter Security Sensor Technologies Handbook" for more information on exterior IDS sensors.

Table 5-2. False Alarm Causes—Exterior IDS Sensors.

Sensor Type	False Alarm Cause	Notes
Active Infrared	Animals Wind-blown debris	Fencing mitigates animal false alarms
Passive Infrared (PIR)	Reflected light Radiated heat	Not recommended
Microwave	Nearby movement outside IDS area	Use of dual-technology PIR minimizes false alarms
Dual Technology	Same as PIR and microwave	Good choice. Uses both microwave and PIR
Vibration	Railroads—trains Roadways—vehicles Runways—airplanes Rock quarries—explosions Seismic event	Only works well in low background vibration areas
Coaxial Strain-Sensitive	Wind flexing fence EMI	Temperamental
Fiber-Optic	Improper noise level adjustment Animal activity	Recommended technology, provided suitable fence-mount is provided and animals are excluded from the area
Buried Cable	Ground shifting due to standing or puddling water, or erosion.	Varying terrain or material composition (asphalt pavement to grass to gravel) requires adjusting sensitivity to match each material
Ported Cable	EMI Movement of nearby vehicles or medium to large animals Congregation of small animals.	Very susceptible to EMI from large electrical equipment or substations and should not be used near these installations

5-5 VIDEO ANALYTICS FOR IDS.

Although video analytics can be very effective as a surveillance tool (see Chapter 4, paragraph VIDEO ANALYTICS), it should not be considered a primary IDS technology on par with the proven interior and exterior sensors described previously in this chapter. For most common IDS applications, traditional IDS sensors are generally superior to video analytics in terms of probability of detection, nuisance alarm rate, integration with alarm monitoring systems, and cost. The designer may consider specifying video analytics as an IDS sensor for projects where unusual site conditions bring into question the viability of all other sensor technology options.

5-6 “AND/OR” CONFIGURATION OPTIONS.

Subcomponents of an IDS can be configured in an “AND” or “OR” configuration. In the “AND” configuration, two or more sensors must detect intrusion for an alarm notification to occur. In the “OR” configuration, only a single sensor need go into alarm for a notification to occur. The “AND” configuration is used when a concern about nuisance alarms exists. The “OR” configuration is more secure and is used to increase the probability of detection. An example is pairing two microwave sensor fields. In the “AND” configuration, both Field A and Field B have to be in alarm to cause alarm notification. In the “OR” configuration, if either Field A or Field B go into alarm, then an alarm signal is sent to the Dispatch Center. Addressable sensors allow the capability to switch the “AND/OR” configuration from the Dispatch Center. However for some facilities, such as SCIFs, this feature must be disabled. Table 5-3 displays the advantages and disadvantages of each configuration.

Table 5-3. Advantages and Disadvantages of “AND” and “OR” Configurations.

	Pros	Cons
AND	Decreased nuisance alarms	Decreased probability of detection
OR	Increased probability of detection	Increased nuisance alarms

5-7 IDS DESIGN GUIDANCE.

The IDS Designer must first determine the design objectives for the project, usually expressed as a Probability of Detection (Pd). Some sample requirements are a Pd of 95% for most assets and a Pd of 99% for critical assets. Understanding the requirement, the designer can then go about laying out the ESS and strategy.

5-7.1 Critical Asset Case Study.

Consider a case study of having to provide a Pd of 99% for a critical asset. Some sample vendor-specifications for three types of IDS sensors are shown in Table 5-4.

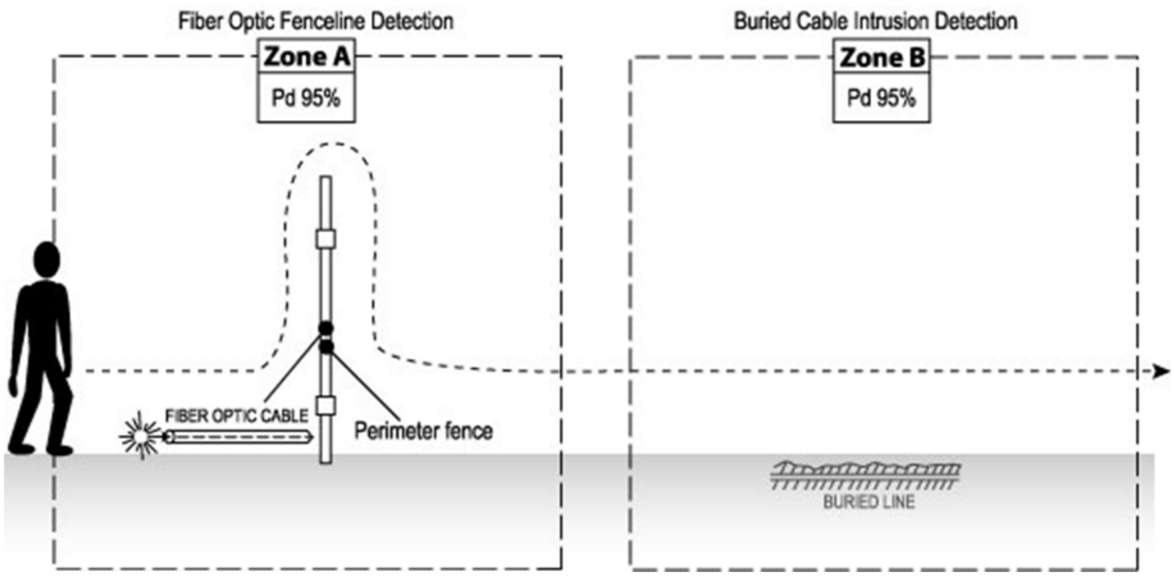
Table 5-4. Sample Probability of Detection Factors.

Product	Probability of Detection
Buried Cable	95%
Fence-Mounted Fiber Optic	95%
Microwave	99%

For the purpose of demonstrating the application of different approaches, two alternatives for meeting the project requirement are presented. While an individual component probability of detection may not meet a more demanding specification, layering or combining components can result in a higher overall system probability of detection as illustrated below:

- Option A: Use a microwave perimeter system with a Pd of 99%. The equipment and system meets the project objectives and no other IDS methods are technically required to meet the specified intrusion detection range.
- Option B: If the scenario is such that terrain contour makes microwave technology unfeasible, the IDS designer could consider a zoned approach of combining a fence mounted fiber-optic detection system with a buried cable detection system as shown in Figure 5-13.

Figure 5-13. Zoned Detection System.



5-7.1.2 Probability of Detection (Pd) Calculation.

If the two detection systems shown in Figure 5-13 are integrated in an electrical "OR" logic, an alarm from either system results in an IDS alarm. The resultant net Pd can be calculated as follows:

(Pd)A = 95%; therefore the probability of not being detected is (1-Pd) = 1-0.95= 5%

The probability of not being detected in Zone B is similarly calculated as 5% as well.

The net probability of not being detected by either Zone A or Zone B can be calculated by multiplying the chances of not being detected in either A or B together as follows:

= (1-Pd) A * (1-Pd) B
=5% * 5%
=0.25%
=0.0025.

Thus the probability of not being detected by either intrusion system A or B is 0.25%, which is another way of saying the probability of being detected is 99.75% or nominally 99%.

In the above example, two solutions of meeting a requirement to meet the Pd of 99% were analyzed. There are other options than the two discussed. The example presented is an academic case study to demonstrate different values of Pd for and methods of layered protection. It is based on convenient Pd factors for two common intrusion detection technologies based (fiber optic fence line and buried cable). For each project, the IDS designer will have to design a solution taking into account project requirements, available technology, site-specific information, and possible causes of false alarms.

5-7.2 Additional IDS Design Guidance.

Additional IDS design guidance is provided in Tables 5-5 and 5-6.

Table 5-5. IDS Design Guidance.

Issue	Recommendations
Door Status Monitoring	Restricted area perimeter monitoring should be included at all building entrance and exit points, to include perimeter doors, roof hatch openings, and doors used for emergency egress. Doors for emergency egress should include an audible device (door screamer) on the secured side. All door monitoring should be via balance magnetic switches. The status switch contacts must be closed when the door is closed.
Redundant Path for Alarms	In large critical systems, plan an alternate path for alarms. One method of achieving this is to route IDS alarms into the ACS and out to the Dispatch Center as an alternate path to a normal primary route of having the IDS inputs report directly to the Dispatch Centers.

Table 5-6. Exterior IDS Applications Table.

Application	Sensor Type	Notes
Fence Line	Taut wire	Very sensitive, high maintenance.
	Coaxial strain-sensitive	Works, susceptible to EMI.
	TDR	When fence is not in good condition.
	Fiber Optic	More expensive, but better filtering.
Gates	BMS	Simplest device, provide lightning protection.
	Fence detection systems	Will detect a fence intruder that climbs the gate.
	Magnetic loop sensor	Will detect vehicles only.
Open areas	Microwave	Works well in desert environments, does not work well around trees and un-cleared line-of-sight areas.

	Ported Coaxial	Does not work well near electrical substations, certain geographic areas with unusual magnetic influences. Can be effective, when used as part of a double-fence system.
Note: Table is not all inclusive of all exterior sensor options. Refer to text above for more detail.		

5-8 SUMMARY.

In general, intrusion detection is challenging. There is no one single sensor system that works in all applications. Realistically, the best Pd that can be achieved by a single system is 95 percent. Given enough time and resources, all intrusion detection systems can be defeated. For simple installations with lower security needs, a fiber-optic fence-perimeter detection-system works well. For higher security applications, double fences/intermediate, gravel bed and microwave sensors offer improved security.

CHAPTER 6 DATA TRANSMISSION MEDIA (DTM)

6-1 INTRODUCTION.

A critical element in an integrated ESS is the data transmission media (DTM) that transmits information from sensors, access control devices, and video components to display and assessment equipment. A DTM link is a path for transmission of data between two or more components, and back to the Dispatch Center. An effective DTM link ensures rapid and reliable transmission of data, is resistant to compromise, has redundancy, and is conducive to rapid fault detection and repair. A number of technology issues are relevant to implementing the DTM, such as bandwidth analysis, secure communications, network topology, communication redundancy, transmission modes or protocols, and transmission media. These issues are discussed in the following sections.

6-2 BANDWIDTH ANALYSIS.

With any data-intensive transmission network, such as an electronic security system network, it is important to determine the amount of bandwidth consumed by the system under normal and high-traffic conditions. This can affect network cost, reliability, and transmission speed. Of the three ESS subsystems, CCTV generally requires the most bandwidth and IDS requires the least. ACS bandwidth requirements are generally low, but bandwidth usage will spike during database synchronization cycles. For the DTM, design a system capable of handling the total bandwidth (plus contingency) for each link required in the system. Table 6-1 presents bandwidth usage values for some common ESS components.

6-3 SECURE COMMUNICATIONS.

No matter what transmission mode or media is selected, it is important that a method for securing communications be included. This includes physical protection, such as providing conduit for all conductors, as well as electronic protection, such as encrypting communication transmissions and supervising alarm circuits. Refer to Chapter 9 for the subsection on Tamper Protection, which includes a discussion on physical protection of conductors as well as more general information on encryption requirements.

6-4 NETWORK TOPOLOGY.

One of the initial steps in designing and evaluating a security DTM is to identify the topology to be used. Additionally, the designer must coordinate network requirements with installation security and the communications office. Typically, networked security systems are a Proprietary Security Network. Refer to Chapter 8, “ESS Subsystem Integration” for more information.

Table 6-1. Bandwidth Usage Values.

Component	Bandwidth Usage Range (kilobits per second)		
	Low	High	High bandwidth usage results from:
IDS Local Processor	1	3	high alarm rate, encryption
ACS Local Processor	5	50	high-volume portal traffic, large database synchronizations
IP Camera	100	70,000	high frame rate and resolution, low compression ratio
ESS Workstation	100	100,000	large number of simultaneous video streams

6-4.1 General Network Topologies.

Three general network topologies are possible: star, ring, and fully meshed. These concepts apply to intra-site system architectures as well as inter-site regional configurations. A brief description of each topology follows.

6-4.1.1 Star.

The star, or “hub and spoke” network involves a central Dispatch Station (or head-end) and single communication lines out to individual sites (or field panels). The disadvantage to a star topology is that if one of the links is disabled or severed then communication is lost to that node. The unconnected node may still operate through distributed intelligence, but will be unable to receive updates from and transmit alarms to the rest of the system. For example, if a new credential holder were added to the access list, this information could be downloaded to a remote site or panel from a central location. With a severed link, these updates are not available unless the information was uploaded at the local site/panel. Conversely, if a credential holder were deleted from the access database, a “severed” site/panel would continue to allow access until communications were re-established or a local upload made. Figure 6-1 shows a star topology for both an inter-site architecture and an intra-site architecture.

6-4.1.2 Ring.

The ring topology communicates through a loop. This topology is slightly more robust than a star topology in that if a link fails, communications can still be maintained through the “backside” direction on the loop. Communications may be slower in this backup mode of operation but would be sustainable. Figure 6-2 shows a ring topology for both the inter-site and intra-site scenario.

6-4.1.3 Fully Meshed.

The most robust topology is a fully meshed topology depicted in Figure 6-3. This topology has backup means of communication, such that if any one link is disabled or severed, data has an alternate path to communicate directly between nodes. This is the preferred ESS network topology.

Figure 6-1 Star Topologies.

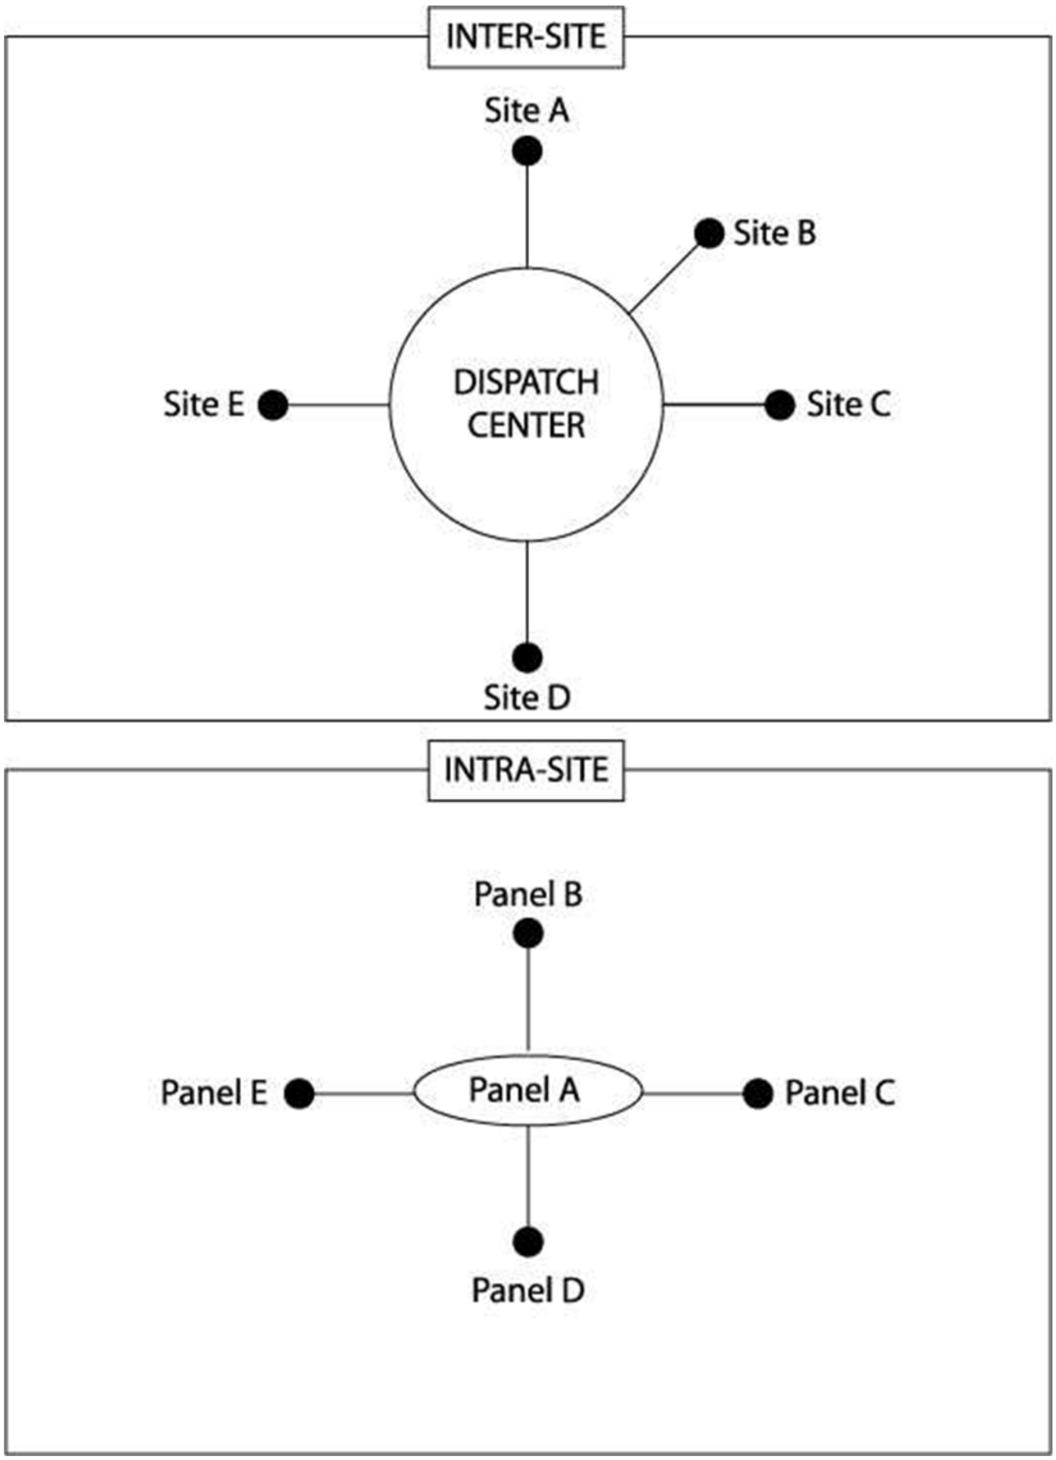


Figure 6-2. Ring Topologies.

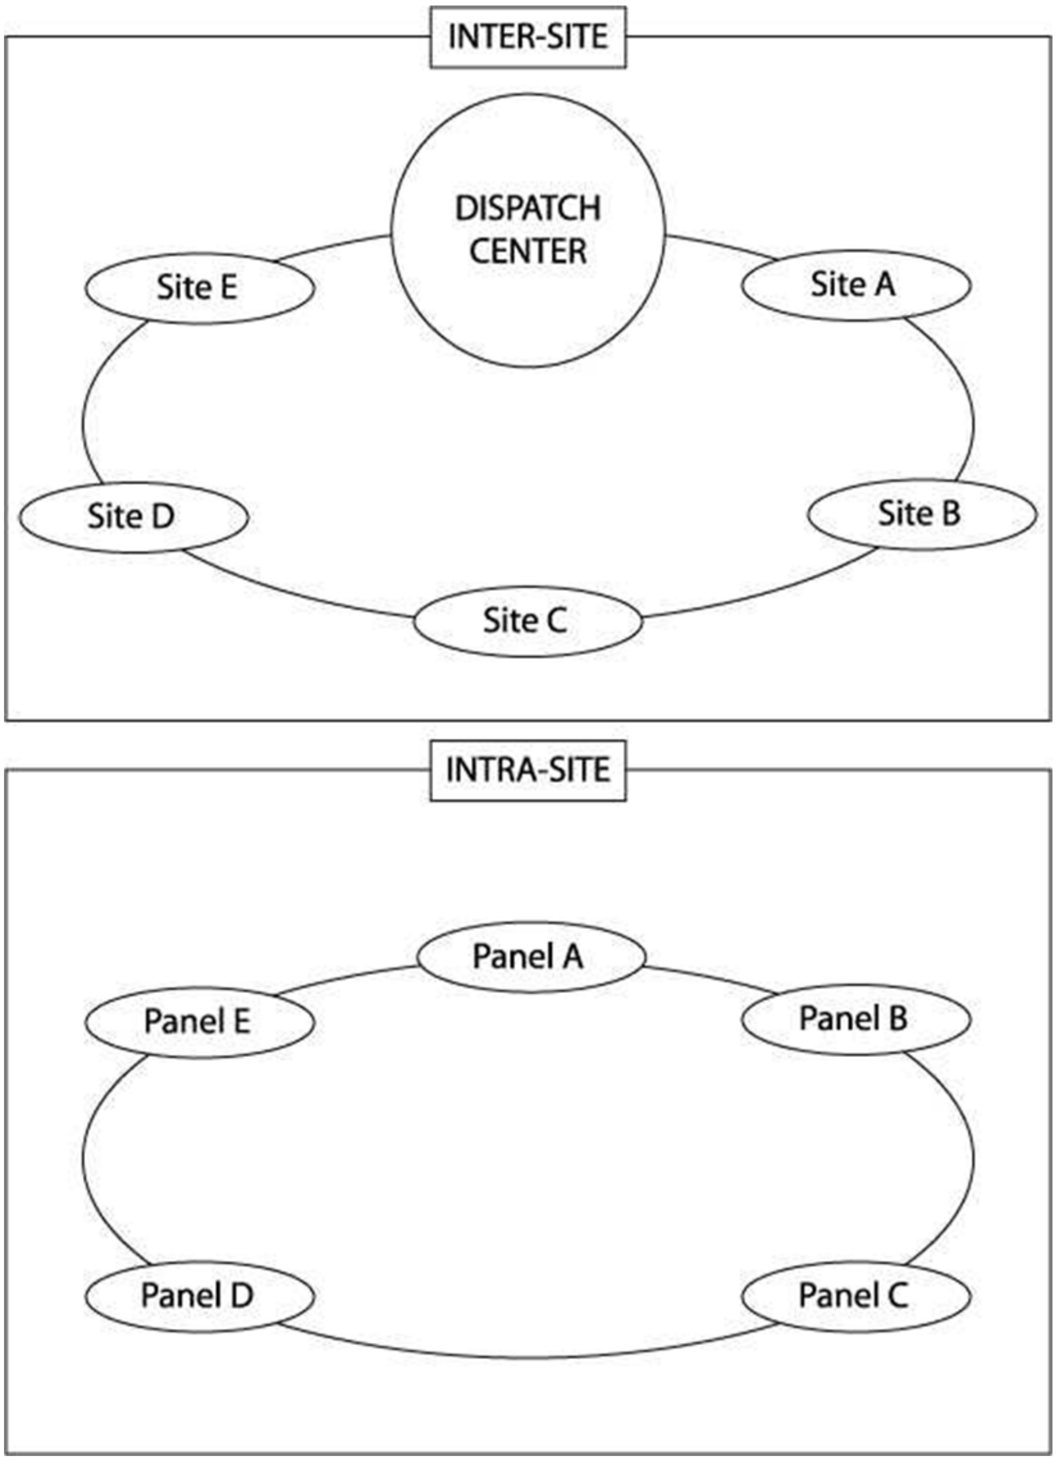

Figure 6-3. Fully-Meshed Topologies.

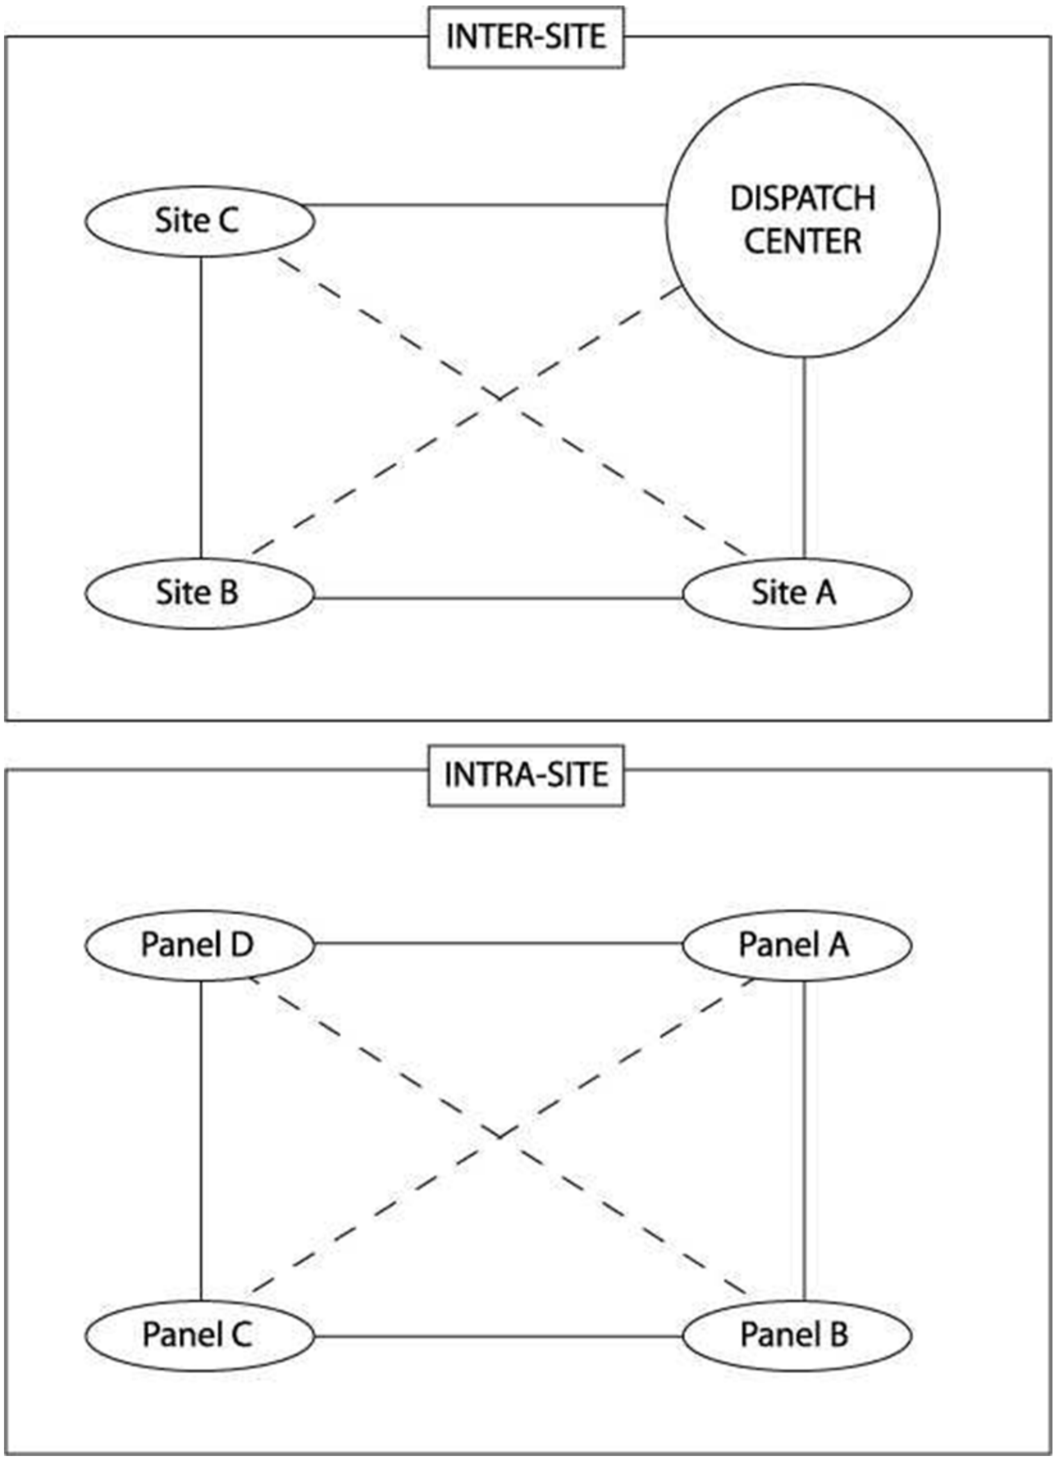


6-5 COMMUNICATION REDUNDANCY.

Typically the only communication redundancy made is between subsystem field panels and the system head-end. Redundancy between field panels and devices is cost prohibitive. A common method of achieving communication redundancy is running primary as well as backup RS-485 lines. If this is done, it is best to use different raceway routing schemes.

New product developments and improved design configurations increasingly harden communication system redundancy. This concept is generally more applicable to network backbones as opposed to vendor-specific ESS subsystems, such as ACS, CCTV, and IDS. Redundant communication paths are established such that if a component or link goes down, communication is maintained through an alternate communication path. While some people refer to these designs as “self-healing”, the term is really a misnomer because the failed component is still a failed component. Alternate communication paths are employed until the fault can be corrected.

6-6 TRANSMISSION MODES/PROTOCOLS.

Several modes and protocols exist for electronic security data transmission including serial communication (RS-485, RS-232), network communication using Ethernet protocol, modem, and wireless. The designer must consider protocol compatibility as well as data rate and distance requirements when selecting the appropriate data transmission methods for a project. The information presented in Table 6-2 will aid in this selection process. This information is discussed in the following section as part of an overview of the data transmission media commonly specified for ESS projects.

6-7 TRANSMISSION MEDIA.

6-7.1 Hardwired.

Hardwired refers to using dedicated proprietary (DoD-owned) circuits to transmit data/video between DTM nodes. Dedicated circuits can be copper or fiber-optic, both of which are discussed below.

6-7.1.1 Copper Circuits.

Copper circuits can meet most ESS data transmission needs from alarm circuits transmitting a simple state change to network links operating at speeds up to 1 Gb/s. As shown in Table 6-2, copper circuits are capable of supporting lower data rates out to distances of 1,000 feet (305 m) and greater, but copper Ethernet links can be no longer than 330 feet (100 m). Single-pair high-speed digital subscriber line (SHDSL) technology is a good option for achieving moderately high data rates at fairly long distances over a single copper pair. Disadvantages of copper circuits include susceptibility to electromagnetic interference, radio-frequency interference and damage from lightning strikes.

6-7.1.2 Fiber Optic Cable.

Fiber optic allows transmission over longer distances by using light, which does not have the higher resistance loss over distance of copper circuits. Furthermore, fiber optic is not affected by electromagnetic interference or lightning. As seen in Table 6-2, fiber optic cable, when compared to copper, allows high data rate links to be established over much greater distances. For example, a Gigabit Ethernet link of 6.2 miles (10,000 m) is possible with fiber, compared to only 330 feet (100 m) with copper. Since the cost of a data transmission system can be a significant component of overall ESS cost, the designer must evaluate the advantages of fiber links in light of their higher cost compared to copper circuits. Of the two varieties of fiber optic cable, single-mode fiber offers greater distance capabilities than multi-mode fiber but is more expensive to implement.

6-7.2 Direct Subscriber Lines (T 1 Lines).

Direct subscriber lines, also called T-1 lines, are commonly used in data transmission media systems for connecting remote sites. T-1/DS1 lines are permanent point-to-point links through public networks. The bandwidth capacity of a T-1 line is 1.544 Mbps. The cost of the leased line is dependent on distance and existing capacity or infrastructure. T-1 lines are uniquely assigned to a customer, such that only the DoD information would be transmitted over the assigned point-to-point link.

6-7.3 Wireless.

For security reasons, only use wireless if other media cannot be used. Wireless broadband networks make use of radio frequency transmission between towers. Wireless systems have high data transmission rates and do not require installation of cable, nor rely on existing copper infrastructure. Wireless communications are affected by line-of-sight topography and extreme weather conditions (such as rain, snow, or fog). Some radio modem units can provide data transmission rates of several megabits per second - at ranges up to ten or more miles between modems. One disadvantage of wireless systems is the systems are susceptible to jamming.

6-7.3.1 Wireless Security

Security can be achieved by vendor encryption and decryption at each node. The design and cost estimate must consider equipment and software for equipment and software for authentication servers and encryption systems.

6-7.3.2 Frequency Allocation.

Frequency allocation or radio frequency spectrum planning is a critical issue and must be an early project design consideration. Frequency allocation is a long lead-time item. Employment of radio frequency transmitting equipment outside of the continental United States may require approval by the Host nation. Refer to service policies for frequency allocation.

6-7.4 Free-Space Optics (FSO).

FSO, also called free-space photonics (FSPO), refers to the transmission of modulated visible or infrared (IR) beams through the atmosphere to obtain broadband communications. Most frequently, laser beams are used. FSO operates similar to fiber optic transmission, except that information is transmitted through space rather than a fiber optic cable. FSO systems can function over distances of several kilometers, but each link requires a clear line-of-sight unless mirrors are used to reflect the light energy. FSO systems offer advantages of reduced construction cost in that fiber optic lines do not have to be installed, but there are limitations. Rain, dust, snow, fog, or smog can block the transmission path and shutdown the network.

Table 6-2. Data Transmission.

Protocol / Media	Data Rate @ Distance
Supervised alarm circuit / copper, single pair	state change @ 1,000 feet (305 m)
RS232 / copper	19.2 kb/s @ 50 feet (15 m)
	9.6 kb/s @ 500 feet (150 m)
	4.8 kb/s @ 1,000 feet (300 m)
	2.4 kb/s @ 3,000 feet (900 m)
V.35 / copper	1.5 Mb/s @ 50 feet (15 m)
	56 kb/s @ 102 feet (31 m)
	19.2 kb/s @ 513 feet (156 m)
	9.6 kb/s @ 1,025 feet (312 m)
	4.8 kb/s @ 2,050 feet (625 m)
	2.4 kb/s @ 4,100 feet (1250 m)
RS422 / copper	10 Mb/s @ 40 feet (12 m)
	1 Mb/s @ 200 feet (61m)
	100 kb/s @ 4,000 feet (1220 m)
RS485 / copper	10 Mb/s @ 40 feet (12 m)
	1 Mb/s @ 200 feet (61m)
	100 kb/s @ 4,000 feet (1220 m)
SHDSL / copper, single pair	256 kb/s @ 21,980 feet (6,700 m)
	1.5 Mb/s @ 16,404 feet (5,000 m)
	2.3 Mb/s @ 13,780 feet (4,200 m)
10BASE-T Ethernet / copper, two pairs	10 Mb/s @ 328 feet (100 m)
Fast Ethernet / copper, two pairs	100 Mb/s @ 328 feet (100 m)
Fast Ethernet / multi-mode fiber, two fibers	100 Mb/s @ 1,804 feet (550 m)
Fast Ethernet / single-mode fiber, two fibers	100 Mb/s @ 32,808 feet (10,000 m)

Gigabit Ethernet / copper, four pairs	1 Gb/s @ 328 feet (100 m)
Gigabit Ethernet / multi-mode fiber, two fibers	1 Gb/s @ 1,804 feet (550 m)
Gigabit Ethernet / single-mode fiber, two fibers	1 Gb/s @ 32,808 feet (10,000 m)

6-8 TECHNOLOGY COMPARISION.

Table 6-3 provides a comparison matrix of different DTM technologies for ESS.

Dedicated conductors are highlighted for on-base applications and T-1 lines are highlighted for interbase applications as a general guide. Whichever method is used, initial calculations have to be made on the data rate and distance requirements.

6-9 ENCRYPTION.

An ESS designer is responsible for reviewing applicable security policies and consulting with information assurance (IA) personnel to determine data transmission encryption requirements and methods on a project-by-project basis. Two details must be addressed when making this determination - the types of data being transmitted and the data transmission techniques being used. As a general guideline, ESS data associated with very high security assets (such as SCIFs) or containing personally identifiable information (such as biometrics) must be encrypted. Encryption will generally be required when any ESS data is transmitted using techniques such as wireless links and shared or public networks that are inherently more susceptible to interception than hardwired circuits and closed, restricted ESS networks.

Refer to Chapter 9 for additional information on tamper protection and encryption requirements.

Table 6-3. DTM Technologies for ESS.

	Hardwired	Leased T-1 Lines	Wireless	Free Space Optics
Suitability On Base	Recommended application.	Does not make sense when base level information infrastructure can be used.	Generally requires line of sight.	May make sense, can be used when there is line of sight.
Suitability Inter Base	Rarely achievable, because of property line boundaries.	Recommended application. Can cross property lines.	A workable application	May make sense.
Initial Cost	Dependent on distance. Principle cost is per linear foot of trenching/ conductors.	Low, which is good. Must provide interface to site's demarcation point for supplier.	Construction costs of towers and tie-ins have to be computed.	Reduced initial cost because conductors are not used. Need transmit/ receive equipment.
Recurring Cost	Low, which is good. Minimal maintenance cost of installed conductors.	One T-1 line at 1.544 Mbps can be estimated at $500/month. Obtain vendor quote.	Relatively low, which is good if DoD-owned. Otherwise obtain vendor quote.	Low if DoD equipment. Leased equipment requires vendor quote.
Considerations	Best technology. Not affected by line of sight.	Reasonable alternative to "hardwired." Not affected by line of sight.	Generally requires line-of-sight. Approved frequencies must be used.	Requires line of sight or mirrors.
Security	Very good, especially if totally contained on DoD property and encrypted.	Second or third best choice. Usually dedicated conductors are used from one provider.	Not recommended by CIA studies, but may make sense on DoD property if there is little chance of interception.	Signals can be blocked. Hard to transmit forged signals.
Weather Effects	Not affected. Best technology from weather consideration.	Not affected. As good as "hardwired."	Not as bad as free space optics, but can be affected by heavy rain and snow.	Rain, dust, snow, fog, or smog can block transmission and shutdown network.

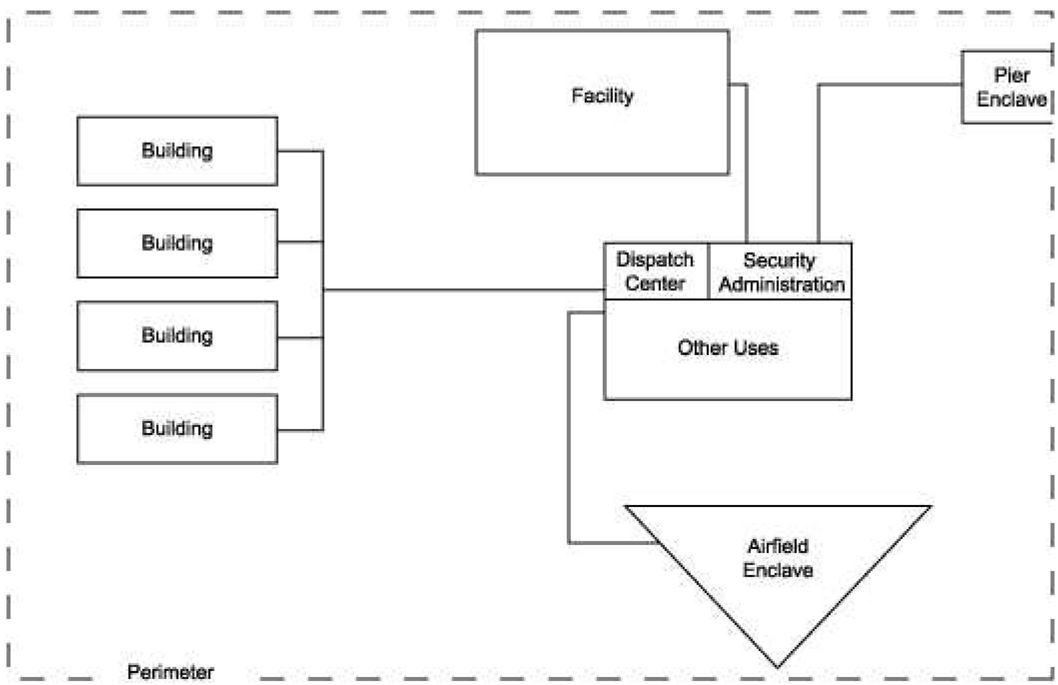
CHAPTER 7 DISPATCH CENTER

7-1 INTRODUCTION.

7-1.1 Dispatch Center.

The Dispatch Center, also known as the Security Operations Center (SOC), Security Control Center (SCC), or Central Monitoring Station is an area that serves as a central monitoring and assessment space for the ACS, CCTV, and IDS systems. The Dispatch Center must meet the applicable requirements of NFPA 1221. In this space, operators assess alarm conditions and determine the appropriate response, which may entail dispatching of security forces. Normally, the Dispatch Center is staffed by trained personnel 24 hours a day, seven days a week. The Dispatch Center may be co-located with other installation functions. Refer to Figure 7-1.

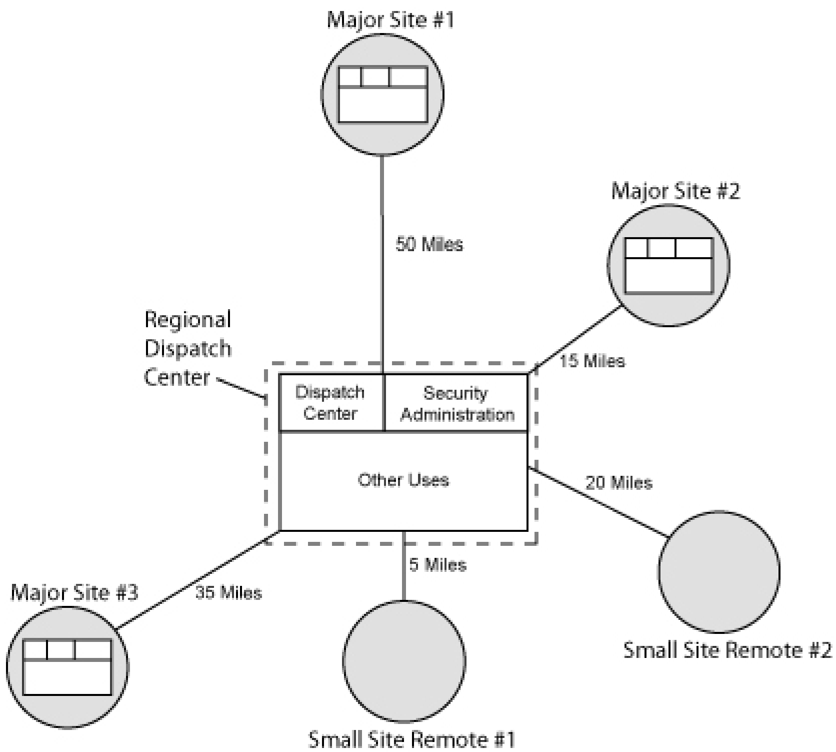
Figure 7-1. Dispatch Center Centrally Located.



7-1.2 Regional Dispatch Center (RDC).

When several regional installations or sites interface and report to a centralized dispatch center, that space or building may be known as a Regional Dispatch Center (RDC). Refer to Figure 7-2.

Figure 7-2. Example RDC.



7-1.3 Small Facility Options.

Small facilities not located on a DoD installation such as Reserve Centers, medical clinics, or pharmacies may be connected to a Central Station or Police Station.

7-2 SPACE.

7-2.1 Space Programming.

Space programming for a Dispatch Center must consider the following:

a. Equipment wall space

b. Provide a minimum 36 inches (900 mm) space both in front and in back of equipment racks and a minimum side clearance of 24 inches (600 mm) on end equipment racks.

c. Counter space for consoles

d. Personnel space for each operator

e. Space for UPS equipment

f. Access requirements for maintenance or repair.

g. Conduit space requirements for future system wiring or enhancements.

H. Future growth or expansion space

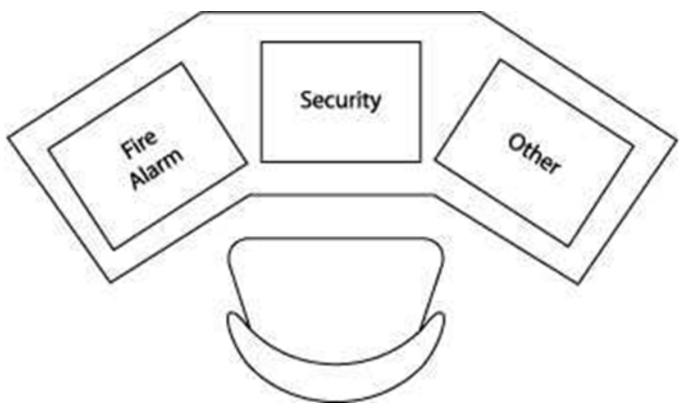
7-3 LIGHTING.

The Dispatch Center space should be designed for normal interior lighting levels according to the classification of the space: equipment room or Dispatch Center. Consideration must be given to selectable lighting or dimmers that allow reducing the lighting behind or near system displays. Use of dimmers or task lighting must be considered at operator's areas. Indirect lighting should be a consideration. The design should strive for no glare on monitor screens.

7-4 CONSOLES.

A determination should be made early as to how many consoles are required. The layout for a simple Dispatch Center console is displayed in Figure 7-3. Although security system monitors may be co-located with other functions such as a 911 call center and fire alarm monitoring personnel, most commands find a separate administrative personal computer and printer is required in the Dispatch Center. A conceptual layout for a small to medium sized Dispatch Center is displayed in Figure 7-4.

Figure 7-3. Sample Simple Dispatch Center Console Layout.

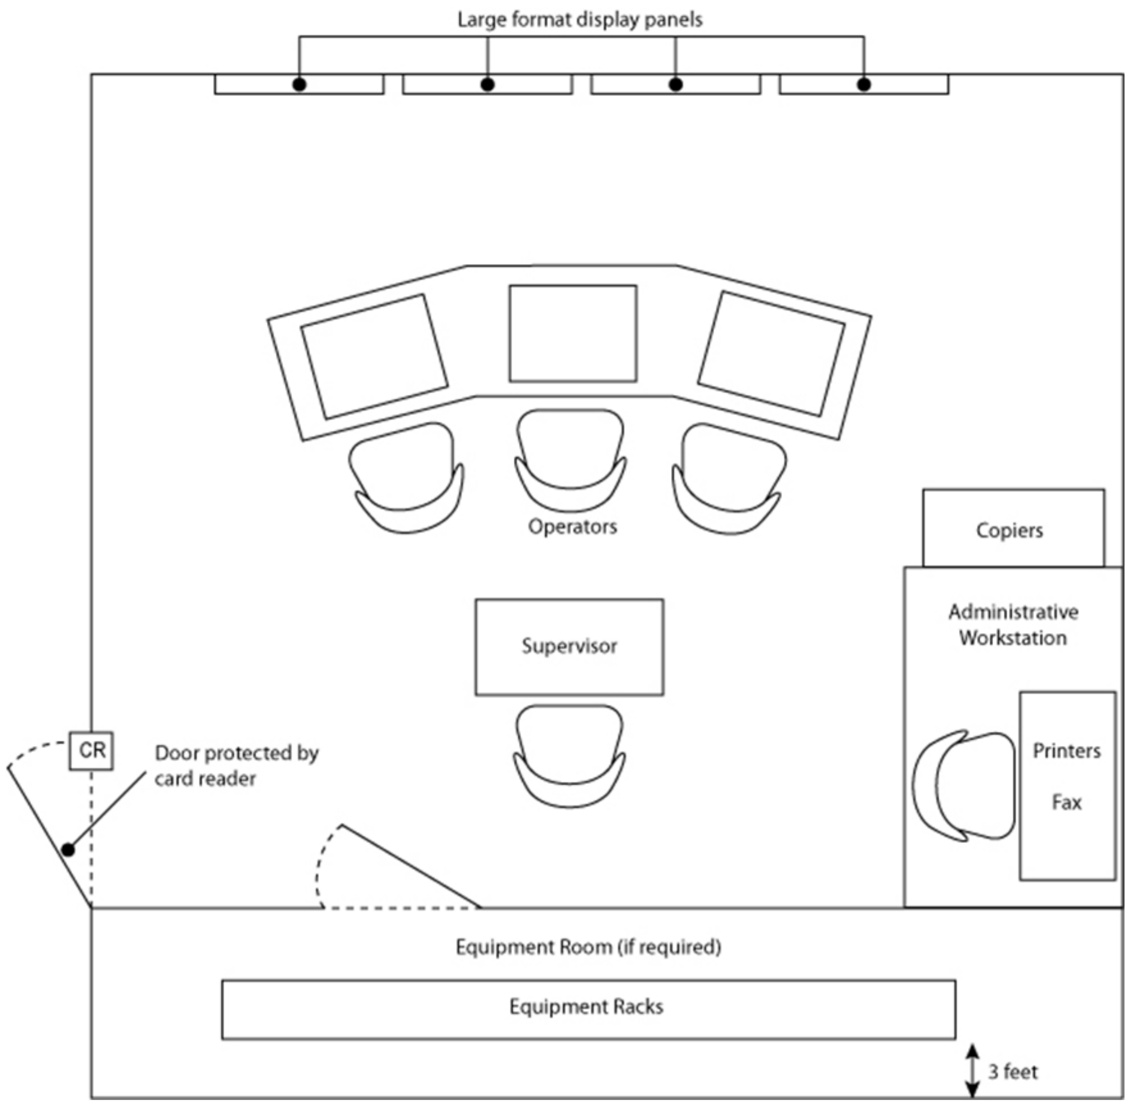


7-5 MONITORS.

Monitors must be ergonomically mounted. Current products allow wall-mounted flat-screen displays and smaller, hinged, flat-panel monitors that can be swiveled out and adjusted for individual operators.

The quantity, size, and resolution of monitors are all important design considerations, with the primary goal being to maximize the effectiveness of operators in performing their duties. For a single-operator workstation, two to four monitors is generally adequate, recognizing that more is not necessarily better. Monitors in the 20 - 24-inch (500 – 600 mm) display range providing HD 1080p resolution are a good, economical option for most ESS applications.

Figure 7-4. Sample Small-Medium Dispatch Center Space Layout.



7-6 GROUNDING/POWER CONDITIONING.

It is a good practice to provide a dedicated ground bus bar in the Dispatch Center for grounding the ESS panels. Refer to NFPA 70 and ANSI/TIA-J-STD-607 for additional guidance on grounding, surge protection, and power conditioning.

7-7 HEATING, VENTILATION AND AIR CONDITIONING.

Dispatch Centers lend themselves to “packaged HVAC equipment systems” because of the relatively low heat load, as opposed to centralized systems for bigger, more complex building types.

7-7.1 Environmental Considerations.

Typical environmental conditions for a Dispatch Center are as follows:

- 72 degrees Fahrenheit plus/minus five degrees.
- 50% Relative Humidity (RH) plus/minus 10%. If the relative humidity drops below 30%, there can be equipment problems due to abnormally high level of static electricity. Conversely, too high a humidity can result in condensation, which may cause electrical shorting or corrosion problems.

7-7.2 Load Calculation Considerations.

HVAC heat/cooling loads can be calculated by considering these heat loads:

a. Personnel and Equipment. The average staffing count of personnel in conjunction with the kilowatt (kw) load of associated electrical equipment such as DVRs and ESS servers as well as internal lighting loads must all be considered when calculating this heat load component. For personnel, ASHRAE 62.1 recommends 20 cfm (9.4 l/s) flow rate per occupant. Refer to UFC 3-501-01 and utilize equipment loads based on the room configuration.

b. Shell Load. Shell load considers the perimeter walls, ceilings, windows, and associated solar gains of the external surfaces.

c. Outside Air. This load component varies according to the climatic conditions of the Dispatch Center location.

7-7.3 Components Considerations.

Components to consider are air handlers, ductwork, inlets and outlets (diffusers and grills), as well as heating and cooling sources.

7-8 SUPPORT ROOMS.

A good practice is to plan for space in a room near the Dispatch Center to house support equipment. This room can be used to house local ESS equipment such as digital recording equipment (DVRs), local security panels, and termination cabinets. Additional HVAC capability may be required in dedicated equipment spaces due to the heat generated by equipment.

This Page Intentionally Left Blank

CHAPTER 8 ESS SUBSYSTEM INTEGRATION

8-1 OVERVIEW.

Since the different subsystems of a facility's total ESS are drawn on a number of different technologies (i.e. camera technology, biometric technology, microwave intrusion technology, and information transfer technology), the manufacturers of subsystems tend to be uniquely different. As a result, system integration or making the subsystems and components "talk to each other" reliably and consistently is a major portion of an ESS design. The purpose of this chapter is to briefly consider some of the system integration issues associated with an ESS.

8-2 COMMUNICATION FROM THE IDS TO THE ACS.

As covered in Chapter Two, "Electronic Security System (ESS) Overview," for an intermediate system, the IDS may already be an integral part of the ACS. In these systems (depicted in Figure 2-7), basic intrusion detection devices are brought into a combined ACS/IDS system as digital inputs on local security panels. All that is required is to allocate digital input points in the closest security panels and program the ACS to provide an alarm on event.

For some facilities, however, the IDS and ACS will be separate. This is a fairly common scenario in which each IDS zone within a facility is equipped with an IDS local processor connected to the Dispatch Center for the sole purpose of IDS alarm monitoring, and doors/portals within the facility are controlled by a local ACS administered and monitored by the owner/tenant. In facilities where the two systems are separate, the IDS and ACS often share a common need to monitor the position of certain doors. Rather than having two position sensors on a door (one for IDS and the other for ACS), the designer should specify a single door sensor that has two independent outputs. This allows one output to be wired to the IDS local processor and the other to the ACS local processor. This approach reduces the cost and eliminates the clutter associated with having two sensors on a single door.

8-3 COMMUNICATION FROM THE IDS[1] TO THE CCTV SYSTEM.

Once an intrusion is detected (i.e. door forced open or perimeter fence or microwave intercept), it is generally the practice to make sure the event is being viewed and recorded. Interface of the IDS to the CCTV system can occur through several different means: hardwired conductors, serial communications, and networked connections as discussed below. Activation of an intrusion detection alarm results in an audible alarm that gets the operator's attention.

8-3.1 Hardwired Conductors.

This is older technology, but it is still effective for simple installations. In this case, copper wiring is taken as digital outputs from the IDS or combined ACS/IDS and

[1] or combined ACS/IDS

connected as inputs to the CCTV system to initiate camera recording, and if required, panning to a pre-set location. In the most basic approach, this design requires a pair of wires for each alarm notification output signal.

8-3.2 Serial Communications.

In theory, this is the same principle of operation as the hardwired method with an improvement in that a single serial data link can handle several camera control signals. It is most easily done when the CCTV and IDS (or combined ACS/IDS) are made by the same vendor, but can be done with different vendors if appropriate software drivers are available. While slightly more complicated than the hardwired approach, this method has the advantage of reduced wiring costs.

8-3.3 Software-Based Integration for Networked ESS.

This approach provides flexibility in the initial system setup and allows the user to make configuration changes via software with no additional hardware or wiring investment. For this reason, software-based integration is preferred for most projects, but it requires a networked ESS in which all subsystems are connected to a common IP network. In this approach, all file servers, workstations, video recording devices, cameras, and local processors are connected to the same network via Ethernet cables and switches. This network configuration allows communication between the remote equipment and a server or desktop personal computer (PC), usually located in the Dispatch Center. The desktop PC will have a security program that accesses remote equipment through IP addresses provided during setup. The security program allows the user to access CCTV and IDS/ACS information. When using this approach, having adequate bandwidth is important due to the large amount required for video information. As mentioned, network security is also of paramount importance, and for DoD projects a dedicated security network is recommended. Cost savings of reduced point-to-point wiring have to be compared to possible new costs of installing a dedicated network. A drawback to this approach is that typically the manufacturer of both the CCTV and IDS/ACS has to be the same vendor unless compatible software drivers for allowing both systems to talk to each other are available.

8-4 COMMUNICATION FROM THE CCTV SYSTEM TO THE ACS.

Cameras may be used to visually assess access control alarms in the same way they are used to assess intrusion alarms. Cameras may also be used to visually confirm the identity of a person requesting entry into a secure area before releasing the portal (referred to as video verification by some ACS vendors). The IDS/CCTV integration techniques described above also apply to ACS/CCTV integration.

8-5 COMMUNICATION FROM THE ACS TO THE DISPATCH CENTER.

ACS alarms may be transmitted from a facility to the Dispatch Center. The designer must determine for each project whether a facility owner/tenant will monitor ACS alarms locally or will rely on the Dispatch Center to provide ACS monitoring services. If the

Dispatch Center will monitor ACS alarms, the monitored facility must be equipped with a local processor that is compatible with the existing central monitoring system.

8-6 DESIGN GUIDANCE ON IT SYSTEM COORDINATION.

Fiber optic cables typically come in multiples of twelve strands, with 12-strand and 24-strand fiber optic cable being very common. While there are no technical limitations on combining ESS with other base systems, such as IT or Instrumentation and Control, it is preferable to keep ESS fibers dedicated for security purposes only from a security standpoint. If other unrelated systems are on a common fiber, other vendors or organizations will have closer access to the security communications. Plan for future expansion (provide a minimum of 20%) spare capacity (fibers).

This Page Intentionally Left Blank

CHAPTER 9 GENERAL CONSIDERATIONS AND CROSS-DISCIPLINE COORDINATION

9-1 GENERAL CONSIDERATIONS.

9-1.1 General.

The highest security should be applied close to the critical asset. Avoid burdening the entire general population with the highest level of security. Other considerations include:

- All local processors should be located within the secure area.
- Annunciators, controls and displays subsystems should be located in areas closed off from public access or view.
- Certifications and Listings.

9-1.1.2 Equipment and Systems.

Equipment and systems should be proven with a demonstrated history of reliability. One way of achieving this criterion is to specify listed or certified products/systems such as:

- United States: Underwriter's Laboratory (UL) or similar nationally recognized testing and listing agency. Refer to UL 294 for a standard on ACS.
- European Union: CE listing. CE certifications, referred to as "CE Marking" may be required by the Host Nation for systems provided in Europe. The letters "CE" are an abbreviation of a French phrase "Conformite Europeene". The marking indicates that the manufacturer has conformed with all the obligations required by the European Union (EU) marketplace.

9-1.1.3 Spare Capacity.

An ESS must have the capability to be easily expanded or modified for simple changes, such as adding a card reader or camera, over the near-term life of the system. Accordingly, the ESS designer should plan for a nominal 20% expansion capacity when designing a new system.

9-1.2 System Acceptance Testing.

The ESS technical specifications or scope of work must include requirements for the ESS installation contractor to conduct comprehensive testing of every component and feature in order to demonstrate acceptable system performance to the Government. This section discusses system testing and ownership acceptance procedures.

9-1.2.1 Labeling.

Major equipment must have labels to identify the system and device. Cables must be labeled at origination, termination, and within enclosures using permanent labels.

9-1.2.2 Test Documentation and Acceptance Forms.

The ESS installation contractor must prepare a test plan along with detailed test procedures and submit these to the Government for approval prior to testing. The ESS designer must include this requirement in the technical specifications or the Scope of Work.

9-1.2.3 Pre-Test Walkthrough.

A pre-test walkthrough should be performed just prior to the start of the final acceptance testing. This allows the final acceptance test to go smoothly and prevents mishaps and additional testing. The walkthrough also provides a good opportunity to check installation workmanship and validate equipment types and quantities against the design requirements. The designer should participate in the walkthrough along with the installation contractor and the Government representative.

9-1.2.4 Training.

Include administrator and operator training and add the number of hours required to the system specifications. Typically, several training sessions with a minimum of one per work shift should be considered. It is a good practice to define some performance criteria such as "upon training completion, the tenant command must be able to unilaterally make additions or deletions to the ACS database."

9-1.3 Operation and Maintenance.

In specifying ESS, the designer must consider maintenance, service, repair, and sustainability of systems and the associated components. Systems with arduous requirements should be reconsidered.

9-2 GENERAL COORDINATION.

Throughout the planning and design process the designer must coordinate closely with security (Physical Security Officer) and anti-terrorism personnel (Antiterrorism Officer), end-users, base communications officer (information technology and information assurance), fire and safety personnel, and the installation facilities engineering office.

9-3 CIVIL COORDINATION.

9-3.1 Gate Control (Vehicle Gates and Sally Ports).

A sally port is a secure controlled entry and exit portal, utilized for inspections and to prevent tailgating. Sally ports may require control hardware for interlocking gates. Refer to UFC 4-022-01 Security Engineering: Entry Control Facilities/Access Control Points for more information on sally ports and entry control points.

9-3.2 Underground Site Work.

Inter-building DTM communications are often made by buried direct conductors. Underground site work needs to coordinate with existing civil drawings and buried utilities.

9-3.3 Outdoor Perimeter Security Features.

Perimeter security projects often involve clearing, grading, drainage improvement, erosion control and paving, and these design elements must be coordinated with local site development and environmental representatives. Civil Engineering input must be solicited when designing above-ground perimeter security features such as fences, passive vehicle barriers, towers, and poles.

9-4 ARCHITECTURAL COORDINATION.

Past experience shows that the biggest disconnect in project design and a construction cost is due to lack of coordination between commands, security, engineers, and ESS installation personnel. It is imperative that planned ESS component locations be identified early in initial design and planning stages in order to coordinate conduit installation and electronic module interface requirements for security locks and equipment. Additionally, coordination in the project programming stage will give persons responsible for collateral equipment the time necessary to plan for the facility's necessary equipment.

Detailed door-by-door coordination reviews must be conducted during design development and creation of construction documents.

9-4.1 Balance of Security with Convenience.

Other architectural issues that need to be considered include balancing security with convenience, entries and exits, life safety code considerations, space planning, doors, and door locks. These are discussed in the following sections.

There is a natural conflict between making a facility as convenient as possible for operation and maintaining a secure facility. Convenience should be considered during the different phases of the design review; however, the requirement for security must not be sacrificed for convenience. Proper security controls will reduce the flow rate and ease of ingress and egress for a facility. These issues must be addressed in initial planning to facilitate additional entry points or administrative requirements.

9-4.1.1 Entries and Exits.

In general, provide separate entries and exits. Establish the number of entry/exit points consistent with security and Life Safety requirements.

9-4.1.2 Space Planning.

Early in the project, architectural issues for Dispatch Center space, wall space for security panels and floor space for ESS equipment racks and consoles need to be discussed. Normally, security panels will go in telecommunication rooms. The ESS designer must coordinate with the telecommunications system designer and local Information Technology personnel for space requirements in the telecommunications room.

DoD criteria require that telecommunication rooms are separate from electrical equipment rooms. These spaces will be climate controlled separately from adjacent spaces.

9-4.1.3 Doors.

Access control is achieved through locking an opening such as a door or gate. Using the example of card reader controlled doors, the door is controlled through a door locking mechanism. When deciding which locking mechanism to use, a decision must be made as to whether the door is “fail-safe” or “fail-secure.” While most facilities will make all egress doors able to be opened from the “secure-side” in the egress path during a fire emergency, there are options as to whether the controlled door is able to be opened from the “public-side.”

9-4.1.3.1 Fail-Safe.

Fail-safe doors fail unlocked on loss of electrical power. This means that if power is lost the door hardware is configured such that the door can be opened by anyone from the “public-side.” While affording great convenience, this configuration is vulnerable to intrusion during a power-loss event.

9-4.1.3.2 Fail-Secure.

Fail-secure refers to entry from the public-side. Fail-secure doors fail locked on loss of electrical power. This means that if power is lost the door hardware is configured such that the door cannot be opened from the public-side. These doors need to be keyed such that they can be manually unlocked by appropriate response personnel until the security alarm panel and electrical power can be reset. Emergency doors are required to be able to be opened for exiting during a fire-emergency except for certain restricted institutional facilities (prisons and high-security hospitals).

Recommendation: Unless there is a compelling convenience reason for making a door fail-safe, most ESS projects are designed such that the door hardware is Fail-Secure.

9-4.1.4 Door Coordination.

Door control impacts (door hardware needs or changes) are sometimes overlooked in project construction cost estimates. Inventory of doors and assessment of door and hardware suitability must be an early design consideration for assessing project door interface requirements. Door coordination is one of the most frequent (and costly) problem areas on security projects. It is important that the ESS designer coordinate with the project architect to ensure that the proper door hardware is specified and installed.

9-4.1.5 Door Locks.

9-4.1.5.1 Electric Locks.

The electric lock is a very secure method to control a door. An electric lock actuates the door bolt. For very secure applications dual locks can be used (for example, a retractable bolt on the top of the door and an additional retractable bolt on the side). In some cases, power is applied to engage the handle, so the user can retract the bolt vice the electric operator actually retracting the bolt. Most electric locks can have built-in position switches and request-to-exit hardware. While offering a high security level, electric locks carry a cost premium. In addition to the lock itself, a special door hinge and internal are required. For retrofit applications, electric locks usually require purchase of a new door.

9-4.1.5.2 Electric Strikes.

The difference between an electric strike and an electric lock is the mechanism that is activated at the door. In an electric-lock door the bolt is moved. In an electric-strike door the bolt remains stationary and the strike (or cover latch) is retracted. As in electric locks, electric strikes can be configured for fail-safe or fail-secure operation. The logic is the same. In fail-safe configuration the strike retracts when de-energized on loss of power. This allows the door to be opened from the public side. In fail-secure configuration the strike remains in place causing the door to be locked from the public side and requires manual key entry to unlock the door from the public side. Again, as with electric locks, unimpeded access is allowed in the direction of egress by manual activation of the door handle/lever when exiting from the secure side. For retrofit situations electric strikes rarely require door replacement and can often be done without replacing the doorframe.

Electric strikes should be protected with a cover guard. Exposed electric strikes can be over-ridden (pried open) by an intruder with a pocket knife or screwdriver.

9-4.1.5.3 Magnetic Locks.

The magnetic lock is popular because it can be easily retrofitted to existing doors. The magnetic lock is surface-mounted to the door and doorframe. Power is applied to magnets continuously to hold the door closed. Magnetic locks are normally fail-safe, which may be a problem for unstaffed facilities in that a power disruption that will leave the site unsecured until security personnel arrive or power is restored. Magnetic locks should be the designer's last choice for door locking mechanisms and should only be considered on a retrofit project.

Magnetic locks do have a security disadvantage. In the United States, life safety requirements generally favor the use of a passive infrared (PIR) sensor as the primary request-to-exit (REX) device for doors equipped with magnetic locks. While enhancing overall building safety, this configuration in which a REX PIR sensor is mounted above the secure side of the door allows possible compromise of the magnetic door lock in the following scenario:

- Person A is on the secure side and walks past the door with no intent to exit
- The magnetic lock is released by the activation of the REX PIR sensor. This activation generates a "click" sound.
- Person B is on the public side of the door and, upon hearing the "click", opens the unlocked door and enters the secure area.

9-5 LIFE SAFETY CODE COORDINATION.

Applicable life safety and existing codes/standards must be met. In the event of an emergency, building occupants must be able to follow emergency procedures quickly and safely. The ESS designer must coordinate with the fire protection engineer (for items such as exit plan considerations and fire alarm system integration) to implement security without comprising life safety code standards. Physical security system designs need to be coordinated with and comply with NFPA 101 and the *ABA Accessibility Standard for Department of Defense*.

9-6 ELECTRICAL COORDINATION.

Electrical issues that need to be considered include power, backup power, grounding, bonding, lightning protection, cable type, electromagnetic interference, tamper protection, voltage drop considerations, power reliability, harmonics, raceway, labeling, shielding, fire alarm system interface, and lighting. These are discussed in the following sections.

9-6.1 Power.

ESS loads should be fed from distribution panels within the protected area. A good practice is to use distribution panels with dedicated security system breakers that can be locked.

9-6.2 Backup Power.

9-6.2.1 Battery Backup.

The minimum requirement for battery backup for an IDS and its monitoring station is eight hours[2]. This may be provided by batteries integral to the IDS, uninterruptible power supply (UPS), or generators, or any combination. Emergency backup power for IDS will not generate the requirement for a UPS or generator. If a generator or UPS is not available for backup, provide backup with batteries.

[2] Based on DoD O-2000.12-H, Antiterrorism Handbook

In the event of primary power failure, the IDS must:

- Automatically transfer to an emergency electrical power source without causing alarm activation.
- Initiate an audible or visual indicator at the PCU to provide an indication of the primary or backup electrical power source in use.
- Initiate an audible or visual indicator at the monitoring station indicating a failure in a power source or a change in power source.

9-6.2.2 Backup Power for CCTV.

Depending on criticality of an asset and the availability of security forces to assess alarms, consideration should be given for providing backup power for CCTV systems used for assessing alarm conditions. Backup power must be provided for CCTV systems that employ video analytics as the primary means of intrusion detection and considered when used for surveillance around critical assets.

9-6.3 Grounding, Bonding, and Lightning Protection.

Refer to UFC 3-520-01 Interior Electrical Systems, UFC 3-575-01, ANSI/TIA J-STD-607, NFPA 70, and NFPA 780 as applicable.

9-6.4 Cable Type.

Data communication signals are sensitive to changes in capacitance and resistance associated with different cable types. Digital “1s” and “0s” trigger on sharp LRC (inductance, resistance, and capacitance) time constants. The ESS designer should specify low capacitance cable and sufficient twists per foot that meet manufacturers’ specifications.

9-6.5 Surge Protection.

Provide surge protective devices for all systems identified in NFPA 780. Refer to UFC 3-520-01 for the requirements.

9-6.6 Electromagnetic Interference (EMI).

Interference can be introduced to unprotected communication lines that are in close proximity to electrical power wiring, radio frequency sources, large electric motors, generators, induction heaters, power transformers, welding equipment, and electronic ballasts. Protection from EMI includes avoiding the sources of the interference by physical separation or shielding wire lines by means of specialty wiring (coaxial, twisted shielded (foil) pairs, and metal sheathed cables), and metallic conduit systems.

9-6.7 Tamper Protection.

Tamper protection for ESS can be physical protection, line supervision, encryption, and/or tamper alarming of enclosures and components. \1\ /1/ All tamper alarm signals must be monitored continuously whether the system is in the access or secure mode of operation.

9-6.7.1 Cable Routing.

All conduit and cabling associated with the ESS should be installed within the perimeter of the protected area to the greatest extent possible. A communications link from a protected area to a central monitoring system is an obvious exception to this guideline.

9-6.7.2 Signal and DTM Supervision.

Line supervision is a term used to describe the various techniques that are designed to detect or inhibit manipulation of communication networks. All signal and DTM lines must incorporate some level of line supervision. Line supervision for ESS must detect and annunciate communication interruptions or compromised communications between field devices, workstations, and the associated central system. Field device signals must be supervised by monitoring the circuit and initiate an alarm in response to opening, closing, shorting, or grounding of the signal. DTM supervision must initiate an alarm upon any manipulation or disruption of the signal.

9-6.7.3 Encryption.

Encryption provides a level of protection against interception and malicious use of ESS data associated with high-security facilities and personally identifiable information. In general, encryption must comply with NIST FIPS standards. Refer to specific service policy for the asset being protected.

9-6.7.4 Physical Protection of Exterior ESS.

Physically protect exterior ESS. All exterior intrusion detection sensors and access control readers must have tamper resistant enclosures and integral tamper protection switches. All enclosures, cabinets, housings, boxes, and fittings having hinged doors or removable covers that are protected by employed sensors must be locked, welded, brazed, or secured with tamper resistant security fasteners and be tamper-alarmed. Route exterior ESS sensor communication and power cables that are not directly protected by sensors by the following methods:

- In rigid or intermediate metal conduit as defined by NFPA 70.
- In concrete encased duct.
- In conduit buried a minimum of twenty-four inches (0.6 meters) below finished grade.
- Suspended at a minimum of 15.5 feet (4.5 meters) above the finished grade.

9-6.7.5 Physical Protection of Interior ESS.

All intrusion detection sensors, access control readers, and assessment equipment located outside controlled areas must have tamper resistant enclosures. All interior intrusion detection sensors and access control readers must have integral tamper protection switches. All ESS cabling should be routed within the protected area to the greatest extent possible. Additionally, the following design criteria must be applied:

a. All enclosures, cabinets, housings, boxes, and fittings having hinged doors or removable covers must be locked, welded, brazed, or secured with tamper resistant security fasteners and be tamper-alarmed.

b. Any metallic conduit that leaves an area that processes classified information such as a SCIF must be decoupled (insert of nonmetallic conduit) when exiting the area.

c. For ordnance facilities, metallic conduit must be run underground for at least 50 feet (15 m) from the structure. Refer to UFC 3-575-01 for additional requirements.

d. Comply with applicable security policy requirements for installing IDS communications wiring in conduit. Apply security policy for the specific asset being protected. For example, security policy for SCIFs requires: "IDS-associated cabling that extends beyond the SCIF perimeter must be installed in rigid conduit or must employ line security". There is no universal requirement for IDS wiring to be installed in conduit.

9-6.8 Radio Frequencies.

RF systems must employ some form of tamper protection such as:

- The security system must use dedicated frequencies to transmit ESS alarm data.
- The system must detect and report intentional and unintentional jamming attempts.

9-6.9 Voltage Drop Considerations.

Standard voltage drop calculations need to be made by the designer for calculating ESS conductor size. This is especially important for CCTV cameras, which may be located some distance from interior termination cabinets and will probably be outside. The system designer must strive for a voltage drop of 10% or less.

9-6.10 Harmonics

Harmonics in a power system are typically the odd multiples of 60 Hz such as 180 Hz and 300 Hz and are generated by switching power supplies such as in a computer, by adjustable frequency motor drives, by lighting ballasts, by UPS systems, by electric welders, and by other rectifier type equipment. Harmonics in a system are measured in total harmonic distortion (THD).

9-6.10.1 In a Power System

Harmonics in a power system can cause overheating of cables and equipment along with false operations. NFPA 70 requires designs to consider harmonics and IEEE 519 is a reference standard. When a neutral of a multiphase feed has significant harmonics, it is to be oversized. UL and the IEEE both have methods for de-rating standard transformers for harmonics.

9-6.10.2 Mitigation

Mitigation of harmonics involves either isolating the harmonic source from the rest of the power system or in isolating sensitive equipment from the harmonics. Methods of mitigation involve use of oversized/de-rated standard transformers or harmonic K-rated transformers (K4 or K13 being common), use of oversized neutrals in distribution systems (full size is adequate for feeds to individual equipment), use of input line reactors or output filters (usually on motor drives), and use of surge suppressors at panelboards, in wall receptacles, in power bars, or built into the input of ends loads, such as a security panel.

9-6.10.3 Electrical Noise Reduction

To further reduce electrical noise, a copper equipment ground sized per NFPA 70 (unless the cable is already shielded) and copper grounding electrode conductors sized per NFPA 70 should be run in raceways in addition to bonding metallic raceways and enclosures together.

9-6.11 Raceway.

All conduit, wireway, and raceway must meet the requirements of NFPA 70.

Conduit runs must have a maximum of three 90-degree bends or any combination of bends not-to-exceed 270 degrees.

9-6.12 Labeling.

Cables must be labeled at origination, termination, entry into and exit from enclosures with permanent labels.

9-6.13 Shielding.

When required, shielded cable must only be grounded at one end, typically back at the local security panel to prevent open loop grounds.

9-6.14 Fire Alarm System.

In the United States most egress doors are required to unlock (in the path of emergency egress) in the event of a fire emergency. (Note: certain institutional facilities are exempt from this automatic door-unlock requirement, for example, prisons, hospitals, and other high security facilities.) Methods vary on how this may be accomplished. Meet requirements of NFPA 101. If free egress hardware is supplied (which is possible when electric locks or electric strikes are used), then that is all that is required. If magnetic locks are supplied, this life safety function has to be achieved by interfacing the ACS with the fire alarm system. The ESS design needs to include the elements identified in Figure 9-1 for system interface.

Figure 9-1. Elements of a Fire Alarm System.

- Wire and conduit from the fire alarm system to the security system. It is required that the power and communication lines not be placed in the same conduit.
- Assignment of fire alarm input/output addresses. The fire alarm system sends a signal (fire alarm system output) to each individual door controller in the event of a fire alarm signal.
- Assignment of security system input/output addresses.
- Termination of the fire alarm/security system interface on the fire alarm system.
- Termination of the fire alarm/security system interface on the security system.
- Programming of the fire alarm system to achieve door unlock signals in the event of a fire alarm signal.
- Programming of the security system to achieve door unlock signals in the event of a fire alarm signal.
- Door access control hardware all needs to be “home run” to a local junction box for ease of troubleshooting and repair.

9-6.15 Intercom System.

While not a requirement, site-specific factors may require provision of an intercom or similar auxiliary communication system at entry portals (such as motorized gates) to communicate with entering personnel from the Dispatch Center or other location.

9-6.16 Lighting.

While not an official part of ESS, lighting is an effective part of the overall physical protection design, see UFC 3-530-01. Lighting may be considered as a countermeasure for protection of each critical asset. Coordination with the electrical/lighting engineer needs to occur for placement of lighting to enhance viewing of CCTV systems, as discussed in Chapter Four.

Lighting at guard check-points must be sufficient to clearly allow a guard to verify the picture ID on access badges. Some installations may provide a fixed camera at an automatically operated gate for both surveillance and verification of a visual credential for access. In these cases, lighting must similarly be sufficient to allow accurate verification of the picture ID.

9-7 MATERIAL ENTRY CONTROL.

Other mandates will dictate specific requirements, but the following are typical considerations for material entry control as it relates to ESS and physical security:

- Material entry control circulation should be separated from general facility traffic.
- Loading docks are typically monitored by fixed cameras.
- Rollup doors are normally monitored by an interior point sensor such as a BMS.
- Shipping and receiving areas are normally caged or secured with a restricted access scheme, such as a higher card access hierarchy level.

CHAPTER 10 MODEL DESIGN APPROACH

10-1 INTRODUCTION.

Other documents provide guidance or directives on design and construction of DoD facilities. This chapter presents a model approach on how to design an ESS. The intent of this chapter is not to set new directives, but rather to communicate a process that works well.

Two principle project approaches are design-bid-build and design-build. The model design process outlined in this chapter is applicable to both approaches.

10-2 PROJECT PLANNING.

As discussed in Chapter 2, ESS is a portion of the overall physical security scheme for a facility and must be integrated into the overall physical protection plan.

10-2.1 Balance Project Funding and Project Scope.

Heightened levels of a security system provide increased resistance to intrusion and attack. Increased security brings increased construction costs and complexity. The more complex the system, the more the cost of operation and maintenance will increase. The level of security elements and security requirements need to be identified and reconciled with project funds early in a project. The design team's challenge is to balance security requirements with life safety, convenience, maintenance, and operational costs.

10-2.2 Existing Site and Building Plans.

Locating and obtaining site plans and building plans for associated buildings should be accomplished during the planning stage. CAD drawings are preferred. Early in the design process, the ESS designer should conduct site surveys to verify the accuracy of the existing plans with regard to current site conditions.

10-2.3 Site Surveys.

Site surveys include a capacity assessment of existing systems to include the following issues:

a. ACS: How many spare card reader slots are available at what panels?

b. What type of credential is used?

c. Is there badging (issuing new badges) capability?

d. CCTV: How many spare camera ports back at central server?

e. Is archiving capability present?

f. IDS: any expansion capability?

g. Transmission system bandwidth availability.

h. Approval of radio frequency emitters by local jurisdiction or host nations

i. Coordination of DTM transmission Lines

For existing and new DTM transmission lines, coordinate with the base communications officer (information technology).

10-2.4 Dispatch Center.

Identification of the location of the central monitoring facility (space) for the ESS must be made. If sufficient space does not exist for the current project, the Dispatch Center needs to be identified and a scheme for central monitoring made (i.e. a new command center space is required). A determination of Dispatch Center connectivity (DTM) requirements needs to be made. Connectivity requirements refer to bandwidth and pathway considerations. Additionally, distance issues and availability of points of connection needs to be reviewed. There will be additional project cost if new pathways and connections are required.

10-2.5 Multi-Organizational Interfaces.

Meetings with end users and facility security specialists need to be held. Additionally, determine facility and security forces operational requirements.

10-2.6 Space Planning.

The ESS designer must interact early to reserve space requirements in a new building (square footage area) for ESS components such as equipment racks, consoles, operator stations, and administrative stations.

10-3 INITIAL DRAWING PREPARATION.

A good start for drawing production is to begin with security plan drawings and a system block diagram.

10-3.1 Cable Schedule.

For identifying different cable types required for a project, a good approach is to use a cable schedule and show the conductor count and cable legend on riser diagrams. This approach is illustrated in Figures 10-1 and 10-2.

Figure 10-1 Cable Counts on Riser Diagrams.

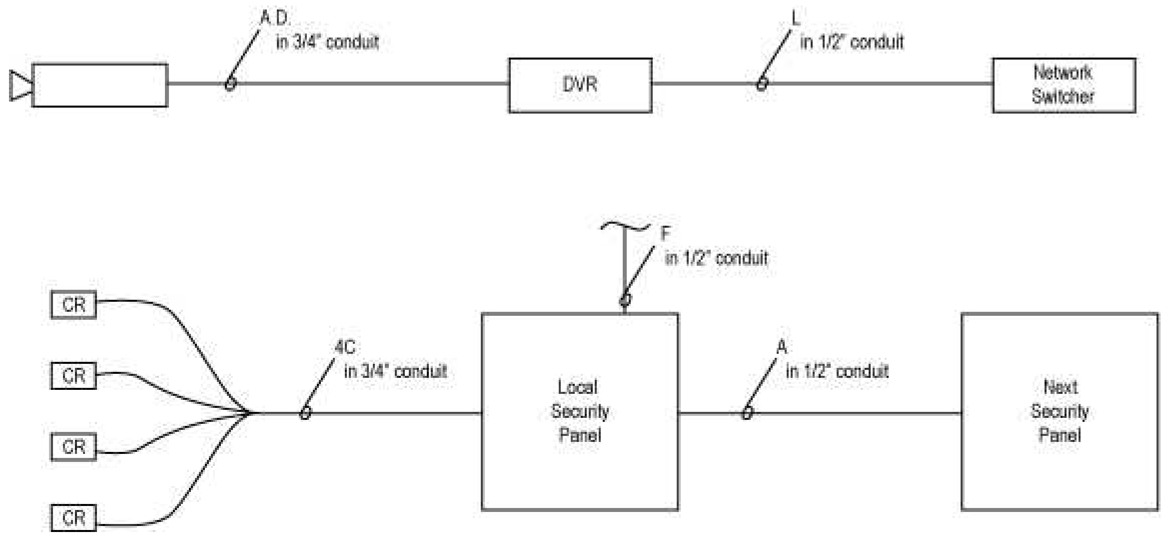


Figure 10-2. Sample Cable Schedule.

Cable Legend	Style	Type	Use
A	#16/1 TSP	Communication Cable Plenum Rated (CMP)	RS-485
C	#20 AWG/ 3 TSP	Communications Cable Riser Rated (CMR)	Card reader cable
D	#20 Coaxial	RG-59U	CCTV Video
E	#18 Solid /shield	RG-6U	CCTV Video
F	2 #12 w/1 #12 ground	THHN	120 VAC Wiring
G	#18/1 TP	Communications Cable General Purpose (CMG)	CCTV Video
L	8-C	CAT6	Ethernet cable
U	24-strand	50 micron	Fiber optic cable
W	-----------	50 FT VGA	Workstation to display

10-3.2 Functional Matrix.

A document defining the functionality to the system is a useful tool similar to the one, and an example shown in Figure 10-3.

10-4 BASIS OF DESIGN.

Some projects require a Basis of Design. Typically a Basis of Design is done as a report and includes: a functional description of systems, a narrative of systems requirements, some base drawings such as the functional matrix, and documentation of factors effecting the ultimate design and functionality of a system.

Figure 10-3. Functional Matrix.

	ACTION	A: Signal sent to security system @ Dispatch Center	B: DVR records camera image	C: Guard verifies alarm with camera	D: UPS system or batteries engage	E: Local door sounder to alarm	F: PTZ camera "moves" to preset location	G: Door unlocks until fire alarm panel is reset	H: Door unlocks	I: Motorized gate opens	J: Response force mobilized
1	Valid card reader attempt	●							●		
2	"Lost card" attempt	●	●	●							
3	Outdoor microwave sensor alarm	●	●	●			●				
4	Local security panel power loss	●			●						
5	Door held open alarm	●	●	●		●	●				
6	Door forced entry alarm	●	●	●		●	●				
7	Tamper switch activated on local security panel	●									
8	Fixed camera video motion detection activated	●	●	●							
9	Interior motion sensor alarm	●									
10	Tamper notification activated on security device	●									
11	Glass break sensor alarm	●									
12	Fence sensor alarm	●	●	●			●				
13	Fire panel alarm	●						●			
14	Remote door access activated	●							●		
15	Remote gate access activated	●	●							●	
16	Emergency exit door opened	●				●					

10-5 SCHEMATIC DESIGN PHASE.

During schematic design, system solutions for the project issues (problems) identified during programming will be generated. The key product for this phase will be outlined technical specifications and one-line riser diagrams. The schematic design documents can be used to provide the first cost estimate not based on concepts.

Initial panel board schedules should be started to indicate power sources for ESS equipment. Any new needs for power panels should be identified by electrical power one-line diagrams.

10-6 DESIGN DEVELOPMENT PHASE.

During the design development phase, project plans and specifications will be completed. Drawings should include the following:

- Legends and abbreviations
- Site plans
- Floor plans
- Riser diagrams
- Mounting details
- Door hardware schedule (may be on architectural plans)
- Sequence of construction when applicable
- Site and floor plans will include power panel locations, security panels, consoles, sensors, cameras, card readers, power circuits, and other related equipment. Riser diagrams should include all devices (including location and zoning requirements), cabling, power connections, grounding, and required system interfaces.

The system designer should have owner feedback on any changes to devices upon completion of the design development review meeting.

10-7 BIDDING.

Installers and integrators must be experienced in the installation, tuning, and programming of ESS. Require a minimum of three years of documented experience for the types of systems the project includes.

SOC—Security Operations Center

TDR—Time Domain Reflectometry

UPS—Uninterruptable Power Supply

VMD—Video Motion Detection

WAN— Wide Area Network

B-2 DEFINITION OF TERMS

Access Control System (ACS). An automated system that interfaces with locking mechanisms that momentarily permit access (for example, by unlocking doors or gates) after verifying entry credentials (i.e. using a card reader). Other DoD documents may refer to the ACS as an Automated Access Control System or an Electronic Entry Control system. The ACS may also be referred to as an Automated Access Control System (AACS), Electronic Access Control System, and Electronic Entry Control.

Balanced Magnetic Switch (BMS). A door position switch using a switch held in a balanced or center position by interacting magnetic fields when not in an alarm condition.

Base Level Information Infrastructure, That information technology (IT) infrastructure which exists on DoD proprietary or leased property.

Base Operations Center (BOC). An operations center for a DoD base that has equipment and personnel for operational responses. Typically, the BOC is the receiving point for emergency alarms from fire alarm, ESS and 911 calls. This location is typically staffed by trained staff twenty-hour hours a day. The BOC may have a law enforcement desk of handling domestic dispute or interface with local and federal authorities. The BOC typically will house the Dispatch Center, which is the centralized location for receiving and assessing ESS alarms.

Charge-coupled device (CCD). A semiconductor technology used to build light-sensitive electronic devices such as cameras and image scanners. Such devices may detect either color or black and white.

Closed Circuit Television (CCTV) System. The system that allows video assessment of alarm conditions via remote monitoring and recording of video events.

Common Access Card (CAC). The CAC, a "smart" card about the size of a credit card, is the standard identification for active-duty military personnel, Selected Reserve, DoD civilian employees, and eligible contractor personnel. It is also the principal card used to enable physical access to buildings and controlled spaces, and it provides access to defense computer networks and systems.

Central Processing Unit (CPU). In a computer-based system, the component such as a microprocessor, programmable logic controller (PLC), or similar device that functions as the overall system coordinator, performing automated alarm functions, control of peripheral devices, operator interface, alarm reporting, and event logging. CPU is synonymous with the “head-end” of a system and is conceptually the “brains” of the associated system. Contemporary systems use distributed intelligence such that PC functions are downloaded to each local panel, which improves system reliability in the event a communications line is severed.

Data Transmission Media (DTM). The system that allows for Electronic Security Systems (ESS) data transmission and communication between system nodes and also back to the Dispatch Center. In other words, the DTM is the security communications system and can consist of dedicated conductors, wireless networks, leased T-1 lines, or virtual private networks. DTM includes both Base Level Information Infrastructure (BLII: on-base) as well as Defense Information Infrastructure (DII: inter-base).

Defense Information Infrastructure. That Information Technology (IT) infrastructure that is not on DoD proprietary or leased property and requires transmission of information across property boundary lines, for example, inter-base communications.

Dispatch Center. The space that serves as a central monitoring and assessment facility for the ACS, CCTV, and IDS systems. The key components of a Dispatch Center include consoles, monitors, and printers. Normally, the Dispatch Center is staffed 24 hours a day, seven days a week by trained personnel. Other names for the Dispatch Center include Security Operations Center (SOC), Security Command Center and Security Control Center (SCC), Central Monitoring Station, Data Transmission Center (DTC), and Alarm Control Center (ACC).

Electronic Security System (ESS). The integrated electronic system that encompasses interior and exterior Intrusion Detection Systems (IDS), Closed Circuit Television (CCTV) systems for assessment of alarm conditions, Access Control Systems (ACS), Data Transmission Media (DTM), and alarm reporting systems for monitoring, control, and display.

Electronic Security System Console (ESSC). While not always specifically referred to as the ESSC, most security systems end up with a console that houses monitoring and server interface equipment. Generally, this console is located in the Dispatch Center.

Electromagnetic Interference (EMI). A naturally occurring phenomenon when the electromagnetic field of one device disrupts, impedes, or degrades the electromagnetic field of another device by coming into proximity with it. With ESS, devices are susceptible to EMI because electromagnetic fields are a byproduct of the passing electricity through a wire. Data lines that have not been properly shielded are susceptible to EMI. A good example of an ESS application is using shielded wiring from a field card reader back to the local ACS panel.

False Acceptance Rate – (FAR). The rate or percentage at which a false credential is inaccurately accepted as being valid by an ACS. A sample FAR for a product could be 0.1%.

False Alarm. An alarm when there is no alarm stimulus.

False Rejection Rate (FRR). The rate or percentage at which an ACS product or system rejects an authorized credential holder.

Frame Rate Per Second (FPS). When referring to CCTV video image, this term refers to how often the visual still image is being updated. Most movies at the cinema operate at thirty fps. Recommended values for alarm and non-alarm CCTV video fps are provided in the CCTV technical section of the document.

Intrusion Detection System (IDS). A system consisting of interior and exterior sensors, surveillance devices, and associated communication subsystems that collectively detect an intrusion of a specified site, facility, or perimeter and annunciate an alarm.

Local Area Network (LAN). A geographically limited data communication system for a specific user group consisting of a group of interconnected computers sharing applications, data and peripherals.

Liquid Crystal Display (LCD). A type of display used for ESS monitors and other applications. LCDs utilize two sheets of polarizing material with a liquid crystal solution between them. An electric current passes through the crystals to align so that light cannot pass through them. Each crystal, therefore, is like a shutter, either allowing light to pass through or blocking the light. LCD displays can be monochrome or color. Monochrome displays are typically blue or dark gray images on top of a grayish-white background.

Multiplexing (MUXing). Combining two or more information channels into a common transmission/storage medium. With old VHS tape systems, the term referred to the storage of four different CCTV camera recordings onto a single VHS tape. With current technology, it is sometimes used to refer to transmission media. For example, a bigger transmission line can be used to bring back six door contact signals from a remote site to a centralized facility on one line as opposed to six different lines. The end result of multiplexing on transmission media is construction cost savings of installing fewer conductors.

Nuisance Alarm. An alarm resulting from the detection of an appropriate alarm stimulus, or failure to use established entry control procedures, but which does not represent an attempt to intrude into the protected area. Examples of nuisance alarms would be an improper opening of a monitored exit door or activation of an exterior intrusion detection system by a DoD maintenance crew. Animal activation of detection systems is a potential cause of nuisance alarms. Another example would be a wind-generated alarm of a fence monitoring system caused by flexing of the fence. Numerous nuisance alarms can cause complacency.

Premise Control Unit (PCU). A PCU is an electronic device that continuously monitors the alarm status of local intrusion detection sensors and duress devices and transmits alarm conditions to a remote monitoring station. The PCU allows authorized personnel to place the alarm zone in an “armed” or “disarmed” state via a local keypad, credential reader or biometric device. The term “PCU” is generally synonymous with the terms “IDS local processor” and “intrusion panel”.

Personal Identification Number (PIN). An identification string used as a password to authenticate identity and gain access to a location or computer resource. Although there are alphanumeric product options, most hardware entry devices make use of a numeric keypad. Many computer resource programs require an alphanumeric string.

Physical Protection System, Physical Security System. Means of preventing unauthorized physical access to a system, such as fences, walls, locks, sensors, surveillance, and so on.

Probability of Detection (Pd). A measure of an intrusion detection sensor’s performance in detecting an intruder within its detection zone.

Proprietary Security Network. A completely self-contained dedicated local area network (LAN) with security system software installed and run on a host server (computer). Proprietary Security Networks are dedicated to the ESS with no outside (Internet, LAN, or WAN) connections.

Regional Dispatch Center (RDC). A centralized security command center for multiple bases and facilities within a geographic region. This location is typically staffed twenty-four hours a day by staff trained to assess and initiate response for ESS alarms. The RDC requires interface and communication systems to different bases and facilities. The RDC concept is a trend of economically consolidating different base ESS at one centralized location to save money and infrastructure of having different discrete base operations center.

Security Equipment Integration Working Group (SEIWG). A working group responsible for a standard (SEIWG-012) pertaining to information encoded on an access control card. This standard is generally referred to as "SEIWG," although there are other SEIWG specifications as well. Originally designed by the DoD, the standard's intent was to provide requirements for an access card that could store enough data to determine information such as the individual cardholder, from which branch of the military the card was issued, and from which base the card was issued, all within the available 40 digits of data storage. The DoD's specification for the CAC is based on the SEIWG standard. To meet the SEIWG standard, three important issues beyond the card and reader must also be addressed:

- The access control software must address the complete SEIWG specification.
- The field panel must handle the 40 digits information resident to the CAC.
- The communication between the card reader and the field panel must be secure.

Sensitive Compartmented Information (SCI). Classified information concerning or derived from intelligence sources, methods, or analytical processes that is required to be handled within formal access control systems established by the Director of National Intelligence.

Sensitive Compartmented Information Facility (SCIF). A facility capable of storing Sensitive Compartmented Information (SCI) material. Requirements for these facilities are defined in ICS 705-1.

Time Domain Reflectometry (TDR). Use of sending an electronic signal down a conductor (wiring or cabling) and measuring the time it takes for the signal or part of the signal to return to determine the location of a conductor flaw or disturbance. The signal's reflection begins at the flaw or disturbance point. Once the signal returns, time is converted to distance, then divided by the speed of light, multiplied by the proper velocity of propagation, and the result in divided by two. As used in Intrusion Detection Systems, it is a technology for a fence mounted system that detects intruders climbing or flexing the fence fabric (and thereby inducing a conductor flaw).

Uninterruptible Power Supply (UPS). A power supply system that includes a rectifier, battery, and inverter to maintain power in the event of a power outage. UPS systems are specified by hours of operation to sustain power during an outage (six hours, ten hours, or twenty-four hours). UPS systems can be standby power systems or on-line systems. Typically, a centralized UPS is not a mandated requirement for an ESS project.

Video Analytics/IVS. Video Analytics, also known as IVS (Intelligent Video Surveillance) is the practice of using computers to automatically identify things of interest without an operator having to view the video. IVS consists of algorithms that detect movement or changes in live and recorded video to see whether the movement or changes mean a possible threat is about to occur or occurring. These algorithms work by examining each pixel of the video and putting together all the pixel changes. If many pixels are changing in one area and that area is moving in a direction, the software considers this to be motion. Depending on the policies and alerts you have setup, you will be notified of this motion or other actions can be automatically taken by the software such as motion tracking which follows the motion until it is no longer detected.

Wide Area Network (WAN). An internetwork that uses telecommunication links to connect geographically distant networks.

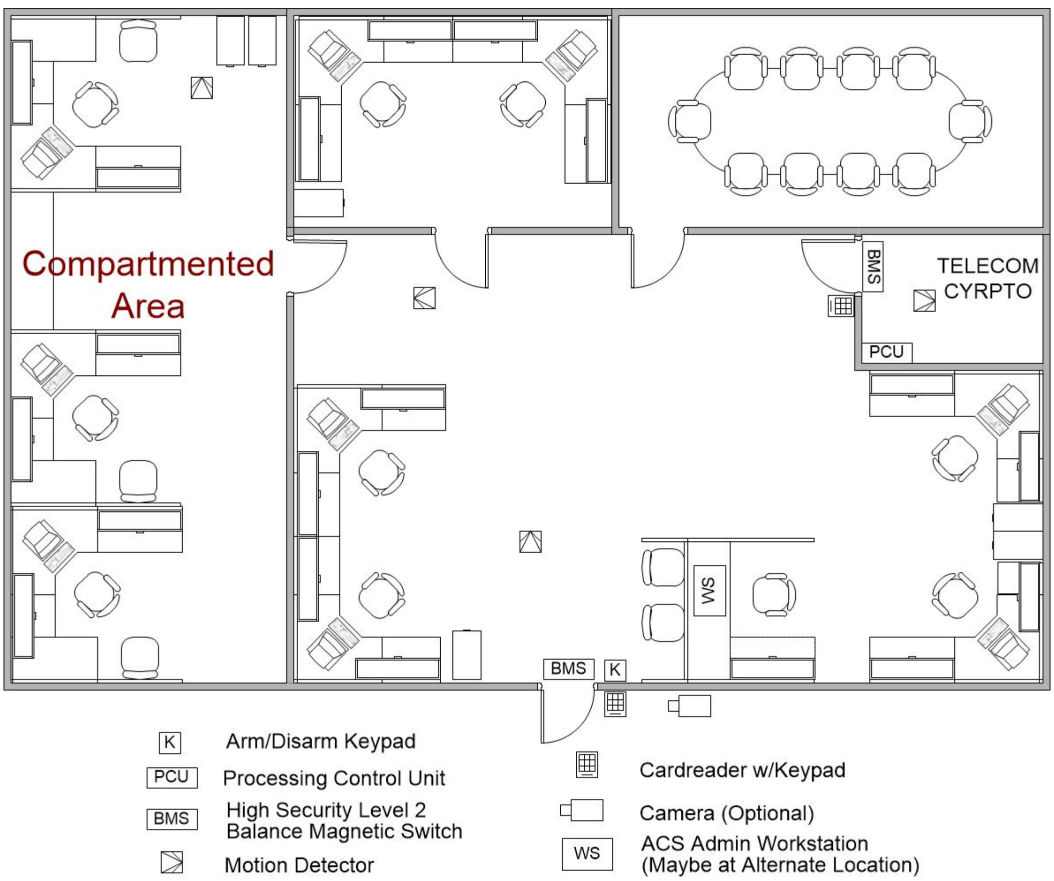
APPENDIX C NOTIONAL INTERIOR IDS CONFIGURATIONS

The information provided in this appendix is intended to aid the designer in understanding and applying policy-directed IDS requirements. It is not comprehensive as it addresses only a few high-security assets and summarizes only the most critical technical requirements. Using this information as a starting point, the designer must identify all security policies that pertain to each project and ensure that all IDS requirements are addressed in the design. **\1**

C-1 SENSITIVE COMPARTMENTED INFORMATION FACILITY (SCIF).



C-1.1 DoD Criteria Document.

UFC 4-010-05, Sensitive Compartmented Information Facilities Planning, Design, and Construction.

C-1.2 Policy Baseline.

- Director of National Intelligence, Intelligence Community Standard (ICS) 705-1 Physical and Technical Security Standards for Sensitive Compartmented Information Facilities.

- DoD Manual 5105.21, Sensitive Compartmented Information (SCI) Administrative Security Manual: Administration of Information and Information Systems Security.

C-1.3 Baseline Intrusion Detection System (IDS) Requirements.

- Must be protected by an IDS when not occupied.
- Provide point sensors on all doors, and man-passable openings. Provide motion sensors within SCIF to protect all windows, doors, and man-passable openings and detect movement within the SCIF to include compartmented areas.
- Emergency exit doors must be secured, alarmed, and monitored 24 hours per day.
- Interior areas of a SCIF through which reasonable access could be gained, including walls common to areas not protected at the SCI level, must be protected by IDS consisting of motion sensors and Level 2 high security switches (HSS).
- IDS must be installed in accordance with UL 681 and consist of:
  - Point Sensors that meet UL 634 Level 2 high security switches (HSS). Level 2 rated switches only include Balanced Magnetic Switches that pass additional performance testing.
  - Motion detection sensors must be UL 639 listed. Dual-technology sensors may be used when authorized and when each technology transmits alarm conditions independent of the other technology (“or” configuration).
- Premise Control Units (PCUs) must be located within perimeter of a SCIF.

C-1.4 Cameras.

Cameras are not allowed within the SCIF.

C-1.5 Tamper Protection.

- All IDS systems; including any access control system equipment, must be equipped with tamper detection devices that must be monitored continuously whether the system is in the access or secure mode of operation. Upon detection, an alarm (not fault) condition must be transmitted to the PCU or monitoring station.
- IDS-associated cabling that extends beyond the SCIF perimeter must be installed in rigid conduit or must employ line supervision.
- All system sensors should be located within the perimeter of the SCIF. Cabling between all sensors and the PCU must be dedicated to the system, contained within the SCIF. With Accrediting Official (AO)

approval, sensors external to the SCIF perimeter and any perimeter equipment used may be connected to the IDS provided the lines are installed on a separate zone and routed within grounded conduit.

C-1.6 External Transmission Line Security.

- Any system transmission line that leaves a SCIF must have line supervision and be encrypted to National Institute of Standards and Technology FIPS 140-2. Alternative methods must be approved by the AO.

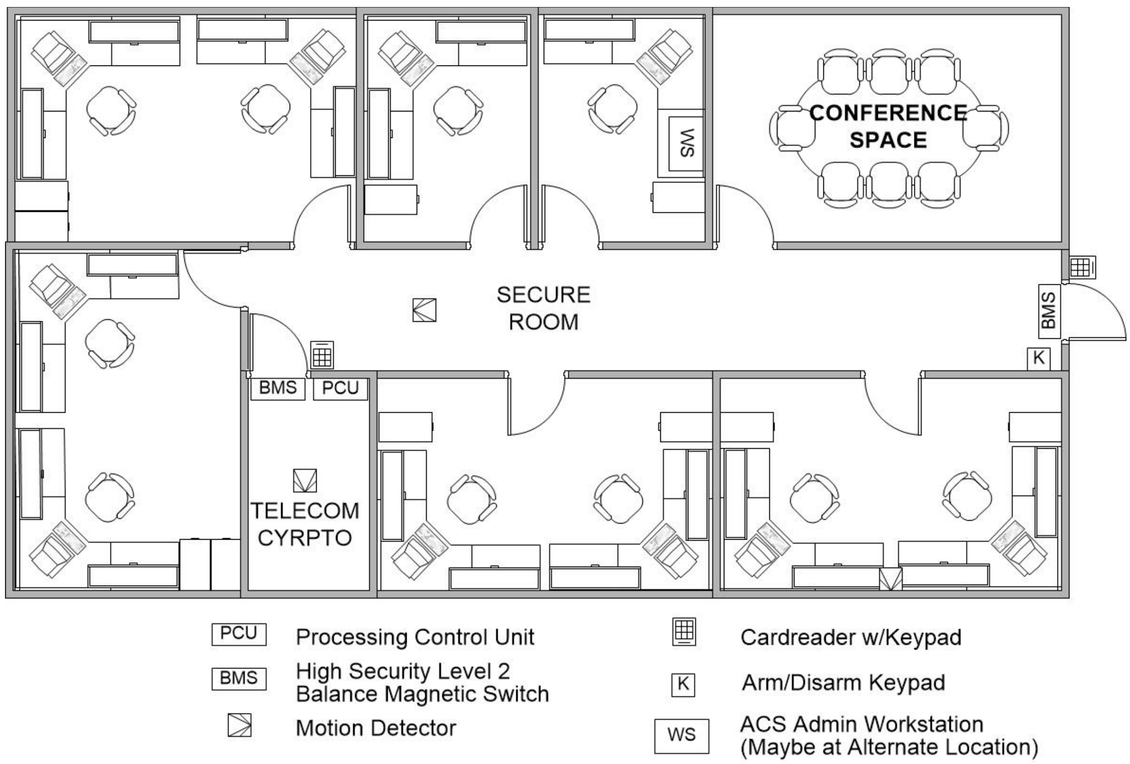
C-1.7 Emergency Backup Electrical Power.

- Twenty four hours of uninterruptible backup power is required. This may be provided by batteries integral to the ESS, uninterruptible power supply (UPS), generators, or any combination thereof. In the event of primary power failure, the system must automatically transfer to an emergency electrical power source without causing alarm activation.
- An audible or visual indicator at the PCU must provide an indication of the primary or backup electrical power source in use. Equipment at the monitoring station must visibly and audibly indicate a failure in a power source or a change in power source. The individual system that failed or changed must be indicated at the PCU or monitoring station as directed by the AO.

C-1.8 Optional Equipment.

- External CCTV Camera to monitor primary entrance.

C-2 SECURE ROOM (TOP SECRET OR SECRET OPEN STORAGE)



C-2.1 Policy Baseline.

- DoD Manual 5200.01, DoD Information Security Program: Protection of Classified Information
- SECNAV M-5510.36 Department of the Navy Information Security Program
- AFI 31-401 Department of the Air Force Information Security Program Management
- AR 380-5 Department of the Army Information Security Program

C-2.2 Baseline Intrusion Detection System (IDS) Requirements.

- Must be protected by an IDS when not continuously manned or under constant surveillance. If an IDS is not required, a continuously manned secure area should be equipped with an alerting system on all potential entrances into the secure area that cannot be observed by the occupants.
- All perimeter doors and man-passable openings into the secure area must be protected by High Security Switch (HSS) and a motion detection sensor.

- Keypad at Primary Entrance.
- Perimeter emergency exit doors must be secured, alarmed, and monitored 24 hours per day.
- IDS must be installed in accordance with UL 681 and consist of:
    - Level 2 high security switches (HSS) that meet UL 634, and/or other government approved sensors.
    - Motion detection sensors UL 639 listed. Dual-Technology Sensors are authorized when each technology transmits alarm conditions independent of the other technology.
- Premise Control Units (PCUs) must be located within a secure room.

C-2.3 Cameras.

Cameras are not allowed within spaces that contain classified materials.

C-2.4 Tamper Protection.

- All IDS systems, including any access control system connected must be equipped with tamper detection devices that must be monitored continuously whether the system is in the access or secure mode of operation. Upon detection, an alarm (not fault) condition must be transmitted to the PCU or monitoring station.
- System associated cabling that extends beyond the protected area perimeter must be installed in conduit and must employ electronic line supervision. Electronic line supervision will entail a polling or multiplexing system or equivalent. If line supervision is unavailable, two independent means of alarm signal transmission to the monitoring location must be provided.
- All system sensors must be located within the protected area.
- Cabling between all sensors and the PCU must be dedicated to the system, contained within the protected area.

C-2.5 External Transmission Line Security.

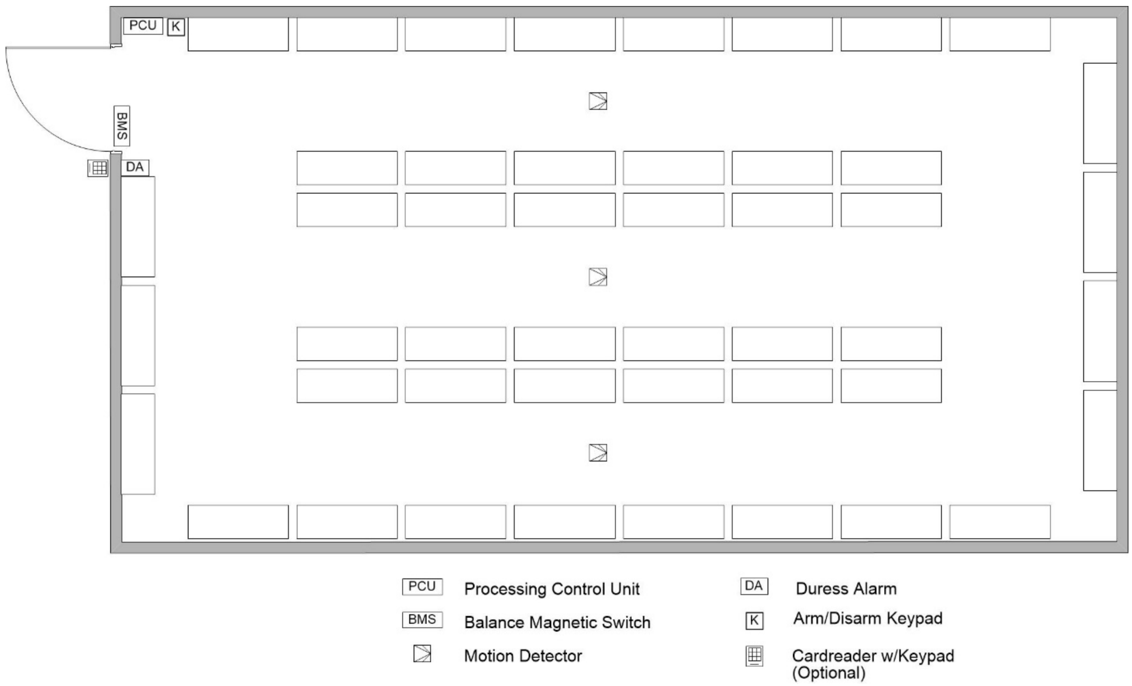
- Any system transmission line that leaves the protected area must be encrypted to National Institute of Standards and Technology FIPS 140-2.

C-2.6 Emergency Backup Electrical Power.

- Eight hours of uninterruptible backup power is required. This may be provided by an uninterruptible power supply (UPS), batteries integral to the ESS, generators, or any combination thereof. In the event of primary power failure, the system must automatically transfer to an emergency electrical power source without causing alarm activation.

- An audible or visual indicator at the PCU must provide an indication of the primary or backup electrical power source in use. Equipment at the monitoring station must visibly and audibly indicate a failure in a power source or a change in power source. **/1/**

C-3 ARMS STORAGE AREA (ARMORY, ARMS ROOM, READY ISSUE ROOM).



C-3.1 Policy Baseline.

- DoD Manual 5100.76, Physical Security of Sensitive Conventional Arms, Ammunition, and Explosives (AA&E),
- OPNAV INSTRUCTION 5530.13C Department of the Navy Physical Security Instruction for Conventional Arms, Ammunition, and Explosives.
- MCO 5530.14A Marine Corps Physical Security Program Manual
- AFI 31-101 Department of the Air Force Integrated Defense
- AR 190-11 Department of the Army Physical Security of Arms, Ammunition, and Explosives

C-3.2 Baseline Intrusion Detection System (IDS) Requirements.

- Must be protected by an IDS when not continuously manned or under constant surveillance.

- All perimeter doors and man-passable openings into the storage area must be protected by High Security Switch (HSS) and a motion detection sensor.
- Duress alarm at all issue ports.
- Keypad at entrance and for all separated (unit-based) interior storage areas that require an independent IDS capability.
- Perimeter emergency exit doors must be secured, alarmed, and monitored 24 hours per day.
- IDS must be installed in accordance with UL 681 and consist of:
    - Level 2 high security switches (HSS) that meet UL 634, and/or other government approved sensors.
    - Motion detection sensors UL 639 listed.
- Premise Control Units (PCUs) should be located within the protected area.

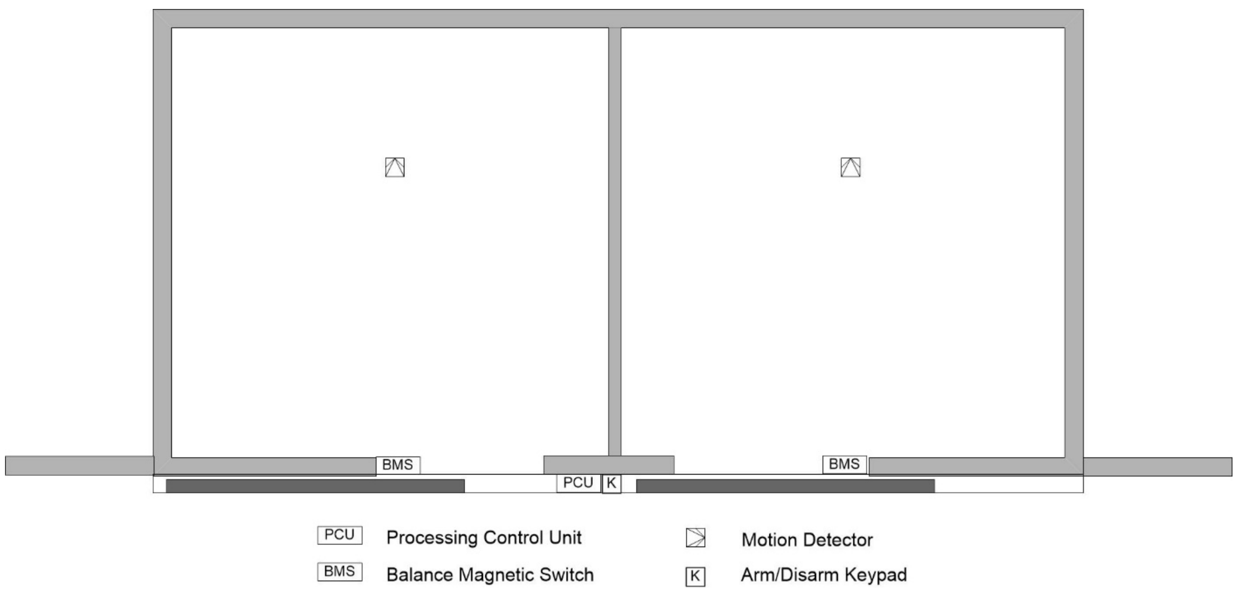
C-3.3 Tamper Protection.

- All IDS systems, including any access control system connected must be equipped with tamper detection devices that must be monitored continuously whether the system is in the access or secure mode of operation. Upon detection, an alarm (not fault) condition must be transmitted to the PCU or monitoring station.
- System associated cabling that extends beyond the protected area perimeter must be installed in conduit and must employ electronic line supervision. Electronic line supervision will entail a polling or multiplexing system or equivalent. If line supervision is unavailable, two independent means of alarm signal transmission to the monitoring location must be provided.
- All system sensors must be located within the protected area.
- Cabling between all sensors and the PCU must be dedicated to the system, contained within the protected area.

C-3.4 Emergency Backup Electrical Power.

- Eight hours of uninterruptible backup power is required[3]. This may be provided by an uninterruptible power supply (UPS), batteries integral to the ESS, generators, or any combination thereof. In the event of primary power failure, the system must automatically transfer to an emergency electrical power source without causing alarm activation.
- An audible or visual indicator at the PCU must provide an indication of the primary or backup electrical power source in use. Equipment at the monitoring station must visibly and audibly indicate a failure in a power source or a change in power source.

C-4 MAGAZINE



C-4.1 Policy Baseline.

- DoD Manual 5100.76, Physical Security of Sensitive Conventional Arms, Ammunition, and Explosives (AA&E),
- OPNAV INSTRUCTION 5530.13C Department of the Navy Physical Security Instruction for Conventional Arms, Ammunition, and Explosives.
- MCO 5530.14A Marine Corps Physical Security Program Manual
- AFI 31-101 Department of the Air Force Integrated Defense
- AR 190-11 Department of the Army Physical Security of Arms, Ammunition, and Explosives

C-4.2 Baseline Intrusion Detection System (IDS) Requirements.

[3] Based on DoD O-2000.12-H, Antiterrorism Handbook

- Must be protected by an IDS when not continuously manned or under constant surveillance.
- All perimeter doors and man-passable openings into the magazine must be protected by High Security Switch (HSS) and a motion detection sensor.
- Keypad at entrance of all separated (unit-based) storage areas that require an independent IDS capability.
- IDS must be installed in accordance with UL 681 and consist of:
  - Level 2 high security switches (HSS) that meet UL 634, and/or other government approved sensors.
  - Motion detection sensors UL 639 listed.
- Premise Control Units (PCUs) should be located within the protected area.

C-4.3 Tamper Protection.

- All IDS systems, including any access control system connected must be equipped with tamper detection devices that must be monitored continuously whether the system is in the access or secure mode of operation. Upon detection, an alarm (not fault) condition must be transmitted to the PCU or monitoring station.
- System associated cabling that extends beyond the protected area perimeter must be installed in conduit and must employ electronic line supervision. Electronic line supervision will entail a polling or multiplexing system or equivalent. If line supervision is unavailable, two independent means of alarm signal transmission to the monitoring location must be provided.
- All system sensors must be located within the protected area.
- Cabling between all sensors and the PCU must be dedicated to the system, contained within the magazine.

C-4.4 Emergency Backup Electrical Power.

- Eight hours of uninterruptible backup power is required[4]. This may be provided by an uninterruptible power supply (UPS), batteries integral to the ESS, generators, or any combination thereof. In the event of primary power failure, the system must automatically transfer to an emergency electrical power source without causing alarm activation.
- An audible or visual indicator at the PCU must provide an indication of the primary or backup electrical power source in use. Equipment at the

[4] Based on DoD O-2000.12-H, Antiterrorism Handbook

monitoring station must visibly and audibly indicate a failure in a power source or a change in power source.

U.S. ARMY CORPS OF ENGINEERS

NAVAL FACILITIES ENGINEERING COMMAND (Preparing Activity)

AIR FORCE CIVIL ENGINEER CENTER

Record of Changes (changes are indicated by ...)

Change No.	Date	Location

This UFC supersedes UFC 4-022-01, dated 25 May 2005.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Subject: UFC 4-022-01, Entry Control Facilities / Access Control Points

Cancels: UFC 4-022-01, Security Engineering: Entry Control Facilities / Access Control Points, dated 25 May 2005

Reasons for Revision: UFC 4-022-01 was updated for the following reasons:

- To eliminate information that could be referenced from other references, especially tables, charts, figures, and diagrams.
- To improve consistency and uniformity of terminology.
- To remove ambiguous language and clarify between recommendations and requirements.
- To minimize the amount of service-specific items.
- To incorporate new and updated standards and requirements.
- To eliminate extraneous information so pertinent information is more accessible.
- To reduce misunderstandings of some of its provisions.
- To address situations not previously addressed by the standards.
- To improve consistency of interpretation.
- To reduce redundancy or inconsistency with other UFCs that were not available at the time of the previous version of this document.
- To eliminate standards or recommendations that were unnecessary or that had been superseded by other UFCs.
- To eliminate materials covered by other documents and to reference them where appropriate.
- To incorporate information based on new studies and research or new or revised national standards.

Impact. Most of the changes result in overall life cycle cost savings. Further impacts include the following:

- More consistent application of the provisions of the document due to clearer and more consistent guidance.
- Improved designs and reduced construction costs due to the changes of requirements versus recommendations.

Non Unified Issues. Document content is unified and consistent for all services and agencies of the Department of Defense.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE.

This document presents the required baseline approach to the design of Continental United States (CONUS) and Outside Continental United States (OCONUS) Entry Control Facilities (ECFs) and Access Control Points (ACPs) at Department of Defense (DoD) military installations. The term “Entry Control Facilities/Access Control Points” encompasses the overall layout, organization, infrastructure, and facilities at entrance locations onto United States military installations. ECF is synonymous with the term Access Control Point (ACP) used in some service publications. This UFC identifies design features necessary to ensure that infrastructure constructed today will have the flexibility to support current and future technologies, a changing threat environment, and changes in operations.

1-2 APPLICABILITY.

This UFC provides planning and design criteria and guidance for DoD components and participating organizations. This document applies to all construction, renovation, modernization, and repair projects for entry control facilities/access control points (ECF/ACP).

This UFC is not intended to guide the development of entry control points (ECPs). ECPs are defined as an internal access control portal to a building or building compound once one passes through an existing installation ECF/ACP or after one has already been vetted and permitted into and within a controlled perimeter. The definition of a controlled perimeter is included in other security engineering UFC documents.

1-3 SCOPE AND GUIDANCE.

Commanders, security personnel, planners, designers, architects, and engineers must use this UFC when evaluating existing and providing new ECFs/ACPs of an installation. Technical information considered generally known to professional designers, architects, or engineers or readily available in existing technical references (Unified Facilities Criteria - UFC, FHWA, AASHTO, SDDCTEA etc.) has not been included.

1-4 VULNERABILITY AND RISK ASSESSMENT.

In accordance with DoD security and antiterrorism (AT) policies, a vulnerability and risk assessment must be conducted prior to beginning any security project. Upon identifying facility or asset vulnerabilities to threats, physical security measures such as access control, fences, gates, vehicle barriers and Electronic Security Systems (ESS) may be deployed to reduce vulnerabilities. In summary, this document assumes the planning phases, including the risk analysis, are complete prior to beginning design. For information on Security Engineering Planning and Design process, refer to UFC 4-020-01 and UFC 4-020-02FA (described in the section “Security Engineering UFC Series” in this chapter). The engineering risk analysis conducted as part of UFC 4-020-01 should be consistent with the terrorism risk analysis conducted by the installation security/AT staff.

1-5 EXAMPLES AND APPLICATION.

The examples provided in this UFC are notional and will need to be site adapted using sound engineering and security practices as required by site constraints and the credentialing process of those professions. Consult with service guidelines and policies for specific facility related requirements. Consult with most recent source document for the most up to date information. This UFC is not intended to address procedural issues such as tactics and techniques; however, a well-designed ECF/ACP can enhance and improve operations. UFC 4-020-01, Security Engineering: Facilities Planning Manual contains information regarding the application and use of Security Engineering UFC documents and should be consulted prior to using this UFC in the project development process.

1-6 DOD BUILDING CODE.

Comply with UFC 1-200-01, DoD Building Code (General Building Requirements). UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-7 ECF/ACP MISSION, PRIORITIES AND FUNCTIONS.

The objective of ECFs/ACPs is to secure the installation from unauthorized access and intercept contraband (weapons, explosives, drugs, classified material, etc.) while maximizing vehicular traffic flow by ensuring the proper level of access control and safety for all DoD personnel, visitors, and commercial traffic to an installation. ECF/ACP priorities include:

- Security
- Safety
- Capacity
- Sustainability

1-7.1 ECF/ACP Function.

An ECF/ACP and its facilities when required perform a variety of functions including visitor processing, vehicle registration, ID checks, privately owned vehicle (POV) inspections, and commercial/large vehicle inspections. An ECF/ACP when required should accommodate pedestrians and a variety of vehicles, including passenger vehicles, trucks, oversize vehicles, construction equipment, buses, recreational vehicles, motorcycles, and bicycles.

1-7.2 ECF/ACP Checklist.

Appendix D is a checklist for the development of ECF/ACP designs that is provided to assist in the planning and design stages to determine the requirements and major features for proposed ECF/ACP projects.

1-7.3 Security Concerns.

It is well established that installations must focus on threats that can be mitigated at the first line of defense–the installation perimeter. ECFs/ACPs and the access control they provide are extremely important to defense-in-depth and effective risk mitigation.

An ECF/ACP:

- Is a part of the installation perimeter and a legal line of demarcation and provides the first physical security boundary layer that restricts entry/access to DoD installations.
- Must accommodate Random Antiterrorism Measures (RAM), for sustained operations
- Must be able to operate at all Force Protection Conditions (FPCONs), including 100% vehicle inspections.
- Must have security features that protect against vehicle-borne threats and illegal entry.

1-7.4 Safety Concerns.

ECFs/ACPs must have a working environment that is both safe and comfortable for Security Forces personnel. Security Forces safety includes provisions for personal protection against attack and errant drivers; consider climate, location, and orientation.

Design the ECF/ACP so that persons and vehicles entering and leaving the facility do so in a safe and orderly manner to protect themselves, security personnel, and pedestrians from harm.

1-7.5 Capacity.

Design the ECF/ACP to maximize the flow of traffic without compromising safety, security, or causing undue delays that may affect installation operations or off-installation public highway users. A traffic engineering and safety study is recommended prior to the modification of an existing ECF/ACP and prior to the implementation of active vehicle barriers (AVB) and automated equipment. A traffic engineering and safety study is required prior to the major modification of an existing ECF/ACP and prior to the design of a new ECF/ACP.

1-7.6 **Sustainability.**

The ECF/ACP should reduce energy costs, facility maintenance and operations costs through sustainable design where appropriate. Refer to the DoD Building Code for additional guidance.

1-8 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. The most recent edition of referenced publications applies, unless otherwise specified.

1-9 GLOSSARY.

Appendix E contains acronyms, abbreviations, and terms.

1-10 POLICY REQUIREMENTS.

The requirement to provide entry and access control comes from DoD Instruction/Directives, Geographic Combatant Commander (GCC) Instructions, Service Instruction/Directives, and Regional or Installation requirements. Consult Headquarters, Major Command, Regional, and Installation personnel to establish project requirements.

1-11 DOD REQUIREMENTS.

There are several instructions and publications within the Department of Defense (DoD) that establish required access control procedures for an installation, objectives of an ECF/ACP, and the responsibility for the operation of the facility. The most recent versions of these documents can be obtained from DoD, agency and service web sites. The intent of the references listed in Appendix A is to provide designers with the most relevant and specialized requirements for ECFs/ACPs. Other specific design requirements exist for various aspects of design such as buildings and roadways and are found in the DoD Building Code indicated above.

Specific to access control, Directive-Type Memorandum (DTM) 09-012, Interim Policy Guidance for DoD Physical Access Control establishes DoD access control policy and the minimum DoD security standards for controlling entry to DoD installations and stand-alone facilities.

1-12 NATIONAL REQUIREMENTS.

ECFs/ACPs must meet nationally accepted standards as applicable per Multi-Service Regulation (Army Regulation (AR) 55-80, Chief of Naval Operations Instruction (OPNAVINST) 11210.2, Air Force Manual (AFMAN) 32-1017, Marine Corps Order (MCO) 11210.2D and Defense Logistics Agency Regulation (DLAR) 4500.19) DoD Transportation Engineering Program and Code of Federal Regulations (CFR) – Title 23: Highways, Chapter I, Subchapter G, Part 655, subpart f: Traffic Control Devices on Federal-Aid and Other Streets and Highways. Title 32: National Defense, Subtitle A, Chapter V, Part 634, Subpart D: Traffic Supervision. These references and other nationally recognized documents are found in Appendix A under National Design Standards.

1-13 GEOGRAPHIC COMBATANT COMMANDER REQUIREMENTS.

Geographic Combatant Commanders (GCC) issue requirements for antiterrorism and physical security for installations within their area of responsibility. Ensure any such requirements are incorporated in addition to the requirements found in DoD and Service Directive/Instructions. Resolve any differences in the requirements by applying the most stringent requirement.

1-14 INSTALLATION SPECIFIC REQUIREMENTS.

The FPCON and RAM specified in an installation AT Plan impact the operation, capacity, and design of the ECF/ACP. Ensure any such requirements are incorporated in addition to the requirements found in this UFC. Resolve any differences in the requirements for the design of an ECF/ACP by applying the most stringent requirement.

1-15 OCONUS REQUIREMENTS.

Code of Federal Regulations Title 32, National Defense, Part 634, Subpart D-Traffic Supervision establishes that it is the Commander’s responsibility to develop traffic codes based on the Status of Forces Agreement (SOFA) with the host nation. For ECFs/ACPs developed at OCONUS installations, refer to the SOFA agreement for direction on which standard to apply. If the SOFA agreement is not explicit on which standard dictates, the most stringent requirement must be applied.

Specific service requirements may also apply.

1-16 DOD SECURITY ENGINEERING UFC SERIES

This UFC is one of a series of security engineering Unified Facilities Criteria documents that cover minimum standards, planning, preliminary design, and detailed design for security and antiterrorism. The manuals in this series are designed to be used sequentially by a diverse audience to facilitate development of projects throughout the design cycle. The manuals in this series include the following, and the intended process for applying them is illustrated in Figure 1-1.

1-16.1 DoD Minimum Antiterrorism Standards for Buildings.

UFC 4-010-01 establishes standards that provide minimum levels of protection against terrorist attacks for the occupants of all DoD inhabited buildings. This UFC is intended to be used by security and antiterrorism personnel and design teams to identify the minimum requirements that must be incorporated into the design of all new construction and major renovations of inhabited DoD buildings. They also include recommendations that should be, but are not required to be incorporated into all such buildings.

1-16.2 Security Engineering Facilities Planning Manual.

UFC 4-020-01 presents processes for developing the design criteria necessary to incorporate security and antiterrorism into DoD facilities and for identifying the cost implications of applying those design criteria. Those design criteria may be limited to the requirements of the minimum standards, or they may include protection of assets other than those addressed in the minimum standards (people), aggressor tactics that are not addressed in the minimum standards or levels of protection beyond those required by the minimum standards.

The cost implications for security and antiterrorism are addressed as cost increases over conventional construction for common construction types. The changes in construction represented by those cost increases are tabulated for reference, but they represent only representative construction that will meet the requirements of the design criteria. The manual also addresses the tradeoffs between cost and risk. The Security Engineering Facilities Planning Manual is intended to be used by planners as well as security and antiterrorism personnel with support from planning team members.

1-16.3 Security Engineering Facilities Design Manual.

UFC 4-020-02FA provides interdisciplinary design guidance for developing preliminary systems of protective measures to implement the design criteria established using UFC 4-020-01. Those protective measures include building and site elements, equipment, and the supporting manpower and procedures necessary to make them all work as a system. The information in UFC 4-020-02FA is in sufficient detail to support concept level project development, and as such can provide a good basis for a more detailed design. The manual also provides a process for assessing the impact of protective measures on risk. The primary audience for the Security Engineering Design Manual is the design team, but it can also be used by security and antiterrorism personnel.

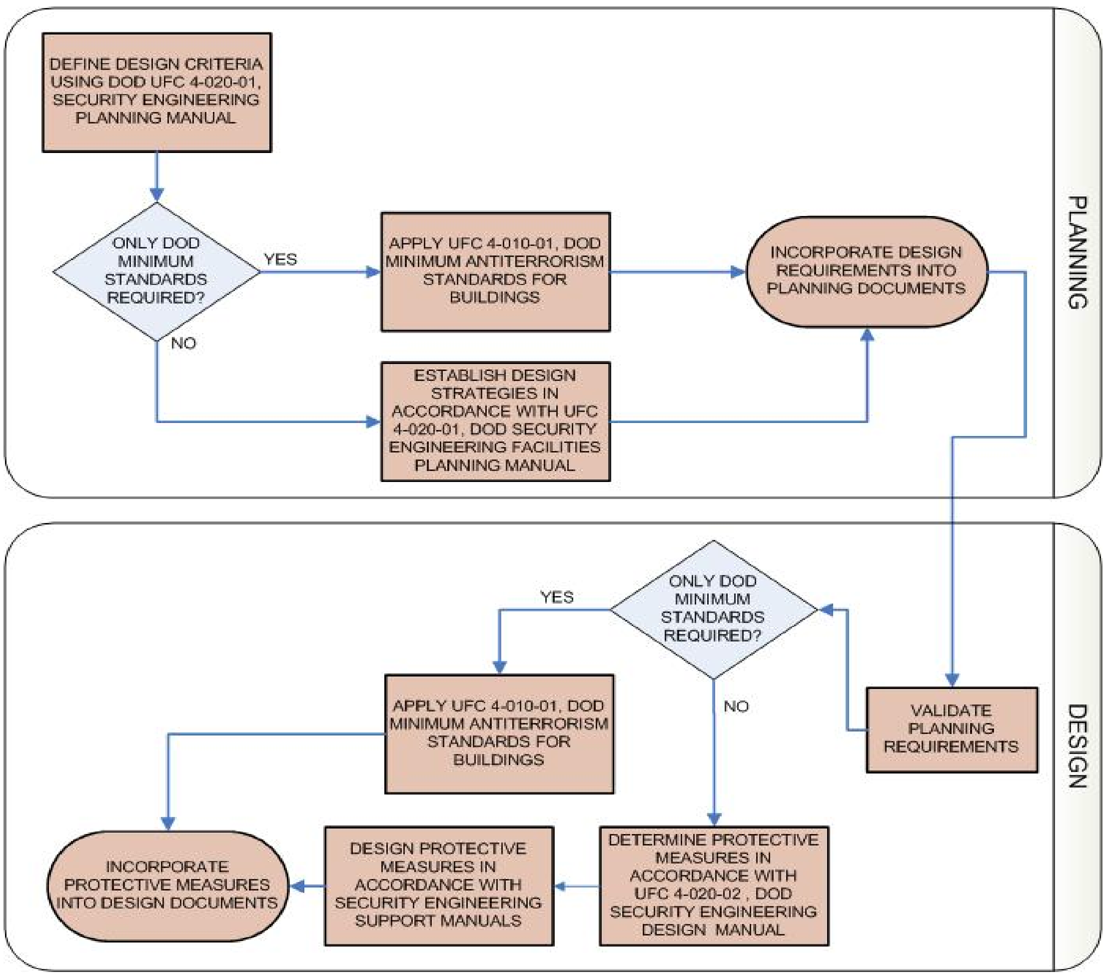
1-16.4 Security Engineering Support Manuals.

In addition to the standards, planning, and design UFCs mentioned above, there is a series of additional UFCs that provide detailed design guidance for developing final designs based on the preliminary designs developed using UFC 4-020-02FA. These support manuals provide specialized, discipline specific design guidance. Some address specific tactics such as direct fire weapons, forced entry, or airborne contamination. Others address limited aspects of design such as resistance to progressive collapse or design of portions of buildings such as mail rooms. Still others address details of designs for specific protective measures such as vehicle barriers or electronic security systems. The Security Engineering Support Manuals are intended to be used by the design team during the development of final design packages.

1-16.5 Security Engineering UFC Application.

The application of the security engineering series of UFCs is illustrated in Figure 1-1. UFC 4-020-01 is intended to be the starting point for any project that is likely to have security or antiterrorism requirements. By beginning with UFC 4-020-01, the design criteria will be developed that establishes which of the other UFCs in the series will need to be applied. The design criteria may indicate that only the minimum standards need to be incorporated, or it may include additional requirements, resulting in the need for application of additional UFCs. Even if only the minimum standards are required other UFCs may need to be applied if sufficient standoff distances are unavailable. Applying this series of UFCs in the manner illustrated in Figure 1-1 will result in the most efficient use of resources for protecting assets against security and antiterrorism related threats.

Figure 1-1 Security Engineering UFC Application



This Page Intentionally Left Blank

CHAPTER 2 CLASSIFICATIONS AND FUNCTIONS

2-1 ECF/ACP USE CLASSIFICATIONS.

ECFs/ACPs are classified based on the intended function and anticipated usage of the ECF/ACP. The four "use" classifications are outlined in Table 2-1. The use classification is a function of the type of traffic, hours of operation, and FPCON considerations.

Table 2-1 ECF/ACP Use Major Classifications

Use Classification	Operational Hours	FPCON Considerations	Typical Operation
Primary	24/7, Open continuously	Open thru FPCON Delta	Vehicle registration/Visitor Pass capacity. Regular operations, visitors with authorization. Could also be designated as truck and delivery ECF/ACP.
Secondary	Regular hours, closed at times	Potentially closed at or above FPCON Charlie	Regular operations, visitors with authorization. Could also be designated as truck and delivery ECF/ACP.
Limited Use	Only opened for special purposes	Closed at most times	Tactical vehicles, Construction Equipment/Vehicles, HAZMAT, special events, emergency access... etc.
Pedestrian Access	Varies	Potentially closed at or above FPCON Charlie	Personnel only. Could be located near installation housing areas, near schools, or as part of a Primary or Secondary ECF/ACP.

The guidance contained in this UFC is intended for primary and secondary ECFs/ACPs. Primary and Secondary ECFs/ACPs must provide the means to defeat a vehicular and/or pedestrian threat through permanent measures. Limited-use ECFs/ACPs or internal/restricted area entry control points (ECP) may require significantly less infrastructure due to reduced operations. Limited Use ECFs/ACPs must provide means to defeat vehicular and/or pedestrian threats through temporary or permanent measures. Limited Use ECFs/ECPs/ACPs do not have routine hours of operation. A Pedestrian ECF/ACP may be part of an ECF/ACP that accommodates vehicles or it may stand alone.

2-2 ECF/ACP FUNCTION.

An ECF/ACP can have many functions. Not all functions are required at every ECF/ACP. Functions for each ECF/ACP are based on the installation's mission, AT Plan, ECF/ACP use classification, and land area. Functions may change to meet the demands of higher FPCON levels. The basic functions associated with an ECF/ACP are:

- Processing visitors
- Vehicle ID checks
- Personnel ID checks
- Privately Owned Vehicle (POV) Inspections
- Commercial/Large Vehicle Inspections

2-2.1 Site Functions.

ECF/ACP site functions include, but are not limited to, Approach Zone, Access Control Zone, Response Zone, Passive Vehicle Barriers, Active Vehicle Barriers (AVB), Command and Control, ID check area, Overwatch, Canopies, Turn Arounds, Search Areas, Lighting, and CCTV.

2-2.2 Building Functions.

Visitor Control Center (VCC), Guard Booths (Vehicle ID Check and Pedestrian ID Check), Search Area Building, Command and Control, Communications, Mechanical, Electrical, Latrine, Storage, and Overwatch are some building function components of the ECF/ACP.

2-2.3 Multi-Function ECFs/ACPs.

Where appropriate, ECF/ACP functional requirements should be consolidated or isolated to best maintain an installation's mission.

2-2.3.1 Mixed Vehicles.

An installation with limited access control space may combine all the above functions within a single ECF/ACP or an installation with high commercial vehicle demand may designate one isolated ECF/ACP for commercial vehicle inspections. When combining or isolating ECF/ACP functional requirements, designers must consider the destination of each user (visitors, commercial vehicles, etc.) and the real estate available to provide adequate facilities.

2-2.3.2 Commercial Vehicles.

Within a combined ECF/ACP, truck processing must be segregated from POV processing. Traffic lanes that require speed management to delay a high performance passenger vehicle should exclude truck traffic from these lanes. The effectiveness of most speed management techniques for passenger vehicles decreases when trucks must use the same lanes.

2-2.3.3 **Oversized Vehicles.**

When designating the functions for all ECFs/ACPs at an installation, give consideration to the requirements to support oversized, atypical vehicles such as those frequently encountered during construction operations or during mobilization of military vehicles and equipment. These atypical vehicles should be supported by at least one limited use or primary/secondary ECF/ACP, which may require modifications such as wider lanes, limiting the use of channelization islands, or limiting potential obstructions. It is recommended that canopies cover all inbound lanes and that random, infrequent oversized vehicles be directed to limited use ECFs/ACPs or be directed through outbound lanes with the appropriate traffic management.

2-3 **ECF/ACP FUNCTIONAL DIAGRAMS.**

The functional diagrams shown in Figure 2-1 through 2-4 illustrate general relationships and desired adjacencies for different types of ECFs/ACPs. These can be modified based on installation or site-specific requirements for an ECF/ACP. See SDDCTEA Pamphlet 55-15 *Traffic and Safety Engineering for Better Entry Control Facilities, Army Standard for Access Control Points' and 'Army Access Control Points Standard Design*, and Air Force Civil Engineer Center's *Facilities Dynamic Prototypes Design: Entry Control Facilities/Installation Access Control Points (ECF/IACP)* for additional layout options.

The UFC defines functional flow requirements for ECPs/ACPs including visitor processing, truck inspection, and random inspections. All ECFs/ACPs must have a mechanism to conduct select inspections after the ID check area. In some cases, security requirements may require that all vehicles be inspected prior to entry. Where and when random inspection activities occur, facilities and procedures must be developed to minimize the impact to traffic flow on the main approach.

Figure 2-1 Visitors/DoD Personnel ECF/ACP – Functional Relationships

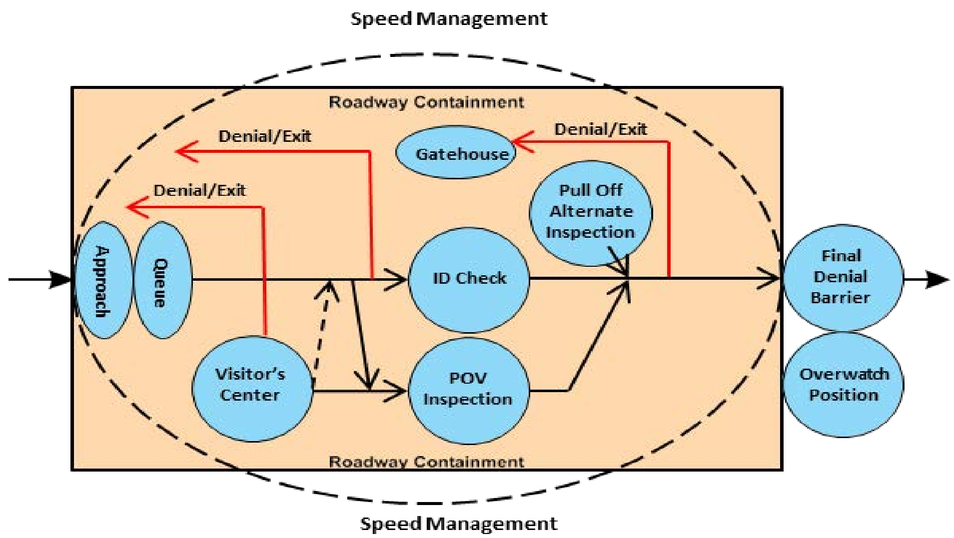


Figure 2-2 DoD/Authorized Personnel Only ECF/ACP – Functional Relationships

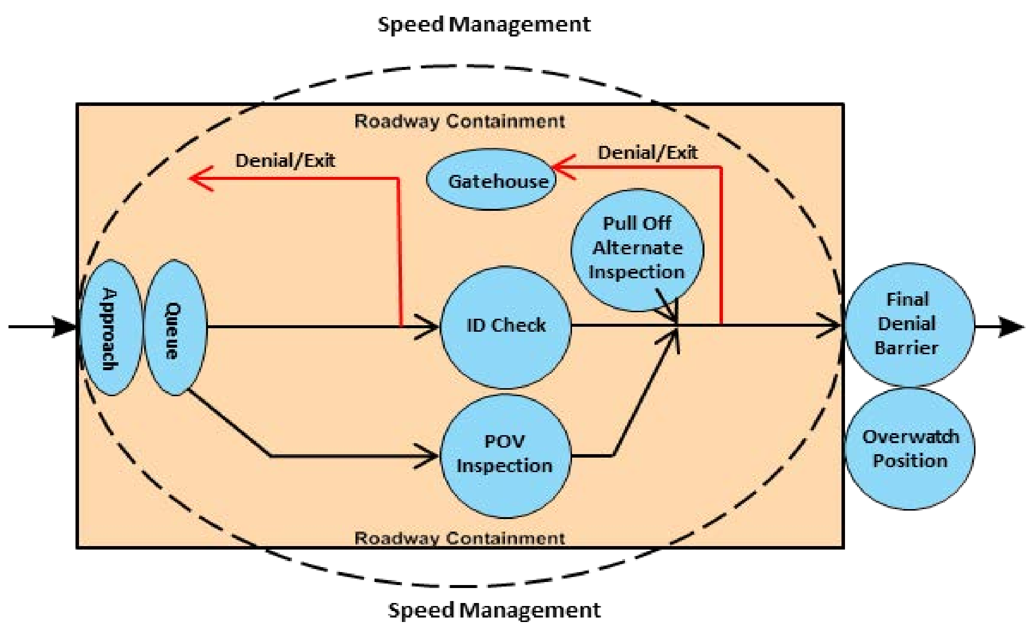

Figure 2-3 Commercial Vehicle ECF/ACP: Functional Relationships

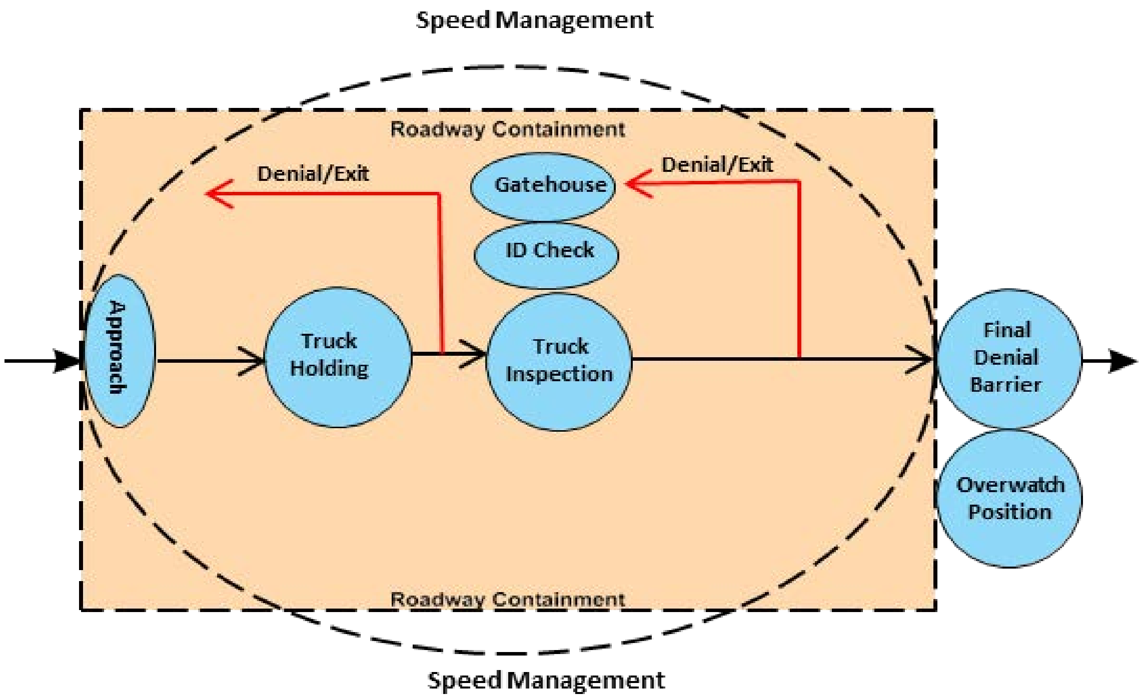

Figure 2-4 Primary ECF/ACP w/POV, Visitor, and Commercial Vehicle Processing

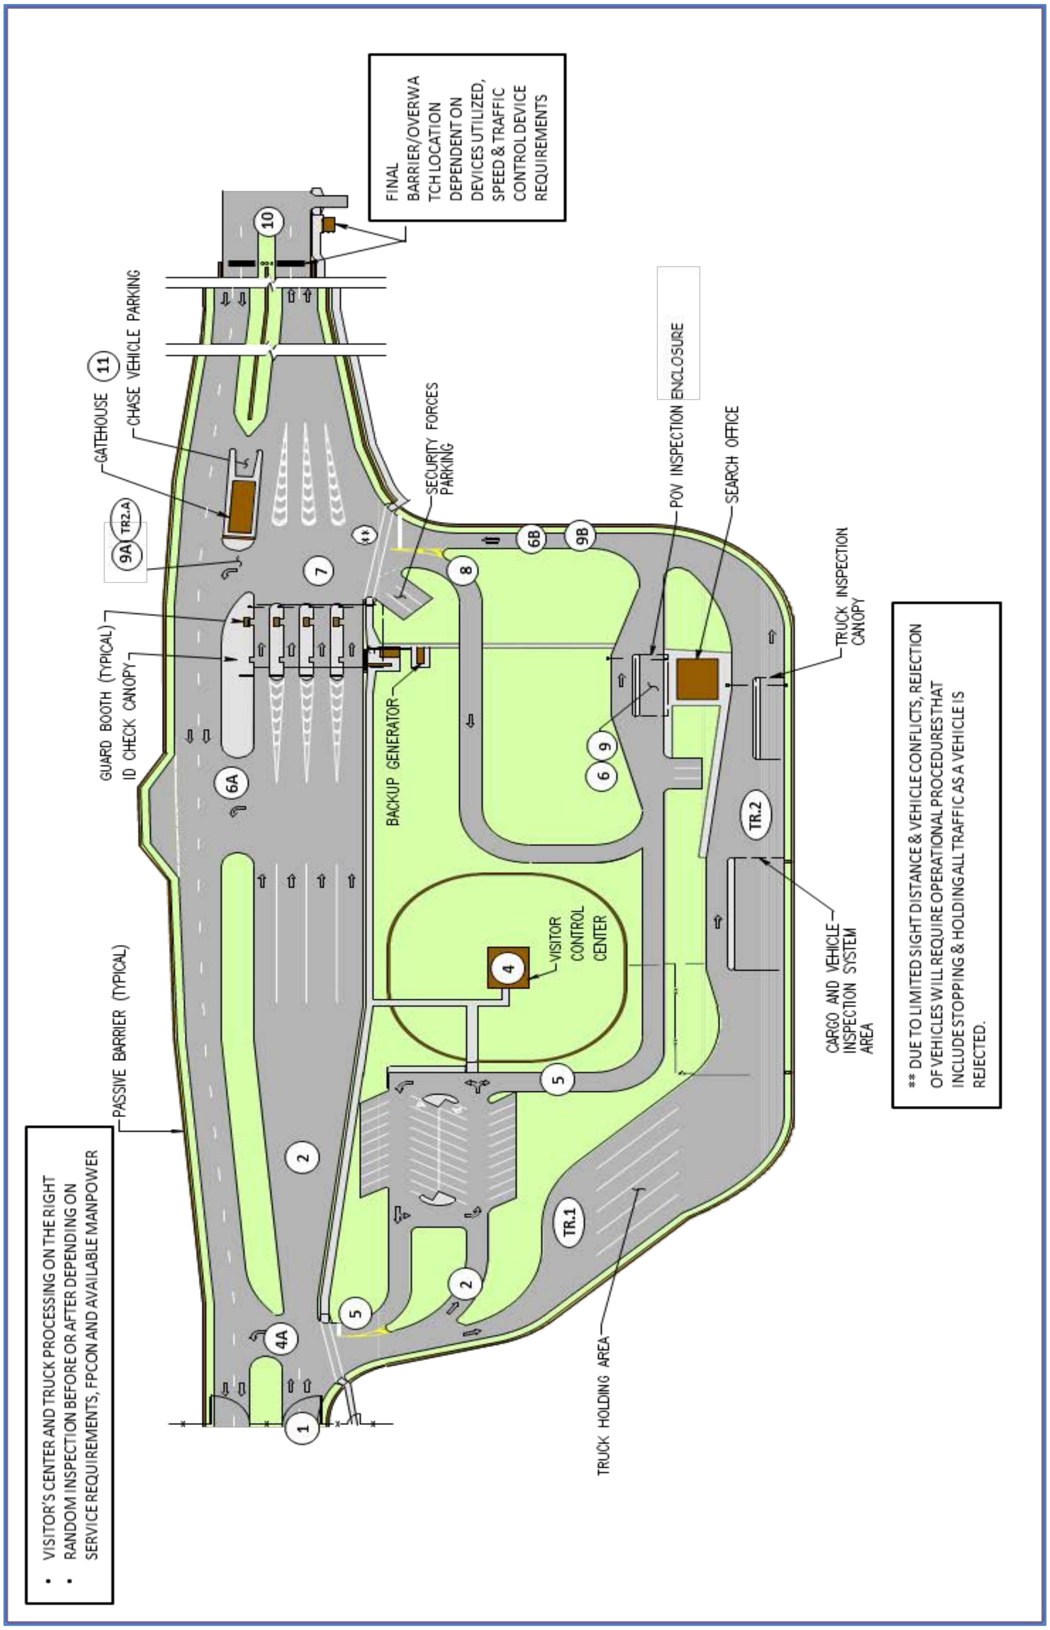

Table 2-2 ID #s for Figure 2-4

APPROACH ZONE	ACCESS CONTROL ZONE	RESPONSE ZONE
1 - Approach	**6/8/9** - ID Check Area POV and Truck including Search Office	**6B/9B** – Onto the Installation or Turnaround/Rejection Point at 9A/TR.2A
2 - Queue	**TR.2** – Truck Inspection	**10** - Final Denial Barrier and Overwatch Location

4A- Turnaround	**6A** – Turnaround/Rejection Point	
TR.1 - Truck Holding Area		

This Page Intentionally Left Blank

CHAPTER 3 PLANNING AND SITE SELECTION CRITERIA

3-1 PLANNING.

Proper planning will help ensure that ECFs/ACPs meet an installation's needs, satisfy ECF/ACP priorities, satisfy ECF/ACP functions, and accommodate future development plans. Through proper ECF/ACP planning and design:

- Needed security can be achieved
- Safety of motorists can be provided
- Safety of guards can be enhanced
- Traffic and safety impacts can be mitigated
- Sustainable elements can be integrated
- Clear and intuitive transaction experience for entry candidate and gatekeeper can be achieved
- Facilities can provide an aesthetic sense of professionalism

The following stakeholders should be involved in the planning and design of an ECF/ACP:

Installation Stakeholders

- Antiterrorism Officer (ATO)/Security Forces
- Engineering and Public Works
- Community/Master Planning
- Safety Officers
- Communication Officers
- Installation Command
- Housing Contacts

Other Military Stakeholders

- Surface Deployment and Distribution Command Transportation Engineering Agency (SDDCTEA)
- ECF/ACP Service Branch Representative
- Command Groups
- Major/Tenant Commands

Other Stakeholders

- Local Police
- Emergency Services (Fire/Ambulance)
- Local Municipality/County
- State Department of Transportation (DOT)
- Federal Highway Administration (FHWA)

3-2 TRAFFIC ENGINEERING AND SAFETY STUDY.

A traffic engineering and safety study must be conducted or validated by SDDCTEA prior to initiating ECF/ACP planning and programming documentation. This engineering and safety study is recommended prior to the modification of an existing ECF/ACP and prior to the implementation of active vehicle barriers (AVB) and automated equipment. A traffic engineering and safety study is required prior to the major modification of an existing ECF/ACP and prior to the design of a new ECF/ACP. Traffic engineering and safety study guidance is defined in SDDCTEA Pamphlets 55-15 and 55-8. Traffic engineering and safety study must be performed in accordance with Institute of Transportation Engineers (ITE) or the host nation. As a minimum, the study must develop and identify demand requirements/volumes for vehicles, and also include pedestrians and multi-modal transportation. Recommend traffic engineering and safety study be included as part of the contracted engineering effort to develop the request for proposal (RFP) for a design build construction project.

The traffic engineering and safety study must, at a minimum, include the following:

- Current peak hour demand volume for both POVs and commercial vehicles.
- Current peak hour vehicle search demand volume for both POVs and commercial vehicles.
- Current peak hour pedestrian and bicycle demand volume.
- Reasonable development of proposed Design Hourly Volume (DHV).
- ECF/ACP capacity impacts caused by intersections or other roadway features prior to the approach zone and immediately after the response zone. Intersections and other roadway features that are located within the approach and response zones must also be analyzed for traffic volume impacts.
- Identify the required number of ID check lane.
- Identify visitor control center (VCC) processing and parking requirements.

SDDCTEA Pamphlets 55-15/55-8 provides additional study elements to be considered.

3-3 SITE SELECTION CRITERIA.

The ECF/ACP must be planned, designed, and so located as not to create un-safe off-Installation traffic queuing or any other un-safe traffic practices as defined by Surface Deployment and Distribution Command Transportation Engineering Agency (SDDCTEA) and all other applicable roadway standards/criteria.

When considering alternative locations for an ECF/ACP, a properly designed concept is needed. The concept must be drawn to a scale satisfying geometric design requirements, meeting service requirements and must include the appropriate number of lanes determined by the traffic engineering study and needed features. The concept can be used to determine if a site is a feasible location for an ECF/ACP. It is important to include the stakeholders in the alternative evaluation process as they may have considerations to be addressed.

3-3.1 Location and Master Plan Coordination.

Installation Master Plans and Future Development Plans must depict future ECF/ACP needs and locations when possible. When ECFs/ACPs are depicted on master plans and future development plans, they must be based on the results of a traffic engineering and safety study and must be scaled to meet design requirements.

Comply with the requirements of UFC 4-010-01. ECF/ACP selection is dependent on several considerations and it is beneficial to consider alternatives. Key considerations include:

- Antiterrorism Standards
- Master Plans and Future Development Plans
- Compatible Land Use
- Environmental Constraints
- Topography
- Utilities
- Proximity to Majority of Final Facility Destinations
- Other Restrictions

3-3.1.1 Compatible Land Use.

If possible, ECFs/ACPs should not be located near mission-critical areas, restricted areas or residential areas unless the ECF/ACP's purpose is to serve that area. Carefully evaluate master and future development plans for the installation and the surrounding community when selecting a site for a new ECF/ACP or modifying existing facilities. All ECF/ACP development plans must accommodate future modifications necessitated by increased demand or revised security measures.

3-3.1.2 Environmental Constraints.

Consider the impact to existing environmental systems as well as constraints that may prohibit development in certain areas, including wetlands, protected habitats and resources, and restoration sites.

3-3.2 Master Plans and Future Development Plans.

ECFs/ACPs are key nodes within installation circulation plans. Base circulation/transportation plans address the critical relationship between circulation and land use. The installation's future development, mission changes, population, facilities, and infrastructure must be synchronized with its circulation system. The ECF/ACP designer must consult with the installation planner regarding development scenarios, future facility projects, land use patterns, strategic vision, base capacity profile and other planning considerations impacting access to base cantonment area, military family housing, training and operating areas, and critical linkages with regional transportation systems.

The base planner can also facilitate coordination with Antiterrorism/Force Protection (AT/FP) experts to assist the designer's understanding of spatial separation requirements, controlling threats, and needed ECF/ACP levels of service. Growth and expansion must also be addressed during these conversations.

3-3.3 **Sustainability.**

Sustainability is a major factor in installation planning. Impacts on ECF/ACP design will include considerations for multi-modal (or intermodal) access to the installation. Emphasis on alternative transportation modes suggests future demand for pedestrian, bicycle, and van/car pool or bus lanes to expedite safe access to the installation. (Visitor Center projects must also be integrated into base transportation plans.) Intermodal suggests coordination with off-base circulation systems to consider connections to public transit, light rail, park & ride and pedestrian access points to emphasize sustainable transportation systems. Additionally, base planners will coordinate with local community planners for integrated circulation between the regional and installation networks.

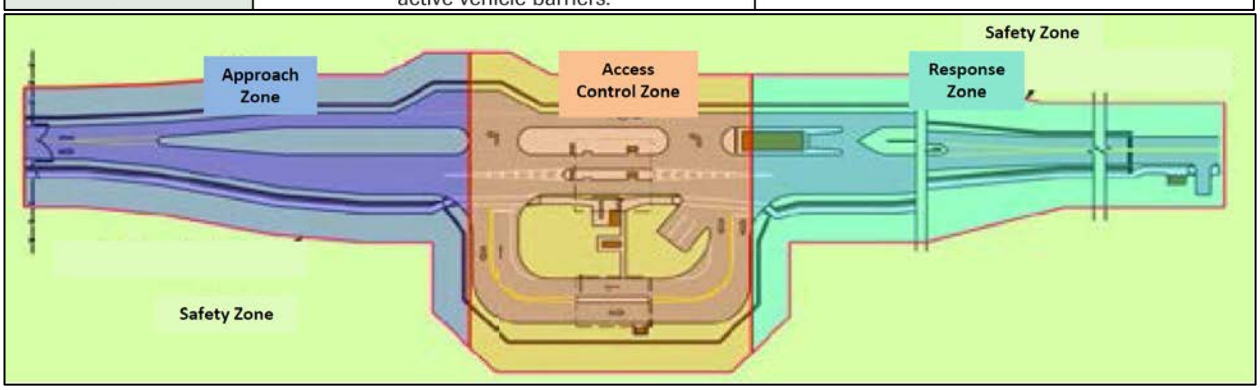
CHAPTER 4 ORGANIZATION AND OPERATION OF AN ECF/ACP

4-1 ECF/ACP ZONES.

An ECF/ACP is subdivided into four zones, each encompassing specific functions and operations. Beginning at the installation property boundary, the zones include the approach zone, access control zone, response zone, and the safety zone. Specific components are used within each zone to conduct the necessary operations. The location of each zone of the ECF/ACP is illustrated in Figure 4-1.

Figure 4-1 ECF/ACP Zones

Zone	Location	Goals
Safety	Extends in all directions beyond passive and active barriers.	Protect assets and personnel from explosions.
Approach	Installation boundary to a point just before the ID checkpoint.	Reduce speed, sort vehicles, provide stacking room, identify potential threats.
Access Control	A point just before and after the ID checkpoint.	Identify vehicles and personnel; provide surveillance, random inspection, visitor processing, and rejection capabilities.
Response	A point just after the ID checkpoint to the active vehicle barriers.	Provide measures to react to and resist a threat.



Source: SDDCTEA Pamphlet 55-15

4-1.1 Approach Zone.

The Approach Zone lies between the installation boundary/entrance and the beginning of the Access Control Zone. For the purpose of traffic and security analysis, it is appropriate to consider the approach beyond the installation boundary. The Approach Zone is the interface between the off-installation road network and the access control zone, and the area where all vehicles must traverse before reaching the ID checkpoint within the Access Control Zone. Refer to Section 5-3 for Approach Zone requirements and design methodology.

4-1.1.1 Design Elements.

The Approach Zone must include design elements to support the following functions and operations:

- Reduce the speed of incoming vehicles to, or below, the design speed of the ECF/ACP.
- Perform sorting of traffic by vehicle type (e.g., sorting commercial/large vehicles or visitors into the proper lane) before reaching the inspection area or checkpoint.
- Provide adequate stacking distance for vehicles waiting for entry, especially during times of peak demand, to ensure minimal impact on traffic approaching the installation and on traffic safety operations of adjacent public highways.
- Provide the first opportunity to identify potential threat vehicles, including those attempting entry through the outbound lanes of traffic.

4-1.1.2 **Size of the Approach Zone.**

The length of the Approach Zone is based on available land, distance required for queuing and performing traffic sorting, and the space required to create additional lanes of traffic without queuing excessively onto adjacent public highways, based on FPCON Bravo+ conditions. The design must also support measures that may be needed during higher FPCON levels, the use of RAMS at lower FPCON levels, and the temporary placement of traffic barriers as specified in the Installation AT Plan to constrain and slow traffic. Space may also be required to support speed management techniques to mitigate high-speed threats.

4-1.2 **Access Control Zone.**

The Access Control Zone is the central part of the ECF/ACP and includes guard facilities and traffic management equipment used by the security forces. The Access Control Zone begins at the turn around prior to the ID check and extends to the end of the turn around/rejection lane immediately after the ID check area. The design of the Access Control Zone must be flexible enough to ensure the infrastructure can support future inspection demands, access control equipment, and technologies. Refer to Section 5-4 for Access Control Zone requirements and design methodology.

When designing the Access Control Zone, evaluate impacts to process the following types of traffic depending on the intended functions of the ECF/ACP:

- Pedestrians
- Bicycles
- POV of authorized personnel
- Government vehicles
- Visitor vehicles
- Military convoys
- Delivery vans, commercial/large vehicles/trucks, and buses
- Construction Equipment/Oversized vehicles

4-1.2.1 Typical Operations in the Access Control Zone.

Access control zone procedures must include manual and automated actions to:

- Verify vehicle identity
- Verify personnel identity
- Conduct surveillance of the vehicle and its contents
- Conduct random or complete inspections of the vehicle and contents

Visitor and/or vehicle passes must be issued at a centralized visitor control center in the Approach Zone.

4-1.2.2 Inspection and Control of Vehicles.

The frequency of complete inspections is dependent of the FPCON level, the use of RAM, or the suspicions raised from general surveillance. Design inspection areas to accommodate one or more vehicles requiring detailed inspection. The number of inspection areas must be determined by the anticipated number of vehicles to be inspected during RAM or elevated FPCON levels. Generally, inspections take approximately 2 to 5 minutes. Consider monitoring and control of both inbound and outbound traffic. At high FPCONs, installations may conduct vehicle checks or check visitor passes as personnel are leaving the installation.

If a vehicle is denied entry during identification checks, the access control zone must have room for that vehicle to be re-directed to exit the installation. Traffic arms can be used to control traffic when a vehicle is being rejected from the ECF/ACP. Random and complete inspections must be done in the access control zone but not in the travel or ID Check lanes open for processing. Pull off alternate vehicle inspection area should be provided immediately after the ID check area to accommodate vehicles identified for search or other assistance.

4-1.2.3 Support for Automation.

In addition to supporting manual procedures, design of the Access Control Zone may need to accommodate automated identification equipment /entry (AIE) systems. To use automated systems, vehicles will need to be channeled to the proper locations. Design automated operations to mimic current procedures, which usually include identification of personnel and sometimes their vehicles.

Where the automated system is known, design the Access Control Zone to provide the required number of processing lanes and necessary infrastructure on the ID check islands to support the system. If the exact type of automated equipment and procedures used for vehicle or personnel identification is unknown, provide a flexible layout on the ID check islands where the electrical power, data and communications infrastructure is installed to support any existing or future installation of an automated system with limited disruption to operations of the ECF/ACP.

4-1.2.3.1 **Navy Automation.**

Appendix B provides information on the equipment, connectivity, and system schematic used for the Navy's Automated Vehicle Gate.

4-1.2.3.2 **Army Automation.**

Appendix C describes the Army's Automated Installation Entry program. Specific information must be acquired from the Product Manager for Force Protection Systems (PM-FPS).

4-1.3 **Response Zone.**

The Response Zone is the area extending from the end of the Access Control Zone to the final denial AVB. The Response Zone defines the end of the ECF/ACP. Design the Response Zone so that the security forces have time to react to a threat, operate the AVB, and close the ECF/ACP if necessary. When inbound and outbound travel is separated by a median, the response zone is measured from the trailing end of the last point of inspection or turn around/denial/exit roadways to the final denial AVB. When inbound and outbound travel is not separated by a median the Response Zone is measured from the trailing end of the inspection roadway (end of turn around/rejection lane immediately after ID check area) to the final denial AVB. Refer to Section 5-5 for Response Zone requirements and design methodology.

4-1.4 **Safety Zone.**

Consider the effects an explosion may have on nearby DoD personnel, buildings, or assets. The safety zone extends from the passive vehicle barriers in all directions to protect installation personnel from an explosion at the within the ECF/ACP corridor. Refer to UFC 4-010-01 for information on safety zone/stand-off distances at entry control facilities/access control points. The minimum explosive weights in UFC 4-010-01 apply to personal operating vehicle (POV) and Commercial vehicle ECF/ACP unless increased by other Service or COCOM policy. There is no required minimum antiterrorism standards for non-DoD personnel, buildings, or assets outside the installation and adjacent to the safety zone. Consider in the development of the safety zone any exclusion zones, which may be required to minimize radiation exposure for inspection systems. For explosive threats above the minimum antiterrorism standards see UFC 4-020-01.

CHAPTER 5 DESIGN GUIDELINES

5-1 INTRODUCTION.

The following design considerations are provided for primary and secondary ECFs/ACPs. For Commercial/Large Vehicle Inspection, follow the additional guidelines in Chapter 6.

5-2 GENERAL LAYOUT AND DESIGN GUIDELINES.

This section reviews the general layout and design guidelines for the various zones of an ECF/ACP. Further details concerning specific elements are provided in later sections.

5-2.1 Containment and Control of Vehicles.

The design of an ECF/ACP must ensure that vehicles are contained through an arrangement of passive and active vehicle barriers (AVB). AVBs require some action, either by personnel, equipment, or both, to prevent entry of a threat vehicle. Passive vehicle barriers are used to direct and channel the flow of traffic in the desired direction.

DoD approved passive and AVB systems are designed based on their capacity to stop two threat vehicles, a four door full size sedan and a 7.5 ton single unit truck. The characteristic of these two vehicles will be used to design the containment and control of threat vehicles within the ECF/ACP safety zone. However, the design basis threat may also be determined by a site-specific threat assessment or specified by the installation commander with respective service approval. In these cases the service or agency identified threat vehicle and/or barrier capacity must be considered baseline. Some services may establish minimum barrier capacities or specify threat vehicles for primary and secondary ECFs/ACPs. The velocity of the threat vehicle will be determined based on vehicle characteristics and the roadway layout. The allowable penetration following impact must be based on site considerations and the proximity of inhabited facilities or high value assets. Further information concerning design and specification of active and passive vehicle barrier systems is provided in UFC 4-022-02.

5-2.1.1 Perimeter Fence and Gate.

The ECF/ACP typically begins at the installation perimeter. In most cases, the perimeter is defined and secured with a fence. Each ECF/ACP must have a gate enabling the ECF/ACP to be closed at the installation perimeter when not in use. This gate must maintain an equivalent level of security as the adjacent fence/barriers. In addition, the gate must have signage and retroreflectivity as detailed in SDDCTEA Pamphlet 55-15 and Manual on Uniform Traffic Control Devices (MUTCD) and the Department of Defense (DoD) Supplement To The National Manual on Uniform Traffic Control Devices.

5-2.1.2 **Vehicle Containment Within the Roadway.**

Vehicle containment within the roadway is necessary to prevent inbound vehicles from unauthorized access and must extend from the installation perimeter to the final denial AVB to be effective. Passive vehicle barriers must encompass a contiguous perimeter around the ECF/ACP, with the final denial AVBs completing the containment. Arrange barrier to ensure that a vehicle will not circumvent the ECF/ACP once the vehicle has entered.

5-2.1.2.1 **Passive Vehicle Barriers.**

Passive vehicle barriers utilized must be tested products listed on the DoD Anti-Ram Vehicle Barrier List.

Consider the potential debris hazard produced by passive vehicle barrier systems exposed to a blast during an attack and the effect on any nearby buildings or assets. Further information concerning barrier debris minimization is provided in UFC 4-022-02. The aesthetics and design of the barrier system should be consistent with the installation's exterior architectural plan and the surrounding architectural and landscape features. Breaks in the passive vehicle barrier system of the ECF/ACP must not exceed 3 feet (0.9 m) in width for traffic having a 90-degree approach and 4 feet (1.2m) in width for traffic paralleling the barrier. The location and installation of passive vehicle barriers must conform to the requirements of the American Association of State Highway and Transportation Officials (AASHTO) *Roadside Design Guide* for objects placed near roadways. All passive vehicle barriers installed within the clear zone must meet the requirements of AASHTO's Manual for Assessing Safety Hardware (MASH) approved for crash safety.

5-2.2 **Personnel Protection.**

Design the ECF/ACP to enhance safety of the security personnel operating in the access control zone. All ECF/ACP facilities, or other manned posts, must be afforded crash protection (from traffic in either direction). Passive vehicle barriers such as bollards, reinforced concrete walls or knee-walls, or crash cushions must be used to protect personnel standing on the traffic islands; however, these elements must meet clear zone requirements as detailed in SDDCTEA Pamphlet 55-15 and AASHTO Roadside Design Guide.

An example of a barrier system would be a short, concrete bull nose wall with impact attenuator at the appropriate location on the traffic island. Traffic islands separating directions of travel require protective devices on both sides of the island. Traffic islands separating similar directions of travel only require protective devices on the leading edge of the island. By elevating the personnel on an island, they are protected from accidental impact during identification checks. The bull nose with impact attenuator is designed to protect the personnel from potential injury caused by a vehicle leaving the roadway or lane. This type of system not only enhances the safety of security personnel, but it also offers the personnel cover in the event of an attack. See SDDCTEA Pamphlet 55-15 for further information concerning barriers and crash cushions. The height of crash protection barriers needs to be reviewed closely to assure there are no conflicts with traffic or guard sightlines.

5-2.3 **Capability to Reject Unauthorized Vehicles.**

Unauthorized vehicles may enter the ECF/ACP and the design must support rejecting these vehicles as follows:

- Provide turn around/denial/exit points as shown in Figure 2-1 through Figure 2-4; one located before the ID check area and one located immediately after the ID check area. See Access Control Zone Requirement and Guidelines for additional information.
- Implement operating procedures and consider the use of traffic arms to halt traffic such that rejected traffic can be safely directed to the turn around/denial/exit point.

Design turn around/denial/exit points in accordance with SDDCTEA Pamphlet 55-15 and with the following characteristics:

- Design turn around/denial/exit points for the largest vehicle identified in the traffic engineering and safety study that is expected to enter the installation on a regular basis, but not less than a single unit vehicle (SU).
- ECFs/ACPs designed for smaller vehicles (POV) must be capable of rejecting a commercial vehicle (AASHTO Wheel Base (WB)-67) before the post ID check area due to the likelihood of commercial vehicles attempting to enter the installation through POV ECPs/ACPs.
- If space is unavailable to support a single movement, consider the impact on the flow of traffic while a vehicle makes a three-point turn or similar movement. If the impact is infrequent or acceptable, or large vehicles are not expected at the ECF/ACP, then the required space can be minimized.
- Sign the turn around/denial/exit area per the Manual on Uniform Traffic Control Devices (MUTCD) and the DoD Supplement to the MUTCD.

5-2.4 **Traffic Considerations.**

The effect of an ECF/ACP design on the surrounding roadways and intersections is of paramount concern. If congestion occurs, and there is inadequate vehicle processing and stacking distance, the queues may extend into adjacent intersections or cause congestion on feeder roads. Find additional guidance in SDDCTEA Pamphlet 55-15.

5-2.4.1 **Design Capacity.**

The design capacity is based on the peak hour traffic demand volume that the ECF/ACP handles without unreasonable congestion and/or negatively impacting the surrounding local roadway system. Consider both current and future traffic demands. Since some disruption in the level of service is expected at high FPCON(s) (Charlie or Delta), design the ECF/ACP to minimize congestion at FPCON Bravo and below.

5-2.4.2 **Traffic Congestion.**

At FPCON Charlie and Delta, some congestion may occur but this is sometimes offset by the installation reducing the population seeking to enter the installation to mission essential personnel only. Where possible, minimize the congestion during FPCON Charlie or Delta. If the final capacity achieved at an ECF/ACP is below the expected peak hour traffic volume, congestion can be reduced by implementing staggered work hours, encouraging carpooling, adding lanes, and/or tandem processing (no more than two) guards per lane.

5-2.4.3 **Lane Requirements.**

The number of lanes planned for an ECF/ACP must be sufficient to handle the expected volume of traffic, especially during times of peak demand such as morning rush hour and must consider both manual and automated operations (handheld, structurally mounted). Additional guidance can be found in SDDCTEA Pamphlet 55-15.

Provide a number of ID Check lanes sufficient to process the traffic volume demand identified in the traffic engineering and safety study. Analysis must consider the length of the queue and the number of ID Check lanes required to preclude off-installation impacts to roadways.

5-2.4.4 **ECF/ACP Smart Decision Evaluator.**

The ACP/ECF SMART Decision Evaluator was developed to provide perspective on the issues associated with each approach to ECF/ACP vehicle processing so that when combined with practical knowledge, decisions are made with full awareness of the ramifications. The ACP/ECF SMART Decision Evaluator has been designed to require a minimal amount of data entry when determining lane requirements.

The SMART Decision Evaluator:

- Provides comprehensive perspective
- Provides awareness of ramifications through costs and associated risks
- Is derived from common engineering, security and economic principals

Recommend utilizing the ACP/ ECF SMART Decision Evaluator (or other methods to accomplish the same results) to evaluate the existing, short-term and long-term impact of security, manpower, automation, and roads and traffic for DoD developed ECF/ACP. For additional information visit the U.S. Army's Transportation Engineering Agency website:
https://www.sddc.army.mil/sites/TEA/Functions/SpecialAssistant/TrafficEngineeringBranch/Pages/default.aspx

5-2.5 **Geometric Design.**

Geometric design is dependent on design speed, roadway classification, and design vehicle. Also, the type of ECF/ACP, space available, and traffic volume may impact design. This section is intended to provide basic guidance on general design features.

Design criteria can be classified into the following areas: cross-section features; horizontal curvature and alignment; and vertical curvature and clearances.

5-2.5.1 **General Guidelines.**

In general, the design criteria for inbound and outbound travel lanes must be based on the design vehicle (identified from the traffic engineering and safety study) and the speed at which the design vehicle is expected to travel. For roadways leading to/from inspection areas, visitor centers, and other facilities within the ECF/ACP, the design vehicle dimensions and maneuverability considerations must dictate the design. An example of maneuverability of the design vehicle is the minimum inside turning radius of the vehicle.

Consult with AASHTO's *A Policy on Geometric Design of Highways and Streets, Roadside Design Guide*, SDDCTEA Pamphlets 55-15 and 55-17, and service guidance regarding geometric design to include the following elements. Use the more stringent criteria. See Appendix A for references.

- Design guidelines and criteria
  - Design speed
  - Roadway classification
  - Design vehicle
- Cross-sections
  - Travel Way and Lane Width
  - Curb and gutter
  - Shoulders
  - Clear zone
  - Medians and traffic islands
- Turning movements and turning radii
  - Turn around/denial/exit points
- Horizontal alignment
  - Horizontal curves
  - Lane widening
  - Horizontal Tangents and Transitions
  - Horizontal Sight Distance
- Vertical alignments
  - Vertical clearance
  - Vertical curvature
- Other geometric elements
  - Transition tapers
  - Drainage
  - Landscaping

5-2.6 **Speed Management.**

The control of vehicle speeds at ECFs/ACPs is a common concern. The roadway geometry and passive vehicle barrier alignment will contribute in limiting the maximum attainable speed of threat vehicles. Speed management for threat speed mitigation must include horizontal curvature designed in conformance to SDDCTEA Pamphlet 55-15 along with national and state roadway design criteria.

To control the speed of non-threat vehicles, other options, such as traffic calming and signing can be considered. The use of traffic calming devices must be evaluated by a traffic engineering and safety study.

5-2.6.1 **In-Roadway Barrier Guidance.**

Do not design for in-roadway barriers, bollards, and other fixed objects as speed management techniques for threat speed mitigation at new ECFs/ACPs. In-roadway barriers and bollards may be utilized at existing ECFs/ACPs to obtain additional response time if they are installed and delineated as prescribed in SDDCTEA Pamphlet 55-15 and if it is demonstrated that the lane reductions do not unduly delay traffic or cause back-up into the public throughway or create other unsafe situation.

5-2.6.2 **Speed Hump/Table Guidance.**

Speed humps and speed tables are not for threat speed mitigation. Speed humps and speed tables may be used for speed management and to gauge motorist intent in the approach zone only. If used, provide speed humps and speed tables in accordance with the applications and profiles detailed in SDDCTEA Pamphlet 55-15 and per FHWA and ITE guidelines.

5-2.7 **Traffic Control Devices.**

All traffic signals, signs, and pavement markings must be in conformance with the MUTCD/ DoD Supplement to the MUTCD, SDDCTEA Pamphlets 55-15 and Pamphlet 55-17 as well as applicable state, local, and OCONUS requirements.

The above indicated documents provide guidance on the following:

- Signs and Signals
    - Requirements
    - Types
    - Sizes and Legibility
    - Retroreflectivity requirements
- Speed Limit Signing
- Guide Signing
- Pavement Markings
    - Longitudinal

  - o Transverse
- Traffic cones
- Barrier delineation

5-2.8 **Multimodal and Alternative Transportation Considerations.**

The use of transit as well as pedestrian and bicycle activity must be considered while analyzing the conditions at an existing ECF/ACP or developing a new ECF/ACP. All modes must be accommodated to the appropriate level at ECFs/ACPs.

Accommodating alternate modes of transportation can help reduce the demand of vehicles seeking entry during peak periods.

5-2.8.1 **Pedestrian Access.**

When pedestrian access control is required, ensure that proper sidewalk and safety provisions direct pedestrian traffic to the Access Control Zone and separate it from vehicular traffic. Design pedestrian access to ensure security personnel can maintain visual contact with the pedestrians as they approach the ECF/ACP. Plan sidewalks to integrate into the existing site layout and accommodate new facilities. Breaks may be provided in the passive vehicle barriers surrounding the ECF/ACP to allow pedestrian access to the ECF/ACP. Provide sidewalks with a minimum width of 4 feet (1.2 m). Provide crosswalks with a minimum 6 feet (1.8 m) wide. Design elements for pedestrians must be compliant with Architectural Barrier Act (ABA) and AASHTO *A Policy on Geometric Design of Highways and Streets* requirements and to the requirements of Public Rights of Way Guidelines (PROWAG). PROWAG is endorsed by SDDCTEA and FHWA and provides additional guidance of the construction of ABA compliant facilities on or adjacent to roadways.

Where turnstiles or other pedestrian controls are utilized they must either be manned/controlled/metered by guard personnel or equipment that must be included to validate credentials. Other considerations in the selection of turnstiles or similar access control devices include the control of potential tailgating and the likelihood that personnel will have equipment or luggage, which may require additional space in the turnstile. Consider if pedestrian inspection areas will be required based on pedestrian demand and any requirement to inspect personnel and packages. See UFC 4-022-03, *Security Fences and Gates* for additional guidance on personnel gates including turnstiles.

5-2.9 **Parking Guidance.**

Incorporate parking in the design of the ECF/ACP to support security vehicles, visitors and vehicles associated with shift changes of security personnel. Where an ECF/ACP includes a visitor control center, sufficient parking will be necessary to support this facility. The number of parking spaces to provide should be based on the methodology outlined in SDDCTEA Pamphlet 55-15 and must meet ABA requirements.

Locate spaces to minimize the walking distance and potential interference with moving or parked vehicles. Implement UFC 4-010-01 as applicable.

5-2.10 Landscaping and Aesthetics.

ECPs/ACPs provide the first public impression of the installation. They should present the proper appearance for visitors, employees, and military personnel. The layout, landscaping, and architecture of the facilities are factors in this image. The architectural design of the facilities should comply with the installation or command's architectural design standards.

Include line-of-sight considerations in the landscape design. It is important that the line-of-sight of security personnel through the ECF/ACP not be impeded. This includes consideration of overwatch positions, which require an adequate and acceptable line-of-fire.

5-3 APPROACH ZONE REQUIREMENTS AND GUIDELINES.

Design the approach zone to accommodate design traffic demand without off-installation impacts per the direction previously indicated in the traffic engineering and safety study section of this document.

Base the layout of the approach zone on the following guidelines:

- Provide an entry gate that joins the installation perimeter that fully contains the ECF/ACP.
- Provide a passive vehicle barrier system that tie into the entry gate and the access control zone passive vehicle barrier system.
- Maximize the length of the approach zone to provide optimal stacking distance for the traffic queue.
- Reversible lanes can increase throughput and flexibility where space is unavailable for additional lanes.
- Sort traffic by vehicle type. For example, use the farthest right lane for truck traffic. Rejection of these vehicles requires additional space for their larger turning radii.
- Wrong way detection must be considered for all the outbound lanes.
- ECFs/ACPs must have the minimum ability for a wheel base (WB)-67 vehicles to be rejected prior to the identification (ID) check area for a POV only ECF/ACP. ECFs/ACPs that accept commercial vehicles (combined POV/truck gate or exclusive truck gate) must provide for a WB-67 vehicle to be rejected. OCONUS projects must have requirements similar to CONUS. OCONUS projects must provide a means to reject a WB-67 or OCONUS equivalent vehicle prior to the ID check area.

5-4 ACCESS CONTROL ZONE REQUIREMENTS AND GUIDELINES.

Design the access control zone to manage authorized vehicles and personnel, to reject unauthorized vehicles, and minimize the adverse impacts on traffic.

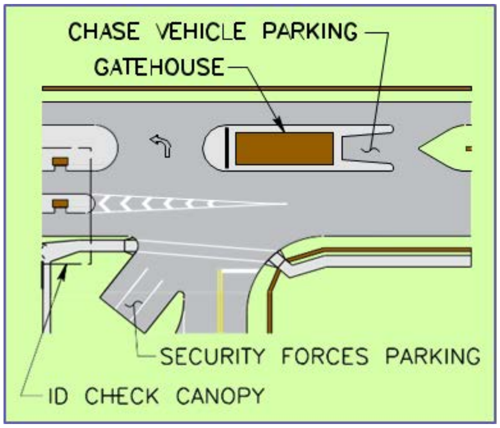
Base the layout of the access control zone on the following guidelines:

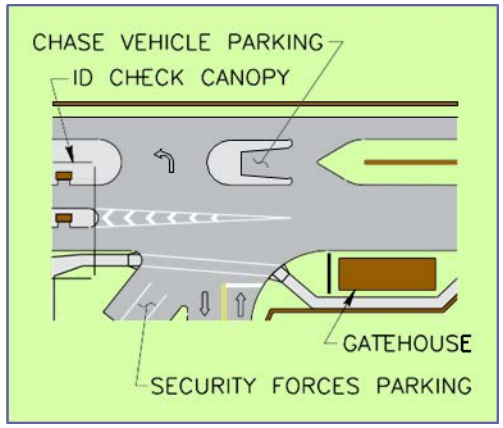
- Provide the capability to process visitors. Visitor processing must be conducted prior to entry into the installation.
- Provide an Identification (ID) check area where guards and/or automated equipment validate drivers and vehicle occupant's identifications. Provide infrastructure to support identification and search areas for the inbound lanes.
- Provide a passive vehicle barrier system that ties into the approach zone passive vehicle barrier system and the response zone passive vehicle barrier system that presents a fully contained ECF/ACP. If the site cannot accommodate an approach zone as described previously, provide a passive vehicle barrier system tied into the installation perimeter barrier system and the response zone passive vehicle barrier system that presents a fully contained ECF/ACP.
- Provide raised curbed islands between all inbound lanes or outbound lanes designed as reversible lanes in the ID check area. Islands must be 50 feet (15.25m) in length for single processing and 75 feet (23m) in length for tandem processing. Consider providing curb cuts or a step down area for security personnel at ID Check positions but make sure roadway drainage, equipment installation, and safety of the guard is not compromised. Cover all inbound lanes in the main ID check area and all search areas as required with an overhead canopy to protect against inclement weather, facilitate identification and inspection procedures, and provide a platform for lighting and Closed Circuit Television (CCTV). Maintain a minimum 3 feet (0.9m) setback from the face of curb to the guard facilities on the island. Must also include, as a minimum, a 1 foot (0.3 m) horizontal clearance between face of traffic island curb and guard facility roof, gutters or any other objects protruding from the guard facility. Maintain a minimum lateral clearance of 2 ft (610 mm) in the access control zone to allow security personnel to pass between fixed objects and obstructions and the roadway. See Figures 5-11 and 5-12 for additional details.
- As shown in Figures 2-1 through 2-4 and 5-1, it is recommended that two turn around/denial/exit points be provided. One occurring prior to the central ID check area guard booth and the other occurring after this point but prior to or within an area assessable from the gatehouse. Where only one turn around/denial/exit point is possible, the rejection should occur following the ID check area.
- Provide a gatehouse for each ECF/ACP. The gatehouse serves as the central control center for the ECF/ACP by providing shelter for security personnel and controls for the vehicle barriers, traffic control devices, access controls, lighting, and surveillance equipment. Where low numbers of visitors

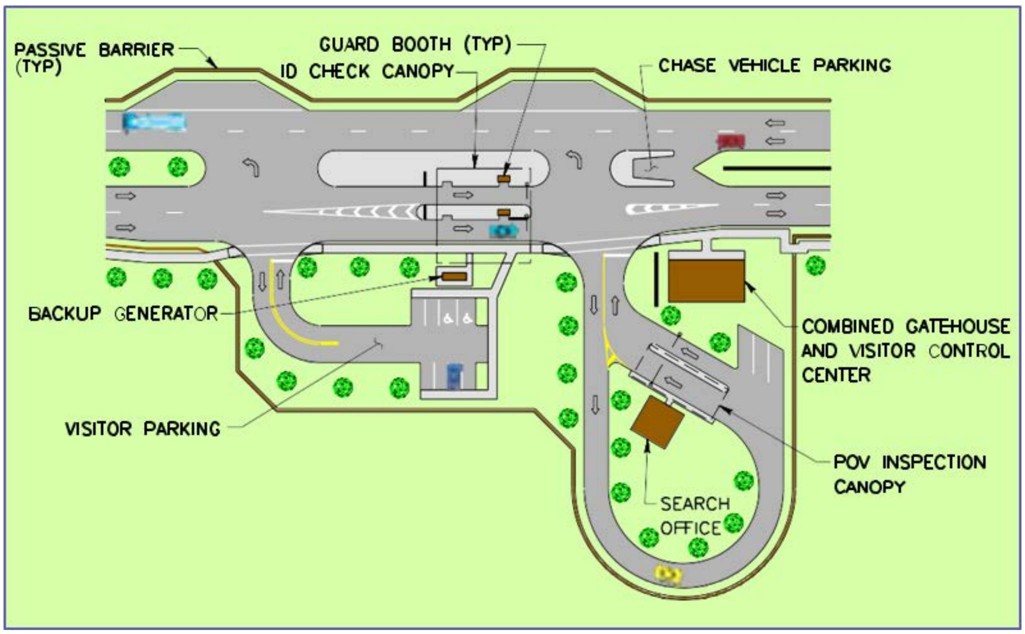
are expected, the visitor center may be combined with the gatehouse to reduce the ECF/ACP footprint and maximize manpower; however, there must be a ballistic rated separation between the guards and the portion of the building accessible to the public. The gatehouse can be centrally located on a median, or may be positioned to the side of the ECF/ACP. See Figure 5-1 for gatehouse location options.

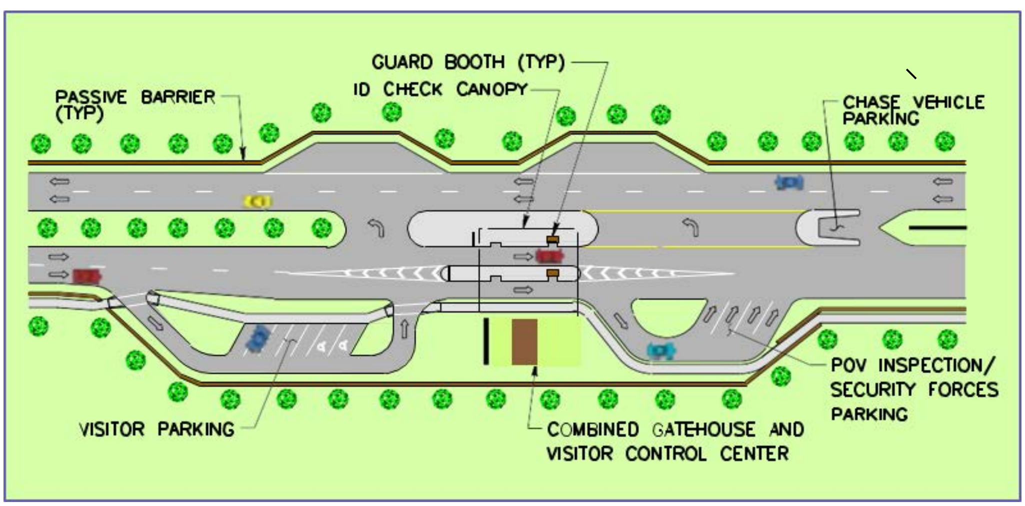
- Provide a vehicle search area(s) that is located with the access control zone, easily accessible from the ID check area, sized in accordance with the search volumes identified in the traffic engineering and safety study and provides an enclosed shelter for vehicle occupants removed from vehicles during search operations.
- Provide pull off alternate vehicle inspect area immediately after the ID check area to accommodate vehicles identified for search or other assistance. This alternate inspection area will not have the same requirements of a dedicated vehicle inspection facility.
- Provide guard booths for each entry lane within the ID check area.
- Where reversible lanes are utilized ensure that all MUTCD/DoD Supplement to MUTCD requirements are met.

Figure 5-1 Gatehouse Location Options









5-5 RESPONSE ZONE REQUIREMENTS AND GUIDELINES.

5-5.1 Layout Guidelines for the Response Zone.

Design the response zone with a sufficient length to provide adequate reaction time, safety time and deployment time in response to the applicable threat. Provide AVBs at the termination of the ECF/ACP to provide the capability to stop threat vehicles from gaining entry to the installation. The necessary length of the response zone and location of the final denial AVBs is based on the provision of adequate response time.

5-5.1.1 Determining Length of Response Zone.

The length of the response zone is calculated based on the velocity of the threat vehicle, the subsequent rate of acceleration, and the required response time. Response time is the time required for complete activation of the AVBs once a threat is detected. This implies the distance required to provide an adequate response time is measured from a starting position and velocity where threat can be assumed detected ,i.e., assessment of the threat, has already occurred. The location of the threat vehicle when first detected is based on the threat scenario and site plan. The rate of acceleration is dependent on the type of vehicle. Generally, the acceleration capabilities of threat vehicles are known.

The length of the response zone can be minimized, or the available response time maximized, by using speed management to control the velocity of vehicles as they travel through the approach and response zones. Also, by reducing the response zone length, there is reduction in the site area required for the ECF/ACP. Implementation of speed management measures are most effective when installed within the response zone because these measures are effective against all four threat scenarios indicated below.

5-5.1.2 Threat Scenarios.

The length of the response zone determines the placement of the final denial AVBs. AVBs must be installed on all inbound and outbound lanes in the response zone to defeat all threat scenarios.

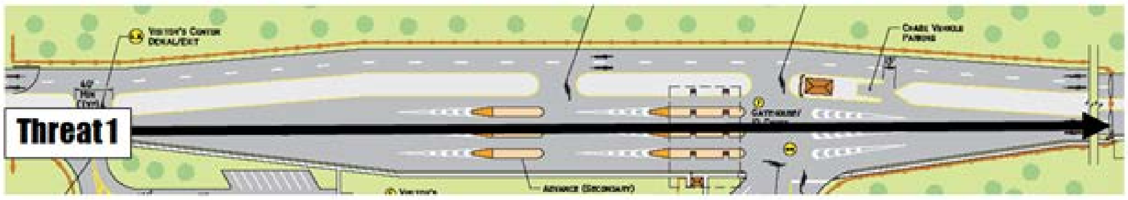
Consider all scenarios when designing the Response Zone, determine which scenario governs, and verify the adequacy of the response time and AVB selected. ECFs/ACPs must be designed to defeat the following four threat scenarios as a minimum.

5-5.1.2.1 Vehicle Threat Scenario #1.

Vehicle Threat Scenario #1 - Threat vehicle enters the ECF/ACP in the inbound or outbound lane(s) at the maximum speed attainable at the ECF/ACP entrance and then immediately accelerates at its maximum acceleration rate through the ECF/ACP. This scenario often includes either or both wrong way detection or over speed detection used to alert the ECF/ACP personnel of the threat and establishes the point within the

ECF/ACP in which the threat is detected. See Figure 5-2 for a graphic representation of this threat scenario.

Figure 5-2 Vehicle Threat Scenario #1 Diagram

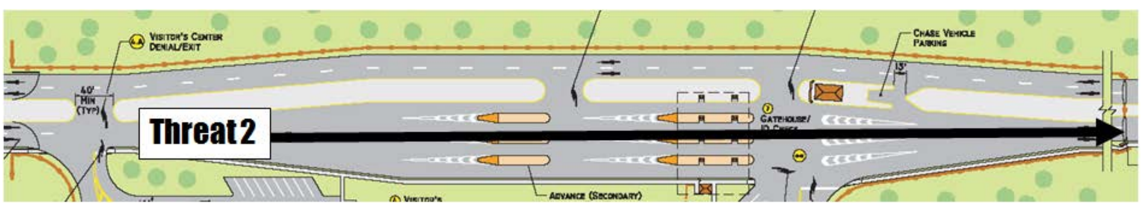


5-5.1.2.2 **Vehicle Threat Scenario #2.**

Vehicle Threat Scenario #2 - Threat vehicle enters the ECF/ACP in the inbound or outbound lane(s) at or under the posted speed limit and then, later at some point farther in the approach zone, accelerates at its maximum acceleration rate through the rest of the ECF/ACP. This scenario often includes overspeed detection to establish the starting point and the initial velocity of the threat vehicle. See Figure 5-3 for a graphic representation of this threat scenario.

Note that ‘some point’ must be interpreted as being the worst case threat delay time from point of detection to Active Vehicle Barrier (AVB) location(s) in the response zone. If multiple zones of overspeed detection are utilized the analysis will include the worst case situations for each overspeed zone.

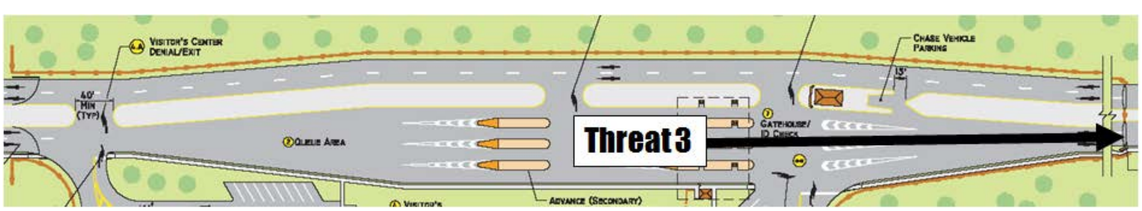
Figure 5-3 Vehicle Threat Scenario #2 Diagram



5-5.1.2.3 **Vehicle Threat Scenario #3**

Vehicle Threat Scenario #3 - Threat vehicle attempts to covertly enter the ECF/ACP, but is detected and denied entry by guards at the ID Check Area. Vehicle driver then defies guards and accelerates at its maximum acceleration rate through the rest of the ECF/ACP. The initial velocity of this threat must be 25 mph. See Figure 5-4 for a graphic representation of this threat scenario.

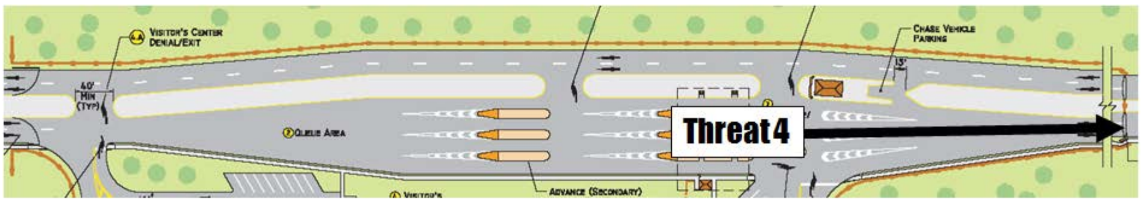
Figure 5-4 Vehicle Threat Scenario #3 Diagram



5-5.1.2.4 **Vehicle Threat Scenario #4.**

Vehicle Threat Scenario #4 - Similar to Threat Scenario 3 above, except the driver of the denied vehicle drives toward the turn around/denial/exit point or search area at the ECF/ACP speed limit of 10mph as if complying with guard instructions, but then fails to turn and instead accelerates through the rest of the ECF/ACP. The initial velocity of this threat is no less than 10 mph. See Figure 5-5 for a graphic representation of this threat scenario.

Figure 5-5 Vehicle Threat Scenario #4 Diagram



5-5.1.2.5 **Additional Threat Considerations.**

Additional threat scenarios and initial velocity conditions may be considered and analyzed if supported by a local vulnerability or threat assessment and/or variations in facilities located in atypical ECF/ACP configurations. Consult service subject matter experts for more guidance.

5-5.1.3 **Threat Vehicle Characteristics.**

- **Acceleration Rate -** Threat calculations must utilize the acceleration rate of 11.3 feet per second squared (feet/second/second - ft/s^2) ($3.4\ m/s^2$) when determining delay
  - Where applicable the lower acceleration rates associated with trucks/commercial vehicles can be utilized for calculating the required stopping capability of passive and active vehicle barrier systems; however, lower acceleration rates are not relevant to delay calculations.
- **Deceleration Rate -** Threat calculations must utilize a deceleration rate of 24.1 feet per second squared (feet/second/second - ft/s^2) ($7.3\ m/s^2$) when calculating delay.
- **Friction Factors -** Threat calculations must utilize a friction factor of 1.0. Calculations performed for threat purposes differ significantly from calculations typically performed for consideration of driver comfort. Lower friction factors associated with highway safety must not be used for threat calculations.
- **Maximum Velocity -** The maximum velocity of the 4,630 pounds (2100 kg) baseline threat vehicle utilized for delay calculations must be 130 mph (210

kph). This parameter must be utilized for calculation of delay unless a 'local' threat assessment and/or policy identifies a vehicle that is capable of a greater velocity. The addition of larger vehicles or trucks through mandatory incorporation of threats identified in 'local' threat assessments and/or policies must not be considered justification for use of a reduced velocity in delay calculations.

  - The maximum velocity of specific threat vehicles (where local threat analysis and/or policy identifies a specific vehicle) must be obtained from manufacturer specifications.

  - The maximum velocity of other vehicle classes (where a type of vehicle e.g. 'pickup truck' is identified in local threat analysis and/or policy) must be calculated through acquisition of information on at least five vehicles within the type and averaging the top speed of the lot. If significant outliers (atypical vehicles with unusual characteristics) exist they may be removed from the sample set.

- **Vehicle Mass -** The baseline threat vehicle must be a large passenger car as defined in ASTM F2656. The weight of the baseline threat vehicle is 4,630 pounds (2100 kg) and the mass is 143.8 slugs (2100 kg). This mass must be utilized for kinetic energy calculations unless a vehicle of larger mass is included due to the aforementioned incorporation of local threat analysis and/or policy.

  - **Modification of baseline vehicle threat -** The baseline threat vehicle must be adjusted in accordance with all applicable 'local' threat analysis and policy. All relevant 'local' threat analyses and policy must be reviewed and incorporated. Classification of such documentation is not justification for exclusion of baseline threat vehicle for barrier impact energy and/or delay calculations. Both the baseline vehicle and the additional vehicle(s) (identified by 'local' threat assessment and/or policy) must be analyzed and the more stringent of results must be applied.

5-5.1.4 **Threat Delay Calculation.**

Key considerations in evaluating threats include:

- The minimum acceleration rate of a threat vehicle must be no less than 11.3 ft/s^2 (3.4 m/s^2) indicated above . Initial velocities for Threats 1 and 2 will be established based on geometric constraints. The maximum velocity for unconstrained conditions (no geometric curvature or features that will limit maximum speed must be 130 mph (210 kph). 130 mph (210 kph) is also the maximum velocity for threat calculations unless a higher speed is identified by local threat assessment and/or service policy.

- On declines, the acceleration must be adjusted by the angle of the decline. An adjustment on inclines will be considered if response zone requirements cannot be satisfied.
- The threat calculations will not consider the use of speed humps, speed tables, removable bollards, etc., as a factor in reducing the velocity unless validated through an traffic engineering and safety study by the responsible service in coordination with SDDCTEA or as detailed in SDDCTEA Pamphlet 55-15.

The following equations are the primary equations used for calculating response time for an ECF/ACP. Additional instructions can be found in the UFC 4-022-02.

Formulas for Calculating Velocity

For Tangents: $V_F = \sqrt{V_O^2 + 2aL}$ For Curves: $V_S = \sqrt{(f + e)gR}$

Formulas for Calculating Time

For Tangents: $T = \dfrac{2L}{V_F + V_O}$ For Curves: $T = \dfrac{L}{V_S}$

V_F = Final Velocity
V_O= Initial Velocity
a = Acceleration
L = Distance
T= Time

V_S= Skidding Velocity
f = Coefficient of friction
e= Super elevation (%)
g= gravity coefficient (9.8)
R= radius of horizontal curvature

5-5.1.5 **Response Time.**

The response time begins the instant the threat is detected. The response time includes guard reaction time, time for barrier safety system, and barrier deployment time. The response time minimums are as follows:

- Guard reaction time must be no less than 3 seconds for Threat Scenarios #1 through #3 and a minimum of 1 second for Threat Scenario #4 based on the emergency operation controls being in the immediate vicinity of the guard personnel.
- Safety and signal sequence time must be no less than 4 seconds. Barriers collocated at neighboring intersections may require additional time as prescribed by SDDCTEA Pamphlet 55-15. Note: The four seconds is specific to the Signs and Signals safety scheme. Other approved SDDCTEA safety systems as well as other parameters (posted speed limit, barriers at an intersection, road geometry) may require a different time.
- Threat calculations must not assume less than 2 seconds for AVB deployment.

- The time for security personnel to react to a threat and initiate the response is dependent on the standard operating procedures and location of emergency operation controls.
- Barriers located on roadways with a posted speed limit in excess of 30mph may require additional safety time.
- The time assumed for the reaction of personnel must be determined based on the specific conditions and layout of the ECF/ACP; however, it must not be assumed to be less than 3 seconds as noted above. When evaluating the threat scenario associated with rejection, the reaction time for personnel may be reduced to 1 second only where the guard personnel have been notified of a specific action to be taken by an identified vehicle and guard personnel have had time to prepare for activation of AVBs.

If possible, maximize the response time by lengthening the Response Zone, which will increase the distance between the Access Control Zone and the final denial AVBs. In certain instances, there may not be enough space available to provide an acceptable response time. In those cases, it may be necessary to utilize a different barrier deployment and/or speed management strategy that must be approved by the appropriate service representative with consultation from SDDCTEA.

5-5.2 **Passive Vehicle Barriers.**

Provide passive vehicle barriers that tie into the access control zone passive vehicle barriers as well as the final denial AVBs presenting a fully contained ECF/ACP. The DoD anti-ram vehicle barrier list contains many tested commercial passive barriers systems. This list is available on the PDC Web site: https://pdc.usace.army.mil . Additional guidance is detailed in UFC 4-022-02.

5-5.3 **Active Vehicle Barriers.**

ECFs/ACPs must be provided with active vehicle barriers (AVB) to enable the ECF/ACP to be closed (fully contained) and to prevent a threat vehicle from breaching the security. Recommend either net or wedge-style AVBs for each lane as required. Drop arm/beams and bollards are not recommended as AVBs in an Emergency Fast Operation (EFO) system. Tire shredder and claw type systems are prohibited as AVBs. These devices are not capable of stopping a potential threat vehicle with any certainty or specified distance. At ECFs/ACPs, AVBs must be capable of deploying in less than 2 seconds or less. Additional considerations:

- The non-deployed AVB must not result in unsafe roadway obstruction.
- AVBs across multiple lanes (intersections or alone) must consider vehicle presence detection system vulnerabilities (i.e., a vehicle presence detection system in one lane will suppress entire system).
- Wedges are desirable for AVBs at intersections since they operate independently.

- Use separate AVBs on the inbound and outbound lanes, when there is more than one lane per given direction of travel.

5-5.3.1 **Barrier Certification.**

Selected active vehicle barriers (AVBs) must be included on the list of DoD Certified Anti-Ram Vehicle Barriers maintained by the U.S. Army Corps of Engineers (USACE) Protective Design Center (PDC). The DoD certified anti-ram vehicle barrier lists are available on the PDC Web site: https://pdc.usace.army.mil . Additional guidance is detailed in UFC 4-022-02.

5-5.4 **Design and Safety Considerations.**

The design and operation of the ECF/ACP must include provisions to protect innocent users of the ECF/ACP from operation of the AVB whether deployment is accidental, during a test, or during an actual response to a threat. AVBs must be programmed with the required response time necessary to allow the sequencing of the AVB safety system to warn motorists of the activation, and to allow non-threat vehicles within the vicinity of the AVBs to safety traverse or stop before the AVBs prior to their deployment.

AVBs must be designed, implemented, and operated in accordance with UFC 4-022-02, UFGS 34 71 13.19 *Active Vehicle Barriers,* and UFGS 34 41 26.00 10 *Access Control Point Control System.* AVB safety requirements include proper signage, signals and delineation as well as providing adequate sequencing and timing as defined in SDDCTEA Pamphlet 55-15. Specific safety elements include:

- Delineation of AVBs
- Approved Safety Schemes
- Vehicle Presence Detection

5-5.4.1 **Delineation of AVBs.**

AVBs must be delineated as prescribed in Department of Defense (DoD) Supplement To The National Manual on Uniform Traffic Control Devices (MUTCD) and detailed in UFGS-34 71 13.19 *Active Vehicle Barriers*. This includes:

- Red and white retroreflective markings/material that is visible on both sides of the barrier when deployed.
- Supplemental barrier lights for AVBs with limited deployable surfaces.
- Use of in-roadway lights where the previous alternatives are not suitable/feasible or additional delineation is warranted.

5-5.4.2 **Recommended Safety Scheme.**

A SDDCTEA Pamphlet 55-15 recommended safety scheme must be implemented. Deviations from these safety schemes must be approved by the appropriate service representative with consultation from SDDCTEA. The recommended safety schemes are:

- Conventional AVB Traffic and Safety Control System
- AVB System Collocated at an Intersection
- AVB System Staggered at an Intersection
- High Efficiency Presence Detection System
- Stop Control Safety Scheme
- Barrier Normally Closed/Platooning Safety Scheme
- Other systems approved by SDDCTEA that provide an equivalent level of safety

Refer to SDDCTEA Pamphlet 55-15 for additional guidance, updates, and example layouts for each of safety schemes.

5-5.4.2.1 **Conventional AVB Traffic and Safety Control System.**

Proper signing, signaling, and delineation are required on the approach to the AVBs for the inbound and outbound lanes. Refer to SDDCTEA Pamphlet 55-15 for additional guidance, updates, and example layout with appropriate signs and signals.

5-5.4.2.2 **AVB System Collocated at an Intersection.**

If necessary, AVBs should be collocated to downstream intersections if the inbound traffic queue from the intersection extends through the proposed AVB location or the proposed AVB location is too close to the intersection for outbound traffic to stop safely after traversing the intersection When an AVB system is collocated at an intersection, the intersection must be signalized on all approaches and should operate a normal phasing sequence unless preempted by barrier deployment.. Refer to SDDCTEA Pamphlet 55-15 for additional guidance, updates, and example layout with appropriate signs and signals.

5-5.4.2.3 **AVB System Staggered at an Intersection.**

An alternative AVB system can be incorporated at an intersection where the additional time required for an outbound vehicle to clear the intersection cannot be met. To eliminate the additional clearance time required, outbound AVB(s) can be moved a minimum of 200 feet (61 m) away from the intersection towards the identification check area. Both the inbound and outbound AVB(s) locations must meet the minimum response time of 9 seconds. When utilizing this strategy, the outbound threat will typically govern the design of the ECF. Designers should implement additional speed management strategies and technologies on the outbound lane(s) to mitigate a wrong way threat. Refer to SDDCTEA Pamphlet 55-15 for additional guidance, updates, and example layout with appropriate signs and signals.

5-5.4.2.4 **High Efficiency Presence Detection System.**

The high efficiency presence detection scheme is a modified version of vehicle presence detection system that is no longer an option. The system uses a conventional traffic signal with detection to improve traffic flow across the AVBs.

If there are no vehicles detected, the traffic arm is down and the traffic signal is red. When a vehicle approaches, it is detected, the traffic arm rises and the signal turns green allowing the vehicle to continue. If more vehicles are following, the signal remains green, the traffic arm stays up and vehicles continue on. Once the last vehicle exits and a new vehicle is not detected after a few seconds, the traffic signal turns yellow then red and the traffic arm lowers. The high efficiency presence detection system can also operate in a normally closed configuration. The operation is similar to the prior description, except the active vehicle barrier will open prior the traffic arm opening and the active vehicle barrier will close after the traffic arm closed. Refer to SDDCTEA Pamphlet 55-15 for additional guidance, updates, and example layout with appropriate signs and signals.

5-5.4.2.5 **Stop Control Safety Scheme.**

The Stop Control Scheme is an alternate AVB strategy to signalization. It utilizes stop signs instead of signalization at AVBs to reduce the required response time and distance. By utilizing stop signs, motorists are forced to stop at the barriers eliminating the required safety time with signalization (yellow and red time). This system is useful where there is limited real estate and vehicle volumes are below 800 veh/hr/ln. Refer to SDDCTEA Pamphlet 55-15 for additional guidance, updates, and example layout with appropriate signs and signals.

5-5.4.2.6 **Barrier Normally Closed/Platooning.**

Barrier Normally Closed/Platooning Safety System requires that two sets of barriers be installed to create an “entrapment area” in each inbound and outbound lane. One of the two barriers in each entrapment area must be closed to prevent unauthorized entry. This system can be utilized when real estate for the ECF is limited and vehicle volumes are low. The distance between the two sets of barriers must be large enough to accommodate the largest vehicle served by the ECF/ACP, or it could be made larger to provide space for platooning multiple vehicles to increase vehicular throughput. Refer to SDDCTEA Pamphlet 55-15 for additional guidance, updates, and example layout with appropriate signs and signals.

5-5.4.2.7 **Exit Only.**

The Exit Only safety scheme is used at locations that will operate with the traffic leaving the installation. The system operates in the same manner as described under High Efficiency Presence Detection System for normally closed operation.

5-5.4.3 **Vehicle Safety Detection.**

For all options (midblock or collocated at intersections) install AVB vehicle safety detection systems immediately before and after the AVBs to prevent deployment of barriers while a vehicle is crossing. The vehicle safety detection system must be able to detect all roadway vehicles including high clearance trucks, motorcycles, and bicycles. Refer to SDDCTEA Pamphlet 55-15 for additional guidance and updates. The vehicle safety detection system must be installed in conformance with UFGS 34 41 26.00 10 *Access Control Point Control System*. The vehicle safety detection system for each lane must be tied to the Emergency Fast Operation (EFO) sequence; however, they must be capable of operating independently of one another. During EFO activation, a barrier must not initially activate if the vehicle safety detection system indicates the presence of a vehicle.

To avoid tailgating to defeat the barriers, it may be necessary to deploy the barrier as soon as that first vehicle clears the vehicle safety detection system, regardless of whether a second vehicle enters into the vehicle safety detection system. This may add a requirement for additional equipment and programing. Refer to Traffic Detector Handbook (FHWA-HRT-06-139) for additional guidance on vehicle safety detection systems.

5-5.5 **Control Requirements.**

AVB controls must conform to UFGS 34 41 26.00 10 *Access Control Point Control System*.

Locate the main, multi-function control panel for the AVB systems in the Command and Control (Gatehouse) location.

- The control panel must require a key for normal operation and control all lanes.
- Provide a single separate emergency activation control on the panel to initiate the EFO mode of the AVBs in all entrance and exit lanes.
- A protected, emergency activation control for the AVBs must be located, as a minimum, at each guard facility or post (channelization island, gatehouse, ID Check Island and guard booth, search area(s) and overwatch position). Controls located in the overwatch position must be capable of being secured, deactivated or removed when the position is not manned.

5-5.6 **Detection Systems.**

Due to the dangers associated with EFO/emergency activation of AVBs and the potential for false alarms, in no case will emergency activation of the AVBs be triggered through automatic detection and response. All AVB deployments must be based on the actions of the security personnel manning the ECF/ACP (such as push button or hand operated switches).

Detection devices such as video, radar, Light Detection and Ranging (LIDAR) and inductive loops may be utilized for the following purpose:

- Wrong-Way Detection - Wrong-way sensors can be deployed in all outbound lanes at the ECF/ACP entrance and after each turn-around to monitor for illegal outbound entry. Wrong-way detectors are allowed to be several different types per UFGS 34 41 26.00 10.
- Overspeed Detection - Detection devices in the approach zone can be used to monitor vehicles approaching at a high rate of speed. In many cases, the system can be developed to distinguish between cars and trucks. Point overspeed monitors speed at a particular location, while, continuous overspeed detection provides overspeed for the entire approach zone and access control zone. Continuous overspeed detection may be more suitable for addressing the various threat scenarios. Overspeed detectors are allowed to be several different types per UFGS 34 41 26.00 10; however, local weather conditions and topology requirements must be taken into account.
- Vehicle Presence Detection and AVB Safety - Vehicle presence and AVB safety sensors must be deployed at all AVBs to detect a vehicle immediately over the barrier. Where practical and when the vehicle presence safety scheme is utilized, redundancy must be integrated into the design by deploying multiple technologies such as loops and break beams. This will provide protection should one technology fail and will increase the likelihood that motorcycles and bicycles are detected.
- Traffic Flow Monitoring - Detection devices can be used to monitor queuing traffic at an ECF/ACP or on a neighboring roadway.

Additional guidance on detection devices is contained in SDDCTEA Pamphlet 55-15.

5-6 VEHICLE INSPECTION CONSIDERATIONS.

All ECFs/ACPs must have a process in place to conduct select inspections. Vehicle inspections are dependent on local directives and RAM, but generally take two forms:

- Random inspection
- Select inspection based on guard concern or random anti-terrorism measures

Once vehicles have been inspected, they should not have to pass through the ID check area again. The inspection area exit lane may bypass the ID check area and merge with other inbound traffic in the response zone.

5-6.1 Location of Inspection Area.

Since vehicle content inspection can be time consuming, it is important to allow the inspection to occur without impeding the flow of traffic through the ECF/ACP. To the extent possible, the inspection area should not be immediately adjacent to inbound traffic lanes. While this separation is primarily for safety reasons, some screening of the inspection procedure from public view is also desired. Appropriate obscuration features must be in place to accomplish this. Also, the inspection area will be equipped with an inspection office that is ABA compliant. At ECFs/ACPs with a visitor's center, direct access from the visitor's center to the inspection area should be provided if practical.

The inspection area can occur prior or adjacent to, or after the ID check area in the access control zone.

- Prior to ID Check - For advance random inspections, especially when there are numerous lanes, it is beneficial to provide advance islands for the guards to stand on as they select and direct motorists into random inspection areas and direct suspect vehicles to the inspection area. A pull-off/alternate inspection area will be provided if the typical inspection area layout cannot be provided. The pull-off area provides an area just after the ID check area where alternate inspections can be conducted, ID discrepancies addressed, or driver's questions answered. When required, include a pull-off area on the exit lane where vehicle inspections can be conducted.
- After ID Check - When inspections take place after the ID check area, the access to the inspection area needs to be as close as geometrically possible and must be within the line of sight of the guard.
- To facilitate both random and select/RAM inspections, access to the inspection area must be provided both before and after the ID check location.

If possible, design inspection facilities adjacent to the ID check area to allow bi-directional access. This permits advance random inspections as well as post ID inspections and maximizes operational flexibility.

5-6.2 Inspection Shelters.

When required, include a covered inspection area. Provide sufficient seating for the number of expected occupants who will be undergoing or queuing up to undergo vehicle inspections. A small waiting area should be provided to protect vehicle occupants from inclement weather and moving vehicles. Figure 5-6 shows an example plan for a POV inspection area and shelter. For larger (commercial and large vehicle) ECFs/ACPs, an inspection office combined with a gatehouse may be considered. Figure 5-7 shows an example of a combined commercial vehicle inspection and inspection office.

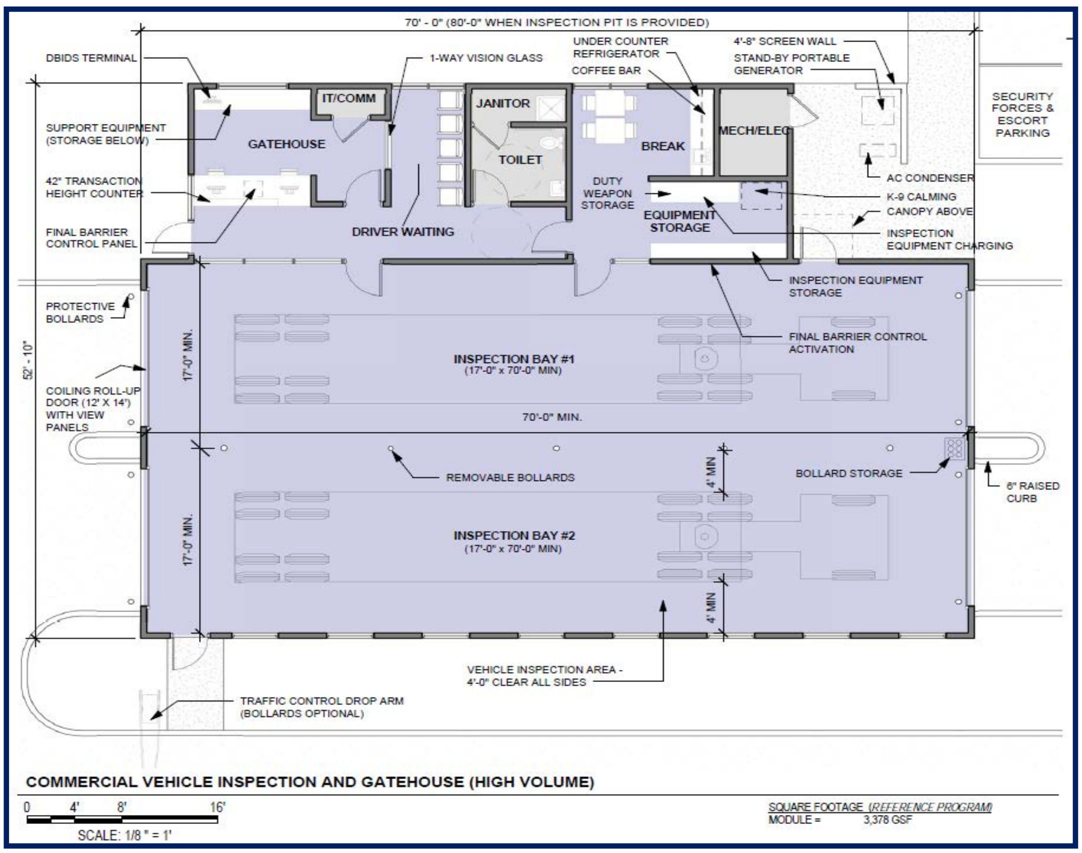
Figure 5-7 Inspection Shelter and Inspection Office Example - Commercial



Source: Air Force Civil Engineer Center

5-6.3 Location and Support for Inspection Equipment.

Most vehicle inspections are conducted with manual procedures using tools or hand-held detectors. Provide space required to store this equipment and to conduct battery-charging operations. Other types of inspection equipment are of a more permanent nature, and require planning for their deployment.

5-7 FACILITY DESIGN GUIDELINES.

This section outlines design guidelines for the various facilities associated with an ECF/ACP. Facilities (visitor control center, gatehouse, guard booths, overwatch) at the ECF/ACP should provide a comfortable, safe working environment for security personnel. Consult with service guidelines for specific facility requirements. The basic considerations in determining the size of the facilities are:

- Number of personnel assigned during normal operations
- Usage
- Space required for electronic, electrical, and mechanical equipment, and counter or work space

5-7.1 Gatehouse, Guard Booth, and Overwatch.

Since gatehouse, guard booths and overwatch facilities are located in the immediate vicinity of the explosive threats they are trying to prevent from entering the installation; it is impractical and impossible to provide protection from the possible effects of an explosive device. In addition, the occupancy of the gatehouse, guard booths, and overwatch facilities are typically below the threshold for the requirements of UFC 4-010-01 *DOD Minimum Antiterrorism Standards for Buildings*. Therefore, typically no protective design elements are required for the gatehouse, guard booths and overwatch facilities to mitigate the effects of an explosive device. However, in some instances Service Secretary and/or Agency Head and/or Geographic Combatant Commander policy requires one or more of these building types to be hardened against a blast of a specific charge weight.

5-7.2 Visitor Control Center.

The visitor control center (VCC) occupancy may exceed the threshold for the requirements of UFC 04-010-01 and protective elements may be required.

5-7.3 Personnel Safety.

Where facilities are located near the roadway, provide a minimum platform width of 3 feet (0.9m) behind the curb. This width is the minimum necessary for security personnel to stand post adjacent to the facility, therefore additional platform width is recommended to provide additional safety through increased lateral clearance and space for security personnel carrying weapons or equipment.

5-7.4 General Requirements.

This section outlines the requirements that are common to all guard facilities.

5-7.4.1 Construction.

Design the facilities as required in UFC 1-200-01. Provide corrosion resistant materials for the guard facilities, especially pre-manufactured facilities, due to the perils of environmental exposure commonly encountered at some installations and the high visibility of these structures.

5-7.4.2 Physical Security and Protective Design.

Determine the required physical security design features in accordance with installation requirements and UFC 4-020-01*, Security Engineering Facilities Planning Manual.*

Threats that may commonly be considered include forced entry and ballistic attack. Provide ballistic protection equivalent to Underwriters Laboratories (UL) 752 Level III for all guard facilities as a minimum. Consult with COCOM/Service policy if protection from a higher threat is required. Provide this protection in the design and construction of the exterior envelope including windows, doors, walls, and other equipment. Table 5-1 provides examples of the wall thickness required for commonly encountered materials adequate for ballistic resistance against UL 752 Level III. Table 5-2 provides examples of the wall thickness required for commonly encountered materials adequate for ballistic resistance against UL 752 Level V. Additional information and guidance can be found in UFC 4-023-07, *Design to Resist Direct Fire Weapons.*

Table 5-1 Thickness of Common Materials for Resistance Against UL 752 Level III

UL 752 Level III (.44 Mag)	
Wall Material	**Wall Thickness**
Concrete Masonry (Fully Grouted)	4 in (102 mm)*
Brick	4 in (102 mm)*
Reinforced Concrete (3000 psi)	2.5 in (63.5 mm)
Steel Plate (mild)	5/16 in (8 mm)
Steel Plate (armor)	1/4 in (6 mm)

Table 5-2 Thickness of Common Materials for Resistance Against UL 753 Level V

UL 752 Level V (7.62 mm)	
Wall Material	**Wall Thickness**
Concrete Masonry (Fully Grouted)	6 in (152 mm)*
Brick	6 in (152 mm)*
Reinforced Concrete (3000 psi)	4 in (102 mm)
Steel Plate (mild)	9/16 in (14.3 mm)
Steel Plate (armor)	7/16 in (11.1 mm)

Some mechanical equipment installed in the exterior envelope of a guard facility may not be capable of providing sufficient ballistic resistance. Therefore, locate the equipment to minimize potential exposure to projectile penetration or provide ballistic hardened equipment and/or louvers. As an example, it may be prudent to install the heating, ventilating, and air conditioning (HVAC) equipment on the roof of the gatehouse or guard booth to reduce penetrations in the walls. Provide roof ballistic protection only where there are sightlines to the roof.

5-7.4.2.1 **Passive Vehicle Barrier Protection.**

Provide passive vehicle barrier protection for facilities located less than 3 feet (0.9 m) behind the face of curb when adjacent to a curbed roadway section.

Provide passive vehicle barrier protection for facilities located less than 7 feet (2.1 m) from the traveled lane when adjacent to a shouldered roadway section.

5-7.5 **Common Facility Requirements.**

5-7.5.1 **Windows and Glazing.**

Provide translucent or figured glazing per UFC 4-023-07. Glazing must limit viewing into the facility to the extent possible without restricting views out of the facility during day and night operations. The intent is to reduce the visible signature of security personnel, as seen from the outside of the gatehouse, without reducing the ability of security personnel to see out. The Illuminating Engineering Society of North America (IESNA) Handbook-10 suggests specular-reflecting, low transmission glazing at a tilted angle can be used in the windows to limit view into the guard facilities from the exterior.

Any windows provided in the overwatch positions must not interfere with the capability to respond to an attack. Therefore, any windows must be capable of being fully opened/removed quickly or have a substantial gun port to enable unobstructed line of fire from the position.

5-7.5.2 **Floors/Walkways.**

The finished floor elevation must be 6 inches (152 mm) or more above grade or the adjacent walkways, unless the facility is located on a raised island. If the facility is on an island, the minimum finished floor elevation will be the elevation of the island. Provide floors and walkways with anti-skid surfaces. Anti-fatigue mats should be provided at all security personnel posts to relieve fatigue and discomfort from standing for long periods of time.

5-7.5.3 **Environmental Control.**
