This chapter covers performance consideration for design build and design bid build for self-contained, low energy and water consumption systems which can be decentralized and use minimal area for washing requirements.

8-2 PLANNING.

8-2.1 Planning Considerations.

In addition to Master Planning considerations included in Chapter 3, Consideration for Decentralized Washing Operation are not only Installations concern, but now have been expanded to include all DoD Resources. Each agency has unique wash requirements. Installations not only have heavy DoD requirements but have multiple missions and commands to provide for. Further, Installations have requirements for Installation maintenance and repair that require;

- Utility Operations
- On-site Contractor Operations

- Road Maintenance and Snow Removal
- Landfill Operations
- Emergency Repair Operations

8-2.2 Requirements.

These requirements do not meet the needs of large centralized wash operations but would support equipment that require normal cleaning to be performed. This will involve utility vehicles and trucks that need to be cleaned on a regular basis. Likewise, Reserve and Guard units which are not on large installations require cleaning after training missions and prior to and after deployments. Decentralized facilities can easily be customized for specialty washing situations. This includes equipment with specialty coatings or wash requirements. When reviewing requirements, agencies should perform site survey and utilize the check list of guidelines in Appendix D.

An overall assessment and historical usage data needs to be considered while Agencies perform preplanning and planning to decide the best type of facility for their washing needs. Wheeled Vehicles are more compatible to a Decentralized Wash Facility. Self-contained washing stations using rapidly cleaned and recycled wash water designed for rapid throughput is a sensible alternative to a Centralized Wash Facility. The Net Zero concepts for energy, water, and waste water are required considerations. The planning phase must assess the overall facility needs and balance these needs with energy and water conservation. The use of decentralized facilities which are smaller, self-contained, less expensive move toward these goals and must be part of the consideration for the washing requirements of the command.

8-3 DESIGN CONCEPT FOR DECENTRALIZED VEHICLE WASH STATIONS.

8-3.1 Overview.

Decentralized Wash Facilities need to be flexible to account for the varying needs of military units whether Regular, Reserve, Guard or other installation functions. Since a decentralized station uses a much smaller area than the Centralized Facility covered in Chapters 1 through 7, there will be less demand for utilities and overall site development. Concept considerations for the Decentralized Wash Facility are discussed below.

8-3.2 Conceptual Design.

In many cases the method of washing military vehicles can be achieved through more economical and environmental friendly solutions, but may require more hands on washing by the vehicle user. Hence, serious consideration must be given to the needs for cleaning and the ability of the user to perform cleaning operations.

8-3.2.1 Type of Command or Function.

The type of Command and or installation must be considered prior to selecting whether a large Central Facility or a smaller Decentralized Facility. The Planning and Design Team should analyze the throughput requirements for vehicle washing. The decentralized type of facility could provide a faster cleaning process than a large central platform facility. A decentralized facility is more compatible with a broader range of vehicles found on installations and in reserve and guard commands. Hence, more vehicles may be cleaned such as utility trucks, dump trucks, construction equipment, etc.

8-3.2.2 Vehicle Type and Quantity.

In the modern force, the type of vehicle to be washed is different than previous years. Current vehicles are more mobile and are wheeled in many cases. The central facility utilizes stationary washing platforms (Chapter 5) while the decentralized facility utilizes hand held high pressure cannon operations. The central facility utilizes high pressure stands and undercarriage high volume water cannons, designed for heavy track vehicles. The decentralized facility utilizes operator hand held specially adapted hand held water cannons to clean vehicles. This is a more hands on approach but is adapted to allow for more close observation of cleaning with a tool that meets most cleaning needs. The decentralized facility may be designed with multiple lanes which can be calculated with the formulas in Chapter 3 with the following modified wash durations.

- Tracked Vehicles 12 minutes
- Heavy Trucks 8 minutes
- Humvees 6 minutes
- Construction Equipment 12 minutes
- Utility Trucks 10 minutes

8-3.2.3 Available Funding.

The design team needs to assess whether the action is funded by MILCON, O&M or other funding type. The use of a Decentralized Facility provides for expansion capability and with lower funding requirements can be adaptability to installation or command funding.

8-3.2.4 Design Method/Contract Type.

A Decentralized Facility can be a Design Bid Build contract type (AE or In- House), or a Design Build Contract. The decentralized wash facility in design build considerations can utilize the design parameters noted in Paragraph 8.4.

8-3.2.5 Total Water Requirements.

The Central Wash Facility utilizes large land area with retention ponds for water make up water and waste water treatment. It is specific in the requirement for

treatment and is an extensive design. Designs Teams and Planners must be careful not to modify the requirements set forth in this UFC for Central Wash Facilities because make up water cleaning and reuse parameters have specific requirements.

The Decentralized Facility utilizes the concept to have a self-contained treatment process requiring a small amount of make-up water and includes water treatment methods noted in Paragraph 8.4. The concept of a self-contained method with rapid water treatment in intended to decrease the amount of make-up water, separate oil and heavy metals, and utilize settlement and water treatment methods. The small amount of make-up water can be harvested with natural water collection and storage methods. (Net Zero)

8-3.2.6 Energy Requirements.

A smaller Decentralized Facility will reduce the reduce energy requirements when compared to the large, centralized equipment. The Decentralized Facility will require a minimum 208/120 Volt, 200 amp 3-Phase Service. No less than 200 amps for each 2 lanes of wash stations should be planned. The exact power requirements will vary depending on equipment requirements or optional features, i.e. lighting, heating, AC, etc.

8-3.2.7 Land Area Available and/or Required.

A Decentralized Facility will require a concrete wash platform with a centrally sloped, precast/monolithic concrete collection basin. The basin should be capable of handling heavy settling and oil separation. The decentralized facility will also require an equipment room. It is recommended that the building be constructed of split faced concrete block as metal buildings not conducive to the wet environment created by a wash facility. The general layout is shown in Figure 8-3. The Design team must also identify approach and departure lanes and a small area for a solids holding waste bin. The land requirements for the Central Vehicle Wash Facility are covered in Chapter 3.

8-3.2.8 Waste Water Discharge Requirements.

The concept requirements for Decentralized Wash Facility Waste Water will depend on state requirements for water discharge. With that being said, the concept of a self-contained Decentralized Facility is to eliminate wash water discharge. All wash water should be recycled by pre-treating at the source then treating it with a water treatment/purification system directly at the wash facility.

8-4 DESIGN & CONSTRUCTION: “DECENTRALIZED” NET ZERO WASH FACILITY.

8-4.1 Design Features.

The goal of the "Net Zero" design should be considered to allow users a way to wash their equipment faster, better, safer; while drastically reducing water consumption.

8-4.1.1 Capabilities.

The Net Zero wash facility design must address all phases of the cleaning process by effectively removing mud or debris from the equipment or vehicle. Then the suspended solids must be separated from the water so that the water can be recycled or safely discharged to sanitary facilities.

- The design must utilize a safe, efficient cleaning process that minimizes cleaning time, maximizes thru-put and allows for quick, easy operation of the wash facility.
- The wash water from the cleaning process should be collected & pre-treated in the pre-cast or monolithic poured drive down collection pit (DDP). By using a multi chamber design, the heavy solids and free-floating oils and greases are removed so that the water can be treated and safely recycled or discharged to sanitary sewer.
- In a “Closed Loop” recycle design that requires NO discharge to sanitary, the wash water must be treated and purified to ensure the recycled water remains compliant with applicable standards. A minimum of 10% of the water must be treated and purified, on a daily basis, then returned back into the system.
- Extracted solids (mud) from the DDP must be dewatered to the point it can pass a “paint filter” test. After initial testing, the solid waste can be returned to landfill in most cases. This process drastically reduces the cost of tainted solids removal and Hazardous Waste Exposure. (Local/State testing & regulations apply)
- The design must take into account the level of water treatment required. Water will be exposed to skin or inhaled so pathogens and other organisms that could harm humans or wildlife should be eliminated.

8-4.1.2 Equipment.

Each component of the “Closed Loop” design is essential to the overall performance of the wash facility. The main equipment components of the system are:

8-4.1.2.1 Pre-Cast/Monolithic Drive Down Collection Pit (DDP).

Pre-treatment is one of the most important features of any recycle system. The DDP must be able to remove heavy solids (i.e. mud, rocks, dirt, etc.), separate and treat “free floating” oils/greases from the wash water and provide a minimum of 80 gallons per minute (GPM) to supply the water cannons. The processes used for pre-treatment may include tumbling, gravity separation, and weir wall separation. The DDP should be multi-chambered for maximum solids separation and dwell time.

8-4.1.2.2 Water Wands.

In lieu of traditional “fire hoses” which are ineffective, hard to handle, and pose serious safety hazards, hand held “water wands” will be the preferred method to effectively clean and “de-muck” vehicles covered in heavy solids (mud).

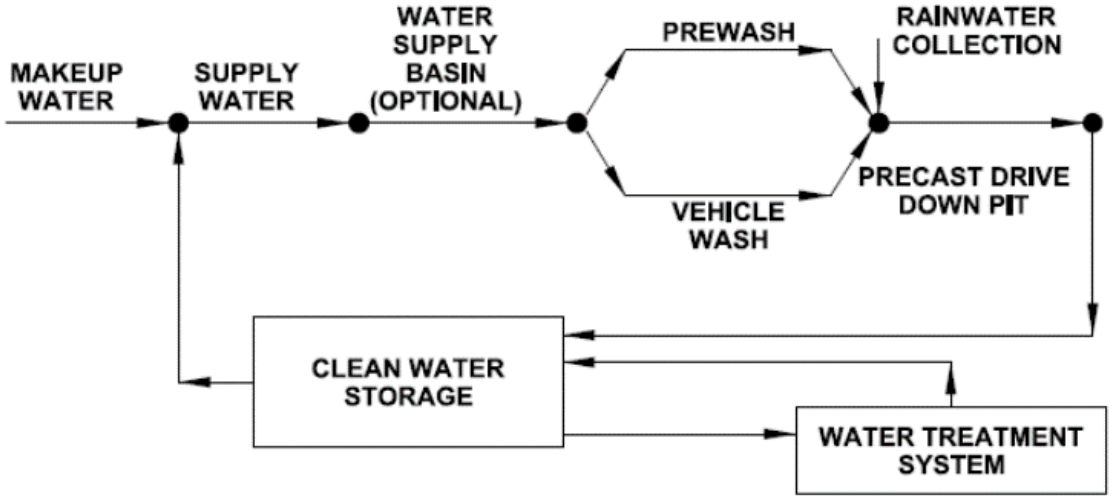
8-4.1.2.3 Water Treatment System (WTS).

Often called Water Recovery Systems, WTS's are used in closed loop design when water quality is paramount. In the first stage of the water treatment process, suspended solids, emulsified oil/grease and heavy metals must be removed from the wash water leaving a clear phase of water for recycle or when necessary, discharge to sanitary. Suspended solids are removed to sub-micron levels, emulsions are broken & coagulated and heavy metals are oxidized and removed from the water. WTS's used several different methods for treatment that can be customized based on the specific application. The overall process can include a combination of such methods as settlement, oxidation, filtration, flocculation, or coagulation.

The WTS must be easy to use and maintain with a minimum use of consumables, drastically reducing operation and maintenance costs. As the heart of a recycle design, it must control all phases of the circulation processes. Water treatment systems are typically packaged systems that can be procured through a performance specification. Equipment manufacturers can provide insight into each specific case and may be consulted in the specification of the equipment assuming none of the language is proprietary to the system.

8-4.1.2.4 Water Purifier.

The final stage of water treatment, in a closed loop design, is a water purification system that can provide fresh water to the wash rack to make up for evaporation and carry-off. The system must be able to physically remove pathogens, particulates and turbidity from the treated water.



8-4.1.2.5 Dewatering Containers.

In this design, the heavy solids are de-watered, with specifically designed hoppers or "roll off" containers, sufficiently enough for the solids to be safely returned to "landfill" (after proper testing). After passing through a filtering screen specifically designed to the type of soil at each location, the water drains back to the drive down pit to be treated and reused.

8-4.1.3 Design Configurations.

Designs must be available in different configurations allowing for flexible use at multiple locations depending on the needs or requirements of the user. Because of the smaller footprint, this wash facility can be strategically placed to maximize efficiency, minimize traffic patterns and increase thru-put.

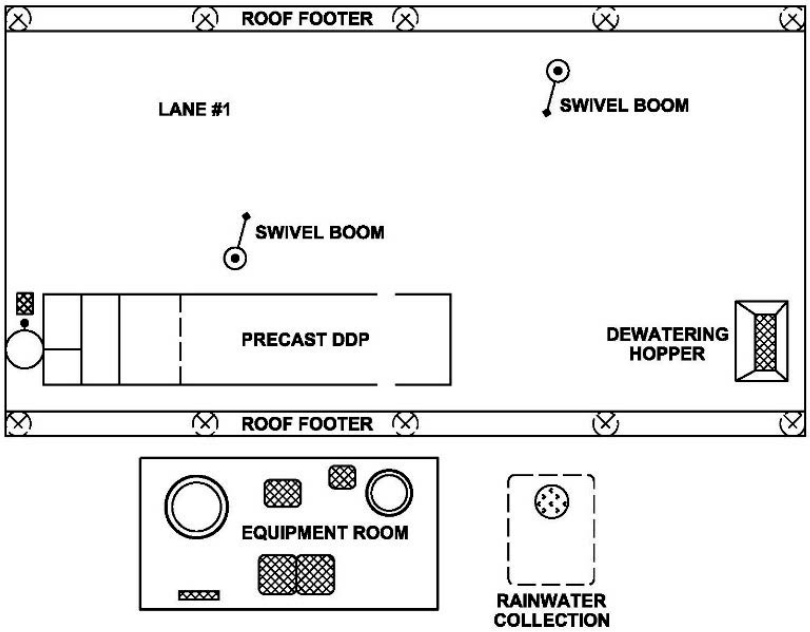


Figure 8-1 Decentralized Wash Facility Layout

8-4.1.3.1 Single Lane Design.

Up to 50 vehicles and/or items of equipment in less than 8 hours. With anticipated water use less than 500 gallons of fresh water to replace evaporation and carry-off.

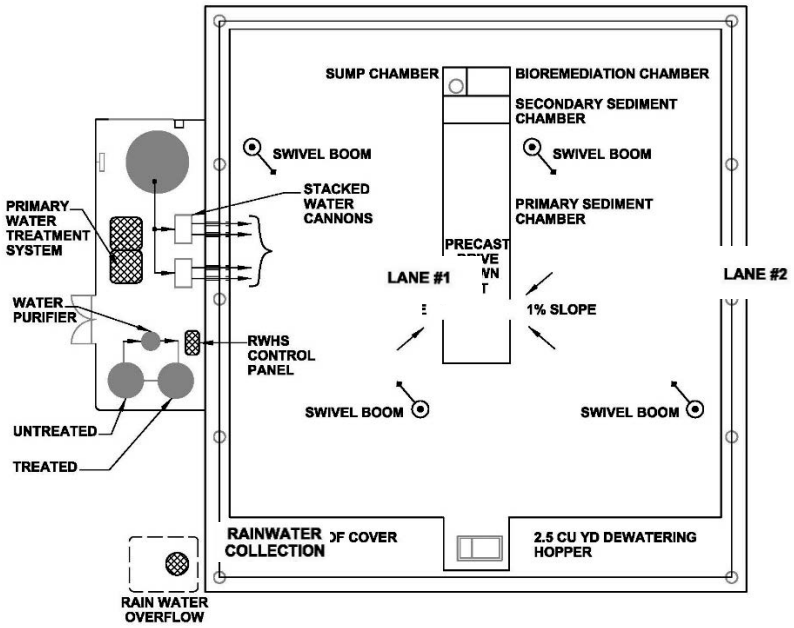

Figure 8-2 Single Lane, Heavy Solids Wash Rack

8-4.1.3.2 Dual Lane Design.

Versatile design, will handle most unit requirements. Up to 100 vehicles and/or items of equipment in less than 8 hours. With anticipated water use less than 1,000 gallons of fresh water to replace evaporation and carry-off.

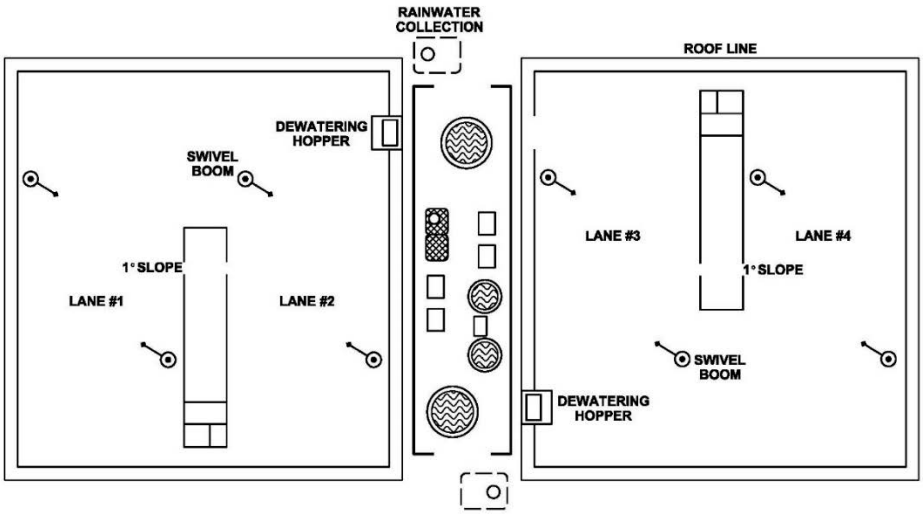

Figure 8-3 Dual Lane, Net Zero, Heavy Solids Wash Rack

8-4.1.3.3 Quad Lane Design.

Units requiring high volume thru-put. Up to 200 vehicles and/or items of equipment in less than 8 hours with anticipated water use less than 2,000 gallons of fresh water to replace evaporation and carry-off. In addition, this is the ideal design to use on the egress side of existing bird baths for heavy tracked vehicles to increase thru-put.

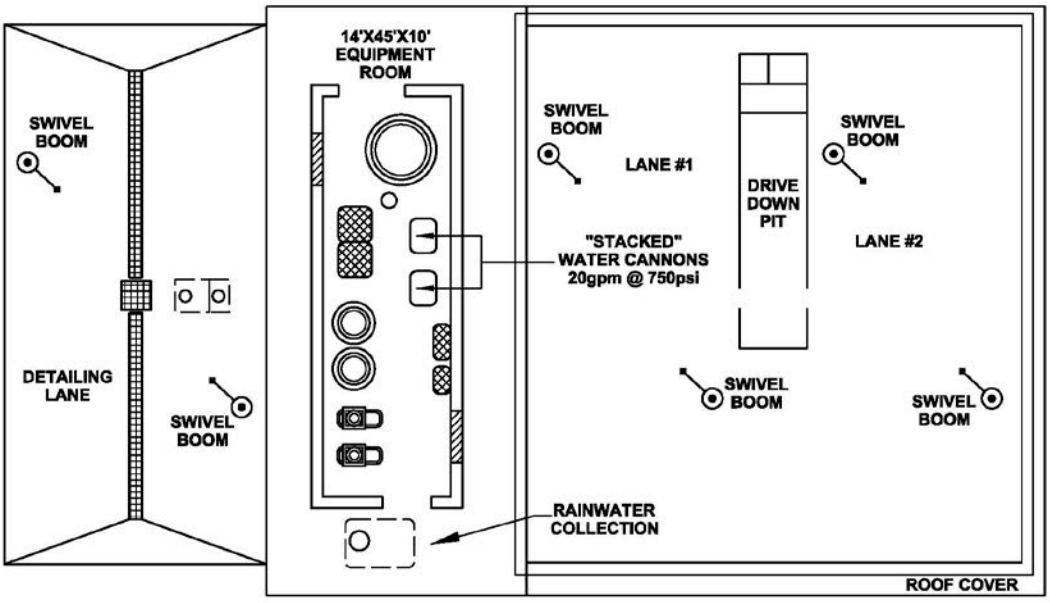

Figure 8-4 Quad Lane, Net Zero, Heavy Solids Wash Rack

8-4.1.3.4 Dual Lane-Combo Design.

Most versatile design, ideal for a variety of units. Handles the most diverse assortment of vehicles and equipment. Utilizes both hand held water cannons for heavy solids removal as well and hot water pressure washers for detail cleaning.

Figure 8-5 Dual Lane, Net Zero Wash Lane with Heavy Solids and Detailing Lanes

8-4.1.4 Design Options.

- Roof Cover (Required for Net Zero and “Closed Loop” Systems.
- Rain Water Harvesting Systems. (Requires Roof Cover)
- Enclosed Wash Facility
- Heated Pad (Snow Melt/Radiant Heat) for use in cold climates
- Lighting

8-4.2 Construction Details.

8-4.2.1 Site Preparation.

The wash facility should be positioned for easy access and to maximize drive thru traffic for increased thru-put. Existing soil conditions should be tested and confirmed. Removal of existing structures (if any), tear out and haul away requirements must be determined. Proximity to and rerouting of existing utilities must be considered during the siting phase.

8-4.2.2 Utilities.

- Electrical. See section 3-2.4.3 Electrical for requirements.
- Plumbing. A fresh water line (Minimum 1”, 60-80 psi) and a discharge line to sanitary (If applicable) may need to be piped underground to and from the wash facility. The internal plumbing to and from the equipment should be a minimum of Sch-80 PVC where the manufacturer does not have a generally accepted standard for the application.

- In regions where freezing conditions may occur, the water supply piping, valves and fittings at the wash stations must be “winterized” for protection from damage due to freezing.

8-4.2.3 Drive-Down Collection Pit (DDP).

For durability, water tightness and overall effectiveness, a multi-chambered, monolithically poured or pre-cast DDP is required. The DDP should be coated with a special epoxy coating to assure water tightness and prevent leaching of any kind. Tank design shall performed to ensure effective solids separation. Dwell time and flow rate will depend on the application and location of the wash facility.

8-4.2.4 Concrete Pad.

The concrete wash pad should be specified to meet the load requirements of the vehicles and items of equipment using the wash facility. A base should be designed and adjusted for existing soil conditions. The concrete pad should be a “sump” design; so that all wash water will drain into the collection pit. Footers should be included for the roof cover.

8-4.2.5 Equipment Room.

The equipment room will contain all of the equipment and should be sized appropriately (minimum 10’ ceiling height). Typically, the room is built using split-faced concrete block as metal buildings are not suitable for a wet environment. The room should have a gable roof, roll-up door and a man door. Lighting should be designed for adequate illumination of equipment for maintenance and repair. Interior and exterior electrical features should be in a NEMA 3R enclosure to prevent the ingress of water. Exterior lighting should be provided as required for washing and maintenance operations. Heating systems should be provided in climate zones where freezing is expected and ventilation fans should be provided to prevent overheating of the room. Where required by the building contents, exhaust fans should be provided to prevent the building up of chemical fumes. Wall hydrants and floor drains should be provided where required to service the equipment.

8-4.2.6 Roof Covers.

To achieve Net Zero status, a roof cover must be used to prevent rainwater from overfilling the system. Typical roof covers are fabricated of galvanized steel (in order to withstand the wet environment) in a clear span, gable design. A gutter system can be used to collect and harvest rainwater.

8-5 OPERATION AND MAINTENANCE.

The Closed Loop, Net Zero designed Wash Rack is designed as a system to ensure water conservation and water quality for washing vehicles and other equipment. The operation of the wash facility should be designed to facilitate ease of use and maintenance. Training on the features of the Closed Loop System is paramount for all operators and maintainers. Therefore, when in use, a trained operator must be present to ensure maximum efficiency during the course of operation.

8-5.1 Operation and Organization Maintenance Tasks.

Operator and Organization maintenance tasks will be taught by the system designer. Maintenance above Organizational level will be performed by appropriate military service personnel or by contractor logistics support as specified in the system design. Training will include proper operating and maintaining procedures and appropriate manuals (DVD) in order for units to train additional operators and maintainers.

8-5.2 Maintenance.

As with any equipment, regular maintenance is required to ensure proper working order. The responsibility for operating and maintaining this system will be determined at the time of contract award. Equipment operations, maintenance, and repair manuals will be specified and required to be provided by the contractor at completion of the construction contract.

If contractor logistics support is required for maintenance and for parts, appropriate manuals (DVD) will specify how to obtain the requisite support.

8-6 PERFORMANCE.

Performance standards should be established including parameters for past performance of equipment, water quality and thru-put efficiency.

8-6.1 Past Performance.

The equipment used in this design should have a proven, successful past performance under these specific guidelines and treating similar applications.

8-6.2 Water Quality.

When considering “Performance Standards”, particularly in a Closed-Loop, 100% recycle system, the quality of the recycled water is paramount. Parameters to be considered must include Biochemical Oxygen Demand (BOD), Total Dissolved Solids (TDS), Total Suspended Solids (TSS) and Hexane Extractable Material (HEM); Oil and Grease. Meeting these parameters makes the water suitable to be re-used for washing. There are two specific areas of consideration that a Decentralized; Closed-Loop system must focus on.

- The pre-treatment system (DDP) has the most significant impact on the quality of water that the “user” is constantly exposed to during the washing process. The multi-chambered design must be able to reduce BOD’s to <10 mg/L. TSS’s must be reduced to 120 – 400 mg/L and most importantly, HEM; Oil and Grease must be Non-Detect (ND). TDS is not addressed in this stage.
- The water treatment and purification systems must be able to treat the wash water to significantly tighter standards for this water to be used to replace carry-off and evaporation. BOD, TSS, and HEM must all be Non-Detect. TDS levels must be in the range of 500 – 800 mg/L.

APPENDIX B BEST PRACTICES

B-1 CASE STUDY: DECENTRALIZED VEHICLE WASH FACILITY.

B-1.1 Background.

The existing wash station consisted of a simple drain in a small concrete pad that led to a sand oil/water separator that discharged to sanitary sewer. A secondary, single wash lane was also located at the Maintenance Shop. It had a trench drain that also led to a sand oil/water separator that discharged to sanitary sewer. Portable pressure washers and garden hoses were used for the actual cleaning. Estimates placed water consumption in the hundreds of thousands of gallons annually. The largest single usage of water was coming from washing the vehicles and equipment returning from Monthly and/or Annual Training.

Figure B-1 Decentralized Dual Lane Wash Facility

Because of limited space at the facility and the number of vehicles to be washed, a decentralized, Net Zero dual lane wash facility was constructed.

B-1.2 Construction.

B-1.2.1 Site work.

The Wash facility was positioned on-site for one-way, drive thru traffic to maximize thru-put. Existing soil conditions and GEO testing were performed.

The small existing concrete wash lane was removed and the new wash facility was placed in the same location.

B-1.2.2 Utilities.

B-1.2.2.1 Electrical.

In the example project a 230v 3PH 200 AMP electrical service was run from a nearby utility pole to the main electrical panel of the equipment room. Although this does not meet the electrical criteria guidelines for size of service and having 3 phase power, it was better for the project. As part of determining the requirements, overall costs to the government does need to be considered. The decision to use the available power source was better for the project as a whole. The cost for a new medium voltage distribution would not save enough cost to the government in the efficiency difference between the single phase and 3 phase power to justify the first cost of the new service.

B-1.2.2.2 Plumbing.

A 1” fresh water line was tied into the existing fresh water line at the pre-existing wash pad. A backflow preventer was installed inline before entering the equipment room. The fresh water is used as “make-up” water only if the rainwater collection tank is empty.

All non-pressurized internal plumbing was installed using Sch. 80 PVC including the sump and drain line to the drive down collection pit.

1” Sch. 80 galvanized Steel pipe was installed from the equipment room to each of the four (4) swivel booms. The galvanized pipe was wrapped in a 4 mil polyethylene sleeve for additional protection against corrosion. The pipe was pressure tested at 750 PSI minimum.

B-1.2.2.3 Rainwater harvesting.

A minimum 1,000 gallon cistern was placed underground next to the equipment room. The gutter system from the roof canopy drains directly into the tank. Excess water drains through an overflow in the tank into a nearby drainage ditch. A sump pump was installed in the cistern to provide “make-up” water to the system “on-demand”.

B-1.2.3 Precast Drive Down Pit (DDP) Install.

A precast drive down collection pit measuring 36’L x 8’6”W x 4’T and weighing 44,000 lbs. was delivered onsite. A 70 ton crane was used to set the DDP in place. The DDP established all grades and slopes for the concrete pad and footers.

Sediment should be removed from the drive down collection pit on a regular basis; however, the exact frequency of cleanings will depend on variations of soiling, user requirements, and other considerations unique to the installation. The dewatering container should also be emptied on a regular basis.

B-1.2.4 Wash Pad.

A wash pad measuring 66’ x 72’ was poured around the drive down collection pit including a 3’ apron for roof structure columns and an 8’ apron for the dewatering container. The 4,000 PSI concrete was poured 12” thick with two (2) mats of #6 rebar, 12” OC. The finished grade of the concrete is a “sump design”, where all wash water on the pad drains back into the DDP. Footers for the roof cover were engineered with a 3’ x 3’ x 3’ minimum.

B-1.2.5 Roof Cover.

A clear span, gable roof was installed over both of the wash lanes. The roof structure is fabricated galvanized steel in order to withstand the wet environment. A gutter system was installed to direct rainwater into the underground holding tank.

B-1.2.6 Equipment Room.

An equipment room of 14’W x 36’L x 10’H (ceiling height) was built using split-faced cinder block. The color of the cinder block was chosen to match existing buildings. A roll-up door was installed to accommodate equipment installation (or future removal). An additional man door was installed. The roof is a gable truss design with an exterior metal roof and open ceiling interior.

B-1.2.7 Equipment.

B-1.2.7.1 Water Cannons and Swivel Booms.

Two “stacked” water cannons (a total of 4 water cannons) were installed in the equipment room. The four water cannons provide 20 GPM each at 750 PSI of recycled water to the swivel booms on the wash pad and are fed from a 1,800 gallon cone-bottom tank. The swivel booms are powder-coated steel mounted on concrete pedestals with a 6’ swivel boom arm allowing a 16’ minimum clearance underneath.

Attached to the end of the booms are 30’ of high pressure hose with a hand-held variable pressure trigger gun. The operation of the water cannons is controlled by a remote on/off switch.

B-1.2.7.2 Water Treatment Systems.

For the first stage of primary water treatment, an electro-coagulation (EC) system was installed. The system treats the wash water, removing heavy metals, suspended solids and emulsified oil & grease, and then sends the water to the purifier for final treatment. The system automatically controls all of the water flow throughout the wash facility including all pumps, floats and valves.

A microbiological water purifying system was installed to polish the water treated by the EC System. The water is purified, removing pathogens, particulates and turbidity and used to provide make-up water to the system for the loss of wash water through evaporation and carry-off.

B-1.2.7.3 Dewatering Container.

To treat the solids from the drive down pit, a 2.5 cu. Yd “self-dumping” dewatering hopper was set in place on the wash pad. After the pit is drained, the front loader can remove the solids from the DDP and dump them into the hopper. Using a specifically design filter, the solids stay in the hopper and the water drains back into the collection pit.

B-1.3 Performance.

B-1.3.1 Cleaning Process

An ARNG Unit completed a Training Exercise and on their return washed 98 Vehicles in 6 hours and used <1200 Gallons of water. Vehicles consisted of HEMTT's, Heavy Trucks, Humvee's and tracked vehicles. Solids load was Light to Moderate.

Average Wash Times per Lane:

1.	HEMTT’s	10-12 Minutes
2.	Heavy Trucks	5-7 Minutes
3.	Humvees	3-5 Minutes
4.	Tracked Vehicle	10-12 Minutes

B-1.3.2 Solids Separation

Immediately following the completion of washing the vehicles a mud settling test was performed on-site. After 30 minutes, most of the solids had settled out and after 24 hours, all solids had settled leaving a clear phase of water.

B-1.3.3 Water Quality

During the washing, water samples were collected at various locations and sent to an independent lab for testing. The test results are below.

1. In the primary chamber of the drive down collection pit (where the wash water drains directly from the vehicles).

a. BOD	4.73	mg/L	Untreated
b. TDS	2,225	mg/L	
c. TSS	1,220	mg/L	
d. HEM-Total	12	mg/L	
e. HEM-SGT	ND	mg/L	

f. HEM-Polar 12 mg/L

2. From nozzle of hand-held water cannon gun after pre-treatment by the drive down collection pit.

a. BOD 2.08 mg/L

b. TDS 2,055 mg/L

c. TSS 130 mg/L

d. HEM-Total ND mg/L

e. HEM-SGT ND mg/L

f. HEM-Polar ND mg/L

3. From “Clean” Tank after water treatment and purification

a. BOD ND mg/L

b. TDS 630 mg/L

c. TSS ND mg/L

d. HEM-Total ND mg/L

e. HEM-SGT ND mg/L

f. HEM-Polar ND mg/L

B-1.4 Conclusion.

This Net Zero Wash Facility is used daily to wash vehicles, tools & equipment and also used during monthly and annual training activities at the installation.

This wash facility design provides a capability that meets all DOD requirements for environmental compliance, sustainability and water conservation that allows for a more efficient, cost effective cleaning operation. Consequently, this results in a better use of the military’s land and drastically reduces water consumption while remaining environmentally compliant throughout the cleaning process.

B-2 DESIGN EXAMPLE

B-2.1 Introduction.

The following fictional case study example illustrates the planning and design procedures presented in this manual. This example involves Fort Swampy, a U.S. Army Forces Command (FORSCOM) installation which also trains National Guard units. The installation is located in a region with annual precipitation level of 63 inches (1.6

meters), and a 1-hr., 10-yr design storm of 2 inches (5.1 centimeters) intensity. The evaporation rate at the installation is 68 inches (1.7 meters) per year. The soil in the training areas contains some expansive, cohesive clays that will be a problem to remove from vehicles during the rainy periods throughout the year. Freezing temperatures are not expected at the installation. The prevailing winds are from the west-northwest.

B-2.2 Master Planning Considerations.

B-2.2.1 Training Schedule.

Two major training activities were scheduled at Fort Swampy last year, with the same number of major exercises expected to continue in the future. The installation requires vehicle washing all year. Table B-1 lists all of the troop units on-post by motor pool assignment. During a major exercise, the installation sends all working vehicles to the field. Range Control reports that it takes from 2 to 4 days to recall all of the vehicles from the field. Daily training activities consist of three or four company teams going to and returning from the field. Each company team consists of approximately 8 tracked vehicles and 30 wheeled vehicles. The National Guard units perform both monthly and annual training activities at the installation. The installation has provided the planner with a summary of the estimated number and types of N. 0. vehicles returning from the training field on a monthly basis. This information is listed in Table B-2 and graphically in Figure B-2 to show the distribution of vehicles used throughout the training year.

B-2.2.2 Number and Types of Vehicles.

B-2.2.2.1 Regular Army.

Table B-1 shows the vehicle types by motor pool. Several units are in each motor pool. A major training exercise assumes that every unit in every motor pool goes out to the field. Skirted vehicles, such as the M-l tank, are more difficult to clean since dirt can collect under the skirt. Fort Swampy currently has 85 M-l tanks, and more are expected to be acquired in the future. Seventy-nine percent of the vehicles are wheeled.

B-2.2.2.2 National Guard Units.

- The following vehicles will return after the monthly National Guard Training events:

31 light track	146 light wheel
26 heavy track (no M-ls)	58 heavy wheel
57 total tracked vehicles	204 total wheeled vehicles

- Seventy-eight percent of the total number of vehicles to be washed at the CVWF are wheeled.

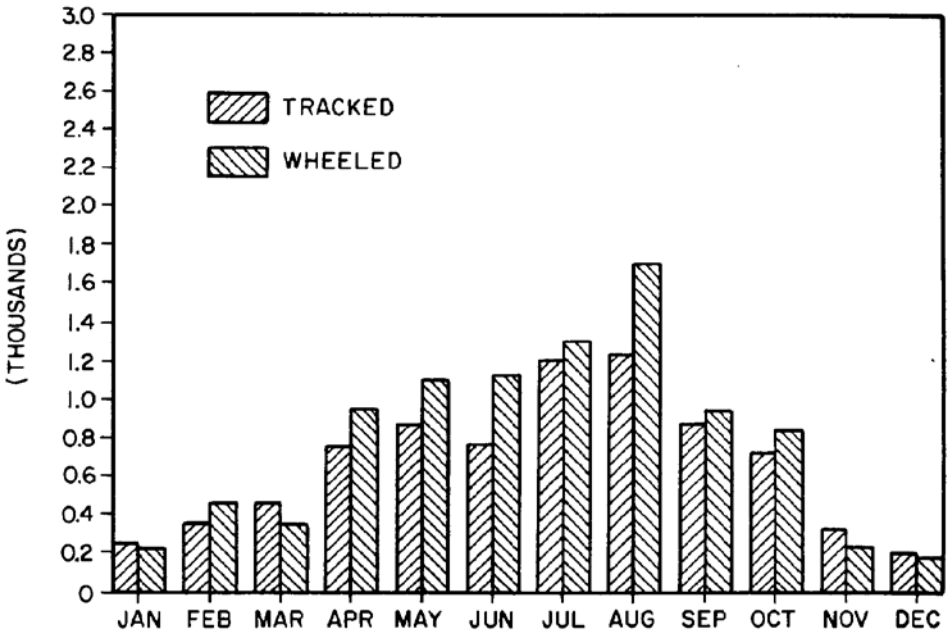

Table B-1 Number of Vehicle Types by Motor Pool Assignment

Unit Names by Motorpool	Heavy Track	Light Track	Heavy Wheel	Light Wheel	Nonstandard and Trailers
HNC Infantry	2	6	5	11	4
Infantry	85	11	49	18	2

Figure B-2 Vehicles Returning from the Training Areas each Month

B-2.2.3 Washing Requirements.

The Regular Army at Fort Swampy requires that all vehicles be washed as they return from field exercises. The installation requires that vehicles returning from major field exercises be washed within a period of 54 hours. Vehicles returning from routine, daily training activities must be washed within a period of 3 hours. The National Guard requires its vehicles to be washed within 8 hours of completing field exercises. Both the installation and the National Guard have indicated some flexibility with these washing times. Night time washing operations must be provided to meet the installation's requirements; therefore, lighting will be provided in the preparation, bath, wash station, and vehicle assembly areas. Vehicle interior washing capabilities are also required by the installation. Since the vehicles are returned to the motor pools for maintenance inspections, they must receive a detailed washing.

B-2.2.4 Vehicle Soiling.

Soil samples taken from the training areas, as well as off dirty vehicles, have been tested in a soils laboratory. A grain size analysis (dispersed) was made as described in Chapter 3. Results indicated a composition of 14 percent sand, 54 percent silt, and 32 percent clay. From the soil classification diagram (Figure 3-3), the soil is a silty clay with a soil type number (Si) of 4. Based on the amount of rain received annually at the installation and the fact that the rainy season is also a training season, the climatic factor was chosen as 2.0. From equation 3-1, the soiling index (Si) is calculated to be 8, which indicates heavy soiling conditions and thus potentially longer washing times using standard means. A nondispersed particle size analysis was also made by the laboratory which indicated that 50 percent of the particles were larger than 0.05 mm, 80 percent of the particles were larger than 0.02 mm, 90 percent of the particles were larger than 0.01 mm, and 97 percent of the particles were larger than 0.005mm.

B-2.2.5 Installation Requirements.

B-2.2.5.1 Prewash.

A bath prewash is indicated at Fort Swampy because cohesive soil found in the training areas, combined with the limited washing period, require the type of prewashing best served by a bath facility. To achieve the desired soaking action on the skirted M-1 tanks for gross soil removal, the depth of water in the bath should be adjustable up to 3.5 feet (1.1 meters).

B-2.2.5.2 Wash Stations.

The wash stations will be the standard design described in Chapter 4. Interior wash equipment will be included. Since tracked vehicles will also be using the wash stations, each island must be protected by concrete barriers and all pavement in the CVWF must be constructed of concrete.

B-2.2.5.3 Preparation Area.

Since the CVWF will have a bath, two preparation areas are required. The first area will be located before the bath to allow troops to prepare the vehicles for washing and to queue-up behind the bath lane. The second preparation area will be between the bath exit and the entrance to the wash stations, this is a queuing area for vehicles that have left the bath or have bypassed the bath.

B-2.2.5.4 Waste Washwater Treatment.

Fort Swampy purchases potable water from a local water district at a current price of $1 per 1000 gallons (3785 liters). The existing wastewater treatment system at the installation does not have the capacity to treat the large hydraulic and solids loadings expected from the CVWF. In addition, the State will not allow discharge to the environment. Therefore, a total recycle system is required. Due to the high clay content of soils in the training area, laboratory settling tests have indicated extremely long detention times should be required for a lagoon treatment, therefore a sand filter system was chosen as the form of secondary treatment.

B-2.2.5.5 Makeup Water.

Sources have been investigated and the only reliable, environmentally acceptable source of makeup water is the potable water system. The potable water supply is limited to 3 million gallons (11.36 million liters) per day. Daily water usage at the installation is 2 million gallons (7.57 million liters) per day, with 1 million gallons (3.79 million liters) reserved for firefighting. No water is available for expansion facilities. However, it is estimated that the motor pools now use 0.13 to 0.20 million gallons (0.49 to 0.76 million liters) of water per day to wash vehicles. Part of this volume of conserved water can be used as makeup water for the new CVWF.

B-2.2.6 Sizing.

B-2.2.6.1 Bathprewash.

The designer estimates that the processing rate through the bath will be 6 vehicles per hour per tracked vehicle lane and 11 vehicles per hour per dual-purpose lane. This decision was based on the soiling index computed for the site and the processing rates given in Chapter 3 and illustrated on Figure 3-4.

- Regular Army. The designer uses equations 3-2 and 3-3 from Chapter 3 to determine how many tracked and dual-purpose lanes are needed for prewashing Regular Army vehicles. The tracked lanes will be used for most of the large tactical vehicles; therefore, dual-purpose lanes are estimated without including the tracked vehicles, as discussed in Chapter 3. The installation has estimated that 80 percent of the tracked vehicles and 65 percent of the wheeled vehicles returning from the field will require immediate washing in the bath with the rest bypassing to the wash stations. It has been assumed that trailers and nonstandard vehicles, such as bulldozers and goers, will proceed directly to the wash stations.

Other vehicles, such as ambulances and support vehicles, may not require immediate washing and will use the facility at a later time. Malfunctioning vehicles may be returned to the motor pool directly or may be left in the field until all other vehicles return. The designer has also considered vehicles in-tow such as tanks and trailers. Using the vehicle counts from table B-2, the number of tracked and dual-purpose lanes required for washing after a major training exercise are computed:

$$\text{Number of tracked lanes: } \frac{0.80\times(538\text{ veh})}{6\text{ veh/hr/lane}\times(54\text{ hr})} = 1.33\text{ lanes} \qquad \text{eq. B-1}$$

$$\text{Number of dual} - \text{purpose lanes: } \frac{0.65\times(1973\text{ veh})}{11\text{ veh/hr/lane}\times(54\text{ hr})} = 2.16\text{ lanes} \qquad \text{eq. B-2}$$

Since the installation is flexible with respect to washing times, the designer rounds the number of lanes as described in Chapter 3. One tracked lane and two dual-purpose lanes were recommended to accommodate the Regular Army's needs. Using the above information, the numbers of tracked and dual-purpose lanes required for washing after routine daily training exercises are computed:

$$\text{Number of tracked lanes: } \frac{0.80\times 8\text{ veh/team}\times 4\text{ teams}}{6\text{ veh/hr/lane}\times 3\text{ hr}} = 1.42\text{ lanes} \qquad \text{eq. B-3}$$

$$\text{Number of dual} - \text{purpose lanes: } \frac{0.65\times 30\text{ veh/team}\times 4\text{ teams}}{11\text{ veh/hr/lane}\times 3\text{ hr}} = 2.36\text{ lanes} \qquad \text{eq. B-4}$$

It is apparent that the one tracked vehicle lane and the two dual purpose lanes estimated above will meet the requirements for both major training exercises and routine daily training activities.

- National Guard. The same computation is used to compare the bath requirements for the National Guard units except that a high percentage of vehicles will use the bath because there are few support vehicles and all units are to be returned to the motor pool extremely clean. It is estimated that 90 percent of tracked vehicles and 75 percent of wheeled vehicles will use the bath prewash. Using information from above, the number of bath lanes required is computed:

$$\text{Number of tracked lanes: } \frac{0.90\times 57\text{ veh}}{6\text{ veh/hr/lane}\times 83\text{ hr}} = 1.07\text{ lanes} \qquad \text{eq. B-5}$$

$$\text{Number of dual} - \text{purpose lanes: } \frac{0.75\times 204\text{ veh}}{11\text{ veh/hr/lane}\times 8\text{ hr}} = 1.74\text{ lanes} \qquad \text{eq. B-6}$$

A comparison of the results shows that the one tracked lane and two dual-purpose lanes will satisfy both Regular Army and National Guard needs at the prewash facility. Designer realizes that light-tracked vehicles may be washed in the dual-purpose lanes.

B-2.2.6.2 Wash Stations.

The clay content in the soils at the installation and the requirement that vehicles return to the motor pools well cleaned for inspection and maintenance after washing suggest that the processing time required for troops to do a detailed washing at the wash stations will be at the high end of the range. From the processing rates given in Chapter 3 (Figure 3-4) and the soiling index (Si) previously computed, the designer has determined that 3.75 vehicles can be processed per hour in each wash station following the prewash. For the tracked vehicles not using the prewash, a processing rate of 1.75 vehicles per hour is selected; and for wheeled vehicles not using the prewash, a processing rate of 5 vehicles per hour is selected. Compute the number of wash lanes required after a major training exercise:

$$\text{Tracks from bath:} \quad \frac{0.80 \times 538 \text{ veh}}{3.75 \text{ veh/hr/lane} \times 54 \text{ hr}} = 2.12 \qquad \text{eq. B-7}$$

$$\text{Tracks bypassing bath:} \quad \frac{0.20 \times 538 \text{ veh}}{1.75 \text{ veh/hr/lane} \times 54 \text{ hr}} = 1.14$$

$$\text{Wheeled from bath:} \quad \frac{0.65 \times 1973 \text{ veh}}{3.75 \text{ veh/hr/lane} \times 54 \text{ hr}} = 6.33$$

$$\text{Wheeled bypassing bath:} \quad \frac{0.35 \times 1973 \text{ veh}}{5 \text{ veh/hr/lane} \times 54 \text{ hr}} = 2.56$$

$$\text{Total Wash Lanes} = 12.15 \text{ lanes}$$

The number of lanes required to meet the daily training exercise is computed:

$$\text{Tracks from bath:} \quad \frac{0.80 \times 32 \text{ veh}}{3.75 \text{ veh/hr/lane} \times 3 \text{ hr}} = 2.28 \qquad \text{eq. B-8}$$

$$\text{Tracks bypassing bath:} \quad \frac{0.20 \times 32 \text{ veh}}{1.75 \text{ veh/hr/lane} \times 3 \text{ hr}} = 1.22$$

$$\text{Wheeled from bath:} \quad \frac{0.65 \times 120 \text{ veh}}{3.75 \text{ veh/hr/lane} \times 3 \text{ hr}} = 6.93$$

$$\text{Wheeled bypassing bath:} \quad \frac{0.35 \times 120 \text{ veh}}{5 \text{ veh/hr/lane} \times 3 \text{ hr}} = 2.80$$

$$\text{Total Wash Lanes} = 13.23 \text{ lanes}$$

Requirements for the Regular Army exceed those for the National Guard and because the installation is flexible in regard to wash times, the designer selects 12 wash stations.

B-2.2.7 Site Selection.

B-2.2.7.1 Geography.

The site selected over several possibilities is adjacent to the only main route, Range Road that the vehicles will travel as they return to the cantonment area from the training fields.

B-2.2.7.2 Geology.

The site has 45 feet (13.7 meters) of relief over a 25-acre (0.10-square kilometer) area. The site is on the top of a ridge that is approximately 200 feet (61 .0 meters) wide and 700 feet (213.4 meters) long. Site borings have shown that the water table will not interfere with construction or operation of the CVWF. The site has never been used for any purpose. Engineers have determined that if work to lengthen or widen the ridge is to be done at the site, it will raise construction costs considerably due to the location of the bedrock. Figure B-3 shows a topographic map of the site.

B-2.2.7.3 Utilities.

All required utilities are within a reasonable distance to the proposed site. A 10 inch (25.4-centimeter) potable water line runs parallel to Range Road. Electrical and telephone lines also run parallel to this road. The latrines can be tied into the sanitary sewer lines which are within 0.75 miles (1.2 kilometers) of the site. As long as wastewater from the facility is recycled, the added load from the CVWF is not expected to burden any of the existing sewer lines.

B-2.3 Engineering and Design.

B-2.3.1 Bath Design.

Figure B-4 shows the bath arrangement for the new Fort Swampy CVWF consisting of one tracked lane and two dual purpose lanes. Dimensions are taken from the definitive drawings and entrance and exit slopes are selected as shown. Overall length is computed using these slopes.

B-2.3.1.1 Water Cannons.

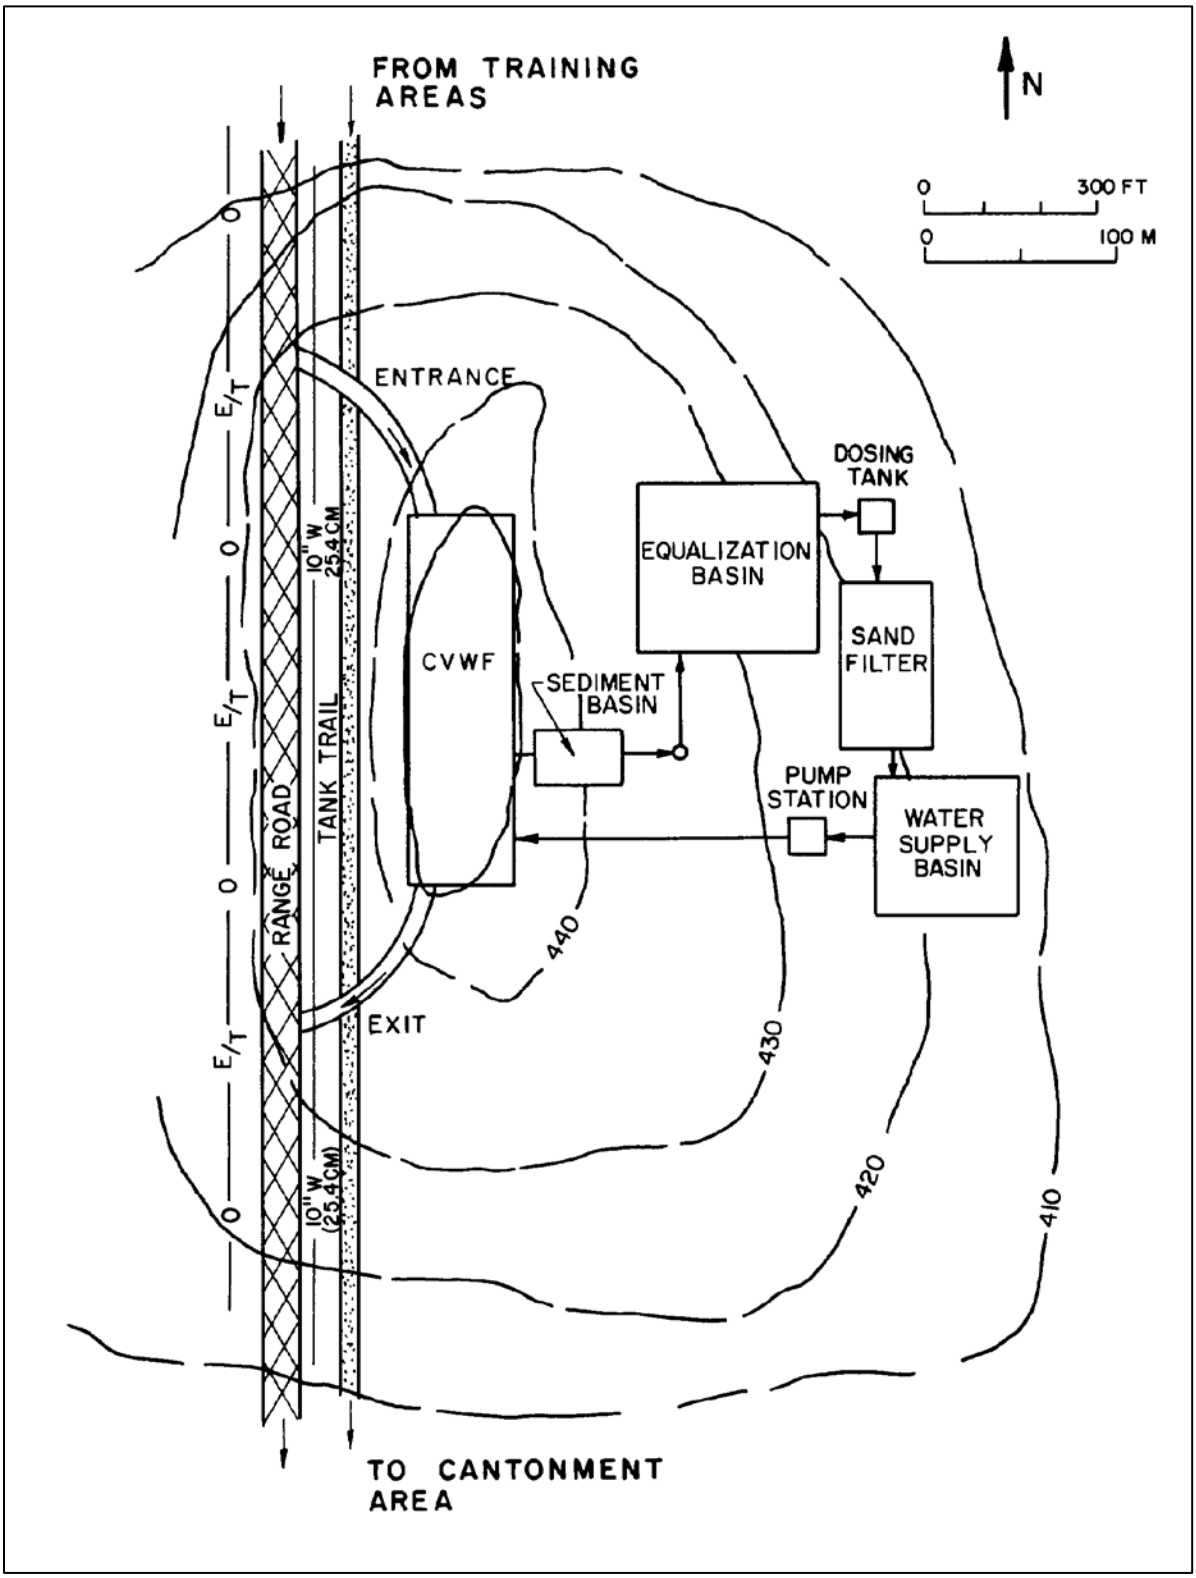
The flow rate from the water cannons in all lanes is selected as 80 gallons per minute (gpm) (303 liters per minute). The delivered pressure selected is 100 pounds per square inch (psi) (6.8 atmospheres). These are the maximum flow rate and pressure values recommended and are chosen because the soil consists of clays which are not easily removed.

B-2.3.1.2 Flexors.

Flexors in the dual-purpose lane should be exposed 4 inches (10.1 centimeters) with a center-to-center spacing of 17 inches (43.2 centimeters), since about the same number of light- and heavy-wheeled vehicles are expected to use the bath. The tracked lane

should have flexors exposed 10 inches (25.4 centimeters) and spaced 5.5 feet (1.7 meters) o.c. because the primary user will be heavy tracked vehicles.

Figure B-3 Site Map with a Proposed Layout – Fort Swampy



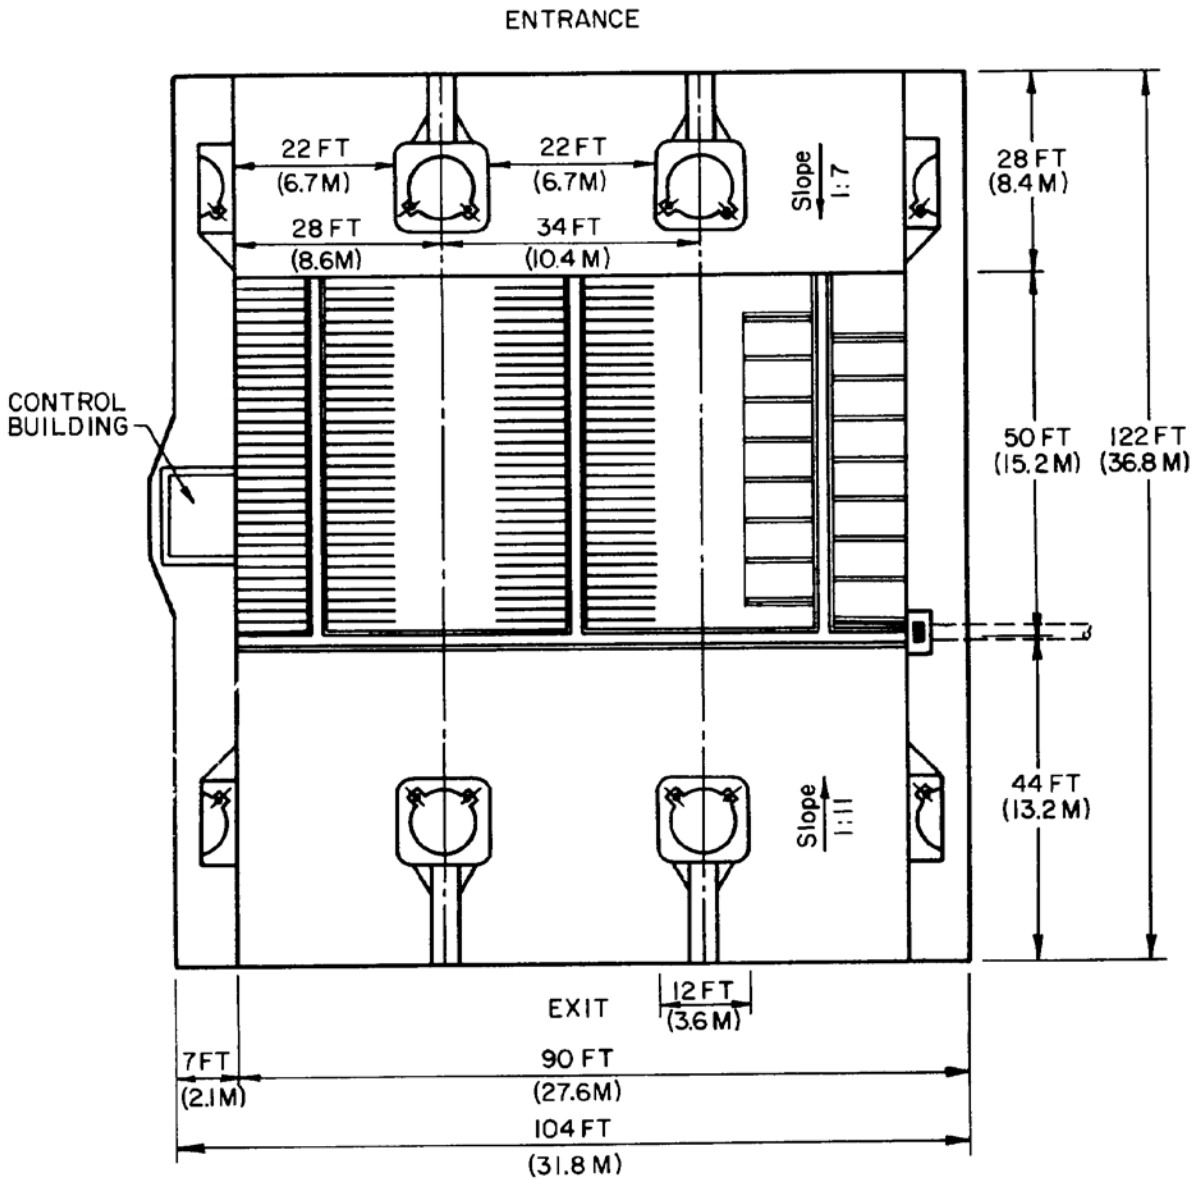


Figure B-4 Bath Design

B-2.3.1.3 Entrance Ramp.

Because Fort Swampy does not have freezing weather, the maximum slope on the entrance ramp, 1 in 7, can be used. This design will give a projected ramp length of 24.5 feet (7.5 meters).

B-2.3.1.4 Exit Ramp.

The maximum slope of 1 in 11 can be used for the exit ramp. With this slope, the projected ramp length is 38.5 feet (11.7 meters).

B-2.3.2 Wash Station Design.

The flow rate selected per hose is 30 gpm (114 liters per minute) at 90 psi (6.1 atmospheres) pressure. These are the maximum flow rate and pressure values recommended and were chosen because the soil consists of clays which are not easily removed. Interior washing points, which are low-pressure, low-flow outlets consisting of yard hydrant and utility hose will be placed at each island. The limited area for construction on the natural ridge will dictate the configuration of the wash station area. Two configurations, A and B, are evaluated.

B-2.3.2.1 Configuration A.

With the 12 stations placed in a linear fashion perpendicular to traffic flow and a standard center-to-center spacing of 25 feet (7.6 meters), the total width of the wash station would be 300 feet (91.2 meters) (Figure B-5). Adding the width of the bypass lane, 22 feet (6.7 meters), yields a facility width of 322 feet (97.9 meters), which is too wide to be constructed on this narrow ridge.

B-2.3.2.2 Configuration B.

This configuration would place the islands in two parallel rows, with a queuing area down the center of the rows and two bypass lanes on the outside of the stations (Figure B-6). Half islands are placed at the ends of each row. The islands would be placed at a 60 degree skew to the normal flow of traffic. This layout would require more area to be cleared and paved, but the facility width would be no more than 180 feet (54.9 meters), which is less than the constraint imposed by the ridge. The designer chooses configuration B as the best alternative after performing a cost comparison.

B-2.3.3 Vehicle Preparation Areas.

The installation has stated that three vehicles queuing to enter each bath lane should be sufficient. Other vehicles waiting to use the facility can queu-up along Range Road adjacent to the wash facility. If traffic problems occur, Range Control will coordinate the number of vehicles leaving the training areas with the wash facility activities.

B-2.3.3.1 Entrance Vehicle Preparation Area.

The entrance vehicle preparation area should provide enough room for three vehicles per lane to wait to be washed in the bath. The longest tracked vehicle to use the facility is the M-l tank, which is some 32 feet (9.8 meters) long. The longest wheeled vehicle is the M- 978 Tanker Truck at 33 feet (10 meters). At least 52 feet (12.8 meters) per vehicle should be allowed (10 feet (3.lm) clear on each end). Therefore, the preparation area should be at least 156 feet (47.5 meters) long. An additional 20 percent or 30 feet (9.0 meters) of entrance staging is added yielding a total length of 165 feet (50.3 meters).

B-2.3.3.2 Preparation Area between the Bath and Wash Stations.

The preparation area between the bath and the wash stations should be at least two vehicle lengths, rounded to 60 feet (18.2 meters) with all other factors considered. The assembly area after the wash stations should also allow for two vehicles, again rounded to 60 feet (18.2 meters).

B-2.3.3.3 Aisle Space between Wash Station Islands

The aisle space between the two rows of islands should be at least 75 feet (22.9 meters) wide to allow the vehicles to maneuver and queue and the Exit lanes should be a minimum of 22 feet (6.7 meters) wide. The exit vehicle assembly area will be the full width of the facility, 159 feet (48.5 meters). Figure B-6 shows these dimensions.

B-2.3.4 Sizing the Treatment System.

B-2.3.4.1 Water Usage Factor.

A bath system is to be installed. The soils on the vehicles will be partially cohesive, and not easily removed; therefore, a reasonable steady rate of vehicles is expected through the bath and the wash stations. The designer selects the following estimates for the various water usage factors, based on experience: $U_1 = 1.0$; $U_2 = 0.90$ (bath full); $U_3 = 0.80$; $U_4 = 0.20$; $U_5 = 0.20$; $U_6 = 0.20$; $U_7 = 0.80$; $U_8 = 0.20$.

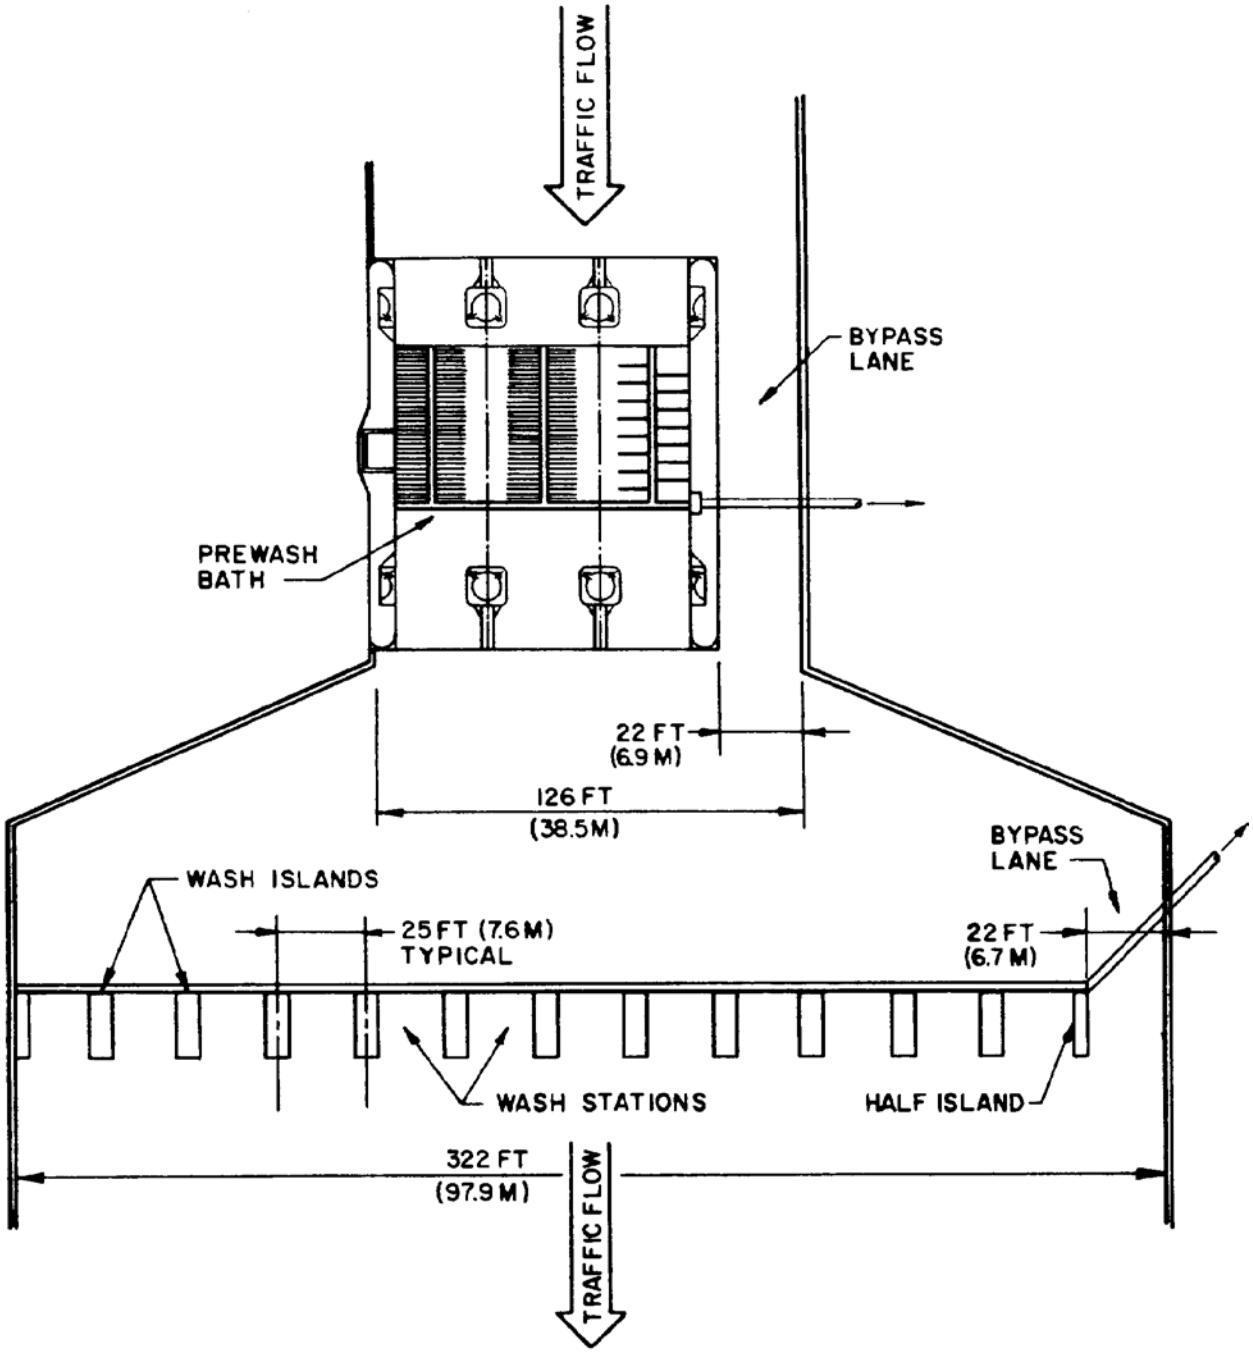
B-2.3.4.2 Cleanup Time.

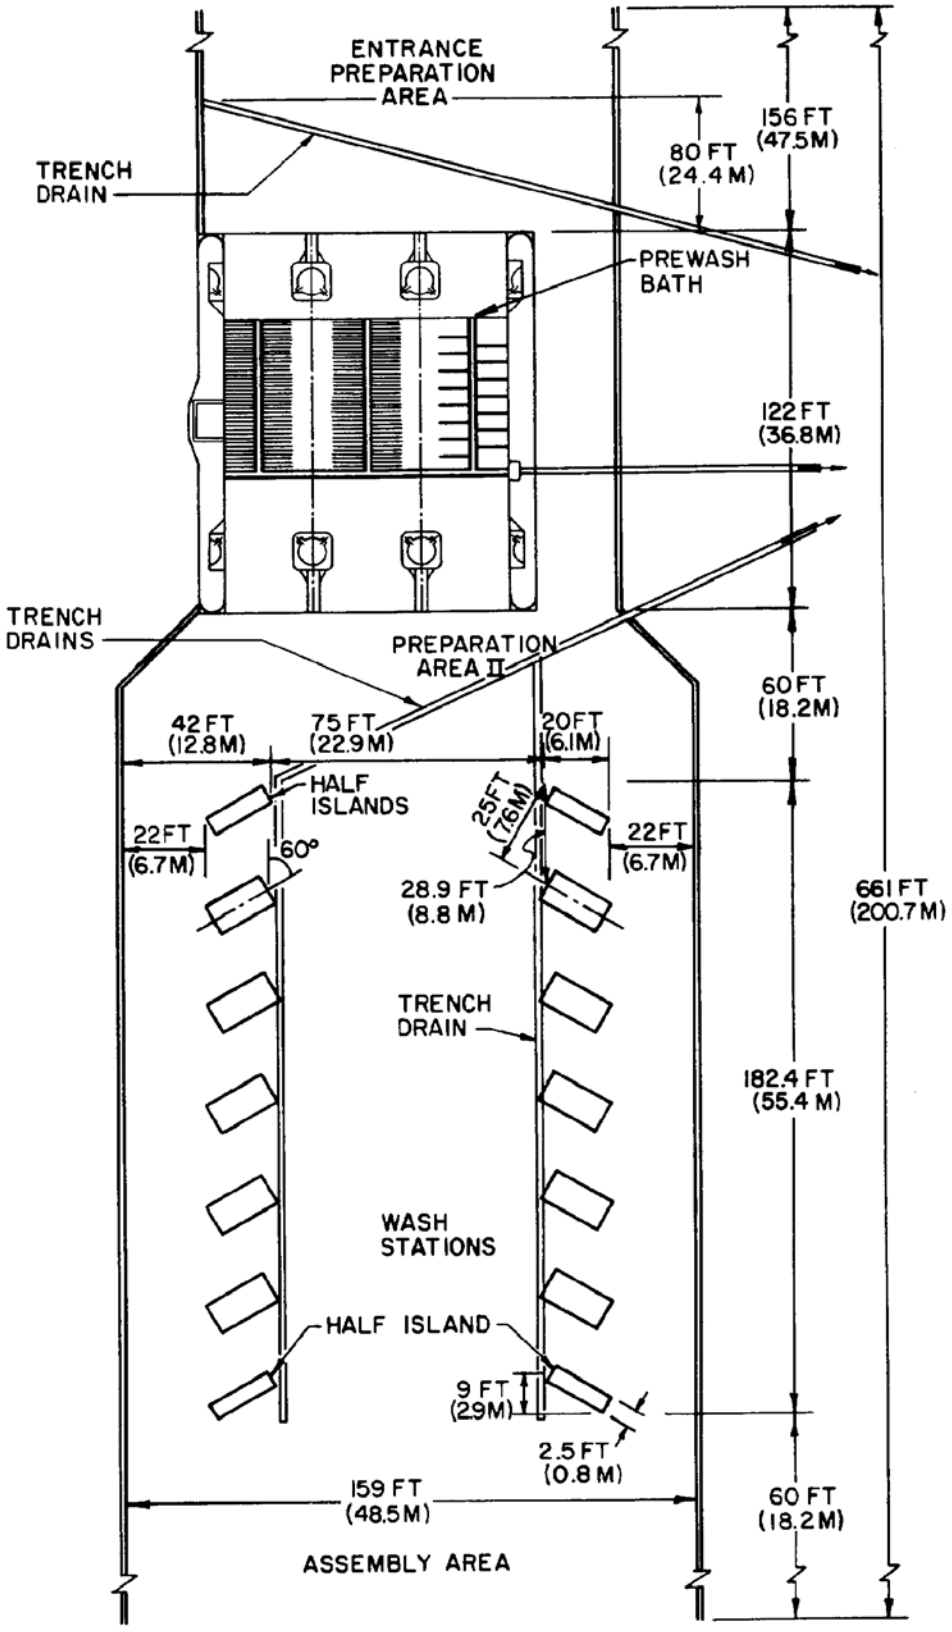
The cleanup time (K) is estimated to be 1 hour based on the 30 minutes it will take the operator to drain the bath (T_D) and an additional 30 minutes for troops to hose down the bath and staging areas. It is assumed that bath flushing and area clean-up will occur once per wash period.

B-2.3.4.3 Flow Rate.

Using the parameters defined in Chapter 6, the designer computes various flow conditions.

Figure B-5 Configuration A





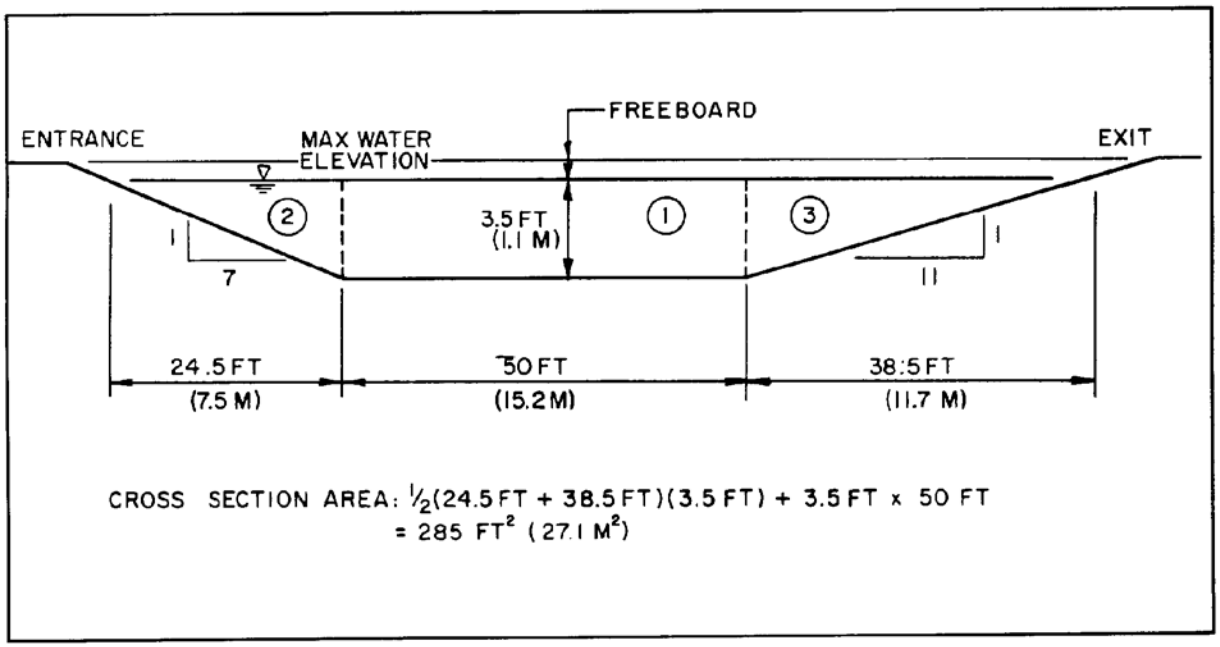


Figure B-6 Configuration B

a. Bath Drain Flow Rate, Q_1.

Refer to Figure B-7.

Figure B-7 Cross Section of the Bath

Q_1 = (width x cross section) x 7.48 gpcf/drain time

Q_1 = (90 ft x 285 sf) x 7.48/30 min

Q_1 = 6,395 gpm (24,207 Lpm)

b. Bath Overflow, Q_2.

Q_2 = Number of cannons x cannon discharge

Q_2 = N_{wc} x F_{wc}

Q_2 = 12 x 80 gpm

Q_2 = 960 gpm (3,634 Lpm)

c. Wash Station Flow, Q_3.

Q_3 = Number of wash station hoses x hose discharge

Q_3 = N_{st} x F_{st}

Q_3 = 24 x 30 gpm

Q_3 = 720 gpm (2,725 Lpm)

d. Entrance Area Trench Flush Flow, Q_4.

Q_4 = Number of flusher points x flusher discharge

$Q_4 = N_{fl} \times F_{fl}$

Q_4 = 1 x 75 gpm

Q_4 = 75 gpm (284 Lpm)

e. Bath Flush Flow, Q_5.

Q_5 = Number of flush points x flusher discharge

$Q_5 = N_{ud} \times F_{ud}$

Q_5 = 4 x 750 gpm

Q_5 = 3000 gpm (11,355 Lpm)

f. Wash Station Trench Flushes Flow, Q_6.

Q_6 = Number of flush points x flusher discharge

$Q_6 = N_{tz} \times F_{tz}$

Q_6 = 3 x 75 gpm

Q_6 = 225 gpm (852 Lpm)

g. Interior Hydrant Flow at Wash Stations, Q_7. A total of six duplex hose bibs are placed on alternating full islands to serve the 12 wash stations.

Q_7 = Number of interior washpoints x hose discharge

$Q_7 = N_{int} \times F_{int}$

Q_7 = 12 x 10 gpm

Q_7 = 120 gpm (454 Lpm)

h. Clean-up Yard Hydrant Flow, Q_8. A total of six hydrants, strategically placed, are required to hose down the paved areas.

Q_8 = Number of hydrant hose connections x hydrant discharge

$Q_8 = N_y \times F_y$

Q_8 = 6 x 30 gpm

Q_8 = 180 gpm (681 Lpm)

i. Storm Runoff from Paved Wash Facility, Q_9. Use Rational Formula with runoff coefficient, C, of 0.95 and a rainfall intensity for a 1-hr., 1-yr storm of 2.0 inches. Then,

Q_9 = C x I x length x width/43,560 gfpa

Q_9 = 0.95 x 2.0 x 580 ft. x 160 ft./43,560 gfpa

Q_9 = 4.05 cfs 0r 1818 gpm (6881 Lpm)

j. Rainfall Falling on Open Basins, Q_{10}. Estimate surface area of dual-cell sediment basin:

L x W x 2 = 150 ft x 50 ft x 2 = 15,000 sf

Estimate surface area of equalization basin:

L x W = 300 ft x 300 ft = 90,000 sf

Estimate surface area of sand filters:

L x W =3 00 ft x 150 ft = 45,000 sf

Estimate surface area of washwater supply basin:

L x W = 300 ft x 300 ft = 90,000 sf

Then: $Q_{10} = C \times I \times A_B/143{,}560$ sfpA

Q_{10} = 1.0 x 2.0 x 240,000 sf/43,560 sfpA

Q_{10} = 11 cfs or 4,937 gpm (18,686 Lpm)

k. Summary of CVWF Flow Rates. A summary of computed flows is presented in Table B-3.

l. Overflow Rate, Q_{over}. Using equation 6-5, calculate the sediment basin overflow rate during the washing period. The designer assumes that the entrance preparation area trench flusher, represented by Q_4, and the bath flushers, represented by Q_5, are not in operation after the bath is filled and, therefore these values are not used in the calculation. Apply the appropriate usage factor at each flow source. Then,

$Q_{over} = U_2Q_2 + U_3Q_3 + U_6Q_6 + U_7Q_7$

Q_{over} = 0.90 (960 gpm) + 0.80 (720 gpm) + 0.20 (225 gpm) +

0.30)(120 gpm)

Q_{over} = 1,581 gpm (5,984 Lpm)

B-2.3.4.4 Volumes.

Using equations defined in Chapter 6, the designer computes the various component volumes for the following selected average daily conditions:

Clean-up period, K, = 60 min

Daily wash period, T_w, = 180 min

Total Wash and clean-up, T_2, = 240 min

Storm Duration, T_s, = 60 min

a. Earth Volume Drained, V_1. Assume only one bath fill/flush per wash period. Then,

V_1 = Bath volume x Number of fills

V_1 = 90 ft x 285 sf x 7.48 gpcf x 1 fill

V_1 = 191,862 gal (726,198 L)

b. Bath Overflow Volume, V_2.

V_2 = Bath weir overflow rate x (wash period + clean up)

$V_2 = Q_2 \times T_2$ = 960 gpm x 240 min

V_2 = 230,400 gal (872,064 L)

c. Wash Station Volume, V_3.

V_3 = Wash station flow rate x wash period

$V_3 = Q_3 \times T_w$ = 720 gpm x 180 min

V_3 = 129,600 gal (490,536 L)

d. Entrance Trench Flusher Volume, V_4.

V_4 = Trench flush flow rate x cleanup period

$V_4 = Q_4 \times K$ = 75 gpm x 60 min

V_4 = 4500 gal (17,032 L)

Table B-3 Summary of CVWF Flow Rates

Parameter		Discharge Points		Unit Flow Rate		Total Flow (Q)	
				gpm	Lpm	gpm	Lpm
Q_1	Bath		Outflow	6,395	24,207	6,395	24,207
Q_2	Water Cannons	12	Cannons	80	303	960	3,634
Q_3	Wash Stations	24	Hoses	30	114	720	2,725
Q_4	Prep Flushers	1	Flusher	75	284	75	284
Q_5	Bath Flushers	4	Flushers	75	2,040	3,000	11,355
Q_6	Trench Flushers	3	Flushers	75	284	225	852
Q_7	Interior Wash	12	Hoses	10	38	120	454
Q_8	Yard Hydrants	6	Nozzles	30	114	180	681
Q_9	Rainfall Pavement	2.13	Acres	1,818	6,881	1,818	6,881
Q_{10}	Rainfall Basins	5.51	Acres	4,937	18,686	4,937	18,686

e. Bath Flusher Volume, V_5.

V_5 = Bath flusher flow rate x cleanup period

$V_5 = Q_5 \times K = 3{,}000$ gpm x 60 min

$V_5 = 180{,}000$ gal (681,300 L)

f. Wash Station Trench Flusher Volume, V_6.

V_6 = Trench flusher flow rate x (wash period + clean-up)

$V_6 = Q_6 \times T_2 = 225$ gpm x 240 min

$V_6 = 54{,}000$ gal (204,390 L)

g. Interior Wash Water Volume, V_7.

V_7 = Interior wash flow rate x wash period

$V_7 = Q_7 \times T_w = 12$ gpm x 180 min

$V_7 = 21{,}600$ gal (81,756 L)

h. Clean-up Yard Hydrant Volume, V_8.

V_8 = Yard hydrant flow rate x cleanup period

$V_8 = Q_8 \times K = 180$ gpm x 60 min

$V_8 = 10{,}800$ gal (40,878 L)

i. Pavement Runoff Volume, V_9.

V_9 = Pavement runoff rate x storm duration

$V_9 = Q_9 \times T_s = 1{,}818$ gpm x 60 min

$V_9 = 109{,}080$ gal (412,868 L)

j. Rainfall Volume Added to Basins, V_{10}.

V_{10}= Rainfall rate x storm duration

$V_{10} = Q_{10} \times T_S = 4{,}937$ gpm x 60 min

$V_{10} = 296{,}220$ gal (1,121,193 L)

k. Summary of Average Daily Volume. Table B-4 summarizes the computed average daily volumes for the stated design conditions at Fort Swampy.

l. Total Average Daily Volume for Facility, V_{avg}. The designer uses equation 6-2, however, designer chooses not to include pavement runoff volume, V_9 or rainfall volume on basins, V_{10}. Designer also assumes that flush water will be withdrawn from the washwater supply basin and therefore, V_1, V_5, and V_6 are included in the computation. Then,

$$V_{avg} = U_1V_1 + U_2V_2 + U_3V_3 + U_4V_4 + U_5V_5 + U_6V_6 + U_7V_7 + U_8V_8$$

$$V_{avg} = 1.0\ (191{,}862) + 0.9\ (230{,}400) + 0.8\ (129{,}600) + 0.2\ (4{,}500) +$$
$$0.2\ (180{,}000) + 0.2\ (54{,}000) + 0.8\ (21{,}600) + 0.2\ (10{,}800)$$

$V_{avg} = 570{,}042$ gal (2,157,609 L)

B-2.3.4.5 Calculate Maximum Volume for the Peak Use Period, V_{max}.

The designer computes the various component maximum volumes for the following selected peak use conditions:

Clean-up period, K, = 60 min (1 hr)

Peak use period, T_w, = 3240 min (55 hr)

Total wash and clean-up, T_t, = 3300 min (56 hr)

Storm duration, T_s, = 60 min (1 hr)

The designer assumes that one bath fill, B, will be withdrawn from the equalization basin.

Table B-4 Summary of Average Daily Volume

Parameter		Discharge Points		Total Flow Rate		Operating Time	Volume (V)	
				gpm	Lpm	min	gal	L
V_1	Bath		Outflow	6,395	24,207	30	191,862	726,198
V_2	Water Cannons	12	Cannons	960	3,634	240	230,400	872,064
V_3	Wash Stations	24	Hoses	30	2,725	180	129,600	490,536
V_4	Prep Flushers	1	Flusher	75	284	60	4,500	17,032
V_5	Bath Flushers	4	Flushers	3,000	11,355	60	180,000	681,300
V_6	Trench Flushers	3	Flushers	225	852	240	54,000	204,390
V_7	Interior Wash	12	Hoses	120	454	180	21,600	81,756
V_8	Yard Hydrants	6	Nozzles	180	681	60	10,800	40,878
V_9	Rainfall Pavement	2.13	Acres	1,818	6,881	60	109,080	412,868
V_{10}	Rainfall Basins	5.51	Acres	4,937	18,686	60	296,220	1,121,193

a. Maximum Bath Volume Drained, V_1.

$V_1 = V_B$ x Number of fills

V_1 = 191,862 gal x 1

V_1 = 191,862 gal (726,198 L)

b. Maximum Bath Overflow Volume, V_2.

V_2 = Bath overflow rate x (total wash period + clean-up)

$V_2 = Q_2 \times T_2$ = 960 gpm x 3,300 min

V_2 = 3,168,000 gal (11,990,880 L)

c. Maximum Volume from Wash Stations, V_3.

V_3 = Wash station flow rate x peak wash period

$V_3 = Q_3 \times T_w$ = 720 gpm x 3,240 min

V_3 = 2,332,800 gal (8,829,648 L)

d. Maximum Volume from Entrance Trench Flusher, V_4.

V_4 = Entrance trench flusher flow rate x clean-up period

$V_4 = Q_4 \times K$ = 75 gpm x 60 min x 3 cleanups

V_4 = 13,500 gal (51,098 L)

e. Maximum Volume from Bath Flushing, V_5.

V_5 = Bath flusher flow rate x cleanup period

$V_5 = Q_5 \times K$ = 3,000 gpm x 60 min

V_5 = 180,000 gal (681,300 L)

f. Maximum Volume from Wash Station Flushing, V_6.

V_6 = Flusher flow rate x (wash + cleanup + two additional cleanup periods)

$V_6 = Q_6 \times (T_1 + 2K)$

V_6 = 225 gpm (3,300 min + 2 x 60 min)

V_6 = 769,500 gal (2,912,558 L)

g. Maximum Interior Wash Water Volume, V_7.

V_7 = Interior wash flow rate x wash period

$V_7 = Q_7 \times T_w$ = 120 gpm x 3,240 min

V_7 = 388,880 gal (1,471,608 L)

h. Maximum Volume from Yard Hydrants, V_8.

V_8 = Yard hydrant flow rate x clean-up period x number clean-ups

$V_8 = Q_6 \times K \times 3$=10,800 gal x 60 min x 3

V_8 = 32,400 gal (122,634 L)

i. Maximum Pavement Runoff Volume, V_9.

V_9 = Pavement runoff rate x storm duration

$V_9 = Q_9 \times T_S$ = 1,818 gpm x 60 min

V_9 = 109,080 gal (412,868 L)

j. Maximum Rainfall Volume on Basins, V_{10}.

V_{10} = Rainfall rate x storm duration

$V_{10} = Q_{10} \times T_S$ = 4,937 gpm x 60 min

V_{10} = 296,220 gal (1,121,193 L)

k. Summary of Maximum Volumes. Table B-5 summarizes the computed maximum volumes for the stated conditions at Fort Swampy.

Table B-5 Summary of Maximum Volumes

Parameter		Discharge Points		Total Flow Rate		Operating Time	Volume (V)	
				gpm	Lpm	min	gal	L
V_1	Bath		Outflow	6,395	24,207	30	191,862	726,198
V_2	Water Cannons	12	Cannons	80	3034	3,300	3,168,000	11,990,880
V_3	Wash Stations	24	Hoses	30	114	3,240	2,332,800	8,829,648
V_4	Prep Flushers	1	Flusher	75	284	180	13,500	51,098
V_5	Bath Flushers	4	Flushers	750	2840	60	180,000	681,300
V_6	Trench Flushers	3	Flushers	75	284	3,420	769,500	2,912,558
V_7	Interior Wash	12	Hoses	10	38	3,240	388,000	1,471,608
V_8	Yard Hydrants	6	Nozzles	30	114	180	32,400	122,634
V_9	Rainfall Pavement	2.13	Acres	1,818	6,881	60	109,080	412,868
V_{10}	Rainfall Basins	5.51	Acres	4,937	18,686	60	296,220	1,121,193

l. Calculate Maximum Wash Volume for Facility, V_{max}.

$V_{max} = U_1V_1 + U_2V_2 + U_3V_3 + U_4V_4 + U_5V_5 + U_6V_6 + U_7V_7 + U_8V_8$

V_{max} = 1.0 (191,862 gal) + 0.9 (3,168,000gal) + 0.8 (2,332,800 gal)

+ 0.2 (13,500 gal) + 0.2 (180,000 gal) +0.2 (769,500 gal) +

0.8 (388,800 gal) + 0.2 (32,400 gal)

V_{max} = 54,319,422 gal (20,512,512L) or

V_{max} = 724,522 cf (20,287 CM)

B-2.3.4.6 Sediment Basin Design.

The effective water depth of the basin will be 8 feet (2.4 meters) and free board is 2 feet (0.6 meters). The sediment depth will be determined by calculations. Settling tests performed on soils found in the training areas showed that 82 percent of the suspended solids will settle in less than 2 hours (120 minutes). This can be checked theoretically by using Stokes Law and the nondispersed soil particle gradation test results, after the basin size has been determined.

a. Operation. A dual-celled sediment basin is required. One cell will be used to settle solids during continuous washing and the adjacent basin will detain the surge volume created when the bath is flushed. A dual-cell arrangement will also allow one cell to be closed for cleaning while the other is treating wastewater; the wastewater will not have the designed detention time, but the wash facility will be operable. The installation has indicated that the basins will be cleaned every 6 months and it will take approximately 5 days to drain and clean each cell.

b. Water Volume. In addition to a sediment volume, each cell in the basin must be able to hold the greater of the overflow and bath volume or the stormwater volume; therefore, the bath and the overflow volumes are compared with the stormwater volume to determine which value will control the basin site. The total volume of water required in each cell is computed:

V_w = Bath overflow volume + bath volume

= Q_{over} detention time + V_B

V_w = 1,581 gpmx 120 min + 202,633 gal

V_w = 392,353 gallons (1,485,056 L)

V_w = 52,453 cf (1,469 CM)

Calculate storm water volume:

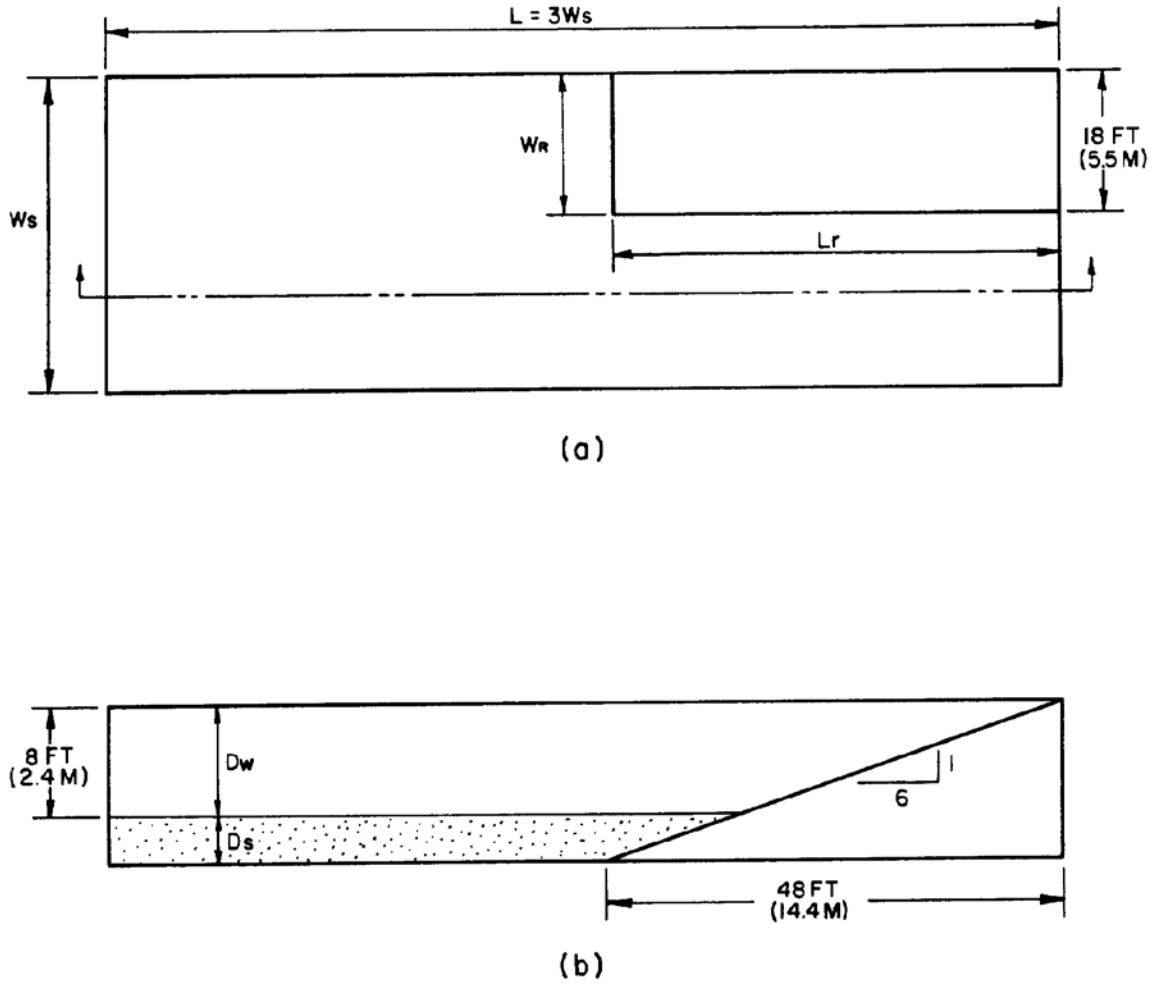
V_{st} = paved area storm runoff

V_{st} = V_o/7.48 gpcf

V_{st} = 109,080/7.48 = 14,582 cf (408 CM)

Since the overflow plus the bath volume is larger than the stormwater runoff volume, the overflow plus bath volume is the controlling factor and each cell is sized to detain at least 52,453 cf (1504 CM) of water. The designer chooses an effective water depth of 8 ft. (2.4 M), an access ramp slope of 1 on 6, a ramp width of 18 ft. and a basin length-to-width ratio of 3 to 1. Figure B-8 shows the general geometry of each cell. The dimensions of the basin are then calculated using the information given and noting that the volume occupied by the ramp must be considered:

V_{sw}= L_S x W_S x D_W - 1/2 x L_r x D_w x W_r = 52,453



V_{sw} = 3W_s x W_s x 8 – 1/2 x 48 x 8 x 18 = 52,453

W_s = 2,042

W_s = 45 ft. (13.7 M) and

L_s = 135 ft. (41.2M)

Figure B-8 Water Volume Configuration: (a) Plan View and (b) Cross Section

c. Sediment Volume. The designer estimates that the installation has average-to-heavy soiling conditions. By applying Stokes Law, using Q_{over} with the basin size previously calculated, and checking the soil particle size

information, removal of 82 percent of the soil, as determined by settling tests, is verified. Using equations 6-3 and 6-4 with data from Table B-2: Sediment Volume = (Tracked vol. + Wheeled vol.) x duration of wash season x sediment basin trap efficiency.

$$\text{Sediment Volume} = \left(\frac{2.0 \text{ cu ft}}{\text{wash}} \times \frac{665 \text{ washes}}{\text{month}} + \frac{0.6 \text{ cu ft}}{\text{wash}} \times \frac{783 \text{ washes}}{\text{month}}\right) \times 6 \text{ months} \times 0.82 \text{ percent cleaning}$$

= 8,855 cf (248 CM)

The same equations that were used to size the cell based on water volume are used to size the cell for the sediment volume, except that the volume of the ramp is assumed negligible. The width and length of the cell are known, and the depth is calculated. Thus –

$(L_s - L_r) \times W_x \times D_s$ = Sediment volume

(145 ft - 48 ft) x 48 ft x D_s = 8,855 cf

D_s= 1.9 ft. (0.58M)

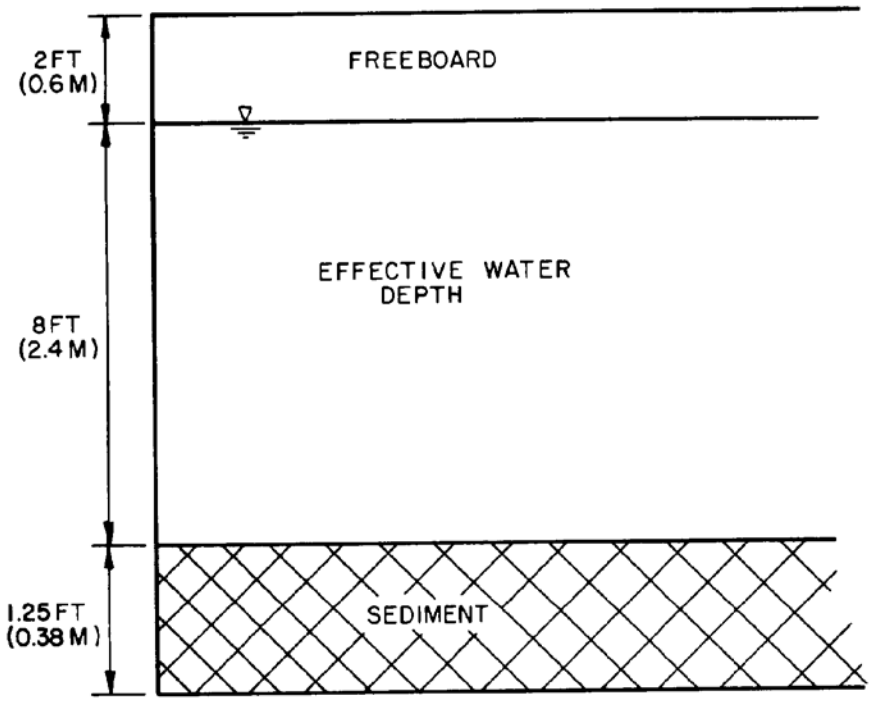
say D_s = 2.0 ft. (0. 61M)

d. Total Cell Size. The calculated sediment basin dimensions are summarized in Figure B-9.

B-2.3.4.7 Equalization Basin.

The volume of water in the equalization basins is based on the greater of V_{avg} for any assumed 5 day wash period or V_{max}.

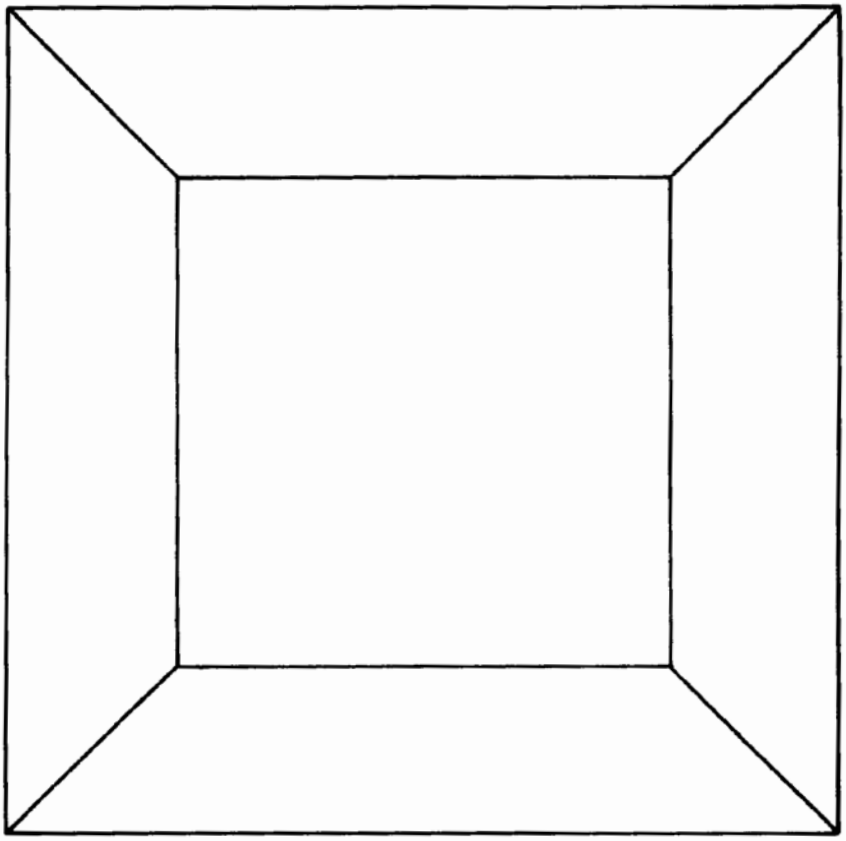
V_{EB} = 5 x V_{avg} = 5 x 570,042 gal = 2,850,210 gal (10,788,045 L)



V_{EB} = 381,044 cf (10,699 CM) or;

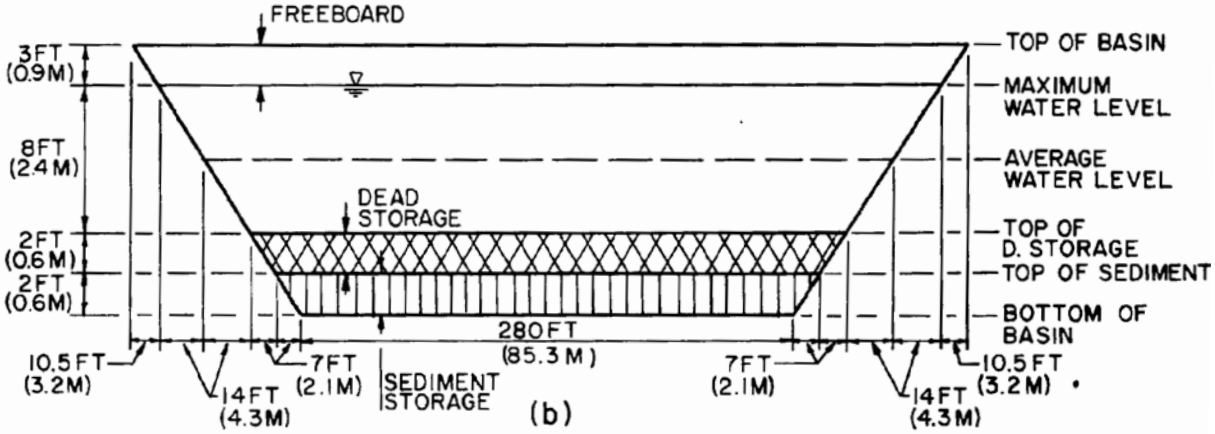
V_{EB} = V_{max} = 724,522 cf (20,287 CM)

The designer uses a safety factor of 1.25 times the value of V_{max} or 905,653 cf (25,358 CM to size the basin. The designer selects an effective water depth of 8 ft. (2.4 M), 2.0 ft. (0.6 M) of sediment storage, 2.0 ft. (0.6 M) of dead storage or a total depth of 15 ft. (3.7 M). The average area at the midpoint of the equalization basin water zone is:



905,653 cf/8 ft = 113,207 sf (10,528 SM)

Figure B-9 Overall Cell Configuration



The designer selects to use a square basin (Figure B-10) with side slopes of 1 to 3.5. The basin is sized by taking the square root of the average area required to determine the average length and width of the basin. This method gives the average basin size – 336 feet by 336 feet (102 meters by 102 meters). With the slope of the walls at 1 to 3.5, 7.0 ft (2.2 M) are added to the average side for each foot (meter) of depth above or subtracted below the average depth. The length of the basin at the water surface would be 364 feet by 364 feet (110 meters by 110 meters). With 3 feet (0.9 meters) of freeboard added, the overall top dimension of the basin will be 385 feet by 385 feet (117 meters by 117 meters). Subtracting 3.5 feet (1.1 meters) off of each side for each foot (meter) below the average depth, the dimensions of the bottom of the basin, with 2 feet (0.6 meters) allowed for sediment storage and 2 feet (0.6 meters) allowed for dead storage, would be 280 feet by 280 feet (86 meters by 86 meters).

Figure B-10 Equalization Basin: (a) Plan View and (b) Cross Section

(a)

(b)

B-2.3.4.8 Intermittent Sand Filters.

The installation has indicated that the facility need not be fully operational for 7 days after a major washing operation that takes about 2 days (54 hours). The designer chooses two filters, which will allow one filter to operate while the other one is allowed to rest. A loading rate of 8 inches (20.3 centimeters) per filter dose will be used. The filter dose frequency is every 8 hours. The designer calculates the area required for the sand filters:

Filter Area = A_F = V_{max} / Dosing Rage

$$A_F = \frac{724{,}522 \text{ cf}}{(2 \text{ days} + 7 \text{ days})} \times \frac{\text{acre/day}}{650{,}000 \text{ gal}} \times \frac{7.48 \text{ gpcf}}{\text{cu ft}}$$

$$A_F = 0.93 \text{ acres or } 19{,}040 \text{ sf } (1{,}770 \text{ SM})$$

Thus, each filter should be 0.47 acres or 20,473 sf (1,904 SM).

B-2.3.4.9 Dosing Base.

The designer has performed an economic study which showed that a dosing basin would be cost-effective when compared with installing larger pumps. Water can flow by gravity to the sand filter. Small pumps can take water from the equalization basin to the dosing basin. With a dosing basin, the designer is able to use smaller pumps for charging the dosing basin over a long period of time. The basin is sized to hold the volume of water to charge one filter. The volume is calculated as follows:

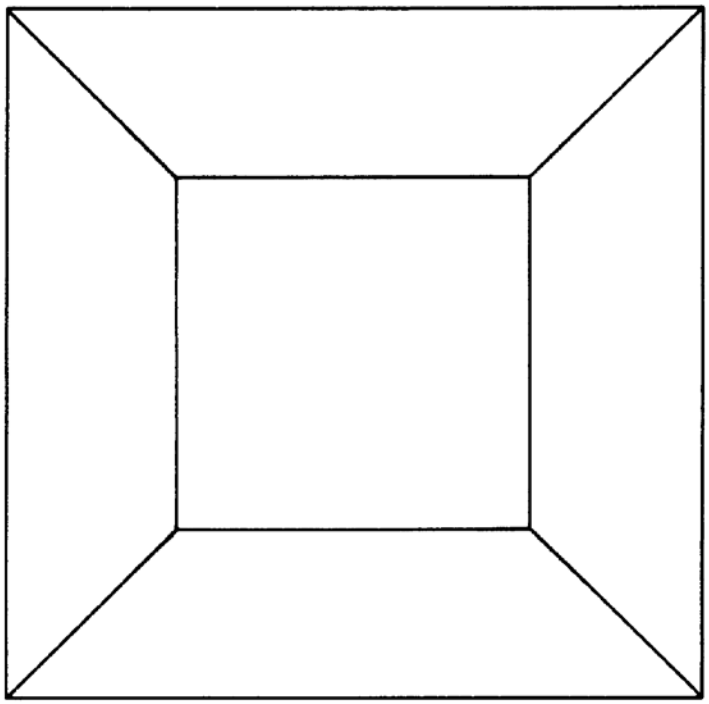
$$\text{Volume} = 20{,}473 \text{ sf} \times \frac{8 \text{ inches}}{\text{charge}} \times \frac{\text{foot}}{\text{inches}} \times \frac{7.48 \text{ gal gpcf}}{\text{cu ft}}$$

$$\text{Volume} = 102{,}093 \text{ gal } (386{,}422 \text{ L})$$

B-2.3.4.10 Water Supply Basin.

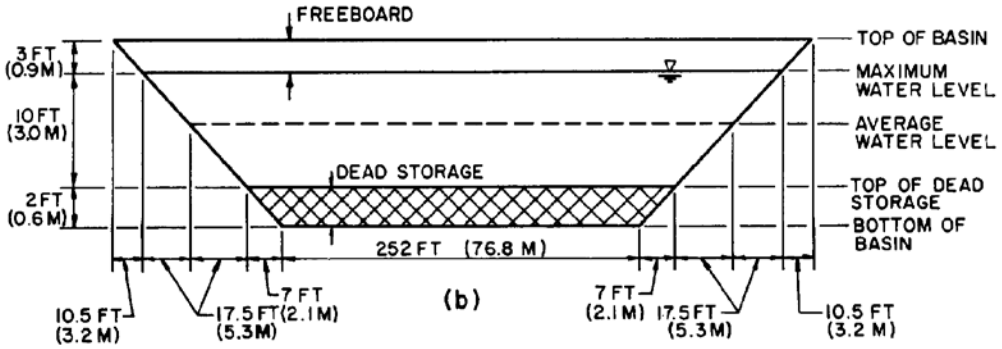
Design criteria call for the size of the water supply basin to be the larger of V_{max} (724,522 cf or 20,287 CM); or V_{ave} for an S day wash period.

V_{ave} = 5 x Vave = 5 x 570,042 gal



V_{ave} = 2,850,210 gal (10,788,045 L) or 381,044 cf (10,669 M)

Since V_{max} is larger than five times V_{ave}, the designer uses a safety factor of 1.25 times V_{max} to size the water supply basin or 905,653 cf (25,358 CM). Because of the large water volume required, the designer chooses an effective depth of 10 feet (3.0 meters) with 2.0 feet (0.6 meters) of dead storage for a total depth of 12 feet (3.7 meters). The water surface area can then be calculated as follows:



A_{ws} = 905,653 cf / 10 ft. = 90,565 sf

Using the method described for sizing the equalization basin and assuming a square basin gives the average basin size at the midpoint of water depth is 301 feet by 301 feet (92 meters by 92 meters). With the side slopes of 1 to 3.5, the dimensions of the basin at the top of the water level would be 336 feet by 336 feet (102.4 meters by 102.4 meters). With the 3 feet (0.9 meters) of freeboard added, the overall top dimension of the basin will be 357 feet by 357 feet (109 meters by 109 meters). The bottom of the basin would be 252 feet by 252 feet (77 meters by 77 meters) (Figure B-11).

Figure B-11 Water Supply Basin: (a) Plan View and (b) Cross Section

(a)

(b)

B-2.3.4.11 Makeup Water.

An economic analysis has revealed that, if wells are drilled as the primary source of makeup water for the CVWF, the return on investment will be 37 years. Since the design life of the facility is only 20 to 2 years; the installation chooses to use the existing potable water supply as a source of makeup water since the supply is dependable. The existing 10-in. (25.4-cm) water line running adjacent to Range Road can be tapped. Makeup water will be added to the water supply basin at night when demand on the potable water supply is lowest.

B-2.3.4.12 Emergency Discharge.

The closest sanitary sewer connection is approximately 0.75 mi. (1.2 km). The designer decides to provide a sewer from the water supply basin to the existing sanitary sewer line to handle emergency overflows. This will prevent overflows from otherwise being discharged to the environment.

B-2.3.4.13 Check Calculations.

Figure B-12 shows the expected water volume in the equalization basin at any given time during the washing activities. This graph confirms that at no time during a major wash will the equalization basin volume of 5.5 mg be exceeded during the peak water usage period. The projected volume for the water supply basin is also plotted (Figure B-13). This graph show that 5.5 Mg is sufficient to ensure that an adequate supply of wash water is available at all times.

Figure B-12 Equalization Basin Water Balance – Water Volume versus Time

WBDG Whole Building Design Guide

WTS water treatment system

C-2 DEFINITION OF TERMS

Assembly Area: Paved space located after the wash stations to allow replacement of interior items, drying, assembly of vehicles into units, and final inspection prior to exiting the CVWF.

Bentonite: Clay with a high content of the mineral montmorillonite group. Characterized by high adsorption and very high volume changes with wetting and drying.

Biological Treatment: Process in which bacteria and other microorganisms use waste constituents as a food source; results in the breakdown of complex organic materials into simple, more stable sub-stances.

Bypass Lane: Driving lane reserved for vehicles in the CVWF to go past the prewash basin and/or the wash stations to expedite forward movement.

Cantonment: Developed portion (city-like area) of a permanent military installation.

Central Vehicle Wash Facility: Structure designed specifically to clean large numbers of tactical or transportation motor pool vehicles.

Chemical Oxygen Demand: Standard laboratory procedure for measuring the oxygen required for oxidation of carbonaceous (organic) material in wastewater.

Cleanup Time: Period required to clean a CVWF, including drainage and cleaning of the prewash bath.

Cohesive Soil: Fine-grained soil that sticks together, such as a clay or silt.

Collection System: Network of underground conduits and appurtenances that receives and conveys wastewater.

Colloids: Microscopic suspended particles that do not settle in a standing liquid and can be removed only by coagulation or biological action.

Control Building: Structure at a CVWF that provides the operator a central location to observe the washing operations and regulate pumps, valves, and other equipment.

Detention Time: Theoretical period that it takes a particle of matter to flow through a tank or basin.

Dissolved Solid: Solid material remaining in a wastewater after filtering; deter- mined by specific tests.

Dosing Tank: Receptacle that automatically and hydraulically empties itself each time it is filled to capacity.

Drainage Area: Rainfall catchment area common to a single runoff point.

Drainage Structure: Construction used to collect and/or divert surface waters to a collection system; includes inlets, trench drains, catch basins, and manholes.

Dual-Purpose Lab: Area of a prewash facility that serves both wheeled and tracked vehicles.

Effective Depth: Usable depth of sediment basin and/or lagoon for treatment or settling purposes, after deducting the depth reserved for storage of solids and freeboard allowance.

Effluent: Liquid flowing out of a reservoir, basin, tank, or other container.

Energy Dissipater: Structure used to dampen erosion potential of a flowing body of water by reducing its forward velocity.

Equalization Basin: Receptacle used to dampen variations in the flow of water.

Evaporation Rate: Rate at which water becomes a vapor and is lost from a body of water.

Filter Charge: Total volume of water necessary to flood the surface of a filter to a specific depth.

Filter Medium: Granular material (sand and/or gravel) in a filter through which water passes.

Filtration: Unit operation in which solid or colloidal material is separated from a liquid by movement through a granular or porous material such as sand.

Flexor: Device installed in the bottom of a water bath at a prewash facility for causing the wheels or tracks of a vehicle to move up and down (flex) to assist in removing dirt from the vehicle.

Flushers: Devices such as water sprays that increase water flow and velocity to prevent solids deposition or to remove deposited solids in a pipe, channel, or other conduit.

Freeboard: Distance in elevation from the maximum water surface of a tank or basin to the top of its walls or overflow.

Grade: Inclination or slope of a surface in terms of a ratio or percentage of vertical rise to horizontal distance.

Grease: General term used to describe the lubricants applied to tactical and TMP vehicles.

Hardstand: Impervious surface, either bituminous or concrete, used as a pavement for pedestrian and/or vehicular traffic.

Hydraulic Loading: Volume of a liquid per unit time applied to a given system or treatment process

Hydrogen Ion Concentration (pH): Measure of the number of hydrogen ions in a solution indicting acidity/alkalinity.

Impervious: Term used to describe the condition in which water or some other fluid cannot easily pass through a material such as soil.

Inflow: Water or wastewater entering a basin, pond, channel, or other storage or collection facility.

Influent: Liquid flowing into a container, basin, or tank.

Interior Wash: Low-pressure, low-flow volume of water used to clean the interior of tactical vehicles, such as truck beds and cab areas.

Intermittent Sand Filter: Filter system with a granular medium (sand and/or gravel) which is flooded at given time intervals with a water or wastewater for treatment.

Lagoon: Pond-like body of water used to treat industrial, commercial, and sanitary wastewaters.

Loading: Rate at which a filter charge is applied to a filter.

Makeup Water: Water added to a system or process to compensate for the amount of water lost due to leakage, percolation, evaporation, release, overflows, usage, or similar action.

Manhole: Structure, usually located at the junction of two or more underground pipes, which allows access to pipes for inspection and maintenance.

Oil Skimmer: Device used for removing oil and grease from a water surface.

Percolation: Downward movement of a liquid through a soil.

Permeability: Term describing the ability of water to move through a soil when the soil is saturated.

Pond: Engineered impoundment containing raw or partially treated wastewater in which aerobic and/or anaerobic stabilization occurs (also see lagoon).

Porosity: Ratio, usually expressed as a percentage, or the volume of voids in a given soil mass to the total volume of the soil mass.

Potable Water: Water supply that is safe for human consumption.

Preparation Area: Paved area for troops to remove trash from vehicle interiors, plug drain holes, open bilge pump discharge lines, and other tasks prior to the prewash or wash facilities.

Primary Treatment: The first phase in treating wastewater in which all debris and settleable solids, along with floating materials (e.g., oil and grease) are removed.

Roller Compacted Concrete: A stiff concrete, low in water content which is placed with a paver-compactor and then rolled.

Sanitary Plant: Wastewater treatment plant designed to process a municipal waste (sanitary, commercial, or industrial).

Secondary Treatment: Second phase in wastewater treatment in which the major portion of the suspended solids and a portion of dissolved solids are removed by physical and/or biological means.

Sediment Basin: Receptacle immediately downstream of the wash stations and prewash, if provided, designed to settle and contain solids from a CVWFs wastewater.

Settling Test: A way to determine the rate at which a particular material settles from a quiescent water.

Staff Gauge: Device for measuring water depth in a basin, pond, or lagoon.

Stop: Device used to limit the movement of a piece of equipment.

Surface Water: Water found on the surface of the ground due to rainfall or snow melt; includes incidental water (e.g., that dripping from vehicles).

Suspended Solids: Weight unit of measurement of the non-settling particles or solids in a dispersed state in the wastewater.

Total Dissolved Solids: Weight unit of measurement indicating the sum of all dissolved solids (volatile and nonvolatile) in a water or wastewater.

Transportation Motor Pool: Facility that provides and maintains commercial vehicles for daily use at an installation (cars, buses, trucks, etc.).

Turbidity: Measure of water clarity.

Usage Factor: Estimated percentage of time that the maximum water usage condition will exist at a CVWF.

Valve Box: A pre-manufactured structure made of concrete, steel, plastic, or fiberglass, which is placed around an underground valve.

Wash Period: Time during which vehicles are washing at a CVWF.

Wash Station: Area of a CVWF where high-pressure, high-flow volumes of water are supplied to hoses for cleaning vehicles.

Wastewater Treatment Plant: Facility designed to process sanitary, commercial, and/or industrial wastewater.

Water Cannon: Device used to direct a large volume of water, at high pressure, toward an object.

Water Supply Basin: Receptacle at a CVWF that holds treated water for reuse at prewash and wash stations.

Weir: Usually a flat piece of metal with a characteristic shape (rectangular, V-notched, etc.) which is inserted into flowing Water for determining the flow rate.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
NEW DOCUMENT SUMMARY SHEET

Subject: UFC 4-215-01, *Armories and Arms Rooms*

Cancels: This is a new Tri-Service document. This is to be used in conjunction with other Tri-Service UFC documents in the development of Armories and Arms Rooms. A listing of documents is in Appendix A - References

Description: The UFC 4-215-01, *Armories and Arms Rooms*, represents another step in the effort to bring uniformity to the planning, design and construction of military facilities. The document requires the use of the latest building codes including the International Building Code.

New military requirements were incorporated and improved references to other documents have been identified for energy conservation, sustainable development, and antiterrorism standards.

This is the first Tri-Service criteria document to be published for this building type.

Reason for Creating this Document: The existing guidance was inadequate for the following reasons:

- The Services are currently using their own individual criteria documents, ex. AF Guides, NAVFAC Instructions, Army Technical Instructions, and Marines P-numbered management manuals. This document promotes criteria uniformity, and reduces current reliance upon individual Service specific documents.

- The existing Service-specific guidance did not properly reference and identify recently updated and published Tri- Service documents.

Impact: The following direct benefits will result with the new UFC 4-215-01, *Armories and Arms Rooms.*

- Creation of a single source for common DoD Armory criteria and an accurate reference to individual Service-specific documents.

- Eliminates misinterpretation and ambiguities that could lead to design and construction conflicts.

- Facilitates updates and revisions and promotes agreement and uniformity of design and construction between the Services.

Unification Issues:

Section 2-8.1: Air Force's approval authority for installation of emergency power systems at Armories is the Air Force Civil Engineer Center (AFCEC), as opposed to the other Services which allow the Installation Commander as the approval authority.

Section 3-4.3.2: Army does not require provision for card readers with key pads at equipment cage (platoon, company) doors and office doors.

Section 3-4.6.1: The Army does not require lockers to be provided for showering or changing clothes. This is due to the Army typically constructing only "Arms Rooms" within other facilities; thus, the existence of an "Arms Room" would not require showers and associated lockers for showering and changing.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC provides requirements for a unified approach to the planning, programming, and design of DoD Armories and Arms Rooms. These facilities store only very limited amounts of small arms ammunition; thus, this document does not cover facilities utilized for storing ammunition or explosives. For facilities storing ammunition or explosives that fall under DoD 6055.09-M, *DOD Ammunition and Explosive Safety Standards*, refer to requirements in UFC 4-420-01, *Ammunition and Explosives Storage Magazines*.

1-2 APPLICABILITY.

This UFC applies to all military service elements and contractors involved in the planning, design, and construction of DoD armories and arms rooms worldwide. The information in this UFC applies to the design of all construction projects, to include new construction, additions, alterations, and renovation projects in the continental United States (CONUS) and outside the continental United States (OCONUS).

1-3 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *General Building Requirements*. UFC 1-200-01 provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-4 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-5 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

This Page Intentionally Left Blank

CHAPTER 2 PLANNING CRITERIA

2-1 PHYSICAL SECURITY.

Physical security is that part of security concerned with physical measures designed to safeguard personnel; to prevent unauthorized access to equipment, installations, material, and documents; and to safeguard them against espionage, sabotage, damage, and theft.

The applicable DoD and Service-specific physical security documents for Armories and Arms Rooms are as follows:

- DoD Military Handbook 1013/1A, Section 2
- DoDM 5100.76, *Physical Security of Sensitive Conventional Arms, Ammunition, and Explosives*, for pre-design considerations.
- Navy: OPNAVINST 5530.13C, *Physical Security Instruction for Conventional Arms, Ammunitions, and Explosives*
- Marine Corps: MCO 5530.14A, *Marine Corps Physical Security Program Manual*
- Army: Army Regulation (AR) 190-11, *Physical Security for Arms, Ammunition, and Explosives*
- Air Force: Air Force Instruction (AFI) 31-101, *Integrated Defense* (FOUO).

Include representatives from the intended facility users, as well as the designated military installation intelligence officers, operational officers, security and law enforcement officials, and engineering and planning personnel in the planning and design process.

2-1.1 Threat Assessment.

Generally, arms storage structures are designed according to the physical security regulations and instructions listed above. Local threat considerations need to be taken into consideration and the "design basis threat" can be established using UFC 4-020-01, *DoD Security Engineering Facilities Planning Manual*.

2-2 SCOPE OF FACILITY.

Comply with DoDM 5100.76. Armory facility functional design is driven by inventory control, storage, equipment repair and maintenance, delivery, management methodologies, and any additional functions accommodated in the specific facility. These functions and how they drive the design of the facility are described in greater detail herein. Arms, ammunition and explosives (AA&E) storage is driven by Security Risk Categories (SRC) per DoDM 5100.76. For Army Arms Rooms representative risk categories are established per AR 190-11.

2-2.1 Armories and Arms Rooms.

"Armory" is a facility, usually free-standing, containing one or more separate weapon storage and distribution spaces. See Appendix B, Drawing B-1, for the layout of a typical Armory. An "Arms room" is a single room built inside, or adjacent to, another building for the purpose of storing and distributing weapons. See Appendix B, Drawing B-3, for the layout of a typical Arms Room.

2-2.1.1 Armory.

Navy and Marine Corps armories are categorized in UFC 2-000-05N, *Facility Planning Criteria for Navy/Marine Corps Shore Installations*, Category Code 143 45. An armory for Fleet Marine Force air and ground units provides temperature and humidity controlled, and secure space for storing and maintaining weapons assigned to personnel. In planning for a Marine Corps armory, the method is to build the space requirements by weapon and ammunition count. To calculate space requirements, the space allocation for a Navy and Marine Corps armory can be determined by using the UFC 2-000-05N, *Facility Planning Criteria for Navy/Marine Corps Shore Installations* space planning tool on the NAVFAC portal. Adjustments can be made for units that do not conform to infantry battalion model, such as squadron or logistics battalion. Navy and Marine Corps Armories store limited amounts of safety and security ammunition and may also be authorized for storing ammunition with those personal weapons that have been authorized for storage by the Commanding Officer in a container in the facility.

The Army also has large free-standing weapons storage facilities in specialized circumstances (identification of which is FOUO); however, the Army more typically stores weapons in an Arms Room within another facility.

The weapons/equipment within the armory is typically stored within cabinets, wall lockers, gun racks, shelving, boxes/crates, or wall boards. In most cases, this method of storage allows some stacking of the weapons/equipment which can reduce floor space requirements. See Appendix B, Drawing B-1, for the typical layout of an Armory.

2-2.1.1.2 Portable Armory.

An armory constructed and designed to be relocatable. They are a custom fabrication built in accordance with Naval Surface Warfare Specification 3046-93.2. Relocatable Armories are not permanent Armory solutions. Portable armories must also comply with DoDM 5100.76 and the Service-specific requirements within AR 190-11 and OPNAVINST 5530.13C.

2-2.1.2 Arms Rooms.

Army arms rooms are constructed according to the requirements of Army Regulation (AR) 190-11; these are facilities, similar in function to the weapons storage spaces of armories, with very limited maintenance and repair facilities. Standard Army practice is to have an arms room built inside or adjacent to each line company headquarters building. Arms rooms are also located inside military police buildings, special operations centers, reserve training facilities, and other installations. If required, add space for a small amount of ammunition storage. See Appendix B, Drawing B-3, for the layout of a typical Arms Room.

Air Force arms rooms are governed by Air Force Instruction (AFI) 31-101, ETL 11-18, *Small Arms Range Design and Construction*, and AFMAN 32-1084, *Facility Requirements*. Air Force weapons repair and maintenance facilities are normally located in a Combat Arms Facility.

Navy and Marine Corps arms rooms must comply with OPNAVINST 5530.13C.

2-2.1.3 Modular Arms Room.

Governed by Federal Specification (Fed. Spec.) AA-V-2737, *Modular Vault Systems*. Modular arms rooms' construction is placed inside a building during new construction, is inserted inside an existing building, or is an addition to an existing structure. It may be a free-standing arms room, constructed of precast concrete or steel plate. The physical security requirements for a modular arms room are the same as for a standard arms room or armory building. These are not to be confused with portable armories.

2-3 ARMORY PLANNING DETERMINATIONS.

Planning the size and layout of armory facilities depends upon the following determinations.

2-3.1. Inventory and Number of Personnel to be Serviced.

The facility inventory, number of workers, and number of personnel to be serviced drives the overall area of the facility. Use individual service space planning criteria and user input to determine specific needs. This area will be provided by the DoD Form 1391 for the project.

2-3.2. Weapons Distribution Protocols.

The weapons distribution protocol affects the layout of the facility. In most armories the weapons are distributed through Issue Ports. The design of the Issue Ports is a determinant of the types of weapons that can be issued. Issue Port size is regulated by Physical Security requirements. See Issue Port details in Appendix B.

Larger weapons and accessories may require special distribution procedures that mandate that weapons and accessories be distributed through the facility doorways. The protocol for these issues will be established by the facility user.

For Arms Rooms, weapons issue is through the Class 5 Armory Door or day gate. The day gate can be configured with an issue window or as a Dutch door to facilitate issuance and return of weapons and equipment.

2-3.3. Weapons Storage.

Determine weapons storage requirements during initial project planning. High-density storage systems may be necessary to accommodate the quantity and variation of the weapons and supporting equipment requiring storage. The configuration and mobility of selected storage systems may impact the funding source required to obtain the system, either as facility construction costs or installed equipment costs (FF&E), and must be programmed accordingly in the project funding documentation (DD 1391, etc.) by the facility planner. Configuration of storage systems will also impact decisions regarding structural systems, fire protection requirements, security systems and lighting.

2-3.4. Weapons Cleaning Stations.

The type, number, and arrangement of weapons cleaning station worktables and accessories are an integral part of the building functional planning. The cleaning process will take place in a covered area, typically located outside but adjoining the facility in temperate climates and incorporated into the facility in harsh climates. Outside covered areas will be scheduled at one-half square footage. Supplemental heating may be necessary for outside cleaning areas.

Interior weapons cleaning rooms are located outside the secure perimeter of the armory.

The size of the weapons cleaning area is based on the number of personnel using the space, and the amount of time allowed for cleaning. For Air Force facilities, AFMAN 32-1084 requires 15 SF per each person cleaning weapons concurrently.

2-3.4.1 Location.

The location of the weapons cleaning areas will be reflected in the space planning allowances shown in the project funding documentation (DD 1391, etc.), either as an exterior covered space square footage requirement or as additional interior square footage in the facility.

2-3.4.2 Interior Location.

For interior locations, the type, number, and arrangement of weapons cleaning and repair worktables and accessories will be designed as an integral part of the building interior.

2-4 STAFFING AND OFFICE MANAGEMENT.

Determine staffing requirements for armories to size the administrative areas, staff lockers, and toilets, in accordance with the individual service's space criteria. Staffing for arms rooms would be located in an adjacent office with visual control of the room entrance.

2-5 OTHER FACILITY FUNCTIONS.

For the armory to accommodate one or more of the following additional functions, specialized areas will be required. These spaces should be outside of the secure perimeter of the armory.

- Personnel training functions - classrooms.
- Non-Standard weapons inventory, servicing, and/or fabrication functions – machine shops, wood shop, indoor firing range.
- Small arms shop (Category Code 215 10) contained in a Navy or Marine Corps Armory or for a small arms shop in support of multiple facilities.

2-6 SPACE ASSESSMENT.

See the Functional Data Sheets in Chapter 4 for additional information on the space types and their relationships to each other.

2-6.1 Other Functions.

If the program calls for it, add a gunsmith shop for weapon construction and maintenance. Air Force weapons repair and maintenance are normally provided in a Combat Arms Facility. Add other functions defined by the program.

2-6.2 Break Area.

Armory areas as required for, recycling bins space, and coffee machine, microwave oven and refrigerator.

2-6.3 Loading Considerations.

If a loading dock is necessary to accommodate material transfer in and out of the facility, coordinate it with storage requirements.

2-6.4 Support Areas.

Accommodate staff needs such as offices and administrative tasks, toilets, lockers, showers, and janitor closets. The areas are determined by the staffing requirements. These spaces can be located outside of the secure perimeter of the armory.

2-6.4.1 Building Services Areas.

These spaces accommodate building services such as mechanical, electrical, and communications. Provide separate Mechanical and Electrical Equipment rooms, sized according to the size of the facility, with direct access to the exterior only. The Mechanical and Electrical rooms are not required to be within the secure perimeter. Provide lockable doors for the Mechanical and Electrical rooms. Interior access is prohibited.

- Where requested by user, provide toilet facilities accessed from the exterior of the building as part of the building program, in addition to interior toilets.
- Trash & Garbage Removal and Recycling. Garbage storage, removal and recycling systems will be determined prior to design, based on installation requirements.
- Segregated areas for special wastes.
- Other Facility Functions. These spaces will be determined by the specific facility requirements and the individual service's space planning criteria.

2-7 BUILDING SITE PLANNING.

The armory functions are important to the mission for any installation. Consider the following factors in the site selection and planning.

2-7.1 Location.

The following must be addressed when locating a facility:

- In locating the facility, the first consideration is physical security. Provide a clear, unobstructed view of the fence openings and entry path from the facility entrance.
- Site selection must take into account the requirement that an armed response force must be able to respond on-site to the armory location within 15 minutes of an alarm or report of intrusion, in accordance with DoDM 5100.76.
- For Armories, another important siting consideration is locating it in close proximity to the operational hub of the regiment, battalion, or company, when possible.

2-7.2 Parking.

Provide adequate parking as close to the facility as possible within antiterrorism (AT) requirements. Parking must be located outside of clear zone.

2-7.3 Fencing.

DoDM 5100.76 does not require fencing for armories. Provide security fencing around the perimeter of the entire building site when dictated by the installation/base commander. When fencing is required, per DoDM 5100.76, establish clear zones that extend a minimum of 12 feet (3.66 m) on the outside and 30 feet (9.14 m) on the inside of fence (or to the maximum extent within available land space if minimum requirements cannot be met). For more stringent clear zone requirements for Marine Corps facilities, refer to MCO 5530.14A.

2-8 BUILDING SUPPORT SYSTEMS.

2-8.1 Emergency Power.

Coordinate with Installation Commanding Officer to determine if emergency power is required to support the critical mission and identify the requirements, including load to be served and time duration, in the project funding documents. Emergency power may be required to provide air-conditioning/humidity control in weapons storage areas, and other systems to support the mission. **Service Exception:** For **Air Force**, the Air Force Civil Engineering Center (AFCEC) is the approval authority for installation of emergency power systems.

This Page Intentionally Left Blank

CHAPTER 3 GENERAL DESIGN CRITERIA

3-1 GENERAL.

3-2 PHYSICAL SECURITY.

See Chapter 2 paragraph “Physical Security” and “Armories and Arms Rooms” for additional design requirements.

3-3 SITE WORK.

3-4 ARCHITECTURE AND INTERIOR DESIGN.

3-5 ELECTRICAL DESIGN.

In addition to the criteria established in UFC 1-200-01 and the references therein, comply with the following armory-specific requirements:

3-5.1 Telecommunications Systems.

Refer to specific requirements for spaces in Chapter 4, Room Data Sheets. In arms rooms, consider providing phone to allow communication with security forces.

3-5.2 Power.

Provide ceiling-mounted power cord reels at each worktable in weapons maintenance areas. Floor mounted flush receptacles and conduit stub-ups are not permitted.

3-5.3 Lighting.

Provide lamp breakage protection (wire guards) for lighting fixtures in rooms as required in spaces in Chapter 4, Room Data Sheets. Provide site security lighting in accordance with the requirements of UFC 3-530-01. Provide security lighting for all arms storage areas and facilities. The lighting must be sufficient to allow guards or individuals responsible for maintaining surveillance to see illegal acts such as forced entry or the unauthorized removal of arms. Provide a minimum of 0.2 foot-candles (2 lux) illumination measured on the horizontal plane at ground level, sufficient to allow detection of unauthorized activity. Locate exterior light switches so they are only accessible to authorized personnel.

3-5.4 Emergency Power.

When identified in the project funding documents, provide emergency power generator to support mission requirements. Army Regulation AR190-11 requires a minimum 4 hour power source (battery) to operate security features.

3-5.5 Electronic Security Systems (ESS).

Coordinate ESS requirements for the facility with the Service-specific documents identified in Chapter 2 paragraph titled “Physical Security”. Design the ESS in accordance with UFC 4-021-02, *Electronic Security Systems*.

3-5.5.1 Intrusion Detection System (IDS)

Provide an IDS including the following, unless there is a documented exception.

- Point sensors on doors and other “accessible openings” exceeding 96 square inches (619 square centimeters)

- Interior volumetric sensors, including coverage of all shelving and gun racks. When required by user, provide individual IDS sensing for each weapons storage area. Ensure IDS components are not rendered useless by blocked line of sight.

- A duress alarm (panic button) at each issue port (for Navy and Marine facilities)

- Line supervision on transmission lines. If line supervision is unavailable, two independent means of alarm signal transmission is required.

- Reporting to a central monitoring station where alarms will sound and from which a response force can be dispatched. An alarm bell located only at the protected location is not acceptable.

3-5.5.2 Access Control Systems

Provide card reader with keypads at entry to building. Provide key pad, with card reader when required, at the entrance of each interior weapons storage area. Card readers must be approved for use by service's security authorities.

3-5.5.3 Closed Circuit Television (CCTV)

Provide CCTV system when required.

3-6 HEATING, VENTILATION, AND AIR CONDITIONING (HVAC) DESIGN.

In addition to UFC 1-200-01, *General Building Requirements,* and the stated and cross referenced requirements for HVAC Systems, comply with the following:

3-6.1 Maximum Ductwork Size.

Where possible, limit maximum ductwork size penetrating the perimeter of the secure area (roof or walls) to less than the dimensions for a "man-passable opening" as defined in MIL HDBK 1013/1A. Where the "man-passable opening" dimensions must be exceeded, provide hardening at the opening in accordance with MIL HDBK 1013/1A.

3-6.2 Controls.

Specify direct digital control (DDC) system per UFGS 23 09 23.13 20, *BACnet Direct Digital Control Systems for HVAC*, or UFGS 23 09 23, *Lonworks Direct Digital Control for HVAC and Other Building Control Systems*. Coordinate DDC specification to ensure proper interface to existing or planned base-wide DDC/EMCS system.

Refer to Room Data Sheets in Chapter 4 for spaces which require humidity control.

3-6.3 Ventilation.

Ventilation systems for the Weapons Repair and Maintenance Workshops and any interior weapons cleaning areas must comply with UFC 3-410-04, *Industrial Ventilation.*

3-7 PLUMBING DESIGN.

In addition to UFC 1-200-01, *General Building Requirements,* and cross referenced requirements therein, comply with the following in the design of the plumbing system for this facility type:

- Provide hose bibbs at exterior weapons cleaning areas. In lieu of hose bibbs, provide freeze proof hydrants where the climate demands.

- Locate air compressor(s) and air dryer(s) in the Mechanical Room when feasible. If outdoors, provide outdoor rated compressed air system, mounted on a slab, for the covered weapons cleaning area and the indoor weapons repair and

maintenance workshops. Provide compressed air outlets at the worktables. Equip interior compressed air outlets with ceiling hung hose reels.

3-8 FIRE PROTECTION.

Refer to UFC 1-200-01, *General Building Requirements,* and comply with stated and cross referenced requirements for Fire Protection Systems, with the following additions or exceptions for this facility type:

3-8.1 Fire Suppression Systems.

For armories 5,000 square feet (464.5 sq. m.) or greater, provide automatic sprinkler protection throughout the facility and for the outdoor weapons cleaning areas when attached to the building.

3-8.2 Fire Alarm Systems.

Provide a Fire Alarm System for armories of 5,000 square feet (464.5 sq. m.) or greater. Fire alarm systems are not required for portable armories.

3-8.3 Installations with a Single Armory

For Installations that have only one armory, and that armory houses the Installation's Security Forces weapons and ammunition, mitigation of risks associated with loss of security forces weapons and ammunition due to fire shall be provided by one of the methods below.

- Provide automatic sprinkler protection throughout the building, regardless of size.
- The installation Security Officer must maintain a written contingency plan in the event the armory and contents are destroyed due to fire. This written plan must be approved by the installation Commanding Officer.

3-8.4 Mass Notification Systems.

When required for an inhabited building, provide mass notification system in accordance with UFC 4-021-01, *Design and O&M: Mass Notification Systems*.

This Page Intentionally Left Blank

CHAPTER 4 SPECIFIC DESIGN CRITERIA

4-1 INTRODUCTION.

This chapter identifies the specific design requirements for each functional area as outlined in the space program. Tables 4-1 through 4-12 provide this data in a standard Functional Data Sheet format.

Armory planning determinations, along with other basic building design and operation determinations, establish the size, layout, and design of the facility functional spaces. The various components below may apply to an armory or an arms room project.

The interior construction specialties, equipment and furnishings criteria provided in these tables are broken down as follows:

- Casework/Built-in Equipment. This includes anything physically attached or plumbed to the building such as counters, cabinets, casework, toilet accessories, and window treatments.
- Furnishings, Fixtures, and Equipment (FF&E). This includes contractor-furnished, contractor-installed loose items such as desks, tables, chairs, bookshelves, and televisions (if mounted, TV mount would be built-in).
- User-provided FF&E. This includes all government-furnished, government-installed items, which are typically limited to office equipment such as computers, printers, copiers, and projectors (if mounted, projector mount would be built-in).

4-2 ISSUE PORTS.

Provide issue ports for Navy and Marine Corps armories. The issue port accommodates distribution of weapons to authorized personnel. For the Navy and Marines, OPNAVINST 5530.13C and MCO 5530.14A require openings “not to exceed 190 in-sq when open; and when not in use will be secured with material comparable to that forming the adjacent walls.” (NOTE: DoDM 5100.76 requires IDS point sensors on any “accessible openings,” which is defined as 96 sq in (0.06 square meters)). Provide at least one issue port at each caged or separate unit arms room.

See Appendix B – Drawings for Issue Port drawings.

TABLE 4-1 ENTRY CANOPY

Description/Usage	Provide a canopy or enclosure at the main entrance to the facility for personnel who must wait at the facility entrance. It may be a column supported canopy. Determine the size by the number of personnel to be served, arrival and departure considerations, and the procedure followed.
Ceiling Ht.	11’ – 4” (3.45 m) min (new construction)
Finishes	Floor: Sealed Concrete Base: N/A Walls: N/A Ceiling: Painted or prefinished
Plumbing	None
HVAC	None
Fire Protection	None
Power	None
Lighting	Provide per Chapter 3
Communication	None
Acoustics	None
Casework/Built-in Equipment	None
Furnishings Fixtures & Equip. (FF&E)	None
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-2 VESTIBULE

Description/Usage	A vestibule is appropriate to prevent major heat loss and gain, and to screen and protect visitors prior to entry into the facility proper.
Ceiling Ht.	11’ – 4” (3.45 m) min (new construction)
Doors	Use hollow metal doors with half glass for the outside door(s). If the inside of the vestibule is on the secure perimeter, the inside door must be GSA-approved Class 5 Armory Door. At the inside of the armory door, provide a day gate for added security.
Finishes	Floor: Sealed Concrete; consider recessed entry mat. Base: Resilient Walls: Epoxy on CMU or concrete. Provide wall guard protection at locations subject to cart traffic. Ceiling: Painted exposed structure
Plumbing	None
HVAC	Provide per Chapter 3
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3
Lighting	Provide per Chapter 3. Provide lamp protection.
Communication	Provide per Chapter 3
Acoustics	None
Casework/Built-in Equipment	None
Furnishings Fixtures & Equip. (FF&E)	None
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-3 CORRIDOR

Description/Usage	Circulation. The semi-public areas of the facility allow for circulation to other functions.
Ceiling Ht.	11’ – 4” (3.45 m) min (new construction)
Finishes	Floor: Sealed Concrete Base: Resilient Walls: Epoxy on CMU or concrete/expanded metal. Provide wall guard protection at locations subject to cart traffic. Ceiling: Painted exposed structure
Plumbing	None
HVAC	Provide per Chapter 3
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3
Lighting	Provide per Chapter 3. Provide lamp protection.
Communication	Provide per Chapter 3
Acoustics	None
Casework/Built-in Equipment	Tackboards
Furnishings Fixtures & Equip. (FF&E)	None
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-4 DUTY OFFICE

Description/Usage	Administrative office
Ceiling Ht.	8’ – 0” (2.44 m) min
Finishes	Floor: Resilient tile Base: Resilient Walls: Painted walls. Ceiling: Acoustical panel
Plumbing	None
HVAC	Provide per Chapter 3
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3
Lighting	Provide per Chapter 3
Communication	Provide per Chapter 3
Acoustics	Provide per Chapter 3
Casework/Built-in Equipment	None
Furnishings Fixtures & Equip. (FF&E)	Office furniture
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-5 MECHANICAL ROOM

Description/Usage	Mechanical equipment housed here. Access only from the exterior of the building.
Ceiling Ht.	11’ – 4” (3.45 m) min. (new construction)
Finishes	Floor: Sealed Concrete Base: Resilient Walls: Painted CMU or concrete Ceiling: Painted exposed structure
Plumbing	Provide per Chapter 3
HVAC	Provide per Chapter 3
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3
Lighting	Provide per Chapter 3
Communication	Provide per Chapter 3
Acoustics	None
Casework/Built-in Equipment	None
Furnishings Fixtures & Equip. (FF&E)	None
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-6 STAFF TOILETS/SHOWERS

Description/Usage	Male and female toilets and shower facilities.
Ceiling Ht.	8’ – 0” (2.44 m) min
Finishes	Floor: Porcelain tile Base: Porcelain or Ceramic tile Walls: Ceramic tile wainscot 48” high except, full height ceramic tile or solid surface material in showers. Painted walls. Ceiling: Moisture resistant acoustical panel ceiling or mold-resistant gypsum board.
Plumbing	Lavatories, urinals, water closets, showers
HVAC	Provide per Chapter 3
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3
Lighting	Provide per Chapter 3
Communication	Provide per Chapter 3
Acoustics	No special requirements
Casework/Built-in Equipment	Vanity cabinets for lavatories. Toilet partitions and accessories. Provide solid surfacing material at countertops. Lockers and benches if required
Furnishings Fixtures & Equip. (FF&E)	
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-6A EXTERIOR TOILETS

Description/Usage	Optional male and female toilet facilities, accessed from the exterior of the building. Primarily required for Armories in remote locations.
Ceiling Ht.	8’ – 0” (2.44 m) min
Finishes	Floor: Sealed Concrete Base: None Walls: Painted walls. Ceiling: Moisture resistant acoustical panel ceiling or mold-resistant gypsum board.
Plumbing	Lavatories, urinals, water closets
HVAC	Provide per Chapter 3
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3
Lighting	Provide per Chapter 3
Communication	Provide per Chapter 3
Acoustics	No special requirements
Casework/Built-in Equipment	Toilet accessories.
Furnishings Fixtures & Equip. (FF&E)	None
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-7 ELECTRICAL CLOSET

Description/Usage	Electrical panels and other equipment. Access only from the exterior of the building.
Ceiling Ht.	11’ – 4” (3.45 m) min (new construction)
Finishes	Floor: Sealed Concrete Base: Resilient Walls: Painted CMU or concrete Ceiling: Painted exposed structure
Plumbing	None
HVAC	Provide per Chapter 3
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3
Lighting	Provide per Chapter 3
Communication	Provide per Chapter 3
Acoustics	None
Casework/Built-in Equipment	None
Furnishings Fixtures & Equip. (FF&E)	None
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-8 COMMUNICATIONS ROOM

Description/Usage	Communications equipment housed here.
Ceiling Ht.	11’ – 4” (3.45 m) min. (new construction)
Finishes	Floor: Sealed Concrete Base: Resilient Walls: Painted. Provide ¾-inch (19 mm) plywood attached to wall for attachment of IT and telephone equipment. Ceiling: Painted exposed structure
Plumbing	None
HVAC	Provide per Chapter 3
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3
Lighting	Provide per Chapter 3
Communication	Provide per Chapter 3
Acoustics	None
Casework/Built-in Equipment	Communications racks
Furnishings Fixtures & Equip. (FF&E)	None
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-9 JANITORS CLOSET

Description/Usage	Cleaning supplies and equipment storage.
Ceiling Ht.	8’ – 0” (2.44 m) min
Finishes	Floor: Sealed Concrete Base: Resilient Walls: Painted Ceiling: Painted GWB ceiling.
Plumbing	Floor mop sink
HVAC	Provide per Chapter 3
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3
Lighting	Provide per Chapter 3
Communication	None
Acoustics	None
Casework/Built-in Equipment	Storage shelving for cleaning supplies and equipment; mop rack.
Furnishings Fixtures & Equip. (FF&E)	None
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-10 COVERED WEAPONS CLEANING AREA

Description/Usage	Exterior column supported canopy with concrete slab. Determine the size by the number of personnel to be served, arrival and departure considerations, and the procedure followed. Provide space for weapons cleaning tables, cleaning equipment, and clearing of weapons.
Ceiling Ht.	11’ – 4” (3.45 m) min (new construction)
Finishes	Floor: Concrete Base: N/A Walls: N/A Ceiling: Painted ceiling.
Plumbing	Hose bibbs. Use freeze proof hydrants in lieu of hose bibbs where climate demands. Provide compressed air system with compressed air outlets at worktables (50 psi and 15 scfm, verify these requirements during design).Provide emergency eyewash station.
HVAC	Provide radiant heating. Coordinate the type of heating allowed with fire protection requirements where solvent vats are provided.
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3
Lighting	Provide per Chapter 3. Provide lighting at 30 footcandles (300 lux) ambient and 50 footcandles (500 lux) at task with vacancy sensor (manual on, vacancy off). Provide lamp protection (wire guards).
Communication	None
Acoustics	None
Casework/Built-in Equipment	Weapons cleaning tables
Furnishings Fixtures & Equip. (FF&E)	Weapons cleaning equipment, weapons clearing barrels, hazardous material storage for oily rags. Trash containers.
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-10A INTERIOR WEAPONS CLEANING AREA

Description/Usage	Interior building space for weapons cleaning. Required for areas with harsh climates. Determine the size by the number of personnel to be served, arrival and departure considerations, and the procedure followed. Provide space for weapons cleaning tables, cleaning equipment, and clearing of weapons.
Ceiling Ht.	11' – 4" (3.45 m) min (new construction)
Finishes	Floor: Sealed Concrete Base: N/A Walls: Epoxy Paint Ceiling: Painted exposed structure.
Plumbing	Compressed air system with ceiling hung hose reels at worktables (50 psi and 15 scfm, however, verify requirements during design). Deep sinks. Emergency eyewash station.
HVAC	Provide per Chapter 3. Coordinate the type of heating allowed with fire protection requirements where solvent vats are provided. Provide special ventilation in accordance with Chapter 3, HVAC Design, to control solvent vapors.
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3
Lighting	Provide per Chapter 3. Provide lighting at 30 footcandles (300 lux) ambient and 50 footcandles (500 lux) at task with vacancy sensor (manual on, vacancy off). Provide lamp protection (wire guards).
Communication	None
Acoustics	None
Casework/Built-in Equipment	Weapons cleaning tables
Furnishings Fixtures & Equip. (FF&E)	Weapons cleaning equipment, weapons clearing barrels, hazardous material storage for oily rags.
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-11 WEAPONS REPAIR AND MAINTENANCE WORKSHOPS

Description/Usage	Weapons repair and regular maintenance. The square footage of repair and maintenance workspace areas will be determined by the program. In some armories this space may have secondary functions as a training space.
Ceiling Ht.	11' – 4" (3.45 m) min (new construction)
Finishes	Floor: Sealed Concrete Base: Resilient Walls: Epoxy on CMU or concrete. Ceiling: Painted exposed structure
Plumbing	Compressed air system with ceiling hung hose reels (50 psi and 15 scfm, however, verify requirements during design). Hand sink and emergency eyewash.
HVAC	Provide humidity control to limit the relative humidity to no greater than 40% at 80 degrees Fahrenheit (26.7 degrees Celsius). Design to 68 deg F (20.0 deg C) dry bulb and 40% RH for indoor design heating conditions, and 75 deg F (23.9 deg C) dry bulb and 40% RH for indoor design cooling conditions. Provide special ventilation in accordance with Chapter 3, HVAC Design, to control solvent vapors.
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3. Provide power reels.
Lighting	Provide per Chapter 3. Provide lamp protection. Provide lighting at 30 footcandles (300 lux) ambient and 50 footcandles (500 lux) at task
Communication	Provide per Chapter 3. Provide duress alarm at each issue port.
Acoustics	None
Casework/Built-in Equipment	None
Furnishings Fixtures & Equip. (FF&E)	Weapons maintenance workbenches, tables, stools, hand tools, power tools and parts cabinets
User-Provided Equip. (GF&GI)	Tools and Parts
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)	

TABLE 4-12 WEAPONS STORAGE AREA

Description/Usage	The weapons and equipment within the armory are typically stored within cabinets, gun racks, shelving, boxes/crates, or wall boards. In most cases, this method of storage allows some stacking of the weapons/equipment which can reduce floor space requirements. Provide storage space for gun cases, ammunition cases, etc. The areas are determined by analysis of the need, the number of personnel to be served, and the defined delivery cycles. An armory will have multiple cages, each for a company-sized unit (approximately 105 personnel), with weapons racks, locking cage door with a key / pushbutton lock. Provide a minimum of one issue port for each caged area or separate arms room. Provide space for weapon cleaning. Allow space for a small workbench with power if required by User. Provide workbench if requested.
Ceiling Ht.	11’ – 4” (3.45 m) clear to underside of concrete (new construction)
Finishes	Floor: Sealed Concrete Base: Resilient Walls: Epoxy on CMU or concrete. Ceiling: Painted exposed structure.
Plumbing	None
HVAC	Provide humidity control to limit the relative humidity to no greater than 40% at 80 degrees Fahrenheit (26.7 degrees Celsius). If personnel will be working in these areas, design to 68 deg F (20.0 deg Celsius) dry bulb and 40% RH for indoor design heating conditions, and 75 deg F (23.9 deg Celsius) dry bulb and 40% RH for indoor design cooling conditions.
Fire Protection	Provide per Chapter 3
Power	Provide per Chapter 3. Provide power for workbench(es) if required by User.
Lighting	Provide per Chapter 3. Provide lamp protection (wire guards).
Communication	Provide per Chapter 3. Provide duress alarm at each issue port for Navy and Marine facilities. Locate motion detector on corridor cage wall.
Acoustics	No special requirements
Casework/Built-in Equipment	Equipment cages of woven wire mesh partitions, shelving, and wallboards. If storage requirements warrant high-density or wall-mounted storage shelving/racks/boards, these items must be coordinated and included in construction. Consider structural loads, IDS sensors and fire protection systems during design of high-density storage. Storage shelving/racks may require attachment to floor or structure.

TABLE 4-12 WEAPONS STORAGE AREA

Furnishings Fixtures & Equip. (FF&E)	Free-standing weapons racks and cabinets. Workbenches, if requested.
User-Provided Equip. (GF&GI)	None
For use during project execution by the appropriate Service agency	
Occupancy	
Min. net ft^2(m^2)

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

AUTHORIZED BY:

RANDY E. BROWN, SES
Director
Air Force Civil Engineer Center

FACILITIES CRITERIA (FC) CHANGE SUMMARY SHEET

Document: FC 4-218-01F, *Air Force Criteria for Precision Measurement Equipment Laboratory Design and Construction.*

Superseding: Facilities Criteria (FC) 4-218-01F, *Air Force Criteria for Precision Measurement Equipment Laboratory Design and Construction*.

Description: This FC prescribes Air Force criteria for design and construction of new Precision Measurement Equipment Laboratories (PMELs) and updates to existing facilities on Air Force installations. It incorporates the provisions of Unified Facilities Criteria (UFC) 3-410-01, *Heating, Ventilating, and Air Conditioning Systems*, and UFC 3-401-01, *Mechanical Engineering.*

Reasons for Document:

- Supersedes FC 4-218-01F, incorporating Criteria Change Request (CCR) 7691.
- Provides a design guide for Architect and Engineering firms, design agencies, planners, and Air Force organizations for the design of PMEL facilities.
- Updates existing criteria to reflect new and revised industry standards.

Impact:

- Improves energy efficiency.
- Ensures that PMEL environmental systems provide temperature and humidity conditions that will enable performance of traceable measurements for Test, Measurement, and Diagnostic Equipment (TMDE).

Unification Issues:

- Design criteria for Air Force PMEL facilities are specific to accommodate Air Force-unique organizational and operational considerations.

Disclaimer:

- Use of the name or mark of any specific manufacturer, commercial product, commodity, or service in this publication does not imply endorsement by the Air Force.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This FC provides guidelines for evaluating, planning, programming, and designing PMEL Facilities. Alteration and renovation projects should update existing facilities to meet the guidance and criteria within budgetary constraints. This FC is not intended as a substitution for thorough review by individual Program Managers and Operations Staff in the appropriate agency. This FC is a guide for site selection and design of a new metrology laboratory or for modification of an existing facility. This FC outlines standards for design and construction of Type II and Type III PMELs.

1-2 REQUIREMENTS.

Requirements which directly affect the accuracy and integrity of the measurements made and are unique to a calibration laboratory are addressed. Criteria in this FC must not be used as sole justification for a new facility or to improve an existing facility if the facility's condition does not adversely affect the environmental requirements enabling performance of traceable measurements.

1-3 APPLICABILITY.

\2 This UFC follows the same applicability as UFC 1-200-01, paragraph 1-3, with no exceptions. **/2/**

1-4 USERS OF THIS DOCUMENT.

This FC is intended to be a source of basic architectural and engineering information for all individuals involved in the planning, design, and evaluation of PMEL facilities.

1-4.1 Architects and Engineers.

Architects and engineers (A/Es) who provide design services for PMEL facility construction or renovation will be under the direction of the AFCEC Facility Engineering Directorate.

1-4.2 Planning Personnel.

Planning personnel will use this FC along with other documents for programming new or replacement facilities, pre-design planning, or assessing the extent of improvements required in an existing or new PMEL in order to achieve the standard established herein.

1-4.3 Additional Users.

Additional users include:

- Headquarters staff, Air Force Installation and Mission Support

Center (AFIMSC) detachments, and Primary Subordinate Units (PSUs).

- Major command staff/regions.
- Installation commanders.
- Installation facilities management.
- Installation technical proponents.
- Program directors.
- Facility/program operations staff.

1-5 RESPONSIBILITIES.

1-5.1 Air Force Civil Engineer Center (AFCEC).

AFCEC establishes standards and criteria for Air Force PMEL design and construction and provides technical assistance to the design agents and base PMEL managers.

1-5.2 Air Force Metrology and Calibration (AFMETCAL).

AFMETCAL manages the Air Force Metrology and Calibration program.

1-5.3 Base Civil Engineer (BCE).

Ensures this FC is referenced in all PMEL project design documents, and reviews A/E Design Documents to ensure compliance. Hosts preplanning workshops prior to the development of programming documentation for new construction or upgrades.

1-6 SCOPE OF FACILITY.

The PMEL Facility is composed of the Administrative Area, the Calibration and Repair (C/R) Area and the Support Areas. The scope may vary depending on the location and mission requirements. All of the program areas are described in greater detail in Chapters 2 and 4. These criteria apply to Type II and Type III PMELs.

1-7 REFERENCES.

Appendix A contains a list of references used in this document. If the publication date of the code or standard is not included, use the latest available issuance of the reference.

1-8 GLOSSARY.

Refer to Appendixes B and C for definitions of acronyms, abbreviations, and terms.

1-9 PROGRAM AREAS.

1-9.1 Administrative Support, Calibration and Repair, and Support Area.

Tables 1-1a through 1-1d list the core and optional functional program areas for PMEL facilities. These functional program areas are administrative support, calibration and repair, support and special requirements. These are traditional for a typical PMEL, and core areas may be adjusted to accommodate mission requirements. The administrative support area includes equipment check-in, a service entrance, technical library, conference room, break room, and offices. The C/R area includes force and pressure measurement, equipment storage, azimuth reference, a temperature/humidity-sensitive area, a night vision area, and shield room, if survey indicates a need. The support area includes an equipment cleaning room, shipping and receiving, a liquid flow calibration area, and covered equipment area. A 68 degree room, if required, is a separate modular control module.

Table 1-1a. Functional Program Areas

Program Area	Description
Administrative Support Area	
Equipment check-in and check-out, vestibule, and lobby	Minimal entry space in front of control and/or vestibule. Usually combined with the waiting and equipment check-in and pickup. Include a customer service counter to separate the customer from the equipment storage and processing areas. Provide a waiting area with seating and computerized check-in as required for customers.
Service entrance	Service entrance (with canopy) for oversized equipment entry with sealed double doors between the calibration and repair area and the building exterior. Fully enclose the canopy to create an insulated entryway in extreme climates.
Conference room, classroom & training room	Conference room for meetings, planning, and classroom for training personnel.
Break room, copier, and work layout	Break area, copier, and layout space. Food and beverages. May have refrigerator and self-serve (vending). Include copy machine with electrical outlets and work table for drawings and paperwork and small storage area.
Restrooms/janitor supply room	Restrooms for PMEL staff/visitors and janitor supply room with supplies.
Technical library	Library containing technical orders (TOs), equipment descriptions, maintenance manuals, and Air Force manuals and instructions.
Offices	
Flight Chief/Site Manager’s office	Private office.
Laboratory Chief’s office	Private office
Administrative offices	Offices for administrative staff.
Quality Assurance Supervisor office	Private office

Table 1-1b. Functional Program Areas

Program Area	Description
Calibration and Repair (C/R)	

C/R area	This area is maintained under a positive pressure at specified temperature and humidity levels. Various functions occur within this area; some require specific areas or rooms. The C/R area includes: the shield room, technical library, force and pressure measurement, equipment storage, azimuth reference, and a 68 degree room, if required. A positive static pressure as compared to surrounding areas is required to prevent infiltration of dust-laden air. Excess ventilation air for pressurization and a continuous air barrier system to control infiltration and exfiltration in buildings to maintain air tightness is required. Air locks are required for entry into the C/R area. Locate the C/R area adjacent to other conditioned areas.
Temperature/humidity sensitive area	This is a special temperature/humidity sensitive controlled area for PMELs that do not have a requirement for a 68 degree room. The temperature and humidity requirements for this area are **1**\ 73 ± 1.8°F (22.8 ± 1°C) and a relative humidity of 35, +10/-15%. The temperature may not vary more than 1°F (0.5°C) in any one-hour period during normal system operation. Maximum temperature gradient across the room is 1.8°F (1°C). /**1**/
Force and pressure measurement area	Safety screens or shields may be required in the immediate vicinity of force and pressure calibration equipment to protect operators and other laboratory personnel from flying projectiles, high pressure gas, or fluids.
Night vision area	Night vision calibration area for testing under controlled conditions of lighting, temperature, and humidity. Calibration of the night vision ANV-126 test set should be done in a room with ambient lighting levels of less than 0.1 foot candle (1.08 lux) in the general area of the test set. The ANV-20/20 low light level calibration requires total darkness during the adjustment procedures for night vision test set calibration.
Shield room	Usually constructed of copper screening to minimize effects of excessive electromagnetic interference (EMI) or radio frequency interference (RFI), a shield room typically is not required unless EMI/RFI survey results indicate a need.

Table 1-1b. Functional Program Areas (Continued)

Program Area	Description
Calibration and Repair (continued)	
Azimuth reference	If an external azimuth reference line is required, the line can range in length up to one mile terminating at a target mount, depending on location. However, only a few selected PMELs are designated as azimuth verification facilities. The primary azimuth references are established within the facility by an optical target collimator located on an isolated pier. The directions of the external line and the normals to the collimator are determined by observing Polaris (the North Star) from outside the facility. Transfer of direction from Polaris and/or the line to the optical reference is accomplished using a precision theodolite. The PMEL verification facility is an environmentally-controlled facility. Facilities must be located to permit laying out unobstructed lines of sight to the target monument, ranging 45 degrees either side of astronomic north, and in an area relatively free from vibrational disturbances such as heavy local traffic. The test area in the PMEL must provide a steady state internal environment with regard to temperature and air movement. Since total darkness is necessary to conduct azimuth reference surveys, ensure appropriate lighting design is provided. Stable piers are provided for the optical reference collimator and temperature is maintained at 73 ± 6 °F (22.8 ± 3.3 °C) throughout the year.
Liquid flow calibration area	A specially-equipped, isolated area required in PMELs to perform liquid flow meter calibration using propylene glycol as primary test fluid. The enclosure housing a liquid flow calibration area must be constructed of non-combustible or fire resistive materials as defined by the National Fire Protection Association (NFPA). This generally refers to masonry, reinforced concrete, or protected steel construction. The facility also must be equipped with a minimum of two exits, separated to preclude both being cut off in the event of a localized fire. Ensure that doors swing out in the direction of egress per NFPA 101, *Life Safety Code* and NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*. Outward-swing exit doors are required where chemicals are used for testing. Floor space is determined by considering the type and number of flow calibrators needed for the mission. Double doors are required to facilitate installation of flow calibrator units. The liquid flow room is located outside the calibration and repair area.

Table 1-1c. Functional Program Areas

Program Area	Description
Special Requirements	
68 degree room (modular control module)	This is a special temperature controlled area in some PMELs where a 68 degree room is required to maintain a closely-controlled environmental area for calibration and use of higher-accuracy dimensional TMDE. These conditions can be maintained using an off-the-shelf, self-contained, environmental control module, as an option. The environmental control system must maintain 68 ± 1 °F (20° ± 0.5 °C) and an optimum relative humidity of 35, +10/-15%. The temperature may not change more than 1 °F (0.5 °C) in any one hour period during normal system operation.

Table 1-1d. Functional Program Areas

Program Area	Description
Support Area	
Equipment cleaning room	A specially-equipped and isolated area is required for cleaning and washing mechanical, electrical, and electronic equipment. The TMDE cleaning room is separate from the C/R area, and supplied with utilities for cleaning parts. Requirements for the area are determined by the types of equipment to be serviced. Each cleaning unit requires a minimum 15 ft^2 (1.4 m^2) additional floor space. A stainless steel sink and drain board with hot and cold water and exhaust hood is required. Provide an equipment canopy-type exhaust hood with a wall-mounted manual timer, with capability of variable operation up to 2 hours (i.e., twist type or similar occupant-controlled timer). Where a canopy-type hood would pull fumes into the breathing zone, consider installing a bench-style slot-type hood to pull fumes away from the breathing zone. The drying oven for standard cleaning rooms requires 212 cfm (6 m^3/min) for the purge blower intake and exhaust. Provide a vacuum port in the equipment cleaning room.
Shipping and receiving	A shipping and receiving area is required to facilitate loading and unloading of customer equipment for shipment and for short term storage. Install gasket-type stops, astragals, and automatic door bottoms on air lock doors located closest to the C/R area. Seal joints between doors and frames with gaskets.
Covered equipment area	Provide a protected entrance for unloading equipment: either a double-entry door with a drive-through canopy; or a service entry with a roll-up door large enough to allow a small truck or van to back into the unloading area. Quantity and size of equipment handled and weather conditions should determine which entry is appropriate. Consider a covered entry for extreme or cold weather.

CHAPTER 2 FUNCTIONAL REQUIREMENTS

2-1 DESIGN APPROACH.

The design criterion in this section simplifies construction or renovation to a wide variety of PMELs, including the basic requirements which apply to any PMEL. All Air Force construction projects, regardless of scope, shall comply with A7C Policy Memorandum*, "Air Force Sustainable Design and Development (SDD) Implementing Guidance*."

2-1.1 Structural, Mechanical, Electrical, and Plumbing Requirements.

Using the internal and site layouts, locate interfaces between the facility structure and equipment items. Verify the design contains openings, conduit, and raceways to install cables, equipment, and piping with minimum disruption to finished work. During the pre- design stages of the project, the PMEL supervisor must provide the design agent with technical data for any equipment which requires special connections.

2-1.2 The Commissioning Process and Verification of Operation.

The commissioning process ensures that a facility and its components will perform as designed and intended. Optimally, the commissioning process starts during planning and programming prior to design. It continues during design with review of design information, performance data in specifications, and evaluation of submissions. During construction, the commissioning process includes checklists, scheduling of tests, testing and verification, and documentation. Commissioning includes witnessing field tests, adherence to specified performance criteria. Commissioning of building systems is critical to ensuring their expected operation. Commissioning of heating, ventilation, and air conditioning (HVAC) systems must be provided by certified commissioning agents as required by UFC 1-200-02, *High Performance and Sustainable Building Requirements*, and construction documents must follow Unified Facilities Guide Specification (UFGS) 01 91 00.00 40, *Commissioning,* and UFGS 23 08 00.00 10, *Commissioning of HVAC Systems*. Performance testing must be conducted during both peak seasons to ensure compliance with functional and performance requirements as described for each space. Certified commissioning agents will have in-depth knowledge of commissioning processes and technical expertise on projects of similar scope, size, and complexity.

2-1.3 Environmentally Safe Materials and Indoor Air Quality.

Ensure that mission and user requirements, as well as occupant health and safety are considered during design, construction and operations for material selection and environmental systems. Hazardous materials used in the laboratory must be considered in the design. The user will provide the design agent a list of hazardous materials, including quantity, use, and location in the laboratory. Refer to UFC 1-200-02.

2-2 SPACE REQUIREMENTS.

The space requirements for PMEL office spaces and functional area rooms are found in Air Force Manual (AFMAN) 32-1084, *Facility Requirements*. The space requirements are based on the typical PMEL. The size of the PMEL varies depending on the inventory and type of facility (Type II or Type III).

2-3 FUNCTIONAL LAYOUT.

2-3.1 Functional Layouts for Overall Building.

Figures 2-1 through 2-4 show the functional layouts for the overall building, and the C/R, support, and administrative areas.

Figure 2-1 Overall Building Functional Layout

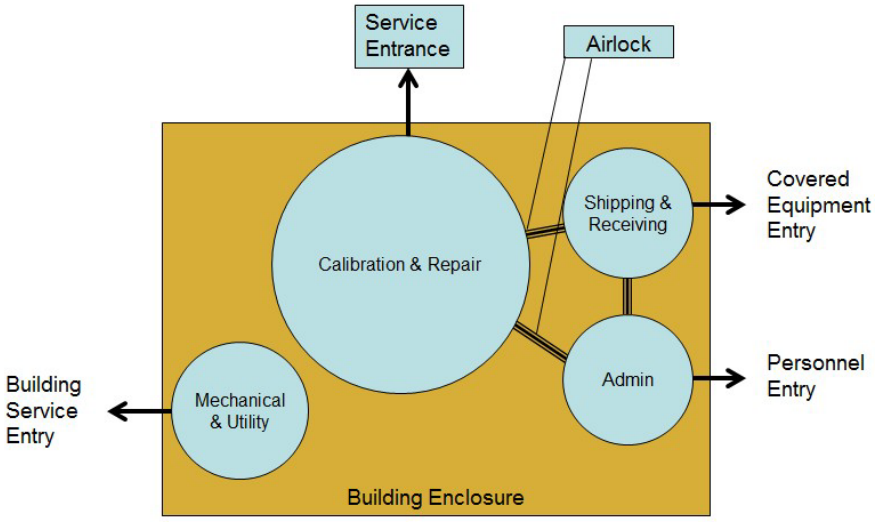

Figure 2-2 Calibration and Repair Area Functional Layout

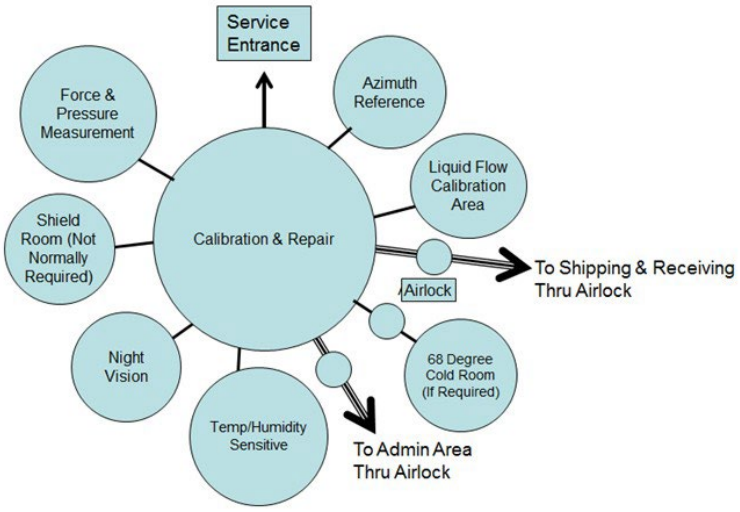

Figure 2-3 Support Area Functional Layout

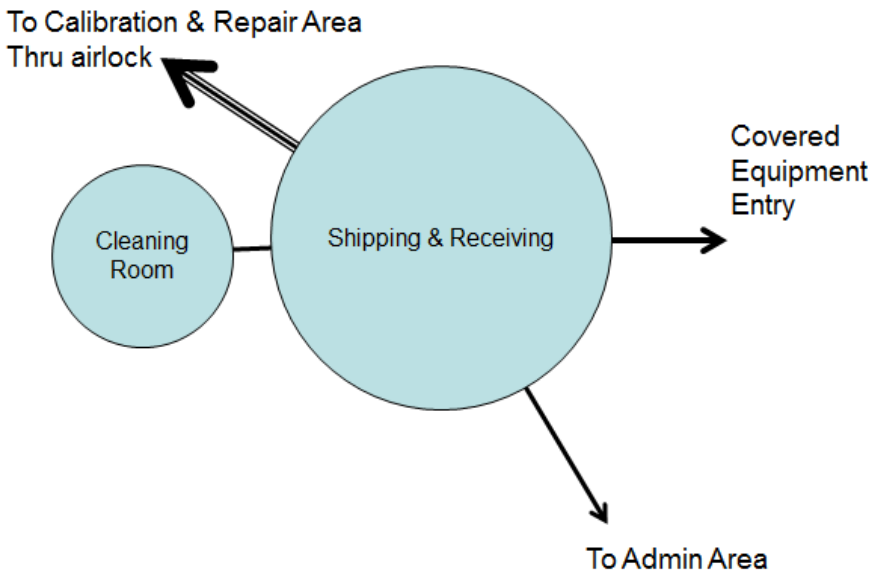

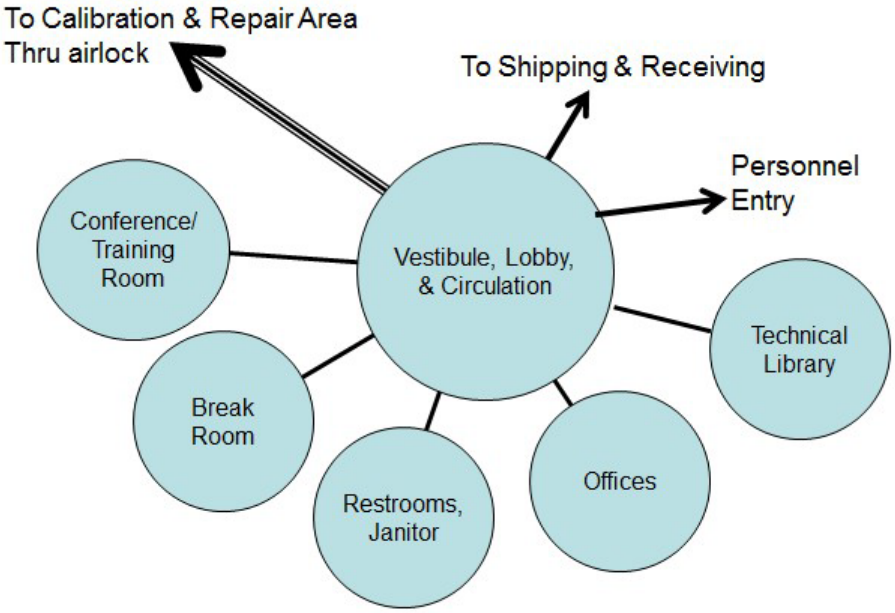

Figure 2-4 Administrative Area Functional Layout

2-3.2 Alterations to Existing Facilities.

Figures 2-1 through 2-4 illustrate acceptable layouts for the overall building. These layouts may have to be modified to accommodate alterations to existing structures. However, proposed modifications must be sent to AFMETCAL for approval. Existing

buildings being considered for modification should be assessed as to whether they can support all the core and optional spaces and dimensional requirements.

2-3.3 Other Considerations.

Consider the site of the existing facility and its limitations with regard to the PMEL requirements. Only permanent facilities should be considered for conversion to a PMEL facility. Ensure that existing buildings can accommodate the environmental temperature requirements of a PMEL facility.

Quantities of workload, physical size of workload, proposed workload, or expansion of workload are the primary factors in determining the design of PMEL support areas. From quantities of equipment that will be received, processed, and stored daily, initial floor space requirements can be estimated. Human engineering and the integration of other PMEL operations must be considered to determine location and layout of the support areas. Equipment storage areas must be isolated from visitors for security and to prevent unauthorized movement of equipment.

2-3.4 Location of Rooms, Spaces, and Equipment.

Locate rooms, spaces, and equipment to ensure orderly workflow, and provide security and property management. Incompatible areas should not be in close proximity; e.g., equipment that vibrates should not be near the C/R area when vibration may affect measurements. Moisture-generating areas such as restrooms and break rooms should not be near the C/R area. Limit outside walls in the C/R area as much as possible.

North and east exposures are preferred. Ensure traffic from movement of equipment, technicians, and customers are isolated from the C/R area. Where possible, design doors and air locks to allow movement of large PMEL equipment and appropriate material handling equipment within the facility. Whenever practical, locate the C/R area adjacent to other environmentally-conditioned areas.

CHAPTER 3 GENERAL DESIGN CRITERIA

3-1 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *General Building Requirements*. UFC 1-200-01 provides guidance on applicability of model building codes, government-unique criteria for typical design disciplines and building systems, and guidance regarding accessibility, antiterrorism, security, high performance sustainability requirements, and safety. Use this FC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein. This chapter provides general criteria only and consists mainly of references to the technical design criteria documents and general considerations. Chapter 4 provides the specific design requirements for PMEL facilities.

3-2 STRUCTURE.

3-2.1 Foundation.

The foundation is site specific and must be designed upon known geotechnical considerations, by an engineer knowledgeable of the local conditions. Facilities must be located to permit laying out unobstructed lines of sight to the target monument, ranging from 45 degrees either side of astronomic north, which is specific to PMELs with Azimuth Reference only. Refer to UFC 3-101-01, *Architecture*, for additional guidance.

3-2.2 Vibration.

The PMEL facility site must be isolated from sources of vibration such as railroads, local heavy vehicle or aircraft traffic, crane or machine operations, foot traffic, or similar disturbances. An infrequently used option is constructing the facility below ground level. An acceptable vibration level for a PMEL is anything less than 10 µin (0.25 µm) displacement peak for frequencies from 0.1 to 30 Hz. The maximum acceleration peak is 0.001 g for frequencies from 30 to 200 Hz. To minimize vibration, apply the guidance in paragraphs 3-2.2.1 through 3-2.2.8.

3-2.2.1 Expansion and Isolating Joints.

Use expansion/isolation joints in the concrete floor on the outside toe of the walls defining the conditioned area to isolate the thermal mass of the floor and reduce vibration transmission. Use vibration isolating joints in the utility room where walls and floor adjoin the main structure.

3-2.2.2 Vibration Equipment Location.

Locate vibration-generating equipment such as blowers, compressors, heating and air conditioning units, vacuum pumps, and transformers on separate, isolated utility pads. Equipment that vibrates should not be located near the C/R area.

3-2.2.3 Specialized Shock Mounts.

Use specialized shock mounts, air bag supports, or isolated massive blocks.

3-2.2.4 Steel Spring Type Isolators.

Mount air conditioning equipment (condenser/compressor or fan coil units) to the structure using steel spring type isolators which limit vibration transmission to 0.001 g or less.

3-2.2.5 Flexible Boots.

Use flexible boots or connectors to reduce vibration transmission through ductwork, piping, and rigid tubing.

3-2.2.6 Rigid Conduit Contact.

Do not allow rigid conduit such as feeders, subfeeders, and their supports to contact other non-supporting objects.

3-2.2.7 Flexible Neoprene-Jacketed Conduits.

Use flexible neoprene-jacketed conduits for connections to vibration producing equipment. Install flexible bonding ground straps to ensure continuity of the ground.

3-2.2.8 Air Bearings and Isolators.

Use vibration isolators or air bearings mounted on workbenches and surface plates where extensive isolation techniques cannot be used. This will reduce vibration transmitted to sensitive instrumentation in contact with these surfaces.

3-2.3 Structural Elements in the Superstructure.

Use masonry walls, metal studs, steel joists, steel columns, and steel beams in the superstructure. Where possible, locate specially conditioned areas within the structure so the walls are interior partitions. The building must be single-story, ground floor, and concrete slab construction; exterior doors must not face prevailing winds. Ensure proper floor load bearing design to account for ancillary equipment. Interior partitions must extend above the vapor barrier of the ceiling.

3-3 EXTERIOR DESIGN.

In general, the building’s image, theme, and fixtures must be consistent with the functions offered. The building design should reflect the local geographical and cultural environment and comply with the appropriate Service and Installation architectural standards.

3-3.1 Exterior Finishes.

The exterior color, texture, and design should be consistent with the programs offered and the local environment in accordance with Installation standards. They should also be appropriate for the building type.

3-3.2 Entrances/Exits.

The main facility entrance to the lobby should serve as a welcome and transition point; elements such as a covered entry are very desirable. In cold climates, provide a canopy (or a recess) at required egress doors to ensure that doors can open completely without obstruction from snow and ice. The number and location of exits must comply with UFC 3-600-01, *Fire Protection Engineering for Facilities,* to preclude being cut off in the event of a localized fire.

3-3.2.1 Covered Equipment Entry.

Provide a protected entrance for unloading equipment: either a double-entry door with a drive through canopy; or a service entry with a roll-up door large enough to allow a small truck or van to back into the unloading area. Quantity and size of equipment handled and weather conditions should determine which entry is appropriate.

3-3.2.2 Service Entrance (Oversized Equipment Entry).

Where oversized equipment cannot be moved through the air lock, provide a set of tightly-sealed double doors between the C/R area and the building exterior. Equip doors with low leakage seals to prevent exfiltration from pressurized C/R areas. Provide a canopy to shield equipment and the laboratory from precipitation when moving oversized equipment in and out. Fully enclose the canopy to create an insulated entryway in extreme climates.

3-3.3 Exterior Walls and Mold.

Comply with current industry standards, UFC 3-101-01, and UFC 3-410-01, *Heating, Ventilating, and Air Conditioning Systems*, during design to help prevent the development of mold in exterior walls.

3-3.4 Doors and Windows.

Provide windows to allow natural light into the facility, considering antiterrorism and energy conservation/sustainable design issues (reference paragraphs 2-1 and 3-6). All windows and unused doors or other openings shall be sealed to prevent non-conditioned air infiltration and dust contamination from outside. Design and arrange doors opening into the PMEL to maintain effective dust and temperature controls. Minimize the number of doors for personnel passage consistent with fire and safety regulations.

3-3.5 Exterior Signage.

The main entrance should be equipped with a clearly visible sign that provides the program hours of operation. Ensure that signage complies with Installation requirements and UFC 3-120-01, *Design: Sign Standards*. Sign placement and type are site-specific, but signs must be strategically located, adequately lit, and of sufficient size to permit proper viewing by individuals approaching the facility.

3-3.6 Utility Rooms.

Mechanical equipment is usually housed separately from major electrical equipment, which should be located in a dedicated electrical utility room. It is critical that equipment fits the space without crowding and allows adequate space for maintenance. Designers should plan on equipment utilizing a minimum of 15 percent of the total structure area. Utility rooms must be structurally (seismically) separate from the rest of the PMEL building. Mechanical and electrical utility rooms must comply with UFC 3-401-01, *Mechanical Engineering*, UFC 3-501-01, *Electrical Engineering*, and UFC 3-520-01, *Interior Electrical Systems*.

3-4 INTERIOR DESIGN AND CONSTRUCTION.

Interior walls should be Type I or Type II construction as outlined in the International Building Code® using noncombustible materials. Interior walls and ceiling should be insulated and have as much thermal mass on the controlled area side of the wall as possible. If the wall is stud construction, use two layers of 5/8-inch (16-millimeter) gypsum board on the C/R side, with batt insulation, air barrier, and 1/2-inch (13-millimeter) gypsum board on the outside. Tape and seal all gypsum board and seal the sill plate. Good workmanship is essential in finishing each joint and seam of the walls to minimize air infiltration and exfiltration. Refer to UFC 3-101-01 for additional guidance. Interior construction should be extremely durable. Use no hollow core wood doors. All interior glass must be tempered safety glass and mirrors must be made of break-resistant materials. Do not place exterior windows (except for optical windows, as required) in the C/R area; however, sealed glass viewing ports may be installed in calibration areas to permit viewing without entering. Pass-through windows are not permitted.

3-4.1 Interior Wall and Ceiling Construction.

3-4.1.1 Vapor Barriers for Walls and Ceilings.

Vapor barriers usually are placed on the warm side of a wall and ceiling. If the primary method of environmental control is cooling, or if heating and cooling are used about equally, place the vapor barrier away from (outside) the conditioned area. This will reduce the probability of moisture buildup, and result in fewer penetrations of the vapor barrier, since most power outlets will be facing into the conditioned area. Where heating is the primary method of environmental control, place the barrier toward the inside of the wall and the ceiling. On concrete masonry units, use foil-face rigid insulation on the outside of the wall. Fur out and finish the wall. Install a vapor barrier underneath new floor slabs. Seal all penetrations in walls, ceilings, and floors.

3-4.1.2 Air Barrier Systems for Walls and Ceilings.

Provide a continuous air barrier system to control air infiltration and exfiltration in environmentally-controlled areas. The purpose of the air barrier is to make the walls and ceiling airtight with materials having a low air permeance or resistance to air flow, to seal the joints and penetrations, and to control air pressure relationships within the building. An air barrier must be provided between spaces that have either significantly different temperature or humidity requirements. Provide excess ventilation air for pressurization and a continuous air barrier system to control infiltration and exfiltration to maintain air tightness. Avoid selecting materials that are too air-permeable, such as fiberboard, perlite board, and uncoated concrete block in air barrier systems.

3-4.2 Clean Construction Protocol.

Cleanliness within a PMEL facility is necessary to: (1) protect precise measurement surfaces from abrasive damage caused by dust particles; (2) prevent contamination of fluids, chemicals, and metals used during the calibration process; although cleanliness and particle filtration requirements for most PMELS are not as stringent as for clean rooms, incorporating clean construction protocol (CCP) in design and construction contracts is recommended.

3-4.3 Interior Finishes.

Finishes should take into account the intended uses, be appropriately durable, and be low maintenance. Finishes should have good acoustical, noise reducing characteristics. All interior finishes must comply with UFC 3-600-01. Facility interior design must comply with Air Force corporate facilities standards, UFC 3-120-10, *Interior Design*, and Air Force interior design standards, as well as applicable installation or agency design standards and policies. Prepare surfaces to prevent, or at least reduce, dust accumulation. Clean concrete masonry thoroughly to remove dirt, fungus, grease, oil, glaze, loose particles, and scale. Fill voids to give a smooth surface without pits or holes. Repair joints, cracks, holes, and other surface defects in gypsum wallboard so the surface is flush and smooth. Where there are painted surfaces, use a smooth, non- chalking, mildew-resistant semi-gloss finish which will stand up to frequent cleaning.

Use light neutral tints, such as light blue or beige, to prevent eye fatigue, increase light reflectivity, and improve lighting efficiency.

3-4.4 Counters and Cabinets.

Counters, casework, and workbenches should be of high-quality and durable construction. Specify Architectural Woodwork Institute (AWI) Premium or Custom for finishes per *AWI Architectural Woodwork Standards*. Workbenches and surface plates mounted on vibration isolators or air bearings should be used in PMELs where extensive isolation techniques cannot be used. This will reduce vibration transmitted to sensitive instrumentation in contact with these surfaces.

3-4.5 Non-conductive Floor Covering.

Non-conductive floor covering has a minimum resistance of 1 x 10^9 ohms (1 giga-ohm). Non-conductive flooring is required to protect personnel servicing equipment where voltages up to 3,000 volts may be present. [Note: Vinyl flooring is inherently non- conductive, provided conductive materials (such as carbon, graphite, etc.) have not been added to reduce the resistance to modify it as either conductive (2.5 x 10^4 to 1 x 10^6 ohms) or static-dissipative (1 x 10^6 to 1 x 10^9 ohms)]. Sheet vinyl is recommended because its smooth, continuous surface simplifies daily cleanup including chemical and mercury spills. Epoxy resin flooring is a suitable alternative, provided it is non-conductive.

3-5 SITE DESIGN AND ORGANIZATION.

The site design and all exterior features must comply with the antiterrorism standards in paragraph 3-6.

3-5.1 Landscaping.

Refer to UFC 3-201-02, *Landscape Architecture*, for landscaping requirements and any base or agency design standards.

3-5.2 Parking and Access Drives.

Provide adequate parking for both staff and patrons with the appropriate access drives. Comply with UFC 3-201-02. Also refer to AFMAN 32-1084.

3-5.3 General Site Lighting.

Ensure that parking areas and the facility have adequate lighting for safety, evacuation, and security measures. Comply with UFC 3-530-01, *Interior and Exterior Lighting Systems and Controls*. Include parking and lighting requirements in final site plan.

3-5.4 Service Drive.

The size of required service vehicles should be verified by the designer prior to planning the service access areas. Provide a service vehicle apron and consolidate service access when possible.

3-6 ANTITERRORISM.

Refer to UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings*, for antiterrorism requirements. Provide controlled access, including protection from unauthorized entry, and security for maintaining classified equipment and documents.

3-7 SERVICES.

3-7.1 Plumbing.

Design domestic hot and cold water, sanitary and storm drainage, propane, fuel oil, and natural gas systems to meet the requirements of UFC 3-420-01, *Plumbing Systems*, and local Installation standards.

3-7.2 Fire Protection.

Refer to UFC 3-600-01 for fire protection requirements. The PMEL facility must have a complete automatic sprinkler system and a fire alarm evacuation system conforming to UFC 3-600-01.

3-7.3 Lighting.

Provide lighting and control systems throughout the facility in accordance with UFC 3-530-01. Refer to Chapter 4 for specific lighting design criteria for each functional area.

3-7.3.1 Illuminance.

Facilities require a minimum uniform illumination, depending on the task requirement, calculated at the midlife of the tubes, as measured at bench level in the various areas. Light shall be evenly distributed to minimize glare, spectral reflection, and radiant heat to the extent that measurements are nominally unaffected by any of these parameters. Refer to TO 00-20-14, *Technical Manual: Air Force Metrology and Calibration Program,* for specific absolute minimum illumination levels in various PMEL rooms. The following areas should have a minimum 50 foot-candles (538 lux) design level: equipment storage, restrooms/toilets, janitor's closet, bench stock, stairways, corridors, halls, airlocks, elevators, shipping docks, and utility/storage rooms. Other areas in the PMEL not listed above will have a minimum 100 foot-candles (1076 lux) design lighting level.

Additional general lighting shall be used for tasks that are difficult to perform within the ambient light level. Other areas must conform to UFC 3-530-01. Provide zone lighting by work area when required, and locate switches near the air lock entrances. Motion sensor lighting is prohibited in the C/R areas. Provide lighting controls per ASHRAE Standard 90.1, *Energy Standard for Buildings Except Low-Rise Residential Buildings*, in areas not involved with the calibration process.

3-7.3.2 Emergency Lighting.

Provide emergency lighting in accordance with NFPA 101, Section 7.9. Evaluate the standard carefully, as its requirements may not include considerations for the unique layout and equipment configurations in a metrology facility. Installed emergency lights are recommended. Ensure emergency lights have a battery backup installed. If portable lights are mounted on the wall, locate an electrical receptacle near the light.

3-7.3.3 Hazardous (Classified) Area Lighting.

Class 1 Division 2 hazardous area light fixtures should be used in hazardous (classified) areas housing pressurized flammable liquids. Protect luminaries located above hazardous classified areas as required in NFPA 70, Article 501, Section 130, (B)(1) through (B)(3).

3-7.4 Electrical.

Provide electric service, distribution equipment, wiring receptacles, grounding, interior and exterior lighting, control, emergency lighting, telephone, communication systems, fire alarm, other health and safety alarms, and intrusion systems in accordance with NFPA 70, UFC 3-520-01, and the latest Installation design requirements. Service grounding system and all wiring methods must meet the current NFPA 70 requirements. All service equipment must be Underwriters Laboratories (UL) listed. Alternately, published proof from an approved independent testing laboratory may be provided.

3-7.4.1 Voltage Regulation.

Voltage drop of the building wiring system will not exceed 3% to any outlet. Provide outlets for technical testing with regulating equipment to maintain voltage within ±2 percent of the basic voltage, except 28 Vdc, which will be regulated to ±3%. Time constant (response time) of the voltage regulators should not exceed 0.3 seconds, and total harmonic distortion must not exceed 5%. Power conditioning and continuation interface equipment (PCCIE) must be supplied by the using agency.

3-7.4.2 Types of Electrical Power.

Normally, electric service will be provided at 480 Vac, 3-phase, 60 Hz. Table 3-1 lists possible PMEL power requirements for testing. This list does not include lighting and air conditioning requirements. Power demand varies depending on the workload of the individual PMEL. The PMEL superintendent will assist the Base Civil Engineer in determining power requirements and equipment heat loads, and identifying any special mission requirements. Design 400 Hz distribution systems to the requirements of UFC 3-555-01N, *400 Hertz Medium Voltage Conversion/Distribution and Low Voltage* Utilization *Systems* (note: motor generator is not real property installed equipment [RPIE]).

Table 3-1. Power Requirements for PMEL Facilities Testing

Nominal System Voltage	Phase	Frequency
277/480	1 & 3	50/60 ± 1 Hz
120/240	1 & 3	50/60 ± 1 Hz
120/208	1 & 3	50/60 ± 1 Hz
208 or 240	1	50/60 ± 1 Hz
120/240	1 & 3	400 ± 10 Hz
120/208	1 & 3	400 ± 10 Hz
28	DC	N/A
220/240	1 & 3	50/60 ± 1 Hz

3-7.4.3 Tagging and Labeling.

Tag or label electrical power outlets, connectors, or receptacles with a technical description of the type or amplitude of a voltage source, the power rating, and phase or connection scheme, and indicate the breaker servicing them.

3-7.4.4 Wiring Installation.

Install electrical wiring in metal raceways, concealed but accessible, in attics, plenums, or utility housings. Install wiring for frequencies greater than 60 Hz in nonferrous raceways and label with the correct frequency. Extend utilities into the C/R area within utility chases concealed in walls and partitions. Do not use under-the-ceiling utility services. Direct overhead utility connections to workbenches and stations are permitted if the most feasible and economical and if the design minimizes dust collection. Use gaskets and seals to maintain room pressure and prevent dust infiltration where ducts, pipes, and conduit penetrate walls.

3-7.4.5 Grounding.

Install grounding in accordance with the National Electrical Code, and Air Force Instruction (AFI) 32-1065, *Grounding Systems*. The resistance to ground of the service ground must be 10 ohms or less. Where 10 ohms cannot be obtained with basic electrode configuration due to high soil resistivity, rock formations, or other terrain features, consider alternate methods for reducing the resistance to earth. Power the C/R area from (an) isolation transformer(s) with an electrostatic shield between the primary and secondary windings installed as a separately derived system as close as practical to the loads. A table, bonded at each end to a static bus bar, may be used in place of the equipotential plane, as appropriate.

3-7.4.6 Electromagnetic Interference/Radio Frequency Interference (EMI/RFI).

The amount of EMI/RFI generated by nearby overhead high voltage lines, radio and TV transmitters, and microwave antennas determines the suitability of a site, and the extent of internal facility shielding required. Most building sites not close to sources of EMI/RFI will meet the electromagnetic requirements for PMELs, since average

magnetic field in the vicinity of overhead electrical distribution lines drops off rapidly with distance. However, EMI from overhead high voltage power lines, radio/TV transmitters and aircraft operations may introduce calibration errors. With maximum currents of up to 243 amperes, average maximum field exposure is approximately 13.53 milligauses at zero feet (zero meters) and 2.48 milligauses at 100 feet (30.5 meters). These levels of exposure would be acceptable for most laboratories. EMI/RFI levels should be reevaluated whenever generators are installed after a PMEL is operational. If excessive EMI/RFI is suspected, contact AFMETCAL.

3-7.4.7 Internal Electromagnetic Interference (EMI/RFI) Control.

Within the laboratory itself, interference suppression should include RF-shielded lenses, ballast RF suppressors, and power line filters for fluorescent lighting. EMI/RFI is best controlled by following the guidance in Military Standard (MIL STD) 188-124B, *Grounding,* Bonding*, and Shielding for Common Long Haul Tactical Communication Systems Including Ground Based Communications - Electronics Facilities and Equipments*; MIL STD 188-125-1, *Department of Defense Interface Standard: High-Altitude Electromagnetic Pulse (HEMP) Protection for Ground-Based C4I Facilities Performing Critical, Time-Urgent Missions*, *Part 1*, *Fixed Facilities*; Military Handbook (MIL HDBK) 419, *Grounding, Bonding, and Shielding for Electronic Equipment and Facilities*; and MIL HDBK 423, *High-Altitude Electromagnetic Pulse (HEMP) Protection for Fixed and Transportable Ground-Based C4I Facilities*.

3-7.4.8 Electrical Outlets and Cabling.

Computer network, intercom, and telephone conduits and outlets should be installed during construction at enough locations to meet current layout and future expansion needs. Cabling should be installed in conduit in the walls, and in metal raceways above suspended ceilings. A doorbell should be installed on the customer entry door. Electrical power loads should not be on the same circuits providing electricity to the calibration areas.

3-7.4.9 Emergency Electrical Power Disconnects.

Emergency electrical power switches or disconnects are recommended at a central location in every room of the calibration area. They should be well-marked, unobstructed, and have a lockout feature. Electrical power switches should not turn off the overhead lights.

3-7.4.10 Electrical Receptacles.

Location and type of electrical receptacles must match the purpose of the equipment served and comply with the National Electrical Code (NEC). It is recommended to locate electrical receptacle high on the wall for portable emergency lights and at mid-wall level for connecting to work benches located along the walls. Do not use the common 60 Hz, 120 Vac receptacles for 28 Vdc, 50 Hz, or 400 Hz services. Install receptacles in accordance with NEC Articles 406, 501, 502, 503, and 647 as shown below:

- Install sufficient number of receptacles and circuits to allow for future changes in layout due to relocation or addition of new measurement systems.

- Install general-use receptacles so that they are accessible every four feet. Do not install a general purpose receptacle in the center of a wall where large equipment or furniture is typically located. Do not install more than six duplex receptacles on a single circuit and situate circuits so that each room has access to at least two circuits.

- Install and mark receptacles in hazardous locations in accordance with NEC Articles 501, 502, and 503.

- Determine placement of special-use receptacles by the location of equipment to be supported. Provide one additional circuit above work benches to allow for future expansion of work bench or services. Mark special-use receptacles in accordance with NEC Article 647.7.

3-7.4.11 Main Power Panels or Services.

If possible, especially in locations having frequent inclement weather, no two adjacent receptacles should be on a single circuit.

3-7.4.12 Backup Power.

Provide a means for connecting a portable backup power unit to serve critical circuits within the PMEL. Use a double-throw switch; and, if feasible, provide a matching plug and receptacle approved by the Base Civil Engineer. Locate the switch for easy access by a power unit. Comply with isolated neutral requirements in NEC 250-5(d), *Alternating-Current Circuits and Systems to be Grounded, Separately Derived Systems*.

3-7.4.13 Electrical Utility Room.

Install electrical facility equipment such as transformers, power distribution systems, frequency converters, rectifiers, and voltage regulators in the utility room. The 28 Vdc power supply and the 400 Hz motor-generator or frequency converter will be provided by the using agency and installed by the contractor. Follow applicable portions of the NEC and Occupational Safety and Health Administration (OSHA) standards. Provide PCCIE for testing and powering sensitive electronic equipment. The using agency (PMEL) must obtain PCCIE through the PCCIE program office, AFLCMC/HBZBD, 6039 Wardleigh Road, Building 1206, Hill AFB UT 84056, (801)-777-5752. PCCIE maintenance is the responsibility of the using agency.

3-7.4.14 Antenna Ports.

An antenna port must be installed in a PMEL facility during construction. Port location is dependent on the location of certain instruments (e.g., precise time (GPS) receivers).

Antenna port penetrations through the walls in the C/R area should be properly finished and sealed to prevent loss of positive pressure.

3-7.5 Communications and Data.

A phone and intercom system is required to allow two-way conversation between rooms in the PMEL facility. Provide conduit runs and terminal boxes to support the intercom, telephone, and computer systems as part of facility design. Include data outlets in walls, recessed floor boxes, and offices to provide internet connection for work areas.

Confirm the technical design requirements for the phone and intercom system with the Laboratory Manager. Provide local area network (LAN) internet connections to work benches for access to technical manuals and maintenance procedures as required.

3-7.6 Alarm System.

Provide an alarm system for intrusion detection to protect equipment and assets. The calibration area environment shall have an alarm system which will relay an alarm when the temperature or humidity is out of tolerance. Provisions for an alarm system must be identified during the planning/programming process.

3-7.7 Heating, Ventilating, and Air Conditioning (HVAC).

Design the HVAC system to meet the requirements of UFC 3-401-01, UFC 3-410-01, and UFC 3-410-02, *Lonworks® Direct Digital Control for HVAC and Other Local Building Systems*.

3-7.7.1 HVAC Design Criteria.

Climatic design criteria will be obtained from UFC 3-400-02, *Design: Engineering Weather Data*. Systems will be designed and sized to maintain space temperature and humidity requirements at the following ambient load conditions:

- The 0.4% dry bulb temperature and the corresponding mean coincident wet bulb temperature.
- The 1% humidity ratio and the corresponding mean coincident dry bulb temperature.
- The 99% dry bulb temperature and the corresponding mean coincident wet bulb temperature.

3-7.7.2 HVAC Systems Required.

Provide separate HVAC zone controls to meet the environmental requirements of the following areas: C/R, administration, support, and shipping and receiving. Provide HVAC system(s) specific to the building (i.e., NOT connected to a central system servicing other buildings). Where a 68 degree room is required, a modular environmental enclosure system can be considered as an option.

3-7.8 HVAC Design Considerations.

3-7.8.1 Equipment Heat Gain.

The using agency must provide the test and measurement equipment specifications, approximate equipment location, and use patterns so that heat gains can be accurately estimated during the predesign stages of the project.

3-7.8.2 Design Analysis.

The HVAC design analysis for new facilities or renovation of existing facilities must include a psychometric analysis documenting that the system meets the PMEL design criteria. The analysis must provide calculations of system cooling load, energy/mass transfer through conditioning equipment and fans, and a system schematic indicating the dry bulb and wet bulb temperatures (or humidity ratios) of outside air, mixed air, supply air, and return air flow streams. The cooling load for this analysis must be based on the load conditions as previously identified. Refer to UFC 3-401-01 and UFC 3-410-01 for details on HVAC design analysis. Provide capability to tie into the base-wide Energy Management Control System (EMCS), if available.

3-7.8.3 Ventilation Air.

Supply ventilation air to satisfy UFC 3-410-01 given the number of occupants and to provide for air exhausted from hoods, etc., to meet the positive pressure requirements for the rooms and the building as a whole. Integrate static pressure monitoring of individual rooms to ensure proper control of ventilation air. See paragraph 3-7.9.5 regarding use of a dedicated outdoor air system. Refer to UFC 3-410-04N, *Industrial Ventilation,* and UFC 3-410-01, for further details on ventilation air systems.

3-7.8.4 Ventilation Filtering.

Filter ventilation air before it enters an air handler, heat recovery equipment, or preconditioning equipment. Use extended media filters with a Minimum Efficiency Reporting Value (MERV) of 8 or greater, in accordance with ASHRAE 52.2-2012, *Method of Testing General Ventilation Air-Cleaning Devices for Removal Efficiency by Particle Size*.

3-7.8.5 HVAC Zone Design.

Provide single zone controls to isolate environmental requirements for each major PMEL area. Size the cooling coils for each space to maintain the required temperature and relative humidity under the location design conditions listed in UFC 3-400-02. Determine the minimum acceptable room air change rate from UFC 3-410-01. The design requirement is to provide an even temperature, consistent with required temperature gradients, throughout the controlled spaces.

3-7.8.6 Air Distribution.

Design the air distribution system to circulate air throughout the facility to prevent stratification. Use non-unidirectional air flow pattern control. Specifications apply within the space 3 feet to 4.9 feet (0.9 meter to 1.5 meters) above the floor (working area); air velocity in the working area must be 25 ± 9.8 fpm (7.6 ± 3 meters per minute). Keep noise level below 45 dB as measured by a meter meeting ANSI/ASA S1.4, *American National Standard Electroacoustics – Sound Level Meters*. Locate heat-generating equipment (such as temperature baths) to prevent heat buildup; also isolate high-heat-generating equipment to maintain temperature within required limits. Localized exhaust may be used for this purpose, provided makeup air requirements do not adversely affect system operation. Locate and select supply air diffusers to ensure even-conditioning of the space. Locate return air grills above heat producing equipment to quickly remove excess heat and minimize temperature fluctuations.

3-7.8.7 HVAC System Response.

The system must heat, cool, humidify, and dehumidify as required at all anticipated flow rates. Design and construction documents must specify: the maximum difference in temperature and humidity between supply air and room air (to establish the rate of change of the room environment); and the number, type, and location of room thermostats and humidistats and how the environmental system should respond to their signals. Duct design should not rely on adjusting dampers on diffusers or grills for control because of the effect on air distribution patterns. Where required, provide dampers inside ducts and install access panels.

3-7.8.8 Air Locks for Calibration and Repair (C/R) Area.

Access into the C/R area is only through air locks. Provide a shoe cleaner at the entrance to the air lock, including a grounded touch pad to dissipate electricity. Use a minimum 6-foot (1.8-meter) -wide air lock at the entrance to the C/R area, with a door opening at least 5 feet (1.5 meters) wide to accommodate large equipment. The air lock must be at least 9 feet (2.7 meters) long to ensure both sets of doors are not open at the same time. Door interlocking systems are not necessary. Double doors are preferred (exception: a sliding door may be used). If double doors are used, install a pair of 3-foot (0.9-meter) -wide double doors to allow movement of large pieces of equipment when necessary. Do not position air lock doors in-line with building entry doors. Air lock doors must have 24- by 30-inch (610- by 760-millimeter) shatterproof glass vision panels (or the closest standard size that fits) and bumpers to prevent equipment and cart damage. Air will flow from the C/R area through the air lock toward the administrative or shipping and receiving areas. Install gasket-type stops, astragals, automatic door bottoms on air lock doors located closest to the C/R areas, and a properly sized grille above the inside air lock doors to permit air flow through the air lock. Seal joints between doors and frames with gaskets.

3-7.8.9 Modular Environmental Enclosure Considerations.

Provide an off-the-shelf, self-contained, environmentally-controlled module where a 68 degree room is required, as an option. Typically, they are more cost effective and

provide better environmental control for the stringent environmental requirements. Their self- contained environmental system provides temperature and relative humidity control, and dust particle filtration. The modular structure is normally installed inside the PMEL, but separate from the C/R area. Before contracting construction of a modular environmental enclosure, consider: (1) size (fits the space); (2) possible vibration and electromagnetic interference; and (3) volume and type of work to be processed. The environmental enclosure system should include the following line items as shown in Table 3.2.

Table 3-2. Modular Environmental Enclosure Design Considerations

Design Features
External duct work, plumbing, wiring, painting, and testing as part of the installation
An electrical supply system providing protection from voltage surges, spikes, or transient noise.
Control equipment with good earth ground.
A suitable drain for condensate disposal in the fan-coil area.
A smooth concrete floor for the enclosure installation, with maximum deviation in the horizontal plane of 3/8 in (9.5 mm).
Non-conductive vinyl floor covering.
If required for the humidification system, a year-round supply of potable water operating at a flow rate and pressure required by the system.

3-7.9. HVAC Equipment Selection.

3-7.9.1 Maintainability.

To ensure maintainability, select and locate equipment to provide adequate access for servicing, filter replacements, and coil removal.

3-7.9.2 Moisture Carryover.

To preclude moisture carryover, coil face velocities must not exceed 550 fpm (167.6 m/min).

3-7.9.3 Cooling Coil Characteristics and Performance Requirements.

Specify cooling coil characteristics and performance requirements in the construction bid documents. These requirements include total cooling capacity, sensible capacity, coil design entering and leaving air conditions (wet and dry bulb temperatures), design airflow rate, face velocities, coil sensible heat ratio, and entering chill water temperature.

3-7.9.4 Dehumidification and Energy Consumption.

Select equipment that will meet the design requirements for dehumidification and provide the lowest life cycle cost and energy consumption.

3-7.9.5 Dedicated Outdoor Air System (DOAS).

DOAS systems should be considered, with other options, for humidity control and supplying ventilation air, especially in high-humidity areas. The DOAS supplies a volume of preconditioned makeup/outside ventilation air to the calibration areas of the PMEL. The system must be equipped with heating and cooling (chilled water/glycol) coils and controls to temper outside air to a neutral dry bulb temperature and regulate humidity levels. In some climates, an air-to-air heat exchanger may be beneficial to precondition makeup air. Humidity in non-administrative areas will be controlled by regulating the humidity in the outside/makeup air system. Coils must meet 99% design conditions. Ensure that DOAS systems are designed to handle both the ventilation and zone-generated latent loads. In humid areas, the amount of conditioned outside air required to dehumidify the calibration areas (see Figure 2-2) may exceed the amount required for ventilation and makeup. In these cases, a portion of the return air can be drawn through this system and dehumidified with the outside air stream. To facilitate inspection and cleaning of coils, install access doors between coils, and ensure coils are no more than eight rows deep. Also consider using desiccants in areas of high humidity. Refer to UFC 3-410-01 for further design details.

3-7.9.6 Ducted Return Air System.

Provide a fully-ducted return air system. Use of the space above the ceiling as a plenum is not allowed.

3-7.9.7 Piping Insulation.

Insulate piping with an operating temperature below dew point with jacketed insulation meeting the cold piping requirements of UFGS 23 07 00, *Thermal Insulation for* Mechanical *Systems*. The insulation jacket must be sealed to provide an exterior vapor barrier.

3-7.9.8 Maintenance Access.

Sufficiently safe access space must be provided for the maintenance of valves, variable air volume (VAV) boxes, dampers, controls, and other HVAC components.

3-7.9.9 Equipment Compliance with Design.

Construction specifications must provide documentation that HVAC equipment submittals for proposed equipment are in compliance with the design specifications. Design calculations should recognize the effect of brief deviations in outside temperature and humidity beyond those listed. Careful application of the weather data

found in UFC 3-400-02 is essential to develop designs that meet critical environmental control requirements. The designer should optimize the selection of cooling equipment to take into account all aspects of performance, reliability, maintainability, and capital and maintenance costs. Calculate equipment sizing as described in UFC 3-410-01.

3-7.9.10 Chilled Water Equipment Selection.

A chilled water system with reheat is the recommended option to maintain required temperature tolerances in PMELs. A central building chilled water system with modulating control is most satisfactory for the required 40 to 42 °F (4.4 to 5.5 °C) water. The optimum supply and return water temperature differential must be determined by life cycle cost analysis. Select compressors that are the most efficient over the range of anticipated loads.

3-7.9.11 Recording Devices, Monitoring and Alarms.

Temperature and humidity must be monitored and recorded continuously, and pressure must be monitored. The recording system must be continuous, and use self-contained sensors/recorders, or remote sensors with centrally-located recorders. Sensors are required in each separate room in the calibration area, and a minimum of one set of sensors for every 2000 ft^2 (186 m^2) of calibration area. When selecting recording devices, consider accuracy and response time; critical environments require immediate response and high accuracy. Mount sensors in the center of the room away from walls, vibration, sunlight, and supply air diffusers, as near as possible to the most critical area of measurement. If the PMEL facility is monitored by a base-wide EMCS system, the system will transmit an alarm when any space goes out of tolerance for temperature, humidity, or pressure. Notice of the alarm will be communicated by automatic notification back to PMEL staff. Both the recording device and the alarm system will indicate real time. All sensors, including wall-mounted assemblies, will be removable for calibration. Refer to TO 00-20-14.

3-7.9.12 Accuracy of Recording Devices.

The following requirements apply to temperature and humidity recorders:

- Recording devices monitoring 68 °F (20 °C) C/R areas must be accurate to a minimum of ± 0.5 °F (± 0.28 °C), ± 5% RH.
- Recording devices monitoring 73 °F (22.8 °C) C/R areas must be accurate to a minimum of ± 2.0 °F (± 1.11 °C), ± 5% RH.
- Recording devices must be calibrated across the full range for the area being monitored.
- If a computerized system is used to record environmental data, the time between data samples shall not exceed 15 minutes.
- Daily or weekly charts must be used when not using computerized or roll type recording devices.

3-7.9.13 Room Filtration.

The 68 degree room must have a filtration system which satisfies a particle count not exceeding 700 particles per ft^3 (24,700 particles per m^3) of atmosphere, 5 microns and larger; and 100,000 particles per ft^3 (3,530,000 particles per m^3) of atmosphere, 0.5 microns and larger. Accurately describe filter installation to ensure easy access and quick changing of filters, minimizing air system shutdown. Install diaphragm-activated draft gages with remote audible alarms across all filter banks to signal when filter replacement is required. (Reference UFC 3-410-01 for details on filter requirements.)

For all other spaces, air filters will have a MERV of 8 when tested by an acceptable atmospheric dust spot test. (Reference ANSI/ASHRAE 52.2-2012.)

Add filter specification and installation requirements to the maintenance manual for the building.

3-7.10 Compressed Air and Nitrogen Systems.

3-7.10.1 Compressed Air and Nitrogen Supply.

Compressed air and nitrogen must be supplied considering the requirements for the type and number of flow calibrators necessary to accommodate the workload. Compressed air delivered to flow calibrators must be of instrument quality conforming to the requirements of ANSI/ISA-S7.0.01, *Quality Standard for Instrument Air*.

Compressed nitrogen must conform to the requirements of Defense Logistics Agency (DLA) A-A-59503A (Commercial Item Description) *Nitrogen, Technical*, Type I, Class I Grade B. Service must be adequate to support the simultaneous operation of all major systems in the facility. Refer to NFPA 55, *Compressed Gases and Cryogenic Fluids Code*, for safety considerations for compressed air and nitrogen gas.

3-7.10.2 Compressed Air Quality.

Use oil-free, dry, compressed air for technical use in the C/R area. Compressed air for the equipment cleaning room must be supplied from an oil-free compressor. The compressed air supplied to the cleaning stations must have an adjustable regulator with a 0-35 psig range at the stations. Compressed air must conform to ANSI/ISA S7.0.01, with minimum pressure of 120 psig (827 kPa). The pressure of compressed air used at work benches should be reduced with a precision valve and a 0-827 kPa gauge.

Compressed air quality for technical use in the C/R area or for operating TMDE must satisfy operating manuals for the TMDE to be serviced. In no case will the oil content of compressed air be greater than 24 ppm (wt) and the compressed air no greater than -40 °F (-40 ºC) atmospheric dew point. (For more information on atmospheric dew point, refer to the latest version of ASHRAE's *Fundamentals* Handbook, chapter

on psychrometrics). Reduce the line pressure at the work stations, generally to 15 psig (103 kPa), depending on mission requirements. This quality may be achieved using dryers fitted with appropriate pre-filters or coalescent air filters that remove oil and particulates. Provide an in-line oil monitor to check quality. Supply a refrigerated dryer for high flow requirements. Minimum filter requirement for equipment cleaning areas for the incoming airline is 75 microns. All air lines into the laboratory must have an automatic blow-down valve ahead of each filter. Each top connection and line tie must lead off the top of the line. The number of outlets and total capacity may vary by individual laboratory; but normally, a minimum 20 scfm (9.4 L/s) is needed. Each PMEL organization will determine specific requirements and incorporate them into the design criteria. Install the air compressor in the utility room as **2**\ furniture, fixtures, and equipment (FF&E) /**2**/ and size it to satisfy total facility requirements. Mark compressed air lines to show pressure and appropriate piping color code for the service.

3-7.10.3 Dry Nitrogen.

Water-pumped dry nitrogen (oil free) is required for technical use. It must conform to DLA A-A-59503A. Install dry nitrogen cylinders in the utility room. Piping run to the C/R area must be rated at 1600 psig (11032 kPa). Mark nitrogen lines to show pressure.

Review design requirements to determine the number of lines required.

3-8 SUSTAINABLE DESIGN.

Use an integrated approach to the planning and design of PMEL Facilities that minimizes energy consumption and optimizes life cycle cost renewable energy possibilities. Comply with the guidance in UFC 1-200-02, which addresses Air Force sustainable policy.

This Page Intentionally Left Blank

CHAPTER 4 SPECIFIC DESIGN CRITERIA

4-1 PMEL FUNCTIONAL AREA DESIGN CRITERIA.

This chapter identifies the specific design requirements for each functional area. Tables 4-1 through 4-13 provide this data in a standard Functional Data Sheet format.

Table 4-1. Administrative Offices

Description/ Usage	The administrative offices consist of a mix of private and open office space. Locate the site manager's office and the administrative staff near the main laboratory entrance to control building access and to receive visitors. Generally speaking, the following office spaces are provided: Flight Chief or Site Manager, Laboratory Chief, Administrative and support staff, and Quality Assurance Supervisor. The main laboratory entrance is usually combined with a waiting and equipment check-in and pickup area. Refer to AFMAN 32-1084 for office space sizes and requirements.
Min. Ceiling Ht.	9 ft (2.74 m) finished ceilings to provide a finished surface and to conceal conduits
Finishes	**Walls.** Painted gypsum wall board with flush and smooth surface to reduce dust. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductive material. Static dissipative carpet may be added for offices. **Ceiling.** Acoustical Ceiling Panels (ACP). Provide air-tight, dust-tight ceiling access panels for environmental system balancing and required maintenance. **Windows.** Where possible, locate offices on exterior wall and provide windows for natural light admission.
Plumbing	Drinking fountain.
HVAC	Reference the most recent Air Force or installation policy on temperature set points for HVAC systems.
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Ensure an adequate number of circuits to power all equipment. Provide standard duplex outlets in closed offices as required. Install additional outlets for data, telephones and to operate shared equipment such as printers, fax, etc.
Lighting	100 foot-candles (1076 lux) ambient lighting.
Communication	**CCTV.** None required. **CATV/Internal Video:** None required. **PA/Audio.** One speaker, with controls in the Flight Chief's/Site Manager's office. **Telephone.** One line per staff plus one additional line for fax and copier. **Data.** One outlet per staff plus one outlet for each printer, copier, scanner, etc. **Security.** None required.
Casework/Built-in Equipment	A custom-built customer service counter to separate customer incoming equipment storage from the completed equipment storage and calibration areas.
Furnishings Fixtures & Equipment (FF&E)	**Private Offices**—Furniture for 120 ft^2 (11 m^2) or 100 ft^2 (9.3 m^2) office: desk, credenza, filing cabinet, desk chair, and two side chairs. **Workstations**—Furniture for 64 ft^2 (6 m^2) workstation: desk chair and side chair for open offices. Workstation systems furniture must provide adequate space for filing and overhead storage.
Special Requirements	Side lights next to the office doors for supervision and security.
For use during project execution by the appropriate Service agency	
Occupancy	Staff, customers
Min. net ft^2 (m^2)	

Table 4-2. Conference Room/Training Room

Description/ Usage	This space is used as a conference and training room for related PMEL business. In sizing the room, consider number of personnel that will use the room; and training aids and furnishings required. Locate near the Flight Chief's/Site Manager's office and provide space for special PMEL projects.
Min. Ceiling Ht.	9 ft (2.74 m)
Finishes	**Walls.** Painted gypsum wall board with flush and smooth surface to reduce dust. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductive material. Static dissipative carpet may be added. **Ceiling.** ACP; air-tight, dust-tight ceiling access panels for environmental system balancing and required maintenance.
Plumbing	None required.
HVAC	Reference the most recent Air Force or installation policy on temperature set points for HVAC systems.
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Ensure an adequate number of circuits to power all equipment. Provide standard duplex outlets in closed offices as required. Install additional outlets for data, telephones and to operate equipment such as printers, fax.
Lighting	100 foot-candles (1076 lux) ambient lighting. Provide dimmable recessed lighting for training purposes.
Communication	**CCTV.** Outlets as required for coverage. **CATV/Internal Video.** One outlet as required. **PA/Audio.** One speaker. **Telephone.** One line with conference room capability. **Data.** Minimum of one outlet. Consider providing additional outlets for training purposes for internet data connection. **Security.** None required.
Casework/Built-in Equipment	Storage closet for training materials and audio-visual cart. Provide an electrically operated retractable screen, a built-in computer projector, and conference call capability.
Furnishings Fixtures & Equipment (FF&E)	CCTV cameras per the outlet count. Tables, chairs, bulletin board with tack surface and dry-erase board. Consider providing overhead projector, printer, and TV, VCR, and DVD player.
Special Requirements	Consider the acoustics of the space and features to eliminate potential distractions. Provide a minimum sound transmission coefficient (STC) rating of 50 to 55. Provide a vision panel in the door.
For use during project execution by the appropriate Service agency	
Occupancy	Staff, customers
Min. net ft^2 (m^2)	

Table 4-3. Shipping, Receiving, and Equipment Storage

Description/ Usage	Shipping and receiving area dedicated to customer support for test items. Includes control counter to receive and pickup test items. Install equipment storage area in conjunction with shipping and receiving.
Min. Ceiling Ht.	10 ft (3.05 m)
Finishes	**Walls.** Painted gypsum wall board with flush and smooth surface to reduce dust. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductive material. **Ceiling.** ACP; air-tight, dust-tight ceiling access panels for environmental system balancing and required maintenance.
Plumbing	Work sink with hot and cold water connections and a floor drain.
HVAC	Reference the most recent Air Force or installation policy on temperature set points for HVAC systems
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Outlets per code and additional outlets as necessary to operate any dedicated equipment.
Lighting	100 foot-candles (1076 lux) ambient lighting.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** One speaker. **Telephone.** One line with internal two-way communication. **Data.** One outlet per staff member, plus one outlet for each printer, copier, scanner, etc. **Security.** None required.
Casework/Built-in Equipment	Work bench(s) within the storage area for equipment inspection and review. Secure storage area for equipment, tools, supplies, and test items. Include adequate shelving, bins, and open end cubicles to store equipment. Install additional areas as required for storage, depending on volume of workflow.
Furnishings Fixtures & Equipment (FF&E)	None required.
Special Requirements (Covered Equipment Area)	A protected entrance for unloading equipment: either a double-entry door with a drive-thru canopy; or a service entry with a roll-up door large enough to allow a small truck or van to back into the unloading area. The quantity and size of equipment handled and weather conditions should determine which entry is appropriate.
For use during project execution by the appropriate Service agency	
Occupancy	Staff, customers
Min. net ft^2 (m^2)	

Table 4-4. 68 Degree Room

Description/ Usage	Where a 68 degree room is required, provide an area in the PMEL, with utilities, to install an off the shelf modular environmental control module. The 68 degree room is used to maintain a closely-controlled environmental area for calibration and use of higher accuracy dimensional TMDE.
Min. Ceiling Ht.	10 ft (3.05 m)
Finishes	**Walls.** Painted gypsum wall board with flush and smooth surface to reduce dust. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductive material. **Ceiling.** ACP; air-tight, dust-tight ceiling panels for environmental system balancing and required maintenance.
Plumbing	None required.
HVAC	68 ± 1 °F (20 ± 0. 6 °C) and an optimum RH of 35, +10/-15%. The temperature may not vary more than 1 °F (0.6 °C) in any one hour period during normal system operation. Maximum temperature gradient across the room is 2 °F (1.1 °C). A minimum positive static pressure of 0.05 inch of water (12.5 pascals) compared to ambient pressure is required to prevent infiltration of dust-laden air.
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Outlets per code and additional outlets as necessary to operate any dedicated equipment.
Lighting	100 foot-candles (1076 lux) ambient lighting using permanent overhead-recessed vapor-proof/dust-resistant fixtures sealed with gaskets to prevent air or moisture leakage and dust accumulation/intrusion from the interstitial area.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Onespeaker. **Telephone.** One line with internal two-way communication. **Data.** One LAN Internet connection per work bench, and a WLAN signal, if required. **Security.** None required.
Casework/Built-in Equipment	Work bench(s) within the storage area for equipment inspection and repair.
Furnishings Fixtures & Equipment (FF&E)	Modular environmental enclosure system will be provided, per user requirements, to meet environmental requirements. The modular structure is normally erected inside the building, along with the environmental control system, electrical system, laboratory equipment, and furniture. Typically, the modular system is more cost effective based on life cycle cost.
Special Requirements	The 68 degree room must have a filtration system which satisfies a particle count not exceeding 700 particles per ft^3 (24,700 particles per m^3) of atmosphere, 5 microns and larger; and 100,000 particles per ft^3 (3,530,000 particles per m^3) of atmosphere, 0.5 microns and larger. Design the filter installation to ensure easy access and quick changing of filters, minimizing air system shutdown. Install diaphragm-activated draft gages with remote audible alarms across all filter banks to signal when filter replacement is required.
For use during project execution by the appropriate Service agency	
Occupancy	Staff, customers
Min. net ft^2 (m^2)	

Table 4-5. Calibration and Repair (C/R) Area

Description/ Usage	This area is maintained under a positive pressure at specified temperature and humidity levels. Air locks are required for entry into the C/R area. Locate the C/R area adjacent to other conditioned areas. Use only oil-free, dry, compressed air.
Min. Ceiling Ht.	10 ft (3.05 m)
Finishes	**Walls.** Painted gypsum wall board with flush and smooth surface to reduce dust. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductive material. **Ceiling.** ACP; air-tight, dust-tight ceiling panels for environmental system balancing and required maintenance.
Plumbing	None required.
HVAC	73 ± 6°F (22.8 ± 3.3 °C) for Type II and Type III PMELs. Size cooling coils to maintain an optimum operational RH level of 35, +10/-15%. Refer to UFC 3-400-02. A minimum positive static pressure of 0.05 inch of water (12.5 pascals) compared to ambient pressure is required to prevent infiltration of dust-laden air. Exhaust ventilation systems must accommodate the fume hoods over the temperature calibration baths.
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Outlets per code and additional outlets as necessary to operate any dedicated equipment, such as printers, fax, etc.
Lighting	100 foot-candles (1076 lux) ambient lighting using permanent overhead-recessed vapor-proof/dust-resistant fixtures sealed with gaskets to prevent air or moisture leakage and dust accumulation/intrusion from the interstitial area.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Onespeaker. **Telephone.** One line with internal two-way communication. **Data.** One LAN internet connection per work bench plus an outlet for printer/copier/ scanner. Ensure WLAN signal is available, if required. **Security.** None required.
Casework/Built-in Equipment	Work bench(s) within the storage area for equipment inspection and repair.
Furnishings Fixtures & Equipment (FF&E)	A monolithic surface of gypsum or plaster construction with finished joints between the walls and ceiling. If the wall is stud construction, use two layers of 5/8-in (16-mm) gypsum board. Install compressive base sill plate seals under all walls enclosing this area. Tape and seal all wall and ceiling penetrations (conduit, pipe, duct and light fixtures, etc.) to ensure positive pressure in the area.
Special Requirements	Air locks: Use a minimum 6 ft- (1.8 m-) wide air lock at the entrance to the C/R area, with a door opening at least 5 ft (1.5 m) wide to accommodate large equipment. Install gasket-type stops, astragals, and automatic door bottoms on airlock doors located closest to the C/R Area. Seal joints between doors and frames with gaskets.
For use during project execution by the appropriate Service agency	
Occupancy	Staff, customers.
Min. net ft^2 (m^2)	

Table 4-6. Temperature/Humidity Sensitive Area

Description/ Usage	This is a special temperature/humidity sensitive (T/H S) controlled area for PMELs that do not have a requirement for a 68 degree room.
Min. Ceiling Ht.	10 ft (3.05 m)
Finishes	**Walls.** Painted gypsum wall board with flush and smooth surface to reduce dust. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductive material. **Ceiling.** ACP; air-tight, dust-tight ceiling panels for environmental system balancing and required maintenance.
Plumbing	None required.
HVAC	The temperature and humidity requirements for this area are 73 ± 2 °F (22.8 ± 1.1 °C) and an RH of 35, +10/-15%. Though room temperature may vary by 4 °F (2.2 °C), the temperature may not vary more than 1 °F (0.5 °C) in any one hour period during normal system operation. Maximum temperature gradient across the room is 2 °F (1.1 °C). A minimum positive static pressure of 0.05 inch of water (12.5 pascals) compared to ambient pressure is required to prevent infiltration of dust-laden air.
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Outlets per code and additional outlets as necessary to operate any dedicated equipment.
Lighting	100 foot-candles (1076 lux) ambient lighting using permanent overhead-recessed vapor-proof/dust-resistant fixtures sealed with gaskets to prevent air or moisture leakage and dust accumulation/intrusion from the interstitial area.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Onespeaker. **Telephone.** One line with internal two-way communication. **Data.** One LAN internet connection per work bench plus an outlet for a printer, copier, and scanner. Ensure WLAN signal is available, if required. **Security.** None required.
Casework/Built-in Equipment	Work bench(s) within the storage area for equipment inspection and repair.
Furnishings Fixtures & Equipment (FF&E)	A modular clean room may be provided to meet these requirements. Modular environmental enclosure systems are available as controlled laboratories for high precision metrology. The self-contained environmental system provides temperature and relative humidity control, and dust particle filtration. The modular structure is normally erected inside a building, along with the environmental control system, the electrical system, laboratory equipment, and furniture.
Special Requirements	None required.
For use during project execution by the appropriate Service agency	
Occupancy	Staff, customers.
Min. net ft^2 (m^2)	

Table 4-7. Liquid Flow Calibration Area

Description/ Usage	A specially-equipped, isolated area required in PMELs to perform liquid flow meter calibration using propylene glycol. Ensure that doors swing out in the direction of egress per the NFPA 101. Determine floor space by considering the type and number of flow calibrators necessary for the mission. Include space for work benches, tool storage, and systems furniture as required.
Min. Ceiling Ht.	10 ft (3.05 m), or high enough to reasonably clean mission equipment.
Finishes	**Walls.** Painted gypsum wall board with flush and smooth surface to reduce dust. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductive material. **Ceiling.** ACP; air-tight, dust-tight ceiling panels for environmental system balancing and required maintenance.
Plumbing	Supply chilled water considering the requirements of flow calibrator heat exchangers. Minimum service consists of 20 gpm (75.7 L/min) of 40 ± 5 °F (4.4 ± 2.7 °C) water for a low flow liquid flow calibrator and 25 gpm (94.6 L/min) of chilled water for a high flow liquid flow calibrator supplied using 1.5 inch tubing.
HVAC	Ventilate the area according to the requirements of 29 CFR 1910, *Occupational Safety and Health Standards*. Provide a ventilation rate of not less than 1 cfm per square foot of solid floor area. Temperature requirement is 73 ± 6 °F (22.8 ± 3.3 °C) and an RH of 35, +10/-15%. A minimum positive static pressure of 0.05 inch of water (12.5 pascals) as compared to ambient pressure is required to prevent infiltration of dust-laden air.
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Outlets per code and additional outlets as necessary to operate any dedicated equipment. Each liquid flow calibrator requires a 3-phase, 208V, 20 amp outlet.
Lighting	100 foot-candles (1076 lux) recessed vapor-proof/dust-resistant fixtures.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** One speaker. Provide an emergency call/alarm in the liquid flow calibration area. **Telephone.** One line per staff. **Data.** LAN internet connections and ensure WLAN signal is available, if required. **Security.** None required.
Casework/Built-in Equipment	Install double doors to facilitate installation of large liquid flow calibration units and test equipment. Two sizes of liquid flow calibrators may be installed: low flow liquid flow calibrator footprint: 1.9 ft x 6.3 ft (0.6 m x 1.9 m); high flow liquid flow calibrator footprint: 2.17 ft x 13.9 ft (0.67 m x 4.24 m). The number of calibrators may vary from one to four, depending on mission.
Furnishings Fixtures & Equip. (FF&E)	Furniture for 64 ft^2 (6 m^2) workstation: desk chair and side chair for open offices. Workstation systems furniture must provide adequate space for filing and overhead storage.
Special Req.	Supply utilities, services, furnishings, tools, and equipment, including the following: Compressed air, cleaning system, exhaust system, work bench with lipped stainless steel top that drains into the sink, and a vacuum port. Supply oil-free dry compressed air at 80 psig (552 kPa) and 75 gpm (284 L/min) for a low flow liquid flow calibrator and 80 psig (552 kPa) and 150 gpm (568 L/min) for a high flow liquid flow calibrator.
For use during project execution by the appropriate Service agency	
Occupancy	Staff, customers.
Min. net ft^2 (m^2)	

Table 4-8. Equipment Cleaning Room

Description/ Usage	A specially-equipped and isolated area required for cleaning and washing of mechanical, electrical, and electronic equipment. Install a drying oven meeting the requirements of the standard PMEL cleaning room. Install a bench type slot hood or canopy hood to remove fumes from calibration baths and gas monitors
Min. Ceiling Ht.	10 ft (3.05 m), or high enough to reasonably clean mission equipment.
Finishes	**Walls.** Ceramic wall tile or other hard surfaces approved for the cleaning room. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductivematerial. **Ceiling.** ACP; air-tight, dust-tight ceiling panels for environmental system balancing and required maintenance.
Plumbing	Hot and cold water supply piping and floor drain with mercury trap to be connected to the government supplied cleaning system and utility sink..
HVAC	Reference most recent Air Force or installation policy on temperature set points for HVAC systems. Exhaust ventilation systems must accommodate the fume hoods over temperature calibration baths. Install a bench style slot hood to pull fumes away from the breathing zone where a canopy type hood would allow fumes into the breathing zone. The drying oven requires 212 cfm (6 m^3/min) of room air for the purge blower intake and exhaust.
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Dedicated 120/240 Vac single-phase 20 amp circuit hard-wired to a government- or contractor-supplied electronic drying oven with disconnect switch. This circuit should not be connected to the electrical distribution system serving the calibration area.
Lighting	100 foot-candles (1076 lux) ambient lighting using permanent overhead-recessed vapor-proof/dust-resistant fixtures sealed with gaskets to prevent air or moisture leakage and dust accumulation/intrusion from the interstitial area.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** One speaker and an emergency call/alarm in the equipment cleaning room that sounds at the control counter in the event of an emergency. **Telephone.** None required. **Data.** None required. **Security.** None required.
Casework/Built-in Equipment	Install a cleaning unit and drying oven in the equipment cleaning room. Each cleaning unit or drying oven requires 15 ft^2 (1.4 m^2) of floor space. See the Power and HVAC sections above for electrical and exhaust requirements.
Furnishings Fixtures & Equip. (FF&E)	Install a built-in eye-wash system for safety requirements. A vacuum port will be provided in the equipment cleaning room. Install a deep industrial sink and work bench with lipped stainless steel top that drains into the sink. **2**\ Properly size air compressor to meet facility requirements. /**2**/
Special Req.	Locate the cleaning and washing area outside the calibration area. Supply utilities, services, furnishings, tools, and equipment, including the following: compressed air with oil-free compressor, cleaning system, drying oven, and exhaust vent system. Install a vacuum port in the equipment cleaning room.
For use during project execution by the appropriate Service agency	
Occupancy	Staff, customers.
Min. net ft^2 (m^2)	

Table 4-9. Copy/Work/Break Room

Description/ Usage	This space is used as a staff workroom for copying, meetings, breaks, and lunches.
Min. Ceiling Ht.	9 ft (2.74 m)
Finishes	**Walls.** Painted gypsum wall board with flush and smooth surface to reduce dust. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductive material. Static dissipative carpet may be added for copy/ work/break room. **Ceiling.** ACP; air-tight, dust-tight ceiling panels for environmental system balancing and required maintenance.
Plumbing	Two-compartment countertop sinks with hot and cold water supply. Floor drain. If an icemaker is desired, provide a cold water connection.
HVAC	Reference the most recent Air Force or installation policy on temperature set points for HVAC systems
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Outlets per code; one additional outlet at counter height for convenience; additional outlets necessary to operate dedicated equipment such as the copier, fax machine, printers, coffee machine, refrigerator, time clocks, microwave, and various other office machines.
Lighting	100 foot-candles (1076 lux) lighting fixtures with dimmable lights.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Onespeaker. **Telephone.** One line. **Data.** Outlets as required for equipment. **Security.** None required.
Casework/Built-in Equipment	Two separate solid-surface countertops: one for food/break functions and one for administrative functions as required
Furnishings Fixtures & Equipment (FF&E)	Copier, fax machine, printers, table, chairs, microwave, coffee machine, refrigerator, bulletin board with tack surface, dry-erase board, and other office equipment as required.
Special Requirements	Locate copy/work/break room on exterior wall and provide windows for natural light admission. Provide a vision panel in the door.
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Customers.
Min. net ft^2 (m^2)	

Table 4-10. Public Toilets/Janitor's Closet

Description/ Usage	These toilet rooms are used primarily by visitors, PMEL staff, and customers checking in or picking up equipment. They should be located near the main laboratory entrance in the waiting room and equipment check-in and pickup area.
Min. Ceiling Ht.	9 ft (2.74 m)
Finishes	**Walls.** Epoxy or enamel painted moisture-resistant gypsum wall board with a ceramic tile wainscot. Consider full ceramic tile walls with integral patterns. Use a dark-colored epoxy grout. **Floor.** Ceramic tile with integral patterns. Use a dark-colored epoxy grout. **Ceiling.** Epoxy or enamel painted moisture-resistant gypsum board. None needed for janitor's closet.
Plumbing	Wall-hung water closets, wall-hung urinals and lavatories based on the applicable code for the calculated occupancy of the laboratory. Floor drain and a keyed hose bib.
HVAC	Ventilate exhaust to the outside per code. Provide 8 to 12 air changes per hour.
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Outlets per code.
Lighting	50 foot-candles (538 lux) lighting fixtures
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Onespeaker. **Telephone.** None required. **Data.** None required. **Security.** None required.
Casework/Built-in Equipment	Solid-surface countertop with either underhung or integral sink. Solid composite toilet and urinal partitions. Consider permanent ceramic-tile partitions. Toilet accessories: toilet paper dispensers, paper towel dispenser with integral trash receptacle, robe hooks, grab bars, sanitary napkin disposal (female water closet stalls), seat cover dispensers, and soap dispensers. Mirror.
Furnishings Fixtures & Equipment (FF&E)	None required.
Special Req.	Janitor's closet associated with or in proximity of these toilets. This closet includes a floor mop sink with hot and cold water and a hose connection, a floor drain, and storage for pails, mops, vacuums, and related cleaning supplies and equipment. Include a lockable door (which can be opened from the inside) with a vision panel. Lockable cabinets for cleaning supplies. Exhaust ventilation in janitor's closet to remove chemical fumes.
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Customers.
Min. net ft^2 (m^2)	

Table 4-11. Night Vision Area

Description/ Usage	Night vision calibration area for testing under controlled conditions of lighting, temperature, and humidity. The night vision ANV-126 NVD Infinity Focus System should be calibrated in a room with ambient lighting levels of less than 0.1 foot-candles in the general area of the test set. The ANV-20/20, field deployable, low light level calibration system requires total darkness during the adjustment procedures for the night vision test to accomplish calibration.
Min. Ceiling Ht.	10 ft (3.05 m)
Finishes	**Walls.** Painted gypsum wall board with flush and smooth surface to reduce dust. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductive material. **Ceiling.** ACP; air-tight, dust-tight ceiling panels for environmental system balancing and required maintenance.
Plumbing	None required.
HVAC	73 ± 6 °F (22.8 ± 3.3 °C) and a RH of 35, +10/-15%. A minimum positive static pressure of 0.05 inch of water (12.5 pascals) compared to ambient pressure is required to prevent infiltration of dust-laden air.
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Outlets per code and additional outlets as necessary to operate any dedicated equipment.
Lighting	During non-test conditions, provide 100 foot-candles (1076 lux) ambient lighting. Night vision calibration lighting levels must meet minimum requirements of the test set being calibrated.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Onespeaker. **Telephone.** One line with internal two-way communication. **Data.** LAN internet connections and ensure WLAN signal is available, if required. **Security.** None required.
Casework/Built-in Equipment	Work bench(s) within the night vision area for equipment inspection and review. Secure storage area for equipment, tools, supplies, and test items. Include adequate shelving, bins, and open end cubicles to store equipment. Install additional areas as required for storage, depending on volume of workflow.
Furnishings Fixtures & Equipment (FF&E)	None required.
Special Requirements	None required.
For use during project execution by the appropriate Service agency	
Occupancy	Staff, customers.
Min. net ft^2 (m^2)	

Table 4-12. Force and Pressure Measurement Area

Description/ Usage	The Force and Pressure Measurement area may require safety screens in the immediate vicinity of the force and calibration equipment to protect operators and other personnel from flying projectiles, high pressure gas, or fluids. This area is part of the C/R area, but can be part of the Dimensional Measurement lab.
Min. Ceiling Ht.	10 ft (3.05 m)
Finishes	**Walls.** Painted gypsum wall board with flush and smooth surface to reduce dust. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductive material. **Ceiling.** ACP; air-tight, dust-tight ceiling panels for environmental system balancing and required maintenance.
Plumbing	None required.
HVAC	73 ± 6 °F (22.8 ± 3.3 °C) for Type II and Type III PMELs. An optimum operational RH level is 35, +10/-15%. A minimum positive static pressure of 0.05 inch of water (12.5 pascals) compared to ambient pressure is required to prevent infiltration of dust-laden air.
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Outlets per code and additional outlets as necessary to operate any dedicated equipment.
Lighting	100 foot-candles (1076 lux) ambient lighting using permanent overhead-recessed vapor-proof/dust-resistant fixtures sealed with gaskets to prevent air or moisture leakage and dust accumulation/intrusion from the interstitial area.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Onespeaker. **Telephone.** One line with internal two-way communication. **Data.** One outlet per work bench. Ensure WLAN signal is available, if required. **Security.** None required.
Casework/ Built-in Equipment	Work bench(s) for equipment inspection and repair.
Furnishings Fixtures & Equipment (FF&E)	Safety screens to protect personnel, as required.
Special Requirements	If double doors are used, install a pair of 3-ft-wide double doors to allow movement of large pieces of equipment when necessary. Consider placing force and pressure measuring equipment in isolated parts of the room or space as an added measure for personnel and equipment protection.
For use during project execution by the appropriate Service agency	
Occupancy	Staff, customers.
Min. net ft^2 (m^2)	

Table 4-13. Technical Library

Description/ Usage	The library contains TOs, equipment descriptions, maintenance manuals, Air Force Manuals and Instructions. It is used by PMEL technicians, supervisors, and staff to provide data for precision measurement calibration activities, including library research and internet downloads of technical manuals.
Min. Ceiling Ht.	9 ft (2.74 m)
Finishes	**Walls.** Painted gypsum wall board with flush and smooth surface to reduce dust. **Floor.** Vinyl (non-conductive) plastic floor covering of continuous length or other suitable non-conductive material. Static dissipative carpet may be added to the technical library if located outside the C/R area.
Plumbing	None required.
HVAC	Reference the most recent Air Force or installation policy on temperature set points for HVAC systems.
Fire Protection	Refer to UFC 3-600-01 for fire protection requirements.
Power	Outlets per code; one additional outlet at counter height for convenience; additional outlets necessary to operate dedicated equipment such as a copier, fax machine, printer, and various other office machines.
Lighting	100 foot-candles (1076 lux). Consider dimmable lights.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** One speaker. **Telephone.** One line. **Data.** Minimum of four LAN internet outlets for library research. **Security.** None required.
Casework/Built-in Equipment	Bookshelves to house technical library collection
Furnishings Fixtures & Equipment (FF&E)	Copier, fax machine, printers, table, chairs, bulletin board with tack surface, dry-erase board, and other office equipment as required.
Special Requirements	None required.
For use during project execution by the appropriate Service agency	
Occupancy	Staff, customers.
Min. net ft^2 (m^2)

APPENDIX C DEFINITION OF TERMS

For additional definitions, reference TO 00-20-14, *Air Force Metrology and Calibration Program*.

Air Force Metrology and Calibration Program (AFMETCAL Program): An Air Force program that provides measurement standards and equipment, professional and technical metrologists, performing work centers (PWCs), a system of worldwide Precision Measurement Equipment Laboratory (PMEL) facilities, measurement equipment users, calibration data, and integrated planning. This program ensures the reliability and accuracy of systems, subsystems, and equipment. The program provides for the calibration and repair of Test, Measurement, and Diagnostic Equipment (TMDE).

Calibration: A comparison between equipment items, one of which is a measurement standard of known accuracy, to detect, correlate, adjust, and report any variation in the accuracy the other item(s).

Metrology: The science or system of weights and measures used to determine conformance to technical requirements. This includes the development of standards and systems for absolute and relative measurements.

Precision Measurement Equipment Laboratory (PMEL): The base-level AFMETCAL Program focal point. It is the activity authorized to possess and use base measurement standards. PMELs use base measurement standards to maintain working standards. The workin g standards are used to maintain (troubleshoot, align, repair, and calibrate) TMDE designated as PMEL responsibility. Authorizations for PMEL equipment and facility requirements are tailored to meet specific requirements for supported missions. PMELs are the base-level link for measurement transfer and maintenance self- sufficiency for all systems in the Air Force. PMEL types include:

Type IIA. A base-level PMEL with a 68 degree room providing support to an Air Logistics Complex (ALC) and/or a large geographical area.

Type IIB. A base-level PMEL established to support aircraft, missiles, ground systems and/or other equipment on base or in the local area.

Type IIC. A base-level PMEL with a 68 degree room supporting research, development, test or evaluation programs, as well as other operational and support functions.

Type III. A PMEL supporting a specific mission. It normally receives calibration support from a Type II PMEL.

Type IV. A PMEL that supports a specific weapon system. It uses a transportable measurement system in fixed and deployed locations. A Type IV PMEL receives calibration support from a Type II PMEL.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
NEW SUMMARY SHEET

Document: UFC 4-310-03, *DoD Fuels Laboratory Standards*, dated 7 March 2019

Superseding: None

Description: This new UFC provides general criteria and standard procedures for the design and construction of military land-based laboratory facilities which test liquid fuels.

Reasons for Document:

- Provide uniform requirements for construction of DoD fuels laboratories based on required fuel testing requirements.
- Provide requirements for planning, facility design, and construction documentation required for new fuel laboratory facilities.
- Provide requirements for modernization or expansion of existing fuel laboratories, if improvements can be justified in terms of obsolescence, expanded operational requirements, safety, environmental compliance, or excessive maintenance costs.

Impact:

- Creates a single source for common DOD fuels laboratories criteria.
- Enable designs and construction to meet appropriate uniform requirements for specific fuel testing locations to ensure proper fuel quality for use within DoD.

Unification Issues

None

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This UFC contains criteria and guidance for design and construction of military land-based laboratory (lab) facilities that test liquid fuels.

1-2 APPLICABILITY.

This UFC should be used by facility planners, engineers, and architects for individual project planning and preparing engineering and construction documentation. Requirements apply to both new construction and to modernization or expansion of existing fuel laboratories when improvements can be justified in terms of obsolescence, expanded operational requirements, safety, environmental compliance, or excessive maintenance costs. Operations and maintenance personnel should use this UFC for facility design, modifications, and improvements.

1-3 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, General Building Requirements. UFC 1-200-01 provides applicable model building codes and government-unique criteria for typical design disciplines and building systems, as well as requirements for accessibility, antiterrorism, security, high performance and sustainability, and safety. Use this UFC in addition to UFC 1-200-01 and other UFCs and government criteria referenced herein.

1-4 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service implementation policy.

1-5 SERVICE HEADQUARTERS SUBJECT MATTER EXPERTS (SME)

Policies, obligations, and responsibilities of the military branches may vary; consult the SME at the appropriate Service headquarters for interpretation.

- Army: Headquarters, U.S. Army Corps of Engineers, POL Facilities Proponent (CECW-EC).
- Air Force: The Air Force Fuels Facilities SME (AFCEC/COS). When applicable, route requests through the Regional Fuels Engineer (USAFE/PACAF) prior to the Air Force Fuels Facilities SME.
- Navy/Marine Corps: NAVFAC POL Facility SME (NAVFAC EXWC, CI11).

1-5.1 Service Provider Subject Matter Expert (SME).

DLA Installation Support for Energy (DLA DS-FEI) is the Executive Agent as defined in DoD 4140.25M.

1-6 WAIVERS AND EXEMPTIONS.

For specific interpretations, waivers, or exemption, contact the appropriate Service headquarters SMEs and refer to MIL-STD-3007 for the waiver process.

Recommended UFC language generated from recurring waivers and exemptions will be considered by the Fuels Discipline Working Group (FDWG), with supporting rationale for inclusion included on voting agendas.

1-7 REFERENCES.

Appendix A lists references related to laboratory facilities contained in this UFC. The publication date of the code or standard is not included; the latest available issuance of the reference has been used.

1-8 PROJECTS OUTSIDE OF CONTINENTAL UNITED STATES.

For fueling projects located outside of CONUS, use host nation standards (if more stringent), this UFC, and applicable Service policy.

1-9 GLOSSARY.

Appendix B contains abbreviations and acronyms, and definitions of terms.

CHAPTER 2 TECHNICAL REQUIREMENTS

2-1 BASIC LAB REQUIREMENTS.

Laboratories are classified as Type A, B, or C to match testing required in MIL-STD-3004. These requirements apply to all labs. Requirements for counter space, ventilation, and electrical are summarized in Table 2-1. Specific requirements for each lab are determined by the tests performed in the lab.

2-1.1 Petroleum Products.

Petroleum products are hazardous due to toxic, explosive, flammable, and environmentally damaging properties.

2-1.2 Codes, Standards and Regulations.

Design must conform to all applicable criteria and guidance, including local and federal codes, military standards, and installation standards. Approved DD Form 1391 must specify what lab type is required to meet assigned tasks to support MIL-STD-3004.

Use references listed in Appendix A. Other standards may be acceptable provided they satisfy minimum requirements for the testing lab.

2-1.3 Architectural.

2-1.3.1 Floors.

To retain shower water and fuel spills, recess for laboratory room floors a minimum of 6 in. (150 mm), or provide another means of permanent spill control. If only eyewash units are used, the floor does not need to be recessed, but must be sloped 1/8-inch per foot to a floor drain. Floors must be designed to support minimum loads of 150 pounds per square foot (7.18 kilopascals). The finish should be monolithic, without seams or joints, to resist fuel spills. Flooring must incorporate a cove-type base of the same material as the flooring.

2-1.3.2 Cabinets.

Cabinets must be of metal construction and sourced from a manufacturer that specifically designs and builds laboratory fixtures. Coordinate with the user as to the type of cabinets that will be required.

2-1.3.3 Countertops.

Where fuel or chemicals may contact countertops, a standard 4-inch (100 millimeter) chemical- and fuels-resistant backsplash must be installed. Counters must be made of an epoxy resin or other type of material typically used for chemical analysis. For instrumentation, countertops must support 150 pounds per square foot (7.18 kilopascals) minimum load. Countertops typically are black, but verify with the user the

color needed to accommodate types of testing. At some installations, a white epoxy resin countertop may be required for the visual test.

2-1.4 Mechanical.

2-1.4.1 Heating, Ventilating and Air Conditioning (HVAC) System.

Labs work spaces must have dedicated HVAC systems and must provide a minimum outdoor air ventilation rate in accordance with ASHRAE 62.1 and comply with UFC 3-410-01.

- Lab HVAC systems must work seamlessly. When a lab hood is energized, conditioned make-up air must enter the lab to replace the air being exhausted. The design must ensure minimum turbulence around the hood, and ensure all components work together in a variety of scenarios; e.g., lab hoods are normally shut down when not in use; fresh air would normally go to minimum volume when the building is unoccupied.
- Lab rooms must maintain slightly negative air pressure relative to the rest of the building (adjacent rooms) 24 hours per day, 7 days per week.

2-1.4.1.1 Lab Operating Temperature.

Operating temperature must be maintained at 73° F +/- 5° F (23 +/- 2 ° C), 55° F (13° C) maximum dew point, and humidified if relative humidity drops below 30%.

2-1.4.1.2 Recirculation of Air from the Laboratory.

Recirculation of air from the laboratory to other portions (offices) of the building is prohibited, per NFPA 45.

2-1.4.1.3 Exhaust.

Labs must provide exhaust 24 hours per day, 7 days per week, from within 6 inches of the lab floor; i.e., the exhaust intake must be mounted no more than 6 inches above the lab floor. For C type labs, maintain a minimum airflow of 50 cubic feet per minute (25 liters/second).

2-1.4.1.4 Energy Recovery Systems.

Use of energy recovery systems must be considered. To prevent possible cross-contamination, do not use recovery wheels with fume hoods.

2-1.4.1.5 High Performance and Sustainable Building Requirements.

Comply with UFC 1-200-02.

2-1.4.2 Plumbing.

Comply with UFC 3-420-01.

2-1.4.3 Sinks.

Sinks must supply both hot and cold running water. For cleaning lab glassware, hot water must be supplied at 130° F (54° C).

2-1.5 Electrical.

This UFC applies to facilities within the United States. Installations outside the United States may have location-specific power requirements.

2-1.5.1 Primary Power Distribution.

A dedicated service transformer is required for facility primary power distribution. The transformer must step down voltage from the installation primary voltage to 120/208V three-phase power. HVAC and other mechanical loads typically require three-phase power. When part of a larger building, laboratories must have dedicated distribution panels.

2-1.5.2 Stand-By-Generator.

This UFC does not require use of a stand-by generator, nor does any specific service or installation have a requirement that the fuels laboratory have emergency power. However, the laboratory must be considered inoperable and possibly uninhabitable during a prolonged power outage. At a minimum, the facility must have backup power capability via a quick connection point through a manual transfer switch (MTS). A built-in stand-by generator with automatic transfer switch (ATS) may be justified based on the power reliability of a specific installation and the criticality of the laboratory mission.

2-1.5.3 Service Entrance Conductors.

Service entrance conductors must be extended from the service transformer or MTS to a main distribution panel (MDP) in the mechanical room. The MDP must be service entrance-rated and equipped with molded case circuit breakers. Feeders must be extended from the MDP to feed the large mechanical loads and 208Y/120V panel boards. The 208Y/120V panel boards must feed lighting, small mechanical loads, receptacle loads, and other 120V or 208V equipment. Identify laboratory equipment utilizing 208V for disconnect placement.

2-1.5.4 Lab Equipment Transformer.

Some lab equipment may be available only as 240V, requiring a second transformer with a 120/240V single-phase secondary. Identify laboratory equipment requiring 240V for disconnect placement.

2-1.5.5 Lighting.

Design lighting to intensities recommended in UFC 3-530-01, *Interior and Exterior Lighting Systems and Controls*. In general, laboratory lighting will be non-hazardous,

but specific areas/locations may require special lighting; e.g., the hazardous storage area must have explosion-proof fixtures.

- Provide occupancy sensor controls and manual override switches throughout the facility. LED lighting is acceptable in place of fluorescent.
- Exit signs and emergency light fixtures must have battery backup; exit lights will use LED lamps.

2-1.5.6 Electrical Outlets and Switches.

Electrical outlets and switches must be located above counter- or tabletop-height. Space regular duplex outlets (120V) every 4 feet along countertops to support various equipment items. Dedicated 208V and 240V outlets must positioned to accommodate equipment that requires power other than 120V. Consult the end user regarding these specific power requirements. As a minimum for each laboratory, provide two 240V outlets near the ends of counters to allow use by either countertop or floor-standing equipment.

2-1.5.7 Lighting Building Exterior Walls.

Illuminate building exterior walls using full cut-off wall pack LED fixtures controlled via photocell mounted on the exterior of the building -- not on the roof.

2-1.5.8 Facility Grounding.

The facility must be grounded in accordance with NFPA 70, *National Electrical Code*®. Execute underground connections by exothermic process. Existing systems must be tested and supplemented as needed to obtain a ground resistance of 25 ohms or less.

2-1.5.9 Personnel and Equipment Grounding Bar.

Provide a personnel and equipment grounding bar for all laboratory countertops. Provide a personnel grounding touch pad or bar at laboratory entrances.

2-1.5.10 Lightning Protection.

Provide lightning protection per UFC 3-575-01 and NFPA 780.

2-1.5.11 Exterior Raceways.

Use rigid steel conduit or intermediate metal conduit (IMC) in exposed locations. Install electric metallic tubing (EMT) where concealed in walls and above finished ceilings. Exposed exterior conduits or exposed conduits in hazardous classified areas must be rigid galvanized steel. Use PVC underground. Transition PVC conduit to PVC-coated rigid steel conduit for below grade elbows and where conduits rise through concrete slabs.

2-1.5.12 Electrical Classification.

Electrical installations in the laboratory work areas are considered non-classified with exceptions identified in paragraphs 2-2.4, 2-.3.2, and 2-3.4.

[C] 2-.1.5.12 The laboratory work areas are non-classified due to following mitigating factors:

- Procedural limits on fuel quantity to be tested or stored within the laboratory.
- Storage of fuel samples in ventilated cabinets or otherwise approved containers.
- Training of operators and the area being off limits to non-essential personnel.
- Reasonable expectation that any fuel spills will be cleaned up immediately.
- Physical separation of the hazardous storage area (a hazardous area) from the laboratory.
- Required fire sprinklers.
- Combustible gas monitors in larger labs with piped in Hydrogen, Oxygen, Acetylene or other gases which would increase the fire potential.
- Use of fume hood(s) and dedicated HVAC system to remove any fuel vapors.
- Elevating all electrical outlets to at or above counter-top height. The test equipment itself is not hazardous area rated, therefore requiring the rest of the electrical system to be hazardous area rated would not increase safety.
- Open flame tests are required in the laboratory, but would be prohibited in a hazardous area.

2-1.6 Fire Protection Requirements.

Comply with UFC 3-600-01 and NFPA 45.

Determine what chemicals and fuels will be tested and stored in the lab. Document and include client requirements in the design analysis. Table 2-2 lists some typical chemicals and fuels. Chemical/sample storage rooms must be classified as Class 1, Division 2, and Group D, in accordance with NFPA 70. Lab facilities must be Type I or Type II construction (IBC Classification).

2-1.7 Emergency Eyewash and Shower.

Provide an OSHA emergency eyewash and shower supplied per Appendix D of UFC 3-420-01. Designers must review availability of existing utilities and evaluate conditions at each site.

2-2 TYPE A TESTING LAB.

Requirements for counter space, ventilation, electrical, and other features are listed in Table 2-1.

2-2.1 Facility Description.

A facility capable of performing a Type A Test is described in MIL-STD 3004. These facilities are the largest of the DoD laboratories, very expensive, and few in number relative to Type B and C labs. Because requirements for labs are project-specific, a single uniform standard is not practical, making requirements for smaller labs, as a minimum, apply to all types. Examples of Type A labs include Wright Patterson AFB, Vandenberg AFB, RAF Mildenhall, Kadena Air Base, NAS Patuxent River, and New Cumberland Army Depot.

a. The Type A test consists of a complete conformance specification acceptance test. Sample size must include 1 gallon (3.8 liters), with 5 gallons (18.9 liters) for special tests, as specified in MIL-STD 3004.

b. Table 2-1 is a list of tests; Figure 2-1 provides a diagram of a Type A laboratory.

2-2.2 Architectural.

2-2.2.1 Design.

Building size must be based on space requirements, as indicated in Table 2-1 or as approved by the Service Control Point identified in UFC 3-460-01, to provide the user with a complete operational facility. Finishes of building exteriors must follow installation standards for materials.

2-2.2.2 Handicapped Accessibility.

Handicapped accessibility requirements will be incorporated into the building design in accordance with the ADA-ABA American with Disabilities Act and Architectural Barriers Act Accessibility Guidelines for Buildings and Facilities.

2-2.2.3 Building Requirements.

Use Table 2-1 to determine space layout. Multiple test stations may be added as required to accomplish the number of tests for each station. The functional areas for a large laboratory facility must include the spaces described in paragraphs 2-2.2.3.1 through 2-2.2.3.9, as a minimum:

2-2.2.3.1 Laboratory Rooms.

Approximate size of lab rooms should be between 2,000 and 3,200 net square feet (185 and 298 net square meters). Size maybe adjusted as required for a larger lab with rooms or areas being added for additional requirements.

a. A Type A lab must be sized to handle all required testing for the basic lab requirements, including fuels and lubricating oils. Fuels and lubricants typically tested inside the lab include:

- aviation gasoline (AVGAS)
- biofuels
- biomass fuel
- biodiesel
- diesel fuel
- ethanol, fuel grade
- gasoline
- heavy distillates
- aviation turbine fuel (e.g., JP-5, JP-8, Jet A, F-24)
- kerosene
- LNG, LPG
- natural gas
- petroleum and crude oil feedstocks
- petroleum coke and fly-ash
- lube oil

b. For typical fuel tests conducted inside the lab, see Table 2-1.

c. A Type A lab must be set up to allow individual testing of the items listed above and can be separated into two testing rooms. One room must be large -- approximately 1,800 net square feet (167 net square meters) -- with a flash room and balance room located adjacent to the lab. The other must be a minimum of 500 net square feet (47 net square meters), adjacent to the larger room. Each room/lab area must be set up to test the listed items and must be laid out to allow separate areas for each test (reference Table 2-1). Several testing stations could be combined into one. When required, include additional space in each Type A lab for a filtration room or equipment storage.

2-2.2.3.2 Non Hazardous Storage Room.

This room (or rooms) is used to store non-hazardous chemicals, and will include noncombustible storage compartments and work tables.

a. Size: The approximate size of this area should be 400 net square feet (37 net square meters).

b. Flooring: Flooring must be monolithic in type, without seams or joints, and must resist chemical and fuel spills. A cove base of the same material must extend up approximately 8 in. (200 mm).

c. Walls: Walls must be constructed using steel studs with a maximum 16 in. (400 mm) on center, covered with 5/8-in. (16-mm) gypsum wallboard or concrete masonry, and a backsplash or wainscot at all casework. Backsplash or wainscot must be chemical- and fuels-resistant.

d. Counters: Counters must be epoxy resin-type typically used for chemical analysis, resistant to chemical and fuel spills, and easily cleaned. Most counters are black; but the color must be selected by the using agency as appropriate to support its testing operations.

e. Ceilings: Ceilings must consist of 5/8-in. (16 mm) gypsum wallboard over steel studs, mounted at 16 in. (400 mm) on center. The minimum ceiling mounting height must be 8 ft (2400 mm) above the finish floor. Ceilings must be painted with one coat of primer and two coats of semi-gloss paint. Color must be selected from manufacturer standard paint samples.

2-2.2.3.3 Hazardous Storage Room.

The hazardous storage room provides space for the storage of chemicals and flammable and hazardous materials. Refer to Table 2-2 for a list of potential chemicals that may be stored in this room. This room must have direct access to the exterior. In addition, a storage area for pressurized bottles must be located on the exterior of the building adjacent to the hazardous storage room, and also have exterior access.

a. Flooring: Reference paragraph 2-2.2.3.2.b.

b. Walls: Reference paragraph 2 2.2.3.2.c.

2-2.2.3.4 Filtration Room.

The filtration room must be approximately 250 net square feet (23 net square meters), and adjacent to the laboratory areas to provide filtered air into the laboratory. This room (or area) may be inside the laboratory or within a support area.

2-2.2.3.5 Balance Room and Flash Room.

Each of these rooms must be approximately 150 net square feet (13 net square meters) each. Locate both rooms next to and with access into the laboratory areas. Provide backsplash or wainscot that is chemical- and fuel-resistant.

a. Counters: Reference paragraph 2-2.2.3.2.d.

b. Ceilings: Reference paragraph 2-2.2.3.2.e.

2-2.2.3.6 Administrative Office Spaces.

Provide a minimum of one open office approximate size of 375 net square feet (35 net square meters) and one single office approximately 150 net square feet (12 net square meters). Administration offices must be separated from the lab area but must be adjacent to it for ease of access. Size the administration office area to accommodate the number of assigned staff.

a. Walls: Walls must be constructed using steel studs with a maximum 16 in. (400 mm) on center, and covered with 5/8-in. (16-mm) gypsum wallboard.

b. Flooring: Flooring may be resilient or porcelain tile.

c. Ceilings: Use acoustical tile for ceilings.

2-2.2.3.7 Break Room Spaces.

Provide a break area of approximately 300 net square feet (28 net square meters) adjacent to office areas and away from the hazardous storage and laboratory areas. The break room must include space for a counter, table, and refrigerator.

a. Walls: Reference paragraph 2-2.2.3.6.a.

b. Flooring: Reference paragraph 2-2.2.3.6.b.

c. Ceilings: Reference paragraph 2-2.2.3.6.c.

2-2.2.3.8 Support Space.

Mechanical, electrical, and communication rooms must be sized to accommodate equipment required for the building. Rooms must be accessible from the exterior of the building, or comply with current security requirements. Walls must constructed using steel studs at a minimum of 16 in. (400 mm) on center, covered with 5/8-in. (16-mm) gypsum wallboard or painted concrete masonry. Flooring may be resilient or porcelain tile, or sealed concrete. Ceilings for these spaces may be exposed to the underside of any metal decking or roof.

2-2.2.3.9 Toilet and Locker Rooms.

Men’s and women’s toilet and locker rooms must be sized according to the number of people that will be using the spaces. Locate these rooms between the break room and laboratory to achieve separation and promote proper industrial hygiene.

a. Walls: Walls must be constructed using steel studs with a minimum 16 in. (400 mm) on center, covered with 5/8-inch (16-mm) gypsum wallboard.

b. Tile: Wallboard must be covered with a porcelain tile wainscot with backboard in the toilet room and locker area, and full-height porcelain tile with backboard in the shower room.

c. Flooring: Shower flooring should include shower pans or porcelain tile. Flooring for the toilet and locker areas can be ceramic or porcelain tile.

d. Ceilings: Ceilings must be 5/8-in. (16 mm) gypsum wallboard.

2-2.3 Mechanical.

Comply with requirements in paragraph 2-3.3 for a Type B lab.

2-2.4 Electrical.

In addition to the basic lab requirements of paragraph 2-1.4, Type A labs must be equipped with combustible gas monitors with alarms as indication of either an HVAC failure or piped natural gas (or other gas) leak creating a potentially dangerous buildup of explosive gases.

Type A labs must also have hazardous areas that require electrical explosion-proofing. These areas are classified Hazardous, Class 1 Division 1:

- Hazardous storage room
- Areas within 5 feet (1524 mm) of hazardous storage cabinets (or refrigerator)
- Interior of lab fume hoods
- 5 feet (1524 mm) around any fuel waste containers larger than 5 gallons (18.9 liters).

2-3 TYPE B TESTIG LAB.

Requirements for counter space, ventilation, electrical, and other items are listed in Table 2 1.

2-3.1 Facility Description.

A Type B testing lab is a facility capable of performing Type B tests, as described in MIL-STD 3004. A Type B-1 test consists of a partial analysis comprising the checking of principal characteristics most likely to have been affected in the course of moving the product. A Type B-2 test consists of a partial analysis to check characteristics susceptible to deterioration due to age. Examples of Type B labs include Hunter Army Airfield, Ft Rucker, Ft Campbell, Chibana, FLC Norfolk, FLC Jacksonville, Naval Station Rota, and FLC Point Loma. See Figure 2-2.

A Type B-3 test consists of partial analysis for contaminations -- in particular, for controlling the return (or reintroduction) of pipeline interface products. Sample sizes must include 1 gallon (3.8 liters), and 5 gallons (18.9 liters) for special tests, as indicated in MIL-STD 3004. For a minimum list of tests, see Table 2-1.

2-3.2 Architectural.

2-3.2.1 Architectural Design.

Size of building must be based on tests as indicated in Table 2-1 to provide the user with a complete operational facility. Size of this type of facility may be increased as mission at each installation dictates. Minor modifications to the configuration may be

developed during review conferences. Finishes of the exterior of buildings for this project must follow base standards for exterior materials.

2-3.2.1.1 Handicapped Accessibility.

Handicapped accessibility requirements will be incorporated into the building design. The design must follow the ADA-ABA American with Disabilities Act and Architectural Barriers Act Accessibility Guidelines for Buildings and Facilities.

2-3.2.2 Building Requirements.

Functional areas for a medium-sized laboratory facility must include spaces as described in paragraphs 2-3.2.2.1 through 2-3.4.

2-3.2.2.1 Laboratory Room.

The laboratory room contains testing supplies, laboratory casework, laboratory counters tops, and small storage cabinets. Finish materials -- flooring, walls, casework, and countertops -- must resist flammable and combustible liquids. The approximate size of the laboratory room must be between 1,200 and 2,000 net square feet (112 and 186 net square meters).

Laboratory casework must be designed and installed to provide an efficient working environment. Required built-in equipment includes laboratory hoods, work tables, and laboratory casework.

a. Counters: Counter heights must be adjusted to allow for a proper working height with required equipment from a standing position. Laboratory counters must be a black epoxy resin material typically used for a laboratory rooms, and resistant to chemical and fuel spills and easily cleaned.

b. Cabinets: Cabinets must be constructed using metal that will resist rusting and must conform to industry standards for scientific laboratory equipment. Cabinets must be flush-front in construction, with interiors built for storage of equipment and flammable or combustible liquids. Upper storage cabinets must have glass fronts.

c. Flooring: Flooring must be a monolithic type without seams or joints, and resistant to chemical and fuel spills.

d. Walls: Reference paragraph 2-2.2.3.2.c.

Fuels and lubricants tested inside the lab typically include:

- aviation gasoline (AVGAS)
- biofuels
- biodiesel
- diesel fuel
- ethanol, fuel grade

- fuel oil, gas oil, bunker fuel
- gasoline
- aviation turbine fuel (JP-5, JP-8, Jet A, F-24, etc.)
- kerosene
- lube oil

For fuel testing typically done inside the lab, see Table 2-1.

2-3.2.2.2 Chemical Analysis Room.

The approximate size of the chemical analysis room is 260 net square feet (24 net square meters). Adjust the size as needed to accommodate the number of personnel assigned to this area. Casework must be designed and installed to provide an efficient working environment.

a. Counters: Counters must be made of black epoxy resin, typically used for chemical analysis, and must resist chemical and fuel spills and be easily cleaned. Adjust counters to heights correct for working with required equipment from a standing position.

b. Cabinets: Reference paragraph 2-3.2.3.1.b.

c. Flooring: Reference paragraph 2-2.2.3.2.b.

d. Walls: Reference paragraph 2-2.2.3.2.c.

2-3.2.2.3 Non Hazardous Storage Room.

This space houses non-hazardous chemicals, and will include noncombustible storage compartments and work tables. The approximate size is 200 net square feet (37 net square meters).

a. Flooring: Reference paragraph 2-2.2.3.2.b.

b. Walls: Walls must be constructed using steel studs with a maximum 16 in. (400 mm) on center, covered with 5/8-in. (16-mm) gypsum wallboard or concrete masonry, and a backsplash or wainscot at all casework.

2-3.2.2.4 Hazardous Storage Room.

The hazardous storage room is used to store hazardous and nonhazardous chemicals, along with noncombustible storage compartments and work tables. The approximate size of the hazardous storage room is 100 net square feet each (10 net square meters each).

a. Counters: Counters must be black epoxy resin material typically used for chemical analysis, resistant to chemical and fuel spills, and must be easily cleaned.

b. Flooring: Reference paragraph 2-2.3.2.2.b.

c. Walls: Reference paragraph 2-2.2.3.2.c.

d. Ceilings: Reference paragraph 2-2.2.3.2.e.

2-3.2.2.5 Filtration Room.

The filtration room must be approximately 250 net square feet (23 net square meters), and adjacent to the laboratory areas to provide filtered air into the laboratory. This room (or area) may be inside the laboratory or within a support area.

2-3.2.2.6 Balance Room and Flash Room.

Each of these rooms must be approximately 150 net square feet (13 net square meters) each. Locate both rooms next to and with access into the laboratory areas. The balance area may be located within the laboratory if only one table is required. Casework must be designed and installed to provide an efficient working environment.

a. Counters: Counters must be an epoxy resin type typically used for chemical analysis. Counters must be resistant to chemical and fuel spills and must be easily cleaned. Color of counters must be selected from standard color of epoxy resin types. Counter heights must be adjusted to allow for a proper working height with required equipment from a standing position.

b. Cabinets: Reference paragraph 2-3.2.2.1.b.

c. Flooring: Reference paragraph 2-2.2.3.2.b.

d. Walls: Walls must be constructed using steel studs at 16 inches (400 mm) on center covered with 5/8-in. (16-mm) gypsum wallboard, with a backsplash or wainscot at casework that is chemical and fuels resistant.

e. Ceilings: Reference paragraph 2-2.2.3.2.e.

2-3.2.3 Administrative Office Spaces.

Size the administration office area to accommodate the number of assigned staff. Provide a minimum of one open office approximate size of 375 net square feet (35 net square meters) and one single office approximately 150 net square feet (12 net square meters). Administration offices must be separated from the lab area but must be adjacent to it for ease of access.

a. Walls must be constructed using steel studs with a maximum 16 in. (400 mm) on center, and covered with 5/8-in. (16-mm) gypsum wallboard.

b. Flooring may be resilient or porcelain tile. Use acoustical tile for ceilings.

2-3.2.3.1 Support Spaces.

Mechanical, electrical, and communication rooms must be sized to accommodate equipment required for the building. Rooms must be accessible from the exterior of the building, or comply with current security requirements. Walls must constructed using steel studs at a minimum of 16 in. (400 mm) on center, covered with 5/8-in. (16-mm) gypsum wallboard or painted concrete masonry. Flooring may be resilient or porcelain

tile, or sealed concrete. Ceilings for these spaces may be exposed to the underside of any metal decking or roof.

2-3.2.3.2 Toilet and Locker Rooms.

Men's and women's toilet and locker rooms must be sized according to the number of people that will be using the spaces. Locate these rooms between the break room and laboratory to achieve separation and promote proper industrial hygiene. Walls must be constructed using steel studs with a minimum 16 in. (400 mm) on center, covered with 5/8-inch (16-mm) gypsum wallboard. Wallboard must be covered with a porcelain tile wainscot with backboard in the toilet room and locker area, and full-height porcelain tile with backboard in the shower room. Shower flooring should include shower pans or porcelain tile. Flooring for the toilet and locker areas can be ceramic or porcelain tile. Ceilings must be 5/8-in. (16 mm) gypsum wallboard.

2-3.3 Mechanical.

Items described in paragraphs 2-3.3.1 and 2-3.3.2 are required in addition to Type C++ requirements (paragraph 2-4.3).

2-3.3.1 Lab Operating Temperature.

Lab operating temperature must be maintained 24 hours a day, 7 days a week, or as directed by project requirements.

2-3.3.2 Hazardous Storage Room.

The hazardous storage room is classified as a Class 1 Division 1 Hazardous Space which requires all equipment associated with the room to be explosion-proof. The room must be exhausted 24 hours per day, 7 days a week, to remove vapors and ensure a slightly negative air pressure relative to the rest of the building (adjacent rooms).

2-3.4 Electrical.

In addition to the basic lab requirements of paragraph 2-1.4, Type B labs must be equipped with combustible gas monitors with alarms as indication of either an HVAC failure or piped natural gas (or other gas) leak allowing a dangerous buildup of potentially explosive gases.

Type B labs will also have hazardous areas that require electrical explosion-proofing. These areas are considered Hazardous (Classified) Locations, Class 1 Division 1:

- Chemical storage room
- Areas within and 5 feet (1524 mm) around hazardous storage cabinets (or refrigerator).
- Interior of fume hoods

- 5 feet (1524 mm) around any fuel waste containers larger than 5 gallons (18.9 liters).

2-4 TYPE C TESTING LAB.

Requirements for each lab are determined by the tests performed in the lab. Requirements for counter space, ventilation, electrical, and other items are listed in Table 2-1.

2-4.1 Facility Description.

A Type C lab is a facility capable of performing a Type C test, as described in MIL STD 3004. A Type C test consists of a quick, simple, partial analysis for verification of product quality, and to ensure no change has taken place. Type C tests are sometimes referred to as identifications tests. A number of labs are referred to as C++ labs. The Air Force has C++ labs at many installations capable of all of the C-level tests, plus several additional tests. In the Air Force C++ labs, a lab fume hood and additional counter space is required. For a list of tests, see Table 2-1.

Fuels and lubricants tested inside the lab typically include:

- AVGAS
- aviation turbine fuel (JP-5, JP-8, Jet A, F-24)
- gasoline
- E85
- diesel
- kerosene
- B20
- burner fuel oils
- lube oil

Examples of C Type labs include Ft Polk, Ft Irwin, Quantico, Ft Drum. Typical Type C++ labs are found on Air Force Bases, including Eglin, Grand Forks, Ellsworth, and Holloman. See Figures 2-3 and 2-4.

2-4.2 Architectural.

2-4.2.1 Handicapped Accessibility.

These labs will accommodate able-bodied individuals only. If the Type C or C++ lab is part of a larger building, and the building must be designed in accordance with ABA/ADA, the Type C or C++ lab does not need to be designed in accordance with ABA/ADA.

2-4.3 Mechanical.

Paragraphs 2-4.3.1 through 2-4.5 are required in addition to basic lab requirements (paragraph 2-1.3).

2-4.3.1 Lab Operating Temperature.

Lab operating temperature must be maintained during normal business hours; night setback is acceptable unless otherwise directed by project requirements.

2-4.3.2 Fume Hood.

2-4.3.2.1 Science Fume Hood.

A science fume hood must be of benchtop design, categorized as an Educational Fume Hood, with a minimum opening of 18 in. x 8 in. (457 mm x 200 mm), and minimum working space of 24 in. wide (W) x 13 in. deep (D) x 22 in. high (H) (610 mm W x 330 mm D x560 mm H); ducted; exhausting approximately 100 cfm (50 liters/sec).

The hood may be designed to operate while the sash (hood access door) is in the partially-opened position only. In addition:

- An on/off switch for the exhaust fan must be provided near the fume hood.
- Exhaust ductwork must be sealed.
- Exhaust streams must be exhausted directly to the building exterior.
- Face velocity must be designed to 100 fpm (0.5 m/s).
- Exhaust fan must be located on the roof, in accordance with NFPA 45.
- Exhaust fan must be of spark-resistant construction.
- Exhaust fan motor must be explosion-proof if located in the air stream.
- Exhaust stack discharge velocity must be at least 3,000 fpm (15 m/s).
- Exhaust must be a minimum of 30 ft (9 m) from any building fresh air intake.
- Exhaust must be labeled “WARNING – Chemical Laboratory Exhaust”
- Exhaust stack must discharge vertically and be located a minimum of 10 ft (3 m) above adjacent roof lines.

2-4.4 Lab Fume Hood.

For a typical Air Force C++ lab, a 47- or 60-in. (1200- or 1525-mm) lab fume hood is required (size is dictated by the number of samples/tests to be performed on a daily basis), and must be ducted, approximately 750 cfm (354 liters/sec) or 1000 cfm (472 liters/sec), respectively. The hood must be designed to operate while the sash (hood access door) is in any position (fully opened to fully closed). Good ventilation is

achieved by using a lab fume hood in a small room, even when the test is not performed in the hood. In addition:

- An on/off switch for the exhaust fan must be provided near the fume hood.
- Exhaust duct work must be chemical-resistant.
- Exhaust duct work must be sealed.
- Exhaust duct work must not be manifolded together with other lab hoods on a constant volume system.
- Exhaust streams containing concentrations of flammable vapors above the lower explosion limit (LEL) must not be connected to a centralized exhaust system, per ANSI/ASSE Z9.5, *Laboratory Ventilation*.
- Hood must be equipped with a flow indicator, flow alarm, or face velocity alarm indicator set to alarm when the face velocity falls outside the range of 80 to 100 fpm (0.4 to 0.5 m/s).
- Face velocity must be designed to 100 fpm (0.5 m/s).
- Exhaust fan must be located on the roof in accordance with NFPA 45.
- Exhaust fan must be of spark-resistant construction.
- Exhaust fan motor must be explosion-proof if located in the air stream.
- Exhaust stack discharge velocity must be at least 3,000 fpm (15 m/s).
- Exhaust must be a minimum of 30 feet (9 m) from any building fresh air intake.
- Exhaust must be labeled “WARNING – Chemical Laboratory Exhaust”.
- Exhaust stack must discharge vertically and be located a minimum of 10 ft (3 m) above adjacent roof lines.
- Controls (air, water, gas,) must be located exterior to the hood within easy reach.

During commissioning, the following tests and measurements must be performed in accordance with ANSI/ASSE Z9.5:

- Airflow visualization tests
- Cross drafts velocity tests
- Exhaust flow measurements
- Face velocity tests
- Hood static pressure measurement
- Tracer gas testing

2-4.4.2 Make-up Air for Fume Hood.

Make-up air for the fume hood must meet the lab operating temperature requirements.

2-4.4.3 Vacuum Pump.

A vacuum pump must be provided serving the lab fume hood if required by the appropriate fuel test. The vacuum pump must be installed higher than the hood for the vacuum line to drain back into the fume hood. An on/off switch must be located near the fume hood. The vacuum pump requires good ventilation, so installation in the same room as the lab hood is adequate. **Note:** A vacuum pump is not required for a Type C testing lab.

2-4.4.4 Floor Drains.

Floor drains must be provided for emergency showers. Drains must be equipped with a positive sealing plug which is inserted in the drain at all times when not in use, or some other means of stopping the drain system. Drains are opened only as needed or after liquid is approved for discharge into the drain system.

2-4.4.5 Deionizer Water Tap.

A water supply tap for a Type II deionizer water equipment (typically wall-mounted) must be provided for Type C++. Provide a deionizer tap for Type C only when requested.

2-4.4.6 Glassware Cleaning.

The lab must be designed for glassware cleaning (dishwasher), but is not required for Type C and C++ labs unless the number of daily samples is high enough based on installation throughput and manpower requirements.

a. Prior to cleaning glassware, all fuel from testing is dumped into containers which are either recycled or properly disposed of. Lab personnel are trained not to dump fuels (hazardous waste) into any sink or floor drain. Glassware is essentially empty, except for any residual fuel clinging to the container. Detergents used to clean and break down the residual fuel from the glassware are subsequently dumped into the drain system.

b. There is no state or federal regulation which requires special treatment of discharge from a DoD fuels lab operating under these conditions. A local or host nation requirement may specifically address and require oil/water separators, intermediary containment basins, or some other means to address residual fuel. A large lab with high quantities of samples might justify environmental concerns to assure safe discharge.

2-4.5 Electrical.

See Basic Lab Requirements, paragraph 2-1.4.

2-5 FIGURES.

Figure 2-1 Bubble Diagram Type A Laboratory

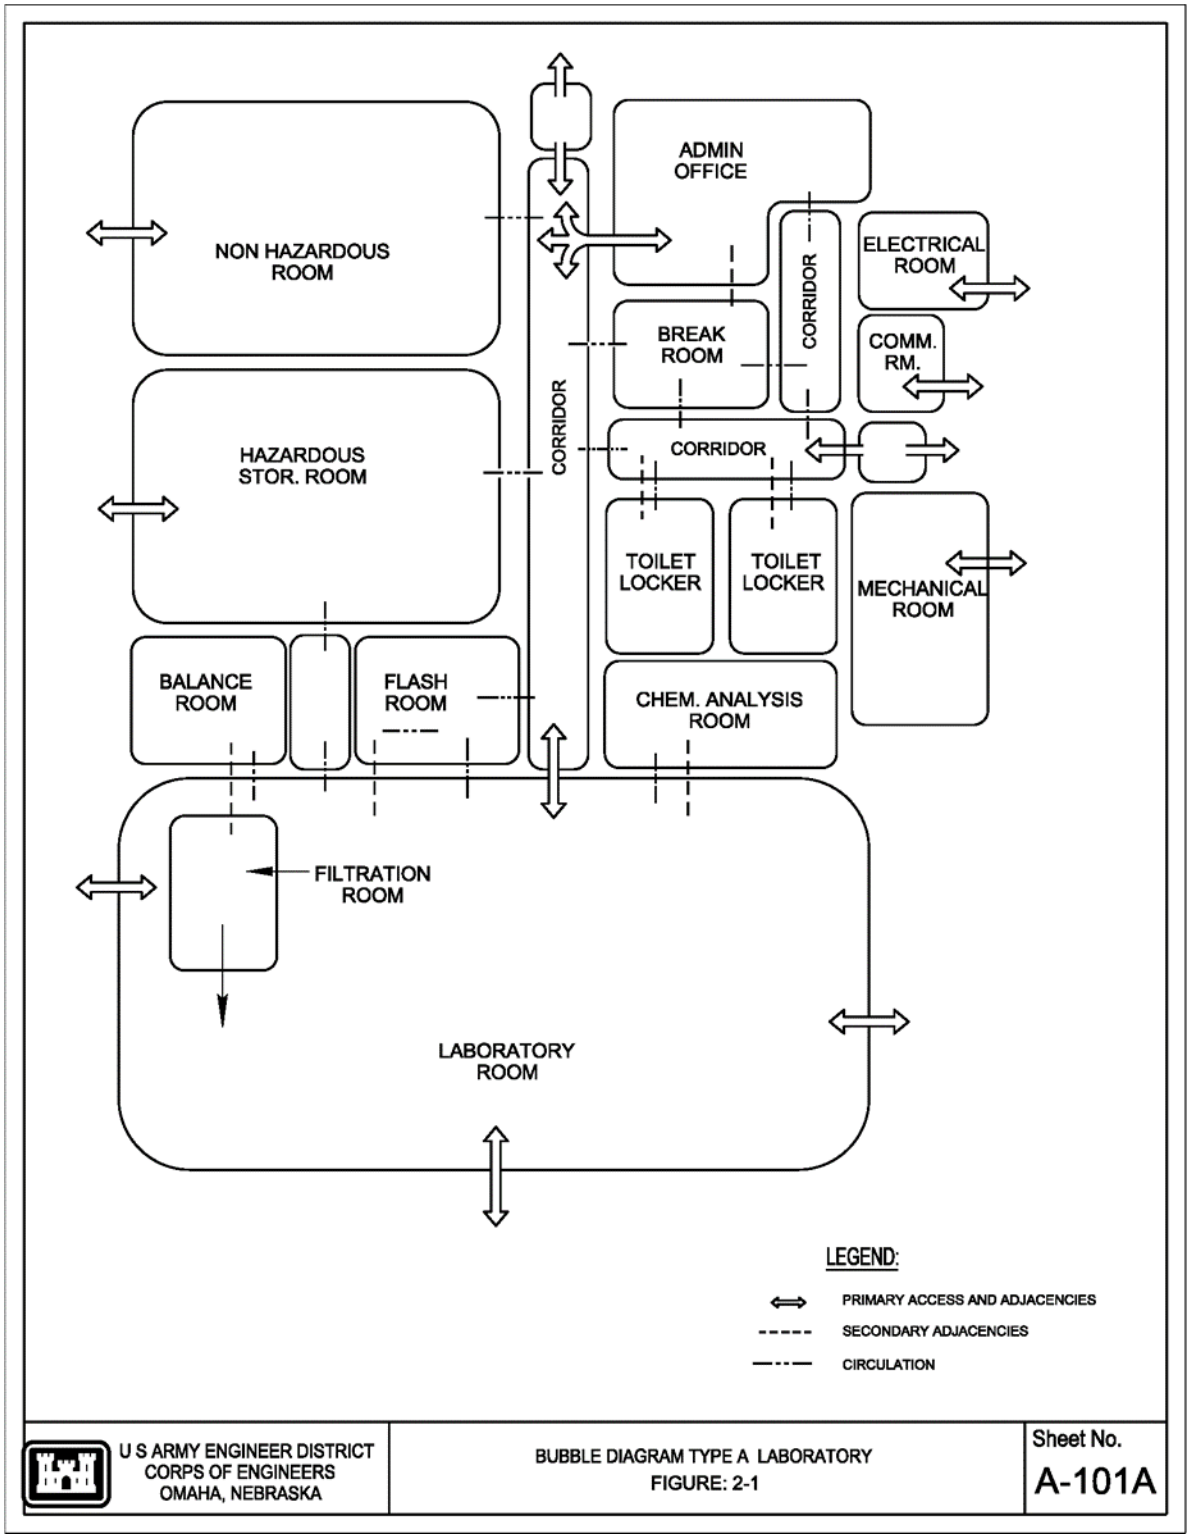

Figure 2-2 Bubble Diagram Type B Laboratory

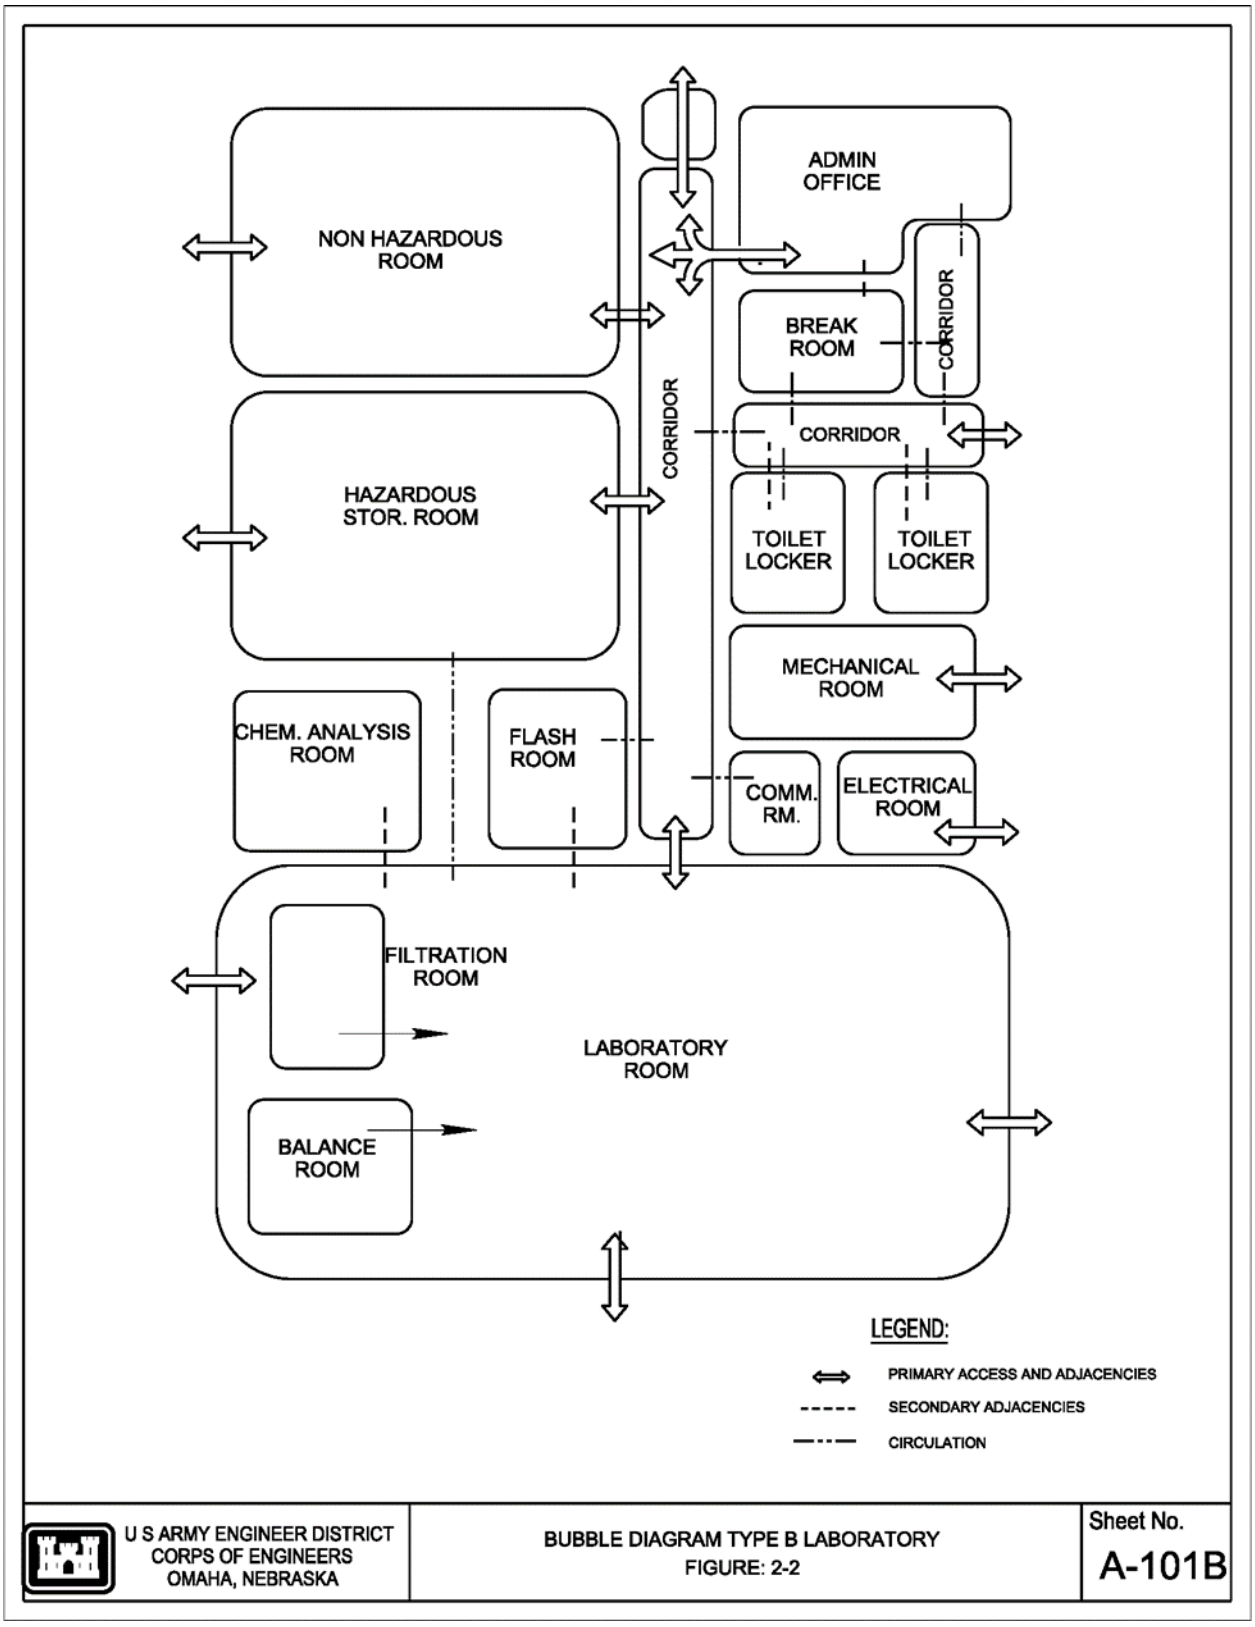

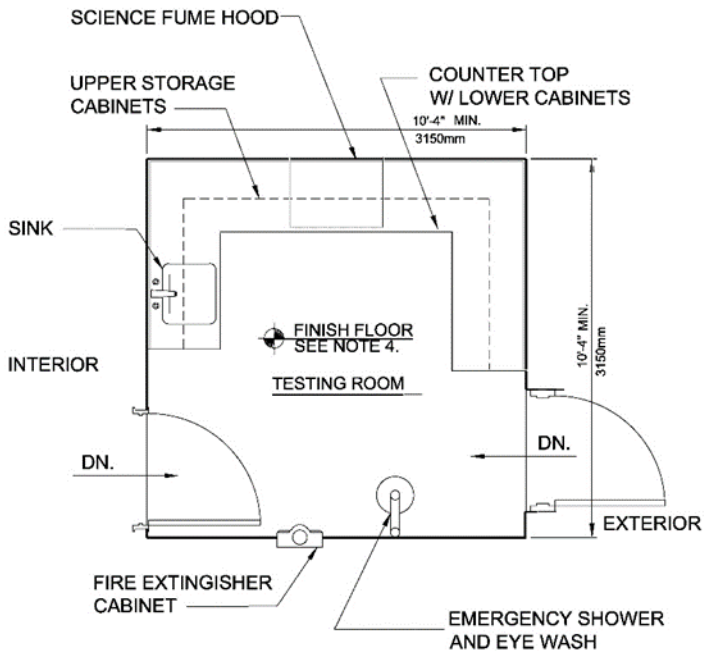

Figure 2-3 Typical C Laboratory Floor Plan

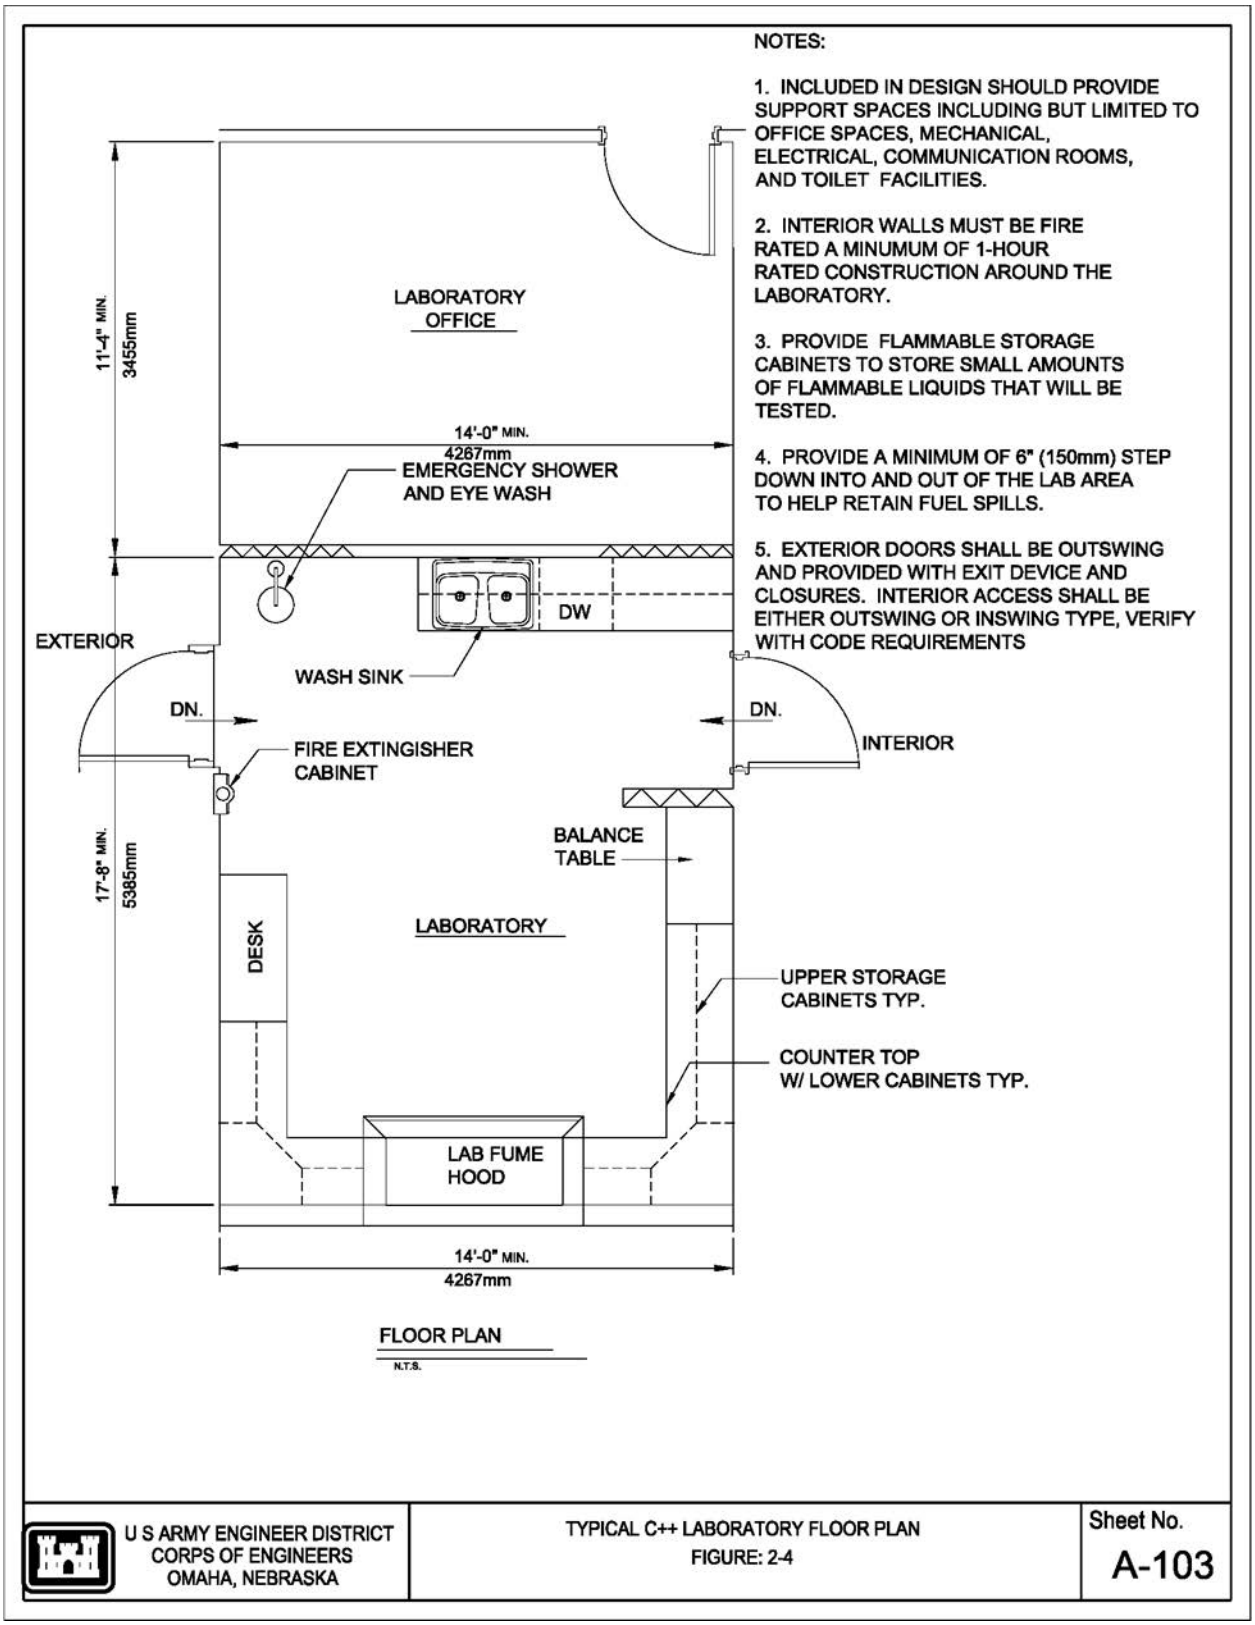
NOTES:

1. INCLUDED IN DESIGN SHOULD PROVIDE SUPPORT SPACES INCLUDING BUT LIMITED TO OFFICE SPACES, MECHANICAL, ELECTRICAL, COMMUNICATION ROOMS, AND TOILET FACILITIES.

2. INTERIOR WALLS MUST BE FIRE RATED A MINUMUM OF 1-HOUR RATED CONSTRUCTION AROUND THE LABORATORY.



3. PROVIDE FLAMMABLE STORAGE CABINET TO STORE SMALL AMOUNTS OF FLAMMABLE LIQUIDS THAT WILL BE TESTED.

4. FINISH FLOOR OF TESTING ROOM SHALL BE A MINIMUM OF 6" (150mm) BELOW FLOORS IN ADJACENT INTERIOR ROOMS WHEN AN EMERGENCY SHOWER IS INSTALLED.

5. EXTERIOR DOORS SHALL BE OUTSWING AND PROVIDED WITH EXIT DEVICE AND CLOSURE. INTERIOR ACCESS SHALL BE EITHER OUTSWING OR INSWING, VERIFY WITH CODE REQUIREMENTS.

This UFC supersedes Military Handbook 1039/2, dated 30 June 2000. The format of this document does not conform to UFC 1-300-01, however it will be reformatted at the next revision.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD(AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Support Agency (AFCESA) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request (CCR). The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

1-2 APPLICABILITY....1-1
1-2.1 Air Force Requirements....1-1

APPENDIX A MIL-HDBK 1039/2…..…….....……. A-1

CHAPTER 1

INTRODUCTION

1-1 **PURPOSE AND SCOPE**. This UFC is comprised of two sections. Chapter 1 introduces this UFC and provides alternate requirements of other Tri-Service agencies. Appendix A contains the full text copy of the previously released Military Handbook (MIL-HDBK) 1039/2. This UFC serves as criteria until such time as the full text UFC is developed from the MIL-HDBK and other sources.

1-2 **APPLICABILITY**. This UFC applies to all Navy service elements and Navy contractors; all other DoD agencies may use either document unless explicitly directed otherwise.

1-2.1 **Air Force Requirements**. Air Force pressure vessels must be inspected in accordance with AFI 32-1068, *Heating Systems and Unfired Pressure Vessels* as a minimum. Air Force Bases may adopt as an alternative to AFI 32-1068, procedures of this UFC for inspection and certification of unfired unmanned pressure vessels.

APPENDIX A

MILITARY HANDBOOK 1039/2
UNMANNED PRESSURE TEST FACILITIES SAFETY CERTIFICATION MANUAL

ABSTRACT

This document is approved for use by all departments and agencies of the Department of Defense (DOD).

Unmanned pressure test facilities have been in use by DOD personnel for centuries. To date there has not been a requirement to have these specialized facilities certified. Certification has been a standard requirement for all other classes of pressure vessel and certification standards and criteria has been developed for each class of pressure vessel. One such standard is MIL-HDBK-1152, Inspection and Certification of Boilers and Unfired Pressure Vessels. This document has been used by public works boiler and pressure vessels inspectors in an attempt to certify unmanned pressure test facilities. However, the criteria contained in MIL-HDBK-1152 are inappropriate for this type of pressure vessel. This document is written with the hopes of providing criteria and guidance for the certification and safe use of these specialized types of pressure vessels.

Section 1: INTRODUCTION

1.1 System Certification. This document provides specific certification guidelines for the design, construction, modification, repair, operation, and maintenance of Department of Defense unmanned pressure test facilities. Except as noted in par. 1.4, Department of Defense unmanned pressure test facilities include all pressure vessels used for testing and evaluating equipment or for unmanned medical or physiological experiments. System certification is a recommended prerequisite for all unmanned pressure test facilities used or operated by Department of Defense personnel, military or civilian. This prerequisite pertains to in-service systems built by the Department of Defense or private industry and privately owned systems that are under contract and operated by Department of Defense personnel. Exemptions from system certification may be granted through an operational waiver granted by the NAVFAC System Certification Authority (SCA).

1.1.1 Objective. The objective of system certification is to verify, by means of an independent technical review and evaluation, that when approved operating and maintenance procedures are followed, the pressure vessel system provides acceptable levels of safety to personnel and property throughout its specified operating range. This objective is accomplished by performing a detailed review of the material and procedural adequacy of the system.

1.1.2 Principal Participants. The principal participants in the system certification process are: (1) the system sponsor, (2) the system applicant, and (3) the SCA, NAVFACENGCOM.

1.1.2.1 System Sponsor. The system sponsor is normally the organizational unit responsible for funding the development, construction, repair, alteration, operation and/or maintenance of the unmanned pressure test facility. For systems already in existence and having achieved initial certification (see Section 3), the sponsor will normally be the parent command.

1.1.2.2 System Applicant. The applicant is normally the organizational unit responsible for the day-to-day operation and maintenance of the system. The applicant applies to the SCA for certification, and deals directly with the SCA in all certification related matters.

The sponsor and the applicant may be the same organizational unit, as in the case of an Acquisition Manager applying for initial certification of a newly developed system. Throughout the remainder of this document, only the term applicant is used when discussing the certification process. This does not, however, exclude the sponsor from participation in the process wherever appropriate.

1.1.2.3 SCA. The certification process is most effective and least complicated when:

a) The applicant designates a single, knowledgeable individual to serve as the point of contact for the certification effort.

b) The applicant has a clear understanding of the certification process.

c) The SCA has a clear understanding of the candidate system.

d) The SCA and the applicant communicate freely and frequently.

The importance of a continuing exchange of information between the applicant and the SCA cannot be overemphasized. Through open discussions and negotiation, the applicant and the SCA can establish a realistic balance between cost and time considerations and system certification objectives. Also, the SCA will gain a better knowledge and understanding of the candidate pressure vessel system through frequent contact with the applicant.

The ability of the system either to fulfill its mission or to meet program goals, other than safety, is not within the purview of the SCA.

1.2 Standard DOD Syntax Summary. This document utilizes standard DOD syntax regarding permissive, advisory, and mandatory language. Intended word meanings are as follows:

a) "Must" has been used only when application of a procedure is mandatory.

b) "Should" has been used only when application of a procedure is recommended.

c) "May" and "need not" have been used only when application of a procedure is discretionary.

d) "Will" has been used only to indicate futurity. It is never to indicate any degree of requirement for application of a procedure.

1.3 Purpose. The purpose of this document is to describe the system certification process and to provide guidance in implementing a certification program. Technical information and justification submitted by the applicant forms the basis for determining the material and procedural adequacy of each system

to perform safely. This document describes the procedures and criteria used by the SCA that must be followed by the applicant.

Sections 2 through 5 provide detailed information about the certification process and the documentation required by the SCA. Appendices A and B provide technical requirements that must be met to successfully achieve certification. Appendix C provides guidance for the required documentation. Glossary contains a list of definitions. In hopes of achieving a more comprehensive understanding, readers are encouraged to review these definitions before proceeding with the remainder of the document.

1.4 Scope and Applicability. As stated previously, the scope of this document includes unmanned pressure test facilities used for testing and evaluation purposes or for unmanned medical or physiological experiments. It also includes the associated piping, mechanical, and electrical subsystems required to operate these pressure vessels. It further ensures the safety of operating personnel and the protection of property. Safety of the objects or subjects being tested is not within the scope of this document.

More specifically this document applies to pressure vessels of the classes described in Tables 1 and 2. Examples include, but are not limited to:

a) Pressure vessels used to subject test article(s) to a simulated Deep Ocean Environment using a liquid (incompressible) or gaseous (compressible) media
b) Pressure vessels that perform Medical Research using compressible test media (air, helium, helium/oxygen, hydrogen, hydrogen/oxygen, etc,)
c) Pressure vessels that perform helium soak (integrity) testing of components that will later be subjected to a Manned Hyperbaric Environment

Pressure vessels used for the storage of gases or liquids are covered by other standards such as MIL-HDBK-1152, American National Standards Institute (ANSI) NB-23, National Board Inspection Code, or Department of Transportation (DOT) specifications. Also, open tanks and towers used for testing equipment are not within the scope of this document.

1.4.1 Unmanned Pressure Test Facility Classification Criteria. Classification of the unmanned pressure test facility should be determined as follows:

a) First, choose the appropriate classification with regard to design pressure and size of the vessel in accordance with Table 1.

b) Secondly, review pressurization media of the test

facility in accordance with Table 2. The most restrictive classification derived from the two tables should apply.

For further clarification of certification requirements for each pressure vessel class, see Table 3.

1.5 System Certification Procedures. The basis for system certification will be the evaluation of the OQE (refer to par. 2.5.2 for definition) submitted by or in the custody of the applicant and such on-site surveys and audits as are deemed necessary by the SCA. Where applicable, OQE should, encompass areas of:

a) Design

b) System drawings

c) Materials of construction

d) Construction, fabrication, and assembly

e) Quality assurance/control

f) Testing

g) Operability

h) Maintainability

Table 1
Unmanned Pressure Test Classification

	=< 6" I.D. Any Length	> 6" I.D. to 5 ft^3	> 5 ft^3 to 50 ft^3	> 50 ft^3
< 15 psig	Not Required	Not Required	Not Required	Class C
15 to 150 psig	Not Required	Class C	Class B	Class A
> 150 to 600 psig	Class C	Class B	Class A	Class A
> 600 psig	Class B	Class A	Class A	Class A

Table 2
Pressurization Media

	< 15 psig	15 to 150 psig	> 150 to 600 psig	> 600 psig
Pressure Media Liquid	Not Required	Class C	Class B	Class B
Pressure Media Gas	Not Required	Class B	Class A	Class A
Pressure Media Hazardous[(1)] (Gas or Liquid)	Class A	Class A	Class A	Class A

[1]Hazardous Media is defined as any gas or liquid that is flammable, toxic, or poisonous

1.5.1 New System. For a new system design, the applicant should present OQE documenting the above areas to the SCA during one or more formal design/construction reviews as appropriate. Preparation and presentation of this OQE must be specifically required by the terms of the contract or specifications and is the responsibility of the applicant. For a newly fabricated system which is an exact duplicate (e.g., design, material, depth limits, temperature, environment, etc.,) of a certified system, on-site surveys of the configuration, quality control, testing records, previous certification documents, and a demonstration of the system may provide sufficient OQE.

1.5.2 Existing System. For a system already in existence and possibly in service, the assembly of sufficient OQE might require considerable effort. If OQE is not retrievable, the information may have to be recreated. To recreate OQE, the applicant may have to resort to nondestructive and/or destructive testing, inspection, and design review analysis. The applicant should consult with the SCA for direction as to the required OQE necessary to certify the existing facility based on its intended use.

The criteria required by this document will not necessarily cause the system certification of current tenure to be suspended or terminated prior to normal expiration. However, all recertifications and continuances should be judged using the criteria established by this document.

It must be recognized that new information that may become

available during the on-site survey, or subsequent to certification, may indicate the existence of an unsafe condition that previously had not been identified. In such cases, when the potential danger from the newly reported condition warrants, the SCA will direct a reevaluation of the system design. Suspension or termination of certification may result.

Section 2: THE SYSTEM CERTIFICATION PROCESS

2.1 Introduction. This section explains the major events during the system certification process and provides information for assisting the applicant in preparing the required documents (refer to Appendix C). Figure 1 represents the sequence of the major events and identifies whether the action is the responsibility of the SCA or the applicant. The Glossary defines the terms used throughout the certification process. These definitions should be reviewed before proceeding with the remainder of this document.

2.2 Application for System Certification. The certification process begins when the applicant submits a letter to the Commander, NAVFACENGCOM, in standard DOD format, requesting certification of his or her unmanned pressure test facility. The application should include the following items:

a) Identification of the applicant and a point of contact

b) General system description

c) Desired system use, type of intended testing

The SCA should respond to the application, making comments as appropriate, and request funding and request submission of the following documents:

a) Scope of Certification (SOC)

b) Milestone Event Schedule (MES)

c) System drawings

2.2.1 Scope of Certification (SOC). The applicant should submit a detailed list of all portions of the system and its ancillary equipment, which are expected to fall within the SOC as defined in the Glossary. The SOC boundaries will be approved or modified by the SCA.

As an aid in defining the SOC, especially for complex systems, the applicant is referred to the hazard analysis techniques described in the Hazard Analysis section of MIL-STD-882, System Safety Program Requirements. Additional guidance is provided by the hazard categories defined in par. 2.2.2 and Figure 2.

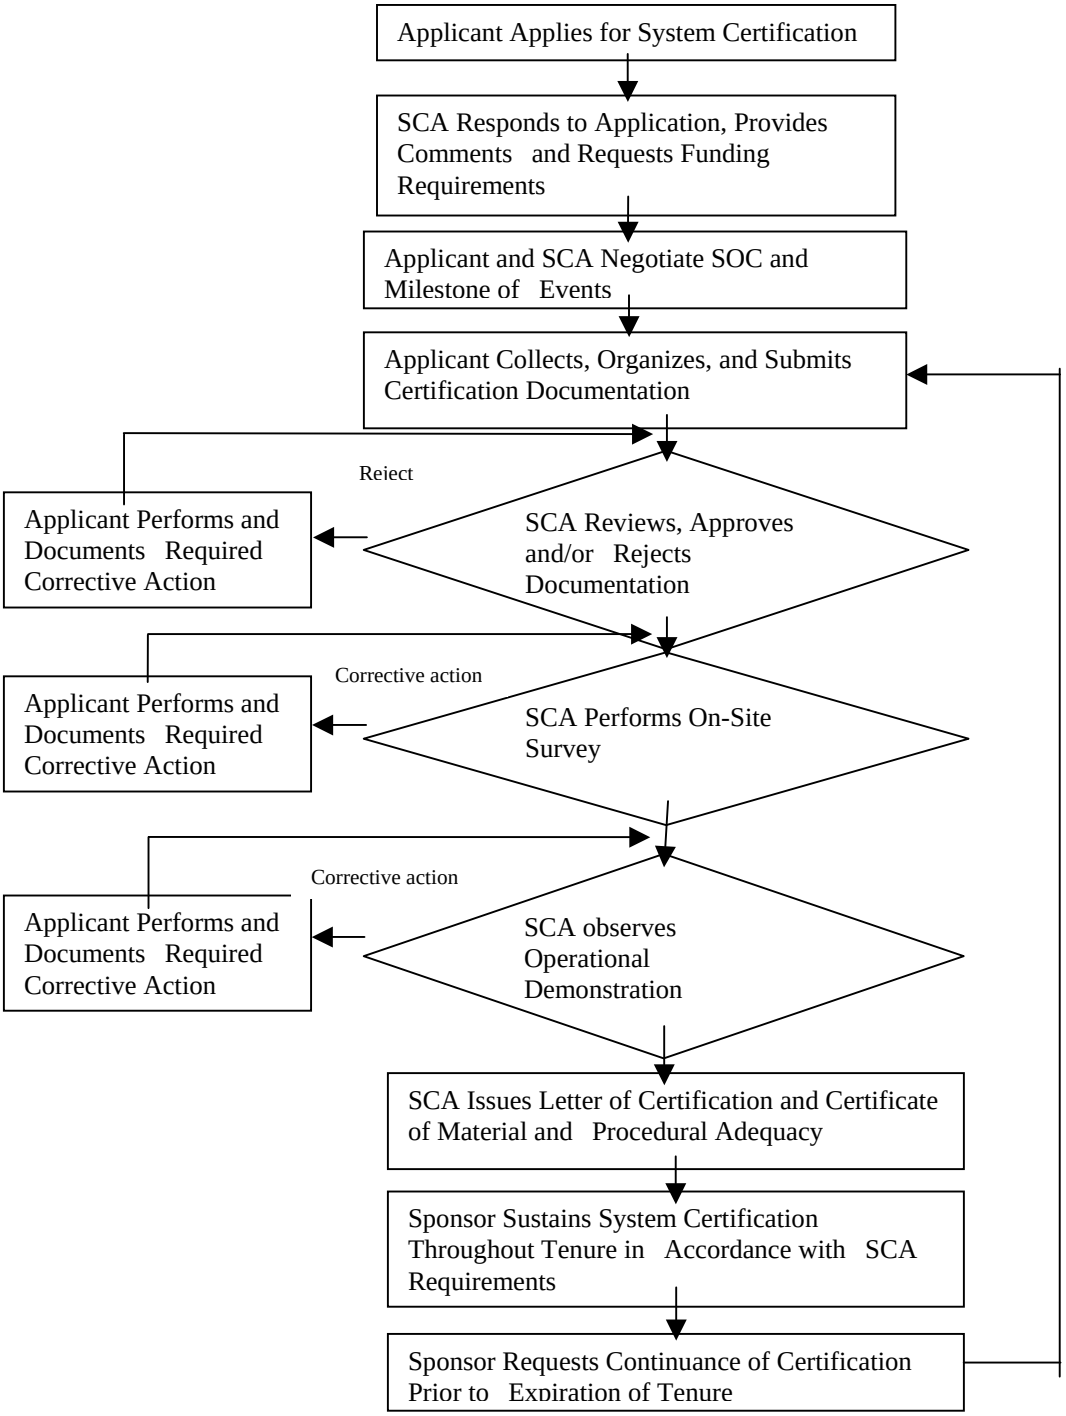

Figure 1
Certification Sequence of Events

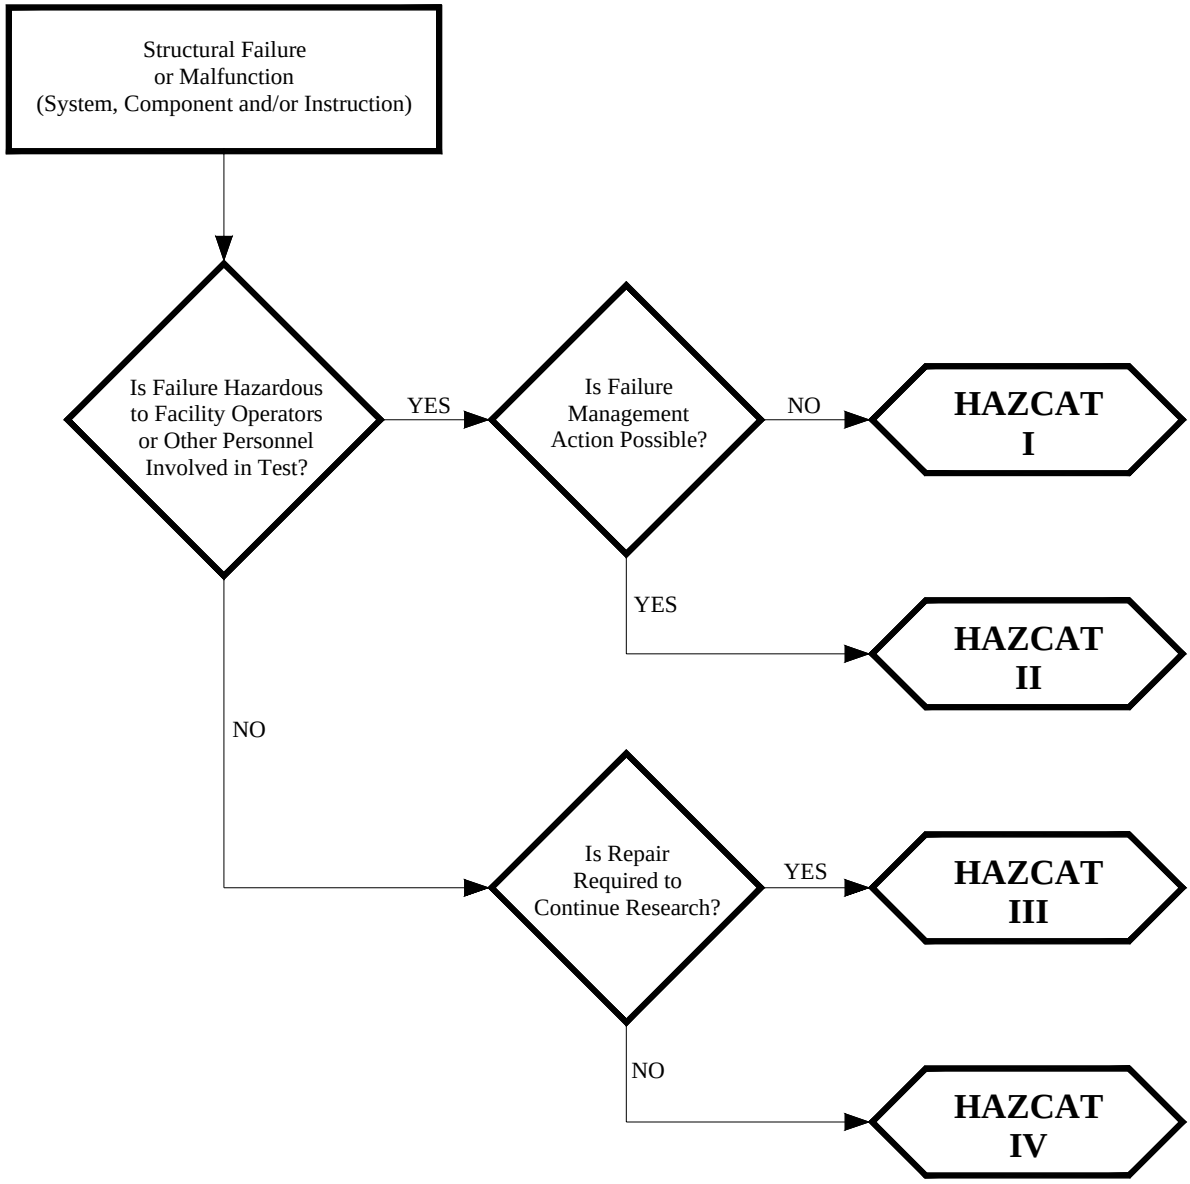

Figure 2
Hazard Category Identification

It is recognized that individual system designs will vary to such an extent that no single list can encompass the entire spectrum of SOC's. The following is a list of specific areas that generally require inclusion in the SOC. This list is provided for purposes of illustration and should not be considered as all inclusive or universally applicable:

a) Pressure hull, pressure vessels, hard structure, and appurtenances (penetrations, seals, etc.,).

b) Life support subsystems that provide an acceptable atmosphere for unmanned medical and physiological experiments.

c) Pressurization and depressurization systems including, but not limited to, piping systems and pressurized storage facilities.

d) Non-compensated equipment, subject to pressure, which may implode or explode.

e) Fire fighting devices or subsystems.

f) Electrical power subsystems that include internal and external electrical protective devices where failure could result in malfunction of a critical component or subsystem or create a shock hazard.

g) Subsystems and components that protect personnel directly or indirectly against the effects of accidents and hazards.

2.2.2 Hazard Category Criteria. In the analysis of a structural or functional failure of a system, equipment, or component, the following hazard category (HAZCAT) evaluation criteria are used (Figure 2 is used as a guide):

a) HAZCAT I. Catastrophic failure, which exposes operator/test personnel to hazards that would likely result in death, or severe injury (permanent total disability). Upon failure, operator action cannot be taken to manage or mitigate the hazards. Testing operations aborted.

b) HAZCAT II. Critical failure, which exposes operator/test personnel to hazards that would likely result in injury (permanent partial disability). Upon failure, operator action can be taken to manage or mitigate the hazards. Testing operations likely aborted.

c) HAZCAT III. Marginal failure, which would not likely expose operator/test personnel to any significant hazards. Upon failure, operator action is required to manage or repair the failure; otherwise testing operations must be aborted.

d) HAZCAT IV. Negligible failure, which would not likely expose operator/test personnel to any significant hazards. Testing operations may continue without management action.

Note – the above hazard categories do not contain a probability of mishap occurrence. These categories suggest a probability of end result associated with the hazard severity. HAZCAT I and HAZCAT II categories are acceptable only when the probability of mishap has been mitigated by design, testing, procedures, and inspection to improbable, as defined by MIL-STD-882.

2.2.2.1 HAZCAT Guidelines. Generally, most components within a specific system are all the same HAZCAT. Since HAZCAT I designation means a malfunction endangers the lives of operator/test personnel and no failure action is possible, stricter material selection and control; fabrication and installation procedures; and quality control testing is required on these items.

Likewise, HAZCAT II items have more stringent requirements than HAZCAT III and HAZCAT IV items. Additionally it is recognized that failure of a HAZCAT II item, such as a pressurized gage isolation valve, could result in operator death or severe injury. However, the probability that the severity would be as great as that encountered during failure of a HAZCAT I item (such as a pressure vessel) is considered improbable. Therefore, when determining HAZCAT boundaries, engineering judgment on a case basis, as well as consultation with the SCA, may be required.

The following guidelines are provided to assist in the determination of HAZCAT designations:

a) HAZCAT I items include the pressure boundary to which the operator/test personnel are exposed and the first pressure piping isolation valves connected to the pressure boundary. HAZCAT I items, dependent on design of the facility, may also include other system piping and components. For example, if hazardous gases or fluids exist, then all piping and components containing them would be HAZCAT I. Items include:

(1) Pressure vessel and hatches

(2) Pressure vessel view ports

(3) Pressure vessel penetrator fittings

b) HAZCAT II items include systems, equipment, and components which have sufficient isolation boundaries that injury can be precluded by securing the source of pressure, gas flow, fluid flow or electrical power. Items include:

(1) Ancillary piping, high pressure gages and instrumentation, and associated valves/components

(2) Electrical switch gear

c) HAZCAT III items include systems, equipment, and components that failure would compromise the research/test being conducted. Items include:

(1) Pumps

(2) Control valves

(3) Monitoring and control instrumentation

d) HAZCAT IV items include systems, equipment, and components that are not critical to the research or test evolution and can be repaired at a convenient time. Items include:

(1) Filtration equipment

(2) Building support systems

2.2.3 Milestone Event Schedule (MES). The certification MES should include a list of sequential events in the certification process with estimated dates of completion. The time required for documentation submissions, technical reviews and deficiency should be considered in the MES to ensure timely completion of the certification process prior to the desired system use date. Figure 3 is an MES for a typical system. It may be reproduced and filled in and submitted by the applicant. If it does not meet the needs of a particular system, the applicant may develop and submit one of original design. The initial MES may be submitted at the same time the initial SOC is submitted or may be submitted after the SOC has been approved by the SCA.

2.3 Submission of Supporting Documentation. Utilizing the approved SOC as a guide, the applicant should prepare and submit the following documentation in accordance with the MES:

a) Design review information.

(1) System drawings

(2) Design calculations

(3) Hazard analysis

b) Construction, fabrication, and assembly information

c) Quality program information

d) Test program information

e) Operating and emergency procedures

f) Maintenance procedures

g) Configuration management plan

Additional information may be required in the course of the certification process to fully justify any area that concerns the SCA.

2.4 Review and Approval of Supporting Documentation. All supporting documentation submitted should be reviewed by the SCA for technical adequacy and for conformance to the requirements of this document. When additional technical expertise is required, the SCA may obtain assistance from the headquarters technical staff or such other experts as may be appropriate. Design information should normally be reviewed during formal design reviews. Obtaining SCA concurrence with the design is strongly recommended prior to beginning construction.

2.5 On-Site Survey. As required, the SCA and his designated representative should conduct one or more on-site survey(s) of the system. The purpose of a survey is to verify that the "as-built" system has been fabricated in accordance with the approved documentation and that it can be operated safely and maintained effectively. Each survey should be officially requested in writing by the applicant and confirmed by the SCA. A request for a survey should be made to the SCA at least 90 days prior to the desired date of the survey. Normally, a survey should not be scheduled until after the system drawings and operating and emergency procedures have been approved.

2.5.1 Survey Team Personnel. The SCA will assemble a survey team to perform an on-site survey of the system. The type and complexity of the system will determine the size and make-up of the survey team. Typically, the areas of expertise of the survey team will include mechanical, electrical, hydraulic, ocean, and structural engineering. Quality assurance (QA) specialists may also frequently be included. For a relatively simple system, a single individual may represent the SCA.

2.5.2 Objective Quality Evidence (OQE). OQE is any statement of fact, either quantitative or qualitative, pertaining to verification of the quality of a product or service based on observations, measurements, or tests. Evidence will be expressed in terms of specific quality requirements or characteristics. These characteristics are identified in drawings, specifications, and other documents that describe the item, process, or procedure. One of the main objectives of the survey is to review

the OQE to ensure that the system is actually built as designed and that it will perform safely to the limits for which certification is requested. Accordingly, the survey team will review OQE in sufficient detail and depth to support a conclusion as to the acceptability of the system. The applicant should ensure, prior to a survey, that necessary OQE not previously submitted to the SCA is readily available for the survey team. Appendix C provides additional guidance on OQE.

System Certification Milestone Event
Schedule
15

Instructions: For each event applicable to the applicant’s system, enter the date of completion in the appropriate box of the 24-month grid provided.

2.5.3 Survey Coverage. The survey should include, but not be limited to, a review of the following items:

a) As-built drawings and documentation of the system

b) Drawing control procedures and records

c) QA procedures, results, and records

d) Non-destructive testing (NDT) qualifications and records

e) Construction, fabrication, assembly, and test procedures results, and records (e.g., welding/brazing procedures, records, and personnel qualifications)

f) System proof and performance test procedures and results

g) System cleaning procedures and results, including sampling points and pass/fail criteria

h) Accessibility to vital equipment and components

i) Quality of workmanship

j) System component identification and color coding

k) Gauge, instrument, and relief valve calibration data

l) Repair and maintenance procedures and records

m) Re-entry control procedures and records

n) Operating and emergency procedures (OPs and EPs)

o) A physical review of system hardware to determine general material condition

p) Operational demonstration of the system using the OPs and EPs

2.5.4 Preparation for Survey. The applicant is responsible to make every effort to prepare in advance for the on-site survey. All formally documented procedures requiring SCA review and approval should have been provided to the SCA prior to requesting the survey. The system should be operationally ready and all obvious deficiencies corrected prior to commencement of the survey. The supporting OQE discussed throughout this document should be available at the survey site in an organized fashion. It is essential that qualified personnel, knowledgeable in all aspects of the system (operation, design, testing, QA, maintenance, etc.,), be available and ready to assist the survey

team. It is important to note that the applicant is responsible for the accuracy and completeness of documents presented regardless of their source. The applicant or designated representative should review all records and data supplied from industrial or support activities prior to the survey. Those that are incomplete or in error will be rejected and returned for correction. All documentation should be presented in an organized and audit ready form. The SCA should be able to quickly and easily trace the documentation to the hardware and vice versa.

2.5.5 Survey Guidelines. As in all safety related inspection programs, the intentional concealment of known deficiencies by either action or inaction is deliberate malpractice and could result in death or serious injury. Deficiencies that are known to the applicant and inadvertently overlooked by the survey team should be brought to the attention of the SCA and discussed. Certification survey cards should not be viewed as representative of either command or personal failure. Rather, cards should be viewed as the subjective findings of personnel, who are conscientious and responsible for ensuring the safety of the operators and the protection of property.

2.6 System Certification Survey Cards. Deficiencies noted during the survey and recommended corrective action will be documented in the form of System Certification Survey Cards (SCSCs). Survey cards are classified by the SCA as follows:

a) Category 1A. Corrective action must be accomplished prior to use of the system. For an unmanned pressure test facility that has already been certified, the issuance of a Category 1A SCSC should result in either the termination or suspension of the existing certification. Prior to further use of the system, full re-certification or removal of the suspension by the SCA is required.

b) Category 1B. Corrective action must be accomplished prior to system certification. The issuance of a Category 1B SCSC should permit use of the system for the purpose of operational demonstration pursuant to certification only.

c) Category 1C. Corrective action must be accomplished prior to the date or event specified on the card to sustain certification. Certification, sustaining certification or continuation of certification may be granted in the interim. Unless advance justification is provided, failure to correct the deficiency and notify the SCA officially in writing by the specified date or event should cause termination or suspension of certification.

d) Category 1D. Corrective action must be accomplished on specified component and SCSC cleared prior to its use, while the over all system retains it’s certification.

e) Category 2. Corrective action is desirable, but not mandatory. Category 2 deficiencies may be corrected at the applicant's option, but should be addressed by the applicant even if no action is taken.

Each card has space for the survey team to record its findings and recommendations. Separate space is provided for a statement of corrective action. Figure 4 is a sample SCSC. At the conclusion of the survey, a critique will be held. The survey team leader will review and discuss all survey cards and their recommended corrective actions with the system applicant or his designated representative. The critique is open to all interested parties. Frank discussion and free exchange of information are encouraged. Any disagreement by the applicant with the findings or with the categorization of any of the SCSCs should be discussed during the critique. Further, if the applicant has completed some or all of the corrective action for one or more of the deficiencies found, he should make this information known at the critique.

The survey team leader may, as a courtesy, leave preliminary copies of the survey cards. These copies are for discussion purposes only. Expenditure of resources should not be undertaken based on these unofficial cards as they are subject to change prior to official issue.

Upon completion of the survey, the SCA will forward the results of the survey team's evaluation of the system to the applicant for action, via the appropriate chain of command. The SCA will provide copies of the survey cards to other activities, when requested by the applicant. If many Category 1A or 1B survey cards are issued during a survey, a follow-on survey may be required. If a follow-on survey is necessary, the SCA will inform the applicant in writing. The SCA may revise a card or downgrade an SCSC category after its initial issuance. Reasons for revising an SCSC include:

a) A partial clearing of the deficiency.

b) A change in the nature of the deficiency based on additional information.

c) Discovery of a new deficiency closely related to deficiency already documented on an SCSC.

d) Splitting a single SCSC into multiple SCSCs for ease of tracking status by subsystem.

A SCSC may be downgraded if it can be shown that the lower category is more appropriate than the originally assigned category. SCSCs that include more than one recommended corrective action would not normally be revised based solely on the completion of one of the recommended corrective actions. SCSCs may be revised or downgraded either unilaterally, by the

SCA, or based on a request from the applicant.

When action identified by a specific card has been completed, a brief summary should be written on the card and the card signed by a senior representative of the applicant. Cards must then be returned to the SCA, via the chain of command, for clearing. Should the clearing of the card involve supporting documentation (e.g., re-entry control forms, test memos, NDT records, calibration data, etc.,), the documentation should be referenced on the card and copies returned with it. When the submitted corrective action is satisfactory to the SCA, two representatives of the SCA should sign the card and return it to the applicant. Normally, one of the signing individuals will be the one who wrote the card. Double signature by the SCA will clear the card. If the action taken by the applicant does not satisfy the finding, but instead alters the system mission so that personnel safety will no longer be an issue, the SCA may cancel the card. The applicant may, with supporting justification, request that an SCSC be canceled. The request to cancel a card should be documented by the applicant on the card with the technical justification attached to the card. A senior representative of the applicant and two representatives of the SCA must also sign canceled cards. The SCA will normally provide copies of officially cleared or canceled cards to the applicant for record purposes.

All Category 1A and 1B deficiencies must be cleared or canceled prior to certification. Category 1C deficiencies must be cleared or canceled prior to the date or event specified by the SCA to sustain certification. Category 1D cards must be cleared prior to use of the specified component. Category 2 deficiencies may be corrected at the applicant's option, but should be addressed by the applicant even if no action is taken. Following the granting of either initial certification or re-certification of an unmanned pressure test facility, there are two additional times when survey cards may be issued. These are:

a) During a survey performed within the tenure of certification to ensure that certification is being adequately sustained.

b) During a survey requested by the applicant to continue certification beyond the original tenure of certification.

2.7 Operational Demonstration. A satisfactory survey including correction of all Category 1A discrepancies may permit, with the concurrence of the SCA, the commencement of a certification operational demonstration to the depth or pressure limits stated in the certification application. The SCA or his appointed representative will participate in or observe the operational demonstration of the system. The SCA may elect not to observe an operational demonstration of an unmanned pressure test facility that has had a history of safe and satisfactory performance.

The SCA may certify or re-certify an unmanned pressure test facility for full certification depth based on operational demonstrations to a depth less than the full certification depth. This alternative can be exercised by the SCA for those systems that have a history of safe and satisfactory performance and pressurization to full depth is not possible or practical.

The certification operational demonstration may be conducted in conjunction with other DOD program requirements. Satisfactory completion of the certification operational demonstration and clearing of all open Category 1B SCSCs generally will justify the granting of system certification.

2.8 Issuance of Certificate. A certificate of Certification of System Adequacy may be issued by the SCA after the successful completion of the operational demonstration and the correction of deficiencies. The SCA should specifically state the operational limits, parameters and tenure for which the certification is granted. The SCA should also specify the terms and conditions of system certification and additional requirements as appropriate. The officer in charge of the facility is thereafter responsible for sustaining system certification and requesting continuation of system certification or re-certification.

2.9 Tenure of Certification. Tenure of certification is the length of time for which certification is granted. The tenure of certification for unmanned pressure test facilities should be determined by the guidelines provided in Table 3. The granting of system certification, by the SCA, does not automatically ensure that it will remain in effect for the full, stated period. System certification should not be granted for the entire design life of the system. The tenure of system certification may be negotiated to coincide with planned events such as overhaul or refurbishment.

Table 3
Unmanned Pressure Test Facility Certification Requirements

CLASS - A	CLASS – B	CLASS - C
3yr SCA Visit	6yr SCA Visit with 3yr documentation review	6yr Certification, No SCA Visit, submit documentation

-Re-Entry Control Program, CWP, and Maintenance Manual	-Maintenance Log required	-Maintenance Log required
-OP/EP SCA Approval	-OP/EP Local Approval	OP/EP Local Approval

2.9.1 Termination or Suspension of System Certification

2.9.1.1 Termination of Certification. Termination of certification is a withdrawal of system certification. Once certification is terminated, the system cannot be re-certified without a complete SCA review of all work undertaken since the last certification survey.

2.9.1.2 Suspension of Certification. Suspension of certification is a temporary withdrawal of certification that remains in effect while one or more actual or potential violations of the terms of certification are investigated and corrected. Use of the system during the suspension is not authorized. Prior to reinstating system certification, an on-site review of the problem area(s) by the SCA may be required.

Once the deficiencies are corrected to the satisfaction of the SCA, the original system certification will be reinstated.

2.9.1.3 Conditions for Termination or Suspension. System certification may be terminated or suspended, at the discretion of the SCA, as a result of the following:

a) Violation of the limits or terms of the letter granting certification (e.g., pressure, time, temperature, etc.,).

b) Recognition of the existence of an unsafe condition.

c) Expiration of tenure of system certification.

d) Modifications to equipment or components within the SOC without the concurrence of the SCA.

e) Overhaul, repair, or alteration, as defined in Section 5.

f) Expiration of a lease contract.

g) Failure to correct Category 1C cards by specified date or event.

h) Issuance of a Category 1A or 1B survey card.

i) Casualty to the system pending the issuance of an investigative report dealing with the incident.

2.9.2 Sustaining System Certification. Sustaining system certification comprises those actions required of the applicant to ensure the SCA that the facility remains in the as-certified condition throughout the tenure of certification. As stated previously, granting system certification does not automatically ensure that system certification will remain in effect for the full certification period. The responsibility for sustaining system certification during the certification period rests with the officer-in-charge of the facility.

2.9.2.1 Design Changes and Alterations. SCA concurrence must be obtained for any design changes or proposed alterations to equipment within the SOC, or which could impact the SOC. Each proposed design change or alteration should contain an evaluation of the effects of the change to the safe operation, of the system, in accordance with the requirements of this document. Accomplishment of design changes and alterations within the SOC without SCA concurrence should result in termination or suspension of system certification.

2.9.2.2 Repairs and Maintenance. The facility should be

maintained so that all systems, subsystems, and components within the SOC are functioning properly, in an as-certified condition, prior to each operational use.

All work and testing accomplished during routine repairs and maintenance should be in accordance with the requirements in Section 5. Only qualified personnel should perform repairs, maintenance, inspections and testing. Documentation requirements for repairs, non-routine maintenance, and testing should be recorded in accordance with the requirements of Appendix C.

2.9.2.3 System Certification Survey. A system certification survey, as described in par. 2.5, may be performed when deemed necessary by the SCA as a condition of sustaining or continuing system certification. Unsatisfactory survey results may result in termination or suspension of system certification.

2.9.2.4 Operating Limits. The system should be operated only within its certified operational limits. Operation outside of the authorized limits without a valid waiver is not allowed and may result in termination or suspension of system certification. Any violation should be immediately reported to the SCA, stating the cause or justification.

2.9.2.5 Unusual Situations. The SCA should be advised of any situation, which may prevent the system from maintaining its intended operational capability. These may include, but are not limited to, exceeding certified pressure, physical damage, fires, emergency pressure excursions, and casualties resulting in injury or death. Further, a report should be submitted containing an evaluation of the extent of damage, proposed repair methods, and probable cause of the emergency (e.g., personnel error, nature of the operations, system or component failures, etc.,). It is not intended that these emergency situations include failures that only temporarily interrupt the operational capability of the system and are corrected by routine repairs.

2.9.3 Continuation of System Certification. Continuation of system certification is an extension by the SCA of the certification period beyond that initially granted. This is normally done to permit continued use of a system that has had no changes to the basic design, SOC, or general operating characteristics and where the material condition of the system will support the continuation. During this continuation of system certification, all requirements noted in par. 2.9.2 should be observed. The applicant should arrange with the SCA for a continuation of certification and should submit a request for an on-site survey no less than 90 days prior to the desired certification date.

2.9.4 Re-certification. Re-certification is a new certification of a system where the existing certification has expired or has been terminated. To re-certify a system, the SCA

should determine those requirements of this document that must be accomplished. Following a re-certification, all requirements noted in par. 2.9.2 should be observed.

2.9.5 Extension of Certification. The SCA may extend system certification for short duration in three cases:

a) When emergency operational commitments of the system prevent it from being available for an on-site survey at the time of the expiration of certification.

b) When the system is scheduled for overhaul within 90 days after expiration of the current certification.

c) When the SCA is unavailable due to prior commitments.

Extensions of certification will be granted only for systems that have required no more than routine maintenance and repairs during the original tenure of certification. Any non-routine work performed on the system should be reported to the SCA. The SCA requires equipment hydrostatic test dates, gage calibration dates and a statement that the system is operational prior to granting an extension of certification. If requested, the applicant should provide the SCA with a list of all work accomplished on the system during the tenure of certification and justification for the request for an extension.

2.10 Transfer of System Custody

2.10.1 Permanent Transfer. Unmanned pressure test facilities may be permanently transferred. The SCA should be kept apprised of all pending transfers. After authorization for a permanent transfer has been granted, the following action should be accomplished:

a) The custodial command should inform the recipient command of the operational condition of the system, including all operational and documentation deficiencies and outstanding SCSCs.

b) The custodial command should prepare a "turnover file" consisting of as-built system drawings, all re-entry control documentation, test records, technical manuals, operating and emergency procedures, a complete Preventive Maintenance System (PMS) package, and all certification survey documentation from previous surveys. The turnover file should accompany the system to the recipient command.

2.10.2 Recipient Command. After receipt of the system hardware and certification documentation, the recipient command should take the following action:

a) Establish a formal QA plan and re-entry control procedures.

b) Verify that system drawings, technical manuals, and operating and emergency procedures reflect the as-built condition of the system. All required drawings and operating and emergency procedure revisions should be submitted to the SCA for review and approval.

c) Initiate the preventive maintenance plan for the system.

d) Request an on-site survey of the system by the SCA.

Upon completion of a successful on-site survey, the SCA will grant the system a new certification. This procedure applies to all systems.

Section 3: INITIAL CERTIFICATION

3.1 Introduction. This chapter describes the criteria that must be met to obtain initial certification for an unmanned pressure test facility. Assembly of the necessary OQE and adherence to these criteria should coincide with the design and construction or fabrication of the new system. For a system designed, manufactured, and placed in service outside the purview of this document (i.e., a system built by and for private interests, placed in service, then purchased by DOD), the task of assembling the necessary documentation may be very difficult, if not impossible. In such cases, additional testing and analysis is generally required. The level of documentation complexity will vary according to the class of the facility. (See Tables 1 and 2.)

3.2 Design Review Information The applicant should submit the documentation and evidence described in the following paragraphs to the SCA for review and approval. During review of this evidence, the SCA may require the applicant to supply additional information. If, in the course of supplying information required by the SCA, it becomes necessary for the designer and or builder to disclose information he considers proprietary or classified, he should so identify it. The SCA should cooperate with the designer and builder in the protection of such information.

The design documentation submitted by the applicant for review and approval should include the following:

a) SOC

b) MES

c) Summary description of the system

d) Subsystem descriptions

e) Design parameters

f) Design analysis

(1) Design calculations

(2) Stress analysis

g) System drawings

h) Operability and maintainability criteria and procedures

i) Justification of materials

j) Flammable materials data

k) Hazard analysis

For new systems, the applicant should provide items (a) through (e) above to the SCA for review and/or approval prior to conducting formal design reviews.

Items (f) through (k) should be forwarded to the SCA by the applicant at least 60 days prior to convening each formal design review or as required by the MES. The number and scope of formal design reviews will be governed by the size and complexity of the system and can be negotiated between the applicant and the SCA.

3.2.1 System Scope of Certification and Milestone Event Schedule. The applicant should submit the SOC and MES (both described in Section 2) to the SCA for review and approval.

3.2.2 Summary Description of the System. To aid the SCA in performing a safety evaluation, the applicant should submit a summary description of the pressure vessel system including design and construction details. A written explanation of the features of the system, along with appropriate schematic drawings should be included. The content of the summary description should be commensurate with the complexity of the system. Simple systems need only brief summary descriptions; complex systems obviously require more detail.

3.2.3 Subsystem Descriptions. Each subsystem within the SOC should be described. These subsystems normally include fluid systems, electrical systems, compressed air and gas systems, and other significant mechanical, electrical, or structural features required for the complete operation of the facility.

Each subsystem design submitted must include both a written description and a function or flowchart diagram. The description should clearly delineate objectives of the design. Safety considerations should also be included. It should also include an analysis of the consequences of a failure or loss in the normal operating mode. The diagram should clearly show how the subsystem accomplishes its intended function. Sufficient information should be included to identify the specific components and their location, size, material, etc.

3.2.4 Design Parameters. Design parameters of the system must be identified. Design parameters provide the basis for evaluating system adequacy. Design parameters that the applicant must consider and which will be evaluated by the SCA include:

a) Design safety factors

b) Design life and service period (useful life, number

of cycles, etc.,)

c) Effect of ambient operating conditions and the effect of mechanical shock and vibrations on design life

d) Depth and pressure limitations

e) Design temperature limits

f) Identification of anticipated hazards

g) Corrosion allowance and resistance requirements

h) Soil and foundation considerations where applicable

i) Floor loads including hydrostatic test weight

3.2.5 Design Analysis. A complete and thorough design analysis should be submitted for SCA review and concurrence. The design analysis should consist of formal design calculations and a complete stress analysis as explained below.

3.2.5.1 Design Calculations. Design calculations should be submitted for SCA review and concurrence to demonstrate the adequacy of design. All assumptions should be clearly stated. Calculations should show the effect of building to worst-case dimensions and tolerances. Potential effects of corrosion should be considered. Appropriate reference should be made to applicable test data or operating experience when either is used to support a calculation technique. Design calculations should clearly show the adequacy of the item analyzed in terms of the system design parameters. Information must be submitted in sufficient detail to permit independent analysis of the design. Documentation submitted by the applicant should be tabulated to ensure that the information completely covers the design.

3.2.5.2 Stress Analysis. Applicant should verify the adequacy of the design by performing detailed stress analyses and, when appropriate, by conducting the tests described herein. Applicable sections and provisions of pressure vessel and piping design codes should be applied. Test programs in support of system certification should consider all ramifications of the stress analyses. Stress analyses and test reports submitted by the applicant should also consider the most critical loading case which includes the cumulative detrimental effects of design allowances, dimensional variations, and tolerances. Applicant may request that specific designs utilizing standard materials or components be exempted from stress analysis, based on technical justification. In cases where the pressure boundary is a unique and complex shape, destructive testing may be required if the validity of a stress analysis is in question. The SCA will then make a determination of those materials and systems that do not

require the stress analyses and will inform the applicant whether material may be exempted.

Examples of loads to be considered are:

a) Weight of water used for hydrostatic testing

b) Static loads imposed by the clamping or securing devices used to secure the system

c) Maximum operating pressure of the gas or fluid within the system

d) Thermal stresses due to the operating temperature range of the system

e) Reactions due to differential thermal expansion between the system and the structure to which it may be fixed or due to elastic expansion of the system caused by internal pressure

f) Shock, including accidental blows

g) Vertical and horizontal loads on foundations where applicable

h) Seismic requirements where applicable

i) Dynamic loads, such as those encountered from collapse of any non-pressure-compensated elements

j) Fatigue loads of the pressure resisting components and piping for a specified number of cycles

3.2.6 System Drawings. Certification of all unmanned pressure test facilities should require drawings meeting the requirements of MIL-DTL-31000, Technical Data Packages or acceptable commercial standards and which are adequate to support technical design reviews. The level of drawing detail should reflect the level of design maturity that has been attained at the time of each design review. The function and complexity of the subsystem being reviewed should determine the number and type of drawings required for an adequate technical design review. In addition to showing system and subsystem configuration, drawings normally required to support a technical design review must have adequate detail to show material, fabrication, cleaning, testing, and special assembly requirements. In most cases where mechanical or electrical systems are being reviewed, system schematic diagrams with the above information are acceptable. However, where critical equipment such as the pressure hull is being evaluated, actual assembly or fabrication drawings are required for the final design review. The applicant should submit up-to-date copies of drawings, signed by the appropriate

technical agent, for each subsystem to be evaluated during a design review.

Each component that provides a control, sensing, or similar essential function that impacts the operation of the system (valves, gauges, pressure regulators, etc.,) should have a unique identifier made up of a system designation and a number. A table should be provided identifying system designations. These unique identifiers should be shown on the drawings and should be used in the operating and emergency procedures.

When the final system design has been approved, a complete set of product drawings should be produced and distributed as determined by the Acquisition Manager. Where appropriate, the drawings should specify any special material control requirements. The Acquisition Manager should confer with the SCA to determine which drawings will be required to maintain system certification and should ensure that those drawings are distributed to the activity that will operate the system after initial system certification has been achieved. The system operators will then continuously keep those drawings current by ensuring that they reflect as-built system configuration. This may be accomplished by "red-line" marking of the drawings. Red line drawings must be officially revised after each system overhaul or major configuration change, whichever comes first. All drawing revisions should be formally documented and the reason and authority for each revision should be explicitly stated on the drawing. Each component or item on the as-built drawings should be identified by the manufacturer's model or type number, part number, vendor identification, applicable military specification, federal specification or standard as appropriate.

3.2.7 Operability and Maintainability. The criteria and procedures for which operation and maintenance are based should be explained and supported by technical manuals and other documentation. Include emergency procedures.

3.2.7.1 Operating and Emergency Procedures. The applicant should develop and submit operating and emergency procedures that cover all foreseeable normal and emergency evolutions the system may be required to undergo. Refer to par. 3.6 for detailed requirements concerning operating and emergency procedures.

3.2.7.2 Maintenance Procedures. The applicant should provide the SCA with formal maintenance procedures for all systems, subsystems and components within the scope of certification. This requirement can be met using DOD PMS and pre- and post-operational procedures. These procedures will be considered in the certification process as they relate to safe operation of the system.

3.2.8 Justification of Materials. All materials and their applications, used in the design of an unmanned pressure test facility, should be justified. It is not the intent of this document to limit materials and their applications. New materials, or time-tested materials in new applications, may be used if sufficient data exists to ensure the material adequacy of the system. Justifying data must include the requirements for care, preservation and maintenance of new materials for the projected life cycle of the material. The less information and experience available concerning a given material for a specific application, the greater the burden upon the applicant to justify the proposed material for the application. For the purpose of system certification, types of materials and components are grouped into three categories that are defined in Appendix A.

3.2.8.1 Design Practices. When required by the SCA, material selection, design, and fabrication techniques should be justified in accordance with military and recognized commercial engineering practices. Proper consideration should be given to complex configurations and intersections, cyclic fatigue, and low temperature requirements. Examples of recognized engineering design practices are:

a) American Society of Mechanical Engineers (ASME), Boiler and Pressure Vessel Code, Section VIII, Divisions 1 and 2

b) ASME PVHO-1, Safety Standard for Pressure Vessels for Human Occupancy

c) NAVFAC Design Manual (DM)-39, Hyperbaric Facilities

d) ASME B31.1, Power Piping Code

3.2.8.2 Design Criteria. For typical design criteria of unmanned pressure test facilities, the applicant should refer to the following appendices of this document:

a) Appendix A: Categorization of Scope of Certification Materials and Components

b) Appendix B: Design Parameters for Unmanned Pressure Test Facilities

c) Appendix C: Required Documentation

3.2.9 Flammable Materials Data. The applicant should submit, for review and approval, a list of all potentially flammable materials to be used during construction, or to be installed or used in the unmanned pressure test facility. Flammable materials are those which will ignite or explode from an electric spark or when heated and will continue burning in the presence of air or in any oxygen-enriched atmosphere. Flammable materials should be evaluated under both normal and emergency atmospheric conditions. As applicable, all material data should be submitted in standard

Material Safety Data Sheet (MSDS) format.

3.2.10 Hazard Analysis. As part of the design process, a hazard analysis must be performed to evaluate the effects of all possible failures. The hazard analysis must be performed assuming that only one failure occurs at a time, not multiple failures occurring at the same time. The applicant should submit the hazard analysis of the system for review and approval by the SCA. The hazard analysis should describe the possible effects of a mechanical failure or an operator error for each component or subsystem. Those failures that could affect personnel safety should clearly show what features, warnings or procedures have been incorporated into the design, operation, and maintenance of the system to preclude or minimize the probability of failure. It is the responsibility of the applicant to ensure that conditions identified as significant safety hazards are eliminated or reduced to the lowest practical level.

Mishaps are not always the result of equipment failure. Human error, when responding to a routine command, a minor problem, or operation of a control function at the wrong time can result in a catastrophe. Operating and emergency procedures must be specific, clear and concise to avoid confusion. The hazard analysis should show that this type of failure has been considered in the design of the system and that safeguards have been taken to reduce the likelihood of such an occurrence. MIL-STD-882 provides an acceptable set of guidelines for the conduct of a hazard analysis. The application and tailoring guidelines given in MIL-STD-882 should be carefully followed to make the hazard analysis no more complicated than is necessary to prove the safety of the design. Hazard Categories, as they pertain to unmanned pressure test facilities, are defined in Section 2.

3.3 Fabrication And Assembly Documentation is required to verify that fabrication and assembly procedures meet engineering standards necessary to deliver a safe, reliable system. Copies of all documentation must be submitted with the certification package or otherwise made available for SCA review in a manner negotiated between the SCA and the applicant. All written fabrication and assembly processes that may affect the designed performance of the system must be identified. Documentation must include fabrication drawings and specifications, as well as supplementary information, not necessarily specified on the drawings, but which affects the process. Information of importance includes, but is not limited to the following:

a) Fabrication/assembly procedures

b) Process instructions

c) Welding procedures

d) Brazing procedures

e) NDT procedures

f) Cleaning procedures

g) Quality assurance procedures and inspections

h) Personnel qualifications

i) Fabrication and assembly documentation

j) Any other processes, procedures, or instructions required for construction of the unmanned pressure test facility

Adequacy of these processes must be substantiated by a history of satisfactory use or by documented qualifications and tests.

3.3.1 Fabrication/Assembly Procedures. Fabrication/assembly procedures must define the scope of work and provide production personnel with step-by-step instructions on how the work is to be accomplished. When fabrication/assembly procedures are written to accomplish repairs, maintenance or modifications, they should state the specific reason for performing the work. These instructions are required wherever fabrication, assembly, cleaning and/or testing of components or systems, within the SOC boundaries, is to be performed during initial certification. Fabrication/assembly procedures should also provide all inspection and retest requirements and any warnings or cautions that must be observed while performing the work. Fabrication/assembly procedures should be generated prior to commencing work. Where work procedures already exist (e.g., technical manuals, standard process instructions, approved drawings, PMS, etc.,), the specific paragraphs from those documents should be called out in the fabrication/assembly procedure. The person responsible for the work, inspections and retest of the system or component should sign each work procedure. Any change to the scope of work being performed should cause a revision to the fabrication/assembly procedure to be issued. All fabrication/assembly procedures should be made available to the SCA for review during on-site surveys.

3.3.2 Process Instructions. Process instructions are those standardized procedures that have been developed by a production activity for work that they commonly perform. To be used in a fabrication/assembly procedure, the process instruction must provide step-by-step instructions for accomplishing the work. All process instructions that the production activity intends to use during fabrication or repair of an unmanned pressure test facility should be provided to the SCA for review. In some cases, (e.g., welding, brazing, NDT and cleaning), the SCA or his designated representative must approve process instructions prior

to use.

3.3.3 Welding Procedures. All welding should be performed in accordance with written and approved welding procedures (see 3.3.2). Welding procedures must include requirements for documenting welder qualification and criteria for weld joint acceptance. The applicant must make available the written welding procedures and the welder qualification records, including any destructive/nondestructive test records required for proof-of-welder qualification on the specific material selected, for SCA review. Any repair involving heat or welding should be accomplished in accordance with approved written procedures and subjected to the tests and inspections specified for construction. All welded pipe joints must be documented and inspected in accordance with the P-1 requirements in NAVSEA S9074-AR-GIB-010/278 or ANSI/ASME B31.1, Power Piping, as supplemented by NAVFAC required inspections and documentation. The fabrication activity must provide traceability between the joint record and the actual welded joint for each welded pipe joint or structural weld joint.

The following procedures are typical of satisfactory welding practices:

NAVSEA S9074-AR-GIB-010/278, Requirements for Fabrication Welding and Inspection, and Casting Inspection and Repair for Machinery, Piping and Pressure Vessels

NAVSEA T9074-AD-GIB-010/1688, Requirements for Fabrication, Welding, and Inspection of Submarine Structure

MIL-STD-1689, Fabrication, Welding and Inspection of Ships Structure

ANSI/ASME B31.1, Power Piping (with additional NAVFAC inspection/ documentation)

The following procedures are typical of satisfactory welder qualification practices:

NAVSEA S9074-AQ-GIB-010/248, Requirements for Welding and Brazing Procedure and Performance Qualification

ASME Boiler and Pressure Vessel Code, Section IX, Welding Qualifications

3.3.4 Brazing Procedures. In piping systems fabricated with brazed joints, all brazing should be performed in accordance with written and approved brazing procedures (see 3.3.2) which meet or exceed the requirements of Class P-3A, Special Category I, Table 3.1, described in NAVSEA 0900-LP-001-7000, Fabrication and Inspection of Brazed Piping Systems. Brazing procedures must

include requirements for documenting brazier/brazing operator qualification and criteria for brazed joint acceptance. The applicant must make available the written brazing procedures and the brazier/brazing operator qualification records, including any destructive test records required for proof of brazier/brazing operator qualification, for SCA review. Any repair to joints involving heat or brazing should be accomplished in accordance with approved written requirements and subjected to, as a minimum, the tests and inspections specified for construction.

For all brazed piping systems, ultrasonic testing is required only for those brazed joints located between the chamber hull and the first manually operated stop valve external to the chamber hull. When ultrasonic testing or other nondestructive tests are required on brazed joints within the SOC, the test records should be made available to the SCA for review. All records should clearly indicate that each joint has met the specification requirements and must be signed by a qualified inspector.

3.3.5 Non-Destructive Testing. All nondestructive test (NDT) records of welds performed within the SOC should be made available to the SCA for review. All NDT records should clearly indicate that each joint has satisfactorily met or exceeded the specification requirements and must be signed by a qualified inspector.

3.3.6 Assembly Procedures. Special procedures for assembly of components and systems (e.g., torque specifications, lubrication requirements, etc.,) should normally be called out in technical manuals and on approved drawings. Where used, assembly procedures should be issued prior to the start of production and should be followed by personnel performing the work. All assembly procedures to be used should be called out in the fabrication/assembly procedure. When assembly procedures are provided as drawing notes or technical manuals, the fabrication/assembly procedure should call out the specific paragraphs that apply. Assembly procedures should be verified as completed by the person responsible for the work and these records should be available for SCA review during the on-site survey.

3.3.7 Cleaning Procedures. Where applicable, cleaning of piping systems should be performed in accordance with approved written cleaning procedures. Cleaning may be accomplished during fabrication/assembly, upon final completion of assembly, or in a combination of both, in accordance with the overall contamination control process developed by the production activity or invoked by the applicant. Cleaning procedures should include methods for sampling and criteria for acceptance. Quantitative analysis to verify system cleanliness must be performed prior to use of the system. Hydrocarbon contamination is of particular concern because hydrocarbons may be flammable. For guidance in cleaning

and analysis, refer to Appendix B.

3.3.8 Quality Assurance Procedures and Inspections. Prior to any work on an unmanned pressure test facility, the applicant should prepare a formal Quality Assurance (QA) plan that lists the procedures to be followed and the inspections to be performed. In cases where costly or non-typical work is to be done, it is strongly recommended that the applicant submit the QA plan to the SCA for concurrence. Past experience has demonstrated that significant time, effort and cost savings can be realized when the SCA has reviewed and concurred with the proposed QA plan prior to commencing work.

3.3.9 Personnel Qualifications. Where required by specification or standard, personnel involved in critical fabrication and inspection procedures must be trained and qualified to perform such tasks. The qualification records of welders, braziers and NDT inspectors should be up to date and available for SCA review.

3.4 Quality Assurance Program. The QA program should be a planned and systematic pattern of all the actions necessary to provide adequate confidence that the facility conforms to established technical requirements. The applicant should ensure that QA provisions are maintained which demonstrate that a system meets these requirements. The quality assurance provisions should result in recorded data related to:

a) Configuration management and drawing control

b) Material control

c) Fabrication and manufacturing control

d) Cleanliness control

e) Testing and inspection control

f) Fabrication/assembly procedures

The vigorous enforcement of a comprehensive QA program for all parts of the system in which failure can result in a hazard to personnel will greatly decrease the chance that substandard workmanship practices or materials will degrade the safety of the system. QA provisions are more easily applied during construction of a system. However, it is the responsibility of the applicant to establish means by which the quality of an existing system may be evaluated. QA programs developed in accordance with ISO 9000, International Standards for Quality Management, or similar industry-developed standards are typical of satisfactory practices.

QA and personnel safety are inseparable. QA considerations are required in all areas that affect the safety of the system operators. These areas include, for example, initial forming, fabrication, assembly, cleaning, testing, inspection and preparation for delivery of all SOC items. The authority and responsibility of QA personnel in each of these areas should be clearly delineated. Manufacturing, fabrication, and assembly work conducted within the builder's plant, system maintenance facility or industrial activity should be carefully controlled. Such control should include a formal review and an engineering evaluation of all manufacturing processes, tolerances and deviations. An equally effective control over purchased materials and subcontracted work should be provided.

It is incumbent upon the applicant to conduct periodic internal QA audits during the course of production work. Internal audits often uncover deficiencies that, if left uncorrected, could cause extensive rework with associated cost and schedule overruns. The applicant should submit and retain copies of information relative to the quality provisions in sufficient depth, detail and organization to permit audit and evaluation by the SCA. QA documentation should be legible, accurate and complete. Each document should be dated and signed and should indicate, by the signature, that the work or procedure meets the requirements of the approved QA Plan. Such data is vital in the effort to sustain/continue certification. The applicant is responsible to make arrangements for the retention, storage and retrieval of all QA documents. The applicant should advise the SCA prior to disposing of such records.

3.4.1 Configuration Management and Drawing Control. The applicant is responsible for establishing configuration control of the unmanned pressure test facility design and documentation. The applicant must ensure that only current drawings are used and that obsolete drawings are removed from all points of issue and use. The applicant should maintain the technical data and drawings that reflect as-built conditions of the system.

3.4.2 Material Control. The applicant should show that the program for material control is effective for new construction and during overhaul or repair of existing systems. The program should ensure that materials used conform to the applicable technical requirements. A system of documenting the identity of tested and approved materials should be implemented. Controls should be established to prevent the inadvertent use of other than specified material. See Appendix C for material OQE requirements.

3.4.3 Fabrication and Manufacturing Control. The applicant should show how the QA program ensures that the system has been manufactured in accordance with the approved drawings, specifications and manufacturing processes. All production

records required by the fabrication specifications and drawings should be completed, signed, dated, and made available, as appropriate, for review by the SCA.

The hazards associated with the performance requirements of an unmanned pressure test facility dictate that only the highest quality workmanship be acceptable. Consequently, the evaluation of the workmanship evident in the finished system is a significant factor in determining the acceptability of the individual system. Acceptance standards to verify high quality workmanship are available from both military and commercial sources that establish acceptance/rejection criteria.

3.4.4 Cleanliness Control. The applicant should show that the program for achieving and maintaining cleanliness of all piping systems is under the close control of the builder during and after system assembly.

The applicant should use only SCA approved cleaning procedures during and after system fabrication. Failure to keep these systems clean may cause serious injury or death to the system operators. Appendix B provides additional guidance concerning cleanliness control of unmanned pressure test facilities. Once a system is verified clean within acceptable limits, no re-entry is allowed into that system without strict adherence to re-entry controls. Any uncontrolled opening of an unmanned pressure test facility to the surrounding atmosphere may require re-cleaning of the entire system to re-establish system cleanliness.

The final levels of cleanliness should meet the requirements that have been specified and justified by the applicant and that have been accepted by the SCA. Records of the date, method and results of sampling should be kept and made available to the SCA for review. Documentation of system cleanliness should include cleaning sheets and sketches and should indicate that each component, section or subsection of a system has been satisfactorily cleaned and that the entire system is free of contamination.

3.4.5 Testing and Inspection Control. The applicant should show that there is an effective test and inspection system in place. The system must establish the inspections and tests necessary to substantiate that items within the SOC are in conformance with the specified requirements. All inspection and test requirements should be identified in the fabrication/assembly procedures. The inspection system should incorporate clear, complete, and current instructions for inspection and should include criteria for acceptance and rejection. Records of all inspections and tests should be maintained and should indicate the nature and number of observations made the number and type of deficiencies found and the nature of the corrective action taken. Where no deficiencies are found, the satisfactory condition should be noted. All test and inspection documents should clearly show the following as a

minimum:

a) The testing activity.

b) The items, subsystems, and systems tested.

c) The procedure used, including minimum acceptance criteria (where applicable).

d) Test results that either meet or exceed requirements. Departures from test requirements must be justified, documented and approved by the cognizant technical authority.

e) The dated signatures of individuals responsible for testing and final evaluation of test data.

The inspection system should serve to verify that the latest applicable drawings, specifications and process controls, with all authorized changes incorporated, are used for fabrication, inspection and testing. The inspection system should describe the training and qualification of inspectors and should include demonstration of competency in techniques such as radiographic, ultrasonic, dye penetrant and magnetic particle inspection, as applicable. The inspection system should also provide for calibration of inspection equipment. In those areas where competence in technique must be demonstrated, it is imperative that the inspection be conducted by a qualified person other than the person performing the work to be inspected, unless specifically allowed by the inspection criteria; e.g. NAVSEA 0900-LP-001-7000, Fabrication and Inspection of Brazed Piping Systems. Test documents and data that fail to meet test criteria, are incomplete or are not technically evaluated and signed off as satisfactory by an authorized representative of the applicant will be rejected by the SCA. Additional guidance concerning test requirements is provided in Appendix C.

3.5 System Testing Program. The applicant should develop and implement a written test program. It should outline a comprehensive and integrated series of tests which fully demonstrates the adequacy of all systems and equipment within the SOC.

The test program should be approved by the SCA prior to execution and should be kept current by the applicant so that it can be utilized for future testing required to sustain certification. The test program should not be revised without prior approval by technical authority and the concurrence of the SCA.

The applicant must provide test results (data) to the SCA for review. Approval will be dependent upon satisfactory results and evaluation by an authorized representative of the applicant.

3.5.1 Test Categories. The test categories listed in items (a) through (d) below must verify that the candidate system

operates safely as designed. Upon satisfactory completion of these tests, the applicant should request an on-site certification survey.

a) Factory acceptance tests (FAT). This category covers testing performed by an equipment or component manufacturer to ensure that the material functions in accordance with specified limits. FATs should be required on all material where operation is of such a critical nature that failure to perform within the specified limits would jeopardize the safety of the operators. Testing of this material at the factory is usually required in cases where material/component testing is of such a specialized nature that the unmanned pressure test facility fabricator may not have the necessary test apparatus. Acrylic for view ports is an example of material that requires a FAT.

b) Prototype/first article testing (PFT). This category of test may be required to prove the design of critical components or entire systems that are developmental in nature. Performance of materials, components and systems that are unique or untried in a similar environment and are within the Scope of Certification (SOC) must be demonstrated by such tests. PFTs will often incorporate life cycle testing to verify that a component or system will operate within design limits and will not fail prematurely.

c) Pre-installation and Pre-operational tests. Pre-installation tests (PIT) are those tests that are performed on components prior to installation in a system (often referred to as bench tests). Hydrostatic and bench seat tightness testing of valves are examples of PIT level testing. Pre-operational tests (POT) are those tests performed at the system level, but prior to operating the system. Insulation resistance and continuity tests and mechanical system tightness tests are examples of POT level testing. These tests should normally be conducted on each system produced.

d) System operational and system integration tests. System operational tests (SOT) are required to verify that separately each subsystem operates satisfactorily within its design parameters. System integration tests (SIT) are performed to verify that all subsystems can be operated concurrently, as designed. SITs are also used to verify that the system operating procedures can be used to operate the system safely prior to conducting operational testing.

3.5.2 General Requirements for Test Procedures. The applicant should submit an index of all FATs, PFTs, PITs, POTs, SOTs and SITs test procedures to the SCA, indicating those within the Scope of Certification. The design agent should approve all SOTs and SITs test procedures. Once the test procedures have been approved, the test director is authorized to modify them to

suit conditions prevailing at the time of the test. For example, the test director may authorize the substitution of a piece of test equipment for one called out in the test procedure because of availability. However, only the design agent may authorize changes to a test parameter, such as a test pressure. Operational and system integration test procedures for systems within the SOC must be reviewed by the SCA. The format of the test procedures should provide both the test procedure and the data to be collected in a single document.

As each step in the test procedure that requires data to be recorded is satisfactorily completed, the witnessing representative of the builder's test or QA organization should so indicate by his dated signature. If the test requires that a particular parameter be within a specified range, both the range and the actual value must be recorded.

A test schedule should be provided to allow the SCA to schedule his presence at the test site for those tests he chooses to witness. The SCA reserves the right to require a rerun of any or all of the system operational and integration tests if results are not clear or are inconclusive. Upon completion of all system testing, an indexed documentation package containing all completed tests that were evaluated with satisfactory results should be provided to the SCA.

Specific component and system testing requirements are provided in applicable sections of Appendix B and C.

3.6 Operating And Emergency Procedures (OPs and EPs). The applicant should make normal and emergency operating procedures available for review by the SCA. For Class A Systems, all operating and emergency procedures should be approved in writing by the SCA. During the on-site survey, the SCA will verify the adequacy of and the operators' compliance with the OPs and EPs. Compliance with approved operating and emergency procedures is a requirement for sustaining system certification. Any changes to these procedures must have the approval of the SCA. For Class B and C Systems, OPs and EPs may be approved at the local level. Written operating and emergency procedures are required for the following purposes:

a. To ensure that the normal operation of the facility is within the range of conditions for which certification is granted

b) To ensure that there are adequate procedures to cope with emergencies

c) To ensure that there are checklists of prerequisites for various major evolutions (e.g., pre- and post-operational procedures)

d) To ensure that the duties of operating personnel are adequately defined

e) To ensure that up-to-date information is available for the training of operators and that it is consistent with safe operation of the facility

The procedures should be supplemented as necessary by diagrams, system alignment procedures, system shutdown procedures, pre- and post-operation procedures and other such procedures as they relate to normal and emergency operations. Component designation on all operating and emergency procedures must be consistent with the system drawings and as built conditions. Refer to Appendix C for a sample of an operating or emergency procedure form (Figure C.9).

Specific emergency procedures are dependent upon the type and complexity of the facility involved. Conditions typically covered by emergency procedures include rapid increase/decrease in pressure and fire in the building.

Additional emergency procedures may be required depending on the type and complexity of the system.

Operating and emergency procedures for systems within the SOC should be demonstrated during the on-site survey. This should include a demonstration of the accessibility to vital equipment or systems to ensure that personnel can safely operate the equipment and systems under normal and emergency conditions. Where an actual demonstration is not practical, the applicant may propose an alternate means of demonstrating acceptability of the procedures. In cases where it is found that a procedure cannot be performed in a satisfactory manner, the applicant must prepare an acceptable procedure for accomplishing the desired objective.

3.7 Maintenance Program. Sustaining system certification is predicated on maintaining the system in the "as certified" condition. The applicant must prepare a maintenance program that includes, as a minimum, the following elements:

a) Preventive maintenance procedures including calibration and alignment of instrumentation and servicing of other equipment in the facility

b) Corrective maintenance procedures that include repair and replacement of components and spare parts control

c) For Class A Systems, the applicant should ensure that a system of controlled work procedures (CWPs) and reentry control have been formally promulgated. For complex systems, the SCA may request that the CWP format be submitted for review. When a system has been cleaned and/or tested in accordance with certification requirements, no re-entry into that system should

be accomplished without strict adherence to the CWPs. For further information, see Appendix C

The applicant should provide instructions for conducting periodic inspections and tests to ensure continued safe operation of the system. The instructions should include the scope of the inspections and tests and should provide pass/fail criteria. Maintenance should be conducted on all items of equipment within the SOC. NAVFAC MO-406, Hyperbaric Facilities Maintenance Manual may be used as guidance. For other systems covered by this document, the applicant should submit a formal preventive and corrective maintenance program to the SCA for concurrence. In addition to the above elements, this program should include personnel responsibilities and provide both record keeping requirements and detailed, step-by-step procedures.

3.8 Operating And Maintenance Manual. Depending on the complexity of the facility, operating and maintenance manuals may be required. These manuals should describe all equipment and all phases of system operation. The following sections should be included, as applicable:

a) System Description. This section should identify and describe the purpose and functional operation of all systems and subsystems. System drawings should also be

b) Component Description. Sufficient design information should be included to identify and describe all major system components and their functions. Component drawings showing internal parts should be included.

c) Instrumentation and Controls. This section should discuss the control philosophy used in the system design and provide a detailed description of the controls and instrumentation used.

d) Operating Procedures. This section should identify all normal system operations and evolutions that involve personnel. The approved operating procedures may be provided as part of this document or separately if desired.

e) Emergency Procedures. This section should identify conditions requiring emergency action and provide procedures to be followed in the event of their occurrence. Emergency action is defined as operation under conditions of system malfunction or failure such as component failure, physical damage, or fire. The approved emergency procedures may be provided as part of this document or separately if desired (See 3.6.).

f) System Limitations, Precautions, and Set points. In this section, the applicant should clearly identify all system operational limitations. This section should also state all precautions to be taken during normal operation to preclude

potentially unsafe conditions. A list of system operation set points that represent the normal operation of the system should be included.

g) System Maintenance. This section should describe all required preventive maintenance and basic repair procedures for supporting the facility. All components that must be repaired by the manufacturer or depot level repair facility should be identified. While step-by-step detailed preventive maintenance procedures may be promulgated separately, the basic repair procedures should be included in this section.

h) System Storage and Start-up. This section should describe all disassembly and maintenance required to place the system in lay-up for an extended period of time. Additionally, instructions for system start-up, after extended storage, should be provided. These instructions should include all assembly, maintenance and testing required to bring the system out of storage and into an operationally ready condition.

i) System Troubleshooting. This section should provide guidance to be used to assess the symptoms, then locate and repair probable causes of a system malfunction. For the procedures used to repair failed components, this section may refer to the section on system maintenance.

3.9 Granting Initial Certification. The responsibility of the Acquisition Manager is defined in Section 4. It is the responsibility of the Acquisition Manager to ensure that the system is considered certifiable prior to its transfer to a user command. To be certifiable, the SCA must concur that all system design, fabrication and testing has been performed satisfactorily, in accordance with previously approved technical specifications. In addition, all system drawings, technical manuals, PMS and certification related documents should have been approved and issued. Custody of an unmanned pressure test facility will normally be transferred from the Acquisition Manager to the user command once the SCA deems the system certifiable but prior to granting initial system certification.

In addition, the Acquisition Manager should prepare a "turn-over file" consisting of as-built system drawings, fabrication records, test records, technical manuals, operating and emergency procedures and a complete Preventive Maintenance System (PMS) package. The turnover file should accompany the system to the user command.

After receipt of the system hardware and certification documentation, the user command should take the following action:

a) Establish a formal QA plan

b) Initiate the preventive maintenance plan for the system

c) Review and submit any necessary operating and emergency procedures to the SCA

d) Request an on-site survey of the system by the SCA

Upon completion of a successful on-site survey the SCA will grant the system "Initial Certification“.

Section 4: RESPONSIBILITIES OF THE ACQUISITION MANAGER

4.1 Introduction. This section defines the responsibility of the Acquisition Manager in relation to certification requirements for unmanned pressure test facilities built for use by DOD personnel. The Department of Defense acquisition program is set forth in the DOD Federal Acquisition Regulations Supplement (DFARS). The management of acquisition programs is guided by DOD Directive 5000.1 A Defense Acquisition, and DOD Instruction 5000.2 Defense Acquisition Management Policies and Procedures. In addition, system safety certification procedures must be clearly defined and strictly followed in every phase of the procurement process. This is due to the life critical nature of unmanned pressure test facilities, with particular attention being applied in regards to safety to outside operators and other personnel in the vicinity of the unmanned pressure test facility. Therefore, the Acquisition Manager should establish the certification effort in the earliest conceptual phase of the program.

The Acquisition Manager is designated as the applicant for initial certification of a new facility until the new facility is delivered to the designated user activity. Early and frequent communication between the applicant and the SCA is essential to the efficient prosecution of the system certification process. This point cannot be overemphasized.

In all aspects of the certification process, the line of communication is between the SCA and the applicant and not between the SCA and the contractor, manufacturer or procurement agency hired or contracted by the Acquisition Manager to provide the unmanned pressure test facility. While discussions and conferences with these organizations are useful, the line of action and responsibility is between the SCA and the applicant.

During a major overhaul or repairs involving configuration changes to the system, the individual parent command should assume the responsibilities of the Acquisition Manager.

4.2 System Certification Requirements In Contracts. The Acquisition Manager who contracts for or otherwise arranges for the design, construction, testing and delivery of a new unmanned pressure test facility must translate system certification criteria and documentation requirements, clearly and concisely, into contract specifications. The use of this document as a contract reference document, which allows the contractor to interpret certification requirements, should be avoided. If a contractor anticipates lease or purchase by DOD of an unmanned pressure test facility, he is building, he should become familiar with the documentation requirements necessary to support the system certification process.

However, lease or purchase agreements entered into by DOD must be specific enough in content to preclude any interpretation of the

requirements of this document by manufacturers or vendors. Areas of particular importance in the preparation of contract specifications are described in the following paragraphs.

4.2.1 Material Specifications. All materials used for the construction, fabrication and assembly of parts, components, subsystems and systems which are within the scope of certification must meet or exceed the specifications set forth in Appendix A. This material should also be provided with documented objective quality evidence (OQE) and test data verifying its acceptability, in accordance with Appendix C. The Acquisition Manager should ensure that contract specifications are complete and accurate in this respect and that deviations from these specifications are authorized only with the approval of the appropriate technical authority and the concurrence of the SCA.

4.2.2 Performance and Procedure Specifications. The Acquisition Manager should ensure that the performance and procedure specifications for the construction, fabrication and assembly of the facility are clearly and accurately described in contract documents.

4.2.3 Quality Assurance (QA). The Acquisition Manager should ensure that contract documents require the contractor to provide a Quality Assurance Program plan that specifically addresses the critical requirements of system certification. Contract documents should recommend the designation of a certification manager within the contractor's organization who will serve as a single point of contact between the contractor and the Acquisition Manager on matters concerning system certification.

4.3 Document Control. It is the responsibility of the Acquisition Manager to ensure that adequate document control procedures are developed and implemented in the earliest phase of the procurement process and that these procedures are strictly adhered to in every phase and at all levels of the procurement process. All documentation required by this document should be reviewed and evaluated by the Acquisition Manager, or his agent, prior to submission to the SCA. If an agent is used, the agent should not be affiliated with the fabricator.

4.4 Preparation Of Certification Application. The Acquisition Manager, as system applicant, should prepare and submit the application for system certification. The application for system certification should be prepared in accordance with the provisions of Section 2 of this document and should be submitted to the SCA with all required documentation attached.

4.5 Configuration Management Plan. The Acquisition Manager, as system applicant, should ensure that a configuration

management plan is developed and prepared during the appropriate phase of the procurement process. DODINST 5000.2 provides policy and guidance for the preparation of configuration management plans.

4.6 Technical Design Reviews. The Acquisition Manager is required to conduct design reviews. The SCA should conduct independent technical review to assess the adequacy and safety of all systems associated with the facility.

This applies to both new systems and those systems that are undergoing significant modifications.

It is strongly recommended that the Acquisition Manager invite the SCA to participate in the normal system technical design review process. An understanding between the Acquisition Manager and the SCA should be reached early in the system design regarding technical design reviews. The number, timing and level of detail of the technical design reviews should be dependent upon the uniqueness and complexity of the system. These points should be negotiated between the Acquisition Manager and the SCA and promulgated in the certification Milestone Event Schedule.

The design review process is best served when the Acquisition Manager assembles additional technical personnel, not affiliated with the system designer, to review the system design. Sufficient technical expertise should be used in the design review process to ensure that electrical, structural, mechanical and piping systems are thoroughly evaluated.

The SCA recognizes that the level of detail provided in each design review will depend on how far along the actual subsystem design has progressed. Therefore, it is imperative that the design review team review all design documentation prior to conducting each formal review.

For complex systems, the Acquisition Manager should issue a design review check-off list for each subsystem to be reviewed. This check-off list should include verification that all the required design review information is available for technical review. The Acquisition Manager, technical design review team and SCA should complete the check-off list during the design review.

At the completion of each technical design review the Acquisition Manager should issue findings and recommendations regarding all system design deficiencies. The methods of issue of previous review findings should be discussed between the SCA and Acquisition Manager prior to each design review. Those deficiencies that are determined by the Acquisition Manager and SCA to be within the Scope of Certification should be identified as such.

All identified safety related design deficiencies must be

resolved before the construction contract is awarded. Design deficiencies not resolved prior to the award of the construction contract will require a change order to the construction contract, which in most cases, causes additional costs and time delays to the Government.

The Acquisition Manager should avoid awarding the construction contract prior to resolution of all identified safety related design deficiencies.

4.7 Associated Documents. The Acquisition Manager, as system applicant, should ensure that all associated documents, such as technical manuals, preliminary design, final design, test memos, etc., are prepared and submitted in accordance with the Milestone Event Schedule during the acquisition process. The Acquisition Manager should ensure that all associated documents are submitted to the SCA in a timely manner and that there is adequate time allocated in the Milestone Event Schedule to allow the SCA to conduct a thorough review of the associated documents. The Acquisition Manager should review SCA comments and take appropriate action on safety related issues.

4.8 Construction Review Board. It is recommended that the Acquisition Manager conduct Construction Review Board (CRB) meetings during the period that the facility is being fabricated. The CRB should meet frequently at the construction facility, with frequency being dependent upon the complexity of the facility being built.

Section 5: REPAIR AND OVERHAUL

5.1 Introduction. Periodically, unmanned pressure test facilities require repair or overhaul wherein industrial work is performed within the certification boundary beyond that which is normally conducted during routine maintenance procedures. During such industrial periods, system certification should be terminated until the requirements for re-certification, specified in Section 2, have been satisfied.

During significant configuration changes, the responsibilities of the acquisition manager may shift from the user command to another command or program office. However, the user command to which the system is assigned should remain the applicant for system certification. Close coordination between the acquisition manager, the applicant and the SCA is crucial to ensure that the system certification process does not become disjointed and unmanageable.

In all instances, the number and extent of technical design reviews should be negotiated between the applicant and the SCA.

It is the responsibility of the system applicant to ensure that the requirements for re-certification are satisfied during repair or overhaul periods. As stated in Section 1, the line of communication concerning certification is between the SCA and the system applicant and not between the SCA and the activity responsible for the performance of the work. The applicant may designate an individual or organization to act as certification manager, who will be the single point of contact for liaison both with the overhaul organization and with the SCA on matters concerning certification.

5.2 Certification Status During Repair Or Overhaul. When the supporting building facilities undergo any major facility upgrade that would affect the performance or operational integrity of the unmanned pressure test facility, system certification is terminated.

Often, component or minor system repair is required between scheduled overhauls. Minor work on the facility that does not involve hot work (welding/brazing) and that does not modify the certified system configuration does not terminate system certification if the work and testing are documented under re-entry control. Though notification to the SCA is not required, all documentation of the minor work and testing will be reviewed at the next certification on-site survey. Examples of minor work that does not terminate or suspend system certification are:

a) Repairing leaking valves by replacing valve software

b) Replacing unmanned pressure test facility components (mechanical joints) with the same kind as specified by

the system drawing

c) Re-qualifying system hoses, volume tanks, high pressure gas flasks, high pressure fluid tanks, filter housings or moisture separators by hydrostatic testing required by PMS

d. Calibrating gages and relief valves

e) Re-certifying DOT 3AA flasks/bottles

f) System configuration changes in support of mission testing documented on controlled work procedures

Should the scope of work exceed minor work (as described above), termination or suspension of system certification may be required. This applies whether the work is accomplished during scheduled maintenance, as day-to-day work, or to correct a casualty. The applicant should immediately notify the SCA when this work is required so the SCA can make a determination with respect to termination or suspension. Examples of significant work that may terminate or suspend system certification are:

a) Welding or brazing on the pressure boundary

b) Overhauling the unmanned pressure test facility.

5.3 Pre-Overhaul Requirements. Prior to the commencement of overhaul or repair of an unmanned pressure test facility, the applicant should submit the following to the SCA for review:

a) A detailed definition of the scope of the overhaul, including a list of repairs, alterations, modifications and significant components to be replaced, etc.,

b) The overhaul or repair work package should include, as appropriate, drawings, description of work, quality assurance provisions, tests and inspections to be accomplished. All procedures or processes to be followed must also be included.

c) A schedule showing major overhaul milestones.

Pre-Overhaul information should be submitted as early as possible to allow sufficient time for review by the SCA. The SCA, as early as possible, in conjunction with appropriate technical authorities, should review all work and procedures/processes that involve system certification.

In cases where the work package includes alterations, the Naval Facilities Engineering Command Hyperbaric Facilities Maintenance Manual, NAVFAC MO-406, may be used to provide guidance for the control of the alteration process. The timing of formal technical design reviews should be negotiated between the applicant and the SCA and should be dependent upon the complexity and uniqueness of the alteration.

5.4 Overhaul. All unmanned pressure test facilities should be overhauled, as described below. The length of time between overhauls of a particular facility should be determined by the activity, sponsor and SCA, but should not exceed 10 years. Should a facility be taken out of service (mothballed) for more than two years, an overhaul should be conducted prior to placing the facility back in service.

The overhaul of unmanned pressure test facilities should be accomplished in three phases as follows:

a) A pre-overhaul test and inspection of existing systems and components must be performed to determine the condition of the facility.

b) All systems and components that do not perform to specifications must be repaired or replaced to bring the facility into conformance.

c) The facility should undergo final system functional testing to verify the acceptability of the work performed.

Functional testing includes those tests that are performed upon completion of an overhaul. Functional testing is to be witnessed by a SCA representative and should include all systems of the facility.

The level of overhaul accomplished should be based on the criticality of the respective system.

5.4.1 Hazard Categories. All systems, equipment, components and procedures should be evaluated and assigned a hazard category (HAZCAT) as defined in Section 2. The HAZCAT is based upon the potential hazard to operators or other personnel involved in the test evolution, as well as systems associated with the loss of pressure boundary integrity and/or loss of functional operation. It is emphasized that the facility operators and test support personnel are the individuals to whom this HAZCAT analysis program is directed.

5.4.1.1 HAZCAT I Systems. All components that are a part of a HAZCAT I system should be evaluated and refurbished to the "as new" condition. The "as new" condition of a component is that condition which was acceptable in the original design, and/or meets the quality control requirements of the Commercial or Military Specification for that component. The "as new" condition includes, but is not limited to, the following:

a) complete internal/external visual inspection

b) replacement of all software

c) operational test

d) cleaning

In the event the component cannot be restored to "as new" condition, an in-kind replacement for the required component should be installed. The in-kind replacement must pass all the tests for the design requirements of the original component. General maintenance of all HAZCAT I components should be performed and documented. NAVFAC MO-406 may be used as a guide. In-kind replacement of a component is defined as replacement with an identical component if that component is still manufactured. In the event an identical component is no longer manufactured, the replacement component must meet all of the original component's design criteria. Should there be any doubt as to whether a component is an in-kind replacement, contact the SCA.

5.4.1.2 HAZCAT II Systems. All HAZCAT II systems should be envelope functionally tested to their complete design parameters. Envelope functional testing is defined as testing each component of the respective HAZCAT II system to its system design parameters (i.e., ball valves, completely shut off and fully open; needle valve, fine tuned and flow as required for original design; pressure gauges, accurately record tested parameters). In addition, Functional Testing, as performed originally when the system was installed, should be conducted for all HAZCAT II systems. HAZCAT II system components should not be removed or refurbished, unless the component does not perform or if a noticeable flaw is found during functional testing of the system. General maintenance of all HAZCAT II system components should be performed and documented, NAVFAC MO-406 may be used as a guide.

5.4.1.3 HAZCAT III and IV Systems. All HAZCAT III and IV systems should be demonstration tested to system design requirements. Demonstration testing is the functional testing level performed originally when the system was installed. HAZCAT III and IV system components should not be removed or refurbished unless the component does not perform, or if a noticeable flaw is found during demonstration testing of the system. General maintenance of all HAZCAT III and IV system components should be performed and documented, NAVFAC MO-406 may be used as a guide

5.5 Routine Maintenance. As defined in Section 2, all HAZCAT I, II, III AND IV system components should receive routine maintenance as required by facilities PMS or as required by the manufacturer of the respective component. General maintenance should include, but is not limited to: replacement of belts, pulleys, lubrication, filters, calibration, o-rings, calibration of gauges, periodic testing of relief devices, replacement of filter elements, calibration of sensors and indicators, etc.,

5.6 Document Control. The requirement for adequate document control during overhaul and repair is as essential to re-certification as it is in the initial certification process.

The applicant should ensure that all documentation required to support design, material selection, work procedures, tests and inspections are prepared and maintained in accordance with the requirements of Section 2 and Appendix C.

For major modifications due to system alterations, the Acquisition Manager should ensure that applicable fabrication and test documentation (i.e., drawings, technical manuals, test memoranda, etc.,) are revised and then reviewed by the SCA. For repairs, the responsibility for updating this documentation lies with the applicant.

5.7 Procedures. Those procedures required to perform work, inspection and testing should meet the requirements set forth in Section 3.3 and be so specified in contract documents. These procedures should be available for review and concurrence by the SCA during on-site surveys.

5.8 Quality Assurance (QA). Quality assurance requirements during overhaul and repair should be the same as those specified in par. 3.3.8 of this document and should be specified in contract documents.

5.9 Re-Entry Control. Particular attention must be directed to the proper use of approved re-entry control procedures as described in Appendix C. Re-entry control forms must be accurately completed and must contain all required signatures prior to re-entry into a system that is within the scope of certification. Prior to use of the system, all re-entry control actions must be satisfactorily completed and signed or have an approval for a departure from specifications approved.

5.10 Retest Requirements. Repairs and modifications to systems require the same stringent testing requirements as newly designed systems. The following guidelines should be used to determine the level of testing required during systems overhaul periods:

a) Factory Acceptance Tests will not be required unless the replacement equipment is of such a specialized nature that the repair activity is unable to perform testing.

b) Pre-installation tests will be required only for replaced or repaired components.

c) Pre-operational tests will be required only when a subsystem is repaired or modified. These tests need to be performed to ensure that those sections of the system that were repaired or modified are properly reinstalled.

d) System operational tests should be conducted on all subsystems that have been repaired, modified or placed in lay-up when time permits and personnel are available. The extent of system operational testing may be negotiated with the SCA.

Additional information concerning test requirements is provided in Section 3.5 and in Appendix C.

5.11 Technical Requirements. The primary sources of technical requirements are the documents that the facility was designed to, such as:

a) ASME Section VIII Division 1 or Division 2, Boiler and Pressure Vessel Code

b) ANSI/ASME B31.1, Power Piping Code

c) NFPA 70 National Electric Code

Other documents that may be used for guidance are:

a) NAVFAC DM-39, Hyperbaric Facilities Design Manual

b) NAVFAC MO-406, Hyperbaric Facilities Maintenance Manual

c) NAVFAC MIL-HDBK-1152, Inspection and Certification of Boilers and Unfired Pressure Vessels

d) ANSI/NB-23, National Board Inspection Code

APPENDIX A
CATEGORIZATION OF SCOPE OF CERTIFICATION MATERIALS AND COMPONENTS

A.1 INTRODUCTION

This appendix contains guidance for categorizing materials and components within the Scope of Certification (SOC). Categorization of a material or component is dependent upon its application and service experience. The proposed application, (configuration, joining techniques, etc.,) must be reviewed to determine the proper categorization for each material or component.

For the purpose of system certification, materials and components are grouped into three categories:

Category 1: Materials and components for which considerable operating experience in pressure vessel applications is available.

Category 2: Materials and components which are commonly used in a variety of military and commercial applications, but with little or no past experience for the proposed unmanned pressure test facility application. Generally, Category 2 material requires testing to verify that it will be acceptable for its intended use in the new application.

Category 3: Materials and components that may be developmental, or do not have a documented history of satisfactory use in pressure vessel applications.

These material and component categories are not to be confused with the hazard level categories of MIL-STD-882 and as defined in Section 2. Solely as an aid in assessing the reliability of materials and components in specific unmanned pressure test facility applications, the material and component categories described above were conceived. The applicant must justify the materials and their applications as used in the design of the pressure vessel system for the expected service environments. All materials considered to be within the SOC should be identified. Their relative location in the system should be described, and verification of material compatibility with the intended environment and with each other should be analyzed.

The applicant should justify the adequacy of the proposed material and its application. The less information and experience available regarding a proposed material or component for a particular application, the greater is the burden of proof for the acceptability of the material. This burden of proof is the responsibility of the applicant.

A.2 CATEGORY 1 - MATERIALS AND COMPONENTS

To be classified as a Category 1 material, the material must be manufactured to a commonly used commercial or federal specification. Additionally, extensive experience in fabrication of the specific component configuration (e.g., commercial off-the-shelf) and a history of operation in a specific environment must be presented to the SCA. For piping systems, compatibility with both the specific internal and external fluids/gases to which the piping will be exposed must be proven by previous usage.

Unusual configurations or applications of these materials and/or components with no documented history of use in the specific environment might, however, place them in Category 2.

All view ports made of acrylic plastic should comply with the requirements of ASME PVHO-1. View port materials other than acrylic plastic will be considered Category 3 materials

A.3 CATEGORY 2 - MATERIALS AND COMPONENTS

Materials manufactured to a recognized commercial or federal standard, but with no documented history of use in the specific pressure vessel environment, fall into this category. Materials used in standard commercial (or military) applications that are not commercial off-the-shelf are also in this category. The use of Category 2 materials and components requires justification by complete design analysis of material properties and operating stresses. Approval of a material or component for use in a specific application will be based on the supporting technical information provided by the applicant.

A.3.1 Structural Materials. For pressure vessels and hard structure, the applicant should submit information on material in accordance with Appendix B. For other structural components (i.e., foundations, weight handling strength members, etc.,) the applicant should submit the following information as justification for the use of each Category 2 material or component:

a) The commercial or federal specification and the chemical and physical properties of the base material in the condition it will be used. If the material is to be welded, brazed, cold worked, work hardened, etc., the acceptable material properties at the completion of fabrication should also be specified.

b) Proof of weldability and fabricability (if the fabrication process or possible future repairs include welding).

c) Fatigue data, preferably data in the high-stress, low-cycle range (below 10,000 cycles), which considers the effect of the environment (e.g., seawater, fresh water, oil, O_2, HeO_2 and hydrogen).

d) Data collected over a sufficient time period to justify the adequacy of the material with respect to general corrosion, susceptibility to stress-corrosion cracking, and compatibility with adjacent materials in its intended environment.

e) Nondestructive testing results on the material, the heat-affected zone (HAZ), and the weld joints, as appropriate.

A.3.2 Pressure Compensating and Hydraulic System Fluids. As a minimum, the applicant should submit the following:

a) A list of the applicable military, federal or commercial specifications

b) Information covering flammability, resistance to deterioration and compatibility with system component.

c) Information relating to possible toxicological hazards if used inside the unmanned pressure test facility

A.3.3 Electrical System Materials. All electrical system materials and components should, as a minimum, meet the requirements of Appendix B and the National Electric Code.

A.4 CATEGORY 3 - MATERIALS AND COMPONENTS

The basis for testing and the criteria for acceptance of new materials and components will not necessarily be the same as for those currently in use. The proof of the acceptability for the material or component and the justification of the acceptance criteria must be provided by the applicant. For example, the applicant should demonstrate the effect of defects and manufacturing variations on the reliability of the material or component by appropriate model and/or prototype testing in a simulated service environment. The applicant must establish that a design using the new material or component provides at least the same degree of safety as proven materials (Category 1) in a similar application. As such, this may result in a higher factor of safety being required for Category 3 materials.

Examples of Category 3 pressure vessel and other structural materials are those generally characterized by low ductility, such as ultra high-strength metals, glass, metallic composites, concrete and ceramic materials.

For pressure vessels and other structural materials, the applicant should submit the same information that is required for Category 2 material. In addition, as justification for the use of a Category 3 material, formal test data should be provided to the SCA covering, as a minimum, the following information:

a) Basic process to be used in producing the material. Sufficient information is required to demonstrate that the process results in reproducible material properties.

b) Effect of flaws, such as cracks, inclusions and porosity, on material performance.

c) Effects of temperature on material performance and on crack propagation rate.

d) Results of destructive tests of samples fabricated from the material and comparison of these results with the design basis predictions of the failure point.

e) Results of nondestructive test requirements applied to the base material and joints as appropriate.

f) Results of fatigue testing based on operating pressure differentials and external loading.

g) Hazards involved in fabrication or use of the material with respect to flammability.

h) Additional testing or information as required by the SCA.

Should the designer choose to use Category 3 materials for purposes other than as structural pressure vessel components, fully documented technical justification will be required. As a minimum, the applicant should submit the information required in paragraph A.3 plus additional information as may be required by the SCA to justify the use of Category 3 material or components.

APPENDIX B
DESIGN PARAMETERS FOR UNMANNED PRESSURE TEST FACILITIES

B.1 INTRODUCTION

This appendix provides guidance to the designer of an unmanned pressure test facility in the form of requirements, recommendations, information and preferred approaches pursuant to safety certification. It is not to be considered as all-inclusive. It is written to provide guidance in those areas of design where experience exists and design parameters have been established. The applicant must review the requirements for the specific facility for which he is seeking certification, then coordinate those requirements with the design guidance of this document. Established pressure vessel design guidance are provided in the following documents:

a) NAVFAC DM 39, Hyperbaric Facilities

b) ASME/ANSI PVHO-1, Safety Standards for Pressure Vessels for Human Occupancy

c) ASME Boiler and Pressure Vessel Code, Section VIII, Division 1 and Division 2, Pressure Vessels

d) ASME B31.1, Power Piping

The final responsibility for all aspects of a safe design lies ultimately with the applicant and cannot be assigned to any document or textbook.

B.2 STRUCTURAL DESIGN CONSIDERATIONS

The information provided herein may not be applicable to every design attribute for unique systems or systems used in unique environments. All unusual circumstances that may affect the system design should be brought to the attention of the SCA during the initial design phase. The designer should consider conditions such as the effects of shock, vibration, creep, thermal transients, implosions, material deterioration due to environmental effects, or any other condition that may be applicable to a specific design.

Pressure vessels are complex structures that may contain penetrations for piping, electrical cables, hatches, view ports or other appurtenances. These structures may also contain geometrical discontinuities, such as hemisphere-to-cylinder intersections and saddles for foundations. The physical properties of the materials from which these structures are fabricated, such as modulus of elasticity, yield strength, ultimate strength, fatigue strength and fracture toughness interact in a complex fashion. Thus, a rational design procedure, which accounts for fatigue, yield, fracture, buckling and all pertinent material properties, should be applied to ensure a safe structure. The burden of proof is upon the applicant to design a pressure vessel and demonstrate by use of analytical and/or experimental means that the structure will function as intended for its expected life.

B.2.1 Fatigue. A fatigue analysis should be submitted for all pressure vessels that do not comply with the requirements of the ASME Boiler and Pressure Vessel Code. This fatigue analysis may be based on specimen and/or model tests. Suitable fatigue strength reduction factors should be applied to the specimen or model test results to account for variations in properties, scatter in the test results and the uncertainties involved in applying specimen and model fatigue data to fabricated full-scale structures. The fatigue analysis must consider at least the following design parameters:

a) Magnitude and nature of peak stresses, stress concentration factors used in the calculation of peak stresses, should be based on experimental data on similar structures;

b) Material properties and method of fabrication;

c) Maximum deviation in material thickness, assembly techniques and allowable flaws;

d) Geometry of the structure and details of penetrations and attachments;

e) Previous fabrication and operating history of the material;

f) Effects of residual stresses, thermal stresses and strain rate;

g) Type and method of loading and environmental effects such as corrosion/erosion;

h) Maximum anticipated number of load cycles.

When pressure vessels are constructed of Category 3 material (see Appendix A), sufficient destructive fatigue tests of full-scale prototypes or models should be performed to determine the fatigue

life of the design.

Pressure vessels designed to comply with the requirements of the ASME Boiler and Pressure Vessel Code, Section VIII, Division 1, may not require a fatigue analysis if SCA concurrence is obtained. Pressure vessels designed to comply with the requirements of the ASME Boiler and Pressure Vessel Code, Section VIII, Division 2, do not require a fatigue analysis if condition A or condition B of Article AD-160.2 are met.

B.2.2 Fracture Toughness. The applicant should ensure that the materials used to fabricate the pressure vessel, or any pressure boundary component exhibit adequate resistance to fracture. Specifically, the design analysis submitted to the SCA should demonstrate that brittle fracture is not a possible mode of failure by considering at least the following:

a) Magnitude, nature and rate of stresses (both applied and residual);

b) Temperature range to which the structure may be subjected in service;

c) Size, location and density of flaws initially present in the material and those that occur as a result of cyclic operations;

d) Environmental effects such as corrosion and/or erosion; Specifically, the environmental effects on crack initiation and propagation (e.g., stress-corrosion cracking) must be evaluated;

e) Effects of creep and strain rate on fracture toughness;

f) Localized effects due to penetrations, attachments and other vessel or component restraints (i.e., stress risers);

g) Effects of fabrication processes and heat treatments on the fracture characteristics of the material. In particular for welded construction, properties of the weld rod and base metal within the heat-affected zone and resultant induced internal stresses should be considered;

h) Material thickness

The material properties used in the fracture analysis should be based on appropriate tests such as tensile and compressive strength tests, K_{Ic} (fracture toughness) tests, K_{Iscc} (stress corrosion cracking) tests, Charpy V-notch impact tests, dynamic tear tests, drop-weight tests and explosion bulge tests as discussed in Appendix A. Where appropriate test data is not available, fracture mechanics type tests should be conducted. Further, the design analysis must consider possible variations in

material properties and, in particular, the effect of material thickness on fracture characteristics. The structural design basis used by the applicant for the analysis of brittle fracture should be verified by destructive testing of the pressure hull and component models and structures, or, where possible, by reference to existing information and service experience. All plates, parts and components must demonstrate adequate strength and toughness over the range of design operating temperature. Toughness characteristics of ferrous materials should be referenced to the Nil Ductility Transition Temperature (NDTT).

B.3 DESIGN STRENGTH PARAMETERS OF INTERNALLY-LOADED PRESSURE VESSELS

In general, the applicant should demonstrate the structural integrity of the pressure vessel under loading conditions to be representative of those expected in service. Therefore, the designer must take into consideration the effects of temperature, cyclical loading, creep, ductility, corrosion rates and anisotropy. Examples of pertinent fabrication variables include material reproducibility, fabrication flaws and defects, vessel openings, intersections of different shells of revolution and attendant reinforcement(s), residual fabrication stresses and deviations from the nominal geometry.

B.3.1 Inelastic Stability (Yield). For stable pressure vessel structures (i.e., stiffened or un-stiffened shells which permit the level of load-induced membrane stresses to approach the material yield point), the ratio of the pressure that would produce yield to the design operating pressure should be justified. In determining the pressure at which yield occurs, all fabrication and design-induced restraint and geometric variables should be considered and their effect(s) included. This is because the strength of moderately stable vessels can be detrimentally affected by such variables (i.e., yield can occur at levels of membrane stress below calculated levels of yield stress).

B.3.2 Stress Analysis. The applicant should perform a complete stress analysis of the pressure vessel and demonstrate that all stresses are within the design criteria and that the vessel's fatigue life is adequate for its expected service life. For Category 1 and 2 materials, the allowable stresses under internal pressure should be justified to the SCA. The stress levels defined in paragraph B.3.3 may be used as guidelines; however, the applicant must demonstrate compliance with only B.3.3.c., maximum peak stress. The design requirements for Category 3 materials must be comprehensive, provide at least the same degree of conservatism as the design requirements for Category 1 and 2 materials and should be approved by the SCA.

B.3.3 Verification of System Design Pressure. For Category 1 and 2 materials, model testing or use of existing model test data

must be used to verify the calculated system design pressure. There are three alternative methods of verification (SCA approval of the method chosen must be obtained prior to testing):

a) When comparable hull geometries and identical materials have been successfully tested to a pressure greater than the system design pressure of the vessel to be certified, the existing test data can be substituted for destructive model testing of the structure under review. Any geometric differences between the hull requiring verification and the comparable hull for which test data exists should be brought to the attention of the SCA.

b) For new designs that do not fall within the parameters described in paragraph (a) above, the calculated failure pressure may be verified by performing destructive model tests, either full or reduced scale. When such testing is performed, the structural model should be large enough to contain representative prototype geometries, material properties, and fabrication process restraints, tolerances and residual stresses.

c) Nondestructive pressure testing of the actual vessel to be put into service in accordance with applicable requirements of the ASME will be acceptable as verification of the calculations. All others will be non-destructively pressure tested to 1.5 times the maximum operating pressure. When this option is chosen, the calculated failure pressure must be greater than 1.5 times the maximum operating pressure by a factor of safety sufficient to preclude damaging the structure during the test. The SCA should approve the ratio of failure pressure to test pressure prior to testing. Clearly, use of this method requires that the decision be made very early in the design process because of the profound effect on the structural design.

For Category 3 materials, the above testing requirements may not be appropriate or adequate. The testing used must demonstrate the same degree of conservatism as the testing requirements for Category 1 and 2 materials. The factor of safety and all testing parameters should require SCA approval.

B.3.3.1 Testing Procedures/Test Instrumentation. For all vessels, a detailed test procedure should be developed and provided to the SCA for review and approval prior to testing. The test should be of sufficient duration to demonstrate that the combined stress/temperature/time loads do not produce permanent deformation or damage in the structure. If the tested structure is to be used in service, a complete set of instrumentation readings should be recorded at the maximum operating pressure (this may be accomplished during instrumented testing to 1.5 times the maximum operating pressure). The test procedure should include a detailed strain gage plan, which specifies the number,

type and location of all gages. Strain gages should be placed at points of:

a) General stress level

b) Fatigue

c) Low quality analysis

d) Uncertain dimensions

e) Geometrical discontinuities

f) High stress between openings

The test procedure should duplicate the loading conditions expected in service and, where applicable, should be such that the mode of failure is identifiable. Upon completion of testing, the recorded strain gage data should be used to verify the calculated performance of the structure. The complete test report should be provided to the SCA for review and approval.

B.4 DESIGN OF PRESSURE VESSELS TO COMMERCIAL CODES

Pressure vessels, within the scope of certification, should be designed and fabricated in accordance with the ASME Boiler and Pressure Vessel (BPV) Code, Section VIII, an equivalent published design code, a standard approved by the SCA, or the design should meet the applicable criteria of Sections B.2 and B.3 herein. When designing to ASME BPV Code, Section VIII or other commercial codes, the allowable stress values given in that specific code are to be used. These allowable stress values reflect a factor of safety empirically determined for the material and application for each specific code.

B.4.1 Documentation Requirements for Pressure Vessels Built to Commercial Codes. When using commercial codes in designing and fabricating pressure vessels, the SCA requires documentation, as outlined in the following subsections, in addition to that which is specified in the commercial code.

B.4.1.1 Vessel Drawings. Drawings must completely identify the vessel and all the appurtenances (foundations, penetrations, attachments, etc). All welds should be detailed and fully located. All components should be fully specified on the Bill of Material and notes should fully explain or define processes, specifications, procedures and/or special instructions. Vessel weight, internal (floodable) volume and cycle life (when required) should be stated on the Top Assembly Drawing for each vessel.

B.4.1.2 Design Calculations. Design calculations should be provided showing worst-case dimensions and tolerances, and clearly stating all design assumptions and load conditions. The

calculations should be in standard engineering data sheet format that clearly indicate that the design, as depicted in the drawings, is fully satisfactory and meets all design requirements of the ASME BPV Code, Section VIII Division 1 or 2 as appropriate. The design calculations should show that they meet the above requirements for the design life of the vessel, and be signed by the design engineer.

B.4.1.3 Manufacturer's Documentation. The Manufacturer's Data Report should be submitted for each vessel. Copies of the completed and signed ASME Manufacturer's Data Reports for Pressure Vessels (Form U-1/U-1A) should be submitted with applicable ASME Manufacturers Partial Data Reports (Form U-2).

A copy of the Certification of Authorization from the ASME Boiler and Pressure Vessel Committee, or the equivalent from other approved commercial code committees, authorizing the manufacturer to fabricate vessels of the designed class should be attached to the Manufacturer's Data Report.

B.4.2 Material Verification. All materials comprising the pressure vessel (pressure containing material) and all materials welded to the pressure vessel should be documented to verify compliance with the Bill of Materials and applicable specifications. This should also include welding rods used on the pressure boundary.

B.4.3 Welding Procedures. Copies of all welding procedures required for the fabrication of the pressure vessel and attachments should be provided to the SCA. In addition, documentation verifying approval of these procedures should also be provided.

B.4.3.1 Welder Qualifications. Documentation should be provided verifying that all welders that produce welds on the pressure vessel are qualified to the approved welding procedure for the type and position of each weld made. The document should clearly state that the welder is qualified to perform the procedure and his qualifications are current under applicable code requirements.

B.4.3.2 Weld Records and Maps. The weld records should consist of a chamber weldment joint identification drawing, or map, for each chamber pressure shell and piping system. All chamber joint weld locations should be shown and a joint identification number assigned to each weld. A chamber weldment record form for each welded joint, including non-pressure retaining joints and brackets, should be prepared. The weldment record form should contain the following information:

a) Joint Identification Number (JID) number

b) Joint design type

c) Base metal type with heat and lot number

d) Filler metal type with heat and lot number

e) Fit up and inspection results

f) Welding procedure number

g) Heat treatment if required

h) Welder or brazier number

i) Type of inspection and results

j) Disposition of joint (pass/fail)

k) Any repairs of joint

l) Inspection procedure number

m) NDT inspection number

n) Signature and date

B.4.3.3 NDT Records. Copies of all nondestructive testing (NDT) records should be provided. Qualification records of nondestructive test personnel should be maintained and provided to the SCA.

B.4.3.4 Dye Penetrant (PT) Inspection. Records of dye penetrant inspections should be maintained and should consist of:

a) Type(s) of dye penetrant tests

b) Identification of assembly, part, etc.,

c) Number of cracks

d) Type(s) of cracks

e) Signature and date of the assigned responsible individual verifying all specified PT inspection including PT of any required repairs has been accomplished and is satisfactory

B.4.3.5 Radiographic (RT) Inspection. Chambers are required to have full radiographic testing (RT) of all pressure retaining butt welds (joint efficiency of 1). Records of radiographic weld inspection should contain, as a minimum, the following:

a) Date of exposure of the radiograph

b) Positively identified location of weld radiographed

c) Type of material and material thickness

d) Type of weld joint

e) Approved procedure identification

f) Energy source (isotope type, intensity, kilo-voltage and focal spot size of x-ray machine)

g) Type of film, screens, source-to-film distance, and exposure time

h) Penetrameter designation

i) Image Quality Indicator (IQI) sensitivity reading

j) Applicable acceptance standards

k) Flaws (unacceptable slag, porosity, or other indications)

l) Acceptance or rejection

m) Date of interpretation and signature of film interpreter(s)

n) Interpreter's documented qualification level should be noted

o) Diagram (radiograph map) indicating the specific location of each radiograph coded to its unique number

Where required by contract, a copy of the actual radiographs should be provided to the government.

B.4.3.6 Ultrasonic (UT) Inspection. Records of ultrasonic inspection should contain, as a minimum, the following:

a) Date of the ultrasonic inspection

b) Description and unique item identification, weld location and joint identification

c) Type of material and material thickness

d) Type of weld joint and length of weld inspected

e) Approved procedure identification

f) Equipment used for inspection (instrument and search unit): manufacturer and model number, transducer size and type, search beam angle, test frequency, couplant

g) Calibration standard number

h) Applicable acceptance standard

i) Reference block identification

j) Discontinuities that exceed the DRL (Disregard Level)

k) Acceptance or rejection

l) Signature of inspection personnel and date

m) If supplemental ultrasonic inspection techniques are used that contribute to the final inspection results, they should be recorded

B.4.3.7 Heat Treatment Procedures and Records. Copies of the procedures and records of all heat treatments performed on the chamber should be attached to the Manufacturer's Data Report.

B.4.3.8 Charpy Impact Test Data. When Charpy Impact testing of materials is required by the applicable commercial code, a copy of the Charpy Impact Test data should be attached to the Manufacturer's Data Report.

B.4.3.9 Material Repair Report. A report on repairs of any defects in the materials used for the fabrication of chambers should be attached to the Manufacturer's Data Report.

B.4.3.10 Technical Manual. Each pressure vessel system should be supplied with all operating, maintenance, technical and parts manuals and instructions necessary for the safe operation of all devices or components supplied with or part of the pressure vessel system.

B.5 MATERIAL SELECTION

Selection of the proper materials to be used in the manufacture of pressure vessels is critical to ensuring system safety. The specific end use of each structural component must be evaluated on the basis of its operating environment, life expectancy and intended use. The use of inappropriate material in a pressure vessel may result in a catastrophic failure and cause fatal or critical injury to personnel and substantial damage to property.

B.5.1 Corrosion. Corrosion effects must be considered during the initial selection of the material and throughout the design process. The following list represents typical types of corrosion that must be considered:

a) Electrolytic corrosion - stray electrical currents that can accelerate corrosion.

b) Crevice corrosion - crevices in or between materials retard the formation of oxide film within these crevices.

The oxide film that forms on the surrounding surface will act as a cathode and the crevice will act as an anode that accelerates the corrosion within the crevice.

c) De-alloying corrosion - In some alloy compositions, corrosion will attack one or more of the components of the alloy, which will result in weakening of the material.

d) Galvanic corrosion - When two different metals are coupled in the marine environment, one will act as an anode and the other will act as a cathode depending on the relative positions of the metals within the galvanic series and the relative size of the exposed metal surfaces of each. This will accelerate corrosion. The applicant should consider this when choosing materials to use in the design of the system.

e) Stress corrosion - certain alloys are susceptible to stress corrosion cracking, which can only occur when the material is exposed to a corrosive environment while under tensile stress. In the case of some high strength steels and titanium alloys, this form of corrosion can be propagated at highly accelerated rates, depending on environmental conditions.

f) Pitting - pitting can be a serious problem in pressure vessels and components. Pitting is normally limited to alloys of steel and aluminum. Hatch and view port seating surfaces have been known to leak due to pitting.

Painting, anodizing and plating are all common and cost-effective methods of corrosion protection. These processes provide only a thin layer protection, however. When this surface protection is scratched, the exposed bare metal is subject to accelerated local corrosion.

B.5.2 Protective Finishes. Finishes applied to pressure containing and critical load bearing elements should not be of a type likely to permit the development of hidden pitting. The application of all protective finishes to surfaces in contact with breathing gases should be performed in accordance with written and approved procedures.

Metal applied as a surface finish, coating or cladding should be lower on the electrochemical scale than the metal to which it is applied. Clad welding is a process that deposits corrosion resistant metal over the area to be protected. This process can be used to protect critical hatch and view port seating surfaces and is effective in eliminating pitting and general corrosion. The applicant should justify that use of dissimilar metals in contact, where dissimilar metals are defined by MIL-STD-889, Dissimilar Metals, does not present an unacceptable corrosion potential.

B.5.3 Toxicity. As a precaution, the designer should consider the toxic effects of materials. Materials, such as paints, insulations, sealants, adhesives, plastics, fabrics, fittings, and other items and equipment containing material or components which may give off noxious fumes at any temperature below 200 degrees Fahrenheit or which could cause occupational illness, should not be installed or applied within the unmanned pressure test facility. For paints, sealants or adhesives, this requirement applies after drying or curing. The SCA may require Material Safety Data Sheets (MSDSs) for materials used inside pressure vessels and on other surfaces in contact with pressurization media.

Mercury, asbestos, cadmium, magnesium and beryllium are examples of materials that should not be used in an unmanned pressure test facility without adequate protection and justification.

B.5.4 Flammability. Every effort should be made to eliminate, or at least minimize, flammable material in the unmanned pressure test facility. It should be understood that materials that are nonflammable at atmospheric pressures might be highly flammable when subjected to increased oxygen concentrations and/or elevated pressure.

If aluminum paint is used inside an unmanned pressure test facility, precautions should be taken to ensure that it is not applied over rusted steel. A primer, not containing red lead or iron oxide, should be used under the aluminum paint.

Magnesium and alloys containing significant amounts of magnesium should not be used in the unmanned pressure test facility because of their high combustibility.

The applicant should provide sufficient information to permit an independent evaluation of the suitability and adequacy of the materials used.

B.6 DESIGN OF PENETRATIONS INTO AND THROUGH THE PRESSURE VESSEL

The applicant for the unmanned pressure test facility is responsible for the safe and adequate design of all openings or penetrations in the pressure envelope. When using the ASME pressure vessel code as a guide, the designer must carefully consider additional loads such as piping loads and make provision for them.

All possible modes of failure, including leakage, must be considered during the design phase of the system. Sufficient testing must be performed and documented to confirm the structural integrity and leak tightness of each penetration.

All vents, drains, exhausts, or other exits from the pressure envelope, should be equipped with a means of positively securing or locking against accidental opening or closing.

Penetrations with gasketed sealing areas should have corrosion protection provisions for these areas.

Alternative design methods may be approved by the SCA on a case-by-case basis.

B.6.1 Piping Penetrations. Pipe penetrations to the pressure envelope should be located and arranged so that, in the event of flooding, loss of atmosphere or similar emergency, a maximum amount of atmosphere will become entrapped in the unmanned pressure test facility. Emergency shutoff capability should be provided to protect the internal breathing atmosphere from exhaust, full flooding, or contamination.

B.6.2 Electrical Penetrations. The bodies of electrical penetrators and connectors that may be exposed to water or spray should be made of corrosion-resistant material. Electrical penetrations to the pressure envelope should be gas-/watertight, even when the connecting cables have been damaged. Pin-type connections or cable entrances into compensated enclosures are the preferred methods and should be used on all new design pressure vessels. Terminal tube entrances are acceptable on existing pressure vessels when evidence of compatibility of the cable jacket and insulation with the compensating medium is provided.

B.6.3 View Ports. The applicant should show that view port design is adequate for the system pressure and temperature range, environmental conditions and expected number of pressure cycles. The materials used must have adequate fatigue strength for the stress levels incurred over the expected life of the vessel. Resistance to the stresses applied continuously over long periods of time, as well as cyclic stresses, must be properly considered. Full specification must be made of the materials used; their composition; thermal, chemical, or physical treatment(s) required; dimensions and tolerances; and renewal or replacement criteria. Where necessary, view ports must be protected against accidental impact or other mechanical abuse. Although the use of various materials for view ports is not restricted, acrylic view ports have a demonstrated high level of success and are recommended above all other types when design parameters permit the use of acrylic. View port penetrators should be designed such that the view port seals against an integrally machined sealing surface when pressure is applied (i.e., the retaining ring should not be part of the primary sealing boundary when pressure is applied). Acrylic materials, view port designs and view port penetrators should conform to ASME/ANSI PVHO-1, Safety Standards for Pressure Vessels for Human Occupancy unless prior approval is obtained from the SCA.

In-service (i.e., used) view port defect criteria should be based on view port material, dimensions, and loading conditions, and must be determined separately for each view port design. SCA

approval is required for used view port defect criteria. Crazing and cracks are not allowed in new or used view ports. Chips and scratches may be allowed in used view ports and the acceptable sizes of each, if permitted, will depend upon the view port design. The service life of a view port also depends on the view port design. For designs that are in accordance with ASME/ANSI PVHO-1, view port service lives are either 10 or 20 years, depending upon the view port design.

B.6.4 Hatches/Closures. For Category 1 or 2 materials, all pressure retaining closures, including hatches, doors, covers, and caps or plugs for openings should have a demonstrated (by hydrostatic test using strain gages) factor of safety of at least 1.5 times the maximum operating pressure. The mating flanges of all hatches and doors should be integral to the pressure vessel shell.

For Category 3 materials, the criteria stated for Category 1 and 2 materials may not be appropriate or adequate. Therefore, the criteria used must demonstrate the same degree of conservatism as the criteria for Category 1 and 2 materials and require SCA approval.

The ease and speed with which a closure can be opened or closed, and whether tools are required to do so, should be a design consideration. In all cases when these factors are important, SCA approval of the closure design should be obtained.

B.6.5 Seals. Sealing materials and techniques must be shown to be adequate for the range of pressures, temperatures, pressurizing media, vibrations, lubricants, and atmospheric environments specified for the system. Seals should not be subject to failure due to the effects of a non-lethal extinguishable fire inside or outside the system, attack by the fire extinguishing agent(s) used by the system, or by thermal shock caused by the application of the extinguishing agent(s). The effects of ultraviolet light, pressure cycling, stress concentrations, differential thermal expansion, differences in moduli of elasticity, tolerances and aging should be considered when designing seals.

In systems that may contain elevated oxygen concentrations, only oxygen compatible materials should be used.

B.7 FABRICATION DESIGN CRITERIA

Prior to the start of fabrication, the applicant should demonstrate to the SCA that accepted commercial or military guidelines are being used during the system fabrication process. In cases where the applicant desires to use fabrication procedures developed to commercial specifications, recorded data, in addition to that required by the commercial specification, may be required to provide the SCA with assurance that those procedures have been followed.

B.7.1 Welding and Brazing. All welded and brazed pressure-retaining construction should be performed in accordance with written and approved procedures, as discussed in Section 3, Sections 3.3.3 and 3.3.4. Welding and brazing of structural members may require the use of approved procedures depending on the application. The applicant is responsible for the integrity of the joint design and the proper choice of filler material.

B.7.2 Threaded Fasteners. The design of all critical threaded fasteners, including bolts, studs and nuts, should meet the requirements of the Screw-Thread Standards for Federal Services, FED-STD-H28, Screw-Thread Standards for Federal Service. Studs and bolts should be of sufficient length so that, when nuts are tightened to their appropriate torque values, at least 1 thread is exposed. Where practicable, the number of threads exposed should not exceed 5; however, in no case should the thread exposure exceed 10 threads. Any fastener design not covered in FED-STD-H28 or ASTM A325, Standard Specification for Structural Bolts, Steel, Heat-Treated, 120/105 ksi Minimum Tensile Strength must be brought to the attention of the SCA for approval.

B.7.3 Locking Devices for Critical Mechanical Fasteners. The need for locking devices on mechanical fasteners should be evaluated by the applicant. In cases where the loss of a fastener would cause a critical failure, locking devices should be used. Generally, a locking device should provide a positive locking action, be simple to install and should lend itself to easy inspection without disturbing the locking feature.

If the locking device does not meet the above guidance, or is unique in design, the applicant should bring this device to the attention of the SCA, with sufficient information to justify the safety and integrity of the device. The justification should include recommended inspection procedures and acceptance standards.

If locking devices are not practical, critical fasteners should be marked with a "torque stripe" which identifies the relative locations of parts when properly torqued.

B.8 DESIGN OF PIPING SYSTEMS

When designing piping systems, the applicant should employ the design requirements of established military or commercial standards where a substantial body of service experience exists in similar applications.

Maximum System Pressure (MSP) is the highest pressure that can exist anywhere in a system or subsystem during any condition (i.e., uncontrolled pressure excursion). MSP is generally understood to be the relief valve set pressure and must include the effect of static head pressure. Pressure ratings for all piping and components should be equal to or greater than the MSP

of the system or line of which they form a part. Piping subject to external pressure should be designed for the maximum differential pressure that can exist in either direction during operating, shutdown or test conditions; otherwise suitable over pressure protection should be provided.

Maximum Operating Pressure (MOP) is the highest pressure that can exist in a system or subsystem under normal operating conditions. All piping components must undergo a hydrostatic strength test based on the MOP, with no external leakage or permanent distortion permitted. Additional information concerning testing requirements can be found in Appendix C.

B.8.1 Piping. Consideration should be given to material type, wall thickness, minimum bend radius, back-wall thinning allowance and inner radius wrinkling when specifying the method of piping system fabrication.

B.8.1.1 Structural Considerations. The applicant should consider the structural adequacy and fatigue life of the piping system for all anticipated in-service conditions. Some in-service conditions include the following:

a) Weight of pipe fittings, valves and other components including cleaning or testing fluids

b) Internal or external pressure, both static and cyclic

c) Restraint of hangers and supports

d) Thermal expansion and contraction

e) Shock, impact, vibration and water hammer

f) Mechanical loads caused by operation of the system

g) Effects of the corrosion

Piping which, if ruptured, would depressurize the unmanned pressure test facility should be protected against damage. Suitable routing, shielding, etc., may accomplish this. Piping connections should be designed and arranged so that it is physically impossible to inadvertently connect a system of one pressure or service to a system of a different pressure or service. If gas reservoirs, such as cylinders, are included in a system, a readily-accessible valve should be provided to stop gas flow from the reservoir.

B.8.1.2 Pipe Hangers. Arrangement and design of pipe hangers should be carefully considered as a basic element of the piping design. Piping support spacing should be IAW Table B.1 and ASME B31.1, Power Piping.

Piping and tubing should be supported as close to bends as

possible. Piping alone should not be used as the sole support for relatively heavy components (e.g., large valves, moisture separators or filter housings). Components should be supported so that the force required to operate them (or other normal operational loads) does not cause visible deflection, rotation or vibration. One line should not be used to support another, although clamp blocks may be used to support two or more adjacent lines as long as the blocks are attached to non-piping structural members.

B.8.1.3 Piping Flexibility. Piping should be designed to have sufficient flexibility to prevent failures resulting from the conditions listed in Section B.8.1.1.

In certain cases piping flexibility calculations are required by the SCA as a further measure of assurance prior to system fabrication. Detailed sketches of piping under examination may be required with the calculation report. Where required, calculations should show maximum stresses and their location in each section of piping under examination. Calculations should be submitted in a detailed form that will permit their review without difficulty and should include a statement delineating the following:

a) Theoretical basis of the calculations

b) Method of performing the calculations

c) Simplifying assumptions

d) Sign and symbol conventions

e) Assumed material and dimensional data

f) Other pertinent information such as hull deflections

The piping flexibility analysis should also consider the flexibility of piping components. The applicant's piping flexibility analysis should include calculations of the bending moments, twisting moments, and reaction forces imposed on each critical component in the piping system. Flexibility analysis is not required for pipe up to and including 3/8 inch IPS or for tubing up to and including 1/2 inch OD. Additional information on the flexibility analysis can be found in ASME B-31.1.

Table B.1
Pipe Support Spacing

PIPE SUPPORT SPACING		
Nominal Pipe Size (Inches)	Span (Inches)	
	Gas Service	Liquid Service
1/8	24-28	18-24

1/4	38-44	30-36
3/8	50-60	40-46
1/2	60-70	50-56
3/4	85-95	65-75
1	95-100	85-100
1-1/4	120-140	110-120
1-1/2	120-140	110-120
2	120-140	110-120
2-1/2	120-140	110-120
3	120-140	110-120

TUBING SUPPORT SPACING

Nominal Tubing Size O.D. (Inches)	Span (Inches)
	Gas and Liquid Service
1/8	18-24
1/4	24-30
5/16	30-40
3/8	40-50
1/2	50-60
3/4	60-70
1	70-80

B.8.1.4 Materials. In general, piping materials should be in accordance with MIL-STD-777, Schedule of Piping, Valves, Fittings, and Associated Piping Components for Naval Surface Ships. However, materials called out in ASME B-31.1 may be used with prior SCA approval. Consideration should be given to eliminate contact between dissimilar metals where galvanic effects of corrosion may occur. Specific approval must be obtained from the SCA for the use of non-metallic piping and piping components. Refer to Appendix A for additional information on material categories.

B.8.1.5 Pipe Joints. Only pipe joint designs that are fabricated, assembled and tested to accepted military or commercial standards may be used (typically; butt welds, socket welds, bolted flange connections and O-ring faced fittings). Other joint designs (typically; bite type, flared, compression fittings and threaded joints) must be justified to the SCA. Brazed joints, while considered standard practice in shipboard pipe systems, should be justified for portable and shore based systems.

The number of pipe joints should be kept to a minimum. Wherever possible, bending of the pipe should be considered. MIL-STD-1627, Bending of Pipe or Tube for Ship Piping Systems provides specific requirements and limitations for bending pipe or tube. All pipe and tube fittings should be used only at temperatures and pressures not exceeding ratings recommended by the manufacturer.

Lines, which must be connected and disconnected during system

operation, should be equipped with appropriate pressure venting capabilities. Lines which are required to be disconnected during set-up and take-down of the unmanned pressure test facility must be provided with suitable caps or plugs to maintain cleanliness and prevent damage to threads. Both male and female connections should be so protected. Caps, which introduce moisture, and tapes, that leave adhesive deposits, should not be used for this purpose. Closure devices, when not in use, should be stored in a way that prevents contamination.

B.8.1.5.1 Welded Pipe Joints. Welded pipe joints are the preferred method of joining pipe that will not require disassembly for system repair or maintenance. The welding process melts the base metal to form a joint that is often as strong as the surrounding piping and resists cracking due to piping flexure. Welded pipe joints must meet the requirements of ASME B31.1 and supplemental requirements of the SCA.

B.8.1.5.2 Brazed Pipe Joints. Brazed pipe joints are used to permanently join piping material that is not weldable (i.e., copper and copper-nickel). Brazed joints are not as strong as welded joints because the process only melts a soft filler metal, not the base metal. Brazing of austenitic stainless steels should not be performed without express permission of the SCA. All unmanned pressure test facility brazed pipe joints should meet the requirements of NAVSEA 0900-LP-001-7000, Category P-3a, Special Category (I) and should be performed in accordance with NAVSEA/NAVFAC-approved procedures.

B.8.1.5.3 O-Ring and Flanged Pipe Joints. Mechanical piping unions and flanges include a wide variety of designs that rely on a mechanical action (i.e., torquing of bolts or nuts) to compress a soft seal. Flange fittings are most often used in designs for large diameter shore-based liquid or steam system piping. The use of face seal o-ring unions are recommended over bolted flanges. MS boss fittings, with o-ring seals, are preferred over threaded pipe joints because galling of the threads is less likely and the threads are not relied upon to form the seal. Additional design requirements for bolted flanges and blanks and all alignment and assembly requirements for mechanical joints should be in accordance with Navy Ships Technical Manual (NSTM), Chapter 505 and ASME B-31.1.

B.8.1.5.4 Threaded Pipe Joints. Experience has shown that these connections are susceptible to corrosion, shock and vibration damage, and leakage. Consideration must be given to pressure limitations due to a reduction in wall thickness of the pipe at the tapered threads. Should a component only be procurable with threaded end fittings, a means must be provided upstream and downstream of the component to permit its removal without disturbing the threaded joints. Any compound (e.g., antiseize thread tape) or lubricant used in threaded joints should be suitable for the service conditions and should not react unfavorably with the service fluid or piping materials.

B.8.1.5.5 Flared Pipe Fittings. Flared pipe fittings and their joints should conform to the range of wall thicknesses and method of assembly recommended by the manufacturer. Care should be taken with cutting and flaring tools so as to not induce work hardening of the tube end, which can make the material more susceptible to brittle fracture. Flared fittings should not be used without specific NAVFAC approval.

B.8.1.5.6 Flareless Pipe Fittings. Flareless, mechanical friction or bite-type connections should not be used on piping components where failure could cause uncontrolled depressurization or flooding of pressure vessels, mission support systems, electrical assemblies or other mission components. The use of such fittings in control and monitoring systems may be permitted only if:

a) they can be quickly isolated from the rest of the system in case of failure and,

b) a redundant means of providing the control and monitoring functions is available

Flareless and non-standard fittings, including proprietary fittings, should not be used without specific NAVFAC approval. Approval for joint design should be based on past experience and/or tests that demonstrate that the joint is safe for the operating conditions.

B.8.1.6 Flexible Hoses/Flexible Pipe. In most applications and for permanent installations, flexible hose is a poor substitute for rigid pipe or tubing. The use of flexible hose should be limited to applications where excessive flexing or vibration of rigid piping dictates its use. When hose is to be subjected to considerable vibration or flexing, sufficient slack should be provided to avoid mechanical loading. Sharp bends or twisting should be avoided. Bend radii should not be less than the manufacturer's recommended minimum bend radius. All hoses should have a rated working pressure equal to or greater than the system design pressure for the system in which they are used. A pressure safety factor of four times the hose rated working pressure to burst pressure should be the minimum used for flexible hose. Flexible hose material should be compatible with the intended service. Cleaning solutions must be compatible with the hose materials and must be able to clean the hose to the same level as the system in which it is used.

When hoses and connectors are used in applications where they may be subjected to mechanical loading, they should be provided with strain relief devices. These devices should be designed to prevent damage to the hoses and connectors as well as to prevent accidental disconnection of the hoses if they are pulled. Provisions should be made to connect the strain relief device to a nearby structural member. The most common form of strain

relief is a small diameter wire cable with eyes at each end for shackles. The cable is attached to the hose by marlin at regular intervals. All high-pressure hoses are required to have this strain relief device except those that are permanently installed.

The safe useful life for each flexible hose in the unmanned pressure test facility should be specified and inspection requirements and criteria should be established. Periodic replacement of rubber hoses should be anticipated. Rubber hoses used in critical applications should be replaced every five and one-half years from date of manufacture. Rubber hoses used in non-critical applications should be replaced at least every 12 years. Metal, PTFE and thermoplastic hoses have no predetermined life but require annual inspection and testing. In all cases, hose inspection and replacement criteria should be in accordance with approved PMS.

All flexible hoses that are not permanently installed should be provided with suitable end caps that protect the hose end fittings from mechanical damage and prevent contamination when not connected for use.

The applicant should maintain a hose log for recording the inspection and test records and the life history of each flexible hose in the system.

Quick disconnect fittings used on flexible hoses should be readily accessible and capable of being disconnected under pressure in an emergency. Provision should be made to prevent accidental disconnection, i.e., a positive locking mechanism requiring more than one mechanical action to disconnect.

B.8.2 Piping Components. Care must be exercised when installing piping components in the system to ensure that gas or liquid flow is in the proper direction through the component. Most components have a designed direction for flow and this should be observed. Where components permit bi-directional flow, they should be installed to take best advantage of the design. For example, valves that serve as both inlet and outlet on high-pressure flasks should be installed so that when they are closed the flask pressure acts from below the seat and not on the valve stem packing. Piping components should always be installed in accordance with the manufacturers' recommendations, unless deviation is approved by NAVFAC.

All manually operated piping system components should be readily accessible and easily operable under normal and emergency conditions.

All piping system components should be selected for flow that is adequate for the most demanding mission conditions expected for the unmanned pressure test facility. These conditions should be specified when justifying the selection of a component.

Unmanned pressure vessels are of two types, those pressurized using a gas and those pressurized using fluid. Because of the differences in the pressurizing medium, selection of components of the different systems should be given different considerations.

B.8.2.1 Components of Gas Pressurized Systems. Only seamless piping or tubing is authorized in DOD unmanned pressure test facilities.

B.8.2.1.1 Compressors. Required features include pressure gages for each stage of compression, running hour meter, high-pressure shutdown, high temperature shutdown/alarm and low oil pressure shutdown/alarm. It is recommended that automatic condensate drains be installed on compressors. Consideration must be given to the location of the compressor inlet in regards to possible contamination from machinery exhaust fumes or other airborne contaminants. Proper inlet filtration should be provided. A dry type, non-shedding inlet filter is recommended.

B.8.2.1.1.1 Coolers. High temperatures associated with high-pressure air compressors may cause compressor lubricants to break down. Therefore, compressor inter-stage coolers and after coolers may be required to bring the discharge temperatures down to an acceptable level.

B.8.2.1.2 Moisture Separators. All high-pressure air compressors require moisture separators to remove liquid contaminants from the compressed air. The moisture separator capacity is selected according to compressor output flow rate and temperature and the anticipated environment that the compressor will be used in.

Separators should be located downstream of any after coolers to trap the condensation resulting from the air cooling process and compressor oil which may enter the outlet gas stream. All separators must be provided with drain valves to remove collected liquid. For maximum efficiency, moisture separators should be installed in a straight length of pipe at least 10 pipe diameters downstream of the nearest valve or fitting and should be drained regularly during operation. All moisture separators should be visually and hydrostatically tested. The periodicity for hydrostatically testing the moisture should be negotiated with the SCA.

B.8.2.1.3 Back Pressure Regulators. High-pressure air compressors should be equipped with a backpressure regulator located downstream of the moisture separator. Backpressure regulators should be designed to maintain a specified minimum operating pressure (normally 1000 psig or greater in accordance with the compressor manufacturer's requirements) at the compressor outlet. The backpressure regulator is used to seat the compressor piston rings and prevent excessive compressor lubricating oil from entering the system piping.

B.8.2.1.4 Filters. Compressor outlet filters are to be located downstream of the moisture separator and backpressure regulator and upstream of the rest of the system. All installed filter housings (except compressor inlet housings) should be hydrostatically tested. The periodicity for hydrostatic testing should be negotiated with the SCA. Depending on system design, additional particulate filters may be required to protect sensitive system components.

Components should have a working pressure that is greater than the maximum system pressure and the purification chambers should conform to ASME Code for unfired pressure vessels, Section VIII, Division 1.

B.8.2.1.5 Valves. For guidance on the selection of valves for a particular application refer to MIL-STD-777, NSTM Chapter 505, ASME B31.1 or NAVFAC DM-39.

Valves utilizing a soft seat design are preferable to those employing a metal-to-metal seat design.

Periodic inspection and maintenance should be performed in accordance with PMS. Pressure boundary hydrostatic and seat tightness testing of valves should be in accordance with NSTM Chapter 505.

B.8.2.1.6 Receivers and Volume Tanks. All air systems that are supplied air from a compressor should incorporate medium or low-pressure receivers or volume tanks. These components help to eliminate pulsations in the compressor discharge, and act as storage tanks, allowing the compressor to shut down during periods of light load. Receivers and volume tanks should be fabricated using approved specifications for pressure vessels described in Section B-5.1. In general, receivers and volume tanks are fabricated in accordance with Section VIII of the ASME Boiler and Pressure Vessel Code. All receivers and volume tanks should be equipped with pressure gages, drain valves and relief valves. Receivers and volume tanks should be inspected in accordance with MIL-HDBK-1152, Inspection and Certification of Boilers and Unfired Pressure Vessels. More information on receivers and volume tanks can be found in NSTM Chapter 551.

B.8.2.1.7 Flasks. If high-pressure gas cylinders or flasks are installed, they should be designed and fabricated in accordance with DOD-approved specifications such as MIL-F-22606, Flask Compressed Gas and End Plugs for Air, Oxygen and Nitrogen or standards of DOT or ASME. Each gas flask should have a readily accessible isolation valve to stop gas flow to the system. The flask isolation valve must be able to withstand full flask pressure. Each air flask should incorporate a method for periodically draining moisture from its interior (i.e., drain valve, dip tube). MIL-F-22606 system air/gas flasks should be periodically inspected and undergo either nondestructive testing

or hydrostatic testing. DOT and ASME flasks should be inspected and hydrostatically tested in accordance with DOT or ASME requirements.

B.8.2.1.8 System Pressure Gages. The need for accurate, reliable, readable pressure gages in unmanned pressure test facilities cannot be overstated. Sufficient gages should be located throughout the system so that operators are able to monitor pressures at all times. Location of gages at the following points in a system is essential:

a) Gas manifolds

b) Volume tanks

c) H.P. bank manifold

d) Upstream and downstream of reducing valves

e) On each compressor stage and at outlet

The prudent designer will locate pressure gages at other locations throughout the system as operating needs, configuration or layout may require. Gage operating ranges should be selected so that system minimum and maximum operating pressure fall between one-fourth and three-fourths of full scale. Pressure gages in the system should be accurate to within "1% of full scale.

Unless specifically exempted by the SCA, each gage should be provided with a gage isolation valve that is readily accessible and may be closed to isolate a defective gage from the system. Valves that act as both isolation valve and calibration connection port are recommended.

All gages must be securely mounted in a location that permits easy reading of the dial and access for removal. Gages must be protected from mechanical vibration, shock and inadvertent mechanical damage. Care must be taken when mounting gages not to obstruct or block the operation of the "blow-out" plug.

When a gage is calibrated, a calibration data sheet should be prepared and retained as part of the certification documentation. A calibration sticker showing the date of calibration and the next calibration due date should be affixed to the gage dial or housing. Calibration should be accomplished only by a qualified calibration activity. The accuracy of helical-type Bourdon-tube gages may be verified by performing a comparison check with a gage that has been calibrated to a national standard. Gage comparison checks may be performed by qualified personnel within the command, however, those gages requiring adjustments must be forwarded to a qualified calibration activity. The dates and results of comparison checks should be documented and retained. All gage calibration and comparison should be performed in

accordance with approved system PMS.

B.8.2.1.9 Special Considerations for Oxygen Systems. The applicant should give special consideration and analysis to the use of oxygen in the specific unmanned pressure test facility design. Oxygen leaks are extreme fire hazards. Every attempt should be made to design oxygen-piping systems to eliminate the possibility of leaks. Use of seamless stainless steel piping/tubing is permitted in oxygen systems. Wherever possible, high-pressure portions of the oxygen system should be welded, vice using mechanical fittings. Quick-opening valves should not be used in high-pressure oxygen systems.

For further guidance on designing oxygen systems refer to ASTM G88, Standard Guide for Designing Systems for Oxygen Service; NFPA 53M, Manual on Fire Hazards in Oxygen Enriched Atmosphere and CGA G-4, Oxygen. Deviation from any of the above criteria requires technical justification and approval from the SCA.

B.8.2.1.10 Special Considerations for Hydrogen Systems. The applicant should give special consideration to the use of hydrogen in a UPTF. Dialog with the SCA early in the planning and design process is strongly recommended. The primary emphasis of the design is to prevent a flammable mixture of hydrogen and air or oxygen from forming. This can be broken down into two areas;

1. hydrogen gas leaking from the vessel, component or piping

2. flammable mixtures of hydrogen, oxygen or air within the piping system or vessel.

In the design of hydrogen piping systems special consideration should be given to the choice of piping joints, type of components and location of ancillary equipment. Special safety features and operating procedures should be considered to prevent the inadvertent forming of a flammable mix within piping or the pressure vessel.

Consideration should be given to monitoring equipment to alert operators of hydrogen gas leaks or hydrogen flames that may be undetectable to the naked eye.

The following additional references should be considered when designing a UPTF utilizing hydrogen as a pressurization media:

a) Flame Arresters in Piping Systems. API Publication 2028, Second Edition, American Petroleum Institute, December 1991.

b) Hydrogen as a Diving Gas. UHMS Publication number 69(WS-HYD), Undersea and Hyperbaric Medical Society, February 1987.

c) McCarty, R.D. Hydrogen: Its Technology and Implications. CRC Press, Inc., 1975.

d) NASA Hydrogen Safety Handbook.

e) Standard for Purged Enclosures for Electrical Equipment in Hazardous (Classified) Areas. NFPA 496, National Fire Protection Association, 1989.

f) Standard for Gaseous Hydrogen Systems at Consumer Sites. NFPA 50A, National Fire Protection Association, 1989.

B.8.2.2 Components of Fluids Pressurized Systems.

B.8.2.2.1 Pumps. Pump selection should be based upon the system fluid, the operating pressure and the flow capacity that is required. Once these operating parameters have been determined, pump selection is determined by an overlay of system and pump curves. Pumps should be located to maximize the net positive suction head and to minimize air entrainment into the system.

Pumps should be equipped with one pressure relief valve per each stage. Each stage of a pump should be provided with a temperature gauge for monitoring bearing temperature and with a pressure gauge. When pumping potentially contaminated fluids, a filter should be provided upstream of the pump to remove debris that could cause pump/system inefficiencies (e.g., cracked impeller, build-up in suction and discharge piping). The filter should be placed in an easily accessible location for ease of maintenance.

When installing pumps, consideration should be given to minimizing the effects of vibrations when choosing foundation mountings and piping connections. Consult with the manufacturer's recommendations for installation.

When high flow and low-pressure conditions are needed, centrifugal pumps should be considered for use. If these pumps are used in series, ensure that each pump is rated for the proper inlet pressure (i.e., the inlet pressure will increase for each consecutive pump).

When low flow and high-pressure conditions are needed, positive displacement pumps should be considered for use. This type of pump should also be considered when pumping high viscous fluids (i.e., if the viscosity is the same as or greater than SAE-30 motor oil (at room temperature)). Positive displacement pumps may also be used for metering flow. Some examples are external gear pumps and sliding vane pumps.

B.8.2.2.2 Valves. Valves should be selected based upon the system fluid, operating pressure and flow capacity that are required. Valves produced to a commercial or military standard are acceptable as long as the design pressure of the valve meets

or exceeds the system operating pressure. The soft goods (e.g. O-rings, gaskets) contained in the valves should be compatible with the system fluid.

Consult manufacturer's literature for recommendation on routine maintenance.

Ball Valves should be used in "on/off" applications and should not be used for throttling.

Globe/Plug Valves should be used in locations where throttling is necessary.

Needle Valves should be used in by-pass applications and where precise control is needed.

B.8.2.3 Piping Component Testing. All piping system components should be subjected to adequate strength and leak tests to ensure that the system is safe. The requirements for material OQE and component testing are given in Appendix C. All test results must be formally documented and available for SCA review during on-site surveys.

B.8.3 General Considerations for Piping Systems. It is essential that all seals, gaskets and o-rings in unmanned pressure test facilities be fabricated from the proper material. Gaskets containing asbestos material should not be used without approval of the SCA.

B.8.3.1 Identification and Labeling. All piping and components including fittings should be identified in sufficient detail on the system drawings (i.e., description, material, part number, pressure rating) to prevent replacement with an unsuitable part. Unless specifically exempted by the SCA, all hoses, valves, pressure vessels, gages, filters, etc., must be marked or labeled to indicate function and content.

Unless authorized by the SCA, all piping and piping system components used for the transmission or monitoring of liquid or gas within a system should be marked and color-coded to identify the specific gas or liquid contained and the direction of flow. Where piping is located behind a panel, an accurate schematic should appear on the panel. Color-coding of piping systems not identified in Table B.2 should be negotiated with the SCA. A labeling system should be used to identify each component by type of gas or liquid, by color and by word or letter symbol.

Table B.2.
Suggested Color Code And Component Designation
For Unmanned Pressure Test Facilities

Gas System	Designation	Color Code

Helium	HE	Buff
Oxygen	OX	Green
Helium-Oxygen mix	HE-OX	Buff & Green
Nitrogen	NIT	Light Gray
Exhaust	EXH	Silver
Air (low pressure)	ALP	Black
Air (high pressure)	AHP	Black
Chilled Water	CW	Blue & White
Hot Water	HW	Red & White
Potable Water	PW	Blue
Fire Fighting Material	FP	Red

Piping system components must have a standardized labeling scheme throughout, with unique component identifiers that match the system drawings and system operating and emergency procedures. Such standardization is important for approval of operating and emergency procedures, continuity of system manuals and personnel training.

B.8.3.2 Cleaning and Testing. All cleaning and testing of piping for unmanned pressure test facilities should be in accordance with NAVFAC approved procedures. Cleaning of oxygen, helium, HEOX and NITROX piping systems should meet the requirements of MIL-STD-1330, Precision Cleaning and Testing of Shipboard Oxygen, Helium, Helium-Oxygen, and Nitrogen Systems.

All pressure retaining components of the piping system must be hydrostatically tested for strength and porosity after completion of the installation and/or after welding or brazing. Individual components (e.g., valves, pressure regulators, volume tanks, etc.,) may be tested prior to installation in the system. In gas systems, pressure-measuring devices, such as gages and sensors, should not be hydrostatically tested due to the possibility of component damage.

Additional tests must also be performed to ensure system tightness and proper operation of components. General testing requirements are provided in Section 3. Appendix C provides specific component testing requirements for installation and repair of components.

Protection devices such as caps, plugs and plastic bags should be used to prevent entrance of foreign materials whenever the system integrity is broken and to protect the sealing surfaces of the components. Both male and female connections should be protected. Caps, plugs and plastic bags that introduce particulate contamination from shedding, moisture and tapes that leave adhesive deposits should not be used for this purpose. Caps and plugs should be cleaned to the acceptable level of system cleanliness before each use in accordance with approved cleaning procedures. When not in use, protection devices should

be stored in a way that prevents their contamination.

B.9 DESIGN OF ELECTRICAL SYSTEMS

Consideration must be given to the electrical requirements for all unmanned pressure test facilities and supporting equipment. This covers a wide range of equipment from heavy machinery such as pumps, compressors and handling equipment to precise instrumentation for monitoring, control, communications and data acquisition.

Although they cannot always be eliminated, electrical components exposed to high oxygen concentrations inside an unmanned pressure test facility pressure hull are potentially hazardous. The applicant should justify their use and should show their potential for creating a fire hazard in a hazard analysis. Electrical systems must be designed to the requirements of NFPA-70.

B.9.1 Power Requirements. The applicant should provide an estimate of he power requirements, both normal and emergency, to support the unmanned pressure test facility. The applicant should show how much power is required from the support facility and how much of the unmanned pressure test facility is self-supporting.

B.9.2 Electrical Connectors and Penetrators. The bodies of pressure vessel electrical penetrators and connectors exposed to water should be made of corrosion resistant material. Connector pins and sockets should be corrosion resistant or plated to prevent corrosion and electrical discontinuities. Provisions should be made to protect the pressure vessel from corrosion in the gasketed areas of the penetrators. Electrical connectors and individual hull penetrator designs should be technically justified for their intended applications.

B.9.3 Electrical Connectors. Connector design should permit the operator to readily disconnect the cable assembly and any other electrical conductor without receiving an electrical shock. System design or operating procedures should not allow disconnecting connectors when the circuit is energized.

Electrical connectors must be designed to prevent incorrect connection and accidental disconnection. This may be accomplished by size selection, key fitting, or other means. Color-coding or other visual identification alone is usually insufficient.

B.9.4 Electrical Penetrators. Pin-type connections for cable entrances into compensated enclosures are preferred; however, terminal tube entrances are acceptable provided evidence of compatibility of the cable jacket and insulation with the compensating medium is provided.

The electrical hull penetrator is part of the primary pressure boundary. Therefore, pressure test data should be provided to ensure that its hydraulic life is defined in relation to the design life of the hull and thermal shock to the connector.

B.9.5 Lighting Systems. If lighting is required, it is preferred that light sources be located external to the unmanned pressure test facility and provided internally through ports, light pipes, or other suitable means. In this case, infrared filters or other means may be required to dissipate heat from the port.

When lights are installed inside an unmanned pressure test facility chamber or capsule, the housings must be adequately designed so as not to explode or implode, and the wiring to the fixture must be sufficiently rugged to withstand inadvertent impact and mechanical loads without causing a fire or shock hazard.

B.9.6 Instrumentation. Instrumentation must be electrically isolated from the unmanned pressure test facility personnel, but not located in a manner that might subject it to erroneous readout. Electrical failure of one instrument must not impair the use of another. All instrumentation must be compatible with its intended environment and must not create a fire, electrical or toxic hazard.

B.10 ENVIRONMENTAL CONDITIONING COMPONENTS

Hyperbaric chamber heating/cooling systems may be required where environmental conditions dictate. The electrical components of heating/cooling systems should be located outside the pressure hull whenever possible. Heated/cooled gas or water may flow through the pressure hull, or the hull itself may be heated/cooled. If the hull is to be heated or cooled by an electrical device, the applicant should provide verification that no electrical current may pass through the hull.

B.11 OPERABILITY AND MAINTAINABILITY

The applicant should demonstrate the operability and maintainability of the facility. The facility must perform reliably under worst-case conditions. Mean time between failures must be longer than the longest mission duration. A comprehensive operation and maintenance technical manual, including troubleshooting instructions, should be developed and submitted for review.

B.12 REMOTE CONTROL SYSTEMS

The designer should furnish detailed design information for all remote control systems and components. Information provided to the SCA must clearly discuss the capability of the system to function in the intended environment (i.e., temperature,

pressure, humidity). Descriptions must be furnished for all remote control systems. The descriptions should include an analysis of the consequences of a failure or loss of normal mode, and describe automatic and manual backup control features available for emergency recovery or surfacing procedures. Test data in support of system and component reliability for the intended service must also be provided. Design information and test data must be in sufficient detail to permit an independent evaluation of the adequacy of the controls in their environment, under all normal and emergency operating conditions.

B.12.1 Remote Control Power Supply. Remote control power supplies may be manual, mechanical, pneumatic, hydraulic, or electrical. The choice should be based on reliability in the environment in which the power supply must function. The designer should furnish information that substantiates the reliability of the power supply in the intended environment. This information may be based either on previous use of the power supply or on tests.

All critical remote controls must have two independent sources of power. Failure of one of the power sources should not hinder the use of the other power source.

B.12.2 Remote Control Monitoring. Remote control systems should require devices that monitor system status and responses. Indication of malfunction or failure in a control actuator must be provided to the operator. The applicant should define the level of monitoring required based on the criticality of the system. The monitoring system design should be submitted to the SCA for concurrence.

B.12.3 Remote Control Actuators. A remote control actuator is any device or group of devices used to accomplish a desired control function. The design should be such that the control actuator is not subject to false alarms or extraneous signals that produce undesired responses. Switches and controls that are used to manually energize a control actuator must be located so that they are not inadvertently energized.

Remote control actuators should be designed to be fail-safe. Individual remote control actuators should be capable of being isolated from other remote control actuators that share a common power supply. For electrical remote control actuators, this requires either fuses or circuit breakers on all lines connecting each remote control actuator to the power supply. For hydraulic or pneumatic remote control actuators, this requires appropriate check valves or isolation valves on all lines connecting the power supply to the remote control actuator.

Where a remote control actuator normally operates automatically, provision should be made to allow the operator to manually override the automatic control. The manual control should bypass as much of the automatic control system as is practical.

APPENDIX C

REQUIRED DOCUMENTATION

C.1 MAINTENANCE AND REPAIRS

Work within the Scope of Certification (SOC) must be done in a controlled fashion to ensure certification is not voided. All work within the SOC on class-A chambers, should either be done in accordance with a controlled work procedure (CWP) or a re-entry control (REC) package. For Class-B and Class-C chambers, a maintenance log sheet should be filled out for all work within the Scope of Certification. An example of a Maintenance Log Outline Sheet is provided as Figure C.1.

C.1.1 Controlled Work Procedure (CWP). Work that is of a repetitive nature such as maintenance, equipment set-ups and alterations in support of testing may be accomplished using a CWP. All controlled work procedures should state:

a) Facility/Title

b) Safety Procedures
   tag out/isolation, depressurization, etc.,

c) Material required for installation
   penetrators by serial number
   soft goods
   test set-ups

d) Detailed work procedures
   list work steps in order
   list special work instructions

e) Testing required
   list test set-up requirements
   pressure, time, pass/fail criteria

f) Signature of person performing work and testing

CWPs may be pre-printed in a fill-in-the-blank format and used on an as needed basis. Controlled work procedures for each application should have individual numbers and be retained on file until the next certification audit. An example of an acceptable controlled Work Procedure is provided in Figure C.2.

Note: Deviation from the certified design within the Scope of Certification requires SCA Approval.

Facility _____ Date _____

_____ Maintenance _____ Repair _____ Design Change (requires Cert Board approval)

Caution: Verify system is NOT pressurized/powered prior to starting work and that the system CAN NOT be pressurized/electrified during work!

Short description of why work was performed:

List parts repaired/replaced:

Craftsman performing work _____Sign/date: _____

Supervisor's approval of work _____Sign/date: _____

Figure C.1
Maintenance Log Outline

C.1.2 Re-Entry Control (REC). REC is a system for maintaining positive control of work performed within the certification boundaries of the unmanned pressure test facility. The system provides for monitoring and documenting the following:

a) What system worked on

b) Why work was required

c) What work was accomplished, including safety precautions, materials and components used, re-test requirements, test data and supporting documentation

d) Who did what work (Craftsman)

e) Who authorized and accepted the work (Facility Manager or his designated representative.

f) Who maintains documentation (REC Supervisor)

When any maintenance or work is performed which breaches the certification boundaries of the UPTF the REC supervisor must first initiate a REC. This is accomplished by filling out the REC log, completing a REC sheet obtaining authorization from the facility manager (or designated representative). The necessary work or maintenance can now be performed on the facility. Upon successful test completion, the REC sheet is completed and all applicable maintenance check-off sheets, inspection records, testing records, and fabrication records are attached to the REC sheet. Once the closure complete signature is obtained from the Facility Manager, the REC can then be closed out by the REC supervisor by placing the REC package on file and completing the REC log entry.

Under Normal circumstances the unmanned pressure test facility should not be operated with an open REC. However, if the system or Sub-system affected by the REC can be isolated to ensure the safety of operators, craftsmen, and property, the Facility Manager may authorize operation of the Unmanned Pressure Test Facility.

C.1.2.1 Exceptions to Re-Entry Control. Certain UPTF require frequent entry into the certified boundary for routine operations or maintenance actions to enable mission accomplishment. Any operational controls believed to be adequate in lieu of re-entry control or controlled work procedures should be submitted to the SCA for approval. Examples of actions not requiring a REC are:

a) Normal operation of access hatches, pressure boundary doors or similar operations covered by an operating procedure (OP).

b) Removal of portable gas flasks for charging.

c) Gauge calibration, reference or sampling line changes where the ID of the line is 0.25 inches or smaller and the pressurization medium is considered non-flammable.

Note: No exceptions from re-entry control other than those listed above are authorized. Recommendations for exception from re-entry control will be considered on a case-by-case basis by the SCA. When entering systems under a REC exemption normal caution must be observed in protecting the system integrity and cleanliness.

C.1.2.2 Energy Control (Lockout/Tag-Out). Lockout/Tag-out procedures are used to identify equipment and components which are (1) in need of maintenance or repair, or (2) define REC boundaries and are not to be operated while the REC is open (i.e., work in progress). Commands must develop suitable lockout/tag-out procedures to control energy during maintenance or servicing of equipment that meet the following requirements (Navy plans must be in accordance with OPNAVINST 5100.23, Navy Occupational Safety and Health (NAVOSH) Program Manual or USACE EM-385-1-1, Safety and Health Requirements Manual for contractor personnel):

a) Command instruction that clearly defines Lockout/Tag-out procedures to be used for the unmanned pressure test facility

b) Both Lockout/Tag-Out devices shall indicate the identity of the employee applying the device, cognizant shop of code, telephone number where the employee can be reached during working hours, his/her supervisor, date applied, and the machine, equipment or system component that is deenergized.

C.1.2.3 Supporting Documentation/Objective Quality Evidence. Objective quality evidence (OQE) is supporting documentation that enables verification of installed components and raises confidence in the installation. For UPTFs the major area of concern is the primary pressure boundary. Pressure vessels, hull penetrators, fittings and piping up to and including the hull isolation valve, soft goods and repair kits, are examples of components requiring OQE. OQE ranges from ASME code documentation, level of cleanliness documentation, soft goods packaging, and certificates of conformance (COC) from manufacturers verifying part or kit numbers.

C.1.2.4 Re-Entry Control Log Instructions (FIG C.2).

Block (1) Enter name or designation of the subject Unmanned Pressure Test Facility.

Block (2) Enter REC number (example 6003; 6 is the year group 1996, 003 is the third REC of that year).

Block (3) Enter the revision, for the initial issue REC and alphabetical letters for each revision thereafter.

Block (4) Enter the name of the system Re-Entered.

Block (5) Enter the name of the REC supervisor.

Block (6) Enter dates for when REC number is issued, when work is started and when the REC is completed.

Block (7) Enter any remarks or associated REC numbers.

(1) FACILITY

(2) REC NO.	(3) REV	(4) SYSTEM RE-ENTERED	(5) REC SUP (Print Name)	(6) DATES			(7) REMARKS (Include associated RECs)
				ISSUE	START	COMPLETE	

Figure C.2
Re-Entry Manned Pressure Test Facility Control Log

C.1.2.5 Re-Entry Control Form Instructions for Figure C.3.

Block (1) The assigned technician should identify the system or components being re-entered. Only one system can be entered on one REC. Where more than one system is involved, separate associated RECs must be written.

Block (2) Obtain the appropriate sequential serial number from the REC log and enter it on the Re-entry Control form (an example of a REC Log can be found in figure C.2. Revision should be entered on the initial version of all RECs. If a revision is made, prepare a new REC form with the original number, plus the next revision letter, obtained from the REC log. Attach the revised REC to the front of the original and make the required entries in the log.

Block (3) Enter the applicable reason for the REC. When other is checked, state the reason in the space provided.

Block (4) Enter the number of pages in the REC.

Block (5) Enter the applicable drawing and revision or reference numbers for the systems identified in Block 1. Where specific plans/drawings do not exist, system drawings may be referenced or sketches can be prepared and approved by the appropriate technical authority.

Block (6) Enter the valve, circuit breaker or device numbers that have been tagged out.

Block (7) List by name all other systems affected by this REC, included non-certified systems.

Block (8) Describe in brief detail the work to be accomplished. List steps to be performed, including special actions required to retain certification of the balance of the system. Provide enough detail for craftsman to complete the removal, repair, testing and reinstallation. The boundaries of the re-entry should be detailed in specific terms, a simple sketch may be attached to the REC for clarity. The identity of all joints to be affected by this work must be clearly indicated and any new material to be installed must be listed Other supporting OQE should be attached to the REC Form. The craftsman’s signature indicates that the work was performed as documented.

Block (9) List steps to prevent contamination of the system being re-entered.

Block (10) Mark the recertification requirements that will be supported with documentation in the REC package. The SCA may be contacted when questions about recertification requirements arise.

Block (11) Facility Manager should review the REC for completeness and clarity, signature authorizes work to commence.

Block (12) Facility Manager, or representative, should review the completed REC package for its compliance with documentation requirements. Upon satisfactory review the supervisor or his representative should sign the REC and file the package for future SCA review.

C.1.2.5.1 Test Line-Up. A test line-up (TLU) or approved operating procedure (OP) should be initiated by the REC supervisor and will be included as part of all Re-Entry control packages as Objective Quality Evidence (OQE) of the valve line up used for testing. The TLU will include a simple line drawing, or photocopy of an existing drawing, of the portion of or entire system being tested. The drawing should be marked to indicate valve positions (open/closed) during the test. A key should be included to define any symbols or colors used. This drawing may also be used to show the valves that were tagged out during the work procedure. The Test Director may, if preferred, list the valves in the system on the TLU and indicate the open or closed position and any special instructions to describe the sequence of the test procedure.

C.1.2.5.2 Test Line-Up Instructions (FIG C.4).

Block (1) Enter the system or component being tested and enter the REC number the test supports.

Block (2) Enter the gas or fluid used for the test (He, O_2, N_2, air, water, etc.).

Block (3) Enter the intended test pressure in psig.

Block (4) A sketch, copy of an existing drawing, or valve list should be included for the system undergoing testing and indicating the valve positions used for the test.

Block (5) The test director should sign stating the test line-up was completed per documented instructions. Note: Any variation from documented test method will be annotated and signed.

Block (6) A witness should sign stating the line-up was completed as documented.

C.1.2.6 Joint Tightness Test. A joint tightness test subjects mechanically joined pressure containing boundaries of pipe and piping components to an internal pressure equal to 100% of maximum operating pressure. It is used after joint assembly to help identify leakage in mechanically joined pipe and piping components. Unless otherwise specified, test pressure tolerance should be maintained within + or - 3% (but no greater than 100 psig) of the specified test pressure. The duration for the joint tightness test is to be not less than 15 minutes (not less than 5 minutes if the test is conducted in a shop or a bench test) soak time plus sufficient time for inspection. All joints, when possible, should be checked for leakage using a leak detection solution. A sonic leak detector may be used in conjunction with the leak detection solution to help find leaks. System fluid is the preferred test medium for joint tightness testing, however, for O_2 systems, nitrogen may be used due to safety concerns. Requests for other fluid substitutions should be directed to the SCA.

C.1.2.6.1 Acceptance Criteria. Acceptance criteria for joint tightness testing of all systems, except those tested with helium or hydrogen, should be zero leakage. For systems using helium or hydrogen as the test medium, the acceptance criteria should be zero leakage except at valve stem seals where a leakage rate of 0.6cc/min for each stem seal is permitted. This is identified by only small bubbles forming in the solution like foam but no bubbles large enough to be identified as an individual bubble with the naked eye.

C.1.2.6.2 Joint Tightness Test Instructions (FIG C.5).

Block (1) Enter the name of the command at which the work is being performed.

Block (2) Enter the REC number that this test is associated with.

Block (3) Enter the system or component that is being tested.

Block (4) Enter a short description of the item being tested.

Block (5) Enter the required test pressure (100% of operational pressure).

Block (6) Enter the time the test was started and the time the test was completed.

Block (7) The facility Manager (or designated representative) should review the REC including the proposed test. Signature in this block allows testing to begin.

Block (8) Enter the joint numbers tested. Joint numbers may be assigned at the time of the test by including a sketch identifying the location and orientation of each joint.

Block (9) Enter the results of each joint test (sat or unsat). If a joint is unsatisfactory it must be repaired and

retested with the appropriate documentation being added to the REC package.

Block (10)If required, make a sketch to show the joint configuration clearly marking the joint numbers.

Block (11)The test technician should sign stating the test was completed as documented.

C.1.2.7 System Tightness Test. A system tightness test is performed when the scope of work exceeds the complexity at which a joint tightness test can be performed. When a system is applying for initial certification or has undergone an extensive overhaul a system tightness test should be run. This test is used to identify long-term leakage of an entire system. The system is gradually pressurized to 100% of maximum operating pressure. Data is then taken to measure the change in pressure, corrected for temperature, over an extended period of time. System tightness tests, unless otherwise specified by the SCA, should be at least 6 hours in duration. The test pressure tolerance used to perform this test should be within + or - 3% (but not greater than 100 psig) of the specified test pressure.

Step 1 Pressurize the entire system to its maximum operational pressure with the appropriate pressurization medium.

Step 2 Ensure accurate temperature monitoring throughout the system being tested.

Step 3 Allow approximately two (2) hours for the temperature to stabilize and repressurize if necessary.

Step 4 Log the test pressure and temperature hourly. Monitor the tightness of the installed using A and B below.

a) For gas filled systems, apply leak detecting soap solution to all joints (mechanical, welded, brazed, etc.,) within the test boundaries. Solution should be applied at least hourly. For liquid filled systems, look for physical evidence of leaks.

b) Verify installation of a calibrated pressure gage for monitoring pressure within the system undergoing test. Observation of the test pressure is required to ensure that the test pressure is maintained throughout the test duration and that no piping leakage goes undetected due to piping porosity that may not be detected by the leak detecting solution. For systems with small volumes, acceptable tightness of the system based on the pressure drop method may be indeterminate. Therefore, step A should be an integral part of all tightness tests.

C.1.2.7.1 Acceptance Criteria.

a) Leak detecting solution method: For systems tested with Helium or Hydrogen, mechanical joints (such as union connections) shall have no detectable leakage. Only leakage allowed is 0.6 cc/min for each valve system seal. This rate is identified by the formation of only foam like bubbles, no large bubbles. Systems pressurized with other media should exhibit no leakage.

b) Pressure drop method: Calculate the corrected pressure as specified below. The pressure drop is considered acceptable if it is less than 1% of the test pressure (test pressure divided by 100). If the leakage exceeds 1% the source must be found, leak repaired and test repeated until acceptable.

The system corrected pressure (Pc) is found by the following formula:

$$Pc = [(Pf+14.7\ psig) \times [(Ti+460°F)/(Tf+460°F)]] - 14.7\ psig$$

$$\Delta P = Pi-Pc$$

Where:
Pi = pressure as read at start of test (psig)
Ti = temperature as read at start of test(°F)
Tf = temperature taken hourly for pressure correction (°F)
Pf = pressure taken hourly, to be corrected (psig)
Pc = corrected pressure (psig)
ΔP = pressure drop (psi)

Figure C.6
Unmanned Pressure Test Facility System Tightness Test

C.1.2.7.3 Hydrostatic/Pneumatic Test Instructions (FIG C.7).

Block (1) Enter the command or unit where the facility is located.

Block (2) Enter the REC number with which the test is associated or the Job Control Number (JCN).

Block (3) Enter the system or component this test supports.

Block (4) Enter a description of the item being tested.

Block (5) Enter any references for the test (drawings, manuals, etc,.).

Block (6) Enter any required test and inspection points.

Block (7) Make a diagram of the test area.

Block (8) Enter the required test pressure.

Block (9) The facility supervisor (or designated representative) should review the proposed test, signature in this block authorizes testing to begin.

Block (10) Enter the actual test pressure obtained during the test.

Block (11) Mark the test result (SAT or UNSAT).

Block (12) Record any remarks or observations.

Block (13) The test technician should sign stating the test was completed as documented.

C.1.2.8 Hose Log (FIG C.8). A hose log must be maintained for all flexible hoses. Hose logs may be divided into facilities that the hoses support but must be maintained in an auditable fashion. Locally generated forms may be used with the SCA’s concurrence.

C.1.2.9 Operation Log. The operation log is the official chronological record of procedures and events that occur during each pressurization of the test facility. The operation log must be retained by the command and available for SCA review. The minimum data items in the operation log include:

a) Date of test facility pressurization

b) Purpose of test

c) Maximum test pressure

d) Identification of operator(s)

e) Note(s) on unusual events during operation or with

equipment

f) Signature of operator(s)

GLOSSARY

For purposes of this document, the following words or phrases are as defined.

Accessibility to vital equipment The ability to reach, read, and/or operate vital equipment and devices.

Accident A happening that is not expected, foreseen, or intended under normal circumstances.

Alteration A change from the as-certified design, material, configuration, or performance.

Appurtenance An accessory added to a major component (e.g., view ports hatches, support rails, connectors, piping, etc.,).

Builder Contractor or agency that constructs the unmanned pressure test facility.

Casualty An incident which causes damage or interruption of the normal operation of the unmanned pressure test facility and which may result in physical injury to personnel.

Catastrophe Any extreme or sudden disastrous malfunction which jeopardizes the safety of the facility operators or causes major damage to the facility.

Certifiable See System certification.

Certificate The document attesting to the system certification granted by the SCA.

Certification See System certification.

Certification Scope See Scope of certification.

Emergency A sudden, unexpected malfunction or other set of circumstances in the System operation which requires immediate attention.

Explodable items Any item containing a non-compensated volume that has the potential for failure under internal

	pressure.
Fail Safe	Material or equipment designed or arranged so that failure or malfunction renders it harmless or inert.
Fire resistant	A material that will immediately self extinguish when the source of ignition is removed, when tested in an atmosphere representative of its intended use environment.
Foundation	The permanently installed part of a pressure vessel system which serves exclusively to support the Pressure vessel system.
Hard structure	Pressure resistant structures, including reinforced openings and penetrations, but other than the pressure vessels, which may experience high differential pressure and that are designed to the same criteria as the pressure vessel.
Heat resistant	A material that does not give off noxious fumes at its operating temperature or at any temperature below 200° F and which is not degraded in respect to performing its intended function when exposed to a temperature of 400°F for 5 minutes.
Implodable item	Any item containing a non-compensated compressible volume that has the potential for failure under external pressure.
Material adequacy	Designed and constructed of proper materials and (materially adequate) performance tested in accordance with accepted engineering principles to provide for safety of the pressure vessel system personnel.
Maximum operating pressure	The highest pressure that can exist in a system or subsystem during any condition.
Maximum System Pressure	The maximum pressure that the system can experience.
Milestone event	A list of sequential events in the certification schedule process with estimated completion dates.

Operator(s)	1. The organization, agency, or firm having responsibility for the operation, repair, and maintenance of the pressure vessel system. 2. The personnel who physically control the operating parameters of the pressure vessel system.
Penetration	The assembly, component shaft packing gland, seal, or other device which penetrates the pressure resistant structure (e.g., pressure vessel or hard structure).
Pressure vessel	See definition of Unmanned Pressure Test Facility.
Procedural adequacy	The procedures used in the operation and maintenance of the pressure vessel system, suitable and sufficient to provide for the safety of the occupants and operators of the system, before, during, or after any credible operational or emergency evolution.
Procedures	Instructions, checklists, and maintenance guides, prepared in a manner that provides the occupants and operators a detailed, safe sequence of operations of the pressure vessel system in all of its various normal and emergency operating modes.
Re-certification	A new certification for system adequacy of a pressure vessel system fabricated, assembled, and performance tested in accordance with acceptable engineering principles.
Repair	A restoration to the original condition or replacement that does not change the original material, configuration, or performance, using procedures previously approved.
Replacement-in-kind	Replacement with parts or components meeting original specification requirements.
Scope of Certification (SOC)	A list defining those systems, subsystems, components, portions of the pressure vessel system,

	maintenance, and operational procedures which are needed to preserve the physical well being of the pressure vessel system personnel.
Sponsor	The agency/organization that is making application for system certification or re-certification of a pressure vessel system. For the pressure vessel System being developed, the sponsor will normally be that agency or organization tasked with development of the capability provided by the pressure vessel system. For existing pressure vessel systems, the sponsor will normally be that element within the organizational chain responsible for operational readiness and deployment of the specific pressure vessel system.
Survey	To examine, inspect, and review in detail all items falling within the scope of certification to determine their material and procedural adequacy.
Survey team	The personnel representing the System Certification Authority to perform the on site verification of the pressure vessel system survey.
Suspension of certification	The temporary revocation of certification that does not require full re-certification. Manned use of the system during suspension is not authorized.
Sustaining system certification	Actions required of the sponsor to ensure the SCA that the pressure vessel system remains in the as-certified condition for the tenure of certification.
System certification	The procedure including application, independent technical review, survey, and approval to ensure the adequacy of the pressure vessel system to safely perform over its operational/emergency spectrum. System certification is a combination of two major areas of review: material adequacy and procedural adequacy. This replaces the old term "material certification".

System Certification Authority (SCA)	The code within NAVFAC that has been delegated, through the Navy chain of command, the responsibility to conduct the Certification process.
System design pressure	The pressure used in the calculation of piping and piping components minimum section thicknesses.
Tenure	Tenure of Certification is the length of time for which certification is granted.
Termination of certification	The cancellation of system certification, requiring full system review to re-certify.

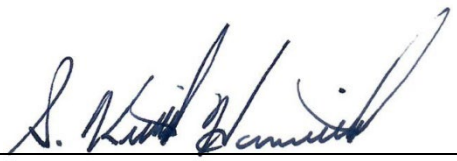
FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:



- Whole Building Design Guide website https://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

The DDESB has established minimum AE safety standards for personnel and property that have the potential of being exposed to the effects of an accidental explosion.

These standards govern the design, construction, and use of all AE storage facilities within the DoD.

Magazines are used to store AE materials. Magazines are classified as Aboveground Magazines (AGM) or Earth-Covered Magazines (ECM). ECMs are further divided (7-Bar, 3-Bar, or Undefined). Magazines are not designed to resist the damaging effects of its own exploding contents; it is accepted that the exploding magazine will be heavily damaged or even destroyed if an internal explosion occurs. The intended function of a magazine is to mitigate a sympathetic detonation of either AE or an adjacent magazine. The structure is designed to resist an external detonation, thereby interrupting the propagation chain.

DoD explosives safety standards are contained in Defense Explosives Safety Regulation (DESR) 6055.09. DDESB Technical Paper 15 (TP 15) provides a ready resource for DDESB-approved protective construction as well as the explosives safety criteria associated with them. Service-specific explosives safety standards that implement the DoD standards are contained in the following documents:

- **DoD Contractors**: DoD 4145.26-M.
- **Air Force**: DESR 6055.09 AFMAN 91-201 Explosives Safety Standards.
- **Army:** AR 385-10, *U.S. Army Safety Program* and DA PAM 385-64, *Ammunition and Explosives Safety Standards*.
- **Navy**: NAVSEA OP 5, Ammunition and Explosives Safety Ashore.

1-2 REISSUES AND CANCELS.

This UFC supersedes UFC 4-420-01 dated 05-01-2015 with Change 1 dated 10-12-2022.

1-3 PURPOSE AND SCOPE.

This UFC serves as a reference tool to assist in the planning and design of Ammunition and Explosives (AE) storage magazines for the Department of Defense (DoD), by providing definitions and information related to the design, selection, and siting of these unique facilities. This UFC is intended to assist in the selection of a magazine design by providing available options and information related to the use of designs that have been used in the past and have been approved by the Department of Defense Explosives Safety Board (DDESB). The individual DoD Services can also provide additional guidance on the selection of magazine designs.

A web site designed to be a companion resource to this UFC is located on the Whole Buildings Design Guide and can be accessed at: https://www.wbdg.org/design/ammo_magazines.php . This web site provides the following additional information and resources:

- Available electronic copies of referenced military regulations, manuals and standards.
- Available design drawings, approval letters, and specifications for 7-Bar and 3-Bar Earth-Covered Magazines (ECM) that have been approved for new construction.
- Available drawings and related information for the designs of 7-Bar and 3-Bar ECM that are no longer approved for new construction but still in use.
- Available drawings and related information for the designs of ECM and Aboveground magazines (AGM) and containers that have been approved for restricted use.
- A listing of the existing magazine designs that are classified as undefined.
- Available drawings for barricade design utilizing various construction materials.
- Links to additional related resources and publications.

This UFC, when used with the companion web site, provides planners and designers of AE storage facilities access to up-to-date information and resources needed in the selection and design of new storage magazines and in the evaluation of existing facilities.

1-4 APPLICABILITY.

This UFC follows the same applicability as UFC 1-200-01, APPLICABILITY for the planning, design, and construction of DoD AE storage facilities worldwide.

1-5 EXCEPTIONS

Specialized magazines, such as containers and magazines with reduced net explosive weights (NEWs) and/or reduced quantity-distances (QD) are not covered by this document. DDESB TP 15 provides a listing of specialized magazines (both Earth-Covered and Aboveground) and shipping containers that have been approved with a reduced NEW and/or a reduce QD, along with requirements, restrictions, and conditions for use in Table AP1-4.

1-6 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance

and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-7 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-8 GLOSSARY.

APPENDIX C contains acronyms, abbreviations, and terms.

1-9 REFERENCES.

APPENDIX D contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

This Page Intentionally Left Blank

CHAPTER 2 TECHNICAL REQUIREMENTS

2-1 MAGAZINE TYPES.

AE storage magazines are classified as either Earth-Covered Magazines (ECM) or Aboveground Magazines (AGM). Magazines are considered uninhabited structures and are used for storage only. The use of a preapproved standard design for new magazine construction is strongly recommended. A non-preapproved design may be used where a standard preapproved design is not suitable due to special circumstances, and the design meets all applicable requirements of DESR 6055.09.

For identification of various magazine types, the *Magazine Identification and Codex Development Guide* developed by the Ammunition & Explosives Facilities Working Group (AEFAC-WG) can be referenced. https://flankspeed.sharepoint-mil.us/sites/NAVFACLANTAMMagazineCriteria.

2-1.1 Earth-Covered Magazines (ECM).

In general, an ECM allows for lesser separation distances than an Aboveground Magazine (AGM) based on the same net explosive weight (NEW). ECM design criteria are specified in DESR 6055.9, Volume 2, Enclosure 5. DESR 6055.09 defines three basic ECM designations: "7-Bar," "3-Bar," and “Undefined,” based primarily on the relative strength of the magazine headwall and doors and the relative strength of the roof for non-arch or “flat roof” magazines. This designation is based on the structural strength and ability of the magazine to withstand blast loadings resulting from an accidental explosion of an adjacent magazine as a Potential Explosion Site (PES). Siting criteria, based on ECM designation, ensure a consistent level of protection across the AE storage area. Designations for previously designed ECM’s are contained in DDESB publication TP-15, *Approved Protective Construction*. In addition, the earth cover for ECMs must meet specific requirements, including minimum top cover thickness and slope, per DESR 6055.09 V2.E5 and DDESB TP-15. If the magazine design or earth cover requirements are not met, the ECM must be sited as an AGM and the storage capacity of adjacent PESs is significantly reduced. Storage capacity of magazine will also be downgraded.

2-1.1.1 7-Bar ECM.

A 7-Bar ECM provides the highest resistance to blast loading. Magazines designated as 7-Bar were referred to as “Standard” magazines prior to 1997.

2-1.1.2 3-Bar ECM.

A 3-Bar ECM provides a lower level of resistance to blast loading than a 7-Bar ECM, but more than an Undefined ECM. In 1997, this designation was established as an intermediate designation between “Standard” and “Non-standard.”

2-1.1.3 Undefined ECM.

An Undefined ECM has not been shown by analysis or testing to be capable of providing a level of resistance equivalent to either a 7-Bar or 3-Bar ECM. Magazines designated as Undefined were referred to as “Non-standard” magazines prior to 1997.

2-1.1.4 Aboveground Magazines (AGM).

All above grade magazines that are not Earth-Covered, or an ECM with less than the minimum 2 feet (0.61 m) of cover, are considered AGM. This also includes storage pads for AE stored in the open.

2-2 SITING CRITERIA.

To ensure the prevention of unacceptable damage or injuries in the event of an accidental explosion, siting criteria have been established to define minimum required separation distances between a PES and surrounding Exposed Sites (ESs). The minimum separation distances, commonly referred to as explosives safety Quantity-Distances (QDs), are based upon several factors including, but not limited to:

- The level of protection mandated by the applicable explosives safety standard.
- The ES type and classification.
- The net explosive weight (NEW).
- The hazard classification of the AE at a PES.
- The physical orientation between the PES and the ES.
- The presence of effective barricading.

Minimum explosives safety QDs are defined in the applicable DoD and Service-specific explosives safety standards for various applications. These QDs are based on maximum levels of risk considered acceptable for various types of ES. Separation distances are not absolute safe distances but are relative protective or safe distances. Whenever practicable, use of greater distances than those shown in the explosives safety standards should be considered.

Generally, explosives safety site plans are required for construction projects involving new PESs, new facilities (explosive or non-explosive) within the QD arcs of existing PESs, as well as for the upgrading or renovation of existing facilities (explosive or non-explosive) that might impact the explosives safety criteria applied to these facilities (e.g., removal of a protective feature that previously allowed the facility to be sited at a lesser distance or a change of mission that requires the facility to now be at a greater distance). These site plans are reviewed at various authority levels to ensure explosives safety criteria are being met by the proposed work. DoD requires most explosives safety site plans to be forwarded to the DDESB for review and approval (see the section in Chapter 2, entitled “Design Approvals”). See DoD and Service explosives

safety criteria for more detail on when a site plan is required and what level of site plan review and approval must be accomplished prior to commencing projects.

2-2.1 Magazines as Potential Explosion Sites (PES).

Magazines are not designed for, nor do they provide containment of, effects from an internal explosion. Thus, magazines pose a hazard to surrounding ESs due to the potential for accidental explosions, which may result in blast overpressures, primary fragmentation, secondary debris, cratering and thermal effects. DESR 6055.09 defines minimum explosives safety QDs between a magazine as a PES and surrounding ESs including other magazines, operating buildings, inhabited buildings, and public traffic routes to ensure uniform minimum explosives safety standards for DoD facilities. In general, the required separation distances are greater from an AGM than an ECM based on the same quantity of NEW.

2-2.2 Magazines as Exposed Sites (ES).

Minimum explosives safety QDs have been established between a PES and a magazine as an ES to provide appropriate protection. Tables specifying minimum QD requirements can be found in the DoD and Service explosives safety documents. In general, required separation distances are greater for an AGM than for an ECM. For ECM, required separation distances are generally greater for a 3-Bar ECM than a 7-Bar ECM and greater still for an Undefined ECM.

The minimum explosives safety QDs between magazines is commonly referred to as the inter-magazine distance (IMD). The required IMD is dependent on several factors including but not limited to:

- The physical orientation of the magazines.
- The structural classification of each magazine as an ES.
- The NEW and type of AE within each magazine as a PES.
- The presence of an effective barricade.

2-2.3 Approved ECM NEW Limits.

With respect to an ECM's structural strength designation, approved ECM NEW limits are based on their ability to withstand blast loads generated from an adjacent PES and **NOT** on their capacity for storage. Certain 7-Bar ECM have approved NEW limits that are less than the 500,000 lbs (226,800 kg) typically assigned to a 7-Bar ECM based on the limitations of their design as an ES and not on capacity as a PES.

Many military installations have ECMs that have not been evaluated against 7-Bar and 3-Bar strength requirements, and by default must be treated as Undefined (for arch-type ECMs) or AGM (for box-type ECMs). If, using the available structural drawings, an ECM (as an ES) cannot be shown by structural analysis to meet the loading requirements for a 7-Bar or 3-Bar ECM from an adjacent PES ECM containing 500,000 lbs (226,800 kg)

NEW, then it may be possible to demonstrate that the ES ECM could meet 7-Bar or 3-Bar loading requirements if the surrounding PES NEWs were reduced. In other words, the ES ECM design could be site approved as a 7-Bar or 3-Bar ECM for a quantity less than 500,000 lbs (226,800 kg) in an adjacent PES ECM. An advantage in doing this is that placing this information in automated explosives site planning software, such as Explosives Safety Siting (ESS) or Assessment Systems for Hazard Surveys (ASHS), allows the installation to determine more efficient separation distances for future storage construction. Selection of an appropriate magazine type to meet a specific siting requirement should be done in consultation with an experienced explosives safety site planning professional to ensure efficient use of existing real- estate and facilities while meeting mission requirements.

2-2.4 Barricades.

Barricades are used to decrease the required minimum separation distances between magazines and between magazines and other PESs. Specific requirements on the design and siting of front barricades as well as the reduction in the minimum separation distance resulting from a properly sited and constructed barricade are provided in the DoD and Service-specific explosives safety standards. Army Definitive Drawing 149-30-01 illustrates several conceptual barricade designs utilizing various construction materials. ECM front barricades should be located as close as possible to the front of the ES (protected) ECM. The side of the barricade facing the protected ECM front should be a vertical, or near vertical earth retaining structure with the opposite side meeting ECM side slope requirements of the section in Chapter 3, entitled, “Earth Cover”. The front barricade must also meet the barricaded IMD geometry requirements of DESR 6055.09. When properly sited and constructed, barricades offer protection against high-velocity, low angle fragments.

2-2.5 Floodplain.

The finished floor level of the magazine must be at or above the minimum Design Flood Elevation per UFC 3-201-01.

Verify the required elevation of the finished floor level with local, regional, and other required governing jurisdictions. The highest required elevation must govern.

2-3 DESIGN APPROVALS.

Site and construction plans for AE storage facilities must be approved by the sponsoring Service safety organization and the DDESB to ensure that the minimum DoD and Service-specific explosives safety standards have been addressed. See DoD and Service explosives safety criteria for more detail on when a site plan is required and what level of site plan review and approval must be accomplished prior to commencing projects.

2-3.1 Magazine Design Approval.

The design for all new ECMs must be reviewed and approved by the sponsoring Service's explosives safety organization and subsequently by the DDESB to ensure compliance with minimum explosives safety design and construction criteria, including earth cover depth and slope, grounding, electrical equipment and installation, and lightning protection. DDESB approval does not address conventional load or physical security requirements. In addition, the approval of all 7-Bar and 3-Bar ECMs, and all flat-roofed Undefined ECMs, requires the submission of test results and/or detailed structural calculations in accordance with UFC 3-340-02, *Structures to Resist the Effects Accidental Explosions*, to validate compliance with the blast design requirements of DESR 6055.09.

New designs or designs that involve modifications to blast resisting elements of a magazine's design must meet the requirements specified in DDESB-PD Policy Memorandum available on the WBDG website.

2-3.1.1 Quality Control Review

Per the DDESB-PD Policy Memorandum, a quality control review is required by a competent DoD blast design agency, such as the Naval Facilities Engineering and Expeditionary Warfare Center (NAVFAC EXWC) or the U.S. Army Engineering and Support Center Huntsville (CEHNC). These organizations operate on a cost reimbursable basis and early coordination for funding and schedule is advised. It is important to note that new ECM designs require a substantial review process; consequently, adequate time and resources must be allocated to allow for appropriate Service and DoD review prior to approval for construction.

2-3.1.2 Lightning Protection

The lightning protection system design for all new AGM designs must be reviewed and approved by the DDESB. New AGM designs involving protective construction to either reduce the NEW for which the facility is to be sited, or to reduce the required QD, must be reviewed and approved by the DDESB; this approval requires the submission of test results and/or detailed structural calculations to validate the proposed protective construction characteristics.

2-3.1.3 Use of Foreign Materials at OCONUS Locations.

Approved standard designs must be checked for adequacy when adapted for construction with foreign materials at OCONUS locations. Specifically, steel strengths, bar diameters, plate thicknesses, structural steel member dimensions, and concrete compressive strengths may vary for OCONUS locations. In addition to ensuring such modifications do not impact the conventional load capacity of a magazine design, the dynamic response of blast resisting elements of the design needs to be checked by a qualified structural engineer to ensure UFC 3-340-02 response criteria are met.

Modifications that alter the blast response of the magazine are to be treated as new ECM designs as detailed in the preceding paragraph.

2-3.1.4 Coordination with Service Organizations.

The Service explosives safety office may require other explosives-safety related design information (e.g., ordnance ground system design) for review and approval. The Service design authority may require other non-explosives safety related design information (e.g., ability to withstand soil loads) for review and approval.

Prior to the start of a design, it is essential to closely coordinate the requirements with the sponsoring Service's explosives safety organization to avoid excessive problems and delays in completing the design and obtaining the necessary approvals. The Service explosives safety organization will coordinate as necessary with the DDESB.

2-3.2 Approved ECM Designs.

2-3.2.1 7-Bar and 3-Bar ECM Designs Approved for New Construction.

To facilitate the design and approval process for AE storage magazines, several approved designs have been developed for 7-Bar and 3-Bar ECMs. DDESB TP-15, Table AP1-1, includes a listing and basic description of 7-Bar and 3-Bar ECMs approved for new construction.

The most current construction drawings, approval letters, and additional information and notes related to the approved designs can be accessed at the Whole Building Design Guide website: http://www.wbdg.org/design/ammo_magazines.php. Table AP1-1 of DDESB TP-15 identifies additional limitations, restrictions, and conditions associated with the use of approved designs.

2-3.2.2 Site Adaptation of Approved Designs.

Once a standard ECM or AGM design has been approved by the DDESB and listed in TP 15, the design does not have to be reapproved for subsequent uses unless changes affecting the explosives safety aspects of the design have been made. Approved designs can be site-adapted or tailored to the requirements of a specific site. Allowed, site specific adaptation primarily involves minor modifications to the foundation, subgrade preparation, and the drainage systems to suit local soil and site characteristics along with design of supporting facilities (utilities, physical security and pavement). Any changes to the approved designs, other than minimal site adaptation, that may affect the explosives safety aspects of a magazine design must be approved by the sponsoring Service's explosives safety organization and subsequently by the DDESB prior to construction. (Note: Even if using an approved design, a site plan is still necessary to validate that required QD is met to surrounding ESs and from surrounding PESs. With regard to the ECM design, the site plan need only identify the approved drawing numbers if using a previously approved design that has not been changed other than for minimal site adaptation.) When adapting approved designs, reference the drawings numbers of the Standard on the project plans.

2-3.2.2.1 Risk Category

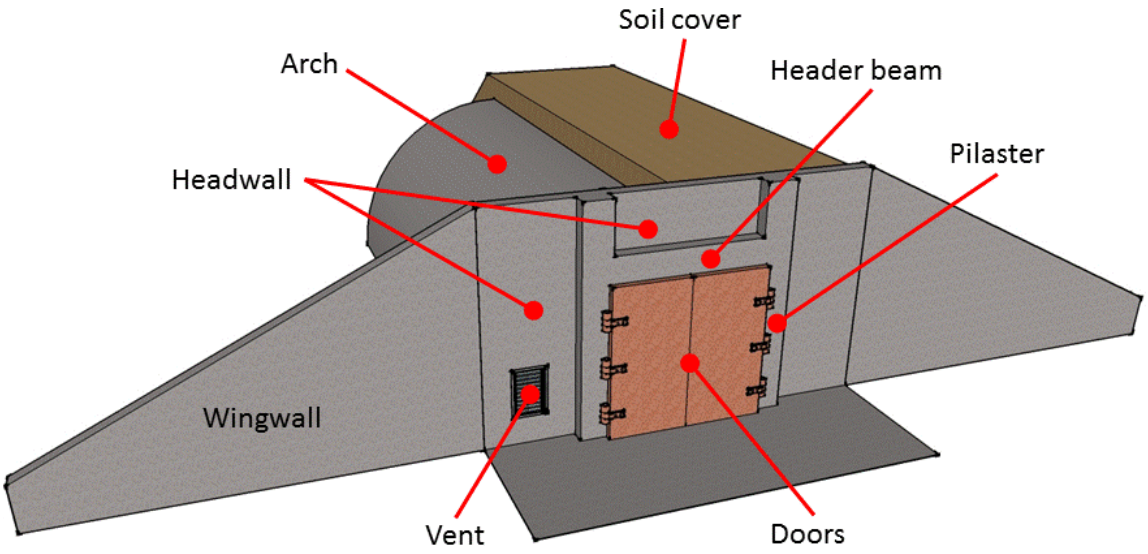
The risk category for the standard ECM and AGM designs is III, as outlined in UFC 3-301-01, Table 2-2. If the government directs the DOR to change to a higher risk category, this could potentially change the structural components of the magazine which could adversely affect the 7-bar and 3-bar structural designation. These changes must be approved by the sponsoring service's explosives safety organization and subsequently by the DDESB prior to construction.

2-3.2.2.2 Project Start

When beginning a project, the DOR must go to the Whole Building Design Guide website and download the standard magazine design drawing. The DOR must not use previously site adapted drawings from another installation. After downloading the drawings, the DOR must begin the site adaption process.

2-3.2.2.3 Modifications

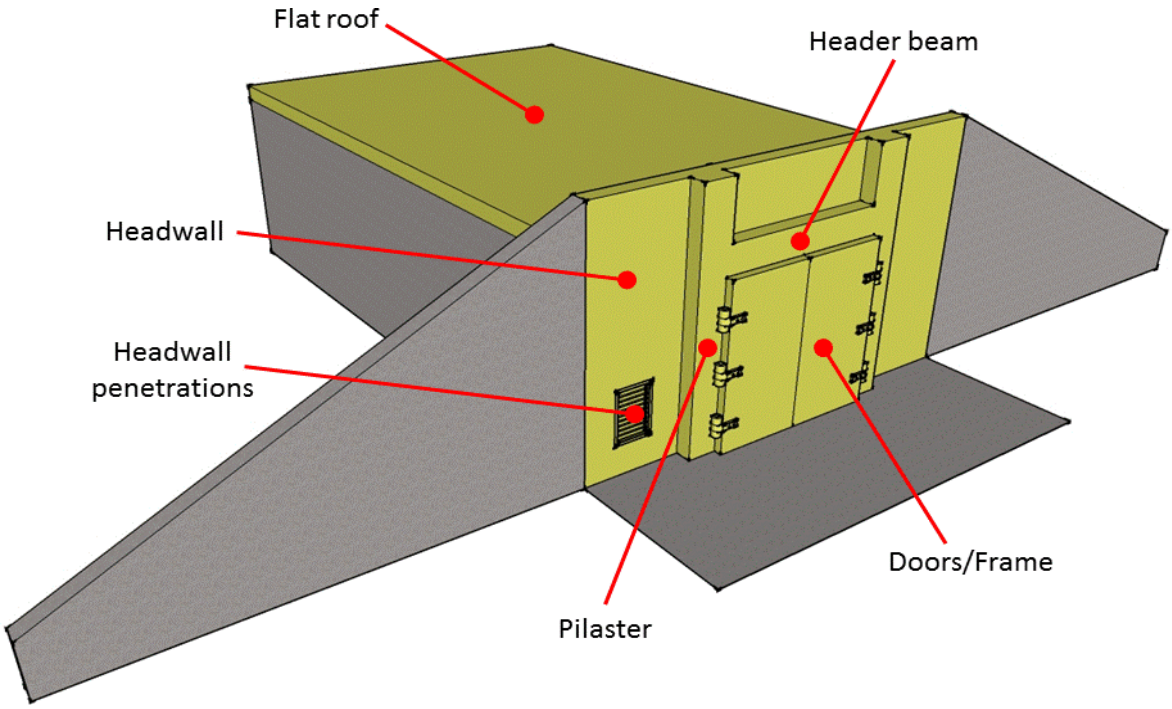
Throughout design and construction, the DOR must ensure that modifications made during the site adaption process do not impact the blast-resisting elements of the approved design. This typically includes the required soil cover geometry, magazine headwall, blast door(s) and frame, pilasters and header beams that support the doors against blast loads, and the roof elements. For blast doors that include a bottom support, foundation/slab modifications must ensure that the door support conditions of the standard design are not altered. Any modifications or changes to the above must be referenced back to the service-specific explosive safety office. See Figures 2-1 and 2-2 for a graphic showing the typical elements of an ECM and typical blast-resisting elements of an ECM.



2-3.2.2.4 Navy standard magazines approved for new construction:

If Navy standard drawings are used, the Designer of Record (DOR) must adhere to all standard drawing "NOTES TO DESIGNER" and "DEPARTMENT OF DEFENSE EXPLOSIVE SAFETY BOARD (DDESB) APPROVAL NOTES". A CAD version of the standard drawings is available upon request. When using Navy standard drawings for NAVFAC projects, a new set of drawings, with unique NAVFAC Drawing Numbers must be created using the Navy standard border, customized for the project. The drawing numbers associated with the original unedited standard magazine drawings must also be listed on the title sheet of the set with a note clearly identifying the source, name and date of the standard design.

The DOR is responsible for the site-adapt design and must provide a Designer of Record Note on a General Notes sheet indicating that they have reviewed the standard drawings and that the DOR's site adapted design satisfies all design requirements. The DOR must edit the notes (on the notes sheet) as appropriate to include the pertinent site adapt information. Such information includes but is not limited to foundation design, wind, seismic, and any other transient and static load data used in the site-adapted



design. Portions of the new drawing set, which have been edited to include the required site adapted design, must be clearly identified in the drawing package.

Figure 2-1 Typical ECM Components

Note: Second vent location may vary with design and not shown for clarity.

Figure 2-2 Typical ECM Components Resisting Direct Blast Loads

Note: Second vent location may vary with design and not shown for clarity.

2-3.2.3 7-Bar and 3-Bar ECM Designs No Longer Approved for New Construction.

The Whole Building Design Guide web site and DDESB TP-15, Table AP1-2 contain lists of ECM designs that have been previously approved for 7-Bar or 3-Bar siting but are no longer approved for new construction. In most cases, these designs have not been updated to satisfy criteria changes. The intent of this list is to assist activities in sitings involving existing magazines. NEW limitations and/or restrictions associated with their DDESB approval must be observed. These designs can be used as the basis for new ECM designs, but they must be updated to comply with current explosives safety requirements, current construction methods and criteria, and are reviewed and approved by the DDESB. Any updated design drawings must clearly identify all changes and revisions made to the original design prior to approval.

Available electronic drawings, approval letters, and additional information and notes related to current approved designs can be accessed at the following web site: http://www.wbdg.org/design/ammo_magazines.php.

2-3.2.4 Undefined ECM Designs.

DDESB TP-15, Table AP1-3 contains a listing of ECM designs that are classified as undefined. These designs have not been shown by analysis or testing to have the structural capacity of either a 7-Bar or 3-Bar ECM. This table and the accompanying notes identify additional limitations, restrictions, or conditions associated with the use of these designs.

An undefined ECM can be structurally analyzed in accordance with UFC 3-340-02, *Structures to Resist the Effects of Accidental Explosions,* to determine its structural capabilities and potentially justify an upgrade to its classification. HNC-EDC-S-13-10, *Guide for Evaluating Blast Resistance of Existing Undefined Arch-Type Earth-Covered Magazines*, illustrates procedures that can be used for a preliminary determination of the adequacy of the headwall and doors of an existing arch-type ECM to provide an acceptable level of protection from a given quantity of explosives at a known distance. A complete analysis is required to ensure the design complies with current explosives safety requirements as well as current construction methods and criteria, prior to reclassifying the ECM design. The sponsoring Service's explosives safety organization and the DDESB must review and approve the upgraded classification.

2-3.3 Magazine Construction and Explosives Safety Site Approval.

Prior to construction, an explosives safety site plan for all new AE storage magazines must be reviewed and approved by the sponsoring Service explosives safety organization and the DDESB to ensure that the magazine has been sited in accordance with the minimum explosives safety QD appropriate to the magazine type and classification. An exception to this allows approval by a Service explosives safety organization for security and limited amounts of ammunition without DDESB approval; refer to DESR 6055.09 for exceptions.

2-4 MAGAZINE SELECTION CONSIDERATIONS.

Selection of the most suitable magazine design to use at a given site will depend on a number of factors including, but not limited to:

- The specific configuration (pallet or container size and stacking requirements).
- Physical security.
- The hazard classification and quantity of AE that is anticipated to be stored in the magazine.
- The cost of construction and maintenance.
- Siting limitations or restrictions.
- Ordnance storage and delivery operations.
- Flexibility for future revisions to operations or mission.
- AE non-compatibility.
- Trench or no-trench at base of magazine door.

Some of these factors are discussed below. Facility planners / designers should involve both end user and installation explosives safety personnel in the earliest stages of the planning and design process to ensure the selection will both meet the users end requirements and be in compliance with explosives safety requirements.

The use of an approved standard design for new magazine construction is strongly recommended within the DoD except where a preapproved design is not suitable due to special circumstances.

2-4.2 Net Explosive Weight (NEW) Limits.

Each of the approved magazine standard designs is rated for a maximum quantity of HD 1.1 AE that can be stored in adjacent PESs, expressed as maximum NEW, for the structure to be considered an ECM as an ES. Most ECMs approved for new construction are rated up to 500,000 lbs HD 1.1 NEW, but that should be verified in the selection of the ECM type. However, it is likely that existing legacy ECMs at the site may have NEW rating restrictions which may provide a constraint that prevents the new ECMs from being sited for the full 500,000 lbs HD 1.1. See Section 2.3 for additional details.

2-4.2.1 QD Relationships.

A magazine is sited using explosives safety QD relationships corresponding to the maximum amount of NEW that will be stored within the magazine, the NEW rating of adjacent magazines, and applicable criteria to surrounding exposures. The quantity of AE stored must never exceed the maximum sited NEW value.

2-4.2.2 Installation-Level Control of Stored Quantities.

Lastly, a magazine may have a licensed NEW that is less than the sited NEW. The licensed NEW represents an installation-level control of stored quantities based on mission requirements. Often a magazine will be sited to store the maximum capacity based on available space to maximize mission flexibility. Licensing is sometimes used to restrict quantities located within a magazine to match the needs of the mission. This allows the installation additional control of the quantity of explosives within facilities while maintaining mission flexibility.

2-4.3 Magazine Characteristics.

2-4.3.1 Shapes and Sizes.

ECM types that have been used in the past are shown in DDESB TP-15 and on the WBDG website. The physical dimensions and configurations of 7-Bar and 3-Bar ECM designs approved for new construction are provided in Table AP1-1 of TP-15.

Some approved ECM designs allow variable lengths to provide greater flexibility in sizing a magazine to its specific intended use.

2-4.3.2 Door Openings.

The approved 7-Bar and 3-Bar magazine designs have various door opening sizes. The door opening size must be selected based on current and anticipated future usage requirements and in consideration of the usage requirements for material handling equipment (MHE).

2-4.3.3 Door Types.

Magazine doors are vertical swinging or sliding type, single or double leaf. Doors are either manually or electrically operated. Electrically operated doors must have an option for manual operation. Doors and door hardware must not use dissimilar metals or must be dielectrically insulated from each other.

- Refer to UFGS 08 39 55.00 20 for Navy’s ECM door specification.
- Refer to UFGS 08 39 53, Blast Resistant Doors (Earth-Covered Magazines) specification.

Note: Doors are designed for specific bearing conditions under external blast loading and site adaption may not include altering the design bearing surface of the doors (top, side, and bottom).

2-4.3.4 Storage Options.

AE is usually stored within a magazine utilizing forklifts. An overhead bridge crane storage option has been developed for some magazine designs (e.g., the CLWS magazine). A self-supporting built-in crane can be installed after construction; however,

the planner must consult with the service-specific explosive safety office to ensure the crane does not affect the explosive safety classification of the magazine.

2-4.4 Storage and Loading Plans.

AE packaging information and suggested storage loading plans have been developed for many of the approved magazine designs. These plans are to assist in the effective use of magazines and may be used to estimate the potential storage capacity of various types of ordnance within a given magazine.

- The U.S. Army Materiel Command (AMC) provides Storage and out loading drawings for various AE within certain ECMs. These drawings, indexed in AMC 19-48-75-5, may be obtained at the Defense Acquisition University web site: https://www.dau.edu/cop/ammo/page/AMC-Drawings
- For Navy applications, additional standard layout plans for palletized ammunition, missiles, and torpedoes within ECMs are provided in FC 2-000-05N, Series 420. https://www.wbdg.org/dod/ufc/fc-2-000-05n

2-5 ELECTRICAL PLANNING.

Perform an electrical hazards survey to determine the structure's hazardous location classification per NFPA 70 Article 500. This classification is based on the possibility of an explosive atmosphere existing within the magazine rather than the material stored inside the magazine. Ordnance storage magazines that store only "DoD-titled ammunition and explosives" (AE) in its original packaging will typically only need to meet industrial standards for electrical service.

Perform a survey of the surrounding area to determine the grounding and lightning protection requirements for the facility. This survey might confirm that unique installation requirements apply to minimize the total resistance to ground. Ground connection locations must be established while ensuring that future maintenance can be accomplished. Verify that the exterior distribution requirements in DESR 6055.09 can be achieved.

2-6 MAGAZINE RETROFIT CONSIDERATIONS

Structural elements of existing magazines may need to be retrofitted or replaced due to deterioration of structural properties or performance, or due to changes in the site plan, siting criteria, or other changes that result in an increase of the current demands. Planners and designers must follow project-specific design requirements and criteria to be developed by the controlling DoD Service for the project. DDESB site approval is required for the retrofit design before commencing work. General considerations for retrofit of the blast elements of existing magazines are provided below.

2-6.1 Replacement of ECM Doors.

When doors of existing ECMs are replaced, except for undefined magazines, the ECM will lose its rating and subsequently requires reapproval. When doors of existing ECMs are replaced the doors and locking system must be upgraded to meet current Physical Security requirements.

Attention must be given to the blast load capacity of the new door and the associated loads transferred by the new door to the supporting structural elements of the magazine (e.g., header beam, headwall, pilasters). In general, when the new replacement door has a higher blast load capacity than the existing door, the associated loads that are transferred to the supporting structural elements are higher than those of the existing door. All the structural elements in the load path of the loads transferred by the new door must be verified to be able to withstand the associated loads within the applicable response limits as defined by the project-specific design requirements.

2-6.2 Strengthening of Blast-Resisting Structural Elements.

When required, strengthening of existing ECM's structural blast elements (e.g., header beam, headwall, pilasters, roof) must be designed to meet the project-specific design requirements as determined by the controlling DoD Service for the project. When increasing the flexural capacity of a structural blast element, other limit states where the design load is based on the flexural capacity of the element (such as diagonal tension and direct shear) must be verified for the new loads based on the increased flexural capacity of the element. Similarly, other structural elements that must withstand loads that are transferred by the strengthened element must be verified. For example, if a header beam's flexural capacity is increased, in addition to verifying the diagonal tension and direct shear capacity of the header beam, the pilasters must be verified for the loads transferred by the strengthened header beam. Similarly, if the roof slab's flexural capacity is increased, in addition to verifying the diagonal tension and direct shear capacity of the slab, the columns and walls may need to be verified for the loads transferred by the strengthened roof slab. If needed, shear, torsional, or axial load capacity of structural blast elements must be also increased through retrofits to resist the increased demands resulting from the increased flexural capacity of a strengthened structural element.

This Page Intentionally Left Blank

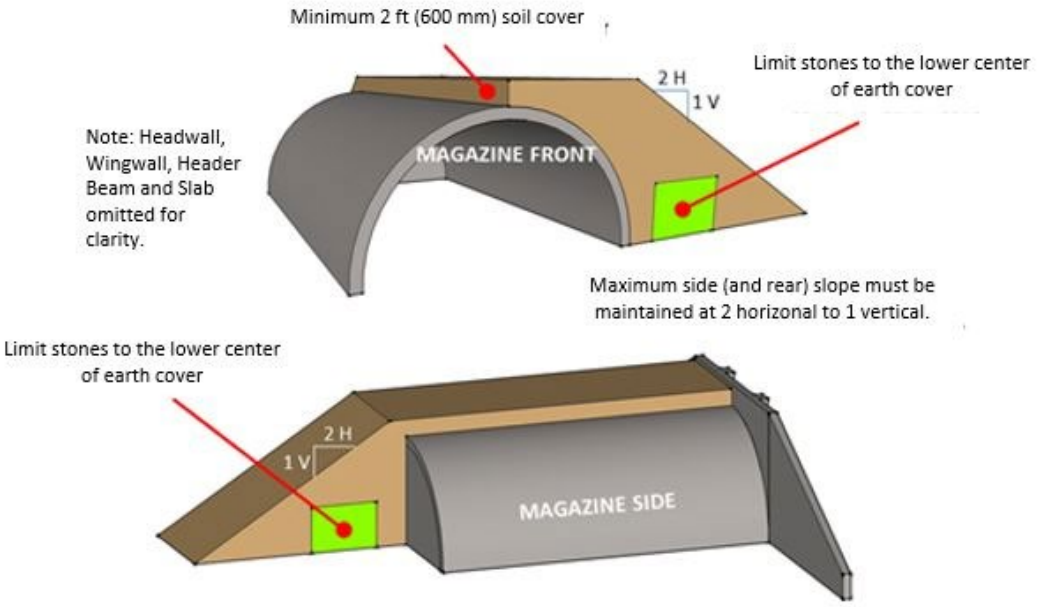
CHAPTER 3 DESIGN

3-1 EARTH COVER.

The earth cover over the top of an earth-covered magazine must be a minimum of 2 feet (0.61 m). The steepest incline must be maintained at 2 horizontals to 1 vertical. The earth-cover above, to the sides, and to the rear of an ECM is the critical element of its design. The earth slope to the sides and rear of the magazine should continue to grade level and should not be terminated with a retaining wall or otherwise interrupted. Standard ECM designs are validated through detonation tests in which the earth cover to the sides and rear of the magazines continue to grade level. Elimination of a portion of this earth cover may invalidate this testing, and the magazine may not be considered an ECM as an ES and/or a PES for siting purposes without an accompanying engineering analysis providing justification approved by DoD review authorities. Additionally, while use of common earth cover between ECMs (e.g., earth cover between two ECMs intersecting above ground level) is allowed per DoD criteria, it is not recommended. DoD IMD criteria is based on ECM tests without common earth cover (e.g., two horizontals to one vertical slope), limited scaled tests suggest that an acceptor ECM which shares common earth cover with an adjacent donor ECM may sustain greater damage in an accidental detonation. Other explosives safety criteria (e.g., NATO) require increased separation distances when common earth cover is used between ECMs. If the earth cover between two adjacent ECMs intersects at a height greater than one-half the exterior magazine height (not including the earth cover), the planner must coordinate with their service-specific explosive safety office to assess siting impacts.

3-1.1 Material.

The material for the earth cover must be free from deleterious organic matter (large tree roots and similar materials), trash, debris, and stones heavier than 10 pounds (4.54 kg) or larger than 6 inches (15.24 cm) in any dimension. The presence of large stones (cobbles) will be limited to the lower, central portions of the earth cover, and such stones will not be used as surface cover over the magazine soil cover where they may contribute to hazardous debris (refer to Figure 3-1). Clay soils must not be used due to excessive cohesion and the potential to contribute to hazardous debris. Gravel or crushed stone must not be used as it does not comply with DESR 6055.09 requirements for reasonable cohesiveness. Compact the material and prepare as necessary to maintain structural integrity and provide erosion control. In locations where it is impossible to use a suitable material to maintain side slope or where rainfall is insufficient to maintain a grass cover, use other suitable materials and stabilization methods to ensure the structural integrity of the cover.



3-1.2 Additional Guidance

For additional guidance, refer to Engineering Research & Development Center (ERDC) study *Erosion Control of Earth-Covered Magazines to Maintain Minimum Cover Requirements* conducted in 2019.

3-1.3 Roof Live Load

The roof of the ECM must be designed for a minimum of 100 psf live load. This live load must not be reduced.

Figure 3-1 ECM Earth Cover

3-2 FLOOR DESIGN.

The design floor live load must be the maximum anticipated loading of stored material within the magazine during its useful life. Considerations must also be given to wheel loading from weight handling equipment (especially large or side loading vehicles).

Floor live loading as shown on the Standard Approved Magazine Drawings is based upon the anticipated maximum loading for that particular magazine type. Where soil conditions are poor, the design floor live loading may be reduced if it can be demonstrated that a reduced floor loading will be acceptable at a given location based on the actual anticipated usage. In such case, the maximum design floor live loading must be prominently posted at the entrance and within the magazine structure. Under all cases, the minimum floor live loading for any magazine type must be 500 PSF (2441 kg/sm).

3-3 FOUNDATIONS/SLABS.

3-3.1 Magazines based on Standard Approved Magazine Drawings

When considering a magazine based on Standard Approved Magazine Drawings:

- Unless a more detailed analysis is warranted, it is required that foundations redesigned for poor soil conditions must have a safe working static load capacity equal to or greater than the safe working load capacity of the foundations of the Standard Approved Magazine Drawings
- Foundations for earth retention walls must be designed using conventional design methods.
- Foundations that support elements of the magazine that are required to resist dynamic incident pressures from an external explosion from a PES must have an ultimate dynamic load capacity equivalent or greater to the ultimate dynamic load capacity of the foundations shown on the Standard Approved Magazine Drawings. Elements of the magazine that are required to resist the loading from a PES typically include structural walls and columns supporting roof elements.

3-3.2 Floor Flatness and Levelness

Provide the following minimum flatness and levelness: F-numbers: Ff=35, Fl=25.

3-4 WATERPROOFING, DRAINAGE, AND CORROSION PROTECTION.

The soil cover of ECMs can lead to moisture issues within the structure, deterioration of structural components, and degradation of stored AE. Ensure that the magazine is watertight and offers adequate protection to the stored AE from water intrusion. An elastomeric membrane is appropriate for concrete magazines and a bituminous waterproofing is more suitable for steel magazines. Protect the waterproofing membrane from backfilling and compaction operations during construction.

- Provide a subsurface drainage system around the ECM to adequately channel the water away from the structure. Subsurface drainage systems must consist of perforated drain piping surrounded by gravel and protected with landscaping fabric. Extend subsurface drainage systems between magazine and mechanical room walls where necessary to ensure proper drainage is provided.
- Provide an interior perimeter trench drain system within the magazine to accept incidental leaks and condensation. Mechanical rooms must be provided with floor drains or floor sinks to accept condensate produced by mechanical equipment.
- Where blast door trenches are included in the design, provide means of drainage at low points. Ensure that blast door trench drains are accessible for cleaning and maintenance. All floor drains must be provided with a

strainer. Drain openings within the mechanical room or magazine must be protected from rodent entry with holes no larger than 1/4-inch (0.635 cm).

- Consult with the installation public works department regarding the termination of drain piping. Comply with applicable federal, state, and local codes when connecting to storm or sanitary drain systems. Indicated drainage systems are not intended to be the only permitted systems. Designer must develop systems that meet the specific project drainage requirements.

3-4.2 Ordnance Handling, Loading and Offloading Area.

For new construction of magazines, a concrete area may be required by the service or activity in front of the magazine for handling, staging, inspection, loading and offloading ordnance. This paved area, if required, will ensure adequate space is available to handle ordnance in accordance with required safety. The area provides critical space and clearances for ordnance staging, set down, and maneuvering containerized weapons and/or pallets to/from flat bed and enclosed commercial conveyances. The paved area must not be part of an adjacent road but must connect with the adjacent road with an adequate turning radius or short access road. The paved area must be measured from the face of either, the magazine headwall where there is no loading dock or from the face of the magazine loading dock.

3-4.2.1 Paved Area Slope

The paved area must drain away from the magazine in a single continuous plane and the grade must be 0.5% minimum with a 2.0% maximum slope away from the magazine.

3-4.2.2 Navy Only Paved Area Requirements

For the Navy only, where the above required paved area is not available in front of the magazine, the planner must coordinate with the Local Ordnance Handling Activity and the respective Echelon III command must review and assess the impacts to ordnance handling safety. If the appropriate area is not provided, the Echelon III command must provide written (via email) concurrence of the proposed alternative to ensure all risk management concerns have been addressed or mitigated.

3-4.3 Corrosion Protection

Reference UFC 3-301-01 and other UFC documents for corrosion protection requirements. For structural concrete: provide 2-1/2" (6.35 cm) concrete cover to primary reinforcement at exposed concrete or a waterproof coating in Environmental Severity Classification (ESC) C4 through C5 project locations.

When constructing a magazine in accordance with standard drawings: If the concrete cover changes or the design exceeds the concrete cover required by the approved

standard drawings, changes must be approved by the sponsoring service's explosives safety organization and subsequently by the DDESB prior to construction.

3-5 VENTILATION, TEMPERATURE AND HUMIDITY CONTROL.

Typically, ECMs contain some form of ventilation. This is usually accomplished by louvered openings in the headwall and ventilator stacks that exit through the rear wall and penetrate through the earth cover. Due to the broad range of possible storage products and weather conditions, the criteria for a specific project should be provided by the using activity. Coordinate with the user to confirm specific project requirements.

3-5.1 Ventilation Only.

Where the using activity identifies natural or mechanical ventilation only as sufficient space environmental control, verify the following and confirm potential consequences are acceptable to the user.

- If occasional interior magazine surface condensation is not acceptable to the user, prepare an analysis to determine the potential for that condensation. The large thermal mass of concrete and earth berm changes temperature more slowly than ambient air. Under certain circumstances, the ambient air can quickly become warmer and moister (a suddenly warm spring day) than it was a short time earlier. If the interior surface temperature remains cool (below the air dew point) for an extended period of time due to thermal mass, the result could be interior surface condensation.
- If condensation is likely and unacceptable to the user, determine a method to keep surfaces above dew point (i.e. heat space, insulate walls) or lower ventilation air dew point by mechanical cooling with reheat or desiccant system.
- All potential options must also be judged based on the considerations listed in "Temperature and Humidity Control."

3-5.1.1 Natural Ventilation Systems.

Provide natural ventilation systems in accordance with *ASHRAE Handbook, Fundamentals*. Intake and relief opening free areas should be approximately equal wherever practical. Vertically separate intake and relief opening elevations as much as possible to promote airflow induced by temperature differentials. Intake louvers must be hinged with a locking hasp for access and inspection.

Natural ventilation openings may consist of louvers, stacks, or both. Provide the size and quantity of openings required to meet the natural ventilation systems criteria:

- The smallest opening in the path of flow must have a free area to floor area ratio not less than 0.05%.

- The smallest opening in the path of flow must have a free area to space volume ratio of not less than 0.0025%.

Natural ventilation openings must be designed to resist forced entry in accordance with UFC 4-026-01. Consult with the using activity regarding additional special security requirements and the inclusion of fire dampers at the natural ventilation openings.

3-5.2 Temperature and Humidity Control.

In some cases, due to specific criteria or determination that ventilation alone is inadequate, the AE product being stored may require more than just ventilation control. Specific criteria for special storage requirements should be provided by the using activity. For this application, some form of heating and cooling will be required. For cooling, heating, and humidity control systems, the following must be considered:

- Consider potential mechanical systems based on ability to achieve environmental control, availability of thermal utilities such as (installation chilled water or steam utilities), remoteness of installation, maintenance requirements, the availability of service and parts, and familiarity of proposed systems with facility management staff.
- Mechanical systems employing the use of natural gas are not permitted.
- Determine location of mechanical equipment. Indoor mechanical equipment must be located in a dedicated mechanical room wherever possible. To mitigate debris hazards, do not locate outdoor mechanical equipment in or on the earth cover.
- Avoid mechanical utility/piping penetrations into the roof structure of the magazine or mechanical room.
- Determine acceptable paths of connection from mechanical equipment to interior of magazine. Penetrations through the walls of the magazine and mechanical room must be waterproofed. Provide modular compression seals or cast-in-place sleeves or other elements that must be securely embedded in walls.
- Underground ductwork materials and joining methods must be carefully selected to ensure longevity of installation in the project environment. Give special consideration to corrosion from soils and moisture. Installation must be constructable and must withstand the pressure of compacted soil.
- Coordinate lightning protection with mechanical equipment and establish bonding requirements to ensure continuity of duct and piping.
- Mechanical humidity control using mechanical cooling requires some form of reheat. Reheat must be in accordance with ASHRAE 90.1.
- Mechanical humidity control using a desiccant drying system requires some form of desiccant regeneration (either integral to a package unit or

by desiccant replacement). Base final determination on a Life Cycle Cost Analysis.

- Determine the hazardous location classification of the atmosphere within the magazine and select equipment and materials compatible with that classification (e.g. Class 1, Division 2). Provide equipment with spark-proof construction and explosion proof motors where required.
- Consider the use of air curtains at the blast door to mitigate air exchange with the outdoor air where indoor environmental control requirements justify their inclusion.
- Evaluate the need for pneumatic door sealing systems and consult with the using activity regarding their inclusion. Coordinate installation and operational requirements with related disciplines including architecture, electrical, and structural.
- Mechanical openings into the magazine must be designed to resist forced entry in accordance with UFC 4-026-01.
- Coordinate with the user on the criticality of maintaining the space environmental conditions and determine if sensors and status points should be provided and connected to the base Energy Monitoring and Control System for remote monitoring or to another central monitoring site.
- Control panels for HVAC controls must be located in the mechanical room such that they may be accessed without entering the magazine. Sensors located within the magazine, if any, must be intrinsically safe.

3-5.2.1 System Design Calculations

Refer to UFC 3-410-01 for requirements regarding mechanical system design calculations. Confirm and document the indoor and outdoor design conditions with the using activity. Heat loads must reflect the installation conditions including the thermal mass effect of earth fill and cover. Assembly U-value calculations must be provided. Blast door U-value calculations must account for thermal bridging that may be inherent to the door’s design.

3-5.2.2 Engineering Weather Data

Refer to UFC 3-400-02 Design – Engineering Weather Data for information on access to and use of weather data in the required heat load analyses.

3-5.3 Structural Coordination.

Any mechanical work must maintain the structural integrity of the magazine design.

- If required, consider implementation of blast valves (explosion dampers) and/or blast attenuation chambers.

- Coordinate location of any mechanical penetration with structural requirements, including possible designed blow out walls or roofs.
- Consult with the Service explosive safety organization.
- If required by the using activity, coordinate installation requirements of snow/ice melt systems with structural slab/foundation design and electrical grounding.
- Note that any mechanical penetration into the blast-resistant elements of an ECM (aside from those specifically noted in the Standard drawings) must be reviewed by a competent DoD blast design agency to ensure they do not compromise the protective construction of the structure.

3-6 FIRE PROTECTION AND LIFE SAFETY.

Fire Protection and Life Safety must comply with the requirements outlined in the paragraph entitled "*Ammunition and Explosives Storage Facilities*" within UFC 3-600-01, *Fire Protection Engineering For Facilities*. AE storage facilities may be ECMs or AGMs as defined by DESR 6055.09. An AE storage facility can be used for AE storage only. An AE storage facility may not be used for handling; processing; testing; servicing; and inspection of ammunition, explosives, propellants, and oxidizers.

For Navy Projects, contact Government Project Manager or Contracting Officer for NAVSEA OP5 information.

3-7 PHYSICAL SECURITY.

Design AE facilities in accordance with DoDM 5100.76 and DESR 6055.09. Additional Service-specific guidance implementing DoDM 5100.76 are contained in OPNAV Instruction 5530.13D Department of the Navy *Physical Security Instruction for Conventional Arms, Ammunition and Explosives (AA&E)*, 26 September 2003, Army Regulation 190-11, *Physical Security of Arms, Ammunition and Explosives, 15 November 2006 (For Official Use Only)*, MCO 5530.14A Marine Corps Physical Security Program Manual, and AFI 31-101 Department of the Air Force Integrated Defense.

Approved magazine standard designs identify minimum physical security features, including high security hasps on doors, steel bars at openings and conduit for electronic security systems. The goal is to provide a forced entry delay time that exceeds the response force response time. Coordinate the security requirements for a specific magazine with the Service and installation security personnel. The below information is provided to assist the end user in determining requirements for magazine door locking devices:

- MIL-DTL-43607J, Padlock, Key Operated, High Security, Shrouded Shackle states: *“The padlock shall withstand a concentrated forced entry* attack using battery powered tools for an accumulated work time of at least one minute.” To improve forced entry resistance of structures with High Security Padlocks and Hasps, an Anti-Intrusion Barrier (AIB) can be

added to protect the locking system and increase the forced entry delay times against hand and battery powered tools.

- The Internal Locking Device (ILD) is a government developed and patented High Security Locking System that mitigates the “exposure to attack” that external locking systems are prone to. This system has been tested to withstand 10 minutes of forced entry resistance against hand and battery powered tools. The ILD is an approved alternative to the current high security padlock and hasp requirement. The ILD is best suited to high security applications and in locations where extreme climate makes opening and securing externally mounted padlocks impractical.
- ILD Locks and associated Boltworks as a locking system are required for all new ECM doors or planned upgrades to ECM doors for Security Risk Category I and II.

3-7.1 Assistance with Physical Security Components and Requirements.

For help with information on security hardware selection, requirements, specifications, national stock numbers, purchasing, and troubleshooting of equipment failures, call the Department of Defense Lock Program Technical Support Hotline (800) 290-7607, (805) 982-1212, DSN 551-1212, or send e-mail to: W_NAVFAC_DoD_Lock_Program_Support@navy.mil

Additional information can be found at https://exwc.navfac.navy.mil/DoD-Lock-Program/

3-8 ELECTRICAL DESIGN.

Provide site electrical utilities, lightning protection systems, grounding and bonding system, interior distribution systems, communications and security according to UFC 3-501-01, *Electrical Engineering*, and the latest installation design requirements.

- Site Electrical Utilities may include distribution service entrance equipment, overhead power distribution, underground electrical systems, service entrance grounding electrode, metering, and exterior site lighting.
- Lightning protection system, grounding and bonding system may include catenary system, faraday cage system, exterior buried grounding ring electrode, air terminals, lightning conductor, mast system, guardrails on headwall as air terminal components, down conductors, ground rods, test wells, static and ordnance grounding.
- Interior distribution systems may include distribution equipment, surge protective devices (SPDs), wiring devices, raceways, conductors, interior lighting and power systems, bridge crane system, and hazardous locations.
- Communications and electronic security includes telecommunications systems and electronic security systems (ESS). Telecommunications rooms (TR) are not required within each magazine. Individual/remote

magazines may utilize a telecommunications enclosure (TE) within the structure, however, either space conditioning must be provided or the equipment must be rated for the environment, and the TE must be NEMA 3RX rated. Sites with multiple magazines must provide one centralized TR located in one of the adjacent site buildings where all telecommunications equipment is to be located. The telecommunications equipment at this location must be in a conditioned space. The telecommunications equipment must be located such that the maximum cable length from the patch panel through the structured cabling system to the furthest outlet of the magazines being served does not exceed 295 feet (90 m). No distance restriction when using fiber optic cable. If telecommunications needs are minor, a TE may be substituted in lieu of a TR.

In addition to the criteria identified above, comply with DESR 6055.09 and the following Magazine-specific requirements.

3-8.1 Hazardous (Classified) Location.

Coordinate with local tenant to determine if the magazine is classified as a hazardous location established as outlined in Chapter 2, paragraph titled “Electrical Planning”. For Navy projects only, NCC/NAVFAC must contact local tenants to complete the NCC form (identifying hazardous classified location).

Explosion-proof fixtures and equipment are not required unless the magazine is classified as a hazardous location.

3-8.2 Power.

Electric lines serving the magazine must be installed underground from a point not less than 50 feet (15 m) from the facility. The electric lines must be installed in metal conduit, as required by DESR 6055.09, V2.E3.6.2.

The service entrance equipment can be installed inside of the magazine or on the exterior magazine headwall. Any electrical service entrance equipment or external disconnecting means, which serves as power disconnection to the magazine, must be readily accessible. Ensure to provide working clearances in front of electrical equipment as defined per NFPA 70 as continuous and unobstructed to egress pathway. Ensure to provide dedicated space above the equipment in accordance with NFPA 70 for conduits routing if located on wall surfaces. Coordinate the location of the equipment with the user. All interior conduits must be galvanized steel rigid metal conduit. If required on site, locate ground fault circuit interrupted (GFCI) duplex receptacles and electrical control equipment 48 inches (121.92 cm) above the floor.

3-8.3 Lighting.

Provide two separate exterior lighting systems:

- Photocell-controlled for security lighting (0.2 foot-candles (fc), 2 lux).

- Switched lighting for loading activities (5 fc, 50 lux).

Provide interior lighting system:

- Switched lighting per bay or area for warehousing activities. Incorporate manual on/off lighting controls. However, DORs must coordinate with users for the Activity within the magazines as identified within the provisions of ASHRAE 90.1.
- Lighting design must follow UFC 3-530-01. Provide footcandles or lux requirements as shown on illumination performance table.

Note: For Army projects, coordinate with the user and Activity to determine if there is a requirement for interior and exterior lighting, including lighting required to support electronic security systems. Otherwise, do not include in the project.

3-8.4 Earth Electrode System (Grounding).

Provide an earth electrode system (EES) for each facility including the following components:

a. A ground ring electrode around the entire circumference of the magazine in accordance with NFPA 780. The ground ring electrode must be installed at a depth of 30 inches (76.2 mm cm) instead of 18 inches (45.72 cm). Use a minimum of 2/0 AWG (133 kcmil) bare copper wire for the ground ring electrode and for all connections to the ground ring. For the Navy, the ground ring electrode is termed a “secondary ground ring”.

b. For the Navy, as a minimum, provide grounding electrodes at each change in direction of the ground ring.

c. Single point ground bus bar, static ground bus bar and ordnance ground bus bar (if required to be provided) must be bonded to the ground ring electrode outside of the magazine.

d. Provide at least two ground test wells at opposite corners of the magazine. Additional test wells must be provided for the single point ground bus bar and ordnance ground bus bar. When possible, locate all test wells in front of the magazine and install the rear test well outside the earth-covered mound with extension of grounding conductors for accessibility. Determine the precise test well locations during the project design to consider periodic access to the test wells given the installation location. Assemble test wells with bolted connections to facilitate future testing. Ensure that the cables are not bonded to or touching the ground rod as they course up from the buried location to the bonding/connection point.

e. Connect all inaccessible connection points in the earth electrode grounding system using an exothermic weld connection or with a high compression connection using a hydraulic or electric compression tool to provide the correct circumferential pressure.

f. If an additional demising wall is added, obtain an approval from the service authority for any additional static & ordnance ground bus bars as required.

3-8.5 Bonding.

Provide bonding as follows:

- Bond together all reinforcing steel bars within the structure, forming an electrically continuous Faraday-like shield.
- Bond between individual reinforcing bars using metallic wire ties at a maximum of 5 feet (1.22 m) in each direction. Note that welding is not permitted for reinforcing bars used in ECMs or other magazines that rely on protective construction for reduced NEW/ESQDs.
- Bond between structural elements (roof to wall, wall or arch to floor slab, wall panel to wall panel) or other areas where reinforcing steel is discontinuous.
- For Navy magazines, welding or brazing to the reinforcement in structural reinforced concrete members, (including walls, beams, slabs and columns, etc.) is not permitted.
- Bond between the floor slab to the ground ring electrode at or near each corner of the structure. For magazines with perimeters greater than 400 feet (122 m), provide one additional connection for each 100 feet (30.48 m) or fraction thereof; equally space the connections around the magazine's perimeter.
- Bond other points (test wells, ground rods, lighting protection system down conductor, electrical panel, ordnance and static inserts, doors' metallic parts, metallic equipment enclosures, and single point ground bar) to the ground ring electrode. The ground ring electrode must be permitted to service as the single-point ground required by the NEC.
- The bonded connections between structural elements, and to the ground electrode ring, must be made with 2/0 AWG (133 kcmil) bare copper wire with exothermic or approved compression connections. For the ordnance ground, use minimum 2/0 AWG (133 kcmil) insulated conductor in PVC conduit to isolate from metallic objects. If a cathodic protection system is used, it must be a galvanic system and comply with requirements in UFC 3-570-01 *Cathodic Protection*.

3-8.6 Lightning Protection.

Provide lightning protection per UFC 3-575-01, *Lightning and Static Electricity Protection Systems,* and the grounding requirements defined herein to protect the exposed portions of the facility. However, if justification can be provided per DESR 6055.09, then lightning protection is not mandatory.

- Lightning protection will incorporate the metallic (Faraday-like) cage type system by bonding together the rebar as mentioned in 3-8.5 and bonding together the structural components of the magazine as required by NFPA 780, or other services applicable requirements. Additionally, 3/16-inch (0.476 cm) thick minimum and 42-inch-high (106.68 cm) maximum metal guardrails may be utilized as strike termination devices on the magazine headwalls, which will be bonded to the ground ring electrode at both ends. This will provide a two-way path to ground ring electrode and will be bonded via ground rods (one is minimum) at each end of headwall.
- The lightning protection system must be bonded to the ground ring electrode. An air terminal with two down conductors for each ventilator will be provided and bonded to the ground ring electrode.
- For these magazine facilities, ensure compliance with the 100-feet (30.5 m) radius striking distance requirement in NFPA 780.
- Third party inspections must be required based on service requirements. Refer to paragraph 3-10 for additional special inspection requirements.

3-8.7 Bonding of Horizontal Sliding Doors.

Provide bonding from door's grounding reel and door's railing to the structure (steel/re-enforcing steel).

- Bonding path should continue with/through the structure steel to grounding ring electrode. Bond door's rail at three locations: one at each end and one at middle of the door's rail.
- Provide bonding with 1 ohm resistance maximum for lightning protection.
- For Air Force and Army projects: If the door can be proven to be inherently bonded by their weight, then flexible bonding is not required. However, the resistance must be measured at initial construction and recorded in the base-line records for the facility.

3-8.8 Snow Melting System.

Snow melting systems are optional. When snow and ice are a concern, and Activity requires a "snow melting system," use the appropriate heat intensity for the applicable geographic area per ASHRAE Handbook, *HVAC Applications*, Chapter "Snow Melting," Class III.

3-8.9 Communications.

Communications outside plant pathways and cabling for phone lines or electronic security at the magazine is optional based on munition category and branch of the military.

- At a minimum each magazine will include one 4” (10.16 cm) conduit extended 10 feet (3.048 meters) outside the foundation for potential future use when the requirement arises.
- Any communication lines must be buried underground in metal conduit for a minimum of 50 feet (15.24 meters) before entering the facility, as required by DESR 6055.09, V2.E3.6.2.
- Phone services at the magazine are optional. When phone is required a POTS, phone will be mounted on the exterior headwall of the magazine. Locate to not be obscured when the magazine door is open.
- Communications infrastructure and cabling will be designed and installed in accordance with UFC 3-580-01, Telecommunications Interior Infrastructure Planning and Design.

3-8.10 Electronic Security.

Electronic security systems (ESS) are optional based on the type and classification of munitions to be stored.

- When electronic security systems are required, they will be designed and installed in accordance with UFC 4-021-02, Electronic Security Systems. When ESS is included the following magazine specific criteria will be incorporated into the design.
- When Internal Locking Devices (ILD) are deployed the internal contact of the ILD must be integrated with the Intrusion Detection System (IDS), if equipped with an IDS.
- Keypads for arming and disarming of the magazine must be mounted exterior on the magazine head wall. Locate to not be obscured when the magazine door is open.

3-8.11 Additional Electrical Requirements (Navy Only).

Incorporate details addressing specific electrical requirements for Navy occupied magazines that are available on the Whole Building Design Guide at https://www.wbdg.org/navy/cad/electrical-details-magazine. Details are available in *.pdf and *.dwg formats.

3-9 ADDITIONAL ELECTRICAL CONSTRUCTION QUALITY CONTROL.

Incorporate the following inspection, testing and photographic documentation during construction of the Earth Electrode System and bonds into the project specifications. Include a plan view sketch identifying locations of photographs and tests.

a. Inspect all concrete reinforcing steel bonding connections for positive contact between individual bars. Document with photographs at 10-feet (3.048 m) intervals.

b. Inspect bonding connections (2/0 AWG (133 kcmil) conductor) between structural elements at each location. Provide photographic verification and continuity testing of a random sample (10% minimum) of the connections. If any of the results are greater than 1 ohm, correct the deficiencies and sample additional 10% random sample. If any of the additional results are deficient, test 100% of the connections.

c. Test continuity and provide photographic documentation at all bonding connections to the ground ring electrode. Include:

- Each end of the floor slab connection.
- Each ground rod location and test well.
- Each lightning protection system down conductor.
- The electrical panel (service entrance grounding electrode conductor).
- All ordnance and static inserts / ground bus bars.
- Single point ground bus bar.
- Ground cross connection cables and other connections as identified in Service standard designs.

3-9.1 Lightning Protection System, Bonding and Grounding Quality Control Submittal Requirements to be included in the project specifications.

The Lightning Protection System, Bonding and Grounding Quality Control Plan must:

- Indicate the contractor's understanding and explanation of the QC process.
- Include Special Inspector (SI) qualifications and responsibilities.
- Include shop QC Manager (or in-house inspector) qualifications and responsibilities.
- A list of challenging issues (available material challenges, shipping challenges, schedule challenges, etc.)
- Special procedures and processes.
- Include a discussion of SI record keeping and required bi-weekly submittals and any other submittals to the contractor’s QC Manager, etc.
- Show coordination between Special Inspector, In-House Inspector, Shop QC manager, Contractor QC manager.

3-9.2 Lightning Protection System, Grounding and Bonding Quality Control Pre-Construction Meeting to be included in the project specifications.

The contractor must conduct a quality control pre-construction meeting to review the grounding and bonding quality control plan submittal. The meeting must include the

Designer of Record (DOR), Contractor QC manager, Special Inspector, Grounding/Bonding Contractor, Contractor Superintendent, government Engineering Technician (ET), the government Construction Manager (CM), and a government representative familiar with lightning protection, grounding and bonding systems for magazines.

3-10 SPECIAL INSPECTIONS.

Special inspections must be performed during construction of magazines. When developing a new magazine design or site adapting a standard design, the DOR must develop a list of Special Inspections in accordance with the International Building Code (IBC), Chapter 17. Special Inspections must include submittal of photographs and written inspection documentation on the bonding of the structural steel reinforcing bars for construction of concrete ECMs, as well as any other necessary IBC Chapter 17 requirements identified in consultation with the Service's explosives safety organization. See Appendix D for an example schedule of Special Inspection items.

3-11 STRUCTURAL OBSERVATIONS.

Provide structural observations per UFC 3-301-01 for structures.

3-12 DDESB AND SERVICE-SPECIFIC EXPLOSIVES SAFETY CONTACTS.

DDESB:

APPENDIX A BEST PRACTICES

A-1 B 7-BAR AND 3-BAR ECM APPROVED FOR NEW CONSTRUCTION (IP UNITS).

The Whole Building Design Guide web site provides a listing of 7-Bar AND 3-Bar ECM designs that have been approved for new construction including internal dimensions, door opening dimensions and the maximum NEW that can be stored in the magazine. All new ECM projects must use the most current version of the approved design drawings - refer to the following website for further information; https://www.wbdg.org/building/ammunition-explosive-magazines. The source of this information is DDESB TP 15, Table AP1-1.

Magazine types are graphically depicted in the approved designs for 7-Bar and 3-Bar ECM. The most current version of the approved design drawings, approval letters, and additional information related to the approved designs can be accessed at the following web site: https://www.wbdg.org/dod/ecm/ecm-approved-new-construction approved-new-construction

This Page Intentionally Left Blank

APPENDIX B SPECIAL INSPECTIONS

Special inspections are based on Chapter 17 of the IBC. The following Special Inspection Schedule must be revised to reflect specific project requirements and materials used. However, at a minimum the special items related to the blast structural strength designation must be inspected as shown on this schedule.

Table B-1 Special Inspection Schedule/Verification

Item	Extent of Inspection[1]	Reference	Comments/Scope
Concrete Construction			
Reinforcing Steel Placement	P	ACI 318: 20, 25.2, 25.3, 26.6.1-26.6.3	Inspect size, spacing, cover, positioning, and grade of reinforcing steel. Verify reinforcing bars are free of form oil or other deleterious materials. Inspect bar laps and mechanical splices. Verify bars are adequately tied and supported on chairs or bolsters. For magazines with precast walls, verify that the vertical footing dowels have been located per the contract documents.
Welding of Reinforcement	C	AWS D1.4, ACI 318: 26.6.4	Inspect all reinforcing steel welds. Verify weldability of reinforcing steel. Inspect pre-heating of steel when required. Welding of reinforcement in structural concrete is not allowed without approval.
Concrete Placement	C	ACI 318: 26.5	Inspect placement of concrete. Verify concrete conveyance and depositing avoids segregation or contamination. Verify concrete is properly consolidated. Observe installation of precast panels.
Sampling and Testing of Concrete	C	ASTM C172 ASTM C31 ACI 318: 26.5, 26.12	
Curing and Protection	P	ACI 318: 26.5.3-26.5.5	Inspect curing, cold weather protection, and hot weather protection procedures.
Formwork	P	ACI 318: 26.11.1.2(b)	Inspect formwork for shape, location, and dimensions of the concrete member being formed. For precast wall construction, verify ducts to receive the footing dowels are located per the contract documents.
Door Construction			
Fabricator Certification/ Quality Control Procedures	S		Review of fabricator's quality control procedures or AISC certification.
Fabricator Inspection	P		Inspect in-plant fabrication, or review fabricator's approved independent inspection agency's reports.

1 – Inspection Intervals are as follows:
C – Continuous: The full-time observation of work requiring special inspection by an approved special inspector who is present in the area where the work is being performed.
P – Periodic: The part-time or intermittent observation of work requiring special inspection by an approved special inspector who is present in the area where the work has been or is being performed and at the completion of the work.
S – Surveillance review of Shop Drawing submittal

Item	Extent of Inspection[1]	Reference	Comments/Scope
Electrical Construction		NFPA 780, DESR 6055.09	
Reinforcing steel bonding connections	P		Inspect all components establishing the Faraday-like shield including concrete reinforcing steel bonds and bonds between structural elements to ensure electrical continuity. Include photo documentation of the electrical bonding construction phase.
ECM Grounding	P		Inspect the bond between the floor slab and the Ground Ring Electrode. Include photo documentation of the electrical grounding construction phase.
Earth Electrode System	P		Prior to burial, inspect the Earth Electrode System conductors to ensure no damage, breakage, or corrosion has occurred to the conductors.
Lightning Protection System (LPS)	P		Inspect LPS components for secure mounting and protection against accidental mechanical displacement, and to ensure no damage, breakage, or corrosion has occurred.
Other Bonds	P		Inspect all other items bonded to the Ground Ring Electrode for corrosion and loose connections that might result in high-resistance connections.
Continuity Testing	P		Witness continuity testing.
Special Items Related to Blast Strength Designation			
Earth Cover	P		Inspect depth gauges on roof prior to earth cover placement for size and stability. Inspect earth cover depth and slope to ensure a 2 feet (0.61 m) minimum is provided above structure.

Door Laps	C		Inspect door laps at top and bottom of door frame.

1 – Inspection Intervals are as follows:
C – Continuous: The full-time observation of work requiring special inspection by an approved special inspector who is present in the area where the work is being performed.
P – Periodic: The part-time or intermittent observation of work requiring special inspection by an approved special inspector who is present in the area where the work has been or is being performed and at the completion of the work.

C-2 DEFINITION OF TERMS.

Ammunition and Explosives (AE): Includes, but is not necessarily limited to, all items of U.S.-titled (i.e., owned by the U.S. Government through the DoD Components) ammunition; propellants, liquid and solid; pyrotechnics; high explosives; guided missiles; warheads; devices; and chemical agent substances, devices, and components presenting real or potential hazards to life, property and the environment. Excluded are wholly inert items and nuclear warheads and devices, except for considerations of storage and stowage compatibility, blast, fire, and non-nuclear fragment hazards associated with the explosives.

Bar: Short for barometric pressure. It is a common expression of the peak design pressure for ECMs.

Barricade: An intervening natural or artificial barrier of such type, size, and construction that limits the effect of an explosion on nearby buildings or exposures in a prescribed manner.

Barricaded Magazine: A magazine with an intervening barricade between it and either a PES or an ES.

Earth-Covered Magazine (ECM): An aboveground, earth-covered structure that meets DoD criteria for soil cover depth and slope requirements. ECMs are AE storage magazines that are covered by soil above, on the sides, and the rear. ECMs have three possible strength designations: 7-Bar, 3-Bar, or Undefined. The strength of an ECM's headwall and door determines its designation.

Exposed Site (ES): A location exposed to the potential hazardous effects from an explosion at a PES.

Hazard Division (HD): A division or subdivision denoting the character and predominant hazard within UN classes 1, 2,3,4,5 and 6.

Intermagazine Distance (IMD): Distance to be maintained between two AE storage locations.

Magazine: Any building or structure used exclusively for the storage of AE.

Maximum Credible Event (MCE): In hazards evaluation, the MCE from a hypothesized accidental explosion, fire, or toxic chemical agent release (with explosives contribution) is the worst single event that is likely to occur from a given quantity and disposition of AE. The event must be realistic with a reasonable probability of occurrence considering the explosion propagation, burning rate characteristics, and physical protection given to the items involved. The MCE evaluated on this basis may then be used as a basis for effects calculations and casualty predictions.

Net Explosive Weight (NEW): The total weight of all explosive substances (i.e., high explosive weight, propellant weight, and pyrotechnic weight) in the AE, expressed in pounds (lbs). The metric equivalent is net explosive quantity (NEQ).

Potential Explosion Site (PES): A location of a potential quantity of AE that will create blast, fragment, thermal, or debris hazard in the event of an accidental explosion of its contents.

Quantity-Distance (QD): The quantity of explosive material and distance separation relationships that provide defined levels of protection. The relationships are based on levels of risk considered acceptable for specific exposures and are tabulated in applicable QD tables in DESR 6055.09. These separation distances do not provide absolute safety or protection. Greater distances than those specified in DESR 6055.09 should be used if practical.

This FC supersedes ETL 11-7, *Nuclear Weapons-Capable Maintenance and Storage Facilities*, dated 1 September 2011.

FOREWORD

Facilities Criteria (FC) provide functional requirements (i.e., defined by users and operational needs of a particular facility type) for specific DoD Component(s), and are intended for use with unified technical requirements published in DoD Unified Facilities Criteria (UFC). FC are applicable only to the DoD Component(s) indicated in the title and do not represent unified DoD requirements. Differences in functional requirements between DoD Components may exist due to differences in policies and operational needs.

All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and, in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the FC, the SOFA, the HNFA, and the BIA, as applicable.

Because FC are coordinated with unified DoD technical requirements, they form an element of the DoD UFC system applicable to specific facility types. The UFC system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and are applicable to the Military Departments, Defense Agencies, and DoD Field Activities. The UFC System also includes technical requirements and functional requirements for specific facility types, both published as UFC documents and FC documents.

FC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet site listed below.

FC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects.

EDWIN H. OSHIBA, SES
Director, AF Civil Engineer Center

FACILITIES CRITERIA (FC)
NEW SUMMARY SHEET

Document: FC 4-420-07F, *Air Force Nuclear Weapons-Capable Maintenance and Storage Facilities*

Superseding: ETL 11-7, *Nuclear Weapons-Capable Maintenance and Storage Facilities*

Description:

This document provides criteria specific to new and existing nuclear weapons-capable maintenance and storage facilities, including unique criteria related to design, construction, sustainment, restoration, and modernization.

Reasons for Document:

This document supersedes ETL 11-7 to provide facilities criteria for the use and guidance of those charged with the design, construction, renovation, and maintenance of nuclear weapons-capable maintenance and storage facilities. The performance goals of this document are to ensure that:

- Lightning strikes to the facility will not result in a side flash inside the facility that will compromise the surety of nuclear weapons
- Facility power systems, including all emergency power systems, are adequate to supply power to facility systems required to maintain the surety of nuclear weapons
- Facility structural supports for hoists, cranes, and lifting devices are adequately rated for the design loads
- Security meets the requirements of Department of Defense (DoD) S-5210.41/Air Force Manual (AFMAN) 31-108
- Nuclear surety deviations for existing facilities and essential facility systems are documented in accordance with AFI 91-101
- Blast containment and isolation systems mitigate contamination of facilities and weapons by limiting radiation transport mechanisms such as explosions, blasts, and fires
- Studies, including a fire hazard analysis (FHA), an electromagnetic radiation environment (EMRE) survey, and a facility characterization for the seven-foot rule (if implemented), are conducted to support the adequate design and operational issues in these areas, ensure the safety of weapons, and provide baseline documentation

- Updates to these studies, including for the FHA, EMRE, and facility characterization (if implemented), are conducted if any proposed facility change or modification involves, affects, or impacts systems covered by the existing studies, and the updated studies reflect the effect of the modification on study conclusions and recommendations

- Fire safety designs are implemented to ensure that:

  - Fire during any operational state will not prevent the facility plant from maintaining nuclear weapons in a safe, secure, and stable condition

  - Fire will not result in a radiological release that adversely affects the public, facility personnel, or the environment

  - Fire hazards to personnel are minimized by adding areas of refuge to restricted access/egress rooms

  - A fire will be limited such that facility damage, economic loss, and interruption of support to DoD missions are limited to an acceptable level, as defined by the Cognizant Office of Responsibility

- Provide criteria for new combined industrial and storage limited-access facilities

This document is intended to be used as a basis for the development of detailed design documents (including scope, basis of design, technical requirements, plans, drawings, specifications, cost estimates, request for proposals, and invitations for bids) used for the procurement of facilities, facility similar equipment, and other infrastructure systems. This document must be used as a reference document and requirement in the procurement of architectural and engineering (A&E) services and other consulting services to prepare detailed design documents, including those for design-build projects. It is not intended to be used in lieu of detailed design documents in the procurement of facility construction.

Impact:

Relative to ETL 11-7, this FC should have no impact on design cost, initial cost, energy savings, or life cycle costs.

Disclaimer: Use of the name or mark of any specific manufacturer, commercial product, commodity, or service in this publication does not imply endorsement by the Air Force.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE

1-1.1 General

This document provides criteria specific to new and existing nuclear weapons-capable maintenance and storage facilities, including unique criteria related to (but not limited to) facility sustainment, restoration, and modernization (FSRM), and military construction (MILCON), including design and construction. These criteria apply both to spaces where nuclear weapons may be located and to spaces and supporting systems required for nuclear weapons surety. These facilities are relatively few in number and are uniquely designed to protect the Air Force mission, ensure continuity of facility operations, limit property damage, and provide on-site personnel safety.

1-1.2 Basis of Design

This document is intended to be used as a basis for the development of detailed design documents (including scope, basis of design, technical requirements, plans, drawings, specifications, cost estimates, request for proposals, and invitations for bids) used for the procurement of facilities, facility similar equipment, and other infrastructure systems.

1-1.3 Procurement of Services

This document must be used as a requirement in the procurement of architectural and engineering (A&E) services and other consulting services to prepare detailed design documents, including those for design-build projects. It is not intended to be used in lieu of detailed design documents in the procurement of facility construction.

1-1.4 Performance Goals

The performance goals of this document are to ensure that:

- Lightning strikes to the facility will not result in a side flash inside the facility that will compromise the surety of nuclear weapons
- Facility power systems, including all emergency power systems, are adequate to supply power to facility systems required to maintain the surety of nuclear weapons
- Facility structural supports for hoists, cranes, and lifting devices are adequately rated for the design loads
- Security meets the requirements of DoD S-5210.41 / AFMAN 31-108
- Nuclear surety deviations for existing facilities and essential facility systems are documented in accordance with AFI 91-101

- Blast containment and isolation systems mitigate contamination of facilities and weapons by limiting radiation transport mechanisms such as explosions, blasts, and fires
- Studies, including an FHA, an EMRE survey, and a facility characterization for the seven-foot rule (if implemented), are conducted to support the adequate design and operational issues in these areas, ensure the safety of weapons, and provide baseline documentation
- Updates to these studies, including for the FHA, EMRE, and facility characterization (if implemented), are conducted if any proposed facility change or modification involves, affects, or impacts systems covered by the existing studies, and the updated studies reflect the effect of the modification on study conclusions and recommendations
- Fire safety designs are implemented to ensure that:
    - Fire during any operational state will not prevent the facility from maintaining weapons in a safe, secure, and stable condition
    - Fire will not result in a radiological release that adversely affects the public, facility personnel, or the environment
    - Fire itself will not cause a loss of life to those not intimately exposed to the fire origin, and injuries are minimized for those that are intimately exposed
    - Fire hazards to personnel are minimized by adding areas of refuge to restricted access/egress rooms
    - A fire will be limited such that facility damage, economic loss, and interruption of support to DoD missions are limited to an acceptable level, as defined by the Cognizant Office of Responsibility

1-2 APPLICABILITY

This document is applicable to Air Force installations with nuclear weapons-capable maintenance and storage facilities.

1-3 GENERAL BUILDING REQUIREMENTS

Comply with UFC 1-200-01. UFC 1-200-01 provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high-performance and sustainability requirements, and safety. Use this FC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

Topics and criteria not included in this FC are those adequately addressed in the engineering criteria for DoD buildings as found in published UFC documents.

Unique fire protection and life safety criteria have been developed for nuclear weapons-capable maintenance and storage facilities as included in this FC.

1-4 REFERENCES

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-5 GLOSSARY

Appendix C contains acronyms, abbreviations, and terms.

1-6 CRITERIA

National consensus criteria are utilized for the facilities addressed in this document as appropriate; however, consensus criteria for some systems and components necessary to accomplish the Air Force mission are not available. This document contains special criteria as needed to meet mission requirements.

1-7 CONFLICTS WITH EXISTING CRITERIA

In case of conflict with any UFC, the criteria in this document will take precedence.

1-8 COGNIZANT OFFICE OF RESPONSIBILITY

The following organizations each serve in the role of Cognizant Office of Responsibility for the establishment of specific requirements in this document:

- Air Force Civil Engineer Center, Operations and Programs Support Division (AFCEC/CO): Serves as preparing activity for this document and serves as the Cognizant Office of Responsibility for civil engineering-related issues. AFCEC also serves as the Cognizant Office of Responsibility for personnel safety-related issues. Equivalencies and exemptions to the requirements of this document (see paragraph 1-9) are issued by AFCEC after receiving coordination from other applicable Cognizant Offices of Responsibility.
- Air Force Nuclear Weapons Center (AFNWC): Serves as a Cognizant Office of Responsibility with particular emphasis on the effects on nuclear surety from facility design issues and FHAs.
- Air Force Safety Center, Weapons Safety Division (HQ AFSEC/SEW): Serves as a Cognizant Office of Responsibility for both nuclear weapons surety and specific personnel safety-related issues as annotated in this document.

- Headquarters Air Force Security Forces, Nuclear Security Division (AF/A4SN): Serves as a Cognizant Office of Responsibility for security-related issues.

The following organization serves in the role for implementation of specific requirements of this document:

- Headquarters, Air Force Global Strike Command (HQ AFGSC): Provides guidance to maintain operational and readiness issues affecting nuclear surety.

1-9 EQUIVALENCIES AND EXEMPTIONS

1-9.1 Equivalencies

Equivalencies to established criteria of this document may be proposed and developed by a Cognizant Office of Responsibility if the alternate engineering design provides an equivalent level of protection to that intended by this document. Requests for approval must be submitted to AFCEC by the appropriate Cognizant Office of Responsibility and must include written justification, including items such as a hazard analysis, cost comparison, criteria used, and other pertinent data. Lack of funds will not be considered sufficient justification for non-compliance with established criteria. Approved equivalencies and alternatives apply only to the specific facility involved and do not constitute blanket approval for similar cases. For issues involving physical security, refer to DoD S-5210.41-M / AFMAN 31-108. For issues involving weapons safety, refer to AFI 91-101.

NOTE: Nuclear surety deviations must also comply with paragraph 1-10 of this document.

NOTE: Certain paragraphs in this document include text similar to "…as approved by the Cognizant Office of Responsibility." That text is intended to indicate that the Cognizant Office of Responsibility is authorized to select a design option or modify that specific criteria without the requirement to submit a request for equivalency to AFCEC.

1-9.2 Exemptions

Exemptions to established criteria of this document may be proposed and developed by a Cognizant Office of Responsibility. Requests for approval must be submitted to AFCEC by the appropriate Cognizant Office of Responsibility and must include written justification. An exemption must demonstrate that the criteria cannot be technically executed or execution of the criteria will increase a hazard or create a new hazard and no technical alternatives exist. Request for exemption must include written justification, including items such as a hazards analysis, cost comparison, alternatives considered, and other pertinent data. Lack of funds or cost savings will not be considered sufficient justification for non-compliance with established criteria. Exemptions apply only to the

specific facility or project involved and do not constitute blanket approval for similar cases. Exemptions must follow the process outlined in MIL-STD-3007F. For issues involving physical security, refer to DoD S-5210.41-M / AFMAN 31-108. For issues involving weapons safety, refer to AFI 91-101.

NOTE: Nuclear surety deviations must also comply with paragraph 1-10 of this document.

NOTE: Certain paragraphs in this document include text similar to "…as approved by the Cognizant Office of Responsibility." That text is intended to indicate that the Cognizant Office of Responsibility is authorized to select a design option or modify that specific criteria without the requirement to submit a request for exemption to AFCEC.

1-10 NUCLEAR SURETY DEVIATIONS AND WAIVERS

In addition to the requirements of this document, all modifications/alterations to an existing nuclear-certified facility or an essential facility system as listed within this document must be documented using the deviation process outlined in AFI 91-101, Chapter 3. That document establishes procedures for MAJCOMs to request deviations to nuclear enterprise-related policy and guidance. This documentation requirement for deviations also includes security deviations.

For the purposes of facility nuclear certification, specific requirements herein are identified in a separate document known as the Certification Requirements Plan (CRP), in accordance with AFI 63-125. Those specific requirements included in the CRP depend on the individual facility's design and function.

If a proposed design modification/alteration conflicts with required nuclear surety-related design criteria, MAJCOMs must use the process in AFI 91-101 to obtain approval. Deviation requests are not required to be submitted for an existing operational system or component solely due to enhanced safety criteria that was implemented after the system or component was originally operationally certified. However, when subsequently modifying/altering an existing system or component, that enhanced safety criteria becomes applicable and deviation requests are required.

Waivers must be adjudicated using the process outlined in AFI 33-360.

1-11 RETROACTIVITY

1-11.1 Level of Protection

The provisions of this document are considered necessary to provide an acceptable level of protection against loss of life and property and to minimize impact to the facility mission. This document applies to new and existing facilities.

1-11.2 Application

Unless specifically noted in this document, the provisions of this document must not be applied retroactively unless determined by the FHA or other approved documented analyses that the existing situation involves a distinct hazard to life, mission, property, or the environment.

1-11.3 Alterations and Limitations

This document also applies when a facility is altered, renovated, or modernized (see specific definitions of these terms in UFC 3-600-01). It is recognized that certain requirements within this document are not possible or practical in existing structures; therefore, a documented evaluation will be provided to the Cognizant Office of Responsibility and, if applicable, to the system program manager (SPM) in accordance with AFI 63-125 as a technical justification for the acceptability of the proposed configuration. Such justifications must provide a sound technical basis for nonconformance that may include a benefit-to-cost analysis.

CHAPTER 2 LIGHTNING PROTECTION SYSTEMS AND SIDE FLASH PROTECTION

NOTE: Cognizant Offices of Responsibility for this chapter are AFCEC and AFSEC.

2-1 SCOPE

This chapter provides the criteria necessary for adequate protection of weapons from the energy of lightning strikes to new and existing nuclear weapons-capable facilities.

2-2 LIGHTNING PROTECTION SYSTEMS

2-2.1 Requirements

Lightning protection systems (LPS) for nuclear weapons-capable maintenance and storage facilities must meet the requirements of:

- Department of Defense Directive (DoDD) 6055.9E
- DoD 6055-09-M

Air Force LPSs must also comply with the following:

2-2.1.1 All facilities, except for underground facilities, will be provided with an LPS in accordance with National Fire Protection Association (NFPA) 780, AFI 32-1065, AFMAN 91-201, AFMAN 91-118, and UFC 3-520-01.

2-2.1.2 Underground facilities do not require an LPS. A counterpoise grounding system will be provided that meets the requirements of NFPA 70, AFI 32-1065, UFC 3-520-01, and AFMAN 91-201.

2-2.2 Design Approaches

LPSs will be designed to traditional LPS parameters. These systems must be designed to meet the requirements of AFI 32-1065, AFMAN 91-201, and NFPA 780. Traditional LPS design consists of the use of strike termination means, low impedance paths to ground, and earth electrode systems, coupled with bonding of all conductive penetrations into the protected facility, surge suppression, and side flash protection.

2-2.3 Special Documentation of LPS During Construction

During construction, establish clear, comprehensive documentation (including photographs) of the as-built installation of the LPS counterpoise, connection to ground rods, and interconnection to other systems. The photos must be taken while the counterpoise and connections are still exposed and visible prior to the placement of backfill or other coverage material. The installing contractor will include this documentation with the project as-built submittals with written certification of its accuracy. Provide Geographic Information System (GIS) data coordinates of photograph/connection locations and of the permanent reference points to enable base personnel to subsequently locate and uncover any connection point in the system. The

installing contractor will include this geospatial data with the project as-built submittals with written certification of its accuracy.

2-3 NUCLEAR WEAPONS SIDE FLASH PROTECTION REQUIREMENTS

2-3.1 Requirements

Side flash protection must be addressed as required in AFMAN 91-118 and AFMAN 91-201.

2-3.2 Lightning Side Flash Protection Policy for Nuclear Weapons Configurations

Apply standards in accordance with AFMAN 91-201. This is commonly referred to as the “seven-foot rule.”

2-3.3 Side Flash Protection Characterization

When the facility is determined under AFMAN 91-118 and AFMAN 91-201 as being subject to characterization under the seven-foot rule reduction, each bond will be given a unique identification number and be permanently tagged to display this number and the purpose of the bond, such as “FARADAY SHIELD BOND.” Document the location, configuration, and identity of each bond in a permanently maintained drawing file and with a geospatial record. Documentation must also include photos that show the connection method of the facility rebar forming the Faraday shield and the bonding of the penetrations.

2-3.3.1 Metallic Penetrations

Bonds will have a maximum resistance of 1 ohm across the connection to the Faraday shield to ground.

2-3.3.2 Alternative Measures for Communications and Data Circuits

When it is not practical to install suppression capable of interrupting the energy levels of the established 1 percentile lightning strike on communications and data circuits, alternatives must be in place to minimize the possibility of the lightning energy entering the facility through these conductors. Provide an evaluation and analysis of these alternatives to the Cognizant Offices of Responsibility for review and approval prior to implementation. Factors to consider in determining the practicality of installing the required surge suppression or the acceptability of alternatives will include at least:

- The quantity and associated costs of installing the required surge suppressors for the number of conductors involved
- The volume of space necessary to install the required suppression units
- The exposure of the portions of the system that are external to the Faraday shield to lightning strikes

- The impact on system performance if installing the required suppression units
- The protection provided using standard commercial surge suppressors manufactured for the application

2-3.3.3 Design of New Facilities

Design new facilities to successfully complete the characterization process prior to activating the facility.

2-3.3.4 Testing of New Facilities

Complete the characterization evaluation prior to activating the facility.

2-3.3.5 Testing of Existing Facilities

Complete the characterization evaluation prior to reducing the required separation distances less than those required by the seven-foot rule.

2-3.3.6 Documentation Retention

The facility will maintain documentation of the characterization process, including at least these items:

- Cognizant Offices of Responsibility requirements
- Testing methodology
- Transfer impedance evaluation results
- Bonding methodology
- Faraday shield bonding records
- Bonding length calculations
- Suppression alternatives and mitigation methods

This Page Intentionally Left Blank

CHAPTER 3 ELECTRICAL POWER AND LIGHTING SYSTEMS

NOTE: Cognizant Office of Responsibility for this chapter is AFCEC.

3-1 SCOPE

This chapter provides the criteria for electrical power and lighting systems necessary to protect weapons from electrical energy and provide emergency power and lighting to maintain essential operations without impacting mission requirements.

3-2 ELECTRICAL SYSTEMS

NOTE: Cognizant Office of Responsibility for this paragraph is AFCEC.

3-2.1 Design Criteria

Electrical systems for nuclear weapons-capable maintenance and storage facilities must be designed to meet the requirements of UFC 3-501-01, UFC 3-520-01, UFC 3-520-05, and UFC 3-550-01. Electrical systems will comply with NFPA 70 and Institute of Electrical and Electronics Engineers (IEEE) C2, *National Electrical Safety Code* (NESC), except as modified by UFC 3-501-01, UFC 3-520-01, or UFC 3-550-01. Electrical systems must comply with AFI 32-1062, AFI 32-1065, and AFMAN 91-201.

Facilities will be provided with an emergency power system to supply electrical power to all facility subsystems necessary to maintain the safety and security of nuclear weapons in accordance with AFI 32-1062.

3-2.2 Special Documentation of Grounding System

During construction, establish clear, comprehensive documentation (including photographs) of the as-built installation of the facility's grounding electrode system, connection to ground rods, and interconnection to other systems. The photos must be taken while the grounding electrode system and connections are still exposed and visible, prior to the placement of backfill or other coverage material. Include geospatial data from permanent reference points to enable base personnel to subsequently locate and uncover any connection point in the system. The installing contractor will include this documentation with the project as-built submittals with written certification of its accuracy.

3-2.3 Transformers

3-2.3.1 Indoors

Dry-type or liquid-filled transformers using FR3 dielectric fluid will be used for indoor applications. Transformers with hydrocarbon-based insulating oils will not be used indoors. Polychlorinated biphenyl (PCB) -filled transformers will not be used. The installation will comply with NFPA 70 requirements for transformers located inside buildings.

3-2.3.2 Separation Distances Outdoors

Outdoor transformers must meet the minimum separation distances from structures as specified in AFMAN 91-201 and UFC 3-600-01.

3-2.3.3 Cold Weather Conditions

Outdoor transformers, other than dry-type transformers, must contain insulating oils suitable for the cold weather conditions of the geographic location of the nuclear weapons-capable maintenance and storage area.

NOTE: Some dielectric fluids used as an alternative to hydrocarbon-based oils have significant changes in their dielectric properties when exposed to below-freezing conditions. Although these fluids may function appropriately in a continuously energized transformer that keeps the fluids warm, the transformer must always remain energized. It may not be possible to safely reenergize these transformers from an extended shutdown period in cold environments.

3-2.3.4 Testing

3-2.3.4.1 Transformers containing insulating mineral oils will be tested at least every five years to the specifications of the American Society for Testing and Materials (ASTM).

3-2.3.4.2 Testing frequency will be increased to at least annually for any transformer showing indication of abnormal mineral oil conditions or impending transformer breakdown.

3-2.3.4.3 Results of the testing will be evaluated to detect impending transformer breakdown and permit corrective maintenance before a transformer failure causes an unplanned power outage.

3-2.3.4.4 Testing must include at least the following:

- Dissolved gas-in-oil analysis (IEEE C57.104 and ASTM D3612)
- Oil testing, including:
  - Dielectric breakdown strength (ASTM D877 and ASTM D1816)
  - Neutralization (ASTM D974)
  - Interfacial tension (ASTM D971)
  - Color (ASTM D1524)
  - Moisture content (ASTM D1533)
  - Specific gravity (ASTM D1298)
  - Transparency and opacity (ASTM D1524)
  - Power factor (ASTM D924)

3-2.3.5 Spare Transformers

If the FHA report identifies critical transformers that, if lost, could have a severe impact to the facility mission, and if these transformers have a long replacement time (e.g., longer than 30 days), feasibility of procurement of a spare transformer must be evaluated by the installation commander and the results of the evaluation provided to HQ AFGSC.

3-2.4 Cabling

Cabling within nuclear weapons-capable maintenance and storage facilities must meet the specifications in UFC 3-520-01. The specific areas that must exceed the criteria within UFC 3-520-01 are addressed in paragraphs 3-2.4.1 through 3-2.4.3.

3-2.4.1 Combustible Cable Insulation and Jacketing Material

Combustible cable insulation and jacketing material will meet the fire and flame test requirements of IEEE 383. Meeting the requirements of IEEE 383 will not eliminate the need for other fire protection features as specified in this document.

3-2.4.2 Fiber Optic Cable Insulation and Jacketing Material

Fiber optic cable insulation and jacketing material will meet the fire and flame test requirements of IEEE 383.

3-2.4.3 Wire Management Systems

All wiring, including power, signal, communication, and control, will be installed in metallic conduit, except that metallic conduit is not required for those portions of underground conduit more than 50 feet (15.3 meters) from the facility (see AFMAN 91-201). Wireways or cable trays will not be used without approval of the Cognizant Office of Responsibility. Wireways and cable trays will not be used to run cables through the boundary of a blast containment zone.

3-2.4.3.1 Wireways

If the use of wireways is approved by the Cognizant Office of Responsibility, wireways will be made of noncombustible materials.

3-2.4.3.2 Cable Trays

If the use of cable trays is approved by the Cognizant Office of Responsibility, only metal will be used for cable trays (e.g., fiberglass-reinforced plastics are not permitted).

If the use of cable trays is approved by the Cognizant Office of Responsibility, cable tray fire breaks must be installed every 20 feet (6.1 meters) for vertical cable trays that rise over 30 feet (9.1 meters) unless they are protected with a fire-resistive coating. Access to cable shafts must be provided every 40 feet (12.2 meters), with the topmost

access within 20 feet (6.1 meters) of the cable shaft ceiling. Automatic sprinkler protection and smoke detection must be provided at the ceiling of the vertical shaft.

If the use of cable trays is approved by the Cognizant Office of Responsibility, horizontal cable trays must be provided with cable tray fire breaks every 50 feet (15.2 meters) unless the cable trays are protected with a fire-resistive coating.

3-2.4.3.3 Conduits

Conduits with an inside diameter larger than the trade size of 4 inches (standard metric size 103 millimeters) that pass through a fire barrier wall must be provided with an internal fire seal that has a fire-resistive rating equivalent to that of the fire barrier, and the internal fire seal will be permitted to be installed on either side of the barrier but in a location that is as close to the barrier as possible. Blast walls will also be provided with an explosion-proof conduit seal meeting the requirements of NFPA 70 for a Class I, Division 1 boundary.

Conduits with an inside diameter equal to or less than the trade size of 4 inches (standard metric size 103 millimeters) that pass through a fire barrier wall that is not also a blast wall will be provided with a fire-rated internal seal unless the conduit extends greater than 5 feet (1.5 meters) on each side of the fire barrier. In this case, the conduit opening will be provided with noncombustible material to prevent the passage of smoke and hot gases. The fill depth of the material packed to a depth of 2 inches (51 millimeters) will constitute an acceptable smoke and hot gas seal in this application.

Conduits with an inside diameter equal to or less than the trade size of 4 inches (standard metric size 103 millimeters) that pass through a fire barrier wall that is also a blast wall must be provided with an explosion-proof conduit seal meeting the requirements of NFPA 70 for a Class I, Division 1 boundary.

3-2.5 Battery Rooms

Battery rooms will comply with UFC 3-520-05. Loss of ventilation in a battery room will cause an alarm to be received at a constantly attended location (e.g., in the security control room or munitions squadron control). Exhaust air from the battery room is not required to be discharged directly to the outside for battery rooms located in underground (see Chapter 14) or restricted access/egress (see Chapter 17) areas of the facility.

3-2.6 Electrical System Analyses

Current electrical coordination, short-circuit, and load flow analyses for the facility will be maintained and kept with other facility records. These analyses will be used to ensure that proposed system modifications will not adversely affect system reliability.

3-2.7 Priority and Normal Electrical Power Loads

3-2.7.1 Priority Loads

Priority loads are designated as electrical system loads whose failure could result in loss of human life or serious injuries, or result in serious mission or security issues. Priority loads will be served by a permanent emergency engine generator power system. These loads include, but are not limited to:

- Security systems
- Entry control systems
- Maintenance area lighting and power
- Storage area lighting
- Shelter-in-place (refuge area) lighting and power
- Egress lighting
- Life safety systems
- Mechanical systems associated with a blast containment management system (BCMS)
- Fire alarm and reporting systems

3-2.7.2 Normal Loads

Normal loads are any electrical system loads not classified as a priority load.

3-2.8 Hardening of Electrical Power Systems

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC, AF/A4S, and AFSEC.

Electrical power systems located within and serving the controlled areas of nuclear weapons-capable maintenance and storage facilities will be required to be hardened against unauthorized access and intentional acts that may result in damage to the systems. Hardening must incorporate one or more of these features: location within secured facility boundaries, active surveillance, alarms, physical barriers, access controls, shock- or vibration-resistant equipment mounts, or other methods that will prevent unauthorized access and damage to the supply, distribution, or controls of the normal and emergency power systems.

3-2.9 Emergency Power Systems

Emergency power systems must be capable of supporting all priority loads (see paragraph 3-2.7). Emergency power system types include, at a minimum, a real property installed equipment (RPIE) permanent engine-driven electric generator. In

addition, other types of electrical power systems may be approved by the Cognizant Office of Responsibility, such as uninterruptable power supplies (UPS) that use batteries as an interim source of emergency power. The capacity of a new or modified emergency power system must be approved by AFCEC at the 65 percent design point per AFI 32-1062.

3-2.9.1 Fuel Systems for Emergency Engine Generator Power Systems

Fuel systems for emergency engine generator power systems, including on-premises supply, will be afforded the same level of hardness required for the emergency engine generator power system itself. Furthermore, the on-premises supply will be sufficient to enable the emergency power systems to support all priority loads for at least 72 hours.

3-2.9.2 Automatic Transfer Switch (ATS)

ATSs connected to normal power and emergency power supplies must utilize a two-source-design, bypass-isolation transfer switch configuration. The design must allow the transfer switch to be isolated for inspection, calibration, and maintenance without requiring electrical system shutdown. The design must allow any single circuit breaker to be isolated for inspection, calibration, and maintenance of equipment without requiring electrical system shutdown. Circuit breaker-type bypass isolation transfer switches must be utilized when electrical coordination is required.

3-2.9.3 Manual Transfer Switch

Manual transfer switches connected to normal power and emergency power supplies must be provided with isolation and bypass breakers to allow the manual transfer switch or any single breaker to be isolated for inspection, calibration, and maintenance without requiring electrical system shutdown.

3-2.9.4 Tertiary Connection Point

Facilities will be provided with a tertiary connection point for a mobile engine generator system independent of the permanently installed facility engine generator set. This connection point must be capable of sustaining all priority loads.

3-2.10 Surge Protection

3-2.10.1 Existing Facilities

For existing facilities, unless approved in the FHA, provide surge protection sized to reduce transient voltages, including those produced by lightning, to a harmless level on all entering or exiting metallic power, intrusion detection, communication antennas, and instrumentation lines in accordance with UFC 3-520-01. Install the surge protection as near as practical to where the conductor enters the interior of the facility.

3-2.10.2 New Facilities

For all new facilities, surge protection must meet the requirements in Chapter 2 in addition to the requirements in UFC 3-520-01, AFI 32-1065, and AFMAN 91-201.

3-3 TEMPORARY ELECTRICAL WIRING

Comply with NFPA 70 and the requirements listed in paragraph 10-5.

3-4 LIGHTING

NOTE: Cognizant Office of Responsibility for this paragraph is AFCEC.

3-4.1 Normal Lighting

Normal lighting will be provided as required by UFC 3-530-01.

3-4.2 Photoluminescent Egress Path Marking

Non-powered luminescent path markings must be provided for egress access routes in all areas that may contain nuclear weapons and leading to areas of refuge. Non-powered luminescent path markings will meet the performance requirements listed in NFPA 101. The installation of luminescent path markings will consider the amount of ambient lighting available throughout the day to ensure the level is sufficient to keep the marking charged in accordance with the manufacturer's requirements.

3-4.3 Photoluminescent Egress Door Marking

Egress doors in areas that may contain nuclear weapons and doors into areas of refuge must be marked with non-powered photoluminescent signs that are uniquely marked to avoid confusion with normal egress doors. These signs will be installed in accordance with the manufacturer's requirements. Particular attention must be given to the requirement for the level of background ambient lighting to ensure the signs remain charged. If this criterion cannot be met then electrically powered exit marking must be used (e.g., light-emitting diode [LED] signs).

3-4.4 Emergency Lighting

Emergency lighting will be provided for the egress access routes, security staging and operating locations, and firefighting staging and operating locations in accordance with NFPA 101. Emergency lighting for security staging and operating locations and firefighting staging and operating locations may be required to be at a higher level to meet operational requirements. The required illumination levels will be documented in the FHA. Self-testing emergency lighting fixtures will be installed in all areas except when limited by EMRE considerations. In those EMRE-limited locations, normal power to the emergency lighting will be provided by a dedicated electrical circuit to allow periodic testing without de-energizing other electrical equipment.

3-4.4.1 Testing

Permanently mounted emergency lighting units using batteries will be tested and inspected to verify proper operation based on the requirements of NFPA 101.

3-5 SECURITY LIGHTING

AF/A4SN serves as the Cognizant Office of Responsibility for this section.

Security lighting will be in accordance with DoD S-5210.41-M / AFMAN 31-108. The Cognizant Office of Responsibility will specify if the facility will be classified as a lighted site or unlighted site.

CHAPTER 4 STRUCTURAL SUPPORT FOR HOISTS, CRANES, AND LIFTING DEVICES

NOTE: Cognizant Offices of Responsibility for this chapter are AFCEC and AFSEC.

4-1 SCOPE

This chapter provides criteria to ensure facility structural elements are capable of supporting the safety design requirements for those hoists, cranes, and lifting devices that are subject to AFMAN 91-118. In general, this chapter provides structural criteria that exceeds the minimum requirements of UFC 1-200-01.

4-2 STRUCTURAL REQUIREMENTS

Ensure items such as load frames, hoist trolleys, test and storage stands, and handling units provide at least the design load capability. See AFI 91-203 for additional requirements. The design load is the rated load multiplied by a factor as required in AFMAN 91-118. This design load is considered the minimum load for design of the facility structural elements required to support the hoist, crane, or similar device.

This Page Intentionally Left Blank

CHAPTER 5 SECURITY SYSTEMS

NOTE: Cognizant Office of Responsibility for this chapter is AF/A4S.

5-1 SCOPE

This chapter provides criteria for the physical security necessary to meet the applicable DoD nuclear weapon system safety standards and considers systems design, access analysis, and other features to ensure the applicable standards have been met.

5-2 DESIGN CRITERIA

5-2.1 Minimum Physical Security Design

At a minimum, physical security design will be in accordance with DoD S-5210.41 / AFMAN 31-108.

5-2.2 Systems Engineering Perspective

Physical security system designs will be approached from a systems engineering perspective to identify potential impacts to the safety of nuclear weapons systems and to ensure compatibility (including an EMRE survey) with nuclear weapon systems.

5-2.3 Security Integration

Facility design must account for electronic security system (ESS) and Remote Targeting Engagement System (RTES) infrastructure requirements (e.g., wall penetrations, power/communications system requirements) to ensure construction and facility certification. See Chapter 7 for additional requirements.

5-3 SECURITY CONTROL ROOM COMPLEX

5-3.1 When Required

Provide a security control room complex when required by other chapters in this document.

5-3.2 Physical Separation

The security control room complex must be protected against exposure fire damage and will be separated from other fire areas of the plant by floors, walls, doors, and ceilings having a minimum fire resistance rating of 3 hours.

5-3.3 Windows

Windows in fire barriers for the security control room complex will be provided with a listed or approved fire shutter or automatic wall curtain having a minimum fire resistance rating of 3 hours.

5-3.4 Peripheral Rooms

Peripheral rooms supporting the security control room complex but within the same fire area must have an automatic water-based suppression system, and will be separated from the control room by noncombustible construction with a minimum fire resistance rating of 1 hour.

5-3.5 Ventilation System Openings

Ventilation system openings between the control room and the peripheral rooms must have automatic smoke or combination fire and smoke dampers installed that will close on operation of the fire detection or fire suppression systems.

5-3.6 Manual Firefighting

Manual firefighting capability will be provided for:

- Fires originating within a cabinet, console, or connecting cables
- Exposure fires involving combustible materials in the general surrounding room areas

A fire hose station will be installed immediately outside of the security control room (see Chapter 11).

5-3.7 Portable Fire Extinguishers

Portable Class A and Class C fire extinguishers will be located in the security control room. Clean agent or carbon dioxide (CO_2) portable fire extinguishers will be used for electrical hazards.

5-3.8 Smoke Detection

Smoke detectors will be provided in the control room complex, including the interior of electrical cabinets and consoles (see Chapter 11).

5-3.9 Breathing Apparatus

Provision for breathing air (e.g., dedicated ventilation system or breathing apparatus) for the security control room operators must be readily available, with a minimum 72-hour capacity.

5-3.10 Smoke Venting

Manually operated smoke venting of the security control room will be available to the control room personnel (see Chapter 11).

5-3.11 Electrical Cables

All electrical cables that enter the control room will terminate in the control room. No cabling will be routed through the control room from one area to another. Fully enclosed electrical raceways located in such under-floor and ceiling spaces, if over 1 cubic foot (0.03 cubic meter), must have automatic fire suppression internally. Area automatic fire suppression must be provided for under-floor and ceiling spaces if used for cable runs unless all cable is located in 4-inch (standard metric size 103 millimeter) or smaller steel conduit, or unless cables are fully enclosed within raceways internally protected by automatic fire suppression. See Chapter 3 regarding the use of wireways or raceways and for requirements for conduit seals.

5-3.12 Air Handling

Air handling functions will be ducted separately from cable runs. If cables are routed in under-floor or ceiling spaces, these spaces will not be used as air plenums for ventilation of the control room.

This Page Intentionally Left Blank

CHAPTER 6 FACILITY AUTOMATA AND SOFTWARE

NOTE: Cognizant Office of Responsibility for this chapter is AFSEC.

6-1 SCOPE

This chapter provides criteria for facility automata and software that is unique and developed or written specifically to control essential facility systems (EFS).

6-2 DEFINITION OF EFS

EFS are defined as those facility systems that directly impact the safe maintenance, handling, and storage of nuclear weapons (see AFMAN 91-118).

6-3 AUTOMATA AND SOFTWARE REQUIREMENTS

6-3.1 Software

All software (including facility security system software) that is unique and developed or written specifically to control EFS must meet the requirements of AFMAN 91-119.

6-3.2 Exempted Embedded Software and Firmware

Embedded software and firmware that is installed by the equipment manufacturer, is commercially available, is incapable of being modified without the manufacturer's authorization, and is common to all identical equipment without modification to the program itself does not fall under the requirements of AFMAN 91-119 and does not require separate nuclear safety certification for the software and firmware.

6-4 EFS DESIGN CONSIDERATIONS

6-4.1 Protection of EFS Interfaces

Control of EFS is nearly always accomplished by embedded software and firmware, or, in some instances, by unique software written specifically for that purpose. Typically, EFS are interconnected and provide integrated systems operations. Interfaces between EFS must be designed to ensure the nuclear surety environment is maintained. Design considerations may include, but are not limited to:

- Placing control panels and interface connections and equipment in locked, secure cabinets and placing the cabinets in a secure environment
- Ensuring the interconnections and equipment are passive
- Minimizing exposure of interconnection wiring to unauthorized access (i.e., enclosing in conduit)

6-4.2 Protection from Power Fluctuations

All software and computer system hardware for EFS must be robust and insensitive to normal power fluctuations, spikes, and dips. Hardware will be provided with supplemental power such as battery backup or UPS, or be connected to a power supply that has reserve capabilities.

CHAPTER 7 CONTAINMENT AND ISOLATION FEATURES

NOTE: Cognizant Office of Responsibility for this chapter is AFSEC.

7-1 SCOPE

This chapter provides criteria and requirements for hazard classification and containment and isolation features for the purpose of limiting the spread of contamination and consequential damage to weapons, areas within the facility, and the environment.

NOTE: Fire protection (e.g., automatic sprinklers) and fire detection (e.g., fire alarm systems) are intended to be configured to coincide with required containment zones and with corresponding heating, ventilation, and air conditioning (HVAC) zones. This will reduce penetrations through the barrier walls by the fire protection equipment and also improve the survivability of the systems (refer to Chapters 5 and 11). Life safety issues related to containment are discussed in subsequent chapters of this document.

7-2 REFERENCES

Guidance for hazard classification and containment and isolation system features, including blast, fire, and contamination, is provided in the following documents:

- AFMAN 91-201
- AFMAN 91-118
- DoD 6055.09
- DOE O 440.1B
- UFC 3-340-02
- DDESB Memorandum “Minimum Requirements to Validate Explosive Safety Protective Construction,” dated 21 October 2008
- DDESB Technical Paper 16, “Methodologies for Calculating Primary Fragment Characteristics,” Revision 4, dated 2 August 2012

7-3 DESIGN FEATURES

Facility containment and isolation design features shall include, as a minimum:

- The ability to contain and/or isolate the maximum credible event (MCE), also referred to as the design basis accident (government-furnished information). If the MCE does not involve a blast scenario, measures are still required to prevent spread of contamination

- The ability to mitigate contamination of facilities, weapons, and the environment by limiting radiation transport mechanisms such as explosions, blasts, and fires
- Incorporation of containment and/or isolation zones for the purpose of limiting the spread of contamination and consequential damage to the facility, stored critical assets, or to the environment
- Blast-resistant barriers separating blast zones (if required) that are capable of withstanding explosions commensurate with the maximum credible event of the zone as described in paragraph 7.5
- Compatibility between factors such as site requirements, blast zones and/or containment zones, overpressures, isolation requirements, HVAC, penetrations, doors, and drainage requirements
- Appropriate filtering capable of removing radioactive airborne materials from exhaust air (not including tritium gas).
- The capability for venting or isolating the facility with respect to environmental air
- The capability for monitoring the interior of the facility for specific types of radiation
- Integration with other systems, such as HVAC, fire alarm, and security, to achieve a coordinated and managed environment.
- The ability to accomplish remote control of containment/isolation systems by specific authorized personnel in the facility control center

7-4 CONTAINMENT SYSTEM ELEMENTS

7-4.1 Containment Zones

Containment zones shall be arranged to coincide with HVAC zones and fire zones (as separated by fire barrier walls) to the maximum extent possible (also see Chapter 11).

7-4.2 Radiological Filter Systems

A radiological filter system will be provided to protect against contaminated air being released to the outside environment without suitable filtering. The radiological filter system may be designed to serve one or more containment zones.

7-4.3 Plumbing Valves

7-4.3.1 Remotely air-operated, quick-acting isolation ball valves will be added in the construction to aid in contaminant control in air systems. Remotely air-operated quick-acting isolation ball valves shall be placed on domestic water lines, sewer lines,

fuel lines, and other plumbing lines to prevent contaminating particles from reaching the water source. These valves shall be configured to fail in the closed position.

7-4.3.2 These valves shall be integrated with the radiation monitoring system**.**

7-5 BLAST CONTAINMENT/ISOLATION SYSTEM ELEMENTS

When the MCE includes a potential blast, the elements of this section apply.

NOTE: Not all facilities require the use of blast containment and isolation features. Contact the Cognizant Offices of Responsibility for the applicability of this chapter to a new or existing facility.

7-5.1 Blast Containment and Isolation System Elements

Blast containment and isolation system elements include, but are not limited to, blast containment zones, blast-resistant barriers (i.e., walls, floors, and ceilings), blast doors, blast valves, HVAC systems, and plumbing systems.

7-5.2 Blast Containment Zones

Blast containment zones shall be arranged to coincide with HVAC zones and fire zones (as separated by fire barrier walls) to the maximum extent possible (also see Chapter 11). Blast containment zones shall be constructed to be as gastight as possible. The construction of the area shall meet the gastight criteria, e.g., reinforced concrete, steel blast doors, pipes, valves, and seals. Each area shall be designed such that both during and after an explosive event the gastight capability of the area will not be less than that required of the seals of the blast doors (see paragraph 7-5.4)

7-5.3 Blast-Resistant Barriers

Blast-resistant barriers, such as walls, floors, and ceilings, will be designed to resist blast loads in any area subject to accidental explosion. Concrete cracking shall be limited to discontinuous hairline-type cracks such that the migration of contaminants through these cracks will be severely limited. Spalling on the protected side of the wall shall be limited, and the integrity of the wall shall be maintained considering the combined fragment impact and blast pressure commensurate with the maximum credible event. Penetrations of the blast-resistant barriers shall be limited to only those services necessary to serve the blast zone encompassed by the blast-resistant barriers. The penetrations will be protected by blast valves, explosion-proof seals, or other such means necessary to maintain the integrity of the barrier. Where sprinkler piping penetrates a blast barrier, other means of protection shall be considered to ensure that the system maintains NFPA code compliance, such as zoning the sprinkler systems such that a single sprinkler system would service a single blast zone.

NOTE: When necessary to prevent subsequent criticality events following a blast the sprinkler system inside the blast zone may need to be isolated simultaneously with the operation of the blast valves.

7-5.4 Blast Doors

7-5.4.1 Configuration

The preferred configuration is a single-leaf swing blast door; however, other configurations are acceptable (e.g., vertical sliding blast doors) if the blast doors will provide the required protection and blast containment.

7-5.4.2 Construction

The doors shall be constructed of material that will provide the required blast resistance characteristics. When required, the door shall also be constructed of material that will provide the required delay characteristics. There shall be specific test data or modeling, as approved by the Cognizant Office of Responsibility, which demonstrates the capability of the material selected to meet the required blast resistance and, if required, also delay characteristics.

7-5.4.3 Blast Resistance

The door material shall be of sufficient thickness and strength to withstand the blast pressures imposed on it. At a minimum, it shall resist the blast pressure associated with the maximum credible event of the area being protected.

7-5.4.4 Door Operators

The door operating system shall include a stored energy system that shall be capable of operating through not less than two complete cycles without relying on external power. Furthermore, upon loss of power, the door operating system shall automatically cycle the doors to a failsafe position that meets the applicable security and safety requirements.

7-5.4.5 Door Control

NOTE: Cognizant Offices of Responsibility for this paragraph are AFSEC and AF/A4S.

Controls for the door operators shall be compatible with the physical security requirements mandated by the applicable criteria of DoD S-5210.41-M / AFMAN 31-108. A manual means of opening the door from either side shall be provided.

7-5.4.6 Seals

Blast doors shall be provided with seals around the perimeter of the door. Blast door systems, including the seals, shall be gastight before and after an explosive detonation and fragmentation impact. The maximum leakage permitted around the seals is 1 standard cubic foot (28.3 liters) of air per hour per 1 linear foot (30.5 centimeters) of seal. Each blast door system shall be designed with the inherent capability to test leakage around the seals with the door and seals in place and without separate equipment or special procedures.

7-5.4.7 Hinge Requirements

The hinge design capacity shall be at least 150 percent of the calculated load to which the hinge will be subjected, including each component and mounting hardware. The life expectancy of the hinges shall be not less than 20 years, with a normal number of operating cycles per day based on a conservative evaluation of past facility operations (for existing facilities) or anticipated operations (for new facilities). The hinges shall allow the door to be adjusted in both the x- and y-axis of the door plane, which shall not require specialized tools, hinge disassembly, machining of hinge or door surfaces, cutting or welding, or any other such special procedures.

7-5.4.8 Equivalency to Fire Doors

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC and AFSEC

In most cases, blast doors will be within fire-rated walls. Blast doors are not listed by nationally recognized testing laboratories as fire doors; however, based on their massive construction, they likely meet most of the listing agencies' criteria for a fire door. In cases where a blast door is within a fire barrier wall, a qualified fire protection engineer shall evaluate the door and determine if it meets the intent and function of a fire-rated door. The evaluation should include at least the types and amount of combustible materials used in construction of the door, a qualitative consideration of the door’s thermal transfer characteristics, the means of mounting the door into the blast wall and the door frame, and the size and means of sealing gaps around the door when closed. The evaluation shall be reviewed and approved by the Cognizant Office of Responsibility. If the evaluation proves that the door is not equivalent to a fire-rated door, other means shall be provided to ensure that the rating of the wall is maintained. Such configurations can include a fire-rated vestibule with fire-rated doors.

7-5.4.9 Communication Capability

Capability for communication by personnel shall be present on both sides of the blast doors.

7-5.4.10 Emergency Operation of Vertical Blast Doors

NOTE: Cognizant Offices of Responsibility for this paragraph are AFSEC and AF/A4S

If vertical blast doors are used, they shall be evaluated and configured such that in the event of an explosion within the space, the damaged door can be operated from the exterior of the room by an emergency means (e.g., providing the door with the necessary hardware to permit the use of a forklift to lift the door after an explosive event).

7-5.5 Blast Valves

NOTE: Cognizant Office of Responsibility for this paragraph is AFSEC

Blast valves shall be installed on HVAC hardened ducts and plumbing piping that penetrate blast-resistant barriers. These valves and their installation shall prevent over- and under-pressure blast waves from reaching the supply and exhaust airstreams. These valves shall be self-contained and capable of automatically closing upon an explosive event.

7-5.6 HVAC Systems

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC and AFSEC

7-5.6.1 Zones

HVAC zones will be arranged to coincide with blast zones and fire areas to the maximum extent possible (refer to Chapter 11).

7-5.6.2 Valves

Blast valves and gastight butterfly valves will be used to isolate each ventilation air pipe crossing blast-resistant barriers. Butterfly valves (Wafer-Sphere®) shall be the quick-acting, gastight isolation type that are air driven, spring closed to isolate a zone immediately after an internal blast. Butterfly valves shall be triggered by blast detectors located within each contamination zone.

7-5.6.3 Hardened Duct

Hardened duct will be used for any duct penetrating a blast-resistant barrier or for any duct extending through a blast zone. Duct that remains entirely within a blast zone is not required to be a hardened duct.

7-5.6.4 Individual Air Handling Components

Each blast-protected containment zone will be served by individual air-handling components designed so that any contaminated air generated within that containment zone shall not be able to enter any containment zones or HVAC zones. Operation of any single blast containment zone shall not impair operation of the ventilation system for other containment zones or HVAC zones in the facility.

7-5.6.5 Ventilation Air Plenums

Ventilation air shall be supplied and exhausted through the blast wall from the mechanical plenums in either steel ducts or welded Schedule 40 steel pipes. The use of flexible ducts shall be permitted only with the approval of the Cognizant Office of Responsibility.

7-5.6.6 Containment of Blast Byproducts

The various weapon handling areas of the main facility will each be designed to contain the byproducts of an accidental explosion entirely within themselves until the byproducts can be safely vented outside.

7-5.7 Penetrations

Penetrations through blast resistant barriers include electrical conduit, hydraulic piping, compressed air piping, domestic water piping, floor drains, and water suppression piping. This list is not exhaustive. Penetrations will be limited to only those services necessary to serve that particular blast zone.

Wireways and cable trays shall not be permitted to cross the boundary of a blast containment zone (refer to Chapter 3).

7-5.8 Fire Sprinkler System

Remotely air-operated quick-acting isolation ball valves shall be placed on sprinkler lines for individual blast zones when it is necessary to prevent subsequent nuclear criticality events following a blast. These valves shall be configured to fail in the closed position. These valves shall also close at the same time as the blast valves. The valves shall be electrically supervised by the fire alarm system and initiate a trouble signal when closed.

7-5.9 Electrical

Explosion-proof conduit seals shall be provided for each conduit run passing through the boundary of a blast containment zone (refer to Chapter 3). Wireways and cable trays are not permitted to cross the boundary of a blast containment zone (refer to Chapter 3).

This Page Intentionally Left Blank

CHAPTER 8 STUDIES AND DOCUMENTATION

8-1 SCOPE

This chapter provides criteria and requirements for conducting the specified studies in sufficient detail to ensure the safety of weapons and to provide baseline documentation to the Cognizant Office of Responsibility. The unique requirements for fire safety, including fire suppression systems and life safety components, are a key issue; however, principles of fire safety applicable to other types of facilities that handle special nuclear materials are available within certain national consensus standards and within the Department of Energy (DOE). Such principles were considered in developing this chapter.

The principles of facility safety, life safety, and fire protection required for nuclear weapons-capable maintenance and storage facilities were developed by collecting and refining criteria from DoD fire protection guidance, munitions safety guidance, and national consensus fire safety standards, including NFPA 801, NFPA 804, and NFPA 805. Also considered were DOE criteria, including DOE O 420.1C, DOE O 440.1B, and DOE-STD-1066-2012.

NOTE: Specific and unique fire protection and life safety criteria have been developed for nuclear weapons-capable maintenance and storage facilities. These criteria would not be appropriate for most DoD buildings. Consequently, the criteria in this document will take precedence in case of conflict with UFC-3-600-01.

8-2 APPLICATION

Studies will be accomplished on all nuclear weapons-capable maintenance and storage facilities as described in the following sections. Following the initial study efforts, if any proposed facility change or modification involves, affects, or impacts systems covered by the studies, they will be updated to include the effect of the modification on the study conclusions and recommendations.

These studies, new or revised, will be used to support or maintain facility certification actions. Facility certification actions will be accomplished in accordance with AFI 63-125.

8-3 FIRE HAZARD ANALYSIS (FHA)

NOTE: Cognizant Offices of Responsibility for this paragraph are AFNWC and AFCEC.

The purpose of the FHA is to comprehensively and quantitatively assess the risk from a fire originating from within individual fire areas in an Air Force facility to ascertain if Air Force fire safety objectives are being met.

8-3.1 FHA References

8-3.1.1 The FHA should include appropriate requirements and guidelines from the most current editions of the following publications:

- UFC 3-600-01
- NFPA 801
- AFMAN 91-201
- AFI 91-202
- Department of Defense Instruction (DoDI) 6055.06
- DoDD 6055.9E
- DoD 6055-09-M
- NFPA 550
- Society of Fire Protection Engineers (SFPE) *Handbook of Fire Protection Engineering*
- NFPA 13
- NFPA 14
- NFPA 72
- NFPA 101
- NFPA *Fire Protection Handbook*

NOTE: Other NFPA standards not included in this list should be considered, when appropriate.

8-3.1.2 With respect to nuclear weapons safety, security, and control, the FHA must be guided by the concepts and requirements contained in the most current edition of applicable publications, including, but not limited to:

- AFI 90-201
- Air Force Policy Directive (AFPD) 91-1
- AFI 91-101
- AFI 91-102
- AFI 91-103
- AFI 91-107
- AFI 91-116
- AFMAN 91-118
- DoDD 3150.02

- DoDM 3150.02
- DoD S-5210.41-M / AFMAN 31-108

8-3.2 Qualifications of FHA Personnel

8-3.2.1 The FHA will be accomplished by one or more qualified engineers.

8-3.2.2 At least one qualified engineer will be a fire protection engineer.

8-3.2.3 At least one qualified engineer will be an engineer who must meet one of the following conditions:

- At least five years of experience in design, construction, operations, or maintenance for civilian-owned or government-owned nuclear reactors or other nuclear facilities.
- At least five years of experience in design, construction, operations, or maintenance of US Navy nuclear-powered reactors.
- At least five years of experience in the design, commissioning, operations, maintenance, or de-commissioning of nuclear weapons.

8-3.2.4 A qualified engineer is defined as an individual meeting one of the following conditions:

- A registered professional engineer (P.E.) who has passed the engineering written examination administered by the National Council of Examiners for Engineering and Surveys (NCEES) in his or her area of expertise.
- An engineer who is not registered but can demonstrate a minimum of 10 years of documented engineering experience in his or her area of expertise, and who has been specifically approved by the Cognizant Offices of Responsibility to serve in the capacity of a qualified engineer.

8-3.2.5 The qualified engineer(s) will be supported by an engineering firm having experience in performing FHAs for a wide range and types of facilities and hazards—especially nuclear hazards. The engineering firm will have employees or ready access to individuals who are knowledgeable of nuclear facility operations, maintenance procedures, equipment design, training of facility personnel, and firefighting procedures. The engineering firm will have employees or ready access to individuals who are knowledgeable of issues unique to nuclear weapons-capable maintenance and storage facilities (e.g., security requirements versus life safety requirements).

8-3.2.6 The qualified engineer(s) accomplishing the FHA will obtain support from other appropriate engineering disciplines as needed, including, but not limited to, fire

protection, nuclear, electrical, mechanical, civil, structural, chemical, and systems engineers.

8-3.2.7 The qualified engineers accomplishing the FHA will consult with appropriate government or national laboratory representatives who are knowledgeable of weapon design and weapon system responses to ensure potential fires will not exceed weapon safety limits.

8-3.3 General FHA Considerations

8-3.3.1 Fire Areas

The focus of the FHA will be the individual fire areas. Fire areas are those areas of the facility that are bounded by fire barriers. Where a facility is not subdivided by fire-rated construction, the exterior walls and roof of the facility will define the fire area.

8-3.3.2 Conflicts

The FHA will identify specific sections of national consensus codes and standards that might be considered in conflict with the nuclear safety and security requirements of the facility. These will be documented within the FHA and alternative measures to achieve fire protection objectives will be recommended where appropriate.

NOTE: Conflicts between the specific requirements of this document and national consensus codes and standards are not required to be documented in the FHA.

8-3.3.3 Air Distribution Systems

The FHA must consider fire propagation and the potential for fire-induced radiological dispersal through the facility's air distribution system. These effects will be considered for both the normal operating mode of the air distribution system as well as operation in alternate modes, including system shutdown that may result from the fire.

8-3.3.4 Flammable and Combustible Materials

The quantity and associated hazards of flammable and combustible materials that can be expected to be found within the fire area will be factored into the analyses. Consideration must also be given to the presence of normal as well as unexpected transient combustible materials associated with the function and operation of the facilities.

8-3.3.5 High-Bay Locations

FHAs for high-bay locations will consider the effects of smoke and hot gas stratification that may occur at some intermediate point below the roof or ceiling. Similarly, the effect of smoke movement through doors and dampers held open by fusible links must be addressed. The impact of the height to automatic fire suppression and detection systems will also be evaluated. A fire model may be necessary to evaluate the response time of the suppression and detection systems at the ceiling of high-bay areas.

8-3.3.6 Natural Hazards

The FHA must consider natural hazards (e.g., earthquake, flood, wind, lightning, wild land fires) as related to their impact on fire safety within the facility.

8-3.3.7 Hostile Act Scenarios

The FHA will consider certain hostile act scenarios (defined by AF/A4SN) and their impact on fire-induced radiological dispersal.

8-3.3.8 Fire Models

Tools that will be used in the development of an FHA include fire models such as those developed by the National Institute of Standards and Technology (NIST); however, the use of such models is predicated on their being conservative and validated. Air Force acceptance of individual models will be considered on a case-by-case basis.

8-3.3.9 Fire Protection: Defense-In-Depth

Fire protection criteria are based on the principle of defense-in-depth. This document supplements and, in some cases, modifies the fire protection requirements of UFC 3-600-01 to meet the unique mission requirements of these facilities. Defense-in-depth is achieved when a balance of each of the following elements is provided in the facility:

- Preventing the initiation of fires
- Rapidly detecting all fires that do occur
- Controlling and promptly extinguishing fires to limit damage, personnel injury, and consequences to acceptable levels
- Providing a level of fire protection for structures, systems, and components so that a fire that is not promptly extinguished will not prevent essential facility functions from being performed and weapon safety limit from being exceeded

8-3.3.10 Life Safety Objectives

The FHA will analyze if life safety objectives are achieved, including:

- Any occupants that are not within the affected fire area are protected to a level such that they can safely exit the facility
- Occupants within the fire area must be protected to a level such that they have a reasonable expectation to safely exit the facility or be able to safely stay within a designated area of refuge
- Life safety configurations must also be arranged to provide adequate protection for essential and emergency response personnel

8-3.4 Determination of FHA Update for Existing Facilities

For existing facilities, the approved FHA will be evaluated by the owning facility program office no later than the end of the fifth calendar year after the date of the last FHA. If no changes have occurred to a maintenance or maintenance and storage facility's baseline configuration or maintenance concept of operations then the owning facility program office may defer the requirement for an FHA update for one additional five-year period by documenting that "no changes have occurred to the facility's baseline configuration or maintenance concept of operations" and update the existing approved FHA with that determination in a memorandum for record signed by the facility program office manager. If no changes have occurred to a storage-only facility's baseline configuration or storage concept of operations then the owning facility program office may continue to defer the requirement for an FHA update for additional five-year periods by documenting that "no changes have occurred to the facility's baseline configuration or storage concept of operations" in a memorandum for record signed by the facility program office manager. If it is determined that changes have occurred to the facility's baseline configuration then a FHA update will be required by a qualified engineer (see paragraph 8-3.5.3). Additionally, an updated FHA may be required when configuration changes are made to the existing facility's structure or systems if the changes have, or may have, impacted the facility's compliance with the fire prevention and fire protection requirements of this document. When updating the FHA for existing facilities, the qualified engineer(s) will contact facility personnel who are knowledgeable of facility maintenance, operations, equipment, training, and procedures. Additionally, the qualified engineer(s) will contact nuclear certification personnel at AFNWC/NTS, HQ AFGSC/A4C, HQ AFGSC/A4W and AFSEC/SEW.

8-3.5 FHA Content

8-3.5.1 Design FHA

During the design phase, the FHA for a new or existing facility must include an assessment of the risk from fire and related hazards (e.g., direct flame impingement, hot gases, smoke migration, firefighting water damage and drainage) in relation to existing or proposed fire safety features to ensure the facility can be safely controlled and stabilized during and after a fire. The Design FHA will be initiated early in the design phase to ensure an acceptable level of protection is being incorporated into the design. The Design FHA will be updated throughout the design phase as significant design changes occur that may affect any individual fire area. This Design FHA will serve as the basis document for the Post-Construction FHA. The level of detail necessary for an acceptable Design FHA is directly related to the complexity of the facility, the scope of the proposed design changes (for existing facilities), and the potential risk to the public and facility personnel. The scope and content of a Design FHA will be limited to those issues that are relevant to the facility. The Design FHA must comprehensively, qualitatively, and quantitatively accomplish the following:

8-3.5.1.1 Assess the potential and probability for fires within each new or modified fire area within a facility.

8-3.5.1.2 Evaluate the effects of possible fires and related perils (e.g., direct flame impingement, hot gases, smoke migration, firefighting water damage) in relation to the capabilities of fire safety features to ensure fire events can be safely controlled and stabilized for each new or modified fire area.

8-3.5.1.2.1 The evaluation will assume all potentially vulnerable systems will be damaged within the fire area. Acceptable exceptions to this assumption are water-filled steel pipes, tanks, and similar components of superior structural integrity with welded fittings and adequate pressure relief. Passive fire protection features, such as blank fire-rated walls, floors, and ceilings, and continuous fire-rated cable wraps, are assumed to remain viable.

8-3.5.1.2.2 The evaluation will determine the effect of possible fires when any single automatic fire detection or fire suppression system is not available to perform its intended function. Active fire protection features, such as fire dampers, window shutters, and self-closing fire doors in fire barrier walls, will also be evaluated using the criteria of a single fire protection feature not being available.

NOTE: This non-availability may result from an equipment failure (non-fire related) or because the fire occurs during a time the system has been disabled for routine maintenance.

If redundant automatic fire protection systems are provided in the area, only the one system or component that causes the most vulnerable condition need be assumed to be unavailable. Passive fire protection features, such as blank fire-rated walls, floors, and ceilings, and continuous fire-rated cable wraps, are assumed to remain viable.

8-3.5.1.3 Model the thermal parameters of fire events for each new or modified fire area that may contain a nuclear weapon and compare the results to weapons safety screening levels. Non-classified weapons safety screening levels (available from the government) must be used in the modeling.

8-3.5.1.4 Evaluate the impact of the facility fire protection and prevention system on nuclear criticality following the fire events and blast events (if applicable) for each new or modified fire area.

8-3.5.1.5 Model the fire events in each new or modified fire area designated as underground or limited egress areas and evaluate the safety to life for occupant egress, including the ability to use designated areas of refuge.

8-3.5.1.6 Establish the probability of resultant injuries to occupants for fire events within each new or modified fire area within a facility.

8-3.5.1.7 Establish the probability of damage to buildings or equipment for fire events within each new or modified fire area.

8-3.5.1.8 Evaluate the impact on mission continuity from the fire events for each new or modified fire area.

8-3.5.1.9 Quantify the costs related to fire damage to buildings or equipment from the fire events for each new or modified fire area.

8-3.5.1.10 For new facilities, determine the fire event creating the maximum credible fire loss (MCFL) and maximum possible fire loss (MPFL) for all analyzed fire events with respect to facility function as well as value.

8-3.5.1.10.1 In determining the MCFL, the basic assumption will be that automatic fire protection and suppression systems function properly as designed but that manual fire suppression activities are not possible for the first 30 minutes of the fire event in any controlled-access areas of the facility.

8-3.5.1.10.2 In determining the MPFL, which might be used by the government to assess the need for fire protection systems, the basic assumption will be that there is no automatic or manual fire suppression.

8-3.5.1.10.3 The loss determination for MCFL and MPFL must include all direct and indirect costs associated with the fire and clean-up operations. Clean-up costs due to radioactive contamination will be based on service-specific historical data or estimated from other historical data (e.g., data used by the DOE).

8-3.5.2 Post-Construction FHA

Prior to operation and certification of a new or modified facility, a Post-Construction FHA must be accomplished. The Post-Construction FHA must include at least the following:

- Evaluation of the as-built construction to ensure the validity of the Design FHA.
- Assessment of facility programs for minimizing the effects of fire on personnel, facilities, equipment, and mission.
- Assessment of organizational response, requirements, capabilities, training, and procedures as related to fire protection and response.
- Assessment of the adequacy of portable fire protection and prevention systems and equipment.

8-3.5.3 Updated FHA for Existing Facility

When required (see paragraph 8-3.4), an updated FHA for an existing facility will include at least the following:

- Evaluation of the design changes to the facility since the last FHA and the potential effects of those changes on nuclear surety and life safety.
- Evaluation of the potential effects of operational changes in weapons handling, maintenance, or storage since the last FHA.
- Assessment of any changes made to organizational response, requirements, capabilities, training, and procedures, as related to fire protection and response, since the last FHA.
- Assessment of any changes to facility programs intended to minimize the effects of fire on personnel, facilities, equipment, and mission since the last FHA.
- Assessment of any changes in portable fire protection and prevention systems and equipment since the last FHA.

8-3.6 Additional Considerations

The FHA must examine compliance and noncompliance in existing and post-construction facilities and will include these elements:

- Recommendations for correction or mitigation of noncompliance; the recommendations must identify specific mitigation strategies for the noncompliance (e.g., the need for a fire suppression system, the type of fire suppression needed, and the water requirement)
- For any noncompliance, the FHA will include a risk assessment of the noncompliance in case the recommendations are not approved for implementation
- Recommendations for improvement of features in compliance
- For recommendations for improvement of features in compliance, the FHA will include a qualitative risk assessment in case the improvement is not approved for implementation

Once approved by the Cognizant Offices of Responsibility, the results of the FHA will take precedence over previous or conflicting design criteria.

8-3.7 FHA Report

As a minimum, the FHA report must contain and document these items:

- All specific evaluations, modeling, analyses, considerations, and other requirements as detailed in paragraph 8-3 of this document
- A description and assessment of general facility construction, including the type, location, ratings (in hours), and construction of fire barriers

- A description and assessment of fire detection and fire suppression systems, equipment, and related components (including, but not limited to, HVAC systems)
- A description and assessment of fire hazards from adjacent facilities and construction, as appropriate
- An inventory of all priority electrical loads (e.g., fire alarm, emergency power) within the fire area that are susceptible to fire damage, including mechanical and electrical systems, which must function effectively during and after a fire event; this will also include an assessment of the adequacy and protection afforded these priority electrical loads
- Critical transformers that, if lost, would have a severe impact on the facility mission
- Emergency lighting illumination levels for security staging and operating locations and firefighting staging and operating locations
- An evaluation of the potential for flame spread, fire spread, and smoke development due to cabling within the facility with respect to the requirements in Chapter 3
- An assessment of fire response and fire response plans, including organization, capabilities, training, and requirements
- An itemization of areas and issues of noncompliance, including the comprehensive and qualitative risk assessment of the noncompliance items if not accomplished
- An itemization of areas and issues in compliance that are recommended as candidates for improvement
- Recommendations for correction or mitigation of noncompliance
- Recommendations for action on candidates for improvement
- A description of any critical process equipment
- A description of any high-value property
- The potential for a toxic, biological, or radiological incident due to fire
- Life safety considerations
- Emergency planning
- Recovery potential
- Exposure to fire potential and the potential for fire spread between two fire areas

8-3.8 Implementation of FHA Results

Project requirements for existing buildings and design adjustments for new facilities are developed based on the results of the FHA or other analyses performed on existing structures and approved by the Cognizant Offices of Responsibility. To the greatest extent practical, the level of protection for existing and new structures should be identical; however, implementing current levels of protection into all existing structures will not be feasible. In these cases, a technical evaluation or other approved analysis can provide to the Cognizant Offices of Responsibility a suitable justification for the acceptability of the existing configuration.

8-4 EMRE SURVEY

NOTE: Cognizant Office of Responsibility for this paragraph is AFSEC.

An EMRE survey is a comprehensive assessment of the EMRE within each facility to ensure that exposures of weapons systems to the EMRE from all equipment installed or used within the facility, individually and collectively, does not result in an overall EMRE that exceeds the weapons stockpile-to-target sequence (STS) levels. The EMRE survey will meet or exceed the requirements and guidelines of the most current edition of AFMAN 91-118, Section 2I, paragraph 2.45.9, and Section 4H, paragraphs 4.8.1.7 and 4.8.1.10 (see paragraph 8-4.1 of this document for other references).

NOTE: An EMRE survey is typically funded by the facility occupant.

8-4.1 EMRE References

The EMRE survey must meet or exceed the requirements and guidelines of the most current edition of these publications. (Other publications may also apply.)

- AFMAN 91-201
- DoDD 6055.9E
- DoD 6055-09-M

The EMRE survey will consider the concepts and requirements with respect to nuclear weapons safety, security, and control as contained in the most current edition of these publications. (Other publications may also apply.)

- AFI 90-201
- AFPD 91-1
- AFI 91-101
- AFI 91-102
- AFI 91-103
- AFI 91-107

- AFI 91-116
- AFMAN 91-118, Section 2I, paragraph 2.45.9, and Section 4H, paragraphs 4.8.1.7 and 4.8.1.10
- DoDD 3150.02
- DoDM 3150.02

8-4.2 Qualifications of Survey Personnel

EMRE calculations (straw-man analysis) during project design should be performed by the electrical engineer on the project.

EMRE surveys for background or at facilities will be accomplished by the 85th Engineering Installation Squadron (EIS) Specialized Engineering Flight, Keesler Air Force Base, Mississippi.

8-4.3 Survey Frequency

8-4.3.1 New Facilities

On all new facilities, a background EMRE survey will be accomplished at the beginning of the design process at the site where the facility is to be built.

During design, analyze anticipated EMRE emitters using straw man data to project anticipated EMRE levels and to adjust facility design, equipment selection, and procedures as necessary to reduce EMRE levels. In these cases, the survey will consist of an analysis of anticipated EMRE emitters using straw man data to project EMRE levels.

8-4.3.2 Post-Construction Survey

Conduct a complete EMRE survey upon activation of the facility to ensure actual levels do not exceed maximum permitted EMRE values.

8-4.3.3 Existing Facilities

The EMRE survey will be accomplished on any existing facility when configuration changes are made to the facility or facility systems or changes are made in the tools and equipment that impact the EMRE. The EMRE survey will help ensure the overall EMRE, as a result of such changes, does not exceed the weapon's STS levels.

8-4.3.4 Renewal

The EMRE survey will be updated on all facilities no later than the end of the fifth calendar year after the date of the last EMRE survey.

8-4.4 EMRE Survey-Specific Requirements

8-4.4.1 EMRE Survey Elements

The EMRE survey must:

8-4.4.1.1 Accomplish discrete tests of all unintentional EMRE emitters used in close proximity to critical equipment within the facility. These unintentional EMRE emitters include, but are not limited to, fluorescent lighting; motors; hand tools; computers and monitors; communication equipment such as phones and intercoms; entertainment devices such as televisions, MP3 players, and radios; and fire alarm control panels.

8-4.4.1.2 Accomplish discrete tests of all intentional EMRE emitters used in close proximity to critical equipment within the facility. These intentional EMRE emitters include, but are not limited to, computers using wireless devices or networks; radio transmitters; motion sensors; and “lossy” antenna distribution systems.

8-4.4.1.3 Measure ambient levels in representative areas and measure specific classes of emitters used in close proximity to critical equipment.

8-4.4.1.4 Perform an external ambient survey outside of the facility to obtain an overview of the typical EMRE levels encountered in the nearby area.

8-4.4.1.5 Evaluate and analyze the results to determine compliance with AFMAN 91-201. Identify compatibility anomalies and make recommendations for mitigating these anomalies.

8-4.4.2 EMRE Survey Report

As a minimum, the EMRE survey report must contain and document these items:

- A detailed list of test equipment with calibration dates
- A detailed list of the equipment tested (including locations, if appropriate for the equipment)
- A testing strategy and survey plan
- A graphical comparison of EMRE from tested equipment in comparison to appropriate STS curves
- A simulated composite EMRE environment to determine the maximum practicable level that could be expected
- Conclusions on any findings and recommendations for corrective measures

8-5 FACILITY CHARACTERIZATION

NOTE: Cognizant Office of Responsibility for this paragraph is AFSEC.

8-5.1 General Requirement

Facility characterization will meet the criteria and requirements of Chapter 2.

NOTE: Facility characterization may be accomplished when deviation from the seven-foot rule as defined in AFMAN 91-201 is proposed. Facilities that have not been characterized must comply with the seven-foot rule. Any deviation from the seven-foot rule requires specific approval of the Cognizant Office of Responsibility.

8-5.2 Specific Requirements

8-5.2.1 Facility characterization will be accomplished:

- By the 85th EIS Specialized Engineering Flight, Keesler Air Force Base, Mississippi
- On all new facilities upon completion of the facility construction
- On existing facilities when specifically approved by the Cognizant Office of Responsibility
- On any facility that has been previously characterized and when configuration changes to the facility or facility systems are made that may have impacted the facility characterization requirements of this document. A qualified electrical engineer will determine if a total or partial revision to the previous facility characterization is required.

8-5.2.2 Facility characterizations will be updated on all facilities no later than the end of the tenth calendar year after the date of the last facility characterization.

8-5.2.3 On facilities that have been characterized, comply with the requirements in AFMAN 91-201, including the requirements for periodic maintenance and inspection. This must include retesting the Faraday shield, bonding, and surge suppression features.

8-6 FIRE DEPARTMENT BASELINE NEEDS ASSESSMENT

NOTE: Cognizant Office of Responsibility for this paragraph is AFCEC.

8-6.1 Baseline Needs Assessment

The base fire department must have a baseline needs assessment that establishes the minimum required capabilities of base firefighting forces. This includes minimum staffing, apparatus, facilities, equipment, training, fire pre-plans, off-site assistance requirements, and procedures. Information from this assessment will be incorporated into the site emergency plan. Baseline needs assessments are approved by the Cognizant Offices of Responsibility.

8-6.2 Updates

Baseline needs assessments for firefighting forces are periodically performed through independent assessors who are regarded as experts in the field. Frequencies of updates are not formally established but updates are performed when there is a significant change in base or facility mission, size, or hazards.

8-7 FIRE PREVENTION PROGRAMS

NOTE: Cognizant Office of Responsibility for this paragraph is AFSEC.

Nuclear weapons-capable maintenance and storage facilities will implement fire prevention programs. Such programs can be part of an overall base fire prevention program or be established as a specialized program for the facility.

At a minimum, the fire prevention program must include:

- Fire department inspections
- Combustible loading limitations and inspections
- Storage criteria
- Use and handling of flammable and combustible liquids
- Use of heat-producing appliances
- Hot work and hot work permits
- Roofing operations permits
- Use of fuel-fired heaters and equipment

8-8 FIRE PROTECTION IMPAIRMENTS AND DEFICIENCIES

NOTE: Cognizant Office of Responsibility for this paragraph is AFCEC.

Nuclear weapons-capable facilities will have implemented fire protection impairment and deficiency programs. These programs can be part of an overall base impairment and deficiency program or be established as a specialized program for the facility.

The programs must include the identification, tagging, and tracking of impaired equipment, and the determination of compensatory fire protection and prevention measures.

The programs will comply with AFI 32-10141.

8-8.1 Application

The programs must apply to all active fire protection systems, including automatic sprinkler systems, fire detection systems, filter plenum fire suppression, and special hazard suppression systems. The application of the program to passive fire protection systems, including fire barriers, dampers, lightning protection components, and fire extinguishers, and to any work activities not directly related to active fire protection systems, may be included at the discretion of the facility manager unless otherwise directed by the Cognizant Offices of Responsibility.

8-8.2 Tracking Requirements

A fire protection system impairments and deficiencies program will be used to track and trend all system failures, planned outages, minor system discrepancies, or removal of systems from active service. Systems removed from service for the purpose of facility demolition must be tracked until demolition completion.

8-8.3 Impairment Coordinator

The facility user will designate an impairment coordinator to track impairments and deficiencies.

CHAPTER 9 FIREFIGHTING GUIDANCE

NOTE: Cognizant Office of Responsibility for this chapter is AFCEC.

9-1 SCOPE

This chapter provides criteria and requirements for developing detailed pre-fire plans. Pre-fire plans are also known as pre-incident plans and the terms can be used interchangeably.

9-2 DEVELOPMENT OF PRE-FIRE PLANS

Detailed pre-fire plans will be developed for all facility areas. The plans will detail the fire area configurations and fire hazards along with any nuclear weapon-related components and fire protection systems and features. Pre-fire plans will be reviewed and, if necessary, updated at least every two years. Pre-fire plans will be available in the security control room.

In developing a schedule for pre-fire plans, these items will be considered:

- Potential life safety hazard
- Facility size and complexity
- Value
- Mission importance
- Presence of hazardous materials
- Susceptibility to natural phenomena

The emergency response organizations must be trained to the pre-fire plan program as well as the individual pre-fire plans.

9-3 ELEMENTS OF PRE-FIRE PLANS

The physical elements of a pre-fire plan are addressed in paragraphs 9-3.1 through 9-3.9.9.

9-3.1 Internal Site Conditions

9-3.1.1 Construction and Building Features

Include information on these features:

- Construction, floor construction, construction of interior walls, suspended ceiling assemblies, raised floors, concealed spaces, windows for rescue, confined space, and fire resistance of structural members
- Area and height

- Building services, including utilities (electric, transformers, emergency power, domestic water, compressed and liquefied gases, steam, and fuels)
- Building features: the structural integrity of walls, roofs, and floors, including added live and dead loads; indications of deterioration and structural weakening and other conditions that would impact fire spread; ability of responding personnel to access the building; and the potential for falling debris

9-3.1.2 Occupant Considerations

The number and type of occupants in a facility will have a substantial impact on the pre-fire plan. Critical information to be gathered includes the expected number of occupants and their duties within the facility.

9-3.1.3 Life Safety Considerations

Life safety considerations are a priority that must be addressed to permit responding emergency service personnel to assist immediate and safe evacuation of facility personnel. Considerations must also be included on the actions of the facility security personnel and their duties during emergency events.

Unique life safety egress facility configurations must be documented within the pre-fire plan.

9-3.2 External Site Conditions

9-3.2.1 Fences

The height and construction of fences will be noted. Security measures for these fences will also be included.

9-3.2.2 Exposures

The grounds surrounding the facility will be evaluated to identify buildings, structures, equipment, and storage that could be exposed by an incident.

9-3.3 Communications Impact

Include the results of a functional test of the communications system as it will be used in an emergency. This information is critical for many of the unique facilities across the Air Force.

Data regarding communications impact that will be recorded include the following:

- Interference or poor coverage as a result of construction or radio system design, including coverage in below-grade and shielded areas, interiors of large structures, and the upper floors of high-rise buildings
- Assignment of radio channels
- Other supplemental communications available within or external to the facility

9-3.4 Security Data

Information about security measures will be included to ensure prompt ingress to the facility at all times on a need-to-know basis. Comply with security classification requirements for the installation.

9-3.5 Personnel Interactions

The interaction between firefighting personnel and the facility and external security personnel must be addressed within the pre-fire plan. In a number of situations, fire forces and security forces may have conflicting missions during an emergency. These situations must be addressed within the pre-fire plan so agreements between the two groups may be established in advance. It is also advisable to practice drills that implement these agreements to ensure they can be carried out in the proper manner.

9-3.6 Defend-in-Place Methods

Defend-in-place methods to be used because complete evacuation is either impossible or impractical will be noted within the pre-fire plan. Comply with security classification requirements for the installation.

9-3.7 Hazards Information

9-3.7.1 Hazardous Materials Coordinator

If a facility has an individual or department that is responsible for maintaining material safety data sheets (MSDS) and inventories of hazardous materials, the pre-fire plan will contain information on contacting this individual. If a facility or base has an internal computer-based hazardous materials system, means to access this system will be detailed within the plan.

9-3.7.2 Special Hazards

Special hazards within the facility will be documented. These hazards may include flammable and combustible liquids, explosives, toxic agents, radioactive materials (ionizing radiation and contamination), reactive chemicals, electrical and mechanical hazards, and special hazards.

9-3.8 Incident Operations

The plan will address the standard response to the facility and the incident command system as it applies to the building.

9-3.9 Fire Protection Systems Information

Information on fire protection systems (detection and suppression) will be determined in the development of the pre-fire plan. The required information is addressed in paragraphs 9-3.9.1 through 9-3.9.9.

9-3.9.1 Information on Primary Water Supply

Included will be the required fire flow for the building based on criteria developed in the approved FHA. Evaluation of the water supply may require testing of the water system or obtaining information from the installation engineering branch.

9-3.9.2 Fire Department Connections (FDC)

Data concerning the FDCs will be included within the plan. The information required is the physical location, areas covered, and the type of system supplied.

9-3.9.3 Fire Pumps

Data regarding facility fire pumps will be provided that includes the location, type of driver, capacity, water source, operation (automatic, manual, or remote manual), areas served, and contact information for the department responsible for maintenance and operation during an emergency.

9-3.9.4 Fire Hydrants

Data regarding facility fire hydrants will be provided that includes the location and type of each hydrant, number and diameter of each outlet, size of the water main location, and the approximate flow at 20 pounds per square inch gauge (psig) (138 kilopascals gauge).

9-3.9.5 Automatic Sprinkler Systems

Data concerning automatic sprinkler protection will be documented, including the type of system (wet, dry, pre-action), hazard classification of the system and occupancy, location of all controlling valves for the system, location and identification of all risers, location of audible flow alarms, and extent of the sprinkler coverage.

9-3.9.6 Standpipe System

Data concerning standpipe systems will be documented that includes the type of system, location and size of outlets, pressure available at the hose outlets, water supply, location of isolation valves, and the location and identification of all risers.

9-3.9.7 Protective Signaling Systems

Data for the facility fire alarm systems will include the method of system activation, areas of coverage, location of the fire alarm control panel and the remote fire alarm panels, type of detectors, any public address system or voice alarm capability, and the method and extent of occupant notification. Information on the DoD-required mass notification system (MNS) will be included, including details on the configuration of the system (e.g., combination system with the fire alarm system or stand-alone system).

9-3.9.8 Special Hazard Protection Systems

Data for special hazard fire protection systems that will be included within the pre-fire plan include the type of system, hazard, or area protected by the system, location of control panels, activation method, personnel hazards of the protective agent (if any), and method and extent of occupant notification.

9-3.9.9 Smoke Management

Data regarding any smoke management systems will be included. This may include the type of system, location of the areas served by the system, and location of the primary control panel for the system. This will also include any portable ventilation equipment or systems (see Chapter 12).

9-4 ROBOTIC FIREFIGHTING RESPONSE VEHICLES

The use of robotic firefighting response vehicles located within areas capable of maintaining or storing nuclear weapons may be considered when necessary to reduce the response time to an incident. Use of such vehicles is not a general practice and must not be implemented without prior approval of the Cognizant Office of Responsibility. Requests to use robotic firefighting methods will evaluate operational impacts such as training, staffing levels, initial and recurring equipment costs, required supplies and costs, environmental impacts, EMRE, and other related issues.

This Page Intentionally Left Blank

CHAPTER 10 TEMPORARY INTERIOR CONSTRUCTION

NOTE: Cognizant Office of Responsibility for this chapter is AFSEC.

10-1 SCOPE

This chapter provides criteria and requirements for temporary interior construction. For the purposes of this document, “temporary” is defined as any structure in place for less than 12 months. Any temporary construction features not covered by this chapter will, by default, be required to meet the criteria of permanent construction.

10-2 FIRE-RETARDANT WOOD

If wood is used for interior temporary construction, the wood must be noncombustible, limited-combustible, or fire-retardant, pressure-impregnated wood. Fire-retardant coatings are not acceptable on walking surfaces or surfaces subject to mechanical damage. Industrial safety personnel will be contacted prior to coating scaffolding with a fire-retardant coating since the coating may have an effect on the wood that must be evaluated.

10-3 FIRE-RETARDANT TARPAULINS

The use of interior temporary coverings will be limited to special conditions for which interior temporary coverings are necessary, e.g., contamination control structures (interior tents). They must be constructed of approved fire-retardant plastics or tarpaulins and meet the testing requirements of NFPA 701.

10-4 FIRE EXTINGUISHERS

All interior temporary construction must have the appropriate type and size of portable fire extinguisher, spaced in accordance with NFPA 10.

10-5 TEMPORARY ELECTRICAL WIRING

The potential for ignition of flammable materials will be minimized by requiring that all temporary electrical wiring:

- Be kept to a minimum
- Be suitable for the location
- Be installed and maintained in accordance with NFPA 70 or IEEE C2, as appropriate
- Be arranged so energy can be isolated by operation of a single switch
- Be arranged so energy can be isolated when not needed

10-6 TEMPORARY HEATING APPLIANCES

10-6.1 Types Permitted

Only safely installed, approved, electrically powered heating devices will be used in all locations. All heating devices must comply with AFI 91-203.

10-6.2 Automatic Shutdown Feature

Heating devices must be situated so they are not likely to overturn and will be provided by the factory with an automatic shutoff feature per AFI 91-203.

10-6.3 Monitoring and Maintenance

Temporary heating equipment, when used, will be monitored and maintained by properly trained personnel.

10-7 PLASTIC SHEATHING

If plastic sheathing is used for temporary construction or containment structures (plastic tents), it must meet the testing requirements of NFPA 701.

CHAPTER 11 FIRE PROTECTION SYSTEMS

NOTE: Cognizant Office of Responsibility for this chapter is AFCEC.

11-1 SCOPE

This chapter includes the criteria and requirements for fire detection, fire suppression, fire alarm, and mass notification systems (MNS) applicable to nuclear weapons-capable maintenance and storage facilities.

11-2 GENERAL REQUIREMENTS

Fire protection systems will be designed in accordance with UFC 3-600-01, except as modified in this document.

Fire suppression and fire detection systems will be configured to coincide with the blast zones (if provided) and HVAC zones unless approved by the Cognizant Office of Responsibility.

NOTE: This requirement is intended to reduce the number of penetrations through the blast walls by the fire protection equipment and may also improve the survivability of the fire protection systems.

11-3 LISTED EQUIPMENT

Fire protection equipment must be listed or approved for its intended service by a nationally recognized testing laboratory (NRTL), except for certain equipment for which such listing or approval is not practical because of the unique nature of nuclear weapons-capable facilities. For example, a blast door or security door, by nature of its construction, might serve adequately as a fire door but has never been listed or approved for such a purpose. In these cases, the use of non-listed or non-approved equipment will be approved by the Cognizant Office of Responsibility.

11-4 WATER SUPPLIES

11-4.1 Two Independent Sources

At least two independent sources of water must be provided, each of not less than 300,000 gallons (1,135,600 liters). A water supply independent of the potable water supply is not required for water-based fire suppression systems unless so specified in the FHA. Examples of independent water supply systems include:

- Base/municipal potable water system capable of supplying not less than 300,000 gallons (1,135,600 liters) in one elevated tank (can count as one independent source of water)

- Base/municipal potable water system capable of supplying not less than 300,000 gallons (1,135,600 liters) in each of two or more elevated tanks (can count as two independent sources of water)
- Base/municipal potable water system supplied by a reservoir exceeding 1,000,000 gallons (3,785,400 liters), with at least two independent supply connections from the reservoir to the potable water system (can count as two independent sources of water)
- One elevated water tank with a capacity of 300,000 gallons (1,135,600 liters) (can count as one independent source of water)
- Several smaller elevated water tanks with a combined capacity of 300,000 gallons (1,135,600 liters) supplying the same water main (can count as one independent source of water)
- Two elevated water tanks, each with a capacity of 300,000 gallons (1,135,600 liters) (can count as two independent sources of water)
- Two ground-level water tanks, each with a capacity of 300,000 gallons (1,135,600 liters), with dedicated fire pumps (can count as two independent sources of water)
- Pressure tanks internal to the facility (e.g., when the FHA permits a tank volume of less than 300,000 gallons [1,135,600 liters]).

11-4.2 Interconnection

The water supplies must be interconnected such that if fire pumps are used, they can take suction from any source. A failure in one source must not cause both sources to fail.

11-4.3 Replenishing Supply

The water source for replenishing the supply for fire protection in at least one tank must be capable of restoring the tank within an eight-hour period.

11-4.4 Multiple Water Supplies

If multiple water supplies are used, each water supply must be connected to the fire main by a separate connection that is arranged and valve-controlled to minimize the possibility of multiple supplies being simultaneously impaired. Generally, the two supplies should be connected such that they are hydraulically remote from each other.

11-4.5 Water Supply Limitations

Provide a water supply that will not be susceptible to bio-fouling, scaling, microbiologically induced corrosion (MIC), or sedimentation. The tanks must not be supplied by an untreated, raw water source.

11-5 FIRE SUPPRESSION SYSTEMS

11-5.1 Water-Based Fire Suppression Systems

An automatic water-based suppression system will be provided in all areas of the facility and must be designed to control and suppress a fire based on the fire hazard in each area. This analysis will be included in the FHA. Refer to Chapter 12 for fire suppression systems installed to protect filters that collect combustible material.

NOTE: Based on the hazards generally found within nuclear weapons-capable maintenance and storage facilities, it is expected that a wet-pipe type of automatic sprinkler system or water mist fire suppression system will be needed in most areas, with a dry-pipe type of system used in those areas subject to temperatures below or approaching freezing (e.g., truck bays, earth-covered magazines). Firefighting foam-based fire suppression systems are expected to be required in special areas such as refueling areas or areas where the FHA identifies hazards from combustible or flammable liquids.

11-5.1.1 Hardening of System

Suppression systems in weapon handling areas must be hardened against possible internal or external damage to the building (e.g., breach control valves, redundant sprinkler headers). See Chapter 7 for additional requirements for individual blast zones when it is necessary to prevent subsequent nuclear criticality events following a blast.

NOTE: Appendix B provides guidance on the selection and design of hardened fire protection systems.

11-5.1.2 Calculations

Domestic water distribution systems that also serve fire protection requirements will be designed to simultaneously meet the calculated fire protection demand (e.g., sprinklers and hose streams) and the peak domestic demand. When not otherwise identified, the peak domestic demand will be calculated as 2.5 times the calculated average daily demand plus appropriate special demands. The domestic water distribution system will be capable of meeting this combined demand at a minimum residual pressure of 20 pounds per square inch (psi) (137.9 kilopascals) at ground elevation for a period of not less than two hours.

11-5.1.3 Looped System

Water-based fire suppression systems must be looped with at least two independent means of water supply into the fire suppression system. The supply points must be separated so that external damage to one supply point (e.g., mechanical damage by a backhoe) must not simultaneously damage other supply points. This separation will be no less than 20 feet (6.1 meters).

11-5.1.4 Piping Under Buildings

Water supply piping must not be located under buildings. The water distribution piping to a building may penetrate the building slab at a location as close as practical to the building's exterior wall.

11-5.1.5 Sectional Control Valves

Sectional control valves will be provided to isolate damaged portions of the looped fire suppression system while permitting undamaged portions to remain in service.

11-5.1.6 Outside Screw and Yoke (OS&Y) Valve

In addition to an exterior isolation valve, each system must be equipped with an approved OS&Y gate valve or other approved interior isolation valve.

11-5.1.7 Location of Risers and Alarm Valves

Sprinkler system risers and alarm valves will be located as close as practical to a building or fire zone entry point intended for access by responding emergency service personnel.

11-5.1.8 Independence

The piping serving each zone of an automatic water-based suppression system must be independent from piping to other zones.

11-5.1.9 Alarm Annunciation

Each fire suppression system will be equipped with approved alarming devices that will annunciate an alarm in a constantly attended area (e.g., installation fire department) and will activate internal and external fire alarms in the facility.

11-5.1.10 Domestic Water

Within the facility, domestic water will be supplied to the greatest extent practical by a separate service line and not be designed as a combined fire protection and potable water service or as a combined process and potable water service. Where combined fire and domestic-process water systems are necessary (e.g., to reduce penetrations through blast containment walls), the distribution piping must be provided with isolation valves so domestic or process systems can be isolated from the fire protection system.

11-5.2 Foam Fire Suppression Systems

Foam fire suppression systems designed in accordance with NFPA 11 will be used where flammable or combustible liquids are of significant concern and in other areas as specified in the FHA.

11-5.3 Water Mist Systems

Water mist systems designed in accordance with NFPA 750 will be used in nuclear weapons-capable maintenance and storage facilities in lieu of automatic sprinklers when specified in the FHA.

11-5.4 Fire Suppression Systems for Specific Hazards

11-5.4.1 Enclosed Vehicle Loading Docks

Enclosed vehicle loading docks must be provided with automatic fixed water-based suppression systems. Automatic sprinkler systems must be designed for a density of no less than 0.30 gallon per minute per square foot (12.2 liters per minute per square meter). The area of the entire vehicle loading dock or 5000 square feet (465 square meters) (whichever is less) will be considered the sprinkler design area unless otherwise approved by the Cognizant Office of Responsibility.

NOTE: Generally, it is expected that these enclosed vehicle loading docks will be protected with dry-pipe sprinklers.

11-6 SEISMIC CAPABILITIES

The water supply systems will be capable of supplying water to automatic water-based fire suppression systems, standpipes, and hose stations in all areas designated for the transportation, storage, and maintenance of nuclear weapons following a design basis earthquake.

11-7 SUPPLY MAINS AND HYDRANTS

11-7.1 Yard Fire Main Loop

11-7.1.1 Design and Installation

An underground yard fire main loop will be designed and installed in accordance with NFPA 24. The loop will be sized to accommodate emergent mission requirements.

Design of the pipe and provision for water treatment must consider the potential for tuberculation and MIC. Means for easily inspecting and flushing the systems will be provided.

11-7.1.2 Isolation

Means will be provided to isolate portions of the yard fire main loop for maintenance or repair without simultaneously shutting off both supplies to fixed fire suppression systems and fire hose stations. Approved visually indicating sectional control valves such as post-indicator valves will be provided to isolate portions of the main for maintenance or repair. Isolation valves must be configured so that no more than five connections (sprinkler systems, hydrants, or hose connections) are impaired at any one time.

11-7.1.3 Headers

Each automatic suppression system and standpipe will be supplied from two physically separated headers supplied by the yard fire main loop. Schedule 40 or thicker steel piping and fittings meeting the requirements of American Society of Mechanical Engineers (ASME) B31.1 will be used above ground for the headers (up to and including the first valve) supplying the automatic suppression systems where such headers are part of the seismically analyzed hose standpipe system. Where provided, such headers will be considered an extension of the yard main system. Each sprinkler and standpipe system will be equipped with an OS&Y gate valve or other listed or approved shutoff valve.

11-7.2 Hydrants

11-7.2.1 Location

Hydrants will be located every 250 feet (76 meters) apart on the yard main system when the yard loop also supplies water to above-ground buildings that support the underground facility. Valves will be installed to permit isolation of outside hydrants from the fire main for maintenance or repair without interrupting the water supply to automatic or manual fire suppression systems.

11-7.2.2 Compatibility

Threads compatible with those used by local fire departments will be provided on all hydrants.

11-8 STANDPIPES AND HOSE STATIONS

11-8.1 Standpipe Locations

Class I dry standpipes designed in accordance with NFPA 14 will be provided within each fire area and within each enclosed vehicle loading dock.

11-8.2 Standpipe Connections

Fire department connections to the standpipes will be located near the locations of entry to the fire area that will be used by emergency responders. Connections will be

provided in stairwells in multi-story facilities. The size and type of threads on the standpipe connections must be compatible with the equipment used by the fire department. A fire hose station will be installed immediately outside of the security control room (see Chapter 5).

11-8.3 Hose Station Locations

Hose stations or a mobile means of providing hose and associated equipment, such as hose carts or trucks, will be provided in all fire areas designated for the transportation, storage, or maintenance of nuclear weapons.

11-8.4 Water Flow Rate and Nozzle Pressures

Water flow rate and nozzle pressures as determined in the FHA must be provided to hose stations.

NOTE: Hose station pressure reducers may be needed for the safety of fire department personnel as specified in the FHA.

11-8.5 Hose Nozzles

The types of hose nozzles to be located at each hose station will be based on the fire area's particular fire hazards and on the operational requirements of the fire department. Hose nozzles must have shutoff capability and be able to control water flow from fully open to fully shut. Hoses and nozzles may be omitted at locations where so documented in the FHA.

NOTE: The commonly used combination spray and straight-stream nozzle should not be used in areas where a straight stream could cause unacceptable damage or create an electrical hazard to firefighting personnel. Approved electrically safe, fixed fog nozzles should be provided at locations where high-voltage electrical shock hazards could exist.

11-9 VALVES

11-9.1 Inspection and Supervision

All fire protection water supply and fire suppression system control valves must be supervised by one of the following methods:

- Electrical supervision with audible and visual signals in the security control room or other suitable constantly attended location.
- Locking valves in their normal position when so documented in the FHA. Keys will be controlled and made available only to authorized personnel.
- Sealing valves in their normal positions when so documented in the FHA. This option will be utilized only where valves are located within fenced areas or under the direct control of approved facility personnel.

11-9.2 Operators

Operators (e.g., hand wheels) of valves that require manual manipulation must be readily accessible. If the hand wheel is located more than 5 feet (1.5 meters) above the floor or ground, the hand wheel must be provided with either a chain operator or a permanent platform. The platform must be of sufficient size to allow the operator to safely perform the manual action.

11-10 FIRE PUMPS

Fire pumps are not required for nuclear weapons-capable maintenance and storage facilities when reliable means of meeting the fire protection demands are provided and when the omission of the fire pumps is approved by the Cognizant Office of Responsibility.

11-10.1 Design and Installation

Fire pumps must be designed and installed in accordance with NFPA 20 to ensure that at least100 percent of the required flow rate and pressure are available, assuming failure of the largest pump or pump controller. The flow requirements will be met based on 100 percent of the capacity of the pump (not 150 percent as is commonly used in other types of facilities).

11-10.2 Configuration

11-10.2.1 Multiple Facilities

Fire pumps may be configured to serve more than one nuclear weapons facility when approved by the Cognizant Office of Responsibility.

11-10.2.2 Number of Pumps

For maximum reliability, three fire pumps will be provided so that two pumps meet the maximum demand plus hose streams. When approved by the Cognizant Office of Responsibility, use of two fire pumps is an acceptable alternative, provided either of the fire pumps can supply the maximum demand plus hose streams at no more than 120 percent of the fire pump’s rated capacity.

11-10.2.3 Flow Testing

Fire pumps will be configured to permit ease of flow testing. Provide a test discharge header that is piped back into the tank or provide piping to a location where the test nozzles can be flowed with minimal operational impact (e.g., into a pond or open field).

11-10.2.4 Separation of Pumps

Each pump and its driver and controls must be separated from other fire pumps by 2-hour-rated fire barriers and also from the rest of the facility by 2-hour-rated fire barriers.

11-10.2.5 Manual Shutdown

Fire pumps must be provided with automatic start but only manual shutdown. The manual shutdown must be located at the pump controllers. A remote manual start is permitted in addition to the automatic start.

11-10.2.6 Sectionalizing Valves

Individual fire pump connections to the yard fire main loop will be provided and separated with sectionalizing valves between connections such that loss of one fire pump connection to the loop can be isolated without isolating the other pumps.

11-10.2.7 Jockey Pump

A method of automatic pressure maintenance of the fire protection water system (commonly referred to as a jockey pump) must be provided independent of the fire pumps.

11-10.2.8 Alarm Annunciation

Means will be provided to immediately notify a constantly attended location (e.g., installation fire department) of the operation, failure, or receipt of supervisory signals of the fire pumps.

11-11 GASEOUS FIRE SUPPRESSION SYSTEMS

An automatic total flooding or local application gaseous fire suppression system may be installed to supplement but not replace the required automatic water-based suppression system. The requirement for such a system must be approved by the Cognizant Office of Responsibility for the protection of unique situations or to address unique hazards. The system will be designed and installed in accordance with NFPA 2001.

11-11.1 Annunciation

Operation of gaseous fire suppression systems will annunciate an alarm in a constantly attended location.

11-11.2 Ventilation System Design

Ventilation system design must prevent space over-pressurization during agent injection and provide adequate sealing to prevent loss of agent.

11-11.3 Disarming Device

Provisions for locally disarming automatic gaseous suppression systems will be secured and maintained under strict administrative control. Activation of the disarming device will initiate a supervisory alarm on the fire alarm control panel.

11-11.4 Prohibited Systems

Installation of carbon dioxide, Halon 1211, and Halon 301 systems are prohibited.

11-11.5 Global Warning Potential

Procurement of hydrofluorocarbon gases with high global warming potential are to be avoided, when possible, in accordance with Federal Acquisition Regulations.

11-12 SMOKE DETECTION SYSTEMS

An approved smoke detection system is required in all areas of a facility where nuclear weapons are stored, inspected, or maintained in addition to the automatic suppression system. Also, smoke detection will be provided in the security control room complex (see Chapter 5), sleeping rooms, computer or information technology rooms, and in the vicinity of the fire alarm control panel (FACP), in addition to the automatic suppression system. An approved smoke detection system is not required in support areas (e.g., offices, mechanical spaces, corridors) where an automatic water-based fire suppression system has been provided (see paragraph 11-5). Appliances and other smoke detection equipment will be installed in accordance with NFPA 72 and UFC 3-600-01.

NOTE: An air-aspirating type of ultrasensitive smoke detection (i.e., very early smoke detection) or other smoke detection technology (e.g., open-area light-scattering smoke detection) should be used in areas designated as approved for the storage of nuclear weapons when EMRE requirements can be met (refer to Chapter 8).

11-13 FIRE ALARM SYSTEMS AND MASS NOTIFICATION SYSTEMS (MNS)

A combination system serving as the fire alarm system and MNS will be installed in accordance with UFC 3-600-01 and UFC 4-021-01.

11-13.1 Voice Communication

Means will be provided to allow a person observing a fire at any location in the facility to quickly and reliably alert the appropriate personnel using voice communication to the security control room or other suitable constantly attended location.

11-13.2 Signal Transmission

Signals will be transmitted to a constantly attended location from which required notifications and emergency response can be initiated. All signals must be permanently recorded in accordance with NFPA 72. These signals will include fire, trouble, and supervisory signals, and include at least the following:

- Actuation of any fire detection device
- Actuation of any fixed fire suppression system
- Actuation of any manual fire alarm station

- Starting of any fire pump
- Actuation of any supervisory device or signal
- Indication of alarm system trouble condition

11-13.3 Fire Department Notification

Means will be provided to promptly notify the fire department of any fire emergency in such a way as to allow the fire department to determine an appropriate course of action.

11-13.4 Security Forces Notification

Means will be provided to promptly notify the security forces of the nuclear weapons-capable maintenance and storage facility of any fire emergency in such a way as to allow the security forces to determine an appropriate course of action.

11-14 PORTABLE FIRE EXTINGUISHERS

See Chapter 5.

This Page Intentionally Left Blank

CHAPTER 12 HEATING, VENTILATION, AND AIR CONDITIONING (HVAC)

NOTE: Cognizant Office of Responsibility for this chapter is AFCEC.

12-1 SCOPE

This chapter includes the criteria and requirements for HVAC applicable to nuclear weapons-capable maintenance and storage facilities.

12-2 DESIGN CONSIDERATIONS

12-2.1 Design of the System

HVAC systems for nuclear weapons-capable maintenance and storage facilities must be designed to meet the requirements of UFC 3-400-02, UFC 3-401-01, and UFC 3-410-01.

Suitable design of the ventilation system can limit the consequences of a fire by preventing the spread of the products of combustion to other fire areas. The design of the ventilation system must provide a means to ventilate, exhaust, or isolate the fire area as necessary, and consideration must be given to the consequences of failure of the ventilation system due to fire, causing loss of control for ventilating, exhausting, or isolating a given fire area.

12-2.1.1. The capability to ventilate, exhaust, or isolate is particularly important in underground nuclear weapons-capable maintenance and storage facilities to ensure the habitability of rooms and spaces that will remain occupied throughout the fire emergency (e.g., security control rooms). Areas of refuge also require particular attention since these are designated locations designed to help occupants survive for a specified period of time if they become trapped by a fire.

12-2.1.2. Automatic damper closure or shutdown of ventilation systems must be designed based on considerations of nuclear safety, nuclear security, and the life safety of personnel.

12-2.1.3. Facilities will be provided with 100 percent redundant chiller systems for those areas of the facility where lack of cooling could result in loss of human life or serious injuries, or result in serious mission or security issues.

12-2.1.4. In addition to the normal HVAC function, ventilation systems will also protect against chemical-biological (CB) agents when required by the Cognizant Offices of Responsibility.

12-2.2 Balanced Air Differentials

Ventilation of a nuclear weapons-capable storage facility involves balanced air differentials between building or blast zones, comfort ventilation, and heat removal from areas where heat is generated by equipment. This need for ventilation also includes fire

area isolation and smoke removal equipment, and may include equipment for high efficiency particulate air (HEPA) filtering of radioactive particulates.

12-2.3 Ventilation Design Standards

The design standards of the ventilation system will be in accordance with UFC 1-200-01.

12-2.4 Configuration

HVAC zones, fire areas (or zones), and blast zones (if used) should be arranged to coincide with each other (refer to Chapters 7 and 11).

12-3 INTERCONNECTIONS

Interconnections of individual fire areas via the ventilation system must be kept to a minimum. If an interconnection is made, it must be properly protected by fire stopping, fire and smoke dampers, and blast containment, as appropriate.

12-4 PORTABLE VENTILATION EQUIPMENT

In the event that fixed ventilation systems malfunction or are damaged and not capable of removing smoke and heat, portable ventilation equipment must be available. This equipment will be staged in the facility or be verified as readily available from the installation fire department. Sizing of the portable equipment and means to provide any required electrical power must be considered in the FHA and documented within the fire pre-plan.

12-5 HVAC INTAKE AND OUTLET LOCATIONS

HVAC intakes must be located and protected to prevent the accidental or intentional introduction of harmful gases or other materials.

Intakes and outlets for air-cleaning systems must be located to reduce the potential for the spread of radioactive contamination during maintenance.

12-6 FIRE, SMOKE, AND COMBINATION FIRE AND SMOKE DAMPERS

12-6.1 Fire Area Boundaries

Dampers will be provided at those fire area boundaries required to have a fire resistance rating of greater than 1 hour for both ventilation duct penetrations and air transfer openings. Where shutdown of the ventilation system is not permitted due to operational or security requirements, fire dampers will not be required for ventilation duct penetrations and an alternative means of protecting against fire propagation must be provided.

NOTE: This section is intended to address fire barriers within blast zones. Interconnections between blast zones are strongly discouraged.

NOTE: The need for automatic dampers and ventilation system shutdown can be minimized by installing separate ventilation systems for each fire area and blast zone or by installing fire-resistive ducting enclosures that provide the required fire barrier while passing through adjacent areas.

12-6.2 Fire Rating

Dampers having a rating of 1.5 hours must be installed where ventilation ducts penetrate fire barriers having a required fire resistance rating of 2 hours. Where ventilation ducts penetrate required 3-hour fire barriers, approved dampers having a fire protection rating of 3 hours must be installed.

12-6.3 Access

Access will be provided to ensure the damper can be properly and easily inspected, tested, and maintained, with particular consideration for the required periodic replacement of the damper's thermal elements.

12-6.4 Installation in Fire Barriers

Dampers will be installed directly into the fire barrier wall in accordance with the manufacturer's requirements. Dampers will be equipped with visible indicators to show damper position.

12-6.5 Listing

Dampers must be designed and installed in accordance with their listing and, where possible, installed in a configuration such that air movement in the duct assists in closing the damper.

12-7 FILTERS

12-7.1 Pre-filters

Air pre-filters located upstream or as part of the final HEPA filter exhaust plenums will be listed as Class 1 air filter units as tested in accordance with UL 900.

12-7.2 HEPA Filters

When used in nuclear ventilation exhaust systems, HEPA filters must meet the requirements for HEPA filters in ASME AG-1, Section FC, and be listed as a "high-efficiency, particulate, air filter unit" as tested in accordance with UL 586.

12-7.3 Self-Cleaning Filters

Self-cleaning filters are not permitted.

12-7.4 Spare Filters

At least a 100 percent supply of specialized spare filters, such as HEPA filters, will be maintained.

12-7.5 Noncombustible Materials

Roughing or pre-filters, where necessary, must be constructed of noncombustible materials.

12-7.6 Filter Framing Systems

Filter framing systems may be constructed of combustible material provided that the material has a flame spread rating of 25 or less and a smoke developed rating of 50 or less.

12-7.7 Filter Plenum Fire Separation

Filter plenums located inside nuclear weapons-capable buildings must be separated from all parts of the facility by 2-hour fire-rated construction.

12-7.8 Small Filter Plenums

Small filter plenums that serve as a final filter and have a leading surface area of 16 square feet (1.5 square meters) or less need not be separated by fire-rated construction from other parts of a facility or be located in a separate fire-rated enclosure if the filter plenum is located in an area provided with an automatic sprinkler system designed and installed in accordance with UFC 3-600-01.

12-7.9 Fire Suppression Systems

12-7.9.1 Fire suppression systems will be installed to protect filters that collect combustible material.

12-7.9.2 Where combustible filters, combustible particulates, or combustible ductwork (e.g., fiberglass-reinforced plastic) is present in the ventilation system, fire suppression systems must be provided. Additional fire protection features will be provided as appropriate for the fire hazard and the requirements documented in the FHA.

12-7.9.3 Fixed water spray systems must be provided for charcoal absorber beds containing more than 100 pounds (45.4 kilograms) of charcoal.

12-7.9.4 Automatic and manual water deluge spray systems will be provided inside all final filter plenums for protection of the filters where they have a leading filter surface area greater than 16 square feet (1.5 square meters).

12-7.9.5 Deluge spray sprinkler systems must operate upon activation of the fire alarm system heat detectors or pilot sprinklers located in either the final ducting or filter plenum housing. Manual activation will also be provided.

12-7.9.6 The design of the water deluge spray systems must reflect the potential for filter failure mechanisms, such as filter media damage resulting from weakened media due to water absorption and excessive differential pressures during water discharge.

NOTE: Such filter failure mechanisms can be significantly mitigated by throttling back fan controls to reduce filter pressure or by providing redundant filters.

12-7.9.7 Automatic deluge spray systems will be designed per the applicable provisions of NFPA 13 and NFPA 15, and as follows:

- Water spray density will be 0.25 gallon per minute per square foot (10.2 liters per minute per square meter) over the entire filter area or 1 gallon per minute (3.8 liters per minute) per 500 cubic feet per minute (14.2 cubic meters) of air flow, whichever is greater.
- Spray sprinklers must be of the deluge type.

12-7.9.8 The spray pattern of the deluge sprinklers must be in the form of a downward vertical water curtain approximately 6 inches (15 centimeters) in front of the pre-filter or demister. In addition, deluge sprinklers must be spaced so that each sprinkler does not exceed 4 lineal feet (1.2 lineal meters) of curtain coverage.

12-7.9.9 Manual spray systems must be designed per NFPA 15 with these specific requirements:

- Water spray density will be 0.25 gallon per minute per square foot (10.2 liters per minute per square meter) over the entire filter area.
- Nozzles will be deluge spray nozzles that form a full-circle, solid-cone discharge.
- Spray nozzles will be horizontally directed at the face of the first series of HEPA filters so all areas of the first stage filters and framing support system are wetted.
- Activation will be by activating the deluge valve or by opening a normally closed valve. Control devices to activate the manual spray system will be provided in the process operator's control room or other locations accessible to emergency response personnel. When a deluge valve is

used, manual activation may also be provided at the location of the deluge valve.

12-7.9.10 Water for the deluge spray systems must be provided by two separate water supply connections for reliability.

12-7.9.11 Automatic and manual water spray system water supplies will be hydraulically calculated. They must be capable of supplying a simultaneous flow of water for two hours to the automatic and manual water spray systems as well as the overhead ceiling automatic sprinkler systems in the fire area providing air to the HVAC plenum.

12-7.10 Demisters

12-7.10.1 Where automatic deluge spray systems are installed in filter plenum enclosures that do not contain pre-filters, metal demisters will be installed downstream of the automatic deluge spray sprinklers and upstream of the first series of HEPA filters.

Where automatic deluge spray systems are installed in the final filter plenum enclosures that contain pre-filters, water spray deluge sprinklers will be located upstream from the pre-filters.

NOTE: In this configuration, the pre-filters act as a demister.

Demisters must be located as far away as practical from HEPA filters but no closer than 36 inches (91 centimeters), and at approximately 6 inches (15 centimeters) from the deluge spray sprinklers.

12-7.10.2 Demisters will have an approximately 100 weight percent efficiency for water drops 50 microns and larger. They will have efficiency greater than 99 weight percent for 1 to 50 microns when air flow velocities are present of 500 to 600 feet per minute (150 to 185 meters per minute), or at operating air flow velocities with the deluge system operating water flow delivery rate.

12-7.11 Fire Screens

Fire screens must be located upstream from the pre-filters and final filter plenums. Fire screens with metal meshes from eight to sixteen openings per inch (three to six openings per square centimeter) will be provided and located at least 4 to 5 feet (1.2 to 1.5 meters) upstream from all pre-filters and at least 20 feet (6.1 meters) upstream from all final filter plenum enclosures. Where pre-filters are located in final filter enclosures, fire screens will be located at least 20 feet (6.1 meters) upstream from the pre-filters.

12-7.12 Heat Detection

Heat detectors or pilot sprinklers, when required to comply with paragraph 12-7.9, will be provided in ducting prior to final filter enclosures. Airflow must be considered when

determining detector or pilot sprinkler location. Heat detectors or pilot sprinklers will also be provided in the final filter enclosures. If filter plenum automatic deluge spray systems are actuated by pilot sprinklers, heat detectors are not required in the ducting or the final filter enclosure unless specified in the FHA.

12-7.13 Fire Alarm

The detection system or pilot sprinkler system will be arranged to detect a rise in airflow temperatures, actuate automatic fire suppression systems, and transmit an alarm to a constantly attended location (refer to paragraph 11-13.2). A pilot-operated system will be used only when an automatic water deluge spray system is installed.

12-7.14 Fire Detector Configuration for Testing

12-7.14.1 Fire detectors must be engineered and installed so they can be tested during the life of the detector. Easily removable panels will be provided to allow access for inspection and maintenance.

12-7.14.2 Where radiological contamination is not a concern, fire detectors may be installed such that the fire detector can be removed from the plenum enclosure and externally tested.

12-7.14.3 Remote testing must be provided for detectors that are not accessible due to facility configurations or personnel hazards.

12-7.14.4 If line-type heat detection is used, a heat testing pad will be provided outside of the plenum for operability testing of the system.

12-7.15 Lighting

Lighting must be provided inside the filter plenum in front of or between the filter banks in the area where the automatic and manual sprinklers and nozzles are located. Such lighting may be provided with an on-and-off switch, provided the switch is located outside the plenum at an accessible location.

12-7.16 Viewing Ports

Window viewing ports constructed of either wire glass, laminated lead safety glass, or fire-rated glass will be provided for viewing inside the filter plenum. The window viewing ports will be provided at each location where fire protection spray system sprinklers and nozzles are located and will be placed such that all sprinklers and nozzles are visible from the outside of the plenum to facilitate flow testing of the system.

12-8 DUCTWORK

Ductwork from areas containing radioactive materials that passes through nonradioactive areas must be of noncombustible construction and will be protected from possible exposure fires by materials having a fire resistance rating as approved by the

Cognizant Offices of Responsibility. For blast zones (see Chapter 7) this includes a requirement for hardened ductwork (i.e., steel piping).

Where the corrosive nature of the effluents conveyed precludes the use of metallic ducts, other materials will be permitted as approved by the Cognizant Offices of Responsibility.

12-9 SMOKE CONTROL

12-9.1 Where Required

Smoke control systems must be provided for facilities or portions of facilities classified as an “underground structure” or “limited access structure” as defined in NFPA 101.

12-9.2 Venting

Smoke, corrosive gases, and non-radioactive substances released by a fire will be vented from their place of origin directly to a location outside the facility where these substances will have the minimum potential to affect personnel outside of the facility.

12-9.3 Circulation

The smoke control system must be designed, located, and protected such that airborne corrosive products or contamination are not circulated (e.g., once-through ventilation systems).

12-9.4 Control of Radioactive Materials

Radioactive materials released by fire will be confined or removed and filtered from the exhaust ventilation airstream. Smoke exhaust from areas that contain radioactive substances must not be ventilated outside the building unless filtered through at least two stages of HEPA filters. Smoke control systems for such areas will be connected to treatment systems to preclude release of radioactive substances.

12-9.5 Release of Radioactive Material

The possible release to the environment of smoke containing radioactive materials must be monitored and modeled in accordance with emergency plans.

12-9.6 Fresh Air Inlets

Fresh air inlets will be located where contaminants are least likely to be present to reduce the potential of introducing smoke, toxic materials, or radioactive contaminants into the facility.

12-9.7 Enclosed Stairwells

Enclosed stairwells will be designed to minimize smoke infiltration during a fire via stairwell pressurization systems.

12-9.8 Natural Convection

Where natural convection ventilation is approved by the Cognizant Offices of Responsibility, the smoke and heat ventilation will provide a minimum ratio of vent area to floor area of at least 1 to 200, except in oil hazard areas, where at least a 1 to 100 ratio must be provided.

12-9.9 Firefighting

To facilitate manual firefighting, a method of operation of the smoke control systems must be provided for switchgear rooms, battery rooms, emergency power generation areas, fuel oil storage areas, and other areas where the potential exists for heavy smoke and heat conditions. The method of operation may be provided using local controls in the vicinity of the affected area or by remote controls under control of facility leadership.

12-10 LEAK TESTING

Open flame or combustion-generated smoke will not be used for leak testing.

12-11 POWER SUPPLIES AND CONTROLS

The power supply and controls for an HVAC system will be located outside the fire area served by the system. The security control room, facility control room, or other designated control location will be capable of remote monitoring and control of every ventilation system.

This Page Intentionally Left Blank

CHAPTER 13 HOT WORK

NOTE: Cognizant Office of Responsibility for this chapter is AFSEC.

13-1 SCOPE

Hot work includes any temporary operation involving open flames or that produces heat or sparks, including brazing, cutting, grinding, soldering, arc welding, work on a pipe that would conduct heat through a wall or in contact with a wall, or torch-applied roofing. Non-powered (i.e., manual) cutting and grinding that do not generate sufficient heat or sparks to be considered a significant source of ignition to surrounding combustible materials do not require a permit.

13-2 PERMITS

Hot work must be coordinated and permitted through the appropriate local or base fire department.

This Page Intentionally Left Blank

CHAPTER 14 UNDERGROUND FACILITIES

NOTE: Cognizant Office of Responsibility for this chapter is AFCEC.

14-1 SCOPE

This chapter includes requirements in addition to the requirements of Chapters 1 through 13 (unless otherwise specified) that are applicable to facilities where nuclear weapons-capable maintenance and storage areas are located underground.

14-2 ARCHITECTURAL REQUIREMENTS

Architectural requirements are provided in UFC 1-200-01.

14-2.1 Construction Type

Buildings will be constructed to be fire-resistant or noncombustible (Type I or Type II in accordance with the International Building Code [IBC]). All walls, floors, and structural components, except interior finish materials in office and support areas, will be of noncombustible construction. Use of combustible interior finishes must be minimized.

14-2.2 Hardened Fire Protection Systems

Buildings will be provided with hardened fire suppression systems in all areas and smoke detection systems (refer to Chapter 11 and Appendix B).

14-2.3 Fire Areas

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC and AFSEC.

Facilities capable of storing nuclear weapons components will be subdivided into separate fire areas to minimize the risk of fire spread and the resultant consequential damage from fire gases, smoke, heat, radioactive contamination, and firefighting activities. In addition, the subdivision into fire areas must allow adequate access for manual fire suppression activities and be as consistent as possible with the blast zones.

14-2.3.1 Establishment of Boundaries

The boundaries of fire areas will be as established in the FHA based on general fire protection criteria that include these elements:

- Types, quantities, density, and locations of combustible materials and radioactive materials
- Location of blast doors and security access portals
- Location and configuration of equipment
- Consequences of inoperable equipment

- Location or zoning of fire detection and suppression systems
- Personnel safety, exiting, area of refuge requirement

14-2.3.2 Boundary Objectives

In underground facilities, fire area boundaries will accomplish fire protection objectives, including:

- To separate all contiguous buildings or portions thereof serving different purposes, such as storage, maintenance, service, administration, and other occupancy designations
- To separate weapons maintenance areas and weapons storage areas from each other and from adjacent areas
- To separate other types of maintenance areas from adjacent areas
- To separate security and other control rooms, computer rooms, and combined control and computer rooms from adjacent areas
- To separate rooms with major concentrations of electrical equipment, such as switchgear rooms and relay rooms, from adjacent areas
- To separate battery rooms from adjacent areas
- To separate each fire pump and its associated equipment from all other pumps in the same room or pump house
- To separate each fire pump from adjacent areas
- To separate warehouse areas and combustible storage areas from adjacent areas
- To separate standby or emergency power generators from each other and from adjacent areas
- To separate fan rooms and plenum chambers from adjacent areas
- To separate office areas from adjacent areas

14-2.3.3 Fire Barriers Separating Fire Areas

Fire barriers separating fire areas will have a minimum 3-hour fire resistance rating with listed 3-hour-rated penetration seals, and comply with the International Building Code.

14-2.3.4 Fire Doors and Fire Windows in Fire Barriers

Fire doors and fire windows used in fire barriers will be installed and maintained in accordance with NFPA 80. In the case of blast doors in fire barriers, refer to Chapter 7 of this document.

Typically, closed fire doors in fire barriers will be identified with a sign indicating, “Fire Door — Keep Closed.”

Windows in fire barriers, such as for a security control room or computer room, must be provided with a listed or approved fire shutter, automatic wall curtain, or fire resistance glazing.

14-2.4 Vertical Shafts and Plenums

To prevent the vertical spread of fire, all stairways, elevator shafts, escape ladders, and other vertical shafts and plenums must be enclosed with barriers having a fire resistance rating of at least 2 hours. Openings in such barriers must be protected with listed automatic or self-closing fire doors having a fire protection rating of at least 1.5 hours.

14-3 COMBUSTIBLE MATERIALS AND FINISHES

14-3.1 Weapons Storage Areas

Combustible materials must be excluded from fire areas designated for weapons storage, except for incidental amounts of combustible materials as determined by the FHA. Such incidental amounts might include solid wood blocks that serve as chocks for weapons support or small amounts of solvent used for weapons maintenance in the storage location.

14-3.2 Blast Shielding Materials

Permanent and temporary shielding materials will be noncombustible or limited combustible, based on:

- ASTM E84
- NFPA 253
- NFPA 255
- UL 94

Polystyrene used for sand walls is not required to be encased with fire-resistant materials.

14-3.3 Interior Finishes

14-3.3.1 Interior Wall and Ceiling Finish

Interior wall and ceiling finish in areas for processing or storing radioactive materials will be Class A in accordance with NFPA 255.

NOTE: The design should consider a potential radiation contamination incident and include wall and ceiling finishes that are easy to clean.

14-3.3.2 Interior Floor Finish

Interior floor finish in areas for processing or storing radioactive materials will be Class I in accordance with NFPA 253.

NOTE: The design should consider a potential radiation contamination incident and include floor finishes that are easy to clean.

14-3.4 Other Materials

Thermal insulation materials, radiation shielding materials, ventilation duct materials, soundproofing materials, and suspended ceilings, including light diffusers and their supports, will be noncombustible or limited combustible. If polypropylene or polyethylene is required for neutron shielding, it must be totally encased with a noncombustible material such as steel or 5/8-inch (16-millimeter) type X gypsum board. Approximately 3/8-inch (10-millimeter) vent holes must be provided within the encasement to permit the venting of gases from the poly material.

NOTE: Encasement is required because many plastic materials, including flame- and fire-retardant materials, will burn with an intensity and energy production in a range similar to that of ordinary hydrocarbons. When burning, they produce heavy smoke that obscures visibility and can plug air filters, especially charcoal and HEPA filters. When burning, halogenated plastics also release free chloride and hydrogen chloride. These gases are toxic to humans and corrosive to equipment.

14-4 HAZARD CONTROL

14-4.1 Flammable and Combustible Liquids

14-4.1.1 Where oil-burning equipment, stationary combustion engines, or gas turbines are used, they will be installed and used in accordance with NFPA 31 or NFPA 37, as appropriate.

14-4.1.2 Flammable and combustible liquid and gas piping will be in accordance with ASME B31.1 or the ASME *Boiler and Pressure Vessel Code*, Section III, as applicable.

14-4.2 Hydraulic Systems

Hydraulic systems will use only listed fire-resistant hydraulic fluids.

14-4.3 Solvents

Where a flammable or combustible solvent is used, it must be handled such that the uncontrolled release of vapors is not permitted.

14-4.4 Gases

Flammable and combustible gases will be stored and handled in accordance with NFPA 54, NFPA 55, and NFPA 58.

Bulk flammable gas storage, either compressed or cryogenic, will not be permitted inside structures capable of storing nuclear weapons.

Storage of flammable gas, such as hydrogen, will be located outdoors or in separate detached buildings so a fire or explosion will not adversely affect any nuclear weapons storage facility systems or equipment.

14-5 LIQUID RUN-OFF CONTROL

Drainage will be provided in all areas of the facility for the removal of all liquids directly to safe areas, or for containment in the area without adverse flooding of equipment and without endangering other areas.

14-5.1 Methods

Drainage and the prevention of equipment water damage will be accomplished by one or more of these methods:

- Floor drains
- Floor trenches
- Open doorways or other wall openings
- Curbs for containing or directing drainage
- Equipment pedestals
- Pits, sumps, and sump pumps

14-5.2 Sump Pump Systems

Waste and drainage sump pump systems must be provided with 100 percent redundant pumps.

14-5.3 Drainage and Drainage Facility Size

Drainage and any associated drainage facilities for a given area will be sized to accommodate the volume of liquid produced by all of these sources:

- The spill of the largest single container of any flammable or combustible liquids in the area.
- The credible volume of discharge (as determined by the FHA) released by the automatic suppression system operating for a period of 30 minutes

unless the approved FHA authorizes use of a different flow rate and duration.

- The contents of piping systems and containers that could fail in a fire.
- The volume of water discharged based on a manual firefighting flow rate of 500 gallons per minute (1,890 liters per minute) for 30 minutes unless the approved FHA authorizes use of a different flow rate and duration.
- For areas open to the outside, such as underground loading docks, credible environmental factors such as rain and snow.

14-5.4 Staging Equipment

Necessary equipment must be staged to assist with routing water from the affected area. The use of the staging equipment will be addressed in the fire department pre-fire plan.

14-5.5 Floor Drainage

Floor drainage from areas containing flammable or combustible liquids will be trapped to prevent the spread of burning liquids beyond the fire area.

14-5.5.1 Areas with Radioactive Materials

Floor drainage from areas containing nuclear weapons components must be trapped to prevent the spread of radioactive materials beyond the facility's controlled boundaries. If the drainage system leads to tanks, the tanks will be designed to be criticality safe.

Water drainage from areas that might contain radioactivity must be collected, sampled, and analyzed before discharge to the environment or outside the boundaries of the facility.

Water released during fire suppression operations in areas containing radioactivity will be drained to a location that would be acceptable for the containment of radioactive materials.

14-5.5.2 Facilities with Gaseous Fire Suppression Systems

Where gaseous fire suppression systems are installed, floor drains will be provided with adequate seals or the fire suppression system will be sized to compensate for the loss of the gaseous fire suppression agent through the drains.

14-6 THROUGH PENETRATION FIRE STOPS

14-6.1 Where Required

Fire stops for penetrations such as pipes, conduits, bus ducts, cables, wires, pneumatic tubes and ducts, and similar building service equipment that passes through fire barriers

will be provided to prevent the spread of fire using listed or approved materials (caulking) or devices (sleeves).

If the fire barriers coincide with or are also serving as a blast-resistant barrier, these penetrations will also require blast-resistant devices. If the blast-resistant device is sufficient to serve as protection from the spread of fire, no additional protection is necessary. If the blast-resistant penetration device is not listed or approved for fire penetrations, it can be evaluated by a qualified fire protection engineer and accepted as a fire barrier product by the Cognizant Office of Responsibility.

14-6.2 Annular Spaces

The annular space between the penetrating item and the through opening in the fire barrier must be filled with a qualified (listed or approved) fire-resistive penetration seal assembly capable of maintaining the fire resistance of the fire barrier. The assembly will be qualified by tests in accordance with fire test protocols or be protected by a listed fire-rated device for the specified fire-resistive period. Penetration seals provided for electrical and mechanical openings will be listed as meeting the requirements of ASTM E814 or UL 1479.

14-6.3 Conduit Seals

Refer to Chapter 3.

14-6.4 Leak Testing

Open flame- or combustion-generated smoke must not be used for leak testing.

14-7 COMMUNICATIONS

Communication systems using a commonly described “lossy” antenna distribution system within the facility will be limited as much as possible and will be within the allowable electromagnetic radiation (EMR) limits of the applicable STS.

All electrical equipment and devices are either intentional or unintentional EMR emitters as defined in Chapter 8. All such equipment to be used in close proximity to critical equipment interior to the facility must not exceed the allowable EMR limits of the applicable STS. Anticipated EMR emitters will be analyzed to evaluate anticipated EMRE levels. If the EMRE levels exceed allowable limits, facility design, equipment selection, or procedures must be adjusted to mitigate EMRE levels.

14-8 LIFE SAFETY AND MEANS OF EGRESS

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC and AFSEC.

14-8.1 Life Safety Performance Criteria

The following performance criteria will be met during all operational modes and plant configurations:

- Provide safe egress or areas of refuge for all occupants of the facility.
- Provide adequate protection, including emergency lighting and communication, for essential personnel to perform necessary weapons safety and security functions in case of a fire event.
- Provide adequate protection (e.g., self-contained breathing apparatus [SCBA] units, supplied air connections) for other facility personnel designated to provide emergency response services during or following a fire.

14-8.2 Occupancy Classification

14-8.2.1 Storage

Those areas involved in the storage of nuclear weapons will be considered special-purpose industrial occupancies and as underground spaces as defined in NFPA 101.

Warehouses and storage areas designated for the storage of materials other than nuclear weapons will conform to the ordinary hazard storage occupancy (refer to Chapters 6 and 42 of NFPA 101) and underground space requirements in NFPA 101.

14-8.2.2 Maintenance

Those areas involved in the maintenance of nuclear weapons will be considered special-purpose industrial occupancies and as underground spaces as defined in NFPA 101.

14-8.2.3 Other Areas

General office areas, break rooms, security control rooms, office buildings, and training facilities will conform to the business occupancy and underground space requirements in NFPA 101.

14-8.3 Occupant Load

In determining the exiting requirements for a nuclear weapons-capable maintenance and storage facility, the actual number of assigned personnel and expected number of visitors during operations, maintenance, and testing, with an added safety factor of 20 percent, will be used to determine the occupant load in lieu of other criteria within NFPA 101.

14-8.4 Number of Means of Egress

Fire areas will have at least one means of egress for those facilities protected throughout by an automatic fire suppression system. When nuclear security requirements prohibit the use of approved egress components (such as a listed fire door meeting the requirements of NFPA 101) for the means of egress, an area of refuge must also be provided within the fire area (refer to paragraph 14-9.6).

Two means of egress out of the fire area will be provided for facilities not protected throughout by a fire suppression system. One of these means of egress may be an area of refuge. When nuclear security requirements prohibit the use of approved egress components (such as a listed fire door meeting the requirements of NFPA 101) for the means of egress, an area of refuge must be provided within the fire area (refer to paragraph 14-9.6).

14-8.5 Horizontal Exit

A horizontal exit will be considered to be any adjacent fire area separated by at least 3-hour fire-rated construction and accessible through listed fire doors meeting the requirements of NFPA 101 and NFPA 80.

14-8.6 Area of Refuge

An area of refuge must:

- Be separated from adjacent areas by at least 3-hour fire-rated construction
- Minimize the entrance of smoke
- Be protected throughout by automatic sprinklers
- Be provided with two-way communication (including instructions on the operation of the equipment)

Areas of refuge must be provided with protective heat-resistant clothing, emergency drinking water, and sufficient breathing air to permit survival for at least 72 hours based on the expected occupant load. The occupant capacity for the area of refuge will be established in the FHA.

NOTE: When possible, the area of refuge within a fire area should be located near the nuclear security access doors into the fire area.

14-8.7 Travel Distances

14-8.7.1 Weapon Storage Areas

For weapon storage areas, travel distances to an exterior exit, horizontal exit, or area of refuge within the fire area will not exceed 400 feet (122 meters) for facilities protected throughout by an automatic fire suppression system. For facilities not protected

throughout by an automatic fire suppression system, these travel distances will not exceed 200 feet (61 meters).

14-8.7.2 All Other Areas

For all other areas, travel distances to an exterior exit, horizontal exit, or area of refuge within the fire area will not exceed 300 feet (91 meters) for facilities protected throughout by an automatic fire suppression system. For facilities not protected throughout by an automatic fire suppression system, these travel distances will not exceed 200 feet (61 meters).

14-8.8 Common Path of Travel

14-8.8.1 Weapon Storage Areas

For weapon storage areas, common path of travel distances are not limited, provided the areas are protected with an automatic fire suppression system. For facilities not protected throughout by an automatic fire suppression system, common path of travel must not exceed 75 feet (23 meters).

14-8.8.2 All Other Areas

For all other areas, common path of travel must not exceed 100 feet (30 meters) for facilities protected throughout by an automatic fire suppression system. For facilities not protected throughout by an automatic fire suppression system, common path of travel must not exceed 75 feet (23 meters).

14-8.9 Dead-End Corridors

14-8.9.1 Weapon Storage Areas

For weapon storage areas, dead-end corridor distances are not limited, provided travel distances and common path of travel distances are not exceeded (see paragraphs 14-9.7 and 14-9.8).

14-8.9.2 All Other Areas

For all other areas, dead-end corridors must not exceed 50 feet (15 meters) for facilities protected throughout by an automatic fire suppression system. For facilities not protected throughout by an automatic fire suppression system, dead-end corridors must not exceed 20 feet (6.1 meters).

14-8.10 Special Locking Devices

Special locking devices (e.g., dead bolts and slide bolts) may be installed and left engaged on exit doors during periods of occupancy in addition to the normal door locking devices, provided the devices are required by security, are clearly visible to the building occupants, and the building occupants are advised of their presence.

NOTE: Such locking devices should be marked or painted with a bright contrasting color (e.g., orange, yellow, red) to be clearly visible to the occupants.

14-9 FIRE HYDRANTS IN VEHICLE LOADING TUNNELS

Hydrants will be installed within approximately 50 feet (15 meters) of each end of each vehicle loading tunnel provided for the underground structures.

14-10 SECURITY CONTROL ROOM COMPLEX

See Chapter 5 for security control room complex requirements.

14-11 COMMUNICATIONS

For all communication systems that are wireless or EMR-emitting devices, the restrictions of Chapter 8 will be implemented, as appropriate.

Prior to the introduction of wireless devices, the devices must be reviewed by the Host Wing, Weapons Safety Office.

This Page Intentionally Left Blank

CHAPTER 15 INDUSTRIAL FACILITIES

NOTE: Cognizant Office of Responsibility for this chapter is AFCEC.

15-1 SCOPE

This chapter includes requirements in addition to the requirements (unless otherwise specified) of Chapters 1 through 13 that are applicable to ground-level industrial facilities where nuclear weapons-capable activities such as inspection, testing, and maintenance take place, but not storage. For restricted access/egress, ground-level facilities where inspection, testing, maintenance, and storage takes place will comply with Chapter 17 in lieu of this chapter. For underground facilities, comply with Chapter 14 in lieu of this chapter.

15-2 ARCHITECTURAL REQUIREMENTS

Architectural requirements are provided in UFC 1-200-01.

15-2.1 Construction Type

Buildings will be constructed to be fire-resistant or noncombustible (Type I or Type II in accordance with the IBC). All walls, floors, and structural components, except interior finish materials in office and support areas, will be of noncombustible construction. Use of combustible interior finishes will be minimized.

15-2.2 Hardened Fire Protection Systems

Buildings will be provided with hardened fire suppression systems in all areas and smoke detection systems (refer to Chapter 11 and Appendix B).

15-2.3 Fire Areas

Facilities capable of inspecting, maintaining, or storing nuclear weapons components must be subdivided into separate fire areas to minimize the risk of fire spread and the resultant consequential damage from fire gases, smoke, heat, radioactive contamination, and firefighting activities. In addition, the subdivision into fire areas will allow adequate access for manual fire suppression activities and be as consistent as possible with the blast zones.

15-2.3.1 Establishment of Boundaries

The boundaries of fire areas will be established in the FHA based on general fire protection criteria that include these elements:

- Types, quantities, density, and locations of combustible materials and radioactive materials
- Location of blast doors and security access portals

- Location and configuration of equipment
- Consequences of inoperable equipment
- Location or zoning of fire detection and suppression systems
- Personnel safety, exiting, and area of refuge requirements
- Building separations and occupancy separation requirements

15-2.3.2 Boundary Objectives

In industrial facilities, fire area boundaries will accomplish fire protection objectives, including:

- To separate all contiguous buildings or portions thereof serving different purposes, such as storage of combustible materials, maintenance, service, administration, and other occupancy designations
- To separate weapons maintenance areas from adjacent areas
- To separate fueling areas from adjacent areas
- To separate security and other control rooms, computer rooms, or combined control and computer rooms from adjacent areas
- To separate rooms with major concentrations of electrical equipment, such as switchgear rooms and relay rooms, from adjacent areas
- To separate battery rooms from adjacent areas
- To separate each fire pump and its associated equipment from all other pumps in the same room or pump house
- To separate each fire pump from adjacent areas
- To separate warehouse areas and combustible storage areas from adjacent areas
- To separate standby or emergency power generators from each other and from adjacent areas
- To separate fan rooms and plenum chambers from adjacent areas
- To separate office areas from adjacent areas

15-2.3.3 Fire Barriers Separating Fire Areas

Fire barriers separating fire areas must have a minimum 2-hour fire resistance rating with listed 2-hour-rated penetration seals.

15-2.3.4 Fire Doors and Fire Windows in Fire Barriers

Fire doors and fire windows in fire barriers will be installed and maintained in accordance with NFPA 80. In the case of blast doors in fire barriers, refer to paragraph 7-4.3.8 of this document.

Typically, closed fire doors in fire barriers will be identified with a sign indicating, “Fire Door — Keep Closed.”

Windows in fire barriers, such as for a security control room or computer room, must be provided with a listed or approved fire shutter, automatic wall curtain, or fire resistance glazing.

15-2.4 Vertical Shafts and Plenums

To prevent vertical spread of fire, all stairways, elevator shafts, escape ladders, and other vertical shafts and plenums will be enclosed with barriers having a fire resistance rating of at least 2 hours. Openings in such barriers must be protected with listed automatic or self-closing fire doors having a fire protection rating of at least 1.5 hours.

15-3 COMBUSTIBLE MATERIALS AND FINISHES

15-3.1 Blast Shielding Materials

Permanent and temporary shielding materials will be noncombustible or limited combustible, based on:

- ASTM E84
- NFPA 253
- NFPA 255
- UL 94

Polystyrene used for sand walls is not required to be encased with fire-resistant materials.

15-3.2 Interior Finishes

15-3.2.1 Interior Wall and Ceiling Finish

Interior wall and ceiling finish in areas processing or storing radioactive materials must be Class A in accordance with NFPA 255.

NOTE: The design should consider a potential radiation contamination incident and include wall and ceiling finishes that are easy to clean.

15-3.2.2 Interior Floor Finish

Interior floor finish in areas processing or storing radioactive materials will be Class I in accordance with NFPA 253. If required to meet weapon maintenance environmental conditions, anti-static flooring having less than a Class I fire rating is permitted when approved by the Cognizant Office of Responsibility.

NOTE: The design should consider a potential radiation contamination incident and include floor finishes that are easy to clean.

15-3.3 Other Materials

Thermal insulation materials, radiation shielding materials, ventilation duct materials, soundproofing materials, and suspended ceilings, including light diffusers and their supports, must be noncombustible or limited combustible. If polypropylene or polyethylene is required for neutron shielding, it must be totally encased with a noncombustible material such as steel or 5/8-inch (16-millimeter) type X gypsum board. Approximately 3/8-inch (10-millimeter) vent holes must be provided within the encasement to permit the venting of gases from the poly material.

NOTE: Encasement is required because many plastic materials, including flame- and fire-retardant materials, will burn with an intensity and energy production in a range similar to that of ordinary hydrocarbons. When burning, these materials produce heavy smoke that obscures visibility and can plug air filters, especially charcoal and HEPA filters. When burning, halogenated plastics also release free chloride and hydrogen chloride. These gases are toxic to humans and corrosive to equipment.

15-4 HAZARD CONTROL

15-4.1 Flammable and Combustible Liquids

15-4.1.1 Where oil-burning equipment, stationary combustion engines, or gas turbines are used, they will be installed and used in accordance with NFPA 31 or NFPA 37, as appropriate.

15-4.1.2 Flammable and combustible liquid and gas piping will be in accordance with ASME B31.1 or the ASME *Boiler and Pressure Vessel Code*, Section III, as applicable.

15-4.2 Hydraulic Systems

Hydraulic systems must use only listed fire-resistant hydraulic fluids. Such fluids will be approved by the Factory Mutual Research Corporation or the Mine Safety and Health Administration.

15-4.3 Solvents

Where a flammable or combustible solvent is used, it will be handled such that the uncontrolled release of vapors is not permitted.

15-4.4 Gases

Flammable and combustible gases will be stored and handled in accordance with NFPA 54, NFPA 55, and NFPA 58.

Bulk flammable gas storage, either compressed or cryogenic, will not be permitted inside structures capable of maintaining nuclear weapons.

Storage of flammable gas, such as hydrogen, will be located outdoors or in separate detached buildings so that a fire or explosion will not adversely affect any nuclear weapons maintenance facility systems or equipment.

15-5 REFUELING AREAS

15-5.1 Automatic Fire Suppression

Automatic foam fire suppression systems will protect the area from the hazards defined within the FHA and be designed in accordance with NFPA 11.

15-5.2 Electrical Equipment

Electrical equipment will comply with NFPA 70, including Chapter 5, “Special Occupancies,” and other NFPA 70 requirements related to hazardous locations.

15-5.3 Fuel Transfer Pumps

Where pumps are used for liquid fuel transfer, means will be provided to shut down liquid transfer in the event of a spill or fire.

15-5.4 Fuel Storage Tanks

Fuel storage (i.e., day tanks) located within refueling areas must not exceed 200 gallons (757 liters).

Fuel storage tanks will be equipped with overfill protection.

15-5.5 Fuel Line Shutoff

Fuel supply lines entering refueling areas must be arranged with a spring-loaded automatic shutoff valve that is activated via a fusible link.

15-5.6 Curbing in Refueling Areas

Refueling areas must be provided with curbing designed to capture the entire contents of the fuel within the facility and the discharge of the fire suppression system for 30 minutes.

15-5.7 Ventilation

15-5.7.1 Refueling Areas

Refueling areas will be provided with either a gravity system or a continuous mechanical exhaust ventilation system.

15-5.7.2 Exhaust Location

Exhaust air must be taken from a point near a wall on one side of the room and within 12 inches (30.5 centimeters) of the floor, with one or more make-up inlets located on the opposite side of the room within 12 inches (30.5 centimeters) of the floor.

15-5.7.3 Air Openings

The location of both the exhaust and inlet air openings must be arranged to provide air movement across all portions of the floor to prevent the accumulation of vapors.

15-5.7.4 Recirculation

Exhaust from the room must be conducted directly to the exterior of the building and must not be recirculated.

15-5.7.5 Ducts

If ducts are used, they must not be used for any other purpose and will comply with NFPA 91.

15-5.7.6 Make-Up Air

If make-up air to a mechanical system is taken from within the building, the opening will be equipped with a fire door or damper as required in NFPA 91.

15-5.7.7 Gravity Systems

For gravity systems, the make-up air must be supplied from outside of the building.

15-5.7.8 Capacity

Mechanical ventilation systems must provide at least 1 cubic foot per minute (28.3 liters per minute) of exhaust air for each square foot (0.09 square meter) of floor area, but not less than 150 cubic feet per minute (4,248 liters per minute).

15-5.7.9 Dispensing Areas

The mechanical ventilation system for dispensing areas must be equipped with an airflow switch or other equally reliable method that is interlocked to sound an audible alarm upon failure of the ventilation system.

15-5.7.10 Air Intake Height

The minimum height of air intakes in these areas must be in accordance with UFC 4-010-01.

15-5.8 Static Electricity

Means must be provided to minimize the generation of static electricity in the refueling area. See AFI 91-203, NFPA 77, and NFPA 407.

15-6 LIQUID RUN-OFF CONTROL

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC and AFSEC.

Drainage will be provided in all areas of the facility for the removal of all liquids directly to safe areas, or for containment in the area without adverse flooding of equipment and without endangering other areas.

15-6.1 Methods

Drainage and the prevention of equipment water damage will be accomplished by one or more of these methods:

- Floor drains
- Floor trenches
- Open doorways or other wall openings
- Curbs for containing or directing drainage
- Equipment pedestals
- Pits, sumps, and sump pumps

15-6.2 Sump Pump Systems

Waste and drainage sump pump systems must be provided with 100 percent redundant pumps.

15-6.3 Drainage and Drainage Facility Size

Drainage and any associated drainage facilities for a given area will be sized to accommodate the volume of liquid produced by all of these sources:

- The spill of the largest single container of any flammable or combustible liquids in the area
- The credible volume of discharge (as determined by the FHA) released by the automatic suppression system operating for a period of 30 minutes, unless the approved FHA authorizes a different flow rate and duration
- The contents of piping systems and containers that could fail in a fire
- The volume of water discharged based on a manual firefighting flow rate of 500 gallons per minute (1,890 liters per minute) for 30 minutes unless the approved FHA authorizes a different flow rate and duration
- For areas open to the outside, such as underground loading docks, credible environmental factors such as rain and snow

15-6.4 Staging Equipment

Necessary equipment must be staged to assist with routing water from the affected area. The use of the staging equipment will be addressed in the fire department pre-fire plan.

15-6.5 Floor Drainage

Floor drainage from areas containing flammable or combustible liquids must be trapped to prevent the spread of burning liquids beyond the fire area.

15-6.5.1 Areas with Radioactive Materials

Floor drainage from areas containing nuclear weapons components must be trapped to prevent the spread of radioactive materials beyond the facility's controlled boundaries. If the drainage system leads to tanks, the tanks will be designed to be criticality safe.

Water drainage from areas that might contain radioactivity must be collected, sampled, and analyzed before discharge to the environment or outside the boundaries of the facility.

Water released during fire suppression operations in areas containing radioactivity must be drained to a location that would be acceptable for the containment of radioactive materials.

15-6.5.2 Facilities with Gaseous Fire Suppression Systems

Where gaseous fire suppression systems are installed, floor drains must be provided with adequate seals or the fire suppression system will be sized to compensate for the loss of the gaseous fire suppression agent through the drains.

15-7 THROUGH PENETRATION FIRE STOPS

15-7.1 Where Required

15-7.1.1 Penetrations

Fire stops for penetrations such as pipes, conduits, bus ducts, cables, wires, pneumatic tubes and ducts, and similar building service equipment that passes through fire barriers will be provided to prevent the spread of fire using listed or approved materials (caulking) or devices (sleeves).

15-7.1.2 Blast-Resistant Barrier

If the fire barriers coincide with or are also serving as a blast-resistant barrier, these penetrations will also require blast-resistant devices. If the blast-resistant device is sufficient to serve as protection from the spread of fire, no additional protection is necessary. If the blast-resistant penetration device is not listed or approved for fire penetrations, it can be evaluated by a qualified fire protection engineer and accepted as a fire barrier product by the Cognizant Office of Responsibility.

15-7.2 Annular Spaces

The annular space between the penetrating item and the through opening in the fire barrier will be filled with a qualified (listed or approved) fire-resistive penetration seal assembly capable of maintaining the fire resistance of the fire barrier. The assembly must be qualified by tests in accordance with fire test protocols or be protected by a listed fire-rated device for the specified fire-resistive period. Penetration seals provided for electrical and mechanical openings will be listed as meeting the requirements of ASTM E814 or UL 1479.

15-7.3 Conduit Seals

Refer to Chapter 3.

15-7.4 Leak Testing

Open flame- or combustion-generated smoke must not be used for leak testing.

15-8 COMMUNICATIONS

NOTE: Cognizant Office of Responsibility for this paragraph is AFSEC.

Communication systems using a lossy antenna distribution system within the facility will be limited as much as possible and will be within the allowable EMR limits of the STS.

All electrical equipment and devices are either intentional or unintentional EMR emitters and must be evaluated as discussed in Chapter 8. All such equipment to be used in close proximity to critical equipment interior to the facility must not exceed the

allowable EMR limits of the STS. Anticipated EMR emitters will be analyzed to evaluate anticipated EMRE levels. If the EMRE levels exceed allowable limits, facility design, equipment selection, or procedures must be adjusted to mitigate EMRE levels.

15-9 LIFE SAFETY AND MEANS OF EGRESS

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC and AFSEC.

15-9.1 Life Safety Performance Criteria

The following performance criteria must be met during all operational modes and plant configurations:

- Provide safe egress or areas of refuge for all occupants of the facility.
- Provide adequate protection, including emergency lighting and communication, for essential personnel to perform necessary weapons safety and security functions in case of a fire event.
- Provide adequate protection (e.g., SCBA units, supplied air connections) for other facility personnel designated to provide emergency response services during or following a fire.

15-9.2 Occupancy Classification

Industrial facilities involved in the inspection, testing, and maintenance of nuclear weapons will be considered special purpose industrial occupancies as defined in NFPA 101.

General office areas, break rooms, security control rooms, office buildings, and training facilities will conform to the business occupancy requirements in NFPA 101.

Warehouses and storage areas designated for the storage of materials other than nuclear weapons will conform to the ordinary hazard storage occupancy requirements in NFPA 101 (refer to Chapters 6 and 42 of NFPA 101).

15-9.3 Occupant Load

In determining the exiting requirements for a nuclear weapons-capable maintenance and storage facility, the actual number of assigned personnel and expected number of visitors during operations, maintenance, and testing with an added safety factor of 30 percent will be used to determine occupant load in lieu of other criteria within NFPA 101.

15-9.4 Number of Means of Egress

15-9.4.1 Two Means of Egress

Fire areas must have at least two means of egress, including those facilities protected throughout by an automatic fire suppression system.

15-9.4.2 Single Means of Egress

A single means of egress will be permitted from any story or section of an industrial facility, provided that the exit can be reached within 100 feet (30 meters) for a sprinklered facility (50 feet [15 meters] for a nonsprinklered facility) and when the single means of egress is approved by the Cognizant Offices of Responsibility.

15-9.4.3 Refueling Areas

Refueling areas must have not less than two means of egress, one of which must include an exit directly to the exterior of the facility.

15-9.4.4 Area of Refuge

When nuclear security requirements prohibit the use of approved egress components (such as a listed fire door meeting the requirements of NFPA 101) in the means of egress, an area of refuge must be provided within the fire area (refer to paragraph 15-10.6.

15-9.5 Horizontal Exit

A horizontal exit will be considered to be any adjacent fire area separated by at least 2-hour fire-rated construction and accessible through listed fire doors meeting the requirements of NFPA 101 and NFPA 80.

15-9.6 Area of Refuge

An area of refuge will:

- Be separated from adjacent areas by at least 3-hour fire-rated construction
- Minimize the entrance of smoke
- Be protected throughout by automatic sprinklers
- Be provided with two-way communication (including instructions on the operation of the equipment)

An area of refuge will be provided with protective heat-resistant clothing, emergency drinking water, and sufficient breathing air to permit survival for at least 72 hours based on the expected occupant load. The occupant capacity for the area of refuge will be established in the FHA.

NOTE: When possible, the area of refuge within a fire area should be located near the nuclear security access doors into the fire area.

15-9.7 Travel Distances

Travel distances to an exterior exit, horizontal exit, or area of refuge within the fire area must not exceed 400 feet (122 meters) for facilities protected throughout by an automatic fire suppression system. For facilities not protected throughout by an automatic fire suppression system, travel distances to an exterior exit, horizontal exit, or area of refuge within the fire area must not exceed 200 feet (61 meters).

For refueling areas, travel distances to an exterior exit must not exceed 75 feet (23 meters).

15-9.8 Common Path of Travel

The common path of travel must not exceed 100 feet (30 meters) for facilities protected throughout by an automatic fire suppression system. For facilities not protected throughout by an automatic fire suppression system, the common path of travel must not exceed 75 feet (23 meters).

15-9.9 Dead-End Corridors

Dead-end corridors must not exceed 50 feet (15 meters) for facilities protected throughout by an automatic fire suppression system. For facilities not protected throughout by an automatic fire suppression system, dead-end corridors must not exceed 20 feet (6.1 meters).

15-9.10 Special Locking Devices

Special locking devices (such as dead bolts and slide bolts) may be installed and left engaged on exit doors during periods of occupancy in addition to the normal door locking devices, provided the devices are required by security, are clearly visible to the building occupants, and the building occupants are advised of their presence.

NOTE: Such locking devices should be marked or painted with a bright contrasting color (e.g., orange, yellow, red) to be clearly visible to the occupants.

15-10 SECURITY CONTROL ROOM COMPLEX

See Chapter 5 for security control room complex requirements.

15-11 COMMUNICATIONS

For all communication systems that are wireless or EMR emitting devices, the restrictions in Chapter 8 must be considered and implemented as appropriate.

Prior to the introduction of wireless devices, the devices must be reviewed by the Host Wing, Weapons Safety Office.

15-12 ELECTROEXPLOSIVE DEVICES (EED)

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC and AFSEC.

15-12.1 Storage and Testing Area Criteria

Areas where EEDs are stored or tested will meet the following criteria:

15-12.1.1 Separation

EED areas must be separated from the remainder of the industrial facility by not less than 3-hour-rated walls.

15-12.1.2 Seals

All permanent penetrations into and out of the room will be sealed by a listed or approved means (i.e., penetration seals, fire and smoke dampers).

Penetrations provided for use in remote testing or remote electrical testing may be covered with a movable steel door or “flap” that is configured with a small slit that allows temporary wiring needed for the testing to penetrate the wall.

15-12.1.3 Ventilation Ductwork

Ventilation ductwork that penetrates the room must be equipped with fire or combination fire and smoke dampers with at least a 3-hour fire rating. Alternate means of protection of the ductwork (i.e., without dampers) are not permitted.

15-12.1.4 Blast Doors

Blast doors into the rooms will be evaluated by a qualified fire protection engineer to determine if the door may be considered as equivalent to that of a 3-hour-rated fire door. Use of blast doors for this purpose must be approved by the Cognizant Offices of Responsibility.

15-12.1.5 Fire Suppression

The room must be protected by an automatic sprinkler fire suppression system.

NOTE: The sprinklers should be supplied from above the ceiling and also provided with sprinkler guards. These features will help reduce damage to the sprinkler system due to explosion.

15-12.1.6 Grounding

Grounding or bonding to an earth ground will be provided (refer to Chapter 3).

15-12.2 Deflagration Venting

Areas where EEDs are stored or tested must be provided with deflagration venting in accordance with NFPA 68. The following features will be provided:

NOTE: According to the NFPA *Fire Protection Handbook*, industry experience shows that detonations cannot be adequately vented; however, deflagration venting should still be provided as a best management practice.

15-12.2.1 Exterior Wall

The vent area will be located in an exterior wall.

15-12.2.2 Symmetry

The vent area will be distributed symmetrically and evenly on the external wall.

15-12.2.3 Vent Closures

The types of building vent closures permitted include:

- Hinged doors
- Windows and panel closures that swing in the outward direction and have latches or similar hardware that automatically release under calculated release pressure
- Friction, spring-loaded, or magnetic latches of the type used for doors on industrial ovens

15-12.2.4 Fasteners

Shear and pull-through fasteners are permitted to be used where the vent design requires large areas, such as the entire wall of an EED room.

15-12.2.5 Restraints

The means of restraining large panels will be documented in the FHA.

15-12.2.6 Restriction of Vent Area

No restraint for any vent closure will result in restricting the vent area.

15-12.2.7 Total Mass of Closure

Any hardware added to a vent closure will be included when determining the total mass of the closure.

15-12.2.8 Hinges

Hinged doors or covers will be permitted to be designed to function as vent closures. The hinge must be designed to ensure the closure device remains intact during venting.

15-12.3 Inspection

Explosive venting systems will be inspected annually and the inspection will include at least these system conditions:

- The opening is clear of obstructions on both sides.
- The exhaust from the opening does not discharge to an occupied area.
- Changes made to the venting system installation since the last inspection.
- The venting system is not corroded or otherwise damaged.
- The explosive venting configuration is clearly identified.
- The explosive venting configuration is not damaged and will not be obstructed by snow, ice, insects, animals, plant growth, or other environmental conditions.
- The explosive venting device will not be impeded in its operation.

15-13 ARMORIES

15-13.1.1 Fire Rating

Armories will be separated from the remainder of the facility by a minimum of 2-hour fire-rated walls and 1.5-hour-rated fire doors.

15-13.1.2 Fire Stops

Penetrations into armories must be fire stopped (e.g., fire dampers, penetration seals) in addition to security requirements.

15-13.1.3 Automatic Sprinklers

Armories will be protected with automatic sprinklers unless approved in the FHA when the introduction of water through the sprinkler system creates a greater hazard. The sprinkler piping into an armory may be valved to permit isolation of the system in the event of an emergency when approved by the Cognizant Office of Responsibility.

15-13.1.4 Security Doors

Security doors into armories will be evaluated by a qualified fire protection engineer to determine if a door may be considered as equivalent to that of a 1.5-hour-rated fire door. Use of security doors for this purpose must be approved by the Cognizant Office of Responsibility.

This Page Intentionally Left Blank

CHAPTER 16 EARTH-COVERED MAGAZINE (ECM) STRUCTURES

NOTE: Cognizant Offices of Responsibility for this chapter are AFCEC and AFSEC.

16-1 SCOPE

This chapter includes requirements in addition to the requirements (unless otherwise specified) of Chapters 1 through 13 that are applicable to ECM structures where nuclear weapons are authorized to be stored but not tested or maintained.

16-2 ARCHITECTURAL REQUIREMENTS

16-2.1 Uniform Minimum Ammunition and Explosive (AE) Safety Standards

Uniform minimum AE safety standards established by the Department of Defense Explosives Safety Board (DDESB) will be incorporated.

NOTE: The DDESB has established uniform minimum AE safety standards for personnel and property that have the potential of being exposed to the effects of an accidental explosion. These standards govern the design, construction, and use of all AE storage magazines within DoD.

16-2.2 ECM Siting

ECM structures will be sited using DDESB uniform minimum AE safety standards.

16-2.3 Hardened Fire Protection Systems

Buildings will be provided with hardened fire suppression systems in all areas and smoke detection systems (refer to Chapter 11 and Appendix B).

NOTE: ECM structures are built to store AE. ECM structures are not necessarily designed to contain the damaging effects from an internal explosion, although these structures will usually contain the effects of a very small quantity of AE. Instead, ECMs are intended to protect their contents from an explosion that may occur in an adjacent structure, such as another ECM, piers, aboveground magazines, rail sidings, or classification yards. The ECM may not be adequate to prevent damage to its contents from all external events. Protection from such events should be addressed in the FHA.

16-3 APPROVAL REQUIREMENTS

16-3.1 DDESB Review

Plans for ECM structure modification and new construction must be reviewed and approved by the local wing weapons safety office in accordance with AFMAN 91-201. The ECM modification or new construction will be included in a site plan package that will be reviewed and approved by the DDESB to ensure that minimum DoD explosive safety considerations have been addressed. Situations requiring approval include:

- New construction or major modification
- Changes in use of facilities that affect the siting separation distances

16-3.2 Pre-approved ECM Designs

If pre-approved ECM designs are used, the project site plan and the drawing numbers of the ECM design must be submitted for approval. All new 7- and 3-bar ECM designs must be approved by the DDESB before they may be used. The approval will require the submission of test results or detailed structural calculations.

16-3.3 Undefined ECM Designs

All new, undefined ECM designs require prior approval from the DDESB to ensure that minimum design and construction criteria are met.

16-4 LIFE SAFETY AND MEANS OF EGRESS

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC and AFSEC.

16-4.1 Life Safety Performance Criteria

These performance criteria will be met during all operational modes and ECM configurations:

- Provide safe egress for all occupants of the facility.
- Provide adequate protection, including emergency lighting and communication, for essential personnel to perform necessary weapons safety and security functions in case of a fire event.

NOTE: Typical DoD ECMs are small structures that are occupied only for brief periods to permit the addition or removal of weapons systems from the structure. The weapons systems are then transported to an industrial facility (refer to Chapter 15), an underground facility (refer to Chapter 14), or transported off the DoD installation. The only other expected periods of occupancy will be temporary access by a limited number of personnel to perform maintenance on the ECM's infrastructure systems. Otherwise, security measures will effectively prevent access by all personnel to the ECM. Life safety performance criteria provided in the FHA should incorporate such operational considerations.

16-4.2 Occupancy Classification

ECM structures used for the storage of nuclear weapons will be considered special-purpose industrial occupancies.

16-4.3 Occupant Load

In determining the exiting requirements for a nuclear weapons-capable maintenance and storage facility, the actual number of assigned personnel and expected number of security personnel during operations in the ECM with an added safety factor of 20 percent will be used to determine occupant load in lieu of other criteria within NFPA 101.

16-4.4 Number of Means of Egress

One means of egress from an ECM is permitted.

16-4.5 Travel Distances

Travel distances to an exterior exit must not exceed 400 feet (122 meters) for facilities protected throughout by an automatic fire suppression system. For facilities not protected throughout by an automatic fire suppression system, travel distances to an exterior exit must not exceed 200 feet (61 meters).

16-4.6 Common Path of Travel

The common path of travel distance is not limited.

16-4.7 Dead-End Corridors

Dead-end corridors are not permitted.

This Page Intentionally Left Blank

CHAPTER 17 COMBINED MAINTENANCE AND STORAGE FACILITIES

NOTE: Cognizant Office of Responsibility for this chapter is AFCEC unless otherwise specified.

17-1 SCOPE

This chapter includes requirements in addition to the requirements (unless otherwise specified) of Chapters 1 through 13 that are applicable to restricted access/egress facilities where combined maintenance and storage activities such as inspection, testing, fueling, and periodic maintenance take place. This type of facility is located at ground level but portions of the facility exterior walls are strengthened to resist an exterior threat in accordance with DoDM S-5210.41 / AFMAN 31-108. For facilities that are located underground, comply with Chapter 14 in lieu of this chapter.

17-2 ARCHITECTURAL REQUIREMENTS

17-2.1 Construction Type

Buildings will be constructed to be fire-resistant or noncombustible (Type I or Type II in accordance with the IBC). All walls, floors, and structural components, except interior finish materials in office and support areas, will be of noncombustible construction. Use of combustible interior finishes will be minimized.

17-2.2 Fire Areas

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC and AFSEC.

Facilities capable of inspecting, maintaining or storing nuclear weapons components will be subdivided into separate fire areas to minimize the risk of fire spread and the resultant consequential damage from fire gases, smoke, heat, radioactive contamination, and firefighting activities. In addition, the subdivision into fire areas will allow adequate access for manual fire suppression activities and be as consistent as possible with the blast zones (when provided).

17-2.2.1 Establishment of Boundaries

The boundaries of fire areas will be established in the FHA based on general fire protection criteria that include these elements:

- Types, quantities, density, and locations of combustible and flammable materials, and of radioactive materials
- Location of blast doors (if provided)
- Location of security access portals
- Location and configuration of equipment
- Consequences of inoperable equipment

- Location or zoning of fire detection and suppression systems
- Personnel safety, exiting, and area of refuge requirements
- Building separations and occupancy separation requirements

17-2.2.2 Boundary Objectives

In limited-access combined industrial and storage facilities, fire area boundaries will accomplish fire protection objectives, including:

- To separate all contiguous buildings or portions thereof serving different purposes, such as storage, maintenance, service, administration, and other occupancy designations
- To separate weapons storage areas from adjacent areas
- To separate weapons maintenance areas from adjacent areas
- To separate fueling areas from adjacent areas
- To separate security and other control rooms, computer rooms, or combined control and computer rooms from adjacent areas
- To separate rooms with major concentrations of electrical equipment, such as switchgear rooms and relay rooms, from adjacent areas
- To separate battery rooms from adjacent areas
- To separate each fire pump and its associated equipment from all other pumps in the same room or pump house
- To separate each fire pump from adjacent areas
- To separate warehouse areas and combustible storage areas from adjacent areas
- To separate standby or emergency power generators from each other and from adjacent areas
- To separate fan rooms and plenum chambers from adjacent areas
- To separate office areas from adjacent areas

17-2.2.3 Fire Barriers Separating Fire Areas

Fire barriers separating fire areas must be of a minimum 3-hour fire resistance rating with listed 3-hour-rated penetration seals.

17-2.2.4 Fire Doors and Fire Windows in Fire Barriers

Fire doors and fire windows used in fire barriers will be installed and maintained in accordance with NFPA 80. In the case of blast doors in fire barriers, refer to paragraph 7-4.3.8.

Normally, closed fire doors in fire barriers will be identified with a sign indicating, “Fire Door — Keep Closed.”

Windows in fire barriers, such as for a security control room or computer room, will be provided with a listed or approved fire shutter, automatic wall curtain, or fire resistance glazing.

17-2.3 Vertical Shafts and Plenums

To prevent vertical spread of fire, all stairways, elevator shafts, escape ladders, and other vertical shafts and plenums will be enclosed with barriers having a fire resistance rating of at least 2 hours. Openings in such barriers will be protected with listed automatic or self-closing fire doors having a fire protection rating of at least 1.5 hours.

17-3 COMBUSTIBLE MATERIALS AND FINISHES

17-3.1 Areas Where Weapons Are Maintained or Stored

Combustible materials, other than materials fully contained within and designed to serve as part of the weapon or weapon delivery vehicle/system, must be excluded from fire areas designated for weapon maintenance and storage except for incidental amounts of combustible materials as determined by the FHA. Such incidental amounts might include solid wood blocks that serve as chocks for weapons support or small amounts of solvent used for weapons maintenance.

17-3.2 Blast Shielding Materials

Permanent and temporary shielding materials must be noncombustible or limited combustible, based on:

- ASTM E84
- NFPA 253
- NFPA 255
- UL 94

Polystyrene used for sand walls is not required to be encased with fire-resistant materials.

17-3.3 Interior Finishes

17-3.3.1 Interior Wall and Ceiling Finish

Interior wall and ceiling finish in areas processing or storing radioactive materials will be Class A in accordance with NFPA 255.

NOTE: The design should consider a potential radiation contamination incident and include wall and ceiling finishes that are easy to clean.

17-3.3.2 Interior Floor Finish

Interior floor finish in areas processing or storing radioactive materials will be Class I in accordance with NFPA 253. If required to meet weapon maintenance environmental conditions, anti-static flooring having less than a Class I fire rating is permitted when approved by the Cognizant Office of Responsibility.

NOTE: The design should consider a potential radiation contamination incident and include floor finishes that are easy to clean.

17-3.4 Other Materials

Thermal insulation materials, radiation shielding materials, ventilation duct materials, soundproofing materials, and suspended ceilings, including light diffusers and their supports, will be noncombustible or limited combustible. If polypropylene or polyethylene is required for neutron shielding, it must be totally encased with a noncombustible material such as steel or 5/8-inch (16-millimeter) type X gypsum board. Approximately 3/8-inch (10-millimeter) vent holes must be provided within the encasement to permit the venting of gases from the poly material.

NOTE: Encasement is required because many plastic materials, including flame- and fire-retardant materials, will burn with an intensity and energy production in the range similar to that of ordinary hydrocarbons. When burning, these materials produce heavy smoke that obscures visibility and can plug air filters, especially charcoal and HEPA filters. When burning, halogenated plastics also release free chloride and hydrogen chloride. These gases are toxic to humans and corrosive to equipment.

17-4 HAZARD CONTROL

17-4.1 Flammable and Combustible Liquids

17-4.1.1 Where oil-burning equipment, stationary combustion engines, or gas turbines are used, they will be installed and used in accordance with NFPA 31 or NFPA 37, as appropriate.

17-4.1.2 Flammable and combustible liquid and gas piping will be in accordance with ANSI B31.1 or the ASME *Boiler and Pressure Vessel Code*, Section III, as applicable.

17-4.2 Hydraulic Systems

Hydraulic systems must use only listed fire-resistant hydraulic fluids.

17-4.3 Solvents

Where a flammable or combustible solvent is used, it must be handled such that the uncontrolled release of vapors is not permitted.

17-4.4 Gases

Flammable and combustible gases will be stored and handled in accordance with NFPA 54, NFPA 55, and NFPA 58.

Bulk flammable gas storage, either compressed or cryogenic, will not be permitted inside structures capable of maintaining or storing nuclear weapons.

Storage of flammable gas, such as hydrogen, will be located outdoors or in separate detached buildings so a fire or explosion will not adversely affect any nuclear weapons maintenance and storage facility systems or equipment.

17-4.5 Automatic Sprinkler System

In addition to the requirements of Chapter 11 of this document, provide a conventional wet-pipe sprinkler system designed for Extra Hazard Group 1 occupancy (0.3 gpm/ft^2 over 2500 ft^2 [12.2 mm/min over 232 m^2]) for all areas subject to maintenance, fueling, transport, or storage for fueled weapons delivery vehicles/systems.

17-5 REFUELING AREAS

17-5.1 Automatic Foam Fire Suppression

An automatic, local application, foam fire suppression system will be provided. The system will protect the area from the hazards defined within the FHA and be designed in accordance with NFPA 11. Foam concentrate and water will be provided to permit continuous operation of the system for 30 minutes. Activation of the foam discharge will be accomplished by a fire detection system meeting the requirements of Chapter 11. A pressure proportioning-type foam concentrate tank must be utilized for the foam system. High-expansion foam (if used) will be discharged at a rate to cover the hazard by least 2 feet (0.6 meter) within two minutes, and air to the high-expansion foam generator may be supplied from either within or exterior to the refueling area.

17-5.2 Electrical Equipment

Electrical equipment will comply with NFPA 70, including Chapter 5, “Special Occupancies,” and other NFPA 70 requirements related to hazardous locations.

17-5.3 Fuel Transfer Pumps

Where pumps are used for liquid fuel transfer, means will be provided to shut down liquid transfer in the event of a spill or fire.

17-5.4 Fuel Holding Tanks

Fuel holding tanks (i.e., operationally required tanks) located within refueling areas must not exceed 200 gallons (757 liters) per tank, with a maximum of two fuel holding tanks per refueling area.

Fuel holding tanks will be equipped with overfill protection.

17-5.5 Fuel Line Shutoff

Fuel supply lines entering refueling rooms will be arranged with a spring-loaded automatic shutoff valve that is activated via a fusible link.

17-5.6 Containment in Refueling Rooms

Refueling rooms will be designed to capture the entire contents of the fuel within the refueling room and the discharge of automatic fire sprinkler and foam fire suppression systems for 30 minutes. Drainage to a separate location must be approved by the Cognizant Office of Responsibility.

17-5.7 Ventilation

17-5.7.1 General

Refueling rooms will be provided with either a gravity system or a continuous mechanical exhaust ventilation system.

17-5.7.2 Exhaust Location

Exhaust air will be taken from a point near a wall on one side of the room and within 12 inches (30.5 centimeters) of the floor, with one or more make-up inlets located on the opposite side of the room within 12 inches (30.5 centimeters) of the floor.

17-5.7.3 Air Openings

The location of both the exhaust and inlet air openings will be arranged to provide air movement across all portions of the floor to prevent the accumulation of vapors.

17-5.7.4 Recirculation

Exhaust from the room must be conducted directly to the exterior of the building and must not be recirculated.

17-5.7.5 Ducts

If ducts are used, they must not be used for any other purpose and will comply with NFPA 91.

17-5.7.6 Make-Up Air

If make-up air to a mechanical system is taken from within the building, the opening must be equipped with a fire door or damper as required in NFPA 91.

17-5.7.7 Gravity Systems

For gravity air systems, the make-up air must be supplied from outside of the building.

17-5.7.8 Capacity

Mechanical ventilation systems must provide at least 1 cubic foot per minute (28.3 liters per minute) of exhaust air for each square foot (0.09 square meter) of floor area, but not less than 150 cubic feet per minute (4,248 liters per minute).

17-5.7.9 Dispensing Areas

The mechanical ventilation system for dispensing areas will be equipped with an airflow switch or other equally reliable method that is interlocked to sound an audible alarm upon failure of the ventilation system.

17-5.7.10 Air Intake Height

The minimum height of air intakes in these areas will be in accordance with UFC 4-010-01.

17-5.8 Static Electricity

Means will be provided to minimize the generation of static electricity in the refueling area. See AFI 91-203, NFPA 77, and NFPA 407.

17-6 LIQUID RUN-OFF CONTROL

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC and AFSEC.

Drainage must be provided in all areas of the facility for the removal of all liquids directly to safe areas, or for containment in the area and without endangering other areas. (See paragraph 17-7.6.)

17-6.1 Methods

Drainage and the prevention of equipment water damage will be accomplished by one or more of these methods:

- Floor drains
- Floor trenches
- Open doorways or other wall openings
- Curbs for containing or directing drainage
- Equipment pedestals
- Pits, sumps, and sump pumps

17-6.2 Sump Pump Systems

Waste and drainage sump pump systems will be provided with 100 percent redundant pumps.

17-6.3 Drainage and Drainage Facility Size

Drainage and any associated drainage facilities for a given area will be sized to accommodate the volume of liquid produced by all of these sources:

- The spill of the largest single container of any flammable or combustible liquids in the area (see paragraph 17-6.6 for refueling rooms)
- The credible volume of discharge (as determined by the FHA) released by the automatic suppression system operating for a period of 30 minutes, unless the approved FHA authorizes a different flow rate and duration
- The contents of piping systems and containers that could fail in a fire
- The volume of water discharged based on a manual firefighting flow rate of 500 gallons per minute (1,890 liters per minute) for 30 minutes unless the approved FHA authorizes use of a different flow rate and duration
- For areas open to the outside, such as underground loading docks, credible environmental factors such as rain and snow

17-6.4 Staging Equipment

Necessary equipment must be staged to assist with routing water from the affected area. The use of the staging equipment will be addressed in the fire department pre-fire plan.

17-6.5 Floor Drainage

Floor drainage from areas containing flammable or combustible liquids must be trapped to prevent the spread of burning liquids beyond the fire area.

17-6.5.1 Areas with Radioactive Materials

Floor drainage from storage and maintenance areas capable of containing nuclear weapons components must be trapped to prevent the spread of radioactive materials beyond the facility's controlled boundaries.

Water drainage from areas that might contain radioactivity must be collected, sampled, and analyzed before discharge to the environment or outside the boundaries of the facility.

Water released during fire suppression operations in areas containing radioactivity must be drained to a location that would be acceptable for the containment of radioactive materials.

17-6.6 Criticality Hazards

NOTE: The Cognizant Office of Responsibility for this paragraph is AFSEC.

Nuclear weapons-capable storage and maintenance areas will be designed to be criticality safe if required by the Cognizant Office of Responsibility, including consideration of the operation of automatic sprinklers and other fire suppression systems. Floor drains must be provided. Appropriate drain lines, storage, and handling systems capable of handling potentially contaminated water must be provided.

17-7 THROUGH PENETRATION FIRE STOPS

17-7.1 Where Required

17-7.1.1 Penetrations

Fire stops for penetrations such as pipes, conduits, bus ducts, cables, wires, pneumatic tubes and ducts, and similar building service equipment that passes through fire barriers will be provided to prevent the spread of fire using listed or approved materials (caulking) or devices (sleeves).

17-7.1.2 Blast-Resistant Barrier

If the fire barriers coincide with or are also serving as a blast-resistant barrier, these penetrations will also require blast-resistant devices. If the blast-resistant device is sufficient to serve as protection from the spread of fire, no additional protection is necessary. If the blast-resistant penetration device is not listed or approved for fire penetrations, it can be evaluated by a qualified fire protection engineer and accepted as a fire barrier product by the Cognizant Office of Responsibility.

17-7.2 Annular Spaces

The annular space between the penetrating item and the through opening in the fire barrier must be filled with a qualified (listed or approved) fire-resistive penetration seal

assembly capable of maintaining the fire resistance of the fire barrier. The assembly must be qualified by tests in accordance with fire test protocols or be protected by a listed fire-rated device for the specified fire-resistive period. Penetration seals provided for electrical and mechanical openings must be listed as meeting the requirements of ASTM E814 or UL 1479.

17-7.3 Conduit Seals

Refer to Chapter 3.

17-7.4 Leak Testing

Open flame- or combustion-generated smoke will not be used for leak testing.

17-8 COMMUNICATIONS

NOTE: Cognizant Office of Responsibility for this paragraph is AFSEC.

Communication systems using a lossy antenna distribution system within the facility will be limited as much as possible and must be within the allowable EMR limits of the STS.

All electrical equipment and devices are either intentional or unintentional EMR emitters as defined in Chapter 8. All such equipment to be used in close proximity to critical equipment interior to the facility must not exceed the allowable EMR limits of the STS. Anticipated EMR emitters must be analyzed to evaluate anticipated EMRE levels. If the EMRE levels exceed allowable limits, facility design, equipment selection, or procedures must be adjusted to mitigate EMRE levels.

17-9 LIFE SAFETY AND MEANS OF EGRESS

NOTE: Cognizant Office of Responsibility for this paragraph is AFCEC.

17-9.1 Life Safety Performance Criteria

The following performance criteria will be met during all operational modes and facility configurations:

- Provide safe egress or areas of refuge for all occupants of the facility.
- Provide adequate protection, including emergency lighting and communication, for essential personnel to perform necessary weapons safety and security functions in case of a fire event.

17-9.2 Occupancy Classification

17-9.2.1 Industrial facilities involved in the inspection, testing, and maintenance of nuclear weapons and weapon delivery vehicles/systems will be considered limited-access special purpose industrial occupancies as defined in NFPA 101.

17-9.2.2 Those areas involved in the storage of nuclear weapons and weapons delivery vehicles/systems will be considered limited-access special purpose industrial occupancies as defined in NFPA 101.

17-9.2.3 Support and storage areas designated for the storage of materials other than nuclear weapons will conform to the ordinary hazard storage occupancy (refer to Chapters 6 and 42 of NFPA 101) and, if applicable, limited-access requirements in NFPA 101.

17-9.2.4 General office areas, break rooms, security control rooms, and training areas will conform to the business occupancy requirements, and, if applicable, limited-access requirements in NFPA 101.

17-9.3 Occupant Load

In determining the exiting requirements for a limited-access nuclear weapons-capable maintenance and storage facility, the actual number of assigned personnel and expected number of visitors during operations, maintenance, and testing with an added safety factor must be used to determine occupant load in lieu of other criteria within NFPA 101. The safety factor will be 30 percent for maintenance areas and 20 percent for storage areas.

17-9.4 Number of Means of Egress

17-9.4.1 Fire areas designated as not limited-access must have at least two means of egress.

17-9.4.2 A single means of egress will be permitted from any story or section of a non-restricted access/egress fire area, provided the exit can be reached within 100 feet (30 meters) and when the single means of egress is approved by the Cognizant Office of Responsibility.

17-9.4.3 Limited-access fire areas must have at least one means of egress. When nuclear security requirements prohibit the use of approved egress components (such as a listed fire door meeting the requirements of NFPA 101) for the means of egress, an area of refuge must also be provided within the fire area (see paragraph 17-10.6).

17-9.4.4 Refueling room must have not less than two means of egress.

17-9.5 Horizontal Exit

A horizontal exit will be considered to be any adjacent fire area separated by at least 3-hour fire-rated construction and accessible through listed fire doors meeting the requirements of NFPA 101 and NFPA 80.

17-9.6 Area of Refuge

An area of refuge will:

- Be separated from adjacent areas by at least 3-hour fire-rated construction
- Minimize the entrance of smoke
- Be protected throughout by automatic sprinklers
- Be provided with two-way communication (including instructions on the operation of the equipment)

An area of refuge must be provided with protective heat-resistant clothing, emergency drinking water, and sufficient breathing air to permit survival for at least 72 hours based on the expected occupant load. The occupant capacity for the area of refuge will be established in the FHA.

NOTE: When possible, the area of refuge within a fire area should be located near the nuclear security access doors into the fire area.

17-9.7 Travel Distances

For weapon maintenance and storage areas, travel distances to an exterior exit, horizontal exit, or area of refuge within the fire area must not exceed 400 feet (122 meters).

For refueling rooms, travel distances to an exit must not exceed 75 feet (23 meters).

For all other limited-access areas, travel distances to an exterior exit, horizontal exit, or area of refuge within the fire area must not exceed 300 feet (91 meters)

17-9.8 Common Path of Travel

For weapon storage areas, common path of travel distances are not limited. For all other limited-access areas, the common path of travel must not exceed 100 feet (30 meters).

17-9.9 Dead-End Corridors

For restricted access/egress areas, dead-end corridors distances are not limited, provided travel distances and common path of travel distances are not exceeded. For all other areas, dead-end corridors must not exceed 50 feet (15 meters).

17-9.10 Special Locking Devices

Special locking devices (such as dead bolts and slide bolts) may be installed and left engaged on exit doors during periods of occupancy in addition to the normal door locking devices, provided that the devices are required by security, are clearly visible to the building occupants, and the building occupants are advised of their presence.

NOTE: Such locking devices should be marked or painted with a bright contrasting color (e.g., orange, yellow, red) to be clearly visible to the occupants.

17-10 ELECTROEXPLOSIVE DEVICES (EED)

NOTE: Cognizant Offices of Responsibility for this paragraph are AFCEC and AFSEC.

17-10.1 Storage and Testing Area Criteria

Areas where EEDs are stored or tested will meet the following criteria:

17-10.1.1 Separation

EED areas will be designed to withstand the internal explosive hazard and will be separated from the remainder of the facility by not less than 3-hour-rated walls.

17-10.1.2 Seals

All permanent penetrations into and out of the room must be sealed by a listed or approved means (i.e., penetration seals, fire and smoke dampers).

Penetrations that are provided for use in remote testing or remote electrical testing may be covered with a movable steel door or “flap” that is configured with a small slit that allows temporary wiring needed for the testing to penetrate the wall.

17-10.1.3 Ventilation Ductwork

Ventilation ductwork that penetrates the room must be equipped with fire or combination fire and smoke dampers with at least a 3-hour fire rating. Alternate means of protection of the ductwork (i.e., without dampers) are not permitted.

17-10.1.4 Blast Doors

Blast doors will be designed to withstand the internal explosive hazard and be evaluated by a qualified fire protection engineer to determine if the door may be considered as equivalent to that of a 3-hour-rated fire door. Use of the blast doors for this purpose must be approved by the Cognizant Offices of Responsibility.

17-10.1.5 Fire Suppression

The room will be protected by an automatic sprinkler fire suppression system.

NOTE: The sprinklers should be supplied from above the ceiling and also provided with sprinkler guards. These features will help reduce damage to the sprinkler system due to explosion.

17-10.1.6 Grounding

Grounding or bonding to an earth ground must be provided (see Chapter 3).

17-10.2 Deflagration Venting

Areas where EEDs are stored or tested must be provided with deflagration venting in accordance with NFPA 68.

17-11 ARMORIES

17-11.1 Fire Rating

Armories must be separated from the remainder of the facility by a minimum of 2-hour fire-rated construction and 1.5-hour-rated fire doors.

17-11.2 Fire Stops

Penetrations into armories will be fire stopped (e.g., fire dampers, penetration seals) in addition to security requirements.

17-11.3 Automatic Sprinklers

Armories must be protected with automatic sprinklers. The sprinkler piping into an armory may be valved to permit isolation of the system in the event of an emergency when approved by the Cognizant Office of Responsibility.

17-11.4 Security Doors

Security doors into armories will be evaluated by a qualified fire protection engineer to determine if a door may be considered as equivalent to that of the required fire-rated door. Use of the security doors for this purpose must be approved by the Cognizant Office of Responsibility.

17-12 FIRE HYDRANTS FOR ENTRY/EXIT POINTS

Fire hydrants will be installed within approximately 50 feet (15 meters) of each entry/exit point for over-the-road vehicle loading dock.

17-13 SECURITY CONTROL ROOM COMPLEX

See Chapter 5 for security control room complex requirements.

17-14 COMMUNICATIONS

For all communication systems that are wireless or EMR emitting devices, the restrictions within Chapter 8 will be implemented as appropriate.

Prior to the introduction of wireless devices, the devices must be reviewed by the Host Wing, Weapons Safety Office.

APPENDIX B BEST PRACTICES

B-1 GUIDELINES FOR POTENTIALLY SURVIVABLE FIRE PROTECTION SYSTEM ARCHITECTURES

B-1.1 INTRODUCTION

This document defines a spectrum of facility-related requirements for nuclear weapons-capable maintenance and storage facilities. These requirements include, but are not limited to, requirements for design, construction, and maintenance. There are relatively few of these facilities and, since they have unique design features, national consensus standards are either not available or are not applicable to these facilities.

The principles of fire safety required for nuclear weapons-capable maintenance and storage facilities documented herein were developed by collecting and refining criteria from the DoD, fire protection and munitions safety experts, and national consensus fire safety standards. The document requires that an approved fire detection system and suppression system (e.g., automatic sprinkler system, water mist system, or foam-water system) be installed in all areas of the facility unless shown to be unnecessary in the FHA. The automatic sprinkler system must be designed and installed in accordance with NFPA 13 and UFC 3-600-01.

Water-based fire suppression systems are required to be hardened against possible internal or external damage. This appendix describes different approaches to increase the survivability of a required suppression system and increase the capabilities of a suppression system in a damaged area. Less-conventional, alternative survivable systems for meeting the document's hardening requirements are also described.

B-1.2 OBJECTIVE

The objective of these guidelines is to identify potential approaches to increase the survivability of required water-based fire suppression systems and to identify other potentially more survivable systems for weapons storage facilities.

B-1.3 FACILITY TYPES AND DESCRIPTIONS

B-1.3.1 Facility Types

Several types of nuclear weapons-capable maintenance and storage facilities are discussed in this appendix: ECMs, industrial facilities, and underground facilities. ECMs and underground storage areas are used primarily for storing various munitions. These facilities typically consist of a large, open area with little, if any, floor-to-ceiling compartmentalization. Industrial facilities and portions of underground storage are used for such activities as inspection, maintenance, and testing of munitions. These facilities consist of separated use areas, including administration portions (office spaces), maintenance bays, and mechanical rooms.

B-1.3.2 Compartmented Areas

Facilities capable of storing nuclear weapons and components must be subdivided into separate fire areas to minimize the risk of fire spread and the resultant consequential damage from fire gases, smoke, heat, radioactive contamination, and to aid in firefighting activities. Fire area boundaries must be provided to separate contiguous buildings or portions thereof serving different purposes, such as storage, maintenance, service, administration, and other occupancy areas as dictated by the facility design.

B-1.3.3 Open Areas

ECMs and underground storage areas typically consist of a limited number of large weapon storage areas. These areas can potentially have relatively large footprints.

B-1.4 PERFORMANCE OBJECTIVES

The system can be designed to meet three performance objectives:

- Maintaining capabilities of the system in undamaged areas.
- Containing the fire to the damaged area.
- Controlling or suppressing the fire in the damaged area.

Paragraph B-1.5 identifies approaches and techniques to configure the system to meet some or all of these objectives.

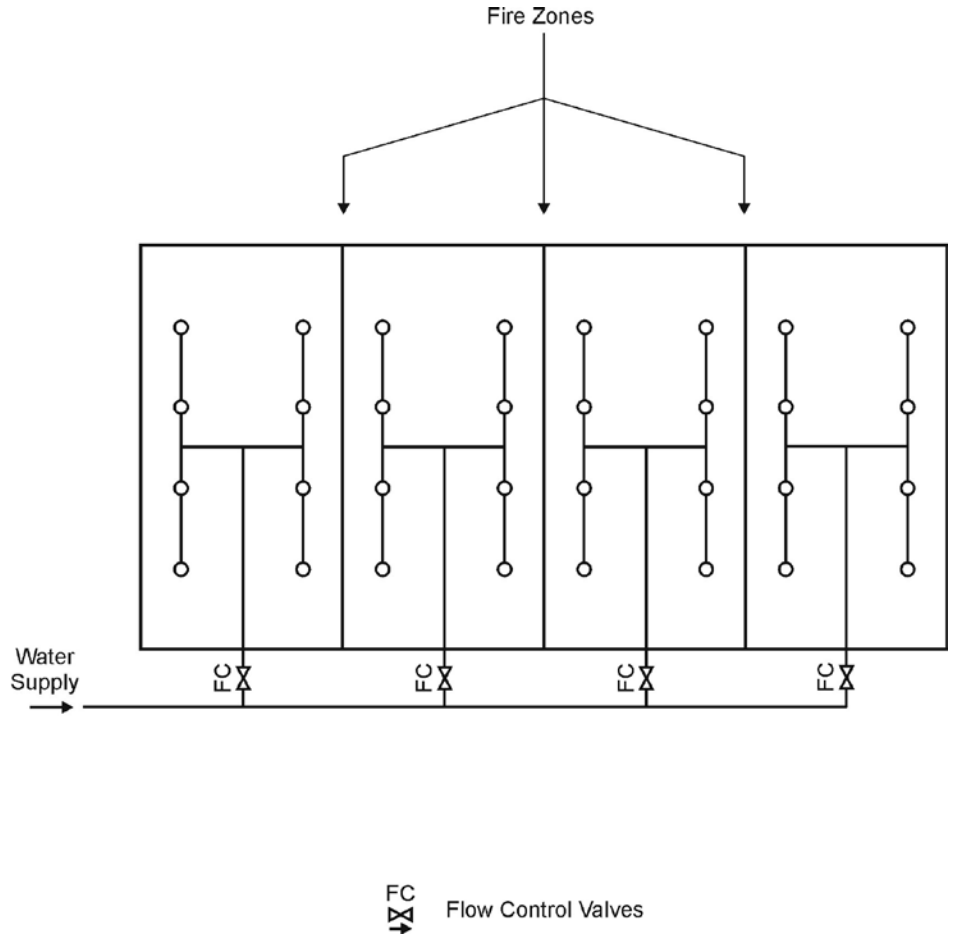
B-1.5 SURVIVABLE ARCHITECTURES

The performance objectives of the system will dictate the required architecture. The systems with the greatest capabilities would be the most complex and expensive. Conversely, systems with reduced capabilities would be the simplest and most economical to design and install. The approaches addressed in this paragraph progress from simple to more complex (i.e., in the order of the performance objectives listed in paragraph B-1.4).

B-1.5.1 Architectures for Maintaining Capabilities in Undamaged Areas

To maintain the capabilities in the undamaged areas, the system must be segregated into fire zones (referred to in this appendix as fire areas). At a minimum, a reliable water supply must be provided. Also, rupture isolation for installed agent piping must be provided. This can be accomplished using flow control valves located within each fire zone boundary.

B-1.5.1.1 Simplest Approach



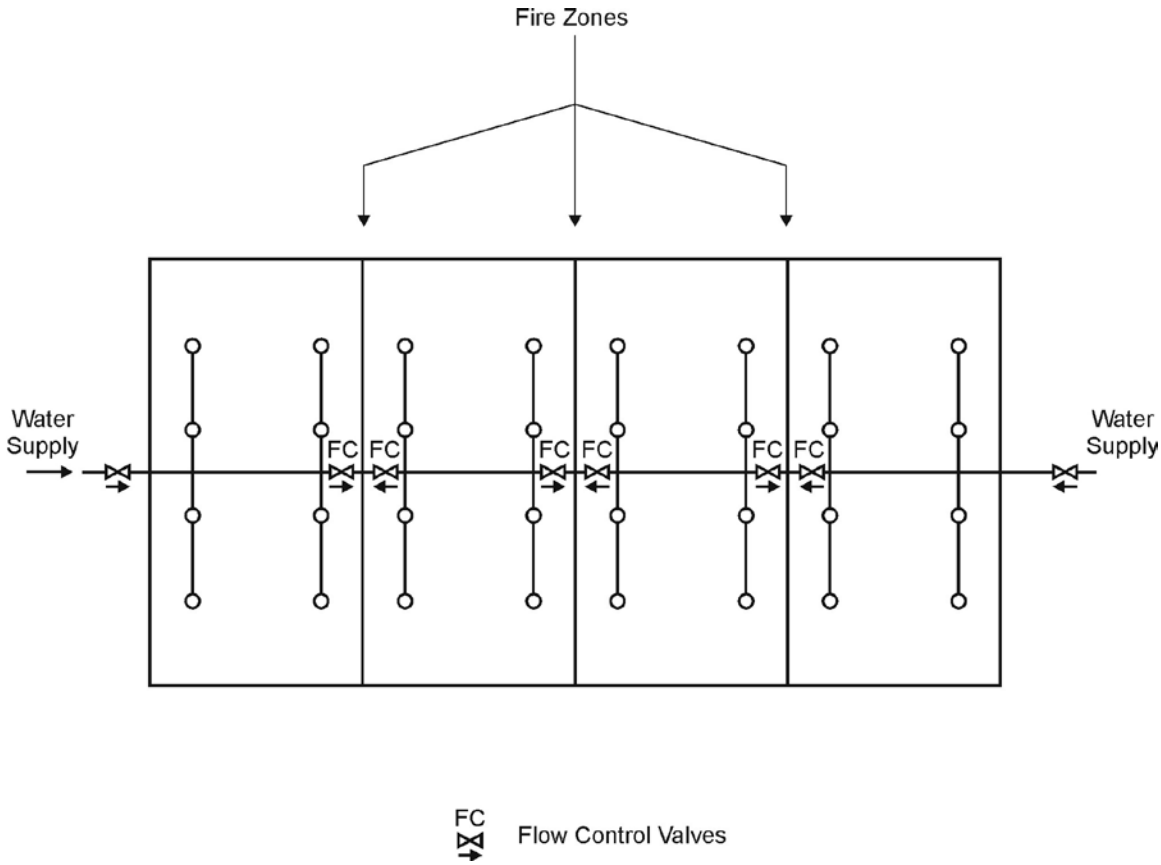
The simplest approach is to install the distribution main and control valves for each zone at a survivable location. These are potentially survivable locations:

- Low in the facility at the junction between the wall and the floor (baseboard)
- Any area that runs the length of the facility that is outside of the potential damage area from the initiating event

Installing the main in the concrete floor slab or even below grade just outside the building may also be options.

Figure B-1 shows a single survivable distribution main located outside of the facility supplied from one end with only a single control valve for each fire zone. Rupture isolation is provided by the control valves for each zone. This approach is adequate only if the distribution main and control valves are outside the damaged area.

Figure B-1 Survivable Distribution Main Architecture



B-1.5.1.2 Alternate Approach

A second approach would be to provide redundant water supplies that enter from opposite ends of the facility. These supplies would feed into opposite ends of a distributed fire main supplying all of the fire suppression systems in the facility.

Figure B-2 shows a single distribution main supplied from opposite ends of the building, with control valves located on both sides of each fire zone boundary.

Figure B-2 Basic Survivable Architecture

B-1.5.1.2.1 Flow Control Valves

These flow control valves can be either manually operated or automatic. Manually operated flow control valves are the simplest and the easiest to install but require a manned response for the system to operate properly. Automatic valves have the advantage of not requiring a manned response but are more expensive. Automatic valves can be either self-contained mechanical or electrical valves (referred to as excess flow valves).

B-1.5.1.2.2 Excess Flow Valves

Excess flow valves automatically close if the flow through the system exceeds a preset value. The simplest type of excess flow valve is a mechanical valve (a spring-loaded piston or flapper) that is pushed closed by the friction produced by the higher flow rates. Electrical excess flow valves (sometimes referred to as smart valves) are equipped with either flow or pressure sensors that assess the flow condition through the valve and automatically secure the valve if the preset value is exceeded. These valves are

expensive and require power to be run to each valve. A backup power supply (i.e., battery) may also be required, depending on the reliability of the primary power supply. These valves are not standard fire protection system components and have been developed and tested by the U.S. Navy and the petroleum industry.

B-1.5.1.2.3 Fully Automated System

A fully automated system is the most complex and expensive. This system consists of electrical valves operated by a separate computerized control system. In addition to the control valves, the pipe network must be instrumented to provide information to the control system. An industrial flow control system used in processing-type facilities could be adapted for this application. In addition, many of the commercially available fire detection and alarm panels can be programmed to control a simple automated system.

B-1.5.2 Architectures for Containing and Combating Fire in the Damaged Area

Maintaining the capabilities of the system in the undamaged zones is the first step in containing the fire to the damaged area. The surviving parts of the system in the undamaged area may not prevent the fire from spreading into the undamaged areas. Specifically, the surviving adjacent zones may not activate until fire has spread into that area.

As currently designed, the adjacent zones have no capabilities against the fire in the damaged area. To obtain these capabilities (containment or suppression of the fire in the damaged area), the system would need to be modified to include additional nozzles, or a new or different system would need to be considered.

B-1.5.2.1 Detection and Control System

Modifying the existing sprinkler system or selecting a new system for this application would result in a more sophisticated and complex system than the conventional sprinkler systems commonly in use. Specifically, the modified or new systems would need to be controlled by a separate detection and control system. This is required since the added component or new system used to combat the fire in the damaged area must be located away from the damage. The fire detection system required in Chapter 11 of this document could be used to control this more sophisticated system, minimizing the cost to obtain these additional capabilities. All of the architectures and systems discussed in the following paragraphs would incorporate the required fire detection system to control the fire suppression system.

B-1.5.2.2 Applicability

The discussion in paragraphs B-1.5.2.3 through B-1.5.2.5 applies only to open areas within the facility. Compartmented areas (office-type spaces, shops, and services areas) are difficult to protect from adjacent zones. This is typically acceptable since the open storage areas are a primary hazard of concern.

As a final point, a conventional automatic sprinkler system may not be the best choice for protecting large, open spaces. Namely, larger fires are required to activate the automatic sprinkler system in open storage areas. This may justify the need for a more sensitive detection system that could be used to control the fire suppression system.

The following paragraphs identify two approaches that can be used to increase the capabilities of the required automatic sprinkler system against a damage scenario.

B-1.5.2.3 Approach 1: Switch to Deluge Sprinkling

Since larger fires are typically required to activate automatic sprinklers in large, open areas, deluge sprinkling may be a better option than thermally activated heads.

B-1.5.2.3.1 System Activation

The detection system installed in the space would activate the system. The activation criteria (for the undamaged system) can be selected based on the ambient conditions in the facility and the nature of the hazard. For example, a default can be to activate the system using 135 degrees F (57 degrees C) intrinsically safe heat detectors. If a more sensitive detection system is required, cross-zoned smoke detectors are an option.

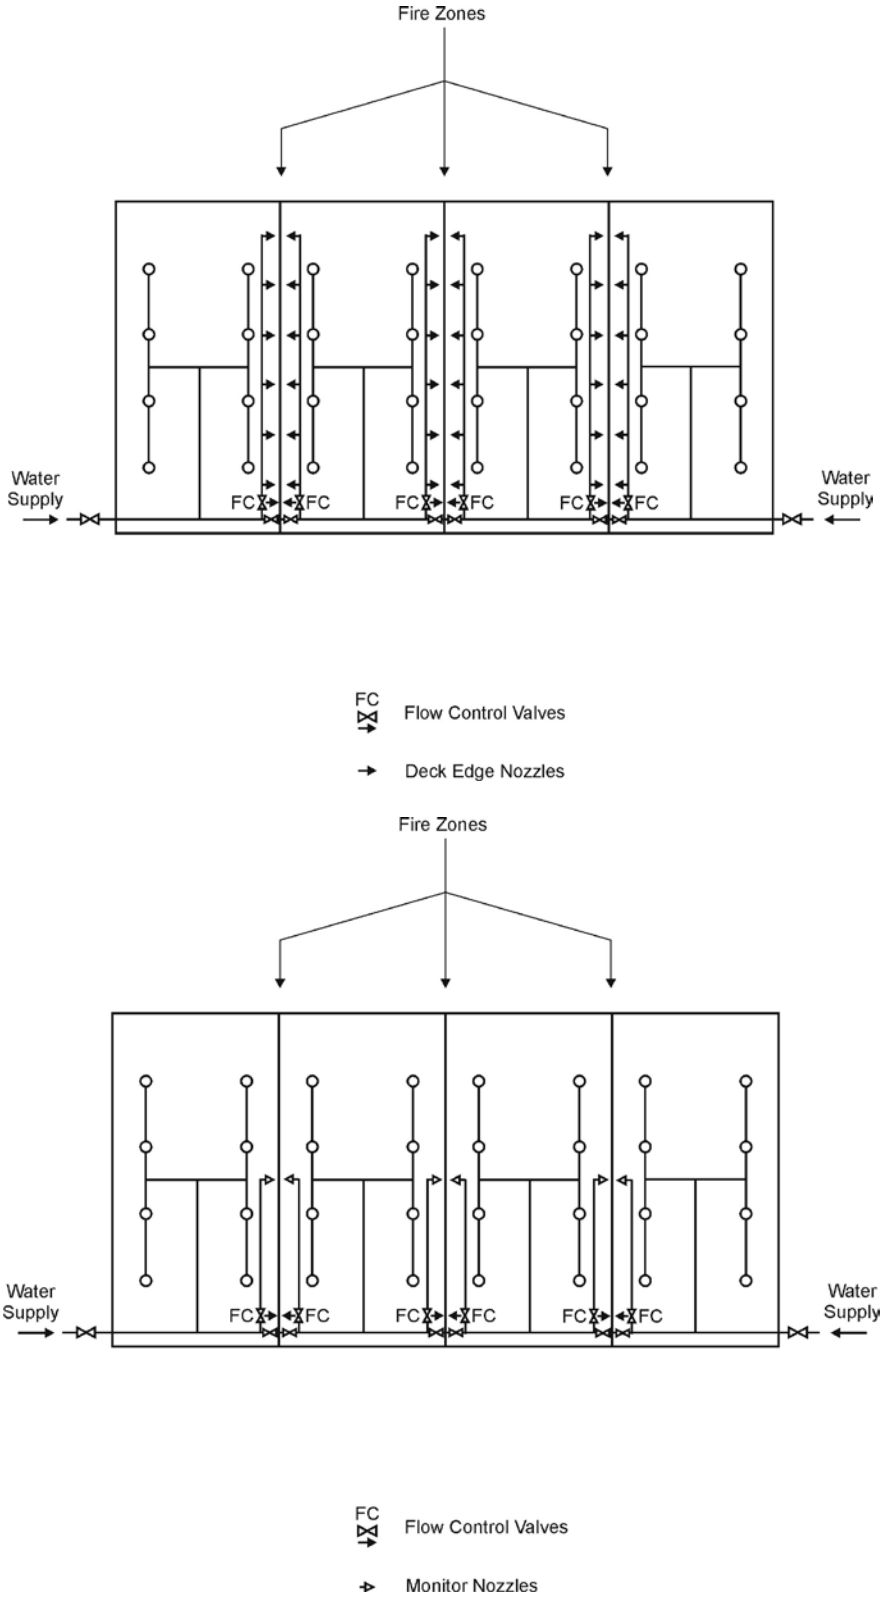
B-1.5.2.3.2 Adjacent Zones

The system can be programmed to automatically discharge water in the zones adjacent to the damaged area. This will help prevent fire spread into these zones or areas by pre-wetting any combustible materials located in these areas.

B-1.5.2.3.3 Flow Rates

Electrical excess flow valves would need to be used for this application (controlled by the detection system) due to the higher flow rates associated with the deluge sprinkling zones. The flow rates of a deluge sprinkling zone may be similar to a damaged system in many scenarios.

B-1.5.2.4 Approach 2: Add Nozzles or Monitors to the Existing System



To combat the fire in the damaged area, additional nozzles or monitors would need to be added to the system. These nozzles or monitors would be installed high in the adjacent zones, spraying into the damaged area or zone. If the damaged area or zone is separated from the adjacent zone by a wall, the nozzles or monitors can be installed in the boundary to spray into the damaged area. Acceptability of penetrating the zone boundary must be considered since this is a violation of fundamental zone integrity criteria (i.e., zones are not typically penetrated).

The simplest approach would be to add a line of nozzles on both sides of each fire zone boundary, spraying into the adjacent zone. An approved “deck edge”-type system (the nozzle arrangements used to protect the flight decks of U.S. Navy surface

combatants but installed high in the space) is recommended for this application. Another approach would be to provide one or more 125-gallons-per-minute (473 liters per minute) monitors (depending on the size of the fire zone) on both sides of each fire zone boundary, spraying into the adjacent zone. The monitors must be located at a place that is least likely to be obstructed by the contents in the space. A drawing of the two approaches is provided in Figure B-3.

The branch line containing the supplemental nozzles or monitors would be equipped with an electrically operated valve controlled by the installed fire detection system. The system can be programmed to automatically discharge water into the damaged zone if any or all of the detectors in that zone are reported as damaged (each detector is in “FAULT”). This approach provides the potential to combat the fire in the damaged area.

Figure B-3 Systems That Discharge Water in the Damaged Area

B-1.5.2.5 Aqueous Film-Forming Foam (AFFF)

The default for the two systems (nozzles or monitors) would be to discharge water since they are basically add-ons to the automatic sprinkling system; however, water has only limited capabilities against a potential Class B fire. Specifically, the water would have some effect in controlling the fire but would not be able to suppress or extinguish the fire. To suppress or extinguish the fire, the system would need to discharge aqueous film-forming foam (AFFF).

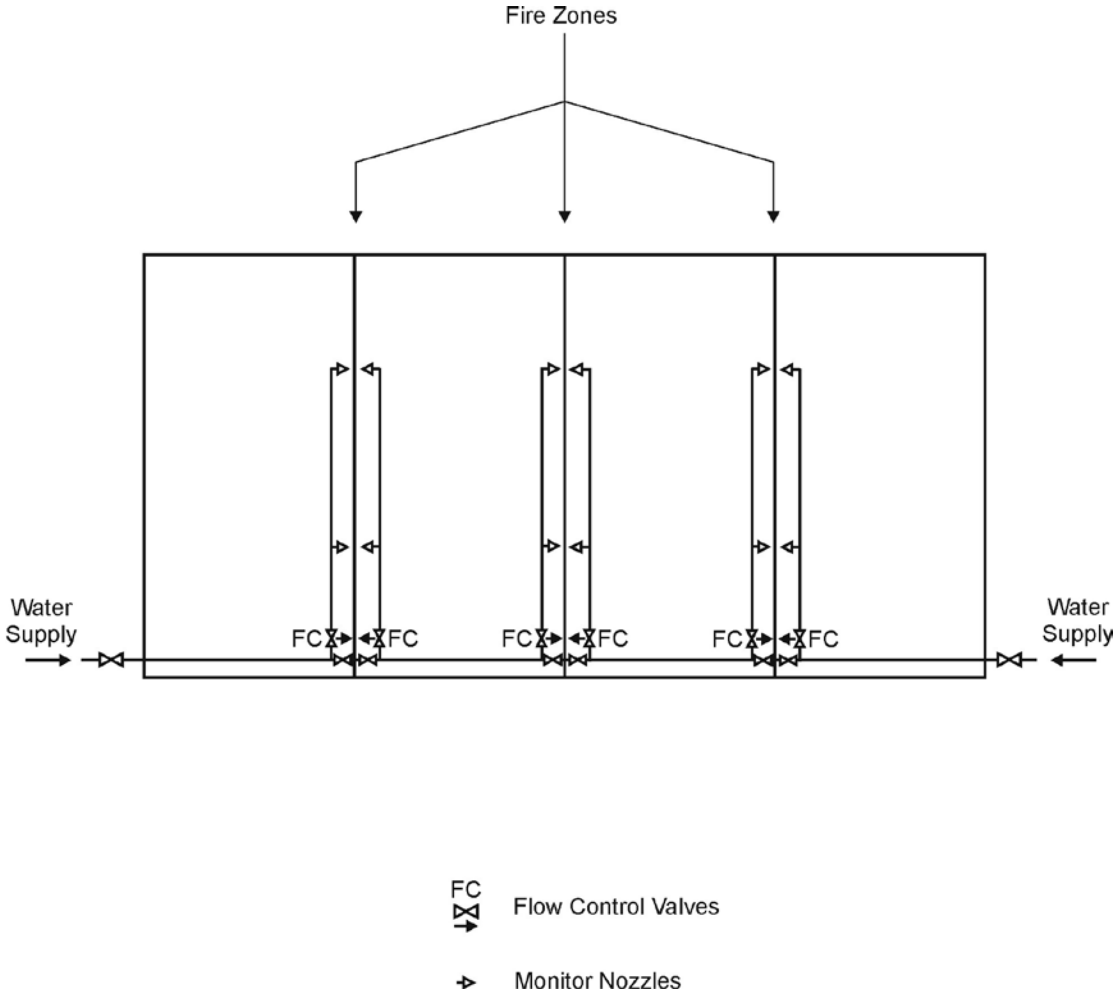
To add the ability to discharge AFFF, proportioning systems would need to be added to both ends of the distributed fire main. The system would be designed to discharge water in the sprinkler mode but would switch to AFFF when the valves to the branch lines containing the additional nozzles or monitors are opened.

The previous two approaches can be used to supplement either the automatic (system with thermally activated heads) or deluge sprinkler systems.

B-1.5.3 Alternative Systems for Containing and Combating Fire in the Damaged Area

The two systems described in this paragraph could be installed as a substitute for the required automatic sprinkler system. Both systems would incorporate a supply main capable of rupture isolation as described in paragraph B-1.5.1. Both systems would also be controlled by the fire detection system installed in the space (required in Chapter 11 of this document or added to control the hardened system). The activation criteria (for the undamaged system) can be selected based on the ambient conditions in the facility and the nature of the hazard. The default can be to activate using 135 degrees F (57 degrees C) intrinsically safe heat detectors. If a more sensitive detection system is required, cross-zoned smoke detectors may be an option. The system would activate when one or a group of detectors are damaged (the detector is in “FAULT”).

B-1.5.3.1 Approach 1: Replace the Sprinkler System with Monitors



One approach would be to replace the required automatic sprinkler system with one consisting solely of monitors. A system produced using monitors has a better chance of being survivable due to the stream reach characteristics of the device (i.e., the monitor can be located away from the damage) and the reduced amount of piping (no overhead nozzle grid). The system will be designed to provide the same application density (water flow rate per unit area) as the automatic sprinkler system being replaced. In addition, the system would be sized for the simultaneous discharge of the two largest fire zones. An example of a system with monitors is shown in Figure B-4.

B-1.5.3.1.1 Configuration

As shown in Figure B-4, the monitors are located outside of the zone they are protecting. If the damaged area or zone is separated from the adjacent zone by a wall, the monitors would be installed in the boundary, spraying into the damaged area.

Each zone contains two monitors (or more, depending on the size of the zone) located adjacent to the protected area. This approach can work only if there is an uncluttered and unobstructed space for the monitors to be installed with direct coverage of the protected area. The branch line containing the monitors would be equipped with an electrically operated valve controlled by the installed fire detection system. The monitors would be set to automatically oscillate through the protected zone (bounded by limit switches).

Figure B-4 System Consisting of Monitors

B-1.5.3.1.2 AFFF Capability

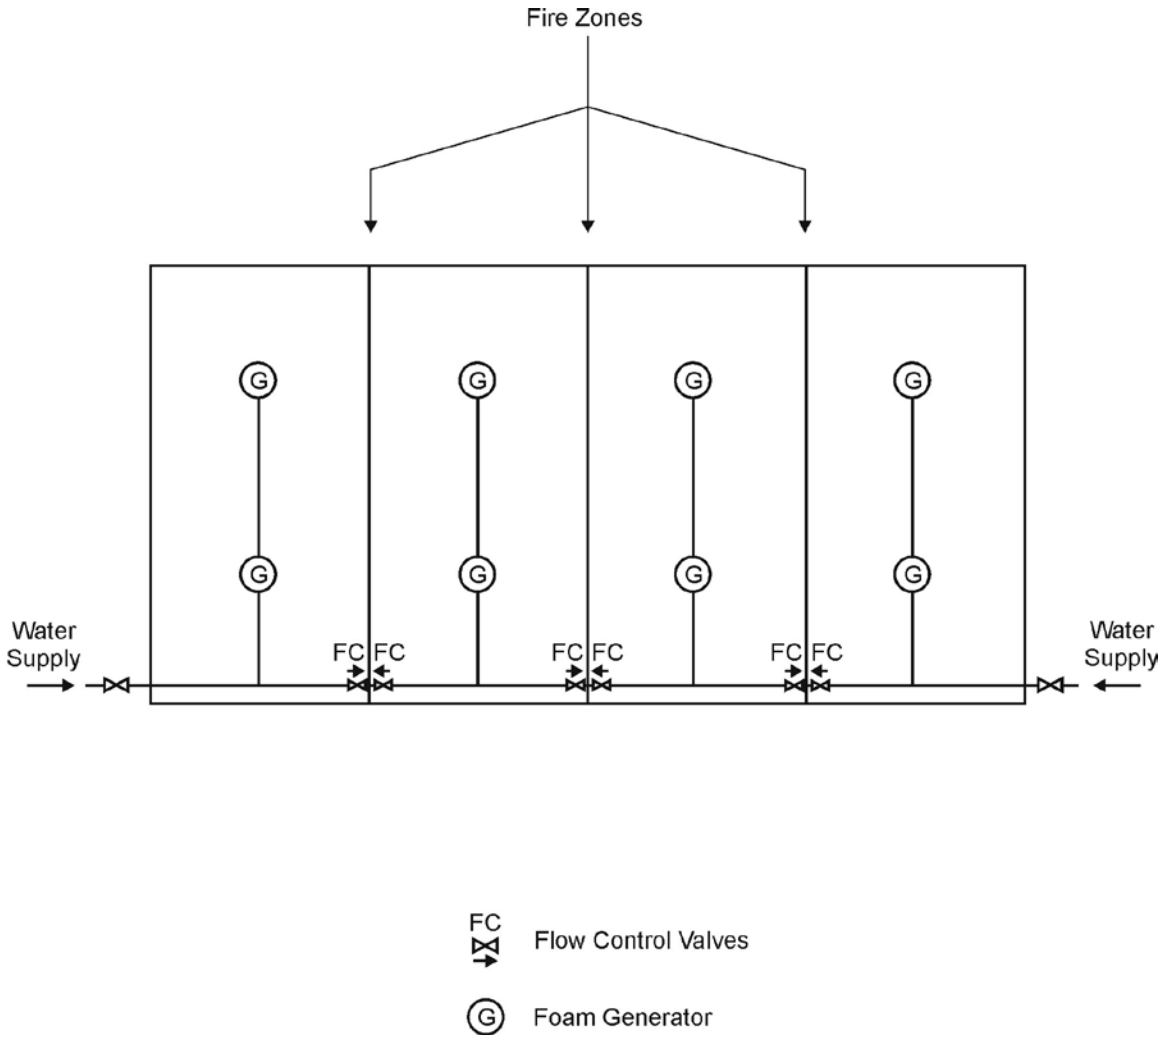
Since water has only limited capabilities against a potential Class B fire, the system would also be capable of discharging AFFF. To add this capability, proportioning systems would need to be added to both ends of the distributed fire main. The system would be designed to discharge water when the detectors go into ALARM but would switch to AFFF when the detectors have been damaged (show a “FAULT”). This system

is a cost-effective option that provides protection against an incipient-type fire as well as more damaging incidents.

B-1.5.3.1.3 Disadvantages

The primary disadvantage of the system is that monitors require more maintenance than a fixed overhead nozzle grid. There is also a greater chance of “false positive” actuations, i.e., operation of the fire suppression system due to a false detection signal.

B-1.5.3.2 Approach 2: Replace the Sprinkler System with High-Expansion Foam



A significantly different approach would be to replace the automatic sprinkler system with a high-expansion foam system. A high-expansion foam system has potentially better capabilities in a damage scenario than an automatic sprinkler system. This is primarily due to the flow characteristics of the foam, i.e., foam would flow from adjacent zones through any penetrations into the damaged area. Another significant advantage of the system is that it has good capabilities against Class B fires. Automatic sprinkler systems have very limited capabilities against Class B fires. The disadvantage of high-expansion foam is that the system needs to be designed to fill the entire enclosure, i.e., high-expansion foam systems can be zoned properly only if the zones are separated by physical barriers to confine the foam in the protected area. Discharging foam throughout the entire area is a major disadvantage for the system during an inadvertent activation or during a smaller, incipient fire scenario (due to clean-up and potential collateral damage issues).

B-1.5.3.2.1 Requirements

The system would be designed to meet the requirements of NFPA 11. For large, open areas or facilities, the system would be designed to uniformly discharge foam throughout the entire area containing the ordnance; however, the system architecture would be designed with zones—but only for rupture isolation purposes because the rupture isolation would allow the undamaged generators in the space to operate properly. For facilities that have fire zones segregated by walls, the system would be designed similar to the system containing monitors, with the foam generators installed in the adjacent zone spraying through the fire zone boundary into the damaged area or zone.

NFPA 11 requires that the system fill the enclosure to a minimum depth of 10 percent above the height of the highest combustible material or 2 feet (0.6 meter) above the highest combustible, whichever is greater. This must occur in a specified maximum time period ranging from two to eight minutes, depending on the type of construction, the presence of an automatic sprinkler system, and the type of materials stored in the space. For this application, it is recommended that the system fill the space to the required depth in less than two minutes. The concentrate and water supplies should have a minimum capacity of 15 minutes. An example of a high-expansion foam system for a large, open area or facility is shown in Figure B-5.

Figure B-5 Example High-Expansion Foam System

B-1.5.3.2.2 Configuration

As shown in this figure, the system supply lines or mains are similar to the automatic sprinkler system described in paragraph B-1.5.1. As with the automatic sprinkler system, the system would be supplied from opposite ends of the facility. A bladder tank proportioning system would be required at both supply points (not shown in the drawing). Rupture isolation is accomplished using flow control valves located on both sides of each fire zone boundary. Mechanical excess flow valves are recommended for this application (most cost-effective and simplest to install).

Due to the simple architecture of the system, only two control valves are required (one at each end of the system). Both valves would be activated by the fire detection system in the event of a fire. Any damaged piping would automatically be isolated and foam would flow from the remaining generators in the space.

B-1.6 SUMMARY AND CONCLUSIONS

The performance objectives of the system will dictate the required architecture. The systems with the greatest capabilities would be the most complex and expensive. Conversely, systems with reduced capabilities would be the simplest and most economical to design and install.

B-1.6.1 Simplest Approach

Maintaining the capabilities of the water-based fire suppression system in the undamaged area is the first step in preventing significant fire spread to adjacent areas. The suppression system must be segregated into fire zones (referred to in this appendix as fire areas). A reliable water supply must be provided. The easiest approach is to supply the system with redundant water supplies at opposite ends of the facility. Rupture isolation must also be provided. Rupture isolation can be accomplished using flow control valves located on both sides of each fire zone boundary. Mechanical excess flow valves are recommended for this application because these valves are the most cost-effective and simplest to install.

In this design, the adjacent zones have no capabilities against the fire in the damaged area. To combat the fire in the damaged area, the suppression system would need to be modified to include additional nozzles, or a new or different system would need to be considered.

B-1.6.2 More Complex Approaches

Modifying the existing sprinkler system or selecting a new system for this application would result in a more sophisticated and complex system than the conventional automatic sprinkler systems commonly in use. Specifically, these modified or new systems would need to be controlled by a separate detection and control system. The fire detection system required in Chapter 11 of this document can be used to control this more sophisticated system, minimizing the cost to obtain these additional capabilities.

Alternative modifications, such as installing additional nozzles or monitors in the adjacent zones that project into the damaged area, would increase the capabilities of the existing system in the damaged area. A line of nozzles similar to a “deck edge”-type system but installed high in the space could be used for this application. Another approach would be to install monitors that automatically oscillate through the damaged area. The monitors would need to be located at a place that is least likely to be obstructed by the contents in the space for the system to be effective and reliable. For these two systems to be effective against a potential Class B fire, the systems would need to be capable of discharging AFFF.

Two less conventional systems have the capability to combat the ensuing fire in a damage scenario: a system consisting solely of monitors and a high-expansion foam system. Monitors can be located outside the zone they are protecting, allowing the system to maintain some capabilities in the damaged area. To be effective against a

potential Class B fire, the system consisting of monitors would need to be capable of discharging AFFF. High-expansion foam has good capabilities against Class B fires and would flow foam into the damaged areas from adjacent zones. High-expansion foam has the disadvantage of needing to fill the entire open area. (High-expansion foam can be zoned only if the protected area is bounded by physical barriers). Either system could be used as a substitute for an automatic sprinkler system.

UPS	uninterruptable power supply

C-2 DEFINITION OF TERMS

Area of Refuge: A room or space that is designated, marked, and suitably equipped to provide a temporary place of safety for building occupants while awaiting rescue during a fire emergency.

Characterization: The process that includes the following: testing and analyzing a facility to determine the effectiveness of a Faraday shield (also known as low impedance testing); electrically bonding metallic penetrations to the Faraday shield; installing appropriate surge suppression; and establishing a reduced safe separation distance (SSD) based on specific test results and analyses.

Combustible: Capable of undergoing combustion.

Combustible Liquid: A liquid that has a closed-cup flash point at or above 100 degrees F (37.8 degrees C).

Criticality: The state of sustaining a chain reaction, as in a nuclear reactor.

Criticality Incident: An accidental, self-sustained nuclear fission chain reaction.

Defense in Depth: A principle aimed at providing a high degree of fire protection by achieving a balance of preventing fires from starting; detecting fires quickly and suppressing those fires that occur, thereby limiting damage; and designing a nuclear facility to limit the loss of life, property, and environment to fire and to ensure continuity of facility operation and safety.

Deflagration: Propagation of a combustible zone at a velocity that is less than the speed of sound in the unreacted medium.

Detonation: Propagation of a combustion zone at a velocity that is greater than the speed of sound in the unreacted medium.

Electromagnetic Radiation (EMR): EMR is a ubiquitous phenomenon that takes the form of self-propagating waves in a vacuum or in matter. It consists of electric and magnetic field components that oscillate in phase perpendicular to each other and perpendicular to the direction of energy propagation. Electromagnetic radiation is classified into several types according to the frequency of its wave; these types include (in order of increasing frequency and decreasing wavelength) radio waves, microwaves, terahertz radiation, infrared radiation, visible light, ultraviolet radiation, X-rays, and gamma rays.

Fire Area: An area that is physically separated from other areas by space, barriers, walls, or other means to contain fire within that area.

Fire Barrier: A continuous vertical or horizontal construction assembly designed and constructed to limit the spread of heat and fire and to restrict the movement of smoke.

Fire Door: A door assembly rated in accordance with NFPA 252 and installed in accordance with NFPA 80.

Fire Hazard Analysis (FHA): An analysis that evaluates potential fire hazards and appropriate fire protection systems and features to mitigate the effects of fire in any area.

Fire Model: Mathematical prediction of fire growth, environmental conditions, and potential effects on structures, systems, or components based on the conservation equations or empirical data.

Fire Prevention: Measures directed toward avoiding the inception of fire.

Fire Protection: Methods of providing fire detection, control, and extinguishment.

Fire-Rated Cables: Cables with an hourly fire resistance rating based on maintaining functionality when exposed to the fire tests in NFPA 251.

Fire-Rated Internal Seal: A conduit seal that is a tested and approved hourly rated fire seal in accordance with ASTM E814.

Fire-Rated Penetration Seal: An assembly provided in a fire barrier opening for the passage of pipes, cable trays, and so forth, to maintain the fire resistance rating of the fire barrier.

Fire-Resistant Hydraulic Fluid: A listed hydraulic fluid or lubricant that is difficult to ignite due to its high fire point and auto-ignition temperature and that does not sustain combustion due to its low heat of combustion.

Fire Resistance Rating: The time, in minutes or hours, that materials or assemblies have withstood a fire exposure as established in accordance with an approved test procedure appropriate for the component under consideration.

Flame Spread Rating: A relative measurement of the surface burning characteristics of building materials when tested in accordance with NFPA 255.

Flammable Liquid: A liquid that has a closed-cup flash point that is below 100 degrees F (37.8 degrees C) and a maximum vapor pressure of 40 pounds per square inch absolute (psia) (2,069 Torr) at 100 degrees F (37.8 degrees C).

Hot Work: Any temporary operation involving open flames or producing heat or sparks, including brazing, cutting, grinding, soldering, arc or gas welding, plasma welding, or torch-applied roofing. Cutting and grinding classified as hot work is limited to operations that produce significant sources of heat or spraying sparks such that they are considered ignition sources to surrounding combustible materials.

Hot Work Permit: A daily or weekly authorization document provided by the fire department for performing hot work outside of an established permissible welding area.

Limited Access Facility: A structure or portions of a structure lacking emergency openings (see NFPA 101).

Limited-Combustible: A building construction material not complying with the definition of noncombustible material that, in the form in which it is used, has a potential heat value not exceeding 3,500 Btu/lb (8,141 kJ/kg) where tested in accordance with NFPA 259 and complies with (a) or (b) below. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition will be considered combustible. (a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 inch (3.2 millimeters) that has a flame spread index not greater than 50. (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion.

Mass Notification System (MNS): A system that provides real-time information to all building occupants or personnel in the immediate vicinity of the building during emergency situations.

Maximum Credible Fire Loss (MCFL): A worst-case fire scenario in which all installed fire protection features operate as designed.

Maximum Possible Fire Loss (MPFL): A worst-case fire scenario in which all fire protection features are not operable and the fire is involved within the entire fire area that is bounded by not less than 3-hour fire barrier walls.

Noncombustible: Not capable of supporting combustion.

National Consensus Standards: Standards, such as those by NFPA, that are consensus by preparation and approval, based on a very specific set of regulations. Generally, these standards are only mandatory when adopted.

Nationally Recognized Testing Laboratory (NRTL): A laboratory that provides fire testing and labeling services to list or approve products. Generally, such laboratories are certified by a national laboratory certification agency.

Occupancy: The purpose for which a building or portion thereof is used or intended to be used.

Radiation: The emission and propagation of energy through matter or space by means of electromagnetic disturbances that display both wave-like and particle-like behavior.

Radioactivity: The spontaneous decay or disintegration of an unstable atomic nucleus accompanied by the emission of radiation.

Redundant Component, System, or Subsystem: A component, system, or subsystem that independently duplicates the essential function of another component, system, or subsystem.

Self-Contained Breathing Apparatus (SCBA): An approved device that provides the user with a safe supply of breathing air via a compressed air cylinder, positive pressure regulator, and full-face mask. The air supply is generally for 30 to 45 minutes.

Through-Penetration Firestop: A tested, fire-rated construction consisting of the materials that fill the openings through the wall or floor around penetrating items such as cables, cable trays, conduits, ducts, and pipes, and their means of support to prevent the spread of fire.

Underground Facility: A structure or portions of a structure in which the floor level is below the level of exit discharge (see NFPA 101).

This UFC supersedes UFC 4-440-01A, dated March 1, 2005 and UFC 4-442-01N, dated January 16, 2004.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site https://www.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

UNIFIED FACILITIES CRITERIA (UFC)
NEW SUMMARY SHEET

Document: UFC 4-440-01, *WAREHOUSES AND STORAGE FACILITIES*

Superseding: UFC 4-440-01A *Storage Depots* and UFC 4-442-01N *Design; Covered Storage.*

Description: This new UFC, "*WAREHOUSES AND STORAGE FACILITIES*" replaces UFC 4-440-01A, *Storage Depots* (Army) and UFC 4-442-01N, *Design: Covered Storage* (Navy). These existing UFCs are not unified. The Army document is former TM 5-840-02 dated October 7, 1994. The Navy document is former Military Handbook 1032/2 dated September 30, 1987.

Reasons for Document:

- The new UFC will provide updated guidance for new warehouses and covered storage facilities.

Impact:

- The result of these changes is a document which can more practically be used as part of a construction contract and is more easily understood by the users, more relevant to current practice and is properly coordinated with other Government requirements documents.

Non-Unified Items:

- Differing policies for Navy and Marine Corps, Army, and Air Force appear in paragraphs entitled "*Controlled Humidity Warehouse", "Flammable / Hazardous Storage Within Other Storage Facilities",* and "*Flammable / Hazardous Materials Storage"*.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC), UFC 4-440-01, contains criteria for planners, engineers, and architects on the planning, engineering, and design of Department of Defense (DoD) storage facilities. The information in this UFC applies to the design of all new construction projects, to include additions, alterations, and renovation projects in the continental Unites States (CONUS) and outside the continental US (OCONUS). Alteration and renovation projects must update existing facilities to meet the guidance and criteria contained in this UFC within budgetary constraints. This is supplementary guidance to be used in conjunction with Facility Requirements Documents (FRD), Facility Requirements Supplements (FRS), Intrusion Detection Systems Engineering Plans (IDSEP), Installation Appearance Plan (IAP), and other DoD material for the planning and construction of DoD storage facilities and to support the preparation of DD 1391 project documentation.

1-2 APPLICABILITY.

This UFC will be used for planning individual projects, preparing engineering documentation, and preparing contractual documents for construction. It is intended to present the basis for standardization of practices and identify a common baseline to be used during the planning of new facilities or the modification of existing facilities.

1-2.1 Conflicts in Criteria

Where conflicts appear between the general criteria contained in the Whole Building Design Guide (WBDG) website and the guidance in this document, the guidance in this UFC governs.

> **Exception:** Navy and Marine Corps planning criteria is governed by UFC 2-000-05N, *(P-80) Facility Planning Criteria for Navy/Marine Corps Shore Installations*. Conflicts must be brought to the attention of the UFC 2-000-05N program manager through a Criteria Change Request (CCR). To submit a CCR go to the following link: https://cms.wbdg.org/ccrs/new?ufc=2-000-05N

1-3 GENERAL BUILDING REQUIREMENTS

Comply with UFC 1-200-01*, General Building Requirements*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this FC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-4 TYPES OF STORAGE FACILITIES

The criteria in this UFC cover the design requirements for warehouse facilities; General Purpose Warehouse, Controlled Humidity Warehouse, \1\ Hazardous Materials Storage, /1/ and Shed Storage, or the combination of these storage facility types. These criteria address the factors which affect the functional effectiveness of warehouse facilities. Included in these factors are siting, system selection, facility layout, area, storage height, life-cycle costs, energy efficiency, and internal details. Since modern storage facilities are integrated operations in which the structure and materials handling/ storage equipment function as a system, coordination and integration of equipment and structure requirements is essential to proper operation of the system. The more common facility types following:

1-4.1 General Purpose Warehouse

General Purpose Warehouse includes, conditioned, semi-conditioned, and unconditioned types, with and without overhead crane capability. The general purpose warehouse provides space for bulk and bin storage, aisle space, receiving and shipping space, packing and crating space, and office and toilet space.

1-4.2 Humidity Controlled Warehouse

A humidity controlled warehouse is similar to a general purpose warehouse except that it is designed with enhanced features for humidity control, such as: humidity control equipment and enhanced building envelope design. This warehouse may be a separate building or contiguous with a general purpose warehouse. Requirements for controlled humidity space must be thoroughly justified. Such requirements must be considered a portion of the total space allowed for the facility type. Use DoD Real Property Classification System (RPCS); Category Codes 441-10 through 441-40 facility types. Planning for storage of material in controlled humidity space for varying periods of time is authorized when the use of such space performs the following:

a. Permits technical material and material highly sensitive to moisture to be stored in a state of readiness for immediate issue.

b. Permits a reduction in the cost in initial preservation or re-preservation of material.

c. Affords significant reduction in either the reactivation time or the reactivation cost of material, or both.

d. Maintains the condition of any material being held in temporary storage while awaiting repair, disposition, preservation or re-preservation, or assembly of components.

e. Affords the desired supplemental protection to material already subjected to preservation treatment

1-4.3 Shed Storage

A shed is a roofed structure without complete side or end walls. Sheds are typically used for storage of gas cylinders, drummed Petroleum/Oil/Lubricant (POL), vehicles, unfinished lumber, and other construction material. In areas where it is impractical to use shed space for the storage of materials because of weather conditions, storage requirements must be included as warehouse space and complete justification must be submitted. Sheds storing hazardous materials are subject to special design requirements and must comply with criteria in Chapter 4 of this UFC.

1-4.3.1 General Purpose Shed

Provide minimum utilities consisting of electricity for lighting and electrically operated equipment and tools. Provide fire protection in proportion to the type of material stored and the loss potential.

1-4.4 Hazardous Materials Storage within Other Storage Facilities

Hazardous materials warehouses differ significantly from general purpose warehouses due to the materials stored and the provisions made to prevent, and remove through proper ventilation, mists, gases, and vapors in accordance with National Fire Protection Association (NFPA) *Flammable and Combustible Liquids Code*, NFPA 30 and NFPA 430, *Code for the Storage of Liquid and Solid Oxidizers*. Materials considered for storage in this category facility include paints, certain packaged Petroleum/Oil/Lubricant (POL) materials, chemicals, acids, corrosive liquids, oxidizing materials, and other similar hazardous flammable materials. Space justified for hazardous materials storage must be considered a portion of the total space allowed for the facility type. Such space must not exceed 5 percent of the total space. Such flammable and combustible liquid storage area(s) must comply with the requirements of Chapter 4 of this UFC.

Use DoD Real Property Classification System (RPCS); Category Codes 441-10 through 441-40 facility types.

1-5 EXCLUSIONS

Design of the following types of storage facilities is not covered by this UFC:

1-5.1 Cold Storage

Cold storage warehousing is planned to satisfy the primary function of preservation of the quality of perishable foods and general supply materials that require refrigeration. The warehouse will include freeze and chill space, processing facilities, and mechanical areas. Cold Storage warehouses are not included. See Unified Guide Specification (UFGS) 11 41 11, *Refrigerated and Frozen Food Storage Equipment* for additional guidance.

1-5.2 Liquid Storage

Bulk tanks and associated equipment for liquid fuel storage and storage of liquids other than water, fuel tanks, and propellant tanks are not included. Refer to UFC 3-460-01, *Design: Petroleum Fuel Facilities*.

1-5.3 Ammunition Storage

Magazines, specialized warehouses, tanks, and open pads for storage of ammunition, inert ammunition components, liquid propellants, and weapon related batteries are not included.

1-5.4 Open Storage

Non-covered storage areas, paved or otherwise are not included.

1-5.5 Hazardous Waste Storage

Facilities which are used for storage of hazardous waste or are otherwise subjected to the requirements of 40 Code of Federal Regulations (CFR) *Protection of Environment*, Part 264 *Standards for Owners and Operators of Hazardous Waste Treatment, Storage, and Disposal Facilities* \1\/1/are not included.

1-6 APPENDICES

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

Appendix B identifies background information and best practices for accomplishing design and engineering services.

Appendix C contains acronyms, abbreviations, and terms.

CHAPTER 2 PLANNING AND LAYOUT

2-1 PROJECT INITIATION AND PLANNING

This UFC provides information required for preparation of DD Form 1391, which initiates project development. This includes information about functions, space allowances, overall building size, site evaluation, and special factors to consider in developing overall scope and cost estimates. It provides data and criteria needed at each stage of planning, project engineering, and the design process.

2-1.1 Project Analysis and Engineering Phase

After a project is initiated, it is analyzed and defined. During the Project Analysis stage, the project team meets to define the project so as to have a clear understanding of the project goals and objectives. The Customer, Design Agent, and Architect / Engineer (A/E) team then develops the project documentation based on an analysis of unique customer needs, requirements, established criteria, and site and environmental constraints. Information gathered provides the basis for defining the preliminary design and supports the project engineering phase, parametric cost estimating (PCE), and programming process. Information required includes space planning, site design, selection of the appropriate plan, water supply, and building design, elements and concepts. Unique local requirements concerning building program and design criteria are included in the PCE.

Functional concept planning for new facilities or modernization of existing facilities must include guidance and information contained in this document and data from reference documents identified in this publication.

2-1.1.1 Antiterrorism

Antiterrorism requirements are established as part of the design program and are identified as a separate line item in the DD Form 1391 estimate.

2-1.1.2 Navy and Marine Corps

Navy and Marine Corps planning criteria is governed by UFC 2-000-05N, *(P-80) Facility Planning Criteria for Navy/Marine Corps Shore Installations*.

2-2 GEOGRAPHIC PLANNING

Planning and design of warehouse facilities must address the specific climatic and geographic conditions of the intended site. In all climate regions consider solar orientation to maximize energy efficiency, passive solar and daylighting potential of the building. Refer to UFC 1-200-02, *High Performance and Sustainable Building Requirements*.

2-3 STORAGE / HANDLING SYSTEM

New facilities or modernization of existing facilities must consider the evaluation of alternative materials handling systems, selection of handling and storage equipment, design of operations, and layout of the building.

2-3.1 Design Parameters

The following design parameters must be observed when collecting data and analyzing requirements associated with the material storage and handling requirements of a planned warehouse facility:

2-3.1.1 Load Size

Standard cargo load size (including pallet) is 40 inches x 48 inches x 36 inches high (1020 millimeters [mm] x 1220 mm x 915 mm), or 40 cubic feet (ft3) (1.13 cubic meters [mm3]) which is equal to 1 Measurement Ton (M/T). The average storage load is 0.8 M/Ts (32 ft3, 0.91 mm3) which equates to a pallet size 40 inches x 48 inches x 28.8 inches (1020 mm x 1220 mm x 730 mm). A 48-inch (1220 mm) vertical pallet rack beam spacing is provided by the standard pallet rack configuration for this average height load. Maximum DOD allowances for loaded pallets with overhanging loads are 43 inches x 52 inches (1090 mm x 1320 mm). Planning must accommodate such vertical dimensions or be adjusted where loads differ significantly from the average height. In special cases such as automated storage/retrieval system racks, it may be necessary to maintain the 40-inch x 48-inch (1020 mm x 1220 mm) dimensions due to equipment restrictions.

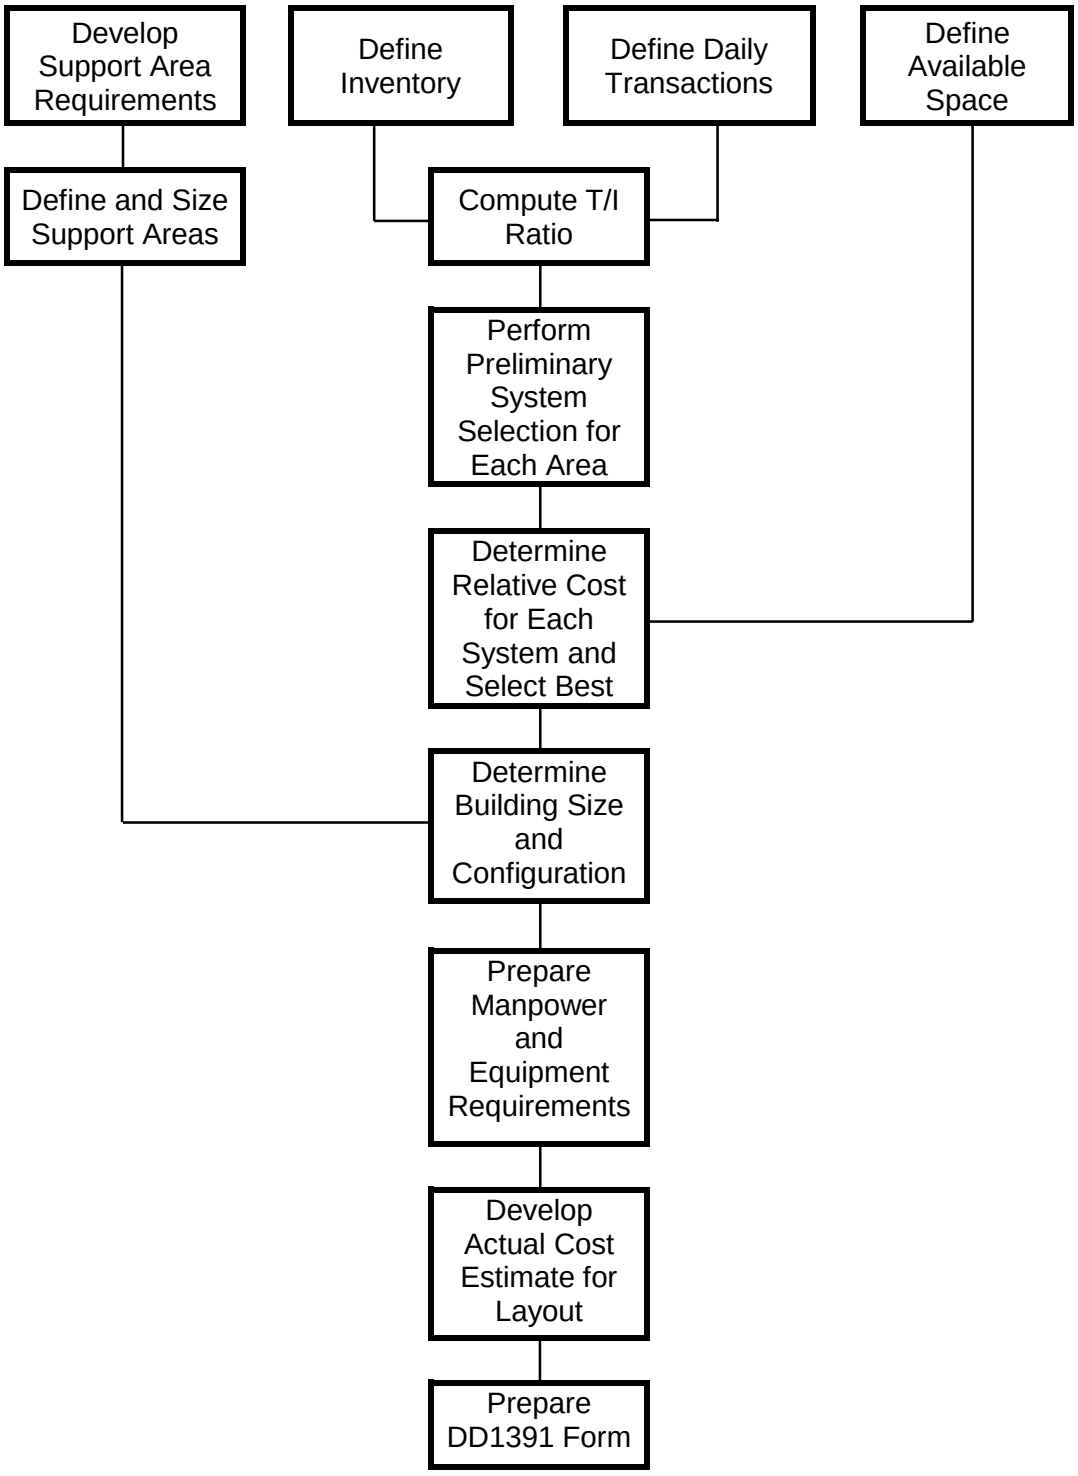
2-3.1.2 Cost Standards

Storage costs, handling costs, and handling times relative to actual performance of an activity must be evaluated before comparisons are made between proposed designs and current operations if applicable.

2-3.1.3 Storage Height

Economical storage height is dictated by safety requirements, site restrictions, foundation cost, aviation restrictions, materials handling equipment availability, and storage requirements. These characteristics must be considered when making system evaluations.

2-3.1.3.1 Hazardous Materials Warehouses Storage Height



Hazardous materials warehouses are limited to a maximum storage height of 25 feet (7620 mm) or less. See the paragraph entitled “Material Handling Equipment”.

2-3.2 Procedures

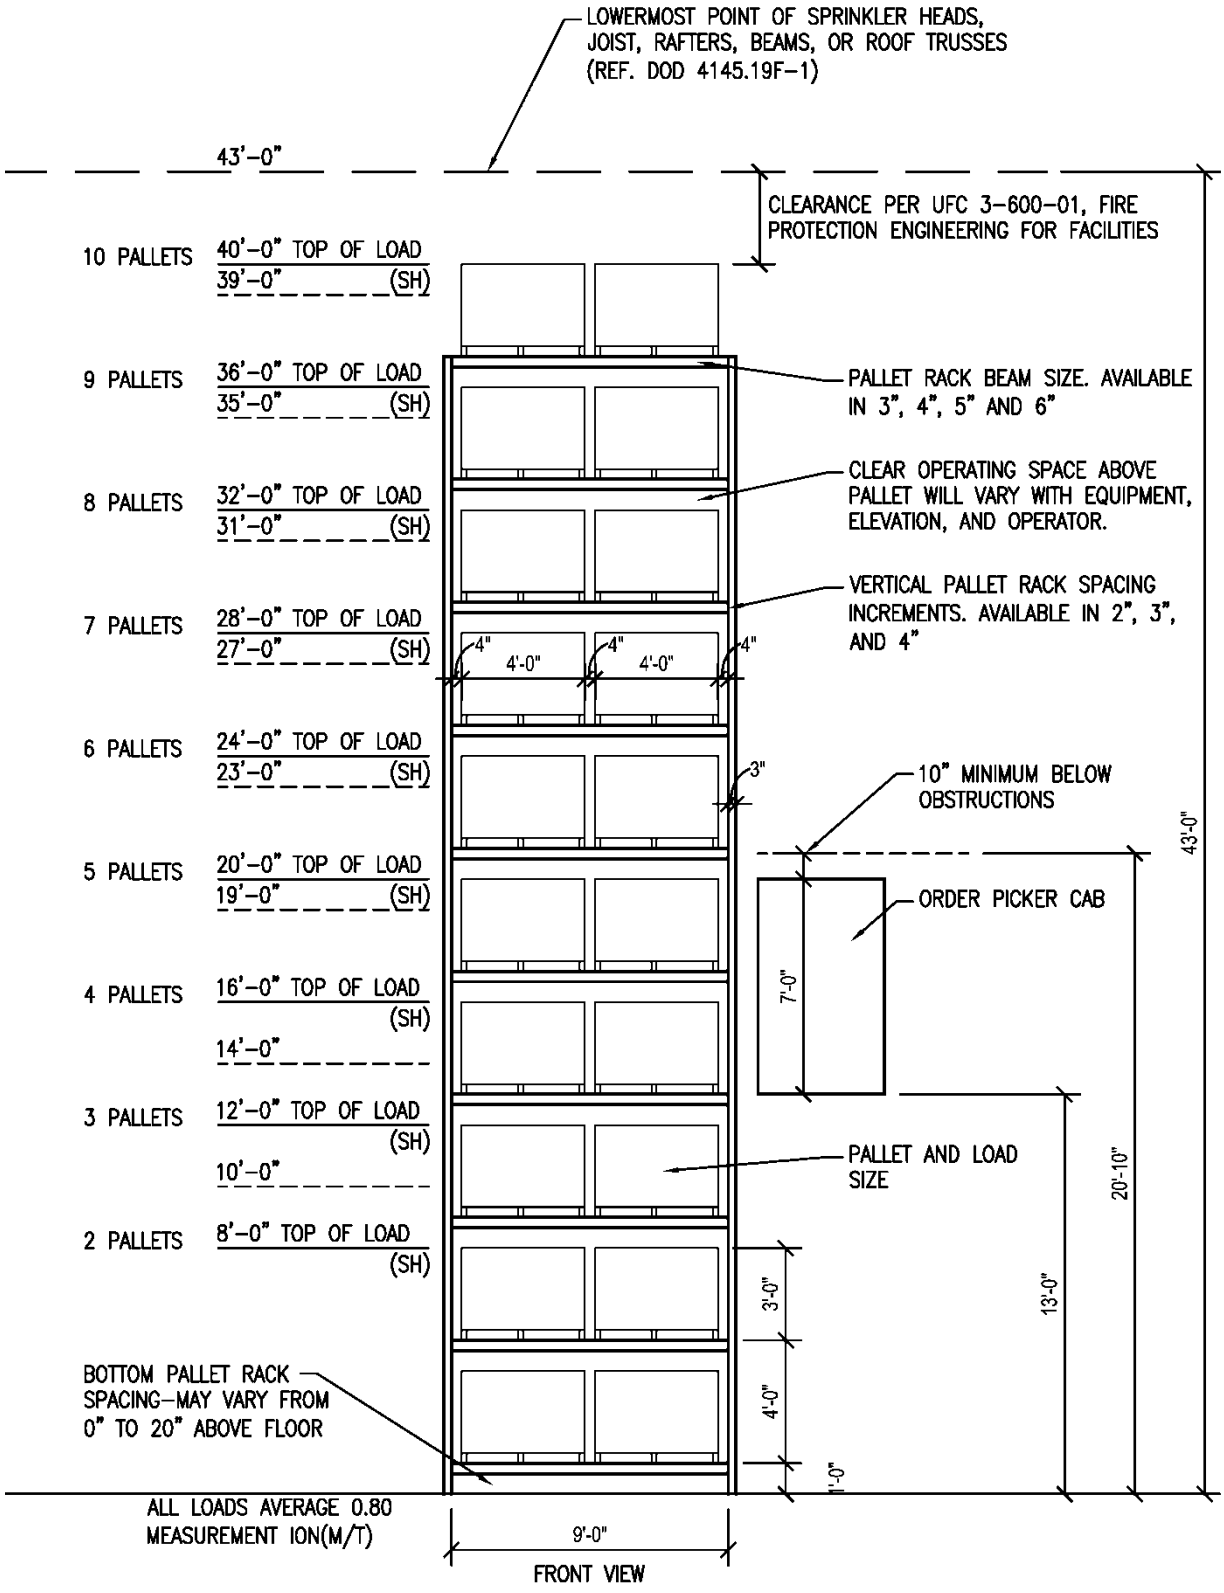
The following steps should be followed in developing a facility concept. Figure 2-1 illustrates these steps in flowchart form. The Activity or Project Manager must

designate in the project scope the following factors, as well as any special requirements for storage or handling.

Figure 2-1 System Selection Flowchart

2-3.2.1 Define Inventory

State inventory levels in terms of 0.80 measurement ton (m/t) (32 ft3 or 0.91 mm3) pallet loads or 0.0095 m/t (0.38 cubic foot; 0.011 cu. M) shelf boxes. Separate inventory into groups with similar storage, handling, or transaction characteristics. The major inventory item attributes to be evaluated must include temperature sensitivity, hazardous characteristics, stackability, dimension, volume, and weight. Examples are pallet storage, bin storage, high and low activity material, pre-positioned war reserve stocks, etc. Establish maximum/minimum inventory levels per group.



2-3.2.2 Define Daily Transactions

Define daily activity characteristics of each inventory group. For pallet systems activity levels must be defined in terms of daily quantities of pallets stored and retrieved. Define daily activity for binnables and rackables order picking systems in a line item (stock keeping unit) format.

2-3.2.3 Define Available Space

Define the space available for system installation for both new facility designs and conversion of existing facilities. Determine available Net Square Feet (NS) and allowable Stacking Height (SH) to define the available storage area in terms of Total Cubic Feet (TCF). When determining Stacking Height, the allowable stacking load, floor load capacity, and floor condition (surface condition, expansion joints, cracks, and flatness) must be considered. Figure 2-2 shows a typical height pattern for pallet racks up to the limit of the stacking capability of standard forklift equipment.

Figure 2-2 Standard Pallet Rack Elevation / Parameters

2-3.2.4 Compute Transaction/Inventory (T/I) Ratio

Compute the system T/I ratio based upon the defined inventory and transaction quantities. Develop separate T/I ratios for each inventory or handling group identified by the procedure in the paragraph entitled “Define Inventory”.

2-3.2.5 Select System

Taken together, physical characteristics of inventory and storage facility narrow the range of acceptable materials handling systems. Identify requirements or limitations which will affect system operations. Evaluate and perform preliminary system selections based on the computed T/I ratios for each area or inventory group. Evaluate and identify alternative systems for each area.

2-3.2.6 Determine Cost

Determine the relative cost for each system and select the most effective system for the funds available.

2-3.2.7 Determine Covered Storage Area

Determine the required building area for the selected system(s). Include cube and stacking height values as per UFC 2-000-05N (P-80) *Facility Planning Criteria for Navy and Marine Corps Shore Installations*.

2-3.2.8 Determine Support Area Requirements and Sizes

Evaluate and develop Support Area requirements. Support Areas consist of all other warehouse areas other than the Storage Area (SA). These include support functions such as supervisory offices, receiving, shipping, rest rooms, employee services, crating operations, packing/ packaging operations, battery charging rooms, inspection, identification, preservation, training rooms, mechanical equipment rooms, etc. Define and size Support Areas based on manpower and equipment requirements per each space and function.

2-3.2.9 Integrate Layout

Develop a composite building layout by integrating the various storage and support areas into a facility layout. Incorporate functional adjacency requirements of spaces. If the Storage Area includes hazardous materials storage the facility layout must take into account separation/safety considerations. Hazardous materials storage areas must be isolated in combination layouts. Combine the separate operations into a composite facility plan by adjusting column spacing to produce a common dimension while maintaining compatibility among the various systems. Explore 3 different layouts to ensure pre-construction system optimization.

2-3.3 Material Handling Equipment

The following materials handling equipment are essential components of warehouse facilities and their characteristics must be considered during the design phase.

2-3.3.1 Pallet Handling Equipment

This equipment may be either vehicular (truck-like) or specifically designed (i.e., storage/retrieval machine) for transporting and storing the standard pallet.

2-3.3.1.1 Fork Trucks

Propane, gas or diesel powered fork trucks can have a significant impact on ventilation requirements and indoor usage must be avoided where practical. Facilities are to be designed so that no gasoline, diesel or LPG/Propane fueled fork trucks are permitted to be used for prolonged periods of time. These types of fork trucks are to make quick drop-offs of material and electric fork trucks should move the stock within the warehouse facility.

When gasoline, diesel or LPG/Propane fueled fork trucks are required by the user activity the ventilation and/or climate control systems must be design to accommodate the expected quantity of fork trucks and duration of indoor use. Refueling for these types of fork trucks must be provided on the exterior of the building. Provide a spill containment dike for gasoline and diesel fork trucks in accordance the paragraph entitled "*Dikes"*.

2-3.3.1.2 Conveyer Systems

Conveyer Systems must be selected and designed to achieve energy conservation goals. They must include controls to automatically shut-down to conserve energy when not in use for a preset period of time. High efficiency, variable speed motors with "soft start" functions must be utilized to conserve energy and minimize maintenance.

2-3.3.2 Order Picking Equipment

This equipment is designed to aid a worker in the selection and transportation of supplies and may be vehicle based or designed as an application specific piece of equipment.

2-3.3.3 Transport Systems

These systems are designed for the movement of supplies between two or more locations within or outside of a facility. They may be designed to transport packaged loads (pallets or shelf boxes), loose loads, bulk liquids, or solids.

2-3.4 Storage Equipment

The following types of storage equipment are essential components of warehouse facilities and their characteristics must be considered during the design phase.

Storage equipment will be provided to store materials properly, off the floor. It will also be securely fastened to the slab and/or other structural supports designed to support the equipment per equipment manufacturer's installation requirements. Storage equipment will be protected by proper means from contact by material handling and operational equipment.

2-3.4.1 Pallet Rack

Pallet racks must be designed for safe storage of palletized loads based on the standard pallet as described in the paragraph entitled "Load Size". Designs for other size pallets may be used in conjunction with appropriately sized pallet racks and pallet handling fork lift equipment. These include double-deep racks, cantilever racks, drive-in and drive thru rack systems, side-loading fork lifts, and double-reach fork lifts. \1\Idle pallets must be stored in accordance with NFPA 230 and sprinkler protection provided in accordance with NFPA 13. /1/

2-3.4.2 Shelving/Bins

Shelving and bins are designed for storage of package type items in less than pallet load quantities. Industrial grade steel shelving and storage bins are modular in nature and are composed of front and rear upright posts, shelves, dividers. Bin storage units are a sub-group of industrial shelving in which the storage shelves are divided into smaller compartments. If a shelf is divided into two or more compartments, the compartments are classified as bins.

2-3.4.2.1 Shelving

Shelving is used for economical storage of small hand stackable items which are not suited to mechanized handling and storage due to their handling characteristics, activity, or quantity. Shelving is most often used for small parts storage in order picking systems and is suitable for either manual or mechanized operations.

Shelving is generally available in standard unit heights of 85 to 87 inches (2160mm to 2210mm) and a unit width of 36 inches (914mm). Typical depths are 12 inches (304mm), 18 inches (457mm), and 24 inches (609mm). The range of widths varies from 24 to 48 (609mm to 1220mm) inches while the depth ranges from 9 to 36 inches (228mm to 914mm). Shelf uprights are available in either beaded post or angle post configurations. Shelving is available in either open or closed design. Closed design includes solid back and side panels which provide load containment and minimize possible accumulation of unwanted dust and dirt. Open shelving is less expensive and utilizes sway braces to provide rigidity.

2-3.4.2.2 Bins

Bin storage is, in most instances, identical in application to shelf storage but is generally applied to smaller items which do not need the entire width of a conventional shelf module. Bin storage represents a small part of the total storage system in terms of physical space although it may represent a significant portion of the total storage in terms of item positions.

2-3.4.3 Special

Special storage equipment consists of devices designed for specific purposes such as cantilever rack, vertical sheet storage rack, pallet stacking frames, rigid and collapsible metal bins, etc.

2-3.4.4 Installation and Operation Tolerances

Observe the following tolerances for installation and operation of storage equipment. These tolerances apply in the absence of more stringent manufacturer tolerances.

a. Plumbness of pallet racks and high rise shelving +/- 1/16 inch (+-1.6 mm) over total height.

b. Pallet rack beam elevation +-1/4 inch (+-6.4 mm) between adjacent beams.

c. Rail guide position +1/4, -0 inches (+6.4 mm, -0 mm) from specified rail spacing.

d. Wire guide position +-1/4 inch (+-6.4 mm) from specified centerline.

e. Pallet rack aisle spacing +-1/4 inch (+-6.4 mm) from design aisle width.

f. Down-aisle rack offset +-1/4 inch (+-6.4 mm) from aisle centerline.

2-4 MATERIAL HANDLING SYSTEMS CONSIDERATIONS

2-4.1 Receiving Shipping Operations

Review vehicle and material flow characteristics, including:

a. Types of vehicles to be serviced.

b. Location of rail and road access.

c. Location with respect to other facility operations.

d. Support area requirements, such as staging areas and offices.

2-4.2 Order Picking Operations

Review load and documentation requirements, including:

a. Type of product being processed.

b. Documentation requirements.

c. Packing/packaging requirements.

2-5 SUPPORT AREAS

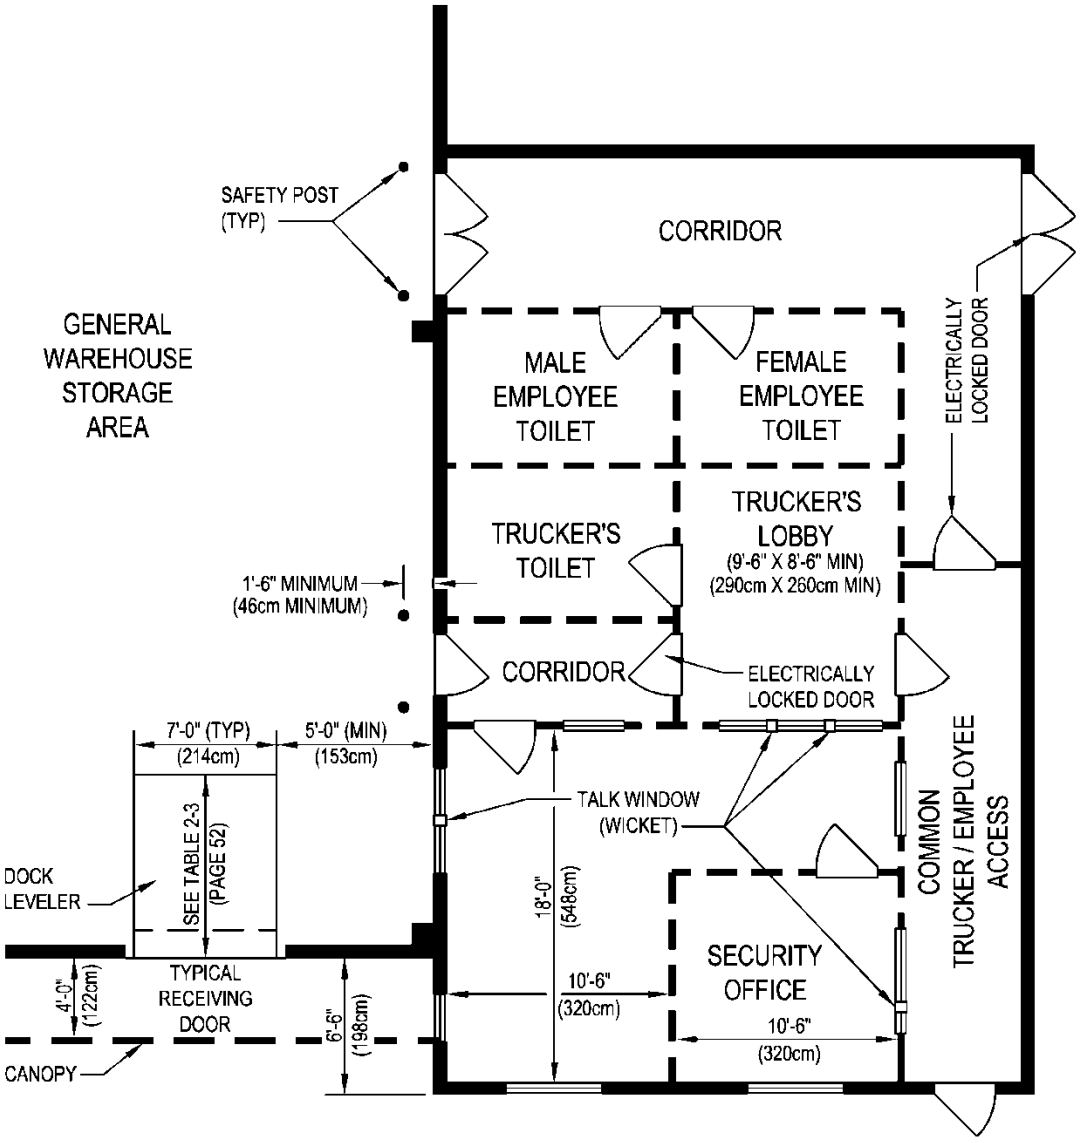
Separate support areas from hazardous materials storage areas with a 2-hour fire wall and from combustible or flammable storage areas with a 4-hour fire wall. Direct access between support areas and hazardous materials storage areas is not permitted. Refer to table 2-1 for space estimating criteria for administrative and supervisory offices. Refer to UFC 2-000-05N (P80), *Facilities Planning Criteria for Navy and Marine Corps Shore Installations* for criteria relating to other warehouse support functions.

Table 2-1 Administrative and Supervisory Offices and Support Area Space Requirements

LOCATION	LENGTH		WIDTH		AREA	
	m	ft	m	ft	m	ft
Private Offices						
Warehouses Manager	6.1	20	4.9	16	29.7	320
Personnel Manager	4.3	14	3.7	12	15.6	168
Open Office Dividers						
Managers	3.7	12	3.7	12	13.4	144
Assistants	3.0	10	2.4	8	7.4	80
Secretaries	2.4	8	2.4	8	5.9	64
Accounts Payable	1.5	5	2.1	7	3.3	35
Inventory Control	1.5	5	2.1	7	3.3	35
Procurement	1.8	6	2.4	8	4.5	48
Operations	1.8	6	1.8	6	3.3	36
Meeting Area	3.0	10	3.0	10	9.3	100
Interview Area	2.4	8	2.4	8	5.9	64
Programmers	2.4	8	2.4	8	5.9	64
Open Support Services						
Files	0.3	1	1.5	5	0.5	5
Reception/Lobby Area	9.1	30	6.1	20	55.7	600
Main Aisles (1)	--	--	--	--	--	--
Secondary Aisles (2)	--	--	--	--	--	--
Photocopy Machine	1.8	6	1.2	4	2.2	24
Closed Support Services						
Mail Room	7.6	25	3.7	12	27.9	300
Restrooms	7.3	24	2.4	8	17.8	192
Janitorial Closet	1.8	6	1.2	4	2.2	24
Clothes Closet	3.0	10	0.6	2	1.8	20
Supply Room	5.5	18	3.7	12	20.1	216
Computer Room	7.6	25	6.1	20	46.5	500
Conference Room	7.6	25	6.1	20	46.5	500
Lunch/Break Room (3)	18.3	60	6.1	20	111.5	1200
First-Aid Room	4.9	16	3.7	12	17.8	192

Areas considered for support of a storage facility include the following:

2-5.1 Supervisory Offices



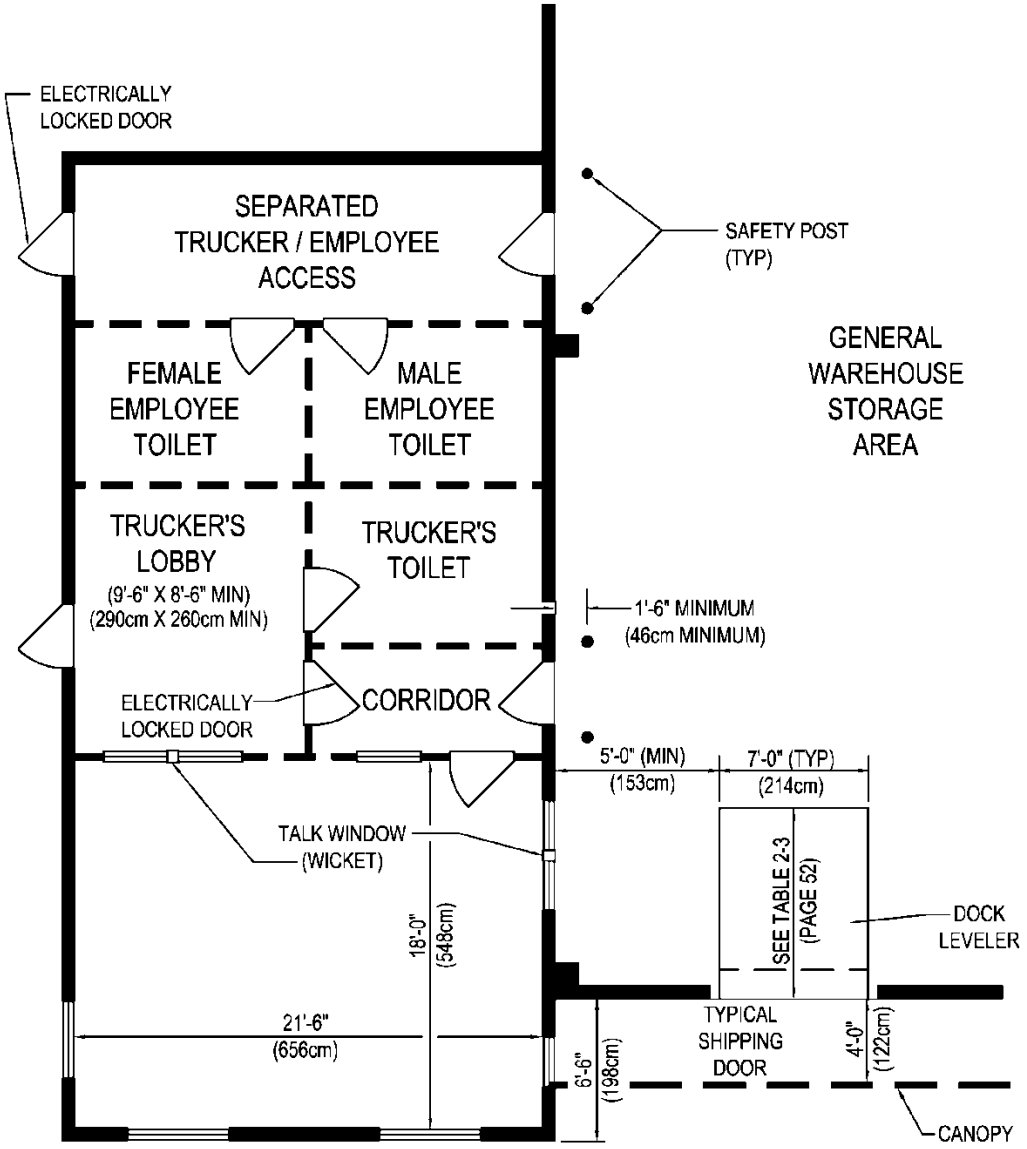
Provide offices for supervisory personnel such as foremen, crew leaders, etc. Offices must accommodate two people and provide filing space, one desk, and two chairs per person. Offices must be located near their associated activity areas. Offices may consist of prefabricated partition-type enclosures or more permanent forms of construction such as concrete block.

Separate shipping and receiving office areas may be required in larger facilities and combined hazardous materials and general storage facilities for safe operation and to expedite the flow of paperwork associated with the increased activity. A facility with few employees may use a single multipurpose office located away from any hazardous materials storage area. Office location and arrangement must provide separation of work functions and maintain security by controlling access to the facility. Offices must permit an unobstructed view of the inside and outside dock areas. Rest room facilities for both truck drivers and employees may be integrated into the office design.

2-5.2 Receiving Office

The typical functional area relationships for the Administration and Warehouse Facilities provide space for a building and site security system and office space for receiving personnel. The secured entrance, lobby and rest room for truck drivers provides controlled entry into the facility. Separate rest rooms are provided for supervisory and warehouse personnel. See figure 2-3.

Figure 2-3 Typical Receiving Office Layout - Functional Dimensions



NOTE: LAYOUT SHOWN FOR ADJACENCIES AND CRITICAL DIMENSIONS ONLY

2-5.3 Shipping Office

The typical shipping office provides a separate entrance, lobby, and rest room for truck drivers. A central office area and separate rest room facilities are provided for shipping department and supervisory personnel. See figure 2-4.

Figure 2-4 Typical Shipping Office Layout - Functional Dimensions

NOTE: LAYOUT SHOWN FOR ADJACENCIES AND CRITICAL DIMENSIONS ONLY

2-5.4 Rest Rooms

Separate rest room facilities may be provided for supervisory and general warehouse personnel.

2-5.5 Employee Services

Employee service areas consist of break rooms, canteen and vending machine facilities, and locker rooms. Size these areas to accommodate the expected number of employees. Multiple installations may be required to place these facilities within required distances from employee activity areas. Refer to UFC 3-101-01, *Architecture* for Space Planning and Criteria and UFC 3-420-01, *Plumbing Systems* for specific requirements.

2-5.6 Crating Operations

General purpose storage facilities may require crating of large or odd shaped items prior to storage or shipment. Variability in requirements for materials, product size, and tools necessitates individual design of crating areas. Refer to DoD 4140.1-R, *Supply Chain Material Management Regulation*, title 49 CFR *Transportation* for criteria.

2-5.7 Packing/Packaging Operations

Requirements for small item packaging may be met through use of multipurpose packing table work stations. Small item packaging must support a supply of cartons, filler material, tape, glue, labels, and scales. The design of small item packing operations must be approached on an individual facility basis.

2-5.7.1 Design

The design of small package packing station depends upon the relationship between package characteristics and throughput patterns. If the movement through the packing operation is homogeneous in terms of product characteristics and packing requirements, it is possible to install conveyor type equipment. If the packing operations must accommodate a heterogeneous mixture, a customized work station must be provided.

Refer to DoD 4140.1-R, Supply Chain Material Management Regulation, title 49 CFR Transportation for criteria. Repackaging of damaged hazardous materials packages must be performed in a designated safe area.

2-5.8 Battery Charging Area

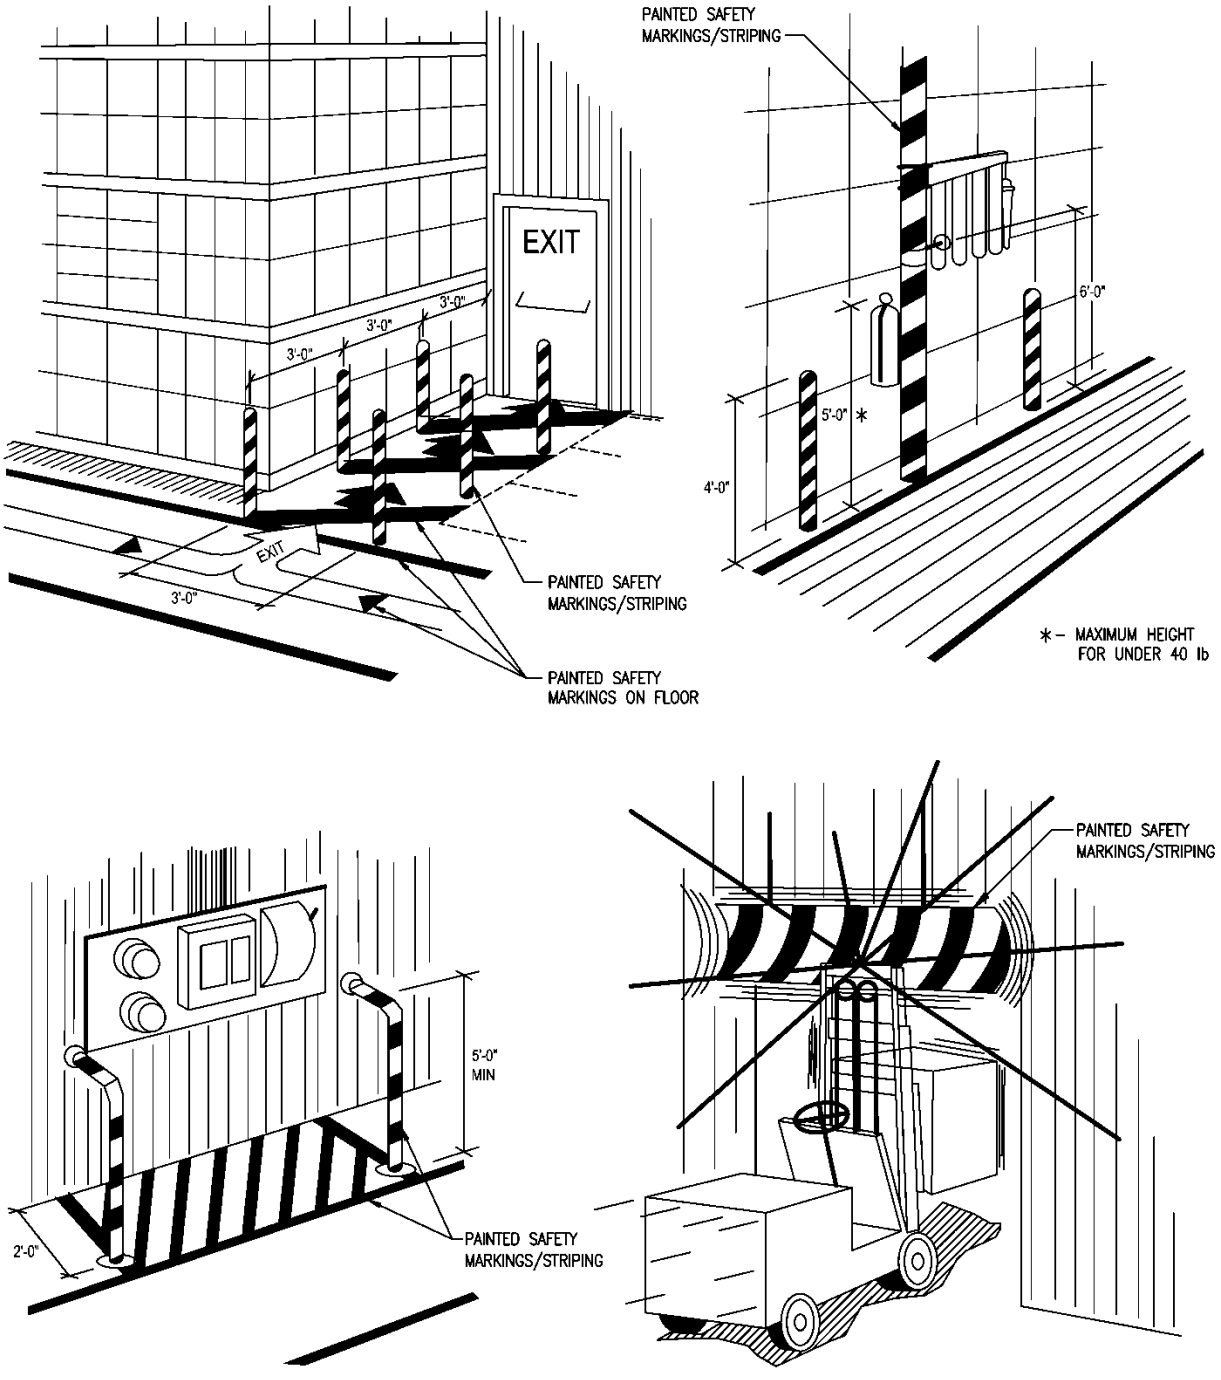
Provide an equipped and ventilated room or area for the charging of materials handling vehicle batteries. For additional requirements see section titled “Battery Charging and Handling Operations”.

2-6 PARKING

Provide parking space for \1\/1/facility employees. Parking areas must be separated from truck docks and other activity areas. Site security must be enforced by separating the storage facility from the remainder of the activity and further isolating parking from receiving and shipping functions. Refer to UFC 3-201-01, *Civil Engineering* for parking requirements.

2-7 TRAFFIC FLOW

Arrangement of the facility on the site and internal arrangement of the material handling systems must be evaluated to reduce or eliminate areas of conflicting traffic. Consider interaction with installation traffic flow.



2-8 SAFETY

All DoD facilities must comply with DoD Instruction 6055.1 and host services' Occupational Safety and Health Requirements.\1\This includes but is not limited to the following:/1/

- Provide safety markings on walls and floors in accordance with title 29 CFR 1910.22, General Requirements and title 29 CFR 1910.144, Safety Color Code for Marking Physical Hazards (Reference Figure 2-5 Typical Safety Markings). Define areas for fork-truck battery charging. Provide fire protection equipment. \1\./1/ Provide specialized safety equipment (eye wash/shower, spill lockers, etc.) in hazardous materials areas. Provide all additional safety features required by the Occupational Safety and Health Administration (OSHA), in accordance with Title 29 Code of Federal Regulations (CFR) Part 1910, Occupational Safety and Health Standards.
- Provide exterior safety markings for fork truck refueling and vehicular operations.
- Provide all additional site safety features required by UFC 3-201-01, *Civil Engineering.*

Figure 2-5 Typical Safety Markings

Perspective Views

CHAPTER 3 GENERAL DESIGN CRITERIA

3-1 GENERAL DESIGN FACTORS

Providing easy and rapid materials handling and adequate clear storage space are the prime considerations in warehouse design.

3-1.1 Material Movement

Transport paths and building layout must avoid discontinuities and elevation changes which impede material movement. \1\ The transport path must be clear of structural columns or beams. /1/

Locate warehouse facilities on a site to take advantage of highway and rail facilities. Evaluate location of the facility on the site to reduce or eliminate areas of conflicting traffic.

3-1.2 Expansion Capability

Consider present and future requirements in building construction and site location to permit future expansion of facilities in an orderly, safe, and cost-efficient manner.

3-1.3 Flexible Design

Where facility usage is uncertain or subject to change, building design must use the universal bay dimension of 33 feet x 64 feet (10,060 mm x 19,510 mm).

3-1.4 Requirements of Specific Buildings

Building requirements are dictated by the function of the facility. Refer to table 3-1 for general requirements for specific types of buildings.

Table 3-1 Special Requirements for Warehouse Types

BUILDING TYPE	FUNCTIONS	SPECIAL REQUIREMENTS
General Purpose Warehouse	All-purpose structure for storing and handling supplies not requiring special considerations.	Fire protection separation between buildings; Refer to UFC 3-600-01, *Fire Protection Engineering for Facilities*, for required building separation based upon construction and exposure.
Heavy Materials Warehouse	Storing and handling heavy and bulky supplies incapable of being handled by forklift trucks, but which may be handled more economically by overhead traveling cranes.	Overhead electrical traveling cranes to handle loads too heavy or bulky to be handled by forklift trucks. Fire walls must be designed and constructed to avoid interference with operation traveling crane(s). Railroad service tracks within building. Flooring elevations at same level as top of inside railroad tracks. Door for truck entry into building and truck entrances at floor level. Ventilation: continuous ridge ventilators in unheated and non-humidified buildings only. Heating: storage areas are not heated.
Aeronautical Materials Warehouse	Storage of spare parts and component assemblies of aircraft.	Truck and rail access. High, clear storage space and large doors. Overhead traveling cranes. Heating and cooling required only for personnel comfort. Dehumidification required. Bins or storage shelves.
Hazardous Materials Warehouse	Storage and handling of hazardous chemicals and highly combustible materials.	Floor: 6 in. (150 mm) below the floor elevation of outside platforms or provide floor trenches for spill control. Flat floor with no drains or slope. Chemical resistant floor coating. Outside drainage with valve. Corrosive materials storage areas with external access doors. Ventilation: continuous mechanical from floor and roof; minimum of 1.5 air changes per hour (where all containers are sealed).
Humidity Controlled Warehouse	Preserving of stores at maximum relative humidity of 40 percent.	Proper equipment for dehumidifying. Additional electrical requirements. Measures to effectively seal openings.
Medical Warehouse	Storage of medical supplies: 1. Small auxiliary facility for hospital or dispensary. 2. Large medical supply warehouse.	Diversified functional elements include: Refrigeration, dehumidification, narcotics vaults, and heated spaces. Small facility is located and designed to best fit in local needs and support the parent structure. Large supply warehouse is a large building designed to meet present and foreseeable needs over wide areas for specified periods and situations.
Receiving, Shipping and Issue Buildings	Receiving: central point for receipt of shipments. Shipping: central point for outloading. Issue: standard storage buildings arranged for issuing supplies.	Based on the needs for receipt, unpackaging, inspecting, sorting, assembling, storage, repackaging, issue, reshipment, and other necessary handling. Special interior arrangements to carry out its mission and possibly special outloading facilities and techniques. Provisions for local issue are met by special interior layout, such as in packaging and sorting space, assembly space, inspection, bins, counters, enclosures, space for item accounting, and provisions for personnel traffic. Requirements are determined largely by the characteristics of the using agency.
Miscellaneous Facilities	Bulk Storage bias: storage of large lots of loose, solid materials. Warehouse bins: provide additional storage space in warehouse buildings.	Varying depending on the needs of the installations and materials to be contained. Materials, shape, and size determined by local needs. Arrange in double rows, back to back, and at right angles in main aisles: single rows may be arranged against walls. Passageways between open faces of bins must be a minimum of 36 in. (915 mm) wide. Metal Units: width, 36 in. (915 mm); height, 7 ft. 3 in. (2.51 m); depth, 18 in. (460 mm).
Boxing and Crating Buildings	Boxing and crating material.	One portion of building outfitted for necessary industrial operations; another portion for processing depot supplies; and the remainder devoted to storage of manufacturing stocks and assembled units.
Preservation Buildings	Special operations for preserving supplies.	Special equipment and facilities for preserving supplies before being placed in storage.
Cold Storage	Preserving stores in controlled climate ranging from -5° F (-21° C) to 50° F (10° C).	Proper equipment for cooling. Additional electrical requirements. Measures to effectively seal openings. Additional insulation requirements. Maximum utilization for storage space.

3-2 BUILDING SHAPE AND PROPORTIONS

Observe the following cautions relating to building size and shape:

3-2.1 Travel Distance

Arrange buildings or increments of buildings for minimum distance between high activity operations. Square buildings minimize perimeter wall area for a given floor area. Aspect ratios (ratio of length to width) of 1.25 or less are considered square. If possible, avoid aspect ratios exceeding 3.00 for conventional warehousing operations.

3-2.2 Irregular Shapes

Avoid irregular shapes, such as U or L.

3-2.3 Height

High-rise storage is preferred over low height buildings on a life-cycle cost basis since storage costs per unit stored, over the life of the project, decrease as height is increased. Coordinate building height parameters with storage system characteristics, as illustrated in figure 2-2.

3-2.4 Area

Limit building size based on restrictions due to loss potential and fire and hazardous chemicals safety and site restrictions. Fire protection separation between buildings; Refer to UFC 3-600-01, *Fire Protection Engineering for Facilities*, for required building separation based upon construction and exposure.

3-3 BUILDING SPACING

Required spacing between buildings to facilitate operations and aid in fire prevention, protection, and hazardous chemical spills (liquid/gas) control, will vary according to the type of construction and exposure classification. Refer to UFC 1-200-01, *General Building Requirements and* UFC 3-600-01, *Fire Protection Engineering for Facilities* for fire protection engineering requirements. Otherwise, observe the following:

3-3.1 Rail Side

Allow 120 feet (36.6 m) between faces of walls.

3-3.2 Truck Side

Allow 175 feet (53.3 m) between faces of walls.

3-3.3 Warehouses In-Line

Where a Warehouse or series of Warehouses are to be provided on a single site in a row or series of rows, in-line, allow 30 feet to 150 feet (9.1 m to 45.7 m) between faces of walls.

3-3.4 Hazardous Materials Facilities

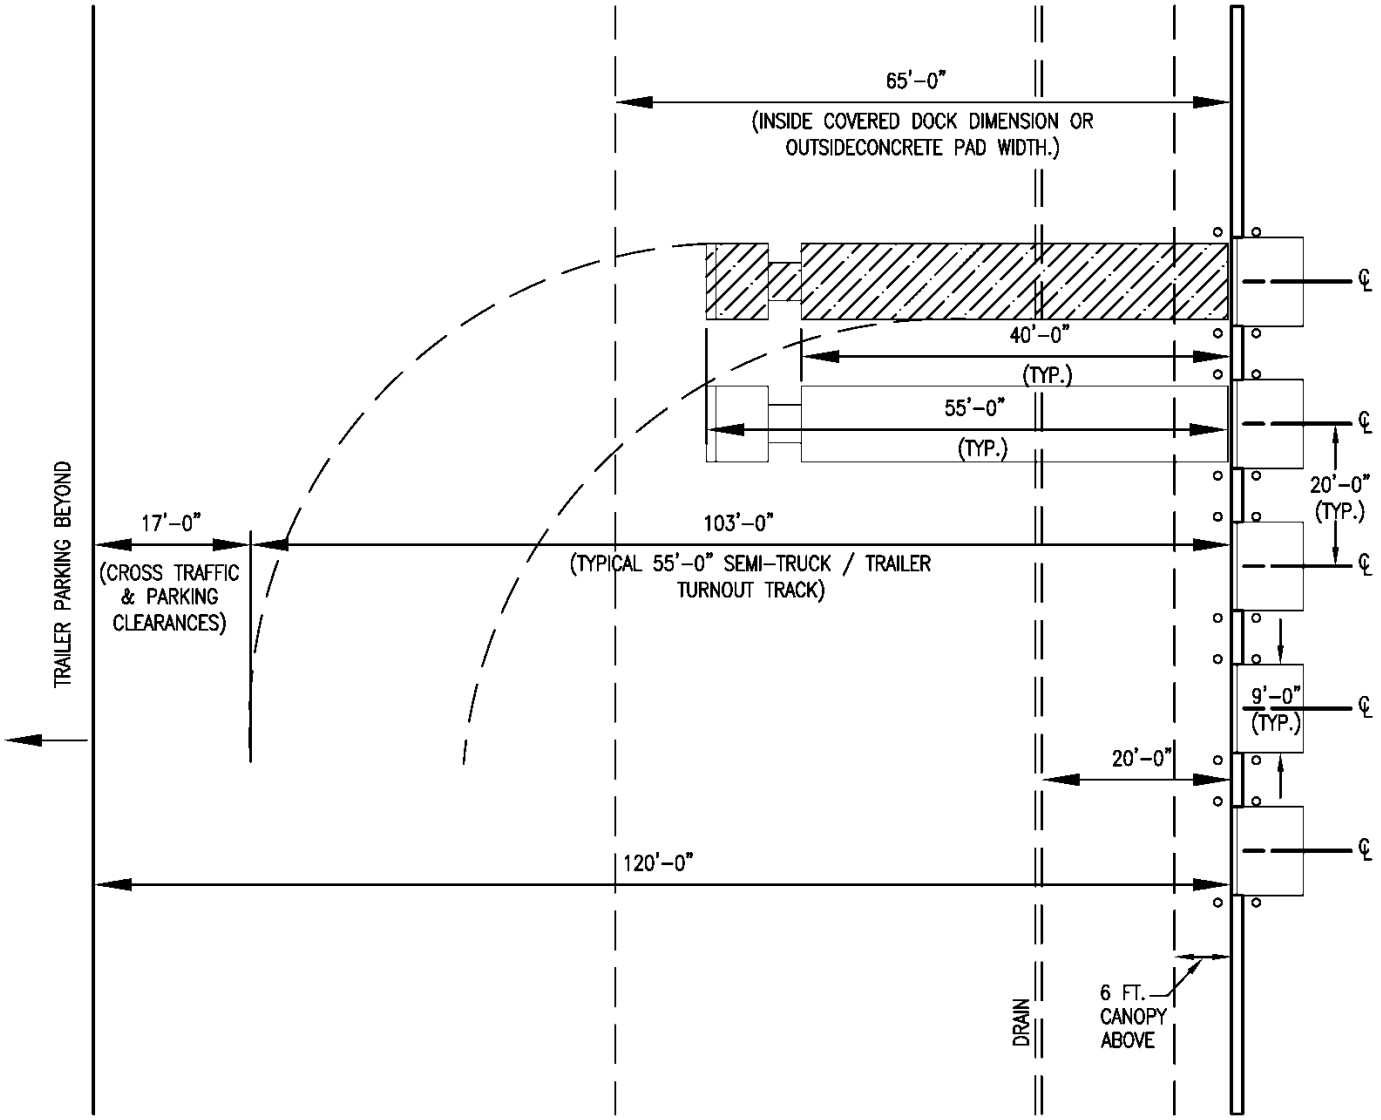
Provide a buffer zone between the facility or portion of facility containing Hazardous Materials and the nearest inhabited area, stream, or body of water in accordance with UFC 1-200-01, *General Building Requirements* and UFC 3-600-01, *Fire Protection Engineering for Facilities*.

3-4 DOCKING FACILITIES

Provide maneuvering space to facilitate loading and unloading operations at warehouse rail and truck docks (see figure 3-1). Protect building corners and dock areas from vehicle impact by using concrete-filled steel pipes (see figure 3-2). Provide safety equipment and fall protection per OSHA and applicable codes and regulations.

Figure 3-1 Truck Apron Criteria (Functional Dimensions)

Plan View



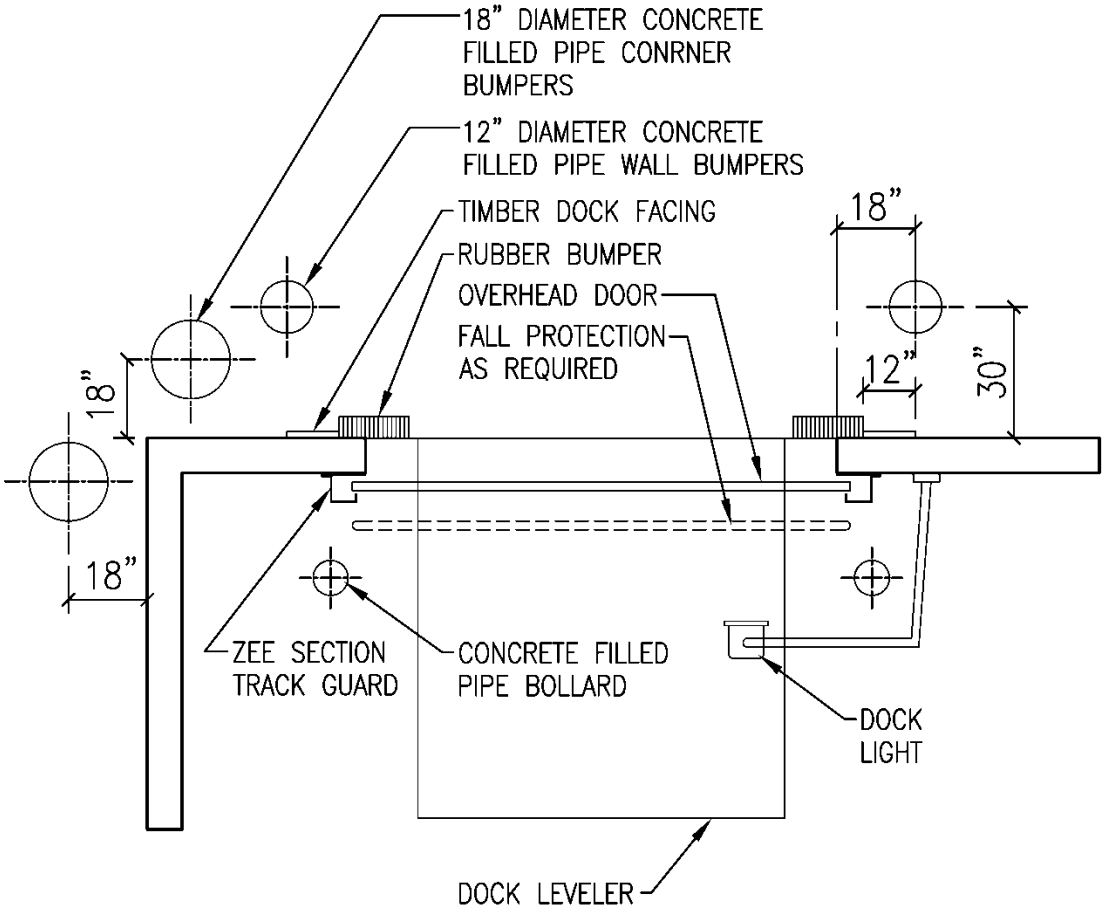


Figure 3-2 Building Protection Devices

Plan View

3-4.1 Truck Dock

Truck dock height will vary between 44 and 52 inches (1120 mm and 1320 mm) depending on the class of trucks served (see table 3-2). Use a 48-inch (1220 mm) height for general highway tractor-trailer service. Configure truck docks to conform to building, site, and traffic flow requirements (see figure 3-3). Figure 3-4 shows a typical dock section. Slope dock apron areas away from the building, as illustrated in figure 3-5. Provide doors of a size consistent with truck characteristics, as shown in figure 3-6. Open uncovered exterior truck dock platforms are not recommended. Provide space to load and unload flatbed and low-boy trucks and to move material in and out of the warehouse using a rolling A-Frame hoist or similar material handling equipment. A dock adjacent to the ramp of the building may be equipped with a 5-ton (4500 kilogram [kg]) monorail, interrupted at the door with a moveable (swing) section. A 12 x 12 foot (3660 mm x 3660 mm) door must be specified with this option. All outside supports must have protective barriers.

Table 3-2 Truck and Rail Vehicle and Dock Heights

TYPE OF TRUCK	BED HEIGHT				OVERALL HEIGHT		DOCK HEIGHT		DOCK LEVELER LENGTH (Minimum)	
	Minimum		Maximum		Minimum ft-in (mm)	Maximum ft-in (mm)				
	In	mm	in	mm			in	mm	ft	m
Container	56	1420	62	1570	12’-2” (3710)	13’-6” (4110)	52	1320	6’ – 10’	1.8 – 3.0
Reefer	50	1270	60	1520	12’-6” (3810)	13’-6” (4110)	52	1320	6’ – 8’	1.8 – 2.4
Flatbed (1)	48	1220	60	1520	---	---	48	1320	6’ – 12’	1.8 – 3.7
Double Axle Semi (2)	46	1170	56	1420	12’-0” (3660)	13’-6” (4110)	48	1220	6’ – 8’	1.8 – 2.4
Straight Semi (2)	44	1120	52	1320	12’-0” (3660)	13’-6” (4110)	48	1220	8’	2.4
City Delivery	42	1070	48	1220	11’-0” (3350)	12’-6” (3810)	48	1220	6’ – 8’	1.8 – 2.4
Stake Body	42	1070	48	1220	---	---	48	1220	6’ – 8’	1.8 – 2.4
High Cube Van	32	810	38	960	13’-0” (3960)	13’-6” (4110)	43	1220	8’ – 12’	2.4 – 3.7
Furniture Van (3)	24	610	36	910	13’-0” (3960)	13’-6” (4110)	30	1090	8’	2.4
Step Van (3)	20	510	30	760	8’-6” (2590)	10’-0” (3050)	30	760	6’ – 10’	1.8 – 3.0
Panel Truck (3)	20	510	24	610	8’-0” (2440)	9’-0” (2740)	30	760	8’ – 10’	2.4 – 3.0
Low Boy (3)	20	510	24	610	---	---	30	760	8’ – 10’	2.4 – 3.0
Box Car (4)	41	1040	44	1120	---	---	44	760	6’	1.8
Reefer Rail Car (4)	46	1170	52	1320	---	---	48	1120	5’ – 6’	1.5 – 1.8

Notes:

(1) Dock height range of 48”- 52” (1220-1320 mm).
(2) Dock height of 50” (1270 mm) if serving semis only.
(3) Dock height of 48”-50” (1220-1270 mm) recommended with exterior ramp to elevate truck to provide nominal 30” (760 mm) dock height.
(4) Minimum dock leveler length determined by required clearance between rail car and dock.

Figure 3-3 Truck Dock Configurations

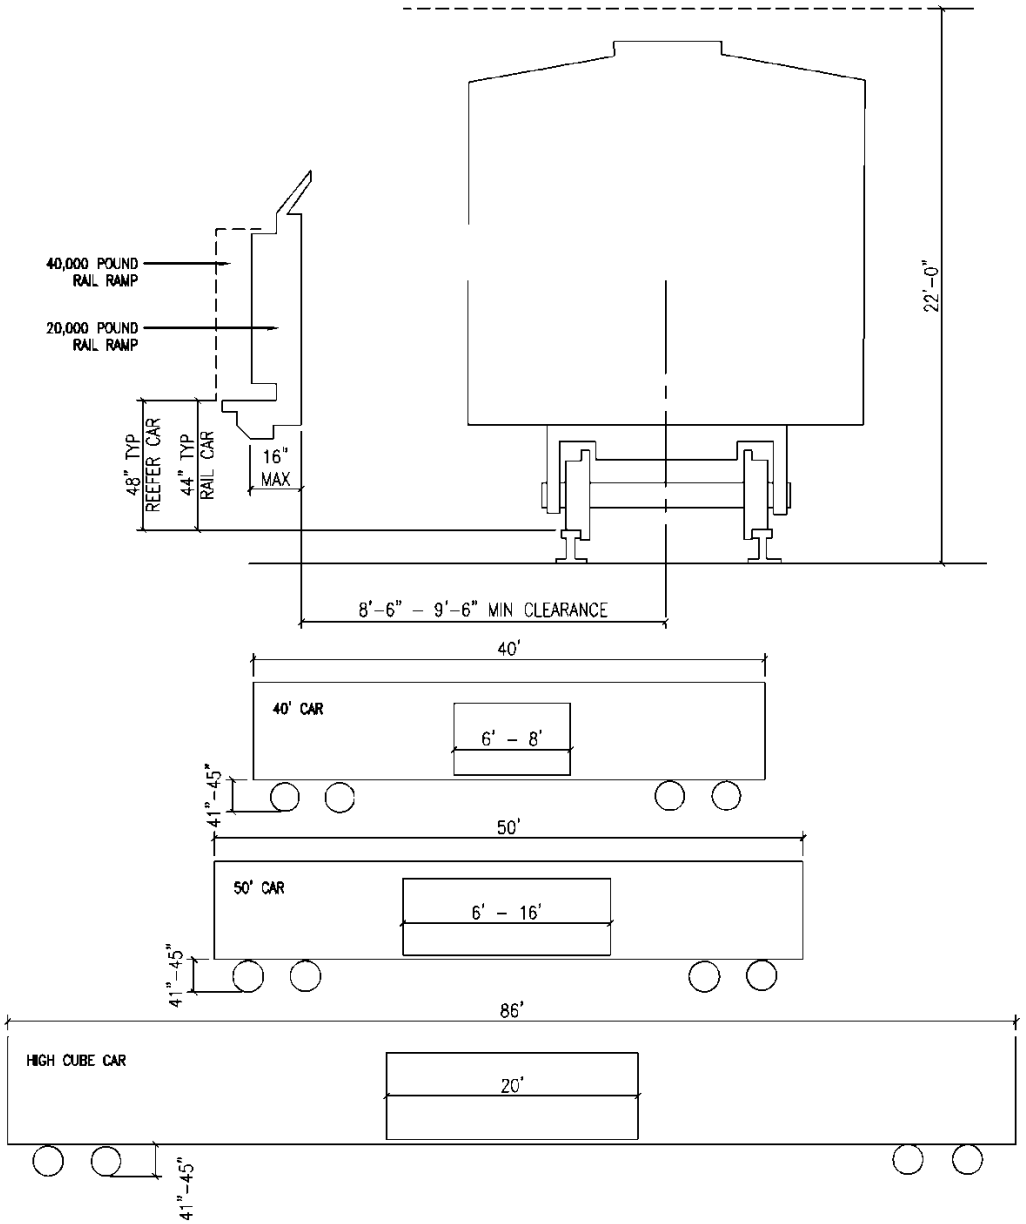
Figure 3-6 Door Size Characteristics

Perspective View and Sections



3-4.2 Rail Docks

If rail access is available include provisions for rail docks (see figure 3-7) as an option in the design of all storage facilities exceeding 40,000 square feet (3716 sq. m). There are three primary types of rail dock:

Figure 3-7 Rail Car Characteristics

Section and Elevations

3-4.2.1 Outside Docks

Outside rail docks use through-the-wall access to rail cars without using an outside platform. Use inflatable seals to seal the space between the rail car and the warehouse. Include a wall-mounted dock board to provide access to the rail car.

3-4.2.2 Inside Docks

Inside rail docks may place the tracks inside the building in a pit constructed to place the car floor at the same level as the warehouse floor or on a floor level track. Pit type installations must include track-mounted dock boards. Because of the large amount of warehouse storage space occupied by this type of dock, inside docks are not recommended except under extreme circumstances in which sheltering of the car or additional security is required.

3-4.2.3 Platforms

Platforms for rail service must extend the full length of the building and be 15 feet (4570 mm) wide. Platform height above rails must be 3 feet 8 inches (1118 mm) for general use. Equip platforms with track-mounted dock boards. See the paragraph entitled, “Dock and Platform Weather Protection”.

3-4.3 Ramp Access

Provide ramps at the end of rail platforms and at one warehouse truck dock door for vehicle access. Ramp slope must not exceed 10 percent.

For occupant accessibility requirements see the paragraph entitled, “Accessibility for the Disabled”.

3-4.4 Dock Levelers

Provide dock levelers at all truck and rail dock positions. Dock leveler life is directly affected by load weight, fork truck weight, and frequency of use. Specify dock leveler capacity to provide a minimum 20 year life (see table 3-3).

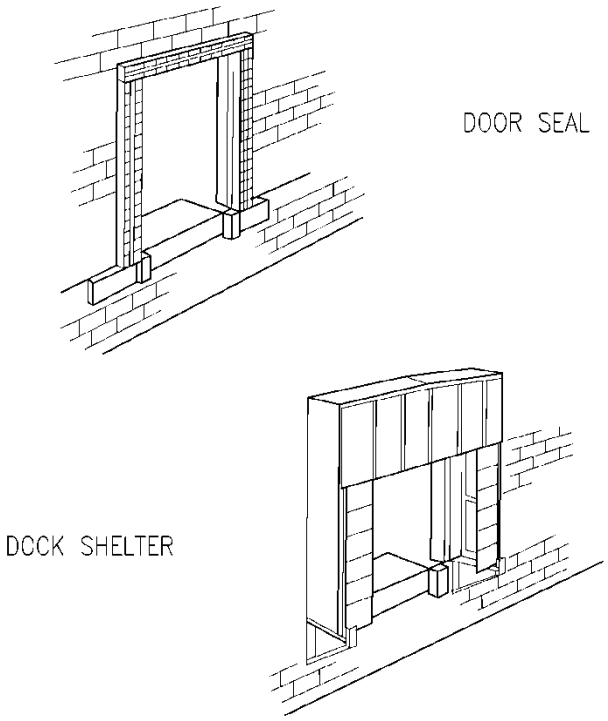
Interior Dock levelers must be equipped with dock leveler seals.

Table 3-3 Dock Leveler Life (Years) Based on Impact Loading

`RATED CAPACITY	WORKING SHIFTS	MAXIMUM GROSS LOAD (Including weight of fork truck and load)				
		5,000 lb. (2,270 kg)	10,000 lb. (4,540 kg)	15,000 lb. (6,800 kg)	20,000 lb. (9,070 kg)	25,000 lb. (11,340 kg)
20,000 lb (9,070 kg)	1	+	13	-	-	-
	2	19	7	-	-	-
	3	9	-	-	-	-
30,000 lb (13,600 kg)	1	+	+	13	-	-
	2	+	13	6	-	-
	3	18	5	-	-	-
40,000 lb (18,140 kg)	1	+	+	20	8	-
	2	+	+	9	-	-
	3	+	+	5	-	-
50,000 lb (22,680 kg)	1	+	+	+	16	11
	2	+	+	15	8	-
	3	+	18	9	-	-
60,000 lb (27,220 kg)	1	+	+	+	18	12
	2	+	+	+	8	-
	3	+	+	15	-	-

Notes:

+ Estimated life in excess of 20 years.



- Estimated life less than 5 years

3-4.5 Dock and Platform Weather Protection

Provide dock shelters or door seals in heated, air conditioned, and dehumidified warehouses, to seal the space between the truck or railcar and the building (see figure 3-8). Full width canopies must be used to shield all docks and rail service platforms from precipitation. Provide gutters and downspouts and connect to underground stormwater drainage system.

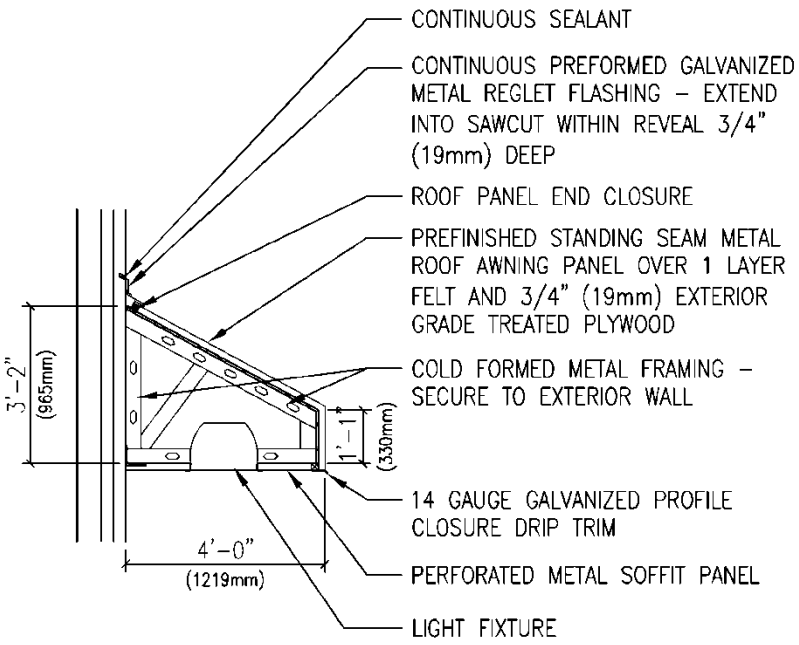
Figure 3-8 Truck Dock Weather Seals

Perspective Views

3-4.5.1 Dock Shelters

Use dock shelters in applications where truck size cannot be controlled. Sealing action is achieved through the wiping action of the shelter on the trailer when a truck backs into and through the shelter to the dock. Use shelters when the dock wall is not capable of resisting the compressive forces exerted by a door seal.

3-4.5.2 Door Seals



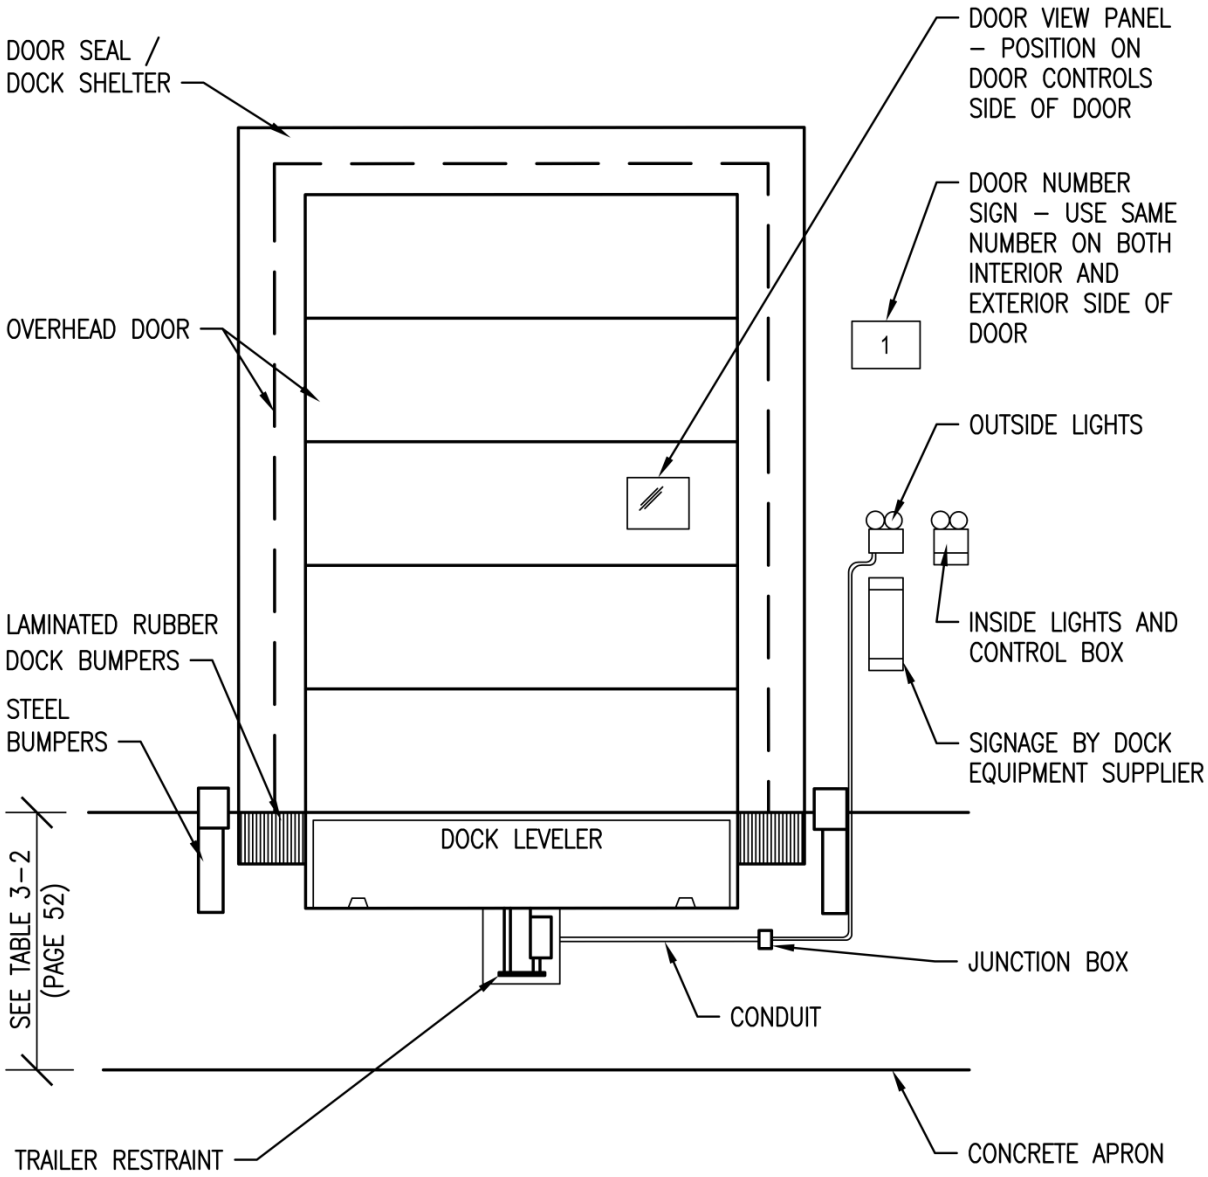
Door seals achieve a seal by compressing between the building wall and the trailer. Door seals provide greater sealing efficiency than dock shelters but require a structural wall capable of resisting compressive forces. Use of door seals requires close coordination of door opening size and trailer size. Excessive size incompatibility will require use of a dock shelter. Provide fire retardant door seals.

3-4.5.3 Canopy

Provide a minimum 4 foot (1830 mm) full length canopy (figure 3-9) over outside docks to protect the trailer and door interface and dock shelter or door seal from excessive weather exposure. This requirement must be evaluated with the site solar angle to alleviate solar loading in the cooling season and optimize solar gain in the heating season.

Figure 3-9 Truck Dock Canopy

Section



Storm drainage from canopies is prohibited to drain on grade at docks/platforms. Provide exterior downspouts connected to an underground storm water system.

3-4.6 Safety Equipment

Equip each truck dock with safety equipment consisting of wheel chocks and door-mounted lights to illuminate the trailer interior. Dock levelers must be equipped with manually or electrically operated trailer restraints with wheel chocks as a secondary safety measure. Figure 3-10 illustrates a typical installation of a dock shelter, dock leveler, and trailer restraint device.

Figure 3-10 Trailer Restraint System

Elevation View

Provide fall protection per requirements of 29 CFR 1910.23, *Guarding Floor and Wall Openings and Holes*.

Provide two safety posts for each personnel door on the warehouse storage side of the door. See figure 2-3 and figure 2-4 for examples of safety posts applications.

3-5 STRUCTURAL

Refer to UFC 1-200-01, *General Building Requirements*; UFC 3-301-01, *Structural Engineering*; and UFC 3-310-04, *Seismic Design for Buildings* for structural engineering and seismic design requirements.

3-5.1 Ground Floors

Slab-on-grade systems for the offices and shop spaces of the facility must be designed in accordance with UFC 3-301-01, *Structural Engineering*. Fiber reinforced concrete systems must not be used inside the building. Slab-on-grade must have adequate thickness to support wall line loads. For slab-on-grade subject to forklift traffic, the minimum compressive strength for the concrete must be 4,000 psi (27580 kPa).

3-5.1.1 Reinforcement

Provide crack control using reinforcement consisting of minimum number 6 welded wire fabric in a 6- by 6-inch (150 mm x 150 mm) mesh or alternative non-reinforced methods.

3-5.1.2 Thickness

Floor thickness will be determined by a combination of live load, dead load, strength of concrete, and subgrade conditions. Refer to UFC 1-200-01, *General Building Requirements*, UFC 3-301-01, *Structural Engineering* and UFC 3-220-01, *Geotechnical Engineering,* for structural engineering and geotechnical engineering procedures for foundation design. Floors in warehouse facilities must be no less than 6 inches (150 mm) thick.

3-5.1.3 Static Load

Floors must be designed to support the estimated static load of stored material and storage equipment.

3-5.1.4 Impact Load

Floor design must incorporate the effects of Impact loads caused by operation of materials handling equipment. Consult equipment manufacturers for characteristics of specific vehicle impact loads

3-5.2 Superstructure

The superstructure of the warehouse must be a steel frame unless alternate structural frame systems are determined to be better suited for the facility.

The superstructure must be designed to accommodate structure supported shelving and equipment.

3-5.2.1 Structural Bracing

Structural bracing must be located so as not to impair functionality of storage areas. Exposed structural bracing must not be permitted in any administrative spaces.

3-5.2.2 Selection Factors

Determination of a structural frame system other than steel must show careful study of the advantages and disadvantages of alternative systems, as well as the reasons for using the system considered most suitable. Before selecting structural systems, determine if the building will be wall-bearing or framed construction.

Investigate the following during selection of the structural system:

a. Availability of materials.

b. Speed of erection.

c. Local labor and construction practices.

d. Quality of local materials.

e. Limitations on materials by Department of Defense, Bureau of the Budget, or other mandatory standards.

f. Mandatory standard drawings and specifications for certain types of buildings, such as ammunition magazines.

g. Criteria for design of structures in typhoon, hurricane, and other high wind areas. Refer to UFC 3-301-01, *Structural Engineering*.

3-5.2.3 Conventional Construction

Conventional column/beam/truss construction or pre-engineered designs may be used for buildings up to 44 feet (13 410 mm) in height.

3-5.2.4 Rack Supported Construction

Rack supported construction, in which the storage (pallet rack) system provides the building support in the storage area, must be evaluated for all structures over 44 feet (13 410 mm) in height. For lower buildings, this method of construction must be reviewed for economic suitability.

3-5.2.5 Main Structural Framing Materials

3-5.2.5.1 Weathering Steel

Weathering steel must not be used.

3-5.2.5.2 Hollow Structural Sections

HSS members must be sealed to keep water from entering the section and animals from nesting inside. 1/4 inch (6.35 mm) diameter weep holes are allowed as necessary to release any thermal pressure built-up from within the members.

3-5.2.5.3 Exposed Structural Steel

Exposed steel shapes must be selected to minimize their surface area. All exposed steel connections must be designed to shed water. Exposed steel must be designed to permit the complete inspection of all fasteners and welds.

All exposed structural steel must be coated with a high performance coating system consisting of an epoxy primer, a high solids polyurethane intermediate coat and a high solids polyurethane top coat. Refer to UFC 3-190-06, *Protective Coatings and Paints*.

3-5.2.5.4 Corrosive Environments

Refer to UFC 3-301-01, *Structural Engineering* for requirements of steel structures in corrosive environments.

3-5.2.6 Secondary Structural System

The walls and partitions of the warehouse must be non-load bearing and must not be considered as elements of the lateral load resisting system. The walls of the office and shop portion(s) of the facility may be designed as load bearing if structurally isolated from the warehouse structure.

3-5.2.7 Strength and serviceability requirements

In addition to the loads described in or incorporated by reference by UFC 1-200-01, *General Building Requirements,* the design must account for all loads imposed by bridge cranes or other specialty equipment supported by the structure. Cold-Formed steel framing systems must be designed for vibration serviceability.

The structural frame must be designed to accommodate 125% of the loading from overhead bridge cranes. The designer must consider the effect of pattern loads resulting from multiple loaded hooks. All crane hardware and lifted loads must be treated as live loads in the load combinations defined in chapter 16 of the IBC, except for patented tracks, tracks, supports, sway braces and similar elements which are immobile and may be defined as dead loads.

3-5.2.7.1 Gravity loads

In determining design load combinations for structures in which the dead load of one portion of the building serves as stability enhancing function for another portion of the building (i.e. Cantilevered construction), the following cases must be considered in addition to the basic load cases.

3-5.2.7.2 Factored Load Combinations

If the dead load of any portion of the facility, including a structurally isolated administration and shop structure sharing a common foundation, is used to resist uplift forces, it must be factored by 0.9 in strength design analysis and by 0.6 in stress design analysis if it favorably contributes to the performance of the system.

3-5.2.7.3 Wind and Snow Loads

Refer to UFC 3-301-01, *Structural Engineering.*

3-5.2.7.4 Seismic Loads

Refer to UFC 1-200-01, *General Building Requirements*; UFC 3-301-01, Structural Engineering; and UFC 3-310-04, *Seismic Design for Buildings*, for structural engineering and seismic design requirements.

3-5.2.7.5 Thermal Loads

In addition to the thermal loads of the IBC, the designer must account for anticipated differential thermal effects from solar heating (e.g., on long sun-exposed exterior steel compared to shaded steel such as roof trusses, joists or decking) or inside/outside differences (particularly a “stratification” effect in the warehouse storage bay). Consider the local climate conditions when selecting the final differential temperature range, as a minimum, a temperature differential of 50°f (28°c) must be used for design. The deflections caused by differential thermal effects must be investigated by the engineer of record. Some architectural fascia elements and weather seals around large overhead doors are particularly vulnerable to detrimental deflections. The differential thermal effects are a serviceability concern and must be investigated using unfactored loads.

The design must also control deflections to within the limits imposed by section 1604 of the IBC in compliance with UFC 3-301-01, *Structural Engineering* unless stricter control is necessary to support equipment, fascia or other appurtenances. The warehouse roof must meet the requirements of a structure “supporting a non-plaster ceiling” and the walls must meet the requirements of a “partition with flexible finishes.” The administrative area must meet the deflection requirements appropriate to finish type. If the warehouse and administrative area framing is constructed as a single frame, the combined structure must meet the most stringent requirements described above.

3-5.2.7.6 Deflection and Drift

The deflection of structural elements, evaluated under service level loads, must provide for the serviceability of the structure and all of its components, including but not limited to exterior walls and cladding, partition walls, hangar doors, bridge cranes, utilities and other appurtenances. However, in no instance must the deflection of any structural element exceed the limits of the IBC. The lateral drift (sideways) of the structure as a whole, evaluated under service level loads, must provide for the serviceability of the structure and all of its components, including but not limited to exterior walls and

cladding, partition walls, overhead doors, bridge cranes, utilities and other appurtenances. However, in no instance must the drift of the structure exceed the mean roof height divided by 320. If the structure has multiple roof elevations, this requirement must be independently met at each roof level.

3-6 EXTERIOR DESIGN

Exterior walls of the warehouse must be of a construction suitable to the building type, be compatible with the design of the existing building / adjacent buildings with regards to building form, height, materials selection, color and architectural detailing and be protected from abuse, both interior and exterior. Exterior walls and building signage must be compatible with the Installation Appearance Plan (IAP) or other written documents. For Design/Build projects, coordinate any specific requirements for materials prior to issuing the RFP.

Exterior design and architecture must comply with UFC 1-200-01, *General Building Requirements,* UFC 3-101-01, *Architecture* and UFC 1-200-02, *High Performance and Sustainable Building Requirements.*

3-6.1 Surface Treatment

The chemical properties of materials and finishes for exterior surfaces must have the highest possible resistance to the effects of weather and salt-corrosive atmosphere.

Where metal panels are used for exterior wall and roof surfaces, provide a factory applied finish system to resist corrosive climatic effects.

3-6.2 Roofing Systems

Low-slope roofs must be used to minimize potentially unusable space caused by the roof rise associated with sloped roofs. Sloped roofs having a pitch exceeding 1 inch per foot (83 mm per meter) must be avoided for warehouse facilities unless available roofing materials require a greater pitch. When the roof slope exceeds 2 inch per foot (166 mm per meter) the sprinkler operating area and sequence will be impacted. Sheds may have a roof pitch of 2 inches per foot (166 mm per meter) or greater.

Refer to UFC 1-200-01, *General Building Requirements* and UFC 3-110-03, *Roofing*.

The following criteria apply:

a. Combustible roofing is permitted only in emergency construction.

b. Roofing construction may consist of steel decking, reinforced concrete, or precast concrete panels.

c. Gutters and downspouts must be used. Positive measures must be taken to prevent accumulations of mud, snow, or ice. Where downspouts are to

outlet on-grade splash blocks of adequate size for downspout capacity must be provided.

d. Refer to UFC 3-110-03, *Roofing*, for standards concerning materials and installation for built-up roofing.

e. Provide a drop ceiling in the warehouse when the roof slope is greater than 2 inch per foot (166 mm per meter).

3-6.2.1 Low-Slope

Low-slope roofs must have a minimum pitch of 1/2 inch per foot (42 mm per meter).

3-6.2.2 Steep Slope

Sloped roofs having a pitch of 3-4 inches per foot (250-333 mm per meter) may be used in small spans where roof rise can be limited to 5 feet (1525 mm) or less.

3-6.3 Exterior Walls

Exterior walls may be of insulated metal siding, brick or concrete masonry, or tilt up precast or cast-in-place concrete panels. When metal walls are used, the first 4 feet (1220 mm) of wall above the floor must be of reinforced masonry construction to protect the structure from fork truck impact and provide additional security. Walls located on sides designated for future expansion must be removable.

3-6.4 Dock Doors

Size dock doors consistent with the types of delivery vehicles expected to operate around the facility.

See table 3-4 for recommended door sizes.

Table 3-4 Recommended Door and Portal Sizes

Description	Width		Height	
	inches	mm	inches	mm
Standard Truck Door	9’-0”	2,743.2 mm	10’-0”	3,048.0 mm
Air Lines of Communication (ALOC) Door	10’-0”	2,743.2 mm	10’-0”	3,048.0 mm
Transporter Door	10’-0”	3,048.0 mm	10’-0”	3,048.0 mm
Firewall Door (interior between bays)	15’-0”	4,572.0 mm	15’-0”	4,572.0 mm
Oversized Door	12’-0”	3,657.6 mm	10’-0”	3,048.0 mm
Forklift Ramp Door	15’-0”	4,572.0 mm	15’-0”	4,572.0 mm
Truck Well Door	12’-0”	3,657.6 mm	15’-0”	4,572.0 mm

3-6.4.1 Dock Door Height

Truck dock doors must be at least 9 feet (2745 mm) high.

3-6.4.2 Dock Door Width

Truck dock doors must be at least 9 feet (2745 mm) wide.

3-6.4.3 Dock Door Safety Hardware

Provide safety hardware meeting the requirements of UL 325, *Door, Drapery, Gate, Louver, and Window Operators and Systems* and ANSI B11.19, *Performance Requirements for Safeguarding*.

3-6.5 Fire Doors

In heater rooms and transformer vaults, doors must be metal-covered or industrial-type metal fire doors, as required. \1\/1/Refer to UFC 3-600-01, *Fire Protection Engineering for Facilities*.

3-6.6 Windows

All fenestration must conform to the recommendations of the Threat / Vulnerability Assessment and Risk Analysis. Place windows to prevent illicit entry accomplished by reaching adjacent entry door hardware.

Use windows meeting American Architectural Manufacturers Association (AAMA) type HC60 window specifications (AAMA WSG-11, *Window Selection Guide*). Windows must be thermally broken pre-finished aluminum with tinted, low–e glass. Use laminated glazing and comply with UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings* in portions of the building that qualify as “inhabited”, including “inside” windows exposed by the warehouse bay. Both panes must have laminated glazing. Specify commercial grade windows with heavy-duty insect screen for operating section. Solar glazing with low “e” glass is required in regions with plentiful sunlight.

3-6.7 Doors and Hardware

Exterior doors with closers must be Level 4, physical performance Level A doors complying with ANSI/SDI A250.8, *Standard Steel Doors and Frames*. Frames must match door level. Exterior door frames must be welded type.

Provide Grade 1 hardware typical. Locksets must be mortise type, Series 1000 as defined by ANSI/BHMA - A156.13, *Mortise Locks and Latches* for shop and maintenance level doors. Hinges for doors with closers must be full mortise butt hinges except where special types are required. Closers must be the best and highest grade available from each manufacturer. Exterior doors must have overhead rain drips and door drips.

3-6.8 Signage

Provide exterior signage in accordance with UFC 3-120-01, *Design: Sign Standards*.

3-7 INTERIOR DESIGN

Durability is extremely important when specifying materials for interior construction and finishes. Warehouses regularly handle heavy equipment throughout the facility. All finishes and components must be selected based on the operations performed in the warehouse, and shop spaces. These conditions will lead to greater interior damage being incurred compared to many other facility types.

Refer to UFC 1-200-01, *General Building Requirements* and UFC 3-120-10, *Interior Design.*

3-7.1 Interior Walls

Interior wall construction will vary depending upon use, finish, and required fire and corrosion resistance. Refer to UFC 1-200-01, *General Building Requirements*.

3-7.2 Doors and Windows

Windows must be provided for office and service structures when located on an exterior wall. A continuous narrow band of high windows may be justified in large warehouses by savings in electric lighting costs as determined by energy modeling.

3-7.2.1 Doors

Provide interior door openings and portals of sufficient height and width to permit passage of materials handling equipment. Size doors and portals consistent with the types of trucks expected to operate in the facility. These requirements do not apply to personnel type exit doors.

See table 3-4 for standard door and portal sizes.

3-7.2.1.1 Door Height

Doors must provide a minimum of 6 inches (150 mm) clearance for the highest loads or vehicles expected to operate in the facility.

3-7.2.1.2 Door Width

Doors must provide a minimum of 12 inches (300 mm) clearance on each side of passing materials handling equipment.

3-7.2.1.3 Hardware

Provide Grade 1 hardware typical. Locksets must be mortise type, Series 1000 as defined by ANSI/BHMA - A156.13, *Mortise Locks and Latches*. Locksets for administrative spaces may be Series 4000 as defined by ANSI/BHMA - A156.2, *Bored and Preassembled Locks and Latches*. Hinges for doors with closers must be full mortise butt hinges.

Metal overhead doors must be chain hoist operated, except when frequent use demands motorized operation.

3-7.3 Signage

Provide safety markings on walls and floors (figure 2-5.) Refer to Title 29 Code of Federal Regulations (CFR) Part 1910, *Occupational Safety and Health Standards*.

Provide interior signage in accordance with the requirements of UFC 3-120-01, *Design: Sign Standards*.

3-7.3.1 Identification

Provide identification signage to inform personnel of area identification, function, services, safety, and storage locations.

3-7.3.2 Warning

Identify all hazards, hazardous equipment, and restricted areas with suitable warning signage.

3-7.4 Warehouse Storage Area

The warehouse must be provided with durable finishes. The exterior walls must have as a minimum, a protective panel along the exterior walls that will prevent damage to the exterior finish system. The minimum protection can be provided by a metal panel attached to the wall panel girts. The protective panel must extend to at least 7 feet (2.13 meters) above the warehouse floor. Alternatively, masonry may be provided.

3-7.4.1 Floors

Critical attention to floor design and construction is essential to proper operation of narrow aisle high-rise storage systems. Provide a Class 5 floor in accordance with American Concrete Institute (ACI) *Guide for Concrete Floor Slab Construction*, AC1 302.1R-04 and UFC 1-200-01, *General Building Requirements*, for areas not otherwise specified.

3-7.4.1.1 Finishes

Floor hardeners, dressings, or toppings are required for durability in areas of exceptionally high activity such as main aisles, towline paths, or industrial shop areas. Sealers are required for dust control.

3-7.4.2 Superflat Floors

High rise, narrow aisle storage systems with aisles less than 96 Inches (2440 mm) wide and storage heights exceeding 20 feet (6100 mm) require extremely smooth and flat floors to control operating tolerances. Superflat floors must be designed and specified for vehicles such as turret trucks and man-up order picking trucks. Provide superflat, class 9 floors in accordance with ACI 302.1R-04, *Guide for Concrete Floor and Slab Construction*.

3-7.4.2.1 Construction Guidelines

In order to assure that superflat tolerances can be achieved, the following design and construction guidelines must be followed:

a. Clearly identify on the design drawings those areas of the warehouse floor which must meet superflat tolerances.

b. Incorporate a requirement in the construction contract for test slabs to assure that the superflat floor tolerances can be achieved with the contractor's proposed operations.

c. All longitudinal construction joints must be located outside of the aisles in which the trucks operate. Space transverse weakened plane joints to control random cracking and potential slab warping. A transverse joint spacing of 20 feet (6100 mm) will generally be satisfactory. Transverse joints must be sawed and sealed.

d. Locate floor drains, cleanouts, conduits, and other floor discontinuities outside of the aisles and where appropriate to allow for access by maintenance personnel to perform routine maintenance.

e. Specify a concrete mix having a low water-cement ratio and low shrinkage characteristics. Achieve concrete workability through use of plasticizers in lieu of additional water.

f. During construction, pour concrete between rigid forms in lanes less than 20 feet (6100 mm) wide. Strike off concrete with a vibrating screed.

g. After initial floating, use a 10 foot (3050 mm) long transverse scraping straightedge (highway straightedge) to remove high spots.

h. Check the surface of the plastic concrete frequently with a 10 foot (3050 mm) long straightedge placed both parallel and transverse to the

centerline. Correct any high spots and fill any low spots using the highway straightedge.

i. Use of a boom operated laser leveling screed is greatly encouraged to achieve superflat floor tolerances.

3-7.4.2.2 Measurement

Refer to ACI 302.1R-04, *Guide for Concrete Floor and Slab Construction* for measurement requirements for class 9 superflat floors and the following requirements:

a. In specifying floor flatness for turret truck and order-picking truck operations, require a complete (100%) profile analysis of the wheel path portion of the concrete floor in the storage aisles and a statistical profile analysis of other portions of the concrete floor on which turret trucks and order-picking trucks will operate.

b. For measurement of floor flatness, require use of special floor flatness profile measurement equipment such as the "Profilograph" or an equivalent measuring equipment technique. Measurements must be taken at 20 ft. (6 m) intervals in each of two perpendicular directions.

c. Require in the specifications that the general contractor provide certification to be prepared by the measuring equipment operator. Certification states that the "wheel path" and other portions of the concrete floor to be used for turret truck and order-picking truck operations must completely meet maximum rated productivity floor flatness requirements of the Headquarters Office of the truck manufacturer(s). Floors which fail to meet the required tolerances will be corrected as directed by the Contracting Officer.

d. All noncritical floor slabs must be specified to be an ACI Class Bx floor. See ACI 302.1 R-04, *Guide for Concrete Floor and Slab Construction* for Class Bx criteria.

3-7.4.3 Wire Guide Requirements

When electronic wire guide vehicle controls are used, observe the following floor design criteria:

3-7.4.3.1 Conduits

Avoid installing conduits in the floor.

3-7.4.3.2 Reinforcing

Reinforcing steel must be located at least 2 inches (50 mm) below the concrete surface. Wire mesh must be tack-welded together wherever possible. Rebar and wire mesh must be grounded.

3-7.4.3.3 Expansion Joints

Where possible, expansion joints must not be located under storage racks. When expansion joints are located in the storage aisle, they must run parallel to the aisle and not be within 3 inches (75 mm) of the centerline of the storage aisle or within materials handling equipment wheel tracks. Expansion joint material used in hazardous materials storage areas must be compatible with the contents of the materials being stored.

3-7.4.4 Walls

All unfinished items must be painted.

Paint wall surfaces a light color(s) to reduce lighting demands.

3-7.4.5 Ceilings

Paint all structural steel, deck and other non-prefinished items.

3-7.5 Shops and Storage Rooms

3-7.5.1 Walls and Partitions

Walls must be painted concrete masonry units or concrete around shop spaces. Partitions separating shops may be impact resistant gypsum wall board on metal studs. For shops without ceilings, partitions must extend to structure above.

3-7.5.2 Floors

Floor finish must be an epoxy floor coating compliant with Master Painter's Institute - MPI 212, *Floor Coating, Thin Film, for Aircraft Maintenance Facilities* or sealed concrete.

3-7.5.3 Ceilings

Shops must not have suspended ceilings. All exposed piping, structure, deck, ductwork, etc. must be painted.

3-7.6 Administration and Office Spaces

3-7.6.1 Partitions

Partitions separating administration spaces from the warehouse space must be concrete masonry construction. Partitions separating administrative spaces may be gypsum board construction. Partitions are not required to extend to above the ceiling for similar office types and spaces where noise between offices is not an acoustical issue or required for personnel counseling. Paint all unfinished materials.

3-7.6.2 Floors

Floor finishes must be standard type finishes based on the expected usage of the spaces. Provide a wall base in all spaces.

3-7.6.3 Ceilings

Provide suspended acoustical ceilings in all administrative spaces.

3-7.7 Toilet and Locker Rooms

3-7.7.1 Partitions

Provide CMU partitions around toilet and locker rooms. Partitions around perimeter of space must extend to floor or roof construction above. Provide ceramic tile wainscot and ceramic base. Provide ceramic tile wall finishes to the ceiling on all walls in showers.

3-7.7.2 Floors

Floor finishes must be ceramic tile.

3-7.7.3 Ceilings

Ceilings in toilets must be gypsum wall board. Ceilings in locker rooms must be suspended acoustical ceilings with a water resistant membrane. Ceilings in showers must be water resistant gypsum board. Plaster is not allowed.

3-7.7.4 Lockers

Provide personnel lockers in dedicated locker rooms. The number of personnel lockers must be identified in the RFP. Lockers are provided for personnel to keep personal items or clothing during their work shift. Provide lockers with solid sides and louvered doors.

Lockers must be 9” x 21” x 72” (229mm x 533mm x 1829mm) high and must be single tier type. All lockers must be metal and must have capability to receive padlocks.

3-7.8 Corridors and Stairs

3-7.8.1 Partitions

Partitions in corridors and stairs must be painted masonry or painted gypsum board. Gypsum board must be impact resistant type to 8 feet (2.44 meters) above the floor or stair level. Corridor partitions and rooms without ceilings must extend to the deck above.

3-7.8.2 Floors

Floor finishes for these spaces must be as determined by the designer but minimum finish must be a resilient flooring system.

3-7.8.3 Ceilings

Corridors must have suspended acoustical ceilings, typical.

3-7.9 Support Spaces

Support spaces such as mechanical, pump rooms, and electrical rooms must be provided as required. These spaces must be as determined by the requirements of the project.

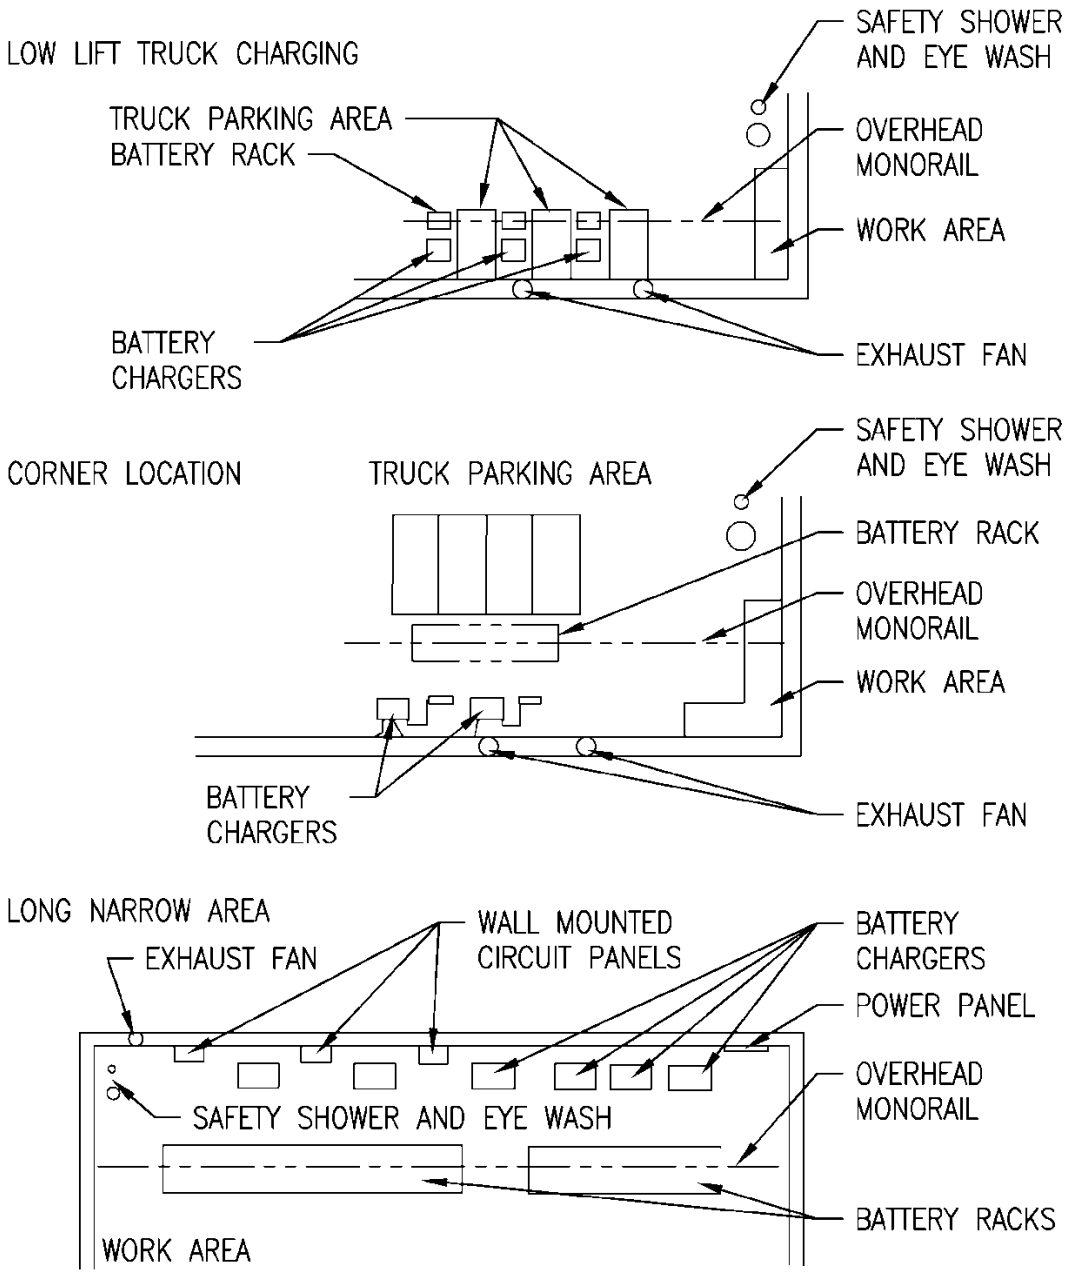
Partitions in corridors, around mechanical, electrical, and similar type spaces must be painted masonry. Corridor partitions and rooms without ceilings must extend to the deck above. All exposed piping, structure, deck, ductwork, etc. must be painted.

3-7.10 Battery Charging and Handling Operations

Provide an equipped and ventilated area for the charging of materials handling vehicle batteries. Figures 3-11, 3-12 and 3-13 illustrate typical battery charging layouts. Hydrogen detectors must be provided at Battery Charging Areas.

Figure 3-11 Battery Charging Area (Open Locations)

Plan Views



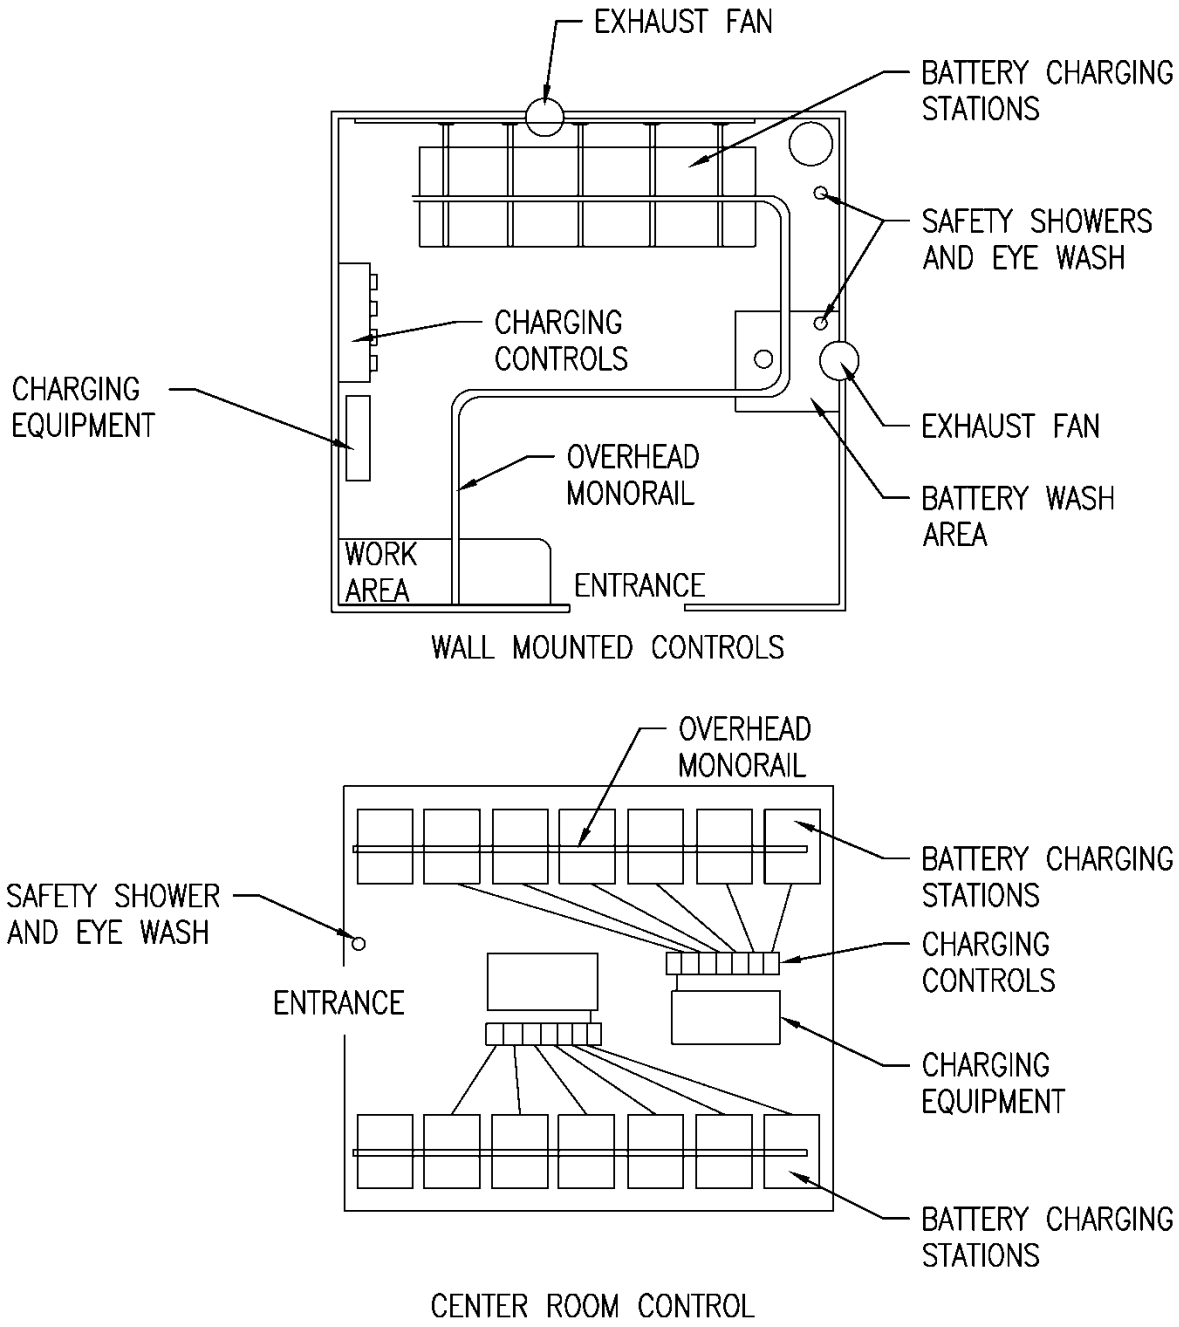


Figure 3-12 Battery Charging Area (One-Entrance Room)

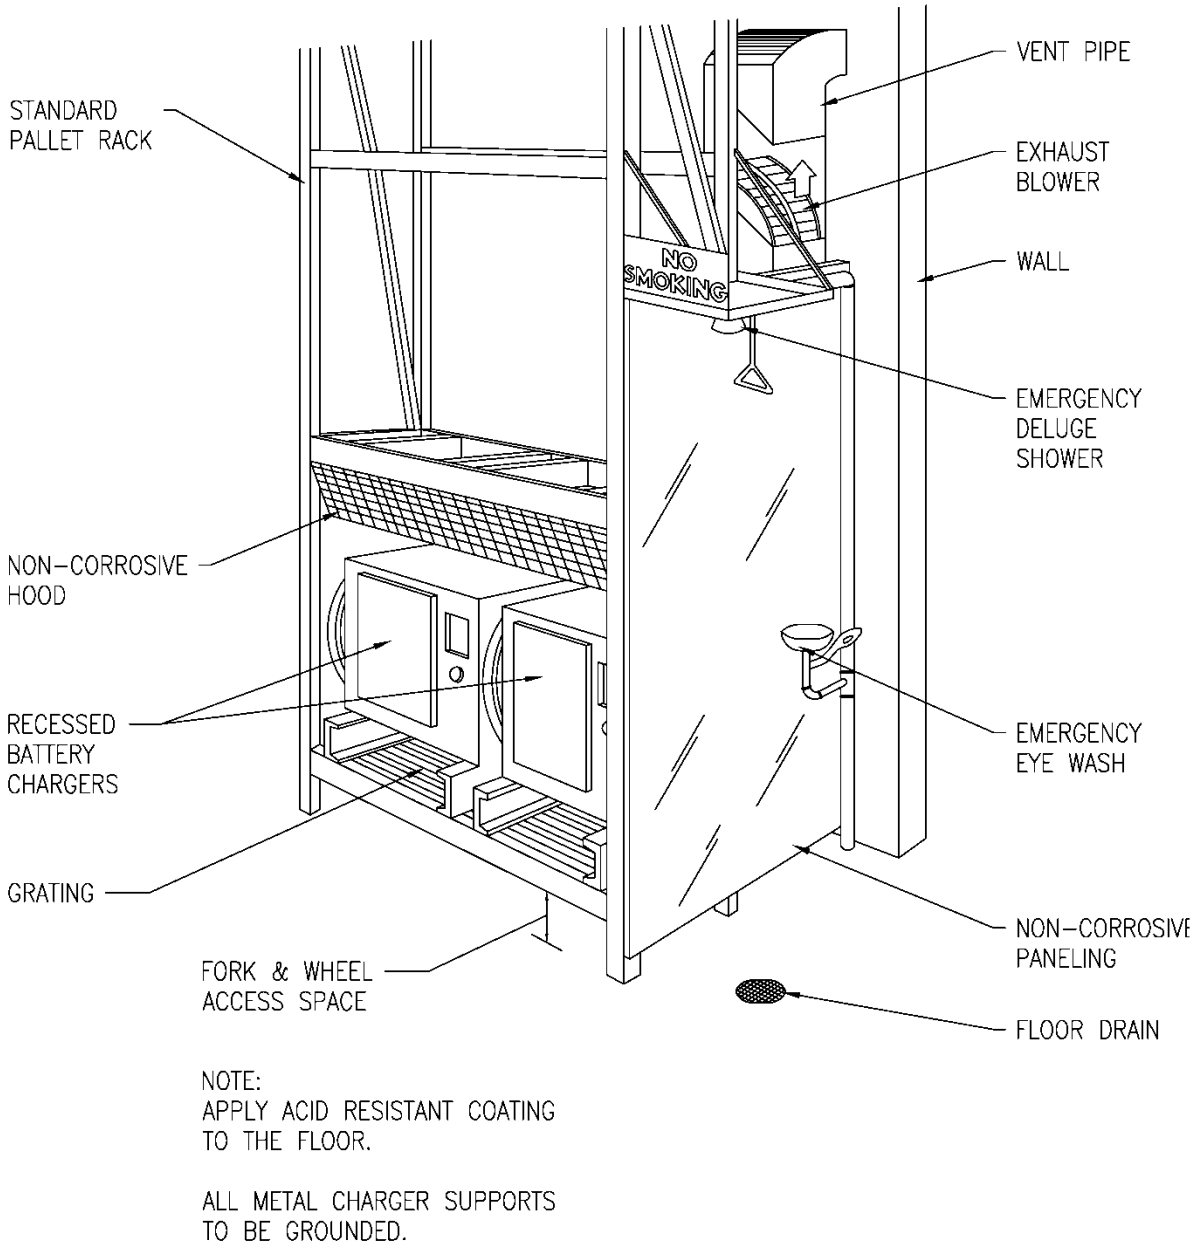
Plan Views

3-7.10.1 Containment Pit

Contact the local environmental office for regulations about handling contaminated water.

Provide a spill containment pit with a floor grate to capture water and contaminants from the safety shower/eyewash and accidental battery discharge. The pit must be equipped with a shut off valve to allow for proper neutralization of contaminated water before discharging. The pit must be large enough to hold the entire contents of the largest battery serviced in the area as well as all the water from a 15 minute shower.



3-7.10.2 Safety Showers / Spill Control

Provide facilities for the emergency drenching of the eyes and body, flushing and neutralizing spilled electrolyte, and protecting charging apparatus from damage (figure 3-13) in accordance with UFC 3-420-01, *Plumbing Systems*. Battery charging areas must be equipped with neutralizing chemicals. Floors must be treated with an acid resistant coating. Install permanent eyewash and shower facilities wherever permanent charging or servicing areas are constructed.

Figure 3-13 Typical Battery Charger Installation

(With Eye Wash/Shower using Standard Pallet Rack)

Perspective View

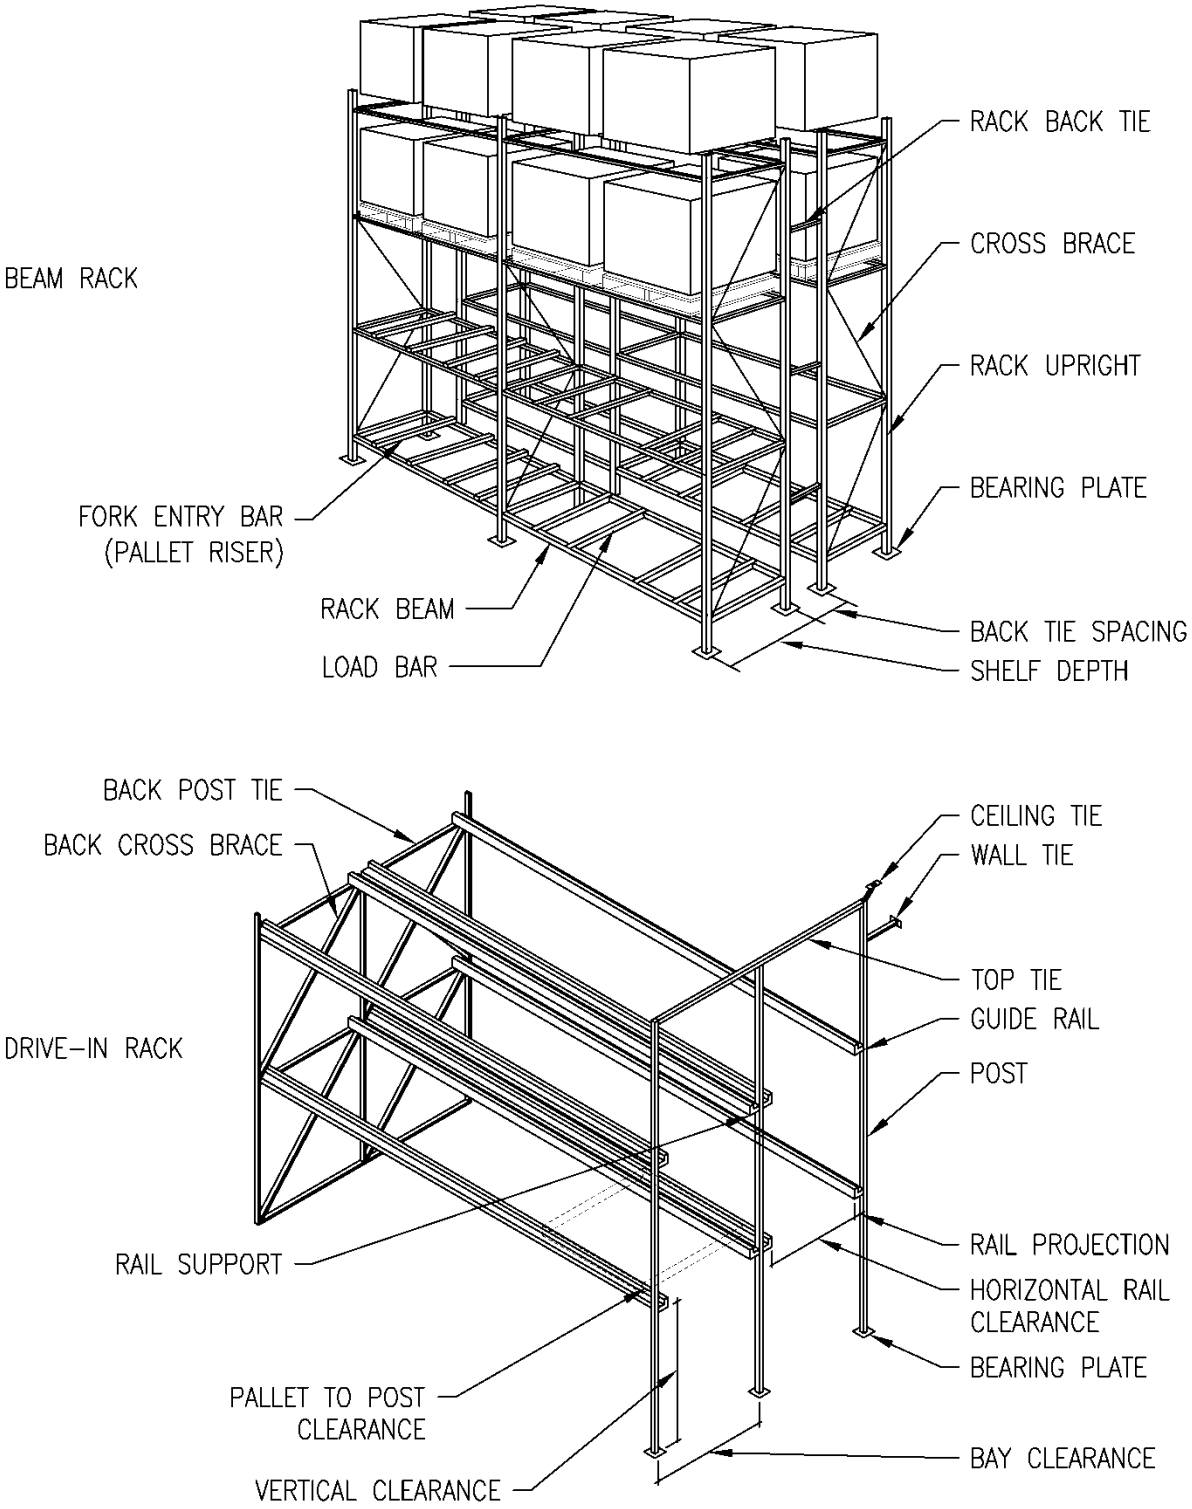
\1\Note: Refer to paragraph *Containment Pit* for spill containment requirement. /1/.

3-7.10.3 Battery Handling Equipment

Provide specialized battery handling equipment in battery charging and work areas. Equipment used must be selected based on the characteristics of the vehicle and battery being serviced, the activity of the charging station, and the maintenance work performed on the battery. Devices include handling beams, jib hoists, special charging stations, and battery transporters.

3-7.10.4 Ventilation

Provide ventilation in accordance with UFC 3-410-04N, *Industrial Ventilation*.

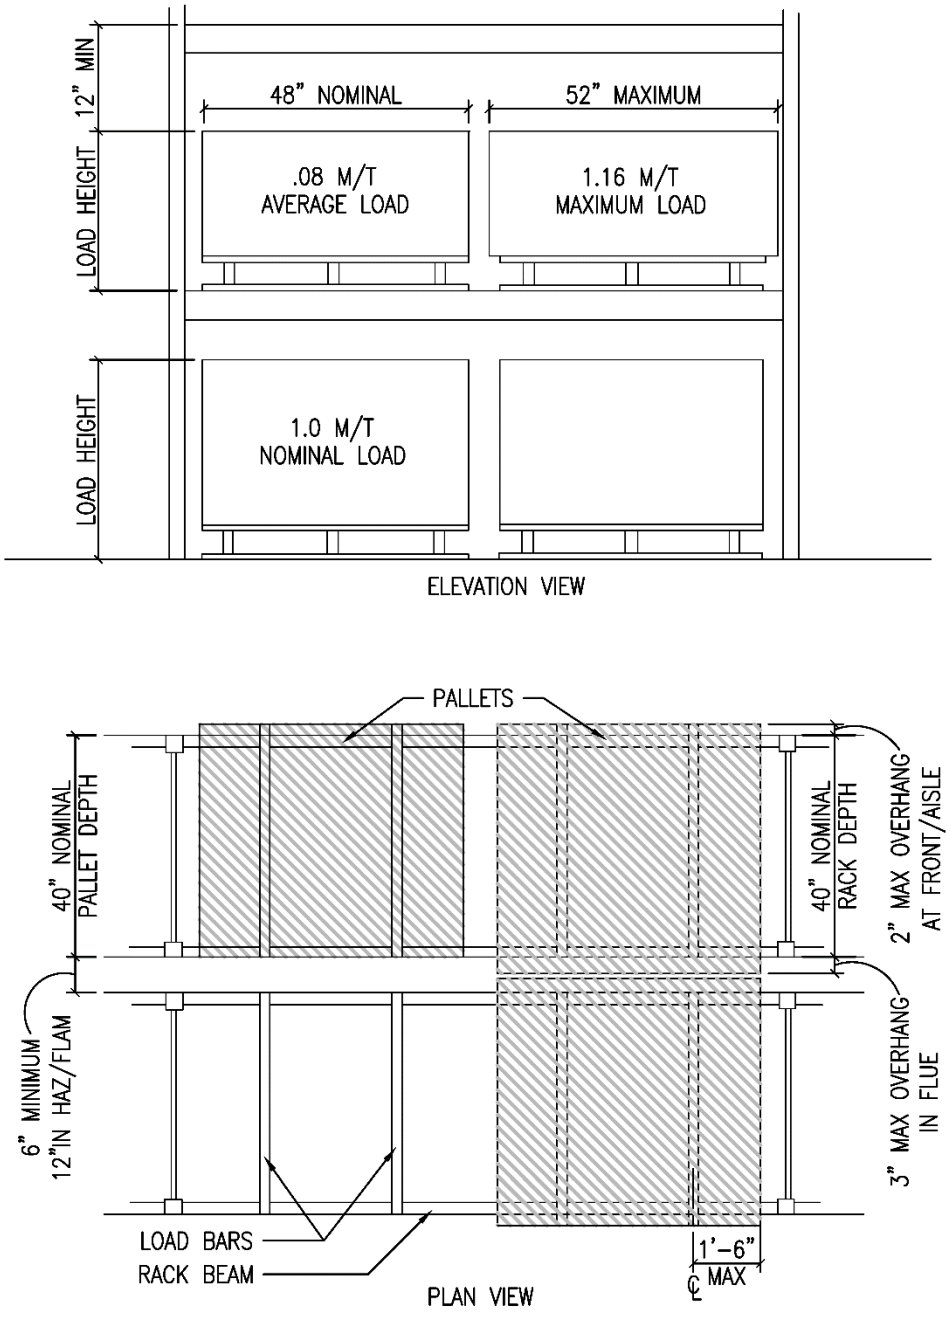


Provide natural and mechanical exhaust ventilation to ensure diffusion of the gases from the battery and to prevent the accumulation of an explosive mixture. Provide ventilation to limit hydrogen gas buildup to no more than 1 percent by volume in room air. If battery charging room air is air conditioned as part of a general building air conditioning system, exhaust air directly to the outdoors and do not return it to the air distribution system. Required air changes must be based on the expected activity in the charging room, but must be no less than six air changes per hour. Activity must consider the number of cells being charged at a given time and the charging current being used. Provide an air velocity rate across battery charging shelves of at least 125 feet per minute (0.64 meters per second). Interlock the ventilation system with the chargers to prevent charger operation unless the ventilation system is operating.

3-7.11 Pallet Racks

Selective pallet racks (see figure 3-14) consist of uprights, pallet beams, bracing, and miscellaneous accessories. Minimum design load must be 3,000 pounds (1360 kg) per pallet.

Figure 3-14 Pallet Rack Terminology



Perspective Views

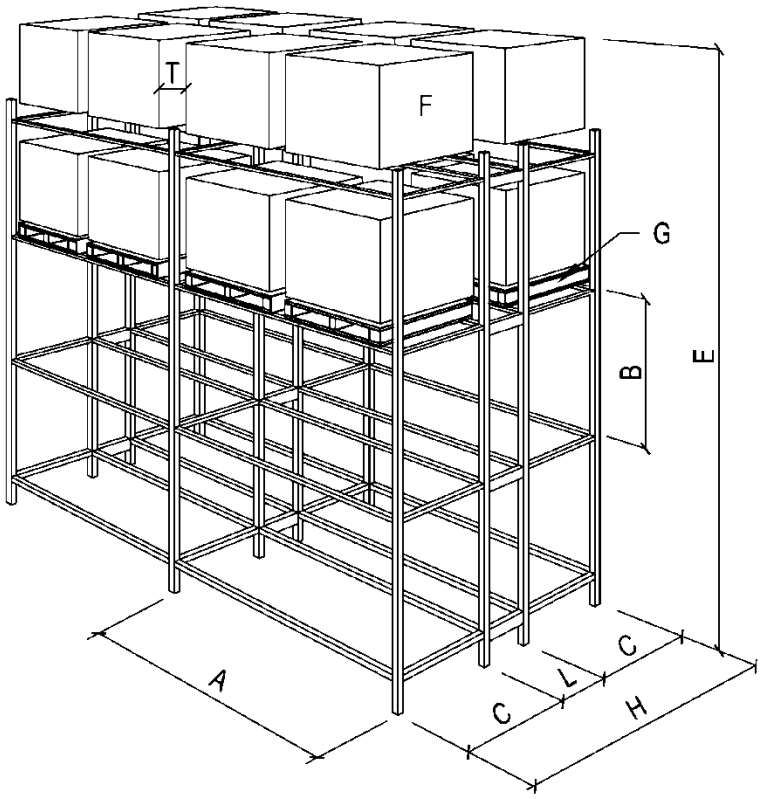
3-7.11.1 Dimensions

Pallet racks must have a 40-inch (1020 mm) depth and accommodate standard 40- x 48-inch (1020 mm x 1220 mm) pallets without front or rear pallet overhang (see figure 3-15). Use of other sizes of pallet racks or pallets must be documented and justified. Beam to beam vertical spacing averages 48 inches (1220 mm) (see figure 2-2).

Figure 3-15 DoD Pallet Arrangement

3-7.11.2 Stability

Rack stability is influenced by loading conditions, attachment, and rack assembly. Racks exceeding a 6:1 height to depth ratio must be securely anchored or braced externally. For standard racks, this applies to racks exceeding 20 feet (6096 mm) in height.



3-7.11.3 Flue Space

Flue space must comply with National Fire Protection Association (NFPA).

- Fire protection requirements dictate a minimum longitudinal flue space (figure 3-16) of 6 inches (150 mm).
- Flues must be 12 inches (300 mm) deep in refrigerated areas.
- In hazardous materials storage areas, provide 12-inch (300 mm) flues between back-to-back racks. Flues of 8-12 inches (200-300 mm) must be provided between backs of racks and walls.
- Standard pallet racks provide a minimum 4-inch (100 mm) transverse flue space.

Figure 3-16 Pallet Rack Fire Protection Terminology

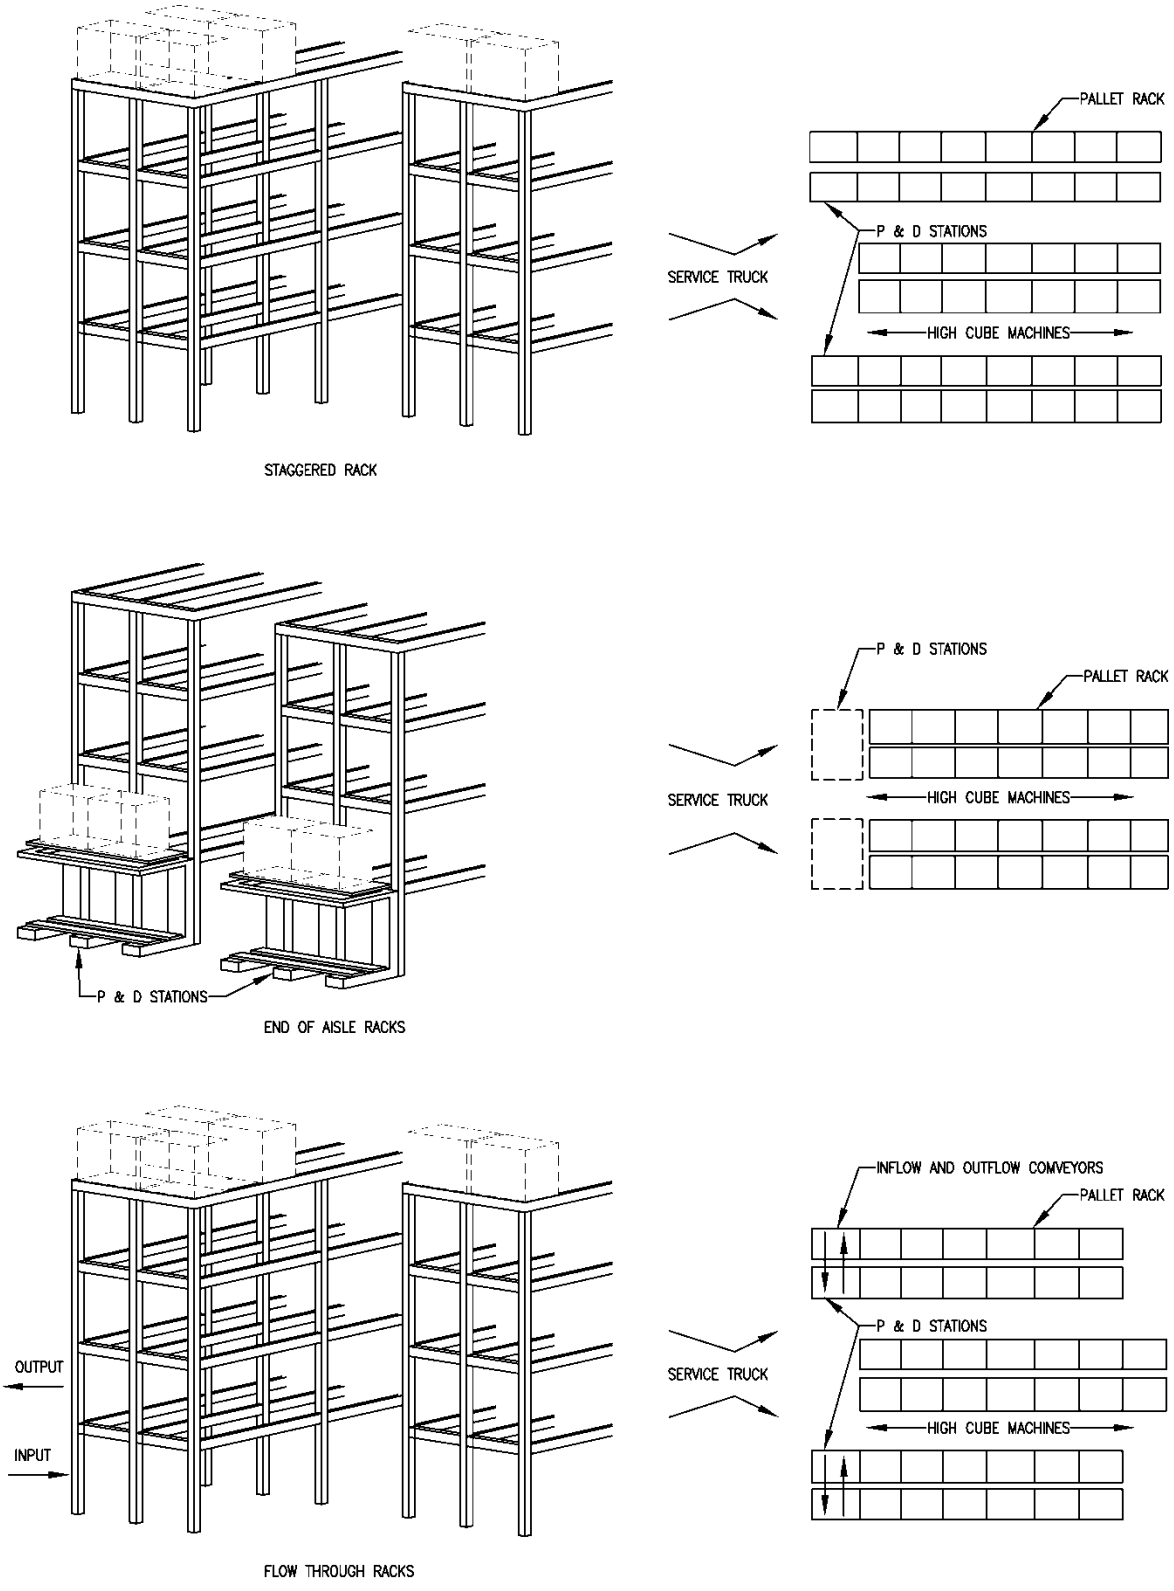
G – PALLET
H – RACK DEPTH

3-7.11.4 Attachment



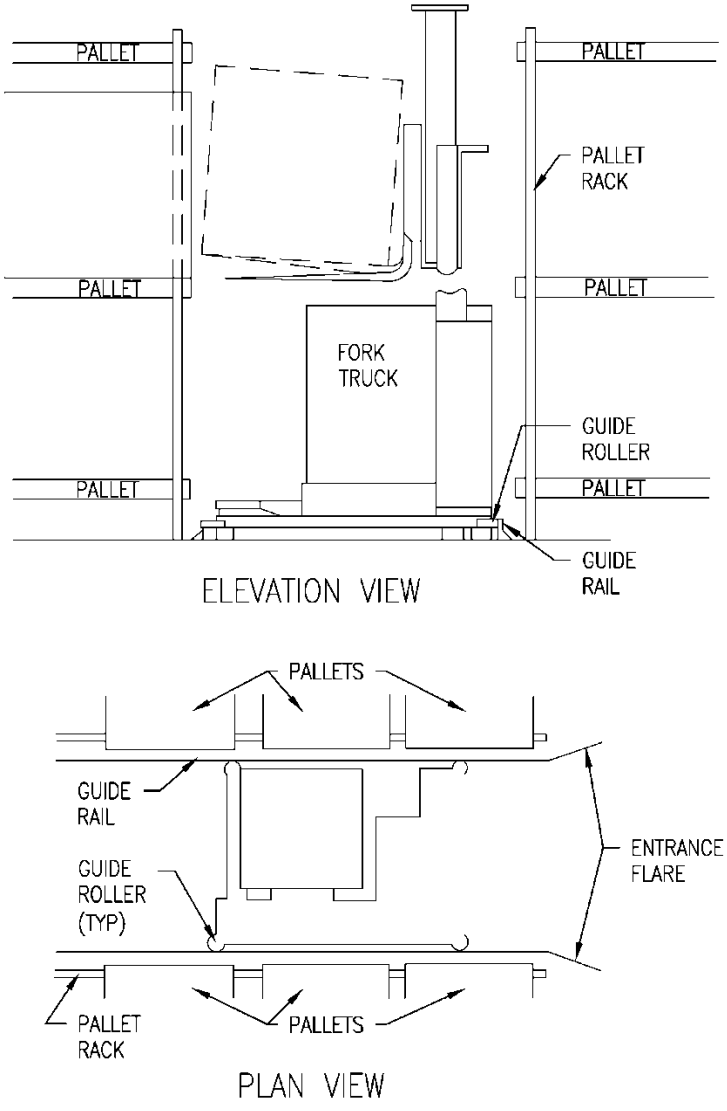
Securely attach all pallet racks to floors, walls, and each other, to ensure stability and safety.

3-7.11.5 System Interface

Interface operations with pallet rack using pickup and delivery (P&D) stations, as illustrated in figure 3-17. Provide additional cross-aisle width to accommodate these P&D stations.

Figure 3-17 Pickup and Delivery (P&D) Stations

Perspective Views and Plan Views



3-7.12 Aisle Dimensions

Coordinate aisle dimensions with specific equipment requirements. Observe the following:

3-7.12.1 Rail Guidance

Coordinate rail locations with pallet rack and vehicle characteristics (see figure 3-18). Provide sufficient cross aisle width to accommodate the entrance flare.

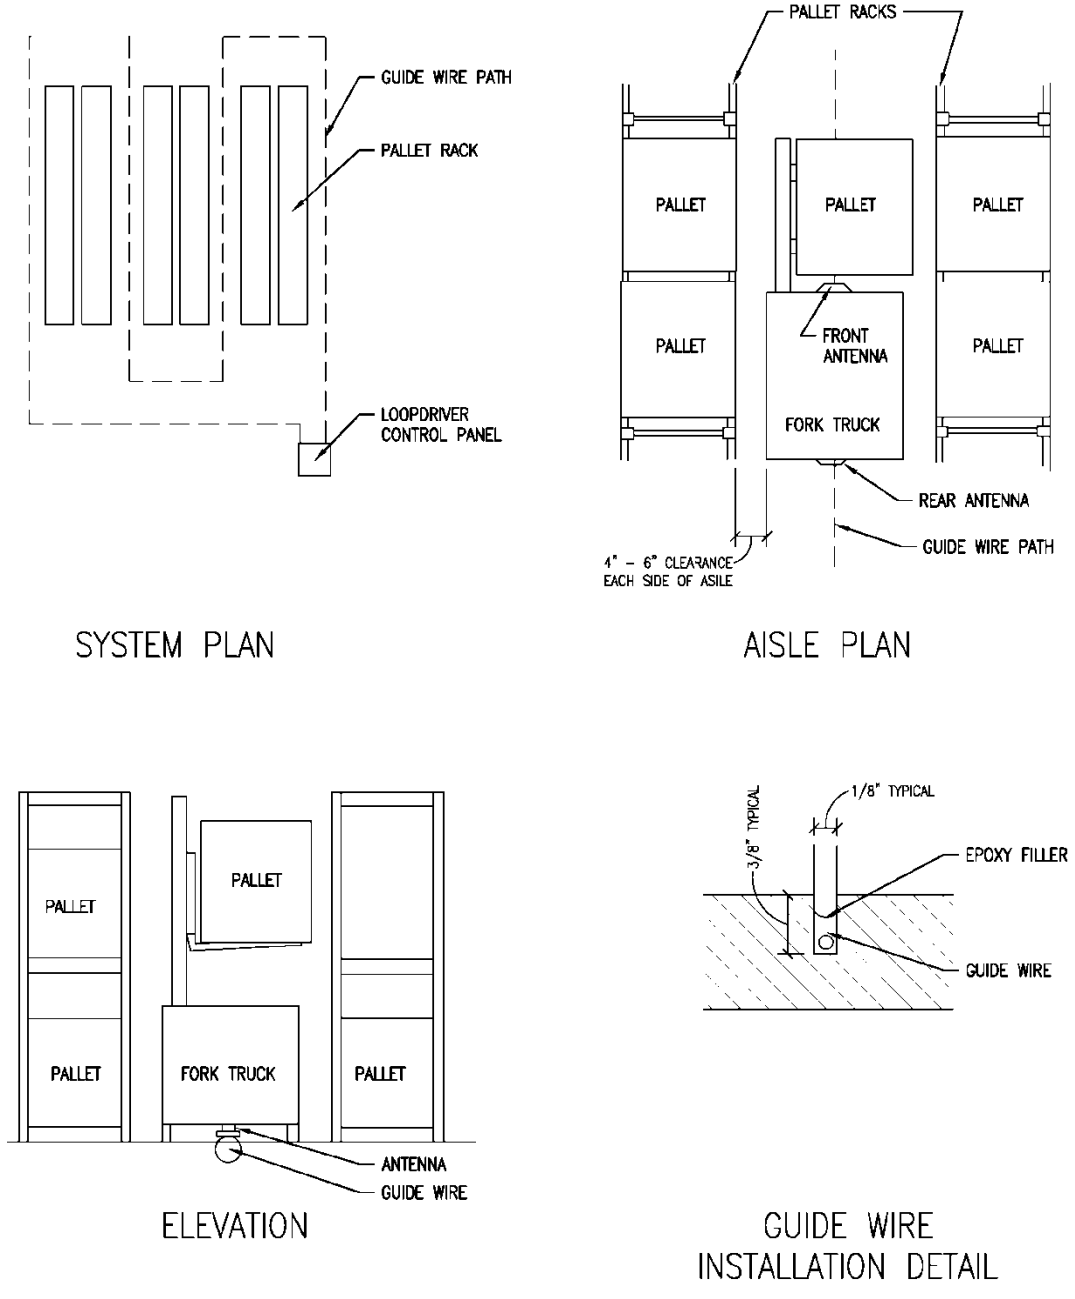


Figure 3-18 Typical Rail Guidance System

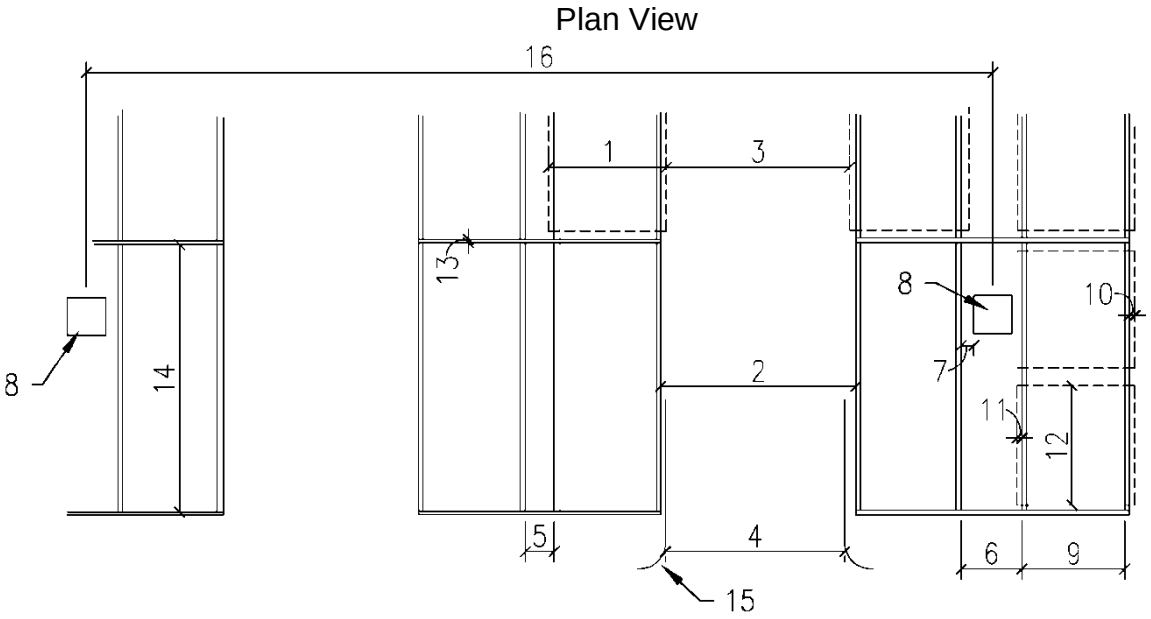
3-7.12.2 Wire Guidance

Coordinate guide wire locations with pallet rack and vehicle characteristics (see figure 3-19). Review guide wire location plan to provide a continuous loop and avoid crossovers. Install loop driver and control panel in a protected location.

Figure 3-19 Typical Wire Guidance System

3-7.12.3 Transport Aisles

Width of transport aisles must be at least twice the vehicle width plus 18 inches (145 mm) to permit two-way traffic.



3-7.12.4 Fire Protection

Aisle width will affect sprinkler requirements and water demand.

3-7.13 Building Bay Dimensions

Modular building dimensions must be developed considering the relationship between column spacing, rack dimensions, aisle patterns, machinery and operations. Apply a 33 ft. x 64 ft. (10,060 mm x 19,510 mm) bay size when warehouse construction must be planned without knowledge of specific warehousing systems to be installed within new facilities. The universal bay size will not represent the optimum column spacing for every system. Figure 3-20 illustrates column spacing parameters which affect bay dimensions. For large facilities designed for a specific system, greater utilization of building area will be obtained by selecting a column spacing matching the requirements of the material handling system.

Figure 3-20 Building Column Spacing Parameters

15. GUIDE RAIL ENTRY
16. BUILDING COLUMN SPACING

3-7.13.1 Universal Bay Size

If a general purpose facility is required, or a specific materials handling system has not been selected, maintain versatility in selecting the universal pattern subject to the following considerations:

a. The universal pattern will not represent the optimum spacing for all systems.

b. The facility may be costlier than necessary because of the inefficient use of space. A smaller building can generally be constructed if the optimum column spacing is used.

c. Use of the universal pattern will permit the building to fulfill a variety of missions due to its ability to function with many materials handling systems.

3-7.13.2 Optimum Bay Size

Use of the optimum bay size for a particular materials handling system will provide the most efficient use of the building area. In addition:

a. Use of the optimum bay size will reduce the size of the required building due to more efficient use of the building cube.

b. Ultimate versatility of the facility will be reduced because the column pattern will not fit every system.

3-7.13.3 Comparison of Bay Sizes

The information presented in table 3-5 provides comparison information to enable a designer to measure the effects of changes to the building bay size. Use of the universal bay size results in an average 7 percent increase in required building area.

Table 3-5 Building Bay Size Comparison

SYSTEM	OPTIMUM BAY SIZE ft-in x ft-in (mm x mm)	MODULAR EQUIVALENT BAY SIZE ft-in x ft-in (mm x mm)	BAY DIMENSION FOR FIT ft-in (mm)	SPACE UTILIZATION IN UNIVERSAL BAY %
Counterbalance Truck	39’-2” x 39’-2” (11,940 x 11,940)	39’-2” x 58’-4” (11,940 x 17,780)	64’-0” (19,510)	91.1%

Mini-S/R Machine	26’-0” x 51’-0” (7,920 x 15,540)	26’-0” x 63’-6” (7,920 x 19,350) 26’-0” x 63’-6” (7,920 x 19,350)	33’-0” (10,060) 64’-0” (19,510)	78.8% 99.2%

3-7.13.4 Clear Storage Height

For clearance requirements between top of storage load and any overhead obstructions and sprinklers refer to NFPA 13. Refer to DOD 4140.1-R, *DoD Supply Chain Material Management Regulation* for details.

Consider the following:

- Clearance from sprinkler deflectors to the top of storage load will affect sprinkler requirements and water demand.

- Clear building height requirements for specific levels of storage, as well as three modular clear heights covering a range of storage levels, are summarized in table 3-6. Construction of a warehouse facility to a modular height greater than that required for the desired system or level of storage will result in an unutilized cube and extra construction and operating costs.

Table 3-6 Required Clear Building Heights

SYSTEM	PALLET STORAGE LEVELS								
	2	3	4	5	6	7	8	9	10
Counterbalance truck	8'-6" (2,590 mm)	12'-6" (3,810 mm)	18'-0" (5,490 mm)	22'-0" (6,700 mm)	-- --	-- --	-- --	-- --	-- --

Carousel	10'-0" (3050 mm)	-- --	-- --	20'-0" (6100 mm)	29'-0" (8,840 mm)	-- --	-- --	-- --	-- --
Mini-S/R Machine	-- --	-- --	-- --	-- --	24'-5" (7,440 mm)	-- --	-- --	34'-6" (10,510 mm)	44'-7" (13,590 mm)
Modular Building Clear Height	19'-0" (5,790 mm)			31'-0" (9,450 mm)			47'-0" (14,330 mm)		
Height Use Efficiency	47% - 105%			65% - 100%			73% - 95%		

Notes:

- Hybrid Truck Storage above 10 levels is not listed.
- Clear height includes sprinkler clearances per NFPA 13. Clear height does not include clearance allowance for draft curtains.
- Pallet storage levels based on a standard 48 in (1220 mm) vertical spacing.
- Height use efficiency is ratio of required clear building height to modular building clear height.

(1) 20 ft (6,096 mm) high system.
(2) 30 ft (9,144 mm) high system.
(3) 40 ft (12,192 mm) high system.

3-7.14 Telecommunication Systems

Provide telephones, service entrances, telephone cabinets, conduit runs, and telephone outlets. Locate at least one telephone in each office. Provide in accordance with UFC 3-580-01 *Telecommunications Building Cabling Systems Planning and Design*.

3-7.14.1 Navy and Marine Corps

For Navy and Marine Corps projects use UFC 3-580-10 *Navy and Marine Corps Intranet (NMCI) Standard Construction Practices* where NMCI is a requirement.

3-7.14.2 Army

For Army projects, building telecommunications must be designed to satisfy Army Installation Information Infrastructure Architecture (I3A) Policy.

3-7.15 Alarm Systems

Provide fire, hydrogen, ventilation failure, hazardous chemical spill, neutralizer tank and security alarms.

3-7.15.1 Fire Alarms

Provide storage facilities with fire alarm system that transmits a signal to the fire department, in accordance with UFC 3-600-01, *Fire Protection Engineering for Facilities*.

3-7.15.2 Hazardous Chemical Spill Alarms

Provide hazardous chemical storage areas with alarms signaling release or spillage of stored chemicals.

3-7.15.3 Security Alarms

Protect stored materials with Electronic Security Systems (ESS) when required by Agency policies and as defined by the DoD Security Programs Guidance.

3-7.16 Casework

Counters, casework, and cabinets must be of high-quality and durable construction. Specify Architectural Woodwork Institute (AWI) Premium or Custom for finishes per AWI Quality Standards Illustrated. Casework, cabinet doors, and drawer faces must be provided as veneer panel core. Doors, drawers, and casework faces must be plastic laminate at a minimum. Countertops are to be solid surface/solid composite plastics only. Specify .75-in. (20-mm) minimum thickness for plywood, plywood backing, and solid wood panels.

3-7.17 Elevators and Lifts

Elevators may be needed if required for ADA/ABA compliance or the activity specifically requests an elevator. See the section on Accessibility for further clarification.

Size elevator based on activity requirements. If elevators are required at least one elevator must accommodate a 24 in. wide x 84 in. long (610 mm x 2,134 mm) emergency stretcher.

3-7.18 Furniture Considerations

Coordinate with the Comprehensive Interior Design package during the design process. All case goods and hardware will be coordinated with the Structural Interior Design package for the project to ensure matching woods, stains, and finishes as best possible. Selection of materials and finishes for the main entry point area(s) will accommodate heavy use.

3-7.19 Equipment Considerations

Coordinate the use and location of recycling centers throughout the common areas to complement the interior design while supporting sustainability guidance.

All appliance colors must be coordinated with the FF&E. The construction contractor or design/build contractor will submit cut/datasheets of proposed equivalents/substitutions appliances for review/approval. Purchase appliances meeting Energy Star program standards and specifications as included in this guide. Qualifying products are listed on the Energy Star website.

3-8 PEST CONTROL

Incorporate pest control measures into building design to ensure the efficient control and quarantine of insects, rodents, and other pests. Refer to Armed Forces Pest Management Board Technical Guide No. 17, *Military Handbook – Design of Pest Management Facilities*. Measures must include:

a. Establishment of construction needs and maintenance criteria for prevention of pests.

b. Land drainage; clearing and control of vegetation in outside storage and pest breeding areas.

c. Application of pesticides on materials, in buildings, on the ground, and as soil treatment.

d. Use of wood preservatives

3-9 ACCESSIBILITY FOR THE DISABLED

Every facility must be designed to ensure access in accordance with UFC 1-200-01, *General Building Requirements*.

3-10 ACOUSTICS

Design the facility to provide a comfortable acoustical environment and provide comprehensive sound isolation and sound absorption measures for individual spaces as appropriate. Provide acoustical design to prevent sound from noisy spaces such as corridors, toilets, elevator machine rooms, and mechanical rooms from having negative impact on the adjacent spaces.

Use the "suggested design values" STC ratings in UFC 3-450-01, *Noise and Vibration Control*, as the basis for the sound design of partition, door and window assemblies for the facility. Utilize gypsum board wall "improvements" to increase the STC of gypsum board "stud type" partitions to achieve the project sound requirements. Unless noted otherwise extend partitions and seal to the structure above around rooms that have a noise source such as but not limited to corridors, toilets, elevator machine rooms, training rooms, maintenance rooms, activity rooms, and mechanical rooms. Unless indicated in chapter 4, STC ratings do not need to be field verified. Do not provide any special acoustical conditions in the project unless specifically recommended by an acoustical study.

3-11 CONVEYING SYSTEMS

Conveying systems may not be required. For projects which require conveying systems, provide them in accordance with the following:

3-11.1 Overhead Bridge Cranes

Verify the crane capacity with the governing authority, but provide no less than a 5 ton (4.5 metric ton) overhead bridge crane. All cranes must be Duty Service Class C. All bridge cranes must be supported from patented track systems designed by the crane manufacturer. All overhead bridge cranes must be under running, double girder electric cranes.

Provide all cranes in accordance with Air Force Instruction 91-203, Air Force Consolidated Occupational Safety Instruction; Navy Crane Center Instruction 11450.2, *Design of Navy Shore Weight Handling Equipment*; title 29 CFR 1910.179(j), *Inspections;* title 29 CFR 1910.179(k), *Testing*; and the American National Standards Institute ANSI MH27.1, *Specifications for Patented Track Underhung Cranes and Monorail Systems*; and relevant portions of the Crane Manufacturing Association of America CMAA Specification 70, *Top Running Bridge and Gantry Type Multiple Girder Electric Overhead Traveling Cranes*, and the Crane Manufacturing Association of America CMAA Specification 74, *Top Running and Under Running Single Girder Electric Overhead Cranes Utilizing Under Running Trolley Hoist*.

3-11.1.1 Hook Height

Hook height is to the saddle of the hook and must be determined by the overall height of the facility. Hook height for any facility must be no less than 20 feet (6.10 m).

3-11.1.2 Hook Coverage

The bridge crane must provide loaded hook coverage to within 12 feet (3.66 m) of the inside face of all walls and to within 15 feet (4.57 m) of the inside face of the warehouse dock doors. Where multiple cranes are provided, fully loaded hooks must be capable of locating within 15 feet (4.57 m) of each other.

3-11.1.3 Travel Speeds

Overhead bridge cranes must have electric motorized bridge, trolley and hoist. One crane must be used per warehouse module, with the bridge designed to travel the full width of the module. Trolley and bridge must be capable of operating at a slow speed of 15 to 20 ft/min (0.07 to 0.1 m/s) for positioning loads and at a high speed for moving loads of 60 ft/min (0.3 m/s); the hoist must be capable of operating at a slow speed of 3 to 4 ft/min (0.01 to 0.02 m/s) and at a high speed of 12 ft/min (0.06 m/s). Refer to UFGS 41 22 13.13 *Bridge Cranes* and UFGS 41 22 13.15 *Bridge Cranes, Overhead Electric, Under Running*.

3-12 MOTOR AND CONTROLS

Bridge, trolley and hoist controls must provide for two-speed reversing of a two-speed, squirrel-cage motor. The controls must be equipped with reduced voltage starting for the motors. Controls must be operable from the floor.

Provide service catwalks or platforms to maintain overhead bridge cranes. Ensure all safety requirements are met; see UFGS 01 35 26, *Governmental Safety Requirements*. The access must be from inside the warehouse.

3-13 PLUMBING

3-13.1 General

Provide plumbing in accordance with UFC 1-200-01, *General Building Requirements* and UFC 3-420-01, *Plumbing Systems.*

3-13.1.1 Emergency Shower / Eyewash Fixtures and Floor Drains

Provide emergency eyewash/shower fixtures and drainage system as required by this UFC and in accordance with UFC 3-420-01, *Plumbing Systems*.

3-13.2 Compressed Air

Provide compressed air where required by the governing authority.

3-14 ENVIRONMENTAL CONTROL

Provide heating in all offices in all heating zones. Provide air conditioning in offices. Determine requirements for environmental control in storage space based on the temperature requirements of material stored and the extent and activity level of occupancy. Need for heating of storage spaces must be clearly demonstrated. Warehouses for storage of materials not subject to freezing must not be heated. In warehouses containing materials subject to freezing, design heating system to maintain an inside winter temperature of 45°F (7°C). Maintain a temperature of 55°F (13°C) in warehouse areas with active employment. Refer to UFC 3-410-01, *Heating, Ventilating, and Air Conditioning Systems*.

The designer must consider a minimum of three HVAC systems that meet all the criteria and perform a life cycle cost analysis for the basis of selection. Refer to UFC 1-200-02, *High Performance and Sustainable Building Requirements* and UFC 3-410-01, *Heating, Ventilating, and Air Conditioning Systems*.

3-14.1 General

Provide HVAC in accordance with UFC 1-200-01, *General Building Requirements* and Unified Facilities Criteria series 3-400, *Mechanical*.

3-14.2 Heating

Provide heating in accordance with UFC 3-410-01, *Heating, Ventilating, and Air Conditioning Systems* and as follows:

- The heating system must be a steam, hot water, gas fired hot air, or solar system. Provide unit heaters or hot air registers at cargo doors and over aisles between stored materials.

- Direct-fired hot air systems must not be used for hazardous materials warehouses.

- Selection of unit heaters, spot heating systems, and design of total heating systems, must be considered on energy and life-cycle cost basis.

3-14.2.1 Heating Plant

The heating plant must be located in a mechanical room with no access to the storage area. When the mechanical room is located inside the warehouse, the following must be observed:

a. Provide a wall with a 2-hour fire resistance rating between the heater room and storage area.

b. All access to the heating area must be from the outside only.

c. When infrared unit heaters are used, provide safe clearances in accordance with the manufacturer's safety instructions.

3-14.2.2 Infiltration Rate

Design for an infiltration rate of two air changes per hour in the warehouse area. This rate is dependent upon the installation of dock door seals.

3-14.2.3 Radiant Floor Heating System

Investigate the use of an under floor heating system for the warehouse storage areas.

Under floor heating systems must be 2 in. minimum and 3 in. maximum (50.8 mm and 76.2 mm) from the bottom of the floor slab. Depth of under floor heating system and slab thickness must be coordinated with the rack / shelving fastener depth to avoid conflict and damage to the heating system.

3-14.2.4 Cold Jet Destratifiers

Consider the installation of cold jet destratifiers based on an economic analysis.

3-14.2.5 High Volume Low-Speed Fans

Consider the installation of high volume low-speed (HVLS) fans based on an economic analysis.

3-14.2.6 Space Thermometer

A switch activated by opening the dock doors must override the space thermostat to stop the heating equipment in the warehouse area. Provide a minimum temperature thermostat field set at 34°F (1°C) to override the heating deactivation switch during door-open periods of subfreezing ambient temperatures. After the doors are closed, the room thermostat must assume control. Heating system recovery time must be a maximum of 60 minutes after the doors are closed.

3-14.2.7 Automatic Thermostatic Control

The automatic thermostatic control must meet the requirements of UFC 3-410-01, *Heating, Ventilating, and Air Conditioning Systems*.

3-14.2.8 Heating Zones

Provide heating zones to maximize energy savings and to meet sustainability requirements.

3-14.3 Ventilation

Provide ventilation in accordance with UFC 3-410-01, *Heating, Ventilating, and Air Conditioning Systems*, and UFC 3-410-04N, *Industrial Ventilation*.

Toxic fumes generated by gas powered fork trucks must be exhausted. It is recommended that gas powered fork trucks not operate inside the warehouse area.

3-14.4 Humidity Control

Provide humidity control in accordance with UFC 3-410-01, *Heating, Ventilating, and Air Conditioning Systems*, and UFC 3-410-04N, *Industrial Ventilation*.

3-14.5 Air Conditioning

Provide air conditioning in accordance with UFC 3-410-01, *Heating, Ventilating, and Air Conditioning Systems*.

Office areas in cooling zones must be air-conditioned by either high efficiency small area units or a central system, as appropriate. Consider radiant floor cooling systems for air conditioned storage areas.

3-14.6 Energy Conservation

Provide energy conservation measures to meet the project sustainability requirements. Refer to UFC 1-200-02, *High Performance and Sustainable Building Requirements*.

3-14.7 Insulation

Warehousing facilities that require heating or cooling must be insulated. Determine the amount and type of insulation by a life-cycle cost analysis.

3-14.8 Mechanical Equipment Requirements

3-14.8.1 Corrosion Protection

Provide special finish coatings on the interior and the exterior surfaces of HVAC equipment exposed to the weather, including all coil surfaces and interior equipment surfaces belonging to the first HVAC equipment (excluding louvers) in the supply ductwork system that is subjected to outside supply air. The coating must not act as an insulating barrier to the HVAC heat exchange capability. Unit casing – standard factory paint is not acceptable. Specify appropriate protection requirements, salt test hours of at least 3,000 hours. Coils must be copper tube/copper fin with a phenolic type coating applied by immersion. Spray-on coatings are not allowed.

Equipment located inside that handles outside air:

- Evaluate the outside air percentage; copper tube/copper fin or copper tube/aluminum fin with phenolic coating is suitable for low outside air percentages.
- Evaluate cooling and heating capacity reductions resulting from phenolic coating application whose thickness is typically three mils thick.

- Consider using copper tube / copper fin with phenolic type coating for 100 percent outside air units.

3-14.9 Noise and Vibration Control

Design mechanical systems and equipment to limit noise and vibration in accordance with UFC 3-450-01, *Noise and Vibration Control*.

3-15 FIRE PROTECTION

Provisions for fire protection and life safety will conform to National Fire Protection Association (NFPA) *Life Safety Code* NFPA 101, UFC 1-200-01, *General Building Requirements* and UFC 3-600-01, *Fire Protection Engineering for Facilities*.

3-15.1 Fire Protection Sprinkler Systems

For new construction and rehabilitation projects, install sprinkler systems in accordance with National Fire Protection Association (NFPA) *Standard for the Installation of Sprinkler Systems* NFPA 13 and UFC 3-600-01, *Fire Protection Engineering for Facilities*.

The following must be considered:

a. Coordinate location of ceiling mounted fixtures including destratification units with the placement of sprinklers.

b. The type of sprinkler protection provided and the water supply requirements can vary based on the following:

- Clearance from the sprinkler deflector to the top of storage
- Aisle width
- Storage height
- Storage configuration
- Type of storage (commodity)
- If the commodity is encapsulated or nonencapsulated

c. It is recommended to provide sprinkler protection that does not require in-rack sprinklers. Control Mode Specific Application (CMSA) and Early Suppression Fast-Response (ESFR) sprinklers can be used. Warehouses with a roof height greater than 15 feet must be protected with the customer defined storage arrangement (i.e., high pile, rack storage, etc.) to the maximum storage height allowable. For example, the sprinkler system for a warehouse using pile storage with a 25 ft roof

height will be designed to a maximum storage height of 22 ft regardless of the defined storage height.

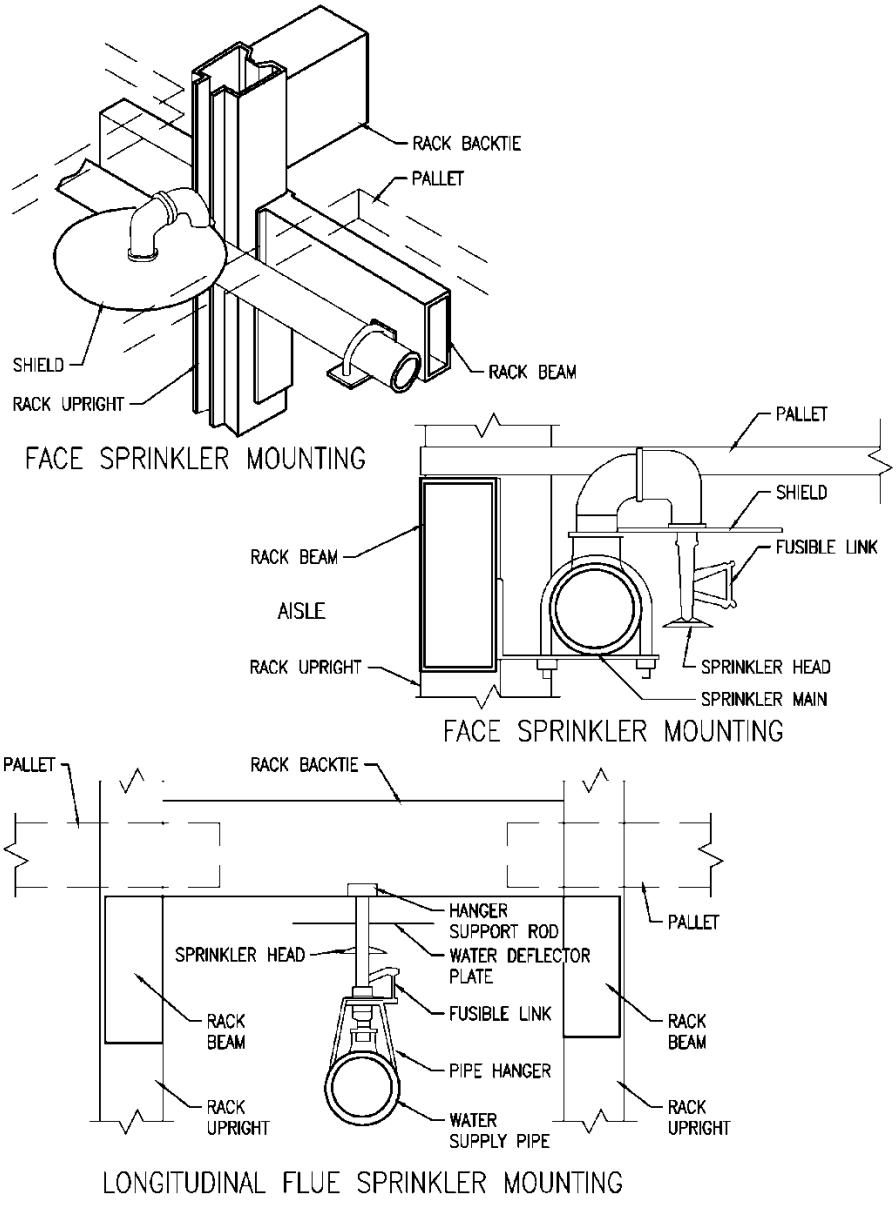
3-15.1.2 Storage System Sprinklers

In general purpose, controlled humidity, refrigerated and other type warehouses where hazardous materials are not to be stored, provide \1\ /1/ face and flue sprinklers per NFPA 13. Rack shelving must not be adjustable on rack levels where \1\ /1/ face and flue sprinklers are provided. Additional flue sprinklers may be required depending upon storage height and its relationship to the\1\ /1/ sprinklers. Face and flue sprinklers must be placed at or below each 108-inch (2745 mm) open frame shelf at the required levels in a manner which prevents sprinkler damage during storage operations, as illustrated in figure 3-21. The sprinklers at all other shelf levels must be capable of vertical adjustment using mechanically grooved fittings.

3-15.1.3 In-Rack Sprinkler System

In-rack sprinklers must be provided in accordance with NFPA 13.

3-15.2 Fire Alarm Systems



Install addressable building fire alarms systems that are compatible with the base system and connect to the base reporting system.

3-15.3 Smoke Detectors

Install smoke detectors in accordance with UFC 3-600-01, *Fire Protection Engineering for Facilities* and NFPA 72, *National Fire Alarm and Signaling Code*.

Figure 3-21 Standard Face and Longitudinal Flue Sprinkler Mounting

(to Prevent Pallet and Load Interference)
Detail and Sections

3-16 ELECTRICAL

Provide site electrical utilities, interior distribution systems, communications and security, and site lighting according to UFC 1-200-01, *General Building Requirements,* UFC 3-501-01, *Electrical Engineering* and the latest installation design requirements.

a. Site Electrical Utilities includes equipment, overhead power distribution, underground electrical systems, grounding, metering, exterior site lighting, and cathodic protection systems.

b. Site Lighting – Provide lighting to ensure occupants have a means of safely moving between outdoor spaces. Refer to the Installation Appearance Plan (IAP) in the selection of light poles and signs. Provide adequate site lighting at any point where there is a change in grade requiring steps, near handicap and motorcycle parking areas, and near main entrances to buildings. Provide exterior lighting in parking areas, building entrances, and walkways.

c. Interior distribution systems include service entrance and distribution equipment, TVSS, dry type transformers, wiring devices, raceways, conductors, interior lighting systems, emergency power systems, lightning protection systems, hazardous locations, housing distribution, and systems furniture.

d. Communications and security includes telecommunications systems, television systems, electronic security systems (ESS), and intercommunication systems.

3-16.1 Power

Provide separate dedicated panel boards to serve each separate user area.

Shops and Maintenance Administration

Serve shop spaces by distinct panels dedicated to shop and equipment loads only. Do not supply office spaces from shop circuits or panels. Except as specifically noted otherwise, feed loads located in each Shop space must be from panel boards located within the Shop space.

3-16.2 Emergency Power

Coordinate and provide emergency power as dictated by the mission.

3-16.3 Lighting

Design in accordance with UFC 3-530-01, *Design: Interior and Exterior Lighting and Controls*.

3-16.3.1 Interior Lighting

Refer to UFC 1-200-01, *General Building Requirements* and UFC 3-530-01, *Design: Interior, Exterior Lighting and Controls* for guidance on system selection. Lighting requirements may be minimized by providing natural daylighting and specialized lighting on the materials handling equipment, as required by the user.

3-16.3.2 Exterior Lighting

Provide dock lights every 25 feet (8 m) of rail dock and for each truck dock for illumination of rail car, truck, or trailer interior.

Provide lighting at parking lots, maneuvering areas, outride storage, and, where required, fence lighting.

3-16.4 Receptacles

Locate convenience outlets in accordance with UFC 3-520-01, *Interior Electrical Systems*. There must be a minimum of one receptacle on every wall.

3-16.5 Battery Chargers

Provide circuits to power battery chargers for battery-operated materials handling equipment.

3-16.6 Lightning Protection

Provide lightning protection in accordance with UFC 3-575-01 *Lightning and Static Electricity Protection Systems*.

3-17 CIVIL

Refer to UFC 1-200-01, *General Building Requirements* and UFC 3-201-01, *Civil Engineering* for physical security, antiterrorism, standoff distances, setbacks, Low Impact Design (LID), storm drainage, geotechnical site investigation, vehicular and pedestrian circulation, and other site related requirements.

3-17.1 Siting

When siting the Warehouse, place emphasis on operation, function, energy efficiency and safety. Comply with the requirements of UFC 1-200-01, *General Building Requirements.*

3-17.1.1 Site Organization

Provide efficient access to the delivery drive aisle(s). Develop a sense of order, arrival, orientation, and community in planning the site. Arrange the placement of structures in relationship to one another to create outdoor spaces for use as passive or active recreation areas. Organize the site using functional zones and the appropriate relationship of functions. Other factors to consider include topography, vegetative cover, existing construction, weather elements, wind direction, soil conditions, flood

hazards, natural and man-made obstructions, adjacent land use and accessibility of utilities. Vehicular parking, pedestrian access and traffic flow must also be given careful consideration.

Truck traffic must be separated from other vehicular traffic. Truck delivery routes must be planned so drivers are not backing up to the dock on their blind side. Truck arrival route must be counterclockwise to the facility.

3-17.1.2 Finished Floor Elevation

Establishing the finished floor elevation of the project is one of the most important aspects of site planning. The finished floor elevation affects grading, cut and fill, and visual impact of the facility and interior and exterior transitions. In addition, the finished floor elevation has a significant impact on the landscape architect's ability to effectively introduce plant materials into the new environment. When the approach is to "level the site" without sensitivity to other demands, the results lack visual interest. Closely combine efforts of the landscape architect, architect, and civil engineer to achieve the most optimum design results. Provide the facility's minimum finished floor elevation and the mechanical/electrical equipment pad elevations in accordance with UFC 3-201-01, *Civil Engineering*.

3-17.2 Utilities

Design utilities in accordance with UFC 3-201-01, *Civil Engineering*.

3-17.3 Utility Metering

Provide metering in accordance with UFC 1-200-02, *High Performance and Sustainable Building Requirements*.

3-18 SUSTAINABLE DESIGN

Refer to UFC 1-200-01, General Building Requirements and UFC 1-200-02, *High Performance and Sustainable Building Requirements* for minimum requirements and guidance to achieve high performance and sustainable facilities.

CHAPTER 4 HAZARDOUS MATERIALS STORAGE GENERAL DESIGN CRITERIA

4-1 GENERAL

Requirements from Chapter 1 – 3 of this UFC must be applicable to Hazardous Materials Storage Facilities except as modified by Chapter 4.

Reference UFC 1-200-01; *General Building Requirements* for Use and Occupancy requirements.

4-2 HAZARDOUS MATERIALS STORAGE

Space justified for hazardous materials storage must be considered a portion of the total space allowed for the facility type. Use DoD Real Property Classification System (RPCS); Category Codes 441-10 through 441-40 facility types. Such space must not exceed 5 percent of the total space unless justified. Hazardous materials storage must be designed and constructed in accordance with the standard references listed in the paragraph in Chapter 4 entitled, “General” for storage of materials classified as hazardous to health, environment, and property, i.e., flammables, acids, caustics, oxidizers, water reactives, or others considered hazardous by the following Code of Federal Regulations (CFR's): Title 29 CFR 1910, *Occupational Safety and Health Standards*; 40CFR - *Protection of Environment*; 49CFR - *Transportation* - parts 171-177, *Hazardous Materials Safety;* and FED-STD-313, *Material Safety Data, Transportation Data, and Disposal Data for Hazardous Materials Furnished to Government Activities*.

4-2.1 Compliance Standards

Comply with \1\NFPA 400, Hazardous Materials Code and /1/the following federal, industry, and association standards.

4-2.1.1 Federal Regulations

Comply with requirements of 29CFR - *Occupational Safety and Health Standards*, 40CFR - *Protection of Environment*, 49CFR - *Transportation*, Army Pamphlet DA PAM 710-7, *Hazardous Materials Management Program,* DoD 4140.1-R, *Supply Chain Material Management Regulation*, and Army TM 38-400/ Navy NAVSUP PUB 572/ Air Force AFJMAN 23-210/ Marine Corps MCO 4450-14/ Defense Logistics Agency DLAM 4145.12, *Joint Services Manual (JSM) for Storage and Materials Handling*.

4-2.2 Hazardous Materials Storage

Hazardous materials storage facilities must be designed and constructed to offer protection against the physical, health, or environmental hazards presented by the material. Storage and handling of hazardous materials must be confined to buildings or parts of buildings meeting the requirements of this section.

4-2.3 Design Criteria

Facility design and layout must take into consideration the incompatibility of hazardous materials and hazardous materials groups. Individual facility design and layout must be based upon the specific types and categories of hazardous materials that are to be handled and stored.

4-2.3.1 Building Spacing

Provide a buffer zone between the facility and the nearest inhabited area, stream, or body of water in accordance with UFC 1-200-01, *General Building Design Requirements* and UFC 3-600-01, *Fire Protection Engineering for Facilities*.

4-2.3.2 Docking Facilities

Dock areas in hazardous materials facilities must provide a manually operated valve in the outside drain trench to prevent spills from entering the storm sewer system. The drain must discharge into a sump sized to accommodate the expected quantity of discharge.

4-2.4 Storage Requirements

Accommodate the following storage requirements in the design of hazardous materials storage areas within other warehouse types listed in the paragraph entitled “Types of Storage Facilities”.

a. The storage area must be designed to prevent surface or groundwater contamination in the event of a spill or leak, and to capture completely each class of material individually.

b. In acid or caustic liquid storage, a man-up type vehicle MUST be used. Otherwise, the liquids must be stored on the floor to keep the loads below the operator's eye level.

c. Spill Containment must be provided as required by the paragraph entitled “Segregation of Materials”.

4-2.5 Material Handling Equipment

Electrically powered materials handling equipment is the only type of powered material handling equipment rated for use in hazardous materials storage areas. Use vehicles which have all electrical equipment completely enclosed in hazardous materials warehouses. Type EX vehicles, which have all fittings and equipment, designed, constructed, and assembled for use in atmospheres containing flammable vapors, dust; and fibers, may be required for unique chemicals or applications. Verify the need for any additional requirements which may be imposed by special storage conditions.

4-3 SEGREGATION OF MATERIALS

Provide segregated storage areas for materials having incompatible hazardous characteristics.

4-3.1 Categories of Materials

Normally, six categories of hazardous materials must be accommodated and provided segregated storage areas within a hazardous materials storage facility. Other categories may be encountered in some designs and require additional segregated storage areas. These materials as defined by OSHA consist of the following:

4-3.1.1 Flammable and Combustible Liquids

Liquids are defined by National Fire Protection Association (NFPA) *Flammable and Combustible Liquids Code*, NFPA 30 as any material having a fluidity greater than 300 penetration asphalt, when tested in accordance with the *Standard Test Method for Penetration of Bituminous Materials*, ASTM D5/D5M.

4-3.1.1.1 Flammable

Flammable liquids have a flash point below 100°F (38°C) and a vapor pressure not exceeding 40 psi absolute (275 kPa) at 100°F (38°C). These liquids are also classified as Class I liquids.

4-3.1.1.2 Combustible

Combustible liquids have a flash point of 100°F (38°C) or higher. Combustible liquids are further classified as Class II for flash points at or above 100°F (38°C) and below 140°F (60°C), and Class III for flash points at or above 140°F (60°C).

4-3.1.2 Acids

Acids and acid mists and gases react with arsenides, borides, carbides, cyanides, fluorides, phosphides, selenides, silicides, sulfides, sulfites, and tellurides to generate toxic fumes. They also liberate hydrogen upon contact with metals and hydrides.

4-3.1.3 Oxidizers

Oxidizing materials are those chemicals which will decompose readily under certain conditions to yield oxygen. They may cause a fire in contact with combustible materials, may react violently with water, and when involved in a fire may react violently. Typical oxidizers include: organic and inorganic peroxides, permanganates, chlorates, perchlorates, persulfates, organic and inorganic nitrates, bromates, perbromates, chromates, and dichromates.

4-3.1.4 Poisons

Poisons are materials that cause death by systemic poisoning rather than by corrosive destruction of tissue. Under adverse conditions, such as a leak, spill, fire, or poor

ventilation, a common chemical or compound (e.g., ammonia) may be considered poisonous.

4-3.1.5 Water Reactive Materials

These materials react with water, steam, or water solutions to produce flammable gases, toxic gases, explosive gases, or heat. Flammable gas producers include calcium, cobalt, hydrides, lithium, potassium, rubidium alloys, and sodium. Explosive gas producers include arsenides, borides, carbides, nitrides, phosphides, selenides, silicides, sulfides, and tellurides. Heat producers include acid anhydrides, concentrated acids, and concentrated alkalis. It is essential that no water-based fire extinguishment system be used in storage areas designated for water reactive materials. \1\ /1/

4-3.1.6 Caustics

Caustics (alkalis) may liberate hydrogen upon contact with aluminum. They are not compatible with acids and must be segregated from acids for safe and efficient operations.

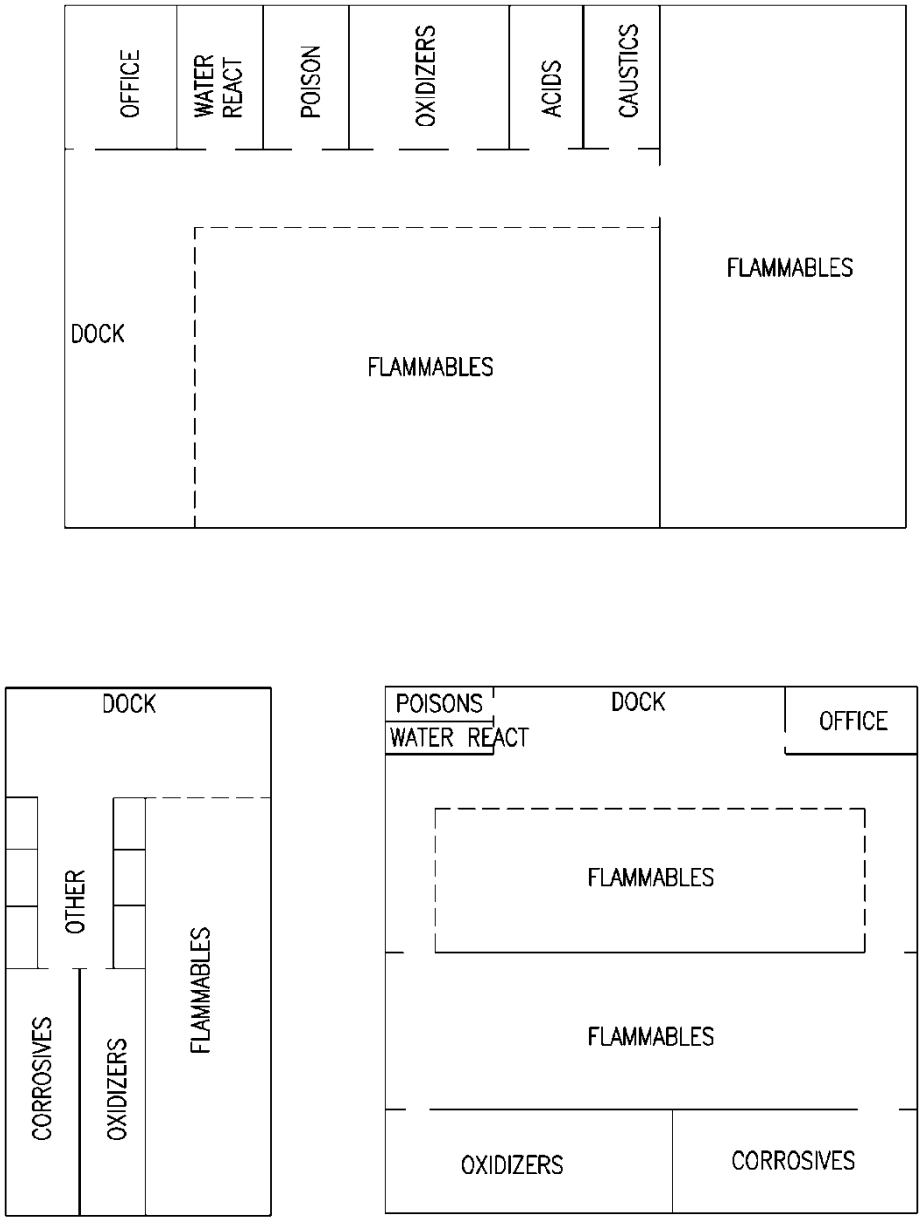
4-3.1.7 Organic Peroxides

Organic peroxides must be stored in a segregated storage area, separated from all other materials.

4-3.2 Segregation Requirements

Provide for segregated storage of hazardous materials as required by Army Pamphlet DA PAM 710-7, *Hazardous Material Management Program,* DoD 4140.1-R, *Supply Chain Material Management Regulation*, and Army TM 38-400/ Navy NAVSUP PUB 572/ Air Force AFJMAN 23-210/ Marine Corps MCO 4450-14/ Defense Logistics Agency DLAM 4145.12, *Joint Services Manual (JSM) for Storage and Materials Handling*. Typical segregated storage block layouts are shown in figure 4-1. Comply with the following segregation requirements:

a. Acids must be isolated from other materials, including chemicals within the corrosives area.



b. Flammable liquids must be isolated from acids and oxidizers.

c. Organic acids must be isolated from oxidizers.

d. Oxidizers must be isolated from all flammable and combustible liquids.

Figure 4-1 Hazardous Materials Storage Segregation Layouts

Plan Views

4-3.2.1 Compressed Gas Cylinders

Compressed gas cylinders of flammable and nonflammable gases, and gases classified as oxidizers, must be stored in sheds and neither in hazardous materials warehouses or hazardous materials storage areas within a general storage warehouse. Small cylinders in boxes, which are an integral part of other equipment, may be stored in hazardous materials warehouses, if properly segregated from incompatible materials.

4-3.2.2 Drummed Petroleum/Oil/Lubricant (POL)

Drummed POL products with a flash point of more than 100°F (38°C) must be stored in shed or open storage facilities with sealed pavements and berms/dikes to contain spills. Outside storage for drummed POL may be used, provided the drums are of corrosion resistant material or are hot-dipped galvanized for corrosion protection.

4-3.2.3 Other Materials

Dry corrosive materials, Other Regulated Materials, and radioactive materials having no other hazard, may be stored in general purpose warehouses. All other radioactive materials must be stored in a designated, separate area in accordance with DLAI 4145.8 / NAVSUPINST 4000.34C / AFJI 23-504 / MCO P4400.105E*, Radioactive Commodities in the DOD Supply Systems*.

4-3.3 Combined Shed Storage

When a hazardous materials warehouse is combined with shed storage, provide a 4-hour fire wall to separate the two storage areas. Shed and warehouse floors must be at the same elevation, with spill containment trenches or drains at fire doors. Access to the shed must be from the dock area of the warehouse, NOT from within a storage area.

4-4 SPILL CONTAINMENT AND CONTROL

Means of providing containment and removal must be provided in the event of spills. Refer to 29 CFR 1910.106 for additional information.

4-4.1 Exterior Containment

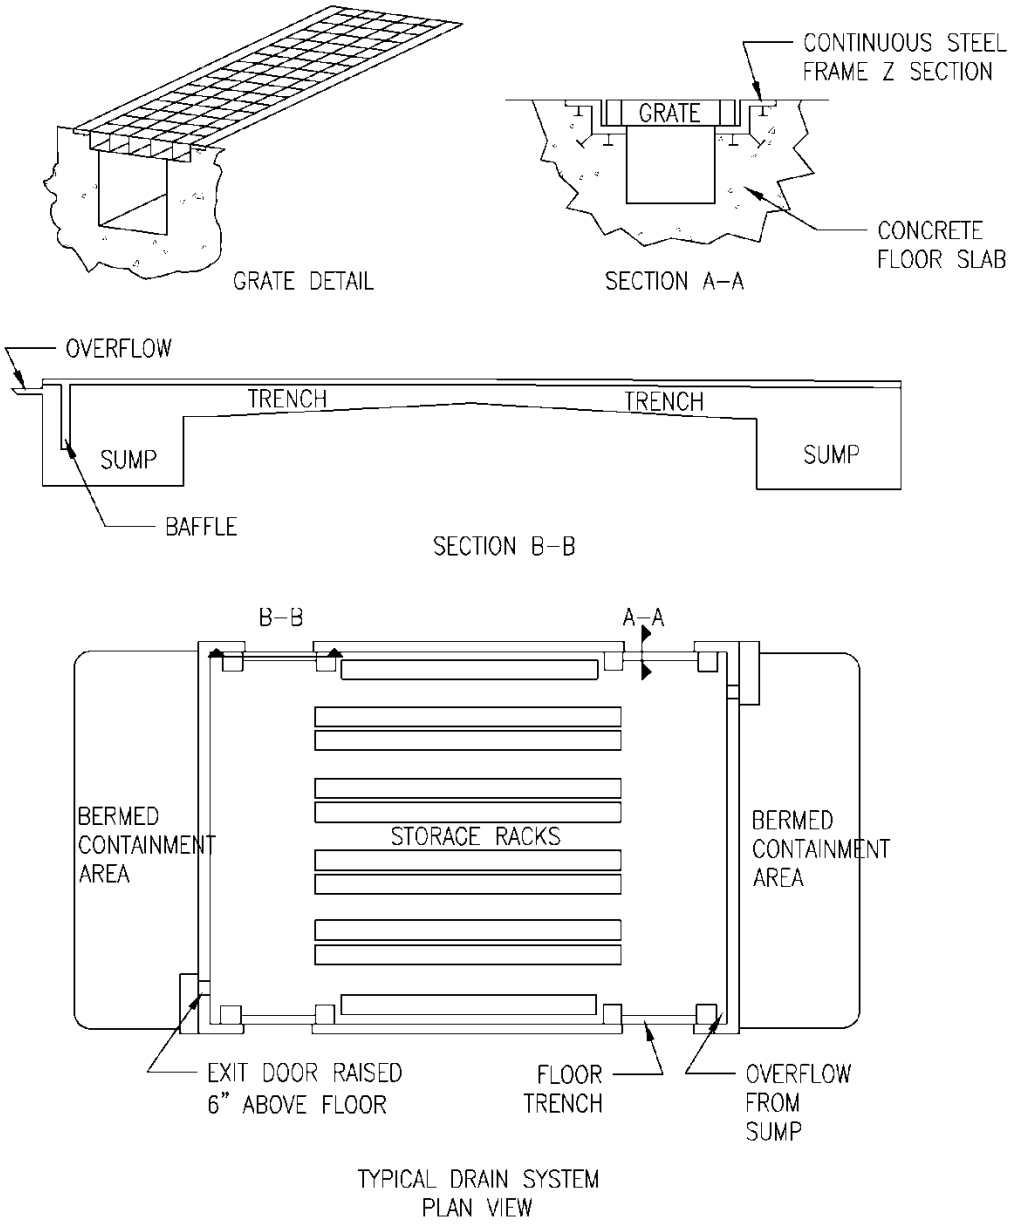
Exterior containment areas must be graded in a manner to divert possible spills away from buildings or other exposures or be surrounded by a curb at least 6 inches high, see paragraph in Chapter 4 entitled “Dikes”. When curbs are used, provisions must be made for draining of accumulations of ground or rain water or spills of flammable liquids. Drains are to terminate at a safe location and must be accessible to operation under fire conditions.

4-4.2 Interior Containment

Inside storage rooms must be constructed to meet the required fire-resistive rating for their use. Such construction must comply with the test specifications set forth in Standard Methods of Fire Tests of Building Construction and Materials, NFPA 251. Openings to other rooms or buildings are to be provided with noncombustible liquid-tight raised sills or ramps at least 4 inches in height or the floor in the storage area must be at least 4 inches below the surrounding floor. Openings must be provided with approved self-closing fire doors. The room must be liquid-tight where the walls join the floor. A permissible alternate to the sill or ramp is an open-grated trench inside of the room that drains to a safe location, see paragraph in Chapter 4 entitled “Floor Trenches and Capture System”. Where other portions of the building or other properties are

exposed, windows must be protected as set forth in the Standard for Fire Doors and Windows, NFPA No. 80.

4-4.3 Dikes



Dikes must be used for containment of spills for gasoline and/or diesel fork truck refueling stations and commodities stored or handled outside of buildings. In accordance with National Fire Protection Association (NFPA) *Flammable and Combustible Liquids Code*, NFPA 30, their volume must be not less than 110% of liquid that can be released from a fork truck or the largest storage container within the diked area or a 10% minimum of all materials to be stored in the area, whichever is greater.

4-4.4 Floor Trenches and Capture Systems

Where a continuous floor trench with grating is used in areas of hazardous materials storage for the capture and control of hazardous chemical spills see figure 4-2. All spill containment systems must provide separate containment as described in the paragraph in Chapter 4 entitled, “Containment”. Secure grate frame support channels to concrete floors. Grate design must provide for the ability to latch the removable grate sections at aisle crossings and cargo doors to ensure that grates will remain firmly in place when material handling equipment moves over them. The cross section of the grate frame members must be "Z-", rather than "L-", shaped so that two legs of the "Z" form a pocket for grates and the third leg is in the horizontal plane at floor level, as illustrated in figure 4-2. This protects the edges of concrete around grate frames from impact damage from the wheels of materials handling equipment.

Where a trench passes in front of a personnel door use \1\concrete cover or solid concrete plates sufficient /1/ to prevent a fire in the trench from blocking the exit door.

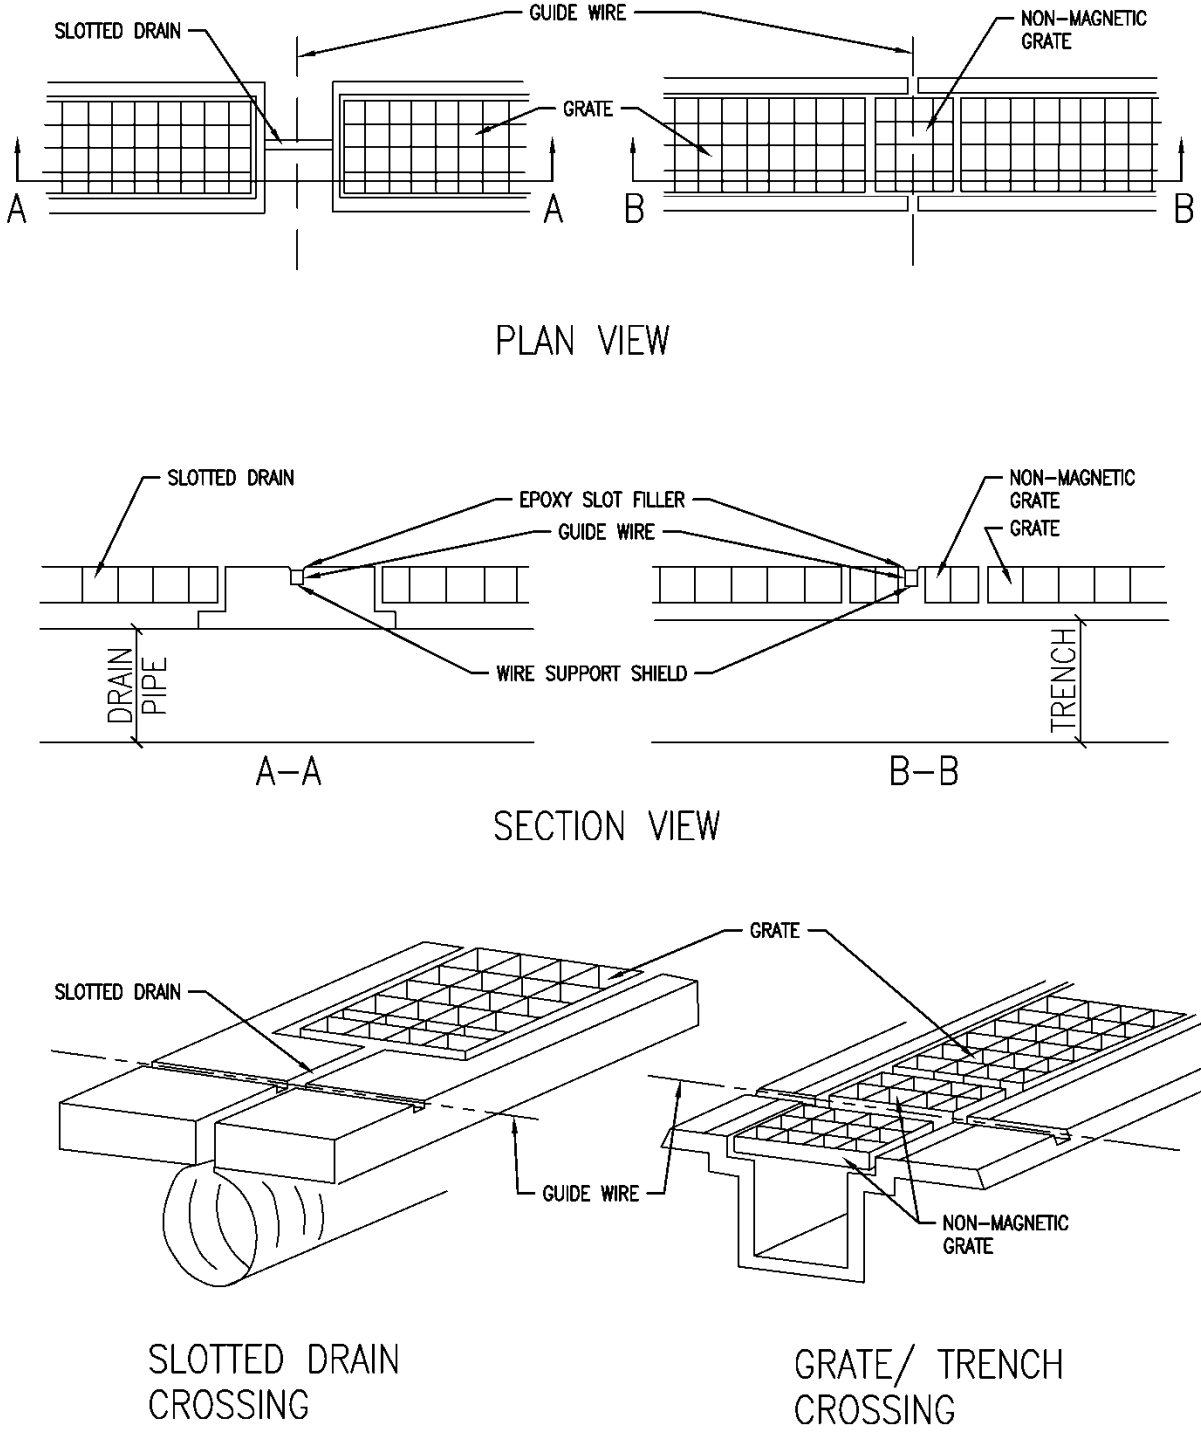


Figure 4-2 Spill Capture/Containment System

4-4.4.1 Electronic Guide Wire Crossing

When floor-buried electronic guide wire is used to guide material handling vehicles across trench grates that cross aisles or are at cargo doors, use a nonmagnetic grate section extending at least 6 inches (150 mm) on each side of the wire path so that the magnetic field of the guide wire is not distorted by passing the wire through a ferrous or magnetic grate. Alternatively, use slotted drains and pass the guide wire under the drains and shield the guide wire when passing through ferrous or magnetic grates or drains. Figure 4-3 illustrates typical crossing methods.

Figure 4-3 Electronic Guide Wire Crossing

4-4.5 Recessed Floor

When required for specific design or containment needs, interior storage floor surfaces may be recessed 6 inches (150 mm) below the level of adjoining dock, office, and support areas to prevent the flow of spilled hazardous liquids into these areas. Vehicle access ramps must be provided at all doorways into such areas. The use of this method is discouraged due to operational inefficiencies and the additional space requirements caused by the ramps.

4-4.6 Containment

Use grate-covered interior 350 gallon (1323 l) sumps in conjunction with the trench system to provide spill or leakage containment for the lesser of 1,000 gallons (3785 l) or 10 percent of the total free flowing liquid volume of all containers stored in each segregated area. Provide a containment capacity of 1,000 gallons (3785 l) at the truck apron adjacent to the shipping and receiving area. Include a controlled flow system to prevent spilled or leaking materials from entering the environment.

4-4.7 Drainage

Install pallet racks and associated mechanical vehicle guidance systems so as to permit the unimpeded flow of spilled liquids to collecting trenches. Maintain floor flatness requirements. Floor drains connecting to the sanitary sewer are not permitted in storage areas of hazardous materials.

APPENDIX B BEST PRACTICES

B-1 GENERAL

This appendix identifies background information and practices for accomplishing design and engineering services. The Designer of Record (DOR) is expected to review and interpret this guidance and apply the information according to the needs of the project. If a Best Practices document has guidelines or requirements that differ from the UFGS or UFC, the UFGS and the UFC must prevail. If a Best Practices document has guidelines or requirements that are not discussed in the UFGS or UFC, the DOR must submit a list of the guidelines or requirements being used for the project with sufficient documentation to the Government Project Manager for review and approval prior to completing design.

B-2 WHOLE BUILDING DESIGN GUIDE

The Whole Building Design Guide (**WWW.WBDG.ORG**) provides additional information and discussion on practice and facility design, including a holistic approach to integrated design of facilities.

The WBDG provides access to Construction Criteria Base (CCB) criteria, standards and codes for the DoD Military Departments, National Aeronautics and Space Administration (NASA), and others. These include, UFC, UFGS, Performance Technical Specifications (PTS), design manuals, and specifications. For approved Government employees, it also provides access to non-government standards.

B-3 FACITILTY DESIGN

Comply with UFC (Latest Version), FC, and other related criteria as noted in UFC 1-200-01, General Building Requirements under the heading “UNIFIED FACILITY CRITERIA”.

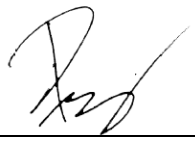
Includes changes in Table B-1: changes to room codes DNTB1, DNTC1, DNTE1, DNTG1, DNTG2, DNTG3, DNTG4, DNTP1, DNTP2, NBCD1, and NBCD2; and adds room codes PHHR1 and SHRM2. Adds definitions for Ambulatory Care Center and Hospital and eliminates third unnumbered paragraphs.
2	25 Oct 23	Correct captions for Table B-1, change med gas for DNTE1, and provide missing Table B-1 page (room codes OFA03 through OPD01).
3	30 Nov 23	Corrections in Table B-1 - Task lighting.

This UFC supersedes UFC 4-510-01, dated 30 May 2019, with Change 2 dated 4 December 2019.

This Page Intentionally Left Blank

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.



UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

9-2.8 Coordination with Medical and Dental Equipment. 74
9-3 DRAINAGE SYSTEMS. 74
9-3.1 Sanitary Drainage System. 74
9-3.2 Storm Drainage System. 77
9-4 FUEL GAS SERVICE. 77
9-5 MEDICAL GAS SYSTEMS. 77
9-5.1 Application of NFPA 99 to Dental Systems. 79
9-5.2 Application of NFPA 99 to Veterinary Care. 79
9-5.3 Systems for Medical Clinics and Ambulatory Care Clinics. 79
9-5.4 Systems for Dental Clinics. 79
9-5.5 Corrugated Medical Tubing. 79
9-5.6 Medical Gas Equipment Rooms. 79
9-5.7 Underground Piping. 80
9-5.8 System Control Valves. 80
9-5.9 Alarm Systems. 80
9-5.10 Gas System Sources (Storage). 80
9-5.11 Color Coding and Labeling. 81
9-5.12 Medical Gas Systems Outlets. 81
9-5.13 Power Source for Medical Gas Systems. 81
9-5.14 Medical Compressed Air (MA). 81
9-5.15 Dental Compressed Air (DA). 84

9-5.16 Laboratory Air (LA). 86
9-5.17 Instrument Air (IA). 87
9-5.18 Process Air (PA). 88
9-5.19 Medical Surgical Vacuum (MV) System. 89
9-5.20 Dental Surgical Vacuum (DSV). 92
9-5.21 Oral Evacuation (OE). 93
9-5.22 High-Volume Laboratory Dust Evacuation (LDE). 96
9-5.23 Waste Anesthesia Gas Disposal (WAGD). 96
9-5.24 Oxygen (O). 97
9-5.25 Nitrous Oxide (NO). 99
9-5.26 Nitrogen (N). 100
9-5.27 Carbon Dioxide (CO2). 100
9-5.28 Process Gas. 101
CHAPTER 10 HEATING, VENTILATION, AND AIR CONDITIONING 103
10-1 GENERAL. 103
10-1.1 Applicability. 103
10-1.2 Supporting Documents. 103
10-2 DESIGN CONDITIONS. 103
10-2.1 Weather Data. 103
10-2.2 Interior Design Conditions. 104
10-2.3 Space Ventilation. 104
10-2.4 Ambient Outdoor Design Conditions. 104
10-2.5 Critical Care Spaces. 104
10-2.6 Laboratories. 105
10-2.7 Temperature during Smoke Control Operation. 105
10-2.8 Mechanical Equipment Rooms. 105
10-2.9 Humid Climate Definition. 105
10-2.10 NFPA 99 Risk Assessment. 105
10-3 REFRIGERANTS. 106
10-4 LIFE-CYCLE COST AND ENERGY ANALYSIS. 106
10-5 ELIGIBILITY FOR AIR CONDITIONING. 106
10-5.1 Total Air Conditioning. 106

10-5.2 Food Service Area. 106
10-5.3 Medical Warehouses. 106
10-6 MECHANICAL EQUIPMENT SPACE. 106
10-6.1 Mechanical Room. 106
10-6.2 Energy Plant. 107
10-7 HVAC SYSTEM DESIGN FOR FUNCTIONAL AREAS. 108
10-7.1 Critical Care Spaces. 108
10-7.2 Sensitive Equipment Areas. 109
10-7.3 Patient Bedrooms. 110
10-7.4 Temporary and Deployable Facilities. 110
10-7.5 Rooms with Critical Pressurization Requirements. 110
10-8 GENERAL DESIGN CONSIDERATIONS. 111
10-8.1 Plant Sizing and Optimization. 111
10-8.2 Contaminant Removal. 112
10-8.3 Interdepartmental Air System Restriction. 112
10-8.4 Air Filtration. 112
10-8.5 Balancing Ports and Features. 112
10-8.6 Additions and Alterations to Existing Facilities. 113
10-8.7 Cooling and Heating Load Calculations. 114
10-8.8 Piping Systems. 115
10-8.9 Insulation for Mechanical Systems. 116
10-9 HVAC SYSTEM CONTROLS. 116
10-9.1 Energy Conservation. 116
10-9.2 Temperature Control. 116
10-9.3 Control Precision. 116
10-9.4 Humidity Control. 116
10-9.5 Direct Digital Controls (DDC). 117
10-9.6 Air Handling Equipment Control. 118
10-10 STEAM SYSTEMS. 119
10-10.1 Humidification Steam Source. 119
10-10.2 Sterilizer Steam Source. 119
10-11 AIR HANDLING AND DISTRIBUTION. 120

10-11.1 AHU Requirements. 120
10-11.2 Energy/Heat Recovery Systems. 120
10-11.3 System Shutdown Capability. 120
10-11.4 Outdoor Air Intakes. 121
10-11.5 Noise Control. 122
10-11.6 Duct Design. 123
10-11.7 Cleanliness of Air Handling and Distribution Equipment. 124
10-12 MAINTENANCE PROVISIONS. 124
10-12.1 General Personnel Access. 124
10-12.2 Equipment Clearances. 125
10-12.3 Suspended and Mounted Mechanical Equipment. 125
10-12.4 Air Distribution System Components. 125
10-12.5 HVAC System Balancing Provisions. 125
10-13 VIBRATION CONTROL. 125
10-14 INTERDISCIPLINARY COORDINATION. 126
10-14.1 Architectural Coordination for Rooms with Critical Pressurization Requirements. 126
10-14.2 Fire Protection Features. 126
10-14.3 Essential Electrical Service. 127
10-14.4 Seismic Design Requirements. 127
10-14.5 Design Coordination. 127
10-15 FUEL STORAGE REQUIREMENTS. 128
10-16 VENTILATION DESIGN. 128
10-16.1 Ventilation Air Changes. 128
10-16.2 General Exhaust Provisions. 129
10-16.3 Space Pressurization. 130
10-16.4 Laboratory Ventilation. 130
10-16.5 Exhaust Canopies. 132
10-16.6 Laminar Flow Clean Benches. 132
10-16.7 Bench-Back Slot Hoods. 132
10-16.8 Portable Bench-Top Hoods. 132
10-16.9 Medical Equipment. 133
10-16.10 Kitchen Hoods. 133

10-16.11 Pharmaceutical Admixture Rooms. 133
10-16.12 MRI Quench Exhaust. 133
10-17 AIRBORNE INFECTION ISOLATION AND PROTECTIVE ENVIRONMENT ROOM DESIGN. 133
10-17.1 Airborne Infection Isolation Bedrooms. 134
10-17.2 Protective Environment Rooms. 135
10-17.3 Airborne Infection Isolation Exam or Waiting Rooms. 135
CHAPTER 11 ELECTRICAL 137
11-1 GENERAL. 137
11-1.1 Scope. 137
11-1.2 Supplemental Criteria and Standards. 137
11-1.3 OCONUS Criteria. 139
11-1.4 Campus and Other Large Facilities. 140
11-2 AREA DESIGNATIONS. 140
11-2.1 Patient Care Space. 140
11-2.2 Wet Locations. 140
11-2.3 Wet Procedure Locations. 140
11-3 EXTERIOR ELECTRICAL. 140
11-3.1 Primary Voltage. 140
11-3.2 Normal Source Site Investigation. 140
11-3.3 Hospital Normal System. 141
11-3.4 Ambulatory Care Clinics Normal System. 142
11-3.5 Medical and Dental Clinics Normal System. 143
11-3.6 Medical Research Facilities and Laboratories Normal System. 143
11-3.7 Veterinary Facilities Normal System. 143
11-3.8 Other Medical Facilities Normal System. 143
11-4 ESSENTIAL ELECTRICAL SYSTEM. 143
11-4.1 Facility. 143
11-4.2 General. 145
11-4.3 Alternate Power Source. 146
11-4.4 Generator Sets. 146
11-4.5 Location of Generator Sets. 147
11-4.6 Engine Starting. 148

11-4.7 Manual Test Switches. 148
11-4.8 Generator Set Operation. 148
11-4.9 Automatic Transfer Switch (ATS). 149
11-4.10 Ground Fault Protection Equipment. 151
11-4.11 Remote Alarm Annunciator. 151
11-4.12 Fuel Storage System. 151
11-4.13 Loads on the Alternate Source. 152
11-4.14 Essential Loads. 152
11-4.15 Alternate Source Testing. 155
11-5 INTERIOR ELECTRICAL SYSTEMS. 155
11-5.1 System Voltage. 155
11-5.2 Interior Distribution. 155
11-5.3 Short Circuit, Selective Coordination, and Arc Flash. 157
11-5.4 Electrical Rooms. 158
11-5.5 Isolation Power System. 159
11-5.6 Conduit, Cable Tray, and Wire. 160
11-5.7 Branch Circuits. 161
11-5.8 Radiology Provisions. 161
11-5.9 Receptacle Identification. 164
11-5.10 Patient Care Grounding. 165
11-5.11 Inhalation Anesthetizing Location. 165
11-5.12 Electromagnetic Shielding for Medical Instrumentation. 165
11-6 LIGHTING. 165
11-6.1 Design. 165
11-6.2 Battery-Operated Lighting. 169
11-6.3 Patient Bedrooms. 170
11-6.4 Special Location Requirements. 170
11-6.5 Corridors. 171
11-6.6 Dental Clinic. 171
11-6.7 Eye LASIK/PRK Rooms. 171
11-6.8 Exterior Signage. 172
11-6.9 Exterior Lighting. 172

11-6.10 Dimming. 172
11-6.11 Ultraviolet (UV) Filters. 172
11-6.12 Maintenance Area Lighting. 173
11-6.13 Auditorium. 173
11-6.14 Continuity of Service. 173
11-6.15 Accessibility. 173
11-7 HELIPAD LIGHTING, MARKING, AND CONTROLS. 173
11-8 LIGHTNING PROTECTION. 174
CHAPTER 12 COMMUNICATIONS 183
12-1 GENERAL. 183
12-1.1 Design Criteria. 183
12-1.2 Approved Product Lists (APLs). 183
12-2 COMMUNICATIONS SPACES. 183
12-2.1 Telecommunication Rooms (TRs) (COMC1). 183
12-2.2 Communications Radio Equipment Room (COM04). 185
12-2.3 Integrated Monitor and Alarm Room. 187
12-2.4 Refrigerator Monitoring. 187
12-2.5 Server Room (CMP01). 187
12-2.6 Service Entrance Facility (EF) (COMC2). 188
12-3 OUTSIDE PLANT INFRASTRUCTURE AND CABLING. 188
12-3.1 Outside Plant Purpose. 188
12-3.2 Outside Plant Duct Work. 188
12-3.3 Outside Plant FO Cable. 188
12-3.4 Outside Plant Twisted Pair Copper Cable. 189
12-3.5 Outside Plant CATV Cable. 189
12-4 RMF AUTHORIZATION PROCESS REQUIREMENTS. 189
12-4.1 Information Technology Systems. 189
12-4.2 Stand-alone Information Systems. 189
12-4.3 MIL-STD 1691. 190
12-5 NETWORK TIME SYNCHRONIZATION (NTS) SYSTEM. 190
12-5.1 Purpose. 190
12-5.2 Date and Time Properties. 190

12-5.3 Electrical Power. 190
12-6 TELEPHONE SYSTEM CRITERIA. 191
12-6.1 Type of Service. 191
12-6.2 Central Telephone Equipment. 191
12-6.3 Integrated Intercommunication (Intercom) System. 191
12-6.4 Patient Bedside Telephones. 192
12-7 TELECOMMUNICATIONS INFRASTRUCTURE SYSTEM (TIS). 192
12-7.1 UTP Copper Backbone Cable. 192
12-7.2 FO Backbone Cable. 192
12-7.3 Horizontal Copper Cable. 193
12-7.4 Horizontal FO Cable. 193
12-7.5 Work Area Outlets (WAO). 193
12-7.6 Data Communications Wireless Access Points (WAPs). 194
12-7.7 Cable Tray. 195
12-7.8 Grounding. 195
12-8 DEDICATED INTERCOM SYSTEM. 195
12-9 NURSE CALL (NC) SYSTEM. 195
12-9.1 Purpose. 195
12-9.2 Capabilities and Typical Locations. 196
12-9.3 Procurement. 196
12-9.4 UL 1069. 196
12-9.5 Common Criteria. 196
12-9.6 Networked NCAV System. 199
12-9.7 NCTV System. 210
12-9.8 Enhanced Supplemental Operations. 213
12-10 INTERNAL CELLULAR ANTENNA SYSTEMS (IRES). 214
12-11 RADIO PAGING SYSTEM. 214
12-11.1 Radio Paging (RP). 214
12-11.2 Page System Interfaces. 214
12-11.3 System Function. 215
12-11.4 Emergency Response Team Pagers. 215
12-11.5 Antennae Type and Mounting. 215

12-11.6 Power Requirements. 215
12-11.7 Transmitter and Encoder. 215
12-12 INTERACTIVE TELEVISION (ITV) SYSTEM. 215
12-12.1 Electrical Power. 216
12-12.2 Empty Conduit and Boxes and Cable Trays. 216
12-12.3 Structural Support. 216
12-12.4 Equipment Space Support. 216
12-13 TV BROADBAND DISTRIBUTION NETWORK. 216
12-13.1 Purpose. 216
12-13.2 Procurement. 216
12-13.3 Commercial TV Service. 216
12-13.4 Broadband Distribution Network. 217
12-13.5 TV Outlets and Signal Level. 218
12-13.6 Flat-Panel HDTVs and Connecting and Mounting Items Configuration. 218
12-13.7 Electrical Power. 218
12-14 ELECTRONIC SECURITY SYSTEM (ESS). 218
12-15 RADIO AND PUBLIC ADDRESS (PA) SYSTEM. 219
12-15.1 System Purpose. 219
12-15.2 System Components. 219
12-15.3 System Configuration. 220
12-15.4 System Performance. 221
12-15.5 Electrical Power. 222
12-16 SOUND REINFORCEMENT SYSTEM. 222
12-16.1 Purpose. 222
12-16.2 Inputs. 222
12-16.3 Headroom. 223
12-17 INTEGRATED AUDIO VIDEO SYSTEMS (AV). 223
12-18 PHYSIOLGICAL PATIENT MONITORING SYSTEM. 223
12-18.1 System Requirements. 224
12-18.2 Fetal Monitoring. 224
12-18.3 Neonatal Monitoring. 224
12-18.4 Anesthesia and Respiratory Gas Analysis System. 224

12-19 EMERGENCY MEDICAL SERVICE (EMS) COMMUNICATIONS. 225
12-19.1 Electrical Power. 225
12-19.2 Empty Conduit and Boxes. 225
12-19.3 Structural Support. 225
12-20 EMS RECORDER SYSTEM. 225
12-20.1 EMS Recorder Function and Features. 225
12-20.2 System Inputs and Mounting. 226
12-21 OTHER PROVIDED SYSTEMS. 226
12-21.1 Empty Conduit and Boxes and Cable Trays. 226
12-21.2 Structural Support. 226
12-21.3 Equipment Space Support. 226
CHAPTER 13 ACCESSIBILITY PROVISIONS FOR THE DISABLED 227
13-1 GENERAL. 227
13-2 GENERAL EXCEPTIONS. 227
13-3 DOD EXCEPTIONS/EXCLUSIONS. 227
13-4 SPECIFIC MILITARY MEDICAL FACILITY REQUIREMENTS. 227
13-4.1 Parking. 227
13-4.2 Patient Sleeping Rooms. 227
13-4.3 Patient Dressing Rooms. 227
13-4.4 Telephones. 227
13-5 WAIVERS. 228
CHAPTER 14 FIRE PROTECTION AND LIFE SAFETY 229
14-1 GENERAL. 229
14-2 FACILITY FIRE PLAN. 229
14-3 LIFE SAFETY COMPLIANCE FOR BUILDING REHABILITATION. 229
14-3.1 Life Safety Assessment. 229
14-3.2 Health Care and Ambulatory Health Care Occupancies. 229
14-3.3 Interim Life Safety Measures. 230
14-4 AUTOMATIC SPRINKLER PROTECTION. 230
14-4.1 Components and Hardware. 230
14-4.2 Audiometric Booths. 230
14-4.3 Defend in Place. 231

14-5 FIRE ALARM, FIRE DETECTION, AND MASS NOTIFICATION. 231
14-5.1 Autonomous Control Unit and Local Operating Console..... 231
14-5.2 Occupant Notification..... 231
14-5.3 Smoke Detection Used in Conjunction with Smoke Compartmentation. 232
14-5.4 Behavioral Health. 233
14-6 MANAGEMENT OF SMOKE..... 233
14-6.1 New Smoke Control Systems. 233
14-6.2 Existing Smoke Control Systems..... 233
14-7 WATER SUPPLY. 233
14-8 INTERSTITIAL BUILDING SYSTEM (IBS). 233
14-9 SPECIAL DETAILED REQUIREMENTS BASED ON USE AND OCCUPANCY. 233
14-9.1 Dental Treatment. 233
14-9.2 Research Facilities. 234
14-9.3 Veterinary Care and Animal Research Facilities..... 234
14-9.4 Pharmacy Storage. 235
14-9.5 Areas with Heat-Producing Appliances..... 235
CHAPTER 15 FURNITURE, FIXTURES AND EQUIPMENT..... 237
15-1 GENERAL. 237
15-1.1 IDENTIFICATION of FF&E. 237
15-1.2 APPROVAL of SUBSTITUTIONS..... 237
15-2 PROCUREMENT..... 237
15-3 FUNDING SOURCE 237
15-4 LOGISTICAL RESPONSIBILITY. 238
15-5 DESIGN..... 238
15-5.1 Casework..... 238
15-5.2 Technically Complex Equipment and Medical System. 239
15-5.3 Equipment Connectivity. 239
15-5.4 Automatic External Defibrillator (AED)..... 240
15-5.5 Hyperbaric Medicine. 240
CHAPTER 16 TRANSPORTATION AND LOGISTICS..... 241
16-1 GENERAL. 241

16-1.1 Scope. 241
16-1.2 Transportation Systems Evaluation. 241
16-1.3 Medical Transportation and Logistics Consultant. 241
16-2 TRANSPORTATION AND LOGISTIC ANALYSIS REQUIREMENTS. 242
16-2.1 Transportation Logistic Analysis. 243
16-2.2 Elevator Traffic Study and Analysis. 244
16-2.3 Material Management Analysis (MMA). 247
16-2.4 Waste Management Analysis (WMA). 248
16-3 FACILITY DESIGN. 249
16-3.1 Traffic Separation. 249
16-3.2 Transportation Systems. 249
16-3.3 Vertical Automation. 249
16-3.4 Equipment/Materials Separation. 250
16-3.5 Clean and Soiled Material Separation. 250
16-3.6 Escalators. 250
16-4 ELEVATOR DESIGN. 252
16-4.1 Codes. 252
16-4.2 Elevator Selection. 252
16-4.3 Elevator Location and Travel Distances. 254
16-4.4 Elevator Location, Lobbies, and Groupings. 254
16-4.5 Passenger and Service Elevator Features. 259
16-5 MATERIAL MANAGEMENT DESIGN. 262
16-5.1 AGV Systems. 262
16-5.2 Pneumatic Tubes. 262
16-5.3 Mobile Robots. 263
16-5.4 Dumbwaiters and Cart Lifts. 263
16-6 WASTE MANAGEMENT DESIGN. 265
16-6.1 Waste Categories. 265
16-6.2 Waste Collection and Transport. 265
16-6.3 Regulations, Codes, and Standards. 266
16-6.4 Gravity Chutes. 266
16-6.5 Pneumatic Trash/Linen. 266

CHAPTER 17 CONSTRUCTION 269
17-1 CONTRACT AWARD. 269
17-2 COMMISSIONING DURING CONSTRUCTION. 269
17-3 CONSTRUCTION CONTRACT CHANGES. 269
17-3.1 Process for Reporting Changes. 269
17-3.2 Process for Approving Funds. 269
17-4 CONSTRUCTION FUNDS. 269
17-4.1 Funds Management. 269
17-4.2 Funds Availability. 269
17-5 NOTIFICATION OF CONTRACTOR CLAIMS. 270
17-6 LIFE SAFETY ASSESSMENT. 270
17-7 DEMOLITION OF VACATED FACILITIES. 270
CHAPTER 18 BUILDING INFORMATION MODELING (bim) 271
18-1 GENERAL. 271
18-1.1 MHS BIM Objectives. 271
18-1.2 Corresponding Project Model Uses. 271
18-1.3 Applicability. 272
CHAPTER 19 COMMISSIOINING 273
19-1 GENERAL. 273
19-2 SUPPLEMENTAL CRITERIA. 273
19-3 PRELIMINARY COMMISSIONING REQUIREMENTS 273
19-3.1 Level of Commissioning. 273
19-3.2 Roles and Responsibilities. 273
19-4 TOTAL BUILDING COMMISSIONING. 274
19-4.1 Process Overview. 274
19-4.2 Commissioning Leadership Structure. 275
19-4.3 Commissioning During Design. 277
19-4.4 Commissioning During Construction. 277
19-5 SMALL PROJECT COMMISSIONING. 277
19-5.1 Process overview. 277
19-5.2 Oversight of the testing. 278
19-5.3 Requirements during construction. 278

19-6 SPECIFIC SYSTEM REQUIREMENTS. 278
19-6.1 Interoperability. 278
19-6.2 Addition and Alteration Considerations. 278
APPENDIX A BEHAVIORAL HEALTH DESIGN 279
A-1 GENERAL. 279
A-2 SCOPE OF BEHAVIORAL HEALTH SERVICES. 279
A-2.1 Inpatient Functions. 279
A-2.2 Outpatient Functions. 279
A-3 BEHAVIORAL HEALTH PROGRAM. 279
A-3.1 Concept. 279
A-3.2 Behavioral Health Design Guide. 280
A-3.3 Functional Program and Safety Risk Assessment. 280
A-4 CONSULTING SERVICES. 280
A-5 DESIGN CRITERIA. 281
A-5.1 Environment. 281
A-6 EQUIPMENT SPECIFICATIONS. 289
APPENDIX B ARCHITECTURAL AND ENGINEERING DESIGN REQUIREMENTS 291
B-1 GENERAL. 291
B-2 LEGEND & NOTES. 291
B-2.1 Room Code. 291
B-2.2 Room Function. 291
B-2.3 Space Parameter Notes. 292
B-3 ARCHITECTURAL. 292
B-3.1 Materials and Finishes. 292
B-3.2 CEILING HEIGHT. 295
B-3.3 DOOR SIZE. 295
B-3.4 NOISE. 296
B-4 ARCHITECTURAL NOTES. 296
B-5 STRUCTURAL. 298
B-6 ELECTRICAL. 299
B-6.1 LIGHTING. 299
B-6.2 ESSENTIAL POWER. 300

B-7 MEDICAL GASES. 300
B-7.1 MEDICAL GAS NOTES. 301
B-8 HVAC. 302
B-8.1 HVAC Notes. 304
APPENDIX C DESIGN SUBMITTALS AND DOCUMENTATION 3367
C-1 GENERAL. 337
C-2 APPLICATION. 337
C-3 GENERAL REQUIREMENTS. 337
C-3.1 Design Analysis. 337
C-3.2 Drawings and Format. 337
C-3.3 Specifications. 338
C-3.4 Cost Estimates. 338
C-3.5 Building Systems Risk Assessment. 338
C-4 5 PERCENT SUBMITTAL. 339
C-4.1 5 Percent Submittal Design Analysis. 339
C-4.2 5 Percent Submittal Drawings. 339
C-4.3 5 Percent Submittal Cost Estimates. 340
C-5 20 PERCENT SUBMITTAL. 340
C-5.1 Scope Changes. 341
C-5.2 Record Copy. 341
C-5.3 20 Percent Design Analysis. 341
C-5.4 20 Percent Submittal Design Drawings. 346
C-5.5 20 Percent Submittal Calculations. 349
C-6 35 PERCENT SUBMITTAL. 350
C-6.1 35 Percent Submittal Design Analysis. 350
C-6.2 35 Percent Submittal Design Drawings. 357
C-6.3 35 Percent Submittal Calculations. 363
C-6.4 35 Percent Design Drawing Record Copy. 364
C-7 65 PERCENT DESIGN SUBMITTAL. 364
C-8 100 PERCENT AND FINAL DESIGN SUBMITTAL. 364
C-9 REQUEST FOR PROPOSAL (RFP) FOR DESIGN-BUILD (DB) PROJECTS. 364
C-10 RFP DEVELOPMENT SUBMITTALS. 365

C-11 AFTER CONTRACT AWARD. 365
APPENDIX D UNIVERSAL X-RAY ROOM 367
D-1 GENERAL. 367
D-1.1 Applications. 367
D-2 SPECIFIC REQUIREMENTS. 367
D-2.1 Electrical Raceway System. 367
D-2.2 Floor Trench. 367
D-2.3 Core Drilling. 367

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC) 4-510-01 provides technical guidance and mandatory requirements to implement laws, regulations, executive orders, and policies to sustain, operate, plan, design, and construct DoD medical, dental and all other medically related facilities authorized by Title 10, United States Code (Reference (k)) and policies. This document defines performance and quality requirements as defined in MIL-STD-3007 for Military Medical Facilities supporting Health Service Support as defined in Joint Publication 4-02 (JP 4-02) throughout the life cycle. Federal legislation, Executive Orders (EOs), DoD Directives, DoD Instructions, and selected technical data, publications, and standards are referenced in the text by basic designation only and form a part of these criteria to the extent required by these references.

1-2 REISSUES AND CANCELS.

This UFC reissues and cancels UFC 4-510-01, dated 30 May 2019, with Change 2 dated 4 December 2019.

1-3 APPLICABILITY.

UFC 4-510-01 (hereafter referred to as 'this document') applies to medically unique portions of Category Code series 500 hospital and medical facilities and Category Code series 310 medically related research laboratories in the Defense-Wide Military Construction (MILCON) program, or other medically specific appropriations as provided by Congress. These requirements apply to **\1** Medical Treatment Facility (MTF) projects **/1/** and to veterinary, medical-related research, medical training facilities, and other projects which require conformance with UFC 4-510-01. This document should be employed by the Department of Defense (DoD) Components to sustainment, restoration, or modernization projects, in facility additions or alteration projects, or in Operations and Maintenance (O&M) projects.

1-4 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein. The requirements of this UFC take precedence over conflicts between this UFC and UFC 3- Series requirements.

1-5 POLICY.

As stated in DoD Instruction (DoDI) 6015.17, it is DoD policy to design efficient, economical, and safe facilities that sustain an effective combat force, support the DoD medical mission, and comply with the provisions of Title 10 U.S. Code (U.S.C.).

Detailed instructions and procedures, which may be developed and issued by the Design and Construction Agents must be consistent with the policy statements and criteria contained herein. Projects must:

a. Meet the current established operating requirements of the DoD Project Sponsor.

b. Provide reasonable flexibility in the design to accommodate future changes.

c. Meet applicable Federal legislation, codes, standards, and criteria.

d. Ensure that The Joint Commission (TJC), Accreditation Association for Ambulatory Health Care (AAAHC), or other applicable accreditations are achieved for Medical Treatment Facilities.

e. Meet certification requirements for Centers for Disease Control and Prevention (CDC), DoD Project Sponsor, Association for Assessment & Accreditation of Laboratory Animal Care (AAALAC), and Biosafety in Microbiological and Biomedical Laboratories (BMBL), or other applicable entities for laboratories.

f. Provide functional facilities at the most economical and practical life-cycle cost (LCC).

g. Be aesthetically compatible with the local environs and published Installation Design Guidelines.

1-5.1 Supplemental Technical Criteria.

The Design and Construction Agent(s) may maintain supplemental technical criteria to execute their organization's established design and construction regulations and procedures. Design and Construction Agents must produce designs for a complete and usable facility within the DoD Project Sponsor approved programmed scope and programmed authority.

1-6 FUNCTIONAL AUTHORITY.

The program functional and regulatory authority for applicable facilities is the Defense Health Agency.

Requests for project-specific waivers and exemptions to any UFC criteria or this document will be submitted in accordance with MIL-STD-3007. Regardless of DoD Project Sponsor, requests must have concurrence/nonconcurrence from the Defense Health Agency Facilities Enterprise (DHA-FE), as the Functional Authority for medical facilities, before final approval authority decisions are pursued.

1-7 ROLES & RESPONSIBILITIES.

1-7.1 Project Sponsor.

The DoD Project Sponsor is the DoD Agency or Service Component that provides the funding for the project. In most projects the DoD Project Sponsor will be the DHA-FE; however, other DoD Agencies can utilize these criteria for their medical projects.

The DoD Project Sponsor provides clinical and functional input on all aspects of facility sizing, functional requirements, and facility-essential or critical-use requirements such as, utility, sewer, water, and operational needs, and must work in partnership with the Design and Construction Agents throughout the design and construction process.

1-7.2 Design and Construction Agents.

The Design and Construction Agents are listed below.

1-7.2.1 U.S. Army Corps of Engineers (USACE).

The Headquarters USACE Program Integration Division (CEMP-II) is the primary USACE point of contact with the Functional Authority and DoD Project Sponsor for non-medically specific design and construction aspects of applicable facility projects and is responsible for all non-medically related program management issues and resolution between the Functional Authority, the DoD Project Sponsor, and USACE. The USACE Medical Facilities Mandatory Center of Expertise and Standardization, Huntsville Engineering and Support Center (CEHNC-EDX), has multi-disciplinary expertise in medical design criteria, standards, and policy, and has sole USACE responsibility for oversight, decision, and technical review of medically unique aspects of applicable projects. USACE's geographical District Offices must closely coordinate with CEHNC-EDX for all medically specific aspects of project design, construction, management, and execution of design and construction projects located within their respective geographical regions, including quality assurance (QA) and oversight of design and construction. CEHNC-EDX is responsible for assisting USACE geographical District Offices with project-specific design instructions to supplement the Architect/Engineer Firm (A/E) Scope of Work (SOW), for interfacing with the Functional Authority and DoD Project Sponsor regarding technical issues and mandatory submissions during both design and construction.

1-7.2.2 Naval Facilities Engineering Systems Command Headquarters (NAVFAC HQ) Medical Facilities Program Office (MFPO).

NAVFAC HQ MFPO is the Navy's point of contact with the Functional Authority and DoD Project Sponsor to provide the technical expertise for medical design and construction. NAVFAC HQ MFPO is the Navy's technical authority regarding project management and for providing project-specific design instructions to supplement the A/E SOW. NAVFAC HQ MFPO is responsible for technical issues, mandatory design and construction submissions, technical guidance, criteria, and all project standards, from project initiation to beneficial occupancy.

1-7.2.3 Air Force Civil Engineer Center (AFCEC).

AFCEC is the primary point of contact with the DoD Project Sponsor for all applicable facility design and construction projects in the United Kingdom and provides project management, technical reviews, and guidance for the Air Force.

Table 1-1 Responsibility Matrix

PROCESS GROUPS	FUNCTIONAL AUTHORITY	DoD PROJECT SPONSOR	DESIGN & CONSTRUCTION AGENTS
GROUP 1: STRATEGIC FACILITIES MANAGEMENT 1.1 Establish Program Policy 1.2 Authorize, Conduct, and Administer Research and Innovation Efforts Related to MHS Facilities 1.3 Integrate Inter-Agency Market Based Planning	R	C	C
GROUP 2: REQUIREMENTS PLANNING 2.1 Local Planning, Requirements Development and Gap Analysis 2.2 Analysis and Evaluation of Potential Solutions/Options 2.3 Business Planning, Market Solution Planning and Facility Requirements Planning	C	R	C
GROUP 3: DESIGN/CONSTRUCTION EXECUTION 3.1 Project Sponsor Representatives Coordination 3.2 Project Delivery and Contract Management	C	C	R
GROUP 4: FACILITY ACTIVATION AND OPERATIONS 4.1 Facility Transition and Activation 4.2 Facility Operations, Repairs, Maintenance, Sustainment, Restoration, and Modernization 4.3 Facility Specific Operations and Maintenance 4.4 Facility De-commissioning and Disposal	C	R	C
Key: R = Responsible; owns the problem or project C = To be consulted; has information or capability needed to complete the work			

1-8 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-9 GLOSSARY.

Appendix H contains acronyms, abbreviations, and terms.

1-10 REFERENCES.

Appendix I contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

This Page Intentionally Left Blank

CHAPTER 2 PREDESIGN

2-1 GENERAL.

This chapter and its references provide requirements for predesign information required by the Design and Construction Agents to execute the design of applicable facilities. Predesign information includes requirements from the planning processes as defined and described in this chapter. Ensure that projects submitted contain sufficient planning, accurate scope, adequate documentation, and a valid cost estimate and realistic schedule for successful execution.

2-2 PREDESIGN PROJECT DOCUMENTATION.

Projects under consideration for budget submission must undergo additional detailed planning to include: additional project documentation; collection of relevant site, environmental, and Installation specific information; and development of other guidance essential for subsequent project design. The DoD Project Sponsor must prepare this information that is used by the Design and Construction Agent as the basis of design. Within 30 days of initial project Design Authorization (DA) release, this information/documentation must be submitted electronically to the Design and Construction Agent.

2-2.1 Documents Prior to DA.

Prior to release of the initial project DA, the DoD Project Sponsor must update and prepare this basic project documentation.

2-2.2 Functional Program.

The DoD Project Sponsor will develop the strategic objectives and the facility and operational requirements for the project (the Functional Program) in written narrative form as part of the project documentation. The DoD Project Sponsor will issue the Functional Program in a standard format with standardized content for consistency across all projects. This narrative must be coordinated with the Program for Design.

The DHA-FE current form for this narrative is titled the “Facility Planning Functional Program”.

2-2.3 Program for Design (PFD) and Project Room Contents (PRC).

The DoD Project Sponsor will develop the PFD facility space allocation and PRC requirements for installed equipment and furniture at an individual room level.

2-2.4 Existing Facilities Surveys.

The DoD Project Sponsor will provide facility deficiency tabulations and upgrade surveys to the Design and Construction Agent. The DoD Project Sponsor will provide an updated Deficiency Tabulation Report and updated estimate of costs and duration to

correct the deficiencies to establish the requirements in support of facility alteration projects.

2-2.5 Site Information.

For additions and new facilities, the DoD Project Sponsor will provide a completed site checklist as a project document. Sites with known contamination must not be considered, unless no other siting options are available and the appropriate cost and adequate schedule for mitigation are applied to the project for cleanup and other costs. The completed site checklist must reference or include Installation master plans for the specific site under consideration for development.

Site information collected for project design must be comprehensive and used to avoid site-related scope and cost impacts during construction. As applicable to a project, this information includes:

a. Area maps: location and site maps (including grades, access control points).

b. Description of existing site condition including previous use and contamination potential and environmental impacts.

c. Any Wetlands or other areas reserved for Fish & Wildlife preservation which would have a cost impact if encroached upon.

d. The statement regarding the facility's contingency-mode or mission assurance status and related additional sustained operations requirements.

e. Specific Installation requirements or restrictions, style of architecture, construction season limitations, seismic, wind, and snow considerations.

f. SOFA or other local host country agreements or criteria.

g. Soil and foundation conditions.

h. Utility distribution.

i. Site restrictions, for example, Air Installations Compatible Use Zones (AICUZ), potential helipad approach/departure zone obstructions, flood plain, rights-of-way.

j. Site security requirements and restrictions.

k. The National Capital Planning Commission (NCPC) requirements.

l. Cyber Security requirements.

m. Completed NEPA documentation.

n. Code restrictions and other surrounding building types and condition.

o. Any local traffic patterns or constraints (schools or high occupancy buildings), public transportation routes.

p. High noise levels or toxic fumes adjacent to building site affecting building occupants. Such as proximity to flightline operations or maintenance/cargo handling/refueling.

2-2.5.1 Utility Availability.

The site information must include a discussion of utility availability including water, sewage, storm drainage, electrical power, communications systems, existing fuel sources, and central steam, heating, or chilled water systems, including the tap-in locations. It must also include the available capacities, power service characteristics and locations, electrical distribution, water and wastewater needs or considerations, and the DoD Project Sponsor's intention, if any, for future expansion/construction of these services. Any abandoned utilities within the site footprint shall also be identified.

2-2.6 National Environmental Policy Act (NEPA) Documentation.

Provide a copy of the appropriate level of NEPA documentation as required by the NEPA, or host-nation equivalents for projects outside of the United States. If not completed, provide a plan and timeline for completion, in accordance with requirements of the NEPA.

2-2.7 Force Protection/Security Requirements/Cybersecurity.

The project documentation must include a situation report based on consideration of all applicable threat levels. Reference UFC 4-010-01, UFC 4-020-01, and UFC 4-010-06 for force protection, security, and cybersecurity requirements.

2-2.8 Mission Essential Facilities and Related Requirements.

If a project facility is identified by the hosting Installation as 'mission essential,' the DoD Project Sponsor will coordinate project requirements with the hosting Installation Command. During planning, it must be determined which operations within the facility need to be maintained, and to what extent, under a range of risk situations. The conclusions of this assessment must be documented in the project planning assumptions. Any added facility scope and cost related to 'mission essential' status must be included in the development of the project DD Form 1391.

2-2.9 Contingency Mode Functional Program (where applicable).

During healthcare requirements identification and facility requirements planning, the DoD Project Sponsor must define contingency operations and requirements in a contingency mode functional program. In addition to operational changes required to accommodate increased workload and levels of patient care, strategies to maintain operations over a stated period of time must be clearly stipulated. The impact on patient and staff access, utility services, emergency power availability, water supply, and sewer service must be assessed and included as design requirements.

The Functional Program must address medical mobilization expansion requirements where such temporary measures are included in the contingency mode of operations.

2-2.10 Fire Protection and Life Safety Considerations.

Fire protection and life safety considerations for alteration projects must be based on a completed Life Safety Assessment (LSA) as described in Chapter 14. In projects involving alteration or additions, the limitations of work in the existing areas of the facility must be determined and specifically addressed in the project DD Form 1391. Provide documentation of fire department access, supervision of protected premises, and fire service water supply.

2-2.11 Electrical.

Project document must include a description of exterior electrical power distribution systems covered in Chapter 11. Where exterior electrical service is connected from existing primary feeder, the Designer of Record (DoR) must coordinate with the Design and Construction Agent and receive direction regarding point of connection and concurrence that the existing circuit can support the new facility.

2-2.12 Communications.

Project documentation must include a description of all required systems covered in Chapter 12 to a level enabling development of a programmatic cost estimate. The infrastructure for various digital radiography technologies must be assessed and addressed. An Information System Cost Estimate (ISCE) must be included in DD Form 1391 development.

2-2.13 Commissioning.

Project documentation must include a description of the commissioning requirements for the project as covered in Chapter 19 to a level enabling development of a programmatic cost estimate. During planning, the DoD Project Sponsor must anticipate a requirement for commissioning based on facility and project type and include commissioning in the Budget-Ready DD Form 1391. As applicable, commissioning costs must be estimated during planning using DoD facility cost guidance.

2-2.14 Parking Requirement Calculation.

The DoD Project Sponsor must calculate and report on the 1391, the number of parking spaces including ABA spaces required consistent with the calculation method described in Appendix G and if applicable, the scope for any structured parking, including the number of spaces and where limited by known site restriction with the estimated number of floors (levels) above grade.

2-2.15 Addition-Alteration Facility & Demo Information.

For addition or alteration projects, information must be provided on the type and characteristics of the existing construction, size of the facility, roof and access, condition of utilities and services, existence of code or safety issues, environmental information or surveys, current HAZMAT report, and descriptions of previous alterations or additions of significance.

2-2.16 Safety Risk Assessment (SRA).

Provide predesign project documentation of the initial project-specific patient and staff SRA. These must be conducted by the DoD Project Sponsor. The project-specific SRA must be utilized to determine which design strategies are appropriate for the type of facility, and for incorporation in the project design. See Chapter 3 for SRA process requirements.

2-3 SCOPE AND COST CONSIDERATIONS.

During planning, the DoD Project Sponsor will be comprehensive in anticipating and considering scope and costs resulting from conditions that are applicable to a project. These scope and cost considerations may be based on specific studies or based on typical facility and project types. The scope and costs of such items or conditions must be estimated in the planning DD Form 1391 using DoD facility cost guidance.

2-3.1 Improvement/Alteration/Additions.

The criteria contained herein are not to be used as the sole justification for any addition, alteration, or improvement to an existing facility. These criteria define requirements that must be met when improvement or alterations of existing facilities, or sub-portions or systems thereof, are specifically authorized by reference in the project document, and justified during the above described programming and planning processes.

2-3.1.1 Levels of Facility Alteration.

All costs associated with projects containing altered areas (including the cost of temporary structures if required), **\1** Life Cycle Cost (LCC), **/1/** and other cost impacts must be categorized according to the following definitions:

2-3.1.1.1 Level 1.

Level 1 alterations include minor partition layout changes, new finishes, minor casework and equipment changes, minor modifications to HVAC distribution systems, and minor electrical branch circuit changes. The estimated cost of Level 1 alterations should not exceed 30 percent of replacement cost for the facility.

2-3.1.1.2 Level 2.

Level 2 alterations include Level 1 changes, minor to major partition layout changes with associated modifications to the HVAC distribution systems and electrical power and light requirements, minor structural modifications, new plumbing fixtures, allowances for roof repair, and changes in mechanical system insulation when asbestos is present. The estimated cost of Level 2 alterations should not exceed 50 percent of replacement cost for the facility.

2-3.1.1.3 Level 3.

Level 3 alterations include Level 1 and 2 changes, gutting of the building to structural frame without demolishing floors, exterior walls and roof assembly, modifications to structural frame, main electrical distribution system, air handling units (AHUs) and auxiliary equipment, plumbing system, and energy plant. The estimated cost of Level 3 alterations should not exceed 75 percent of replacement cost for the facility.

2-3.1.2 Cost of Alteration.

When proposed alteration project costs exceed 75 percent of the replacement cost for a facility, and when total facility replacement is feasible, selection of the total facility replacement option will be required.

2-3.2 Site Investigation.

The DoD Project Sponsor is responsible for all facility and site investigations required to generate design and cost impacts for planning and programming. Investigations may include, but are not limited to, inspection of concealed spaces (for example above-ceiling areas, chases, equipment rooms, and other reasonably accessible spaces to permit evaluation and accurate depiction of as-built conditions), environmental material testing or surveys, existing condition drawings and reports, and any other substantial information that would affect cost, scope, or schedule. When all possible, document site investigations with pictures, in particular areas that are confined or that depict complicated conditions.

2-3.3 Interstitial Building System (IBS).

In projects where IBS design concepts are under consideration as part of the base scope of the project, the scope and cost of IBS design concepts must be included as a separate line item in the DD Form 1391 and later updated in the project DD Form 1391. See Appendix E for IBS criteria.

2-3.4 Parking Facilities.

The scope (to include number of spaces) and estimated cost of parking provisions, surface or structured, must be determined during planning and included in the DD Form 1391. Cost of structured parking, appropriate road access and infrastructure must be included as a separate DD Form 1391 line item. DHA-FE is the sole Approving

Authority over Military Medical Facility parking requirements. The MHS parking policies and the standards for calculating parking requirements are located in Appendix G.

2-3.5 Future Expansion.

Consideration for future expansion must be incorporated into planning for all projects. Consider external and internal expansion of vital functions such as ancillary and utility services. Do not locate future expansion in areas that cause significant disruption to the future operations of the facility or significant cost (for example main entry, removal of mechanical rooms). Building site, vehicular access, structural systems, departmental adjacencies, functional layouts within departments, and utility type and source all play major roles in developing an economically expandable design. Provision for future expansion is authorized when approved by the DoD Project Sponsor. The scope and cost of approved expansion capability must be included as a separate line item in the project DD Form 1391.

2-3.6 Special Environmental Conditions.

Consideration must be given to water requirements for the facility, including availability and capacity of Installation water treatment facilities. Identify and provide documentation on Installation or environmental remediation requirements, if any, beyond those described in this document during the initial planning phase of the project, and adequately program associated costs into the budget for the project.

2-3.7 Emergency Power.

Consideration must be given regarding emergency power supply and availability. Identify Installation requirements, if any, beyond those described in this document during the initial planning phase of the project, and adequately program associated costs into the budget for the project. Give consideration to additional supply and availability requirements pursuant to determination of: reliability of power supply; facility Mission Assurance status; and special contingency mode Functional Program. Reference Chapter 11. Scope and cost emergency power supply must be included as a separate line item in the project DD Form 1391.

2-3.8 Antiterrorism/Force Protection (AT/FP).

Identify scope impact during the initial planning phase and adequately program associated costs int DD Form 1391 (reference Chapter 5).

2-3.9 Demolition of Vacated Facilities.

The DoD Project Sponsor must provide a descriptive plan for the disposition and extent of vacated facilities as part of the project planning package and adequately program associated costs into the budget for the project. Provide any documented HAZMAT report or survey data.

2-3.10 Sustainability Considerations.

The scope and cost of sustainable design features must be developed during the planning stage and included in DD Form 1391 (reference Chapter 4). Indicate the applicability of the Guiding Principle requirements and sustainability goals for the project in accordance with UFC 1-200-02. Provide a list of Renewable Energy Technologies that may be incorporated into the design of the facility (line item in the DD1391).

2-3.11 Special Studies.

Include special scope and cost considerations resulting from special facility studies performed prior to design or existing information where required or applicable for:

a. Material Handling and Transportation (reference Chapter 16)

b. Food Service (reference Appendix F)

c. Temporary facilities planned for occupancy during construction

d. Storm water management

e. Hazardous Containing Materials

f. Geotechnical

g. Identification of “Other” unique project requirements:

Identify and coordinate unique project requirements such as Construction restrictions due to airfield/waterfront operations, Explosive Safety Site Approval, base access restrictions, building hardening provisions for seismic, wind, or flood prone areas.

CHAPTER 3 DESIGN

3-1 GENERAL.

This chapter defines DoD Project Sponsor requirements for design procedures, submittals, and documentation. The Design and Construction Agent(s) may establish additional or fewer project-specific requirements in coordination with the DoD Project Sponsor to meet specific project requirements.

3-2 DESIGN CODES AND CRITERIA.

All DoD facilities must comply with UFC 1-200-01. Refer to UFC 1-200-01 for the effective dates for UFCs, codes and criteria. When scope, cost, and schedule permit, the Design and Construction Agent may include new or updated codes and criteria.

3-3 DESIGN PARAMETERS.

3-3.1 Scope and Cost.

3-3.1.1 Documentation.

During Concept Design (0–35 percent) or RFP development, the A/E must produce documentation that meets project requirements and complies with criteria while establishing final project scope and an appropriate Programmed Amount (PA), Design Directive Amount (DDA), or both.

3-3.1.2 Changes.

For projects submitted in the President's Budget or projects with funds appropriated by Congress, the project scope and cost are as stated on the submitted or enacted DD Form 1391. Cost and scope changes to these projects must be processed in accordance with Title 10 U.S.C. Section 2853 by the DoD Project Sponsor. For projects not yet submitted in the President's Budget, there is some flexibility to adjust scope and cost. The degree of flexibility varies with the level of design. Project scope is locked for DBB projects with the 20 percent deliverable and for DB projects with the draft RFP. Project cost is locked for DBB and other delivery method projects with the 35 percent deliverable, and for DB projects with the final RFP.

3-3.1.3 Added project.

In the event a project is added to the MILCON program by Congressional insert, the project scope, cost, and criteria are locked when the DD Form 1391 is submitted to Congress.

3-3.1.4 Functional changes during design.

The most cost-effective time to address functional requirements is during the 20 percent and 35 percent design development process. Functional changes must be addressed

not later than the 35 percent design. Changes to the functional design after 35 percent design dramatically increase cost with redesign work and possibly construction modifications. After the 35 percent design is approved, functional changes must be submitted as a user change request with justification to the DoD Project Sponsor for approval.

3-3.2 Gross Building Area Calculation.

Gross area accounting rules are illustrated in Table 3-1 and Figure 3-1. Gross area tabulation is the square footage measurement used on the project DD Form 1391. The gross area documentation requires calculation of the building gross floor area illustrated with small scale, single-line dimensioned drawings as demonstrated in Figure 3-1. The gross area includes the total area of all floors with a floor-to-clear height of 7 ft (2.1 m) or greater, including those building features listed in Table 3-1. Gross area is measured from the outer-most exterior surfaces of all enclosing walls. Utilize the instructions in Figure 3-1 to calculate the gross building area.

3-3.3 Departmental Building Area Calculation.

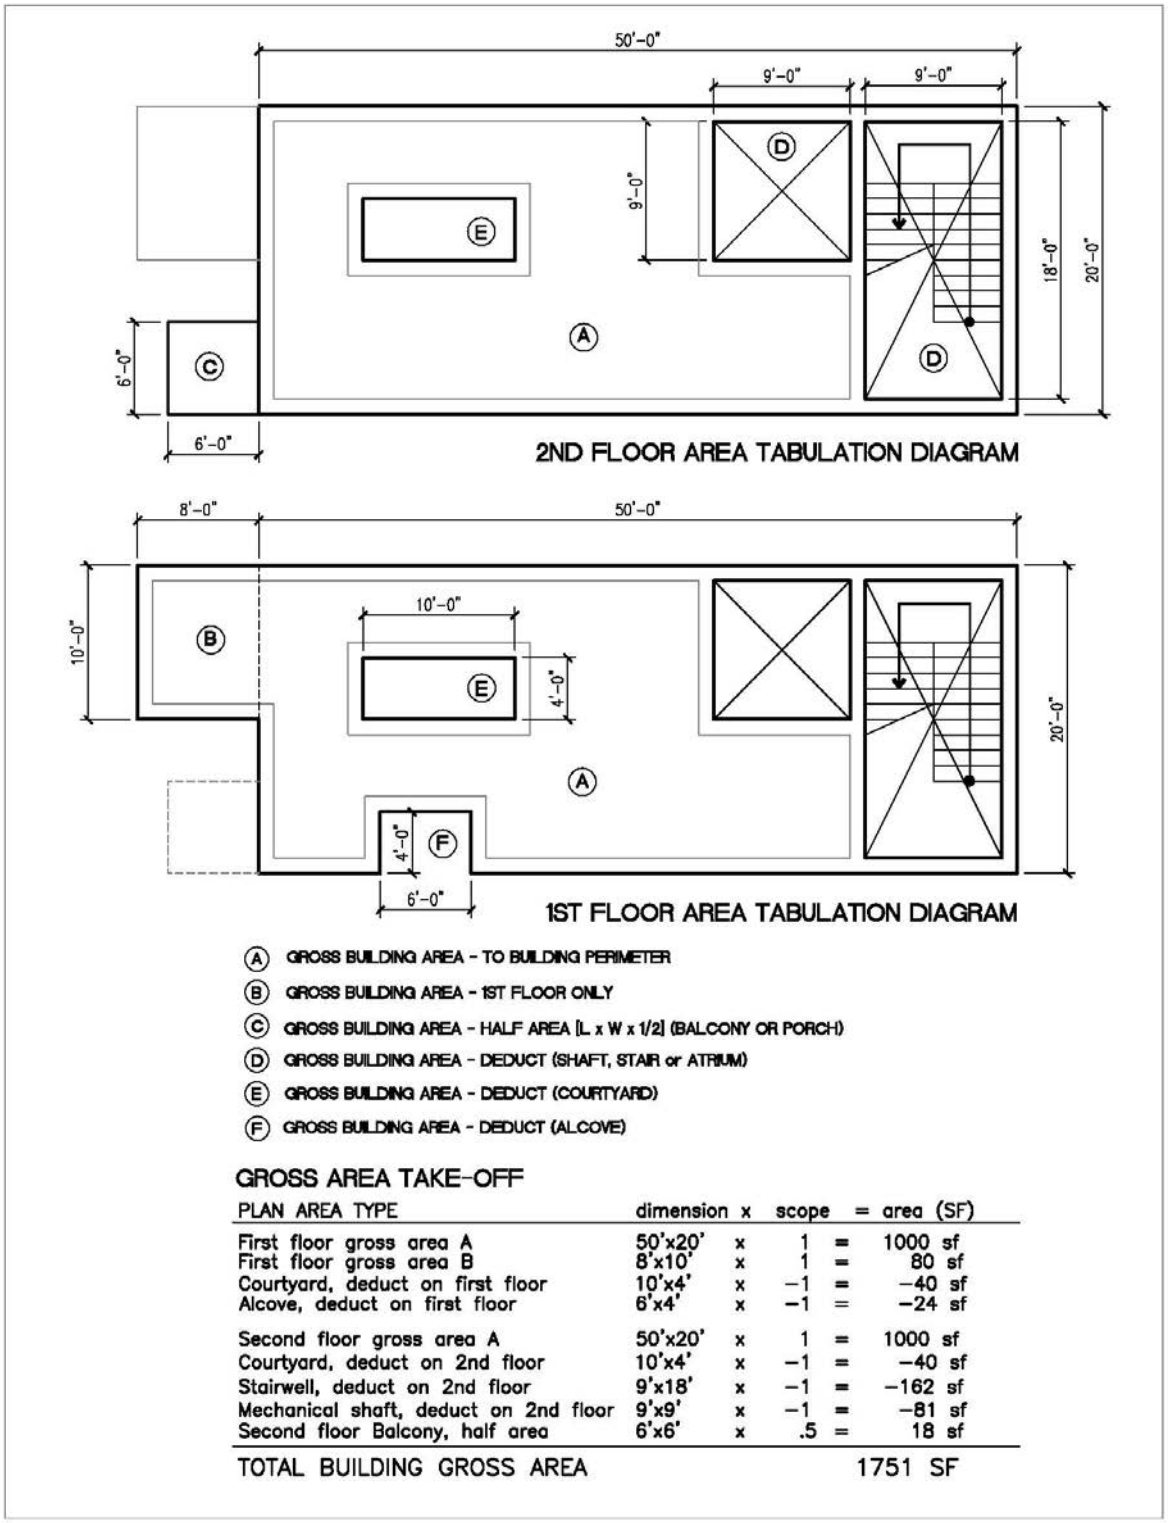
Departmental gross area calculations are illustrated in Figure 3-2. Departmental tabulation is the **\1** area **/1/** measurement associated with the Two-Step Method in the "DoD Space Planning Criteria Chapter 130: Net to Gross Conversion Factors". The Two-Step Method calls for allocating the building gross area between the various departments shown in the project Program for Design and overall building common areas not assigned to a specific department. The gross area rules of Table 3-1 and Figure 3-1 must apply to departmental tabulation. The instructions in Figure 3-2 must be used to calculate the departmental gross areas. A single line diagram must be provided with the design deliverable to clearly convey how the building gross area was proportioned.

Table 3-1 Gross Area Accounting Rules

Building/ Project Feature	Primary/ Supporting Facility Cost	Include in Building Gross Area (DD Form 1391)	Full or Half Area	Comment	Include in Gross Area on Property Record Card (DD Form 1354)
Departmental Scope	Primary	Yes	Full	Included in PFD. Refer to Figure 3-1 Areas A & B	Yes

Building/ Project Feature	Primary/ Supporting Facility Cost	Include in Building Gross Area (DD Form 1391)	Full or Half Area	Comment	Include in Gross Area on Property Record Card (DD Form 1354)
Walls and Partitions	Primary	Yes	Full	Included in departmental gross and circulation grossing factor. Refer to Figure 3-1 Areas A & B	Yes
Ambulance Garage	Primary	No	Full	Authorized when included as separate line on DD Form 1391	Yes
Ambulance Shelter	Primary	No	Half	Authorized when included as separate line on DD Form 1391	Yes
Atrium	Primary	Yes	Full	Included in circulation grossing factor. Count only floor area. Refer to Figure 3-1 Area E	Yes
Attic or Roof Sloping Space	Primary	No	N/A	Unoccupied space only	No
Circulation					
Building Circulation	Primary	Yes	Full	Included in circulation grossing factor. Refer to Figure 3-1 Areas A & B	Yes
Vertical Circulation (elevator shaft, interior stairwells, escalators, lifts, and trash chutes)	Primary	Yes	Full	Included in circulation grossing factor. Count only at one floor in gross area. Net area on subsequent floors must not be included. Refer to Figure 3-1 Area D	Yes

Building/ Project Feature	Primary/ Supporting Facility Cost	Include in Building Gross Area (DD Form 1391)	Full or Half Area	Comment	Include in Gross Area on Property Record Card (DD Form 1354)
Exterior Open Stairs	Primary	Yes	Half	Included in circulation grossing factor. Count only at one floor in gross area. Net area on subsequent floors must not be included. Refer to Figure 3-1 Area D	Yes
Alcove	Primary	No	N/A	Refer to Figure 3-1 Area F	No
Attached Covered but Not Enclosed Walks, Passageways, Ramps, and Canopies	Primary	No	Half	Tabulate scope separately for DD Form 1354	Yes
Unattached Covered but Not Enclosed Walks, Passageways, Ramps, and Canopies	Supporting	No	Half	Tabulate scope separately for DD Form 1354	No
Unattached Roof Overhangs, Soffits for Weather Protection	Supporting	No	N/A		No
Crawl Space	Primary	No	N/A	Unoccupied space only	No
Loading Dock/Logistics					



Building/ Project Feature	Primary/ Supporting Facility Cost	Include in Building Gross Area (DD Form 1391)	Full or Half Area	Comment	Include in Gross Area on Property Record Card (DD Form 1354)
Enclosed Loading Dock	Primary	Yes	Full	Authorized when included on PFD. Refer to Figure 3-1 Areas A & B	Yes
Unenclosed Loading Dock	Supporting	No	Half	Tabulate scope separately for DD Form 1354. Refer to Figure 3-1 Area F	Yes
Mechanical/Electrical/Communications					
Mechanical Space	Primary	Yes	Full	Included in mechanical grossing factor. Refer to Figure 3-1 Areas A & B	Yes
Electrical Space	Primary	Yes	Full	Included in electrical grossing factor. Refer to Figure 3-1 Areas A & B	Yes
Telecommunication Room (TR)	Primary	Yes	Full	Included in electrical grossing factor. Refer to Figure 3-1 Areas A & B	Yes
Enclosed Building Connectors	Primary	Yes	Full	Include in Building Gross Square Feet	Yes
Interstitial Space	Primary	No	Full	Authorized when included as separate line on DD Form 1391 and Life-Cycle Cost justified	Yes
Penthouse with Over 7 ft (2.1 m) Clear	Primary	Yes	Full	Included in mechanical grossing factor	Yes

Building/ Project Feature	Primary/ Supporting Facility Cost	Include in Building Gross Area (DD Form 1391)	Full or Half Area	Comment	Include in Gross Area on Property Record Card (DD Form 1354)
Penthouse with Under 7 ft (2.1 m) Clear	Primary	No	N/A	Excluded from building gross area when the average ceiling height is less than 7 ft (2.1 m) measured from the underside of a structural system and with perimeter walls measuring a minimum of 59 in (1500 mm) in height	Yes
Mezzanines or Platform for Stacking of Logistical Storage and Mechanical Equipment	Primary	No	Full	Tabulate scope separately for DD Form 1354	No
Roof Top Equipment	Primary	No	Full	Unoccupied space	Yes
Roof Top Equipment Maintenance Vestibule with Over 7 ft (2.1 m) Clear	Primary	Yes	Full	Manufacture enclosure integral with equipment for maintenance personnel	Yes
Roof Top Equipment Maintenance Vestibule with Under 7 ft (2.1 m) Clear	Primary	No	N/A	Manufacture enclosure integral with equipment for maintenance personnel	Yes
Pad Mounted Equipment	Support	No	N/A		Yes

Building/ Project Feature	Primary/ Supporting Facility Cost	Include in Building Gross Area (DD Form 1391)	Full or Half Area	Comment	Include in Gross Area on Property Record Card (DD Form 1354)
Mechanical and Utility Shafts Connecting Two or More Floors	Primary	Yes	Full	Included in mechanical/electrical grossing factor. Count only at one floor in gross area. Net area on subsequent floors must not be included. Refer to Figure 3-1 Area G	Yes
Central Utility Plant	Primary	No	Full	Tabulate scope separately for DD Form 1354 when authorized as separate line on DD Form 1391	No
Internal Pump and Utility Rooms (for example fire pump, bottle gas storage)	Primary	Yes	Full	Fire pump room is included in mechanical grossing factor. Other rooms may be included unless specifically included in a department within the PFD, whereas bottle gas storage is included in departmental scope	Yes
External Pump House and Utility Buildings (for example sewage lift station)	Supporting	No	Full	Tabulate scope separately for DD Form 1354	No
Utility Tunnels	Supporting	No	N/A		No

Building/ Project Feature	Primary/ Supporting Facility Cost	Include in Building Gross Area (DD Form 1391)	Full or Half Area	Comment	Include in Gross Area on Property Record Card (DD Form 1354)
Equipment Yards	Supporting	No	N/A		No
Other					
Exterior Balconies	Primary	Yes	Half	Tabulate scope separately for DD Form 1354. Refer to Figure 3-1 Area C	Yes
Exterior Sun Shades	Primary	No	N/A		No
Courtyard	Supporting	No	N/A		Yes
Exterior Ramp, Stoops, and Pads	Supporting	No	N/A		No
Attached Roof Overhangs, Soffits for Weather Protection	Primary	No	N/A		No
Green Roof and Roof Top Healing Gardens and Unenclosed Roof Terraces	Supporting	No	N/A		No
Smoking Shelters	N/A	N/A	N/A	Not authorized	No

Figure 3-1 Instructions for Preparing Gross Area Tabulation

GROSS AREA TAKE-OFF

PLAN AREA TYPE	dimension	x	scope	=	area (SF)
First floor gross area A	50'x20'	x	1	=	1000 sf
First floor gross area B	8'x10'	x	1	=	80 sf
Courtyard, deduct on first floor	10'x4'	x	−1	=	−40 sf
Alcove, deduct on first floor	6'x4'	x	−1	=	−24 sf
Second floor gross area A	50'x20'	x	1	=	1000 sf
Courtyard, deduct on 2nd floor	10'x4'	x	−1	=	−40 sf
Stairwell, deduct on 2nd floor	9'x18'	x	−1	=	−162 sf
Mechanical shaft, deduct on 2nd floor	9'x9'	x	−1	=	−81 sf
Second floor Balcony, half area	6'x6'	x	.5	=	18 sf
TOTAL BUILDING GROSS AREA					1751 SF

Note: 1000 sf = 92.9 sm

3-3.3.2 Measuring instructions.

3-3.3.2.1 Terms.

This chapter uses Net Square Feet (NSF), Departmental Gross Square Feet (DGSF), and Building Gross Square Feet (BGSF) as defined in DoD Space Planning Criteria Chapter 130.

3-3.3.2.2 Departments.

Space and Equipment Planning System (SEPS) provides Net Area for specific rooms in a facility. Rooms are grouped into individual departments, such as Physical Therapy, Pharmacy and Common Areas. Some rooms in individual departments are not intended to be co-located and may be located outside of the general department area. Specific common area rooms, intended to be distributed throughout the facility, are combined in the Common Areas Department.

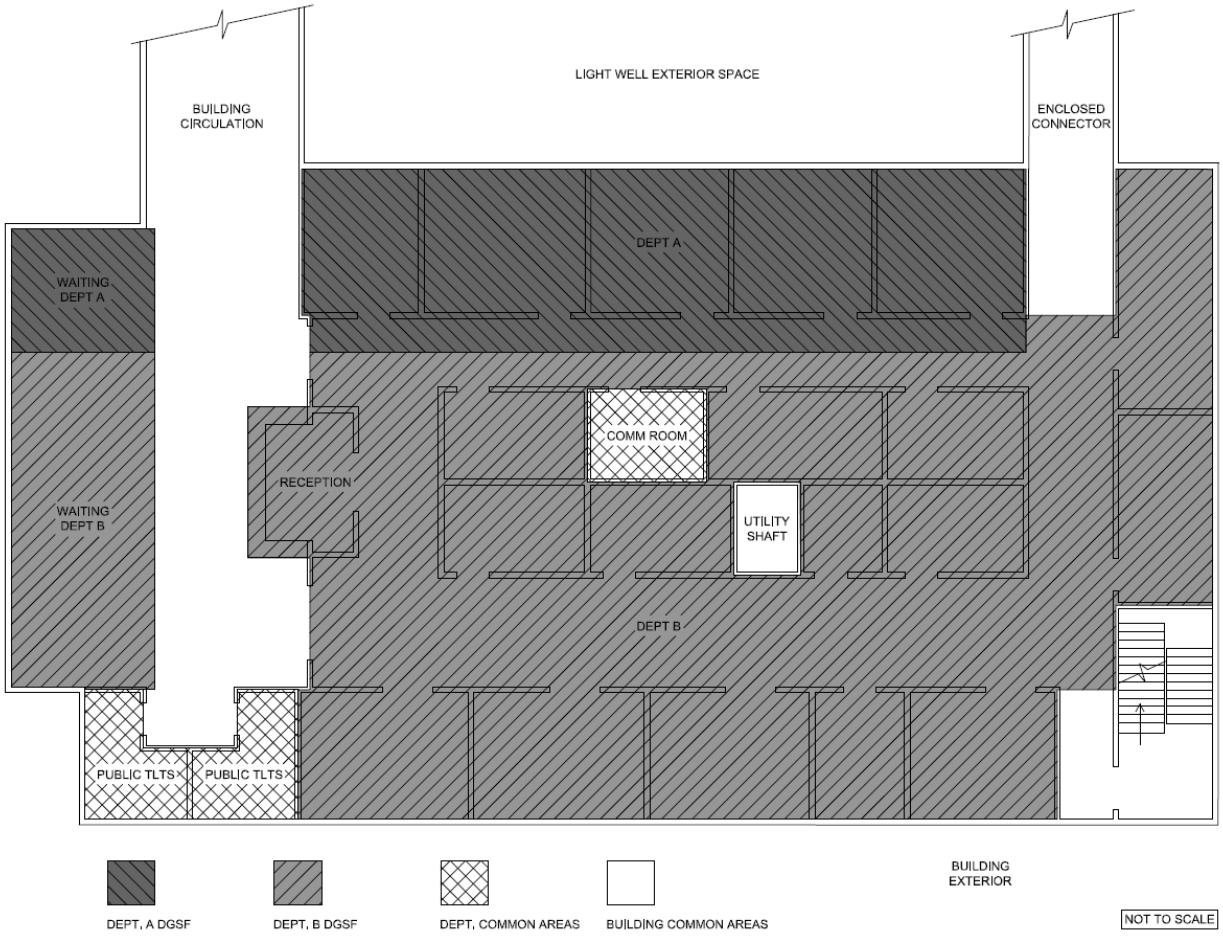
3-3.3.2.3 Departmental grossing factor.

SEPS applies a unique departmental grossing factor to departmental NSF to determine DGSF, which includes area of the rooms defined in the individual department, internal circulation, and interior walls/partitions. DGSF includes half of the wall thickness between other departments but does not include exterior walls.

3-3.3.2.4 Building grossing factor.

SEPS applies a building grossing factor to the sum of all DGSFs to determine the BGSF. The BGSF includes all areas within the exterior skin of the building according to the gross area rules of Table 3-1 and Figure 3-1. It includes all departmental areas and areas not specifically defined in the PFD, such as public corridors, building circulation, atria, walls/partitions, mechanical and electrical spaces, vertical circulation, and shafts.

3-3.3.2.5 Common area rules.



Departmental and Building Common Area rules are defined in Figure 3-2. The following are additional examples and rules:

a. Pro-rating example for shared room: **\1** Department A Waiting net area is defined as 100 sf (9.3 sm) and Department B Waiting net area is defined as 50 sf (4.6 sm) in the PFD. The as designed waiting net area is 120 sf (11.1 sm). The pro-rated net areas for Department A Waiting is 120*(100/150) = 80 sf (11.1*(9.3/13.9) = 7.4 sm) and for Department B Waiting is 120*(50/150) = 40 sf (11.1*(4.6/13.9) = 3.7 sm). **/1/**

b. For facilities that have multiple CATCODES specified in the project 1391: Dedicated Building Common Areas must be assigned to the respective CATCODE. Shared Building Common Areas must be prorated to each CATCODE at the designer's discretion, with the basis for pro-rating used

to determine the appropriate accounting of area to CATCODE being provided.

Figure 3-2 Instructions for Preparing Departmental Gross Area Calculations

Notes for Figure 3-2

1) Individual departmental gross area includes individual rooms in a department, corridors and walls within a departmental area, and half of the common wall shared with other departments and/or building common areas.
2) Shared walls between departments and/or building common areas shall be measured from the centerline of the wall.
3) For areas without partitions such as waiting areas, use the assigned floor area of the furniture seating area, or building feature (i.e. change in flooring or ceiling).
4) For rooms that are shared by multiple departments, pro-rate the area based on the individual departmental PFD areas that are combined.
5) For corridors that feed two or more rooms from two departments, assign half of the corridor to each department. For single rooms from a different department, the corridor will be assigned to the larger department.
6) The Common Areas Department includes telecommunication rooms, janitor closets, public toilets and other common rooms as identified on the PFD. These distributed areas shall be reported on the Net Area Tabulation sheet back to the Common Areas Department rather than the department where they are located on the floor plate.

3-3.4 Design to Cost.

During the final design phase (35 percent through 100 percent design completion) for DBB projects, the A/E must produce a set of construction documents within the PA, DDA, or both, established at Concept Design approval. If design requirements or refinements cause the estimated project cost to exceed the established PA or DDA, the Design and Construction Agent must present cost adjustment or reduction alternatives to the DoD Project Sponsor before completing the design documents.

For DB projects, cost is established at construction contract award. No cost updates are required to the DoD Project Sponsor post construction award.

3-4 DESIGN SEQUENCE AND RESPONSIBILITIES.

Detailed design submission requirements, including sequence, submittals, and documentation, are provided in Appendix C.

3-4.1 Title 10 U.S.C. Section 2807 Action.

The Design and Construction Agent is responsible for providing the estimated A/E design contract and other design costs and schedule to the DoD Project Sponsor for inclusion in Block 12 supplemental data on DD Form 1391. Using this estimate, the DoD Project Sponsor will determine if a project requires notification to Congress in accordance with Title 10 U.S.C. Section 2807. The DoD Project Sponsor personnel must notify the Design and Construction Agent when the notification letters have been signed and the date after which the contract can be awarded, and forward copies to the appropriate personnel. The Design and Construction Agent is required to strictly adhere to the statute and not obligate funds for design until the 14-day Section 2807 waiting period has expired.

3-4.2 Design Authorization (DA).

The DoD Project Sponsor will issue the DA to the Design and Construction Agent as appropriate to meet design and programming milestones. The Design and Construction Agent must manage design in accordance with established policies and procedures unless otherwise coordinated with the DoD Project Sponsor. The Design and Construction Agent must not pursue any level of design beyond that authorized by the DoD Project Sponsor.

3-4.3 Authorization to Advertise Construction.

The Design and Construction Agent must provide a Current Working Estimate (CWE) worksheet and the final design or RFP to the DoD Project Sponsor to request authorization to advertise the construction contract. Bid options must be clearly delineated on the CWE worksheet. The DoD Project Sponsor will notify the Design and Construction Agent when the project is approved for advertising.

3-4.4 Authorization to Award Construction.

The Design and Construction Agent must provide a CWE worksheet based on the latest construction estimate and bid results, accepted bid options, and other information the DoD Project Sponsor requires when Title 10 U.S.C. Section 2853 notification is required. When Title 10 U.S.C. Section 2853 action is complete, the DoD Project Sponsor will notify the Design and Construction Agent that the project is approved for award.

3-5 REVIEW OF DESIGN DELIVERABLES, ROLES, AND RESPONSIBILITIES.

3-5.1 Design and Construction Agent.

The Design and Construction Agent is responsible for executing the A/E and contractor's contract. They are also responsible for the overall design development, review of all design deliverables for contract compliance in accordance with codes, criteria; project design is in accordance with authorized project scope, cost, and schedule; the design incorporates best value design and construction practices; reviews for constructability; cost schedule risk analysis and mitigating strategies; development and review construction contract documents in accordance with approved acquisition strategy; incorporated accepted design review comments, ensures the designer complied with the approved quality control practices, and practices good stewardship of Government resources.

3-5.2 Installation Manager.

The Installation Manager is responsible for reviewing design deliverables for compliance with environmental requirements (NEPA), storm water management, and various permits; meeting the intent of the Installation master plan and exterior architectural standards; connection to the existing infrastructure and maintainability of the infrastructure utility systems; Installation force protection, traffic, fire protection, security standards; and real property transfer (DD Form 1354).

3-5.3 DoD Project Sponsor.

The DoD Project Sponsor is responsible for reviewing design deliverables for project planning and functional requirements (spaces, contents, finishes, departmental adjacencies, ability to support the flow of patients and logistics within facility and its compliance with the design concept of operations) to meet the medical program requirements; clarification of medical unique criteria; maintainability of the design solution; utility connection for medical equipment and suitability for initial outfitting; making notifications to Congress when design deviates from prior notifications; reviewing the design deliverables for compliance with the DD form 1391 and, project scope, criteria, and schedule. They are also responsible for the initial outfitting and transition (IO&T) of the facilities. They may comment on other aspects of the design deliverables.

3-6 REPORTING REQUIREMENTS.

The Design and Construction Agent must report project data as required in the Title 10 U.S.C. Section 2851 Monthly Report to the DoD Project Sponsor.

3-7 DESIGN CONSIDERATIONS.

3-7.1 General.

All design elements, including functional, architectural, electrical, energy, fire protection and life safety, mechanical, structural, Safety Risk Assessment (SRA), and other features, must be coordinated.

3-7.1.1 Dedicated Administrative Area.

When directed by Design Authorization in coordination with the Design and Construction Agent, administrative buildings and separate administrative suites (no internal spaces will be considered), and training buildings, which are not intended to flex into clinical (refer to the Functional Program) should use the technical requirements of UFC 1-200-01 General Building Requirements and not additional requirements of this UFC (cable trays, plenum returns, etc.).

3-7.1.2 Interstitial Building System (IBS).

The DoD Project Sponsor approval for the use of IBS design, and whether the DoD system module or alternate non-DoD system module concept design is used, must be made no later than the 20 percent submission and must include consideration of the required economic comparison with conventional design. See Appendix E for IBS criteria.

3-7.1.3 Safety.

The DoR must follow the concepts from the most current ANSI/ASSP Z590.3: Prevention through Design Guidelines for Addressing Occupational Hazards and Risks in Design and Redesign Processes. Through the application of Prevention through Design concepts, decisions pertaining to occupational hazards and risks can be incorporated into the process of design and redesign of work premises, tools, equipment, machinery, substances, and work processes including their construction, manufacture, use, maintenance, and ultimate disposal or reuse. This standard also provides guidance for a life-cycle assessment and design model that balances environmental and occupational safety and health goals over the life span of a facility, process, or product.

All DoD facilities must comply with DoDI 6055.01 and applicable Occupational Safety and Health Administration (OSHA) safety and health standards.

3-7.1.4 Equipment Room Locations.

The DoD Project Sponsor's preference is to locate mechanical, and electrical equipment rooms with exterior at grade access. Major equipment rooms must have exterior access with paved surfaces for wheeled transport of equipment. Provide horizontal and vertical access to interior, below-grade, or upper-level equipment rooms including transport of the largest items of equipment that may require replacement. Equipment rooms must be designed so the largest serviceable part of equipment can be transported in/out of the building. This includes transporting the equipment without voiding warranties or reducing the end-state performance of the equipment.

3-7.1.5 Distribution Equipment Space Clearances.

Provide the greater of manufacturer recommended maintenance and design criteria clearances in accordance with Chapter 9, Chapter 10, Chapter 11, and Chapter 12.

3-7.1.6 Utility Distribution Considerations.

Locate service isolation and balancing devices and terminal equipment that require periodic inspection or maintenance above corridors.

3-7.2 World-Class Checklist.

A project-specific checklist must be developed and provided in accordance with Appendix C. If the DoR is unable to incorporate a mandatory feature, justification must be included in the 35 percent design submittal.

3-7.3 Functional Program During Design.

During concept design, the design phase portion of the Functional Program is finalized by the Project Delivery Team. This document provides a departmental and area-specific narrative and graphic that documents what functions the organization envisions inside a facility as well as how those functions operate. It is a concise but detailed description of the projected operation of the facility that pulls together information concerning the mission and organizational purpose, types of services being performed, and patient and staff "flow" throughout the spaces. It may include the functional description of the spaces, special requirements specific to those spaces, and adjacency requirements within and among the various departments and clinics. The document depicts the routine, daily actions of staff and patients, the flow of supplies, the use of equipment and all other pertinent functions within the building. Refer to Appendix C for the functional narrative required in the 35 percent Design Analysis. For DB projects, the designer preparing the RFP documents may assist in the Functional Program development and ensure the RFP documents are coordinated with the Functional Program.

3-7.4 Parking.

Patient and staff parking guidance is provided in Appendix G. The amount of parking required is determined using the parking formulas provided. Design must ensure ease of patient access.

3-7.5 Future Expansion.

Provide external horizontal building expansion of 20% of the enacted DD Form 1391 gross building area divided by the number of number of floors within the project unless the project requirements state otherwise. Departments most likely to be expanded or converted for future adaptation need be located adjacent to the expansion zone or internal soft spaces.

The tenets of flexibility are:

a. Select sites wherever feasible and plan for the ability for expansion, horizontal and or vertical.

b. Facilities should have the capacity for adaptation and for possible conversion to alternative use.

c. Ensure continuous high-performance facilities by separating building components and systems for maintenance, according to their expected technical or utility lifespan.

d. Consider the potential impacts of future horizontal and vertical expansions on adjacent spaces, departments, chases, utilities, structure, and all other important features of the facility.

3-7.6 Alterations and Additions to Existing Facilities.

For alteration and building addition projects, the A/E must conduct thorough investigations of existing facilities to become knowledgeable of facility conditions. The A/E must establish the existing condition and characteristics of each affected facility to include: utilities and services, systems, existence of code and life safety issues, construction type, requirements for maintaining a secure environment, and infection control as they pertain to the design, construction, and phasing of the work. These investigations and their impact on design of facility alterations and additions must be described in the project design documents.

Alterations to existing equipment and systems, including temporary connections, changes to system performance, or measures necessary to sustain service, must also be shown and described in detail in the project design documents. The A/E must evaluate the impact on existing systems where connections are made that increase overall system demand. The locations of new connections must clearly be shown, described, or both. The A/E must determine and document any project work that must necessitate a reduction or interruption of any service to an existing occupied space.

3-7.7 Safety Risk Assessment.

A Safety Risk Assessment (SRA) must be applied from the programming phase through construction to guide, inform and aid in incorporation of risk based safety practices into each MILCON project. The SRA must be that developed by the Center for Health Design. It must be utilized to determine which design strategies are appropriate for the type of facility, and for incorporation in the proposal and design. A project-specific SRA must be submitted in accordance with Appendix C. The SRA must be initiated by the DoD Project Sponsor during the planning phase of the project. Management of the SRA must be the responsibility of the A/E of record as the SRA continues to evolve with additional levels of detail as needed to support the creation of a safe environment throughout the design, construction, and commissioning phases.

3-7.8 NFPA 99 Risk Assessment.

A NFPA 99 Risk Assessment for Risk Category, Space Category, and Building System Category must be developed and provided in accordance with Appendix C.

3-8 PROJECT COST ESTIMATES.

The Design and Construction Agent must review and approve all construction cost estimates. Construction cost estimates must separate the costs by the type of appropriations.

Cost estimates for building systems developed during design must include the costs associated with providing the Real Property Installed Equipment (RPIE) and the infrastructure to support Personal Property (PP). RPIE and PP is further defined in Chapter 15.

3-9 FUNDS MANAGEMENT POLICY.

3-9.1 Title 10 U.S.C. Section 2853 Action.

The Design and Construction Agent must provide the CWE to the DoD Project Sponsor with their request for authority to award a construction contract. When a project requires notification to Congress in accordance with Title 10 U.S.C. Section 2853, the Design and Construction Agent must plan for and allow at least four weeks to complete the Congressional Notification process prior to the desired award date. The DoD Project Sponsor will notify the Design and Construction Agent when the Congressional Notification correspondence is within 14 days of being complete so that a contract award may be made.

When a project requires reprogramming action in accordance with the applicable MILCON Appropriations Act, the Design and Construction Agent should allow three months prior to the desired award date after additional funds are secured. Projects that are authorized and appropriated through non-standard MILCON funding, such as Supplemental Appropriations or Base Realignment and Closure (BRAC), may require additional notification time so the DoD Project Sponsor can complete unique notification

and coordination requirements. DoD Project Sponsor personnel must notify the Design and Construction Agent when the notification letters have been signed, and forward copies to appropriate personnel. The Design and Construction Agent is required to strictly adhere to the statute and not obligate funds for award until the waiting period has expired.

3-9.2 Return of Excess Funds.

At the DoD Project Sponsor's request, the Design and Construction Agent must return any cost savings (difference between project funds allocated and award CWE) to the DoD Project Sponsor.

3-10 HISTORICAL ANALYSIS GENERATOR (HAG) DATA.

The Design and Construction Agent is responsible for loading construction contract award data into the HAG (also known as HII) database within 30 days of contract award. (Refer to the Historical Analysis Generator website.) These data are used to generate historical Guidance Unit Costs (GUCs) for publication in UFC 3-701-01, in accordance with the latest version of UFC 3-730-01.

CHAPTER 4 SUSTAINABLE DESIGN PRINCIPLES

4-1 GENERAL.

This chapter supplements UFC 1-200-02 High Performance and Sustainable Building Requirements by describing requirements and developing uniformity specific to applicable facilities.

4-2 DESIGN PROCESS.

Analyze LCC effectiveness in support of the military medical mission, to include first cost, energy consumption, annual O&M, and other associated direct costs when evaluating sustainable design features and systems. Prioritize sustainable features that have the highest potential for cost-effective implementation. Do not de-scope sustainable design elements that have been shown to be LCC effective to reduce cost.

4-3 SUPPORTING DOCUMENTS.

Supporting documents include DoD Project Sponsor and Design and Construction Agent publications and regulations including sustainable design policies applicable to DoDM projects, Medical Design Instructions (MDIs), Engineering Technical Letters (ETLs), project-specific design instructions, engineering and construction bulletins, and other DoD-related criteria.

This Page Intentionally Left Blank

CHAPTER 5 ANTITERRORISM (AT) AND PHYSICAL SECURITY

5-1 GENERAL.

This chapter provides facility design criteria and guidance for antiterrorism, physical security, and crime prevention. These programs are intended to protect assets: people, facilities, and equipment from terrorism and other hostile manmade threats.

5-2 ADDITIONAL CRITERIA.

The Planning Team uses UFC 4-020-01 DoD Security Engineering Planning Manual, to develop the security and AT requirements. UFC 4-020-01 and the multiple supporting AT UFCs referenced by UFC 4-020-01 implement the facility requirements of DoD Instruction (DoDI) 2000.16, for new and existing construction. This criteria provides minimum construction requirements which must be incorporated in inhabited new construction and major renovations projects. See additional regulatory requirements for physical security of controlled substances in 21 CFR 1301.72. AT and physical security systems required by this chapter must also comply with NFPA 101.

5-3 DESIGN CRITERIA PLANNING TEAM.

Ensure appropriate key personnel are identified and are represented to ensure their varied interests relating to security and AT requirements are included. The specific membership of a planning team will be based on local considerations, but the following functions must be represented; facility user, engineer, security, intelligence, and Antiterrorism Officer.

5-4 ELECTRONIC SECURITY SYSTEMS (ESS).

5-4.1 Purpose.

Provide an ESS utilizing various combinations of capabilities for Access Control Systems (ACS), Duress Alarm Systems (DAS), Infant Protection Alarm System (IPAS), Intrusion Detection Systems (IDS), Video Surveillance system (VSS), Behavioral Health Staff Assist (BHSA) Alarm system, and photo badging. Refer to Chapter 12 for additional information and requirements for communication supporting infrastructure and interoperability.

5-4.2 Systems Considerations.

ESS is an integrated electronic system that encompasses interior and exterior ACS, DAS, IPAS, IDS, VSS, BHSA Alarm system, and photo badging. An assessment of ESS alarm systems requirements must be conducted for facilities in accordance with the project Functional Program and in coordination with the DoD Project Sponsor. Multiple ESS components may be integrated to provide an overall facility security system.

5-4.2.1 Stand-Alone Clinic Facilities Projects.

For stand-alone clinic facility projects, provide ESS with all the capabilities identified for ACS, DAS, IDS, VSS as appropriate for the services noted in the project Functional Program. Project-specific criteria must be fully coordinated with the DoD Project Sponsor.

5-4.2.2 Inpatient Facility Projects.

For inpatient MTF projects, provide an ESS with all the capabilities identified herein as a turn-key system that is networked together for a totally integrated ESS for the facility. An interface with the facility Radio Page (RP) System or other wireless personal communications device must be included (reference Chapter 12) so alarm events can be communicated to the facility security staff (for quick response), and the facility NTS System (reference 12-5, Network Time Synchronization System).

5-4.3 ESS Components and Funding Restrictions.

The systems and equipment items listed here require Proponent funds to purchase and install the items. The construction project can fund all infrastructure and utility support. Therefore, a listing for separate line-item funding and accounting is required for these items. The Military Interdepartmental Purchase Request (MIPR) of Proponent funding to the contracting agency is required to pay for the totally integrated ESS that must be provided as a turn-key system from a single qualified ESS contractor. Refer to MIL-STD-1691 Table 6-1 Systems Planning Matrix for property type designations for the ESS System and its subcomponents.

5-4.3.1 ESS: Access Control System (ACS).

Reference UFC 4-021-02 Electronic Security Systems for components and requirements associated with the ESS: Access Control System.

5-4.3.2 ESS: Duress Alarm System (DAS).

Reference UFC 4-021-02 Electronic Security Systems and Table 5-1 for components and requirements associated with the ESS: Duress Alarm System. Reference Appendix A for details on the functionality and requirements associated with the BHSA Alarm system.

This proponent-funded duress alarm equipment is not included as part of the door access control system.

5-4.3.3 ESS: Infant Protection Alarm System (IPAS).

Infant Protection Alarm System is required for all Medical Facilities with Pediatric Units, Labor and Delivery Units, Obstetric Units, Neonatal ICUs. Coordinate expansion of the IPAS to cover additional inpatient Units, as noted in 5-4.9 and per the project Functional Program.

5-4.3.4 ESS: Intrusion Detection System (IDS).

Reference UFC 4-021-02 for components and requirements associated with the ESS: Intrusion Detection System. Also reference Table 5-1for intrusion detection locations and component types.

5-4.3.5 ESS: Video Surveillance System (VSS) Equipment.

Reference UFC 4-021-02 for components and requirements associated with the ESS: Video Surveillance System. UFC 4-021-02 refers to this system as CCTV.

5-4.3.6 ESS: Behavioral Health Staff Assist (BHSA) Alarm System.

Reference Appendix A for details on the functionality and other requirements associated with BHSA Alarm system and the associated Duress Alarms for Behavioral Health inpatient and outpatient settings.

5-4.4 System Configuration and Major Functional Components.

Major functional components include but are not limited to:

a. ESS network
b. Intrusion detection and alarm system
c. Door access control system
d. Video surveillance system
e. Infant Protection alarm system
f. Behavioral Health Staff Assist alarm system

Major interfaces in inpatient MTFs include:

a. Interface with Radio Page (RP) Systems (reference 12-11)
b. Interface with Network Time Synchronization (NTS) System (reference 12-5)

5-4.5 ESS Network.

Provide an independent, dedicated, industry-standard network with DISA and DoD Project Sponsor standard LAN technology, protocols, equipment, and cabling to interconnect all provided electronic security capabilities into an integrated ESS in support of facility-wide security requirements and operations. During design consider all outlying medical buildings using the hospital ESS Network for Access Control. The facility Information System network must not be used for ESS networking:

a. As an independent, stand-alone network, the application design must incorporate the requirements of the DHA Cybersecurity Guidance for Facility-Related Control Systems (FRCS) and Medical Device and

Equipment (MDE) in support of the Risk Management Framework (RMF) process outlined in Chapter 12. This must include the system network architecture, software, hardware, and security requirements.

b. Servers and workstations must meet standardized baseline requirements and specifications as defined by DISA and DHA. Servers and workstations must utilize the most current DoD approved operating system and must provide central databases for all the operating systems, application programs, and data logging. In hospitals and medical centers which have an onsite Radio Page System and/or other wireless networked personal communication devices, the ESS network must also provide an interface with these facility systems to communicate security events to the staff.

c. Network Infrastructure (switches, routers, etc.) must meet the standard baseline specifications as defined by DISA and DHA. When possible, network electronics must match NiPR infrastructure for patch management and network administration.

5-4.5.1 Integrator Network Major Components.

The ESS integrator network must be configured as a Client Server network with the major components listed here to serve all the specified capabilities:

a. LAN and infrastructure

b. Database servers

c. Digital video servers and digital video recorders

d. System Operator Workstations

e. Management Workstation

f. Maintenance Workstation

g. System software

5-4.6 Intrusion Detection and Duress Alarm.

5-4.6.1 Sensors and Locations.

Intrusion detection and duress alarm locations and sensor types are as indicated in Table 5-1. Table 5-1 is provided for guidance. Specific design must be in accordance with the project Functional Program.

Table 5-1 Intrusion Detection and Duress Alarm Locations and Sensor Types

Location	Balanced Magnetic Switch	Motion Detector	Duress Alarms
Inpatient and Outpatient Pharmacy	X	X	
Inpatient and Outpatient Pharmacy dispensing Window(s) and consult rooms	X	X	X
Reception and Nurse Stations			X
Pharmacy Vault and vault-based equipment	X	X	
Food Service Account Office	X	X	X
Cashier Locations	X	X	X
Logistics Vault	X	X	
Logistics Warehouse	X	X	
Silver recovery central Collection point	X	X	
Behavioral Health			X*
Admissions Cubicles			X
Command Office			X
*This includes both inpatient and outpatient Behavioral Health settings. See Appendix A for locations of Duress Systems equipment and operational requirements in Behavioral Health settings.			

A balanced magnetic switch must be placed on each door or window of locations indicated in the Functional Program and Table 5-1 as requiring balanced magnetic switches and that could provide access. The motion detector must cover the entire area being protected. Locate the motion detectors in coordination with the systems furniture and equipment. Video surveillance monitoring and recording must be activated by the intrusion detection and duress alarms unless the cameras are recording 24/7/365 and meet recording period capacity as required by the DoD Project Sponsor for forensic purposes. The intrusion detection and duress capability design must follow the DoD

Project Sponsor regulations and other applicable specifications and be coordinated with the facility and Installation security staffs.

5-4.6.2 Remote Alarm Reporting.

Any combination of intrusion or duress alarms that requires immediate military police response must be communicated to the Installation Security Office. For the implementation of this function, provide an interface to the existing Installation ESS network. The system contractor must field coordinate the exact configuration and location of this interface with the Installation Security Office.

The selection of alarms to be routed to the Installation Security Office must be under software control from the facility ESS Management Operator Workstation. The initial list of alarms to be programmed for remote reporting at the time of facility ESS activation must be coordinated with the Contracting Officer.

5-4.7 Door Access Control.

Provide electronic door access control capability, as a minimum, at the locations listed here and as required by the project-specific criteria. The capability must:

a. Provide for addition of access authorization to CAC cards as the primary access control card; and

b. Include photo badging equipment to produce access control cards, and a Management Workstation to issue access cards, when CAC card usage is not feasible; and

c. Generate and maintain a listing of current authorized access by individual, location, and time; and

d. Discontinue access authorization for issued cards. Monitor and control of door access activity and events must utilize the integrator network Workstations. Where required, provide an interface between the video surveillance and the door access control capabilities to initiate video monitoring and recording of surveillance cameras anytime these doors are opened unless an authorized access control card has been read by the card reader or an authorized personal identification number (PIN) is entered in an access control keypad. This must be as further defined herein in paragraph 5-4.8.

A staff identification card system with multiple levels of access control may be provided.

5-4.7.1 Access Controlled Door Locations.

Electronic door access control devices must, as a minimum, be provided at these locations:

a. All building exterior doors, including doors to the first floor mechanical and electrical equipment rooms

b. Each door between waiting areas/general circulation corridors to clinical spaces

c. Each storage room entrance door

d. Each Pharmacy entrance door

e. Each Pharmacy vault door

f. Server Room Support Equipment (CMP04) door

g. Each Cashier Office door

h. Each Behavioral Health Unit entrance door

i. Command suite entry door

j. All Telecommunication Room doors

k. Service Entrance Facility (COMC2) door

l. Server Room (CMP01) door

m. Communications Radio Equipment (COM04) door

n. Penthouse equipment room door

o. Each staff locker room door

p. Inpatient Records room door

q. Outpatient Records room door

r. Multimedia equipment room door

s. Security Department entry doors

t. Medication Rooms

u. Mail Room

v. Select elevators as directed by the DoD Project Sponsor

w. Additional locations must be as directed by the DoD Project Sponsor

5-4.7.2 Door Access Control Major Components.

Reference UFC 4-021-02 for components and requirements associated with the ESS: Access Control System. Major components of the door access control system are listed in UFC 4-021-02.

5-4.8 ESS: Video Surveillance System (VSS).

The provided video surveillance capability must perform functions for capturing, viewing, controlling, monitoring, and recording of video surveillance scenes for specified locations throughout the facility and site. Operation for monitoring and control functions for video surveillance must take place at system integrator network Operator Workstations. Where required, all images from all video cameras must be digitally recorded on video camera servers at all times. Provide as many video camera servers

as are required for recording all images from all video cameras. Recording parameters, to include frame rate, resolution, and record duration, must be as specified by the DoD Project Sponsor and verified by the system contractor. All alarms routed over the ESS integrator network must be received and processed for automatic initiation of special video monitoring and recording protocols for the alarm event point and a designated zone associated with the alarm event point.

5-4.8.1 Color Video Camera Coverage.

Color video images of surveillance scenes from points throughout the facility and site must include but not be limited to these locations:

a. Main Entry Lobby area
b. Ground level Elevator Lobby area
c. Mechanical Room door
d. Cashier Office
e. Cashiers locations in food service and Installation exchange
f. Vaults
g. Entrances and exits from the Labor and Delivery (L&D) Unit, NICU, Pediatric and Behavioral Health Units
h. Server Room Support Equipment (CMP04) door
i. Service Entrance Facility (COMC2) door
j. Server Room (CMP01) door
k. Communications Radio Equipment (COM04) door
l. Emergency Waiting areas
m. Emergency Walk-In Entrance and Reception
n. Ambulance dock and entry area
o. Corridors connecting buildings
p. Pharmacy dispensing windows and Waiting Area
q. Pharmacy narcotic counting & prescription preparation area
r. Main and secondary building entrances and exits
s. Service elevator lobbies
t. Loading docks and dock dumpster areas
u. All Parking Lot areas
v. Inpatient Behavioral Health outdoor areas
w. Additional locations must be as directed by the DoD Project Sponsor

All other locations can be covered using black and white cameras as directed by the DoD Project Sponsor.

5-4.8.2 Video Surveillance Major Components.

Reference UFC 4-021-02, Chapter 4, for components and requirements associated with the ESS: Video Surveillance System.

5-4.9 ESS: Infant Protection Alarm System (IPAS).

Provide the capability to detect and report alarms if an attempt is made to abduct an infant or pediatric patient from protected patient care areas, such as the L&D Unit, Obstetric Unit, Pediatric Unit, Med/Surg Unit when infants or pediatric patients are admitted to them, Level 1 Well Baby/Holding Nursery and Level II, III or IV Neonatal ICUs. To protect the infants or pediatric patients in these units, an interactive tag must be attached to each patient in the units. The tag must signal an alarm and the VSS must begin recording if there is any unauthorized attempt to remove the patient from the secured unit (exit alarm) or if there is an unauthorized removal of the tag or strap from the patient (tag tamper alarm). In an alarm condition, electromagnetic locks on exit doorways from the unit must be activated to delay or prevent the unauthorized individual from being able to leave the unit with the patient and allow time for the staff in the area to respond to the alarm.

The system must be continuously supervised to detect any tampering or removal of a monitoring device. Any detected unauthorized tampering with, or unauthorized removal of equipment must generate an alarm condition. All alarms must be concurrently routed in real-time to all Operator Workstations and transmitted to the security staff and staff in the alarmed unit via radio page or other wireless networked personal communication device. Operation and management of the IPAS capability must take place at Infant Protection Workstations installed in the designated Nurse Station of each unit. The electromagnetic door locks must be interfaced with the facility fire alarm and fire detection system to unlock the doors in the event of a fire or other emergency. Also, if there are elevators within the perimeter of a protected area, an alarm condition signal must be routed to the elevator controls to prevent the elevators from arriving in or leaving the protected unit area.

5-4.9.1 Infant Protection Major Components.

Major components to provide Infant Protection Alarm capability include, but are not limited to:

a. Network adapters
b. Infant Protection Workstations
c. RF readers
d. Low frequency (LF) readers
e. Infant tags and straps

f. Door position switches

g. Exit door dome lights with tone device

h. Electromagnetic door locks and power supplies

i. Proximity card readers

j. Speakers

k. Infant protection software

5-4.10 ESS: Behavioral Health Staff Assist (BHSA) Alarm System.

Appendix A describes the required functionality of the primary signaling (response managed within the unit or clinic) and secondary signaling (elevated response by resources external to the unit or clinic) for the BHSA Alarm system. **\1\ /1/** The primary signaling capability must consist of wired and wireless components as prescribed by Appendix A.

The secondary (external to the unit or clinic) signaling for BHSA Alarm system must consist of centrally located Duress Alarm components as prescribed by paragraph 5-4.6.2 and Appendix A.

5-4.11 Basic Design Requirements.

5-4.11.1 Electrical Power.

ESS equipment in inpatient MTFs must be powered from the essential electrical system with branch assignments per Table 12-1. AC powered equipment must be protected by either an internal battery backup or a UPS unit which must provide at least 15 minutes of full power during an AC power failure. UPS units must comply with **\1** Underwriter's Laboratory (UL) **/1/** 1778 and 47 CFR Part 15.

Power all video cameras from camera power supplies located in the nearest Telecommunications Room (TR).

5-4.11.1.1 DoD Assessment and Authorization.

The ESS must be RMF certified in accordance with DoD Assessment and Authorization Process. This certification requires the system to have a number of security characteristics and features.

5-5 SPECIAL CONSIDERATIONS FOR SECURITY SENSITIVE AREAS AND ROOMS.

Sensitive areas and rooms must be designed to store valuable assets (for example, funds, narcotics, dangerous drugs, and controlled substances and materials). The most cost-effective method of providing adequate security for these assets must be selected.

5-5.1 Safes.

Drugs classified as Schedule I or II controlled substances under the Controlled Substance Act of 1970 must be stored in safes or vaults. Drugs classified as Schedule III–V may also be stored in safes or vaults as deemed appropriate by the DoD Project Sponsor.

5-5.2 Vaults.

Features to be considered for vault storage areas are outlined in 21 CFR 1301.72 and DoD Project Sponsor directives.

5-5.3 Pharmacies.

Walls, floors, ceilings, doors, and service windows of pharmacies must provide resistance to forced and covert entry where necessary and required by the DoD Project Sponsor physical security regulations. Doors and windows must be kept to a minimum and doors must be keyed separately from the master key system. IDS sensors must be installed at all doors and windows including windows opening to corridors. As a minimum, walls surrounding pharmacies must be constructed full height from floor slab to structure above.

5-5.3.1 Doors.

Doors must be provided with security hinges and must be locked with security locksets. Doors must be solid core wood or hollow core steel. Other considerations include “peep holes”, two-way intercom system with camera, and card access system with keypad for the main staff entrance door, double-locking locksets with 1 in. (25 mm) throws, warning signs stating doors must remain unlocked during normal operating hours (for emergency egress), and warning signs stating “Controlled Area.”.

5-5.3.2 Service Windows.

Provisions, such as roll-up shutters, must be made for securing all service windows after normal operating hours. Frames holding roll-up shutters and security screens, or bars must be securely fastened with smooth-headed bolts with nuts peened in place.

5-5.3.3 Utility Openings.

Duct terminals and connecting points must be in exposed locations where they may be readily observed to detect tampering. Openings of 96 in^2 (0.062 m^2) or larger must be protected **\1** in accordance with (IAW) **/1/** MIL HDBK 1013/1.

5-5.4 Medical Supply Storage Areas or Facilities.

In addition to the criteria provided for pharmacies, high value, critical, and pilferable resources stored in this type of storage area or facility must be protected in accordance with specific requirements as defined by 21 CFR 1301.72 and the DoD Project Sponsor.

5-5.5 Other Security Sensitive Areas and Rooms.

Other activities or locations may be identified by the DoD Project Sponsor as security sensitive. These areas and rooms must minimize the security risk for these activities or locations. Package inspection devices may also be considered for mail rooms. Design ESS in accordance with UFC 4-021-02.

CHAPTER 6 ARCHITECTURAL

6-1 GENERAL.

This chapter provides architectural design guidance. Design of applicable facilities must emphasize architectural design excellence while balancing economical, functional, energy efficient, and sustainable architectural design elements. Principles of Evidence Based Design (EBD) and world-class facility standards must be included where applicable, based on project scope and building type. Designs must adhere to general healthcare industry standards, DoD and DoD Project Sponsor specific functional requirements, Core UFCs such as UFC 3-101-01, and criteria specified herein.

6-2 EXTERNAL DESIGN.

Adhere to applicable Installation design guidance and individual DoD Project Sponsor exterior design standards where applicable. Give special attention to provide convenient and Architectural Barriers Act (ABA) compliant patient access and drop off areas. Consider safety and separation of public, staff, emergency, and logistics travel paths as an integral part of the design.

6-3 EXTERIOR WALL DESIGN

All facilities must comply with the requirements listed in Chapter 4 and with any DoD Project Sponsor or Design and Construction Agent directives mandating increased energy performance.

6-4 FENESTRATION AND WINDOWS.

Provide natural day lighting to maximum extent possible throughout the facility. Exterior windows must be provided in normal nursing care areas. Intensive Care and Cardiac Care bedrooms, Prosthodontic Dental Treatment Rooms (DTRs), and Prosthodontic-Ceramics Laboratories should also be provided with natural lighting or artificial lighting balanced to the natural wavelength. Natural lighting may be provided in Dermatology Clinics if required by the DoD Project Sponsor. Exterior windows must also be provided per host nation requirements where it exceeds DoD criteria.

6-5 INTERIOR CONSTRUCTION.

6-5.1 Aseptic Environments.

An Infection Control Risk Assessment (ICRA) must be developed to address risk management during the project. The risk assessment must include requirements that address patient care, facility design, construction, construction phasing, ventilation, safety, and epidemiology. Selection of interior construction and finishes must consider the need for aseptic environments. Use smooth, nonporous, seamless materials to minimize contamination and reduce housekeeping requirements. Smooth, seamless wall and floor coverings facilitate cleaning. Cabinetry should be designed and installed without gaps behind or underneath base units. At a minimum, these areas must be

designed for ease of housekeeping, with elimination of materials or surfaces that could harbor contamination and to minimize maintenance requirements:

a. Oral Surgery Rooms, DTRs

b. Special Procedure Rooms, for example, Cardiac Catheterization, Angiography, Endoscopy

c. Operating Rooms (ORs), including C-Section and Hybrid

d. Emergency and Trauma Rooms

e. Decontamination Rooms in Surgery, Labor/Delivery, Dental, and Central Processing and Distribution (CPD)

f. Sterile Storage Rooms (Surgery, Labor/Delivery, Dental, CPD)

g. Sub sterile and Recovery Rooms (Surgery and Labor/Delivery)

h. All Patient Treatment Rooms

i. Intravenous Admixture and Chemotherapy Preparation Rooms in Pharmacy

6-5.2 Interior Design.

All finished designs must comply with Appendix B.

\1 Design all direct patient care spaces at full scope in accordance with the Program for Design (PFD) area requirement. Design all other spaces to meet the PFD area requirements without varying more than plus or minus 10 percent. Approval from the DoD Project Sponsor is required to deviate from these requirements. Record all area differences from the PFD in the submittal requirements, Appendix C, specific to the net area calculations with narrative justification. **/1/**

6-6 FRONT DESK AND RECEPTION AREAS.

For areas that regularly receive patients for care or administrative reasons, patients and users must have a clear understanding of where to go upon check-in and must be within immediate, physical reach of attendants if directional or medical assistance is required.

Position and design the front desk or reception areas to provide direct observation of the entry area and the waiting area of each department to ensure that the desk attendant(s) have unobstructed line of sight to the patients in the area and can physically access anyone needing assistance or summon other staff to assist.

6-7 FLOORS.

Reference Appendix B for required floor finishes. Ensure floor to receive finish is properly cured, level and free from any loose material prior to any installation.

6-8 WALL AND PARTITION SYSTEMS.

Reference Appendix B. Provide systems that permit modification with the minimum cost and difficulty within acoustical and fire criteria, except in areas subject to severe impact. Interior non-load bearing metal studs must be a minimum 20 gauge, 16 in. (405 mm) on center. The DoR will determine if more stringent structural requirements apply. Provide non-combustible wall backing **\1** (alternatively fire-retardant wood blocking may be used as coordinated with the equipment vendor and DoR) **/1/** at all wall-hung equipment and accessories. Architectural acoustics must be coordinated across all building systems. Resilient channels are prohibited to be used. Consider the use of other methods and products to control sound, vibration and achieving required STC ratings listed in Appendix B.

6-8.1 Use of Full Height Partitions.

Full height partitions (floor to structural slab above) must be used where required to meet fire or smoke separation, critical pressurization, and sound performance requirements and in the rooms, spaces, and compartments listed below for physical security purposes. Refer to Appendix B and paragraphs 10-7.5 and 10-14.1 for construction and leak test requirements for rooms with critical pressurization.

a. Medical Record Storage areas (paper file areas or large centralized areas), Legal, credentials, quality, and Human Resource records storage areas

b. Materiel Services Storage areas

c. CPD Storage areas

d. Pharmacy

e. Prosthodontics and Ceramic Laboratory

f. Medical Equipment Maintenance and Repair

g. Orthotic Appliance Manufacturing

h. Facility Engineer Maintenance Shops

i. Pulmonary Function and Laboratory

j. Medical Service Account (MSA) Funds Storage

k. Labor, Delivery, and Recovery Rooms (LDR)/Labor, Delivery, Recovery, and Postpartum Rooms (LDRPs)

l. Corridors

m. Neonatal Intensive Care Unit (NICU), Nurseries, and Pediatric Inpatient Rooms

n. Behavioral Health Inpatient and Seclusion Rooms

6-8.2 Barriers.

Design protective barrier partitions to protect occupants or equipment in rooms, spaces, and compartments from fire, smoke, radiation exposure, electrical interference, magnetic resonance imaging (MRI) shielding, or for physical security purposes.

6-8.3 Protection and Safety Features.

Use door and wall guard systems (for example corner guards, crash rails, handrails, chair rail, wall protection panels) in all patient care areas subject to frequent abrasion and impact. Areas include, but not limited to, corridors, alcoves, patient treatment rooms, utility (soiled/clean) rooms, CPD, gurney storage, laboratories, kitchens, loading docks and others.

Provide handrails in corridors where patients routinely travel and public areas where travel along a wall is possible. Handrails are not necessary in administrative areas.

6-8.4 Toilet Facilities.

Provide appropriate floor slope, water containment, and drainage as required. Give consideration to slip resistant surfaces in wet areas. All thresholds must meet ABA requirements.

6-8.5 Toilet Partitions.

In locations where toilet partitions are utilized, provide ceiling hung type, unless directed otherwise by the Design and Construction Agent.

6-9 CEILINGS.

6-9.1 Support.

Suspended ceiling surfaces cannot be used for the direct support of cubicle curtain tracks and ceiling lights. Ceiling-mounted accessories must be secured through the ceiling to secondary support members.

6-9.2 Utility Access.

Provide maximum accessibility in corridor ceilings to the mechanical, electrical, plumbing and telecommunication distribution systems. Do not use concealed-spline ceiling systems requiring special tools to lower tile assemblies. Identify the access panels into ceiling plenums in order to identify the type of utility present and coordinate with all disciplines.

6-10 VESTIBULES.

Provide exterior vestibules at primary patient entrances. Vestibules must comply with ABA requirements and should be of sufficient depth to allow the outside doors to close

before the inside doors are opened. The Design and Construction Agent may waive this requirement in moderate climates if justification concerning energy and life cycle cost are provided.

6-11 DOORS.

6-11.1 Automatic Doors.

Electrically operated or hydraulically operated automatic doors must be provided for Emergency Trauma entrances and primary patient entrances of MTFs.

6-11.2 Doors, Frames, and Hardware.

Door sizes and types are as indicated in Appendix B. Unless otherwise stipulated by the Design and Construction Agent, all door frames must be hollow metal. Refer to Chapter 14 for fire protection and life safety labeling requirements. Provide a glass view panel in OR doors and other areas where staff may be transporting non-ambulatory patients. At patient toilets, provide rescue hardware that, in an emergency, allow access to the room regardless of privacy lock type or obstruction on interior side of door. Door hardware must be of Builders Hardware Manufacturers Association (BHMA) Grade 1, meet ABA requirements, and be aesthetically compatible with the design of the facility.

6-12 SUSTAINABLE DESIGN.

Reference Chapter 4 for sustainable design principles.

6-13 WAYFINDING PLAN.

A wayfinding plan must be generated for all new medical facilities. The Design and Construction Agent must substantiate that all architectural and engineering systems, specifications, and contract documents support the elements and features proposed in the wayfinding plan. Signage, a tool associated with wayfinding, must be fully coordinated and consistent with the facility's wayfinding plan. Development of a wayfinding plan must begin at the start of a project's design and conclude with the project's final design submission.

For addition/alteration projects, coordinate the wayfinding plan with existing conditions. In the absence of a base or facility wayfinding master plan, evaluate and assess one's ability to navigate, via wayfinding cues, from the existing facility to the addition/alteration project. Consider adjacencies, circulation, building entrance locations, parking considerations, and overall building configuration as part of this evaluation.

6-14 BEHAVIORAL HEALTH.

See Appendix C and Appendix A for other specific requirements.

This Page Intentionally Left Blank

CHAPTER 7 STRUCTURAL

7-1 GENERAL.

This chapter provides criteria for the selection, analysis, and design of structural system(s) and materials, including Seismic criteria, to be used for applicable facilities.

7-2 DESIGN CRITERIA.

Structural design must be in accordance with UFC 3-301-01. The Risk Category of buildings and other structures must be based on the nature of occupancy in accordance with Table 2-2 of UFC 3-301-01 for the purpose of applying design load. The desired seismic level of performance for a particular facility is dependent on the nature of the occupancy and whether the structure is required for post-earthquake recovery. The structural engineer of record must assign a Risk Category, as defined in UFC 3-301-01, based on the facility function and the desired seismic performance level. The Authority of Jurisdiction must review and approve the designation.

If required by the DD Form 1391, certain facilities may require only key areas to be operational after the Design Earthquake. Areas that are not required to remain operational may be assigned a lower Risk Category only if both the structural and non-structural systems are designed by the structural engineer of record to be seismically independent or fully isolated from areas that are required to remain operational. Systems that are required to be operational following the Design Earthquake are identified as Designated Seismic Systems in accordance with ASCE 7.

7-3 DESIGN LOADINGS.

Unless otherwise indicated herein, the minimum design loadings must be in accordance with UFC 3-301-01. Floor live loads must be in accordance with UFC 3-301-01, and as amended by Appendix B of this UFC.

7-4 POST-EARTHQUAKE EMERGENCY STATUS.

During the planning period, an evaluation of water for potable and fire suppression purposes, fuel, sanitary sewer, and power, is required for all Risk Category IV facilities in Seismic Design Categories D through F to support continued operations 72 hours after a seismic event. Onsite storage of these lifeline utilities may be required when established by the project DD Form 1391.

7-5 CONCEPT DESIGN DEVELOPMENT.

Develop project specific seismic design concepts. Coordinate the type of structural system to be used in the early concept development of the functional layout, in accordance with UFC 3-301-01. Specific project criteria include mechanical, electrical, medical gases, and communication systems design criteria.

7-6 DESIGN OF NON-STRUCTURAL SYSTEMS.

Design all non-structural systems in accordance with UFC 3-301-01. Special Designated Seismic Systems are non-structural building systems, utility services, equipment, and medical equipment required to remain operational after an earthquake to sustain life safety systems. Some Designated Seismic Systems known as “Active” require Special Seismic Component Certification to ensure that they do not change state or fail during an earthquake. “Active” Designated Seismic Equipment is a limited subset of Designated Seismic Systems that have parts that rotate, move mechanically, or are energized during operation; and may be limited to motors greater than 10 horsepower or greater than 200 MBH. Pipes, ducts conduits, and similar apparatus are not “Active”. Special seismic component certification must be based on shake table testing per ICC-ES AC156 unless the component is inherently rugged. See UFC 3-301-01, Appendix E-1. Develop a complete list of Designated Seismic Systems and Active Designated Seismic Systems for approval and identify in the Construction Documents. Where applicable, Designated Seismic Systems must be placed above tsunami inundation elevation height as determined by ASCE 7, Chapter 6 including onsite power generators. **\1**

7-6.1 Equipment and Furniture.

From the Equipment and Furniture in the PRC, identify the items where falling may pose a life safety hazard or displacement may cause injury or damage to Designated Seismic Systems. For these items, identify and specify Special Seismic Component Certification requirements and design seismic anchorage and/or bracing elements per ASCE 7 as amended by UFC 3-301-01. Provide a table in the construction documents that defines requirements for this equipment and furniture. **/1/**

7-6.2 Hazardous Materials – Special Storage Provisions.

Provide special storage equipment or accessories that are convenient for normal daily use and functional after earthquakes. Examples of such equipment are lower profile shelves with face bars to secure shelves to the wall or floor and restrain their contents, specially designed racks for restraining reserve oxygen (O) and nitrous oxide (NO) tanks, and special bins for storing anesthetic gas containers.

7-6.3 Hazardous Materials – Fuel Gas Piping.

Brace piping and provide shut-off valves. Use malleable fittings and valves and provide swing joints where necessary.

7-6.4 Electrical Systems – Vibration Isolation.

Where vibration isolation is not required, bolt generators directly to an appropriate foundation. Where vibration isolation is necessary, provide restraining clips at vibration isolators to prevent failure of the isolation mountings in earthquake vibration conditions.

7-6.5 Emergency Generators.

Where practicable, use generators with integral radiator cooling systems. Where auxiliary cooling systems are necessary, install cooling towers or remote radiators at grade level. Brace cooling towers or radiators and provide special bracing for piping. All emergency generators must be set above tsunami inundation height as determined by ASCE 7, Chapter 6 and above the flood design elevation per ASCE 24.

7-6.6 Medical Systems and Equipment – Stationary equipment.

Secure stationary equipment or shelving to a partition or floor. Shelving or equipment with doors that does not require continuous access must have automatic positive latching devices.

Blood bank, drug storage, critical refrigerators, freestanding incubators, and centrifuges should be secured.

7-6.7 Medical Systems and Equipment – Fragile equipment.

Secure sequential multiple blood analyzers and other fragile laboratory equipment. Anchor related shelving and provide lips and face bars as necessary.

7-6.8 Medical Systems and Equipment – Wheeled equipment.

Wheeled equipment must have wheel locks and must be assigned a specific location when not in use. Wheeled equipment must have programmed closets or alcoves whenever possible to limit rolling. Portable equipment must be stored in recessed cabinets secured to partitions, whenever possible.

7-6.9 Supply Storage.

Supply cabinets must have either plastic or tempered glass sliding doors, and the doors must slide closed automatically. Open shelving should have a shelf rim to preclude supplies from being shaken from their storage position.

7-6.10 Medical Gas Bottles.

Metal boxes attached to the floor and equipped with double chains must be provided for medical gas bottles. Wheeled carts carrying oxygen or other medical gases must be equipped with wheel locks and chains for fastening to walls.

7-7 EVALUATION OF EXISTING FACILITIES.

For existing facilities, the Design and Construction Agent and the DoD Project Sponsor must verify the performance objective or Risk Category and the Designated Seismic Systems required, as established in the planning documents. The performance objectives are defined in UFC 3-301-01, and must consider operational mission, disaster preparedness, and medical post-earthquake needs.

7-7.1 Seismic Hazards Evaluation Considerations.

Seismic Structural Evaluations. Seismic structural evaluations and retrofit of existing buildings must be conducted in accordance with UFC 3-301-01. For proposed facility alteration projects, seismic structural evaluations must be conducted during the project requirements planning phase (see Chapter 2).

7-8 ADDITIONAL DESIGN CONSIDERATIONS.

Several aspects of structural design typically associated with facilities are addressed here. It is essential that structural design considerations enter into the earliest stages of concept planning and design, to ensure compatibility with medical function and architectural and equipment features.

7-8.1 Vibration.

Structural vibration requires special consideration. Designs must limit vibration in floor framing systems and must ensure adequate isolation and damping of vibrations produced by HVAC equipment, emergency generators, elevator equipment, human activity, and other machinery. Provide a vibration design in accordance with the following standards:

- Structural steel structures – AISC Design Guide 11: Floor Vibrations Due to Human Activity.
- Reinforced concrete structures – CRSI Design Guide for Vibrations of Reinforced Concrete Floor Systems.
- Steel Joist Institute Technical Digest 5, Vibration Analysis of Steel Joist-Concrete Floor Systems.
- UFC 3-450-01.

7-8.2 Vibration Limits.

Limit floor vibration according to manufacturer requirements for all other vibration sensitive equipment. The below noted floor vibration limitation must apply to the floor above where said equipment is attached to the ceiling structure. Limit hospital floor vibration to 0.5% g or less, except in the case of the following stricter requirements wherein the maximum acceptable floor velocity is listed in micro inches per second. These values must be superseded by any explicit manufacturer requirements:

- Hospital patient rooms: 6000 mips
- Standard operating rooms, surgery suites, bench microscopes up to 100X, and laboratory robots: 4000 mips
- Bench microscopes up to 400X: 2000 mips

- Microsurgery, eye surgery, neurosurgery, and bench microscopes greater than 400X: 1000 mips
- Magnetic resonance imagers: 500 mips

7-8.3 Magnetic Resonance Equipment (MRI) Foundations.

Provide non-ferrous foundation reinforcement for MRI foundation according to manufacturer requirements. Ensure that primary structural foundations surrounding MRI rooms are free of ferrous materials that may cause magnetic interference. Consult with the equipment manufacturer.

This Page Intentionally Left Blank

CHAPTER 8 - NOT USED

This Page Intentionally Left Blank

CHAPTER 9 PLUMBING AND MEDICAL GASES

9-1 GENERAL.

This chapter provides design requirements for plumbing and medical gas systems. The primary purpose of these systems is to provide safe and reliable support to the medical functional mission. In addition, appropriate design consideration must be incorporated to ensure system maintainability, economy and energy efficiency, and adaptability to future facility modification or expansion.

9-1.1 Supplemental Criteria and Standards.

This chapter may be supplemented with individual Military Department (MilDep) criteria, including Installation-specific requirements, as established by the Design and Construction Agent. Minimum design requirements must be as provided by the International Plumbing Code (IPC) in accordance with UFC 3-420-01, the NFPA Standards, and the other documents noted in this chapter.

9-1.2 Plumbing Systems.

Plumbing systems include domestic cold and hot water; sanitary, storm, and industrial (acid) waste drainage; water treatment, for example, softening, deionization, reverse osmosis; fuel gas; and landscape irrigation. Plumbing systems must be designed to be safe, reliable, and maintainable. Selection of materials, equipment, and installation techniques must consider LCC effectiveness and maintainability in addition to medical functional requirements. Designers must provide for appropriate system isolation and balance with necessary equipment and design practices to avoid cross-connections and backflow.

9-1.3 Medical Gas and Vacuum Systems.

Medical gas and vacuum systems include compressed air (medical, dental, instrument, medical laboratory, dental laboratory, process), vacuum (medical, dental surgical, oral evacuation [OE], waste anesthesia gas disposal [WAGD]), exhaust (laboratory dental), positive pressure gases (nitrogen [N], oxygen [O], nitrous oxide [NO], carbon dioxide [CO2]), and the associated equipment, for example, piping, filters, regulators, alarms, manifolds, and tanks.

9-1.4 Seismic Requirements.

Seismic design criteria for bracing and utility systems, for example, storage, redundancy, are provided in Chapter 7.

9-1.5 Corrosion Protection.

All piping that must be installed in an environment that supports galvanic reaction must be protected from corrosion in accordance with MilDep criteria and the standards and recommended practices of the National Association of Corrosion Engineers.

9-1.6 NFPA 99 Risk Assessment.

A Risk Assessment must be performed in accordance with NFPA 99 to establish the System Categories for all medical gas and plumbing systems. See Appendix C for the timing and responsibilities of the Risk Assessment.

9-1.7 Piping Coordination.

All piping systems must be installed in a manner that promotes cleanliness, protection of room contents and addresses infection control concerns. **\1\ /1/** Piping must be concealed under floor, within walls, and/or above ceilings, except in dedicated mechanical spaces.

Piping must not be routed within the room or above the ceilings of communications, electrical and server rooms unless dedicated to serving the room as indicated in Chapters 11 and 12. Where feasible, avoid routing piping above other sensitive areas such as: operating rooms, delivery rooms, nurseries, food preparation areas, food serving areas, food storage areas, sterile processing clean side, and radiology equipment in procedure rooms, control rooms and equipment rooms. Where routing over sensitive areas cannot be avoided, provide all wet and drainage piping with special protection provisions (for example double wall containment piping or drip pans with leak detection) to protect the space below from leakage and/or condensation.

9-2 POTABLE WATER SUPPLY SYSTEM.

9-2.1 Quality.

All potable water supplies must have an established potability monitoring program to be acceptable for use by an MTF. When an MTF project includes a non-potable water service, for example, “gray water,” for systems, such as irrigation, heating, or cooling, the design must provide for requirements for signage, pipe labeling, and other means as needed to clearly identify the system (including outlets) as unsafe for human consumption.

9-2.2 Continuity of Service.

For hospitals and ambulatory surgery centers, provide a minimum of two water services, fed from either separate mains and sources or separate connections to a multi-sourced network, each designed for full demand (serving potable and process systems). These services must enter the building at separate locations from a piped loop around the facility with isolation valves. The purpose of this provision is to provide an uninterrupted supply of potable water or permit swift service restoration in the event of a water main break. If two separate water sources are not reasonably available, the Design and Construction Agent may seek authorization from the DoD Project Sponsor to utilize onsite storage in lieu of a second water service.

9-2.3 Backflow Prevention.

Backflow prevention must meet the requirements of UFC 3-420-01, the International Plumbing Code and be coordinated with the Design and Construction agent for maintenance accessibility and testing. Configure the backflow preventer(s) for device testing without disruption to the building water service for any MTF with 24/7 operation. Where Continuity of Service requirements allow for a single water service connection, parallel backflow preventers must be provided. Where dual service connections are required, ensure either connection can fully support the facility while the other supply backflow preventer is out of service.

9-2.3.1 Devices and Methods.

All potable water discharge points, such as a faucet discharging into a reservoir sink or tub, must be provided with an adequate air gap in accordance with UFC 3-420-01. Fixtures or equipment where the discharge point is positioned below the reservoir rim must be fitted with a vacuum breaker. Examples of concern include the devices listed here:

a. Bedpan washers, or similar fixtures including a flushometer valve

b. Flexible hoses or shower heads of length sufficient to reach below fixture rim, typically found in procedure rooms, hydrotherapy bath equipment, laboratories, and food service areas, for example, washers, steam tables

c. Laboratory or other serrated-nozzle fixtures designed to accept flexible tubing

d. Water delivery outlets serving therapeutic, surgical, or autopsy or mortuary procedures

e. Hose bibbs and wall hydrants

For the protection of make-up supplies to low-hazard equipment, for example, autoclaves and fire protection sprinkler systems, double-check backflow preventers may suffice. For the protection of sources supplying the building with potable water, and for high hazard equipment and processes, reduced-pressure backflow preventers are required. Designers must include provisions for drainage of the discharge from these devices; refer to Table 9-1 and Table 9-2.

9-2.4 Water Treatment.

A water chemistry analysis **\1** of all potential water sources to the facility (primary and alternate) reporting, at a minimum, the parameters indicated in Table 9-1 must be used as the basis for determining the facility water treatment design scope related to hardness, corrosivity, waterborne pathogen control, specialized treatment for high purity systems, etc. Water testing location must be coordinated with the DoD Project Sponsor and is typically at the point of connection or line of demarcation of real property

ownership. Facility water treatment requirements must be based on the recommendations of a qualified water treatment specialist and coordinated with the Installation, the water supplier, the Water Management Program and all unique water requirements for equipment and systems within the facility. Water treatment requirements must address the use of centralized vs. decentralized treatment based on life cycle cost considerations. These evaluations must include domestic water and all specialty water systems. The water treatment specialist must not be affiliated with any water treatment manufacturer or vendor and be independent from the Contractor for DB projects. **/1/**

Water treatment equipment for any facility operating 24/7 must include sufficient redundancy to enable routine maintenance, backflushing and regeneration without disruption to the facility water supply. Water treatment technologies for the control of waterborne pathogens are discussed in paragraph 9-2.5.

Table 9-1 Water Testing Parameters

Parameter	Units
Water Temperature	^{o}C
Water pH	-
Total Alkalinity	as CaCO3
Total Hardness	as CaCO3
Calcium	mg/l
Magnesium	mg/l
Sodium	mg/l
Chlorides	mg/l
Sulfates	mg/l
Nitrate	mg/l
Iron	mg/l
Manganese	mg/l
Lead	µg/L
Copper	mg/l
Conductivity	µS/cm
Total Dissolved Solids	mg/l
Chlorine Residual	mg/l
Langelier Index	Dimensionless
Calcium carbonate precipitation potential	as CaCO3
Dissolved inorganic carbonate (DIC)	as C
Equilibrium alkalinity	as CaCO3
Rysnar Saturation Index	dimensionless
Larson’s Ratio	Dimensionless
Chloride to Sulfate Mass Ratio	Dimensionless

Table 9-2 Potential Backflow Preventer Discharge Rates

Assembly Pipe Size in NPS inches (DN mm)	Discharge GPM (L/S) at 60 PSI (414 kPa)	Discharge GPM (L/S) at 150 PSI (1034 kPa)
¾–1 ¼ (20-32)	75 (4.7)	140 (8.8)
1 ½–2 (40-50)	170 (10.7)	280 (17.7)
2 ½–3 (65-80)	250 (15.8)	400 (25.2)
4–6 (100-150)	500 (31.5)	850 (53.6)
8–10 (200-250)	525 (33.1)	890 (56.2)

Table 9-3 Floor Drain Flow Rates

Drain Size	Flow Rate*
Inches (DN mm)	GPM (L/S)
4 (100)	88 (5.6)
6 (150)	264 (16.7)
8 (200)	575 (36.3)
10 (250)	1050 (66.2)
12 (300)	1700 (107.3)
* Flow rates for a floor drain with slotted cover and ⅛ in. per ft (10.4 mm per m) drain pipe slope.	

9-2.4.1 Scale Control.

Provide water softening when the water supply to **\1** a facility has a hardness of 170 mg/l of CaCO3 or more (85 mg/l of CaCO3 for a dental facility). Design the softening system to deliver water with hardness between 50-85 mg/l of CaCO3 unless specialized equipment in the facility requires more stringent standards. Potable water must not be less than 50 mg/l as CaCO3 due to the corrosive nature of overly softened water. All water softening systems must include a proportional blending valve and a bypass meter to ensure positive control over the discharge hardness. Include provisions for softener regeneration discharge, which may require a floor sink or receptor. Provide full automation of softener regeneration process and the ability to monitor blended water hardness, softener status and alarm conditions at the building automation system. All softener materials and additives used for potable water must be NSF certified for drinking water use. **/1/**

9-2.4.2 High Purity Water Systems.

Water purification is the process by which contaminants or impurities, which undesirably affect the performance of specific equipment or the outcome of medical and laboratory tests, are removed from the water. Water purification systems include reverse osmosis,

deionization, ultra-filtration, and ultraviolet (UV) sterilization. Type I and Type III reagent grade water, as specified in ASTM D 1193, are used in various applications such as for medicine preparation processes in pharmacies, in distillation units, for designated laboratory outlets, and in selected equipment for renal dialysis, glassware washing, central sterile supply, and other medical and laboratory functions. Their use must be coordinated with DoD Project Sponsor and the Design and Construction Agent. The designer is responsible to determine local and central treatment options and treatment system combinations to best meet DoD Project Sponsor needs and overall LCC **\1** as part of the water treatment analysis in 9-2.4. The water treatment specialist must confirm the required water quality for each end use and validate the system design can deliver the required water quality. **/1/** Refer to Chapter 10 for make-up water treatment design guidance for steam systems. **\1**

9-2.4.2.1 Sterile Processing.

Design water system to deliver water to sterile processing fixtures and equipment to meet water quality requirements of AAMI TIR 34 and equipment manufacture's recommendations. Large sterile processing departments in hospitals, or central instrumentation processing centers (CIPCs), typically involve larger workloads, more equipment, and more water demand. In these instances, centralized high purity water system should be evaluated which may involve pre-treatment (softening and carbon filtration), principle treatment (reverse osmosis, de-ionized water, or combination), distribution (water storage tank, recirculation at 2-3 fps (0.6 to 0.9 m/s), UV disinfection), and other microbial monitoring, testing, and sanitation features. These systems may also serve other high purity water demands in the facility. Small sterile processing, such as dental instrumentation processing centers (DIPC's), have the same water quality requirements, but have lower workloads, less sterile processing equipment, and less water demand. These small spaces are typically served with point-of-use treatment at a better LCC.

9-2.4.2.2 Reagent Water.

Reagent grade water (RGW) is water that is suitable for use in a specified procedure such that it does not interfere with the specificity, accuracy, and precision of the procedure. Process definitions alone (such as "RO", "DI", "Distilled") do not in themselves adequately define required water quality.

Design water system to deliver water quality that meets user and equipment requirements. Reagent water quality must be classified using ASTM Standard D 1193 reagent water type 1, 2, 3, or 4. When bacterial levels need to be controlled, the level of water quality required must additionally be classified as Type A, B, or C. Reagent grade water must be monitored for resistivity, microbial content, and total organic carbon.

9-2.4.2.3 Laboratory Water Systems.

Design water system to deliver water quality that meets user and equipment requirements for the laboratory. This typically includes compliance with the Clinical Laboratory Standards Institute (CLSI) Preparation and Testing of Reagent Water in the Clinical Laboratory for water requirements. Provide monitoring of resistivity, microbial content, and total organic carbon. **/1/**

9-2.5 Waterborne Pathogens Control.

The relative danger that Legionella and other waterborne pathogens, including pseudomonas, pose in any given facility is a function of (a) “system” factors that promote or discourage colonization, (b) the relative vulnerability of the patient population, and (c) climate and groundwater temperature. Procedures that increase aspiration increase the risk of infection from waterborne pathogens, as does the presence of aerosol-generating sources, such as showers and whirlpool baths. In addition to potential contamination danger from hot water systems, cold water systems pose the risk of supporting pathogen colonization if the piping systems are subjected to heat sources. The temperature of cold water systems might inadvertently be elevated into ranges more conducive to pathogen colonization by ground temperatures, piping located in attics, ceiling spaces, equipment rooms, crawlspaces, other unconditioned spaces, or by being located adjacent to hot water or steam piping. All of these risk factors must be considered when designing the domestic water system.

9-2.5.1 Scale, Sediment, and Biofilm.

Scale, sediment, and biofilm are contaminants that support Legionella bacteria (and other waterborne pathogens) colonization. The extent to which these contaminants support colonization is a function of factors including potable water service quality (including the presence of living aquatic amoebae such as are found in biofilms), system operating temperatures, and pipe material. Standard control technologies for scale and sediment deposits normally minimize the contribution of these factors to pathogen colonization. Biofilms are resistant to some treatments.

9-2.5.2 System Design.

Design the building water system to address management of water temperature, minimize water age, reduce stagnation, maintain a sufficient disinfectant residual, and minimize the use of materials that support colonization to maintaining water quality and manage control of waterborne pathogens.

9-2.5.2.1 Water Management Program \1\ (WMP). /1/

For new Hospitals and Ambulatory Surgery Centers comply with ASHRAE 188 to develop a Water Management Program in conjunction with a Water Infection Control Risk Assessment (format per CDC toolkit). The Program and its required analyses must address all potable and non-potable building water systems and incorporate all control measures prescribed in this Chapter plus any control measures that result from

the analyses. Coordinate the ASHRAE 188 Water Management Program and Water Infection Control Risk Assessment with the Facility Water System Management Team (for example Facility Water Safety Committee, Program Team, etc.) or DoD Project Sponsor to obtain facility and location specific information. Reference ASHRAE Guideline 12 for additional information. For additions or alterations to existing Hospitals and Ambulatory Surgery Centers, update and expand the existing Water Management Program to address the new conditions.

The Water Management Program must be developed and submitted during the 35% design for DBB acquisition or RFP development phase for DB acquisition for determination of design features. During final design, update the Water Management Program to comply with the Elements of Performance in the Environment of Care prescribed in The Joint Commission for the Water Management Program and submit for approval. **\1**

9-2.5.2.2 WMP Requirements for Projects with Limited Water System Impact.

/1/ For small projects affecting a Hospital or Ambulatory Surgery Center with limited impact to the water systems, verify compliance with the existing Water Management Program and provide a compliance report.

9-2.5.2.3 Supplemental Disinfection.

For all Hospitals, provide a supplemental disinfection system(s) with residual disinfection properties for waterborne pathogen control of the potable water system. Examples of systems include, but are not limited to, copper-silver ionization, chlorine dioxide, etc. Hot and cold water must be analyzed separately and provided with separate treatment systems if required by the analysis. Hot and cold water supplies must be provided with separate supplemental disinfection systems where water temperature impacts the required concentrations and controls to maintain efficacy. Provide permanent continual monitoring and trending of water temperature, pH, pressure, chlorine residual and any other environmental sampling or monitoring required for the selected treatment system. Trend, display, and alarm all monitoring points on the building automation system.

The selection of a supplemental disinfection system must be based on a comparison of all feasible alternatives for treatment systems which provide a measurable residual disinfection at the distal points. See ASHRAE Guideline 12 for further information. Comparison criteria must include efficacy for waterborne pathogens of local concern, local ordinances which may impose restrictions on implementation or operations, compatibility with the public water primary disinfection methods and byproducts, and life cycle cost. The supplemental disinfection system must be registered by the manufacturer with the EPA as a biocide for drinking water. Comply with applicable federal, state, and local government requirements. Start-up and activation of the treatment system must be integrated into the Commissioning Plan including documenting the baseline (pre-activation) and post-activation water quality; pre and post disinfection agent (for example copper ions, residual chlorine), etc. These tests

must be performed by a laboratory in addition to any field testing required by the manufacturer. A plan for on-going distal flushing and monitoring must be established in accordance with the manufacturer's recommendations and implemented immediately upon system activation (even before building occupancy). The plan must initially be implemented by the construction contractor and then integrated into the facility's ongoing maintenance plans.

Exception: Supplemental disinfection may be omitted where approved by CEHNC-EDX/MFPO with concurrence from the DoD Project Sponsor and the Facility Water System Management Team, as supported by the Water Management Program and its required analyses. The analyses must demonstrate that sufficient control measures are in place to address all potentially hazardous conditions without the need for the supplemental disinfection.

9-2.5.2.4 Connections to Existing Systems.

For addition and alteration projects, designers must take into consideration the likely presence of biofilms, sediments, and scale and how its disruption may impact the new and existing systems. These considerations must be addressed within the Water Management Program.

Flushing, disinfection, and testing plans for the associated existing system must be coordinated with local shutdown policies and procedures and be approved by the Design and Construction Agent and the Facility Water System Management Team. These plans must address all new piping and all existing piping potentially affected by the work. This requirement includes but is not limited to all piping downstream of the tie-in point and any piping that is inactive during construction.

9-2.5.2.5 Piping Materials.

Potable water distribution within the building must be copper or stainless steel. Specify equipment, and fixture components intended for direct water contact to be of materials that inhibit bacteria colonization, such as copper. For inpatient MTFs, avoid materials that support colonization, such as natural rubbers and some plastics, whenever practicable.

9-2.5.2.6 Piping Design/Distribution.

Design hot and cold water distribution mains to maintain balanced flow throughout. Design piping runs as short as practicable. Avoid creating piping "zones," which experience infrequent use and, therefore, stagnation. As practicable, route mains close to fixtures to minimize the lengths of branch piping runs. Avoid stagnant piping sections, for example, dead legs. To avoid water temperature rise, design cold water piping, distribution, and insulation to limit heat transfer from hot water piping or other heat sources. The developed length of hot water piping from the hot water recirculation piping to showers, emergency showers, and emergency eyewashes must not exceed 6

ft (1.8 m). The developed length of hot water piping from the hot water recirculation piping to all other fixtures must not exceed 10 ft (3.0 m).

9-2.5.2.7 Location of Temperature Limiting Devices.

Locate temperature limiting devices as close as practicable to the fixture discharge. Do not exceed a 6 ft (1.8 m) developed length from the temperature limiting device to the fixture discharge.

9-2.5.2.8 Hot Water Generation.

Provide a central system for hot water generation. To avoid stagnant storage conditions, consider semi-instantaneous and instantaneous hot water heaters where feasible and when onsite storage is not required by other criteria.

Exception: electric instantaneous water heaters (for example tankless point-of-use) may be considered where remote sinks or lavatories are more than 150 ft (45.7 m) away from a hot water circulation loop but may only be utilized when approved by the Design and Construction Agent.

9-2.5.2.9 Water Storage Tank Design.

Water storage or holding tanks, both cold and hot, must be designed to have continuous flow. Consider using horizontal tanks with baffles to limit stagnation.

9-2.6 Domestic Hot Water Systems.

9-2.6.1 Hot Water Demand.

The demand load can be calculated using several different methods, examples of which are contained in the ASHRAE Handbook: HVAC Applications and the American Society of Plumbing Engineers (ASPE) Data Book. The preferred method for calculating hot water demand for a facility is the Per Fixture method. This method provides a means to account for various uses within each facility and permits the tabulation of the hot water load using a specified demand for each fixture.

Table 9-4 provides a list of representative fixtures taken from MIL-STD-1691 and their demands based on data provided in ASHRAE Handbook: HVAC Applications and the ASPE Data Book. For any fixture not shown, the designer must determine the demand rate based upon experience, standard practice, and available DoD Project Sponsor input. The Per Fixture method is adequate for typical usage. Expanded usage for food service, non-standard fixtures, or abnormal usage patterns (extreme low- or high-demand peaks or erratic peak duration and occurrence) must be factored into the sizing calculations. For example, food service fixture demand factors need to be adjusted if disposable service ware is used. Concentrated patient treatment for sick call, or other instances of high-peak usage are other examples of fixture hot water demand adjustment.

9-2.6.2 Hot Water Storage Tank Sizing Factors.

The Demand Factor and Storage Capacity Factor are listed in the ASHRAE Handbook: HVAC Applications and the ASPE Data Book for given building types, which includes hospitals but not medical clinics, dental clinics, nor laboratories. A Demand Factor of 0.40 and Storage Capacity Factor of 1.00 must be used for clinics. Factors for facilities with laboratory space greater than 10 percent of the total facility space must be coordinated with the Design and Construction Agent. The Probable Maximum Demand is factored by the Storage Capacity Factor to determine the Storage Tank Capacity. The Storage Tank Capacity is the capacity required to be available for use. Storage tanks are not considered to be 100 percent usable and thus, a Usable Storage Tank Factor must be applied to the Calculated Storage Tank Capacity, unless the water in the entire tank is recirculated. The percent capacity considered usable for most tanks is 70, thereby resulting in a 1.43 Usable Storage Tank Factor. The Usable Storage Tank Factor for systems utilizing instantaneous generators or multiple tank arrangements must be coordinated with the Design and Construction Agent.

Table 9-4 Hot Water Demand per Fixture

FIXTURE	GPH (L/h)	HW SFU
Sink, Clinic	4 (15.1)	3
Sink, Plaster	10 (37.8)	3
Sink, Service (General)	20 (75.7)	3
Lavatory, Public (General)	6 (22.7)	1½
Lavatory, Patient (Private)	2 (7.5)	1
Lavatory, Clinic	8 (30.3)	3
Basin, Mop Service	20 (75.7)	3
Shower, Staff or Patient Group	75 (283.9)	3
Shower, Patient (Private)	30 (113.6)	2
Shower, Hydrotherapeutic	400 (1514)	11
Bathtub	20 (75.7)	3
Bath, Whirlpool, Arm	35 (132.5)	3
Bath, Whirlpool, Arm/Foot/Knee	15 (56.8)	3
Bath, Whirlpool, Leg	100 (377.5)	7
Bath, Body Hydrotherapy (Hubbard)	600 (2271)	17
Bath, Sitz	30 (113.6)	3

General Notes:

1. SFU = supply fixture units.
2. Summing individual fixture demands provides the Possible Maximum Demand. A Demand Factor is applied to the Possible Maximum Demand to calculate the Probable Maximum Demand. The Probable Maximum Demand is the rate at which the heater must generate hot water, or the recovery rate.

9-2.6.3 Domestic Water Heater Redundancy.

Provide facilities with Category 1 or 2 Spaces (per Appendix B) with multiple water heaters and storage tanks. Total installed capacity to meet or exceed design capacity. Individual heaters and storage tanks to be sized such that the loss of any unit would reduce system capacity by no more than 33%.

9-2.6.4 Hot Water Design Temperature.

Generate and store domestic hot water at a minimum 140 ºF (60.0 ºC). Temper water with a master thermostatic mixing valve at the hot water generator to minimum 130 ºF (54.4 ºC) hot water supply. Recirculate water from all points of use complying with the maximum developed length requirements of paragraph 9-2.5.3.3. Limit the recirculation system temperature drop to 6 ºF (3.3 ºC) for a minimum return temperature of 124 degrees F (51.1 degrees C), providing isolating and balancing provisions.

9-2.6.4.1 Thermal Eradication.

Provide system capability to increase the domestic hot water storage and supply temperature to 180 ºF (82.2 ºC) for a thermal eradication process occurring under the direction of the Infection Control Officer with restricted system use and no general demand.

9-2.6.4.2 Patient and Visitor Toilet Facilities.

Provide ASSE 1070 compliant point of use water temperature limiting devices for supplying tempered water to lavatories and sinks intended for use by patients or visitors. Grouped fixtures may be served from a common water temperature limiting device within the limits of the maximum developed length requirements of paragraph 9-2.5.3.4.

9-2.6.4.3 Showers and Baths.

Provide shower and bath-shower combination valves as point of use balanced-pressure, thermostatic or combination balanced-pressure/thermostatic type valves that conform to the requirements of ASSE 1016/ASME A112.1016/CSA B125.16 or ASME A112.18.1/CSA B125.1. Valves must be equipped with a field adjustable means to limit the maximum setting of the valve to 120 ºF (49.0 ºC).

9-2.6.4.4 Supply and Utility Areas.

Central sterile supply, soiled utility rooms equipped with bedpan washers, cart wash areas, and special pathological wash areas must be provided with 140 ºF (60.0 ºC) hot water.

9-2.6.4.5 Food Service Areas.

Review and comply with the Dishwashing and Ware Washing requirements in Appendix F and the Tri-Service Food Code (TSFC). Provide these areas with 140 °F (60.0 °C) hot water. Mechanical ware-washing and sanitizing equipment normally require 180 °F (82.2 °C) water. Provide Booster heaters to obtain the temperatures required.

9-2.6.4.6 Renovation, Additions and Alteration Projects.

Where a project includes upgrading an existing domestic hot water system to the current higher supply water temperature requirements, precautions for the prevention of scalding must be included.

9-2.7 Plumbing Fixtures and Other Equipment.

Plumbing fixtures should conform generally to American Society of Mechanical Engineers International (ASME) Standards Series A112 or International Association of Plumbing and Mechanical Officials (IAPMO) Standards Series Z124. For uniformity, all fixtures must be identified by the Joint Schedule Number (JSN) provided in MIL-STD-1691. Quantities of fixtures must be in accordance with the International Building Code and International Plumbing Code but not less than indicated in the approved PFD and PRC.

9-2.7.1 Accessibility Fixtures.

Provide accessible fixtures in accordance with Chapter 13.

9-2.7.2 Drinking Water Coolers.

Locate public drinking water coolers convenient to each public waiting room and elsewhere as required by the IPC and as directed by the DoD Project Sponsor. The standard rating and performance must conform to Air Conditioning and Refrigeration Institute (ARI) Standard 1010.

9-2.7.3 Emergency Shower and Eye Wash Fixtures.

Emergency shower and eye wash fixtures must be designed in accordance with the American National Standards Institute (ANSI) Standard Z358.1.

9-2.7.4 Water Usage Conservation.

Water usage conservation design must comply with UFC 1-200-02.

9-2.7.5 Wall Hydrants.

Provide wall hydrants where required by UFC 3-420-01 and within 20 ft (6 m) of any loading dock, emergency room ambulance drop-off, and ambulance shelter.

9-2.7.6 Urinals.

Urinals must be low flow with a maximum water use of 0.125 GPF (0.5 LPF). Waterless urinals may only be used when approved by the DoD Project Sponsor.

9-2.8 Coordination with Medical and Dental Equipment.

Medical and Dental equipment can have special water quality and pressure requirements. Plumbing designers must carefully analyze the building water supply condition before starting a project design. When a facility building water supply cannot meet equipment manufacturer's requirements, local (or centralized) water treatment systems and/or water pressure boosters must be provided in appropriate mechanical spaces.

9-2.8.1 Dental Water Purification Systems.

Dental water is specially treated water for patient use which undergoes multiple stages of filtration to achieve zero Total Dissolved Solids (TDS), chlorine and chemical free, prevent biofilm and bacterial growth in the water lines etc. The need for on-site production of dental pure water must be coordinated with the DoD Project Sponsor. Dental water purification systems may be direct feed or bottle-fill systems as determined by the DoD Project Sponsor. Installation of the purification system must be in accordance with manufacturer's recommendations and instructions. This includes providing any required pre-filters, booster pumps, water storage tanks, and dental water faucets. The purified water may also be used for sterilizers by direct feed or water faucet. Provide an additional water faucet with direct feed installation systems. Connect the dental water purification system to the building's essential electrical system where provided. Piping material downstream of the dental water purification system may be either type 304 or 316 stainless steel or material recommended by the dental water purification system manufacture. Do not use copper pipe downstream of the purification system.

9-3 DRAINAGE SYSTEMS.

9-3.1 Sanitary Drainage System.

The sanitary waste system must be connected to an approved existing sanitary sewer system, either Government or private as appropriate. If an existing sewage disposal system is not available, an approved alternative system must be provided. For example, a holding tank may be acceptable for remote locations, for temporary service while awaiting the installation or retrofit of an approved sewage disposal system, or a backup such as for hardened or essential facilities. Any alternative to an approved central sanitary system must be coordinated with the Installation's local approving authority. When connected to a local public system, code requirements in excess of the IPC imposed by the local regulatory agencies must be considered in the design. The system must be designed to avoid excessive back pressure and aspiration effects. If a facility sanitary waste requires lifting or pumping, comply with UFC 3-240-01. Connect

this equipment to the emergency power system if one exists or is included in the project scope.

9-3.1.1 Cleanouts.

Provide cleanouts in accordance with the International Plumbing Code to permit access to all sections of the sanitary sewage system. Locate the cleanouts to avoid or minimize disruption of medical functions. Do not locate cleanouts above ceilings; extend cleanouts to the floor above.

9-3.1.2 Protection of Special Fixtures and Equipment.

Fixtures and equipment used for sterilization, and food preparation, processing, or storage, must be protected from contamination by backflow of waste. An indirect waste line, such as an air break or physical disconnection (open drain) at the associated waste outlet, must be incorporated into the system design. These provisions also apply to equipment that cannot be easily cleaned. Included are sterilizers, glass washers, refrigerators, kitchen equipment, dental laboratory equipment, for example, boil-out assembly tanks, and vacuum system separator tanks.

9-3.1.3 Special Drainage Equipment.

Interceptors must be provided when precious materials or heavy metals, such as silver and barium, or sediment is in the waste drainage from spaces such as cast rooms, prosthodontics laboratories, barium procedure areas, and spaces employing blood analyzers. Interceptors for barium waste must be aluminum. Flush rim floor drains must be provided in Autopsy. Food waste disposers must be provided in kitchens on dishwashers, pot and pan sinks, and other sinks as designated. Grease traps must be provided with grease-producing kitchen equipment including prewash sinks, pot washers or sinks, and floor drains serving kettles. Separators must be provided in areas where petroleum products are subject to dripping or spills, such as ambulance garages and mechanical equipment rooms. **\1**

9-3.1.4 Coordination with Medical and Dental Equipment.

Placement of floor drains and floor sinks for specialized equipment must be coordinated to minimize infection control risk. Special consideration must be given to drains in rooms where infection control restrictions are heightened due to potential contamination of equipment, instruments, or supplies (for example central sterilization, dental instrument processing, pharmacy, etc.). For example, floor drains should not be located in Sterile Storage rooms and floor drains for pass-through sterilizers should be located in the loading-side room rather than the unloading side room. **/1/**

9-3.1.5 Special Purpose Waste Lines.

9-3.1.5.1 Acid Waste.

Separate waste lines must be provided for acid waste from laboratories when justified by the quantities, concentration, or both, of reagent expected to be introduced. Acid-resistant waste piping must be utilized for such applications and, must pass through a neutralizing or dilution tank before combining with building waste. If more than test tube quantities of acid or strong base solutions are to be discharged into the waste system, neutralization is required.

9-3.1.5.2 Radioactive Waste.

Separate waste lines must be provided for radioactive waste from laboratories and nuclear medicine treatment rooms. There are various radioactive materials to be found in medical facilities. The particular radioactive waste for a given facility must be identified. The appropriate prescribed manner of disposal in accordance with 10 CFR (Code of Federal Regulations) Part 20—Standards for Protection Against Radiation and local safety standards must be incorporated into the design.

9-3.1.6 General-Purpose Floor Drains.

General-purpose floor drains must be considered for rooms in which water-using plumbing fixtures or equipment are located. These include physical therapy (PT) rooms that are equipped with hydrotherapy equipment, central sterile areas for sterilizers and sanitizing washers, food service areas, wash-down and housekeeping spaces, and mechanical equipment rooms that contain water-using equipment. Floor drains are not required at emergency shower or eyewash locations but may be provided to facilitate mandatory testing. Provide properly sized floor drainage system for restrooms designed for more than single occupancy, where equipment wash-down might occur, and capture unplanned water dump from fixtures/equipment to prevent damage to adjacent spaces, to include floors below, following UFC 3-420-01. Floor drains, where provided, must follow the criteria in UFC 3-420-01.

9-3.1.7 Trap Priming.

Where a trap seal is subject to loss by evaporation, a trap seal primer valve must be installed. When utilized, automatic primers must incorporate a backflow prevention feature. Other means of trap prime maintenance are not permitted.

9-3.1.8 Retrofit or Alteration Considerations.

The replacement of older existing fixtures with lower-flow fixtures may alter system performance. Provide a system that ensures transport of solid wastes utilizing strategies that include flows from other water-consuming appliances, plumbing fixtures, (for example lavatory faucets, flushing urinals, showerheads), increased slope, or change of pipe diameter in accordance with UFC 3-420-01.

9-3.1.9 Elevator Pit Sumps.

Elevator pits must be provided with a sump and sump pump. Pumped designs must include integral oil sensors and must deliver fluids to an indirect connection to the sanitary or storm drainage systems, such as a floor drain. The sump discharge line must include a check valve to prevent backflow of fluid into the sump. If permitted by the local jurisdiction, a direct connection to the storm drainage system may be considered. Designers should also assess whether the DoD Project Sponsor requires an oil interceptor. No other drains or sump discharges must be connected to the elevator pit drain or sump. This equipment must be connected to the alternative power source if one exists or is included in the project scope. Refer to Chapter 16 for additional requirements.

9-3.1.10 Mercury Control.

Facilities containing operations that generate mercury wastes in the free or leachable states (for example dental filling amalgams) must be provided with ISO 11143 certified amalgam separators and comply with any additional Federal, state, or local requirements. See also paragraph 9-5.21.1.

9-3.1.11 Dialysis Waste Box.

Provide dialysis waste box drains with automatic trap primers and/or automatic disinfection systems.

9-3.2 Storm Drainage System.

9-3.2.1 Cleanouts.

Provide storm sewer cleanouts in accordance with the International Plumbing Code to permit access to all sections of the storm sewer system. Locate the cleanouts to avoid or minimize disruption of medical functions. Do not locate cleanouts above ceilings but instead extend the cleanout to the floor above (except for the top floor). Avoid placing cleanouts in high traffic areas.

9-4 FUEL GAS SERVICE.

Applications for fuel gas utilization include a fuel source for space heating, domestic hot water generation, cooking, generation of steam for humidification and sterilization, and as a point-of-use heat or flame source to support medical and laboratory functions. Fuel gas system design, including liquefied petroleum gas systems, must be in accordance with NFPA 54, 58, and 59A, as applicable.

9-5 MEDICAL GAS SYSTEMS.

Medical gas systems for all applications covered by this UFC must comply with NFPA 99 as limited by this UFC and United Facilities Guide Specifications (UFGS) 22 60 70 Gas and Vacuum Systems for Healthcare Facilities. Unless otherwise noted, the term

"medical gas systems" in this UFC refers to all medical gas, dental gas, and vacuum systems. Refer to Table 9-5 for general medical gas systems information.

Table 9-5 Medical Gas Systems[a]

Reference NFPA 99

System	Appendix B Notation	System Pressure
Compressed Air		
Medical Compressed Air	MA	50-55 psig (345–380 kPa)
Dental Compressed Air	DA	90-95 psig (620–655 kPa)
Laboratory Air – Dental	LA	30-35 psig (210–245 kPa)
Laboratory Air – Medical	LA	50-55 psig (345–380 kPa)
Instrument Compressed Air	IA	50-185 psig (345–1275 kPa)
Process Air	PA	120-125 psig (830–865 kPa)
Vacuum		
Medical Surgical Vacuum	MV	15-19 in-HgV (51–65 kPaV)
Dental Surgical Vacuum	DSV	15-19 in-HgV (51–65 kPaV)
Oral Evacuation	OE	6-8 in-HgV (21–27 kPaV)
High Volume Lab Dust Evacuation	LDE	50 in-HgV (10 kPaV)
Waste Anesthesia Gas Disposal	WAGD	6 in-HgV (21 kPaV)[b c]
Gases		
Oxygen	O	50-55 psig (345–380 kPa)
Carbon Dioxide	CO2	50-55 psig (345–380 kPa)
Nitrous Oxide	NO	50-55 psig (345–380 kPa)
Nitrogen	N	50-185 psig (345–1275 kPa)

a. Other gas systems included in this chapter but not in Appendix B: Gas (natural or propane) – flame or heat source.

b. This is a minimum value; vacuum controlled by healthcare provider administering the anesthesia gas.

c. For veterinary care, design pressure must be coordinated with the anesthetizing equipment.

9-5.1 Application of NFPA 99 to Dental Systems.

Dental gas and vacuum systems must comply with NFPA 99 and this UFC. Allowances/exceptions in NFPA 99-2018 Chapter 15 which reduce/relax NFPA 99 Chapter 5 system requirements are NOT permissible; as such do not incorporate any of the exempted features into designs for dental systems. All requirements for piping, piping installation, warning systems, testing and verification must follow NFPA 99 Chapter 5 for the system category determined in NFPA 99 Chapter 15. For example, if a Dental Air system is determined by NFPA 99 Chapter 15 to be Category 2, the system must meet all Category 2 requirements in NFPA 99 Chapter 5 as well as the prescriptive requirements in this UFC.

9-5.2 Application of NFPA 99 to Veterinary Care.

Medical gas systems for veterinary care must comply with NFPA 99 even though NFPA 99 indicates an exclusion for veterinary care. The required Risk Assessment process must be carefully implemented with the unique considerations of the veterinary patients and caregivers to arrive at appropriate System Categories.

9-5.3 Systems for Medical Clinics and Ambulatory Care Clinics.

Centrally-piped medical gas/air/vacuum systems are not normally required or authorized for outpatient medical treatment clinics, with the exception of ambulatory care clinics. If attached to a facility having central systems, designers must consider extending service lines to the clinic if LCC effective.

9-5.4 Systems for Dental Clinics.

Centrally-piped systems must normally be provided for dental compressed air (DA), OE, dental surgical vacuum (DSV), high volume laboratory dust evacuation (LDE), and dental laboratory air (LA). A separate system for WAGD must be required unless the DoD Project Sponsor designates the DSV system for that purpose. Fuel gas (natural or propane) must be provided as required to support prosthodontic and orthodontic laboratories and DTRs. For freestanding clinics with fewer than five chairs, selection of a central system for gases as opposed to point-of-use systems must be based upon LCC considerations.

9-5.5 Corrugated Medical Tubing.

Corrugated Medical Tubing (CMT) may only be utilized if approved by the Design and Construction Agent. CMT may be advantageous for emergency repairs or temporary facilities however it is limited in size, has a higher pressure drop than standard medical gas copper tubing and must not be utilized for wet vacuum systems.

9-5.6 Medical Gas Equipment Rooms.

Install medical gas system equipment such as air compressors and vacuum pumps in a mechanical equipment space complying with NFPA 99. The medical gas system

equipment space must be ventilated and conditioned in accordance with manufacturer's recommendation or mechanical room criteria (Appendix B Room Code MECH1), whichever more stringent.

9-5.7 Underground Piping.

Underground medical gas piping must be protected in a continuous concrete trench or steel pipe enclosure and comply with NFPA 55 section 7.1.17 Underground Piping and NFPA 99 section 5.1.10.11.5 Underground Piping Outside of Buildings. Consider provisions for future replacement of piping. Piping must not be installed under a building.

9-5.8 System Control Valves.

All medical gas centrally-piped systems must be provided with shut-off valves and zone valve box assemblies in accordance with NFPA 99. Additional shut-off valves must be included as designated by the Design and Construction Agent to provide system section isolation for maintenance or alterations.

9-5.9 Alarm Systems.

Medical gas alarm systems must be provided for all centrally-piped systems in accordance with NFPA 99 except that the use of a centralized computer system (for example Building Automation System) in lieu of a Master Alarm Panel is not permitted. A Building Automation System may be utilized for monitoring only of a medical gas system.

9-5.10 Gas System Sources (Storage).

Gas system sources or storage provisions must be designed in accordance with NFPA 99. Flammable and nonflammable storage containers must be stored in separate enclosures. Bulk oxygen storage design must be in accordance with NFPA 55.

9-5.10.1 Point-of-Use Sources.

Point-of-use cylinders are defined as B, D, or E sizes. The designer must coordinate with the DoD Project Sponsor the provisions for point-of-use cylinder storage when use is planned. Storage in the storage room for central system cylinder banks is permissible. The point-of-use cylinder volume must be included in the total when determining the storage room ventilation requirements. Design must incorporate Compressed Gas Association (CGA) requirements of Pamphlet P-2.

9-5.10.2 Alternative Compressed Air Sources.

Alternative compressed air sources, such as pneumatic control air or shop air compressors, must not be used as a source for medical compressed air (MA), DA, LA, instrument air (IA), or process air (PA).

9-5.10.3 Oxygen Concentrators.

Oxygen Concentrators may only be considered for utilization in unique circumstances where a reliable source for oxygen delivery is not available such as in forward deployed isolated locations. A written request documenting the requirement for this type of system must be provided and coordinated with the DoD Project Sponsor and the Design Construction Agent. When authorized these systems must comply with NFPA 99.

9-5.11 Color Coding and Labeling.

Labeling and color identification of piping must be in accordance with NFPA 99 and the CGA Pamphlet C-9. System components must also be labeled for identification to prevent tampering and inadvertent closing. In particular, shut-off valves and pressure gauges must be labeled in accordance with NFPA 99.

9-5.12 Medical Gas Systems Outlets.

Appendix B contains guidance for allocation and location of medical services and outlets in the various spaces within a facility. Refer to the MHS Space Templates for typical locations of medical equipment that may require medical gas. The designer must coordinate the gas types and outlet quantities with the DoD Project Sponsor. Additional outlets and gas types may be provided when justified by the DoD Project Sponsor. All outlets must comply with the latest edition of NFPA 99 and the requirements of CGA Pamphlet V-5. There are Diameter Index Safety System (DISS) and quick connect-type outlets, with three primary configurations of the quick connect outlet (geometric configuration, pin index, latching type). Therefore, the designer must also coordinate the outlet type configuration with the DoD Project Sponsor so users must not have to use outlet adapters for existing medical equipment.

The use of a central medical gas system to serve an outlet that indirectly supports the medical function, such as in a laboratory, may be justified. If so, the branch piping and outlets must be in accordance with NFPA 99. Non-medical uses are not permissible except for unique circumstances with documented waiver requests, coordinated with the DoD Project Sponsor and Design and Construction Agent, reviewed individually.

9-5.13 Power Source for Medical Gas Systems.

Medical gas system equipment must be served by an EES where determined through an NFPA 99 Risk Assessment or where otherwise required within NFPA 99 or this UFC.

9-5.14 Medical Compressed Air (MA).

The MA system must be an independent centrally-piped system consisting of two or more medical air compressors and a central receiver, all conforming to the requirements of NFPA 99. It must be used only for medical functions requiring breathable air to support respiration or for air-driven instruments that discharge into the pharynx. The MA system must not be used to satisfy any other compressed air requirements. The

system design must include automatic operation of the compressors, including alternating lead and lag status.

9-5.14.1 Air Quality Standards.

Medical air compressors must be specifically designed and manufactured for Medical Air purposes, meeting NFPA 99 and these requirements. Intake air must be direct from outdoors or from an HVAC supply air system operational 24/7 and in compliance with NFPA 99 paragraph 5.1.3.6.3.11(E) with the following clarification: HVAC supply air systems with motors or drivebelts in the air stream may be utilized as an air source provided that an intermediate filter of MERV 13 (or better) is located downstream of the fan(s) and cooling coils.

Filtration of intake air must include redundant activated carbon filters with redundant pre-filters and final filters (located downstream of the carbon filters). System pressure regulators and filters must be duplexed with the ability to isolate any device.

9-5.14.2 General Requirements.

MA must be provided by two or more compressors with provisions for automatic, alternating, and simultaneous operation. The compressors must be sized such that if any one compressor fails, the remaining compressor(s) must provide 100 percent of maximum system demand. Provide an alarm to indicate compressor failure that annunciates at the master medical gas alarm panel. All system components downstream of the compressors must be sized for 100 percent standard system demand and be duplexed. The receiver must be sized per manufacturer recommendation and must have an automatic drain feature.

9-5.14.3 Air Drying.

System must include an air dryer of the desiccant type capable of drying the air to a dew point of -40 ^{o}F (-40 ^{o}C). Designers must consider: **\1**

a. **/1/** Desiccant dryers are capable of drying the air to a dew point as low as -40 ^{o}F (-40 ^{o}C), which may be considered too low for some medical applications. When required by the DoD Project Sponsor, the design must include specification of equipment accessories that permit upward adjustment of air moisture to the required dew point. **\1**

b. **/1/** To improve the efficiency of a desiccant dryer system, a refrigerated dryer may be used to precondition the intake air to the desiccant dryer. When mechanical refrigeration systems are specified, designers must include specification of a cycling feature for all systems under 5 hp (3.7 kW) to minimize the possibility of icing and moisture carryover. Designers must evaluate whether anticipated flow conditions require the cycling feature for systems 5 hp (3.7 kW) and over.

9-5.14.4 MA Demand.

System demand must be calculated utilizing the peak flow and simultaneous use data in Table 9-6 as a minimum. The simultaneous use factors must be used with judgment and modified to adapt to special conditions if required.

Table 9-6 Medical Compressed Air (MA) System Demand

	General Demand[1]			Ventilator Demand[2]			
	SCFM (SLPM)	Units	Usage Factor	SCFM (SLPM)	Units	Qty	Usage Factor
Ventilator Locations:							
Recovery Phase 1 (RRSS1)	2.0 (57)	Bed	25%	2.6 (75)	Bed	1	100%
Patient Bedrooms, ICU[3]	2.0 (57)	Bed	50%	2.6 (75)	Bed	1	100%
Biomedical Equipment Repair (BMER1)	1.5 (42)	Outlet	10%	2.6 (75)	Room	1	100%
Anesthesia Ventilator Locations:							
Operating Room[4]	0.5 (14)	Room	100%	0.9 (25)	Room	1	100%
Veterinary Surgery (VS001)	0.5 (14)	Room	50%	0.9 (25)	Room	1	100%
Veterinary, Surgery, Preparation / Dental (VSPD1)	0.5 (14)	Bed	50%	0.9 (25)	Room	1	100%
Trauma – (TRET1 & TRET3)	0.5 (14)	Room	25%	0.9 (25)	Room	1	100%
Radiology (XABP1 & XCCE1)	0.5 (14)	Room	10%	0.9 (25)	Room	1	100%
Medical Air for Peripheral Device Locations:							
Exam/Treatment[5]	1.1 (30)	Room	10%				
LDR/LDRP (LDRP1, LDRP3) includes infant armoire	1.0 (28)	Room	50%				
Observation (OOTR1)	1.1 (30)	Bed	10%				
Anesthesia Workroom (ANCW1)	1.1 (30)	Room	10%				
Respiratory Equipment, Clean (OPRC1)	1.5 (42)	Station	10%	2.6 (75)	Room	1	100%
All Other Room Codes[6]	0.5 (42)	Outlet	10%				

[1] Demand for devices not including ventilators.
[2] Ventilator demands (locations and flow rates) must be validated for each project but will not be less than provided for in this table.
[3] ICU Bedroom category includes Room Codes BRIC1, BRII1, BRII2, BRIT2, BRUN1, NYIC2, NYEC1, NYIR1, NYUN1, NYUN2.
[4] Operating Room category includes Room Codes ORCS1, ORCT1, ORGS1, ORHY1, ORNS1, OROS1, LDDR1.
[5] Emergency Room category includes Room Codes EXEB1, EXEN2, EXER1, EXER2, TRET4, TRET5.
[6] All room codes in Appendix B that have one or more medical air outlet requirements.

9-5.15 Dental Compressed Air (DA).

A centrally-piped DA system with two or more compressors and other components described herein must be provided in accordance with NFPA 99. DA must be used for drying applications during dental procedures and as a power or drive source for lifts, locks, and pneumatic dental instruments and equipment. DA, unlike MA, is not used for breathing or respiratory support of any kind and must not be used to satisfy MA requirements. Air that is normally used for dental laboratory restorative and fabrication techniques may be provided by the DA system.

9-5.15.1 Air Quality Standard.

Dental Air compressors must be designed and manufactured IAW NFPA 99, UFGS 22 60 70 and these requirements. Intake air must be direct from outdoors or from an HVAC supply air system operational 24/7 and in compliance with NFPA 99 paragraph 5.1.3.6.3.11(E) with the following clarification: HVAC supply air systems with motors or drivebelts in the air stream may be utilized as an air source provided that an intermediate filter of MERV 13 or better is located downstream of the fan(s) and cooling coils.

Filtration of intake air must include redundant activated carbon filters with redundant pre-filters and final filters (located downstream of the carbon filters). System pressure regulators and filters must be duplexed with the ability to isolate any device.

9-5.15.2 DA Components.

DA must be provided by two or more equally sized compressors, with provisions for automatic, alternating, and simultaneous operation. Each compressor must be sized such that if any one compressor fails, the remaining compressor(s) must provide 65 percent of standard demand. Provide an alarm to indicate compressor failure that annunciates to the master medical gas alarm panel. All system components downstream of compressors must be sized for maximum combined compressor output. In-line pressure regulators must be provided when DA and dental LA systems are served by a common compressor. Each laboratory supply main must have a pressure regulator. Dryer type must be desiccant.

9-5.15.3 DA System Demand.

The system must be sized using these criteria:

Select a DTR Usage Factor:

Number of DTR Chairs	DTR Usage Factor (DUF)
1–3	1.0
4–6	0.9
7–12	0.8
13–19	0.7
20 and up	0.6

Equation 9-1. DTR Demand = No. of DTR chairs X 3 SCFM (85 SLPM) X DUF

Select a lab usage factor:

Number of Technicians	Lab Usage Factor (LUF)
1–5	0.6
6–10	0.5
11–19	0.4
20 and up	0.3

Equation 9-2. Lab Demand = No. of Technicians X 1 SCFM (28 SLPM) X LUF
+ No. of sand/shell blasters X 4 SCFM (113 SLPM) X LUF
+ No. of air chisels X 3 SCFM (85 SLPM) X LUF
+ No. of denture presses X 1 SCFM (28 SLPM) X LUF
+ No. of micro-blasters X 6 SCFM (170 SLPM) X LUF
+ No. of high speed hand pieces X 3 SCFM (85 SLPM) X LUF

Equation 9-3. Sterilization demand = No. of hand piece purge stations X 1 SCFM (28 SLPM)

Equation 9-4. Standard demand = DTR demand + Lab demand + Sterilization demand

Select the optimum compressor grouping:

Table 9-7 Compressor Grouping

Type	System Usage Factor (SUF)
Duplex	0.65
Triplex	0.33
Quadplex	0.25

Equation 9-5. Compressor size = SUF X Standard demand

The receiver must be sized based on Table 9-7

Table 9-8 Receiver Size

Number of DTR Chairs	Gallons (Liters) per DTR Chair
1–6	10 (37.8)
7–9	9 (34.0)
10–12	8 (30.3)
13–15	7 (26.5)
16–18	6 (22.7)
19–21	5 (19.9)
>21	4 (15.1)

9-5.16 Laboratory Air (LA).

The medical or dental LA system must be a centrally-piped system consisting of two or more compressors and a central receiver, all conforming to the requirements of NFPA 99.

9-5.16.1 Air Quality Standard.

Laboratory Air compressors must be designed and manufactured IAW NFPA 99, UFGS 22 60 70 and these requirements. Intake air must be direct from outdoors or from an HVAC supply air system operational 24/7 and in compliance with NFPA 99 paragraph 5.1.3.6.3.11(E) with the following clarification: HVAC supply air systems with motors or drivebelts in the air stream may be utilized as an air source provided that an intermediate filter of MERV 13 or better is located after the fan(s) and cooling coils.

Filtration of intake air must include redundant activated carbon filters with redundant pre-filters and final filters (located downstream of the carbon filters). System pressure regulators and filters must be duplexed with the ability to isolate any device.

9-5.16.2 LA System Components.

LA must be provided by two equally sized compressors with provisions for automatic, alternate, and simultaneous operation. Each compressor must be sized to provide 65 percent of maximum demand. Provide an alarm to indicate compressor failure that annunciates to the master medical gas alarm panel. All system components downstream of compressors must be sized for maximum combined compressor output. A DA generator package used to service an LA system must be supplied by a dedicated main located just downstream of the final package component and inside the equipment room.

9-5.16.3 LA System Demand.

Determine the LA system flow demand by the number of work stations and their function plus the requirements for laboratory equipment. The DoD Project Sponsor must provide this information. The designer in conjunction with the Design and Construction Agent must establish the flow rates. Medical LA system flow rate demand must be 1 SCFM (28 SLPM) per outlet. Dental LA system flow rate demand is determined by the sizing procedure shown in paragraph 9-5.15.3. The simultaneous use factors must be as listed in Table 9-9.

Table 9-9 Medical Laboratory Air (LA) System Demand

No. of Outlets	Use Factor	Minimum SCFM (SLPM)
1–2	100	
3–12	80	3 (1.4)
13–38	60	10 (4.7)
39–115	40	25 (11.8)
116–316	30	50 (23.6)
317–700	20	95 (44.8)

9-5.17 Instrument Air (IA).

An IA system is **\1** a Medical Support Gas intended to power medical and dental devices not related to human respiration, for example, surgical hand tools, surgical arms, surgical columns, and SPD support. This system may be utilized in lieu of a piped nitrogen (N) system. The DoD Project Sponsor in conjunction with the Design and Construction Agent must identify IA requirements. IA must not be used to satisfy medical air requirements. IA systems must be designed in accordance with the requirements of NFPA 99. System pressure must be determined within the range identified in Table 9-5 and coordinated with all intended uses.

Each individual use location, for example, individual OR, DTRs, must be provided with a local pressure control panel for the purpose of independently regulating pressure at that location. Provide additional pressure control panels where needed to meet the intended use. Where all end uses are determined to be uniform in pressure, pressure control panels may be eliminated with the concurrence of the DoD Project Sponsor and Design and Construction Agent. **/1/**

9-5.17.1 Air Quality Standard.

Air compressors used for IA must conform to the requirements of NFPA 99, UFGS 22 60 70 and these requirements. IA quality must be as defined in NFPA 99. System must include an air dryer of the desiccant type capable of drying the air to a dew point of -40

°F (-40 °C). Intake air must be direct from outdoors or from an HVAC supply air system operational 24/7 and in compliance with NFPA 99 paragraph 5.1.3.6.3.11(E) with the following clarification: HVAC supply air systems with motors or drivebelts in the air stream may be utilized as an air source provided that an intermediate filter of MERV 13 or better is located after the fan(s) and cooling coils.

Filtration of intake air must include redundant activated carbon filters with redundant pre-filters and final filters (located downstream of the carbon filters). System pressure regulators and filters must be duplexed with the ability to isolate any device.

9-5.17.2 IA System Components.

The number of compressors for an IA system must be a function of the application; however, at least two compressors must be provided. For stand-alone clinics, one compressor with a standby header may be provided. Coordinate the compressor arrangement with the Design and Construction Agent. The compressors must be sized such that if any one compressor fails, the remaining compressor(s) must provide 100 percent of maximum system demand. Provide an alarm to indicate compressor failure that annunciates at the master medical gas alarm panel. All system components downstream of the compressors must be sized for 100 percent standard system demand and be duplexed. The receiver must have an automatic drain feature and must be sized per manufacturer recommendation.

9-5.17.3 IA System Demand.

The number of workstations and their functions plus the requirement of any equipment must determine the IA system flow demand. The piping system must be suitable to deliver 15 SCFM (425 SLPM) per outlet, with a demand usage factor of 100 percent. System capacity must be determined using these equations:

Capacity (SLPM) = 340 + ([n-1] X 85) or

Capacity (SCFM) = 12 + ([n-1] X 3)

Where: n = number of locations or tools

9-5.18 Process Air (PA).

PA may be a centrally-piped system when warranted by the application, for example, medical service column adjustment, shop operations, door operators. The DoD Project Sponsor, in conjunction with the Design and Construction Agent, must identify PA requirements. When approved by the Design and Construction Agent, LA or IA may be used to satisfy PA requirements. PA is not required to be oil free, but must be suitable for the application as recommended by the equipment manufacturer.

9-5.19 Medical Surgical Vacuum (MV) System.

The MV system must be a centrally-piped, dry vacuum system containing two or more continuous duty pumps with a central receiver. The system must meet the requirements of NFPA 99 and must be sized so that if one pump fails, the remaining pump(s) can supply 100 percent of the total system demand. The system design must include automatic operation of the vacuum pumps including alternating lead and lag status. Provide an alarm to indicate vacuum pump failure that annunciates to the master medical gas alarm panel. Refer to Table 9-10.

Table 9-10 Medical Vacuum Source Sizing

Occupancy/Location	Diversity Factor	High Demand
Anesthetizing Locations:		
Special Surgery and Cardiovascular	A	Y
Major Surgery and Orthopedic	A	Y
Minor Surgery/Cystology	A	Y

Med. Laboratory	B	N

9-5.19.1 Applications.

The MV must be used only for medical functions involving patient care, therapy, and diagnostic functions as described here. It may also serve DSV requirements for DTRs and oral surgeries, and small laboratories in patient care areas that function in direct support of medical functions. Analysis, research, or teaching laboratories located within a facility may also be served by the MV, provided that a separate system connection or main is located at the vacuum receiver, with a shut-off valve and trap with a drain valve. Laboratories not supporting medical functions must have a vacuum system separate from the MV.

9-5.19.2 Demand.

Size vacuum system pumps and piping in accordance with these equations:

$$\text{Demand Medical Vacuum} = \text{Demand}_A + \text{Demand}_B + \text{Demand}_C$$

Where: Demand_A = # Inlets for Diversity Factor A X 0.25 SCFM/inlet (7 SLPM/inlet) X Diversity Factor A

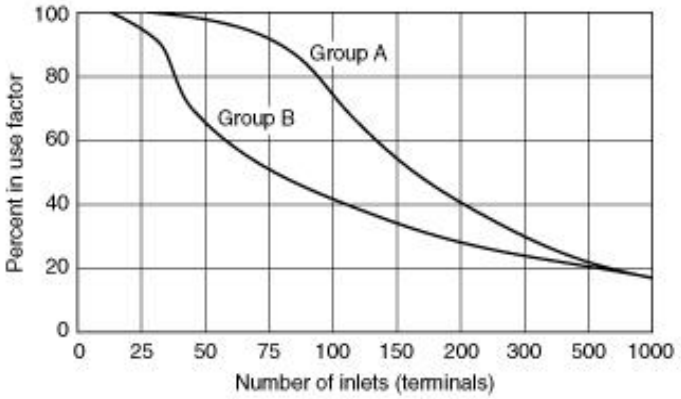
$Demand_B$ = # Inlets for Diversity Factor B X 0.25 SCFM/inlet (7 SLPM/inlet) X Diversity Factor B

$Demand_C$ = # Rooms with High Demand X 1.5 SCFM/room (42 SLPM/room)

It is important to note that $Demand_A$ and $Demand_B$ have a diversity factor determined by Figure 9-1, whereas $Demand_C$ assumes no diversity .

For example, the demand for a medical vacuum system for five **\1** Operating Rooms with 12 each medical vacuum inlets would be calculated as follows: ***/1/***

Demand Medical Vacuum = $Demand_A$ + $Demand_B$ + $Demand_C$



Where: $Demand_A$ = 12 medical vacuum inlets per OR per Appendix B X 5 ORs X 0.25 SCFM/inlet X 0.97 Diversity Factor for 60 inlets with “A” Diversity Factor = 14.55 SCFM

$Demand_B$ = 0

$Demand_C$ = 5 Rooms with High Demand X 1.5 SCFM/inlet
= 7.5 SCFM

Medical Vacuum Demand = 14.55 + 0 + 7.5 = 22 SCFM

Figure 9-1 Simultaneous Use Factors for Medical Vacuum

Note 1: If the medical-surgical vacuum system is to be used for the disposal of waste anesthetic gases, caution must be taken to ensure that the system is designed for the additional volume required. It is recommended that 4-3.3.1, Waste Anesthetic Gas Disposal, be consulted as well. It is essential that the design team consult with medical and hospital staff when determining the minimum number of station inlets.

Note 2: It should be understood that the percentage in use factors obtained from this figure represent an average hospital. Hospitals with heavier-than-average use can require higher use factors.

1. This graph is adapted from 1999 version of NFPA 99.
2. It is understood that percentage in use factors represent a typical hospital and may need to be increased, but must not be decreased without approval from the Design and Construction Agent.

9-5.19.3 Inlets.

The intended use of “Y-connectors” as a means of increasing available inlets is not recommended. A justified need for a vacuum inlet must be accommodated with another wall inlet, not a Y-connector. Verify with the DoD Project Sponsor that the number of vacuum inlets proposed must support the planned medical function operation without the use of Y-connectors.

9-5.19.4 Performance.

Design system pressure drop must be a maximum of 3 in-Hg (10 kPA) at the calculated demand flow rate. Performance is verified IAW NFPA 99 as follows: Flow each inlet (one at a time) at a flow rate of 3 SCFM (85 SLPM)) while maintaining 12 in-HgV (41 kPaV) at any adjacent station inlet.

9-5.19.5 Slide Brackets.

Vacuum bottle slide brackets must be provided for all medical vacuum inlets. Vacuum bottles must be used at all vacuum inlets to prevent liquids and solids from entering the piping network. Vacuum bottles must be provided with an overflow shut-off device to prevent carryover of fluids or solids into the piping system. Brackets must be positioned to provide proper clearance for flow meters and adapters and to eliminate conflict with electrical receptacles. Thus, it is recommended that the vacuum outlet be located at either end of a group of medical gas outlets, with the slide bracket to the outside, for example, in a healthcare station head wall unit. If two vacuum inlets are required at a given station, locate one at each end of the outlet group with the slide brackets to the outside. It is critical to coordinate vacuum inlet and slide locations with the designer and the DoD Project Sponsor to avoid interference with other items without compromising the medical function.

9-5.19.6 Exhaust.

Exhaust the medical vacuum system in accordance with NFPA 99 but do not combine with any other system exhaust.

9-5.19.7 Filtration.

Provide inlet filtration on central supply systems per NFPA 99. Filters must be sized for 100 percent of peak calculated demand while one filter or filter bundle is isolated. Ensure adequate space is provided at filters to allow clearance for maintenance personnel to access filter housings to replace filter elements.

9-5.20 Dental Surgical Vacuum (DSV).

A central DSV system may be supplied for areas in dental clinics where MV is required as specified in Appendix B. This system is also a dry system with a centrally-piped distribution system and receiver; no liquids or solids must be transported in the distribution system. Individual separators must be located in each applicable DTR. The

system must consist of two or more vacuum pumps and a central receiver. The system must be sized so that upon failure of one pump, the remaining pump(s) must maintain the minimum vacuum specified while providing 100 percent of the calculated demand. The system design must include automatic operation of the vacuum pumps including alternating lead and lag status. Provide an alarm to indicate vacuum pump failure that annunciates to the master medical gas alarm panel. For dental clinics located in a hospital, the MV system may be used in lieu of a DSV system.

9-5.20.1 Performance.

A minimum vacuum of 19 in-Hg (65 kPa) must be maintained at the receiver. System pressure drop must be such that the most remote inlet must have a minimum vacuum of 12 in-Hg (41 kPa) under peak demand conditions. System pressure drop must be a maximum of 3 in-Hg (10 kPa) at the calculated demand flow rate.

9-5.20.2 Demand.

Calculate system demand based on 2 SCFM (57 SLPM) for each DTR DSV inlet with the demand factors in Table 9-11:

Table 9-11 DSV Demand Factors

No. of DTR DSV Inlets	Use Factor
1–6	1.0
7–10	0.8
>10	0.6

9-5.20.3 Exhaust.

Exhaust the Dental Surgical Vacuum system in accordance with NFPA 99 but do not combine with any other system exhaust.

9-5.21 Oral Evacuation (OE).

A central low vacuum, high volume OE system must be installed in dental clinics to provide scavenging, collection, and disposal of liquids, solids, and aerosols from dental procedures. This is a wet system with liquids and solids transported through wetted piping from the collection point to one or more liquid or air separator tanks located upstream of two or more vacuum pumps. The tank serves as a collector for the fluids and solids and provides a means of automatic draining by indirect connection to the sanitary sewer. The tank draining system must include an automatic wash down feature for larger systems in a facility having greater than 10 DTR chairs. The vacuum pumps must be sized so that when one pump is inoperable, the remaining pump(s) must provide the required vacuum pressure and fluid flow for a minimum of 70 percent of the system demand. The system design must include automatic operation of the

vacuum pumps including alternating lead and lag status. Provide an alarm to indicate vacuum system fault, for example, pump failure, which annunciates to the master medical gas alarm panel. Protocol must include alarm initiation when a pump is not appropriately operating.

9-5.21.1 Components.

The service inlet normally is floor mounted in a utility center at the dental chair, or wall mounted with a means of connection to clinical end items, such as the high volume hose. The separator(s) must receive all liquid, air, and solids upstream of vacuum pump(s). Liquids and solids must be discharged from the separator(s), with piped gravity flow through an air gap into a trapped and vented receptor, for example, floor drains, sinks, standpipe receptors for small system suspended tank installations, connected to the sanitary waste system. Amalgam separators must be provided IAW paragraph 9-3.1.10 Mercury Control and must be configured centrally for a single point of collection at the vacuum producers. Additional point-of-use collection may be utilized where requested by the DoD Project Sponsor. The liquid/solid separator tank must discharge a minimum of once during a 24-hour interval for a one-tank system, when a high liquid level sensor activates for a two-tank system, or multiple daily discharges as recommended by the manufacturer. Separator overflow protection must be included to protect during periods of abnormal usage or when the automatic discharge malfunctions.

9-5.21.2 Performance.

The system operating range must be 6–8 in-HgV (20–27 kPaV). A minimum vacuum of 6 in-HgV (20 kPaV) must be maintained at the farthest inlet. System pressure drop must be a maximum of 1 in-Hg (3 kPa) at the calculated demand flow rate. A flow rate of 7 SCFM (200 SLPM) per inlet must be measured while maintaining 6 in-Hg (20 kPa) at the farthest inlet.

9-5.21.3 Demand.

Calculate the system demand based on 7 SCFM (200 SLPM) per inlet-nozzle orifice. The demand usage factor is normally 100 percent. Verify the specific usage factor with the Design and Construction Agent.

9-5.21.4 Separator Tank.

The separator and collector tanks must be sized per manufacturer recommendations but must be a minimum of 2.75 gallons (10.45 liters) per DTR chair. Multiple tanks must be provided for more than 20 chairs and must be considered for 20 or fewer chairs if continuous operation is necessary. Tank drainage piping must slope from the tank discharge point down to the discharge point at the floor drain or standpipe receptor.

9-5.21.5 Equipment Location.

The OE equipment must be located below the DTR floor level. Locate the separator tank adjacent to or stacked with the vacuum pump. Size the pipe to maintain system pressure loss within the maximum limit. The tank drain valve discharge must be a minimum 0.5 foot (150 mm) above the floor to accommodate the pipe slope, drain line turndown, and the indirect connection air gap to the sanitary drainage system receptor. The sanitary waste centerline of pipe must be a minimum 1 foot (300 mm) below the floor to accommodate the floor drain trap. The equipment room must be located as near the DTRs as possible to minimize distribution piping bends and pipe length. Equipment placement in the mechanical room must be arranged to provide the most direct connection to the distribution piping, the sanitary waste line, and the exhaust discharge point, in that order.

9-5.21.6 Piping Distribution.

Piping from each dental treatment chair must continuously slope back to the first separator at the vacuum source equipment to facilitate transportation of fluids and particulate. Minimum required slope is 1/4 in. per 10 ft (20 mm per 10 m). Distribution system piping must be a minimum 2 in. (DN50) in diameter. Where maintenance access is required, piping must be installed in accessible locations in covered trenches, tunnels, or crawl spaces. Provide cleanout fittings at every change of direction greater than 45 degrees and at every change in slope. Minimum clearances and access to cleanouts must comply with the cleanout requirements for sanitary piping in the International Plumbing Code, Section 708 Cleanouts.

In existing buildings, when piping must be routed above the dental treatment chairs or limited rise is necessary, observe the following requirements:

a. Minimize lift height.

b. Vertical pipe run from inlet to overhead pipe must be ½ in. (DN15) or in accordance with manufacturer's recommendation.

c. The vertical pipe must "tee" into the top of the overhead branch main.

d. The available vacuum level to satisfy performance requirements stated in paragraph 9-5.22.2 must be based on a reduction of the pump-generated vacuum at the rate of 1 in-Hg (3.4 kPa) for each 1.1 ft (335 mm) rise.

e. Provide cleanout fittings at the base of all risers.

9-5.21.7 Exhaust.

The exhaust pipe material and size, including the connection to the equipment discharge point, must be in accordance with manufacturer's recommendation. The number of bends and total length must be minimized. The exhaust piping must be a dedicated run from the equipment connection to the discharge point outside the facility, sloping back to the equipment and must not be connected to any other system exhaust. The exhaust discharge must be protected from backflow of air or liquids by detailing an

appropriate discharge arrangement, such as a gooseneck or shroud with screen with a check valve, or using a flapper valve approved by the manufacturer. The discharge point must be separated a minimum of 33 ft (10 m) from the DA or MA system intake and any HVAC system outdoor air intake.

9-5.22 High-Volume Laboratory Dust Evacuation (LDE).

The LDE system must scavenge and centrally separate, filter, and collect material trimmings, grinding debris (toxic and nontoxic), and particulates from polishing and finishing operations in the dental laboratory. Point-of-use dust collection may be provided for some operations per DoD Project Sponsor requirements.

9-5.22.1 System Components.

The LDE system for dental laboratories must consist primarily of one belt-driven vacuum pump complete with a preset, field-adjustable ingestion valve, exhaust silencer, and a central cyclonic separator with a filter bag system.

9-5.22.2 Performance.

The vacuum at the farthest inlet must be a minimum of 1.25 in-Hg (4.2 kPa). A flow rate of 60 SCFM (1700 SLPM) per technician work station inlet and 150 SCFM (4250 SLPM) per equipment item inlet must be measured while maintaining the 3 in-Hg (10 kPa) at the separator. Verify the equipment requirements with the DoD Project Sponsor.

9-5.22.3 Demand.

The system demand must be calculated based on the inlet flow rate requirement. Apply the usage factor values shown in Table 9-12 for the given number of inlets.

Table 9-12 LDE System Utilization Factors

Lab Size	Usage Factor	Separator Filter
# of inlets	percent	square feet (square meters)
1–4	100	60 (5.6)
5–10	80	120 (11.1)
11–15	70	160 (14.8)
16–24	60	220 (20.4)

9-5.23 Waste Anesthesia Gas Disposal (WAGD).

The WAGD system must be a centrally-piped, dry vacuum system containing two or more continuous duty pumps with a central receiver. It must meet the requirements of NFPA 99 and be sized so that if one pump fails, the remaining pump(s) can supply 100 percent of the total system demand. The system design must include automatic operation of the vacuum pumps including alternating lead and lag status. Provide an

alarm to indicate vacuum pump failure that annunciates to the master medical gas alarm panel.

For Veterinary Facilities, the design vacuum pressure must be carefully evaluated and established in coordination with the intended anesthetizing equipment and include provisions for pressure/flow rate adjustment and visual monitoring at each inlet.

9-5.23.1 Applications.

WAGD must be incorporated into the facility design. A dedicated WAGD system must be provided in accordance with NFPA 99. When permitted by NFPA 99, the DSV system may be used for WAGD in dental clinics. Inlets must be provided in anesthesia locations. Verify that the system vacuum pump is suitable for the high oxygen and nitrous oxide exhaust content associated with anesthetizing procedures.

9-5.23.2 Demand and Performance.

Base design on a demand of 1.8 SCFM (50 SLPM) per patient care station except for veterinary care which must be based on a demand of 0.18 SCFM (5 SLPM) per patient care station.

9-5.23.3 Exhaust.

Exhaust the WAGD system in accordance with NFPA 99 but do not combine with any other system exhaust.

9-5.24 Oxygen (O).

Oxygen (O) is used in the gaseous state to sustain life through direct delivery to the patient. Oxygen can be stored as a gas in cylinders or as a liquid in bulk tanks. The Federal Register (49 CFR 172) classifies oxygen primarily as a non-flammable gas with a secondary classification as an oxidizer; it can increase the range of flammability of other materials and gases when present in sufficient concentration. Its storage requires proper construction and ventilation in accordance with NFPA 99 and NFPA 55 for both a pressurized non-flammable gas and as a pressurized oxidizer gas. The oxygen system must not be used to supply non-patient uses with limited exceptions defined in NFPA 99 paragraph 5.1.3.5.2 Permitted Locations for Medical Gases. Separate point-of-use services must be used for such non-patient applications.

9-5.24.1 Provision of Central Systems.

When more than five outlets are provided and used on a routine basis, central oxygen storage and distribution systems must be provided, such as is typically the case with medical centers, hospitals, and large clinics. Point-of-use (“roll-in”) cylinders should be utilized for clinical applications involving few oxygen outlets and infrequent utilization.

9-5.24.2 Emergency Connections.

Provide an emergency oxygen supply connection (EOSC) on the building exterior as required by NFPA 99 except that an in-building oxygen reserve is not to be considered as a substitute for an EOSC. Provide an Auxiliary Source Connection as required by NFPA 99 except that it must be provided for all types of central supply systems, not just for cryogenic fluid supply systems. These connections may be used as a temporary auxiliary source of supply.

9-5.24.3 System Demand.

The piping system must be designed to deliver 0.7 SCFM (20 SLPM) at the outlet, utilizing a 100 percent usage factor for outlets in Category 1 Spaces and factors for outlets in other areas as defined in Table 9-13. Historical usage data from replaced or similar facilities may be used as a guideline when determining system demand instead of the method presented in 9-5.24.4. Reference paragraph 9-5.24.5 for additional design considerations for determining the required capacity of liquid bulk tanks.

Table 9-13 Oxygen System Utilization Factors

Number of Outlets	Percent Usage (%)
1–3	100
4–12	75
13–20	50
21–40	31
41–80	25
81 or more	15

9-5.24.4 Storage Capacity Sizing Method.

In the absence of available historical oxygen consumption data, Table 9-14 must be used in estimating required system storage capacity for inpatient MTFs. For facilities with predominantly outpatient functions, designers must work with the DoD Project Sponsor to estimate consumption rates and appropriate storage capacities.

Table 9-14 Cylinder Manifold Systems

Number of Beds	Minimum Number of Cylinders[1] [2]
1–50	8
51–75	12
76–100	16
101–125	20
126–150	24
1 Per bank of “H” cylinders	
2 Study must be performed that includes an analysis of an appropriate diversity factor and the cost-effective option between cylinder and bulk storage.	

9-5.24.5 Liquid Bulk-Tank Storage.

Designers must coordinate with the DoD Project Sponsor to consider the economic aspects of storage capacity. Excessive capacity translates to higher utilization costs due to boil off. Tank must be sized to account for boil off. Too little capacity may lead to higher costs because of more frequent tank refills, which includes vented oxygen cost as well as delivery fees. Designers must also consider the availability of an oxygen refill service. For remote locations, oversized capacity may be more practical and economical to minimize deliveries and provide for unexpected consumption increases. The selection between purchasing or leasing the bulk storage tank and ancillary equipment must be coordinated. Economic and logistic factors relative to the given supplier(s) must be considered. Consider provisions for future replacement of piping. The standard tank sizes are shown in Table 9-15.

Table 9-15 Oxygen Bulk Tank Sizes

Liters	Gallons
1,895	500
5,680	1,500
11,355	3,000
22,710	6,000
34,065	9,000
41,635	11,000
49,205	13,000
68,130	18,000
75,700	20,000

9-5.24.6 System Monitoring.

The central oxygen system design must facilitate oxygen system purity monitoring with an outlet placed in the biomedical maintenance area, or other area, as directed by the Design and Construction Agent. This outlet must be upstream (on the source side) of other oxygen outlets.

9-5.25 Nitrous Oxide (NO).

Nitrous oxide is an anesthetic gas capable of inducing the first and second stages of anesthesia when inhaled. It is classified as a nonflammable gas; however, it can increase the range of flammability of other materials and gases when present in sufficient concentration. Its storage requires proper construction and ventilation in accordance with NFPA 99. Nitrous oxide manifolds must not be located outside in cold climates due to the low vapor pressure of nitrous oxide at low temperatures.

9-5.25.1 System Demand.

The piping system must be designed to provide for a demand of 0.7 SCFM (20 SLPM) per patient care station. The system manifold must be sized to provide a minimum of 1/2 cylinder per week per patient care station (based on H-size cylinders). The minimum number of cylinders per header must be two.

9-5.26 Nitrogen (N).

Nitrogen is **\1** a Medical Support Gas primarily used as an operating or driving means for surgical hand tools and equipment. This system may be utilized in lieu of the IA system. The number of outlets must be the same as depicted for IA in Appendix B. The cylinder manifold system must be designed and installed in accordance with NFPA 99. System pressure must be determined within the range identified in Table 9-5 and coordinated with all intended uses.

9-5.26.1 Pressure Control Panel.

Each individual use location, for example, individual OR, DTRs, must be provided with a local pressure control panel for the purpose of independently regulating pressure at that location. Provide additional pressure control panels where needed to meet the intended use. Where all end uses are determined to be uniform in pressure, pressure control panels may be eliminated with the concurrence of the DoD Project Sponsor and Design and Construction Agent. **/1/**

9-5.26.2 Demand.

The piping system must be suitable to deliver 15 SCFM (425 SLPM) per outlet, with a demand usage factor of 100 percent. The system manifold must be sized to provide a minimum of 2 cylinders per week per orthopedic or neurosurgery OR and 1 cylinder per week per all other anesthetizing locations (based on H-size cylinders). The minimum number of cylinders per header must be two.

9-5.27 Carbon Dioxide (CO2).

Carbon dioxide is used during laparoscopic procedures to facilitate the insertion of surgical instruments into the body. It is pumped into the body to create space between the muscles and the organs, providing the surgeon a clear view of the area to be operated. Carbon dioxide is above its triple point under ordinary conditions of storage and is actually a liquid in the cylinders (but not a cryogenic liquid). It is classified as a nonflammable gas and its storage requires proper construction and ventilation in accordance with NFPA 99. The cylinder manifold system must be designed and installed in accordance with NFPA 99. Carbon dioxide manifolds must not be located outside in cold climates due to the low vapor pressure of CO2 at low pressure.

Design the piping system to provide a minimum demand of 2.0 SCFM (57 SLPM) per outlet with a 100 percent usage factor. In determining the storage capacity, designers must evaluate the CO2 demand of the equipment intended for each facility and in

consultation with the DoD Project Sponsor. At a minimum, the system manifold must be sized to provide a 1/2 cylinder per medical location (based on H-size cylinders). The minimum number of cylinders per header must always be two.

9-5.28 Process Gas.

Process gas is natural or propane that is used as a point-of-use heat or flame source. The process is typically found in laboratories and sometimes in other areas, such as equipment repair and DTRs, to support medical or dental functions. The gas system design must be in accordance with NFPA 54 and 58. **\1**

9-5.28.1 Process Gas Load and Outlet Demand.

/1/ The load is the sum of the consumption rates for the given apparatus or equipment to be serviced. Laboratory burners are typically sized at 5000 Btuh (1465 W) for small burners and 10,500 Btuh (3075 W) for large burners. For other equipment, such as casting ovens, use manufacturer's data.

Demand is based upon the number of outlets shown in Table 9-16.

Table 9-16 Process Gas Utilization Factors

Number of Outlets	Percent Usage (%)
1–8	100
9–16	90
17–29	80
30–79	60
80–162	50
163–325	40
326–742	35
743–1570	30
1571–2900	25
>2900	20

CHAPTER 10 HEATING, VENTILATION, AND AIR CONDITIONING

10-1 GENERAL.

This chapter provides HVAC design requirements for applicable facilities. The primary requirement of the HVAC system(s) is the support of medical function and the assurance of occupant health, comfort, and safety. The HVAC system functions not only to maintain minimum requirements of comfort and ventilation, but is an essential tool for the control of infection, removal of noxious odors, dilution and expelling of contaminants, and establishment of special environmental conditions conducive to medical procedures and patient healing. Subject to these requirements, appropriate consideration must be given to the HVAC design to ensure system maintainability, economics and energy efficiency, and adaptability to future facility modification or expansion.

10-1.1 Applicability.

This criterion applies to new and existing facilities. Applicability to existing facilities is restricted to upgrade or replacement projects, and for those specific systems or services included in the scope of the project authorization. For existing facilities, when complete compliance with the technical criteria of this chapter is not economically practicable, consideration must be given to substitution of other recognized industry standards or criteria upon application to the DoD Project Sponsor as provided under Chapter 3. All facilities must comply with the applicable standards of the NFPA.

10-1.2 Supporting Documents.

This guidance may be supplemented by Design and Construction Agent, and DoD Project Sponsor publications, including project specific Medical Design Instructions, UFCs, Technical Manuals, ETLs, and other criteria. Minimum HVAC design criteria must be in accordance with the latest editions of the ASHRAE Handbook series, the American Conference of Governmental Industrial Hygienists (ACGIH) publication Manual of Recommended Practices for Industrial Ventilation, and NFPA Standards 45, 90A, 96, 99, 101, and 801, as well as applicable governmental regulations. Other industry and Government standards must be utilized for HVAC design as applicable.

10-2 DESIGN CONDITIONS.

10-2.1 Weather Data.

Weather data must be obtained from UFC 3-400-02. **\1** Obtain the outdoor humidification design conditions not included in UFC 3-400-02 from the ASHRAE Handbook of Fundamentals. If given Military Installations are not listed in the data above, or **/1/** have access to more recent or accurate information of weather conditions in their region, designers must coordinate use of this information with the Design and Construction Agent.

10-2.2 Interior Design Conditions.

Interior design conditions must be in accordance with Appendix B or as otherwise addressed in this chapter.

10-2.3 Space Ventilation.

Minimum total and outdoor air change rates must be in accordance with Appendix B. Supply higher air change rates as required to meet air conditioning or make-up air requirements as supported by engineering calculations. See 10-16, Ventilation Design, for additional guidance and requirements.

10-2.4 Ambient Outdoor Design Conditions.

10-2.4.1 Facilities Housing Critical Care and Other Inpatient Services.

a. Design the HVAC cooling based on the largest of the three following Total Cooling conditions: the 0.4 percent dry bulb temperature, and corresponding mean coincident wet bulb temperatures; the 0.4 percent wet bulb temperature and corresponding mean coincident dry bulb temperature; and the 0.4 percent humidity ratio and corresponding mean coincident dry bulb temperature.

b. Design the heating based on the 99.6 percent dry bulb temperature.

c. Design the cooling tower evaporation rate based on the 0.4 percent wet bulb temperature.

d. Design humidifiers based on the 99.6 percent humidity ratio and corresponding mean coincident dry bulb temperature.

10-2.4.2 Outpatient Facilities Not Housing Critical Care.

a. Design the HVAC cooling based on the largest of the three following Total Cooling conditions: the 1.0 percent dry bulb temperature and corresponding mean coincident wet bulb MCWB temperature; the 1.0 percent wet bulb temperature and corresponding mean coincident dry bulb temperature; and the 1.0 percent humidity ratio and corresponding mean coincident dry bulb temperature.

b. Design the heating based on the 99 percent dry bulb temperature.

c. Design the cooling tower evaporation rate based on the 1.0 percent wet bulb temperature.

d. Design humidifiers based on the 99 percent humidity ratio and corresponding mean coincident dry bulb temperature.

10-2.5 Critical Care Spaces.

Critical Care Spaces are identified in Appendix B.

10-2.6 Laboratories.

Space design and ventilation requirements for clinical laboratories are indicated in Appendix B. Research laboratories, to include animal holding facilities in research laboratory facilities, must be designed in accordance with the ASHRAE Handbook of Fundamentals, the Biosafety in Microbiological and Biomedical Laboratories, and Guide for Care and Use of Laboratory Animals.

10-2.7 Temperature during Smoke Control Operation.

When a supply air system is required to operate on 100 percent outdoor air during smoke mode operation, the system must be designed with sufficient heating capacity to maintain a minimum **\1** AHU discharge temperature of 45 ºF (7.5 ºC) **/1/** under the 99.6 percent winter design conditions.

10-2.8 Mechanical Equipment Rooms.

Mechanical equipment rooms must be conditioned as needed to meet the manufacturers recommended conditions for any sensitive electronic equipment, such as variable frequency drives, microprocessor-based controls or circuit breakers, or other electronic components unless those devices are installed in conditioned cabinets. Designer must confirm the requirements of such equipment and consider not only the manufacturers allowable conditions but also the potential degradation of performance within the allowable conditions in determining the room design temperature (for example elevated temperatures reduce the life expectancy of backup batteries). Mechanical equipment rooms without temperature sensitive equipment or where that equipment is otherwise installed in a conditioned cabinet must be designed to maintain temperatures within 10 degrees F of summer ambient design temperature. In humid climates, mechanical rooms that are contiguous with the occupied building must be conditioned to a humidity level equivalent to the occupied areas to minimize transfer of moist, unconditioned air to the interior of the building.

10-2.9 Humid Climate Definition.

A humid climate is a region that meets or exceeds both of the cooling load criteria indicated herein. The charts and tables referenced can be found in the region-specific climate data reports entitled Engineering Weather Data (EWD) available from the **\1** 14th Weather Squadron (14WS) **/1/** as referenced in UFC 3-400-02. Humid climates are defined as regions where the latent load is three times the sensible load AND where the monthly latent load exceeds the monthly sensible load for two or more consecutive months of the year. (Reference data field “Ventilation Cooling Load Index” and graph “Average Ventilation and Infiltration Loads”, as referenced in UFC 3-400-02.)

10-2.10 NFPA 99 Risk Assessment.

A Risk Assessment must be performed in accordance with NFPA 99 to establish the System Categories for all HVAC systems. See Appendix C for the timing and responsibilities of the Risk Assessment.

10-3 REFRIGERANTS.

Refrigeration equipment must utilize refrigerant having an Ozone Depletion Potential (ODP) of not greater than 0.0 (refer to the U.S. Environmental Protection Agency [EPA] Significant New Alternatives Program [SNAP] for acceptable refrigerants). Refrigeration room design must include the safety features, such as sensing devices and purge ventilation system, as required for the particular refrigerant in accordance with ASHRAE Standards 15 and 34.

10-4 LIFE-CYCLE COST AND ENERGY ANALYSIS.

Life-cycle cost and energy analysis required in conformance with this chapter, or necessary for the evaluation of building sustainability features or performance, must be in accordance with criteria referenced in Chapter 1 and Chapter 4.

10-5 ELIGIBILITY FOR AIR CONDITIONING.

10-5.1 Total Air Conditioning.

Air conditioning is required in all normally occupied facilities and spaces to meet the interior conditions listed in Appendix B. “Normally occupied spaces” include such spaces incidental to the facility as corridors and circulation areas. Normally unoccupied, or intermittently occupied, spaces, such as restrooms, locker rooms, soiled linen rooms, janitor closets, indoor stairwells, and similar spaces accessible to medical staff or the public and having exterior exposure, must be air conditioned (in addition to being provided with the required ventilation) to maintain reasonable conditions.

10-5.2 Food Service Area.

Design air conditioning of the kitchen areas to minimize energy costs including compliance with ASHRAE 90.1, while providing a reasonably comfortable environment for kitchen staff.

10-5.3 Medical Warehouses.

Base HVAC design upon the environmental requirements of the stored materials. Provide air conditioning for spaces within medical warehouses that are normally occupied, including Administrative or Break Rooms, as required to meet the design conditions listed in Appendix B. Provide air conditioning for any warehouse spaces housing computer or other environmentally-sensitive equipment.

10-6 MECHANICAL EQUIPMENT SPACE.

10-6.1 Mechanical Room.

Locate mechanical rooms for major mechanical equipment such as central station air-handling units, heat exchangers, central pumps, medical gas supplies, vacuum pumps, and air compressors within the facilities with direct access to the outside of the building.

Exceptions to locate AHUs in conditioned penthouse equipment rooms may be considered by the Design and Construction Agent if justified from a cost or functionality standpoint, provided that stairwell access, at a minimum, is provided. For multi-story facilities, direct access to rooftop AHU penthouses must be provided from an elevator. Rooftop mounted air handlers must not be used in any new facility in excess of 15,000 ft^2 (1400 m^2) gross **\1** area, **/1/** except for temporary or deployable facilities, due to the difficulty of maintenance access, and consideration of safety and working conditions for O&M personnel. Mechanical room location and layout must consider:

a. Sufficiency of space to enable access for operation, maintenance, and replacement of equipment.

b. Minimization of distribution runs.

c. Relative location to electrical equipment rooms: Consider NFPA 70 vertical clearance and dedicated space requirements for electrical equipment which may restrict or preclude the routing of piping and ductwork through these locations.

d. Do not locate adjacent to Communication Rooms: adjacency of mechanical rooms and Communications Rooms create congested above-ceiling conditions where cable trays and ductwork converge.

e. Adjacency to corridors, as a path for the routing of ductwork.

f. Adjacency to spaces having stringent noise control requirements, or spaces with high ceilings that may restrict duct distribution space.

g. Potential future expansion of mechanical system capacity.

Equipment rooms must be designed to provide a minimum of 24 in. (610 mm) clearance on all sides of AHUs. Sufficient access must be provided for removal and replacement of filters, coils, fans, motors, pumps, and other associated equipment, with piping, ductwork, and conduit installed such as not to block the access-way. Unions, flanged fittings, or other readily demountable connections must be provided at equipment piping connections to facilitate removal.

10-6.2 Energy Plant.

Chilled water, steam and hot water generators may be located in a separate energy plant. Install utility lines connecting the energy plant to the facility within a tunnel or other accessible enclosure providing maintenance access and protection from the elements. Provide access such that any valves, fittings, or equipment requiring periodic maintenance or inspection are accessible to workers without using lifting equipment. Accessibility to all other equipment within the enclosure may be accomplished with removable panels or coverings readily accessible to mobile cranes or rigging equipment. Where authorized by the Design and Construction Agent and DoD Project Sponsor, pre-fabricated direct-buried utility lines with closed-cell foam insulation, integral leak detection, and exterior sheathing may be utilized for water services only (for example chilled and heating hot water) provided that all valves or maintenance items are installed in man-holes.

10-7 HVAC SYSTEM DESIGN FOR FUNCTIONAL AREAS.

The primary considerations of the HVAC design are to provide the environmental conditions required to meet the functional requirements. Medical facilities must be primarily served by central-station AHUs using single duct terminal reheat, and variable air volume (VAV), or constant air volume (CAV) terminals, as appropriate for room conditioning and pressure control. Where electric resistance heating is utilized in accordance with UFC 3-410-01, provide with modulating capacity control (for example SCR technology). When utilized, VAV systems must be of the pressure independent, minimum air quantity type. Direct Expansion (DX) coils must not be used in VAV systems. Induction-type terminal units (for example chilled beams) may be utilized but only to meet sensible loads (non-condensing) and the air changes induced by these devices may not be counted toward the total air change requirement in Appendix B (see total air change definition in paragraph 10-16.1). With the exception of sensitive equipment spaces; mechanical, electrical, and plumbing (MEP) rooms, all-water (for example fan coil units), unitary, and fan-powered VAV systems are not acceptable, due to concerns with maintenance, noise, and limited ability to meet filtration and ventilation requirements.

10-7.1 Critical Care Spaces.

These spaces must normally be served by single-duct terminal reheat systems. Simultaneous temperature, humidity, and pressurization control requirements for these spaces preclude the use of other types of systems. Air handling systems serving Critical Care Spaces must be of the draw-through arrangement, in order to utilize the supply fan heat to avoid a saturated supply airstream.

10-7.1.1 Operating Room Air Systems.

The room air supply system for Operating Rooms (C-Section, Cystoscopic, Cardiothoracic, Integrated, Hybrid, Neurology, Orthopedic, and General) must be a ceiling supply type, located over the operating table or treatment area, using non-aspirating “low velocity” 25–35 cfm/ft^2 (124–178 L/s/m^2) diffusers that isolate the air over the operating or treatment area. Extend the area of the primary supply diffuser array a minimum of 12 in. (305 mm) beyond the footprint of the surgical table on each side. Use no more than 30 percent of the primary supply diffuser array area for non-diffuser uses such as lights, gas columns, etc. Room exhaust and return provisions must consist of a minimum of two exhaust or return registers, located at diagonally opposing corners of the room, mounted with bottoms of registers approximately 8 in. (200 mm) above finished floor. In addition to the required low return or exhaust registers, return or exhaust may be accommodated using registers placed high on the walls.

10-7.1.2 Continuity of Service.

The design for the HVAC systems serving Critical Care Spaces must include:

a. The AHUs serving OR suites must be separate, independent units serving only the respective Surgical or Obstetrical Department or portions thereof, to enhance the reliability of these systems and minimize demand on the EES. However, if justified from a cost or functional standpoint, and where authorized by the Design and Construction Agent and the DoD Project Sponsor, the AHU(s) serving each suite may also provide service to other Patient Care or support areas outside the respective Surgical or Obstetrical Department. A maximum of four ORs should be served by any single AHU. Where a Surgical or Obstetrical Department has four or fewer ORs, these should be served by at least two separate air handling systems, to enhance reliability.

b. HVAC equipment, including controls, that serve Critical Care Spaces (including ventilation and pressure controls for isolation/protective environment bedrooms) must be connected to the EES. This must include a sufficient number of chillers and boilers, with necessary supporting equipment, to meet critical design loads. Boilers must have dual-fuel burners that are not solely dependent on one source of fuel for ignition **\1** to support utility service interruptions. If two separate fuel sources are not reasonably available, the Design and Construction Agent may seek authorization from the DoD Project Sponsor to utilize one fuel source with onsite backup in lieu of a second fuel source. ***/1/***

c. Designs must include features to minimize HVAC service interruptions to Critical Care Spaces, without the provision of redundant AHUs or distribution systems. Provisions must be such that service interruption to any Critical Care Space, as a result of failure of an AHU component or its supporting electrical or controls systems, must be minimized. Such features may include the provision of multiple, isolatable, heating and cooling coils; spare stock of replacement motors, drive belts, and bearings in the immediate vicinity of the equipment room; multi-fan units; or other measures providing for continuity or expeditious restoration of service.

d. AHUs, with associated controls, that serve Critical Care Spaces and patient bedrooms must be connected to the EES.

10-7.2 Sensitive Equipment Areas.

These are spaces or areas in which equipment or processes require special environmental control, including continuous (24 hours per day, year-round) air conditioning and individual room temperature or humidity control. Examples include Telecommunications Rooms and closets, data storage equipment spaces, Data Centers, spaces housing computer equipment supporting imaging and special treatment systems. For those spaces which are critical to continued facility operations, backup or redundant features must be provided to ensure continuity of air conditioning in the event of primary air conditioning equipment failure or when the primary system includes night-setback or economizer features. This may also include the requirement for connection of air conditioning equipment to the EES. Where feasible, the main building systems

must be utilized for primary cooling/outdoor air and a redundant system utilized for back-up cooling.

10-7.3 Patient Bedrooms.

Normal-care patient bedrooms may be served by dual duct, VAV, or single duct reheat systems. All systems utilized must maintain minimum ventilation quantities under all conditions of operation. Perimeter heating systems may be considered in conjunction with these air systems.

Isolation bedrooms must be served by airflow systems that maintain a constant differential between supply and exhaust airflow rates to maintain the required relative pressurization of the space to the adjacent spaces and corridor. Refer to more detailed design guidance and requirements for isolation bedrooms under paragraph 10-17. Pressurization control equipment serving protective environment and airborne infection isolation bedrooms must be connected to the electrical EES.

10-7.4 Temporary and Deployable Facilities.

When considerations of logistics, equipment availability, limited O&M capability, or expediency dictate, deployable facilities may be served by unitary equipment meeting—to the extent practicable—the ventilation, filtration, and environmental conditions established in Appendix B. Temporary facilities may utilize unitary, all-water, or fan-powered VAV systems when authorized by the Design and Construction Agent and DoD Project Sponsor.

10-7.5 Rooms with Critical Pressurization Requirements.

All spaces in Appendix B with air balance requirements of “++” or “- -” (to include associated anterooms and toilet rooms) must be designed and constructed with the volume differentials and room construction integrity to maintain a differential pressure of 0.02 in. w.g. (5 Pa) between the subjected room and adjacent space, which must be demonstrated during commissioning. The volume differentials noted in Appendix B are a baseline and may need to be adjusted in order to achieve the required pressure differential. Designer must evaluate the room size, fixed openings (for example door undercuts) and anticipated construction integrity in establishing the design volume differentials. The Designer must also consider the need to increase the room differential pressure to provide sufficient margin above the alarm value of 0.01 in. w.g. (2.5 Pa) to minimize false alarms and ensure the integrity of the reading.

In order to prove the integrity of the air barrier, a leak-test of the room must be performed. Tests must be conducted with the room under positive pressurization, regardless of whether the end-state requirement is negative or positive. Provide temporary positive pressure high enough to ensure a valid test, approximately 0.05 in. w.g. (13 Pa). With the room under pressure, the test must consist of moving a smoke pencil at a rate of not more than 1 in/s (25 mm/s) along all construction seams and interfaces, to include floor and structural ceiling partition interfaces, outlet boxes, and all

partition penetrations by piping, conduit, cable, or other equipment. The visible passage of smoke at any point must be considered a failure, requiring resealing prior to repetition of the test. This test must be witnessed by the Government and commissioning team.

Rooms must be provided with a pressure indicating instrument or gauge, located on the outside wall near the door, that must visibly indicate that not less than a 0.01 in. w.g. (2.5 Pa) differential pressure (negative or positive according to room type) is maintained under static (door closed) conditions, and that must alarm if the pressure is not maintained for a period exceeding 30 seconds. In addition, the pressure differential and alarms must be monitored by the building control system. If the alarm can be disabled or silenced locally, the building control system must monitor whether the alarm has been disabled or silenced.

10-8 GENERAL DESIGN CONSIDERATIONS.

10-8.1 Plant Sizing and Optimization.

For all facilities justifying a degree of redundancy in the capacity of primary energy plants, the precise number, capacity, and configuration of primary heat exchangers and pumps must be determined in accordance with the requirements noted here.

10-8.1.1 Facilities with Critical Environments.

These facilities include all MTFs with inpatient functions, ambulatory surgery centers, and for selected research and laboratory facilities in which loss in ability to condition the facility would result in loss of critical research or animals at prohibitive cost to the Government. The plant must be sized and configured such that:

a. For inpatient MTFs, with one major heat exchanger or pump out of service, the remaining plant equipment is sufficient to serve all critical loads, including patient bedrooms and labor rooms, plus one-half of all remaining loads within the facility.

b. For ambulatory surgery centers, with one major heat exchanger or pump out of service, the remaining plant equipment is sufficient to serve all critical loads to include surgery, surgical delivery, surgical prep, surgical recovery, decontamination, and sterile preparation and storage, plus one-half of clinical area loads.

c. For research and laboratory facilities, with one major heat exchanger or pump out of service, remaining capacity must be sufficient to serve the critical environmental loads, plus all support spaces, such as computer records, critical to the continued operation of the facility.

d. For all facilities with critical environmental requirements, with one major heat exchanger or pump out of service for an extended period (one day or more) of maintenance, during the “off” season for such service, the remaining plant equipment must be sufficient to meet the entire facility’s maximum load.

e. For all such facilities, plant optimization must in addition be based on LCCA of the most life-cycle economical number, capacity, and configuration of prime heat exchangers and pumps.

10-8.1.2 Energy Plants for Other Facilities.

When energy plants consisting of multiple primary heat exchangers are justified, on a project by project basis, for large outpatient clinics or ambulatory care clinics without operating rooms, the plant must be designed on the basis of LCCA of the most life-cycle economical number, capacity, and configuration of prime heat exchangers and pumps.

10-8.2 Contaminant Removal.

HVAC systems must be designed to remove or reduce to acceptable levels volatile chemical and airborne microbiological contaminants within the facility. Systems must be designed to remove excessive moisture in facility spaces and to control moisture and dust accumulation in AHUs, distribution elements, and chases, to avoid conditions permitting the growth of pathogenic, allergenic, or otherwise objectionable microorganisms.

10-8.3 Interdepartmental Air System Restriction.

In general, individual facility departments should be served by dedicated air handling systems in order to increase system flexibility, energy conservation, facilitate comfort control, and reduce demands upon the EES. When laboratories, pharmacies, Emergency Department, or other facility departments are required to operate during normally-unoccupied areas of the balance of the facility, these must be served by dedicated air handling and distribution systems.

10-8.4 Air Filtration.

Individual space air filtration must be provided as indicated in Appendix B. MERV 8 “roughing” filters must be provided upstream of all coils, velocity sensing devices, or other devices requiring protection from dust accumulation. “Roll filters,” cleanable media, or other filtration systems requiring more intensive maintenance are not acceptable. Designers must carefully consider the location of filters relative to humidifiers to minimize the possibility of wetting the filter media. High capacity cartridge-type filters, in lieu of bag type filters, must be provided for units serving Critical Care Spaces due to the propensity for the latter to release particles during air handler startup and shutdown.

10-8.5 Balancing Ports and Features.

Necessary controls, instrumentation, and balancing ports and devices must be provided to establish and maintain the required space temperature, relative humidity (RH), and air changes rate, and to facilitate balancing procedures for all systems.

10-8.6 Additions and Alterations to Existing Facilities.

10-8.6.1 Site Investigation.

Designers must conduct thorough investigations of existing facilities to be upgraded or modified, to become knowledgeable with facility conditions as established by the terms of their design contracts. This includes the need to inspect concealed spaces, for example, above-ceiling plenums, equipment rooms, and chases, to permit evaluation and accurate depiction of as-built conditions that can affect new work. Design and Construction Agents must ensure that this requirement is met; it is advantageous that the expected scope of the site investigation be discussed in detail with the designer during project pre-negotiation and "kickoff" meetings. Generally, designers should be required to directly inspect all equipment rooms and all above-ceiling areas in such a number of locations as to reasonably establish the existing conditions. In facilities with "hard" ceilings, this may require the creation of a suitable number of inspection openings: Design and Construction Agents must define in the Project Design Instructions the responsibility for making and repairing such openings. Structural and architectural building elements, as well as existing equipment, that restrict equipment distribution space should be directly verified to the extent reasonably practicable. The design team must recognize the economic advantages of a detailed designer site investigation: if the designers do not verify conditions, the construction contractor must do so, normally at a cost premium reflected in higher bidding costs (unknown conditions) and change orders (changed conditions).

10-8.6.2 Modifications to Existing Systems.

Too often in the past, addition and alteration project design documents have failed to provide the detailed engineering guidance required to sustain operation of systems serving occupied areas, leaving this engineering responsibility in the hands of QA personnel or construction contractors. The results have included loss of critical services, inadequate system performance, project completion delays, and costly change orders. Therefore, it is hereby emphasized that it is the responsibility of the project designer to carry out all aspects of the design that can reasonably be accomplished during the design phase. Modifications to existing equipment and systems, including temporary connections, changes to system performance, or measures necessary to sustain service, must be shown and described in detail in project design documents. Designers must evaluate the impact on existing systems of extensions of service that increase system demand. The locations of new connections must clearly be shown or described, or both. The designer must determine, and document for the Design and Construction Agent's information, any project work that must necessitate a reduction or interruption of any service to an existing, occupied area. Consider and document Interim Life Safety Measures (ILSM) for use by the facility in accordance with Chapter 14.

10-8.6.3 Protection of Patients from Construction Contaminants.

For additions or alterations to existing hospitals, measures must be provided to minimize contamination of existing hospital areas during the construction period and the associated HVAC systems serving them. Measures to reduce the potential of contamination and nosocomial infections include but are not limited to: negative isolation of construction areas, construction of effective dust barriers (including double-barrier air locks at entrances and exits) separating construction from occupied areas, protection of air distribution systems serving occupied areas, and disinfection of any reused ductwork. Designers must consult with the facility's infection control representative during the design process to ensure thorough coordination of design features that may affect patient welfare. See also the Sheet Metal and Air Conditioning National Contractors Association (SMACNA) IAQ Guidelines for Occupied Buildings under Construction.

10-8.6.4 Construction Phasing Plan.

Reference Appendix C.

10-8.6.5 Commissioning Considerations.

Reference Chapter 19 and Appendix C.

10-8.7 Cooling and Heating Load Calculations.

10-8.7.1 Heating Load Calculation.

Calculations used for determination of primary and airside (including reheat) heating equipment must not include credit for internal load sources, including lighting, people, and equipment. These loads are typically not present, or are much reduced, at night and on weekends. Heat calculations should also take into consideration morning warm-up loads when night setback temperatures are utilized in non-ward areas.

10-8.7.2 Equipment Heat Generation.

In many spaces within facilities, the primary component of cooling loads will be equipment heat generation. It is therefore necessary for accurate load determination that the HVAC designer coordinate on a project-by-project basis with the medical or research equipment designer, and with the individual DoD Project Sponsor, to identify all individual equipment items and the corresponding load contributions. To estimate equipment usage duration and frequency, designers must gather information from the DoD Project Sponsor, or if unavailable from that source the manufacturer, personal experience, or other sources. In performing load calculations, designers must consider the as-designed equipment provisions of each unique space. "Rules of thumb" loading assumptions are not acceptable for final design calculations.

10-8.7.3 Lighting Loads.

Lighting loads present a significant component of facility cooling loads and, as such, require consideration of the as-designed lighting fixture numbers and characteristics of each space. “Rules of thumb” lighting load assumptions are not acceptable as the basis for final design load calculations.

10-8.8 Piping Systems.

10-8.8.1 Pipe Routing.

Piping distribution systems should be routed above corridors whenever practicable, to minimize leaks, maintenance intrusion, and noise in occupied areas of the facility. Pipes must not be routed through Telecommunications Rooms and Electrical Rooms unless dedicated to serving that room.

10-8.8.2 Thermal Expansion.

Designers are responsible for designing all aspects of piping systems necessary for the control of thermal expansion, and for showing the necessary control features on design drawings. This includes showing and dimensioning, as applicable, the approximate locations of guides, anchors, expansion ells and offsets, and flexible couplings, as well as any other piping features that may affect expansions forces in the piping. The intent of this requirement is to ensure that this critical aspect of piping design is accomplished by the qualified mechanical engineer selected for the project design, and not by a construction contractor of unknown engineering ability or qualification. In the case of direct-burial, (for example pipe within a pipe, underground heat distribution systems) engineering of the expansion compensation features by the system manufacturer may be preferred or necessary. Designers must design piping systems such that piping expansion forces are isolated from equipment. Where piping systems subject to thermal expansion are seismically braced, coordinate the thermal expansion design with the seismic bracing. Include any seismic bracing in the expansion/flexibility analysis. Design and Construction Agents must ensure contractor’s shop-drawing layout drawings of piping systems subject to thermal expansion are reviewed by the designer or by an equally qualified engineer representative of the Government.

10-8.8.3 Steam and Condensate Piping.

Steam mains **\1** operating above a gauge pressure of 15 psi (100 kPa) **/1/** must not be distributed in above-ceiling areas of spaces normally occupied by patients or public within a facility, to include corridors. Designers must show the required direction and degree of line slope on drawings, and must provide and show the locations and details of drip traps and other drainage features. Piping for clean steam and associated condensate return must be stainless steel.

10-8.9 Insulation for Mechanical Systems.

Insulation thicknesses and thermal characteristics must be not less than cited per ASHRAE 90.1. Insulation with higher "U" values must be provided when shown to be life-cycle cost effective. Insulation materials must be as permitted by the UFGS; it is important to note that under no circumstances will mineral wool or fiberglass insulation be permitted on new chilled water systems or other systems handling fluids at a temperature below 60 ºF (16 ºC).

10-9 HVAC SYSTEM CONTROLS.

10-9.1 Energy Conservation.

All designs must comply with UFC 1-200-02. Additional information on energy conservation design is referenced at Chapter 4.

10-9.2 Temperature Control.

Individual room temperature controls must be provided for all Critical Care Spaces, sensitive equipment spaces, patient bedrooms, labor rooms, and laboratories, to closely maintain the room conditions provided in Appendix B. Utilize zoned temperature control for other spaces within the facility. Serve only rooms with similar exposures and load profiles by a single zone, with a maximum of six spaces per zone. Serve all conference rooms, classrooms, and other rooms with unique exposures or load profiles by individual zones. Unless a separate means of room heating (such as perimeter heating) is available, provide terminal reheat for all terminal units serving normally occupied spaces.

Wound Intensive Care (Burn Care Rooms) must be provided with room temperature controls to maintain temperatures up to 100 degrees F with humidity control as indicated in paragraph 10-9.4.

10-9.3 Control Precision.

Temperature controllers must maintain space temperature within +/-2 Fº (1 Cº) of active set-point, as provided for the individual spaces in Appendix B. The summer and winter design set-points normally differ. For some spaces, a temperature range is given as the summer or winter interior design condition in lieu of a specific temperature set-point. The HVAC system for such spaces must be designed with the capability, under design conditions, to maintain any selected temperature within that range.

10-9.4 Humidity Control.

Humidity controls must be provided as necessary to meet the requirements given for individual spaces in Appendix B. **\1** Provide central AHU humidifiers for units serving Critical Care Spaces, including patient bedrooms unless a psychrometric analysis demonstrates the space humidity will remain within the range specified in Appendix B.

/1/ If necessary to maintain the RH within the allowable range, humidity controls must be provided on a room basis for these Critical Care Spaces:

a. ORs

b. Cystoscopy Rooms

Humidity controls for Wound Intensive Care (Burn Care Rooms) must be provided on a room basis in order to maintain 35–50 percent RH +/-5 percent at room temperatures up to 100 ºF (38 ºC). Humidity controls for all other spaces may be provided on a zone or system basis as determined to be sufficient to maintain the required conditions.

10-9.4.1 AHU Humidifying Equipment.

Air handling system humidification must be achieved utilizing direct steam injection, with a steam source in accordance with paragraph 10-10.1 utilizing humidifiers of the rapid absorption, steam jacketed distribution type designed to deliver dry steam and accomplish complete re-evaporation within 3 feet of the discharge manifold, under the air velocity and temperature conditions designed. No equipment must be located in the AHU casing within the downstream re-evaporation distance, and the inner casing liner within this section must be constructed of stainless steel. Designers are responsible to designate the location of steam injectors relative to ductwork and AHU components, and so design them as to minimize concerns with moisture collection in or on the downstream elements. To minimize the risk of introducing condensation into the air stream, design humidifier control sequences such that the supply air relative humidity will not exceed 85% under winter heating load conditions. Provide safeties including but not limited to a dedicated air flow switch and duct high-humidity limit switch.

10-9.4.2 Trim Humidification for Critical Care Spaces.

Humidification must be achieved utilizing direct steam injection, with a steam source in accordance with paragraph 10-10.1. Humidifier must be separated a minimum 15 ft (5 m) upstream from high-efficiency final filtration, or any other duct equipment, elbow, or takeoff; when this separation cannot practicably be achieved, rapid-absorption-type humidifiers must be provided with design as indicated in paragraph 10-9.4.1. Ductwork within the downstream re-evaporation distance must be constructed of stainless steel with provisions for drainage of condensate.

10-9.5 Direct Digital Controls (DDC).

The DDC System must be a complete system suitable for the control of the HVAC system and other building level systems as specified. Reference UFC 4-010-06 for cybersecurity requirements. When a DoD Project Sponsor determines that communication between a facility's DDC system and a remote Utility Monitoring and Control System (UMCS) is required, the design must ensure that the DDC system is seamlessly compatible with the UMCS system.

No remote UMCS system, in other words not located in the facility or its associated energy plant, will be permitted to exercise control over any hospital HVAC system

equipment providing service to Critical Care Spaces. Remote UMCS systems may be provided with monitoring, alarm, and reporting capabilities as necessary to facilitate maintenance activities.

10-9.6 Air Handling Equipment Control.

10-9.6.1 Building Pressure Control.

All systems must maintain the building at relative positive pressure to the outside environment, with the exception of those spaces on perimeter walls required to maintain a negative pressure relative to contiguous spaces. For facilities in humid climates, and for all facilities of three stories or more in height, automatic controls must be provided to actively monitor and control building pressurization via pressure monitoring at strategic locations on each level, and manipulation of outdoor air, exhaust volume flow rates, or both. All systems that modulate outdoor air, including all VAV air handling systems, must include accurate airflow measurement arrays located in accordance with manufacturer's recommendations as part of their control system. Positive building pressure must be maintained at all times (24/7) for all facilities located in humid climates.

10-9.6.2 VAV AHU Controls.

All VAV systems must be provided with supply and return fans. Airside economizer must be provided where economically life-cycle cost effective. Fan speeds must be modulated by means of variable-frequency drivers (VFDs). For units utilizing multiple fans (for example fan arrays), provide each fan with a separate VFD. Supply fans must modulate based upon maintaining a fixed static pressure at a location remotely located in the ductwork sufficient to ensure operation of all VAV terminal devices. Supply, return, and outdoor airflow rates must be measured by the DDC control system, and the return fan must modulate to maintain a fixed differential airflow below that of the supply fan. A high supply duct static sensor and shutdown capability must be provided.

10-9.6.3 Variable Exhaust Controls.

HVAC controls for laboratories, treatment rooms with coughing booths, autopsy procedure rooms, and other rooms having equipment requiring variable or intermittent exhaust requirements, must be provided that maintain the required room relative pressurization and room conditions for all modes of operation of the equipment, for example, on or off, minimal to maximum sash height, according to the user's intended operation. Variable flow controls must be provided for the general exhaust of such rooms as well as for the equipment, to allow measurement and tracking of supply to exhaust flow differential by the DDC system.

10-10 STEAM SYSTEMS.

10-10.1 Humidification Steam Source.

Steam generated by heating system boilers (or any other steam) containing amines, oxygen scavengers, or other treatment chemicals must not be used for space humidification in any air handling unit or air distribution system serving Critical Care spaces. Separate steam generators for humidification must be provided for these systems and must be constructed throughout of 316 stainless steel.

In systems serving non-critical care spaces, if authorized by the Design and Construction Agent, central steam systems utilizing chemically treated steam generated under the following conditions may be utilized:

10-10.1.1 Water Source.

Water entering humidifiers or primary steam generators must originate from one of the following sources.

- Potable water
- RO water
- DI water

10-10.1.2 Treatment Chemicals.

With the exception of the three specific amines listed below, boiler treatment chemicals as regulated by 21 CFR 173.310 may be utilized. Chemicals and minerals must not be present in the steam in concentrations that are known to be hazardous to health or that might contribute to an indoor air quality problem. All chemical dosing must be accomplished with automated equipment. The specific chemicals listed below may be present in steam, but they must not exceed the following concentrations in the steam.

- Cyclohexylamine (CHA): 10 ppm
- Diethylaminoethanol (DEAE): 5 ppm
- Morpholine: 10 ppm

10-10.2 Sterilizer Steam Source.

Steam generated by boilers located in an onsite (hospital-dedicated) boiler plant may be utilized for sterilization steam subject to approval by the DoD Project Sponsor. As hospital authorities cannot normally exercise a reasonable degree of supervision or control over treatment chemicals utilized in base-wide or district systems, steam from these sources may not be utilized for direct sterilization. Unlike humidification steam, which is injected directly into the air supply, little sterilizer steam escapes into a facility's general environment. Under a reasonably responsible boiler treatment program, any steam that does escape typically will not result in dangerously high levels, for example,

Occupational Safety and Health Administration (OSHA) Recommended Exposure Limits (RELs), of treatment chemicals in the environment.

10-11 AIR HANDLING AND DISTRIBUTION.

10-11.1 AHU Requirements.

AHUs are to be double-wall, internally-insulated, readily maintainable units suitable for utilization in medical facilities. Draw-through units are normally preferred to utilize fan heat to increase the DB air temperature above the saturation point and minimize the possibility of wetting downstream filters, attenuators, or other components. If draw-through units are not provided, an alternative, energy-efficient heating source must be provided to ensure that supply air delivered from the AHU is at least 2 Fº (1 Cº) above saturation temperature. Provide for minimum 18 in. (460 mm) wide access doors **\1** to allow unobstructed access to both the upstream and downstream surface of each heating coil, cooling coil, and heat recovery device, to facilitate coil inspection, cleaning, maintenance, proper installation of the unit freeze stat, and calibration of control sensors. **/1/** When unit heating or cooling capacity are provided—in part or total—by heat reclaim devices, AHUs must be provided with conventional preheat and cooling coils sized for the total system load, to ensure continued service when heat reclaim equipment is out of service.

10-11.2 Energy/Heat Recovery Systems.

Where energy recovery systems are provided, design and construct such systems to comply with the following:

Locate energy recovery systems upstream of intermediate filters. For exhaust systems serving spaces without a "Y" in the exhaust column of Appendix B, provide systems that allow no more than 5% cross-contamination of exhaust air back to the supply airstream via purge, leakage, carryover, or transfer.

For exhaust systems serving any room that has a Y in the exhaust column of Appendix B, provide systems where the supply airstream components and the exhaust airstream components are fully separated by an air gap of adequate distance to prevent cross-contamination that is open to the atmosphere (for example run-around pumped coils).

10-11.3 System Shutdown Capability.

To the extent practical and cost effective, non-critical, non-bedroom area HVAC systems must be designed to permit shutdown (night setback and setup, outdoor air shutdown) of individual areas or departments not in operation on a 24-hour basis. In any facilities in which any spaces are exhausted during non-occupied hours, the HVAC design must provide for conditioned make-up air to prevent a negative pressure within the facility relative to the outside, and the admittance of unconditioned, unfiltered infiltration air. For facilities not located in humid climates and where no spaces are exhausted during non-occupied hours, negative building pressure may be prevented by

shutdown of the HVAC system and isolation from the outside by closing outdoor, relief, and exhaust air dampers.

Air distribution systems must comply with the requirements in UFC 4-010-01 except as modified herein. Due to the nature of operations in medical facilities, completely shutting down HVAC in areas that would risk the health of patients, visitors, and staff is not a decision to be made lightly, and inadvertent activation of the HVAC shutdown must be minimized. The quantity and locations for Emergency Air Distribution Shutoff Switches must be coordinated with the Design and Construction Agent. In any case a minimum of one (1) shutdown switch must be provided. All shutdown switches must be protected from accidental activation by a flip up cover or other double action device. Emergency Air Distribution Shutoff switches for systems serving any critical care spaces, spaces with critical pressurization requirements ("++" or "- -" in Appendix B), or other spaces where HVAC shutdown would pose an immediate danger, must be by keyed switches. These switches must be provided with the following signage “Danger! Critical Care HVAC Shutdown, Exposure Hazard”. Signage must be red background with white letters and be placed above any cover for each individual button. Keyed switches permit responsible personnel in leadership to weigh the risk associated with intentionally degrading a life preserving internal environment to protect against the introduction (or distribution) of an airborne hazard into the facility. Switches for systems serving only non-critical care spaces must be provided with the following signage “Emergency Use Only! Mechanical HVAC System Shutdown”. Signage must be red background with white letters and be placed above any cover for each individual button.

10-11.4 Outdoor Air Intakes.

Outdoor air intakes must be located as far as practical, but not less than 30 ft (10 m), from exhaust outlets of ventilation systems, cooling towers, combustion equipment stacks, MV systems exhaust, plumbing vent stacks, emergency generator exhaust, or from areas that may collect vehicular exhaust and other noxious fumes. Locate the bottom of air intakes serving central systems as high as practical but not less than the distance above ground level required by UFC 4-010-01, or if installed above the roof, at least 3 ft (1 m) above roof level. Outdoor air must not be drawn from equipment rooms. Designers must utilize judgment in the location of contaminant exhausts, and not simply apply the “9M rule” without further consideration of wind direction and velocity, building geometry, and characteristics of the contaminant stream. Appropriate consideration must be given to prevailing wind direction and the season, for example, summer or winter, as applicable; however, designers are cautioned not to rely on prevailing wind direction(s) as a primary factor in the avoidance of intake contamination. In particular, use extreme caution in locating outdoor air intakes in proximity to parking areas, ambulance garages, loading docks, exhaust air outlets, and equipment stacks. Where appropriate, the Design and Construction Agent will provide individual Project Design Instructions for special computational fluid dynamics (CFD) or wind tunnel modeling to provide greater assurance of the correct location of outdoor air intakes.

10-11.5 Noise Control.

Noise criteria for individual rooms and spaces in the facility are provided in Appendix B.

10-11.5.1 Room Breakout.

The HVAC designer must coordinate with the architectural designer to control equipment noise passing from mechanical rooms into adjacent spaces through the surrounding walls or partitions.

10-11.5.2 Crosstalk.

The compromising of patient privacy by transmission of audible speech from one room to another via ductwork is of great concern in medical facilities and must be addressed by HVAC designers. Examination rooms, physician's offices, and toilets require the designer's particular attention. Ductwork connecting adjacent rooms must have the necessary attenuating characteristics to eliminate audible speech transmission. Typically, this is addressed by the provision of well-separated "takeoffs" or several duct elbows in the intervening ductwork, or both.

10-11.5.3 Air Fixtures.

Air distribution supply, return, and exhaust fixtures, for example, diffusers or grills, must be sized to provide air inlet and outlet velocities consistent with room noise criteria level requirements as provided in Appendix B. Designers must be aware that diffuser manufacturer's published noise characteristics are based upon idealized inlet conditions. Poor installation of flex duct, abrupt branch duct connections, elbows located immediately at the diffuser collar, and similar poor connections may result in unacceptable noise levels. Spin-in or other 90-degree duct drop connections to diffusers must be equipped with equalizing grids as necessary to ensure uniform air distribution at the diffuser inlets.

10-11.5.4 Air Velocity.

Designers must limit air velocities in ductwork, air transfer grills, or door undercuts to values consistent with ASHRAE recommendations to control noise generation.

10-11.5.5 VAV/Constant Air Volume (CAV) Terminal Units.

VAV terminal units and constant velocity controllers are a frequent source of noise generation in air distribution systems. Designers must specify or schedule units with minimum inlet sizes for incremental ranges of flow and must indicate maximum sound power output for each unit, at the maximum inlet static pressure that the designer anticipates the unit will be exposed to. If integral sound attenuating devices are required, these must be indicated for the respective terminal unit(s) in specifications or drawing schedules.

10-11.5.6 Exterior Noise Sources.

Designers must evaluate the sound characteristics of exterior equipment provided as part of the project design (such as cooling towers and emergency generators) to ensure that such sources do not result in interior noise levels exceeding limitations provided in Appendix B.

10-11.6 Duct Design.

Design duct systems in accordance with the ASHRAE Handbook series, ACGIH Industrial Ventilation: A Manual of Recommended Practice, NFPA 96, and SMACNA HVAC Systems Duct Design. Maximum velocity in ductwork mains must not exceed 1,800 fpm (9 m/s) over occupied spaces, or a maximum of 2,500 fpm (12.7 m/s) elsewhere, and velocities in branch ducts and takeoffs must not exceed recommended levels in those references. Ductwork plans must indicate the static pressure class required for sealing and reinforcement for all types of duct. Access panels must be provided as necessary for access to fire dampers, smoke dampers, humidifying equipment, control equipment to include reheat coils, and other equipment requiring periodic inspection or maintenance. All supply air, with the exception of air transferred between spaces for the purpose of pressurization, and flexible terminal equipment connections must be provided in sheet metal ductwork.

10-11.6.1 Non-Corrosive Ductwork Material.

Ductwork installed downstream of high efficiency final filters (MERV 14 or greater, see Appendix B) serving Critical Care Spaces must be of stainless steel or aluminum, including all accessories such as dampers, fasteners, and turning vanes. This provision does not apply for ductwork downstream of high-efficiency filters when these are located at the AHUs (filters noted in the “intermediate” column in Appendix B). Stainless steel ductwork downstream from trim humidifiers must extend for the manufacturer’s cataloged re-evaporation distance. Exhaust ducts for glass washers, dishwashers, and cart washers must be non-corrosive and must have soldered or welded joints and must be pitched to drain.

10-11.6.2 Return Air Plenums.

Provide fully ducted return air systems for all facilities, except stand-alone administrative buildings or deployable facilities. Temporary facilities may be considered for plenum returns where authorized by the Design and Construction Agent and the DoD Project Sponsor. Corridors must not be used as return air plenums in any portions of a facility. Exceptions allowing transfer air for toilets and janitor closets, as provided in NFPA 90A and 101, will be permitted.

10-11.6.3 Duct lining.

The utilization of duct lining materials is prohibited in all medical facilities. These materials may harbor dust and moisture, providing an ideal environment for the propagation of pathogenic or noxious microorganisms. Factory fabricated sound

attenuators, packed type, constructed with a perforated inner steel liner and Mylar® or foil underlay separating the packing from the airstream, must be provided to attenuate noise. Such attenuators must comply with ASTM C1071 and UL 181.

10-11.6.4 Balancing Provisions.

Duct branches serving each individual space must be provided with a manual balancing damper, accessible above the ceiling, located as remote from the space supply or return fixture, for example, diffuser or register, as practicable. The balancing damper provided as part of air diffusers is not to be used for system balancing. Duct systems which are fully welded due to containment requirements (for example, Biosafety laboratories, compounding rooms etc.) must be provided with permanent taps to facilitate pitot-traverse airflow measurement at main duct branches. These permanent taps must consist of welded nipples of the same material as the ductwork, with threaded caps, gasketed with material suitable for the materials in the airstream. Similar permanent pitot-traverse taps must be provided in the exhaust ducts serving Neat and Dilute chemical agent laboratories, and in kitchen grease hood exhaust. For the latter, tap nipples must extend to an accessible location outside of the fire-resistant duct enclosure material.

10-11.6.5 Telecommunication Rooms.

Ducts must not be routed through Telecommunications Rooms in compliance with TIA-569.

10-11.7 Cleanliness of Air Handling and Distribution Equipment.

During project construction, protect all AHU and distribution equipment (including all ductwork and fittings exposed to the air stream) from contamination by dust and debris. Cover or seal the equipment until installation and keep open ends of ductwork covered until final connections to diffusers and registers are made. Thoroughly clean any AHUs that are operated during building construction and install new filters before beneficial occupancy of the facility. “Thoroughly cleaned” in this sense is defined as wiped clean of any visible dust or debris. Thoroughly clean any ductwork that has not been properly protected prior to installation or acceptance of the facility.

10-12 MAINTENANCE PROVISIONS.

10-12.1 General Personnel Access.

Safe and practical means of personnel access must be provided to, and within, all areas of the facility where equipment is located, to adequately provide for O&M and replacement of the equipment. Access to equipment rooms from outside the facility should be provided where feasible. Within equipment rooms, provide clearance to all service points to mechanical equipment to allow adequate personnel access and working space in accordance with equipment manufacturer’s recommendations; but as a minimum, maintain 30 in. (770 mm) at all service points and 5.5 ft (1.7 m) of overhead clearance for O&M access-ways. Proper clearance must be provided such that

personnel do not have to climb over equipment or crawl on hands and knees. When rooftop AHUs are provided on multiple story facilities, provide elevator access with direct means of transporting materials to the units via hydraulic handcart without damage to the roof.

Provide convenient stairway access when rooftop AHUs are provided on single story facilities; in addition, the HVAC designer must coordinate with the site designer to provide for a practical location for a mobile crane to approach within reasonable proximity of the AHU(s) for periodic transportation of maintenance or replacement parts and equipment.

10-12.2 Equipment Clearances.

Minimum clearances between electrical and mechanical equipment must be as required by NFPA 70. Ensure that practical means are provided for the removal and replacement of the largest and heaviest equipment item(s) located in the facility. Provide adequate pull space for all coils, heat exchangers, chillers, boiler tubes, and filters. Sufficient space must be provided in above-ceiling areas to facilitate equipment installation and O&M. For building designs utilizing interstitial floor distribution zones, further guidance is provided at Appendix E.

10-12.3 Suspended and Mounted Mechanical Equipment.

Where suspended and mounted equipment is installed, provide a minimum of 5.5 ft (1.7 m) of clearance for headroom as required. In refrigeration equipment rooms, provide overhead clearances required by ASHRAE 15. For any work station or location requiring maintenance access that is not readily accessible from an 8 ft (2.5 m) portable ladder, provide a fixed ladder or catwalk.

10-12.4 Air Distribution System Components.

Design outdoor air intake plenums, AHU casings, and distribution ductwork to permit access for periodic cleaning or disinfection.

10-12.5 HVAC System Balancing Provisions.

Adequate access must be provided to facilitate operation, adjustment, and testing at all HVAC balancing and measuring points and equipment, including automatic and manual damper operators, air terminal units, pilot tube ports, valves, and sensing devices.

Prior to Test and Balance (TAB) perform Duct Air Leakage Testing (DALT) in accordance with UFC 3-410-01 on all duct systems regardless of pressure class, to include all return, all exhaust, and all portions of supply upstream of terminal units.

10-13 VIBRATION CONTROL.

Provide mechanical equipment and systems designed in accordance with UFC 3-450-01 to prevent transmission of vibrations to the structure.

10-14 INTERDISCIPLINARY COORDINATION.

10-14.1 Architectural Coordination for Rooms with Critical Pressurization Requirements.

All spaces in Appendix B with air balance requirements of "++" or "- -" (and associated anterooms) must be designed and constructed with full height room partitions, extending from floor to structural ceiling, with all joints and penetrations sealed to prevent the passage of air.

10-14.2 Fire Protection Features.

Refer to Chapter 14 for fire protection features.

10-14.2.1 Smoke and Fire Dampers.

In support of defend-in-place evacuation, design HVAC service zones to coincide with smoke compartments whenever practicable. Ductwork penetrations of fire and smoke - rated walls should be minimized, to minimize the required number of smoke and fire dampers and complexity of controls. Coordinate with the architectural design to ensure that necessary access for inspection or service of these dampers is provided.

10-14.2.2 Ventilation for Commercial Cooking.

Air supply and exhaust systems must be of the mechanical ventilation type and must meet the requirements of NFPA 90A and 96. Grease-laden vapor exhaust ductwork must be in accordance with NFPA 96.

10-14.2.3 Smoke Management Operation.

Comply with Chapter 14.

10-14.2.4 Commissioning of HVAC Systems with Fire Alarm and Fire Detection.

Guide specifications typically do not contain provisions for the simultaneous testing of HVAC and fire alarm and fire detection features or systems, which can have complex, interwoven operational requirements in some facilities. For each project where applicable, designers must develop or modify specifications as needed to provide for testing of HVAC systems under fire alarm conditions, to permit verification not only of correct function, but of acceptable speed of response. In more complex systems involving smoke evacuation or compartmentalization and pressurization, or provisions of smoke/exhaust in support of defend-in-place evacuations, detailed testing protocols, system diagrams, or both, must be developed to clearly convey the required scope of the commissioning effort. (Reference Chapter 19).

10-14.3 Essential Electrical Service.

10-14.3.1 Capacity.

The HVAC system equipment serving Critical Care Spaces must be connected to the EES to ensure service continuation in the event of normal power disruption, in accordance with the requirements of NFPA 99. Cooling, as well as heating, must be maintained to Critical Care Spaces in the event of normal power outage.

10-14.3.2 Commissioning.

Service guide specifications do not adequately address testing requirements for HVAC and EES interoperability. HVAC systems connected to the EES must be shown to function as intended under conditions of normal power interruption. Testing of the EES must be conducted in conjunction with any components of the HVAC system required for support. For example, thermostatically operated louvers may be required in emergency generator rooms for make-up air, generator radiator cooling may be a function of such HVAC components as pumps or cooling tower. Testing must verify the actual connection of HVAC equipment to the EES in accordance with the design following normal power outage, in the priority sequence established by the design. Designers must supplement or modify guide specifications to ensure that such verification testing is adequately detailed and described. (Reference Chapter 19)

10-14.4 Seismic Design Requirements.

Refer to Chapter 7 for seismic provisions for the HVAC system equipment and components. Designers must be responsible for ensuring that seismic bracing of HVAC piping is coordinated by design with thermal expansion compensation features, to allow for the necessary pipe movement with temperature changes.

10-14.5 Design Coordination.

Designers are responsible to coordinate the HVAC with the electrical, communications, architectural, and structural aspects of the design to ensure that equipment can reasonably be installed by a contractor providing equipment, and following installation procedures, within the terms of his contract. For this reason, designers are instructed to base equipment room and distribution space designs upon spatial envelopes (including maintenance clearances) that must accommodate any of at least three manufacturers of major equipment. Routes of ductwork and piping must be carefully coordinated with other elements, considering required slope, insulation, bracing, reinforcement, slope, and maintenance access. This practice in no way infringes on or substitutes for the construction contractor’s responsibility, to be defined in project specifications, to coordinate the installation work of all trades and to provide detailed shop drawings showing the proposed construction.

10-14.5.1 Equipment Rooms.

To ensure adequate coordination, designers must consider not only the HVAC equipment, but the work requirements of other trades. Ensure adequate clearance around AHUs to permit bolting the units together and securing them to their housekeeping pads, meanwhile providing space for the general contractor to install wall partitions. Consider the locations of plumbing and medical gas equipment. Ensure it is possible for maintenance workers to access all controls, electrical panels, valves, and instrumentation. Be aware of NFPA 70 clearance and vertical dedicated space requirements for electrical equipment. Coordinate parameters such as ductwork and outdoor air plenums with the locations of lighting.

10-14.5.2 Above-Ceiling Plenums and Chases.

Designers must anticipate the worst-case insulation, duct reinforcement, equipment support, slope, and fitting characteristics associated with ductwork and piping distribution systems, and be careful to coordinate the location of these systems with other equipment, including in particular cable trays and lighting fixtures with their vertical access and clearance space requirements. Ensure that access space is considered for damper operators, low-point steam drip assemblies, VAV terminal units, reheat coil controls and instrumentation, service valves, and access doors for ductwork for cleaning or damper inspection.

10-15 FUEL STORAGE REQUIREMENTS.

Refer to paragraph 7-4 for requirements for assessing the extent of onsite fuel storage for facilities in seismic threat regions. Additional fuel storage guidance for boiler plants must be obtained from the individual service criteria.

Provide factory-assembled automatic particulate filtration, dewatering and fuel additive injection system to maintain the purity of fuel in storage. Design the system to circulate the fuel from the storage tank, through the system, and back to the storage tank with capacity to turn over the largest connected full tank one time within 72 hours. Provide pre-filter, coalescing filter, and fine particle filters as part of the fuel filtration system. Design the system to maintain water content of fuel to less than 10 ppm and include an automatic wastewater holding and removal system. Provide a fuel additive injection system that includes chemical storage tank and chemical pump that can automatically add chemicals to the fuel being circulated. Chemical storage tank to be sized to hold two years supply of additive recommended by additive supplier. Include biocide treatment, cetane boosters, stabilizers or other additives as recommended by the maintenance treatment system manufacturer.

10-16 VENTILATION DESIGN.

10-16.1 Ventilation Air Changes.

Provide the minimum air change rates for each space, for outdoor air and total air, required by Appendix B. Total air changes as established by Appendix B must consist

of the outdoor air changes, plus re-circulated airflow through a main AHU having the minimum filtration called out for that space in the appendix. For rooms with a positive pressurization requirement, calculate the total air changes based on the supply volume and for rooms with a negative pressurization requirement, calculate the total air changes based on the exhaust/return volume.

10-16.1.1 Occupied room requirement.

Whenever a room is occupied, the minimum air change rates must be provided.

10-16.1.2 Critical care requirement.

The minimum outdoor air change rate from Appendix B in Critical Care Spaces must be maintained at all times. Increase the minimum outdoor air calculated below as needed to ensure that the minimum outdoor air change rate is maintained for Critical Care Spaces.

10-16.1.3 Outdoor Air Correction Calculation.

Provide minimum outdoor air at the AHU equal to the corrected Outdoor Air Intake (Vot), per the following equation:

Equation 10-1. Vot = Vou / (1 + X – Z)

Where:

Vou = the sum of all individual space outdoor air requirements for spaces served by the AHU,

X = the ratio of Vou to total ventilation air calculated to be required, and

Z = the largest ratio of outside air to ventilation air for any of the spaces served by the AHU.

10-16.2 General Exhaust Provisions.

Provide exhaust systems for animal holding areas, autopsy and morgue spaces, laboratory fume hoods, radioisotope hoods, bacteriological cabinet, kitchens, laundry, toilets, isolation rooms, equipment rooms, and other areas as noted in Appendix B, or as designated on an individual project basis. Do not connect duct systems conveying potentially hazardous exhaust, for example, ethylene oxide (ETO) sterilizers and lab hoods, to any general or toilet exhaust system. Provide duct systems conveying isolation room exhaust dedicated to isolation rooms and their associated anterooms and toilet rooms, and not connected with other exhaust systems. Locate all exhaust discharge outlets to prevent short-circuiting to air intakes or other building openings. Locate exhaust fans at the end of the exhaust duct run (exhaust ducts to be under negative pressure).

10-16.3 Space Pressurization.

The required pressurization of individual spaces, relative to adjacent spaces or corridors, is indicated in Appendix B. Where a negative or positive pressurization are required for a given critical or patient bedroom space, that pressurization must be maintained by the HVAC system under all conditions of operation, including periods of reduced ventilation or night setback.

10-16.4 Laboratory Ventilation.

Exit corridors must not be utilized to directly supply or exhaust air from the laboratory, although “transfer” of air to and from corridors may be utilized to establish required room pressurization. Negative pressurization of laboratories in relation to surrounding occupancies must be maintained under all conditions of HVAC system and fume hood operation.

10-16.4.1 Exhaust Systems.

Provide independent exhaust systems for all laboratories. Laboratories containing hazardous chemical, microbiological, or radioactive airborne particles or gases must be provided with independent exhaust systems in accordance with NFPA 45 and should utilize high plume exhaust designed to remove and dilute the air so it does not contaminate the roof area or have the potential to be re-entrained into the building. Exhaust ducts from chemical fume hoods are permitted to be combined with general laboratory exhaust systems within the same laboratory unit in accordance with guidance in NFPA 99 and NFPA 45. Maintain air change rates within laboratories at all times to prevent the spread of airborne contaminants within the space. Where hood exhaust is used to meet the required air change rates, incorporate a bypass with the general exhaust system for times when the hood is not in use or is shut down for maintenance. Exhausts from hoods handling perchloric acid or other strong oxidizing agents, materials, or agents requiring high-efficiency particulate air (HEPA) filtration, or exhausts which, when combined, chemically interact or change the explosion or ignition limits, may not be combined with any other laboratory exhaust system. Additional guidance for hood and exhaust design is contained in the ASHRAE Handbook series, the Manual of Recommended Practices for Industrial Ventilation, NFPA 45, ASHRAE 15, and ASHRAE 62.1. Exhaust duct discharge height must be above the building recirculation cavity boundary. In all cases, exhaust discharge must have sufficient stack height, velocity, and distance from building openings, outdoor air intakes, or recirculating air currents, to preclude reentry into the building. Air velocity in exhaust ductwork must be sufficient to transport the contaminant vapors, fumes, dusts, or other particulate matter for which the fume hood(s) is designed. Refer to paragraph 10-11.6.4 for requirements for permanent pitot traverse ports in certain hazardous exhaust applications.

10-16.4.2 Laboratory Fume Hoods, General.

Fume hoods must be located in areas of minimal air turbulence, away from doors, windows, and traffic, to minimize disruption of required sash airflow. HVAC system and fume hood controls must be designed such that operation or shutdown of any fume hood in a given space must not disrupt the required room air balance or the required sash airflow at other hoods operating in the space. General-purpose laboratory fume hoods that control personnel exposure to chemicals and physical contaminants must have a minimum sash face velocity of 100fpm (0.50 m/s). Fume hoods must be provided with audible and visual alarms to indicate inadequate sash airflow conditions.

10-16.4.3 Radioactive Material and Radioisotope Hoods.

Duct systems serving hoods for radioactive material must be constructed of acid-resistant-type stainless steel for their entire length. Ductwork must be flanged with neoprene gasketed joints to facilitate dismantlement for decontamination. Fume hood exhaust must remain in constant operation and must be filtered with carbon or HEPA filters as required to meet Nuclear Regulatory Commission (NRC) requirements. The location of filters in the system must be chosen to best facilitate their safe removal, disposal, and replacement by maintenance personnel. All filters must be automatically monitored to provide indication that change-out is required. All hoods must comply with requirements of the NRC.

10-16.4.4 Canopy Hoods for Prosthetic Dental Laboratories.

Canopy hoods for Prosthetic Dental Laboratories, and exhaust ductwork extending for a distance 10 ft (3 m) downstream from the hood connection, must be fabricated of material that is corrosion resistant to the caustic fumes emanating from boil-out tanks and casting activities conducted in the laboratory.

10-16.4.5 Biological Safety Cabinets (BSCs).

Class, type, and location of BSCs must be as directed by the DoD Project Sponsor. Class II BSCs are provided with HEPA filtration of recirculated air or building exhaust, and are provided in such areas as Microbiology and Mycology. The required open door or sash face velocity for Class I and Class II Type A BSCs must be 75 fpm (0.38 m/s), and for Class II Types B1, B2, and B3, must be 100 fpm (0.51 m/s). For further information of biological safety hood class, type, application, and exhaust requirements, refer to the ASHRAE Handbook series, OSHA Part 1910, Biosafety in Microbiological and Biomedical Laboratories, and NSF/ANSI Standard 49.

10-16.4.6 Perchloric Acid Hoods.

Hoods for handling of perchloric acid and other strong oxidizing agents, and the associated exhaust ductwork, must be constructed of stainless steel. Internal water spray systems must be provided for hood and all ductwork to facilitate the periodic washdown. Joints must be welded and ground smooth, and all ductwork pitched back toward the hood to facilitate drainage. Welding must be in accordance with AWS D18.1

Hygienic Welding. More detailed guidance is provided by the ACGIH publication Manual of Recommended Practices for Industrial Ventilation.

10-16.4.7 Containment Laboratories BSL-3 and BSL-4.

These laboratories deal primarily with indigenous or exotic agents that may cause serious or potentially lethal disease as a result of exposure by inhalation. The HVAC design for these laboratories must ensure the continuous negative pressurization and exhaust of the space. The exhaust air from these spaces must not be recirculated to any other area of the building, but must be transported through dedicated exhaust ductwork to be directly discharged to the outside of the building. Design of BSL-3 and BSL-4 laboratory exhausts must comply with Biosafety in Microbiological and Biomedical Laboratories, DA PAM 385-69, and DoDM 6055.18-M.

10-16.5 Exhaust Canopies.

Exhaust canopies must be provided for equipment or appliances generating high heat or moisture (steam) loads, such as glassware washers, boil-out tanks, drying ovens, sterilizers, and stills. In some cases, specially designed canopy hoods may be necessary to control personnel exposure to hazardous chemical vapors. Canopy hood design must comply with the ACGIH data for “Canopy Hood” from the Manual of Recommended Practices for Industrial Ventilation.

10-16.6 Laminar Flow Clean Benches.

These horizontal flow hoods are used in pharmacy for preparing intravenous fluids and similar laboratory processes. Clean benches recirculate room air and do not require exterior air supply or exhaust systems.

10-16.7 Bench-Back Slot Hoods.

Slot hoods are typically built into the wall behind laboratory benches to exhaust vapors, gases, and odors that are released with little energy or velocity. Typical applications are laboratories, brace shops, and other spaces in which volatile chemicals are routinely used. Design of these hoods must be in accordance with ACGIH guidelines, with a slot velocity of 2,000 fpm (10 m/s).

10-16.8 Portable Bench-Top Hoods.

Portable hoods with glass viewing panels and interior lighting may be used to control chemical contaminants of minor toxicity and odors. They must be attached to built-in exhaust outlets with flexible ducts. Each built-in exhaust system outlet must provide a minimum of 160 CFM (76 L/s) or a face velocity of 75 fpm (0.38 m/s) at the hood, whichever provides the maximum mass flow of air. The exhaust duct opening must be provided with a blast gate and sealing plug to stop airflow when the unit is not in service.

10-16.9 Medical Equipment.

Reference Chapter 15 for special ventilation requirements of medical equipment.

10-16.10 Kitchen Hoods.

Equip all hoods over cooking service equipment with fire extinguishment systems, automatic washdown, listed grease extractors, and heat-actuated fan controls. Cleanout openings and required fire protective enclosures and separations must be provided in horizontal exhaust duct systems serving these hoods and grease exhaust ducts in accordance with NFPA 96.

10-16.11 Pharmaceutical Admixture Rooms.

Pharmacy admixture rooms must be in compliance with USP 797 and/or USP 800, Pharmacists' Pharmacopoeia. For each project, designers must interview DoD Project Sponsor personnel to evaluate the nature of drug compounding procedures, including risk level, for each compounding room, as the basis for determining required room air changes, filtration levels, protective equipment, and separation area (anteroom) requirements for the designated clean room level.

10-16.12 MRI Quench Exhaust.

Provide a dedicated cryogen quench vent run as directly as possible to the outdoors. Design the quench vent to meet the requirements of the MRI system manufacturer. Fully insulate the quench vent to the point of discharge. Provide a weather-head to prevent the introduction of horizontally driven precipitation, snow accumulation and animal intrusion at the discharge of the quench vent. Separate the quench vent discharge point from any air intake or operable window as specified in this chapter concerning outdoor air intakes. Clearly mark a 25 ft (7.5 m) radius exclusion zone around the quench vent discharge.

10-17 AIRBORNE INFECTION ISOLATION AND PROTECTIVE ENVIRONMENT ROOM DESIGN.

Isolation rooms consist of airborne infection isolation and protective environment rooms. The former is intended for the patient suffering from a known or suspected infectious disease and is provided with engineering controls that assist in preventing the spread of the disease from the room. Protective environment rooms are provided for the patient having an immune system deficiency and require engineering controls to assist in protecting the patient from contamination from outside the room. Rooms must be one or the other, and not "switchable" from airborne infection isolation to protective environment function, or vice versa. Provide rooms with pressure-monitoring alarms and gauges mounted on the outside corridor wall; when a central DDC control operator's station is provided, the alarm should in addition be connected to that system.

10-17.1 Airborne Infection Isolation Bedrooms.

Design airborne infection isolation bedrooms to incorporate requirements and guidance contained in the Guidelines for Preventing the Transmission of Mycobacterium Tuberculosis in Health-Care Facilities (the TB Guidelines), published in the Federal Register Vol. 59, No. 208. Provide negative pressure, exhaust to the outside, and minimum total and outdoor air change rates (12/2, respectively) as referenced in Appendix B. Connect the exhaust ductwork from isolation bedrooms, only with the associated toilet, anteroom (if provided), or other isolation rooms and their associated anterooms and toilet rooms. Where the design includes additional associated rooms that only open directly to the isolation bedroom, apply the Appendix B HVAC requirements for isolation bedrooms to these rooms, and connect the exhaust from these rooms to the isolation bedroom exhaust system. Power isolation bedroom exhaust systems from the EES. Supply bedroom suites by air systems provided with constant-volume control and measuring terminal units that automatically maintain the supply airflow rate set-point to each space. Provide constant volume exhaust systems maintaining a fixed exhaust flow rate for each space. Discharge isolation bedroom exhaust in a vertical direction no less than 10 ft (3 m) above the adjoining roof surface. Provide no less than 30 ft (10 m) horizontal separation from isolation bedroom exhaust and any outdoor air intakes, openable windows/doors, or areas normally accessible to the public. When bedroom exhaust is located such as to prevent re-entrainment into outdoor air intakes or other building openings, HEPA filtration of the exhaust is not required.

10-17.1.1 Existing Facilities.

In existing facilities, only those bedrooms designated by the facility specifically for use as tuberculosis isolation bedrooms are required to be designed in accordance with the TB Guidelines referenced in paragraph 10-17.1. TB Isolation bedrooms must be negatively pressurized, exhausted, and must be provided with 12 air changes per hour if economically or physically practicable. When not practicable to achieve this air change rate, TB isolation bedrooms must have a minimum of 6 air changes per hour, to be supplemented by HEPA filter or UV germicidal irradiation (UVGI) systems specifically designed for TB Room applications and providing the equivalent of an additional 6 air changes per hour. Fixed-in-place HEPA filtration units are preferable to portable units, and upper-level UVGI systems are preferred over duct-mounted units, to enhance reliability. Room exhaust must be conducted to the outside of the building; when designed to avoid re-entrainment into outdoor air intakes or other building openings, HEPA filtration of the exhaust is not required.

10-17.1.2 Isolation Suite Relative Pressurization.

When an anteroom is provided for the isolation bedroom interposing between the bedroom and corridor to provide a “buffer” airspace for additional protection, there are several recognized design approaches for corridor-anteroom-bedroom relative pressurization. A recommended design is to provide for the anteroom to be under

negative pressure relative to the corridor, and positively pressurized relative to the bedroom.

10-17.2 Protective Environment Rooms.

The air supply to the protective environment room and associated anteroom and toilet room must be constant flow and must be provided with HEPA filtration. 12/2 total and outdoor air changes, respectively, are required for these rooms. As with airborne infection isolation bedrooms, there are several recognized approaches to the relative corridor-anteroom-bedroom pressurization; a recommended approach is to establish the anteroom positively pressurized relative to the corridor, and negatively pressurized relative to the bedroom.

When upgrading existing protective environment bedrooms to this criteria, 12/2 air changes per hour must be provided if economically and physically practicable. When impractical, these bedrooms must be provided with a minimum of 6 total air changes per hour and supplemented by HEPA filtration or UVGI systems to provide the equivalent of 12 air changes.

10-17.3 Airborne Infection Isolation Exam or Waiting Rooms.

Airborne infection isolation exam or waiting rooms, including pediatric and emergency waiting rooms, must be provided with a minimum of 12 total air changes, as provided in Appendix B. Exhaust ductwork from these rooms must only be connected to the exhaust from other isolation rooms and their associated anterooms and toilet rooms, and not be connected with other exhaust systems.

This page Intentionally Left Blank

CHAPTER 11 ELECTRICAL

11-1 GENERAL.

11-1.1 Scope.

This chapter provides policy and guidance for planning, design, and construction of electrical power and illumination systems for applicable facilities. Criteria is noted throughout the chapter and included in Appendix B and Appendix I. Criteria also include the General Building Requirements established by UFC 1-200-01, including the core electrical engineering UFC's. The core electrical engineering UFC's, of which UFC 3-501-01 is the top-level, in conjunction with criteria in this chapter, establish minimum design requirements. In the event of conflict this UFC is the ruling criteria.

11-1.2 Supplemental Criteria and Standards.

This chapter may be supplemented with individual MilDep criteria, including installation-specific requirements, as established by the Design and Construction Agent.

11-1.2.1 Seismic.

Design essential electrical systems to function after a seismic event occurs. Provide seismic design in accordance with Chapter 7.

11-1.2.2 Durability.

Provide a minimum rating of continuous full design load for installed electrical systems and electrical equipment, except where other criteria mandate larger ratings, to meet the facility reliability requirements.

11-1.2.3 Maintainability.

Provide a means in the design to remove and maintain equipment and field-install wiring without interruption to essential electrical system loads. Provide standard equipment and sizes to the extent practical to allow interchangeability and simplify parts stock. Provide a removal path for all installed equipment. Where draw-out equipment is utilized, provide means to rack equipment in and out, and provide space for maneuverability during servicing.

11-1.2.4 Efficiency.

Provide power factor correction if the power factor is less than 0.95. Provide balanced three-phase loading such that phase unbalance at nominal voltage does not exceed 5% between A, B, and C phases.

11-1.2.5 Economy.

Evaluate alternative system configurations, and component types and sizing for economic value consistent with other criteria factors.

11-1.2.6 Power Conditioning.

Systems that incorporate solid-state devices are susceptible to electrical system transients that may cause system malfunction or equipment component damage. Do not install power conditioning equipment at the utilization point of the building electrical system, unless explicitly required for specific items of equipment by the MilDep or by an A-E or designer evaluation of solid-state requirements for intensive care areas and approved for installation by the DoD Project Sponsor. Provide transient and surge protection for CFCI systems that utilize solid-state devices. Normally provide static UPS with the equipment and system being served. However, determine UPS requirement or provisions on a project-by-project basis. Determine provisions for future installed power conditioning equipment on a project-by-project basis.

11-1.2.7 Voltage Tolerance.

Provide nominal voltage ratings and operating tolerances in compliance with maximums and minimums established by ANSI C84.1. Consider all system voltage drops and supply variation in order to ensure voltage levels are met, from the high voltage main electric supply substation to the low voltage point of utilization. Provide voltage regulators within the facility when the tolerance to demand peaks is not met through conductor sizing or automatic load tap changers in the high voltage main electric supply substation transformer. Provide voltage drop on branch circuits and feeders in accordance with UFC 3-501-01. Base load current for calculation of voltage drop on the circuit capacity as required by UFC 3-501-01; except for feeders, the load current may be based on the frame size of the replaceable plug unit in an adjustable breaker.

11-1.2.8 Risk Assessment for System Categories.

Perform a risk assessment in accordance with NFPA 99 to determine risk categories for activities, systems, or equipment; and the essential power requirement. Use the results of this assessment in conjunction with paragraph 11-4.14 and B-6.2 below to determine loads served and sizing of the alternate power source. The results of the assessment are in addition to the equipment otherwise prescriptively required within this UFC to be served by the essential electrical system. See Appendix C for the timing and responsibilities of the risk assessment.

11-1.2.9 Growth.

Provide the following growth factors:

a. Load Capacity. Provide a minimum 20% spare load growth at 100% demand throughout the electrical system, to include primary feeders, transformers, generators, secondary feeders, and distribution equipment.

b. Bus Space. Provide a minimum of 20% empty bus space in all switchgear, switchboards, and panelboards.

c. Wall Space. Provide a minimum 20% horizontal wall space, to include floor space for cubicle gear, within each separate electrical room for system expansion.

d. Spare Breakers. If the design includes draw-out breakers and the facility includes Category 1 space or is 24/7 or is in-patient; provide one spare draw-out in each frame size on the normal power side and essential power side.

11-1.2.10 Elevators.

Provide design for elevators in compliance with ASME A17.1 and UFC 3-490-06.

11-1.2.11 Containment Laboratories BSL-3, BSL-3+, and BSL-4.

Design BSL-3, BSL-3+, and BSL-4 laboratories in compliance with Biosafety in Microbiological and Biomedical Laboratories, DA PAM 385-69 and DoDM 6055.18-M.

11-1.2.12 Alternative Energy Sources.

If alternative energy sources such as fuel cells or photovoltaics are provided, connect to the normal power system.

11-1.3 OCONUS Criteria.

Comply with requirements herein, except where alternative design standards have been developed and approved in accordance with Chapter 1, to achieve the intent of criteria without compromising safety or property.

11-1.3.1 Federal Republic of Germany.

Incorporate the Hospital Electrical Code Study (U.S. versus German Codes) into Federal Republic of Germany projects to provide equivalent safety to U.S. construction and aid in Joint Commission certification. The study consists of a series of recommendations by subject. Each recommendation is to be considered a design or operational requirement, which either supplements or replaces criteria of this chapter. The study provides for the use of German codes, standards, equipment, materials, and construction practices; through the imposition of the more stringent requirement or the analysis of equivalent safety. The analysis of equivalent safety is based upon specific O&M procedures identified at the Landstuhl Regional Medical Center. These procedures include a comprehensive maintenance program through in-house forces, complete and annual testing of all systems, and a safety program. Consequently, the study only applies to facilities meeting these O&M requirements as identified within the study. A copy of the study is available on the World Class Facilities Toolkit or upon request from CEHNC-EDX.

11-1.4 Campus and Other Large Facilities.

Medium voltage may be approved for the central utility plant, where essential power demand exceeds capacity of commercially available distribution gear, or where facilities are separated from the central utility plant over a distance impractical to transmit power. Submit life cycle cost analysis to include staffing of medium voltage engineers, for approval by the Design and Construction Agent. If medium voltage is approved by the Design and Construction Agent, provide a primary selective, secondary radial system design; which is otherwise in compliance with this chapter.

11-2 AREA DESIGNATIONS.

11-2.1 Patient Care Space.

NFPA 70 and NFPA 99 establish minimum safety practices and requirements for patient care spaces. “Critical”, “general”, “basic” and “support” patient care spaces are identified in Appendix B by NFPA 99 category code 1 through 4. For medical research facilities, laboratories, and veterinary facilities, provide the essential electrical system in compliance with NFPA 99 and NFPA 70 article 517 even though an exclusion is provided in these codes for care not rendered to human beings.

11-2.2 Wet Locations.

Wet locations are those patient care areas that are normally subject to wet conditions, including areas with standing water on the floor or areas where routine dousing or drenching of work spaces is performed, and those areas defined in NFPA 99 and NFPA 70. However, wet conditions as a result of routine housekeeping procedures or an incidental spill of liquid are not considered wet locations.

11-2.3 Wet Procedure Locations.

Wet procedure locations are defined in NFPA 99. They include operating and C-section rooms, but not labor and delivery rooms. Define wet procedure locations in the project requirements documents.

11-3 EXTERIOR ELECTRICAL.

11-3.1 Primary Voltage.

Common primary distribution voltages for military installations are 4.16 kV, 12.47 kV, 13.2 kV, 13.8 kV, and 34.5 kV. However, 12.47 kV, 13.2 kV, and 13.8 kV are the normal primary distribution voltages serving medical facilities.

11-3.2 Normal Source Site Investigation.

Provide exterior electrical systems in compliance with IEEE C2, except where technical criteria are more stringent. Provide site electrical evaluations in accordance with the requirements within this document. Coordinate electrical utility siting with other utilities.

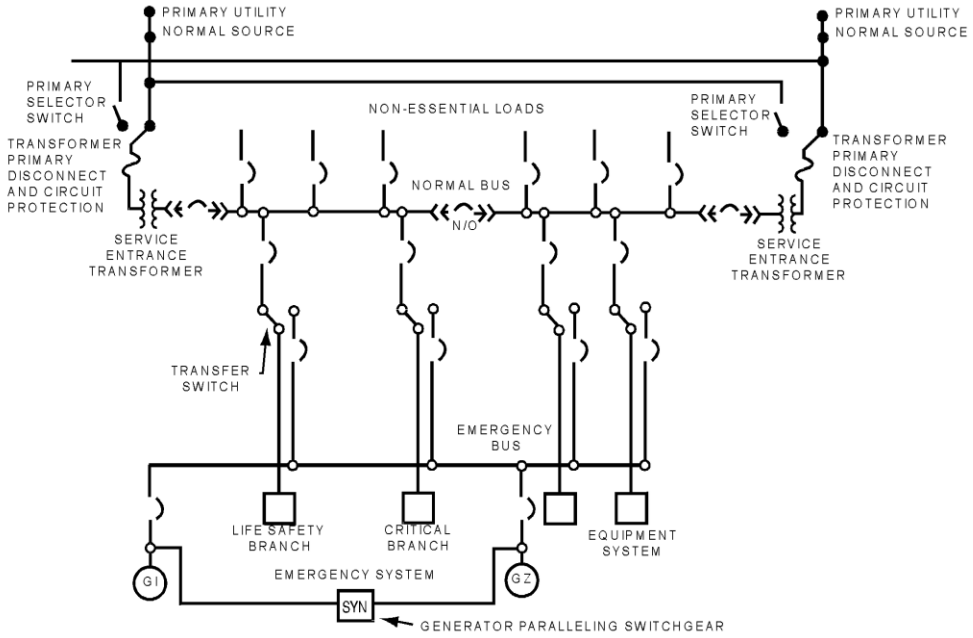
Provide underground distribution on site and visual screening by location or landscaping elements where appropriate for the project to improve overall site aesthetics.

11-3.3 Hospital Normal System.

11-3.3.1 Primary Feeders.

Provide hospitals with two primary feeders, each serving one end of a double-ended substation or to a selector switch serving a multi-ended network substation (Reference Annex B Multi-Ended Network Substation and Annex C Expandable Dual-Ended Substation for additional criteria related to substation design). Size each feeder to carry the full hospital demand, plus 20% spare load growth at 100% demand. Install each feeder in an underground, concrete-encased duct bank within the hospital site. Connect primary feeders to different power sources (main electric supply substations) if available, and differently route the two primary feeders such that they are electrically and geographically separated. Where two main electric supply substations are not available, the service feeders may be connected to two different sections of a true open loop system.

11-3.3.2 Open Loop System.



A true open loop system configuration is a utility primary feeder where both ends originate from different main electric supply substations or switching stations, or different breakers and transformers in the same main electric supply substation, and have the capacity to serve the total loop load from either end. Consider both the main electric supply substation primary (high voltage) and secondary (medium voltage) loop configuration, redundancy within the main electric supply substation design (for example, double ended), and outage history in the overall reliability determination. The Government and Public Utility each have defined responsibilities (ownership), and where reliability does not meet standards, provide normal power back up of systems to sustain operations if requested by the DoD Project Sponsor.

11-3.3.3 Transformer Substation.

Provide a manually-operated primary selector switch and fused load break disconnect switch for each transformer as indicated in Figure 11-1. Transformers should normally be located outside the hospital but may be located within the building where practicable and economical. Design double-ended unit substation distribution systems for hospitals, medical centers, and specially-designated facilities. Arrange the double-ended substation for easy expansion from each end. Provide identical and interchangeable tiebreaker and main feeder breakers of double-ended substations. Provide draw-out power class breakers (tie, main feeder, and sub-feeder) for all double-ended and single-ended substations. Size each transformer in the double-ended unit substation to serve approximately 60–70% of the substation demand load (linear and nonlinear) before forced air cooling is initiated, at 100% of demand load plus 20% future load growth with forced air cooling initiated. Provide Impedance-matched transformers. Provide coordinated transient/surge and fault protection for double and

single-ended unit substations. Provide selective system protection. Design all double-ended substations for normal open tie breaker operation, which is interlocked with the main breakers, so that all three breakers “main-tie-main” cannot be closed simultaneously. Upon loss of a single transformer or its feeder, the main breaker is automatically opened and the tie breaker is automatically closed to add its load to the remaining transformer.

Figure 11-1 Hospital One-line Traditional Diagram

\1\ /1/

11-3.3.4 Fire Pump Controller.

To prevent unnecessary generator starting due to loss of only one of the two normal power sources, provide an ATS connected to both normal sources to supply normal power to the fire pump controller.

11-3.3.5 Grounding.

Provide adequate system ground for safety and for reliable operation of sensitive users and facility equipment. Typical communications system equipment used in hospitals requires 5-ohm system ground for proper operation. Bond all grounding systems together as required by NFPA 70.

11-3.4 Ambulatory Care Clinics Normal System.

For ambulatory surgery centers, provide dual sources of normal power as described in paragraph 11-3.3. For other ambulatory care clinics, provide normal power as

described in paragraph 11-3.3 Hospital Normal System, except provide only a single primary source and single-ended substation(s).

11-3.5 Medical and Dental Clinics Normal System.

For medical and dental clinics, provide normal power as described in paragraph 11-3.3, except provide only a single primary source and **\1** single transformer. **/1/**

11-3.6 Medical Research Facilities and Laboratories Normal System.

For medical research facilities and laboratories, provide dual sources of normal power as described in paragraph 11-3.3, except a single primary source and single-ended substation(s) is permissible if requested by the DoD Project Sponsor.

11-3.7 Veterinary Facilities Normal System.

Design veterinary facilities as described in paragraph 11-3.3, except provide only a single primary source and **\1** single transformer. **/1/**

11-3.8 Other Medical Facilities Normal System.

Other facilities include blood donor facilities, medical warehouses, or other facilities which do not include patient care space. Design other facilities as described in paragraph 11-3.3, except provide only a single primary source and single transformer, unless described otherwise in programming documents.

11-4 ESSENTIAL ELECTRICAL SYSTEM.

11-4.1 Facility.

11-4.1.1 Hospitals.

Hospitals must be provided with an essential electrical system in compliance with this chapter.

11-4.1.2 Ambulatory Care Clinics.

Design ambulatory surgery centers and ambulatory care clinics with Category 1 spaces in compliance with the requirements of paragraph 11-4.1.1. Design ambulatory care clinics without operating rooms or other Category 1 space in compliance with paragraph 11-4.1.3.

11-4.1.3 Medical and Dental Clinics.

Justification for an emergency generator is required in the planning and programming phase in order to authorize funding. An essential electrical system, with an alternate source of power, will be required if the facility contains Category 2 space; refer to the

patient care space categories in Appendix B. Design the electrical system in accordance with paragraph 11-4.1.1, except as described otherwise in this section.

11-4.1.3.1 System Configuration.

If an essential electrical system is required, provide the system in compliance with NFPA 99 for the space category. If the facility contains Category 2 space, but not Category 1, provide a generator or battery system for the alternate power source; and perform a life cycle cost analysis no later than concept design, to select the economic choice in coordination with the DoD Project Sponsor. For the intent of this section, the battery system only provides for cessation of procedures upon loss of normal power. For either system, provide a permanent switching means to connect a portable or temporary alternate source of power in accordance with NFPA 70 article 700.

11-4.1.3.2 Generator.

If a generator is selected for the alternate power source, a single diesel generator may be used. Locate the generator indoors within a separate room or outdoors in an exterior enclosure with skid mount tank. The fuel supply is to be no less than 8 hours at full load. Provide leak protection system. If an exterior enclosure is used, provide architectural screening compatible with the building and grounds; force protection in accordance with UFC 4-010-01; a sound attenuating enclosure; and hospital grade silencer.

11-4.1.3.3 Battery System.

A battery system for the alternate power source is not allowed for Category 1 space, but is permitted for Category 2 through 4 spaces. If the battery system is used, provide capacity to sustain full connected load at rated voltage for a minimum of 1½ hours. Design the system in accordance with NFPA 111, NFPA 855, and UFC 3-520-05. Provide a separate room for the system if required by the battery type.

11-4.1.3.4 Essential Loads.

Arrange the system to automatically connect the alternate power source to the load within 10 seconds. Design the essential electrical system to supply life safety and task illumination, outlets related to patient safety, and mechanical equipment as determined by the NFPA 99 risk assessment. This typically includes but is not limited to surgical vacuum, medical air, waste anesthetic gas disposal, and any other system or equipment which is necessary for safe and orderly cessation of procedures and all related anesthesia and resuscitation equipment. The critical branch of the essential electrical system is omitted for an NFPA 99 Type 2 system; and in this situation, adjust branch loads as described in paragraph 11-4.14. Provide a minimum of one normal and one essential power circuit in Category 2 spaces or provide separate essential circuits originating from separate essential branch transfer switches.

11-4.1.3.5 Miscellaneous.

Electric driven fire pumps may be connected to the normal power supply if an analysis in accordance with NFPA 20 and UFC 3-600-01 proves the supply is reliable. Normal power may be supplied by a single primary feeder and single ended substation. Draw-out construction is not required for circuit breakers and automatic transfer switch(es). A separate room is not required for automatic transfer switch(es) if the location complies with NFPA 110. If the load is 150 kVA or less, a single transfer switch may be used as permitted by NFPA 70. An interior door for the main electrical room is not required.

11-4.1.4 Medical Research Facilities and Laboratory Facilities.

Justification for an emergency generator is required in the planning and programming phase in order to authorize funding. Provide an emergency and or standby system with an alternate source of power if included in the programming documents.

11-4.1.5 Veterinary Facilities.

Justification for an emergency generator is required in the planning and programming phase in order to authorize funding. An essential electrical system with an alternate source of power will be required if the facility contains Category 1 or 2 space; refer to the patient care space categories in Appendix B. Provide the essential electrical system in compliance with NFPA 70 and NFPA 99, even though an exclusion is provided in these codes for veterinary care. Design the electrical system in accordance with paragraph 11-4.1.3, except if the facility contains Category 1 space, provide a generator for the alternate power source and the fuel supply of no less than 24 hours at full load. Dual sources of critical power, originating from separate critical branch transfer switches are required in some spaces by Appendix B; and the dual sources may be critical and normal.

11-4.1.6 Other Medical Facilities.

Other medical facilities include blood donor centers, medical warehouses, and other facilities which do not include patient care space. Provide an emergency and or standby system with an alternate source of power if included in the programming documents. Justification for an emergency generator is required in the planning and programming phase in order to authorize funding.

11-4.2 General.

Provide the alternate power source in conformance with NFPA 70 and NFPA 99, except where technical criteria from the DoD Project Sponsor is more stringent. Provide adjustable trip spare circuit breakers, raceway, and buss bar connection box for load bank testing. Size load bank breaker for 100% capacity of one generator set; and provide a second breaker, 100 A, 3-phase, for the load bank fans. Cable to be provided by user after turnover. Provide additional load capacity to those hospitals assigned mobilization or mass casualty response missions as identified in the project DD Form

1391. Design the emergency power source as a separately derived power source. Provide true root mean square (RMS) metering for load monitoring.

11-4.3 Alternate Power Source.

Provide an alternate power source to supply the essential electrical system during interruption of the normal source as required by NFPA 70 and NFPA 99. Provide parallel operation by two or more generator sets in accordance with Figure 11-1 (see Annex B and Annex C for alternate configurations); except where the essential electrical system load is 150 kVA or less, one generator set may be considered. Consider factory service, parts, and supplier support in the design.

Provide generator sets of equal capacity and rating when operated in parallel with matched impedance and loss characteristics, and designed to carry in parallel or through priority transfer equipment the maximum demand load (linear and nonlinear) of the essential electrical system. Evaluate motor starting and X-ray unit momentary kVA loads when sizing generator sets. Size each generator set for the capacity to serve all non-sheddable loads (life safety and critical branches, medical air compressor, medical-surgical vacuum pumps, jockey pumps, fire pumps, generator set fuel pumps, other generator set accessories, and non-sheddable helipad loads) plus 20% future load growth at 100% demand. Provide generator set performance class and transient limits in compliance with UFC 3-540-01, and include block loading calculations in the project documentation. Hospitals built under the 1971 version of NFPA 70 may have a life-support branch that is the second critical branch supplied by a separate ATS.

11-4.4 Generator Sets.

Provide diesel-electric generator sets in conformance to Table 11-1. The preferred generating voltage is the highest utilization voltage proposed for the facility. Normally, 480Y/277 V, 3-phase, 60 Hz, 4-wire system is the highest utilization voltage. Higher voltages may be generated where line losses would otherwise be excessive. Include automatic start-and-stop equipment, solid-state battery chargers, fuel storage tanks, remote NFPA 110 panel and audible and visual warning devices to alert of less than four hours of fuel supply, and day tanks and radiators (as required) all as part of the generator set design. Provide the generator set with a hospital grade exhaust silencer and the ability to start and assume its full electrical loads within 10 seconds from the interruption of the normal source. Provide protective relaying for generator sets and related equipment in accordance with the recommendations of IEEE STD 242, including reverse power relays in accordance with NFPA 110 to prevent damage from commercial power or other onsite generators. Equip all generator sets with an isochronous governor to ensure stable voltage, frequency, and power by preventing erratic load operations and allowing computerized equipment to operate directly from the essential electrical system.

11-4.5 Location of Generator Sets.

Locate generator sets in the central utility, provided it is sufficiently close to minimize line losses and cable runs. When the central utility plant is remote from the medical structure, locate generator sets in a building adjacent to or within the medical structure. Locate generator sets and related switch gear rooms (auxiliaries) near the building exterior to facilitate installation and replacement of equipment. Arrange generator sets and auxiliaries so minimum facility modifications are required for future installation or replacement. Do not install service entrance transformers and other equipment not supporting the essential electrical system in the same area (room) as the generator sets. Provide a view window in, or adjacent to, the entrance door.

Do not locate generator sets and auxiliaries below finish-grade level. Locate generator sets and auxiliaries directly accessible from the facility's interior and exterior to a vehicular way. In regions subject to flooding, locate equipment above the Design Flood Elevation and provide flood proofing in accordance with paragraph 11-5.4.4.

Table 11-1 Continuous and Emergency-Rated Diesel-Electric Generator Sets

Power Class Categories:
1. **Prime Power Class** engines are for use with diesel-electric generator sets expected to provide power on a continuous basis, that is in excess of 4000 hours annually or in excess of 40,000 hours during the initial 10 years of operation, to serve as the sole or primary source of power.
2. **Standby Power Class** engines are for use with diesel-electric generator sets expected to provide power on a standby basis for a significant number of hours each year, that is between 1000 and 4000 hours annually or between 10,000 and 40,000 hours during the initial 10 years of operation.
3. **Emergency Power Class** engines are for use with diesel-electric generator sets expected to provide power on an emergency basis for a short period of time, that is less than 1000 hours annually or less than 10,000 hours during the initial 10 years of operation.
DESIGN APPLICATION:
1. For 50-Hz power, the indicated speed limits should be reduced to the nearest synchronous speed for that frequency.
2. Hospital and ambulatory care center diesel-electric generator sets are normally Emergency Power Class.
3. For diesel-electric generator sets used for co-generation in hospital and ambulatory care center, provide either Prime Power Class or Standby Power Class.

11-4.6 Engine Starting.

Provide electric or pneumatic starting for generator sets in conformance to NFPA 70, NFPA 99, and NFPA 110. Where electric start is used, provide dual heavy-duty electric starters on generator sets above 1,250 kVA.

11-4.7 Manual Test Switches.

Provide manual test switches for each ATS of the essential electrical system. Provide a group of test switches at a single point in the generator set control area, and one test switch with each ATS. Wire the two test switches associated with each ATS in series to allow testing at either location. Provide capability to test either individual ATS or the entire essential electrical system. Upon depressing any test switch a simulation of a normal power source failure is to occur. The simulation is to automatically cause the generator sets to crank, to attain rated frequency and voltage, and to transfer associated essential electrical system loads from the normal source to the alternate power source; and after 30 minutes of operation in the emergency mode, automatically transfer essential electrical system loads back to the normal source. If for any reason during the simulation, the generator sets experience difficulty while in the emergency mode, immediately transfer load to the normal source automatically. During this simulation, continue serving nonessential hospital loads from normal source without interruption. Install a manual override switch that can be actuated to keep essential hospital loads on the alternate power source as long as desired and which permits generator sets to operate indefinitely beyond the 30-minute automatic transfer restoration time.

11-4.8 Generator Set Operation.

11-4.8.1 Generator Starting.

Design generator sets to function as discussed here. After one second following interruption of the normal source, each generator set is to receive the starting signal simultaneously from the ATS, whereupon each generator set is to automatically crank and attain normal speed and voltage. Do not bundle the starting signal together or series connect between ATS’s. Voltage for sensing devices to start generator sets is to be taken from each phase of the incoming normal power terminal of each ATS and hardwired back to the generator set start controls. The first generator sets to reach preset voltage and frequency conditions are to be automatically connected to the emergency bus.

11-4.8.2 Paralleling and Load Transfer.

Provide system protection to prevent simultaneous connection of non-synchronized generator sets to the dead emergency bus. Provide a priority selective device programmed or preset to transfer the non-sheddable loads from the normal bus to the emergency bus within 10 seconds from time of normal source interruption. The remaining generator set(s) are to automatically synchronize with the emergency bus,

close the respective generator SET breaker, and connect the generator sets in parallel for normal operation. After this, automatically transfer the equipment system loads to the emergency bus by programmed or preset incremental steps.

11-4.8.3 Load Shedding System.

Where two or more units are paralleled, provide a load management system in compliance with NFPA 99 and 110. For such system, provide automatic load shedding with manual override that will commence should one or more of the generator sets fail to crank or is shut down for any reason during the operation, or if the total load were to exceed a preset value beyond which a cascading shutdown could occur. Schedule the remaining generator set(s) to serve only the non-sheddable loads, and if possible, highest priority equipment system loads until the failed unit(s) is energized and connected to the emergency bus. For such a condition, provide a programming device to shed all or part of the equipment loads to keep the remaining generator(s) within its kW rating. Design the system in accordance with UFC 3-540-01 and provide for load prioritization by operation and maintenance. Provide a system with redundant processors with wiring and control not shared with other building systems. Provide load priority, sequence, and time delay.

11-4.8.4 Manual Override.

Provide a manual start switch to override the automatic start of the generator sets so they can be cranked, synchronized, and connected on the emergency bus. Provide manual controls to allow the synchronizing and paralleling of the generator sets.

11-4.8.5 Return to Normal Power Source.

Thirty minutes following the return of a stable, normal source, automatically transfer essential system loads to the normal source. Provide an automatic timer for this transfer, having an adjustable time range from 2 to 30 minutes (set at 30 minutes). Following transfer of the loads, generator sets are to continue to run unloaded for a period of not less than 15 minutes for cool-down before shutdown; after which controls automatically reset for a new cycle. Provide a manual start switch to override the automatic start of generator sets so they can be manually cranked, synchronized, and connected to the emergency bus if automatic controls fail.

11-4.9 Automatic Transfer Switch (ATS).

Provide double-throw, open-transition, ATSs with draw-out construction. Use 4-pole ATSs when serving line-to-neutral loads or a combination of line-to-neutral and line-to-line 3-phase loads. Use 3-pole ATSs when serving only 3-phase line-to-line loads. Provide ATSs which are UL tested with the main up-stream breaker to ensure coordinated withstand compatibility between the ATS and the interruption time of the breakers. Circuit-breaker-type transfer switches are not acceptable. Provide green indicator lights to identify normal power and red to identify emergency power in each ATS. Provide each ATS with at least three normally open and three normally closed

spare shaft contacts. Equip each ATS with a load break bypass isolation switch (BP/IS) to maintain normal or emergency power while the ATS is being repaired or maintained. Provide for BP/IS operation with not more than two movements of the hand to either position regardless of the position or condition of the ATS. **\1\ /1/** Provide an in-phase monitor to prevent an out-of-phase transfer in each ATS feeding high efficiency motors rated 25 hp (18.6 kW) or larger. Provide in-phase transfer without control of the frequency of either power source to prevent excessive motor in-rush current. Use of closed-transition switching for facilitating essential system testing **\1** or paralleling with utility requires DoD Project Sponsor authorization, approval by the Installation Management Organization (IMO), and approval by the utility as described in UFC 3-540-01 **/1/**. The BP/IS for the ATSs serving nonessential equipment can be optional.

11-4.9.1 ATS and BP/IS Location.

For hospitals and ambulatory surgery centers, locate the ATS and BP/IS equipment in a separate room with 2-hour fire-rated construction having direct access from the normal main power equipment room and the alternate power source equipment room.

11-4.9.2 ATS and BP/IS Testing.

Provide for conduction of laboratory testing, for example, UL, Factory Mutual (FM), or other nationally recognized authority, on the ATS and BP/IS equipment, unless it was completed on a previous randomly selected standard production unit of the same model and capacity as the specified ATS and BP/IS equipment. Conduct the overload, endurance, and temperature tests (in sequence) as listed here:

a. General
b. Normal Operation
c. Overvoltage
d. Under-voltage
e. Overload
f. Endurance

o. Strength of Insulating Base and Support.

It is important to note that no deviations from the test sequence are permitted. Approval is not granted to deviate from the overload, endurance, and temperature test sequence.

11-4.10 Ground Fault Protection Equipment.

Do not provide ground fault protection devices on the essential electrical system. Provide ground fault detection features, when required, to indicate a ground fault and sound an audible alarm but not trip the breaker, for the generator circuit breaker and essential electrical main distribution board circuit breakers. Provide activation level for each ground fault alarm sensor when the ground fault current is 10% of the breaker rating or 50 A, whichever is less.

11-4.11 Remote Alarm Annunciator.

Provide a remote alarm annunciator that receives power from a storage battery in a location readily observed by operating personnel at a regular workstation. Indicate alarm conditions on the annunciator of the alternate power source, as indicated in NFPA 99 and NFPA 110, and include (but is not limited to): battery and battery charger malfunction, engine generator run status, engine generator alarms, and less than a 3-hour fuel supply in the day tank and 24-hour supply in the main storage tank. Provide a separate audible and visible derangement signal within the hospital at a continuously monitored location. Reference Chapter 12 for details. This derangement signal need not display individual alarm conditions; however appropriate labeling is required.

11-4.12 Fuel Storage System.

11-4.12.1 Fuel Tanks.

Provide fuel storage tanks and installations in compliance with NFPA 30 and local, state, and Federal Environmental Protection Agency (EPA) policies and regulations. Provide a 4-day capacity at full load for the fuel oil tank sized to the nearest standard size. For remote locations OCONUS and for prime power projects, fuel storage capacities may be larger based on mission requirements or risk analysis as determined by the DoD Project Sponsor. If underground fuel storage tanks are required, provide double-walled with leak detection in accordance with EPA standards. Provide separate day tanks for each generator set, sized for not less than four hours of operation at full load, with an overflow back to the main storage tank. Base fuel usage at full load on manufacturer's full load test data. Follow NFPA 37 for fuel tanks inside of structures.

11-4.12.2 Transfer Pumps and Fuel Filtration.

Provide at least two transfer pumps arranged such that all pumps are capable of drawing from and returning fuel to any selected main storage tank. Provide quantity and sizing of pumps such that should any pump be out of service, the remaining pump(s) will meet the total fuel demand of all boilers (if applicable) and generators. Provide fuel filtration system per recommendations of the generator set manufacturer, to meet NFPA 110 and maintain the integrity of on-site fuel for up to 10 years. Include

automatic particulate filtration, dewatering, and fuel additive injection in the fuel filtration system. Fuel filtration system does not apply to systems with 8 hours or less capacity.

11-4.12.3 Fuel.

\1 Design engine-generators to operate on No. 2-D diesel conforming to ASTM D975. **/1/** Do not use natural gas or comparable gas fuel as an operating fuel for hospital emergency power generation.

11-4.13 Loads on the Alternate Source.

Provide a capacity in the alternate power source to supply the facility's essential electrical system as outlined in NFPA 70 and NFPA 99, as modified herein, and as required by items listed in Appendix B. Do not oversize generator sets such that load banks are necessary for testing under load as required by accreditation authorities. It is important to note that operating generator sets at low loads leads to fouled combustion and unreliable performance. Supplying a mixture of normal, critical, and equipment branch power to critical care areas is more reliable and is recommended in NFPA 99. Additional loads may be added to the critical branch or equipment system by the DoD Project Sponsor as needed to improve the facility's operations. Do not connect other loads to the life safety branch other than those loads identified in NFPA 70 and NFPA 99.

11-4.14 Essential Loads.

Essential loads are divided into three branches: life safety, critical, and equipment. These loads receive both normal and emergency power. Essential branch assignment is specified for medical gas in Chapter 9, and for telecommunication systems in Chapter 12. An NFPA 99 Type 1 system has life safety, critical, and equipment branches; while an NFPA 99 Type 2 system only has life safety and equipment branches. The branch assignment provided in this UFC is for an NFPA 99 Type 1 essential electrical system. For a facility without Category 1 space which has an NFPA 99 Type 2 essential electrical system, map critical branch loads to life safety and equipment branches in accordance with NFPA 70 and 99.

11-4.14.1 Life Safety Branch Loads.

The life safety branch provides emergency power to ensure patient and personnel safety during the interruption of normal power source. The lighting, receptacle, and equipment limitations listed here are defined by NFPA 70 and NFPA 99. Life safety branch provides power to the following:

a. Egress illumination, which includes 25% of corridor and 50% of stairway illumination, plus 25% of assembly areas, such as dining rooms.

b. All battery chargers for emergency battery-powered lighting units used in the event of a life safety branch outage.

c. Exit signs for marking of egress.

d. Fire alarm systems and piped medical gas alarm systems, including smoke detectors, medical vacuum system alarms, and alarms for ventilation for smoke evacuation for those areas where patient evacuation is not feasible.

e. Emergency communications used to notify the general population (radio paging [RP] and intercom systems) including telephone system, power and lighting for communication closets and crisis control centers, and associated equipment. Various related systems are included as directed.

f. Selected power, task lighting, and receptacles at generator set locations; in transformer, switchboard, mechanical, and electrical equipment rooms; repair shops and other equipment rooms; and charger for battery-powered emergency light sets.

g. Elevator cab lighting, control, communication, and signal systems.

h. Electric-powered doors used for building egress.

i. Auxiliary functions of fire alarm mass notification systems complying with NFPA 72.

j. Fuel transfer pump, battery charger, jacket water heaters, alarms, controls, air compressors for pneumatic start, and other similar generator systems accessories essential for generator operation.

11-4.14.2 Critical Branch Loads.

The critical branch provides essential electrical system alternate power to supply task illumination, fixed equipment, selected receptacles, and special power circuits serving areas and functions related to patient care during the interruption of normal power as listed here, derived from NFPA 70 and NFPA 99. The critical branch provides power to the following:

a. NC, telephone equipment rooms and closets, and selected computer equipment and selected data outlets.

b. Oxygen and medical gases equipment, MV pumps, and medical surgical compressed air system, and surgical vacuum pumps.

c. In patient rooms (on inpatient nursing units), provide one duplex receptacle per bed, including mobilization beds, located in the patient service console. Provide two additional wall-mounted duplex receptacles in single bedrooms and pediatric bedrooms.

d. Receptacles in nursery isolation rooms, cystoscopy, intravenous pyelogram (IVP) rooms, cardiac catheterization room, radiographic special procedure rooms, **\1\ /1/** and recovery rooms as indicated in Appendix B.

e. All receptacles and hard wired equipment in selected rooms in the surgery suite, the delivery suite, nursery, coronary care unit, ICUs, hemodialysis, and emergency department rooms/spaces as required by Appendix B.

f. All equipment for the refrigerated storage of blood, biological, and pathology specimens, and medicines.

g. Two X-ray rooms (including one fluoroscopic room) **\1\ /1/**.

h. Laboratories, incubators, analysis, blood bank, bone and tissue banks, chemistry, hematology, plus selected receptacles.

i. One flash sterilizer in each surgical suite and delivery suite cluster core and in central sterilization.

j. Selected receptacles in admitting and disposition, pharmacy, treatment rooms, nurse stations, **\1** oral surgery dental treatment rooms, comprehensive dental treatment rooms and periodontic dental treatment rooms. **/1/**

k. Medication preparation stations and nourishment stations.

l. Electronic data equipment for patient records.

11-4.14.3 Equipment Branch Loads.

Equipment branch feeders and branch circuits connected to the emergency and alternate power source automatically supply loads in a delayed selective order through ATSs. The equipment list noted here is derived from NFPA 99 and NFPA 70. The equipment branch provides power to the following:

a. One passenger type and one hospital service elevator per hospital wing (or section if applicable) to operate on a selective basis.

b. Fire pumps, jockey pumps, and controls (non-sheddable loads); with own listed controller and configured for 10-second start-transfer. See exception, paragraph 11-4.1.3.

c. Food service refrigeration, morgue refrigeration, pharmacy, laboratory, research, and other locations as determined by risk analysis of the DoD Project Sponsor.

d. Essential power for auxiliaries and controls to provide safe operation of the heating plant.

e. Medical vacuum, waste anesthesia evacuation, and medical air system.

f. Dental vacuum, dental air, and waste anesthesia gas disposal serving Category 2 spaces for oral surgery and comprehensive treatment as determined by the DoD Project Sponsor and NFPA 99 risk assessment.

g. HVAC systems, including cooling and heating equipment and controls for all critical care areas per Chapter 10.

h. Domestic water, sump, and sewage equipment necessary for continuous hospital operations.

i. Special purpose exhaust systems, hoods in laboratories including radioisotope hoods, and isolation room exhaust fans.

j. The pneumatic tube system (PTS).

k. Helipad lighting and visual navigational aids. Note: If night/twilight operations are required, provide 15 minutes of battery backup to obtain no-break system and connect as a Priority 2 load. Where helipad operations are essential, provide a Priority 1 non-sheddable equipment connection.

11-4.15 Alternate Source Testing.

Test alternate power source essential electrical systems for proper operation before final acceptance, as required by NFPA 99 and 110. Prior to testing, make all connected loads operational and operate within normal demand load tolerances. Design alternate power systems to facilitate periodic system-wide and component testing and inspection.

11-5 INTERIOR ELECTRICAL SYSTEMS.

Conform to NFPA codes, except where technical criteria from UFC 3-520-01 and this document are more stringent. Use only copper conductors. Use only copper bus in switchgear, switchboards, panelboards, and for grounding points.

11-5.1 System Voltage.

Systems with 480Y/277 V, 460 V, 208Y/120 V, 240 V, and 120 V low voltages, and 4.16 kV and 6.9 kV medium voltages are common utilization voltages found at military installations. However, 480Y/277 V and 208Y/120 V are the standard utilization voltages for new and existing medical facilities. Only chillers may be served by medium voltage, and when so, provide separate generators to supply them that are not part of the essential electrical system.

11-5.2 Interior Distribution.

11-5.2.1 Utilization Voltage.

Serve interior lighting and power loads at the highest voltage practicable. Supply fluorescent and high intensity discharge (HID) lighting systems and building power loads by a 480Y/277 V system. Use dry-type transformers to furnish 208Y/120 V power for receptacles and small equipment loads. Provide a 208Y/120 V system where the use of higher voltage is not cost effective.

11-5.2.2 Transformers.

Provide dry-type transformers in accordance with UFC 3-520-01 and TSEWG TP-5, using de-rating or harmonic mitigating transformers for non-linear loads. Analyze non-linear loads in each building area using Table 11-2 Sample Nonlinear Load Analysis Matrix. Where transformer-type voltage regulators are used to maintain nominal voltage within plus or minus 5% (see paragraph 11-1.2.7), use an automatic step or induction

transformer regulator with adjustable high and low-voltage limit controls and a voltage meter.

11-5.2.3 Switchgear, Switchboards, and Panelboards.

In this chapter switchgear, switchboards, and panelboards conform to definitions in NFPA 70. Switchgear below 1000 V is metal enclosed and above 1000 V metal clad per IEEE C37.20 series of standards. **\1**

11-5.2.3.1 General.

Provide solid-state, adjustable trip circuit breakers as required to meet the overcurrent protection coordination requirements of paragraph 11-5.3. Provide ground fault protection, including ground fault protection of the essential electrical system, in accordance with NFPA 70 and NFPA 99.

11-5.2.3.2 Draw-out.

Provide draw-out breakers in hospitals, ambulatory surgery centers, and 24/7 patient care facilities for unit substations, service entrance equipment, equipment with buss work 2000 A or greater, and the essential electrical system down to the first level below an ATS. An exception is the first level below an ATS supplying motor control centers or panel boards 600 A or less. Provide draw-out breakers similarly in other facilities in which buss work is 2000 A or more. **/1/**

11-5.2.4 Power to Fire Alarm Fire Detection Mass Notification.

In lieu of providing dedicated distribution panel(s) to supply the fire alarm detection mass notification system as required by UFC 3-520-01; provide dedicated circuits from life safety branch panels and comply with the power supply requirements of NFPA 72. Follow UFC 3-520-01 if no essential electrical system is available.

11-5.2.5 Power to Telecommunication Spaces.

\1 UFC 3-580-01 requires a dedicated distribution panel in each TR. In an MTF that has an essential electrical system, a TR my require circuits from multiple panels, but space is limited to one panel only. If the building has a Type 1 essential electrical system, provide a critical branch panel in the TR. If the building has a Type 2 essential electrical system, provide an equipment branch panel in the TR. Serve the remaining loads in the TR with dedicated circuits from the normal panel or other essential electrical panels in the electrical room in accordance with Table 12-1 power branch assignments. **/1/** Follow UFC 3-580-01 if no essential electrical system is available.

11-5.3 Short Circuit, Selective Coordination, and Arc Flash.

Conduct short-circuit, protective devices coordination, and arc flash studies in accordance with UFC 3-501-01 and NFPA 99. Conduct the studies in the design stage and again in the construction stage with the actual equipment installed. Provide protective devices settings within the studies. Base the selection of protective devices and equipment for a new electrical system on the study analysis. For additions or modifications to an existing system, include all the protective devices affected in the

existing system in the analysis. Coordinate all protective devices for **\1** the period of time that a fault's duration extends beyond 0.1 second. **/1/** Series rated protective equipment or devices is not allowed. Incorporate transient/surge protection in the selective coordination analysis.

11-5.4 Electrical Rooms.

11-5.4.1 Main Electrical Rooms.

Main electrical rooms include service points, rooms with generators or other large equipment assemblies such as substations and feeder panels; in which direct access is required for initial installation, for removal and replacement, for maintenance, or for ease of access by maintenance staff. Provide main electrical rooms with direct exterior access to a vehicular pathway and loading point. Provide main electrical rooms additionally with access from the facility's interior if any of the following apply:

a. The facility is 24/7.

b. The electrical service is 1,200 A or more.

11-5.4.2 Branch Electrical Rooms.

Branch electrical rooms include electrical closets and related distribution. Provide a minimum of one branch electrical room for each smoke compartment. Provide a minimum of one branch electrical room for each 22,500 ft^2 (2,090 m^2). Do not feed loads beyond the smoke compartment in which the branch electrical room is located. Do not exceed three percent voltage drop on branch circuits. Do not oversize branch circuits such that junction box jumpers are required.

11-5.4.3 Location and Layout Considerations.

Consider the following impacts for electrical room location and layout:

a. Provide access off of a primary through corridor. Swing entry door(s) out 180 degrees, so as not to impede traffic flow in the corridor or violate clearance requirements of NFPA 70 within the room.

b. Consider relative location to mechanical rooms, in order to minimize above ceiling congestion of raceway, cable trays, ducting, and piping. Pipes and other equipment foreign to electrical equipment are not permitted to be located in, enter, or pass through electrical rooms or spaces.

c. Do not locate electrical rooms adjacent to TRs.

d. Locate electrical rooms to minimize runs, but not interfere with patient care areas. Locate panelboards in critical care areas in the vicinity of their loads. Provide access to operating staff only.

e. Do not locate electrical rooms adjacent to spaces having stringent noise control requirements. Locate dry-type transformers and automatic transformer type regulators away from noise-sensitive areas.

f. Provide adequate ventilation to maintain an ambient temperature not to exceed 86 ^{o}F (30 ^{o}C).

g. For facilities with more than one floor, stack electrical rooms vertically.

h. Provide sufficiency of space to enable access for operation and maintenance, or equipment replacement. Show the footprint for each piece of equipment with working space and NFPA 70 clearance requirements on the drawings submitted.

i. **\1** Locate electrical panels in electrical rooms in new construction. There are two exceptions. First, TRs, due to special circuiting requirements, follow paragraph 11-5.2.5. Second, **/1/** limited dedicated panels provided in the room served such as X-ray, server, mechanical, and operating rooms; where all of the following apply:

- Ready access to the panel is required by the room function or the room equipment is subject to frequent change.
- All branch circuits in that panel serve that specific room only and the room provides access to only qualified individuals.

11-5.4.4 Flood Proofing of Electrical Rooms.

Base flood elevation (BFE) and design flood elevation (DFE) are defined in ASCE 24. The former is one percent chance of occurrence in any given year; latter is the datum specified on community flood hazard map. Electrical rooms should be above grade for access and reliability of equipment; though may be located below grade, provided the location naturally drains above the DFE and flood resistant construction is provided below DFE in accordance with International Building Code (IBC) Section 1612 and ASCE 24. DFE is to be no less than two feet above BFE, except where higher elevation is required by ASCE 24. For the intent of this paragraph, natural drainage is defined as not dependent upon a sewer line, which may back up; and where impractical to provide natural drainage, slope floors to sumps affixed with alternating duplex pumps on essential power and elevate equipment on pads 8 inches above floor level. Provide a hoist shaft for equipment removal and a stairwell for direct access for main equipment rooms located below grade. Provide anti-desiccant strip heaters in electrical equipment located below grade. Protect exterior openings from in-flow, such as stairwell, hoist shaft, drive, or loading dock. Provide sump pump capacity to meet predicted precipitation events. Provide seals in raceway exiting the building 5-foot line designed for the number and size of cables enclosed.

11-5.5 Isolation Power System.

Provide an isolation power system in Category 1 spaces designated wet procedure locations (see paragraph 11-2.3). Provide each operating room with a minimum of two

single-phase panelboards. Connect isolation power panels to the same phase. Locate isolation power panels and the line isolation monitor in the room served. Do not use ground fault circuit interrupters (GFCI)'s. Design isolation power system in accordance with NFPA 70 and 99. Provide grounding in accordance with paragraph 11-5.11.

11-5.6 Conduit, Cable Tray, and Wire.

In this chapter, conduit and raceway conform to definitions in NFPA 70. Provide insulated copper conductors in metallic raceways installed in accordance with NFPA 70 and UFC 3-520-01 except as noted below. Run a green insulated copper ground conductor with all feeders and branch circuits. Provide an independent neutral in addition to the separate green insulated grounding conductor in all single-phase circuits. In new construction, provide uniformly sized branch circuits from the branch circuit breaker to point of utilization; do not upsize conductors where a junction box and jumpers are required to make the final connection. The use of metal-clad and armored cable is prohibited inside the facility, except where integral to listed assemblies. PVC conduit may only be used below slab on grade in accordance with NFPA 70 and applicable UFCs, in which grade transitions are required to be metallic. Additional requirements are as follows:

a. Serve each electrical room on each floor of multi-story facilities by separate or independent feeder risers of insulated copper conductor in steel conduit. Locate the equipment serving the risers in these facilities in ATS rooms for the essential electrical system and the main electrical rooms for the normal power system.

b. Use only steel compression fittings with electrical metallic tubing (EMT). Do not use die-cast fittings.

c. Do not install conductors to furnish emergency power in the same raceway with normal power conductors.

d. Install all normal and emergency power junction boxes, pull boxes, and similar parts in order to be readily accessible. Install clearly identified access panels as necessary for proper maintenance and operation of the electrical distribution system.

e. Install low voltage control wiring, typically used for lighting and receptacle control, in non-flexible metallic raceway or cable tray separate from telecommunications cable tray.

f. Terminate horizontal telecommunication raceway at the cable tray with a fitting specially designed to clamp the raceway to the tray (for solid type tray) or a specially designed clamp to bond the raceway to the tray (for welded wire type tray).

g. Bond TR ground bars in accordance with TIA-607 with ground conductors placed in raceway.

11-5.7 Branch Circuits.

Provide circuits for patient care areas in compliance with NFPA 70 and NFPA 99, except where applicable criteria require more stringent standards.

11-5.8 Radiology Provisions.

11-5.8.1 X-Ray Rooms.

Supply radiological equipment by a 3-phase, 5-wire neutral and ground 480Y/277 V feeder from the main distribution switchboard to an enclosed circuit breaker disconnect located adjacent to the associated X-ray control room. Do not include X-ray loads in the demand load. Evaluate effect of X-ray unit momentary kVA load on transformer voltage regulation. Increase transformer size as necessary and size feeders for satisfactory system performance. Do not provide separate service transformers to the X-ray units. Provide a single-phase 120/208 V branch circuit panelboard in each room for X-ray unit peripheral equipment. Additional requirements for Universal X-ray rooms are contained within Appendix D.

11-5.8.2 Mobile X-Ray Unit Outlets.

Mobile X-ray equipment in nursing units are normally battery operated. Provide duplex receptacles rated 20 A, 125 V for battery recharging in designated areas and connect to the equipment branch of the essential electrical system. Receptacles.

\1 In this chapter, receptacles conform to definitions in NFPA 70. A receptacle is a single contact device unless stated otherwise. ***/1/*** Provide specification grade receptacles, heavy duty, normally straight blade type, rated 20 A, 125 V, 2-pole, 3-wire, grounded type. Provide no less than 20 A rating for all other receptacles including those dedicated to medical equipment. Provide 20 A rated general purpose multi outlet branch circuits to serve receptacles. Do not place more than four duplex receptacles on a circuit serving desk locations (work stations) and provide a non-shared neutral. Do not place more than six duplex receptacles on a circuit in other locations, including patient care spaces, and more stringent requirements follow in the paragraphs below. Where a power receptacle is incorporated in the same metal box with a television or data outlet, provide a partitioned metal box with separate power and signal conduits as required. Offset outlets in adjoining room walls to isolate airborne sound as specified in Appendix B and as required by the Fire and Smoke Protection Features chapter of the IBC. Coordinate special purpose receptacles with the equipment to be provided.

11-5.8.3 General Purpose Receptacles.

Provide a minimum of one duplex receptacle per wall in each room or interior area, except as noted below. Do not exceed 12 ft (3.6 m) spacing. In rooms where partitions exceed 10 ft (3.0 m) in length, provide an additional duplex for each additional 10 ft (3.0 m) feet of wall space or fraction thereof. Provide minimum of one duplex within 12 in. (300 mm) of each telecommunication outlet. Provide two duplexes at each desk location (work station), including future desk locations in offices which have a second

telecommunication outlet. Provide six duplex in offices; except provide eight duplex in offices with a plumbing connection box (for future conversion to an examination room). Provide one duplex every 3 ft (900 mm) of casework in nurse stations, nurse substations, reception counters, and control counters. Provide one duplex every 50 ft (15 m) in corridor walls. In alcoves fronting corridors in which equipment may be located, provide duplex receptacles in addition to corridor receptacles, so no point on the wall is more than 3 ft (900 mm) from a receptacle. Provide one duplex within 25 ft (7.5 m) of installed equipment requiring maintenance. Do not provide receptacles in public toilets, staff toilets outside of command areas, closets, janitor closets, and scrub rooms. Do not use floor receptacles where the wiring device extends above the floor. Provide general purpose receptacles in addition to special purpose and dedicated outlets for special equipment. See DoD Project Sponsor to identify receptacles in special areas.

11-5.8.4 Hospital-Grade Receptacles.

Provide hospital-grade receptacles where required by NFPA 70, including all Category 1 and 2 locations, and any location with either a patient bed or patient service console.

11-5.8.5 Telecommunication Rooms.

\1 Provide TRs with receptacles as described in Chapter 12 and at least one duplex receptacle on each wall. **/1/**

11-5.8.6 Tamper-resistant Receptacles.

Provide tamper-resistant receptacles in locations required by NFPA 70 and 99 and as follows. Provide tamper-resistant receptacles in all areas where children may be present to include corridors, waiting areas, and examination rooms. In pediatrics, also provide tamper-resistant receptacles in patient rooms, bathrooms, playrooms, and activity rooms. In behavioral health, provide tamper-resistant receptacles in accordance with Appendix A. Use receptacles designed to prevent shock hazards from metallic objects that might be inserted into the receptacle slots; do not use tamper-resistant receptacle covers.

11-5.8.7 Ground Fault Circuit Interrupters.

Provide Class A, GFCI receptacle protection in wet locations and where required by NFPA 70. See paragraph 11-2 for definition of wet locations and wet procedure locations. Do not provide GFCI on circuits serving critical life support equipment where interruption of power could cause injury or death, for example, wet procedure locations in operating rooms. GFCI breakers are not permitted, except as noted. Provide a dedicated Class A, GFCI circuit breaker and circuit for each behavior health in-patient room in which receptacles are located controlled by a single switch outside the room under staff control. Wet locations include the following:

- Hydrotherapy

- Therapeutic pool areas
- Patient toilet areas with or without showers
- Staff lockers with toilet or shower areas
- Staff lounge with kitchen facilities
- Outdoor receptacles
- Other locations required by NFPA 99 and NFPA 70
- Receptacles accessible from a building roof
- Crawl spaces
- Emergency Shower/Emergency Eyewash

11-5.8.8 Patient Bedrooms.

Provide critical care patient bed locations (patient headwalls) with a minimum of 14 duplex receptacles. Provide general care patient bed locations (patient headwall) with a minimum of eight duplex receptacles. Do not place more than two duplex receptacles on a separate 20 A, 125 V circuit in critical care patient bed locations.

11-5.8.9 Renal Dialysis Units.

Within renal dialysis units, provide four hospital-grade duplex receptacles on each side of the patient bed or lounge chair. Provide normal and critical branch power.

11-5.8.10 Nurseries.

Provide each intensive care nursery with 16 simplex receptacles. Provide each intermediate care nursery with eight simplex receptacles. Provide each nursery in admission, observation, and continuing care with four simplex receptacles. Provide each normal care nursery with one simplex receptacle. Provide 20 A, 125 V, 2-pole, 3-wire, straight blade, grounded type receptacles. Do not use floor-mounted receptacles. Ceiling-mounted receptacles or groups of receptacles should be considered for nursery locations not adjacent to a wall or column. Provide a minimum of one flush-mounted receptacle for mobile fluoroscopy units in each nursery, with these characteristics: 60 A, 250 V, 2-pole, 3-wire, twist lock, grounded type.

11-5.8.11 Operating Rooms.

\1 Provide not less than six duplex receptacles on each wall mounted three feet above the floor. Provide each service column with not less than 12 simplex or six duplex receptacles. Do not place more than four (simplex) wall receptacles on a 20 A, 125 V circuit. Do not place more than two (simplex) service column receptacles on a 20 A,

125 V circuit. **/1/** Provide switch class rated circuit breakers and 20 A, 125 V, 2-pole, 3-wire, straight blade, grounded type receptacles. Provide one 60 A, 250 V, 2-pole, 3-wire, twist lock, grounded-type, flush-mounted receptacle in each operating room for a mobile fluoroscopy unit or laser photo coagulator. Arrange the 20 A, 125 V duplex wall receptacles such that adjacent receptacles are served from a different isolation power panel and equally divide the patient service column receptacles circuits between isolation power panels.

11-5.8.12 Laboratory Receptacles.

Laboratory benches are supplied as casework or furniture, fixtures, and equipment (FF&E) depending upon programming and the project design. See FF&E in Chapter 15. For casework benches, provide strip mounted duplex receptacles 18 in. (450 mm) or less on center and connect adjacent receptacles to different circuits. For FF&E benches with prefabricated wiring, estimate load and determine connection requirements. Provide raceway and wiring with the required number of circuits to a connection point adjacent to the FF&E bench, to enable the IO&T contractor to complete the connection.

11-5.8.13 Examination and Treatment.

Provide examination and treatment rooms with no less than eight duplex receptacles.

11-5.8.14 Automatic Receptacle Control.

Provide automatic receptacle control in accordance with ASHRAE 90.1 for offices, conference rooms, reproduction rooms, break rooms, classrooms, and individual work stations. Do not provide automatic control in any area which may endanger the health, safety, or security of patients, staff, or visitors; such as examination, diagnosis, treatment, laboratory, nurse stations, patient care, emergency department, or utility. Provide split circuit type (half-controlled) receptacles. Provide a hard wired system that does not use flexible cords.

11-5.9 Receptacle Identification.

Identify receptacles connected to the life safety, critical, and equipment branches with red bodies to identify essential power and mark the device plate “EMERGENCY”. Also identify the panelboard and circuit number on the device plate for all receptacles, both normal and essential. Mark device plates with steel stamped or silk-screened letters, by laminated plastic nameplates with contrasting color center core, or by embossed aluminum or stainless steel tape. Provide letters not less than ¼ in. (6 mm) high. Do not use pressure sensitive or thermal tapes. In behavioral health, pediatrics, and other areas where it is necessary to protect against the label being removed and ingested, use silk screened letters.

11-5.10 Patient Care Grounding.

Provide a grounding system in general care areas and critical care areas, including all anesthetizing locations, as required by NFPA 99 and NFPA 70. Include grounding system design and initial testing in the contract documents.

11-5.11 Inhalation Anesthetizing Location.

Flammable anesthetics are no longer used in the United States, but if their use is re-instituted an isolation power system would be required in these locations in accordance with NFPA 70 (see paragraph 11-5.5).

11-5.12 Electromagnetic Shielding for Medical Instrumentation.

Designated areas of hospitals and health research laboratories may require electromagnetically shielded enclosures. Base the degree of the attenuation required for the enclosure on the manufacturer's recommendation for the instrumentation to be used in the designated space. Specify the type of enclosure and the class of attenuation in the final design. When shielded enclosures are not provided, take other measures to limit RFI and EMI in rooms that contain sensitive medical equipment, for example, electroencephalography (EEG), eye LASIK/PRK, and electron microscope rooms. For example, select lighting in which the ballast does not emit electromagnetic radiation. Do not locate such rooms near or directly above or below electrical equipment or mechanical rooms. Do not route high-voltage feeders in the vicinity of these rooms.

11-6 LIGHTING.

11-6.1 Design.

11-6.1.1 General.

Design lighting in accordance with Appendix B, Illuminating Engineering Society (IES) Lighting Handbook, and IES RP-29. This UFC governs where conflicts exist. Do not use electronic ballasts and drivers in the facility which generate electromagnetic fields or radio frequencies that interfere with life support equipment or patient implant life support devices (for example, pacemakers, heart monitors). Provide electronic ballasts and drivers in the facility which are electromagnetically compatible with the operating environment. Do not use ballast or drivers with inverters which operate in the 20-25 kHz, 32-39 kHz, and above 60 kHz range because of interference. For the intent of this section, lighting is designated general illumination and task illumination. General and task illumination are generally in-ceiling mounted and maintained illumination levels meet criteria specified in Appendix B within plus or minus 10%.

Task illumination is also provided by FF&E lighting equipment, but the illumination from this equipment does not contribute to the levels specified in Appendix B. This lighting equipment is identified in the PRC, see Chapter 15, and is characterized by being either moveable (adjustable arm or focus) or is part of the equipment (integral to or an

accessory). For example, ceiling mounted surgical task lights, floor (wheeled) surgical task lights, and under shelf work station lights.

11-6.1.2 Control.

Provide lighting controls in accordance with Appendix B and UFC 3-530-01 subject to the functional and operational intent of the facility. Do not provide automatic control in a manner which could endanger the health, safety, or security of patients, visitors, or staff. Do not use time-scheduled controls in patient care or utility spaces. Provide override devices where automatic controls are installed. Where occupancy/vacancy controls are used, provide dual technology type. Do not use occupancy/vacancy controls in treatment or utility rooms, as turning lights off in these areas could create a safety hazard. Where day lighting strategies are employed for energy conservation, accomplish de-lighting with automatic lighting controls utilizing photo sensors to provide continuous dimming of the electric lighting system. Do not use de-lighting in patient care rooms and areas. Where Appendix B lighting controls result in general illumination levels which exceed the allowable lighting power density, provide individual control of lamps/arrays within fixtures, to split illumination into an allowable general level and a separate task level, to meet applicable exemptions.

11-6.1.3 Sources.

Provide fluorescent or light emitting diode (LED) lighting to the maximum amount practicable. Do not mix sources; use either all fluorescent or all LED luminaires within a project. An exception is allowed to mix sources for violet fraction, as described in paragraph 11-6.6, and also for low level luminaires which have a negligible contribution to overall illumination and color variation, such as exit sign, information sign, step, night, FF&E task, and accent lighting. For exterior lighting see paragraph 11-6.9. Provide recessed luminaires in rooms with lay-in acoustical tile ceilings and recessed or surface-mounted luminaires in rooms with gypsum board on plaster ceilings, except where other types are required by the functional design. Generally, use industrial type or open strip type luminaires in rooms with unfinished ceilings and protect each from breakage. Mount luminaires in large storage and supply rooms to readily permit relocation within **\1** 6 ft (1.8 m).**/1/** In locations subject to occasional wet or damp conditions, such as near emergency showers, provide requisite listing. Tandem wiring, where ballasts or drivers in one luminaire supply lamps or arrays in another, is not permitted. In unconditioned buildings or spaces, specify a luminaire that has been UL listed for 140 ^{o}F (60 ^{o}C) or above. Use of HID lamps in patient care areas is not permitted. “U” shaped fluorescent lamps are not permitted. Tubular LED (TLED) lamps are not permitted. Base the fluorescent lighting system baseline energy efficiency on the use of 28-watt T5 and 32-watt T8 lamps. Provide LED luminaires with a 5-year warranty by the manufacturer. Minimize types of luminaires and lighting sources as far as practical to simplify operation and maintenance.

11-6.1.4 Color.

The same color requirements apply to fluorescent and LED sources. Provide 4000K correlated color temperature (CCT) throughout the facility. This single CCT is used to maintain consistency and to coordinate with task lighting provided as FF&E.

11-6.1.4.1 Chromaticity.

Provide chromaticity of lighting products to fall within an ANSI C78.377 4-step quadrangle centered at 4000K. Chromaticity for different units in the production is required to be enclosed by a 3-step MacAdam ellipse. Compliance is to be verified by the manufacturer or an independent photometric testing laboratory with a minimum test size of 10 units and warrantied by the manufacturer. The chromaticity of every unit in the test sample is required to be contained in the ANSI 4-step quadrangle. The entirety of the MacAdam ellipse, centered at the mean chromaticity of the samples, need not be fully contained in the 4-step quadrangle. For all units in the test sample, change in chromaticity from the zero-hour measurement to the 6000 measurement hours is required to be within a total linear distance of 0.003 on the International Commission on illumination (CIE) 1976 Uniform Chromaticity Scale (UCS) (u', v') chromaticity diagram. All interior lighting products are to comply with the following performance criteria, which are based on IES TM-30. The light source spectral power distribution (SPD) and the IES TM-30 color vector graphic are required submittals.

a. Fidelity Index: Rf ≥ 80,

b. Relative Gamut Index: 97 ≤ Rg ≤ 110,

c. Fidelity Index, Hue-Bin 1: Rf,h1 ≥ 78,

d. Chroma Shift, Hue-Bin 1: -9% ≤ Rcs,h1 ≤ +9%.

11-6.1.4.2 Violet Fraction.

In areas defined in Appendix B and as described in paragraph 11-6.6, where color matching is a critical function, provide the violet fraction for LED general lighting products between four and six percent. Violet fraction is computed as the optical radiation from 360 to 430 nm divided by the optical radiation from 360 to 830 nm. This criterion is in addition to the criteria for chromaticity, CCT, color shift, and color rendition.

$$\text{Violet fraction } (\%) = \frac{\text{Optical radiation from 360 to 430 nm}}{\text{Optical radiation from 360 to 830 nm}} \text{ x } 100$$

11-6.1.4.3 Exceptions.

The following exceptions are allowed during the transitional period for industry to adapt, produce, and document a variety of products meeting the TM-30 metrics. Exceptions only apply if products from three manufacturers are not readily available meeting TM-30 metrics. The TM-30 metrics are fidelity index, gamut index, hue-bin one fidelity, and

hue-bin one chroma shift; plus violet fraction. All other lighting requirements specified herein must also be met.

a. Exception No. 1, Decorative Lighting: Decorative lighting, as defined in ASHRAE 90.1, is not required to meet the gamut index and hue-bin one metrics; but is required to meet the fidelity index. If fidelity index products are unavailable; color rendering index (CRI) 80 or greater will be considered an acceptable alternative.

b. Exception No. 2, Unusual Location: Architectural focal points and utility spaces are not required to meet the gamut index and hue-bin one metrics; but are required to meet the fidelity index. If fidelity index products are unavailable; CRI 80 or greater will be considered an acceptable alternative. Architectural focal points are defined as entry and atrium (but not to include patient waiting). Utility spaces are mechanical and electrical rooms, elevator pits, tunnels, etc.

c. Exception No. 3, LED Luminaires: If TM-30 metric products are unavailable, CRI 90 or greater LED luminaires will be considered an acceptable alternative to the fidelity index, gamut index, and hue-bin one metrics.

d. Exception No. 4, Fluorescent Lamps: If TM-30 metric products are unavailable, CRI 85 or greater lamps will be considered an acceptable alternative to the fidelity index, gamut index, hue-bin one metrics, color consistency, and color shift; except provide CRI 90 lamps where indicated in Appendix B.

e. Exception No. 5, Violet Fraction: If LED luminaires are unavailable to meet violet fraction, CRI 90 or greater will be considered an acceptable alternative.

11-6.1.4.4 Submittals.

Confirm the list of factors in Annex D Luminaire Design Review Checklist, through catalog cuts or manufacturer letters, in both the design and construction phases. Annex D is not all inclusive and is intended to be used in conjunction with the UFGS. TM-30 submittal data will not be required for the metric for which an exception above applies.

11-6.1.4.5 UFGS Coordination.

Modify the UFGS to accommodate the minimum requirements contained herein. After the transitional period the UFGS and other criterion will be updated.

11-6.1.5 Glare.

Provide indirect LED lighting or utilize a refractor to eliminate glare. Shield LED light sources in the luminaires with physical separation or refractors to avoid a direct view of light sources and the resultant glare. Avoid placing non-exam lighting directly over a location where a patient lying supine or angled in a bed or gurney will be. Consider

illuminance of the point source in LED lighting designs, in relationship to the ambient background, and eliminate glare though higher mounting heights or using more luminaires at lower lumens. Do not locate luminaires utilizing T5HO lamps below 8 ft 6 in. (2.6 m) unless specifically designed to control brightness.

11-6.1.6 Uniformity.

Design illumination to meet IES uniformity. For rooms in which the furniture or equipment layout is changeable, for example office and examination rooms, include the entire room in the task area. In rooms with ceiling curtains or other partitions, for example examination rooms, meet uniformity within the entire room with curtain or partition closed.

11-6.1.7 Flicker.

Provide LED fixtures in compliance with IEEE 1789. Limit the maximum percent flicker to less than or equal to the flicker frequency x 0.08. For dimmable LED products, comply at full output and throughout the dimming range.

11-6.1.8 Nameplates.

Identify luminaire driver/array/lamp replacement by an appropriate marking on the fixture reflector. Marking should indicate replacement with the original equipment by name only and should not be visible through the fixture lens.

11-6.1.9 Life.

Provide LED luminaires with a minimum L70 lumen maintenance value of 60,000 hours.

11-6.1.10 Illumination of means of egress.

Provide illumination of means of egress in both the normal and emergency modes of operation in accordance with NFPA 101. Illuminate egress paths with the minimum NFPA 101 illumination at all times the building is occupied, controlled by a switch class circuit breaker, with higher illumination level(s) motion controlled, as required by UFC 3-530-01. Hallways adjacent to sleeping rooms and nursing stations are an exception; manually switch higher illumination level(s) to avoid disturbances to patients and staff. Provide emergency lighting in all electrical rooms, mechanical rooms, and TRs.

11-6.2 Battery-Operated Lighting.

Provide 25% of the general and task lighting in the operating rooms, emergency treatment rooms, cystoscopy, cardiac catheterization rooms, and any other room with invasive procedures with 1½-hour battery backup for general ceiling-mounted luminaires that provide general or task illumination that operates without interruption during periods of normal and emergency power lapse. Provide not less than 500 lux of maintained illumination measured at floor level in these rooms with luminaires which fully illuminate when on battery backup or UPS. Provide all permanently installed

surgical task luminaires with a minimum of 1½ hours of no-break power to bridge the power interruption due to loss of normal power or essential electrical system failure. Locate batteries for lights in operating rooms outside those rooms. Provide 15% of lighting in nurseries with 1½-hour battery backup. Provide a minimum of two battery-powered lights in each generator set location and emergency switchboard location and central Communications Room. Provide a battery-backup luminaire above each blood draw station unless lighting is connected to essential power.

11-6.3 Patient Bedrooms.

In patient bedrooms, provide one wall-mounted direct or indirect, or ceiling mounted indirect luminaire or a medical wall module system, with lighting features as described herein, at each bed for task (reading) and general illumination. Each wall unit is to provide upward directed light for general illumination and downward light for patient use. Each ceiling unit is to have separate general and patient use illumination. Control general illumination at the door and at the wall unit with a three-way switch. Control patient's use lighting at the bed. Provide quiet-operating switches. Consider use of low-voltage switching utilizing the nurse call handset. Provide night-lights mounted in the patient service console at each bed which are photo cell controlled and manually controlled at the corridor door. Provide an additional task (exam) luminaire located over the patient bed and switched at the patient head wall.

11-6.4 Special Location Requirements.

Comply with the following location requirements:

a. Mounting. Provide recessed luminaires in nurseries, surgery, obstetrical suites, emergency treatment rooms, examination rooms, and laboratories.

b. Nurse stations. Provide selective switching at nurse stations to achieve 33%, 66%, and 100% illumination levels for fluorescent and full range dimming for LED.

c. Supine patients. Provide low-brightness diffused lighting in recovery rooms, coronary and ICUs, and X-ray therapy rooms where patients may be in a supine position for extended periods. Where indirect sources are not feasible or not desirable, locate luminaires outside of direct view of patients.

d. Electroencephalogram. Provide electroencephalogram rooms with dimmable luminaires.

e. Examination. For examination purposes in ICUs, isolation rooms, single patient bedrooms, labor rooms, and recovery, provide an exam luminaire operated by a conveniently located switch above each bed.

f. Behavioral Health. Provide lighting in behavioral health unit in compliance with Appendix A. Provide recessed, anti-ligature, of tamperproof construction, with impact-resistant lenses, for all fixtures including night

lights. Control night lights with a photocell, with a manual switch outside the room.

g. X-ray. Provide X-ray rooms with indirect lighting; in other radiographic procedure rooms, coordinate the location of the room lights with the X-ray equipment. Provide “In-Use” warning lights for universal X-ray rooms and therapeutic X-ray rooms in accordance with Appendix D. Do not provide diagnostic X-ray rooms with “In-Use” lights. Refer to Chapter 15 for more details.

11-6.5 Corridors.

Illuminate wayfinding signage by the corridor lighting system or provide separate fixtures to insure visibility. For corridor lights which are adjacent to intensive care bedrooms and nursing units, provide one-third increment switch controlled for fluorescent and full range dimming for LED.

11-6.6 Dental Clinic.

Arrange ceiling-mounted luminaires symmetrically within all dental treatment rooms and provide full range diming. In oral surgery provide dimmers that default to full intensity and function as an on/off switch in the event a dimmer fails.

11-6.6.1 Violet Fraction.

In areas such as prosthetics laboratory and dental treatment rooms, that involve the visual matching of human teeth to resins, crowns, veneers, or other restorations; provide violet fraction for general illumination as specified in paragraph 11-6.1.4.2. Violet fraction is generically met with fluorescent sources, therefore this requirement only applies to LED sources.

Currently, limited LED products are available which meet the violet fraction requirement. Therefore, if LED lighting is a project requirement, a sole source waiver for LED luminaires in dental areas approved by the Contracting Office in the Geographic District, may be required before commencing design. However, if the waiver is not sought and fluorescent lighting is used in dental areas instead, as an exception, the remainder of the project may still be LED.

11-6.7 Eye LASIK/PRK Rooms.

Provide ceiling-mounted shielded luminaires in eye LASIK/PRK rooms which are fully dimmable and with ballast or driver filters integral to the luminaire assembly. Provide one filter per ballast or driver in the luminaire assembly to suppress/eliminate electromagnetic and radio frequency interference with the LASIK equipment. Provide UPS power for the LASIK equipment and lighting in each room that provides a minimum of 1½-hour of no-break-power in addition to the critical branch of the essential electrical system. Provide an “In-Use” warning light outside each eye LASIK/PRK room.

11-6.8 Exterior Signage.

Provide stencil-faced with red trans illuminated letters exterior signage for "EMERGENCY SERVICES" which is readily visible, identifiable, and legible at all entrance drives. Provide contrast level of illuminated signage which is symmetrical and does not deviate more than plus or minus 5%. Provide trans illuminated letters indicating the facility name in signage for facilities having after-dark operations. Design illuminated signs for rapid replacement (not to exceed 15 minutes). Coordinate sign locations with illumination of access roads, parking areas, and building entrances to minimize requirements for additional illumination of signage.

11-6.9 Exterior Lighting.

Provide exterior lighting in accordance with UFC 3-530-01 and as follows. Provide lighting for the safety of patients, visitors, staff, and for operation and maintenance. Illuminate parking areas and walks, including accessible areas intended for night use, to an average of no less than 10.8 lux , measured on 12 in. (300 mm) intervals of incident light on the area served. Illuminate other areas, including roadways and utility areas, in accordance with the recommendations of IESNA and UFC 3-530-01, following the more stringent requirement. Provide a CCT not less than 3000K or more than 4000K, a CRI not less than 70, and an LED product L70 lumen maintenance life equal to or greater than 50,000 hours. Design lighting to eliminate glare and trespass between site-structure-surround areas; by complying with IES Model Lighting Ordinance (MLO) lighting zones and backlight, uplight, and glare (BUG) ratings; and by complying with ASHRAE 90.1 lighting power density (LPD).

11-6.10 Dimming.

Furnish eye lane, eye examination and eye LASIK/PRK rooms, and group therapy observation room illumination with recessed and full range dimmable luminaires. Locate dimmers for eye lanes and eye examination rooms close to the examination chair and on/off switches at the room entrance. Maximum illumination level in group therapy observation rooms with respect to illumination level in group therapy (mirror) rooms should not exceed manufacturer's recommended ratio for one-way mirrors utilized. For general lighting in fluoroscopic and radiographic special procedures rooms, provide dimming at the control stand or at the door entrance, as required (in the event a dimmer failure, lights are to default to full intensity and the switches function as an on/off switch).

11-6.11 Ultraviolet (UV) Filters.

Provide UV filters for fluorescent lighting in infant care areas to prevent retina damage to premature infants, and other areas where cataracts are a major concern. Provide indirect lighting in premature infant areas for all new construction.

11-6.12 Maintenance Area Lighting.

Illuminate interior utility tunnels and walk-in pipe chases by 10.8 lux of incident light for the safety of maintenance personnel. Provide pilot light equipped switches for these fixtures and locate switches in areas that are normally occupied. Illuminate elevator shafts in accordance with UFC 3-490-06. Locate receptacles for temporary work lights as determined by the Design and Construction Agent.

11-6.13 Auditorium.

Control the down light luminaire over the podium from the podium and the entrance.

11-6.14 Continuity of Service.

Provide spares in the initial procurement to insure color matching for the LED lighting system serving critical care spaces. For each luminaire in a critical care space served from either the essential or emergency branch within a facility, including battery backup luminaires not connected to the branch, provide a 5% stock of replacement matching LED arrays and pre-programmed LED drivers, with a minimum of one per fixture type.

11-6.15 Accessibility.

Provide maintenance access to luminaires by placing them where they can be reached, by the use of lowering devices, or by built-in access provisions such as catwalks or trolleys. Where specialized equipment is used to gain access, provide said equipment with the fixture and provide adjacent built-in storage. Only step ladders may be considered for portable ladders and height is limited to 20 feet by OSHA. Do not consider moveable machinery such as scissor lifts as meeting this requirement.

11-7 HELIPAD LIGHTING, MARKING, AND CONTROLS.

Provide helipad marking, lighting, and controls in accordance with UFC 3-535-01 and UFC 3-535-02. Design facilities for hospital configuration, visual meteorological conditions (VMC), non-instrument, to include those listed in Table 11-3. Provide retro-reflective markings per UFC 3-535-02. Provide capability to control lighting locally at helipad, remotely within facility, and radio controlled by pilot (see Annex A).

Provide a 2-box Chase Helicopter Approach Path Indicator (CHAPI) visual glide slope indicator when needed based on site conditions described in UFC 3-260-01 and UFC 5-535-01. Provide the usual CHAPI glide slope angle of six degrees unless a steeper glide slope is needed to avoid obstacles. If required, provide a waiver request to UFC 3-535-01 to adjust the glide slope angle.

Table 11-3 Medical Helipad Visual Facilities Requirements

Facility	VMC Day Non-Instrument	VMC Night Non-Instrument	Remarks
Perimeter Lights	NA	R	
Wing Lights	NA	R	
Landing Direction Lights	NA	OPT	
Approach Direction Lights	NA	OPT	
Helipad Floodlights	NA	R	
Visual Glide Slope Indicator	OPT	R	
Helipad Beacon	R	R	
Wind Direction Indicator	R	R	Provide obstruction light and illuminate sock
Retro-reflective Marking	R	R	
Local and Remote Control	R	R	
Essential Power	R	R	

Legend: NA = Not-applicable, OPT = Optional, R = required

11-8 LIGHTNING PROTECTION.

Provide lightning protection in accordance with UFC 3-575-01. Provide a risk assessment in accordance with NFPA 780 and provide a lightning protection system if protection is recommended by the assessment. If the system is required, provide it in accordance with NFPA 780, with components meeting UL, and with a UL Lightning Protection Inspection Certificate certified to NFPA 780 upon completion. In order to obtain the UL inspection certificate, A UL listed installer is required in construction phase; therefore, clarify in bid documents and list three Contractors for OCONUS locations. For additions to existing facilities with a lightning protection system, the existing system is required to be recertified before the new portion can be connected to the existing lightning protection system.

Annex A. Hospital Helipad Radio Control Operation

Provide the radio controller in accordance with AC150/5345-49C and function as noted here:

a. The pilot can activate the hospital helipad lighting by keying the microphone from the helicopter after tuning to the assigned frequency.

b. The pilot can key his microphone three times within a 5-second interval and on the third pulse a relay is energized, which turns on the wind indicator illumination, CHAPI, and the perimeter light pattern.

c. The floodlights can be activated by keying the microphone five times.

d. The lights are to remain on until the pilot keys his microphone seven times. This is to activate the turn off time delay relay, which de-energize the lights at the end of the 15 minute delay.

e. When the lights have been activated by the radio controller, the “OFF” function of the remote “ON-OFF” switch in the manual controller, located in the hospital emergency room (ER) is bypassed.

f. The brightness of the CHAPI, floodlights, and perimeter lights can only be controlled from the manual control panel in the ER.

g. If the microphone has been keyed seven times (floodlight turn off signal), the radio controller can be reset by keying the microphone three or five times.

h. The hospital ER is to be equipped with the manual controller and a base radio station capable of manual or radio operations.

Annex B. Multi-Ended Network Substation

1. GENERAL.

The multi-ended network (fully automatic) substation (see Figure 11-2) design philosophy eliminates many switching time delays; simplifies the monitor and control functions; standardized equipment; reduces equipment size; provides expansion capability for future load growth; and maintains reliability, durability, and maintainability. When using the multi-ended network or the double-ended substation to replace an existing substation, all downstream equipment requires short circuit current validation and power system coordination.

2. NORMAL HOSPITAL SOURCE ALTERNATE DESIGN CONFIGURATION.

For electrical design criteria related to power supply, see documents listed in Appendix I. Provide hospitals with two primary service feeders, each connected to one side of the automatic (with alternate manual operator) load break primary selector switch with manual load break BP/ISs that serves a multi-ended network substation. Provide each feeder with the capacity to serve the full hospital demand plus 20% spare load growth. Install each feeder underground within the hospital site. Provide the primary selector switch with BP/ISs with the capacity to serve not less than the sum of the 3-transformer kVA ratings and have load limiting equal to the full hospital demand plus 20% spare load growth. Monitor both primary feeders with an automatic function. If power is lost to the feeder serving the load, transfer the load to the other feeder in not more than 30 Hz (cycles) if power exists on that primary feeder. Connect service feeders to different power sources, if available, and to two differently routed distribution system feeders. Where two power sources are not available, the service feeders may be connected to two different sections of a true loop system.

Transformers should normally be located outside the hospital, but may be located within the building where practicable and economical. Design multi-ended network substation distribution systems for hospitals, medical centers, and specially designated facilities. Size each transformer in the multi-ended network transformer substation to carry 50% of the full hospital demand and spare load (linear and nonlinear) growth capacity. Use identical and impedance matched transformers. Provide all multi-ended network transformer substations with coordinated surge and fault protection and selective system protection. The capacity of the main feeder panel bus is to be not less than the sum of the transformer capacity.

3. AUTOMATIC PRIMARY FEEDER SELECTOR SWITCHES (APFSS).

The APFSS (not to be construed as an ATS) may be double-throw with draw-out construction. The APFSS rating is to be not less than the sum of the three 3-transformer kVA ratings and have adjustable load or fixed limiting control (the loading control may limit the capacity to that of two transformers). Contacts may have viewing ports for ease of contact inspection. Provide indicator lights for the APFSS to identify

which normal primary feeder is connected to the load (green in color). Load transfer to either **\1** of the normal primary feeders **/1/** is to be achieved with not more than 30 Hz (cycles) of load interruption. Provide the APFSS with a load break BP/IS to maintain normal primary service feeder connection for when the APFSS is being repaired or maintained. The BP/IS can be initiated with not more than two movements of the hand to either position regardless of the position or condition of the APFSS. Two vacuum power circuit breakers with load break BP/IS may be used.

4. **TRANSFORMERS.**

a. Each service entrance transformer of the multi-ended substation with fans is sized to carry 40% of the design load as to utilize standard off-the-shelf units and increase transformer efficiency. Each of the three transformers are equipped with forced air-cooling fans to increase the continuous capacity rating of each transformer by 34–50% of the design load when activated. The fans are automatically activated when the load on any transformer exceeds the no fan rating by a temperature indicator and current relay. If the fans are not activated when the temperature indicator or the current relay exceed the manufacturer's setting, provide alarms so load shedding can be initiated. Each transformer is to have the ability to carry a 10% overload for short periods of time without fans.

b. If a service entrance transformer fails, is offline for maintenance, or the normal bus receives no power from any one of the service entrance transformer feeders, automatically activate the fans on the remaining two service entrance transformers to allow 100% of the total hospital load to be assumed. There is no time delay in the load shifting to the remaining two transformers.

c. Where each transformer of the multi-ended network substation is sized for no fan application, size each transformer to carry not less than 50% of the full hospital demand and spare load (linear and nonlinear) growth capacity. Each transformer feeder serving the normal bus is to be equipped with an alarm to indicate power loss from that feeder to the normal bus.

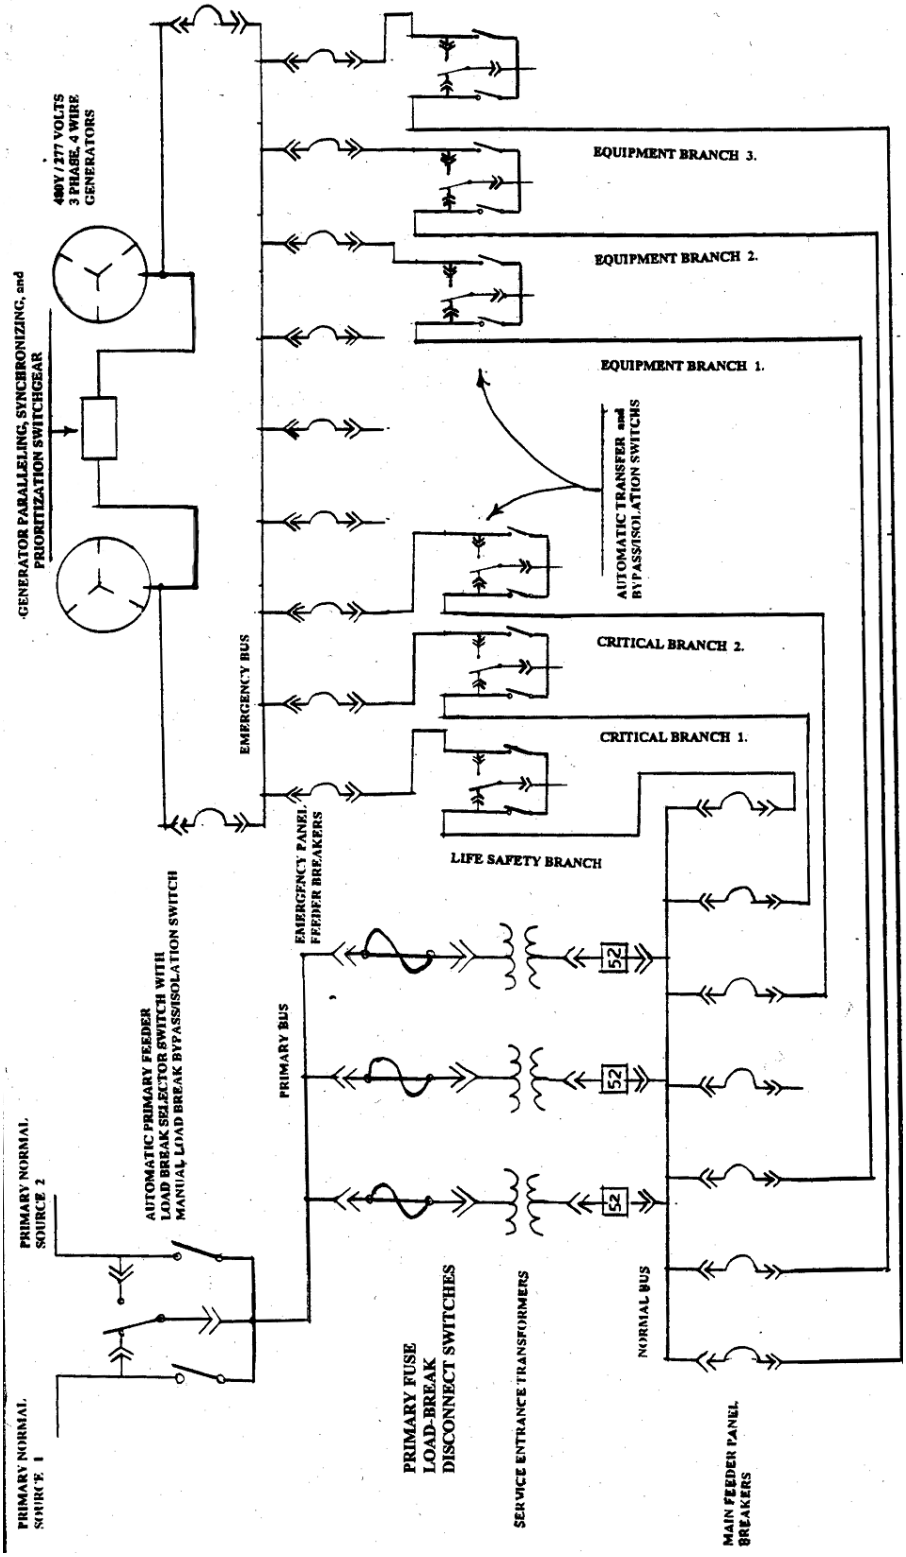
d. Each transformers in the multi-ended network substation is to be identical and impedance matched.

5. **52 DEVICES.**

Size the 52 devices (AC power circuit breaker devices, draw-out type) to support the transformer capacity.

a. Lay out equipment in a manner that allows load center expansion without requiring replacement. New sections can be added to either end of the load center.

b. Size the main load center bus for not less than the sum of the 3-transformer kVA ratings.



6. GROUND FAULT.

Provide ground fault protection for the facility in conformance to the requirements in NFPA 70, NFPA 99, and this document.

7. STANDARDS.

Provide true RMS reading metering and protective relays and devices in compliance with Institute of Electrical and Electronics Engineers (IEEE) standards.

Figure 11-2 Multi-Ended Network Substation System Diagram

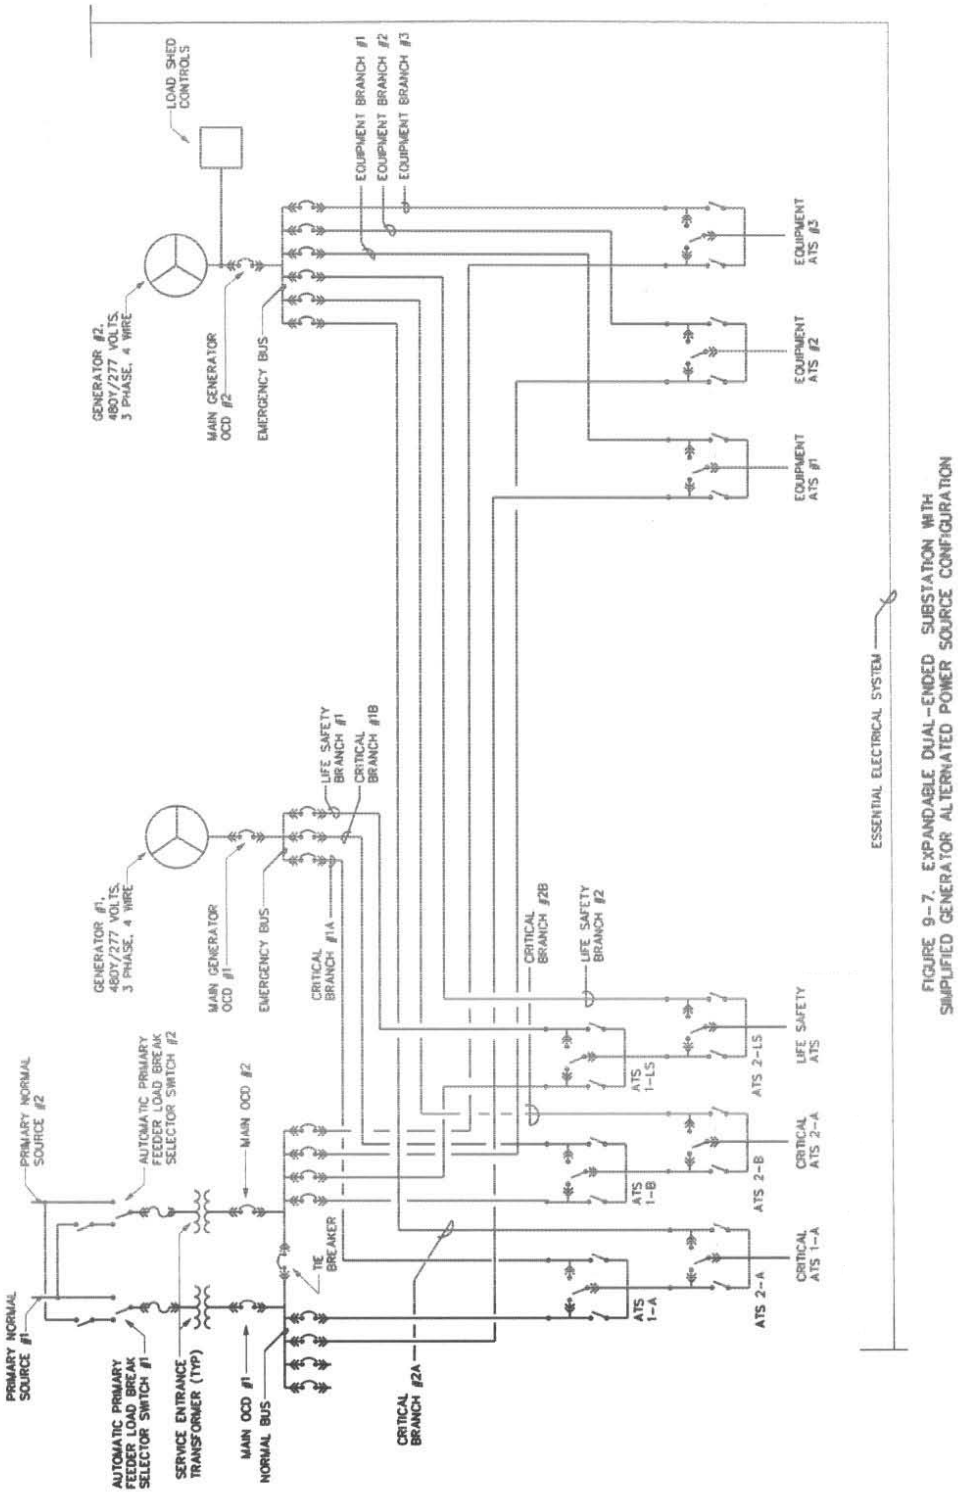
Annex C. Expandable Dual-Ended Substation

See Figure 11-3 and the following requirements:

a. The bus for the substation is sized for the total substation capacity at 100% demand.

b. Generators “1” and “2” do not operate in parallel with each other or the normal power source (utility), but are separate and independent.

c. The normal power side of the ATSs is the default position when power is available and when there is no normal or alternate power available.



d. Generator “1” is sized to support all loads that cannot be shed plus 20% future load growth at 100% demand.

e. Generator “2” is sized to support all sheddable equipment loads of the essential electrical system, non-essential loads plus 20% future load growth at 100%, or the loads addressed in item “4” here, whichever is greater.

f. Load shed controls shed the lowest priority loads (first) on generator “2” when ATS 2-A, 2-B, and 2-LS are transferred to generator “2.” The AC equipment for non-delayed automatic connection are non-sheddable loads.

g. BP/IS is 4-pole, double-throw construction with normal power, open, and emergency power positions.

Figure 11-3 Expandable Dual-Ended Substation

Annex D. Luminaire Design Review Check List

Confirm the factors in Table D-1 Luminaire Factors, as applicable to the design, through catalog cuts or manufacturer letters, in both design and construction phases. This list is not all inclusive and is intended to be used in conjunction with the UFGS.

Table D-1 Luminaire Factors

- Color Consistency: Within a 3-step MacAdam ellipse contained within the ANSI 4-step quadrangle. (Note: May be on cutsheet, otherwise need letter from manufacturer. A 4-step MacAdam ellipse is required in the current specification)
- Color Shift: Du'v' < 0.003 at 6000 hours of operation (Note: Letter from manufacturer)
- Fidelity Index (Rf): ≥ 80 (Note: Likely will eventually be on cutsheet, but currently need letter from manufacturer)
- Gamut Index (Rg): 97≤ Rg ≤110 (Note: Likely will eventually be on cutsheet, but currently need letter from manufacturer)
- Hue-Bin One Fidelity (Rf,h1): > 78 (Note: May eventually be on cutsheet, but currently need letter from manufacturer)
- Hue-Bin One Chroma Shift (Rcs,h1): between -9% and 9% (Note: May eventually be on cutsheet, but currently need letter from manufacturer)
- Violet Fraction: Where white matching is required, provide violet fraction between 4% and 6% (Note: Letter from manufacturer and possible sole source justification, as limited LED products. If LED luminaires are unavailable, use CRI 90 instead.)
- Life: LED Luminaires are to have a minimum L70 lumen maintenance value of 60,000 hours. (Cutsheet – note increase from the L70 of 50,000 hours required in the current specifications)
- CCT of 4000K. (Cutsheet)
- Flicker: Comply with IEEE 1789 (Note: Letter from manufacturer)
- Warranty: 5-year (Note: Cutsheet)

CHAPTER 12 COMMUNICATIONS

12-1 GENERAL.

The planning and engineering of communications systems for applicable facilities must conform to the design criteria contained in this chapter. These facilities use various integrated voice, data, imaging, visual, video information, electronic security, and telemedicine systems to provide quality healthcare. Not all systems listed in this chapter apply to all projects. The DoR must consult with the Design and Construction Agent to establish the systems that are required for each specific project.

12-1.1 Design Criteria.

Communication systems, equipment, and facilities must be designed in conformance with ABA, NFPA 70, NFPA 72, NFPA 99, NFPA 101, Telecommunications Industry Association TIA-568, TIA-569, TIA-606, TIA-607, TIA-758, DHA Technical Requirements-Guidance LAN-WLAN Modernization, DHA Server Room, Computer Room, and Telecommunications Room Design Criteria, and applicable DoD Project Sponsor and DHA standards and criteria. In the event of a conflict with any Standards, this UFC take precedence. This UFC does not take precedence over Code Requirements.

Exception: DoD Project Sponsors other than DHA-FE may have other criteria which should be followed instead of the DHA criteria. However, if DHA-FE will be responsible to operate the facility, follow the DHA criteria.

12-1.2 Approved Product Lists (APLs).

Electronic equipment included with the various systems must utilize, to the greatest extent practicable, equipment listed on the General Services Administration (GSA) APL, Joint Interoperability Testing Committee (JITC) APL and the Defense Information Systems Agency (DISA) Unified Capability (UC) APL. Contractor must review and comply with annual NDAA Guidance on approved products and manufacturers and source restrictions. Facility Related Control System equipment not on an APL and meeting the requirements of an existing Risk Management Framework Authority to Operate may be approved for use by the Design and Construction Agent.

12-2 COMMUNICATIONS SPACES.

12-2.1 Telecommunication Rooms (TRs) (COMC1).

TRs must be located central to the area served and not located on exterior walls. TRs must not share walls with electrical rooms or mechanical spaces. TRs must not have exterior doors. TRs may be combined with Entrance Facilities EF. **\1** Special consideration for TR location must be coordinated with the DoD Project Sponsor for single story facilities less than 10,000 sf (929 sm) and non-healthcare facilities. **/1/** The Communications DoR is to design space requirements and layout of each TR based on the following:

a. **\1** The minimum size of TRs will be the greater of the following: 130 square feet (12 sq m) or 1.1 percent of the area served. The TR serving area must be sized so as to not exceed the maximum cable length in TIA-568.2 and TIA-569.

b. **/1/** Equip the TRs with utility support in accordance with TIA 569, DHA Technical Requirements-Guidance LAN-WLAN Modernization, DHA Server Room, Computer Room, and Telecommunications Room Design Criteria, and Table 12-1 below.

c. Floor space is to be square or rectangular in shape and have no minimum dimension less than 10 ft (3 m) in length. Door must be 180 degree outswing with no window. For Security requirements, see Chapter 5 Antiterrorism (AT) and Physical Security.

d. TRs are to be vertically stacked with a common footprint to route risers from the bottom TR to the top TR without horizontal offsets. Locate slab penetrations along interior of TR walls.

Exception: TR locations are to accommodate the functional layout. **\1** If **/1/** approved by the Design and Construction Agent, and with the concurrence by the DoD Project Sponsor, the requirement for vertical stacking may be relaxed as needed to accommodate clinical functionality.

e. Pipes, plumbing, and other equipment foreign to the TR are not permitted to be located in, enter, or pass through TRs, or be in the walls which enclose the TR.

f. Floor space is to be reserved for Network and Wireless Local Area Network (WLAN) equipment in accordance with TIA 569 and will accommodate the number of WAO and WLAN outlets to be served within the service area of the specific TR.

g. DoR is to account for all additional equipment to be installed within each TR and adjust the floor space requirements to accommodate the additional non-network equipment.

h. DoR is required to maintain a 3 ft (1 m) minimum clearance on the front and rear of all equipment racks. A maximum equipment depth of 30 in. (760 mm) will be planned for two-post TR closet racks. This equates to 3 ft (1 m) clearance in front of the two post rack and a minimum of 5 ft - 6 in. (1.7 m) behind the two post rack. **\1** A minimum of a 3 ft (1 m) clearance at one end of each row is required for unobstructed passage and maintenance. **/1/**

i. TRs are three dimensional spaces and utilize the total volume for equipment and maintenance. In accordance with the above criteria, there must be no plumbing, ductwork, conduits, or other materials within the TR unless they directly support the TR. If ceiling surface is a roof, condensate protection must be provided and installed to the extent required for the protection of room contents.

j. Circuits serving equipment in the Telecommunications Room must be connected in accordance with Table 12-1 below and must be provided to serve each TR for each branch of the electrical systems (normal and essential electrical systems) required for service in each TR. Coordinate electrical requirements with Chapter 11.

k. Electrical services and outlets are to be installed for the Network racks as directed in the DHA Server Room, Computer Room and Telecommunication Room Design Criteria. Power for other equipment must be as required by the network manufacturer. A minimum of two dedicated NEMA L6-30R outlets and four NEMA 5-20R with two receptacles per circuit must be installed for each network rack in the TR. TR network rack receptacles are to be installed overhead.

12-2.2 Communications Radio Equipment Room (COM04).

A separate communications head end equipment room with sufficient space for personnel circulation and equipment maintenance must be provided in inpatient facilities for antenna-based systems such as cable television (CATV), public address and program distribution (PAPD), Emergency Medical Service (EMS), Network Time Synchronization (NTS), Internal Cellular Antenna Systems (IRES), and Radio Page (RP) System. Design the room, including utility support, in accordance with TIA-569. The room must be equipped with weatherproof conduit penetrations to the exterior locations to support the physical interfaces such as coaxial cables and emergency power required by the equipment in accordance with Table 12-1. Pathways must be provided from the 24-hour monitoring location to the headend room to support the EMS radio coaxial or control cables as required for the facility. In addition, the room must be designed as a server room (CMP01) with infrastructure and services as required, to include including fiber and copper cabling and utilities. **\1** Pipes, plumbing, and other equipment foreign to the space are not permitted to be located in, enter, or pass through space, or be in the walls which enclose the space. **/1/**

Systems operating in a client server environment, such as Interactive Television (ITV), Nurse Call and Electronic Security Systems (ESS) must have the server component of the system located in the Server Room (CMP01).

When the design of the facility limits the implementation of a headend room, the equipment associated with these systems must be within the room that is located at the highest elevation available (for example penthouse). Design the room, including utility support, in accordance with TIA-569. The designated room must meet the same design requirements for the head end room. The DoR must coordinate the use of a penthouse to house headend equipment with the DoD Project Sponsor.

Table 12-1 Essential Electrical System Branch Assignment for Communication Systems

Communications Systems	Branch Assignment
Telephone Switching System (TSS)[1]	Life Safety (517.33.D)
PAPD	Life Safety (517.33.D)
Radio Paging (RP)	Life Safety (517.33.D)
Physiological Monitoring (acute areas)	Critical (517.34.A[2], a-d)[5]
EMS Radios	Life Safety (517.33.D)
Local Area Network (LAN) Electronic Equipment at TR[2]	Critical[5]/Life Safety[3] 517.34.A(6)/517.33.D
NTS System	Critical (517.34.A[10])[5]
Nurse Call (NC), including subsystems[4]	Critical (517.34.A[4])[5]
Telephone Rooms and TRs, other than data switch	Critical (517.34.A[6])[5]
Internal Cellular Antenna Systems (IRES)	Life Safety (517.33.D)
Electronic Security	Equipment
Wireless Access	Power over Ethernet (PoE) supplied from LAN electronic equipment in TR
1. When installed within the facility. If installed in separate structure, telephone system must have a properly rated Emergency Power System (EPS) designed in accordance with NFPA 70 Section 700 with the operational characteristics and requirements of the served facility. Provide one quad power outlet near every data outlet in all facilities.	
2. For the purposes of this document, LAN electronic equipment does not include workstations. Workstation requirements are to be addressed on a case by case basis with the DoD Project Sponsor. Provide racks in the appropriate communications spaces to support Telecommunications switches. Media Converters locations for analog devices must be coordinated with the DoD Project Sponsor.	
3. LAN electronic equipment at the TR will be treated as part of the TSS in facilities with Voice over Internet Protocol (VoIP)-based TSS or facilities utilizing telephone instruments that are VoIP PoE and rely on TR primary power for functionality.	
4. Includes infant or patient tracking systems and door access systems interfaced with the NC System.	
\1 5. The branch assignment provided in this table is for an NFPA 99 Type 1 essential electrical system. For a facility without Category 1 space which has an NFPA 99 Type 2 essential electrical system, map critical branch loads to the life safety and equipment branches in accordance with NFPA 70 and 99. **/1/**	

12-2.3 Integrated Monitor and Alarm Room.

A central communication room must be provided in inpatient MTFs and ambulatory care clinics. The central communication room size must be based on the quantity of wall-mounted graphic displays, annunciator displays, and other monitor and control equipment. Install monitors, annunciators, and control equipment in the room for any or all of these systems:

a. Fire detection and alarm system with mass notification controller.

b. Generator monitor and alarm system.

c. Medical gas monitors and alarms.

d. Electronic security operator workstations for security monitoring and control of access control and video surveillance.

e. Public address master microphone and paging zone selector panel.

f. RP console.

g. NC failure alarm and Code Blue and other Code Call Annunciator Stations.

h. Elevator Emergency Phones.

i. Infant Protection Alarm System (IPAS)

\1 Pipes, plumbing, and other equipment foreign to the space are not permitted to be located in, enter, or pass through space, or be in the walls which enclose the space. **/1/**

12-2.4 Refrigerator Monitoring.

Refrigeration alarms for the morgue, pharmaceuticals, vaccines, blood bank, and other mission critical refrigerators must be addressed by the DoD Project Sponsor. DoR must comply with DHA PI 6205.01 for Temperature Sensitive Medical Monitoring Systems, Chapter 11, and Safety Risk Assessment. DoR must provide infrastructure to support the refrigerator Monitoring System.

12-2.5 Server Room (CMP01).

A separate main Information Systems Server room must be provided in accordance with the DHA Server Room, Computer Room and Telecommunications Room Design Criteria. DoR must coordinate with the DoD Project Sponsor and local IT Staff to determine the correct size of the server room based upon its RPIE and PP contents. The room must be sized to accommodate the equipment planned for installation in the space. The designers must provide power distribution, HVAC with temperature and humidity controls, access control, fire detection, alarm, suppression, uninterruptable power supplies (UPSs), and voice and data cables to support the GFGI and CFCI equipment. The Fiber Main Distribution Frame (FMDF) must be located in this room and all fiber backbone cables in the facility must be terminated on the FMDF. Fiber from each Building Distribution Frame (BDF) must also terminate on this frame. Cables must be distributed via racks above the equipment cabinets. For systems physically

located in the building, the server component must be located in the Server Room (CMP01). If the facility does not have a Server Room (CMP01), the DoR will coordinate with the DoD Project Sponsor to identify the parent facility and/or approved location for each systems server component. **\1** Pipes, plumbing, and other equipment foreign to the space are not permitted to be located in, enter, or pass through space, or be in the wall which enclose the space. **/1/**

12-2.6 Service Entrance Facility (EF) (COMC2).

Provide a separate entrance facility (EF). The entrance facility is the space housing the point of entrance of the telecommunications service. It is the demarcation point between the outside plant cabling and the inside plant distribution cabling. Inpatient MTFs and ambulatory surgery centers require two separate EFs with physically separate feed paths in accordance with NFPA 99. **\1** Pipes, plumbing, and other equipment foreign to the EF is not permitted to be located in, enter, or pass through, or be in the walls which enclose the EF. **/1/**

12-3 OUTSIDE PLANT INFRASTRUCTURE AND CABLING.

12-3.1 Outside Plant Purpose.

Provide connectivity to the Installation Wide Area Network (WAN), the Installation telephone system, and other Installation systems via a system of underground ducts and cables.

12-3.2 Outside Plant Duct Work.

All outside plant cabling must be installed in underground ductwork. A system of maintenance holes and or hand holes must be provided at distances and bend radii meeting TIA 758. All buried ducts provided by the project must be encased in concrete from the nearest manhole or hand hole.

Each project must have a minimum of two ducts, each 4 in. (100 mm) in diameter. All of the ducts must be fully populated with inner ducts, except for duct banks with more than one spare duct must provide one spare duct with no inner duct. Fabric mesh inner ducts are acceptable. All unused or inner ducts must be provided with a nonmetallic pull cord.

12-3.3 Outside Plant FO Cable.

Each project must be provided with single-mode fiber optic (FO) cable. The FO cable must connect to the nearest connection point available to the Installation WAN. Provide a minimum of two physically separate pathways for inpatient MTFs and ambulatory surgery centers, each with 48 strands of single mode fiber. The two fiber paths must be connected to two different Installation WAN nodes and be routed into two different service entrance facilities in the project. Provide other projects with a single path consisting of a minimum of 12 strands of single-mode FO cable.

12-3.4 Outside Plant Twisted Pair Copper Cable.

Twisted pair copper cables must be provided when required by the DoD Project Sponsor for telephone, life safety systems, devices inoperable with VoIP technologies and other project-required connectivity to their various Installation systems. The number of twisted pairs must be based on the facility requirement plus 50 percent spare capacity rounded up to the next larger standard cable size.

When twisted pair copper cables are required for inpatient MTFs and ambulatory surgery centers, provide with two diverse, physically independent, and redundant pathways with twisted pair copper connectivity. The two redundant paths must be routed into the entrance facilities.

12-3.5 Outside Plant CATV Cable.

CATV outside plant cables must be coordinated with the CATV provider on the Installation. A single connection to the Installation CATV service from a single service entrance facility must be provided. The CATV cable must be installed underground. It is not a requirement for it to be installed in the underground duct system.

12-4 RMF AUTHORIZATION PROCESS REQUIREMENTS.

All information systems must be assessed for compliance with DoD security requirements and authorized for operation by a designated DHA Authorizing Official (AO). If the system is not owned by DHA, the DoD Project Sponsor's AO must authorize the system. The Risk Management Framework (RMF) process is a standard process under which all DoD information systems must achieve and maintain their Authority to Operate (ATO). Reference UFC 4-010-06 for requirements.

12-4.1 Information Technology Systems.

Information Systems (ISs)/Platform ITs (PITs) and Local Area Networks (LANs) that access, transmit, process, store, and/or display DoD information, regardless of classification or sensitivity, and/or connect to any DoD IS/PIT and/or LAN must be Authorized to Operate. The RMF process is initiated by the DoD Project Sponsor's local Information Technology and Cybersecurity personnel with the information being provided by the system vendor or provider. Medical systems must be authorized according to the manner in which the system will be used by the Medical Treatment Facility. The DoD Project Sponsor will determine the RMF authorization process requirements. The RMF process will require input and possible system modifications by the system's vendor or provider and support from the DoD Project Sponsor. The DoD Project Sponsor's Information Systems Security Manager (ISSM) office is the point of contact for all RMF authorization requirements.

12-4.2 Stand-alone Information Systems.

Information Systems (IS) and Platform Information Technology (PIT) Systems that are disconnected from the rest of the DoD Information Network (DoDIN) or Medical

Community of Interest (Med-COI) must be authorized through the RMF Process. Reference the DHA RMF SIS and CRN AA Guide for Stand-alone Information Systems (SIS) and Closed Restricted Network (CRN) implementations.

12-4.3 MIL-STD 1691.

MIL-STD 1691 provides a reference list of existing systems that must be reviewed for RMF requirements. Information Systems, including Medical Systems, are generally defined as those containing administrative and/or clinical information. Building Control Systems, Medical Systems, and Information Systems typically found in healthcare facilities are identified in **\1** MIL-STND 1691 **/1/** Table 6-1.

12-5 NETWORK TIME SYNCHRONIZATION (NTS) SYSTEM.

12-5.1 Purpose.

Provide a NTS in projects if there are systems that require precise time synchronization and no existing NTS capability is available. Provide an NTS System that receives precise date and time data from a global positioning system (GPS) satellite, or location specific approved alternative, and distribute this data to all Telecommunications Systems in the facility requiring precise date and time synchronization. The DoR must work with the ISSM to identify the NTS system's security requirements, placement within the networks, and configuration to ensure secure operation within the accreditation boundaries of the networks connected. **\1** Provide all interconnecting hardware, software, and cabling to link to the various Telecommunications Systems.

Provide a GPS receiver with built-in sensitive antenna to receive precise data and time from GPS satellite transmission. The GPS receiver must be weatherproof and constructed for indoor or outdoor installation. The GPS receiver must be located to provide unobstructed reception from the GPS satellite. **/1/**

12-5.2 Date and Time Properties.

Date and time synchronization must automatically occur at least once a day. Time synchronization must typically be within +/-0.02 seconds. Date synchronization must include automatic time zone and updating for daylight saving time and leap year.

12-5.3 Electrical Power.

NTS System and equipment must be powered from the essential electrical system emergency power critical branch per Table 12-1. AC-powered equipment must be protected by a UPS unit that must provide at least 15 minutes of full power during an AC power failure. UPS units must comply with UL 1778 and 47 Code of Federal Regulations (CFR) Part 15.

12-6 TELEPHONE SYSTEM CRITERIA.

12-6.1 Type of Service.

The DoR will coordinate with the DoD Project Sponsor and Installation Service provider to determine the appropriate telecommunications solution for the facility. The solution may be a VoIP based telephone system or a hybrid solution of analog and VoIP. The type of service available on the Installation and the project-specific criteria must determine the type of service provided. A mix of the two types of telephone systems may be used in the same facility.

12-6.2 Central Telephone Equipment.

All facilities must receive high reliability service from the Installation Service Provider. All redundancy and reliability requirements of NFPA 99 must be met.

12-6.2.1 Telephone System Features.

The features listed below must be provided with the telephone system. All required hardware and software to provide these features must be included:

a. Call detail recording
b. Automatic diagnostics with local and remote alarms
c. Remote diagnostics
d. Power fail automatic restart
e. Automatic call distribution
f. Voice mail service

12-6.2.2 Emergency Stand Alone Service.

Provide all facilities with the ability to make telephone calls internal to the facility in the event all connections to the Installation are severed. The VoIP service for these facilities must be provided over networks with Assured LAN Services (ASLAN).

12-6.3 Integrated Intercommunication (Intercom) System.

These intercom systems must be completely provided by the telephone system hardware and software with no external equipment and coordinated with the DoD Project Sponsor. These intercom systems must provide communication among department heads, secretaries, and other designated staff members.

Reference paragraph 12-8 for dedicated intercom services.

12-6.4 Patient Bedside Telephones.

Telephones with a dial pad in the handset or the handset integrated into the bedrail must be provided in patient bedrooms. The project DoR must coordinate patient bedroom telephone service with the Installation Service Provider utilizing appropriate telephone instruments compliant with infection control requirements.

12-7 TELECOMMUNICATIONS INFRASTRUCTURE SYSTEM (TIS).

Provide a TIS throughout the facility which must be designed and installed in accordance with UFC 3-580-01, TIA-568, TIA-569, TIA-606, and TIA-607 and tested in accordance with TIA-568 and the DHA Technical Guidance LAN-WLAN Modernization. The TIS must be a universal wiring network to serve all of the voice and data needs of the facility. The TIS must include horizontal and backbone unshielded twisted pair (UTP) copper cables and FO backbone cables. The TIS must support voice, facsimile, data, voice grade wireless network and other special services within the facility. All TIS backbones to TRs supporting the Clinical Information System(s) must have dual cable feeds occupying dual pathways in accordance with all requirements of NFPA 99 for the category of the facility under construction. The TIS cables must be installed in conduit and cable tray. All cables must be terminated on both ends. Cables and outlets must be marked in accordance with the DoD Project Sponsor or local Installation standard. In the absence of the DoD Project Sponsor standard or local installation standard, TIA-606 must be followed. For Installations outside the contiguous United States, shielded twisted pair cables may be required by the project-specific criteria.

12-7.1 UTP Copper Backbone Cable.

Provide a dedicated multi-pair UTP copper cable to support voice applications which must be run from the BDF to each TR. The cable must be sized to accommodate the initial installed capacity plus 50 percent. The cable insulation must be rated for the environment installed in accordance with NFPA 70. In facilities with an installed TSS, the associated main distribution frame (MDF) must replace the BDF cited here. Backbone copper cables must be terminated on patch panels. For new facilities in which VoIP is to be installed, the backbone copper cable to each TR must be reduced to the minimum count needed to accommodate legacy medical systems, alarm and signaling circuits. Minimum count must be 25 pair.

12-7.2 FO Backbone Cable.

Provide a minimum of 12 strands of single mode fiber optic cable between the FMDF to each TR. Final strand count required to support the project will be coordinated with the DoD Project Sponsor. All TIS backbones to TRs supporting the Clinical Information System(s) must have dual cable feeds occupying dual pathways in accordance with all requirements of NFPA 99 for facilities with Category 1 and 2 room designations as defined per Appendix B. The FMDF must be located in the server room or other location identified by the DoD Project Sponsor. Patch panels must be used to terminate all backbone FO cables. Where multiple vertical stacks of TRs are used in Inpatient

MTFs and ambulatory surgery centers, a 24-strand single-mode FO cable must connect each of the TRs on the top of each stack.

12-7.3 Horizontal Copper Cable.

The horizontal cable must consist of four-pair UTP cable rated Category (Cat) 6A or higher. The cable must be installed between patch panels in the TRs and the user outlets. The horizontal UTP cable must support the voice and data needs of the user. When a VoIP system is to be used there will be no difference or distinction between voice and data cable.

12-7.4 Horizontal FO Cable.

Horizontal FO cable will only be installed when required, as coordinated with the Design and Construction Agent, and approved by the DoD Project Sponsor.

12-7.5 Work Area Outlets (WAO).

WAO outlets must be located to support user work stations throughout the facility. A standard outlet must consist of a minimum 4 11/16 in. (120 mm) X 4 11/16 in. (120 mm) X 2 1/8 in. (55 mm) deep back box with a plaster ring that is equal to the wall thickness plus covering, and a one inch conduit to the cable tray **\1\ /1/**. The cover plate must include four available positions for jacks. All UTP jacks must be 8 pin modular rated at Cat 6A or higher. Standard outlets must at a minimum contain three wired jacks in accordance with DHA Technical Requirements-Guidance LAN-WLAN Modernization. Two outlets of (3) jacks each per 100 sf (9.3 sm) administrative office or area are required. The DoR will coordinate outlet requirements with the PRC. The facility must not be wired to support uncertain future changes. Desk outlets must be mounted 18 inches (415 mm) above the finished floor. A minimum of **\1** 12 **/1/** in. (305 mm) of slack on each cable must be coiled into the outlet box.

12-7.5.1 Equipment.

Provide additional outlets, as required, to support both Log Cat A and Log Cat C equipment, paying particular attention to locations such as laboratories, radiology, inpatient bedrooms, nursing team centers, and conference rooms as prescribed the PRC. Additional outlets will be provided above the UFC 4-510-01 and the PRC minimum requirements where required to support equipment and to meet the functional requirements for each room.

12-7.5.2 Wall Telephone Outlets.

Provide single position modular jack telephone outlet designed to support wall-mounted telephone sets that are Architectural Barriers Act (ABA) compliant. Use faceplates for wall height telephone outlets that have one ANSI/TIA/EIA Cat 6A-rated jack and studs for mounting a wall-type telephone set. Where restricted by casework, adjust outlets and appropriately note location on the floor plan and elevation.

12-7.5.3 Modular Furniture Outlets.

Modular Furniture Outlets may be accommodated by wall-mounted or floor-mounted WAO outlets where appropriate, or by the use of consolidation points as allowed by TIA-568 and UFC 3-580-01 open office wiring requirements. The Intermediate Termination Point may be located either above the ceiling or in the distribution zone with connecting conduit to the modular furniture connection point. The use of “power poles” is permitted only if approved by the Design and Construction Agent in coordination with the DoD Project Sponsor.

12-7.5.4 Pharmacy Ceiling Outlets.

Provide ceiling height outlets in Pharmacy locations to accommodate clinical systems. The DoR must coordinate the location and number of outlets with the DoD Project Sponsor.

12-7.5.5 GFGI Systems.

Provide outlets to support Government Furnished Government Installed (GFGI) systems. Coordinate with the DoD Project Sponsor to determine what systems are to be installed and to identify the data wiring and quantity of outlets required to support the systems.

12-7.5.6 Elevator TIS Outlet.

Cabling and a TIS outlet must be provided in elevator machinery rooms for each elevator car for the connection of elevator telephone sets. Telephone instruments must be furnished by the elevator supplier and instruments will provide a direct ring-down or hotline to a 24-hour staffed location.

12-7.5.7 Conference Room Outlets.

Conference rooms must contain outlets to support voice, data, and video teleconferencing. In addition to the voice and data outlets along the walls, outlets must be provided under conference tables to accommodate voice and data instruments and connections for computer inputs to a wall-mounted flat-screen monitor. Combination power and voice/data outlets for conference room tables will be coordinated with the DoD Project Sponsor.

12-7.6 Data Communications Wireless Access Points (WAPs).

Design of new medical facilities must include site preparation for the DHA DAD IO/J6 wireless data network based upon the predictive heat map survey. The government will provide the predictive survey at 65% design. The outlet configuration will be designed in accordance with DHA Technical Requirements-Guidance LAN-WLAN Modernization. This site preparation must consist of providing outlet boxes and cable in trays or conduit for the WAPs. The outlets for the WAPs must be installed above the ceiling and must be a standard size TIS outlet. Two Cat 6A cables must be installed from the nearest TR

and terminated on modular jacks in the outlet. Adjustments to obtain the final WAP configuration must be based on a physical survey using active equipment.

12-7.7 Cable Tray.

Provide cable trays above the suspended ceilings in the corridors for all communications systems cables. Cable trays must be located above the ceiling and be installed to provide 12 in. (305 mm) of clearance above, and 12 in. (305 mm) on at least one side of the cable trays, to ensure ease of accessibility for wiring changes. The Design and Construction Agent, in coordination with the DoD Project Sponsor, may approve a reduction of the clearance above the cable tray to 8 in. (205 mm) when unable to achieve the required clearance, and minor and infrequent incursions into the minimum access spaces if determined that adequate access is provided to allow cables to be removed and/or installed. The cable tray system design and installation must be in full compliance with TIA-569. The DoR must provide a cross sectional model to ensure adequate clearance above ceiling tiles and cable trays. Cable trays for communications systems must not be shared with electrical power systems cables. For facilities with an IBS, cable trays must be installed in the distribution zone instead of the connection zone. J-Hooks must not be used in new construction projects. J-Hooks may only be used in an alteration project where cable trays are not part of the existing structure and space above the ceiling is limited.

12-7.8 Grounding.

All TRs must include a Primary Bonding Busbar (PBB) or Secondary Bonding Busbar (SBB) and be bonded in accordance with TIA-607.

12-8 DEDICATED INTERCOM SYSTEM.

Intercom functions must generally be provided by the telephone system. Dedicated point-to-point intercom systems where the use of the telephone system or direct ring-down telephone circuits is not satisfactory, may be provided. Intercom systems must provide two-way voice communications and may include one- or two-way video communications. Other intercom functions and all dial intercom functions must be by the telephone system.

12-9 NURSE CALL (NC) SYSTEM.

12-9.1 Purpose.

The NC System will communicate patient and caregiver calls for various levels of assistance from appropriate caregiver responders. The communications must include explicit information about the specific call location and level of assistance needed. Consult with the DoD Project Sponsor to determine if the NC System is required to interface with the Medical Facility network. Regardless of network connectivity, the NC System must meet the Assessment and Authorization Process requirements outlined in this chapter. The NC System must meet the requirements of NFPA 99 and be listed to UL 1069 standards for the purpose as installed. A NC System that will be connected to

the Clinical Information System must meet the above requirements and be identified for use in a shared network environment. The Clinical Information System must be managed and controlled as prescribed in NFPA 99.

12-9.2 Capabilities and Typical Locations.

NC System capabilities and typical installation locations must be as defined as noted in the following:

12-9.2.1 Nurse Call Audio Visual System (NCAV).

The Networked NCAV System must provide simultaneous multimedia communication of calls that includes alert tones, visual indicators, selectable voice annunciation, alphanumeric video displays, full duplex voice intercom, and alphanumeric RP.

Provide a Networked NCAV System in inpatient MTFs located in the following areas: patient units (Medical/Surgical, Intensive and Neonatal Intensive Care, Cardiac Care, L&D), the Emergency Department and associated Urgent Care area, the surgical services area, pre-operative holding areas, and post-operative recovery areas. **\1** If required and defined by Appendix A, provide Networked NCAV Systems for inpatient behavioral health units that include tamper resistant equipment and limited patient call capability. **/1/**

12-9.2.2 Nurse Call Tone Visual System (NCTV).

The NCTV System must provide simultaneous multimedia communication of calls that includes alert tones, visual indicators, selectable voice annunciation, and alphanumeric video displays. NCTV communications media do not include full duplex voice intercom.

Provide a NCTV System in Ambulatory Care Centers located in the following areas: medical and dental services, ancillary service areas such phlebotomy and imaging, and blood donor areas. **\1\ /1/**When an MTF includes both inpatient and outpatient services, the NCTV system must be integrated with the Networked NCAV System.

12-9.3 Procurement.

The NC System must be procured as a turn-key system from a single qualified NC System contractor.

12-9.4 UL 1069.

All NC Systems must be listed to UL 1069 standards for the purpose as installed.

12-9.5 Common Criteria.

The application design, configuration, and installation of all NC Systems must comply with these common criteria:

12-9.5.1 Electronic Supervision.

Code Blue and other Code Stations, Annunciator Stations, Master Stations, Patient Stations, and associated wiring to each of these stations must be electronically supervised in accordance with UL 1069, with any failure condition annunciated at the local control or monitoring station, and communicated as further defined herein.

12-9.5.2 Keep-Alive Feature.

All personal computer (PC) based Master Stations and Annunciator Stations must be equipped with a "keep-alive" feature that will automatically re-boot the station if it is turned off for any reason.

12-9.5.3 Call Assurance.

When a call is placed from any call station or device, a call assurance indicator lamp on the station or device must illuminate to indicate that the call has been registered on the system. The call assurance lamp must remain illuminated until the call is cancelled.

12-9.5.4 Alert Signal.

A signal to alert staff to a call must be an audio tone or an alternate voice annunciation. **\1** The audio volume of an alert tone is not permitted to fall below the minimum perceptible decibel level. The adjustment of the alert tone audio volume on any type of station or light must be a maintenance procedure and not an operator function. The alert signal must have an automatic reset feature that turns the alert tone back to announce a new call when the temporary mute feature is activated for the current call. **/1/**

A computer-generated voice annunciation alert of a call, by type and location, must be provided as a user selectable alternative to the alert tone. This alternative must not affect or substitute for any displayed call information.

12-9.5.5 Tone and Visual Call Signals.

12-9.5.5.1 Call Annunciation.

Each call must be annunciated by various combinations of alert tones and visual indicators. **\1\ /1/** In inpatient MTFs that have NCTV and NCAV Systems, the tone and visual signals must be consistent for each System call type and priority.**\1**

12-9.5.5.2 Visual Call Signals. /1/

Visual steady or flashing illumination colors must provide clear and absolute distinction between call types and priorities on the dome and zone lights, and at the duty, annunciator, and master stations. Visual call illumination on zone and dome lights must be identical for each call type. **\1**

12-9.5.5.3 Tone Call Signals. /1/

Tone signals must sound at different intermittent pulse rates to allow adequate distinction between call types and priorities at the duty annunciator, master stations and on dome lights. Audible annunciation is required at all zone lights in accordance with UL 1069.

12-9.5.5.4 Call Routing – Zone Lights.

Within a patient care unit, the routing of call types from any call station, or combination of call stations, must be programmable to allow annunciation of calls on one or more zone lights. Each zone light must be programmed to illuminate in a pattern of zone lights that guides staff from any corridor in the unit directly to the room where the call was initiated.

Zone Light Activation Matrices must be developed. Each zone light must be given an identification (ID) number that must be indicated on the Telecommunications Systems drawings. A Matrix must be developed for each patient care unit served by the NC System. Each Matrix will list all zone lights by their ID number within each patient care zone, and correlate each zone light to the patient care room(s) where a call is initiated to activate zone lights. These Matrices must be included with the submittals beginning at 35% design.

12-9.5.5.5 Call Annunciation Priorities.

All NC systems must simultaneously process and signal all calls regardless of the call priority. When several different priority calls are active on the system at any one time, the signal for the highest priority call must take precedence on call tones and visual indicators that signal several call categories. For example: If dome and zone lights signal an emergency call by a solid red light with intermediate pulse rate tone, and a Code Blue call by a flashing red light with fast rate tone pulse, the dome and zone lights must signal a flashing red light with fast pulse tone when an emergency and code call occur at the same time.

12-9.5.5.6 Call Processing Rates.

a. Except for Code Blue and other Code calls, all calls must be processed from the origination call station to the call destination within 4 seconds.

b. Code Blue and other Code calls must be processed from the call initiation station to the call destinations within eight (8) seconds. The eight seconds must include a four (4) second delay in the initiation of these calls to allow staff to quickly abort accidentally initiated code calls.

c. The call processing rates defined here do not include any RP System transmission time for the alphanumeric RP of calls.

12-9.5.6 Code Blue and other Code Stations.

Each Code Blue and other Code call stations must be physically separate stations and they will not be part of any other station. These stations must be mounted as high as practical to be out of reach of children.

12-9.5.7 Dome and Zone Lights Lamps.

Dome and zone lights must utilize LED lamps. Incandescent lamps are unacceptable.

12-9.5.8 Main Terminal and Equipment Panels.

Locate the main terminal and equipment panel for each NC system in the TR nearest the area serviced and provide for system wire termination, low-voltage power supply that provides power to all stations and lights, and circuitry for system operation, as determined by the system application design. Locate the main terminal equipment in the Server room if it is determined by DHA-FE and the DoD Project Sponsor to be a Server.

12-9.5.9 Standardized System Features and Capability.

All of the systems in each NC System category must have the same standardized performance features and capability. System features and capability not required in a particular patient care unit may not be activated at the time of installation. However, the facility maintenance staff must be able to activate inactive features and capability at any time after installation without impacting the fundamental capabilities of the system, or without assistance from the system contractor.

12-9.5.10 Electrical Power.

The NC System and equipment must be powered per Table 12-1. AC powered equipment must be protected by a UPS unit providing at least 15 minutes full power during an AC power failure. UPS units must comply with UL 1778 and 47 CFR Part 15.

12-9.6 Networked NCAV System.

The NCAV Systems must include operational nodes of a totally integrated network of the major functional components and interfaces that provide a comprehensive facility-wide multimedia capability for the NC fundamental operations and enhanced supplemental operations.

12-9.6.1 Operations.

12-9.6.1.1 Fundamental Operations.

Provide for the communication of these calls from within a patient care unit:

a. Patient and caregiver calls for assistance and information

b. Auxiliary medical device alarm calls

c. Bed exit alarm calls

12-9.6.1.2 Enhanced Supplemental Operations.

Provide enhanced supplemental operations to the fundamental operation for the routing of calls, data, and messages within patient care units and over a system-wide network to facilitate:

a. Central annunciation of designated types of calls, including code calls and equipment failure alarms.

b. Automatic downloading of patient Admissions-Discharge-Transfer (ADT) module data via interface with the Medical Community of Interest (Med-COI). A Nurse Call system that will be connected to the Clinical Information System must meet the above requirements, be authorized for use via the RMF Process and be identified for use in a shared network environment. The Clinical Information System must be managed and controlled as prescribed in NFPA 99.

c. A central database for the logging of all calls and the generation of statistical management reports from a Call Logging Workstation and from designated computers on the hospital network.

d. System operational status monitoring and maintenance from a Central Maintenance Workstation.

e. Processing and transmission of NC data and messages to alphanumeric radio pagers or other wireless communications devices carried by staff, and processing of NC data and messages to GFGI-wide area alphanumeric pagers leased from a local Radio Common Carrier that are carried by staff.

f. Swing routing of calls from any call station to any Master Station in the unit or in adjacent areas.

12-9.6.2 NCAV System Network.

The NC network must be an adjunct network of the facility LAN. Whether the Nurse Call system design provides a Med-COI connected or a Stand-alone Information System (SIS), provide an industry standard network architecture that includes industry standard LAN technology, software, protocols, equipment, and cabling to interconnect all NC major functional components and major interfaces into an integrated NC capability that supports facility-wide communications and all NC functions. When possible, all network management devices (switches, routers, firewall, etc.) must be on the DoDIN Approved Products List (APL).

The Nurse Call System will require an Authority to Operate (ATO) and must comply with DoDI 8510.01 and UFC 4-010-06. As discussed in paragraph 12-9.1, the contractor must consult with the DoD Project Sponsor to determine if the NC System is required to

interface with the Medical Community of Interest (Med-COI) network. **\1** All NC systems that connect to the Med-COI must be in accordance with the DHA Procedural Instruction (PI), "Standard Isolation Architecture for Cybersecurity of Facility Related Control Systems (FRCS)". Nurse Call systems that are connected to the Clinical Information System must meet the above requirements and be identified for use in a shared network environment. The Clinical Information System must be managed and controlled as prescribed in NFPA 99.

12-9.6.2.1 NCAV Servers. /1/

Servers must include the appropriate DHA approved operating system (OS) and application software. Servers must also provide central databases for all of the systems' application programs and data, call logging data, interface with the facility RP or other wireless personal communications device system, and interface with the facility NTS System. Servers must also meet the RMF Requirements for an ATO and be capable of interface with the Med-COI in accordance with the DHA Procedural Instruction (PI), "Standard Isolation Architecture for Cybersecurity of Facility Related Control Systems (FRCS)".

12-9.6.3 NCAV System Major Components.

Provide the following NCAV System major components at the locations indicated. Also refer to paragraph 12-9.5.

12-9.6.3.1 Bed interface outlet stations.

A bed interface outlet station must be located behind each inpatient bed equipped with a communications side rail or bed exit alarm system. The station connector must be compatible with the connector on the bed communications cable.

12-9.6.3.2 Patient Stations.

Single Patient Stations must be provided for each medical/surgical unit patient bed, each critical care unit patient bed, each LDR/LDRP bedroom, each inpatient unit exam, procedure, and treatment room, each emergency exam treatment room and patient care station, each pre-operative patient care station, Phase I post-anesthesia recovery patient care station, and Phase II recovery patient care station.

12-9.6.3.3 Cord Sets and Holders.

Provide the following types of cord sets for each location, except where noted:

a. Pillow Speaker Cord Sets. A pillow speaker cord set must be provided for each patient station in all inpatient bedroom types, excluding inpatient behavioral health bedrooms. In these locations, the patient station cord set receptacle must accommodate the simultaneous use of both a pillow speaker cord set and a push button or pneumatic cord set. The cord set

must be a component in the UL 1069 Listing for the system, or be approved by the Nurse Call Manufacturer for use with their system.

b. Push Button Cord Sets. A push button cord set must be provided for each patient station in each inpatient unit exam, treatment and procedure room, each emergency exam treatment room, each patient station in the pre-operative holding and the post-operative recovery areas. Provide push button cord sets for 25 percent of the patient stations in all other locations. The cord set must be a component in the UL 1069 Listing for the system, or be approved by the Nurse Call Manufacturer for use with their system.

c. Pneumatic Cord Sets. Pneumatic cord sets must be provided for 25 percent of the patient stations in all rooms and cubicles. Cord set must be a component in the UL 1069 Listing for the system or be approved by the Nurse Call Manufacturer for use with their system.

d. Cord Set Holder. A wall bracket must be provided to hold cord sets when not in use.

e. Push Button Stations. Only push button stations will be provided in Behavioral Health areas as required by Appendix A.

12-9.6.3.4 Code Blue Stations.

Code Blue Stations must be provided as a minimum, in the following locations: each medical/surgical unit patient bed, each critical care unit patient bed, each LDR/LDRP bedroom, newborn/well baby nursery, each inpatient unit exam, procedure and treatment room, Cesarean delivery rooms, diagnostic radiography and fluoroscopy rooms, CT scanner rooms, MRI scanner rooms, stereotactic mammography rooms, ultrasound rooms, cystoscopy rooms, bronchoscopy rooms, endoscopy rooms, oral surgery dental operatories, emergency exam treatment rooms and each emergency patient care station, emergency treatment and procedure room, pre-operative patient care station, Phase I post-anesthetic (PACU) patient care station, and Phase II recovery patient care station. Code Blue stations in Behavioral Health units must be in accordance with Appendix A.

12-9.6.3.5 Device Alarm Jack Stations.

Device alarm jack stations must be adjacent to each patient station.

12-9.6.3.6 Duty Stations.

Duty Stations must be provided, as a minimum, in staff lounges, clean core areas, clean and soiled workrooms and storage, nourishment pantry, medication preparation room, changing locker and other areas identified by the DoD Project Sponsor. Each duty station will provide an audible tone without voice, and visual indication that a call has been initiated on the NC system.

12-9.6.3.7 Emergency Pull Cord Stations.

Emergency Pull Cord Stations must be adjacent to each toilet in public, patient and staff restrooms, and in each patient shower and tub, each medical/surgical unit patient, critical care unit and each LDR/LDRP toilet/lavatory location. In showers, locate the station on the shower head wall and above the shower head; these stations must be water resistant. In Behavioral Health settings emergency pull cord stations must be replaced with emergency push button stations.

12-9.6.3.8 Emergency Push Button Stations.

Emergency Push Button Stations must be provided, as a minimum, in each; Intensive, Continuing Care, and Isolation bassinet location; Level 1 Holding Nursery, Admissions.

12-9.6.3.9 Staff Assistance Stations.

Staff assistance stations must be provided, as a minimum, in dayrooms, conference rooms, waiting rooms, interview rooms, emergency procedure and trauma rooms, and Nursery parent teaching and feeding rooms. Each staff station will include the functionality of a duty station plus two-way voice communication.

12-9.6.3.10 Staff Assistance Stations with Emergency Call Button.

Staff assistance stations with an emergency call button must be provided, as a minimum, in each OR, cystoscopy room, cardiac catheterization room, angiography procedure room, Nursery procedure room, isolation and seclusion ante-rooms, day rooms, interventional procedure room, Dialysis Stations, Blood Donor Stations, Immunization rooms, and inpatient pediatric play rooms. Behavioral Health inpatient and outpatient settings must be equipped in accordance with Appendix A.

12-9.6.3.11 Master Stations.

Master stations must be provided, as a minimum, at the following nurse stations: all inpatient care units, Emergency Department, pre-operative unit, Phase I post-anesthetic (PACU) unit, Phase II recovery unit, and at the control desk in the surgical suite.

12-9.6.4 Peripheral Equipment.

Provide the Networked NCAV System peripheral equipment defined here at the locations indicated.

12-9.6.4.1 Main Central Annunciator.

Provide a Main Central Annunciator Station to annunciate all Code calls and failure alarms throughout the entire NC System until the call is cancelled at the initiation point. The main central Annunciator Station location must be approved by the Design and Construction Agent in coordination with the DoD Project Sponsor.

12-9.6.4.2 Call Logging Workstation.

A Call Logging Workstation must be provided for the collection, processing, storage, statistical analysis, report generation, and archiving of call data. The Call Logging Workstation must be capable of printing real-time call data by patient's name, sex, age, room, and bed, the time each call is placed, answered, set on service reminder, or canceled at the Master Station or when logged at the Central Annunciator Station. This workstation must be located in an area approved by the Design and Construction Agent in coordination with the DoD Project Sponsor.

12-9.6.4.3 Maintenance Workstations.

Two Maintenance Workstations must be provided to support remote monitoring, diagnostics, and troubleshooting of failures throughout the system, testing of major NC System components, and for the downloading and installation of software upgrades from the manufacturer. One workstation will support the maintenance of the system stations and lights and must be located in the Facility Management Department. The other workstation must be located in a designated area identified by the DoD Project Sponsor.

12-9.6.5 Duplex Voice Intercom.

Provide a full duplex, non-blocking voice intercom between Master Stations and Voice Calling Stations (patient stations, staff stations, and duty stations) and for voice communications on the NCAV System. A simplex intercom that utilizes voice activation or other switching circuits to permit transmission in only one direction at a time, or that may clip portions of a two-way conversation, are not permitted.

12-9.6.6 Networked NCAV System Interfaces.

Provide the following interfaces at the locations indicated.

12-9.6.6.1 Bed Side Rail Communications and Bed Exit System Interface.

Provide interface at the Bed Interface Outlet Station via the bed communications cable. Side rail controls must allow initiation and routing of a patient call, and provide on/off control of room and reading lights. A bed exit system must initiate a bed exit alarm when the patient exits the bed.

12-9.6.6.2 Interface for Remote Control of Over-Bed Lights.

Provide an interface for on/off remote control of the inpatient bedroom reading and room lights at each bed location via an interconnection to a solid-state, low-voltage light controller. (Reference Chapter 11 Electrical)

12-9.6.6.3 ITV System Interface.

Provide pillow speaker interface in accordance with paragraph 12-12 at each inpatient bed station and the associated patient flat-panel, high-definition television (HDTV) for these functions: HDTV on/off and channel selection control, and remote sound from a pillow speaker cord set. If requested by the DoD Project Sponsor, pillow speaker must also interface with patient interactive access to on-demand and scheduled education and message channels, and interactive access to programs such as patient surveys or food service menu.

12-9.6.6.4 RP Interface.

Provide a networked NCAV System RP server interface to the RP Systems (reference paragraph 12-11) that will automatically route calls to the RP System for transmission to radio pagers assigned to staff.

12-9.6.6.5 Medical Community of Interest (Med-COI) Interface.

When directed by the DoD Project Sponsor, the Networked NCAV System server must interface directly to the Med-COI and the Clinical Information System to automatically download patient ADT module data for use by master stations and whiteboards and to interface with hands free wireless communications devices carried by the staff. A Nurse Call system that is connected to the Clinical Information System must meet the requirements associated with the RMF Process, obtain an ATO and connect in accordance with the DHA PI, “Standard Isolation Architecture for Cybersecurity of Facility Related Control Systems (FRCS)”. A Nurse Call system that is connected to the Clinical information system must meet the above requirements and be identified for use in a shared network environment. The Clinical Information System must be managed and controlled as prescribed in NFPA 99.

12-9.6.6.6 NCTV System Interface.

Provide a networked NCAV System interface to the NCTV System (reference paragraph 12-9.7) to integrate the NCTV System with the enhanced supplemental operations of the Networked NCAV System. This requires the NCTV System to add a network capability that will link the network to the NCAV System LAN.

12-9.6.6.7 NTS System Interface.

Provide an NTS System (reference paragraph 12-5) interface with a NCAV System network server for time and date synchronization.

12-9.6.7 NCAV System Call Types.

The following are NCAV System call types:

a. Patient Routine Call

b. Patient Priority Call

c. Cord Disconnect Call

d. Bed Disconnect Call

e. Emergency Call

f. Staff Assistance Call

g. Code Blue Call

h. Other Code Call

i. Medical Device Service Alarm Call

j. Bed Exit Alarm Call

k. Duplex Voice Intercom Call

l. Service Dispatch and Reminder Call

m. Information Message Call

n. Failure Alarm Call

12-9.6.8 Call Annunciation Modes.

Each call must annunciate throughout the system by various combinations of alert tones, visual and video indications, and the digital display of alphanumeric data and text messages. The specific annunciation for each call type must be as described herein for each type and source of call.

12-9.6.8.1 Master Stations.

On Master Stations, an intermittent call alert tone must sound. A touch-screen color video monitor must graphically and digitally display the call type and call initiation room and bed location. Alphanumeric data and text message information must indicate associated patient data, associated staff assignment data, and associated radio pager assignment data. The facility room name and number must identify the call initiation room. Call data, information, and status must remain displayed on the video monitor until the call is cancelled.

12-9.6.8.2 Central Annunciator Stations.

On Central Annunciator Stations, an intermittent call alert tone must sound. A touch-screen color video monitor must alphanumerically indicate the call type and call initiation patient care unit and room location, or failure alarm call type and equipment location. The video monitor display must indicate at least ten calls simultaneously, and include a scrolling feature that will display additional calls that are not simultaneously displayed. The facility room name and number must identify the call initiation room location. Call data, information, and status must remain displayed on the video monitor until the call is cancelled.

12-9.6.8.3 Duty Stations.

On duty stations, LED lamp(s) with steady or flashing illumination must indicate calls by the call priority level, and sound an alert tone.

12-9.6.8.4 Pagers and Other Devices.

On pagers or other networked wireless personal communications devices carried by the staff, an alert tone or vibration must activate, and an alphanumeric data and text message must indicate the call type, and identify the room and bed location where the call was initiated. For routine calls that are first answered by an attendant, the pager or other networked wireless personal communication device must also indicate that a service dispatch message has been sent by the attendant. The room name and number must identify the call initiation room and bed.

12-9.6.8.5 Annunciation.

The alert tones, and visual and video indication displays for all types and priorities of calls must continue to alert until the call has been answered and cancelled. Except for routine calls, all other calls must be cancelled at the initiating call station. Routine calls may be cancelled at either the initiating station or at the answering Master Station on audio equipped systems. NCTV calls must be cancelled at the initiating station.

12-9.6.9 Call Annunciation Priorities.

The annunciation of all call types must be sequenced in a four level priority rank order, from a high priority, Number 1, to a low priority, Number 4, as listed in Table 12-2. Coordinate Code Call names, meanings, and priority levels with the DoD Project Sponsor.

Table 12-2 Call Annunciation Priorities

Priority Level	Call Type
#1 Code	Code Blue
	Other Code Calls
#2 Emergency	Emergency
	Bed Exit Alarm
	Medical Device Emergency Alarm
	Staff Assistance
	Failure Alarm
#3 Priority	Patient Priority
	Call Cord Disconnect

Priority Level	Call Type
	Bed Cable Disconnect
#4 Routine	Patient Routine
	Medical Device Routine Alarm
	Voice Intercom - Staff and Duty Stations

12-9.6.9.1 Call Types.

All call types must be simultaneously processed regardless of the priority level. However, when several different priority level calls are present on the system at any one time, the highest priority call must take precedence over lower priority calls. For Master Stations and Annunciator Stations that display calls in a list, the displayed list of calls must be in priority order, with the highest priority calls at the top. All call types, regardless of the priority level, must remain indicated until cancelled.

12-9.6.10 Call Routing.

Call routing throughout the networked system must be software programmable to provide the selectable call routing defined here. All patient data and caregiver data associated with any call must automatically accompany the call routing.

a. Calls initiated from a patient toilet or shower room that is entered directly from within the patient bedroom must visually annunciate on the dome light located outside the entry into the patient bedroom.

b. Calls from a dedicated patient toilet room that is entered directly from within another room must visually and audibly annunciate on the dome light located outside the entry door into the toilet room, and visually on the dome light located outside the entry into the other room.

12-9.6.10.1 Call Routing – Master Stations.

Master Station features must allow the attendant to select a call routing, to include the routing of voice intercom between any Master Station and any audio call station, as defined here. If the network or call routing feature should fail, all calls must revert to the original UL 1069 designated Master Station.

a. A default call routing scheme within each patient care zone must be established for calls between each call initiating station and the Master Station(s) in the NCAV System. If there is more than one Master Station in the NCAV System, then the default call routing to each Master Station must be user defined and approved by the User Representative.

b. Any call from a call initiating station can be selectively routed to, and answered from, any Master Station in the NCAV System.

c. Any one Master Station in the NCAV System must be able to handle any combination of calls, or all of the calls, from any call initiating station in the NCAV System.

d. Any combination of Master Stations throughout the NCAV System can be programmed to operate in a parallel mode. When operating in a parallel mode, all calls that would normally be routed to a Master Station must now be routed to all Master Stations at the same time. The parallel mode feature can be either a default setting or an attendant selectable mode at any Master Station.

e. An authorized attendant, using password protection, must be able to perform at any Master Station, a selective call capture function whereby any call initiating station that has been default programmed for call routing to another Master Station must be rerouted to the capturing Master Station. The attendant must be able to selectively capture a single room, groups of rooms, or all of the rooms that have been default assigned to another Master Station. The rerouting of calls from any room must include all associated patient and staff data that has been programmed for the room, including staff assignments.

f. Master Stations that have relinquished reception of calls to another Master Station via the call capture function must retain the manual capability to announce a RP.

g. An authorized attendant, using password protection, must be able to perform a selectable recapture function at any Master Station, of all calls from the NCAV System, or any call station that has been captured by another Master Station by performing a selectable recapture function.

h. All call routing, call capturing, and call recapturing operations must be password protected.

12-9.6.10.2 Call Routing – Main Central Annunciator Station.

The annunciation of a normal local call on a Master Station, the RP of the call, and the call types listed here must be automatically routed to the Main Central Annunciator Station located in an area identified by the DoD Project Sponsor.

a. Code Blue calls

b. Other Code calls

c. Failure alarm calls

12-9.6.10.3 Call Routing – Infant Distress Central Annunciator Station.

In addition to the normal local call annunciation on a Master Station, and the radio page of the call, all infant distress calls must also be automatically routed to the Infant Distress Central Annunciator Station.

12-9.6.10.4 Call Routing – Duty Stations.

All duty stations must be equipped to annunciate all call types.

12-9.6.10.5 Call Routing – Call Logging Server and Call Logging Workstation.

All call data from the NCAV System must be routed to the call logging database in the call logging server. The call logging database will be accessed from the NCAV System Call Logging Workstation and any additional location identified by the DoD Project Sponsor in coordination with the facility Information Technology Representative. Call logging application programs used to access the call logging database and to generate call data reports must be installed on designated computers on the hospital network. Failure of the Call Routing or Call Logging feature, to include, but not limited to, out of logging space conditions or a network failure, must not cause degradation of the basic services as defined in UL 1069.

12-9.6.10.6 Call Routing – Maintenance Workstations.

All failure alarm calls from all major functional components of the network and all systems must be routed to the Maintenance Workstation(s). Failure of the Call Routing or Call Logging feature, to include, but not limited to, out of logging space conditions or a network failure, must not cause degradation of the basic services as defined in UL 1069.

12-9.6.10.7 Call Routing – RP System Pagers.

All calls and failure alarms on the Networked NCAV System must be routed by NC selectable duty assignment programming via the NCAV RP Server interface (reference paragraph 12-11), for transmission to RP System Pagers assigned to designated staff. Failure of the Call Routing Radio Page feature must not cause degradation of basic services as defined in UL 1069.

12-9.7 NCTV System.

12-9.7.1 Overall Configuration and Capability.

There are two typical configurations for the application of the NCTV System: one configuration is for installation in ACCs to include blood donor centers and the second configuration is for installation in inpatient MTFs. Both configurations must provide the same fundamental operations for patient and staff calls, and communications operations. However, the configuration for inpatient MTFs must provide enhanced supplemental operations for signaling and data handling from the NCTV System when it is integrated with the enhanced supplemental operations of the NCAV System in the facility. The common fundamental operations of both configurations, and the enhanced supplemental operations for inpatient MTFs must be as defined here.

An inpatient MTF that is equipped with a Networked NCAV System (reference paragraph 12-9.6) that provides enhanced supplemental operations, must be linked as

nodes on a network provided as part of the NCTV System., with the NCTV network linked to the Networked NCAV Systems network. The NCTV System must have the same enhanced supplemental communications capabilities as the NCAV System, to include alphanumeric RP or other wired networked personal communications devices, central annunciation of code and failure calls, and the central logging of all call transactions.

12-9.7.2 NCTV System Major Components and Locations.

Provide the following NCTV System major components at the locations indicated.

12-9.7.2.1 Emergency Call Stations.

Emergency Call Stations must be located as directed herein.

a. Patient toilets (beside and toward the front of each toilet)
b. Staff toilets that may be used by patients (beside and toward the front of each toilet)
c. Public toilets (beside and toward the front of each toilet)
d. Patient showers (waterproof unit on shower head wall above shower head)
e. Phase II recovery patient care stations (adjacent to the patient's head)
f. Phase I post-anesthesia recovery (PACU) patient care stations
g. Pre-operative patient care stations
h. Emergency Laboratory Phlebotomy area or rooms
i. Blood Donor stations
j. Physical Therapy treatment stations and the exercise gym
k. Special Procedure rooms: coronary, neurological or peripheral angiography, electrophysiology procedures, cystoscopy, bronchoscopy, colonoscopy, and endoscopy
l. Operating rooms
m. Pulmonary function laboratory and testing rooms
n. Immunization and Allergy injection rooms
o. Dialysis patient care stations
p. Cardiac Rehab Exercise gym
q. Electroencephalogram (EEG) Testing rooms
r. Stress Electrocardiogram (ECG) and Echocardiogram rooms
s. Medical Radioisotope Laboratories
t. Patient dressing rooms and locker area

u. Dental oral surgery rooms

v. CT Scanner rooms

w. MRI Scanner rooms

12-9.7.2.2 Code Blue Station Locations.

The minimum required locations must be located as directed herein.

a. Procedure rooms that utilize high-level disinfection or sterile instruments, and some environmental controls that are not required to support an operating room or Dental oral surgery rooms

b. ECG Echocardiogram rooms

c. Physical Therapy Exercise gym

d. Laboratory Phlebotomy areas or room

e. Blood Donor rooms

f. Renal dialysis rooms

g. Immunization and Allergy Injection rooms

h. Chemotherapy infusion rooms

i. CT Scanner rooms

j. MRI Scanner rooms

12-9.7.2.3 Dome Lights and Whiteboard Locations.

Locate a dome light above or beside the entry to each room and each patient care station that will be equipped with an Emergency Call Station or Code Blue Station. Dome lights without a tone device must be located above or beside the entry to each room and each patient care station that will be outfitted with any of these NC System components: patient station, emergency pull cord station, emergency push button station, or Code Blue station. Dome lights with a tone device must be located outside the door to a dedicated toilet room that is accessed from within another room.

Zone lights must be located at each corridor intersection within multi-corridor units. White Board (WB) Stations must be located at the Nurse Station or Team Center in each patient care unit.

12-9.7.2.4 Zone Lights with Tone Locations.

Locate a ceiling mounted zone light with tone at each corridor intersection within multi-corridor areas.

12-9.7.2.5 System Annunciator Station Location.

The system annunciator station will be located in an area that is continuously monitored by staff.

12-9.7.3 Call Types and Alarms Signaled.

Call types and alarms signaled will include:

a. Call from a patient or staff for emergency assistance from an emergency pull cord station or an emergency push button station

b. Call from staff for Code Blue assistance from a Code Blue station

c. Call from staff for Other Code assistance from Other Code stations

d. Failure alarms from electronically supervised wiring, Code Blue Stations, Other Code Stations, and Annunciator Stations

12-9.7.4 Call Priorities.

The processing of calls must be sequenced in a two-level priority rank order, from a high priority, Number 1, to a low priority, Number 2, as listed here:

Priority Number	Call Categories
1	Code Blue and Other Codes
2	Emergency and Failure Alarm

12-9.7.5 Annunciator Station Function and Call Routing.

When a call is activated on the NCTV System, an intermittent call alert tone will sound on the system Annunciator Station. The Annunciator Station touch-screen color video monitor screen must alphanumerically identify the call type and call initiation room. The Annunciator Station must simultaneously process and display multiple calls. All calls must continue to be indicated until cancelled at the call initiation station.

A call signal cannot be cancelled at any Annunciator Station; it must be cancelled at the initiating call station. A tone mute icon may be used to temporarily silence a current call tone signal. The tone signal circuit must have an automatic reset feature that allows the tone signal to sound when the next call is placed.

12-9.8 Enhanced Supplemental Operations.

An MTF that is equipped with a Networked NCAV System (reference paragraph 12-9.6) that provides enhanced supplemental operations, to include an onsite RP System, the NCTV System must be configured with an integrated network that will be interconnected with the Networked NCAV System to fully utilize these NCAV enhanced supplemental operations for the routing of calls and data to facilitate:

a. The processing and transmission of call data and messages to alphanumeric pagers or other wireless networked personal communications devices carried by the staff

b. Central annunciation of code calls and failure alarms

c. The logging of all calls, and the generation of statistical management reports by a central database

d. Central system operational status monitoring and maintenance from a Maintenance Workstation

This enhancement will require the NCTV System to have the fundamental capability to be upgraded with all necessary networking hardware and software, and will include the provision of identical Radio Pagers for the NCTV System. The NCTV System Annunciator Stations must be upgraded with the hardware and software, to include a keyboard and a mouse, to allow manual alphanumeric RP from the Annunciator Stations.

12-10 INTERNAL CELLULAR ANTENNA SYSTEMS (IRES).

Provide a RF Distribution System to support communications from fire, emergency, and other first responder systems in accordance with NFPA Section 11.10 and NFPA 1225 for all facilities greater than 50,000 GSF (4645 GSM). Permitted operations include the RP System and the local fire service radio system. The signal sources may be either external or internal to the facility and the service will be capable of bi-directional services internally or externally. Systems that service fire radios must meet cabling and battery backup requirements per the local Installation Fire Marshall. Other frequencies and system requirements will be identified by the DoD Project Sponsor. Site requirements, field strength surveys, engineering & design documents, and test results will be provided as part of the system.

12-11 RADIO PAGING SYSTEM.

12-11.1 Radio Paging (RP).

Provide **\1** a paging system with paging receivers to support 100 percent coverage within the MTF. **/1/** The RP system design must provide 100 percent coverage within the MTF.

12-11.2 Page System Interfaces.

The RP System must interface with these following systems as noted in their respective sections of this chapter: Telephone System (numeric paging only) (reference paragraph 12-6), NC System (reference paragraph 12-9), Electronic Security System (reference Chapter 5, and IRES (reference paragraph 12-10).

12-11.3 System Function.

The RP system must utilize tone and vibration alert paging receivers that display an alphanumeric message. Each pager must be accessible by dialing a discrete set of digits via the telephone system. Access to the RP system must also be available at the central control console within the health facility when provided and at each NCAV System control station. The DoR must provide space for control and coaxial cables as well as the AC power, and the conduit for the system. Location of head end equipment and system components must be coordinated with the DoD Project Sponsor.

12-11.4 Emergency Response Team Pagers.

Pagers assigned to members of the code and other emergency response teams must have at least two separate and distinct alert tones: one for routine and priority calls and one for emergency calls. These pagers must also have two separate access codes: one for calls to individual pagers, and one for group alerts. The group alert code must signal all pagers in a group simultaneously.

12-11.5 Antennae Type and Mounting.

The antenna type selection, and the mounting height determination must provide complete facility coverage. Provide an antenna and mast that conforms to TIA-222 and TIA-329. A wireway, conduit, or cable tray must be provided from the transmitter location to the antenna. In the presence of an IRES, an appropriate low-level signal from the RP System transmitter must be directly injected into the IRES to supply coverage. With this type of design, an external antenna is not required.

12-11.6 Power Requirements.

All RP equipment must be connected to the life safety branch of the EPS and rated for continuous duty.

12-11.7 Transmitter and Encoder.

The transmitter must comply with FCC Emission Designator 11K0F2D for 12.5 KHz Narrow Band Transmission and appear as a listed device with the JITC. Provide two transmitters and encoders in a hot-swap configuration. Provide a Maintenance and Programming station.

12-12 INTERACTIVE TELEVISION (ITV) SYSTEM.

The ITV system is a proponent funded television receiver system used for patient entertainment and education and funded separately from MILCON.

Provide the following to support this system:

12-12.1 Electrical Power.

Provide electrical power to support the requested ITV systems in accordance with the electrical code and Table 12-1, and the device location provided by the System Contractor.

12-12.2 Empty Conduit and Boxes and Cable Trays.

Provide junction boxes and empty conduits with pull strings for the installation of cables. Calculate cable requirements into cable tray capacity calculations and provide adequate cable tray capacity to support these systems. Where system wiring will be designed to be connected utilizing the facility TIS, the specific location must be identified. Provide outlets, wiring and patch panel capacity in TRs to support these systems. Provide conduits from head end equipment location to the antennas mounted on the roof and, if required, conduits for coaxial and control cables for all system components associated with the Ambulance Dispatch.

12-12.3 Structural Support.

Provide structural support and sufficient mounting space for the antennas.

12-12.4 Equipment Space Support.

Provide floor space and racks as required in Communications Radio Equipment Room (COM04). Include this equipment in the TR Floor Space Calculations where equipment is located in TRs.

12-13 TV BROADBAND DISTRIBUTION NETWORK.

12-13.1 Purpose.

Provide a TV broadband distribution network to receive and distribute TV program channels from a commercial TV service to flat-panel HDTVs throughout a stand-alone facility.

12-13.2 Procurement.

Procure the entire TV network as a turn-key system from a single qualified TV network contractor.

12-13.3 Commercial TV Service.

The DoD Project Sponsor must select and separately contract for the provision of TV program channels from a locally available commercial TV service.

The system application designer must request and obtain from the DoD Project Sponsor the ID of the TV service that must be used, and obtain a detailed description of the facility space and infrastructure requirements that must be provided to accommodate

the TV service signal reception or entry and any headend equipment to be installed in the facility.

12-13.3.1 Facilities and Infrastructure for the TV Service.

Provide the facilities, space, and infrastructure to accommodate the installation requirements of the commercial TV service. **\1**

12-13.3.1.1 CATV Facilities and Infrastructure. /1/

For CATV service, provide the facilities and infrastructure to accommodate the routing of the CATV service trunk-line entry from the nearest source on the Installation to the network headend in a facility TR, including the CATV trunk-line and trunk amplifier (as may be required). The trunk-line routing into the facility may be via an underground duct or an underground cable link from an overhead pole adjacent to the facility site. **\1**

12-13.3.1.2 SATV Facilities and Infrastructure. /1/

For SATV service, provide the facilities and infrastructure to accommodate the installation of an SATV service roof-top antenna, cable entry into a facility TR, and any required headend equipment provided by the SATV service.

12-13.4 Broadband Distribution Network.

The broadband distribution network must consist of cable and equipment to receive, process, and distribute all TV program channels received from the TV service. The TV distribution network can be configured either as a broadband coaxial network or a gigabit Ethernet network for the communication of all TV channels to all TV outlets throughout the facility. The distribution network must conform to the radiation standards specified in 47 CFR Part 76. **\1**

12-13.4.1.1 RF Broadband Coaxial Cable Distribution Network. /1/

An RF broadband coaxial cable distribution network must include quad shield coaxial cables, power supplies, amplifiers, splitters, directional couplers and taps, attenuators, terminators, TV outlets, and any other required equipment. **\1**

12-13.4.1.2 Ethernet Network. /1/

A gigabit Ethernet network must be configured as a dedicated network including network switches, patch panels, FO and UTP cable, modular TV outlets, and equipment racks for the mounting of all equipment. The network must conform to TIA/EIA criteria standards. The fiber and copper cabling and network outlets required for this system are in addition to those required for the Telecommunications Infrastructure System (TIS) in this chapter.

12-13.5 TV Outlets and Signal Level.

TV outlets must be provided in these locations:

a. Waiting Rooms
b. Conference Rooms
c. Classrooms
d. Patient Education rooms
e. Lounges
f. Inpatient Behavioral Health Activity rooms
g. Behavioral Health Group Therapy rooms
h. Patient bedrooms
i. Emergency exam treatment rooms

For Coaxial/RF based systems, the TV signal level at each TV outlet must be between +3 dBmV and +9 dBmV.

12-13.6 Flat-Panel HDTVs and Connecting and Mounting Items Configuration.

Provide devices to interface the flat-panel HDTVs with the TV distribution network. **\1\ /1/** Provide jumper cables for connection of the flat-panel HDTVs to the TV outlet jack and any network interface devices. The cable between the network interface device and the HDTV must be an HDMI cable.

Provide wall brackets and furniture mounts for the mounting of all flat-panel HDTVs. Coordinate the requirements for in-wall support plates for wall mounting brackets with the architectural and structural design, and the requirements for casework or furniture mounts with the architectural design and the PRC List.

12-13.7 Electrical Power.

Provide a quad AC power receptacle at all TV outlet locations. The AC power receptacle must be mounted in a separate back box from the TV outlet back box and be located adjacent to the TV outlet.

12-14 ELECTRONIC SECURITY SYSTEM (ESS).

Electronic security system requirements are included in Chapter 5 Antiterrorism (AT) and Physical Security and in Appendix A.

12-15 RADIO AND PUBLIC ADDRESS (PA) SYSTEM.

12-15.1 System Purpose.

Provide a zoned loudspeaker paging and zoned music program system that must evenly distribute recorded or live voice messages or recorded music throughout designated areas of the facility. The distributed sound must be free of noise and distortion. It must be balanced and highly intelligible per the Modified Rhyme Test (MRT) of ANSI/ASA S3.2. The system must be capable of individually and simultaneously paging all separate independent zones provided by the system configuration.

12-15.2 System Components.

Provide the following system components:

12-15.2.1 Headend Equipment.

12-15.2.1.1 Equipment Racks.

Provide floor-mounted equipment racks and double sided cable management to house all headend equipment.

12-15.2.1.2 Auxiliary Inputs.

Provide rack space and preamplifier input ports to support the specified number of auxiliary inputs identified by the DoD Project Sponsor in coordination with the facility Information Technology Representative. The rack space and input ports must support a minimum of two auxiliary inputs.

12-15.2.1.3 Distribution Equipment.

Provide mixer-preamplifiers, power amplifiers, mixer amplifiers, input modules, partial octave graphic equalizers, and input selection switches for connecting program inputs to the distribution system.

12-15.2.1.4 Monitor Panel.

Provide a system monitor panel with selector switch and speaker to check each zone output, voice input, and zone selection.

12-15.2.1.5 Telephone Interface Couplers.

Provide telephone interface couplers for loudspeaker paging. The telephone interface must be coordinated with Installation Telecommunications service provider. The number and type of telephone lines provided must be based on the system configuration. There must be one unique telephone number provided for each local loudspeaker paging zone and the all-call loudspeaker paging to all zones in the system.

Telephone system interface equipment must be provided as part of the PA system. Loudspeaker paging control functions such as call answer, tone announcement before the page, and automatic preset time out must be accomplished by the telephone interface couplers.

a. Coordinate and define the telephone system interface and programming requirements for loudspeaker paging access with the DoD Project Sponsor.

b. Local zone loudspeaker paging access from the telephone system must be programmed for access only from telephones within the local zone.

c. Wide area and all-call loudspeaker paging access from the telephone system must be restricted to selected telephones as defined by the DoD Project Sponsor.

12-15.2.2 Loudspeaker System.

Provide low power loudspeakers for uniform sound distribution at low volume levels. For maximum coverage, corridor speakers must be spaced apart at a maximum distance that is twice the ceiling height. Provide speakers with separate volume controls in individual rooms. Volume control and bypass relay features must be provided for paging speakers in designated areas as defined by the DoD Project Sponsor. The bypass relay must allow for all-call paging to bypass the local volume control and be audible at normal system volume. Speakers will not be provided in normally occupied spaces such as patient bedrooms, offices, exam rooms, procedure rooms, Emergency exam treatment rooms, and procedure rooms. Provide speakers that are designed to provide even sound dispersion over the 20 Hz–20 KHz frequency range within the entire speaker coverage area.

12-15.2.2.1 Indoor Loudspeaker Assemblies.

Provide cone speakers with enclosures and baffles in all indoor locations.

12-15.2.2.2 Outdoor Loudspeaker Assemblies.

Provide weather resistant cone speakers with enclosures and baffles in outdoor ceiling locations. Provide horn speakers in outdoor wall mount locations.

12-15.2.3 Microphones.

Provide the type and quantity of microphones with control switches and mounts identified by the DoD Project Sponsor in coordination with the facility Information Technology Representative.

12-15.3 System Configuration.

Provide a system configured in accordance with these specifications:

12-15.3.1 All Call Capability.

Provide an ‘all zone’ paging capability, which will have priority over all other paging functions in the facility except the Mass Notification System, as described in Chapter 14 Fire Protection and Life Safety. The All Call capability may be accessed via a microphone, telephone, or both. The microphone access must have priority over the telephone access for all zone types.

12-15.3.2 Local Zones.

Provide local loudspeaker paging zones for all areas and services of the facility where patients are seen for diagnosis or treatment. Local zones must be accessed using the telephone system, microphones, or both, as defined by the DoD Project Sponsor in coordination with the facility Information Technology Representative. All Call paging must override local and zone paging. The ability to control loudspeaker volume must be provided from a controlled access area inside the local zone floor space.

12-15.3.3 Medical/Dental Zoning.

Provide two separate wide area zones, one for medical and one for dental, where these services are combined in a facility. An All Call for the entire facility must be provided.

12-15.3.4 Auditorium Zone.

In a facility that has an auditorium equipped with an AV system (reference paragraph 12-17), loudspeaker paging in the auditorium must be limited to only the All Call loudspeaker paging.

12-15.3.5 Microphone Applications.

Telephone system input is the preferred method and must be provided for all systems and zones. The DoD Project Sponsor in coordination with the facility Information Technology Representative provides guidance on the number and location of microphone stations, which must be limited.

12-15.4 System Performance.

The loudspeaker system must provide even sound distribution throughout the designated area, +/-3 decibel (dB) for the 1/1 octave band centered at 4,000 Hz. The system must provide uniform frequency response throughout the designated area, +/-3 dB as measured with 1/3-octave bands of pink noise at locations across the designated area selected by the Contracting Officer. The system must be capable of delivering 75 dB average program level with additional 10 dB peaking margin sound pressure level (SPL) in the area without causing the associated amplifier to exceed normal operating specifications for power or distortion. Unless otherwise specified, the reference SPL is 20 micro pascal. The minimum audio SPL to ambient noise ratio must be at least +15 dB in all areas. The system must not have any audible hum, noise, buzz, or rattle at a

loudspeaker. The electrical/acoustic signal-to-noise ratio for the entire system must be a minimum of 66 dB.

12-15.5 Electrical Power.

PA system equipment in inpatient MTFs must be powered from the essential electrical system emergency power life safety branch per Table 12-1. AC powered equipment must be protected by a UPS unit that must provide a minimum of 15 minutes of full power during an AC power failure. All UPS units must comply with UL 1778 and 47 CFR Part 15.

12-16 SOUND REINFORCEMENT SYSTEM.

12-16.1 Purpose.

Provide distortion and noise-free, highly intelligible (per the MRT of ANSI/ASA S3.2), balanced, and evenly dispersed sound reproduction and reinforcement from multiple sources to an audience in auditoriums and large conference rooms as required by the DoD Project Sponsor.

12-16.2 Inputs.

The sound reinforcement system must accept input from multiple sources such as wired and wireless microphones, digital audio, video programming and playback devices, and PC-based programming. **\1\ /1/** The system must address the specific functions of the space where it will be located in relation to the number and types of inputs.

The major components of the system must consist of, but not be limited to:

a. Preamplifiers and power amplifiers
b. Partial octave graphic equalizers
c. Sound mixer/amplifier
d. Wired microphones with goose neck stands
e. Wired handheld microphones
f. Wireless microphones and wireless receivers
g. Compact disc (CD)/digital video disc (Blu-Ray) recorders/players
h. Auditorium wireless hearing assistance systems
i. Auditorium sound combiner and switching
j. Volume controls
k. Auxiliary input ports to support a minimum of two sources with preamplifiers and rack space for auxiliary source equipment
l. Speakers to include enclosures and baffles

12-16.3 Headroom.

Provide a system with a minimum of 3 dB of headroom.

12-17 INTEGRATED AUDIO VIDEO SYSTEMS (AV).

Provide an integrated AV system for an auditorium or a large conference center. The auditorium or conference center will have the ability to simultaneously perform all required functions in all sections of the auditorium, or in the conference center that may be divided into multiple spaces by moveable partitions.

a. Audio functions must be provided to allow for the functions described in paragraph 12-16. In addition to those functions, provide monitor speakers for the stage area. Provide for sound feedback monitoring and stabilization. Provide wireless hearing assistance systems in auditoriums with receivers for a total of 5 percent of the auditorium capacity. Provide surround sound capability.

b. Provide the ability to display video from various sources and ensure that the display will be visible from all areas of the auditorium or conference center. Provide a video feedback screen that will allow the presenter to see what is being displayed. Provide a motorized screen and data projectors or appropriate large flat-panel displays as specified by the DoD Project Sponsor and per the PRC. Provide a control room to house equipment and a control console station. Provide the capability to record and reproduce presentations.

c. Provide a control console that includes video switching capability, audio switching and mixing, pan tilt zoom (PTZ) camera controls, motorized screen control, and lighting control for the auditorium or conference center.

d. Provide the capability to control motorized screens, audio volume, recording capability, and microphones from a podium or control station.

e. Provide the capability to interface with the ITV System for the live broadcast of programs when indicated by the DoD Project Sponsor.

12-18 PHYSIOLGICAL PATIENT MONITORING SYSTEM.

An empty conduit system with pull cords must be provided for the installation of the physiological patient monitoring system equipment and cabling. All equipment including monitors, computers, and printers must be connected to the critical branch of the EPS. A GFGI UPS must be provided by the DoD Project Sponsor and comply with the DHA Performance Standard Section 27 52.13.

12-18.1 System Requirements.

Data entry points must be monitored by a central computer. A minimum of one **\1** 4 11/16 in. (120 mm) by 4 11/16 in. (120 mm) by 2 1/8 in. (55 mm) deep back box and one 1 in. (25 mm) conduit with pull cord **/1/** must be provided from each data entry point to the communication system cable tray. Conduits with pull cords must be provided from the central physiological monitor computer location to the communication system cable tray.

12-18.1.1 Locations.

At a minimum, data entry and monitor points must be provided as specified here. Provide conduit to the printer and monitor at each Nurse Station if the system is not networked.

a. Emergency trauma rooms, exam treatment rooms and patient care stations, nurse stations

b. Patient bedrooms to include critical care, medical/surgical, L&D, and post-partum

c. Surgical Services Operating rooms with outlet located in the ceiling service console, Phase I and II post-anesthesia recovery patient care stations and nurse stations, and the anesthesia work room

d. Special Procedure rooms to include coronary, neurological or peripheral angiography, electrophysiology procedures, cystoscopy, bronchoscopy, colonoscopy, and endoscopy

e. C-Section Delivery rooms and associated recovery patient care stations

12-18.2 Fetal Monitoring.

A conduit with pull wire must be provided from each L&D patient labor and delivery room (LDR/LDRP, C-section OR), antepartum bedroom, L&D stress testing room and triage exam room, to a pull box above the ceiling at the associated Nurse Station. A minimum of one conduit with pull wire must be provided from the pull box to the Nurse Station for the monitors.

12-18.3 Neonatal Monitoring.

A conduit with pull wire must be provided from each NICU, isolation and newborn nursery bassinet location, LDR/ LDRP, and postpartum bedroom to a pull box above the ceiling at the associated Nurse Station.

12-18.4 Anesthesia and Respiratory Gas Analysis System.

Conduit with pull wire must be provided to the anesthesia workroom, where the analyzer and central processing unit are to be located, from:

a. Each OR ceiling column

b. 25 percent of the patient service consoles serving each Phase I and II post anesthesia recovery patient care station, to include isolation rooms

c. Each special procedure room at the head of the table

d. Each C-section delivery recovery patient care station service console

Conduit must be provided to the anesthesia administrative suite and to the blood gas lab for printer or cathode ray tube units. All conduit must be installed from the outlet to the cable tray system.

12-19 EMERGENCY MEDICAL SERVICE (EMS) COMMUNICATIONS.

The EMS system consists primarily of GFGI radio equipment, which is used for voice and telemetry communications with military and civilian ground and air ambulances.

12-19.1 Electrical Power.

Provide power for all radios and remote control units from the life safety branch of the emergency system.

12-19.2 Empty Conduit and Boxes.

Provide junction boxes and empty conduits with pull strings for the installation of cables. Identify system(s) and their location(s) as indicated by the DoD Project Sponsor, that must be connected utilizing the facility TIS. Provide conduits from the EMS communications equipment to the antennas mounted on the roof and conduits for coaxial and control cables from the Ambulance Dispatch to the associated head end equipment.

12-19.3 Structural Support.

Provide structural support and sufficient mounting space for the antennas.

12-20 EMS RECORDER SYSTEM.

Provide a multichannel recorder system as required by the DoD Project Sponsor for inpatient Facilities. The system must include these functions and features:

12-20.1 EMS Recorder Function and Features.

The EMS recorder must typically be installed in the Ambulance Dispatch area. The system must be used to record voice communications on selected telephone lines and all EMS radios. The telephone lines recorded must include, but are not limited to, all active lines of the Emergency Department Nurse Station and the Ambulance Dispatch telephones. The actual lines to be recorded must be defined by the DoD Project Sponsor. Two-way audio communications from each of the EMS radios must be recorded. The recorder must, at a minimum, have these features:

a. Recording media must have a minimum of 24 hours of recording capacity.

b. A minimum of ten channels plus one channel that records time in hours, minutes, and seconds for record retrieval. Channels must be calculated as one channel per each monitored telephone line, and one additional channel for each radio service monitored.

c. A microprocessor-based control system that provides system control and diagnostics.

d. A rapid search system that enables fast retrieval of time-dated information.

e. Search and playback capability from digital memory while the system continues to record the prescribed channels.

12-20.2 System Inputs and Mounting.

The system must accommodate multiple input impedances to allow recording from the varied media components. The system must be rack-mounted in a free-standing cabinet.

12-21 OTHER PROVIDED SYSTEMS.

Reference MILSTD 1691, Section 6 for a full list of RPIE and PP systems provided on individual projects under separate funding from MILCON.

For RPIE and PP systems, provide electrical power to support the identified additional systems in accordance with the electrical code and Table 12-1.

12-21.1 Empty Conduit and Boxes and Cable Trays.

Provide junction boxes and empty conduits with pull strings for the installation of cables. Calculate cable requirements into cable tray capacity calculations and provide adequate cable tray capacity to support any of additional systems. Identify the additional system(s) and the location(s) that is to be connected utilizing the facility TIS. Provide outlets, wiring and patch panel capacity in TRs to support these systems.

12-21.2 Structural Support.

Provide structural support and sufficient mounting space for the antennas.

12-21.3 Equipment Space Support.

Provide floor space, port capacity, rack space, etc. as required to support these systems. Include this equipment in the Server Room (CMP01), head end equipment room (COM04) and Telecommunications Room Floor Space Calculations as required.

CHAPTER 13 ACCESSIBILITY PROVISIONS FOR THE DISABLED

13-1 GENERAL.

This chapter provides design guidance on the application of accessibility provisions within DoDM MILCON. All applicable facilities must be designed and constructed to be accessible to persons with physical disabilities in accordance with the ABA Accessibility Standard for DoD Facilities (DoD Standards) and implemented by DoD Policy Memorandum (Subject: Access for People with Disabilities) dated 31 October 2008.

13-2 GENERAL EXCEPTIONS.

Sites, buildings, and facilities are exempt to the extent specified by the ABA Accessibility Standard for DoD Facilities (DoD Standards).

13-3 DOD EXCEPTIONS/EXCLUSIONS.

Facility exceptions and exclusions to the DoD Standards are outlined in the DoD Policy Memorandum.

13-4 SPECIFIC MILITARY MEDICAL FACILITY REQUIREMENTS.

13-4.1 Parking.

Provide accessible parking and passenger loading zone facilities as required by paragraphs F208.2.1, Hospital Outpatient Facilities; F208.2.2, Rehabilitation Facilities and Outpatient Physical Therapy Facilities; F209.3, Medical Care and Long-Term Care Facilities; and complying with Section 502, Parking Spaces, and Section 503, Passenger Loading Zones, of the DoD Standards.

13-4.2 Patient Sleeping Rooms.

All patient bedrooms (sleeping rooms) and bedroom toilet rooms are to be accessible. Turning space, clear floor or ground space, and toilet and bathing rooms within patient sleeping rooms are to comply with Section 805, Medical Care and Long-Term Care Facilities, of the DoD Standards.

13-4.3 Patient Dressing Rooms.

All patient dressing rooms are to be accessible and located on an accessible route. In renovation projects, where structurally impracticable to make all dressing rooms accessible, one patient dressing room for each sex (or a unisex) on each accessible floor or level are to be made accessible.

13-4.4 Telephones.

If pay telephones are provided, comply with Section F217, Telephones, of the DoD Standards.

13-5 WAIVERS.

Any other deviation from the ABA Accessibility Standard for DoD Facilities must be made through the waiver process in accordance with the DoD Policy Memorandum.

CHAPTER 14 FIRE PROTECTION AND LIFE SAFETY

14-1 GENERAL.

This chapter provides policy and design guidance related to fire protection engineering and life safety for applicable facilities.

14-2 FACILITY FIRE PLAN.

Prepare the facility fire plan (as defined in NFPA 99) in accordance with the minimum requirements for “emergency action plan” in NFPA 101, which includes direct participation by designated stakeholders from the Installation, in order for a complete design to be executed and delivered.

14-3 LIFE SAFETY COMPLIANCE FOR BUILDING REHABILITATION.

Building rehabilitation will comply with the minimum requirements established in the chapter for “Existing Facilities” of UFC 3-600-01 as well as the contents of this section. For all projects involving rehabilitation work in facilities with either health care or ambulatory health care occupancies, where the classification of the work category includes extensive modification; reconstruction; changes of use; changes of occupancy classification; or addition in accordance with NFPA 101, the DoD Project Sponsor may evaluate existing facilities in accordance with the conditions established in this section to determine and document the original level of fire protection and life safety afforded the occupants in a report as part of the project initiation process.

14-3.1 Life Safety Assessment.

The preparation of a Life Safety Assessment (or LSA) is required for all projects in accordance with paragraph 14-3. Provide the LSA, including life safety plans, to the DoD Project Sponsor as well as to the facility for upload to the TJC electronic Statement of Conditions (eSOC) account as required to assist in the accreditation process at beneficial occupancy. For the purposes of meeting the requirement to prepare the LSA, the DoD Project Sponsor may require that the preparer of the LSA meet not only the minimum qualifications for the “Qualified Fire Protection Engineer” in UFC 3-600-01 but also has a minimum of seven years of experience in the design and review of medical facilities.

14-3.2 Health Care and Ambulatory Health Care Occupancies.

For health care and ambulatory health care occupancies as established by NFPA 101, it is acceptable to use a copy of the most recent TJC eSOC or Life Safety Assessment, provided either one has been updated within 12 months or less prior to project initiation for this specific facility.

14-3.3 Interim Life Safety Measures.

Develop and implement a specific set of safety measures, also referred to as Interim Life Safety Measures (or ILSMs) by TJC. Such safety measures consist of a series of administrative actions intended to temporarily compensate for significant hazards posed either by existing fire protection or life safety deficiencies to NFPA 101 or by such hazards resulting from construction activities. The ILSMs will be incorporated into the accompanying report to assist the project delivery team with scope of work development, design development, and construction execution.

14-4 AUTOMATIC SPRINKLER PROTECTION.

Provide automatic sprinkler protection as required by UFC 3-600-01, except as modified below in this section.

14-4.1 Components and Hardware.

Provide components and hardware for automatic sprinkler protection in accordance with UFC 3-600-01 unless otherwise modified herein.

14-4.1.1 MRI Shielded Enclosures.

Provide non-ferrous piping for all areas of MRI shielded enclosures.

14-4.1.2 Behavioral Health.

Provide quick-response “institutional sprinklers” throughout the fire compartment(s) or floor(s) in behavioral health areas that require hard ceilings (for example gypsum wallboard or plaster) and, these sprinklers must have the following performance characteristics.

a. Tamper-resistant features designed to make them more suitable than other types of sprinklers for installation in environments where vandalism is a concern, in order to reduce the likelihood of false activation and the possibility of the escutcheon (or any components of the sprinkler itself) from being removed and used as a weapon.

b. Ligature-resistant features designed to reduce the likelihood of attaching heavy loads to the sprinkler assembly and being able to use any component as an anchor point prior to failure of the sprinkler assembly.

c. However, in such areas with suspended ceilings (for example lay-in acoustical tile), develop and implement additional safeguards with approval from the Design and Construction Agent.

14-4.2 Audiometric Booths.

Extend automatic sprinkler protection into audiometric booths 16 sf (1.5 sm) or greater in area.

14-4.3 Defend in Place.

Where buildings are required to be separated into smoke compartments (as established by NFPA 101), subdivide and electronically supervise the automatic sprinkler protection accordingly (per smoke compartment). Provide all piping for automatic sprinklers in a given smoke compartment as one system and electronically supervise each compartment (or zone) using a dedicated control valve assembly (with associated check valve, waterflow indicator, and tamper supervision).

14-5 FIRE ALARM, FIRE DETECTION, AND MASS NOTIFICATION.

Provide fire alarm and fire detection, as required by UFC 3-600-01, and mass notification, as required by UFC 4-010-01, except as modified below in this section.

14-5.1 Autonomous Control Unit and Local Operating Console.

Provide autonomous control units (or ACUs). However, due to the nature of operations in medical facilities, provide accompanying local operating consoles (or LOCs) as directed by the Design and Construction Agent. Also, do not provide LOCs in normally unoccupied building service equipment support areas (or NUBSESAs) as established by NFPA 101.

14-5.2 Occupant Notification.

Provide occupant notification in accordance with NFPA 72 and NFPA 99 unless otherwise modified herein.

14-5.2.1 Direct Viewing.

Provide visual notification appliances in direct view of all exits, all nurses' stations, and at all locations, such as in mechanical equipment rooms, where the operating noise level exceeds the level of the audible alarm as permitted by NFPA 72.

14-5.2.2 Audiometric Booths.

Provide visual notification inside of an audiometric booth except where visual notification already being installed outside of the booth can be seen from an occupant within the booth.

14-5.2.3 Private Operating Mode.

Provide occupant notification, where the defend-in-place strategy is employed, in accordance with this subsection.

a. Permit the use of private operating mode, as defined and established in NFPA 72, in all facilities, excluding those facilities not rendering medical treatment to patients, for example, medical warehouses, central utility plants, and telecommunication buildings.

b. Carefully review and incorporate occupant notification, where the private operating mode is used, during the design, with a special emphasis on the additional duties, responsibilities, and associated training expected for the staff at the facility to learn and maintain.

c. Provide audible notification for all facilities in accordance with NFPA 72, except within Category 1 spaces (as defined in NFPA 99), such as surgical operating rooms, critical care rooms, or similar areas, where alarm activation is likely to cause injury or death to a patient.

d. Upon operation of a fire alarm initiating device, notify staff and occupants only in the zone of alarm origin via audible signaling using three-pulse temporal pattern, visible signaling, and textual signaling (where mass notification is either required or is being provided).

e. Simultaneously transmit a voice message to the rest of the building (and other buildings) as necessary in an effort to notify enough staff to respond to the zone of alarm origin. Do not activate visible appliances outside of the zone of alarm origin.

f. Subsequent activations of initiating devices in the same zone of alarm origin will not initiate any new alarm outputs but will appear at the fire alarm control unit and printer. Subsequent to the original alarm, activation of initiating devices in a different zone will initiate the audible three-pulse temporal signal and other related visual and textual notification appliances in the new zone and will initiate a new voice message to the locations, as determined above, to identify the new location of alarm.

g. Program both audible and visual signals to continue to operate for five minutes or until the system is acknowledged and silenced by an operator. Only activate the visual notification appliances in the zone of alarm origin and not in the zones where the voice message is used.

h. The voice message is to be preceded by a tone alert and must be announced with no less than three rounds of it to bring staff to the zone of alarm origin.

i. Manual operation of the voice system will override all automatic voice messages in the system.

14-5.3 Smoke Detection Used in Conjunction with Smoke Compartmentation.

Where smoke detectors are provided to hold doors open between smoke compartments, provide them on both sides of the opening between smoke compartments. Program such smoke detectors for their respective zone to initiate the proper alarm as well as to close the door(s) served.

14-5.4 Behavioral Health.

Provide institutional-style manual pull stations in behavioral health areas, where keys are used to operate or lock covers.

14-6 MANAGEMENT OF SMOKE.

Provide smoke management and control systems in accordance with NFPA 92 and the appropriate sections of NFPA 101.

14-6.1 New Smoke Control Systems.

Zoned smoke control systems, as defined in NFPA 92, are not required for new projects.

14-6.2 Existing Smoke Control Systems.

Existing smoke control systems must comply with NFPA 92 or at the time of contractual acquisition of the system(s). Decommission zoned smoke control systems not in compliance with NFPA 92.

14-7 WATER SUPPLY.

Where the seismic chapter in this UFC requires on-site storage to be provided, design the secondary water supply to meet the largest expected demand for fire suppression purposes.

14-8 INTERSTITIAL BUILDING SYSTEM (IBS).

Comply with the related appendix in this UFC for projects incorporating IBS design concepts.

14-9 SPECIAL DETAILED REQUIREMENTS BASED ON USE AND OCCUPANCY.

This section provides specific criteria for medically unique occupancies and hazards. However, when this section does not otherwise address a particular occupancy or hazard, comply with NFPA 101.

14-9.1 Dental Treatment.

The following rooms are used to perform treatment or provide anesthesia, or both, which render the patient incapable of taking action for self-preservation under emergency conditions without assistance of others in facilities providing dental treatment:

a. Dental Treatment Room, Comprehensive [DNTC1]

b. Dental Treatment Room, Periodontics [DNTP2]

c. Dental Treatment Room, Oral Surgery [DNTS1]

d. Dental Treatment Room, Recovery [DNTR1] when provided in support of one of the above rooms.

When more than three of any combination of patient chairs, either in dental treatment rooms or associated recovery rooms, are located in a single facility; an occupancy classification of ambulatory health care is considered present and must be applied to either the entire facility or the portion(s) thereof containing these rooms.

14-9.2 Research Facilities.

Comply with the minimum requirements in NFPA 45 for laboratories where chemicals are used or handled. Comply with the minimum requirements of NFPA 2 in laboratories where hydrogen is used or handled.

14-9.2.1 Flame Spread and Smoke Developed Indices.

Provide and document flame spread and smoke developed indices for the interior finish installation for all walls, ceilings and floors in laboratories categorized as either Biosafety Level 3 (BSL-3) or Biosafety Level 4 (BSL-4), as established in Biosafety in Microbiological and Biomedical Laboratories, to ensure compliance with NFPA 101.

14-9.2.2 Spot-Type Photoelectric Detection.

Provide spot-type photoelectric smoke detection throughout laboratory spaces in facilities where laboratory function protocol requires occupants to be suited, for example, wearing positive-pressure, supplied-air protective suits.

14-9.3 Veterinary Care and Animal Research Facilities.

Throughout animal housing facilities classified as Animal Health Care (Category 1) or Research (Category 3), comply with the minimum requirements in NFPA 150 except as modified in this section. Since UFC 3-600-01 establishes that NFPA 5000 must not be used in projects for DoD, all references to NFPA 5000 in NFPA 150 are instead to be considered references to UFC 3-600-01, which identifies NFPA 101.

a. With regard to the provision of occupant notification, assume that evacuation of animals is not practical in animal research facilities (subclassified as Category 3 by NFPA 150).

b. Where fire alarm notification would adversely affect the needs of the animals and occupants subject to approval from the Design and Construction Agent and where private mode is already being employed, provide alternative notification devices (for example private-mode flashing lights or beacons) in animal areas.

14-9.4 Pharmacy Storage.

Storage spaces of pharmacies, including receiving areas and main shelving spaces, within health care and ambulatory health care occupancies are considered hazardous areas as defined by NFPA 101. Separate such storage spaces within pharmacies using one-hour fire-rated construction. Where pharmacy storage spaces are open to dispensing or other pharmacy work areas, provide the one-hour fire-rated separation at the pharmacy perimeter walls.

14-9.5 Areas with Heat-Producing Appliances.

Apply the minimum requirements from NFPA 101 for “special hazard protection” to any area(s) being served by Bunsen burners, which includes providing smoke partitions having passive fire protection features, such as automatic or self-closing door assemblies and protection of penetrations to limit the transfer of smoke.

This Page Intentionally Left Blank

CHAPTER 15 FURNITURE, FIXTURES AND EQUIPMENT

15-1 GENERAL.

This chapter provides guidance on furniture, fixtures and equipment (FF&E) for facilities. FF&E procurement and installation responsibility for project planning and execution must be in accordance with MIL-STD-1691 and this chapter. These sources provide a uniform basis to identify items of construction and material, and to identify logistical and financial responsibility.

15-1.1 IDENTIFICATION of FF&E.

The DoD Project Sponsor develops a PRC report of FF&E using the SEPS program report module. The determination of FF&E requirements must be made not later than the end of the 20% design period or final Request for Proposal (RFP) submission timeline, depending on project delivery method, and must be complete by the time the floor plan is locked. Consideration to reuse FF&E are dependent on the age, condition, remaining service life, and other maintenance considerations to the extent practical for the project. Final decisions on FF&E acquisition or reuse in support of all Initial Outfitting (I/O) activities must be completed as late as possible in project development but scheduled to align with facility operational milestones and project delivery method.

15-1.2 APPROVAL of SUBSTITUTIONS.

When design and space planning changes necessitate substitution of FF&E, the Design and Construction Agent must coordinate change details with the DoD Project Sponsor. When the substitution results in a change in the Logistical Category (LOGCAT) or equipment funding source as defined in the MIL-STD-1691, the change is coordinated with the DoD Project Sponsor.

15-2 PROCUREMENT.

Provide FF&E in accordance with MIL-STD-1691 and applicable project specific guidance. Procurement includes applicable manufacturer’s literature for installation, user operation and service/maintenance (including schematics). The DoD Project Sponsor determines which items of existing FF&E transfer to the new, altered, or temporary facility whenever feasible and economical.

15-3 FUNDING SOURCE

The Funding Source identifies the appropriation fund used to program, purchase and install building systems, FF&E, and control systems in Defense Health Program (DHP) project delivery. There are two property designations: “RPIE” (Real Property Installed Equipment), which are resources using “Project Funds”, and “PP” (Personal Property, sometimes referred to as operational equipment), generally referenced as “Initial Outfitting and Transition” or IO&T funds. Use of appropriations for outfitting of facilities is prescribed in Federal Management Regulation (FMR) Volume 03, Chapter 17.

15-4 LOGISTICAL RESPONSIBILITY.

Equipment is procured and installed in accordance with the LOGCAT as defined in the MIL STD 1691 Policy, and this document. The policy document can be found on the World Class Facility Toolkit.

The LOGCAT codes shown in Table 15-1 are used to identify procurement and installation responsibility. The responsibility column contains the acronym used to identify responsibilities of Government and Contractor relative to procurement and installation. The description column provides a definition of the LOGCAT code.

Table 15-1 Logistical Responsibility (LOGCAT)

LOGCAT	Responsibility	Description
A	CFCI	Contractor Furnished Contractor Installed. Equipment purchased and installed by the construction contractor.
B	GFCI	Government Furnished Contractor Installed. Equipment purchased or provided by the Government (or entity conducting business on behalf of the Government) and installed by the construction contractor.
C	GFGI	Government Furnished Government Installed. Equipment is provided by the Government and installed by the Government (equipment vendor, Initial Outfitting contractor).
D	Leased (VFVI)	Vendor Furnished Vendor Installed. Leased or rented equipment, arranged by the Government, or any similar type arrangement requiring special funding and/or condition.
R	GFCI or GFGI	Reuse. Transferred and reused equipment assets. May be Government Furnished Contractor Installed or Government Furnished Government Installed

15-5 DESIGN.

15-5.1 Casework.

All built-in casework must be fabricated and designated by materials, construction methods, and fabrication that align with the highest grade quality and infection control standards for casework for use in high-performing healthcare building applications. Typical industry standards for medical/laboratory grade materiel applied in the absence of project specific requirements/guidance. Corrosion resistant steel (CRS) or other nonporous, seamless joint casework are mandatory in these areas: operating and C-section rooms; their sub-sterile and clean-up areas; laboratory (as required by the DoD Project Sponsor); central sterile supply, decontamination and clean-up areas (including Dental); Autopsy and its associated clean-up areas.

Movable, modular (“systems”) casework systems may be used in projects deemed appropriate by the DoD Project Sponsor.

15-5.2 Technically Complex Equipment and Medical System.

Planning for and inclusion of complex medical technologies, to include but not limited to linear accelerators, positron emission tomography (PET), lithotripsy units, MRI systems, hyper and hypo baric chambers, robotic surgical systems, and automated product delivery systems, in a MILCON project is the responsibility of the DoD Project Sponsor. Design must be in accordance with the appropriate Code of Federal Regulations (CFR), National Council on Radiation Protection and Measurements (NCRP) guidelines, associated non-governmental standards for unique technologies, the recommendations and guidance of the respective manufacturer, Facility Guidelines Institute (FGI) and other federal entities as applicable. Close coordination by the DoD Project Sponsor, design team, and manufacturer’s technical representatives is critical to ensure staff and patient safety measures are in place, and all clinical functionality and capability is met.

15-5.2.1 Shielding Requirements.

When equipment or systems require shielding to minimize exposure to primary and secondary radiation, the DoR is responsible to include on the design team a qualified expert (medical or health physicist) who is regularly engaged in the design of radiation shielding, and certified by American Board of Radiology, American Board of Medical Physics, American Board of Health Physics, or Canadian College of Physicists in Medicine. The using MilDep’s Health Physicist or their qualified representative must be consulted during the early planning and/or design stages to ensure all aspects of the design, both clinical and technical, are met, and shielding reports are retained by the DoD Project Sponsor for audit purposes.

The Construction Contractor is responsible for the shielding system installation and integrity certification by a qualified expert. It is highly recommended that the Construction Contractor consult with the using MilDep’s Health Physicist or their qualified representative during design and construction to ensure continuity from planning and design through final building acceptance.

15-5.3 Equipment Connectivity.

The project delivery team (PDT) must work closely with Health Information Technology and Logistics staff early in planning and throughout the design and construction phases to make every effort to comply with cybersecurity requirements for Facility-Related Control Systems and Medical Devices and Equipment. The design for equipment and utilities that support active and passive medical devices must comply with the Standard Isolation Architecture for Cybersecurity of Medical Devices and Equipment (MDE) as well as cybersecurity principles based on medical cybersecurity industry best practices.

15-5.4 Automatic External Defibrillator (AED).

The location and number of recessed or semi-recessed Automatic External Defibrillator (AED) cabinets is determined during project design. The DoR is responsible to ensure quantity, placement, and all appropriate markings (signage) are shown in the final design solution. The DoR coordinates with the Design and Construction Agent and DoD Project Sponsor clinical representative to ensure adequate placement and facility coverage.

15-5.5 Hyperbaric Medicine.

Hyperbaric oxygen therapy is used as an adjunct to the clinical and surgical treatment of wounds and certain diseases. It consists of administering oxygen to the patient at pressures greater than 1 atmosphere (atm) in a compressed air multi-person chamber or oxygen mono-chamber. The DoD agency responsible for design requirements and certification is the Naval Facilities Engineering Command. This agency is available to assist the Design and Construction Agent, DoD Project Sponsor, and DoR as needed. Reference UFC 4-159-01N.

CHAPTER 16 TRANSPORTATION AND LOGISTICS

16-1 GENERAL.

This chapter provides guidance for the study, selection, and design of transportation and logistics systems including but not limited to; elevators, escalators, dumbwaiters, material delivery equipment (automatic guided vehicles [AGVs] and Autonomous Mobile Robots [AMRs]), pedestrian traffic, service cart systems, pneumatic tube station (PTS), gravity and pneumatic chute return systems for linen and trash, and Central Material Management Systems in CAT 500 facilities. The elevator UFC 3-490-06, in conjunction with criteria in this chapter, establish minimum design requirements. In the event of conflict this UFC is the ruling criteria.

16-1.1 Scope.

This chapter applies to horizontal and vertical circulation within facilities, and the transportation devices, equipment, and methodologies required for efficient, cost-effective, and timely movement of people, equipment, materials, and related materials-management logistical functions. Addition/alteration projects are to meet these guidelines to the extent practical and provide a holistic design approach in addressing correction of existing facility shortcomings.

This chapter does not prescribe when systems are required or where they should be employed. Table 16-1 prescribes when different technical analyses are required based on a facility's size; depending on the results of the analysis different transportation systems may be required. It is the responsibility of the DoR to develop a holistic and efficient design incorporating the DoD Project Sponsor's operational and functional needs.

16-1.2 Transportation Systems Evaluation.

For all projects requiring a Transportation Logistics Analysis (TLA) as described in paragraph 16-2.1, the Design and Construction Agent must ensure the services of a qualified Medical Transportation and Logistics Consultant (MTLC) are included in the request for planning and architectural services. The MTLC must be an integral part of the design team, and be involved in every aspect of the design as it relates to transportation and logistics. This includes, but is not limited to, departmental adjacencies, vertical and horizontal circulation, facility logistics, and waste management. Refer to Table 16-1 for project analysis requirements.

The Design and Construction Agent must ensure all transportation and material handlings systems selected are procured, installed, and commissioned in accordance with design documents and applicable codes and standards.

16-1.3 Medical Transportation and Logistics Consultant.

A qualified MTLC to the DoR is an individual who has received comprehensive training and experience in the areas of materials management, food and nutrition, solid waste

management, horizontal and vertical transportation, central sterile processing, and materials handling for a period of not less than five years. These services should be specific to transportation and logistics and must be documented. The MTLC must demonstrate prior experience on projects that relate to the scope and nature of the project to include OCONUS locations, if applicable. The MTLC must not be involved in the sale, installation, distribution, manufacture, or representation of conveyance or material management equipment.

Table 16-1 Analysis Requirements

Analysis	Facility Characteristic
TLA	Any facility >200,000 BGSF (18,580 BGSM) All major renovations and new construction of ambulatory care clinics, hospitals, and medical centers
ETSA	All facilities >1 story
MMA	All facilities >100,000 BGSF (9290 BGSM)
WMA	All facilities >100,000 BGSF (9290 BGDM)
Notes: Facilities include medical and dental clinics, research and laboratory buildings, ambulatory care clinics, ambulatory surgery centers, hospitals, and medical centers.	
ETSA	Elevator Traffic Study and Analysis
MMA	Material Management Analysis
TLA	Transportation Logistics Analysis
WMA	Waste Management Analysis

16-2 TRANSPORTATION AND LOGISTIC ANALYSIS REQUIREMENTS.

Different transportation and logistics analyses are required for facility designs as indicated in Table 16-1. These analyses must address the transportation, logistics, and waste management requirements of the project as required by this document. When required by Table 16-1, the different analyses must be submitted with the Design Analysis narratives beginning with the initial design submission and through the final design submission.

16-2.1 Transportation Logistic Analysis.

The MTLC must prepare a TLA in accordance with Table 16-1. The analysis must take into account total staff and patient travel times and travel distance with the objective of minimizing both travel times and distances to achieve higher staff efficiencies and lower patient environmental exposure.

16-2.1.1 TLA Requirements.

The TLA must address all aspects of a facility's transportation, logistics, and waste management methodology to include but not limited to; traffic demand, vertical and horizontal travel distances, mix of traffic type in the areas to be served, mode of containerization, and items specifically addressed in the other studies. The TLA must document the following:

a. Elevator Traffic Study and Analysis (ETSA). Reference paragraph 16-2.2.

b. Material Management Analysis (MMA) to include a comparison of automatic vs. manual material handling systems. Automatic systems include: AGVs, AMRs, PTS, and pneumatic chutes in addition to other or newer technologies. Reference paragraph 16-2.3.

c. Waste Management Analysis (WMA). Reference paragraph 16-2.4.

d. Life cycle cost analysis (LCCA) to be used to evaluate the alternatives and to determine the appropriate system.

e. The MTLC to sign the TLA certifying the information contained therein is accurate, vendor neutral, and based on empirical data.

f. The TLA to take into account the existing transportation systems and processes for addition/alteration projects.

g. The TLA to describe in detail the MTLC recommendations to maximize the transportation and logistics efficiencies and how the recommendations are implemented into the design.

h. The TLA to focus on defining process methodologies that optimize spatial adjacencies and minimize overall patient, staff, and material movements in design.

i. When required by the Design and Construction Agent, the TLA to include the use of simulation to more accurately analyze and optimize departmental adjacencies and horizontal and vertical transportation solutions.

16-2.1.2 TLA supporting documents.

Base the TLA on:

a. Empirical data provided by the DoD Project Sponsor.

b. Site visits to an existing facility identified by the DoD Project Sponsor.

c. Data including site constraints, Design CONOPS (including CONOPS for the logistical departments like food service, linen and waste management, materials management, housekeeping, pharmacy, central sterile supply) and projected workload for the new facility.

d. Elevator loading density and the load/unload time based on site visits to account for unique conditions at a facility and the cultural aspects of the area, for example, amount of “personal space” required by individuals, number of visitors per patient, number of escorts or companions accompanying outpatients.

16-2.2 Elevator Traffic Study and Analysis.

Prepare the ETSA to determine the appropriate types, locations, sizes, speeds, and groupings of elevators that result in a cost-effective and efficient operation.

16-2.2.1 ETSA Requirements.

The ETSA must document the following:

a. ETSA to be prepared by an independent elevator consultant on all ambulatory care clinics, hospitals, and medical centers.

b. Conformance to Chapter 16, specifically paragraphs 16-3 and 16-4.

c. A description of the elevator systems proposed (each elevator type should be broken down separately based on types per Table 16-4), function, travel, stops, building population, handling capacity, interval, etc.,) including an analysis with drawings of the walking distances, elevator types, and locations as described in paragraph 16-4.3. Prohibit the use of general terminology of “electric traction”. MRL elevators are to be separate and specifically identified. Otherwise, the default for language associated with electric traction would be geared or gearless traction with machine room.

d. The population (number of working and visiting population within the facility).

e. The number and average size of material movements within the facility.

f. The peak hours of vertical transportation, including but not limited to: Morning Shift Change Peak (primarily a peak period in upward travel), Lunch Peak (heavy two-way traffic), Afternoon Shift Change Peak (primarily a peak period in downward travel, with moderate opposing traffic).

g. The elevator loading densities used for each proposed elevator for working and visiting population, for example, pedestrians, person on crutches/walker, wheelchairs, gurneys, beds, and carts. Include extra “spare capacity” when determining the aggregate elevator cab size.

h. In determining the proposed elevator speeds provide:

i. The handling capacity calculations

j. The assumed population load/unload times

k. The proposed elevator wait and response times

Table 16-2 Elevator Performance Guide

Table presents minimum acceptable elevator performance based on elevator type and building type.

PASSENGER ELEVATORS		
Building Type	**Average Interval Required**	**Handling Capacity**
Hospital, medical center, or ambulatory surgery center	30 to 35 Seconds	13 - 15% of the calculated building elevator population for the area served (plus 20% migration for multiple elevator groups)
Medical clinic, dental clinic, or ambulatory care clinic	35 to 40 Seconds	11 - 13% of the calculated building elevator population for the area served (plus 20% migration for multiple elevator groups)
Research or laboratory building	40 to 45 Seconds	11 - 13% of the calculated building elevator population for the area served (plus 10% migration for multiple elevator groups)
Admin building	40 to 45 Seconds	10 - 12% of the calculated building population
Parking garage	45 to 50 Seconds	110% of the calculated elevator population for the area serviced
Notes:		
1	Passenger elevators are intended for use by the public. (See paragraph 16-4.2 and Appendix H for definitions)	
2	Passenger elevators to be Class “A” loading as a minimum	

PATIENT SERVICE ELEVATORS		
Building Type	**Average Interval Required**	**Handling Capacity**
Hospital, medical center, or ambulatory surgery center	35 to 40 Seconds	115% of the calculated traffic
Medical clinic, dental clinic, or ambulatory care clinic	40 to 45 Seconds	110% of the calculated traffic
Notes:		
1	Patient Service elevators are intended for use by staff movement and for the transport of bed-bound inpatients. (See paragraph 16-4.2 and Appendix H for definitions)	
2	Service/Staff elevators to be Class “C3” as a minimum	

MATERIALS HANDLING SERVICE ELEVATORS		
Building Type	**Average Interval Required**	**Handling Capacity**
Hospital, medical center, or ambulatory surgery center	35 to 40 Seconds	13 -15% of the calculated elevator population for the area served (plus migration)
Medical clinic, dental clinic, or ambulatory care clinic	40 to 45 Seconds	11 - 13% of the calculated elevator population for the area served (plus migration)
Research or laboratory building	45 to 50 Seconds	11 - 13% of the calculated elevator population for the area served (plus migration)
Notes:		
1	Logistics elevators are intended for use by staff for material and equipment movement. (See paragraph 16-4.2 and Appendix H for definitions)	
2	Logistics elevators to be Class “C1” as a minimum

Poor – Under 10%</td></tr>
</table>

16-2.3 Material Management Analysis (MMA).

Material to be manually moved throughout a facility unless the designer can show an automated system is physically, safely, and economically justified. The specific systems included in a project must be determined by detailed physical, functional, and economic factors including LCCA. Prepare the MMA to determine the appropriate types, locations, sizes, speeds, and design of MMA that result in a cost-effective and efficient operation.

16-2.3.1 MMA Requirements.

The MMA must document when the DoD Project Sponsor does not require an automated system and continue no further. When required, the MMA must document the following:

a. Conformance to Chapter 16, specifically paragraphs 16-3 and 16-5.

b. Proposed automated systems including but not limited to AGV, PTS, and mobile robots.

c. The users of the proposed systems.

d. The number of Full-Time Equivalent (FTE) on staff for the movement of materials.

e. Location, size, speeds of proposed systems.

f. Specific requirements for each type of system, for example, dry vs. wet PTS.

g. An LCCA comparing manual movement vs. proposed alternatives.

16-2.4 Waste Management Analysis (WMA).

The preliminary design of a waste management system requires consideration of the operational and mission characteristics of the facility, the existing waste disposal practices of the facility or base/post, the governmental regulations affecting the design, and the costs and application of system handling and disposal technologies.

16-2.4.1 WMA Requirements.

When required, the WMA must document the following:

a. Conformance to Chapter 16, specifically paragraphs 16-3 and 16-6.

b. Determination of the waste stream components and soiled linen types.

c. Estimation of waste and soiled linen volumes.

d. Concepts for segregation, holding at the generating departments, and central bulk holding.

e. Space, utility, and life safety requirements for departmental holding rooms.

f. Concepts for collecting and transporting waste and soiled materials within the facility.

g. Soiled dock arrangement, layout, and equipment.

h. Waste Management Center (WMC) space, layout, equipment, and support utility requirements.

i. Concepts for the disposal of each waste category.

j. Proposed Waste Management Systems including, but not limited to, gravity chutes and pneumatic trash/linen systems.

k. Life-cycle costing studies including Regulated Medical Waste (RMW) processing equipment.

l. Aspects of RMW processing; O&M, safety, infection control.

m. Accommodations for empty wood pallet(s) storage and pick up area

16-3 FACILITY DESIGN.

Transportation and logistics requirements must be integrated into the overall facility design. Design the overall floor plan and circulation to provide the most direct routing practical. Separate different types of traffic as required in paragraph 16-3.1.

16-3.1 Traffic Separation.

Establish traffic patterns to separate the various traffic types in an efficient, logical, safe, and secure manner, while maintaining levels of aseptic control consistent with the requirements of the facility. Consider all of these factors for separation for horizontal and vertical circulation: patient privacy; accessible access; aseptic control; routing efficiency; utilization of appropriate hardware systems, safety, and security. Where circulation conflicts occur, prioritize traffic as listed here:

a. Patient

b. Staff

c. Equipment

d. Visitors

e. Materials/logistics (may be combined use – supply elevators with staff)

16-3.2 Transportation Systems.

The DoR must consider traffic demand, vertical travel distance, mix of traffic type in the areas to be served, and mode of containerization. Traffic demand and vertical travel distance must determine equipment type and speed required. Traffic mix and mode of containerization must determine load capacity, platform size, configuration, and door type.

16-3.3 Vertical Automation.

Systems designed exclusively for vertical only transportation of materials on carts must use elevators, guide path, and other devices, as applicable. Designs must consider future upgrade to allow horizontal travel.

16-3.4 Equipment/Materials Separation.

Separate the equipment/materials traffic from patient and visitor traffic as noted on the Elevator Traffic Separation Guide, Table 16-3, which presents recommended arrangement of elevators by facility configuration and mission. Where separate elevators are not required, separate the materials traffic by schedule and policy. Maximize separation between visitor/patient and staff/materials/logistics. Primary horizontal materials circulation should occur on a single level, with vertical penetrations that are convenient to heavy use areas. Do not move AGVs, carts, pallet trucks, and similar material carriers long distances on floors and corridors routinely traveled by patients or visitors. Use two (or more) single elevators in distributed areas if traffic needs dictate more than one service/AGV elevator.

16-3.5 Clean and Soiled Material Separation.

Materials management programs must provide for clean and soiled separation consistent with all applicable codes and standards, including those of TJC.

16-3.5.1 Soiled Material.

Soiled materials are normally transported in separate covered or closed carts designed to provide containment of the material and to maintain infection control. Soiled material transport may occur in the same corridor and elevator systems that handle other traffic. However, soiled materials are not transported on the same elevator at the same time with patients, visitors, or clean or sterile materials. Transport circulation design must allow soiled carts to be properly washed prior to reuse as a soiled container and washed and sanitized prior to use for transporting clean materials.

16-3.5.2 Sterile Material.

Transport all sterile material for use in Surgery, Catheterization, and Labor/Delivery or other areas requiring sound aseptic controls from the sterile processing/storage area to its destination via a clean route that must not compromise the integrity of the material. Where case carts are used, they must be transported from sterile storage to the clean surgical core by means that protect the cart and its contents from contact with less clean environments.

16-3.6 Escalators.

Escalators may be considered if justified by traffic studies. Design escalators in accordance with all applicable codes, including UFC 3-490-06, IBC and ASME A17.1, A17.3, and A17.5.

Table 16-3 Elevator Traffic Separation Guide

	Facility Types				
Facility Characteristics	**Hospital, medical center, or ambulatory surgery center**	**Medical clinic, dental clinic, or ambulatory care clinic**	**Research or laboratory building**	**Admin building**	**Warehouse or parking garage**
Facilities <50,000 BGSF (4645 BGSM)	Separate Passenger. Separate Inpatient. Separate Materials Traffic	Combine regardless of traffic types	Combine regardless of traffic types	Combine regardless of traffic types	Combine regardless of traffic types
Facilities >50,000 but <100,000 BGSF (>4645 BGSM but < 9290 BGSM)	Separate Passenger. Separate Inpatient. Separate Materials Traffic	Combine elevators or Separate Passenger and Materials Traffic	Combine elevators or Separate Passenger and Materials Traffic	Combine elevators or Separate Passenger and Materials Traffic	Combine elevators or Separate Passenger and Materials Traffic
Facilities >100,000 but <200,000 BGSF (>9290 BGSM but < 18580 BGSM)	Separate Passenger Traffic. Separate Inpatient Traffic. Separate Materials Traffic	Combine elevators or Separate Passenger and Materials Traffic	Separate Passenger. Combine Materials and Special Use Traffic	Combine elevators or Separate Passenger and Materials Traffic	Not Applicable
Facilities >200,000 BGSF (> 18580 BGSM)	Separate Passenger. Separate Inpatient. Separate Materials Traffic	Combine elevators or Separate Passenger and Materials Traffic	Separate Passenger Traffic. Combine Logistic Traffic	Not Applicable	Not Applicable

Notes:
1. The decision to separate or combine any elevator function must be supported in the ETSA.
2. Combined passenger and service elevators may be installed where combined use is possible without interfering with normal activities in the healthcare facility. Avoid mixing patient transport with any other traffic.

16-4 ELEVATOR DESIGN.

All multistory facilities must have at least two elevators. The ETSA must include a risk assessment to determine if at least one is to be sized to accommodate a gurney (see appendix H for definition). All multistory inpatient and surgical facilities must have not less than two elevators sized to accommodate a gurney.

16-4.1 Codes.

Elevators to be designed in accordance with UFC 3-490-06 where applicable, all applicable Federal, state, and local codes, including ASME A17.1, A17.3, 17.5, and elevator design requirements for earthquake/seismic loads in accordance with ASCE 7. This includes designing to the appropriate rating/load classification for the intended application. Elevators must be designed to meet all DoD and ABA provisions applicable to the project.

16-4.2 Elevator Selection.

Elevators in medical facilities provide for three major functions: passenger movement, inpatient movement, and material handling. Passenger elevators are intended for use by the public, staff, and other ambulatory patients. Patient Service elevators are intended for use by staff movement and for the transport of patients (wheelchair and/or bed-bound inpatients). Dedicated elevators are patient assist/trauma elevators intended for patient transport from Critical Care Areas, for example ER trauma rooms, to the ORs. Materials Handling Service elevators are intended for use by staff for material, supplies and equipment movement. Special Use elevators are intended for loading docks, mortuary, or the transport of animals. Where allowed by Table 16-3, a single set of elevators can serve multiple functions. All elevators must meet the following:

16-4.2.1 Elevator Types and Speed.

Elevator types and speed guidelines are shown in Table 16-4. Higher speeds may be used if needed to satisfy traffic demands. Elevator selections must not exceed the elevator rise criteria given in Table 16-4.

16-4.2.2 Elevators for Inpatient Facilities.

Inpatient facility Patient Service elevators to have interior car dimensions that accommodates a patient bed/ gurney with attendants. Cars to be a minimum 5 ft 8 in. (1727 mm) wide by 8 ft 5 in. (2565 mm) deep. Car doors are to provide a minimum clear opening of 4 ft 6 in. (1372 mm) wide and 7 ft (2134 mm) high. All other elevator dimensions to meet the requirements of Tables 16-5 and 16-6.

16-4.2.3 Elevators for Existing Facility.

Do not resize existing elevators that can accommodate patient beds. Other existing elevators may require renovation depending on the results of the ETSA.

16-4.2.4 Elevators for Hospital and Ambulatory Surgery Centers (Front and Rear Opening).

Front and rear opening hospital and ambulatory surgery center elevators may be used as combined use for passenger and service/staff traffic when space or budget restrictions limit use of separate passenger elevators.

16-4.2.5 Passenger Elevators.

Passenger elevators are required to be wide car configuration, have center opening doors, be a minimum 4000 lb (1815 kg) capacity, and have a minimum 4 ft 0 in. (1220 mm) wide door opening. See additional elevator minimum dimensions and requirements in Tables 16-5 and 16-6.

16-4.2.6 Patient Service Elevators.

Patient Service elevators are required to be deep car configuration, have side opening or center opening doors, be a minimum 5000 lb (2270 kg) capacity, and have a minimum 4 ft 6 in. (1372 mm) wide door opening. See additional minimum elevator dimensions and requirements in Tables 16-5 and 16-6.

16-4.2.7 Materials Handling Service Elevators.

Material Handling Service elevators are required to be deep car configuration, have side opening or center opening doors, be a minimum 5000 lb (2270 kg) capacity and have a minimum 4 ft 6 in. (1372 mm) wide door opening. See additional minimum elevator dimension and requirements in Table 16-5 and 16-6.

16-4.2.8 Trauma Elevators.

Trauma elevators are required to be deep car configuration, have center opening doors, be a minimum of 6000 lb (2720 Kg) capacity and have a minimum 5 ft 0 in. (1525 mm) wide door opening. Larger capacity and car sizes to be used for facilities that require three or more attendants and possibly equipment to accompany patient transport.

16-4.2.9 Traction Elevators.

Specify overhead machine room geared hoisting machine elevators for up to four stops with a minimum rise of 32 ft (9.7 m) and minimum rated speed of 200 fpm (61.0 m/min). Specify overhead machine room geared hoisting machine elevators for up to ten stops with a minimum rise of 64 ft (19.5 m) and minimum rated speed of 350 fpm (106.9 m/min) in coordination with Table 16-4.

16-4.2.10 Hydraulic Elevators.

Specify oil hydraulic direct plunger elevators for up to four stops with a minimum rise of 16 ft (4.88 m) and minimum rated speed of 150 fpm (45.7 m/min) in coordination with Table 16-4. Holeless plunger will be considered for difficult site conditions. Provide

necessary machine room ventilation and equipment cooling, overload protection with a preferred 120 starts per hour.

16-4.2.11 Machine Room-Less (MRL) Elevators.

MRL elevators are only allowed where deemed appropriate by the Design and Construction Agent in coordination with the DoD Project Sponsor. Provide written justification and Life Cycle Cost Analysis (LCAA). If allowed, they are be used for passenger elevators ONLY with minimum capacity limitation of 4000 lb (1815 Kg) with 3 stops or more in coordination with Table 16-4 and Table 16-5 or Table 16-6.

16-4.3 Elevator Location and Travel Distances.

Elevators must be designed, arranged, and placed within the building to; minimize patient/staff travel distance and time, provide convenient access to healthcare delivery services, and provide cost-effective elevator performance (direct capital cost of elevators, indirect cost of the space dedicated to their function, and O&M are major cost components of any building). The walking distance from the elevator doors to the center point of the farthest occupied room should not exceed 200 ft (61 m) unless there is adverse impact to operational functionality or elevator locations. The A/E must provide a description of the elevator system(s) proposed, including an analysis of the walking distances, elevator types, and locations for evaluation. The DoD Project Sponsor, in coordination with the Design and Construction Agent, must evaluate the proposed elevator system(s) to determine if proposed travel distances from elevators to healthcare delivery services and administrative areas are acceptable based upon the mission, population served, and operational concepts.

Additional elevators may be required based upon an assessment by the DoD Project Sponsor in coordination with the Design and Construction Agent. These elevators must be in addition to the main elevators provided for efficient and effective travel throughout the building, in compliance with Section 16-4. These additional elevators are intended for staff use only, thus should be located away from main thoroughfares and should not be located where the public can interfere with clinical activities. These elevators must provide average intervals of under 45 seconds and provide a handling capacity equal to 10 percent of the population within the area of service provided. Elevators added for this purpose must be of service type and be access controlled by staff.

16-4.4 Elevator Location, Lobbies, and Groupings.

Placement of elevators must meet the travel distance requirements of paragraph 16-4.3, Material and traffic separation of paragraphs 16-3.1 through 16-3.5 while considering the requirements of paragraphs 16-4.4.1 through 16-4.4.3.

16-4.4.1 Elevator Location.

Place elevators on the direct horizontal path between the areas they serve, wherever possible. Locate elevators so that visitors do not normally pass service, material, or convenience cars en route to passenger cars, unless those cars are substantially hidden.

Table 16-4 Elevator Selection Guide

Table presents minimum elevator types and performance parameters by elevator travel distance.

Elevator Rise		Speed in Feet / Minute (Meter / Minute)				Capacities in Pounds (Kilogram)	
		Elevator Types					
Stops	Travel Distance in feet (meter)	Hydraulic	MRL[6]	Geared Traction (w/MR)	Gearless Traction (w/MR)	Passenger	Service
2	<16 (4.9)	125[4] (38.1)	NA	NA	NA	4000[2] (1815)	5000[3] [5] (2270)
3–4	32-48 (9.8 - 14.6)	150[4] (45.7)	350 (106.7)	200[4] (61.0)	NA	4000[2] (1815)	5000[3] [5] (2270)
5–10	64-144 (19.5 - 44.0)	NA	350 (106.7)	350[4] (106.7)	NA	4000[2] (1815)	5000[3] [5] (2270)
11–17	160-256 (48.8 - 78.0)	NA	350-500 (106.7 - 152.4)	350[4] (106.7)	500[4] (152.4)	4000[2] (1815)	5000[3] [5] (2270)
18+	272 (82.9)	NA	NA	NA	500–700[4] (152.4 - 213.4)	4000[2] (1815)	5000[3] [5] (2270)

Notes:

1. This table identifies the type of equipment and the associated speed based solely on the Rule of Thumb of the height of the building.
2. Wide Car configuration required with passenger elevators.
3. Deep Car configuration required with service and combination elevators.
4. Application to be utilized by elevator consultant in preparation of ETSA.
5. 6000 lb (2720 kg) capacity minimum required if facility has motorized beds or as determined by the ETSA.
6. Only where deemed appropriate by the Design and Construction Agent in coordination with the DoD Project Sponsor. Provide written justification and Life Cycle Cost Analysis (LCAA).

NA – Not allowed

Table 16-5 Elevator Dimension – Front Openings Guide

Table presents minimum elevator dimensional parameters for front opening elevator types.

Capacity	Hostway Width[7]	Hostway Depth[7]	Clear Interior Width[4]	Clear Interior Depth[4]	Clear Door Width[4]	Clear Door Height[4]	Door Type
6000 lb (2720 kg) Deep Car	9’-1” (2768 mm)	11’-5” (3480 mm)	6’-0” (1829 mm)	9’-8” (2946 mm)	5’-0” (1525 mm)	7’-0”[3] (2134 mm)	Side Opening or Center Opening[5]
5000 lb (2270 kg) Deep Car	8’-2” (2489 mm)	10’-1” (3073 mm)	5’-8” (1728 mm)	8’-5” (2565 mm)	4’-6” (1372 mm)	7’-0”[3] (2134 mm)	Side Opening
4500 lb (2040 kg) Deep Car	8’-2” (2489 mm)	9’-6” (2896 mm)	5’-8” (1728 mm)	7’-9” (2362 mm)	4’-0” (1220 mm)	7’-0”[3] (2134 mm)	Side Opening
4000 lb (1815 kg) Deep Car	8’-2” (2489 mm)	9’-0” (2743 mm)	5’-8” (1728 mm)	7’-3” (2210 mm)	4’-0” (1220 mm)	7’-0”[3] (2134 mm)	Side Opening
4000 lb (1815 kg) Wide Car	9’-4” (2845 mm)	7’-8” (2337 mm)	7’-8” (2337 mm)	5’-5” (1651 mm)	4’-0” (1220 mm)	7’-0”[3] (2134 mm)	Center Opening

Notes:

1. All dimensions are for non-seismic zone.
2. All dimensions do not include counterweight safeties.
3. 8 ft 0 in. (2438 mm) also available.
4. All elevator car/cab minimum dimensions listed are pre-determined to accommodate ABA standards, ambulance stretcher and/or other requirements.
5. Elevators dedicated only to AGV system operation (not shared with people) to have a minimum 4 ft 0 in. (1220 mm) clear door width, minimum 5 ft 0 in. (1525 mm) clear interior width, minimum 8 ft 5 in. (2565 mm) clear interior depth, and allow for a maximum single AGV wheel load of 1,050 pounds (476 kg), except for fork style AGV, which requires minimum 10 ft 7 in. (3227 mm) clear interior depth and has maximum single AGV wheel load of 1,150 lb (522 kg). Minimum capacity for AGV system-dedicated elevators to be 5000 lb (2270 kg).
6. Center opening doors are preferred, unless annotated otherwise in the table above. Center-opening doors take less time to operate than single-slide doors of the same width. Center-opening doors are also more efficient as they provide two-way traffic.
7. Hoistway dimensions may vary based on manufacturer. A/E or DoR to coordinate.

Table 16-6 Elevator Dimension – Front and Rear Openings Guide

Table presents minimum elevator dimensional parameters for front and rear opening elevator types.

Capacity	Hostway Width(7)	Hostway Depth(7)	Clear Interior Width(4)	Clear Interior Depth(4)	Clear Door Width(4)	Clear Door Height(4)	Door Type
6000 lb (2720 kg) Deep Car	9’-1” (2768 mm)	12’-4” (3759 mm)	6’-0” (1829 mm)	9’-8” (2946 mm)	5’-0” (1525 mm)	7’-0”(3) (2134 mm)	Side Opening or Center Opening(5)
5000 lb (2270 kg) Deep Car	8’-2” (2489 mm)	10’-11” (3327 mm)	5’-8” (1728 mm)	8’-6” (2590 mm)	4’6” (1372 mm)	7’-0”(3) (2134 mm)	Side Opening
4500 lb (2040 kg) Deep Car	8’-2” (2489 mm)	10’-4” (3150 mm)	5’-8” (1728 mm)	7’-10” (2387 mm)	4’-0” (1220 mm)	7’-0”(3) (2134 mm)	Side Opening
4000 lb (1815 kg) Deep Car	8’-2” (2489 mm)	9’-10” (2997 mm)	5’-8” (1728 mm)	7’-4” (2235 mm)	4’-0” (1220 mm)	7’-0”(3) (2134 mm)	Side Opening
4000 lb (1815 kg) Wide Car	9’-4” (2845 mm)	7’-4” (2235 mm)	7’-8” (2337 mm)	5’-5” (1651 mm)	4’-0” (1220 mm)	7’-0”(3) (2134 mm)	Center Opening

Notes:

1. All dimensions are for non-seismic zone.
2. All dimensions do not include counterweight safeties.
3. 8 ft 0 in. (2438 mm) also available.
4. All elevator car/cab minimum dimensions listed are pre-determined to accommodate ABA standards, ambulance stretcher and/or other requirements.
5. Elevators dedicated only to AGV system operation (not shared with people) to have a minimum 4 ft 0 in. (1220 mm) clear door width, minimum 5 ft 0 in. (1525 mm) clear interior width, minimum 8 ft 5 in. (2565 mm) clear interior depth, and allow for a maximum single AGV wheel load of 1,050 pounds (476 kg), except for fork style AGV, which requires minimum 10 ft 7 in. (3227 mm) clear interior depth and has maximum single AGV wheel load of 1150 lb (522 kg). Minimum capacity for AGV system-dedicated elevators to be 5000 lb (2270 kg).
6. Center opening doors are preferred, unless annotated otherwise in the table above. Center-opening doors take less time to operate than single-slide doors of the same width. Center-opening doors are also more efficient as they provide two-way traffic.
7. Hoistway dimensions may vary based on manufacturer. AE/DoR to coordinate.

from view. Consider operational impacts such as noise, vibration, temperature, and other environmental factors when adjacent to critical treatment areas or those having sensitive equipment. Place adjacent car entrances either in straight lines or in opposite banks to each other.

Where AGV systems are used that require more than one elevator, single elevators must be distributed to minimize horizontal travel on patient floors. On the service levels, consideration should be given to open both sides to allow drive-through capability to achieve higher throughput. On the patient floors, there must be two openings (front and rear) into secure access AGV lobbies/vestibules used for the primary purpose of temporary staging, picking up, and delivering carts. Adequate space inside these lobbies should be coordinated with AGV system vendors prior to finalizing the design.

16-4.4.2 Elevator Lobbies.

Elevator ingress/egress should be from a distinct elevator lobby and not directly from a corridor. Minimum/maximum lobby depth for service cars are 12–14 ft (3.7–4.3 m) when the opening opposes a wall and 14–16 ft (4.3–4.9 m) when the opening opposes another elevator. Minimum/maximum lobby depth for passenger cars are 10–12 ft (3.1–3.7 m) when the opening opposes a wall and 12–14 ft (3.7–4.3 m) when the opening opposes another elevator.

16-4.4.2.1 Elevator Access.

Where elevators are accessed from corridors, they must be located on one side of the corridor only with a maximum of three cars. Elevators must be set back 8–12 ft (2.5–3.7 m) for service and combined use cars and 4–8 ft (1.2–2.4 m) for passenger cars.

16-4.4.2.2 Elevator Separation.

Where two or more elevator group lobbies are adjacent, provide walls or other building features to prevent a free flow of traffic between those lobbies (to minimize one user from placing calls to both groups). Where Table 16-3 requires separation of elevators, passenger elevators must not share the same lobby with service and materials handling elevators. Acoustically isolate all elevator lobbies from Critical Care Areas.

16-4.4.3 Elevator Groupings.

For service and combined use cars, two in a row are preferred and not more than three in a row should be used; for passenger cars three in a row are preferred and not more than four in a row should be used.

If more than six service cars or eight passenger cars are required in one area, provide two smaller, strategic groups.

16-4.5 Passenger and Service Elevator Features.

Passenger and service elevators must meet the requirements of the subparagraph below.

16-4.5.1 Operation.

Elevators are to be arranged to operate with or without attendants and be provided with key operated switches for hospital priority service. Each elevator bank to be equipped for emergency operation by means of a key operated switch at each landing. This switch must cause the closest available car to bypass all other calls in response to an emergency call. Duplex collective operation to be provided for two-car banks. Three- or four-car banks must be a group operation. An on-demand microprocessor system must be provided for all elevator controls.

16-4.5.2 Code Blue Controls.

Provide medical emergency elevator control, sometimes called Code Blue Control, as a means of overriding normal operation of elevators capable of medical emergency transportation of a patient in bed, accompanied by attendants. This control feature must be provided in conjunction with, or in addition to, controls provided for fire department emergency use. Firefighters' operation, as defined in ASME A17.1, must override Code Blue Control.

16-4.5.3 Doors.

Passenger elevators to have center opening doors unless allowed by the Design and Construction Agent. Two-speed side opening doors may be provided in facilities with separate material handling systems (reference Table 16-3). Door closing time must comply with ASME code requirements. Minimum door opening speed to be 2.5 fps (0.8 m/s) except for high speed elevators (500 fpm (152.4 m/min) and over) where the door opening speed to be 2.5-3.0 fps (0.8 – 0.9 m/s). Equip service elevators with buttons to extend door open time, adjustable between 0 to 30 seconds. All elevator car doors must be provided with infrared screen detectors.

16-4.5.4 Signals.

Install hall position indicators at the main floor(s) containing the command and outpatient entrances. Provide hall push-button stations with call register lights. Install hall lanterns with an audible signal on all elevators. Install car position indicators in each car with floor designations, a floor directory signal, and direction arrows. Car operating panels must use car register-type floor buttons. Provide a lobby control panel on elevator banks with two or more cars.

16-4.5.5 Emergency Power.

When otherwise required, connect elevators to operate on alternate source emergency power in conformance with electric power and lighting criteria. Emergency power

selection switches are required for each bank of elevators. The elevator control system must have an ATS which returns each elevator to the main egress level, one car at a time. The last car to arrive at the main floor must automatically be selected to operate at normal design speed.

During an emergency power condition, ASME A17.1 requires all groups of elevators, which are supplied with an alternate power source, to automatically sequence one at a time to the main egress level. Once all cars have reached the designated level, the elevator system must automatically select one car within the group to operate. A manual override switch must also be provided, so emergency personnel may select a particular car if desired.

16-4.5.6 Machine Rooms, Control Rooms, and Machinery Spaces.

Locate electric traction elevator machine rooms above elevator hoist ways. Machine rooms must be sized to accommodate the maximum space requirements anticipated from competitively bid projects, including provisions of space to service and maintain equipment, as well as any additional DoD required equipment and functions including, but not limited to emergency descent to fire fighters' designated level for elevators that are not served by an emergency generator. In the event of a flood zone location, the Machine Room can be located on the first floor above the flood zone. Provide air conditioning in machine rooms to maintain ambient temperature below 85 ^{o}F (29.4 ^{o}C) and above 60 ^{o}F (15.6 ^{o}C). Provide filters to remove dust. Size hydraulic elevator rooms accordingly for the equipment, place them adjacent to the elevator, and on the lowest served floor. Electrically and acoustically isolate all elevator equipment rooms to prevent interference with building electronic equipment and objectionable noises.

The MRL control room closet must be located adjacent to the elevator hoistway and accessible from the corridor. Follow UFC 3-490-06 requirements for elevator control rooms and elevator machinery spaces except for the following:

a. The MRL elevator control equipment must be located in a dedicated control room/ closet. The use of door jamb control equipment is prohibited. Control rooms must be sized to accommodate the elevator panels, disconnects, controller and other related equipment. It must be possible to remove major equipment components of each elevator for repair or replacement without dismantling components of an adjacent elevator.

b. Proprietary elevator systems, components, parts, motors, and software is strictly prohibited.

16-4.5.7 Elevator Car Enclosure.

Car lighting to be either indirect or of the luminous ceiling type. Provide mechanical exhaust for elevator cars. Provide protective cab interior blanket hooks and one set of full-height blankets per cab.

16-4.5.8 AGV System Elevator Features.

When determining elevator usage requirements for AGV systems, consideration must be given to whether the elevator is to be dedicated for exclusive use of the AGV system. The elevator must be dedicated to sole use by the AGV system if the AGV system requires greater than 50–60 percent of any single elevator. If the AGV system usage is less than 50–60 percent of the elevator, then the AGV/elevator interface must allow for a manual mode of operation to accommodate other material conveyances.

16-4.5.8.1 Shared Use Elevators.

For shared (automatic and manual) use elevators, the AGV system must release the elevator for manual movements when all automatic transports have been completed. The AGV system must request automatic mode when needed and the elevator controls must disable hall call buttons and flash “Elevator in Automatic Mode” warning signs in the halls. After all cabin calls are answered and the doors close, the elevator must change from manual mode to automatic mode. The specific signals and sequencing of them for AGV/elevator interface must be specified by the AGV system vendor after selection and the elevator manufacturer must conform to it as well as maximum leveling and gap tolerances. Fire service level and alternate fire service levels must be identified in the TLA.

16-4.5.8.2 Shared Mode Elevators.

Shared Mode Elevators must include flashing lights with the words “Elevator in Automatic Mode” on all landings to indicate when the AGV system has requested use of the elevator. A flashing sign with audible warning must activate inside the cabin after the elevator doors have closed, there are no more cabin calls, and the elevator control changes from manual mode to automatic mode.

16-4.5.8.3 AGV System Interface.

The elevator controls must include an AGV system interface terminal strip to which discrete, potential free contacts rated for 24 volts are wired in the machine room. Supporting elevator software/logic must control the contacts inputs and outputs (I/O) in accordance with a specification to be provided by the selected AGV system vendor. A manual key switch for entering automatic mode must be located in the elevator cabin.

Each AGV system elevator controller must have discrete I/O terminals to receive and transmit.

AGV elevator doors must have switches on each door to signal when the doors are completely closed as well as completely open so as not to restrict the clear opening. Leveling circuitry must be incorporated to prevent signaling the arrival of the cabin to a floor when the cabin is not within the leveling tolerance.

16-5 MATERIAL MANAGEMENT DESIGN.

16-5.1 AGV Systems.

Design the AGV systems to incorporate the latest state-of-the-art in proven technology; systems not proven in at least five previous similar applications must be avoided. System must be an integrated turnkey automated cart transportation system.

AGV systems may utilize a variety of transportation vehicles (transporters) including “cart carrying” type and forklift type; towing type transporters are not desired because they do not transport carts with the casters off the floor.

16-5.1.1 Design.

The design must establish horizontal rights-of-way to:

a. Aid in directing traffic to the appropriate vertical core, while avoiding inappropriate elevators and other building areas;

b. Provide high levels of patient privacy and protection from high noise levels; and

c. Eliminate potential contamination of clean and sterile areas.

16-5.1.2 AGV Elevators.

The elevators that provide vertical transport for AGVs must open into enclosed pickup and delivery (P&D) lobbies with motorized door access to the main circulation corridors on the patient floors. Consider two vestibules - one accessible from each elevator door - for separate soiled and clean cart staging areas. Where higher cart transport volumes exist, a path must be included for AGV vehicle travel from the clean side to the soiled side without having to use the elevator cabin. Recommendations for positive/negative air pressure or motorized doors between these areas must be included.

16-5.2 Pneumatic Tubes.

Provision of PTSs must be consistent with requirements for a particular facility regardless of the size of the facility. No specific correlation can be made between the number of beds in a MTF and the need for a PTS. Facility parameters and FTE usage are the primary drivers for the use of pneumatic tubes.

a. Design systems to reach individual project peak traffic requirements, plus a minimum spare capacity of 20 percent. Designs must provide for soft handling of all systems where laboratory specimens and other delicate items are transmitted.

b. Select tube systems that provide automatic control of carrier movement. A selector device that permits correspondence with any station served by the system must set the destination of the carrier.

16-5.3 Mobile Robots.

Mobile robots must be considered only when they have been proven in other similar applications in at least five similar hospitals and can be considered for travel through any corridor to nursing units and to patient rooms.

Mobile robots that interface with elevators must use a similar interface method to the AGV system interface described elsewhere. Mobile robot travel must be segregated from AGV system traffic routes and AGV elevators unless they use the same control system.

16-5.4 Dumbwaiters and Cart Lifts.

Dumbwaiters must meet the requirements of the following subparagraphs.

16-5.4.1 Codes.

Dumbwaiters to comply with applicable Federal, State, Local and Elevator codes including ASME A17.1, A17.2, A17.5, NFPA 70, ASME/UL – 10B and 508.

16-5.4.2 Dumbwaiters, Counter Loading.

Automatic loading and unloading are to be considered. Dumbwaiters without automated devices to have powered or manual doors. Provide bi-parting type powered doors with door safety reversing edges. Locate machine at the bottom of the hoistway.

16-5.4.3 Dumbwaiters, Floor Loading.

Floor loading dumbwaiters to have powered vertical panel slide-up door with safety reversing edge. Bi-parting doors can be utilized in conjunction with a larger pit depth along with drawbridges to provide a smooth entrance for wheeled carts. Locate machine at top of hoistway.

16-5.4.4 Dumbwaiter Platform Size.

Dumbwaiter systems are to be limited to a maximum platform size of 1550 in^2 (1 m^2) x 48 in. (1219 mm) high and maximum capacity of 500 lb (227 kg). A platform size of 30 by 48 in. (762 by 1219 mm) is acceptable. Automatic loading and ejection devices of larger capacity and size, used in conjunction with automatic cart lifts, and conform to the ASME standards for elevators. Determine the dimensions of the car lift platform by the largest cart selected for dietary, linen, or other materials distribution.

16-5.4.5 Dumbwaiter and Cart Lift Control.

Distribution and return programs must be provided for dumbwaiter and cart lift operation. The control station must contain a switch for program selection and a series of dispatch buttons that correspond to the floors served. Design the system to permit

dispatching carts to any landing from the central dispatching area and to provide for return of carts only to the central dispatching area.

16-5.4.6 Dumbwaiter and Cart Lift Signals.

Stations at each floor or landing must contain lights to indicate which program is in effect.

Table 16-7 Dumbwaiter and Cart Lift Parameters

Dumbwaiter Rise		Type				Speed	
Stops	**Travel Distance in feet (meter)**	**Motor**	**Light**	**Medium**	**Heavy**	**fpm (m/min)**	**Notes**
2	<16 (4.88)	Winding Drum	X	X	NA	50 (15.2)	(2)
3-4	32-48 (9.75 - 14.63)	Traction		X	NA	200 (61.0)	(2)
5-10	64-144 (19.51 - 43.89)	Traction		X	NA	300 (91.4)	(2)
11+	135+ (41.15)+	Traction		X	NA	300 (91.4)	(2)
Notes:							
Light-Duty Dumbwaiter 100 - 200 lb (45 – 91 kg) (up to 24” wide x 24” deep x 36” high) (610 mm wide x 610 mm deep x 915 mm high)							
Medium-Duty Dumbwaiter 200 - 750 lb (91 – 340 kg) (up to 38” wide x 38” deep x 48” high) (965 mm wide x 965 mm deep x 1219 mm high)							
Heavy-Duty Material Lift 750 - 2500 lb (340 – 1134 kg) (up to 60” wide x 96” deep x 96” high) (1524 mm wide x 2438 mm deep x 2438 mm high)							
NA – Not Applicable							
1.	This table identifies the type of equipment and the associated speed based solely on the Rule of Thumb of the height of the building.						
2.	Application to be determined by elevator consultant in preparation of ETSA.						

16-5.4.7 Cart Lifts with Automated Transfer Devices.

Doors must be power operated with upper and lower safety edges. Maximum cart lift capacity to be 1000 lb (453 kg).

16-6 WASTE MANAGEMENT DESIGN.

The waste management system must be designed to help maintain aseptic environments in the hospital, and to minimize or eliminate physical and infection hazards to patients, hospital staff, and the general public, at the lowest LCC to the Government. The design objectives should include hazardous waste optimization/process improvements, recycling, waste minimization, and hazardous material substitution to more environmentally friendly products/processes.

16-6.1 Waste Categories.

The categories of medical facility waste are: Regulated Medical Waste (RMW), Hazardous Waste (HW), Recyclable Materials (RM), and general waste. Each of the categories of waste requires individual design consideration of handling, storage, and disposal by the facility. In addition, regulatory requirements differ for each category dependent upon the geographic location (state or country), relative personnel and public hazards and environmental impact.

16-6.2 Waste Collection and Transport.

The waste management system must be fully coordinated with the transportation design to determine the most appropriate means and routing of transport of wastes inside and outside of the facility. Consideration should include: regional waste collection service provider to account for dumpster sizes (usually provided by the Installation / DPW); dumpster loading/unloading offsets; and minimum turning radius of waste removal trucks. Automatic or manual systems should be considered. The design must avoid creating conditions that require or involve the double-handling of waste, especially RMW and HW.

a. Where facilities receive palletized supplies, designate an exterior area for the storage of empty/idle pallets waiting for disposal.

b. Provide easy access to dumpsters from back-of-house materials management/waste management areas. If dumpsters are located at a distance from the facility due to ATFP or other reasons, ensure ramps or other means are provided to allow the transport of wheeled trash carts from the facility to the dumpster.

c. Supply and loading dock areas should be provided with overhead weather protection by either a canopy or overhang.

d. If Nuclear Medicine, Decay Storage (NMDS1) and Nuclear Medicine, Decay Calibration (NMDC1) rooms are included in the Program for Design (PFD), coordinate the location with the DoD Project Sponsor and identify

the path of travel to meet 10 CFR 35.92, 10 CFR 20.1201, and 10 CFR 20.1301.

16-6.3 Regulations, Codes, and Standards.

The preliminary design of the waste management system must comply with all applicable Federal, state, and local codes and regulations, including: Nuclear Regulatory Commission (NRC) guidelines; NFPA 82; 40 CFR 261–265 and 40 CFR Part 22; 49 CFR 171–180; 29 CFR 1910.1200, 29 CFR 1910.1030, and 29 CFR 1910.134. Guidelines and advisory standards available from the NFPA, the CDC, National Institute for Occupational Safety and Health (NIOSH), Department of Health and Human Services (HHS), and TJC must be utilized as applicable and considered minimum criteria for facility design. The WMA must be based on regulations and standards enforced by the local authority.

16-6.4 Gravity Chutes.

Gravity chutes to comply with NFPA 82 unless otherwise modified herein.

a. Consider gravity chutes either alone or in combination with horizontal pneumatic chutes, for internal general and soiled linen transportation (down only) in multistory facilities. Also, consider hospital service elevators, AGVs, and cart lifts for internal transportation of solid wastes in multistory buildings. Consider that the AGV system has to move empty linen carts down from patient areas and these movements can be used for transport of soiled linen at very little, if any, incremental cost.

b. Collection areas for soiled linen to be located near the loading dock.

c. Provide chute access on user levels through a separate room with dimensions adequate for holding the collection cart, with room doors closed, while the attendant is charging the chute.

d. Size terminal rooms to accumulate the amount of materials dictated by the WMA. Minimum dimension must allow accumulation of 24 hours of collected materials. Design must ensure that collected material does not block the entrance door or hinder the pickup operation.

e. Masonry waste chutes are prohibited. Refractory lined chutes are prohibited. Automatic sprinklers are required in all chutes regardless of construction.

16-6.5 Pneumatic Trash/Linen.

Pneumatic trash/linen systems to comply with NFPA 82 unless otherwise modified herein.

a. Pneumatic trash/linen systems are either fully pneumatic or gravity pneumatic. In general, no station to be designed that is “up send” in nature. All materials should travel in the down direction after first being

loaded into the system. Verify system traffic capabilities by detailed traffic studies.

b. Fully pneumatic systems are continuous sealed transport systems (run) from source (material loading) to disposition (collection room or compactors) consisting of full vacuum stations equipped with interlocked doors, an air source, and the same size diameter transport piping throughout.

c. Vertically aligned charging doors of the same chute system must be interlocked so that only one station can be charged at one time, thereby reducing the possibility of charges jamming within the chute. Provide gravity chutes with negative pressure, relative to the charging area, to eliminate aerosol discharged into the charging areas when charging doors are opened.

d. Fully pneumatic systems are allowed where deemed appropriate by the Design and Construction Agent in coordination with the DoD Project Sponsor. Provide written justification and LCCA.

e. Gravity-pneumatic systems, a combination of gravity chutes for vertical transportation, and pneumatic chutes for horizontal transportation are subject to the same fire protection requirements as gravity systems.

f. Gravity chutes must be equipped with a storage section at the bottom of the chute. Gravity chute charging stations equipped with electric control systems may be loaded with as many bags of waste or linen as necessary. Bags are accumulated in the storage section and are removed as a single load on demand.

g. Both gravity-pneumatic and fully-pneumatic chutes must be manually charged, enclose charging doors and frames in fire-rated rooms. Sprinklers in the charging stations must protect pneumatic chutes. Charging stations must have a receiving compartment with an outer and inner door. When the door is opened to put in a load, the inner door must be automatically locked so that the load cannot freely enter the chute. When the outer door is closed, the inner door must open in its sequential turn and the load to be automatically transported by negative pressure to its point of discharge. Only one load to move through each leg of a pneumatic chute system at one time.

This Page Intentionally Left Blank

CHAPTER 17 CONSTRUCTION

17-1 CONTRACT AWARD.

The DoD Project Sponsor will provide authority to the Design and Construction Agent to award a construction contract in accordance with Chapter 3 Design.

17-2 COMMISSIONING DURING CONSTRUCTION.

Reference Chapter 19 Commissioning.

17-3 CONSTRUCTION CONTRACT CHANGES.

17-3.1 Process for Reporting Changes.

The Design and Construction Agent specifies reporting procedures as follows:

b. For projects assigned to USACE, proposed project changes impacting unique medical technical criteria covered under this document must be coordinated with the CEHNC-EDX for their comment and recommendation.

b. For projects assigned to NAVFAC HQ MFPO, they have responsibility for changes as they require and deem appropriate.

c. For projects in the United Kingdom, the AFCEC has responsibility for changes as they require and deem appropriate.

17-3.2 Process for Approving Funds.

Changes must be submitted for approval to the designated Design and Construction Agent (USACE, NAVFAC HQ MFPO, or AFCEC/CFM) in accordance with their established business practices. All discretionary changes must be submitted in accordance with DoD Project Sponsor policy.

17-4 CONSTRUCTION FUNDS.

17-4.1 Funds Management.

The DoD Project Sponsor will sub-allocate all of the appropriated design and construction funds to the Design and Construction Agent who must manage the funds at the project level.

17-4.2 Funds Availability.

If funds are required for changes that exceed the amount available and the authorized contingency is inadequate, the Design and Construction Agent must notify and request additional funds from the DoD Project Sponsor in writing, along with justification for additional contingency funds, and cite source of funds. The Design and Construction

Agent must notify the DoD Project Sponsor if actual requirements exceed the appropriated amount.

17-5 NOTIFICATION OF CONTRACTOR CLAIMS.

The Design and Construction Agent must notify the DoD Project Sponsor of submitted contractor claims that have been approved by the Contracting Officer or the Board of Contract Appeals within 30 working days of date of the determination to reimburse the contractor for claims that require additional funding. Such claims must be accompanied with a narrative explanation, recommended resolution, and estimated final cost.

17-6 LIFE SAFETY ASSESSMENT.

Refer to Chapter 14 for LSA requirements.

17-7 DEMOLITION OF VACATED FACILITIES.

The demolition of vacated facilities must be reported on the project DD Form 1354 in accordance with UFC 1-300-08.

CHAPTER 18 BUILDING INFORMATION MODELING (BIM)

18-1 GENERAL.

BIM is an enabling tool and process for facilities projects within the MHS to more effectively achieve current requirements described throughout this document and assist the MHS in achieving fundamental Facility Life Cycle Management (FLCM) requirements in supporting the delivery of applicable facilities.

18-1.1 MHS BIM Objectives.

The MHS BIM objectives support and provide improvements for:

a. Clearly and concisely defining the requirements for models, facility data, processes, and respective deliverables.

b. Interoperability and analysis across the FLCM.

   i. Automated SEPS to BIM PFD analysis for validation to actual design/construction.

   ii. Automated SEPS to BIM PRC analysis for validation.

   iii. Defense Medical Logistics Standard Support - Facilities Management (DMLSS-FM) and future LogiCole integration.

   iv. Defense Medical Logistics Standard Support - Equipment and Technology Management (DMLSS-E&TM) and future LogiCole Medical Equipment integration.

c. Planning and programming analysis.

d. Design coordination/process and design criteria validation.

e. Construction and commissioning execution and QA/QC.

f. Risk management from Interference Management through virtual design and construction processes.

g. Simulation and visualization of healthcare operations.

h. IO&T efforts.

i. Quality and efficiency enhancements distributed across all current and future projects for continual process and product improvements.

j. Data-enhanced deliverables for facility owners, users, and operations and maintenance available prior to handover.

18-1.2 Corresponding Project Model Uses.

The United States National BIM Standard (NBIMS–US™) defines standard “BIM Uses” (also referred to as “Model Uses”). Each of the MHS BIM Objective have corresponding Model Uses as identified below as the minimum mandatory model uses required for

every project. Contractor selected elective model uses are encouraged to provide enhanced project outcomes and additional consideration for contractor selection.

18-1.2.1 Design Phase Model Uses.

The Design Phase model Uses include:

a. Design Authoring

b. Progress Reviews

c. Interference Management or Clash Detection (3D Coordination)

d. Program Validation

e. Construction and Operations Building information exchange (COBie) for the MHS (COBie-MHS)

18-1.2.2 Construction phase Model Uses.

The Construction Phase Model Uses include:

a. Interference Management or Clash Detection (3D Coordination)

b. Program Verification

c. Record Modeling

d. COBie-MHS

18-1.3 Applicability.

To ensure these objectives are uniformly achieved, all projects are required to implement the MHS BIM Minimum Requirements established for projects funded, or to be operated and maintained, under DHP funds. This applies to all projects CONUS or OCONUS, except Unspecified Minor Construction (UMC). The MHS BIM Minimum Requirements are located at http://facilities.health.mil/repository/getfile/1463.

CHAPTER 19 COMMISSIOINING

19-1 GENERAL.

This chapter addresses the Total Building Commissioning (TBCx) requirements and the process to be implemented as required by Federal regulations and the Federal Leadership in High Performance and Sustainable Buildings Memorandum of Understanding.

Upon receipt of DA for A/E Award (for the A/E that develops full design for DBB projects or the DoR that develops the RFP for DB projects), the Design and Construction Agent and DoD Project Sponsor must jointly determine the commissioning leadership structure, the extent, and the level of commissioning services required during all project phases as appropriate for the specific project; this must be communicated in the project requirements documents.

19-2 SUPPLEMENTAL CRITERIA.

Guidance for the Commissioning process is contained in ASHRAE Standard 202, ASHRAE Guideline 0, ASHRAE Guideline 1.1, ASTM E2813, **\1** ASTM E2947, **/1/** and NFPA 4. Other references are available that describe similar processes that may be used at the DoD Project Sponsor and Design and Construction Agent's discretion.

19-3 PRELIMINARY COMMISSIONING REQUIREMENTS.

In order to verify design and performance, and ensure that the Government requirements are met, employ commissioning practices appropriate to the size and complexity of the building and its system components and document specific roles and responsibilities for key commissioning participants.

19-3.1 Level of Commissioning.

Provide Commissioning for projects that are greater than 10,000 GSF (92.9 GSM) with a Construction cost of greater than $3 million dollars as described in paragraph 19-4. For small, non-complex, projects provide commissioning as described in paragraph 19-5.

Exception: When deemed appropriate by the DoD Project Sponsor and recommended by the Design and Construction Agent based on the project size and complexity, the commissioning requirements to be used (paragraph 19-4 or 19-5) shall be as directed by the DoD Project Sponsor.

19-3.2 Roles and Responsibilities.

Based on the commissioning leadership structure determined for the project, clearly define the roles and responsibilities of key commissioning participants to ensure that all required tasks are provided and that responsibility is appropriately assigned.

19-4 TOTAL BUILDING COMMISSIONING.

19-4.1 Process Overview.

TBCx must be executed during all project phases, including the design, construction, post-construction, and warranty phases. TBCx must at a minimum include the commissioning requirements of this chapter. TBCx must verify that building systems perform interactively according to the intent of the design, and that the systems meet the DoD Project Sponsor's operational needs. The Commissioning process must execute and document the commissioning activities required to comply with the Third Party Certification (TPC) requirements for the Project. Provide all commissioning documentation required to meet the TPC requirements.

The minimum systems listed here must be commissioned as appropriate for the specific project:

a. HVAC systems, including electronic digital control systems and building energy management systems.

b. Plumbing systems and associated controls.

c. Medical and dental gas, compressed air, and vacuum systems.

d. Steam (high, medium, and low pressure), clean steam, and other major energy plant equipment.

e. EPSs and their interfaces to other critical building system operations.

f. Lighting systems: automatic daylighting controls, manual daylighting controls, occupancy sensing devices, and automatic shut-off controls.

g. Fire suppression, smoke control, smoke or fire dampers, fire detection and alarm systems, and mass notification systems, and their interfaces to other building system components.

h. Communication systems including telecommunication infrastructure, NC, ITV, intrusion detection, infant abduction, other ESSs, and other communication systems.

i. Building systems that are incrementally constructed and commissioned, such as in phased construction projects.

j. Energy conservation equipment and systems, including solar hot water system and any renewable energy systems.

k. Water and energy measurement devices.

l. Building envelope, including exterior walls, fenestration, roofs, and openings.

19-4.2 Commissioning Leadership Structure.

The Commissioning leadership structure, including roles and responsibilities, must be fully defined in the project requirements documents, as the structure may vary depending on the acquisition strategy, size, complexity of the project, and expertise of the participants. Regardless of leadership structure, the process requires full and open communication for all parties to maximize the benefits of the process. The principal Commissioning Lead definitions and roles are noted here:

19-4.2.1 Commissioning Specialist for the Government (CxG).

The CxG is an entity having expertise in the commissioning of medical facilities of a scope and complexity comparable to the individual project, and employed regularly in building commissioning. Refer to paragraph 19-4.2.5 for additional qualifications.

a. The CxG may be person(s) employed by the Design and Construction Agent, or an entity directly contracted by the Design and Construction Agent, but not affiliated with the construction contractor. The CxG must provide management and oversight of the Commissioning process through the design, construction, and warranty phases to ensure it is effectively and thoroughly implemented.

b. The CxG must have documented commissioning authority experience in at least two building projects and be independent of the work of design and construction.

c. The CxG must meet the requirements and perform the roles specified for the commissioning authority required by the project's TPC. For small DB projects, the commissioning authority role may be provided by an independent third-party commissioning agent hired as a first tier subcontractor to the DB contractor as defined in paragraph 19-4.2.3 and they must meet the requirements and perform the additional roles defined for the CxG in this paragraph. Specific roles include the development and maintenance of the Owner's Project Requirements (OPR), development of the draft Commissioning Plan, and assisting in the development of Systems Manuals for the commissioned systems. At the discretion of the Design and Construction Agent and DoD Project Sponsor, the CxG must conduct a Lessons-Observed meeting at the end of the Commissioning process to discuss the process used, discuss what worked well and what could be improved, develop recommended improvements for future similar projects, and document the meeting in a closeout report.

19-4.2.2 Commissioning Specialist for the Design Phase (CxD).

The CxD must be an entity on the Design A/E staff, or directly contracted by the A/E, having expertise in the commissioning of medical facilities of a scope and complexity

comparable to the individual project, and employed regularly in building commissioning. Refer to paragraph 19-4.2.5 for additional qualifications.

For DBB projects, the CxD must be responsible for development of all design phase commissioning documentation, including hands-on development of the Commissioning Plan, and commissioning specifications to include Pre-Functional Checklists (PFCs) and Functional Performance Tests (FPTs). For DB projects, the CxD must be responsible for developing commissioning scope requirements for inclusion in the RFP.

19-4.2.3 Commissioning Specialist for the Construction Phase (CxC).

The CxC must be an entity employed as a first tier subcontractor by the construction contractor, independent from the installing contractors, having expertise in the commissioning of medical facilities of a scope and complexity comparable to the individual project, and employed regularly in building commissioning. Refer to paragraph 19-4.2.5 for additional qualifications.

The CxC must be responsible for scheduling and coordinating all construction phase commissioning activities, refinement of PFCs and FPTs to match the specific purchased equipment, and direct oversight and reporting of the execution of the Commissioning process.

19-4.2.3.1 Design After Award CxC Responsibilities.

For projects which include design-after-award activities (for example Design-Build), the CxC must additionally be responsible for development of all commissioning documents required during design, including the Commissioning Plan and commissioning specifications to include PFCs and FPTs.

19-4.2.4 Commissioning Lead Role Application.

The CxG is required for all project procurement methods. The CxD is typically required for DBB projects and may be utilized during DB RFP preparation for DB projects. The CxC is typically required for DBB and DB projects.

19-4.2.5 Commissioning Lead Qualifications.

The Commissioning Specialist entities must be members of, or certified by, a nationally recognized commissioning organization. Each entity must employ a commissioning professional who must be the Commissioning Lead for their area of responsibility. In addition, each entity must employ additional staff to ensure adequate attention to all systems requiring commissioning as identified in paragraph 19-4.1.

Table 19-1 provides the minimum qualification requirements for Commissioning Lead personnel:

Table 19-1 Commissioning Lead Personnel Qualifications

Qualification	CxG	CxD	CxC
Registered Professional Engineer (P.E.)	YES	YES	
Proven hands-on experience in the commissioning of projects of equivalent scope	YES	YES	YES
Certified as a commissioning professional by a nationally recognized commissioning organization	YES	YES	YES

19-4.3 Commissioning During Design.

The Commissioning process must be fully defined in the design phase for each project. The CxG should be involved early in project development to facilitate the development of the DoD Project Sponsor's OPR document, which records the expectations and requirements for the commissioned systems, and the Commissioning Plan, which outlines the process, commissioned systems, participants, roles and responsibilities, communication procedures, and deliverables. The scope and rigor of Commissioning activities to be completed during construction need to be defined in the contract documents so that they are clearly understood and can be adequately bid. The CxG should review the design documents at various stages of development to verify that the designed systems are commissionable, and suggest alternative designs that would save energy, allow for system optimization, and decrease overall LCC. The CxG must oversee the development of the Commissioning Specifications by the CxD and/or CxC for design after award work features, which define the specific SOW and the roles, responsibilities, and requirements of the construction contractor's commissioning team members. The specifications must also include draft PFC and FPT procedures for each system to be commissioned to adequately define the scope and rigor required.

19-4.4 Commissioning During Construction.

During the construction project, it is necessary for the CxG to oversee the contractor's commissioning execution as managed by the CxC to verify that the contractor's proposed testing procedures, personnel, and instrumentation fully meet the design document requirements, that the tests are properly conducted, and results documented. As part of the commissioning process, verify that adequate training has been provided on all commissioned systems.

19-5 SMALL PROJECT COMMISSIONING.

19-5.1 Process overview.

Perform Functional Performance Testing/Acceptance Testing (FPT/AT) in accordance with this section using generally accepted engineering standards. Incorporate FPT/AT into the design and construction of the project to verify systems specified in this section perform in accordance with construction documents.

The minimum systems listed in paragraph 19-4.1 must be covered by FPT/AT as appropriate for the specific project.

19-5.2 Oversight of the testing.

The Government will designate an Acceptance Representative to lead, review, and oversee completion of FPT/AT activities. The Acceptance Representative will review construction documents to verify relevant sensor locations, devices, and control sequences are properly documented.

The construction documents must indicate who is to perform acceptance tests and the details of the tests to be performed.

19-5.3 Requirements during construction.

Verify proper installation and start-up of the systems. Provide a minimum 7 day trend log of the system operation prior to the FPT/AT. Perform FPT/AT, complete test forms and include a signature and license number, as appropriate, for the party who has performed the test.

Verify a system manual has been prepared that includes O&M documentation, full warranty information, and provides operating staff the information needed to understand and optimally operate building systems.

19-6 SPECIFIC SYSTEM REQUIREMENTS.

19-6.1 Interoperability.

Various systems, such as HVAC systems, fire alarm and fire detection systems, EPSs, communication systems, and others, have complex, interwoven operational requirements in medical facilities. For each project where applicable, designers must develop new and modify existing specifications as needed to provide for integrated systems testing to validate interoperability of these systems and to verify correct function, acceptable speed of response, operation in normal and failure modes, and restoration to normal operation. Integrated systems testing of fire systems and life safety systems must be provided in accordance with NFPA 4. In all cases, detailed testing protocols or system diagrams must be developed to clearly convey the required scope of the commissioning effort.

19-6.2 Addition and Alteration Considerations.

For addition and alteration projects, commissioning specifications must be developed to describe the step by step procedures required for interim, as well as final, commissioning for systems constructed (or altered) and placed in operation on a temporary, or sequential, basis.

APPENDIX A BEHAVIORAL HEALTH DESIGN

A-1 GENERAL.

This appendix provides mandatory criteria for the design and development of the built environment for Behavioral Health (BH) functions in new and existing MTFs.

A-2 SCOPE OF BEHAVIORAL HEALTH SERVICES.

A-2.1 Inpatient Functions.

DoD Space Planning Criteria Chapter 460 outlines BH services and programs provided in MTFs in the Military Health System (MHS).

Services specifically covered in Chapter 460 are for 24-hour healthcare operations that are provided on inpatient units for Behavioral Health and Substance Abuse / Alcohol Rehabilitation programs. Additionally, Partial Hospitalization Program, which is a day treatment program for patients who need intensive treatment but not 24 hour care, is often collocated with an inpatient BH Unit. The Partial Hospitalization Program will follow the requirements specified for inpatient BH Units in this appendix if the Program is located in an inpatient MTF.

A-2.2 Outpatient Functions.

DoD Space Planning Criteria Chapter 318 outlines services and programs provided in an outpatient BH setting. Where outpatient is used in this appendix, it includes freestanding BH facilities that include the services noted below, as well as BH clinics located within a hospital or medical center. Services specifically covered in this chapter are Behavioral Health, Child and Adolescent BH Services, the Family Advocacy Program, and the Substance Use Disorder Clinic.

DoD Space Planning Criteria Chapter 350 includes spaces that support the care of BH patients who seek treatment at the Emergency Department (ED).

A-3 BEHAVIORAL HEALTH PROGRAM.

A-3.1 Concept.

In accordance with specific BH project requirements, the DoD Project Sponsor will develop the Functional Program to describe how the inpatient BH Unit, or outpatient clinic, will function within the physical environment. The MilDep's Surgeon General's BH Consultant and facility end users will also assist with developing the Functional Program to identify how the design criteria, as outlined in this appendix, will be implemented and identified when developing the scope of work for the project.

A-3.2 Behavioral Health Design Guide.

Design the inpatient BH Unit, and where appropriate the outpatient BH clinic to meet all of the requirements of the Behavioral Health Design Guide (BHDG), which is available from Behavioral Health Facility Consulting, LLC.

Exception: Due to the changing nature of behavioral health design, consider using the most current BHDG for product selections and finishes. The DoD Project Sponsor may require specific safety features from the current BHDG.

A-3.3 Functional Program and Safety Risk Assessment.

Develop the Functional Program in conjunction with the BH Safety Risk Assessment (SRA), also available at the link, to identify project specific design requirements. Safety levels identified by the BH SRA for the inpatient unit may not be the same in all areas nor be the same for each unit/population; and are fundamentally correlated to an understanding by the facility staff of a patient's intent for self-harm. For example, during the day the activity room may be Level 2, however at night on the weekends, it may be a Level 3. The Functional Program and SRA should take into account the number and location of staff in regard to specific areas or spaces. Review and update the Functional Program and the SRA during development of the RFP, and throughout the design and construction phases of the project. The A/E of Record is responsible for maintaining and updating the SRA during design and construction. Refer to Chapter 3 for specific SRA requirements and Appendix C for design submittal requirements.

A-4 CONSULTING SERVICES.

For BH projects, the A/E of Record must provide the services of a qualified behavioral health consultant at project initiation. The consultant must provide design, FF&E, and Low Voltage Systems input to inform the 35 percent design effort. The consultant must also provide input on the project SRA throughout the design process to identify potential safety concerns, review for compliance with the Functional Program, in relation to adjacencies, flow, and with the BHDG for product selection related to interior finishes, toilet accessories, hardware, electrical fixtures, etc. The consultant will present possible solutions, and explain the positive and negative elements of each, in collaboration with the DoD Project Sponsor. A qualified BH consultant is one who has been in business or employed as a BH professional or provider, for a period of not less than five years, and has had experience with the planning and design of inpatient and outpatient BH medical facilities. The consultant must not be involved in the sale, installation, distribution, manufacture, or representation of BH equipment. Furthermore, the consultant must demonstrate prior experience with DoD MTFs that relates to the scope and nature of the project to include locations OCONUS, if applicable.

A-5 DESIGN CRITERIA.

A-5.1 Environment.

Design a safe, functional, therapeutic, and aesthetically pleasing, non-institutional BH environment that “normalizes life” for patients, staff, and visitors. There are four “areas of concern” that must be considered when designing a BH environment: 1) Patient Safety – reducing risks for suicide/self-harm or harm to other patients; 2) Staff Safety – reducing risks or opportunities for patients to harm attending staff; 3) Structural Resistance – reducing damage to facilities and preventing an increase in maintenance costs; and 4) Life Safety - egress for inpatient behavioral health may include delayed egress locking devices, for patients, staff and visitors. The Functional Program will include the following: applicable codes and regulations, to include operational risk mitigation strategies (for example staff rounding, monitoring by staff, and doors-open policy during daytime hours), the findings of the BH SRA, and include the implementation of the design criteria set forth in this appendix to provide direction on several means of improving safety of staff and patients in BH settings. The Functional Program will state unequivocally that, whereas safety of staff and patients is paramount, the design intent is to limit the “institutional” look of the BH environment. Generally speaking, the using MilDep Surgeon General’s BH Consultants have not supported such measures as bullet-proof glass surrounding reception desks, or security staff and metal detectors at entrances to Outpatient BH Clinics. The implementation of such extraordinary measures will be identified early and incorporated into the SRA and project documents following full discussion with the Design and Construction Agent and the DoD Project Sponsor.

A-5.1.1 Exterior Spaces.

Consider the inclusion of an outdoor area during project design to support respite and group activities as a component of the inpatient BH therapeutic environment. This outdoor area, which may have attached or unattached canopies or overhangs, will comply with Chapter 3 for scope and cost estimating. Plan the location and design of this outdoor space to reduce the risk of elopement, climbing, jumping, impalement and concealment in relation to wall surfaces, furniture selection and placement, sufficient lighting for nighttime, staff sight lines and video surveillance use, and landscaping features are essential. Include the outdoor area in the SRA. Apply design considerations and safety features noted in the sections below.

A-5.1.2 Interior Spaces.

Drivers that influence the selection of materials include safety, durability and maintenance, infection control, integrated wayfinding, and sustainability. Every effort must be made to eliminate ligature points, sharp edges, and the potential to make weapons out of objects or materials. The term ligature resistant as used in this appendix is defined as “without points where a cord, rope, bed sheet, or other fabric/material can be looped or tied to create a sustainable point of attachment that

may result in self-harm or loss of life." This is consistent with The Joint Commission's definition.

The DoD Project Sponsor are responsible for the validation of the SEPS generated PRC to ensure JSNs reflect the BHDG requirements and support the SRA.

A-5.1.3 Architecture.

Incorporate the following guidance when developing the design and layout of spaces for BH care for inpatient and outpatient settings:

a. Avoid dead-end corridors, alcoves or other architectural features that provide concealment or blind spots.

b. Provide column-free spaces in patient bedrooms, group therapy or counseling rooms, activity rooms and other rooms where patients and staff interact.

c. Provide staff areas that promote team collaboration and HIPAA compliance while maintaining visibility and connection between the care team and patients. Design staff areas to provide an area of refuge (but not as used in the context of NFPA 101) for staff safety.

d. Maximize windows to exterior and interior spaces to create a sense of transparency, openness, and safety.

e. Segregate noisy activities (art therapy) and quiet activities (patient bedrooms or counseling spaces) to improve processes and consolidate disciplines.

f. Outfit the "transition zone" between the inpatient bathroom and the bedroom with ligature resistant fixtures and features and select a bathroom door that aligns with the SRA requirements specific to a particular patient or groups of patients who may not be permitted access to the inpatient bathroom.

g. Locate staff support spaces such as janitor closets and soiled utility rooms, in an area that promotes access without having to enter secure patient areas. To enhance safety, provide self-closing and self-locking mechanisms on the doors of staff rooms that are directly accessible from the secure patient care area. Mount the closer on the staff side of the door. Provide tamper-resistant locksets and a vision panel in the door of electrical and communications rooms that are located in the secure patient area of an inpatient unit.

h. Orient and layout furniture and equipment in BH provider/counselor offices, group therapy rooms and other locations where staff and patients interact to provide a clear path of egress or an "escape corridor."

i. Locate two means of egress for each group therapy room (OPMH1), either on opposite ends or sides of the room.

j. Do not reduce the size of BH counseling rooms (OFDC1, OFDC2) from 120 NSF, as noted in DoD Space Planning Criteria Chapters 460 and 318.

A-5.1.4 Furniture, Fixtures and Artwork.

For the inpatient BH Unit, provide furniture and fixtures that have rounded edges and curves and meets or exceeds the requirements noted in the BHDG to maximize safety for patients, staff, and visitors. Minimize the amount of furniture in BH patient bedrooms and outfit with furniture that is heavily weighted or fixed to the floor, is non-breakable and contains no compartments for hiding. Utilize ligature resistant clothes hooks. Coordinate the placement of inpatient BH Unit furniture with the ceiling plan to avoid patients gaining access to ceiling fixtures or ligature points. Select artwork for all BH settings that is soothing and provides a connection to nature. Avoid abstract artwork or finishes that produce animated or other illusions. The DoD Project Sponsor will define specific inpatient BH Unit requirements for location of artwork as well as provide instructions for mounting and hanging of artwork to avoid ligature risks or detachment from the wall. Provide wall mural artwork in BH patient bedrooms, and elsewhere in the BH setting to minimize safety risks. Shower curtains are prohibited in inpatient bathrooms. Provide cabinet and drawer locks for all areas where patients may be unsupervised for even short durations as identified in the Functional Program and the SRA.

A-5.1.5 Finishes.

Incorporate colors, textures and surfaces that are soothing, do not produce a harsh glare, shiny surface, or distorted reflections, and provide a connection to nature. Construct wall and other room finish materials to resist intentional damage or removal. For the Inpatient BH setting incorporate wall and ceiling finishes that are abrasion and indention resistant; wood veneer products that have a natural finish and meet or exceed the latest ANSI/HPVA HP-1 tolerance standards. For other specific finishes, provide products that meet or exceed the minimum requirements as noted in the BHDG.

A-5.1.6 Walls.

For inpatient BH settings, construct wall assemblies with impact and abrasion resistant gypsum board. Utilize heavier construction materials, as recommended by the safety guidelines in the BHDG, for the inpatient BH Unit seclusion room(s) and Emergency Department secure holding room(s). Wall cove base used for inpatient BH Units should be cut into short lengths not to exceed 14 in (360 mm). Secure the base along the edge with pick resistant caulk to prevent tampering or hiding contraband. Do not use metal trim wall cove base. Do not use wall cove base in seclusion or secure hold rooms; extend wall gypsum to the floor and finish with pick resistant caulk.

Construct outdoor areas dedicated to the inpatient BH unit with smooth wall surfaces that have no grooves or crevices to prevent climbing, and are ligature-resistant. Wall height must be a minimum of 14 ft (4.27 m) above the outdoor finished floor area.

A-5.1.7 Ceilings.

Apply the Appendix B requirements specified for ceiling type and height to all room codes noted in the project specific Program for Design (PFD). Where hard ceilings are specified for the inpatient BH setting per the Functional Program and SRA, provide impact resistant gypsum board with key lockable access panels that comply with the BHDG. Where lay-in ceilings are permitted, provide security clips to restrict access to ligature points in the space above the drop ceiling. The installation of motion sensors above lay-in ceilings to alert staff to patient tampering is not a mandatory safety measure and should only be used where required by the project SRA. Coordinate the location of ceiling fixtures such as overhead lights, sprinklers, and registers on an inpatient BH Unit with room furniture plans and the safety guidelines in the current BHDG. Ensure furniture cannot be moved, stacked, or climbed upon to access any ceiling fixtures or materials. Wherever devices and accessories (for example lights, air grilles, access panels, toilet accessories, etc.) are mounted on the ceiling or wall and they do not fit securely, finish the edges or flanges with pick resistant caulk to fill the gaps.

A-5.1.8 Floors.

Apply the Appendix B requirements specified for flooring material to all BH room codes in both inpatient and outpatient settings. Minimize joints and seams to the furthest extent possible in all BH rooms outfitted with tile or sheeting to enhance safety.

A-5.1.9 Doors.

Apply requirements for door locking, latching, and access control arrangements (for example fail-safe electronic locks and fail-secure electronic locks) in accordance with Chapter 5 and UFC 3-600-01. Wherever a BH inpatient crosses the threshold of a door, utilize ligature resistant hardware. Design a sally port at the primary entry to the inpatient BH Unit that locks and unlocks in sequence to optimize access control. Apply the requirements for sequential locking to a sally port at any secondary entries. Where patient bedroom doors require locking, provide ligature resistant “classroom” type door locks. All inpatient BH Unit doors and hardware, including, but not limited to, hinges and handles, must comply with the requirements in the current BHDG. Identify which doors on the inpatient BH Unit require risk-mitigation devices installed to decrease the risk that the top of a corridor door will be used as a ligature point; and which doors require barricade risk mitigation strategies such as outward swinging doors; double-acting doors; a door in a door; an unequal pair of double egress doors, or an additional door with outward swing. Provide additional risk mitigation strategies, such as appropriate rounding and monitoring by staff, or requiring that doors be left open during certain hours. All solid doors installed in a BH setting will be outward swinging or utilize rescue hardware that provides double acting, continuous pivot hinges.

Reevaluate inpatient BH Unit door types and hardware requirements as needed, and document in the Functional Program and SRA prior to finalizing the contract documents.

A-5.1.10 Windows and Glazing.

Glazing thickness will be calculated by the manufacturer. Laminated glazing is the preferred alternative to glass-clad polycarbonate glazing.

A-5.1.10.1 Interior windows.

Install impact-resistant glass products in all patient accessible areas inclusive of interior window surfaces in all inpatient BH Units. Impact-resistant glass products are recommended for outpatient facilities in areas where patients may be left unattended. Test interior windows in accordance with American Architectural Manufacturers Association AAMA 501.8-13: Standard Test Method for Determination of Resistance to Human Impact of Window Systems Intended for Use in Psychiatric Applications.

A-5.1.10.2 Exterior Windows.

Install impact-resistant glass products on the interior face of exterior windows where the window sill is 6 ft 6 in. (1961 mm) or less. Design exterior windows to resist impact loads of 2000 ft-lb (2712 N·m) applied from the inside. Where operable windows are used, also test hinges and locking devices. Install integral blinds and ligature resistant blind hardware for the exterior windows in BH patient bedrooms. For other inpatient BH areas or outpatient settings, install window roller shade treatments specifically manufactured for use in the BH setting that meet or exceed the current safety requirements of the BHDG.

A-5.1.11 Mechanical HVAC.

HVAC Air Diffusion Devices (for example grilles, registers, etc.): Install tamper and ligature resistant air diffusion devices in accordance with the current BHDG. Where perforated diffusion devices are required, perforations must be a maximum of 3/16 in. (5 mm).

A-5.1.11.1 Thermostats.

Install thermostats in accordance with the current BHDG.

A-5.1.11.2 CO2 sensors.

CO2 sensors may not currently be available in a ligature resistant style and should only be installed where permitted by the project SRA. CO2 sensors may be installed within ducts.

A-5.1.12 Plumbing.

Install ligature resistant plumbing fixtures in inpatient BH settings; include floor mounted toilets with back water supply constructed of high impact resistant materials that promote a residential versus institutional setting. Shut-off valves and cleanouts for fixtures in BH patient bedrooms must be directly accessible from the corridor. Install

tamper / vandal resistant drains in all inpatient bathrooms, toilet/showers, kitchenettes, and laundry rooms. Install a floor drain for each shower and a second floor drain for the bathroom area. Select drain types (standard round or trench drains) that are tamper and ligature resistant and that minimize opportunities for intentional blockage. At locations where inpatients will be unsupervised during showering, install a “timing” system that has a re-set capability to limit the length of time that shower water may continuously flow.

A-5.1.13 Electrical.

Install electrical power outlets in all areas of the inpatient BH setting that are tamper / vandal resistant and GFCI. Install in inpatient BH settings electrical switches and outlets made of polycarbonate material that are affixed with tamper / vandal resistant screws to reduce the risk of exposing the wiring. The Functional Program and SRA should indicate if outlets will be installed in the BH Unit patient bedrooms and toilet/showers. Wherever outlets are installed in these inpatient rooms, they must have a dedicated circuit. Do not install outlets in the BH Unit seclusion room(s) or the ED secure holding room(s). In the outpatient setting, install tamper resistant outlets.

A-5.1.14 Lighting.

Identify the use of, and placement of table lamps for the outpatient setting in the Functional Program and SRA. Do not outfit the secure area of inpatient BH Unit with table lamps. Install tamper / vandal resistant and ligature resistant light fixtures with impact resistant lenses in the inpatient BH setting. Install light fixtures in all inpatient BH areas, including corridors, counseling, interview, activity, patient bedrooms, and all areas not under direct observation by staff, including blind spots and areas not under video surveillance. In the BH patient bedroom, install a tamper/vandal resistant, ligature resistant night light that is situated close to floor level to light the path of travel from the patient bed into the patient bathroom. Activation of the night light will be by room lighting level and by a switch exterior to the patient bedroom. Install interior lights in painted hollow metal frames with laminated glazing in inpatient BH settings. Calculate the glazing thickness and the size of the glazing stop based on the size of the light. Secure the glazing stops with tamper /vandal resistant screws to secure the glazing stops. The Functional Program to identify all BH rooms that require dimming beyond those that are already required to have dimming capability per Appendix B. Install impact and tamper / vandal resistant device plates (switches, receptacles, covers) secured with tamper resistant fasteners all areas where BH light fixtures are required per the Functional Program and SRA. Securely mount and fasten emergency exit signs to walls with tamper-resistant screws. Do not mount emergency exit signs to ceilings.

A-5.1.15 Communication.

A-5.1.15.1 Audio/Visual.

At the primary entry to a BH Unit, install an audio/visual communications system that will connect this entrance to the staff /nurse station, or another location as directed in the Functional Program, to provide call-to-enter capability.

A-5.1.15.2 Nurse Call.

Install Nurse Call push buttons in BH patient bedrooms and the associated bedroom toilet area and the shower, and in patient toilets in all BH settings. Pull cords are prohibited. On the inpatient BH Unit, install ceiling mounted speakers and microphones to facilitate the staff call-back function. Do not install a dome light over the inpatient toilet/shower door. Install a Nurse Call override switch outside each BH Unit bedroom and seclusion room, and each ED secure holding room.

A-5.1.15.3 Behavioral Health Staff Assist Alarm System.

Install a standalone BHSA Alarm system in all BH settings that complies with the DHA Performance Standard 28-26-36. The BHSA Alarm system is a component of the Electronic Security system and is categorized as Personal Property according to Section 6 of MIL-STD-1691. The BHSA Alarm system is independent of the Nurse Call system, the Intrusion Detection system, and the Duress Alarm system. Additionally, DO NOT connect the BHSA Alarm system to the facility local area network (LAN) or the wireless local area network (WLAN). Incorporate wireless BHSA alarm pendants to be worn by the staff, and wall mounted wireless or wired devices. The Functional Program and the SRA to indicate the locations of the wall mounted devices, to include specific rooms, corridors, and areas throughout the BH setting. Install ligature resistant wall mounted devices adjacent to the door inside an enclosed room. Transmit all BHSA Alarm device signals to the same annunciator station located at the reception point, nurse station, or other location identified in the Functional Program. When a signal is activated, an alarm tone will sound, and a graphical display at the BHSA alarm annunciator station will indicate the signal origination point, and the location of the staff member sending the alarm. The wireless pendant must comply with the DHA Performance Standard 28-26-36. The location feature will be deactivated when the staff member is outside of the BHSA alarm zone. The components of the BHSA Alarm system provide an opportunity for BH staff to be “first” responders and intervene in situations that do not require assistance from the facility security office or the Installation Provost Marshall. If a situation escalates and an emergency arises, the Duress Alarm system will be activated.

A-5.1.15.4 Wi-Fi Transmitters.

Install recessed, ligature resistant ceiling mounted Wi-Fi transmitters with a break-away feature to support the wireless IT system and the BHSA Alarm system.

A-5.1.15.5 Duress Alarm System.

Install a Duress Alarm system that allows staff to immediately activate a Duress Alarm button or equivalent in the event that a situation requires an elevated level of response from either the Facility Security office or Installation security. Integrate communication capabilities between the Duress Alarm system and other entities on the Installation as determined by the Functional Program and the SRA. Install wiring, conduit, power supply, buttons, and other appurtenances to support the Duress Alarm system at each Duress Alarm annunciator station. Install Duress Alarm buttons in areas where staff are present at all times; for inpatient BH Units, this is the staff / nurse station, and for outpatient BH settings it is the reception desk.

A-5.1.16 Video Surveillance System.

For inpatient BH units, install Video Surveillance System (VSS) cameras at locations determined by the DoD Project Sponsor, and identified in the Functional Program. Install VSS cameras that capture video monitoring only; no audio recording function is permitted for BH settings. Install monitoring stations on the inpatient BH Unit and at a central security location in the inpatient MTF, as directed in the Functional Program. As a minimum, install cameras in locations to assist with supervision of the admissions / triage area, group activity areas, corridors, entrances, fire exits, staff / nurse station(s), exercise areas (interior and exterior), and patient laundry. DO NOT install VSS cameras in BH patient bedrooms; however, they may be installed in the seclusion room(s) on the BH Unit or in the secure holding room(s) in the ED. Cameras must be tamper /vandal resistant and they may be unique for the BH Unit or ED BH spaces rather than integrated with the MTF security system. Install ligature resistant, wall or ceiling mounted VSS cameras mounted with tamper resistant fasteners. Install camera cases and lenses that are impact resistant or shatter proof.

A-5.1.17 Televisions.

Do not install Televisions (TVs) in BH patient bedrooms. Locate TVs in other spaces for inpatient and outpatient settings as reflected in the project's PRC. Install wall mounted TVs that meet or exceed the current safety requirements noted in the BHDG.

A-5.1.18 Security.

In accordance with the Functional Program and SRA, install a small safe in a secured location close to, but outside, the primary entrance of the inpatient BH Unit to allow security personnel to stow side arms prior to entering the Unit. Remote release of BH Unit entry doors is prohibited. For inpatient BH settings, provide the following minimum security requirements: control of corridor lighting including motion detectors, securing of patient bedroom doors, notification of patient bedroom door switch position to staff / nurse station, incorporation of a sally port at the secondary BH Unit entrance(s), VSS monitoring activated by motion detectors, and Electronic Security System access control at entrances/exits (interior and exterior), staff-only spaces, stairwells, etc. For outpatient settings, install as part of the Electronic Security System, electronic access

control from reception/waiting to treatment areas and from the treatment areas to any back-of-house corridors. For outpatient BH settings, provide VSS cameras associated with the duress alarm button located at reception.

A-5.1.19 Fire Protection and Life Safety.

See Chapter 14 for additional requirements. Design specific fire protection and life safety features to support the BH environment (for example eliminating strobes or fire alarms from Child Observation, Group Therapy, and other rooms where these devices may lead to panic, or trigger undue stress in BH patients).

A-6 EQUIPMENT SPECIFICATIONS.

Specify equipment requirements that meet or exceed the standards as noted in the current BHDG. Vendors will often use the terms “tamper-proof”, “tamper-resistant”, “vandal proof”, and “institutional,” and apply them arbitrarily. Closely examine the specifications and equipment submittals provided by both the construction contractor and for initial outfitting purchases to ensure they meet the requirements of the BHDG, the Functional Program, and the SRA.

This Page Intentionally Left Blank

APPENDIX B ARCHITECTURAL AND ENGINEERING DESIGN REQUIREMENTS

B-1 GENERAL.

Appendix B is a compilation of mandatory architectural and engineering design criteria organized by standard Room Codes. The Design and Construction Agent, in conjunction with the DoD Project Sponsor, may provide additional criteria to meet special needs, for example, bariatric design, demountable partitions, contingency facilities. The Room Codes used to organize this appendix are the same as the codes used to organize the PFD and the Equipment List so that the initial design requirements should be well established for the A/E. For Room Codes that are used but are not included in Table B-1, the room criteria must be obtained from the DoD Project Sponsor. A period (".") indicates that there is no specific requirement for this parameter or the parameter matches the ambient conditions.

B-2 LEGEND & NOTES.

B-2.1 Room Code.

Room identifier from DoD Space Planning Criteria. This five digit Code is the reference key that ties the criteria to the project PFD.

- * An asterisk (*) prior to the Room Code indicates that it is a new Room Code added since the previous UFC version.
- The letter "X" in the fifth digit indicates that the criteria applies to multiple spaces/room codes in accordance with PFD.

B-2.2 Room Function.

Room function from DoD Space Planning Criteria.

B-2.2.1 Code.

Category of Patient Care Space in accordance with NFPA 99. The listed code defines the category for the expected Patient Care Space function. The DoD Project Sponsor must define room function and reassess codes to be used for the specific project. The A/E must validate the room function and propose appropriate changes to a room category for Patient Care Spaces. The A/E will ensure the architectural and engineering criteria are appropriate for the code used. A waiver will be required for changes to room categories.

The categories of Patient Care Spaces are independent from and should not be confused with Building System Categories. Building System Categories must be as defined in NFPA 99.

1 Category 1 – Critical Care Space

2 Category 2 – General Care Space

3 Category 3 – Basic Care Space

4 Category 4 – Support Space

C Category to be determined by the DoD Project Sponsor

N Not applicable. This room is not intended for patient examination or treatment.

B-2.3 Space Parameter Notes.

For room codes that do not have Architectural and Engineering design parameters listed, utilize the following notes:

a. For this room code, utilize the Architectural and Engineering parameters of the room where this area is located unless otherwise directed by the DoD Project Sponsor.

b. This new room code is under development. Architectural and Engineering parameters must be provided by the Design and Construction Agent and DoD Project Sponsor.

c. Provide emergency power for selected electrical receptacles.

d. Provide essential power only as required by the DoD Project Sponsor for selected equipment connections.

e. Provide dedicated exhaust for this area.

f. Provide minimum of 700 lux for this area.

B-3 ARCHITECTURAL.

B-3.1 Materials and Finishes.

FL Floor and base finishes. See Architectural Note 1.

<u>Poured flooring finishes</u>

AR Acrylic resin system with integral coved base. See Architectural Note 9.

ER Poured epoxy resin system with integral coved base. Includes epoxy terrazzo flooring systems. See Architectural Note 9.

PR Poured resin flooring– either AR or ER, consistent in rooms with the same room code.

PS Poured specialty flooring with integral base.

<u>Tile flooring finishes</u>

CP Carpet Tile with rubber base. See Architectural Note 2 and 12.

CT Ceramic or Porcelain tile with ceramic/porcelain tile base.

LV Luxury vinyl tile with rubber base. See Architectural Note 2.

RT Rubber tile with rubber base.

SD Static Dissipative Tile with rubber base.

UT User specific tile: For projects where Navy provides the facility maintenance, use LV. Otherwise, use LV or RT with Design and Construction Agent approval after coordination with the DoD Project Sponsor.

Sheet flooring finishes

SM Sheet material: either SR or SV, consistent in rooms with the same room code. For projects where Navy provides the facility maintenance, use SV.

SR Sheet rubber with integral rubber base. **\1** See architectural note 6. **/1/**

SV Sheet vinyl with integral vinyl base. See Architectural Note 3.

US User specific sheet: For projects where Navy provides the facility maintenance, use SV. Otherwise, use SR.

Other flooring finishes

CS Concrete sealer. Resilient base on gypsum wallboard and plaster walls. No base on concrete or block walls.

MA Match finishes of the adjacent area where this space is located.

PF Prefabricated.

SF Safety Flooring with rubber base or integral base for wet areas.

SP Special. Determined by the Design and Construction Agent in coordination with the DoD Project Sponsor. Describe specific finish requirements in the final RFP for DB projects or by the 35% design submittal for DBB projects.

WL Wall Material & Finish. First character is wall material. Second and third characters are finish. See Architectural Note 1.

Wall Material (first character)

C Concrete.

B Concrete block or clay tile.

G Gypsum wallboard. See Architectural Note 4.

L Lead lined gypsum wallboard. See Architectural Note 11.

S Special. Determined by the Design and Construction Agent in coordination with the DoD Project Sponsor.

Wall finish material (second and third characters)

AT Acoustical wall treatment, such as fabric, panels, or alternate material on painted finish.

CS Concrete sealer.

CT Ceramic or Porcelain tile.

LG Liquid Glaze Coat. See Architectural Note 5.

PF Prefabricated.

PT Paint.

EL Epoxy coating, seamless, lead lined.

EP Epoxy coating, seamless.

SP Special. Determined by the Design and Construction Agent in coordination with the DoD Project Sponsor.

SS Solid surface material wall cladding. See Architectural Note 13.

CLG Ceiling Material and Finish. See Architectural Note 1. First character is ceiling material. Second and third characters are finish.

Ceiling material (first character)

A Acoustic ceiling tile.

C Concrete.

E No ceiling required, exposed to floor/roof above.

G Gypsum wallboard.

S Special. Determined by the Design and Construction Agent in coordination with the DoD Project Sponsor.

Ceiling Finish Material (Second and third characters)

CS Concrete sealer.

LG Liquid Glaze Coat.

PF Prefabricated.

PT Paint.

SP Special. Determined by the Design and Construction Agent in coordination with the DoD Project Sponsor.

EP Epoxy coating, seamless, with coved corners.

T1 Standard finish.

T2 Waterproof finish.

XP No ceiling or finish required, exposed to floor/roof above.

B-3.2 CEILING HEIGHT.

CLG HT Ceiling height in feet and inches (millimeters), unless noted otherwise.

A 10 ft (3050 mm) minimum.

B If ceiling is provided, 10 ft (3050 mm) minimum.

C No ceiling required, exposed to floor/roof above.

D 9 ft (2750 mm) minimum or as required to accommodate equipment usage.

VAR Varies (Designer's choice).

B-3.3 DOOR SIZE.

DR SIZE Door width in feet and inches (millimeters), unless noted otherwise.

A Pair 30 in. (760 mm) doors

B Pair 36 in. (915 mm) doors

C { not used }

D Double doors, uneven: 48 in. (1220 mm) and 18 in. (460 mm)

E Pair 36 in. (915 mm) doors or 48 in. (1220 mm) doors as directed by the DoD Project Sponsor.

F { not used }

G In clinics, provide 42 in. (1672 mm) doors
In hospitals, provide uneven double doors, 42 in. (1672 mm) and 18 in. (459 mm)

H Pair 48 in. (1220 mm) doors, 8 ft - 6 in. (2591 mm) breakaway glass doors, or uneven double doors (48 in. (1220 mm) and 18 in. (458 mm)) as directed by the DoD Project Sponsor.

I 10 ft (3050 mm) by 10 ft (3050 mm) minimum. Number as required by dock.

J Main OR door, pair 36 in. (915 mm) doors. Staff door from clean corridor, 48 in. (1220 mm) door. Door to sub-sterile, 42 in. (1220 mm) door.

K Main OR door, pair 36 in. (915 mm) doors or 48 in. (1220 mm) and 18 in. (458 mm) uneven doors or 42. in (1672 mm) and 18 in. (458 mm) uneven doors as directed by the DoD Project Sponsor. Staff door from clean corridor, 48 in. (1220 mm) door. Door to sub-sterile, 42in. (1672 mm) door.

L Open (no door).

M Open (no door) or 36 in. (915 mm) door as directed by the DoD Project Sponsor.

N Open (no door) or 48 in. (1220 mm) door as directed by the DoD Project Sponsor.

O Open (no door) unless directed otherwise by the DoD Project Sponsor.

P Open (no door). Provide cubicle curtain only at entrance to cubicle and minimum 48 in. (1220 mm) door into area where the cubicles are located.

Q Open (no door). Provide cubicle curtain only at entrance to cubicle and minimum 48 in. (1220 mm) door into area where the cubicles are located.

SP Special. Determined by the Design and Construction Agent in coordination with the DoD Project Sponsor.

VAR Varies (Designer's choice).

VET Special door in veterinary facility. See Architectural Note 10.

B-3.4 NOISE.

NC The first line indicates the allowable range (minimum to maximum) noise coefficient (NC) required in the room. See Architectural Note 7.

STC The second line indicates the composite Sound Transmission Class (STC) required. See Architectural Note 8.

SP Special requirements. Determined by the Design and Construction Agent in coordination with the DoD Project Sponsor.

STC 50* An asterisk after the 50 designates that the STC requirement is 50 for all facilities except those where Navy provides facility maintenance, in which case the STC requirement is 40.

B-4 ARCHITECTURAL NOTES.

1. When two finishes are appropriate for a room, provide the preferred finish (1st line) shown in Table B-1, unless the Design and Construction Agent selects the alternate finish (2nd line) after coordinating with the DoD Project Sponsor. Provide the finishes shown in Appendix B used unless otherwise coordinated and approved by the DoD Project Sponsor and directed by the Design and Construction Agent.

2. Rubber Base. Rubber coved base for use with resilient tile and carpet. Coved base must terminate and butt at the face return of steel door jambs. Fire-retardant wood blocking or metal runners must be provided at the steel stud base channel runner for all gypsum board corridor walls.

3. Sheet Vinyl. Solid, seamless vinyl in roll format with routed, welded, grooved seams where melted vinyl is used for an impervious, waterproof seal. Chemical sealants are unacceptable. Cushioned sheet vinyl may not be used. Provide seamless sheet vinyl base integral with the flooring, using the same joint sealing application technique of grooved, melted, welded, vinyl, for an impervious waterproof seal.

4. Gypsum wallboard. Minimum 5/8 in. (15.9 mm). Ensure that the proper gypsum wallboard product used is appropriate for the application (wet areas, fire resistance, damp conditions, radiation protection, etc.). Utilize lead lined gypsum board where lead lined walls are determined to be required, reference Architectural Note 11.

5. Liquid Glaze Coat (LGC). This coating is a seamless, sprayed-on, lusterless, semi-gloss, two-component, polyester epoxy or polyurethane finish. As an alternative, water-based epoxy with semi-gloss finish may be used. In humid climates, avoid the use of LGC on interior surface of exterior wall.

6. Sheet Rubber. Solid, seamless rubber in roll format with routed, welded, grooved seams where melted rubber is used for an impervious, waterproof seal. Provide seamless sheet rubber base integral with the flooring, using the same joint sealing application technique of grooved, melted, welded, rubber for an impervious waterproof seal. Sheet rubber flooring requires heat and chemical welds for a proper installation (chemical welds for vertical seams and sanitary wall base applications). Provide thickness of sheet rubber flooring as required for the space or application, with a minimum thickness of 1/8 in. (3.0 mm).

7. The acoustical noise level range in the room is the design value for the NC-level for the background (ambient) noise level.

8. The STC specifies the performance of the room enclosure in isolating against airborne sound. The wall partition/ceiling system, including penetrations, must be designed to this composite value. This design value is generally considered as a minimum rating. For corridor walls that contain a door, window, or other penetration, a composite STC 35 may be used, unless the room has special acoustical privacy concerns as determined by the DoD Project Sponsor. The composite STC rating is the calculated value that considers the STC rating and the area percentages of the individual wall, door, and other components. Maintain the specified STC for common walls with public spaces, service areas, and rooms with higher STC requirements.

9. Provide non-slip finishes in corridors and all areas where pedestrian traffic is anticipated. Provide smooth finish where greater degree of cleanability is required (under cage racks, for example).

10. Provide vermin-proof hollow metal doors, 48 x 96 in (1220 x 2440 mm), with 12 x 12 in (305 x 305 mm) red glass vision panel and recessed hardware. Provide door seals. Do not provide door lock.

11. A health physicist must determine the required degree of protection to minimize exposure to primary and secondary radiation, as required to achieve compliance with NCRP Report No. 147. Shielding must be designed by the health physicist. Due to the intended use, rooms BMCW2, XDR01 and XDRF1 require a minimum of 1/16-inch thick lead shielding, or more if so determined by the health physicist. Rooms requiring shielding must be certified in accordance with NCRP Report No. 102 and the MilDep qualified expert.

12. Carpet Tile must meet TARR (Texture Appearance Retention Rating) classification ratings based on location areas where it is being used. Reference the Carpet and Rug Institute (CRI) Fact Sheet for more information.

Space Definition	Traffic Classification	TARR Classification
Chapel, Staff sleeping & watch areas	Moderate	≥ 2.5 TARR
Training Rooms, Conference, Private Offices, Classrooms, Consultation Rooms, Libraries, Lounges	Heavy	≥ 3.0 TARR
Open Office, Cafeteria, Corridors, Lobbies, Clinical Waiting Areas (outpatient/pharmacy/ancillary zones), Entrance Areas, Playrooms-OB/GYN-Peds Clinics,	Severe	≥ 3.5 TARR

13. Solid surface material wall cladding. Minimum ¼ in (6.4 mm) thickness and full height wall application. Follow manufacturer's recommended installation methods for seaming and for properly integrating wall cladding with flooring materials and ceilings.

B-5 STRUCTURAL.

Minimum uniformly distributed live load in psf (kpa), unless noted otherwise.

A Design for minimum of actual wheel loads or 150 psf (7.2 kpa).

B Design for minimum actual equipment loads or 150 psf (7.2 kpa).

C Design for minimum actual equipment loads or 100 psf (4.8 kpa).

D Design for minimum actual weight of shelves plus 3.1 lb/filling inch (55 kg/filling meter) or 150 psf (7.2 ka).

E Floor loading is being reviewed. Obtain required floor loading from the Design and Construction Agent.

F Reference UFC 3-301-01 for floor loading requirements.

B-6 ELECTRICAL.

B-6.1 LIGHTING.

LEV Maintained lighting level in lux with permanently installed building fixtures. Where multi-level lighting levels are indicated, provide multi-level switching for fluorescent fixtures and full range dimming for LED fixtures with conventional on/off switching unless otherwise noted. The first line is the general lighting level and the second line is the task illumination level provided by permanently installed building light fixtures. These lighting levels are in addition to supplemental lighting provided with furniture or equipment. However, the DoD Project Sponsor may direct that the task lighting be provided with the office furniture in administrative areas, except for dual purpose clinical/administrative rooms, rather than permanently installed light fixtures.

N Lighting Notes.

A Provide full range dimming in room.

B Provide recessed ceiling exam fixture that provides required task illumination on bed or patient area controlled at the headwall.

C { not used }

D Provide sealed and gasketed recessed troffers, suitable for use in operating rooms. Those fixtures that have battery backup must have full illumination when energized by battery or uninterruptable power supply (UPS).

E Explosion Proof design typically required.

F Provide lighting control at individual task location in lieu of multi-level switching.

G Provide Safelight for film processing as required by Equipment List.

H Provide full range dimming at task location.

I Provide recessed ceiling mounted task illumination with full range dimming.

J Ceiling mounted lights must be switch controlled to achieve 50 percent and 100 percent illumination levels.

K Provide Violet Fraction of the light source between 4% and 6%. Reference Chapter 11.

B-6.2 ESSENTIAL POWER.

ES PWR Essential power required in room. Provide additional essential power as required by NFPA 99.

PW Approximate percentage of general power outlets on essential system or note as listed below.

R Selected receptacles (not less than 50 percent of the receptacles).

R1 One receptacle per bed.

RA All receptacles.

RC Dedicated receptacles for critical care (reference NFPA 70, Article 517).

LT Approximate percentage of lighting on essential system or note as listed below.

L Task Lighting.

LB Task Lighting, General Illumination, and battery powered lighting. Reference Chapter 11.

LG General Illumination.

LS Task Lighting and Selected General Illumination identified and coordinated with the DoD Project Sponsor.

N Essential Power notes.

E Selected equipment connections.

U Provide essential power only as required by the DoD Project Sponsor.

S Special (Non-standard areas).

B-7 MEDICAL GASES.

The number of outlets/inlets required for each gas type is listed in the appropriate column. The number of outlets/inlets must be increased as required to support the equipment listed in the PRC.

MA Medical Compressed Air

DA Dental Compressed Air

LA Laboratory Compressed Air

PA Process Compressed Air

MV Medical Vacuum

DSV Dental Surgical Vacuum

OE Oral Evacuation

LDE Laboratory Dust Evacuation

O Oxygen

NO Nitrous Oxide

CO2 Carbon Dioxide

IA Instrument Compressed Air

WAGD Waste Anesthetic Gas Disposal

N See Medical Gas Notes.

B-7.1 MEDICAL GAS NOTES.

N Notes

A. Each patient is provided with the number of outlet(s) listed.

Each patient is provided medical vacuum inlet(s). See individual listing.

Each patient is provided access to a medical air outlet. Where two patients share a common wall, they may share a single outlet, excluding behavioral health patients. Do not provide in pediatric play area.

B. The medical gases specified must be per patient station, workstation, etc.

C. Coordinate with the DoD Project Sponsor for location of outlets/inlets.

D. All anesthetizing locations must have a WAGD system. Use of medical vacuum system is not recommended for evacuation in DoD facilities. DSV may be used in DTRs for anesthesia scavenging where a central system is installed.

E. One each O, MA, and MV is required at the headwall unit and the infant resuscitation area of the birthing room.

F. { not used }

G. The medical gases specified must be per bassinet or infant station.

H. The medical gases specified must be per 4 bassinets or infant stations. Where the LDR birthing room concept is used, a minimum of one grouping must be provided in each LDR.

I. For equipment testing and calibration, equipment must be tested with the specific gas used in normal operation.

J. Provide valve regulator station for PA. **\1**

K. Locate 1 DA and 1 OE at each 12 o'clock column and each DTR chair as called out in the PRC. **/1/**

L. A natural gas outlet (mounted under counter) and a LA outlet (mounted under counter) must be provided at each dental work station as shown in Table B-1.

M. All contingency beds require 1 O, 1 MV, and 1 MA per bed station. In bed expansion situations in "peace time" facilities also provide 1 O, 1 MV, and 1 MA per contingency bed expansion requirements noted in the PFD.

B-8 HVAC.

BL Air Balance

++ Room exhaust, return, or both, is 20 percent less than supply*

\+ Room exhaust, return, or both, is 10 percent less than supply

nr No requirement. Room exhaust, return, or both, may equal supply **\1**

\- **/1/** Room exhaust, return, or both, is 10 percent more than supply

\- - Room exhaust, return, or both, is 20 percent more than supply*

EX Room exhausted. If supply is provided, exhaust room Air Change must be in addition to the amount of supply provided.

R Letter "r" indicates the HVAC Notes provide the required air balance

*Note: for "++" and "- -"spaces, the required differential pressurization is 0.02 inch water column, reference paragraph 10-7.5. Utilize the 20 percent offset as a baseline and adjust air flows and/or increase room integrity as required in order to achieve the required pressure differential.

AC Air Change is the minimum total air changes per hour (AC/H) required to meet ventilation requirements. These rates are considered the minimum required for normal health and comfort consideration. Additional air may be required for temperature, dilution, and odor control, as well as air requirements for such items as hoods, glove boxes, clean air stations, combustion equipment, and dust collectors.

- A Letter "a" indicates that the total air changes must be based on calculations.
- r Letter "r" indicates the HVAC Notes provide the required minimum air change.

OA Outdoor Air is the minimum outdoor air changes per hour required to meet ventilation requirements.

- A Letter "a" Indicates that the outdoor air changes are to be based on ANSI/ASHRAE 62.1.

TEMP Interior design temperature in degrees Fahrenheit (degrees Celsius) for cooling and heating load calculations. When cooling is required during winter, such as in interior zones, temperature listed under summer conditions should be used.

- SM Design temperature for summer months.
- WN Design temperature for the space during heating season.
- * Summer Design Temperature must be 15 ^{o}F (8.3 ^{o}C) less than 1 percent Outside Design Temperature but must not be less than 75 ^{o}F (23.9 ^{o}C) or greater than 78 ^{o}F (25.6 ^{o}C) unless otherwise noted.
- R Design must accommodate a variable (to user) temperature range of 68–75 ^{o}F (20.0–23.9 ^{o}C).
- SP Special. Determined by the Design and Construction Agent.

RH Relative Humidity. This is the relative humidity to be maintained in a space as part of the designed conditions. Relative humidity range is 30–60 percent unless noted otherwise.

- Y Provide relative humidity range of 30-60 percent

R Provide a user adjustable humidistat in the space, accommodating a variable humidity range of 30-60 percent

S Maintain relative humidity of 20-60 percent. Design to provide minimum 30% RH

T Maintain relative humidity of 55 percent, +/-5 percent.

FL Filtration indicates the level and location of filtration required. See HVAC Note B.

IN. Intermediate filtration in MERV.

FN. Final filtration in MERV.

Hepa HEPA filter required.

r Letter “r” indicates that the HVAC Notes provide the required filtration.

EX Exhaust.

Y Indicates room air to be exhausted, not recirculated.

R See HVAC Notes.

B-8.1 HVAC Notes.

N Notes.

A. Nursery Isolation Room relative pressurization requirements may vary among individual facilities, depending upon functional requirements. A/Es must coordinate with the DoD Project Sponsor for each facility to determine whether disease isolation (negative pressurization) or protective isolation (positive pressurization) is required.

B. General Filtration. Filter efficiencies noted here are in accordance with the Minimum Efficiency Reporting Value (MERV) ratings of ANSI/ASHRAE Standard 52.2. Filters with a MERV rating of 8 must be provided for all outdoor air. These filters must be located upstream of air-conditioning equipment. Intermediate Filters indicated in column “IN” must be located downstream of the supply fan. Final filters indicated in column “FN” must be located at air outlets or in close proximity to outlets (coordinate with the DoD Project Sponsor). All filters should be installed to prevent leakage between the filter segments and between the filter and its supporting frame.

C. During periods of non-use, the air volume may be reduced to 6 air changes per hour, while maintaining the required air balance.

D. When the DoD Project Sponsor intends the routine usage of nitrous oxide in the DTR, routine being defined as exceeding 5 hours per week, this criteria must apply:

- DTR room air changes must be not less than 12 total AC/H.
- The room must be totally exhausted.
- Provide a minimum of one low-level exhaust register, sized to remove a minimum of 20 percent of the total room exhaust volume.
- During period of non-use, air change rate may be reduced to 3 total AC/H.

E. General, Isolation Rooms. For Airborne Infection Isolation Bedrooms, bedroom to be negative to anteroom, anteroom to be negative to corridor. For Protective Environment Bedrooms, bedroom to be positive to anteroom, anteroom to be positive to corridor.

F. Minimum air change and pressure relationship is based on this room supporting both bronchoscopy and endoscopy procedures. If the facility CONOPS specifically states that this room is intended to provide both proctoscopy and endoscopy procedures, the minimum air change required is 10 AC/H and room exhaust is 10% more than the room supply. If the facility CONOPS specifically states that this room is intended to provide endoscopy procedures only, the minimum air change required is 6 AC/H and room exhaust is 10 percent more than the room supply.

G. Design in accordance with NFPA 99.

H. May require vehicle exhaust, carbon monoxide (CO) detection.

I. Same as Note D, except the following:

- During period of non-use, air change rate may be reduced to 5 total AC.
- Positive pressurization must be maintained.

J. For projects incorporating brace/appliance fitting or shop applications, evaluate room and equipment exhaust requirements for removal of toxic or flammable fumes and dust.

K. Consult manufacturer recommendations for temperature requirements for electrical/electronic equipment. In humid climates, fan rooms must not be ventilated with unconditioned outdoor air.

L. Up to 50 percent of supply air may be air that is transferred from administrative areas of the building.

M. Provide exhaust or fume hoods, and localized exhaust.

N. Verify computer heat load requirement.

O. Provide adjustable (to user) humidistat within the room.

P. Provide adjustable (to user) thermostat within the room.

Q. HEPA filtration of room exhaust is required unless an exhaust reentrainment analysis (wind tunnel or computational fluid dynamics modelling) demonstrates sufficient separation from public areas (for example sidewalks), building openings (for example windows, doors) and outdoor air intakes. Exhaust of tuberculosis (TB) isolation room, toilet, and anteroom to be by dedicated exhaust system, in other words exhaust system serving only TB isolation room(s). Isolation room pressure to remain constant—not switchable from Disease Isolation mode to Protective Isolation mode, or vice versa.

R. Consult with the Design and Construction Agent and DoD Project Sponsor to determine if compliance with USP 797 and/or USP 800 is required. If compliance is required, design in accordance with the applicable USP(s). Reference paragraph 10-16.11. If compliance is not required, then provide an air balance of “++”, a minimum of 4 air changes per hour, minimum MERV 13 intermediate filtration and room air can be recirculated.

S. Provide emergency, pediatric, and radiology waiting rooms with 20% more exhaust than supply, 12 air changes, 2 outdoor air changes, and exhaust these rooms directly to the outside, independent from other exhausts. If the space is an enclosed room with a door, meet the requirements for a “room with critical pressurization” per paragraph 10-7.5. For all other waiting areas there is no requirement for pressure balance, provide 6 air changes, 1 outdoor air change, and the space may be recirculated.

T. Provide a minimum of one low-level exhaust register, sized to remove a minimum of 20 percent of the total room exhaust volume.

U. Comply with UFC 4-010-01 requirements for mail room and loading dock ventilation.

V. Provide ability for user to select temperature and humidity in the ranges specified. Once set, the temperature must not deviate from setpoint by more than 1 ^{o}F (0.6 ^{o}C) within a 10 minute period and the RH must not deviate from setpoint by more that 2 percent RH per 10 minute period. The temperature and RH must be maintained at all times (24/7/365). Also provide a fluorine gas detection system, alarms, and emergency exhaust system with low level exhaust inlets to evacuate the room in the event of a fluorine gas leak.

W. Design in accordance with the applicable USP 797 and/or USP 800. Reference paragraph 10-16.11.

X. Provide exhaust canopies near all steam utilizing equipment loading and unloading doors.

APPENDIX C DESIGN SUBMITTALS AND DOCUMENTATION

C-1 GENERAL.

This appendix contains mandatory criteria for design submittals and documentation. It addresses narratives, drawings, calculations, specifications, and cost estimates required at various submission levels during the production of contract documents for each project.

C-2 APPLICATION.

The submission requirements in this appendix identify minimum design deliverables related to medical-specific criteria. This list is not comprehensive and must be supplemented or incorporated into comprehensive project specific submission requirements by the Design and Construction Agent.

C-3 GENERAL REQUIREMENTS.

These general requirements apply to all projects, acquisition types and submissions.

C-3.1 Design Analysis.

The Design Analysis includes the narrative and calculations and serves as a documented design history of each technical discipline represented in the project. The descriptions of systems being proposed must continue to be elaborated and expanded through all subsequent design submissions. The Design Analysis must document all design directives provided to the designer(s) of record, as well as all major decisions by the designer(s) of record regarding the design for particular systems. Attention must be given to ensure that the Design Analysis provides a complete detailed narrative on the scope, equipment, function, operation, and design history of each system. The Design Analysis serves as the basic document against which the design shown on the drawings and in the specifications is checked.

Arrange the Design Analysis into indexed and tabulated PDF binders by discipline in the same order as the corresponding technical chapters of UFC 4-510-01 as well as a comprehensive binder with all disciplines. Identify and date all documents according to project title and level of submission. Project title must exactly reflect that which is noted on the enacted DD Form 1391.

C-3.2 Drawings and Format.

Drawing format and submissions must be as follows unless otherwise directed by the Design and Construction Agent.

C-3.2.1 Building Information Modeling (BIM).

Utilize BIM to develop all designs and produce all drawings. All plans must be of sufficient scale to be legible when printed at half size. Provide electronic drawings in

PDF, BIM, and CAD format. Provide PDF binders with all drawings in order as well as providing individual files. Provide electronic submissions on CD/DVD and via upload. Reference Chapter 18 for specific execution. Submittals to Health Information Technology (HIT) must commence with the 65% submittal stage.

C-3.2.2 Perspective Drawing Sketch and Final Rendering.

C-3.2.2.1 Perspective Drawing Sketch.

The perspective drawing sketch must best depict the proposed facility and its prominent design features as directed by the Design and Construction Agent. This sketch must be the basis for subsequent rendering requirements.

C-3.2.2.2 Rendering.

A final rendering must be prepared from the perspective drawing sketch that reflects all review comments. Digital copies of the photo-realistic rendering must be provided to the DoD Project Sponsor by the Design and Construction Agent via CD electronic format, or in framed format on a case by case basis when so requested by the DoD Project Sponsor. The framed photographs must be titled, single matted, framed, and glazed with non-glare tempered glass or plexiglass. The frame must be 28 in. by 20 in. (710 mm by 510 mm) in dimension and of a brushed aluminum finish. Other photographs must be distributed as determined by the Design and Construction Agent.

C-3.3 Specifications.

Provide specifications as required for each submission.

C-3.4 Cost Estimates.

Provide cost estimates as required for each submission in electronic format.

C-3.5 Building Systems Risk Assessment.

Not later than the 20 percent design (DBB process) submission, the Architect-Engineer (A/E) must conduct a risk assessment to confirm or establish the Building System Category for each of the various facility systems in accordance with NFPA 99. For the DB process, the assessment must be conducted by the A/E and included as part of the RFP development. In all cases, the assessment must be fully coordinated with the DoD Project Sponsor and the Design and Construction Agent at each submittal milestone, and document system requirements necessary to adequately safeguard occupant safety, health, and comfort based on the intended CONOPS and acuity of the patient population to be served by that facility. The completed Risk Assessment will be provided to the DoD Project Sponsor by the Design and Construction Agent for concurrence.

C-4 5 PERCENT SUBMITTAL.

C-4.1 5 Percent Submittal Design Analysis.

Include pros and cons of presented block plans, preliminary site information, and architectural, transportation, and engineering considerations. Provide an Executive Summary of the 5 Percent Report documenting the selected solution to be further developed to 20 percent design.

C-4.2 5 Percent Submittal Drawings.

C-4.2.1 Site Plans.

The A/E must develop and present alternative site plans supporting the three block plan proposals. For each site plan, show the following:

a. Site Master Plan of each alternative and include; location and orientation of all new building structures, Installation impacts, adjacent building/structures impact, environmental adjacencies, roads, paths and service access, previous demolished structures, potential site contaminants (firing range, fuel containment, etc.), known utilities location/layout overview, and any easements and land-use agreements. Include existing structures (note whether they are to remain or be considered for demolition).

b. Antiterrorism standoff distances.

c. Site views that will cause an impact to the orientation of the building such as, natural weather conditions, for example, wind/sandstorms and seasonal sun orientation.

d. Existing site topography that may impact building development.

e. Major utility connection locations (points of origin).

f. On- and offsite vehicular and service traffic patterns to include primary and secondary roadways surrounding the site.

g. Parking requirements as shown on the DD Form 1391 (surface or structured).

h. Future building expansion (20 percent of the enacted DD Form 1391 gross building area [in GSF (GSM)]); include future parking structure locations as applicable.

i. Site noise/sound, smell generating conditions, for example, proximity to major highway, adjacency to an airport, sewage treatment, etc.

j. Optional location or methodology to incorporate the VA or other organization’s program, if applicable.

C-4.2.2 Block Plans.

Up to three block plans and site access/orientation studies must be developed to convey the project requirements. Each block plan must show floor to floor and departmental relationships; exterior elevation views; location of vertical and horizontal transportation systems, for example, elevators, escalators, and stairs; interior circulation patterns; operational movement of materials, supplies and people; and impacts to corridor widths due to transportation solutions or other unique conditions, for example, AGVs, IBS, or similar systems. Include principle key dimensions. Site access/orientation must show placement of the facility and drives on the selected site, neighboring issues that may impact the project, and must convey pedestrian and vehicular movement across and within the site. The site plan should identify and convey restrictions that may impact the placement and orientation of the facility. The A/E must develop a final block plan representative of the selected solutions for the 20 percent submittal.

C-4.2.3 Rehabilitation Work.

Clearly delineate the extent and scope of rehabilitation work, including all associated work in these areas such as: connections, demolition, finishes, upgrades, utilities, ductwork, IT support, etc. Indicate limits of construction, access control means, interim life safety design, Infection Control Risk Assessment (ICRA) based temporary barriers, security monitoring, schematic HVAC reconfiguration, and any other relevant information to demonstrate how the rehabilitation work will be conducted without compromising life, health, or safety.

C-4.3 5 Percent Submittal Cost Estimates.

C-4.3.1 Parametric Cost Estimates.

Provide a parametric cost estimate for each block plan developed, including any requested design solution(s) that could exceed the budget.

C-5 20 PERCENT SUBMITTAL.

This Submittal includes development of the room-by-room floor plans, building elevations, and preliminary analysis of major architectural and engineering systems based on the selected block plan. It identifies and resolves all major PFD changes, solidifies all space requirements, coordinates departmental or mission realignment, and ensures that the designed scope complies with the appropriate authorization scope.

The Submittal must illustrate the building massing, aesthetics, exterior finishes, and identify specific architectural and engineering features. Include O&M access for primary MEP and communication equipment, primary distribution pathways, storm-water management strategy to meet the requirements of EISA, establish the cost and scope for providing necessary utility services to and from the building, and identify major building entrances from parking and pedestrian paths of travel. The Submittal must

consider and establish preliminary phasing considerations and scope impacts, and address transportation, logistics, and waste management requirements of the facility.

C-5.1 Scope Changes.

Scope changes must be submitted and authorized to the Design and Construction Agent by the DoD Project Sponsor with the 20 Percent Submittal. Scope changes are defined as those that materially affect the characteristics of the facilities (for example, Category Code) or increase the GSF as defined in Block 8 of the DD1391. Refer to Chapter 3. Provide a clear justification and basis for any increases to the GSF, for example, mission changes, workload increases, and increases in troop numbers due to troop or unit reassignments.

C-5.2 Record Copy.

The Design and Construction Agent must submit a record copy of the 20 percent submittal to the DoD Project Sponsor. No approval from the DoD Project Sponsor is required at the 20 percent submittal. However, a presentation to the DoD Project Sponsor will be required if the project has exceeded the authorized scope or is over budget.

C-5.3 20 Percent Design Analysis.

The following are minimum 20 Percent Design Analysis Submittal describing proposed architectural and engineering aspects of the project.

C-5.3.1 Executive Summary

The executive summary must include this narrative information:

a. Rationale for the selected block plan scheme;

b. Proposed architectural and engineering systems;

c. Approach to sustainable design, energy reduction, and other related energy compliant features to the project;

d. Designed scope and budget compared to the authorized scope and budget;

e. Specific military base requirements impacting the design of the project, for example, building exterior finishes, excessive noise factors, and other site/building constraints; and

f. Utility services available and their points of entry into the project's site, including privatized utilities and their impact on scope and cost to the project.

C-5.3.2 Codes and Criteria

Include a separate chapter to identify a single, consolidated list of applicable criteria, with an effective date noted with each criterion, for all disciplines to follow in the project. List all mandatory criteria, codes, and standards with which the project must comply.

C-5.3.3 World-Class Checklist.

A World-Class Checklist in accordance with the World Class Toolkit requirements must be developed for every project providing direct patient care and must include all architectural and engineering disciplines. It must be applied across the entire life of a project, from conception to recapitalization, and apply to rehabilitation of a facility. For projects involving rehabilitation work including addition/renovation projects, refer to the original project's World-Class Checklist and documentation to ensure these standards are maintained and continued.

C-5.3.4 Civil.

Refine the 5 percent submittal site investigation and utilities report. Discuss approach to Storm-water Management and "Low Impact Development". Address pedestrian circulation, parking requirements, and vehicular circulation for all selected vehicle types. Refer to Chapter 2 and Appendix G.

C-5.3.5 Architectural.

Address the overall architectural concept including: exterior wall systems and finish materials, acoustics (both exterior and interior), base architectural plan, floor-to-floor heights, roofing materials, slope(s), styles, energy conservation features, sustainable design, commissioning, as well as accessibility provisions for the disabled. Describe how proposed material selections and finishes must support aseptic environments, infection control and patient/staff safety.

Address impact of technically complex equipment and medical systems (for example imaging equipment; MRI, lithotripsy units; audiology booths; sterilizers, etc.) and determine scope in preparation for future design development requiring specialty consultant involvement (for example health physicist report). Refer to Chapter 15 and Appendix D.

Further develop the Safety Risk Assessment (SRA) initiated by the DoD Project Sponsor during predesign, as indicated in paragraph 3-7.7. Refer to Appendix A for requirements for Behavioral Health.

C-5.3.6 Interstitial Building System (IBS).

If applicable to the project, address IBS to include its design, documentation, and technical requirements in accordance with Appendix E.

C-5.3.7 Structural.

Discuss and describe the justification and basis for the proposed system.

C-5.3.8 Seismic.

Discuss the seismic design considerations and the level of protection required. Evaluate the seismic impacts to the structural design system being proposed for new facilities. For projects involving rehabilitation work including addition/alteration projects, provide a preliminary Facility Upgrade Report that includes a Seismic Structural Assessment and Evaluation Study.

C-5.3.9 Heating, Ventilation, and Air Conditioning.

Identify the project specific design weather data to be utilized. Discuss design considerations and space requirements for the primary and secondary HVAC systems being considered and how they compare based on Life Cycle cost Analysis. Identify equipment redundancies, continuity of service, spare capacity, and space provisions for future expansion of energy plants and mechanical rooms. Identify required minimum zoning to coordinate with continuity of service and smoke compartments (for example defend-in-place strategy). Also, demonstrate how the design will provide weather-protection; direct floor-to-ground access for equipment O&M, for example, pallet transport via hydraulic hand carts; and practical means of future replacement. Prepare a preliminary Air Balance Summary identifying each room in the project, corresponding room code, summer/winter design temperature and relative humidity, and applicable ventilation requirements such as the minimum total air changes, outdoor air changes, as well as special ventilation requirements to be developed in further design stages (for example USP 797, USP 800, BSL criteria etc.).

Perform a preliminary analysis of site specific and building specific considerations for air intakes and exhausts per paragraph 10-11.4 including considering the impacts of surrounding buildings. Address health and odor aspects for air intakes. Identify all intakes and exhaust sources which must be evaluated including those for surrounding buildings (for example laboratory exhaust, sanitary vents, standby generators exhaust, boiler exhaust, cooling tower discharge, kitchen exhaust, vehicle exhaust etc.). Provide any building siting or orientation recommendations to reduce noted risks. Provide a recommended analysis approach for the detailed 35% analysis (for example basic prescriptive separation, numerical dispersion modelling, computational fluid dynamics analysis, wind tunnel modeling analysis etc.) supported by the building and site specific risks and considerations.

C-5.3.10 Plumbing and Medical Gas.

Discuss design considerations and space requirements for plumbing systems to include: domestic hot, cold, recirculation water, high purity water systems, water supply, water quality, existing water management program coordination, conceptual water system analysis, waterborne pathogen control, water treatment, continuity of service,

hot water generation, storage requirements, temperatures; and distribution systems, fuel gas, sanitary waste and vent, and storm drains. Provide a water chemistry analysis IAW Chapter 9 or utilize local historical test data to conceptualize water treatment requirements. Address compliance with post-seismic storage and water conservation criteria and regulations, if applicable.

Discuss design considerations and space requirements for medical gas systems to include types, storage, and distribution systems. Identify the System Category of each medical gas system in accordance with the Risk Assessment. Identify all locations where medical gas is utilized and how it is to be served (and stored) whether provided centralized with on-site producers, bottle manifolds or with portable bottles, as coordinated with the DoD Project Sponsor.

C-5.3.11 Electrical.

The Design Analysis must present design considerations and interior/exterior space requirements for electrical systems as required by UFC 3-501-01, paragraphs 3-2.1, 3-2.2, and 3-2.3. Include voltage selection; availability of primary power as required by Chapter 11; reliability of the primary distribution system; normal and essential (Type 1 or 2) or standby (Emergency, Legally-Required, Non-Essential / Optional) electrical systems; and lighting systems. Address compliance with seismic requirements in Chapter 7.

C-5.3.12 Communications.

Discuss design considerations and space requirements for all communications systems required for the project. Include listing of each technology system to be included per the project room contents list and brief discussion of its functionality. Discuss method for inclusion of ports per room type and/or equipment requirements.

C-5.3.13 Fire Protection and Life Safety.

Address the fire detection, fire alarm, fire extinguishment, and fire suppression systems and features for the project. In addition, address life safety and means of egress.

Address anticipated active and passive fire protection features and systems, type(s) of construction, height, and area limitations, building separation, fire rating of materials, and occupancy classification(s) in the project. For projects involving rehabilitation work, provide an LSA as described in Chapter 14.

C-5.3.14 Physical Security.

Discuss the physical security system design, consideration, parameters, major features, and space requirements for the overall facility and specialized areas such as those processing classified or sensitive information. Refer to Appendix A for requirements for Behavioral Health.

C-5.3.15 Antiterrorism/Force Protection (AT/FP).

Discuss site, design, space considerations and requirements for AT/FP systems. Project must conform to requirements of UFC 4-010-01. Deviations to include improvements or detriments to the UFC 4-010-01 standards must remain within the limits specified by UFC 4-010-01 paragraph 1-1.3.2 and all requirements of the remaining document.

C-5.3.16 Sustainability and Energy Conservation Compliance.

Discuss status toward meeting the requirements of UFC 1-200-02; update sustainable rating system points; refine energy consumption status relative to achieving the required 30% (minimum) energy reduction as compared to the ANSI/ASHRAE 90.1 baseline; and update status of additional sustainability goals for the project. This narrative must include separate sections for Architecture, Site, Mechanical, and Electrical. Include proposed checklist.

C-5.3.17 Commissioning.

A preliminary Commissioning Plan must be developed and submitted that defines the method by which commissioning must be performed. The Commissioning Plan must outline and define its processes to include; commissioned systems, participants, roles and responsibilities, communication procedures, and deliverables. Discuss procedures for achieving required commissioning of all commissioned systems. Reference Chapter 19 for additional information.

C-5.3.18 Transportation and Logistics.

Provide a preliminary, overall Transportation Logistics Analysis (TLA) that discusses the rationale for the proposed transportation, logistics, waste management, and food service solutions. The TLA must include impacts to programmed scope and cost and: (1) an Elevator Traffic Study and Analysis (ETSA); (2) an LCCA for automatic and manual material handling systems; (3) a Waste Management Analysis (WMA), and (4) a Food Service Study, as applicable. The WMA must include the major design parameters and features that address trash removal; hazardous, infectious, and biological waste; retort sterilizers; incinerators; and other waste handling features of the design. See Chapter 16 and Appendix F for additional requirements regarding these studies. In addition, address and discuss PTS's, as well as dumbwaiters and AGV systems.

C-5.3.19 Interior/Exterior Signage and Wayfinding.

A preliminary Interior/Exterior Signage and wayfinding master plan must be provided that addresses necessary orientation cues and information for patients, staff and visitors who navigate in and around a facility. Identify travel paths major interior intersections, and other benchmarks to successfully move from one destination to another. Analyze a facility's spatial organization and layout to identify specific areas, directional challenges, and wayfinding tools that can help in navigation. Consider all types of functions and

activities a person must perform when in a medical facility. Reference Chapter 6 for further requirements in developing this master plan.

C-5.3.20 Food Service.

If applicable, discuss the food service design and considerations to include optimal movement of food products to ensure effective monitoring and control of food temperatures through conventional flow while minimizing personnel cross-traffic, backtracking, and queuing conditions.

C-5.3.21 Specifications.

Provide a list of project specific specifications to be utilized.

C-5.3.22 Construction Phasing.

Develop a written narrative of the overall requirements for a phased approach to the construction that addresses all work associated with all the major disciplines. Develop a preliminary construction phasing plan that addresses “major” areas of work requiring specific parameters, sequence, or milestones. This phasing plan is not a detailed technical sequence of normal construction work, but describes any constraints that would prevent the contractor from doing all areas of the work simultaneously or at his discretion. Preliminary identification of phased areas and durations should be identified with reference to scope, constructability, timing, and overall construction length. Provide duration for relocation where subsequent construction activity is dependent on staff relocation from existing facility to new facility. Requirements unique to phased projects such as swing space, utilities that must serve two areas simultaneously, demolition sequence, and engineering system support for isolated or independent areas, must be addressed in reference to the operational, constructability, and cost constraints of the project.

C-5.3.23 Rehabilitation Work.

For projects involving rehabilitation work including addition/alteration projects, develop and discuss a preliminary construction phasing plan that supports continued/uninterrupted operations of the existing facility during construction and associated impact on construction costs and scope. Identify the requirements for temporary buildings to serve as swing space. In addition, identify actions that reduce or interrupt service to an existing, occupied area. Identify potential temporary connections, extensions of service that increase system demand, locations of new connections, or other measures necessary to sustain service for engineering systems within the existing building.

C-5.4 20 Percent Submittal Design Drawings.

The following are minimum 20 percent submittal drawings depicting proposed architectural and engineering aspects of the project.

C-5.4.1 Civil Drawings.

Show building locations, future expansion, existing and proposed structures, topography, final master plan of the site, utilities (include point of origin), utility modifications, pedestrian paths, roads, parking (surface and structured), ATFP, and easements.

C-5.4.2 Architectural Drawings.

Provide floor plans for each floor showing all programmed spaces and corridors; key building dimensions; structural grid system (including columns and type of system proposed) and key building dimensions; electrical and mechanical equipment rooms; stairs, elevators, and escalators; transportation equipment for movement of material and supplies; and specific locations of vertical and horizontal transportation systems, for example, pneumatic tubes, dumb waiters, automated guidance systems. All spaces identified in the PFD must be labeled with the Room Name and Room Code, in addition to the programmed and designed net areas. Also, addition/alteration projects must include preliminary demolition drawings with photographs depicting existing conditions. Provide preliminary exterior elevations with proposed finishes, floor to floor heights and overall dimensions.

Utility Services Distribution / Physical Space Requirements for Equipment and Distribution Systems. Provide conceptual interdisciplinary cross section drawings of the most congested utility areas (for example near vertical chases, elevators, mechanical rooms, communications rooms, etc.) to demonstrate that the floor to floor heights, above ceiling space, crawl spaces and chase areas are sufficient for utility installation as well as future operations and maintenance activities. Designate installation zones for each utility. Include all technical systems in the congested areas (for example HVAC main ducts, heating and cooling mains, plumbing mains, fire sprinkler pipe, electrical cables and lighting, communications cable trays, pneumatic tube systems, seismic restraints and supports etc.). Include piping slope considerations where that may require additional clearances. Base HVAC utility sizing on block heating and cooling load estimates and zoning concept. Label each utility and show required clearances with measurements. Base cable tray dimensions on industry standard sizes per fill rate estimates.

C-5.4.3 Interstitial Building System (IBS).

If applicable, a preliminary IBS design must be developed. Establish the floor to ceiling heights for the IBS supported by the most stringent preliminary equipment, utility dimensions and crossings. Demonstrate that adequate space is provided for maintenance access and compliance with NFPA 101 Means of Egress requirements.

C-5.4.4 HVAC.

Establish the minimum size and number of mechanical rooms, utility tunnels, and utility pathways based on estimates of building demands and equipment capacities, zoning,

equipment redundancies, considering required components and clearances. Provide plans showing single line drawings of the HVAC distribution systems to the areas served. Establish minimum vertical space requirements clearances for any above ceiling space, crawl space or IBS based on required HVAC distribution system sizes, piping slopes etc., coordination with other discipline utilities. Provide conceptual AHU sizes and utility requirements based on the block load calculations.

C-5.4.5 Plumbing and Medical Gas.

Establish the minimum size of mechanical rooms based on estimates of demands, anticipated water treatment requirements, equipment capacities and considering mandatory components, redundancies, and clearances. Provide plans showing single line drawings of the plumbing distribution systems to the areas served. Demonstrate space provisions for all medical gas producers, bottle manifolds and storage locations as well as main distribution lines.

C-5.4.6 Electrical.

Submit drawings that are compliant with paragraph 3-3 of UFC 3-501-01. Submit the following drawings, at a minimum: 1) site plan showing existing utility primary power and preliminary locations of new exterior normal and essential / standby electrical equipment; 2) building floor plans for Power and Lighting showing size and location of electrical rooms; and 3) Single Line Diagram(s).

C-5.4.7 Communications.

Establish the minimum size and number of Telecommunications Rooms and Server rooms based on estimates of building demands and equipment capacities. Provide plans showing riser drawings of the distribution systems from Telecommunications Rooms to the areas served. Submit drawings utilizing diamond analysis assuming 180 ft sides for layout of information and communication technology (ICT) spaces. Identify aligned TR stacks within the facility free of any fixed adjacencies in Chapter 12. Provided initial estimate of total rack units per TR and total rack requirement for sizing efforts under the engineered solution. Identify location of entrance facility. Provide two EFs with greatest separation practical for NFPA 99 Category 1 and 2 facilities. Identify outside plant pathways to two separate installation/provider nodes for NFPA 99 Category 1 and 2 facilities. Submit drawings of initial fiber backbone riser indenting physically independent pathways for Category 1.

C-5.4.8 Food Service.

If applicable, provide plans showing an initial layout of food service areas. Show circulation paths from servers to seating, loading dock to storage, kitchen to inpatient units, general material movement, principal dimensions, and dining seating counts. Optimize movement of food products and minimize personnel cross-traffic, backtracking, and queuing conditions. Reference Appendix F for additional requirements.

C-5.4.9 Construction Phasing.

When required by the Design and Construction Agent, provide a graphic "Node" diagram of major elements and areas showing proposed sequential and parallel phased work. Indicate interim swing space, temporary facilities, and locations of existing and relocated functions with time duration for any Government moves.

C-5.4.10 Rehabilitation Work.

For projects involving rehabilitation work including addition/alteration projects, update and continue to differentiate where existing conditions end and new conditions begin. Define extent and scope of rehabilitation. Provide documentation of existing conditions.

a. Existing building as-builts.

b. Statement of conditions.

c. Existing/Prior hazardous material abatement reports and studies.

C-5.5 20 Percent Submittal Calculations.

C-5.5.1 A/E Calculations.

All calculations that support A/E features within the design must be provided including but not limited to those required in the Design Analysis. Supporting documentation must include life cycle cost analysis (LCCA) per UFC 1-200-02, to include energy systems, renewable systems, lighting, solar hot water use, and utility demand. Documentation should also include validation of the parking requirements.

C-5.5.2 Gross, Departmental & Net Area Tabulations.

Gross, departmental, and net area tabulations for all floors must be submitted with a small-scale, single-line, dimensioned key plan, and must be provided to reflect the total space required per Chapter 3. Provide a departmental area summary tabulation to include: net areas, net to gross area and factor, and net area difference. Functional areas and or rooms must address room quantity, net area, and total area comparing the net as-designed area against the PFD values. Comparison must include: net areas, departmental gross areas, minimum grossing ratios, and building gross area. Provide justification if deviation between as-designed and PFD values is greater than +/- 10 percent, except for rooms programmed for 50 SF or less.

C-5.5.3 20 Percent Submittal Cost Estimates.

Provide schematic cost estimates reflecting all design features and elements. Update all project costs based on refined project design details. Provide an updated DD Form 1391. Show Post Construction Award Services (PCAS) and "Other" special cost as separate line items.

C-6 35 PERCENT SUBMITTAL.

This submittal is a minimum 35 percent of the total design across all disciplines and incorporates response to all review comments. This is considered the “technical submission” in which all major architectural and engineering systems and A/E design decisions are finalized into the project scope and costs. Load demand, equipment sizing, energy consumption, LCC, NFPA 101 compliance, and other calculations for all building systems and features defined herein must be provided and reflected in the cost estimate. A formal 35 percent design presentation to the DoD Project Sponsor may be required. Final changes to the project’s enacted DD Form 1391 description, justification, and execution timelines are made at this submittal level.

C-6.1 35 Percent Submittal Design Analysis.

Concept design narratives and related technical calculations further refining the 20 percent design requirements to a 35 percent design effort must be provided as noted here:

C-6.1.1 World-Class Checklist.

Update the draft World-Class Checklist.

C-6.1.2 Civil.

Include the site investigation, geotechnical investigation, and utilities reports. Summarize the civil design parameters, parking requirements in accordance with Appendix G, and major features of the design.

C-6.1.3 Architectural.

Address the overall architectural concept including interior design (in accordance with Appendix B) and exterior finish materials, wall systems, roofing systems, acoustics (exterior and interior), base architectural plan, floor-to-floor heights, and contingency and mobilization features. Shielding requirements based on a health physicist report for all radiation areas. Provide a final functional narrative that describes alignment of the design with the Functional Program developed for the project. Demonstrate through the required Dew Point Analysis (per UFC 3-410-01) how the proposed exterior building envelope systems are coordinated with space temperature and humidity requirements to prevent condensation and mold growth. Describe how proposed material selections and finishes promote aseptic environments and infection control and patient/staff safety.

C-6.1.4 Interstitial Building System (IBS).

If applicable, update the design parameters and major features, including interstitial space considerations.

C-6.1.5 Structural.

Address the selected structural foundation and framing systems considered and provide an economic basis for system selection. Summarize the structural design parameters and major features of the design.

C-6.1.6 Seismic.

Summarize the seismic design considerations including “S” values and the level of protection required. Discuss post-earthquake operation requirements. For projects involving rehabilitation work, complete the Facility Upgrade Report.

C-6.1.7 HVAC.

Provide a summary of the primary and secondary HVAC systems considered and the economic basis for system selection. Summarize the proposed control systems, building pressure control scheme, humidification features, and the energy conservation features being considered. Provide room-by-room and zone heating and cooling load calculations, AHU sizing and utility requirements. Interior equipment loads must be identified on a space by space basis. Provide a fully developed room-by-room Air Balance Summary including each room name, number, room code, number of people, summer/winter design temperatures and relative humidity, minimum outdoor air changes, minimum total air changes, space pressurization minimum load driven air flows, design supply/return/exhaust/transfer/exfiltration air flows and primary outdoor air fraction at design condition. Provide calculations for minimum outdoor air at each AHU in accordance with Chapter 10. Provide duct pressure drop calculations. Provide piping thermal expansion calculations (thermal stress and flexibility analysis) for all systems identified in UFC 3-410-01 plus all heating hot water and chilled water systems larger than 4 in. (100 mm) to support the proposed piping layout, supports and thermal expansion features. Provide catalog information for equipment used as the basis of design. Provide report on the detailed air intake and exhaust analysis including any resultant recommendations on building siting, orientation, intake or exhaust configurations, or special filtration.

C-6.1.8 Plumbing and Medical Gas.

Describe the plumbing systems to include domestic hot, cold, recirculating, high purity water, fuel gas, sanitary waste and vent, and storm drains. Summarize the water supply, quality, water treatment, required storage, distribution systems and all waterborne pathogen prevention features. Provide a water chemistry analysis IAW Chapter 9. Describe the water treatment requirements and arrangement (for example centralized, decentralized, redundancies etc.) necessary to meet the domestic water requirements as well as specialized medical equipment requirements (for example sterilizers, washer/disinfectors etc.). Discuss hot water generation, storage, temperatures, distribution systems. Provide the ASHRAE 188 Water Management Program and it’s required analyses. Provide the supplemental disinfection analysis to support the selection of waterborne pathogen control treatment system. Provide sizing

calculations for all plumbing systems including sizing of piping, booster pumps, treatment systems, storage etc. Provide catalog information for equipment used as the basis of design.

Identify the System Category of each medical gas system in accordance with the Risk Assessment. Identify all locations where medical gas is utilized and how it is to be served (and stored) whether provided centralized with on-site producers, bottle manifolds or with portable bottles, as coordinated with the DoD Project Sponsor. Provide source sizing calculations and node to node pipe sizing calculations for all medical gas systems. Provide historical use data where relevant to sizing. Provide catalog information for equipment used as the basis of design.

C-6.1.9 Electrical.

The Design Analysis must illustrate the further development of the design from the Concept Design phase, as required by UFC 3-501-01, paragraph 3-2. Include complete descriptions of required coordination with the utility, connection to primary power source, establishment of utilization voltage, routing of exterior power, and connections to the service equipment and all downstream distribution, and the essential (Type 1 or 2) or standby (Emergency, Legally-Required, Non-Essential / Optional) electrical system. Update the load analysis and all calculations as required by UFC 3-501-01, paragraph 3-2. Include NFPA 99 risk analysis for wet procedure locations in accordance with Chapter 11. Provide cut sheets for all electrical equipment.

C-6.1.10 Communications.

Summarize all communication system design parameters and major features. Provide cut sheets for all communication equipment. Discuss the general framework of the networking design or diagram including MEDCOI and traditional IT systems. Determine which systems require interconnectivity and identify if connection is physical or logical. Discuss location of installation nodes for end point destination and note how physical independent pathways will be ensured for NFPA 99 Category 1 and 2 systems.

C-6.1.11 Fire Protection and Life Safety.

Address and evaluate the fire protection and life safety design parameters and major features to include (but not limited to): fire detection, fire alarm, fire extinguishment, and fire suppression systems. Summarize the life safety considerations, design parameters, and major features. Address type of construction, height and area limitations, building separation, fire rating of materials, life safety features, and occupancy classification. For projects involving rehabilitation work, provide a summary of the analysis of the FSES Study and latest LSA Report. Include related design considerations and criteria that have been coordinated among all the affected disciplines.

Evaluate the fire protection and life safety features in accordance with UFC 3-600-01 in terms of what is required and what will be provided to accommodate the scope of the work for this project along with a drawing, or set of drawings, to support this analysis (in

the form of a narrative). Utilize the following requirements to further clarify the preparation of the fire protection and life safety design narrative (or FPLSDN).

a. Provide a description of the use(s) proposed in each facility, including all functions, operations, and procedures, to support the designer's determination of the occupancy classification(s) in accordance with NFPA 101 and the use and group classification(s) in accordance with IBC for all fire areas and smoke compartments of the proposed facility. Also, address the use of the IBS, high-rise provisions and any other features impacting the fire safety/protection design (as applicable).

b. Prepare a tabular summary to represent each proposed subdivision of building space [for each floor in multi-story facilities] to clearly identify all fire separations and smoke compartments required by either the IBC or NFPA 101.

c. Address interior wall and ceiling finish and interior floor finish identifying classification and flame spread ratings and smoke-developed indices and extent of plastics to be provided as finish materials.

d. Describe protection of all vertical openings, including enclosure requirements for stairs, elevators, escalators, conveyors, dumbwaiters, chutes, atriums, malls, and light wells (as applicable).

e. Describe provisions for life safety, especially in terms of the means of egress. Identify types and numbers of exits; capacity and arrangement of the means of egress; performance parameters of the means of egress, namely common path of travel, dead-end corridor, and total travel distance; discharge from exits; exit marking and illumination of means of egress; emergency lighting; opening protectives; and special security features.

f. Identify FAFDMN and voice communication requirements for field devices. Indicate facility operations that impact selection of FAFDMN with consideration given to type of evacuation, patient and staff evacuation procedures, and layout of fire separations and smoke compartments. Include functional description for alarm initiation, alarm indication and emergency notification; signaling circuits and appliances, sequences of operations, annunciation of alarm, trouble and supervisory signals, and interface with other building systems as well as other fire protection features (or systems). Indicate system configuration (for example conventional hardwired, addressable, multiplex, or intelligent) and type of signal communication (for example digital or analog). Indicate FAFDMN requirements as they relate to other building systems, for example, HVAC.

g. Describe the fire (or emergency) reporting system(s) in service at the Installation, for example, central station fire alarm reporting system.

h. Document the current conditions of the available water supply in terms of volumetric waterflow rates (in gallons per minute) and waterflow pressures

(in pounds per square inch), including a copy of the most current fire hydrant flow test report. This flow report shall be inserted as an attachment to the FPLSDN. If there is on-site water storage, identify its components and the available volumetric capacity. Provide a description for types and locations of system equipment and existing facility fire flow demands.

i. If fire hydrant water flow test results support the necessity to install a fire pump or a tank for water storage or both, indicate design criteria (for example NFPA 20 or NFPA 22), equipment type, arrangement, and capacity and pump ratings. Include pump equipment power, alarm and supervision requirements, automatic and manual fire pump control requirements, and FAFDMN interface and supervision requirements.

j. Identify objective and scope for smoke control or smoke management in the project, particularly the relevant performance criteria that the QFPE intends to meet. Indicate the type(s) of smoke control and management proposed to meet criteria. Identify building systems that must be interfaced to provide smoke management. Summarize design considerations, control parameters and operational features.

k. Identify layout and distribution parameters for fire extinguisher cabinets.

l. Elaborate upon facility features for emergency power distribution, including control and switching requirements for life safety, critical and equipment loads with load shedding and restoration features (as applicable).

m. Consider each of following special hazards and features, which may impact the overall level of fire protection being provided.

(1) Security (for example electric door releases, door hardware, and locking arrangements)

(2) Malls/atriums

(3) Automatic data processing and electronic facilities

(4) Elevator control/FAFDMN interface

(5) Emergency power

(6) Emergency vehicle easements

(7) Explosion prevention

(8) Flammable and combustible liquids handling and storage

(9) High-frequency electrical equipment

(10) Radio Frequency Interference (RFI) shielding

(11) Underground structures/areas, including crawlspace(s)

(12) Waste handling (medical and hazardous)

(13) Limited-access structures or areas

(14) Special storage arrangements and configurations

C-6.1.12 Physical Security.

Summarize the security system design parameters and major features.

C-6.1.13 Antiterrorism/Force Protection (AT/FP).

Summarize the AT/FP system design parameters and major features.

C-6.1.14 Sustainability and Energy Performance/Conservation Compliance.

Discuss status toward meeting the requirements of UFC 1-200-02; update sustainable rating system points; refine energy consumption status relative to achieving the required 30% (minimum) energy reduction as compared to the ANSI/ASHRAE 90.1 baseline; and update status of additional sustainability goals for the project. Discuss all energy conservation design features considered and those incorporated.

C-6.1.15 Commissioning.

Summarize the Commissioning Plan and process to achieve the required commissioning of all commissioned systems. Include the final Commissioning Plan incorporating comments received. Further clarify the process by which commissioning must be performed.

C-6.1.16 Transportation and Logistics.

Summarize the recommendations and analyses (pros and cons), rational, and scope and cost impacts of the overall Transportation and Logistics Study to include all sub-studies, for example, Elevator Traffic Study and Analysis, Life-Cycle Cost Analysis for automatic and manual material handling systems, a Waste Management Study, and a Food Service Study (include all food serve areas). The MTLC must also present at the 35 percent design meetings describing how the facility design addresses the transportation, logistics, and waste management requirements of the facility. The Transportation and Logistics Analysis (TLA) must be developed enough to finalize and address any functional requirements of the facility layout required at the 35 percent submission.

C-6.1.17 Interior/Exterior Signage and Wayfinding.

Summarize the Interior/Exterior Signage and wayfinding master plan recommendations, solutions, and tools for patients, staff, and visitors to navigate in and around a facility. Identify any scope and cost impacts to proposed recommendations, solutions, and tools. Summarize the types of functions and activities a person may perform in a medical facility.

C-6.1.18 Food Service.

If applicable, summarize the food service design. Discuss its parameters and major features to include optimal movement of food products to all designated locations; minimal cross-traffic, backtracking, and queuing conditions; and separation of personnel traffic.

C-6.1.19 Equipment Specifications.

Equipment List. The A/E must further refine the initial for-record equipment list into a viable medical facility room contents list or room-by-room contents listing. Coordinate all categories of equipment for each room identified on the list as well as substitutions or changes with the DoD Project Sponsor. The type, quantity, and location of biological, radioisotope, fume, canopy, and laminar air hoods must also be indicated in the equipment list. Provide appropriate equipment data and catalog cut sheet(s) for all items of equipment having unique utility requirements, heat loads, structural support, or space requirements.

Develop requirements for all equipment that does not have current information, as directed by the Design and Construction Agent.

C-6.1.20 Specifications.

Provide outline specifications.

C-6.1.21 Construction Phasing.

A written narrative must be provided, developed, and documented by the A/E that shows one overall workable phasing plan. This phasing plan must indicate proposed construction duration and describe major elements of the work and any impacts on or by the Government. The phasing plan must include the scope and timing sequence of each identifiable phase or major activity with required precedents, procurement, Government move durations, commissioning, and outfitting. Each phase must be described in terms of the work involved and what work has to come before and after the phase. Phasing elements affecting the Government but not the contractor, such as Government only actions, should be determined and documented.

C-6.1.22 Rehabilitation Work.

For projects involving rehabilitation work including addition/alteration projects, further identify work activities in a phasing plan that would impact any requirements for continued operation of a facility, including temporary utilities, swing space, implementation of hygienic barriers, and temporary access routing.

C-6.2 35 Percent Submittal Design Drawings.

C-6.2.1 Civil (Site).

Show building location, future expansion, existing and proposed structures, topography, final master plan of the site, utilities (include point of origin), utility modifications, roads, pedestrian paths, parking (surface and structured), and landscaping.

C-6.2.2 Architectural.

C-6.2.2.1 Floor.

For each floor, show floor elevation; all programmed spaces; corridors; structural grid systems (including columns); electrical/communications/mechanical equipment rooms; all vertical and horizontal transportation, for example, stairs, elevators, escalators, pneumatic tubes, dumbwaiters; and AGV to meet functional requirements and CONOPS for the building. All spaces identified in the PFD must be labeled with the Room Name and Room Code. Provide programmed and designed net area tabulations. Provide key building dimensions. Identify accessible maneuvering clearances (for example turning radius and door/fixture clearances, etc.) for all applicable spaces and components. Plans must be coordinated with the life safety-building code composite plans.

C-6.2.2.2 Reflected Ceiling.

Show ceiling grid and light fixture placement.

C-6.2.2.3 Exterior Elevations and Major Building and Wall Sections.

Include all exterior views and multiple cross sections through all unique building areas. Provide floor to floor, as well as roof and parapet heights. Wall sections must show and describe building envelope materials.

C-6.2.2.4 Utility Services Distribution / Physical Space Requirements for Equipment and Distribution Systems.

Provide interdisciplinary cross section drawings of the most congested utility areas (for example near vertical chases, elevators, mechanical rooms, communications rooms, etc.) to demonstrate that the floor to floor heights, above ceiling space, crawl spaces and chase areas are sufficient for utility installation as well as future operations and maintenance activities. Designate installation zones for each utility. Include all technical systems in the selected areas (for example HVAC main ducts, heating and cooling mains, plumbing mains, fire sprinkler pipe, electrical, telecommunications cable trays, pneumatic tube systems, seismic restraints and supports etc.). Include piping slope considerations where that may require additional clearances. Base HVAC utility sizing on room-by-room heating and cooling load calculations and the zoning concept. Label each utility and show required clearances with measurements.

C-6.2.3 Interstitial Building System (IBS).

If applicable, a conceptual IBS design must be developed, for example, plans and sections delineating interdisciplinary cross-sections at critical locations. Validate floor-to-ceiling heights for the IBS supported by the most stringent equipment and utility dimensions. Show defined maintenance access and Means of Egress in compliance with NFPA 101. Develop interdisciplinary crossings at congested areas to demonstrate sufficiency of space.

C-6.2.4 Structural.

Provide drawings of the selected structural system adequately developed so no additional major engineering decisions are required.

C-6.2.5 HVAC.

Provide equipment room drawings in plan and elevation showing major equipment of all disciplines including architectural and structural elements, and depict the required access, maintenance, and code clearances. Footprints of air handling and other major equipment must be established from catalog dimensional data of three manufacturers and demonstrate that all required AHU elements have been included. Include clearance space for component cleaning, removal, and maintenance. Provide AHU equipment schedules, AHU configuration plans and sections, control schematics and sequence of operations. Show coordinated distribution mains (dimensioned) on the floor plans. If integral sound attenuating devices are required in VAV/CAV terminal units, indicate these on the plans for the respective terminal unit(s). Design all aspects of the piping systems to control thermal expansion and distribution as supported by piping stress calculations. In the design drawings, show all control features such as pipe guides, anchors, expansion joints, expansion ells, offsets, flexible couplings, and other piping features that may affect expansion forces in the piping. For steam and condensate piping, show the required direction, degree of line slope, details of drip traps, and other drainage features.

Identify all HVAC control zones and the type of zone control devices to be used (VAV, CAV etc.). Provide air handling unit zoning diagrams identifying which areas are served by each AHU. Provide space pressurization and airflow diagrams. Provide single line dimensioned distribution drawings for all ductwork, and for the main heating, chilled water, and steam services, throughout the facility. Provide schematic diagrams for all piping systems; identify locations of all outdoor air intakes and exhaust air discharge points.

C-6.2.6 Plumbing and Medical Gas.

Provide plumbing and medical gas system plans, including central equipment, and main distribution lines. Show layout of the technical rooms in plan and elevation for plumbing and medical gas systems including architectural and structural elements and major equipment of all coordinating disciplines. Equipment dimensions must be based on the

catalog dimensional data of three manufacturers. Include clearance space for component cleaning, removal, and maintenance. Water supply and gravity drainage mains must be dimensioned. For sanitary piping and vacuum piping, show the required slope and cleanouts including access clearances. Provide schematic diagrams and riser diagrams for all plumbing and medical gas systems including all functional components and pipe sizes.

C-6.2.7 Electrical.

Show placement and location of electrical room layouts, light fixtures, receptacles, motor controls, panelboards, and distribution equipment. Provide single line diagrams of the normal/essential electrical systems, emergency power, and uninterruptable power supply (UPS). Include the grounding system design and initial testing requirements in the project design documents.

C-6.2.8 Communications.

Provide site utility plans for voice, data, security, and television (TV) systems indicating all communications ductwork, manholes, hand-holes, and cable routing required to tie the new facility into the existing installation-wide networks/systems. Indicate all existing communications cables on, or adjacent to, the immediate project site.

C-6.2.8.1 Facility Communications.

Show layout of communication equipment, devices, and closets. Develop, in detail, a nurse call Zone Light Activation Matrix (including identification numbers) must be detailed on the telecommunication systems project design documents. A matrix must be developed for each patient care unit served.

Provide enlarged communication room elevations to include equipment racks, wall mounted equipment and devices. Verify all drawings identify port locations to match project PRC. Provide heat maps for wireless access points. Provide heat maps for IRES emergency management radios if included or to verify not needed (facilities smaller than 50,000 sf (4650 sm) with signal strength of 80 dB).

Provide, for each communications system, riser diagrams; identification and associated proposed location for each major item of equipment; and identification of cable sizes and types and termination equipment. Provide initial rack layout based on standard medical device sizing such as switches and vendor equipment both contractor provided or government provided (estimated).

C-6.2.9 Physical Security.

If ESSs are included in the project design, these systems must be detailed in the project design documents. Include information such as sensor locations, floor plans, riser diagrams, security equipment schedules, monitoring and control equipment, alarm control panels, switches, and access control devices.

C-6.2.10 Fire Protection and Life Safety.

Coordinate all design features with applicable criteria and all architecture and engineering disciplines. At a minimum, the plans to graphically represent fire protection and life safety features shall identify the following. As appropriate, indicate both the minimum requirement and the actual provision being incorporated into the project.

a. Prepare life safety-building code composite plans at a minimum scale of 1/8” = 1’-0” (1:100) utilizing a set of architectural floor plans with room names and numbers, clearly identifying horizontal and vertical means of egress, any vertical openings, such as elevators and other shafts, utility rooms, and structural support elements. The following shall be indicated: occupancy classification and sub-classification per NFPA 101 and Use-Group Classification per IBC of all fire areas; delineation of smoke compartments (or barriers); location of all fire-rated separations, including fire-rated door assemblies and dampers with specific fire-resistance ratings identified; fire pumps; fire extinguishing cabinets; and number and locations of all required exits, exit capacities (number of people per exit), means of egress and travel distances of all fire areas and smoke compartments. Identify performance parameters of the means of egress, including proposed measurements and maximum limitations of travel distance, common path of travel, and dead-end corridor, on each floor and compartment, as well as the specific location where each measurement was taken. It is noted that any travel distance measurements shall be taken both to an exit and to a smoke barrier (where smoke compartments are required) in compliance with NFPA 101. Utilize egress tags at each interior exit to a vertical component of egress, like a stair, and at each exterior exit from the facility, which shall each identify the following four parameters: (1) minimum clear width required, (2) actual clear width proposed, (3) calculated maximum number of occupants that the particular component is capable of serving, and (4) estimated number of occupants anticipated to use that particular component based upon a reasonable distribution of occupants performed by the QFPE.

b. The following is the minimum information that shall be either graphically represented in the drawings or detailed in the specifications prepared for the performance-based fire suppression design in this project: fire hydrant waterflow data; location of area(s) to be protected by sprinklers or standpipes; identification of sprinkler system type, sprinkler hazard classification(s), and respective sprinkler design density, design area, hose stream demand (including location of the hose stream demand), duration of water supply, and sprinkler spacing and area of coverage, for each system proposed. The QFPE shall review the technical notes in UFGS 21 13 13 and incorporate those that apply as the specification section for automatic sprinkler protection is being developed. The zoning of automatic sprinkler protection shall be coordinated with the building smoke compartments, where applicable, and shall indicate locations of

other areas protected by other automatic extinguishing and suppression systems.

c. The following is the minimum information that shall be graphically represented in the drawings prepared for the performance-based fire suppression design in this project:

(1) Layout and distribution of all piping and equipment from the point of connection to the water supply to the sprinkler cross mains.

(2) Locations of service mains, interior feed mains, control valves, sprinkler risers, drain lines and discharge points, sectional valves, and inspector's test valves.

(3) Location of the backflow preventer (including provisions for draining and access for maintenance) where the potable water supply system is at risk of contamination from any fire suppression system.

(4) Details of pipe restraints for underground piping, for example, pipe clamps, tie rods, mechanical retainer glands, and thrust blocks. If required, identify size of wall or floor sleeve(s) to meet earthquake requirements.

(5) All concealed spaces requiring sprinkler protection, such as spaces above suspended ceilings, that are built of combustible material or that can contain combustible materials, such as storage and communication cabling without a fire rating.

d. Prepare fire alarm/fire detection/mass notification plans to graphically represent locations of all FAFDMN control and annunciation panels; all connections for notification, monitoring and control; all FAFDMN initiating and indicating circuits and locations of connected devices, including control of respective HVAC units for either smoke control (see NFPA 90A) or smoke management or both; and all interfaces with other building systems.

C-6.2.11 Interior/Exterior Signage and Wayfinding.

Graphically indicate specific interior/exterior signage and wayfinding locations, proposed solutions, and tools that relates to the facility.

C-6.2.12 Food Service.

Food service equipment items must be identified in detail in the project design documents and represent the latest available technology. Specific equipment locations, utility requirements including ventilation, and equipment installation must also be shown. Include mounting heights for all wall-hung equipment items.

C-6.2.13 Equipment (to include FFE).

Show all Categories of equipment. Show all equipment (to include FFE) on the equipment drawings and floor plans at a minimum scale of 1/4" = 1'-0" (1:50). Clearly identify and differentiate between RPIE and PP equipment. Provide plans showing Log Cat A and B items with heavy, solid lines and showing Log Cat C, D and R items with dashed lines. Provide JSNs as indicated in the PRC on floor plans, on all Interior Design FF&E sheets, and in tabular format for all applicable logistical categories. Provide separate Architectural equipment plans and Interior Design FF&E plans. Indicate and properly detail the type, quantity, and location of biological, radioisotope, fume, canopy, and laminar air hoods on the drawings. Coordinate all equipment locations and details to ensure adequate utility requirements, structural support, or space requirements are provided.

C-6.2.14 Structural Interior Design (SID).

Provide a 35 percent SID package. The SID package must be fully coordinated with all interior and exterior finishes, colors, and materials. Key the room finishes schedule to the plans by room number, room code, and room name, for each room labeled in the PFD. Include proposed SID color scheme/selections. Provide color boards (or binders) with samples of finishes or pictures - scanned pictures are not permitted. An aseptic environment ICRA must be coordinated with the SID package to define infection control risks associated within each project. Reference paragraph 6-5.1 for additional details. The wayfinding plan must also be an integral part of the facility's SID package and enhance the design features. The ICRA and the wayfinding plan are critical to begin early in the design process. See Glossary for expanded definitions of the SID.

C-6.2.15 Comprehensive Interior Design (CID).

Provide a 35 percent CID package for furniture and accessory selection. The CID package must be fully coordinated with all finishes, colors, and materials included in the SID package. Provide CID floor plans, table of all JSNs, and binders with samples of finishes - scanned pictures are not permitted. Provide description and cut sheets for all CID items. Include specific artwork selections. Reference paragraph 6-5.2 for additional details. See Glossary for expanded definitions of the CID.

C-6.2.16 Construction Phasing.

Provide a graphic "node" diagram (not a bar chart or time-scaled bar chart) to show the relationships established in the phasing narrative. The graphic representation of the phasing plan in the contract documents should not indicate durations (numerical or graphical) except for the contractually established durations such as Owner moves. Individual phase durations should be considered only in developing the Government's proposed overall contract duration. This phasing plan should not be confused with the requirement to determine the overall constructability and construction timeline that may involve a more detailed milestone chart. The phasing should be coordinated and documented in the design drawings either as a segregated set with all engineering

disciplines addressed or have associated drawings within each discipline. A separate overall phasing plan must be developed for the Government's use only to inform, educate, and track Government actions. It should include interaction of Government activities such as move times, swing space durations, and Government outfitting and training activities. This plan must further delineate the coordination of required actions of the Government that are not a part of the contractor's responsibility or contract.

C-6.2.17 Rehabilitation Work.

For projects involving rehabilitation work including addition/alteration projects, provide 35 percent demolition drawings indicating removal of structural, architectural, MEP, communications systems, and asbestos and other hazardous materials.

C-6.3 35 Percent Submittal Calculations.

C-6.3.1 Calculations.

Provide conceptual level calculations for all engineering systems being proposed as identified in the Design Analysis requirements and as required here.

C-6.3.2 Gross and Net Area Tabulations.

Update all gross and net area tabulations based on refined floor plans.

C-6.3.3 Health Physicist Report.

Provide a Health Physicist Report and coordinate with related design drawings and specifications. Refer to Chapter 15 and Appendix D.

C-6.3.4 Sustainability and Energy Performance/Conservation Compliance.

Discuss status toward meeting the requirements of UFC 1-200-02; update sustainable rating system points; refine energy consumption status relative to achieving the required 30% (minimum) energy reduction as compared to the ANSI/ASHRAE 90.1 baseline; and update status of additional sustainability goals for the project.

C-6.3.5 35 Percent Submittal Cost Estimates.

C-6.3.5.1 Cost Estimate.

Update all project costs. Align all revised costs in accordance with the DD Form 1391 format. Provide any changes to the project's DD Form 1391 description, justification, and execution timelines.

C-6.4 35 Percent Design Drawing Record Copy.

The record copy of the 35% design drawing submittal must be provided to the Design and Construction Agent documenting the outcome of the 35 percent meeting and must be submitted in accordance with the directives established above.

C-7 65 PERCENT DESIGN SUBMITTAL.

The Design and Construction Agent must develop the specific submittal requirements to define this level of effort. The project design documents must reflect a 65 percent level of coordination across all architecture, interior design, equipment, and engineering disciplines. Specifications should include a preliminary Division 01.

C-8 100 PERCENT AND FINAL DESIGN SUBMITTAL.

The Design and Construction Agent must develop the specific submittal requirements to define this level of effort. When the design is complete, the Design and Construction Agent must submit a complete copy of the final submittal documents, for example, drawings, specifications, equipment SID & CID packages, cost estimate, instructions to bidders. These documents must be fully coordinated across all architecture and engineering disciplines within 30 days of completing the 100 percent design documents.

C-9 REQUEST FOR PROPOSAL (RFP) FOR DESIGN-BUILD (DB) PROJECTS.

The RFP for Design/Build (DB) acquisition projects must clearly define all the requirements and background information that a DB contractor must have to estimate, bid, design, and construct the project. These requirements must be included in the RFP as appropriate to the project:

a. Project Technical Requirements

b. Updated DD Form 1391

c. Program for Design (PFD)

d. Medical Concept of Operations (CONOPS) for the facility

e. Project Room Contents (PRC)

f. Requirements for:

(1) Comprehensive Interior Design (CID)

(2) Structural Interior Design (SID)

(3) Additional requirements as determined by the Design and Construction Agent to facilitate fast track construction.

(4) User needs specific to the design of the facility

(5) Installation approved site location Base Commander signed document.

C-10 RFP DEVELOPMENT SUBMITTALS.

These submittals are required during the RFP development:

a. 5 Percent Level Design Report.

b. Draft RFP (RFP Development). If 20 percent design is provided, include all required submittal items in Section C-5.

c. Final RFP (RFP Development). If 35 percent design is provided, include all required submittal items in Section C-6.

C-11 AFTER CONTRACT AWARD.

Following the successful selection of a DB contractor and award of a DB contract, the DB contractor must provide these comprehensive submittals to include, but not limited to, the following as previously defined:

a. Final 35 Percent Design Submittal.

b. 65 Percent Design Submittal.

c. 100 Percent Design Submittal.

d. 100% Corrected Final.

APPENDIX D UNIVERSAL X-RAY ROOM

D-1 GENERAL.

This appendix contains mandatory criteria for Universal X-ray Room design and construction. The Universal X-ray Room is capable of accepting radiographic and fluoroscopic equipment, regardless of manufacturer, with minimal facility modification.

D-1.1 Applications.

The Universal X-ray Room applies to Room Codes XDR01 and XDRF1 (see Appendix B). The DoR selects an X-ray system for a basis of design based on the JSN provided in the PRC. The DoR designs this room to accommodate the selected system, the criteria listed here, NCRP Report No. 147 Structural Shielding for Medical X-Ray Imaging Facilities, and using MilDep specific criteria (TB Med 521, AFI 48-148, etc.).

D-2 SPECIFIC REQUIREMENTS.

D-2.1 Electrical Raceway System.

The Electrical Raceway System includes a floor trench, wall ducts, and ceiling cable trays that meet the criteria listed here, and additional requirements of the X-ray system selected as a basis of design for installation (reference Figures D-1, D-2, and D-3). All raceways and cable trays must be UL-listed (CE for Europe) for enclosure of wiring to all X-ray system components and concealed in floors, walls or above the ceiling.

D-2.2 Floor Trench.

Floor trench is a bottom-type trench duct, with nominal 3.5 in. (89 mm) by 12 in. (300 mm) duct and a 12 in. (300 mm) wide by 1/4 in. (6 mm) thick steel cover plate. Cover plate is installed flush with the floor with the same finish insert as the floor. Provide a gasket on the cover plate to maintain water tightness. Location of floor trench to the radiology table is determined based on the X-ray system selected for the basis of design.

D-2.3 Core Drilling.

Provide oversized conduits below the floor deck in lieu of floor trench when the Universal X-Ray Room is located on a floor other than ground level.

D-2.4 Wall Ducts.

Wall ducts are nominal 3.5 in. (89 mm) by 10. in (250 mm) with 12 in. (300 mm) wide flush-mounted cover plates finished to match the walls. Transition wall ducts to the floor trench or the conduit below the floor deck.

D-2.4.1 Ceiling Cable Trays.

Ceiling cable trays are nominal 3.5 in. (89 mm) by 12 in. (300) with 3 in. (76 mm) load depth National Electrical Manufacturers Association (NEMA) Class 12A ladder type installed above the finished ceiling.

D-2.4.2 Partition Separation.

Provide partitions to separate high- and low-voltage cables in all trenches, ducts, and cable trays.

D-2.5 Electrical Service Requirements.

Provide copper feeder conductors and adequate power service to each Universal X-Ray Room to ensure the X-ray system can be installed without additional facility-related electrical work.

D-2.5.1 Power Quality.

Provide the specified nominal voltage (480 V) +/-5 percent to each Universal X-ray Room. Provide special power conditioning equipment, where required with the X-ray system installation.

D-2.5.2 X-Ray Equipment Service.

Provide 150 ampere, 480Y/277 V, 3 phase (5 wire, neutral, and ground) service to the room. Provide an adjustable trip, 150 ampere, 3 pole, shunt trip circuit breaker in a NEMA 1, flush-mounted enclosure.

D-2.5.3 Emergency Shutdown.

Provide a large, clearly identified push button to actuate the shunt trip circuit breaker to disconnect all power to the X-ray system.

D-2.5.4 Auxiliary Panelboard.

Provide a 120/208 V, single phase, 100 A panelboard with a 50 A shunt trip main breaker to support the single phase loads in each room. Provide a 20 pole space panelboard with at least two 20 A, 2 pole circuit breakers, and five 20 A, 1 pole circuit breakers. This panelboard may be served from the nearest general-purpose 120/208 V transformer, or a dedicated step-down transformer fed from the 480 V service to the room. Calculations are based on 180 A maximum demand if fed from the 480 V service to the room.

D-2.5.5 Voltage Drop and Regulation.

Ensure total voltage drop in a branch circuit and feeder conductors does not exceed 2 percent from the facility distribution transformer to the Universal X ray Room. Total

voltage regulation of the distribution transformer, feeder, and branch circuit conductors will not exceed 5 percent. For circuits that serve only one room, this calculation is based on the maximum demand current of the single X-ray generator. For circuits that serve more than one room, this calculation is based on the maximum demand current of the two largest rooms. Calculations are based on 180 A minimum demand. Size wiring for a maximum of 1 percent impedance.

D-2.5.6 Distribution Transformers.

Distribution transformers are not dedicated solely to the X-ray system. Voltage regulation is better when an X-ray system is connected to a transformer that is partially loaded with other equipment. Connect X ray systems line to line, never line to neutral.

D-2.5.7 Essential Power.

Provide essential power for X-ray systems, illumination, and duplex receptacles in accordance with the using MilDep guidance documents.

D-3 WARNING LIGHTS.

Provide “X-ray In-Use” warning light outside and above patient entry door. The “X-ray In-Use” light is controlled by applying power to the X-ray system control console. Provide conduit and wiring from the “X-ray in Use” light to the X-ray unit control console.

D-4 OTHER REQUIREMENTS.

D-4.1 Walls.

Provide studs on either side of the vertical electrical raceways. Design walls to support 220 pounds vertical to horizontal pull. Provide double walls between adjacent X-ray rooms. Full height partitions with wall backing and support are required for wall bucky units and control panels, or any wall that supports radiographic and/or fluoroscopic equipment.

D-4.2 Ceiling Support System.

Provide an overhead tube mount support system with a load-bearing capacity of 1000 pounds vertical point load and 50 pounds per square foot uniformly distributed load. Ceiling support system to cover the complete ceiling area of the room. Spanning members are mounted perpendicular to the centerline of the X-ray table and positioned at 25 5/8 in. (67 mm) on center to provide 2 ft (610 mm) of clearance between members. Suspend acoustical ceiling from the spanning members. Bottom of spanning members are flush with the finished ceiling.

D-4.3 Floors.

When a floor trench is utilized, provide appropriately thickened slab to accommodate the floor trench.

D-4.4 Radiology Shielding.

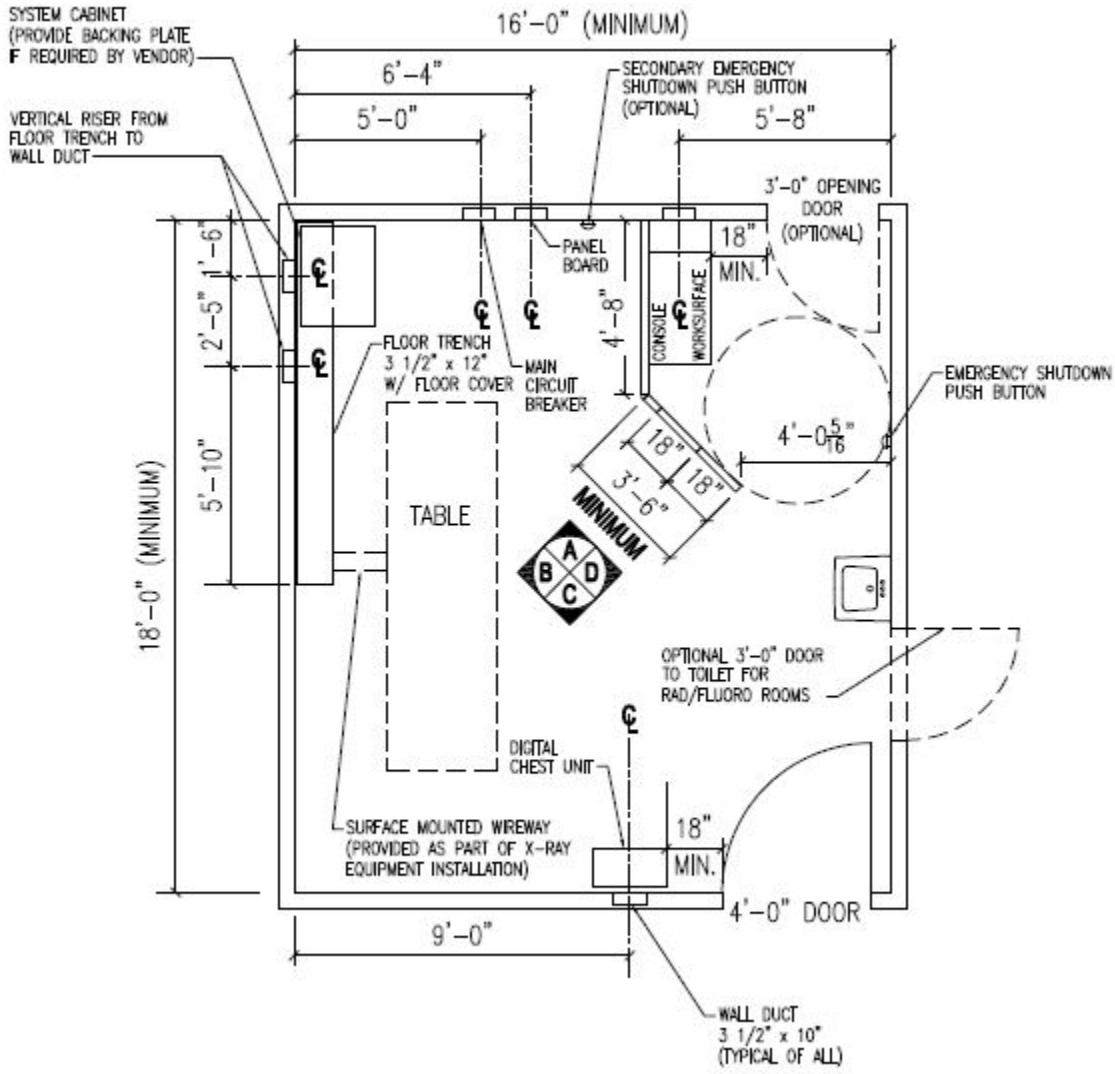
Lead shielding will at a minimum meet the following requirements:

a. The design is certified by the DoR's health physicist to ensure that the required degree of protection is achieved in compliance with NCRP Report No. 147. Certify in accordance with NCRP Report No. 102 and the using MilDep qualified expert guidance. Lead shielding design and certification report is the responsibility of the DoR.

b. Provide Lead shielding of 1/16 in. (1.6 mm) lead or lead equivalent up to 7 ft (2.14 m) above the finished floor. Avoid penetrations through the shielding or mitigate penetrations when necessary.

c. Apply lead shielding to the Universal X-ray Room side of the wall partitions and laminated behind gypsum board for protection. The construction Contractor is responsible for the shielding installation in accordance with the approved plans and specifications and to provide the shielding integrity certification.

D-4.4.1 Additional Requirements.



Use built-in or modular shielding for the control booth. Maximize viewing pane(s) where practical so that the operator has an unrestricted view of the patient, wall bucky and x-ray table during all x-ray exposures in the room.

Locate all ductwork, grilles, registers, and diffusers above or flush with the ceiling to avoid conflict with overhead equipment rail travel and shielding. Route thermostat transmission lines to avoid penetration of shielding.

D-4.5 Fire Protection.

Ensure all automatic sprinkler heads are recessed.

APPENDIX E INTERSTITIAL BUILDING SYSTEM (IBS)

E-1 GENERAL.

This appendix provides mandatory criteria for the use and application of IBS concepts, including interstitial utility spaces.

E-2 IBS DESIGN CONCEPT.

The primary concept of interstitial spaces located between functional floor spaces is a non-traditional design feature that permits locating the majority of facility utility distribution and terminal equipment within the interstitial space, and not within functional spaces. This IBS concept offers the DoD several advantages over standard building design in providing convenient installation, maximizing utility access and maintainability, providing for future building flexibility, while minimizing disruption to medical or laboratory services.

E-2.1 DoD Systems Module Concept.
